in the ∞-category of spectral Deligne-Mumford stacks (Theorem 16.1.0.1). Our goal in this section is to study the ∞-category $\mathrm{QCoh}(\mathsf{X})$ of quasi-coherent sheaves on the pushout X. Note that every quasi-coherent sheaf $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ determines objects $\mathscr{F}_0 = g'^* \mathscr{F} \in \mathrm{QCoh}(\mathsf{X}_0)$ and $\mathscr{F}_1 = f'^* \mathscr{F} \in \mathrm{QCoh}(\mathsf{X}_1)$, together with an equivalence $\alpha : f^* \mathscr{F}_0 \simeq g^* \mathscr{F}_1$ in the ∞-category $\mathrm{QCoh}(\mathsf{X}_{01})$. Our starting point is the observation that $\mathscr{F}$ is determined (up to canonical equivalence) by the triple $(\mathscr{F}_0, \mathscr{F}_1, \alpha)$. More precisely, we have the following:

Theorem 16.2.0.1. *Suppose we are given a pushout diagram of spectral Deligne-Mumford stacks σ :*

$$\begin{array}{ccc} \mathsf{X}_{01} & \xrightarrow{f} & \mathsf{X}_0 \\ \downarrow{g} & & \downarrow{g'} \\ \mathsf{X}_1 & \xrightarrow{f'} & \mathsf{X}, \end{array}$$

where f and g are closed immersions. Then the induced diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{X}_{01}) & \longleftarrow & \mathrm{QCoh}(\mathsf{X}_0) \\ \uparrow & & \uparrow \\ \mathrm{QCoh}(\mathsf{X}_1) & \longleftarrow & \mathrm{QCoh}(\mathsf{X}) \end{array}$$

determines a fully faithful embedding $\theta : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{X}_0) \times_{\mathrm{QCoh}(\mathsf{X}_{01})} \mathrm{QCoh}(\mathsf{X}_1)$. Moreover, θ restricts to an equivalence of ∞-categories

$$\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \to \mathrm{QCoh}(\mathsf{X}_0)^{\mathrm{cn}} \times_{\mathrm{QCoh}(\mathsf{X}_{01})^{\mathrm{cn}}} \mathrm{QCoh}(\mathsf{X}_1)^{\mathrm{cn}}.$$

The assertion of Theorem 16.2.0.1 is local on X, so we can reduce to the case where $\mathsf{X} = \operatorname{Sp\acute{e}t} A$ is affine. In this case, Theorem 3.1.2.1 guarantees that X_0, X_1, and X_{01} are also affine, so that the diagram σ is induced by a diagram of connective $\mathbb{E}_\infty$-rings τ :

$$\begin{array}{ccc} A & \longrightarrow & A_0 \\ \downarrow & & \downarrow \\ A_1 & \longrightarrow & A_{01}. \end{array}$$

Since σ is a pushout diagram of closed immersions, τ is a pullback diagram of $\mathbb{E}_\infty$-rings, and the maps $\pi_0 A_0 \to \pi_0 A_{01} \leftarrow \pi_0 A_1$ are surjections. We can therefore reformulate Theorem 16.2.0.1 as follows:

Theorem 16.2.0.2. *Suppose we are given a pullback diagram of $\mathbb{E}_\infty$-rings τ :*

$$\begin{array}{ccc} A & \longrightarrow & A_0 \\ \downarrow & & \downarrow \\ A_1 & \longrightarrow & A_{01}. \end{array}$$

Then the induced functor $\theta : \mathrm{Mod}_A \to \mathrm{Mod}_{A_0} \times_{\mathrm{Mod}_{A_{01}}} \mathrm{Mod}_{A_1}$ is fully faithful. If τ is a pullback diagram of connective $\mathbb{E}_\infty$-rings and the map $\pi_0 A_0 \to \pi_0 A_{01}$ is surjective, then θ restricts to an equivalence of ∞-categories $\mathrm{Mod}_A^{\mathrm{cn}} \to \mathrm{Mod}_{A_0}^{\mathrm{cn}} \times_{\mathrm{Mod}_{A_{01}}^{\mathrm{cn}}} \mathrm{Mod}_{A_1}^{\mathrm{cn}}$.

Warning 16.2.0.3. The the situation of Theorem 16.2.0.2, the functor θ need not be an equivalence, even when τ is a diagram of connective $\mathbb{E}_\infty$-rings which induces surjections $\pi_0 A_0 \to \pi_0 A_{01} \leftarrow \pi_0 A_1$. For example, let κ be a field and let $A_0 = \kappa[x]$, $A_{01} = \kappa$, and $A_1 = \kappa[y]$ (regarded as discrete $\mathbb{E}_\infty$-rings). Let M denote the A_0-module given by $\bigoplus_{m \in \mathbf{Z}} \Sigma^{2m} A_{01}$, and let N be the A_1-module given by $\bigoplus_{m \in \mathbf{Z}} \Sigma^{2m+1} A_{01}$. Then $A_{01} \otimes_{A_0} M$ and $A_{01} \otimes_{A_1} N$ are both equivalent to the A_{01}-module $P = \bigoplus_{i \in \mathbf{Z}} \Sigma^i A_{01}$. We may therefore choose an equivalence $\alpha : A_{01} \otimes_{A_0} M \simeq A_{01} \otimes_{A_1} N$. The triple (M, N, α) can be regarded as an object of the fiber product $\mathrm{Mod}_{A_0} \times_{\mathrm{Mod}_{A_{01}}} \mathrm{Mod}_{A_1}$ which does not lie in the essential image of the functor θ (since $M \times_P N \simeq 0$).

16.2.1 Clutching in the Stable Case

The first assertion of Theorem 16.2.0.2 is a consequence of the following more general claim:

Proposition 16.2.1.1. *Let R be an $\mathbb{E}_2$-ring and let $\mathcal{C}$ be a stable R-linear ∞-category. Suppose we are given a pullback diagram τ :*

$$\begin{array}{ccc} A & \longrightarrow & A_0 \\ \downarrow & & \downarrow \\ A_1 & \longrightarrow & A_{01} \end{array}$$

in Alg_R. *Then the induced functor*

$$F : \mathrm{LMod}_A(\mathcal{C}) \to \mathrm{LMod}_{A_0}(\mathcal{C}) \times_{\mathrm{LMod}_{A_{01}}(\mathcal{C})} \mathrm{LMod}_{A_1}(\mathcal{C})$$

is fully faithful.

Proof. Let G denote a right adjoint to F and fix $M \in \mathrm{LMod}_A(\mathcal{C})$; we wish to show that the unit map $M \to (G \circ F)(M)$ is an equivalence. Unwinding the definitions, this is equivalent to showing that the map

$$M \to (A_0 \otimes_A M) \times_{A_{01} \otimes_A M} (A_1 \otimes_A M)$$

is an equivalence; that is, we must show that the diagram σ :

$$\begin{array}{ccc} A \otimes_A M & \longrightarrow & A_0 \otimes_A M \\ \downarrow & & \downarrow \\ A_1 \otimes_A M & \longrightarrow & A_{01} \otimes_A M \end{array}$$

is a pullback diagram in $\mathcal{C}$. Since $\mathcal{C}$ is stable, this is equivalent to showing that σ is a pushout diagram in $\mathcal{C}$. The relative tensor product over A preserves colimits, so we need only verify that τ is a pushout diagram in RMod_A. This equivalent to the requirement that τ be a pushout diagram of spectra. Since the ∞-category of spectra is stable, we reduce to our assumption that τ is a pullback diagram (in either Sp or Alg_R). □

16.2.2 Clutching in the Prestable Case

To complete the proof of Theorem 16.2.0.2, we will need a refinement of Proposition 16.2.1.1 in the setting of *prestable* ∞-categories.

Proposition 16.2.2.1. *Let R be a connective $\mathbb{E}_2$-ring and let $\mathcal{C}$ be a prestable R-linear ∞-category. Suppose we are given a pullback diagram*

$$\begin{array}{ccc} A & \longrightarrow & A_0 \\ \downarrow & & \downarrow f \\ A_1 & \xrightarrow{g} & A_{01} \end{array}$$

in $\mathrm{Alg}_R^{\mathrm{cn}}$*. If $\mathcal{C}$ is separated and the map f induces a surjective ring homomorphism $\pi_0 A_0 \to \pi_0 A_{01}$, then the inducted functor*

$$f : \mathrm{LMod}_A(\mathcal{C}) \to \mathrm{LMod}_{A_0}(\mathcal{C}) \times_{\mathrm{LMod}_{A_{01}}(\mathcal{C})} \mathrm{LMod}_{A_1}(\mathcal{C})$$

is an equivalence of ∞-categories.

Proof of Theorem 16.2.0.2. Apply Proposition 16.2.2.1 to the special case where $R = A$ and $\mathcal{C} = \mathrm{Mod}_A^{\mathrm{cn}}$. □

Proof of Proposition 16.2.2.1. Passing to stabilizations, we obtain a functor

$$F : \mathrm{LMod}_A(\mathrm{Sp}(\mathcal{C})) \to \mathrm{LMod}_{A_0}(\mathrm{Sp}(\mathcal{C})) \times_{\mathrm{LMod}_{A_{01}}(\mathrm{Sp}(\mathcal{C}))} \mathrm{LMod}_{A_1}(\mathrm{Sp}(\mathcal{C}))$$

which admits a right adjoint G. We first claim that G carries the fiber product

$$\mathrm{LMod}_{A_0}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0} \times_{\mathrm{LMod}_{A_{01}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}} \mathrm{LMod}_{A_1}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$$

into $\mathrm{LMod}_A(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$. To see this, suppose we are given objects $M \in \mathrm{LMod}_{A_0}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$ and $N \in \mathrm{LMod}_{A_1}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$ and equivalences $A_{01} \otimes_{A_0} M \simeq P \simeq A_{01} \otimes_{A_1} N$ in the ∞-category $\mathrm{LMod}_{A_{01}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$. We must show that the fiber product $M \times_P N$ belongs to $\mathrm{LMod}_A(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$. In the stable ∞-category $\mathrm{Sp}(\mathcal{C})$, we have a fiber sequence

$$M \times_P N \to M \oplus N \to P.$$

Since M, N, and P belong to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$, it will suffice to show that the map $\pi_0(M \oplus N) \to \pi_0 P$ is an epimorphism in the abelian category $\mathcal{C}^{\heartsuit}$. In fact, we claim that $\pi_0 M \to \pi_0 P$ is an epimorphism. Choose a cofiber sequence $I \to A_0 \xrightarrow{f} A_{01}$ in RMod_{A_0}. Since f induces a surjective ring homomorphism $\pi_0 A_0 \to \pi_0 A_{01}$, the module I is connective. We therefore have an induced cofiber sequence $I \otimes_{A_0} M \to M \to P$ in $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$, which proves that the map $\pi_0 M \to \pi_0 P$ is an epimorphism in $\mathcal{C}^{\heartsuit}$.

It follows from the above argument that F and G determine adjoint functors

$$\mathrm{LMod}_A(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0} \underset{G_{\geqslant 0}}{\overset{F_{\geqslant 0}}{\rightleftarrows}} \mathrm{LMod}_{A_0}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0} \times_{\mathrm{LMod}_{A_{01}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}} \mathrm{LMod}_{A_1}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0},$$

and the prestability of $\mathcal{C}$ guarantees that $F_{\geqslant 0}$ can be identified with our original functor f. We wish to prove that $F_{\geqslant 0}$ is an equivalence of ∞-categories. Proposition 16.2.1.1 implies that the functor F is fully faithful, so the functor $F_{\geqslant 0}$ is automatically fully faithful. To complete the proof, it will suffice to show that the functor $G_{\geqslant 0}$ is conservative. Let $\alpha : X \to Y$ be a morphism in the ∞-category

$$\mathrm{LMod}_{A_0}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0} \times_{\mathrm{LMod}_{A_{01}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}} \mathrm{LMod}_{A_1}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$$

such that $G_{\geqslant 0}(\alpha)$ is an equivalence. Then $G_{\geqslant 0}(\mathrm{cofib}(\alpha)) \simeq 0$. We will complete the proof by showing that $\mathrm{cofib}(\alpha) \simeq 0$, so that α is an equivalence.

Unwinding the definitions, we can identify $\mathrm{cofib}(\alpha)$ with a triple of objects

$$M \in \mathrm{LMod}_{A_0}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0} \qquad P \in \mathrm{LMod}_{A_{01}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0} \qquad N \in \mathrm{LMod}_{A_1}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$$

together with equivalences $A_{01} \otimes_A M \simeq P \simeq A_{01} \otimes_{A_1} N$. We will prove by induction on n that $M \in \mathrm{LMod}_A(\mathrm{Sp}(\mathcal{C}))_{\geqslant n}$ and $N \in \mathrm{LMod}_{B'}(\mathrm{Sp}(\mathcal{C}))_{\geqslant n}$. Provided that this is true for all n, our assumption that $\mathcal{C}$ is separated will imply that $M \simeq N \simeq 0$ so that $\mathrm{cofib}(\alpha) \simeq 0$ as desired.

In the case $n = 0$, there is nothing to prove. Assume therefore that $M \in \mathrm{LMod}_A(\mathcal{C})_{\geqslant n}$ and $N \in \mathrm{LMod}_A(\mathcal{C})_{\geqslant n}$. Since $G(\mathrm{cofib}(\alpha)) = M \times_P N \simeq 0$, we have an isomorphism

$\pi_n M \oplus \pi_n N \to \pi_n P$ in the abelian category $\mathcal{C}^{\heartsuit}$. The first part of the proof shows that the map $\pi_n M \to \pi_n P$ is an epimorphism, so that $\pi_n N \simeq 0$. It follows that $N \in \mathrm{LMod}_{A_1}(\mathrm{Sp}(\mathcal{C}))_{\geqslant n+1}$ and therefore $P \simeq A_{01} \otimes_{A_1} N$ belongs to $\mathrm{LMod}_{A_{01}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant n+1}$. In particular, we have $\pi_n P \simeq 0$, so that $\pi_n M \simeq \pi_n M \oplus \pi_n N \simeq \pi_n P \simeq 0$ and therefore $M \in \mathrm{LMod}_{A_0}(\mathrm{Sp}(\mathcal{C}))_{\geqslant n+1}$, as desired. □

We can use Proposition 16.2.2.1 to deduce a categorified version of Proposition 16.2.1.1, which serves as a sort of counterpart to the descent results of §D.4 and D.6:

Corollary 16.2.2.2. *For every connective $\mathbb{E}_2$-ring A, let $\mathrm{LinCat}_A^{\mathrm{sep}}$ denote the full subcategory of $\mathrm{LinCat}_A^{\mathrm{PSt}}$ spanned by those prestable A-linear ∞-categories $\mathcal{C}$ which are separated. Let*

$$\begin{array}{ccc} A & \longrightarrow & A_0 \\ \downarrow & & \downarrow f \\ A_1 & \xrightarrow{g} & A_{01} \end{array}$$

be a pullback diagram of connective $\mathbb{E}_2$-rings, and suppose that f induces a surjective ring homomorphism $\pi_0 A \to \pi_0 A_{01}$. Then the induced map

$$F : \mathrm{LinCat}_A^{\mathrm{sep}} \to \mathrm{LinCat}_{A_0}^{\mathrm{sep}} \times_{\mathrm{LinCat}_{A_{01}}^{\mathrm{sep}}} \mathrm{LinCat}_{A_1}^{\mathrm{sep}}$$

is fully faithful.

Proof. We note that F is the restriction of a functor

$$F' : \mathrm{LMod}_{\mathrm{LMod}_A^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \to \mathrm{LMod}_{\mathrm{LMod}_{A_0}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \times_{\mathrm{LMod}_{\mathrm{LMod}_{A_{01}}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})} \mathrm{LMod}_{\mathrm{LMod}_{A_1}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$$

which admits a right adjoint G'. To prove that F is fully faithful, it will suffice to show that the unit map $u : \mathcal{C} \to (G' \circ F')(\mathcal{C})$ is an equivalence whenever $\mathcal{C} \in \mathrm{LMod}_{\mathrm{LMod}_A^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ is a separated prestable A-linear ∞-category. Unwinding the definitions, we can identify u with the equivalence $\mathcal{C} \to \mathrm{LMod}_{A_0}(\mathcal{C}) \times_{\mathrm{LMod}_{A_{01}}(\mathcal{C})} \mathrm{LMod}_{A_1}(\mathcal{C})$ of Proposition 16.2.2.1. □

16.2.3 Properties of Quasi-Coherent Sheaves

In the situation of Theorem 16.2.0.2, many important geometric properties of quasi-coherent sheaves $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ can be tested "piecewise":

Proposition 16.2.3.1. *Suppose we are given a pushout diagram of spectral Deligne-Mumford stacks σ :*

$$\begin{array}{ccc} \mathsf{X}_{01} & \xrightarrow{i} & \mathsf{X}_0 \\ \downarrow j & & \downarrow j' \\ \mathsf{X}_1 & \xrightarrow{i'} & \mathsf{X}, \end{array}$$

where i and j are closed immersions. Let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$, and set

$$\mathscr{F}_0 = j'^* \mathscr{F} \in \mathrm{QCoh}(\mathsf{X}_0) \qquad \mathscr{F}_1 = i'^* \mathscr{F} \in \mathrm{QCoh}(\mathsf{X}_1).$$

Then:

(1) *The quasi-coherent sheaf $\mathscr{F}$ is n-connective if and only if $\mathscr{F}_0$ and $\mathscr{F}_1$ are n-connective.*

(2) *The quasi-coherent sheaf $\mathscr{F}$ is almost connective if and only if $\mathscr{F}_0$ and $\mathscr{F}_1$ are almost connective.*

(3) *The quasi-coherent sheaf $\mathscr{F}$ has* Tor*-amplitude $\leqslant n$ if and only if $\mathscr{F}_0$ and $\mathscr{F}_1$ have* Tor*-amplitude $\leqslant n$.*

(4) *The quasi-coherent sheaf $\mathscr{F}$ is flat if and only if $\mathscr{F}_0$ and $\mathscr{F}_1$ are flat.*

(5) *The quasi-coherent sheaf is perfect to order n if and only if $\mathscr{F}_0$ and $\mathscr{F}_1$ are perfect to order n.*

(6) *The quasi-coherent sheaf $\mathscr{F}$ is almost perfect if and only if $\mathscr{F}_0$ and $\mathscr{F}_1$ are almost perfect.*

(7) *The quasi-coherent sheaf $\mathscr{F}$ is perfect if and only if $\mathscr{F}_0$ and $\mathscr{F}_1$ are perfect.*

(8) *The quasi-coherent sheaf $\mathscr{F}$ is locally free of finite rank if and only if $\mathscr{F}_0$ and $\mathscr{F}_1$ are locally free of finite rank.*

Proof. The "only if" directions follow immediately from Propositions 6.2.5.2 and 2.9.1.4. To prove the reverse directions, we may work locally on X and thereby reduce to the case where $\mathsf{X} = \mathrm{Sp\acute{e}t}\, A$ is affine. Then σ is determined by a pullback square of $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc} A & \longrightarrow & A_0 \\ \downarrow & & \downarrow \\ A_1 & \longrightarrow & A_{01} \end{array}$$

for which the maps $\pi_0 A_0 \to \pi_0 A_{01} \leftarrow \pi_0 A_1$ are surjective. The quasi-coherent sheaf $\mathscr{F}$ corresponds to an A-module M. Set

$$M_0 = A_0 \otimes_A M \qquad M_{01} = A_{01} \otimes_A M \qquad M_1 = A_1 \otimes_A M.$$

To prove (1), we may assume without loss of generality that $n = 0$. The desired result then follows from the first step in the proof of Proposition 16.2.2.1. Assertion (2) is a consequence of (1). Assertion (4) follows from (1) and (3), assertion (6) follows from (5), assertion (7) follows from (3), (6), and Proposition HA.7.2.4.23 , and assertion (8) follows from (4), (6), and Proposition HA.7.2.4.20 .

We now prove (3). Assume that M_0 and M_1 have Tor-amplitude $\leqslant n$ over A_0 and A_1, respectively. We wish to show that M has Tor-amplitude $\leqslant n$ over A. Let N be a discrete A-module; we wish to show that $M \otimes_A N$ is n-truncated. Let $I_0 \subseteq \pi_0 A$ be the kernel of the map $\pi_0 A \to \pi_0 A_0$, and define $I_1 \subseteq \pi_0 A$ similarly. We have an exact sequence of discrete A-modules $0 \to I_0 N \to N \to N/I_0 N \to 0$. Note that $N/I_0 N$ admits the structure of an A_0-module, so that $M \otimes_A (N/I_0 N) \simeq M_0 \otimes_{A_0} (N/I_0 N)$ is n-truncated. We are therefore reduced to proving that $M \otimes_A I_0 N$ is n-truncated. We have a short exact sequence

$$0 \to I_0 I_1 N \to I_0 N \to I_0 N / I_0 I_1 N \to 0.$$

Since the quotient $I_0 N/I_0 I_1 N$ admits the structure of an A_1-module, we deduce that $M \otimes_A (I_0 N/I_0 I_1 N) \simeq M_1 \otimes_{A_1} (I_0 N/I_0 I_1 N)$ is n-truncated. We are therefore reduced to proving that $M \otimes_A I_0 I_1 N$ is n-truncated. Note that the ideal $I_0 I_1$ belongs to the kernel of the map $\pi_0 A \to \pi_0 A_0 \oplus \pi_0 A_1$, and therefore to the image of the map $\pi_1 A_{01} \to \pi_0 A$. It follows that the ideal $I_0 I_1$ has the structure of a module over $\pi_0 A_{01}$, and is therefore annihilated by I_0. We conclude that $I_0 I_1 N$ admits the structure of an A_0-module, so that $M \otimes_A I_0 I_1 N \simeq M_0 \otimes_{A_0} I_0 I_1 N$ is n-truncated as desired.

It remains to prove (5). Assume that M_0 and M_1 are perfect to order n; we wish to show that M is perfect to order n. Using (2), we deduce that M is almost connective. Replacing M by a shift, we may assume that M is connective. We now proceed by induction on n, the case $n < 0$ being trivial. If $n = 0$, we must show that $\pi_0 M$ is finitely generated as a module over $\pi_0 A$ (Proposition 2.7.2.1). Since M_0 and M_1 are perfect to order 0 and the maps $\pi_0 M \to \pi_0 M_0$ and $\pi_0 M \to \pi_0 M_1$, we can choose finitely many elements of $\pi_0 M$ whose images generate $\pi_0 M_0$ and $\pi_0 M_1$. This choice of elements determines a fiber sequence $M' \to A^m \to M$. Then $A_0 \otimes_A M'$ and $A_1 \otimes_A M'$ are connective, so that (1) implies that M' is connective. It follows that the map $\pi_0 A^m \to \pi_0 M$ is surjective, so that M is perfect to order 0 as desired.

Now suppose that $n > 0$. The argument above shows that $\pi_0 M$ is finitely generated, so we can choose a fiber sequence $M' \to A^m \to M$ where M' is connective. Using Proposition 2.7.2.1, we deduce that $A_0 \otimes_A M'$ and $A_1 \otimes_A M'$ are perfect to order $n-1$ as modules over A_0 and A_1, respectively. Invoking the inductive hypothesis, we conclude that M' is perfect to order $n-1$, so that M is perfect to order n by Proposition 2.7.2.1. □

16.3 Clutching for Spectral Deligne-Mumford Stacks

Suppose we are given a diagram of spectral Deligne-Mumford stacks $\mathsf{X}_0 \xleftarrow{i} \mathsf{X}_{01} \xrightarrow{j} \mathsf{X}_1$, where i and j are closed immersions. Theorem 16.1.0.1 implies that there exists a pushout

diagram

$$\begin{array}{ccc} \mathsf{X}_{01} & \xrightarrow{i} & \mathsf{X}_0 \\ \downarrow{\scriptstyle j} & & \downarrow \\ \mathsf{X}_1 & \longrightarrow & \mathsf{X} \end{array}$$

in the ∞-category of spectral Deligne-Mumford stacks, and Theorem 16.2.0.1 implies that there is a close relationship between quasi-coherent sheaves on X and quasi-coherent sheaves on the individual constituents X_0 and X_1 (together with a compatibility over X_{01}). In this section, we will discuss the following nonlinear analogue:

Theorem 16.3.0.1. *Suppose we are given a pushout diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}_{01} & \xrightarrow{i} & \mathsf{X}_0 \\ \downarrow{\scriptstyle j} & & \downarrow \\ \mathsf{X}_1 & \longrightarrow & \mathsf{X}, \end{array}$$

where i and j are closed immersions. Then the diagram

$$\begin{array}{ccc} \mathrm{SpDM}_{/\mathsf{X}} & \longrightarrow & \mathrm{SpDM}_{/\mathsf{X}_1} \\ \downarrow & & \downarrow \\ \mathrm{SpDM}_{/\mathsf{X}_0} & \longrightarrow & \mathrm{SpDM}_{/\mathsf{X}_{01}} \end{array}$$

is a pullback diagram of ∞-categories.

16.3.1 Gluing and Base Change

Theorem 16.3.0.1 is a consequence of the following simple observation:

Proposition 16.3.1.1. *Suppose we are given a pushout diagram of spectral Deligne-Mumford stacks σ :*

$$\begin{array}{ccc} \mathsf{X}_{01} & \xrightarrow{i} & \mathsf{X}_0 \\ \downarrow{\scriptstyle j} & & \downarrow \\ \mathsf{X}_1 & \longrightarrow & \mathsf{X}, \end{array}$$

where i and j are closed immersions. Let $f : \mathsf{Y} \to \mathsf{X}$ be a map of spectral Deligne-Mumford stacks. Then the diagram σ' :

$$\begin{array}{ccc} \mathsf{Y} \times_{\mathsf{X}} \mathsf{X}_{01} & \xrightarrow{i'} & \mathsf{Y} \times_{\mathsf{X}} \mathsf{X}_0 \\ \downarrow{\scriptstyle j'} & & \downarrow \\ \mathsf{Y} \times_{\mathsf{X}} \mathsf{X}_1 & \longrightarrow & \mathsf{Y} \end{array}$$

is also a pushout square of spectral Deligne-Mumford stacks (note that the morphisms i' and j' are also closed immersions, by Corollary 3.1.2.3).

Proof. The assertion is local on both X and Y. We may therefore assume without loss of generality that $\mathsf{X} = \operatorname{Sp\acute{e}t} A$, so that σ is determined by a pullback diagram of connective $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc} A & \longrightarrow & A_1 \\ \downarrow & & \downarrow \\ A_0 & \longrightarrow & A_{01} \end{array}$$

where the maps $\pi_0 A_0 \to \pi_0 A_{01} \leftarrow \pi_0 A_1$ are surjective. We may also assume that $\mathsf{Y} = \operatorname{Sp\acute{e}t} R$ is affine. In this case, σ' is determined by the diagram of connective $\mathbb{E}_\infty$-rings τ :

$$\begin{array}{ccc} R & \longrightarrow & R \otimes_A A_1 \\ \downarrow & & \downarrow \\ R \otimes_A A_0 & \longrightarrow & R \otimes_A A_{01}. \end{array}$$

Since the operation of tensor product with R is exact, τ is a pullback diagram. The desired result now follows from Proposition 16.1.3.1. □

Proof of Theorem 16.3.0.1. Suppose we are given a pushout diagram

$$\begin{array}{ccc} \mathsf{X}_{01} & \xrightarrow{i} & \mathsf{X}_0 \\ \downarrow{\scriptstyle j} & & \downarrow \\ \mathsf{X}_1 & \longrightarrow & \mathsf{X}, \end{array}$$

where i and j are closed immersions. We wish to prove that the canonical map

$$G : \mathrm{SpDM}_{/\mathsf{X}} \to \mathrm{SpDM}_{/\mathsf{X}_0} \times_{\mathrm{SpDM}_{/\mathsf{X}_{01}}} \mathrm{SpDM}_{/\mathsf{X}_1}$$

is an equivalence of ∞-categories. Let us identify objects of the codomain of G with triples $(\mathsf{Y}_0, \mathsf{Y}_1, \alpha)$, where $\mathsf{Y}_0 \in \mathrm{SpDM}_{/\mathsf{X}_0}$, $\mathsf{Y}_1 \in \mathrm{SpDM}_{/\mathsf{X}_1}$, and $\alpha : \mathsf{X}_{01} \times_{\mathsf{X}_0} \mathsf{Y}_0 \simeq \mathsf{X}_{01} \times_{\mathsf{X}_1} \mathsf{Y}_1$ is an equivalence in $\mathrm{SpDM}_{/\mathsf{X}_{01}}$. Given such a triple, let $\mathsf{Y}_{01} = \mathsf{X}_{01} \times_{\mathsf{X}_0} \mathsf{Y}_0$. We have a commutative diagram

$$\begin{array}{ccccc} \mathsf{Y}_0 & \xleftarrow{i'} & \mathsf{Y}_{01} & \xrightarrow{j'} & \mathsf{Y}_1 \\ \downarrow & & \downarrow & & \downarrow \\ \mathsf{X}_0 & \xleftarrow{i} & \mathsf{X}_{01} & \xrightarrow{j} & \mathsf{X}_1 \end{array}$$

where both squares are pullbacks. It follows that i' and j' are closed immersions, so that there exists a pushout diagram

$$\begin{array}{ccc} \mathsf{Y}_{01} & \xrightarrow{i'} & \mathsf{Y}_0 \\ \downarrow{\scriptstyle j'} & & \downarrow \\ \mathsf{Y}_1 & \longrightarrow & \mathsf{Y} \end{array}$$

of spectral Deligne-Mumford stacks (Theorem 16.1.0.1). The construction $(\mathsf{Y}_0, \mathsf{Y}_1, \alpha) \mapsto \mathsf{Y}$ determines a functor $F : \mathrm{SpDM}_{/\mathsf{X}_0} \times_{\mathrm{SpDM}_{/\mathsf{X}_{01}}} \mathrm{SpDM}_{/\mathsf{X}_1} \to \mathrm{SpDM}_{/\mathsf{X}}$ which is left adjoint to G. It follows from Proposition 16.3.1.1 that the counit map $v : F \circ G \to \mathrm{id}$ is an equivalence. We now prove that u is also an equivalence. Fix an object $(\mathsf{Y}_0, \mathsf{Y}_1, \alpha) \in \mathrm{SpDM}_{/\mathsf{X}_0} \times_{\mathrm{SpDM}_{/\mathsf{X}_{01}}} \mathrm{SpDM}_{/\mathsf{X}_1}$, so that we have a pushout diagram τ :

$$\begin{array}{ccc} \mathsf{Y}_{01} & \xrightarrow{i'} & \mathsf{Y}_0 \\ \downarrow{\scriptstyle j'} & & \downarrow \\ \mathsf{Y}_1 & \longrightarrow & \mathsf{Y} \end{array}$$

as above. We wish to prove that the induced maps

$$\phi : \mathsf{Y}_0 \to \mathsf{X}_0 \times_{\mathsf{X}} \mathsf{Y} \qquad \psi : \mathsf{Y}_1 \to \mathsf{X}_1 \times_{\mathsf{X}} \mathsf{Y}$$

are equivalences. We will prove that ϕ is an equivalence; the proof that ψ is an equivalence is similar. The assertion is local on X and Y; we may therefore assume that $\mathsf{X} \simeq \mathrm{Sp\acute{e}t}\, A$ and $\mathsf{Y} \simeq \mathrm{Sp\acute{e}t}\, R$ are affine. It follows that X_0, X_1, and X_{01} are affine; write

$$\mathsf{X}_0 \simeq \mathrm{Sp\acute{e}t}\, A_0 \qquad \mathsf{X}_{01} \simeq \mathrm{Sp\acute{e}t}\, A_{01} \qquad \mathsf{X}_1 \simeq \mathrm{Sp\acute{e}t}\, A_1$$

$$\mathsf{Y}_0 \simeq \mathrm{Sp\acute{e}t}\, R_0 \qquad \mathsf{Y}_{01} \simeq \mathrm{Sp\acute{e}t}\, R_{01} \qquad \mathsf{Y}_1 \simeq \mathrm{Sp\acute{e}t}\, R_1.$$

Then α determines an equivalence $\beta : A_{01} \otimes_{A_0} R_0 \simeq A_{01} \otimes_{A_1} R_1$, and we can identify the triple (R_0, R_1, β) with an object of $\mathrm{Mod}^{\mathrm{cn}}_{A_0} \times_{\mathrm{Mod}^{\mathrm{cn}}_{A_{01}}} \mathrm{Mod}^{\mathrm{cn}}_{A_1}$. Using Proposition 16.2.2.1, we deduce that (R_0, R_1, β) is determined by an object $M \in \mathrm{Mod}^{\mathrm{cn}}_A$. Then Proposition 16.1.3.1 supplies an equivalence $\theta : R \simeq R_0 \times_{R_{01}} R_1 \simeq (A_0 \times_{A_{01}} A_1) \otimes_A M \simeq M$. To prove that ϕ is an equivalence, it will suffice to show that it induces an equivalence of $\mathbb{E}_\infty$-rings $R_0 \otimes_R A \to A_0$. It now suffices to observe that the underlying map of spectra is given by the composition $R_0 \otimes_R A \overset{\theta}{\simeq} R_0 \otimes_R M \simeq A_0$. □

16.3.2 Properties Persistant Under Clutching

In the situation of Proposition 16.3.1.1, many important properties of morphism $f : \mathsf{Y} \to \mathsf{X}$ can be tested after pullback along the closed immersions $\mathsf{X}_0 \hookrightarrow \mathsf{X} \hookleftarrow \mathsf{X}_1$.

Proposition 16.3.2.1. *Suppose we are given a pushout diagram of spectral Deligne-Mumford stacks σ :*

$$\begin{array}{ccc} \mathsf{X}_{01} & \xrightarrow{i} & \mathsf{X}_0 \\ \downarrow{\scriptstyle j} & & \downarrow \\ \mathsf{X}_1 & \longrightarrow & \mathsf{X}, \end{array}$$

where i and j are closed immersions. Let $f : \mathsf{Y} \to \mathsf{X}$ be a map of spectral Deligne-Mumford stacks. Set $\mathsf{Y}_0 = \mathsf{X}_0 \times_{\mathsf{X}} \mathsf{Y}$, $\mathsf{Y}_1 = \mathsf{X}_1 \times_{\mathsf{X}} \mathsf{Y}$, and let $f_0 : \mathsf{Y}_0 \to \mathsf{X}_0$ and $f_1 : \mathsf{Y}_1 \to \mathsf{X}_1$ be the projection maps. Then:

(1) *The map f is locally of finite generation to order n if and only if both f_0 and f_1 are locally of finite generation to order n (for any $n \geqslant 0$).*

(2) *The map f is locally almost of finite presentation if and only if both f_0 and f_1 are locally almost of finite presentation.*

(3) *The map f is locally of finite presentation if and only if f_0 and f_1 are locally of finite presentation.*

(4) *The map f is étale if and only if both f_0 and f_1 are étale.*

(5) *The map f is an equivalence if and only if both f_0 and f_1 are equivalences.*

(6) *The map f is an open immersion of and only if both f_0 and f_1 are open immersions.*

(7) *The map f is flat if and only if both f_0 and f_1 are flat.*

(8) *The map f is affine if and only if both f_0 and f_1 are affine.*

(9) *The map f is a closed immersion if and only if both f_0 and f_1 are closed immersions.*

(10) *The map f is separated if and only f_0 and f_1 are separated.*

(11) *The map f is n-quasi-compact if and only if f_0 and f_1 are n-quasi-compact, for $0 \leqslant n \leqslant \infty$.*

(12) *The map f is proper if and only if f_0 and f_1 are proper.*

Proof. The "only if" directions are obvious. The converse assertions are all local on X, so we may assume without loss of generality that $\mathsf{X} = \operatorname{Sp\acute{e}t} A$ is affine. In this case, the diagram σ is determined by a pullback square of connective $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc} A & \longrightarrow & A_1 \\ \downarrow & & \downarrow \\ A_0 & \longrightarrow & A_{01}, \end{array}$$

where the maps $\pi_0 A_0 \to \pi_0 A_{01} \leftarrow \pi_0 A_1$ are surjective.

We first prove (1). The assertion is local on Y, so we may assume that $\mathsf{Y} = \operatorname{Sp\acute{e}t} R$ is affine. By assumption, the $\mathbb{E}_\infty$-algebras $R_0 = A_0 \otimes_A R$ and $R_1 = A_1 \otimes_A R$ are of finite generation to order n over A_0 and A_1, respectively. We wish to show that R is of finite generation to order n over A. We first treat the case $n = 0$. Then $\pi_0 R_0$ and $\pi_0 R_1$ are finitely generated as commutative rings over $\pi_0 A$. Since the maps $\pi_0 R \to \pi_0 R_0$ and $\pi_0 R \to \pi_0 R_1$ are surjective, we can choose a finite collection $x_1, \ldots, x_n \in \pi_0 R$ whose images generate $\pi_0 R_0$ and $\pi_0 R_1$ over $\pi_0 A$. Let $B = A\{X_1, \ldots, X_n\}$ denote the $\mathbb{E}_\infty$-algebra over A freely generated by a collection of indeterminates $X_1, \ldots, X_n$, so that there is a map of $\mathbb{E}_\infty$-algebras $\phi : B \to R$ which is determined uniquely up to homotopy by the requirement that $\phi(X_i) = x_i \in \pi_0 R$ for $1 \leqslant i \leqslant k$. Let I denote the fiber of ϕ, and regard I as a R-module. Then $A_0 \otimes_A I$ and $A_1 \otimes_A I$ can be identified with the fibers of the induced maps

$$A_0\{X_1, \ldots, X_k\} \to R_0 \qquad A_1\{X_1, \ldots, X_k\} \to R_1,$$

and are therefore connective. It follows that I is connective, so that ϕ induces a surjection $\pi_0 B \simeq (\pi_0 A)[X_1, \ldots, X_k] \to \pi_0 R$. This proves that $\pi_0 R$ is finitely generated as a commutative ring over $\pi_0 A$, so that R is of finite generation to order 0 over A.

We next prove (1) in the case $n \geqslant 1$. Assume that R_0 and R_1 are of finite generation to order n over A_0 and A_1, respectively. Then the relative cotangent complexes

$$L_{R_0/A_0} \simeq R_0 \otimes_R L_{R/A} \qquad L_{R_1/A_1} \simeq R_1 \otimes_R L_{R/A}$$

are perfect to order n over R_0 and R_1, respectively. Using Proposition 16.2.3.1, we deduce that $L_{R/A}$ is perfect to order n as an R-module. Consequently, to show that R is of finite presentation to order n over A, it will suffice to show that $\pi_0 R$ is finitely presented as a commutative ring over $\pi_0 A$ (Proposition 4.1.2.1). Let $\phi : B \to R$ and $I = \operatorname{fib}(\phi)$ be defined as above. We have surjective maps

$$\pi_0 I \to \pi_0(A_0 \otimes_A I) \to \ker((\pi_0 A_0)[X_1, \ldots, X_k] \to \pi_0 R_0)$$
$$\pi_0 I \to \pi_0(A_1 \otimes_A I) \to \ker((\pi_0 A_1)[X_1, \ldots, X_k] \to \pi_0 R_1).$$

Since $\pi_0 R_0$ and $\pi_0 R_1$ are finitely presented as commutative rings over $\pi_0 A_0$ and $\pi_0 A_1$, respectively, we can choose a finite collection of elements $y_1, \ldots, y_m \in \pi_0 I$ whose images generate the ideals

$$\ker((\pi_0 A_0)[X_1, \ldots, X_k] \to \pi_0 R_0) \qquad \ker((\pi_0 A_1)[X_1, \ldots, X_k] \to \pi_0 R_1).$$

Let $A\{Y_1, \ldots, Y_m\}$ be the corresponding free $\mathbb{E}_\infty$-algebra over A, so that the choice of elements y_i determine a commutative diagram of $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc} A\{Y_1, \ldots, Y_m\} & \longrightarrow & A \\ \downarrow & & \downarrow \\ B & \longrightarrow & R. \end{array}$$

Let B' denote the pushout $A \otimes_{A\{Y_1,\ldots,Y_m\}} B$, so that we obtain a map of $\mathbb{E}_\infty$-rings $\psi : B' \to R$. Then B' is of finite presentation over A, so that $\pi_0 B'$ is finitely presented as a commutative ring over $\pi_0 A$. By construction, ψ induces a surjection $\pi_0 B' \to \pi_0 R$. Let $J \subseteq \pi_0 B'$ denote the kernel of this surjection. To complete the proof, it will suffice to show that J is a finitely generated ideal in $\pi_0 B'$.

Let $B'_0 = A_0 \otimes_A B'$, and define B'_1 and B'_{01} similarly. We have a pullback diagram of connective $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc} B' & \longrightarrow & B'_0 \\ \downarrow & & \downarrow \\ B'_1 & \longrightarrow & B'_{01}. \end{array}$$

By construction ψ induces isomorphisms $\pi_0 B'_0 \simeq \pi_0 R_0$ and $\pi_0 B'_1 \simeq \pi_0 R_1$. It follows that J is contained in the kernel of the map $\pi_0 B \to \pi_0 B'_0 \times \pi_0 B'_1$, which is the image of the boundary map $\pi_1 B'_{01} \to \pi_0 B'$. It follows that the action of $\pi_0 B'$ on J factors through the acton of $\pi_0 B'_{01}$. Since J belongs to the kernel of the map $\pi_0 B' \to \pi_0 B'_{01}$, we deduce that $J^2 = 0$. Consequently, the map $J \to \mathrm{Tor}_0^{\pi_0 B'}(\pi_0 R, J) \simeq \pi_0(R \otimes_{B'} \mathrm{fib}(\psi))$ is bijective. To prove that J is a finitely generated ideal in $\pi_0 B'$, it suffices to show that $\pi_0(R \otimes_{B'} \mathrm{fib}(\psi))$ is finitely generated as a module over $\pi_0 R$. Applying Theorem HA.7.4.3.1 , we obtain a canonical isomorphism $\pi_0(R \otimes_{B'} \mathrm{fib}(\psi)) \simeq \pi_1 L_{R/B'}$. Since $L_{R/B'}$ is 1-connective, it will suffice to show that $L_{R/B'}$ is perfect to order 1 as an R-module. We have a fiber seqence

$$R \otimes_{B'} L_{B'/A} \to L_{R/A} \to L_{R/B'}.$$

By construction, B' is finitely presented over A, so that $L_{B'/A}$ is perfect as a B'-module. Using Remark 2.7.0.7, we are reduced to showing that $L_{R/A}$ is perfect to order 1 as an R-module, which was already proven above. This completes the proof of (1).

Assertion (2) follows immediately from (1). We now prove (3). As before, we may suppose that $\mathsf{Y} = \mathrm{Sp\acute{e}t}\, R$ is affine. Then R_0 and R_1 are locally of finite presentation over A_0 and A_1, respectively, so that the relative cotangent complexes $L_{R_0/A_0} \simeq R_0 \otimes_R L_{R/A}$ and $L_{R_1/A_1} \simeq R_1 \otimes_R L_{R/A}$ are perfect. Using Proposition 16.2.3.1, we deduce that $L_{R/A}$ is a perfect R-module. Since R is almost of finite presentation over A (by (2)), we deduce from Theorem HA.7.4.3.18 that R is locally of finite presentation over A.

We now prove (4). Once again we may suppose that $\mathsf{Y} = \mathrm{Sp\acute{e}t}\, R$ is affine. If R_0 and R_1 are étale over A_0 and A_1, then we obtain

$$R_0 \otimes_R L_{R/A} \simeq L_{R_0/A_0} \simeq 0 \simeq L_{R_1/A_1} \simeq R_1 \otimes_R L_{R/A}.$$

Using Theorem 16.2.0.2 we deduce that $L_{R/A} \simeq 0$. Since R is almost of finite presentation over A (by (2)), it follows from Lemma B.1.3.3 that R is étale over A.

Assertion (5) follows immediately from Theorem 16.3.0.1. Assertion (6) follows from (4) and (5), since f is an open immersion if and only if f is étale and the diagonal map $\mathsf{Y} \to \mathsf{Y} \times_{\mathsf{X}} \mathsf{Y}$ is an equivalence. To prove (7), we may assume without loss of generality that $\mathsf{Y} = \operatorname{Sp\acute{e}t} R$ is affine. In this case, the desired result follows from Proposition 16.2.3.1. Assertion (8) follows from Theorem 16.1.0.1.

We now prove (9). Assume that f_0 and f_1 are closed immersions. It follows from (8) that f is affine, so that $\mathsf{Y} \simeq \operatorname{Sp\acute{e}t} R$ for some connective $\mathbb{E}_\infty$-ring R. We have a fiber sequence of A-modules $I \to A \to R$. The map f is a closed immersion if and only if the map $\pi_0 A \to \pi_0 R$ is surjective, which is equivalent to the requirement that I is connective. Since f_0 and f_1 are closed immersions, the tensor products $A_0 \otimes_A I$ and $A_1 \otimes_A I$ are connective. It follows from Proposition 16.2.3.1 that I is connective, as desired.

Assertion (10) follows by applying (9) to the diagonal map $\mathsf{Y} \to \mathsf{Y} \times_{\mathsf{X}} \mathsf{Y}$. To prove (11), it suffices to treat the case where $n < \infty$. We proceed by induction on n. If $n > 0$, it suffices to show that if we are given a pair of étale maps $\mathsf{U} \to \mathsf{Y} \leftarrow \mathsf{V}$ where U and V are affine, then $\mathsf{U} \times_{\mathsf{Y}} \mathsf{V}$ is $(n-1)$-quasi-compact. If Y_0 and Y_1 are n-quasi-compact, then the spectral Deligne-Mumford stacks

$$\mathsf{X}_0 \times_{\mathsf{X}} (\mathsf{U} \times_{\mathsf{Y}} \mathsf{V}) \qquad \mathsf{X}_1 \times_{\mathsf{X}} (\mathsf{U} \times_{\mathsf{Y}} \mathsf{V})$$

are $(n-1)$-quasi-compact, so that the desired result follows from the inductive hypothesis. It therefore suffices to treat the case $n = 0$. Suppose that Y can be described as the colimit of a diagram of open substacks $\{\mathsf{Y}_\alpha\}_{\alpha \in P}$ indexed by a filtered poset P. Since Y_0 is quasi-compact, there exists an index $\alpha \in P$ such that $\mathsf{Y}_\alpha \times_{\mathsf{Y}} \mathsf{Y}_0 \simeq \mathsf{Y}_0$. Enlarging α if necessary, we may suppose that $\mathsf{Y}_\alpha \times_{\mathsf{Y}} \mathsf{Y}_1 \simeq \mathsf{Y}_1$. It then follows from (5) that the open immersion $\mathsf{Y}_\alpha \hookrightarrow \mathsf{Y}$ is an equivalence.

We now prove (12). Suppose that f_0 and f_1 are proper. Then (1) implies that f is locally of finite type, (11) implies that f is quasi-compact, and (10) implies that f is separated. In order to prove that f is proper, it will suffice to show that f is universally closed. Replacing f by a pullback of f if necessary, we are reduced to showing that f is closed. Let $K \subseteq |\mathsf{X}|$ be a closed subset; we wish to show that the image of $f(K) \subseteq |\mathsf{Y}|$ is closed. This follows from the observation that $f(K)$ is given by the union of the images of the sets $K \times_{|\mathsf{X}|} |\mathsf{X}_0|$ and $K \times_{|\mathsf{X}|} |\mathsf{X}_1|$ along the closed maps

$$|\mathsf{X}_0| \xrightarrow{f_0} |\mathsf{Y}_0| \hookrightarrow |\mathsf{Y}| \hookleftarrow |\mathsf{Y}_1| \xleftarrow{f_1} |\mathsf{X}_1|.$$

□

Corollary 16.3.2.2. *Suppose we are given a pushout diagram of spectral Deligne-Mumford* *stacks*

$$\begin{array}{ccc} \mathsf{X}_{01} & \xrightarrow{i} & \mathsf{X}_0 \\ \downarrow{\scriptstyle j} & & \downarrow \\ \mathsf{X}_1 & \longrightarrow & \mathsf{X} \end{array}$$

where i and j are closed immersions. If X_0 and X_1 are separated, then X is also separated.

Proof. We wish to show that the diagonal map $\delta : \mathsf{X} \to \mathsf{X} \times \mathsf{X}$ is a closed immersion. Using Proposition 16.3.2.1, we may reduce to proving that each of the vertical maps appearing in the diagram

$$\begin{array}{ccccc} \mathsf{X}_0 & \longleftarrow & \mathsf{X}_{01} & \longrightarrow & \mathsf{X}_1 \\ \downarrow{\scriptstyle \delta_0} & & \downarrow{\scriptstyle \delta_{01}} & & \downarrow{\scriptstyle \delta_1} \\ \mathsf{X}_0 \times \mathsf{X} & \longleftarrow & \mathsf{X}_{01} \times \mathsf{X} & \longrightarrow & \mathsf{X}_1 \times \mathsf{X} \end{array}$$

is a closed immersion. We will prove that δ_0 is a closed immersion; the proof in the other two cases are similar. We can factor δ_0 as a composition

$$\mathsf{X}_0 \xrightarrow{\delta'} \mathsf{X}_0 \times \mathsf{X}_0 \xrightarrow{\delta''} \mathsf{X}_0 \times \mathsf{X}.$$

Here δ' is a closed immersion (by virtue of our assumption that X_0 is a separated spectral algebraic space), and δ'' is a pullback of the closed immersion $\mathsf{X}_0 \to \mathsf{X}$. □

16.3.3 Application: Deformations of Spectral Deligne-Mumford Stacks

For every connective $\mathbb{E}_\infty$-ring R, let $\mathrm{SpDM}_R = \mathrm{SpDM}_{/\operatorname{Sp\acute{e}t} R}$ denote the ∞-category of spectral Deligne-Mumford stacks over R. The ∞-category SpDM_R depends functorially on R. In particular, if we fix a spectral Deligne-Mumford stack X_0 defined over a field κ, then the construction $R \mapsto \mathrm{SpDM}_R \times_{\mathrm{SpDM}_\kappa} \{\mathsf{X}_0\}$ determines a functor $M : \mathrm{CAlg}^{\mathrm{art}}_\kappa \to \widehat{\mathcal{C}\mathrm{at}}_\infty$, which assigns to each Artinian κ-algebra R the ∞-category $M(R)$ of deformations of X_0 over R: that is, the ∞-category whose objects are pullback diagrams

$$\begin{array}{ccc} \mathsf{X}_0 & \longrightarrow & \mathsf{X}_R \\ \downarrow & & \downarrow \\ \operatorname{Sp\acute{e}t} \kappa & \longrightarrow & \operatorname{Sp\acute{e}t} R. \end{array}$$

If R is a nonzero connective $\mathbb{E}_\infty$-ring, then the ∞-category SpDM_R contains noninvertible morphisms, and is not essentially small. However, if R is an Artinian $\mathbb{E}_\infty$-algebra over κ, then the augmentation map $R \to \kappa$ determines a conservative functor $\mathrm{SpDM}_R \to \mathrm{SpDM}_\kappa$, so that $M(R)$ is a Kan complex.

Theorem 16.3.3.1. *Let κ be a field and let X_0 be a spectral Deligne-Mumford stack over κ. Then the construction $R \mapsto M(R)$ determines a formal moduli problem $M : \mathrm{CAlg}^{\mathrm{art}}_\kappa \to \mathcal{S}$.*

Proof. Let κ be a field and let $\mathsf{X}_0 \to \operatorname{Sp\acute{e}t} \kappa$ be a map of spectral Deligne-Mumford stacks over κ. For every pullback diagram

$$\begin{array}{ccc} R & \longrightarrow & R_0 \\ \downarrow & & \downarrow \\ R_1 & \longrightarrow & R_{01} \end{array}$$

in $\mathrm{CAlg}_\kappa^{\mathrm{art}}$ where the maps $\pi_0 R_0 \to \pi_0 R_{01} \leftarrow \pi_0 R_1$ are surjective, we obtain a pushout square of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \operatorname{Sp\acute{e}t} R_{01} & \longrightarrow & \operatorname{Sp\acute{e}t} R_0 \\ \downarrow & & \downarrow \\ \operatorname{Sp\acute{e}t} R_1 & \longrightarrow & \operatorname{Sp\acute{e}t} R \end{array}$$

where the morphisms are closed immersions. It then follows from Theorem 16.3.0.1 that the map $M(R) \to M(R_1) \times_{M(R_{01})} M(R_1)$ is a homotopy equivalence. It follows immediately from the definitions that $M(\kappa)$ is contractible.

To complete the proof, it will suffice to show that the ∞-groupoid $M(R)$ is essentially small for each object $R \in \mathrm{CAlg}_\kappa^{\mathrm{art}}$. Since R is Artinian, there exists a finite sequence of maps

$$R = R_0 \to R_1 \to \cdots \to R_n \simeq \kappa,$$

where each of the maps $R_i \to R_{i+1}$ fits into a pullback square

$$\begin{array}{ccc} R_i & \longrightarrow & R_{i+1} \\ \downarrow & & \downarrow \\ \kappa & \longrightarrow & \kappa \oplus \Sigma^{m_i}(\kappa). \end{array}$$

We will prove that each $M(R_i)$ is essentially small, using descending induction on i. When $i = n$, $M(R_i)$ is contractible and there is nothing to prove. To carry out the inductive step, we note that there is a fiber sequence $M(R_i) \to M(R_{i+1}) \to M(\kappa \oplus \Sigma^{m_i}(\kappa))$. Since $M(R_{i+1})$ is essentially small and $M(\kappa \oplus \Sigma^{m_i}(\kappa))$ is locally small, it follows immediately that $M(R_i)$ is essentially small. □

Remark 16.3.3.2. Let κ be a field of characteristic zero, and let X_0 be a spectral Deligne-Mumford stack over κ. It follows from Theorems 16.3.3.1 and 13.3.0.1 that there exists a differential graded Lie algebra $\mathfrak{g}_*$ over κ with the following universal property: for every Artinian $\mathbb{E}_\infty$-algebra R over κ, there is a canonical homotopy equivalence

$$\mathrm{Map}_{\mathrm{Lie}_\kappa}(\mathfrak{D}(R), \mathfrak{g}_*) \simeq \mathrm{SpDM}_R \times_{\mathrm{SpDM}_\kappa} \{\mathsf{X}_0\}.$$

That is, deformations of X_0 are "controlled" by the differential graded Lie algebra $\mathfrak{g}_*$. It is possible to describe the differential graded Lie algebra $\mathfrak{g}_*$ more explicitly: in good cases, it can be obtained as the global sections of the tangent complex of X over κ. We refer the reader to §19.4 for a more detailed discussion.

16.4 Approximations to Formal Moduli Problems

The notion of formal moduli problem introduced in Definition 12.1.3.1 is a very general one, which includes (as a special case) the formal completion of any reasonable algebro-geometric object at a point (see Example 16.1.3.2). However, there are also many functors $X : \mathrm{CAlg}^{\mathrm{cn}}_{\kappa} \to \mathcal{S}$ which do not quite satisfy the requirements of being a formal moduli problem, but are nevertheless of interest in deformation theory. The deformation functors that we will study in §16.5 and §16.6 are of this nature. In this section, we will introduce a generalization of the notion of formal moduli problem (see Definition 16.4.1.5) which incorporates these examples as well.

16.4.1 n-Proximate Formal Moduli Problems

We begin by introducing some terminology.

Definition 16.4.1.1. Let $n \geqslant -2$ be an integer. We will say that a diagram of spaces

$$\begin{array}{ccc} X' & \longrightarrow & Y' \\ \downarrow & & \downarrow \\ X & \longrightarrow & Y \end{array}$$

is *n-Cartesian* if the induced map $\phi : X' \to X \times_Y Y'$ is n-truncated (that is, the homotopy fibers of ϕ are n-truncated).

Example 16.4.1.2. If $n = -2$, then a commutative diagram of spaces is n-Cartesian if and only if it is a pullback square.

The following lemma summarizes some of the basic transitivity properties of Definition 16.4.1.1:

Lemma 16.4.1.3. *Let $n \geqslant -2$ be an integer, and suppose we are given a commutative diagram*

$$\begin{array}{ccccc} X' & \longrightarrow & Y' & \longrightarrow & Z' \\ \downarrow & & \downarrow & & \downarrow \\ X & \longrightarrow & Y & \longrightarrow & Z \end{array}$$

in $\mathcal{S}$. If the right square is n-Cartesian, then the outer square is n-Cartesian if and only if the left square is n-Cartesian.

Using Lemma 16.4.1.3, we immediately deduce the following generalization of Proposition 12.1.3.2.

Proposition 16.4.1.4. *Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context, and let $X : \mathbf{A}^{\text{art}} \to \mathcal{S}$ be a functor. Let $n \geqslant 0$ be an integer. The following conditions are equivalent:*

(1) *Let σ :*

$$\begin{array}{ccc} A' & \longrightarrow & B' \\ \downarrow & & \downarrow \phi \\ A & \longrightarrow & B \end{array}$$

be a diagram in $\mathbf{A}^{\text{art}}$. If σ is a pullback diagram and ϕ is small, then $X(\sigma)$ is an $(n-2)$-Cartesian diagram in $\mathcal{S}$.

(2) *Let σ be as in (1). If σ is a pullback diagram and ϕ is elementary, then $X(\sigma)$ is an $(n-2)$-Cartesian diagram in $\mathcal{S}$.*

(3) *Let σ be as in (1). If σ is a pullback diagram and ϕ is the base point morphism $* \to \Omega^{\infty - m} E_\alpha$ for some $\alpha \in T$ and $m > 0$, then $X(\sigma)$ is an $(n-2)$-Cartesian diagram in $\mathcal{S}$.*

Definition 16.4.1.5. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context and let $n \geqslant 0$ be an integer. We will say that a functor $X : \mathbf{A}^{\text{art}} \to \mathcal{S}$ is a *n-proximate formal moduli problem* if $X(*)$ is contractible and X satisfies the equivalent conditions of Proposition 16.4.1.4.

Example 16.4.1.6. A functor $X : \mathbf{A}^{\text{art}} \to \mathcal{S}$ is a 0-proximate formal moduli problem if and only if it is a formal moduli problem, in the sense of Definition 12.1.3.1.

Remark 16.4.1.7. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context, and suppose we are given a pullback diagram

$$\begin{array}{ccc} X' & \longrightarrow & Y' \\ \downarrow & & \downarrow \\ X & \longrightarrow & Y \end{array}$$

in $\text{Fun}(\mathbf{A}^{\text{art}}, \mathcal{S})$. If X and Y' are n-proximate formal moduli problems and Y is an $(n+1)$-proximate formal moduli problem, then X' is an n-proximate formal moduli problem.

Definition 16.4.1.8. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context and let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathbf{A}^{\text{art}} \to \mathcal{S}$. We will say that f is *n-truncated* if the induced map $X(A) \to Y(A)$ is n-truncated, for each $A \in \text{Art}$.

16.4.2 Classification of n-Proximate Formal Moduli Problems

Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context and let $n \geqslant 0$ be an integer. Roughly speaking, a functor $X : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ is an n-proximate formal moduli problem if the axioms of Definition 12.1.3.1 are *approximately* satisfied (where the degree of approximation required depends on n). The main result of this section asserts that, if $\mathbf{A}$ admits a deformation theory, then this is equivalent to the requirement that X can be approximated by a functor which satisfies the axioms of Definition 12.1.3.1 exactly.

Theorem 16.4.2.1. *Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context which admits a deformation theory, and let $X : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ be a functor such that $X(*)$ is contractible (here $*$ denotes the final object of $\mathbf{A}$). The following conditions are equivalent:*

(1) *The functor X is an n-proximate formal moduli problem.*

(2) *There exists an $(n-2)$-truncated map $f : X \to Y$, where Y is an n-proximate formal moduli problem.*

(3) *Let L denote a left adjoint to the inclusion* $\mathrm{Moduli}^{\mathbf{A}} \subseteq \mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$ *(see Remark 12.1.3.5). Then the unit map $X \to LX$ is $(n-2)$-truncated.*

Remark 16.4.2.2. In the statement of Theorem 16.4.2.1, the implications $(3) \Rightarrow (2) \Rightarrow (1)$ do not require the assumption that $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ admits a deformation theory. We do not know if the implication $(1) \Rightarrow (3)$ holds in greater generality.

Remark 16.4.2.3. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context which admits a deformation theory, and let $X : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ be an n-proximate formal moduli problem. It follows from Theorem 16.4.2.1 that there exists an $(n-2)$-truncated natural transformation $\alpha : X \to Y$, where Y is a formal moduli problem. In fact, the formal moduli problem Y (and the natural transformation α) are uniquely determined up to equivalence. To prove this, we note that α factors as a composition $X \xrightarrow{\beta} LX \xrightarrow{\gamma} Y$, where β is $(n-2)$-truncated and γ is a map between formal moduli problems. For each $\alpha \in T$ and each $m \geqslant 0$, we have homotopy equivalences

$$\Omega^n X(\Omega^{\infty - m - n} E_\alpha) \simeq \Omega^n LX(\Omega^{\infty - m - n} E_\alpha) \simeq LX(\Omega^{\infty - m} E_\alpha)$$

$$\Omega^n X(\Omega^{\infty - m - n} E_\alpha) \simeq \Omega^n Y(\Omega^{\infty - m - n} E_\alpha) \simeq Y(\Omega^{\infty - m} E_\alpha).$$

From this it follows that γ induces an equivalence $LX(\Omega^{\infty - m} E_\alpha) \to Y(\Omega^{\infty - m} E_\alpha)$. Since LX and Y are formal moduli problems, we conclude that γ is an equivalence.

16.4.3 Approximating the Tangent Complex

The main ingredient in our proof of Theorem 16.4.2.1 is to show that if $X : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ is an n-proximate formal moduli problem and $LX \in \mathrm{Moduli}^{\mathbf{A}}$ is the associated formal moduli problem, then the tangent complex of LX can be computed directly from X. To make this idea precise, we need to introduce a bit of notation. In what follows, let us identify $\mathrm{Sp} = \mathrm{Sp}(\mathcal{S})$ with the ∞-category of reduced and excisive functors $\mathcal{S}_*^{\mathrm{fin}} \to \mathcal{S}$. Let $L_0 : \mathrm{Fun}(\mathcal{S}_*^{\mathrm{fin}}, \mathcal{S}) \to \mathrm{Sp}$ denote a left adjoint to the inclusion. If $X : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ is any functor, then the composition $X \circ E_\alpha$ is a functor from $\mathcal{S}_*^{\mathrm{fin}}$ to $\mathcal{S}$, and therefore determines a spectrum $L_0(X \circ E_\alpha)$.

Remark 16.4.3.1. Suppose that $F : \mathcal{S}_*^{\mathrm{fin}} \to \mathcal{S}$ is a functor which preserves final objects. Using Example HA.6.1.1.28 , we see that $L_0 F \in \mathrm{Sp}$ is given by the formula $(L_0 F)(K) = \varinjlim_n \Omega^n L_0(\Sigma^n K)$. In particular, the functor L_0 is left exact when restricted to the full subcategory $\mathrm{Fun}_*(\mathcal{S}_*^{\mathrm{fin}}, \mathcal{S}) \subseteq \mathrm{Fun}(\mathcal{S}_*^{\mathrm{fin}}, \mathcal{S})$ spanned by those functors which preserve final objects.

We will need the following:

Proposition 16.4.3.2. *Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context which admits a deformation theory and let L denote a left adjoint to the inclusion functor $\mathrm{Moduli}^{\mathbf{A}} \subseteq \mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$. Suppose that $X : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ is an n-proximate formal moduli problem for some $n \geqslant 0$.*

For each $\alpha \in T$, the canonical map $X(E_\alpha) \to (LX)(E_\alpha)$ induces an equivalence of spectra $L_0(X \circ E_\alpha) \to (LX) \circ E_\alpha$.

Proof. The proof proceeds by induction on n. In this case $n = 0$, $X \simeq LX$ and $X \circ E_\alpha$ is a spectrum, so there is nothing to prove. Assume therefore that $n > 0$. Let $\mathcal{C}$ be the full subcategory of $\mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$ spanned by the $(n-1)$-proximate formal moduli problems, and let $\mathcal{C}_{/X}$ denote the fiber product $\mathcal{C} \times_{\mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})} \mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})_{/X}$. By the inductive hypothesis, the map $L_0(Y \circ E_\alpha) \to (LY) \circ E_\alpha$ is an equivalence of spectra for each $Y \in \mathcal{C}_{/X}$. It will therefore suffice to prove the following assertions (for each $\alpha \in T$):

- (a) The spectrum $L_0(X \circ E_\alpha)$ is a colimit of the diagram $\{L_0(Y \circ E_\alpha)\}_{Y \in \mathcal{C}_{/X}}$ in the ∞-category Sp.
- (b) The spectrum $(LX) \circ E_\alpha$ is a colimit of the diagram $\{(LY) \circ E_\alpha\}_{Y \in \mathcal{C}_{/X}}$ in the ∞-category Sp.

To prove (a), we note that L_0 preserves colimits (being a left adjoint) and that the construction $Y \mapsto Y(E_\alpha)$ carries colimit diagrams in $\mathrm{Fun}_*(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$ to colimit diagrams in $\mathrm{Fun}_*(\mathcal{S}_*^{\mathrm{fin}}, \mathcal{S})$, where $\mathrm{Fun}_*(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$ denotes the full subcategory of $\mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$ spanned by those functors which preserve final objects and $\mathrm{Fun}_*(\mathcal{S}_*^{\mathrm{fin}}, \mathcal{S})$ is defined similarly. It will therefore suffice to show that X is a colimit of the diagram $\mathcal{C}_{/X} \to \mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$. (and therefore also of the underlying functor $\mathcal{C}_{/X} \to \mathrm{Fun}_*(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$). We prove a more general assertion: namely, that the identity functor from $\mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$ to itself is a left Kan extension of the inclusion $\mathcal{C} \to \mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$. This follows from Proposition HTT.4.3.2.8 and Lemma HTT.5.1.5.3 , since $\mathcal{C}$ contains the corepresentable functor $\mathrm{Spf}\, R$ for each $R \in \mathbf{A}^{\mathrm{art}}$.

We now prove (b). Fix an index $\alpha \in T$, and let $F : \mathcal{C}_{/X} \to \mathrm{Sp}$ be the functor given by $Y \mapsto (LY) \circ E_\alpha$. Let $*$ denote the final object of $\mathbf{A}$ and let $X_0 = \mathrm{Spf}(*)$ denote the functor corepresented by $*$, so that X_0 is an initial object of $\mathrm{Fun}_*(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$. Let $X_\bullet$ denote the Čech nerve of the map $X_0 \to X$, and let $\mathcal{C}^0_{/X}$ denote the full subcategory of $\mathcal{C}_{/X}$ spanned by those maps $Y \to X$ which factor through X_0. We first prove:

$(*)$ The functors $L|_{\mathcal{C}_{/X}} : \mathcal{C}_{/X} \to \mathrm{Moduli}^{\mathbf{A}}$ and $F : \mathcal{C}_{/X} \to \mathrm{Sp}$ are left Kan extensions of $L|_{\mathcal{C}^0_{/X}}$ and $F|_{\mathcal{C}^0_{/X}}$.

To prove $(*)$, choose an object $Y \in \mathcal{C}_{/X}$, and let $\mathcal{C}^0_{/Y}$ be the full subcategory of $\mathcal{C}_{/Y}$ spanned by those morphisms $Z \to Y$ which factor through $Y_0 = X_0 \times_X Y$. We wish to prove that $LY \in \mathrm{Moduli}^{\mathbf{A}}$ and $FY \in \mathrm{Sp}$ are colimits of the diagrams $L|_{\mathcal{C}^0_{/Y}}$ and $F|_{\mathcal{C}^0_{/Y}}$, respectively. Let $Y_\bullet$ denote the simplicial object of $\mathcal{C}^0_{/Y}$ given by the Cech nerve of the map $Y_0 \to Y$, so that $Y_n \simeq X_n \times_X Y$. The construction $[n] \mapsto Y_n$ determines a left cofinal map $\mathbf{\Delta}^{\mathrm{op}} \to \mathcal{C}^0_{/Y}$; it will therefore suffice to show that the canonical maps

$$u : |LY_\bullet| \to LY \qquad v : |FY_\bullet| \to FY$$

are equivalences. Using Theorem 12.3.3.5 and condition (4) of Definition 12.3.3.2, we deduce that the construction $Z \mapsto Z \circ E_\alpha$ determines a functor $\mathrm{Moduli}^{\mathbf{A}} \to \mathrm{Sp}$ which commutes with sifted colimits. Consequently, to prove that u is an equivalence, it will suffice to show that v is an equivalence for every choice of index $\alpha \in T$. It follows from Remark 16.4.1.7 that each Y_m is an $(n-1)$-proximate formal moduli problem. Using the inductive hypothesis, we are reduced to showing that the canonical map $\theta : |L_0(Y_\bullet \circ E_\alpha)| \to L_0(Y(E_\alpha))$ is an equivalence of spectra. Note that $Y_\bullet \circ E_\alpha$ is the Čech nerve of the natural transformation $Y_0 \circ E_\alpha \to Y \circ E_\alpha$ in the ∞-category $\mathrm{Fun}_*(\mathcal{S}^{\mathrm{fin}}_*, \mathcal{S})$. Since the functor L_0 is left exact when restricted to $\mathrm{Fun}_*(\mathcal{S}^{\mathrm{fin}}_*, \mathcal{S})$ (Remark 16.4.3.1), we conclude that $L_0(Y_\bullet(E_\alpha))$ is a Čech nerve of the map $L_0(Y_0 \circ E_\alpha) \to L_0(Y \circ E_\alpha))$, so that θ is an equivalence as desired.

To prove (b), we must show that $(LX) \circ E_\alpha$ is a colimit of the diagram F. Since F is a left Kan extension of $F|_{\mathcal{C}^0_{/X}}$, it will suffice to show that $(LX) \circ E_\alpha)$ is a colimit of the diagram $F|_{\mathcal{C}^0_{/X}}$ (Lemma HTT.4.3.2.7). The simplicial object $X_\bullet$ determines a left cofinal map $\mathbf{\Delta}^{\mathrm{op}} \to \mathcal{C}^0_{/X}$. We are therefore reduced to proving that the map $|(LX_\bullet) \circ E_\alpha| \to (LX) \circ E_\alpha$ is an equivalence of spectra. Since the construction $Z \mapsto Z \circ E_\alpha$ determines a functor $\mathrm{Moduli}^{\mathbf{A}} \to \mathrm{Sp}$ which preserves sifted colimits, it will suffice to show that $|LX_\bullet| \simeq LX$ in $\mathrm{Moduli}^{\mathbf{A}}$. This is equivalent to the assertion that LX is a colimit of the diagram $L|_{\mathcal{C}^0_{/X}}$.

Using $(*)$ and Lemma HTT.4.3.2.7 , we are reduced to proving that LX is a colimit of the diagram $L|_{\mathcal{C}_{/X}}$. Since L preserves small colimits, this follows from the fact that X is a colimit of the inclusion functor $\mathcal{C}_{/X} \hookrightarrow \mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$. □

16.4.4 The Proof of Theorem 16.4.2.1

Our proof of Theorem 16.4.2.1 will require a few more preliminaries.

Lemma 16.4.4.1. *Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context and let $X : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ be an n-proximate formal moduli problem. For each $\alpha \in T$ and each $m \geqslant 0$, the canonical map $\theta : X(\Omega^{\infty-m} E_\alpha) \to \Omega^{\infty-m} L_0(X \circ E_\alpha))$ is $(n-2)$-truncated.*

Proof. We observe that θ is a filtered colimit of a sequence of morphisms

$$\theta_{m'} : X(\Omega^{\infty-m} E_\alpha) \to \Omega^{m'} X(\Omega^{\infty-m-m'} E_\alpha).$$

It will therefore suffice to show that each $\theta_{m'}$ is $(n-2)$-truncated. Each $\theta_{m'}$ is given by a composition of a finite sequence of morphisms $X(\Omega^{\infty-p} E_\alpha) \to \Omega X(\Omega^{\infty-p-1} E_\alpha)$, which is $(n-2)$-truncated by virtue of our assumption that X is an n-proximate formal moduli problem. □

Lemma 16.4.4.2. *Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context and let $f : X \to Y$ be a natural transformation between n-proximate formal moduli problems $X, Y : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$. Assume that, for every index $\alpha \in T$ and each $m \geqslant 0$, the map of spaces $X(\Omega^{\infty-m} E_\alpha) \to Y(\Omega^{\infty-m} E_\alpha)$ is $(n-2)$-truncated. Then, for each $A \in \mathbf{A}^{\mathrm{art}}$, the map $X(A) \to Y(A)$ is $(n-2)$-truncated.*

Proof. Since A is Artinian, we can choose a sequence of elementary morphisms

$$A = A_0 \to A_1 \to \cdots \to A_p \simeq *.$$

We will prove that the map $\theta_i : X(A_i) \to Y(A_i)$ is $(n-2)$-truncated by descending induction on i. The case $i = p$ is clear (since θ is a morphism between contractible spaces and therefore a homotopy equivalence). Assume therefore that $i < p$ and that θ_{i+1} is $(n-2)$-truncated. Since the map $A_i \to A_{i+1}$ is elementary, we have a fiber sequence $A_i \to A_{i+1} \to \Omega^{\infty-m} E_\alpha$ in $\mathbf{A}^{\mathrm{art}}$. Let F be the homotopy fiber of the map $X(A_{i+1}) \to X(\Omega^{\infty-m} E_\alpha)$, and let F' be the homotopy fiber of the map $Y(A_{i+1}) \to Y(\Omega^{\infty-m} E_\alpha)$. We have a map of fiber sequences

$$\begin{array}{ccccc} F & \longrightarrow & X(A_{i+1}) & \longrightarrow & X(\Omega^{\infty-m} E_\alpha) \\ \downarrow \psi & & \downarrow \theta_{i+1} & & \downarrow \phi \\ F' & \longrightarrow & Y(A_{i+1}) & \longrightarrow & Y(\Omega^{\infty-m} E_\alpha). \end{array}$$

Since ϕ is $(n-2)$-truncated by assumption and θ_{i+1} is $(n-2)$-truncated by the inductive hypothesis, we conclude that ψ is $(n-2)$-truncated. The map θ_i factors as a composition

$X(A_i) \xrightarrow{\theta_i'} Y(A_i) \times_{F'} F \xrightarrow{\theta_i''} Y(A_i)$, where θ_i'' is a pullback of ψ and therefore $(n-2)$-truncated. It will therefore suffice to show that θ_i' is $(n-2)$-truncated. Since Y is an n-proximate formal moduli problem, the map $Y(A_i) \rightarrow F'$ is $(n-2)$-truncated, so the projection $Y(A_i) \times_{F'} F \rightarrow F$ is $(n-2)$-truncated. It will therefore suffice to show that the composite map $X(A_i) \xrightarrow{\theta_i'} Y(A_i) \times_{F'} F \rightarrow F$ is $(n-2)$-truncated, which follows from our assumption that X is an n-proximate formal moduli problem. □

Proof of Theorem 16.4.2.1. The implication (3) ⇒ (2) is obvious. We next show that (2) ⇒ (1). Let $X : \mathbf{A}^{\mathrm{art}} \rightarrow \mathcal{S}$ be a functor for which $X(*)$ is contractible and there exists an $(n-2)$-truncated map $f : X \rightarrow Y$, where Y is an n-proximate formal moduli problem. We wish to show that X is an n-proximate formal moduli problem. Choose a pullback diagram

$$\begin{array}{ccc} A' & \longrightarrow & A \\ \downarrow & & \downarrow \phi \\ B' & \longrightarrow & B \end{array}$$

in $\mathbf{A}^{\mathrm{art}}$ where ϕ is small; we wish to show that left square in the diagram of spaces

$$\begin{array}{ccccc} X(A') & \longrightarrow & X(A) & \longrightarrow & Y(A) \\ \downarrow & & \downarrow & & \downarrow \\ X(B') & \longrightarrow & X(B) & \longrightarrow & Y(B) \end{array}$$

is $(n-2)$-Cartesian. Our assumption that f is $(n-2)$-truncated guarantees that the right square is $(n-2)$-Cartesian; it will therefore suffice to show that the outer square is $(n-2)$-Cartesian (Lemma 16.4.1.3). Using Lemma 16.4.1.3 again, we are reduced to showing that both the left and right squares in the diagram

$$\begin{array}{ccccc} X(A') & \longrightarrow & Y(A') & \longrightarrow & Y(A) \\ \downarrow & & \downarrow & & \downarrow \\ X(B') & \longrightarrow & Y(B') & \longrightarrow & Y(B) \end{array}$$

are $(n-2)$-Cartesian. For the left square, this follows from our assumption that f is $(n-2)$-truncated; for the right square, it follows from our assumption that Y is an n-proximate formal moduli problem.

We now complete the proof by showing that (1) ⇒ (3). Assume that $X : \mathbf{A}^{\mathrm{art}} \rightarrow \mathcal{S}$ is an n-proximate formal moduli problem and let $L : \mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S}) \rightarrow \mathrm{Moduli}^{\mathbf{A}}$ be a left adjoint to the inclusion; we wish to show that the canonical map $X \rightarrow LX$ is $(n-2)$-truncated. According to Lemma 16.4.4.2, it will suffice to show that the map $\phi : X(\Omega^{\infty-m} E_\alpha) \rightarrow LX(\Omega^{\infty-m} E_\alpha)$ is $(n-2)$-truncated for each $\alpha \in T$ and each $m \geqslant 0$. Using Proposition 16.4.3.2, we can identify

ϕ with the canonical map $X(\Omega^{\infty-m}E_\alpha) \to \Omega^{\infty-m}L_0(X \circ E_\alpha))$, which is $(n-2)$-truncated by Lemma 16.4.4.1. □

16.5 Deformations of Objects

Let X be an algebraic variety defined over a field κ and let $\mathscr{E}$ be an algebraic vector bundle on X. A *first order deformation* of $\mathscr{E}$ is an algebraic vector bundle $\overline{\mathscr{E}}$ over the scheme $\overline{X} = X \times_{\operatorname{Spec}\kappa} \operatorname{Spec}\kappa[\epsilon]/(\epsilon^2)$, together with an isomorphism $i^*\overline{\mathscr{E}} \to \mathscr{E}$ (where i denotes the closed immersion $X \hookrightarrow \overline{X}$). Standard arguments in deformation theory show that the collection of isomorphism classes of first-order deformations can be identified with the cohomology group $\mathrm{H}^1(X; \mathrm{End}(\mathscr{E}))$, while the automorphism of each first order deformation of $\mathscr{E}$ is given by $\mathrm{H}^0(X; \mathrm{End}(\mathscr{E}))$. Our goal in this section is to place these observations in a more general context:

- In the definition above, we can replace the ring of dual numbers $\kappa[\epsilon]/(\epsilon^2)$ by an arbitrary $R \in \mathrm{CAlg}^{\mathrm{art}}_\kappa$ to obtain a notion of a *deformation of $\mathscr{E}$ over R*. Let $\mathrm{ObjDef}_{\mathscr{E}}(R)$ denote a classifying space for deformations of $\mathscr{E}$ over R. Then $\mathrm{ObjDef}_{\mathscr{E}}$ can be regarded as a functor $\mathrm{CAlg}^{\mathrm{art}}_\kappa \to \mathcal{S}$. We will see below that this functor is a formal moduli problem.

- The isomorphisms

$$\mathrm{H}^0(X; \mathrm{End}(\mathscr{E})) \simeq \pi_1 \mathrm{ObjDef}_{\mathscr{E}}(\kappa[\epsilon]/(\epsilon^2)) \quad \mathrm{H}^1(X; \mathrm{End}(\mathscr{E})) \simeq \pi_0 \mathrm{ObjDef}_{\mathscr{E}}(\kappa[\epsilon]/(\epsilon^2))$$

  follow from an identification of the $\Gamma(X; \mathrm{End}(\mathscr{E}))$ with the (shifted) tangent complex $\Sigma^{-1}T_{\mathrm{ObjDef}_{\mathscr{E}}}$; here $\Gamma(X; \mathrm{End}(\mathscr{E}))$ denotes the *derived* global sections of the vector bundle $\mathrm{End}(\mathscr{E})$ on X.

- The definition of $\mathrm{ObjDef}_{\mathscr{E}}(R)$ does not require R to be commutative. Consequently, we can extend the domain of definition of $\mathrm{ObjDef}_{\mathscr{E}}$ to $\mathrm{Alg}^{\mathrm{art}}_\kappa$, and thereby regard $\mathrm{ObjDef}_{\mathscr{E}}$ as a formal $\mathbb{E}_1$-moduli problem (see Definition 14.0.0.4). We will see that the identification $\Gamma(X; \mathrm{End}(\mathscr{E})) \simeq \Sigma^{-1}T_{\mathrm{ObjDef}_{\mathscr{E}}}$ is multiplicative: that is, it can be regarded as an equivalence of nonunital $\mathbb{E}_1$-algebras (where $\Sigma^{-1}T_{\mathrm{ObjDef}_{\mathscr{E}}}$ is equipped with the nonunital $\mathbb{E}_1$-algebra structure given by Remark 14.2.2.2).

- The definition of the formal moduli problem $\mathrm{ObjDef}_{\mathscr{E}}$ depends only on the algebraic vector bundle $\mathscr{E}$ as an object of the stable ∞-category $\mathrm{QCoh}(X)$ of quasi-coherent sheaves on X. We will therefore consider the more general problem of deforming an object E of an arbitrary stable κ-linear ∞-category $\mathcal{C}$.

16.5.1 Conventions

Let κ be a field and let Mod_κ denote the ∞-category of κ-modules. Recall that a *stable κ-linear ∞-category* is a Mod_κ-module object of the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ of presentable stable ∞-categories (see Variant D.1.5.1). Note that since Mod_κ is a symmetric monoidal ∞-category, there is no need to distinguish between left modules and right modules: any stable κ-linear ∞-category $\mathcal{C}$ can be regarded either as left-tensored or right-tensored over Mod_κ. In particular, if $A \in \mathrm{Alg}_\kappa$ is an $\mathbb{E}_1$-algebra over κ, then we can consider the ∞-categories $\mathrm{LMod}_A(\mathcal{C})$ and $\mathrm{RMod}_A(\mathcal{C})$ of left and right A-module objects of $\mathcal{C}$, respectively. Suppose we are given an object E of a stable κ-linear ∞-category $\mathcal{C}$. We will be interested in two different relationships that E might bear to an $\mathbb{E}_1$-algebra over κ:

(a) To every $\mathbb{E}_1$-algebra A over κ, we can associate a forgetful functor $\mu : \mathrm{LMod}_A(\mathcal{C}) \to \mathrm{LMod}_\kappa(\mathcal{C}) \simeq \mathcal{C}$, given by restriction of scalars along the unit map $\kappa \to A$. We define a *left action of A on E* to be an object $\overline{E} \in \mathrm{LMod}_A(\mathcal{C})$ together with an equivalence $E \simeq \mu(\overline{E})$. There is a universal example of such a left action: giving a left action of A on E is equivalent to giving a morphism $A \to \mathrm{End}(E)$ in Alg_κ, where $\mathrm{End}(E)$ denotes the endomorphism algebra of E (see Corollary HA.4.7.1.41).

(b) To every augmented $\mathbb{E}_1$-algebra B over κ, we can associate a functor $\mathrm{RMod}_B(\mathcal{C}) \to \mathrm{RMod}_\kappa(\mathcal{C}) \simeq \mathcal{C}$, given by extension of scalars $C \mapsto C \otimes_B \kappa$ (along the augmentation map $B \to \kappa$). We define a *deformation of E over B* to be an object $E_B \in \mathrm{RMod}_B(\mathcal{C})$ together with an equivalence $E_B \otimes_B \kappa \simeq E$.

As we will see, these two notions are related by Koszul duality.

Remark 16.5.1.1. The reader might object that the distinction between right and left modules in the above discussion is artificial. For every algebra object $A \in \mathrm{Alg}_\kappa$, there is a canonical equivalence of ∞-categories $\mathrm{LMod}_A(\mathcal{C}) \simeq \mathrm{RMod}_{A^{\mathrm{rev}}}(\mathcal{C})$, where A^{rev} denotes the algebra A equipped with the opposite multiplication (see Remark HA.4.1.1.7). Consequently, we can replace left actions by right actions in (a), or right actions by left actions in (b). However, in what follows, it will be convenient not to make these replacements. When analyzing a fixed object $E \in \mathcal{C}$, algebras A which act on E itself will act on the left, and augmented algebras B over which we have a deformation of E will act on the right. This will help us to avoid confusion in the discussion which follows, and has the added benefit of being compatible with our conventions for the Koszul duality functor $\mathfrak{D}^{(1)}$ studied in Chapter 14.

16.5.2 Classifying Spaces of Deformations

We now observe that deformations of an object $E \in \mathcal{C}$ depend functorially on the ring they are defined over:

Construction 16.5.2.1. Let κ be a field, let $\mathcal{C}$ be a stable κ-linear ∞-category, and let $E \in \mathcal{C}$ be an object. Let $\mathrm{RMod}(\mathcal{C})$ denote the ∞-category of pairs (B, E_B) where $B \in \mathrm{Alg}_\kappa$ and E_B is a right B-module object of $\mathcal{C}$. The forgetful functor

$$q : \mathrm{RMod}(\mathcal{C}) \to \mathrm{Alg}_\kappa \qquad (B, E_B) \mapsto B$$

is a coCartesian fibration. Let $\mathrm{RMod}^{\mathrm{coCart}}(\mathcal{C})$ denote the subcategory of $\mathrm{RMod}(\mathcal{C})$ spanned by the q-coCartesian morphisms, so that q restricts to a left fibration $\mathrm{RMod}^{\mathrm{coCart}}(\mathcal{C}) \to \mathrm{Alg}_\kappa$. We will abuse notation by identifying E with an object of $\mathrm{RMod}^{\mathrm{coCart}}(\mathcal{C})$ (via the equivalence $\mathrm{RMod}_\kappa(\mathcal{C}) \to \mathcal{C}$). Set $\mathrm{Defor}[E] = \mathrm{RMod}^{\mathrm{coCart}}(\mathcal{C})_{/E}$. We will refer to $\mathrm{Defor}[E]$ as the *∞-category of deformations of E*.

There is an evident left fibration $\theta : \mathrm{Defor}[E] \to \mathrm{Alg}^{\mathrm{aug}}_\kappa$, whose fiber over an object $B \in \mathrm{Alg}^{\mathrm{aug}}_\kappa$ can be identified with the Kan complex $(\mathrm{RMod}_B(\mathcal{C}) \times_{\mathcal{C}} \{E\})^{\simeq}$ of deformations of E over B. Consequently, we can view the construction $B \mapsto (\mathrm{RMod}_B(\mathcal{C}) \times_{\mathcal{C}} \{E\})^{\simeq}$ determining a functor $\mathrm{ObjDef}^+_E : \mathrm{Alg}^{\mathrm{aug}}_\kappa \to \widehat{\mathcal{S}}$.

Let $\mathcal{C}$ be as in Construction 16.5.2.1. Proposition 16.2.1.1 implies that for every pullback diagram

$$\begin{array}{ccc} B & \longrightarrow & B_0 \\ \downarrow & & \downarrow \\ B_1 & \longrightarrow & B_{01} \end{array}$$

in Alg_κ, the induced functor $\mathrm{RMod}_B(\mathcal{C}) \to \mathrm{RMod}_{B_0}(\mathcal{C}) \times_{\mathrm{RMod}_{B_{01}}(\mathcal{C})} \mathrm{RMod}_{B_1}(\mathcal{C})$ is fully faithful. This immediately implies the following:

Proposition 16.5.2.2. *Let κ be a field, let $\mathcal{C}$ a stable κ-linear ∞-category, and let $E \in \mathcal{C}$ be an object. Then, for every pullback diagram*

$$\begin{array}{ccc} B & \longrightarrow & B_0 \\ \downarrow & & \downarrow \\ B_1 & \longrightarrow & B_{01} \end{array}$$

in $\mathrm{Alg}^{\mathrm{aug}}_\kappa$, the induced map $\mathrm{ObjDef}^+_E(B) \to \mathrm{ObjDef}^+_E(B_0) \times_{\mathrm{ObjDef}^+_E(B_{01})} \mathrm{ObjDef}^+_E(B_1)$ has (-1)-truncated homotopy fibers (that is, it induces a homotopy equivalence onto its essential image).

Corollary 16.5.2.3. *Let κ be a field, let $\mathcal{C}$ a stable κ-linear ∞-category, let $E \in \mathcal{C}$ an object, and let $\mathrm{ObjDef}^+_E : \mathrm{Alg}^{\mathrm{aug}}_\kappa \to \widehat{\mathcal{S}}$ be as in Construction 16.5.2.1. Then:*

(1) *The space $\mathrm{ObjDef}^+_E(\kappa)$ is contractible.*

(2) *Let $V \in \mathrm{Mod}_\kappa$. Then the space $\mathrm{ObjDef}^+_E(\kappa \oplus V)$ is essentially small.*

(3) *Let* $B \in \mathrm{Alg}_\kappa^{\mathrm{aug}}$ *be Artinian. Then the space* $\mathrm{ObjDef}_E^+(B)$ *is essentially small.*

Proof. Assertion (1) is immediate from the definitions. To prove (2), we note that for each $B \in \mathrm{Alg}_\kappa^{\mathrm{aug}}$, the space $\mathrm{ObjDef}_E^+(B)$ is locally small (when regarded as an ∞-category). We have a pullback diagram

$$\begin{array}{ccc} \kappa \oplus V & \longrightarrow & \kappa \\ \downarrow & & \downarrow \\ \kappa & \longrightarrow & \kappa \oplus \Sigma(V) \end{array}$$

so that Proposition 16.5.2.2 guarantees that $\mathrm{ObjDef}_E^+(\kappa \oplus V)$ is a summand of $\Omega\,\mathrm{ObjDef}_E^+(\kappa \oplus \Sigma(V))$, and therefore essentially small. We now prove (3). Assume that B is Artinian, so that there exists a finite sequence of maps $B \simeq B_0 \to B_1 \to \cdots \to B_n \simeq \kappa$ and pullback diagrams

$$\begin{array}{ccc} B_i & \longrightarrow & \kappa \\ \downarrow & & \downarrow \\ B_{i+1} & \longrightarrow & \kappa \oplus \Sigma^{m_i}(\kappa). \end{array}$$

Using (1), (2), and Proposition 16.5.2.2, we deduce that each $\mathrm{ObjDef}_E^+(B_i)$ is essentially small using descending induction on i. □

16.5.3 Deformations as a Moduli Problem

We now restrict our attention to deformations of an object $E \in \mathcal{C}$ over Artinian $\mathbb{E}_1$-algebras.

Notation 16.5.3.1. Let κ be a field, let $\mathcal{C}$ be a stable κ-linear ∞-category, and let $E \in \mathcal{C}$ an object. We let ObjDef_E denote the composite functor $\mathrm{Alg}_\kappa^{\mathrm{art}} \hookrightarrow \mathrm{Alg}_\kappa^{\mathrm{aug}} \xrightarrow{\mathrm{ObjDef}_E^+} \widehat{\mathcal{S}}$. It follows from Corollary 16.5.2.3 that the functor ObjDef_E takes essentially small values, and can therefore be regarded as a functor from $\mathrm{Alg}_\kappa^{\mathrm{art}}$ to $\mathcal{S}$.

More informally: the functor ObjDef_E assigns to each $B \in \mathrm{Alg}_\kappa^{\mathrm{art}}$ a classifying space for pairs (E_B, μ), where $E_B \in \mathrm{RMod}_B(\mathcal{C})$ and $\mu : E_B \otimes_B \kappa \to E$ is an equivalence in $\mathcal{C}$.

Combining Corollary 16.5.2.3 and Proposition 16.5.2.2, we obtain the following:

Corollary 16.5.3.2. *Let κ be a field, let $\mathcal{C}$ be a stable κ-linear ∞-category, and let $E \in \mathcal{C}$ be an object. Then the functor $\mathrm{ObjDef}_E : \mathrm{Alg}_\kappa^{\mathrm{art}} \to \mathcal{S}$ is a 1-proximate formal moduli problem (see Definition 16.4.1.5).*

Notation 16.5.3.3. Let κ be a field, and let $L : \mathrm{Fun}(\mathrm{Alg}_\kappa^{\mathrm{art}}, \mathcal{S}) \to \mathrm{Moduli}_\kappa^{(1)}$ denote a left adjoint to the inclusion. If $\mathcal{C}$ is a stable κ-linear ∞-category and $E \in \mathcal{C}$ is an object, we let $\mathrm{ObjDef}_E^\wedge$ denote the formal $\mathbb{E}_1$-moduli problem $L(\mathrm{ObjDef}_E)$. By construction, we have a natural transformation $\mathrm{ObjDef}_E \to \mathrm{ObjDef}_E^{\wedge}$. It follows from Theorem 16.4.2.1 that this natural transformation is (-1)-truncated: that is, it exhibits $\mathrm{ObjDef}_E(R)$ as a summand of $\mathrm{ObjDef}_E^{\wedge}(R)$, for each $R \in \mathrm{Alg}_\kappa^{\mathrm{art}}$. Moreover, $\mathrm{ObjDef}_E^{\wedge}$ is characterized up to equivalence (as a formal $\mathbb{E}_1$-moduli problem) by this property: see Remark 16.4.2.3.

16.5.4 Statement of the Main Theorem

Let κ be a field and let $\mathcal{C}$ be a stable κ-linear ∞-category. For each object $E \in \mathcal{C}$, we let $\mathrm{End}(E) \in \mathrm{Mod}_\kappa$ denote the classifying object for endomorphisms of M: that is, $\mathrm{End}(E)$ is an object of Mod_κ equipped with a map $a : \mathrm{End}(E) \otimes E \to E$ in $\mathcal{C}$ having the following universal property: for every object $V \in \mathrm{Mod}_\kappa$, composition with a induces a homotopy equivalence $\mathrm{Map}_{\mathrm{Mod}_\kappa}(V, \mathrm{End}(E)) \simeq \mathrm{Map}_{\mathcal{C}}(V \otimes E, E)$. The existence of the object $\mathrm{End}(E)$ follows from Proposition HA.4.2.1.33 . Moreover, it follows from the results of §HA.4.7.1 show that we can regard $\mathrm{End}(E)$ as an object of Alg_κ and E as a left module over $\mathrm{End}(E)$. In what follows, it will be convenient to view $\mathrm{End}(E)$ as a *nonunital* $\mathbb{E}_1$-algebra over κ, which can be identified with the augmentation ideal of the augmented $\mathbb{E}_1$-algebra $\kappa \oplus \mathrm{End}(E)$.

We can now state our main result:

Theorem 16.5.4.1. *Let κ be a field, let $\mathcal{C}$ be a stable κ-linear ∞-category, let $E \in \mathcal{C}$ be an object, and let $\Psi : \mathrm{Alg}_\kappa^{\mathrm{aug}} \to \mathrm{Moduli}_\kappa^{(1)}$ be the equivalence of ∞-categories of Theorem 14.0.0.5. Then there is a canonical equivalence of formal $\mathbb{E}_1$-moduli problems $\mathrm{ObjDef}_E^{\wedge} \simeq \Psi(\kappa \oplus \mathrm{End}(E))$.*

Remark 16.5.4.2. In the situation of Theorem 16.5.4.1, for each Artinian $\mathbb{E}_1$-algebra B over κ, we have a (-1)-truncated map

$$\mathrm{ObjDef}_E(B) \hookrightarrow \mathrm{ObjDef}_E^{\wedge}(B) \simeq \mathrm{Map}_{\mathrm{Alg}_\kappa^{\mathrm{aug}}}(\mathfrak{D}^{(1)}(B), \kappa \oplus \mathrm{End}(E)) \simeq \mathrm{Map}_{\mathrm{Alg}_\kappa}(\mathfrak{D}_B^{(1)}, \mathrm{End}(E)).$$

In other words, to every deformation E_B of E over B, we can associate a left action of the Koszul dual $\mathfrak{D}^{(1)}(B)$ on E which determines the deformation E_B up to a contractible space of choices. However, in some cases there exist actions of $\mathfrak{D}^{(1)}(B)$ on E which do not arise in this way (these actions correspond to a more general kind of deformation of E: see Remark 16.5.7.3).

Example 16.5.4.3. Let κ be a field and regard Mod_κ as a κ-linear ∞-category. Let V be a finite-dimensional vector space over κ and define ObjDef_V as above. We will see below that ObjDef_V is a formal $\mathbb{E}_1$-moduli problem (Proposition 16.5.7.1), so that $\mathrm{ObjDef}_V|_{\mathrm{CAlg}_\kappa^{\mathrm{art}}}$ is a formal moduli problem over κ. Assume now that κ has characteristic zero, and let $\Phi : \mathrm{Lie}_\kappa \to \mathrm{Moduli}_\kappa$ be the equivalence of Theorem 13.0.0.2. Combining Theorems 16.5.4.1 and 14.3.0.1, we deduce that $\mathrm{ObjDef}_V|_{\mathrm{CAlg}_\kappa^{\mathrm{art}}}$ corresponds, under the equivalence Φ, to the matrix algebra $\mathrm{End}(V)$ (equipped with its usual Lie bracket).

Remark 16.5.4.4. Let κ be a field, let $\mathcal{C}$ be a stable κ-linear ∞-category, and let $E \in \mathcal{C}$ be an object. For each $R \in \mathrm{Alg}_\kappa^{\mathrm{art}}$, Theorem HA.4.8.4.1 yields a canonical homotopy equivalence

$$\mathrm{ObjDef}_E(R) = \mathrm{RMod}_R(\mathcal{C})^{\simeq} \times_{\mathcal{C}} \{E\} \simeq \mathrm{Map}_{\mathrm{LinCat}_\kappa}(\mathrm{LMod}_R, \mathcal{C})^{\simeq} \times_{\mathcal{C}} \{E\}.$$

It follows that $\mathrm{ObjDef}_E(R)$ depends only on the κ-linear ∞-category LMod_R, together with the distinguished object $\kappa \in \mathrm{LMod}_R$ (supplied by the augmentation $R \to \kappa$), so that the construction $R \mapsto \mathrm{ObjDef}_E(R)$ enjoys some extra functoriality. This special feature of ObjDef_E is reflected in the structure of the associated formal $\mathbb{E}_1$-moduli problem $\mathrm{ObjDef}_E^\wedge$: according to Theorem 16.5.4.1, $\mathrm{ObjDef}_E^\wedge$ has the form $\Psi(A)$, where $A \in \mathrm{Alg}_\kappa^{\mathrm{aug}}$ is an augmented $\mathbb{E}_1$-algebra over κ whose augmentation ideal $\mathfrak{m}_A \simeq \mathrm{End}(E)$ is itself unital.

16.5.5 Construction of the Equivalence

The equivalence $\mathrm{ObjDef}_E^\wedge \simeq \Psi(\kappa \oplus \mathrm{End}(E))$ of Theorem 16.5.4.1 arises from a natural transformation $\mathrm{ObjDef}_E \to \Psi(\kappa \oplus \mathrm{End}(E))$. We will obtain this natural transformation from a somewhat elaborate construction.

Construction 16.5.5.1. Let κ be a field, let $\mathcal{C}$ be a stable κ-linear ∞-category, and let $E \in \mathcal{C}$ be an object. We let $\lambda : \mathcal{M}^{(1)} \to \mathrm{Alg}_\kappa^{\mathrm{aug}} \times \mathrm{Alg}_\kappa^{\mathrm{aug}}$ denote the pairing of Construction **??**, so that we can identify objects of $\mathcal{M}^{(1)}$ with triples (A, B, ϵ) where $A, B \in \mathrm{Alg}_\kappa$ and $\epsilon : A \otimes_\kappa B \to \kappa$ is an augmentation. We will also regard the ∞-category $\mathcal{C}$ as bitensored over Mod_κ.

Given an object $(A, B, \epsilon) \in \mathcal{M}^{(1)}$ and an object $(B, E_B, \mu) \in \mathrm{Defor}[E]$, we regard $A \otimes_\kappa E_B$ as an object of the ∞-category of bimodules ${}_A\mathrm{BMod}_{A \otimes_\kappa B}(\mathcal{C})$, so that $(A \otimes_\kappa E_B) \otimes_{A \otimes_\kappa B} \kappa$ can be identified with an object of $\mathrm{LMod}_A(\mathcal{C})$ whose image in $\mathcal{C}$ is given by $E_B \otimes_B \kappa \simeq E$. This observation determines a functor $\rho : \mathcal{M}^{(1)} \times_{\mathrm{Alg}_\kappa^{\mathrm{aug}}} \mathrm{Defor}[E] \to \mathrm{LMod}(\mathcal{C}) \times_{\mathcal{C}} \{E\}$, given on objects by

$$(A, B, \epsilon : A \otimes_\kappa B \to \kappa, E_B, \mu : E_B \otimes_B \kappa \simeq E) \mapsto (A \otimes E_B) \otimes_{A \otimes_\kappa B} \kappa$$

(see Corollary HA.4.7.1.40). Let $\mathrm{LMod}^{\mathrm{aug}}(\mathcal{C})$ denote the fiber product $\mathrm{Alg}_\kappa^{\mathrm{aug}} \times_{\mathrm{Alg}_\kappa} \mathrm{LMod}(\mathcal{C})$. Since an augmentation on $A \otimes_\kappa B$ induces an augmentation on A, we can lift ρ to a functor $\overline{\rho} : \mathrm{Defor}[E] \times_{\mathrm{Alg}_\kappa^{\mathrm{aug}}} \mathcal{M}^{(1)} \to \mathrm{Defor}[E] \times (\mathrm{LMod}^{\mathrm{aug}}(\mathcal{C}) \times_{\mathcal{C}} \{E\})$ which factors as a composition

$$\mathrm{Defor}[E] \times_{\mathrm{Alg}_\kappa^{\mathrm{aug}}} \mathcal{M}^{(1)} \xrightarrow{i} \widetilde{\mathcal{M}}^{(1)} \xrightarrow{\lambda'} \mathrm{Defor}[E] \times (\mathrm{LMod}^{\mathrm{aug}}(\mathcal{C}) \times_{\mathcal{C}} \{E\})$$

where i is an equivalence of ∞-categories and λ' is a categorical fibration. It is not difficult to see that λ' is a left representable pairing of ∞-categories, which induces a duality functor $\mathfrak{D}_E^{(1)} : \mathrm{Defor}[E]^{\mathrm{op}} \to \mathrm{LMod}^{\mathrm{aug}}(\mathcal{C}) \times_{\mathcal{C}} \{E\}$. Concretely, the functor $\mathfrak{D}_E^{(1)}$ assigns to each object $(B, E_A, \mu) \in \mathrm{Defor}[E]^{\mathrm{op}}$ the object $(\mathfrak{D}^{(1)}(B), E)$, where we regard E as a left $\mathfrak{D}^{(1)}(B)$-module object of $\mathcal{C}$ via the equivalence $E \simeq E_B \otimes_B \kappa \simeq (\mathfrak{D}^{(1)}(B) \otimes_\kappa E_B) \otimes_{\mathfrak{D}^{(1)}(B) \otimes_\kappa B} \kappa$.

Corollary HA.4.7.1.40 supplies an equivalence of ∞-categories $\eta : \mathrm{LMod}(\mathcal{C}) \times_{\mathcal{C}} \{E\} \simeq (\mathrm{Alg}_{\kappa})_{/\operatorname{End}(E)}$, hence also an equivalence $\mathrm{LMod}^{\mathrm{aug}}(\mathcal{C}) \times_{\mathcal{C}} \{E\} \simeq (\mathrm{Alg}_{\kappa}^{\mathrm{aug}})_{/\kappa \oplus \operatorname{End}(E)}$. We therefore obtain a diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{Defor}[E]^{\mathrm{op}} & \longrightarrow & (\mathrm{Alg}_{\kappa}^{\mathrm{aug}})_{/\kappa\oplus\operatorname{End}(E)} \\ \downarrow & & \downarrow \\ (\mathrm{Alg}_{\kappa}^{\mathrm{aug}})^{\mathrm{op}} & \xrightarrow{\mathfrak{D}^{(1)}} & \mathrm{Alg}_{\kappa}^{\mathrm{aug}} \end{array}$$

which commutes up to canonical homotopy, where the vertical maps are right fibrations. This diagram determines a natural transformation $\beta^{+} : \mathrm{ObjDef}_E^{+} \to X$, where $X : \mathrm{Alg}_{\kappa}^{(1),\mathrm{art}} \to \mathcal{S}$ denotes the functor given on objects by $X(B) = \mathrm{Map}_{\mathrm{Alg}_{\kappa}^{\mathrm{aug}}}(\mathfrak{D}^{(1)}(B), \kappa \oplus \operatorname{End}(E)) \simeq \mathrm{Map}_{\mathrm{Alg}_{\kappa}}(\mathfrak{D}^{(1)}(A), \operatorname{End}(E))$. Restricting to the case where B is Artinian, we obtain a natural transformation $\beta : \mathrm{ObjDef}_E \to \Psi(\kappa \oplus \operatorname{End}(E))$, where $\Psi : \mathrm{Alg}_{\kappa}^{\mathrm{aug}} \to \mathrm{Moduli}_{\kappa}^{(1)}$ is the equivalence of Theorem 14.0.0.5.

16.5.6 The Proof of Theorem 16.5.4.1

Using Construction 16.5.5.1, we can formulate a more precise version of Theorem 16.5.4.1:

Proposition 16.5.6.1. *Let κ be a field, let $\mathcal{C}$ be a stable κ-linear ∞-category, and let $E \in \mathcal{C}$ be an object. Then the natural transformation $\beta : \mathrm{ObjDef}_E \to \Psi(\kappa \oplus \operatorname{End}(E))$ of Construction 16.5.5.1 induces an equivalence of formal $\mathbb{E}_1$-moduli problems $\mathrm{ObjDef}_E^{\wedge} \simeq \Psi(\kappa \oplus \operatorname{End}(E))$. In other words, for every object $B \in \mathrm{Alg}_{\kappa}^{\mathrm{art}}$, the natural map*

$$\mathrm{ObjDef}_E(B) \to \Psi(\kappa \oplus \operatorname{End}(E))(B) \simeq \mathrm{Map}_{\mathrm{Alg}_{\kappa}^{\mathrm{aug}}}(\mathfrak{D}^{(1)}(B), \kappa \oplus \operatorname{End}(E))$$

has (-1)-truncated homotopy fibers (see Remark 16.4.2.3).

To prove Proposition 16.5.6.1, it will suffice to show that the map $\mathrm{ObjDef}_E^{\wedge} \to \Psi(\kappa \oplus \operatorname{End}(E))$ induces an equivalence of tangent complexes (Proposition 12.2.2.6). Using the description of the tangent complex of $\mathrm{ObjDef}_E^{\wedge}$ supplied by Proposition 16.4.3.2, we are reduced to proving the following special case of Proposition 16.5.6.1:

Proposition 16.5.6.2. *Let κ be a field, let $\mathcal{C}$ be a stable κ-linear ∞-category, and let $E \in \mathcal{C}$ be an object. For each $m \geqslant 0$, the natural transformation $\beta : \mathrm{ObjDef}_E \to \Psi(\kappa \oplus \operatorname{End}(E))$ of Construction 16.5.5.1 induces a (-1)-truncated map*

$$\begin{aligned} \mathrm{ObjDef}_E(\kappa \oplus \Sigma^m(\kappa)) &\to \mathrm{Map}_{\mathrm{Alg}_{\kappa}^{\mathrm{aug}}}(\mathfrak{D}^{(1)}(\kappa \oplus \Sigma^m(\kappa)), \kappa \oplus \operatorname{End}(E)) \\ &\simeq \mathrm{Map}_{\mathrm{Alg}_{\kappa}}(\mathfrak{D}^{(1)}(\kappa \oplus \Sigma^m(\kappa)), \operatorname{End}(E)). \end{aligned}$$

Proof. We have a commutative diagram

$$\begin{array}{ccc} \mathrm{ObjDef}_E(\kappa \oplus \Sigma^m(\kappa)) & \longrightarrow & \mathrm{Map}_{\mathrm{Alg}_\kappa}(\mathfrak{D}^{(1)}(\kappa \oplus \Sigma^m(\kappa)), \mathrm{End}(E)) \\ \downarrow & & \downarrow \\ \Omega\,\mathrm{ObjDef}_E(\kappa \oplus \Sigma^{m+1}(\kappa)) & \xrightarrow{\theta} & \Omega\,\mathrm{Map}_{\mathrm{Alg}_\kappa}(\mathfrak{D}^{(1)}(\kappa \oplus \Sigma^{m+1}(\kappa)), \mathrm{End}(E)), \end{array}$$

where the left vertical map is (-1)-truncated by Corollary 16.5.3.2 and the right vertical map is a homotopy equivalence. It will therefore suffice to show that θ is a homotopy equivalence. Let $B = \kappa \oplus \Sigma^{m+1}(\kappa)$ and let $E_B = E \otimes_\kappa B \in \mathrm{RMod}_B(\mathcal{C})$. We can identify the domain of θ with the homotopy fiber of the map $\xi : \mathrm{Map}_{\mathrm{RMod}_B(\mathcal{C})}(E_B, E_B) \to \mathrm{Map}_{\mathcal{C})}(E, E)$. We have a fiber sequence $\Sigma^{m+1}E \to E_B \to E$ in $\mathrm{RMod}_B(\mathcal{C})$, where B acts on E via the augmentation $B \to \kappa$. It follows that the homotopy fiber of ξ is given by

$$\begin{aligned} \mathrm{Map}_{\mathrm{RMod}_B(\mathcal{C})}(E_B, \Sigma^{m+1}E) &\simeq \mathrm{Map}_{\mathcal{C}}(E_B \otimes_B \kappa, \Sigma^{m+1}E) \\ &\simeq \mathrm{Map}_{\mathcal{C}}(E, \Sigma^{m+1}E) \\ &\simeq \mathrm{Map}_{\mathrm{Mod}_\kappa}(\Sigma^{-m-1}(\kappa), \mathrm{End}(E)) \end{aligned}$$

The map θ is induced by a morphism $\nu : \Sigma^{-m-1}(\kappa) \to \mathfrak{D}^{(1)}(\kappa \oplus \Sigma^m(\kappa))$ in Mod_κ. Let $\mathrm{Free}^{(1)} : \mathrm{Mod}_\kappa \to \mathrm{Alg}_\kappa$ be a left adjoint to the forgetful functor, so that ν determines an augmentation $(\kappa \oplus \Sigma^m(\kappa)) \otimes_\kappa \mathrm{Free}^{(1)}(\Sigma^{-m-1}(\kappa)) \to \kappa$. This pairing exhibits $\kappa \oplus \Sigma^m(\kappa)$ as a Koszul dual of $\mathrm{Free}^{(1)}(\Sigma^{-m-1}(\kappa))$, and therefore also exhibits $\mathrm{Free}^{(1)}(\Sigma^{-m-1}(\kappa))$ as a Koszul dual of $\kappa \oplus \Sigma^m(\kappa)$ (see Theorem 14.1.3.2). It follows that θ is a homotopy equivalence, as desired. □

16.5.7 Connectivity Hypotheses

We conclude this section with a few observations concerning the discrepancy between the deformation functor ObjDef_E of Notation 16.5.3.1 and the associated formal $\mathbb{E}_1$-moduli problem $\mathrm{ObjDef}^{\wedge}_E$ of Notation 16.5.3.3. Under some mild additional hypotheses, one can show that these two functors are equivalent:

Proposition 16.5.7.1. *Let κ be a field, let $\mathcal{C}$ be a separated prestable κ-linear ∞-category. For every object $E \in \mathrm{Sp}(\mathcal{C})_{\geqslant 0}$, the functor $\mathrm{ObjDef}_E : \mathrm{Alg}^{\mathrm{art}}_\kappa \to \mathcal{S}$ of Notation 16.5.3.1 is a formal $\mathbb{E}_1$-moduli problem.*

Proof. Let $B \in \mathrm{Alg}^{\mathrm{art}}_\kappa$. We first show that if $(E_B, \mu) \in \mathrm{ObjDef}_E(B)$, then $E_B \in \mathrm{RMod}_B(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$. Since B is Artinian, we can choose a finite sequence of maps

$$B \simeq B_0 \to B_1 \to \cdots \to B_n \simeq \kappa$$

and pullback diagrams

$$\begin{array}{ccc} B_i & \longrightarrow & \kappa \\ \downarrow & & \downarrow \\ B_{i+1} & \longrightarrow & \kappa \oplus \Sigma^{m_i}(\kappa) \end{array}$$

for some integers $m_i > 0$. We prove by descending induction on i that $E_B \otimes_B B_i$ belongs to $\mathrm{RMod}_{B_i}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$. In this case $i = n$, this follows from our assumption that $E \in \mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. If $i < n$, it follows from the inductive hypothesis since we have a fiber sequence

$$\Sigma^{m_i - 1}(E) \to E_B \otimes_B B_i \to E_B \otimes_B B_{i+1}$$

in $\mathrm{Sp}(\mathcal{C})$.

Proposition 16.2.2.1 implies that if

$$\begin{array}{ccc} B & \longrightarrow & B_0 \\ \downarrow & & \downarrow f \\ B_1 & \xrightarrow{g} & B_{01} \end{array}$$

is a pullback diagram in $\mathrm{Alg}_\kappa^{\mathrm{art}}$ where the maps f and g induce surjections $\pi_0 B_0 \to \pi_0 B_{01} \leftarrow \pi_0 B_1$, then the functor

$$\mathrm{RMod}_B(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0} \to \mathrm{RMod}_{B_0}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0} \times_{\mathrm{RMod}_{B_{01}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}} \mathrm{RMod}_{B_1}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$$

is an equivalence of ∞-categories. It follows immediately that

$$\begin{array}{ccc} \mathrm{ObjDef}_E(B) & \longrightarrow & \mathrm{ObjDef}_E(B_0) \\ \downarrow & & \downarrow \\ \mathrm{ObjDef}_E(B_1) & \longrightarrow & \mathrm{ObjDef}_E(B_{01}) \end{array}$$

is a pullback diagram in $\mathcal{S}$. □

Corollary 16.5.7.2. *Let κ be a field, let $\mathcal{C}$ be separated prestable κ-linear ∞-category, and let $E \in \mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. Then the natural transformation $\beta : \mathrm{ObjDef}_E \to \Psi(\kappa \oplus \mathrm{End}(E))$ of Construction 16.5.5.1 is an equivalence. In other words, $\mathrm{ObjDef}_E : \mathrm{Alg}_\kappa^{\mathrm{art}} \to \mathcal{S}$ is the formal $\mathbb{E}_1$-moduli problem which corresponds, under the equivalence of Theorem 14.0.0.5, to the augmented $\mathbb{E}_1$-algebra $\kappa \oplus \mathrm{End}(M)$.*

Proof. Combine Theorem 16.5.4.1, Corollary 16.5.3.2, and Theorem 16.4.2.1. □

Remark 16.5.7.3. Let κ be a field. For $B \in \mathrm{Alg}_\kappa^{\mathrm{art}}$, let $\mathrm{RMod}_B^!$ denote the ∞-category of Ind-coherent right B-modules over B (see §14.5). One can show that $\mathrm{RMod}_B^!$ has the structure of a κ-linear ∞-category (depending functorially on B). For any κ-linear ∞-category $\mathcal{C}$, let $\mathrm{RMod}^!_B(\mathcal{C})$ denote the relative tensor product $\mathcal{C} \otimes_{\mathrm{Mod}_\kappa} \mathrm{RMod}^!_B$. The equivalence $\mathrm{RMod}^!_B \simeq \mathrm{LMod}_{\mathfrak{D}^{(1)}(B)}$ of Proposition 14.6.1.1 is κ-linear, and (combined with Theorem HA.4.8.4.6) determines an equivalence $\mathrm{RMod}^!_B(\mathcal{C}) \simeq \mathrm{LMod}_{\mathfrak{D}^{(1)}(B)}(\mathcal{C})$. Let $E \in \mathcal{C}$ and let $X : \mathrm{Alg}^{\mathrm{art}}_\kappa \to \mathcal{S}$ be the formal $\mathbb{E}_1$-moduli problem associated to $\kappa \oplus \mathrm{End}(E)$. Then X is given by the formula

$$\begin{aligned} X(B) &= \mathrm{Map}_{\mathrm{Alg}^{\mathrm{aug}}_\kappa}(\mathfrak{D}^{(1)}(B), \kappa \oplus \mathrm{End}(E)) \\ &\simeq \mathrm{Map}_{\mathrm{Alg}_\kappa}(\mathfrak{D}^{(1)}(B), \mathrm{End}(E)) \\ &\simeq \mathrm{LMod}_{\mathfrak{D}^{(1)}(B)}(\mathcal{C}) \times_{\mathcal{C}} \{E\} \\ &\simeq \mathrm{RMod}^!_B(\mathcal{C}) \times_{\mathcal{C}} \{E\}. \end{aligned}$$

In other words, the formal $\mathbb{E}_1$-moduli problem X assigns to each $B \in \mathrm{Alg}^{\mathrm{art}}_\kappa$ the classifying space for pairs (E_B, μ), where $E_B \in \mathrm{RMod}^!_B(\mathcal{C})$ and μ is an equivalence of E with the image of E_B in the ∞-category $\mathcal{C}$. The (-1)-truncated map $\mathrm{ObjDef}_E(B) \hookrightarrow \mathrm{ObjDef}^\wedge_E(B) \simeq X(B)$ is induced by fully faithful embedding $\mathrm{RMod}_B(\mathcal{C}) \hookrightarrow \mathrm{RMod}^!_B(\mathcal{C})$, which are in turn determined by the fully faithful embeddings $\mathrm{RMod}_B \hookrightarrow \mathrm{RMod}^!_B$ of Proposition 14.5.3.2. From this point of view, we can view Proposition 16.5.7.1 as a generalization of Proposition 14.5.4.3: it asserts that the fully faithful embedding $\mathrm{RMod}_B(\mathcal{C}) \hookrightarrow \mathrm{RMod}^!_B(\mathcal{C})$ induces an equivalence on connective objects (where we declare an object of $\mathrm{RMod}^!_B(\mathcal{C})$ to be connective if its image in $\mathcal{C}$ is connective).

16.6 Deformations of Categories

Let κ be a field and let $\mathcal{C}$ be a stable κ-linear ∞-category. In §16.5, we studied the problem of deforming a fixed object $E \in \mathcal{C}$. In this section, we will study the problem of the deforming the ∞-category $\mathcal{C}$ itself. For every Artinian $\mathbb{E}_2$-algebra B over κ, we will introduce a classifying space $\mathrm{CatDef}_{\mathcal{C}}(B)$ which parametrizes stable (right) B-linear ∞-categoriers $\mathcal{C}_B$ equipped with an equivalence $\mathcal{C} \simeq \mathcal{C}_B \otimes_{\mathrm{LMod}_B} \mathrm{Mod}_\kappa$. We will show that, modulo size issues, the construction $B \mapsto \mathrm{CatDef}_{\mathcal{C}}(B)$ is a 2-proximate formal $\mathbb{E}_2$-moduli problem (Corollary 16.6.2.4; in good cases, we can say even more: see Theorems **??** and 16.6.10.2). Using Theorem 16.4.2.1, we deduce that there is a 0-truncated natural transformation $\mathrm{CatDef}_{\mathcal{C}} \to \mathrm{CatDef}^\wedge_{\mathcal{C}}$, where $\mathrm{CatDef}^\wedge_{\mathcal{C}}$ is a formal $\mathbb{E}_2$-moduli problem (which is uniquely determined up to equivalence: see Remark 16.4.2.3). According to Theorem 15.0.0.9, the formal moduli problem $\mathrm{CatDef}^\wedge_{\mathcal{C}}$ is given by $R \mapsto \mathrm{Map}_{\mathrm{Alg}^{(2),\mathrm{aug}}_\kappa}(\mathfrak{D}^{(2)}(R), A)$ for an essentially unique augmented $\mathbb{E}_2$-algebra A over κ. The main result of this section identifies the augmentation ideal $\mathfrak{m}_A$ (as a nonunital $\mathbb{E}_2$-algebra) with the *κ-linear center* of the ∞-category $\mathcal{C}$ (Theorem 16.6.3.8): in other words, with the chain complex of Hochschild cochains on $\mathcal{C}$.

Remark 16.6.0.1. Our presentation in this section will follow that of §16.5: most of our results are direct parallels of analogous (but easier) statements about the deformation theory of an object E of a fixed κ-linear ∞-category $\mathcal{C}$.

16.6.1 Conventions on Deformations

Let R be an $\mathbb{E}_2$-ring. Then we can regard the ∞-category LMod_R of left R-modules as an associative algebra object of the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ of presentable stable ∞-categories. We define a *stable left R-linear ∞-category* to be a left module over LMod_R in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$, and a *stable right R-linear ∞-category* to be a right module over LMod_R in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$.

Warning 16.6.1.1. Throughout the rest of this book, we use the term *stable R-linear ∞-category* to refer to a stable *left* R-linear ∞-category (see Variant D.1.5.1). However, in this section it will be important to distinguish between left and right actions of LMod_R. Of course, the difference is slight: the datum of a stable left R-linear ∞-category is equivalent to the datum of a stable right R^{rev}-linear ∞-category, where R^{rev} denotes the $\mathbb{E}_2$-ring obtained by reversing the multiplication on R (see Warning **??**). In particular, when R is an $\mathbb{E}_\infty$-ring, there is no difference between left and right R-linear ∞-categories; in this case, we will refer to either simply as a *stable R-linear ∞-category*.

Let $\phi : A \to B$ be a morphism of $\mathbb{E}_2$-rings. If $\mathcal{C}$ is a stable (left or right) B-linear ∞-category, then we can regard $\mathcal{C}$ as a stable (left or right) A-linear ∞-category by restriction of scalars along ϕ. In either case, the restriction of scalars functor admits a left adjoint, which we call *extension of scalars along ϕ*. If $\mathcal{D}$ is a stable right A-linear ∞-category, we denote its extension of scalars by $\mathcal{D} \otimes_A B = \mathcal{D} \otimes_{\mathrm{LMod}_A} \mathrm{LMod}_B$ or by $\mathrm{RMod}_B(\mathcal{D})$. If $\mathcal{D}$ is a stable left A-linear ∞-category, we denote its extension of scalars by $B \otimes_A \mathcal{D} = \mathrm{LMod}_B \otimes_{\mathrm{LMod}_A} \mathcal{D}$ or by $\mathrm{LMod}_B(\mathcal{D})$.

Let κ be a field and let $\mathcal{C}$ be a stable κ-linear ∞-category. Suppose that B be an $\mathbb{E}_2$-algebra over κ equipped with an augmentation $\epsilon : B \to \kappa$. We define a *deformation of $\mathcal{C}$ over B* to be a pair $(\mathcal{C}_B, \mu)$, where $\mathcal{C}_B$ is a stable right B-linear ∞-category and $\mu : \mathcal{C}_B \otimes_B \kappa \to \mathcal{C}$ is an equivalence of stable κ-linear ∞-categories. Our first observation is that the collection of such deformations depends functorially on B.

Construction 16.6.1.2. Let κ be a field. We let $\mathrm{RCat}(\kappa)$ denote the ∞-category given by the fiber product $\mathrm{Alg}_\kappa^{(2)} \times_{\mathrm{Alg}(\mathcal{P}\mathrm{r}^{\mathrm{St}})} \mathrm{RMod}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$. We view the objects of $\mathrm{RCat}(\kappa)$ as pairs $(B, \mathcal{D})$, where B is an $\mathbb{E}_2$-algebra over κ and $\mathcal{D}$ is a stable right B-linear ∞-category. Projection onto the first factor furnishes a coCartesian fibration $q : \mathrm{RCat}(\kappa) \to \mathrm{Alg}_\kappa^{(2)}$. We let $\mathrm{RCat}(\kappa)^{\mathrm{coCart}}$ denote the subcategory of $\mathrm{RCat}(\kappa)$ spanned by the q-coCartesian morphisms (so a morphism from $(A, \mathcal{C})$ to $(B, \mathcal{D})$ in $\mathrm{RCat}(\kappa)^{\mathrm{coCart}}$ consists of a morphism $\phi : A \to B$ of $\mathbb{E}_2$-algebras over κ together with a B-linear equivalence $\mathcal{C} \otimes_A B \simeq \mathcal{D}$).

Let $\mathcal{C}$ be a stable κ-linear ∞-category and regard $(\kappa, \mathcal{C})$ as an object of $\mathrm{RCat}(\kappa)$. We let $\mathrm{Defor}[\mathcal{C}]$ denote the ∞-category $\mathrm{RCat}(\kappa)^{\mathrm{coCart}}_{/(\kappa,\mathcal{C})}$. We will refer to $\mathrm{Defor}[\mathcal{C}]$ as the *∞-category of deformations of $\mathcal{C}$*. This ∞-category is equipped with an evident left fibration

$$\rho : \mathrm{Defor}[\mathcal{C}] \to (\mathrm{Alg}^{(2)}_{\kappa})_{/\kappa} = \mathrm{Alg}^{(2),\mathrm{aug}}_{\kappa},$$

which is classified by a functor $\mathrm{CatDef}^{+}_{\mathcal{C}} : \mathrm{Alg}^{(2),\mathrm{aug}}_{\kappa} \to \widehat{\mathcal{S}}$. Unwinding the definitions, we see that if B is an augmented $\mathbb{E}_2$-algebra over κ, then we can identify $\mathrm{CatDef}^{+}_{\mathcal{C}}(B)$ with the underlying Kan complex of the ∞-category $\mathrm{RMod}_{\mathrm{LMod}_B}(\mathcal{P}\mathrm{r}^{\mathrm{St}}) \times_{\mathrm{Mod}_{\mathrm{Mod}_{\kappa}}(\mathcal{P}\mathrm{r}^{\mathrm{St}})} \{\mathcal{C}\}$ of deformations of $\mathcal{C}$ over B.

16.6.2 Deformations as a Formal Moduli Problem

We now analyze the behavior of Construction 16.6.1.2 with respect to fiber products of $\mathbb{E}_2$-algebras.

Proposition 16.6.2.1. *Let κ be a field, let $\mathcal{C}$ be a stable κ-linear ∞-category, and let $\mathrm{CatDef}^{+}_{\mathcal{C}} : \mathrm{Alg}^{(2),\mathrm{aug}}_{\kappa} \to \widehat{\mathcal{S}}$ be as in Construction 16.6.1.2. Then for every pullback diagram*

$$\begin{array}{ccc} B & \longrightarrow & B_0 \\ \downarrow & & \downarrow \\ B_1 & \longrightarrow & B_{01} \end{array}$$

in $\mathrm{Alg}^{(2),\mathrm{aug}}_{\kappa}$, the induced map

$$\theta : \mathrm{CatDef}^{+}_{\mathcal{C}}(B) \to \mathrm{CatDef}^{+}_{\mathcal{C}}(B_0) \times_{\mathrm{CatDef}^{+}_{\mathcal{C}}(B_{01})} \mathrm{CatDef}^{+}_{\mathcal{C}}(B_1)$$

is 0-truncated (that is, the homotopy fibers of θ are discrete).

Proof. If A is an $\mathbb{E}_2$-ring and $\mathcal{D}$ and $\mathcal{E}$ are stable right A-linear ∞-categories, we let $\mathrm{Fun}_A(\mathcal{D}, \mathcal{E})$ denote the ∞-category of right LMod_A-linear functors from $\mathcal{D}$ to $\mathcal{E}$.

If $\mathcal{E}$ is a stable right B-linear ∞-category, then Proposition 16.2.1.1 implies that the canonical map

$$\mathcal{E} \to (\mathcal{E} \otimes_B B_0) \times_{\mathcal{E} \otimes_B B_{01}} (\mathcal{E} \otimes_B B_1)$$

is fully faithful. Consequently, for any other stable right B-linear ∞-category $\mathcal{D}$, the induced map

$$\begin{aligned} \mathrm{Fun}_B(\mathcal{D}, \mathcal{E}) &\to \mathrm{Fun}_B(\mathcal{D}, \mathcal{E} \otimes_B B_0) \times_{\mathrm{Fun}_B(\mathcal{D}, \mathcal{E} \otimes_B B_{01})} \mathrm{Fun}_B(\mathcal{D}, \mathcal{E} \otimes_B B_1) \\ &\simeq \mathrm{Fun}_{B_0}(\mathcal{D} \otimes_B B_0, \mathcal{E} \otimes_B B_0) \times_{\mathrm{Fun}_{B_{01}}(\mathcal{D} \otimes_B B_{01}, \mathcal{E} \otimes_B B_{01})} \mathrm{Fun}_{B_1}(\mathcal{D} \otimes_B B_1, \mathcal{E} \otimes_B B_1) \end{aligned}$$

is fully faithful. Passing to the underlying Kan complexes and taking $\mathcal{D}$ and $\mathcal{E}$ to be deformations of $\mathcal{C}$ over B, we deduce that the commutative diagram

$$\begin{array}{ccc} \{\mathcal{D}\} \times_{\mathrm{CatDef}^+_{\mathcal{C}}(B)} \{\mathcal{E}\} & \longrightarrow & \{\mathcal{D}\} \times_{\mathrm{CatDef}^+_{\mathcal{C}}(B_0)} \{\mathcal{E}\} \\ \downarrow & & \downarrow \\ \{\mathcal{D}\} \times_{\mathrm{CatDef}^+_{\mathcal{C}}(B_1)} \{\mathcal{E}\} & \longrightarrow & \{\mathcal{D}\} \times_{\mathrm{CatDef}^+_{\mathcal{C}}(B_{01})} \{\mathcal{E}\} \end{array}$$

is (-1)-Cartesian (in the sense of Definition 16.4.1.1). Since this conclusion holds for every pair of deformations $\mathcal{D}$ and $\mathcal{E}$, we conclude that the diagram

$$\begin{array}{ccc} \mathrm{CatDef}^+_{\mathcal{C}}(B) & \longrightarrow & \mathrm{CatDef}^+_{\mathcal{C}}(B_0) \\ \downarrow & & \downarrow \\ \mathrm{CatDef}^+_{\mathcal{C}}(B_1) & \longrightarrow & \mathrm{CatDef}^+_{\mathcal{C}}(B_{01}) \end{array}$$

is 0-Cartesian, as desired. □

Corollary 16.6.2.2. *Let κ be a field, let $\mathcal{C}$ be a stable κ-linear ∞-category, and let $\mathrm{CatDef}^+_{\mathcal{C}} : \mathrm{Alg}^{(2),\mathrm{aug}}_{\kappa} \to \widehat{\mathcal{S}}$ be as in Construction 16.6.1.2. Then:*

(1) *The space $\mathrm{CatDef}^+_{\mathcal{C}}(\kappa)$ is contractible.*

(2) *Let $V \in \mathrm{Mod}_{\kappa}$. Then $\mathrm{CatDef}^+_{\mathcal{C}}(\kappa \oplus V)$ is locally small, when regarded as an ∞-category. In other words, each connected component of $\mathrm{CatDef}^+_{\mathcal{C}}(\kappa \oplus V)$ is essentially small.*

(3) *Let $B \in \mathrm{Alg}^{(2),\mathrm{aug}}_{\kappa}$ be Artinian. Then the space $\mathrm{CatDef}^+_{\mathcal{C}}(B)$ is locally small (that is, each connected component of $\mathrm{CatDef}^+_{\mathcal{C}}(B)$ is essentially small).*

Proof. Assertion (1) is immediate from the definitions. To prove (2), we note that for each $B \in \mathrm{Alg}^{(2),\mathrm{aug}}_{\kappa}$ and every point $\eta \in \mathrm{CatDef}^+_{\mathcal{C}}(B)$ corresponding to a pair $(\mathcal{C}_B, \mu)$, the space $\Omega^2(\mathrm{CatDef}^+_{\mathcal{C}}(B), \eta)$ can be identified with the homotopy fiber of the restriction map

$$\mathrm{Map}_{\mathrm{Fun}_B(\mathcal{C}_B, \mathcal{C}_B)}(\mathrm{id}, \mathrm{id}) \to \mathrm{Map}_{\mathrm{Fun}_{\kappa}(\mathcal{C}, \mathcal{C})}(\mathrm{id}, \mathrm{id})$$

and is therefore essentially small. We have pullback diagrams

$$\begin{array}{ccc} \kappa \oplus V & \longrightarrow & \kappa \\ \downarrow & & \downarrow \\ \kappa & \longrightarrow & \kappa \oplus \Sigma(V) \end{array} \qquad \begin{array}{ccc} \kappa \oplus \Sigma(V) & \longrightarrow & \kappa \\ \downarrow & & \downarrow \\ \kappa & \longrightarrow & \kappa \oplus \Sigma^2(V) \end{array}$$

so that Proposition 16.6.2.1 guarantees that the map $\mathrm{CatDef}^+_{\mathcal{C}}(\kappa \oplus V) \to \Omega^2 \mathrm{CatDef}^+_{\mathcal{C}}(\kappa \oplus \Sigma^2(V))$ has discrete homotopy fibers. It follows that each path component of $\mathrm{CatDef}^+_{\mathcal{C}}(\kappa \oplus V)$

is a connected covering space of the essentially small space $\Omega^2 \operatorname{CatDef}^+_{\mathcal{C}}(\kappa \oplus \Sigma^2(V))$, and is therefore essentially small.

We now prove (3). Assume that B is Artinian, so that there exists a finite sequence of maps $B \simeq B_0 \to B_1 \to \cdots \to B_n \simeq \kappa$ and pullback diagrams

$$\begin{array}{ccc} B_i & \longrightarrow & \kappa \\ \downarrow & & \downarrow \\ B_{i+1} & \longrightarrow & \kappa \oplus \Sigma^{m_i}(\kappa). \end{array}$$

We prove that each $\operatorname{CatDef}^+_{\mathcal{C}}(B_i)$ is locally small using descending induction on i. Using (1), (2), and the inductive hypothesis, we deduce that $X = \operatorname{CatDef}^+_{\mathcal{C}}(\kappa) \times_{\operatorname{CatDef}^+_{\mathcal{C}}(\kappa \oplus \Sigma^{m_i}(\kappa))} \operatorname{CatDef}^+_{\mathcal{C}}(B_{i+1})$ is locally small. Proposition 16.6.2.1 implies that the map $\operatorname{CatDef}^+_{\mathcal{C}}(B_{i+1}) \to X$ has discrete homotopy fibers. It follows that every connected component of $\operatorname{CatDef}^+_{\mathcal{C}}(B_{i+1})$ is a connected covering space of a path component of X, and is therefore essentially small. □

Notation 16.6.2.3. Let κ be a field and let $\mathcal{C}$ be a stable κ-linear ∞-category. We let $\operatorname{CatDef}_{\mathcal{C}} : \operatorname{Alg}^{(2),\mathrm{art}}_{\kappa} \to \widehat{\mathcal{S}}$ denote the composition of the functor $\operatorname{CatDef}^+_{\mathcal{C}}$ of Construction 16.6.1.2 with the inclusion $\operatorname{Alg}^{(2),\mathrm{art}}_{\kappa} \hookrightarrow \operatorname{Alg}^{(2),\mathrm{aug}}_{\kappa}$.

Corollary 16.6.2.4. *Let κ be a field and let $\mathcal{C}$ be a stable κ-linear ∞-category. Then there exists a formal $\mathbb{E}_2$-moduli problem $\operatorname{CatDef}^{\wedge}_{\mathcal{C}} : \operatorname{Alg}^{(2),\mathrm{art}}_{\kappa} \to \mathcal{S}$ and a natural transformation $\alpha : \operatorname{CatDef}_{\mathcal{C}} \to \operatorname{CatDef}^{\wedge}_{\mathcal{C}}$ which is 0-truncated. In particular, we can regard $\operatorname{CatDef}_{\mathcal{C}} : \operatorname{Alg}^{(2),\mathrm{art}}_{\kappa} \to \widehat{\mathcal{S}}$ as a 2-proximate formal $\mathbb{E}_2$-moduli problem (in a larger universe); see Theorem 16.4.2.1.*

Proof. Combining Corollary 16.6.2.2, Proposition 16.6.2.1, and Theorem 16.4.2.1, we deduce the existence of a formal moduli problem $\operatorname{CatDef}^{\wedge}_{\mathcal{C}} : \operatorname{Alg}^{(2),\mathrm{art}}_{\kappa} \to \widehat{\mathcal{S}}$ and a 0-truncated natural transformation $\alpha : \operatorname{CatDef}_{\mathcal{C}} \to \operatorname{CatDef}^{\wedge}_{\mathcal{C}}$. For each $m \geqslant 0$, we see that the space

$$\operatorname{CatDef}^{\wedge}_{\mathcal{C}}(\kappa \oplus \Sigma^m(\kappa)) \simeq \Omega^2 \operatorname{CatDef}^{\wedge}_{\mathcal{C}}(\kappa \oplus \Sigma^{m+2}(\kappa)) \simeq \Omega^2 \operatorname{CatDef}_{\mathcal{C}}(\kappa \oplus \Sigma^{m+2}(\kappa))$$

is essentially small (see the proof of Corollary 16.6.2.2). For an arbitrary object $B \in \operatorname{Alg}^{(2),\mathrm{art}}_{\kappa}$, we can choose a finite sequence of maps $B = B_0 \to B_1 \to \cdots \to B_n \simeq \kappa$ and pullback diagrams

$$\begin{array}{ccc} B_i & \longrightarrow & \kappa \\ \downarrow & & \downarrow \\ B_{i+1} & \longrightarrow & \kappa \oplus \Sigma^{m_i}(\kappa). \end{array}$$

Using that $\operatorname{CatDef}^{\wedge}_{\mathcal{C}}$ is a formal $\mathbb{E}_2$-moduli problem, we deduce that each $\operatorname{CatDef}^{\wedge}_{\mathcal{C}}(B_i)$ is essentially small by descending induction on i, so that $\operatorname{CatDef}^{\wedge}_{\mathcal{C}}(B)$ is essentially small. □

Remark 16.6.2.5. The formal $\mathbb{E}_2$-moduli problem $\operatorname{CatDef}^{\wedge}_{\mathcal{C}}$ appearing in Corollary 16.6.2.4 is unique (up to a contractible space of choices): see Remark 16.4.2.3.

16.6.3 The Main Theorem

Let κ be a field, let $\mathcal{C}$ be a stable κ-linear ∞-category, and let $\mathrm{CatDef}^{\wedge}_{\mathcal{C}}$ be the formal $\mathbb{E}_2$-moduli problem of Corollary 16.6.2.4. Using Theorem 15.0.0.9 (and its proof), we see that there exists an (essentially unique) augmented $\mathbb{E}_2$-algebra A over κ for which the functor $\mathrm{CatDef}^{\wedge}_{\mathcal{C}}$ is given by $\mathrm{CatDef}^{\wedge}_{\mathcal{C}}(B) = \mathrm{Map}_{\mathrm{Alg}^{(2),\mathrm{aug}}_{\kappa}}(\mathfrak{D}^{(2)}(B), A)$. Our next goal is to make the relationship between A and $\mathcal{C}$ more explicit.

Definition 16.6.3.1. Let κ be an $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a stable κ-linear ∞-category. We let $\mathrm{LCat}(\kappa)$ denote the fiber product $\mathrm{Alg}^{(2)}_{\kappa} \times_{\mathrm{Alg}(\mathcal{P}\mathrm{r}^{\mathrm{St}})} \mathrm{LMod}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$ whose objects are pairs $(A, \mathcal{D})$, where A is an $\mathbb{E}_2$-algebra over κ and $\mathcal{D}$ is a stable left A-linear ∞-category (see Construction 16.6.1.2). The construction $(A, \mathcal{D}) \mapsto \mathcal{D}$ determines a forgetful functor $\mathrm{LCat}(\kappa) \to \mathrm{LinCat}^{\mathrm{St}}_{\kappa}$ (here $\mathrm{LinCat}^{\mathrm{St}}_{\kappa}$ denotes the ∞-category of stable κ-linear ∞-categories). We let $\mathrm{LCat}(\kappa)_{\mathcal{C}}$ denote the fiber product $\mathrm{LCat}(\kappa) \times_{\mathrm{LinCat}_{\kappa}} \{\mathcal{C}\}$: that is, the ∞-category whose objects are $\mathbb{E}_2$-algebras A together with an action of A on $\mathcal{C}$ (in the sense of §D.1). We will say that an object $(A, \mathcal{C}) \in \mathrm{LCat}(\kappa)_{\mathcal{C}}$ *exhibits A as the κ-linear center of $\mathcal{C}$* if $(A, \mathcal{C})$ is a final object of $\mathrm{LCat}(\kappa)_{\mathcal{C}}$.

Remark 16.6.3.2. In the situation of Definition 16.6.3.1 Corollary HA.4.7.1.42 implies that the forgetful functor $\mathrm{LMod}(\mathrm{LinCat}_{\kappa}) \times_{\mathrm{LinCat}_{\kappa}} \{\mathcal{C}\} \to \mathrm{Alg}(\mathrm{LinCat}_{\kappa})$ is a right fibration. It follows that the forgetful functor $q : \mathrm{LCat}(\kappa)_{\mathcal{C}} \to \mathrm{Alg}^{(2)}_{\kappa}$ is also a right fibration, so that an object $(A, \mathcal{C}) \in \mathrm{LCat}(\kappa)_{\mathcal{C}}$ is final if and only if the right fibration q is represented by the object $A \in \mathrm{Alg}^{(2)}_{\kappa}$. In other words, a κ-linear center A of $\mathcal{C}$ can be characterized by the following universal property: for every $A' \in \mathrm{Alg}^{(2)}_{\kappa}$, the space $\mathrm{Map}_{\mathrm{Alg}^{(2)}_{\kappa}}(A', A)$ can be identified with the space $\mathrm{LinCat}_{A'} \times_{\mathrm{LinCat}_{\kappa}} \{\mathcal{C}\}$ parametrizing actions of A' on $\mathcal{C}$.

Proposition 16.6.3.3. *Let κ be an $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a stable κ-linear ∞-category. Then there exists an object $(A, \mathcal{C}) \in \mathrm{LCat}(\kappa)_{\mathcal{C}}$ which exhibits A as a κ-linear center of $\mathcal{C}$.*

Proof. Let $\mathcal{E}$ be an endomorphism object of $\mathcal{C}$ in LinCat_{κ}: that is, $\mathcal{E}$ is the ∞-category of κ-linear functors from $\mathcal{C}$ to itself. We regard $\mathcal{E}$ as a monoidal ∞-category, so that $\mathcal{C}$ is a left $\mathcal{E}$-module object of LinCat_{κ}. According to Theorem HA.4.8.5.11 , the symmetric monoidal functor

$$\mathrm{Alg}_{\kappa} \to (\mathrm{LinCat}_{\kappa})_{\mathrm{Mod}_{\kappa}/} \qquad A \mapsto \mathrm{LMod}_A$$

admits a right adjoint G. It follows that G induces a right adjoint G' to the functor

$$\mathrm{Alg}^{(2)}_{\kappa} \simeq \mathrm{Alg}(\mathrm{Alg}_{\kappa}) \to \mathrm{Alg}((\mathrm{LinCat}_{\kappa})_{\mathrm{Mod}_{\kappa}/}) \simeq \mathrm{Alg}(\mathrm{LinCat}_{\kappa}).$$

Unwinding the definitions, we see that $A = G'(\mathcal{E})$ is a κ-linear center of $\mathcal{C}$. □

Remark 16.6.3.4. Let κ be an $\mathbb{E}_\infty$-ring and $\mathcal{C}$ a κ-linear ∞-category The proofs of Proposition 16.6.3.3 and Theorem HA.4.8.5.11 furnish a somewhat explicit description of the κ-linear center A of $\mathcal{C}$, at least as an $\mathbb{E}_1$-algebra over κ: it can be described as the endomorphism ring of the identity functor $\mathrm{id}_{\mathcal{C}} \in \mathcal{E}$, where $\mathcal{E}$ denotes the ∞-category of κ-linear functors from $\mathcal{C}$ to itself.

Example 16.6.3.5. Let κ be the sphere spectrum and let $\mathcal{C}$ be a presentable stable ∞-category, which we view as a stable κ-linear ∞-category. Then the center of $\mathcal{C}$ (in the sense of Construction D.1.5.4) coincides with the κ-linear center of $\mathcal{C}$.

Example 16.6.3.6. Let κ be an $\mathbb{E}_\infty$-ring, let $R \in \mathrm{Alg}_\kappa$ be an $\mathbb{E}_1$-algebra over κ, and let $\mathfrak{Z}(R) = \mathfrak{Z}_{\mathbb{E}_1}(R) \in \mathrm{Alg}_\kappa^{(2)}$ be a center of R (see Definition HA.5.3.1.12). Then $\mathfrak{Z}(R)$ is a κ-linear center of the ∞-category $\mathrm{LMod}_R(\mathrm{Mod}_\kappa)$.

Remark 16.6.3.7. Let κ be an $\mathbb{E}_\infty$-ring, let $\mathcal{C}$ be a stable κ-linear ∞-category, and let $A \in \mathrm{Alg}_\kappa^{(2)}$ denote the κ-linear center of $\mathcal{C}$. The homotopy groups $\pi_n A$ are often called the *Hochschild cohomology groups* of $\mathcal{C}$. In the special case where $\mathcal{C} = \mathrm{LMod}_R(\mathrm{Mod}_\kappa)$ for some $R \in \mathrm{Alg}_\kappa$, Example 16.6.3.6 allows us to identify the homotopy groups $\pi_* A$ with $\mathrm{Ext}^{-*}_{{}_R\mathrm{BMod}_R(\mathrm{Mod}_\kappa)}(R, R)$.

We are now ready to formulate the main result of this section.

Theorem 16.6.3.8. *Let κ be a field and let $\mathcal{C}$ be a stable κ-linear ∞-category. Then the functor $\mathrm{CatDef}^\wedge_{\mathcal{C}} : \mathrm{Alg}_\kappa^{(2),\mathrm{art}} \to \mathcal{S}$ of Corollary 16.5.3.2 is given by*

$$\mathrm{ObjDef}^\wedge_{\mathcal{C}}(B) = \mathrm{Map}_{\mathrm{Alg}_\kappa^{(2),\mathrm{aug}}}(\mathfrak{D}^{(2)}(B), \kappa \oplus \mathfrak{Z}(\mathcal{C})) \simeq \mathrm{Map}_{\mathrm{Alg}_\kappa^{(2)}}(\mathfrak{D}^{(2)}(B), \mathfrak{Z}(\mathcal{C})).$$

where $\mathfrak{Z}(\mathcal{C})$ denotes the κ-linear center of $\mathcal{C}$.

16.6.4 Construction of the Equivalence

Let κ be a field and let $\mathcal{C}$ be a stable κ-linear ∞-category. Theorem 16.6.3.8 predicts the existence of a 0-truncated map $\mathrm{ObjDef}_{\mathcal{C}}(B) \to \mathrm{Map}_{\mathrm{Alg}_\kappa^{(2)}}(\mathfrak{D}^{(2)}(B), \mathfrak{Z}(\mathcal{C}))$, depending functorially on $B \in \mathrm{Alg}_\kappa^{(2),\mathrm{art}}$. Our proof begins with an explicit construction of this map.

Construction 16.6.4.1. Let κ be a field, and let $\lambda^{(2)} : \mathcal{M}^{(2)} \to \mathrm{Alg}_\kappa^{(2),\mathrm{aug}} \times \mathrm{Alg}_\kappa^{(2),\mathrm{aug}}$ be the Koszul duality pairing on $\mathbb{E}_2$-algebras (so that the objects of $\mathcal{M}^{(2)}$ can be identified with triples (A, B, ϵ), where A and B are $\mathbb{E}_2$-algebras over κ and $\epsilon : A \otimes_\kappa B \to \kappa$ is an augmentation).

Let $\mathcal{C}$ be a stable κ-linear ∞-category and let $\mathrm{Defor}[\mathcal{C}]$ be as in Construction 16.6.1.2. Given an object $(A, B, \epsilon) \in \mathcal{M}^{(2)}$ and an object $(B, \mathcal{C}_B, \mu) \in \mathrm{Defor}[\mathcal{C}]$, we regard the tensor product $A \otimes_\kappa \mathcal{C}_B$ as an object of the ∞-category

$${}_{\mathrm{LMod}_A}\mathrm{BMod}_{\mathrm{LMod}_{A \otimes_\kappa B}}(\mathrm{LinCat}_\kappa),$$

so that we can regard $(A \otimes_\kappa \mathcal{C}_B) \otimes_{A \otimes_\kappa B} \kappa$ as a stable left A-linear ∞-category whose image in LinCat_κ coincides with $\mathcal{C}$. This construction determines a functor $\mathcal{M}^{(2)} \times_{\mathrm{Alg}_\kappa^{(2),\mathrm{aug}}} \mathrm{Defor}[\mathcal{C}] \to \mathrm{LCat}(\kappa)_{\mathcal{C}}$, where $\mathrm{LCat}(\kappa)_{\mathcal{C}}$ as in Definition 16.6.3.1. The induced map

$$\lambda : \mathcal{M}^{(2)} \times_{\mathrm{Alg}_\kappa^{(2),\mathrm{aug}}} \mathrm{Defor}[\mathcal{C}] \to \mathrm{LCat}(\kappa)_{\mathcal{C}} \times \mathrm{Defor}[\mathcal{C}]$$

factors as a composition

$$\mathcal{M}^{(2)} \times_{\mathrm{Alg}_\kappa^{(2),\mathrm{aug}}} \mathrm{Defor}[\mathcal{C}] \xrightarrow{i} \widetilde{\mathcal{M}}^{(2)} \xrightarrow{\lambda'} \mathrm{LCat}(\kappa)_{\mathcal{C}} \times \mathrm{Defor}[\mathcal{C}]$$

where i is an equivalence of ∞-categories and λ' is a categorical fibration. It is not difficult to see that λ' is a left representable pairing of ∞-categories, which induces a duality functor $\mathfrak{D}_{\mathcal{C}}^{(2)} : \mathrm{Defor}[\mathcal{C}]^{\mathrm{op}} \to \mathrm{LCat}(\kappa)_{\mathcal{C}}$. Concretely, the functor $\mathfrak{D}_{\mathcal{C}}^{(2)}$ assigns to each object $(B, \mathcal{C}_B, \mu) \in \mathrm{Defor}[\mathcal{C}]^{\mathrm{op}}$ the object $(\mathfrak{D}^{(2)}(B), \mathcal{C})$, where we regard $\mathcal{C}$ as a stable left $\mathfrak{D}^{(2)}(B)$-linear ∞-category by means of the canonical equivalence $\mathcal{C} \simeq (A \otimes_\kappa \mathcal{C}_B) \otimes_{A \otimes_\kappa B} \kappa$.

Let $\mathfrak{Z}(\mathcal{C})$ denote the κ-linear center of $\mathcal{C}$ (Definition 16.6.3.1), so that we have a canonical equivalence of ∞-categories $\eta : \mathrm{LCat}(\kappa)_{\mathcal{C}} \simeq (\mathrm{Alg}_\kappa^{(2)})_{/\mathfrak{Z}(\mathcal{C})} \simeq (\mathrm{Alg}_\kappa^{(2),\mathrm{aug}})_{/\kappa \oplus \mathfrak{Z}(\mathcal{C})}$. Composing the equivalence η with the functor $\mathfrak{D}_{\mathcal{C}}^{(2)}$, we obtain a diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{Defor}[\mathcal{C}]^{\mathrm{op}} & \xrightarrow{\eta \circ \mathfrak{D}_{\mathcal{C}}^{(2)}} & (\mathrm{Alg}_\kappa^{(2),\mathrm{aug}})_{/\kappa \oplus \mathfrak{Z}(\mathcal{C})} \\ \downarrow & & \downarrow \\ (\mathrm{Alg}_\kappa^{(2),\mathrm{aug}})^{\mathrm{op}} & \xrightarrow{\mathfrak{D}^{(2)}} & \mathrm{Alg}_\kappa^{(2),\mathrm{aug}} \end{array}$$

which commutes up to canonical homotopy, where the vertical maps are right fibrations. This diagram determines a natural transformation $\beta^+ : \mathrm{CatDef}_{\mathcal{C}}^+ \to X^+$, where $X^+ : \mathrm{Alg}_\kappa^{(2),\mathrm{aug}} \to \mathcal{S}$ denotes the functor given by the formula

$$X^+(B) = \mathrm{Map}_{\mathrm{Alg}_\kappa^{(2),\mathrm{aug}}}(\mathfrak{D}^{(2)}(B), \kappa \oplus \mathfrak{Z}(\mathcal{C})) \simeq \mathrm{Map}_{\mathrm{Alg}_\kappa^{(2)}}(\mathfrak{D}^{(2)}(B), \mathfrak{Z}(\mathcal{C})).$$

16.6.5 The Proof of Theorem 16.6.3.8

By virtue of Remark 16.4.2.3, Theorem 16.6.3.8 is a formal consequence of the following more precise assertion:

Proposition 16.6.5.1. *Let κ be a field, let $\mathcal{C}$ be a stable κ-linear ∞-category, and let $\mathfrak{Z}(\mathcal{C}) \in \mathrm{Alg}_\kappa^{(2)}$ denote a κ-linear center of $\mathcal{C}$. Let $X : \mathrm{Alg}_\kappa^{(2),\mathrm{aug}} \to \mathcal{S}$ denote the functor given by the formula $X(B) = \mathrm{Map}_{\mathrm{Alg}_\kappa^{(2)}}(\mathfrak{D}^{(2)}(B), \mathfrak{Z}(\mathcal{C}))$. Then the natural transformation β^+ of Construction 16.6.4.1 induces a 0-truncated map $\beta : \mathrm{CatDef}_{\mathcal{C}} \to X$.*

Since the functor X appearing in Proposition 16.6.5.1 is a formal $\mathbb{E}_2$-moduli problem, the natural transformation $\beta : \mathrm{CatDef}_{\mathcal{C}} \to X$ factors as a composition $\mathrm{CatDef}_{\mathcal{C}} \to \mathrm{CatDef}^{\wedge}_{\mathcal{C}} \xrightarrow{\overline{\beta}} X$. We wish to show that $\overline{\beta}$ is an equivalence of formal $\mathbb{E}_2$-moduli problems (which implies Proposition 16.6.5.1, by virtue of Theorem 16.4.2.1). According to Proposition 12.2.2.6, it will suffice to show that $\overline{\beta}$ induces an equivalence of tangent complexes. Using the description of the tangent complex of $\mathrm{CatDef}^{\wedge}_{\mathcal{C}}$ supplied by Proposition 16.4.3.2, we are reduced to proving the following special case of Proposition 16.6.5.1:

Proposition 16.6.5.2. *Let κ be a field and let $\mathcal{C}$ be a stable κ-linear ∞-category. For each $m \geqslant 0$, the natural transformation β^+ of Construction 16.6.4.1 induces a 0-truncated map $\mathrm{CatDef}_{\mathcal{C}}(\kappa \oplus \Sigma^m(\kappa)) \to \mathrm{Map}_{\mathrm{Alg}^{(2)}_\kappa}(\mathfrak{D}^{(2)}(\kappa \oplus \Sigma^m(\kappa)), \mathfrak{Z}(\mathcal{C}))$.*

Proof. We have a commutative diagram

$$\begin{array}{ccc} \mathrm{CatDef}_{\mathcal{C}}(\kappa \oplus \Sigma^m(\kappa)) & \longrightarrow & \mathrm{Map}_{\mathrm{Alg}^{(2)}_\kappa}(\mathfrak{D}^{(2)}(\kappa \oplus \Sigma^m(\kappa)), \mathfrak{Z}(\mathcal{C})) \\ \downarrow & & \downarrow \\ \Omega^2 \mathrm{CatDef}_{\mathcal{C}}(\kappa \oplus \Sigma^{m+2}(\kappa)) & \xrightarrow{\theta} & \Omega^2 \mathrm{Map}_{\mathrm{Alg}^{(2)}_\kappa}(\mathfrak{D}^{(2)}(\kappa \oplus \Sigma^{m+2}(\kappa)), \mathfrak{Z}(\mathcal{C})), \end{array}$$

where the left vertical map is 0-truncated by Corollary 16.6.2.4 and the right vertical map is a homotopy equivalence. It will therefore suffice to show that θ is a homotopy equivalence. Set $B = \kappa \oplus \Sigma^{m+2}(\kappa)$, let $\mathcal{C}_B = \mathcal{C} \otimes_\kappa B$, let $\mathcal{E}$ denote the ∞-category of κ-linear functors from $\mathcal{C}$ to itself, and let $\mathcal{E}_B$ denote the ∞-category of B-linear functors from $\mathcal{C}_B$ to itself, so that we have a canonical equivalence $\gamma : \mathcal{E}_B \simeq \mathrm{RMod}_B(\mathcal{E})$. Let $\mathrm{id}_{\mathcal{C}} \in \mathcal{E}$ denote the identity functor from $\mathcal{C}$ to itself. Under the equivalence γ, the identity functor from $\mathcal{C}_B$ to itself can be identified with the free module $\mathrm{id}_{\mathcal{C}} \otimes_\kappa B \in \mathrm{RMod}_B(\mathcal{E})$. Unwinding the definitions, we see that the domain of θ can be identified with the homotopy fiber of the map

$$\xi : \mathrm{Map}_{\mathcal{E}_B}(\mathrm{id}_{\mathcal{C}} \otimes_\kappa B, \mathrm{id}_{\mathcal{C}} \otimes_\kappa B) \simeq \mathrm{Map}_{\mathcal{E}}(\mathrm{id}_{\mathcal{C}}, \mathrm{id}_{\mathcal{C}} \otimes_\kappa B) \to \mathrm{Map}_{\mathcal{E}}(\mathrm{id}_{\mathcal{C}}, \mathrm{id}_{\mathcal{C}}).$$

We have a canonical fiber sequence $\Sigma^{m+2}\,\mathrm{id}_{\mathcal{C}} \to \mathrm{id}_{\mathcal{C}} \otimes_\kappa B \to \mathrm{id}_{\mathcal{C}}$ in the stable ∞-category $\mathcal{E}$, so that the homotopy fiber of ξ is given by

$$\mathrm{Map}_{\mathcal{E}}(\mathrm{id}_{\mathcal{C}}, \Sigma^{m+2}\,\mathrm{id}_{\mathcal{C}}) \simeq \mathrm{Map}_{\mathrm{Mod}_\kappa}(\Sigma^{-m-2}(\kappa), \mathfrak{Z}(\mathcal{C})).$$

The map θ is induced by a morphism $\nu : \Sigma^{-m-2}(\kappa) \to \mathfrak{D}^{(2)}(\kappa \oplus \Sigma^m(\kappa))$ in Mod_κ. Let $\mathrm{Free}^{(2)} : \mathrm{Mod}_\kappa \to \mathrm{Alg}^{(2)}_\kappa$ be a left adjoint to the forgetful functor, so that ν determines an augmentation $(\kappa \oplus \Sigma^m(\kappa)) \otimes_\kappa \mathrm{Free}^{(2)}(\Sigma^{-m-2}(\kappa)) \to \kappa$. The proof of Proposition 15.3.2.1 shows that this pairing exhibits $\mathrm{Free}^{(2)}(\Sigma^{-m-2}(\kappa))$ as the Koszul dual of $\kappa \oplus \Sigma^m(\kappa)$, from which it immediately follows that θ is a homotopy equivalence. □

16.6.6 Compactly Generated Deformations

Let κ be a field. To any stable κ-linear ∞-category $\mathcal{C}$, we can associate the 2-proximate formal $\mathbb{E}_2$-moduli problem $\mathrm{CatDef}_{\mathcal{C}} : \mathrm{Alg}_{\kappa}^{(2),\mathrm{art}} \to \widehat{\mathcal{S}}$ of Notation 16.6.2.3. By definition, $\mathrm{CatDef}_{\mathcal{C}}(B)$ parametrizes arbitrary deformations of $\mathcal{C}$ over B. In practice, we might not want to consider *all* deformations of $\mathcal{C}$: for example, if $\mathcal{C}$ is compactly generated, then we might want to restrict our attention to deformations which are compactly generated.

Notation 16.6.6.1. Let κ be a field and let $\mathcal{C}$ be a compactly generated stable κ-linear ∞-category. For every object $B \in \mathrm{Alg}_{\kappa}^{(2),\mathrm{art}}$, we let $\mathrm{CatDef}^c_{\mathcal{C}}(B)$ denote the summand of $\mathrm{CatDef}_{\mathcal{C}}(B)$ given by deformations $(\mathcal{C}_B, \mu : \mathcal{C}_B \otimes_B \kappa \simeq \mathcal{C})$ for which the ∞-category $\mathcal{C}_B$ is also compactly generated. It follows from Propositions C.6.2.1 and C.6.2.2 that this condition is compatible with extension of scalars, so that the construction $B \mapsto \mathrm{CatDef}^c_{\mathcal{C}}(B)$ determines a functor $\mathrm{CatDef}^c_{\mathcal{C}} : \mathrm{Alg}_{\kappa}^{(2),\mathrm{art}} \to \widehat{\mathcal{S}}$.

Proposition 16.6.6.2. *Let κ be a field and let $\mathcal{C}$ be a compactly generated stable κ-linear ∞-category. For every object $B \in \mathrm{Alg}_{\kappa}^{(2),\mathrm{art}}$, the space $\mathrm{CatDef}^c_{\mathcal{C}}(B)$ is essentially small. Consequently, we can view $\mathrm{CatDef}^c_{\mathcal{C}}$ as a $\mathcal{S}$-valued functor on $\mathrm{Alg}_{\kappa}^{(2),\mathrm{art}}$.*

Proof. Since B is Artinian, we can choose a finite sequence of maps

$$B \simeq B_0 \to B_1 \to \cdots \to B_n \simeq \kappa$$

and pullback diagrams

$$\begin{array}{ccc} B_i & \longrightarrow & \kappa \\ \downarrow & & \downarrow \\ B_{i+1} & \longrightarrow & \kappa \oplus \Sigma^{m_i}(\kappa) \end{array}$$

for some integers $m_i > 0$. We will show that each of the spaces $\mathrm{CatDef}^c_{\mathcal{C}}(B_i)$ is essentially small using descending induction on i. For $i < n$, Proposition 16.6.2.1 implies that the canonical map

$$\theta : \mathrm{CatDef}_{\mathcal{C}}(B_i) \to \mathrm{CatDef}^c_{\mathcal{C}}(\kappa) \times_{\mathrm{CatDef}^c_{\mathcal{C}}(\kappa \oplus \Sigma^{m_i}(\kappa))} \mathrm{CatDef}^c_{\mathcal{C}}(B_{i+1})$$

has discrete homotopy fibers, and the codomain of θ is essentially small by our inductive hypothesis (note that $\mathrm{CatDef}^c_{\mathcal{C}}(\kappa \oplus \Sigma^{m_i}(\kappa))$ is locally small by virtue of Corollary 16.6.2.2). It will therefore suffice to show that the homotopy fibers of θ are essentially small. Let η be a point of the codomain of θ, given by a compatible triple of deformations

$$\mathcal{C}_{B_{i+1}} \in \mathrm{CatDef}^c_{\mathcal{C}}(B_{i+1}) \qquad \mathcal{C}_{\kappa \oplus \Sigma^{m_i}(\kappa)} \in \mathrm{CatDef}^c_{\mathcal{C}}(\kappa \oplus \Sigma^{m_i}(\kappa)) \qquad \mathcal{C}_{\kappa} \in \mathrm{CatDef}^c_{\mathcal{C}}(\kappa).$$

By assumption, these ∞-categories are generated by their full subcategories of compact objects

$$\mathcal{C}^c_{B_{i+1}} \subseteq \mathcal{C}_{B_{i+1}} \qquad \mathcal{C}^c_{\kappa \oplus \Sigma^{m_i}(\kappa)} \subseteq \mathcal{C}_{\kappa \oplus \Sigma^{m_i}(\kappa)} \qquad \mathcal{C}^c_{\kappa} \subseteq \mathcal{C}_{\kappa}\,.$$

To show that the homotopy fiber of θ over the point η is essentially small, it will suffice to show there is only a bounded number of equivalence classes of full B_i-linear subcategories $\mathcal{C}_{B_i} \subseteq \mathcal{C}_{B_{i+1}} \times_{\mathcal{C}_{\kappa \oplus \Sigma^{m_i}(\kappa)}} \mathcal{C}_\kappa$ which are compactly generated and for which the projection maps induce equivalences

$$\mathcal{C}_{B_i} \otimes_{B_i} B_{i+1} \to \mathcal{C}_{B_{i+1}} \qquad \mathcal{C}_{B_i} \otimes_{B_i} \kappa \to \mathcal{C}_\kappa .$$

We conclude by observing that any such $\mathcal{C}_{B_i}$ is determined by its full subcategory of compact objects, which is contained in the (essentially small) ∞-category $\mathcal{C}^c_{B_{i+1}} \times_{\mathcal{C}^c_{\kappa \oplus \Sigma^{m_i}(\kappa)}} \mathcal{C}^c_\kappa$. □

Remark 16.6.6.3. In the situation of Proposition 16.6.6.2, the inclusion $\mathrm{CatDef}^c_{\mathcal{C}} \hookrightarrow \mathrm{CatDef}_{\mathcal{C}}$ is (-1)-truncated. Using Corollary 16.6.2.4 and Theorem 16.4.2.1, we deduce that $\mathrm{CatDef}^c_{\mathcal{C}}$ is a 2-proximate formal moduli problem. Moreover, the composite map $\mathrm{CatDef}^c_{\mathcal{C}} \to \mathrm{CatDef}_{\mathcal{C}} \to \mathrm{CatDef}^{\wedge}_{\mathcal{C}}$ is 0-truncated, so that we can view $\mathrm{CatDef}^{\wedge}_{\mathcal{C}}$ as the formal $\mathbb{E}_2$-moduli problem associated to both $\mathrm{CatDef}^c_{\mathcal{C}}$ and $\mathrm{CatDef}_{\mathcal{C}}$.

16.6.7 Tame Compact Generation

Let κ be a field and let $\mathcal{C}$ be a compactly generated stable κ-linear ∞-category. One advantage of working with the functor $\mathrm{CatDef}^c_{\mathcal{C}}$ of Notation 16.6.6.1 is that it is generally "closer" to being a formal $\mathbb{E}_2$-moduli problem than the functor $\mathrm{CatDef}_{\mathcal{C}}$. Before making this precise, we need to introduce a bit of terminology.

Definition 16.6.7.1. Let $\mathcal{C}$ be a stable ∞-category. We will say that $\mathcal{C}$ is *tamely compactly generated* if it satisfies the following conditions:

(a) The ∞-category $\mathcal{C}$ is compactly generated (that is, $\mathcal{C}$ is generated under filtered colimits by the full subcategory $\mathcal{C}^c \subseteq \mathcal{C}$ spanned by the compact objects).

(b) For every pair of compact objects $C, D \in \mathcal{C}$, the groups $\mathrm{Ext}^n_{\mathcal{C}}(C, D)$ vanish for $n \gg 0$.

Example 16.6.7.2. Let X be a quasi-compact, quasi-separated spectral algebraic space. Then the ∞-category $\mathrm{QCoh}(\mathsf{X})$ is tamely compactly generated.

Theorem 16.6.7.3. *Let κ be a field and let $\mathcal{C}$ be a stable κ-linear ∞-category which is tamely compactly generated. Then the functor* $\mathrm{CatDef}^c_{\mathcal{C}}$ *of Notation 16.6.6.1 is a* 1*-proximate formal moduli problem.*

Remark 16.6.7.4. In the situation of Theorem 16.6.7.3, any compactly generated deformation of $\mathcal{C}$ over an Artinian $\mathbb{E}_2$-algebra is automatically tamely compactly generated: see Proposition 16.6.9.2.

We will give a proof of Theorem 16.6.7.3 a bit later in this section. First, let us consider its consequences. Combining Theorems 16.6.7.3, 16.4.2.1, and 16.6.3.8, we obtain the following:

Corollary 16.6.7.5. *Let κ be a field and let $\mathcal{C}$ be a stable κ-linear ∞-category which is tamely compactly generated. Then, for every object $B \in \mathrm{Alg}_{\kappa}^{(2),\mathrm{art}}$, the canonical map*

$$\mathrm{CatDef}^{c}_{\mathcal{C}}(B) \to \mathrm{CatDef}^{\wedge}_{\mathcal{C}}(B) \simeq \mathrm{Map}_{\mathrm{Alg}_{\kappa}^{(2)}}(\mathfrak{D}^{(2)}(B), \mathfrak{Z}(\mathcal{C}))$$

is (-1)-truncated.

Remark 16.6.7.6. If $\mathcal{C}$ is a stable κ-linear ∞-category which is tamely compactly generated, Corollary 16.6.7.5 asserts every compactly generated deformation of $\mathcal{C}$ over an algebra $B \in \mathrm{Alg}_{\kappa}^{(2),\mathrm{art}}$ is determined (up to essentially unique equivalence) by an action of the Koszul dual $\mathfrak{D}^{(2)}(B)$ on the ∞-category $\mathcal{C}$. Under much stronger assumptions, one can ensure that the inclusion $\mathrm{CatDef}^{c}_{\mathcal{C}} \hookrightarrow \mathrm{CatDef}^{\wedge}_{\mathcal{C}}$ is an equivalence, so that every action of $\mathfrak{D}^{(2)}(B)$ on $\mathcal{C}$ determines a deformation of $\mathcal{C}$ over B (see Theorem 16.6.10.2). In general, this is not the case: there are actions of $\mathfrak{D}^{(2)}(B)$ on $\mathcal{C}$ which do not arise from deformations of $\mathcal{C}$ (at least heuristically, these correspond to *curved* deformations of the ∞-category $\mathcal{C}$).

16.6.8 Piecewise Compactness

Before giving the proof of Theorem 16.6.7.3, we need to establish a few facts about compact objects of tamely compactly generated stable ∞-categories. To maintain terminological consistency with the rest of this book, we will use the term *stable R-linear ∞-category* to refer to a stable left R-linear ∞-category (as in Variant D.1.5.1), though in our intended application we will be interested in the case of right R-linear ∞-categories.

Notation 16.6.8.1. If $\mathcal{C}$ is a compactly generated stable ∞-category, we let $\mathcal{C}^{c}$ denote the full subcategory of $\mathcal{C}$ spanned by the compact objects.

The main fact we will need is the following:

Proposition 16.6.8.2. *Let A be a connective $\mathbb{E}_2$-ring and let $\mathcal{C}$ be a stable A-linear ∞-category which is tamely compactly generated. Suppose we are given a pullback diagram*

$$\begin{array}{ccc} A & \longrightarrow & B \\ \downarrow & & \downarrow \\ A' & \longrightarrow & B' \end{array}$$

of connective $\mathbb{E}_2$-rings which induces surjective maps $\pi_0 B \to \pi_0 B'$ and $\pi_0 A' \to \pi_0 B'$. Then the natural map $\theta^{c} : \mathcal{C}^{c} \to (B \otimes_A \mathcal{C})^{c} \times_{(B' \otimes_A \mathcal{C})^{c}} (A' \otimes_A \mathcal{C})^{c}$ is an equivalence of ∞-categories.

The proof of Proposition 16.6.8.2 will require some preliminaries. Recall that if R is an $\mathbb{E}_2$-ring and $\mathcal{C}$ is a stable R-linear ∞-category, then we can regard $\mathcal{C}$ as enriched over the monoidal ∞-category LMod_R. In particular, to every pair of objects $C, D \in \mathcal{C}$ we can associate a mapping object $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D) \in \mathrm{LMod}_R$, characterized by the universal property $\mathrm{Map}_{\mathrm{LMod}_R}(M, \underline{\mathrm{Map}}_{\mathcal{C}}(C, D)) \simeq \mathrm{Map}_{\mathcal{C}}(M \otimes_R C, D)$.

Lemma 16.6.8.3. *Let R be an $\mathbb{E}_2$-ring and let $\mathcal{C}$ be a stable R-linear ∞-category. If $C \in \mathcal{C}$ is compact, then the construction $D \mapsto \underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$ determines a colimit-preserving functor $\mathcal{C} \to \mathrm{LMod}_R$.*

Proof. It is clear that the construction $D \mapsto \underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$ commutes with limits and is therefore an exact functor. To prove that it preserves colimits, it suffices to show that it preserves filtered colimits. For this, it suffices to show that the construction $D \mapsto \Omega^{\infty}\underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$ preserves filtered colimits (as a functor from $\mathcal{C}$ to $\mathcal{S}$), which is equivalent to the requirement that C is compact. □

Let R be an $\mathbb{E}_2$-ring and let $\mathcal{C}$ be a stable R-linear ∞-category. Given an object $N \in \mathrm{LMod}_R$ and a pair of objects $C, D \in \mathcal{C}$, the canonical map $N \otimes_R \underline{\mathrm{Map}}_{\mathcal{C}}(C, D) \otimes_R C \to N \otimes_R D$ in $\mathcal{C}$ is classified by a morphism of left R-modules $\lambda : N \otimes \underline{\mathrm{Map}}_{\mathcal{C}}(C, D) \to \underline{\mathrm{Map}}_{\mathcal{C}}(C, N \otimes_R D)$.

Lemma 16.6.8.4. *Let R be an $\mathbb{E}_2$-ring and let $\mathcal{C}$ be an R-linear ∞-category. Let $C, D \in \mathcal{C}$ and let $N \in \mathrm{LMod}_R$. If C is a compact object of $\mathcal{C}$, then the map $\lambda : N \otimes_R \underline{\mathrm{Map}}_{\mathcal{C}}(C, D) \to \underline{\mathrm{Map}}_{\mathcal{C}}(C, N \otimes_R D)$ is an equivalence.*

Proof. Using Lemma 16.6.8.3, we deduce that the functor $N \mapsto \underline{\mathrm{Map}}_{\mathcal{C}}(C, N \otimes D)$ preserves small colimits. It follows that the collection of objects $N \in \mathrm{LMod}_R$ for which λ is an equivalence is closed under colimits in LMod_R. We may therefore suppose that $N \simeq \Sigma^n(R)$ for some integer n, in which case the result is obvious. □

Lemma 16.6.8.5. *Suppose we are given a morphism of $\mathbb{E}_2$-rings $R \to R'$, let $\mathcal{C}$ be a stable R-linear ∞-category, and let $\mathcal{C}' = R' \otimes_R \mathcal{C} \simeq \mathrm{LMod}_{R'}(\mathcal{C})$. Let $F : \mathcal{C} \to \mathcal{C}'$ be a left adjoint to the forgetful functor $G : \mathcal{C}' \to \mathcal{C}$, given on objects by $F(C) = R' \otimes_R C$. For every pair of objects $C, D \in \mathcal{C}$, the evaluation map $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D) \otimes C \to D$ induces a map*

$$(R' \otimes_R \underline{\mathrm{Map}}_{\mathcal{C}}(C, D)) \otimes_{R'} F(C) \simeq F(\underline{\mathrm{Map}}_{\mathcal{C}}(C, D) \otimes_R C) \to F(D),$$

which is classified by a morphism of left R'-modules $\alpha : R' \otimes_R \underline{\mathrm{Map}}_{\mathcal{C}}(C, D) \to \underline{\mathrm{Map}}_{\mathcal{C}'}(F(C), F(D))$. If $C \in \mathcal{C}$ is compact, then α is an equivalence.

Proof. The image of α under the forgetful functor $\mathrm{LMod}_{R'} \to \mathrm{LMod}_R$ coincides with the equivalence $R' \otimes_R \underline{\mathrm{Map}}_{\mathcal{C}}(C, D) \to \underline{\mathrm{Map}}_{\mathcal{C}}(C, R' \otimes_R D)$ of Lemma 16.6.8.4. □

Lemma 16.6.8.6. *Suppose we are given a pullback diagram of $\mathbb{E}_2$-rings*

$$\begin{array}{ccc} A & \longrightarrow & B \\ \downarrow & & \downarrow \\ A' & \longrightarrow & B' \end{array}$$

Let $\mathcal{C}$ be a stable A-linear ∞-category. Then an object $C \in \mathcal{C}$ is compact if and only if its images in $A' \otimes_A \mathcal{C}$ and $B \otimes_A \mathcal{C}$ are compact.

Proof. The "only if" direction is obvious, since the forgetful functors $\mathrm{LMod}_B(\mathcal{C}) \to \mathcal{C} \leftarrow \mathrm{LMod}_{A'}(\mathcal{C})$ preserve filtered colimits. For the converse, suppose that $C \in \mathcal{C}$ has compact images $C_{A'} \in (A' \otimes_A \mathcal{C})$ and $C_B \in (B \otimes_A \mathcal{C})$. Then the image of C in the fiber product $\mathcal{D} = (A' \otimes_A \mathcal{C}) \times_{(B' \otimes_A \mathcal{C})} (B \otimes_A \mathcal{C})$ is compact. Since the natural map $\mathcal{C} \to \mathcal{D}$ is fully faithful (Proposition 16.2.1.1) and preserves filtered colimits, we conclude that C is compact. □

Lemma 16.6.8.7. *Let $f : R \to R'$ be a morphism of connective $\mathbb{E}_2$-rings, let $\mathcal{C}$ be a stable R-linear ∞-category, and set $\mathcal{C}' = R' \otimes_R \mathcal{C} \simeq \mathrm{LMod}_{R'}(\mathcal{C})$. If $\mathcal{C}$ is tamely compactly generated, then $\mathcal{C}'$ is tamely compactly generated.*

Proof. Let $F : \mathcal{C} \to \mathcal{C}'$ denote the canonical map, given by $(C \in \mathcal{C}) \mapsto (R' \otimes_R C \in \mathrm{LMod}_{R'}(\mathcal{C}) \simeq \mathcal{C}')$. We note that $\mathcal{C}'$ is compactly generated: in fact, $\mathcal{C}'$ is generated under small colimits by the essential image of the composite functor map $\mathcal{C}^c \hookrightarrow \mathcal{C} \xrightarrow{F} \mathcal{C}'$, which consists of compact objects (since F is left adjoint to a forgetful functor). It follows that the ∞-category $\mathcal{C}'^c$ is the smallest stable full subcategory of $\mathcal{C}'$ which contains $F(\mathcal{C}^c)$ and is closed under retracts. Let $\mathcal{X} \subseteq \mathcal{C}'$ be the full subcategory spanned by those objects C such that for every $D \in \mathcal{C}'^c$, we have $\mathrm{Ext}^n_{\mathcal{C}'}(C, D) \simeq 0$ for $n \gg 0$. It is easy to see that $\mathcal{X}$ is stable and closed under retracts. Consequently, to show that $\mathcal{C}'^c \subseteq \mathcal{X}$, it will suffice to show that $F(C_0) \in \mathcal{X}$ for each $C_0 \in \mathcal{C}^c$. Let us regard C_0 as fixed, and let $\mathcal{Y}$ be the full subcategory of $\mathcal{C}'$ spanned by those objects D for which the groups $\mathrm{Ext}^n_{\mathcal{C}'}(F(C_0), D)$ vanish for $n \gg 0$. Since $\mathcal{Y}$ is stable and closed under retracts, it will suffice to show that $F(D_0) \in \mathcal{Y}$ for each $D_0 \in \mathcal{C}^c$. In other words, we are reduced to proving that the homotopy groups $\pi_{-n}\underline{\mathrm{Map}}_{\mathcal{C}_B}(F(C_0), F(D_0))$ vanish for $n \gg 0$. Using Lemma 16.6.8.5, we are reduced to proving that the spectrum $R' \otimes_R \underline{\mathrm{Map}}_{\mathcal{C}}(C_0, D_0)$ is $(-n)$-connective for some $n \gg 0$. Using our assumption that R and R' are connective, we are reduced to showing that $\underline{\mathrm{Map}}_{\mathcal{C}}(C_0, D_0)$ is $(-n)$-connective for $n \gg 0$, which follows from our assumption that $\mathcal{C}$ is tamely compactly generated. □

Proof of Proposition 16.6.8.2. Suppose we are given a pullback diagram

$$\begin{array}{ccc} A & \longrightarrow & B \\ \downarrow & & \downarrow \\ A' & \longrightarrow & B' \end{array}$$

of connective $\mathbb{E}_2$-rings which induces surjective ring homomorphisms $\pi_0 B \to \pi_0 B'$ and $\pi_0 A' \to \pi_0 B'$, and let $\mathcal{C} = \mathcal{C}_A$ be a stable A-linear ∞-category which is tamely compactly generated. Define

$$\mathcal{C}_B = B \otimes_A \mathcal{C}_A \qquad \mathcal{C}_{B'} = B' \otimes_A \mathcal{C}_A \qquad \mathcal{C}_{A'} = A' \otimes_A \mathcal{C}_A,$$

and let $\theta : \mathcal{C}_A \to \mathcal{C}_B \times_{\mathcal{C}_{B'}} \mathcal{C}_{A'}$ be the fully faithful embedding of Proposition 16.2.1.1. Then θ restricts to a fully faithful embedding $\theta^c : \mathcal{C}^c_A \to \mathcal{C}^c_B \times_{\mathcal{C}^c_{B'}} \mathcal{C}^c_{A'}$, and we wish to prove that θ^c is essentially surjective.

Let us identify objects of $\mathcal{C}_B \times_{\mathcal{C}_{B'}} \mathcal{C}_{A'}$ with triples $(C_B, C_{A'}, \eta)$ where $C_B \in \mathcal{C}_B$, $C_{A'} \in \mathcal{C}_{A'}$, and η is an equivalence $B' \otimes_B C_B \simeq B' \otimes_{A'} C_{A'}$. Given such a triple, we will denote the object $B' \otimes_B C_B \simeq B' \otimes_{A'} C_{A'}$ by $C_{B'}$. Note that θ admits a right adjoint G, given by $(C_B, C_{A'}, \eta) \mapsto C_B \times_{C_{B'}} C_{A'}$. By virtue of Lemma 16.6.8.6, it will suffice to show that the counit transformation $v : \theta \circ G \to \mathrm{id}$ is an equivalence when restricted to objects of $\mathcal{C}^c_B \times_{\mathcal{C}^c_{B'}} \mathcal{C}^c_{A'}$. Choose such an object $(C_B, C_{A'}, \eta)$ (so that C_B and $C_{A'}$ are compact) and let $C_A = C_B \times_{C_{B'}} C_{A'}$; we wish to show that the canonical maps

$$\phi : B \otimes_A C_A \to C_B \qquad \phi' : A' \otimes_A C_A \to C_{A'}$$

are equivalences. We will show that ϕ is an equivalence; the argument that ϕ' is an equivalence is similar. Let $\mathcal{X} \subseteq \mathcal{C}_B$ be the full subcategory spanned by those objects $D_B \in \mathcal{C}_B$ such that ϕ induces an equivalence $\phi_0 : \underline{\mathrm{Map}}_{\mathcal{C}_B}(D_B, B \otimes_A C_A) \to \underline{\mathrm{Map}}_{\mathcal{C}_B}(D_B, C_B)$. We wish to show that $\mathcal{X} = \mathcal{C}_B$. Since $\mathcal{X}$ is closed under small colimits, it will suffice to show that $\mathcal{X}$ contains $B \otimes_A D_A$ for every compact object $D_A \in \mathcal{C}_A$. Let $D_{A'}$ and $D_{B'}$ be the images of D_A in $\mathcal{C}_{A'}$ and $\mathcal{C}_{B'}$, respectively. Using Lemma 16.6.8.4, we can identify ϕ_0 with the canonical map $B \otimes_A \underline{\mathrm{Map}}_{\mathcal{C}_A}(D_A, C_A) \to \underline{\mathrm{Map}}_{\mathcal{C}_B}(D_B, C_B)$. Note that we have a pullback diagram

$$\begin{array}{ccc} \underline{\mathrm{Map}}_{\mathcal{C}_A}(D_A, C_A) & \longrightarrow & \underline{\mathrm{Map}}_{\mathcal{C}_B}(D_B, C_B) \\ \downarrow & & \downarrow \\ \underline{\mathrm{Map}}_{\mathcal{C}_{A'}}(D_{A'}, C_{A'}) & \longrightarrow & \underline{\mathrm{Map}}_{\mathcal{C}_{B'}}(D_{B'}, C_{B'}) \end{array}$$

and that Lemma 16.6.8.4 guarantees that the underlying maps

$$B' \otimes_{A'} \underline{\mathrm{Map}}_{\mathcal{C}_{A'}}(D_{A'}, C_{A'}) \to \underline{\mathrm{Map}}_{\mathcal{C}_{B'}}(D_{B'}, C_{B'}) \leftarrow B' \otimes_B \underline{\mathrm{Map}}_{\mathcal{C}_B}(D_B, C_B)$$

are equivalences. By virtue of Proposition 16.2.2.1, it will suffice to show that there exists an integer $n \gg 0$ such that $\underline{\mathrm{Map}}_{\mathcal{C}_B}(D_B, C_B)$ and $\underline{\mathrm{Map}}_{\mathcal{C}_{A'}}(D_{A'}, C_{A'})$ belong to $(\mathrm{LMod}_B)_{\geqslant -n}$ and $(\mathrm{LMod}_{A'})_{\geqslant -n}$, respectively. This follows from the fact that the ∞-categories $\mathcal{C}_B$ and $\mathcal{C}_{A'}$ are tamely compactly generated (Lemma 16.6.8.7). □

16.6.9 The Proof of Theorem 16.6.7.3

Let κ be a field and let $\mathcal{C}$ be a stable κ-linear ∞-category which is tamely compactly generated. Let $\mathrm{CatDef}^c_{\mathcal{C}} : \mathrm{Alg}^{(2),\mathrm{art}}_\kappa \to \mathcal{S}$ be the functor defined in Notation 16.6.6.1. For $B \in \mathrm{Alg}^{(2),\mathrm{art}}_\kappa$ we let $\mathrm{CatDef}^{\mathrm{tcg}}_{\mathcal{C}}(B)$ denote the summand of $\mathrm{CatDef}^c_{\mathcal{C}}(B)$ consisting of those deformations $(\mathcal{C}_B, \mu : \mathcal{C}_B \otimes_B \kappa \simeq \mathcal{C})$ for which $\mathcal{C}_B$ is tamely compactly generated. It follows from Lemma 16.6.8.7 that the construction $B \mapsto \mathrm{CatDef}^{\mathrm{tcg}}_{\mathcal{C}}(B)$ determines a functor $\mathrm{CatDef}^{\mathrm{tcg}}_{\mathcal{C}} : \mathrm{Alg}^{(2),\mathrm{art}}_{\kappa} \to \mathcal{S}$. Theorem 16.6.7.3 is an immediate consequence of the following pair of assertions:

Proposition 16.6.9.1. *Let κ be a field and let $\mathcal{C}$ be a stable κ-linear ∞-category which is tamely compactly generated. Then the functor $\mathrm{CatDef}^{\mathrm{tcg}}_{\mathcal{C}} : \mathrm{Alg}^{(2),\mathrm{art}}_{\kappa} \to \mathcal{S}$ is a 1-proximate formal $\mathbb{E}_2$-moduli problem.*

Proposition 16.6.9.2. *Let κ be a field and let $\mathcal{C}$ be a stable κ-linear ∞-category which is tamely compactly generated. Then $\mathrm{CatDef}^{\mathrm{tcg}}_{\mathcal{C}} = \mathrm{CatDef}^{c}_{\mathcal{C}}$. In other words, if $\mathcal{C}_B$ is a deformation of $\mathcal{C}$ which is defined over an Artinian $\mathbb{E}_2$-algebra B and $\mathcal{C}_B$ is compactly generated, then it is automatically tamely compactly generated.*

Proof of Proposition 16.6.9.2. Let $\mathcal{D} \subseteq \mathcal{C}_B$ denote the full subcategory spanned by those objects D such that, for each $C \in \mathcal{C}^c_B$, the groups $\mathrm{Ext}^n_{\mathcal{C}_B}(C, D)$ vanish for $n \gg 0$. Note that if $C, D \in \mathcal{C}^c_B$, then

$$\mathrm{Ext}^n_{\mathcal{C}_B}(C, D \otimes_B \kappa) \simeq \mathrm{Ext}^n_{\mathrm{RMod}_{\kappa}(\mathcal{C}_B)}(C \otimes_B \kappa, D \otimes_B \kappa)$$

vanishes for $n \gg 0$ by virtue of our assumption that $\mathcal{C}$ is tamely compactly generated. It follows that $\mathcal{D}$ contains $D \otimes_B \kappa$ for every compact object $D \in \mathcal{C}_B$. Since B is Artinian, we can choose a finite sequence $B = B_0 \to \cdots \to B_n$ and pullback diagrams

$$\begin{array}{ccc} B_i & \longrightarrow & \kappa \\ \downarrow & & \downarrow \\ B_{i+1} & \longrightarrow & \kappa \oplus \Sigma^{m_i}(\kappa). \end{array}$$

In particular, we have fiber sequences of B-modules

$$B_i \to B_{i+1} \to \Sigma^{m_i}(\kappa).$$

It follows by descending induction on i that $D \otimes_B B_i$ belongs to $\mathcal{D}$ for every compact object $D \in \mathcal{C}_B$. Taking $i = 0$, we deduce that every compact object of $\mathcal{C}_B$ belongs to $\mathcal{D}$, so that $\mathcal{C}_B$ is tamely compactly generated as desired. □

Proof of Proposition 16.6.9.1. For every connective $\mathbb{E}_2$-ring R, let $\chi(R)$ denote the subcategory of $\mathrm{RMod}_{\mathrm{LMod}_R}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$ whose objects are stable right R-linear ∞-categories which are tamely compactly generated and whose morphisms are R-linear functors which preserve compact objects. It follows from Lemma 16.6.8.7 that the construction $R \mapsto \chi(R)$ determines a functor $\mathrm{Alg}^{(2),\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_{\infty}$. We will prove the following:

$(*)$ For every pullback diagram of connective $\mathbb{E}_2$-rings σ :

$$\begin{array}{ccc} A & \longrightarrow & B \\ \downarrow & & \downarrow \\ A' & \longrightarrow & B' \end{array}$$

for which the maps $\pi_0 B \to \pi_0 B'$ and $\pi_0 A' \to \pi_0 B'$ are surjective, the induced functor $F : \chi(A) \to \chi(B) \times_{\chi(B')} \chi(A')$ is fully faithful.

Assuming $(*)$, we deduce that the induced map of spaces $\chi(A)^{\simeq} \to \chi(B)^{\simeq} \times_{\chi(B')^{\simeq}} \chi(A')^{\simeq}$ is (-1)-truncated. Specializing to the case where σ is a pullback diagram of Artinian $\mathbb{E}_2$-algebras over κ and passing to homotopy fibers over the point $\mathcal{C} \in \chi(\kappa)$, we conclude that the map $\mathrm{CatDef}^{\mathrm{tcg}}_{\mathcal{C}}(A) \to \mathrm{CatDef}^{\mathrm{tcg}}_{\mathcal{C}}(B) \times_{\mathrm{CatDef}^{\mathrm{tcg}}_{\mathcal{C}}(B')} \mathrm{CatDef}^{\mathrm{tcg}}_{\mathcal{C}}(A')$ is (-1)-truncated, so that $\mathrm{CatDef}^{\mathrm{tcg}}_{\mathcal{C}}$ is a (-1)-proximate formal moduli problem (see Proposition 16.4.1.4).

It remains to prove $(*)$. Let us identify objects of the fiber product $\chi(B) \times_{\chi(B')} \chi(A')$ with triples $(\mathcal{D}_B, \mathcal{D}_{A'}, \eta)$ where $\mathcal{D}_B$ is a stable right B-linear ∞-category which is tamely compactly generated, $\mathcal{D}_{A'}$ is a stable right A'-linear ∞-category which is tamely compactly generated, and η is a B'-linear equivalence $\mathcal{D}_B \otimes_B B' \simeq \mathcal{D}_{A'} \otimes_{A'} B'$. Given such a triple, we let $\mathcal{D}_{B'}$ denote the ∞-category $\mathcal{D}_B \otimes_B B' \simeq \mathcal{D}_{A'} \otimes_{A'} B'$. The functor F admits a right adjoint G, which carries a triple $(\mathcal{D}_B, \mathcal{D}_{A'}, \eta)$ to the full subcategory of $\mathcal{D}_B \times_{\mathcal{D}_{B'}} \mathcal{D}_{A'}$ generated under small colimits by $\mathcal{D}^c_B \times_{\mathcal{D}^c_{B'}} \mathcal{D}^c_{A'}$. We wish to show that the unit map $u : \mathrm{id} \to G \circ F$ is an equivalence. In other words, we wish to show that if $(\mathcal{D}_B, \mathcal{D}_{A'}, \eta) = F(\mathcal{D}_A)$ for some tamely compactly generated stable right A-linear ∞-category $\mathcal{D}_A$, then the canonical map $\mathcal{D}_A \to \mathcal{D}_B \times_{\mathcal{D}_{B'}} \mathcal{D}_{A'}$ is fully faithful and its essential image is the subcategory generated by $\mathcal{D}^c_B \times_{\mathcal{D}^c_{B'}} \mathcal{D}^c_A$ under small colimits. This follows immediately from Proposition 16.6.8.2. $\square$

16.6.10 Unobstructible Objects

We can improve further on Theorem 16.6.7.3 if we are willing to to impose some stronger conditions on the κ-linear ∞-category $\mathcal{C}$.

Definition 16.6.10.1. Let $\mathcal{C}$ be a presentable stable ∞-category. We will say that an object $C \in \mathcal{C}$ is *unobstructible* if C is compact and the groups $\mathrm{Ext}^n_{\mathcal{C}}(C, C)$ vanish for $n \geqslant 2$.

Theorem 16.6.10.2. *Let κ be a field and let $\mathcal{C}$ be a stable κ-linear ∞-category. Assume that $\mathcal{C}$ is tamely compactly generated and that there exists a collection of unobstructible objects $\{C_\alpha\}$ which generates $\mathcal{C}$ under small colimits. Then the functor $\mathrm{CatDef}^{\mathrm{c}}_{\mathcal{C}} : \mathrm{Alg}^{(2),\mathrm{art}}_{\kappa} \to \mathcal{S}$ of Notation 16.6.6.1 is a formal $\mathbb{E}_2$-moduli problem.*

Corollary 16.6.10.3. *Let κ be a field and let $\mathcal{C}$ be a stable κ-linear ∞-category. Assume that $\mathcal{C}$ is tamely compactly generated and that there exists a collection of unobstructible* *objects $\{C_\alpha\}$ which generates $\mathcal{C}$ under small colimits. Then the composite map*

$$\mathrm{CatDef}^c_{\mathcal{C}} \to \mathrm{CatDef}_{\mathcal{C}} \to \mathrm{CatDef}^{\wedge}_{\mathcal{C}}$$

is an equivalence. Consequently, the functor $\mathrm{CatDef}^c_{\mathcal{C}}$ *is given by*

$$\mathrm{CatDef}^c_{\mathcal{C}}(B) = \mathrm{Map}_{\mathrm{Alg}^{(2)}_\kappa}(\mathfrak{D}^{(2)}(B), \mathfrak{Z}(\mathcal{C})),$$

where $\mathfrak{Z}(\mathcal{C})$ denotes the κ-linear center of $\mathcal{C}$.

Proof. Combine Theorems 16.6.10.2 and 16.6.3.8 with Remarks 16.6.6.3 and 16.4.2.3. □

Remark 16.6.10.4. In the situation of Corollary 16.6.10.3, for every Artinian $\mathbb{E}_2$-algebra B over κ we obtain an equivalence

$$\{\text{Compactly generated deformations of } \mathcal{C} \text{ over } B\} \simeq \{\text{Actions of } \mathfrak{D}^{(2)}(B) \text{ on } \mathcal{C}\}.$$

In other words, $\mathcal{C}$ has no "curved" deformations (see Remark **??**).

Warning 16.6.10.5. The hypotheses of Theorem 16.6.10.2 are very restrictive: many κ-linear ∞-categories of interest (such as the ∞-categories of quasi-coherent sheaves on most algebraic varieties of dimension $\geqslant 2$) cannot be generated by unobstructible objects.

The proof of Theorem 16.6.10.2 will require some preliminaries. Our first lemma gives an explanation for the terminology of Definition 16.6.10.1.

Lemma 16.6.10.6. *Let κ be a field, let $f : B \to B'$ be a small morphism between augmented $\mathbb{E}_2$-algebras over κ. Let $\mathcal{C}_B$ be a tamely compactly generated B-linear ∞-category, let $\mathcal{C}_{B'} = \mathcal{C}_B \otimes_B B'$, and let $\mathcal{C} = \mathcal{C}_B \otimes_B \kappa$. Suppose that $C \in \mathcal{C}_{B'}$ is a compact object whose image in $\mathcal{C}$ is unobstructible. Then there exists a compact object $C_B \in \mathcal{C}_B$ and an equivalence $C_{B'} \simeq C_B \otimes_B B'$ in $\mathcal{C}_{B'}$.*

Proof. Let $C \in \mathcal{C}$ denote the image of $C_{B'}$. Since f is small, we can choose a finite sequence of morphisms $B = B_0 \to \cdots \to B_n \simeq B'$ and pullback diagrams

$$\begin{array}{ccc} B_i & \longrightarrow & \kappa \\ \downarrow & & \downarrow \\ B_{i+1} & \longrightarrow & \kappa \oplus \Sigma^{m_i}(\kappa) \end{array}$$

in $\mathrm{Alg}^{(2),\mathrm{aug}}_\kappa$, where each $m_i \geqslant 1$. We prove by descending induction on i that $C_{B'}$ can be lifted to a compact object $C_i \in \mathcal{C}_B \otimes_B B_i$, the case $i = n$ being trivial. Assume that C_{i+1} has been constructed. Let $\mathcal{C}' = \mathcal{C} \otimes_\kappa (\kappa \oplus \Sigma^{m_i}(\kappa))$. According to Proposition 16.6.8.2, we have an equivalence of ∞-categories $\mathcal{C}^c_i \to \mathcal{C}^c_{i+1} \times_{\mathcal{C}'^c} \mathcal{C}^c$. Consequently, to show that C_{i+1} can be lifted to an object $C_i \in \mathcal{C}^c_i$, it will suffice to show that C_{i+1} and C have the same image in $\mathcal{C}'^c$. This is a special case of the following assertion:

(∗) Let $X, Y \in \mathcal{C}'$ be objects having the same $C \in \mathcal{C}$. If C is unobstructible, then there is an equivalence $X \simeq Y$ in $\mathcal{C}'$.

To prove (∗), we let $\mathrm{ObjDef}_C : \mathrm{Alg}_\kappa^{(1),\mathrm{art}} \to \mathcal{S}$ be defined as in Notation 16.5.3.1; we wish to prove that any two points of the space $\mathrm{ObjDef}_C(\kappa \oplus \Sigma^{m_i}(\kappa))$ belong to the same path component. According to Proposition 16.5.6.2, $\mathrm{ObjDef}_C(\kappa \oplus \Sigma^{m_i}(\kappa))$ can be identified with a summand of the mapping space $\mathrm{Map}_{\mathrm{Alg}_\kappa^{(1)}}(\mathfrak{D}^{(1)}(\kappa \oplus \Sigma^{m_i}(\kappa)), \mathrm{End}(C))$. Since the Koszul dual $\mathfrak{D}^{(1)}(\kappa \oplus \Sigma^{m_i}(\kappa))$ is the free associative algebra generated by $\Sigma^{-m_i-1}(\kappa)$, we have a canonical isomorphism

$$\pi_0 \mathrm{Map}_{\mathrm{Alg}_\kappa^{(1)}}(\mathfrak{D}^{(1)}(\kappa \oplus \Sigma_\kappa^{(m_i)}), \mathrm{End}(C)) \simeq \pi_{-m_i-1} \mathrm{End}(C) \simeq \mathrm{Ext}_{\mathcal{C}}^{m_i+1}(C, C).$$

These groups vanish by virtue of our assumption that C is unobstructible. □

Remark 16.6.10.7. In the situation of Lemma 16.6.10.6, if we assume that $\mathrm{Ext}^1_{\mathcal{C}}(C, C)$ vanishes, then lifting of $C_{B'}$ to $\mathcal{C}_B$ is unique up to equivalence: that is, C is *undeformable.*

Lemma 16.6.10.8. *Let κ be a field, let $B \in \mathrm{Alg}_\kappa^{(2),\mathrm{aug}}$ be an Artinian augmented $\mathbb{E}_2$-algebra over κ, let $\mathcal{C}_B$ be a tamely compactly generated B-linear ∞-category, and let $\mathcal{C} = \mathcal{C}_B \otimes_B \kappa$. Let $\{C_\alpha\}$ be a collection of objects of $\mathcal{C}$ which generates $\mathcal{C}$ under small colimits, and suppose that each C_α can be lifted to an object $\overline{C}_\alpha \in \mathcal{C}_B$ (so that $C_\alpha \simeq \overline{C}_\alpha \otimes_B \kappa$). Then the collection of objects $\{\overline{C}_\alpha\}$ generates $\mathcal{C}_B$ under small colimits.*

Proof. Let $\mathcal{E}$ be the full subcategory of $\mathcal{C}_B$ generated by $\{\overline{C}_\alpha\}$ under small colimits. Then $\mathcal{E}$ contains $\overline{C}_\alpha \otimes_B M$ for every connective left B-module M. Taking $M = \kappa$, we deduce that $\mathcal{E}$ contains the images of the objects $\{C_\alpha\}$ under the forgetful functor $\theta : \mathcal{C} \to \mathcal{C}_B$. Since θ preserves small colimits, it follows that $\mathcal{E}$ contains the essential image of θ. In particular, $\mathcal{E}$ contains $C \otimes_B \kappa$ for each object $C \in \mathcal{C}_B$. Since B is Artinian, we can choose a finite sequence

$$B = B_0 \to \cdots \to B_n \simeq \kappa$$

and pullback diagrams

$$\begin{array}{ccc} B_i & \longrightarrow & \kappa \\ \downarrow & & \downarrow \\ B_{i+1} & \longrightarrow & \kappa \oplus \Sigma^{m_i}(\kappa). \end{array}$$

It follows by descending induction on i that $\mathcal{E}$ contains $C \otimes_B B_i$ for each $C \in \mathcal{C}_B$. Taking $i = 0$, we deduce that $\mathcal{E} = \mathcal{C}_B$. □

Proof of Theorem 16.6.10.2. Theorem 16.6.7.3 implies that $\mathrm{CatDef}^c_{\mathcal{C}}$ is a 1-proximate formal moduli problem. Suppose we are given a pullback diagram

$$\begin{array}{ccc} B & \longrightarrow & B_0 \\ \downarrow & & \downarrow \\ B_1 & \longrightarrow & B_{01} \end{array}$$

in $\mathrm{Alg}^{(2),\mathrm{art}}_{\kappa}$ which induces surjective maps $\pi_0 B_0 \to \pi_0 B_{01} \leftarrow \pi_0 B_1$. Then the map

$$\theta : \mathrm{CatDef}^c_{\mathcal{C}}(B) \to \mathrm{CatDef}^c_{\mathcal{C}}(B_0) \times_{\mathrm{CatDef}^c_{\mathcal{C}}(B_{01})} \mathrm{CatDef}^c_{\mathcal{C}}(B_1)$$

is (-1)-truncated, and we wish to show that it is a homotopy equivalence. Fix a point of the fiber product $\mathrm{CatDef}^c_{\mathcal{C}}(B_0) \times_{\mathrm{CatDef}^c_{\mathcal{C}}(B_{01})} \mathrm{CatDef}_{\mathcal{C},\omega}(B_1)$, which determines a pair $(\mathcal{C}_{B_0}, \mathcal{C}_{B_1}, \eta)$ where $\mathcal{C}_{B_0}$ is a compactly generated stable right B_0-linear ∞-category, $\mathcal{C}_{B_1}$ is a compactly generated stable right B_1-linear ∞-category, and η is a B_{01}-linear equivalence $\mathcal{C}_{B_0} \otimes_{B_0} B_{01} \simeq \mathcal{C}_{B_1} \otimes_{B_1} B_{01}$.

Let $\mathcal{C}_{B_{01}}$ denote the ∞-category $\mathcal{C}_{B_0} \otimes_{B_0} B_{01} \simeq \mathcal{C}_{B_1} \otimes_{B_1} B_{01}$, and let $\mathcal{C}_B$ denote the full subcategory of $\mathcal{C}_{B_0} \times_{\mathcal{C}_{B_{01}}} \mathcal{C}_{B_1}$ generated under small colimits by $\mathcal{C}^c_{B_0} \times_{\mathcal{C}^c_{B_{01}}} \mathcal{C}^c_{B_1}$. We wish to show that $\mathcal{C}_B$ is a deformation of $\mathcal{C}$ over B satisfying $\theta(\mathcal{C}_B) \simeq (\mathcal{C}_{B_0}, \mathcal{C}_{B_1}, \eta)$. Unwinding the definitions, it suffices to show that the canonical maps $q : \mathcal{C}_B \otimes_B B_0 \to \mathcal{C}_{B_0}$ and $q' : \mathcal{C}_B \otimes_B B_1 \to \mathcal{C}_{B_1}$ are equivalences. We will show that q is an equivalence; the proof for q' is similar.

We first claim that q is fully faithful. Since the domain and codomain of q are compactly generated and the functor q preserves compact objects, it will suffice to show that q is fully faithful when restrict to compact objects. The collection of compact objects of $\mathcal{C}_B \otimes_B B_0$ is generated, under retracts and finite colimits, by the essential image of the free functor $F : \mathcal{C}_B \to \mathcal{C}_B \otimes_B B_0 \simeq \mathrm{RMod}_{B_0}(\mathcal{C}_B)$. It will therefore suffice to show that for every pair of compact objects $C, D \in \mathcal{C}_B$, the functor q induces an equivalence of left B_0-modules $\xi : \underline{\mathrm{Map}}_{\mathrm{RMod}_{B_0}(\mathcal{C}_B)}(F(C), F(D)) \to \underline{\mathrm{Map}}_{\mathcal{C}_{B_0}}(qF(C), qF(D))$. We can identify $\mathcal{C}^c_B$ with the fiber product $\mathcal{C}^c_{B_0} \times_{\mathcal{C}^c_{B_{01}}} \mathcal{C}^c_{B_1}$, so that C and D correspond to triples (C_0, C_1, γ) and (D_0, D_1, δ), where $C_0, D_0 \in \mathcal{C}^c_{B_0}$, $C_1, D_1 \in \mathcal{C}^c_{B_1}$, and $\gamma : C_0 \otimes_{B_0} B_{01} \simeq C_1 \otimes_{B_1} B_{01}$ and $\delta : D_0 \otimes_{B_0} B_{01} \simeq D_1 \otimes_{B_1} B_{01}$ are equivalences in $\mathcal{C}_{B_{01}}$. Set $C_{01} = C_0 \otimes_{B_0} B_{01} \simeq C_1 \otimes_{B_1} B_{01}$ and $D_{01} = D_0 \otimes_{B_0} B_{01} \simeq D_1 \otimes_{B_1} B_{01}$.

Using Lemma 16.6.8.5, we can identify ξ with the natural map $B_0 \otimes_B \underline{\mathrm{Map}}_{\mathcal{C}_B}(C, D) \to \underline{\mathrm{Map}}_{\mathcal{C}_{B_0}}(C_0, D_0)$. Here we have an equivalence

$$\underline{\mathrm{Map}}_{\mathcal{C}_B}(C, D) \simeq \underline{\mathrm{Map}}_{\mathcal{C}_{B_0}}(C_0, D_0) \times_{\underline{\mathrm{Map}}_{\mathcal{C}_{B_{01}}}(C_{01}, D_{01})} \underline{\mathrm{Map}}_{\mathcal{C}_{B_1}}(C_1, D_1).$$

Using Lemma 16.6.8.5 and Proposition 16.2.1.1, we are reduced to proving that $\underline{\mathrm{Map}}_{\mathcal{C}_{B_0}}(C_0, D_0)$ and $\underline{\mathrm{Map}}_{\mathcal{C}_{B_1}}(C_1, D_1)$ are n-connective for some integer n. This follows because $\mathcal{C}_{B_0}$ and $\mathcal{C}_{B_1}$ are tamely compactly generated (Proposition 16.6.9.2).

It remains to prove that the functor q is essentially surjective. Note that the essential image of q is closed under small colimits. Using Lemma 16.6.10.6, it will suffice to show that the essential image of q contains every object $C \in \mathcal{C}^c_{B_0}$ whose image in $\mathcal{C}$ is unobstructible. To prove this, it suffices to show that $C \otimes_{B_0} B_{01}$ can be lifted to a compact object of $\mathcal{C}_{B_1}$, which is a special case of Lemma 16.6.10.6. □

Part V

Representability Theorems

Let R be a commutative ring and let X be an R-scheme. Suppose that we want to give an explicit presentation of X. We might achieve this by choosing a covering of X by open subschemes $\{U_\alpha\}_{\alpha \in I}$, where each U_α is an affine scheme given by the spectrum of a commutative R-algebra A_α. Let us assume for simplicity that each intersection $U_\alpha \cap U_\beta$ is itself an affine scheme, which can be described as the spectrum of the localization $A_\alpha[x_{\alpha,\beta}^{-1}]$ for some element $x_{\alpha,\beta} \in A_\alpha$. To specify X, we need to supply the following data:

(a) For each $\alpha \in I$, a commutative R-algebra A_α. If X is of finite presentation over R, then the algebra A_α could be given by generators and relations as a quotient

$$R[x_1, \ldots, x_n]/(f_1(x_1, \ldots, x_n), \ldots, f_m(x_1, \ldots, x_m))$$

for some collection of polynomials f_i.

(b) For every pair of indices $\alpha, \beta \in I$, a pair of elements $x_{\alpha,\beta} \in A_\alpha$ and $x_{\beta,\alpha} \in A_\beta$, together with an R-algebra isomorphism $\phi_{\alpha,\beta} : A_\alpha[x_{\alpha,\beta}^{-1}] \simeq A_\beta[x_{\beta,\alpha}^{-1}]$.

Moreover, the isomorphisms $\phi_{\alpha,\beta}$ should be the identity when $\alpha = \beta$, and satisfy the following cocycle condition:

(c) Given $\alpha, \beta, \gamma \in I$, the commutative ring $A_\gamma[x_{\gamma,\beta}^{-1}, \phi_{\beta,\gamma}(x_{\beta,\alpha})^{-1}]$ should be a localization of $A_\gamma[x_{\gamma,\alpha}^{-1}]$. Moreover, the composite map

$$A_\alpha \to A_\alpha[x_{\alpha,\gamma}^{-1}] \xrightarrow{\phi_{\alpha,\gamma}} A_\gamma[x_{\gamma,\alpha}^{-1}] \to A_\gamma[x_{\gamma,\beta}^{-1}, \phi_{\beta,\gamma}(x_{\beta,\alpha})^{-1}]$$

should be obtained by composing (localizations of) $\phi_{\alpha,\beta}$ and $\phi_{\beta,\gamma}$.

In §1.1, we introduced the notion of a *spectral scheme*. The notion of a spectral scheme is entirely analogous the classical notion of a scheme. However, the analogues of (a), (b), and (c) are much more complicated in the spectral setting. The data of an affine spectral scheme over a commutative ring R is equivalent to the data of an $\mathbb{E}_\infty$-algebra over R. These are often quite difficult to describe using generators and relations. For example, the polynomial ring $R[x]$ generally does not have a finite presentation as an $\mathbb{E}_\infty$-algebra over R (unless we assume that R has characteristic zero). These complications are amplified when we pass to the non-affine situation. In the spectral setting, (b) requires us to construct equivalences between $\mathbb{E}_\infty$-algebras, which are often difficult to specify concretely. Moreover, since $\mathbb{E}_\infty$-algebras form an ∞-category rather than an ordinary category, the analogue of the cocycle condition described in (c) is not a condition but an additional datum (namely, a homotopy between two $\mathbb{E}_\infty$-algebra maps $A_\alpha \to A_\gamma[x_{\gamma,\beta}^{-1}, \phi_{\beta,\gamma}(x_{\beta,\alpha})^{-1}]$ for every triple $\alpha, \beta, \gamma \in I$), which must be supplemented by “higher” coherence data involving four-fold intersections and beyond.

For these reasons, it can be difficult to provide “hands-on” constructions in the setting of spectral algebraic geometry.

Fortunately, there is another approach to describing a scheme X. Rather than trying to explicitly construct the commutative rings associated to some affine open covering of X, one can instead consider the functor h_X represented by X, given by the formula $h_X(R) = \mathrm{Hom}(\operatorname{Spec} R, X)$. The scheme X can be recovered from the functor h_X (up to canonical isomorphism). The situation for spectral schemes is again entirely analogous: every spectral scheme X determines a functor $h_{\mathsf{X}} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, and the construction $\mathsf{X} \mapsto h_{\mathsf{X}}$ determines a fully faithful embedding from the ∞-category of spectral schemes to the ∞-category $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ (Corollary **??**). In many case, it is easier to describe a spectral scheme (or spectral Deligne-Mumford stack) X by specifying the functor h_{X} than by specifying its structure sheaf $\mathscr{O}_{\mathsf{X}}$. This motivates the following general question:

Question 16.0.0.1. Given a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, under what circumstances is X representable by a spectral Deligne-Mumford stack?

In the setting of classical algebraic geometry, the analogous question is addressed by the following theorem of Artin:

Theorem 16.0.0.2 (Artin Representability Theorem)**.** *Let R be a Grothendieck ring (see Definition* **??***) and let X be functor from the category of commutative R-algebras to the category of sets. Then X is representable by an algebraic space X which is locally of finite presentation over R if the following conditions are satisfied:*

(1) *The diagonal map $X \to X \times_{\operatorname{Spec} R} X$ is representable by algebraic spaces (which must be quasi-compact schemes, if we wish to require that X is quasi-separated).*

(2) *The functor X is a sheaf for the étale topology.*

(3) *If B is a complete local Noetherian R-algebra with maximal ideal $\mathfrak{m}$, then the natural map $X(B) \to \varprojlim X(B/\mathfrak{m}^n)$ is bijective.*

(4) *The functor X admits an obstruction theory and a deformation theory, and satisfies Schlessinger's criteria for formal representability.*

(5) *The functor X commutes with filtered colimits.*

This result is of both philosophical and practical interest. Since conditions (1) through (5) are reasonable expectations for any functor X of a reasonably geometric nature, Theorem 16.0.0.2 provides evidence that the theory of algebraic spaces is natural and robust (in other words, that it exactly captures some intuitive notion of “geometricity”). On the other hand, if we are given a functor X, it is usually reasonably easy to check whether or not Artin's criteria are satisfied. Consequently, Theorem 16.0.0.2 can be used to construct a great number of moduli spaces.

Remark 16.0.0.3. We refer the reader to [4] for the original proof of Theorem 16.0.0.2. Note that in Artin's formulation, condition (3) is replaced by the weaker requirement that the map $X(B) \to \varprojlim X(B/\mathfrak{m}^n)$ has dense image (with respect to the inverse limit topology). Moreover, Artin's proof required a stronger assumption on the commutative ring R; for a careful discussion of the removal of this hypothesis, we refer the reader to [43].

Our goal in this paper is to prove an analogue of Theorem 16.0.0.2 in the setting of spectral algebraic geometry. Let R be an Noetherian $\mathbb{E}_\infty$-ring such that $\pi_0 R$ is a Grothendieck ring, and suppose we are given a functor $X : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$. Our main result (Theorem 16.0.1) supplies necessary and sufficient conditions for X to be representable by a spectral Deligne-Mumford n-stack which is locally almost of finite presentation over R. For the most part, these conditions are natural analogues of the hypotheses of Theorem 16.0.0.2. The main difference is in the formulation of condition (4). In the setting of Artin's original theorem, a deformation and obstruction theory are auxiliary constructs which are not uniquely determined by the functor X. The meaning of these conditions are clarified by working in the spectral setting: they are related to the problem of extending the functor X to $\mathbb{E}_\infty$-rings which are nondiscrete. In Chapter 17, we will make this idea more precise by studying various conditions on a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ which are *necessary* for representability. We will be primarily interested in conditions of a deformation-theoretic nature: that is, conditions which describe the relationship between $X(\overline{A})$ and $X(A)$, where $\overline{A}$ is a *square-zero* extension of A by some A-module M (see Definition HA.7.4.1.6). For example:

(a) Any representable functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ admits a *cotangent complex* $L_X \in \mathrm{QCoh}(X)^{\mathrm{cn}}$ (see Definition 17.2.4.2), which can be used to describe the relationship between $X(\overline{A})$ and $X(A)$ in the case where $\overline{A}$ is the trivial square-zero extension $A \oplus M$ for some connnective A-module M.

(b) Any representable functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ is *infinitesimally cohesive*: that is, it satisfies a gluing formula for infinitesimal thickenings (see Definition 17.3.1.5). In combination with (a), this allows us to describe the relationship between $X(\overline{A})$ and $X(A)$ for *arbitrary* square-zero-extensions (see Remark 17.3.1.8).

(c) Any representable functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ is *nilcomplete* (see Definition 17.3.2.1): for any $A \in \mathrm{CAlg}^{\mathrm{cn}}$, the space $X(A)$ can be realized as the limit of the tower of spaces

$$\cdots \to X(\tau_{\leqslant 3} A) \to X(\tau_{\leqslant 2} A) \to X(\tau_{\leqslant 1} A) \xrightarrow{X} (\tau_{\leqslant 0} A) = X(\pi_0 A).$$

This is useful in combination with (a) and (b), since each truncation $\tau_{\leqslant n} A$ can be regarded as a square-zero extension of $\tau_{\leqslant n-1} A$.

(*d*) If $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ is representable by a spectral Deligne-Mumford n-stack (for some $n < \infty$), then X is *integrable* (see Definition 17.3.4.1). If A is a complete local Noetherian ring with maximal ideal $\mathfrak{m}$, the space $X(A)$ can be realized as the limit of the tower

$$\cdots \to X(A/\mathfrak{m}^4) \to X(A/\mathfrak{m}^3) \to X(A/\mathfrak{m}^2) \xrightarrow{X} (A/\mathfrak{m}).$$

This is again useful in combination with (*a*) and (*b*), since each quotient $A/\mathfrak{m}^n$ can be realized as a square-zero extension of $A/\mathfrak{m}^{n-1}$.

Roughly speaking, assertions (*a*) and (*b*) correspond to Artin's criterion (4), while assertion (*d*) corresponds to Artin's criterion (3) (assertion (*c*) has no counterpart in classical algebraic geometry, but is a natural companion to (*a*) and (*b*)). In Chapter 18, we will use these ideas to establish a spectral analogue of Theorem 16.0.0.2:

Theorem 16.0.1 (Spectral Artin Representability Theorem)**.** Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor, and suppose we are given a natural transformation $X \to \operatorname{Spec} R$, where R is a Noetherian $\mathbb{E}_\infty$-ring and $\pi_0 R$ is a Grothendieck ring. Let $n \geqslant 0$. Then X is representable by a spectral Deligne-Mumford n-stack which is locally almost of finite presentation over R if and only if the following conditions are satisfied:

(1) For every discrete commutative ring A, the space $X(A)$ is n-truncated.

(2) The functor X is a sheaf for the étale topology.

(3) The functor X is nilcomplete, infinitesimally cohesive, and integrable.

(4) The functor X admits a connective cotangent complex L_X.

(5) The natural transformation f is locally almost of finite presentation (see Definition 17.4.1.1).

Theorem 18.3.0.1 can be regarded as a spectral analogue of Artin's representability criterion in classical algebraic geometry (see Theorem 16.0.0.2). However, it plays a more central role than its classical counterpart. Many moduli spaces of interest in classical algebraic geometry can be constructed directly, without resorting to an abstract representability theorem. In spectral algebraic geometry, direct constructions are more problematic: it is difficult to specify geometric objects by explicitly describing their coordinate rings, so the "functor of points" perspective becomes indispensable. In Chapter 19, we will illustrate this point by describing several applications of Theorem 18.3.0.1 (we will meet more examples in Part VIII, when we consider the analogue of Artin's theorem in the setting of *derived* algebraic geometry).

Chapter 17

Deformation Theory and the Cotangent Complex

Let A be a commutative ring and let B be a commutative algebra over A. We let $\Omega_{B/A}$ denote the module of Kähler differentials of B relative to A. More precisely, $\Omega_{B/A}$ is the B-module generated by symbols $\{dx\}_{x \in B}$ subject to the relations

$$d(x+y) = dx + dy \qquad d(xy) = xdy + ydx \qquad d\lambda = 0 \text{ if } \lambda \in A.$$

The theory of Kähler differentials can be relativized. To every morphism of schemes $f : X \to Y$, one can associate a quasi-coherent sheaf $\Omega_{X/Y}$ on X, called the *sheaf of relative Kähler differentials*, which is essentially characterized by the formula $\Omega_{X/Y}(U) \simeq \Omega_{\mathscr{O}_X(U)/\mathscr{O}_Y(V)}$ whenever $U \subseteq X$ is an affine open subset whose image $f(U)$ is contained in an affine open subset $V \subseteq Y$. The sheaf $\Omega_{X/Y}$ plays a central role in classical algebraic geometry: if f is smooth, then $\Omega_{X/Y}$ is a locally free sheaf which plays the role of a relative cotangent bundle for the morphism f.

The theory of Kähler differentials has an analogue in the setting of spectral algebraic geometry. To every morphism $\phi : A \to B$ of $\mathbb{E}_\infty$-rings, one can associate an object $L_{B/A} \in \mathrm{Mod}_B$, which we refer to as the *relative cotangent complex of* ϕ, which is universal among those B-modules M for which the projection map $B \oplus M \to B$ is equipped with a section (in the ∞-category CAlg_A); see §**??** for a more detailed discussion. Like the classical theory of Kähler differentials, this construction can be relativized. In §17.1, we associate to each morphism of spectral Deligne-Mumford stacks $f : \mathsf{X} \to \mathsf{Y}$ a relative cotangent complex $L_{\mathsf{X}/\mathsf{Y}}$, which we can regard as a quasi-coherent sheaf on X (Proposition 17.1.2.1). The relative cotangent complex $L_{\mathsf{X}/\mathsf{Y}}$ can be regarded as kind of "relative cotangent bundle" of f, with the caveat that it is usually not a vector bundle: the relative cotangent complex $L_{\mathsf{X}/\mathsf{Y}}$ is locally free of finite rank if f is differentially smooth, and the converse holds under some mild finiteness hypotheses (Proposition 17.1.5.1).

Recall that a spectral Deligne-Mumford stack X is determined by the functor $h_{\mathsf{X}} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ represented by X (given by $h_{\mathsf{X}}(R) = \mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{X})$; see Proposition 1.6.4.2). It follows that for any morphism $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks, the relative cotangent complex $L_{\mathsf{X}/\mathsf{Y}} \in \mathrm{QCoh}(\mathsf{X})$ can be recovered from the associated natural transformation $h_{\mathsf{X}} \to h_{\mathsf{Y}}$. In §17.2, we make this observation explicit by associating a relative cotangent complex $L_{X/Y}$ to any (sufficiently nice) natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ (Definition 17.2.4.2). This "functor of points" approach has the advantage of making sense in many situations where the functors X and Y are not representable, or not yet known to be representable. This will be crucial in our discussion of representability questions in Chapter 18: the existence of a relative cotangent complex $L_{X/Y}$ is often the main ingredient in showing that a map $f : X \to Y$ is relatively representable (see Theorems 18.1.0.2 and 18.3.0.1).

Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. By definition, the relative cotangent complex $L_{X/Y}$ (if it exists) is a quasi-coherent sheaf on X with the property that, for every commutative diagram

$$\begin{array}{ccc} \operatorname{Spec} A & \xrightarrow{\eta} & X \\ \downarrow & \nearrow & \downarrow f \\ \operatorname{Spec}(A \oplus M) & \longrightarrow & Y, \end{array}$$

the space of dotted arrow rendering the diagram commutative can be identified with $\mathrm{Map}_{\mathrm{Mod}_A}(\eta^* L_{X/Y}, M)$. We can summarize the situation more informally with the following slogan:

$(*)$ Lifting of trivial square-zero extensions along a morphism $f : X \to Y$ are controlled by the relative cotangent complex $L_{X/Y}$.

For many applications, $(*)$ alone is not very useful: one would like to analyze more general lifting problems of the form σ :

$$\begin{array}{ccc} \operatorname{Spec} A & \xrightarrow{\eta} & X \\ \downarrow & \nearrow & \downarrow f \\ \operatorname{Spec} \overline{A} & \longrightarrow & Y, \end{array}$$

where $\overline{A}$ is an *arbitrary* square-zero extension of A by a (connective) A-module M (see Definition HA.7.4.1.6). In this case, the general philosophy of deformation theory suggests that there should be an obstruction class $\alpha \in \mathrm{Ext}^1_A(\eta^* L_{X/Y}, M)$ which vanishes if only if the lifting problem depicted in the diagram σ admits a solution; moreover, if such a solution exists, then the space of solutions should form a torsor for the mapping space $\mathrm{Map}_{\mathrm{Mod}_A}(\eta^* L_{X/Y}, M)$. In §17.3, we will see that this expectation is correct under the additional assumption that X and Y are *infinitesimally cohesive* (see Definition 17.3.1.5 and Remark 17.3.1.8). We also introduce the related notions of *cohesive*, *nilcomplete*, and *integrable* functors $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ (Definitions 17.3.1.1, 17.3.2.1, and 17.3.4.1). Taken together, these conditions express the idea that X has a well-behaved deformation theory, and can be studied effectively using "infinitesimal" methods.

The deformation-theoretic ideas studied in §17.3 can be regarded as a partial answer to Question 16.0.0.1: they allow us to formulate a list of axioms on a natural transformation $f : X \to Y$ which are necessarily satisfied if f is relatively representable. In order to guarantee that these axioms are also sufficient, it is necessary to introduce some finiteness hypotheses on f. In §17.4, we introduce the notion of *local almost finite presentation* for a natural transformation $f : X \to Y$ (Definition 17.4.1.1). Under mild hypotheses, we prove that this agrees with the notion of almost finite presentation studied in Chapter 4 in the case where f is relatively representable (Corollary 17.4.2.2).

Recall that if Z is an algebraic variety over $\mathbf{C}$, then the *Zariski tangent space* to Z at a $\mathbf{C}$-valued point $z \in Z(\mathbf{C})$ can be defined as the fiber product $Z(\mathbf{C}[\epsilon]/(\epsilon^2)) \times_{Z(\mathbf{C})} \{z\}$. In §17.5, we consider an analogue of this construction in the setting of spectral algebraic geometry: if $f : X \to Y$ is an infinitesimally cohesive morphism of functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, then we can associate a well-defined *tangent complex* $T_{X/Y}(\eta) \in \mathrm{Mod}_A$ to each point $\eta \in X(A)$ (Definition 17.5.1.1). Under the assumption that f admits a cotangent complex, the tangent complex $T_{X/Y}(\eta)$ can be described as the A-linear dual of $\eta^* L_{X/Y}$. In §17.5, we establish a partial converse: under appropriate hypotheses, the existence of $L_{X/Y}$ is equivalent to the assumption that the tangent complexes $T_{X/Y}(\eta)$ satisfy some mild finiteness conditions (Theorem 17.5.4.1).

Warning 17.0.0.1. Let $f : X \to Y$ be a morphism of schemes, which we will identify with the corresponding spectral Deligne-Mumford stacks. Our definition of the cotangent complex $L_{X/Y} \in \mathrm{QCoh}(X)$ is based on a globalization of *topological* André-Quillen homology, rather than classical André-Quillen homology. Consequently, it generally does not agree with usual cotangent complex studied in algebraic geometry (for example, in [99] and [100]), which we will denote by $L^{\mathrm{alg}}_{X/Y}$. There is a canonical map $\theta : L_{X/Y} \to L^{\mathrm{alg}}_{X/Y}$, which is an equivalence if X is a $\mathbf{Q}$-scheme. In general, θ induces isomorphisms $\pi_n L_{X/Y} \to \pi_n L^{\mathrm{alg}}_{X/Y}$ for $n \leqslant 1$ and an epimorphism when $n = 2$. The algebraic cotangent complex $L^{\mathrm{alg}}_{X/Y}$ plays a central role in the theory of *derived* algebraic geometry, which we will study in §VIII and §**??**.

Contents

17.1 The Cotangent Complex of a Spectrally Ringed ∞-Topos

In §HA.7.3 , we defined the relative cotangent complex $L_{B/A}$ of a morphism of $\mathbb{E}_\infty$-rings $\phi : A \to B$. In this section, we will study a generalization of the construction $\phi \mapsto L_{B/A}$, where we replace ϕ by a map of spectrally ringed ∞-topoi $(\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ (which reduces to the theory described in §HA.7.3 when we take $\mathcal{X} = \mathcal{Y} = \mathcal{S} = \mathcal{S}\mathrm{hv}(*)$).

17.1.1 Definitions

We begin by introducing some terminology. Let $(\mathcal{X}, \mathscr{A})$ be a spectrally ringed ∞-topos, and let $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})_{\mathscr{A}//\mathscr{A}}$ denote the ∞-category of augmented $\mathscr{A}$-algebra objects of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$. It follows from Theorem HA.7.3.4.7 that the ∞-category $\mathrm{Mod}_{\mathscr{A}}$ of $\mathscr{A}$-module objects of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ can be identified with the stabilization of the ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})_{\mathscr{A}//\mathscr{A}}$. In particular, there canonical map $\Omega^{\infty} : \mathrm{Mod}_{\mathscr{A}} \to \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})_{\mathscr{A}//\mathscr{A}}$. If $\mathscr{M}$ is a $\mathscr{A}$-module object of $\mathrm{Mod}_{\mathrm{Sp}}(\mathcal{X})$, we will denote its image under the functor Ω^{∞} by $\mathscr{A} \oplus \mathscr{M}$, and refer to it as the *trivial square-zero extension of $\mathscr{A}$ by $\mathscr{M}$*.

Definition 17.1.1.1. Let $(\mathcal{X}, \mathscr{A})$ be a spectrally ringed ∞-topos and let $\mathscr{M} \in \mathrm{Mod}_{\mathscr{A}}$. A *derivation of $\mathscr{A}$ into $\mathscr{M}$* is a section of the tautological map $\mathscr{A} \oplus \mathscr{M} \to \mathscr{A}$. We let $\mathrm{Der}(\mathscr{A}, \mathscr{M}) = \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})_{/\mathscr{A}}}(\mathscr{A}, \mathscr{A} \oplus \mathscr{M})$ denote the space of derivations of $\mathscr{A}$ into $\mathscr{M}$.

Remark 17.1.1.2. In the situation of Definition 17.1.1.1, a derivation of $\mathscr{A}$ into $\mathscr{M}$ can be identified with a pair (s, h), where $s : \mathscr{A} \to \mathscr{A} \oplus \mathscr{M}$ is a morphism of CAlg-valued sheaves on $\mathcal{X}$ and h is a homotopy from the composite map

$$\mathscr{A} \xrightarrow{s} \mathscr{A} \oplus \mathscr{M} \to \mathscr{A}$$

to the identity map $\mathrm{id}_{\mathscr{A}}$. It follows that, as a morphism of Sp-valued sheaves on $\mathcal{X}$, we can identify s with a product of the identity map $\mathrm{id} : \mathscr{A} \to \mathscr{A}$ and some auxiliary map $d : \mathscr{A} \to \mathscr{M}$. We will often abuse terminology by referring to the map d as a *derivation of $\mathscr{A}$ into $\mathscr{M}$*. Beware that this terminology is slightly misleading: the pair (s, h) is generally not determined by $d \in \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})}(\mathscr{A}, \mathscr{M})$, even up to homotopy. Roughly speaking, we can think of the pair (s, h) as witnessing the fact that the map $d : \mathscr{A} \to \mathscr{M}$ satisfies the Leibniz rule, up to coherent homotopy.

Definition 17.1.1.3 (The Cotangent Complex)**.** Let $\mathcal{X}$ be an ∞-topos. We let

$$L : \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X}) \to \mathrm{Mod}(\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}))$$

denote the absolute cotangent complex functor defined in §HA.7.3.2. To each object $\mathscr{A} \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$, we let $L_{\mathscr{A}} \in \mathrm{Mod}_{\mathscr{A}}$ denote the image of $\mathscr{A}$ under the functor L. We refer to $L_{\mathscr{A}}$ as the *absolute cotangent complex of $\mathscr{A}$*. The object $L_{\mathscr{A}}$ can be characterized up to equivalence as follows: there exists a derivation $d \in \mathrm{Der}(\mathscr{A}, L_{\mathscr{A}})$ for which evaluation on d induces a homotopy equivalence $\mathrm{Map}_{\mathrm{Mod}_{\mathscr{A}}}(L_{\mathscr{A}}, \mathscr{M}) \to \mathrm{Der}(\mathscr{A}, \mathscr{M})$ for every object $\mathscr{M} \in \mathrm{Mod}_{\mathscr{A}}$. We will refer to d as the *universal derivation*.

Variant 17.1.1.4 (The Relative Cotangent Complex)**.** Let $\mathcal{X}$ be an ∞-topos and let $\phi : \mathscr{A} \to \mathscr{B}$ be a morphism of CAlg-valued sheaves on $\mathcal{X}$. Then the *relative cotangent complex $L_{\mathscr{B}/\mathscr{A}}$* is given by the cofiber of the map $\mathscr{B} \otimes_{\mathscr{A}} L_{\mathscr{A}} \to L_{\mathscr{B}}$ determined by ϕ (see §HA.7.3.3).

The formation of cotangent complexes is compatible with pullback, in the following sense:

Proposition 17.1.1.5. *Let $\phi^* : \mathcal{Y} \to \mathcal{X}$ be a geometric morphism of ∞-topoi, let $\mathscr{A} \in \mathrm{CAlg}(\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{Y}))$, and let $d : \mathscr{A} \to \mathscr{A} \oplus L_{\mathscr{A}}$ be the universal derivation. Then the induced map*

$$\phi^* \mathscr{A} \to \phi^*(\mathscr{A} \oplus L_{\mathscr{A}}) \simeq \phi^* \mathscr{A} \oplus \phi^* L_{\mathscr{A}}$$

induces an equivalence $\phi^* L_{\mathscr{A}} \to L_{\phi^* \mathscr{A}}$.

Proof. Let $\mathscr{M} \in \mathrm{Mod}_{\phi^* \mathscr{A}}$; we wish to show that the pullback of d induces a homotopy equivalence

$$\theta : \mathrm{Map}_{\mathrm{Mod}_{\phi^* \mathscr{A}}}(\phi^* L_{\mathscr{A}}, \mathscr{M}) \to \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})_{/\phi^* \mathscr{A}}}(\phi^* \mathscr{A}, \phi^* \mathscr{A} \oplus \mathscr{M}).$$

Unwinding the definitions, we can identify θ with the composite map

$$\begin{aligned} \mathrm{Map}_{\mathrm{Mod}_{\mathscr{A}}}(L_{\mathscr{A}}, \phi_* \mathscr{M}) &\xrightarrow{\theta'} \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{Y})_{/\mathscr{A}}}(\mathscr{A}, \mathscr{A} \oplus \phi_* \mathscr{M}) \\ &\xrightarrow{\theta''} \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{Y})_{/\phi_* \phi^* \mathscr{A}}}(\mathscr{A}, \phi_*(\phi^* \mathscr{A} \oplus \mathscr{M})). \end{aligned}$$

The universal property of d implies that θ' is a homotopy equivalence, and θ'' is a homotopy equivalence because the diagram

$$\begin{array}{ccc} \mathscr{A} \oplus \phi_* \mathscr{M} & \longrightarrow & \phi_*(\phi^* \mathscr{A} \oplus \mathscr{M}) \\ \downarrow & & \downarrow \\ \mathscr{A} & \longrightarrow & \phi_* \phi^* \mathscr{A} \end{array}$$

is a pullback square. □

Example 17.1.1.6. Let $\mathcal{C}$ be a small ∞-category, and let $\mathcal{X} = \mathcal{P}(\mathcal{C}) = \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ be the ∞-category of presheaves on $\mathcal{C}$. We can identify $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ with the ∞-category $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ of presheaves of spectra on $\mathcal{C}$, and $\mathrm{CAlg}(\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}))$ with the ∞-category $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathrm{CAlg})$ of presheaves of $\mathbb{E}_\infty$-rings on $\mathcal{C}$. If $\mathscr{A} : \mathcal{C}^{\mathrm{op}} \to \mathrm{CAlg}$ is such a presheaf, then Proposition 17.1.1.5 implies that $L_{\mathscr{A}}$ is given pointwise by the formula $L_{\mathscr{A}}(C) = L_{\mathscr{A}(C)}$ for $C \in \mathcal{C}$; here the right hand side denotes the $\mathscr{A}(C)$-module given by the absolute cotangent complex of the $\mathbb{E}_\infty$-ring $\mathscr{A}(C)$.

Example 17.1.1.7. Let $\mathcal{X}$ an arbitrary ∞-topos. Then there exists a small ∞-category $\mathcal{C}$ such that $\mathcal{X}$ is equivalent to an accessible left exact localization of $\mathcal{P}(\mathcal{C})$. Let us identify $\mathcal{X}$ with its image in $\mathcal{P}(\mathcal{C})$, and let $f^* : \mathcal{P}(\mathcal{C}) \to \mathcal{X}$ denote a left adjoint to the inclusion. Let $\mathscr{A}$ be a sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$, so that we can identify $\mathscr{A}$ with a functor $\mathcal{C}^{\mathrm{op}} \to \mathrm{CAlg}$.

Combining Example 17.1.1.6 with Proposition 17.1.1.5, we deduce that $L_{\mathscr{A}} = f^* \mathscr{M}$, where $\mathscr{M} \in \mathrm{Mod}_{\mathscr{A}}(\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathrm{Sp}))$ is given by the formula $\mathscr{M}(C) = L_{\mathscr{A}(C)}$. In other words, $L_{\mathscr{A}}$ is the sheafification of the presheaf obtained from $\mathscr{A}$ by pointwise application of the algebraic cotangent complex functor $A \mapsto L_A$ defined in §HA.7.3.2 .

Definition 17.1.1.8. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ be a spectrally ringed ∞-topos. We let L_{X} denote the absolute cotangent complex $L_{\mathscr{O}_{\mathsf{X}}} \in \mathrm{Mod}_{\mathscr{O}_{\mathsf{X}}}$. We will refer to L_{X} as the *absolute cotangent complex* of X.

If $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathsf{Y}})$ is another spectrally ringed ∞-topos and $\phi : \mathsf{X} \to \mathsf{Y}$ is a morphism of spectrally ringed ∞-topoi, we let $L_{\mathsf{X}/\mathsf{Y}} \in \mathrm{Mod}_{\mathscr{O}_{\mathsf{X}}}$ denote the relative cotangent complex of the morphism $\phi^* \mathscr{O}_{\mathsf{Y}} \to \mathscr{O}_{\mathsf{X}}$ in $\mathrm{CAlg}(\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}))$; we refer to $L_{\mathsf{X}/\mathsf{Y}}$ as the *relative cotangent complex* of the morphism ϕ.

Remark 17.1.1.9. Let $\phi : \mathsf{X} \to \mathsf{Y}$ be a map of spectrally ringed ∞-topoi. If the structure sheaf of X is the pullback of the structure sheaf of Y, then the relative cotangent complex $L_{\mathsf{X}/\mathsf{Y}}$ vanishes. In particular, if ϕ is étale, then $L_{\mathsf{X}/\mathsf{Y}} \simeq 0$.

Remark 17.1.1.10. Suppose we are given morphisms of spectrally ringed ∞-topoi $\mathsf{X} \xrightarrow{\phi} \mathsf{Y} \xrightarrow{\psi} \mathsf{Z}$. Using Propositions 17.1.1.5 and HA.7.3.3.5 , we deduce that the diagram

$$\begin{array}{ccc} \phi^* L_{\mathsf{Y}/\mathsf{Z}} & \longrightarrow & L_{\mathsf{X}/\mathsf{Z}} \\ \downarrow & & \downarrow \\ \phi^* L_{\mathsf{Y}/\mathsf{Y}} & \longrightarrow & L_{\mathsf{X}/\mathsf{Y}} \end{array}$$

is a pushout square in the stable ∞-category $\mathrm{Mod}_{\mathscr{O}_{\mathsf{X}}}$. Since $L_{\mathsf{Y}/\mathsf{Y}} \simeq 0$, we obtain a fiber sequence $\phi^* L_{\mathsf{Y}/\mathsf{Z}} \to L_{\mathsf{X}/\mathsf{Z}} \to L_{\mathsf{X}/\mathsf{Y}}$.

17.1.2 The Cotangent Complex of a Spectral Deligne-Mumford Stack

When restricted to spectral Deligne-Mumford stacks, the constructions of §17.1 do not leave the world of spectral algebraic geometry.

Proposition 17.1.2.1. *Let X be a nonconnective spectral Deligne-Mumford stack. Then the cotangent complex L_{X} is a quasi-coherent sheaf on X.*

Corollary 17.1.2.2. *Let $\phi : \mathsf{X} \to \mathsf{Y}$ be a morphism of nonconnective spectral Deligne-Mumford stacks. Then the relative cotangent complex $L_{\mathsf{X}/\mathsf{Y}}$ is a quasi-coherent sheaf on X.*

The proof of Proposition 17.1.2.1 will require some preliminary observations.

Remark 17.1.2.3. Let $\phi : A \to B$ be an étale morphism of $\mathbb{E}_\infty$-rings. Then the relative cotangent complex $L_{B/A}$ vanishes (Corollary HA.7.5.4.5). It follows that, for every $\mathbb{E}_\infty$-ring R, every R-module M, and every map $\eta : L_R \to \Sigma M$, the diagram of spaces

$$\begin{array}{ccc} \mathrm{Map}_{\mathrm{CAlg}}(B, R^\eta) & \longrightarrow & \mathrm{Map}_{\mathcal{C}}(B, R) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathrm{CAlg}}(A, R^\eta) & \longrightarrow & \mathrm{Map}_{\mathrm{CAlg}}(A, R) \end{array}$$

is a pullback square. In particular, taking $\eta = 0$, we obtain a pullback square

$$\begin{array}{ccc} \mathrm{Map}_{\mathrm{CAlg}}(B, R \oplus M) & \longrightarrow & \mathrm{Map}_{\mathcal{C}}(B, R) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathrm{CAlg}}(A, R \oplus M) & \longrightarrow & \mathrm{Map}_{\mathrm{CAlg}}(A, R). \end{array}$$

Remark 17.1.2.4. Let $\mathcal{X}$ be an ∞-topos, let $\mathscr{A}$ be a sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$, and let $\overline{\mathscr{A}}$ be a square-zero extension of $\mathscr{A}$. Using Remark 17.1.2.3, we deduce:

- (a) If $\mathscr{A}$ is local (Henselian, strictly Henselian), then $\overline{\mathscr{A}}$ is also local (Henselian, strictly Henselian).
- (b) Assume that $\mathscr{A}$ is local, and let $\mathscr{B}$ be another local sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$. Then a morphism $\phi : \mathscr{B} \to \overline{\mathscr{A}}$ is local if and only if the composite map $\mathscr{B} \xrightarrow{\phi} \overline{\mathscr{A}} \to \mathscr{A}$ is local. In particular, the projection map $\overline{\mathscr{A}} \to \mathscr{A}$ is local.

Lemma 17.1.2.5. *Let A be an $\mathbb{E}_\infty$-ring and let $\mathsf{X} = (\mathcal{X}, \mathscr{O}) = \mathrm{Sp\acute{e}t}\, A$ denote the corresponding nonconnective spectral Deligne-Mumford stack. Then the cotangent complex $L_{\mathscr{O}}$ is a quasi-coherent sheaf on X. The equivalence $\mathrm{Mod}_A \simeq \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A)$ carries L_A to the absolute cotangent complex $L_{\mathscr{O}}$.*

Proof. The universal derivation $\mathscr{O} \to \mathscr{O} \oplus L_{\mathscr{O}}$ induces a morphism

$$A \simeq \Gamma(\mathcal{X}; \mathscr{O}) \to \Gamma(\mathcal{X}; \mathscr{O} \oplus L_{\mathscr{O}}) \simeq A \oplus \Gamma(\mathcal{X}; L_{\mathscr{O}})$$

in $\mathrm{CAlg}_{/A}$, which is classified by a map of A-modules $\epsilon : L_A \to \Gamma(\mathcal{X}; L_{\mathscr{O}})$. Let $\mathscr{M}$ denote a preimage of L_A under the equivalence $\mathrm{QCoh}(\mathsf{X}) \simeq \mathrm{Mod}_A$, so that ϵ determines a morphism $\epsilon' : \mathscr{M} \to L_{\mathscr{O}}$ in $\mathrm{Mod}_{\mathscr{O}}$. We will prove that ϵ' is an equivalence. To prove this, let $\mathscr{M}' \in \mathrm{Mod}_{\mathscr{O}}$ be arbitrary. We wish to show that composition with ϵ' induces a homotopy equivalence

$$\theta : \mathrm{Map}_{\mathrm{Mod}_{\mathscr{O}}}(L_{\mathscr{O}}, \mathscr{M}') \to \mathrm{Map}_{\mathrm{Mod}_{\mathscr{O}}}(\mathscr{M}, \mathscr{M}') \simeq \mathrm{Map}_{\mathrm{Mod}_A}(L_A, \Gamma(\mathcal{X}; \mathscr{M}')).$$

Invoking the universal properties of $L_{\mathscr{O}}$ and L_A, we can identify θ with the map

$$\theta' : \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})_{/\mathscr{O}}}(\mathscr{O}, \mathscr{O} \oplus \mathscr{M}') \to \mathrm{Map}_{\mathrm{CAlg}_{/A}}(A, A \oplus \Gamma(\mathcal{X}; \mathscr{M}')).$$

It follows from Remark 17.1.2.4 (and the universal property of $\mathsf{X} = \operatorname{Spét} A$) that this map is a homotopy equivalence. □

Proof of Proposition 17.1.2.1. The assertion is local on X (Proposition 17.1.1.5). We may therefore assume without loss of generality that X is affine, in which case the result follows from Lemma 17.1.2.5. □

We note the following additional consequence of Lemma 17.1.2.5:

Proposition 17.1.2.6. *Suppose we are given a pullback square*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle \phi} & & \downarrow \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y} \end{array}$$

of nonconnective spectral Deligne-Mumford stacks. Then the canonical map

$$\phi^* L_{\mathsf{X}/\mathsf{Y}} \to L_{\mathsf{X}'/\mathsf{Y}'}$$

is an equivalence in $\operatorname{QCoh}(\mathsf{X}')$*.*

Proof. The assertion is local on Y; we may therefore assume without loss of generality that $\mathsf{Y} = \operatorname{Spét} A$ is affine. Similarly, we can assume that $\mathsf{Y}' = \operatorname{Spét} A'$ and $\mathsf{X}' = \operatorname{Spét} B$ are affine. Then $\mathsf{X}' \simeq \operatorname{Spét} B'$, where $B' = A' \otimes_A B$. Using Lemma 17.1.2.5, we are reduced to proving that the canonical map $B' \otimes_B L_{B/A} \to L_{B'/A'}$ is an equivalence of B'-modules, which is a special case of Proposition HA.7.3.3.7 . □

We close this section with a variant of Proposition 17.1.2.1:

Proposition 17.1.2.7. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack (Definition 8.1.3.1). Then the cotangent complex $L_{\mathscr{O}_{\mathfrak{X}}} \in \operatorname{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ is weakly quasi-coherent (see Definition 8.2.3.1).*

Proof. The assertion is local on $\mathfrak{X}$, so we may assume without loss of generality that $\mathfrak{X} = \operatorname{Spf} A$ for some adic $\mathbb{E}_\infty$-ring A. Let $f : \mathfrak{X} \to \operatorname{Spét} A$ be the canonical map and let us regard $\operatorname{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ as a stable A-linear ∞-category. Then $f^* L_{\operatorname{Spét} A} \simeq L_A \otimes_A \mathscr{O}_{\mathfrak{X}}$ is weakly quasi-coherent, and we have a fiber sequence $f^* L_{\operatorname{Spét} A} \to L_{\mathsf{X}} \to L_{\mathsf{X}/\operatorname{Spét} A}$. Consequently, to show that L_{X} is weakly quasi-coherent, it will suffice to show that $L_{\mathsf{X}/\operatorname{Spét} A}$ is weakly quasi-coherent.

Let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition, so that we can identify the structure sheaf $\mathscr{O}_{\operatorname{Spf} A}$ with the CAlg-valued presheaf given by $(B \in \operatorname{CAlg}^{\text{ét}}_A) \mapsto B^{\wedge}_I$. Unwinding the definitions, we see that $L_{\mathfrak{X}/\operatorname{Spét} A}$ can be identified with the sheafification of the presheaf given by $B \mapsto L_{B^{\wedge}_I / B}$. Note that if $\{B_n\}_{n>0}$ is a tower of B-algebras satisfying the requirements of Lemma 8.1.2.2, then the unit map $B_n \to B_n \otimes_B B^{\wedge}_I$ is an equivalence for each $n > 0$, so that

$$B_n \otimes_B L_{B^{\wedge}_I / B} \simeq L_{(B_n \otimes_B B^{\wedge}_I)/B_n} \simeq 0.$$

Using Lemma 8.1.2.3, we deduce that the I-completion of $L_{B^{\wedge}_I / B}$ vanishes: that is, each of the relative cotangent complexes $L_{B^{\wedge}_I / B}$ is I-local when regarded as an A-module. It follows that the sheaf $L_{\mathfrak{X} / \operatorname{Sp\acute{e}t} A}$ is an I-local object of the stable A-linear ∞-category $\operatorname{Mod}_{\mathscr{O}_{\mathfrak{X}}}$, and is therefore weakly coherent by Proposition 8.3.2.2. □

In the situation of Proposition 17.1.2.7, the cotangent complex $L_{\mathfrak{X}}$ is generally not quasi-coherent. However, we can remedy this by passing to the completion:

Definition 17.1.2.8. Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. We let $L^{\wedge}_{\mathfrak{X}}$ denote the quasi-coherent sheaf on $\mathfrak{X}$ obtained by applying Construction 8.2.4.1 to the cotangent complex $L_{\mathfrak{X}}$ (which is weakly quasi-coherent by virtue of Proposition 17.1.2.7). We will refer to $L^{\wedge}_{\mathfrak{X}}$ as the *completed cotangent complex of* $\mathfrak{X}$.

More generally, if $f : \mathfrak{X} \to \mathfrak{Y}$ is a morphism of formal spectral Deligne-Mumford stacks, we let $L^{\wedge}_{\mathfrak{X}/\mathfrak{Y}} \in \operatorname{QCoh}(\mathfrak{X})$ denote the quasi-coherent sheaf obtained by applying Construction 8.2.4.1 to the relative cotangent complex $L_{\mathfrak{X}/\mathfrak{Y}}$. Equivalently, we can described $L^{\wedge}_{\mathfrak{X}/\mathfrak{Y}}$ as the cofiber of the canonical map $f^{\star} L^{\wedge}_{\mathfrak{Y}} \to L^{\wedge}_{\mathfrak{X}}$.

Example 17.1.2.9. Let A be an adic $\mathbb{E}_\infty$-ring and let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition. Then the equivalence $\operatorname{QCoh}(\operatorname{Spf} A) \simeq \operatorname{Mod}_A^{\operatorname{Cpl}(I)}$ of Corollary 8.2.4.15 carries the completed cotangent complex $L^{\wedge}_{\operatorname{Spf} A}$ to the A-module $(L_A)^{\wedge}_I$.

Example 17.1.2.10. Let X be a spectral Deligne-Mumford stack, let $K \subseteq |\mathsf{X}|$ be a cocompact closed subset, and let $\mathsf{X}^{\wedge}_K$ denote the formal completion of X along K (Definition 8.1.6.1). Then the completed cotangent complex $L^{\wedge}_{\mathsf{X}^{\wedge}_K / \mathsf{X}}$ vanishes. To prove this, we can work locally and thereby reduce to the case where $\mathsf{X} \simeq \operatorname{Sp\acute{e}t} A$ is affine, in which case the desired result follows from the proof of Proposition 17.1.2.7.

17.1.3 Square-Zero Extensions

We now discuss square-zero extensions which are not necessarily trivial.

Construction 17.1.3.1 (The Square-Zero Extension of a Derivation)**.** Let $\mathcal{X}$ be an ∞-topos, $\mathscr{A}$ a sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$, and $\mathscr{M} \in \operatorname{Mod}_{\mathscr{A}}$. Let $\eta : L_{\mathscr{A}} \to \Sigma \mathscr{M}$ be a morphism of $\mathscr{A}$-modules, so that η determines a derivation $d_\eta : \mathscr{A} \to \mathscr{A} \oplus \Sigma \mathscr{M}$ (in the ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})_{/\mathscr{A}}$). Similarly, the zero map $L_{\mathscr{A}} \to \Sigma \mathscr{M}$ classifies a map $d_0 : \mathscr{A} \to \mathscr{A} \oplus \Sigma \mathscr{M}$.

Form a pullback diagram

$$\begin{array}{ccc} \mathscr{A}^{\eta} & \longrightarrow & \mathscr{A} \\ \downarrow & & \downarrow d_{\eta} \\ \mathscr{A} & \xrightarrow{d_0} & \mathscr{A} \oplus \Sigma \mathscr{M}. \end{array}$$

We will refer to $\mathscr{A}^{\eta}$ as the *square-zero extension of* $\mathscr{A}$ *determined by* η. By construction, there is a canonical fiber sequence $\mathscr{M} \to \mathscr{A}^{\eta} \to \mathscr{A}$ in the ∞-category of Sp-valued sheaves on $\mathcal{X}$.

In general, the passage from a morphism $\eta : L_{\mathscr{A}} \to \Sigma \mathscr{M}$ to the associated square-zero extension $\mathscr{A}^{\eta}$ involves a loss of information. We now study a situation where this is not the case:

Definition 17.1.3.2. Let $\mathcal{X}$ be an ∞-topos and let $n \geqslant 0$ be an integer. We will say that a morphism $\phi : \overline{\mathscr{A}} \to \mathscr{A}$ in $\mathrm{CAlg}(\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}))$ is an *n-small extension* if the following conditions are satisfied:

- (i) The sheaf $\mathscr{A}$ is connective.
- (ii) The fiber $\mathcal{I} = \mathrm{fib}(\phi)$ is n-connective (from which it follows that $\overline{\mathscr{A}}$ is also connective).
- (iii) The fiber $\mathcal{I}$ belongs to $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant 2n}$.
- (iv) The multiplication on $\mathscr{A}$ induces a nullhomotopic map $\mathcal{I} \otimes \mathcal{I} \to \mathcal{I}$.

The following result is a special case of Theorem HA.7.4.1.26 :

Theorem 17.1.3.3. *Let $\mathcal{X}$ be an ∞-topos, let $\mathscr{A}$ be a connective sheaf of $\mathbb{E}_{\infty}$-rings on $\mathcal{X}$, and let $n \geqslant 0$ be an integer. Let $\mathcal{C}$ denote the full subcategory of $(\mathrm{Mod}_{\mathscr{A}})_{L_{\mathscr{A}}/}$ spanned by morphisms of the form $\eta : L_{\mathscr{A}} \to \Sigma \mathcal{I}$, where $\mathcal{I}$ is n-connective and $(2n)$-truncated. Then the construction $\eta \mapsto \mathscr{A}^{\eta}$ determines a fully faithful embedding from $\mathcal{C}$ to $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})_{/\mathscr{A}}$, whose essential image is the collection of n-small extensions $\overline{\mathscr{A}} \to \mathscr{A}$.*

We now show that the class of spectral Deligne-Mumford stacks is closed under construction of square-zero extensions described in §17.1.3.

Proposition 17.1.3.4. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack, $\mathscr{M}$ a connective quasi-coherent sheaf on $\mathcal{X}$, and $\eta : L_{\mathsf{X}} \to \Sigma \mathscr{M}$ a morphism in $\mathrm{QCoh}(\mathsf{X})$. Then the pair $(\mathcal{X}, \mathscr{O}^{\eta}_{\mathcal{X}})$ is also a spectral Deligne-Mumford stack. If X is locally Noetherian and $\mathscr{M}$ is almost perfect, then $(\mathcal{X}, \mathscr{O}^{\eta}_{\mathcal{X}})$ is also locally Noetherian.*

The proof of Proposition 17.1.3.4 will require some preliminaries.

Lemma 17.1.3.5. *Let A be a connective $\mathbb{E}_\infty$-ring, M a connective A-module, and $\eta : L_A \to \Sigma M$ a map of A-modules which determines a square-zero extension $A^\eta \to A$. Then the base change functor $\theta : \mathrm{CAlg}^{\acute{e}t}_{A^\eta} \to \mathrm{CAlg}^{\acute{e}t}_A$ is an equivalence of ∞-categories.*

Proof. We have a short exact sequence of abelian groups

$$\pi_0 A^\eta \to \pi_0 A \to \pi_{-1} M.$$

Since M is connective, the map $\pi_0 A^\eta \to \pi_0 A$ is a surjection. Using the structure theory of étale morphisms (Proposition B.1.1.3), we deduce that θ is essentially surjective. It remains to show that θ is fully faithful. Let $\overline{B}$ and $\overline{B}'$ be étale A^η-algebras, and set $B = A \otimes A^{\eta}\overline{B}$ and $B' = A \otimes_{A^\eta} \overline{B}'$. We wish to show that θ induces a homotopy equivalence

$$\phi : \mathrm{Map}_{\mathrm{CAlg}_{A^\eta/}}(\overline{B}', \overline{B}) \to \mathrm{Map}_{\mathrm{CAlg}_{A^\eta/}}(\overline{B}', B) \simeq \mathrm{Map}_{\mathrm{CAlg}_{A/}}(B', B).$$

We have a pullback diagram of A^η-algebras

$$\begin{array}{ccc} \overline{B} & \longrightarrow & B \\ \downarrow & & \downarrow \\ B & \longrightarrow & (A \oplus \Sigma M) \otimes_{A^\eta} \overline{B}. \end{array}$$

We note that the lower right corner can be identified with the square-zero extension $B \oplus \Sigma N$, where $N = B \otimes_A M$. It follows that ϕ is a pullback of the map

$$\phi_0 : \mathrm{Map}_{\mathrm{CAlg}_{A^\eta/}}(\overline{B}', B) \to \mathrm{Map}_{\mathrm{CAlg}_{A^\eta/}}(\overline{B}', B \oplus \Sigma N).$$

It will therefore suffice to show that ϕ_0 is a homotopy equivalence. The projection $B \oplus \Sigma N \to B$ induces a map

$$\psi : \mathrm{Map}_{\mathrm{CAlg}_{A^\eta/}}(\overline{B}', B \oplus \Sigma N) \to \mathrm{Map}_{\mathrm{CAlg}_{A^\eta/}}(\overline{B}', B)$$

which is left homotopy inverse to ϕ_0. We claim that ψ is a homotopy equivalence. To prove this, fix a map of A^η-algebras $f : \overline{B}' \to B$. We will show that the homotopy fiber of ψ over f is contractible. This homotopy fiber is given by $\mathrm{Map}_{\mathrm{Mod}_{\overline{B}'}}(L_{\overline{B}'/A^\eta}, \Sigma N)$, which is contractible by virtue of our assumption that $\overline{B}'$ is étale over A^η. □

Lemma 17.1.3.6. *Let A be a connective $\mathbb{E}_\infty$-ring, M a connective A-module, and $\eta : L_A \to \Sigma M$ a map of A-modules which determines a square-zero extension A^η of A. Then the induced map $\mathrm{Sp\acute{e}t}\, A \to \mathrm{Sp\acute{e}t}\, A^\eta$ induces an equivalence of the underlying ∞-topoi.*

Proof. According to Lemma 17.1.3.5, we have an equivalence of ∞-categories $\mathrm{CAlg}^{\acute{e}t}_{A^\eta} \simeq \mathrm{CAlg}^{\acute{e}t}_A$. Note that a morphism $\overline{f} : \overline{B}' \to \overline{B}$ in $\mathrm{CAlg}^{\acute{e}t}_{A^\eta}$ is faithfully flat if and only if its image $f : B' \to B$ in $\mathrm{CAlg}^{\text{ét}}_A$ is faithfully flat. The "only if" direction is obvious, and the "if" direction follows from the observation that the map of commutative rings $\pi_0 \overline{B} \to \pi_0 B$ is a surjection with nilpotent kernel, and therefore induces a bijection $|\operatorname{Spec} B| \to |\operatorname{Spec} \overline{B}|$. It follows that the equivalence $\mathrm{CAlg}^{\text{ét}}_{A^\eta} \simeq \mathrm{CAlg}^{\text{ét}}_A$ induces an equivalence after taking sheaves with respect to the étale topology, and therefore induces an equivalence between the underlying ∞-topoi of $\operatorname{Spét} A^\eta$ and $\operatorname{Spét} A$ (see Proposition 1.4.2.4). □

Lemma 17.1.3.7. *Let A be a connective $\mathbb{E}_\infty$-ring, let M be an A-module which is connective as a spectrum, and let $\mathscr{M}$ be the corresponding quasi-coherent sheaf on* $\operatorname{Spét} A = (\mathcal{X}, \mathscr{O})$*. Suppose we are given a map $\eta : L_{\mathscr{O}} \to \Sigma \mathscr{M}$ which determines a square-zero extension $\mathscr{O}^\eta$ of $\mathscr{O}$. Passing to global sections (and using Lemma 17.1.2.5), we obtain a map of A-modules $\eta_0 : L_A \to \Sigma M$ which determines a square-zero extension A^{η_0} of A. Then there is a canonical equivalence $(\mathcal{X}, \mathscr{O}^\eta) \simeq$* $\operatorname{Spét} A^{\eta_0}$ *(in the ∞-category* RTop *of spectrally ringed ∞-topoi).*

Proof. Remark 17.1.2.4 implies that $\mathscr{O}^\eta$ is strictly Henselian. Since A^{η_0} can be identified with the $\mathbb{E}_\infty$-ring of global sections of $\mathscr{O}^\eta$, the universal property of $\operatorname{Spét} A^{\eta_0}$ gives a map of spectrally ringed ∞-topoi $\phi : (\mathcal{X}, \mathscr{O}^\eta) \to \operatorname{Spét} A^{\eta_0}$. Lemma 17.1.3.6 implies that ϕ induces an equivalence at the level of the underlying ∞-topoi. Write $\operatorname{Spét} A^{\eta_0}$ as $(\mathcal{X}, \mathscr{O}')$. We can identify $\mathscr{O}'$ with the sheaf of $\mathbb{E}_\infty$-rings on $(\mathrm{CAlg}^{\text{ét}}_A)^{\mathrm{op}}$ given by a homotopy inverse of the equivalence $\mathrm{CAlg}^{\text{ét}}_{A^{\eta_0}} \to \mathrm{CAlg}^{\text{ét}}_A$ of Lemma 17.1.3.5. Then ϕ induces a map of sheaves $\mathscr{O}' \to \mathscr{O}^\eta$; we wish to show that this map is an equivalence. Unwinding the definitions, we are required to show that for every étale A-algebra B, if we let $\eta' : L_B \to B \otimes_A \Sigma M$ denote the map induced by η, then ϕ induces an equivalence of $\mathbb{E}_\infty$-rings $\mathscr{O}'(B) \to B^{\eta'}$. Using Lemma 17.1.3.5, we are reduced to proving that $B^{\eta'}$ is étale over A^{η_0}, and that the canonical map $A \otimes_{A^{\eta_0}} B^{\eta'} \to B$ is an equivalence. This is a special case of Proposition HA.7.4.2.5 . □

Proof of Proposition 17.1.3.4. The assertion is local on $\mathcal{X}$. We may therefore assume without loss of generality that $\mathsf{X} = \operatorname{Spét} A$ is affine, that $\mathscr{M}$ is the quasi-coherent sheaf associated to a connective A-module M, and we can identify η with an A-module map $\eta_0 : L_A \to \Sigma M$. It follows from Lemma 17.1.3.7 that $(\mathcal{X}, \mathscr{O}^\eta_{\mathcal{X}}) \simeq \operatorname{Spét} A^{\eta_0}$ is an affine spectral Deligne-Mumford stack. For every integer n, we have a short exact sequence of $\pi_0 A^{\eta_0}$-modules $\pi_n M \to \pi_n A^{\eta_0} \to \pi_n A$. If A is Noetherian and $M \in \mathrm{Mod}_A$ is almost perfect, then $\pi_n A$ and $\pi_n M$ are Noetherian objects of the abelian category $\mathrm{Mod}^\heartsuit_A$, and therefore also of the abelian category $\mathrm{Mod}^\heartsuit_{A^{\eta_0}}$. It follows that $\pi_n A^{\eta_0}$ is also a Noetherian object of $\mathrm{Mod}^\heartsuit_{A^{\eta_0}}$. In particular, $\pi_0 A^{\eta_0}$ is a Noetherian ring and each homotopy group $\pi_n A^{\eta_0}$ is a finitely generated module over $\pi_0 A^{\eta_0}$. It follows that A^{η_0} is a Noetherian $\mathbb{E}_\infty$-ring, so that the spectral Deligne-Mumford stack $(\mathcal{X}, \mathscr{O}^\eta_{\mathcal{X}}) \simeq \operatorname{Spét} A^{\eta_0}$ is locally Noetherian as desired. □

17.1.4 Connectivity Estimates

Construction 17.1.4.1. Let $\mathcal{X}$ be an ∞-topos and let $f : \mathscr{A} \to \mathscr{B}$ be a morphism of sheaves of $\mathbb{E}_\infty$-rings on $\mathcal{X}$. The canonical map $\eta : L_{\mathscr{B}} \to L_{\mathscr{B}/\mathscr{A}}$ determines a square-zero extension $\mathscr{B}^\eta$ of $\mathscr{B}$ by $\Sigma^{-1} L_{\mathscr{B}/\mathscr{A}}$. Since the restriction of η to $L_{\mathscr{A}}$ vanishes, the associated square-zero extension of $\mathscr{A}$ is split: that is, the map f factors as a composition

$$\mathscr{A} \xrightarrow{f'} \mathscr{B}^\eta \xrightarrow{f''} \mathscr{B}.$$

In particular, we obtain a map of $\mathscr{A}$-modules $\mathrm{cofib}(f) \to \mathrm{cofib}(f'')$, which induces a map of $\mathscr{B}$-modules

$$\epsilon_f : \mathscr{B} \otimes_{\mathscr{A}} \mathrm{cofib}(f) \to \mathrm{cofib}(f'') \simeq L_{\mathscr{B}/\mathscr{A}}.$$

The following result is a special case of Theorem HA.7.4.3.12:

Theorem 17.1.4.2. *Let $\mathcal{X}$ be an ∞-topos, let $f : \mathscr{A} \to \mathscr{B}$ be a morphism between sheaves of $\mathbb{E}_\infty$-rings on $\mathcal{X}$, and let $\epsilon_f : \mathscr{B} \otimes_{\mathscr{A}} \mathrm{cofib}(f) \to L_{\mathscr{B}/\mathscr{A}}$ be defined as in Construction 17.1.4.1. Assume that $\mathscr{A}$ and $\mathscr{B}$ are connective and that the cofiber $\mathrm{cofib}(f)$ is n-connective (as a sheaf of spectra on $\mathcal{X}$). Then the morphism ϵ_f of Construction 17.1.4.1 is $(2n)$-connective: that is, $\mathrm{fib}(\epsilon_f)$ is a $2n$-connective sheaf of spectra on $\mathcal{X}$.*

Let us collect up some consequences of Theorem 17.1.4.2:

Corollary 17.1.4.3. *Let $\mathcal{X}$ be an ∞-topos and let $f : \mathscr{A} \to \mathscr{B}$ be a morphism of connective sheaves of $\mathbb{E}_\infty$-rings on $\mathcal{X}$. Assume that $\mathrm{cofib}(f)$ is n-connective for some $n \geqslant 0$. Then $L_{\mathscr{B}/\mathscr{A}}$ is n-connective. The converse holds provided that f induces an isomorphism $\pi_0 \mathscr{A} \to \pi_0 \mathscr{B}$.*

Proof. Let $\epsilon_f : \mathscr{B} \otimes_{\mathscr{A}} \mathrm{cofib}(f) \to L_{\mathscr{B}/\mathscr{A}}$ be as in Construction 17.1.4.1, so that we have a fiber sequence of $\mathscr{B}$-modules: $\mathrm{fib}(\epsilon_f) \to \mathscr{B} \otimes_{\mathscr{A}} \mathrm{cofib}(f) \xrightarrow{\epsilon_f} L_{\mathscr{B}/\mathscr{A}}$. To prove that $L_{\mathscr{B}/\mathscr{A}}$ is n-connective, it will suffice to show that $\mathscr{B} \otimes_{\mathscr{A}} \mathrm{cofib}(f)$ is n-connective and that $\mathrm{fib}(\epsilon_f)$ is $(n-1)$-connective. The first assertion is obvious, and the second follows from Theorem 17.1.4.2 (since $2n \geqslant n-1$).

To prove the converse, let us suppose that $\mathrm{cofib}(f)$ is *not* n-connective. We wish to show that $L_{\mathscr{B}/\mathscr{A}}$ is not n-connective. Let us assume that n is chosen as small as possible, so that $\mathrm{cofib}(f)$ is $(n-1)$-connective. By assumption, f induces an isomorphism $\pi_0 \mathscr{A} \to \pi_0 \mathscr{B}$, so we must have $n \geqslant 2$. Applying Theorem 17.1.4.2, we conclude that ϵ_f is $(2n-2)$-connective. Since $n \geqslant 2$, we deduce in particular that ϵ_f is n-connective, so that the map $\pi_{n-1}(\mathscr{B} \otimes_{\mathscr{A}} \mathrm{cofib}(f)) \to \pi_{n-1} L_{\mathscr{B}/\mathscr{A}}$ is an isomorphism. Since $\mathrm{cofib}(f)$ is $(n-1)$-connective and $\pi_0 \mathscr{A} \simeq \pi_0 \mathscr{B}$, the map $\pi_{n-1} \mathrm{cofib}(f) \to \pi_{n-1}(\mathscr{B} \otimes_{\mathscr{A}} \mathrm{cofib}(f))$ is an isomorphism. It follows that $\pi_{n-1} \mathrm{cofib}(f) \to \pi_{n-1} L_{\mathscr{B}/\mathscr{A}}$ is also an isomorphism, so that $\pi_{n-1} L_{\mathscr{B}/\mathscr{A}}$ is nonzero. □

Corollary 17.1.4.4. *Let $\mathcal{X}$ be a sheaf of $\mathbb{E}_\infty$-rings and let $\mathscr{A}$ be a connective sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$. Then the absolute cotangent complex $L_{\mathscr{A}}$ is connective.*

Proof. Let $\mathbf{1}$ denote the initial object of $\mathrm{CAlg}(\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}))$, and apply Corollary 17.1.4.3 to the unit map $\mathbf{1} \to \mathscr{A}$. □

Corollary 17.1.4.5. *Let $f : \mathscr{A} \to \mathscr{B}$ be a map of connective sheaves of $\mathbb{E}_\infty$-rings on an ∞-topos $\mathcal{X}$. Assume that $\mathrm{cofib}(f)$ is n-connective for $n \geqslant 0$. Then the induced map $L_f : L_{\mathscr{A}} \to L_{\mathscr{B}}$ has n-connective cofiber. In particular, the canonical map $\pi_0 L_{\mathscr{A}} \to \pi_0 L_{\pi_0 \mathscr{A}}$ is an isomorphism.*

Proof. The map L_f factors as a composition $L_{\mathscr{A}} \xrightarrow{g} \mathscr{B} \otimes_{\mathscr{A}} L_{\mathscr{A}} \xrightarrow{g'} L_{\mathscr{B}}$. We observe that $\mathrm{cofib}(g) \simeq \mathrm{cofib}(f) \otimes_{\mathscr{A}} L_{\mathscr{A}}$. Since the cotangent complex $L_{\mathscr{A}}$ is connective and $\mathrm{cofib}(f)$ is n-connective, we conclude that $\mathrm{cofib}(g)$ is n-connective. It will therefore suffice to show that $\mathrm{cofib}(g') \simeq L_{B/A}$ is n-connective. Let ϵ_f be as Construction 17.1.4.1, so we have a fiber sequence $\mathscr{B} \otimes_{\mathscr{A}} \mathrm{cofib}(f) \xrightarrow{\epsilon_f} L_{\mathscr{B}/\mathscr{A}} \to \mathrm{cofib}(\epsilon_f)$. It therefore suffices to show that $\mathscr{B} \otimes_{\mathscr{A}} \mathrm{cofib}(f)$ and $\mathrm{cofib}(\epsilon_f)$ are n-connective. The first assertion follows immediately from the n-connectivity of $\mathrm{cofib}(f)$, and the second from Theorem 17.1.4.2 since $2n + 1 \geqslant n$. □

17.1.5 Finiteness Conditions on $L_{\mathsf{X}/\mathsf{Y}}$

Let $\phi : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Many of the algebro-geometric properties of ϕ studied earlier in this book (such as the properties of being étale, fiber-smooth, differentially smooth, locally of finite presentation, and locally almost of finite presentation) can be formulated as properties of the relative cotangent complex $L_{\mathsf{X}/\mathsf{Y}}$:

Proposition 17.1.5.1. *Let $\phi : \mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}}) \to (\mathcal{Y}, \mathscr{O}_{\mathsf{Y}}) = \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Then:*

(1) *If the morphism ϕ is étale, then the relative cotangent complex $L_{\mathsf{X}/\mathsf{Y}}$ vanishes.*

(2) *If the morphism ϕ is locally of finite presentation, then the relative cotangent complex $L_{\mathsf{X}/\mathsf{Y}} \in \mathrm{QCoh}(\mathsf{X})$ is perfect.*

(3) *If the morphism ϕ is locally almost of finite presentation, then the relative cotangent complex $L_{\mathsf{X}/\mathsf{Y}} \in \mathrm{QCoh}(\mathsf{X})$ is almost perfect.*

(4) *If the morphism ϕ is locally of finite generation to order n (see Definition 4.2.0.1), then the relative cotangent complex $L_{\mathsf{X}/\mathsf{Y}} \in \mathrm{QCoh}(\mathsf{X})$ is perfect to order n.*

(5) *If the morphism ϕ is differentially smooth, then the relative cotangent complex $L_{\mathsf{X}/\mathsf{Y}} \in \mathrm{QCoh}(\mathsf{X})$ is locally free of finite rank.*

(6) *If the morphism ϕ is fiber-smooth, then ϕ is flat and, for every field κ and every morphism $\psi : \mathrm{Sp\acute{e}t}\,\kappa \to \mathsf{X}$, we have $\pi_1 \psi^* L_{\mathsf{X}/\mathsf{Y}} \simeq 0$.*

The converse assertions hold if we assume that ϕ exhibits $(\mathcal{X}, \pi_0 \mathscr{O}_{\mathsf{X}})$ as locally finitely 0-presented over $(\mathcal{Y}, \pi_0 \mathscr{O}_{\mathsf{Y}})$ (see Definition 4.2.3.1).

Proof. We may assume without loss of generality that $\mathsf{X} = \mathrm{Sp\acute{e}t}\, A$ and $\mathsf{Y} = \mathrm{Sp\acute{e}t}\, B$ are affine. In this case, Lemma 17.1.2.5 allows us to identify $L_{\mathsf{X}/\mathsf{Y}}$ with the quasi-coherent sheaf associated to the A-module $L_{A/B}$. Assertion (1) now follows from Lemma B.1.3.3, assertions (2) and (3) from Theorem HA.7.4.3.18 , assertion (4) from Proposition 4.1.2.1, assertion (5) from the definition of differential smoothness (see Proposition 11.2.2.1), and assertion (6) from Corollary 11.2.4.2. □

Corollary 17.1.5.2. *Let $\phi : \mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}}) \to (\mathcal{Y}, \mathscr{O}_{\mathsf{Y}}) = \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Then ϕ is an equivalence if and only if it satisfies the following conditions:*

(a) *The underlying map of 0-truncations $(\mathcal{X}, \pi_0 \mathscr{O}_{\mathsf{X}}) \to (\mathcal{Y}, \pi_0 \mathscr{O}_{\mathsf{Y}})$ is an equivalence.*

(b) *The relative cotangent complex $L_{\mathsf{X}/\mathsf{Y}} \in \mathrm{QCoh}(\mathsf{X})$ vanishes.*

17.1.6 Application: Noetherian Approximation

We conclude this section by applying the theory of the cotangent complex to prove a technical result which was needed in §4.4.4. Recall that if $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ is a spectral Deligne-Mumford stack, then $\tau_{\leqslant n} \mathsf{X} = (\mathcal{X}, \tau_{\leqslant n} \mathscr{O}_{\mathsf{X}})$ denotes its n-truncation.

Proposition 17.1.6.1. *Let $n \geqslant 0$, and suppose we are given a commutative diagram σ :*

$$\begin{array}{ccc} \tau_{\leqslant n} \mathsf{X} & \xrightarrow{g} & \mathsf{Y} \\ \downarrow & & \downarrow{\scriptstyle f} \\ \mathsf{X} & \xrightarrow{h} & \mathsf{Z} \end{array}$$

of quasi-compact, quasi-separated spectral algebraic spaces. Assume the following:

(i) *The morphism g is affine.*

(ii) *The morphism f is locally almost of finite presentation.*

(iii) *The spectral algebraic space Y is locally Noetherian.*

Then σ can be extended to a commutative diagram σ':

$$\begin{array}{ccc} \tau_{\leqslant n}\mathsf{X} & \xrightarrow{g} & \mathsf{Y} \\ \downarrow & & \downarrow{\scriptstyle i} \\ \mathsf{X} & \xrightarrow{\overline{g}} & \mathsf{Y}' \\ \downarrow{\scriptstyle \mathrm{id}} & & \downarrow{\scriptstyle f'} \\ \mathsf{X} & \longrightarrow & \mathsf{Z} \end{array}$$

where Y' is locally Noetherian and i induces an equivalence $\tau_{\leqslant n}\mathsf{Y} \to \tau_{\leqslant n}\mathsf{Y}'$.

Proof. Write $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathsf{Y}})$. Let $\mathscr{A} = f^{-1}\mathscr{O}_{\mathsf{Z}} \in \mathcal{S}\mathrm{hv}^{\mathrm{cn}}_{\mathrm{CAlg}}(\mathsf{Y})$ denote the pullback of the structure sheaf of Z along the morphism f. Let $\mathcal{C} = \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{Y})_{\mathscr{A}/}$ denote the ∞-category of $\mathscr{A}$-algebra objects of $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{Y})$. Using the morphism h, we can regard $\mathscr{B} = g_* \mathscr{O}_{\mathsf{X}}$ as an object of $\mathcal{C}$. The diagram σ determines a morphism $u(n) : \mathscr{O}_{\mathsf{Y}} \to \tau_{\leqslant n}\mathscr{B}$ in the ∞-category $\mathcal{C}$. We will show that there exists a commutative diagram

$$\begin{array}{ccc} \cdots & & \cdots \\ \downarrow & & \downarrow \\ \mathscr{O}_{\mathsf{Y}}(n+2) & \xrightarrow{u(n+2)} & \tau_{\leqslant n+2}\mathscr{B} \\ \downarrow & & \downarrow \\ \mathscr{O}_{\mathsf{Y}}(n+1) & \xrightarrow{u(n+1)} & \tau_{\leqslant n+1}\mathscr{B} \\ \downarrow & & \downarrow \\ \mathscr{O}_{\mathsf{Y}}(n) & \xrightarrow{u(n)} & \tau_{\leqslant n}\mathscr{B} \end{array}$$

in the ∞-category $\mathcal{C}$ which satisfies the following conditions:

(*a*) The sheaf $\mathscr{O}_{\mathsf{Y}}(n)$ coincides with $\mathscr{O}_{\mathsf{Y}}$ and the morphism $u(n)$ coincides with u.

(*b*) Each of the pairs $(\mathcal{Y}, \mathscr{O}_{\mathsf{Y}}(m))$ is a locally Noetherian spectral algebraic space.

(*c*) Each of the maps $\mathscr{O}_{\mathsf{Y}}(m+1) \to \mathscr{O}_{\mathsf{Y}}(m)$ induces an equivalence of m-truncations.

Assuming this can be done, we define $\mathscr{O}_{\mathsf{Y}'} = \varprojlim \mathscr{O}_{\mathsf{Y}}(m) \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{Y})$. It follows from (*b*) and (*c*) that the pair $\mathsf{Y}' = (\mathcal{Y}, \mathscr{O}_{\mathsf{Y}'})$ is a spectral algebraic space, and that the natural map $(\mathcal{Y}, \mathscr{O}_{\mathsf{Y}}(m)) \to (\mathcal{Y}, \mathscr{O}_{\mathsf{Y}'})$ induces an equivalence on m-truncations for each $m \geqslant n$ (to prove this, we can work locally and thereby reduce to the case where Y is affine, in which case the result follows immediately from the Postnikov-completeness of the ∞-category $\mathrm{CAlg}^{\mathrm{cn}}$). In particular, we conclude from (*b*) that $\mathsf{Y}' = (\mathcal{Y}, \mathscr{O}_{\mathsf{Y}}(m)$ is locally Noetherian (since this can be tested at the level of m-truncations) and from (*c*) that the natural map $i : \mathsf{Y} \to \mathsf{Y}'$ induces an equivalence of n-truncations. Moreover, the inverse system $\{u(m)\}_{m \geqslant n}$ determines a map $u(\infty) : \mathscr{O}_{\mathsf{Y}'} \to \varprojlim \tau_{\leqslant m} \mathscr{B} \simeq \mathscr{B}$ which classifies a morphism $\overline{g} : \mathsf{X} \to \mathsf{Y}'$ having the desired properties.

It remains to construct the maps $u(m) : \mathscr{O}_{\mathsf{Y}}(m) \to \tau_{\leqslant m} \mathscr{B}$. We proceed by induction on m, with the case $m = n$ handled by (a). To carry out the inductive step, let us assume that $u(m)$ has been constructed for some $m \geqslant n$. It follows from assumptions (b), (c), and Remark 4.2.0.4 that the canonical map $\mathsf{Y} \to (\mathcal{Y}, \mathscr{O}_{\mathsf{Y}}(m))$ is locally almost of finite presentation. Combining this observation with (ii) and Proposition 17.1.5.1, we deduce that the relative cotangent complexes $L_{\mathscr{O}_{\mathsf{Y}} / \mathscr{A}}, L_{\mathscr{O}_{\mathsf{Y}} / \mathscr{O}_{\mathsf{Y}}(m)} \in \mathrm{QCoh}(\mathsf{Y})$ are almost perfect. Using the fiber sequence

$$\mathscr{O}_{\mathsf{Y}} \otimes_{\mathscr{O}_{\mathsf{Y}}(m)} L_{\mathscr{O}_{\mathsf{Y}}(m) / \mathscr{A}} \to L_{\mathscr{O}_{\mathsf{Y}} / \mathscr{A}} \to L_{\mathscr{O}_{\mathsf{Y}} / \mathscr{O}_{\mathsf{Y}}(m)}$$

and Proposition 2.7.3.2, we deduce that $L_{\mathscr{O}_{\mathsf{Y}}(m) / \mathscr{A}}$ is almost perfect (when viewed as a quasi-coherent sheaf on the spectral algebraic space $(\mathcal{Y}, \mathscr{O}_{\mathsf{Y}}(m))$.

Set $\mathscr{F} = g_* \pi_{m+1} \mathscr{O}_{\mathsf{X}}$. Let us regard $\mathscr{F}$ as a $\mathscr{O}_{\mathsf{Y}}(m)$-module via the morphism $u(m)$, so that it is a quasi-coherent sheaf on the spectral Deligne-Mumford stack $(\mathsf{Y}, \mathscr{O}_{\mathsf{Y}}(m))$. Using Proposition 10.5.1.5, we can write $\mathscr{F}$ as the colimit of a filtered diagram $\{\mathscr{F}_\alpha\}$, where each $\mathscr{F}_\alpha \in \mathrm{QCoh}(\mathcal{Y}, \mathscr{O}_{\mathsf{Y}}(m))^{\heartsuit}$ is almost perfect. It follows from Theorem 17.1.4.2 that we can regard $\tau_{\leqslant m+1} \mathscr{B}$ as a square-zero extension of $\tau_{\leqslant m} \mathscr{B}$ by $\Sigma^{m+1} \mathscr{F}$: that is, we have an equivalence $\tau_{\leqslant m+1} \mathscr{B} \simeq (\tau_{\leqslant m} \mathscr{B})^{\eta}$ for some map $\eta : L_{\tau_{\leqslant m} \mathscr{B} / \mathscr{A}} \to \Sigma^{m+2} \mathscr{F}$. Let η' denote the composite map

$$L_{\mathscr{O}_{\mathsf{Y}}(m) / \mathscr{A}} \xrightarrow{u(m)} L_{\tau_{\leqslant m} \mathscr{B} / \mathscr{A}} \xrightarrow{\eta} \Sigma^{m+2} \mathscr{F} .$$

Since $L_{\mathscr{O}_{\mathsf{Y}}(m) / \mathscr{A}}$ is almost perfect, the morphism η' factors as a composition

$$L_{\mathscr{O}_{\mathsf{Y}}(m) / \mathscr{A}} \xrightarrow{\eta''} \Sigma^{m+2} \mathscr{F}_\alpha \to \Sigma^{m+2} \mathscr{F}$$

for some index α. We let $\mathscr{O}_{\mathsf{Y}}(m+1) = \mathscr{O}_{\mathsf{Y}}(m)^{\eta''}$ denote the square-zero extension of $\mathscr{O}_{\mathsf{Y}}(m)$ by $\Sigma^{m+1} \mathscr{F}_\alpha$ determined by η'', so that $u(m)$ lifts to a morphism

$$u(m+1) : \mathscr{O}_{\mathsf{Y}}(m+1) = \mathscr{O}_{\mathsf{Y}}(m)^{\eta''} \to (\tau_{\leqslant m} \mathscr{B})^{\eta} \simeq \tau_{\leqslant m+1} \mathscr{B} .$$

By construction, we have a canonical fiber sequence $\Sigma^{m+1} \mathscr{F}_\alpha \to \mathscr{O}_{\mathsf{Y}}(m+1) \xrightarrow{\rho} \mathscr{O}_{\mathsf{Y}}(m)$, so that the morphism ρ induces an equivalence on m-truncations. It follows from Proposition 17.1.3.4 that the pair $(\mathcal{Y}, \mathscr{O}_{\mathsf{Y}}(m+1))$ is a locally Noetherian spectral Deligne-Mumford stack (and therefore also a spectral algebraic space, since its m-truncation is a spectral algebraic space). □

17.2 The Cotangent Complex of a Functor

Let $\phi : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks, and let $X = h_{\mathsf{X}}$ and $Y = h_{\mathsf{Y}}$ be the functors represented by X and Y, respectively. The relative cotangent complex $L_{\mathsf{X}/\mathsf{Y}}$ is a quasi-coherent sheaf on X (Proposition 17.1.2.1). According to Proposition 6.2.4.1, we can identify quasi-coherent sheaves on X with quasi-coherent sheaves on the functor X. In particular, we can think of $L_{\mathsf{X}/\mathsf{Y}}$ as a rule which assigns an A-module $\eta^* L_{\mathsf{X}/\mathsf{Y}} \in \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A) \simeq \mathrm{Mod}_A$ to each A-valued point $\eta : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$. Unwinding the definitions, we see that if N is a connective A-module, then we can identify A-module maps from $\eta^* L_{\mathsf{X}/\mathsf{Y}}$ into N with dotted arrows completing the diagram

$$\begin{array}{ccc} \mathrm{Sp\acute{e}t}\, A & \xrightarrow{\eta} & \mathsf{X} \\ \downarrow & \nearrow & \downarrow \\ \mathrm{Sp\acute{e}t}(A \oplus N) & \longrightarrow & \mathsf{Y}, \end{array}$$

where the lower horizontal map is given by the composition

$$\mathrm{Sp\acute{e}t}(A \oplus N) \to \mathrm{Sp\acute{e}t}\, A \xrightarrow{\eta} \mathsf{X} \to \mathsf{Y}.$$

The above analysis suggests the possibility of defining the relative cotangent complex for a general natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Our goal in this section is to develop the theory of the cotangent complex in this setting, and to show that it agrees with Definition 17.1.1.8 when we restrict to functors which are represented by spectral Deligne-Mumford stacks (Proposition 17.2.5.1).

17.2.1 Almost Representable Functors

Suppose we are given a natural transformation $f : X \to Y$ between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. In good cases, we would like to associate to f a relative cotangent complex $L_{X/Y} \in \mathrm{QCoh}(X)$. $L_{X/Y} \in \mathrm{QCoh}(X)$. We can think of $L_{X/Y}$ as a rule which assigns to each point $\eta \in X(A)$ an A-module M_η, which is compatible with base change. This module M_η should have the following property: for every connective A-module N, $\mathrm{Map}_{\mathrm{Mod}_A}(M_\eta, N)$ is given by the fiber of the canonical map

$$X(A \oplus N) \to X(A) \times_{Y(A)} Y(A \oplus N)$$

(over the base point determined by η). In the special case where M_η is connective, this mapping property determines M_η up to a contractible space of choices (by the ∞-categorical version of Yoneda's lemma). However, for some applications this is unnecessarily restrictive: the cotangent complex of an Artin stack (over a field of characteristic zero, say) is usually not connective. We will therefore need a mechanism for recovering M_η given the functor that it corepresents on the ∞-category $\mathrm{Mod}_A^{\mathrm{cn}}$ of connective A-modules.

Notation 17.2.1.1. Recall that if $\mathcal{C}$ and $\mathcal{D}$ are ∞-categories which admit final objects, then a functor $F : \mathcal{C} \to \mathcal{D}$ is said to be *reduced* if it preserves final objects. If $\mathcal{C}$ admits finite colimits and $\mathcal{D}$ admits finite limits, we say that F is *excisive* if it carries pushout squares in $\mathcal{C}$ to pullback squares in $\mathcal{D}$. We let $\mathrm{Exc}_*(\mathcal{C},\mathcal{D})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{C},\mathcal{D})$ spanned by those functors which are reduced and excisive.

Lemma 17.2.1.2. *Let $\mathcal{C}$ be a stable ∞-category equipped with a right-bounded t-structure. Then the restriction functor $\theta : \mathrm{Exc}_*(\mathcal{C},\mathcal{S}) \to \mathrm{Exc}_*(\mathcal{C}_{\geqslant 0},\mathcal{S})$ is a trivial Kan fibration.*

Proof. Since θ is obviously a categorical fibration, it will suffice to show that θ is a categorical equivalence. Note that $\mathrm{Exc}_*(\mathcal{C},\mathcal{S})$ is the homotopy limit of the tower of ∞-categories

$$\cdots \to \mathrm{Exc}_*(\mathcal{C}_{\geqslant -2},\mathcal{S}) \to \mathrm{Exc}_*(\mathcal{C}_{\geqslant -1},\mathcal{S}) \to \mathrm{Exc}_*(\mathcal{C}_{\geqslant 0},\mathcal{S}).$$

It will therefore suffice to show that each of the restriction maps

$$\mathrm{Exc}_*(\mathcal{C}_{\geqslant -n},\mathcal{S}) \to \mathrm{Exc}_*(\mathcal{C}_{\geqslant 0},\mathcal{S})$$

is an equivalence of ∞-categories. We have a commutative diagram

$$\begin{array}{ccc} \mathrm{Exc}_*(\mathcal{C}_{\geqslant -n},\mathrm{Sp}) & \longrightarrow & \mathrm{Exc}_*(\mathcal{C}_{\geqslant 0},\mathrm{Sp}) \\ \downarrow & & \downarrow \\ \mathrm{Exc}_*(\mathcal{C}_{\geqslant -n},\mathcal{S}) & \longrightarrow & \mathrm{Exc}_*(\mathcal{C}_{\geqslant 0},\mathcal{S}) \end{array}$$

where the vertical maps (given by composition with $\Omega^\infty : \mathrm{Sp} \to \mathcal{S}$) are equivalences of ∞-categories (Proposition HA.1.4.2.22). It will therefore suffice to show that the forgetful functor

$$\theta : \mathrm{Exc}_*(\mathcal{C}_{\geqslant -n},\mathrm{Sp}) \to \mathrm{Exc}_*(\mathcal{C}_{\geqslant 0},\mathrm{Sp})$$

is an equivalence of ∞-categories. This is clear, since θ has a homotopy inverse given by the construction $F \mapsto \Omega^n \circ F \circ \Sigma^n$. □

Example 17.2.1.3. Let $\mathcal{C}$ be a stable ∞-category equipped with a right-bounded t-structure, let $C \in \mathcal{C}$ be an object, and let $F : \mathcal{C} \to \mathcal{S}$ be the functor corepresented by C. Then F is an excisive functor. It follows from Lemma 17.2.1.2 that F is determined by the restriction $F|_{\mathcal{C}_{\geqslant 0}}$, (up to a contractible space of choices). Combining this observation with Yoneda's lemma (Proposition HTT.5.1.3.2), we see that the object C can be recovered from $F|_{\mathcal{C}_{\geqslant 0}}$ (again up to a contractible space of choices). More precisely, the construction $C \mapsto F|_{\mathcal{C}_{\geqslant 0}}$ determines a fully faithful embedding $\mathcal{C}^{\mathrm{op}} \to \mathrm{Exc}_*(\mathcal{C}_{\geqslant 0},\mathcal{S})$.

Example 17.2.1.4. Let A be a connective $\mathbb{E}_\infty$-ring. Recall that an A-module M is said to be *almost connective* if it is n-connective for some n, and let $\mathrm{Mod}_A^{\mathrm{acn}}$ denote the full subcategory of Mod_A spanned by the A-modules which are almost connective. Example 17.2.1.3 determines a fully faithful embedding

$$\theta : (\mathrm{Mod}_A^{\mathrm{acn}})^{\mathrm{op}} \to \mathrm{Exc}_*(\mathrm{Mod}_A^{\mathrm{cn}},\mathcal{S}).$$

We will say that a functor $\mathrm{Mod}_A^{\mathrm{cn}} \to \mathcal{S}$ is *almost corepresentable* if it belongs to the essential image of the functor θ.

Proposition 17.2.1.5. *Let A be connective $\mathbb{E}_\infty$-ring and let $F : \mathrm{Mod}_A^{\mathrm{cn}} \to \mathcal{S}$ be a functor. Then F is almost corepresentable if and only if the following conditions are satisfied:*

(*a*) *The functor F is reduced and excisive.*

(*b*) *There exists an integer n such that the functor $M \mapsto \Omega^n F(M)$ commutes with small limits.*

(*c*) *The functor F is accessible: that is, F commutes with κ-filtered colimits for some regular cardinal κ.*

Proof. Assume that condition (a) is satisfied, so that F extends to an left exact $F^+ : \mathrm{Mod}_A^{\mathrm{acn}} \to \mathcal{S}$ (Lemma 17.2.1.2). Suppose that F^+ is represented by an almost connective A-module N. Choose n such that $\Sigma^n N$ is connective. Then the functor

$$M \mapsto \Omega^n F(M) \simeq F^+(\Omega^n M) \simeq \mathrm{Map}_{\mathrm{Mod}_A}(N, \Omega^n M) \simeq \mathrm{Map}_{\mathrm{Mod}_A}(\Sigma^n N, M)$$

is corepresented by the object $\Sigma^n N \in \mathrm{Mod}_A^{\mathrm{cn}}$, and therefore preserves small limits. If N is a κ-compact object of Mod_A, then F commutes with κ-filtered colimits, so that (c) is satisfied.

Conversely, suppose that (b) and (c) are satisfied. Choose $n \geqslant 0$ as in (b). Then the restriction $F^+|_{(\mathrm{Mod}_A)_{\geqslant -n}}$ is given by the composition

$$(\mathrm{Mod}_A)_{\geqslant -n} \xrightarrow{\Sigma^n} \mathrm{Mod}_A^{\mathrm{cn}} \xrightarrow{F} \mathcal{S}_* \xrightarrow{\Omega^n} \mathcal{S},$$

and therefore commutes with small limits. Using Proposition HTT.5.5.2.7 , we deduce that $F^+|_{(\mathrm{Mod}_A)_{\geqslant -n}}$ is corepresented by an object $N \in (\mathrm{Mod}_A)_{\geqslant -n}$. Using Lemma 17.2.1.2, we deduce that F^+ is corepresented by N, so that F is almost corepresentable. □

17.2.2 Digression: Local Representability

Let $\mathcal{C}$ be an ∞-category. It follows from the ∞-categorical version of Yoneda's Lemma (Proposition HTT.5.1.3.2) that an object $C \in \mathcal{C}$ is determined (up to canonical equivalence) by the functor $\mathrm{Map}_{\mathcal{C}}(C, \bullet) : \mathcal{C} \to \mathcal{S}$ corepresented by C. We will need a relative version of this assertion, which applies to an arbitrary coCartesian fibration $p : X \to S$.

Definition 17.2.2.1. Let $p : X \to S$ be a coCartesian fibration of simplicial sets. We will say that a map $F : X \to \mathcal{S}$ is *locally corepresentable* (with respect to p) if the following conditions are satisfied:

(1) For every vertex $s \in S$, there exists an object x of the ∞-category X_s and a point $\eta \in F(x)$ which corepresents the functor $F|_{X_s}$ in the following sense: for every object $y \in X_s$, evaluation on η induces a homotopy equivalence $\mathrm{Map}_{X_s}(x, y) \to F(y)$.

(2) Let $x \in X_s$ and $\eta \in F(x)$ be as in (1), let $e : x \to x'$ be a coCartesian edge of X covering an edge $s \to s'$ in S. Let $\eta' \in F(x')$ be the image of η under the map $F(x) \to F(x')$ determined by e. Then η' corepresents the functor $F|_{X_{s'}}$ (that is, for every $y \in X_{s'}$, evaluation on η' induces a homotopy equivalence $\mathrm{Map}_{X_{s'}}(x', y) \to F(y)$).

In the situation of Definition 17.2.2.1, condition (2) ensures that the object x_s representing the functors $F_s = F|_{X_s}$ can be chosen to depend functorially on $s \in S$. We can articulate this idea more precisely as follows:

Proposition 17.2.2.2 (Relative Yoneda Lemma)**.** *Let $p : X \to S$ be a coCartesian fibration of simplicial sets and let $\mathcal{C} \subseteq \mathrm{Fun}_S(S, X)$ denote the full subcategory of $\mathrm{Fun}_S(S, X)$ spanned by those maps $f : S \to X$ which carry each edge of S to a coCartesian edge of X. Then there is fully faithful embedding $\mathcal{C}^{\mathrm{op}} \to \mathrm{Fun}(X, \mathcal{S})$, whose essential image is the full subcategory of $\mathrm{Fun}(X, \mathcal{S})$ spanned by the locally corepresentable functors.*

Proof. Let $\chi : S \to \mathcal{C}\mathrm{at}_\infty$ be a map classifying the coCartesian fibration p (given informally by the formula $\chi(s) = X_s$), so that $\mathcal{C}$ can be identified with the limit of the diagram χ in the ∞-category $\mathcal{C}\mathrm{at}_\infty$ (Proposition HTT.3.3.3.1). Let χ' be the result of composing χ with the "opposition" functor $\mathcal{C}\mathrm{at}_\infty \to \mathcal{C}\mathrm{at}_\infty$.

Let $\mathrm{Dl}(p)$ and $\mathrm{Dl}^0(p)$ be defined as in Construction 14.4.2.1 (so that $\mathrm{Dl}(p) \to S$ is a Cartesian fibration whose fibers are given by $\mathrm{Dl}(p)_s = \mathrm{Fun}(X_s, \mathcal{S})$), and $\mathrm{Dl}^0(p)$ is the full simplicial subset whose fibers $\mathrm{Dl}^0(p)_s$ are the full subcategories of $\mathrm{Fun}(X_s, \mathcal{S})$ spanned by the corepresentable functors. Then the projection $q : \mathrm{Dl}^0(p) \to S$ is a coCartesian fibration classified by the map χ' (Proposition 14.4.2.4). We have an isomorphism of simplicial sets $\theta : \mathrm{Fun}_S(S, \mathrm{Dl}(p)) \simeq \mathrm{Fun}(X, \mathcal{S})$. A map $F : X \to \mathcal{S}$ is locally corepresentable if and only if $\theta^{-1}(F) : S \to \mathrm{Dl}(p)$ factors through $\mathrm{Dl}^0(p)$ and carries edges of S to q-coCartesian edges of $\mathrm{Dl}^0(p)$. Using Proposition HTT.3.3.3.1 , we can identify the limit $\varprojlim \chi'$ with the full subcategory of $\mathrm{Fun}(X, \mathcal{S})$ spanned by the locally corepresentable functors. We conclude the proof by observing that there is a canonical equivalence of ∞-categories $(\varprojlim \chi)^{\mathrm{op}} \simeq \varprojlim \chi'$. □

17.2.3 Local Almost Representability

Suppose that $f : X \to Y$ is a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, and η is a point of $X(A)$. Example 17.2.1.4 shows that if there exists an almost connective A-module M_η which corepresents the functor

$$(N \in \mathrm{Mod}_A^{\mathrm{cn}}) \mapsto (\mathrm{fib}\, X(A \oplus N) \to X(A) \times_{Y(A)} Y(A \oplus N) \in \mathcal{S}),$$

then M_η is determined up to a contractible space of choices. However, we will need a stronger statement in what follows: namely, that M_η can be chosen to depend functorially on the pair (A, η). To prove this, we will need a variant of Proposition 17.2.2.2.

Definition 17.2.3.1. Let $p : X \to S$ be a coCartesian fibration of simplicial sets. Assume that:

(i) For each vertex $s \in S$, the ∞-category X_s is stable and equipped with a right-bounded t-structure $(X_{s,\geqslant 0}, X_{s,\leqslant 0})$.

(ii) For every edge $e : s \to s'$ in S, the associated functor $X_s \to X_{s'}$ is exact and right t-exact.

Let $X_{\geqslant 0}$ be the full simplicial subset of X spanned by those vertices which belong to $X_{s,\geqslant 0}$ for some vertex $s \in S$.

We will say that a map $F : X_{\geqslant 0} \to \mathcal{S}$ is *locally almost corepresentable* (with respect to p) if the following conditions are satisfied:

(1) For every vertex $s \in S$, the induced map $X_{s,\geqslant 0} \to \mathcal{S}$ is reduced and excisive.

(2) Let $F^+ : X \to \mathcal{S}$ be an extension of F such that $F^+|_{X_s}$ is reduced and excisive for each $s \in S$ (it follows from Lemma 17.2.3.4 that F^+ exists and is unique up to a contractible space of choices). Then F^+ is locally corepresentable (in the sense of Definition 17.2.2.1).

Proposition 17.2.3.2. *Let $p : X \to S$ be as in Definition 17.2.3.1, let $\mathcal{C}$ denote the full subcategory of* $\mathrm{Fun}_S(S, X)$ *spanned by those maps which carry each edge of S to a p-coCartesian edge of X. Then there is a fully faithful functor $\mathcal{C}^{\mathrm{op}} \to \mathrm{Fun}(X_{\geqslant 0}, \mathcal{S})$, whose essential image is the full subcategory of* $\mathrm{Fun}(X_{\geqslant 0}, \mathcal{S})$ *spanned by the locally almost corepresentable functors.*

Remark 17.2.3.3. In the situation of Proposition 17.2.3.2, the fully faithful functor $\mathcal{C}^{\mathrm{op}} \to \mathrm{Fun}(X_{\geqslant 0}, \mathcal{S})$ is left exact. In particular, the essential image of this functor is closed under finite limits.

Proposition 17.2.3.2 is an immediate consequence of Proposition 17.2.2.2 together with the following relative version of Lemma 17.2.1.2:

Lemma 17.2.3.4. *Let $p : X \to S$ be as in Definition 17.2.3.1, let $\mathcal{E} \subseteq \mathrm{Fun}(X, \mathcal{S})$ denote the full subcategory of* $\mathrm{Fun}(X, \mathcal{S})$ *spanned by those functors whose restriction to each fiber X_s is reduced and excisive, and define $\mathcal{E}_0 \subseteq \mathrm{Fun}(X_{\geqslant 0}, \mathcal{S})$ similarly. Then the restriction functor $\mathcal{E} \to \mathcal{E}_0$ is a trivial Kan fibration.*

Proof. Since $\mathcal{E} \to \mathcal{E}_0$ is obviously a categorical fibration, it will suffice to show that it is an equivalence of ∞-categories. For every map of simplicial sets $\phi : T \to S$, let $\mathcal{E}(T) \subseteq \mathrm{Fun}(X \times_S T, \mathcal{S})$ denote the full subcategory spanned by those functors $F : X \times_S T \to \mathcal{S}$ whose restriction to $X_{\phi(t)}$ is reduced and excisive for each vertex $t \in T$, and define $\mathcal{E}_0(T)$ similarly. There is an evident restriction map $\psi(T) : \mathcal{E}(T) \to \mathcal{E}_0(T)$. We will prove that this map is an equivalence of ∞-categories for every map $\phi : T \to S$. Note that $\phi(T)$ is the homotopy limit of a tower of functors $\psi(\mathrm{sk}^n T)$ for $n \geqslant 0$. We may therefore assume that T is a simplicial set of finite dimension n. We proceed by induction on n, the case $n = -1$ being vacuous. Let K be the set of n-simplices of T. We have a pushout diagram of simplicial sets

$$\begin{array}{ccc} K \times \partial\,\Delta^n & \longrightarrow & K \times \Delta^n \\ \downarrow & & \downarrow \\ \mathrm{sk}^{n-1} T & \longrightarrow & T, \end{array}$$

which gives rise to a homotopy pullback diagram of functors

$$\begin{array}{ccc} \psi(K \times \partial\,\Delta^n) & \longleftarrow & \psi(K \times \Delta^n) \\ \uparrow & & \uparrow \\ \psi(\mathrm{sk}^{n-1} T) & \longleftarrow & \psi(T). \end{array}$$

It will therefore suffice to prove that $\psi(\mathrm{sk}^{n-1} T)$, $\psi(K \times \partial\,\Delta^n)$, and $\psi(K \times \Delta^n)$ are equivalences. In the first two cases, this follows from the inductive hypothesis. In the third case, we can write $\psi(K \times \Delta^n)$ as a product of functors $\psi(\{v\} \times \Delta^n)$ indexed by the elements of K. We are therefore reduced to proving the Lemma in the case $S = \Delta^n$.

For $0 \leqslant i \leqslant n$, let X_i denote the fiber of p over the ith vertex of $S = \Delta^n$. Using Proposition HTT.3.2.2.7 , we can choose a composable sequence of maps

$$\theta : X_0^{\mathrm{op}} \to X_1^{\mathrm{op}} \to \cdots \to X_n^{\mathrm{op}}$$

and a categorical equivalence $M(\theta)^{\mathrm{op}} \to X$, where $M(\theta)$ denotes the mapping simplex of the diagram θ (see §HTT.3.2.2). Note that each of the maps in the above diagram is exact and right t-exact, so that θ restricts to a sequence of maps

$$\theta_0 : (X_{0,\geqslant 0})^{\mathrm{op}} \to \cdots \to (X_{n,\geqslant 0})^{\mathrm{op}}$$

and we have a categorical equivalence $M(\theta_0)^{\mathrm{op}} \to X_{\geqslant 0}$. For every simplicial subset $T \subseteq S = \Delta^n$, let $\mathcal{E}'(T)$ denote the full subcategory of $\mathrm{Fun}(T \times_S M(\theta)^{\mathrm{op}}, \mathcal{S})$ spanned by those functors whose restriction to each X_i is reduced and excisive, and define $\mathcal{E}'_0(T) \subseteq \mathrm{Fun}(T \times_S M(\theta_0)^{\mathrm{op}}, \mathcal{S})$ similarly. We have a commutative diagram

$$\begin{array}{ccc} \mathcal{E}(T) & \longrightarrow & \mathcal{E}_0(T) \\ \downarrow & & \downarrow \\ \mathcal{E}'(T) & \longrightarrow & \mathcal{E}'_0(T) \end{array}$$

where the vertical maps are categorical equivalences. It follows from the inductive hypothesis that the restriction map $\mathcal{E}'(T) \to \mathcal{E}'_0(T)$ is a categorical equivalence for every proper simplicial subset $T \subseteq S$. To complete the proof, it will suffice to show that $\mathcal{E}'(S) \to \mathcal{E}'_0(S)$ is a categorical equivalence.

Let σ denote the face of $S = \Delta^n$ opposite the 0th vertex. We have a commutative diagram

$$\begin{array}{ccc} \mathcal{E}'(S) & \longrightarrow & \mathcal{E}'_0(S) \\ \downarrow & & \downarrow \\ \mathcal{E}'(\sigma) & \longrightarrow & \mathcal{E}'_0(\sigma), \end{array}$$

where the bottom horizontal map is a categorical equivalence. It will therefore suffice to show that this diagram is a homotopy pullback square: that is, that the map

$$\rho : \mathcal{E}'(S) \to \mathcal{E}'_0(S) \times_{\mathcal{E}'_0(\sigma)} \mathcal{E}'(\sigma)$$

is a categorical equivalence. Let $\mathcal{C} = X_0$ and $\mathcal{C}_{\geqslant 0} = X_{0,\geqslant 0}$. Unwinding the definitions, we see that ρ is a pullback of the canonical map

$$\rho_0 : \mathrm{Fun}(S, \mathrm{Exc}_*(\mathcal{C}, \mathcal{S})) \to \mathrm{Fun}(S, \mathrm{Exc}_*(\mathcal{C}_{\geqslant 0}, \mathcal{S})) \times_{\mathrm{Fun}(\sigma, \mathrm{Exc}_*(\mathcal{C}_{\geqslant 0}, \mathcal{S}))} \mathrm{Fun}(\sigma, \mathrm{Exc}_*(\mathcal{C}, \mathcal{S})).$$

It follows from Lemma 17.2.1.2 that this map is a trivial Kan fibration. □

17.2.4 Functorial Definition of the Cotangent Complex

We now specialize the formal considerations of §17.2.1, §17.2.2, and §17.2.3 to the situation of interest.

Notation 17.2.4.1. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor. Let $\overline{\mathrm{CAlg}}^{\mathrm{cn}} \to \mathrm{CAlg}^{\mathrm{cn}}$ be a left fibration classified by X, and let Mod^X denote the fiber product $\mathrm{Mod}(\mathrm{Sp}) \times_{\mathrm{CAlg}} \overline{\mathrm{CAlg}}^{\mathrm{cn}}$. More informally, we let Mod^X denote the ∞-categories whose objects are triples (A, η, M), where A is a connective $\mathbb{E}_\infty$-ring, $\eta \in X(A)$ is a point, and $M \in \mathrm{Mod}_A$ is an A-module spectrum. Let $\mathrm{Mod}^X_{\mathrm{acn}}$ denote the full subcategory of Mod^X spanned by those triples (A, η, M) where M is almost connective (that is, M is n-connective for $n \ll 0$). The forgetful functor $q : \mathrm{Mod}^X_{\mathrm{acn}} \to \overline{\mathrm{CAlg}}^{\mathrm{cn}}$ is a coCartesian fibration. Moreover, the ∞-category of coCartesian sections of q is canonically equivalent to $\mathrm{QCoh}(X)^{\mathrm{acn}}$, the full subcategory of $\mathrm{QCoh}(X)$ spanned by the almost connective quasi-coherent sheaves on X (see Remark 6.2.2.7).

Let $\mathrm{Mod}^X_{\mathrm{cn}}$ denote the full subcategory of Mod^X spanned by those triples (A, η, M) where M is connective. Applying Proposition 17.2.3.2, we deduce that $\mathrm{QCoh}(X)^{\mathrm{acn}}$ is equivalent to the full subcategory of $\mathrm{Fun}(\mathrm{Mod}^X_{\mathrm{cn}}, \mathcal{S})^{\mathrm{op}}$ spanned by those functors $\mathrm{Mod}^X_{\mathrm{cn}} \to \mathcal{S}$ which are locally almost corepresentable (relative to q).

Definition 17.2.4.2 (The Relative Cotangent Complex)**.** Suppose we are given a natural transformation $\alpha : X \to Y$ between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. We define a functor $F : \mathrm{Mod}^X_{\mathrm{cn}} \to \mathcal{S}$ by the formula

$$F(A, \eta, M) = \mathrm{fib}(X(A \oplus M) \to X(A) \times_{Y(A)} Y(A \oplus M)),$$

where the fiber is taken over the point of $X(A) \times_{Y(A)} Y(A \oplus M)$ determined by η. We will say that α *admits a cotangent complex* if the functor F is locally almost corepresentable relative to q. In this case, we let $L_{X/Y} \in \mathrm{QCoh}(X)$ denote a preimage for F under the fully faithful embedding $\mathrm{QCoh}(X)^{\mathrm{aperf}} \to \mathrm{Fun}(\mathrm{Mod}^X_{\mathrm{cn}}, \mathcal{S})^{\mathrm{op}}$ given in Notation 17.2.4.1. We will refer to $L_{X/Y}$ as the *relative cotangent complex of X over Y*.

In the special case where Y is a final object of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$, we will say that X *admits a cotangent complex* if the essentially unique map $\alpha : X \to Y$ admits a cotangent complex. In this case, we will denote the relative cotangent complex $L_{X/Y}$ by L_X and refer to it as the *absolute cotangent complex* of X.

Remark 17.2.4.3. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ and $F : \mathrm{Mod}^X_{\mathrm{cn}} \to \mathcal{S}$ be functors. Unwinding the definitions, we see that F is locally almost corepresentable if and only if the following conditions are satisfied:

(a) For every connective $\mathbb{E}_\infty$-ring A and every point $\eta \in X(A)$, the induced functor $F_\eta : \mathrm{Mod}^{\mathrm{cn}}_A \to \mathcal{S}$ is corepresented by an almost connective A-module M_η (which is uniquely determined up to contractible ambiguity: see Example 17.2.1.4).

(b) Let $\eta \in X(A)$ be as in (a), and suppose we are given a map of connective $\mathbb{E}_\infty$-rings $A \to A'$. Let $\eta' \in X(A')$ denote the image of η. Then the functor $F_{\eta'}$ is corepresented by $A' \otimes_A M_\eta$. More precisely, for every A'-module N, the canonical map

$$\mathrm{Map}_{\mathrm{Mod}_{A'}}(A' \otimes_A M_\eta, N) \simeq \mathrm{Map}_{\mathrm{Mod}_A}(M_\eta, N) \simeq F_\eta(N) \to F_{\eta'}(N)$$

is a homotopy equivalence.

We can rephrase condition (b) as follows:

(b') The functor F carries p-Cartesian morphisms in $\mathrm{Mod}^X_{\mathrm{cn}}$ to homotopy equivalences, where $p : \mathrm{Mod}^X_{\mathrm{cn}} \to \overline{\mathrm{CAlg}}^{\mathrm{cn}}$ denotes the projection map (here $\overline{\mathrm{CAlg}}^{\mathrm{cn}}$ is defined as in Notation 17.2.4.1).

Example 17.2.4.4. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor. Then X admits a cotangent complex if and only if the following conditions are satisfied:

(a) For every connective $\mathbb{E}_\infty$-ring A and every point $\eta \in X(A)$, define $F_\eta : \mathrm{Mod}^{\mathrm{cn}}_A \to \mathcal{S}$ by the formula $F_\eta(N) = X(A \oplus N) \times_{X(A)} \{\eta\}$. Then the functor F_η is corepresented by an almost connective A-module M_η.

(b) For every map of connective $\mathbb{E}_\infty$-rings $A \to B$ and every connective B-module M, the diagram of spaces

$$\begin{array}{ccc} X(A \oplus M) & \longrightarrow & X(B \oplus M) \\ \downarrow & & \downarrow \\ X(A) & \longrightarrow & X(B) \end{array}$$

is a pullback square.

In this case, the absolute cotangent complex $L_X \in \mathrm{QCoh}(X)$ is described by the formula $\eta^* L_X = M_\eta \in \mathrm{Mod}_A$ for $\eta \in X(A)$.

Using Proposition 17.2.1.5, we can reformulate condition (a) as follows:

(a') For every point $\eta \in X(A)$, the functor $F_\eta : \mathrm{Mod}_A^{\mathrm{cn}} \to \mathcal{S}$ is reduced, excisive, and accessible. Moreover, there exists an integer $n \geqslant 0$ such that the functor $M \mapsto \Omega^n F_\eta(M)$ preserves small limits.

Remark 17.2.4.5. Fix an integer n and a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Then $\mathrm{QCoh}(X)_{\geqslant n}$ is a full subcategory of $\mathrm{QCoh}(X)^{\mathrm{acn}}$ which is closed under small colimits. The construction of Notation 17.2.4.1 determines a fully faithful embedding $\mathrm{QCoh}(X)^{\mathrm{op}}_{\geqslant n} \to \mathrm{Fun}(\mathrm{Mod}^X_{\mathrm{cn}}, \mathcal{S})$ which commutes with small limits. It follows that the essential image of this embedding is closed under small limits. From this we deduce the following:

($*$) Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be the limit of a diagram of functors $\{X_\alpha : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}\}$. Assume that each X_α admits a cotangent complex which is n-connective. Then X admits a cotangent complex which is n-connective. Moreover, we have a canonical equivalence $L_X \simeq \varinjlim_\alpha f_\alpha^* L_{X_\alpha}$, where $f_\alpha : X \to X_\alpha$ denotes the projection map.

Remark 17.2.4.6. Suppose we are given a pullback diagram

$$\begin{array}{ccc} X' & \xrightarrow{g} & X \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f} \\ Y' & \longrightarrow & Y \end{array}$$

in the ∞-category $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. If f admits a cotangent complex, then f' also admits a cotangent complex. Moreover, we have a canonical equivalence $L_{X'/Y'} \simeq g^* L_{X/Y}$ in the ∞-category $\mathrm{QCoh}(X')$.

Remark 17.2.4.6 admits the following converse:

Proposition 17.2.4.7. *Let $f : X \to Y$ be a morphism in the ∞-category $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. Suppose that, for every corepresentable functor $Y' : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ and every natural transformation $\phi : Y' \to Y$, the projection map $Y' \times_Y X \to Y'$ admits a cotangent complex. Then f admits a cotangent complex.*

Proof. Let $\mathrm{Mod}^X_{\mathrm{cn}}$ be as in Definition 17.2.4.2, and let $F : \mathrm{Mod}^X_{\mathrm{cn}} \to \mathcal{S}$ be given by the formula $F(R, \eta, M) = \mathrm{fib}(X(R \oplus M) \to X(R) \times_{Y(R)} Y(R \oplus M))$. We wish to show that F is locally almost corepresentable. We will show that F satisfies conditions (a) and (b') of Remark 17.2.4.3.

To verify condition (a), let us fix a point $\eta \in X(R)$ and consider the functor $F_\eta : \mathrm{Mod}^{\mathrm{cn}}_R \to \mathcal{S}$ given by the restriction of F. Let $Y' : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be the functor corepresented by R. Then η determines a natural transformation $Y' \to Y$. Let $X' = Y' \times_Y X$, and let $F' : \mathrm{Mod}^{X'}_{\mathrm{cn}} \to \mathcal{S}$ be the functor given by the formula

$$F'(R_0, \eta_0, M_0) = \mathrm{fib}(X'(R_0 \oplus M_0) \to X'(R_0) \times_{Y'(R_0)} Y'(R_0 \oplus M_0)).$$

Since the projection map $X' \to Y'$ admits a cotangent complex, the functor F' is locally almost corepresentable and therefore satisfies condition (a) of Remark 17.2.4.3. We now observe that η lifts canonically to a point $\eta' \in X'(R)$. The restriction of F' to the fiber of $\mathrm{Mod}^{X'}_{\mathrm{cn}}$ over (R, η') agrees with F_η. It follows that F_η is corepresentable by an almost connective R-module, as desired.

We now verify condition (b'). Choose a morphism $\alpha : (R, \eta, M) \to (R', \eta', M')$ in $\mathrm{Mod}^X_{\mathrm{cn}}$ which induces an equivalence $R' \otimes_R M \to M'$. We wish to prove that $F(\alpha)$ is a homotopy equivalence. Let $F' : \mathrm{Mod}^{X'}_{\mathrm{cn}} \to \mathcal{S}$ be defined as above, and observe that α lifts canonically to a morphism $\overline{\alpha}$ in $\mathrm{Mod}^{X'}_{\mathrm{cn}}$. Since F' is locally almost corepresentable, it satisfies condition (b') of Remark 17.2.4.3. It follows that $F'(\overline{\alpha})$ is a homotopy equivalence. Since F' is the composition of F with the forgetful functor $\mathrm{Mod}^{X'}_{\mathrm{cn}} \to \mathrm{Mod}^X_{\mathrm{cn}}$, we deduce that $F(\alpha)$ is a homotopy equivalence. □

17.2.5 Comparison with the Geometric Definition

Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. We now have two *a priori* different definitions of the relative cotangent complex $L_{\mathsf{X}/\mathsf{Y}}$: one given by Definition 17.1.1.8 (where we regard X and Y as spectrally ringed ∞-topoi) and one given by Definition 17.2.4.2 (where we identify X and Y with the associated functors $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$). We now show that these definitions are essentially equivalent (Corollary 17.2.5.4). We begin by considering the case $\mathsf{Y} = \mathrm{Spét}\, S$.

Proposition 17.2.5.1. *Let $\mathfrak{X} = (\mathcal{X}, \mathcal{O})$ be a formal spectral Deligne-Mumford stack, and let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ denote the functor represented by $\mathfrak{X}$. Then X admits a cotangent complex L_X. Moreover, we can identify L_X with the image of the completed cotangent complex $L^{\wedge}_{\mathfrak{X}}$ under the equivalence of ∞-categories $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{cn}} \simeq \mathrm{QCoh}(X)^{\mathrm{cn}}$ of Theorem 8.3.4.4.*

Proof. Let $\mathrm{Mod}^X_{\mathrm{cn}}$ denote the ∞-category introduced in Definition 17.2.4.2. Let $F : \mathrm{Mod}^X_{\mathrm{cn}}$ be the functor given by $F(R, \eta, M) = X(R \oplus M) \times_{X(R)} \{\eta\}$. For each object $(R, \eta, M) \in \mathrm{Mod}^X_{\mathrm{cn}}$, let us regard $\mathcal{S}\mathrm{hv}^{\text{ét}}_R$ as the underlying ∞-topos of both $\mathrm{Spét}\, R$ and $\mathrm{Spét}(R \oplus M)$, let $\widetilde{M}$ denote the quasi-coherent $\mathscr{O}_{\mathrm{Sp\acute{e}t}\, R}$-module corresponding to M, and regard η as a morphism of spectrally ringed ∞-topoi from $\mathrm{Sp\acute{e}t}\, R$ to $\mathfrak{X}$. Unwinding the definitions, we obtain canonical homotopy equivalences

$$\begin{aligned}
F(R, \eta, M) &\simeq \mathrm{Map}_{\mathrm{fSpDM}_{\mathrm{Sp\acute{e}t}\, R/}}(\mathrm{Sp\acute{e}t}(R \oplus M), \mathfrak{X}) \\
&\simeq \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{S}\mathrm{hv}^{\mathrm{\acute{e}t}}_R)_{/\mathscr{O}_{\mathrm{Sp\acute{e}t}\, R}}}(\eta^{-1}\mathscr{O}_{\mathfrak{X}}, \mathscr{O}_{\mathrm{Sp\acute{e}t}(R \oplus M)}) \\
&\simeq \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{S}\mathrm{hv}^{\mathrm{\acute{e}t}}_R)_{/\mathscr{O}_{\mathrm{Sp\acute{e}t}\, R}}}(\eta^{-1}\mathscr{O}_{\mathfrak{X}}, \mathscr{O}_{\mathrm{Sp\acute{e}t}\, R} \oplus \widetilde{M}) \\
&\simeq \mathrm{Map}_{\mathrm{Mod}_{\eta^{-1}\mathscr{O}_{\mathfrak{X}}}}(L_{\eta^{-1}\mathscr{O}_{\mathfrak{X}}}, \widetilde{M}) \\
&\simeq \mathrm{Map}_{\mathrm{Mod}_{\eta^{-1}\mathscr{O}_{\mathfrak{X}}}}(\eta^{-1} L_{\mathscr{O}_{\mathfrak{X}}}, \widetilde{M}) \\
&\simeq \mathrm{Map}_{\mathrm{Mod}_{\mathscr{O}_{\mathrm{Sp\acute{e}t}\, R}}}(\eta^{*} L_{\mathscr{O}_{\mathfrak{X}}}, \widetilde{M}) \\
&\simeq \mathrm{Map}_{\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R)}(\eta^{*} L^{\wedge}_{\mathfrak{X}}, \widetilde{M}) \\
&\simeq \mathrm{Map}_{\mathrm{Mod}_R}(\Gamma(\mathrm{Sp\acute{e}t}\, R; \eta^{*} L^{\wedge}_{\mathfrak{X}}), M).
\end{aligned}$$

□

Proposition 17.2.5.2. *Suppose we are given a commutative diagram*

$$\begin{array}{ccccc} & & Y & & \\ & \overset{f}{\nearrow} & & \overset{g}{\searrow} & \\ X & & \xrightarrow{h} & & Z \end{array}$$

in the ∞-category $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. Assume that g and h admit cotangent complexes. Then f admits a cotangent complex. Moreover, we have a canonical fiber sequence $f^* L_{Y/Z} \to L_{X/Z} \to L_{X/Y}$ in the stable ∞-category $\mathrm{QCoh}(X)$.

Proof. Let $\mathrm{Mod}^X_{\mathrm{cn}}$ be the ∞-category introduced in Definition 17.2.4.2. We define functors $F', F, F'' : \mathrm{Mod}^X_{\mathrm{cn}} \to \mathcal{S}$ by the formulae

$$F'(R, \eta, M) = \mathrm{fib}(X(R \oplus M) \to Y(R \oplus M) \times_{Y(M)} X(M))$$

$$F(R, \eta, M) = \mathrm{fib}(X(R \oplus M) \to Z(R \oplus M) \times_{Z(M)} X(M))$$

$$F''(R, \eta, M) = \mathrm{fib}(Y(R \oplus M) \to Z(R \oplus M) \times_{Z(M)} Y(M)),$$

so that we have a fiber sequence of functors $F' \to F \xrightarrow{\alpha} F''$. Let $\theta : (\mathrm{QCoh}(X)^{\mathrm{acn}})^{\mathrm{op}} \to \mathrm{Fun}(\mathrm{Mod}^X_{\mathrm{cn}}, \mathcal{S})$ be the fully faithful functor of Proposition 17.2.3.2. Since g and h admit cotangent complexes, we have equivalences $F \simeq \theta(L_{X/Z})$ and $F'' \simeq \theta(f^* L_{Y/Z})$. Since θ is fully faithful, the natural transformation α is induced by a map $\beta : f^* L_{Y/Z} \to L_{X/Z}$. It follows from Remark 17.2.3.3 that F' is equivalent to $\theta(\mathrm{cofib}(\beta))$. □

Corollary 17.2.5.3. *Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Suppose that X and Y admit cotangent complexes L_X and L_Y. Then f admits a cotangent complex. Moreover, we have a canonical fiber sequence $f^* L_Y \to L_X \to L_{X/Y}$ in the stable ∞-category $\mathrm{QCoh}(X)$.*

Corollary 17.2.5.4. *Let $\phi : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks, and let $f : X \to Y$ be the induced map between the functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ represented by X and Y. Then f admits a cotangent complex. Moreover, we can identify $L_{X/Y}$ with the image of the relative cotangent complex $L_{\mathsf{X}/\mathsf{Y}}$ under the equivalence of ∞-categories $\mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(X)$.*

Proof. Combine Corollary 17.2.5.3 with Proposition 17.2.5.1. □

17.3 Cohesive, Nilcomplete, and Integrable Functors

For every spectral Deligne-Mumford stack X, let $h_{\mathsf{X}} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ denote the functor represented by X, given by the formula $h_{\mathsf{X}}(R) = \mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Spét}\, R, \mathsf{X})$. According to Theorem **??**, the construction $\mathsf{X} \mapsto h_{\mathsf{X}}$ determines a fully faithful embedding from the ∞-category SpDM of spectral Deligne-Mumford stacks to the ∞-category $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ of $\mathcal{S}$-valued functors on $\mathrm{CAlg}^{\mathrm{cn}}$. This embedding h is useful in part because the target ∞-category $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ has very strong closure properties: for example, it admits all small limits and colimits, while the ∞-category SpDM does not. Beware, however, that there are several *naturally occurring* colimits in the ∞-category SpDM which are not preserved by the functor h:

(*a*) Let $\{\mathsf{X}_\alpha\}$ be a (small) diagram of spectral Deligne-Mumford stacks in which the transition morphisms $\mathsf{X}_\alpha \to \mathsf{X}_\beta$ are étale. Then there exists a colimit $\mathsf{X} = \varinjlim \mathsf{X}_\alpha$ in the ∞-category of spectral Deligne-Mumford stacks. However, the canonical map $\varinjlim h_{\mathsf{X}_\alpha} \to h_{\mathsf{X}}$ is generally not an equivalence.

(*b*) Suppose we are given a pullback diagram of connective $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc} A' & \longrightarrow & A \\ \downarrow & & \downarrow f \\ B' & \xrightarrow{g} & B, \end{array}$$

where f and g induce surjective ring homomorphisms $\pi_0 A \to \pi_0 B \leftarrow \pi_0 B'$. Then the associated diagram of closed immersions

$$\begin{array}{ccc} \mathrm{Spét}\, A' & \longleftarrow & \mathrm{Spét}\, A \\ \uparrow & & \uparrow \\ \mathrm{Spét}\, B' & \longleftarrow & \mathrm{Spét}\, B \end{array}$$

is a pushout square (see Proposition 16.1.3.1). However, this pushout square is usually not preserved by the functor $h : \mathrm{SpDM} \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$.

(c) Let R be a connective $\mathbb{E}_\infty$-ring. Then the affine spectral algebraic space $\mathrm{Spét}\, R$ can be identified with the colimit of the diagram $\{\mathrm{Spét}\, \tau_{\leqslant n} R\}_{n \geqslant 0}$ (Proposition 17.3.2.3). However, this colimit is not preserved by the functor $h : \mathrm{SpDM} \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ unless R is truncated.

(d) Let R be a complete local Noetherian ring with maximal ideal $\mathfrak{m}$. Then the affine spectral algebraic space $\mathrm{Spét}\, R$ can be identified with the colimit of the diagram $\{\mathrm{Spét}\, R/\mathfrak{m}^n\}$ in the ∞-category of spectral algebraic spaces (Proposition 17.3.4.2). However, this colimit is not preserved by the functor h unless $\mathfrak{m}$ is nilpotent.

In case (a), we can remedy the situation by replacing the ∞-category $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ by the full subcategory $\mathcal{S}\mathrm{hv}_{\mathrm{ét}}(\mathrm{CAlg}^{\mathrm{cn}})$ spanned by those functors which are sheaves with respect to the étale topology. Our goal in this section is to introduce the classes of *cohesive*, *nilcomplete*, and *integrable* functors $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ (see Definitions 17.3.1.1, 17.3.2.1, and 17.3.4.1), which provide analogous remedies for (b), (c), and (a slight variant of) (d).

17.3.1 Cohesive Functors

We begin by studying functors $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ which are, in some sense, compatible with gluing along closed immersions.

Definition 17.3.1.1. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor. We will say that X is *cohesive* if it satisfies the following condition:

($*$) For every pullback diagram

$$\begin{array}{ccc} A' & \longrightarrow & A \\ \downarrow & & \downarrow f \\ B' & \xrightarrow{g} & B \end{array}$$

in $\mathrm{CAlg}^{\mathrm{cn}}$ for which the maps $\pi_0 A \to \pi_0 B$ and $\pi_0 B' \to \pi_0 B$ are surjective, the induced diagram

$$\begin{array}{ccc} X(A') & \longrightarrow & X(A) \\ \downarrow & & \downarrow X(f) \\ X(B') & \xrightarrow{X(g)} & X(B) \end{array}$$

is a pullback square in $\mathcal{S}$.

Example 17.3.1.2. Let X be a locally spectrally ringed ∞-topos, and let $h_{\mathsf{X}} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be the functor given by $h_{\mathsf{X}}(R) = \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{X})$ be the functor represented by X. Then h_{X} is cohesive (Proposition 16.1.3.1). In particular, any functor which is representable by a (formal) spectral Deligne-Mumford stack is cohesive.

Example 17.3.1.3. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a geometric stack, in the sense of Definition 9.3.0.1. Then X is cohesive: this follows by Theorem 9.3.0.3, Theorem 16.2.0.2, and Proposition 16.2.3.1.

Remark 17.3.1.4. Using Proposition 16.1.3.1, we can reformulate condition $(*)$ of Definition 17.3.1.1 as follows:

$(*')$ For every pushout diagram of spectral Deligne-Mumford stacks σ :

$$\begin{array}{ccc} \mathsf{Y}_{01} & \xrightarrow{i} & \mathsf{Y}_0 \\ \downarrow{\scriptstyle j} & & \downarrow \\ \mathsf{Y}_1 & \longrightarrow & \mathsf{Y}, \end{array}$$

where i and j are closed immersions and Y is affine, the associated diagram

$$\begin{array}{ccc} \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}},\mathcal{S})}(h_{\mathsf{Y}_{01}}, X) & \longleftarrow & \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}},\mathcal{S})}(h_{\mathsf{Y}_0}, X) \\ \uparrow & & \uparrow \\ \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}},\mathcal{S})}(h_{\mathsf{Y}_1}, X) & \longleftarrow & \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}},\mathcal{S})}(h_{\mathsf{Y}}, X) \end{array}$$

is a pullback square of spaces.

If X is cohesive and satisfies étale descent, then condition $(*')$ holds more generally without the assumption that Y is affine.

In the study of deformation theory, it will be useful to consider the following variant of Definition 17.3.1.1:

Definition 17.3.1.5. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor. We will say that X is *infinitesimally cohesive* if the following condition is satisfied:

$(*)$ Suppose we are given a pullback diagram

$$\begin{array}{ccc} A' & \longrightarrow & A \\ \downarrow & & \downarrow{\scriptstyle f} \\ B' & \xrightarrow{g} & B \end{array}$$

in $\mathrm{CAlg}^{\mathrm{cn}}$, where the maps $\pi_0 A \to \pi_0 B$ and $\pi_0 B' \to \pi_0 B$ are surjections of commutative rings whose kernels are nilpotent ideals in $\pi_0 A$ and $\pi_0 B'$. Then the induced diagram

$$\begin{array}{ccc} X(A') & \longrightarrow & X(A) \\ \downarrow & & \downarrow{\scriptstyle f} \\ X(B') & \xrightarrow{g} & X(B) \end{array}$$

is a pullback square in $\mathcal{S}$.

Remark 17.3.1.6. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor. If X is cohesive, then X is infinitesimally cohesive. In particular, if X is representable by a (formal) spectral Deligne-Mumford stack, then X is infinitesimally cohesive.

Remark 17.3.1.7. Let $\{X_\alpha\}_{\alpha \in A}$ be a filtered diagram of functors from $\mathrm{CAlg}^{\mathrm{cn}}$ to $\mathcal{S}$ having colimit X. If each X_α is cohesive (infinitesimally cohesive), then so is X.

Remark 17.3.1.8. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Let R be a connective $\mathbb{E}_\infty$-ring, and let $\widetilde{R}$ be a square-zero extension of R by a connective R-module M, classified by a map of R-modules $d : L_R \to \Sigma M$. We then have a commutative diagram of spaces σ :

$$\begin{array}{ccc} X(\widetilde{R}) & \longrightarrow & X(R) \\ \downarrow & & \downarrow \\ X(R) & \longrightarrow & X(R \oplus \Sigma M). \end{array}$$

Let η be a point of $X(R)$ and let $X(\widetilde{R})_\eta$ denote the fiber product $X(\widetilde{R}) \times_{X(R)} \{\eta\}$. Suppose that X admits a cotangent complex L_X, so that we can identify $\eta^* L_X$ with an R-module. Let ν denote the composite map $\eta^* L_X \to L_R \xrightarrow{d} \Sigma M$. Then the diagram σ determines a map $\theta : X(\widetilde{R})_\eta \to P$, where P denotes the space of paths from ν to the base point of the mapping space $\mathrm{Map}_{\mathrm{Mod}_R}(\eta^* L_X, \Sigma M)$. If X is infinitesimally cohesive, then σ is a pullback diagram, so that θ is a homotopy equivalence. In this case, η can be lifted to a point of $X(\widetilde{R})$ if and only if ν represents the zero element of the abelian group $\mathrm{Ext}^1_R(\eta^* L_X, M)$.

We can summarize Remark 17.3.1.8 informally as follows: if $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ is an infinitesimally cohesive functor which admits a cotangent complex L_X, then L_X "controls" the deformation theory of the functor X. We will later prove that the converse holds under some additional assumptions (Proposition 17.3.6.1).

17.3.2 Nilcomplete Functors

We now study functors $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ which are determined by their values on truncated $\mathbb{E}_\infty$-rings.

Definition 17.3.2.1. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor. We will say that X is *nilcomplete* if, for every connective $\mathbb{E}_\infty$-ring R, the canonical map $X(R) \to \varprojlim X(\tau_{\leqslant n} R)$ is a homotopy equivalence.

Remark 17.3.2.2. Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack, and let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be an arbitrary functor. For each $n \geqslant 0$, let $\tau_{\leqslant n} \mathsf{X} = (\mathcal{X}, \tau_{\leqslant n} \mathcal{O}_{\mathcal{X}})$. We then have a canonical map

$$\theta : \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(h_{\mathsf{X}}, X) \to \varprojlim \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(h_{\tau_{\leqslant n} \mathsf{X}}, X).$$

If X is affine and X is nilcomplete, then the map θ is a homotopy equivalence. It follows that if X is nilcomplete and satisfies étale descent, then θ is a homotopy equivalence for an arbitrary spectral Deligne-Mumford stack X.

Proposition 17.3.2.3. *Let $\mathsf{X} = (\mathcal{X}, \mathcal{O})$ be a locally spectrally ringed ∞-topos, and assume that the sheaf $\mathcal{O}$ is connective. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be the functor represented by X (so that X is given by the formula $X(R) = \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{X})$). Then X is nilcomplete.*

Proof. Fix a connective $\mathbb{E}_\infty$-ring R and write $\mathrm{Sp\acute{e}t}\, R = (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$. We note that for every integer $n \geqslant 0$, we have an equivalence $\mathrm{Sp\acute{e}t}\, \tau_{\leqslant n} R \simeq (\mathcal{Y}, \tau_{\leqslant n} \mathcal{O}_{\mathcal{Y}})$. We wish to show that the canonical map

$$\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}((\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}), \mathsf{X}) \to \varprojlim_n \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}((\mathcal{Y}, \tau_{\leqslant n} \mathcal{O}_{\mathcal{Y}}), \mathsf{X})$$

is a homotopy equivalence. Note that a map of spectrally ringed ∞-topoi $(\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) \to \mathsf{X}$ is local if and only if the induced map $(\mathcal{Y}, \tau_{\leqslant 0} \mathcal{O}_{\mathcal{Y}}) \to \mathsf{X}$ is local; it will therefore suffice to show that the map

$$\theta : \mathrm{Map}_{\mathrm{RTop}}((\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}), \mathsf{X}) \to \varprojlim_n \mathrm{Map}_{\mathrm{RTop}}((\mathcal{Y}, \tau_{\leqslant n} \mathcal{O}_{\mathcal{Y}}), \mathsf{X})$$

is a homotopy equivalence. Let $\mathrm{Fun}^*(\mathcal{X}, \mathcal{Y})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{X}, \mathcal{Y})$ spanned by the geometric morphisms $f^* : \mathcal{X} \to \mathcal{Y}$. To prove that θ is a homotopy equivalence, it will suffice to show that it induces a homotopy equivalence after passing to the homotopy fiber over any geometric morphism $f^* \in \mathrm{Fun}^*(\mathcal{X}, \mathcal{Y})^{\simeq}$. In other words, we must show that the canonical map $\mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{Y})}(f^* \mathcal{O}, \mathcal{O}_{\mathcal{Y}}) \to \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{Y})}(f^* \mathcal{O}, \tau_{\leqslant n} \mathcal{O}_{\mathcal{Y}})$ is an equivalence. For this, it suffices to show that $\mathcal{O}_{\mathcal{Y}} \simeq \varprojlim \tau_{\leqslant n} \mathcal{O}_{\mathcal{Y}}$, which was established in the proof of Theorem 1.4.8.1. □

The following reformulation of Definition 17.3.2.1 is sometimes convenient:

Proposition 17.3.2.4. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor. The following conditions are equivalent:*

(1) *The functor X is nilcomplete.*

(2) *Suppose we are given a tower of connective $\mathbb{E}_\infty$-rings*

$$\cdots \to R(2) \to R(1) \to R(0)$$

satisfying the following condition: for every integer n, the tower of abelian groups

$$\cdots \to \pi_n R(2) \to \pi_n R(1) \to \pi_n R(0)$$

is eventually constant. Then the canonical map $X(\varprojlim R(n)) \to \varprojlim X(R(n))$ is a homotopy equivalence.

Proof. Let R be an arbitrary connective $\mathbb{E}_\infty$-ring. Then the Postnikov tower

$$\cdots \to \tau_{\leqslant 2} R \to \tau_{\leqslant 1} R \to \tau_{\leqslant 0} R$$

satisfies the hypothesis appearing in condition (2). It follows that (2) $\Rightarrow$ (1). For the converse, let us assume that X is nilcomplete and let

$$\cdots \to R(2) \to R(1) \to R(0)$$

be a tower of connective $\mathbb{E}_\infty$-rings satisfying the hypothesis of (2). Set $R = \varprojlim R(n)$. We have a commutative diagram

$$\begin{array}{ccc} X(R) & \longrightarrow & \varprojlim_n X(R(n)) \\ \downarrow & & \downarrow \\ \varprojlim_m X(\tau_{\leqslant m} R) & \longrightarrow & \varprojlim_{n,m} X(\tau_{\leqslant m} R(n)) \end{array}$$

Since X is nilcomplete, the vertical maps in this diagram are homotopy equivalences. Consequently, to show that the upper horizontal map is a homotopy equivalence, it suffices to show that the lower horizontal map is a homotopy equivalence. For this, it suffices to show that for every $m \geqslant 0$, the map $X(\tau_{\leqslant m} R) \to \varprojlim_n X(\tau_{\leqslant m} R(n))$ is a homotopy equivalence. This is clear, since the tower

$$\cdots \to \tau_{\leqslant m} R(2) \to \tau_{\leqslant m} R(1) \to \tau_{\leqslant m} R(0)$$

is eventually constant (with value $\tau_{\leqslant m} R$). □

The following result will be needed in §17.5:

Proposition 17.3.2.5. *Let R be a connective $\mathbb{E}_\infty$-ring, let $Y = \operatorname{Spec} R$, let $f : X \to Y$ be a morphism in $\operatorname{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$, and let $X_0 : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ denote the functor given by $X_0(A) = \operatorname{fib}(X(A) \to Y(A))$. Suppose that the following conditions are satisfied:*

(*a*) *For every morphism* $A \to B$ *in* $\mathrm{CAlg}_R^{\mathrm{cn}}$ *every connective* B*-module* M*, the diagram*

$$\begin{array}{ccc} X_0(A \oplus M) & \longrightarrow & X_0(B \oplus M) \\ \downarrow & & \downarrow \\ X_0(A) & \longrightarrow & X_0(B) \end{array}$$

is a pullback square.

(*b*) *For every truncated object* $A \in \mathrm{CAlg}_R^{\mathrm{cn}}$ *and every point* $\eta \in X_0(A)$*, the functor* F_η *given by* $F_\eta(M) = X_0(A \oplus M) \times_{X_0(A)} \{\eta\}$ *is corepresentable by an almost connective* A*-module* $L_{X/Y}(\eta)$*.*

(*c*) *The functor* X *is nilcomplete.*

Then f *admits a cotangent complex.*

Proof. Using assumption (*a*) and the argument of Example 17.2.4.4, we are reduced to proving that for every $A \in \mathrm{CAlg}_R^{\mathrm{cn}}$ and every point $\eta \in X_0(A)$, the functor F_η described in (*b*) is almost corepresentable. For every integer $n \geqslant 0$, let η_n denote the image of η in $X_0(\tau_{\leqslant n} A)$. Then assumption (*b*) guarantees the existence of almost connective objects $L_{X/Y}(\eta_n)$ corepresenting the functors F_{η_n}, and (*a*) gives equivalences

$$\tau_{\leqslant n-1} A \otimes_{\tau_{\leqslant n} A} L_{X/Y}(\eta_n) \simeq L_{X/Y}(\eta_{n-1})$$

for $n > 0$. Choose an integer m such that $L_X(\eta_0)$ is m-connective. It follows that each $L_{X/Y}(\eta_n)$ is m-connective, and that the maps $L_{X/Y}(\eta_n) \to L_{X/Y}(\eta_{n-1})$ are $(m+n)$-connective for $n > 0$. Let N denote the limit of the tower

$$\cdots \to L_{X/Y}(\eta_2) \to L_{X/Y}(\eta_1) \to L_{X/Y}(\eta_0)$$

in the ∞-category Mod_A. Then N is m-connective, and the canonical map $N \to L_{X/Y}(\eta_n)$ is $(m+n+1)$-connective for every integer n. Let M be a connective A-module. We may assume without loss of generality that $m \leqslant 0$. Using assumptions (*a*) and (*c*), we obtain homotopy equivalences

$$\begin{aligned}
F_\eta(M) &\simeq \varprojlim_k F_\eta(\tau_{\leqslant k+m} M) \\
&\simeq \varprojlim_k F_{\eta_k}(\tau_{\leqslant k+m} M) \\
&\simeq \varprojlim_k \mathrm{Map}_{\mathrm{Mod}_{\tau_{\leqslant k} A}}(L_{X/Y}(\eta_k), \tau_{\leqslant k+m} M) \\
&\simeq \varprojlim_k \mathrm{Map}_{\mathrm{Mod}_{\tau_{\leqslant k} A}}(\tau_{\leqslant k+m} L_{X/Y}(\eta_k), \tau_{\leqslant k+m} M) \\
&\simeq \varprojlim_k \mathrm{Map}_{\mathrm{Mod}_A}(\tau_{\leqslant k+m} L_{X/Y}(\eta_k), \tau_{\leqslant k+m} M) \\
&\simeq \varprojlim_k \mathrm{Map}_{\mathrm{Mod}_A}(N, \tau_{\leqslant k+m} M) \\
&\simeq \mathrm{Map}_{\mathrm{Mod}_A}(N, M)
\end{aligned}$$

depending functorially on M. It follows that the functor F_η is corepresented by the A-module N. □

17.3.3 Nilcompletion

The failure of a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ to be nilcomplete can be corrected.

Definition 17.3.3.1. Let $u : X \to \widehat{X}$ be a natural transformation between functors $X, \widehat{X} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. We will say that *$u$ exhibits $\widehat{X}$ as a nilcompletion of X* if the following conditions are satisfied:

(a) The functor $\widehat{X}$ is nilcomplete.

(b) For every nilcomplete functor $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, composition with u induces a homotopy equivalence $\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(\widehat{X}, Y) \to \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(X, Y)$.

It is immediate from the definition that if a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ admits a nilcompletion $\widehat{X}$, then $\widehat{X}$ is uniquely determined up to equivalence and depends functorially on X. For existence, we note the following:

Proposition 17.3.3.2. *Every functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ admits a nilcompletion $\widehat{X}$, given concretely by the formula $\widehat{X}(R) = \varprojlim_n X(\tau_{\leqslant n} R)$.*

Proof. Let $\mathcal{C} \subseteq \mathrm{CAlg}^{\mathrm{cn}}$ denote the full subcategory spanned by the truncated objects. Note that the canonical map $X(R) \to \widehat{X}(R)$ is a homotopy equivalence for $R \in \mathcal{C}$. It follows that $\widehat{X}$ is nilcomplete. Moreover, if $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ is nilcomplete, then Y is a right Kan extension of $Y|_{\mathcal{C}}$. It follows that the canonical map $\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(\widehat{X}, Y) \to \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(X, Y)$ can be identified with $\mathrm{Map}_{\mathrm{Fun}(\mathcal{C}, \mathcal{S})}(\widehat{X}|_{\mathcal{C}}, Y|_{\mathcal{C}}) \to \mathrm{Map}_{\mathrm{Fun}(\mathcal{C}, \mathcal{S})}(X|_{\mathcal{C}}, Y|_{\mathcal{C}})$. □

Remark 17.3.3.3. In the situation of Proposition 17.3.3.2, we can also write $\widehat{X}(R) \simeq \varprojlim X(R_n)$ for *any* tower $\{R_n\}$ of truncated objects of $\mathrm{CAlg}^{\mathrm{cn}}_R$, provided that the maps $R \to R_n$ become m-connective for $n \gg m$.

We now show that the process of nilcompletion has a mild effect on the deformation theory of a functor X.

Proposition 17.3.3.4. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor and let $\widehat{X}$ be its nilcompletion. If X is cohesive (infinitesimally cohesive), then $\widehat{X}$ has the same property.*

Proof. We show that if X is cohesive, then $\widehat{X}$ is cohesive; the proof for infinitesimally cohesive functors is the same. Suppose we are given a pullback diagram of connective $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc} A' & \longrightarrow & A \\ \downarrow & & \downarrow f \\ B' & \xrightarrow{g} & B, \end{array}$$

where the ring homomorphisms $\pi_0 A \to \pi_0 B$ and $\pi_0 B' \to \pi_0 B$ are surjective. We wish to show that the diagram σ :

$$\begin{array}{ccc} \widehat{X}(A') & \longrightarrow & \widehat{X}(A) \\ \downarrow & & \downarrow \\ \widehat{X}(B') & \longrightarrow & \widehat{X}(B) \end{array}$$

is a pullback square of spaces. Using the description of $\widehat{X}$ supplied by Proposition 17.3.3.2 (and Remark **??**), we deduce that σ is the limit of a tower of diagrams σ_n :

$$\begin{array}{ccc} X(\tau_{\leqslant n} A \times_{\tau_{\leqslant n} B} \tau_{\leqslant n} B') & \longrightarrow & X(\tau_{\leqslant n} A) \\ \downarrow & & \downarrow \\ X(\tau_{\leqslant n} B') & \longrightarrow & X(\tau_{\leqslant n} B), \end{array}$$

each of which is a pullback square by virtue of our assumption that X is cohesive. □

Proposition 17.3.3.5. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor and let $\widehat{X}$ be its nilcompletion. Then the restriction map $\mathrm{QCoh}(\widehat{X}) \to \mathrm{QCoh}(X)$ induces an equivalence of ∞-categories $\mathrm{QCoh}(\widehat{X})^{\mathrm{acn}} \to \mathrm{QCoh}(X)^{\mathrm{acn}}$.*

Proof. Let $\mathcal{C} \subseteq \mathrm{CAlg}^{\mathrm{cn}}$ be the full subcategory spanned by the truncated objects. We prove, more generally, that for any natural transformation $f : X \to Y$ between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, if the induced map $X|_{\mathcal{C}} \to Y|_{\mathcal{C}}$ is an equivalence, then the restriction functor

$\mathrm{QCoh}(Y)^{\mathrm{acn}} \to \mathrm{QCoh}(X)^{\mathrm{acn}}$ is also an equivalence. For every functor $U : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, let U' be a left Kan extension of $U|_{\mathcal{C}}$. We then have a commutative diagram of pullback functors

$$\begin{array}{ccc} \mathrm{QCoh}(Y)^{\mathrm{acn}} & \xrightarrow{f^*} & \mathrm{QCoh}(X)^{\mathrm{acn}} \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(Y')^{\mathrm{acn}} & \longrightarrow & \mathrm{QCoh}(X')^{\mathrm{acn}}, \end{array}$$

where the lower horizontal map is an equivalence. It will therefore suffice to show that the vertical maps are equivalences. In other words, we are reduced to proving that for every functor $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, the restriction functor $u_Y^* : \mathrm{QCoh}(Y)^{\mathrm{acn}} \to \mathrm{QCoh}(Y')^{\mathrm{acn}}$ is an equivalence. Note that the construction $Y \mapsto u_Y^*$ carries colimits in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ to limits in $\mathrm{Fun}(\Delta^1, \widehat{\mathcal{C}\mathrm{at}_\infty})$. We can therefore reduce to the case where the functor $Y = h^R$ is the functor corepresented by an $\mathbb{E}_\infty$-ring R. In this case, we can identify u_Y^* with the natural map

$$\mathrm{Mod}_R^{\mathrm{acn}} \to \varprojlim_n \mathrm{Mod}_{\tau_{\leq n} R}^{\mathrm{acn}} \qquad M \mapsto \{\tau_{\leq n} R \otimes_R M\},$$

which is evidently an equivalence of ∞-categories. □

Proposition 17.3.3.6. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor and let $\widehat{X}$ be its nilcompletion. Suppose that X admits a cotangent complex L_X. Then $\widehat{X}$ admits a cotangent complex $L_{\widehat{X}} \in \mathrm{QCoh}(\widehat{X})^{\mathrm{acn}}$.*

Proof. We will show that the functor $\widehat{X}$ satisfies conditions (a) and (b) of Remark 17.2.4.3. Let A be a connective $\mathbb{E}_\infty$-ring and let $\eta \in \widehat{X}(A)$. Then η determines a compatible sequence of points $\eta_n \in X(\tau_{\leq n} A)$. For each $n \geq 0$, we regard $\eta_n^* L_X$ as a module over $\tau_{\leq n} A$. Choose an integer m such that $\eta_0^* L_X$ is $(-m)$-connective; it then follows that $\eta_n^* L_X$ is $(-m)$-connective for each $n \geq 0$ (Proposition 2.7.3.2). Set $K = \varprojlim \eta_n^* L_X$, so that K is a $(-m)$-connected A-module and the canonical map $(\tau_{\leq n} A) \otimes_A K \to \eta_n^* L_X$ is an equivalence for each n. For every A-module M, we have canonical homotopy equivalences

$$\begin{aligned} \widehat{X}(A \oplus M) \times_{\widehat{X}(A)} \{\eta\} &\simeq \varprojlim_n X((\tau_{\leq n} A) \oplus (\tau_{\leq n} M)) \times_{X(\tau_{\leq n} A)} \{\eta_n\} \\ &\simeq \varprojlim_n \mathrm{Map}_{\mathrm{Mod}_{\tau_{\leq n} A}}(\eta_n^* L_X, \tau_{\leq n} M) \\ &\simeq \varprojlim_n \mathrm{Map}_{\mathrm{Mod}_A}(K, \tau_{\leq n} M) \\ &\simeq \mathrm{Map}_{\mathrm{Mod}_A}(K, M). \end{aligned}$$

This completes the verification of condition (a). To prove (b), suppose we are given a morphism of connective $\mathbb{E}_\infty$-rings $A \to A'$. Let η'_n denote the image of η in $X(\tau_{\leq n} A')$ and set $K' = \varprojlim \eta'^*_n L_X$. We wish to show that the canonical map $\theta : A' \otimes_A K \to K'$ is an equivalence. To prove this, we note that for each $n \geqslant 0$, the n-truncation of θ agrees with the n-truncation of the canonical map $(\tau_{\leqslant n+m} A') \otimes_{\tau_{\leqslant n+m} A} \eta^*_{n+m} L_X \to \eta'^*_{n+m} L_X$, which is an equivalence by virtue of our assumption that X satisfies condition (b) of Remark 17.2.4.3. □

Remark 17.3.3.7. In the situation of Proposition 17.3.3.6, the canonical map $L_{\widehat{X}}|_X \to L_X$ is an equivalence: in other words, the cotangent complex $L_{\widehat{X}}$ is the image of L_X under the equivalence $\mathrm{QCoh}(X)^{\mathrm{acn}} \to \mathrm{QCoh}(\widehat{X})^{\mathrm{acn}}$ of Proposition 17.3.3.5. In particular, the relative cotangent complex $L_{X/\widehat{X}}$ vanishes.

17.3.4 Integrable Functors

Let A be a connective $\mathbb{E}_\infty$-ring which is complete with respect to a finitely generated ideal $I \subseteq \pi_0 A$, and let $\mathrm{Spf}\, A$ denote the formal spectrum of A (Construction 8.1.1.10). According to Theorem 8.5.3.1, the restriction map

$$\mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, A, \mathsf{X}) \to \mathrm{Map}_{\mathrm{fSpDM}}(\mathrm{Spf}\, A, \mathsf{X})$$

is a homotopy equivalence whenever X is a quasi-separated spectral algebraic space. If A is Noetherian and the ideal $I \subseteq \pi_0 A$ is maximal, then the same assertion holds more generally for any spectral Deligne-Mumford n-stack X (see Proposition 17.3.4.2 below). Motivated by this observation, we introduce the following:

Definition 17.3.4.1. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor. We will say that X is *integrable* if the following condition is satisfied:

$(*)$ Let A be a local Noetherian $\mathbb{E}_\infty$-ring which is complete with respect to its maximal ideal $\mathfrak{m} \subseteq \pi_0 A$. Then the inclusion of functors $\mathrm{Spf}\, A \hookrightarrow \mathrm{Spec}\, A$ induces a homotopy equivalence

$$X(A) \simeq \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(\mathrm{Spec}\, A, X) \to \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(\mathrm{Spf}\, A, X).$$

Here we abuse notation by identifying the formal spectrum $\mathrm{Spf}\, A$ with the functor that it represents (see Theorem 8.1.5.1).

Proposition 17.3.4.2. *Let X be a spectral Deligne-Mumford n-stack for some $n < \infty$ and let X denote the functor represented by X. Then X is integrable.*

Proof. Let A be a local Noetherian $\mathbb{E}_\infty$-ring which is complete with respect to its maximal ideal and let $\mathrm{Spf}\, A$ denote the formal spectrum of A, which we regard as an object of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. Choose a tower of A-algebras

$$\cdots \to A_2 \to A_1 \to A_0$$

satisfying the requirements of Lemma 8.1.2.2, so that $\operatorname{Spf} A \simeq \varinjlim \operatorname{Spec} A_n$ (Proposition 8.1.5.2). Each of the maps $\pi_0 A_i \to \pi_0 A_0$ is surjective with nilpotent kernel, and therefore induces an equivalence of ∞-categories $\mathrm{CAlg}^{\text{ét}}_{A_i} \to \mathrm{CAlg}^{\text{ét}}_{A_0}$. For every functor $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ satisfying étale descent, let $Y(m) \in \mathcal{S}\mathrm{hv}^{\text{ét}}_{A_0}$ be the functor given by the composition

$$\mathrm{CAlg}^{\text{ét}}_{A_0} \simeq \mathrm{CAlg}^{\text{ét}}_{A_m} \to \mathrm{CAlg}^{\mathrm{cn}} \xrightarrow{Y} \mathcal{S},$$

and let $Y(\infty)$ denote the image of $(Y|_{\mathrm{CAlg}^{\text{ét}}_A}) \in \mathcal{S}\mathrm{hv}^{\text{ét}}_A$ under the pullback map $\mathcal{S}\mathrm{hv}^{\text{ét}}_A \to \mathcal{S}\mathrm{hv}^{\text{ét}}_{A_0}$. Then the canonical map $X(A) \to \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(\operatorname{Spf} A, X) \to \varprojlim_{m \geqslant 0} X(A_m)$ can be identified with the composition

$$X(A) \xrightarrow{\theta} X(\infty)(A_0) \xrightarrow{\theta'} \varprojlim_m X(m)(A_0).$$

Proposition B.3.1.4 implies that A is Henselian, so that θ is a homotopy equivalence by Proposition B.6.5.4. To prove that θ' is a homotopy equivalence, it will suffice to verify the following assertion:

$(*)$ Let $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor which is representable by a spectral Deligne-Mumford n-stack. Then the canonical map $\phi_Y : Y(\infty) \to \varprojlim Y(m)$ is an equivalence in the ∞-topos $\mathcal{S}\mathrm{hv}^{\text{ét}}_{A_0}$.

To prove $(*)$, choose an étale surjection $u : Y_0 \to Y$, where Y_0 is representable by a disjoint union of affine spectral Deligne-Mumford stacks. Let $Y_\bullet$ denote the Čech nerve of u, so that $Y \simeq |Y_\bullet|$. Then ϕ_Y can be identified with the composite map

$$Y(\infty) \simeq |Y_\bullet(\infty)| \xrightarrow{\phi} |\varprojlim_m Y_\bullet(m)| \xrightarrow{\phi'} \varprojlim_m Y(m).$$

We first claim that ϕ' is an equivalence. Note that the simplicial object $\varprojlim_m Y_\bullet$ is given by the Čech nerve of the map $v : \varprojlim Y_0(m) \to \varprojlim Y(m)$. Since $\mathcal{S}\mathrm{hv}^{\text{ét}}_{A_0}$ is an ∞-topos, the map ϕ' is an equivalence if and only if v is an effective epimorphism. Let B_0 be any étale A_0-algebra, so that B_0 admits an essentially unique lift to an étale A_m-algebra B_m for each m. Since u is étale, the canonical map $Y_0(B_m) \to Y_0(B_0) \times_{Y(B_0)} Y(B_m)$ is a homotopy equivalence for each m. It follows that v is a pullback of the map $Y_0 \to Y$, which is an effective epimorphism by virtue of our assumption that u is an étale surjective.

Using the above argument, we see that ϕ_Y is an equivalence if and only if ϕ is an equivalence. Consequently, to prove that ϕ_Y is an equivalence, it will suffice to show that ϕ_{Y_p} is an equivalence. We now proceed by induction on n. If $n > 1$, then each Y_p is representable by a spectral Deligne-Mumford $(n-1)$-stack, so that the desired result follows from the inductive hypothesis. If $n = 1$, then each Y_p is representable by a spectral algebraic space; it will therefore suffice to verify $(*)$ in the special case where Y is representable by a spectral algebraic space. In this case, for each $p \geqslant 0$, the canonical map $Y_p(R) \to Y_0(R)^p$ is injective for every discrete commutative ring R. It will therefore suffice to verify $(*)$ under the assumption that there exists a map $Y \to Z$ which induces a monomorphism $Y(R) \to Z(R)$ for every discrete commutative ring R, where Z is representable by a disjoint union of affine spectral Deligne-Mumford stacks. In this case, each Y_p is itself a disjoint union of affine spectral Deligne-Mumford stacks. It will therefore suffice to verify $(*)$ in the special case $Y = \coprod_\alpha Y_\alpha$, where each Y_α is corepresented by a connective $\mathbb{E}_\infty$-ring R_α.

Let B_0 be an étale A_0-algebra; we wish to show that the canonical map $\gamma : Y(\infty)(B_0) \to \varprojlim Y(m)(B_0)$ is a homotopy equivalence. Without loss of generality, we may suppose that the spectrum of B_0 is connected. In this case, γ is given by a disjoint union of maps $\gamma_\alpha : Y_\alpha(\infty)(B_0) \to Y_\alpha(m)(B_0)$. It will therefore suffice to show that each γ_α is a homotopy equivalence. Let B be a finite étale A-algebra satisfying $B_0 \simeq B \otimes_A A_0$ (see Proposition B.6.5.2). We are then reduced to showing that the canonical map

$$\mathrm{Map}_{\mathrm{CAlg}}(R_\alpha, B) \to \varprojlim_m \mathrm{Map}_{\mathrm{CAlg}}(R_\alpha, \varprojlim(B \otimes_A A_m))$$

is a homotopy equivalence. To prove this, it suffices to show that B is given by the limit of the diagram $\{B \otimes_A A_m\}$. Since B is a finite flat A-module, this follows from the identification $A \simeq \varprojlim_m A_m$. □

17.3.5 An Integrability Criterion

In good cases, the integrability of a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ can be tested at the level of discrete commutative rings:

Proposition 17.3.5.1. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor which is nilcomplete, infinitesimally cohesive, and admits a cotangent complex. The following conditions are equivalent:*

(a) *The functor X is integrable.*

(b) *For every complete local Noetherian ring A, the canonical map*

$$X(A) \simeq \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(\operatorname{Spec} A, X) \to \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(\operatorname{Spf} A, X)$$

is a homotopy equivalence. Here $\operatorname{Spf} A$ denotes the formal spectrum of A (with respect to the maximal ideal of $\pi_0 A$), which we identify with an object of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$.

(c) *For every complete local Noetherian ring A with maximal ideal $\mathfrak{m}$, the canonical map*

$$X(A) \to \varprojlim_n X(A/\mathfrak{m}^n)$$

is a homotopy equivalence.

The proof of Proposition 17.3.5.1 will require some preliminaries.

Lemma 17.3.5.2. *Let A be a Noetherian commutative ring, let $I \subseteq A$ be an ideal, and let M be a finitely generated discrete A-module. For each integer $n > 0$, the tower $\{\mathrm{Tor}_n^A(A/I^m, M)\}_{m \geqslant 0}$ is trivial as a* Pro-*object in the category of A-modules.*

Proof. We proceed by induction on n. Since M is finitely generated, we can choose a surjection $\phi : A^d \to M$. Since A is Noetherian, the kernel $K = \ker(\phi)$ is also finitely generated. For each integer m, we have an exact sequence

$$0 = \mathrm{Tor}_n^A(A/I^m, A^r) \to \mathrm{Tor}_n^A(A/I^m, M) \to \mathrm{Tor}_{n-1}^A(A/I^m, K) \xrightarrow{\psi_m} \mathrm{Tor}_{n-1}^A(A/I^m, A^r).$$

In particular, we obtain a monomorphism of Pro-objects

$$\{\mathrm{Tor}_n^A(A/I^m, M)\}_{m \geqslant 0} \hookrightarrow \{\mathrm{Tor}_{n-1}^A(A/I^m, K)\}_{m \geqslant 0}.$$

If $n > 1$, then the inductive hypothesis implies that $\{\mathrm{Tor}_{n-1}^A(A/I^m, K)\}_{m \geqslant 0}$ vanishes (as a Pro-objects), so that $\{\mathrm{Tor}_n^A(A/I^m, M)\}_{m \geqslant 0}$ also vanishes. If $n = 1$, we are reduced to proving that the maps ψ_m determine a monomorphism $\{K/I^m K\}_{m \geqslant 0} \to \{(A/I^m A)^r\}_{m \geqslant 0}$, which follows from the Artin-Rees lemma. □

Remark 17.3.5.3. Let B be a connective $\mathbb{E}_\infty$-ring, and suppose we are given a tower

$$\cdots \to M_2 \to M_1 \to M_0$$

of discrete B-modules. Then $\{M_m\}_{m \geqslant 0}$ is a zero object of $\mathrm{Pro}(\mathrm{Mod}_B)$ if and only if, for every integer k, there exists an integer $k' \geqslant k$ such that the map $M_{k'} \to M_k$ vanishes. In particular, if we are given a map of connective $\mathbb{E}_\infty$-rings $\phi : A \to B$, then the tower $\{M_m\}_{m \geqslant 0}$ vanishes as a Pro-object of Mod_B if and only if it vanishes as a Pro-object of Mod_A.

Lemma 17.3.5.4. *Let A be a Noetherian commutative ring, let $I \subseteq A$ be an ideal, and let M be a connective A-module such that each homotopy group of M is annihilated by the ideal I. Then, for every integer $n \geqslant 0$, the tower $\{\tau_{\leqslant n}(M \otimes_A A/I^m)\}_{m \geqslant 0}$ is equivalent to $\tau_{\leqslant n} M$ as a* Pro-*object of* Mod_A.

Proof. We may assume without loss of generality that M is truncated (since $\tau_{\leqslant k}(M \otimes_A A/I^m)$ does not change if we replace M by $\tau_{\leqslant k} M$). Writing M as as a successive extension of modules of the form $\Sigma^d(\pi_d M)$, we may reduce to the case where M admits the structure of a module over A/I.

Fix an integer $n \geqslant 0$, and let $\mathcal{C}$ denote the full subcategory of Mod_A spanned by those A-modules which are connective and n-truncated. We may assume without loss of generality that $M \in \mathcal{C}$. We view $\mathcal{C}$ as a symmetric monoidal ∞-category, with tensor product $\otimes^\tau$ given by $N \otimes^\tau N' = \tau_{\leqslant n}(N \otimes_A N')$. We wish to prove that the canonical map

$\theta_M : M \to \{M \otimes^{\tau} A/I^m\}_{m \geqslant 0}$ is an equivalence in $\mathrm{Pro}(\mathcal{C})$. Note that θ_M is given by tensoring M with $\theta_{A/I}$ over A/I. It will therefore suffice to show that $\theta_{A/I}$ is an equivalence when viewed as a morphism in $\mathrm{Pro}(\mathrm{Mod}_{A/I}(\mathcal{C}))$. Unwinding the definitions, we are reduced to proving that $\theta_{A/I}$ determines isomorphisms

$$\{\mathrm{Tor}_d^A(A/I, A/I^m)\}_{m \geqslant 0} \simeq \begin{cases} A/I & \text{if } d = 0 \\ 0 & \text{if } 0 < d \leqslant n. \end{cases}$$

in the abelian category of Pro-objects in discrete A/I-modules. This is obvious when $d = 0$, and follows from Lemma 17.3.5.2 (together with Remark 17.3.5.3) when $d > 0$. □

Remark 17.3.5.5. Let $f : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings, and suppose we are given a tower of morphisms $\{\phi_m : M_m \to N_m\}$ in the abelian category of discrete B-modules. Then $\{\phi_m\}$ is an equivalence of Pro-objects of Mod_B if and only if it is an equivalence of Pro-objects of Mod_A. This follows immediately from Remark 17.3.5.3, applied to the towers $\{\ker(\phi_m)\}$ and $\{\mathrm{coker}(\phi_m)\}$.

Lemma 17.3.5.6. *Let A be a Noetherian commutative ring, let $I \subseteq A$ be an ideal, let R be a connective A-algebra such that the image of I generates a nilpotent ideal in $\pi_0 R$, and let $n \geqslant 0$ be an integer. Then the tower $\{\tau_{\leqslant n}(R \otimes_A A/I^m)\}_{m \geqslant 0}$ is equivalent to $\tau_{\leqslant n} R$ as a* Pro-*object of* CAlg_R.

Proof. Replacing I by a power of I if necessary, we may assume that the image of I vanishes in $\pi_0 R$. We proceed by induction on n, the case $n = 0$ being trivial. To carry out the inductive step, let us suppose that the canonical map

$$\rho : \tau_{\leqslant n-1} R \to \{\tau_{\leqslant n-1}(R \otimes_A A/I^m)\}_{m \geqslant 0}$$

is an equivalence of Pro-objects of CAlg_R. For each integer m, set $K_m = \pi_n(R \otimes_A A/I^m)$ and set $K = \pi_n R$. Applying Theorem HA.7.4.1.26 , we obtain a pullback diagram σ :

$$\begin{array}{ccc} \tau_{\leqslant n} R & \longrightarrow & \tau_{\leqslant n-1} R \\ \downarrow & & \downarrow \\ \tau_{\leqslant n-1} R & \longrightarrow & (\tau_{\leqslant n-1} R) \oplus \Sigma^{n+1} K \end{array}$$

with a map into a tower of pullback diagrams σ_m :

$$\begin{array}{ccc} \tau_{\leqslant n}(R \otimes_A A/I^m) & \longrightarrow & \tau_{\leqslant n-1}(R \otimes_A A/I^m) \\ \downarrow & & \downarrow \\ \tau_{\leqslant n-1}(R \otimes_A A/I^m) & \longrightarrow & \tau_{\leqslant n-1}(R \otimes_A A/I^m) \oplus \Sigma^{n+1} K_m. \end{array}$$

Applying the inductive hypothesis, we are reduced to proving that the canonical map

$$\theta : (\tau_{\leqslant n-1} R) \oplus \Sigma^{n+1} K \to \{\tau_{\leqslant n-1}(R \otimes_A A/I^m) \oplus \Sigma^{n+1} K_m\}_{m \geqslant 0}$$

is an equivalence of Pro-objects of CAlg_R. The map θ factors as a composition

$$(\tau_{\leqslant n-1} R) \oplus \Sigma^{n+1} K \xrightarrow{\theta'} \{\tau_{\leqslant n-1} R \oplus \Sigma^{n+1} K_m\}_{m \geqslant 0} \xrightarrow{\theta''} \{\tau_{\leqslant n-1}(R \otimes_A A/I^m) \oplus \Sigma^{n+1} K_m\}_{m \geqslant 0}$$

where θ'' is a pullback of ρ and therefore an equivalence by the inductive hypothesis. To prove that θ' is an equivalence, it will suffice to show that the canonical map $\nu : K \to \{K_m\}_{m \geqslant 0}$ is an equivalence of Pro-objects in $\tau_{\leqslant n-1} R$. By virtue of Remark 17.3.5.5, it will suffice to show that ν is an equivalence of Pro-objects in Mod_A, which follows from Lemma 17.3.5.4. □

Lemma 17.3.5.7. *Let A be a Noetherian commutative ring, let $I \subseteq A$ be an ideal, and choose a tower of A-algebras*

$$\cdots \to A_2 \to A_1 \to A_0$$

satisfying the requirements of Lemma **??**. *Then, for every integer $m \geqslant 0$, the tower $\{\tau_{\leqslant n} A_m\}_{m \geqslant 0}$ is equivalent (as a pro-object of* CAlg*) to the tower $\{A/I^m\}_{m \geqslant 0}$.*

Proof. It will suffice to show that the canonical map $\{\tau_{\leqslant n} A_m\}_{m \geqslant 0} \to \{A/I^m\}_{m \geqslant 0}$ is an equivalence of Pro-objects of $\tau_{\leqslant n} \mathrm{CAlg}^{\mathrm{cn}}_A$. Let $R \in \tau_{\leqslant n} \mathrm{CAlg}^{\mathrm{cn}}_A$; we wish to show that the canonical map

$$\theta : \varinjlim \mathrm{Map}_{\mathrm{CAlg}_A}(A/I^m, R) \to \varinjlim \mathrm{Map}_{\mathrm{CAlg}_A}(A_m, R)$$

is a homotopy equivalence. If the image of I does not generate a nilpotent ideal in $\pi_0 R$, then the domain and codomain of θ are both empty and there is nothing to prove. Let us therefore suppose that the image of I generates a nilpotent ideal in R; we wish to show that the direct limit $\varinjlim \mathrm{Map}_{\mathrm{CAlg}_A}(A/I^m, R)$ is contractible. Since R is n-truncated, we can rewrite this direct limit as $\varinjlim \mathrm{Map}_{\mathrm{CAlg}_R}(\tau_{\leqslant n}(R \otimes_A A/I^m), R)$, which is contractible by virtue of the fact that the tower $\{\tau_{\leqslant n}(R \otimes_A A/I^m)\}_{m \geqslant 0}$ is equivalent to R as a Pro-object of CAlg_R (Lemma 17.3.5.6). □

Proof of Proposition 17.3.5.1. The implication $(a) \Rightarrow (b)$ is obvious. We next prove that $(b) \Rightarrow (a)$. Let A be a local Noetherian $\mathbb{E}_\infty$-ring which is complete with respect to the maximal ideal $\mathfrak{m} \subseteq \pi_0 A$. Choose a tower of A-algebras $\{A_m\}_{m > 0}$ satisfying the requirements of Lemma 8.1.2.2, so that $\mathrm{Spf}\, A$ represents the functor $\varinjlim_m \mathrm{Spec}\, A_m$. For every connective A-algebra B, we can regard B as an adic $\mathbb{E}_\infty$-ring (with ideal of definition $\mathfrak{m}(\pi_0 B)$), so that the formal spectrum $\mathrm{Spf}\, B$ represents the functor $\varinjlim_m \mathrm{Spec}(A_m \otimes_A B)$. Let θ_B denote the canonical map $X(B) \to \varprojlim_m X(A_m \otimes_A B) \simeq \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(\mathrm{Spf}\, B, X)$. We wish to show that θ_A is a homotopy equivalence.

Consider the diagram

$$\begin{array}{ccc} X(A) & \longrightarrow & \varprojlim_n X(\tau_{\leqslant n} A) \\ \downarrow & & \downarrow \\ \varprojlim_m X(A_m) & \longrightarrow & \varprojlim_{m,n} X(A_m \otimes_A \tau_{\leqslant n} A). \end{array}$$

The upper horizontal map is a homotopy equivalence since X is nilcomplete, and the bottom horizontal map is a homotopy equivalence by Proposition 17.3.2.4. It follows that θ_A can be identified with the limit of the tower of maps $\{\theta_{\tau_{\leqslant n} A}\}_{n \geqslant 0}$. It will therefore suffice to show that each $\theta_{\tau_{\leqslant n} A}$ is a homotopy equivalence. We may therefore replace A by $\tau_{\leqslant n} A$ and thereby reduce to the case where A is n-truncated for some integer n.

If $n = 0$, then A is discrete and the desired result follows from (b). Let us therefore assume that $n > 0$. Let $A' = \tau_{\leqslant n-1} A$ and let $M = \Sigma^{n+1}(\pi_n A)$, so that A fits into a pullback diagram

$$\begin{array}{ccc} A & \longrightarrow & A' \\ \downarrow & & \downarrow \\ A' & \longrightarrow & A' \oplus M. \end{array}$$

Since X is infinitesimally cohesive, we obtain a pullback diagram

$$\begin{array}{ccc} \theta_A & \longrightarrow & \theta_{A'} \\ \downarrow & & \downarrow \\ \theta_{A'} & \longrightarrow & \theta_{A' \oplus M} \end{array}$$

in the ∞-category $\mathrm{Fun}(\Delta^1, \mathcal{S})$. The inductive hypothesis implies that $\theta_{A'}$ is a homotopy equivalence. It will therefore suffice to show that $\theta_{A' \oplus M}$ is a homotopy equivalence. Using the inductive hypothesis, we are reduced to proving that the canonical map

$$\psi : X(A' \oplus M) \rightarrow X(A') \times_{\varprojlim X(A_m \otimes_A A')} \varprojlim X((A_m \otimes_A A') \oplus (A_m \otimes_A M)).$$

Using the assumption that X is infinitesimally cohesive, we can identify the right side with $\varprojlim_m X(A' \oplus (A_m \otimes_A M))$. To show that ψ is a homotopy equivalence, it will suffice to show that ψ induces a homotopy equivalence after passing to the fibers over any point $\eta \in X(A')$. Since X admits a cotangent complex, this is equivalent to the assertion that the canonical map

$$\mathrm{Map}_{\mathrm{Mod}_{A'}}(\eta^* L_X, M) \rightarrow \varprojlim \mathrm{Map}_{\mathrm{Mod}_{A'}}(\eta^* L_X, A_m \otimes_A M).$$

For this, it suffices to show that the canonical map $M \rightarrow \varprojlim_m A_m \otimes_A M$ is an equivalence. Since M is connective, this is equivalent to the requirement that M is $\mathfrak{m}$-complete, where

$\mathfrak{m}$ denotes the maximal ideal of $\pi_0 A$ (Remark ??). This completeness follows from our assumption that A is complete, since M is an almost perfect A-module (Proposition 7.3.5.7). This completes the proof that $(b) \Rightarrow (a)$.

To prove that (b) and (c) are equivalent, it will suffice to show that for every complete local Noetherian ring A with maximal ideal $\mathfrak{m}$, the canonical map $\rho : X(A) \to \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(\mathrm{Spf}\, A, X)$ is a homotopy equivalence if and only if the canonical map $X(A) \to \varprojlim_n X(A/\mathfrak{m}^n)$ is a homotopy equivalence. To prove this, choose $\{A_m\}_{m \geqslant 0}$ as above. Since X is nilcomplete, we can identify ρ with the composite map

$$X(A) \to \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(\mathrm{Spf}\, A, X) \simeq \varprojlim_{m} X(A_m) \simeq \varprojlim_{m,n} X(\tau_{\leqslant n} A_m).$$

The desired result now follows from Lemma 17.3.5.7. □

17.3.6 A Differential Criterion for Infinitesimal Cohesiveness

Our next goal is to establish a converse to Remark 17.3.1.8:

Proposition 17.3.6.1. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a nilcomplete functor which admits a cotangent complex. The following conditions are equivalent:*

(1) *For every pullback diagram*

$$\begin{array}{ccc} A' & \longrightarrow & A \\ \downarrow & & \downarrow{\scriptstyle f} \\ B' & \longrightarrow & B, \end{array}$$

of connective $\mathbb{E}_\infty$-rings, if the map f induces a surjection of commutative rings $\pi_0 A \to \pi_0 B$ with nilpotent kernel, then the diagram of spaces

$$\begin{array}{ccc} X(A') & \longrightarrow & X(A) \\ \downarrow & & \downarrow \\ X(B') & \longrightarrow & X(B) \end{array}$$

is a pullback square.

(2) *The functor X is infinitesimally cohesive.*

(3) *Let R be a connective $\mathbb{E}_\infty$-ring, M a connective R-module, $\eta : L_R \to \Sigma M$ a derivation, and R^η the corresponding square-zero extension of R by M, so that we have a pullback square*

$$\begin{array}{ccc} R^\eta & \longrightarrow & R \\ \downarrow & & \downarrow \\ R & \longrightarrow & R \oplus \Sigma M. \end{array}$$

Then the diagram

$$\begin{array}{ccc} X(R^{\eta}) & \longrightarrow & X(R) \\ \downarrow & & \downarrow \\ X(R) & \longrightarrow & X(R \oplus \Sigma M) \end{array}$$

is a pullback square in $\mathcal{S}$.

Before giving the proof of Proposition 17.3.6.1, let us sketch a sample application:

Proposition 17.3.6.2. *Let $f : X \to Y$ be a natural transformations between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Assume that X and Y are nilcomplete, infinitesimally cohesive and admit cotangent complexes, and that the relative cotangent complex $L_{X/Y}$ is $(n+2)$-connective for some integer $n \geqslant 0$. The following conditions are equivalent:*

(1) *For every commutative ring R (regarded as a discrete $\mathbb{E}_\infty$-ring), the map f induces a homotopy equivalence $X(R) \to Y(R)$.*

(2) *For every n-truncated connective $\mathbb{E}_\infty$-ring R, the map f induces a homotopy equivalence $X(R) \to Y(R)$.*

Proof. The implication (2) ⇒ (1) is obvious. Conversely, suppose that (1) is satisfied. We must show that for every n-truncated connective $\mathbb{E}_\infty$-ring A, the map f induces a homotopy equivalence $f_A : X(A) \to Y(A)$. The proof proceeds by induction on n. When $n = 0$, the desired result follows from (1). If $n > 0$, then $\tau_{\leqslant n} A$ is a square-zero extension of $\tau_{\leqslant n-1} A$ (Corollary HA.7.4.1.28). We therefore have a pullback square of $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc} \tau_{\leqslant n} A & \longrightarrow & \tau_{\leqslant n-1} A \\ \downarrow & & \downarrow \\ \tau_{\leqslant n-1} A & \longrightarrow & \tau_{\leqslant n-1} A \oplus M, \end{array}$$

where $M = \Sigma^{n+1}(\pi_n A)$. Since X and Y are infinitesimally cohesive, to prove that $f_{\tau_{\leqslant n} A}$ is a homotopy equivalence, it will suffice to show that $f_{\tau_{\leqslant n-1} A}$ is a homotopy equivalence and $f_{\tau_{\leqslant n-1} A \oplus M}$ is (-1)-truncated (that is, it is equivalent to the inclusion of a summand). In the first case, this follows from the inductive hypothesis. For the second case, consider the commutative diagram

$$\begin{array}{ccc} X(\tau_{\leqslant n-1} A \oplus M) & \longrightarrow & Y(\tau_{\leqslant n-1} A \oplus M) \\ \downarrow & & \downarrow \\ X(\tau_{\leqslant n-1} A) & \longrightarrow & Y(\tau_{\leqslant n-1} A). \end{array}$$

We wish to prove that the upper horizontal map is (-1)-truncated. Since the bottom horizontal map is a homotopy equivalence, it will suffice to prove that we obtain a (-1)-truncated map after passing to the homotopy fibers over any point $\eta \in X(\tau_{\leqslant n-1}A)$. Unwinding the definitions, we are reduced to proving that the canonical map

$$\mathrm{Map}_{\mathrm{Mod}_{\tau_{\leqslant n-1}A}}(\eta^* L_X, M) \to \mathrm{Map}_{\mathrm{Mod}_{\tau_{\leqslant n-1}A}}(\eta^* f^* L_Y, M)$$

is (-1)-truncated. Using the fiber sequence $\eta^* f^* L_Y \to \eta^* L_X \to \eta^* L_{X/Y}$, we are reduced to proving that $\eta^* L_{X/Y}$ is $(n+2)$-truncated, which follows from our hypothesis. □

Corollary 17.3.6.3. *Let $f : X \to Y$ be a natural transformations between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Assume that X and Y are infinitesimally cohesive, nilcomplete, and admit cotangent complexes. Then f is an equivalence if and only if the following conditions are satisfied:*

(1) *For every commutative ring R (regarded as a discrete $\mathbb{E}_\infty$-ring), the map f induces a homotopy equivalence $X(R) \to Y(R)$.*

(2) *The relative cotangent complex $L_{X/Y}$ is trivial.*

Proof. It is clear that if f is an equivalence then conditions (1) and (2) are satisfied. Conversely, suppose that (1) and (2) are satisfied. We wish to show that for every connective $\mathbb{E}_\infty$-ring R, the canonical map $\theta : X(R) \to Y(R)$ is a homotopy equivalence. Since X and Y are nilcomplete, the map θ is a limit of maps $\theta_n : X(\tau_{\leqslant n}R) \to Y(\tau_{\leqslant n}R)$. It will therefore suffice to show that each θ_n is a homotopy equivalence, which follows from Proposition 17.3.6.2. □

We now turn to the proof of Proposition 17.3.6.1.

Lemma 17.3.6.4. *Let $f : A \to B$ be a map of connective $\mathbb{E}_\infty$-rings. Suppose that f induces a surjection of commutative rings $\pi_0 A \to \pi_0 B$ whose kernel I is a nilpotent ideal of $\pi_0 A$. Then we can write A as the limit of a tower*

$$\cdots \to B(2) \to B(1) = B$$

in the ∞-category $\mathrm{CAlg}_{/B}$ with the following property: each $B(n+1)$ is a square-zero extension of $B(n)$ by a $B(n)$-module $\Sigma^{k_n} M$, where M is discrete and $k_n \geqslant 0$. Moreover, we can assume that the sequence of integers $\{k_n\}_{n \geqslant 0}$ tends to infinity as n grows.

Proof. Choose an integer m such that $I^m = 0$. For $k \leqslant m$, we define $B(k)$ by the formula $B \times_{\pi_0 B} (\pi_0 A / I^k)$. Since $\pi_0 A / I^{k+1}$ is a square-zero extension of $\pi_0 A / I^k$ by I^k / I^{k+1}, we deduce that $B(k+1)$ is a square-zero extension of $B(k)$ by the discrete module I^k / I^{k+1} for $0 < k < m$. We next define $B(k) \in \mathrm{CAlg}_A$ for $k > m$ using induction on k, so that the fiber of the map $A \to B(k)$ is $(k-m)$-connective. Assume that $B(k)$ has been defined for $k \geqslant m$, and let $M = \pi_{k-m} \operatorname{fib}(A \to B(k))$. Since the map $\pi_0 A \to \pi_0 B(k)$ is an isomorphism, Theorem HA.7.4.3.1 implies that $L_{B(k)/A}$ is $(k-m+1)$-connective and that there is a canonical isomorphism $\pi_{k-m+1} L_{B(k)/A} \simeq M$. In particular, there exists a map of $B(k)$-modules $\eta : L_{B(k)/A} \to \Sigma^{k-m+1} M$ which induces an isomorphism $\pi_{k-m+1} L_{B(k)/A} \simeq M$. Let $B(k+1) = B(k)^\eta$ denote the square-zero extension of $B(k)$ by $\Sigma^{k-m} M$ classified by η. We now observe that by construction, the canonical map $A \to B(k+1)$ has $(k-m+1)$-connective fiber. □

Proof of Proposition 17.3.6.1. The implications (1) ⇒ (2) and (2) ⇒ (3) are obvious (and do not require any assumptions on X). Let us prove that (3) ⇒ (1). Suppose we are given a pullback square of connective $\mathbb{E}_\infty$-rings σ :

$$\begin{array}{ccc} A' & \longrightarrow & A \\ \downarrow & & \downarrow \\ B' & \longrightarrow & B, \end{array}$$

where the maps $\pi_0 A \to \pi_0 B$ is a surjection with nilpotent kernel. We wish to show that $X(\sigma)$ is a pullback square in $\mathcal{S}$. Choose a tower

$$\cdots \to B(3) \to B(2) \to B(1) = B$$

satisfying the requirements of Lemma 17.3.6.4. For each integer $n \geqslant 1$, let $B'(n) = B(n) \times_B B'$, so that we have a pullback square $\sigma(n)$:

$$\begin{array}{ccc} B'(n) & \longrightarrow & B(n) \\ \downarrow & & \downarrow \\ B' & \longrightarrow & B. \end{array}$$

Since X is nilcomplete, Proposition 17.3.2.4 implies that $X(\sigma)$ is a limit of the tower $\{X(\sigma(n))\}_{n \geqslant 1}$. It will therefore suffice to show that each $X(\sigma(n))$ is a pullback square in $\mathcal{S}$. The proof proceeds by induction on n, the case $n = 1$ being trivial. If $n > 1$, we consider the commutative diagram

$$\begin{array}{ccc} X(B'(n)) & \longrightarrow & X(B(n)) \\ \downarrow & & \downarrow \\ X(B'(n-1)) & \longrightarrow & X(B(n-1)) \\ \downarrow & & \downarrow \\ X(B') & \longrightarrow & X(B). \end{array}$$

The inductive hypothesis implies that the lower square is a pullback diagram. To prove that the outer square is a pullback diagram, it suffices to show that the upper square is a pullback diagram. By hypothesis, $B(n)$ is a square-zero extension of $B(n-1)$ by a connective $B(n-1)$-module M. We therefore have a commutative diagram

$$\begin{array}{ccccc} X(B'(n)) & \longrightarrow & X(B(n)) & \longrightarrow & X(B(n-1)) \\ \downarrow & & \downarrow & & \downarrow \\ X(B'(n-1)) & \longrightarrow & X(B(n-1)) & \longrightarrow & X(B(n-1) \oplus \Sigma M) \end{array}$$

where the square on the right is a pullback diagram by virtue of assumption (3). To prove that the left square is a pullback, it will suffice to show that the outer rectangle is a pullback. Note that the bottom horizontal composite admits a factorization

$$B'(n-1) \to B'(n-1) \oplus \Sigma M \to B(n-1) \oplus \Sigma M.$$

We may therefore form a commutative diagram

$$\begin{array}{ccccc} B'(n) & \longrightarrow & R & \longrightarrow & B(n-1) \\ \downarrow & & \downarrow & & \downarrow \\ B'(n-1) & \longrightarrow & B'(n-1) \oplus \Sigma M & \longrightarrow & B(n-1) \oplus \Sigma M \\ & & \downarrow & & \downarrow \\ & & B'(n-1) & \longrightarrow & B(n-1) \end{array}$$

where every square is a pullback diagram. Since the vertical composition on the right is an equivalence, it follows that the vertical compositon in the middle is an equivalence: that is, we can identify R with $B(n-1)$. Applying the functor X, we obtain a diagram of spaces

$$\begin{array}{ccccc} X(B'(n)) & \longrightarrow & X(B'(n-1)) & \longrightarrow & X(B(n-1)) \\ \downarrow & & \downarrow & & \downarrow \\ X(B'(n-1)) & \longrightarrow & X(B'(n-1) \oplus \Sigma M) & \longrightarrow & X(B(n-1) \oplus \Sigma M) \\ & & \downarrow & & \downarrow \\ & & X(B'(n-1)) & \longrightarrow & X(B(n-1)). \end{array}$$

The upper left square is a pullback diagram by assumption (3). Since X admits a cotangent complex, the lower right square is also a pullback diagram (Example 17.2.4.4). Since the vertical composite maps are equivalences, the rectangle on the right is a pullback diagram. It follows that the upper left square is a pullback square, so that the upper rectangle is a pullback square as desired. □

17.3.7 Deformation-Theoretic Conditions on Morphisms

We now introduce relative versions of Definitions 17.3.1.1, 17.3.1.5, 17.3.2.1, and 17.3.4.1:

Definition 17.3.7.1. Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. We will say that f is:

(a) *cohesive* if, for every pullback diagram

$$\begin{array}{ccc} A' & \longrightarrow & A \\ \downarrow & & \downarrow \\ B' & \longrightarrow & B \end{array}$$

of connective $\mathbb{E}_\infty$-rings such that $\pi_0 A \to \pi_0 B$ and $\pi_0 B' \to \pi_0 B$ are surjective, the cubical diagram of spaces

$$\begin{array}{ccccccc} X(A') & & \longrightarrow & & X(A) & & \\ \downarrow & \searrow & & & \downarrow & \searrow & \\ & & Y(A') & \longrightarrow & & & Y(A) \\ \downarrow & & \downarrow & & \downarrow & & \downarrow \\ X(B') & & \longrightarrow & & X(B) & & \\ & \searrow & \downarrow & & & \searrow & \downarrow \\ & & Y(B') & \longrightarrow & & & Y(B) \end{array}$$

is a limit.

(b) *infinitesimally cohesive* if, for every pullback diagram

$$\begin{array}{ccc} A' & \longrightarrow & A \\ \downarrow & & \downarrow \\ B' & \longrightarrow & B \end{array}$$

of connective $\mathbb{E}_\infty$-rings such that $\pi_0 A \to \pi_0 B$ and $\pi_0 B' \to \pi_0 B$ are surjections with nilpotent kernel, the diagram of spaces

$$\begin{array}{ccccccc}
X(A') & & \longrightarrow & & X(A) & & \\
\downarrow & \searrow & & & \downarrow & \searrow & \\
& & Y(A') & \longrightarrow & & & Y(A) \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
X(B') & & \longrightarrow & & X(B) & & \\
& \searrow & \downarrow & & & \searrow & \downarrow \\
& & Y(B') & \longrightarrow & & & Y(B)
\end{array}$$

is a limit cube.

(c) *nilcomplete* if, for every connective $\mathbb{E}_\infty$-ring A, the diagram

$$\begin{array}{ccc}
X(A) & \longrightarrow & \varprojlim X(\tau_{\leqslant n} A) \\
\downarrow & & \downarrow \\
Y(A) & \longrightarrow & \varprojlim Y(\tau_{\leqslant n} A)
\end{array}$$

is a pullback square.

(d) *integrable* if, for every complete local Noetherian $\mathbb{E}_\infty$-ring A, the diagram

$$\begin{array}{ccc}
X(A) & \longrightarrow & \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(\operatorname{Spf} A, X) \\
\downarrow & & \downarrow \\
Y(A) & \longrightarrow & \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(\operatorname{Spf} A, Y)
\end{array}$$

is a pullback square; here $\operatorname{Spf} A$ denotes the formal spectrum of A, regarded as an object of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$.

Example 17.3.7.2. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be an arbitrary functor, and let $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be the constant functor taking the value $* \in \mathcal{S}$. Then there is a unique natural transformation $f : X \to Y$ (up to homotopy). Moreover, the natural transformation f is cohesive (infinitesimally cohesive, nilcomplete, integrable) if and only if X is cohesive (infinitesimally cohesive, nilcomplete, integrable).

Remark 17.3.7.3. Suppose we are given a diagram

$$\begin{array}{ccccc}
& & Y & & \\
& \overset{f}{\nearrow} & & \overset{g}{\searrow} & \\
X & & \xrightarrow{h} & & Z
\end{array}$$

in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$, where g is cohesive (infinitesimally cohesive, nilcomplete, integrable). Then f is cohesive (infinitesimally cohesive, nilcomplete, integrable) if and only if h is cohesive (infinitesimally cohesive, nilcomplete, integrable).

Taking Z to be the final object of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$, we deduce that if $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ is cohesive (infinitesimally cohesive, nilcomplete, integrable), then a morphism $f : X \to Y$ is cohesive (infinitesimally cohesive, nilcomplete, integrable) if and only if X is cohesive (infinitesimally cohesive, nilcomplete, integrable).

Remark 17.3.7.4. Let $f : X \to Y$ be a morphism in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. Suppose we are given a field κ and a point $\eta \in X(\kappa)$. We define a functor $X^{\wedge} : \mathrm{CAlg}^{\mathrm{sm}}_{\kappa} \to \mathcal{S}$ by the formula

$$X^{\wedge}(A) = \mathrm{fib}(X(A) \to Y(A) \times_{Y(\kappa)} X(\kappa)).$$

If the morphism f is infinitesimally cohesive, then the functor $X^{\wedge}$ is a formal moduli problem (in the sense of Definition 12.1.3.1) and therefore has a well-defined tangent complex $T_{X^{\wedge}} \in \mathrm{Mod}_{\kappa}$ (Definition 12.2.2.1). Unwinding the definitions, we see that this tangent complex is characterized up to equivalence by the formula

$$\mathrm{Map}_{\mathrm{Mod}_{\kappa}}(M^{\vee}, T_{X^{\wedge}}) \simeq X^{\wedge}(\kappa \oplus M) \simeq \mathrm{fib}(X(\kappa \oplus M) \to Y(\kappa \oplus M) \times_{Y(\kappa)} X(\kappa)),$$

where M varies over perfect connective κ-modules. If f admits a relative tangent cocomplex $L_{X/Y}$, then the right hand side can be identified with $\mathrm{Map}_{\mathrm{Mod}_{\kappa}}(\eta^* L_{X/Y}, M)$. We can therefore identify $T_{X^{\wedge}}$ with the κ-linear dual $(\eta^* L_{X/Y})^{\vee}$ of $\eta^* L_{X/Y}$.

17.3.8 Relativization and Fibers

Roughly speaking, a morphism $f : X \to Y$ in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ is cohesive (infinitesimally cohesive, nilcomplete, integrable) if and only if each fiber of f is cohesive (infinitesimally cohesive, nilcomplete, integrable). We now articulate this idea more precisely.

Notation 17.3.8.1. Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Given a point $\eta \in Y(R)$, we let $X_{\eta} : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ given on objects by the formula $X_{\eta}(A) = X(A) \times_{Y(A)} \{\eta_A\}$, where $\eta_A \in Y(A)$ denotes the image of η.

Suppose now that η induces an equivalence $\mathrm{Spec}\, R \to Y$: that is, for every $\mathbb{E}_{\infty}$-ring A, evaluation at η induces a homotopy equivalence $\mathrm{Map}_{\mathrm{CAlg}}(R, A) \to Y(A)$. In this case, the construction $X \mapsto X_{\eta}$ induces an equivalence of ∞-categories $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/Y} \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}_R, \mathcal{S})$ (Corollary HTT.5.1.6.12).

Now let $F : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ be an arbitrary functor. The above discussion shows that there is an equivalence $F \simeq X_{\eta}$ for some natural transformation $f : X \to \mathrm{Spec}\, R$ in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$, which is determined uniquely up to a contractible space of choices. In this case, we will denote the functor X by $\underline{F}$. We will say that F is *cohesive* (*infinitesimally cohesive*, *nilcomplete*, *integrable*) if the functor $\underline{F}$ is cohesive (infinitesimally cohesive, nilcomplete, *integrable*). Since $\operatorname{Spec} R$ is cohesive and nilcomplete, we see from Remark 17.3.7.3 that F is cohesive (infinitesimally cohesive, nilcomplete, integrable) if and only if the natural transformation f is cohesive (infinitesimally cohesive, nilcomplete, integrable).

Remark 17.3.8.2. Let R be a connective $\mathbb{E}_\infty$-ring, let $F : \mathrm{CAlg}_R^{\mathrm{cn}} \to \mathcal{S}$ be a functor, and let $\underline{F} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be as in Notation 17.3.8.1. If F classifies a left fibration $p : \mathcal{C} \to \mathrm{CAlg}_R^{\mathrm{cn}}$, then $\underline{F}$ classifies the left fibration given by the composite map $\mathcal{C} \xrightarrow{p} \mathrm{CAlg}_R^{\mathrm{cn}} \to \mathrm{CAlg}^{\mathrm{cn}}$. More informally: we can identify $\underline{F}(A)$ with a classifying space for pairs (ϕ, η), where $\phi : R \to A$ is a map of $\mathbb{E}_\infty$-rings and $\eta \in F(A)$, where A is regarded as an R-algebra via the map ϕ.

Remark 17.3.8.3. Let R be a connective $\mathbb{E}_\infty$-ring and let $F : \mathrm{CAlg}_R^{\mathrm{cn}} \to \mathcal{S}$ be a functor. Unwinding the definitions, we deduce:

- The functor F is cohesive if and only if, for every pullback diagram

$$\begin{array}{ccc} A' & \longrightarrow & A \\ \downarrow & & \downarrow{\scriptstyle f} \\ B' & \xrightarrow{g} & B \end{array}$$

  in $\mathrm{CAlg}_R^{\mathrm{cn}}$ for which the maps $\pi_0 A \to \pi_0 B$ and $\pi_0 B' \to \pi_0 B$ are surjective, the induced diagram

$$\begin{array}{ccc} X(A') & \longrightarrow & X(A) \\ \downarrow & & \downarrow{\scriptstyle f} \\ X(B') & \xrightarrow{g} & X(B) \end{array}$$

  is a pullback square in $\mathcal{S}$.

- The functor F is infinitesimally cohesive if and only if, for every pullback diagram

$$\begin{array}{ccc} A' & \longrightarrow & A \\ \downarrow & & \downarrow{\scriptstyle f} \\ B' & \xrightarrow{g} & B \end{array}$$

  in $\mathrm{CAlg}_R^{\mathrm{cn}}$ for which the maps $\pi_0 A \to \pi_0 B$ and $\pi_0 B' \to \pi_0 B$ are surjective with nilpotent kernel, the induced diagram

$$\begin{array}{ccc} X(A') & \longrightarrow & X(A) \\ \downarrow & & \downarrow{\scriptstyle f} \\ X(B') & \xrightarrow{g} & X(B) \end{array}$$

  is a pullback square in $\mathcal{S}$.

- The functor F is nilcomplete if and only if, for every connective R-algebra A, the canonical map $F(A) \to \varprojlim F(\tau_{\leqslant n} A)$ is a homotopy equivalence.

- The functor F is integrable if and only if, for every local Noetherian $\mathbb{E}_\infty$-algebra A over R which is complete with respect to its maximal ideal $\mathfrak{m}$, the canonical map $F(A) \to \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}_R^{\mathrm{cn}}, \mathcal{S})}(Y, F)$, where $Y : \mathrm{CAlg}_R^{\mathrm{cn}} \to \mathcal{S}$ is the functor which assigns to each R-algebra B the full subcategory of $\mathrm{Map}_{\mathrm{CAlg}_R}(A, B)$ spanned by those maps which annihilate some power of the maximal ideal $\mathfrak{m}$.

Proposition 17.3.8.4. *Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. The following conditions are equivalent:*

(1) *The map f is cohesive (infinitesimally cohesive, nilcomplete, integrable).*

(2) *For every pullback diagram*

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow{\scriptstyle f'} & & \downarrow \\ Y' & \longrightarrow & Y \end{array}$$

in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$, the map f' is cohesive (infinitesimally cohesive, nilcomplete, integrable).

(3) *For every pullback diagram*

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow{\scriptstyle f'} & & \downarrow \\ Y' & \longrightarrow & Y \end{array}$$

in $\mathrm{CAlg}^{\mathrm{cn}}$ where Y' is a corepresentable functor, the map f' is cohesive (infinitesimally cohesive, nilcomplete,integrable).

(4) *For every connective $\mathbb{E}_\infty$-ring R and every point $\eta \in Y(R)$, the functor $X_\eta : \mathrm{CAlg}_R^{\mathrm{cn}} \to \mathcal{S}$ is cohesive (infinitesimally cohesive, nilcomplete,integrable).*

Proof. The implications (1) ⇒ (2) ⇒ (3) are obvious, and the equivalence (3) ⇔ (4) follows from Remark 17.3.7.3. We will complete the proof by showing that (3) ⇒ (1). For simplicity, let us treat the assertion concerning nilcomplete functors; the proofs in the other cases are essentially the same. Let R be a connective $\mathbb{E}_\infty$-ring; we wish to show that the diagram

$$\begin{array}{ccc} X(R) & \longrightarrow & \varprojlim X(\tau_{\leqslant n} R) \\ \downarrow & & \downarrow \\ Y(R) & \longrightarrow & Y(\tau_{\leqslant n} R) \end{array}$$

is a pullback square. Equivalently, we wish to show that for every point $\eta \in Y(R)$, the induced map

$$X(R) \times_{Y(R)} \{\eta\} \to \varprojlim (X(\tau_{\leqslant n} R) \times_{Y(\tau_{\leqslant n} R)} \{\eta\})$$

is a homotopy equivalence (here we abuse notation by identifying η with its image in $Y(\tau_{\leqslant n} R)$, for each $n \geqslant 0$). The point η determines a natural transformation $Y' \to Y$, where $Y' : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ is the functor corepresented by R. Since η lies in the essential image of the map $Y'(R) \to Y(R)$, we may replace f by the projection map $f' : X \times_Y Y' \to Y'$. In this case, the desired result follows from (3). □

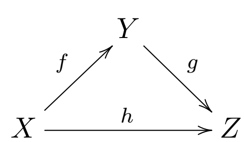
Corollary 17.3.8.5. *Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, and suppose that f is relatively representable by spectral Deligne-Mumford stacks. Then f is cohesive, nilcomplete, and admits a cotangent complex. Moreover, the relative cotangent complex $L_{X/Y} \in \mathrm{QCoh}(X)$ is connective.*

Proof. The first two assertions follow from Proposition 17.3.8.4, Example 17.3.1.2, and Proposition 17.3.2.3. For the third, we combine Propositions 17.2.4.7 and 17.2.5.1. □

17.3.9 Cohesive Functors and the Relative Cotangent Complex

Using the notion of an infinitesimally cohesive morphism, we can formulate a useful variant of Proposition 17.2.5.2:

Proposition 17.3.9.1. *Let*



be a commutative diagram in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. Assume that g is infinitesimally cohesive and admits a cotangent complex. Then f is infinitesimally cohesive and admits a cotangent complex if and only if h is infinitesimally cohesive and admits a cotangent complex.

Proof. The "if" direction follows immediately from Remark 17.3.7.3 and Proposition 17.2.5.2. For the converse, let us suppose that f is infinitesimally cohesive and admits a cotangent complex. Remark 17.3.7.3 implies that h is infinitesimally cohesive. We will complete the proof by showing that h admits a cotangent complex.

Let $\mathrm{Mod}^X_{\mathrm{cn}}$ be the ∞-category defined in Example **??**, and let $F : \mathrm{Mod}^X_{\mathrm{cn}} \to \mathcal{S}$ be defined by the formula

$$F(R, \eta, M) = \mathrm{fib}(X(R \oplus M) \to X(R) \times_{Z(R)} Z(R \oplus M)).$$

We wish to prove that F is locally almost corepresentable. Define $F', F'' : \mathrm{Mod}^X_{\mathrm{cn}} \to \mathcal{S}$ by the formulae

$$F'(R, \eta, M) = \mathrm{fib}(X(R \oplus M) \to X(R) \times_{Y(R)} Y(R \oplus M))$$

$$F''(R, \eta, M) = \mathrm{fib}(Y(R \oplus M) \to Y(R) \times_{Z(R)} Z(R \oplus M)),$$

so that we have a fiber sequence of functors $F' \to F \to F''$. Note that each of these functors is naturally pointed, so we get a fiber sequence $\Omega F \to \Omega F'' \to F'$. Since f and g admit cotangent complexes, the functors F' and F'' are locally almost corepresentable. It follows that ΩF is locally almost corepresentable (Remark 17.2.3.3). Since h is infinitesimally cohesive, the functor F is given by the formula $F(R, \eta, M) \simeq (\Omega F)(R, \eta, \Sigma M)$ and is therefore also locally almost corepresentable. □

Remark 17.3.9.2. Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Suppose that f is infinitesimally cohesive and admits a cotangent complex $L_{X/Y} \in \mathrm{QCoh}(X)$. Let A be a connective $\mathbb{E}_\infty$-ring and let $\overline{A}$ be a square-zero extension of A by a connective A-module M, so that we have a pullback diagram of $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc} \overline{A} & \longrightarrow & A \\ \downarrow & & \downarrow \\ A & \longrightarrow & A \oplus \Sigma M. \end{array}$$

This diagram satisfies the hypotheses of case (b) of Definition 17.3.7.1, so that we obtain a limit diagram

$$\begin{array}{ccccccc} X(\overline{A}) & & \longrightarrow & & X(A) & & \\ \downarrow & \searrow & & & \downarrow & \searrow & \\ & & Y(\overline{A}) & \longrightarrow & & & Y(A) \\ X(A) & & \downarrow & \longrightarrow & X(A \oplus \Sigma M) & & \downarrow \\ & \searrow & & & & \searrow & \\ & & Y(A) & \longrightarrow & & & Y(A \oplus \Sigma M). \end{array}$$

We can think of this as giving us a pullback square

$$\begin{array}{ccc} X(\overline{A}) & \longrightarrow & X(A) \\ \downarrow & & \downarrow \\ X(A) \times_{Y(A)} Y(\overline{A}) & \longrightarrow & X(A \oplus \Sigma M) \times_{Y(A \oplus \Sigma M)} Y(A). \end{array}$$

Fixing a point $\eta \in X(A)$ having image $\eta_0 \in Y(A)$, we obtain a fiber sequence of spaces

$$\{\eta\} \times_{X(A)} X(\overline{A}) \to \{\eta_0\} \times_{Y(A)} Y(\overline{A}) \to \mathrm{Map}_{\mathrm{Mod}_A}(\eta^* L_{X/Y}, \Sigma M).$$

We can summarize the situation as follows: to every point $\overline{\eta}_0 \in Y(\overline{A})$ lifting η_0, we can associate a class $\sigma \in \mathrm{Ext}^1_A(\eta^* L_{X/Y}, M)$, which vanishes if and only if the lifting problem

$$\begin{array}{ccc} \mathrm{Spec}\, A & \xrightarrow{\eta} & X \\ \downarrow & \nearrow & \downarrow f \\ \mathrm{Spec}\, \overline{A} & \xrightarrow{\overline{\eta}_0} & Y \end{array}$$

admits a solution.

Proposition 17.3.9.3. *Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Suppose that f is infinitesimally cohesive and that f admits a relative cotangent complex $L_{X/Y} \in \mathrm{QCoh}(X)$. Let A be a connective $\mathbb{E}_\infty$-ring, and let $\overline{A}$ be a square-zero extension of A by a connective A-module M. Then:*

(1) *If $\eta^* L_{X/Y}$ is a projective A-module for each $\eta \in X(A)$, then the canonical map $X(\overline{A}) \to X(A) \times_{Y(A)} Y(\overline{A})$ is surjective on connected components.*

(2) *If $L_{X/Y}$ vanishes, then the canonical map $X(\overline{A}) \to X(A) \times_{Y(A)} Y(\overline{A})$ is a homotopy equivalence.*

In the case of representable functors, we have the following converse:

Proposition 17.3.9.4. *Let $\phi : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks representing functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, and suppose that the underlying map $\tau_{\leqslant 0} \mathsf{X} \to \tau_{\leqslant 0} \mathsf{Y}$ is locally finitely 0-presented (see Definition 4.2.3.1). Then:*

(1) *The map ϕ is étale if and only if, for every connective $\mathbb{E}_\infty$-ring A and every square-zero extension $\overline{A}$ of A by a connective A-module, the map $X(\overline{A}) \to X(A) \times_{Y(A)} Y(\overline{A})$ is a homotopy equivalence.*

(2) *The map ϕ is differentially smooth if and only if, for every connective $\mathbb{E}_\infty$-ring A and every square-zero extension A^{η} of A by a connective A-module, the map $X(\overline{A}) \to X(A) \times_{Y(A)} Y(\overline{A})$ is surjective on connected components.*

(3) *The map ϕ is fiber-smooth if and only if ϕ is flat and, for every discrete $\mathbb{E}_\infty$-ring A and every square-zero extension A^{η} of A by a discrete A-module, the map $X(\overline{A}) \to X(A) \times_{Y(A)} Y(\overline{A})$ is surjective on connected components.*

Proof. We first prove (1). Applying Proposition 17.1.5.1, we see that ϕ is étale if and only if the relative cotangent complex $L_{\mathsf{X}/\mathsf{Y}}$ vanishes. The "only if" direction now follows immediately from Proposition 17.3.9.3. To prove the converse, fix an étale map $\eta : \operatorname{Spét} A \to \mathsf{X}$. If the canonical map $X(A \oplus M) \to X(A) \times_{Y(A)} Y(A \oplus M)$ is a homotopy equivalence, then the mapping space $\operatorname{Map}_{\operatorname{Mod}_A}(\eta^* L_{\mathsf{X}/\mathsf{Y}}, M)$ is contractible. Taking $M = \eta^* L_{\mathsf{X}/\mathsf{Y}}$, we deduce that $\eta^* L_{\mathsf{X}/\mathsf{Y}}$ vanishes.

To prove the "if" directions of (2) and (3), we can reduce to the case where X and Y are affine, in which case the desired results follow from Propositions 11.2.2.1 and Corollary 11.2.4.2. The "only if" direction of (2) follows from Proposition 17.3.9.3 and 17.1.5.1. We will complete the proof by verifying the "only if" direction of (3). Suppose that ϕ is fiber-smooth, and that we are given a lifting problem

$$\begin{array}{ccc} \operatorname{Spét} A & \xrightarrow{\eta} & \mathsf{X} \\ \downarrow & \nearrow & \downarrow{\scriptstyle \phi} \\ \operatorname{Spét} \overline{A} & \longrightarrow & \mathsf{Y}, \end{array}$$

where A is a discrete $\mathbb{E}_\infty$-ring and $\overline{A}$ is a square-zero extension of A by a discrete A-module M. To prove that this lifting problem admits a solution, it will suffice to show that the group $\operatorname{Ext}^1_A(\eta^* L_{\mathsf{X}/\mathsf{Y}}, M)$ vanishes (see Remark 17.3.9.2). This follows from the fact that $\tau_{\leqslant 1} \eta^* L_{\mathsf{X}/\mathsf{Y}}$ is a projective A-module (see Proposition 17.1.5.1). $\square$

17.4 Finiteness Conditions on Morphisms

Let $f : X \to Y$ be a morphism of schemes. Recall that f is said to be *locally of finite presentation* if it satisfies either of the following equivalent conditions:

(a) For every pair of affine open subsets $\operatorname{Spec} A \simeq U \subseteq Y$ and $\operatorname{Spec} B \simeq V \subseteq X \times_Y U$, the morphism f exhibits B as a finitely presented A-algebra.

(b) For every filtered diagram of commutative rings $\{R_\alpha\}$ having colimit R, the diagram

$$\begin{array}{ccc} \varinjlim X(R_\alpha) & \longrightarrow & X(R) \\ \downarrow & & \downarrow \\ \varinjlim Y(R_\alpha) & \longrightarrow & Y(R) \end{array}$$

is a pullback square.

In §4.2, we studied several finiteness conditions that can be placed on a morphism $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks, which are defined using a variant of (a)

(see Definition 4.2.0.1). Our goal here is to provide alternative definitions for these notions which are closer in spirit to (b), and have the virtue of making sense for arbitrary functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. The contents of this section can be summarized as follows:

- (i) In §17.4.1, we introduce several finiteness conditions on a natural transformation $f : X \to Y$ of functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$: the conditions that f is *locally of finite presentation*, *locally almost of finite presentation*, and *locally of finite generation to order* n for $n \geqslant 0$ (Definition 17.4.1.1).

- (ii) In §17.4.2, we show that if $f : X \to Y$ is a functor which admits a cotangent complex $L_{X/Y}$, then there is a close relationship between finiteness conditions on f and finiteness conditions on $L_{X/Y}$. In particular, we show that if f is locally of finite presentation (locally almost of finite presentation, locally of finite generation to order n), then $L_{X/Y}$ is perfect (almost perfect, perfect to order n). Moreover, the converse assertions hold under some mild additional assumptions (see Proposition 17.4.2.1, Corollary 17.4.2.2, and Proposition 17.4.2.3).

- (iii) In §17.4.3, we show that if X and Y are (representable by) spectral Deligne-Mumford m-stacks for some $m < \infty$, then the finiteness conditions introduced in Definition 17.4.1.1 agree with the analogous finiteness conditions appearing in Definition 4.2.0.1 (Proposition 17.4.3.1).

17.4.1 Local Finite Presentation

We now introduce several finiteness conditions on a morphism $f : X \to Y$ in the ∞-category $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$.

Definition 17.4.1.1. Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. We will say that f is *locally of finite presentation* if the following condition is satisfied:

- (a) Let $\{A_\alpha\}$ be a filtered diagram of connective $\mathbb{E}_\infty$-rings with colimit A. Then the canonical map
$$\theta : \varinjlim X(A_\alpha) \to X(A) \times_{Y(A)} \varinjlim Y(A_\alpha)$$
is a homotopy equivalence.

We say that f is *locally almost of finite presentation* if it satisfies the following weaker condition:

- (b) Let $m \geqslant 0$, and let $\{A_\alpha\}$ be a filtered diagram of m-truncated connective $\mathbb{E}_\infty$-rings with colimit A. Then the canonical map
$$\theta : \varinjlim X(A_\alpha) \to X(A) \times_{Y(A)} \varinjlim Y(A_\alpha)$$

is a homotopy equivalence.

If $n \geqslant 0$, we say that f is *locally of finite generation to order* n if the following still weaker condition is satisfied:

(c) Let $\{A_\alpha\}$ be a filtered diagram of connective $\mathbb{E}_\infty$-rings having colimit A. Assume that each A_α is n-truncated and that the transition maps $\pi_n A_\alpha \to \pi_n A_\beta$ are monomorphisms. Then the canonical map

$$\theta : \varinjlim X(A_\alpha) \to X(A) \times_{Y(A)} \varinjlim Y(A_\alpha)$$

is a homotopy equivalence.

Remark 17.4.1.2. A morphism $f : X \to Y$ in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ is locally almost of finite presentation if and only if it is locally of finite generation to order n for every integer $n \geqslant 0$.

Remark 17.4.1.3. Suppose we are given a commutative diagram

$$\begin{array}{ccccc} & & Y & & \\ & \overset{f}{\nearrow} & & \overset{g}{\searrow} & \\ X & & \xrightarrow{h} & & Z \end{array}$$

in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. Suppose that g is locally of finite presentation (locally almost of finite presentation, locally of finite generation to order n). Then f is locally of finite presentation (locally almost of finite presentation, locally of finite generation to order n) if and only if h is locally of finite presentation (locally almost of finite presentation, locally of finite generation to order n).

Remark 17.4.1.4. Let $\{X_\alpha\}$ be a diagram in the ∞-category $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ having colimit $X = \varinjlim_\alpha X_\alpha$, and let $f : X \to Y$ be a natural transformation. If each each of the composite maps $X_\alpha \to X \xrightarrow{f} Y$ is locally of finite presentation (locally almost of finite presentation, locally of finite generation to order n), then so is f.

We have the following counterpart of Proposition 17.3.8.4:

Proposition 17.4.1.5. *Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. The following conditions are equivalent:*

(1) *The map f is locally of finite presentation (locally almost of finite presentation, locally of finite generation to order n).*

(2) *For every pullback diagram*

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \longrightarrow & Y \end{array}$$

in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$*, the map* f' *is locally of finite presentation (locally almost of finite presentation, locally of finite generation to order* n*).*

(3) *For every pullback diagram*

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \longrightarrow & Y \end{array}$$

in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ *where* Y' *is a corepresentable functor, the map* f' *is locally of finite presentation (locally almost of finite presentation, locally of finite generation to order* n*).*

Remark 17.4.1.6. Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Suppose that there exists a connective $\mathbb{E}_\infty$-ring R and a point $\eta \in Y(R)$ which exhibits Y as the functor corepresented by R. Let $X_\eta : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ be as in Notation 17.3.8.1. Then:

(a) The map f is locally of finite presentation if and only if the functor X_η commutes with filtered colimits.

(b) The map f is locally almost of finite presentation if and only if, for every integer $m \geqslant 0$, the restriction $X_\eta|_{\tau_{\leqslant m} \mathrm{CAlg}^{\mathrm{cn}}_R}$ commutes with filtered colimits.

(c) The map f is locally of finite generation to order n if and only if, for every filtered diagram $\{A_\alpha\}$ of connective $\mathbb{E}_\infty$-rings having colimit A, if each A_α is n-truncated and each of the transition maps $\pi_n A_\alpha \to \pi_n A_\beta$ is a monomorphism, then the canonical map $\varinjlim X_\eta(A_\alpha) \to X_\eta(A)$ is a homotopy equivalence.

17.4.2 Finite Presentation and the Cotangent Complex

Let $f : X \to Y$ be a morphism in the ∞-category $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. If f admits a cotangent complex, then the finiteness conditions appearing in Definition 17.4.1.1 can often be reformulated as conditions on $L_{X/Y} \in \mathrm{QCoh}(X)$.

Proposition 17.4.2.1. *Let* $f : X \to Y$ *be a natural transformation of functors* $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$*, and suppose that* f *admits a cotangent complex* $L_{X/Y}$*. Then:*

(1) *If f is locally of finite generation to order n, then the relative cotangent complex $L_{X/Y} \in \mathrm{QCoh}(X)$ is perfect to order n.*

(2) *Assume that f is infinitesimally cohesive and satisfies the following additional condition:*

(∗) *For every filtered diagram $\{A_\alpha\}$ of commutative rings having colimit A, the diagram of spaces*

$$\begin{array}{ccc} \varinjlim X(A_\alpha) & \longrightarrow & X(A) \\ \downarrow & & \downarrow \\ \varinjlim Y(A_\alpha) & \longrightarrow & Y(A) \end{array}$$

is a pullback square.

If the relative cotangent complex $L_{X/Y}$ is perfect to order n, then f is locally of finite generation to order n.

Corollary 17.4.2.2. *Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Assume that f admits a cotangent complex. Then:*

(1) *If f is locally almost of finite presentation, then the relative cotangent complex $L_{X/Y} \in \mathrm{QCoh}(X)$ is almost perfect.*

(2) *Assume that f is infinitesimally cohesive and satisfies condition (∗) of Proposition 17.4.2.1. If $L_{X/Y}$ is almost perfect, then f is locally almost of finite presentation.*

Proof. Combine Proposition 17.4.2.1 with Remark 17.4.1.2 □

Proof of Proposition 17.4.2.1. Suppose first that f is locally of finite generation to order n. Choose a connective $\mathbb{E}_\infty$-ring A and a point $\eta \in X(A)$; we wish to show that $\eta^* L_{X/Y} \in \mathrm{Mod}_A$ is perfect to order n. We will verify that $\eta^* L_{X/Y}$ satisfies the third criterion of Proposition 2.7.0.4. Let $\{M_\alpha\}$ be a filtered diagram of discrete A-modules having colimit M, where the transition maps $M_\alpha \to M_\beta$ are monomorphisms; we wish to show that the canonical map $\theta : \varinjlim \mathrm{Map}_{\mathrm{Mod}_A}(\eta^* L_{X/Y}, \Sigma^n M_\alpha) \to \mathrm{Map}_{\mathrm{Mod}_A}(\eta^* L_{X/Y}, \Sigma^n M)$ is a homotopy equivalence. To prove this, we may replace A by $\tau_{\leq n} A$ and thereby reduce to the case where A is n-truncated. Unwinding the definitions, we see that θ can be obtained from the commutative diagram σ :

$$\begin{array}{ccc} \varinjlim X(A \oplus \Sigma^n M_\alpha) & \longrightarrow & X(A) \times_{Y(A)} \varinjlim Y(A \oplus \Sigma^n M_\alpha) \\ \downarrow & & \downarrow \\ X(A \oplus M) & \longrightarrow & X(A) \times_{Y(A)} Y(A \oplus \Sigma^n M_\alpha) \end{array}$$

by passing to homotopy fibers in the horizontal direction. We now conclude by observing that our hypothesis that f is locally of finite generation to order n guarantees that σ is a pullback square. This completes the proof of (1).

We now prove (2). Using Proposition 17.4.1.5, we can reduce to the case where the functor Y is corepresentable by a connective $\mathbb{E}_\infty$-ring R. The assumption that f is infinitesimally cohesive then implies that X is infinitesimally cohesive (Remark 17.3.7.3). Let $X_\eta : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ be as in Remark 17.4.1.6. Assumption $(*)$ implies that the restriction of X_η to $\mathrm{CAlg}^{\heartsuit}_R$ commutes with filtered colimits. We will show that X_η satisfies condition (c) of Remark 17.4.1.6. Fix a diagram $\{A_\alpha\}$ in $\mathrm{CAlg}^{\mathrm{cn}}_R$ indexed by a filtered partially ordered set I, where where each A_α is n-truncated and the transition maps $\pi_n A_\alpha \to \pi_n A_\beta$ are monomorphisms. Set $A = \varinjlim_\alpha A_\alpha$. For $0 \leqslant i \leqslant n$, let $\theta_i : \varinjlim_\alpha X_\eta(A_\alpha) \to X_\eta(A)$ denote the canonical map. We will show that each of the maps θ_i is a homotopy equivalence. The proof proceeds by induction on i. In the case $i = 0$, this follows from assumption $(*)$.

To carry out the inductive step, let us assume that $i > 0$ and that θ_{i-1} is a homotopy equivalence. For each α, set $A'_\alpha = \tau_{\leqslant i-1} A_\alpha$ and $M_\alpha = \pi_i A_\alpha$, so that we have a filtered system of pullback diagrams

$$\begin{array}{ccc} \tau_{\leqslant i} A_\alpha & \longrightarrow & A'_\alpha \\ \downarrow & & \downarrow \\ A'_\alpha & \longrightarrow & A'_\alpha \oplus \Sigma^{i+1} M_\alpha. \end{array}$$

Set $A' = \varinjlim_\alpha A'_\alpha \simeq \tau_{\leqslant i-1} A$ and $M = \varinjlim_\alpha M_\alpha$, and let $\rho : \varinjlim X_\eta(A'_\alpha \oplus \Sigma^{i+1} M_\alpha) \to X_\eta(A' \oplus M)$ be the canonical map. Since the functor X_η is infinitesimally cohesive, we can identify θ_i with the fiber product $\theta_{i-1} \times_\rho \theta_{i-1}$ in the ∞-category $\mathrm{Fun}(\Delta^1, \mathcal{S})$. Consequently, to show that θ_i is a homotopy equivalence, it will suffice to show that ρ has (-1)-truncated homotopy fibers.

We have a commutative diagram

$$\begin{array}{ccc} \varinjlim X_\eta(A'_\alpha \oplus \Sigma^{i+1} M_\alpha) & \xrightarrow{\rho} & X_\eta(A' \oplus \Sigma^{i+1} M) \\ \downarrow u & & \downarrow v \\ \varinjlim X_\eta(A'_\alpha) & \xrightarrow{\theta_{i-1}} & X_\eta(A'), \end{array}$$

where the lower horizontal map is a homotopy equivalence by virtue of our inductive hypothesis. It will therefore suffice to show that the map ρ induces a (-1)-truncated map from each homotopy fiber of u to the corresponding homotopy fiber of v. Fix a point of the space $\varinjlim X_\eta(A'_\alpha)$, which we can represent by an element $\overline{\eta} \in X_\eta(A'_\alpha)$ for some $\alpha \in I$. Unwinding the definitions, we see that the homotopy fiber of u over $\overline{\eta}$ can be identified with the direct limit $\varinjlim_{\beta \geqslant \alpha} \mathrm{Map}_{\mathrm{Mod}_{A'_\alpha}}(\overline{\eta}^* L_{X/Y}, \Sigma^{i+1} M_\beta)$, while the homotopy fiber of v

over $\theta_{i-1}(\overline{\eta})$ can be identified with $\mathrm{Map}_{\mathrm{Mod}_{A'_\alpha}}(\overline{\eta}^* L_{X/Y}, \Sigma^{i+1} M)$. We are therefore reduced to showing that the map

$$\varinjlim_{\beta \geqslant \alpha} \mathrm{Map}_{\mathrm{Mod}_{A'_\alpha}}(\overline{\eta}^* L_{X/Y}, \Sigma^{i+1} M_\beta) \to \mathrm{Map}_{\mathrm{Mod}_{A'_\alpha}}(\overline{\eta}^* L_{X/Y}, \Sigma^{i+1} M)$$

has (-1)-truncated homotopy fibers. In other words, we wish to show that the colimit $\varinjlim_{\beta \geqslant \alpha} \mathrm{Map}_{\mathrm{Mod}_{A'_\alpha}}(\overline{\eta}^* L_{X/Y}, K_\beta)$ is contractible, where K_β denotes the fiber of the canonical map $\Sigma^{i+1} M_\beta \to \Sigma^{i+1} M$. Since each K_β is n-truncated and the colimit $\varinjlim K_\beta$ vanishes, this follows from our assumption that $\overline{\eta}^* L_{X/Y}$ is perfect to order n as an A'_α-module. □

Proposition 17.4.2.3. *Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, and assume that f admits a cotangent complex. Then:*

(1) *If f is locally of finite presentation, the relative cotangent complex $L_{X/Y} \in \mathrm{QCoh}(X)$ is perfect.*

(2) *Assume that f is nilcomplete, infinitesimally cohesive, and satisfies condition $(*)$ of Proposition 17.4.2.1. If $L_{X/Y}$ is perfect, then f is locally of finite presentation.*

Proof. We first prove (1). Choose a connective $\mathbb{E}_\infty$-ring A and a point $\eta \in X(A)$; we wish to show that $\eta^* L_{X/Y} \in \mathrm{Mod}_A$ is perfect. Since $L_{X/Y}$ is locally almost connective, we can choose an integer k such that $\eta^* L_{X/Y} \in (\mathrm{Mod}_A)_{\geqslant -k}$. To prove that $\eta^* L_{X/Y}$ is perfect, it will suffice to show that it is a compact object of $(\mathrm{Mod}_A)_{\geqslant -k}$. For this, we note that the functor corepresented by $\eta^* L_{X/Y}$ is given by

$$M \mapsto \Omega^k \operatorname{fib}(X(R \oplus \Sigma^k M) \to X(R) \times_{Y(R)} Y(R \oplus \Sigma^k M)),$$

which commutes with filtered colimits if f is locally of finite presentation.

We now prove (2). Using Proposition 17.4.1.5, we may assume without loss of generality that Y is corepresentable by a connective $\mathbb{E}_\infty$-ring R. Let $X_0 : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ be the functor given by the formula $X_0(A) = \operatorname{fib}(X(A) \to Y(A))$, as in Remark 17.4.1.6. We wish to prove that X_0 commutes with filtered colimits.

Let $\{A_\alpha\}$ be a diagram of connective $\mathbb{E}_\infty$-rings indexed by a filtered partially ordered set P, and set $A = \varinjlim A_\alpha$. We wish to prove that the canonical map $\varinjlim X_0(A_\alpha) \to X_0(A)$ is a homotopy equivalence. For this, it suffices to show that for every point $\eta \in X_0(\pi_0 A)$, the induced map

$$\theta : \varinjlim X_0(A_\alpha) \times_{X_0(\pi_0 A)} \{\eta\} \to X_0(A) \times_{X_0(\pi_0 A)} \{\eta\}$$

is a homotopy equivalence. Since $X_0|_{\mathrm{CAlg}^\heartsuit_R}$ commutes with filtered colimits, we may assume that η is the image of a point $\eta_\alpha \in X_0(\pi_0 A_\alpha)$ for some $\alpha \in P$. For $\beta \geqslant \alpha$, let η_β denote the image of η in $X_0(\pi_0 A_\beta)$. Then we can identify θ with the canonical map

$$\varinjlim_{\beta \geqslant \alpha} X_0(A_\beta) \times_{X_0(\pi_0 A_\beta)} \{\eta_\beta\} \to X_0(A) \times_{X_0(\pi_0 A)} \{\eta\}.$$

To prove that this map is a homotopy equivalence, it will suffice to show that for every integer $n \geqslant 0$, the induced map

$$\theta_n : \tau_{\leqslant n} \varinjlim_{\beta \geqslant \alpha} (X_0(A_\beta) \times_{X_0(\pi_0 A_\beta)} \{\eta_\beta\}) \to \tau_{\leqslant n}(X_0(A) \times_{X_0(\pi_0 A)} \{\eta\})$$

is a homotopy equivalence.

For every map of $\mathbb{E}_\infty$-rings $A_\alpha \to B$, let η_B denote the image of η_α in $X_0(\pi_0 B)$. Our proof relies on the following assertion:

($\star$) There exists an integer $m \geqslant 0$ with the following property: for every map of connective $\mathbb{E}_\infty$-rings $A_\alpha \to B$, the canonical map

$$\tau_{\leqslant n}(X_0(B) \times_{X_0(\pi_0 B)} \{\eta_B\}) \to \tau_{\leqslant n}(X_0(\tau_{\leqslant m} B) \times_{X_0(\pi_0 B)} \{\eta_B\})$$

is a homotopy equivalence.

Let m satisfy the condition of ($\star$). We have a commutative diagram

$$\begin{array}{ccc} \tau_{\leqslant n} \varinjlim_{\beta \geqslant \alpha} (X_0(A_\beta) \times_{X_0(\pi_0 A_\beta)} \{\eta_\beta\}) & \xrightarrow{\theta_n} & \tau_{\leqslant n}(X_0(A) \times_{X_0(\pi_0 A)} \{\eta\}) \\ \downarrow & & \downarrow \\ \tau_{\leqslant n} \varinjlim_{\beta \geqslant \alpha} (X_0(\tau_{\leqslant m} A_\beta) \times_{X(\pi_0 A_\beta)} \{\eta_\beta\}) & \xrightarrow{\theta'_n} & \tau_{\leqslant n}(X_0(\tau_{\leqslant m} A) \times_{X_0(\pi_0 A)} \{\eta\}) \end{array}$$

where the vertical maps are homotopy equivalences. Consequently, to prove that θ_n is a homotopy equivalence, it suffices to show that θ'_n is a homotopy equivalence. This follows from the fact that the functor X is locally almost of finite presentation (which follows from Corollary 17.4.2.2).

It remains to prove ($\star$). Since $L_{X/Y}$ is perfect, $\eta_\alpha^* L_{X/Y}$ is a dualizable object of $\mathrm{Mod}_{\pi_0 A_\alpha}$. Let V denote a dual of $\eta_\alpha^* L_{X/Y}$, and choose an integer k such that V is k-connective. We claim that $m = n - k$ satisfies the condition of ($\star$). Choose a map of connective $\mathbb{E}_\infty$-rings $A_\alpha \to B$. We will prove that the map

$$X_0(B) \times_{X_0(\pi_0 B)} \{\eta_B\} \to X_0(\tau_{\leqslant m} B) \times_{X_0(\pi_0 B)} \{\eta_B\}$$

is $(n+1)$-connective.

Since the functor X is nilcomplete (Remark 17.3.7.3), $X_0(B) \times_{X_0(\pi_0 B)} \{\eta_B\}$ is the homotopy inverse limit of the tower $\{X_0(\tau_{\leqslant m'} B) \times_{X_0(\pi_0 B)} \{\eta_B\}\}_{m' \geqslant m}$. It will therefore suffice to show that the transition maps

$$\gamma_{m'} : X_0(\tau_{\leqslant m'+1} B) \times_{X_0(\pi_0 B)} \{\eta_B\} \to X_0(\tau_{\leqslant m'} B) \times_{X_0(\pi_0 B)} \{\eta_B\}$$

are $(n+1)$-connective for each $m' \geqslant m$.

Set $M = \pi_{m'+1} B$, so that there is a pullback diagram of connective $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc} \tau_{\leqslant m'+1} B & \longrightarrow & \tau_{\leqslant m'} B \\ \downarrow & & \downarrow \\ \tau_{\leqslant m'} B & \longrightarrow & \tau_{\leqslant m'} B \oplus \Sigma^{m'+2} M. \end{array}$$

Since X is infinitesimally cohesive (Remark 17.3.7.3), this diagram gives us a pullback square of spaces

$$\begin{array}{ccc} X_0(\tau_{\leqslant m'+1} B) \times_{X_0(\pi_0 B)} \{\eta_B\} & \xrightarrow{\gamma(m')} & X_0(\tau_{\leqslant m'} B) \times_{X_0(\pi_0 B)} \{\eta_B\} \\ \downarrow & & \downarrow \\ X_0(\tau_{\leqslant m'} B) \times_{X_0(\pi_0 B)} \{\eta_B\} & \xrightarrow{\gamma'} & X_0(\tau_{\leqslant m'} B \oplus \Sigma^{m'+2} M) \times_{X_0(\pi_0 B)} \{\eta_B\}. \end{array}$$

It will therefore suffice to show that the map γ' is $(n+1)$-connective. We note that γ' has a left homotopy inverse

$$\epsilon : X_0(\tau_{\leqslant m'} B \oplus \Sigma^{m'+2} M) \times_{X_0(\pi_0 B)} \{\eta_B\} \to X_0(\tau_{\leqslant m'} B) \times_{X_0(\pi_0 B)} \{\eta_B\}.$$

Consequently, we are reduced to proving that the homotopy fibers of ϵ are $(n+2)$-connective. Choose a point of $X_0(\tau_{\leqslant m'} B) \times_{X_0(\pi_0 B)} \{\eta_B\}$, corresponding to a point $\eta' \in X_0(\tau_{\leqslant m'} B)$ lifting η_B. Unwinding the definitions, we see that the homotopy fiber of ϵ over this point is given by the mapping space

$$\begin{aligned} \mathrm{Map}_{\mathrm{Mod}_{\tau_{\leqslant m'} B}}(\eta'^* L_{X/Y}, \Sigma^{m'+2} M) &\simeq \mathrm{Map}_{\mathrm{Mod}_{\pi_0 B}}(\eta_B^* L_{X/Y}, \Sigma^{m'+2} M) \\ &\simeq \mathrm{Map}_{\mathrm{Mod}_{\pi_0 A_\alpha}}(\eta_\alpha^* L_{X/Y}, \Sigma^{m'+2} M) \\ &\simeq \Omega^\infty(V \otimes_{\pi_0 A_\alpha} \Sigma^{m'+2} M). \end{aligned}$$

Since V is k-connective, $V \otimes_{\pi_0 A_\alpha} \Sigma^{m'+2} M$ is $(k+m'+2)$-connective. It now suffices to observe that $k + m' + 2 \geqslant n + 2$, since $m' \geqslant m = n - k$. □

17.4.3 Relationship with Geometric Finiteness Conditions

We conclude this section by studying the relationship of finiteness conditions of Definition 17.4.1.1 with the analogous conditions on morphisms of spectral Deligne-Mumford stacks studied in Chapter 4.

Proposition 17.4.3.1. *Let X and Y be spectral Deligne-Mumford stacks representing functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, let $\phi : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks, and let $f : X \to Y$ be the natural transformation determined by ϕ. Assume that ϕ is a relative Deligne-Mumford m-stack for some integer $m \gg 0$, and let $f : X \to Y$ denote the induced map of functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Then:*

(1) *For every integer $n \geqslant 0$, the morphism f is locally of finite generation to order n (in the sense of Definition 17.4.1.1) if and only if ϕ is locally of finite generation to order n (in the sense of Definition 4.2.0.1).*

(2) *The map f is locally almost of finite presentation (in the sense of Definition 17.4.1.1) if and only if ϕ is locally almost of finite presentation (in the sense of Definition 4.2.0.1).*

(3) *The map f is locally of finite presentation (in the sense of Definition 17.4.1.1) if and only if ϕ is locally of finite presentation (in the sense of Definition 4.2.0.1).*

The proof of Proposition 17.4.3.1 will require some preliminaries.

Lemma 17.4.3.2. *Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ and let $n \geqslant 0$. Suppose that there exists an integer $m \geqslant -2$ which satisfies the following condition:*

($*_m$) *For every n-truncated object $A \in \mathrm{CAlg}^{\mathrm{cn}}$, the induced map $X(A) \to Y(A)$ has (m)-truncated homotopy fibers.*

Let $X', Y' : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ denote the sheafification of X and Y with respect to the étale topology. If f is locally of finite generation to order n, then the induced map $f' : X' \to Y'$ is also locally of finite presentation to order n.

Proof. We proceed by induction on m. In the case $m = -2$, the map $f : X(A) \to Y(A)$ is an equivalence whenever A is n-truncated, and the desired result is obvious. To carry out the inductive step, let us assume that $m > -2$ and that f is locally of finite generation to order n. It follows that the relative diagonal $\delta : X \to X \times_Y X$ is also locally of finite generation to order n. Since δ satisfies condition ($*_{m-1}$), our inductive hypothesis guarantees that the relative diagonal $\delta' : X' \to X' \times_{Y'} X'$ is locally of finite generation to order n.

Fix a connective $\mathbb{E}_\infty$-ring R and a point $\eta \in Y(R)$, define $X_\eta : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ as in Notation 17.3.8.1, and define X'_η similarly. Note that we can identify X'_η with the sheafification of X_η with respect to the étale topology. By virtue of Remark 17.4.1.6, it will suffice to proving the following:

(i) For every diagram $\{A_\alpha\}_{\alpha \in I}$ in $\mathrm{CAlg}^{\mathrm{cn}}_R$ indexed by a filtered partially ordered set I, where each A_α is n-truncated and each transition map $\pi_n A_\alpha \to \pi_n A_\beta$ is a monomorphism, the canonical map $\rho : \varinjlim X'_\eta(A_\alpha) \to X'_\eta(A)$ is a homotopy equivalence; here $A = \varinjlim_{\alpha \in I} A_\alpha$.

In the situation of (i), our hypothesis that δ' is locally of finite generation to order n guarantees that the relative diagonal of ρ is a homotopy equivalence: that is, the homotopy fibers of ρ are (-1)-truncated. It will therefore suffice to show that ρ is surjective on connected components.

Fix a point $x' \in X'_\eta(A)$. Since X'_η is the sheafification of X_η with respect to the étale topology, there exists a finite collection of étale maps $\{A \to A(i)\}_{1 \leqslant i \leqslant n}$ with the following properties:

- (a) The map $A \to \prod_{1 \leqslant i \leqslant n} A(i)$ is faithfully flat.
- (b) For $1 \leqslant i \leqslant n$, let $x'_i \in X'_\eta(A(i))$ denote the image of x. Then x'_i lifts (up to homotopy) to a point $x_i \in X_\eta(A(i))$.

Using the structure theory of étale morphisms (Proposition B.1.1.3), we may choose an index $\alpha \in I$ and a collection of étale morphisms $A_\alpha \to A_\alpha(i)$, together with equivalences $A(i) \simeq A_\alpha(i) \otimes_{A_\alpha} A$. Enlarging α, we may assume that the map $A_\alpha \to \prod A_\alpha(i)$ is faithfully flat.

For $\beta \geqslant \alpha$, let us define a functor $\mathscr{F}_\beta : \mathrm{CAlg}^{\text{ét}}_{A_\alpha} \to \mathcal{S}$ by the formua $\mathscr{F}_\beta(B) = X'_\eta(B \otimes_{A_\alpha} A_\beta)$. Define $\mathscr{F} : \mathrm{CAlg}^{\text{ét}}_{A_\alpha} \to \mathcal{S}$ by the formula $\mathscr{F}(B) = X'_\eta(B \otimes_{A_\alpha} A)$, so that we have an evident map $\psi : \varinjlim_{\beta \geqslant \alpha} \mathscr{F}_\beta \to \mathscr{F}$. Since the map δ' is locally of finite generation to order n, the map ψ is (-1)-truncated. To complete the proof, it will suffice to show that the point $x' \in X'_\eta(A) \simeq \mathscr{F}(A_\alpha)$ belongs to the essential image of the map $\psi(A_\alpha) : \varinjlim_{\beta \geqslant \alpha} \mathscr{F}_\beta(A_\alpha) \to \mathscr{F}(A_\alpha)$. Note that $\mathscr{F}$ and each $\mathscr{F}_\beta$ are m-truncated sheaves with respect to the étale topology on $\mathrm{CAlg}^{\text{ét}}_{A_\alpha}$, so that the colimit $\varinjlim_{\beta \geqslant \alpha} \mathscr{F}_\beta$ is also a sheaf with respect to the étale topology. Consequently, the assertion that x' belongs to the essential image of $\psi(A_\alpha)$ can be tested locally with respect to the étale topology on A_α. We may therefore replace A_α by $A_\alpha(i)$ and thereby reduce to the case where x' belongs to the essential image of the map $X_\eta(A) \to X'_\eta(A)$. In this case, the desired result follows from our assumption that f is locally of finite presentation to order n. □

Remark 17.4.3.3. In the statement of Lemma 17.4.3.2 (in in its applications given below), we can replace the étale topology by the Zariski or Nisnevich topologies: the proof carries over without essential change.

Recall that if R is an $\mathbb{E}_\infty$-ring, we let $\mathcal{S}\mathrm{hv}^{\text{ét}}_R$ denote the full subcategory of $\mathrm{Fun}(\mathrm{CAlg}^{\text{ét}}_R, \mathcal{S})$ spanned by those functors which are sheaves with respect to the étale topology.

Lemma 17.4.3.4. *Let R be a connective $\mathbb{E}_\infty$-ring and let $\mathscr{F}$ be a truncated object of $\mathcal{S}\mathrm{hv}^{\text{ét}}_R$. For every map of $\mathbb{E}_\infty$-rings $R \to A$, let $\mathscr{F}_A$ denote the image of $\mathscr{F}$ in the ∞-category $\mathcal{S}\mathrm{hv}^{\text{ét}}_A$ (in other words, the pullback of $\mathscr{F}$ along the map $\mathrm{Spét}\, A \to \mathrm{Spét}\, R$). Then the functor $A \mapsto \mathscr{F}_A(A)$ commutes with filtered colimits.*

Proof. Choose an integer m such that $\mathscr{F}$ is n-truncated. Let $X : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ be a left Kan extension of $\mathscr{F} : \mathrm{CAlg}^{\text{ét}}_R \to \mathcal{S}$. For every connective R-algebra A, we have

$X(A) \simeq \varinjlim_{R' \to A} \mathscr{F}(R')$, where the colimit is taken over the full subcategory of $\mathrm{CAlg}_{R//A}$ spanned by those R' which are étale over R. Since this ∞-category is filtered, we deduce that $X(A)$ is m-truncated for every object $A \in \mathrm{CAlg}_R^{\mathrm{cn}}$. Because every étale R-algebra is a compact object of CAlg_R, the functor X commutes with filtered colimits. Note that the functor $A \mapsto \mathscr{F}_A(A)$ is the sheafification of X with respect to the étale topology. The desired result now follows from Lemma 17.4.3.2. □

Lemma 17.4.3.5. *Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Assume that f is a relative étale Deligne-Mumford n-stack: that is, for every morphism $Y' \to Y$ where Y' is representable by a connective $\mathbb{E}_\infty$-ring R, the fiber product $X \times_Y Y'$ is representable by a spectral Deligne-Mumford n-stack which is étale over* $\mathrm{Spét}\, R$*. Then f is locally of finite presentation.*

Proof. Using Propositon 17.4.1.5, we may suppose that Y is corepresentable. The desired result now follows by combining the criterion of Remark 17.4.1.6 with Lemma 17.4.3.4. □

Lemma 17.4.3.6. *Let $f : R \to A$ be a map of connective $\mathbb{E}_\infty$-rings, and assume that the fiber of f is m-connective for $m \geqslant 0$. If B is an n-truncated $\mathbb{E}_\infty$-ring, then the mapping space* $\mathrm{Map}_{\mathrm{CAlg}_R}(A, B)$ *is $(n - m - 1)$-truncated.*

Proof. We define a diagram of objects $R = R(0) \to R(1) \to R(2) \to \cdots$ in the ∞-category $(\mathrm{CAlg}_R)_{/A}$ by induction. Assuming that $R(i)$ has been defined, let $K(i)$ denote the fiber of the map $R(i) \to A$, and form a pushout diagram

$$\begin{array}{ccc} \mathrm{Sym}^* K(i) & \longrightarrow & R \\ \downarrow & & \downarrow \\ R(i) & \longrightarrow & R(i+1). \end{array}$$

We first claim that the canonical map $\varinjlim R(i) \to A$ is an equivalence of $\mathbb{E}_\infty$-algebras over R. To prove this, it suffices to show that θ induces an equivalence in the ∞-category of R-modules. This is clear, since colimit $\{R(i)\}$ agrees with the colimit of

$$R(0) \to \mathrm{cofib}(K(0) \to R(0)) \to R(1) \to \mathrm{cofib}(K(1) \to R(1)\} \to \cdots,$$

which contains a cofinal subsequence taking the constant value A.

We next claim that each $K(i)$ is m-connective. Equivalently, we claim that each of the maps $\pi_j R(i) \to \pi_j A$ is surjective for $i = m$ and bijective for $i < m$. This is true by hypothesis when $i = 0$; we treat the general case using induction on i. Since $K(i)$ is

m-connective, we have equivalences

$$\begin{aligned}\tau_{\leqslant m-1}R(i+1) &\simeq \tau_{\leqslant m-1}(R\otimes_{\mathrm{Sym}^* K(i)} R(i))\\ &\simeq \tau_{\leqslant m-1}(\tau_{\leqslant m-1}R\otimes_{\tau_{\leqslant m-1}\mathrm{Sym}^* K(i)} \tau_{\leqslant m-1}R(i))\\ &\simeq \tau_{\leqslant m-1}(\tau_{\leqslant m-1}R\otimes_{\tau_{\leqslant m-1}R} \tau_{\leqslant m-1}R(i))\\ &\simeq \tau_{\leqslant m-1}R(i)\\ &\simeq \tau_{\leqslant m-1}A.\end{aligned}$$

The surjectivity of the map $\pi_m R(i) \to \pi_m A$ follows from the surjectivity of the map $\pi_m R \to \pi_m A$.

Note that $\mathrm{Map}_{\mathrm{CAlg}_R}(A,B)$ can be identified with the homotopy limit of the tower of spaces $\{\mathrm{Map}_{\mathrm{CAlg}_R}(R(i),B)\}_{i\geqslant 0}$, and that the mapping space $\mathrm{Map}_{\mathrm{CAlg}_R}(R,B)$ is contractible. To prove that $\mathrm{Map}_{\mathrm{CAlg}_R}(A,B)$ is $(n-1-m)$-truncated, it will suffice to show that each of the maps $\theta_i : \mathrm{Map}_{\mathrm{CAlg}_R}(R(i+1),B) \to \mathrm{Map}_{\mathrm{CAlg}_R}(R(i),B)$ is $(n-m-1)$-truncated. Note that θ_i is a pullback of the map

$$\theta'_i : * \simeq \mathrm{Map}_{\mathrm{CAlg}_R}(R,B) \to \mathrm{Map}_{\mathrm{CAlg}_R}(\mathrm{Sym}^* K(i),B) \simeq \mathrm{Map}_{\mathrm{Mod}_R}(K(i),B).$$

It will therefore suffice to show that each of the mapping spaces $\mathrm{Map}_{\mathrm{Mod}_R}(K(i),B)$ is $(n-m)$-truncated. This follows from our assumption that $K(i)$ is m-connective and B is n-truncated. □

Proof of Proposition 17.4.3.1. The implication (1) ⇒ (2) is obvious. Note that f is locally of finite presentation if and only if it locally almost of finite presentation and $L_{X/Y}$ is perfect (Proposition 17.4.2.3). To prove that (2) ⇒ (3), it will suffice to show that ϕ is locally of finite presentation if and only if it is locally almost of finite presentation and $L_{\mathsf{X}/\mathsf{Y}}$ is perfect. This assertion is local on X and Y. We may therefore suppose that X and Y are affine, in which case the desired result follows from Theorem HA.7.4.3.18 .

It remains to prove (1). Using Proposition 17.4.1.5, we can reduce to the case where $\mathsf{Y} = \mathrm{Spét}\, R$ is affine, so that X is a spectral Deligne-Mumford m-stack. Suppose first that f is locally of finite generation to order n. Choose an étale map $u : \mathrm{Spét}\, A \to \mathsf{X}$; we wish to show that A is of finite generation to order n over R. Unwinding the definitions, we see that this is equivalent to the requirement that the composite map $\mathrm{Spec}\, A \to X \xrightarrow{f} Y = \mathrm{Spec}\, R$ is of finite generation to order n. This follows from Remark 17.4.1.3, since f is locally of finite generation to order n (by assumption) and g is locally of finite presentation (Lemma 17.4.3.5).

We now prove the converse. We first treat the case where X is a coproduct of affine spectral Deligne-Mumford stacks $\{\mathsf{X}_\alpha\}_{\alpha\in S}$, indexed by some finite set S. For every finite subset $T \subseteq S$, let $\mathsf{X}_T = \coprod_{\alpha\in T}\mathsf{X}_\alpha$, and let X_T denote the functor represented by X_T. If X is locally of finite generation to order n over Y, then each X_T has the same property. Since each X_T is affine, we conclude that the map $X_T \to Y$ is locally of of finite generation to order n, so that the induced map $\varinjlim_{T \subseteq S} X_T \to Y$ is locally of finite generation to order n (here the colimit is taken over the filtered partially ordered set of finite subsets of S). Note that X is the sheafification of $\varinjlim_{T \subseteq S} X_T$ with respect to the étale topology. It follows from Lemma 17.4.3.2 that X is locally of finite generation to order n over Y.

We now treat the general case. Choose an étale surjection $u : \mathsf{X}_0 \to \mathsf{X}$, where X_0 is a coproduct of affine spectral Deligne-Mumford stacks. Let $X_0 : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ denote the functor represented by X_0. For every connective $\mathbb{E}_\infty$-ring A, let $X'(A)$ denote the essential image of the map $X_0(A) \to X(A)$. Since u is an étale surjection, the inclusion $X' \hookrightarrow X$ exhibits X as a sheafificaton of X' with respect to the étale topology. Using Lemma 17.4.3.2, we are reduced to proving that the map $X' \to Y$ is locally of finite generation to order n. Choose a filtered diagram $\{A_\alpha\}$ in $\mathrm{CAlg}^{\mathrm{cn}}$ having colimit A, where each A_α is n-truncated and each of the transition maps $\pi_n A_\alpha \to \pi_n A_\beta$ is a monomorphism; we wish to show that the map $\theta : \varinjlim X'(A_\alpha) \to X'(A) \times_{Y(A)} \varinjlim Y(A_\alpha)$ is a homotopy equivalence. The map θ fits into a commutative diagram

$$\begin{array}{ccc} \varinjlim X_0(A_\alpha) & \longrightarrow & X_0(A) \times_{Y(A)} \varinjlim Y(A_\alpha) \\ \downarrow{\scriptstyle \theta'} & & \downarrow{\scriptstyle \psi} \\ \varinjlim X'(A_\alpha) & \xrightarrow{\theta} & X'(A) \times_{Y(A)} \varinjlim Y(A_\alpha). \end{array}$$

Lemma 17.4.3.5 implies that this diagram is a pullback square, and the fact that X_0 is a coproduct of affine spectral Deligne-Mumford stacks guarantees that θ' is a homotopy equivalence. We now complete the proof by observing that ψ is surjective on connected components (by construction). □

17.5 The Tangent Complex

Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Suppose that we wish to show that f admits a relative cotangent complex $L_{X/Y}$, in the sense of Definition 17.2.4.2. As a starting point, we note that the *dual* of $L_{X/Y}$ is well-defined under very mild hypotheses. In §17.5.1, we show that if f is infinitesimally cohesive, then to each point $\eta \in X(A)$ we can associate an A-module $T_{X/Y}(\eta)$, which we will refer to as the *relative tangent complex of X over Y at the point η* (Construction 17.5.1.1). In §17.5.2, we study conditions under which the formation of tangent complexes is compatible with extension of scalars (Proposition 17.5.2.1), so that we can regard the construction $\eta \mapsto T_{X/Y}(\eta)$ as a quasi-coherent sheaf on X. Specializing to the case $Y = \operatorname{Spec} R$ for some Noetherian $\mathbb{E}_\infty$-ring R which admits a dualizing complex, we obtain an existence criterion for the cotangent complex $L_{X/Y}$ (Theorem 17.5.4.1). The proof makes use of characterization of those functors $\mathrm{Mod}_R^{\mathrm{cn}} \to \mathcal{S}$ which are corepresentable by almost perfect R-modules (Theorem 17.5.3.1), which we establish using ideas from §6.6.

17.5.1 The Tangent Complex at a Point

In §18, we studied the tangent complex associated to a formal moduli problem X over a field κ. We now introduce a "global" variant of this construction.

Construction 17.5.1.1. Let $f : X \to Y$ be an infinitesimally cohesive natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. For every connective $\mathbb{E}_\infty$-ring A and every point $\eta \in X(A)$, let $F_\eta : \mathrm{Mod}_A^{\mathrm{cn}} \to \mathcal{S}$ denote the functor given by the formula

$$F_\eta(M) = \mathrm{fib}(X(A \oplus M) \to Y(A \oplus M) \times_{Y(A)} X(A)),$$

where the fiber is taken over the point determined by η. Since f is infinitesimally cohesive, the canonical map $F_\eta(M) \to \Omega F_\eta(\Sigma M)$ is an equivalence for each $M \in \mathrm{Mod}_A^{\mathrm{cn}}$, so that the functor F_η is reduced and excisive (Proposition HA.1.4.2.13). Applying Lemma 17.2.1.2, we deduce that F_η admits an essentially unique extension to a left exact functor $F_\eta^+ : \mathrm{Mod}_A^{\mathrm{acn}} \to \mathcal{S}$. We can identify the restriction $F_\eta^+|_{\mathrm{Mod}_A^{\mathrm{perf}}}$ with an object of $\mathrm{Ind}((\mathrm{Mod}_A^{\mathrm{perf}})^{\mathrm{op}}) \simeq \mathrm{Ind}(\mathrm{Mod}_A^{\mathrm{perf}}) \simeq \mathrm{Mod}_A$ (see §HA.7.2.4). We will denote the corresponding A-module by $T_{X/Y}(\eta)$, and refer to it as the *relative tangent complex of f at the point η*. It is characterized by the following universal property: for every connective perfect A-module M, we have a canonical homotopy equivalence $F_\eta(M) \simeq \Omega^\infty(T_{X/Y}(\eta) \otimes_A M)$. In particular, we have a homotopy equivalence $\Omega^{\infty-n} T_{X/Y}(\eta) \simeq F_\eta(\Sigma^n A)$ for each $n \geqslant 0$.

Example 17.5.1.2. Let $f : X \to Y$ be an infinitesimally cohesive morphism in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$, and suppose that f admits a relative cotangent complex $L_{X/Y}$. For every point $\eta \in X(A)$, the functor F_η of Construction 17.5.1.1 is given by $F_\eta(M) = \mathrm{Map}_{\mathrm{Mod}_A}(\eta^* L_{X/Y}, M)$. It follows that the relative tangent complex $T_{X/Y}(\eta)$ can be identified with the A-linear dual $\underline{\mathrm{Map}}_A(\eta^* L_{X/Y}, A)$ of $\eta^* L_{X/Y}$.

Variant 17.5.1.3. In the situation of Construction 17.5.1.1, suppose we are given an almost connective A-module N. The functor $M \mapsto F_\eta^+(M \otimes_A N)$ is left exact, and therefore its restriction to perfect A-modules determines an A-module $T_{X/Y}(\eta; N)$ equipped with canonical equivalences $\Omega^{\infty-n} T_{X/Y}(\eta; N) \simeq F_\eta(\Sigma^n N)$. Note that we have $T_{X/Y}(\eta) \simeq T_{X/Y}(\eta; A)$. Moreover, the construction $N \mapsto T_{X/Y}(\eta; N)$ is an exact functor from Mod_A to itself.

Remark 17.5.1.4. Let $f : X \to Y$ be an infinitesimally cohesive morphism in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$, let $\phi : A \to A'$ be a map of connective $\mathbb{E}_\infty$-rings, let $\eta \in X(A)$ and let η' denote its image in $X(A')$. Define functors $F_\eta : \mathrm{Mod}_A^{\mathrm{cn}} \to \mathcal{S}$ and $F_{\eta'} : \mathrm{Mod}_{A'}^{\mathrm{cn}} \to \mathcal{S}$ as in Construction 17.5.1.1, and let $U : \mathrm{Mod}_{A'}^{\mathrm{acn}} \to \mathrm{Mod}_A^{\mathrm{acn}}$ denote the forgetful functor. Then ϕ induces a natural transformation of reduced excisive functors $F_\eta \circ (U|_{\mathrm{Mod}_A^{\mathrm{cn}}}) \to F_{\eta'}$, which extends to a natural transformation of left exact functors $F_\eta^+ \circ U \to F_{\eta'}^+$. For every A'-module N, we obtain a map of A-modules $T_{X/Y}(\eta; N) \to T_{X/Y}(\eta'; N)$. This map is an equivalence if f is cohesive and ϕ induces a surjection $\pi_0 A \to \pi_0 A'$.

Remark 17.5.1.5. Suppose we are given a pullback diagram

$$\begin{array}{ccc} X & \longrightarrow & X' \\ \downarrow & & \downarrow \\ Y & \longrightarrow & Y' \end{array}$$

in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$, where the vertical maps are infinitesimally cohesive. Let A be a connective $\mathbb{E}_\infty$-ring, let $\eta \in X(A)$, and let η' denote the image of η in $X'(A)$. These is a canonical equivalence of A-modules $T_{X/Y}(\eta) \simeq T_{X'/Y'}(\eta')$.

17.5.2 Compatibility with Base Change

Let $f : X \to Y$ be an infinitesimally cohesive morphism between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Suppose that $\phi : A \to A'$ is a morphism of connective $\mathbb{E}_\infty$-rings. Let η be a point of $X(A)$, and let η' denote the image of η in $X(A')$. Applying Remark 17.5.1.4 in the special case $N = A'$, we obtain a natural map A-modules

$$T_{X/Y}(\eta) = T_{X/Y}(\eta; A) \to T_{X/Y}(\eta; A') \to T_{X/Y}(\eta', A') = T_{X/Y}(\eta').$$

Extending scalars along ϕ, we obtain a morphism of A'-modules $\rho : A' \otimes_A T_{X/Y}(\eta) \to T_{X/Y}(\eta')$. Our goal in this section is to prove the following:

Proposition 17.5.2.1. *Let $f : X \to Y$ be a morphism in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$, where Y is corepresentable by a Noetherian $\mathbb{E}_\infty$-ring R, and let $X_0 : \mathrm{CAlg}_R^{\mathrm{cn}} \to \mathcal{S}$ denote the functor given by $X_0(A) = \mathrm{fib}(X(A) \to \mathrm{Map}_{\mathrm{CAlg}}(R, A))$. Assume that f is cohesive, nilcomplete, and locally almost of finite presentation. The following conditions are equivalent:*

(1) *For every morphism $\phi : A \to B$ in $\mathrm{CAlg}_R^{\mathrm{cn}}$ and every connective B-module M, the diagram*

$$\begin{array}{ccc} X_0(A \oplus M) & \longrightarrow & X_0(B \oplus M) \\ \downarrow & & \downarrow \\ X_0(A) & \longrightarrow & X_0(B) \end{array}$$

is a pullback square.

(2) *For every point $\eta \in X(A)$ and every flat morphism $\phi : A \to B$ carrying η to a point $\eta' \in X(B)$, the natural map $B \otimes_A T_{X/Y}(\eta) \to T_{X/Y}(\eta')$ is an equivalence, where η' denotes the image of η in $X(B)$.*

(3) *For every discrete integral domain A and every point $\eta \in X(A)$ which exhibits A as a finitely generated algebra over $\pi_0 R$, the natural map $A[x] \otimes_A T_{X/Y}(\eta) \to T_{X/Y}(\eta')$ is an equivalence, where η' denotes the image of $\eta \in X(A[x])$.*

(4) *For every discrete integral domain A with fraction field K, every point $\eta \in X(A)$ which exhibits A as a finitely generated algebra over $\pi_0 R$, and every extension field L of K, the canonical map $L \otimes_A T_{X/Y}(\eta) \to T_{X/Y}(\eta')$ is an equivalence, where η' denotes the image of η in $X(L)$.*

Remark 17.5.2.2. If f satisfies the equivalent conditions of Proposition 17.5.2.1, then the construction $(\eta \in X(A)) \mapsto (T_{X/Y}(\eta) \in \mathrm{Mod}_A)$ determines a quasi-coherent sheaf on the functor X, which we will denote by $T_{X/Y}$ and refer to as the *tangent complex of f*.

Proof of Proposition 17.5.2.1. We first show that (1) $\Rightarrow$ (2). Fix a point $\eta \in X(A)$, let B be a flat $\mathbb{E}_\infty$-algebra over A, and let $\eta' \in X(B)$ denote the image of η. Define $F_\eta : \mathrm{Mod}_A^{\mathrm{cn}} \to \mathcal{S}$ and $F_{\eta'} : \mathrm{Mod}_B^{\mathrm{cn}} \to \mathcal{S}$ as in Construction 17.5.1.1. To prove that the canonical map $B \otimes_A T_{X/Y}(\eta) \to T_{X/Y}(\eta')$ is an equivalence, it will suffice to show that for each $n \geqslant 0$ the map $\theta : \Omega^{\infty-n}(B \otimes_A T_{X/Y}(\eta)) \to \Omega^{\infty-n} T_{X/Y}(\eta')$ is a homotopy equivalence of spaces. Since B is flat over A, we can write B as a filtered colimit $\varinjlim P_\alpha$, where each P_α is a free A-module of finite rank (Theorem HA.7.2.2.15). We can then identify θ with the composite map

$$\begin{aligned} \Omega^{\infty-n}(B \otimes_A T_{X/Y}(\eta)) &\simeq \varinjlim \Omega^{\infty-n}(P_\alpha \otimes_A T_{X/Y}(\eta)) \\ &\simeq \varinjlim F_\eta(\Sigma^n P_\alpha) \\ &\xrightarrow{\theta'} F_\eta(B) \\ &\xrightarrow{\theta''} F_{\eta'}(B). \end{aligned}$$

The map θ' is a homotopy equivalence by virtue of our assumption that f is locally almost of finite presentation, and the map θ'' is a homotopy equivalence by virtue of assumption (1).

The implications (2) $\Rightarrow$ (3) and (2) $\Rightarrow$ (4) are obvious. We next show that (3) $\Rightarrow$ (1). Choose a connective $\mathbb{E}_\infty$-ring R and a point $\eta \in Y(R)$, and let $X_0 : \mathrm{CAlg}_R^{\mathrm{cn}} \to \mathcal{S}$ be as in Notation 17.3.8.1. We wish to show that for every morphism $\phi : A \to B$ in $\mathrm{CAlg}_R^{\mathrm{cn}}$ and every connective B-module M, the diagram σ_M :

$$\begin{array}{ccc} X_0(A \oplus M) & \longrightarrow & X_0(B \oplus M) \\ \downarrow & & \downarrow \\ X_0(A) & \longrightarrow & X_0(B) \end{array}$$

is a pullback square. Since X is nilcomplete, σ_M is the limit of the diagrams $\sigma_{\tau_{\leqslant n} M}$. It will therefore suffice to show that each $\sigma_{\tau_{\leqslant n} M}$ is a pullback diagram. We proceed by induction on n, the case $n = 0$ being trivial. If $n > 0$, we have a fiber sequence of B-modules $\tau_{\leqslant n} M \to \tau_{\leqslant n-1} M \to \Sigma^{n+1} N$ where $N \simeq \pi_n M$ is a discrete B-module. The square $\sigma_{\tau_{\leqslant n} M}$ fits into a larger diagram

$$\begin{array}{ccccc} X_0(A \oplus \tau_{\leqslant n} M) & \longrightarrow & X_0(B \oplus \tau_{\leqslant n} M) & \longrightarrow & X_0(B \oplus \tau_{\leqslant n-1} M) \\ \downarrow & & \downarrow & & \downarrow \\ X_0(A) & \longrightarrow & X_0(B) & \longrightarrow & X_0(B \oplus \Sigma^{n+1} N) \end{array}$$

The right square in this diagram is a pullback since X is cohesive. It will therefore suffice to show that the outer rectangle is a pullback diagram. That is, we must show that the outer rectangle in the diagram

$$\begin{array}{ccccc} X_0(A \oplus \tau_{\leqslant n} M) & \longrightarrow & X_0(A \oplus \tau_{\leqslant n-1} M) & \longrightarrow & X_0(B \oplus \tau_{\leqslant n-1} M) \\ \downarrow & & \downarrow & & \downarrow \\ X_0(A) & \longrightarrow & X_0(A \oplus K) & \longrightarrow & X_0(B \oplus \Sigma^{n+1} N) \end{array}$$

is a pullback square. Since the left square is a pullback by virtue of our assumption that X is cohesive, it suffices to show that the right square is also a pullback. This square fits into a commutative diagram

$$\begin{array}{ccc} X_0(A \oplus \tau_{\leqslant n-1} M) & \longrightarrow & X_0(B \oplus \tau_{\leqslant n-1} M) \\ \downarrow & & \downarrow \\ X_0(A \oplus \Sigma^{n+1} N) & \longrightarrow & X_0(B \oplus \Sigma^{n+1} N) \\ \downarrow & & \downarrow \\ X_0(A) & \longrightarrow & X_0(B) \end{array}$$

where the outer rectangle is a pullback square by the inductive hypothesis. It will therefore suffice to show that $\sigma_{\Sigma^{n+1} N}$ is a pullback diagram.

Since N is a module over $\pi_0 B$, $\sigma_{\Sigma^{n+1} N}$ fits into a commutative diagram

$$\begin{array}{ccccc} X_0(A \oplus \Sigma^{n+1} N) & \longrightarrow & X_0(B \oplus \Sigma^{n+1} N) & \longrightarrow & X_0(\pi_0 B \oplus \Sigma^{n+1} N) \\ \downarrow & & \downarrow & & \downarrow \\ X_0(A) & \longrightarrow & X_0(B) & \longrightarrow & X_0(\pi_0 B) \end{array}$$

The right square is a pullback diagram by virtue of our assumption that X is cohesive. It will therefore suffice to show that the outer rectangle is a pullback. Equivalently, we must show that the outer rectangle in the diagram

$$\begin{array}{ccccc} X_0(A \oplus \Sigma^{n+1} N) & \longrightarrow & X_0(\pi_0 A \oplus \Sigma^{n+1} N) & \longrightarrow & X_0(\pi_0 B \oplus \Sigma^{n+1} N) \\ \downarrow & & \downarrow & & \downarrow \\ X_0(A) & \longrightarrow & X_0(\pi_0 A) & \longrightarrow & X_0(\pi_0 B) \end{array}$$

is a pullback square. Since the left square is a pullback (because X is cohesive), we are reduced to proving that the right square is a pullback. In other words, we may replace A by $\pi_0 A$ and B by $\pi_0 B$, and thereby reduce to the case where A and B are discrete.

Write A as a filtered colimit of subalgebras A_α which are finitely generated over $\pi_0 R$. Since f is locally almost of finite presentation, the functor X_0 commutes with filtered colimits when restricted to $(n+1)$-connective R-algebras. It will therefore suffice to show that each of the diagrams

$$\begin{array}{ccc} X_0(A_\alpha \oplus \Sigma^{n+1} N) & \longrightarrow & X_0(B \oplus \Sigma^{n+1} N) \\ \downarrow & & \downarrow \\ X_0(A_\alpha) & \longrightarrow & X_0(B). \end{array}$$

We may therefore replace A by A_α and thereby reduce to the case where A is finitely generated as an algebra over $\pi_0 R$. In particular, A is a Noetherian ring. Choose a surjection of commutative A-algebras $P \to B$, where P is a polynomial ring over A. We then have a commutative diagram

$$\begin{array}{ccccc} X_0(A \oplus \Sigma^{n+1} N) & \longrightarrow & X_0(P \oplus \Sigma^{n+1} N) & \longrightarrow & X_0(B \oplus \Sigma^{n+1} N) \\ \downarrow & & \downarrow & & \downarrow \\ X_0(A) & \longrightarrow & X_0(P) & \longrightarrow & X_0(B). \end{array}$$

The right square is a pullback since X_0 is cohesive. It will therefore suffice to show that the left square is a homotopy pullback. Write $P \simeq \varinjlim P_\beta$, where each P_β is a polynomial ring over A on finitely many generators. It will therefore suffice to show that each of the diagrams

$$\begin{array}{ccc} X_0(A \oplus \Sigma^{n+1} N) & \longrightarrow & X_0(P_\beta \oplus \Sigma^{n+1} N) \\ \downarrow & & \downarrow \\ X_0(A) & \longrightarrow & X_0(P_\beta). \end{array}$$

is a pullback square. Write $P_\beta = A[x_1, \ldots, x_k]$. Working by induction on k, we can reduce to the case where $k = 1$: that is, we are given a discrete $A[x]$-module N, and we wish to show that the diagram τ :

$$\begin{array}{ccc} X_0(A \oplus \Sigma^{n+1} N) & \longrightarrow & X_0(A[x] \oplus \Sigma^{n+1} N) \\ \downarrow & & \downarrow \\ X_0(A) & \longrightarrow & X_0(A[x]) \end{array}$$

is a pullback square.

Let N_0 denote the underlying A-module of N, and regard $N_0[x]$ as an $A[x]$-module. We have a short exact sequence of discrete $A[x]$-modules $0 \to N_0[x] \to N_0[x] \to N \to 0$, hence a fiber sequence $\Sigma^{n+1} N \to \Sigma^{n+2} N_0[x] \to \Sigma^{n+2} N_0[x]$. It follows that τ fits into a commutative diagram

$$\begin{array}{ccccc} X_0(A \oplus \Sigma^{n+1} N) & \longrightarrow & X_0(A[x] \oplus \Sigma^{n+1} N) & \longrightarrow & X_0(A[x] \oplus \Sigma^{n+2} N_0[x]) \\ \downarrow & & \downarrow & & \downarrow \\ X_0(A) & \longrightarrow & X_0(A[x]) & \longrightarrow & X_0(A[x] \oplus \Sigma^{n+2} N_0[x]). \end{array}$$

Our assumption that X is cohesive guarantees that the right square is a pullback. It will therefore suffice to show that the outer rectangle is also a pullback. Equivalently, we must show that the outer rectangle in the diagram

$$\begin{array}{ccccc} X_0(A \oplus \Sigma^{n+1} N) & \longrightarrow & X_0(A \oplus \Sigma^{n+2} N_0[x]) & \longrightarrow & X_0(A[x] \oplus \Sigma^{n+2} N_0[x]) \\ \downarrow & & \downarrow & & \downarrow \\ X_0(A) & \longrightarrow & X_0(A \oplus \Sigma^{n+2} N_0[x]) & \longrightarrow & X_0(A[x] \oplus \Sigma^{n+2} N_0[x]) \end{array}$$

is a pullback square. Since the left square is a pullback (because X is cohesive), it will suffice to show that the right square is also a pullback. This square fits into a larger diagram

$$\begin{array}{ccc} X_0(A \oplus \Sigma^{n+2} N_0[x]) & \longrightarrow & X_0(A[x] \oplus \Sigma^{n+2} N_0[x]) \\ \downarrow & & \downarrow \\ X_0(A \oplus \Sigma^{n+2} N_0[x]) & \longrightarrow & X_0(A[x] \oplus \Sigma^{n+2} N_0[x]) \\ \downarrow & & \downarrow \\ X_0(A) & \longrightarrow & X_0(A[x]). \end{array}$$

It will therefore suffice to show that the lower square and the outer rectangle in this diagram are pullback squares. For this, it suffices to verify the following general assertion: for every discrete A-module T, the diagram τ_T :

$$\begin{array}{ccc} X_0(A \oplus \Sigma^{n+2} T[x]) & \longrightarrow & X_0(A[x] \oplus \Sigma^{n+2} T[x]) \\ \downarrow & & \downarrow \\ X_0(A) & \longrightarrow & X_0(A[x]) \end{array}$$

is a pullback square.

Since f is locally almost of finite presentation, the construction $T \mapsto \tau_T$ commutes with filtered colimits. Writing T as a filtered colimit of its finitely generated submodules, we are reduced to proving that τ_T is an equivalence when T is finitely generated over A. Since A is Noetherian, T is also Noetherian. Working by Noetherian induction, we can assume that for every nonzero submodule $T' \subseteq T$, the diagram $\tau_{T/T'}$ is a pullback square. If $T = 0$, there is nothing to prove. Otherwise, T has an associated prime: that is, we can choose a nonzero element $x \in T$ whose annihilator is a prime ideal $\mathfrak{p} \subseteq A$. Let T' denote the submodule of T generated by x. The diagram τ_T fits into a commutative square

$$\begin{array}{ccccc}
X_0(A \oplus \Sigma^{n+2} T[x]) & \longrightarrow & X_0(A[x] \oplus \Sigma^{n+2} T[x]) & \longrightarrow & X_0(A[x] \oplus \Sigma^{n+2} T/T'[x]) \\
\downarrow & & \downarrow & & \downarrow \\
X_0(A) & \longrightarrow & X_0(A[x]) & \longrightarrow & X_0(A[x] \oplus \Sigma^{n+3} T'[x]).
\end{array}$$

Since X is cohesive, the right square is a pullback. It will therefore suffice to show that the outer rectangle is a pullback. This is equivalent to the outer rectangle in the diagram

$$\begin{array}{ccccc}
X_0(A \oplus \Sigma^{n+2} T[x]) & \longrightarrow & X_0(A \oplus \Sigma^{n+2} T/T'[x]) & \longrightarrow & X_0(A[x] \oplus \Sigma^{n+2} T/T'[x]) \\
\downarrow & & \downarrow & & \downarrow \\
X_0(A) & \longrightarrow & X_0(A \oplus \Sigma^{n+3} T'[x]) & \longrightarrow & X_0(A[x] \oplus \Sigma^{n+3} T'[x]).
\end{array}$$

Since the left square in this diagram is a pullback (by virtue of the assumption that X is cohesive), we are reduced to proving that the right square is also a pullback. To prove this, we consider the rectangular diagram

$$\begin{array}{ccc}
X_0(A \oplus \Sigma^{n+2} T/T'[x]) & \longrightarrow & X_0(A[x] \oplus \Sigma^{n+2} T/T'[x]) \\
\downarrow & & \downarrow \\
X_0(A \oplus \Sigma^{n+3} T'[x]) & \longrightarrow & X_0(A[x] \oplus \Sigma^{n+3} T'[x]) \\
\downarrow & & \downarrow \\
X_0(A) & \longrightarrow & X_0(A[x]).
\end{array}$$

The inductive hypothesis implies that the outer rectangle is a pullback diagram. It will therefore suffice to show that the lower square is also a pullback diagram.

Write $T' = A/\mathfrak{p}$, and consider the diagram

$$\begin{array}{ccccc}
X_0(A \oplus \Sigma^{n+3} T'[x]) & \longrightarrow & X_0(A[x] \oplus \Sigma^{n+3} T'[x]) & \longrightarrow & X_0(A[x]/\mathfrak{p} \oplus \Sigma^{n+3} T'[x]) \\
\downarrow & & \downarrow & & \downarrow \\
X_0(A) & \longrightarrow & X_0(A[x]) & \longrightarrow & X_0(A[x]/\mathfrak{p}).
\end{array}$$

Since X is cohesive, the left square is a pullback. It will therefore suffice to show that the outer rectangle is a pullback. Equivalently, we must show that the outer rectangle in the diagram

$$\begin{array}{ccccc} X_0(A \oplus \Sigma^{n+3}T'[x]) & \longrightarrow & X_0(A/\mathfrak{p} \oplus \Sigma^{n+3}T'[x]) & \longrightarrow & X_0(A[x]/\mathfrak{p} \oplus \Sigma^{n+3}T'[x]) \\ \downarrow & & \downarrow & & \downarrow \\ X_0(A) & \longrightarrow & X_0(A/\mathfrak{p}) & \longrightarrow & X_0(A[x]/\mathfrak{p}) \end{array}$$

is a pullback. Here the left square is a pullback by virtue of our assumption that X is cohesive. We are therefore reduced to proving that the right square is a pullback diagram, which follows assumption (3).

We now complete the proof by showing that (4) $\Rightarrow$ (3). Suppose that (4) is satisfied. We will prove the following more general version of (3):

$(*)$ Let A be a commutative ring, let $\eta \in X(A)$ exhibit A as a finitely generated algebra over $\pi_0 R$, and let M be a finitely generated (discrete) R-module. Let η' denote the image of η in $X(A[x])$. Then the canonical map

$$\psi_M : A[x] \otimes_A T_{X/Y}(\eta; M) \simeq T_{X/Y}(\eta; M[x]) \to T_{X/Y}(\eta', M[x])$$

is an equivalence (see Variant 17.5.1.3).

To prove $(*)$, we first note that A is Noetherian, so that M is a Noetherian A-module. Working by Noetherian induction, we may suppose that $\psi_{M/M'}$ is an equivalence for every nonzero submodule $M' \subseteq M$. If $M = 0$ there is nothing to prove. Otherwise, M has an associated prime ideal: that is, there is an exact sequence $0 \to M' \to M \to M'' \to 0$ where $M' \simeq A/\mathfrak{p}$ for some prime ideal $\mathfrak{p} \subseteq A$. Since $\psi_{M''}$ is an equivalence by virtue of the inductive hypothesis, we are reduced to proving that $\psi_{M'}$ is an equivalence. Since f is cohesive, we may replace A by $A/\mathfrak{p}$, and thereby reduce to the special case where A is an integral domain and $M = A$.

For each nonzero element $a \in A$, we have an exact sequence $0 \to aM \to M \to M/aM \to 0$. The inductive hypothesis implies that $\psi_{M/aM}$ is an equivalence. It follows that multiplication by a induces an equivalence from $\mathrm{cofib}(\psi_M)$ to itself. Let K denote the fraction field of A, so that $K \otimes_A \mathrm{cofib}(\psi_M)$ is equivalent to $\mathrm{cofib}(\psi_M)$. We are therefore reduced to proving that ψ_M induces an equivalence $K[x] \otimes_A T_{X/Y}(\eta) \to K[x] \otimes_{A[x]} T_{X/Y}(\eta')$.

Let $h(x) \in A[x]$ be a polynomial whose image $K[x]$ is irreducible. Let $B = A[x]/(h(x))$, and let $L = K[x]/(h(x))$ be the fraction field of B. Let η'_B denote the image of η in $X(B)$ and define η'_L similarly. Since X is infinitesimally cohesive, can identify $T_{X/Y}(\eta'_B)$ with the cofiber of the map $h(x) : T_{X/Y}(\eta') \to T_{X/Y}(\eta')$. Using condition (4), we can identify

$T_{X/Y}(\eta'_L)$ with the cofiber of $h(x)$ on $K[x] \otimes_{A[x]} T_{X/Y}(\eta')$. We therefore have a commutative diagram of fiber sequences

$$\begin{array}{ccccc} K[x] \otimes_A T_{X/Y}(\eta) & \xrightarrow{h(x)} & K[x] \otimes_A T_{X/Y}(\eta) & \longrightarrow & L \otimes_A T_{X/Y}(\eta) \\ \downarrow & & \downarrow & & \downarrow \\ K[x] \otimes_{A[x]} T_{X/Y}(\eta') & \xrightarrow{h(x)} & K[x] \otimes_{A[x]} T_{X/Y}(\eta') & \longrightarrow & T_{X/Y}(\eta'_L) \end{array}$$

where condition (4) implies that the right vertical map is an equivalence. It follows that multiplication by $h(x)$ acts invertibly on $\mathrm{cofib}(\psi_M)$.

Let K' denote the fraction field of the integral domain $A[x]$. The reasoning above shows that $\mathrm{cofib}(\psi_M) \simeq K' \otimes_{A[x]} \mathrm{cofib}(\psi_M)$. Consequently, to show that $\mathrm{cofib}(\psi_M) \simeq 0$, it will suffice to show that the horizontal map in the diagram

$$\begin{array}{ccc} K' \otimes_A T_{X/Y}(\eta) & \longrightarrow & K' \otimes_{A[x]} T_{X/Y}(\eta') \\ & \searrow \quad \swarrow & \\ & T_{X/Y}(\eta_{K'}) & \end{array}$$

is an equivalence, where $\eta_{K'}$ denotes the image of η in $X(K')$. It now suffices to observe that condition (4) implies that both of the vertical maps are equivalences. □

17.5.3 Digression: A Representability Criterion

Let R be a Noetherian $\mathbb{E}_\infty$-ring, let $f : X \to \operatorname{Spec} R$ be a natural transformation of functors, and let $X_0 : \mathrm{CAlg}_R^{\mathrm{cn}} \to \mathcal{S}$ be the functor given by $X_0(A) = \mathrm{fib}(X(A) \to \mathrm{Map}_{\mathrm{CAlg}}(R, A))$. Arguing as in Example 17.2.4.4, we see that f admits a relative cotangent complex if and only if it satisfies the following pair of conditions:

(a) For every connective $\mathbb{E}_\infty$-ring A and every point $\eta \in X(A)$, define $F_\eta : \mathrm{Mod}_A^{\mathrm{cn}} \to \mathcal{S}$ by the formula $F_\eta(M) = X_0(A \oplus M) \times_{X_0(A)} \{\eta\}$. Then F_η is almost corepresentable (see Example 17.2.1.4).

(b) For every map of connective $\mathbb{E}_\infty$-rings $A \to B$ and every connective B-module M, the diagram of spaces

$$\begin{array}{ccc} X_0(A \oplus M) & \longrightarrow & X_0(B \oplus M) \\ \downarrow & & \downarrow \\ X_0(A) & \longrightarrow & X_0(B) \end{array}$$

is a pullback square.

Under some mild hypotheses, condition (b) is equivalent to the requirement that the tangent complexes of f are preserved by flat base change (Proposition 17.5.2.1). Our goal in this section is to prove a result which is helpful for verifying condition (a):

Theorem 17.5.3.1. *Let R be a Noetherian $\mathbb{E}_\infty$-ring which admits a dualizing module K and let $F : \mathrm{Mod}_R^{\mathrm{cn}} \to \mathcal{S}$ be a functor. Then F is corepresentable by an almost perfect (not necessarily connective) R-module if and only if the following conditions are satisfied:*

(1) *The functor F is reduced and excisive (and therefore admits an essentially unique extension to a left exact functor $F^+ : \mathrm{Mod}_R^{\mathrm{acn}} \to \mathcal{S}$, by Lemma 17.2.1.2).*

(2) *For every connective R-module M, the canonical map $F(M) \to \varprojlim F(\tau_{\leqslant n} M)$ is an equivalence.*

(3) *For every integer n, the restriction $F|_{(\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant n}}$ commutes with filtered colimits.*

(4) *There exists an integer $n \geqslant 0$ such that $F(M)$ is n-truncated for every discrete R-module M.*

(5) *For every R-module M which is truncated and almost perfect, the abelian group $\pi_0 F^+(M)$ is finitely generated as a module over $\pi_0 R$.*

Remark 17.5.3.2. Let R be a Noetherian $\mathbb{E}_\infty$-ring and let Mod_R^b denote the full subcategory of Mod_R spanned by those R-modules which are truncated and almost perfect. Then Mod_R^b is a stable subcategory of Mod_R, and the t-structure on Mod_R restricts to a bounded t-structure $((\mathrm{Mod}_R^b)_{\geqslant 0}, (\mathrm{Mod}_R^b)_{\leqslant 0})$ on Mod_R^b. It follows that the ∞-category $\mathrm{Ind}(\mathrm{Mod}_R^b)$ inherits a t-structure $(\mathrm{Ind}(\mathrm{Mod}_R^b)_{\geqslant 0}, \mathrm{Ind}(\mathrm{Mod}_R^b)_{\geqslant 0})$. Since Mod_R admits filtered colimits (and the t-structure on Mod_R is stable under filtered colimits), the inclusion $\mathrm{Mod}_R^b \to \mathrm{Mod}_R$ induces a t-exact functor $F : \mathrm{Ind}(\mathrm{Mod}_R^b) \to \mathrm{Mod}_R$. We claim that F induces an equivalence $F_{\leqslant 0} : \mathrm{Ind}(\mathrm{Mod}_R^b)_{\leqslant 0} \to (\mathrm{Mod}_R)_{\leqslant 0}$. Since every object of $(\mathrm{Mod}_R^b)_{\leqslant 0}$ is compact when viewed as an object of $(\mathrm{Mod}_R)_{\leqslant 0}$, Proposition HTT.5.3.5.11 implies that the functor $F_{\leqslant 0}$ is fully faithful. To complete the proof, it will suffice to show that $F_{\leqslant 0}$ is essentially surjective. Since the image of $F_{\leqslant 0}$ is closed under filtered colimits and every object $M \in (\mathrm{Mod}_R)_{\leqslant 0}$ can be written as the colimit of the diagram

$$\tau_{\geqslant 0} M \to \tau_{\geqslant -1} M \to \tau_{\geqslant -2} M \to \cdots,$$

it suffice to show that every object $M \in (\mathrm{Mod}_R)_{\leqslant 0} \cap (\mathrm{Mod}_R)_{\geqslant -n}$ belongs to the essential image of $F_{\leqslant 0}$. We proceed by induction on n. When $n = 0$, it suffices to observe that every discrete R-module can be written as a filtered colimit of its finitely generated submodules, which we can identify with objects of $(\mathrm{Mod}_R^b)_{\leqslant 0}$. If $n > 0$, then we have a fiber sequence $\Sigma^{-1}(\tau_{\leqslant -1} M) \xrightarrow{\alpha} \pi_0 M \to M$. The inductive hypothesis guarantees that α is the image of a morphism $\overline{\alpha}$ in $\mathrm{Ind}(\mathrm{Mod}_R^b)_{\leqslant 0}$. Note that the domain of $\overline{\alpha}$ belongs to $\mathrm{Ind}(\mathrm{Mod}_R^b)_{\leqslant -1}$ (in fact, it belongs to $\mathrm{Ind}(\mathrm{Mod}_R^b)_{\leqslant -2}$), so that $\mathrm{cofib}(\overline{\alpha}) \in \mathrm{Ind}(\mathrm{Mod}_R^b)_{\leqslant 0}$ Then $M \simeq \mathrm{cofib}(\alpha) = F(\mathrm{cofib}(\overline{\alpha}))$ belongs to the essential image of $F_{\leqslant 0}$, as desired.

Proof of Theorem 17.5.3.1. Suppose that the functor $F : \mathrm{Mod}_R^{\mathrm{cn}} \to \mathcal{S}$ is given by the formula $F(M) = \mathrm{Map}_{\mathrm{Mod}_R}(N, M)$ for some R-module N. Then conditions (1) and (2) are vacuous. Condition (4) follows from assumption that N is almost connective, and condition (3) from the condition that N is almost perfect. Moreover, if N is almost perfect, then condition (5) follows from Lemma 6.4.3.5.

Now suppose that conditions (1) through (5) are satisfied. We wish to prove that F^+ is corepresentable by an almost perfect R-module. Fix a dualizing module $K \in \mathrm{Mod}_R$. For every R-module M, we let $\mathbb{D}(M)$ denote the R-module $\underline{\mathrm{Map}}_R(M, K)$. It follows from Theorem 6.6.1.8 and Proposition 6.6.1.9 that the construction $M \mapsto \mathbb{D}(M)$ induces a contravariant equivalence from the ∞-category Mod_R^b to itself. We define a functor $G : (\mathrm{Mod}_R^b)^{\mathrm{op}} \to \mathcal{S}$ by the formula $G(M) = F^+(\mathbb{D}(M))$. Assumption (1) implies that the functor G is left exact, and can therefore be identified with an object of $\mathrm{Ind}(\mathrm{Mod}_R^b)$.

We first claim that F satisfies the following stronger version of (4):

(4′) There exists an integer n such that $F^+(M)$ is $(n+m)$-truncated whenever $M \in \mathrm{Mod}_R^{\mathrm{acn}}$ is m-truncated.

To prove (4′), we first apply Proposition HA.1.4.2.22 to factor F^+ as a composition $\mathrm{Mod}_R^{\mathrm{acn}} \xrightarrow{f} \mathrm{Sp} \xrightarrow{\Omega^\infty} \mathcal{S}$, where f is exact. Let $M \in \mathrm{Mod}_R$ be m-truncated and k-connective; we will prove that the spectrum $f(M)$ is $(n+m)$-truncated. The proof proceeds by induction on m, the case $m < k$ being trivial. We have a fiber sequence $\Sigma^m(\pi_m M) \to M \to \tau_{\leqslant m-1} M$. Since the functor f is exact, to prove that $f(M)$ is $(n+m)$-truncated it will suffice to show that $f(\tau_{\leqslant m-1} M)$ and $f(\Sigma^m(\pi_m M))$ are $(n+m)$-truncated. In the first case, this follows from the inductive hypothesis. In the second, we must show that the spectrum $f(\pi_m M)$ is n-truncated. Since $n \geqslant 0$, this is equivalent to the assertion that the space $\Omega^\infty f(\pi_m M) \simeq F(\pi_m M)$ is n-truncated, which follows from (4).

Let n be an integer satisfying (4′). Choose an integer n' such that K is n'-truncated. If $M \in \mathrm{Mod}_R^b$ is $(n+n'+1)$-connective, then $\mathbb{D}(M)$ is $(-n-1)$-truncated so that condition (5) guarantees that $G(M) = F^+\,\mathbb{D}(M)$ is contractible (note that $F^+\,\mathbb{D}(M)$ is automatically nonempty). It follows that, as an object of $\mathrm{Ind}(\mathrm{Mod}_R^b)$, G belongs to $\mathrm{Ind}(\mathrm{Mod}_R^b)_{\leqslant n+n'}$. Applying Remark 17.5.3.2, we conclude that G is the image of an object $N \in (\mathrm{Mod}_R)_{\leqslant n+n'}$ under the right adjoint to the functor $\mathrm{Ind}(\mathrm{Mod}_R^b) \to \mathrm{Mod}_R$ appearing in Remark 17.5.3.2. Unwinding the definitions, we deduce that N represents the functor G: that is, we have homotopy equivalences $G(M) \simeq \mathrm{Map}_{\mathrm{Mod}_R}(M, N)$ for $M \in \mathrm{Mod}_R^b$ which depend functorially on M. In particular, we obtain bijections

$$\pi_i N \simeq \pi_0 \mathrm{Map}_{\mathrm{Mod}_R}(\tau_{\leqslant n+n'}(\Sigma^i R), N) \simeq \pi_0 G(\tau_{\leqslant n+n'}(\Sigma^i R)) \simeq \pi_0 F^+\,\mathbb{D}(\tau_{\leqslant n+n'}\Sigma^i R)).$$

It follows from (5) that each homotopy group of N is finitely generated as a module over $\pi_0 R$. Using Proposition 6.6.1.9, we deduce that $\mathbb{D}(N)$ is an almost perfect R-module, and that we have functorial homotopy equivalences

$$F^+(M) = G(\mathbb{D}(M)) \simeq \mathrm{Map}_{\mathrm{Mod}_R}(\mathbb{D}(M), N) \simeq \mathrm{Map}_{\mathrm{Mod}_R}(\mathbb{D}(N), M).$$

Let $F' : \mathrm{Mod}_R^{\mathrm{acn}} \to \mathcal{S}$ be the functor corepresented by $\mathbb{D}(N)$. For every pair of integers a and b, let $\mathcal{C}(a,b)$ denote the full subcategory $(\mathrm{Mod}_R)_{\leqslant a} \cap (\mathrm{Mod}_R)_{\geqslant b}$, and let $\mathcal{C}_0(a,b)$ denote the full subcategory spanned by those R-modules $M \in \mathcal{C}(a,b)$ which are truncated and almost perfect. Let $\mathcal{C} = \bigcup_{a,b} \mathcal{C}(a,b)$ denote the full subcategory of Mod_R spanned by those R-modules which are truncated and almost connective. Arguing as in Remark 17.5.3.2, we deduce that the inclusion $\mathcal{C}_0(a,b) \to \mathcal{C}(a,b)$ extends to an equivalence $\mathrm{Ind}(\mathcal{C}_0(a,b)) \to \mathcal{C}(a,b)$. Since $\mathbb{D}(N)$ is almost perfect, $F'|_{\mathcal{C}(a,b)}$ commutes with filtered colimits. Condition (3) implies that $F^+|_{\mathcal{C}(a,b)}$ commutes with filtered colimits. Using Proposition HTT.5.3.5.10 , we deduce that the restriction map

$$\mathrm{Map}_{\mathrm{Fun}(\mathcal{C}(a,b),\mathcal{S})}(F'|_{\mathcal{C}(a,b)}, F^+|_{\mathcal{C}(a,b)}) \to \mathrm{Map}_{\mathrm{Fun}(\mathcal{C}_0(a,b),\mathcal{S})}(F'|_{\mathcal{C}_0(a,b)}, F^+|_{\mathcal{C}(a,b)})$$

is a homotopy equivalence. Passing to the homotopy inverse limit over pairs (a,b), we obtain a homotopy equivalence

$$\mathrm{Map}_{\mathrm{Fun}(\mathcal{C},\mathcal{S})}(F'|_{\mathcal{C}}, F^+|_{\mathcal{C}}) \to \mathrm{Map}_{\mathrm{Fun}(\mathrm{Mod}_R^b,\mathcal{S})}(F'|_{\mathrm{Mod}_R^b}, F^+|_{\mathrm{Mod}_R^b}).$$

In particular, the equivalence $F'|_{\mathrm{Mod}_R^b} \simeq F^+|_{\mathrm{Mod}_R^b}$ lifts to a natural transformation $\alpha : F'|_{\mathcal{C}} \to F^+|_{\mathcal{C}}$. Every object $M \in \mathcal{C}$ belongs to $\mathcal{C}(a,b)$ for some pair of integers $a, b \in \mathbf{Z}$. Since $F'|_{\mathcal{C}(a,b)}$ and $F^+|_{\mathcal{C}(a,b)}$ both commute with filtered colimits, we deduce that $\alpha_M : F'(M) \to F^+(M)$ is a filtered colimit of equivalences $F'(M_0) \to F^+(M_0)$, where M_0 is truncated and almost perfect. It follows that α is an equivalence of functors.

To complete the proof that F^+ is corepresentable by an almost perfect R-module, it will suffice to show that α lifts to an equivalence between F^+ and F'. For this, it will suffice to show that F^+ and F' are both right Kan extensions of their restrictions to $\mathcal{C}$. We will need the following criterion:

$(*)$ Let $H : \mathrm{Mod}_R^{\mathrm{acn}} \to \mathcal{S}$ be a functor. Then H is a right Kan extension of $H|_{\mathcal{C}}$ if and only if, for every almost connective R-module M, the canonical map $H(M) \to \varprojlim H(\tau_{\leqslant n} M)$ is an equivalence.

It follows from $(*)$ that F' is a right Kan extension of $F'|_{\mathcal{C}}$, and $(*)$ together with (2) guarantee that F^+ is also a right Kan extension of $F'|_{\mathcal{C}}$.

To prove $(*)$, it will suffice to show that for every object $M \in \mathrm{Mod}_R^{\mathrm{acn}}$, the Postnikov tower $\{\tau_{\leqslant n} M\}_{n \geqslant 0}$ determines a right cofinal functor $\mathrm{N}(\mathbf{Z}_{\geqslant 0})^{\mathrm{op}} \to \mathcal{C} \times_{\mathrm{Mod}_R^{\mathrm{acn}}} (\mathrm{Mod}_R^{\mathrm{acn}})_{M/}$. This is equivalent to the assertion that for every object $N \in \mathcal{C}$, the canonical map

$$\varinjlim \mathrm{Map}_{\mathrm{Mod}_R}(\tau_{\leqslant n} M, N) \to \mathrm{Map}_{\mathrm{Mod}_R}(M, N)$$

is a homotopy equivalence. This is clear, since the assumption that N is truncated implies that the map $\mathrm{Map}_{\mathrm{Mod}_R}(\tau_{\leqslant n} M, N) \to \mathrm{Map}_{\mathrm{Mod}_R}(M, N)$ is a homotopy equivalence for $n \gg 0$. □

17.5.4 Application: Existence of the Cotangent Complex

Let R be an $\mathbb{E}_\infty$-ring and suppose we are given a morphism $f : X \to \operatorname{Spec} R$ in the ∞-category $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. Under some mild finiteness assumptions, the existence of a cotangent complex for f is equivalent to good behavior of the tangent complex of f. More precisely, we have the following result:

Theorem 17.5.4.1. *Let R be a Noetherian $\mathbb{E}_\infty$-ring which admits a dualizing module (Definition 6.6.1.1), let $Y = \operatorname{Spec} R$, and suppose we are given a morphism $f : X \to Y$ in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ which is cohesive, nilcomplete, and locally almost of finite presentation. Assume further that f satisfies the hypotheses of Proposition 17.5.2.1, and that there exists an integer q such that $X(A)$ is q-truncated for every discrete commutative ring A. Then the following conditions are equivalent:*

- (A) *The functor X admits a cotangent complex.*
- (B) *For every Noetherian $\mathbb{E}_\infty$-ring A and every point $\eta \in X(A)$, each homotopy group $\pi_n T_{X/Y}(\eta)$ is a finitely generated module over $\pi_0 A$.*
- (C) *Let A be an integral domain, let $\eta \in X(A)$ exhibit A as a finitely generated module over $\pi_0 R$. Then the homotopy groups $\pi_n T_{X/Y}(\eta)$ are finitely generated as modules over A.*

If these conditions are satisfied, then the relative cotangent complex $L_{X/Y}$ is almost perfect. Moreover, if X is integrable, then (A), (B), and (C) are equivalent to either of the following conditions:

- (D) *Let A be an integral domain and let $\eta \in X(A)$ exhibit A as a finitely generated module over $\pi_0 R$. For every integer n, there exists a finite collection of elements $x_1, x_2, \ldots, x_p \in \pi_n T_{X/Y}(\eta)$ and an element $a \in A$ such that, for every field K and every ring homomorphism $A[a^{-1}] \to K$ carrying η in $\eta_K \in X(K)$ the images of the elements $x_1, \ldots, x_p$ form a basis for the vector space $\pi_n T_{X/Y}(\eta_K)$.*
- (E) *Let A be an integral domain and let $\eta \in X(A)$ exhibit A as a finitely generated module over $\pi_0 R$. For every integer n, there exists a nonzero element $a \in A$ such that $(\pi_n T_{X/Y}(\eta))[a^{-1}]$ is a free $A[a^{-1}]$-module of finite rank.*

The proof of Theorem 17.5.4.1 will require some preliminaries.

Proof of Theorem 17.5.4.1. Note that if f admits a relative cotangent complex $L_{X/Y}$, then $L_{X/Y}$ is almost perfect (since f is locally almost of finite presentation; see Corollary 17.4.2.2).

Suppose first that (A) is satisfied; we will prove (B). Assumption (A) implies that the cotangent complex $L_{X/Y}$ exists and is almost perfect. For each point $\eta \in X(A)$, the tangent complex $T_{X/Y}(\eta)$ is given by the A-linear dual of $\eta^* L_{X/Y}$ (Example 17.5.1.2). In particular, we have isomorphisms $\pi_n T_{X/Y}(\eta) \simeq \mathrm{Ext}_A^{-n}(\eta^* L_{X/Y}, A)$, so that $\pi_n T_{X/Y}(\eta)$ is a finitely generated module over $\pi_0 A$ whenever A is Noetherian (Lemma 6.4.3.5).

The implication $(B) \Rightarrow (C)$ is obvious. We next prove that (C) implies (A). Suppose that condition (C) is satisfied. To prove that X admits a cotangent complex, it will suffice to show that the morphism f admits a cotangent complex (Proposition 17.3.9.1). Using Proposition 17.5.2.1, see that f satisfies conditions (a) and (c) of Proposition 17.3.2.5. It will therefore suffice to show that for every truncated object $A \in \mathrm{CAlg}_R^{\mathrm{cn}}$, the functor $F_\eta : \mathrm{Mod}_A^{\mathrm{cn}} \to \mathcal{S}$ given by $F_\eta(M) = X_0(A \oplus M) \times_{X_0(A)} \{\eta\}$ is almost corepresentable. Write A as the colimit of a filtered diagram $\{A_\alpha\}$ of connective $\mathbb{E}_\infty$-algebras which are of finite presentation over R. Choose $m \geqslant 0$ such that A is m-truncated, so that $A \simeq \varinjlim \tau_{\leqslant m} A_\alpha$. Since f is locally almost of finite presentation, we can assume that η is the image of a point $\eta_\alpha \in X_0(A_\alpha)$ for some index α. Using condition (a) of Proposition 17.3.2.5, we see that F_η factors as a composition $\mathrm{Mod}_A^{\mathrm{cn}} \to \mathrm{Mod}_{\tau_{\leqslant n} A_\alpha}^{\mathrm{cn}} \xrightarrow{F_{\eta_\alpha}} \mathcal{S}$. We may therefore replace A by A_α, and thereby reduce to the case where A is almost of finite presentation over R. Then A admits a dualizing module (Theorem 6.6.4.3). We will show that F_η is almost corepresentable by verifying conditions (1) through (5) of Theorem 17.5.3.1:

(1) The functor $F_\eta : \mathrm{Mod}_A^{\mathrm{cn}} \to \mathcal{S}$ is obviously reduced. Since X is infinitesimally cohesive, the canonical map $F_\eta(M) \to \Omega F_\eta(\Sigma M)$ is an equivalence for every connective A-module M, so that F_η is excisive by Proposition HA.1.4.2.13 .

(2) For every connective A-module M, we claim that the canonical map $F_\eta(M) \to \varprojlim F_\eta(\tau_{\leqslant n} M)$ is a homotopy equivalence. This follows immediately from the nilcompleteness of the functor X.

(3) We claim that F_η commutes with filtered colimits when restricted to $(\mathrm{Mod}_A)_{\leqslant n}$. This is an immediate consequence of our assumption that the map f is locally almost of finite presentation.

(4) Choose an integer n such that $X(B)$ is n-truncated for every commutative ring B. We claim that $F_\eta(M)$ is n-truncated for every discrete A-module M. Since X is cohesive, we can replace A by $\pi_0 A$ and thereby reduce to the case where A is discrete. Then $F_\eta(M)$ is the fiber of a map $X(A \oplus M) \to X(A) \times_{Y(A)} Y(A \oplus M)$ whose domain and codomain are n-truncated, and therefore itself n-truncated.

(5) Using Lemma 17.2.1.2, we can extend F_η to an excisive $F_\eta^+ : \mathrm{Mod}_A^{\mathrm{acn}} \to \mathcal{S}$. We wish to prove that for every object $M \in \mathrm{Mod}_A^b$, the abelian group $\pi_0 F_\eta^+(M)$ is finitely generated

as a discrete module over $\pi_0 A$. Given a fiber sequence $M' \to M \to M''$ in Mod_A^b, we obtain an exact sequence of $\pi_0 A$-modules $\pi_0 F_\eta^+(M') \to \pi_0 F_\eta^+(M) \to \pi_0 F_\eta^+(M'')$. Consequently, to prove that $\pi_0 F_\eta^+(M)$ is finitely generated, it suffices to prove the corresponding assertions for M' and M''. We may therefore reduce to the case where the module M is concentrated in a single degree k. Then $\pi_k M$ is a finitely generated module over the Noetherian ring $\pi_0 A$, and therefore admits a finite composition series with successive quotients of the form $(\pi_0 A)/\mathfrak{p}$, where $\mathfrak{p} \subseteq \pi_0 A$ is a prime ideal. We may therefore assume that $\pi_k M$ has the form $(\pi_0 A)/\mathfrak{p}$. Since X is cohesive, we can replace A by the integral domain $(\pi_0 A)/\mathfrak{p}$, so that $M \simeq \Sigma^k A$. In this case, $\pi_0 F_\eta^+(M) \simeq \pi_k T_{X/Y}(\eta)$ is finitely generated by virtue of assumption (C).

We next show that $(A) \Rightarrow (D)$. Let A be a Noetherian integral domain equipped with a point $\eta \in X(A)$, and let n be an integer. Corollary 17.4.2.2 implies that $\eta^* L_{X/Y}$ is an almost perfect A-module. In particular, the homotopy groups $\pi_m \eta^* L_{X/Y}$ are finitely generated A-modules, which vanish for $m \ll 0$. We may therefore choose a nonzero element $a \in A$ such that $(\pi_m \eta^* L_{X/Y})[a^{-1}]$ is a finitely generated free module over $A[a^{-1}]$ of rank r_m for $m \leqslant -n$. For each $m \leqslant -n$, choose a collection of elements $\{x_{i,m} \in \pi_m \eta^* L_{X/Y}\}_{1 \leqslant i \leqslant r_m}$ whose images form a basis for $(\pi_m \eta^* L_{X/Y})[a^{-1}]$ as a module over $A[a^{-1}]$. These choices determine a map

$$\tau_{\geqslant 1-n}(\eta^* L_{X/Y}) \oplus \bigoplus_{m \leqslant -n} (\Sigma^m A)^{r_m} \to \eta^* L_{X/Y}$$

which is an equivalence after inverting the element a. It follows that if M is an $A[a^{-1}]$-module, the canonical map

$$\mathrm{Map}_{\mathrm{Mod}_A}(\eta^* L_{X/Y}, M) \to \mathrm{Map}_{\mathrm{Mod}_A}(\tau_{\geqslant 1-n} \eta^* L_{X/Y}, M) \times \prod_{m \leqslant -n} (\Omega^{\infty - m} M)^{r_m}.$$

In particular, given a ring homomorphism $A[a^{-1}] \to K$ carrying η to $\eta_K \in X(K)$, taking $M = \Sigma^{-n} K$ gives a vector space isomorphism $\pi_n T_{X/Y}(\eta_K) \simeq \mathrm{Ext}_A^{-n}(\eta^* L_{X/Y}, K) \simeq K^{r_n}$, given by evaluation on the elements $\{x_{i,n}\}_{1 \leqslant i \leqslant r_n}$.

We now show that $(D) \Rightarrow (E)$. Assume that X satisfies (D), let A be an integral domain, and let $\eta \in X(A)$ exhibit A as a finitely generated algebra over $\pi_0 R$. Since R admits a dualizing module, so does A (Theorem 6.6.4.3), so that A has finite Krull dimension d (Remark **??**). Using (D), we can choose $a \in A$ and, for $n - 1 \leqslant m \leqslant n + d + 1$, a finite collection of elements $\{y_{i,m} \in \pi_m T_{X/Y}(\eta)\}_{1 \leqslant i \leqslant r_m}$ with the following property: for every field K equipped with a map $A[a^{-1}] \to K$ carrying η to $\eta_K \in X(K)$, the images of the elements $\{y_{i,m}\}_{1 \leqslant i \leqslant r_m}$ form a basis for the K-vector space $\pi_m(T_{X/Y}(\eta_K))$. For every commutative $A[a^{-1}]$-algebra B, let η_B denote the image of η in $X(B)$, so that the elements $\{y_{i,m}\}$ determines a map of B-modules $\bigoplus_{n-1 \leqslant m \leqslant n+d+1} (\Sigma^m B)^{r_m} \to T_{X/Y}(\eta_B)$. Let us denote the fiber of this map by F_B. Note that if B is a field, then the homotopy groups $\pi_i F_B$ vanish for $n - 1 \leqslant i \leqslant n + d$. We will prove the following assertion:

$(*)$ Let B be a quotient ring of $A[a^{-1}]$ having Krull dimension $\leqslant d'$. Then the homotopy groups $\pi_i F_B$ vanish for $n-1 \leqslant i \leqslant n+d-d'$.

Taking $B = A[a^{-1}]$ and $d = d'$, we deduce that $\pi_{n-1} F_{A[a^{-1}]} \simeq \pi_n F_{A[a^{-1}]} \simeq 0$, so that the map

$$\pi_n(\bigoplus_{n-1 \leqslant m \leqslant n+d+1} (\Sigma^m A[a^{-1}])^{r_m}) \to \pi_n T_{X/Y}(\eta_{A[a^{-1}]})$$

is an isomorphism: that is, the images of the elements $\{y_{i,n}\}_{1 \leqslant i \leqslant r_n}$ comprise a basis for $(\pi_n T_{X/Y}(\eta))[a^{-1}] \simeq \pi_n T_{X/Y}(\eta_{A[a^{-1}]})$ as a module over $A[a^{-1}]$.

It remains to prove $(*)$. We proceed by Noetherian induction on B. If $B = 0$, there is nothing to prove. Otherwise, let $\mathfrak{p}$ be an associated prime of B, so that there exists a nonzero ideal $I \subseteq B$ which is isomorphic, as a B-module, to $B/\mathfrak{p}$. We then have an exact sequence of B-modules $0 \to B/\mathfrak{p} \to B \to B/I \to 0$ which determines a fiber sequence $F_{B/\mathfrak{p}} \to F_B \to F_{B/I}$. It follows from the inductive hypothesis that the homotopy groups $\pi_i F_{B/I}$ vanish for $n-1 \leqslant i \leqslant n+d-d'$. It will therefore suffice to show that the homotopy groups $\pi_i F_{B/\mathfrak{p}}$ vanish for $n-1 \leqslant i \leqslant n+d-d'$. Replacing B by $B/\mathfrak{p}$, we can reduce to the case where B is an integral domain. For every nonzero element $b \in B$, the quotient ring $B/(b)$ has Krull dimension $\leqslant d'-1$. Applying the inductive hypothesis, we deduce that the homotopy groups $\pi_i F_{B/(b)}$ vanish for $n-1 \leqslant i \leqslant n+1+d-d'$. Using the fiber sequence $F_B \xrightarrow{b} F_B \to F_{B/(b)}$, we deduce that multiplication by b induces an isomorphism from $\pi_i F_B$ to itself for $n-1 \leqslant i \leqslant n+d-d'$. It will therefore suffice to show that $K \otimes_B \pi_i F_B$ vanishes for $n-1 \leqslant i \leqslant n+d-d'$, where K denotes the fraction field of B. This follows from our construction, since Proposition 17.5.2.1 supplies an equivalence $K \otimes_B \pi_i F_B \simeq \pi_i(K \otimes_B F_B) \simeq \pi_i F_K$.

We now complete the proof by showing that if X is integrable, then condition (E) implies condition (C). Assume that condition (E) is satisfied. We will show that for every Noetherian commutative ring A, every point $\eta \in X(A)$ which exhibits A as a finitely generated algebra over $\pi_0 R$, and every finitely generated A-module M, the homotopy groups $\pi_n T_{X/Y}(\eta; M)$ are finitely generated A-modules. Proceeding by Noetherian induction, we may suppose that this condition is satisfied for every quotient M/M' of M by a nonzero submodule M'.

If $M \simeq 0$ there is nothing to prove. Otherwise, M has an associated prime ideal: that is, there exists a nonzero element $x \in M$ whose annihilator is a prime ideal $\mathfrak{p} \subseteq A$. Using our inductive hypothesis, we can replace M by Ax and thereby reduce to the case where M has the form $A/\mathfrak{p}$. Using our assumption that f is cohesive, we can replace A by $A/\mathfrak{p}$ and thereby reduce to the case where A is an integral domain and $M = A$. For every ideal $I \subseteq A$, let $F_I : \mathrm{Mod}^{\mathrm{cn}}_{A/I} \to \mathcal{S}$ denote the functor given by $F_I(M) = X_0(A/I \oplus M) \times_{X_0(A/I)} \{\eta_I\}$. Using the inductive hypothesis and the proof of the implication $(C) \Rightarrow (A)$, we see that F_I is corepresented by an almost perfect module over A/I for every nonzero ideal $I \subseteq A$.

Fix an integer n; we wish to show that $\pi_n T_{X/Y}(\eta)$ is finitely generated. Using condition

(E), we can choose a nonzero element $a \in A$ such that the modules $\pi_{n+1} T_{X/Y}(\eta')$ and $\pi_n T_{X/Y}(\eta')$ are finitely generated free modules over $A[a^{-1}]$, where η' denotes the image of η in $X(A[a^{-1}])$. Let $\widehat{A} = \varinjlim A/(a^n)$ denote the completion of A with respect to the principal ideal (a). We have a pullback diagram of A-modules

$$\begin{array}{ccc} A & \longrightarrow & A[a^{-1}] \\ \downarrow & & \downarrow \\ \widehat{A} & \longrightarrow & \widehat{A}[a^{-1}]. \end{array}$$

Let $\widehat{\eta}$ denote the image of η in $X(\widehat{A})$, and define $\widehat{\eta}' \in X(\widehat{A}[a^{-1}])$ similarly. Since X is cohesive, we have a pullback square of tangent complexes

$$\begin{array}{ccc} T_{X/Y}(\eta) & \longrightarrow & T_{X/Y}(\eta') \\ \downarrow & & \downarrow \\ T_{X/Y}(\widehat{\eta}) & \longrightarrow & T_{X/Y}(\widehat{\eta}') \end{array}$$

and therefore a long exact sequence of A-modules

$$\cdots \to \pi_{m+1} T_{X/Y}(\widehat{\eta}') \to \pi_m T_{X/Y}(\eta) \to \pi_m T_{X/Y}(\eta') \oplus \pi_m T_{X/Y}(\widehat{\eta}) \xrightarrow{\rho(m)} \pi_m T_{X/Y}(\widehat{\eta}') \to \cdots$$

We will prove that $\pi_n T_{X/Y}(\widehat{\eta})$ and $\pi_{n+1} T_{X/Y}(\widehat{\eta})$ are finitely generated modules over $\widehat{A}$. Since $\widehat{A}[a^{-1}]$ is flat over $\widehat{A}$ and $A[a^{-1}]$, we can then apply Proposition 17.5.2.1 and Corollary 7.4.2.3 to conclude that $\rho(m+1)$ is surjective and $\ker(\rho(m))$ is a finitely generated A-module, so that $\pi_n T_{X/Y}(\eta)$ is also finitely generated as an A-module.

For every integer $k \geqslant 0$, let $L_k \in \mathrm{Mod}_{A/(a^k)}$ corepresent the functor $F_{(a^k)}$. Since X is locally almost of finite presentation, each L_k is almost perfect. Corollary 8.3.5.6 supplies an equivalence of ∞-categories $\mathrm{Mod}_{\widehat{A}}^{\mathrm{aperf}} \simeq \varprojlim_k \mathrm{Mod}_{A/(a^k)}^{\mathrm{aperf}}$. Under this equivalence, we can identify the inverse system $\{L_k\}_{k \geqslant 0}$ with an almost perfect $\widehat{A}$-module $\widehat{L}$. For each $m \geqslant 0$, let η_k denote the image of η in $X(A/(a^k))$. Set $T = \underline{\mathrm{Map}}_{\widehat{A}}(\widehat{L}, \widehat{A})$, so that we have a canonical identification

$$\begin{aligned} \varprojlim_k T_{X/Y}(\eta_k) &\simeq \varprojlim_k \underline{\mathrm{Map}}_{A/(a^k)}(L_k, A/(a^k)) \\ &\simeq \varprojlim_k \underline{\mathrm{Map}}_{\widehat{A}}(\widehat{L}, A/(a^k)) \\ &\simeq \underline{\mathrm{Map}}_{\widehat{A}}(\widehat{L}, \widehat{A}) \\ &\simeq T. \end{aligned}$$

It follows from Lemma 6.4.3.5 that the homotopy groups of T are finitely generated modules over $\widehat{A}$. We will complete the proof by showing that the map $\rho : T_{X/Y}(\widehat{\eta}) \to T$ is an equivalence.

Since f is cohesive, the canonical map $\widehat{A}/(a) \otimes_A T_{X/Y}(\widehat{\eta}) \to T_{X/Y}(\eta_1)$ is an equivalence. It follows that ρ induces an equivalence after tensoring with $\widehat{A}/(a)$: that is, the homotopy groups of $\mathrm{fib}(\rho)$ are modules over $\widehat{A}[a^{-1}]$. Fix an integer m; we wish to show that $\pi_m \mathrm{fib}(\rho) \simeq 0$. For this, we study the exact sequence $\pi_{m+1} T \xrightarrow{\mu} \pi_m \mathrm{fib}(\rho) \xrightarrow{\nu} \pi_m T_{X/Y}(\widehat{\eta})$. We will show that $\nu = 0$, so that μ is surjective. It then follows that $\pi_m \mathrm{fib}(\rho)$ is a finitely generated module over $\widehat{A}$. Since a acts invertibly on $\pi_m \mathrm{fib}(\rho)$, it then follows from Nakayama's lemma that $\pi_m \mathrm{fib}(\rho) = 0$, as desired.

Choose an element $y_0 \in \pi_m T_{X/Y}(\widehat{\eta})$ belonging to the image of ν; we wish to show that $y_0 = 0$. Note that y_0 is a-divisible: that is, we can find elements $y_1, y_2, \ldots \in \pi_m T_{X/Y}(\widehat{\eta})$ such that $a y_{i+1} = y_i$. If $y_0 \neq 0$, then we can choose a maximal ideal $\mathfrak{m} \subseteq \widehat{A}$ such that the image of y_0 is nonzero in the localization $(\pi_m T_{X/Y}(\widehat{\eta}))_{\mathfrak{m}}$. Let B denote the completion of $\widehat{A}$ at the maximal ideal $\mathfrak{m}$, and let η_B denote the image of η in $X(B)$. Then B is faithfully flat over $\widehat{A}_{\mathfrak{m}}$, so that the image of y_0 is nonzero in $B \otimes_{\widehat{A}} \pi_m T_{X/Y}(\widehat{\eta}) \simeq \pi_m T_{X/Y}(\eta_B)$.

Let $\mathfrak{m}_B$ denote the maximal ideal of B, and choose a tower of $\mathbb{E}_\infty$-algebras $\{B_k\}_{k \geqslant 0}$ satisfying the requirements of Lemma **??**. Using Lemma 17.3.5.7, we see that for every pair of integers $p \geqslant q \geqslant 0$, we have an equivalence

$$\{\tau_{\leqslant p}(B_j \oplus \Sigma^q B_j)\}_{j \geqslant 0} \simeq \{B/\mathfrak{m}_B^j \oplus \Sigma^q B/\mathfrak{m}_B^j\}$$

of pro-objects of CAlg. Since f is nilcomplete and integrable, it follows that the canonical map $T_{X/Y}(\eta_B) \to \varprojlim_j T_{X/Y}(\eta_{B,j})$ is an equivalence, where $\eta_{B,j}$ denotes the image of η in $X(B/\mathfrak{m}_B^j)$. We therefore obtain an equivalence

$$\begin{aligned} T_{X/Y}(\eta_B) &\simeq \varprojlim_j \underline{\mathrm{Map}}_{B/\mathfrak{m}_B^j}((B/\mathfrak{m}_B^j) \otimes_{\widehat{A}} \widehat{L}, B/\mathfrak{m}_B^j) \\ &\simeq \varprojlim_j \underline{\mathrm{Map}}_B(B \otimes_{\widehat{A}} \widehat{L}, B/\mathfrak{m}_B^j) \\ &\simeq \underline{\mathrm{Map}}_B(B \otimes_{\widehat{A}} \widehat{L}, B). \end{aligned}$$

Since $\widehat{L}$ is almost perfect over $\widehat{A}$, $B \otimes_{\widehat{A}} \widehat{L}$ is almost perfect over B, so that the homotopy groups of $T_{X/Y}(\eta_B)$ are finitely generated B-modules by Lemma 6.4.3.5. Since the image of a is contained in the maximal ideal B, it follows from Nakayama's Lemma that $\pi_m T_{X/Y}(\eta_B)$ does not contain any nonzero a-divisible elements. It follows that the image of y_0 in $\pi_m T_{X/Y}(\eta_B) \simeq B \otimes_{\widehat{A}} \pi_m T_{X/Y}(\widehat{A})$ is zero, contrary to our earlier assumption. □

Chapter 18

Artin's Representability Theorem

Our goal in this Chapter is to address the following question: given a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, when is X representable by a spectral Deligne-Mumford stack? We have the following necessary conditions:

(*a*) If X is representable by a spectral Deligne-Mumford stack, then X has a well-behaved deformation theory. More precisely, X must be nilcomplete, infinitesimally cohesive, and must admit a cotangent complex (Propositions 17.3.2.3, 17.3.1.2, and 17.2.5.1).

(*b*) Let $\mathrm{CAlg}^{\heartsuit}$ denote the full subcategory of $\mathrm{CAlg}^{\mathrm{cn}}$ spanned by the discrete $\mathbb{E}_\infty$-rings (so that we can identify $\mathrm{CAlg}^{\heartsuit}$ with the ordinary category of commutative rings). If X is representable by a spectral Deligne-Mumford stack $(\mathcal{X}, \mathcal{O})$, then the restriction $X_0 = X|_{\mathrm{CAlg}^{\heartsuit}}$ also representable by the 0-truncated Deligne-Mumford stack $(\mathcal{X}, \tau_{\leqslant 0}\, \mathcal{O})$.

In §18.1, we will prove that conditions (*a*) and (*b*) are also sufficient (Theorem 18.1.0.2). This can be regarded as an illustration of the heuristic principle

{Spectral Algebraic Geometry} = {Classical Algebraic Geometry}+{Deformation Theory}.

The proof is a straightforward application of the deformation-theoretic ideas developed in Chapter 17: it articulates the idea that any connective $\mathbb{E}_\infty$-ring A can be viewed as an "infinitesimal thickening" of the ordinary commutative ring $\pi_0 A$, since the Postnikov tower $\cdots \to \tau_{\leqslant 3} A \to \tau_{\leqslant 2} A \to \tau_{\leqslant 1 A} \to \tau_{\leqslant 0} A = \pi_0 A$ is a tower of square-zero extensions.

Using Theorem 18.1.0.2, we can reduce many representability questions in spectral algebraic geometry to the analogous questions in classical algebraic geometry. These classical questions can then be addressed using Artin's representability theorem (Theorem 16.0.0.2). However, this sort of reasoning is unnecessarily circuitous: the hypotheses of Artin's theorem are closely related to our condition (*a*), and are somewhat clarified in the setting of spectral algebraic geometry. The remainder of this chapter is devoted to proving the following analogue of Artin's theorem in the setting of spectral algebraic geometry:

(∗) Let R be a sufficiently nice $\mathbb{E}_\infty$-ring and suppose we are given a natural transformation of functors $f : X \to \operatorname{Spec} R$ which is locally almost of finite presentation (Definition 17.4.1.1). Then X is representable by a spectral Deligne-Mumford n-stack if and only if it is nilcomplete, infinitesimally cohesive, integrable, admits a connective cotangent complex, and the homotopy groups $\pi_m X(A)$ vanish for $A \in \mathrm{CAlg}^\heartsuit$ and $m > n$ (Theorem 18.3.0.1).

Our proof of (∗) will use Artin's strategy (together with some simplifications introduced by Conrad and de Jong in [43]), which can be broken naturally into two steps:

(*i*) Suppose first that we are given a κ-valued point $x \in X(\kappa)$, where κ is a finitely generated extension field of some residue field of R. We can then study the formal completion $\widehat{X}$ of X at the point x.Adapting an argument of Schlessinger to the spectral setting, we can choose a formally smooth map $\widehat{u} : \operatorname{Spf}(\widehat{A}) \to \widehat{X}$, where $\widehat{A}$ is a complete local Noetherian $\mathbb{E}_\infty$-ring.

(*ii*) Using approximation arguments, we show $\widehat{u}$ is "close" to being the formal completion of a map $u : \operatorname{Spec}(A) \to X$, where A is almost of finite presentation over R. The techniques used to prove (1) can then be applied to approximate u by an étale map $u' : \operatorname{Spec}(A') \to X$, which plays the role of an étale neighborhood of the point x.

We will carry out step (*i*) in §18.2. With an eye to future applications, we consider more generally the problem of describing a formal neighborhood of a B-valued point of a functor X, where B is a connective $\mathbb{E}_\infty$-ring which is not necessarily a field (or even Noetherian). Step (*ii*) is the subject of §18.3. Our proof makes essential use of Popescu's smoothing theorem, which we discuss in §**??**.

18.1 From Classical to Spectral Algebraic Geometry

To every spectral scheme $(X, \mathscr{O}_X)$, we can associate an ordinary scheme $(X, \pi_0 \mathscr{O}_X)$, which we refer to as the *underlying scheme* of $(X, \mathscr{O}_X)$ (see Remark 1.1.2.10). In this section, we will study the problem of inverting this construction:

$(*)$ Given a scheme $(X, \mathscr{O}_X)$, how can one describe the collection of all spectral schemes having underlying scheme $(X, \mathscr{O}_X)$?

The first observation is that this collection is always nonempty: every scheme $(X, \mathscr{O}_X)$ can be regarded as a spectral scheme, by identifying $\mathscr{O}_X$ with a discrete sheaf of $\mathbb{E}_\infty$-rings on X (Proposition 1.1.8.4). However, this representative might not be well-suited for a particular application. Suppose, for example, that the scheme $(X, \mathscr{O}_X)$ is given as the solution to a moduli problem. In other words, suppose that we are given a functor F from the category $\mathrm{CAlg}^\heartsuit$ of commutative rings to the category $\mathcal{S}\mathrm{et}$ of sets, and that X is characterized by the existence of a natural bijection $F(R) \simeq \mathrm{Hom}_{\mathrm{Sch}}(\operatorname{Spec} R, (X, \mathscr{O}_X))$. In many cases of interest, there is a natural way to extend F to a functor of ∞-categories $\overline{F} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. If $\overline{F}$ is represented by a spectral scheme $(Y, \mathscr{O}_Y)$, then the underlying scheme of $(Y, \pi_0 \mathscr{O}_Y)$ represents the original functor F, and is therefore isomorphic to $(X, \mathscr{O}_X)$ in the category of schemes. Moreover, the data of $(Y, \mathscr{O}_Y)$ is equivalent to the data of the functor $\overline{F}$ (Proposition 1.6.4.2). We may therefore rephrase question $(*)$ as follows:

$(*')$ Let $F : \mathrm{CAlg}^\heartsuit \to \mathcal{S}\mathrm{et}$ be a functor which is representable by a scheme, and let $\overline{F}$: $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor extending F. Under what circumstances is $\overline{F}$ representable by a spectral scheme?

Question $(*')$ is addressed by our first main result:

Theorem 18.1.0.1. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor. Then X is representable by a spectral scheme if and only if it is nilcomplete, infinitesimally cohesive, admits a cotangent complex, and the functor $X|_{\mathrm{CAlg}^\heartsuit}$ is representable by a scheme.*

By virtue of Corollary 1.6.7.4, Theorem 18.1.0.1 is an immediate consequence of the following more general result:

Theorem 18.1.0.2. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor. Then X is representable by a spectral Deligne-Mumford stack if and only if the following conditions are satisfied:*

(1) *There exists a spectral Deligne-Mumford stack Y representing a functor $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ and an equivalence of functors $X|_{\mathrm{CAlg}^{\heartsuit}} \simeq Y|_{\mathrm{CAlg}^{\heartsuit}}$.*

(2) *The functor X admits a cotangent complex.*

(3) *The functor X is nilcomplete.*

(4) *The functor X is infinitesimally cohesive.*

Remark 18.1.0.3. A version of Theorem 18.1.0.2 appears in the third appendix of [214].

18.1.1 A Criterion for Étale Descent

Our first step is to show that any functor X which satisfies the hypotheses of Theorem 18.1.0.2 is a sheaf for the étale topology. This is a consequence of the following more general assertion:

Proposition 18.1.1.1. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor which is nilcomplete, infinitesimally cohesive, and admits a cotangent complex. The following conditions are equivalent:*

(1) *The functor X is a sheaf with respect to the étale topology.*

(2) *The functor $X|_{\mathrm{CAlg}^{\heartsuit}}$ is a sheaf with respect to the étale topology.*

Proof. The implication (1) ⇒ (2) is obvious. To prove the converse, let us suppose that $X|_{\mathrm{CAlg}^{\heartsuit}}$ is a sheaf with respect to the étale topology. We wish to prove that, for every connective $\mathbb{E}_\infty$-ring R, the restriction $X_R = X|_{\mathrm{CAlg}_R^{\text{ét}}}$ is a sheaf with respect to the étale topology. Since X is nilcomplete, X_R is the limit of a tower of functors $\{X_R^n\}_{n \geqslant 0}$ given by the formula $X_R^n(A) = X(\tau_{\leqslant n} A)$. It will therefore suffice to show that each X_R^n is a sheaf with respect to the étale topology. Replacing R by $\tau_{\leqslant n} R$, we may suppose that R is n-truncated. We proceed by induction on n. When $n = 0$, the desired result follows from assumption (2). Let us therefore assume that $n > 0$, so that R is a square-zero extension of $R' = \tau_{\leqslant n-1} R$ by $M = \Sigma^n(\pi_n R)$. We have a pullback diagram of $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc} R & \longrightarrow & R' \\ \downarrow & & \downarrow \\ R' & \longrightarrow & R' \oplus \Sigma M. \end{array}$$

Define functors $Y_R, Z_R : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{S}$ by the formulas

$$Y_R(A) = X(A \otimes_R R') \qquad Z_R(A) = X(A \otimes_R R' \oplus M).$$

Since X is infinitesimally cohesive, we have a pullback diagram of functors

$$\begin{array}{ccc} X_R & \longrightarrow & Y_R \\ \downarrow & & \downarrow \\ Y_R & \longrightarrow & Z_R. \end{array}$$

It follows from the inductive hypothesis that Y_R is a sheaf with respect to the étale topology. To complete the proof, it will suffice to show that Z_R is a sheaf with respect to the étale topology. Applying Lemma D.4.3.2 to the projection map $Z_R \to Y_R$, we are reduced to proving the following:

(∗) For every étale R-algebra A and every point $\eta \in X(\tau_{\leqslant n-1} A)$, the construction

$$B \mapsto \mathrm{fib}(X(\tau_{\leqslant n-1} B \oplus (B \otimes_R M) \to X(\tau_{\leqslant n-1} B)))$$

defines an étale sheaf $\mathscr{F} : \mathrm{CAlg}^{\text{ét}}_A \to \mathcal{S}$.

Invoking the definition of the cotangent complex L_X, we see that the functor $\mathscr{F}$ is given by the formula $\mathscr{F}(B) = \mathrm{Map}_{\mathrm{Mod}_{\tau_{\leqslant n-1} A}}(\eta^* L_X, B \otimes_R M)$. It follows from Corollary D.6.3.4 (and Proposition A.5.7.2) that $\mathscr{F}$ is a hypercomplete sheaf with respect to the flat topology. □

Remark 18.1.1.2. Proposition 18.1.1.1 has many variants which can be proven by the same argument. Suppose that the functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ infinitesimally cohesive, nilcomplete, and has a cotangent complex. Then X is a (hypercomplete) sheaf with respect to the Zariski topology (flat topology, Nisnevich topology) if and only if the restriction $X|_{\mathrm{CAlg}^{\heartsuit}}$ has the same property.

Corollary 18.1.1.3. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor which is nilcomplete, infinitesimally cohesive, and which admits a cotangent complex. Let $\mathsf{Y} = (\mathcal{Y}, \mathscr{O})$ be a spectral Deligne-Mumford stack, let $\mathscr{F}$ be a connective quasi-coherent sheaf on Y, and let Y' denote the spectral Deligne-Mumford stack $(\mathcal{Y}, \mathscr{O} \oplus \mathscr{F})$. Let $Y, Y' : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ denote the functors represented by Y and Y', respectively, and let $\alpha : Y \to Y'$ be the canonical map. Suppose we are given a map $\eta : Y \to X$. If $X|_{\mathrm{CAlg}^{\heartsuit}}$ is a sheaf with respect to the étale topology, then the canonical map*

$$\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{Y/}}(Y', X) \to \mathrm{Map}_{\mathrm{QCoh}(Y)}(\eta^* L_X, \alpha^* L_{Y'}) \to \mathrm{Map}_{\mathrm{QCoh}(Y)}(L_X, \mathscr{F})$$

is a homotopy equivalence.

Proof. It follows from Proposition 18.1.1.1 that X is a sheaf with respect to the étale topology. The assertion is therefore local on Y, so we may reduce to the case where Y is affine. In this case, the desired result follows immediately from the definition of L_X. □

Remark 18.1.1.4. Let $\mathsf{X} = (\mathcal{X}, \mathcal{O})$ be a spectral Deligne-Mumford stack, let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ be connective, and let $\eta : L_{\mathsf{X}} \to \Sigma \mathscr{F}$ be a map of quasi-coherent sheaves, classifying a square-zero extension $\mathcal{O}^\eta$ of $\mathcal{O}$. We have a commutative diagram of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} (\mathcal{X}, \mathcal{O} \oplus \Sigma \mathscr{F}) & \longrightarrow & (\mathcal{X}, \mathcal{O}) \\ \downarrow & & \downarrow \\ (\mathcal{X}, \mathcal{O}) & \longrightarrow & (\mathcal{X}, \mathcal{O}^\eta), \end{array}$$

giving rise to a commutative diagram

$$\begin{array}{ccc} X^+ & \longrightarrow & X \\ \downarrow & & \downarrow \\ X & \longrightarrow & X^\eta \end{array}$$

in the ∞-category $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. Suppose that $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ is an infinitesimally cohesive functor which is a sheaf with respect to the étale topology. Then the induced diagram

$$\begin{array}{ccc} \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(X^+, Y) & \longleftarrow & \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(X, Y) \\ \uparrow & & \uparrow \\ \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(X, Y) & \longleftarrow & \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(X^\eta, Y) \end{array}$$

is a pullback square. To prove this, we use the fact that Y is a sheaf with respect to the étale topology to reduce to the case where X is affine, in which case it follows from the definition of an infinitesimally cohesive functor.

18.1.2 Approximations to Étale Morphisms

The main idea in the proof of Theorem 18.1.0.2 is to show that a map $Y_0 \to X$ which is close to being étale can be approximated by another map $Y \to X$ which is actually étale. We can articulate this more precisely as follows:

Proposition 18.1.2.1. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor which is nilcomplete, infinitesimally cohesive, and admits a cotangent complex. Let Y_0 be a functor which is representable by a spectral Deligne-Mumford stack $(\mathcal{Y}, \mathcal{O}_0)$, and suppose we are given a map $f_0 : Y_0 \to X$ for which the relative cotangent complex $L_{Y_0/X}$ is 2-connective. Assume either that $(\mathcal{Y}, \mathcal{O}_0)$ is affine or that X satisfies étale descent. Then the map f_0 factors as a composition*

$$Y_0 \xrightarrow{g} Y \xrightarrow{f} X$$

where $L_{Y/X} \simeq 0$, Y is representable by a spectral Deligne-Mumford stack $(\mathcal{Y}, \mathcal{O})$, and g is induced by a 1-connective map $\mathcal{O} \to \mathcal{O}_0$.

Proof. We will give the proof under the assumption that X satisfies étale descent; the same argument works in general when $(\mathcal{Y}, \mathscr{O}_0)$ is affine. We will construct $\mathscr{O}$ as the inverse limit of a tower of CAlg-valued sheaves on $\mathcal{Y}$

$$\cdots \to \mathscr{O}_2 \to \mathscr{O}_1 \to \mathscr{O}_0,$$

where each pair $(\mathcal{Y}, \mathscr{O}_k)$ is a spectral Deligne-Mumford stack representing a functor $Y_k : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, equipped with a map $f_k : Y_k \to X$ for which the relative cotangent complex $L_{Y_i/X}$ is $(2^k + 1)$-connective.

Let us assume that $\mathscr{O}_k$ has been constructed and that the relative cotangent complex $L_{Y_k/X}$ is $(1 + 2^k)$-connective. Let $\mathscr{O}_{k+1}$ denote the square-zero extension of $\mathscr{O}_k$ classified by the map $u : L_{Y_k} \to L_{Y_k/X}$ in $\mathrm{QCoh}(Y_k) \simeq \mathrm{QCoh}(\mathcal{Y}, \mathscr{O}_k)$. Let Z_k be the functor represented by $(\mathcal{Y}, \mathscr{O}_k \oplus L_{Y_k/X})$. We have a pushout diagram of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} (\mathcal{Y}, \mathscr{O}_k \oplus L_{Y_k/X}) & \longrightarrow & (\mathcal{Y}, \mathscr{O}_k) \\ \downarrow & & \downarrow \\ (\mathcal{Y}, \mathscr{O}_k) & \longrightarrow & (\mathcal{Y}, \mathscr{O}_{k+1}) \end{array}$$

(see Proposition 17.1.3.4), giving rise to a diagram of functors

$$\begin{array}{ccc} Z_k & \xrightarrow{\delta} & Y_k \\ \downarrow{\scriptstyle \delta'} & & \downarrow \\ Y_k & \longrightarrow & Y_{k+1}. \end{array}$$

We have a canonical nullhomotopy of the restriction of u to $f_k^* L_X$, which gives a homotopy between $f_k \circ \delta$ and $f_k \circ \delta'$ (Corollary **??**). Using Remark 18.1.1.4, we see that this homotopy gives rise to a map $f_{k+1} : Y_{k+1} \to X$ extending f_k. We wish to prove that the relative cotangent complex $L_{Y_{k+1}/X}$ is $(2^{k+1} + 1)$-connective. Let $i : Y_k \to Y_{k+1}$ denote the canonical map. Since $L_{Y_k/X}$ is $(2^k + 1)$-connective, the projection map $q : \mathscr{O}_{k+1} \to \mathscr{O}_k$ is 2^k connective, and therefore induces an isomorphism $\pi_0 \mathscr{O}_{k+1} \to \pi_0 \mathscr{O}_k$. It will therefore suffice to show that $i^* L_{Y_{k+1}/X}$ is $(2^{k+1} + 1)$-connective. This pullback fits into a fiber sequence

$$i^* L_{Y_{k+1}/X} \to L_{Y_k/X} \xrightarrow{\phi} L_{Y_k/Y_{k+1}}.$$

We will prove that the map ϕ is $(2^{k+1} + 1)$-connective. Unwinding the definitions, we see that ϕ factors as a composition

$$L_{Y_k/X} \simeq \mathrm{cofib}(q) \xrightarrow{\phi'} \mathscr{O}_k \otimes_{\mathscr{O}_{k+1}} \mathrm{cofib}(q) \xrightarrow{\epsilon_q} L_{Y_k/Y_{k+1}},$$

where ϵ_q is as in Lemma 17.1.4.2. Since $\mathrm{cofib}(q)$ is $2^k + 1$-connective, the map q is 2^k-connective, so that the map ϕ' is $(2^{k+1} + 1)$-connective. Lemma 17.1.4.2 implies that ϵ_q is $(2^{k+1} + 2)$-connective, so that the composition ϕ is $(2^{k+1} + 1)$-connective as desired.

Let $\mathscr{O}$ denote the sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{Y}$ given by $\varprojlim \mathscr{O}_k$. Since each $\mathscr{O}_k$ is hypercomplete, the inverse limit $\mathscr{O}$ is hypercomplete. For any affine object $U \in \mathcal{Y}$, we have a tower of connective $\mathbb{E}_\infty$-rings

$$\cdots \to \mathscr{O}_2(U) \to \mathscr{O}_1(U) \to \mathscr{O}_0(U),$$

where the map $\mathscr{O}_{k+1}(U) \to \mathscr{O}_k(U)$ is 2^k-connective. It follows that that the projection map $\mathscr{O}(U) \to \mathscr{O}_k(U)$ is 2^k-connective for each k, so that the projection map $\mathscr{O} \to \mathscr{O}_k$ induces an equivalence $\tau_{\leqslant 2^k - 1}\mathscr{O} \to \tau_{\leqslant 2^k-1}\mathscr{O}_k$ for each $k \geqslant 0$. Applying the criterion of Theorem 1.4.8.1, we deduce that $(\mathcal{Y}, \mathscr{O})$ is a spectral Deligne-Mumford stack. Let $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ denote the functor represented by Y. Using the fact that X is a nilcomplete étale sheaf, we deduce that the natural transformations $\beta_i : Y_i \to X$ induce a natural transformation $\beta : Y \to X$.

It is clear from the construction that the map $\mathscr{O} \to \mathscr{O}_0$ is 1-connective. We will complete the proof by showing that $L_{Y/X} \simeq 0$. Fix an integer k; we will show that $L_{Y/X}$ is 2^k-connective. Let $i : Y_k \to Y$ denote the canonical map; since $\mathscr{O} \to \mathscr{O}_k$ is an equivalence, it will suffice to show that $i^* L_{Y/X}$ is 2^k-connective. We have a fiber sequence

$$i^* L_{Y/X} \to L_{Y_k/X} \to L_{Y_k/Y}.$$

Since $L_{Y_k/X}$ is 2^k-connective, it will suffice to show that $L_{Y_k/Y}$ is (2^k+1)-connective. This follows from Corollary 17.1.4.3, since the map $\mathscr{O} \to \mathscr{O}_k$ is 2^k-connective. □

18.1.3 The Proof of Theorem 18.1.0.2

Before turning to the proof of Theorem 18.1.0.2, we record the following observation:

Lemma 18.1.3.1. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O})$ be a spectral Deligne-Mumford stack, and assume that $\mathscr{O}$ is discrete. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be the functor represented by X, and let $X' : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a left Kan extension of $X|_{\mathrm{CAlg}^{\heartsuit}}$. Then the canonical map $X' \to X$ exhibits X as a sheafification of X' with respect to the étale topology.*

Proof. For every object $U \in \mathcal{X}$, let X_U denote the functor represented by the spectral Deligne-Mumford stack $(\mathcal{X}_{/U}, \mathscr{O}|_U)$, and let X'_U be a left Kan extension of $X_U|_{\mathrm{CAlg}^{\heartsuit}}$. Let $\mathcal{X}_0$ denote the full subcategory of $\mathcal{X}$ spanned by those objects for which the canonical map $X'_U \to X_U$ exhibits X_U as a sheafification of X'_U with respect to the étale topology. To complete the proof, it will suffice to show that $\mathcal{X}_0 = \mathcal{X}$. If U is affine, then X_U is corepresented by an object of $\mathrm{CAlg}^{\heartsuit}$, so the canonical map $X'_U \to X_U$ is an equivalence; it follows that $U \in \mathcal{X}_0$. Since $\mathcal{X}$ is generated by affine objects under small colimits (Lemma **??**), it will suffice to show that $\mathcal{X}_0$ is closed under small colimits. Suppose that $U \in \mathcal{X}$ is given as a colimit of a small diagram $\{U_\alpha\}$ of objects of $\mathcal{X}_0$. To prove that $U \in \mathcal{X}_0$, it will suffice to show that for every functor $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, the canonical map

$$\begin{aligned} \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(X_U, Y) &\xrightarrow{\theta_U} \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(X'_U, Y) \\ &\simeq \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\heartsuit}, \mathcal{S})}(X_U|_{\mathrm{CAlg}^{\heartsuit}}, Y|_{\mathrm{CAlg}^{\heartsuit}}) \end{aligned}$$

is a homotopy equivalence. This map fits into a commutative diagram

$$\begin{array}{ccc} \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(X_U, Y) & \xrightarrow{\theta_U} & \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\heartsuit}, \mathcal{S})}(X_U|_{\mathrm{CAlg}^{\heartsuit}}, Y|_{\mathrm{CAlg}^{\heartsuit}}) \\ \downarrow & & \downarrow \\ \varprojlim \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(X_{U_\alpha}, Y) & \xrightarrow{\varprojlim \theta_{U_\alpha}} & \varprojlim \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\heartsuit}, \mathcal{S})}(X_{U_\alpha}|_{\mathrm{CAlg}^{\heartsuit}}, Y|_{\mathrm{CAlg}^{\heartsuit}}). \end{array}$$

Since each U_α belongs to $\mathcal{X}_0$, the lower horizontal map is a homotopy equivalence. It will therefore suffice to show that the vertical maps are homotopy equivalences. In other words, we are reduced to proving that X_U is a sheafification of $\varinjlim X_{U_\alpha}$ with respect to the étale topology. This follows from Lemma **??**. □

Proof of Theorem 18.1.0.2. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor which is nilcomplete, infinitesimally cohesive, and admits a cotangent complex. Suppose that there exists a spectral Deligne-Mumford stack $(\mathcal{Y}, \mathcal{O}_0)$ which represents a functor Y_0 such that $X|_{\mathrm{CAlg}^{\heartsuit}} \simeq Y_0|_{\mathrm{CAlg}^{\heartsuit}}$. We wish to prove that X is representable by a spectral Deligne-Mumford stack.

Since Y_0 is a sheaf for the étale topology, $X|_{\mathrm{CAlg}^{\heartsuit}}$ is also a sheaf for the étale topology. Applying Proposition 18.1.1.1, we deduce that X is a sheaf for the étale topology. Replacing $\mathcal{O}_0$ by $\tau_{\leqslant 0}\, \mathcal{O}_0$, we may assume without loss of generality that the structure sheaf $\mathcal{O}_0$ is discrete. Let $Y'_0 : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a left Kan extension of $Y_0|_{\mathrm{CAlg}^{\heartsuit}}$, so that the equivalence $Y_0|_{\mathrm{CAlg}^{\heartsuit}} \simeq X|_{\mathrm{CAlg}^{\heartsuit}}$ extends to a natural transformation $\alpha : Y'_0 \to X$. It follows from Lemma 18.1.3.1 that the canonical map $Y'_0 \to Y_0$ exhibits Y_0 as a sheafification of Y'_0 with respect to the étale topology. Since X is an étale sheaf, the map α factors as a composition $Y'_0 \to Y_0 \xrightarrow{f_0} X$.

We next prove:

$(*)$ The quasi-coherent sheaf $f_0^* L_X$ is connective, and the canonical map $\pi_0 L_{Y_0} \to \pi_0 f_0^* L_X$ is an isomorphism.

To prove $(*)$, choose an étale map $\eta : \mathrm{Spét}\, R \to (\mathcal{Y}, \mathcal{O}_0)$; we will show that $\eta^* f_0^* L_X$ is connective and the map $\pi_0 \eta^* L_X \to \pi_0 \eta^* f_0^* L_X$ is an isomorphism. Note that $\eta^* f_0^* L_X$ is almost connective; if it is not connective, then there exists a discrete R-module M and a nonzero map $\eta^* \beta_0^* L_X \to M[k]$ for some integer $k < 0$. It then follows that the mapping space $\mathrm{Map}_{\mathrm{Mod}_R}(\eta^* f_0^* L_X, M)$ is non-discrete. The quasi-coherent sheaf L_{Y_0} is connective, so that for any discrete R-module M $\mathrm{Map}_{\mathrm{Mod}_R}(\eta^* L_{Y_0}, M)$ is a discrete space, homotopy equivalent to the abelian group of R-module maps from $\pi_0 \eta^* L_{Y_0}$ to M. We are therefore reduced to proving that the canonical map

$$\mathrm{Map}_{\mathrm{Mod}_R}(\eta^* f_0^* L_X, M) \to \mathrm{Map}_{\mathrm{Mod}_R}(\eta^* L_{Y_0}, M)$$

is a homotopy equivalence. This map is obtained by passing to vertical homotopy fibers in the diagram

$$\begin{array}{ccc} Y_0(R \oplus M) & \longrightarrow & X(R \oplus M) \\ \downarrow & & \downarrow \\ Y_0(R) & \longrightarrow & X(R). \end{array}$$

This diagram is a homotopy pullback square because the horizontal maps are homotopy equivalences (the map $f_0 : Y_0 \to X$ induces a homotopy equivalence after evaluation on any commutative ring R, by assumption).

Since X and Y_0 admit cotangent complexes, the morphism $f_0 : Y_0 \to X$ admits a cotangent complex, which fits into a fiber sequence $f_0^* L_X \to L_{Y_0} \to L_{Y_0/X}$ (see Corollary 17.2.5.3). Using $(*)$, we deduce that $L_{Y_0/X}$ is 1-connective. We will need the following slightly stronger assertion:

$(*')$ The relative cotangent complex $L_{Y_0/X}$ is 2-connective.

To prove $(*')$, we note that $(*)$ gives a short exact sequence $\pi_1 f_0^* L_X \to \pi_1 L_{Y_0} \to \pi_1 L_{Y_0/X} \to 0$ in the abelian category $\mathrm{QCoh}(Y_0)^{\heartsuit}$. Let $\mathscr{F} = \pi_1 L_{Y_0/X}$. If $\mathscr{F}$ is nonzero, then we obtain a nonzero map $\gamma : L_{Y_0} \to L_{Y_0/X} \to \Sigma \mathscr{F}$ whose restriction to $f_0^* L_X$ vanishes. Choose an étale map $\eta : \mathrm{Sp\acute{e}t}\, R \to \mathsf{X}$ such that $M = \eta^* \mathscr{F}$ is nonzero. Then γ determines a derivation $L_R \to \Sigma M$ which classifies a square-zero extension R^γ of R by M. Since R and M are discrete, the $\mathbb{E}_\infty$-ring R^γ is discrete. Since the derivation γ is nonzero, the point $\eta \in Y_0(R)$ cannot be lifted to a point of $Y_0(R^\gamma)$. However, the restriction of γ to $f_0^* L_X$ vanishes, so that $f_0(\eta)$ can be lifted to a point of $X(R^\gamma)$. This is a contradiction, since the map $Y_0(R^\gamma) \to X(R^\gamma)$ is a homotopy equivalence.

Combining $(*')$ with Proposition 18.1.2.1, we deduce that there exists a sheaf of $\mathbb{E}_\infty$-rings $\mathscr{O}$ on $\mathcal{Y}$ equipped with a 1-connective map $q : \mathscr{O} \to \mathscr{O}_0$, such that $(\mathcal{Y}, \mathscr{O})$ represents a functor Y and f_0 factors as a composition $Y_0 \to Y \xrightarrow{f} X$ where $L_{Y/X} \simeq 0$. The map q induces an isomorphism $\pi_0 \mathscr{O} \to \pi_0 \mathscr{O}_0$, so that f induces a homotopy equivalence $Y(R) \to X(R)$ whenever R is discrete. Applying Corollary 17.3.6.3, we deduce that f is an equivalence, so that X is representable by the spectral Deligne-Mumford stack $(\mathcal{Y}, \mathscr{O})$. □

18.2 Schlessinger's Criterion

Let $i : \mathsf{X} \to \mathsf{Y}$ be a morphim of spectral Deligne-Mumford stacks, representing functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Assume that i is a closed immersion which is locally almost of finite presentation. Then the image of i is a cocompact closed subset $K \subseteq |\mathsf{Y}|$. In §8.1.6, we defined the *formal completion* $\mathfrak{Y}$ of Y along K; this is a formal spectral Deligne-Mumford stack which represents the functor

$$\widehat{Y} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S} \qquad \widehat{Y}(R) = \{f : \mathrm{Sp\acute{e}t}(R) \to \mathsf{Y} : f(|\operatorname{Spec}(R)|) \subseteq K\}.$$

Note that a map $f : \mathrm{Sp\acute{e}t}(R) \to \mathsf{Y}$ has the property that $f(|\operatorname{Spec}(R)|)$ is contained in K if and only if the composite map $\mathrm{Sp\acute{e}t}(R^{\mathrm{red}}) \to \mathrm{Sp\acute{e}t}(R) \xrightarrow{f} \mathsf{Y}$ factors through i (in which case the factorization is unique). It follows that the functor $\widehat{Y}$ can be described directly in terms of X and Y via the formula

$$\widehat{Y}(R) = Y(R) \times_{Y(R^{\mathrm{red}})} X(R^{\mathrm{red}}).$$

In this section, we will study an analogous construction in the case where the functors X and Y are not representable (or not yet known to be representable). We begin in §18.2.1 by introducing the *relative de Rham space* $(X/Y)_{\mathrm{dR}}$ of an arbitrary morphism $i : X \to Y$ (Definition 18.2.1.1). In the case where i is locally almost of finite presentation (in the sense of Definition 17.4.1.1), the functor $(X/Y)_{\mathrm{dR}}$ is given by the preceding formula $(X/Y)_{\mathrm{dR}}(R) = Y(R) \times_{Y(R^{\mathrm{red}})} X(R^{\mathrm{red}})$ (Example 18.2.1.5). Our main goal is to address the following:

Question 18.2.0.1. Let $i : X \to Y$ be a natural transformation of functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Under what circumstances is the relative de Rham space $(X/Y)_{\mathrm{dR}}$ representable by a formal spectral Deligne-Mumford stack?

To obtain a satisfying answer to Question 18.2.0.1, it is convenient to impose some additional finiteness constraints. In §**??**, we introduce the notion of a *formal thickening* of formal spectral Deligne-Mumford stacks (Definition 18.2.2.1). A formal thickening is a closed immersion of formal spectral Deligne-Mumford stacks which is locally almost of finite presentation and induces an equivalence of reductions (which we make precise in §8.1.4). In §18.2.3, we address Question 18.2.0.1 by showing that if X is representable by a formal spectral Deligne-Mumford stack and we set $\widehat{Y} = (X/Y)_{\mathrm{dR}}$, then the map $X \to \widehat{Y}$ is (representable by) a formal thickening of formal spectral Deligne-Mumford stacks if and only if the functor $\widehat{Y}$ has a sufficiently well-behaved deformation theory, and the relative cotangent complex $L_{X/\widehat{Y}}$ is 1-connective and almost perfect (Theorem 18.2.3.1). For this result to be useful in practice, it is important to know that the formal thickenings of a fixed formal spectral Deligne-Mumford stack $\mathfrak{X}$ are "not too wild." We address this point in §18.2.4 by showing that if $i : \mathfrak{X} \to \mathfrak{Y}$ is a formal thickening, then $\mathfrak{X}$ is locally Noetherian if and only if $\mathfrak{Y}$ is locally Noetherian (Corollary 18.2.4.4).

The results of this section will play an important role in our proof of the Artin representability theorem in §18.3. Suppose that Y is a functor which is not yet known to be representable Roughly speaking, we would like to apply the results of this section to show that (under some reasonable hypotheses) the functor Y becomes representable after formally completing at any point. Here we encounter a technical obstacle: the points we are interested in are κ-valued points: that is, morphisms $i : \mathrm{Spec}(\kappa) \to Y$ where κ is a field and $\mathrm{Spec}(\kappa)$ denotes the functor corepresented by κ. In general, one does not expect the relative cotangent complex $L_{\mathrm{Spec}(\kappa)/Y}$ of such a morphism to be 1-connective. We will address this point in §18.2.5 by proving a more general version of Theorem 18.2.3.1 (at least in the affine case) which can be used to show that, even without the connectivity of $L_{X/Y}$, the functor $\widehat{Y}$ admits "smooth charts" by formal thickenings of X (Theorem 18.2.5.1).

18.2.1 The de Rham Space

Let X be a smooth algebraic variety defined over the field $\mathbf{C}$ of complex numbers. Let us abuse notation by identifying X with its functor of points, regarded as a functor from the category $\mathrm{CAlg}_{\mathbf{C}}^{\heartsuit}$ of commutative algebras over $\mathbf{C}$ to the category $\mathcal{S}\mathrm{et}$ of sets. In [192], Simpson introduced the *de Rham space* of X: this is another functor from $\mathrm{CAlg}_{\mathbf{C}}^{\heartsuit}$ to $\mathcal{S}\mathrm{et}$, given by the construction $R \mapsto X(R^{\mathrm{red}})$. The terminology is motivated by a relationship with the Grothendieck's theory of algebraic de Rham cohomology: the algebraic de Rham cohomology of X can be identified with the cohomology of the de Rham space of X (with coefficients in its structure sheaf). In this section, we introduce a slight variant on this construction:

Definition 18.2.1.1. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor. The *absolute de Rham space of* X is the functor $X_{\mathrm{dR}} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ given by the formula $X_{\mathrm{dR}}(R) = \varinjlim_I X(\pi_0(R)/I)$, where the direct limit is taken over the filtered system of all nilpotent ideals $I \subseteq \pi_0(R)$.

If $f : X \to Y$ is a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, we define the *relative de Rham space* $(X/Y)_{\mathrm{dR}}$ to be the fiber product $X_{\mathrm{dR}} \times_{Y_{\mathrm{dR}}} Y$, given concretely by the formula

$$(X/Y)_{\mathrm{dR}}(R) = \varinjlim_{I} X(\pi_0(R)/I) \times_{Y(\pi_0(R)/I)} Y(R);$$

here again the direct limit is taken over all nilpotent ideals of $\pi_0(R)$.

Remark 18.2.1.2. Let $f : X \to Y$ be a natural transformation of functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Then f factors as a composition

$$X \xrightarrow{f'} (X/Y)_{\mathrm{dR}} \xrightarrow{f''} Y.$$

Remark 18.2.1.3. Let R be a connective $\mathbb{E}_\infty$-ring and let $f : X \to \mathrm{Spec}(R)$ be a morphism in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$, corresponding to a functor $X' : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$. Then the projection map $(X/\mathrm{Spec}(R))_{\mathrm{dR}} \to \mathrm{Spec}(R)$ corresponds to the functor $\mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ given by $A \mapsto \varinjlim_I X(\pi_0(A)/I)$, where the colimit is taken over all nilpotent ideals of the commutative ring $\pi_0(A)$.

Remark 18.2.1.4 (Compatibility with Base Change)**.** Suppose we are given a pullback diagram

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \longrightarrow & Y \end{array}$$

in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. Then the relative de Rham space $(X'/Y')_{\mathrm{dR}}$ can be identified with the fiber product $Y' \times_Y (X/Y)_{\mathrm{dR}}$.

Example 18.2.1.5. Let $f : X \to Y$ be a natural transformation of functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, and suppose that f is locally of finite presentation to order 1 (Definition 17.4.1.1). Then, for every connective $\mathbb{E}_\infty$-ring R, the diagram

$$\begin{array}{ccc} \varinjlim_I X(\pi_0(R)/I) & \longrightarrow & X(R^{\mathrm{red}}) \\ \downarrow & & \downarrow \\ \varinjlim_I Y(\pi_0(R)/I) & \longrightarrow & Y(R^{\mathrm{red}}) \end{array}$$

is a pullback square, where the colimits are taken over the filtered system of all nilpotent ideals of $\pi_0(R)$. It follows that the relative de Rham space $(X/Y)_{\mathrm{dR}}$ is given concretely by the formula $(X/Y)_{\mathrm{dR}}(R) = Y(R) \times_{Y(R^{\mathrm{red}})} X(R^{\mathrm{red}})$.

Definition 18.2.1.6. Let $f : X \to Y$ be morphism of functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. We will say that Y *is formally complete along* f if, for every commutative ring R, the canonical map $\varinjlim_I X(R/I) \to \varinjlim_I Y(R/I)$ is an equivalence.

Proposition 18.2.1.7. *Let $f : X \to Y$ be any natural transformation of functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, and let $f' : X \to (X/Y)_{\mathrm{dR}}$ be as in Remark 18.2.1.2. Then $(X/Y)_{\mathrm{dR}}$ is formally complete along f'.*

Proof. Let R be a commutative ring. Unwinding the definitions, we can identify the colimit limit $\varinjlim_I (X/Y)_{\mathrm{dR}}(R/I)$ with $\varinjlim_{I \subseteq J} Y(R/I) \times_{Y(R/J)} X(R/J)$, where the latter colimit is indexed by the partially ordered set P of pairs of nilpotent ideals $I \subseteq J \subseteq R$. Under this identification, the canonical map $\varinjlim_I X(R/I) \to \varinjlim_I (X/Y)_{\mathrm{dR}}(R/I)$ is given by the natural map

$$\varinjlim_{(I,J) \in P_0} Y(R/I) \times_{Y(R/J)} X(R/J) \to \varinjlim_{(I,J) \in P} Y(R/I) \times_{Y(R/J)} X(R/J),$$

where P_0 denotes the subset of P consisting of those pairs (I, J) with $I = J$. The desired result now follows from the observation that the inclusion $P_0 \hookrightarrow P$ is left cofinal. $\square$

Corollary 18.2.1.8. *Let $f : X \to Y$ be any natural transformation of functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. The following conditions are equivalent:*

(1) *The functor Y is formally complete along f.*

(2) *The map f induces an equivalence $X_{\mathrm{dR}} \to Y_{\mathrm{dR}}$.*

(3) *The projection map $(X/Y)_{\mathrm{dR}} \to Y$ is an equivalence.*

Proof. The equivalence (1) $\Leftrightarrow$ (2) follows immediately from the definitions, the implication (2) $\Rightarrow$ (3) follows from the existence of a pullback diagram

$$\begin{array}{ccc} (X/Y)_{\mathrm{dR}} & \longrightarrow & Y \\ \downarrow & & \downarrow \\ X_{\mathrm{dR}} & \longrightarrow & Y_{\mathrm{dR}}, \end{array}$$

and the implication (3) $\Rightarrow$ (1) follows from Proposition 18.2.1.7. $\square$

Corollary 18.2.1.9. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor, and let $\mathcal{C} \subseteq \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{X/}$ be the full subcategory spanned by those natural transformations $f : X \to Y$ for which Y is formally complete along X. Then the inclusion functor $\mathcal{C} \hookrightarrow \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{X/}$ admits a right adjoint, given by the construction $Y \mapsto (X/Y)_{\mathrm{dR}}$.*

We now show that deformation-theoretic properties of a map $f : X \to Y$ tend to be inherited by the induced map $X \to (X/Y)_{\mathrm{dR}}$.

Proposition 18.2.1.10. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor. Then the de Rham space $X_{\mathrm{dR}} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ is nilcomplete, infintiesimally cohesive, and admits a cotangent complex, given by the zero object $0 \in \mathrm{QCoh}(X_{\mathrm{dR}})$.*

Proof. Let R be a connective $\mathbb{E}_\infty$-ring. Since each of the maps $X_{\mathrm{dR}}(R) \to X_{\mathrm{dR}}(\tau_{\leqslant n} R)$ is a homotopy equivalence, the canonical map $X_{\mathrm{dR}}(R) \to \varprojlim_n X_{\mathrm{dR}}(\tau_{\leqslant n} R)$ is a homotopy equivalence; this shows that X is infinitesimally cohesive. Given a pullback diagram of connective $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc} R & \longrightarrow & R_0 \\ \downarrow & & \downarrow \\ R_1 & \longrightarrow & R_{01} \end{array}$$

where the underlying ring homomorphisms $\pi_0(R_0) \to \pi_0(R_{01}) \leftarrow \pi_0(R_1)$ are surjective with nilpotent kernel, the square

$$\begin{array}{ccc} X_{\mathrm{dR}}(R) & \longrightarrow & X_{\mathrm{dR}}(R_0) \\ \downarrow & & \downarrow \\ X_{\mathrm{dR}}(R_1) & \longrightarrow & X_{\mathrm{dR}}(R_{01}) \end{array}$$

is a homotopy pullback since each map is a homotopy equivalence. Finally, the existence and vanishing of the cotangent complex $L_{X_{\mathrm{dR}}}$ follows from the observation that the projection map $X_{\mathrm{dR}}(R \oplus M) \to X_{\mathrm{dR}}(R)$ is a homotopy equivalence for every connective R-module M. □

Corollary 18.2.1.11. *Let $f : X \to Y$ be a natural transformation of functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Then:*

(1) *The induced map $X_{\mathrm{dR}} \to Y_{\mathrm{dR}}$ is nilcomplete, infinitesimally cohesive, and admits a relative cotangent complex, given by the zero object $0 \in \mathrm{QCoh}(X_{\mathrm{dR}})$.*

(2) *The projection map $(X/Y)_{\mathrm{dR}} \to Y$ is nilcomplete, infinitesimally cohesive, and admits a relative cotangent complex, given by the zero object $0 \in \mathrm{QCoh}((X/Y)_{\mathrm{dR}})$.*

(3) *The map f is nilcomplete if and only if the induced map $f' : X \to (X/Y)_{\mathrm{dR}}$ is nilcomplete.*

(4) *The map f is infinitesimally cohesive if and only if the induced map $f' : X \to (X/Y)_{\mathrm{dR}}$ is infinitesimally cohesive.*

(5) *Suppose that f admits a cotangent complex $L_{X/Y}$. Then the map $f' : X \to (X/Y)_{\mathrm{dR}}$ admits a cotangent complex, and the canonical map $L_{X/Y} \to L_{X/(X/Y)_{\mathrm{dR}}}$ is an equivalence in $\mathrm{QCoh}(X)$.*

(6) *Suppose that the map $f' : X \to (X/Y)_{\mathrm{dR}}$ is infinitesimally cohesive and admits a cotangent complex. Then f is infinitesimally cohesive and admits a cotangent complex.*

Proof. Assertion (1) follows from Proposition 18.2.1.10, Remark 17.3.7.3, and Proposition 17.2.5.2. Assertion (2) follows from (1), Proposition 17.3.8.4, and Remark 17.2.4.6. Assertions (3) and (4) follow from (2) together with Remark 17.3.7.3. Assertion (5) follows from (2) and Proposition 17.2.5.2. Assertion (6) follows from (2) and Proposition 17.3.9.1. □

Proposition 18.2.1.12. *Let $f : X \to Y$ be a natural transformation of functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Assume that f is locally almost of finite presentation (locally of finite presentation, locally of finite presentation to order n for $n \geqslant 1$). Then the induced map $f' : X \to (X/Y)_{\mathrm{dR}}$ is locally almost of finite presentation (locally of finite presentation, locally of finite presentation to order n for $n \geqslant 1$).*

Proof. We will treat the case where f is locally almost of finite presentation; the other cases are the same. By virtue of Remark 17.4.1.3, it will suffice to show that the projection map

$(X/Y)_{\mathrm{dR}} \to Y$ is locally almost of finite presentation. Using the pullback square

$$\begin{array}{ccc} (X/Y)_{\mathrm{dR}} & \longrightarrow & Y \\ \downarrow & & \downarrow \\ X_{\mathrm{dR}} & \longrightarrow & Y_{\mathrm{dR}}, \end{array}$$

we can further reduce to showing that the map $X_{\mathrm{dR}} \to Y_{\mathrm{dR}}$ is locally almost of finite presentation (Proposition 17.4.1.5). Let $\{R_\alpha\}$ be a filtered diagram of n-truncated connective $\mathbb{E}_\infty$-rings; we wish to show that the diagram σ :

$$\begin{array}{ccc} \varinjlim X_{\mathrm{dR}}(R_\alpha) & \longrightarrow & X_{\mathrm{dR}}(\varinjlim R_\alpha) \\ \downarrow & & \downarrow \\ \varinjlim Y_{\mathrm{dR}}(R_\alpha) & \longrightarrow & Y_{\mathrm{dR}}(\varinjlim R_\alpha) \end{array}$$

is a pullback square. Using Example 18.2.1.5, we can identify σ with the diagram

$$\begin{array}{ccc} \varinjlim X(R_\alpha^{\mathrm{red}}) & \longrightarrow & X(\varinjlim R_\alpha^{\mathrm{red}}) \\ \downarrow & & \downarrow \\ \varinjlim Y(R_\alpha^{\mathrm{red}}) & \longrightarrow & Y(\varinjlim R_\alpha^{\mathrm{red}}), \end{array}$$

which is a pullback square by virtue of our assumption that f is locally almost of finite presentation. □

We close this section with a variant of Proposition 18.2.1.12:

Proposition 18.2.1.13. *Let $f : X \to Y$ be a natural transformation of functors $X, Y :$ $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Assume that f is nilcomplete, infinitesimally cohesive, and admits a relative cotangent complex $L_{X/Y} \in \mathrm{QCoh}(X)$. The following conditions are equivalent:*

(1) *The relative cotangent complex $L_{X/Y} \in \mathrm{QCoh}(X)$ is almost perfect.*

(2) *The induced map $X \to (X/Y)_{\mathrm{dR}}$ is locally almost of finite presentation.*

Warning 18.2.1.14. In the situation of Proposition 18.2.1.13, it is not necessarily true that the map $f : X \to Y$ is locally almost of finite presentation, or that the canonical map $(X/Y)_{\mathrm{dR}}(R) \to Y(R) \times_{Y(R^{\mathrm{red}})} X(R^{\mathrm{red}})$ is an equivalence for $R \in \mathrm{CAlg}^{\mathrm{cn}}$.

Proof of Proposition 18.2.1.13. Using Corollary 18.2.1.11, we can replace Y by the relative de Rham space $(X/Y)_{\mathrm{dR}}$ and thereby reduce to the case where Y is formally complete along f. In this case, the implication (2) ⇒ (1) follows from Proposition 17.4.2.1. We will prove the converse. Assume that f satisfies condition (1); we wish to show that f is locally almost of finite presentation. Without loss of generality we may assume that the functor $Y = \operatorname{Spec}(R)$ is corepresentable by a connective $\mathbb{E}_\infty$-ring R, so that X determines a functor $X' : \operatorname{CAlg}_R^{\mathrm{cn}} \to \mathcal{S}$. We wish to show that X' commutes with filtered colimits when restricted to $\tau_{\leqslant n} \operatorname{CAlg}_R^{\mathrm{cn}}$, for every nonnegative integer n. Using Proposition 17.4.2.1 we can reduce to the case $n = 0$. We first prove the following:

(∗) Let $\{A_s\}_{s \in S}$ be a diagram in $\operatorname{CAlg}_R^{\heartsuit}$ indexed by a filtered partially ordered set S, with transition maps $\alpha_{s,s'} : A_s \to A_{s'}$. Suppose we are given a collection of ideals $I_s \subseteq A_s$ such that $\alpha_{s,s'}(I_s) \subseteq I_{s'}$. If there exists an integer $n \geqslant 0$ such that $I_s^n = (0)$ for all $s \in S$, then the diagram

$$\begin{array}{ccc} \varinjlim X'(A_s) & \longrightarrow & X'(\varinjlim A_s) \\ \downarrow & & \downarrow \\ \varinjlim X'(A_s/I_s) & \longrightarrow & X'(\varinjlim A_s/I_s) \end{array}$$

is a pullback square.

Proceeding by induction on n, we can reduce to the case $n = 2$, so that each A_s is a square-zero extension of A_s/I_s. In this case, Theorem HA.7.4.1.26 supplies a pullback diagram of $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc} A_s & \longrightarrow & A_s/I_s \\ \downarrow & & \downarrow \\ A_s/I_s & \longrightarrow & (A_s/I_s) \oplus \Sigma I_s, \end{array}$$

depending functorially on s. Invoking our assumption that f is infinitesimally cohesive, we are reduced to proving that the upper square in the diagram

$$\begin{array}{ccc} \varinjlim X'(A_s/I_s) & \longrightarrow & X'(\varinjlim A_s/I_s) \\ \downarrow & & \downarrow \\ \varinjlim X'((A_s/I_s) \oplus \Sigma I_s) & \longrightarrow & X'(\varinjlim (A_s/I_s) \oplus \Sigma I_s) \\ \downarrow & & \downarrow \\ \varinjlim X'(A_s/I_s) & \longrightarrow & X'(\varinjlim A_s/I_s) \end{array}$$

is a pullback. Since the vertical compositions are the identity, we are reduced to showing that the bottom square is a pullback. This follows from our assumption that $f : X \to Y$ admits a cotangent complex which is almost perfect.

For every commutative ring A, let $(-nilA)$ denote the (filtered) partially ordered set consisting of nilpotent ideals of A. Our assumption that Y is formally complete along f translates to the following assertion:

$(*')$ For every commutative ring A, the colimit $\varinjlim_{I \in (-nil A)} X'(A/I)$ is contractible.

Now suppose we are given a diagram $\{A_s\}_{s \in S}$ in $\mathrm{CAlg}_R^{\heartsuit}$ indexed by a filtered partially ordered set S, having colimit A; we wish to show that the canonical map $\theta : \varinjlim_{s \in S} X(A_s) \to X(A)$ is a homotopy equivalence. For each element $t \in S$ and every nilpotent ideal $I \subseteq A_t$, assertion $(*)$ guarantees that the diagram $\sigma_{t,I}$:

$$\begin{array}{ccc} \varinjlim_{s \in S} X'(A_s) & \xrightarrow{\theta} & X'(A) \\ \downarrow & & \downarrow \\ \varinjlim_{s \geqslant t} X'(A_s/IA_s) & \longrightarrow & X'(A/IA) \end{array}$$

is a pullback square. Passing to the colimit over t and I, we obtain a pullback square σ :

$$\begin{array}{ccc} \varinjlim_{s \in S} X'(A_s) & \xrightarrow{\theta} & X'(A) \\ \downarrow & & \downarrow \\ \varinjlim_{s \in S} \varinjlim_{I \in (-nil A_s)} X'(A_s) & \xrightarrow{\theta'} & \varinjlim_{I \in {}_{-}nil0(A)} X'(A/I), \end{array}$$

where ${}_{-}nil0(A) \subseteq (-nil A)$ is the subset consisting of those nilpotent ideals having the form JA, where J is a nilpotent ideal of some A_s. Consequently, to complete the proof of Proposition 18.2.1.13, it will suffice to show that the map θ' is a homotopy equivalence. In fact, we claim that the domain and codomain of θ are contractible. For the domain, this follows immediately from $(*')$. For the codomain, it will suffice (by virtue of $(*')$) to show that the canonical map $\varinjlim_{I \in {}_{-}nil0(A)} X'(A/I) \to \varinjlim_{I \in (-nil A)} X'(A/I)$ is a homotopy equivalence. In fact, we claim that the functor

$$(-nil A) \to \mathcal{S} \qquad I \mapsto X'(A/I)$$

is a left Kan extension of its restriction to the subset ${}_{-}nil0(A) \subseteq (-nil A)$. Fix a nilpotent ideal $J \subseteq A$; we wish to show that the canonical map $\rho : \varinjlim_{I \in {}_{-}nil0(A), I \subseteq J} X'(A/I) \to X'(A/J)$ is a homotopy equivalence. To prove this, we observe that every finitely generated nilpotent ideal of A belongs to ${}_{-}nil0(A)$, so that A/J can be written as the colimit of the (filtered) diagram $\{A/I\}_{I \in {}_{-}nil0(A), I \subseteq J}$. Invoking $(*)$, we deduce that ρ fits into a pullback square

$$\begin{array}{ccc} \varinjlim_{I \in {}_{-}nil0(A), I \subseteq J} X'(A/I) & \xrightarrow{\rho} & X'(A/J) \\ \downarrow & & \downarrow \\ \varinjlim_{I \in {}_{-}nil0(A), I \subseteq J} X'(A/J) & \xrightarrow{\rho'} & X'(A/J), \end{array}$$

where the map ρ' is obviously a homotopy equivalence. □

18.2.2 Formal Thickenings

We now study a special class of closed immersions between formal spectral Deligne-Mumford stacks.

Definition 18.2.2.1. Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a morphism of formal spectral Deligne-Mumford stacks. We will say that f is a *formal thickening* if the following conditions are satisfied:

(1) The induced map $\mathfrak{X}^{\mathrm{red}} \to \mathfrak{Y}^{\mathrm{red}}$ is an equivalence (see §8.1.4).

(2) The morphism f is representable by closed immersions which are locally almost of finite presentation. In other words, for every pullback diagram

$$\begin{array}{ccc} \mathfrak{X}' & \longrightarrow & \mathfrak{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathfrak{Y}' & \longrightarrow & \mathfrak{Y} \end{array}$$

where $\mathfrak{Y}'$ is a spectral Deligne-Mumford stack, the fiber product $\mathfrak{X}'$ is also a spectral Deligne-Mumford stack, and the morphism f' is a closed immersion which is locally almost of finite presentation.

Remark 18.2.2.2. In the situation of Definition 18.2.2.1, we can restate condition (1) as follows:

(1′) For every reduced commutative ring R, composition with f induces a homotopy equivalence
$$\mathrm{Map}_{\mathrm{fSpDM}}(\mathrm{Sp\acute{e}t}(R), \mathfrak{X}) \to \mathrm{Map}_{\mathrm{fSpDM}}(\mathrm{Sp\acute{e}t}(R), \mathfrak{Y}).$$

Remark 18.2.2.3. Suppose we are given a pullback diagram of formal spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathfrak{X}' & \longrightarrow & \mathfrak{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathfrak{Y}' & \xrightarrow{g} & \mathfrak{Y}. \end{array}$$

If f is a formal thickening, then so is f'. The converse holds if g is an étale surjection.

Remark 18.2.2.4. Let $f : \mathfrak{X} \to \mathfrak{Y}$ and $g : \mathfrak{Y} \to \mathfrak{Z}$ be formal thickenings of formal spectral Deligne-Mumford stacks. Then the composite map $g \circ f : \mathfrak{X} \to \mathfrak{Z}$ is also a formal thickening.

Remark 18.2.2.5. Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a formal thickening of formal spectral Deligne-Mumford stacks, and let $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ denote the functors represented by $\mathfrak{X}$ and $\mathfrak{Y}$, respectively. Let us abuse notation by identifying f with the induced natural transformation

$X \to Y$. Then Y is formally complete along $f : X \to Y$, in the sense of Definition 18.2.1.6. To prove this, we observe that for every commutative ring R, our assumption that f is locally almost of finite presentation guarantees that we have a pullback diagram

$$\begin{array}{ccc} \varinjlim X(R/I) & \longrightarrow & X(R^{\mathrm{red}}) \\ \downarrow & & \downarrow \\ \varinjlim Y(R/I) & \longrightarrow & Y(R^{\mathrm{red}}), \end{array}$$

where the colimit is taken over all nilpotent ideals $I \subseteq R$. Since the map f induces an equivalence $\mathfrak{X}^{\mathrm{red}} \to \mathfrak{Y}^{\mathrm{red}}$, the right vertical map is a homotopy equivalence, so the left vertical map is a homotopy equivalence as well.

Proposition 18.2.2.6. *Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a morphism of formal spectral Deligne-Mumford stacks. Then f is a formal thickening if and only if it satisfies the following conditions:*

(1) *The morphism f is representable by affine spectral Deligne-Mumford stacks.*

(2) *The morphism f is locally almost of finite presentation.*

(3) *The completed cotangent complex $L^{\wedge}_{\mathfrak{X}/\mathfrak{Y}} \in \mathrm{QCoh}(\mathfrak{X})$ is 1-connective.*

(4) *The induced map $\mathfrak{X}^{\mathrm{red}} \to \mathfrak{Y}^{\mathrm{red}}$ is an equivalence.*

Proof. The necessity of conditions (1) through (4) is clear. For the converse, suppose that (1) through (4) are satisfied; we wish to show that f is representable by closed immersions. To prove this, it will suffice to show that for every map $\mathrm{Spét}(A) \to \mathfrak{Y}$, the projection map $\mathrm{Spét}(A) \times_{\mathfrak{Y}} \mathfrak{X} \to \mathrm{Spét}(A)$ is a closed immersion. It follows from (1) that we can write $\mathrm{Spét}(A) \times_{\mathfrak{Y}} \mathfrak{X} = \mathrm{Spét}(B)$ for some connective $\mathbb{E}_\infty$-ring B. Condition (2) guarantees that B is locally almost of finite presentation over A; in particular, $\pi_0 B$ is finitely generated as an algebra over $\pi_0 A$. Let $x_1, \ldots, x_n$ be a set of generators for $\pi_0 B$ as an algebra over $\pi_0 A$. It follows from (3) that we can arrange (after modifying each x_i by an element of $\pi_0 A$ if necessary) that each x_i is nilpotent in $\pi_0 B$. Then the map $\pi_0 A \to (\pi_0 B)/(x_1, \ldots, x_n)$ is a surjection, whose kernel is a nilpotent ideal $I \subseteq (\pi_0 A)$. We therefore obtain a homomorphism $u : (\pi_0 B) \to (\pi_0 A)/I$. Let v denote the composite map

$$(\pi_0 B) \xrightarrow{u} (\pi_0 A)/I \to (\pi_0 B)/I(\pi_0 B),$$

and let $v' : (\pi_0 B) \to (\pi_0 B)/I(\pi_0 B)$ be the tautological map. Then v and v' agree on $\pi_0 A$. Let $J \subseteq (\pi_0 B)/I(\pi_0 B)$ be the ideal generated by the elements $\{v(x_i) - v'(x_i)\}_{1 \leqslant i \leqslant n}$. The difference between v and v' determines a $(\pi_0 A)$-linear derivation of $(\pi_0 B)$ into J/J^2, which automatically trivial since condition (3) guarantees the vanishing of the module of Kähler differentials $\Omega_{\pi_0 B/\pi_0 A} \simeq \pi_0 L_{B/A}$. It follows that $J = J^2$. Since each x_i is nilpotent in $(\pi_0 B)$, the ideal J is nilpotent, so the equation $J = J^2$ implies that $J = 0$. It follows that $v = v'$, so that v is surjective. In particular, the map $\pi_0 A \to \pi_0 B$ induces a surjection modulo the ideal I. Since the ideal I is nilpotent, it follows from Nakayama's lemma that the map $\pi_0 A \to \pi_0 B$ is surjective, as desired. □

Proposition 18.2.2.7. *Let $f : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings which induces a surjection $\pi_0 A \to \pi_0 B$, and assume that f exhibits B as an almost perfect A-module. Let $I \subseteq \pi_0 A$ be a finitely generated ideal which contains the kernel of $\pi_0(f)$. Let us regard $\pi_0 A$ as equipped with the I-adic topology and $\pi_0 B$ as equipped with the $I(\pi_0 B)$-adic topology. Then the induced map $\mathrm{Spf}(B) \to \mathrm{Spf}(A)$ is a formal thickening.*

Proof. We have a pullback diagram

$$\begin{array}{ccc} \mathrm{Spf}(B) & \longrightarrow & \mathrm{Sp\acute{e}t}(B) \\ \downarrow & & \downarrow \\ \mathrm{Spf}(A) & \longrightarrow & \mathrm{Sp\acute{e}t}(A). \end{array}$$

Our assumptions on f guarantee that the right vertical map is a closed immersion which is locally almost of finite presentation (see Corollary 5.2.2.2), so that the left vertical map is representable by closed immerions which are locally almost of finite presentation. We will complete the proof by verifying condition $(1')$ of Remark 18.2.2.2. Let R be a reduced commutative ring equipped with a map $g : \mathrm{Sp\acute{e}t}(R) \to \mathrm{Spf}(A)$; we wish to show that the homotopy fiber $F = \mathrm{Map}_{\mathrm{fSpDM}}(\mathrm{Sp\acute{e}t}(R), \mathrm{Spf}(B)) \times_{\mathrm{Map}_{\mathrm{fSpDM}}(\mathrm{Sp\acute{e}t}(R), \mathrm{Spf}(A))} \{g\}$ is contractible. Let us identify g with a ring homomorphism $\rho : \pi_0 A \to R$ which annihilates some power of I; we wish to show that ρ factors through $\pi_0 B$. This is clear: the assumption that R is reduced guarantees that ρ vanishes on I and therefore also on the kernel $\ker(\pi_0(f)) \subseteq I$. □

We now show that every formal thickening is locally of the form described by Proposition 18.2.2.7.

Proposition 18.2.2.8. *Let A be a complete adic $\mathbb{E}_\infty$-ring and let $f : \mathfrak{X} \to \mathrm{Spf}(A)$ be a formal thickening. Then there exists an equivalence $\mathsf{X} \simeq \mathrm{Spf}(B)$, where B is an $\mathbb{E}_\infty$-algebra which is almost perfect as an A-module, the map $\pi_0(A) \to \pi_0(B)$ is surjective, and we regard $\pi_0(B)$ as equipped with the $I\pi_0(B)$-adic topology; here $I \subseteq \pi_0(A)$ is an ideal of definition which contains the kernel of the map $\pi_0(A) \to \pi_0(B)$.*

Proof. Choose a tower of connective $\mathbb{E}_\infty$-algebras over A

$$\cdots \to A_4 \to A_3 \to A_2 \to A_1$$

which satisfies the requirements of Lemma 8.1.2.2. Since f is a formal thickening, each fiber product $\mathsf{X} \times_{\mathrm{Spf}(A)} \mathrm{Spét}(A_n)$ has the form $\mathrm{Spét}(B_n)$, where B_n is almost perfect as a module over A_n and the map $\pi_0 A_n \to \pi_0 B_n$ is a surjection. Set $B = \varprojlim B_n \simeq \Gamma(\mathfrak{X}; \mathscr{O}_{\mathfrak{X}})$. Using Proposition 8.4.1.2, we deduce that B is almost perfect as an A-module and the canonical maps $B \otimes_A A_n \to B_n$ are equivalences. Moreover, the fiber $\mathrm{fib}(A \to B)$ can be written as the limit of a tower

$$\cdots \to \mathrm{fib}(A_3 \to B_3) \to \mathrm{fib}(A_2 \to B_2) \to \mathrm{fib}(A_1 \to B_1)$$

of connective A-modules whose transition maps are surjective on π_0. It follows that the fiber of the map $A \to B$ is connective: that is, B is connective and the ring homomorphism $\pi_0 A \to \pi_0 B$ is surjective.

Choose a finite collection of elements x_i which generate $\pi_0 \mathrm{fib}(A_1 \to B_1)$ as a module over the commutative ring $\pi_0 A_1$. Each of the elements x_i can be lifted to an element $\overline{x}_i \in \pi_0 \mathrm{fib}(A \to B)$. Since f is a formal thickening, the canonical map $A_1 \to B_1$ induces an isomorphism $A_1^{\mathrm{red}} \simeq B_1^{\mathrm{red}}$. It follows that each each x_i has nilpotent image in A_1, so that each $\overline{x}_i$ has topologically nilpotent image in $\pi_0 A$. We can therefore choose a finitely generated ideal of definition $I \subseteq \pi_0 A$ which contains the image of each $\overline{x}_i$. Note that the elements $\overline{x}_i$ generate $\pi_0 \mathrm{fib}(A \to B)$ as a module over the commutative ring $\pi_0 A$, so that I contains the kernel of the map $\pi_0 A \to \pi_0 B$. Let us regard B as an adic $\mathbb{E}_\infty$-ring, with ideal of definition $I(\pi_0 B)$. We will complete the proof by showing that the canonical map $\mathfrak{X} \to \mathrm{Spf}(B)$ is an equivalence. To prove this, it will suffice to show that $\mathfrak{X}$ and $\mathrm{Spf}(B)$ represent the same functor on $\mathrm{CAlg}^{\mathrm{cn}}$: that is, that the canonical map

$$\theta : \mathrm{Map}_{\mathrm{fSpDM}}(\mathrm{Spét}(R), \mathfrak{X}) \to \mathrm{Map}_{\mathrm{fSpDM}}(\mathrm{Spét}(R), \mathrm{Spf}(B))$$

is a homotopy equivalence for every connective $\mathbb{E}_\infty$-ring B (see Theorem 8.1.5.1). Fix a map $u : \mathrm{Spét}(R) \to \mathrm{Spf}(A)$; we will show that the induced map

$$\begin{array}{c} \mathrm{Map}_{\mathrm{fSpDM}}(\mathrm{Spét}(R), \mathfrak{X}) \times_{\mathrm{Map}_{\mathrm{fSpDM}}(\mathrm{Spét}(R), \mathrm{Spf}(A))} \{u\} \\ \downarrow \theta_u \\ \mathrm{Map}_{\mathrm{fSpDM}}(\mathrm{Spét}(R), \mathrm{Spf}(B)) \times_{\mathrm{Map}_{\mathrm{fSpDM}}(\mathrm{Spét}(R), \mathrm{Spf}(A))} \{u\} \end{array}$$

is a homotopy equivalence. Without loss of generality, we may assume that u factors through $\mathrm{Spét}(A_n)$ for some $n \geqslant 0$. We are therefore reduced to showing that the map

$$\mathsf{X} \times_{\mathrm{Spf}(A)} \mathrm{Spét}(A_n) \to \mathrm{Spf}(B) \times_{\mathrm{Spf}(A)} \mathrm{Spét}(A_n)$$

is an equivalence of formal spectral Deligne-Mumford stacks. This is clear, since both sides can be identified with $\mathrm{Spét}(B_n)$. $\square$

Corollary 18.2.2.9. *Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a formal thickening of formal spectral Deligne-Mumford stacks. Then the completed relative cotangent complex $L^{\wedge}_{\mathfrak{X}/\mathfrak{Y}} \in \mathrm{QCoh}(\mathfrak{X})$ is 1-connective and almost perfect.*

Proof. The assertion is local on $\mathfrak{Y}$, so we may assume without loss of generality that $\mathfrak{Y} = \mathrm{Spf}(A)$ for some connective $\mathbb{E}_\infty$-ring A which is complete with respect to a finitely generated ideal $I \subseteq \pi_0 A$. Applying Proposition 18.2.2.8, we can write $\mathfrak{X} \simeq \mathrm{Spf}(B)$, where B is almost perfect as an A-module and the map $\pi_0 A \to \pi_0 B$ is surjective. Using Example 17.1.2.9, we see that $L^{\wedge}_{\mathfrak{X}/\mathfrak{Y}}$ is the quasi-coherent sheaf associated to the I-completion of the relative cotangent complex $L_{B/A}$. It now suffices to observe that $L_{B/A}$ is 1-connective (since the map $\pi_0 A \to \pi_0 B$ is surjective) and almost perfect (since B is almost of finite presentation over A by virtue of Corollary 5.2.2.2). □

18.2.3 Existence of Formal Thickenings

We can now formulate the main result of this section.

Theorem 18.2.3.1. *Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Assume that:*

(0) *The functor X is representable by a formal spectral Deligne-Mumford stack $\mathfrak{X}$.*

(1) *The functor Y is nilcomplete, infinitesimally cohesive, and admits a cotangent complex.*

(2) *The relative cotangent complex $L_{X/Y} \in \mathrm{QCoh}(X)$ which is 1-connective and almost perfect.*

(3) *The functor Y is a sheaf for the étale topology.*

Then the relative de Rham space $(X/Y)_{\mathrm{dR}}$ is representable by a formal thickening of $\mathfrak{X}$.

We will deduce Theorem 18.2.3.1 from the following more specific result, whose proof we postpone until §18.2.5:

Theorem 18.2.3.2. *Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, Assume that:*

(0) *The functor X is representable by an affine formal spectral Deligne-Mumford stack $\mathrm{Spf}(B)$.*

(1) *The functor Y is nilcomplete, infinitesimally cohesive, and admits a cotangent complex.*

(2) *The relative cotangent complex $L_{X/Y} \in \mathrm{QCoh}(X)$ is almost perfect and 1-connective.*

(3) *The functor Y is formally complete along f, in the sense of Definition 18.2.1.6.*

Then Y is (representable by) an affine formal spectral Deligne-Mumford stack $\mathrm{Spf}(A)$*, and the map* $\mathrm{Spf}(B) \to \mathrm{Spf}(A)$ *is a formal thickening (in the sense of Definition 18.2.2.1).*

Proof of Theorem 18.2.3.1 from Theorem 18.2.3.2. Let $f : X \to Y$ be any natural transformation satisfying conditions (0) through (3) of Theorem 18.2.3.1. Without loss of generality, we can replace Y by the relative de Rham space $(X/Y)_{\mathrm{dR}}$ and thereby reduce to the case where Y is formally complete along f (see Corollary 18.2.1.11). In this case, we wish to show that Y is representable by a formal thickening of $\mathfrak{X}$.

Write $\mathfrak{X} = (\mathcal{X}, \mathcal{O}_{\mathfrak{X}})$. For each object $U \in \mathfrak{X}$, let X_U denote the functor represented by $\mathfrak{X}_U = (\mathcal{X}_{/U}, \mathcal{O}_{\mathfrak{X}}|_U)$, and define a functor $Y_U : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ by the formula $Y_U(R) = Y(R) \times_{Y(R^{\mathrm{red}})} X_U(R^{\mathrm{red}})$. Let us say that U is *good* if the functor Y_U is representable by a formal spectral Deligne-Mumford stack $\mathfrak{Y}_U$ which is a formal thickening of $\mathfrak{X}_U$. Note that f is locally almost of finite presentation (Proposition 18.2.1.13), so we can identify Y with the functor $Y_{\mathbf{1}}$ where $\mathbf{1}$ is the final object of $\mathcal{X}$ (Example 18.2.1.5). It will therefore suffice to show that the object $\mathbf{1} \in \mathcal{X}$ is good. We will complete the proof by showing that every object $U \in \mathcal{X}$ is good. We first note that Theorem 18.2.3.2 guarantees that every affine object of $\mathcal{X}$ is good. By virtue of Proposition 8.1.3.7, it will suffice to show that the collection of good objects of $\mathcal{X}$ is closed under colimits. Let $\{U_\alpha\}$ be a small diagram in $\mathcal{X}$ having colimit U where each U_α is good. Then $\{\mathfrak{Y}_{U_\alpha}\}$ is a diagram of formal spectral Deligne-Mumford stacks with étale transition maps, and therefore has a colimit $\mathfrak{Z}$ in the ∞-category of formal spectral Deligne-Mumford stacks. It is clear that the canonical map $\mathfrak{X}_U \to \mathfrak{Z}$ is a formal thickening (since this is a local condition). We complete the proof by observing that Y_U is the functor represented by $\mathfrak{Z}$: in fact, both functors can identified with the sheafification (with respect to the étale topology) of $\varinjlim_\alpha Y_{U_\alpha}$. □

We close this section by noting another consequence of Theorem 18.2.3.2:

Corollary 18.2.3.3. *Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a formal thickening of formal spectral Deligne-Mumford stacks. Then $\mathfrak{X}$ is affine if and only if $\mathfrak{Y}$ is affine.*

Proof. The "if" direction follows from Proposition 18.2.2.8. For the converse, suppose that $\mathfrak{X}$ is affine. Let X and Y denote the functors represented by $\mathfrak{X}$ and $\mathfrak{Y}$, respectively, so that f determines a natural transformation $X \to Y$. Then f satisfies the hypotheses of Theorem 18.2.3.2 (condition (2) follows from Corollary 18.2.2.9). It follows that Y is representable by an affine formal spectral Deligne-Mumford stack $\mathfrak{Y}'$. Applying Theorem 8.1.5.1 we obtain an equivalence $\mathfrak{Y} \simeq \mathfrak{Y}'$, so that $\mathfrak{Y}$ is affine. □

18.2.4 The Noetherian Case

We now specialize to the study of locally Noetherian formal spectral Deligne-Mumford stacks.

Proposition 18.2.4.1. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then $\mathfrak{X}$ is locally Noetherian if and only if the following pair of conditions is satisfied:*

(1) *The reduction $\mathfrak{X}^{\mathrm{red}}$ is locally Noetherian.*

(2) *The canonical map $\mathfrak{X}^{\mathrm{red}} \to \mathfrak{X}$ is a formal thickening.*

The proof of Proposition 18.2.4.1 will require some preliminaries.

Lemma 18.2.4.2. *Let R be a commutative ring and let t be an element of R. Suppose that R/tR is Noetherian and that R is (t)-complete (in the sense of Definition 7.3.0.5). Then R is Noetherian.*

Proof. For each $m \geqslant 0$, let I_m denote the kernel of the map $R/tR \xrightarrow{t^k} t^k R/t^{k+1}R$. We then have $0 = I_0 \subseteq I_1 \subseteq I_2 \subseteq \cdots \subseteq R/tR$. The assumption that R/tR is Noetherian guarantees that this sequence stabilizes. Consequently, there exists an integer $m \geqslant 0$ with the following property: for any $k \geqslant m$ and any $y \in R$, if $t^k y$ belongs to $t^{k+1}R$, then we can write $t^m y = t^{m+1} y'$ for some $y' \in R$.

For each integer k, let J_k denote the kernel of the map $t^k : R \to R$. If $k \geqslant m$ and y belongs to J_k, then $t^k y = 0 \in t^{k+1}R$, so we can write $t^m y = t^{m+1} y'$ for some $y' \in R$. Note that y' belongs to J_{k+1} and that $y \equiv ty' \pmod{J_m}$. It follows that $J_k = tJ_{k+1} + J_m$. We have a short exact sequence of Pro-abelian groups

$$0 \to \{J_m\}_{k \geqslant m} \to \{J_k\}_{k \geqslant m} \to \{J_k/J_m\}_{k \geqslant m} \to 0,$$

where transition maps are given by multiplication by t. We therefore obtain a short exact sequence of abelian groups

$$\lim{}^1 \{J_m\}_{k \geqslant m} \to \lim{}^1 \{J_k\}_{k \geqslant m} \to \lim{}^1 \{J_k/J_m\}_{k \geqslant m}$$

where the first term vanishes because $\{J_m\}_{k \geqslant m}$ is trivial as a Pro-object, and the third term vanishes because the tower $\{J_k/J_m\}_{k \geqslant m}$ has surjective transition maps. It follows that $\varprojlim^1 \{J_k\}_{k \geqslant m} \simeq \varprojlim^1 \{\pi_1 \operatorname{cofib}(t^k : R \to R)\}_{k \geqslant m}$ vanishes. Consequently, the assumption that R is (t)-complete is equivalent to the assumption that R is classically (t)-adically complete: that is, it is isomorphic to the inverse limit of the tower $\{R/t^k R\}_{k \geqslant 0}$. Applying Proposition 7.3.8.1, we deduce that R is Noetherian. $\square$

Variant 18.2.4.3. Let R be a commutative ring containing an element t and let M be a discrete R-module. Assume that R and M are (t)-complete, that R/tR is a Noetherian ring, and that M/tM is a finitely generated module over R/tR. Then M is a finitely generated module over R.

Proof. Applying Lemma 18.2.4.2 to the direct sum $R \oplus M$, we deduce that $R \oplus M$ is a Noetherian ring. In particular, the ideal $M \subseteq R \oplus M$ is finitely generated as an $(R \oplus M)$-module, and therefore also as an R-module. □

Proof of Proposition 18.2.4.1. The assertion is local on $\mathfrak{X}$; we may therefore assume without loss of generality that $\mathfrak{X}$ is affine. Write $\mathfrak{X} = \mathrm{Spf}(A)$, where A is a connective $\mathbb{E}_\infty$-ring which is complete with respect to a finitely generated ideal $I \subseteq \pi_0 A$. Set $R = (\pi_0 A)/I$. Assume first that $\mathfrak{X}$ is locally Noetherian, so that A is Noetherian. Then $\mathfrak{X}^{\mathrm{red}} \simeq \mathrm{Sp\acute{e}t}(R^{\mathrm{red}})$ is also locally Noetherian. Moreover, R^{red} is almost perfect as an A-module (Proposition HA.7.2.4.17), so that the map $\mathfrak{X}^{\mathrm{red}} \to \mathfrak{X}$ is a formal thickening by virtue of Proposition 18.2.2.7.

Now suppose that conditions (1) and (2) are satisfied; we will show that A is Noetherian. Note that condition (2) guarantees that R^{red} is almost perfect as an A-module, so that the kernel of the map $\pi_0 A \to R^{\mathrm{red}}$ is a finitely generated ideal $J \subseteq \pi_0 A$. We may therefore replace I by J and thereby reduce to the case where $R = R^{\mathrm{red}}$. In this case, assumption (1) guarantees that R is Noetherian. Write $I = (x_1, \ldots, x_n)$. We proceed by induction on n. Let us begin with the case $n = 0$, so that $R = \pi_0 A$. We wish to show that each homotopy group of A are finitely generated as a module over R. Let J denote the fiber of the map $A \to R$, so that J is 1-connective. It follows that each tensor power $J^{\otimes k}$ is k-connective, so that the canonical map $\pi_* A \to \pi_* \mathrm{cofib}(J^{\otimes k} \to A)$ is an isomorphism for $* < k$. It will therefore suffice to prove the following:

- $(*)$ For each integer k, each homotopy group of the cofiber $\mathrm{cofib}(J^{\otimes k} \to A)$ is finitely generated as an R-module.

We prove $(*)$ by induction on k, the case $k = 0$ being trivial. To carry out the inductive step, we observe that there is a cofiber sequence

$$J^{\otimes k} \otimes_A R \to \mathrm{cofib}(J^{\otimes (k+1)} \to A) \to \mathrm{cofib}(J^{\otimes k} \to A).$$

We are therefore reduced to proving that each homotopy group $J^{\otimes k} \otimes_A R$ Is finitely generated as an R-module: in other words, that $J^{\otimes k} \otimes_A R$ is almost perfect over R. This is clear, since assumption (2) guarantees that J is almost perfect as an A-module. This completes the proof in the case $n = 0$.

Let us now assume that $n > 0$. Let S denote the sphere spectrum, and let $S\{t\}$ denote the free $\mathbb{E}_\infty$-ring on one generator, so that there is a morphism of $\mathbb{E}_\infty$-rings $S\{t\} \to A$ given by $t \mapsto x_n$. We next prove the following:

- $(*)$ Let M be a connective $S\{t\}$-module. Assume that each homotopy group of M is finitely generated as an abelian group and that the action of t on $\pi_* M$ is locally nilpotent. Then each homotopy group of $A \otimes_{S\{t\}} M$ is Noetherian when regarded as a module over the commutative ring $\pi_0 A$.

Note that the canonical map $\pi_*(A \otimes_{S\{t\}} M) \to \pi_*(A \otimes_{S\{t\}} \tau_{\leqslant m} M)$ is an isomorphism for $* \leqslant m$. Consequently, it will suffice to prove $(*)$ under the additional assumption that M is truncated. Writing M as a successive extension of $S\{t\}$ concentrated in a single degree, we can further reduce to the case where M is discrete. In this case, our assumption that the action of t is locally nilpotent allows us to write M as a successive extension of modules on which the action of t is trivial. In this case, we have a short exact sequence of abelian groups

$$0 \to \mathbf{Z}^a \to \mathbf{Z}^b \to M \to 0,$$

which allows us to reduce to the case $M = \mathbf{Z}$. Set $A' = A \otimes_{S\{t\}} \mathbf{Z}$, so that the map $A \to R$ factors through A'. Note that A' is almost perfect as an A-module and is therefore I-complete, and that $I(\pi_0 A') = (x_1, \ldots, x_{n-1})$ is generated by fewer than n elements. Moreover, since A' and R are both almost of finite presentation over A, the map $A' \to R$ is almost of finite presentation. It follows that we can regard $\mathrm{Spf}(A')$ as a formal thickening of $\mathrm{Sp\acute{e}t}(R)$, so our inductive hypothesis guarantees that A' is Noetherian. In particular, each homotopy group of A' is Noetherian when viewed as a module over the commutative ring $\pi_0 A$, which proves $(*)$.

Note that $S\{t\}$ is Noetherian (Proposition HA.7.2.4.31). In particular, each homotopy group $\pi_m S\{t\}$ is finitely generated as a module of the polynomial ring $\pi_0 S\{t\} \simeq \mathbf{Z}[t]$. It follows that the kernel and cokernel of multiplication by t on $\pi_m S\{t\}$ are finitely generated abelian groups, so that $M = \mathrm{cofib}(t : S\{t\} \to S\{t\})$ satisfies the hypotheses of $(*)$. We therefore obtain the following:

$(*')$ Each homotopy group of the cofiber $\mathrm{cofib}(t : A \to A)$ is Noetherian when viewed as a module over the commutative ring $\pi_0 A$.

Note that each quotient $(\pi_m A)/t(\pi_m A)$ can be viewed as a submodule of $\pi_m \mathrm{cofib}(t : A \to A)$, and is therefore also Noetherian as a module over $\pi_0 A$. It is therefore finitely generated when viewed as a module over $(\pi_0 A)/t(\pi_0 A)$. Applying Lemma 18.2.4.2 and Variant 18.2.4.3, we conclude that $\pi_0 A$ is a Noetherian ring and that each $\pi_m A$ is a finitely generated module over $\pi_0 A$, so that A is Noetherian as desired. □

Corollary 18.2.4.4. *Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a formal thickening of formal spectral Deligne-Mumford stacks. Then $\mathfrak{X}$ is locally Noetherian if and only if $\mathfrak{Y}$ is locally Noetherian.*

Proof. Suppose first that $\mathfrak{X}$ is locally Noetherian. Applying Proposition 18.2.4.1, we deduce that $\mathfrak{X}^{\mathrm{red}}$ is locally Noetherian and that the natural map $i : \mathfrak{X}^{\mathrm{red}} \to \mathfrak{X}$ is a formal thickening. Then the canonical map $\mathfrak{Y}^{\mathrm{red}} \to \mathfrak{Y}$ can be identified with the composition $f \circ i$, which is a formal thickening by virtue of Remark 18.2.2.4. Applying Proposition 18.2.4.1, we conclude that $\mathfrak{Y}$ is locally Noetherian.

Conversely, suppose that $\mathfrak{Y}$ is locally Noetherian; we claim that $\mathfrak{X}$ is also locally Noetherian. This assertion is local on $\mathfrak{Y}$, so we may assume that $\mathfrak{Y}$ is affine. Write $\mathfrak{Y} = \mathrm{Spf}(A)$, where A is Noetherian $\mathbb{E}_\infty$-ring which is complete with respect to a finitely generated ideal $I \subseteq \pi_0 A$. Applying Proposition 18.2.2.8, we deduce that $\mathfrak{X} \simeq \mathrm{Spf}(B)$, where B is almost of finite presentation over A and therefore also Noetherian (Proposition HA.7.2.4.31). □

18.2.5 Existence of Formal Charts

We will deduce Theorem 18.2.3.2 from the following variant:

Theorem 18.2.5.1. *Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, where X is corepresentable by a connective $\mathbb{E}_\infty$-ring B. Suppose that f admits a relative cotangent complex $L_{X/Y}$ and that we are given a morphism $\alpha : \mathscr{F} \to L_{X/Y}$ in $\mathrm{QCoh}(X)$, where $\mathscr{F}$ is perfect of* Tor*-amplitude $\leqslant 0$. Assume that:*

(1) *The functor Y is nilcomplete, infinitesimally cohesive, and admits a cotangent complex.*

(2) *The functor Y is formally complete along f.*

(3) *The cofiber* $\mathrm{cofib}(\alpha)$ *is* 1*-connective and almost perfect.*

Then the map f factors as a composition $X \xrightarrow{f'} U \xrightarrow{f''} Y$, where U is representable by an affine formal spectral Deligne-Mumford stack $\mathrm{Spf}(A)$*, the map* $\mathrm{Spf}(B) \to \mathrm{Spf}(A)$ *is a formal thickening, f'' is locally almost of finite presentation, and α can be identified with the natural map $f'^{*} L_{U/Y} \to L_{X/Y}$.*

Remark 18.2.5.2. Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ satisfying conditions (1) and (2) of Theorem 18.2.5.1, and suppose that the relative cotangent complex $L_{X/Y}$ is almost perfect. Then $M = \Gamma(\mathfrak{X}; L_{X/Y}) \in \mathrm{Mod}_B$ is an almost perfect B-module (assuming that the adic $\mathbb{E}_\infty$-ring B is complete), so Corollary 2.7.2.2 guarantees that there is a fiber sequence $M' \to M \to M''$, where M' is perfect of Tor-amplitude $\leqslant 0$, and M'' is 1-connective. It follows that there exists a morphism $\alpha : \mathscr{F} \to L_{X/Y}$ in $\mathrm{QCoh}(X)$, where $\mathscr{F}$ is perfect of Tor-amplitude $\leqslant 0$ and $\mathrm{cofib}(\alpha)$ is 1-connective and almost perfect. Beware that the morphism α is not unique (for example, we can always add a copy of the structure sheaf $\mathscr{O}_X$ to $\mathscr{F}$).

To deduce Theorem 18.2.3.2 from Theorem 18.2.5.1, we will need the following general observation (which will also be useful in the proof of Theorem 18.2.5.1 itself):

Lemma 18.2.5.3. *Let $f : X \to Y$ be a natural transformation of functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Assume that f is nilcomplete, infinitesimally cohesive, and admits a relative cotangent complex $L_{X/Y}$ which vanishes in* $\mathrm{QCoh}(X)$*. If Y is formally complete along f, then f is an equivalence.*

Proof. Since X and Y are infinitesimally cohesive and $L_{X/Y}$ vanishes, Proposition 17.3.9.3 implies the following:

$(*)$ Let $\widetilde{R} \to R$ be a square-zero extension of a connective $\mathbb{E}_\infty$-ring R by a connective R-module M. Then the diagram

$$\begin{array}{ccc} X(\widetilde{R}) & \longrightarrow & X(R) \\ \downarrow & & \downarrow \\ Y(\widetilde{R}) & \longrightarrow & Y(R) \end{array}$$

is a pullback square. In particular, if $X(R) \to Y(R)$ is a homotopy equivalence, then so is $X(\widetilde{R}) \to Y(\widetilde{R})$.

Let R be a connective $\mathbb{E}_\infty$-ring; we wish to show that the map $X(R) \to Y(R)$ is a homotopy equivalence. Since X and Y are nilcomplete, we may assume without loss of generality that R is n-connective for some integer $n \geqslant 0$. We proceed by induction on n. If $n > 0$, then R is a square-zero extension of $\tau_{\leqslant n-1}R$, so that the desired result follows from $(*)$ together with our inductive hypothesis. We may therefore assume that $n = 0$: that is, that R is an ordinary commutative ring. Let $\{I_\alpha\}$ be the collection of all nilpotent ideals of R. We have a commutative diagram σ :

$$\begin{array}{ccc} X(R) & \longrightarrow & \varinjlim_\alpha X(R/I_\alpha) \\ \downarrow & & \downarrow \\ Y(R) & \longrightarrow & \varinjlim_\alpha Y(R/I_\alpha), \end{array}$$

and our hypothesis that Y is formally complete along f guarantees that the right vertical map is an equivalence. It will therefore suffice to show that σ is a pullback square. Writing σ as a filtered colimit of diagrams σ_α :

$$\begin{array}{ccc} X(R) & \longrightarrow & X(R/I_\alpha) \\ \downarrow & & \downarrow \\ Y(R) & \longrightarrow & Y(R/I_\alpha) \end{array}$$

we are reduced to showing that each σ_α is a pullback square, which follows from iterated application of $(*)$. $\square$

Proof of Theorem 18.2.3.2 from Theorem 18.2.5.1. Let $f : X \to Y$ be a natural transformation satisfying the hypotheses of Theorem 18.2.3.2, so that $X \simeq \mathrm{Spf}(B)$ for some complete connective adic $\mathbb{E}_\infty$-ring B. Using Lemma 8.1.2.2, we see that there exists an $\mathbb{E}_\infty$-algebra B' which is almost of finite presentation over B, where $\pi_0(B')$ is the quotient of $\pi_0(B)$ by an ideal of definition. Set $X' = \mathrm{Spec}(B)$, so that $L_{X'/X} \in \mathrm{QCoh}(X')$ is 1-connective and almost perfect. Using the fiber sequence $L_{X/Y}|_X \to L_{X'/Y} \to L_{X'/X}$, we conclude that $L_{X'/Y}$ Is also 1-connective and almost perfect. Taking $\mathscr{F} = 0$ and applying Theorem 18.2.5.1, we conclude that the map $X' \to X \to Y$ factors as a composition $X' \xrightarrow{f'} U \xrightarrow{f''} Y$, where $U \simeq \operatorname{Spf}(A)$ is a formal thickening of $X' \simeq \operatorname{Spét}(B')$, f'' is locally almost of finite presentation, and the restriction $L_{U/Y}|_{X'}$ vanishes. Since f'' is locally almost of finite presentation, $L_{U/Y} \in \operatorname{QCoh}(U)$ is almost perfect (Corollary 17.4.2.2); it follows that $L_{U/Y}$ itself vanishes. Applying Lemma 18.2.5.3 to the morphism f'', we deduce that f'' is an equivalence, so that $Y \simeq \operatorname{Spf}(A)$ is a formal thickening of $\operatorname{Spét}(B')$. Note that the kernel of the map $\pi_0(A) \to \pi_0(B')$ is an ideal of definition for the topology on $\operatorname{Spf}(\pi_0(A))$, so that the morphism $f : \operatorname{Spf}(B) \to \operatorname{Spf}(A)$ is representable (by affine spectral Deligne-Mumford stacks). Since f is locally almost of finite presentation (Proposition 18.2.1.13) and $L_{X/Y}$ is 1-connective, it follows from Proposition 18.2.2.6 that f is a formal thickening. □

We now turn to the proof of Theorem 18.2.5.1. We will need several auxiliary results.

Lemma 18.2.5.4. *Let R be a connective $\mathbb{E}_\infty$-ring, let $\widetilde{R}$ be a square-zero extension of R by a connective R-module I, let M be an R-module which is perfect of* Tor*-amplitude $\leqslant 0$, let N be an almost perfect $\widetilde{R}$-module, and let $u : M \to R \otimes_{\widetilde{R}} N$ be a morphism with 1-connective cofiber. Then we can lift u to a morphism of $\widetilde{R}$-modules $\widetilde{u} : \widetilde{M} \to N$, where $\widetilde{M}$ is perfect of* Tor*-amplitude $\leqslant 0$.*

Proof. Since M is perfect, there exists an integer k such that M is $(-k)$-connective. We proceed by induction on k. In the case $k = 0$, M is a projective R-module of finite rank. Using Corollary HA.7.2.2.19 , we can lift M to an $\widetilde{R}$-module $\widetilde{M}$ which is projective of finite rank. Since M and $\operatorname{cofib}(u)$ are connective, the tensor product $R \otimes_{\widetilde{R}} N$ is connective, which guarantees that N is connective (Proposition 2.7.3.2). It then follows from the projectivity of $\widetilde{M}$ that the composite map $\widetilde{M} \to M \to R \otimes_{\widetilde{R}} N$ can be lifted to a morphism of $\widetilde{R}$-modules $\widetilde{u} : \widetilde{M} \to N$.

We now carry out the inductive step. Assume that $k > 0$. Since M is perfect and $(-k)$-connective, the homotopy group $\pi_{-k} M$ is finitely generated as a module over $\pi_0 R$. We can therefore choose a map $f : \Sigma^{-k} R^d \to M$ which is surjective on π_{-k}. Note that since M and $\operatorname{cofib}(u)$ are $(-k)$-connective, the tensor product $R \otimes_{\widetilde{R}} N$ is $(-k)$-connective, so that N is $(-k)$-connective (Proposition 2.7.3.2). We can therefore lift the composite map

$$\Sigma^{-k} \widetilde{R}^d \to \Sigma^{-k} R^d \to M \xrightarrow{u} \widetilde{R} \otimes_R N$$

to a map $g : \Sigma^{-k} \widetilde{R}^d \to N$. Let v denote the induced map $\operatorname{cofib}(f) \to R \otimes_{\widetilde{R}} \operatorname{cofib}(g)$, so that $\operatorname{cofib}(v) \simeq \operatorname{cofib}(u)$ is 1-connected. Note that $\operatorname{cofib}(f)$ is $(1-k)$-connective, so our inductive hypothesis guarantees that we can lift v to a map $\widetilde{v} : K \to \operatorname{cofib}(g)$, where $P \in \operatorname{Mod}_{\widetilde{R}}$ is perfect of Tor-amplitude $\leqslant 0$. Form a pullback diagram

$$\begin{array}{ccc} \widetilde{M} & \xrightarrow{\widetilde{u}} & N \\ \downarrow & & \downarrow \\ K & \xrightarrow{\widetilde{v}} & \operatorname{cofib}(f). \end{array}$$

It is now easy to see that $\widetilde{u} : \widetilde{M} \to N$ has the desired properties. □

The proof of Theorem 18.2.5.1 is based on the following:

Construction 18.2.5.5. Let $f : X \to Y$ and $\alpha : \mathscr{F} \to L_{X/Y}$ be as in the statement of Theorem 18.2.5.1, where $X = \operatorname{Spec}(B)$. We construct a sequence of natural transformations

$$\operatorname{Spec}(B_0) \to \operatorname{Spec}(B_1) \to \operatorname{Spec}(B_2) \to \cdots \to Y$$

and morphisms $\alpha_n : M_n \to L_{\operatorname{Spec}(B_n)/Y}$ in $\operatorname{QCoh}(\operatorname{Spec}(B_n)) \simeq \operatorname{Mod}_{B_n}$, where M_n is perfect of Tor-amplitude $\leqslant n$ and $\operatorname{cofib}(\alpha_n)$ is 1-connective, as follows:

- Set $B_0 = B$, equipped with the morphism $f_0 = f_0 : \operatorname{Spec}(B_0) \to Y$; we let M_0 denote the image of $\mathscr{F}$ under the equivalence $\operatorname{QCoh}(X) \simeq \operatorname{Mod}_{B_0}$ and $\alpha_0 : M_0 \to L_{\operatorname{Spec}(B_0)/Y}$ the image of α.

- Assume that $n \geqslant 0$ and that we have already specified a natural transformation $f_n : \operatorname{Spec}(B_n) \to Y$ together with a morphism of B_n-modules $\alpha_n : M_n \to L_{\operatorname{Spec}(B_n)/Y}$ with 1-connective cofiber. We let B_{n+1} denote the square-zero extension of B_n by $\Sigma^{-1} \operatorname{cofib}(\alpha_n)$ classified by the composite map $L_{\operatorname{Spec}(B_n)} \to L_{\operatorname{Spec}(B_n)/Y} \to \operatorname{cofib}(\alpha_n)$. The factorization of this composite map through the relative cotangent complex $L_{\operatorname{Spec}(B_n)/Y}$ determines a factorization of f_n as a composition

$$\operatorname{Spec}(B_n) \to \operatorname{Spec}(B_{n+1}) \xrightarrow{f_{n+1}} Y.$$

  By construction, the canonical map $L_{\operatorname{Spec}(B_n)/Y} \to \operatorname{cofib}(\alpha_n)$ factors as a composition

$$L_{\operatorname{Spec}(B_n)/Y} \to L_{B_n/B_{n+1}} \xrightarrow{\rho} \operatorname{cofib}(\alpha_n),$$

  We therefore obtain a fiber sequence

$$L_{\operatorname{Spec}(B_{n+1})/Y}|_{\operatorname{Spec}(B_n)} \to M_n \xrightarrow{\nu} \operatorname{fib}(\rho).$$

  It follows from Theorem HA.7.4.3.12 that ρ is 2-connective. Since M_n is perfect of Tor-amplitude $\leqslant 0$, the map ν is nullhomotopic. It follows that the map α_n factors as a composition We can therefore factor α_n as a composition

$$M_n \xrightarrow{\alpha_n'} L_{\operatorname{Spec}(B_{n+1})/Y}|_{\operatorname{Spec}(B_n)} \to L_{\operatorname{Spec}(B_n)/Y};$$

moreover, this factorization is unique up to homotopy (though not up to contractible choice). We have a fiber sequence $\mathrm{cofib}(\alpha'_n) \to \mathrm{cofib}(\alpha_n) \xrightarrow{\beta} L_{B_n/B_{n+1}}$, where β is surjective on π_1 (Theorem HA.7.4.3.12), so that $\mathrm{cofib}(\alpha'_n)$ is also 1-connective. Applying Lemma 18.2.5.4, we conclude that we can lift α'_n to a morphism of B_{n+1}-modules $\alpha_{n+1} : M_{n+1} \to L_{\mathrm{Spec}(B_{n+1})/Y}$, where M_{n+1} is perfect of Tor-amplitude $\leqslant 0$. By construction, we have an equivalence $B_n \otimes_{B_{n+1}} \mathrm{cofib}(\alpha_{n+1}) \simeq \mathrm{cofib}(\alpha_n)$, so that $\mathrm{cofib}(\alpha_{n+1})$ is 1-connective (Proposition 2.7.3.2).

We let $\overline{U} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ denote the functor given by the direct limit $\varinjlim_n \mathrm{Spec}(B_n)$. Finally, we let U denote the nilcompletion of $\overline{U}$, given by the formula

$$U(R) = \varprojlim_m \overline{U}(\tau_{\leqslant m} R) = \varprojlim_m \varinjlim_n \mathrm{Map}_{\mathrm{CAlg}}(B_n, \tau_{\leqslant m} R).$$

In the situation of Construction 18.2.5.5, the map $f : X \to Y$ factors canonically as a composition $X \xrightarrow{f'} U \xrightarrow{f''} Y$. Our goal for the rest of this section is to prove that this factorization satisfies the requirements of Theorem 18.2.5.1. This will require a somewhat detailed analysis.

Lemma 18.2.5.6. *In the situation of Construction 18.2.5.5, the functor U is nilcomplete, cohesive, and admits a cotangent complex L_U. Moreover, the canonical map $L_{U/Y}|_X \to L_{X/Y}$ can be identified with $\alpha : \mathscr{F} \to L_{X/Y}$.*

Proof. The functor U is nilcomplete by construction. Each of the corepresentable functors $\mathrm{Spec}(B_n)$ preserves small limits, so that the functor $\overline{U} = \varinjlim \mathrm{Spec}(B_n)$ preserves pullback squares. In particular, $\overline{U}$ is cohesive, so that U is cohesive (Proposition 17.3.3.4). To show that U admits a cotangent complex, it will suffice to show that $\overline{U}$ admits a cotangent complex (Proposition 17.3.3.6). By virtue of Proposition 17.3.9.1, it will suffice to show that the map $\overline{U} \to Y$ admits a relative cotangent complex. We will prove this by verifying condition (a) of Remark 17.2.4.3 (condition (b) is automatic, since Y admits a cotangent complex and $\overline{U}$ preserves pullback squares). Fix a point $\eta \in \overline{U}(R)$, where R is a connective $\mathbb{E}_\infty$-ring, and define $F : \mathrm{Mod}_R^{\mathrm{cn}} \to \mathcal{S}$ by the formula $F(N) = \mathrm{fib}(\overline{U}(R \oplus N) \to Y(R \oplus N) \times_{Y(R)} \overline{U}(R)$; we wish to show that F is corepresented by an almost connective R-module. Lift η to a point $\eta_n \in \mathrm{Spec}(B_n)(R)$ for $n \gg 0$, which we identify with a morphism $B_n \to R$. Since each of the maps $\mathrm{Spec}(B_n) \to Y$ admits a cotangent complex, the functor F is given concretely by the formula

$$F(N) = \varinjlim_{n' \geqslant n} \mathrm{Map}_{\mathrm{Mod}_{B_{n'}}}(L_{\mathrm{Spec}(B_{n'})/Y}, N) \simeq \varinjlim_{n' \geqslant n} \mathrm{Map}_{\mathrm{Mod}_R}(R \otimes_{B_{n'}} L_{\mathrm{Spec}(B_{n'})/Y}, N).$$

In other words, $F(N)$ is represented by the Pro-object $\{R \otimes_{B_{n'}} L_{\mathrm{Spec}(B_{n'})/Y}\}_{n' \geqslant n}$ of Mod_R.

Let $\{\alpha_m : M_m \to L_{\operatorname{Spec}(B_m)/Y}\}_{m \geqslant 0}$ be as in Construction 18.2.5.5. Then the system $\{\alpha_m\}_{m \geqslant 0}$ induces a map of towers

$$\theta : \{R \otimes_{B_{n'}} M_{n'}\}_{n' \geqslant n} \to \{R \otimes_{B_{n'}} L_{\operatorname{Spec}(B_{n'})/Y}\}_{n' \geqslant n},$$

whose domain is a constant tower. Consequently, to complete the proof of the existence of $L_{\overline{U}/Y}$, it will suffice to show that θ is an equivalence of Pro-objects. For this, it will suffice to show that for each of the diagrams

$$\begin{array}{ccc} M_{n'} & \xrightarrow{\alpha'_{n'}} & L_{\operatorname{Spec}(B_{n'+1})/Y}|_{\operatorname{Spec}(B_{n'})} \\ \downarrow \mathrm{id} & \swarrow & \downarrow \\ M_{n'} & \xrightarrow{\alpha_{n'}} & L_{\operatorname{Spec}(B_{n'})/Y} \end{array}$$

appearing in Construction 18.2.5.5, there exists a dotted arrow as indicated, rendering the diagram commutative, which is immediate from the construction. □

Lemma 18.2.5.7. *In the situation of Construction 18.2.5.5, each relative cotangent complex* $L_{\operatorname{Spec}(B_n)/Y} \in \operatorname{QCoh}(\operatorname{Spec}(B_n)) \simeq \operatorname{Mod}_{B_n}$ *is almost perfect.*

Proof. We proceed by induction on n. In the case $n = 0$, this is one of the hypotheses of Theorem 18.2.5.1. To carry out the inductive step, let us assume that $n > 0$ and that $L_{\operatorname{Spec}(B_{n-1})/Y}$ is almost perfect. Then $\operatorname{cofib}(\alpha_{n-1})$ is almost perfect, so that B_n is a square-zero extension of B_{n-1} by a (connective) almost perfect module over B_{n-1}. Applying Corollary 5.2.2.5, we deduce that B_{n-1} is almost of finite presentation over B_n, so that L_{B_{n-1}/B_n} is almost perfect as a B_{n-1}-module. Using the fiber sequence

$$B_{n-1} \otimes_{B_n} L_{\operatorname{Spec}(B_n)/Y} \to L_{\operatorname{Spec}(B_{n-1})/Y} \to L_{B_{n-1}/B_n}$$

together with our inductive hypothesis, we conclude that $B_{n-1} \otimes_{B_n} L_{\operatorname{Spec}(B_n)/Y}$ is almost perfect as a B_{n-1}-module. Applying Proposition 2.7.3.2, we conclude that $L_{\operatorname{Spec}(B_n)/Y}$ is almost perfect as a B_n-module. □

Lemma 18.2.5.8. *In the situation of Construction 18.2.5.5, each of the natural transformations* $f_n : \operatorname{Spec}(B_n) \to Y$ *is locally almost of finite presentation.*

Proof. Since Y is formally complete along f, it is also formally complete along f_n. The desired result now follows from Lemma 18.2.5.7 and Proposition 18.2.1.13. □

Lemma 18.2.5.9. *In the situation of Construction 18.2.5.5, the natural transformation* $U \to Y$ *is locally almost of finite presentation.*

Proof. Since the functors U and $\overline{U}$ agree on truncated objects of $\mathrm{CAlg}^{\mathrm{cn}}$, it will suffice to show that the composite map $\overline{U} \to U \to Y$ is locally almost of finite presentation. This follows by combining Lemma 18.2.5.8 with Remark 17.4.1.4. □

Let us now specialize to the case where $\mathscr{F} = 0$.

Lemma 18.2.5.10. *In the situation of Construction 18.2.5.5, if $\mathscr{F} = 0$, then the map $U \to Y$ is an equivalence.*

Proof. Note that U and Y are infinitesimally cohesive and nilcomplete, and that the relative cotangent complex $L_{U/Y}$ vanishes (Lemma 18.2.5.6). Since Y is formally complete along the map $U \to Y$, the desired result follows from Lemma 18.2.5.3. □

Notation 18.2.5.11. In the situation of Construction 18.2.5.5, suppose that $\mathscr{F} = 0$. Let A denote the $\mathbb{E}_\infty$-ring $\Gamma(Y; \mathscr{O}_Y)$. It follows from Lemma 18.2.5.10 that we have a canonical equivalence

$$\begin{aligned} A &= \Gamma(Y; \mathscr{O}_Y) \\ &\simeq \Gamma(U; \mathscr{O}_U) \\ &\simeq \Gamma(\overline{U}; \mathscr{O}_U) \\ &\simeq \varprojlim \Gamma(\mathrm{Spec}(B_n); \mathscr{O}_{\mathrm{Spec}(B_n)}) \\ &\simeq \varprojlim B_n. \end{aligned}$$

In particular A is connective.

Lemma 18.2.5.12. *In the situation of Construction 18.2.5.5, suppose that $\mathscr{F} = 0$ and that $L_{X/Y}$ is m-connective for some positive integer m. Then, for each $n \geqslant 0$, we have the following:*

(a_n) *The relative cotangent complex $L_{\mathrm{Spec}(B_n)/Y}$ is m-connective.*

(b_n) *The fiber* $\mathrm{fib}(B_{n+1} \to B_n$ *is $(m-1)$-connective.*

Proof. Note that (a_0) equivalent to our hypothesis that $L_{X/Y}$ is m-connective. Moreover, the implication $(a_n) \Rightarrow (b_n)$ is immediate (since B_{n+1} is a square-zero extension of B_n by $\Sigma^{-1} L_{\mathrm{Spec}(B_n)/Y}$). To complete the proof, it will suffice to show that (a_n) and (b_n) imply (a_{n+1}). Assume that (a_n) and (b_n) are satisfied, and consider the fiber sequence

$$B_n \otimes_{B_{n+1}} L_{\mathrm{Spec}(B_{n+1})/Y} \to L_{\mathrm{Spec}(B_n)/Y} \xrightarrow{u} L_{B_n/B_{n+1}}.$$

Unwinding the definitions, we can identify u with the canonical map $\mathrm{cofib}(B_{n+1} \to B_n) \to L_{B_n/B_{n+1}}$, whose fiber is $(2m-1)$-connective by Corollary HA.7.4.3.6 . Applying Proposition 2.7.3.2, we conclude that $L_{\mathrm{Spec}(B_{n+1})/Y}$ is $(2m-1)$-connective, and therefore also m-connective (since $m \geqslant 1$). □

Lemma 18.2.5.13. *In the situation of Construction 18.2.5.5, suppose that $\mathscr{F} = 0$ and that $L_{X/Y}$ is m-connective for some $m > 0$. Then:*

(1) *For every integer $n \geqslant 0$, the fiber $\mathrm{fib}(A \to B_n)$ is $(m-1)$-connective.*

(2) *The canonical map $\theta : \mathrm{fib}(A \to B) \to \Sigma^{-1} L_{B/A} \to \Sigma^{-1} L_{\mathrm{Spec}(B)/Y}$ is surjective on π_{m-1}.*

Proof. To prove (1), we note that $\mathrm{fib}(A \to B)$ can be identified with the limit of the tower $\{\mathrm{fib}(B_k \to B_n)\}_{k \geqslant n}$. To show that this limit is $(m-1)$-connective, it will suffice to show that each transition map $\mathrm{fib}(B_k \to B_n) \to \mathrm{fib}(B_{k-1} \to B_n)$ has $(m-1)$-connective homotopy fiber. This homotopy fiber is given by $\mathrm{fib}(B_k \to B_{k-1})$, which is $(m-1)$-connective by Lemma 18.2.5.12.

To prove (2), we note that θ can be identified with the natural map $\mathrm{fib}(A \to B_0) \to \mathrm{fib}(B_1 \to B_0)$, whose homotopy fiber $\mathrm{fib}(A \to B_1)$ is $(m-1)$-connective by virtue of (1). □

Lemma 18.2.5.14. *Let R be a connective $\mathbb{E}_\infty$-ring, let M be an almost perfect A-module, and suppose we are given a tower*

$$\cdots \to N_3 \to N_2 \to N_1 \to N_0$$

of connective A-modules. Then the canonical map

$$\rho_M : M \otimes_A (\varprojlim N_k) \to \varprojlim (M \otimes_A N_k)$$

is an equivalence.

Proof. Since each N_k is connective, the limit $\varprojlim N_k$ is (-1)-connective. It follows that if M is n-connective, then the domain of ρ_M is $(n-1)$-connective. Similarly, if M is n-connective, then each tensor product $M \otimes_A N_k$ is also n-connective, so that the codomain $\varprojlim(M \otimes_A N_k)$ is $(n-1)$-connective. It follows that $\mathrm{cofib}(\rho_M)$ is $(n-1)$-connective.

For any integer n, the assumption that n is almost perfect guarantees that we can choose a fiber sequence $M' \to M \to M''$ where M' is perfect and M'' is n-connective (Corollary 2.7.2.2). We then have a cofiber sequence

$$\mathrm{cofib}(\rho_{M'}) \to \mathrm{cofib}(\rho_M) \to \mathrm{cofib}(\rho_{M''})$$

where the first term vanishes (since $\rho_{M'}$ is an equivalence by virtue of our assumption that M' is perfect) and the third term is $(n-1)$-connective. It follows that $\mathrm{cofib}(\rho_M)$ is $(n-1)$-connective. Since n can be chosen arbitrarily, it follows that $\mathrm{cofib}(\rho_M) \simeq 0$: that is, ρ_M is an equivalence. □

Lemma 18.2.5.15. *In the situation of Construction 18.2.5.5, suppose that $\mathscr{F} = 0$, and let m be a positive integer. Then f fits into a commutative diagram*

$$\begin{array}{ccccc} X & \xrightarrow{f(m)} & Y(m) & \longrightarrow & \operatorname{Spec}(A(m)) \\ & \searrow^{f} & \downarrow & & \downarrow \\ & & Y & \longrightarrow & \operatorname{Spec}(A), \end{array}$$

where the right square is a pullback, the ring homomorphism $\pi_0 A \to \pi_0 A(m)$ is surjective, the $\mathbb{E}_\infty$-algebra $A(m)$ is almost perfect as an A-module, and the relative cotangent complex $L_{X/Y(m)}$ is m-connective.

Proof. We proceed by induction on m. In the case $m = 1$, we can take $A(m) = A$ and $Y(m) = Y$. To carry out the inductive step, let us suppose that $m \geqslant 1$ and that we have constructed a diagram

$$\begin{array}{ccccc} X & \xrightarrow{f(m)} & Y(m) & \longrightarrow & \operatorname{Spec}(A(m)) \\ & \searrow^{f} & \downarrow & & \downarrow \\ & & Y & \longrightarrow & \operatorname{Spec}(A), \end{array}$$

satisfying the requirements of Lemma 18.2.5.15; we will show that it is possible to construct a similar diagram with m replaced by $m+1$. Note that Y can be identified with the nilcompletion of $\widehat{U} \simeq \varinjlim \operatorname{Spec}(B_n)$ (Lemma 18.2.5.10), so that $Y(m)$ can be identified with the nilcompletion of the fiber product

$$\operatorname{Spec}(A(m)) \times_{\operatorname{Spec}(A)} \varinjlim_n \operatorname{Spec}(B_n) \simeq \varinjlim_n \operatorname{Spec}(A(m) \otimes_A B_n).$$

Invoking Lemma 18.2.5.14, we deduce that the canonical map

$$\begin{aligned} A(m) &\simeq A(m) \otimes_A \varprojlim_n B_n \\ &\to \varprojlim_n (A(m) \otimes_A B_n) \\ &\simeq \Gamma(Y(m); \mathscr{O}_{Y(m)}). \end{aligned}$$

is an equivalence.

Since the homomorphism $\pi_0 A \to \pi_0 A(m)$ is surjective, the map $\operatorname{Spec}(A(m))(R) \to \operatorname{Spec}(A)(R)$ is a monomorphism for any ordinary commutative ring R, so the map $Y(m)(R) \to Y(R)$ is (-1)-truncated. If R is a reduced commutative ring, then the composite map

$$X(R) \to Y(m)(R) \to Y(R)$$

is a homotopy equivalence, so the map $X(R) \to Y(m)(R)$ must also be a homotopy equivalence. Note that $Y(m)$ and X are both locally almost of finite presentation over Y, so that $f(m) : X \to Y(m)$ is locally almost of finite presentation (Remark 17.4.1.3). It follows that the map $f(m) : X \to Y(m)$ also satisfies the hypotheses of Theorem 18.2.5.1 (with $\mathscr{F} = 0$). We may therefore replace Y by $Y(m)$ (and A by $A(m)$) and thereby reduce to the case where $L_{X/Y}$ is m-connective.

Since $L_{X/Y}$ is almost perfect (Proposition 17.4.2.1). Let us view $L_{X/Y}$ as a B-module. Then $\pi_m L_{X/Y}$ is finitely generated as a module over the commutative ring $\pi_0 B$, and therefore also as a module over the commutative ring $\pi_0 A$. It follows from Lemma 18.2.5.13 that the canonical map $\pi_{m-1} \operatorname{fib}(A \to B) \to \pi_m L_{B/A} \to \pi_m L_{\operatorname{Spec}(B)/Y}$ is surjective. We can therefore choose a free A-module P of finite rank and a morphism $u : \Sigma^{m-1} P \to \operatorname{fib}(A \to B)$ for which the composite map

$$\rho : \Sigma^m P \xrightarrow{\Sigma(u)} \Sigma \operatorname{fib}(A \to B) \to L_{B/A} \to L_{\operatorname{Spec}(B)/Y}$$

is surjective on π_m. The map u determines a commutative diagram of connective $\mathbb{E}_\infty$-rings σ :

$$\begin{array}{ccc} \operatorname{Sym}^*_A(\Sigma^{m-1} P) & \longrightarrow & A \\ \downarrow & & \downarrow \\ A & \longrightarrow & B. \end{array}$$

Let $A(m+1)$ denote the relative tensor product $A \otimes_{\operatorname{Sym}^*_A(\Sigma^{m-1} P)} A$. By construction, $A(m+1)$ is of finite presentation as an $\mathbb{E}_\infty$-algebra over A and the natural map $\pi_0 A \to \pi_0 A(m+1)$ is surjective on π_0. It follows from Corollary 5.2.2.2 that $A(m+1)$ is almost perfect as an A-module. Moreover, the commutative diagram σ determines a homomorphism of A-algebras $A(m+1) \to B$, which allows us to construct a commutative diagram

$$\begin{array}{ccccc} X & \xrightarrow{f(m)} & Y(m+1) & \longrightarrow & \operatorname{Spec}(A(m+1)) \\ & \searrow^{f} & \downarrow & & \downarrow \\ & & Y & \longrightarrow & \operatorname{Spec}(A) \end{array}$$

where the right square is a pullback. Unwinding the definitions, we see that the relative cotangent complex $L_{X/Y(m+1)}$ can be identified with the cofiber of the map ρ, and is therefore $(m+1)$-connective by construction. □

Remark 18.2.5.16. In the situation of Lemma 18.2.5.15, the fiber $\operatorname{fib}(A(m) \to B)$ is $(m-1)$-connected. To prove this, we can argue as in the proof of Lemma 18.2.5.15 to reduce to the case $Y = Y(m)$ and $A = A(m)$, in which case the desired result follows from Lemma 18.2.5.13.

Lemma 18.2.5.17. *In the situation of Construction 18.2.5.5, suppose that $\mathscr{F} = 0$. Then the map $u : A \to B$ is almost of finite presentation.*

Proof. It will suffice to show that B is of finite generation to order n over A, for each $n \geqslant 0$. Write u as a composition $A \xrightarrow{u'} A(n+2) \xrightarrow{u''} B$, where $A(n+2)$ is defined as in Lemma 18.2.5.15. Then the map u' is almost of finite presentation (Corollary 5.2.2.2) and u'' induces an equivalence $\tau_{\leqslant n} A(n+2) \to \tau_{\leqslant n} B$ (Remark 18.2.5.16), and is therefore of finite generation to order n. Applying Proposition 4.1.3.1, we deduce that u is of finite generation to order n. □

In what follows, we will regard A as an adic $\mathbb{E}_\infty$-ring, by equipping $\pi_0 A$ with the I-adic topology for $I = \ker(\pi_0 A \to \pi_0 B)$. Note that I is a finitely generated ideal (this follows from Lemma 18.2.5.17).

Lemma 18.2.5.18. *In the situation of Construction 18.2.5.5, suppose that $\mathscr{F} = 0$. Then the canonical map $Y \to \operatorname{Spec}(A)$ induces an equivalence $g : Y \simeq \operatorname{Spf}(A)$.*

Proof. We first show that the map $Y \to \operatorname{Spec}(A)$ factors through $\operatorname{Spf}(A)$. Let η be an R-valued point of Y, for some connective $\mathbb{E}_\infty$-ring R; we wish to show that the induced map

$$\eta^* : A = \Gamma(Y; \mathscr{O}_Y) \to \Gamma(\operatorname{Spec}(R); \mathscr{O}_{\operatorname{Spec}(R)}) \simeq R$$

carries I to a nilpotent ideal in $\pi_0 R$. Replacing R by $\pi_0 R$, we can assume that R is discrete. In this case, Lemma 18.2.5.10 supplies an equivalence $Y(R) \simeq U(R) \simeq \widehat{U}(R) \simeq \varinjlim \operatorname{Map}_{\operatorname{CAlg}}(B_n, R)$. It follows that the map $\eta^* : A \to R$ factors through B_n for some $n \geqslant 0$. The desired result now follows from the observation that $I(\pi_0 B_n)$ is a nilpotent ideal in $\pi_0 B_n$.

We next claim that the map $g : Y \to \operatorname{Spf}(A)$ is locally almost of finite presentation. To prove this, we observe that Lemma 18.2.5.10 guarantees that Y agrees with $\overline{U} = \varinjlim \operatorname{Spec}(B_n)$ on truncated objects of $\operatorname{CAlg}^{\operatorname{cn}}$. By virtue of Remark 17.4.1.4, it suffices to show that the map $\operatorname{Spec}(B_n) \to \operatorname{Spf}(A)$ is locally almost of finite presentation. This follows from Lemma 18.2.5.17, applied to the map $f(n) : \operatorname{Spec}(B_n) \to Y$. Note that if R is a reduced commutative ring, then g induces a homotopy equivalence $Y(R) \to \operatorname{Spf}(A)(R)$; this follows by applying the two-out-of-three property to the commutative diagram

$$\begin{array}{ccccc} & & Y(R) & & \\ & \overset{\sim}{\nearrow} & & \searrow & \\ X(R) & & \xrightarrow{\sim} & & \operatorname{Spf}(A)(R). \end{array}$$

Consequently, to show that g is an equivalence, it will suffice to show that the relative cotangent complex $L_{Y/\operatorname{Spf}(A)} \simeq L_{Y/\operatorname{Spec}(A)}$ vanishes (Lemma 18.2.5.3).

Let m be any positive integer, and choose a commutative diagram

$$\begin{array}{ccccc} X & \xrightarrow{f(m)} & Y(m) & \longrightarrow & \operatorname{Spec}(A(m)) \\ & \searrow^{f} & \downarrow & & \downarrow \\ & & Y & \longrightarrow & \operatorname{Spec}(A), \end{array}$$

satisfying the requirements of Lemma 18.2.5.15. We then have equivalences

$$\begin{aligned} L_{Y/\operatorname{Spec}(A)}|_X &\simeq L_{Y(m)/\operatorname{Spec}(A(m))}|_X \\ &\simeq \operatorname{fib}(L_{X/Y(m)} \to L_{B/A(m)}). \end{aligned}$$

Here $L_{X/Y(m)}$ is m-connective by construction, and $L_{B/A(m)}$ is m-connective by virtue of Remark 18.2.5.16. It follows that $L_{Y/\operatorname{Spec}(A)}|_X$ is $(m-1)$-connective. Allowing m to vary, we conclude that $L_{Y/\operatorname{Spec}(A)}|_X \simeq 0$. By virtue of Proposition 2.7.3.2, this guarantees that $L_{Y/\operatorname{Spec}(A)}|_{\operatorname{Spec}(B_n)}$ vanishes for each $n \geqslant 0$, so that $L_{Y/\operatorname{Spec}(A)}|_{\overline{U}} \simeq 0$. Proposition 17.3.3.5 then implies that $L_{Y/\operatorname{Spec}(A)}|_U \simeq 0$, so that $L_{Y/\operatorname{Spec}(A)}$ vanishes by virtue of Lemma 18.2.5.10. □

Lemma 18.2.5.19. *Let $f : X \to Y$ be a morphism satisfying the hypotheses of Theorem* **??** *with $\mathscr{F} = 0$. Then Y is (representable by) a formal thickening of $X = \operatorname{Spec}(B)$.*

Proof. Combine Lemma 18.2.5.18 with Proposition 18.2.2.7. □

Proof of Theorem **??**. Let $f : \operatorname{Spec}(B) = X \to Y$ and $\alpha : \mathscr{F} \to L_{X/Y}$ be as in the statement of Theorem **??**. Applying Construction 18.2.5.5, we obtain a factorization of f as a composition $X \xrightarrow{f'} U \xrightarrow{f''} Y$. It follows from Lemma 18.2.5.6 that the morphism $f' : X \to U$ also satisfies the hypotheses of Theorem **??** (with the sheaf $\mathscr{F}$ replaced by zero). Applying Lemma 18.2.5.19, we conclude that U is (representable by) a formal thickening of X. We conclude by observing that $f'' : U \to Y$ is locally almost of finite presentation (Lemma 18.2.5.9) and that α can be identified with the map $L_{U/Y}|_X \to L_{X/Y}$ (Lemma 18.2.5.6). □

18.3 Artin's Representability Theorem

Let R be an excellent Noetherian ring and let X be a functor from the category of commutative R-algebras to the category of sets. In [4], Artin supplied necessary and sufficient conditions for X to be representable by an algebraic space which is locally of finite presentation over R. Our goal in this section is to prove the following analogue of Artin's result:

Theorem 18.3.0.1 (Spectral Artin Representability Criterion)**.** *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor and suppose we are given a natural transformation $f : X \to \operatorname{Spec} R$, where R is a Noetherian $\mathbb{E}_\infty$-ring and $\pi_0 R$ is a Grothendieck ring. Let $n \geqslant 0$. Then X is representable by a spectral Deligne-Mumford n-stack which is locally almost of finite presentation over R if and only if the following conditions are satisfied:*

(1) *For every discrete commutative ring A, the space $X(A)$ is n-truncated.*

(2) *The functor X is a sheaf for the étale topology.*

(3) *The functor X is nilcomplete, infinitesimally cohesive, and integrable.*

(4) *The functor X admits a connective cotangent complex L_X.*

(5) *The natural transformation f is locally almost of finite presentation.*

18.3.1 Approximate Charts

Let $X \to \operatorname{Spec} R$ be a natural transformation satisfying the hypotheses of Theorem 18.3.0.1. We wish to show that X is representable by a spectral Deligne-Mumford stack: in other words, that there is a good supply of étale morphisms $u : \operatorname{Spec} A \to X$, where A is a connective $\mathbb{E}_\infty$-ring. We begin by looking for maps u which are "approximately" étale at some point of $|\operatorname{Spec} A|$.

Proposition 18.3.1.1. *Let R be an $\mathbb{E}_\infty$-ring, let $Y = \operatorname{Spec} R$, and suppose we are given a natural transformation $q : X \to Y$ of functors $X, Y \in \operatorname{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ satisfying the following conditions:*

(1) *The functor X is infinitesimally cohesive, nilcomplete, and integrable.*

(2) *The $\mathbb{E}_\infty$-ring R is Noetherian and $\pi_0 R$ is a Grothendieck commutative ring.*

(3) *The natural transformation q is locally almost of finite presentation.*

(4) *The map q admits a cotangent complex $L_{X/Y}$.*

Suppose we are given a field κ and a map $f : \operatorname{Spec} \kappa \to X$ which exhibits κ as a finitely generated field extension of some residue field of R. Then the map f factors as a composition $\operatorname{Spec} \kappa \to \operatorname{Spec} B \to X$, where B is almost of finite presentation over R and the vector space $\pi_1(\kappa \otimes_B L_{\operatorname{Spec} B/X})$ vanishes.

Remark 18.3.1.2. Proposition 18.3.1.1 does not require any connectivity assumption on the relative cotangent complex $L_{X/Y}$. Consequently, it can be used to prove a generalization of Theorem 18.3.0.1 to the setting of Artin stacks. We will return to this point in Part **??**.

Proof of Proposition 18.3.1.1. Since κ is a finitely generated field extension of some residue field of R, the relative cotangent complex $L_{\kappa/R}$ is an almost perfect κ-module. Since $L_{X/\operatorname{Spec} R}$ is almost perfect (Corollary 17.4.2.2), the fiber sequence $f^* L_{X/\operatorname{Spec} R} \to L_{\kappa/R} \to L_{\operatorname{Spec} \kappa/X}$ shows that the relative cotangent complex $L_{\operatorname{Spec}(\kappa)/X}$ is almost perfect.

Let $\widehat{X}$ denote the relative de Rham space of the morphism $\operatorname{Spec}(\kappa) \to X$, given by the formula $\widehat{X}(A) = X(A) \times_{X(A^{\mathrm{red}})} \operatorname{Spec}(\kappa)(A^{\mathrm{red}})$. Then we can identify the relative cotangent complex $L_{\operatorname{Spec}(\kappa)/X}$ with $L_{\operatorname{Spec}(\kappa)/\hat{X}}$ (see Corollary 18.2.1.11). Choose a fiber sequence

$$\mathscr{F} \xrightarrow{\alpha} L_{\operatorname{Spec}(\kappa)/\hat{X}} \to \mathscr{G}$$

in the ∞-category $\operatorname{QCoh}(\operatorname{Spec}(\kappa)) \simeq \operatorname{Mod}_\kappa$, where $\mathscr{F}$ is perfect of Tor-amplitude $\leqslant 0$ and $\mathscr{G}$ is 1-connective. Applying Theorem 18.2.5.1, we deduce that the canonical map $\operatorname{Spec}(\kappa) \to \widehat{X}$ factors as a composition $\operatorname{Spec}(\kappa) \to U \to \widehat{X}$, where U is representable by a formal spectral Deligne-Mumford stack $\operatorname{Spf}(A)$ which is a formal thickening of $\operatorname{Sp\acute{e}t}(\kappa)$, and α can be identified with the canonical map $L_{U/\hat{X}}|_{\operatorname{Spec}(\kappa)} \to L_{\operatorname{Spec}(\kappa)/\hat{X}}$. Here A denotes some connective $\mathbb{E}_\infty$-ring which is complete with respect to a finitely generated ideal $I \subseteq \pi_0 A$. Using Proposition 18.2.4.1, we deduce that A is a Noetherian local $\mathbb{E}_\infty$-ring with residue field κ. Since X is integrable and nilcomplete, the composite map $U \to \widehat{X} \to X$ induces a map $\overline{f} : \operatorname{Spec}(A) \to X$ which fits into a commutative diagram

$$\begin{array}{ccc} \operatorname{Spec}(\kappa) & \longrightarrow & \operatorname{Spec}(A) \\ & {\scriptstyle f} \searrow \quad \swarrow {\scriptstyle \overline{f}} & \\ & X. & \end{array}$$

By construction, we have $\pi_n(\kappa \otimes_A L_{\operatorname{Spec}(A)/X}) \simeq 0$ for $n > 0$.

Let $A' = \pi_0 A$. The canonical map $A \to A'$ is 1-connective, so that $L_{A'/A}$ is 2-connective (Corollary HA.7.4.3.2). Using the fiber sequence

$$\kappa \otimes_A L_{\operatorname{Spec}(A)/X} \to \kappa \otimes_{A'} L_{\operatorname{Spec}(A')/X} \to \kappa \otimes_{A'} L_{A'/A},$$

we deduce that $\pi_1(\kappa \otimes_{A'} L_{\operatorname{Spec}(A')/X}) \simeq 0$.

Let $\mathfrak{m}$ denote the maximal ideal of A', so that $A'/\mathfrak{m} \simeq \kappa$. Let A'' be a subalgebra of A' which is finitely generated over $\pi_0 R$ with the following properties:

- The subalgebra A'' contains generators of the field κ over $\pi_0 R$: that is, κ is the fraction field of the integral domain $A''/(A'' \cap \mathfrak{m})$.
- The subalgebra A'' contains a basis for the κ-vector space $\mathfrak{m}/\mathfrak{m}^2$.

Let $\mathfrak{p}$ denote the intersection $A'' \cap \mathfrak{m}$, and let $\widehat{A}''$ denote the completion of the Noetherian local ring $A''_{\mathfrak{p}}$. The conditions above guarantee that the map $v : A''_{\mathfrak{p}} \to A'$ induces an isomorphism of residue fields and a surjection of Zariski cotangent spaces. Since A' is complete with respect to its maximal ideal, v extends to a surjective map $\widehat{v} : \widehat{A}'' \to A'$. In particular, as an $\mathbb{E}_\infty$-algebra over $\widehat{A}''$, A' is almost of finite presentation.

Since A'' is finitely generated over $\pi_0 R$, it is a Grothendieck ring (Theorem **??**). It follows that the map $A''_{\mathfrak{p}} \to \widehat{A}''$ is geometrically regular. Applying Theorem **??**, we deduce that $\widehat{A}''$ can be written as a colimit $\varinjlim_{\alpha \in P} A''_\alpha$ indexed by a filtered partially ordered set P, where each A''_α is a smooth A''-algebra (in the sense of classical commutative algebra). Using Theorem 4.4.2.2 (and Proposition 4.6.1.1), we see that there exists an index α and an equivalence $A' \simeq \tau_{\leqslant 1}(C_\alpha \otimes_{A''_\alpha} \widehat{A}'')$, where C_α is an $\mathbb{E}_\infty$-ring which is finitely 1-presented over A''_α. For $\beta \geqslant \alpha$, let $C_\beta = \tau_{\leqslant 1}(C_\alpha \otimes_{A''_\alpha} A''_\beta)$, so that

$$\varinjlim_{\beta \geqslant \alpha} C_\beta \simeq \tau_{\leqslant 1}(C_\alpha \otimes_{A''_\alpha} \varinjlim_{\beta \geqslant \alpha} A''_\beta) \simeq \tau_{\leqslant 1}(C_\alpha \otimes_{A''_\alpha} \widehat{A}'') \simeq A'.$$

Since the map $X \to \operatorname{Spec}(R)$ is locally almost of finite presentation, the map $\operatorname{Spec}(A') \to X$ factors as a composition $\operatorname{Spec}(A') \to \operatorname{Spec}(A''_\beta) \xrightarrow{u'} X$ for some $\beta \geqslant \alpha$. Set $B = C_\beta$. We will complete the proof by showing that the relative cotangent complex of u' satisfies $\pi_1(\kappa \otimes_B L_{\operatorname{Spec}(B)/X}) \simeq 0$.

We have an exact sequence

$$\pi_2(\kappa \otimes_{A'} L_{A'/B}) \to \pi_1(\kappa \otimes_B L_{\operatorname{Spec}(B)/X}) \to \pi_1(\kappa \otimes_{A'} L_{\operatorname{Spec}(A')/X}).$$

Since the third term vanishes, it will suffice to show that $\pi_2(\kappa \otimes_{A'} L_{A'/B})$ vanishes. Let B' denote the tensor product $B \otimes_{A''_\beta} \widehat{A}''$, so that $A' \simeq \tau_{\leqslant 1} B'$. We have a short exact sequence

$$\pi_2(\kappa \otimes_{B'} L_{B'/B}) \to \pi_2(\kappa \otimes_{A'} L_{A'/B}) \to \pi_2(\kappa \otimes_{B'} L_{A'/B'}).$$

Since the third term vanishes by virtue of Corollary **??**, we are reduced to proving that the homotopy group $\pi_2(\kappa \otimes_{B'} L_{B'/B}) \simeq \pi_2(\kappa \otimes_{\widehat{A}''} L_{\widehat{A}''/A''_\beta})$ vanishes. For this, we use the exact sequence

$$\pi_2(\kappa \otimes_{\widehat{A}''} L_{\widehat{A}''/A''}) \to \pi_2(\kappa \otimes_{\widehat{A}''} L_{\widehat{A}''/A''_\beta}) \to \pi_1(\kappa \otimes_{A''_\beta} L_{A''_\beta/A''}).$$

Note that the tensor product $\kappa' = \widehat{A}'' \otimes_{A''} \kappa$ is equivalent to κ, so that $\kappa \otimes_{\widehat{A}''} L_{\widehat{A}''/A''} \simeq \kappa \otimes_{\kappa'} L_{\kappa'/\kappa} \simeq 0$. It will therefore suffice to show that the homotopy group $\pi_1(\kappa \otimes_{A''_\beta} L_{A''_\beta/A''})$ vanishes. Let $D = A''_\beta \otimes_{A''} \kappa$. Then D is a commutative algebra over κ which is smooth (in the sense of classical commutative algebra) and equipped with an augmentation $D \to \kappa$. We have a canonical isomorphism $\pi_1(\kappa \otimes_{A''_\beta} L_{A''_\beta/A''}) \simeq \pi_1(\kappa \otimes_D L_{D/\kappa})$. Note that the dual of the vector space $\pi_1(\kappa \otimes_D L_{D/\kappa})$ is the set of homotopy classes of D-module maps from $L_{D/\kappa}$ to $\Sigma\kappa$. This set classifies the collection of all isomorphism classes of square-zero extensions $0 \to I \to \widetilde{D} \to D \to 0$ (in the category of commutative algebras over κ) equipped with an isomorphism of D-modules $I \simeq \kappa$. Since D is smooth over κ, every such extension is automatically split. □

18.3.2 Refinement of Approximate Charts

Our next goal is to show that in the situation of Proposition 18.3.2.1, we can modify the map $\operatorname{Spec} B \to X$ to obtain a map which is formally étale, in the sense that the relative cotangent complex $L_{\operatorname{Spec} B/X}$ vanishes.

Proposition 18.3.2.1. *Let R be an $\mathbb{E}_\infty$-ring, let $Y = \operatorname{Spec} R$, and suppose we are given a natural transformation $q : X \to Y$ of functors $X, Y \in \operatorname{Fun}(\operatorname{CAlg}^{\mathrm{cn}}, \mathcal{S})$. Assume that the following conditions are satisfied:*

(1) *The functor X is infinitesimally cohesive, nilcomplete, and integrable.*

(2) *The $\mathbb{E}_\infty$-ring R is Noetherian and $\pi_0 R$ is a Grothendieck commutative ring.*

(3) *The natural transformation q is locally almost of finite presentation.*

(4) *The map q admits a connective cotangent complex $L_{X/Y}$.*

Suppose we are given an a connective $\mathbb{E}_\infty$-ring A and a map $f : \operatorname{Spec} A \to X$. Let $\mathfrak{p}$ be a prime ideal of $|\operatorname{Spec} A|$, and let $\kappa(\mathfrak{p})$ denote the residue field of A at the point p. Then there exists an étale A-algebra A' and a prime ideal $\mathfrak{p}'$ of A' lying over $\mathfrak{p}$ such that the induced map $\operatorname{Spec} A' \to X$ factors as a composition $\operatorname{Spec} A' \to \operatorname{Spec} B \to X$, where B is almost of finite presentation over R, and the relative cotangent complex $L_{\operatorname{Spec} B/X}$ vanishes.

Proof. Assume that $q : X \to Y = \operatorname{Spec} R$ satisfies hypotheses (1) through (4). Let $f : \operatorname{Spec} A \to X$ be an arbitrary map which exhibits A as almost of finite presentation over R, and let $\mathfrak{p}$ be a prime ideal of $\pi_0 A$. We wish to show that, after passing to an étale neighborhood of $\mathfrak{p}$, the map f factors as a composition $\operatorname{Spec} A \to \operatorname{Spec} B \xrightarrow{g} X$, where g exhibits B as almost of finite presentation over R and $L_{\operatorname{Spec} B/X} \simeq 0$. Note that, if these conditions are satisfied, then g induces a homotopy equivalence

$$(\operatorname{Spec} B)(A) \to (\operatorname{Spec} B)(\pi_0 A) \times_{X(\pi_0 A)} X(A).$$

We may therefore replace A by $\pi_0 A$, and thereby reduce to the case where A is discrete.

Write A as a filtered colimit of subalgebras A_α which are finitely generated as commutative rings over $\pi_0 R$. Since $X \to \operatorname{Spec} R$ is locally almost of finite presentation, the map f factors through $\operatorname{Spec} A_\alpha$ for some α. Replacing A by A_α and $\mathfrak{p}$ by $A_\alpha \cap \mathfrak{p}$, we may reduce to the case where A is finitely generated as a commutative ring over R.

Let κ denote the residue field of A at $\mathfrak{p}$, and consider the composite map $f_\kappa : \operatorname{Spec} \kappa \to \operatorname{Spec} A \xrightarrow{f} X$. Applying Proposition 18.3.1.1, we see that f_κ factors as a composition $\operatorname{Spec} \kappa \xrightarrow{j} \operatorname{Spec} B \xrightarrow{g} X$, where B is almost of finite presentation over R and the vector space $\pi_1(\kappa \otimes_B L_{\operatorname{Spec} B/X})$ vanishes. Since the relative cotangent complex $L_{X/Y}$ is connective, the fiber sequence $g^* L_{X/Y} \to L_{B/R} \to L_{\operatorname{Spec} B/X}$ shows that the map $\pi_0 L_{B/R} \to \pi_0 L_{\operatorname{Spec} B/X}$ is surjective. Since $\pi_0 L_{\operatorname{Spec} B/X}$ is a finitely generated module over $\pi_0 B$ (Corollary 17.4.2.2), we can find a finite sequence of elements $b_1, \ldots, b_m \in \pi_0 B$ such that the images of $db_1, db_2, \ldots, db_m$ in $\pi_0 L_{\operatorname{Spec} B/X}$ form a basis for the vector space $\pi_0(\kappa \otimes_B L_{\operatorname{Spec} B/X})$. The choice of these elements determines a map of B-modules $\psi : B^m \to L_{\operatorname{Spec} B/X}$. The κ-module $\kappa \otimes_B \operatorname{cofib}(\psi)$ is 2-connective. Replacing B by a localization if necessary, we may suppose that $\operatorname{cofib}(\psi)$ is 2-connective.

The map $\operatorname{Spec} B \to X$ is locally almost of finite presentation (Remark 17.4.1.3). Set $X' = \operatorname{Spec} \kappa \times_X \operatorname{Spec} B$, so that the projection map $q' : X' \to \operatorname{Spec} \kappa$ satisfies hypotheses (1), (2), and (3). The map f_κ determines a section s of q'. Applying Proposition 18.3.1.1 again, we deduce that s factors as a composition $\operatorname{Spec} \kappa \xrightarrow{\nu} \operatorname{Spec} C \xrightarrow{g'} X'$ where C is almost of finite presentation over κ and $\pi_1(\kappa \otimes_C L_{\operatorname{Spec} C/X'}) \simeq 0$. Using the fiber sequence $g'^* L_{X'/\kappa} \to L_{C/\kappa} \to L_{\operatorname{Spec} C/X'}$, we deduce that $\pi_1(\kappa \otimes L_{C/\kappa}) \simeq 0$. It follows that the ordinary scheme $\operatorname{Spec} \pi_0 C$ is smooth over κ at the point determined by ν. Replacing C by a localization if necessary, we may suppose that the ordinary scheme $\operatorname{Spec} \pi_0 C$ is smooth over κ.

For $1 \leqslant i \leqslant m$, let c_i denote the image of b_i in the commutative ring $\pi_0 C$. Since $\pi_1(\kappa \otimes_C L_{\operatorname{Spec} C/X'}) = 0$, the map $\pi_0(\kappa \otimes_B L_{\operatorname{Spec} B/X}) \to \pi_0(\kappa \otimes_C L_{\operatorname{Spec} C/\kappa})$ is injective: in other words, as functions on the affine scheme $\operatorname{Spec}(\pi_0 C)$, the c_i have linearly independent derivatives and therefore induce a smooth map of ordinary schemes $h : \operatorname{Spec} \pi_0 C \to \mathbf{A}^m_\kappa$. The image of h is a nonempty open subscheme U of the affine space $\mathbf{A}^m_\kappa$. Let $\kappa_0 \subseteq \kappa$ denote the prime field of κ. Then there exists a finite Galois extension κ'_0 of κ_0 such that U contains a point u which is rational over κ'_0. Let κ' be a separable extension of κ containing κ'_0, so that u defines a map of schemes $\operatorname{Spec} \kappa' \to U$. Since h defines a smooth surjection $\operatorname{Spec} \pi_0 C \to U$, we may (after enlarging κ' if necessary) assume that u factors as a composition $\operatorname{Spec} \kappa' \to \operatorname{Spec} \pi_0 C \to U$. This determines a new map $j' : \operatorname{Spec} \kappa' \to \operatorname{Spec} B$, whose composition with g agrees with the composition

$$\operatorname{Spec} \kappa' \to \operatorname{Spec} \kappa \to \operatorname{Spec} A \xrightarrow{f} X.$$

Since κ' is a finite separable extension of κ, we can write $\kappa' = \kappa[x]/(r(x))$ for some separable polynomial r. After localizing A, we can assume that r lifts to a separable polynomial $\overline{r}(x) \in (\pi_0 A)[x]$. Then $(\pi_0 A)[x]/(\overline{r}(x))$ is a finite étale extension of $\pi_0 A$. Using Theorem HA.7.5.0.6 , we can write $(\pi_0 A)[x]/(\overline{r}(x)) \simeq \pi_0 A'$, where A' is a finite étale A-algebra. Replacing A by A', κ by κ', and j by j', we can reduce to the case where j is given by a ring homomorphism $\pi_0 B \to \kappa$ which carries each b_i to an element $\lambda_i \in \kappa$ belongs to a subfield $\kappa'_0 \subseteq \kappa$ which is algebraic over the prime field κ_0.

Choose an integer N and a finite étale $\mathbf{Z}[N^{-1}]$-algebra D such that $\kappa'_0 \simeq \kappa_0 \otimes_{\mathbf{Z}} D$. Enlarging N if necessary, we may suppose that each λ_i can be lifted to an element $\overline{\lambda}_i \in D$. Replacing B by $B[N^{-1}]$ if necessary, we may suppose that N is invertible in $\pi_0 B$, so that

$(\pi_0 B) \otimes_{\mathbf{Z}[N^{-1}]} D$ is a finite étale extension of $\pi_0 B$. Applying Theorem HA.7.5.0.6 , we can write $(\pi_0 B) \otimes_{\mathbf{Z}[N^{-1}]} D \simeq \pi_0 \overline{B}$ for some finite étale extension $\overline{B}$ of B. Moreover, the embedding $\kappa'_0 \hookrightarrow \kappa'$ induces a map $\overline{B} \to \kappa$, which annihilates the elements $b_i - \overline{\lambda}_i \in \pi_0 \overline{B}$. Replacing B by $\overline{B}$ and the elements $b_i \in B$ by the differences $b_i - \overline{\lambda_i}$ (note that this does not change the differentials db_i), we may reduce to the case where the map $j : \operatorname{Spec} \kappa \to \operatorname{Spec} B$ annihilates each b_i.

Let $B_0 = B \otimes_{S\{b_1,\ldots,b_m\}} S$ denote the $\mathbb{E}_\infty$-algebra over B obtained by killing each b_i. We then have a fiber sequence $B_0 \otimes_B L_{\operatorname{Spec} B/X} \to L_{\operatorname{Spec} B_0/X} \to L_{B_0/B}$. We note that $L_{B_0/B} \simeq \Sigma(B_0^m)$, and the boundary map $\Omega L_{B_0/B} \to B_0 \otimes_B L_{\operatorname{Spec} B/X}$ is induced by the map $\psi : B^m \to L_{\operatorname{Spec} B/X}$ given by the elements b_i. Since $\operatorname{cofib}(\psi)$ is 2-connective, we deduce that $L_{\operatorname{Spec} B_0/X}$ is 2-connective. The map $j : \operatorname{Spec} \kappa \to \operatorname{Spec} B$ annihilates each b_i, and therefore factors through $\operatorname{Spec} B_0$. We may therefore replace B by B_0, and thereby reduce to the case where $L_{\operatorname{Spec} B/X}$ is 2-connective.

Proposition 18.1.2.1 implies that the map $g : \operatorname{Spec} B \to X$ factors as a composition $\operatorname{Spec} B \to \operatorname{Spec} \overline{B} \to X$, where $\pi_0 \overline{B} \simeq \pi_0 B$ and $L_{\overline{B}/X} \simeq 0$. It follows from Corollary 17.4.2.2 that $L_{B/\overline{B}} \simeq L_{\operatorname{Spec} B/X}$ is an almost perfect module over B. Since B is almost of finite presentation over R, $L_{B/R}$ is almost perfect. Using the fiber sequence $B \otimes_{\overline{B}} L_{\overline{B}/R} \to L_{B/R} \to L_{B/\overline{B}}$, we deduce that $B \otimes_{\overline{B}} L_{\overline{B}/R}$ is almost perfect as a B-module. It follows from Proposition 2.7.3.2 that $L_{\overline{B}/R}$ is almost perfect as an $\overline{B}$-module. Since $\pi_0 \overline{B} \simeq \pi_0 B$ is finitely presented as an commutative ring over $\pi_0 R$, Theorem HA.7.4.3.18 implies $\overline{B}$ is almost of finite presentation over R. We may therefore replace B by $\overline{B}$, and thereby reduce to the case where $L_{\operatorname{Spec} B/X} \simeq 0$.

We will now complete the proof by showing that there exists a finite étale A-algebra A' with $\kappa \otimes_A A' \neq 0$, such that the induced map $\operatorname{Spec} A' \to X$ factors through $\operatorname{Spec} B$.

Let $\widehat{A}$ denote the completion of the local ring $A_{\mathfrak{p}}$ at its maximal ideal, and let $\mathfrak{m}$ denote the maximal ideal of $\widehat{A}$, so that $\widehat{A}/\mathfrak{m} \simeq \kappa$. Each quotient $\widehat{A}/\mathfrak{m}^{n+1}$ is a square-zero extension of $\widehat{A}/\mathfrak{m}^n$. Since g is infinitesimally cohesive with $L_{\operatorname{Spec} B/X} \simeq 0$, it follows that each of the diagrams

$$\begin{array}{ccc} (\operatorname{Spec} B)(\widehat{A}/\mathfrak{m}^{n+1}) & \longrightarrow & (\operatorname{Spec} B)(\widehat{A}/\mathfrak{m}) \\ \downarrow & & \downarrow \\ X(\widehat{A}/\mathfrak{m}^{n+1}) & \longrightarrow & X(\widehat{A}/\mathfrak{m}^n). \end{array}$$

is a pullback square. Consequently, the diagram

$$\begin{array}{ccc} \varprojlim (\operatorname{Spec} B)(\widehat{A}/\mathfrak{m}^{n}) & \longrightarrow & (\operatorname{Spec} B)(\kappa) \\ \downarrow & & \downarrow \\ \varprojlim X(\widehat{A}/\mathfrak{m}^{n}) & \longrightarrow & X(\kappa) \end{array}$$

is also a pullback square. Since both X and $\operatorname{Spec} B$ are integrable, we obtain a pullback square

$$\begin{array}{ccc} (\operatorname{Spec} B)(\widehat{A}) & \longrightarrow & (\operatorname{Spec} B)(\kappa) \\ \downarrow & & \downarrow \\ X(\widehat{A}) & \longrightarrow & X(\kappa). \end{array}$$

It follows that the map $j : \operatorname{Spec} \kappa \to \operatorname{Spec} B$ admits an essentially unique factorization as a composition $\operatorname{Spec} \kappa \to \operatorname{Spec} \widehat{A} \xrightarrow{\widehat{j}} \operatorname{Spec} B$, where $\widehat{j}$ fits into a commutative diagram

$$\begin{array}{ccc} \operatorname{Spec} \widehat{A} & \xrightarrow{\widehat{j}} & \operatorname{Spec} B \\ \downarrow & & \downarrow g \\ \operatorname{Spec} A & \xrightarrow{f} & X. \end{array}$$

By assumption, $\pi_0 R$ is a Grothendieck ring. Since A is finitely generated as an algebra over $\pi_0 R$, it is also a Grothendieck ring (Theorem **??**), so that the map $A_{\mathfrak{p}} \to \widehat{A}$ is geometrically regular. Applying Theorem **??**, we can write $\widehat{A}$ as a filtered colimit $\varinjlim A_\alpha$, where each A_α is smooth over $A_{\mathfrak{p}}$ (in the sense of classical commutative algebra). Since B is almost of finite presentation over R and the natural transformation $X \to \operatorname{Spec} R$ is locally almost of finite presentation, the natural transformation g is locally almost of finite presentation. It follows that for some index α, there exists a commutative diagram

$$\begin{array}{ccc} \operatorname{Spec} A_\alpha & \longrightarrow & \operatorname{Spec} B \\ \downarrow & & \downarrow g \\ \operatorname{Spec} A & \longrightarrow & X. \end{array}$$

Since A_α is smooth over $A_{\mathfrak{p}}$, we can choose a smooth A-algebra $\overline{A}$ over A such that $A_\alpha \simeq \overline{A} \otimes_A A_{\mathfrak{p}}$. Then A_α can be written as a filtered colimit of A-algebras of the form $\overline{A}[a^{-1}]$, where $a \in A - \mathfrak{p}$. Using the fact that g is locally almost of finite presentation again, we obtain a commutative diagram

$$\begin{array}{ccc} \operatorname{Spec} \overline{A}[a^{-1}] & \longrightarrow & \operatorname{Spec} B \\ \downarrow & & \downarrow g \\ \operatorname{Spec} A & \longrightarrow & X. \end{array}$$

for some $a \in A - \mathfrak{p}$. Note that $v : \operatorname{Spec} \overline{A}[a^{-1}] \to \operatorname{Spec} A$ is a smooth map of affine schemes whose image contains the prime ideal $\mathfrak{p}$. It follows that there exists an étale A-algebra A' such that $\kappa \otimes_A A' \neq 0$, and the map $\operatorname{Spec} A' \to \operatorname{Spec} A$ factors through v. Then the map $\operatorname{Spec} A' \to \operatorname{Spec} A \xrightarrow{f} X$ factors through the map $g : \operatorname{Spec} B \to X$, as desired. $\square$

18.3.3 The Proof of Artin Representability

We now turn to the proof of our main result. Let R be a connective $\mathbb{E}_\infty$-ring and let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor equipped with a natural transformation $f : X \to \operatorname{Spec} R$. Suppose that X is representable by a spectral Deligne-Mumford n-stack X which is locally almost of finite presentation over R. In this case, it is easy to verify that the hypotheses of Theorem 18.3.0.1 are satisfied:

(1) For every discrete commutative ring A, the space $X(A)$ is n-truncated: this follows from our assumption that X is a spectral Deligne-Mumford n-stack (Definition 1.6.8.1).

(2) The functor X is a sheaf for the étale topology: this also follows immediately from the representability of X.

(3) The functor X is nilcomplete, infinitesimally cohesive, and integrable: this follows from Proposition 17.3.2.3, Example 17.3.1.2, and Proposition 17.3.4.2.

(4) The natural transformation f admits a connective cotangent complex $L_{X/\operatorname{Spec} R}$: see Proposition 17.2.5.1.

(5) The natural transformation f is locally almost of finite presentation: this follows from Proposition 17.4.3.1.

Now suppose that R is Noetherian, that $\pi_0 R$ is a Grothendieck ring, and that X satisfies conditions (1) through (5). We wish to prove that X is representable by a spectral Deligne-Mumford stack X. Then X is automatically a spectral Deligne-Mumford n-stack (by virtue of assumption (1)) which is locally almost of finite presentation over R (by condition (5) and Proposition 17.4.3.1). To prove the existence of X, we first note that hypothesis (1) can be restated as follows:

($1'_n$) For every discrete commutative ring A, the map $X(A) \to \mathrm{Map}_{\mathrm{CAlg}}(R, A)$ has n-truncated homotopy fibers.

Note that condition ($1'$) makes sense for all $n \geqslant -2$. We will show that for all $n \geqslant -2$, if $f : X \to \operatorname{Spec} R$ satisfies conditions ($1'_n$), (2), (3), (4), and (5), then X is representable by a spectral Deligne-Mumford stack X.

Our proof now proceeds by induction on n. We begin by treating the case $n = -2$. In this case, condition ($1'$) asserts that the map $X(A) \to \mathrm{Map}_{\mathrm{CAlg}}(R, A)$ is a homotopy equivalence for every discrete commutative ring A. In this case, the existence of X follows from Theorem 18.1.0.2.

Now suppose that $n \geqslant -1$. Let $\mathcal{S}\mathrm{hv}_{\text{ét}}$ denote the full subcategory of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ spanned by those functors which are sheaves for the étale topology. Let S be a set of representatives for all equivalences classes of maps $\operatorname{Spec} B_\alpha \to X$ for which $L_{\operatorname{Spec} B_\alpha / X} = 0$ and exhibit B_α as almost of finite presentation over R, and let X_0 denote the coproduct $\coprod_{\alpha \in S} \operatorname{Spec} B_\alpha$ formed in the ∞-category $\mathcal{S}\mathrm{hv}_{\text{ét}}$, and let $X_\bullet$ denote the simplicial object of $\mathcal{S}\mathrm{hv}_{\text{ét}}$ given by the Čech nerve of the map $X_0 \to X$. Note that each X_m is given as a coproduct (in the ∞-category $\mathcal{S}\mathrm{hv}_{\text{ét}}$)

$$\coprod_{(\alpha_1, \ldots, \alpha_m) \in S^m} X_{\alpha_1, \ldots, \alpha_m},$$

$$X_{\alpha_1, \ldots, \alpha_m} = (\operatorname{Spec} B_{\alpha_1}) \times_X \cdots \times_X (\operatorname{Spec} B_{\alpha_m}),$$

and therefore admits a map

$$X_{\alpha_1, \ldots, \alpha_m} \to \operatorname{Spec}(B_{\alpha_1} \otimes_R \cdots \otimes_R B_{\alpha_m})$$

satisfying condition $(1'_{n-1})$. Applying the inductive hypothesis, we deduce that each $X_{\alpha_1, \ldots, \alpha_m}$ is representable by a spectral Deligne-Mumford stack, so that each X_m is representable by a spectral Deligne-Mumford stack X_m. Proposition 17.4.3.1 implies that each X_m is locally almost of finite presentation over R, so that each of the transition maps $\mathsf{X}_m \to \mathsf{X}_{m'}$ is locally almost of finite presentation. By construction, we have $L_{X_0/X} \simeq 0$, which implies that each transition map $\mathsf{X}_m \to \mathsf{X}_{m'}$ has vanishing cotangent complex. Applying Proposition 17.1.5.1, we deduce that each of the maps $\mathsf{X}_m \to \mathsf{X}_{m'}$ is étale. It follows that the simplicial object $\mathsf{X}_\bullet$ admits a geometric realization $|\mathsf{X}_\bullet|$ in the ∞-category of spectral Deligne-Mumford stacks (Proposition **??**). Lemma **??** implies that $|\mathsf{X}_\bullet|$ represents the functor $|X_\bullet|$, where the geometric realization is formed in the ∞-category $\mathcal{S}\mathrm{hv}_{\text{ét}}$. To complete the proof that X is representable, it will suffice to show that the canonical map $|X_\bullet| \to X$ is an equivalence. Since $\mathcal{S}\mathrm{hv}_{\text{ét}}$ is an ∞-topos, this is equivalent to the requirement that the map $X_0 \to X$ is an effective epimorphism of étale sheaves, which follows from Proposition 18.3.2.1.

Chapter 19

Applications of Artin Representability

Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor from the ∞-category of connective $\mathbb{E}_\infty$-rings to the ∞-category of spaces. In Chapter 18, we established a version of Artin's representability theorem (Theorem 18.3.0.1), which supplies conditions which are sufficient (and, under mild assumptions, also necessary) for the representability of X by a spectral Deligne-Mumford stack X. In this chapter, we will sketch some applications of Theorem 18.3.0.1:

- Let $\mathsf{X} \xrightarrow{f} \mathsf{S} \xrightarrow{g} \mathsf{S}'$ be morphisms of spectral algebraic spaces. In §19.1, we define the *Weil restriction* $\mathrm{Res}_{\mathsf{S}/\mathsf{S}'}(\mathsf{X})$. Using Theorem 18.3.0.1, we show that if f is quasi-separated and locally almost of finite presentation and g is proper, flat, and locally almost of finite presentation, then the Weil restriction $\mathrm{Res}_{\mathsf{S}/\mathsf{S}'}(\mathsf{X})$ is representable by a spectral algebraic space (which is quasi-separated and locally almost of finite presentation over S'); see Theorem 19.1.0.1.

- Let $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ be a morphism of spectral algebraic spaces which is equipped with a section $s : \mathrm{Sp\acute{e}t}\, R \to \mathfrak{X}$. In §19.2, we define the relative Picard functor $\mathscr{P}\mathrm{ic}^s_{\mathsf{X}/R}$ (Definition 19.2.0.2), which classifies line bundles $\mathscr{L}$ on $\mathfrak{X}$ equipped with a trivialization of $s^* \mathscr{L}$. Assuming that f is proper, flat, locally almost of finite presentation, geometrically reduced, and geometrically connected, we show that $\mathscr{P}\mathrm{ic}^s_{\mathsf{X}/R}$ is representable by a spectrally algebraic space which is locally of finite presentation over R (Theorem 19.2.0.5). We also study the representability of several related moduli problems (parametrizing quasi-coherent sheaves of various flavors).

- Let X be a spectral Deligne-Mumford stack and let $\mathfrak{X}$ denote the formal completion of X along a cocompact closed subset $K \subseteq |\mathsf{X}|$ be a cocompact closed subset. In §19.3, we study the relationship between modifications of X along K (that is, proper morphisms $\mathsf{X}' \to \mathsf{X}$ which induce an equivalence over the complement of K) and *formal modifications* of the formal completion $\mathfrak{X}$ (Definition 19.3.1.3). Under mild assumptions, we show that every formal modification of $\mathfrak{X}$ arises from an (essentially unique) modification of X (Theorem 19.3.1.8).

- In §19.4 we introduce a functor Var^+ whose R-valued points are spectral algebraic spaces $\mathfrak{X}$ which are proper, flat, and locally almost of finite presentation over R. The functor Var^+ is not representable by a spectral Deligne-Mumford stack (for two essentially different reasons: algebraic varieties can admit continuous families of automorphisms, and formal algebraic spaces can fail to be algebraizable). Nevertheless, we show that the functor Var^+ has a well-behaved deformation theory (which we will exploit in Chapter **??** to prove the representability of several closely related functors.

Contents

19.1 Existence of Weil Restrictions

Let X be an affine scheme defined over the complex numbers, and let $X(\mathbf{C})$ denote the collection of $\mathbf{C}$-points of X. Then $X(\mathbf{C})$ can be described as the set of $\mathbf{R}$-points of an affine $\mathbf{R}$-scheme Y. For example, if X is given as a closed subscheme of affine space $\mathbf{A}^n$ defined by a collection of polynomial equations $f_\alpha(z_1, \ldots, z_n) = 0$ with complex coefficients, then Y can be described as the closed subvariety of $\mathbf{A}^{2n}$ defined by the real polynomial equations

$$\Re(f_\alpha(x_1 + iy_1, \ldots, x_n + iy_n)) = 0 = \Im(f_\alpha(x_1 + iy_1, \ldots, x_n + iy_n)).$$

Here $\Re(w)$ and $\Im(w)$ denote the real and imaginary parts of a complex number w, respectively. The scheme Y is called the *Weil restriction* of X along the morphism $\operatorname{Spec}\mathbf{C} \to \operatorname{Spec}\mathbf{R}$. It is characterized by the following universal property: for every $\mathbf{R}$-scheme Z, there is a canonical bijection

$$\operatorname{Hom}(Z, Y) \simeq \operatorname{Hom}(Z \times_{\operatorname{Spec}\mathbf{R}} \operatorname{Spec}\mathbf{C}, X),$$

where the Hom-set on the left is computed in the category $\mathbf{R}$-schemes and the Hom-set on the right is computed in the category of $\mathbf{C}$-schemes.

In this section, we will study the operation of Weil restriction in the setting of spectral algebraic geometry. Suppose that we are given a map of spectral Deligne-Mumford stacks $f : \mathsf{S} \to \mathsf{S}'$ together with a map $\mathsf{X} \to \mathsf{S}$. A *Weil restriction* of X along f is another spectral Deligne-Mumford stack Y equipped with a map $\mathsf{Y} \to \mathsf{S}'$ and a commutative diagram

$$\begin{array}{ccc} \mathsf{Y} \times_{\mathsf{S}''} \mathsf{S} & \xrightarrow{\rho} & \mathsf{X} \\ & \searrow \quad \swarrow & \\ & \mathsf{S} & \end{array}$$

satisfying the following universal property: for every map of spectral Deligne-Mumford stacks $\mathsf{Z} \to \mathsf{S}'$, composition with ρ induces a homotopy equivalence

$$\operatorname{Map}_{\mathrm{SpDM}_{/\mathsf{S}'}}(\mathsf{Z}, \mathsf{Y}) \to \operatorname{Map}_{\mathrm{SpDM}_{/\mathsf{S}}}(\mathsf{Z} \times_{\mathsf{S}'} \mathsf{S}, \mathsf{X}).$$

In this case, the spectral Deligne-Mumford stack Y is determined up to canonical equivalence, and will be denoted by $\operatorname{Res}_{\mathsf{S}/\mathsf{S}'}(\mathsf{X})$. Our goal in this section is to prove the following result:

Theorem 19.1.0.1. *Let $f : \mathsf{S} \to \mathsf{S}'$ be a morphism of spectral Deligne-Mumford stacks which is proper, flat, and locally almost of finite presentation. Let $\mathsf{X} \to \mathsf{S}$ be a relative spectral* *algebraic space which is quasi-separated and locally almost of finite presentation. Then there exists a Weil restriction* $\mathrm{Res}_{\mathsf{S}/\mathsf{S}'}(\mathsf{X})$. *Moreover, the canonical map* $\mathrm{Res}_{\mathsf{S}/\mathsf{S}'}(\mathsf{X}) \to \mathsf{S}'$ *is a relative spectral algebraic space which is quasi-separated and locally almost of finite presentation.*

19.1.1 The Quasi-Affine Case

We begin by proving Theorem 19.1.0.1 in the special case where the morphism $\mathsf{X} \to \mathsf{S}$ is quasi-affine:

Proposition 19.1.1.1. *Let* $\phi : \mathsf{S} \to \mathsf{S}'$ *be a morphism of spectral Deligne-Mumford stacks which is proper, flat, and locally almost of finite presentation, and let* $\rho : \mathsf{X} \to \mathsf{S}$ *be a quasi-affine morphism of spectral Deligne-Mumford stacks. Then there exists a Weil restriction* $\mathrm{Res}_{\mathsf{S}/\mathsf{S}'}(\mathsf{X})$. *Moreover, the canonical map* $\rho' : \mathrm{Res}_{\mathsf{S}/\mathsf{S}'}(\mathsf{X}) \to \mathsf{S}'$ *is quasi-affine. Moreover, if* ρ *is affine, then* ρ' *is affine.*

In the case where $\rho : \mathsf{X} \to \mathsf{S}$ is affine, Proposition 19.1.1.1 is an immediate consequence of the following:

Proposition 19.1.1.2. *Let* $\phi : \mathsf{S} \to \mathsf{S}'$ *be a morphism between quasi-compact, quasi-separated spectral algebraic spaces which is proper, flat, and locally almost of finite presentation. Then the pullback functor* $\phi^* : \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{S}')) \to \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{S}))$ *admits a left adjoint* $\phi_\dagger$. *Moreover, the functor* $\phi_\dagger$ *carries connective objects of* $\mathrm{CAlg}(\mathrm{QCoh}(\mathsf{S}))$ *to connective objects of* $\mathrm{CAlg}(\mathrm{QCoh}(\mathsf{S}'))$.

Proof. Let $\mathcal{C}$ denote the full subcategory of $\mathrm{CAlg}(\mathrm{QCoh}(\mathsf{S}))$ spanned by those objects $\mathscr{A}$ for which the functor

$$\mathscr{B} \mapsto \mathrm{Map}_{\mathrm{CAlg}(\mathrm{QCoh}(\mathsf{S}))}(\mathscr{A}, \phi^* \mathscr{B})$$

is corepresentable by an object $\phi_\dagger(\mathscr{A}) \in \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{S}'))$. To prove the existence of $\phi_\dagger$, it will suffice to show that $\mathcal{C} = \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{S}))$. Note that $\mathcal{C}$ is closed under small colimits in $\mathrm{CAlg}(\mathrm{QCoh}(\mathsf{S}))$. Let $\mathrm{Sym}^*_{\mathsf{S}} : \mathrm{QCoh}(\mathsf{S}) \to \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{S}))$ be a left adjoint to the forgetful functor, and define $\mathrm{Sym}^*_{\mathsf{S}'}$ similarly. It follows from Proposition HA.4.7.3.14 that $\mathcal{C}$ is generated under small colimits by the essential image of $\mathrm{Sym}^*_{\mathsf{S}}$. It will therefore suffice to show that $\mathcal{C}$ contains the essential image of $\mathrm{Sym}^*_{\mathsf{S}}$. In other words, it suffices to show that for each quasi-coherent sheaf $\mathscr{F}$ on S, the functor

$$\mathscr{B} \mapsto \mathrm{Map}_{\mathrm{CAlg}(\mathrm{QCoh}(\mathsf{Y}))}(\mathrm{Sym}^*_{\mathsf{Y}}(\mathscr{F}), \phi^* \mathscr{B}) \simeq \mathrm{Map}_{\mathrm{QCoh}(\mathsf{Y})}(\mathscr{F}, \phi^* \mathscr{B})$$

is corepresentable.

According to Proposition 6.4.5.4, the pullback functor $\mathrm{QCoh}(\mathsf{S}) \to \mathrm{QCoh}(\mathsf{S}')$ admits a left adjoint ϕ_+. We then have

$$\mathrm{Map}_{\mathrm{QCoh}(\mathsf{S})}(\mathscr{F}, \phi^* \mathscr{B}) \simeq \mathrm{Map}_{\mathrm{QCoh}(\mathsf{S}')}(\phi_+ \mathscr{F}, \mathscr{B}) \simeq \mathrm{Map}_{\mathrm{CAlg}(\mathrm{QCoh}(\mathsf{S}'))}(\mathrm{Sym}^*_{\mathsf{S}'}(\phi_+(\mathscr{F})), \mathscr{B}).$$

It follows that $\mathrm{Sym}^*_{\mathsf{S}}(\mathscr{F})$ belongs to $\mathcal{C}$, and that we have a canonical equivalence

$$\phi_\dagger(\mathrm{Sym}^*_{\mathsf{S}}(\mathscr{F})) \simeq \mathrm{Sym}^*_{\mathsf{S}'}(\phi_+ \mathscr{F}) = \mathrm{Sym}^*_{\mathsf{S}'}(\phi_*(\mathscr{F} \otimes \omega_{\mathsf{S}/\mathsf{S}'})).$$

This completes the proof of the existence of $\phi_\dagger$.

Now suppose that $\mathscr{A} \in \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{Y}))$ is connective; we wish to show that $\phi_\dagger(\mathscr{A})$ is connective. Let $\mathscr{B}$ be the connective cover of $\phi_\dagger(\mathscr{A})$, and let $u : \mathscr{B} \to \phi_\dagger(\mathscr{A})$ be the tautological map. Since ϕ is flat, the induced map $\phi^*(u) : \phi^*(\mathscr{B}) \to \phi^*\phi_\dagger(\mathscr{A})$ exhibits $\phi^*(\mathscr{B})$ as a connective cover of $\phi^*\phi_\dagger(\mathscr{A})$. Since $\mathscr{A}$ is connective, the unit map $\mathscr{A} \to \phi^*\phi_\dagger(\mathscr{A})$ factors through $\phi^*(\mathscr{B})$. It follows that the map u admits a section, so that $\phi_\dagger(\mathscr{A})$ is a retract of $\mathscr{B}$ and is therefore connective, as desired. □

Proof of Proposition 19.1.1.1. Let $\phi : \mathsf{S} \to \mathsf{S}'$ be a morphism of spectral Deligne-Mumford stacks which is proper, flat, and locally almost of finite presentation, and let $\rho : \mathsf{X} \to \mathsf{S}$ be quasi-affine. We wish to prove that the Weil restriction $\mathrm{Res}_{\mathsf{S}/\mathsf{S}'}(\mathsf{X})$ exists and is quasi-affine over S'. Working locally on S', we can reduce to the case where S' is affine. Then S is a quasi-compact, quasi-separated spectral algebraic space. Let us regard $\mathscr{A} = \tau_{\geq 0}\rho_* \mathscr{O}_{\mathsf{X}}$ as a connective object of $\mathrm{CAlg}(\mathrm{QCoh}(\mathsf{S}))$, so that $\mathscr{A}$ determines an affine morphism $\overline{\rho} : \overline{\mathsf{X}} \to \mathsf{S}$. The tautological map $\rho^* \mathscr{A} \to \mathscr{O}_{\mathsf{X}}$ classifies a map $j : \mathsf{X} \to \overline{\mathsf{X}}$, which is a quasi-compact open immersion by virtue of our assumption that ρ is quasi-affine. Let $\phi_\dagger(\mathscr{A}) \in \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{S}')^{\mathrm{cn}})$ be as in Proposition 19.1.1.2. Then $\phi_\dagger(\mathscr{A})$ determines an affine spectral Deligne-Mumford stack $\overline{\mathsf{Y}}$ over S' equipped with a map $\overline{\psi} : \overline{\mathsf{Y}} \times_{\mathsf{S}'} \mathsf{S} \to \overline{\mathsf{X}}$ in $\mathrm{SpDM}_{/\mathsf{S}}$.

Let $K \subseteq |\overline{\mathsf{X}}|$ be the closed subset complementary to the image of j. Since the open immersion j is quasi-compact, the set K is constructible. Let $K' \subseteq |\overline{\mathsf{Y}} \times_{\mathsf{S}'} \mathsf{S}\,|$ be the inverse image of K, so that K' is also closed and constructible. Let $K'' \subseteq |\overline{\mathsf{Y}}|$ be the image of K' under the projection map $|\overline{\mathsf{Y}} \times_{\mathsf{S}'} \mathsf{S}\,| \to |\overline{\mathsf{Y}}|$. The map ϕ is proper and therefore universally closed, so that K'' is closed. Choose an open immersion $j' : \mathsf{Y} \hookrightarrow \overline{\mathsf{Y}}$ complementary to K''. Since ϕ is locally almost of finite presentation, the set K'' is constructible (Corollary 4.3.4.2), so that j' is quasi-compact. It follows that Y is quasi-affine over S'. By construction, the map $\overline{\psi}$ restricts to a map $\psi : \mathsf{Y} \times_{\mathsf{S}'} \mathsf{S} \to \mathsf{X}$. It follows immediately from the definitions that ψ' exhibits Y as the Weil restriction of X along ϕ. If the map ρ is affine, then $K = \varnothing$ so the open immersion j' is an equivalence, in which case Y is affine over X'. □

19.1.2 Weil Restriction of Functors

To prove Theorem 19.1.0.1 in general, it will be convenient to first work in the more general context of functors $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, neglecting issues of representability.

Notation 19.1.2.1. Fix a functor $Z : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. We will regard $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/Z}$ as a symmetric monoidal ∞-category with respect to the operation of Cartesian product. Given objects $X, Y \in \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/Z}$, we let $\underline{\mathrm{Map}}_{/Z}(X, Y)$ denote a classifying object for morphisms from X to Y (if such an object exists). More precisely, $\underline{\mathrm{Map}}_{/Z}(X,Y)$ denotes an object of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/Z}$ equipped with an evaluation map $e : X \times_Z \underline{\mathrm{Map}}_{/Z}(X,Y) \to Y$ with the following universal property: for every object $W \in \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/Z}$, composition with e induces a homotopy equivalence

$$\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}},\mathcal{S})_{/Z}}(W, \underline{\mathrm{Map}}_{/Z}(X,Y)) \to \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}},\mathcal{S})_{/Z}}(W \times_Z X, Y).$$

Recall that a morphism $f : X \to Y$ in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ is *representable* if, for every connective $\mathbb{E}_\infty$-ring R and every morphism $\operatorname{Spec} R \to Y$, the fiber product $\operatorname{Spec} R \times_Y X$ is representable by a spectral Deligne-Mumford stack.

Proposition 19.1.2.2. *Suppose we are given morphisms $X \to Z \leftarrow Y$ in* $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. *Assume that the functors Y and Z are sheaves with respect to the étale topology, and that the map $X \to Z$ is representable. Then a morphism object $\underline{\mathrm{Map}}_{/Z}(X,Y)$ exists. Moreover, $\underline{\mathrm{Map}}_{/Z}(X,Y)$ is also a sheaf with respect to the étale topology.*

Before proving Proposition 19.1.2.2, let us describe our application of interest:

Construction 19.1.2.3 (Weil Restriction)**.** Let $\mathcal{S}\mathrm{hv}_{\text{ét}}$ denote the full subcategory of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ spanned by those functors which are sheaves with respect to the étale topology. Suppose that $f : S \to S'$ is a representable morphism in $\mathcal{S}\mathrm{hv}_{\text{ét}}$. Then f determines a pullback functor $(\mathcal{S}\mathrm{hv}_{\text{ét}})_{/S'} \to (\mathcal{S}\mathrm{hv}_{\text{ét}})_{/S}$, given by $Z \mapsto Z \times_{S'} S$. Using Proposition 19.1.2.2, we deduce that this pullback functor admits a right adjoint $\mathrm{Res}_{S/S'} : (\mathcal{S}\mathrm{hv}_{\text{ét}})_{/S} \to (\mathcal{S}\mathrm{hv}_{\text{ét}})_{/S'}$, given by the formula $\mathrm{Res}_{S/S'}(X) = \underline{\mathrm{Map}}_{/S'}(S,X) \times_{\underline{\mathrm{Map}}_{/S'}(S,S)} S$. We will refer to $\mathrm{Res}_{S/S'}$ as the functor of *Weil restriction* along the map $S \to S'$.

Remark 19.1.2.4. In the special case where the functors S, S', and X are representable by spectral Deligne-Mumford stacks S, S', and X, the Weil restriction $\mathrm{Res}_{S/S'}(X)$ of Construction 19.1.2.3 is representable by the Weil restriction $\mathrm{Res}_{\mathsf{S}/\mathsf{S}'}(\mathsf{X})$ defined in the introduction to §19.1, provided that the latter Weil restriction exists. Consequently, Theorem 19.1.0.1 can be regarded as an assertion about the representability of the functor $\mathrm{Res}_{S/S'}(X)$.

Proof of Proposition 19.1.2.2. Fix a functor $Z : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, and regard $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/Z}$ as a full subcategory of the ∞-category $\mathcal{C} = \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})_{/Z}$. The ∞-category $\mathcal{C}$ can be regarded as an ∞-topos in a larger universe, so that the Cartesian monoidal structure on $\mathcal{C}$ is closed. In particular, the morphism object $\underline{\mathrm{Map}}_{/Z}(X,Y)$ exists as an object of $\mathcal{C}$. To prove the first assertion, it will suffice to show that for every connective $\mathbb{E}_\infty$-ring R, the space $\underline{\mathrm{Map}}_{/Z}(X,Y)(R)$ is essentially small. Since $Z(R)$ is small, it will suffice to show that for every point $\eta \in Z(R)$, the homotopy fiber $\underline{\mathrm{Map}}_{/Z}(X,Y)(R) \times_{Z(R)} \{\eta\}$ is essentially small. The point η determines a map of functors $\operatorname{Spec} R \to Z$, and we can identify $\underline{\mathrm{Map}}_{/Z}(X,Y)(R) \times_{Z(R)} \{\eta\}$ with the mapping space $\mathrm{Map}_{\mathcal{C}}(\operatorname{Spec} R, \underline{\mathrm{Map}}_{/Z}(X,Y)) \simeq \mathrm{Map}_{\mathcal{C}}(\operatorname{Spec} R \times_Z X, Y)$. Since the morphism $X \to Z$ is representable, the functor $\operatorname{Spec} R \times_Z X$ is representable by a spectral Deligne-Mumford stack $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$. For every object $U \in \mathcal{X}$, let X_U denote the functor represented by the spectral Deligne-Mumford stack $(\mathcal{X}_{/U}, \mathscr{O}_{\mathcal{X}}|_U)$. The construction $U \mapsto \operatorname{Map}_{\mathcal{C}}(X_U, Y)$ determines a functor $F : \mathcal{X}^{\mathrm{op}} \to \widehat{\mathcal{S}}$. To complete the proof, it will suffice to show that for each $U \in \mathcal{X}$, the space $F(U)$ is essentially small. Since Y is a sheaf with respect to the étale topology, the functor F preserves small limits. It will therefore suffice to show that $F(U)$ is essentially small when $U \in \mathcal{X}$ is affine. In this case, we can write $X_U = \operatorname{Spec} R'$, and $F(U)$ can be identified with a homotopy fiber of the map $Y(R') \to Z(R')$.

It remains to show that $\underline{\operatorname{Map}}_{/Z}(X, Y)$ is a sheaf with respect to the étale topology. Let $\mathcal{C}_0$ denote the full subcategory of $\mathcal{C}$ spanned by those maps $W \to Z$ where $W : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ is an étale sheaf, and let $L : \mathcal{C} \to \mathcal{C}_0$ be a left adjoint to the inclusion. We wish to show that $\underline{\operatorname{Map}}_{/Z}(X, Y)$ is L-local. Let $\alpha : W \to W'$ be a morphism in $\mathcal{C}$ such that $L(\alpha)$ is an equivalence; we wish to show that composition with α induces a homotopy equivalence $\theta : \operatorname{Map}_{\mathcal{C}}(W', \underline{\operatorname{Map}}_{/Z}(X, Y)) \to \operatorname{Map}_{\mathcal{C}}(W, \underline{\operatorname{Map}}_{/Z}(X, Y))$. Using the universal property of $\underline{\operatorname{Map}}_{/Z}(X, Y)$, we can identify θ with the canonical map $\operatorname{Map}_{\mathcal{C}}(W' \times_Z X, Y) \to \operatorname{Map}_{\mathcal{C}}(W \times_Z X, Y)$. Since $Y \in \mathcal{C}_0$, we are reduced to proving that $L(\beta)$ is an equivalence, where $\beta : W \times_Z X \to W' \times_Z X$ is the map induced by α. This follows from our assumption that $L(\alpha)$ is an equivalence, since the sheafification functor L is left exact. □

19.1.3 Deformation-Theoretic Properties of Weil Restrictions

We now show that, under mild hypotheses, the constructions of §19.1.2 preserve the deformation-theoretic properties studied in Chapter 17.

Proposition 19.1.3.1. *Suppose we are given morphisms $X \xrightarrow{f} Z \xleftarrow{g} Y$ in $\operatorname{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. Assume that the functors Y and Z are sheaves with respect to the étale topology and that the map $f : X \to Z$ is representable. Then:*

(1) *If the map g is cohesive, then the induced map $\underline{\operatorname{Map}}_{/Z}(X, Y) \to Z$ is cohesive.*

(2) *If the map g is infinitesimally cohesive, then the induced map $\underline{\operatorname{Map}}_{/Z}(X, Y) \to Z$ is infinitesimally cohesive.*

(3) *If the map g is nilcomplete, then the induced map $\underline{\operatorname{Map}}_{/Z}(X, Y) \to Z$ is nilcomplete.*

(4) *Assume that f is representable by spectral algebraic spaces (that is, the map $X(R) \to Z(R)$ has discrete homotopy fibers for every discrete $\mathbb{E}_\infty$-ring R), quasi-compact, and quasi-separated. If g is locally of finite presentation, then the induced map $\underline{\operatorname{Map}}_{/Z}(X, Y) \to Z$ is locally of finite presentation.*

(5) *Assume that f is representable by spectral algebraic spaces, quasi-compact, quasi-separated, and locally of finite* Tor*-amplitude. If g is locally almost of finite presentation, then the induced map $\underline{\mathrm{Map}}_{/Z}(X, Y) \to Z$ is locally almost of finite presentation.*

Corollary 19.1.3.2. *Let $f : S \to S'$ be a representable morphism in $\mathcal{S}\mathrm{hv}_{\acute{e}t}$, and let $p : X \to S$ be an arbitrary morphism in $\mathcal{S}\mathrm{hv}_{\acute{e}t}$. If p is cohesive (infinitesimally cohesive, nilcomplete, locally almost of finite presentation), then the induced map $q : \mathrm{Res}_{S/S'}(X) \to Z$ is cohesive (infinitesimally cohesive, nilcomplete, locally almost of finite presentation).*

Proof. We will show that if p is cohesive, then q is cohesive; the proof in the other three cases is the same. We have a pullback diagram

$$\begin{array}{ccc} \mathrm{Res}_{S/S'}(X) & \longrightarrow & \underline{\mathrm{Map}}_{/S'}(S, X) \\ \downarrow{\scriptstyle q} & & \downarrow{\scriptstyle q'} \\ S' & \longrightarrow & \underline{\mathrm{Map}}_{/S'}(S, S). \end{array}$$

We may therefore reduce to proving that q' is cohesive. For this, it suffices to show that both of the projection maps $\underline{\mathrm{Map}}_{/S'}(S, S) \to S' \leftarrow \underline{\mathrm{Map}}_{/S'}(S, X)$ are cohesive (Remark 17.3.7.3). Using Proposition 19.1.3.1, we are reduced to showing that f and $f \circ p$ are cohesive. In the case of f, this follows from Proposition **??**. Because f and p are both cohesive, Remark 17.3.7.3 guarantees that $f \circ p$ is cohesive. □

Proof of Proposition 19.1.3.1. Using Propositions 17.2.4.7, 17.3.8.4, and Remark 17.4.1.6, we can reduce to the case where $Z = \mathrm{Spec}\, R$ is a corepresentable functor, so that X is representable by a spectral Deligne-Mumford stack $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$. For each object $U \in \mathcal{X}$, let X_U denote the functor represented by the spectral Deligne-Mumford stack $(\mathcal{X}_{/U}, \mathcal{O}_{\mathcal{X}}|_U)$. For the first three assertions, it will suffice to show that if Y is cohesive (infinitesimally cohesive, nilcomplete) then $\underline{\mathrm{Map}}_{/Z}(X_U, Y)$ has the same property, for each object $U \in \mathcal{X}$ (Remark 17.3.7.3). Since Y is a sheaf with respect to the étale topology, the construction $U \mapsto \underline{\mathrm{Map}}_{/Z}(X_U, Y)$ carries colimits in $\mathcal{X}$ to limits in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. It will therefore suffice to show that $\underline{\mathrm{Map}}_{/Z}(X_U, Y)$ is cohesive (infinitesimally cohesive, nilcomplete) in the special case where $U \in \mathcal{X}$ is affine, so that $X_U \simeq \mathrm{Spec}\, R'$ for some connective $\mathbb{E}_\infty$-ring R'. Let $F : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ be the functor corresponding to Y under the equivalence of ∞-categories $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/Z} \simeq \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}_R, \mathcal{S})$. Unwinding the definitions, we see that $\underline{\mathrm{Map}}_{/Z}(X_U, Y)$ corresponds to the functor $F_U : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ given by the formula $F_U(A) = F(R' \otimes_R A)$. We now consider each case in turn:

(1) To prove that $\underline{\mathrm{Map}}_{/Z}(X_U, Y)$ is cohesive, we must show that for every pullback diagram

τ :

$$\begin{array}{ccc} A & \longrightarrow & A_0 \\ \downarrow & & \downarrow \\ A_1 & \longrightarrow & A_{01} \end{array}$$

in $\mathrm{CAlg}_R^{\mathrm{cn}}$ for which the maps $\pi_0 A_0 \to \pi_0 A_{01} \leftarrow \pi_0 A_1$ are surjective, the induced diagram σ :

$$\begin{array}{ccc} F_U(A) & \longrightarrow & F_U(A_0) \\ \downarrow & & \downarrow \\ F_U(A_1) & \longrightarrow & F_U(A_{01}) \end{array}$$

is a pullback square in $\mathcal{S}$. We can identify σ with the diagram

$$\begin{array}{ccc} F(R' \otimes_R A) & \longrightarrow & F(R' \otimes_R A_0) \\ \downarrow & & \downarrow \\ F(R' \otimes_R A_1) & \longrightarrow & F(R' \otimes_R A_{01}). \end{array}$$

This is a pullback square by virtue of our assumption that Y is cohesive, since the diagram of $\mathbb{E}_\infty$-rings τ' :

$$\begin{array}{ccc} R' \otimes_R A & \longrightarrow & R' \otimes_R A_0 \\ \downarrow & & \downarrow \\ R' \otimes_R A_1 & \longrightarrow & R' \otimes_R A_{01} \end{array}$$

is also a pullback square which induces surjections

$$\pi_0(R' \otimes_R A_0) \to \pi_0(R' \otimes_R A_{01}) \leftarrow (R' \otimes_R A_1).$$

(2) The argument is identical to that given in case (1), noting that if the diagram τ induces surjections $\pi_0 A_0 \to \pi_0 A_{01} \leftarrow \pi_0 A_1$ with nilpotent kernels, then τ' has the same property.

(3) Assume that Y is nilcomplete; we wish to show that $\underline{\mathrm{Map}}_{/Z}(X_U, Y)$ is nilcomplete. For this, it suffices to show that for every connective R-algebra A, the canonical map

$$F_U(A) \simeq F(R' \otimes_R A) \to \varprojlim F(R' \otimes_R \tau_{\leqslant n} A) \simeq \varprojlim F_U(\tau_{\leqslant n} A)$$

is an equivalence. This follows from Proposition 17.3.2.4.

We now prove (4). Assume that Y is locally of finite presentation over R, and that X is a quasi-compact, quasi-separated spectral algebraic space. Let us say that an object $U \in \mathcal{X}$

is *good* if the functor $F_U : \mathrm{CAlg}_R^{\mathrm{cn}} \to \mathcal{S}$ commutes with filtered colimits. It is easy to see that the collection of good objects of $\mathcal{X}$ is closed under finite colimits; we wish to prove that the final object of $\mathcal{X}$ is good. Using Proposition 2.5.3.5 and Theorem 3.4.2.1, we are reduced to proving that every affine object $U \in \mathcal{X}$ is good. In this case, we can write $X_U = \operatorname{Spec} R'$ as above, so that F_U is given by the formula $F_U(A) = F(A \otimes_R R')$ and therefore commutes with filtered colimits as desired.

The proof of (5) is similar. It will suffice to show that if X is a quasi-compact, quasi-separated spectral algebraic space of Tor-amplitude $\leqslant d$ over R, then the map $\underline{\mathrm{Map}}_{/Z}(X, Y) \to Z$ is locally of finite presentation to order n. Let us say that a functor $G : \mathrm{CAlg}_R^{\mathrm{cn}} \to \mathcal{S}$ is *good* if it satisfies condition (b) of Remark 17.4.1.6, and let us say that an object $U \in \mathcal{X}$ is *good* if the functor F_U is good. The collection of good functors is closed under finite limits, so the collection of good objects of $\mathcal{X}$ is closed under finite colimits. We wish to prove that the final object of $\mathcal{X}$ is good. Invoking Proposition 2.5.3.5 and Theorem 3.4.2.1 again, we are reduced to proving that every affine object $U \in \mathcal{X}$ is good. In this case, we can write $X_U = \operatorname{Spec} R'$, where R' is flat over R. Then F_U is given by the formula $F_U(A) = F(A \otimes_R R')$. If $\{A_\alpha\}$ is a filtered diagram of m-truncated R-algebras having colimit A, then $\{A_\alpha \otimes_R R'\}$ is a filtered diagram of $(m+d)$-truncated R'-algebras having colimit $\{A \otimes_R R'\}$. If the functor F is good, we deduce that the map

$$\varinjlim F_U(A_\alpha) \simeq \varinjlim F(A_\alpha \otimes_R R') \to F(A \otimes_R R') \simeq F_U(A)$$

is a homotopy equivalence, so that F_U is also good. □

19.1.4 The Cotangent Complex of a Weil Restriction

We now prove an analogue of Proposition 19.1.3.1 for the relative cotangent complex.

Proposition 19.1.4.1. *Suppose we are given morphisms $X \xrightarrow{f} Z \xleftarrow{g} Y$ in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. Assume that f is representable, proper, locally almost of finite presentation, and locally of finite* Tor*-amplitude, and that Y and Z are sheaves the étale topology. Set $H = \underline{\mathrm{Map}}_{/Z}(X, Y)$ and let $e : X \times_Z H \to Y$ be the evaluation map, so that we have a commutative diagram*

$$\begin{array}{ccccc} H & \xleftarrow{\overline{f}} & X \times_Z H & \xrightarrow{e} & Y \\ \downarrow{\scriptstyle q} & & \downarrow{\scriptstyle \overline{q}} & & \downarrow{\scriptstyle g} \\ Z & \xleftarrow{f} & X & \xrightarrow{f} & Z \end{array}$$

where the left square is a pullback. Then:

(1) *If g admits a relative cotangent complex $L_{Y/Z}$, then the projection map $q : H \to Z$ also admits a relative cotangent complex $L_{H/Z}$.*

(2) *The canonical map $g^* L_{Y/Z} \to L_{X \times_Z H/X} \simeq \overline{f}^* L_{H/Z}$ induces an equivalence $\overline{f}_+ g^* L_{Y/Z} \to L_{H/Z}$ in the ∞-category $\mathrm{QCoh}(H)$, where $\overline{f}_+$ is given as in Construction 6.4.5.1. In other words, we have a canonical equivalence $L_{H/Z} \simeq \overline{f}_*(\overline{q}^* \omega_{X/Z} \otimes e^* L_{Y/Z})$, where $\omega_{X/Z}$ denotes the relative dualizing sheaf of f (Definition 6.4.2.4).*

Proof. We will prove (1) by verifying conditions (a) and (b) of Remark 17.2.4.3. We first verify (a). Fix a connective $\mathbb{E}_\infty$-ring R and a point $\eta \in H(R)$, and consider the functor $U : \mathrm{Mod}_R^{\mathrm{cn}} \to \mathcal{S}$ given by the formula

$$U(M) = \mathrm{fib}(H(R \oplus M) \to H(R) \times_{Z(R)} Z(R \oplus M)).$$

Set $X_R = X \times_Z \operatorname{Spec} R$, so that the point η determines a map $\rho : X_R \to Y$. Let $f_R : X_R \to \operatorname{Spec} R$ be the projection map. Then ρ and f_R determine pullback functors

$$f_R^* : \mathrm{Mod}_R \simeq \mathrm{QCoh}(\operatorname{Spec} R) \to \mathrm{QCoh}(X_R) \qquad \rho^* : \mathrm{QCoh}(Y) \to \mathrm{QCoh}(X_R).$$

Unwinding the definitions and applying Proposition 6.4.5.3, we see that the functor U is given by the formula

$$U(M) = \mathrm{Map}_{\mathrm{QCoh}(X_R)}(\rho^* L_{Y/Z}, \pi^* M) \simeq \mathrm{Map}_{\mathrm{Mod}_R}(f_{R+} \rho^* L_{Y/Z}, M).$$

It follows that U is almost corepresented by the object $f_{R+} \rho^* L_{Y/X}$ (which is almost connective by virtue of Proposition **??**). This completes the verification of condition (a) of Remark 17.2.4.3. Condition (b) follows from the second part of Proposition 6.4.5.4, and assertion (2) follows from the construction. □

Remark 19.1.4.2. In the situation of Proposition **??**, suppose that the relative cotangent complex $L_{Y/Z}$ is perfect (almost perfect). Then the relative cotangent complex $L_{H/Z}$ is also perfect (almost perfect). This follows from assertion (2) of Proposition **??** together with Remark 6.4.5.2.

Proposition 19.1.4.3. *Let $f : S \to S'$ be a morphism in $\mathcal{S}\mathrm{hv}_{\acute{e}t}$ which is representable, proper, locally almost of finite presentation, and locally of finite* Tor*-amplitude. Let $g : X \to S$ be an arbitrary morphism in $\mathcal{S}\mathrm{hv}_{\acute{e}t}$ and let $\mathrm{Res}_{S/S'}(X)$ denote the Weil restriction of X along f, so that we have an evaluation map $e : S \times_{S'} \mathrm{Res}_{S/S'}(X) \to X$ which fits into a commutative diagram*

$$\begin{array}{ccccc}
\mathrm{Res}_{S/S'}(X) & \xleftarrow{\overline{f}} & S \times_{S'} \mathrm{Res}_{S/S'}(X) & \xrightarrow{e} & X \\
\downarrow{\scriptstyle q} & & \downarrow{\scriptstyle \overline{q}} & & \downarrow{\scriptstyle g} \\
S' & \xleftarrow{f} & S & \xrightarrow{\mathrm{id}} & S.
\end{array}$$

Suppose then g admits a relative cotangent complex. Then:

(a) *The morphism q admits a relative cotangent complex.*

(b) *The canonical map*

$$e^* L_{X/S} \to L_{S \times_{S'} \mathrm{Res}_{S/S'}(X)/S} \simeq \overline{f}^* L_{\mathrm{Res}_{S/S'}(X)/S'}$$

induces an equivalence $\overline{f}_+ e^* L_{X/S} \to L_{\mathrm{Res}_{S/S'}(X)/S'}$ in the ∞-category $\mathrm{QCoh}(\mathrm{Res}_{S/S'}(X))$.

(c) *If $L_{X/S}$ is almost perfect, then $L_{\mathrm{Res}_{S/S'}(X)/S'}$ is almost perfect.*

Proof. Set $H = \underline{\mathrm{Map}}_{/S'}(S, X)$ and $H_0 = \underline{\mathrm{Map}}_{/S'}(S, S)$, so that we have a pullback diagram

$$\begin{array}{ccc} \mathrm{Res}_{S/S'}(X) & \xrightarrow{u} & H \\ \downarrow{\scriptstyle q} & & \downarrow{\scriptstyle q'} \\ S' & \longrightarrow & H_0. \end{array}$$

The morphism $f : S \to S'$ is representable and therefore admits a cotangent complex $L_{S/S'}$. Moreover, g is infinitesimally cohesive (Corollary 17.3.8.5). Applying Proposition 17.3.9.1 (and our assumption that g admits a relative cotangent complex), we deduce that $(f \circ g)$ admits a relative cotangent complex $L_{X/S'}$. Let $\overline{e} : S \times_{S'} H \to X$ and $\overline{e}_0 : S \times_{S'} H_0 \to S$ be the evaluation maps. and let $p : H_0 \to S'$, $f_H : S \times_{S'} H \to H$, and $f_{H_0} : S \times_{S'} H_0 \to H_0$ be the projection maps.Applying Proposition **??**, we deduce that the morphisms p and $(p \circ q')$ admit relative cotangent complexes, given by $f_{H_0+} \overline{e}_0^* L_{S/S'}$ and $f_{H+} \overline{e}^* L_{X/S'}$, respectively. Applying Proposition 17.2.5.2, we deduce that the map q' admits a relative cotangent complex, $f_{H+} \overline{e}^* L_{X/S}$. Applying Remark 17.2.4.6, we deduce that q admits a relative cotangent complex, which we can identify with $u^* f_{H+} \overline{e}^* L_{X/S} \simeq \overline{f}_+ e^* L_{X/S}$. This proves (a), and a diagram chase shows that this identification coincides with the map $\overline{f}_+ e^* L_{X/S} \to L_{\mathrm{Res}_{S/S'}(X)/S'}$ appearing in (b). Assertion (c) follows from (b) and Remark 6.4.5.2. □

19.1.5 The Noetherian Case

We now study some cases in which we can use Artin's representability theorem (in the form of Theorem 18.3.0.1) to verify the representability of the functors given in Notation 19.1.2.1.

Proposition 19.1.5.1. *Let R be a Noetherian $\mathbb{E}_\infty$-ring such that $\pi_0 R$ is a Grothendieck ring and set $Z = \mathrm{Spec}\, R$. Suppose we are given natural transformations $X \to Z \leftarrow Y$ for some pair of functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ satisfying the following conditions:*

- *The functor X is representable by a spectral algebraic space X which is proper, flat, and locally almost of finite presentation over R.*

- *The functor Y is representable by a spectral algebraic space Y which is quasi-separated and locally almost of finite presentation over R.*

Then the functor $\underline{\mathrm{Map}}_{/Z}(X, Y)$ is representable by a spectral Deligne-Mumford stack which is locally almost of finite presentation over R.

Remark 19.1.5.2. In the situation of Proposition 19.1.5.1, it follows immediately from the definitions that the spectral Deligne-Mumford stack representing $\underline{\mathrm{Map}}_{/Z}(X, Y)$ is a spectral algebraic space, and it follows from Theorem 19.1.0.1 that it has quasi-affine diagonal (and is therefore quasi-separated).

Proof. Set $F = \underline{\mathrm{Map}}_{/Z}(X, Y)$, and let $F_0 : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ be given by the formula $F_0(A) = \mathrm{fib}(F(A) \to Z(A))$. We will show that F is representable by a spectral algebraic space by verifying conditions (1) through (5) of Theorem 18.3.0.1:

(1) If A is a discrete commutative ring, then the space $F(A)$ is discrete. To prove this, it will suffice to show that the fibers of the map $F(A) \to Z(A)$ are discrete (since $Z(A) \simeq \mathrm{Map}_{\mathrm{CAlg}}(R, A))$ is discrete. That is, we must show that if A is a discrete $\mathbb{E}_\infty$-algebra over R, then $F_0(A)$ is discrete. Unwinding the definitions, we have

$$F_0(A) = \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/Z}}(\mathrm{Spec}\, A \times_Z X, Y).$$

Since X is flat over R, $\mathrm{Spec}\, A \times_Z X$ is representable by a spectral algebraic space $\mathrm{Spét}\, A \times_{\mathrm{Spét}\, R} \mathsf{X}$ which is flat over A, and therefore 0-truncated. The desired result now follows from Lemma 1.6.8.8.

(2) The functor F is a sheaf for the étale topology. This follows from Proposition 19.1.2.2.

(3) It follows from Proposition 19.1.3.1 that the forgetful functor $F \to Z$ is nilcomplete and infinitesimally cohesive (in fact, it is even cohesive). We claim that it is integrable. To prove this, suppose that A is a local Noetherian $\mathbb{E}_\infty$-ring which is complete with respect its maximal ideal. Let $\mathrm{Spf}\, A$ denote the formal spectrum of A, which we regard as an object of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. We wish to show that the diagram

$$\begin{array}{ccc} F(A) & \longrightarrow & \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(\mathrm{Spf}\, A, F) \\ \downarrow & & \downarrow \\ Z(A) & \longrightarrow & \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(\mathrm{Spf}\, A, Z) \end{array}$$

is a pullback square. Unwinding the definitions, we must show that for every map of $\mathbb{E}_\infty$-algebra $R \to A$, the canonical map

$$\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/Z}}(\mathrm{Spec}\, A \times_{\mathrm{Spec}\, R} X, Y) \to \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/Z}}(\mathrm{Spf}\, A \times_{\mathrm{Spec}\, R} X, Y)$$

is a homotopy equivalence. This follows immediately from Theorem 8.5.3.1.

(4) It follows from Proposition **??** that the natural transformation $F \to Z$ admits a relative cotangent complex $L_{F/Z}$. Moreover, if $\eta \in F(A)$ is a point classifying a map $u : \operatorname{Spét} A \times_{\operatorname{Spét} R} \mathsf{X} \to \mathsf{Y}$ and $p : \operatorname{Spét} A \times_{\operatorname{Spét} R} \mathsf{X} \to \operatorname{Spét} A$ denotes the projection map, then we have a canonical equivalence $\eta^* L_{F/Z} \simeq p_+ u^* L_{\mathsf{Y}/\operatorname{Spét} R}$. Since $u^* L_{\mathsf{Y}/\operatorname{Spét} R}$ is connective, it suffices to show that the functor p_+ is right t-exact. This is clear, since p_+ is left adjoint to the pullback functor p^* (which is left t-exact by virtue of our assumption that X is flat over R).

(5) The map $F \to Z$ is locally almost of finite presentation. This follows from Proposition 19.1.3.1, since the map $Y \to Z$ is locally almost of finite presentation.

□

19.1.6 The Proof of Theorem 19.1.0.1

We will deduce Theorem 19.1.0.1 from the following non-Noetherian analogue of Proposition 19.1.5.1:

Proposition 19.1.6.1. *Suppose we are given functors $X, Y, Z : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ and natural transformations $f : X \to Z$, $g : Y \to Z$. Assume that f is representable, proper, flat, and locally almost of finite presentation. Assume that g is representable by spectral algebraic spaces, quasi-compact, quasi-separated, and locally almost of finite presentation. Then the map $\underline{\mathrm{Map}}_{/Z}(X, Y) \to Z$ is representable.*

Proof. We may assume without loss of generality that $Z = \operatorname{Spec} R$ for some connective $\mathbb{E}_\infty$-ring R, so that X is representable by a spectral algebraic space X and Y is representable by a quasi-separated spectral algebraic space Y. It follows from Propositions 19.1.3.1 and **??** that the functor $F = \underline{\mathrm{Map}}_{/Z}(X, Y)$ is nilcomplete, infinitesimally cohesive, and admits a cotangent complex. According to Theorem 18.1.0.2, to show that F is representable by a spectral Deligne-Mumford stack, it will suffice to show that the restriction $F|_{\mathrm{CAlg}^{\heartsuit}}$ is representable by a spectral Deligne-Mumford stack, where $\mathrm{CAlg}^{\heartsuit}$ denotes the full subcategory of CAlg spanned by the discrete $\mathbb{E}_\infty$-rings. We may therefore replace R by $\pi_0 R$, and thereby reduce to the case where R is discrete. Write R as the union of finitely generated subrings R_α. Using Theorem 4.4.2.2, we can choose an index α and spectral Deligne-Mumford stacks X_α and Y_α which are finitely 0-presented over R_α, together with equivalences

$$\mathsf{X} \simeq \tau_{\leqslant 0}(\operatorname{Spét} R \times_{\operatorname{Spét} R_\alpha} \mathsf{X}_\alpha) \qquad \tau_{\leqslant 0}\, \mathsf{Y} \simeq \tau_{\leqslant 0}(\operatorname{Spét} R \times_{\operatorname{Spét} R_\alpha} \mathsf{Y}_\alpha).$$

Enlarging α if necessary, we can ensure that X_α is a spectral algebraic space which is proper and flat over R_α (Proposition 5.5.4.1 and Corollary 11.2.6.1 of [90]) and that Y_α is a spectral algebraic space. Then $\mathsf{X} \simeq \operatorname{Spét} R \times_{\operatorname{Spét} R_\alpha} \mathsf{X}_\alpha$. Set $\mathsf{Y}' = \operatorname{Spét} R \times_{\operatorname{Spét} R_\alpha} \mathsf{Y}_\alpha$, let Y' be the functor represented by Y', and set $F' = \underline{\mathrm{Map}}_{/Z}(X, Y')$. Then $F|_{\mathrm{CAlg}^{\heartsuit}} \simeq F'|_{\mathrm{CAlg}^{\heartsuit}}$.

Consequently, we are free to replace Y by Y' and reduce the case where $\mathsf{Y} = \operatorname{Spét} R \times_{\operatorname{Spét} R_\alpha} \mathsf{Y}_\alpha$. We may then replace R by R_α, thereby reducing to the case where R is finitely generated as a commutative ring. In particular, R is a Grothendieck ring (Theorem **??**), so that the desired result follows from Proposition 19.1.5.1. □

We are now in a position to prove our main result.

Proof of Theorem 19.1.0.1. Let $\phi : \mathsf{S} \to \mathsf{S}'$ be a morphism of spectral Deligne-Mumford stacks which is proper, flat, and locally almost of finite presentation, let $\psi : \mathsf{X} \to \mathsf{S}$ be a relative spectral algebraic space which is quasi-separated and locally almost of finite presentation. Then ϕ and ψ determine natural transformations $X \to S \to S'$ between functors $X, S, S' : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. We wish to show that $\mathrm{Res}_{S/S'}(X)$ is representable by a quasi-separated spectral algebraic space which is locally almost of finite presentation over S'. The assertion is local on S', so we may assume without loss of generality that $\mathsf{S}' \simeq \operatorname{Spét} R$ is affine. Write X as a union of quasi-compact open substacks X_α, representing functors $X_\alpha : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. It follows from Proposition 19.1.6.1 that each of the functors $\underline{\mathrm{Map}}_{/S'}(S, X_\alpha)$ and $\underline{\mathrm{Map}}_{/S'}(S, S)$ is representable by a quasi-separated spectral algebraic space, so that $\mathrm{Res}_{S'/S}(X_\alpha) = \underline{\mathrm{Map}}_{/S'}(S, X_\alpha) \times_{\underline{\mathrm{Map}}_{S'}(S,S)} S'$ is also representable by a quasi-separated spectral algebraic space $\mathrm{Res}_{\mathsf{S}/\mathsf{S}'}(\mathsf{X}_\alpha)$. Note that the transition maps $\mathrm{Res}_{\mathsf{S}/\mathsf{S}'}(\mathsf{X}_\alpha) \to \mathrm{Res}_{\mathsf{S}/\mathsf{S}'}(\mathsf{X}_\beta)$ are quasi-compact open immersions (see the proof of Proposition 19.1.1.1), so that the filtered colimit $\varinjlim_\alpha \mathrm{Res}_{\mathsf{S}/\mathsf{S}'}(\mathsf{X}_\alpha)$ is also a quasi-separated spectral algebraic space which represents the functor $\mathrm{Res}_{S/S'}(\varinjlim X_\alpha) = \mathrm{Res}_{S/S'}(X)$. To complete the proof, it will suffice to show that the colimit $\varinjlim_\alpha \mathrm{Res}_{\mathsf{S}/\mathsf{S}'}(\mathsf{X}_\alpha)$ is locally almost of finite presentation over S'. By virtue of Proposition 17.4.3.1, this is equivalent to the requirement that the projection map $\mathrm{Res}_{S/S'}(X) \to S'$ is locally almost of finite presentation, which follows from Corollary 19.1.3.2. □

19.2 The Picard Functor

Let X be a projective algebraic variety over a field κ. The *Picard group* of X is defined to be the group of isomorphism classes of line bundles on X. Under mild hypotheses, one can show that the Picard group of X itself has the structure of an algebraic variety over κ. More precisely, there exists a group scheme E over κ (usually not quasi-compact) whose group $E(\kappa)$ of κ-valued points is canonically isomorphic to the Picard group of X. Our goal in this section is to prove an analogous result in the setting of spectral algebraic geometry.

Construction 19.2.0.1 (The Picard Functor)**.** For every spectral Deligne-Mumford stack X, we let $\mathscr{P}\mathrm{ic}(\mathsf{X})$ denote the full subcategory of $\mathrm{QCoh}(\mathsf{X})^{\simeq}$ spanned by those quasi-coherent sheaves which are locally free of rank 1 (see Definition 2.9.4.1). The construction $\mathsf{X} \mapsto \mathscr{P}\mathrm{ic}(\mathsf{X})$

determines a contravariant functor from the ∞-category SpDM of spectral Deligne-Mumford stacks to the ∞-category of spaces.

Let R be a connective $\mathbb{E}_\infty$-ring and let $f : \mathsf{X} \to \operatorname{Spét} R$ be a map of spectral Deligne-Mumford stacks. We define a functor $\mathscr{P}\mathrm{ic}_{\mathsf{X}/R} : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ by the formula

$$\mathscr{P}\mathrm{ic}_{\mathsf{X}/R}(R') = \mathscr{P}\mathrm{ic}(\operatorname{Spét} R' \times_{\operatorname{Spét} R} \mathsf{X}).$$

In general, it is not reasonable to expect the functor $\mathscr{P}\mathrm{ic}_{\mathsf{X}/R}$ to be representable by a spectral Deligne-Mumford stack over R, because it does not have unramified diagonal: line bundles on X can admit continuous families of automorphisms. To address this issue, we introduce a rigidification of the functor $\mathscr{P}\mathrm{ic}_{\mathsf{X}/R}$:

Definition 19.2.0.2. Let $f : \mathsf{X} \to \mathsf{Y} = \operatorname{Spét} R$ be a map of spectral Deligne-Mumford stacks, and suppose that f admits a section $x : \mathsf{Y} \to \mathsf{X}$. Then pullback along x determines a natural transformation of functors $\mathscr{P}\mathrm{ic}_{\mathsf{X}/R} \to \mathscr{P}\mathrm{ic}_{\mathsf{Y}/R}$. We will denote the fiber of this map by $\mathscr{P}\mathrm{ic}^x_{\mathsf{X}/R} : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$.

More informally, the functor $\mathscr{P}\mathrm{ic}^x_{\mathsf{X}/R}$ assigns to every connective R-algebra R' a classifying space for pairs $(\mathscr{L}, \alpha)$, where $\mathscr{L}$ is a line bundle on $\operatorname{Spét} R' \times_{\operatorname{Spét} R} \mathsf{X}$ and α is an equivalence of R'-modules $R' \to x'^* \mathscr{L}$, where $x' : \operatorname{Spét} R' \to \operatorname{Spét} R' \times_{\operatorname{Spét} R} \mathsf{X}$ is the map determined by x.

Remark 19.2.0.3. In the situation of Definition 19.2.0.2, the fiber sequence

$$\mathscr{P}\mathrm{ic}^x_{\mathsf{X}/R} \to \mathscr{P}\mathrm{ic}_{\mathsf{X}/R} \to \mathscr{P}\mathrm{ic}_{\mathsf{Y}/R}$$

is canonically split by the map $\mathscr{P}\mathrm{ic}_{\mathsf{Y}/R} \mapsto \mathscr{P}\mathrm{ic}_{\mathsf{X}/R}$ given by pullback along the projection $f : \mathsf{X} \to \mathsf{Y}$. It follows that we have an equivalence of functors $\mathscr{P}\mathrm{ic}^x_{\mathsf{X}/R} \times \mathscr{P}\mathrm{ic}_{\mathsf{Y}/R} \simeq \mathscr{P}\mathrm{ic}_{\mathsf{X}/R}$, given informally the formula $(\mathscr{L}, \mathscr{L}') \mapsto \mathscr{L} \otimes f^* \mathscr{L}'$.

Remark 19.2.0.4. Using Remark 19.2.0.3, one can show that the functor $\mathscr{P}\mathrm{ic}^x_{\mathsf{X}/R}$ of Definition 19.2.0.2 is independent of the section x, up to canonical equivalence. Moreover, the definition of $\mathscr{P}\mathrm{ic}^x_{\mathsf{X}/R}$ can be generalized to the case where f does not admit a section.

We are now ready to state our main result.

Theorem 19.2.0.5. *Let $f : \mathsf{X} \to \operatorname{Spét} R$ be a map of spectral algebraic spaces which is flat, proper, locally almost of finite presentation, geometrically reduced, and geometrically connected. For any section $x : \operatorname{Spét} R \to \mathsf{X}$ of f, the functor $\mathscr{P}\mathrm{ic}^x_{\mathsf{X}/R}$ is representable by a spectral algebraic space which is quasi-separated and locally of finite presentation over R.*

The analogue of Theorem 19.2.0.5 in classical algebraic geometry was proven by Artin as an application of his representability criterion. It is possible to use Theorem 18.1.0.2 to deduce Theorem 19.2.0.5 from its classical analogue. We will give a slightly different argument at the end of this section, which appeals instead to Theorem 18.3.0.1. The main point is to show that the functor $\mathscr{P}\mathrm{ic}^x_{\mathsf{X}/R}$ has a well-behaved deformation theory.

19.2.1 Deformations of Modules

Let us regard the construction $R \mapsto \mathrm{Mod}_R$ as a functor from the ∞-category $\mathrm{CAlg}^{\mathrm{cn}}$ of connective $\mathbb{E}_\infty$-rings to the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty$ of (not necessarily small) ∞-categories. Our first goal is to study the deformation theoretic properties of this functor (and some of its variants). Since the functor in question takes values in $\widehat{\mathcal{C}\mathrm{at}}_\infty$, rather than the ∞-category $\mathcal{S}$ of spaces, we will need a mild extension of the terminology of Chapter 17.

Definition 19.2.1.1. Let $\mathcal{C}$ be an ∞-category and let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{C}$ be a functor. We will say that X is *cohesive* (*infinitesimally cohesive*, *nilcomplete*, *integrable*) if, for every corepresentable functor $e : \mathcal{C} \to \mathcal{S}$, the composite functor $e \circ X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ is cohesive (infinitesimally cohesive, nilcomplete, integrable); see Remark **??**.

We will say that a natural transformation $\alpha : X \to Y$ between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{C}$ is *cohesive* (*infinitesimally cohesive*, *nilcomplete*, *integrable*) if, for every corepresentable functor $e : \mathcal{C} \to \widehat{\mathcal{S}}$, the induced natural transformation $e \circ X \to e \circ Y$ is cohesive (infinitesimally cohesive, nilcomplete, integrable), in the sense of Definition 17.3.7.1.

Remark 19.2.1.2. Let $\alpha : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Then α is cohesive (infinitesimally cohesive, nilcomplete, integrable) in the sense of Definition 19.2.1.1 if and only if it is cohesive (infinitesimally cohesive, nilcomplete, integrable) in the sense of Definition 17.3.7.1.

Proposition 19.2.1.3. *Let $F : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ denote the functor given by $R \mapsto \mathrm{Mod}_R^{\mathrm{acn}}$, where $\mathrm{Mod}_R^{\mathrm{acn}}$ denotes the full subcategory of Mod_R spanned by those objects which are almost connective (that is, n-connective for some integer n). Then the functor F is cohesive and nilcomplete.*

Corollary 19.2.1.4. *Let $F' : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{C}\mathrm{at}_\infty$ denote the functor given by $R \mapsto \mathrm{Mod}_R^{\mathrm{perf}}$. Then the functor F' is cohesive, nilcomplete, and commutes with filtered colimits.*

Proof. Let $F : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ be as in Proposition 19.2.1.3, so there is an evident natural transformation $\alpha : F' \to F$. The natural transformation α is cohesive (Proposition 16.2.3.1) and nilcomplete (Proposition 2.7.3.2). Since F is cohesive and nilcomplete, we conclude that F' is cohesive and nilcomplete. The assertion that F' commutes with filtered colimits follows from Corollary 4.5.1.3 and Lemma HA.7.3.5.11 . □

We now turn to the proof of Proposition 19.2.1.3. The assertion that the functor $R \mapsto \mathrm{Mod}_R^{\mathrm{acn}}$ is cohesive follows from Theorem 16.2.0.2. Nilcompleteness is a consequence of the following more general assertion:

Proposition 19.2.1.5. *For every connective $\mathbb{E}_1$-ring R, let $\mathrm{LMod}_R^{\mathrm{acn}}$ denote the full subcategory of LMod_R spanned by the almost connective objects. Then the canonical map*

$$\mathrm{LMod}_R^{\mathrm{acn}} \to \varprojlim \mathrm{LMod}_{\tau_{\leqslant n} R}^{\mathrm{acn}}$$

is an equivalence of ∞-categories.

Proof. We can identify objects of $\varprojlim \mathrm{LMod}^{\mathrm{acn}}_{\tau_{\leqslant n}R}$ with a sequences of objects $\{M_n \in \mathrm{LMod}^{\mathrm{acn}}_{\tau_{\leqslant n}R}\}$ together with equivalences $\alpha_n : M_n \simeq (\tau_{\leqslant n}R) \otimes_{\tau_{\leqslant n+1}R} M_{n+1}$. Using the assumption that M_{n+1} is almost connective, we deduce that M_n is nonzero if and only if M_{n+1} is nonzero. Suppose that M_0 is nonzero, so that M_n is nonzero for every integer n. Then there is some smallest integer $k(n)$ for which $\pi_{k(n)}M_n \neq 0$. Using the isomorphisms α_n, we deduce that all of the integers $k(n)$ are the same; let us denote this common value by k. For each integer n, the fiber of the canonical map $M_{n+1} \to M_n$ is given by the tensor product

$$\mathrm{fib}(\tau_{\leqslant n+1}R \to \tau_{\leqslant n}R) \otimes_{\tau_{\leqslant n+1}R} M_{n+1},$$

and is therefore $(k+n+1)$-connective. It follows that each of the towers of abelian groups $\{\pi_j M_n\}_{n \geqslant 0}$ are constant for $n \geqslant j-k$. Let $M = \varprojlim M_n$, so that the Milnor exact sequences

$$0 \to \lim{}^1\{\pi_{j+1}M_n\} \to \pi_j M \to \lim{}^0\{\pi_j M_n\} \to 0$$

specialize to give isomorphisms $\pi_j M \to \pi_j M_n$ for $n \geqslant j-k$. In particular, we deduce that M is k-connective. We conclude that the functor F admits a right adjoint $G : \varprojlim \mathrm{LMod}^{\mathrm{acn}}_{\tau_{\leqslant n}R} \to \mathrm{LMod}^{\mathrm{acn}}_R$, given by $\{M_n\}_{n \geqslant 0} \mapsto \varprojlim M_n$.

We next show that the unit map $\mathrm{id} \to G \circ F$ is an equivalence of functors from $\mathrm{LMod}^{\mathrm{acn}}_R$ to itself. Let M be a k-connective R-module; we wish to show that the canonical map $M \to \varprojlim (\tau_{\leqslant n}R) \otimes_R M$ is an equivalence. Fix an integer j, and consider the composition

$$\pi_j M \xrightarrow{\phi} \pi_j \varprojlim (\tau_{\leqslant n}R) \otimes_R M \xrightarrow{\psi} \pi_j (\tau_{\leqslant n}R) \otimes_R M.$$

Using the analysis above, we see that ψ is an isomorphism for $n \geqslant j-k$. It will therefore suffice to show that $\psi \circ \phi$ is an isomorphism for $n \geqslant j-k$. This follows from the existence of an exact sequence of abelian groups

$$\pi_j(\tau_{\geqslant n+1}R \otimes_R M) \to \pi_j M \to \pi_j(\tau_{\leqslant n}R \otimes_R M) \to \pi_{j-1}(\tau_{\geqslant n+1}R \otimes_R M),$$

since the k-connectivity of M implies that the abelian groups $\pi_j(\tau_{\geqslant n+1}R \otimes_R M)$ and $\pi_{j-1}(\tau_{\geqslant n+1}R \otimes_R M)$ are trivial.

To complete the proof, it will suffice to show that the functor G is conservative Since G is an exact functor between stable ∞-categories, we are reduced to proving that if $\{M_n\}_{n \geqslant 0}$ is an object of $\varprojlim \mathrm{LMod}^{\mathrm{acn}}_{\tau_{\leqslant n}R}$ such that $\varprojlim M_n \simeq 0$, then each M_n vanishes. Assume otherwise, and let k be defined as above. Then $\pi_k \varprojlim M_n \simeq \pi_k M_0 \neq 0$, and we obtain a contradiction. □

19.2.2 The Atiyah Class

Our next goal is to compute the cotangent complex of the functor appearing in Corollary 19.2.1.4. We begin with a more general discussion.

Notation 19.2.2.1. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ be a spectral Deligne-Mumford stack, let $\mathscr{E} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$, and let $\eta \in \mathrm{Der}(\mathscr{O}_{\mathsf{X}}, \Sigma\mathscr{E})$ (see Definition 17.1.1.1). We let $\mathscr{O}_{\mathsf{X}}^{\eta}$ denote the square-zero extension of $\mathscr{O}_{\mathsf{X}}$ be $\mathscr{E}$ determined by η (Construction 17.1.3.1), so that we have a pullback diagram

$$\begin{array}{ccc} \mathscr{O}_{\mathsf{X}}^{\eta} & \longrightarrow & \mathscr{O}_{\mathsf{X}} \\ \downarrow & & \downarrow \eta \\ \mathscr{O}_{\mathsf{X}} & \longrightarrow & \mathscr{O}_{\mathsf{X}} \oplus \Sigma\mathscr{E}. \end{array}$$

The pair $(\mathcal{X}, \mathscr{O}_{\mathsf{X}}^{\eta})$ is a spectral Deligne-Mumford stack (Proposition 17.1.3.4), which we will denote by X^{η}. In the special case where $\eta = 0$, we will denote X^{η} by $\mathsf{X}^{\mathcal{E}} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}} \oplus \mathscr{E})$.

In the situation of Notation 19.2.2.1, we have a pushout diagram of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathsf{X}^{\Sigma\mathscr{E}} & \xrightarrow{u} & \mathsf{X} \\ \downarrow & & \downarrow \\ \mathsf{X} & \longrightarrow & \mathsf{X}^{\eta} \end{array}$$

where the maps are closed immersions. Applying Theorem 16.2.0.1, we deduce that the diagram of pullback functors

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{X}^{\eta})^{\mathrm{acn}} & \longrightarrow & \mathrm{QCoh}(\mathsf{X})^{\mathrm{acn}} \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{X})^{\mathrm{acn}} & \longrightarrow & \mathrm{QCoh}(\mathsf{X}^{\Sigma\mathscr{E}})^{\mathrm{cn}} \end{array}$$

is a pullback square. Taking $\eta = 0$ and passing to homotopy fibers over some fixed object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{acn}}$, we obtain equivalences

$$\begin{aligned} \mathrm{QCoh}(\mathsf{X}^{\mathscr{E}})^{\mathrm{acn}} \times_{\mathrm{QCoh}(\mathsf{X})} \{\mathscr{F}\} &\simeq \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X}^{\Sigma\mathscr{E}})}(u^*\mathscr{F}, u^*\mathscr{F}) \times_{\mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F},\mathscr{F})} \{\mathrm{id}_{\mathscr{F}}\} \\ &\simeq \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, u_* u^*\mathscr{F}) \times_{\mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F},\mathscr{F})} \{\mathrm{id}_{\mathscr{F}}\} \\ &\simeq \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, \mathscr{F} \oplus (\Sigma\mathscr{E} \otimes \mathscr{F})) \times_{\mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F},\mathscr{F})} \{\mathrm{id}_{\mathscr{F}}\} \\ &\simeq \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, \Sigma(\mathscr{E} \otimes \mathscr{F})); \end{aligned}$$

here the first equivalence follows from the observation that any lifting of $\mathrm{id}_{\mathscr{F}}$ to an endomorphism of $u^*\mathscr{F}$ is automatically invertible. We can summarize the situation as follows:

Proposition 19.2.2.2 (First-Order Deformations of Quasi-Coherent Sheaves)**.** *Let* X *be a spectral Deligne-Mumford stack and suppose we are given quasi-coherent sheaves* $\mathscr{E} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$*,* $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{acn}}$*. Then the* ∞*-category* $\mathrm{QCoh}(\mathsf{X}^{\mathscr{E}}) \times_{\mathrm{QCoh}(\mathsf{X})} \{\mathscr{F}\}$ *is a Kan complex, which is canonically homotopy equivalent to the mapping space* $\mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, \Sigma(\mathscr{E} \otimes \mathscr{F}))$*. In particular, we obtain a canonical bijection*

$$\pi_0 \,\mathrm{QCoh}(\mathsf{X}^{\mathscr{E}}) \times_{\mathrm{QCoh}(\mathsf{X})} \{\mathscr{F}\} \simeq \mathrm{Ext}^1_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, \mathscr{E} \otimes \mathscr{F}).$$

In the situation of Proposition 19.2.2.2, suppose that $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is perfect. Then $\mathscr{F}$ admits a dual $\mathscr{F}^\vee$ in $\mathrm{QCoh}(\mathsf{X})$, and we have a canonical homotopy equivalence

$$\mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, \Sigma(\mathscr{E} \otimes \mathscr{F})) \simeq \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\Sigma^{-1}(\mathscr{F} \otimes \mathscr{F}^\vee), \mathscr{E}).$$

We now wish to apply this observation to the classification of perfect complexes.

Corollary 19.2.2.3. *Let* $\mathrm{Perf}^{\simeq} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ *denote the functor given by* $\mathrm{Perf}^{\simeq}(R) = (\mathrm{Mod}_R^{\mathrm{perf}})^{\simeq}$*. Then* $\mathrm{Perf}^{\simeq}$ *admits a (perfect) cotangent complex.*

Proof. We will show that conditions (a) and (b) of Example 17.2.4.4 are satisfied:

(a) Let R be a connective $\mathbb{E}_\infty$-ring and let $\eta \in \mathrm{Perf}^{\simeq}(R)$, corresponding to a perfect R-module N. Let $F : \mathrm{Mod}_R^{\mathrm{cn}} \to \mathcal{S}$ be the functor defined by the formula $F(M) = \mathrm{Perf}^{\simeq}(R \oplus M) \times_{\mathrm{Perf}^{\simeq}(R)} \{\eta\}$. Applying Proposition **??**, we see that F is almost corepresented by the perfect R-module $\Sigma^{-1}(N \otimes_R N^\vee)$.

(b) For every map of connective $\mathbb{E}_\infty$-rings $R \to R'$ and every connective R'-module M, we must show that the diagram of spaces

$$\begin{array}{ccc} \mathrm{Perf}^{\simeq}(R \oplus M) & \xrightarrow{\theta} & \mathrm{Perf}^{\simeq}(R' \oplus M) \\ \downarrow & & \downarrow \\ \mathrm{Perf}^{\simeq}(R) & \longrightarrow & \mathrm{Perf}^{\simeq}(R') \end{array}$$

is a pullback square. Choose a point $\eta \in \mathrm{Perf}(R)$ corresponding to a perfect R-module N, and let $\eta' \in \mathrm{Perf}(R')$ be its image (corresponding to the perfect R'-module $R' \otimes_R N$). We will prove that θ induces a homotopy equivalence after passing to the homotopy fibers over the points η and η', respectively. Using the proof of (a), we are reduced to showing that the canonical map

$$\mathrm{Map}_{\mathrm{Mod}_R}(N \otimes_R N^\vee, \Sigma M) \to \mathrm{Map}_{\mathrm{Mod}_{R'}}(N' \otimes_{R'} N'^\vee, \Sigma M)$$

is a homotopy equivalence, which is clear.

□

Remark 19.2.2.4. In the situation of Corollary 19.2.2.3, we can be more precise. There is a "universal" perfect quasi-coherent sheaf $\mathscr{F} \in \mathrm{QCoh}(\mathrm{Perf}^{\simeq})$, and the proof of Corollary 19.2.2.3 shows that the cotangent complex $L_{\mathrm{Perf}^{\simeq}}$ can be identified with $\Sigma^{-1}(\mathscr{F} \otimes \mathscr{F}^{\vee})$.

Construction 19.2.2.5 (The Atiyah Class)**.** Let X be a spectral Deligne-Mumford stack, let $\mathscr{E} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$, let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{acn}}$, and let $\eta \in \mathrm{Der}(\mathscr{O}_{\mathsf{X}}, \mathscr{E})$ be a derivation. Then we can identify η with a left homotopy inverse s of the evident map $\mathsf{X} \to \mathsf{X}^{\mathscr{E}}$. The pullback $s^* \mathscr{F}$ can be regarded as an object of the ∞-category $\mathrm{QCoh}(\mathsf{X}^{\mathscr{E}})^{\mathrm{acn}} \times_{\mathrm{QCoh}(\mathsf{X})} \{\mathscr{F}\}$, which (by virtue of Proposition 19.2.2.2) we can identify with a map $\rho_\eta : \mathscr{F} \to \Sigma(\mathscr{E} \otimes \mathscr{F})$ in the ∞-category $\mathrm{QCoh}(\mathsf{X})$.

Specializing to the case where $\mathscr{E} = L_{\mathsf{X}}$ and η is the universal derivation, we obtain a map $\rho_{\mathrm{univ}} : \mathscr{F} \to \Sigma(L_{\mathsf{X}} \otimes \mathscr{F})$. We will refer to ρ_{univ} as the *Atiyah class* of the quasi-coherent sheaf $\mathscr{F}$. In the special case where $\mathscr{F}$ is perfect, we can identify ρ_{univ} with a map $\Sigma^{-1}(\mathscr{F} \otimes \mathscr{F}^{\vee}) \to L_{\mathsf{X}}$, which can be understood as the "derivative" of the map $\mathsf{X} \to \mathrm{Perf}^{\simeq}$ which classifies $\mathscr{F}$.

Remark 19.2.2.6 (Obstruction Theoretic Interpretation of the Atiyah Class)**.** In the situation of Construction 19.2.2.5, suppose that $\mathscr{E} \in \mathrm{QCoh}(\mathsf{X})$ is 1-connective, so that the derivation $\eta \in \mathrm{Der}(\mathscr{O}_{\mathsf{X}}, \mathscr{E})$ determines a square-zero extension $\mathscr{O}_{\mathsf{X}}^{\eta}$ of $\mathscr{O}_{\mathsf{X}}$ by $\Sigma^{-1} \mathscr{E}$. Using Theorem 16.2.0.1, we see that the following conditions are equivalent:

(*a*) The map ρ_η of Construction 19.2.2.5 is nullhomotopic.

(*b*) The object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{acn}}$ can be lifted to an object of $\mathrm{QCoh}(\mathsf{X}^{\eta})$.

Conditions (*a*) and (*b*) are equivalent to the vanishing of a certain obstruction class $o(\eta) \in \mathrm{Ext}^2_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F} \otimes \mathscr{F}^{\vee}, \Sigma^{-1} \mathscr{E})$, which is given by the product of the Atiyah class $[\rho_{\mathrm{univ}}] \in \mathrm{Ext}^1_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F} \otimes \mathscr{F}^{\vee}, L_{\mathsf{X}}))$ with the homotopy class $[\eta] \in \mathrm{Ext}^1_{\mathrm{QCoh}(\mathsf{X})}(L_{\mathsf{X}}, \Sigma^{-1} \mathscr{E})$ of the derivation η.

19.2.3 Diagrams of Perfect Complexes

For later applications, it will be convenient to study the deformation theory of diagrams $K \to \mathrm{Perf}(R)$, where K is a simplicial set.

Notation 19.2.3.1. For every simplicial set K, we let $\mathrm{Perf}_K : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ denote the functor given by the formula $\mathrm{Perf}_K(R) = \mathrm{Fun}(K, \mathrm{Mod}_R^{\mathrm{perf}})^{\simeq}$. If $K = \Delta^0$, we will denote the functor Perf_K simply by Perf.

Example 19.2.3.2. When $K = \Delta^0$, the functor Perf_K of Notation 19.2.3.1 coincides with the functor $\mathrm{Perf}^{\simeq}$ of Corollary 19.2.2.3.

Proposition 19.2.3.3. *Let K be a simplicial set. Then the functor $\mathrm{Perf}_K : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ is cohesive, nilcomplete, and admits a cotangent complex. If K is finite, then Perf_K commutes with filtered colimits and the cotangent complex L_{Perf_K} is perfect.*

Lemma 19.2.3.4. *Let R be a connective $\mathbb{E}_\infty$-ring, let M and N be R-modules, and define a functor $F : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ by the formula $F(R') = \mathrm{Map}_{\mathrm{Mod}_{R'}}(R' \otimes_R M, R' \otimes_R N) \simeq \mathrm{Map}_{\mathrm{Mod}_R}(M, R' \otimes_R N)$. Let $\overline{F}$ denote the image of F under the equivalence of ∞-categories $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}_R, \mathcal{S}) \simeq \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/\operatorname{Spec} R}$. If M is almost connective and N is perfect, then the map $\alpha : \overline{F} \to \operatorname{Spec} R$ admits a cotangent complex. Moreover, there is a canonical equivalence*

$$L_{\overline{F}/\operatorname{Spec} R} \simeq \alpha^*(M \otimes N^\vee),$$

where $N^\vee$ denotes the R-linear dual of N.

Proof. For every connective R-algebra R' and every connective R'-module Q, the fiber of the canonical map $F(R' \oplus Q) \to F(R')$ is given by $\mathrm{Map}_{\mathrm{Mod}_R}(M, Q \otimes_R N) \simeq \mathrm{Map}_{\mathrm{Mod}_R}(M \otimes N^\vee, Q)$. □

Proof of Proposition 19.2.3.3. The assertion that Perf_K is cohesive and nilcomplete follows from Corollary 19.2.1.4. We next show that Perf_K admits a cotangent complex. Writing K as a filtered colimit of finite simplicial sets (and using Remark 17.2.4.5), we can reduce to the case where K is finite. We proceed by induction on the dimension d of K and the number of nondegenerate d-simplices of K. If K is empty, there is nothing to prove. Otherwise, we can choose a pushout diagram of simplicial sets

$$\begin{array}{ccc} \partial \Delta^d & \longrightarrow & \Delta^d \\ \downarrow & & \downarrow \\ K' & \longrightarrow & K. \end{array}$$

Our inductive hypothesis implies that $\mathrm{Perf}_{K'}$ admits a cotangent complex. Using Proposition 17.3.9.1, we are reduced to showing that the restriction map $\mathrm{Perf}_K \to \mathrm{Perf}_{K'}$ admits a relative cotangent complex. We have a pullback diagram of functors

$$\begin{array}{ccc} \mathrm{Perf}_{\partial \Delta^d} & \xleftarrow{\beta} & \mathrm{Perf}_{\Delta^d} \\ \uparrow & & \uparrow \\ \mathrm{Perf}_{K'} & \longleftarrow & \mathrm{Perf}_K, \end{array}$$

so it will suffice to show that the map β admits a relative cotangent complex. If $d = 0$, this follows from Corollary 19.2.2.3. If $d = 1$, it follows from Lemma 19.2.3.4. For $d \geqslant 2$, we can choose a categorical equivalence $T \hookrightarrow \Delta^d$, where $T = \Delta^{\{0,1\}} \amalg_{\{1\}} \cdots \amalg_{\{d-1\}} \Delta^{\{d-1,d\}}$.

Our inductive hypothesis then implies that $\mathrm{Perf}_{\partial \Delta^d}$ and $\mathrm{Perf}_T \simeq \mathrm{Perf}_{\Delta^d}$ admit cotangent complexes, so that β admits a relative cotangent complex by virtue of Proposition 17.2.5.2.

To complete the proof, we observe that if K is finite then the functor Perf_K commutes with filtered colimits by virtue of Corollary 19.2.1.4. In this case, Proposition 17.4.2.3 implies that the cotangent complex L_{Perf_K} is perfect (this also follows from the proof given above). □

We now consider a relative version of Proposition 19.2.3.3.

Proposition 19.2.3.5. *Let R be a connective $\mathbb{E}_\infty$-ring and $f : \mathsf{X} \to \mathrm{Spét}\, R$ be a map of spectral Deligne-Mumford stacks. Define a functor $\mathrm{Perf}_{\mathsf{X}/R} : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ by the formula*

$$\mathrm{Perf}_{\mathsf{X}/R}(R') = \mathrm{QCoh}(\mathrm{Spét}\, R' \times_{\mathrm{Spét}\, R} \mathsf{X})^{\mathrm{perf},\simeq}.$$

Let F denote the image of $\mathrm{Perf}_{\mathsf{X}/R}$ under the equivalence of ∞-categories $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}_R, \mathcal{S}) \simeq \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/\,\mathrm{Spec}\, R}$. Then:

(1) *The functor F is nilcomplete and cohesive.*

(2) *Assume that X is a quasi-compact, quasi-separated spectral algebraic space. Then the natural transformation $F \to \mathrm{Spec}\, R$ is locally of finite presentation.*

(3) *Assume that f is proper and locally almost of finite presentation. Then the functor F is integrable.*

(4) *Assume that f is proper, locally almost of finite presentation, and locally of finite* Tor*-amplitude. Then the natural transformation $u : F \to \mathrm{Spec}\, R$ admits a perfect cotangent complex.*

Proof. Assertions (1), (2) and (4) follow from Proposition 19.1.3.1, Proposition **??**, Remark 19.1.4.2, and Proposition 19.2.3.3. To prove (3), suppose that X is a spectral algebraic space which is proper and locally almost of finite presentation over R; we wish to show that F is integrable. Let A is a local Noetherian $\mathbb{E}_\infty$-ring which is complete with respect to its maximal ideal and let $\mathrm{Spf}\, A$ denote the formal spectrum of A, which we regard as an object of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. We wish to show that if $R \to A$ is a morphism of $\mathbb{E}_\infty$-rings, then the restriction functor

$$\theta : \mathrm{QCoh}(\mathrm{Spét}\, A \times_{\mathrm{Spét}\, R} \mathsf{X})^{\mathrm{perf}} \to \mathrm{QCoh}(\mathrm{Spf}\, A \times_{\mathrm{Spét}\, R} \mathsf{X})^{\mathrm{perf}}$$

is an equivalence of ∞-categories. Using Theorem 8.5.0.3 (together with Corollary 8.3.4.6 and Theorem 8.3.5.2), we deduce that the restriction functor

$$\overline{\theta} : \mathrm{QCoh}(\mathrm{Spét}\, A \times_{\mathrm{Spét}\, R} \mathsf{X})^{\mathrm{aperf}} \to \mathrm{QCoh}(\mathrm{Spf}\, A \times_{\mathrm{Spét}\, R} \mathsf{X})^{\mathrm{aperf}},$$

is an equivalence of symmetric monoidal ∞-categories. We now observe that θ is obtained from $\overline{\theta}$ by restricting to the dualizable objects of $\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X})^{\mathrm{aperf}}$ and $\mathrm{QCoh}(\mathrm{Spf}\, A \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X})^{\mathrm{aperf}}$, respectively. $\square$

Remark 19.2.3.6. In the situation of Proposition 19.2.3.5, we describe the relative cotangent complex $L_{F/\operatorname{Spec} R}$ explicitly. Suppose we are given a point $\eta \in F(A)$, corresponding to a map of connective $\mathbb{E}_\infty$-rings $R \to A$ and a perfect object $\mathscr{F} \in \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X})$. Let $f' : \mathrm{Sp\acute{e}t}\, A \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X} \to \mathrm{Sp\acute{e}t}\, A$ denote the projection onto the first factor. Combining Remark 19.2.2.4 with Proposition 19.1.4.3, we see that $\eta^* L_{F/\operatorname{Spec} R} \in \mathrm{QCoh}(\operatorname{Spec} A) \simeq \mathrm{Mod}_A$ can be identified with $\Sigma^{-1} f'_+(\mathscr{F} \otimes \mathscr{F}^\vee) \simeq \Sigma^{-1} f'_*(\mathscr{F} \otimes \mathscr{F}^\vee)^\vee$, where f'_+ is the functor of Construction 6.4.5.1.

19.2.4 Vector Bundles

We now show that the results of §19.2.2 remain valid if we restrict our attention to perfect complexes which are locally free. First, we need a brief digression.

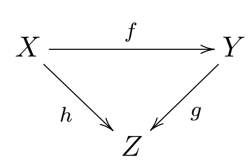
Definition 19.2.4.1. Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. We say that f is an *open immersion* if, for every map $\operatorname{Spec} R \to Y$, the fiber product $X \times_Y \operatorname{Spec} R$ is representable by a spectral Deligne-Mumford stack X_R, and the projection $\mathsf{X}_R \to \mathrm{Sp\acute{e}t}\, R$ is an open immersion (see Example 6.3.3.6). We note that f is an open immersion if and only the following conditions are satisfied:

(a) For every connective $\mathbb{E}_\infty$-ring R, the map $X(R) \to Y(R)$ induces a homotopy equivalence from $X(R)$ to a summand $Y_0(R) \subseteq Y(R)$.

(b) For every point $\eta \in Y(R)$, there exists an open subset $U \subseteq |\operatorname{Spec} R|$ with the following property: if $R \to R'$ is a map of connective $\mathbb{E}_\infty$-rings, then the image of η in $Y(R')$ belong to $Y_0(R')$ if and only if the map of topological spaces $|\operatorname{Spec} R'| \to |\operatorname{Spec} R|$ factors through U.

Remark 19.2.4.2. Let $f : X \to Y$ be an open immersion of functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Then f is cohesive, nilcomplete, integrable, and admits a cotangent complex (Corollary 17.3.8.5). Moreover, the relative cotangent complex $L_{X/Y}$ is a zero object of $\mathrm{QCoh}(X)$. Using Proposition 17.4.3.1, we deduce that f is locally of finite presentation.

Proposition 19.2.4.3. *Suppose we are given a commutative diagram*



in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. *Assume that f is an open immersion. If g is cohesive (infinitesimally cohesive, nilcomplete, integrable, locally of finite presentation to order n, locally almost of finite presentation, locally of finite presentation), then h has the same property. If g admits a cotangent complex, then so does h; moreover, we have a canonical equivalence $L_{X/Z} \simeq f^* L_{Y/Z}$ in* $\mathrm{QCoh}(X)$.

Proof. The first assertions follow from Remark 19.2.4.2. The existence of a cotangent complex $L_{X/Z}$ follows from the existence of $L_{Y/Z}$ by virtue of the criterion supplied by Remark 17.2.4.3. □

Definition 19.2.4.4. Let $\mathrm{Perf} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be the functor defined in Proposition 19.2.3.3. For every connective $\mathbb{E}_\infty$-ring R, we let $\mathrm{Vect}_{\simeq}(R)$ denote the summand of $\mathrm{Perf}(R)$ spanned by those perfect R-modules M which are locally free of finite rank over R, and $\mathrm{Vect}_n(R)$ the summand of $\mathrm{Perf}(R)$ spanned by those perfect R-modules which are locally free of rank n over R.

Using Proposition 2.9.3.2 and Lemma 2.9.3.4, we deduce the following:

Proposition 19.2.4.5. *For every integer $n \geqslant 0$, the inclusions $\mathrm{Vect}_n \hookrightarrow \mathrm{Vect}_{\simeq} \hookrightarrow \mathrm{Perf}$ are open immersions.*

Corollary 19.2.4.6. *The functor $\mathrm{Vect}_{\simeq} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ is cohesive, nilcomplete, locally of finite presentation, and admits a perfect cotangent complex. Moreover, if $\eta \in \mathrm{Vect}_{\simeq}(R)$ classifies a locally free R-module M of finite rank, then $\eta^* L_{\mathrm{Vect}_{\simeq}} \in \mathrm{Mod}_R$ can be identified with the R-module $\Sigma^{-1}(M \otimes_R M^\vee)$.*

For every integer $n \geqslant 0$, the functor $\mathrm{Vect}_n : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ is also cohesive, nilcomplete, locally of finite presentation and admits a perfect cotangent complex, given by the image of L_{Vect_n} in $\mathrm{QCoh}(\mathrm{Vect}_n)$.

Proof. Combine Proposition 19.2.3.3, Remark 19.2.2.4, Proposition 19.2.4.5, and Proposition 19.2.4.3. □

We now specialize to the study of locally free sheaves of rank 1.

Proposition 19.2.4.7. *Let R be a connective $\mathbb{E}_\infty$-ring and $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ be a map of spectral Deligne-Mumford stacks. Let F denote the image of the functor $\mathscr{P}\mathrm{ic}_{\mathsf{X}/R}$ under the equivalence of ∞-categories $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}_R, \mathcal{S}) \simeq \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/\mathrm{Spec}\, R}$. Then:*

(1) *The functor F is nilcomplete and cohesive.*

(2) *Assume that X is a quasi-compact, quasi-separated spectral algebraic space. Then the natural transformation $F \to \mathrm{Spec}\, R$ is locally of finite presentation.*

(3) *Assume that* X *is a spectral algebraic space which is proper and locally almost of finite presentation over* R*. Then* F *is integrable.*

(4) *Assume that* X *is a spectral algebraic space which is proper, locally almost of finite presentation, and locally of finite* Tor*-amplitude over* R*. Then the natural transformation* $F \to \operatorname{Spec} R$ *admits a perfect cotangent complex.*

Proof. Assertions (1), (2), and (4) follow from Proposition 19.1.3.1, Proposition **??**, Remark 19.1.4.2, and Corollary 19.2.4.6. To prove (3), let A be a local Noetherian $\mathbb{E}_\infty$-ring which is complete with respect to its maximal ideal and let $\operatorname{Spf} A$ denote the formal spectrum of A, which we regard as an object of $\operatorname{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. We must show that for any morphism of $\mathbb{E}_\infty$-rings $R \to A$, then the restriction map $\theta : \mathscr{P}\mathrm{ic}(\operatorname{Sp\acute{e}t} A \times_{\operatorname{Sp\acute{e}t} R} \mathsf{X}) \to \mathscr{P}\mathrm{ic}(\operatorname{Spf} A \times_{\operatorname{Sp\acute{e}t} R} \mathsf{X})$ is a homotopy equivalence. To prove this, we observe that Proposition 2.9.4.2 implies that θ is obtained from the symmetric monoidal forgetful functor

$$\overline{\theta} : \mathrm{QCoh}(\operatorname{Sp\acute{e}t} A \times_{\operatorname{Sp\acute{e}t} R} \mathsf{X})^{\mathrm{aperf,cn}} \to \mathrm{QCoh}(\operatorname{Spf} A \times_{\operatorname{Sp\acute{e}t} R} \mathsf{X})^{\mathrm{aperf,cn}}$$

by restricting to the subcategories spanned by invertible objects and equivalences between them. It now suffices to observe that $\overline{\theta}$ is an equivalence of symmetric monoidal ∞-categories (Theorems 8.5.0.3, 8.3.4.4, and 8.3.5.2). □

Remark 19.2.4.8. If $f : \mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to \operatorname{Sp\acute{e}t} R$ is proper, the inclusion $\mathscr{P}\mathrm{ic}_{\mathsf{X}/R} \hookrightarrow \mathrm{Perf}_{\mathsf{X}/R}$ is an open immersion of functors. In this case, we can deduce Proposition 19.2.4.7 from Propositions 19.2.3.5 and 19.2.4.3. Moreover, Remark 19.2.3.6 implies that the cotangent complex of the map $q : F \to \operatorname{Spec} R$ is given by $L_{F/\operatorname{Spec} R} \simeq \Sigma^{-1} q^*(f_* \mathscr{O}_{\mathcal{X}})^\vee$. In particular, the relative cotangent complex of F over $\operatorname{Spec} R$ is constant along the fibers of F. This is a reflection of the fact that the functor $\mathscr{P}\mathrm{ic}_{\mathsf{X}/R}$ admits a group structure, given by the formation of tensor products.

19.2.5 Representability of the Picard Functor

We now turn to the proof of Theorem 19.2.0.5. In fact, we will prove the following slightly stronger result (which implies Theorem 19.2.0.5, by virtue of Proposition 8.6.4.1:

Proposition 19.2.5.1. *Let* $f : \mathsf{X} \to \operatorname{Sp\acute{e}t} R$ *be a morphism of spectral algebraic spaces which is flat, proper, and locally almost of finite presentation. Suppose that the cofiber of the unit map* $u : R \to f_* \mathscr{O}_{\mathsf{X}}$ *has* Tor*-amplitude* $\leqslant -1$*, and let* $x : \operatorname{Sp\acute{e}t} R \to \mathsf{X}$ *be a section of* f*. Then the functor* $\mathscr{P}\mathrm{ic}^x_{\mathsf{X}/R}$ *is representable by a spectral algebraic space which is quasi-separated and locally of finite presentation over* R*.*

Proof. Let $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ denote the image of the functor $\mathscr{P}\mathrm{ic}^x_{\mathsf{X}/R}$ under the equivalence of ∞-categories $\operatorname{Fun}(\mathrm{CAlg}^{\mathrm{cn}}_R, \mathcal{S}) \simeq \operatorname{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/\operatorname{Spec} R}$. Let $Y' = Y \times_{\operatorname{Spec} R} \operatorname{Spec}(\pi_0 R)$.

We will prove that Y' is representable by a quasi-separated spectral algebraic space Y' which is locally almost of finite presentation over $\pi_0 R$. Note that the functors Y and Y' agree on discrete $\mathbb{E}_\infty$-rings. Since the functor Y is nilcomplete, infinitesimally cohesive, and admits a cotangent complex (Proposition 19.2.4.7), it will then follow that Y is representable by a spectral Deligne-Mumford stack Y (Theorem 18.1.0.2). Note that that $\tau_{\leqslant 0}\mathsf{Y} \simeq \tau_{\leqslant 0}\mathsf{Y}'$. Since Y' is a quasi-separated spectral algebraic space, it follows immediately that Y is also a quasi-separated spectral algebraic space. Since $L_{Y/\operatorname{Spec} R}$ is perfect (Proposition 19.2.4.7), Proposition 17.4.2.3 shows that Y is locally of finite presentation over R. We may therefore replace R by $\pi_0 R$ and thereby reduce to the case where R is discrete.

Write R as the union of finitely generated subrings R_α. Using Theorem 4.4.2.2, we can choose an index α, a spectral Deligne-Mumford stack X_α which is finitely 0-presented over R_α, and an equivalence $\mathsf{X} \simeq \tau_{\leqslant 0}(\operatorname{Spét} R \times_{\operatorname{Spét} R_\alpha} \mathsf{X}_\alpha)$. Enlarging α if necessary, we may suppose that X_α is a spectral algebraic space which is proper and flat over R_α (Propositions 5.5.4.1 and 6.1.6.1). Let $f_\alpha : \mathsf{X}_\alpha \to \operatorname{Spét} R_\alpha$ denote the projection map and let M denote the cofiber of the unit map $R_\alpha \to f_{\alpha *} \mathscr{O}_{\mathsf{X}_\alpha}$. Then M is a perfect R_α-module (Theorem 6.1.3.2) and $R \otimes_{R_\alpha} M$ has Tor-amplitude $\leqslant -1$. Let $M^\vee$ be the R_α-linear dual of M, so that $R \otimes_{R_\alpha} M^\vee$ is 1-connective. Enlarging α if necessary, we may suppose that $M^\vee$ is 1-connective, so that M has Tor-amplitude $\leqslant 1$. We may therefore replace R by R_α and X by X_α, and thereby reduce to the case where R is finitely generated as a commutative ring. In particular, we may assume that R is a Grothendieck ring.

We now prove that Y is representable by a spectral algebraic space which is locally almost of finite presentation over R by verifying hypotheses (1) through (5) of Theorem 18.3.0.1. Hypothesis (2) is obvious, and hypotheses (3) and (5) follow immediately from Proposition 19.2.4.7. Let us check the remaining conditions:

(1) For every discrete commutative ring A, the space $Y(A)$ is discrete. Equivalently, we must show that if A is a discrete R-algebra, then the space $\mathscr{P}\mathrm{ic}^x_{\mathsf{X}/R}(A)$ is discrete. Let A be a discrete R-algebra and let $\mathscr{L}$ be a line bundle on $\mathsf{X}_A = \operatorname{Spét} A \times_{\operatorname{Spét} R} \mathsf{X}$. Then the mapping space $\operatorname{Map}_{\operatorname{QCoh}(\mathsf{X}_A)}(\mathscr{L}, \mathscr{L})$ is given by

$$\begin{aligned}
\operatorname{Map}_{\operatorname{QCoh}(\mathsf{X}_A)}(\mathscr{O}_{\mathsf{X}}, \mathscr{L} \otimes \mathscr{L}^\vee) &\simeq \operatorname{Map}_{\operatorname{QCoh}(\mathsf{X}_A)}(\mathscr{O}_{\mathsf{X}}, \mathscr{O}_{\mathsf{X}}) \\
&\simeq \operatorname{Map}_{\operatorname{Mod}_A}(A, A \otimes_R f_* \mathscr{O}_{\mathsf{X}}) \\
&\simeq \Omega^\infty A \oplus \Omega^\infty(A \otimes_R \operatorname{cofib}(u)).
\end{aligned}$$

Our assumption on the Tor-amplitude of $\operatorname{cofib}(u)$ guarantees that $\operatorname{Map}_{\operatorname{QCoh}(\mathsf{X}_A)}(\mathscr{L}, \mathscr{L})$ is homotopy equivalent to the discrete commutative ring $\pi_0 A \simeq \Omega^\infty A$. In particular, if we let $x' : \operatorname{Spét} A \to \mathsf{X}_A$ denote the map induced by x, then pullback along x' induces a homotopy equivalence $\operatorname{Map}_{\operatorname{QCoh}(\mathsf{X}_A)}(\mathscr{L}, \mathscr{L}) \to \operatorname{Map}_{\operatorname{QCoh}(\operatorname{Spec} A)}(x'^* \mathscr{L}, x'^* \mathscr{L})$. It follows that the space $\mathscr{P}\mathrm{ic}^x_{\mathsf{X}/R}(A)$ is discrete.

(4) The natural transformation $Y \to \operatorname{Spec} R$ admits a connective cotangent complex $L_{Y/\operatorname{Spec} R}$. Let $Z : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be the image of the functor $\mathscr{P}\mathrm{ic}_{\mathsf{X}/R}$ under the equivalence of ∞-categories

$$\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}_R, \mathcal{S}) \simeq \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/\operatorname{Spec} R},$$

and let Z_0 be the image of $\mathscr{P}\mathrm{ic}_{\mathrm{Sp\acute{e}t}\, R/R}$ under the same equivalence, so Y can be identified with the fiber of the map $Z \to Z_0$ determined by the section x. Using Remark 19.2.4.8, we deduce that the relative cotangent complexes $L_{Z/\operatorname{Spec} R}$ and $L_{Z_0/\operatorname{Spec} R}$ are given by the pullbacks of the R-modules $\Sigma^{-1}(f_* \mathscr{O}_{\mathsf{X}})^{\vee}$ and $\Sigma^{-1} R$, respectively. It follows that the relative cotangent complex $L_{Y/\operatorname{Spec} R}$ exists, and is given by the pullback of the R-linear dual of $\Sigma^1 \operatorname{fib}(f_* \mathscr{O}_{\mathsf{X}} \xrightarrow{x^*} R) \simeq \Sigma^1 \operatorname{cofib}(u)$. By assumption, $\operatorname{cofib}(u)$ has Tor-amplitude $\leqslant -1$, so that $\Sigma^{-1} \operatorname{cofib}(u)^{\vee}$ is connective and therefore $L_{Y/\operatorname{Spec} R}$ is connective as desired.

This completes the proof that the functor Y is representable by a spectral algebraic space Y which is locally almost of finite presentation over R. The above calculation shows that $L_{Y/\mathrm{Sp\acute{e}t}\, R}$ is perfect, so that Y is locally of finite presentation over R (Proposition 17.1.5.1). It remains to verify that Y is quasi-separated. Suppose we are given a pair of connective $\mathbb{E}_\infty$-rings A and B and maps $\mathrm{Sp\acute{e}t}\, A \xrightarrow{\phi} \mathsf{Y} \xleftarrow{\phi'} \mathrm{Sp\acute{e}t}\, B$; we wish to prove that the fiber product $\mathrm{Sp\acute{e}t}\, A \times_{\mathsf{Y}} \mathrm{Sp\acute{e}t}\, B$ is quasi-compact. Replacing R by $A \otimes_R B$, we may reduce to the case where $A = B = R$. Then ϕ and ϕ' determine line bundles $\mathscr{L}$ and $\mathscr{L}'$ on X equipped with trivializations of $x^* \mathscr{L}$ and $x^* \mathscr{L}'$. For every object $R' \in \mathrm{CAlg}^{\mathrm{cn}}_R$, let $\mathscr{L}_{R'}$ and $\mathscr{L}'_{R'}$ denote the pullbacks of $\mathscr{L}$ and $\mathscr{L}'$ to $\mathsf{X}_{R'}$. Define functors $F, F' : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ by the formulas

$$F(R') = \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X}_{R'})}(\mathscr{L}_{R'}, \mathscr{L}'_{R'}) \qquad F'(R') = \mathrm{Map}_{\mathrm{Mod}_{R'}}(R', R').$$

Since $f_*(\mathscr{L}' \otimes \mathscr{L}^{\vee})$ is perfect, we can identify $F(R')$ with $\mathrm{Map}_{\mathrm{Mod}_R}((f_* \mathscr{L}' \otimes \mathscr{L}^{\vee})^{\vee}, R')$. Note that $\mathscr{L}' \otimes \mathscr{L}^{\vee}$ is a line bundle on X. Since f is flat, the pushforward $f_*(\mathscr{L}' \otimes \mathscr{L}^{\vee})$ has Tor-amplitude $\leqslant 0$, so that $(f_* \mathscr{L}' \otimes \mathscr{L}^{\vee})^{\vee}$ is connective. It follows that the functor F is representable by the affine spectral Deligne-Mumford stack $\mathsf{Z} = \mathrm{Sp\acute{e}t}\, \mathrm{Sym}^*_R(f_*(\mathscr{L}' \otimes \mathscr{L}^{\vee})^{\vee})$ (see Proposition 19.1.1.1). Similarly, the functor F' is representable by the affine spectral Deligne-Mumford stack $\mathrm{Sp\acute{e}t}\, \mathrm{Sym}^*_R(R)$.

Let $g : \mathsf{Z} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X} \to \mathsf{X}$ be the projection onto the second factor. By construction, we have a canonical map of line bundles $\alpha : g^* \mathscr{L} \to g^* \mathscr{L}'$. Lemma 2.9.3.3 implies that there is a quasi-compact open immersion $\mathsf{U} \hookrightarrow \mathsf{Z} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X}$ such that a map $h : \mathrm{Sp\acute{e}t}\, C \to \mathsf{Z} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X}$ factors through U if and only if $h^* \operatorname{cofib}(\alpha)$ is 1-connective. Then U determines a constructible closed subset $K \subseteq |\, \mathsf{Z} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X}\, |$. Since f is proper, the image of K is a constructible closed subset of Z, which determines a quasi-compact open immersion $\mathsf{Z}_0 \hookrightarrow \mathsf{Z}$. Unwinding the definitions, we see that Z_0 represents the subfunctor F_0 of F which carries an object $R' \in \mathrm{CAlg}_R^{\mathrm{cn}}$ to the summand of $F(R') = \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X}_{R'})}(\mathscr{L}_{R'}, \mathscr{L}'_{R'})$ consisting of equivalences of $\mathscr{L}_{R'}$ with $\mathscr{L}'_{R'}$. Unwinding the definitions, we obtain a pullback diagram

$$\begin{array}{ccc} \mathrm{Sp\acute{e}t}\, A \times_{\mathsf{Y}} \mathrm{Sp\acute{e}t}\, B & \longrightarrow & \mathsf{Z}_0 \\ \downarrow & & \downarrow \\ \mathrm{Sp\acute{e}t}\, R & \longrightarrow & \mathsf{Z}'. \end{array}$$

It follows that $\mathrm{Sp\acute{e}t}\, A \times_{\mathsf{Y}} \mathrm{Sp\acute{e}t}\, B$ is quasi-affine (and in particular quasi-compact). □

In the situation of Proposition 19.2.5.1, if the map $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ is fiber smooth, then $\mathscr{P}\mathrm{ic}^x_{\mathsf{X}/R}$ satisfies the valuative criterion of properness:

Proposition 19.2.5.2. *Let $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ be a morphism of spectral algebraic spaces which is proper, fiber smooth, and geometrically connected. Then, for every object $V \in \mathrm{CAlg}_R$ which is a valuation ring with fraction field K, the map $\mathscr{P}\mathrm{ic}^x_{\mathsf{X}/R}(V) \to \mathscr{P}\mathrm{ic}^x_{\mathsf{X}/R}(K)$ is bijective.*

Proof. Without loss of generality we may assume that $V = R$ and the map $\mathrm{Sp\acute{e}t}\, V \to \mathrm{Sp\acute{e}t}\, R$ is the identity. Let $\mathcal{X}$ be the underlying ∞-topos of X. For every object $U \in \mathcal{X}$, let $\mathsf{X}_U = (\mathcal{X}_{/U}, \mathscr{O}_{\mathsf{X}}|_U)$. Set $\mathsf{X}_\eta = \mathrm{Sp\acute{e}t}\, K \times_{\mathrm{Sp\acute{e}t}\, V} \mathsf{X}$, and let $\mathcal{X}_\eta$ be the underlying ∞-topos of X_η, so that we have an open immersion of ∞-topoi $j_* : \mathcal{X}_0 \to \mathcal{X}$. Let $i_* : \mathcal{Y} \to \mathcal{X}$ be the complementary closed immersion, let t denote a uniformizer for the discrete valuation ring V and $\kappa = V/(t)$ its residue field.

Let $\mathscr{L}$ be a line bundle on X_η. We define a functor $F_{\mathscr{L}} : \mathcal{X}^{\mathrm{op}} \to \mathcal{S}$ by the formula

$$F_{\mathscr{L}}(U) = \mathscr{P}\mathrm{ic}(\mathsf{X}_U) \times_{\mathscr{P}\mathrm{ic}(\mathrm{Sp\acute{e}t}\, K \times_{\mathrm{Sp\acute{e}t}\, V} \mathsf{X}_U)} \{\mathscr{L}\}.$$

If U is affine, then $\mathsf{X}_U \simeq \mathrm{Sp\acute{e}t}\, A$ for some commutative ring A, and $\mathscr{L}$ determines an invertible module $M[\frac{1}{t}]$ over $A[\frac{1}{t}]$. Unwinding the definitions, we can identify $F_{\mathscr{L}}(U)$ with the set of all submodules $M \subseteq M[\frac{1}{t}]$ which are invertible over A and generate $M[\frac{1}{t}]$ as modules over $A[\frac{1}{t}]$. Note that the functor $F_{\mathscr{L}}$ is representable by a discrete object of $\mathcal{X}$, which we will denote by $F_{\mathscr{L}}$ (by a slight abuse of notation). Note that $j^* F_{\mathscr{L}}$ is a final object of $\mathcal{X}_\eta$, so we can write $F_{\mathscr{L}} \simeq i_* F'_{\mathscr{L}}$ for some object $F'_{\mathscr{L}} \in \mathcal{Y}$.

There is an evident action of the discrete group $\mathbf{Z} \simeq \mathrm{fib}(\mathscr{P}\mathrm{ic}(\mathrm{Sp\acute{e}t}\, V) \to \mathscr{P}\mathrm{ic}(\mathrm{Sp\acute{e}t}\, K))$ on $F'_{\mathscr{L}}$. We claim that this action exhibits $F'_{\mathscr{L}}$ as a $\mathbf{Z}$-torsor in the topos $\mathcal{Y}^{\heartsuit}$. To prove this, it will suffice to show that for every affine object $U \in \mathcal{X}$, the set $F_{\mathscr{L}}(U)$ is nonempty and is acted on transitively by the group $\mathrm{H}^0(|\,\mathrm{Sp\acute{e}t}\, \kappa \times_{\mathrm{Sp\acute{e}t}\, V} \mathsf{X}_U\,|; \mathbf{Z})$. Let $\mathsf{X}_U = \mathrm{Sp\acute{e}t}\, A$ and $M[\frac{1}{t}]$ be as above; we wish to show that $F_{\mathscr{L}}(U)$ is nonempty and acted on transitively by the group $\mathrm{H}^0(|\,\mathrm{Spec}\, A/tA|; \mathbf{Z})$. Note that A is smooth over V (in the sense of classical commutative algebra) and therefore regular. It follows that $M[\frac{1}{t}]$ can be identified with a fractional ideal of $A[\frac{1}{t}]$, given by a product $\prod_{1 \leqslant i \leqslant k} \mathfrak{p}_i^{m_i}$ for some integers m_i and some prime ideals $\mathfrak{p}_i \subseteq A[\frac{1}{t}]$ of height 1. Let Let $\mathfrak{p}'_i$ be the inverse image of $\mathfrak{p}$ in A, and let $\mathfrak{q}_1, \ldots, \mathfrak{q}_l$ be the set of height one prime ideals of A which contain tA. Then $F_{\mathscr{L}}(U)$ can be identified with the set of all fractional ideals of A having the form $\prod_{1 \leqslant i \leqslant k} \mathfrak{p}'^{m_i}_i \prod_{1 \leqslant j \leqslant l} \mathfrak{q}_j^{n_j}$. Note that since A is smooth over V, A/tA is smooth over the residue field of V, hence a finite product of integral domains, so that the group of continuous $\mathbf{Z}$-valued functions on $|\operatorname{Spec} A/tA|$ can be identified with $\mathbf{Z}^l$. The image of t in each localization $A_{\mathfrak{q}_j}$ is a uniformizer, so the action of $(a_1, \ldots, a_l) \in \mathbf{Z}^l$ on $F_{\mathscr{L}}(U)$ is given by

$$\prod_{1 \leqslant i \leqslant k} \mathfrak{p}'^{m_i}_i \prod_{1 \leqslant j \leqslant l} \mathfrak{q}_j^{n_j} \mapsto \prod_{1 \leqslant i \leqslant k} \mathfrak{p}'^{m_i}_i \prod_{1 \leqslant j \leqslant l} \mathfrak{q}_j^{a_j + n_j}.$$

It is now clear that this action is simply transitive.

To prove Proposition 19.2.5.2, we must show that the diagram

$$\begin{array}{ccc} \mathscr{P}\mathrm{ic}(\mathsf{X}) & \longrightarrow & \mathscr{P}\mathrm{ic}(\mathsf{X}_\eta) \\ \downarrow{\scriptstyle e^*} & & \downarrow \\ \mathscr{P}\mathrm{ic}(\operatorname{Sp\acute{e}t} V) & \longrightarrow & \mathscr{P}\mathrm{ic}(\operatorname{Sp\acute{e}t} K) \end{array}$$

is a pullback square. For this, it will suffice to show that for every line bundle $\mathscr{L}$ on X_η, the induced map

$$\theta : F_{\mathscr{L}}(\mathbf{1}) \to \mathscr{P}\mathrm{ic}(\operatorname{Sp\acute{e}t} V) \times_{\mathscr{P}\mathrm{ic}(\operatorname{Sp\acute{e}t} K)} \{\mathscr{L}\}$$

is a homotopy equivalence. Let $q_* : \mathcal{Y} \to \mathcal{S}$ be the global sections functor and q^* its left adjoint. The $\mathbf{Z}$-torsor $F'_{\mathscr{L}}$ is classified by a point $\eta \in \mathrm{H}^1(\mathcal{Y}; \mathbf{Z}) \simeq \pi_0 q_* q^* S^1$. Since $\operatorname{Sp\acute{e}t} \kappa \times_{\operatorname{Sp\acute{e}t} V} \mathsf{X}$ is smooth over κ and therefore normal, there exists a map of connected spaces $\gamma : K \to S^1$ with $\pi_1 K$ finite, and such that η belongs to the image of the map $\pi_0 q_* q^* K$ (Proposition **??**). The map γ is classified by an element in the group $\mathrm{H}^1(K; \mathbf{Z}) \simeq \mathrm{Hom}(\pi_1 K, \mathbf{Z}) \simeq 0$ and is therefore nullhomotopic, from which it follows that η is trivial. Then $F_{\mathscr{L}}(\{\mathbf{1}\})$ is nonempty and a torsor for the group $\mathrm{H}^0(|\operatorname{Sp\acute{e}t} \kappa \times_{\operatorname{Sp\acute{e}t} V} \mathsf{X}|; \mathbf{Z})$. Similarly, $\mathscr{P}\mathrm{ic}(\operatorname{Sp\acute{e}t} V) \times_{\mathscr{P}\mathrm{ic}(\operatorname{Sp\acute{e}t} K)} \{\mathscr{L}\}$ is a torsor for the group $\mathrm{H}^0(|\operatorname{Sp\acute{e}t} \kappa|; \mathbf{Z}) \simeq \mathbf{Z}$. The fiber $\operatorname{Sp\acute{e}t} \kappa \times_{\operatorname{Sp\acute{e}t} V} \mathsf{X}$ is connected, so the restriction map

$$\mathrm{H}^0(|\operatorname{Sp\acute{e}t} \kappa \times_{\operatorname{Sp\acute{e}t} V} \mathsf{X}|; \mathbf{Z}) \to \mathrm{H}^0(|\operatorname{Sp\acute{e}t} \kappa|; \mathbf{Z}) \simeq \mathbf{Z}$$

is an isomorphism, from which it follows that θ is a homotopy equivalence. □

Corollary 19.2.5.3. *Let $f : \mathsf{X} \to \operatorname{Sp\acute{e}t} R$ be a morphism of spectral algebraic spaces which is proper, fiber smooth, and geometrically connected and let Y be a closed subspace of $\mathscr{P}\mathrm{ic}^x_{\mathsf{X}/\operatorname{Sp\acute{e}t} R}$. Then the projection map $q : \mathsf{Y} \to \operatorname{Sp\acute{e}t} R$ is separated. If Y is quasi-compact, then q is proper.*

Proof. Combine Proposition 19.2.5.1, Proposition 19.2.5.2, Proposition **??**, and Corollary 5.3.1.2. □

19.2.6 Smooth Projective Space

Let S denote the sphere spectrum. In §**??**, we introduced a spectral algebraic space $\mathbf{P}^n_S$, which we referred to as *projective space of dimension* n *over* S (Construction 5.4.1.3). Let $\mathscr{O}$ denote the structure sheaf of $\mathbf{P}^n_S$. As in classical algebraic geometry, there is a tautological line bundle $\mathscr{O}(-1)$ on $\mathbf{P}^n_S$ (Construction 5.4.2.1) and map $\mathscr{O}(-1) \to \mathscr{O}^{n+1}$ (Construction 5.4.2.5) which locally exhibits $\mathscr{O}(-1)$ as a direct summand of $\mathscr{O}^{n+1}$. However, in contrast with classical algebraic geometry, the projective space $\mathbf{P}^n_S$ is not universal with respect to these properties: the universal property of Theorem 5.4.3.1 holds for ordinary commutative rings, but not for arbitrary connective $\mathbb{E}_\infty$-rings. In this section, we will construct a *different* spectral algebraic space, which we will denote by $\mathbf{P}^n_{\mathrm{sm}}$, which has the expected universal property (but suffers from other defects: see Remark **??**).

Construction 19.2.6.1 (Smooth Projective Space as a Functor)**.** Fix a nonnegative integer $n \geqslant 0$. For every connective $\mathbb{E}_\infty$-ring A, let $X(A)$ denote the subcategory of $(\mathrm{Mod}_A)_{/A^{n+1}}$ whose morphisms are equivalences and whose objects are maps $f : L \to A^{n+1}$ with the following property:

- (a) The map f admits a left homotopy inverse (that is, it exhibits L as a direct summand of A^{n+1}).
- (b) The A-module L is projective of rank 1.

Note that $X(A)$ is an essentially small Kan complex. We will regard the construction $A \mapsto X(A)$ as a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$.

Theorem 19.2.6.2. *Let $n \geqslant 0$ be a nonnegative integer. Then the functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ of Construction 19.2.6.1 is representable by a spectral algebraic space.*

Proof. Let $\mathrm{Perf}_{\Delta^1} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be as in Notation 19.2.3.1. For every connective $\mathbb{E}_\infty$-ring R, we will identify $\mathrm{Perf}_{\Delta^1}(R)$ with the Kan complex parametrizing maps $u : M \to N$, where M and N are perfect R-modules. Consider the map $\alpha : \mathrm{Perf}_{\Delta^1} \to \mathrm{Perf}$ given on R-valued points by $(u : M \to N) \mapsto N \in \mathrm{Mod}^{\mathrm{perf}}_R$. Let S denote the sphere spectrum, and let $\beta : \mathrm{Spec}\, S \to \mathrm{Perf}$ be the map classifiying the perfect S-module S^{n+1}. By definition, we can identify X with a subfunctor of the fiber product $\mathrm{Perf}_{\Delta^1} \times_{\mathrm{Perf}} \mathrm{Spec}\, S$, whose R-valued points are given by maps of connective perfect R-modules $(u : M \to R^{n+1})$ for which $\mathrm{cofib}(u)$ is locally free of rank n (which implies that M is locally free of rank 1). Using Proposition 19.2.4.5, we see that this identification determines an open immersion $j : X \hookrightarrow \mathrm{Perf}_{\Delta^1} \times_{\mathrm{Perf}} \mathrm{Spec}\, S$. Applying Propositions 19.2.3.3 and 19.2.4.3, we deduce that the functor X is cohesive, nilcomplete, and admits a perfect cotangent complex. Note that the restriction $X|_{\mathrm{CAlg}^{\heartsuit}}$ is representable by the spectral algebraic space $\mathbf{P}^n_S$ (Theorem 5.4.3.1). Applying Theorem 18.1.0.2, we deduce that the functor X is also representable by a spectral

Deligne-Mumford stack (which has the same 0-truncation as $\mathbf{P}^n_S$, and is therefore a schematic spectral algebraic space). □

Definition 19.2.6.3 (Smooth Projective Space)**.** Let $n \geqslant 0$ be a nonnegative integer. We let $\mathbf{P}^n_{\mathrm{sm}}$ denote a spectral algebraic space which represents the functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ (note that $\mathbf{P}^n_{\mathrm{sm}}$ is well-defined up to equivalence, by virtue of Proposition 1.6.4.2). We will refer to $\mathbf{P}^n_{\mathrm{sm}}$ as *smooth projective space of dimension* n (see Remark 19.2.6.5 below).

Remark 19.2.6.4. It is possible to prove Theorem 19.2.6.2 by explicitly constructing the smooth projective space $\mathbf{P}^n_{\mathrm{sm}}$, using a variant of Construction 5.4.1.3.

Remark 19.2.6.5. Let R be a connective $\mathbb{E}_\infty$-ring and let η be an R-valued point of $\mathbf{P}^n_{\mathrm{sm}}$, classifying a fiber sequence of R-modules $L \to R^{n+1} \to M$ where L and M are locally free of rank 1 and n, respectively. Then the pullback $\eta^* L_{\mathbf{P}^n_{\mathrm{sm}}}$ can be identified with the tensor product $L^{-1} \otimes_R M$ (this can be deduced from the results of §19.2.2, or directly from the definitions). In particular, the cotangent complex $L_{\mathbf{P}^n_{\mathrm{sm}}}$ is locally free of rank n. Applying Proposition 17.1.5.1, we deduce that $\mathbf{P}^n_{\mathrm{sm}}$ is differentially smooth over the sphere spectrum S.

Remark 19.2.6.6. Let $\mathbf{P}^n_S$ be as in Construction 5.4.1.3. The tautological map $\mathscr{O}(-1) \to \mathscr{O}^{n+1}$ on $\mathbf{P}^n_S$ determines a morphism of spectral algebraic spaces $e : \mathbf{P}^n_S \to \mathbf{P}^n_{\mathrm{sm}}$. For $n > 0$, this morphism is *not* an equivalence. However, it is not far off:

(a) The morphism e induces an equivalence from the 0-truncation of $\mathbf{P}^n_S$ to the 0-truncation of $\mathbf{P}^n_{\mathrm{sm}}$. In other words, the projective spaces $\mathbf{P}^n_S$ and $\mathbf{P}^n_{\mathrm{sm}}$ represent the same functor on the category of ordinary commutative rings (this is essentially a reformulation of Theorem 5.4.3.1).

(b) For every connective $\mathbb{E}_\infty$-ring R, the morphism e induces a map

$$e_R : \mathbf{P}^n_R \simeq \mathrm{Sp\acute{e}t}\, R \times_{\mathrm{Sp\acute{e}t}\, S} \mathbf{P}^n_S \xrightarrow{e} \mathrm{Sp\acute{e}t}\, R \times_{\mathrm{Sp\acute{e}t}\, S} \mathbf{P}^n_{\mathrm{sm}}.$$

If R is discrete, then this map exhibits $\mathbf{P}^n_R$ as the 0-truncation of $\mathrm{Sp\acute{e}t}\, R \times_{\mathrm{Sp\acute{e}t}\, S} \mathbf{P}^n_{\mathrm{sm}}$ (this follows from (a), since $\mathbf{P}^n_R$ is flat over R).

(c) If $R = \mathbf{Q}$ (or, more generally, if R is an $\mathbb{E}_\infty$-algebra over $\mathbf{Q}$), then the map e_R is an equivalence This follows from (b) and Remark 19.2.6.5, since every differentially smooth $\mathbf{Q}$-algebra is fiber smooth (Proposition 11.2.4.4) and therefore discrete.

Remark 19.2.6.7. Let us contrast the projective space $\mathbf{P}^n_S$ of Construction 5.4.1.3 with the smooth projective space $\mathbf{P}^n_{\mathrm{sm}}$ of Definition 19.2.6.3 (for $n > 0$):

(i) The projective space $\mathbf{P}^n_S$ is fiber smooth over the sphere spectrum S. In particular, it is flat over S. However, the smooth projective space $\mathbf{P}^n_{\mathrm{sm}}$ is not flat over S.

(ii) The smooth projective space $\mathbf{P}^n_{\mathrm{sm}}$ is differentially smooth over S. In particular, the cotangent complex $L_{\mathbf{P}^n_{\mathrm{sm}}} \in \mathrm{QCoh}(\mathbf{P}^n_{\mathrm{sm}})$ is locally free of finite rank. However, the cotangent complex $L_{\mathbf{P}^n_S} \in \mathrm{QCoh}(\mathbf{P}^n_S)$ is not perfect (though it is almost perfect).

(iii) On the projective space $\mathbf{P}^n_S$, the the line bundles $\mathscr{O}(d)$ have the "expected" cohomology (mirroring Serre's calculation in classical algebraic geometry): for example, if $d \geqslant 0$, then $\Gamma(\mathbf{P}^n_S; \mathscr{O}(d))$ is a locally free S-module of rank $\binom{n+d}{n}$ (Theorem 5.4.2.6). These line bundles extend to the smooth projective space $\mathbf{P}^n_{\mathrm{sm}}$, but their cohomology is substantially more complicated (even for $d = 0$).

(iv) The smooth projective space $\mathbf{P}^n_{\mathrm{sm}}$ is of finite presentation over S, while the projective space $\mathbf{P}^n_S$ is only almost of finite presentation over S.

(v) The projective space $\mathbf{P}^n_S$ is more rigid than its smooth counterpart $\mathbf{P}^n_{\mathrm{sm}}$. For example, there is no automorphism of $\mathbf{P}^1_S$ which exchanges the S-valued points corresponding to 0 and 1, while the smooth projective space $\mathbf{P}^1_{\mathrm{sm}}$ does admit such an automorphism.

(vi) The smooth projective space $\mathbf{P}^n_{\mathrm{sm}}$ represents an easily-described functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ (Construction 19.2.6.1). It is also possible to specify the functor represented by $\mathbf{P}^n_S$, but the description is more complicated.

19.3 Application: Existence of Dilatations

Let X be a Noetherian algebraic space, let $U \subseteq X$ be an open subspace, and let $\mathfrak{X}$ be the formal completion of X along the complement of U. Roughly speaking, one can think of X as obtained by gluing together U and $\mathfrak{X}$ along the "intersection" $\mathfrak{X}_U = U \cap \mathfrak{X}$ (which we view here as a purely heuristic object, though it can be given meaning in the setting of rigid analytic geometry). One prediction of this philosophy is that changing the algebraic space X while keeping U fixed should be equivalent to changing the formal algebraic space $\mathfrak{X}$ while keeping $\mathfrak{X}_U$ fixed. To make this idea more precise, it is convenient to introduce some terminology:

Definition 19.3.0.1. Let $f : X' \to X$ be a morphism of Noetherian algebraic spaces and let $K \subseteq |X|$ be a closed subset with inverse image $K' = f^{-1}(K)$. We will say that f is a *modification centered at* (K', K) if it is proper and the induced map $X' - K' \to X - K$ is an isomorphism. In this case, we will also say that X' is a *dilatation of* X *along* K or that X is a *contraction of* X' *along* K'.

In [5], Artin introduced the notion of a *formal modification* between formal algebraic spaces. Under mild hypotheses, Artin showed that if $\mathfrak{X}$ is the formal completion of a

Noetherian algebraic space X along a closed subset $K \subseteq |X|$, one has equivalences

$$\{ \text{ Dilatations of } X \text{ centered } K \} \xrightarrow{\sim} \{ \text{ Formal modifications } \mathfrak{X}' \to \mathfrak{X} \} \quad (19.1)$$

$$\{ \text{ Contractions of } X \text{ centered } K \} \xrightarrow{\sim} \{ \text{ Formal modifications } \mathfrak{X} \to \mathfrak{X}' \}. \quad (19.2)$$

Our goal in this section is to establish an analogue of (19.1) in the setting of spectral algebraic geometry. We begin in §?? by introducing the notion of a *formal modification* $f : \mathfrak{X}' \to \mathfrak{X}$ between formal spectral Deligne-Mumford stacks (Definition 19.3.1.3). Roughly speaking, the notion of formal modification abstracts those properties one would expect to see if f arose by formally completing a morphism of spectral Deligne-Mumford stacks $F : \mathsf{X}' \to \mathsf{X}$ which is proper, locally almost of finite presentation, and an equivalence over the complement of $|\,\mathfrak{X}\,| = K \subseteq |\,\mathsf{X}\,|$. In §??, we show that in this case, the spectral Deligne-Mumford stack X' can be recovered from X and the formal modification f: that is, the spectral analogue of (19.1) is fully faithful (see Proposition 19.3.2.1). The hard part is to show that it is essentially surjective: that is, that every formal modification $f : \mathfrak{X}' \to \mathfrak{X} = \mathsf{X}^{\wedge}_{K}$ arises as the formal completion of some map $F : \mathsf{X}' \to \mathsf{X}$. To prove this, we can work locally and thereby reduce to the case where $\mathsf{X} = \operatorname{Sp\acute{e}t} R$ for some connective $\mathbb{E}_{\infty}$-ring R. In this case, one might hope to recover X' as the Weil restriction of $\mathfrak{X}'$ along the canonical map $\operatorname{Spf} R \to \operatorname{Sp\acute{e}t} R$. In §19.3.3, we combine ideas of §?? with the spectral Artin representability theorem to show that this Weil restriction is representable by a spectral algebraic space X. The remaining difficulty is to show that X is proper over R, which we deduce from a general criterion established in §19.3.4.

19.3.1 Dilatations and Formal Modifications

We begin by adapting Definition 19.3.0.1 to the setting of spectral algebraic geometry.

Definition 19.3.1.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks and let $K \subseteq |\,\mathsf{Y}\,|$ be a cocompact closed subset. We will say that X is a *dilatation of* Y *centered at* K if f is proper, locally almost of finite presentation, and the induced map $\mathsf{X} - f^{-1}(K) \to \mathsf{Y} - K$ is an equivalence. We let $\operatorname{Dil}_K(\mathsf{Y})$ denote the full subcategory of $\operatorname{SpDM}_{/\mathsf{Y}}$ spanned by those maps $f : \mathsf{X} \to \mathsf{Y}$ which are dilatations centered at K. We will refer to $\operatorname{Dil}_K(\mathsf{Y})$ as the *∞-category of dilatations of* Y *centered at* K.

If $f : \mathsf{X} \to \mathsf{Y}$ is any morphism of spectral Deligne-Mumford stacks and $K \subseteq |\,\mathsf{Y}\,|$ any cocompact closed subset, we obtain an induced map of formal completions $f^{\wedge}_{K} : \mathsf{X}^{\wedge}_{f^{-1}K} \to \mathsf{Y}^{\wedge}_{K}$. Our next goal is to describe some special features enjoyed by $f^{\wedge}_{K}$ in the special case where X is a dilatation of Y centered at K. We take our cue from the following simple observation:

Proposition 19.3.1.2. *Let* $f : \mathsf{X} \to \mathsf{Y}$ *be a morphism of spectral Deligne-Mumford stacks. Then* f *is an equivalence if and only if it satisfies the following conditions:*

(1) *The map f is proper and locally almost of finite presentation.*

(2) *The relative cotangent complex $L_{\mathsf{X}/\mathsf{Y}}$ vanishes.*

(3) *The unit map $\mathscr{O}_{\mathsf{Y}} \to f_* \mathscr{O}_{\mathsf{X}}$ is an equivalence.*

Proof. The necessity of conditions (1), (2), and (3) is obvious. For the converse, suppose that (1), (2), and (3) are satisfied. Combining (1) and (2) with Proposition 17.1.5.1, we deduce that f is étale. In particular, f is locally quasi-finite, so the properness of f guarantees that f is affine (Proposition 17.1.5.1). It now follows from (3) that f is an equivalence, as desired. □

Now suppose that $f : \mathsf{X} \to \mathsf{Y}$ is a formal modification of Y along $K \subseteq |\mathsf{Y}|$. Using Proposition 19.3.1.2, we deduce that the quasi-coherent sheaves $L_{\mathsf{X}/\mathsf{Y}}$ and $\mathrm{cofib}(\mathscr{O}_{\mathsf{Y}} \to f_* \mathscr{O}_{\mathsf{X}})$ are supported on the closed subsets $f^{-1}(K)$ and K, respectively. This motivates the following:

Definition 19.3.1.3. Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a morphism of formal spectral Deligne-Mumford stacks. We will say that f is a *formal modification* if it satisfies the following conditions:

(1) The map f is representable, proper, and locally almost of finite presentation. In other words, for every map $\mathrm{Sp\acute{e}t}\, R \to \mathfrak{Y}$, the fiber product $\mathfrak{X} \times_{\mathfrak{Y}} \mathrm{Sp\acute{e}t}\, R$ is a spectral algebraic space which is proper and locally almost of finite presentation over R.

(2) The completed cotangent complex $L^{\wedge}_{\mathfrak{X}/\mathfrak{Y}} \in \mathrm{QCoh}(\mathfrak{X})$ (Definition 17.1.2.8) is nilcoherent (Definition 8.2.1.1).

(3) The cofiber of the unit map $\mathscr{O}_{\mathfrak{Y}} \to f_* \mathscr{O}_{\mathfrak{X}}$ is a nilcoherent object of $\mathrm{QCoh}(\mathfrak{Y})$.

Warning 19.3.1.4. Definition 19.3.1.3 is somewhat different from the notion of formal modification which appears [5]: in particular, we do not require *a priori* that f satisfy a "valuative criterion" for complete discrete valuation rings.

Proposition 19.3.1.5. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which exhibits X as a dilatation of Y along a cocompact closed subset $K \subseteq |\mathsf{Y}|$. Set $\mathfrak{X} = \mathsf{X}^{\wedge}_{f^{-1}K}$ and $\mathfrak{Y} = \mathsf{Y}^{\wedge}_{K}$, so that we have a pullback diagram of formal spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathfrak{X} & \xrightarrow{g} & \mathsf{X} \\ \downarrow{\scriptstyle f^{\wedge}} & & \downarrow{\scriptstyle f} \\ \mathfrak{Y} & \xrightarrow{g'} & \mathsf{Y}. \end{array}$$

Then $f^{\wedge}$ is a formal modification.

Proof. Note that $L_{\mathsf{X}/\mathsf{Y}}$ and $\mathrm{cofib}(\mathscr{O}_{\mathsf{Y}} \to f_* \mathscr{O}_{\mathsf{X}})$ are almost perfect (Proposition 17.1.5.1 and Theorem 5.6.0.2). Applying Corollary 8.4.1.7, we obtain equivalences

$$L_{\mathfrak{X}/\mathfrak{Y}}^{\wedge} \simeq g^{\star} L_{\mathsf{X}/\mathsf{Y}} \simeq g^{*} L_{\mathsf{X}/\mathsf{Y}}$$

$$\mathrm{cofib}(\mathscr{O}_{\mathfrak{Y}} \to f_*^{\wedge} \mathscr{O}_{\mathfrak{X}}) \simeq g'^{\star} \mathrm{cofib}(\mathscr{O}_{\mathsf{Y}} \to f_* \mathscr{O}_{\mathsf{X}}) \simeq g'^{*} \mathrm{cofib}(\mathscr{O}_{\mathsf{Y}} \to f_* \mathscr{O}_{\mathsf{X}}).$$

Since $L_{\mathsf{X}/\mathsf{Y}}$ and $\mathrm{cofib}(\mathscr{O}_{\mathsf{Y}} \to f_* \mathscr{O}_{\mathsf{X}})$ are supported on $f^{-1}(K)$ and K, respectively, it follows from Proposition 8.3.2.6 that $L_{\mathfrak{X}/\mathfrak{Y}}^{\wedge}$ and $\mathrm{cofib}(\mathscr{O}_{\mathfrak{Y}} \to f_*^{\wedge} \mathscr{O}_{\mathfrak{X}})$ are nilcoherent, as desired. □

Remark 19.3.1.6. Suppose we are given a pullback diagram of formal spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathfrak{X}' & \xrightarrow{g'} & \mathfrak{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathfrak{Y}' & \xrightarrow{g} & \mathfrak{Y}. \end{array}$$

where g (and therefore also g') is representable. If f is a formal modification, then so is f' (see Corollary 8.4.1.8).

Notation 19.3.1.7. Let $\mathfrak{Y}$ be a formal spectral Deligne-Mumford stack. We let $\mathrm{Dil}^{\mathrm{f}}(\mathfrak{Y})$ denote the full subcategory of $\mathrm{fSpDM}_{/\mathfrak{Y}}$ spanned by those maps $f : \mathfrak{X} \to \mathfrak{Y}$ where f is a formal modification. We will refer to $\mathrm{Dil}^{\mathrm{f}}(\mathfrak{Y})$ as the *∞-category of formal dilatations of* $\mathfrak{Y}$.

We can now formulate the main result of this section.

Theorem 19.3.1.8. *Let* Y *be a spectral Deligne-Mumford stack satisfying the following condition:*

(∗) *For every étale map* $\mathrm{Spét}\, R \to \mathsf{Y}$*, the* $\mathbb{E}_\infty$*-ring* R *is Noetherian and* $\pi_0 R$ *is a Grothendieck ring.*

Let K *be a closed subset of* $|\mathsf{Y}|$*. Then the construction* $\mathsf{X} \mapsto \mathsf{X} \times_{\mathsf{Y}} \mathsf{Y}_K^{\wedge}$ *induces an equivalence of* ∞*-categories* $\rho : \mathrm{Dil}_K(\mathsf{Y}) \to \mathrm{Dil}^{\mathrm{f}}(\mathsf{Y}_K^{\wedge})$.

The proof of Theorem 19.3.1.8 will occupy our attention throughout this section. We proceed in three steps:

- We first show that the construction $\mathsf{X} \mapsto \mathsf{X} \times_{\mathsf{Y}} \mathsf{Y}_K^{\wedge}$ is fully faithful (Proposition 19.3.2.1).
- We show that if $\mathsf{Y} = \mathrm{Spét}\, R$ is affine and $f_0 : \mathfrak{X} \to \mathsf{Y}_K^{\wedge}$ is a formal modification, then the Weil restriction $\mathrm{Res}_{\mathsf{Y}_K^{\wedge}/\mathsf{Y}}(\mathfrak{X})$ is representable by a spectral algebraic space X which is locally almost of finite presentation over R (Proposition 19.3.3.2).

- If $\mathsf{Y} = \operatorname{Sp\acute{e}t} R$ is affine and X is a spectral algebraic space which is locally almost of finite presentation over R, for which $\mathsf{X} \times_{\mathsf{Y}} \mathsf{Y}^{\wedge}_{K} \to \mathsf{Y}^{\wedge}_{K}$ is a formal modification and the projection map $\mathsf{X} \times_{\mathsf{Y}} (\mathsf{Y} - K) \to \mathsf{Y} - K$ is an equivalence, then X is automatically proper over R (Proposition 19.3.4.1).

Assuming these results, we can give the proof of Theorem 19.3.1.8:

Proof of Theorem 19.3.1.8. Set $\mathfrak{Y} = \mathsf{Y}^{\wedge}_{K}$. The assertion that the construction $\mathsf{X} \mapsto \mathsf{X} \times_{\mathsf{Y}} \mathsf{Y}^{\wedge}_{K}$ induces an equivalence of ∞-categories $\rho : \operatorname{Dil}_K(\mathsf{Y}) \to \operatorname{Dil}^{\mathrm{f}}(\mathsf{Y}^{\wedge}_{K})$ is local on Y. We may therefore assume without loss of generality that $\mathsf{Y} = \operatorname{Sp\acute{e}t} R$ is affine. The functor ρ is fully faithful by virtue of Proposition 19.3.2.1, so it will suffice to show that ρ is essentially surjective. Let $\mathfrak{X}$ be a formal modification of $\mathsf{Y}^{\wedge}_{K}$, which we will identify with an object of the ∞-category $\operatorname{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. Applying Proposition 19.3.3.2, we deduce that the Weil restriction $\operatorname{Res}_{\mathsf{Y}^{\wedge}_{K}/\mathsf{Y}}(\mathfrak{X})$ is representable by a spectral algebraic space X which is locally almost of finite presentation over R. Unwinding the definitions, we obtain equivalences

$$\mathfrak{X} \simeq \mathsf{X} \times_{\mathsf{Y}} \mathsf{Y}^{\wedge}_{K} \qquad \mathsf{X} \times_{\mathsf{Y}} (\mathsf{Y} - K) \simeq \mathsf{Y} - K.$$

It follows from Proposition 19.3.4.1 that X is proper over R, and is therefore a dilatation of $\operatorname{Sp\acute{e}t} R$ along K which is a preimage of $\mathfrak{X}$ under the functor ρ. □

19.3.2 Full Faithfulness

Our first step is to show that the functor $\rho : \operatorname{Dil}_K(\mathsf{Y}) \to \operatorname{Dil}^{\mathrm{f}}(\mathsf{Y}^{\wedge}_{K})$ appearing in the statement of Theorem 19.3.1.8 is fully faithful. This is an easy consequence of Proposition 9.2.4.4, and does not require any Noetherian hypotheses on Y:

Proposition 19.3.2.1. *Let Y be a spectral Deligne-Mumford stack, let $K \subseteq |\mathsf{Y}|$ be a cocompact closed subset, and let $\mathfrak{Y} = \mathsf{Y}^{\wedge}_{K}$ denote the formal completion of Y along K. Then the construction $\mathsf{X} \mapsto \mathsf{X} \times_{\mathsf{Y}} \mathfrak{Y}$ induces a fully faithful embedding of ∞-categories $\operatorname{Dil}_K(\mathsf{Y}) \to \operatorname{Dil}^{\mathrm{f}}(\mathfrak{Y})$.*

Note that the assertion of Proposition **??** is local on Y, so we can assume without loss of generality that $\mathsf{Y} = \operatorname{Sp\acute{e}t} R$ is affine. In this case, the subset $K \subseteq |\operatorname{Spec} R|$ can be written as the vanishing locus of a finitely generated ideal $I \subseteq \pi_0 R$. If R is I-complete, then Proposition **??** is an immediate consequence of Corollary 8.5.3.4 (which guarantees that the pullback functor $\mathsf{X} \mapsto \mathsf{X} \times_{\operatorname{Sp\acute{e}t} R} \operatorname{Spf} R$ is fully faithful on *all* spectral algebraic spaces which are proper and almost of finite presentation over R, not only those which are dilatations centered at K). To handle the general case, we observe that there is a commutative diagram of ∞-categories

$$\begin{array}{ccc} \operatorname{Dil}_K(\operatorname{Sp\acute{e}t} R) & \longrightarrow & \operatorname{Dil}^{\mathrm{f}}(\operatorname{Spf} R) \\ \downarrow & & \downarrow \sim \\ \operatorname{Dil}_{K'}(\operatorname{Sp\acute{e}t} R^{\wedge}_{I}) & \longrightarrow & \operatorname{Dil}^{\mathrm{f}}(\operatorname{Spf} R^{\wedge}_{I}), \end{array}$$

where K' denotes the inverse image of K in $|\operatorname{Spec} R^{\wedge}_I|$. We are therefore reduced to proving the following:

Lemma 19.3.2.2. *Let R be a connective $\mathbb{E}_\infty$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal defining a closed subset $K \subseteq |\operatorname{Spec} R|$, let $R^{\wedge}_I$ denote the I-completion of R, and let $K' \subseteq |\operatorname{Spec} R^{\wedge}_I|$ denote the inverse image of K. Then pullback along the map $\operatorname{Sp\acute{e}t} R^{\wedge}_I \to \operatorname{Sp\acute{e}t} R$ induces a fully faithful functor $\operatorname{Dil}_K(R) \to \operatorname{Dil}_{K'}(R^{\wedge}_I)$.*

Proof. Let X and Y be spectral Deligne-Mumford stacks over R, and set

$$\mathsf{X}' = \mathsf{X} \times_{\operatorname{Sp\acute{e}t} R} \operatorname{Sp\acute{e}t} R^{\wedge}_I \qquad \mathsf{Y}' = \mathsf{Y} \times_{\operatorname{Sp\acute{e}t} R} \operatorname{Sp\acute{e}t} R^{\wedge}_I .$$

We then have a canonical map

$$\theta_{\mathsf{X},\mathsf{Y}} : \operatorname{Map}_{\operatorname{SpDM}_R}(\mathsf{X}, \mathsf{Y}) \to \operatorname{Map}_{\operatorname{SpDM}_R}(\mathsf{X}', \mathsf{Y}) \simeq \operatorname{Map}_{\operatorname{SpDM}_{R^{\wedge}_I}}(\mathsf{X}', \mathsf{Y}').$$

To prove Lemma 19.3.2.2, we must show that $\theta_{\mathsf{X},\mathsf{Y}}$ is an equivalence whenever X and Y are dilatations of $\operatorname{Sp\acute{e}t} R$ along K. In fact, we will prove a more general assertion: the map $\theta_{\mathsf{X},\mathsf{Y}}$ is an equivalence whenever Y is a dilatation of $\operatorname{Sp\acute{e}t} R$ along K (and X is arbitrary). To show this, we can work locally on X, and thereby reduce to the case where $\mathsf{X} = \operatorname{Sp\acute{e}t} A$ is affine. Let U be the open substack of X complementary to the vanishing locus of I, and set $\mathsf{U}' = \mathsf{X}' \times_{\mathsf{X}} \mathsf{U}$. Applying Proposition 9.2.4.4, we deduce that the diagram

$$\begin{array}{ccc} \operatorname{Map}_{\operatorname{SpDM}_R}(\mathsf{X}, \mathsf{Y}) & \xrightarrow{\theta_{\mathsf{X},\mathsf{Y}}} & \operatorname{Map}_{\operatorname{SpDM}_R}(\mathsf{X}', \mathsf{Y}) \\ \downarrow & & \downarrow \\ \operatorname{Map}_{\operatorname{SpDM}_R}(\mathsf{U}, \mathsf{Y}) & \longrightarrow & \operatorname{Map}_{\operatorname{SpDM}_R}(\mathsf{U}', \mathsf{Y}) \end{array}$$

is a pullback square. It now suffices to observe that the bottom horizontal map is a homotopy equivalence, because the mapping spaces $\operatorname{Map}_{\operatorname{SpDM}_R}(\mathsf{U}, \mathsf{Y})$ and $\operatorname{Map}_{\operatorname{SpDM}_R}(\mathsf{U}', \mathsf{Y})$ are contractible. □

19.3.3 Weil Restriction along $\operatorname{Spf} R \to \operatorname{Sp\acute{e}t} R$

To deduce Theorem 19.3.1.8 from Proposition 19.3.2.1, we need to address the following:

Question 19.3.3.1. Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a formal modification of formal spectral Deligne-Mumford stacks. Suppose that $\mathfrak{Y}$ is the formal completion of a spectral Deligne-Mumford stack Y along a cocompact closed subset $K \subseteq |\mathsf{Y}|$. Can f be obtained as the formal completion of a dilatation $\mathsf{X} \to \mathsf{Y}$ along K?

By virtue of Proposition 19.3.2.1, we know that the spectral Deligne-Mumford stack X is unique (up to equivalence) if it exists. Following Artin ([5]), we proceed in two steps: first, we construct X as an object of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ (that is, we guess a candidate for the functor represented by the hypothetical dilatation X), and then argue that (under some mild assumptions) this functor is actually representable. This functor is easy to describe: it is given by the Weil restriction of $\mathfrak{X}$ along the map $\mathfrak{Y} \to \mathsf{Y}$. To simplify the discussion, let us assume that $\mathsf{Y} = \mathrm{Spét}\, R$ is affine. In this case, the representability is a consequence of the following assertion:

Proposition 19.3.3.2. *Let R be an adic $\mathbb{E}_\infty$-ring and let $f : \mathfrak{X} \to \mathrm{Spf}\, R$ be a morphism of formal spectral Deligne-Mumford stacks. Let us abuse notation by identifying $\mathfrak{X}$, $\mathrm{Spf}\, R$, and $\mathrm{Spét}\, R$ with the corresponding functors $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, and let $X = \mathrm{Res}_{\mathrm{Spf}\, R / \mathrm{Spét}\, R}(\mathfrak{X})$ denote the Weil restriction of $\mathfrak{X}$ along the map $\mathrm{Spf}\, R \to \mathrm{Spét}\, R$ (see Construction 19.1.2.3). Suppose that the following conditions are satisfied:*

(a) The morphism f is representable by spectral algebraic spaces and locally almost of finite presentation (that is, for every map $\mathrm{Spét}\, A \to \mathrm{Spf}\, R$, the fiber product $\mathrm{Spét}\, A \times_{\mathrm{Spf}\, R} \mathfrak{X}$ is a spectral algebraic space which is locally almost of finite presentation over A.

(b) The $\mathbb{E}_\infty$-ring R is Noetherian and $\pi_0 R$ is a Grothendieck commutative ring.

(c) The completed cotangent complex $L^{\wedge}_{\mathfrak{X} / \mathrm{Spf}\, R} \in \mathrm{QCoh}(\mathfrak{X})$ is nilcoherent.

Then the functor X is representable by a spectral algebraic space which is locally almost of finite presentation over R.

The proof of Proposition 19.3.3.2 will require some preliminaries.

Lemma 19.3.3.3. *Let A be a commutative ring equipped with a ring homomorphism $\mathbf{Z}[t] \to A$. For each integer $n \geqslant 0$, set $A(n) = A \otimes_{\mathbf{Z}[t]} \mathbf{Z}[t]/(t^n)$. Suppose we are given an A-module M and a morphism $\phi : N \to A(n) \otimes_A M$ in $\mathrm{Mod}_{A(n)}$. If N admits the structure of an $A(m)$-module for some $m \leqslant n$, then the composite map*

$$N \to A(n) \otimes_A M \to A(n-m) \otimes_A M$$

is nullhomotopic (as a morphism in $\mathrm{Mod}_{A(n)}$).

Proof. Let us identify $A(n) \otimes_A M$ with the mapping object $\underline{\mathrm{Map}}_A(A(n), \Sigma M)$. Without loss of generality, it suffices to treat the universal case

$$\begin{aligned} N &= \underline{\mathrm{Map}}_{A(n)}(A(m), A(n) \otimes_A M) \\ &\simeq \underline{\mathrm{Map}}_{A(n)}(A(m), \underline{\mathrm{Map}}_A(A(n), M)) \\ &\simeq \underline{\mathrm{Map}}_A(A(m), \Sigma M). \end{aligned}$$

In this case, the cofiber $\mathrm{cofib}(\phi)$ can be identified with

$$\underline{\mathrm{Map}}_A(\mathrm{fib}(A(n) \to A(m)), \Sigma M) \simeq A(n-m) \otimes_A M.$$

□

Lemma 19.3.3.4. *Let A be a Noetherian $\mathbb{E}_\infty$-ring which is complete with respect to an ideal $I \subseteq \pi_0 A$, and regard $\mathrm{Spf}\, A$ as an object of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. Suppose we are given a faithfully flat affine étale morphism $\phi : X \to \mathrm{Spf}\, A$. Then we can write $X \simeq \mathrm{Spf}\, C$, where C is a Noetherian $\mathbb{E}_\infty$ which is complete with respect to the ideal $J = I(\pi_0 C) \subseteq \pi_0 C$. Moreover, C is faithfully flat over A.*

Proof. Choose a tower of A-algebras $\{A_n\}_{n>0}$ satisfying the requirements of Lemma 8.1.2.2. Then we can write $X \times_{\mathrm{Spf}\, A} \mathrm{Spec}\, A_1 \simeq \mathrm{Spec}\, B_1$, where B_1 is an étale A_1-algebra. Using the structure theory of étale morphisms (Proposition B.1.1.3), we can choose an étale map $A \to B$ such that $B_1 \simeq A_1 \otimes_A B$. For each $n \geqslant 0$, set $B_n = A_n \otimes_A B$. Since each of the maps $\mathrm{CAlg}^{\text{ét}}_{A_{n+1}} \to \mathrm{CAlg}^{\text{ét}}_{A_n}$ is an equivalence of ∞-categories, we can choose a compatible family of equivalences $X \times_{\mathrm{Spf}\, A} \mathrm{Spec}\, A_n \simeq \mathrm{Spec}\, B_n$, so that $X \simeq \varinjlim_n X \times_{\mathrm{Spf}\, A} \mathrm{Spec}\, A_n$ can be identified with the formal spectrum of B with respect to the ideal $I' \subseteq \pi_0 B$ generated by the image of I. Let C be the I'-completion of B. Since B is étale over A, it is Noetherian. It follows that C is Noetherian and flat over B, hence flat over A. To complete the proof, it will suffice to show that C is faithfully flat over A. For this, it will suffice to prove that the image of the map $|\mathrm{Spec}\, C| \to |\mathrm{Spec}\, A|$ contains every maximal ideal of $\pi_0 A$. This follows from the commutativity of the diagram

$$\begin{array}{ccc} |\mathrm{Spec}\, B_0| & \longrightarrow & |\mathrm{Spec}\, C| \\ \downarrow & & \downarrow \\ |\mathrm{Spec}(\pi_0 A)/I| & \longrightarrow & |\mathrm{Spec}\, A|, \end{array}$$

since I is contained in every maximal ideal of $\pi_0 A$ by virtue of Remark 7.3.4.10. □

Proof of Proposition 19.3.3.2. Let R be an adic $\mathbb{E}_\infty$-ring with ideal of definition $I \subseteq \pi_0 R$, and let $\mathfrak{X} \to \mathrm{Spf}\, R$ be a morphism of formal spectral Deligne-Mumford stacks which satisfies hypotheses (a) through (c) of Proposition 19.3.3.2. In what follows, we will abuse terminology by identifying formal spectral Deligne-Mumford stacks with the functors that they represent. Let $X \in \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ denote the Weil restriction of (the functor represented by) $\mathfrak{X}$ along the map $\mathrm{Spf}\, R \to \mathrm{Sp\acute{e}t}\, R$. We wish to show that X is representable by a spectral algebraic space which is locally almost of finite presentation over R.

Choose a tower of R-algebras $\{R_n\}_{n>0}$ satisfying the requirements of Lemma 8.1.2.2, so that $\mathrm{Spf}\, R \simeq \varinjlim \mathrm{Spec}\, R_n$ (Proposition 8.1.5.2). For each integer $n \geqslant 0$, set $X(n)$ denote the Weil restriction of $\mathfrak{X} \times_{\operatorname{Sp\acute{e}t} R} \operatorname{Sp\acute{e}t} R_n$ along the closed immersion $\operatorname{Sp\acute{e}t} R_n \to \operatorname{Sp\acute{e}t} R$. Let $X' : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ denote the image of X under the equivalence $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/\operatorname{Spec} R} \simeq \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}_R, \mathcal{S})$, given concretely by the formula

$$\begin{aligned} X'(A) &= \mathrm{fib}(X(A) \to \mathrm{Map}_{\mathrm{CAlg}}(R, A)) \\ &\simeq \mathrm{Map}_{\mathrm{fSpDM}_{/\operatorname{Spf} R}}(\operatorname{Sp\acute{e}t} A \times_{\operatorname{Sp\acute{e}t} R} \operatorname{Spf} R, \mathfrak{X}) \end{aligned}$$

We will show that X is representable (by a spectral algebraic space which is locally almost of finite presentation over R) by verifying the hypotheses of Theorem 18.3.0.1.

(2) The functor X is a sheaf for the étale topology. This is an immediate consequence of Proposition 19.1.2.2.

(3) The functor X is nilcomplete, infinitesimally cohesive, and integrable. It follows from Corollary 19.1.3.2 that each of the functors $X(n)$ is nilcomplete and cohesive, so that $X \simeq \varprojlim X(n)$ is also nilcomplete and cohesive. To show that X is integrable, it will suffice to show that each of the maps $X(n) \to \operatorname{Spec} R$ is integrable. Let A be an $\mathbb{E}_\infty$-algebra over R which is local, Noetherian, and complete with respect to its maximal ideal $\mathfrak{m} \subseteq \pi_0 A$. We wish to show that the canonical map

$$\theta : \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/\operatorname{Spec} R}}(\operatorname{Spec} A, X(n)) \to \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/\operatorname{Spec} R}}(\operatorname{Spf} A, X(n))$$

is a homotopy equivalence. Note that $A_n = A \otimes_R R_n$ is again a complete local Noetherian $\mathbb{E}_\infty$-ring which is complete with respect to its maximal ideal, and that $\operatorname{Spf} A_n \simeq \operatorname{Spf} A \times_{\operatorname{Spec} R} \operatorname{Spec} R_n$. We may therefore identify θ with the canonical map

$$\begin{array}{c} \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/\operatorname{Spec} R_n}}(\operatorname{Spec} A_n, \mathfrak{X} \times_{\operatorname{Spf} R} \operatorname{Spec} R_n) \\ \downarrow \\ \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{/\operatorname{Spec} R_n}}(\operatorname{Spf} A_n, \mathfrak{X} \times_{\operatorname{Spf} R} \operatorname{Spec} R_n). \end{array}$$

This map is a homotopy equivalence, since $\mathfrak{X} \times_{\operatorname{Spf} R} \operatorname{Spec} R_n$ is representable by a spectral algebraic space (Proposition 17.3.4.2).

(4) The map $X \to \operatorname{Spec} R$ admits a connective cotangent complex $L_{X/\operatorname{Spec} R}$. We will prove this by verifying analogues of the conditions of Example 17.2.4.4. Suppose we are given a connective $\mathbb{E}_\infty$-ring A and a point $\eta \in X(A)$. Then η determines a map of $\mathbb{E}_\infty$-rings $R \to A$. Let $J \subseteq \pi_0 A$ be the ideal generated by the image of I, and let $\operatorname{Spf} A$ be the formal spectrum of A with respect to the ideal J. Then η determines a representable morphism of formal spectral Deligne-Mumford stacks $\eta_0 : \operatorname{Spf} A \to \mathfrak{X}$. Let us identify

the pullback $\eta_0^* L^{\wedge}_{\mathfrak{X}/\operatorname{Spf} R} \in \operatorname{QCoh}(\operatorname{Spf} A)$ with an almost perfect $A^{\wedge}_J$-module M_η. Let N be an arbitrary connective A-module. For each integer $n \geqslant 0$, set $A_n = R_n \otimes_R A$ and $N_n = R_n \otimes_R N$. Unwinding the definitions, we obtain a canonical homotopy equivalence

$$\begin{aligned}
\operatorname{fib}(X'(A \oplus N) \to X'(A)) &\simeq \varprojlim_n \operatorname{fib}(X'(n)(A \oplus N) \to X'(n)(A)) \\
&\simeq \varprojlim_n \operatorname{Map}_{\operatorname{fSpDM}_{\operatorname{Sp\acute{e}t} A_n // \operatorname{Spf} R}}(\operatorname{Sp\acute{e}t} A_n \oplus N_n, \mathfrak{X}) \\
&\simeq \varprojlim_n \operatorname{Map}_{\operatorname{Mod}_{A_n}}(A_n \otimes_A M_\eta, N_n) \\
&\simeq \varprojlim_n \operatorname{Map}_{\operatorname{Mod}_A}(M_\eta, N_n) \\
&\simeq \operatorname{Map}_{\operatorname{Mod}_A}(M_\eta, N^{\wedge}_J)
\end{aligned}$$

where the last equivalence follows from Lemma 8.1.2.3. Assumption (c) guarantees that M_η is J-nilpotent, so that the canonical map $\operatorname{Map}_{\operatorname{Mod}_A}(M_\eta, N) \to \operatorname{Map}_{\operatorname{Mod}_A}(M_\eta, N^{\wedge}_J)$ is a homotopy equivalence for every A-module N. It follows that the M_η corepresents the functor $N \mapsto \operatorname{fib}(X'(A \oplus N) \to X'(A))$.

To complete the proof of the existence of $L_{X/\operatorname{Spec} R}$, it will suffice to show that every map $A \to A'$ induces an equivalence $\alpha : A' \otimes_A M_\eta \to M_{\eta'}$, where η' denotes the image of η in $X(A')$. Let J' denote the ideal in $\pi_0 A'$ generated by I. Using the commutativity of the diagram

$$\begin{array}{ccc}
\operatorname{Mod}^{\operatorname{aperf}}_{A^{\wedge}_J} & \xrightarrow{\sim} & \operatorname{QCoh}(\operatorname{Spf} A)^{\operatorname{aperf}} \\
\downarrow & & \downarrow \\
\operatorname{Mod}^{\operatorname{aperf}}_{A'^{\wedge}_{J'}} & \xrightarrow{\sim} & \operatorname{QCoh}(\operatorname{Spf} A')^{\operatorname{aperf}},
\end{array}$$

we can identify α with the natural map

$$A' \otimes_A M_\eta \simeq (A' \otimes_A A^{\wedge}_J) \otimes_{A^{\wedge}_J} M_\eta \to A'^{\wedge}_{J'} \otimes_{A^{\wedge}_J} M_\eta.$$

The cofiber of this map is given by $K \otimes_{A^{\wedge}_J} M_\eta$, where $K = \operatorname{cofib}(A' \otimes_A A^{\wedge}_J \to A'^{\wedge}_{J'})$. This cofiber vanishes, since K is J-local and M_η is J-nilpotent.

(5) The map $f : X \to \operatorname{Spec} R$ is locally almost of finite presentation. Choose a set of elements $x_1, \ldots, x_d \in R$ which generate the ideal I. We will proceed by induction on d, the case $d = 0$ being trivial. The proof of (4) shows that the relative cotangent complex $L_{X/\operatorname{Spec} R}$ is almost perfect. By virtue of Corollary 17.4.2.2, it will suffice to show that the functor $X'|_{\operatorname{CAlg}^{\heartsuit}_R}$ commutes with filtered colimits. To prove this, we may replace R by $\pi_0 R$ and thereby reduce to the case where R is discrete. Let CAlg^c_R denote the full subcategory of $\operatorname{CAlg}^{\heartsuit}_R$ spanned by those discrete R-algebras which are finitely

presented over R; we wish to prove that $X'|_{\mathrm{CAlg}^{\heartsuit}_R}$ is a left Kan extension of $X'|_{\mathrm{CAlg}^{c}_R}$. Equivalently, we must show that for every discrete R-algebra A, the canonical map

$$\rho : \varinjlim X'(A_\alpha) \to X'(A)$$

is a homotopy equivalence, where the colimit is taken over all finitely generated R-subalgebras $A_\alpha \subseteq A$.

We will prove that the map ρ is k-connective for each $k \geqslant 0$, using induction on k. Let us first suppose that $k > 0$. To prove that ρ is k-connective, it will suffice to show that for every pair of points $\eta, \eta' \in \varinjlim X'(A_\alpha)$, the canonical map $\xi : \{\eta\} \times_{\varinjlim X'(A_\alpha)} \{\eta'\} \to \varinjlim \{\eta\} \times_{X'(A)} \{\eta'\}$ is $(k-1)$-connective. Choose a finitely generated subalgebra $A_0 \subseteq A$ such that η and η' are the images of points $\eta_0, \eta'_0 \in X'(A_0)$. Replacing R by A_0, we may reduce to the case where $A_0 = R$. In this case, we can identify η_0 and η'_0 with maps $\mathrm{Spf}\, R \to \mathfrak{X}$. Let $\mathfrak{Y}$ denote the fiber product $\mathrm{Spf}\, R \times_{\mathfrak{X}} \mathrm{Spf}\, R$, let $Y \simeq \mathrm{Spec}\, R \times_X \mathrm{Spec}\, R$ be the Weil restriction of $\mathfrak{Y}$ along the map $\mathrm{Spf}\, R \hookrightarrow \mathrm{Sp\acute{e}t}\, R$, and let $Y' : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ be the image of Y under the equivalence of ∞-categories $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})_{\mathrm{Spec}\, R} \simeq \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}_R, \mathcal{S})$. Then ξ can be identified with the canonical map $\varinjlim Y'(A_\alpha) \to Y'(A)$. Since the map $\mathfrak{Y}_0 \to \mathrm{Spf}\, R$ satisfies hypotheses (a) through (c), it follows from the inductive hypothesis that ξ is $(k-1)$-connective.

It remains to treat the case $k = 0$. Consider the map of commutative rings $\mathbf{Z}[t] \to R$ which carries t to x_1. For each integer $m \geqslant 0$, set $R(m) = R \otimes_{\mathbf{Z}[t]} \mathbf{Z}[t]/(t^m)$. For every connective R-algebra A, we set $A(m) = R(m) \otimes_R A$. We first prove:

- $(*)$ For every connective R-algebra A, the canonical map $\mu : X'(A) \to \varprojlim X'(A(m))$ is a homotopy equivalence.

To prove $(*)$, we can identify μ with the map

$$\varprojlim_n X'(R_n \otimes_R A) \to \varprojlim_m \varprojlim_n X'(R_n \otimes_R A(m)).$$

It will therefore suffice to each of the maps

$$X'(R_n \otimes_R A) \to \varprojlim_m X'(R_n \otimes_R A(m))$$

is a homotopy equivalence. Replacing A by $R_n \otimes_R A$, we may reduce to proving $(*)$ in the special case where the image of I generates a nilpotent ideal in $\pi_0 A$. In particular, we may assume that the image of x is a nilpotent ideal in $\pi_0 A$. Since the functor X is nilcomplete, we may also assume that A is r-truncated for some integer r, so that each $A(m)$ is $(r+1)$-truncated. We will complete the proof by showing that A is equivalent to $\{A(m)\}_{m \geqslant 0}$ as a Pro-object of $\tau_{\leqslant r+1} \mathrm{CAlg}^{\mathrm{cn}}_R$. To prove this, we show that for every $(r+1)$-truncated connective R-algebra B, the upper horizontal map in the diagram σ :

$$\begin{array}{ccc} \varinjlim_m \mathrm{Map}_{\mathrm{CAlg}_R}(A(m), B) & \longrightarrow & \mathrm{Map}_{\mathrm{CAlg}_R}(A, B) \\ \downarrow & & \downarrow \\ \varinjlim_m \mathrm{Map}_{\mathrm{CAlg}}(\mathbf{Z}[t]/(t^m), B) & \longrightarrow & \mathrm{Map}_{\mathrm{CAlg}}(\mathbf{Z}[t], B) \end{array}$$

is a homotopy equivalence. This follows from Lemma 17.3.5.7, which asserts that the lower horizontal map is a fully faithful embedding whose essential image is the collection of those maps $\mathbf{Z}[t] \to B$ which carry t to a nilpotent element of $\pi_0 B$.

Our next step is to prove the following:

$(*')$ There exists an integer $m \geqslant 0$ such that the map $\pi_0 X'(A) \to \pi_0 X'(A(m))$ is bijective, for every discrete R-algebra A.

Assume $(*')$ for the moment. Let $I(m)$ denote the ideal in $\pi_0 R(m)$ generated by the image of I. Then $I(m)$ has the same radical as the ideal generated by the images of the elements $x_2, \ldots, x_d \in R$. It follows from our inductive hypothesis that for every integer s, the composite functor $\mathrm{CAlg}^{\mathrm{cn}}_{R(m)} \to \mathrm{CAlg}^{\mathrm{cn}}_R \xrightarrow{X'} \mathcal{S}$ preserves filtered colimits when restricted to s-truncated objects of $\mathrm{CAlg}^{\mathrm{cn}}_{R(m)}$, for every integer s. Since $R(m)$ has Tor-amplitude $\leqslant 1$ as an R-module, it follows that the functor $A \mapsto X'(A(m))$ commutes with filtered colimits when restricted to discrete R-algebras. Combining this observation with $(*')$, we conclude that the functor $A \mapsto \pi_0 X'(A)$ commutes with filtered colimits when restricted to CAlg^0_R. It follows that the map ρ is bijective on connected components, and therefore 0-connective.

We now turn to the prove of $(*')$. By virtue of $(*)$, it will suffice to prove the following:

$(*'')$ There exists an integer $m \geqslant 0$ such that, for every discrete R-algebra A and every integer $n \geqslant m$, the map $X'(A(n+1)) \to X'(A(n))$ has connected homotopy fibers.

Since $\mathfrak{X}$ is quasi-compact, we can choose an étale surjection $u : \mathrm{Spf}\, B \to \mathfrak{X}$ for some complete adic $\mathbb{E}_\infty$-ring B. Let us identify $u^* L^\wedge_{\mathfrak{X}/\mathrm{Spf}\, R}$ with an almost perfect B-module using the equivalence $\mathrm{QCoh}(\mathrm{Spf}\, B)^{\mathrm{aperf}} \simeq \mathrm{Mod}^{\mathrm{aperf}}_B$. Choose a perfect B-module M and a 2-connective map $\lambda : M \to u^* L^\wedge_{\mathfrak{X}/\mathrm{Spf}\, R}$. Since $L^\wedge_{\mathfrak{X}/\mathrm{Spf}\, R}$ is nilcoherent, the map λ is annihilated by x_1^c for some integer $c \gg 0$.

Let $n \geqslant 0$ be an integer and let η be a point of $X'(A(n))$, which we can identify with a representable morphism $\operatorname{Spf} A(n) \to \mathfrak{X}$. Form a pullback diagram

$$\begin{array}{ccc} \mathfrak{Y} & \xrightarrow{\eta'} & \operatorname{Spf} B \\ \downarrow{\scriptstyle u'} & & \downarrow{\scriptstyle u} \\ \operatorname{Spf} A(n) & \xrightarrow{\eta} & \mathfrak{X}. \end{array}$$

Since u is an affine étale surjection, it follows from Lemma 19.3.3.4 that we can choose an equivalence $\mathfrak{Y} \simeq \operatorname{Spf} C$, where C is a faithfully flat $A(n)$-algebra which is complete with respect to an ideal $J \subseteq \pi_0 C$. Pulling λ back along η', we conclude that there exists a perfect C-module N and a 2-connective map $N \to C \otimes_{A(n)} \eta^* L^{\wedge}_{\mathfrak{X}/\operatorname{Spf} R}$ which is annihilated by x_1^c. Since C is faithfully flat over $A(n)$, it follows that the homotopy groups $\pi_i \eta^* L^{\wedge}_{\mathfrak{X}/\operatorname{Spf} R}$ are annihilated by x_1^c for $0 \leqslant i \leqslant 2$.

We now show that $m = 3c+1$ satisfies the requirements of $(*'')$. As a first step, we show that for $n \geqslant m$, the homotopy fiber of the map $X'(A(n+1)) \to X'(A(n))$ is connected over every point $\eta \in X'(A(n))$. Note that $\mathbf{Z}[t]/(t^{n+1+3c})$ is a square-zero extension of $\mathbf{Z}[t]/(t^n)$ by the module $\mathbf{Z}[t]/(t^{1+3c})$. It follows that $A(n+3c+1)$ is a square-zero extension of $A(n)$ by $A(3c+1)$. In particular, the obstruction to lifting η to a point of $X'(A(n+3c+1))$ is measured by an element of the group $\operatorname{Ext}^1_{A(n)}(\eta^* L^{\wedge}_{\mathfrak{X}/\operatorname{Spf} R}, A(3c+1))$. To prove that η can be lifted to a point of $X(A(n+1))$, it will suffice to show that the image of this obstruction in $\operatorname{Ext}^1_{A(n)}(\eta^* L^{\wedge}_{\mathfrak{X}/\operatorname{Spf} R}, A(1))$ vanishes (see Remark 17.3.9.2). In fact, we claim that the map of abelian groups

$$\operatorname{Ext}^1_{A(n)}(\eta^* L^{\wedge}_{\mathfrak{X}/\operatorname{Spf} R}, A(3c+1)) \to \operatorname{Ext}^1_{A(n)}(\eta^* L^{\wedge}_{\mathfrak{X}/\operatorname{Spf} R}, A(1))$$

is zero.

Let v be an element of $\operatorname{Ext}^1_{A(n)}(\eta^* L^{\wedge}_{\mathfrak{X}/\operatorname{Spf} R}, A(3c+1))$. Since A is discrete, the suspension $\Sigma A(3c+1)$ is 2-truncated. We may therefore identify v with a map of $A(n)$-modules $v : \tau_{\leqslant 2} \eta^* L^{\wedge}_{\mathfrak{X}/\operatorname{Spf} R} \to \Sigma A(3c+1)$. We wish to show that the composite map

$$\tau_{\leqslant 2} \eta^* L^{\wedge}_{\mathfrak{X}/\operatorname{Spf} R} \xrightarrow{v} \Sigma A(3c+1) \to \Sigma A(1)$$

is nullhomotopic. Since $\pi_2 \eta^* L^{\wedge}_{\mathfrak{X}/\operatorname{Spf} R}$ is annihilated by x_1^c, it admits the structure of a module over $A(c)$. Applying Lemma 19.3.3.3, we deduce that the composite map

$$\Sigma^2(\pi_2 \eta^* L^{\wedge}_{\mathfrak{X}/\operatorname{Spf} R}) \to \tau_{\leqslant 2} \eta^* L^{\wedge}_{\mathfrak{X}/\operatorname{Spf} R} \xrightarrow{v} \Sigma A(3c+1) \to \Sigma A(2c+1)$$

is nullhomotopic. Consequently, there exists a commutative diagram

$$\begin{array}{ccc} \tau_{\leqslant 2} \eta^* L^{\wedge}_{\mathfrak{X}/\operatorname{Spf} R} & \xrightarrow{v} & \Sigma A(3c+1) \\ \downarrow & & \downarrow \\ \tau_{\leqslant 1} \eta^* L^{\wedge}_{\mathfrak{X}/\operatorname{Spf} R} & \xrightarrow{v'} & \Sigma A(2c+1). \end{array}$$

Since $\pi_1 \eta^* L_{\hat{\mathfrak{X}} / \operatorname{Spf} R}$ is annihilated by x_1^c, it also admits the structure of a module over $A(c)$. Applying Lemma 19.3.3.3 again, we deduce that the composite map

$$\Sigma(\pi_1 \eta^* L_{\hat{\mathfrak{X}} / \operatorname{Spf} R}) \to \tau_{\leqslant 1} \eta^* L_{\hat{\mathfrak{X}} / \operatorname{Spf} R} \xrightarrow{v'} \Sigma A(2c+1) \to \Sigma A(c+1)$$

is nullhomotopic. Consequently, there exists a commutative diaram

$$\begin{array}{ccc} \tau_{\leqslant 1} \eta^* L_{\hat{\mathfrak{X}} / \operatorname{Spf} R} & \xrightarrow{v'} & \Sigma A(2c+1) \\ \downarrow & & \downarrow \\ \tau_{\leqslant 0} \eta^* L_{\hat{\mathfrak{X}} / \operatorname{Spf} R} & \xrightarrow{v''} & \Sigma A(c+1). \end{array}$$

We are therefore reduced to proving that the composite map

$$\tau_{\leqslant 0} \eta^* L_{\hat{\mathfrak{X}} / \operatorname{Spf} R} \xrightarrow{v''} \Sigma A(c+1) \to \Sigma A(1)$$

is nullhomotopic. This follows from Lemma 19.3.3.3, since $\pi_0 \eta^* L_{\hat{\mathfrak{X}} / \operatorname{Spf} R}$ is annihilated by x_1^c and therefore admits the structure of a module over $A(c)$. This completes the proof that the homotopy fiber $X'(A(n+1)) \times_{X'(A(n))} \{\eta\}$ is nonempty.

Suppose that $\overline{\eta}$ and $\overline{\eta}'$ are points of the fiber product $X'(A(n+1)) \times_{X'(A(n))} \{\eta\}$; we will complete the proof of $(*'')$ by showing that $\overline{\eta}$ and $\overline{\eta}'$ belong to the same connected component of $X'(A(n+1)) \times_{X'(A(n))} \{\eta\}$. The first part of the proof shows that $\overline{\eta}$ and $\overline{\eta}'$ can be lifted to points of the fiber product $X'(A(n+2c+1)) \times_{X'(A(n))} \{\eta\}$. Since $A(n+2c+1)$ and $A(n+1)$ are square-zero extensions of $A(n)$ by $A(2c+1)$ and $A(1)$, the sets

$$\pi_0(X'(A(n+2c+1)) \times_{X'(A(n))} \{\eta\}) \qquad \pi_0(X'(A(n+1)) \times_{X'(A(n))} \{\eta\})$$

are torsors for the groups $\operatorname{Ext}^0_{A(n)}(\eta^* L_{\hat{\mathfrak{X}} / \operatorname{Spf} R}, A(2c+1))$ and $\operatorname{Ext}^0_{A(n)}(\eta^* L_{\hat{\mathfrak{X}} / \operatorname{Spf} R}, A(1))$, respectively. We are therefore reduced to showing that the map

$$\operatorname{Ext}^0_{A(n)}(\eta^* L_{\hat{\mathfrak{X}} / \operatorname{Spf} R}, A(2c+1)) \to \operatorname{Ext}^0_{A(n)}(\eta^* L_{\hat{\mathfrak{X}} / \operatorname{Spf} R}, A(1))$$

vanishes. Let w be an element of $\operatorname{Ext}^0_{A(n)}(\eta^* L_{\hat{\mathfrak{X}} / \operatorname{Spf} R}, A(2c+1))$. Since A is discrete, we can identify w with a map of $A(n)$-modules $\tau_{\leqslant 1} \eta^* L_{\hat{\mathfrak{X}} / \operatorname{Spf} R} \to A(2c+1)$. Since $\pi_1 L_{\hat{\mathfrak{X}} / \operatorname{Spf} R}$ is annihilated by x_1^c, Lemma 19.3.3.3 implies that the composite map

$$\Sigma^1(\pi_1 \eta^* L_{\hat{\mathfrak{X}} / \operatorname{Spf} R}) \to \tau_{\leqslant 1} \eta^* L_{\hat{\mathfrak{X}} / \operatorname{Spf} R} \xrightarrow{w} A(2c+1) \to A(c+1)$$

is nullhomotopic. Consequently, there exists a commutative diagram

$$\begin{array}{ccc} \tau_{\leqslant 1} \eta^* L_{\hat{\mathfrak{X}} / \operatorname{Spf} R} & \xrightarrow{w} & A(2c+1) \\ \downarrow & & \downarrow \\ \tau_{\leqslant 0} \eta^* L_{\hat{\mathfrak{X}} / \operatorname{Spf} R} & \xrightarrow{w'} & A(c+1). \end{array}$$

It will therefore suffice to show that the composite map

$$\tau_{\leqslant 0}\eta^* L^{\wedge}_{\mathfrak{X}/\operatorname{Spf} R} \xrightarrow{w'} A(c+1) \to A(1)$$

is nullhomotopic, which again follows from Lemma 19.3.3.3.

(1) We must show that for every commutative ring A, the space $X(A)$ is discrete. Equivalently, we must show that for every discrete R-algebra A, the space $X'(A)$ is discrete. Step (5) shows that the functor $A \mapsto X'(A)$ commutes with filtered colimits when restricted to discrete R-algebras. We may therefore assume that A is finitely generated as an R-algebra, and is therefore Noetherian. Set $J = IA \subseteq A$. For each integer $n \geqslant 1$, set $A_n = R_n \otimes_R A$. Then $X'(A) \simeq \varprojlim_n \operatorname{Map}_{\mathrm{fSpDM}_{/\operatorname{Spf} R}}(\operatorname{Sp\acute{e}t} A_n, \mathfrak{X})$. Since the functors represented by $\mathfrak{X}$ and $\operatorname{Spf} R$ are nilcomplete (Proposition 17.3.2.3), we obtain homotopy equivalences

$$\begin{aligned} X'(A) &\simeq \varprojlim_n \varprojlim_m \operatorname{Map}_{\mathrm{fSpDM}_{/\operatorname{Spf} R}}(\operatorname{Sp\acute{e}t} \tau_{\leqslant m} A_n, \mathfrak{X}) \\ &\simeq \varprojlim_m \varprojlim_n \operatorname{Map}_{\mathrm{fSpDM}_{/\operatorname{Spf} R}}(\operatorname{Sp\acute{e}t} \tau_{\leqslant m} A_n, \mathfrak{X}). \end{aligned}$$

It will therefore suffice to show that for each $m \geqslant 0$, the inverse limit

$$\varprojlim_n \operatorname{Map}_{\mathrm{fSpDM}_{/\operatorname{Spf} R}}(\operatorname{Sp\acute{e}t} \tau_{\leqslant m} A_n, \mathfrak{X})$$

is discrete. Lemma 17.3.5.7 implies that the towers $\{\tau_{\leqslant m} A_n\}_{n>0}$ and $\{A/J^n\}_{n>0}$ are equivalent as Pro-objects of CAlg, so we are reduced to showing that the limit $\varprojlim_n \operatorname{Map}_{\mathrm{fSpDM}_{/\operatorname{Spf} R}}(\operatorname{Sp\acute{e}t} A/J^n, \mathfrak{X})$ is discrete. In fact, each of the individual mapping spaces $\operatorname{Map}_{\mathrm{fSpDM}_{/\operatorname{Spf} R}}(\operatorname{Sp\acute{e}t} A/J^n, \mathfrak{X})$ is discrete, since $\mathfrak{X} \to \operatorname{Spf} R$ is representable by spectral algebraic spaces.

□

19.3.4 A Criterion for Properness

In order to apply Proposition 19.3.3.2 to Question 19.3.3.1, we need to verify that if $\mathfrak{X} \to \operatorname{Spf} R$ is a formal modification, then the Weil restriction $\operatorname{Res}_{\operatorname{Spf} R/\operatorname{Sp\acute{e}t} R}(\mathfrak{X})$ actually proper over R. We will deduce this from the following result, which may be of some independent interest:

Proposition 19.3.4.1. *Let R be a Noetherian $\mathbb{E}_\infty$-ring, let $I \subseteq \pi_0 R$ be an ideal, and let $f : \mathsf{X} \to \operatorname{Sp\acute{e}t} R$ be a morphism in of spectral algebraic spaces which satisfies the following conditions:*

(a) *The morphism f is locally almost of finite presentation.*

(b) *The projection map* $f_0 : \mathfrak{X} = \mathsf{X} \times_{\operatorname{Spét} R} \operatorname{Spf} R \to \operatorname{Spf} R$ *is proper.*

(c) *The map* $\mathsf{X} \times_{\operatorname{Spec} R} \mathsf{U} \to \mathsf{U}$ *is an equivalence, where* U *denotes the open substack* $\operatorname{Spec} R$ *complementary to the vanishing locus of* I*.*

(d) *Then the cofiber of the unit map* $u : \mathscr{O}_{\operatorname{Spf} R} \to f_{0*} \mathscr{O}_{\mathfrak{X}}$ *is nilcoherent (as an object of* $\operatorname{QCoh}(\operatorname{Spf} R)$ *).*

Then X *is proper over* R*.*

The proof will require the following purely algebraic result:

Lemma 19.3.4.2. *Let* R *be a discrete valuation ring, let* $t \in R$ *be a generator of its maximal ideal, and let* B *be a finitely generated* R*-algebra. Assume that* B *is flat over* R *and that* $B[t^{-1}]$ *is finitely generated as an* $R[t^{-1}]$*-module. Then:*

(1) *The quotient ring* B/tB *is finitely generated as an* R/tR*-module.*

(2) *The set* $|\operatorname{Spec} B/tB|$ *is finite, and its topology is discrete.*

(3) *Let* $R^\wedge$ *denote the* (t)*-adic completion of* R*, and let* $B^\wedge$ *denote the* (t)*-adic completion of* B*. Then* $B^\wedge$ *is finitely generated as an* $R^\wedge$*-module.*

Proof. We first prove (1). Suppose that $B[t^{-1}]$ has dimension n as a vector space over the fraction field $R[t^{-1}]$. We claim that B/tB has dimension $\leqslant n$ as a vector space over the residue field R/tR. Suppose otherwise: then there exists a sequence of elements $b_0, \ldots, b_n \in B$ whose images in B/tB are linearly independent over R/tR. Since $B[t^{-1}]$ has dimension n over $R[t^{-1}]$, there exists a dependence relation $\sum \lambda_i b_i = 0$ where the coefficients λ_i belong to $R[t^{-1}]$, and not all of the λ_i vanish. Multiplying by an appropriate power of t, we can assume that each λ_i belongs to R. Let t^m be the largest power of t which divides each b_i. Since B is flat over R, the identity $t^m \sum (t^{-m}\lambda_i) b_i = 0$ implies that $\sum (t^{-m}\lambda_i) b_i = 0$ in B. The maximality of m guarantees that some coefficient $t^{-m}\lambda_i$ has nonzero image in B/tB, contradicting our assumption that the images of the elements b_i are linearly independent over R/tR.

Assertion (2) follows immediately from (1). If (1) is satisfied, then we can choose finitely many elements $x_1, \ldots, x_m \in B^\wedge$ whose images generate $B^\wedge/tB^\wedge \simeq B/tB$ as an $R^\wedge$-module. The cokernel of the induced map $\beta : (R^\wedge)^m \to B^\wedge$ is (t)-complete and satisfies $\operatorname{coker}(\beta)/t \operatorname{coker}(\beta) \simeq 0$, so that $\operatorname{coker}(\beta) \simeq 0$. It follows that β is a surjection, so that condition (3) is satisfied. □

Proof of Proposition 19.3.4.1. Let $f : \mathsf{X} \to \operatorname{Spét} R$ satisfy conditions (a) through (d), set $\mathsf{Y} = \mathsf{X} \times_{\operatorname{Spét} R} \operatorname{Spét}(\pi_0 R)/I$ and let V denote the open substack of X complementary to Y. Choose a collection of étale maps $\{\operatorname{Spét} B_s \to \mathsf{X}\}_{s \in S}$ which are jointly surjective. Assumption

(c) implies that the projection $\mathsf{V} \to \mathsf{U}$ is an equivalence, so that V is quasi-compact. Assumption (b) implies that Y is proper over the commutative ring $(\pi_0 R)/I$, and therefore quasi-compact. We may therefore choose a finite subsets $S_0, S_1 \subseteq S$ such that the collections of maps

$$\{\operatorname{Sp\acute{e}t} B_s \times_{\mathsf{X}} \mathsf{V} \to \mathsf{V}\}_{s \in S_0} \qquad \{\operatorname{Sp\acute{e}t} B_s \times_{\mathsf{X}} \mathsf{Y} \to \mathsf{Y}\}_{s \in S_1}$$

are jointly surjective. It follows that the collection of maps $\{\operatorname{Sp\acute{e}t} B_s \to \mathsf{X}\}_{s \in S_0 \cup S_1}$ is jointly surjective, so that X is quasi-compact. Applying the same argument to each fiber product $\operatorname{Sp\acute{e}t} B_s \times_{\mathsf{X}} \operatorname{Sp\acute{e}t} B_t$ (which we regard as a spectral algebraic space which is locally almost of finite presentation over $B_s \otimes_R B_t$), we conclude that X is quasi-separated.

Let $X : \mathrm{CAlg}_R^{\mathrm{cn}} \to \mathcal{S}$ be the functor represented by X. Since X is a spectral algebraic space, we note that $X(A)$ is discrete whenever $A \in \mathrm{CAlg}_R^{\mathrm{cn}}$ is discrete. In this case, we will abuse notation by identifying $X(A)$ with the set $\pi_0 X(A)$. By virtue of Corollary 5.3.1.2, it will suffice to verify the following:

$(*)$ For every object $A \in \mathrm{CAlg}_R^{\mathrm{cn}}$ which is a discrete valuation ring with residue field K, the map $X(A) \to X(K)$ is bijective.

To prove $(*)$, we can replace X by $\operatorname{Sp\acute{e}t} A \times_{\operatorname{Sp\acute{e}t} R} \mathsf{X}$ and thereby reduce to the case where R is a discrete valuation ring and $A = R$. If $I = 0$, then $\operatorname{Spf} R \simeq \operatorname{Sp\acute{e}t} R$ and the desired result is an immediate consequence of (b). If $I = R$, then $\mathsf{U} \simeq \operatorname{Sp\acute{e}t} A$ and the desired result follows from (c). We may therefore assume (replacing I by its radical if necessary) that I is the maximal ideal $\mathfrak{m}_R \subseteq R$. Let $t \in \mathfrak{m}_R$ be a generator. Note that assumption 9c) guarantees that $X(K)$ is contractible; we will complete the proof by showing that $X(R)$ is contractible.

Let $\overline{\mathscr{O}}$ denote the image (in the abelian category $\mathrm{QCoh}(\mathsf{X})^{\heartsuit}$) of the canonical map $\pi_0 \mathscr{O}_{\mathsf{X}} \to \pi_0 \mathscr{O}_{\mathsf{X}}[t^{-1}]$. Then $\overline{\mathscr{O}}$ is a commutative algebra object of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$, and therefore determines an affine morphism $\overline{\mathsf{X}} \to \mathsf{X}$. Let $\overline{X}' : \mathrm{CAlg}_R^{\mathrm{cn}} \to \mathcal{S}$ denote the functor represented by $\overline{\mathsf{X}}$. Note that the map $\overline{X}(R) \to X(R)$ is a homotopy equivalence. It will therefore suffice to show that $\overline{X}(R)$ is contractible.

Let $\mathcal{I}$ denote the fiber of the composite map $\mathscr{O}_{\mathsf{X}} \to \pi_0 \mathscr{O}_{\mathsf{X}} \to \overline{\mathscr{O}}$. Since X is locally Noetherian, each homotopy group $\pi_n \mathcal{I}$ is almost perfect (when regarded as an object of $\mathrm{QCoh}(\mathsf{X})^{\heartsuit} \subseteq \mathrm{QCoh}(\mathsf{X})$). It follows from (c) that $\mathscr{O}_{\mathsf{X}}[t^{-1}]$ is a discrete object of $\mathrm{QCoh}(\mathsf{X})$, so that $\mathcal{I}[t^{-1}] \simeq 0$. Using the quasi-compactness of X, we conclude that for every integer $n \geqslant 0$, there exists an integer k_n such that $\pi_n \mathcal{I}$ is annihilated by t^{k_n}, so that $\tau_{\leqslant n} \mathcal{I}$ is annihilated by $t^{k_0 + k_1 + \cdots + k_n}$. Using Proposition 2.5.4.4 and Theorem 3.4.2.1, we deduce that there exists an integer m such that the pushforward functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{Mod}_R$ carries $\mathrm{QCoh}(\mathsf{X})_{\geqslant 0}$ into $(\mathrm{Mod}_R)_{\geqslant -m}$. It follows that for each integer n, $\tau_{\leqslant n}(f_* \mathcal{I}) \simeq \tau_{\leqslant n} f_* (\tau_{\leqslant n+m} \mathcal{I})$ is annihilated by $t^{k_0 + \cdots + k_{m+n}}$, so that the restriction of $f_* \mathcal{I}$ to $\mathrm{QCoh}(\operatorname{Spec} R)$ is $\mathfrak{m}_R$-nilpotent. Let $\overline{\mathscr{O}}_{\mathfrak{X}}$ denote the pullback of $\overline{\mathscr{O}}$ to $\mathrm{QCoh}(\mathfrak{X})$, so that we have maps

$$\mathscr{O}_{\operatorname{Spf} R} \xrightarrow{u} f_{0*} \mathscr{O}_{\mathsf{X}} \xrightarrow{u'} f_{0*} \overline{\mathscr{O}}_{\mathfrak{X}}$$

in QCoh(Spf R). Then $\mathrm{cofib}(u)$ is nilcoherent by assumption (d) and $\mathrm{cofib}(u')$ is nilcoherent by Proposition 8.3.2.6, so that $\mathrm{cofib}(u' \circ u)$ is also nilcoherent. We may therefore replace X by $\overline{\mathsf{X}}$, and thereby reduce to the case where X is flat over R.

We now complete the proof by showing that the map $\mathsf{X} \to \mathrm{Spét}\, R$ is an equivalence. For every étale map $\phi : \mathrm{Spét}\, B \to \mathsf{X}$, the $\mathbb{E}_\infty$-ring B is a flat over R. It follows from (c) that $B[t^{-1}]$ is étale over K and is therefore isomorphic to a finite product of separable extensions of K. Since B is R-flat, $B \simeq 0$ if and only if $B[t^{-1}] \simeq 0$. In particular, every nonempty open substack of X has nonempty interesection with $\mathsf{V} \simeq \mathrm{Spét}\, K$. Since V has no nonempty open substacks other than itself, every nonempty open substack of X must contain V.

Using Theorem 3.4.2.1, we can choose a scallop decomposition

$$\varnothing = \mathsf{V}_0 \hookrightarrow \mathsf{V}_1 \hookrightarrow \cdots \hookrightarrow \mathsf{V}_n = \mathsf{X}$$

for the quasi-compact, quasi-separated spectral algebraic space X. Without loss of generality, we may assume that V_1 is nonempty and therefore contains V. For $2 \leqslant i \leqslant n$, we have an excision square

$$\begin{array}{ccc} \mathsf{W}_i & \longrightarrow & \mathrm{Spét}\, B_i \\ \downarrow & & \downarrow \\ \mathsf{V}_{i-1} & \longrightarrow & \mathsf{V}_i, \end{array}$$

where $\mathrm{Spét}\, B_i$ is étale over X and W_i is a quasi-compact open of $\mathrm{Spét}\, B_i$ determined by an open set $W_i \subseteq |\mathrm{Spec}\, B_i|$. By construction, W_i contains the open subset $W_i^\circ = |\mathrm{Spec}\, B_i[t^{-1}]| \subseteq |\mathrm{Spec}\, B_i|$. Using Lemma 19.3.4.2, we see that there are only finitely many prime ideals of B containing t, none of which is contained in another. We may therefore write W_i as the union of W_i° and finitely many maximal ideals $\mathfrak{m}_1, \ldots, \mathfrak{m}_k$ of B_i containing t. Using prime avoidance, we can choose an element $b_i \in \bigcup_{1 \leqslant j \leqslant k} \mathfrak{m}_j$ which is not contained in any other prime ideal of B containing t. We then have an excision square

$$\begin{array}{ccc} \mathrm{Spét}\, B_i[t^{-1}] & \longrightarrow & \mathrm{Spét}\, B_i[b_i^{-1}] \\ \downarrow & & \downarrow \\ \mathsf{W}_i & \longrightarrow & \mathrm{Spét}\, B_i. \end{array}$$

We may therefore replace each B_i by $B_i[b_i^{-1}]$, and thereby reduce to the case where $\mathsf{W}_i \simeq \mathrm{Spét}\, B_i[t^{-1}]$. In this case, each of the maps $\mathsf{W}_i \to \mathsf{V}_{i-1}$ factors through V. We therefore have a pushout diagram:

$$\begin{array}{ccc} \coprod_{2 \leqslant i \leqslant n} \mathrm{Spét}\, B_i[t^{-1}] & \longrightarrow & \coprod_{2 \leqslant i \leqslant n} \mathrm{Spét}\, B_i \\ \downarrow & & \downarrow \\ \mathsf{V} & \longrightarrow & \mathsf{X}. \end{array}$$

Set $B = \prod_{2 \leqslant i \leqslant n} B_i$. Let $R^\wedge$ and $B^\wedge$ denote the (t)-adic completions of R and B, respectively. Using Lemma 19.3.4.2, we see that $B^\wedge$ is finitely generated as an $R^\wedge$-module. Since B is flat over R, the multiplication map $t : B \to B$ is injective. It follows that the map $t : B^\wedge \to B^\wedge$ is also injective, so that $B^\wedge$ is flat over $R^\wedge$. Since $R^\wedge$ is a discrete valuation ring, $B^\wedge$ is a free module of finite rank over $R^\wedge$. Unwinding the definitions, we note that condition (d) asserts that the unit map $u : R^\wedge \to B^\wedge$ induces an equivalence $R^\wedge[t^{-1}] \to B^\wedge[t^{-1}]$. It follows that $B^\wedge$ is a free module of rank 1 over $R^\wedge$, and that the map u is injective. In particular, $B^\wedge$ is faithfully flat as an $R^\wedge$-module, so that $\operatorname{coker}(u)$ is flat over $R^\wedge$. Since $\operatorname{coker}(u)[t^{-1}] \simeq 0$, we conclude that u is surjective and therefore an isomorphism.

We next claim that B is étale over R. Since B is finitely presented over R, it will suffice to show that $L_{B/R} \simeq 0$ (Lemma B.1.3.3). Suppose otherwise: then there is some smallest integer d such that $\pi_d L_{B/R} \neq 0$. Note that B is almost perfect as an object of $\mathrm{CAlg}_R^{\mathrm{cn}}$, so that $L_{B/R}$ is almost perfect and $\pi_d L_{B/R}$ is finitely generated as a B-module. We have already established that $B[t^{-1}]$ is étale over $R[t^{-1}]$, so that $L_{B/R}[t^{-1}] \simeq L_{B[t^{-1}]/R[t^{-1}]} \simeq 0$. It follows that $\pi_d L_{B/R}$ is annihilated by t^k for $k \gg 0$. Then

$$0 \neq \pi_d L_{B/R} \simeq \pi_d(B/t^k B \otimes_B L_{B/R}) \simeq \pi_d(L_{(B/t^k B)/(R/t^k R)}).$$

This is a contradiction, since the map $R \to B$ induces an isomorphism after t-adic completion (and therefore an isomorphism $R/t^k R \to B/t^k B$).

Since the map $\operatorname{Spét} B \to \mathsf{X}$ is an étale surjection, we conclude that X is étale over R. Consequently, to show that $\mathsf{X} \to \operatorname{Spét} R$ is an equivalence, it will suffice to show that the maps

$$\mathsf{X} \times_{\operatorname{Spét} R} \operatorname{Spét} R[t^{-1}] \to \operatorname{Spét} R[t^{-1}]$$

$$\mathsf{X} \times_{\operatorname{Spét} R} \operatorname{Spét}(R/tR) \to \operatorname{Spét}(R/tR)$$

are equivalences (Lemma HA.A.5.11 and Theorem 3.1.2.1). In the first case, this follows immediately from assumption (c). In the second, we note that the existence of the excision square σ supplies an identification $\mathsf{X} \times_{\operatorname{Spét} R} \operatorname{Spét}(R/tR) \simeq \operatorname{Spét}(B/tB)$, so that the desired assertion follows from the fact that the unit map $R/tR \to B/tB$ is an isomorphism. □

19.4 Moduli of Algebraic Varieties

Let X be a proper smooth algebraic variety over the field $\mathbf{C}$ of complex numbers. Recall that a *first order deformation* of X is a flat $\mathbf{C}[\epsilon]/(\epsilon^2)$-scheme $\overline{X}$ equipped with an isomorphism $X \simeq \operatorname{Spec} \mathbf{C} \times_{\operatorname{Spec} \mathbf{C}[\epsilon]/(\epsilon^2)} \overline{X}$. A classical result of deformation theory establishes a bijection from the set of isomorphism classes of first-order deformations of X to the cohomology group $\mathrm{H}^1(X; T_X)$, where T_X denotes the tangent bundle of X. We can describe the situation more informally as follows:

($*$) Let $\mathcal{M}$ denote the "moduli space" of proper algebraic varieties, so that X determines a $\mathbf{C}$-valued point η of $\mathcal{M}$. Then the tangent space to $\mathcal{M}$ at η can be identified with $\mathrm{H}^1(X; T_X)$.

To articulate ($*$) more precisely, it is convenient to introduce a formal definition of the "moduli space" $\mathcal{M}$:

Construction 19.4.0.1 (Moduli of Spectral Algebraic Spaces)**.** Let SpDM denote the ∞-category of spectral Deligne-Mumford stacks, and let $\mathcal{C}$ denote the full subcategory of the fiber product

$$(\mathrm{CAlg}^{\mathrm{cn}})^{\mathrm{op}} \times_{\mathrm{Fun}(\{1\}, \mathrm{SpDM})} \mathrm{Fun}(\Delta^1, \mathrm{SpDM})$$

spanned by morphisms $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$, where f is proper, flat, and locally almost of finite presentation. We let $\mathrm{Var}^+ : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ be a functor which classifies the Cartesian fibration $\mathcal{C} \to (\mathrm{CAlg}^{\mathrm{cn}})^{\mathrm{op}}$ (given by projection onto the first factor).

More informally, if R is a connective $\mathbb{E}_\infty$-ring, then $\mathrm{Var}^+(R)$ is the ∞-category spectral algebraic spaces which are proper, flat, and locally almost of finite presentation over R.

Our goal in this section is to study the functor Var^+ of Construction 19.4.0.1. Our main results can be summarized as follows:

Theorem 19.4.0.2. *Let* $\mathrm{Var}^+ : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ *be as in Construction 19.4.0.1. Then:*

(1) *The functor* Var^+ *is cohesive and nilcomplete.*

(2) *The functor* Var^+ *is locally almost of finite presentation: that is,* Var^+ *commutes with filtered colimits when restricted to* $\tau_{\leqslant n} \mathrm{CAlg}^{\mathrm{cn}}$*, for every integer* $n \geqslant 0$.

(3) *For every connective* $\mathbb{E}_\infty$*-ring* R*, the* ∞*-category* $\mathrm{Var}^+(R)$ *is essentially small. Consequently, we can identify* Var^+ *with a functor* $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{C}\mathrm{at}_\infty$.

(4) *For every simplicial set* K*, let* $\mathrm{Var}^+_K : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ *denote the functor given by the formula* $\mathrm{Var}^+_K(R) = \mathrm{Fun}(K, \mathrm{Var}^+(R))^{\simeq}$*. Then the functor* Var^+_K *admits a* (-1)*-connective cotangent complex (which can be described explicitly using Kodaira-Spencer theory; see §19.4.3).*

(5) *Suppose that* K *is a simplicial set having only finitely many simplices of each dimension. Then the functor* Var^+_K *is locally almost of finite presentation and the cotangent complex to* Var^+_K *is almost perfect.*

Warning 19.4.0.3. The functor Var^+ of Theorem 19.4.0.2 is not integrable. If A is a local Noetherian ring which is complete with respect to its maximal ideal $\mathfrak{m}$, then Corollary 8.5.3.3 implies that the functor $\mathrm{Var}^+(A) \to \varprojlim \mathrm{Var}^+(A/\mathfrak{m}^n)$ is a fully faithful embedding. However, it is generally not essentially surjective: that is, not every proper flat representable morphism $\mathfrak{X} \to \mathrm{Spf}\, A$ is algebraizable in the sense of Remark 8.5.3.6.

Remark 19.4.0.4. Let K be a simplicial set having only finitely many simplices of each dimension and let $\mathrm{Var}^+_K : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be defined as in Theorem 19.4.0.2. Then Var^+_K is *almost* representable by a spectral Deligne-Mumford stack which is locally almost of finite presentation over the sphere spectrum S: it satisfies all of the hypotheses of Theorem 18.3.0.1 *except* for integrability (Warning 19.4.0.3). There are several variants of Construction 19.4.0.1 which give rise to representable functors (for example, we could restrict our attention to morphisms $\mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ of relative dimension $\leqslant 1$). We will return to this point in §**??**.

19.4.1 Nilcompleteness and Cohesiveness

The first assertion of Theorem 19.4.0.2 hold in much greater geneality.

Notation 19.4.1.1. Let $n \geqslant 0$ be a nonnegative integer. Recall that a spectral Deligne-Mumford stack X is said to be *n-truncated* if the structure sheaf $\mathscr{O}_{\mathsf{X}}$ is n-truncated. We let $\mathrm{SpDM}^{\leqslant n}$ denote the full subcategory of SpDM spanned by the n-truncated spectral Deligne-Mumford stacks. The inclusion functor $\mathrm{SpDM}^{\leqslant n} \hookrightarrow \mathrm{SpDM}$ admits a right adjoint $\tau_{\leqslant n} : \mathrm{SpDM} \to \mathrm{SpDM}^{\leqslant n}$, given on objects by the formula $\tau_{\leqslant n}(\mathcal{X}, \mathscr{O}_{\mathsf{X}}) = (\mathcal{X}, \tau_{\leqslant n}\, \mathscr{O}_{\mathsf{X}})$.

Proposition 19.4.1.2. *Let X be a spectral Deligne-Mumford stack. Then the pullback functors*

$$(\mathsf{Y} \in \mathrm{SpDM}_{/\mathsf{X}}) \mapsto (\mathsf{Y} \times_{\mathsf{X}} \tau_{\leqslant n} \mathsf{X} \in \mathrm{SpDM}_{/\tau_{\leqslant n} \mathsf{X}})$$

induce an equivalence of ∞-categories $\mathrm{SpDM}_{/\mathsf{X}} \to \varprojlim \mathrm{SpDM}_{/\tau_{\leqslant n} \mathsf{X}}$.

Proof. For every spectral Deligne-Mumford stack X, let $\mathrm{SpDM}^{\leqslant n}_{/\mathsf{X}}$ denote the full subcategory of $\mathrm{SpDM}_{/\mathsf{X}}$ spanned by those morphisms $\mathsf{Y} \to \mathsf{X}$ where Y is n-truncated. We have a commutative diagram

$$\begin{array}{ccc}
\mathrm{SpDM}_{/\mathsf{X}} & \longrightarrow & \varprojlim_n \mathrm{SpDM}_{/\tau_{\leqslant n} \mathsf{X}} \\
\downarrow & & \downarrow \\
\varprojlim_m \mathrm{SpDM}^{\leqslant m}_{/\mathsf{X}} & \longrightarrow & \varprojlim_n \varprojlim_m \mathrm{SpDM}^{\leqslant m}_{/\mathsf{X}_n},
\end{array}$$

where the horizontal maps are given by pullback and the vertical maps are given by truncation. The lower horizontal map is an equivalence, since the truncated pullback functor $\mathrm{SpDM}^{\leqslant m}_{/\mathsf{X}} \to \mathrm{SpDM}^{\leqslant m}_{/\tau_{\leqslant n} \mathsf{X}}$ is an equivalence for $m \leqslant n$. It follows from Proposition 1.4.9.1 that the vertical maps are equivalences, so that the upper horizontal map is an equivalence as well. □

Corollary 19.4.1.3. *The construction $R \mapsto \mathrm{SpDM}_{/\,\mathrm{Sp\acute{e}t}\, R}$ determines a cohesive and nil-complete functor $\overline{\mathrm{Var}}^+ : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$.*

Proof. The nilcompleteness follows from Proposition 19.4.1.2, and the cohesiveness is a consequence of Theorem 16.3.0.1. □

19.4.2 Deformation-Invariant Properties of Morphisms $\mathsf{X} \to \operatorname{Sp\acute{e}t} R$

Corollary 19.4.1.3 does not apply directly in the situation of Theorem 19.4.0.2, because the classification of proper flat spectral algebraic spaces is different from the classification of general spectral Deligne-Mumford stacks. Nevertheless, our next result guarantees that the deformation theory of the former is controlled by the deformation theory of the latter:

Proposition 19.4.2.1. *Let $\overline{\mathrm{Var}}^{+} : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_{\infty}$ be as in Corollary 19.4.1.3, and let $\overline{\mathrm{Var}}^{+}_{0} : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_{\infty}$ be the functor which assigns to each connective $\mathbb{E}_{\infty}$-ring R the full subcategory of $X(R) \simeq \mathrm{SpDM}_{/\operatorname{Sp\acute{e}t} R}$ spanned by those maps $f : \mathsf{X} \to \operatorname{Sp\acute{e}t} R$ satisfying any one of the following conditions:*

(1) *The map f is locally of finite generation to order n (where $n \geqslant 0$ is some fixed integer).*

(2) *The map f is locally almost of finite presentation.*

(3) *The map f is locally of finite presentation.*

(4) *The map f is n-quasi-compact (where $0 \leqslant n \leqslant \infty$).*

(5) *The map f is separated.*

(6) *The map f is flat.*

(7) *The map f is proper.*

Then the inclusion $j : \overline{\mathrm{Var}}^{+}_{0} \to \overline{\mathrm{Var}}^{+}$ is cohesive and nilcomplete.

Remark 19.4.2.2. In the situation of Proposition 19.4.2.1, let $\overline{\mathrm{Var}}^{+}_{0} : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_{\infty}$ be the functor which assigns to a connective $\mathbb{E}_{\infty}$-ring R the full subcategory of $\overline{\mathrm{Var}}^{+}(R) = \mathrm{SpDM}_{/\operatorname{Sp\acute{e}t} R}$ spanned by those maps of spectral Deligne-Mumford stacks $f : \mathsf{X} \to \operatorname{Sp\acute{e}t} R$ which satisfy some combination of the conditions (1) through (7) appearing in Proposition 19.4.2.1. Then the inclusion $j : \overline{\mathrm{Var}}^{+}_{0} \to \overline{\mathrm{Var}}^{+}$ is cohesive and nilcomplete. It then follows from Corollary 19.4.1.3 that the functor $\overline{\mathrm{Var}}^{+}_{0}$ is cohesive and nilcomplete.

The proof of Proposition 19.4.2.1 will require some preliminaries.

Lemma 19.4.2.3. *Let $f : \mathsf{X} \to \operatorname{Sp\acute{e}t} R$ be a map of spectral Deligne-Mumford stacks, and let $f_0 : \mathsf{X} \times_{\operatorname{Sp\acute{e}t} R} \operatorname{Sp\acute{e}t} \pi_0 R \to \operatorname{Sp\acute{e}t} \pi_0 R$ be the projection onto the second factor. Suppose that f_0 satisfies one of the following conditions:*

(1) *The map f_0 is locally of finite generation to order n (where $n \geqslant 0$ is some fixed integer).*

(2) *The map f_0 is locally almost of finite presentation.*

(3) *The map f_0 is locally of finite presentation.*

(4) *The map* f_0 *is* n*-quasi-compact (where* $0 \leqslant n \leqslant \infty$*).*

(5) *The map* f_0 *is separated.*

(6) *The map* f_0 *is flat.*

(7) *The map* f_0 *is proper.*

Then f *has the same property.*

Proof. We first treat cases (1), (2), and (3). The assertions are local on X, so we may assume that $\mathsf{X} = \operatorname{Spét} A$ is affine. Let $A' = A \otimes_R \pi_0 R$. Assertion (1) is obvious in the case $n = 0$ (see Remark 4.1.1.4). In all other cases, we may assume that f_0 is of finite generation to order 1, so that $\pi_0 A \simeq \pi_0 A'$ is finitely presented as a commutative ring over $\pi_0 R$. It will therefore suffice to show that if $L_{A'/\pi_0 R}$ is perfect to order n (almost perfect, perfect) as a module over A', then $L_{A/R}$ is perfect to order n (almost perfect, perfect) as a module over A (see Proposition 4.1.2.1 and Theorem HA.7.4.3.18). This follows from Proposition 2.7.3.2.

Case (4) is easy, since the underlying ∞-topoi of X and $\mathsf{X}' = \mathsf{X} \times_{\operatorname{Spét} R} \operatorname{Spét} \pi_0 R$ are the same. To treat case (5), we must show that the diagonal map $\delta : \mathsf{X} \to \mathsf{X} \times_{\operatorname{Spét} R} \mathsf{X}$ is a closed immersion of spectral Deligne-Mumford stacks. Since δ admits a left homotopy inverse (given by the projection onto either fiber), it suffices to show that δ induces a closed immersion between the underlying ∞-topoi of X and $\mathsf{X} \times_{\operatorname{Spét} R} \mathsf{X}$. This follows from our assumption on f_0, since the underlying ∞-topos of $\mathsf{X} \times_{\operatorname{Spét} R} \mathsf{X}$ is equivalent to the underlying ∞-topos of $\mathsf{X}' \times_{\operatorname{Spét} \pi_0 R} \mathsf{X}'$.

We now consider case (6). The assertion is local on X, so we may assume that $\mathsf{X} = \operatorname{Spét} A$ is affine. We wish to show that A is flat over R. Let M be a discrete R-module; we wish to show that $A \otimes_R M$ is discrete. This is clear, since M has the structure of a module over $\pi_0 R$, and the tensor product $A \otimes_R \simeq A' \otimes_{\pi_0 R} M$ is discrete by virtue of our assumption that A' is flat over $\pi_0 R$.

It remains to treat case (7). Assume that f_0 exhibits X' as a proper spectral algebraic space over $\pi_0 R$. It follows from (1), (4) and (5) that X is a quasi-compact separated spectral algebraic space which is locally of finite type over R. It will therefore suffice to show that, for every map of connective $\mathbb{E}_\infty$-rings $R \to R'$, the map of topological spaces $\phi : |\,\mathsf{X} \times_{\operatorname{Spét} R} \operatorname{Spét} R'| \to |\operatorname{Spec} R'|$ is closed. This follows from our assumption on f_0, since ϕ can be identified with the map of topological spaces

$$|\,\mathsf{X}' \times_{\operatorname{Spét} \pi_0 R} \operatorname{Spét}(\pi_0 R \otimes_R R')| \to |\operatorname{Spec}(\pi_0 R \otimes_R R')|.$$

□

Proof of Proposition 19.4.2.1. The nilcompleteness of j is a consequence of Lemma 19.4.2.3. We will prove that j is cohesive. In cases (1) through (6), this follows from Proposition

16.3.2.1. Let us consider (7). Suppose we are given a pullback diagram of connective $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc} R & \longrightarrow & R_0 \\ \downarrow & & \downarrow \\ R_1 & \longrightarrow & R_{01} \end{array}$$

where the maps $\pi_0 R_0 \to \pi_0 R_{01} \leftarrow \pi_0 R_1$ are surjective. Fix a map $f : \mathsf{X} \to \operatorname{Spét} R$, and assume that $\mathsf{X} \times_{\operatorname{Spét} R} \operatorname{Spét} R_0$ and $\mathsf{X} \times_{\operatorname{Spét} R} \operatorname{Spét} R_1$ are spectral algebraic spaces which are proper over R_0 and R_1, respectively. It follows from (1), (4), and (5) that X is a quasi-compact separated spectral algebraic space which is locally of finite type over R. To complete the proof, it will suffice to show that for every connective R-algebra R', the map of topological spaces $|\mathsf{X} \times_{\operatorname{Spét} R} \operatorname{Spét} R'| \to |\operatorname{Spec} R'|$ is closed. Replacing R by R', it suffices to show that the map $|\mathsf{X}| \to |\operatorname{Spec} R|$ is closed. Fix a closed subset $K \subseteq |\mathsf{X}|$. Then K is the image of a closed immersion $i : \mathsf{Y} \to \mathsf{X}$ (where we can take the spectral Deligne-Mumford stack Y to be reduced, if so desired). Let $\mathsf{Y}_0 = \mathsf{Y} \times_{\mathsf{X}} \mathsf{X}_0$, and define Y_1 and Y_{01} similarly. We have a pushout diagram of spectral Deligne-Mumford stacks and closed immersions

$$\begin{array}{ccc} \mathsf{Y}_{01} & \longrightarrow & \mathsf{Y}_0 \\ \downarrow & & \downarrow \\ \mathsf{Y}_1 & \longrightarrow & \mathsf{Y}, \end{array}$$

hence a pushout diagram of topological spaces

$$\begin{array}{ccc} |\mathsf{Y}_{01}| & \longrightarrow & |\mathsf{Y}_0| \\ \downarrow & & \downarrow \\ |\mathsf{Y}_1| & \longrightarrow & |\mathsf{Y}|. \end{array}$$

It follows that the image of K in $|\operatorname{Spec} R|$ is the union of the images of the maps

$$|\mathsf{Y}_0| \to |\mathsf{X}_0| \to |\operatorname{Spec} R_0| \hookrightarrow |\operatorname{Spec} R|$$

$$|\mathsf{Y}_1| \to |\mathsf{X}_1| \to |\operatorname{Spec} R_1| \hookrightarrow |\operatorname{Spec} R|.$$

Each of these sets is closed, since X_0 is proper over R_0 and X_1 is proper over R_1. □

19.4.3 Kodaira-Spencer Theory

We now consider the classification of first-order deformations of spectral Deligne-Mumford stacks. We will parallel the discussion of §19.2.2, where we studied the analogous (but easier) problem of classifying first-order deformations of quasi-coherent sheaves. In particular, we make use of Notation 19.2.2.1: if $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathsf{Y}})$ is a spectral Deligne-Mumford stack and we are given a derivation $\eta \in \mathrm{Der}(\mathscr{O}_{\mathsf{Y}}, \Sigma \mathscr{E})$, we let $\mathsf{Y}^{\eta} = (\mathcal{Y}, \mathscr{O}_{\mathsf{Y}}^{\eta})$ denote the "infinitesimal thickening" of Y determined by η; when $\eta = 0$, we denote this thickening simply by $\mathsf{Y}^{\mathscr{E}}$. Note that we have a pushout diagram of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathsf{Y}^{\Sigma \mathscr{E}} & \longrightarrow & \mathsf{Y} \\ \downarrow & & \downarrow \\ \mathsf{Y} & \longrightarrow & \mathsf{Y}^{\eta} \end{array}$$

where the maps are closed immersions. Applying Theorem 16.3.0.1, we deduce that the diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{SpDM}_{/\mathsf{Y}^{\eta}} & \longrightarrow & \mathrm{SpDM}_{/\mathsf{Y}} \\ \downarrow & & \downarrow \\ \mathrm{SpDM}_{/\mathsf{Y}} & \longrightarrow & \mathrm{SpDM}_{/\mathsf{Y}^{\Sigma \mathscr{E}}} \end{array}$$

is a pullback square. Taking $\eta = 0$ and passing to homotopy fibers over some fixed object $\mathsf{X} \in \mathrm{SpDM}_{/\mathsf{Y}}$, we obtain equivalences

$$\begin{aligned} \mathrm{SpDM}_{/\mathsf{Y}^{\mathscr{E}}} \times_{\mathrm{SpDM}_{/\mathsf{Y}}} \{\mathsf{X}\} &\simeq \mathrm{Map}_{\mathrm{SpDM}_{/\mathsf{Y}^{\Sigma \mathscr{E}}}}(\mathsf{X} \times_{\mathsf{Y}} \mathsf{Y}^{\Sigma \mathscr{E}}, \mathsf{X} \times_{\mathsf{Y}} \mathsf{Y}^{\Sigma \mathscr{E}}) \times_{\mathrm{Map}_{\mathrm{SpDM}_{/\mathsf{Y}}}(\mathsf{X}, \mathsf{X})} \{\mathrm{id}_{\mathsf{X}}\} \\ &\simeq \mathrm{Map}_{\mathrm{SpDM}_{/\mathsf{Y}}}(\mathsf{X} \times_{\mathsf{Y}} \mathsf{Y}^{\Sigma \mathscr{E}}, \mathsf{X}) \times_{\mathrm{Map}_{\mathrm{SpDM}_{/\mathsf{Y}}}(\mathsf{X}, \mathsf{X})} \{\mathrm{id}_{\mathsf{X}}\} \\ &\simeq \mathrm{Map}_{\mathrm{SpDM}_{\mathsf{X}//\mathsf{Y}}}(\mathsf{X}^{f^* \Sigma \mathscr{E}}, \mathsf{X}) \\ &\simeq \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(L_{\mathsf{X}/\mathsf{Y}}, \Sigma f^* \mathscr{E}); \end{aligned}$$

here the first equivalence follows from the observation that any lifting of id_{X} to an endomorphism of $\mathsf{X} \times_{\mathsf{Y}} \mathsf{Y}^{\Sigma \mathscr{E}}$ is automatically invertible (Corollary 1.4.7.4). We can summarize the situation as follows:

Proposition 19.4.3.1 (Classification of First-Order Deformations)**.** *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks and let $\mathscr{E} \in \mathrm{QCoh}(\mathsf{Y})^{\mathrm{cn}}$. Then the ∞-category $\mathrm{SpDM}_{/\mathsf{Y}^{\mathscr{E}}} \times_{\mathrm{SpDM}_{/\mathsf{Y}}} \{\mathsf{X}\}$ is a Kan complex, which is canonically homotopy equivalent to the mapping space $\mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(L_{\mathsf{X}/\mathsf{Y}}, \Sigma f^* \mathscr{E})$. In particular, we obtain a canonical bijection*

$$\pi_0(\mathrm{SpDM}_{/\mathsf{Y}^{\mathscr{E}}} \times_{\mathrm{SpDM}_{/\mathsf{Y}}} \{\mathsf{X}\}) \simeq \mathrm{Ext}^1_{\mathrm{QCoh}(\mathsf{X})}(L_{\mathsf{X}/\mathsf{Y}}, f^* \mathscr{E}).$$

In the situation of Proposition 19.4.3.1, suppose that the morphism f is proper, locally almost of finite presentation, and locally of finite Tor-amplitude. Then we can consider the relative dualizing sheaf $\omega_{\mathsf{X}/\mathsf{Y}}$ (Definition 6.4.2.4) and the functor $f_+ : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ of Construction 6.4.5.1. Applying Proposition 6.4.5.3, we obtain a canonical homotopy equivalence

$$\mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(L_{\mathsf{X}/\mathsf{Y}}, \Sigma f^* \mathscr{E}) \simeq \mathrm{Map}_{\mathrm{QCoh}(\mathsf{Y})}(f_+ L_{\mathsf{X}/\mathsf{Y}}, \Sigma \mathscr{E}) \simeq \mathrm{Map}_{\mathrm{QCoh}(\mathsf{Y})}(f_*(\omega_{\mathsf{X}/\mathsf{Y}} \otimes L_{\mathsf{X}/\mathsf{Y}}), \Sigma \mathscr{E}).$$

Notation 19.4.3.2. For any simplicial set K, we let $\mathrm{Var}^+_K : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be the functor introduced in Theorem 19.4.0.2 (given by the formula $\mathrm{Var}^+_K(R) = \mathrm{Fun}(K, \mathrm{Var}^+(R))^{\simeq}$). In the special case $K = \Delta^0$, we will denote Var^+_K by $\mathrm{Var}^+_{\simeq}$ (so that $\mathrm{Var}^+_{\simeq}(R)$ is the underlying Kan complex of the ∞-category of spectral algebraic spaces which are proper, flat, and locally almost of finite presentation over R).

Corollary 19.4.3.3. *The functor* $\mathrm{Var}^+_{\simeq}$ *admits a cotangent complex which is almost perfect and* (-1)*-connective.*

Proof. Let η be an R-valued point of $\mathrm{Var}^+_{\simeq}$, classifying a morphism $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ which is proper, flat, and locally almost of finite presentation. For every connective R-module M, Propositions 19.4.3.1 and 19.4.2.1 supply a canonical homotopy equivalence

$$\mathrm{Var}^+_{\simeq}(R \oplus M) \times_{\mathrm{Var}^+(R)} \{\eta\} \simeq \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(L_{\mathsf{X}/\mathrm{Sp\acute{e}t}\, R}, \Sigma f^* M) \simeq \mathrm{Map}_{\mathrm{Mod}_R}(\Sigma^{-1} f_+ L_{\mathsf{X}/\mathrm{Sp\acute{e}t}\, R}, M).$$

Consequently, the functor $\mathrm{Var}^+_{\simeq}$ satisfies condition (a) of Example 17.2.4.4, and condition (b) follows from the compatibility of f_+ with base change (see Proposition 6.4.5.4). It follows that $\mathrm{Var}^+_{\simeq}$ admits a cotangent complex $L_{\mathrm{Var}^+_{\simeq}}$, satisfying $\eta^* L_{\mathrm{Var}^+_{\simeq}} = \Sigma^{-1} f_+ L_{\mathsf{X}/\mathrm{Sp\acute{e}t}\, R}$. Since the quasi-coherent sheaf $L_{\mathsf{X}/\mathrm{Sp\acute{e}t}\, R}$ is connective and almost perfect, the R-module $\Sigma^{-1} f_+ L_{\mathsf{X}/\mathrm{Sp\acute{e}t}\, R}$ is (-1)-connective (by virtue of our assumption that f is flat) and almost perfect (Remark 6.4.5.2). □

Remark 19.4.3.4. In the situation of Corollary 19.4.3.3, there is a representable morphism of functors $f : \mathcal{E} \to \mathrm{Var}^+_{\simeq}$ which is proper, flat, and locally almost of finite presentation (and universal with respect to those properties). In more invariant terms, the calculation of Corollary 19.4.3.3 shows that there is a canonical equivalence

$$L_{\mathrm{Var}^+_{\simeq}} \simeq \Sigma^{-1} f_+ L_{\mathcal{E}/\mathrm{Var}^+_{\simeq}} \simeq \Sigma^{-1} f_*(\omega_{\mathcal{E}/\mathrm{Var}^+_{\simeq}} \otimes L_{\mathcal{E}/\mathrm{Var}^+_{\simeq}}).$$

Remark 19.4.3.5. In the situation of Corollary 19.4.3.3, suppose that $\eta \in \mathrm{Var}^+_{\simeq}(R)$ classifies a morphism $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ which is locally of finite presentation, so that the cotangent complex $L_{\mathsf{X}/\mathrm{Sp\acute{e}t}\, R}$ is perfect. Let T_{X} denote the dual of $L_{\mathsf{X}/\mathrm{Sp\acute{e}t}\, R}$. Then we have a canonical equivalence

$$\eta^* L_{\mathrm{Var}^+_{\simeq}} \simeq \Sigma^{-1} f_+ L_{\mathsf{X}/\mathrm{Sp\acute{e}t}\, R} \simeq \Sigma^{-1}(f_* T_{\mathsf{X}})^{\vee}.$$

In particular, extensions of X along the closed immersion $\mathrm{Sp\acute{e}t}\, R \hookrightarrow \mathrm{Sp\acute{e}t}(R \oplus \Sigma^n R)$ are classified by elements of

$$\mathrm{Ext}^1_R((f_* T_{\mathsf{X}})^{\vee}, \Sigma^n R) \simeq \mathrm{Ext}^{n+1}_R((f_* T_{\mathsf{X}}^{\vee}, R) \simeq \mathrm{Ext}^{n+1}_R(R, (f_* T_{\mathsf{X}})) \simeq \mathrm{Ext}^{n+1}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{O}_{\mathsf{X}}, T_{\mathsf{X}}).$$

Construction 19.4.3.6 (The Kodaira-Spencer Map)**.** Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks, let $\mathscr{E} \in \mathrm{QCoh}(\mathsf{Y})^{\mathrm{cn}}$, and let $\eta \in \mathrm{Der}(\mathscr{O}_{\mathsf{Y}}, \mathscr{E})$. Then we can identify η with a left homotopy inverse of the evident closed immersion $\mathsf{Y} \to \mathsf{Y}^{\mathscr{E}}$. The pullback $\mathsf{X} \times_{\mathsf{Y}} \mathsf{Y}^{\mathscr{E}}$ (along the morphism s) determines an object of the ∞-category $\mathrm{SpDM}_{/\mathsf{Y}^{\mathscr{E}}} \times_{\mathrm{SpDM}_{/\mathsf{Y}}} \{\mathsf{X}\}$, which (by virtue of Proposition 19.4.3.1) we can identify with a map $\rho_\eta : L_{\mathsf{X}/\mathsf{Y}} \to \Sigma f^* \mathscr{E}$ in the ∞-category $\mathrm{QCoh}(\mathsf{X})$. In the special case where f is proper, locally almost of finite presentation, and locally of finite Tor-amplitude, we can identify ρ_η with a map

$$\rho'_\eta : f_+ L_{\mathsf{X}/\mathsf{Y}} = f_*(\omega_{\mathsf{X}/\mathsf{Y}} \otimes L_{\mathsf{X}/\mathsf{Y}}) \to \Sigma \mathscr{E}.$$

Specializing to the case where $\mathscr{E} = L_{\mathsf{Y}}$ and η is the universal derivation, we obtain maps

$$\rho_{\mathrm{univ}} : L_{\mathsf{X}/\mathsf{Y}} \to \Sigma f^* L_{\mathsf{Y}} \qquad \rho'_{\mathrm{univ}} : f_*(\omega_{\mathsf{X}/\mathsf{Y}} \otimes L_{\mathsf{X}/\mathsf{Y}}) \to \Sigma L_{\mathsf{Y}}.$$

Unwinding the definitions, we see that ρ_{univ} is the boundary map associated to the fiber sequence $f^* L_{\mathsf{Y}} \to L_{\mathsf{X}} \to L_{\mathsf{X}/\mathsf{Y}}$. When f is proper, locally almost of finite presentation, and locally of finite Tor-amplitude, then we will refer to the map ρ'_{univ} as the *Kodaira-Spencer map*. When f is flat, it can be regarded as the "derivative" of the map $\mathsf{Y} \to \mathrm{Var}^+_{\simeq}$ which classifies f.

Remark 19.4.3.7 (Obstruction Theoretic Interpretation of the Kodaira-Spencer Map)**.** In the situation of Construction 19.4.3.6, suppose that $\mathscr{E} \in \mathrm{QCoh}(\mathsf{Y})$ is 1-connective, so that the derivation $\eta \in \mathrm{Der}(\mathscr{O}_{\mathsf{Y}}, \mathscr{E})$ determines a square-zero extension $\mathscr{O}^\eta_{\mathsf{Y}}$ of $\mathscr{O}_{\mathsf{Y}}$ by $\Sigma^{-1} \mathscr{E}$. Using Theorem 16.3.0.1, we see that the following conditions are equivalent:

(*a*) The map ρ_η of Construction 19.4.3.6 is nullhomotopic.

(*b*) The spectral Deligne-Mumford stack X can be "extended" over the closed immersion $\mathsf{Y} \hookrightarrow \mathsf{Y}^\eta$: that is, there exists a pullback diagram

$$\begin{array}{ccc} \mathsf{X} & \xrightarrow{f} & \mathsf{X}' \\ \downarrow & & \downarrow \\ \mathsf{Y} & \longrightarrow & \mathsf{Y}^\eta. \end{array}$$

When f is proper, locally almost of finite presentation, and locally of finite Tor-amplitude, then conditions (*a*) and (*b*) are equivalent to the vanishing of a certain obstruction class $o(\eta) \in \mathrm{Ext}^2_{\mathrm{QCoh}(\mathsf{Y})}(f_*(\omega_{\mathsf{X}/\mathsf{Y}} \otimes L_{\mathsf{X}/\mathsf{Y}}), \Sigma^{-1} \mathscr{E})$, which is given by the product of the Kodaira-Spencer class $[\rho'_{\mathrm{univ}}] \in \mathrm{Ext}^1_{\mathrm{QCoh}(\mathsf{Y})}(f_*(\omega_{\mathsf{X}/\mathsf{Y}} \otimes L_{\mathsf{X}/\mathsf{Y}}), L_{\mathsf{Y}}))$ with the homotopy class $[\eta] \in \mathrm{Ext}^1_{\mathrm{QCoh}(\mathsf{Y})}(L_{\mathsf{Y}}, \Sigma^{-1} \mathscr{E})$ of the derivation η.

19.4.4 The Proof of Theorem 19.4.0.2

Let $\mathrm{Var}^+ : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ be the functor which assigns to each connective $\mathbb{E}_\infty$-ring R the full subcategory $\mathrm{Var}^+(R) \subseteq \mathrm{SpDM}_{/\mathrm{Sp\acute{e}t}\, R}$ spanned by those maps $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ which are proper, flat, and locally almost of finite presentation. We verify each of the assertions of Theorem 19.4.0.2 in turn:

(1) The functor Var^+ is cohesive and nilcomplete: this follows from Proposition 19.4.2.1 and Remark 19.4.2.2.

(2) The functor Var^+ is locally almost of finite presentation: this follows from Theorem 4.4.2.2 and Proposition 5.5.4.1.

(3) For every connective $\mathbb{E}_\infty$-ring R, the ∞-category $\mathrm{Var}^+(R)$ is essentially small. Since Var^+ is nilcomplete, we may assume that R is n-truncated for some $n \gg 0$. In this case, the desired result follows from Theorem 4.4.2.2.

(4) For every simplicial set K, the functor $\mathrm{Var}^+_K : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ admits a (-1)-connective cotangent complex, where Var^+_K is defined by the formula $\mathrm{Var}^+_K(R) = \mathrm{Fun}(K, \mathrm{Var}^+(R))^{\simeq}$. In the case $K = \Delta^0$, this follows from Corollary 19.4.3.3. We now treat the case of a general simplicial set K. Writing K as the union of its finite simplicial subsets and applying Remark 17.2.4.5, we may reduce to the case where K is finite. We will prove more generally that for any inclusion $K' \subseteq K$ of finite simplicial sets, the restriction map $F_K \to F_{K'}$ admits a (-1)-connective relative cotangent complex. We proceed by induction on the dimension of K. Using Proposition 17.3.9.1 repeatedly, we can reduce to the case where K is obtained from K' by adjoining a single nondegenerate simplex, so that we have a pushout diagram of simplicial sets

$$\begin{array}{ccc} \partial\,\Delta^n & \longrightarrow & \Delta^n \\ \downarrow & & \downarrow \\ K' & \longrightarrow & K \end{array}$$

and therefore a pullback diagram of functors

$$\begin{array}{ccc} \mathrm{Var}^+_K & \longrightarrow & \mathrm{Var}^+_{K'} \\ \downarrow & & \downarrow \\ \mathrm{Var}^+_{\Delta^n} & \longrightarrow & \mathrm{Var}^+_{\partial\,\Delta^n} . \end{array}$$

We may therefore replace K by Δ^n and K' by $\partial\,\Delta^n$. If $n \geqslant 2$, we have a commutative diagram of functors

$$\begin{array}{ccccc} & & \mathrm{Var}^+_{K'} & & \\ & \nearrow & & \searrow & \\ \mathrm{Var}^+_K & & \longrightarrow & & \mathrm{Var}^+_{\Lambda^n_1} \end{array}$$

where the lower horizontal map is an equivalence. Since the diagonal map on the right admits a (-1)-connective cotangent complex by the inductive hypothesis, Proposition 17.2.5.2 implies that the restriction map $\mathrm{Var}^+_K \to \mathrm{Var}^+_{K'}$ admits a cotangent complex which is a pullback of $\Sigma L_{\mathrm{Var}^+_{K'} / \mathrm{Var}^+_{\Lambda^n_1}}$, and therefore connective. We may therefore assume that $n \leqslant 1$. If $n = 0$, then we are in the case $K = \Delta^0$ treated above. Let us therefore assume that $n = 1$. According to Proposition 17.2.4.7, it will suffice to show that for every pullback diagram of functors

$$\begin{array}{ccc} U & \longrightarrow & \mathrm{Var}^+_{\Delta^1} \\ \downarrow{\scriptstyle q} & & \downarrow \\ \mathrm{Spec}\, R & \xrightarrow{\eta} & \mathrm{Var}^+_{\partial \Delta^0}, \end{array}$$

the natural transformation q admits a relative cotangent complex (which is (-1)-connective). The map η classifies a pair of spectral Deligne-Mumford stacks X and Y which are proper, flat, and locally almost of finite presentation over R. Unwinding the definitions, we see that the functor U is given by the formula $U(R') = \mathrm{Map}_{\mathrm{SpDM}_{/\,\mathrm{Spét}\, R'}}(\mathsf{X} \times_{\mathrm{Spét}\, R} R', \mathsf{Y} \times_{\mathrm{Spét}\, R} R')$. The existence of a relative cotangent complex of q now follows from Proposition ??. Moreover, if $g \in U(R')$, then $L_{U/\,\mathrm{Spét}\, R}(g)$ can be identified with the R'-module given by $f_+ g^* L_{\mathsf{Y}\,/\,\mathrm{Spét}\, R}$, where $f : \mathsf{X} \times_{\mathrm{Spét}\, R} \mathrm{Spét}\, R' \to \mathrm{Spét}\, R'$ denotes the projection onto the second factor. Since f is flat, the functor f_+ is right t-exact. From this we deduce that $L_{U/\,\mathrm{Spét}\, R}$ is connective (and, in particular, (-1)-connective).

(5) Let K be a simplicial set with finitely many simplices of each dimension. Fix an integer n; we wish to show that the Var^+_K commutes with filtered colimits when restricted to $\tau_{\leqslant n}\, \mathrm{CAlg}^{\mathrm{cn}}$. Let R be an n-truncated connective $\mathbb{E}_\infty$-ring. We may assume without loss of generality that $n \geqslant 1$, so that every object of $\mathrm{Var}^+(R)$ is n-localic (Corollary 1.6.8.6). Note that if X is a spectral algebraic space which is flat over R, then the structure sheaf of X is also n-truncated. It follows from Lemma 1.6.8.8 that $\mathrm{Var}^+(R)$ is equivalent to an $(n+1)$-category (that is, the mapping spaces in $\mathrm{Var}^+(R)$ as n-truncated). Consequently, the restriction map $\mathrm{Var}^+_K \to \mathrm{Var}^+_{\mathrm{sk}^{n+2} K}$ is an equivalence of functors. To prove that Var^+_K commutes with filtered colimits when restricted to $\tau_{\leqslant n}\, \mathrm{CAlg}^{\mathrm{cn}}$, we may replace K by the skeleton $\mathrm{sk}^{n+2} K$ and thereby reduce to the case where the simplicial set K is finite. The desired result then follows immediately from (2). The assertion that the cotangent complex $L_{\mathrm{Var}^+_K}$ is almost perfect follows from Corollary 17.4.2.2 (and can also be proven by direct calculation; for example, see Remark 19.4.3.4).

Remark 19.4.4.1. Let κ be a field. For every κ-linear ∞-category $\mathcal{C}$ and every pair of objects $C, D \in \mathcal{C}$, we let $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D) \in \mathrm{Mod}_\kappa$ denote a classifying object for morphisms from

C to D (see Construction **??**). Suppose that $f : \mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to \operatorname{Spét} \kappa$ be a proper flat morphism of spectral algebraic spaces, so that f is classified by a point $\eta \in \operatorname{Var}^+_{\simeq}(\kappa)$. Let $\widehat{\operatorname{Var}}^+_{\simeq}$ denote the restriction of $\operatorname{Var}^+_{\simeq}$ to the ∞-category $\operatorname{CAlg}^{\mathrm{sm}}_{\kappa}$ of small κ-algebras. Since the functor $\operatorname{Var}^+_{\simeq}$ is infinitesimally cohesive, the functor $\widehat{\operatorname{Var}}^+_{\simeq}$ is a formal moduli problem over κ (see Proposition 12.1.2.9). Using Remark 17.3.7.4 and Corollary 19.4.3.3, we see that the tangent complex of $\widehat{\operatorname{Var}}^+_{\simeq}$ is given by

$$\begin{aligned} T_{\widehat{\operatorname{Var}}^+_{\simeq}} &\simeq \underline{\operatorname{Map}}_{\operatorname{Mod}_{\kappa}}(\eta^* L_{\operatorname{Var}^+_{\simeq}}, \kappa) \\ &\simeq \Sigma \underline{\operatorname{Map}}_{\operatorname{Mod}_{\kappa}}(f_+ L_{\mathsf{X}/\operatorname{Spét}\kappa}, \kappa) \\ &\simeq \Sigma \underline{\operatorname{Map}}_{\operatorname{QCoh}(\mathsf{X})}(L_{\mathsf{X}/\operatorname{Spét}\kappa}, \mathcal{O}_{\mathcal{X}}). \end{aligned}$$

If κ is a field of characteristic zero, then Theorem 13.0.0.2 implies that the shifted tangent complex $\Sigma^{-1} T_{\widehat{\operatorname{Var}}^+_{\simeq}} \simeq \underline{\operatorname{Map}}_{\operatorname{QCoh}(\mathsf{X})}(L_{\mathsf{X}/\operatorname{Spét}\kappa}, \mathcal{O}_{\mathcal{X}})$ is quasi-isomorphic to a differential graded Lie algebra $\mathbf{g}_*$, which determines the formal moduli problem $\widehat{\operatorname{Var}}^+_{\simeq}$ up to equivalence. Note that since the cotangent complex $L_{\mathsf{X}/\operatorname{Spét}\kappa}$ is connective, the homologies of the Lie algebra $\mathbf{g}_*$ are concentrated in nonpositive degrees. Moreover, the zeroth homology group of $\mathbf{g}_*$ can be identified with the space of vector fields on X (that is, the set of κ-linear derivations of the structure sheaf $\mathcal{O}_{\mathcal{X}}$ into itself). With more effort, one can show that induced Lie algebra structure on this set is given by the classical Lie bracket of tangent fields.

19.4.5 Open Loci

If R is a connective $\mathbb{E}_{\infty}$-ring, then the ∞-category $\operatorname{Var}^+(R)$ introduced in Construction 19.4.0.1 is rather unwieldy: it contains *all* spectral algebraic spaces which are proper, flat, and locally almost of finite presentation over R. In practice, it is often convenient to restrict attention to some subcategory of $\operatorname{Var}^+(R)$ spanned by algebraic spaces which satisfy additional requirements. We consider here a few simple examples; we will meet others in §**??**.

Notation 19.4.5.1. Let P be some property of morphisms $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks. For every connective $\mathbb{E}_{\infty}$-ring R, we let $\operatorname{Var}^+_P(R)$ denote the subspace of $\operatorname{Var}^+_{\simeq}(R)$ spanned by those maps $\mathsf{X} \to \operatorname{Spét} R$ which have the property P.

Proposition 19.4.5.2. *Let P be any one of the following properties of a morphism $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks:*

(a) *The property of having relative dimension $\leqslant d$ (Definition 3.3.1.1.*

(b) *The property of being fiber smooth (Definition 11.2.5.5).*

(c) *The property of being geometrically reduced (Definition **??**).*

(d) *The property of being finite flat (Definition 5.2.3.1).*

(e) *The property of being finite étale (Definition 3.3.2.3).*

(f) *The property of being geometrically reduced and geometrically connected (Proposition 8.6.4.1).*

Then the inclusion $\mathrm{Var}^+_P \hookrightarrow \mathrm{Var}^+_{\simeq}$ *is an open immersion of functors (Definition 19.2.4.1).*

Proof. Let R be a connective $\mathbb{E}_\infty$-ring and let $\eta \in \mathrm{Var}^+_{\simeq}(R)$ be a point which classifies a morphism $f : \mathsf{X} \to \mathrm{Spét}\, R$ which is proper, flat, and locally almost of finite presentation. Set $F = \mathrm{Var}^+_P \times_{\mathrm{Var}^+_{\simeq}} \mathrm{Spec}\, R \in \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. By definition, the value of F on a connective $\mathbb{E}_\infty$-ring A can be identified with the summand of $\mathrm{Map}_{\mathrm{CAlg}}(R, A)$ spanned by those maps for which the projection $f_A : \mathsf{X}_A = \mathrm{Spét}\, A \times_{\mathrm{Spét}\, R} \mathsf{X} \to \mathrm{Spét}\, A$ has the property P. We wish to show that F is representable by an open subspace of $\mathrm{Spét}\, A$.

We first treat cases (a), (b), and (c). Let $\mathsf{U} \subseteq \mathsf{X}$ be the largest open substack over which $f|_{\mathsf{U}}$ has the property P. Using Propositions 4.2.2.1, 11.2.5.10, and 8.6.3.1, we see for $A \in \mathrm{CAlg}^{\mathrm{cn}}_R$, the projection map $f_A : \mathsf{X}_A \to \mathrm{Spét}\, A$ has the property P if and only if the projection $\mathsf{X}_A \to \mathsf{X}$ factors through U. Let $K \subseteq |\mathsf{X}|$ be the closed subset complementary to U. Then f_A has the property P if and only if the underlying map $|\mathrm{Spec}\, A| \to |\mathrm{Spec}\, R|$ factors through $|\mathrm{Spec}\, R| - f(K)$. The desired result now follows from the fact that $f(K) \subseteq |\mathrm{Spec}\, R|$ is closed (by virtue of our assumption that f is proper).

Note that (d) is a special case of (a) (since a morphism $f : \mathsf{X} \to \mathsf{Y}$ which is proper, flat, and locally almost of finite presentation is finite flat if and only if it has relative dimension $\leqslant 0$; see Proposition 5.2.3.3). Moreover, case (e) follows from (c) and (d) (since a morphism is finite étale if and only if is finite flat and geometrically reduced). To handle the case (f), we first use (c) to reduce to the case where the projection $f : \mathsf{X} \to \mathrm{Spét}\, R$ is geometrically reduced. Let $M \in \mathrm{Mod}_R$ denote the cofiber of the unit map $R \to \Gamma(\mathsf{X}; \mathscr{O}_{\mathsf{X}})$. Since f is proper, flat, and locally almost of finite presentation, the module M is perfect (Theorem 6.1.3.2). Using Proposition 8.6.4.1, we see that for $A \in \mathrm{CAlg}^{\mathrm{cn}}_R$, the projection map $f_A : \mathsf{X}_A \to \mathrm{Spét}\, A$ is geometrically connected if and only if $M_A = A \otimes_R M$ has Tor-amplitude $\leqslant 1$, or equivalently if the dual $M^\vee_A = A \otimes_R M^\vee$ is 1-connective. The desired result now follows from Lemma 2.9.3.3. □

Definition 19.4.5.3. Let R be a connective $\mathbb{E}_\infty$-ring. A *variety over* R is a spectral algebraic space X equipped with a map $f : \mathsf{X} \to \mathrm{Spét}\, R$ which is proper, locally almost of finite presentation, geometrically reduced, and geometrically connected. We let $\mathrm{Var}(R)$ denote the full subcategory of $\mathrm{Var}^+(R)$ spanned by those objects which are varieties over R.

For each integer $d \geqslant 0$, we let $\mathrm{Var}^{+,\leqslant d}(R)$ denote the full subcategory of $\mathrm{Var}^+(R)$ spanned by those morphisms $f : \mathsf{X} \to \mathrm{Spét}\, R$ which are proper, flat, locally almost of finite presentation, and of relative dimension $\leqslant d$. We let $\mathrm{Var}^{\leqslant d}(R)$ denote the intersection $\mathrm{Var}^{+,\leqslant d}(R) \cap \mathrm{Var}(R)$.

Remark 19.4.5.4. Suppose we are given a pullback diagram of spectral algebraic spaces

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathrm{Sp\acute{e}t}\, R' & \longrightarrow & \mathrm{Sp\acute{e}t}\, R. \end{array}$$

If f exhibits X as a variety over R, then f' exhibits X' as a variety over R'. Consequently, we can regard the construction $R \mapsto \mathrm{Var}(R)$ as a functor $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{C}\mathrm{at}_\infty$, so that the inclusion $\mathrm{Var}(R) \hookrightarrow \mathrm{Var}^+(R)$ depends functorially on R. Similarly, for each $d \geqslant 0$, we can regard the constructions $R \mapsto \mathrm{Var}^{+,\leqslant d}(R)$ and $R \mapsto \mathrm{Var}^{\leqslant d}(R)$ as functors $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{C}\mathrm{at}_\infty$.

Variant 19.4.5.5. For every simplicial set K, we let $\mathrm{Var}_K, \mathrm{Var}_K^{\leqslant d}, \mathrm{Var}_K^{+,\leqslant d} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ denote the functors given by

$$\mathrm{Var}_K(R) = \mathrm{Fun}(K, \mathrm{Var}(R))^{\simeq} \qquad \mathrm{Var}_K^{\leqslant d}(R) = \mathrm{Fun}(K, \mathrm{Var}^{\leqslant d}(R))^{\simeq} \qquad \mathrm{Var}_K^{+,\leqslant d}(R) = \mathrm{Fun}(K, \mathrm{Var}^{+,\leqslant d}(R))^{\simeq}.$$

In the special case where $K = \Delta^0$, we will denote these functors by $\mathrm{Var}_{\simeq}$, $\mathrm{Var}_{\simeq}^{\leqslant d}$, and $\mathrm{Var}_{\simeq}^{+,\leqslant d}$, respectively.

Proposition 19.4.5.6. *Let K be a simplicial set having finitely many vertices. Then the inclusion maps $\mathrm{Var}_K, \mathrm{Var}_K^{\leqslant d}, \mathrm{Var}_K^{+,\leqslant d} \hookrightarrow \mathrm{Var}_K^+$ are open immersions.*

Proof. Without loss of generality, we may assume that $K = \Delta^0$, in which case the desired result follows from Proposition 19.4.5.2. □

Corollary 19.4.5.7. *For every integer $n \geqslant 0$, the functors $\mathrm{Var}, \mathrm{Var}^{\leqslant d}, \mathrm{Var}^{+,\leqslant d} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{C}\mathrm{at}_\infty$ commute with filtered colimits when restricted to $\tau_{\leqslant n}\,\mathrm{CAlg}^{\mathrm{cn}}$.*

Proof. We must show that for each $m \geqslant 0$, the functors $\mathrm{Var}_{\Delta^m}, \mathrm{Var}_{\Delta^m}^{\leqslant d}, \mathrm{Var}_{\Delta^m}^{+,\leqslant d} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ are locally almost of finite presentation. This follows from Proposition 19.4.5.6 and Theorem 19.4.0.2. □

Corollary 19.4.5.8. *The functor $\mathrm{Var}_{\simeq}, \mathrm{Var}_{\simeq}^{\leqslant d}, \mathrm{Var}_{\simeq}^{+,\leqslant d} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ are cohesive, nilcomplete, locally almost of finite presentation, and admits cotangent complexes which are almost perfect and (-1)-connective.*

Proof. Combine Proposition 19.2.4.3, Proposition 19.4.5.6, and Theorem 19.4.0.2. □

Part VI

Structured Spaces

Chapter 20

Fractured ∞-Topoi

Let X be a scheme (which we assume for simplicity to be quasi-compact and quasi-separated). Let Sch_X denote the category whose objects are X-schemes of finite presentation, and let $\mathrm{Sch}_X^{\text{ét}}$ denote the full subcategory of Sch_X spanned by those schemes which are étale over X. Associated to these categories are two different notions of étale sheaf on X:

- One can consider sheaves which are defined only on étale X-schemes: that is, functors $\mathscr{F} : (\mathrm{Sch}_X^{\text{ét}})^{\mathrm{op}} \to \mathcal{S}\mathrm{et}$ which satisfy descent with respect to the étale topology. The category of such functors is a Grothendieck topos, which we will denote by $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{Sch}_X^{\text{ét}})$ and refer to as the *small étale topos* of X.
- One can consider sheaves which are defined on *all* X-schemes of finite presentation: that is, functors $\mathscr{F} : \mathrm{Sch}_X^{\mathrm{op}} \to \mathcal{S}\mathrm{et}$ which satisfy descent for the étale topology. The category of such functors is also a Grothendieck topos, which we will denote by $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{Sch}_X)$ and refer to as the *big étale topos* of X.

Both of these topoi play a useful role in organizing algebro-geometric information about X. We can think of the small étale topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{Sch}_X^{\text{ét}})$ as sort of generalized topological space which "enhances" the Zariski topology on X (which can be recovered as the localic reflection of $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{Sch}_X^{\text{ét}})$). The big étale topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{Sch}_X)$ has a somewhat different role to play: it can be viewed as a *classifying topos* for strictly Henselian (sheaves of) $\mathscr{O}_X$-algebras (see Proposition **??**).

Warning 20.0.0.1. The terminology introduced above is not standard: most authors define the *big étale site* of X to be the category of *all* X-schemes, rather than X-schemes of finite presentation. However, the category Sch_X defined above is closer in spirit to the "big sites" of interest to us in this book, and has the added virtue of being an essentially small category (so that we can refer to $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{Sch}_X)$ as a Grothendieck topos without appealing to any set-theoretic legerdemain).

The category $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{Sch}_X)$ is a prototypical example of what is sometimes called a *gros topos*: an object $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{Sch}_X)$ can be viewed not as a single sheaf, but as a family of sheaves $\{\mathscr{F}_Y \in \mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{Sch}_Y^{\text{ét}})\}_{Y \in \mathrm{Sch}_X}$ which are compatible in the sense that every morphism $f : Y \to Z$ in Sch_X determines a map of sheaves $f^* \mathscr{F}_Z \to \mathscr{F}_Y$ (which is an isomorphism when f is étale). Our goal in this chapter is to introduce some language which formalizes this idea, and to simultaneously introduce some organizational principles which will be useful for formulating various generalizations of algebraic geometry. Since most of our intended applications are higher-categorical in nature, we work in the context of ∞-topoi rather than ordinary Grothendieck topoi (this extra generality actually simplifies certain aspects of the theory).

We begin in §20.1 by introducing the notion of a *fractured ∞-topos*. Roughly speaking, this is an ∞-topos $\mathcal{X}$ equipped with a (usually non-full) subcategory $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ of *corporeal objects*, satisfying certain axioms (see Definition 20.1.2.1). A prototypical example of a fractured ∞-topos is the ∞-category $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathrm{Sch}_X)$ of $\mathcal{S}$-valued sheaves on the big étale site of a scheme X: in this case, the relevant subcategory $\mathcal{S}\mathrm{hv}_{\mathcal{S}}^{\mathrm{corp}}(\mathrm{Sch}_X)$ of corporeal objects is equivalent to $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathrm{Sch}_X^{\circ})$, where Sch_X° denotes the subcategory of Sch_X containing all objects, but only étale morphisms between X-schemes. This is a special case of general construction which we study in §20.6: given a Grothendieck site $\mathcal{G}$ equipped with a distinguished class of "admissible" morphisms (satisfying some conditions which we will axiomatize in §20.2), the ∞-category $\mathcal{S}\mathrm{hv}(\mathcal{G})$ of $\mathcal{S}$-valued sheaves on $\mathcal{G}$ can be regarded as a fractured ∞-topos, where the subcategory of corporeal objects can be identified with sheaves on the subcategory $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$ spanned by the admissible morphisms.

In §20.3, we consider the following question: given a fractured ∞-topos $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$, to what extent can $\mathcal{X}^{\mathrm{corp}}$ be recovered from $\mathcal{X}$? Our main observation is that, under a mild additional assumption, we do not need to remember the *objects* of the subcategory $\mathcal{X}^{\mathrm{corp}}$, only its morphisms. More precisely, we show that $\mathcal{X}^{\mathrm{corp}}$ determines a class of $\mathcal{X}^{\mathrm{corp}}$-*admissible morphisms* in $\mathcal{X}$ (Definition 20.3.1.1), satisfying the axiomatics of §20.2. Moreover, if the collection of corporeal objects of $\mathcal{X}$ is closed under retracts, we show that the subcategory $\mathcal{X}^{\mathrm{corp}}$ can be recovered from the class of $\mathcal{X}^{\mathrm{corp}}$-admissible morphisms (Proposition 20.3.3.11). This gives an alternate approach to the theory of fractured ∞-topoi based on the notion of a *geometric admissibility structure* (Definition 20.3.4.1), which is closely related to earlier work of Joyal-Moerdijk ([109]) and Dubuc ([52]) on "classes of étale morphisms" in a Grothendieck topos.

For our applications in this book, all of the fractured ∞-topoi we will need are supplied by the construction of §20.6: that is, they have the form $\mathcal{S}\mathrm{hv}(\mathcal{G})$, where $\mathcal{G}$ is a geometric site. However, it seems unlikely that *all* fractured ∞-topoi can be obtained by this construction, because of the technical nuisance that not every left exact localization of a presheaf ∞-category arises from a Grothendieck topology. In §20.5, we remedy the situation by defining the notion of a *presentation* of a fractured ∞-topos (Definition 20.5.3.1), and proving that every fractured ∞-topos admits a presentation (Theorem 20.5.3.4). The analysis of this notion relies on some general facts about exact and dense functors to ∞-topoi, which we discuss in §20.4.

Remark 20.0.0.2. Many of the ideas described in this chapter have been developed in work of Carchedi (see [38]). In particular, we are indebted to him for the observation that the corporeal objects of a fractured ∞-topos can again be regarded as an ∞-topos (Proposition 20.1.3.3).

Contents

20.1 Fracture Subcategories

Let X be a scheme (which we assume, for simplicity, to be quasi-compact and quasi-separated), let Sch_X denote the category of finitely presented X-schemes, and let $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathrm{Sch}_X)$ denote the ∞-topos of $\mathcal{S}$-valued sheaves on the category Sch_X (where we regard Sch_X as equipped with the étale topology). Let us abuse notation by not distinguishing between an object $Y \in \mathrm{Sch}_X$ and the representable functor $h_Y \in \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathrm{Sch}_X)$, given by the formula $h_Y(Z) = \mathrm{Hom}_{\mathrm{Sch}_X}(Z, Y)$; that is, we identify Sch_X with its image under the Yoneda embedding $h : \mathrm{Sch}_X \hookrightarrow \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathrm{Sch}_X)$. The ∞-category $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathrm{Sch}_X)$ is generated by this image under small colimits: every sheaf $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathrm{Sch}_X)$ can be recovered as the colimit $\varinjlim_{\eta \in \mathscr{F}(Y)} Y$, indexed by those pairs (Y, η) where $Y \in \mathrm{Sch}_X$ and $\eta \in \mathscr{F}(Y)$. We can describe the situation more informally as follows: every sheaf $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathrm{Sch}_X)$ can be obtained by "gluing together" schemes of finite presentation over X. To carry out this gluing, we are forced to stray far from algebraic geometry: every diagram in the category Sch_X admits a colimit in $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathrm{Sch}_X)$, but such colimits are rarely representable by geometric objects such as schemes. However, if $\{Y_\alpha\}$ is a diagram in Sch_X for which all of the the transition maps $Y_\alpha \to Y_\beta$ are assumed to be étale, then the situation is better: in this case, the colimit $\varinjlim \{Y_\alpha\}$ is representable by a higher Deligne-Mumford stack which is locally of finite presentation over X. Let us refer to an object $\mathscr{F} \in \mathrm{Sch}_{\mathcal{S}}(\mathrm{Sch}_X)$ as *corporeal* if it can obtained in this way. Let $\mathcal{S}\mathrm{hv}_{\mathcal{S}}^{\mathrm{corp}}(\mathrm{Sch}_X)$ denote the subcategory of $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathrm{Sch}_X)$ spanned by corporeal objects and étale morphisms between them. This subcategory has several pleasant features:

(a) The ∞-category $\mathcal{S}\mathrm{hv}_{\mathcal{S}}^{\mathrm{corp}}(\mathrm{Sch}_X)$ is itself an ∞-topos (it is equivalent to the ∞-category $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathrm{Sch}_X^{\text{ét}})$: see Theorem 20.6.3.4, or Corollary 6.2.2 of **??**).

(b) The inclusion functor $j_! : \mathcal{S}\mathrm{hv}_{\mathcal{S}}^{\mathrm{corp}}(\mathrm{Sch}_X) \hookrightarrow \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathrm{Sch}_X)$ commutes with fiber products, and admits a conservative right adjoint j^* which preserves small colimits.

(c) For every morphism $U \to V$ in the ∞-category $\mathcal{X}^{\mathrm{corp}}$, the diagram

$$\begin{array}{ccc} j^*U & \longrightarrow & j^*V \\ \downarrow & & \downarrow \\ U & \longrightarrow & V \end{array}$$

is a pullback square in $\mathcal{X}$ (here the vertical maps are induced by the counit transformation $j_! j^* \to \mathrm{id}$).

Roughly speaking, the adjunction $\mathcal{S}\mathrm{hv}^{\mathrm{corp}}_{\mathcal{S}}(\mathrm{Sch}_X) \underset{j^*}{\overset{j_!}{\rightleftarrows}} \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathrm{Sch}_X)$ encodes the idea that the ∞-topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathrm{Sch}_X)$ is a "gros" ∞-topos, which can be decomposed into the small étale ∞-topoi $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathrm{Sch}^{\mathrm{\acute{e}t}}_Y)$, where Y ranges over the objects of Sch_X. Our goal in this section is to introduce an axiomatic framework for studying variants of this example. This framework is based on the concept of a *fracture subcategory* (Definition 20.1.2.1) of an ∞-topos $\mathcal{X}$: that is, a subcategory $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ which satisfies analogues of conditions (b) and (c) (assertion (a) is then a formal consequence: see Proposition 20.1.3.3).

Remark 20.1.0.1. It may not be immediately obvious that assertions (a), (b), and (c) are true: in other words, that $\mathcal{S}\mathrm{hv}^{\mathrm{corp}}_{\mathcal{S}}(\mathrm{Sch}_X)$ is a fracture subcategory of the ∞-topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathrm{Sch}_X)$. This is a special case of a more general result that we will prove in §20.6: see Theorem 20.6.3.4.

20.1.1 Replete Subcategories

We begin with a brief categorical digression. Recall that if $\mathcal{C}$ is an ∞-category, then a simplicial subset $\mathcal{C}_0 \subseteq \mathcal{C}$ is said to be a *subcategory* of $\mathcal{C}$ if there exists a pullback square

$$\begin{array}{ccc} \mathcal{C}_0 & \longrightarrow & \mathcal{C} \\ \downarrow & & \downarrow \\ (\mathrm{h}\mathcal{C})_0 & \longrightarrow & \mathrm{h}\mathcal{C}, \end{array}$$

where $(\mathrm{h}\mathcal{C})_0$ is a subcategory of the homotopy category $\mathrm{h}\mathcal{C}$ (in the sense of ordinary category theory): see §HTT.1.2.11 .

Proposition 20.1.1.1. *Let $\mathcal{C}$ be an ∞-category and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a subcategory. The following conditions are equivalent:*

(a) *The inclusion map $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ is a categorical fibration.*

(b) *For every morphism $f : X \to Y$ in $\mathcal{C}$ which is an equivalence, if X belongs to $\mathcal{C}_0$, then f belongs to $\mathcal{C}_0$.*

Proof. This is an immediate consequence of Corollary HTT.2.4.6.5 . □

Definition 20.1.1.2. Let $\mathcal{C}$ be an ∞-category. We will say that a subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ is *replete* if it satisfies the equivalent conditions of Proposition 20.1.1.1.

Remark 20.1.1.3. Let $\mathcal{C}$ be an ∞-category. Then a subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ is replete if and only if the homotopy category $\mathrm{h}\mathcal{C}_0$ is a replete subcategory of $\mathrm{h}\mathcal{C}$.

Remark 20.1.1.4. Let $\mathcal{C}$ be an ∞-category. If $\mathcal{C}_0$ is a replete subcategory of $\mathcal{C}$, then the inclusion functor $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ is conservative.

Proposition 20.1.1.5. *Let $F : \mathcal{C} \to \mathcal{D}$ be a functor between ∞-categories. The following conditions are equivalent:*

- (a) *The functor F induces an equivalence from $\mathcal{C}$ to a replete subcategory $\mathcal{D}_0 \subseteq \mathcal{D}$.*
- (b) *For every pair of objects $C, C' \in \mathcal{C}$, the induced map $\mathrm{Map}_{\mathcal{C}}(C, C) \to \mathrm{Map}_{\mathcal{D}}(FC, FC')$ induces a homotopy equivalence from $\mathrm{Map}_{\mathcal{C}}(C, D)$ to a summand $\mathrm{Map}_{\mathcal{D}}(FC, FC')_0 \subseteq \mathrm{Map}_{\mathcal{D}}(FC, FC')$. Moreover, every equivalence $\alpha : FC \to FD$ in the ∞-category $\mathcal{D}$ is contained in the summand $\mathrm{Map}_{\mathcal{D}}(FC, FC')_0$.*

Proof. The implication $(a) \Rightarrow (b)$ is immediate. Conversely, suppose that (b) is satisfied. Let D and D' be objects of $\mathcal{D}$ belonging to the essential image of F, so that we can choose equivalences $\alpha : FC \to D$ and $\beta : D' \to FC'$ for some objects $C, C' \in \mathcal{C}$. Let us say that a morphism $\gamma : D \to D'$ is *good* if the composition $\beta \circ \gamma \circ \alpha$ belongs to the summand $\mathrm{Map}_{\mathcal{D}}(FC, FC')_0 \subseteq \mathrm{Map}_{\mathcal{D}}(FC, FC')$ described in (b). The final assumption of (b) guarantees that this condition does not depend on the choice of equivalences α and β. The collection of good morphisms contains all equivalences and is stable under composition. Let $\mathcal{D}_0 \subseteq \mathcal{D}$ be the subcategory spanned by those objects which belong to the essential image of F and whose morphisms are good. Then $\mathcal{D}_0$ is replete and the functor F induces an equivalence $\mathcal{C} \to \mathcal{D}_0$. □

20.1.2 Fractured ∞-Topoi

We are now ready to introduce the main objects of interest in this section.

Definition 20.1.2.1. Let $\mathcal{X}$ be an ∞-topos. We will say that a subcategory $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ is a *fracture subcategory* if it satisfies the following conditions:

- (0) The subcategory $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ is replete (Definition 20.1.1.2).
- (1) The ∞-category $\mathcal{X}^{\mathrm{corp}}$ admits fiber products, which are preserved by the inclusion functor $j_! : \mathcal{X}^{\mathrm{corp}} \hookrightarrow \mathcal{X}$.

(2) The inclusion functor $j_! : \mathcal{X}^{\mathrm{corp}} \hookrightarrow \mathcal{X}$ admits a right adjoint $j^* : \mathcal{X} \to \mathcal{X}^{\mathrm{corp}}$. Moreover, the functor j^* is conservative and preserves small colimits.

(3) For every morphism $U \to V$ in $\mathcal{X}^{\mathrm{corp}}$, the diagram

$$\begin{array}{ccc} j^*U & \longrightarrow & j^*V \\ \downarrow & & \downarrow \\ U & \longrightarrow & V \end{array}$$

(determined by the counit map $j_! j^* \to \mathrm{id}$) is a pullback square in $\mathcal{X}$.

A *fractured ∞-topos* is a pair $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$, where $\mathcal{X}$ is an ∞-topos and $\mathcal{X}^{\mathrm{corp}}$ is a fracture subcategory of $\mathcal{X}$. In this case, we will say that an object $X \in \mathcal{X}$ is *corporeal* if it belongs to the subcategory $\mathcal{X}^{\mathrm{corp}}$.

Example 20.1.2.2. Let $\mathcal{X}$ be an ∞-topos. Then $\mathcal{X}$ is a fracture subcategory of itself.

Example 20.1.2.3. Let $\mathcal{X}$ be an ∞-topos, and let $F : \mathcal{X} \times \mathcal{X} \to \mathrm{Fun}(\Delta^1, \mathcal{X})$ be the functor which carries a pair of objects $X, Y \in \mathcal{X}$ to the map $X \hookrightarrow X \amalg Y$. Then F induces an equivalence from $\mathcal{X} \times \mathcal{X}$ to a fracture subcategory $\mathrm{Fun}(\Delta^1, \mathcal{X})^{\mathrm{corp}} \subseteq \mathrm{Fun}(\Delta^1, \mathcal{X})$.

Remark 20.1.2.4. Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos and let $j^* : \mathcal{X} \to \mathcal{X}^{\mathrm{corp}}$ be a right adjoint to the inclusion. Then the functor j^* preserves small limits. In particular, if $\mathbf{1}$ denotes a final object of $\mathcal{X}$, then $j^*\mathbf{1}$ is a final object of $\mathcal{X}^{\mathrm{corp}}$. It follows that the ∞-category $\mathcal{X}^{\mathrm{corp}}$ admits finite limits.

Warning 20.1.2.5. In the situation of Definition 20.1.2.1, we do not assume that the inclusion functor $j_!$ preserves final objects: in fact, this condition is never satisfied except in the trivial case $\mathcal{X}^{\mathrm{corp}} = \mathcal{X}$.

Warning 20.1.2.6. The commutative diagram appearing in requirement (3) of Definition 20.1.2.1 is *not* a commutative diagram in the ∞-category $\mathcal{X}^{\mathrm{corp}}$. Every object in the diagram is corporeal, but the vertical maps generally do not belong to $\mathcal{X}^{\mathrm{corp}}$.

Notation 20.1.2.7. Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos. We let $\mathbf{1}^{\mathrm{corp}}$ denote the final object of $\mathcal{X}^{\mathrm{corp}}$ (which is usually not final as an object of $\mathcal{X}$).

Remark 20.1.2.8. Let $\mathcal{X}$ be an ∞-topos, let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a subcategory, and let $j^* : \mathcal{X} \to \mathcal{X}^{\mathrm{corp}}$ be a right adjoint to the inclusion functor. Then $\mathcal{X}^{\mathrm{corp}}$ admits a final object $\mathbf{1}^{\mathrm{corp}}$ (obtained by applying the functor j^* to a final object of $\mathcal{X}$). For every morphism $U \to V$ in $\mathcal{X}^{\mathrm{corp}}$, we obtain a commutative diagram

$$\begin{array}{ccccc} j^*U & \longrightarrow & j^*V & \longrightarrow & j^*\mathbf{1}^{\mathrm{corp}} \\ \downarrow & & \downarrow & & \downarrow \\ U & \longrightarrow & V & \longrightarrow & \mathbf{1}^{\mathrm{corp}} \end{array}$$

in the ∞-category $\mathcal{X}$. Consequently, to prove that the square on the left is a pullback diagram, it suffices to check that the square on the right and the outer rectangle are pullback diagrams. We can therefore replace condition (3) of Definition 20.1.2.1 with the following *a priori* weaker condition:

(3′) For every object $U \in \mathcal{X}^{\mathrm{corp}}$, the induced diagram

$$\begin{array}{ccc} j^*U & \longrightarrow & j^*\mathbf{1}^{\mathrm{corp}} \\ \downarrow & & \downarrow \\ U & \longrightarrow & \mathbf{1}^{\mathrm{corp}} \end{array}$$

is a pullback square in $\mathcal{X}$.

Proposition 20.1.2.9. *Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos and let $j^* : \mathcal{X} \to \mathcal{X}^{\mathrm{corp}}$ be a right adjoint to the inclusion. Then, for every morphism $U \to V$ in $\mathcal{X}^{\mathrm{corp}}$, the diagram σ :*

$$\begin{array}{ccc} U & \longrightarrow & V \\ \downarrow & & \downarrow \\ j^*U & \longrightarrow & j^*V \end{array}$$

(induced by the unit map $\mathrm{id}_{\mathcal{X}^{\mathrm{corp}}} \to j^*|_{\mathcal{X}^{\mathrm{corp}}}$) is a pullback square in $\mathcal{X}^{\mathrm{corp}}$ (and therefore also in $\mathcal{X}$).

Proof. Let $j_! : \mathcal{X}^{\mathrm{corp}} \hookrightarrow \mathcal{X}$ denote the inclusion map. The unit and counit for the adjunction $\mathcal{X}^{\mathrm{corp}} \underset{j^*}{\overset{j_!}{\rightleftarrows}} \mathcal{X}$ determine a commutative diagram

$$\begin{array}{ccc} j_!U & \longrightarrow & j_!V \\ \downarrow & & \downarrow \\ j_!j^*j_!U & \longrightarrow & j_!j^*j_!V \\ \downarrow & & \downarrow \\ j_!U & \longrightarrow & j_!V \end{array}$$

in the ∞-category $\mathcal{X}$, where the vertical composite maps are homotopic to the identity. It follows that the outer rectangle is a pullback square in $\mathcal{X}$. Requirement (3) of Definition 20.1.2.1 guarantees that the lower square is also a pullback, so the upper square is a pullback as well. In other words, the diagram σ is a pullback square in the ∞-category $\mathcal{X}$. Since the functor $j_!$ is conservative (Remark 20.1.1.4) and preserves fiber products (requirement (1) of Definition 20.1.2.1), it follows that σ is also a pullback square in $\mathcal{X}^{\mathrm{corp}}$. □

Example 20.1.2.10. Applying Proposition 20.1.2.9 in the special case where $V = \mathbf{1}^{\mathrm{corp}}$, we deduce that every object $U \in \mathcal{X}^{\mathrm{corp}}$ fits into a canonical fiber sequence $U \to j^*U \to j^*\mathbf{1}^{\mathrm{corp}}$ (in the ∞-category $\mathcal{X}^{\mathrm{corp}}$).

20.1.3 Properties of Fracture Subcategories

Our next goal is to show that any fracture subcategory of an ∞-topos is itself an ∞-topos.

Proposition 20.1.3.1. *Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos. Then for every corporeal object $X \in \mathcal{X}^{\mathrm{corp}}$, the inclusion map $F : \mathcal{X}^{\mathrm{corp}}_{/X} \hookrightarrow \mathcal{X}_{/X}$ is fully faithful.*

Proof. Let $j^* : \mathcal{X} \to \mathcal{X}^{\mathrm{corp}}$ be a right adjoint to the inclusion. The functor F admits a right adjoint G, given by the formula $G(Y) = j^*Y \times_{j^*Y} Y$. It follows from Proposition 20.1.2.9 that the counit map $\mathrm{id} \to G \circ F$ is an equivalence, so that F is fully faithful. □

Remark 20.1.3.2. It follows from Proposition 20.1.3.1 that a fracture subcategory $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ can be identified with a full subcategory $\mathcal{Y} \subseteq \mathcal{X}_{/\mathbf{1}^{\mathrm{corp}}}$ for some (uniquely determined) object $\mathbf{1}^{\mathrm{corp}} \in \mathcal{X}$. Condition (1) of Definition 20.1.2.1 guarantee that $\mathcal{Y}$ is closed under finite limits, and condition (2) guarantees that the inclusion $\mathcal{Y} \hookrightarrow \mathcal{X}_{/\mathbf{1}^{\mathrm{corp}}}$ admits a right adjoint. Beware that $\mathcal{Y}$ is generally not a fracture subcategory of $\mathcal{X}_{/\mathbf{1}^{\mathrm{corp}}}$ (Warning 20.1.3.5).

Proposition 20.1.3.3. *Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos. Then the ∞-category $\mathcal{X}^{\mathrm{corp}}$ is an ∞-topos.*

Proof. Since the forgetful functor $\mathcal{X}^{\mathrm{corp}}_{/\mathbf{1}^{\mathrm{corp}}} \to \mathcal{X}^{\mathrm{corp}}$ is an equivalence, it will suffice to show that $\mathcal{X}^{\mathrm{corp}}_{/\mathbf{1}^{\mathrm{corp}}}$ is an ∞-topos. Remark **??** shows that $\mathcal{X}^{\mathrm{corp}}_{/\mathbf{1}^{\mathrm{corp}}}$ is a full subcategory of $\mathcal{X}_{/\mathbf{1}^{\mathrm{corp}}}$ which is closed under small colimits and finite limits. It will therefore suffice to show that $\mathcal{X}^{\mathrm{corp}}_{/\mathbf{1}^{\mathrm{corp}}}$ is presentable (as in the proof of Proposition HTT.6.3.6.2). Let $G : \mathcal{X}_{/\mathbf{1}^{\mathrm{corp}}} \to \mathcal{X}^{\mathrm{corp}}_{/\mathbf{1}^{\mathrm{corp}}}$ be a right adjoint to the inclusion, given by $G(X) = j^*X \times_{j^*\mathbf{1}^{\mathrm{corp}}} \mathbf{1}^{\mathrm{corp}}$ (as in the proof of Proposition 20.1.3.1). Since the functor $j^* : \mathcal{X} \to \mathcal{X}^{\mathrm{corp}}$ preserves small colimits (which are then preserved by the inclusion $\mathcal{X}^{\mathrm{corp}} \hookrightarrow \mathcal{X}$) and colimits in $\mathcal{X}$ are universal, it follows that the functor G preserves small colimits. Consequently, if $\{X_\alpha\}$ is a small collection of objects which generates $\mathcal{X}_{/\mathbf{1}^{\mathrm{corp}}}$ under small colimits, then the objects $G(X_\alpha)$ generate $\mathcal{X}^{\mathrm{corp}}_{/\mathbf{1}^{\mathrm{corp}}}$ under small colimits. It now suffices to observe that we can choose a regular cardinal κ such that each $G(X_\alpha)$ is a κ-compact object of $\mathcal{X}_{/\mathbf{1}^{\mathrm{corp}}}$ (and therefore also a κ-compact object of $\mathcal{X}^{\mathrm{corp}}_{/\mathbf{1}^{\mathrm{corp}}}$). □

Corollary 20.1.3.4. *Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos. Then $\mathcal{X}$ is generated under small colimits by corporeal objects.*

Proof. Let $\mathcal{C} \subseteq \mathcal{X}$ be the smallest full subcategory which contains $\mathcal{X}^{\mathrm{corp}}$ and is closed under small colimits. Since $\mathcal{X}^{\mathrm{corp}}$ is accessible (Proposition 20.1.3.3), we can choose an essentially small subcategory $\mathcal{X}^{\mathrm{corp}}_0 \subseteq \mathcal{X}^{\mathrm{corp}}$ which generates $\mathcal{X}^{\mathrm{corp}}$ under small colimits. Then $\mathcal{C}$ is the smallest full subcategory of $\mathcal{X}$ which contains $\mathcal{X}^{\mathrm{corp}}_0$ and is closed under small colimits. It follows that the ∞-category $\mathcal{C}$ is presentable. Applying Corollary HTT.5.5.2.9 , we deduce that the inclusion $\mathcal{C} \hookrightarrow \mathcal{X}$ admits a right adjoint $G : \mathcal{X} \to \mathcal{C}$. Let $j^* : \mathcal{X} \to \mathcal{X}^{\mathrm{corp}}$

be a right adjoint to the inclusion, so that j^* factors through G. Our assumption that $\mathcal{X}^{\mathrm{corp}}$ is a fracture subcategory of $\mathcal{X}$ guarantees that j^* is conservative, so the functor G is also conservative. It follows that G is an equivalence of ∞-categories, so that $\mathcal{X} = \mathcal{C}$ as desired. □

Warning 20.1.3.5. Let $\mathcal{X}$ be an ∞-topos. Then a fracture subcategory $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ is never a full subcategory of $\mathcal{X}$, except in the trivial situation where $\mathcal{X}^{\mathrm{corp}} = \mathcal{X}$ (Example 20.1.2.2). To see this, we note that if the inclusion $j_! : \mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ were fully faithful, then the collection of corporeal objects of $\mathcal{X}$ would be closed under small colimits. We could then apply Corollary 20.1.3.4 to deduce that every object of $\mathcal{X}$ is corporeal, so that $\mathcal{X}^{\mathrm{corp}} = \mathcal{X}$.

Remark 20.1.3.6. Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos and let $j^* : \mathcal{X} \to \mathcal{X}^{\mathrm{corp}}$ be a right adjoint to the inclusion. Then j^* preserves all limits (since it is a right adjoint) and all colimits (by assumption). It follows that j^* admits a further right adjoint $j_* : \mathcal{X}^{\mathrm{corp}} \to \mathcal{X}$ which is a geometric morphism of ∞-topoi.

Warning 20.1.3.7. In the situation of Remark 20.1.3.6, the functor $j_* : \mathcal{X}^{\mathrm{corp}} \to \mathcal{X}$ is generally neither faithful (that is, it need not induce an equivalence of $\mathcal{X}^{\mathrm{corp}}$ with a subcategory of $\mathcal{X}$) nor conservative.

Remark 20.1.3.8. Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos, let $j_! : \mathcal{X}^{\mathrm{corp}} \hookrightarrow \mathcal{X}$ denote the inclusion and let $j^* : \mathcal{X} \to \mathcal{X}^{\mathrm{corp}}$ be right adjoint to $j_!$. Then the adjunction $\mathcal{X}^{\mathrm{corp}} \underset{j^*}{\overset{j_!}{\rightleftarrows}} \mathcal{X}$ is monadic: that is, it induces an equivalence of ∞-categories $\mathcal{X} \simeq \mathrm{LMod}_T(\mathcal{X}^{\mathrm{corp}})$, where T denotes the monad $j^* \circ j_!$. This follows from the Barr-Beck theorem (Theorem HA.4.7.3.5), since the functor j^* is conservative and preserves small colimits.

20.2 Admissibility Structures

Let $\phi : A \to B$ be a homomorphism of commutative rings. We will say that ϕ is *local* if it carries noninvertible elements of A to noninvertible elements of B. At the other extreme, we say that ϕ is *localizing* if it induces an isomorphism $A[S^{-1}] \simeq B$, where S is some collection of elements of A. An arbitrary ring homomorphism $\phi : A \to B$ admits an essentially unique factorization $A \xrightarrow{\phi'} A' \xrightarrow{\phi''} B$, where ϕ' is localizing and ϕ'' is local: namely, we can take $A' = A[S^{-1}]$, where S is the collection of all elements $a \in A$ for which $\phi(a)$ is an invertible element of B. We can summarize the situation by saying that the collections of local and localizing morphisms define a factorization system on the category $\mathrm{CAlg}^{\heartsuit}$ of commutative rings.

The category of commutative rings is compactly generated: every commutative ring A can be realized as a filtered direct limit of subrings which are finitely generated (and therefore also finitely presented) over $\mathbf{Z}$. Let $\mathrm{CAlg}^{\heartsuit}_c$ denote the category of finitely presented commutative rings, so that $\mathrm{CAlg}^{\heartsuit} \simeq \mathrm{Ind}(\mathrm{CAlg}^{\heartsuit}_c)$. The factorization system described above above does not restrict to a factorization system on $\mathrm{CAlg}^{\heartsuit}_c$. For example, the reduction map $\mathbf{Z} \to \mathbf{Z}/2\mathbf{Z}$ factors as a composition $\mathbf{Z} \xrightarrow{\phi'} \mathbf{Z}_{(2)} \xrightarrow{\phi''} \mathbf{Z}/2\mathbf{Z}$, where ϕ' is localizing and ϕ'' is local; here the commutative rings $\mathbf{Z}$ and $\mathbf{Z}/2\mathbf{Z}$ are finitely generated, but the localization $\mathbf{Z}_{(2)}$ is not. Nevertheless, the factorization system on $\mathrm{CAlg}^{\heartsuit}$ is *visible* at the level of finitely presented commutative rings in the following sense: every localizing ring homomorphism $\phi : A \to B$ can be written as a filtered colimit of localizing homomorphisms between finitely presented commutative rings (that is, homomorphisms of the form $R \to R[t^{-1}]$, where R is finitely presented).

In this section, we introduce the notion of an *admissibility structure* (Definition **??**), which axiomatizes the essential features of the class of localizing morphisms in the category $(\mathrm{CAlg}^{\heartsuit}_c)^{\mathrm{op}}$ (passage to the opposite category here is a matter of convenience). Our main results can be summarized as follows:

(a) Let $\mathcal{G}$ be a small ∞-category. Then every admissibility structure on $\mathcal{G}$ determines (and is determined by) a factorization system on the ∞-category $\mathrm{Pro}(\mathcal{G})$ (Theorem 20.2.2.5).

(b) Let $\mathcal{G}$ be a small ∞-category. Then every admissibility structure on $\mathcal{G}$ determines (and is determined by) a fracture subcategory of the presheaf ∞-topos $\mathcal{P}(\mathcal{G}) = \mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S})$ (Theorem 20.2.4.1).

Most of this chapter is devoted to expanding on (b): we will later see that *all* fractured ∞-topoi can be obtained as localizations of fractured ∞-topoi having the form $\mathcal{P}(\mathcal{G})$ (see Theorem 20.5.3.4). Moreover, in §20.3 we will see that every fractured ∞-topos $\mathcal{X}$ can itself be regarded as an ∞-category equipped with an admissibility structure (Proposition 20.3.1.3), and this admissibility structure *almost* determines the fracture subcategory $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ (Proposition 20.3.3.11).

Remark 20.2.0.1. The relationship between assertions (a) and (b) will appear as a major theme of Chapter 21.

20.2.1 Definitions

We begin by introducing some terminology.

Definition 20.2.1.1. Let $\mathcal{G}$ be an ∞-category. An *admissibility structure* on $\mathcal{G}$ is a collection of morphisms of $\mathcal{G}$, which we will refer to as *admissible morphisms*, satisfying the following axioms:

(1) Every equivalence in $\mathcal{G}$ is admissible.

(2) Let $f : U \to X$ be an admissible morphism in $\mathcal{G}$, and let $g : X' \to X$ be an arbitrary morphism in $\mathcal{G}$. Then there exists a pullback diagram

$$\begin{array}{ccc} U' & \longrightarrow & U \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ X' & \xrightarrow{g} & X, \end{array}$$

and the morphism f' is admissible.

(3) Let

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ & {\scriptstyle h}\searrow \quad \swarrow{\scriptstyle g} & \\ & Z & \end{array}$$

be a commutative diagram in $\mathcal{G}$, where g is admissible. Then f is admissible if and only if h is admissible.

(4) The collection of admissible morphisms is closed under retracts (when viewed as a full subcategory of the ∞-category $\mathrm{Fun}(\Delta^1, \mathcal{G})$).

If $\mathcal{G}$ is an ∞-category equipped with an admissibility structure, we let $\mathcal{G}^{\mathrm{ad}}$ denote the subcategory of $\mathcal{G}$ containing all objects, whose morphisms are the admissible morphisms in $\mathcal{G}$. We will generally abuse terminology by identifying the admissibility structure on $\mathcal{G}$ with the full subcategory $\mathcal{G}^{\mathrm{ad}}$.

Remark 20.2.1.2. It follows from condition (4) of Definition 20.2.1.1 (or from conditions (1) and (3)) that if $f : U \to V$ is an admissible morphism in $\mathcal{G}$, then any morphism homotopic to f is also admissible.

Remark 20.2.1.3. Let $\mathcal{G}$ be an ∞-category and let $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$ be an admissibility structure on $\mathcal{G}$. Then $\mathcal{G}^{\mathrm{ad}}$ is a replete subcategory of $\mathcal{G}$ (Definition 20.1.1.2): this is a restatement of condition (1) of Definition 20.2.1.1.

Notation 20.2.1.4. Let $\mathcal{G}$ be an ∞-category equipped with an admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$. For each object $X \in \mathcal{G}$, we let $\mathcal{G}^{\mathrm{ad}}_{/X}$ denote the full subcategory of $\mathcal{G}_{/X}$ spanned by the admissible morphisms $U \to X$. Note the ∞-category $\mathcal{G}^{\mathrm{ad}}_{/X}$ can also be described as the overcategory $(\mathcal{G}^{\mathrm{ad}})_{/X}$ (since any morphism in $\mathcal{G}^{\mathrm{ad}}_{/X}$ is itself admissible, by condition (3) of Definition 20.2.1.1).

Example 20.2.1.5. Let $\mathrm{CAlg}^{\heartsuit}_c$ denote the category of finitely generated commutative rings. Then the category $(\mathrm{CAlg}^{\heartsuit}_c)^{\mathrm{op}}$ admits an admissibility structure, whose admissible morphisms are given by those ring homomorphisms $\phi : A \to B$ which exhibit B as isomorphic to a localization $A[t^{-1}]$ for some $t \in A$.

Example 20.2.1.6. Let $\mathcal{T}\mathrm{op}$ denote the category of topological spaces. Then the collection of all open immersions determines an admissibility structure on $\mathcal{T}\mathrm{op}$.

Example 20.2.1.7. Let X be a scheme and let Sch_X be the category of finitely presented X-schemes. Then the collection of étale morphisms determines an admissibility structure on Sch_X.

Example 20.2.1.8. Let $\mathcal{G}$ and $\mathcal{C}$ be ∞-categories which admit finite limits, and suppose we are given a natural transformation $f \to g$ between left-exact functors $f, g : \mathcal{G} \to \mathcal{C}$. Then there is an admissibility structure on $\mathcal{G}$ whose admissible morphisms are those maps $U \to X$ for which the diagram

$$\begin{array}{ccc} f(U) & \longrightarrow & g(U) \\ \downarrow & & \downarrow \\ f(X) & \longrightarrow & g(X) \end{array}$$

is a pullback square in $\mathcal{C}$.

Remark 20.2.1.9. Let $\mathcal{G}$ be an ∞-category with an admissibility structure. Then, for every object $X \in \mathcal{G}$, the ∞-category $\mathcal{G}_{/X}$ inherits an admissibility structure, where we say that a morphism in $\mathcal{G}_{/X}$ is admissible if its image in $\mathcal{G}$ is admissible.

Warning 20.2.1.10. When used in combination with Remark 20.2.1.9, Notation 20.2.1.4 presents some opportunity for confusion. Let $\mathcal{G}$ be an ∞-category equipped with an admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$ and let X be an object of $\mathcal{G}$. Then Remark 20.2.1.9 supplies an admissibility structure $(\mathcal{G}_{/X})^{\mathrm{ad}} \subseteq \mathcal{G}_{/X}$ on the ∞-category $\mathcal{G}_{/X}$. Beware that the subcategory $(\mathcal{G}_{/X})^{\mathrm{ad}}$ does *not* coincide with the subcategory $\mathcal{G}^{\mathrm{ad}}_{/X} \subseteq \mathcal{G}_{/X}$ appearing in Notation 20.2.1.4: the former contains all objects of $\mathcal{G}_{/X}$, while the latter contains only those objects which are given by admissible morphisms $U \to X$.

Remark 20.2.1.11. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor between ∞-categories. Suppose that $\mathcal{C}$ admits pullbacks and that f preserves pullbacks. Then every admissibility structure on $\mathcal{D}$ determines an admissibility structure on $\mathcal{C}$, where we say that a morphism u in $\mathcal{C}$ is admissible if its image $F(u)$ is an admissible morphism of $\mathcal{D}$.

Remark 20.2.1.12. Let $\mathcal{G}$ be an ∞-category equipped with an admissibility structure. Then, for every object $X \in \mathcal{G}$, the ∞-category $\mathcal{G}^{\mathrm{ad}}_{/X}$ admits finite limits, which are preserved by the inclusion $\mathcal{G}^{\mathrm{ad}}_{/X} \hookrightarrow \mathcal{G}_{/X}$. To prove this, it suffices to observe that $\mathcal{G}^{\mathrm{ad}}_{/X}$ contains the final object of $\mathcal{G}_{/X}$ (by virtue of condition (1) of Definition 20.2.1.1) and that it is closed under fiber products. Suppose that we are given morphisms $\alpha : Y_0 \to Y$ and $\beta : Y_1 \to Y$ in $\mathcal{G}^{\mathrm{ad}}_{/X}$. Using condition (3) of Definition 20.2.1.1, we see that α and β are admissible, so that (by virtue of (2)) we can choose a pullback square

$$\begin{array}{ccc} Y_{01} & \xrightarrow{\beta'} & Y_0 \\ \downarrow{\scriptstyle \alpha'} & & \downarrow{\scriptstyle \alpha} \\ Y_1 & \xrightarrow{\beta} & Y \end{array}$$

where α' and β' are also admissible. Condition (3) implies that the composition

$$Y_{01} \xrightarrow{\alpha'} Y_1 \xrightarrow{\beta} Y \to X$$

is admissible, so that $Y_{01} \in \mathcal{G}^{\mathrm{ad}}_{/X}$.

20.2.2 Admissibility Structures and Factorization Systems

We now study the relationship between admissibility structures (in the sense of Definition 20.2.1.1) and factorization systems (in the sense of Definition HTT.5.2.8.8). Our first observation is that if $\mathcal{G}$ is an ∞-category which admits pullback squares, then every factorization system determines an admissibility structure:

Proposition 20.2.2.1. *Let $\mathcal{G}$ be an ∞-category which admits pullbacks, and suppose we are given a factorization system (S_L, S_R) on $\mathcal{G}$ (see Definition HTT.5.2.8.8). Then the collection of morphisms S_R is an admissibility structure on $\mathcal{G}$.*

Proof. Applying Proposition HTT.**??** , we immediately deduce that S_R satisfies conditions (1), (3), and (4) of Definition 20.2.1.1, together with the following weaker form of (2);

(2′) For every pullback diagram

$$\begin{array}{ccc} U' & \longrightarrow & U \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ X' & \longrightarrow & X \end{array}$$

in $\mathcal{G}$, if f belongs to S_R, then f' also belongs to S_R.

Our assumption that $\mathcal{C}$ admits pullbacks guarantees that (2) and (2′) are equivalent. □

Our next goal is to establish a weak converse to Proposition **??**: we will show that every admissibility structure on $\mathcal{G}$ determines a factorization system not on $\mathcal{G}$, but on the ∞-category $\mathrm{Pro}(\mathcal{G})$ of Pro-objects of $\mathcal{G}$ (Theorem 20.2.2.5). We begin by introducing some terminology.

Definition 20.2.2.2. Let $\mathcal{G}$ be an essentially small ∞-category equipped with an admissibility structure, let $\mathrm{Pro}(\mathcal{G})$ denote the ∞-category of Pro-objects of $\mathcal{G}$ (see Definition A.8.1.1) and let $j : \mathcal{G} \to \mathrm{Pro}(\mathcal{G})$ denote the Yoneda embedding. We will say that a morphism $f : U \to X$ in the ∞-category $\mathrm{Pro}(\mathcal{G})$ is *proadmissible* if there exists a small filtered diagram $p : \mathcal{I} \to \mathrm{Fun}(\Delta^1, \mathcal{G})$ such that each $p(I)$ is an admissible morphism of $\mathcal{G}$, and f is a limit of the composite diagram

$$\mathcal{I} \xrightarrow{p} \mathrm{Fun}(\Delta^1, \mathcal{G}) \xrightarrow{j} \mathrm{Fun}(\Delta^1, \mathrm{Pro}(\mathcal{G})).$$

For each object $X \in \mathrm{Pro}(\mathcal{G})$, we let $\mathrm{Pro}(\mathcal{G})^{\text{pro-ad}}_{/X}$ denote the full subcategory of $\mathrm{Pro}(\mathcal{G})_{/X}$ spanned by the proadmissible morphisms $Y \to X$.

Remark 20.2.2.3. Let $\mathcal{G}$ be an essentially small ∞-category equipped with an admissibility structure. The composition $\mathrm{Fun}(\Delta^1, \mathcal{G}) \times \Delta^1 \to \mathcal{G} \xrightarrow{j} \mathrm{Pro}(\mathcal{G})$ classifies a map $\mathrm{Fun}(\Delta^1, \mathcal{G}) \to \mathrm{Fun}(\Delta^1, \mathrm{Pro}(\mathcal{G}))$. According to Proposition HTT.5.3.5.15 , this map induces an equivalence of ∞-categories $\phi : \mathrm{Pro}(\mathrm{Fun}(\Delta^1, \mathcal{G})) \simeq \mathrm{Fun}(\Delta^1, \mathrm{Pro}(\mathcal{G}))$. Let $\mathrm{Fun}^{\mathrm{ad}}(\Delta^1, \mathcal{G})$ denote the full subcategory of $\mathrm{Fun}(\Delta^1, \mathcal{G})$ spanned by the admissible morphisms of $\mathcal{G}$. The inclusion of $\mathrm{Fun}^{\mathrm{ad}}(\Delta^1, \mathcal{G})$ into $\mathrm{Fun}(\Delta^1, \mathcal{G})$ induces a fully faithful embedding $\mathrm{Pro}(\mathrm{Fun}^{\mathrm{ad}}(\Delta^1, \mathcal{G})) \to \mathrm{Pro}(\mathrm{Fun}(\Delta^1, \mathcal{G}))$. Composing with the equivalence ϕ, we obtain a fully faithful embedding $\mathrm{Pro}(\mathrm{Fun}^{\mathrm{ad}}(\Delta^1, \mathcal{G})) \hookrightarrow \mathrm{Fun}(\Delta^1, \mathrm{Pro}(\mathcal{G}))$, whose essential image is spanned by the proadmissible morphisms of $\mathrm{Pro}(\mathcal{G})$.

Remark 20.2.2.4. Let $\mathcal{G}$ be an essentially small ∞-category equipped with an admissibility structure, let $j : \mathcal{G} \to \mathrm{Pro}(\mathcal{G})$ denote the Yoneda embedding, and let $f : U \to X$ be a morphism in $\mathcal{G}$. It follows from Remark 20.2.2.3 (and condition (4) of Definition 20.2.1.1) that $j(f)$ is proadmissible if and only if f is an admissible morphism in $\mathcal{G}$.

We can now formulate the main result of this section:

Theorem 20.2.2.5. *Let $\mathcal{G}$ be an essentially small ∞-category which is equipped with an admissibilty structure, let S denote the collection of all proadmissible morphisms in* $\mathrm{Pro}(\mathcal{G})$*, and let ${}^{\perp}S$ be the collection of all morphisms in* $\mathrm{Pro}(\mathcal{G})$ *which are left orthogonal to every morphism in S (see Definition HTT.5.2.8.1). Then $({}^{\perp}S, S)$ determines a factorization system on* $\mathrm{Pro}(\mathcal{G})$*. In other words, every morphism $f : X \to Z$ admits a factorization*

$$X \xrightarrow{f'} Y \xrightarrow{f''} Z,$$

where $f' \in {}^{\perp}S$ and f'' is proadmissible.

Remark 20.2.2.6. Let $\mathcal{G}$ be an essentially small ∞-category which admits finite limits, and suppose we are given a factorization system (S_L, S_R) on $\mathrm{Pro}(\mathcal{G})$. Then $\mathrm{Pro}(\mathcal{G})$ admits finite limits, so that S_R is an admissibility structure on $\mathrm{Pro}(\mathcal{G})$ (Proposition 20.2.2.1). Applying

Remark 20.2.1.11, we obtain an admissibility structure on $\mathcal{G}$, where a morphism in $\mathcal{G}$ is admissible if its image under the Yoneda embedding $j : \mathcal{G} \hookrightarrow \mathrm{Pro}(\mathcal{G})$ belongs to S_R. Note that since S_R is closed under limits in $\mathrm{Pro}(\mathcal{G})$ (see Proposition HTT.**??**), it follows that S_R contains every proadmissible morphism in $\mathrm{Pro}(\mathcal{G})$. If the reverse inclusion holds (that is, if S_R is generated under filtered limits by morphisms of the form $f : U \to X$, where U and X belong to the essential image of j), then (S_L, S_R) coincides with the factorization system appearing in the statement of Theorem 20.2.2.5.

Remark 20.2.2.7. Let $\mathcal{G}$ be an essentially small ∞-category equipped with an admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$. and regard $\mathrm{Pro}(\mathcal{G})$ as equipped with the factorization system of Theorem 20.2.2.5. If $\mathcal{G}$ admits finite limits, then the construction of Remark 20.2.2.6 produces another admissibility structure on $\mathcal{G}$, determined by the collection of morphisms f in $\mathcal{G}$ whose image under the Yoneda embedding $j : \mathcal{G} \to \mathrm{Pro}(\mathcal{G})$ is proadmissible. It follows from Remark **??** that this admissibility structure coincides with $\mathcal{G}^{\mathrm{ad}}$.

Remark 20.2.2.8. Let $\mathcal{G}$ be an essentially small ∞-category which admits finite limits. Combining Remarks 20.2.2.6 and 20.2.2.7, we see that the construction of Theorem 20.2.2.5 establishes a bijection between the following data:

- Admissibility structures on $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$.
- Factorization systems (S_L, S_R) on $\mathrm{Pro}(\mathcal{G})$ for which every morphism $f : X \to Y$ in S_R can be written as a filtered limit of morphisms $f_\alpha : X_\alpha \to Y_\alpha$ which belong to S_R, where X_α and Y_α belong to the essential image of the Yoneda embedding $j : \mathcal{G} \to \mathrm{Pro}(\mathcal{G})$.

Corollary 20.2.2.9. *Let $\mathcal{G}$ be an ∞-category equipped with an admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$, and suppose we are given morphisms $W \xrightarrow{f} X \xrightarrow{g} Y \xrightarrow{h} Z$ in $\mathcal{G}$. If $g \circ f$ and $h \circ g$ are admissible, then f is admissible.*

Proof. Without loss of generality, we may assume that $\mathcal{G}$ is small. Let us abuse notation by identifying $\mathcal{G}$ with a full subcategory of the ∞-category $\mathrm{Pro}(\mathcal{G})$. Let $({}^{\perp}S, S)$ denote the factorization system of Theorem 20.2.2.5. By virtue of Remark 20.2.2.4, it will suffice to show that the morphism f is right orthogonal to every morphism $u : A \to B$ in ${}^{\perp}S$. Fix a map $A \to W$ in the ∞-category $\mathrm{Pro}(\mathcal{G})$; we wish to show that f induces a homotopy equivalence $f' : \mathrm{Map}_{\mathrm{Pro}(\mathcal{G})_{A/}}(B, W) \to \mathrm{Map}_{\mathrm{Pro}(\mathcal{G})_{A/}}(B, X)$. Consider the diagram

$$\mathrm{Map}_{\mathrm{Pro}(\mathcal{G})_{A/}}(B, W) \xrightarrow{f'} \mathrm{Map}_{\mathrm{Pro}(\mathcal{G})_{A/}}(B, X) \xrightarrow{g'} \mathrm{Map}_{\mathrm{Pro}(\mathcal{G})_{A/}}(B, Y) \xrightarrow{h'} \mathrm{Map}_{\mathrm{Pro}(\mathcal{G})_{A/}}(B, Z).$$

Since $g \circ f$ and $h \circ g$ are admissible, the maps $g' \circ f'$ and $h' \circ g'$ are homotopy equivalences. It follows that g' admits left and right homotopy inverses, and is therefore a homotopy equivalence. Then g' and $g' \circ f'$ are both homotopy equivalences, so that f' is a homotopy equivalence as desired. $\square$

20.2.3 The Proof of Theorem 20.2.2.5

Let $\mathcal{G}$ be an essentially small ∞-category equipped with an admissibility structure. Our proof of Theorem 20.2.2.5 will use a variant of Quillen's "small object" argument. We begin with some general observations about the class of proadmissible morphisms in $\mathrm{Pro}(\mathcal{G})$.

Remark 20.2.3.1. Let $\mathcal{G}$ be an essentially small ∞-category equipped with an admissibility structure and let $X \in \mathrm{Pro}(\mathcal{G})$. Then the ∞-category $\mathrm{Pro}(\mathcal{G})_{/X}$ admits small filtered limits, and the full subcategory $\mathrm{Pro}(\mathcal{G})^{\text{pro-ad}}_{/X} \subseteq \mathrm{Pro}(\mathcal{G})_{/X}$ is closed under small filtered limits.

Lemma 20.2.3.2. *Let $\mathcal{G}$ be an essentially small ∞-category equipped with an admissibility structure and let X be an object of $\mathrm{Pro}(\mathcal{G})$. A morphism $f : U \to X$ is proadmissible if and only if, as an object of $\mathrm{Pro}(\mathcal{G})_{/X}$, U can be identified with a small filtered limit of morphisms $U_\alpha \to X$ which fit into pullback diagrams*

$$\begin{array}{ccc} U_\alpha & \longrightarrow & X \\ \downarrow & & \downarrow \\ j(U'_\alpha) & \xrightarrow{j(f'_\alpha)} & j(X'_\alpha), \end{array}$$

where $j : \mathcal{G} \to \mathrm{Pro}(\mathcal{G})$ denotes the Yoneda embedding and each f'_α is an admissible morphism of $\mathcal{G}$.

Proof. Suppose first that f is proadmissible. Then f can be written as a filtered limit of morphisms $j(f'_\alpha) : j(U'_\alpha) \to j(X'_\alpha)$, where f'_α is an admissible morphism of $\mathcal{G}$. For each index α, we can write X as the filtered limit of a diagram $\{j(X''_\beta)\}$, where $X''_\beta \in \mathcal{G}_{/X_\alpha}$. Since each f'_α is admissible, we can choose pullback diagrams

$$\begin{array}{ccc} U''_\beta & \longrightarrow & X''_\beta \\ \downarrow & & \downarrow \\ U'_\alpha & \xrightarrow{f'_\alpha} & X'_\alpha \end{array}$$

in the ∞-category $\mathcal{G}$. It follows that $U_\alpha \simeq \varprojlim_\beta j(U''_\beta)$ is a fiber product $j(U'_\alpha) \times_{j(X'_\alpha)} X$, and that $U \simeq \varprojlim_\alpha U_\alpha$.

To prove the converse, it will suffice (by virtue of Remark 20.2.3.1) to show that for every pullback diagram

$$\begin{array}{ccc} U_\alpha & \xrightarrow{f_\alpha} & X \\ \downarrow & & \downarrow \\ j(U'_\alpha) & \xrightarrow{j(f'_\alpha)} & j(X'_\alpha), \end{array}$$

with f'_α admissible, the map f_α is proadmissible. Let $\{X''_\beta\}$ be as above. Then f_α is a filtered limit of maps $j(f''_\beta)$, where $f''_\beta : X''_\beta \times_{X'_\alpha} U'_\alpha \to X''_\beta$ is the projection onto the first factor (and therefore admissible, since the collection of admissible morphisms is stable under pullback). □

Corollary 20.2.3.3. *Let $\mathcal{G}$ be an essentially small ∞-category equipped with an admissibility structure, let $f : U \to X$ be a proadmissible morphism in* $\mathrm{Pro}(\mathcal{G})$*, and let $g : X' \to X$ be an arbitrary morphism in* $\mathrm{Pro}(\mathcal{G})$*. Then there exists a pullback diagram*

$$\begin{array}{ccc} U' & \longrightarrow & U \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ X' & \xrightarrow{g} & X \end{array}$$

in $\mathrm{Pro}(\mathcal{G})$*. Moreover, the map f' is proadmissible.*

Lemma 20.2.3.4. *Let $\mathcal{G}$ be an essentially small ∞-category equipped with an admissibility structure. Then the collection of proadmissible morphisms in* $\mathrm{Pro}(\mathcal{G})$ *is closed under composition.*

Proof. Choose proadmissible morphisms $f : X \to Y$ and $g : Y \to Z$ in $\mathrm{Pro}(\mathcal{G})$; we wish to show that $g \circ f$ is proadmissible. By virtue of Lemma 20.2.3.2, we may assume that f is a filtered limit of morphisms $\{f_\alpha : X_\alpha \to Y\}$, where each f_α is the pullback $j(f'_\alpha)$ for some admissible morphism f'_α in $\mathcal{G}$. It suffices to show that each composition $g \circ f_\alpha$ is admissible. Replacing f by f_α, we may assume that there exists a pullback diagram

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ \downarrow & & \downarrow{\scriptstyle h} \\ j(X') & \xrightarrow{j(f')} & j(Y') \end{array}$$

where f' is an admissible morphism of $\mathcal{G}$.

Applying Lemma 20.2.3.2 again, we may assume that g is the limit of a diagram of morphisms $\{g_\beta : Y_\beta \to Z\}_{\beta \in B}$ indexed by a filtered partially ordered set B, such that each g_β is a pullback of $j(g'_\beta)$ for some admissible morphism $g'_\beta : Y'_\beta \to Z'_\beta$ in $\mathcal{G}$. Since $j(Y')$ is a cocompact object of $\mathrm{Pro}(\mathcal{G})$, we may assume that h is factors as a composition $Y \to j(Y_{\beta_0}) \xrightarrow{j(h')} j(Y')$ for some $\beta_0 \in B$. It follows that we can identify X with the limit of the diagram $\{j(Y_\beta) \times_{j(Y')} j(X')\}_{\beta \geq \beta_0}$. It will therefore suffice to show that each of the composite maps

$$j(Y_\beta) \times_{j(Y')} j(X') \to j(Y_\beta) \to j(Z_\beta)$$

is proadmissible. In fact, the map $Y_\beta \times_{Y'} X' \to Z_\beta$ is an admissible morphism in $\mathcal{G}$, since the collection of admissible morphisms is stable under pullback and composition. □

Corollary 20.2.3.5. *Let $\mathcal{G}$ be an essentially small ∞-category equipped with an admissibility structure and let $X \in \mathrm{Pro}(\mathcal{G})$. Then the ∞-category $\mathrm{Pro}(\mathcal{G})^{\text{pro-ad}}_{/X}$ admits small products, and the inclusion functor $\mathrm{Pro}(\mathcal{G})^{\text{pro-ad}}_{/X} \hookrightarrow \mathrm{Pro}(\mathcal{G})_{/X}$ preserves small products.*

Proof. By virtue Remark 20.2.3.1, it will suffice to treat the case of finite products. Proceeding by induction on the number of factors (and noting that $\mathrm{Pro}(\mathcal{G})^{\text{ad}}_{/X}$ contains X as a final object), we are reduced to proving that if $U \to X$ and $V \to X$ are proadmissible morphisms, then there exists a fiber product $U \times_X V$ in $\mathrm{Pro}(\mathcal{G})$, and the map $U \times_X V \to X$ is proadmissible. This follows immediately from Lemma 20.2.3.4 and Corollary 20.2.3.3. □

Proof of Theorem 20.2.2.5. Let $\mathcal{G}$ be an essentially small ∞-category equipped with an admissibility structure and let $f : X \to Z$ be a morphism in $\mathrm{Pro}(\mathcal{G})$; we wish to show that f factors as a composition $X \xrightarrow{f'} Y \xrightarrow{f''} Z$, where f'' is proadmissible and f' is left orthogonal to every proadmissible morphism. We begin by inductively constructing a sequence of maps $\{g_i : X \to Y_i\}_{i \geqslant 0}$, using induction on i. Set $g_0 = f$ and $Y_0 = Z$. To carry out the inductive step, suppose that $g_n : X \to Y_n$ has already been constructed. Let $\{\sigma_\alpha\}$ be a set of representatives for all homotopy equivalence classes of diagrams

$$\begin{array}{ccc} X & \longrightarrow & j(U_\alpha) \\ \downarrow{\scriptstyle g_n} & & \downarrow{\scriptstyle j(h_\alpha)} \\ Y_n & \longrightarrow & j(V_\alpha), \end{array}$$

where h_α is an admissible morphism in $\mathcal{G}$. It follows from Corollary 20.2.3.3 that for each index α, the fiber product $Y'_{n,\alpha} = Y_n \times_{j(V_\alpha)} j(U_\alpha)$ exists, and the projection map $Y'_{n,\alpha} \to Y_n$ is proadmissible. Let Y_{n+1} denote the product of the objects $Y'_{n,\alpha}$, formed in the ∞-category $\mathrm{Pro}(\mathcal{G})_{/Y_n}$, and let $g_{n+1} : X \to Y_{n+1}$ be the product of the maps determined by the diagrams σ_α. We have a tower of morphisms

$$\cdots \to Y_3 \to Y_2 \to Y_1 \to Y_0 = Z$$

in $\mathrm{Pro}(\mathcal{G})_{X/}$, and Corollary 20.2.3.5 implies that each of the morphisms in this diagram is proadmissible. Set $Y = \varprojlim_n Y_n$, so that the map f factors as a composition $X \xrightarrow{f'} Y \xrightarrow{f''} Z$. The morphism f'' is a filtered limit of proadmissible morphisms in $\mathrm{Pro}(\mathcal{G})$, and therefore proadmissible. To complete the proof, it will suffice to show that f' is left orthogonal to all proadmissible morphisms.

Let T be the collection of all morphisms in $\mathrm{Pro}(\mathcal{G})$ which are right orthogonal to f'. We wish to prove that T contains all proadmissible morphisms. Since T is closed under filtered limits, it will suffice to show that T contains $j(h)$ for every admissible morphism $h : U \to V$ in $\mathcal{G}$. Let us therefore assume that we are given a map $X \to j(U)$ in $\mathrm{Pro}(\mathcal{G})$; we wish to prove that composition with f' induces a homotopy equivalence

$$\theta : \mathrm{Map}_{\mathrm{Pro}(\mathcal{G})_{X/}}(Y, j(U)) \to \mathrm{Map}_{\mathrm{Pro}(\mathcal{G})_{X/}}(Y, j(V)).$$

We will prove that θ is n-connective using induction on n. Assume first that $n > 0$, so that θ has nonempty homotopy fibers. To prove that θ is n-connective, it will suffice to show that the diagonal map

$$\delta : \mathrm{Map}_{\mathrm{Pro}(\mathcal{G})_{X/}}(Y, j(U)) \to \mathrm{Map}_{\mathrm{Pro}(\mathcal{G})_{X/}}(Y, j(U)) \times_{\mathrm{Map}_{\mathrm{Pro}(\mathcal{G})_{X/}}(Y, j(V))} \mathrm{Map}_{\mathrm{Pro}(\mathcal{G})_{X/}}(Y, j(V)).$$

is $(n-1)$-connective. This follows by applying the inductive hypothesis after replacing h by the map $h' : U \to U \times_V U$ (which is an admissible morphism in $\mathcal{G}$, since it fits into a commutative diagram

$$\begin{array}{ccc} U & \xrightarrow{h'} & U \times_V U \\ & {\scriptstyle h}\searrow \quad \swarrow & \\ & V & \end{array}$$

where the vertical maps are admissible).

It remains to treat the case $n = 0$. For this, we must show that every morphism $\rho : Y \to j(V)$ in $\mathrm{Pro}(\mathcal{G})_{X/}$ factors through $j(X)$. Since $j(V)$ is cocompact object of $\mathrm{Pro}(\mathcal{G})$, we can assume that the map ρ factors through Y_n for some integer n. In this case, it follows from our construction that there exists a commutative diagram

$$\begin{array}{ccc} Y_{n+1} & \longrightarrow & j(U) \\ \downarrow & & \downarrow \\ Y_n & \longrightarrow & j(V) \end{array}$$

in $\mathrm{Pro}(\mathcal{G})_{X/}$. □

20.2.4 Admissibility Structures and Fracture Subcategories

Our next goal is to establish a relationship between the notion of admissibility structure and the theory of fractured ∞-topoi introduced in §20.1.

Theorem 20.2.4.1. *Let $\mathcal{G}$ be an essentially small ∞-category equipped with an admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$. Let $\mathcal{P}(\mathcal{G}) = \mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S})$ denote the ∞-category of presheaves on $\mathcal{G}$, let $\mathcal{P}(\mathcal{G}^{\mathrm{ad}}) = \mathrm{Fun}((\mathcal{G}^{\mathrm{ad}})^{\mathrm{op}}, \mathcal{S})$ be defined similarly, and let $j_! : \mathcal{P}(\mathcal{G}^{\mathrm{ad}}) \to \mathcal{P}(\mathcal{G})$ denote the functor given by left Kan extension along the inclusion map $j : \mathcal{G}^{\mathrm{ad}} \hookrightarrow \mathcal{G}$. Then the functor $j_!$ induces an equivalence from $\mathcal{P}(\mathcal{G}^{\mathrm{ad}})$ onto a fracture subcategory $\mathcal{P}(\mathcal{G})^{\mathrm{corp}} \subseteq \mathcal{P}(\mathcal{G})$.*

The proof of Theorem 20.2.4.1 will be given in §20.2.5. We begin by establishing some preliminaries. Our starting point is the following mild generalization of Proposition HTT.6.1.5.2:

Proposition 20.2.4.2. *Let $\mathcal{G}$ be a small ∞-category which admits pullbacks, let $j : \mathcal{G} \to \mathcal{P}(\mathcal{G})$ denote the Yoneda embedding, let $\mathcal{X}$ be an ∞-topos, and let $F : \mathcal{P}(\mathcal{G}) \to \mathcal{X}$ be a functor which preserves small colimits. The following conditions are equivalent:*

- (a) *The functor F preserves pullbacks.*
- (b) *The composite functor $f = F \circ j$ preserves pullbacks.*

Proof. Let $\alpha : \mathscr{F} \to \mathscr{G}$ be a morphism in $\mathcal{P}(\mathcal{G})$. We will say that α is *good* if for every pullback square

$$\begin{array}{ccc} \mathscr{F} & \longrightarrow & \mathscr{F} \\ \downarrow & & \downarrow{\scriptstyle \alpha} \\ \mathscr{G}' & \longrightarrow & \mathscr{G} \end{array}$$

in $\mathcal{P}(\mathcal{G})$, the induced diagram

$$\begin{array}{ccc} F(\mathscr{F}') & \longrightarrow & F(\mathscr{F}) \\ \downarrow & & \downarrow{\scriptstyle F(\alpha)} \\ F(\mathscr{G}') & \xrightarrow{\beta} & F(\mathscr{G}) \end{array}$$

is a pullback square in $\mathcal{X}$. Note that the collection of good morphisms in $\mathcal{P}(\mathcal{G})$ is closed under composition (see Lemma HTT.4.4.2.1).

Using the fact that colimits in $\mathcal{X}$ are universal (and the fact that the functor F preserves small colimits), we see that a morphism $\alpha : \mathscr{F} \to \mathscr{G}$ is good if and only if the following *a priori* weaker condition is satisfied:

$(*)$ For every object $C \in \mathcal{G}$ and every morphism $j(C) \to \mathscr{G}$, the induced diagram

$$\begin{array}{ccc} F(j(C) \times_{\mathscr{G}} \mathscr{F}) & \longrightarrow & F(\mathscr{F}) \\ \downarrow & & \downarrow{\scriptstyle F(\alpha)} \\ F(j(C)) & \xrightarrow{\beta} & F(\mathscr{G}) \end{array}$$

is a pullback square in $\mathcal{X}$.

Let us say that an object $\mathscr{G} \in \mathcal{P}(\mathcal{G})$ is *good* if every morphism $\alpha : \mathscr{F} \to \mathscr{G}$ in $\mathcal{P}(\mathcal{G})$ is good. Since colimits in $\mathcal{X}$ are universal and the functor F preserves small colimits, the collection of good morphisms $\mathscr{F} \to \mathscr{G}$ is closed under colimits in the ∞-category $\mathcal{P}(\mathcal{G})_{/\mathscr{G}}$. Using the fact that the ∞-category $\mathcal{P}(\mathcal{G})$ is generated under small colimits by the essential image of the Yoneda embedding j, we deduce that $\mathscr{G}$ is good if and only if it satisfies the following:

$(*')$ For every pair of objects $C, D \in \mathcal{G}$ and every pair of maps $j(C) \rightarrow \mathscr{G} \leftarrow j(D)$ the diagram

$$\begin{array}{ccc} F(j(C) \times_{\mathscr{G}} j(D)) & \longrightarrow & F(j(D)) \\ \downarrow & & \downarrow \\ F(j(C)) & \longrightarrow & F(\mathscr{G}) \end{array}$$

is a pullback square in $\mathcal{X}$.

Note that condition (a) is equivalent to the assertion that every object of $\mathcal{P}(\mathcal{G})$ is good, and condition (b) is equivalent to the assertion that every object in the essential image of the Yoneda embedding $j : \mathcal{C} \rightarrow \mathcal{P}(\mathcal{G})$ is good (this follows from the observation that j is fully faithful and preserves pullbacks). To show that these conditions are equivalent, it will suffice to show that the collection of good objects of $\mathcal{P}(\mathcal{G})$ is closed under small colimits. Using Proposition HTT.4.4.3.3 , we are reduced to showing that the collection of good objects of $\mathcal{P}(\mathcal{G})$ is closed under coequalizers and small coproducts.

We first consider the case of coproducts. Let $\{\mathscr{G}_i\}_{i \in I}$ be a family of good objects of $\mathcal{P}(\mathcal{G})$ indexed by a (small) set I and let $\{\phi_i : \mathscr{G}_i \rightarrow \mathscr{G}\}_{i \in I}$ be a family of morphisms which exhibit $\mathscr{G}$ as a coproduct of the family $\{\mathscr{G}_i\}_{i \in I}$. Suppose we are given a pullback diagram

$$\begin{array}{ccc} \mathscr{F} & \longrightarrow & j(D) \\ \downarrow & & \downarrow{\scriptstyle \alpha} \\ j(C) & \xrightarrow{\beta} & \mathscr{G} \end{array}$$

in $\mathcal{P}(\mathcal{G})$. The map α factors as a composition $j(D) \xrightarrow{\alpha'} \mathscr{G}_i \xrightarrow{\phi_i} \mathscr{G}$ for some $i \in I$. By assumption, the morphism α' is good; it therefore suffices to prove that ϕ_i is good. By a similar argument, we can replace β by a map $\phi_j : \mathscr{G}_j \rightarrow \mathscr{G}$ for some $j \in I$. We are now required to show that if

$$\begin{array}{ccc} \mathscr{F} & \longrightarrow & \mathscr{G}_i \\ \downarrow & & \downarrow{\scriptstyle \phi_i} \\ \mathscr{G}_j & \xrightarrow{\phi_j} & \mathscr{G} \end{array}$$

is a pullback diagram in $\mathcal{P}(\mathcal{G})$, then

$$\begin{array}{ccc} F(\mathscr{F}) & \longrightarrow & F(\mathscr{G}_i) \\ \downarrow & & \downarrow{\scriptstyle F(\phi_i)} \\ F(\mathscr{G}_j) & \xrightarrow{F(\phi_j)} & F(\mathscr{G}) \end{array}$$

is a pullback diagram in $\mathcal{X}$. This follows from the assumption that F preserves coproducts and the fact that coproducts in $\mathcal{X}$ are disjoint (see Lemma HTT.6.1.5.1).

We now complete the proof by showing that the collection of good objects of $\mathcal{P}(\mathcal{G})$ is stable under the formation of coequalizers. Let

$$\mathscr{G}'' \rightrightarrows \mathscr{G}' \xrightarrow{s} \mathscr{G}$$

be a coequalizer diagram in $\mathcal{P}(\mathcal{G})$, and suppose that the presheaves $\mathscr{G}'$ and $\mathscr{G}''$ are good. We must show that any pullback diagram

$$\begin{array}{ccc} \mathscr{F} & \longrightarrow & j(D) \\ \downarrow & & \downarrow{\scriptstyle \alpha} \\ j(C) & \xrightarrow{\beta} & \mathscr{G} \end{array}$$

remains a pullback diagram after applying the functor F. Note that the map α factors as a composition $j(D) \xrightarrow{\alpha'} \mathscr{G}' \xrightarrow{s} \mathscr{G}$. Since $\mathscr{G}'$ is good, the morphism α' is good. It will therefore suffice to show that α'' is good: that is, we must show that every pullback diagram

$$\begin{array}{ccc} \mathscr{F} & \longrightarrow & \mathscr{G}' \\ \downarrow & & \downarrow{\scriptstyle s} \\ j(C) & \xrightarrow{\beta} & \mathscr{G} \end{array}$$

remains a pullback diagram after applying F. Applying the same argument to β, we are reduced to showing that the canonical map $F(\mathscr{G}' \times_{\mathscr{G}} \mathscr{G}') \to F(\mathscr{G}') \times_{F(\mathscr{G})} F(\mathscr{G}')$ is a pullback diagram in $\mathcal{X}$. This follows from Proposition HTT.6.1.4.2 (together with our assumption that $\mathscr{G}'$ is good). □

Corollary 20.2.4.3. *Let $\mathcal{G}$ be an essentially small ∞-category equipped with an admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$, and let $j_! : \mathcal{P}(\mathcal{G}^{\mathrm{ad}}) \to \mathcal{P}(\mathcal{G})$ denote the functor given by left Kan extension along the inclusion. Then the functor $j_!$ preserves pullbacks.*

Proof. Using Proposition 20.2.4.2, we are reduced to showing that the composite functor $\mathcal{G}^{\mathrm{ad}} \hookrightarrow \mathcal{G} \xrightarrow{h} \mathcal{P}(\mathcal{G})$ preserves pullback squares, where h denotes the Yoneda embedding. Since h preserves all pullback squares which exist in $\mathcal{G}$, it will suffice to show that the inclusion $\mathcal{G}^{\mathrm{ad}} \hookrightarrow \mathcal{G}$ preserves pullbacks, which follows from Remark 20.2.1.12. □

Proposition 20.2.4.4. *Let $\mathcal{G}$ be an essentially small ∞-category, let $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$ be an admissibility structure on $\mathcal{G}$, let $j^* : \mathcal{P}(\mathcal{G}) \to \mathcal{P}(\mathcal{G}^{\mathrm{ad}})$ be the restriction map and let $j_! : \mathcal{P}(\mathcal{G}^{\mathrm{ad}}) \to \mathcal{P}(\mathcal{G})$ be a left adjoint to j^* (given by left Kan extension along the inclusion $\mathcal{G}^{\mathrm{ad}} \hookrightarrow \mathcal{G}$). Then, for every morphism $\alpha : \mathscr{F} \to \mathscr{G}$ in $\mathcal{P}(\mathcal{G})$, the diagram σ:*

$$\begin{array}{ccc} j_! j^* j_! \mathscr{F} & \longrightarrow & j_! j^* j_! \mathscr{G} \\ \downarrow & & \downarrow \\ j_! \mathscr{F} & \longrightarrow & j_! \mathscr{G} \end{array}$$

is a pullback square in $\mathcal{P}(\mathcal{G})$ *(where the vertical maps are induced by the counit* $j_! j^* \to \mathrm{id}$*).*

Proof. Let us regard the presheaf $\mathscr{G}$ as fixed. Since the functors j^* and $j_!$ preserve small colimits, the collection of those objects $\mathscr{F} \in \mathcal{P}(\mathcal{G}^{\mathrm{ad}})_{/\mathscr{G}}$ for which σ is a pullback square is closed under small colimits. We may therefore assume without loss of generality that the presheaf $\mathscr{F}$ is representable. Write $\mathscr{G}$ as a colimit $\varinjlim \mathscr{G}_\alpha$, where each of the presheaves $\mathscr{G}_\alpha \in \mathcal{P}(\mathcal{G}^{\mathrm{ad}})$ is representable. Without loss of generality, we may assume that $\mathscr{F} = \mathscr{G}_{\alpha_0}$ for some index α_0 (as an object of the ∞-category $\mathcal{P}(\mathcal{G}^{\mathrm{ad}})_{/\mathscr{G}}$). It will therefore suffice to show that each of the diagrams

$$\begin{array}{ccc} j_! j^* j_! \mathscr{G}_\alpha & \longrightarrow & j_! j^* j_! \mathscr{G} \\ \downarrow & & \downarrow \\ j_! \mathscr{G}_\alpha & \longrightarrow & j_! \mathscr{G} \end{array}$$

is a pullback square. Applying Theorem HTT.6.1.3.9 , we are reduced to showing that each of the diagrams

$$\begin{array}{ccc} j_! j^* j_! \mathscr{G}_\alpha & \longrightarrow & j_! j^* j_! \mathscr{G}_\beta \\ \downarrow & & \downarrow \\ j_! \mathscr{G}_\alpha & \longrightarrow & j_! \mathscr{G}_\beta \end{array}$$

is a pullback square. In other words, it will suffice to verify Proposition 20.2.4.4 in the special case where $\mathscr{F}$ and $\mathscr{G}$ are representable by objects $X, Y \in \mathcal{G}^{\mathrm{ad}}$ (so that the map $\mathscr{F} \to \mathscr{G}$ is induced by an admissible morphism $u : X \to Y$).

Let U be an object of $\mathcal{G}$; we wish to show that the diagram of spaces $\sigma(U)$:

$$\begin{array}{ccc} (j_! j^* j_! \mathscr{F})(U) & \longrightarrow & (j_! j^* j_! \mathscr{G})(U) \\ \downarrow & & \downarrow \\ (j_! \mathscr{F})(U) & \longrightarrow & (j_! \mathscr{G})(U) \end{array}$$

is a pullback. Unwinding the definitions, we can identify $\sigma(U)$ with the diagram

$$\begin{array}{ccc} \varinjlim_{X' \in (\mathcal{G}_{/X})^{\mathrm{ad}}} \mathrm{Map}_{\mathcal{G}}(U, X') & \longrightarrow & \varinjlim_{Y' \in (\mathcal{G}_{/Y})^{\mathrm{ad}}} \mathrm{Map}_{\mathcal{G}}(U, Y') \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathcal{G}}(U, X) & \longrightarrow & \mathrm{Map}_{\mathcal{G}}(U, Y). \end{array}$$

We are therefore reduced to showing that the canonical map

$$\varinjlim_{X' \in (\mathcal{G}_{/X})^{\mathrm{ad}}} \mathrm{Map}_{\mathcal{G}}(U, X') \to \varinjlim_{Y' \in (\mathcal{G}_{/Y})^{\mathrm{ad}}} \mathrm{Map}_{\mathcal{G}}(U, Y' \times_Y X)$$

is a homotopy equivalence. To verify this, it suffices to establish that construction $Y' \mapsto Y' \times_Y X$ determines a left cofinal functor $u^* : (\mathcal{G}_{/Y})^{\mathrm{ad}} \to (\mathcal{G}_{/X})^{\mathrm{ad}}$. This is clear, since the functor u^* admits a left adjoint (given by composition with u). □

Proposition 20.2.4.5. *Let $\mathcal{G}$ be an essentially small ∞-category, let $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$ be an admissibility structure on $\mathcal{G}$, let $j^* : \mathcal{P}(\mathcal{G}) \to \mathcal{P}(\mathcal{G}^{\mathrm{ad}})$ be the restriction map and let $j_! : \mathcal{P}(\mathcal{G}^{\mathrm{ad}}) \to \mathcal{P}(\mathcal{G})$ be a left adjoint to j^* (given by left Kan extension along the inclusion $\mathcal{G}^{\mathrm{ad}} \hookrightarrow \mathcal{G}$). Then:*

(a) *For every presheaf $\mathscr{F} \in \mathcal{P}(\mathcal{G}^{\mathrm{ad}})$, the unit map $u_{\mathscr{F}} : \mathscr{F} \to j^* j_! \mathscr{F}$ is (-1)-truncated.*

(b) *For every morphism $\mathscr{F} \to \mathscr{G}$ in $\mathcal{P}(\mathcal{G}^{\mathrm{ad}})$, the diagram*

$$\begin{array}{ccc} \mathscr{F} & \xrightarrow{u_{\mathscr{F}}} & j^* j_! \mathscr{F} \\ \downarrow & & \downarrow \\ \mathscr{G} & \xrightarrow{u_{\mathscr{G}}} & j^* j_! \mathscr{G} \end{array}$$

is a pullback square.

Proof. We first prove (a). Fix an object $X \in \mathcal{G}$; we wish to show that the unit map $u_{\mathscr{F}}(X) : \mathscr{F}(X) \to (j^* j_! \mathscr{F})(X) = (j_! \mathscr{F})(X)$ is an equivalence. Set $\mathcal{C} = \mathcal{G}^{\mathrm{ad}} \times_{\mathcal{G}} \mathcal{G}_{X/}$; we wish to show that the canonical map $\mathscr{F}(X) \to \varinjlim_{Y \in \mathcal{C}^{\mathrm{op}}} \mathscr{F}(Y)$ is (-1)-truncated. The objects of $\mathcal{C}$ can be identified with morphisms $f : X \to Y$ in the ∞-category $\mathcal{G}$. Let $\mathcal{C}_0$ be the full subcategory of $\mathcal{C}$ spanned by those objects for which f is admissible, and let $\mathcal{C}_1$ be the full subcategory of $\mathcal{C}$ spanned by those objects for which f is not admissible. Using condition (3) of Definition 20.2.1.1, we see that $\mathrm{Map}_{\mathcal{C}}(Y, Z)$ is empty if $Y \in \mathcal{C}_0$ and $Z \in \mathcal{C}_1$, or if $Y \in \mathcal{C}_1$ and $Z \in \mathcal{C}_0$. It follows that we can identify the colimit $\varinjlim_{Y \in \mathcal{C}^{\mathrm{op}}} \mathscr{F}(Y)$ with the coproduct of $\varinjlim_{Y \in \mathcal{C}_0^{\mathrm{op}}} \mathscr{F}(Y)$ and $\varinjlim_{Y \in \mathcal{C}_1^{\mathrm{op}}} \mathscr{F}(Y)$. We are therefore reduced to proving that the canonical map $\mathscr{F}(X) \to \varinjlim_{Y \in \mathcal{C}_0^{\mathrm{op}}} \mathscr{F}(Y)$ is (-1)-truncated. In fact, this map is an equivalence, since the identity map $\mathrm{id} : X \to X$ is an initial object of $\mathcal{C}_0$. This completes the proof of (a).

We now prove (b). Fix an object $X \in \mathcal{G}$ and define $\mathcal{C}$ as above; we wish to show that the diagram of spaces

$$\begin{array}{ccc} \mathscr{F}(X) & \longrightarrow & \varinjlim_{Y \in \mathcal{C}^{\mathrm{op}}} \mathscr{F}(Y) \\ \downarrow & & \downarrow \\ \mathscr{G}(X) & \longrightarrow & \varinjlim_{Y \in \mathcal{C}^{\mathrm{op}}} \mathscr{G}(Y) \end{array}$$

is a pullback square. Arguing as above, we can rewrite this diagram as

$$\begin{array}{ccc} \varinjlim_{Y \in \mathcal{C}_0^{op}} \mathscr{F}(Y) & \longrightarrow & (\varinjlim_{Y \in \mathcal{C}_0^{op}} \mathscr{F}(Y)) \amalg (\varinjlim_{Y \in \mathcal{C}_1^{op}} \mathscr{F}(Y)) \\ \downarrow & & \downarrow \\ \varinjlim_{Y \in \mathcal{C}_0^{op}} \mathscr{G}(Y) & \longrightarrow & (\varinjlim_{Y \in \mathcal{C}_0^{op}} \mathscr{G}(Y)) \amalg (\varinjlim_{Y \in \mathcal{C}_1^{op}} \mathscr{G}(Y)), \end{array}$$

so that the desired result is evident. □

20.2.5 The Proof of Theorem 20.2.4.1

Let $\mathcal{G}$ be an essentially small ∞-category equipped with an admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$, which we regard as fixed throughout this section. Let $j^* : \mathcal{P}(\mathcal{G}) \to \mathcal{P}(\mathcal{G}^{\mathrm{ad}})$ denote the restriction map and let $j_! : \mathcal{P}(\mathcal{G}^{\mathrm{ad}}) \to \mathcal{P}(\mathcal{G})$ be a left adjoint to j^* (given by left Kan extension along the inclusion $\mathcal{G}^{\mathrm{ad}} \hookrightarrow \mathcal{G}$). Our proof of Theorem 20.6.3.4 will require a bit of (temporary) terminology. For any pair of objects $\mathscr{F}, \mathscr{G} \in \mathcal{P}(\mathcal{G})$), it follows from Proposition 20.2.4.5 that the canonical map

$$\mathrm{Map}_{\mathcal{P}(\mathcal{G}^{\mathrm{ad}})}(\mathscr{F}, \mathscr{G}) \to \mathrm{Map}_{\mathcal{P}(\mathcal{G}^{\mathrm{ad}})}(\mathscr{F}, j^* j_! \mathscr{G}) \simeq \mathrm{Map}_{\mathcal{P}(\mathcal{G})}(j_! \mathscr{F}, j_! \mathscr{G})$$

has (-1)-truncated homotopy fibers. We will say that a morphism $f : j_! \mathscr{F} \to j_! \mathscr{G}$ is *admissible* if it belongs to the essential image of this map. Our first goal is to show that this notion of admissible morphism satisfies analogues of the axioms of Definition 20.2.1.1.

Lemma 20.2.5.1. *Let $\mathscr{F}$, $\mathscr{G}$, and $\mathscr{H}$ be objects of $\mathcal{P}(\mathcal{G}^{\mathrm{ad}})$, and suppose we are given morphisms $f : j_! \mathscr{F} \to j_! \mathscr{G}$ and $g : j_! \mathscr{G} \to j_! \mathscr{H}$. Then:*

(a) If f and g are admissible, then the composition $g \circ f$ is admissible.

(b) If g and $g \circ f$ are admissible, then f is admissible.

(c) If f and $g \circ f$ are admissible and f is an effective epimorphism, then g is admissible.

Proof. Assertion (a) is obvious. We next prove (b). Assume that g and $g \circ f$ are admissible; we wish to show that f is admissible. Let us identify f with a map $\widehat{f} : \mathscr{F} \to j^* j_! \mathscr{G}$; we wish to show that $\widehat{f}$ factors through the unit map $u_{\mathscr{G}} : \mathscr{G} \to j^* j_! \mathscr{G}$. Without loss of generality, we can assume that $g = j_!(g_0)$ for some morphism $g_0 : \mathscr{G} \to \mathscr{H}$. Proposition 20.2.4.5 guarantees that the diagram

$$\begin{array}{ccc} \mathscr{G} & \xrightarrow{u_{\mathscr{G}}} & j^* j_! \mathscr{G} \\ \downarrow{\scriptstyle g_0} & & \downarrow{\scriptstyle j^*(g)} \\ \mathscr{H} & \xrightarrow{u_{\mathscr{H}}} & j^* j_! \mathscr{H} \end{array}$$

is a pullback square. Consequently, it will suffice to show that the composite map $j^*(g) \circ \widehat{f}$ factors through $u_{\mathscr{H}}$, which is equivalent to our assumption that $g \circ f$ is admissible.

We now prove (c). Assume that f is admissible and an effective epimorphism, so that we can write $f = j_!(f_0)$ for some morphism $f_0 : \mathscr{F} \to \mathscr{G}$. Note that the morphism f_0 is a pullback of $j^*(f)$ (Proposition 20.2.4.5), and is therefore also an effective epimorphism. Let us identify g with a map $\widehat{g} : \mathscr{G} \to j^* j_! \mathscr{H}$. Form a commutative diagram

$$\begin{array}{ccccc} \mathscr{F}_0 & \longrightarrow & \mathscr{G}_0 & \longrightarrow & \mathscr{H} \\ \downarrow & & \downarrow & & \downarrow u_{\mathscr{H}} \\ \mathscr{F} & \xrightarrow{f_0} & \mathscr{G} & \xrightarrow{\widehat{g}} & j^* j_! \mathscr{H}, \end{array}$$

where both squares are pullbacks. It follows from Proposition 20.2.4.5 that the vertical maps in this diagram are (-1)-truncated. If $g \circ f$ is admissible, then the left vertical map admits a section and is therefore an equivalence. Since f_0 is an effective epimorphism, this guarantees that the middle vertical map is also an equivalence, so that $\widehat{g}$ factors through $u_{\mathscr{H}}$. We then conclude that g is admissible, as desired. □

Remark 20.2.5.2. Suppose we are given a collection of morphisms $\{f_i : j_! \mathscr{F}_i \to j_! \mathscr{G}\}_{i \in I}$, indexed by a set I. Since the functor $j_!$ commutes with coproducts, we can amalgamate the morphisms f_i to obtain a map $f : j_!(\coprod_{i \in I} \mathscr{F}_i) \to j_! \mathscr{G}$. The morphism f is admissible if and only if each f_i is admissible.

Lemma 20.2.5.3. *Let $\mathscr{F}$, $\mathscr{G}$, and $\mathscr{G}'$ be objects of $\mathcal{P}(\mathcal{G}^{\mathrm{ad}})$. Suppose we are given morphisms $f : j_! \mathscr{F} \to j_! \mathscr{G}$ and $g : j_! \mathscr{G}' \to j_! \mathscr{G}$ in the ∞-category $\mathcal{P}(\mathcal{G})$, where f is admissible. Then there exists an object $\mathscr{F}' \in \mathcal{P}(\mathcal{G}^{\mathrm{ad}})$ and a pullback diagram*

$$\begin{array}{ccc} j_! \mathscr{F}' & \xrightarrow{f'} & j_! \mathscr{G}' \\ \downarrow g' & & \downarrow g \\ j_! \mathscr{F} & \xrightarrow{f} & j_! \mathscr{G} \end{array}$$

in $\mathcal{P}(\mathcal{G})$, where f' is admissible.

Remark 20.2.5.4. In the situation of Lemma 20.2.5.3, suppose that g is also admissible. Applying Lemma 20.2.5.1 we deduce that $g \circ f' \simeq f \circ g'$ is admissible, so that g' is also admissible.

Proof of Lemma 20.2.5.3. Set $\mathscr{F}' = \mathscr{G}' \times_{j^* j_! \mathscr{G}} j^* j_! \mathscr{F}$. We then have a commutative diagram

$$\begin{array}{ccc} j_! \mathscr{F}' & \longrightarrow & j_! \mathscr{G}' \\ \downarrow & & \downarrow \\ j_! j^* j_! \mathscr{F} & \longrightarrow & j_! j^* j_! \mathscr{G} \\ \downarrow & & \downarrow \\ j_! \mathscr{F} & \longrightarrow & j_! \mathscr{G} \end{array}$$

where the upper horizontal map is admissible by construction, the upper square is a pullback diagram because the functor $j_!$ preserves pullbacks (Corollary 20.2.4.3), and the bottom square is a pullback diagram by virtue of Proposition 20.2.4.4. It follows that the outer rectangle has the desired properties. □

Lemma 20.2.5.5. *Let $\mathscr{F}_0$, $\mathscr{F}_1$, $\mathscr{F}_2$, and $\mathscr{F}_3$ be objects of $\mathcal{P}(\mathcal{G}^{\mathrm{ad}})$, and suppose we are given morphisms*

$$j_! \mathscr{F}_0 \xrightarrow{f} j_! \mathscr{F}_1 \xrightarrow{g} j_! \mathscr{F}_2 \xrightarrow{h} j_! \mathscr{F}_3 .$$

If $g \circ f$ and $h \circ g$ are admissible, then f is admissible.

Proof. Let $h : \mathcal{G}^{\mathrm{ad}} \to \mathcal{P}(\mathcal{G}^{\mathrm{ad}})$ denote the Yoneda embedding. Then we can choose a collection of object $\{Z_i\}_{i \in I}$ in $\mathcal{G}^{\mathrm{ad}}$ and an effective epimorphism $\rho : \amalg_{i \in I} h(Z_i) \to \mathscr{F}_3$. Using Lemma 20.2.5.3 repeatedly, we can form a commutative diagram

$$\begin{array}{ccc} j_!(\amalg_{i \in I} \mathscr{F}_{0,i}) & \xrightarrow{\phi_0} & j_! \mathscr{F}_0 \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ j_!(\amalg_{i \in I} \mathscr{F}_{1,i}) & \xrightarrow{\phi_1} & j_! \mathscr{F}_1 \\ \downarrow{\scriptstyle g'} & & \downarrow{\scriptstyle g} \\ j_!(\amalg_{i \in I} \mathscr{F}_{2,i}) & \xrightarrow{\phi_2} & j_! \mathscr{F}_2 \\ \downarrow{\scriptstyle h'} & & \downarrow{\scriptstyle h} \\ j_!(\amalg_{i \in I} h(Z_i)) & \xrightarrow{j_!(\rho)} & j_! \mathscr{F}_3 \end{array}$$

where each square is a pullback and the horizontal maps are admissible. Applying Remark 20.2.5.4, we see that the composite maps $g' \circ f'$ and $h' \circ g'$ are both admissible. Note that since $j_!$ preserves small colimits, the morphism $j_!(\rho)$ is an effective epimorphism; it follows that ϕ_0 is an admissible effective epimorphism. Using Lemma 20.2.5.1, we see that f is admissible if and only if $f \circ \phi_0 \simeq \phi_1 \circ f'$ is admissible, if and only if f' is admissible. We may therefore replace the right column in the above diagram by the left column, and thereby reduce to the case where $\mathscr{F}_3$ is a coproduct of objects of the form $h(Z)$ for $Z \in \mathcal{G}^{\mathrm{ad}}$. Using Remark 20.2.5.2, we can reduce further to the case where $\mathscr{F}_3 = h(Z)$ for some $Z \in \mathcal{G}^{\mathrm{ad}}$.

Applying similar arguments to $\mathscr{F}_2$, $\mathscr{F}_1$, and $\mathscr{F}_0$, we can assume that $\mathscr{F}_2 = h(Y)$, $\mathscr{F}_1 = h(X)$, and $\mathscr{F}_0 = h(W)$. Then the morphisms f, g, and h are induced by maps and that the morphisms f, g, and h are induced by maps $W \xrightarrow{f_0} X \xrightarrow{g_0} Y \xrightarrow{h_0} Z$, where $g_0 \circ f_0$ and $h_0 \circ g_0$ are admissible. Applying Corollary 20.2.2.9, we conclude that f_0 is also an admissible morphism of $\mathcal{G}$, so that $f \simeq j_! h(f_0)$ is an admissible morphism in $\mathcal{P}(\mathcal{G})$. □

Lemma 20.2.5.6. *Let $\mathscr{F}$ and $\mathscr{G}$ be objects of $\mathcal{P}(\mathcal{G})$ and let $f : j_! \mathscr{F} \to j_! \mathscr{G}$ be an equivalence in the ∞-category $\mathcal{P}(\mathcal{G})$. Then f is homotopic to $f_!(f_0)$ for some equivalence $f_0 : \mathscr{F} \to \mathscr{G}$ in the ∞-category $\mathcal{P}(\mathcal{G}^{\mathrm{ad}})$.*

Proof. Let f^{-1} denote a homotopy inverse to f. Applying Lemma 20.2.5.5 to the diagram

$$j_! \mathscr{F} \xrightarrow{f} j_! \mathscr{G} \xrightarrow{f^{-1}} j_! \mathscr{F} \xrightarrow{f} j_! \mathscr{G},$$

we deduce that f is admissible: that is, we can write $f = j_!(f_0)$ for some morphism f_0 in $\mathcal{P}(\mathcal{G}^{\mathrm{ad}})$. It follows from Proposition 20.2.4.5 that the morphism f_0 is a pullback of $j^*(f)$, and is therefore an equivalence. □

Proof of Theorem 20.6.3.4. It follows from Proposition 20.2.4.5 and Lemma 20.2.5.6 that the functor $j_! : \mathcal{P}(\mathcal{G}^{\mathrm{ad}}) \to \mathcal{P}(\mathcal{G})$ induces an equivalence from $\mathcal{P}(\mathcal{G}^{\mathrm{ad}})$ to a replete subcategory $\mathcal{P}(\mathcal{G})^{\mathrm{corp}} \subseteq \mathcal{P}(\mathcal{G})$. To complete the proof, it will suffice to show that $\mathcal{P}(\mathcal{G})^{\mathrm{corp}}$ is a fracture subcategory of $\mathcal{P}(\mathcal{G})$: that is, that it satisfies conditions (1), (2), and (3) of Definition 20.1.2.1. Condition (1) follows from Corollary 20.2.4.3, condition (2) from Corollary **??**, and condition (3) from Proposition 20.2.4.4. □

20.3 Geometric Admissibility Structures

Let X be a quasi-compact, quasi-separated scheme, let Sch_X denote the category of X-schemes of finite presentation, and let $\mathrm{Sch}_X^{\text{ét}} \subseteq \mathrm{Sch}_X$ denote the full subcategory spanned by the étale X-schemes. We regard both Sch_X and $\mathrm{Sch}_X^{\text{ét}}$ as Grothendieck sites, and denote the associated ∞-topoi by $\mathcal{S}\mathrm{hv}(\mathrm{Sch}_X)$ and $\mathcal{S}\mathrm{hv}(\mathrm{Sch}_X^{\text{ét}})$, respectively. These ∞-topoi are closely related to one another. For each functor $\mathscr{F} : \mathrm{Sch}_X^{\mathrm{op}} \to \mathcal{S}\mathrm{et}$ and each object $Y \in \mathrm{Sch}_X$, let $\mathscr{F}|_Y$ denote the composition of $\mathscr{F}$ with the forgetful functor $(\mathrm{Sch}_Y^{\text{ét}})^{\mathrm{op}} \to \mathrm{Sch}_X^{\mathrm{op}}$. Then $\mathscr{F}$ is a sheaf for the étale topology on Sch_X if and only if each $\mathscr{F}|_Y$ is a sheaf with respect to the étale topology on $\mathrm{Sch}_Y^{\text{ét}}$. In this case, $\mathscr{F}$ can be functorially recovered from the sheaves $\mathscr{F}|_Y$ together with the natural transition maps

$$\tau_f : f^* \mathscr{F}|_Y \to \mathscr{F}|_Z$$

defined for each morphism $f : Z \to Y$ in Sch_X. We say that a sheaf $\mathscr{F} \in \mathcal{S}\mathrm{hv}(\mathrm{Sch}_X)$ is *Cartesian* if τ_f is an isomorphism for every morphism f in Sch_X. The construction $\mathscr{F} \mapsto \mathscr{F}|_X$ determines an equivalence of ∞-categories $\mathcal{S}\mathrm{hv}(\mathrm{Sch}_X)^{\mathrm{cart}} \to \mathcal{S}\mathrm{hv}(\mathrm{Sch}_X^{\text{ét}})$, where $\mathcal{S}\mathrm{hv}(\mathrm{Sch}_X)^{\mathrm{cart}}$ denotes the full subcategory of $\mathcal{S}\mathrm{hv}(\mathrm{Sch}_X)$ spanned by the Cartesian sheaves (note that if $\mathscr{F}$ is Cartesian, then for any $f : Y \to X$ we have $\mathscr{F}(Y) = \Gamma(Y; f^* \mathscr{F}|_X))$.

The condition that a sheaf $\mathscr{F} \in \mathcal{S}\mathrm{hv}(\mathrm{Sch}_X)$ is Cartesian can be relativized. Given a morphism $\alpha : \mathscr{F} \to \mathscr{G}$ in $\mathcal{S}\mathrm{hv}(\mathrm{Sch}_X)$, let us say that α is *Cartesian* if, for every morphism $f : Z \to Y$ in Sch_X, the diagram

$$\begin{array}{ccc} f^* \mathscr{F}|_Y & \longrightarrow & \mathscr{F}|_Z \\ \downarrow & & \downarrow \\ f^* \mathscr{G}|_Y & \longrightarrow & \mathscr{G}|_Z \end{array}$$

is a pullback square (in the ∞-category $\mathcal{S}\mathrm{hv}(\mathrm{Sch}_Z^{\text{ét}})$). In this section, we introduce the notion of a *geometric admissibility structure* on an ∞-topos $\mathcal{X}$ (Definition 20.3.4.1), which abstracts the essential properties enjoyed by the class of Cartesian morphisms in $\mathcal{S}\mathrm{hv}(\mathrm{Sch}_X)$. Our main result (Theorem 20.3.4.4) asserts that the datum of a geometric admissibility structure on an ∞-topos $\mathcal{X}$ is essentially equivalent to the datum of a fracture subcategory of $\mathcal{X}$ (more precisely, it is equivalent to the datum of a *complete* fracture subcategory of $\mathcal{X}$: see Definition 20.3.3.9).

Remark 20.3.0.1. The framework developed in this section is closely related to the notion of a *class of étale morphisms* studied by Joyal-Moerdijk ([109]) and Dubuc ([52]). More precisely, our notion of *local admissibility structure* (Definition 20.3.2.1) can be regarded as an ∞-categorical version of a class of étale morphisms; our notion of *geometric admissibility structure* is then obtained by adding an additional axiom (Definition 20.3.4.1).

20.3.1 Admissible Morphisms in a Fractured ∞-Topos

In §20.2, we introduced the notion of an admissibility structure on an ∞-category (Definition 20.2.1.1). So far, we have been primarily interested in admissibility structures on *small* ∞-categories $\mathcal{G}$, and their relationships with structures on larger ∞-categories built from $\mathcal{G}$ (such as factorization systems on $\mathrm{Pro}(\mathcal{G})$ and fracture subcategories of $\mathcal{P}(\mathcal{G})$). We now study a class of admissibility structures which live naturally on *large* ∞-categories (more specifically, on fractured ∞-topoi).

Definition 20.3.1.1. Let $\mathcal{X}$ be an ∞-topos and let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fracture subcategory. We will say that a morphism $f : U \to X$ in $\mathcal{X}$ is $\mathcal{X}^{\mathrm{corp}}$-*admissible* if, for every pullback

diagram

$$\begin{array}{ccc} U' & \longrightarrow & U \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ X' & \longrightarrow & X \end{array}$$

where X' is corporeal, the morphism f' also belongs to the subcategory $\mathcal{X}^{\mathrm{corp}}$ (so, in particular, the object U' is also corporeal).

Example 20.3.1.2. Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos, let $X \in \mathcal{X}^{\mathrm{corp}}$ be a corporeal object of $\mathcal{X}$, and let $f : U \to X$ be a morphism in $\mathcal{X}$. The following conditions are equivalent:

(a) The morphism f is $\mathcal{X}^{\mathrm{corp}}$-admissible.

(b) The morphism f belongs to $\mathcal{X}^{\mathrm{corp}}$.

The implication $(a) \Rightarrow (b)$ is trivial, and the converse follows from our assumption that the inclusion $\mathcal{X}^{\mathrm{corp}} \hookrightarrow \mathcal{X}$ preserves pullbacks.

Proposition 20.3.1.3. *Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos. Then the collection of $\mathcal{X}^{\mathrm{corp}}$-admissible morphisms determines an admissibility structure on the ∞-topos $\mathcal{X}$.*

Proof. We verify each requirement of Definition 20.2.1.1 in turn:

(1) Let $f : U \to X$ be an equivalence in $\mathcal{X}$; we wish to show that f is $\mathcal{X}^{\mathrm{corp}}$-admissible. Consider any pullback square

$$\begin{array}{ccc} U' & \longrightarrow & U \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ X' & \longrightarrow & X \end{array}$$

in the ∞-category $\mathcal{X}$. Then f' is an equivalence. If X' is corporeal, then f' belongs to $\mathcal{X}^{\mathrm{corp}}$ (by virtue of the fact that $\mathcal{X}^{\mathrm{corp}}$ is a replete subcategory of $\mathcal{X}$).

(2) Let $f : U \to X$ be a $\mathcal{X}^{\mathrm{corp}}$-admissible morphism in $\mathcal{X}$ and let $g : X' \to X$ be an arbitrary morphism in $\mathcal{X}$. The ∞-category $\mathcal{X}$ admits small limits, so we can form a pullback square

$$\begin{array}{ccc} U' & \longrightarrow & U \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ X' & \xrightarrow{g} & X. \end{array}$$

We wish to show that f' is also $\mathcal{X}^{\mathrm{corp}}$-admissible. To prove this, consider any pullback diagram

$$\begin{array}{ccc} U'' & \longrightarrow & U' \\ \downarrow{\scriptstyle f''} & & \downarrow{\scriptstyle f'} \\ X'' & \longrightarrow & X' \end{array}$$

where X'' is corporeal; we wish to show that f'' belongs to $\mathcal{X}^{\mathrm{corp}}$. This follows from our assumption that f is $\mathcal{X}^{\mathrm{corp}}$-admissible, since the outer rectangle in the diagram

$$\begin{array}{ccccc} U'' & \longrightarrow & U' & \longrightarrow & U \\ \downarrow{\scriptstyle f''} & & \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ X'' & \longrightarrow & X' & \longrightarrow & X \end{array}$$

is also a pullback square.

(3) Suppose we are given maps $X \xrightarrow{f} Y \xrightarrow{g} Z$ in $\mathcal{X}$, where g is $\mathcal{X}^{\mathrm{corp}}$-admissible. We wish to show that f is $\mathcal{X}^{\mathrm{corp}}$-admissible if and only if $g \circ f$ is $\mathcal{X}^{\mathrm{corp}}$-admissible. Assume first that f is $\mathcal{X}^{\mathrm{corp}}$-admissible. Consider any map $Z' \to Z$, where Z' is corporeal, and form a diagram

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \longrightarrow & Y \\ \downarrow{\scriptstyle g'} & & \downarrow{\scriptstyle g} \\ Z' & \longrightarrow & Z \end{array}$$

where both squares are pullbacks. Our assumption that g is $\mathcal{X}^{\mathrm{corp}}$-admissible guarantees that g' belongs to $\mathcal{X}^{\mathrm{corp}}$. In particular, Y' is corporeal. Applying our assumption that f is $\mathcal{X}^{\mathrm{corp}}$-admissible, we deduce that f' belongs to $\mathcal{X}^{\mathrm{corp}}$. It follows that $g' \circ f'$ belongs to $\mathcal{X}^{\mathrm{corp}}$, as desired.

Now suppose that $g \circ f$ is $\mathcal{X}^{\mathrm{corp}}$-admissible, and consider any map $Y' \to Y$, where Y' is corporeal. We then have a commutative diagram

$$\begin{array}{ccccc} X \times_Y Y' & \longrightarrow & Y' & & \\ \downarrow & & \downarrow{\scriptstyle t} & \searrow^{\mathrm{id}} & \\ X \times_Z Y' & \xrightarrow{s} & Y \times_Z Y' & & \\ & \searrow_{u} & & \searrow_{v} & \\ & & & & Y'. \end{array}$$

Our assumptions that g and $(g \circ f)$ are $\mathcal{X}^{\mathrm{corp}}$-admissible guarantee that the morphisms u and v belong to $\mathcal{X}^{\mathrm{corp}}$. Applying Proposition 20.1.3.1, we deduce that s and t also belong to $\mathcal{X}^{\mathrm{corp}}$. The upper left square is a pullback diagram in $\mathcal{X}$ and therefore also in $\mathcal{X}^{\mathrm{corp}}$ (since the inclusion $\mathcal{X}^{\mathrm{corp}} \hookrightarrow \mathcal{X}$ is conservative and preserves pullbacks), so that the projection map $X \times_Y Y' \to Y'$ also belongs to $\mathcal{X}^{\mathrm{corp}}$.

(4) Suppose that $f : U \to X$ is a retract of some morphism $g : V \to Y$ in the ∞-category $\mathrm{Fun}(\Delta^1, \mathcal{X})$, where g is $\mathcal{X}^{\mathrm{corp}}$-admissible. We wish to show that f is also $\mathcal{X}^{\mathrm{corp}}$-admissible. Choose any map $X' \to X$, where X' is corporeal. We then have a commutative diagram

$$\begin{array}{ccccc} U \times_X X' & \longrightarrow & V \times_Y X' & \longrightarrow & U \times_X X' \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle g'} & & \downarrow \\ X' & \xrightarrow{\mathrm{id}} & X' & \xrightarrow{\mathrm{id}} & X', \end{array}$$

where the horizontal composite maps are the identity. Our assumption that g is $\mathcal{X}^{\mathrm{corp}}$-admissible guarantees that g' belongs to $\mathcal{X}^{\mathrm{corp}}$; we wish to show that f' also belongs to $\mathcal{X}^{\mathrm{corp}}$. To prove this, it suffices to show that the full subcategory $\mathcal{X}^{\mathrm{corp}}_{/X'} \subseteq \mathcal{X}_{/X'}$ is closed under retracts. This is clear, since the ∞-category $\mathcal{X}^{\mathrm{corp}}_{/X'}$ is idempotent complete (in fact, it is an ∞-topos: see Proposition 20.1.3.3).

□

20.3.2 Local Admissibility Structures

We now axiomatize some of the special features enjoyed by the admissibility structures obtained from Proposition 20.3.1.3.

Definition 20.3.2.1. Let $\mathcal{X}$ be an ∞-topos. We will say that an admissibility structure $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$ is *local* if it satisfies the following conditions:

(a) If $f : U \to X$ is an arbitrary morphism in $\mathcal{X}$ and there exists an effective epimorphism $\amalg_\alpha X_\alpha \to X$ such that each of the induced maps $X_\alpha \times_X U \to X_\alpha$ is admissible, then f is admissible (in other words, the collection of admissible morphisms is *local* in the sense of Definition HTT.6.1.3.8).

(b) For each object $X \in \mathcal{X}$, the ∞-category $\mathcal{X}^{\mathrm{ad}}_{/X}$ is presentable and the inclusion $\mathcal{X}^{\mathrm{ad}}_{/X} \hookrightarrow \mathcal{X}_{/X}$ preserves small colimits.

Example 20.3.2.2. Let $\mathcal{X}$ be an ∞-topos. Then $\mathcal{X}$ has a local admissibility structure where we declare that *all* morphisms in $\mathcal{X}$ are admissible.

Example 20.3.2.3. Let $\mathcal{X}$ and $\mathcal{Y}$ be ∞-topoi, and suppose we are given geometric morphisms $f^*, g^* : \mathcal{X} \to \mathcal{Y}$ and a natural transformation $\alpha : f^* \to g^*$. Then α determines a local admissibility structure on $\mathcal{X}$, where we declare that a morphism $X \to X'$ in $\mathcal{X}$ is *admissible* if the diagram

$$\begin{array}{ccc} f^* X & \xrightarrow{\alpha(X)} & g^* X \\ \downarrow & & \downarrow \\ f^* X' & \xrightarrow{\alpha(X')} & g^* X' \end{array}$$

is a pullback square in $\mathcal{Y}$ (see Example 20.2.1.8).

Example 20.3.2.4. Let $\mathcal{X}$ be an ∞-topos, so that $\mathrm{Fun}(\Delta^1, \mathcal{X})$ is also an ∞-topos. The ∞-topos $\mathrm{Fun}(\Delta^1, \mathcal{X})$ admits a local admissibility structure, where we declare that a morphism $f \to f'$ in $\mathrm{Fun}(\Delta^1, \mathcal{X})$ is *admissible* if it corresponds to a pullback diagram

$$\begin{array}{ccc} U' & \longrightarrow & U \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ X' & \longrightarrow & X \end{array}$$

in the ∞-topos $\mathcal{X}$. This is a special case of Example 20.3.2.3; it can also be deduced by applying Proposition 20.3.1.3 to the fracture subcategory $\mathrm{Fun}(\Delta^1, \mathcal{X})^{\mathrm{corp}} \subseteq \mathrm{Fun}(\Delta^1, \mathcal{X})$ of Example 20.1.2.3.

Remark 20.3.2.5. Let $\mathcal{X}$ be an ∞-topos, let I be a (small) set, and suppose that for each $\alpha \in I$ we are given a local admissibility structure $\mathcal{X}^{\mathrm{ad}}_{\alpha} \subseteq \mathcal{X}$. Then the intersection $\bigcap_{\alpha \in I} \mathcal{X}^{\mathrm{ad}}_{\alpha}$ is also a local admissibility structure on $\mathcal{X}$.

Remark 20.3.2.6. Let $\mathcal{X}$ be an ∞-topos equipped with a local admissibility structure $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$. For every object $X \in \mathcal{X}$, the ∞-category $\mathcal{X}_{/X}$ is an ∞-topos. Since $\mathcal{X}^{\mathrm{ad}}_{/X}$ is a presentable full subcategory of $\mathcal{X}_{/X}$ which is closed under small colimits (by definition) and finite limits (Remark 20.2.1.12), it follows that $\mathcal{X}^{\mathrm{ad}}_{/X}$ is also an ∞-topos. Moreover, the inclusion functor $\iota^* : \mathcal{X}^{\mathrm{ad}}_{/X} \hookrightarrow \mathcal{X}_{/X}$ is a geometric morphism of ∞-topoi (that is, it preserves small colimits and finite limits).

We will prove in a moment that if $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ is a fractured ∞-topos, then the admissibility structure of Proposition 20.3.1.3 is local (Corollary 20.3.2.8). To prove this, we need the following reformulation of Definition 20.3.1.1:

Proposition 20.3.2.7. *Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos, let $j^* : \mathcal{X} \to \mathcal{X}^{\mathrm{corp}}$ be a right adjoint to the inclusion, and let $f : U \to X$ be a morphism. The following conditions are equivalent:*

(1) *The morphism f is $\mathcal{X}^{\mathrm{corp}}$-admissible.*

(2) *The diagram σ :*

$$\begin{array}{ccc} j^*U & \longrightarrow & U \\ \downarrow{\scriptstyle j^*f} & & \downarrow{\scriptstyle f} \\ j^*X & \longrightarrow & X \end{array}$$

is a pullback square in $\mathcal{X}$.

Proof. Suppose first that (2) is satisfied, and consider any morphism $g : X' \to X$. If X' is corporeal, then g factors as a composition $X' \to g' j^* X \to X$, where g' belongs to $\mathcal{X}^{\mathrm{corp}}$. Extend σ to a commutative diagram

$$\begin{array}{ccccc} U' & \longrightarrow & j^*U & \longrightarrow & U \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle j^*f} & & \downarrow{\scriptstyle f} \\ X' & \xrightarrow{g'} & j^*X & \longrightarrow & X \end{array}$$

where the left square is a pullback. If condition (2) is satisfied, then the outer rectangle is also a pullback square. Consequently, to verify condition (1), it will suffice to show that the morphism f' belongs to $\mathcal{X}^{\mathrm{corp}}$. This is clear, since g' and j^*f belong to $\mathcal{X}^{\mathrm{corp}}$ (since the inclusion $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ preserves pullback squares).

We now show that (1) implies (2). Suppose that f is $\mathcal{X}^{\mathrm{corp}}$-admissible. Let us say that an object $X' \in \mathcal{X}_{/X}$ is *good* if the projection map $U \times_X X' \to X'$ satisfies condition (2): that is, if the left square in the diagram

$$\begin{array}{ccccc} j^*(U \times_X X') & \longrightarrow & U \times_X X' & \longrightarrow & U \\ \downarrow & & \downarrow & & \downarrow{\scriptstyle f} \\ j^*X' & \longrightarrow & X' & \longrightarrow & X \end{array}$$

is a pullback square. Since the right square is a pullback, this is equivalent to the requirement that the outer square is a pullback. Because colimits in $\mathcal{X}$ are universal and the functor j^* preserves colimits, the collection of good objects $X' \in \mathcal{X}_{/X}$ is closed under small colimits.

To complete the proof, it will suffice to show that the object $X \in \mathcal{X}_{/X}$ is good. In fact, we claim that every object $X' \in \mathcal{X}_{/X}$ is good. Since $\mathcal{X}$ is generated under small colimits by corporeal objects (Corollary 20.1.3.4), we may assume without loss of generality that X' is corporeal (when regarded as an object of X). In this case, assumption (1) guarantees that the projection map $U \times_X X' \to X'$ belongs to $\mathcal{X}^{\mathrm{corp}}$. The desired result then follows from condition (3) of Definition 20.1.2.1. □

Corollary 20.3.2.8. *Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos, and let $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$ be the subcategory of $\mathcal{X}$ spanned by the $\mathcal{X}^{\mathrm{corp}}$-admissible morphisms. Then $\mathcal{X}^{\mathrm{ad}}$ is a local admissibility structure on $\mathcal{X}$.*

Proof. We first verify condition (a) of Definition 20.3.2.1. Suppose we are given a pullback diagram

$$\begin{array}{ccc} \amalg U_\alpha & \longrightarrow & U \\ \downarrow{\scriptstyle \amalg f_\alpha} & & \downarrow{\scriptstyle f} \\ \amalg X_\alpha & \xrightarrow{g} & X \end{array}$$

in the ∞-category $\mathcal{X}$, where g is an effective epimorphism and each f_α is $\mathcal{X}^{\mathrm{corp}}$-admissible; we wish to show that f is also $\mathcal{X}^{\mathrm{corp}}$-admissible. Let $j^* : \mathcal{X} \to \mathcal{X}^{\mathrm{corp}}$ denote a right adjoint to the inclusion. Consider the diagram

$$\begin{array}{ccccc} \amalg j^* U_\alpha & \longrightarrow & j^* U & \longrightarrow & U \\ \downarrow & & \downarrow & & \downarrow \\ \amalg j^* X_\alpha & \xrightarrow{j^* g} & j^* X & \longrightarrow & X. \end{array}$$

We wish to show that the square on the right is a pullback (Proposition 20.3.2.7). Since the functor j^* preserves small limits and colimits, the square on the left is a pullback diagram, and the map $j^*(g)$ is an effective epimorphism. It will therefore suffice to show that the outer rectangle is a pullback diagram. To see this, consider the the diagram

$$\begin{array}{ccccc} \amalg j^* U_\alpha & \longrightarrow & \amalg U_\alpha & \longrightarrow & U \\ \downarrow & & \downarrow & & \downarrow \\ \amalg j^* X_\alpha & \longrightarrow & \amalg X_\alpha & \xrightarrow{g} & X. \end{array}$$

The right square is a pullback by definition, and the left square is a pullback by virtue of our assumption that each f_α is $\mathcal{X}^{\mathrm{corp}}$-admissible (Proposition 20.3.2.7). It follows that the outer rectangle is also a pullback diagram, as desired.

We now prove (b). Let $\widehat{\mathcal{C}\mathrm{at}}_\infty$ denote the ∞-category of (not necessarily small) ∞-categories and let $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ denote the subcategory of $\widehat{\mathcal{C}\mathrm{at}}_\infty$ whose objects are presentable ∞-categories and whose morphisms are functors which preserve small colimits. The construction $X \mapsto \mathcal{X}_{/X}$ determines a functor $F : \mathcal{X}^{\mathrm{op}} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ (classifying the Cartesian fibration $\mathrm{Fun}(\Delta^1, \mathcal{X}) \to \mathrm{Fun}(\{1\}, \mathcal{X})$, and the construction $X \mapsto \mathcal{X}^{\mathrm{ad}}_{/X}$ determines a functor $F_0 : \mathcal{X}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ equipped with a natural transformation $\iota : F_0 \to F$. Since $\mathcal{X}$ is an ∞-topos, the functor F preserves small limits. Using (a), we see that F_0 also preserves small limits (see Lemma HTT.6.1.3.7). Let us say that an object $X \in \mathcal{X}$ is *good* if $\mathcal{X}^{\mathrm{ad}}_{/X}$ is presentable and the inclusion $\mathcal{X}^{\mathrm{ad}}_{/X} \hookrightarrow \mathcal{X}$ preserves small colimits: that is, if the canonical map $\iota(X) : F_0(X) \to F(X)$ is a morphism in $\mathcal{P}\mathrm{r}^{\mathrm{L}}$. Since the inclusion functor $\mathcal{P}\mathrm{r}^{\mathrm{L}} \hookrightarrow \widehat{\mathcal{C}\mathrm{at}}_\infty$ preserves small limits (Proposition HTT.5.5.3.13), the collection of good objects of $\mathcal{X}$ is closed under small colimits. To prove (b), we must show that every object $X \in \mathcal{X}$ is good. Using Corollary 20.1.3.4, we can reduce to the case where X is corporeal. Using Example 20.3.1.2, we are reduced to showing that the ∞-category $\mathcal{X}^{\mathrm{corp}}_{/X}$ is presentable and that the inclusion $\mathcal{X}^{\mathrm{corp}}_{/X} \to \mathcal{X}_{/X}$ preserves small colimits. The first assertion follows from Proposition 20.1.3.3, and the second from the fact that the inclusion $\mathcal{X}^{\mathrm{corp}} \hookrightarrow \mathcal{X}$ preserves small colimits (since it admits a right adjoint j^*). □

20.3.3 Corporeal Objects

Let $\mathcal{X}$ be an ∞-topos. According to Corollary 20.3.2.8, every fracture subcategory $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ determines a local admissibility structure $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$. We now consider the problem of recovering $\mathcal{X}^{\mathrm{corp}}$ from $\mathcal{X}^{\mathrm{ad}}$.

Definition 20.3.3.1. Let $\mathcal{X}$ be an ∞-topos and let $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$ be a local admissibility structure on $\mathcal{X}$ (Definition 20.3.2.1). For each object $X \in \mathcal{X}$, the inclusion functor $\mathcal{X}^{\mathrm{ad}}_{/X} \hookrightarrow \mathcal{X}_{/X}$ is a functor between presentable ∞-categories which preserves small colimits, and therefore admits a right adjoint $\rho_X : \mathcal{X}_{/X} \to \mathcal{X}^{\mathrm{ad}}_{/X}$. We will say that the object X is $\mathcal{X}^{\mathrm{ad}}$-*corporeal* if the functor ρ_X preserves small colimits.

Example 20.3.3.2. Let $\mathcal{X}$ be an ∞-topos equipped with a fracture subcategory $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$, let $j^* : \mathcal{X} \to \mathcal{X}^{\mathrm{corp}}$ be a right adjoint to the inclusion functor, and let $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$ be the subcategory of $\mathcal{X}^{\mathrm{corp}}$-admissible morphisms. If $X \in \mathcal{X}^{\mathrm{corp}}$ is a corporeal object of $\mathcal{X}$, then we have $\mathcal{X}^{\mathrm{ad}}_{/X} = \mathcal{X}^{\mathrm{corp}}_{/X}$ (Example 20.3.1.2). It follows that the functor $\rho_X : \mathcal{X}_{/X} \to \mathcal{X}^{\mathrm{ad}}_{/X}$ of Definition 20.3.3.1 is given by the formula $\rho_X(U) = j^*(U) \times_{j^*(X)} X$. Since the functor j^* preserves small colimits, we deduce that X is $\mathcal{X}^{\mathrm{ad}}$-corporeal.

Warning 20.3.3.3. In the situation of Example 20.3.3.2, it is generally not true that every $\mathcal{X}^{\mathrm{ad}}$-corporeal object of $\mathcal{X}$ is corporeal. However, this is not far from being true: see Proposition 20.3.3.11 below.

Example 20.3.3.4. Let $\mathcal{X}$ be an ∞-topos equipped with the local admissibility structure $\mathcal{X}^{\mathrm{ad}} = \mathcal{X}$ of Example 20.3.2.2 (so that every morphism in $\mathcal{X}$ is admissible). Then every object of $\mathcal{X}$ is $\mathcal{X}^{\mathrm{ad}}$-corporeal.

Example 20.3.3.5. Let $\mathcal{X}$ be an ∞-topos, and let us regard the ∞-topos $\mathrm{Fun}(\Delta^1, \mathcal{X})$ as equipped with the local admissibility structure of Example 20.3.2.4. For every pair of objects X and Y, the inclusion $X \hookrightarrow X \amalg Y$ is a $\mathrm{Fun}(\Delta^1, \mathcal{X})^{\mathrm{ad}}$-corporeal object of $\mathrm{Fun}(\Delta^1, \mathcal{X})$.

Remark 20.3.3.6. Let $\mathcal{X}$ be an ∞-topos equipped with a local admissibility structure $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$, and suppose we are given a small collection of objects $X_\alpha \in \mathcal{X}$ having coproduct $X \in \mathcal{X}$. Then the equivalence of ∞-categories $\mathcal{X}_{/X} \simeq \prod_\alpha \mathcal{X}_{/X_\alpha}$ restricts to an equivalence $\mathcal{X}^{\mathrm{ad}}_{/X} \simeq \prod_\alpha \mathcal{X}^{\mathrm{ad}}_{/X_\alpha}$. It follows that X is $\mathcal{X}^{\mathrm{ad}}$-corporeal if and only if each X_α is $\mathcal{X}^{\mathrm{ad}}$-corporeal.

Remark 20.3.3.7. Let $\mathcal{X}$ be an ∞-topos equipped with a local admissibility structure, let $X \in \mathcal{X}$ be an object, and let $\rho_X : \mathcal{X}_{/X} \to \mathcal{X}^{\mathrm{ad}}_{/X}$ be a right adjoint to the inclusion. For every admissible morphism $U \to V$ in $\mathcal{X}_{/X}$, the associated diagram σ :

$$\begin{array}{ccc} \rho_X U & \longrightarrow & \rho_X V \\ \downarrow & & \downarrow \\ U & \longrightarrow & V \end{array}$$

is a pullback square in $\mathcal{X}$. To prove this, let $W = \rho_X V \times_V U$, and let $\mathcal{D}$ denote the full subcategory of $\mathcal{X}_{/W}$ spanned by those maps $W' \to W$ for which the composite map $W' \to W \to X$ is admissible. Since the map $U \to V$ is admissible, the projection map $W \to \rho_X V \in \mathcal{X}^{\mathrm{ad}}_{/X}$ is admissible, so that we can regard W as a final object of $\mathcal{D}$. The diagram σ determines a map $\rho_X U \to W$. To show that σ is a pullback square, it will suffice to show that this map exhibits $\rho_X U$ as a final object object of $\mathcal{D}$. Fix an object $D \in \mathcal{D}$; we wish to show that the diagram

$$\begin{array}{ccc} \mathrm{Map}_{\mathcal{X}}(D, \rho_X U) & \longrightarrow & \mathrm{Map}_{\mathcal{X}}(D, U) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathcal{X}}(D, \rho_X V) & \longrightarrow & \mathrm{Map}_{\mathcal{X}}(D, V) \end{array}$$

is a pullback square. This is clear, since the horizontal maps are homotopy equivalences.

Proposition 20.3.3.8. *Let $\mathcal{X}$ be an ∞-topos equipped with a local admissibility structure $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$. Then:*

(1) *The collection of $\mathcal{X}^{\mathrm{ad}}$-corporeal objects of $\mathcal{X}$ is closed under retracts.*

(2) *Let $f : U \to X$ be an admissible morphism of $\mathcal{X}$. If X is $\mathcal{X}^{\mathrm{ad}}$-corporeal, then U is $\mathcal{X}^{\mathrm{ad}}$-corporeal. The converse holds if f is an effective epimorphism.*

Proof. For each object $X \in \mathcal{X}$, let $\rho_X : \mathcal{X}_{/X} \to \mathcal{X}^{\mathrm{ad}}_{/X}$ denote a right adjoint to the inclusion map. Let $f : Y \to X$ be a morphism in $\mathcal{X}$, and let $f^* : \mathcal{X}_{/X} \to \mathcal{X}_{/Y}$ be the functor given $f^* U = U \times_X Y$. For each $U \in \mathcal{X}_{/X}$, we have an evident map $\rho_X(U) \to U$, which induces a map $u : f^* \rho_X(U) \to f^* U$. Since $f^* \rho_X(U)$ belongs to $\mathcal{X}^{\mathrm{ad}}_{/Y}$, this map factors through $\rho_Y f^* U$. Moreover, this factorization depends functorially on U, and determines a natural transformation of functors $f^* \circ \rho_X \to \rho_Y \circ f^*$.

We now prove (1). Suppose that we are given a commutative diagram

$$\begin{array}{ccccc} & & Y & & \\ & \overset{f}{\nearrow} & & \overset{g}{\searrow} & \\ X & & \xrightarrow{\mathrm{id}} & & X \end{array}$$

in $\mathcal{X}$, where Y is $\mathcal{X}^{\mathrm{ad}}$-corporeal. We wish to prove that X is $\mathcal{X}^{\mathrm{ad}}$-corporeal. Then the identity transformation from ρ_X to itself factors as a composition

$$\rho_X \simeq f^* g^* \rho_X \to f^* \rho_Y g^* \to \rho_X f^* g^* \simeq \rho_X,$$

so that ρ_X is a retract of the composite functor $f^* \rho_Y g^*$. Since Y is $\mathcal{X}^{\mathrm{ad}}$-corporeal, the functor ρ_Y preserves small colimits, so that $f^* \rho_Y g^*$ also preserves small colimits. It follows that ρ_X preserves small colimits, so that X is also $\mathcal{X}^{\mathrm{ad}}$-corporeal.

We now prove (2). Let $f : U \to X$ be an admissible morphism in $\mathcal{X}$. Then a map $V \to U$ is admissible if and only if the composite map $V \to U \to X$ is admissible. In particular, for any map $V \to U$, we have an equivalence $\rho_U(V) \simeq \rho_X(V)$ in the ∞-category $\mathcal{X}$. In other words, we have a homotopy commutative diagram

$$\begin{array}{ccc} \mathcal{X}_{/U} & \xrightarrow{\rho_U} & \mathcal{X}^{\mathrm{ad}}_{/U} \\ \downarrow & & \downarrow \\ \mathcal{X}_{/X} & \xrightarrow{\rho_X} & \mathcal{X}^{\mathrm{ad}}_{/X}, \end{array}$$

where the vertical maps are given by composition with f. If X is $\mathcal{X}^{\mathrm{ad}}$-corporeal, it follows that the composite functor $\mathcal{X}_{/U} \xrightarrow{\rho_U} \mathcal{X}^{\mathrm{ad}}_{/U} \to \mathcal{X}^{\mathrm{ad}}_{/X}$ commutes with small colimits. Since composition with f determines a conservative functor $\mathcal{X}^{\mathrm{ad}}_{/U} \to \mathcal{X}^{\mathrm{ad}}_{/X}$ which preserves small colimits, we conclude that U is also $\mathcal{X}^{\mathrm{ad}}$-corporeal.

Conversely, suppose that U is $\mathcal{X}^{\mathrm{ad}}$-corporeal. For each object $V \in \mathcal{X}_{/X}$, we have an equivalence

$$\rho_X(V) \times_X U = \rho_X(V) \times_X \rho_X(U) \simeq \rho_X(V \times_X U) \simeq \rho_U(V \times_X U),$$

so that the functor $V \mapsto \rho_X(V) \times_X U$ preserves small colimits. If f is an effective epimorphism, then the functor $V \mapsto \rho_X(V)$ also preserves small colimits, so that X is $\mathcal{X}^{\mathrm{ad}}$-corporeal. □

We now establish a weak converse to Example 20.3.3.2. First, we need a definition.

Definition 20.3.3.9. Let $\mathcal{X}$ be an ∞-topos. We will say that a fracture subcategory $\mathcal{X}^{\mathrm{corp}}$ is *complete* if, for every object $X \in \mathcal{X}$ which belongs to $\mathcal{X}^{\mathrm{corp}}$, any retract of X also belongs to $\mathcal{X}^{\mathrm{corp}}$. We will say that a fractured ∞-topos $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ is *complete* if the fracture subcategory $\mathcal{X}^{\mathrm{corp}}$ is complete.

Warning 20.3.3.10. Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos. Then the fracture subcategory $\mathcal{X}^{\mathrm{corp}}$ is itself an ∞-topos (Proposition 20.1.3.3), and is therefore idempotent complete. However, this does not imply that $\mathcal{X}^{\mathrm{corp}}$ is complete in the sense of Definition 20.3.3.9. The inclusion $\mathcal{X}^{\mathrm{corp}} \hookrightarrow \mathcal{X}$ is not fully faithful, so it is possible for there to exist a corporeal object $X \in \mathcal{X}$ equipped with a (coherently) idempotent map $e : X \to X$ which is not contained in $\mathcal{X}^{\mathrm{corp}}$.

Proposition 20.3.3.11. *Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos and let $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$ be the subcategory spanned by the $\mathcal{X}^{\mathrm{corp}}$-admissible morphisms. The following conditions are equivalent:*

(1) *The fracture subcategory $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ is complete (in the sense of Definition 20.3.3.9).*

(2) *An object $X \in \mathcal{X}$ is contained in $\mathcal{X}^{\mathrm{corp}}$ if and only if it is $\mathcal{X}^{\mathrm{ad}}$-corporeal.*

We will deduce Proposition 20.3.3.11 from the following more refined result:

Proposition 20.3.3.12. *Let $\mathcal{X}$ be an ∞-topos equipped with a local admissibility structure $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$ and let $\mathcal{X}_0 \subseteq \mathcal{X}$ be a full subcategory with the following property:*

(i) *Every object of $\mathcal{X}_0$ is $\mathcal{X}^{\mathrm{ad}}$-corporeal.*

(ii) *For every object $X \in \mathcal{X}$, there exists an effective epimorphism $\amalg X_\alpha \to X$, where each U_α belongs to $\mathcal{X}_0$.*

Let X be an arbitrary object of $\mathcal{X}$. Then the following conditions are equivalent:

(a) *The object X is $\mathcal{X}^{\mathrm{ad}}$-corporeal.*

(b) *There exists an admissible effective epimorphism $\amalg U_\alpha \to X$, where each U_α is a retract (in the ∞-category $\mathcal{X}$) of an object V_α which admits an admissible morphism $V_\alpha \to X_\alpha$ for some $X_\alpha \in \mathcal{X}_0$.*

Proof. The implication $(b) \Rightarrow (a)$ follows from Remark 20.3.3.6 and Proposition 20.3.3.8. Conversely, suppose that (a) is satisfied. Using assumption (ii), we can choose an effective epimorphism $u : \amalg X_\alpha \to X$, where each X_α belongs to $\mathcal{X}_0$. Let $X_\bullet$ denote the Čech nerve of u, so that X can be identified with the geometric realization $|X_\bullet|$. Let $\rho_X : \mathcal{X}_{/X} \to \mathcal{X}^{\mathrm{ad}}_{/X}$ be a right adjoint to the inclusion, and for each index α set $U_\alpha = \rho_X(X_\alpha)$. Since X is $\mathcal{X}^{\mathrm{ad}}$-corporeal, the functor ρ_X preserves small colimits. We therefore have an equivalence $X \simeq \rho_X(X) \simeq \rho_X(|X_\bullet|) \simeq |\rho_X(X_\bullet)|$. In particular, the canonical map $\amalg U_\alpha \simeq \rho_X(X_0) \simeq\to X$ is an effective epimorphism. Moreover, each U_α is a retract of the fiber product $V_\alpha = U_\alpha \times_X X_\alpha$. We conclude by observing that each of the projection maps $V_\alpha \to X_\alpha$ is admissible (since it is a pullback of the map $U_\alpha \to X$). □

Proof of Proposition 20.3.3.11. The implication $(2) \Rightarrow (1)$ follows from Proposition 20.3.3.8. Conversely, suppose that the fracture subcategory $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ is complete. Every object $X \in \mathcal{X}^{\mathrm{corp}}$ is $\mathcal{X}^{\mathrm{ad}}$-corporeal by virtue of Example 20.3.3.2. To prove the converse, suppose that $X \in \mathcal{X}$ is $\mathcal{X}^{\mathrm{ad}}$-corporeal. Applying Proposition 20.3.3.12, we deduce that there exists a $\mathcal{X}^{\mathrm{corp}}$-admissible effective epimorphism $f : \amalg U_\alpha \to X$, where each U_α is a retract of some object V_α which admits a $\mathcal{X}^{\mathrm{corp}}$-admissible morphism $g_\alpha : V_\alpha \to X_\alpha$, where X_α is corporeal. The $\mathcal{X}^{\mathrm{corp}}$-admissibility of g_α then guarantees that each V_α is corporeal (Example 20.3.1.2). Invoking our assumption that $\mathcal{X}^{\mathrm{corp}}$ is complete, we conclude that each U_α is corporeal. Let $X_\bullet$ denote the Čech nerve of f. Since the inclusion $\mathcal{X}^{\mathrm{corp}} \hookrightarrow \mathcal{X}$ preserves small colimits, the object $X_0 = \amalg U_\alpha$ is corporeal. Because f is $\mathcal{X}^{\mathrm{corp}}$-admissible, each X_k admits a $\mathcal{X}^{\mathrm{corp}}$-admissible morphism $X_k \to X_0$, and is therefore corporeal (Example 20.3.1.2). It follows that $X_\bullet$ can be regarded as a simplicial object of the subcategory $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$. Since the inclusion $\mathcal{X}^{\mathrm{corp}} \hookrightarrow \mathcal{X}$ preserves small colimits, we conclude that $X \simeq |X_\bullet|$ also belongs to $\mathcal{X}^{\mathrm{corp}}$. □

20.3.4 Geometric Admissibility Structures

Our next goal is to prove a converse of Corollary 20.3.2.8. For this, we need to introduce an additional assumption.

Definition 20.3.4.1. Let $\mathcal{X}$ be an ∞-topos. A *geometric admissibility structure* on $\mathcal{X}$ is a local admissibility structure $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$ which satisfies the following additional condition: the ∞-category $\mathcal{X}$ is generated under small colimits by $\mathcal{X}^{\mathrm{ad}}$-corporeal objects.

Example 20.3.4.2. Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos and let $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$ be the subcategory of $\mathcal{X}^{\mathrm{corp}}$-admissible morphisms. Then every object $X \in \mathcal{X}^{\mathrm{corp}}$ is $\mathcal{X}^{\mathrm{ad}}$-corporeal (Example 20.3.3.2). Since $\mathcal{X}$ is generated under small colimits by corporeal objects (Corollary 20.1.3.4), it follows from Corollary 20.3.2.8 that $\mathcal{X}^{\mathrm{ad}}$ is a geometric admissibility structure on $\mathcal{X}$.

Example 20.3.4.3. Let $\mathcal{X}$ be an ∞-topos, and let us regard the ∞-topos $\mathrm{Fun}(\Delta^1, \mathcal{X})$ as equipped with the admissibility structure of Example 20.3.2.4 (so that admissible morphisms in $\mathrm{Fun}(\Delta^1, \mathcal{X})$ are pullback diagrams in $\mathcal{X}$). According to Example 20.3.3.5, the inclusion $X \hookrightarrow X \amalg Y$ is $\mathrm{Fun}(\Delta^1, \mathcal{X})^{\mathrm{ad}}$-corporeal for every pair of objects $X, Y \in \mathcal{X}$. It is not difficult to see that such objects generate $\mathrm{Fun}(\Delta^1, \mathcal{X})$ under small colimits (in fact, under pushouts), so that $\mathrm{Fun}(\Delta^1, \mathcal{X})^{\mathrm{ad}}$ is a geometric admissibility structure.

We can now formulate our main result:

Theorem 20.3.4.4. *Let $\mathcal{X}$ be an ∞-topos equipped with a geometric admissibility structure $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$. Let $\mathcal{X}^{\mathrm{corp}}$ denote the full subcategory of $\mathcal{X}^{\mathrm{ad}}$ spanned by the $\mathcal{X}^{\mathrm{ad}}$-corporeal objects. Then $\mathcal{X}^{\mathrm{corp}}$ is a complete fracture subcategory of $\mathcal{X}$.*

Remark 20.3.4.5. Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$ be as in Theorem 20.3.4.4 and let $f : U \to X$ be a morphism in $\mathcal{X}$. Then f is admissible if and only if it is $\mathcal{X}^{\mathrm{corp}}$-admissible. The "only if" direction is obvious (since the collection of admissible morphisms in $\mathcal{X}$ is closed under fiber products). Conversely, suppose that f is $\mathcal{X}^{\mathrm{corp}}$-admissible, and choose an effective epimorphism $\amalg X_\alpha \to X$, where each X_α is $\mathcal{X}^{\mathrm{ad}}$-corporeal. Then each projection map $U \times_X X_\alpha \to X_\alpha$ is admissible, so that f is admissible by virtue of our assumption that the admissibility structure $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$ is local.

Remark 20.3.4.6. Let $\mathcal{X}$ be an ∞-topos. Combining Corollary 20.3.2.8, Theorem 20.3.4.4, Remark 20.3.4.5, and Corollary **??**, we obtain a bijective correspondence

$$\begin{array}{c}\{\text{ Geometric admissibility structures } \mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X} \text{ }\} \\ \downarrow \sim \\ \{\text{ Complete fracture subcategories } \mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}. \text{ }\}\end{array}$$

Remark 20.3.4.7. Let $\mathcal{X}$ be an ∞-topos, let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fracture subcategory which is not complete, let $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$ be the subcategory of $\mathcal{X}^{\mathrm{corp}}$-admissible morphisms, and let $\mathcal{X}'^{\mathrm{corp}} \subseteq \mathcal{X}^{\mathrm{ad}}$ be the full subcategory of $\mathcal{X}^{\mathrm{ad}}$ spanned by the $\mathcal{X}^{\mathrm{ad}}$-corporeal objects. Then $\mathcal{X}'^{\mathrm{corp}}$ is a fracture subcategory of $\mathcal{X}$ which contains $\mathcal{X}^{\mathrm{corp}}$ as a full subcategory (Example 20.3.3.2). By virtue of Remark 20.3.4.6, it is characterized by the following two properties:

- The fracture subcategory $\mathcal{X}'^{\mathrm{corp}} \subseteq \mathcal{X}$ is complete.
- A morphism $f : U \to X$ in $\mathcal{X}$ is $\mathcal{X}^{\mathrm{corp}}$-admissible if and only if it is $\mathcal{X}'^{\mathrm{corp}}$-admissible.

We will refer to $\mathcal{X}'^{\mathrm{corp}}$ as the *completion* of the fracture subcategory $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$. Note that Proposition 20.3.3.12 supplies necessary and sufficient conditions for an object $X \in \mathcal{X}$ to belong to $\mathcal{X}'^{\mathrm{corp}}$.

The proof of Theorem 20.3.4.4 will require some preliminaries.

Lemma 20.3.4.8. *Let $\mathcal{X}$ be an ∞-topos equipped with a geometric admissibility structure $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$. Then:*

(1) *The ∞-category $\mathcal{X}^{\mathrm{ad}}$ admits small colimits.*

(2) *The inclusion functor $\mathcal{X}^{\mathrm{ad}} \hookrightarrow \mathcal{X}$ preserves small colimits.*

(3) *Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}^{\mathrm{ad}}$ denote the full subcategory spanned by the $\mathcal{X}^{\mathrm{ad}}$-corporeal objects. Then $\mathcal{X}^{\mathrm{corp}}$ is closed under small colimits in $\mathcal{X}^{\mathrm{ad}}$.*

Proof. Let $\{X_\alpha\}$ be a small diagram in the ∞-category $\mathcal{X}^{\mathrm{ad}}$, and let X denote the colimit $\varinjlim X_\alpha$, formed in the ∞-category $\mathcal{X}$. Our first goal is to show that each of the canonical maps $u_\alpha : X_\alpha \to X$ is admissible. Using our assumption that the admissibility structure $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$ is geometric, we can choose an effective epimorphism $X' \to X$, where X' is $\mathcal{X}^{\mathrm{ad}}$-corporeal. To show that u_α is admissible, it will suffice to show that the projection map $X_\alpha \times_X X' \to X'$ is admissible. We may therefore replace X by X' (and $\{X_\alpha\}$ by the diagram $\{X_\alpha \times_X X'\}$) and thereby reduce to the case where X is $\mathcal{X}^{\mathrm{ad}}$-corporeal.

Let $\rho_X : \mathcal{X}_{/X} \to \mathcal{X}^{\mathrm{ad}}_{/X}$ be a right adjoint to the inclusion, so that we have a morphism of diagrams $\{X_\alpha\} \to \{\rho_X X_\alpha\}$ in the ∞-category $\mathcal{X}_{/X}$. Using Remark 20.3.3.7, we see that this morphism is Cartesian: that is, each of the transition maps $X_\alpha \to X_\beta$ determines a pullback square

$$\begin{array}{ccc} \rho_X X_\alpha & \longrightarrow & \rho_X X_\beta \\ \downarrow & & \downarrow \\ X_\alpha & \longrightarrow & X_\beta \end{array}$$

is a pullback square in $\mathcal{X}_{/X}$. It follows from Theorem HTT.6.1.3.9 that for each index α, the diagram

$$\begin{array}{ccc} \rho_X X_\alpha & \longrightarrow & \varinjlim_\beta \rho_X X_\beta \\ \downarrow & & \downarrow \phi \\ X_\alpha & \longrightarrow & \varinjlim_\beta X_\beta \end{array}$$

is also a pullback square. Since X is corporeal, the functor ρ_X preserves small colimits, so we can identify ϕ with the counit map $\rho_X(X) \to X$. This map is an equivalence (since the identity map $\mathrm{id}_X : X \to X$ is admissible). It follows that the map $\rho_X X_\alpha \to X_\alpha$ is also an equivalence: that is, the map $X_\alpha \to X$ is admissible.

To complete the proofs of (1) and (2), it will suffice to show that X is a colimit of the diagram $\{X_\alpha\}$ in the ∞-category $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$: that is, that a morphism $f : X \to Y$ is admissible if and only if each of the composite maps $X_\alpha \xrightarrow{u_\alpha} X \xrightarrow{f} Y$ is admissible. The "only if" direction follows from the admissibility of u_α (since the collection of admissible morphisms is closed under composition), and the converse follows from the fact that the full subcategory $\mathcal{X}^{\mathrm{ad}}_{/Y} \subseteq \mathcal{X}_{/Y}$ is closed under small colimits (see Definition 20.3.2.1).

We now prove (3). Let $\{X_\alpha\}$ and X be as above, and suppose that each X_α is $\mathcal{X}^{\mathrm{ad}}$-corporeal. The admissibility of each u_α guarantees that the induced map $u : \amalg X_\alpha \to X$ is admissible. Note that $\amalg X_\alpha$ is $\mathcal{X}^{\mathrm{ad}}$-corporeal (Remark 20.3.3.6). Since u is an effective epimorphism, Proposition 20.3.3.8 implies that X is also $\mathcal{X}^{\mathrm{ad}}$-corporeal. □

Lemma 20.3.4.9. *Let $\mathcal{X}$ be an ∞-topos equipped with a geometric admissibility structure $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$ and let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}^{\mathrm{ad}}$ be the full subcategory spanned by the $\mathcal{X}^{\mathrm{ad}}$-corporeal objects. Then $\mathcal{X}^{\mathrm{corp}}$ is a presentable ∞-category.*

Proof. It follows from Lemma 20.3.4.8 that the ∞-category $\mathcal{X}^{\mathrm{corp}}$ admits small colimits. Since the admissibility structure $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$ is geometric, the ∞-category $\mathcal{X}$ is generated under small colimits by the essential image of the inclusion $\mathcal{X}^{\mathrm{corp}} \hookrightarrow \mathcal{X}$. Using the presentability of $\mathcal{X}$, we can choose a small collection of $\mathcal{X}^{\mathrm{ad}}$-corporeal objects $\{X_i\}_{i \in I}$ which generate $\mathcal{X}$ under small colimits. For each $i \in I$, let $\mathcal{C}_i$ denote the fiber product

$$\mathcal{X} \times_{\mathrm{Fun}(\Delta^{\{0,2\}}, \mathcal{X})} \mathrm{Fun}(\Delta^2, \mathcal{X}) \times_{\mathrm{Fun}(\{1\}, \mathcal{X})} \mathcal{X}^{\mathrm{ad}}_{/X_i}$$

whose objects are commutative diagrams

$$\begin{array}{ccc} & U & \\ \nearrow & & \searrow \\ V & \xrightarrow{\mathrm{id}_V} & V \end{array}$$

in the ∞-category $\mathcal{X}$, where U is equipped with an admissible morphism $U \to X_i$. Let $F_i : \mathcal{C}_i \to \mathcal{X}$ denote the projection map onto the first factor. Because the collection of admissible morphisms in $\mathcal{X}$ is closed under retracts, the functor F_i factors through the subcategory $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$. Similarly, the collection of $\mathcal{X}^{\mathrm{ad}}$-corporeal objects of $\mathcal{X}$ is closed under retracts (Proposition 20.3.3.8), so that F_i factors through the subcategory $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}^{\mathrm{ad}}$. Since the ∞-categories $\mathrm{Fun}(\Delta^m, \mathcal{X})$ and $\mathcal{X}^{\mathrm{ad}}_{/X_i}$ are presentable, the ∞-category $\mathcal{C}_i$ is presentable (Proposition **??**). We can therefore choose a small collection of objects $\{C_{i,j}\}_{j \in I_j}$ which generate $\mathcal{C}_i$ under small colimits. Each of the ∞-categories $\mathcal{X}^{\mathrm{ad}}_{/F_i(C_{i,j})}$ is presentable, and is therefore generated by a small collection of objects $\{Y_{i,j,k}\}_{k \in K_{i,j}}$. Note that each $Y_{i,j,k}$ is a $\mathcal{X}^{\mathrm{ad}}$-corporeal object of $\mathcal{X}$ (Proposition 20.3.3.8). Let $\mathcal{E} \subseteq \mathcal{X}^{\mathrm{corp}}$ be the smallest full subcategory which contains each of the objects $Y_{i,j,k}$ and is closed under small colimits. Choose a regular cardinal κ such that each $Y_{i,j,k}$ is κ-compact as an object of $\mathcal{X}$. Then each $Y_{i,j,k}$ is also κ-compact as an object of $\mathcal{E}$, so that the ∞-category $\mathcal{E}$ is κ-accessible. We will complete the proof by showing that $\mathcal{E} = \mathcal{X}^{\mathrm{corp}}$.

Fix an object $X \in \mathcal{X}^{\mathrm{corp}}$; we wish to show that X belongs to $\mathcal{E}$. Applying Proposition 20.3.3.12, we can choose an admissible effective epimorphism $u : \amalg U_\alpha \to X$, where each U_α is a retract of some object V_α which admits an admissible morphism $V_\alpha \to X_i$ for some index i. Let $X_\bullet$ be the Čech nerve of u, so that X can be identified with the geometric realization $|X_\bullet|$. Since $\mathcal{E}$ is closed under small colimits, it will suffice to show that each X_m belongs to $\mathcal{E}$. Writing X_m as a coproduct of objects of the form $U_{\alpha_0} \times_X \cdots \times_X U_{\alpha_m}$, we are reduced to proving the following:

- $(*)$ If W is an object of $\mathcal{X}^{\mathrm{corp}}$ which admits an admissible morphism $W \to U_\alpha$ for some index α, then W belongs to $\mathcal{E}$.

Choose a commutative diagram σ :

$$\begin{array}{ccc} & V_\alpha & \\ \nearrow & & \searrow \\ U_\alpha & \xrightarrow{\mathrm{id}} & U_\alpha, \end{array}$$

where V_α admits an admissible morphism $V_\alpha \to X_i$ for some $i \in I$. Then σ determines an object $C \in \mathcal{C}_i$ satisfying $F_i(C) = U_\alpha$. Let us say that an object $C' \in (\mathcal{C}_i)_{/C}$ is *good* if the fiber product $W \times_{U_\alpha} F_i(C')$ belongs to $\mathcal{E}$. We wish to show that the object $C \in (\mathcal{C}_i)_{/C}$ is good.

Since $\mathcal{E}$ is closed under small colimits in $\mathcal{X}^{\mathrm{corp}}$, the collection of good objects of $(\mathcal{C}_i)_{/C}$ is also closed under small colimits. It will therefore suffice to show that any map $C_{i,j} \to C$ in the ∞-category $\mathcal{C}_i$ exhibits $C_{i,j}$ as a good object of $(\mathcal{C}_i)_{/C}$. This is clear, since $W \times_{U_\alpha} F_i(C_{i,j})$ is an object of the ∞-category $\mathcal{X}^{\mathrm{ad}}_{/F_i(C_{i,j})}$, which is generated under small colimits by the objects $Y_{i,j,k}$. $\square$

Proof of Theorem 20.3.4.4. Let $\mathcal{X}$ be an ∞-topos, let $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$ be a geometric admissibility structure, and let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}^{\mathrm{ad}}$ be the full subcategory spanned by the $\mathcal{X}^{\mathrm{ad}}$-corporeal objects. We will show that $\mathcal{X}^{\mathrm{corp}}$ is a fracture subcategory of $\mathcal{X}$ (automatically complete, by virtue of Proposition 20.3.3.8) by verifying each of the requirements of Definition 20.1.2.1:

(0) The subcategory $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ is replete; this follows immediately from the definitions.

(1) The ∞-category $\mathcal{X}^{\mathrm{corp}}$ admits fiber products, which are preserved by the inclusion functor $j_! : \mathcal{X}^{\mathrm{corp}} \hookrightarrow \mathcal{X}$. Suppose we are given morphisms $f : U \to X$ and $g : X' \to X$ in the ∞-category $\mathcal{X}^{\mathrm{corp}}$. Form a pullback square σ :

$$\begin{array}{ccc} U' & \xrightarrow{g'} & U \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ X' & \xrightarrow{g} & X \end{array}$$

in the ∞-category $\mathcal{X}$. Since the collection of admissible morphisms of $\mathcal{X}$ is stable under pullbacks, we deduce that f' and g' are admissible. Using Proposition 20.3.3.8, we see that U' is $\mathcal{X}^{\mathrm{ad}}$-corporeal. Finally, we observe that a morphism $h : Y \to U'$ is admissible if and only if the composite maps $g' \circ h$ and $f' \circ h$ are admissible, so that σ is also a pullback square in $\mathcal{X}^{\mathrm{corp}}$.

(2) The inclusion functor $j_! : \mathcal{X}^{\mathrm{corp}} \hookrightarrow \mathcal{X}$ admits a right adjoint $j^* : \mathcal{X} \to \mathcal{X}^{\mathrm{corp}}$ which is conservative and preserves small colimits. Since $\mathcal{X}$ and $\mathcal{X}^{\mathrm{corp}}$ are presentable (Lemma 20.3.4.9) and the functor $j_!$ preserves small colimits (Lemma 20.3.4.8), the existence of the functor j^* follows from the adjoint functor theorem (Corollary HTT.5.5.2.9). The functor j^* is conservative by virtue of our assumption that $\mathcal{X}$ is generated under small colimits by $\mathcal{X}^{\mathrm{ad}}$-corporeal objects. Let $\{X_\alpha\}$ be a small diagram in the ∞-topos $\mathcal{X}$ having a colimit X; we wish to show that the canonical map $\phi : \varinjlim j^* X_\alpha \to j^* X$ is an equivalence. Let $\rho : \mathcal{X}_{/j^* X} \to \mathcal{X}^{\mathrm{ad}}_{/j^* X}$ be a right adjoint to the inclusion. Since j^* is conservative, the functor ρ preserves small colimits. Note that we have canonical equivalences $j^* X_\alpha \simeq \rho(X_\alpha \times_X j^* X)$ (this follows by comparing universal properties), so we can identify ϕ with the natural map $\varinjlim \rho(X_\alpha \times_X j^* X) \to \rho(j^* X) \simeq j^* X$. This map is an equivalence, since colimits in $\mathcal{X}$ are universal and the functor ρ commutes with small colimits (by virtue of the fact that $j^* X$ is corporeal).

(3) For every morphism $U \to V$ in $\mathcal{X}^{\mathrm{corp}}$, the diagram

$$\begin{array}{ccc} j^*U & \longrightarrow & j^*V \\ \downarrow & & \downarrow \\ U & \longrightarrow & V \end{array}$$

(determined by the counit map $j_!j^* \to \mathrm{id}$) is a pullback square in $\mathcal{X}$. Equivalently, we must show that the canonical map $j^*U \to U \times_V j^*V$. This follows by comparing the universal property of both sides as objects of the ∞-category $\mathcal{X}^{\mathrm{ad}}_{/j^*V}$.

□

20.4 Exactness and Density

Let $\mathcal{X}$ be a topos and let P be some property of objects of $\mathcal{X}$. Then the following conditions are equivalent:

(a) For every object $X \in \mathcal{X}$, there exists an effective epimorphism $\amalg_\alpha U_\alpha \to X$ where each U_α has the property P.

(b) The category $\mathcal{X}$ is generated under small colimits by objects having the property P.

(c) For every object $X \in \mathcal{X}$, the natural map $\varinjlim_{U \in \mathcal{X}^0_{/X}} U \to X$ is an isomorphism, where $\mathcal{X}^0_{/X}$ denotes the full subcategory of $\mathcal{X}_{/X}$ spanned by those objects which have the property P.

The implications $(c) \Rightarrow (b) \Rightarrow (a)$ are immediate, while the implication $(a) \Rightarrow (c)$ requires more work (see Corollary 20.4.5.3 below). If P satisfies any one of these equivalent conditions, then we say that P holds *locally* on $\mathcal{X}$.

In the setting of ∞-topoi, the analogous equivalence does not hold:

Counterexample 20.4.0.1. Let $Q = \prod_{n \in \mathbf{Z}} [0,1]$ denote the Hilbert cube and let $\mathcal{X} = \mathcal{S}\mathrm{hv}(Q)$ be the ∞-topos of $\mathcal{S}$-valued sheaves on Q. For each open set $U \subseteq Q$, let $\mathscr{F}_U \in \mathcal{X}$ denote the sheaf given by $\mathscr{F}_U(V) = \begin{cases} * & \text{if } V \subseteq U \\ \varnothing & \text{otherwise.} \end{cases}$ Let $\mathcal{U}$ be the collection of all open subsets of Q which are homeomorphic to a product $[0,1) \times Q$. One can show that $\mathcal{U}$ forms a basis for the topology of Q (see [40]), so that the collection of objects $\{\mathscr{F}_U\}_{U \in \mathcal{U}}$ satisfies condition (a). However, we claim that it does not satisfy condition (b). To see this, note that the formation of compactly supported cochain complexes determines a functor $U \mapsto C^*_c(U; \mathbf{Z})$ which extends to a colimit-preserving map $F : \mathcal{X} \to \mathrm{Mod}_{\mathbf{Z}}$ (this is essentially equivalent to the existence of Mayer-Vietoris sequences in compactly supported cohomology). The Hilbert cube Q is compact and contractible, so for each $U \in \mathcal{U}$ we have

$$\mathrm{H}^*_c(U; \mathbf{Z}) \simeq \mathrm{H}^*_c([0,1); \mathbf{Z}) \simeq 0.$$

It follows that the functor F vanishes on the full subcategory of $\mathcal{X}$ generated by $\{\mathscr{F}_U\}_{U \in \mathcal{U}}$ under small colimits. However, the functor F does not vanish identically: its value on the final object of $\mathcal{X}$ is given by $C^*_c(Q; \mathbf{Z}) \simeq \mathbf{Z}$.

In this section, we will show that Counterexample 20.4.0.1 is essentially an infinite-dimensional phenomenon: conditions (a), (b), and (c) are all equivalent if we restrict our attention to the case where the ∞-topos $\mathcal{X}$ is hypercomplete (Proposition 20.4.5.1).

20.4.1 Dense Functors

We begin with some general remarks.

Definition 20.4.1.1. Let $F : \mathcal{D} \to \mathcal{C}$ be a functor between ∞-categories. We will say that F is *dense* if it exhibits identity functor $\mathrm{id}_{\mathcal{C}}$ is a left Kan extension of F along itself.

Remark 20.4.1.2. A functor $F : \mathcal{C} \to \mathcal{D}$ is dense if and only if, for every object $D \in \mathcal{D}$, the evident diagram $(\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{/D})^{\triangleright} \to \mathcal{D}^{\triangleright}_{/D} \to \mathcal{D}$ exhibits D as a colimit of the diagram $(\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{/D}) \to \mathcal{C} \xrightarrow{f} \mathcal{D}$. In particular, this implies that every object of $\mathcal{D}$ can be obtained as the colimit of a diagram which factors through $\mathcal{C}$. Moreover, if $\mathcal{C}$ is small and $\mathcal{D}$ is locally small, then the diagram can be assumed small.

Remark 20.4.1.3. Let $F : \mathcal{C} \to \mathcal{D}$ be a dense functor between ∞-categories and let $q : K \to \mathcal{D}$ be any diagram in $\mathcal{D}$. Then the induced map $F' : \mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{/q} \to \mathcal{D}_{/q}$ is also dense. To prove this, it suffices to observe that for each object $D \in \mathcal{D}_{/q}$, the projection map $\pi : \mathcal{D}_{/q} \to \mathcal{D}$ induces an equivalence of ∞-categories $(\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{/q}) \times_{\mathcal{D}_{/q}} (\mathcal{D}_{/q})_{/D} \simeq \mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{/\pi(C)}$, and that a diagram in $\mathcal{D}_{/q}$ is a colimit provided that its image in $\mathcal{D}$ is a colimit (Proposition HTT.1.2.13.8).

Remark 20.4.1.4. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor and between ∞-categories and let $q : \mathcal{M} \to \Delta^1$ be a correspondence associated to F (so that $\mathcal{M} \times_{\Delta^1} \{0\} \simeq \mathcal{C}$, $\mathcal{M} \times_{\Delta^1} \{1\} \simeq \mathcal{D}$, and q is a coCartesian fibration which determines the map $F : \mathcal{M} \times_{\Delta^1} \{0\} \to \mathcal{M} \times_{\Delta^1} \{1\}$). Then F is dense if and only if the identity map $\mathrm{id}_{\mathcal{M}}$ is a q-left Kan extension of $\mathrm{id}_{\mathcal{M}}|_{\mathcal{C}}$.

Remark 20.4.1.5. Let $f : \mathcal{C} \to \mathcal{D}$ be a functor between ∞-categories where $\mathcal{C}$ is small, $\mathcal{D}$ is locally small, and $\mathcal{D}$ admits small colimits. Using Theorem HTT.5.1.5.6 , we may assume without loss of generality that f factors as a composition $\mathcal{C} \xrightarrow{j} \mathcal{P}(\mathcal{C}) \xrightarrow{F} \mathcal{D}$, where $\mathcal{P}(\mathcal{C}) = \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ denotes the ∞-category of presheaves on $\mathcal{C}$, the functor j is the Yoneda embedding, and F preserves small colimits. Corollary HTT.5.2.6.5 implies that F admits a right adjoint G, given by the composition

$$\mathcal{D} \xrightarrow{j'} \mathrm{Fun}(\mathcal{D}^{\mathrm{op}}, \mathcal{S}) \xrightarrow{\circ f} \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}) = \mathcal{P}(\mathcal{C}),$$

where j' denotes the Yoneda embedding for $\mathcal{D}$; moreover, the transformation

$$f = F \circ j \to (F \circ (G \circ F)) \circ j \simeq (F \circ G) \circ f$$

exhibits $(F \circ G)$ as a left Kan extension of f along itself. It follows that f is dense if and only if the counit map $F \circ G \to \mathrm{id}_{\mathcal{C}}$ is an equivalence of functors. This is equivalent to the requirement that the functor G is fully faithful.

In other words, the functor $f : \mathcal{C} \to \mathcal{D}$ is dense if and only if the induced map $F : \mathcal{P}(\mathcal{C}) \to \mathcal{D}$ exhibits $\mathcal{D}$ as a localization of $\mathcal{P}(\mathcal{C})$. In particular, the Yoneda embedding $\mathcal{C} \to \mathcal{P}(\mathcal{C})$ is dense for any small ∞-category $\mathcal{C}$.

Remark 20.4.1.6. Let $f : \mathcal{C} \to \mathcal{D}$ be as in Remark 20.4.1.5, and let $\mathcal{E}$ be an ∞-category which admits small colimits. Let $\mathrm{LFun}(\mathcal{D}, \mathcal{E})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{D}, \mathcal{E})$ spanned by those functors which preserve small colimits. If f is dense, then composition with f induces a fully faithful functor $\mathrm{LFun}(\mathcal{D}, \mathcal{E}) \to \mathrm{Fun}(\mathcal{C}, \mathcal{E})$. This follows from Theorem HTT.5.1.5.6 , Proposition HTT.5.5.4.20 , and Remark 20.4.1.5.

We now specialize Definition 20.4.1.1 to the case of inclusion functors.

Definition 20.4.1.7. Let $\mathcal{C}$ be an ∞-category. We will say that a full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ is *dense* in $\mathcal{C}$ if the inclusion functor $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ is dense, in the sense of Definition 20.4.1.1.

Example 20.4.1.8. The full subcategory of $\mathcal{S}$ spanned by its final object is dense in $\mathcal{S}$ (this follows immediately from Remark 20.4.1.5).

Example 20.4.1.9. Let us identify $\mathbf{\Delta}$ with the full subcategory of $\mathcal{C}\mathrm{at}_\infty$ spanned by the objects $\{\Delta^n\}_{n \geqslant 0}$. Then $\mathbf{\Delta}$ is dense in $\mathcal{C}\mathrm{at}_\infty$: this follows from Proposition HA.A.7.10 .

Remark 20.4.1.10. A full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ is dense if and only if the identity functor $\mathrm{id}_{\mathcal{C}}$ is a left Kan extension of $\mathrm{id}_{\mathcal{C}} |_{\mathcal{C}_0}$. It follows from Proposition HTT.4.3.2.8 that if $\mathcal{C}_0 \subseteq \mathcal{C}_1 \subseteq \mathcal{C}$ are full subcategories and $\mathcal{C}_0$ is dense, then $\mathcal{C}_1$ is also dense.

Remark 20.4.1.11. Let $f : \mathcal{D} \to \mathcal{C}$ be a dense functor between ∞-categories, and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be the essential image of f. Then $\mathcal{C}_0$ is dense in $\mathcal{C}$. To prove this, let $q : \mathcal{M} \to \Delta^1$ be a correspondence associated to f (as in Remark 20.4.1.4), and let $\mathcal{M}_0$ be the full subcategory of $\mathcal{M}$ spanned by the objects of $\mathcal{D} \simeq \mathcal{M} \times_{\Delta^1} \{0\}$ and $\mathcal{C}_0 \subseteq \mathcal{C} \simeq \mathcal{M} \times_{\Delta^1} \{1\}$. Since f is dense, the identity functor $\mathrm{id}_{\mathcal{M}}$ is a q-left Kan extension of its restriction to $\mathcal{D}$, and therefore also a q-left Kan extension of $\mathrm{id}_{\mathcal{M}} |_{\mathcal{M}_0}$. Let C be an arbitrary object of $\mathcal{C}$, so that C can be identified with a q-colimit of the forgetful functor $\mathcal{M}_0 \times_{\mathcal{M}} \mathcal{M}_{/C} \to \mathcal{M}$. To prove that $\mathrm{id}_{\mathcal{C}}$ is a left Kan extension of $\mathrm{id}_{\mathcal{C}} |_{\mathcal{C}_0}$ at C, it will suffice to show that C is also a q-colimit of the diagram $\mathcal{C}_0 \times_{\mathcal{M}} \mathcal{M}_{/C} \to \mathcal{M}$. For this, it suffices to show that the inclusion

$$\iota : \mathcal{C}_0 \times_{\mathcal{M}} \mathcal{M}_{/C} \hookrightarrow \mathcal{M}_0 \times_{\mathcal{M}} \mathcal{M}_{/C}$$

is left cofinal. This is clear, since the functor ι admits a left adjoint.

20.4.2 Local Left Exactness

Let $f : \mathcal{C} \to \mathcal{X}$ be a dense functor, where the ∞-category $\mathcal{C}$ is small and the ∞-category $\mathcal{X}$ is presentable. Then f exhibits $\mathcal{X}$ as a localization of $\mathcal{P}(\mathcal{C})$ (Remark 20.4.1.5). We now study the condition that this localization be left exact. Note that in this case, the ∞-category $\mathcal{X}$ is necessarily an ∞-topos.

Definition 20.4.2.1. Let $\mathcal{C}$ be a small ∞-category and let $\mathcal{X}$ be an ∞-topos. We will say that a functor $f : \mathcal{C} \to \mathcal{X}$ is *locally left exact* if it is homotopic to a composition

$$\mathcal{C} \xrightarrow{j} \mathcal{P}(\mathcal{C}) \xrightarrow{F} \mathcal{X}$$

where j is the Yoneda embedding and F is a functor which preserves small colimits and finite limits.

We let $\mathrm{Fun}^{\mathrm{llex}}(\mathcal{C}, \mathcal{X})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{X})$ spanned by those functors which are locally left exact.

Remark 20.4.2.2. In the situation of Definition 20.4.2.1, the functor f is automatically homotopic to a composition $\mathcal{C} \xrightarrow{j} \mathcal{P}(\mathcal{C}) \xrightarrow{F} \mathcal{X}$ where j is the Yoneda embedding and F preserves small colimits. Moreover, the functor F is well-defined up to a contractible space of choices (Theorem HTT.5.1.5.6). The functor f is locally left exact if and only if F is left exact.

Warning 20.4.2.3. If $\mathcal{C}$ does not admit finite limits, then locally left exact functors need not be left exact; see Remark 21.2.3.11.

Remark 20.4.2.4. Let $\mathcal{C}$ be a small ∞-category. Then the Yoneda embedding $j : \mathcal{C} \to \mathcal{P}(\mathcal{C})$ preserves all limits which exist in $\mathcal{C}$ (Proposition HTT.5.1.3.2). Consequently, if $\mathcal{X}$ is an ∞-topos and $f : \mathcal{C} \to \mathcal{X}$ is a locally left exact functor, then f preserves all finite limits which exist in $\mathcal{C}$.

Remark 20.4.2.5. Let $\mathcal{X}$ be an ∞-topos, let $\mathcal{C}$ be a small ∞-category, and let $f : \mathcal{C} \to \mathcal{X}$ be a functor which is dense and locally left exact. Write f as a composition $\mathcal{C} \xrightarrow{j} \mathcal{P}(\mathcal{C}) \xrightarrow{F} \mathcal{X}$, where j is the Yoneda embedding and F preserves small colimits. Then F is left exact and admits a fully faithful right adjoint G. For each object $C \in \mathcal{C}$, the functor f induces a map

$f_C : \mathcal{C}_{/C} \to \mathcal{X}_{/fC}$, which extends to a left exact functor $F_C : \mathcal{P}(\mathcal{C})_{/jC} \simeq \mathcal{P}(\mathcal{C}_{/C}) \to \mathcal{X}_{/fC}$. The functor F_C admits a right adjoint $G_C : \mathcal{X}_{/fC} \to \mathcal{P}(\mathcal{C})_{/jC}$, given concretely by the formula $G_C(X) = G(X) \times_{G(fC)} jC$. Note that the counit map $v_C : (F_C \circ G_C)(X) \to X$ is given by the left vertical composition in the diagram

$$\begin{array}{ccc} F(G(X) \times_{G(fC)} jC) & \longrightarrow & F(jC) \\ \downarrow & & \downarrow w \\ (F \circ G)(X) & \longrightarrow & F(G(fC)) \\ \downarrow v & & \\ X. & & \end{array}$$

Since G is fully faithful, the maps v and w are equivalences. The left exactness of F guarantees that the square is a pullback, so that v_C is also an equivalence. Allowing X to vary, we deduce that G_C is fully faithful. Consequently, the functor $f_C : \mathcal{C}_{/C} \to \mathcal{X}_{/fC}$ is also dense and locally left exact.

Warning 20.4.2.6. The terminology of Definition 20.4.2.1 is not standard. Many authors use the term *flat* to refer to the property of being locally left exact (see §21.2.3 for an explanation of this terminology).

Remark 20.4.2.7. If $\mathcal{X}$ is an ∞-topos, then filtered colimits in $\mathcal{X}$ are left exact (Example HTT.7.3.4.7). For any small ∞-category $\mathcal{C}$, it follows that the full subcategory $\mathrm{Fun}^*(\mathcal{P}(\mathcal{C}), \mathcal{X}) \subseteq \mathrm{Fun}(\mathcal{P}(\mathcal{C}), \mathcal{X})$ is closed under filtered colimits, where $\mathrm{Fun}^*(\mathcal{P}(\mathcal{C}), \mathcal{X})$ is spanned by those functors which are left exact and preserve small colimits. Composing with the Yoneda embedding $j : \mathcal{C} \to \mathcal{P}(\mathcal{C})$, we conclude that the collection of locally left exact functors from $\mathcal{C}$ to $\mathcal{X}$ is closed under filtered colimits.

Example 20.4.2.8. Let $\mathcal{C}$ be an ∞-category, let $C \in \mathcal{C}$ be an object, and let $h^C : \mathcal{C} \to \mathcal{S}$ denote the functor corepresented by C. Then h^C is homotopic to the composition $\mathcal{C} \xrightarrow{j} \mathcal{P}(\mathcal{C}) \xrightarrow{e} \mathcal{S}$, where $e : \mathcal{P}(\mathcal{C}) \to \mathcal{S}$ denotes the functor given by evaluation at C. Since the functor e preserves small limits and colimits, we conclude that h^C is locally left exact.

In the case where $\mathcal{X} = \mathcal{S}$ is the ∞-category of spaces, we can make Definition 20.4.2.1 more explicit.

Proposition 20.4.2.9. *Let $\mathcal{C}$ be a small ∞-category, and let $f : \mathcal{C} \to \mathcal{S}$ be a functor. The following conditions are equivalent:*

(1) *Let $\mathcal{C}' \to \mathcal{C}$ be a left fibration classified by f. Then the ∞-category $\mathcal{C}'^{\mathrm{op}}$ is filtered.*

(2) *The functor f belongs to $\mathrm{Pro}(\mathcal{C})^{\mathrm{op}} \subseteq \mathrm{Fun}(\mathcal{C}, \mathcal{S})$.*

(3) *The functor f is locally left exact.*

Proof. The equivalence of (1) and (2) follows immediately from the definitions (see §HTT.5.3.5). We next prove that (2) $\Rightarrow$ (3). Assume that $f \in \mathrm{Pro}(\mathcal{C})^{\mathrm{op}} \subseteq \mathrm{Fun}(\mathcal{C}, \mathcal{S})$. According to Corollary HTT.5.3.5.4 , we can write f as a filtered colimit of corepresentable functors from $\mathcal{C}$ to $\mathcal{S}$. Using Remark 20.4.2.7 and Example 20.4.2.8, we deduce that f is locally left exact.

We complete the proof by showing that (3) $\Rightarrow$ (1). Let K be a finite simplicial set and let $q : K \to \mathcal{C}'$ be a diagram; we wish to prove that q can be extended to a map $\overline{q} : K^{\triangleleft} \to \mathcal{C}'$. Let $q_0 : K \to \mathcal{C}$ be the composition of q with the projection map $\mathcal{C}' \to \mathcal{C}$. Then q can be identified with a vertex of the Kan complex $\mathrm{Fun}_{\mathcal{C}}(K, \mathcal{C}')$, which can be viewed as a limit of the diagram $(f \circ q_0) : K \to \mathcal{S}$ (see Corollary HTT.3.3.3.3). Without loss of generality, we may assume that f is given by the composition $\mathcal{C} \xrightarrow{j} \mathcal{P}(\mathcal{C}) \xrightarrow{F} \mathcal{S}$, where j is the Yoneda embedding and F preserves small colimits. Assumption (3) implies that F preserves finite limits, so that

$$\lim(f \circ q_0) = \lim(F \circ j \circ q_0) = F \lim(j \circ q_0).$$

Write $\lim(j \circ q_0) \in \mathcal{P}(\mathcal{C})$ as a colimit of representable presheaves $\mathscr{F}_\alpha$. Then we can identify q with a point of the colimit $\varinjlim_\alpha F(\mathscr{F}_\alpha)$. It follows that there exists an object $C \in \mathcal{C}$ and a morphism $u : j(C) \to \lim(j \circ q_0)$ such that q lifts to a point $\eta \in F(j(C)) = f(C)$. We conclude by observing that the map u determines an extension $\overline{q}_0 : K^{\triangleleft} \to \mathcal{C}$ extending q_0, and the point η determines a lifting of $\overline{q}_0$ to a map $\overline{q} : K^{\triangleleft} \to \overline{\mathcal{C}}$ extending q. □

20.4.3 A Criterion for Local Left Exactness

The following result can be regarded as a generalization of Proposition HTT.6.1.5.2 :

Proposition 20.4.3.1. *Let $\mathcal{X}$ be an ∞-topos, let $\mathcal{C}$ be a small ∞-category, and let $f : \mathcal{C} \to \mathcal{X}$ be a functor. The following conditions are equivalent:*

(1) *The functor f is locally left exact.*

(2) *For every finite simplicial set K and every map $q : K \to \mathcal{C}$, the canonical map*

$$\varinjlim f|_{\mathcal{C}_{/q}} \to \varprojlim (f \circ q)$$

is an equivalence in the ∞-topos $\mathcal{X}$.

Corollary 20.4.3.2. *Let $\mathcal{C}$ be a small ∞-category which admits finite limits, and let $\mathcal{X}$ be an ∞-topos. Then a functor $f : \mathcal{C} \to \mathcal{X}$ is locally left exact if and only if it is left exact.*

Corollary 20.4.3.3. *Let $\mathcal{X}$ be an ∞-topos, let $\mathcal{C}$ be a small ∞-category, and let $f : \mathcal{C} \to \mathcal{X}$ be a functor. If f is dense and fully faithful, then it is locally left exact.*

Proof. Let K be a finite simplicial set and let $q : K \to \mathcal{C}$ be a diagram, and let $X \in \mathcal{X}$ be a limit of the diagram $f \circ q : K \to \mathcal{X}$. We have an equivalence of ∞-categories

$$\mathcal{C} \times_{\mathcal{X}} \mathcal{X}_{/X} \simeq \mathcal{C} \times_{\mathcal{X}} \mathcal{X}_{/fq} \simeq \mathcal{C}_{/q},$$

so that our assumption that f is dense guarantees that $X = \varprojlim fq$ is a colimit of $f|_{\mathcal{C}_{/q}}$. The desired result now follows from Proposition 20.4.3.1. □

Warning 20.4.3.4. Corollary 20.4.3.3 is not necessarily true if the functor f is not fully faithful. For example, if $\mathcal{C}$ is any weakly contractible ∞-category, then the constant map

$$\mathcal{C} \to \{*\} \hookrightarrow \mathcal{S}$$

is dense, but is usually not locally left exact (since colimits indexed by $\mathcal{C}^{\mathrm{op}}$ need not commute with finite limits).

Proof of Proposition 20.4.3.1. The implication (1) $\Rightarrow$ (2) follows immediately from the definitions. To prove the converse, we proceed as in the proof of Proposition HTT.6.1.5.2 . Using Theorem HTT.5.1.5.6 , we can assume without loss of generality that f is given by a composition $\mathcal{C} \xrightarrow{j} \mathcal{P}(\mathcal{C}) \xrightarrow{F} \mathcal{X}$, where j denotes the Yoneda embedding and the functor F preserves small colimits. Assume that (2) is satisfied; we wish to prove that F is left exact. Taking $K = \varnothing$ in (2), we deduce that F preserves final objects. It will therefore suffice to show that F preserves pullbacks. Let us say that an object $Z \in \mathcal{P}(\mathcal{C})$ is *good* if the following condition is satisfied:

(∗) For every pullback diagram σ :

$$\begin{array}{ccc} W & \longrightarrow & X \\ \downarrow & & \downarrow \\ Y & \longrightarrow & Z \end{array}$$

in $\mathcal{P}(\mathcal{C})$, the image $F(\sigma)$ is a pullback diagram in $\mathcal{X}$.

Since $\mathcal{P}(\mathcal{C})$ is generated under small colimits by the essential image of j and colimits are universal in both $\mathcal{X}$ and $\mathcal{P}(\mathcal{C})$, (∗) is equivalent to the following apparently weaker condition:

(∗′) For every pullback diagram σ :

$$\begin{array}{ccc} W & \longrightarrow & X \\ \downarrow & & \downarrow \\ Y & \longrightarrow & Z \end{array}$$

in $\mathcal{P}(\mathcal{C})$, if both X and Y belong to the essential image of j, then $F(\sigma)$ is a pullback diagram in $\mathcal{X}$.

We wish to show that every object of $\mathcal{P}(\mathcal{C})$ is good. It follows from condition (2) that for each object $C \in \mathcal{C}$, the representable functor $j(C) \in \mathcal{P}(\mathcal{C})$ satisfies $(*')$, and is therefore good. We will complete the proof by showing that the collection of good objects of $\mathcal{P}(\mathcal{C})$ is closed under small colimits. By virtue of Proposition HTT.4.4.3.3 , it will suffice to prove that the collection of good objects of $\mathcal{P}(\mathcal{C})$ is closed under the formation of coequalizers and small coproducts.

We first consider the case of coproducts. Let $\{Z_i\}_{i \in I}$ be small collection of good objects of $\mathcal{P}(\mathcal{C})$ having coproduct $Z \in \mathcal{P}(\mathcal{C})$. We claim that Z satisfies $(*')$. Suppose we are given a pullback diagram σ :

$$\begin{array}{ccc} W & \longrightarrow & X \\ \downarrow & & \downarrow \alpha \\ Y & \xrightarrow{\beta} & Z \end{array}$$

in $\mathcal{P}(\mathcal{C})$, where X and Y belong to the essential image of j. Then α and β determine maps $\alpha_0 : X \rightarrow Z_i$ and $\beta_0 : X \rightarrow Z_j$, for some uniquely determined pair of indices $i, j \in I$. If $i \neq j$, then $W \simeq \emptyset$ and $F(\sigma)$ is a pullback square by virtue of the fact that coproducts in $\mathcal{X}$ are disjoint. If $i = j$, then we can identify W with the fiber product $X \times_{Z_i} Y$, so that $F(\sigma)$ is a pullback diagram by virtue of our assumption that Z_i is good.

We now complete the proof by showing that the collection of good objects of $\mathcal{P}(\mathcal{C})$ is stable under the formation of coequalizers. Let

$$P \rightrightarrows Q \xrightarrow{s} Z$$

be a coequalizer diagram in $\mathcal{P}(\mathcal{C})$, and suppose that P and Q are good. Let σ :

$$\begin{array}{ccc} W & \longrightarrow & X \\ \downarrow & & \downarrow \alpha \\ Y & \xrightarrow{\beta} & Z \end{array}$$

be a pullback diagram, where X and Y belong to the essential image of j. Then α factors as a composition $X \xrightarrow{\overline{\alpha}} Q \xrightarrow{s} Z$. We may therefore identify σ with the outer rectangle in a commutative diagram

$$\begin{array}{ccc} W & \longrightarrow & X \\ \downarrow & & \downarrow \overline{\alpha} \\ Q \times_Z Y & \longrightarrow & Q \\ \downarrow & & \downarrow \\ Y & \longrightarrow & Z. \end{array}$$

Since Q is good, the functor F carries the upper square in this diagram to a pullback square in $\mathcal{X}$. It will therefore suffice to show that F carries the lower square to a pullback as well.

We may therefore replace X by Q and thereby reduce to the case $\alpha = s$. Similarly, we can assume that $\beta = s$. In this case, the desired result follows from Proposition HTT.6.1.4.2 . □

Remark 20.4.3.5. In the statement of Proposition 20.4.3.1, it suffices to assume that condition (2) holds in the special cases $K = \varnothing$ and $K = \Lambda^2_2$.

20.4.4 Comparison with Left Exactness

We now investigate the relationship between left exactness and local left exactness.

Proposition 20.4.4.1. *Let $f : \mathcal{C} \to \mathcal{D}$ be a functor between small ∞-categories, and let $j_{\mathcal{D}} : \mathcal{D} \to \mathcal{P}(\mathcal{D})$ be the Yoneda embedding. The following conditions are equivalent:*

(1) *The functor f is left exact.*

(2) *The functor $j_{\mathcal{D}} \circ f$ is locally left exact.*

Corollary 20.4.4.2. *Let $f : \mathcal{C} \to \mathcal{D}$ be a left exact functor between small ∞-categories, let $\mathcal{X}$ be an ∞-topos, and let $g : \mathcal{D} \to \mathcal{X}$ be a locally left exact functor. Then the composition $(g \circ f) : \mathcal{C} \to \mathcal{X}$ is locally left exact.*

Proof. We have a commutative diagram

$$\begin{array}{ccccc} \mathcal{C} & \xrightarrow{f} & \mathcal{D} & & \\ \downarrow{\scriptstyle j_{\mathcal{C}}} & & \downarrow{\scriptstyle j_{\mathcal{D}}} & \searrow{\scriptstyle g} & \\ \mathcal{P}(\mathcal{C}) & \xrightarrow{F} & \mathcal{P}(\mathcal{D}) & \xrightarrow{G} & \mathcal{X} \end{array}$$

where the vertical maps denote Yoneda embeddings, and the functors F and G preserve small colimits. Since f is left exact, Proposition 20.4.4.1 implies that F is left exact. Since g is locally left exact, the functor G is left exact. It follows that $G \circ F$ is left exact, so that $g \circ f$ is locally left exact. □

Corollary 20.4.4.3. *Let $\mathcal{C}$ be a small ∞-category and let $\mathcal{X}$ be an ∞-topos. If $f : \mathcal{C} \to \mathcal{X}$ is left exact, then f is locally left exact.*

Proof. Let $\mathcal{X}_0$ be a full subcategory of $\mathcal{X}$ which contains the essential image of f. Enlarging $\mathcal{X}_0$ if necessary, we may suppose that $\mathcal{X}_0$ admits finite limits. Then f factors as a composition

$$\mathcal{C} \xrightarrow{f_0} \mathcal{X}_0 \xrightarrow{g} \mathcal{X},$$

where $f_0 = f$ and g is the inclusion functor. The assumption that f is left exact implies that f_0 is left exact, and g is locally left exact by virtue of Corollary 20.4.3.2. It follows from Corollary 20.4.4.2 that f is locally left exact. □

Warning 20.4.4.4. The converse of Corollary 20.4.4.3 is valid when $\mathcal{C}$ admits finite limits (Remark 20.4.2.2), but not in general.

Proof of Proposition 20.4.4.1. Choose a homotopy commutative diagram

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{f} & \mathcal{D} \\ \downarrow{\scriptstyle j_{\mathcal{C}}} & & \downarrow{\scriptstyle j_{\mathcal{D}}} \\ \mathcal{P}(\mathcal{C}) & \xrightarrow{F} & \mathcal{P}(\mathcal{D}), \end{array}$$

where F preserves small colimits. Then $j_{\mathcal{D}} \circ f$ is locally left exact if and only if F is left exact. This is equivalent to the assertion that, for every object $D \in \mathcal{D}$, the composite functor

$$\mathcal{P}(\mathcal{C}) \xrightarrow{F} \mathcal{P}(\mathcal{D}) \xrightarrow{e} \mathcal{S}$$

is left exact, where $e : \mathcal{P}(\mathcal{D}) \to \mathcal{S}$ is given by evaluation at D. Since e preserves small colimits, this is equivalent to the requirement that the functor $(e \circ j_{\mathcal{D}} \circ f) : \mathcal{C} \to \mathcal{S}$ be locally left exact. Note that $e \circ j_{\mathcal{D}}$ is the functor corepresented by D, so that the composite functor $e \circ j_{\mathcal{D}} \circ f$ is classified by the left fibration $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{D/}$. Using Proposition 20.4.2.9, we see that $j_{\mathcal{D}} \circ f$ is locally left exact if and only if the ∞-category $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{D/}$ is filtered, for each object $D \in \mathcal{D}$, which is equivalent to the assumption that f is left exact. □

20.4.5 The Hypercomplete Case

We now return to the question raised at the beginning of this section.

Proposition 20.4.5.1. *Let $\mathcal{X}$ be a hypercomplete ∞-topos and let $\mathcal{C} \subseteq \mathcal{X}$ be an essentially small full subcategory. The following conditions are equivalent:*

- (a) *For every object $X \in \mathcal{X}$, there exists an effective epimorphism $\amalg_\alpha U_\alpha \to X$ where each U_α belongs to $\mathcal{C}$.*
- (b) *The category $\mathcal{X}$ is generated under small colimits by $\mathcal{C}$.*
- (c) *The subcategory $\mathcal{C}$ is dense in $\mathcal{X}$.*

Remark 20.4.5.2. In the situation of Proposition 20.4.5.1, if $\mathcal{C} \subseteq \mathcal{X}$ satisfies any of the equivalent conditions (a) through (c), then the inclusion $\mathcal{C} \hookrightarrow \mathcal{X}$ is locally left exact (Corollary 20.4.3.3). It follows that f exhibits $\mathcal{X}$ as a left exact localization of the ∞-category $\mathcal{P}(\mathcal{C})$.

Corollary 20.4.5.3. *Let $\mathcal{X}$ be an n-topos for $0 \leqslant n < \infty$ and let $\mathcal{C} \subseteq \mathcal{X}$ be an essentially small full subcategory. The following conditions are equivalent:*

- (a) *For every object $X \in \mathcal{X}$, there exists an effective epimorphism $\amalg_\alpha U_\alpha \to X$ where each U_α belongs to $\mathcal{C}$.*

(b) *The category $\mathcal{X}$ is generated under small colimits by $\mathcal{C}$.*

(c) *The subcategory $\mathcal{C}$ is dense in $\mathcal{X}$.*

Proof. The implications $(c) \Rightarrow (b) \Rightarrow (a)$ are immediate. Choose an ∞-topos $\mathcal{Y}$ for which we can identify $\mathcal{X}$ with the full subcategory $\tau_{\leqslant n-1}\mathcal{Y}$ of $(n-1)$-truncated objects of $\mathcal{Y}$. Replacing $\mathcal{Y}$ by its hypercompletion if necessary (which does not change the class of $(n-1)$-truncated objects of $\mathcal{Y}$), we may assume that $\mathcal{Y}$ is hypercomplete. Proposition 20.4.5.3 implies that $\mathcal{C}$ is dense in $\mathcal{Y}$, so that the functor

$$G : \mathcal{Y} \to \mathcal{P}(\mathcal{C}) \qquad G(Y)(C) = \mathrm{Map}_{\mathcal{Y}}(C, Y)$$

is fully faithful. It follows that the restriction $G|_{\mathcal{X}}$ is also fully faithful, so that $\mathcal{C}$ is a dense subcategory of $\mathcal{X}$. □

We will deduce Proposition 20.4.5.1 from the following lemma:

Lemma 20.4.5.4. *Let $\mathcal{X}$ be an ∞-topos and let $\mathcal{C} \subseteq \mathcal{X}$ be an essentially small full subcategory which satisfies condition (a) of Proposition 20.4.5.1. Then the colimit $\varinjlim_{U \in \mathcal{C}} U$ is an ∞-connective object of $\mathcal{X}$.*

Proof. We will prove that the colimit $X = \varinjlim_{U \in \mathcal{C}} U$ is n-connective for each $n \geqslant 0$. We proceed by induction on n. We first note that X is 0-connective (since the final object $\mathbf{1} \in \mathcal{X}$ admits an effective epimorphism $\amalg_{U \in \mathcal{C}} U \to \mathbf{1}$); this completes the proof in the case $n = 0$. To handle the inductive step, it will suffice to show that the diagonal map $\delta : X \to X \times X$ is $(n-1)$-connective. Since colimits in $\mathcal{X}$ distribute over finite products, we can write the product $X \times X$ as a colimit $\varinjlim_{(V,W) \in \mathcal{C} \times \mathcal{C}} V \times W$. Rewriting X as an iterated colimit $\varinjlim_{(V,W) \in \mathcal{C} \times \mathcal{C}} \varinjlim_{U \to V \times W} U$, we can obtain δ as a colimit of maps $\delta_{V,W} : \varinjlim_{U \in \mathcal{C} \times_{\mathcal{X}} \mathcal{X}_{/V \times W}} U \to V \times W$. It will therefore suffice to show that each $\delta_{V,W}$ is $(n-1)$-connective. This follows from the inductive hypothesis, applied to the ∞-topos $\mathcal{X}_{/V \times W}$. □

Proof of Proposition 20.4.5.1. The implications $(c) \Rightarrow (b) \Rightarrow (a)$ are trivial; we will show that $(a) \Rightarrow (c)$. To establish (c), we must show that for every object $X \in \mathcal{X}$, the canonical map $\eta : \varinjlim_{U \in \mathcal{C} \times_{\mathcal{X}} \mathcal{X}_{/X}} U \to X$ is an equivalence. Since $\mathcal{X}$ is hypercomplete, it will suffice to show that η is ∞-connective. This follows from Lemma 20.4.5.4, applied to the ∞-topos $\mathcal{X}_{/X}$. □

20.5 Presentations of Fractured ∞-Topoi

Recall that an ∞-category $\mathcal{X}$ is an ∞-topos if and only if $\mathcal{X}$ can obtained as an accessible left exact localization of a presheaf ∞-category $\mathcal{P}(\mathcal{G})$, where $\mathcal{G}$ is a small ∞-category (Theorem HTT.6.1.0.6). It is convenient to break this assertion down into three parts:

(a) For any small ∞-category $\mathcal{G}$, the presheaf ∞-category $\mathcal{P}(\mathcal{G}) = \mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S})$ is an ∞-topos.

(b) If $\mathcal{Y}$ is an ∞-topos and $\mathcal{X} \subseteq \mathcal{Y}$ is an accessible left exact localization of $\mathcal{Y}$, then $\mathcal{X}$ is also an ∞-topos.

(c) Every ∞-topos $\mathcal{X}$ can be obtained by combining (a) and (b): more precisely, there is an equivalence from $\mathcal{X}$ to an accessible left exact localization of $\mathcal{P}(\mathcal{G})$, for some small ∞-category $\mathcal{G}$.

In §20.2, we established an analogue of (a) in the setting of fractured ∞-topoi. More precisely, we proved that for any small ∞-category $\mathcal{G}$ equipped with an admissibility structure, the presheaf ∞-category $\mathcal{P}(\mathcal{G})$ can be regarded as a fractured ∞-topos (Theorem 20.2.4.1). Our goal in this section is to establish "fractured" analogues of (b) and (c). Given a fractured ∞-topos $\mathcal{Y}^{\mathrm{corp}} \subseteq \mathcal{Y}$ we introduce the notion of a *fractured localization* $\mathcal{X}_0 \subseteq \mathcal{Y}^{\mathrm{corp}}$ (Definition **??**). Our first main result is that any fractured localization $\mathcal{X}_0 \subseteq \mathcal{Y}^{\mathrm{corp}}$ determines an accessible left exact localization $\mathcal{X} \subseteq \mathcal{Y}$ and a fracture subcategory $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ which is equivalent to $\mathcal{X}_0$ (Theorem 20.5.1.2). We then show that every fractured ∞-topos $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ can be obtained by applying this construction to a fractured ∞-topos of the form $\mathcal{P}(\mathcal{G})$, where $\mathcal{G}$ is a small ∞-category equipped with an admissibility structure (Theorem **??**).

20.5.1 Fractured Localizations

We begin by introducing some terminology.

Definition 20.5.1.1. Let $\mathcal{Y}^{\mathrm{corp}} \subseteq \mathcal{Y}$ be a fractured ∞-topos. We say that a full subcategory $\mathcal{X}_0 \subseteq \mathcal{Y}^{\mathrm{corp}}$ is a *fractured localization* of $\mathcal{Y}^{\mathrm{corp}}$ if the following conditions are satisfied:

(a) The inclusion $\mathcal{X}_0 \hookrightarrow \mathcal{Y}^{\mathrm{corp}}$ admits a left exact left adjoint $L_0 : \mathcal{Y}^{\mathrm{corp}} \to \mathcal{X}_0$. Moreover, L_0 is accessible when regarded as a functor from $\mathcal{Y}^{\mathrm{corp}}$ to itself (so that $\mathcal{X}_0$ is an ∞-topos: see Theorem HTT.6.1.0.6).

(b) Let $j^* : \mathcal{Y} \to \mathcal{Y}^{\mathrm{corp}}$ be a right adjoint to the inclusion, and form a pullback diagram of ∞-categories σ :

$$\begin{array}{ccc} \mathcal{X} & \longrightarrow & \mathcal{Y} \\ \downarrow{\scriptstyle \overline{j}^*} & & \downarrow{\scriptstyle j^*} \\ \mathcal{X}_0 & \longrightarrow & \mathcal{Y}^{\mathrm{corp}} . \end{array}$$

Then the diagram σ is left adjointable. In other words, for each object $Y \in \mathcal{Y}$, the canonical map $L_0 j^* Y \to \overline{j}^* LY$ is an equivalence, where $L : \mathcal{Y} \to \mathcal{X}$ denotes a left adjoint to the inclusion (which exists by virtue of Theorem HTT.5.5.3.18).

We can now formulate our main result:

Theorem 20.5.1.2. *Let $\mathcal{Y}^{\mathrm{corp}} \subseteq \mathcal{Y}$ be a fractured ∞-topos, let $\mathcal{X}_0 \subseteq \mathcal{Y}^{\mathrm{corp}}$ be a fractured localization of $\mathcal{Y}$, and form a pullback diagram of ∞-categories*

$$\begin{array}{ccc} \mathcal{X} & \longrightarrow & \mathcal{Y} \\ \downarrow{\scriptstyle \overline{j}^*} & & \downarrow{\scriptstyle j^*} \\ \mathcal{X}_0 & \longrightarrow & \mathcal{Y}^{\mathrm{corp}}. \end{array}$$

Then:

(1) *The inclusion functor $\mathcal{X} \hookrightarrow \mathcal{Y}$ admits an (accessible) left exact left adjoint $L : \mathcal{Y} \to \mathcal{X}$. In particular, the ∞-category $\mathcal{X}$ is an ∞-topos.*

(2) *The functor $\overline{j}^*$ admits a left adjoint $\overline{j}_! : \mathcal{X}_0 \hookrightarrow \mathcal{X}$.*

(3) *The functor $\overline{j}_!$ induces an equivalence from $\mathcal{X}_0$ to a fracture subcategory $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$.*

Warning 20.5.1.3. In the statement of Theorem 20.5.1.2, the ∞-categories $\mathcal{X}_0$ and $\mathcal{X}^{\mathrm{corp}}$ do not coincide as subcategories of $\mathcal{Y}$ (though they are canonically equivalent to one another via the functor $\overline{j}_!$).

The remainder of this section is devoted to the proof of Theorem 20.5.1.2. We begin by observing that Theorem HTT.5.5.3.18 guarantees that the ∞-category $\mathcal{X}$ is presentable, that the inclusion $\mathcal{X} \hookrightarrow \mathcal{Y}$ admits a left adjoint $L : \mathcal{Y} \to \mathcal{X}$, and that the functor $\overline{j}^*$ admits a left adjoint $\overline{j}_!$. Our assumption that $\mathcal{X}_0 \subseteq \mathcal{Y}^{\mathrm{corp}}$ is a fractured localization guarantees that the diagram

$$\begin{array}{ccc} \mathcal{Y} & \xrightarrow{L} & \mathcal{X} \\ \downarrow{\scriptstyle j^*} & & \downarrow{\scriptstyle \overline{j}^*} \\ \mathcal{Y}^{\mathrm{corp}} & \xrightarrow{L_0} & \mathcal{X}_0 \end{array}$$

commutes up to canonical homotopy, where $L_0 : \mathcal{Y}^{\mathrm{corp}} \to \mathcal{X}_0$ is left adjoint to the inclusion. Since L_0 and j^* are left exact, the composite functor $\overline{j}^* \circ L$ is left exact. The functor $\overline{j}^*$ preserves small limits (since it admits a left adjoint) and is conservative (since j^* is conservative), so the functor L is left exact. This completes the proof of assertions (1) and (2) of Theorem 20.5.1.2.

The proof of (3) will require some preliminary observations.

Lemma 20.5.1.4. *The functor $\overline{j}_! : \mathcal{X}_0 \to \mathcal{X}$ preserves pullbacks.*

Proof. The commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathcal{X} & \longrightarrow & \mathcal{Y} \\ \downarrow{\scriptstyle \overline{j}^*} & & \downarrow{\scriptstyle j^*} \\ \mathcal{X}_0 & \longrightarrow & \mathcal{Y} \end{array}$$

yields a commutative diagram of left adjoints

$$\begin{array}{ccc} \mathcal{X} & \xleftarrow{L} & \mathcal{Y} \\ \uparrow{\scriptstyle \overline{j}_!} & & \uparrow{\scriptstyle j_!} \\ \mathcal{X}_0 & \xleftarrow{L_0} & \mathcal{Y}^{\mathrm{corp}}, \end{array}$$

where $j_!$ denotes the inclusion functor. In other words, we can identify $\overline{j}_!$ with the restriction $(L \circ j_!)|_{\mathcal{X}_0}$. Since L is left exact and $j_!$ preserves pullbacks, it follows that $\overline{j}_!$ preserves pullbacks. □

Lemma 20.5.1.5. *For each object $X \in \mathcal{X}_0$, the unit map $\overline{u}_X : X \to \overline{j}^* \overline{j}_! X$ is (-1)-truncated.*

Proof. Unwinding the definitions, we see that $\overline{u}_X$ can be obtained by applying the functor L_0 to the morphism $u_X : X \to j^* j_! X$ of $\mathcal{Y}^{\mathrm{corp}}$. Since the morphism u_X is (-1)-truncated (Proposition 20.1.3.1) and L_0 is left exact, we conclude that $\overline{u}_X$ is (-1)-truncated. □

Notation 20.5.1.6. Let U and V be objects of $\mathcal{X}_0$. It follows from Lemma 20.5.1.5 that the canonical map

$$\mathrm{Map}_{\mathcal{X}_0}(U, V) \to \mathrm{Map}_{\mathcal{X}_0}(U, \overline{j}^* \overline{j}_! V) \simeq \mathrm{Map}_{\mathcal{X}}(\overline{j}_! U, \overline{j}_! V)$$

is (-1)-truncated. We will say that a morphism $f : \overline{j}_! U \to \overline{j}_! V$ is *admissible* if it belongs to the essential image of θ: that is, if f is homotopic to $\overline{j}_!(f_0)$, for some morphism $f_0 : U \to V$.

Lemma 20.5.1.7. *Suppose we are given objects $X_0, X_1, X_2, X_3 \in \mathcal{X}_0$ and morphisms $\overline{j}_! X_0 \xrightarrow{f} \overline{j}_! X_1 \xrightarrow{g} \overline{j}_! X_2 \xrightarrow{h} \overline{j}_! X_3$ in the ∞-category $\mathcal{X}$. If $g \circ f$ and $h \circ g$ are admissible, then f is admissible.*

Proof. Since the functor L_0 is essentially surjective, we can assume without loss of generality that $X_i = L_0 Y_i$ for $0 \leqslant i \leqslant 3$, for some objects $Y_i \in \mathcal{Y}^{\mathrm{corp}}$. We now proceed in several steps:

- Regard h as a morphism from $\overline{j}_! L_0(Y_2) \simeq LY_2$ to $\overline{j}_! L_0(Y_3) \simeq LY_3$. Replacing Y_2 by the pullback $Y_2 \times_{\overline{j}^* LY_3} j^* Y_3$, we can reduce to the case where h is homotopic to $L(h')$, for some map $h' : Y_2 \to Y_3$ in the ∞-category $\mathcal{Y}$.

- Regard g as a morphism from $\overline{j}_! L_0(Y_1) \simeq LY_1$ to $\overline{j}_! L_0(Y_2) \simeq LY_2$. Replacing Y_1 by the pullback $Y_1 \times_{\overline{j}^* LY_2} j^* Y_2$, we can reduce to the case where g is homotopic to $L(g')$, for some map $g' : Y_1 \to Y_2$ in the ∞-category $\mathcal{Y}$.

- Replacing Y_1 by the fiber product $Y_1 \times_{j^* Y_3} Y_3$ (which does not change the image of Y_1 under the functor L_0, by virtue of our assumption that $h \circ g$ is admissible), we can arrange that the composition $h' \circ g'$ is a morphism of $\mathcal{Y}^{\mathrm{corp}}$.

- Regard f as a morphism from $\overline{j}_! L_0(Y_0) \simeq LY_0$ to $\overline{j}_! L_0(Y_1) \simeq LY_1$. Replacing Y_0 by the pullback $Y_0 \times_{\overline{j}^* LY_1} j^* Y_1$, we can reduce to the case where f is homotopic to $L(f')$, for some map $f' : Y_0 \to Y_1$ in the ∞-category $\mathcal{Y}$.

- Replacing Y_0 by the fiber product $Y_0 \times_{j^* Y_2} Y_2$ (which does not change the image of Y_0 under the functor L_0, by virtue of our assumption that $g \circ f$ is admissible), we can arrange that the composition $g' \circ f'$ is a morphism of $\mathcal{Y}^{\mathrm{corp}}$.

Let us regard the ∞-category $\mathcal{Y}$ as equipped with the admissibility structure of Proposition 20.3.1.3, so that $g' \circ f'$ and $h' \circ g'$ are admissible morphisms in $\mathcal{Y}$. Applying Corollary 20.2.2.9, we deduce that f' is also admissible: that is, it is contained in $\mathcal{Y}^{\mathrm{corp}}$ (Example 20.3.1.2). It follows that $f \simeq L(f') \simeq j_!(L_0(f'))$ is an admissible morphism in $\mathcal{X}$, in the sense of Notation 20.5.1.6. □

Lemma 20.5.1.8. *Let U and V be objects of $\mathcal{X}_0$. Then every equivalence $f : \overline{j}_! U \simeq \overline{j}_! V$ is admissible.*

Proof. Let f^{-1} be a homotopy inverse to f, and apply Lemma 20.5.1.7 to the diagram

$$\overline{j}_! U \xrightarrow{f} \overline{j}_! V \xrightarrow{f^{-1}} \overline{j}_! U \xrightarrow{f} \overline{j}_! V.$$

□

Lemma 20.5.1.9. *The functor $\overline{j}_! : \mathcal{X}_0 \to \mathcal{X}$ induces an equivalence from $\mathcal{X}_0$ to a replete subcategory $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$.*

Proof. Combine Lemma 20.5.1.5, Lemma 20.5.1.8, and Proposition 20.1.1.5. □

Proof of Theorem 20.5.1.2. Let $\mathcal{X}^{\mathrm{corp}}$ be as in Lemma 20.5.1.9; we wish to show that $\mathcal{X}^{\mathrm{corp}}$ is a fracture subcategory of $\mathcal{X}$. To prove this, it suffices to verify that the functor $\overline{j}_! : \mathcal{X}_0 \to \mathcal{X}$ satisfies analogues of conditions (1), (2), and (3) of Definition 20.1.2.1:

(1) The functor $\overline{j}_!$ preserves pullbacks: this follows from Lemma 20.5.1.4.

(2) The functor $\overline{j}_!$ admits a right adjoint $\overline{j}^*$, which is conservative and preserves small limits. The existence of $\overline{j}^*$ follows from our construction. The statement that $\overline{j}^*$ is conservative follows from the commutativity of the diagram

$$\begin{array}{ccc} \mathcal{X} & \longrightarrow & \mathcal{Y} \\ \downarrow{\scriptstyle \overline{j}^*} & & \downarrow{\scriptstyle j^*} \\ \mathcal{X}_0 & \longrightarrow & \mathcal{Y}^{\mathrm{corp}}, \end{array}$$

since the functor j^* is conservative. To show that $\overline{j}^*$ preserves small colimits, we use the commutativity of the diagram

$$\begin{array}{ccc} \mathcal{Y} & \xrightarrow{L} & \mathcal{X} \\ \downarrow{\scriptstyle j^*} & & \downarrow{\scriptstyle \overline{j}^*} \\ \mathcal{Y}^{\mathrm{corp}} & \xrightarrow{L_0} & \mathcal{X}_0 \end{array}$$

together with the fact that j^* preserves small colimits.

(3) Let $f : U \to V$ be a morphism in $\mathcal{X}_0$; we wish to show that the induced diagram σ :

$$\begin{array}{ccc} \overline{j}_!\overline{j}^*\overline{j}_!U & \longrightarrow & \overline{j}_!\overline{j}^*\overline{j}_!V \\ \downarrow & & \downarrow \\ \overline{j}_!U & \longrightarrow & \overline{j}_!V \end{array}$$

is a pullback square in $\mathcal{X}$. Let us identify U and V with their images in $\mathcal{Y}^{\mathrm{corp}}$, so that σ is obtained by applying the functor L to the diagram σ_0

$$\begin{array}{ccc} j_!j^*j_!U & \longrightarrow & j_!j^*j_!V \\ \downarrow & & \downarrow \\ j_!U & \longrightarrow & j_!V. \end{array}$$

The diagram σ_0 is a pullback square in $\mathcal{Y}$ by virtue of our assumption that $\mathcal{Y}^{\mathrm{corp}} \subseteq \mathcal{Y}$ is a fracture subcategory. Since the functor $L : \mathcal{Y} \to \mathcal{X}$ is left exact, it follows that $\sigma \simeq L\sigma_0$ is a pullback square in $\mathcal{X}$.

□

20.5.2 Recognition of Fractured Localizations

Let $\mathcal{Y}^{\mathrm{corp}} \subseteq \mathcal{Y}$ be a fractured ∞-topos, let $\mathcal{X}_0 \subseteq \mathcal{Y}^{\mathrm{corp}}$ be a fractured localization, and define $\mathcal{X} = \mathcal{X}_0 \times_{\mathcal{Y}^{\mathrm{corp}}} \mathcal{Y}$ and $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ as in Theorem 20.5.1.2. We then have a commutative diagram of ∞-categories σ :

$$\begin{array}{ccc} \mathcal{Y}^{\mathrm{corp}} & \longrightarrow & \mathcal{Y} \\ \downarrow{\scriptstyle L^{\mathrm{corp}}} & & \downarrow{\scriptstyle L} \\ \mathcal{X}^{\mathrm{corp}} & \longrightarrow & \mathcal{X}, \end{array}$$

where the horizontal maps are inclusions, the functor L is left adjoint to the inclusion $\mathcal{X} \hookrightarrow \mathcal{Y}$, and L_0 is obtained by composing a left adjoint to the inclusion $\mathcal{X}_0 \hookrightarrow \mathcal{Y}^{\mathrm{corp}}$ with the equivalence $\mathcal{X}_0 \simeq \mathcal{X}^{\mathrm{corp}}$. Moreover, the condition that $\mathcal{X}_0 \subseteq \mathcal{X}$ is a fractured localization guarantees that the diagram σ is right adjointable. We now establish a converse to this assertion:

Proposition 20.5.2.1. *Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ and $\mathcal{Y}^{\mathrm{corp}} \subseteq \mathcal{Y}$ be fractured ∞-topoi. Suppose we are given a commutative diagram of ∞-categories σ :*

$$\begin{array}{ccc} \mathcal{Y}^{\mathrm{corp}} & \longrightarrow & \mathcal{Y} \\ \downarrow{\scriptstyle L^{\mathrm{corp}}} & & \downarrow{\scriptstyle L} \\ \mathcal{X}^{\mathrm{corp}} & \longrightarrow & \mathcal{X}, \end{array}$$

where σ is right adjointable and the functor L^{corp} exhibits $\mathcal{X}^{\mathrm{corp}}$ as a left exact localization of $\mathcal{Y}^{\mathrm{corp}}$ (that is, the functor L^{corp} is left exact and has a fully faithful right adjoint). Then:

(1) *The functor L exhibits $\mathcal{X}$ as a left exact localization of $\mathcal{Y}$ (that is, the functor L is left exact and has a fully faithful right adjoint).*

(2) *Let $U^{\mathrm{corp}} : \mathcal{X}^{\mathrm{corp}} \to \mathcal{Y}^{\mathrm{corp}}$ be a right adjoint to L^{corp} and let $\mathcal{X}_0 \subseteq \mathcal{Y}$ be the essential image of U^{corp}. Then $\mathcal{X}_0$ is a fractured localization of $\mathcal{Y}^{\mathrm{corp}}$.*

(3) *Taking right adjoints of the functors appearing in the diagram σ yields a pullback diagram of ∞-categories σ^R:*

$$\begin{array}{ccc} \mathcal{X} & \xrightarrow{U} & \mathcal{Y} \\ \downarrow & & \downarrow \\ \mathcal{X}^{\mathrm{corp}} & \xrightarrow{U^{\mathrm{corp}}} & \mathcal{Y}^{\mathrm{corp}}. \end{array}$$

In other words, $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ is canonically equivalent to the fractured ∞-topos obtained by applying Theorem 20.5.1.2 to the fractured localization $\mathcal{X}_0 \subseteq \mathcal{Y}^{\mathrm{corp}}$.

Remark 20.5.2.2. In the statement of Proposition 20.5.2.1, we do not assume *a priori* that the functor L is left exact (the left exactness of L is part of the conclusion, not the hypothesis).

Proof of Proposition 20.5.2.1. Let $j^* : \mathcal{Y} \to \mathcal{Y}^{\mathrm{corp}}$ and $j'^* : \mathcal{X} \to \mathcal{X}^{\mathrm{corp}}$ denote right adjoints to the inclusion functors. Our assumption that σ is right adjointable supplies a commutative diagram of ∞-categories σ':

$$\begin{array}{ccc} \mathcal{Y} & \xrightarrow{j^*} & \mathcal{Y}^{\mathrm{corp}} \\ \downarrow L & & \downarrow L^{\mathrm{corp}} \\ \mathcal{X} & \xrightarrow{j'^*} & \mathcal{X}^{\mathrm{corp}} . \end{array}$$

The functor L^{corp} admits a right adjoint, and therefore preserves small colimits. Since j^* preserves small colimits, we conclude that $L^{\mathrm{corp}} \circ j^* \simeq j'^* \circ L$ preserves small colimits. The functor j'^* is conservative and preserves small colimits, so L preserves small colimits. Consequently, the diagram σ^R appearing in statement (3) is well-defined.

Let $U : \mathcal{X} \to \mathcal{Y}$ denote a right adjoint to L. We next claim that U is fully faithful. To prove this, it will suffice to show that for each object $X \in \mathcal{X}$, the counit map $v_X : (L \circ U)(X) \to X$ is an equivalence. Since the functor j'^* is conservative, it will suffice to show that $j'^*(v_X)$ is an equivalence in the ∞-category $\mathcal{X}^{\mathrm{corp}}$. Using the commutativity of the diagrams σ^R and σ', we can identify $j'^*(v_X)$ with the counit map $(L^{\mathrm{corp}} \circ U^{\mathrm{corp}})(j'^* X) \to j'^* X$, which is an equivalence by virtue of our assumption that U^{corp} is fully faithful.

We now prove (3). Since U and U^{corp} are fully faithful, it will suffice to show that if $Y \in \mathcal{Y}$ has the property that $j^* Y$ belongs to the essential image of U^{corp}, then Y belongs to the essential image of U. To show that Y belongs to the essential image of U, it will suffice to show that the unit map $u_Y : Y \to (U \circ L)(Y)$ is an equivalence in $\mathcal{Y}$. Because the functor j^* is conservative, we are reduced to showing that $j^*(u_Y)$ is an equivalence in $\mathcal{Y}^{\mathrm{corp}}$. Using the commutativity of the diagrams σ^R and σ', we can identify $j^*(u_Y)$ with the unit map $j^* Y \to (U^{\mathrm{corp}} \circ L^{\mathrm{corp}}(j^* Y)$ in the ∞-category $\mathcal{Y}^{\mathrm{corp}}$. This map is an equivalence, since $j^* Y$ belongs to the essential image of the functor U^{corp} by virtue of our assumption that $Y \in \mathcal{X}'$.

Using (3), we see that (2) is equivalent to the left adjointability of the diagram σ^R. This follows from our assumption that σ is right adjointable. Assertion (1) now follows from Theorem 20.5.1.2. □

20.5.3 Presentations of Fractured ∞-Topoi

We now show that every fractured ∞-topos can be obtained by combining the constructions of Theorems **??** and 20.5.1.2.

Definition 20.5.3.1. Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos. A *presentation of* $\mathcal{X}$ is a functor $h : \mathcal{G} \to \mathcal{X}$, where $\mathcal{G}$ is an essentially small ∞-category equipped with an admissibility structure and h satisfies the following conditions:

(1) The functor h carries $\mathcal{G}^{\mathrm{ad}}$ into $\mathcal{X}^{\mathrm{corp}}$ (in particular, h carries each object of $\mathcal{G}$ to a corporeal object of $\mathcal{X}$.

Let $F : \mathcal{P}(\mathcal{G}) \to \mathcal{X}$ be the colimit-preserving functor determined by h and let $\mathcal{P}(\mathcal{G})^{\mathrm{corp}} \subseteq \mathcal{P}(\mathcal{G})$ be the fracture subcategory of Theorem **??**. It follows from (a) that the functor F carries $\mathcal{P}(\mathcal{G})^{\mathrm{corp}}$ into $\mathcal{X}^{\mathrm{corp}}$, so we obtain a commutative diagram σ :

$$\begin{array}{ccc} \mathcal{P}(\mathcal{G})^{\mathrm{corp}} & \longrightarrow & \mathcal{P}(\mathcal{G}) \\ \downarrow{\scriptstyle F^{\mathrm{corp}}} & & \downarrow{\scriptstyle F} \\ \mathcal{X}^{\mathrm{corp}} & \longrightarrow & \mathcal{X} . \end{array}$$

(2) The diagram σ satisfies the hypotheses of Proposition 20.5.2.1. That is, the diagram σ is right adjointable, and the functor F^{corp} exhibits $\mathcal{X}^{\mathrm{corp}}$ as a left exact localization of $\mathcal{P}(\mathcal{G})^{\mathrm{corp}}$.

Remark 20.5.3.2. Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos and let $h : \mathcal{G} \to \mathcal{X}$ be a presentation of $\mathcal{X}$. Then the functor h is dense and locally left exact: this follows from Proposition 20.5.2.1.

Remark 20.5.3.3. Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos and let $h : \mathcal{G} \to \mathcal{X}$ be a presentation of $\mathcal{X}$. Applying Proposition 20.5.2.1, we conclude that the underlying map $h|_{\mathcal{G}^{\mathrm{ad}}} : \mathcal{G}^{\mathrm{ad}} \to \mathcal{X}^{\mathrm{corp}}$ induces a fully faithful embedding $\mathcal{X}^{\mathrm{corp}} \hookrightarrow \mathcal{P}(\mathcal{G}^{\mathrm{ad}}) \simeq \mathcal{P}(\mathcal{G})^{\mathrm{corp}}$, whose essential image is a fractured localization in the sense of Definition 20.5.1.1. Moreover, the fractured ∞-topos $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ can then be recovered (up to canonical equivalence) by applying the construction of Theorem 20.5.1.2 to this fractured localization.

We can now formulate our main result:

Theorem 20.5.3.4. *Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos. Then $\mathcal{X}$ admits a presentation $h : \mathcal{G} \to \mathcal{X}$, where $\mathcal{G}$ is an essentially small ∞-category equipped with an admissibility structure. Moreover, we can arrange that h is fully faithful, and that a morphism in $\mathcal{G}$ is admissible if and only if its image in $\mathcal{X}$ is admissible.*

Before giving the proof of Theorem 20.5.3.4, let us spell out Definition 20.5.3.1 in more detail.

Lemma 20.5.3.5. *Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos, let $\mathcal{G}$ be an essentially small ∞-category equipped with an admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$, and let $h : \mathcal{G} \to \mathcal{X}$ be a functor. Then h is presentation of $\mathcal{X}$ if and only if it satisfies the following conditions:*

(a) *The functor h carries $\mathcal{G}^{\mathrm{ad}}$ into $\mathcal{X}^{\mathrm{corp}}$.*

(b) *The induced functor $h^{\mathrm{ad}} : \mathcal{G}^{\mathrm{ad}} \to \mathcal{X}^{\mathrm{corp}}$ is locally left exact (Definition 20.4.2.1).*

(c) *The functor $h^{\mathrm{ad}} : \mathcal{G}^{\mathrm{ad}} \to \mathcal{X}^{\mathrm{corp}}$ is dense (Definition 20.4.1.1).*

(d) *For every object $X \in \mathcal{G}$, the canonical map $\varinjlim_{Y \in (\mathcal{G}_{/X})^{\mathrm{ad}}} f(Y) \to f(X)$ in the ∞-topos $\mathcal{X}$ induces an equivalence $\varinjlim_{Y \in (\mathcal{G}_{/X})^{\mathrm{ad}}} f(Y) \to j^* f(X)$, where $j^* : \mathcal{X} \to \mathcal{X}^{\mathrm{corp}}$ is right adjoint to the inclusion functor.*

Proof. Condition (a) is clearly necessary, so assume that it is satisfied. Let $H : \mathcal{P}(\mathcal{G}) \to \mathcal{X}$ be the colimit preserving functor determined by h and define $H^{\mathrm{ad}} : \mathcal{P}(\mathcal{G}^{\mathrm{ad}}) \to \mathcal{X}^{\mathrm{corp}}$ similarly. Then the functor $H^{\mathrm{corp}} : \mathcal{P}(\mathcal{G})^{\mathrm{corp}} \to \mathcal{X}^{\mathrm{corp}}$ can be identified with the composition of H^{ad} with a homotopy inverse to the equivalence $\mathcal{P}(\mathcal{G}^{\mathrm{ad}}) \simeq \mathcal{P}(\mathcal{G})^{\mathrm{corp}}$ given by left Kan extension along the inclusion $\mathcal{G}^{\mathrm{ad}}$. Consequently, the functor H^{corp} is left exact if and only if condition (b) is satisfied, and H^{corp} has a fully faithful right adjoint if and only if condition (c) is satisfied. To complete the proof, it will suffice to show that (d) is equivalent to the right adjointability of the diagram σ :

$$\begin{array}{ccc} \mathcal{P}(\mathcal{G}^{\mathrm{ad}}) & \longrightarrow & \mathcal{P}(\mathcal{G}) \\ \downarrow{\scriptstyle F^{\mathrm{ad}}} & & \downarrow{\scriptstyle F} \\ \mathcal{X}^{\mathrm{corp}} & \longrightarrow & \mathcal{X}. \end{array}$$

Let $U : \mathcal{P}(\mathcal{G}) \to \mathcal{P}(\mathcal{G}^{\mathrm{ad}})$ denote the restriction functor and let $j^* : \mathcal{X} \to \mathcal{X}^{\mathrm{corp}}$ denote a right adjoint to the inclusion, so that σ determines a natural transformation of functors $\alpha : F^{\mathrm{ad}} \circ U \to j^* \circ F$. Note that the domain and codomain of α are colimit-preserving functors, so that α is an equivalence if and only if it induces an equivalence after evaluation on the representable functor $\mathrm{Map}_{\mathcal{G}}(\bullet, X)$ for each $X \in \mathcal{G}$. The equivalence of this assertion with (d) now follows by unwinding the definitions. □

Proof of Theorem 20.5.3.4. Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a fractured ∞-topos. Then $\mathcal{X}^{\mathrm{corp}}$ is a presentable ∞-category, so we can choose an essentially small dense subcategory $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{X}^{\mathrm{corp}}$. Enlarging $\mathcal{G}^{\mathrm{ad}}$ if necessary, we may assume that it has the following closure property

(∗) For every morphism $f : U \to X$ in $\mathcal{G}^{\mathrm{ad}}$ and every morphism $g : X' \to X$, where X' belongs to $\mathcal{G}^{\mathrm{ad}}$, the fiber product $X' \times_X U$ belongs to $\mathcal{G}^{\mathrm{ad}}$.

Let $\mathcal{G}$ be the full subcategory of $\mathcal{X}$ having the same objects as $\mathcal{G}^{\mathrm{ad}}$. Using (∗), we deduce that $\mathcal{G}^{\mathrm{ad}}$ is an admissibility structure on $\mathcal{G}$ (see Proposition 20.3.1.3). We will complete the proof by showing that the inclusion map $\iota : \mathcal{G} \to \mathcal{X}$ is a presentation of $\mathcal{X}$. To prove this, it suffices to verify conditions (a), (b), (c), and (d) of Lemma 20.5.3.5. Conditions (a) and (c) are automatic, and (b) follows from Corollary 20.4.3.3. To verify (d), choose an object $X \in \mathcal{G}$. Let $j^* : \mathcal{X} \to \mathcal{X}^{\mathrm{corp}}$ be a right adjoint to the inclusion, so that we have a canonical equivalence $(\mathcal{G}_{/X})^{\mathrm{ad}} \simeq \mathcal{G}^{\mathrm{ad}} \times_{\mathcal{X}^{\mathrm{corp}}} \mathcal{X}^{\mathrm{corp}}_{/j^*X}$. We are therefore reduced to showing that the canonical map $\varinjlim_{Y \in \mathcal{G}^{\mathrm{ad}} \times_{\mathcal{X}^{\mathrm{corp}}} \mathcal{X}^{\mathrm{corp}}_{/j^*X}} Y \to j^*X$ is an equivalence, which follows from our assumption that $\mathcal{G}^{\mathrm{ad}}$ is dense in $\mathcal{X}^{\mathrm{corp}}$. □

Remark 20.5.3.6. The proof of Theorem 20.5.3.4 shows that if $\mathcal{G}$ is a full subcategory of $\mathcal{X}$ spanned by corporeal objects such that $\mathcal{G}^{\mathrm{ad}} = \mathcal{X}^{\mathrm{corp}} \cap \mathcal{G}$ is dense in $\mathcal{X}^{\mathrm{corp}}$ and satisfies condition $(*)$, then $\mathcal{G}$ is dense in $\mathcal{X}$.

Remark 20.5.3.7. In the proof of Theorem 20.5.3.4, the subcategory $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{X}^{\mathrm{corp}}$ can be chosen as large as we like: in particular, we can arrange that it contains any small collection of corporeal objects of $\mathcal{X}$.

20.5.4 Finite Limits of Corporeal Objects

In the situation of Theorem 20.5.3.4, we can arrange that the properties of the ∞-category $\mathcal{G}$ mirror the properties of the fractured ∞-topos $\mathcal{X}$. For example, we have the following:

Proposition 20.5.4.1. *Let $\mathcal{X}^{\mathrm{corp}} \subseteq \mathcal{X}$ be a complete fractured ∞-topos (Definition 20.3.3.9). The following conditions are equivalent:*

(1) *Let $\mathcal{X}_{\mathrm{corp}}$ be the full subcategory of $\mathcal{X}$ spanned by the corporeal objects (that is, the essential image of the inclusion $\mathcal{X}^{\mathrm{corp}} \hookrightarrow \mathcal{X}$). Then $\mathcal{X}_{\mathrm{corp}}$ is closed under finite limits.*

(2) *There exists a presentation $h : \mathcal{G} \to \mathcal{X}$, where $\mathcal{G}$ is an essentially small ∞-category which admits finite limits, the functor h is fully faithful, and a morphism in $\mathcal{G}$ is admissible if and only if its image belongs to $\mathcal{X}^{\mathrm{corp}}$.*

(3) *There exists a presentation $h : \mathcal{G} \to \mathcal{X}$, where the ∞-category $\mathcal{G}$ admits finite limits.*

Proof. The implication (1) ⇒ (2) follows from the proof of Theorem 20.5.3.4 (where we replace condition $(*)$ by the requirement that $\mathcal{G}$ is closed under finite limits), and the implication (2) ⇒ (3) is trivial. We will show that (3) ⇒ (1). Suppose that $h : \mathcal{G} \to \mathcal{X}$ is a presentation and that $\mathcal{G}$ admits finite limits. Let $\mathcal{X}_0 \subseteq \mathcal{X}$ be the essential image of h. Then $\mathcal{X}_0 \subseteq \mathcal{X}$ is dense (Remark 20.4.1.11) and consists of corporeal objects of $\mathcal{X}$. Note that the functor h is left exact (Lemma 20.5.3.5 and Remark 20.4.2.2), and therefore preserves final objects. In particular, the final object of $\mathcal{X}$ is corporeal. We will complete the proof by showing that the full subcategory $\mathcal{X}_{\mathrm{corp}} \subseteq \mathcal{X}$ is closed under fiber products.

Let us say that a morphism in $\mathcal{X}$ is *admissible* if it is $\mathcal{X}^{\mathrm{corp}}$-admissible (Definition 20.3.1.1). Our assumption that $\mathcal{X}$ is complete guarantees that an object $X \in \mathcal{X}$ is corporeal if and only if it is $\mathcal{X}^{\mathrm{ad}}$-corporeal, where $\mathcal{X}^{\mathrm{ad}} \subseteq \mathcal{X}$ is the subcategory spanned by the admissible morphisms (Proposition 20.3.3.11). Suppose we are given a pullback diagram σ :

$$\begin{array}{ccc} X_{01} & \longrightarrow & X_0 \\ \downarrow & & \downarrow v \\ X_1 & \xrightarrow{w} & X \end{array}$$

in the ∞-topos $\mathcal{X}$, where X_0, X_1, and X are corporeal; we wish to prove that X_{01} is corporeal. Using Proposition 20.3.3.12, we deduce that there exists an admissible effective epimorphism $\amalg U_\alpha \to X$ in $\mathcal{X}$, where each U_α is a retract of an object V_α which admits an admissible morphism $V_\alpha \to W_\alpha$ for some W_α in $\mathcal{X}_0$. We then have an admissible effective epimorphism $\amalg U_\alpha \times_X X_{01} \to X_{01}$. Consequently, to prove that X_{01} is corporeal, it will suffice to show that each fiber product $U_\alpha \times_X X_{01}$ is corporeal (Proposition 20.3.3.8). Replacing X by U_α (and the objects X_i by the fiber products $X_i \times_X U_\alpha$), we may reduce to the case where X is a retract of an object V which admits an admissible morphism $V \to W$ for $W \in \mathcal{X}_0$. Then $X_{01} \simeq X_0 \times_X X_1$ is a retract of $X_0 \times_V X_1$. Since the collection of corporeal objects of $\mathcal{X}$ is closed under retracts (Proposition 20.3.3.8), we can replace X by V and thereby reduce to the case where there exists an admissible morphism $X \to W$, where $W \in \mathcal{X}_0$. We have a commutative diagram

$$\begin{array}{ccc} X & \xrightarrow{\delta} & X \times_W X \\ & \searrow \quad \swarrow & \\ & W & \end{array}$$

where the vertical maps are admissible, so that δ is also an admissible morphism. It follows that the map

$$X_{01} \simeq X_0 \times_X X \times_X X_1 \to X_0 \times_X (X \times_W X) \times_X X_1 \simeq X_0 \times_W X_1$$

is also admissible. Using Proposition 20.3.3.8 again, we are reduced to proving that $X_0 \times_W X_1$ is corporeal. We may therefore replace X by W and thereby reduce to the case where $X \in \mathcal{X}_0$, so that $X \simeq h(Z)$ for some object $Z \in \mathcal{G}$.

We now apply similar reasoning to the object X_0. Invoking Proposition 20.3.3.12, we can choose an admissible effective epimorphism $\amalg U'_\beta \to X_0$ where each U'_β is a retract of an object V'_β which admits an admissible morphism $V'_\beta \to W'_\beta$ for some $W'_\beta \in \mathcal{X}_0$. We then have an admissible effective epimorphism $\amalg U'_\beta \times_X X_1 \to X_{01}$. Using Proposition 20.3.3.8, we are reduced to proving that each fiber product $U'_\beta \times_X X_1$ is corporeal. Since U'_β is a retract of V'_β, the composite map $U'_\beta \to X_0 \to X$ factors through a map $V'_\beta \to X$ for which $U'_\beta \times_X X_1$ is a retract of $V'_\beta \times_X X_1$. Write $W'_\beta = h(Y)$ for some $Y \in \mathcal{G}$. Since h is a presentation of $\mathcal{X}$, the object $V'_\beta \in \mathcal{X}$ can be written as a colimit of objects of the form $h(Y')$ for $Y' \in \mathcal{G}^{\mathrm{ad}}_{/Y}$ (this follows from the density of the functor $\mathcal{G}^{\mathrm{ad}}_{/Y} \to \mathcal{X}^{\mathrm{corp}}_{/h(Y)}$; see Remark 20.4.2.5). In particular, there exists an admissible effective epimorphism $\amalg h(Y_\gamma) \to V'_\beta$, hence an admissible effective epimorphism $\amalg h(Y_\gamma) \times_X X_1 \to V'_\beta \times_X X_1$. We may therefore replace X_0 by $h(Y_\gamma)$ and thereby reduce to the case where X_0 has the form $h(Z_0)$ for some $Z_0 \in \mathcal{G}$.

The morphism $h(Z_0) = X_0 \xrightarrow{v} X = h(Z)$ need not be the image under h of a morphism $Z_0 \to Z$ in $\mathcal{G}$. However, our assumption that $h : \mathcal{G} \to \mathcal{X}$ is a presentation guarantees that we can can choose a collection of admissible morphisms $\{Z_\gamma \to Z_0\}$ in $\mathcal{G}$ which determine an effective epimorphism $\amalg h(Z_\gamma) \to h(Z_0)$, for which each of the composite maps $h(Z_\gamma) \to h(Z_0) = X_0 \to X = h(Z)$ is induced by a morphism $Z_\gamma \to Z$ in the ∞-category $\mathcal{G}$. We then have an admissible effective epimorphism $\amalg h(Z_\gamma) \to h(Z_0)$, which gives rise to an admissible effective epimorphism

$$\amalg h(Z_\gamma) \times_X X_1 \to X_0 \times_X X_1.$$

Using Proposition 20.3.3.8, are reduced to proving that each of the fiber products $h(Z_\gamma) \times_X X_1$ is corporeal. We may therefore replace X_0 by $h(Z_\gamma)$ and thereby reduce to the case where $v : X_0 \to X$ has the form $h(v_0)$ for some morphism $v_0 : Z_0 \to Z$ in the ∞-category $\mathcal{G}$. Similarly, we can assume that w has the form $h(w_0)$ for some morphism $w_0 : Z_1 \to Z$ in $\mathcal{G}$. Since the functor h is left exact, it follows that $X_{01} = h(Z_0) \times_{h(Z)} h(Z_1) \simeq h(Z_0 \times_Z Z_1)$ belongs to the essential image of h, and is therefore corporeal. □

20.6 Geometric Sites

Let X be a quasi-compact, quasi-separated scheme, and let Sch_X denote the category whose objects are X-schemes of finite presentation, endowed with the étale topology. In §20.1, we asserted without proof that the ∞-category $\mathcal{S}\mathrm{hv}(\mathrm{Sch}_X) = \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathrm{Sch}_X)$ can be regarded as a fractured ∞-topos (in the sense of Definition 20.1.2.1). Our goal in this section is to prove a more general form of this assertion. We begin by introducing the notion of a *geometric site* (Definition 20.6.2.1): an essentially small ∞-category $\mathcal{G}$ which is equipped with a Grothendieck topology τ and an admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$ satisfying an appropriate compatibility. Our main result asserts that for any geometric site $\mathcal{G}$, the ∞-category $\mathcal{S}\mathrm{hv}_\tau(\mathcal{G})$ inherits the structure of a fractured ∞-topos, whose subcategory of corporeal objects can be identified with $\mathcal{S}\mathrm{hv}_\tau(\mathcal{G}^{\mathrm{ad}})$ (Theorem 20.6.3.4). This result can be applied to the category $\mathcal{G} = \mathrm{Sch}_X$ by taking τ to be the topology generated by étale coverings and $\mathcal{G}^{\mathrm{ad}}$ to be the subcategory $\mathrm{Sch}_X^{\text{ét}} \subseteq \mathrm{Sch}_X$ of étale morphisms. We will consider several variants of this example in §20.6.4 (and will meet others in Part VII).

20.6.1 Restrictions of Grothendieck Topologies

Throughout this section, we assume that the reader is familiar with the theory of Grothendieck topologies on ∞-categories (see Definition HTT.6.2.2.1 or §A.3). If $\mathcal{G}$ is an ∞-category, we will typically use the symbol τ (or variants thereof) to denote a Grothendieck topology on $\mathcal{G}$. We will say that a collection of morphisms $\{f_\alpha : U_\alpha \to X\}$ in $\mathcal{G}$ is a *τ-covering* if it generates a covering sieve on X: that is, if the full subcategory $\mathcal{G}^{(0)}_{/X} \subseteq \mathcal{G}_{/X}$ spanned by those morphisms $f : U \to X$ which factor through some f_α is a covering sieve with respect to τ. We will denote the ∞-category of $\mathcal{S}$-valued sheaves on $\mathcal{G}$ by $\mathcal{S}\mathrm{hv}_\tau(\mathcal{G})$ to indicate its dependence on τ.

Proposition 20.6.1.1. *Let $f : \mathcal{G}' \to \mathcal{G}$ be a functor between ∞-categories and let τ be a Grothendieck topology on $\mathcal{G}$. Assume that $\mathcal{G}'$ admits pullbacks and that the functor f preserves pullbacks. Then there exists a Grothendieck topology $f^*\tau$ on $\mathcal{G}'$ which is characterized by the following property: a sieve $\mathcal{G}'^{(0)}_{/X} \subseteq \mathcal{G}'_{/X}$ is a covering sieve for $f^*\tau$ if and only if the collection of morphisms $\{f(U) \to f(X)\}_{U \in \mathcal{G}'^{(0)}_{/X}}$ is a τ-covering of X.*

Remark 20.6.1.2. In the statement of Proposition 20.6.1.1, we do not require that the ∞-category $\mathcal{G}$ admits finite limits (in fact, this condition is not satisfied in many examples of interest).

Proof of Proposition 20.6.1.1. We show that the collection of $(f^*\tau)$-covering sieves satisfies the conditions of Definition HTT.6.2.2.1:

(1) For each object $X \in \mathcal{G}'$, the full subcategory $\mathcal{G}'_{/X} \subseteq \mathcal{G}'_{/X}$ is a $(f^*\tau)$-covering sieve. This is clear, since the identity morphism $\mathrm{id} : f(X) \to f(X)$ is a τ-covering.

(2) If $u : X \to Y$ is a morphism in $\mathcal{G}'$ and $\mathcal{G}'^{(0)}_{/Y}$ is a $(f^*\tau)$-covering sieve on Y, then $u^* \mathcal{G}'^{(0)}_{/Y} = \mathcal{G}^{(0)}_{/Y} \times_{\mathcal{G}'_{/Y}} \mathcal{G}'_{/X}$ is a $(f^*\tau)$ covering sieve on X. To prove this, choose a collection of objects $U_\alpha \in \mathcal{G}'^{(0)}_{/Y}$ for which the maps $\{f(U_\alpha) \to f(Y)\}$ generate a τ-covering sieve $\mathcal{G}^{(0)}_{/f(Y)}$ on $f(Y) \in \mathcal{G}'$. Since τ is a Grothendieck topology, the pullback $\mathcal{G}^{(0)}_{/f(Y)} \times_{\mathcal{G}_{/f(Y)}} \mathcal{G}_{/f(X)}$ is also a τ-covering sieve. Our assumption that f preserves finite limits guarantees that this sieve is generated by the maps $\{f(X \times_Y U_\alpha) \to f(X)\}$. It follows that the projection maps $\{X \times_Y U_\alpha \to X\}$ generate a $(f^*\tau)$-covering of X, so that $u^* \mathcal{G}'^{(0)}_{/Y}$ is a $(f^*\tau)$-covering sieve.

(3) Let Y be an object of $\mathcal{G}'$, let $\mathcal{G}'^{(0)}_{/Y} \subseteq \mathcal{G}'_{/Y}$ be a $(f^*\tau)$-covering sieve on Y, and let $\mathcal{G}'^{(1)}_{/Y} \subseteq \mathcal{G}'_{/Y}$ be another sieve with the property that for each object $u : X \to Y$ in $\mathcal{G}'^{(0)}_{/Y}$, the pullback $u^* \mathcal{G}'^{(1)}_{/Y}$ is a $(f^*\tau)$-covering sieve on X. We must show that $\mathcal{G}'^{(1)}_{/Y}$ is a $(f^*\tau)$-covering sieve on Y. We begin by choosing maps $u_\alpha : U_\alpha \to Y$ which belong to $\mathcal{G}'^{(0)}_{/Y}$ for which the induced maps $f(U_\alpha) \to f(Y)$ are a τ-covering of $f(Y) \in \mathcal{G}$. Since each $u_\alpha^* \mathcal{G}'^{(1)}_{/Y}$ is a $(f^*\tau)$-covering sieve, we can choose a collection of maps $V_{\alpha,\beta} \to U_\alpha$ for which the composite maps $V_{\alpha,\beta} \to U_\alpha \to Y$ belong to $\mathcal{G}'^{(1)}_{/Y}$, and for each α the collection of maps $\{f(V_{\alpha,\beta}) \to f(U_\alpha)\}$ is a τ-covering of $f(U_\alpha)$. Since τ is a Grothendieck topology, it follows that the collection of composite maps $f(V_{\alpha,\beta}) \to f(U_\alpha) \to f(Y)$ is a τ-covering of $f(Y)$, so that $\mathcal{G}'^{(1)}_{/Y}$ is a covering sieve as desired.

□

Proposition 20.6.1.3. *Let $f : \mathcal{G}' \to \mathcal{G}$ be a functor between ∞-categories and let τ be a Grothendieck topology on $\mathcal{G}$. Assume that the ∞-category $\mathcal{G}'$ admits pullbacks and that the functor f preserves pullbacks, and let $T : \mathcal{P}(\mathcal{G}) \to \mathcal{P}(\mathcal{G}')$ be the functor given by precomposition with f. Then the functor T carries $\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ into $\mathcal{S}\mathrm{hv}_{f^*\tau}(\mathcal{G}')$.*

Proof. Let $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$. We wish to show that $T(\mathscr{F})$ is a sheaf with respect to the Grothendieck topology $f^*\tau$. Fix an object $X \in \mathcal{G}'$ and a sieve $\mathcal{G}'^{(0)}_{/X}$ which is covering with respect to $(f^*\tau)$; we wish to show that the canonical map $T(\mathscr{F})(X) \to \varprojlim_{U \in \mathcal{G}'^{(0)}_{/X}} T(\mathscr{F})(U)$ is a homotopy equivalence.

Choose a collection of morphisms $\{U_\alpha \to X\}_{\alpha \in I}$ which belong to $\mathcal{G}'^{(0)}_{/X}$, such that the maps $f(U_\alpha) \to f(X)$ generate a τ-covering sieve in $\mathcal{G}_{/f(X)}$. Let $\mathcal{G}'^{(1)}_{/X} \subseteq \mathcal{G}_{/X}$ be the sieve generated by the morphisms $U_\alpha \to X$. We will complete the proof by showing the following:

- (a) The canonical map $\rho : T(\mathscr{F})(X) \to \varprojlim_{U \in \mathcal{G}'^{(1)}_{/X}} T(\mathscr{F})(U)$ is a homotopy equivalence.
- (b) The functor $T(\mathscr{F})|_{\mathcal{G}'^{(0)}_{/X}}$ is a right Kan extension of its restriction to $\mathcal{G}'^{(1)}_{/X}$.

Note that if $u : U \to X$ is a morphism belonging the sieve $\mathcal{G}'^{(0)}_{/X}$, then $T(\mathscr{F})|_{\mathcal{G}'^{(0)}_{/X}}$ is a right Kan extension of $T(\mathscr{F})|_{\mathcal{G}'^{(1)}_{/X}}$ at U if and only if the canonical map $T(\mathscr{F})(U) \to \varprojlim_{V \in u^* \mathcal{G}'^{(1)}_{/X}} T(\mathscr{F})(V)$ is an equivalence. The sieve $u^* \mathcal{G}'^{(1)}_{/X}$ is generated by the fiber products $U_\alpha \times_X U$ whose images in $\mathcal{G}$ generate a covering sieve with respect to τ (since the functor f preserves pullbacks). Consequently, assertion (b) can be deduced from (a) (applied after replacing X by U and $\mathcal{G}'^{(1)}_{/X}$ by $u^* \mathcal{G}'^{(1)}_{/X}$).

It remains to prove (a). Let $\mathcal{G}^{(1)}_{/f(X)}$ denote the sieve in $\mathcal{G}_{/f(X)}$ generated by the maps $f(U_\alpha) \to f(X)$. Then the map ρ can identified with the composition $\mathscr{F}(f(X)) \xrightarrow{\rho'} \varprojlim_{V \in \mathcal{G}^{(1)}_{/f(X)}} \mathscr{F}(V) \xrightarrow{\rho''} \varprojlim_{U \in \mathcal{G}'^{(1)}_{/X}} \mathscr{F}(f(U))$. Our assumption that $\mathscr{F}$ is a sheaf with respect to the Grothendieck topology τ guarantees that ρ' is a homotopy equivalence. We are therefore reduced to showing that ρ'' is a homotopy equivalence. For this, it will suffice to show that f induces a left cofinal map $\mathcal{G}'^{(1)}_{/X} \to \mathcal{G}^{(1)}_{/f(X)}$. Using the criterion of Theorem **??**, we must show that for each morphism $V \to f(X)$ belonging the sieve $\mathcal{G}^{(1)}_{/X}$, the ∞-category $\mathcal{C} = \mathcal{G}'^{(1)}_{/X} \times_{\mathcal{G}^{(1)}_{/f(X)}} (\mathcal{G}^{(1)}_{/f(X)})_{V/}$ is weakly contractible. In fact, the ∞-category $\mathcal{C}^{\mathrm{op}}$ is sifted: it is nonempty (by the definition of the sieve $\mathcal{G}^{(1)}_{/f(X)}$) and admits pushouts (by virtue of our assumption that f preserves fiber products). □

20.6.2 Grothendieck Topologies and Admissibility Structures

We are now ready to introduce our main objects of interest.

Definition 20.6.2.1. Let $\mathcal{G}$ be an ∞-category equipped with a Grothendieck topology τ. We will say that an admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$ is *compatible with* τ if, for every object $X \in \mathcal{G}$ and every covering sieve $\mathcal{G}^{(0)}_{/X} \subseteq \mathcal{G}_{/X}$ with respect to τ, there exists a τ-covering $\{f_\alpha : U_\alpha \to X\}$ where each f_α is an admissible morphism which belongs to the sieve $\mathcal{G}^{(0)}_{/X}$. In this case, we will also say that the Grothendieck topology τ is *compatible with the admissibility structure* $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$, or that $\mathcal{G}^{\mathrm{ad}}$ *and* τ *are compatible*.

A *geometric site* is a triple $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$, where $\mathcal{G}$ is an essentially small ∞-category, $\mathcal{G}^{\mathrm{ad}}$ is an admissibility structure on $\mathcal{G}$, and τ is a Grothendieck topology on $\mathcal{G}$ which is compatible with $\mathcal{G}^{\mathrm{ad}}$.

Remark 20.6.2.2. If $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ is a geometric site, we will often abuse terminology and simply refer to the ∞-category $\mathcal{G}$ as a geometric site; in this case, we implicitly assume that the admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$ and the Grothendieck topology τ have been specified. Beware that there is some danger of confusion here, because we will often consider different geometric sites which have the same underlying ∞-category (see Examples 20.6.4.1 and 20.6.4.2, or Examples 20.6.4.4 and 20.6.4.5).

Remark 20.6.2.3. Let $\mathcal{G}$ be an ∞-category equipped with a Grothendieck topology τ and a compatible admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$. If $\mathcal{G}'^{\mathrm{ad}}$ is an admissibility structure on $\mathcal{G}$ which contains $\mathcal{G}^{\mathrm{ad}}$, then $\mathcal{G}'^{\mathrm{ad}}$ is also compatible with τ.

Example 20.6.2.4. Let $\mathcal{G}$ be an ∞-category which admits pullbacks. Then $\mathcal{G}^{\mathrm{ad}} = \mathcal{G}$ is an admissibility structure on $\mathcal{G}$ which is compatible with every Grothendieck topology on $\mathcal{G}$.

Example 20.6.2.5. Let $\mathcal{G}$ be an ∞-category and let τ be the trivial topology on $\mathcal{G}$ (so that a sieve $\mathcal{G}^{(0)}_{/X} \subseteq \mathcal{G}_{/X}$ is a τ-covering if and only if $\mathcal{G}^{(0)}_{/X} = \mathcal{G}_{/X}$). Then τ is compatible with every admissibility structure on $\mathcal{G}$.

Example 20.6.2.6. Let $\mathcal{T}\mathrm{op}$ denote the category whose objects are topological spaces X and whose morphisms are continuous maps $f : X \to Y$. We regard $\mathcal{T}\mathrm{op}$ as equipped with a Grothendieck topology τ, where a collection of morphisms $\{f_\alpha : U_\alpha \to X\}$ is a τ-covering if and only if, for every point $x \in X$, there exists an open set $U \subseteq X$ containing x, an index α, and a map $g : U \to U_\alpha$ such that the composite map $U \xrightarrow{g} U_\alpha \xrightarrow{f_\alpha} X$ is the identity. The collection of open immersions between topological spaces is an admissibility structure on $\mathcal{T}\mathrm{op}$ which is compatible with the Grothendieck topology τ. We can also equip $\mathcal{T}\mathrm{op}$ with the admissibility structure consisting of all local homeomorphisms between topological spaces; it follows from Remark 20.6.2.3 that this admissibility structure is also compatible with τ.

Remark 20.6.2.7. One can give many variants on Example 20.6.2.6 by restricting our attention to topological spaces which have additional properties or are equipped with additional structures. For example, we can replace $\mathcal{T}\mathrm{op}$ by the category whose objects are topological manifolds and whose morphisms are continuous maps, or by the category whose objects are smooth manifolds and whose morphisms are smooth maps. We will study the latter example in detail in §**??**.

Construction 20.6.2.8. Let $\mathcal{G}$ be an ∞-category equipped with an admissibility structure $\mathcal{G}^{\mathrm{ad}}$. Then the ∞-category $\mathcal{G}^{\mathrm{ad}}$ admits fiber products and the inclusion functor $j : \mathcal{G}^{\mathrm{ad}} \hookrightarrow \mathcal{G}$ preserves fiber products (see Remark 20.2.1.12). Applying Proposition 20.6.1.1, we see that every Grothendieck topology τ induces a Grothendieck topology $j^*\tau$ on the ∞-category $\mathcal{G}^{\mathrm{ad}}$. We will denote this Grothendieck topology by τ^{ad}. Applying Proposition 20.6.1.3, we deduce that precomposition with j determines a functor $j^* : \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G}) \to \mathcal{S}\mathrm{hv}_{\tau^{\mathrm{ad}}}(\mathcal{G}^{\mathrm{ad}})$.

Construction 20.6.2.8 can be applied to an arbitrary Grothendieck topology τ on $\mathcal{G}$. We will generally be interested in this construction on in the case where τ is compatible with the admissibility structure $\mathcal{G}^{\mathrm{ad}}$. In this case, passage from τ to τ^{ad} involves no loss of information:

Proposition 20.6.2.9. *Let $\mathcal{G}$ be an ∞-category equipped with an admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$. Then Construction 20.6.2.8 determines an injective map*

$$\{ \text{ Grothendieck topologies on } \mathcal{G} \text{ compatible with } \mathcal{G}^{\mathrm{ad}} \} \to \{ \text{ Grothendieck topologies on } \mathcal{G}^{\mathrm{ad}} \}.$$

The image of this map consists of those Grothendieck topologies τ_0 on $\mathcal{G}^{\mathrm{ad}}$ with the following property:

- $(*)$ *Let $f : X \to Y$ be a morphism in $\mathcal{G}$ and let $\mathcal{G}^{\mathrm{ad}(0)}_{/Y} \subseteq \mathcal{G}^{\mathrm{ad}}_{/Y}$ be a τ_0-covering sieve on Y. Then the collection of morphisms $\{U \times_Y X \to X\}_{U \in \mathcal{G}^{\mathrm{ad}(0)}_{/Y}}$ generates a τ_0-covering sieve on X.*

Proof. Let τ be a Grothendieck topology on $\mathcal{G}$ and let $\mathcal{G}^{(0)}_{/X} \subseteq \mathcal{G}_{/X}$ be sieve. If $\mathcal{G}^{(0)}_{/X} \cap \mathcal{G}^{\mathrm{ad}}_{/X} \subseteq \mathcal{G}^{\mathrm{ad}}_{/X}$ is a τ^{ad}-covering sieve, then $\mathcal{G}^{(0)}_{/X}$ is a τ-covering sieve. If τ is compatible with $\mathcal{G}^{\mathrm{ad}}$, then the converse holds. It follows immediately that a Grothendieck topology τ compatible with $\mathcal{G}^{\mathrm{ad}}$ can be recovered from τ^{ad}, so that the construction $\tau \mapsto \tau^{\mathrm{ad}}$ is injective.

Now suppose that τ is any Grothendieck topology on $\mathcal{G}$; we show that τ^{ad} satisfies condition $(*)$. Let $f : X \to Y$ be a morphism in $\mathcal{G}$ and let $\mathcal{G}^{\mathrm{ad}(0)}_{/Y} \subseteq \mathcal{G}^{\mathrm{ad}}_{/Y}$ be a τ^{ad}-covering sieve. Then the collection of maps $\{U \to Y\}_{U \in \mathcal{G}^{\mathrm{ad}(0)}_{/Y}}$ generates a τ-covering of Y. Since τ is a Grothendieck topology on $\mathcal{G}$, it follows that collection of maps $\{U \times_Y X \to X\}_{U \in \mathcal{G}^{\mathrm{ad}(0)}_{/Y}}$ generates a τ-covering of Y (in the ∞-category $\mathcal{G}$), and therefore also a τ^{ad}-covering of Y (in the ∞-category $\mathcal{G}^{\mathrm{ad}}$).

Finally, let τ_0 be any Grothendieck topology on $\mathcal{G}^{\mathrm{ad}}$ which satisfies condition $(*)$. We attempt to define a Grothendieck topology τ on $\mathcal{G}$ as follows: a sieve $\mathcal{G}^{(0)}_{/X} \subseteq \mathcal{G}_{/X}$ is a

τ-covering if and only if the intersection $\mathcal{G}^{(0)}_{/X} \cap \mathcal{G}^{\mathrm{ad}}_{/X} \subseteq \mathcal{G}^{\mathrm{ad}}_{/X}$ is a τ_0-covering. To show that τ is a Grothendieck topology, we verify that it satisfies the requirements of Definition HTT.6.2.2.1:

(1) For every object $X \in \mathcal{G}$, the subcategory $\mathcal{G}_{/X} \subseteq \mathcal{G}_{/X}$ is a τ-covering sieve (since $\mathcal{G}^{\mathrm{ad}}_{/X} \subseteq \mathcal{G}^{\mathrm{ad}}_{/X}$ is a τ_0-covering sieve).

(2) Let $f : Y \to X$ be a morphism in $\mathcal{G}$ and let $\mathcal{G}^{(0)}_{/X} \subseteq \mathcal{G}_{/X}$ be a τ-covering sieve on X; we must show that the fiber product $\mathcal{G}_{/Y} \times_{\mathcal{G}_{/X}} \mathcal{G}^{(0)}_{/X}$ is a τ-covering sieve on Y. This follows immediately from assumption $(*)$.

(3) Let $\mathcal{G}^{(0)}_{/X} \subseteq \mathcal{G}_{/X}$ be a τ-covering sieve on an object $X \in \mathcal{G}$ and let $\mathcal{G}^{(1)}_{/X}$ be another sieve with the property that for each object $Y \to X$ of $\mathcal{G}^{(0)}_{/X}$, the fiber product $\mathcal{G}^{(1)}_{/X} \times_{\mathcal{G}_{/X}} \mathcal{G}_{/Y}$ is a τ-covering sieve of Y. We must show that $\mathcal{G}^{(1)}_{/X}$ is a τ-covering sieve of X. The assumption that $\mathcal{G}^{(0)}_{/X}$ is a τ-covering implies that it contains admissible morphisms $\{U_\alpha \to X\}$ which determine a τ_0-covering of X. Since each $\mathcal{G}^{(1)}_{/X} \times_{\mathcal{G}_{/X}} \mathcal{G}_{/U_\alpha}$ is a τ-covering of U_α, we can choose admissible morphisms $V_{\alpha,\beta} \to U_\alpha$ which generate a τ_0-covering sieve, for which the composite maps $V_{\alpha,\beta} \to U_\alpha \to X$ belong to $\mathcal{G}^{(1)}_{/X}$. Then the collection of admissible maps $\{V_{\alpha,\beta} \to X\}$ are contained in $\mathcal{G}^{(1)}_{/X}$ and generate a τ_0-covering sieve on X, so that $\mathcal{G}^{(1)}_{/X} \subseteq \mathcal{G}_{/X}$ is a τ-covering sieve as desired.

We now complete the proof by observing that the Grothendieck topology τ is compatible with $\mathcal{G}^{\mathrm{ad}}$, and that the Grothendieck topology τ^{ad} (obtained by applying Construction **??** to τ) coincides with τ_0. □

20.6.3 From Geometric Sites to Fractured Localizations

Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site and let $\mathscr{F} : \mathcal{G}^{\mathrm{op}} \to \mathcal{S}$ be a $\mathcal{S}$-valued presheaf on $\mathcal{G}$. If $\mathscr{F}$ is a sheaf with respect to the Grothendieck topology τ, then Proposition 20.6.1.3 guarantees that $\mathscr{F}|_{\mathcal{G}^{\mathrm{ad\,op}}}$ is a sheaf with respect to the Grothendieck topology τ^{ad} of Construction 20.6.2.8. We now establish the converse:

Proposition 20.6.3.1. *Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site and let $T : \mathcal{P}(\mathcal{G}) \to \mathcal{P}(\mathcal{G}^{\mathrm{ad}})$ denote the restriction functor. Then the diagram of ∞-categories*

$$\begin{array}{ccc} \mathcal{S}\mathrm{hv}_\tau(\mathcal{G}) & \longrightarrow & \mathcal{P}(\mathcal{G}) \\ \downarrow & & \downarrow T \\ \mathcal{S}\mathrm{hv}_{\tau^{\mathrm{ad}}}(\mathcal{G}^{\mathrm{ad}}) & \longrightarrow & \mathcal{P}(\mathcal{G}^{\mathrm{ad}}) \end{array}$$

is a pullback square. In other words, an object $\mathscr{F} \in \mathcal{P}(\mathcal{G})$ is a sheaf with respect to τ if and only if $\mathscr{F}|_{\mathcal{G}^{\mathrm{ad}\,\mathrm{op}}}$ is a sheaf with respect to τ^{ad}.

Proof. Assume that $T(\mathscr{F})$ is a sheaf with respect to τ^{ad}. Let X be an object of $\mathcal{G}$ and let $\mathcal{G}^{(0)}_{/X} \subseteq \mathcal{G}_{/X}$ be a τ-covering sieve; we wish to show that the canonical map $\mathscr{F}(X) \xrightarrow{\rho} \varprojlim_{Y \in \mathcal{G}^{(0)}_{/X}} \mathscr{F}(Y)$ is a homotopy equivalence. Set $\mathcal{G}^{\mathrm{ad}(0)}_{/X} = \mathcal{G}^{(0)}_{/X} \times_{\mathcal{G}_{/X}} \mathcal{G}^{\mathrm{ad}}_{/X}$, and let $\mathcal{G}^{(1)}_{/X} \subseteq \mathcal{G}_{/X}$ denote the sieve generated by $\mathcal{G}^{\mathrm{ad}(0)}_{/X}$. Since τ is compatible with the admissibility structure $\mathcal{G}^{\mathrm{ad}}$, the sieve $\mathcal{G}^{\mathrm{ad}(0)}_{/X}$ is covering with respect to the topology τ^{ad}. Consequently, our assumption that $T(\mathscr{F})$ is a sheaf with respect to τ^{ad} guarantees that the composite map

$$\mathscr{F}(X) \xrightarrow{\rho} \varprojlim_{Y \in \mathcal{G}^{(0)}_{/X}} \mathscr{F}(Y) \xrightarrow{\rho'} \varprojlim_{Y \in \mathcal{G}^{(1)}_{/X}} \mathscr{F}(Y) \xrightarrow{\rho''} \varprojlim_{U \in \mathcal{G}^{\mathrm{ad}(0)}_{/X}} \mathscr{F}(U)$$

is a homotopy equivalence. Consequently, to show that ρ is a homotopy equivalence, it will suffice to show that ρ' and ρ'' are homotopy equivalences. The map ρ'' is a homotopy equivalence because the inclusion $\mathcal{G}^{\mathrm{ad}(0)}_{/X} \hookrightarrow \mathcal{G}^{(1)}_{/X}$ is left cofinal (for every object $Y \in \mathcal{G}^{(1)}_{/X}$, the fiber product $(\mathcal{G}^{(0)}_{/X}) \times_{\mathcal{G}_{/X}} \mathcal{G}_{Y//X}$ is nonempty and admits finite products, and is therefore weakly contractible). To show that ρ' is a homotopy equivalence, it will suffice to show that $\mathscr{F}|_{\mathcal{G}^{(0)\,\mathrm{op}}_{/X}}$ is a right Kan extension of its restriction to $\mathscr{F}|_{\mathcal{G}^{(1)\,\mathrm{op}}_{/X}}$. Fix an object $Y \in \mathcal{G}^{(0)}_{/X}$ and define

$$\mathcal{G}^{(1)}_{/Y} = \mathcal{G}^{(1)}_{/X} \times_{\mathcal{G}_{/X}} \mathcal{G}_{/Y} \qquad \mathcal{G}^{\mathrm{ad}(0)}_{/Y} = \mathcal{G}^{\mathrm{ad}(0)}_{/X} \times_{\mathcal{G}^{\mathrm{ad}}_{/X}} \mathcal{G}^{\mathrm{ad}}_{/Y},$$

so that $\mathscr{F}$ determines maps

$$\mathscr{F}(Y) \xrightarrow{\theta} \varprojlim_{Z \in \mathcal{G}^{(1)}_{/Y}} \mathscr{F}(Z) \xrightarrow{\theta'} \varprojlim_{V \in \mathcal{G}^{\mathrm{ad}(0)}_{/Y}} \mathscr{F}(V).$$

To prove that $\mathscr{F}|_{\mathcal{G}^{(0)\,\mathrm{op}}_{/X}}$ is a right Kan extension of its restriction to $\mathscr{F}|_{\mathcal{G}^{(1)\,\mathrm{op}}_{/X}}$ at Y, it will suffice to show that θ is a homotopy equivalence. The argument above shows that the inclusion $\mathcal{G}^{\mathrm{ad}(0)}_{/Y} \hookrightarrow \mathcal{G}^{(1)}_{/Y}$ is left cofinal, so that θ' is a homotopy equivalence. We are therefore reduced to showing that $\theta' \circ \theta$ is a homotopy equivalence, which follows from our assumption that $T(\mathscr{F})$ is a sheaf with respect to the topology τ^{ad} (since the sieve $\mathcal{G}^{\mathrm{ad}(0)}_{/Y} \subseteq \mathcal{G}^{\mathrm{ad}}_{/Y}$ is a τ^{ad}-covering). □

Proposition 20.6.3.2. *Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site, let $T : \mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S}) \to \mathrm{Fun}((\mathcal{G}^{\mathrm{ad}})^{\mathrm{op}}, \mathcal{S})$ denote the restriction functor, and let $j^* : \mathcal{S}\mathrm{hv}_\tau(\mathcal{G}) \to \mathcal{S}\mathrm{hv}_{\tau^{\mathrm{ad}}}(\mathcal{G}^{\mathrm{ad}})$ denote the restriction of T (Proposition 20.6.1.3). Then the diagram of ∞-categories*

$$\begin{array}{ccc} \mathcal{S}\mathrm{hv}_\tau(\mathcal{G}) & \longrightarrow & \mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S}) \\ \downarrow{\scriptstyle j^*} & & \downarrow{\scriptstyle T} \\ \mathcal{S}\mathrm{hv}_{\tau^{\mathrm{ad}}}(\mathcal{G}^{\mathrm{ad}}) & \longrightarrow & \mathrm{Fun}((\mathcal{G}^{\mathrm{ad}})^{\mathrm{op}}, \mathcal{S}) \end{array}$$

is left adjointable. In other words, the restriction functor $\mathscr{F} \mapsto \mathscr{F}|_{\mathcal{G}^{\mathrm{ad}}}$ *commutes with sheafification with respect to* τ*.*

Proof. Let $L : \mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S}) \to \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ denote a left adjoint to the inclusion (given by sheafification with respect to τ), and define $L^{\mathrm{ad}} : \mathrm{Fun}((\mathcal{G}^{\mathrm{ad}})^{\mathrm{op}}, \mathcal{S}) \to \mathcal{S}\mathrm{hv}_{\tau^{\mathrm{ad}}}(\mathcal{G}^{\mathrm{ad}})$ similarly. We wish to show that, for every object $\mathscr{F} \in \mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S})$, the canonical map $L^{\mathrm{ad}}(T(\mathscr{F})) \to T(L\mathscr{F})$ is an equivalence. Proposition 20.6.1.3 shows that $T(L\mathscr{F})$ is a sheaf with respect to τ^{ad}. It will therefore suffice to show that the functor T carries L-equivalences to L^{ad}-equivalences.

For each object $X \in \mathcal{G}$, let $h_X : \mathcal{G}^{\mathrm{op}} \to \mathcal{S}$ denote the functor represented by X. Given a sieve $\mathcal{G}^{(0)}_{/X} \subseteq \mathcal{G}_{/X}$, we let $h_{\mathcal{G}^{(0)}_{/X}}$ denote the corresponding subobject of h_X (given by the colimit $\varinjlim_{U \in \mathcal{G}^{(0)}_{/X}} h_U$). The collection of L-equivalences in $\mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S})$ is generated, as a strongly saturated collection of morphisms, by monomorphisms of the form $h_{\mathcal{G}^{(0)}_{/X}} \hookrightarrow h_X$, where $\mathcal{G}^{(0)}_{/X} \subseteq \mathcal{G}_{/X}$ is a τ-covering sieve. It will therefore suffice to show that for every such sieve, the map $T(h_{\mathcal{G}^{(0)}_{/X}}) \to T(h_X)$ is an L^{ad}-equivalence.

For each object $U \in \mathcal{G}^{\mathrm{ad}}$, let $h^{\mathrm{ad}}_U \in \mathrm{Fun}((\mathcal{G}^{\mathrm{ad}})^{\mathrm{op}}, \mathcal{S})$ denote the functor represented by U. The presheaf ∞-category $\mathrm{Fun}((\mathcal{G}^{\mathrm{ad}})^{\mathrm{op}}, \mathcal{S})$ is generated under small colimits by objects of the form h^{ad}_U. It will therefore suffice to show that, for every morphism $u : h^{\mathrm{ad}}_U \to T(h_X)$ (which we can identify with a map $U \to X$ in the ∞-category $\mathcal{G}$), the projection map $\pi : T(h_{\mathcal{G}^{(0)}_{/X}}) \times_{T(h_X)} h^{\mathrm{ad}}_U \to h^{\mathrm{ad}}_U$ is a τ^{ad}-equivalence. Unwinding the definitions, we see that π is the monomorphism classified by the sieve $\mathcal{G}^{\mathrm{ad}(0)}_{/U} \subseteq \mathcal{G}^{\mathrm{ad}}_{/U}$ given by those admissible morphisms $V \to U$ for which the composite map $V \to U \to X$ belongs the sieve $\mathcal{G}^{\mathrm{ad}}_{/X}$. To complete the proof, it suffices to observe that this sieve is covering with respect to the topology τ^{ad}. Unwinding the definitions, we need to show that the sieve $u^* \mathcal{G}^{(0)}_{/X} \subseteq \mathcal{G}_{/U}$ contains a τ-covering sieve which is generated by admissible morphisms. This follows from our assumption that the Grothendieck topology τ is compatible with the admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$. □

Combining Propositions 20.6.3.1 and 20.6.3.2, we obtain the following:

Proposition 20.6.3.3. *Let* $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ *be a geometric site. Let us regard the presheaf ∞-category* $\mathcal{P}(\mathcal{G})$ *as a fractured ∞-topos (see Theorem 20.2.4.1), and let us abuse notation by identifying the fracture subcategory* $\mathcal{P}(\mathcal{G})^{\mathrm{corp}} \subseteq \mathcal{P}(\mathcal{G})$ *with* $\mathcal{P}(\mathcal{G}^{\mathrm{ad}})$*. Then the full subcategory* $\mathcal{S}\mathrm{hv}_{\tau^{\mathrm{ad}}}(\mathcal{G}^{\mathrm{ad}}) \subseteq \mathcal{P}(\mathcal{G}^{\mathrm{ad}})$ *is a fractured localization of* $\mathcal{P}(\mathcal{G}^{\mathrm{ad}})$ *(in the sense of Definition 20.5.1.1).*

Combining Proposition 20.6.3.3 and Theorem 20.5.1.2 (and using the identification $\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G}) = \mathcal{S}\mathrm{hv}_{\tau^{\mathrm{ad}}}(\mathcal{G}^{\mathrm{ad}}) \times_{\mathcal{P}(\mathcal{G}^{\mathrm{ad}})} \mathcal{P}(\mathcal{G})$ of Proposition 20.6.3.1), we obtain the following generalization of Theorem 20.2.4.1:

Theorem 20.6.3.4. *Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site and let $j^* : \mathcal{S}\mathrm{hv}_\tau(\mathcal{G}) \to \mathcal{S}\mathrm{hv}_{\tau^{\mathrm{ad}}}(\mathcal{G}^{\mathrm{ad}})$ be the restriction functor. Then the functor j^* admits a left adjoint $j_! : \mathcal{S}\mathrm{hv}_{\tau^{\mathrm{ad}}}(\mathcal{G}^{\mathrm{ad}}) \to \mathcal{S}\mathrm{hv}_\tau(\mathcal{G})$. Moreover, $j_!$ induces an equivalence from $\mathcal{S}\mathrm{hv}_{\tau^{\mathrm{ad}}}(\mathcal{G}^{\mathrm{ad}})$ to a fracture subcategory $\mathcal{S}\mathrm{hv}^{\mathrm{corp}}_\tau(\mathcal{G}) \subseteq \mathcal{S}\mathrm{hv}_\tau(\mathcal{G})$.*

20.6.4 Examples of Geometric Sites

In this book, our primary interest is in geometric sites which are related to classical and spectral algebraic geometry.

Example 20.6.4.1 (Classical Algebraic Geometry: Zariski Topology)**.** Let Aff denote the category of affine schemes of finite type over $\mathbf{Z}$ (so that Aff is equivalent to the *opposite* of the category of finitely presented commutative rings). We regard Aff as equipped with the admissibility structure $\mathrm{Aff}^{\mathrm{Zar}} \subseteq \mathrm{Aff}$ of Example 20.2.1.5 (whose admissible morphisms are open immersions of the form $\operatorname{Spec} R[t^{-1}] \to \operatorname{Spec} R$, where R is a finitely presented commutative ring and $t \in R$ is an element (see Example 20.2.1.5). Let τ_{Zar} denote the Zariski topology on Aff, so that a collection of morphisms $\{f_\alpha : U_\alpha \to X\}$ is a τ_{Zar}-covering if and only if, for every point $x \in X$, there exists a Zariski-open set $U \subseteq X$ containing x, an index α, and a map of schemes $g : U \to U_\alpha$ for which the composite map $U \xrightarrow{g} U_\alpha \xrightarrow{f_\alpha} X$ is the inclusion. The admissibility structure $\mathrm{Aff}^{\mathrm{Zar}}$ is compatible with the Grothendieck topology τ_{Zar}. We therefore obtain a geometric site $(\mathrm{Aff}, \mathrm{Aff}^{\mathrm{Zar}}, \tau_{\mathrm{Zar}})$, which we will refer to as the *classical Zariski site*.

Example 20.6.4.2 (Classical Algebraic Geometry: Étale Topology)**.** Let Aff denote (the nerve of) the category of affine schemes of finite type over $\mathbf{Z}$ (so that Aff is equivalent to the *opposite* of the category of finitely presented commutative rings. We regard Aff as equipped with the admissibility structure $\mathrm{Aff}^{\text{ét}} \subseteq \mathrm{Aff}$ whose morphisms are étale maps between affine schemes of finite type over $\mathbf{Z}$. Let $\tau_{\text{ét}}$ denote the étale topology on Aff, so that a collection of morphisms $\{f_\alpha : U_\alpha \to X\}$ is a $\tau_{\text{ét}}$-covering if and only if, for every point $x \in X$, there exists an étale map $h : U \to X$ whose image contains x and an index α for which h factors as a composition $U \to U_\alpha \xrightarrow{f_\alpha} X$. The Grothendieck topology $\tau_{\text{ét}}$ is compatible with the admissibility structure $\mathrm{Aff}^{\text{ét}}$. We therefore obtain a geometric site $(\mathrm{Aff}, \mathrm{Aff}^{\text{ét}}, \tau_{\text{ét}})$, which we will refer to as the *classical étale site*.

Remark 20.6.4.3. Many variations on the preceding examples are possible. For example, we could work replace Aff by the category of affine R-schemes of finite presentation where R is some commutative ring, or allow schemes which are not affine, or relax the assumptions that our schemes are of finite type.

We now consider spectral variants of Examples 20.6.4.1 and 20.6.4.2.

Example 20.6.4.4 (Spectral Algebraic Geometry: Zariski Topology)**.** Let $\mathrm{Aff}_{\mathrm{Sp}}$ denote the opposite of the ∞-category CAlg_c of compact $\mathbb{E}_\infty$-rings. For each object $R \in \mathrm{CAlg}_c$, we will denote the corresponding object in $\mathrm{Aff}_{\mathrm{Sp}}$ by $\mathrm{Spét}\, R$ (which we can view as a nonconnective spectral scheme or nonconnective spectral Deligne-Mumford stack). The category $\mathrm{Aff}_{\mathrm{Sp}}$ admits an admissibility structure $\mathrm{Aff}^{\mathrm{Zar}}_{\mathrm{Sp}} \subseteq \mathrm{Aff}_{\mathrm{Sp}}$, whose morphisms are those of the form $\mathrm{Spét}\, R \to \mathrm{Spét}\, R[t^{-1}]$ for $t \in \pi_0 R$. The ∞-category $\mathrm{Aff}_{\mathrm{Sp}}$ also admits a Grothendieck topology τ_{Zar}, where a sieve on an object $\mathrm{Spec}\, R$ is covering if it contains a family of maps of the form $\{\mathrm{Spét}\, R[t_\alpha^{-1}] \to \mathrm{Spét}\, R\}$ for which the elements $t_\alpha \in \pi_0 R$ generate the unit ideal. The Grothendieck topology τ_{Zar} is compatible with the admissibility structure $\mathrm{Aff}^{\mathrm{Zar}}_{\mathrm{Sp}}$. We therefore obtain a geometric site $(\mathrm{Aff}_{\mathrm{Sp}}, \mathrm{Aff}^{\mathrm{Zar}}_{\mathrm{Sp}}, \tau_{\mathrm{Zar}})$, which we will refer to as the *spectral Zariski site*.

Example 20.6.4.5 (Spectral Algebraic Geometry: Étale Topology)**.** The ∞-category $\mathrm{Aff}_{\mathrm{Sp}}$ of Example 20.6.4.4 admits another Grothendieck topology $\tau_{\mathrm{ét}}$, where a sieve on an object $\mathrm{Spét}\, R$ is a $\tau_{\mathrm{ét}}$-covering if it contains a finite collection of étale morphisms $\mathrm{Spét}\, R_\alpha \to \mathrm{Spét}\, R$ for which the induced map $R \to \prod R_\alpha$ is faithfully flat. The Grothendieck topology $\tau_{\mathrm{ét}}$ is compatible with the admissibility structure $\mathrm{Aff}^{\mathrm{ét}}_{\mathrm{Sp}} \subseteq \mathrm{Aff}_{\mathrm{Sp}}$ spanned by the étale morphisms. We therefore obtain a geometric site $(\mathrm{Aff}_{\mathrm{Sp}}, \mathrm{Aff}^{\mathrm{ét}}_{\mathrm{Sp}}, \tau_{\mathrm{ét}})$, which we will refer to as the *spectral étale site*.

20.6.5 Modifications of Admissibility Structures

Let $\mathcal{G}$ be an essentially small ∞-category and let τ be a Grothendieck topology on $\mathcal{G}$. According to Theorem 20.6.3.4, every admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$ which is compatible with τ determines a fracture subcategory $\mathcal{S}\mathrm{hv}^{\mathrm{corp}}_\tau(\mathcal{G}) \subseteq \mathcal{S}\mathrm{hv}_\tau(\mathcal{G})$ (which can be identified with $\mathcal{S}\mathrm{hv}_{\tau^{\mathrm{ad}}}(\mathcal{G}^{\mathrm{ad}})$). Let $h : \mathcal{G} \to \mathcal{S}\mathrm{hv}_\tau(\mathcal{G})$ be the composition of the Yoneda embedding $\mathcal{G} \hookrightarrow \mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S})$ with the sheafification functor $\mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S}) \to \mathcal{S}\mathrm{hv}_\tau(\mathcal{G})$, and define $h^{\mathrm{ad}} : \mathcal{G}^{\mathrm{ad}} \to \mathcal{S}\mathrm{hv}_{\tau^{\mathrm{ad}}}(\mathcal{G}^{\mathrm{ad}})$ similarly. The diagram of ∞-categories

$$\begin{array}{ccc} \mathcal{G}^{\mathrm{ad}} & \xrightarrow{h^{\mathrm{ad}}} & \mathcal{S}\mathrm{hv}_{\tau^{\mathrm{ad}}}(\mathcal{G}^{\mathrm{ad}}) \\ \downarrow & & \downarrow \\ \mathcal{G} & \xrightarrow{h} & \mathcal{S}\mathrm{hv}_\tau(\mathcal{G}) \end{array}$$

commutes, up to canonical equivalence. In particular:

(*i*) For every object $X \in \mathcal{G}$, the sheaf $h(X)$ belongs to $\mathcal{S}\mathrm{hv}^{\mathrm{corp}}_\tau(\mathcal{G})$.

(*ii*) For every admissible morphism $U \to X$ of $\mathcal{G}$, the induced map $h(U) \to h(X)$ is a morphism of $\mathcal{S}\mathrm{hv}^{\mathrm{corp}}_\tau(\mathcal{G})$.

The converse of (ii) is false in general: if $\alpha : U \to X$ is a morphism in $\mathcal{G}$ for which $h(\alpha)$ belongs to $\mathcal{S}\mathrm{hv}^{\mathrm{corp}}_{\tau}(\mathcal{G})$, then α need not be admissible. In fact, many different admissibility structures on $\mathcal{G}$ can give rise to the same fracture subcategory of $\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$:

Proposition 20.6.5.1. *Let $\mathcal{G}$ be an essentially small ∞-category equipped with a Grothendieck topology τ. Suppose we are given admissibility structures $\mathcal{G}^{\mathrm{ad}}_0 \subseteq \mathcal{G} \supseteq \mathcal{G}^{\mathrm{ad}}_1$ satisfying the following conditions:*

(1) *The admissibility structures $\mathcal{G}^{\mathrm{ad}}_0$ and $\mathcal{G}^{\mathrm{ad}}_1$ are both compatible with τ (in the sense of Definition 20.6.2.1), and $\mathcal{G}^{\mathrm{ad}}_0 \subseteq \mathcal{G}^{\mathrm{ad}}_1$.*

(2) *For every morphism $U \to X$ which belongs to $\mathcal{G}^{\mathrm{ad}}_1$, there exists a collection of morphisms $\{V_\alpha \to U\}$ which belong to $\mathcal{G}^{\mathrm{ad}}_0$ and generate a τ-covering of U, and for which the composite maps $V_\alpha \to U \to X$ also belong to $\mathcal{G}^{\mathrm{ad}}_0$.*

Then $\mathcal{G}^{\mathrm{ad}}_0$ and $\mathcal{G}^{\mathrm{ad}}_1$ determine the same fracture subcategory $\mathcal{S}\mathrm{hv}^{\mathrm{corp}}_{\tau}(\mathcal{G}) \subseteq \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$.

Example 20.6.5.2. Let $(\mathrm{Aff}, \mathrm{Aff}^{\mathrm{Zar}}, \tau_{\mathrm{Zar}})$ denote the classical Zariski site of Example 20.6.4.1. Then the category Aff admits another admissibility structure $\mathrm{Aff}'^{\mathrm{Zar}}$, where a morphism $\operatorname{Spec} A \to \operatorname{Spec} B$ in Aff belongs to $\mathrm{Aff}'^{\mathrm{Zar}}$ if and only if it is an open immersion of affine schemes. Then $(\mathrm{Aff}, \mathrm{Aff}'^{\mathrm{Zar}}, \tau_{\mathrm{Zar}})$ is also a geometric site. Moreover, Proposition 20.6.5.1 implies that the admissibility structures $\mathrm{Aff}^{\mathrm{Zar}}$ and $\mathrm{Aff}'^{\mathrm{Zar}}$ determine the same fracture subcategory of $\mathcal{S}\mathrm{hv}_{\tau_{\mathrm{Zar}}}(\mathrm{Aff})$. A similar remark applies to the spectral Zariski site of Example 20.6.4.4.

Proof of Proposition 20.6.5.1. Replacing $\mathcal{G}$ by $\mathcal{G}^{\mathrm{ad}}_1$, we can reduce to the case where $\mathcal{G}^{\mathrm{ad}}_1 = \mathcal{G}$. Set $\mathcal{G}^{\mathrm{ad}} = \mathcal{G}^{\mathrm{ad}}_0$, so that $\mathcal{G}^{\mathrm{ad}}$ determines a fracture subcategory $\mathcal{S}\mathrm{hv}^{\mathrm{corp}}_{\tau}(\mathcal{G}) \subseteq \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$. We wish to show that $\mathcal{S}\mathrm{hv}^{\mathrm{corp}}_{\tau}(\mathcal{G}) = \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$.

Let $h : \mathcal{G} \to \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ denote the sheafified Yoneda embedding (that is, the composition of the Yoneda embedding $\mathcal{G} \to \mathcal{P}(\mathcal{G})$ with the sheafification functor $\mathcal{P}(\mathcal{G}) \to \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$). For each object $X \in \mathcal{G}$, the sheaf $h(X)$ is corporeal. Proposition 20.1.3.1 implies that the inclusion $\mathcal{S}\mathrm{hv}^{\mathrm{corp}}_{\tau}(\mathcal{G})_{/h(X)} \hookrightarrow \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})_{/h(X)}$ is a fully faithful embedding. Unwinding the definitions, we see that $\mathcal{S}\mathrm{hv}^{\mathrm{corp}}_{\tau}(\mathcal{G})_{/h(X)}$ can be identified with the full subcategory of $\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})_{/h(X)}$ generated under small colimits by objects of the form $h(U)$, where $U \to X$ is admissible (that is, it belongs to $\mathcal{G}^{\mathrm{ad}}$). Using assumption (2), we deduce that $\mathcal{S}\mathrm{hv}^{\mathrm{corp}}_{\tau}(\mathcal{G})_{/h(X)} = \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})_{/h(X)}$.

Let us say that an object $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ is *good* if it is corporeal and the inclusion $\mathcal{S}\mathrm{hv}^{\mathrm{corp}}_{\tau}(\mathcal{G})_{/\mathscr{F}} \hookrightarrow \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})_{/\mathscr{F}}$ is an equality. To show that $\mathcal{S}\mathrm{hv}^{\mathrm{corp}}_{\tau}(\mathcal{G}) = \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$, it will suffice to show that every object of $\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ is good. The preceding argument shows that $h(X)$ is good for each $X \in \mathcal{G}$. We will complete the proof by showing that the collection of good objects of $\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ is closed under small colimits.

Suppose we are given a small diagram $\{\mathscr{F}_\alpha\}$ in $\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ having a colimit $\mathscr{F}$, where each $\mathscr{F}_\alpha$ is good; we wish to show that $\mathscr{F}$ is good. Choose an arbitrary morphism $\rho : \mathscr{F}' \to \mathscr{F}$

in $\mathcal{S}\mathrm{hv}_\tau(\mathcal{G})$. Then we can write $\mathscr{F}' = \varinjlim(\mathscr{F}' \times_{\mathscr{F}} \mathscr{F}_\alpha)$. Note that each transition map $\mathscr{F}' \times_{\mathscr{F}} \mathscr{F}_\alpha \to \mathscr{F}' \times_{\mathscr{F}} \mathscr{F}_\beta$ belongs to the subcategory $\mathcal{S}\mathrm{hv}_\tau^{\mathrm{corp}}(\mathcal{G}) \subseteq \mathcal{S}\mathrm{hv}_\tau(\mathcal{G})$ (by virtue of our assumption that $\mathscr{F}_\beta$ is good). It follows that $\mathscr{F}'$ is corporeal, and is the colimit of the diagram $\{\mathscr{F}' \times_{\mathscr{F}} \mathscr{F}_\alpha\}$ in the ∞-category $\mathcal{S}\mathrm{hv}_\tau^{\mathrm{corp}}(\mathcal{G})$. Specializing to the case $\rho = \mathrm{id}_{\mathscr{F}}$, we deduce that $\mathscr{F}$ is also corporeal. To complete the proof, it will suffice to show that the morphism ρ belongs to $\mathcal{S}\mathrm{hv}_\tau^{\mathrm{corp}}(\mathcal{G})$. Equivalently, we must show that each of the composite maps $\mathscr{F}' \times_{\mathscr{F}} \mathscr{F}_\alpha \to \mathscr{F}' \xrightarrow{\rho} \mathscr{F}$ belongs to $\mathcal{S}\mathrm{hv}_\tau^{\mathrm{corp}}(\mathcal{G})$. This follows from the commutativity of the diagram

$$\begin{array}{ccc} \mathscr{F}' \times_{\mathscr{F}} \mathscr{F}_\alpha & \longrightarrow & \mathscr{F}' \\ \downarrow & & \downarrow \rho \\ \mathscr{F}_\alpha & \longrightarrow & \mathscr{F}, \end{array}$$

since the left vertical map belongs to $\mathcal{S}\mathrm{hv}_\tau^{\mathrm{corp}}(\mathcal{G})$ by virtue of our assumption that $\mathscr{F}_\alpha$ is good, and the bottom horizontal map belongs to $\mathcal{S}\mathrm{hv}_\tau^{\mathrm{corp}}(\mathcal{G})$ because $\mathscr{F}$ is a colimit of the diagram $\{\mathscr{F}_\alpha\}$ in the ∞-category $\mathcal{S}\mathrm{hv}_\tau^{\mathrm{corp}}(\mathcal{X})$. □

Chapter 21

Structure Sheaves

Let X be a topological space. There are several different ways of thinking about a sheaf $\mathscr{O}_X$ of commutative rings on X:

(A) We can view $\mathscr{O}_X$ as a sheaf on X taking values in the category $\mathrm{CAlg}^{\heartsuit}$ of commutative rings. From this point of view, $\mathscr{O}_X$ is a functor $\mathcal{U}(X)^{\mathrm{op}} \to \mathrm{CAlg}^{\heartsuit}$, which satisfies the usual sheaf axioms; here $\mathcal{U}(X)$ denotes the partially ordered set of open subsets of X.

(B) We can view $\mathscr{O}_X$ as a *commutative ring object* of the topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(X)$: that is, as an object of $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(X)$ equipped with addition and multiplication maps

$$+, \times : \mathscr{O}_X \times \mathscr{O}_X \to \mathscr{O}_X$$

satisfying the usual commutative ring axioms (which can be translated into the requirement that certain diagrams commute in the category $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(X)$).

(C) We can identify $\mathscr{O}_X$ with a geometric morphism of topoi $\pi_* : \mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(X) \to \mathcal{E}$, where $\mathcal{E}$ is the *classifying topos for commutative rings* (given concretely by the formula $\mathcal{E} = \mathrm{Fun}(\mathrm{CAlg}^{\heartsuit}_c, \mathcal{S}\mathrm{et})$, where $\mathrm{CAlg}^{\heartsuit}_c$ is the category of finitely presented commutative rings).

Our goal in this chapter is to discuss the relationship between (A), (B), and (C) in an ∞-categorical setting, where we replace the topological space X by an ∞-topos $\mathcal{X}$ and the category $\mathrm{CAlg}^{\heartsuit}$ of commutative rings by some other ∞-category $\mathcal{C}$.

We begin by considering the relationship between (A) and (C). Let $\mathcal{C}$ be an arbitrary ∞-category. Recall that a *$\mathcal{C}$-valued sheaf* on an ∞-topos $\mathcal{X}$ is a functor $\mathscr{F} : \mathcal{X}^{\mathrm{op}} \to \mathcal{C}$ which preserves small limits (Definition 1.3.1.4). Our goal in §21.1 is to give a criterion for the existence of a *universal* $\mathcal{C}$-valued sheaf: that is, a $\mathcal{C}$-valued sheaf $\mathscr{F}_0$ on an ∞-topos $\mathcal{E}$ having the property that *any* $\mathcal{C}$-valued sheaf on any ∞-topos $\mathcal{X}$ can be written as a pullback $f^* \mathscr{F}_0$, for any essentially unique geometric morphism $f : \mathcal{X} \to \mathcal{E}$. To fix ideas, let us assume that the ∞-category $\mathcal{C}$ is presentable (which guarantees that there is a good notion of pullback for $\mathcal{C}$-valued sheaves). The main result of §21.1 is that there exists a universal $\mathcal{C}$-valued sheaf if and only if $\mathcal{C}$ is *compactly assembled*: that is, if and only if $\mathcal{C}$ is a retract (in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable ∞-categories) of a compactly generated ∞-category (Theorem **??**).

We will be primarily interested in studying $\mathcal{C}$-valued sheaves in the case where the ∞-category $\mathcal{C}$ is compactly generated. Under this assumption we can write $\mathcal{C} \simeq \mathrm{Ind}(\mathcal{G}^{\mathrm{op}})$, where $\mathcal{G}$ is an essentially small ∞-category which admits finite limits. In this case, the theory of $\mathcal{C}$-valued sheaves can be reformulated directly in terms of the ∞-category $\mathcal{G}$: for any ∞-topos $\mathcal{X}$, there is a fully faithful embedding $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \hookrightarrow \mathrm{Fun}(\mathcal{G}, \mathcal{X})$, whose essential image consists of those functors from $\mathcal{G}$ to $\mathcal{X}$ which preserve finite limits. In §21.2, we will refer to such functors as *$\mathcal{G}$-objects of $\mathcal{X}$* and regard them as objects of a full subcategory $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X}) \subseteq \mathrm{Fun}(\mathcal{G}, \mathcal{X})$ (moreover, we consider also the case where $\mathcal{G}$ does not admit finite limits, in which case we define $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ to consist of the *locally* left exact functors in the sense of Definition 20.4.2.1). We regard the equivalence $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \simeq \mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ as an ∞-categorical analogue of the equivalence between (A) and (B): it allows us to encode the datum of a $\mathcal{C}$-valued sheaf on $\mathcal{X}$ in terms of diagrams in the ∞-topos $\mathcal{X}$ itself. For our purposes, the main virtue of this equivalence is it provides a convenient language for discussing locality conditions on $\mathcal{C}$-valued sheaves and morphisms between $\mathcal{C}$-valued sheaves. For example:

- To every Grothendieck topology τ on $\mathcal{G}$, we can associate a full subcategory $\mathrm{Obj}_{\mathcal{G}}^{\tau}(\mathcal{X})$, whose objects we refer to as *τ-local* $\mathcal{G}$-objects of $\mathcal{X}$ (see Definition 21.2.1.1).
- To every admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$, we can associate a (non-full) subcategory $\mathrm{Obj}_{\mathcal{G}}^{\mathrm{loc}}(\mathcal{X})$ containing all objects, whose morphisms are *local* morphisms between $\mathcal{G}$-objects (see Definition 21.2.4.1).

Specializing to the case where $\mathcal{C}$ is the category of commutative rings (or the ∞-category CAlg of $\mathbb{E}_{\infty}$-rings), this formalism recovers the usual notions of locality for sheaves of rings (or of $\mathbb{E}_{\infty}$-rings) and morphisms between them, as studied in §1).

Let $\mathcal{G}$ be an essentially small ∞-category equipped with an admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$. In §21.4, we show that the collection of local morphisms determines a factorization system on the ∞-category $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$: that is, every morphism $\mathcal{O} \to \mathcal{O}'$ in $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ admits an essentially unique factorization as a composition $\mathcal{O} \xrightarrow{\alpha} \mathcal{O}'' \xrightarrow{\beta} \mathcal{O}'$, where β is local and α is *localizing* (that is, it is left orthogonal to all local morphisms of $\mathcal{G}$-objects). Moreover, if the $\mathcal{G}$-objects $\mathcal{O}$ and $\mathcal{O}'$ are themselves local with respect to some Grothendieck topology τ which is compatible with $\mathcal{G}^{\mathrm{ad}}$, then $\mathcal{O}''$ is also local with respect to τ: consequently, we also obtain a factorization system on the ∞-category $\mathrm{Obj}_{\mathcal{G}}^{\tau}(\mathcal{X})$. This is a special case of a more general assertion (Theorem 21.3.0.1), whose formulation uses the language of fractured ∞-topoi developed in Chapter 20.

Let $\mathcal{G}$ be a small ∞-category equipped with a Grothendieck topology τ and a compatible admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$ (so that the triple $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ is a *geometric site*, in the sense of Definition 20.6.2.1). We define a *$\mathcal{G}$-structured ∞-topos* to be a pair $(\mathcal{X}, \mathscr{O})$, where $\mathcal{X}$ is an ∞-topos and $\mathscr{O}$ is a $\mathcal{G}$-object of $\mathcal{X}$. In §21.4, we organize the collection of $\mathcal{G}$-structured ∞-topoi into an ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$, in which a morphism from $(\mathcal{X}, \mathscr{O})$ to $(\mathcal{X}', \mathscr{O}')$ is given by a pair (f_*, α), where $f_* : \mathcal{X} \to \mathcal{X}'$ is a geometric morphism of ∞-topoi and $\alpha : f^* \mathscr{O}' \to \mathscr{O}$ is a local morphism of $\mathcal{G}$-objects on $\mathcal{X}$. The theory of $\mathcal{G}$-structured ∞-topoi can be regarded as a generalization of the theory of locally spectrally ringed ∞-topoi (hence also of locally ringed spaces, modulo slight caveats), in the sense that the latter can be recovered from the former by choosing the geometric site $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ appropriately (see Examples 21.4.1.13, 21.4.1.14, 21.4.1.17, 21.4.1.18, 21.4.1.19, and 21.4.1.20). We conclude this chapter by studying some of the formal properties enjoyed by the ∞-categories $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ (and of a slightly more general construction, which depends on a fractured ∞-topos rather than a geometric site).

Contents

21.1 $\mathcal{C}$-Valued Sheaves

Let $\mathcal{C}$ be an ∞-category. Recall that a *$\mathcal{C}$-valued sheaf* on an ∞-topos $\mathcal{X}$ is a functor $\mathscr{F} : \mathcal{X}^{\mathrm{op}} \to \mathcal{C}$ which preserves small limits (Definition 1.3.1.4). The collection of all $\mathcal{C}$-valued sheaves on $\mathcal{X}$ can be organized into an ∞-category $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$ which depends functorially on $\mathcal{X}$. More precisely, every geometric morphism of ∞-topoi $\mathcal{X} \underset{f_*}{\overset{f^*}{\rightleftarrows}} \mathcal{Y}$ determines a direct image functor $f_*^{\mathcal{C}} : \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{Y}) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$, given on objects by the formula

$$(f_*^{\mathcal{C}} \mathscr{F})(X) = \mathscr{F}(f^* X).$$

If the ∞-category $\mathcal{C}$ is presentable, then one can use the adjoint functor theorem to show that the functor $f_*^{\mathcal{C}}$ admits a left adjoint $f^*_{\mathcal{C}} : \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{Y})$ (see Proposition **??**). Moreover, the construction $(f^*, \mathscr{F}) \mapsto f^*_{\mathcal{C}} \mathscr{F}$ determines a functor $\mathrm{Fun}^*(\mathcal{X}, \mathcal{Y}) \times \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{Y})$. This motivates the following:

Definition 21.1.0.1. Let $\mathcal{C}$ be a compactly generated ∞-category, let $\mathcal{E}$ be an ∞-topos, and let $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{E})$ be a $\mathcal{C}$-valued sheaf on $\mathcal{E}$. We will say that $\mathscr{F}$ is *universal* if, for every ∞-topos $\mathcal{X}$, the construction $f^* \mapsto f^*_{\mathcal{C}} \mathscr{F}$ induces an equivalence of ∞-categories

$$\mathrm{Fun}^*(\mathcal{E}, \mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}).$$

In this case, we will say that $\mathscr{F}$ *exhibits $\mathcal{E}$ as a classifying topos for $\mathcal{C}$-valued sheaves.*

Our primary goal in this section is to answer the following:

Question 21.1.0.2. Let $\mathcal{C}$ be a presentable ∞-category. Under what conditions does there exist a classifying ∞-topos $\mathcal{E}$ for $\mathcal{C}$-valued sheaves, in the sense of Definition 21.1.0.1?

Our first objective will be to construct a suitable candidate for the classifying ∞-topos $\mathcal{E}$. Let $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{S})$ spanned by those functors which preserve small filtered colimits. In §21.1.1, we show that $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ is an ∞-topos. This is a special case of a more general result (Proposition 21.1.1.2), which does not require the presentability of $\mathcal{C}$.

In general, it is easy to describe geometric morphisms *from* the ∞-topos $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ to another ∞-topos $\mathcal{X}$ (see Corollary 21.1.1.6). However, to classify geometric morphisms in the other direction, we need an additional hypothesis on $\mathcal{C}$. In §21.1.2, we introduce the class of *compactly assembled* ∞-categories (Definition 21.1.2.1), which is an enlargement of the class of compactly generated ∞-categories. The main result of this section, which we prove in §21.1.3, provides a classification of colimit-preserving functors from $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ to $\mathcal{X}$, where $\mathcal{X}$ is an ∞-topos (see Proposition 21.1.3.3 and Theorem 21.1.4.6). We will apply this result in §21.1.4 to give a complete answer to Question 21.1.0.2: if $\mathcal{C}$ is a presentable ∞-category, then there exists a classifying ∞-topos for $\mathcal{C}$-valued sheaves if and only if $\mathcal{C}$ is compactly assembled (Corollary 21.1.4.9). Moreover, if the classifying ∞-topos exists, then it is given by $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ (Theorem 21.1.4.3).

In §21.1.5, we combine the analyses of §21.1.1 and §21.1.4 to show that the construction $\mathcal{C} \mapsto \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ is fully faithful when restricted to compactly assembled ∞-categories (Corollary 21.1.5.3). Moreover, the ∞-topoi having the form $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ where $\mathcal{C}$ is presentable and compactly assembled (that is, those ∞-topoi which classify $\mathcal{C}$-valued sheaves) admit a simple characterization (Proposition 21.1.5.4).

In this book, we will be primarily interested in studying $\mathcal{C}$-valued sheaves in situations where the ∞-category $\mathcal{C}$ is compactly generated. Under this assumption, one can construct a classifying topos for $\mathcal{C}$-valued sheaves more directly (we will return to this point in §21.2). However, there are interesting examples of (presentable) compactly assembled ∞-categories which are not compactly generated. In §21.1.6, we show that an ∞-topos $\mathcal{X}$ is compactly assembled if and only if it is *exponentiable* in the ∞-category $\infty\mathcal{T}\mathrm{op}$ of ∞-topoi (Theorem 21.1.6.12). Notable examples include the ∞-topoi $\mathcal{S}\mathrm{hv}(X)$ where X is a coherent topological space (in which case $\mathcal{S}\mathrm{hv}(X)$ is compactly generated; see the proof of Proposition 21.1.7.8) or where X is a locally compact Hausdorff space (in which case $\mathcal{S}\mathrm{hv}(X)$ is compactly assembled but might not be compactly generated; see Proposition 21.1.7.1 and Remark 21.1.7.2).

Remark 21.1.0.3. Our notion of *compactly assembled ∞-category* is essentially the ∞-categorical version of the notion of *continuous category* studied by Johnstone and Joyal in [104] (except that our definition includes an accessibility hypothesis; see Remark 21.1.2.12). Most of the results in this section can be regarded as ∞-categorical analogues of 1-categorical results which appear in [104].

21.1.1 The ∞-Topoi $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$

We begin with some general remarks.

Notation 21.1.1.1. Let $\mathcal{C}$ and $\mathcal{D}$ be ∞-categories which admit small filtered colimits. We let $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ spanned by those functors $F : \mathcal{C} \to \mathcal{D}$ which preserve small filtered colimits.

Let $\mathcal{C}_0$ be an essentially small ∞-category and let $\mathcal{C} = \mathrm{Ind}(\mathcal{C}_0)$ be the ∞-category of Ind-objects of $\mathcal{C}_0$. Then $\mathcal{C}$ is freely generated by $\mathcal{C}_0$ under (small) filtered colimits. More precisely, there is a fully faithful embedding $j : \mathcal{C}_0 \hookrightarrow \mathcal{C}$ with the following universal property: for any ∞-category $\mathcal{D}$ which admits small filtered colimits, composition with j induces an equivalence of ∞-categories $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{D}) \to \mathrm{Fun}(\mathcal{C}_0, \mathcal{D})$ (Proposition HTT.5.3.5.10). In particular, taking $\mathcal{D} = \mathcal{S}$, we deduce that $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ is equivalent to the ∞-category $\mathrm{Fun}(\mathcal{C}_0, \mathcal{S}) = \mathcal{P}(\mathcal{C}_0^{\mathrm{op}})$ of presheaves on $\mathcal{C}_0^{\mathrm{op}}$, and is therefore an ∞-topos. In fact, this is a special case of a more general phenomenon:

Proposition 21.1.1.2. *Let $\mathcal{C}$ be an accessible ∞-category which admits small filtered colimits and let $\mathcal{X}$ be an ∞-topos. Then the ∞-category $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{X})$ is also an ∞-topos.*

Proof. For any regular cardinal κ, let $\mathrm{Fun}^{\kappa}(\mathcal{C}, \mathcal{X})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{X})$ spanned by those functors which preserve small κ-filtered colimits. It follows immediately from the definitions that the subcategory $\mathrm{Fun}^{\kappa}(\mathcal{C}, \mathcal{X}) \subseteq \mathrm{Fun}(\mathcal{C}, \mathcal{X})$ is closed under small colimits. Since filtered colimits in $\mathcal{X}$ are left exact, it is also closed under finite limits. Taking $\kappa = \omega$, this proves (1).

Choose a regular cardinal κ for which $\mathcal{C}$ is κ-accessible and let $\mathcal{C}_0$ denote the full subcategory of $\mathcal{C}$ spanned by the κ-compact objects, so that the inclusion $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ extends to an equivalence of ∞-categories $\mathrm{Ind}_{\kappa}(\mathcal{C}_0) \simeq \mathcal{C}$. Applying Proposition HTT.5.3.5.10 , we deduce that the restriction functor $\mathrm{Fun}^{\kappa}(\mathcal{C}, \mathcal{X}) \to \mathrm{Fun}(\mathcal{C}_0, \mathcal{X})$ is an equivalence of ∞-categories. Applying Proposition **??**, we deduce that the ∞-category $\mathrm{Fun}^{\kappa}(\mathcal{C}, \mathcal{X})$ is an ∞-topos.

By definition, $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{X})$ is the full subcategory of $\mathrm{Fun}^{\kappa}(\mathcal{C}, \mathcal{X})$ spanned by those functors $F : \mathcal{C} \to \mathcal{X}$ which satisfy the following condition:

(a) For every small filtered ∞-category $\mathcal{J}$ and every functor $\rho : \mathcal{J} \to \mathcal{C}$, the canonical map $\varinjlim_{J \in \mathcal{J}} F(\rho(J)) \to F(\varinjlim_{J \in \mathcal{J}} \rho(J))$ is an equivalence in $\mathcal{X}$.

Using Proposition HTT.5.3.1.18 , we see that (a) is equivalent to the following *a priori* weaker condition:

(b) For every small filtered partially ordered set A and every functor $\rho : A \to \mathcal{C}$, the canonical map $\theta^F_{A,\rho} : \varinjlim_{\alpha \in A} F(\rho(\alpha)) \to F(\varinjlim_{\alpha \in A} \rho(\alpha))$ is an equivalence in $\mathcal{X}$.

For a fixed partially ordered set A, let (b_A) denote the assertion that $\theta^F_{A,\rho}$ is an equivalence for every functor $\rho : A \to \mathcal{C}$. Note that we can write A as a κ-filtered union of κ-small filtered partially ordered sets (Lemma HTT.5.4.2.8). If the functor F belongs to $\mathrm{Fun}^{\kappa}(\mathcal{C}, \mathcal{X})$, then each map $\theta_{A,\rho}$ can be written as a κ-filtered colimit of maps $\theta_{A_0, \rho|_{A_0}}$, where $A_0 \subseteq A$ is filtered and κ-small. Consequently, the functor F belongs to $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{X})$ if and only if it satisfies condition (b_A) whenever A is κ-small.

Note that if we fix a filtered partially ordered set A, then the ∞-category $\mathrm{Fun}(A, \mathcal{C})$ is accessible (Proposition **??**). Consequently, there exists a small collection of functors $\{\rho_i : A \to \mathcal{C}\}_{i \in I(A)}$ which generates $\mathrm{Fun}(A, \mathcal{C})$ under τ-filtered colimits, where τ is some regular cardinal that we can assume is $\geqslant \kappa$. Our assumption that $F \in \mathrm{Fun}^{\kappa}(\mathcal{C}, \mathcal{X})$ then guarantees that the construction $\rho \mapsto \theta^F_{A,\rho}$ commutes with τ-filtered colimits. Consequently, condition (b_A) is equivalent to the following *a priori* weaker condition:

(c_A) For each $i \in I(A)$, the canonical map $\theta^F_{A,\rho_i} : \varinjlim_{\alpha \in A} F(\rho_i(\alpha)) \to F(\varinjlim_{\alpha \in A} \rho_i(\alpha))$ is an equivalence in $\mathcal{X}$.

Let I denote the set of pairs (A, ρ), where A ranges over a set of representatives for isomorphism classes of κ-small filtered partially ordered sets and $\rho : A \to \mathcal{C}$ belongs to $I(A)$. For each pair $(A, \rho) \in I$, the construction $F \mapsto \theta^F_{A,\rho}$ determines a functor $\theta_{A,\rho} : \mathrm{Fun}^{\kappa}(\mathcal{C}, \mathcal{X}) \to \mathrm{Fun}(\Delta^1, \mathcal{X})$ which preserves small colimits and finite limits. Let $\mathrm{Fun}'(\Delta^1, \mathcal{X})$ denote the full subcategory of $\mathrm{Fun}(\Delta^1, \mathcal{X})$ spanned by the equivalences in $\mathcal{X}$ (so that the diagonal embedding $\mathcal{X} \to \mathrm{Fun}'(\Delta^1, \mathcal{X})$ is an equivalence). The above argument shows that we have a pullback diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{X}) & \longrightarrow & \mathrm{Fun}^{\kappa}(\mathcal{C}, \mathcal{X})\theta_{A,\rho} \\ \downarrow & & \downarrow \prod_{(A,\rho) \in I} \\ \prod_{(A,\rho) \in I} \mathrm{Fun}'(\Delta^1, \mathcal{X}) & \longrightarrow & \prod_{(A,\rho) \in I} \mathrm{Fun}(\Delta^1, \mathcal{X}). \end{array}$$

Applying Proposition HTT.6.3.2.2 , we deduce that $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{X})$ is an ∞-topos. □

Remark 21.1.1.3. We will be primarily interested in the special case of Proposition 21.1.1.2 where $\mathcal{X} = \mathcal{S}$ is the ∞-topos of spaces (which often does not lose very much information; see Remark 21.1.2.4 below). The proof of Proposition 21.1.1.2 shows that $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ can be realized as an accessible left exact localization of the presheaf ∞-category $\mathcal{P}(\mathcal{C}_0^{\mathrm{op}}) = \mathrm{Fun}(\mathcal{C}_0, \mathcal{S})$ for an essentially small full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$. In general, we do not know if this localization is determined by a Grothendieck topology on $\mathcal{C}_0$ (or if the ∞-category $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ admits *any* presentation as an ∞-topos of sheaves for a Grothendieck topology).

Our next goal is to show that the ∞-topoi appearing in Proposition 21.1.1.2 can be characterized by a universal mapping property.

Notation 21.1.1.4. Let $\widehat{\mathcal{C}\mathrm{at}}_{\infty}^{\omega}$ denote the subcategory of $\widehat{\mathcal{C}\mathrm{at}}_{\infty}$ whose objects are accessible ∞-categories which admit small filtered colimits and whose morphisms are functors which preserve small filtered colimits.

Proposition 21.1.1.5. *Let $\mathcal{X}$ be an ∞-topos. Then:*

(1) *The construction* $\mathcal{Y} \mapsto \mathrm{Fun}^*(\mathcal{Y}, \mathcal{X})$ *determines a functor* $G : \infty\mathcal{T}\mathrm{op} \to \widehat{\mathcal{C}\mathrm{at}}_\infty^\omega$.

(2) *The functor* G *admits a left adjoint, given on objects by* $\mathcal{C} \mapsto \mathrm{Fun}^\omega(\mathcal{C}, \mathcal{X})$.

Proof. Note that for any ∞-topos $\mathcal{Y}$, the ∞-category $\mathrm{Fun}^*(\mathcal{Y}, \mathcal{X})$ is closed under small filtered colimits in $\mathrm{Fun}(\mathcal{Y}, \mathcal{X})$. In particular, $\mathrm{Fun}^*(\mathcal{Y}, \mathcal{X})$ admits small filtered colimits, and precomposition with any geometric morphism $f^* : \mathcal{Y} \to \mathcal{Z}$ determines a functor $\mathrm{Fun}^*(\mathcal{Z}, \mathcal{X}) \to \mathrm{Fun}^*(\mathcal{Y}, \mathcal{X})$ which preserves small filtered colimits. Consequently, to prove (1), it suffices to show that every ∞-category of the form $\mathrm{Fun}^*(\mathcal{Y}, \mathcal{X})$ is accessible, which is the content of Proposition HTT.6.3.1.13 . Assertion (2) follows from the observation that for $\mathcal{Y} \in \infty\mathcal{T}\mathrm{op}$ and $\mathcal{C} \in \widehat{\mathcal{C}\mathrm{at}}_\infty^\omega$, we have a canonical isomorphism of simplicial sets

$$\mathrm{Fun}^\omega(\mathcal{C}, \mathrm{Fun}^*(\mathcal{Y}, \mathcal{X})) \simeq \mathrm{Fun}^*(\mathcal{Y}, \mathrm{Fun}^\omega(\mathcal{C}, \mathcal{X}));$$

both sides can be identified with the full subcategory of $\mathrm{Fun}(\mathcal{C} \times \mathcal{Y}, \mathcal{X})$ spanned by those functors $F : \mathcal{C} \times \mathcal{Y} \to \mathcal{X}$ which preserve small filtered colimits in the first variable, small colimits in the second variable, and finite limits in the second variable. □

Corollary 21.1.1.6. *For every ∞-topos $\mathcal{Y}$, let* $\mathrm{Pt}(\mathcal{Y}) = \mathrm{Fun}^*(\mathcal{Y}, \mathcal{S})$ *denote the ∞-category of points of $\mathcal{Y}$. Then:*

(1) *The construction* $\mathcal{Y} \mapsto \mathrm{Pt}(\mathcal{Y})$ *determines a functor* $\mathrm{Pt} : \infty\mathcal{T}\mathrm{op} \to \widehat{\mathcal{C}\mathrm{at}}_\infty^\omega$.

(2) *The functor* Pt *has a left adjoint, given on objets by* $\mathcal{C} \mapsto \mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S})$.

21.1.2 Compactly Assembled ∞-Categories

We now introduce the main objects of interest in this section.

Definition 21.1.2.1. Let $\mathcal{C}$ be an ∞-category. We will say that $\mathcal{C}$ is *compactly assembled* if there exists a small ∞-category $\mathcal{C}_0$ such that $\mathcal{C}$ is a retract of $\mathrm{Ind}(\mathcal{C}_0)$ in the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty^\omega$. In other words, there exist functors $U : \mathcal{C} \to \mathrm{Ind}(\mathcal{C}_0)$ and $V : \mathrm{Ind}(\mathcal{C}_0) \to \mathcal{C}$ which preserve small filtered colimits such that the composition $V \circ U$ is equivalent to the identity functor $\mathrm{id}_\mathcal{C} : \mathcal{C} \to \mathcal{C}$.

Remark 21.1.2.2. In the statement of Definition 21.1.2.1, it is not necessary to assume *a priori* that the ∞-category $\mathcal{C}$ is accessible. Suppose that $\mathcal{C}$ admits small filtered colimits, and that there exists a small ∞-category $\mathcal{C}_0$ and a pair of functors

$$U : \mathcal{C} \to \mathrm{Ind}(\mathcal{C}_0) \qquad V : \mathrm{Ind}(\mathcal{C}_0) \to \mathcal{C}$$

which preserve small filtered colimits such that $V \circ U \simeq \mathrm{id}_\mathcal{C}$. It follows that $\mathcal{C}$ can be identified with a limit of the tower of ∞-categories

$$\cdots \to \mathrm{Ind}(\mathcal{C}_0) \xrightarrow{V \circ U} \mathrm{Ind}(\mathcal{C}_0) \xrightarrow{V \circ U} \mathrm{Ind}(\mathcal{C}_0) \xrightarrow{V \circ U} \mathrm{Ind}(\mathcal{C}_0),$$

and is therefore accessible by virtue of Proposition HTT.5.4.7.3 .

Example 21.1.2.3. For any small ∞-category $\mathcal{C}_0$, the ∞-category $\mathrm{Ind}(\mathcal{C}_0)$ is compactly assembled. In particular, any compactly generated ∞-category is compactly assembled.

Remark 21.1.2.4. Let $\mathcal{C}$ be a compactly assembled ∞-category and let $\mathcal{X}$ be a presentable ∞-category. Then $\mathcal{X}$ is tensored over the ∞-category $\mathcal{S}$ of spaces via a functor $\otimes : \mathcal{S} \times \mathcal{X} \to \mathcal{X}$ which preserves small colimits separately in each variable. We define a functor

$$\lambda : \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}) \times \mathcal{X} \to \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{X}) \qquad \lambda(F, X)(C) = F(C) \otimes X.$$

Then λ preserves small colimits separately in each variable, and therefore induces a map of presentable ∞-categories $\mu : \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}) \otimes \mathcal{X} \to \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{X})$. We claim that μ is an equivalence of ∞-categories. To prove this, we observe that μ depends functorially on $\mathcal{C}$, so we can reduce to the case where $\mathcal{C} = \mathrm{Ind}(\mathcal{C}_0)$ for some small ∞-category $\mathcal{C}_0$. In this case, the desired result follows from the observation that μ can be computed as the composition of equivalences

$$\begin{aligned} \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}) \otimes \mathcal{X} &\simeq \mathrm{Fun}(\mathcal{C}_0, \mathcal{S}) \otimes \mathcal{X} \\ &\simeq \mathrm{RFun}(\mathcal{X}^{\mathrm{op}}, \mathrm{Fun}(\mathcal{C}_0, \mathcal{S})) \\ &\simeq \mathrm{Fun}(\mathcal{C}_0, \mathrm{RFun}(\mathcal{X}^{\mathrm{op}}, \mathcal{S})) \\ &\simeq \mathrm{Fun}(\mathcal{C}_0, \mathcal{X}) \\ &\simeq \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{X}). \end{aligned}$$

In particular, if $\mathcal{X}$ is an ∞-topos, then the ∞-topos $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{X})$ of Proposition 21.1.1.2 can be identified with the product of $\mathcal{X}$ with $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ in the ∞-category $\infty\mathcal{T}\mathrm{op}$ of ∞-topoi.

Our first goal is to show that, if $\mathcal{C}$ is a compactly assembled ∞-category, then there is a *canonical* way to realize $\mathcal{C}$ as a retract of an ∞-category of the form $\mathrm{Ind}(\mathcal{C}_0)$. Essentially, the idea is to take $\mathcal{C}_0$ to be $\mathcal{C}$ itself. However, we need to take some care, since the ∞-category $\mathcal{C}$ will usually not be small.

Definition 21.1.2.5. Let $\mathcal{C}$ be an ∞-category (which is not assumed to be small) and let $j : \mathcal{C} \to \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \widehat{\mathcal{S}})$ be the Yoneda embedding (which carries an object $C \in \mathcal{C}$ to the representable functor $\mathrm{Map}_{\mathcal{C}}(\bullet, C)$). We let $\mathrm{Ind}(\mathcal{C})$ denote the smallest full subcategory of $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \widehat{\mathcal{S}})$ which contains the essential image of j and is closed under the formation of small filtered colimits. We will refer to $\mathrm{Ind}(\mathcal{C})$ as *the ∞-category of* Ind-*objects of* $\mathcal{C}$.

Remark 21.1.2.6. When the ∞-category $\mathcal{C}$ is small, the ∞-category $\mathrm{Ind}(\mathcal{C})$ appearing in Definition 21.1.2.5 agrees with the ∞-category $\mathrm{Ind}(\mathcal{C})$ of Definition HTT.5.3.5.1 (this is the content of Proposition HTT.5.3.5.3 and Corollary **??**).

Remark 21.1.2.7. Let $\mathcal{C}$ be a locally small ∞-category: that is, an ∞-category for which the mapping spaces $\mathrm{Map}_{\mathcal{C}}(X, Y)$ are (essentially) small for every pair of objects $C, D \in \mathcal{C}$.

In this case, the essential image of the inclusion $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}) \hookrightarrow \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \widehat{\mathcal{S}})$ contains all representable functors and is closed under small filtered colimits. Consequently, we can (by slight abuse of notation) regard $\mathrm{Ind}(\mathcal{C})$ as a full subcategory of $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$.

Remark 21.1.2.8. Let $\mathcal{C}$ be an ∞-category which is not assumed to be small. Using Remark HTT.5.3.5.9 , we see that the ∞-category $\mathrm{Ind}(\mathcal{C})$ can be characterized by the following universal property:

- The ∞-category $\mathrm{Ind}(\mathcal{C})$ admits small filtered colimits.
- Let $\mathcal{D}$ be any ∞-category which admits small filtered colimits, and let $\mathrm{Fun}^{\omega}(\mathrm{Ind}(\mathcal{C}), \mathcal{D})$ denote the full subcategory of $\mathrm{Fun}(\mathrm{Ind}(\mathcal{C}), \mathcal{D})$ spanned by those functors which preserve small filtered colimits. Then composition with the Yoneda embedding $\mathcal{C} \to \mathrm{Ind}(\mathcal{C})$ induces an equivalence of ∞-categories $\mathrm{Fun}^{\omega}(\mathrm{Ind}(\mathcal{C}), \mathcal{D}) \to \mathrm{Fun}(\mathcal{C}, \mathcal{D})$.

We can summarize the situation more informally as follows: if $\mathcal{D}$ is an ∞-category which admits small filtered colimits, then any functor $f : \mathcal{C} \to \mathcal{D}$ admits an essentially unique extension to a functor $F : \mathrm{Ind}(\mathcal{C}) \to \mathcal{D}$ which preserves small filtered colimits. We will refer to the functor F as the Ind-*extension* of the functor f.

Example 21.1.2.9. Let $f : \mathcal{C} \to \mathcal{D}$ be any morphism of ∞-categories, and let us abuse notation by identifying $\mathcal{C}$ and $\mathcal{D}$ with full subcategories of $\mathrm{Ind}(\mathcal{C})$ and $\mathrm{Ind}(\mathcal{D})$, respectively. Applying Remark 21.1.2.8 to the composite functor $\mathcal{C} \to \mathcal{D} \hookrightarrow \mathrm{Ind}(\mathcal{D})$, we deduce that f admits an essentially unique extension to a functor $F : \mathrm{Ind}(\mathcal{C}) \to \mathrm{Ind}(\mathcal{D})$ which preserves small filtered colimits. Concretely, the functor F is given by left Kan extension along the induced map $f^{\mathrm{op}} : \mathcal{C}^{\mathrm{op}} \to \mathcal{D}^{\mathrm{op}}$. In particular, if the functor f is fully faithful, then F is also fully faithful.

We can now give a characterization of compactly assembled ∞-categories:

Theorem 21.1.2.10. *Let $\mathcal{C}$ be an ∞-category. Then $\mathcal{C}$ is compactly assembled if and only if it satisfies the following conditions:*

(1) *The ∞-category $\mathcal{C}$ is accessible.*

(2) *The ∞-category $\mathcal{C}$ admits small filtered colimits.*

(3) *Let $G : \mathrm{Ind}(\mathcal{C}) \to \mathcal{C}$ be the* Ind-*extension of the identity functor* $\mathrm{id}_{\mathcal{C}}$. *Then G admits a left adjoint $F : \mathcal{C} \to \mathrm{Ind}(\mathcal{C})$.*

Remark 21.1.2.11. Let $\mathcal{C}$ be an arbitrary ∞-category, and let $j : \mathcal{C} \to \mathrm{Ind}(\mathcal{C})$ be the Yoneda embedding. Then $\mathcal{C}$ admits small filtered colimits if and only if the functor $j : \mathcal{C} \to \mathrm{Ind}(\mathcal{C})$ admits a left adjoint G. In this case, the functor G coincides with the Ind-extension of the identity map $\mathrm{id} : \mathcal{C} \to \mathcal{C}$. Consequently, hypotheses (2) and (3) of Theorem 21.1.2.10 can be summarized by saying that the functor j admits a left adjoint, which itself admits a further left adjoint.

Remark 21.1.2.12. In [104], Johnstone and Joyal define a *continuous category* to be a category $\mathcal{C}$ which satisfies conditions (2) and (3) of Theorem 21.1.2.10 (and then characterize such categories as those which satisfy an analogue of Definition 21.1.2.1, without a smallness condition on $\mathcal{C}_0$). Consequently, our notion of compactly assembled ∞-category (Definition 21.1.2.5) is essentially an ∞-categorical analogue of the notion of continuous category (except that we also require accessibility).

Example 21.1.2.13. Let $\mathcal{C}_0$ be a small ∞-category and let $\mathcal{C} = \mathrm{Ind}(\mathcal{C}_0)$. Then $\mathcal{C}$ obviously satisfies conditions (1) and (2) of Theorem 21.1.2.10. We claim that it also satisfies condition (3): that is, the functor $G : \mathrm{Ind}(\mathcal{C}) \to \mathcal{C}$ given by the Ind-extension of $\mathrm{id}_{\mathcal{C}}$ admits a left adjoint $F : \mathcal{C} \to \mathrm{Ind}(\mathcal{C})$. Concretely, the functor F can be described as the Ind-extension of the iterated Yoneda embedding $J : \mathcal{C}_0 \to \mathrm{Ind}(\mathcal{C}_0) \to \mathrm{Ind}(\mathrm{Ind}(\mathcal{C}_0)) = \mathrm{Ind}(\mathcal{C})$. To prove that this functor has the desired universal property, we must show that there exists a homotopy equivalence $\mathrm{Map}_{\mathrm{Ind}(\mathcal{C})}(F(C), X) \simeq \mathrm{Map}_{\mathcal{C}}(C, G(X))$, depending functorially on $C \in \mathcal{C}$ and $X \in \mathrm{Ind}(\mathcal{C})$. Note that both sides are compatible with filtered colimits in C, so it suffices to treat construct such an equivalence when $C \in \mathcal{C}$ is compact. In this case, the the functors $X \mapsto \mathrm{Map}_{\mathrm{Ind}(\mathcal{C})}(F(C), X)$ and $X \mapsto \mathrm{Map}_{\mathcal{C}}(C, G(X))$ both commute with filtered colimits in X, so we can also reduce to the case where X is a compact object of $\mathrm{Ind}(\mathcal{C})$: that is, it arises from an object $D \in \mathcal{C}$. In this case, both mapping spaces can be identified with $\mathrm{Map}_{\mathcal{C}}(C, D)$.

The proof of Theorem 21.1.2.10 depends on the following:

Lemma 21.1.2.14. *Let $G : \mathcal{C} \to \mathcal{D}$ be a functor of ∞-categories which is a retract, in the ∞-category $\mathrm{Fun}(\Delta^1, \mathcal{C}\mathrm{at}_\infty)$, of another functor $G' : \mathcal{C}' \to \mathcal{D}'$. If G' admits a left adjoint and $\mathcal{C}$ is idempotent complete, then G also admits a left adjoint.*

Proof. Since G is a retract of G', we can choose a commutative diagram of ∞-categories

$$\begin{array}{ccccc} \mathcal{C} & \xrightarrow{U} & \mathcal{C}' & \xrightarrow{V} & \mathcal{C} \\ \downarrow{\scriptstyle G} & & \downarrow{\scriptstyle G'} & & \downarrow{\scriptstyle G} \\ \mathcal{D} & \xrightarrow{U'} & \mathcal{D}' & \xrightarrow{V'} & \mathcal{D} \end{array}$$

where the outer rectangle is the identity transformation from G to itself in $\mathrm{Fun}(\Delta^1, \mathcal{C}\mathrm{at}_\infty)$. Let F' denote a left adjoint to G', and fix an object $D \in \mathcal{D}$. For every object $C \in \mathcal{C}$, we have canonical maps

$$\begin{aligned}
\mathrm{Map}_{\mathcal{D}}(D, GC) &\rightarrow \mathrm{Map}_{\mathcal{D}'}(U'DU'GC) \\
&\simeq \mathrm{Map}_{\mathcal{D}}(U'D, G'UC) \\
&\simeq \mathrm{Map}_{\mathcal{D}'}(F'U'D, UC) \\
&\rightarrow \mathrm{Map}_{\mathcal{C}}(VF'U'D, VUC) \\
&\simeq \mathrm{Map}_{\mathcal{C}}(VF'U'D, C) \\
&\rightarrow \mathrm{Map}_{\mathcal{D}}(GVF'U'D, GC) \\
&\simeq \mathrm{Map}_{\mathcal{D}}(V'G'F'U'D, GC) \\
&\rightarrow \mathrm{Map}_{\mathcal{D}}(V'U'D, GC) \\
&\simeq \mathrm{Map}_{\mathcal{D}}(D, GC).
\end{aligned}$$

These maps depend functorially on C, and the composition is homotopic to the identity (functorially in C). It follows that the functor $C \mapsto \mathrm{Map}_{\mathcal{D}}(D, GC)$ is a retract (in the ∞-category $\mathrm{Fun}(\mathcal{C}, \mathcal{S})$) of the functor corepresented by $VF'U'D$. Our assumption that $\mathcal{C}$ is idempotent complete guarantees that the collection of corepresentable functors is closed under retracts in $\mathrm{Fun}(\mathcal{C}, \mathcal{S})$, and therefore contains the functor $C \mapsto \mathrm{Map}_{\mathcal{D}}(D, GC)$. Using the criterion of Proposition HTT.5.2.4.2 , we deduce that G has a left adjoint. □

Before moving on to the proof of Theorem 21.1.2.10, we note the following easy consequence of Lemma 21.1.2.14:

Corollary 21.1.2.15. *Let $\mathcal{C}$ be an ∞-category which is a retract of another ∞-category $\mathcal{C}'$ (that is, there exist functors $U : \mathcal{C} \rightarrow \mathcal{C}'$ and $V : \mathcal{C}' \rightarrow \mathcal{C}$ such that $V \circ U$ is equivalent to the identity functor $\mathrm{id}_{\mathcal{C}}$). Suppose that $\mathcal{C}'$ admits K-indexed colimits, for some simplicial set K. If $\mathcal{C}$ is idempotent complete, then it also admits K-indexed colimits.*

Remark 21.1.2.16. In the statement of Corollary 21.1.2.15, we do not require any compatibility of the functors U and V with K-indexed colimits.

Proof of Corollary 21.1.2.15. Note that an ∞-category $\mathcal{D}$ admits K-indexed colimits if and only if the diagonal map $\delta_{\mathcal{D}} : \mathcal{D} \rightarrow \mathrm{Fun}(K, \mathcal{D})$ has a left adjoint. It will therefore suffice to show that if $\delta_{\mathcal{C}'}$ has a left adjoint and $\mathcal{C}$ is idempotent complete, then the functor $\delta_{\mathcal{C}}$ also admits a left adjoint. This is a special case of Lemma 21.1.2.14 (since the functor $\delta_{\mathcal{C}}$ is a retract of $\delta_{\mathcal{C}'}$). □

Proof of Theorem 21.1.2.10. Suppose first that $\mathcal{C}$ is a compactly assembled ∞-category. Then $\mathcal{C}$ admits small filtered colimits, and $\mathcal{C}$ is accessible by virtue of Remark 21.1.2.2. Let $G : \mathrm{Ind}(\mathcal{C}) \rightarrow \mathcal{C}$ be the Ind-extension of the identity functor; we wish to show that G admits a left adjoint. Write $\mathcal{C}$ as a retract (in the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_{\infty}^{\omega}$) of $\mathcal{C}' = \mathrm{Ind}(\mathcal{C}_0)$, where $\mathcal{C}_0$ is a small ∞-category. Then G is a retract (in the ∞-category $\widehat{\mathcal{C}\mathrm{at}}^{\omega}_{\infty}$, and therefore also in $\widehat{\mathcal{C}\mathrm{at}}_{\infty}$) of the functor $G' : \mathrm{Ind}(\mathcal{C}') \to \mathcal{C}'$ given by the Ind-extension of the identity functor $\mathrm{id}_{\mathrm{Ind}(\mathcal{C}_0)}$. By virtue of Lemma 21.1.2.14, it will suffice to show that the functor G' admits a left adjoint (note that the ∞-category $\mathrm{Ind}(\mathcal{C})$ is automatically idempotent complete, since it admits small filtered colimits), which was established in Example 21.1.2.13.

Now suppose that $\mathcal{C}$ is an ∞-category satisfying conditions (1), (2), and (3) of Theorem 21.1.2.10; we wish to show that $\mathcal{C}$ is compactly assembled. Let $G : \mathrm{Ind}(\mathcal{C}) \to \mathcal{C}$ be the Ind-extension of the identity functor $\mathrm{id}_{\mathcal{C}}$, and let $F : \mathcal{C} \to \mathrm{Ind}(\mathcal{C})$ be a left adjoint to G (whose existence is guaranteed by assumption (3)). Note that G has a fully faithful right adjoint (given by the Yoneda embedding $j : \mathcal{C} \to \mathrm{Ind}(\mathcal{C})$), so that the functor F is also fully faithful. In particular, the composition $G \circ F$ is equivalent to the identity (via the counit map $\mathrm{id}_{\mathcal{C}} \to G \circ F$).

If $\mathcal{C}_0 \subseteq \mathcal{C}$ is an essentially small full subcategory, we will abuse notation by identifying $\mathrm{Ind}(\mathcal{C}_0)$ with its essential image in $\mathrm{Ind}(\mathcal{C})$. Note that the union $\bigcup_{\mathcal{C}_0} \mathrm{Ind}(\mathcal{C}_0)$ contains the essential image of the Yoneda embedding $j : \mathcal{C} \to \mathrm{Ind}(\mathcal{C})$ and is closed under small filtered colimits, and therefore coincides with $\mathrm{Ind}(\mathcal{C})$. Since $\mathcal{C}$ is accessible, there exists a small collection of objects $\{X_\alpha\}$ which generates $\mathcal{C}$ under small filtered colimits. Choose an essentially small full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ for which each $F(X_\alpha)$ belongs to the subcategory $\mathrm{Ind}(\mathcal{C}_0) \subseteq \mathrm{Ind}(\mathcal{C})$. Since the functor F commutes with small filtered colimits, it follows that F factors through a functor $F_0 : \mathcal{C} \to \mathrm{Ind}(\mathcal{C}_0)$. Let $G_0 = G|_{\mathrm{Ind}(\mathcal{C}_0)}$. Then $G_0 \circ F_0$ is equivalent to the identity functor $\mathrm{id}_{\mathcal{C}}$, so that F_0 and G_0 exhibit $\mathcal{C}$ as a retract of $\mathrm{Ind}(\mathcal{C}_0)$ in the ∞-category $\widehat{\mathcal{C}\mathrm{at}}^{\omega}_{\infty}$. □

Corollary 21.1.2.17. *Let $\mathcal{C}$ be an idempotent complete ∞-category. The following conditions are equivalent:*

- (a) *The ∞-category $\mathcal{C}$ is compactly assembled.*
- (b) *There exists a pair of adjoint functors $\mathcal{C} \underset{g}{\overset{f}{\rightleftarrows}} \mathcal{D}$ where $\mathcal{D}$ is an ∞-category of the form $\mathrm{Ind}(\mathcal{D}_0)$ for some small ∞-category $\mathcal{D}_0$, the functor g preserve small filtered colimits, and the unit map $\mathrm{id}_{\mathcal{C}} \to g \circ f$ is an equivalence.*

Proof. Suppose that (a) is satisfied and let $G : \mathrm{Ind}(\mathcal{C}) \to \mathcal{C}$ be an Ind-extension of the identity functor $\mathrm{id}_{\mathcal{C}}$. Then G admits a left adjoint $F : \mathcal{C} \to \mathrm{Ind}(\mathcal{C})$. The proof of Theorem 21.1.2.10 shows that F factors through $\mathrm{Ind}(\mathcal{C}_0)$ for some essentially small subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$. Setting $G_0 = G|_{\mathrm{Ind}(\mathcal{C}_0)}$, we see that the adjunction $\mathcal{C} \underset{G_0}{\overset{F}{\rightleftarrows}} \mathrm{Ind}(\mathcal{C}_0)$ satisfies the requirements of (b) (note that the unit map $\mathrm{id}_{\mathcal{C}} \to G_0 \circ F$ is an equivalence because the functor F is fully faithful: this is equivalent to the full-faithfulness of the Yoneda embedding $j : \mathcal{C} \to \mathrm{Ind}(\mathcal{C})$, since both functors are adjoint to G).

Now suppose we are given an adjunction $\mathcal{C} \underset{g}{\overset{f}{\rightleftarrows}} \mathcal{D}$ satisfying the requirements of (b). Then f and g exhibit $\mathcal{C}$ as a retract of $\mathcal{D}$. Since $\mathcal{C}$ is idempotent-complete, Corollary 21.1.2.15 implies that $\mathcal{C}$ admits small filtered colimits. The functor f automatically preserves small filtered colimits (since it is a left adjoint). Applying Remark 21.1.2.2, we see that $\mathcal{C}$ is accessible, so that f and g exhibit $\mathcal{C}$ as a retract of $\mathcal{D}$ in the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty^\omega$. □

Corollary 21.1.2.18. *Let $\mathcal{C}$ be an ∞-category. The following conditions are equivalent:*

- (a) *The ∞-category $\mathcal{C}$ is presentable and compactly assembled.*
- (b) *The ∞-category $\mathcal{C}$ is presentable. Moreover, in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable ∞-categories, $\mathcal{C}$ can be written as the retract of a compactly generated ∞-category $\mathcal{C}'$.*
- (c) *The ∞-category $\mathcal{C}$ is accessible and admits small filtered colimits. Moreover, in the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty^\omega$, $\mathcal{C}$ can be written as a retract of a compactly generated ∞-category $\mathcal{C}'$.*

Proof. Assume first that (a) is satisfied, and let $G : \mathrm{Ind}(\mathcal{C}) \to \mathcal{C}$ be an Ind-extension of the identity functor. Applying Theorem 21.1.2.10, we deduce that G admits a left adjoint $F : \mathcal{C} \to \mathrm{Ind}(\mathcal{C})$. Moreover, the proof of Theorem 21.1.2.10 shows that F factors through $F_0 : \mathcal{C} \to \mathrm{Ind}(\mathcal{C}_0)$, for some essentially small full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$. Enlarging $\mathcal{C}_0$ if necessary, we may assume that $\mathcal{C}_0$ admits finite colimits. In this case, the functors $F_0 : \mathcal{C} \to \mathrm{Ind}(\mathcal{C}_0)$ and $G|_{\mathrm{Ind}(\mathcal{C}_0)}$ exhibit $\mathcal{C}$ as a retract of $\mathrm{Ind}(\mathcal{C}_0)$ in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable ∞-categories, so that condition (b) is satisfied.

The implication $(b) \Rightarrow (c)$ is obvious. We will complete the proof by showing that $(c) \Rightarrow (a)$. Assume that $\mathcal{C}'$ is a compactly generated ∞-category and that $\mathcal{C}$ is a retract of $\mathcal{C}'$ in the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty^\omega$. Then $\mathcal{C}$ is compactly assembled. In particular, it is accessible, and therefore idempotent complete. To show that it is presentable, it suffices to show that $\mathcal{C}$ admits small colimits. This follows from Corollary 21.1.2.15, since the ∞-category $\mathcal{C}'$ admits small colimits. □

Corollary 21.1.2.19. *Let $\mathcal{C}$ and $\mathcal{D}$ be presentable ∞-categories, and let $\mathcal{C} \otimes \mathcal{D}$ denote their tensor product (in the sense of §HA.4.8.1). If $\mathcal{C}$ and $\mathcal{D}$ are compactly assembled, then $\mathcal{C} \otimes \mathcal{D}$ is also compactly assembled.*

Proof. By virtue of Corollary 21.1.2.18, we can write $\mathcal{C}$ and $\mathcal{D}$ as retracts (in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$) of compactly generated ∞-categories $\mathcal{C}'$ and $\mathcal{D}'$. Then $\mathcal{C} \otimes \mathcal{D}$ is a retract of $\mathcal{C}' \otimes \mathcal{D}'$, and is therefore compactly assembled (since $\mathcal{C}' \otimes \mathcal{D}'$ is also compactly generated). □

21.1.3 Another Universal Property of $\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S})$

Let $\mathcal{C}$ be a compactly assembled ∞-category. Our goal in this section is to characterize $\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S})$ by a universal property in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable ∞-categories:

that is, to classify colimit-preserving functors $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}) \to \mathcal{X}$, when $\mathcal{X}$ is a presentable ∞-category. We begin by treating an easy special case:

Proposition 21.1.3.1. *Let $\mathcal{C}$ be an ∞-category which has the form $\mathrm{Ind}(\mathcal{C}_0)$, for some small ∞-category $\mathcal{C}$. For any presentable ∞-category $\mathcal{X}$, there is a canonical equivalence of ∞-categories*

$$\rho_{\mathcal{C}} : \mathrm{Fun}_{\omega}(\mathcal{C}^{\mathrm{op}}, \mathcal{X}) \simeq \mathrm{LFun}(\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}), \mathcal{X}).$$

Here $\mathrm{Fun}_{\omega}(\mathcal{C}^{\mathrm{op}}, \mathcal{X})$ denotes the full subcategory of $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{X})$ spanned by those functors which preserve small filtered limits.

Proof. Let $\mathcal{C}_c \subseteq \mathcal{C}$ be the full subcategory spanned by the compact objects of $\mathcal{C}$. Note that the Yoneda embedding $j : \mathcal{C}^{\mathrm{op}} \to \mathrm{Fun}(\mathcal{C}, \mathcal{S})$ carries $\mathcal{C}_c^{\mathrm{op}}$ into $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$. We therefore have restriction functors

$$\mathrm{Fun}_{\omega}(\mathcal{C}^{\mathrm{op}}, \mathcal{X}) \to \mathrm{Fun}(\mathcal{C}_c^{\mathrm{op}}, \mathcal{X}) \leftarrow \mathrm{LFun}(\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}), \mathcal{X}).$$

Using Proposition HTT.5.3.5.10 and Theorem HTT.5.1.5.6 , we see that these restriction functors are equivalences of ∞-categories. □

Remark 21.1.3.2. In the statement of Proposition 21.1.3.1, we do not need the full strength of our assumption that $\mathcal{X}$ is presentable: it is enough to assume that $\mathcal{X}$ admits small colimits and small filtered limits. The same observation applies to the all of the other results we prove in this section.

The main result of this section is the following generalization of Proposition 21.1.3.1:

Proposition 21.1.3.3. *Let $\mathcal{X}$ be a presentable ∞-category. For every compactly assembled ∞-category $\mathcal{C}$, there exists an equivalence of ∞-categories $\rho_{\mathcal{C}} : \mathrm{LFun}(\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}), \mathcal{X}) \simeq \mathrm{Fun}_{\omega}(\mathcal{C}^{\mathrm{op}}, \mathcal{X})$. Moreover, these equivalences can be chosen to have the following properties:*

(1) *When $\mathcal{C} = \mathrm{Ind}(\mathcal{C}_0)$ for some small ∞-category $\mathcal{C}$, the functor $\rho_{\mathcal{C}}$ agrees with the equivalence constructed in the proof of Proposition 21.1.3.1.*

(2) *Suppose we are given compactly assembled ∞-categories $\mathcal{C}$ and $\mathcal{D}$ and a pair of adjoint functors $\mathcal{C} \underset{g}{\overset{f}{\rightleftarrows}} \mathcal{D}$ where f and g preserve small filtered colimits. Let $T_0 : \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}) \to \mathrm{Fun}^{\omega}(\mathcal{D}, \mathcal{S})$ be the functor given by precomposition with g. Then the diagram of ∞-categories*

$$\begin{array}{ccc} \mathrm{Fun}_{\omega}(\mathcal{C}^{\mathrm{op}}, \mathcal{X}) & \xrightarrow{\rho_{\mathcal{C}}} & \mathrm{LFun}(\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}), \mathcal{X}) \\ \downarrow{\circ f^{\mathrm{op}}} & & \downarrow{\circ T_0} \\ \mathrm{Fun}_{\omega}(\mathcal{D}^{\mathrm{op}}, \mathcal{X}) & \xrightarrow{\rho_{\mathcal{D}}} & \mathrm{LFun}(\mathrm{Fun}^{\omega}(\mathcal{D}, \mathcal{S}), \mathcal{X}) \end{array}$$

commutes (up to canonical homotopy).

Remark 21.1.3.4. In the situation of Proposition 21.1.3.3, the equivalence $\rho_{\mathcal{C}}$ is characterized by properties (1) and (2). To see this, note that we can choose an adjunction $\mathcal{C} \underset{g}{\overset{f}{\rightleftarrows}} \mathcal{D}$ where $\mathcal{D} = \mathrm{Ind}(\mathcal{D}_0)$ for some small ∞-category $\mathcal{D}_0$, and the functor f is fully faithful (Corollary 21.1.2.17). In this case, property (2) guarantees that we have a commutative diagram

$$\begin{array}{ccc} \mathrm{Fun}_{\omega}(\mathcal{C}^{\mathrm{op}}, \mathcal{X}) & \xrightarrow{\rho_{\mathcal{C}}} & \mathrm{LFun}(\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}), \mathcal{X}) \\ \downarrow{\circ f^{\mathrm{op}}} & & \downarrow{\circ T_0} \\ \mathrm{Fun}_{\omega}(\mathcal{D}^{\mathrm{op}}, \mathcal{X}) & \xrightarrow{\rho_{\mathcal{D}}} & \mathrm{LFun}(\mathrm{Fun}^{\omega}(\mathcal{D}, \mathcal{S}), \mathcal{X}) \end{array}$$

where the vertical maps are fully faithful embeddings. Consequently, the equivalence $\rho_{\mathcal{C}}$ is determined by the equivalence $\rho_{\mathcal{D}}$, which is determined by property (1).

The rest of this section is devoted to the proof of Proposition 21.1.3.3. The essential difficulty that we need to overcome is that the equivalence $\rho_{\mathcal{C}} : \mathrm{Fun}_{\omega}(\mathcal{C}^{\mathrm{op}}, \mathcal{X}) \simeq \mathrm{LFun}(\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}), \mathcal{X})$ of Proposition 21.1.3.1 was constructed using the auxiliary ∞-category $\mathrm{Fun}(\mathcal{C}_c^{\mathrm{op}}, \mathcal{X})$, and is therefore not obviously functorial in $\mathcal{C}$ (with respect to functors that do not preserve compact objects). Our first goal will be to rephrase the proof of Proposition 21.1.3.1 in a way that does not make explicit reference to compact objects of $\mathcal{C}$ (and can therefore be generalized to situations where $\mathcal{C}$ is not generated by compact objects).

Notation 21.1.3.5. Let $\mathcal{C}$ be a compactly assembled ∞-category. We let $\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C}, \mathcal{S})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{S})$ spanned by the corepresentable functors (that is, the essential image of the Yoneda embedding $j : \mathcal{C}^{\mathrm{op}} \to \mathrm{Fun}(\mathcal{C}, \mathcal{S})$). We let $\mathrm{Fun}^{+}(\mathcal{C}, \mathcal{S})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{S})$ spanned by those functors $U : \mathcal{C} \to \mathcal{S}$ which belong either to $\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C}, \mathcal{S})$ or $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$, and let $\mathrm{Fun}^{\circ}(\mathcal{C}, \mathcal{S})$ denote the intersection $\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C}, \mathcal{S}) \cap \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$. Note that $\mathrm{Fun}^{\circ}(\mathcal{C}, \mathcal{S})$ is the full subcategory spanned by those functors $U : \mathcal{C} \to \mathcal{S}$ which are corepresented by *compact* objects of $\mathcal{C}$, and is therefore equivalent to the ∞-category $\mathcal{C}_c^{\mathrm{op}}$. Beware that, in general, the ∞-category $\mathrm{Fun}^{\circ}(\mathcal{C}, \mathcal{S})$ may be empty.

Remark 21.1.3.6 (Functoriality)**.** Suppose we are given a pair of adjoint functors $\mathcal{C} \underset{g}{\overset{f}{\rightleftarrows}} \mathcal{D}$, where $\mathcal{C}$ and $\mathcal{D}$ are compactly assembled and the functors f and g preserve small filtered colimits. Then precomposition with g induces a functor $\mathrm{Fun}(\mathcal{C}, \mathcal{S}) \to \mathrm{Fun}(\mathcal{D}, \mathcal{S})$, which carries $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ into $\mathrm{Fun}^{\omega}(\mathcal{D}, \mathcal{S})$ (since the functor g preserves small filtered colimits) and $\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C}, \mathcal{S})$ into $\mathrm{Fun}^{\mathrm{rep}}(\mathcal{D}, \mathcal{S})$ (since the functor g admits a left adjoint). We therefore obtain a functor $T : \mathrm{Fun}^+(\mathcal{C}, \mathcal{S}) \to \mathrm{Fun}^+(\mathcal{D}, \mathcal{S})$. Note that the diagram of ∞-categories

$$\begin{array}{ccc} \mathcal{C}^{\mathrm{op}} & \longrightarrow & \mathrm{Fun}^+(\mathcal{C}, \mathcal{S}) \\ \downarrow{\scriptstyle f^{\mathrm{op}}} & & \downarrow{\scriptstyle T} \\ \mathcal{D}^{\mathrm{op}} & \longrightarrow & \mathrm{Fun}^+(\mathcal{D}, \mathcal{S}) \end{array}$$

commutes up to canonical homotopy (here the horizontal maps are given by the Yoneda embeddings of $\mathcal{C}$ and $\mathcal{D}$, respectively).

Lemma 21.1.3.7. *Let $\mathcal{C}_0$ be a small ∞-category, let $\mathcal{C} = \mathrm{Ind}(\mathcal{C}_0)$, and let $\mathrm{Fun}^{\circ}(\mathcal{C}, \mathcal{S})$ be the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{S})$ spanned by those functors which are corepresentable by* compact *objects of $\mathcal{C}$. Then:*

(*i*) *For every object $V \in \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$, the inclusion functor*

$$\mathrm{Fun}^{\circ}(\mathcal{C}, \mathcal{S}) \times_{\mathrm{Fun}^+(\mathcal{C},\mathcal{S})} \mathrm{Fun}^+(\mathcal{C}, \mathcal{S})_{/V} \hookrightarrow \mathrm{Fun}^{\mathrm{rep}}(\mathcal{C}, \mathcal{S}) \times_{\mathrm{Fun}^+(\mathcal{C},\mathcal{S})} \mathrm{Fun}^+(\mathcal{C}, \mathcal{S})_{/V}$$

is left cofinal.

(*ii*) *For every object $U \in \mathrm{Fun}^{\mathrm{rep}}(\mathcal{C}, \mathcal{S})$, the inclusion functor*

$$\mathrm{Fun}^{\circ}(\mathcal{C}, \mathcal{S}) \times_{\mathrm{Fun}^+(\mathcal{C},\mathcal{S})} \mathrm{Fun}^+(\mathcal{C}, \mathcal{S})_{U/} \hookrightarrow \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}) \times_{\mathrm{Fun}^+(\mathcal{C},\mathcal{S})} \mathrm{Fun}^+(\mathcal{C}, \mathcal{S})_{U/}$$

is right cofinal.

Proof. By virtue of Proposition HTT.4.1.3.1 , assertions (*i*) and (*ii*) are both equivalent to the following:

(*iii*) Suppose we are given a morphism $\alpha : U \to V$ in $\mathrm{Fun}^+(\mathcal{C}, \mathcal{S})$, where $U \in \mathrm{Fun}^{\mathrm{rep}}(\mathcal{C}, \mathcal{S})$ and $V \in \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$. Let $\mathcal{E}$ be the full subcategory of $\mathrm{Fun}^+(\mathcal{C}, \mathcal{S})_{U//V}$ spanned by those objects whose image in $\mathrm{Fun}^+(\mathcal{C}, \mathcal{S})$ belongs to $\mathrm{Fun}^{\circ}(\mathcal{C}, \mathcal{S})$. Then $\mathcal{E}$ is weakly contractible.

Choose an object $C \in \mathcal{C}$ which corepresents the functor U, so that α is classified by a point $\eta \in V(C)$. Using Proposition HTT.**??** , we see that the weak homotopy type of $\mathcal{E}$ can be computed as a colimit $\varinjlim_{C_0 \to C}(V(C_0) \times_{V(C)} \{\eta\})$, where the colimit is taken over the full subcategory of $\mathcal{C}_{/C}$ spanned by those maps $C_0 \to C$ where C_0 is compact. The desired result now follows from our assumption that the functor V commutes with small filtered colimits. □

Lemma 21.1.3.8. *Let $\mathcal{C}_0$ be a small ∞-category, let $\mathcal{C} = \mathrm{Ind}(\mathcal{C}_0)$, and define $\mathrm{Fun}^{\circ}(\mathcal{C}, \mathcal{S})$ as in Lemma 21.1.3.7. Suppose we are given a functor $F : \mathrm{Fun}^+(\mathcal{C}, \mathcal{S}) \to \mathcal{X}$, where the ∞-category $\mathcal{X}$ admits small colimits. The following conditions are equivalent:*

(a) *The functor F is a left Kan extension of its restriction $F|_{\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S})}$.*

(b) *The functor $F|_{\mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S})}$ is a left Kan extension of its restriction $F|_{\mathrm{Fun}^{\circ}(\mathcal{C},\mathcal{S})}$.*

(c) *The functor $F|_{\mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S})}$ preserves small colimits.*

Moreover, every functor $F_0 : \mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S}) \to \mathcal{X}$ admits a left Kan extension $F : \mathrm{Fun}^{+}(\mathcal{C},\mathcal{S})$.

Proof. The equivalence of (a) and (b) follows from Lemma 21.1.3.7, and the equivalence of (b) and (c) follows from Lemma HTT.5.1.5.5 (since the inclusion $\mathrm{Fun}^{\circ}(\mathcal{C},\mathcal{S}) \hookrightarrow \mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S})$ is equivalent to the Yoneda embedding $\mathcal{C}_c^{\mathrm{op}} \hookrightarrow \mathcal{P}(\mathcal{C}_c^{\mathrm{op}})$, where $\mathcal{C}_c \subseteq \mathcal{C}$ is the full subcategory spanned by the compact objects). To prove the final assertion, it will suffice (by virtue of Lemma 21.1.3.7) to show that every functor $\mathrm{Fun}^{\circ}(\mathcal{C},\mathcal{S}) \to \mathcal{X}$ admits a left Kan extension to $\mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S})$, which also follows from Lemma HTT.5.1.5.5. □

Lemma 21.1.3.9. *Let $\mathcal{C}_0$ be a small ∞-category, let $\mathcal{C} = \mathrm{Ind}(\mathcal{C}_0)$, and define $\mathrm{Fun}^{\circ}(\mathcal{C},\mathcal{S})$ as in Lemma 21.1.3.7. Suppose we are given a functor $F : \mathrm{Fun}^{+}(\mathcal{C},\mathcal{S}) \to \mathcal{X}$, where the ∞-category $\mathcal{X}$ admits small filtered limits. The following conditions are equivalent:*

(a) *The functor F is a right Kan extension of its restriction $F|_{\mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S})}$.*

(b) *The functor $F|_{\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S})}$ is a right Kan extension of its restriction to $F|_{\mathrm{Fun}^{\circ}(\mathcal{C},\mathcal{S})}$.*

(c) *The functor $F|_{\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S})}$ preserves small filtered limits.*

Moreover, every functor $F_0 : \mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S}) \to \mathcal{X}$ admits a right Kan extension $F : \mathrm{Fun}^{+}(\mathcal{C},\mathcal{S}) \to \mathcal{X}$.

Proof. The equivalence of (a) and (b) follows from Lemma 21.1.3.7, and the equivalence of (b) and (c) follows from Lemma HTT.5.3.5.8 (since the inclusion $\mathrm{Fun}^{\circ}(\mathcal{C},\mathcal{S}) \hookrightarrow \mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S})$ is equivalent to the opposite of the inclusion $\mathcal{C}_c \hookrightarrow \mathrm{Ind}(\mathcal{C}_c) \simeq \mathcal{C}$). To prove the final assertion, it will suffice (by virtue of Lemma 21.1.3.7) to show that every functor $\mathrm{Fun}^{\circ}(\mathcal{C},\mathcal{S}) \to \mathcal{X}$ admits a right Kan extension to $\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S})$, which also follows from Lemma HTT.5.3.5.8. □

Lemma 21.1.3.10. *Suppose we are given an adjunction $\mathcal{C} \underset{g}{\overset{f}{\rightleftarrows}} \mathcal{D}$, where $\mathcal{C}$ and $\mathcal{D}$ are compactly assembled ∞-categories, and let $T : \mathrm{Fun}^{+}(\mathcal{C},\mathcal{S}) \to \mathrm{Fun}^{+}(\mathcal{D},\mathcal{S})$ be as in Remark 21.1.3.6. Suppose we are given a functor $F : \mathrm{Fun}^{+}(\mathcal{D},\mathcal{S}) \to \mathcal{X}$, where $\mathcal{X}$ is a presentable ∞-category. Then:*

(i) *If F is a left Kan extension of $F|_{\mathrm{Fun}^{\mathrm{rep}}(\mathcal{D},\mathcal{S})}$, then $F \circ T$ is a left Kan extension of $(F \circ T)|_{\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S})}$.*

(ii) *If the functor $F|_{\mathrm{Fun}^{\mathrm{rep}}(\mathcal{D},\mathcal{S})}$ commutes with small filtered limits, then $(F \circ T)|_{\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S})}$ commutes with small filtered limits.*

(iii) *If F is a right Kan extension of $F|_{\mathrm{Fun}^{\omega}(\mathcal{D},\mathcal{S})}$, then $F \circ T$ is a right Kan extension of $(F \circ T)|_{\mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S})}$.*

(iv) *If the functor $F|_{\mathrm{Fun}^{\omega}(\mathcal{D},\mathcal{S})}$ commutes with small colimits, then the functor $(F \circ T)|_{\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S})}$ commutes with small colimits.*

Proof. Assertion (ii) follows from the observation that the functor f^{op} preserves small filtered limits. Similarly, assertion (iv) follows from the observation that the functor $T|_{\mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S})} \to \mathrm{Fun}^{\omega}(\mathcal{D},\mathcal{S})$ preserves small colimits (since colimits can be computed pointwise on both sides). We will prove (i); the proof of (iii) is similar. Assume that $F : \mathrm{Fun}^{+}(\mathcal{D},\mathcal{S}) \to \mathcal{X}$ is a left Kan extension of $F|_{\mathrm{Fun}^{\mathrm{rep}}(\mathcal{D},\mathcal{S})}$, and fix an object $V \in \mathrm{Fun}^{+}(\mathcal{C},\mathcal{S})$. We will show that $F \circ T$ is a left Kan extension of $(F \circ T)|_{\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S})}$ at V. Without loss of generality we may assume that $V \in \mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S})$ (otherwise the result is trivial); we wish to show that the canonical map $\rho : \varinjlim_{U \in \mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S})_{/V}} (F \circ T)(U) \to (F \circ T)(V)$ is an equivalence. Since F is a left Kan extension $F|_{\mathrm{Fun}^{\mathrm{rep}}(\mathcal{D},\mathcal{S})}$ at $T(V)$, we can identify the codomain of ρ with the colimit $\varinjlim_{V' \in \mathrm{Fun}^{\mathrm{rep}}(\mathcal{D},\mathcal{S})_{/T(V)}} F(V')$. It will therefore suffice to show that the functor T induces a left cofinal map

$$\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S})_{/V} \to \mathrm{Fun}^{\mathrm{rep}}(\mathcal{D},\mathcal{S})_{/T(V)}.$$

In fact, this functor admits a left adjoint (induced by the functor g^{op}). □

Lemma 21.1.3.11. . *Let $\mathcal{C}$ be a compactly assembled ∞-category and let $\mathcal{X}$ be a presentable ∞-category. Then:*

(a) *Let $F_0 : \mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S}) \to \mathcal{X}$ be any functor. Then F_0 admits a left Kan extension $F : \mathrm{Fun}^{+}(\mathcal{C},\mathcal{S}) \to \mathcal{X}$, and the restriction $F|_{\mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S})} : \mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S}) \to \mathcal{X}$ preserves small colimits. Moreover, if F_0 preserves small filtered limits, then F is a right Kan extension of $F|_{\mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S})}$.*

(b) *Let $F_1 : \mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S}) \to \mathcal{X}$ be any functor. Then F_1 admits a right Kan extension $F : \mathrm{Fun}^{+}(\mathcal{C},\mathcal{S}) \to \mathcal{X}$, and the restriction $F|_{\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S})} : \mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S}) \to \mathcal{X}$ preserves small filtered limits. Moreover, if F_1 preserves small colimits, then F is a left Kan extension of $F|_{\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S})}$.*

Proof. We will prove (a); the proof of (b) is similar. Since $\mathcal{C}$ is compactly assembled, the canonical map $\mathrm{Ind}(\mathcal{C}) \to \mathcal{C}$ admits a left adjoint f. Applying Corollary 21.1.2.17, we can choose an adjunction $\mathcal{C} \underset{g}{\overset{f}{\rightleftarrows}} \mathcal{D}$ where $\mathcal{D} = \mathrm{Ind}(\mathcal{D}_0)$ for some small ∞-category $\mathcal{D}_0$, the functors f and g preserve small filtered colimits, and f is fully faithful. Let $\overline{F}_0$ denote the composition

$$\mathrm{Fun}^{\mathrm{rep}}(\mathcal{D},\mathcal{S}) \simeq \mathcal{D}^{\mathrm{op}} \xrightarrow{g^{\mathrm{op}}} \mathcal{C}^{\mathrm{op}} \simeq \mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S})$$

so that $F_0 \simeq \overline{F}_0 \circ T$, where $T : \mathrm{Fun}^+(\mathcal{C}, \mathcal{S}) \to \mathrm{Fun}^+(\mathcal{D}, \mathcal{S})$ is the functor given by composition with g. Applying Lemma 21.1.3.8, we deduce that $\overline{F}_0$ admits a left Kan extension $\overline{F} : \mathrm{Fun}^+(\mathcal{D}, \mathcal{S}) \to \mathcal{X}$, where $\overline{F}|_{\mathrm{Fun}^\omega(\mathcal{D},\mathcal{S})}$ preserves small colimits. Set $F = \overline{F} \circ T$. It follows from Lemma 21.1.3.10 that F is a left Kan extension of $F|_{\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S})} \simeq F_0$, and that $F|_{\mathrm{Fun}^\omega(\mathcal{C},\mathcal{S})}$ preserves small colimits. If the functor F_0 preserves small filtered limits, then the functor $\overline{F}_0$ has the same property, so that $\overline{F}$ is a right Kan extension of its restriction $\overline{F}|_{\mathrm{Fun}^\omega(\mathcal{D},\mathcal{S})}$ (Lemma 21.1.3.9). Applying Lemma 21.1.3.10, we deduce that F is a right Kan extension of its restriction to $\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S})$. □

Lemma 21.1.3.12. *Let $\mathcal{C}$ be a compactly assembled ∞-category, let $\mathcal{X}$ be a presentable ∞-category, and let $F : \mathrm{Fun}^+(\mathcal{C}, \mathcal{S}) \to \mathcal{X}$ be a functor. The following conditions are equivalent:*

- (a) *The functor $F|_{\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S})}$ preserves small filtered limits, and F is a left Kan extension of $F|_{\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C},\mathcal{S})}$.*
- (b) *The functor $F|_{\mathrm{Fun}^\omega(\mathcal{C},\mathcal{S})}$ preserves small colimits, and F is a right Kan extension of $F|_{\mathrm{Fun}^{omega}(\mathcal{C},\mathcal{S})}$.*

Proof. Apply Lemma **??**. □

Notation 21.1.3.13. Let $\mathcal{X}$ be a presentable ∞-category and let $\mathcal{C}$ be a compactly assembled ∞-category. We let $\mathcal{M}[\mathcal{C}, \mathcal{X}]$ denote the full subcategory of $\mathrm{Fun}(\mathrm{Fun}^+(\mathcal{C}, \mathcal{S}), \mathcal{X})$ spanned by those functors $F : \mathrm{Fun}^+(\mathcal{C}, \mathcal{S}) \to \mathcal{X}$ which satisfy the equivalent conditions (a) and (b) of Lemma 21.1.3.12.

Remark 21.1.3.14. Let $\mathcal{X}$ be a presentable ∞-category and let $\mathcal{C}$ be a compactly assembled ∞-category. We have evident restriction maps

$$\mathrm{Fun}_\omega(\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C}, \mathcal{S}), \mathcal{X}) \leftarrow \mathcal{M}[\mathcal{C}, \mathcal{X}] \to \mathrm{LFun}(\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S}), \mathcal{X}).$$

It follows from Lemma 21.1.3.11 and Proposition HTT.4.3.2.15 that these maps are trivial Kan fibrations.

Remark 21.1.3.15. Let $\mathcal{X}$ be a presentable ∞-category and let $\mathcal{C}$ be an ∞-category of the form $\mathrm{Ind}(\mathcal{C}_0)$, where $\mathcal{C}_0$ is a small ∞-category. Then we have a commutative diagram of restriction functors

$$\begin{array}{ccccc} \mathcal{M}[\mathcal{C}, \mathcal{X}] & \longrightarrow & \mathrm{Fun}_\omega(\mathrm{Fun}^{\mathrm{rep}}(\mathcal{C}, \mathcal{S}), \mathcal{X}) & \longrightarrow & \mathrm{Fun}_\omega(\mathcal{C}^{\mathrm{op}}, \mathcal{X}) \\ \downarrow & & \downarrow & & \downarrow \\ \mathrm{LFun}(\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S}), \mathcal{X}) & \longrightarrow & \mathrm{Fun}(\mathrm{Fun}^\circ(\mathcal{C}, \mathcal{S}), \mathcal{X}) & \longrightarrow & \mathrm{Fun}(\mathcal{C}_c^{\mathrm{op}}, \mathcal{X}). \end{array}$$

where the maps in the left square are trivial Kan fibrations and the right horizontal maps are equivalences (given by composition with the equivalences $\mathcal{C}^{\mathrm{op}} \simeq \mathrm{Fun}^{\mathrm{rep}}(\mathcal{C}, \mathcal{S})$ and $\mathcal{C}_c^{\mathrm{op}} \simeq \mathrm{Fun}^{\circ}(\mathcal{C}, \mathcal{S})$). Unwinding the definition, we see that the equivalence $\rho_{\mathcal{C}} : \mathrm{Fun}_{\omega}(\mathcal{C}^{\mathrm{op}}, \mathcal{X}) \simeq \mathrm{LFun}(\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}), \mathcal{X})$ appearing in the proof of Proposition 21.1.3.1 can be written as a composition of the right vertical map with a homotopy inverse of the bottom composition. Using the commutativity of the diagram, we see that $\rho_{\mathcal{C}}$ can also be identified with the composition

$$\mathrm{Fun}_{\omega}(\mathcal{C}^{\mathrm{op}}, \mathcal{X}) \xleftarrow{\sim} \mathrm{Fun}_{\omega}(\mathrm{Fun}_{\mathrm{rep}}(\mathcal{C}, \mathcal{S}), \mathcal{X}) \xleftarrow{\sim} \mathcal{M}[\mathcal{C}, \mathcal{X}] \xrightarrow{\sim} \mathrm{LFun}(\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}), \mathcal{X}).$$

Proof of Proposition 21.1.3.3. For any compactly assembled ∞-category $\mathcal{C}$ and presentable ∞-category $\mathcal{X}$, define $\rho_{\mathcal{C}} : \mathrm{Fun}_{\omega}(\mathcal{C}^{\mathrm{op}}, \mathcal{X}) \to \mathrm{LFun}(\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}), \mathcal{X})$ to be a composition of the restriction map $\mathcal{M}[\mathcal{C}, \mathcal{X}] \to \mathrm{LFun}(\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}), \mathcal{X})$ with a homotopy inverse to the restriction map $\mathcal{M}[\mathcal{C}, \mathcal{X}] \to \mathrm{Fun}_{\omega}(\mathcal{C}^{\mathrm{op}}, \mathcal{X})$. It follows from Proposition **??** that $\rho_{\mathcal{C}}$ is a well-defined equivalence of ∞-categories. By virtue of Remark 21.1.3.15, it agrees with the equivalence constructed in the proof of Proposition 21.1.3.1 in the case where $\mathcal{C}$ has the form $\mathrm{Ind}(\mathcal{C}_0)$, for some small ∞-category $\mathcal{C}_0$. If $\mathcal{D}$ is another compactly assembled ∞-category and we are given an adjunction $\mathcal{C} \underset{g}{\overset{f}{\rightleftarrows}} \mathcal{D}$, where f and g preserve small filtered colimits, then the compatibility of $\rho_{\mathcal{C}}$ and $\rho_{\mathcal{D}}$ follows from the commutativity of the diagram of restriction functors

$$\begin{array}{ccccc}
\mathrm{Fun}_{\omega}(\mathrm{Fun}_{\mathrm{rep}}(\mathcal{D}, \mathcal{S}), \mathcal{X}) & \longleftarrow & \mathcal{M}[\mathcal{D}, \mathcal{X}] & \longrightarrow & \mathrm{LFun}(\mathrm{Fun}^{\omega}(\mathcal{D}, \mathcal{S}), \mathcal{X}) \\
\downarrow & & \downarrow & & \downarrow \\
\mathrm{Fun}_{\omega}(\mathrm{Fun}_{\mathrm{rep}}(\mathcal{C}, \mathcal{S}), \mathcal{X}) & \longleftarrow & \mathcal{M}[\mathcal{C}, \mathcal{X}] & \longrightarrow & \mathrm{LFun}(\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}), \mathcal{X}),
\end{array}$$

where the vertical maps are given by composition with the functor T of Remark 21.1.3.6. □

Remark 21.1.3.16 (Wavy Arrows)**.** Let $\mathcal{C}$ be a compactly assembled ∞-category, let $\mathcal{X} = \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$, and let

$$\rho_{\mathcal{C}} : \mathrm{Fun}_{\omega}(\mathcal{C}^{\mathrm{op}}, \mathcal{X}) \to \mathrm{LFun}(\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}), \mathcal{X})$$

be the equivalence of Proposition 21.1.3.3. Then $\rho_{\mathcal{C}}^{-1}$ carries the identity functor $\mathrm{id}_{\mathcal{X}}$ to an object of $\mathrm{Fun}_{\omega}(\mathcal{C}^{\mathrm{op}}, \mathcal{X}) \subseteq \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathrm{Fun}(\mathcal{C}, \mathcal{S}))$, which we can identify with a bifunctor $W : \mathcal{C}^{\mathrm{op}} \times \mathcal{C} \to \mathcal{S}$. Unwinding the definitions, we see that W classifies the functor $F : \mathcal{C} \to \mathrm{Ind}(\mathcal{C}) \subseteq \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ which is left adjoint to the tautological map $\mathrm{Ind}(\mathcal{C}) \to \mathcal{C}$. More concretely, the functor W is given by the formula $W(C, D) = \mathrm{Map}_{\mathrm{Ind}(\mathcal{C})}(C, F(D))$ (where we abuse notation by identifying an object $C \in \mathcal{C}$ with its image under the Yoneda embedding $\mathcal{C} \to \mathrm{Ind}(\mathcal{C}) \subseteq \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$). Following Johnstone-Joyal, we refer to $W(C, D)$ as the *space of wavy arrows from C to D.*

Example 21.1.3.17. Let $\mathcal{C}_0$ be a small ∞-category and let $\mathcal{C} = \mathrm{Ind}(\mathcal{C}_0)$, and let D be an object of $\mathcal{C}$ which is represented by a filtered diagram $\{D_\alpha\}$ in the ∞-category $\mathcal{C}_0$. Unwinding the definitions, we see that for any $C \in \mathcal{C}$, the space of wavy arrows $W(C, D)$ can be identified with the direct limit $\varinjlim_\alpha \mathrm{Map}_{\mathcal{C}}(C, D_\alpha)$. In particular, there is a tautological map $W(C, D) \to \mathrm{Map}_{\mathcal{C}}(C, D)$, which is an equivalence when C is a compact object of $\mathcal{C}$. More generally, it is useful to think of $W(C, D)$ as a space of "compactly supported" morphisms from C to D (beware, however, that the natural map $W(C, D) \to \mathrm{Map}_{\mathcal{C}}(C, D)$ need not be the inclusion of a summand).

21.1.4 Existence of Classifying ∞-Topoi

Let $\mathcal{C}$ be an accessible ∞-category which admits small filtered colimits. In §21.1.1, we prove that the ∞-category $\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S})$ is an ∞-topos (Proposition 21.1.1.2) and described the functor *corepresented* by $\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S})$ on the ∞-category $\infty\mathcal{T}\mathrm{op}$. Our goal in this section is to show that, under the assumption that $\mathcal{C}$ is compactly assembled, we can also describe the functor *represented* by $\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S})$. Note that, for any ∞-topos $\mathcal{X}$, we can regard the ∞-category $\mathrm{Fun}^*(\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S}), \mathcal{X})$ of geometric morphisms from $\mathcal{X}$ to $\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S})$ as a full subcategory of the ∞-category $\mathrm{LFun}(\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S}), \mathcal{X})$ of *all* colimit-preserving functors from $\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S})$ to $\mathcal{X}$. Consequently, Proposition 21.1.3.3 supplies a fully faithful embedding

$$\phi : \mathrm{Fun}^*(\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S}), \mathcal{X}) \to \mathrm{Fun}_\omega(\mathcal{C}^{\mathrm{op}}, \mathcal{X}).$$

The essential image of this embedding can be described as follows:

Proposition 21.1.4.1. *Let $\mathcal{C}$ be a compactly assembled ∞-category, let $\mathcal{X}$ be an ∞-topos, and let $U : \mathcal{C}^{\mathrm{op}} \to \mathcal{X}$ be a functor which preserves small filtered limits. The following conditions are equivalent:*

(1) *The functor U belongs to the essential image of the fully faithful embedding ϕ : $\mathrm{Fun}^*(\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S}), \mathcal{X}) \to \mathrm{Fun}_\omega(\mathcal{C}^{\mathrm{op}}, \mathcal{X})$ described above.*

(2) *For every sufficiently large regular cardinal κ, the functor $U|_{\mathcal{C}_\kappa^{\mathrm{op}}} : \mathcal{C}_\kappa^{\mathrm{op}} \to \mathcal{X}$ is locally left exact (see Definition 20.4.2.1); here $\mathcal{C}_\kappa$ denotes the full subcategory of $\mathcal{C}$ spanned by the κ-compact objects.*

Proof. Let $G : \mathrm{Ind}(\mathcal{C}) \to \mathcal{C}$ be the Ind-extension of the identity functor $\mathrm{id}_{\mathcal{C}} : \mathcal{C} \to \mathcal{C}$. Applying Theorem 21.1.2.10, we deduce that G admits a left adjoint $F : \mathcal{C} \to \mathrm{Ind}(\mathcal{C})$. Moreover, the proof of Theorem **??** shows that F factors through a functor $F_0 : \mathcal{C} \to \mathrm{Ind}(\mathcal{C}_\kappa)$ for κ sufficiently large. Let $V : \mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S}) \to \mathcal{X}$ be the image of U under the equivalence $\rho_{\mathcal{C}}$ of Proposition 21.1.3.3. We will complete the proof by showing that V is left exact if and only if $U|_{\mathcal{C}_\kappa^{\mathrm{op}}}$ is locally left exact.

Let $G_0 = G|_{\mathrm{Ind}(\mathcal{C}_\kappa)}$, so that we have an adjunction $\mathcal{C} \underset{G_0}{\overset{F_0}{\rightleftarrows}} \mathrm{Ind}(\mathcal{C}_\kappa)$. Set $\overline{U} = U \circ G_0$, so that $U \simeq \overline{U} \circ F_0$. Let $\overline{V} : \mathrm{Fun}^{\omega}(\mathrm{Ind}(\mathcal{C}_\kappa), \mathcal{S}) \to \mathcal{X}$ be the image of $\overline{U}$ under the equivalence $\rho_{\mathrm{Ind}(\mathcal{C}_\kappa)}$ of Proposition 21.1.3.1. By construction, $\overline{V}$ can be identified with the (essentially unique) colimit-preserving functor $\mathrm{Fun}(\mathcal{C}_\kappa, \mathcal{S}) \to \mathcal{X}$ whose composition with the Yoneda embedding $\mathcal{C}_\kappa^{\mathrm{op}} \hookrightarrow \mathrm{Fun}(\mathcal{C}_\kappa, \mathcal{S})$ coincides with the restriction $U|_{\mathcal{C}_\kappa^{\mathrm{op}}}$. Consequently, the functor $\overline{V}$ is left exact if and only if $U|_{\mathcal{C}_\kappa^{\mathrm{op}}}$ is locally left exact. Moreover, the compatibility of Proposition 21.1.3.3 shows that $\overline{V}$ is given by the composition

$$\mathrm{Fun}^{\omega}(\mathrm{Ind}(\mathcal{C}_\kappa), \mathcal{S}) \xrightarrow{T_0} \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}) \xrightarrow{V} \mathcal{X},$$

where T_0 is given by precomposition with G_0. Since T_0 exhibits $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ as a left exact localization of the ∞-topos $\mathrm{Fun}^{\omega}(\mathrm{Ind}(\mathcal{C}_\kappa), \mathcal{S})$, we see that $\overline{V}$ is left exact if and only if V is left exact. □

Corollary 21.1.4.2. *Let $\mathcal{C}$ be a compactly assembled presentable ∞-category and let $\mathcal{X}$ be an ∞-topos. Then a functor $F : \mathcal{C}^{\mathrm{op}} \to \mathcal{X}$ belongs to the essential image of ϕ :* $\mathrm{Fun}^*(\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}), \mathcal{X}) \to \mathrm{Fun}_{\omega}(\mathcal{C}^{\mathrm{op}}, \mathcal{X})$ *if and only if F preserves small limits.*

Proof. Suppose first that F preserves small limits. For any regular cardinal κ, the full subcategory $\mathcal{C}_\kappa \subseteq \mathcal{C}$ spanned by the κ-compact objects is closed under finite colimits. Consequently, the functor $F|_{\mathcal{C}_\kappa^{\mathrm{op}}}$ is left exact, and therefore locally left exact (Corollary 20.4.3.2). Applying Proposition 21.1.4.1, we deduce that F belongs to the essential image of ϕ. Conversely, if F belongs to the essential image of ρ, then Proposition 21.1.4.1 and Corollary 20.4.3.2 guarantee that F is left exact when restricted to $\mathcal{C}_\kappa$ for all sufficiently large κ, and is therefore left exact. Since F also preserves small filtered limits, it preserves all small limits (Proposition **??**). □

For every pair of presentable ∞-categories $\mathcal{C}$ and $\mathcal{D}$, let $\mathrm{RFun}(\mathcal{D}^{\mathrm{op}}, \mathcal{C})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{D}^{\mathrm{op}}, \mathcal{C})$ spanned by those functors which preserve small limits. Then $\mathrm{RFun}(\mathcal{D}^{\mathrm{op}}, \mathcal{C})$ is a model for the tensor product $\mathcal{C} \otimes \mathcal{D}$ of §HA.4.8.1 (see Proposition HA.4.8.1.17). In particular, the ∞-categories $\mathrm{RFun}(\mathcal{D}^{\mathrm{op}}, \mathcal{C})$ and $\mathrm{RFun}(\mathcal{C}^{\mathrm{op}}, \mathcal{D})$ are canonically equivalent to one another. More concretely, we have canonical equivalences

$$\mathrm{RFun}(\mathcal{D}^{\mathrm{op}}, \mathcal{C}) \simeq \mathrm{RFun}(\mathcal{D}^{\mathrm{op}}, \mathrm{RFun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})) \simeq \mathrm{RFun}(\mathcal{C}^{\mathrm{op}}, \mathrm{RFun}(\mathcal{D}^{\mathrm{op}}, \mathcal{S})) \simeq \mathrm{RFun}(\mathcal{C}^{\mathrm{op}}, \mathcal{D}).$$

Specializing to the case where $\mathcal{D} = \mathcal{X}$ is an ∞-topos, we obtain an equivalence $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) = \mathrm{RFun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C}) \simeq \mathrm{RFun}(\mathcal{C}^{\mathrm{op}}, \mathcal{X})$. Consequently, Corollary 21.1.4.2 supplies an equivalence of ∞-categories $\mathrm{Fun}^*(\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}), \mathcal{X}) \simeq \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$. In fact, we have the following stronger result:

Theorem 21.1.4.3. *Let $\mathcal{C}$ be a compactly assembled presentable ∞-category. Then the ∞-category $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ is a classifying ∞-topos for $\mathcal{C}$-valued sheaves, in the sense of Definition 21.1.0.1.*

To deduce Theorem 21.1.4.3, Proposition 21.1.3.3 alone is not sufficient: we will need to understand the ∞-category $\mathrm{LFun}(\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}), \mathcal{X})$ as a *functor* of $\mathcal{X}$. Here we encounter a subtlety: for a fixed ∞-category $\mathcal{C}$, the construction $\mathcal{X} \mapsto \mathrm{LFun}(\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}), \mathcal{X})$ is *a priori* functorial with respect to *colimit*-preserving functors between presentable ∞-categories, while the construction $\mathcal{X} \mapsto \mathrm{Fun}_{\omega}(\mathcal{C}^{\mathrm{op}}, \mathcal{X})$ is *a priori* functorial with respect to functors that preserve (filtered) inverse limits. To address this discrepancy, we need a brief digression.

Notation 21.1.4.4. Let $U : \mathcal{X} \to \mathcal{Y}$ be a functor of ∞-categories. We say that U is a *presentable fibration* if U is both a Cartesian fibration and a coCartesian fibration, and the fiber $\mathcal{X}_Y = U^{-1}\{Y\}$ is presentable for each object $Y \in \mathcal{Y}$.

Let $U : \mathcal{X} \to \mathcal{Y}$ be a presentable fibration and let $\mathcal{C}$ be some other ∞-category. We let $\mathrm{Fun}(\mathcal{C}, \mathcal{X} / \mathcal{Y})$ denote the fiber product

$$\mathrm{Fun}(\mathcal{C}, \mathcal{X}) \times_{\mathrm{Fun}(\mathcal{C}, \mathcal{Y})} \mathcal{Y},$$

so that we have a projection map $\mathrm{Fun}(\mathcal{C}, \mathcal{X} / \mathcal{Y}) \to \mathcal{Y}$ whose fiber over an object Y can be identified with the ∞-category $\mathrm{Fun}(\mathcal{C}, \mathcal{X}_Y)$. In particular, the objects of $\mathrm{Fun}(\mathcal{C}, \mathcal{X} / \mathcal{Y})$ can be identified with pairs (Y, F), where Y is an object of $\mathcal{Y}$ and $F : \mathcal{C} \to \mathcal{X}_Y$ is a functor.

If the ∞-category $\mathcal{C}$ admits small colimits, we let $\mathrm{LFun}(\mathcal{C}, \mathcal{X} / \mathcal{Y})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{X} / \mathcal{Y})$ spanned by those objects (Y, F) for which the functor $F : \mathcal{C} \to \mathcal{X}_Y$ preserves small colimits. Similarly, if the ∞-category $\mathcal{C}$ admits small filtered limits, we let $\mathrm{Fun}_{\omega}(\mathcal{C}, \mathcal{X} / \mathcal{Y})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{X} / \mathcal{Y})$ spanned by those objects (Y, F) for which the functor $F : \mathcal{C} \to \mathcal{X}_Y$ preserves small filtered limits.

Remark 21.1.4.5. Let $U : \mathcal{X} \to \mathcal{Y}$ be a presentable fibration of ∞-categories. Then:

(*a*) Let $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ denote the ∞-category whose objects are presentable ∞-categories and whose morphisms are functors which preserve small colimits. Then, as a coCartesian fibration, U is classified by a functor $\chi : \mathcal{Y} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$, given on objects by $\chi(Y) = \mathcal{X}_Y$. If $\mathcal{C}$ is an ∞-category which admits small colimits, then the projection map $\mathrm{LFun}(\mathcal{C}, \mathcal{X} / \mathcal{Y}) \to \mathcal{Y}$ is also a coCartesian fibration, classified by the functor $Y \mapsto \mathrm{LFun}(\mathcal{C}, \chi(Y)) = \mathrm{LFun}(\mathcal{C}, \mathcal{X}_Y)$.

(*b*) Let $\mathcal{P}\mathrm{r}^{\mathrm{R}}$ denote the ∞-category whose objects are presentable ∞-categories and whose morphisms are functors which are accessible and preserve small limits. Then, as a Cartesian fibration, U is classified by a functor $\chi' : \mathcal{Y}^{\mathrm{op}} \to \mathcal{P}\mathrm{r}^{\mathrm{R}}$, given on objects by $\chi'(Y) = \mathcal{X}_Y$. If $\mathcal{C}$ is an ∞-category which admits small filtered limits, then the projection map $\mathrm{Fun}_{\omega}(\mathcal{C}, \mathcal{X} / \mathcal{Y}) \to \mathcal{Y}$ is also a Cartesian fibration, classified by the functor $Y \mapsto \mathrm{Fun}_{\omega}(\mathcal{C}, \chi(Y)) = \mathrm{LFun}_{\omega}(\mathcal{C}, \mathcal{X}_Y)$.

We can now formulate a more refined version of Proposition 21.1.3.3:

Theorem 21.1.4.6. *Let $\mathcal{C}$ be compactly assembled ∞-category and let $U : \mathcal{X} \to \mathcal{Y}$ be a presentable fibration. Then there exists an equivalence of ∞-categories*

$$\mathrm{Fun}_\omega(\mathcal{C}^{\mathrm{op}}, \mathcal{X} / \mathcal{Y}) \simeq \mathrm{LFun}(\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S}), \mathcal{X} / \mathcal{Y})$$

which is compatible with the projection to $\mathcal{Y}$.

Remark 21.1.4.7. Let $U_0 : \overline{\mathcal{P}\mathrm{r}^{\mathrm{L}}} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ be a coCartesian fibration which is classified by the inclusion functor $\mathcal{P}\mathrm{r}^{\mathrm{L}} \hookrightarrow \widehat{\mathcal{C}\mathrm{at}}_\infty$ (so that the objects of $\overline{\mathcal{P}\mathrm{r}^{\mathrm{L}}}$ can be identified with pairs $(\mathcal{C}, C)$, where $\mathcal{C}$ is a presentable ∞-category and C is an object of $\mathcal{C}$). Then U_0 is a *universal* presentable fibration: every presentable fibration $U : \mathcal{X} \to \mathcal{Y}$ fits into an essentially unique (homotopy) pullback diagram

$$\begin{array}{ccc} \mathcal{X} & \longrightarrow & \overline{\mathcal{P}\mathrm{r}^{\mathrm{L}}} \\ \downarrow{\scriptstyle U} & & \downarrow{\scriptstyle U_0} \\ \mathcal{Y} & \longrightarrow & \mathcal{P}\mathrm{r}^{\mathrm{L}}, \end{array}$$

where the lower vertical map classifies U as a coCartesian fibration. Consequently, to prove Theorem 21.1.4.6 for an arbitrary presentable fibration U, it suffices to treat the case $U = U_0$. Moreover, we can then arrange that the equivalence whose existence is asserted by Theorem 21.1.4.6 is compatible with base change in $\mathcal{Y}$.

Remark 21.1.4.8. In the situation of Theorem 21.1.4.6, it follows that the projection map $\mathrm{LFun}(\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S}), \mathcal{X} / \mathcal{Y}) \to \mathcal{Y}$ is a Cartesian fibration (which can also be deduced easily from the adjoint functor theorem) and that the projection map $\mathrm{Fun}_\omega(\mathcal{C}^{\mathrm{op}}, \mathcal{X} / \mathcal{Y}) \to \mathcal{Y}$ is a coCartesian fibration (which is somewhat less obvious).

Proof of Theorem 21.1.4.6. Let $\mathcal{M}[\mathcal{C}, \mathcal{X} / \mathcal{Y}]$ denote the full subcategory of the ∞-category $\mathrm{Fun}(\mathrm{Fun}^+(\mathcal{C}, \mathcal{S}), \mathcal{X} / \mathcal{Y})$ whose objects are pairs (Y, F) where $Y \in \mathcal{Y}$ and $F : \mathrm{Fun}^+(\mathcal{C}, \mathcal{S}) \to \mathcal{X}_Y$ is a functor which belongs to $\mathcal{M}[\mathcal{C}, \mathcal{X}_Y]$ (see the proof of Proposition 21.1.3.3). Composition with the Yoneda embedding $j : \mathcal{C}^{\mathrm{op}} \to \mathrm{Fun}^+(\mathcal{C}, \mathcal{S})$ and the inclusion $\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S}) \hookrightarrow \mathrm{Fun}^+(\mathcal{C}, \mathcal{S})$ determine forgetful functors

$$\mathrm{Fun}_\omega(\mathcal{C}^{\mathrm{op}}, \mathcal{X} / \mathcal{Y}) \xleftarrow{\phi} \mathcal{M}[\mathcal{C}, \mathcal{X} / \mathcal{Y}] \xrightarrow{\psi} \mathrm{LFun}(\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S}), \mathcal{X} / \mathcal{Y})$$

which are compatible with the projection to $\mathcal{Y}$. To prove Theorem 21.1.4.6, it will suffice to show that ϕ and ψ are equivalences of ∞-categories.

We will show that ψ is an equivalence; the proof for ϕ is similar. Let $\overline{\mathcal{M}}$ denote the full subcategory of $\mathrm{Fun}(\mathrm{Fun}^+(\mathcal{C}, \mathcal{S}), \mathcal{X} / \mathcal{Y})$ spanned by those pairs (Y, F), where $F : \mathrm{Fun}^+(\mathcal{C}, \mathcal{S}) \to \mathcal{X}_Y$ is a right Kan extension of its restriction to $\mathrm{Fun}^\omega(\mathcal{C}, \mathcal{S})$. Let $q : \mathrm{Fun}(\mathrm{Fun}^+(\mathcal{C}, \mathcal{S}), \mathcal{X} / \mathcal{Y}) \to$

$\mathcal{Y}$ and $p : \mathrm{Fun}(\mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S}),\mathcal{X}/\mathcal{Y}) \to \mathcal{Y}$ denote the the projection maps, and set $\overline{q} = q|_{\overline{\mathcal{M}}}$. Note that if $\alpha : M \to M'$ is a q-Cartesian morphism in $\mathrm{Fun}(\mathrm{Fun}^{+}(\mathcal{C},\mathcal{S}),\mathcal{X}/\mathcal{Y})$ where $M' \in \overline{\mathcal{M}}$, then M also belongs to $\overline{\mathcal{M}}$; it follows that α can be regarded as a $\overline{q}$-Cartesian morphism in the ∞-category $\overline{\mathcal{M}}$. The map ψ fits into a pullback diagram

$$\begin{array}{ccc} \mathcal{M}[\mathcal{C},\mathcal{X}/\mathcal{Y}] & \xrightarrow{\psi} & \mathrm{LFun}(\mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S}),\mathcal{X}/\mathcal{Y}) \\ \downarrow & & \downarrow \\ \overline{\mathcal{M}} & \xrightarrow{\overline{\psi}} & \mathrm{Fun}(\mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S}),\mathcal{X}/\mathcal{Y}), \end{array}$$

where $\overline{\psi}$ carries $\overline{q}$-Cartesian morphisms of the ∞-category $\overline{\mathcal{M}}$ to p-Cartesian morphisms of the ∞-category $\mathrm{Fun}(\mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S}),\mathcal{X}/\mathcal{Y})$. Consequently, to prove that ψ is an equivalence of ∞-categories, it will suffice to show that $\overline{\psi}$ is an equivalence of ∞-categories. By virtue of Corollary HTT.2.4.4.4 , it suffices to check that $\overline{\psi}$ induces an equivalence after passing to the fiber over any object $Y \in \mathcal{Y}$. In this case, the desired result follows from Proposition HTT.4.3.2.15 and Lemma **??**. □

Proof of Theorem 21.1.4.3. Let $\infty\mathcal{T}\mathrm{op}$ denote the ∞-category of ∞-topoi. Recall that we have defined $\infty\mathcal{T}\mathrm{op}$ to be the *opposite* of the subcategory of $\widehat{\mathcal{C}\mathrm{at}}_{\infty}$ whose objects are ∞-topoi and whose morphisms are functors which preserve small colimits and finite limits. In particular, the inclusion map $\infty\mathcal{T}\mathrm{op}^{\mathrm{op}} \hookrightarrow \widehat{\mathcal{C}\mathrm{at}}_{\infty}$ classifies a coCartesian fibration $\overline{\infty\mathcal{T}\mathrm{op}}^{\mathrm{op}} \to \infty\mathcal{T}\mathrm{op}^{\mathrm{op}}$, which is a presentable fibration in the sense of Notation 21.1.4.4. Set $\mathcal{E} = \mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S})$ and let $\mathrm{Fun}^{*}(\mathcal{E},\widehat{\infty\mathcal{T}\mathrm{op}}^{\mathrm{op}}/\infty\mathcal{T}\mathrm{op}^{\mathrm{op}})$ be the full subcategory of $\mathrm{Fun}(\mathcal{E},\widehat{\infty\mathcal{T}\mathrm{op}}^{\mathrm{op}}/\infty\mathcal{T}\mathrm{op}^{\mathrm{op}})$ whose objects are pairs $(\mathcal{X},f^{*})$ where $\mathcal{X}$ is an ∞-topos and $f^{*} \in \mathrm{Fun}^{*}(\mathcal{E},\mathcal{X})$. Similarly, let $\mathrm{RFun}(\mathcal{C}^{\mathrm{op}},\widehat{\infty\mathcal{T}\mathrm{op}}^{\mathrm{op}}/\infty\mathcal{T}\mathrm{op}^{\mathrm{op}})$ be the full subcategory $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}},\widehat{\infty\mathcal{T}\mathrm{op}}^{\mathrm{op}}/\infty\mathcal{T}\mathrm{op}^{\mathrm{op}})$ spanned by those pairs $(\mathcal{X},F)$ where $\mathcal{X}$ is an ∞-topos and $F \in \mathrm{RFun}(\mathcal{C}^{\mathrm{op}},\mathcal{X})$. Then the projection maps $\mathrm{Fun}^{*}(\mathcal{E},\widehat{\infty\mathcal{T}\mathrm{op}}^{\mathrm{op}}/\infty\mathcal{T}\mathrm{op}^{\mathrm{op}}) \to \infty\mathcal{T}\mathrm{op}^{\mathrm{op}}$ and $\mathrm{RFun}(\mathcal{C}^{\mathrm{op}},\widehat{\infty\mathcal{T}\mathrm{op}}^{\mathrm{op}}/\infty\mathcal{T}\mathrm{op}^{\mathrm{op}}) \to \infty\mathcal{T}\mathrm{op}^{\mathrm{op}}$ are coCartesian fibrations which are classified by the functors $\mathcal{X} \mapsto \mathrm{Fun}^{*}(\mathcal{E},\mathcal{X})$ and $\mathcal{X} \mapsto \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$, respectively. Using Theorem 21.1.4.6 and Corollary 21.1.4.2, we deduce that the functors $\mathcal{X} \mapsto \mathrm{Fun}^{*}(\mathcal{E},\mathcal{X})$ and $\mathcal{X} \mapsto \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$ are equivalent. □

We can now give a definitive answer to Question 21.1.0.2:

Corollary 21.1.4.9. *Let $\mathcal{C}$ be a presentable ∞-category. The following conditions are equivalent:*

(1) *The ∞-category $\mathcal{C}$ is compactly assembled.*

(2) *There exists a classifying topos for $\mathcal{C}$-valued sheaves.*

Proof. The implication (1) ⇒ (2) follows from Theorem 21.1.4.3. For the converse, suppose that $\mathcal{C}$ is a presentable ∞-category and that there exists a universal $\mathcal{C}$-valued sheaf $\mathscr{F} \in$

$\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{E})$ for some ∞-topos $\mathcal{E}$. Without loss of generality, we may assume that $\mathcal{E}$ is an accessible left exact localization of an ∞-topos of presheaves $\mathcal{P}(\mathcal{G})$, for some small ∞-category $\mathcal{G}$. Let $\iota_* : \mathcal{E} \hookrightarrow \mathcal{P}(\mathcal{G})$ be the inclusion functor, so that ι_* induces a fully faithful embedding $\iota_*^{\mathcal{C}} : \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{E}) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{P}(\mathcal{G}))$ with a left adjoint $\iota_{\mathcal{C}}^* : \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{P}(\mathcal{G})) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{E})$ Then $\iota_*^{\mathcal{C}} \mathscr{F}$ is a $\mathcal{C}$-valued sheaf on the presheaf ∞-topos $\mathcal{P}(\mathcal{G})$, so we can write $\iota_*^{\mathcal{C}} \mathscr{F} \simeq f_{\mathcal{C}}^* \mathscr{F}$ for some essentially unique geometric morphism $f_* : \mathcal{P}(\mathcal{G}) \to \mathcal{E}$. Since the functor $\iota_*^{\mathcal{C}}$ is fully faithful, we have equivalences $\mathscr{F} \simeq \iota_{\mathcal{C}}^* \iota_*^{\mathcal{C}} \mathscr{F} \simeq \iota_{\mathcal{C}}^* f_{\mathcal{C}}^* \mathscr{F}$. Invoking again our assumption that $\mathscr{F}$ is universal, we deduce that the composition $\iota^* \circ f^*$ is equivalent to the identity functor from $\mathcal{E}$ to itself. In other words, ι^* and f^* exhibit $\mathcal{E}$ as a retract (in the ∞-category $\infty\mathcal{T}\mathrm{op}$ of ∞-topoi) of the presheaf ∞-category $\mathcal{P}(\mathcal{G})$. Applying the functor Pt of Corollary 21.1.1.6, we conclude that $\mathcal{C} = \mathrm{Pt}(\mathcal{E})$ is a retract of $\mathrm{Ind}(\mathcal{G}^{\mathrm{op}}) \simeq \mathrm{Pt}(\mathcal{P}(\mathcal{G}))$ in the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_{\infty}^{\omega}$, so that $\mathcal{C}$ is compactly assembled. □

21.1.5 Points of $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$

Let $\mathcal{C}$ be an accessible ∞-category which admits small filtered colimits. Then the ∞-topos $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ is closed under small colimits and finite limits in the larger ∞-category $\mathrm{Fun}(\mathcal{C}, \mathcal{S})$. It follows that, for each object $C \in \mathcal{C}$, the evaluation functor

$$\mathrm{ev}_C : \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}) \to \mathcal{S} \qquad \mathrm{ev}_C(F) = F(C)$$

preserves small colimits and finite limits: that is, it is a point of the ∞-topos $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$. We regard the construction $C \mapsto \mathrm{ev}_C$ as a functor of ∞-categories $\mathrm{ev} : \mathcal{C} \to \mathrm{Pt}(\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}))$.

Proposition 21.1.5.1. *Let $\mathcal{C}$ be a compactly assembled ∞-category. Then the functor $\mathrm{ev} : \mathcal{C} \to \mathrm{Pt}(\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}))$ is an equivalence of ∞-categories.*

Proof. Let us denote the evaluation functor ev by $\mathrm{ev}^{\mathcal{C}}$ to emphasize its dependence on $\mathcal{C}$. We observe that the construction $\mathcal{C} \mapsto \mathrm{ev}^{\mathcal{C}}$ determines a functor $\widehat{\mathcal{C}\mathrm{at}}_{\infty}^{\omega} \to \mathrm{Fun}(\Delta^1, \widehat{\mathcal{C}\mathrm{at}}_{\infty}^{\omega})$. It follows that if $\mathcal{C}$ is a retract of $\mathcal{D}$ in the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_{\infty}^{\omega}$ and the functor $e^{\mathcal{D}}$ is an equivalence, then $e^{\mathcal{C}}$ is also an equivalence. It will therefore suffice to show that the functor $e^{\mathcal{C}}$ is an equivalence in the special case where $\mathcal{C} = \mathrm{Ind}(\mathcal{C}_0)$ for some small ∞-category $\mathcal{C}_0$. In this case, the ∞-topos $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ can be identified with the ∞-category of presheaves $\mathcal{P}(\mathcal{C}_0^{\mathrm{op}})$, so the desired result follows from Proposition **??**. □

Corollary 21.1.5.2. *Let $\mathcal{C}$ and $\mathcal{D}$ be accessible ∞-categories which admit small filtered colimits. If $\mathcal{D}$ is compactly assembled, then the canonical map*

$$F : \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{D}) \to \mathrm{Fun}^*(\mathrm{Fun}^{\omega}(\mathcal{D}, \mathcal{S}), \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}))$$

is an equivalence of ∞-categories.

Proof. The functor F fits into a commutative diagram

$$\begin{array}{ccc} \mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{D}) & \xrightarrow{F} & \mathrm{Fun}^{*}(\mathrm{Fun}^{\omega}(\mathcal{D},\mathcal{S}),\mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S})) \\ & \searrow \quad \swarrow & \\ & \mathrm{Fun}^{\omega}(\mathcal{C},\mathrm{Pt}(\mathrm{Fun}^{\omega}(\mathcal{D},\mathcal{S}))) & \end{array}$$

where the left vertical map is an equivalence by Proposition 21.1.5.1 and the right vertical map is an isomorphism of simplicial sets (see Corollary 21.1.1.6). □

Corollary 21.1.5.3. *Let $\widehat{\mathcal{C}\mathrm{at}}_{\infty}^{\mathrm{ca}}$ denote the subcategory of $\widehat{\mathcal{C}\mathrm{at}}_{\infty}$ whose objects are compactly assembled ∞-categories and whose morphisms are functors which preserve small filtered colimits. Then the construction $\mathcal{C} \mapsto \mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S})$ determines a fully faithful embedding $\widehat{\mathcal{C}\mathrm{at}}_{\infty}^{\mathrm{ca}} \hookrightarrow \infty\mathcal{T}\mathrm{op}$, whose essential image consists of those ∞-topoi which can be written as a retract of a presheaf ∞-category $\mathcal{P}(\mathcal{G})$, for some small ∞-category $\mathcal{G}$.*

Proof. The first assertion follows from Corollary 21.1.5.2. For the second, we observe that $\widehat{\mathcal{C}\mathrm{at}}_{\infty}^{\mathrm{ca}}$ is the idempotent completion of the full subcategory spanned by objects of the form $\mathrm{Ind}(\mathcal{C}_0)$, and that the construction $\mathcal{C} \mapsto \mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S})$ carries $\mathrm{Ind}(\mathcal{C}_0)$ to $\mathcal{P}(\mathcal{C}_0^{\mathrm{op}})$. □

If we restrict our attention to presentable compactly assembled ∞-categories, we can say more.

Proposition 21.1.5.4. *Let $\mathcal{E}$ be an ∞-topos. The following conditions are equivalent:*

(1) *There exists a presentable compactly assembled ∞-category $\mathcal{C}$ and an equivalence $\mathcal{E} \simeq \mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S})$.*

(2) *For every geometric morphism of ∞-topoi $f^{*} : \mathcal{X} \to \mathcal{Y}$, the induced map $\mathrm{Fun}^{*}(\mathcal{E},\mathcal{X}) \xrightarrow{f^{*}\circ} \mathrm{Fun}^{*}(\mathcal{E},\mathcal{Y})$ admits a right adjoint G. Moreover, if the direct image functor $f_{*} : \mathcal{Y} \to \mathcal{X}$ is fully faithful, then so is G.*

(3) *Let $f^{*} : \mathcal{X} \to \mathcal{Y}$ be a geometric morphism of ∞-topoi for which the direct image functor $f_{*} : \mathcal{Y} \to \mathcal{X}$ is fully faithful. Then the functor $\mathrm{Fun}^{*}(\mathcal{E},\mathcal{X}) \xrightarrow{f^{*}\circ} \mathrm{Fun}^{*}(\mathcal{E},\mathcal{Y})$ is essentially surjective. In other words, every lifting problem of the form*

$$\begin{array}{ccc} & \mathcal{X} & \\ {\scriptstyle f_{*}} \nearrow & & \searrow \\ \mathcal{Y} & \longrightarrow & \mathcal{E} \end{array}$$

admits a solution in the ∞-category $\infty\mathcal{T}\mathrm{op}$.

(4) *Let $f_* : \mathcal{E} \to \mathcal{X}$ be a geometric morphism of ∞-topoi which is fully faithful (at the level of underlying ∞-categories). Then f_* admits a left homotopy inverse (in the ∞-category $\infty\mathcal{T}\mathrm{op}$).*

Remark 21.1.5.5. Johnstone defines a topos $\mathcal{E}$ to be *injective* if it satisfies the 1-categorical analogue of condition (3); see [103] and [104].

Proof of Proposition 21.1.5.4. Suppose first that (1) is satisfied. Then $\mathcal{E}$ is a classifying ∞-topos for $\mathcal{C}$-valued sheaves (Theorem 21.1.4.3). In particular, we have equivalences $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X}) \simeq \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$, depending functorially on the ∞-topos $\mathcal{X}$. We now observe that if $f^* : \mathcal{X} \to \mathcal{Y}$ is a geometric morphism of ∞-topoi, then the associated pullback functor $f^*_{\mathcal{C}} : \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{Y})$ is defined as the left adjoint of a direct image functor $f^{\mathcal{C}}_* : \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{Y}) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$, which is given by precomposition with f^*. If the usual direct image functor $f_* : \mathcal{Y} \to \mathcal{X}$ is fully faithful, then f^* is a localization functor, so the functor $f^{\mathcal{C}}_*$ is also fully faithful. That completes the proof that (1) $\Rightarrow$ (2). The implications (2) $\Rightarrow$ (3) $\Rightarrow$ (4) are immediate. We will conclude by showing that (4) $\Rightarrow$ (1). Let $\mathcal{E}$ be an ∞-topos satisfying (4), and write $\mathcal{E}$ as an accessible left exact localization of $\mathcal{P}(\mathcal{G})$, where $\mathcal{G}$ is a small ∞-category which admits finite limits. Applying condition (4), we deduce that $\mathcal{E}$ is a retract of $\mathcal{P}(\mathcal{G})$ in the ∞-category $\infty\mathcal{T}\mathrm{op}$. Applying the criterion of Corollary 21.1.5.3, we deduce that there is an equivalence $\mathcal{E} \simeq \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ for some compactly assembled ∞-category $\mathcal{C}$. We will complete the proof by showing that $\mathcal{C}$ is presentable. Using Proposition 21.1.5.1, we can identify $\mathcal{C}$ with the ∞-category $\mathrm{Pt}(\mathcal{E})$ of points of $\mathcal{E}$. We now observe that $\mathrm{Pt}(\mathcal{E})$ is a retract of $\mathrm{Pt}(\mathcal{P}(\mathcal{G})) \simeq \mathrm{Ind}(\mathcal{G}^{\mathrm{op}})$. Since $\mathcal{G}$ admits finite limits, the ∞-category $\mathrm{Ind}(\mathcal{G}^{\mathrm{op}})$ is compactly generated, so that $\mathcal{C} = \mathrm{Pt}(\mathcal{E})$ is presentable by virtue of Corollary 21.1.2.18. □

21.1.6 Application: Exponentiability of ∞-Topoi

Let X and Y be topological spaces, and let $\mathrm{Hom}_{\mathcal{T}\mathrm{op}}(X, Y)$ denote the set of continuous maps from X to Y. It is often convenient to equip the set $\mathrm{Hom}_{\mathcal{T}\mathrm{op}}(X, Y)$ with the structure of a topological space. Particularly useful is the *compact-open topology*, which has a subbasis consisting of open sets having the form

$$\{f \in \mathrm{Hom}_{\mathcal{T}\mathrm{op}}(X, Y) : f(K) \subseteq U\}$$

where K is a compact subset of X and U is an open subset of Y. In good cases, this is characterized by a universal mapping property.

Proposition 21.1.6.1. *Let X, Y, and Z be topological spaces, and assume that X is a locally compact Hausdorff space. Then there is a canonical bijection*

$$\{\textit{Continuous functions } F : Z \to \mathrm{Hom}_{\mathcal{T}\mathrm{op}}(X, Y)\} \simeq \{\textit{Continuous functions } f : Z \times X \to Y\},$$

which carries a function F to the function f given by the formula $f(z, x) = F(z)(x)$.

Proofs of Proposition 21.1.6.1 can be found in standard texts on point-set topology; see for example [159] (we will sketch a very indirect proof in Remark 21.1.7.7, at least for the special case where Y is sober). In this section, we will study an analogous construction in an ∞-categorical setting, replacing the category $\mathcal{T}\mathrm{op}$ of topological spaces with the ∞-category $\infty\mathcal{T}\mathrm{op}$ of ∞-topoi. Our goal is to answer the following:

Question 21.1.6.2. Let $\mathcal{X}$ and $\mathcal{Y}$ be ∞-topoi. Under what circumstances can the collection of geometric morphisms $f_* : \mathcal{X} \to \mathcal{Y}$ be identified with the points of another ∞-topos $\mathcal{Y}^{\mathcal{X}}$?

Let us begin by making Question 21.1.6.2 more precise.

Notation 21.1.6.3. Let $\infty\mathcal{T}\mathrm{op}$ denote the ∞-category of ∞-topoi. Then $\infty\mathcal{T}\mathrm{op}$ admits finite products (Proposition HTT.6.3.4.6). Beware that if $\mathcal{X}$ and $\mathcal{Y}$ are ∞-topoi, then the product of $\mathcal{X}$ and $\mathcal{Y}$ in $\infty\mathcal{T}\mathrm{op}$ is *not* given by the usual Cartesian product of ∞-categories $\mathcal{X} \times \mathcal{Y}$ (instead, $\mathcal{X} \times \mathcal{Y}$ is the *coproduct* of $\mathcal{X}$ with $\mathcal{Y}$ in $\infty\mathcal{T}\mathrm{op}$). To avoid confusion, we will denote the product of $\mathcal{X}$ and $\mathcal{Y}$ in $\infty\mathcal{T}\mathrm{op}$ by $\mathcal{X} \otimes \mathcal{Y}$. Note that we can identify $\mathcal{X} \otimes \mathcal{Y}$ with the tensor product of $\mathcal{X}$ with $\mathcal{Y}$ in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable ∞-categories (with respect to the symmetric monoidal structure described in §HA.4.8.1 ; see Example HA.4.8.1.19). Less symmetrically, the product $\mathcal{X} \otimes \mathcal{Y}$ can be identified with the ∞-category $\mathcal{S}\mathrm{hv}_{\mathcal{X}}(\mathcal{Y})$ of $\mathcal{X}$-valued sheaves on $\mathcal{Y}$, or with the ∞-category $\mathcal{S}\mathrm{hv}_{\mathcal{Y}}(\mathcal{X})$ of $\mathcal{Y}$-valued sheaves on $\mathcal{X}$.

Definition 21.1.6.4. Let $\mathcal{X}$, $\mathcal{Y}$, and $\mathcal{E}$ be ∞-topoi. We will say that a geometric morphism $e_* : \mathcal{E} \otimes \mathcal{X} \to \mathcal{Y}$ *exhibits $\mathcal{E}$ as an exponential of $\mathcal{Y}$ by $\mathcal{X}$* if the following universal property is satisfied: for any ∞-topos $\mathcal{Z}$, composition with e_* induces a homotopy equivalence

$$\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{Z}, \mathcal{E}) \to \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{Z} \times \mathcal{X}, \mathcal{Y}).$$

Remark 21.1.6.5. Let $\mathcal{X}$ and $\mathcal{Y}$ be ∞-topoi. It follows immediately from the definitions that if there exists a geometric morphism $e_* : \mathcal{E} \otimes \mathcal{X} \to \mathcal{Y}$ which exhibits $\mathcal{E}$ as an exponential of $\mathcal{Y}$ by $\mathcal{X}$, then the ∞-topos $\mathcal{E}$ and the geometric morphism e_* are determined uniquely up to equivalence and depend functorially on both $\mathcal{X}$ and $\mathcal{Y}$. We will indicate this dependence by writing $\mathcal{E} = \mathcal{Y}^{\mathcal{X}}$. Beware that $\mathcal{Y}^{\mathcal{X}}$ is *not* the same as the functor ∞-category $\mathrm{Fun}(\mathcal{X}, \mathcal{Y})$.

Remark 21.1.6.6. Let $\mathcal{X}$ be an ∞-topos, and let $\mathcal{C}$ denote the full subcategory of $\infty\mathcal{T}\mathrm{op}$ spanned by those ∞-topoi $\mathcal{Y}$ for which there exists an exponential $\mathcal{Y}^{\mathcal{X}}$. Then $\mathcal{C}$ is closed under small limits. Moreover, the construction $\mathcal{Y} \mapsto \mathcal{Y}^{\mathcal{X}}$ determines a functor $\mathcal{C} \to \infty\mathcal{T}\mathrm{op}$ which preserves small limits.

Remark 21.1.6.7. Let $\mathcal{X}$, $\mathcal{Y}$, and $\mathcal{E}$ be ∞-topoi, let $e_* : \mathcal{E} \otimes \mathcal{X} \to \mathcal{Y}$ be a geometric morphism, and let $e^* : \mathcal{Y} \to \mathcal{E} \otimes \mathcal{X}$ be left adjoint of e_*. For any ∞-topos $\mathcal{Z}$, composition with e^* induces a functor $\theta_{\mathcal{Z}} : \mathrm{Fun}^*(\mathcal{E}, \mathcal{Z}) \to \mathrm{Fun}^*(\mathcal{Y}, \mathcal{Z} \otimes \mathcal{X})$. Unwinding the definitions, we see that e_* exhibits $\mathcal{E}$ as an exponential of $\mathcal{X}$ by $\mathcal{Y}$ if and only if the following condition is satisfied, for any ∞-topos $\mathcal{Z}$:

$(a_{\mathcal{Z}})$ The functor $\theta_{\mathcal{Z}}$ induces a homotopy equivalence of Kan complexes $\mathrm{Fun}^*(\mathcal{E},\mathcal{Z})^{\simeq} \to \mathrm{Fun}^*(\mathcal{Y},\mathcal{Z}\otimes\mathcal{X})^{\simeq}$

However, it is not difficult to see that e_* exhibits $\mathcal{E}$ as an exponential of $\mathcal{X}$ by $\mathcal{Y}$ if and only if the following *a priori* stronger condition is satisfied, for any ∞-topos $\mathcal{Z}$:

$(b_{\mathcal{Z}})$ The functor $\theta_{\mathcal{Z}}$ is an equivalence of ∞-categories.

The implication $(b_{\mathcal{Z}}) \Rightarrow (a_{\mathcal{Z}})$ is immediate. Conversely, $(b_{\mathcal{Z}})$ can be deduced from $(a_{\mathcal{Z}})$ and $(a_{\mathrm{Fun}(\Delta^1,\mathcal{Z})})$.

Remark 21.1.6.8. Let $\mathcal{X}$ and $\mathcal{Y}$ be ∞-topoi, and suppose that there exists an exponential $\mathcal{Y}^{\mathcal{X}}$. Then points of the ∞-topos $\mathcal{Y}^{\mathcal{X}}$ can be identified with geometric morphisms from $\mathcal{X}$ to $\mathcal{Y}$. More precisely, applying Remark 21.1.6.7 in the case $\mathcal{Z} = \mathcal{S}$, we obtain an equivalence of ∞-categories $\mathrm{Pt}(\mathcal{Y}^{\mathcal{X}}) \simeq \mathrm{Fun}^*(\mathcal{X},\mathcal{Y})$.

Example 21.1.6.9. Let $\mathcal{C}$ be a compactly assembled presentable ∞-category and let $\mathcal{Y} = \mathrm{Fun}^{\omega}(\mathcal{C},\mathcal{S})$ be a classifying ∞-topos for $\mathcal{C}$-valued sheaves (see Theorem 21.1.4.3). For any ∞-topoi $\mathcal{X}$ and $\mathcal{Z}$, we have canonical equivalences

$$\begin{aligned}\mathrm{Fun}^*(\mathcal{Y},\mathcal{X}\otimes\mathcal{Z}) &\simeq \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}\otimes\mathcal{Z}) \\ &\simeq \mathcal{C}\otimes(\mathcal{X}\otimes\mathcal{Z}) \\ &\simeq (\mathcal{C}\otimes\mathcal{X})\otimes\mathcal{Z} \\ &\simeq \mathcal{S}\mathrm{hv}_{\mathcal{C}\otimes\mathcal{X}}(\mathcal{Z}).\end{aligned}$$

It follows that an exponential $\mathcal{Y}^{\mathcal{X}}$ (if it exists) can be identified with a classifying ∞-topos for $(\mathcal{C}\otimes\mathcal{X})$-valued sheaves. In particular, the exponential $\mathcal{Y}^{\mathcal{X}}$ exists if and only if the tensor product $\mathcal{C}\otimes\mathcal{X} \simeq \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$ is compactly assembled. In this case, we can identify $\mathcal{Y}^{\mathcal{X}}$ with the ∞-topos $\mathrm{Fun}^{\omega}(\mathcal{C}\otimes\mathcal{X},\mathcal{S})$.

Example 21.1.6.10. Let $\mathcal{X}$ be any ∞-topos, and let $\mathcal{Y} = \mathrm{Fun}^{\omega}(\mathcal{S},\mathcal{S})$ be the classifying ∞-topos for $\mathcal{S}$-valued sheaves. Applying Example 21.1.6.9 in the special case $\mathcal{C} = \mathcal{S}$, we deduce that an exponential $\mathcal{Y}^{\mathcal{X}}$ exists if and only if the ∞-topos $\mathcal{X}$ is compactly assembed. If this condition is satisfied, then the exponential $\mathcal{Y}^{\mathcal{X}}$ can be identified with the ∞-topos $\mathrm{Fun}^{\omega}(\mathcal{X},\mathcal{S})$ which classifies $\mathcal{X}$-valued sheaves.

Definition 21.1.6.11. Let $\mathcal{X}$ be an ∞-topos. We will say that $\mathcal{X}$ is *exponentiable* if, for any ∞-topos $\mathcal{Y}$, there exists an ∞-topos $\mathcal{E}$ and a geometric morphism $e_* : \mathcal{E}\otimes\mathcal{X} \to \mathcal{Y}$ which exhibits $\mathcal{E}$ as an exponential of $\mathcal{Y}$ by $\mathcal{X}$.

In other words, an ∞-topos $\mathcal{X}$ is exponentiable if the exponential $\mathcal{Y}^{\mathcal{X}}$ exists for any ∞-topos $\mathcal{Y}$. We can now formulate Question 21.1.6.2 more precisely: which ∞-topoi are exponentiable?

Theorem 21.1.6.12. *Let $\mathcal{X}$ be an ∞-topos. The following conditions are equivalent:*

(1) *The ∞-topos $\mathcal{X}$ is exponentiable (Definition 21.1.6.11).*

(2) *There exists an exponential $\mathcal{Y}^{\mathcal{X}}$, where $\mathcal{Y} = \mathrm{Fun}^{\omega}(\mathcal{S}, \mathcal{S})$ is the classifying topos for $\mathcal{S}$-valued sheaves.*

(3) *There exists a classifying ∞-topos for $\mathcal{X}$-valued sheaves (Definition 21.1.0.1).*

(4) *The ∞-category $\mathcal{X}$ is compactly assembled (Definition 21.1.2.1).*

Example 21.1.6.13. Let $\mathcal{X} = \mathcal{P}(\mathcal{G})$ be the ∞-topos of presheaves on a small ∞-category $\mathcal{G}$. Then $\mathcal{X}$ is exponentiable (since it is compactly generated, and therefore compactly assembled).

Example 21.1.6.14. Let $\mathcal{C}$ be a compactly assembled ∞-category and let $\mathcal{X} = \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ be the ∞-topos of Proposition 21.1.1.2. Then $\mathcal{X}$ is exponentiable (since it is a retract of a presheaf ∞-topos; see Corollary 21.1.5.3).

Example 21.1.6.15. Let $\mathcal{C}$ be a compactly assembled presentable ∞-category and let $\mathcal{X}$ be a classifying ∞-topos for $\mathcal{C}$-valued sheaves. Then $\mathcal{X}$ is exponentiable (by virtue of Theorem 21.1.4.3, this is a special case of Example 21.1.6.14).

The proof of Theorem 21.1.6.12 will make use of the following simple observation:

Lemma 21.1.6.16. *Let $\mathcal{Y}$ be an arbitrary ∞-topos. Then there exists a pullback diagram*

$$\begin{array}{ccc} \mathcal{Y} & \longrightarrow & \mathcal{Y}_0 \\ \downarrow & & \downarrow \\ \mathcal{Y}_1 & \longrightarrow & \mathcal{Y}_{01} \end{array}$$

in the ∞-category $\infty\mathcal{T}\mathrm{op}$, where $\mathcal{Y}_0$, $\mathcal{Y}_1$, and $\mathcal{Y}_{01}$ are ∞-topoi of presheaves on small ∞-categories which admit finite limits.

Proof. By virtue of Proposition HTT.6.1.5.3 , we can assume that $\mathcal{Y}$ is an accessible left exact localization of $\mathcal{P}(\mathcal{C})$, where $\mathcal{C}$ is a small ∞-category which admits finite limits. Then we can write $\mathcal{Y} = S^{-1}\mathcal{P}(\mathcal{C})$, where S is some small collection of morphisms in $\mathcal{P}(\mathcal{C})$ (Proposition HTT.5.5.4.2). Let $\mathcal{D} \subseteq \mathcal{P}(\mathcal{C})$ be an essentially small full subcategory which contains the domain and codomain of every morphism in S. Let $L : \mathcal{P}(\mathcal{C}) \to \mathcal{P}(\mathcal{C})$ be the localization functor whose essential image is $\mathcal{Y}$ and let $\iota : \mathcal{D} \hookrightarrow \mathcal{P}(\mathcal{C})$ be the inclusion functor. Then the tautological natural transformation $\iota \to L \circ \iota$ determines a left exact functor $f : \mathcal{D} \times \Delta^1 \to \mathcal{P}(\mathcal{C})$. Applying Proposition HTT.6.1.5.2 , we see that f admits an essentially unique extension to a left exact functor $F^* : \mathcal{P}(\mathcal{D} \times \Delta^1) \to \mathcal{P}(\mathcal{C})$ which preserves small colimits. Let F_* be the right adjoint of F^*, and let $G_* : \mathcal{P}(\mathcal{D}) \to \mathcal{P}(\mathcal{D} \times \Delta^1)$ be the functor given by precomposition with the projection map $\mathcal{D} \times \Delta^1 \to \mathcal{D}$. It is now easy to verify that the inclusion $\mathcal{Y} \hookrightarrow \mathcal{P}(\mathcal{C})$ extends to a pullback diagram

$$\begin{array}{ccc} \mathcal{Y} & \longrightarrow & \mathcal{P}(\mathcal{C}) \\ \downarrow & & \downarrow F_* \\ \mathcal{P}(\mathcal{D}) & \xrightarrow{G_*} & \mathcal{P}(\mathcal{D} \times \Delta^1) \end{array}$$

in the ∞-category $\infty\mathcal{T}\mathrm{op}$. □

Proof of Theorem 21.1.6.12. The implication (1) ⇒ (2) is obvious, the equivalence (2) ⇒ (3) follows from Example 21.1.6.10, and the equivalence (3) ⇒ (4) follows from Corollary 21.1.4.9. We will complete the proof by showing that (4) ⇒ (1). Assume that $\mathcal{X}$ is compactly assembled; we wish to show that the exponential $\mathcal{Y}^{\mathcal{X}}$ exists for every ∞-topos $\mathcal{Y}$. Using Remark 21.1.6.6 and Lemma 21.1.6.16, we can reduce to the case where $\mathcal{Y}$ has the form $\mathcal{P}(\mathcal{G})$, where $\mathcal{G}$ is a small ∞-category which admits finite limits. In particular, we can assume that $\mathcal{Y} \simeq \mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S})$ is a classifying ∞-topos of $\mathcal{C}$-valued sheaves, where $\mathcal{C} = \mathrm{Ind}(\mathcal{G}^{\mathrm{op}})$ is an ∞-category which is presentable and compactly assembled. In this case, Example 21.1.6.9 shows that the ∞-topos $\mathrm{Fun}^{\omega}(\mathcal{C} \otimes \mathcal{X}, \mathcal{S})$ has the desired universal property. □

21.1.7 Example: Locally Compact Topological Spaces

We now relate Theorem 21.1.6.12 to classical point-set topology.

Proposition 21.1.7.1. *Let X be a locally compact Hausdorff space. Then the ∞-topos $\mathcal{S}\mathrm{hv}(X)$ is exponentiable.*

Remark 21.1.7.2. Let X be a locally compact Hausdorff space. By virtue of Theorem 21.1.6.12, Proposition 21.1.7.1 is equivalent to the assertion that the ∞-category $\mathcal{S}\mathrm{hv}(X)$ is compactly assembled. Beware that $\mathcal{S}\mathrm{hv}(X)$ is usually not compactly generated. For example, if $X = \mathbf{R}$, then the ∞-category $\mathcal{S}\mathrm{hv}(X)$ does not contain any non-initial compact objects (note that if $\mathscr{F} \in \mathcal{S}\mathrm{hv}(X)$ is compact, then $\tau_{\leqslant -1} \mathscr{F}$ can be identified with a compact object in the category of open subsets of $\mathbf{R}$: that is, a compact open subset of $\mathbf{R}$).

Proof of Proposition 21.1.7.1. Let $G : \mathrm{Ind}(\mathcal{S}\mathrm{hv}(X)) \to \mathcal{S}\mathrm{hv}(X)$ be the Ind-extension of the identity functor $\mathrm{id}_{\mathcal{S}\mathrm{hv}(X)}$; to show that $\mathcal{S}\mathrm{hv}(X)$ is compactly assembled, it will suffice to show that G admits admits a left adjoint (Theorem 21.1.2.10). Let us say that an object $\mathscr{F} \in \mathcal{S}\mathrm{hv}(X)$ is *good* if the functor $\mathrm{Map}_{\mathcal{S}\mathrm{hv}(X)}(\mathscr{F}, G(\bullet))$ is corepresentable by an object of $\mathrm{Ind}(\mathcal{S}\mathrm{hv}(X))$. We wish to show that every object of $\mathcal{S}\mathrm{hv}(X)$ is good.

For each open set $U \subseteq X$, let $h_U \in \mathcal{S}\mathrm{hv}(X)$ denote the sheaf represented by U (given by the formula $h_U(V) = \begin{cases} * & \text{if } V \subseteq U \\ \varnothing & \text{if } V \nsubseteq U \end{cases}$). Note that the ∞-category $\mathcal{S}\mathrm{hv}(X)$ is generated under small colimits by objects of the form h_U. Since the ∞-category $\mathrm{Ind}(\mathcal{S}\mathrm{hv}(X))$ admits small colimits, the collection of good objects of $\mathcal{S}\mathrm{hv}(X)$ is closed under small colimits. Consequently, to complete the proof of Proposition 21.1.7.1, it will suffice to show that each of the sheaves h_U is good.

For open sets $U, V \subseteq X$, we write $V \Subset U$ if V is contained in a compact subset of U. For fixed U, the collection of open sets V satisfying $V \Subset U$ is filtered by inclusion. We let $h_{\Subset U}$ denote the Ind-object of $\mathcal{S}\mathrm{hv}(X)$ given by the filtered diagram $\{h_V\}_{V \Subset U}$. We will complete the proof by showing that $h_{\Subset U} \in \mathrm{Ind}(\mathcal{S}\mathrm{hv}(X))$ corepresents the functor $\mathrm{Map}_{\mathcal{S}\mathrm{hv}(X)}(h_U, G(\bullet))$. More precisely, we will show that for any filtered diagram $\{\mathscr{F}_\alpha\}$ in the ∞-category $\mathcal{S}\mathrm{hv}(X)$, the canonical map

$$\theta : (\varinjlim_{\alpha} \mathscr{F}_\alpha)(U) = \mathrm{Map}_{\mathcal{S}\mathrm{hv}(X)}(h_U, G(\{\mathscr{F}_\alpha\})) \to \mathrm{Map}_{\mathrm{Ind}(\mathcal{S}\mathrm{hv}(X))}(h_{\Subset U}, \{\mathscr{F}_\alpha\}) \simeq \varprojlim_{V \Subset U} \varinjlim_{\alpha} \mathscr{F}_\alpha(V)$$

is a homotopy equivalence.

For each compact set $K \subseteq X$ and each sheaf $\mathscr{F} \in \mathcal{S}\mathrm{hv}(X)$, let $\mathscr{F}(K)$ denote the direct limit $\varinjlim_V \mathscr{F}(V)$, where V ranges over all open neighborhoods of K. Using a cofinality argument, we can rewrite the codomain of θ as a limit $\varprojlim_{K \subseteq U} \varinjlim_\alpha \mathscr{F}_\alpha(K)$, so that θ factors as a composition

$$(\varinjlim_{\alpha} \mathscr{F}_\alpha)(U) \xrightarrow{\theta'} \varprojlim_{K \subseteq U} (\varinjlim_{\alpha} \mathscr{F}_\alpha)(K) \xrightarrow{\theta''} \varprojlim_{K \subseteq U} \varinjlim_{\alpha} (\mathscr{F}_\alpha(K)).$$

It now follows from Theorem HTT.7.3.4.9 that the map θ' is a homotopy equivalence, and from Corollary HTT.7.3.4.11 that the map θ'' is a homotopy equivalence. □

Proposition 21.1.7.1 asserts that, if X is a locally compact Hausdorff space and $\mathcal{Y}$ is an arbitrary ∞-topos, then there exists an exponential $\mathcal{Y}^{\mathcal{S}\mathrm{hv}(X)}$ in the ∞-category of ∞-topoi. In particular, if Y is another topological space, then we can form the exponential $\mathcal{S}\mathrm{hv}(Y)^{\mathcal{S}\mathrm{hv}(X)}$. We now study the relationship of this exponential with the compact-open topology on the mapping space $\mathrm{Hom}_{\mathcal{T}\mathrm{op}}(X, Y)$.

Lemma 21.1.7.3. *Let $\mathcal{X}$ and $\mathcal{Y}$ be ∞-topoi for which the exponential $\mathcal{Y}^{\mathcal{X}}$ exists, and let $n \geqslant 0$ be an integer. If $\mathcal{Y}$ is n-localic, then $\mathcal{Y}^{\mathcal{X}}$ is n-localic.*

Proof. Let $f^* : \mathcal{Z} \to \mathcal{Z}'$ be a geometric morphism of ∞-topoi which induces an equivalence $\tau_{\leqslant n-1}\,\mathcal{Z} \to \tau_{\leqslant n-1}\,\mathcal{Z}'$; we wish to show that the induced map

$$\theta : \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{Z}, \mathcal{Y}^{\mathcal{X}}) \to \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{Z}', \mathcal{Y}^{\mathcal{X}})$$

is a homotopy equivalence. Invoking the definition of the exponential $\mathcal{Y}^{\mathcal{X}}$, we can identify θ with the induced map

$$\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{Z} \otimes \mathcal{X}, \mathcal{Y}) \to \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{Z}' \otimes \mathcal{X}, \mathcal{Y}).$$

To show that this map is a homotopy equivalence, it will suffice to show that f^* induces an equivalence $\tau_{\leqslant n-1}(\mathcal{Z} \otimes \mathcal{X}) \to \tau_{\leqslant n-1}(\mathcal{Z}' \otimes \mathcal{X})$. This is clear, since both sides can be identified with $(\tau_{\leqslant n-1} \mathcal{S}) \otimes \mathcal{Z} \otimes \mathcal{X} \simeq (\tau_{\leqslant n-1} \mathcal{S}) \otimes \mathcal{Z}' \otimes \mathcal{X}$. □

For any ∞-topos $\mathcal{X}$, let $|\mathcal{Y}|$ denote the associated topological space (Definition 1.5.4.3).
.

Proposition 21.1.7.4. *Let $\mathcal{Y}$ be a 0-localic ∞-topos, and let X be a locally compact Hausdorff space. Then:*

(1) *The exponential $\mathcal{Y}^{\mathcal{S}\mathrm{hv}(X)}$ exists.*

(2) *The ∞-topos $\mathcal{Y}^{\mathcal{S}\mathrm{hv}(X)}$ is 0-localic.*

(3) *The underlying topological space $|\mathcal{Y}^{\mathcal{S}\mathrm{hv}(X)}|$ can be identified with the mapping space $\mathrm{Hom}_{\mathcal{T}\mathrm{op}}(X, |\mathcal{Y}|)$, equipped with the compact-open topology.*

Proof. Assertion (1) follows from Proposition 21.1.7.1 and assertion (2) from Lemma 21.1.7.3. To prove (3), we observe that for any topological space Z, we have canonical maps

$$\begin{aligned}
\mathrm{Hom}_{\mathcal{T}\mathrm{op}}(Z, |\mathcal{Y}^{\mathcal{S}\mathrm{hv}(X)}|) &\xleftarrow{\sim} \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{S}\mathrm{hv}(Z), \mathcal{Y}^{\mathcal{S}\mathrm{hv}(X)}) \\
&\simeq \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{S}\mathrm{hv}(Z) \otimes \mathcal{S}\mathrm{hv}(X), \mathcal{Y}) \\
&\xrightarrow{\sim} \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{S}\mathrm{hv}(Z \times X), \mathcal{Y}) \\
&\xrightarrow{\sim} \mathrm{Hom}_{\mathcal{T}\mathrm{op}}(Z \times X, |\mathcal{Y}|);
\end{aligned}$$

here the first map is an equivalence by (2), the second by the universal property of the exponential, the third by virtue of Proposition HTT.7.3.1.11 (which uses the local compactness of X), and the fourth by our assumption that $\mathcal{Y}$ is 0-localic. Composing these maps, we obtain bijections

$$\mathrm{Hom}_{\mathcal{T}\mathrm{op}}(Z, |\mathcal{Y}^{\mathcal{S}\mathrm{hv}(X)}|) \simeq \mathrm{Hom}_{\mathcal{T}\mathrm{op}}(Z \times X, |\mathcal{Y}|)$$

depending functorially on Z. Applying Proposition 21.1.6.1, we deduce that $|\mathcal{Y}^{\mathcal{S}\mathrm{hv}(X)}|$ is homeomorphic to the mapping space $\mathrm{Hom}_{\mathcal{T}\mathrm{op}}(X, |\mathcal{Y}|)$ (with its compact-open topology). □

Corollary 21.1.7.5. *Let X be a locally compact Hausdorff space and let Y be a sober topological space. Then there is a canonical homeomorphism $\mathrm{Hom}_{\mathcal{T}\mathrm{op}}(X, Y) \simeq |\mathcal{S}\mathrm{hv}(Y)^{\mathcal{S}\mathrm{hv}(X)}|$ (where the left hand side is equipped with the compact-open topology).*

Warning 21.1.7.6. In the situation of Corollary 21.1.7.5, the homeomorphism $\mathrm{Hom}_{\mathcal{T}\mathrm{op}}(X, Y) \simeq |\mathcal{S}\mathrm{hv}(Y)^{\mathcal{S}\mathrm{hv}(X)}|$ determines a geometric morphism of ∞-topoi

$$e_* : \mathcal{S}\mathrm{hv}(\mathrm{Hom}_{\mathcal{T}\mathrm{op}}(X, Y)) \to \mathcal{S}\mathrm{hv}(Y)^{\mathcal{S}\mathrm{hv}(X)}.$$

Beware that this geometric morphism is generally *not* an equivalence. The ∞-topos $\mathcal{S}\mathrm{hv}(Y)^{\mathcal{S}\mathrm{hv}(X)}$ is 0-localic, but the underlying locale generally does not have enough points. For example, if X consists of two points, then e_* can be identified with the canonical map $\mathcal{S}\mathrm{hv}(Y \times Y) \to \mathcal{S}\mathrm{hv}(Y) \otimes \mathcal{S}\mathrm{hv}(Y)$, which need not be an equivalence without additional assumptions on Y.

Remark 21.1.7.7. In the proof of Proposition 21.1.7.4, we constructed a homeomorphism $|\,\mathcal{Y}^{\mathcal{S}\mathrm{hv}(X)}\,| \simeq \mathrm{Hom}_{\mathcal{T}\mathrm{op}}(X, |\,\mathcal{Y}\,|)$ by appealing to the universal property of the compact-open topology (Proposition 21.1.6.1). However, this is not necessary. Specializing the bijection $\mathrm{Hom}_{\mathcal{T}\mathrm{op}}(Z, |\,\mathcal{Y}^{\mathcal{S}\mathrm{hv}(X)}\,|) \simeq \mathrm{Hom}_{\mathcal{T}\mathrm{op}}(Z \times X, |\,\mathcal{Y}\,|)$ to the case where Z is a point, we see that there is an isomorphism of *sets*

$$\beta : \mathrm{Hom}_{\mathcal{T}\mathrm{op}}(X, |\,\mathcal{Y}\,|) \simeq |\,\mathcal{Y}^{\mathcal{S}\mathrm{hv}(X)}\,|,$$

which carries a continuous function $f : X \to |\,\mathcal{Y}\,|$ to the point of $|\,\mathcal{Y}^{\mathcal{S}\mathrm{hv}(X)}\,|$ determined by the associated geometric morphism $f_* : \mathcal{S}\mathrm{hv}(X) \to \mathcal{Y}$. There is a unique topology on $\mathrm{Hom}_{\mathcal{T}\mathrm{op}}(X, |\,\mathcal{Y}\,|)$ for which the map β is a homeomorphism: namely, one declares that a set $U \subseteq \mathrm{Hom}_{\mathcal{T}\mathrm{op}}(X, |\,\mathcal{Y}\,|)$ is open if and only if there exists a (-1)-truncated object $V \in \mathcal{Y}^{\mathcal{S}\mathrm{hv}(X)}$ such that $(f \in U) \Leftrightarrow (f_*$ factors through $(\mathcal{Y}^{\mathcal{S}\mathrm{hv}(X)})_{/V})$. By unwinding the proofs of Theorem 21.1.6.12 and Proposition 21.1.7.4, one can show directly that this topology coincides with the compact-open topology. The argument of Proposition 21.1.7.4 then provides a bijection

$$\mathrm{Hom}_{\mathcal{T}\mathrm{op}}(Z, \mathrm{Hom}_{\mathcal{T}\mathrm{op}}(X, |\,\mathcal{Y}\,|)) \simeq \mathrm{Hom}_{\mathcal{T}\mathrm{op}}(Z \times X, |\,\mathcal{Y}\,|)$$

for every topological space Z. Specializing to the case $\mathcal{Y} = \mathcal{S}\mathrm{hv}(Y)$ for a sober topological space Y, we obtain another proof of Proposition 21.1.6.1 (at least for the special case where the target space Y is sober).

We close this section by mentioning a variant of Proposition 21.1.7.1:

Proposition 21.1.7.8. *Let X be a coherent topological space. Then the ∞-topos $\mathcal{S}\mathrm{hv}(X)$ is exponentiable.*

Proof. For each open subset $U \subseteq X$, let $h_U \in \mathcal{S}\mathrm{hv}(X)$ denote the sheaf represented by U. It follows from Corollary HTT.7.3.5.4 that if $U \subseteq X$ is quasi-compact, then the construction $\mathscr{F} \mapsto \mathscr{F}(U)$ determines a functor $\mathcal{S}\mathrm{hv}(X) \to \mathcal{S}$ which commutes with filtered colimits. This functor is corepresented by h_U, so that h_U is a compact object of $\mathcal{S}\mathrm{hv}(X)$. Since the sheaves h_U (where U is quasi-compact) generate the ∞-category $\mathcal{S}\mathrm{hv}(X)$ under colimits, we deduce that $\mathcal{S}\mathrm{hv}(X)$ is compact generated. Applying Theorem 21.1.6.12, we conclude that $\mathcal{S}\mathrm{hv}(X)$ is an exponentiable ∞-topos. $\square$

21.2 $\mathcal{G}$-Objects

Let X be a topological space and suppose that we wish to study sheaves on X taking values in some category $\mathcal{C}$. Let us suppose that the objects of $\mathcal{C}$ can be understood as "sets with extra structure" (such as abelian groups or commutative rings), so that $\mathcal{C}$ is equipped with a forgetful functor $T : \mathcal{C} \to \mathcal{S}\mathrm{et}$. If the functor T preserves inverse limits, then every $\mathcal{C}$-valued sheaf $\mathscr{O}$ on X determines a $\mathcal{S}\mathrm{et}$-valued sheaf $\mathscr{O}^T$ on X, given by the formula $\mathscr{O}^T(U) = T(\mathscr{O}(U))$. In practice, we often abuse notation by identifying $\mathscr{O}$ with $\mathscr{O}^T$, implicitly remembering that the set-valued sheaf $\mathscr{O}^T$ is equipped with "extra structure" from its origin as a $\mathcal{C}$-valued sheaf. For example, if $\mathcal{C}$ is the category of groups (and $T : \mathcal{C} \to \mathcal{S}\mathrm{et}$ is the usual forgetful functor), then $\mathscr{O}^T$ can be regarded as an group object of the topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(X)$: that is, it is equipped with a multiplication map $m : \mathscr{O}^T \times \mathscr{O}^T \to \mathscr{O}^T$, an inversion map $i : \mathscr{O}^T \to \mathscr{O}^T$, and a unit map $e : \mathbf{1}_X \to \mathscr{O}^T$ (here $\mathbf{1}_X$ denotes a final object of the topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(X)$) which satisfy the usual group axioms, which are encoded by requiring the commutativity of the diagrams

$$\begin{array}{ccc} \mathscr{O}^T \times \mathbf{1}_X & \xrightarrow{\mathrm{id} \times e} & \mathscr{O}^T \times \mathscr{O}^T \\ & {\scriptstyle \sim} \searrow \quad \swarrow {\scriptstyle m} & \\ & \mathscr{O}^T & \end{array} \qquad \begin{array}{ccc} \mathbf{1}_X \times \mathscr{O}^T & \xrightarrow{e \times \mathrm{id}} & \mathscr{O}^T \times \mathscr{O}^T \\ & {\scriptstyle \sim} \searrow \quad \swarrow {\scriptstyle m} & \\ & \mathscr{O}^T & \end{array}$$

$$\begin{array}{ccc} \mathscr{O}^T & \xrightarrow{\mathrm{id} \times i} & \mathscr{O}^T \times \mathscr{O}^T \\ \downarrow & & \downarrow{\scriptstyle m} \\ \mathbf{1} & \xrightarrow{e} & \mathscr{O}^T \end{array} \qquad \begin{array}{ccc} \mathscr{O}^T & \xrightarrow{i \times \mathrm{id}} & \mathscr{O}^T \times \mathscr{O}^T \\ \downarrow & & \downarrow{\scriptstyle m} \\ \mathbf{1} & \xrightarrow{e} & \mathscr{O}^T \end{array}$$

$$\begin{array}{ccc} \mathscr{O}^T \times \mathscr{O}^T \times \mathscr{O}^T & \xrightarrow{m \times \mathrm{id}} & \mathscr{O}^T \times \mathscr{O}^T \\ \downarrow{\scriptstyle \mathrm{id} \times m} & & \downarrow{\scriptstyle m} \\ \mathscr{O}^T \times \mathscr{O}^T & \xrightarrow{m} & \mathscr{O}^T . \end{array}$$

In the setting of spectral algebraic geometry (and several of its variants), we need to consider sheaves on a topological space X (or some variant thereof) which take values in an ∞-category $\mathcal{C}$, rather than an ordinary category. In practice, the ∞-category $\mathcal{C}$ can usually be viewed as "spaces with extra structure," meaning that it is equipped with a well-behaved forgetful functor $T : \mathcal{C} \to \mathcal{S}$ (for example, $\mathcal{C}$ might be the ∞-category $\mathrm{CAlg}^{\mathrm{cn}}$ of connective $\mathbb{E}_\infty$-rings, and T the 0th space functor $\Omega^\infty : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$). In this case, we can again associate to any $\mathcal{C}$-valued sheaf $\mathscr{O}$ a $\mathcal{S}$-valued sheaf $\mathscr{O}^T$, given by the formula $\mathscr{O}^T(U) = T(\mathscr{O}(U))$. However, it becomes more difficult to describe the "extra structure" inherited by $\mathscr{O}^T$. In the higher categorical setting, one must stipulate the existence *witness* to the commutativity of every diagram; these witnesses then satisfy higher-order coherence conditions which are prohibitively difficult to articulate directly. We therefore adopt an alternate approach, where we consider a family of forgetful functors $\{T : \mathcal{C} \to \mathcal{S}\}_{T \in \mathcal{G}}$ indexed by another ∞-category $\mathcal{G}$; the "extra structure" will then be encoded by the functorial dependence of the sheaf $\mathscr{O}^T$ on the object $T \in \mathcal{G}$.

Definition 21.2.0.1. Let $\mathcal{G}$ be an essentially small ∞-category and let $\mathcal{X}$ be an ∞-topos. A *$\mathcal{G}$-object* of $\mathcal{X}$ is a functor $\mathcal{G} \to \mathcal{X}$ which is locally left exact (see Definition 20.4.2.1). We let $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{G}, \mathcal{X})$ spanned by the $\mathcal{G}$-objects of $\mathcal{X}$.

Remark 21.2.0.2. The ∞-category $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ was already studied in Chapter 20, where it was denoted by $\mathrm{Fun}^{\mathrm{llex}}(\mathcal{G}, \mathcal{X})$ (Definition 20.4.2.1). The shift in notation reflects a slightly different perspective: in this chapter, we wish to emphasize the heuristic that an object of $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ should be viewed as an "object" of $\mathcal{X}$ equipped with extra structure.

Notation 21.2.0.3. In the situation of Definition 21.2.0.1, we will typically use the letter $\mathscr{O}$ to denote $\mathcal{G}$-objects of $\mathcal{X}$, and we will write $\mathscr{O}^T$ to denote the value of $\mathscr{O}$ on an object $T \in \mathcal{G}$.

We will be primarily interested in the special case of Definition 21.2.0.1 where the ∞-category $\mathcal{G}$ admits finite limits. In this case, a $\mathcal{G}$-object of $\mathcal{X}$ is simply a functor $\mathscr{O} : \mathcal{G} \to \mathcal{X}$ which preserves finite limits (see Corollary 20.4.3.2). In §21.2.2, we will show that if $\mathcal{G}$ admits finite limits, then the datum of a $\mathcal{G}$-object is equivalent to the datum of a $\mathcal{C}$-valued sheaf, where $\mathcal{C} = \mathrm{Ind}(\mathcal{G}^{\mathrm{op}})$ (Proposition 21.2.2.1). This is a consequence of the following pair of assertions:

(*a*) The presheaf ∞-category $\mathcal{P}(\mathcal{G}) = \mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S})$ is a classifying ∞-topos for $\mathcal{C} = \mathrm{Ind}(\mathcal{G}^{\mathrm{op}})$-valued sheaves (see Proposition **??**).

(*b*) The presheaf ∞-category $\mathcal{P}(\mathcal{G}) = \mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S})$ is a classifying ∞-topos for $\mathcal{G}$-objects.

Here assertion (*a*) depends on the fact that the ∞-category $\mathcal{G}$ admits finite limits, but assertion (*b*) does not. Consequently, the theory of $\mathcal{G}$-objects offers a bit more flexibility than the theory of $\mathcal{C}$-valued sheaves: we give a concrete illustration of this point in §21.2.3. Note that not every ∞-topos arises as a classifying topos in the sense of (*a*) or (*b*) (the ∞-topoi that classify $\mathcal{C}$-valued sheaves are rather special, even without the assumption that $\mathcal{C}$ is compactly generated: see Proposition 21.1.5.4). A general ∞-topos $\mathcal{E}$ need not be equivalent to an ∞-category of presheaves $\mathcal{P}(\mathcal{G})$. However, every ∞-topos $\mathcal{E}$ can be realized as an (accessible) left exact localization of an ∞-category of the form $\mathcal{P}(\mathcal{G})$. In this case, for any ∞-topos $\mathcal{X}$, one has a fully faithful embedding $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X}) \simeq \mathrm{Fun}^*(\mathcal{P}(\mathcal{G}), \mathcal{X}) \simeq \mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$, whose essential image can be viewed as the collection of $\mathcal{G}$-objects of $\mathcal{X}$ which are in some sense "local" with respect to the chosen realization of $\mathcal{E}$. In §21.2.1, we make this heuristic more precise by introducing the notion of a *τ-local $\mathcal{G}$-object*, where τ is a Grothendieck topology on $\mathcal{G}$, and showing that the τ-local $\mathcal{G}$-object are classified by the ∞-topos $\mathcal{S}\mathrm{hv}_\tau(\mathcal{G})$ (Proposition 21.2.1.13).

In §21.2.5, we specialize to the setting of algebraic geometry. When $\mathcal{G} = \mathrm{Aff}$ is the category of affine schemes of finite type over $\mathbf{Z}$, then the notion of local $\mathcal{G}$-object recovers the notion of local commutative ring object when $\mathcal{G}$ is equipped with the Zariski topology of Example 20.6.4.1, and the notion of a strictly Henselian commutative ring object when $\mathcal{G}$ is equipped with the étale topology of Example **??** (see Theorem 21.2.5.1). Replacing Aff by a suitable ∞-categorical analogue (see Examples 20.6.4.4 and **??**), we obtain a similar description of the theory of local and strictly Henselian CAlg-valued sheaves (Theorem 21.2.5.3). Moreover, we show that the notions of *local* morphism between $\mathrm{CAlg}^{\heartsuit}$-valued and CAlg-valued sheaves can be recovered as a special case of the more general notion of *local morphism of $\mathcal{G}$-object* which is determined by a choice of admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$, which we study in §21.2.4 (see Definition 21.2.4.1).

21.2.1 Local $\mathcal{G}$-Objects and Classifying ∞-Topoi

We begin by introducing a slight elaboration on Definition 21.2.0.1.

Definition 21.2.1.1. Let $\mathcal{G}$ be an essentially small ∞-category equipped with a Grothendieck topology τ and let $\mathcal{X}$ be an ∞-topos. We will say that a $\mathcal{G}$-object $\mathscr{O} : \mathcal{G} \to \mathcal{X}$ is *τ-local* if it satisfies the following condition:

(∗) For every collection of morphisms $\{T_\alpha \to T\}$ in $\mathcal{G}$ which generate a τ-covering of the object T, the induced map $\amalg \mathscr{O}^{T_\alpha} \to \mathscr{O}^T$ is an effective epimorphism in the ∞-topos $\mathcal{X}$.

We let $\mathrm{Obj}^\tau_{\mathcal{G}}(\mathcal{X})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{G}, \mathcal{X})$ spanned by the τ-local $\mathcal{G}$-objects of $\mathcal{X}$.

Example 21.2.1.2. In the situation of Definition 21.2.1.1, suppose that the Grothendieck topology τ is trivial: that is, a collection of morphisms $\{u_\alpha : T_\alpha \to T\}$ generates a τ-covering if and only if some u_α admits a section. Then every $\mathcal{G}$-object is τ-local: that is, we have $\mathrm{Obj}^\tau_{\mathcal{G}}(\mathcal{X}) = \mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ for any ∞-topos $\mathcal{X}$.

Variant 21.2.1.3. If X is a topological space, then we let $\mathrm{Obj}^\tau_{\mathcal{G}}(X)$ denote the ∞-category $\mathrm{Obj}^\tau_{\mathcal{G}}(\mathcal{S}\mathrm{hv}(X))$ of $\mathcal{G}$-objects of the ∞-topos $\mathcal{S}\mathrm{hv}(X)$. In the case where the topology τ is trivial, we denote this ∞-category simply by $\mathrm{Obj}_{\mathcal{G}}(X)$.

Example 21.2.1.4. Let X be a topological space, let $\mathcal{U}(X)$ denote the partially ordered set of open subsets of X, and let $\mathcal{G}$ be an essentially small ∞-category which admits finite limits. Then $\mathrm{Obj}_{\mathcal{G}}(X)$ can be identified with the full subcategory of $\mathrm{Fun}(\mathcal{G} \times \mathcal{U}(X)^{\mathrm{op}}, \mathcal{S})$ spanned by those functors

$$\mathscr{O} : \mathcal{G} \times \mathcal{U}(X)^{\mathrm{op}} \to \mathcal{S} \qquad (T, U) \mapsto \mathscr{O}^T(U)$$

satisfying the following pair of requirements:

(a) For every fixed object $T \in \mathcal{G}$, the functor $U \mapsto \mathscr{O}^T(U)$ is a $\mathcal{S}$-valued sheaf on X.

(b) For each fixed open set $U \subseteq X$, the functor $T \mapsto \mathscr{O}^T(U)$ preserves finite limits.

If $\mathcal{G}$ is equipped with a Grothendieck topology τ, then we can identify $\mathrm{Obj}^{\tau}_{\mathcal{G}}(X)$ with the full subcategory of $\mathrm{Obj}_{\mathcal{G}}(X)$ spanned by those functors which satisfy the following additional requirement:

(c) For every τ-covering $\{T_\alpha \to T\}$ in $\mathcal{G}$ and every point $s \in \mathscr{O}^T(U)$, there exists an open covering $\{U_\beta\}$ of U such that each $s|_{U_\beta} \in \mathscr{O}^T(U_\beta)$ can be lifted to a point of $\mathscr{O}^{T_\alpha}(U_\beta)$, for some index α (which might depend on β).

Remark 21.2.1.5. Let $\mathcal{G}$ and X be as in Example 21.2.1.4. In practice, we will take $\mathcal{G}$ to be some relatively concrete class of "test objects" (such as affine schemes of finite type over $\mathbf{Z}$). If $\mathscr{O}$ is an object of the ∞-category $\mathrm{Obj}^{\tau}_{\mathcal{G}}(X)$, then it is useful to think of $\mathscr{O}^T(U)$ as a parameter space for "regular functions from U to T." Conditions (a), (b), and (c) of Example 21.2.1.4 encode natural expectations for how such a theory of "regular function" should behave.

Construction 21.2.1.6 (Pullbacks of $\mathcal{G}$-Objects)**.** Let $\mathcal{G}$ be an essentially small ∞-category equipped with a Grothendieck topology τ and suppose we are given a geometric morphism of ∞-topoi $\pi^* : \mathcal{X} \to \mathcal{Y}$. It follows immediately from the definitions that composition with π^* determines a functor $\mathrm{Obj}^{\tau}_{\mathcal{G}}(\mathcal{X}) \to \mathrm{Obj}^{\tau}_{\mathcal{G}}(\mathcal{Y})$, which we will refer to as the *pullback functor*. We will denote this functor either by $\pi^*_{\mathcal{G}}$ (when we need to emphasize its dependence on $\mathcal{G}$ or distinguish it from the usual pullback functor π^*) or simply by π^* (when its meaning is clear on context). Concretely, we have $(\pi^*_{\mathcal{G}}\, \mathscr{O})^T = \pi^*(\mathscr{O}^T)$ for each $\mathscr{O} \in \mathrm{Obj}^{\tau}_{\mathcal{G}}(\mathcal{X})$ and each $T \in \mathcal{G}$.

Notation 21.2.1.7. In the situation of Construction 21.2.1.6, suppose we are given a $\mathcal{G}$-object $\mathscr{O} \in \mathrm{Obj}^{\tau}_{\mathcal{G}}(\mathcal{X})$ and an object $U \in \mathcal{X}$. We let $\mathscr{O}|_U$ denote the pullback of $\mathscr{O}$ along the étale geometric morphism $\mathcal{X}_{/U} \to \mathcal{X}$. More concretely, we can describe $\mathscr{O}|_U$ as the functor from $\mathcal{G}$ to $\mathcal{X}_{/U}$ given by the formula $(\mathscr{O}|_U)^T = \mathscr{O}^T \times U$.

Remark 21.2.1.8 (Pushforwards of $\mathcal{G}$-Objects)**.** In the situation of Construction 21.2.1.6, suppose that $\mathcal{G}$ admits finite limits and that the Grothendieck topology τ is trivial. In this case, we can identify $\mathrm{Obj}^{\tau}_{\mathcal{G}}(\mathcal{X})$ and $\mathrm{Obj}^{\tau}_{\mathcal{G}}(\mathcal{Y})$ with the ∞-categories $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{G}, \mathcal{X})$ and $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{G}, \mathcal{Y})$ of left exact functors from $\mathcal{G}$ to the ∞-topoi $\mathcal{X}$ and $\mathcal{Y}$, respectively. It follows that composition with the direct image functor $\pi_* : \mathcal{Y} \to \mathcal{X}$ determines functor $\mathrm{Obj}^{\tau}_{\mathcal{G}}(\mathcal{Y}) \to \mathrm{Obj}^{\tau}_{\mathcal{G}}(\mathcal{X})$. We will denote this functor either by $\pi^{\mathcal{G}}_*$ (when we wish to distinguish it from the pushforward functor $\pi_* : \mathcal{Y} \to \mathcal{X}$) by simply by π_* (when there is no danger of confusion). Concretely, it is given by the formula $(\pi^{\mathcal{G}}_*\, \mathscr{O})^T = \pi_*(\mathscr{O}^T)$ for each $\mathscr{O} \in \mathrm{Obj}^{\tau}_{\mathcal{G}}(\mathcal{X})$ and each $T \in \mathcal{G}$. Note that the functor $\pi^{\mathcal{G}}_*$ is right adjoint to the pullback functor $\pi^*_{\mathcal{G}} : \mathrm{Obj}^{\tau}_{\mathcal{G}}(\mathcal{X}) \to \mathrm{Obj}^{\tau}_{\mathcal{G}}(\mathcal{Y})$ of Construction 21.2.1.6.

Warning 21.2.1.9. The hypotheses of Remark 21.2.1.8 are necessary. If we drop either the assumption that $\mathcal{G}$ admits finite limits or that the Grothendieck topology τ is trivial, then the pullback functor $\pi_{\mathcal{G}}^* : \mathrm{Obj}_{\mathcal{G}}^{\tau}(\mathcal{X}) \to \mathrm{Obj}_{\mathcal{G}}^{\tau}(\mathcal{Y})$ need not admit a right adjoint.

We now have the following variant of Definition 21.1.0.1:

Definition 21.2.1.10. Let $\mathcal{G}$ be an essentially small ∞-category equipped with a Grothendieck topology τ. Suppose that $\mathcal{E}$ is an ∞-topos and that $\mathcal{O} \in \mathrm{Obj}_{\mathcal{G}}^{\tau}(\mathcal{E})$ is a τ-local $\mathcal{G}$-object of $\mathcal{E}$. We will say that $\mathcal{O}$ is *universal* if, for every ∞-topos $\mathcal{X}$, the construction $f^* \mapsto f^* \mathcal{O}$ induces an equivalence of ∞-categories

$$\mathrm{Fun}^*(\mathcal{E}, \mathcal{X}) \to \mathrm{Obj}_{\mathcal{G}}^{\tau}(\mathcal{X}).$$

In this case, we will say that *$\mathcal{O}$ exhibits $\mathcal{E}$ as a classifying topos for τ-local $\mathcal{G}$-objects.*

It follows immediately from the definitions that, if there exists a classifying ∞-topos $\mathcal{E}$ for τ-local $\mathcal{G}$-objects, then $\mathcal{E}$ is determined uniquely up to equivalence. We now prove existence by an explicit construction.

Definition 21.2.1.11. Let $\mathcal{G}$ be an essentially small ∞-category equipped with a Grothendieck topology τ. We define the *sheafified Yoneda embedding* $h : \mathcal{G} \to \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ to be the composition

$$\mathcal{G} \xrightarrow{j} \mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S}) \xrightarrow{L} \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G}),$$

where j is the Yoneda embedding for $\mathcal{G}$ and L is a left adjoint to the inclusion $\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G}) \hookrightarrow \mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S})$ (that is, L is the sheafification functor associated to τ).

Warning 21.2.1.12. The terminology of Definition 21.2.1.11 is potentially misleading: the sheafified Yoneda embedding $h : \mathcal{G} \to \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ need not be fully faithful (it is fully faithful if and only if the topology τ is *subcanonical*: that is, if and only if the functor j takes values in $\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$).

Proposition 21.2.1.13. *Let $\mathcal{G}$ be an essentially small ∞-category equipped with a Grothendieck topology τ. Then the sheafified Yoneda embedding $h : \mathcal{G} \to \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ is a universal τ-local $\mathcal{G}$-object of the ∞-topos $\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$. In particular, $\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ is a classifying ∞-topos for τ-local $\mathcal{G}$-objects.*

Proof. Let $\mathcal{X}$ be an arbitrary ∞-topos; we wish to show that composition with the composite functor

$$\mathcal{G} \xrightarrow{j} \mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S}) \xrightarrow{L} \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$$

induces an equivalence of ∞-categories $\mathrm{Fun}^*(\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G}), \mathcal{X}) \to \mathrm{Obj}_{\mathcal{G}}^{\tau}(\mathcal{X})$. When τ is the trivial topology, this follows from the universal property of the presheaf ∞-category $\mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S})$ (see Theorem HTT.5.1.5.6) together with the definition of local left exactness. The general case then follows from universal property of $\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ given in Lemma HTT.6.2.3.20 . □

21.2.2 Comparison with $\mathcal{C}$-Valued Sheaves

We now show that, if $\mathcal{C}$ is a compactly generated ∞-category, then the theory of $\mathcal{C}$-valued sheaves (in the sense of Definition 1.3.1.4) is equivalent to the theory of $\mathcal{G}$-objects (in the sense of Definition 21.2.0.1), where $\mathcal{G} = \mathcal{C}_c^{\mathrm{op}}$ is the opposite of the ∞-category of compact objects of $\mathcal{C}$. More generally, we have the following:

Proposition 21.2.2.1. *Let $\mathcal{X}$ be an ∞-topos and let $\mathcal{G}$ be an essentially small ∞-category which admits finite limits. Then there is a canonical equivalence of ∞-categories $\rho : \mathcal{S}\mathrm{hv}_{\mathrm{Ind}(\mathcal{G}^{\mathrm{op}})}(\mathcal{X}) \to \mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$.*

Proof. Set $\mathcal{C} = \mathrm{Ind}(\mathcal{G}^{\mathrm{op}})$, so that composition with the Yoneda embedding $\mathcal{G}^{\mathrm{op}} \hookrightarrow \mathcal{C}$ induces an equivalence of ∞-categories $\mathrm{Fun}^{\omega}(\mathcal{C}, \mathcal{S}) \simeq \mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S})$. It follows that the ∞-topos $\mathcal{E} = \mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S})$ is a classifying ∞-topos for both $\mathcal{C}$-valued sheaves (Theorem 21.1.4.3) and for $\mathcal{G}$-objects (Proposition 21.2.1.13). In particular, for any ∞-topos $\mathcal{X}$, we have equivalences $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X}) \simeq \mathrm{Fun}^*(\mathcal{E}, \mathcal{X}) \simeq \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$. □

Remark 21.2.2.2. The equivalence ρ of Proposition 21.2.2.1 is characterized informally by the formula

$$\mathrm{Map}_{\mathcal{X}}(X, (\rho \mathscr{F})^T) = \mathrm{Map}_{\mathrm{Ind}(\mathcal{G}^{\mathrm{op}})}(T, \mathscr{F}(X))$$

for $X \in \mathcal{X}$ and $T \in \mathcal{G}$ (here we abuse notation by identifying T with its image in $\mathrm{Ind}(\mathcal{G}^{\mathrm{op}})$).

Variant 21.2.2.3. Let $\mathcal{G}$ be an essentially small ∞-category which admits finite limits and let X be a topological space. Combining Propositions 21.2.2.1 and 1.3.1.7, we obtain an equivalence of ∞-categories $\mathrm{Obj}_{\mathcal{G}}(X) \simeq \mathcal{S}\mathrm{hv}_{\mathrm{Ind}(\mathcal{G}^{\mathrm{op}})}(X)$.

Remark 21.2.2.4 (Functoriality)**.** Suppose we are given a geometric morphism of ∞-topoi

$$\mathcal{X} \underset{\pi_*}{\overset{\pi^*}{\rightleftarrows}} \mathcal{Y}.$$

Then:

- For every ∞-category $\mathcal{C}$, there is a direct image functor $\pi_*^{\mathcal{C}} : \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{Y}) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$, given on objects by the formula $(\pi_*^{\mathcal{C}} \mathscr{F})(X) = \mathscr{F}(\pi^* X)$. In general, the functor $\pi_*^{\mathcal{C}}$ does not admit a left adjoint.

- For every essentially small ∞-category $\mathcal{G}$ equipped with a Grothendieck topology τ, there is a pullback functor $\pi_{\mathcal{G}}^* : \mathrm{Obj}_{\mathcal{G}}^{\tau}(\mathcal{X}) \to \mathrm{Obj}_{\mathcal{G}}^{\tau}(\mathcal{Y})$, given on objects by the formula $(\pi_{\mathcal{G}}^* \mathscr{O})^T = \pi^*(\mathscr{O}^T)$ (Construction 21.2.1.6). In general, the functor $\pi_{\mathcal{G}}^*$ does not admit a right adjoint.

In the special case where $\mathcal{G}$ admits finite limits and the Grothendieck topology τ is trivial, then the functor $\pi_{\mathcal{G}}^*$ *does* admit a right adjoint $\pi_*^{\mathcal{G}}$, given by pointwise composition with π_* (Remark 21.2.1.8). In this case, Proposition 21.2.2.1 supplies equivalences

$$\rho_{\mathcal{X}} : \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \simeq \mathrm{Obj}_{\mathcal{G}}(\mathcal{X}) \qquad \rho_{\mathcal{Y}} : \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{Y}) \simeq \mathrm{Obj}_{\mathcal{G}}(\mathcal{Y}),$$

where $\mathcal{C}$ denotes the compactly generated ∞-category $\mathrm{Ind}(\mathcal{G}^{\mathrm{op}})$. In this case, the direct image functor $\pi_*^{\mathcal{C}}$ admits a left adjoint $\pi_{\mathcal{C}}^*$ (Proposition **??**). The diagram of ∞-categories

$$\begin{array}{ccc} \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) & \xrightarrow{\rho_{\mathcal{X}}} & \mathrm{Obj}_{\mathcal{G}}(\mathcal{X}) \\ \downarrow{\scriptstyle \pi_{\mathcal{C}}^*} & & \downarrow{\scriptstyle \pi_{\mathcal{G}}^*} \\ \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{Y}) & \xrightarrow{\rho_{\mathcal{Y}}} & \mathrm{Obj}_{\mathcal{G}}(\mathcal{Y}) \end{array}$$

commutes by construction. Passing to adjoints, we deduce that the diagram of ∞-categories

$$\begin{array}{ccc} \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{Y}) & \xrightarrow{\rho_{\mathcal{Y}}} & \mathrm{Obj}_{\mathcal{G}}(\mathcal{Y}) \\ \downarrow{\scriptstyle \pi_*^{\mathcal{C}}} & & \downarrow{\scriptstyle \pi_*^{\mathcal{G}}} \\ \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) & \xrightarrow{\rho_{\mathcal{X}}} & \mathrm{Obj}_{\mathcal{G}}(\mathcal{X}) \end{array}$$

also commutes (this also follows from the concrete description of $\rho_{\mathcal{X}}$ and $\rho_{\mathcal{Y}}$ supplied in Remark 21.2.2.2).

The rest of this section is devoted to giving a second proof of Proposition 21.2.2.1, which avoids appealing to the theory of classifying ∞-topoi (and yields some information even in the case where $\mathcal{G}$ does not admit finite limits).

Notation 21.2.2.5. Recall that a functor $f : \mathcal{C} \to \mathcal{D}$ between ∞-categories is said to be *left exact* if, for every object $D \in \mathcal{D}$, the ∞-category $(\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{D/})^{\mathrm{op}}$ is filtered (see Proposition HTT.5.3.2.5). We let $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ spanned by the left exact functors. According to Proposition HTT.5.3.2.9 , if $\mathcal{C}$ admits finite limits, then a functor $f : \mathcal{C} \to \mathcal{D}$ is left exact if and only if it preserves finite limits.

Proposition 21.2.2.6. *Let $\mathcal{X}$ be an ∞-topos, let $\mathcal{G}$ be an essentially small ∞-category, and set $\mathcal{C} = \mathrm{Ind}(\mathcal{G}^{\mathrm{op}})$. Then there is an equivalence of ∞-categories $\rho : \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \to \mathrm{Fun}^{\mathrm{lex}}(\mathcal{G}, \mathcal{X})$, characterized by the formula*

$$\mathrm{Map}_{\mathcal{X}}(X, \rho(\mathscr{F})(T)) = \mathrm{Map}_{\mathcal{C}}(T, \mathscr{F}(X))$$

for $X \in \mathcal{X}$ and $T \in \mathcal{G}$ (here again we abuse notation by identifying T with its image in $\mathcal{C}$).

Corollary 21.2.2.7. *Let $\mathcal{X}$ be an ∞-topos, let $\mathcal{G}$ be an essentially small ∞-category, and set $\mathcal{C} = \mathrm{Ind}(\mathcal{G}^{\mathrm{op}})$. Then the functor ρ of Proposition 21.2.2.6 determines a fully faithful embedding $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \hookrightarrow \mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$.*

Remark 21.2.2.8. In the situation of Corollary 21.2.2.7, if the ∞-category $\mathcal{G}$ admits finite limits, then fully faithful embedding $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \hookrightarrow \mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ coincides with the equivalence of Proposition 21.2.2.1 (this is a reformulation of Remark 21.2.2.2).

The proof of Proposition 21.2.2.6 is essentially formal. Let us begin by reviewing some notation.

Notation 21.2.2.9. Let $\mathcal{C}$ and $\mathcal{D}$ be ∞-categories. We let $\mathrm{LFun}(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ spanned by those functors which admit right adjoints, and $\mathrm{RFun}(\mathcal{C}, \mathcal{D}) \subseteq \mathrm{Fun}(\mathcal{C}, \mathcal{D})$ the full subcategory spanned by those functors which admit left adjoints. By virtue of Proposition HTT.5.2.6.2 , the formation of adjoint functors supplies an equivalence of ∞-categories $\mathrm{RFun}(\mathcal{C}, \mathcal{D}) \simeq \mathrm{LFun}(\mathcal{D}, \mathcal{C})^{\mathrm{op}}$.

Remark 21.2.2.10. Let $\mathcal{C}$ and $\mathcal{D}$ be ∞-categories. Using the evident isomorphism

$$\mathrm{RFun}(\mathcal{C}^{\mathrm{op}}, \mathcal{D}) \simeq \mathrm{LFun}(\mathcal{C}, \mathcal{D}^{\mathrm{op}})^{\mathrm{op}},$$

we can formulate the equivalence of Notation 21.2.2.9 in the following more symmetric form:

$$\mathrm{RFun}(\mathcal{C}^{\mathrm{op}}, \mathcal{D}) \simeq \mathrm{RFun}(\mathcal{D}^{\mathrm{op}}, \mathcal{C}).$$

Remark 21.2.2.11. Let $\mathcal{C}$ be a locally small ∞-category, and let $\mathcal{D}$ be a presentable ∞-category. Using Corollary HTT.5.5.2.9 and Remark HTT.5.5.2.10 , we see that a functor $\mathcal{D}^{\mathrm{op}} \to \mathcal{C}$ admits a left adjoint if and only if it preserves small limits. In particular, if $\mathcal{X}$ is an ∞-topos, we have $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) = \mathrm{RFun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C})$ (see Definition 1.3.1.4), and therefore an equivalence $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \simeq \mathrm{LFun}(\mathcal{C}, \mathcal{X}^{\mathrm{op}})^{\mathrm{op}} \simeq \mathrm{RFun}(\mathcal{C}^{\mathrm{op}}, \mathcal{X})$.

Proposition 21.2.2.12. *Let $\mathcal{G}$ be an essentially small ∞-category, let $\mathcal{X}$ be a presentable ∞-category, and let $j : \mathcal{G} \to \mathrm{Pro}(\mathcal{G})$ denote the Yoneda embedding. Let $G : \mathrm{Pro}(\mathcal{G}) \to \mathcal{X}$ be a functor which preserves filtered limits. The following conditions are equivalent:*

(1) *The functor G admits a left adjoint F.*

(2) *The composite functor $g = G \circ j$ is left exact.*

Proof. Let us regard $\mathrm{Pro}(\mathcal{G})$ as a full subcategory of $\mathrm{Fun}(\mathcal{G}, \mathcal{S})^{\mathrm{op}} = \mathcal{P}(\mathcal{G}^{\mathrm{op}})^{\mathrm{op}}$. Using Theorem HTT.5.1.5.6 , we can assume without loss of generality that g factors as a composition

$$\mathcal{G} \xrightarrow{\overline{j}} \mathcal{P}(\mathcal{G}^{\mathrm{op}})^{\mathrm{op}} \xrightarrow{\overline{G}} \mathcal{X},$$

where $\overline{G}$ is a functor which preserves small limits and $\overline{j}$ is the Yoneda embedding. Using Corollary HTT.5.5.2.9 and Remark HTT.5.5.2.10 , we deduce that $\overline{G}$ admits a left adjoint $\overline{F}$. Unwinding the definitions, we see that $\overline{F}$ carries an object $X \in \mathcal{X}$ to a functor $\overline{F}(X) : \mathcal{G} \to \mathcal{S}$

which classifies the left fibration $\mathcal{X}_{/X} \times_{\mathcal{X}} \mathcal{G} \to \mathcal{G}$. It follows that condition (1) is equivalent to the requirement that $\overline{F}$ takes values in the full subcategory $\mathrm{Pro}(\mathcal{G}) \subseteq \mathcal{P}(\mathcal{G}^{\mathrm{op}})^{\mathrm{op}}$, in which case we can identify $\overline{F}$ with a functor $F : \mathcal{X} \to \mathrm{Pro}(\mathcal{G})$ which is left adjoint to G. Conversely, suppose that G admits a left adjoint F. Then the unit map $u : \mathrm{id}_{\mathcal{X}} \to G \circ F = \overline{G} \circ F$ induces a natural transformation $\alpha : \overline{F} \to F$. To prove (1), it will suffice to show that α is an equivalence. Let $X \in \mathcal{X}$ be an object; we wish to show that α induces an equivalence $\alpha_X : \overline{F}X \to FX$. Equivalently, we must show that for each object $C \in \mathrm{Fun}(\mathcal{G}, \mathcal{S})^{\mathrm{op}}$, the induced map

$$\theta : \mathrm{Map}_{\mathcal{G}}(FX, C) \to \mathrm{Map}_{\mathcal{G}}(\overline{F}X, C)$$

is a homotopy equivalence. Writing C as a limit of representable functors, we may reduce to the case where C belongs to the essential image of $\overline{j}$, so that (in particular) $C \in \mathrm{Pro}(\mathcal{G})$. In this case, the domain and codomain of θ can both be identified with the mapping space $\mathrm{Map}_{\mathcal{X}}(X, GC)$. □

Proof of Proposition 21.2.2.6. Let $\mathcal{G}$ be an essentially small ∞-category, set $\mathcal{C} = \mathrm{Ind}(\mathcal{G}^{\mathrm{op}}$, and let $\mathcal{X}$ be an ∞-topos. The functor ρ appearing in Proposition 21.2.2.6 is given by the composition

$$\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \xrightarrow{\theta} \mathrm{RFun}(\mathcal{C}^{\mathrm{op}}, \mathcal{X}) \subseteq \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{X}) \to \mathrm{Fun}(\mathcal{G}, \mathcal{X}),$$

where θ is the equivalence of Remark 21.2.2.11. We wish to show that this composition is a fully faithful embedding, whose essential image coincides with the full subcategory $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{G}, \mathcal{X}) \subseteq \mathrm{Fun}(\mathcal{G}, \mathcal{X})$. The full faithfulness is a consequence of Proposition HTT.5.3.5.10 , and the description of the essential image follows from Proposition 21.2.2.12. □

21.2.3 Digression: Flatness

Let $\mathcal{G}$ be an essentially small ∞-category and set $\mathcal{C} = \mathrm{Ind}(\mathcal{G}^{\mathrm{op}})$. For any ∞-topos $\mathcal{X}$, Proposition 21.2.2.6 supplies a fully faithful functor

$$\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \simeq \mathrm{Fun}^{\mathrm{lex}}(\mathcal{G}, \mathcal{X}) \subseteq \mathrm{Fun}^{\mathrm{llex}}(\mathcal{G}, \mathcal{X}) = \mathrm{Obj}_{\mathcal{G}}(\mathcal{X});$$

here $\mathrm{Fun}^{\mathrm{llex}}(\mathcal{G}, \mathcal{X})$ denotes the full subcategory of $\mathrm{Fun}(\mathcal{G}, \mathcal{X})$ spanned by the *locally* left exact functors. This functor is an equivalence when the ∞-category $\mathcal{G}$ admits finite limits (see Proposition HTT.6.1.5.2), but not in general. In this section, we study an example which illustrates the difference.

Notation 21.2.3.1. Let $\mathcal{X}$ be an ∞-topos. For any spectrum M, we let $\underline{M} \in \mathrm{Sp}(\mathcal{X})$ denote the constant sheaf (of spectra) on $\mathcal{X}$ with value M. Note that the functor $M \mapsto \underline{M}$ determines a symmetric monoidal functor $\mathrm{Sp} \to \mathrm{Sp}(\mathcal{X})$. In particular, if R is an $\mathbb{E}_1$-ring, then $\underline{R}$ is an associative algebra object of $\mathrm{Sp}(\mathcal{X})$; if M is a right module over R, then $\underline{M}$ inherits the structure of a right module over $\underline{R}$.

Definition 21.2.3.2. Let R be a connective $\mathbb{E}_1$-ring, let $\mathcal{X}$ be an ∞-topos, and let $\mathscr{F}$ be a left $\underline{R}$-module object of $\mathrm{Sp}(\mathcal{X})$. We will say that $\mathscr{F}$ is *R-flat* if the construction $M \mapsto \underline{M} \otimes_{\underline{R}} \mathscr{F}$ determines a t-exact functor $\mathrm{RMod}_R \to \mathrm{Sp}(\mathcal{X})$. We let $\mathrm{LMod}^{\flat}_{\underline{R}}$ denote the full subcategory of $\mathrm{LMod}_{\underline{R}}$ spanned by those left $\underline{R}$-modules which are R-flat.

Remark 21.2.3.3. In the situation of Definition 21.2.3.2, the functor $M \mapsto \underline{M} \otimes_{\underline{R}} \mathscr{F}$ is right t-exact if and only if $\mathscr{F}$ is connective. In particular, every R-flat left $\underline{R}$-module is connective.

Example 21.2.3.4. Let R be a connective $\mathbb{E}_\infty$-ring, let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ be a spectral Deligne-Mumford stack equipped with a morphism $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$, and let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$. Then we can regard $\mathscr{F}$ as a sheaf of $\underline{R}$-modules on $\mathcal{X}$. Moreover, for every R-module M, the tensor product $\underline{M} \otimes_{\underline{R}} \mathscr{F}$ is also a quasi-coherent sheaf on X, whose value on an affine object $U \in \mathcal{X}$ is given by the formula

$$(\underline{M} \otimes_{\underline{R}} \mathscr{F})(U) \simeq M \otimes_R \mathscr{F}(U).$$

In particular, we see that the following conditions are equivalent:

- (i) The quasi-coherent sheaf $\mathscr{F}$ is R-flat (in the sense of Definition 21.2.3.2).
- (ii) For every affine $U \in \mathcal{X}$, the spectrum $\mathscr{F}(U)$ is flat as an R-module (in the sense of Definition HA.7.2.2.10).

Example 21.2.3.5. Let R be a connective $\mathbb{E}_\infty$-ring and let $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ be a map of spectral Deligne-Mumford stacks. Then f is flat (in the sense of Definition 2.8.2.1) if and only it the structure sheaf $\mathscr{O}_{\mathsf{X}}$ is R-flat (in the sense of Definition 21.2.3.2).

Example 21.2.3.6. Let R be a connective $\mathbb{E}_1$-ring and let $\mathcal{X} = \mathcal{S}$ be the ∞-topos of spaces, so that the formation of global sections supplies an equivalence $\Gamma : \mathrm{LMod}_{\underline{R}}(\mathcal{X}) \simeq \mathrm{LMod}_R$. Then a left $\underline{R}$-module $\mathscr{F}$ is flat (in the sense of Definition 21.2.3.2) if and only if the associated left R-module $\Gamma(\mathscr{F})$ is flat (in the sense of Definition HA.7.2.2.10).

Example 21.2.3.7. Let R be a connective $\mathbb{E}_1$-ring and let $\mathcal{X}$ be an ∞-topos with enough points (that is, the collection of geometric morphisms functors $x^* \in \mathrm{Fun}^*(\mathcal{X}, \mathcal{S})$ are jointly conservative). Then a left $\underline{R}$-module $\mathscr{F} \in \mathrm{LMod}_{\underline{R}}(\mathrm{Sp}(\mathcal{X}))$ is R-flat (in the sense of Definition 21.2.3.2) if and only if, for each point $x^* \in \mathrm{Fun}^*(\mathcal{X}, \mathcal{S})$, the stalk $x^* \mathscr{F} \in \mathrm{LMod}_R$ is flat as a left R-module (in the sense of Definition HA.7.2.2.10).

Variant 21.2.3.8. Let R be a connective $\mathbb{E}_1$-ring and let $\mathcal{X}$ be an ∞-topos. We will say that a left $\underline{R}$-module $\mathscr{F}$ is *$\underline{R}$-flat* if the functor

$$(\mathscr{G} \in \mathrm{RMod}_{\underline{R}}) \mapsto \mathscr{G} \otimes_{\underline{R}} \mathscr{F}$$

determines a t-exact functor $\mathrm{RMod}_{\underline{R}} \to \mathrm{Sp}(\mathcal{X})$.

Note that if $\mathscr{F}$ is $\underline{R}$-flat, then it is R-flat (in the sense of Definition 21.2.3.2): this follows from the t-exactness of the constant sheaf functor $M \mapsto \underline{M}$. If the ∞-topos $\mathcal{X}$ has enough points (or, more generally, if $\mathcal{X}$ is hypercomplete), then the converse holds. We do not know if the converse is true in general.

We can now formulate the main result of this section:

Proposition 21.2.3.9. *Let R be a connective $\mathbb{E}_1$-ring, let $\mathrm{LMod}_R^{\mathrm{proj}}$ denote the full subcategory of LMod_R spanned by the finitely generated projective left R-modules, and set $\mathcal{G} = (\mathrm{LMod}_R^{\mathrm{proj}})^{\mathrm{op}}$. Then, for any ∞-topos $\mathcal{X}$, there is a canonical equivalence of ∞-categories $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X}) \simeq \mathrm{LMod}_{\underline{R}}^{\flat}$.*

Example 21.2.3.10. In the situation of Proposition 21.2.3.9, suppose that $\mathcal{X} = \mathcal{S}$ is the ∞-topos of spaces. Invoking Proposition 20.4.2.9, we can identify $\mathcal{G}$-objects of $\mathcal{X}$ with Ind-objects of the ∞-category $\mathcal{G}^{\mathrm{op}} = \mathrm{LMod}_R^{\mathrm{proj}}$. In this case, Proposition 21.2.3.9 reduces to Lazard's theorem (Theorem HA.7.2.2.15), which supplies an equivalence of ∞-categories $\mathrm{LMod}_R^{\flat} \simeq \mathrm{Ind}(\mathrm{LMod}_R^{\mathrm{proj}})$.

Remark 21.2.3.11. In the situation of Proposition **??**, Corollary 21.2.2.7 supplies a fully faithful functor

$$\mathcal{S}\mathrm{hv}_{\mathrm{LMod}_R^{\flat}}(\mathcal{X}) = \mathcal{S}\mathrm{hv}_{\mathrm{Ind}(\mathcal{G}^{\mathrm{op}})}(\mathcal{X}) \hookrightarrow \mathrm{Obj}_{\mathcal{G}}(\mathcal{X}) \simeq \mathrm{LMod}_{\underline{R}}^{\flat}.$$

This functor is usually not an equivalence. For example, if $\mathcal{X}$ has enough points, then we can identify objects of the right hand side with left $\underline{R}$-modules $\mathscr{F}$ having the property that each stalk $x^* \mathscr{F}$ is a flat left R-module (Example 21.2.3.7), while objects of the left hand side are left $\underline{R}$-modules $\mathscr{F}$ having the property that the connective cover $\tau_{\geqslant 0} \mathscr{F}(U)$ is flat left R-module for each $U \in \mathcal{X}$. The latter condition is much more difficult to satisfy (except in some special cases, such as where R is a Dedekind domain).

Proof of Proposition 21.2.3.9. Using R-linear duality, we can identify $\mathcal{G} = (\mathrm{LMod}_R^{\mathrm{proj}})^{\mathrm{op}}$ with the ∞-category $\mathrm{RMod}_R^{\mathrm{proj}}$ of finitely generated projective *right* modules over R.

Since the ∞-category $\mathrm{LMod}_R^{\mathrm{cn}}$ is projectively generated (Corollary HA.7.1.4.15), we have an equivalence of ∞-categories $\mathrm{LMod}_R^{\mathrm{cn}} \simeq \mathrm{Fun}^{\pi}(\mathcal{G}, \mathcal{S})$ where $\mathrm{Fun}^{\pi}(\mathcal{C}, \mathcal{D})$ denotes the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ spanned by those functors which preserve finite products. Passing to sheaves on $\mathcal{X}$, we obtain an equivalence of ∞-categories

$$\theta : \mathrm{LMod}_{\underline{R}}^{\mathrm{cn}} \simeq \mathcal{S}\mathrm{hv}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{X}) \to \mathrm{Fun}^{\pi}(\mathcal{G}, \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X})) \simeq \mathrm{Fun}^{\pi}(\mathcal{G}, \mathcal{X}).$$

Unwinding the definitions, we see that θ is given on objects by the formula $\theta(\mathscr{F})(M) = \Omega^{\infty}(\underline{M} \otimes_{\underline{R}} \mathscr{F})$.

Fix an object $\mathscr{F} \in \mathrm{LMod}_{\underline{R}}^{\mathrm{cn}}$ and set $T = \theta(\mathscr{F})$. To complete the proof, it will suffice to show that the following conditions are equivalent:

(a) The sheaf $\mathscr{F}$ is R-flat, in the sense of Definition 21.2.3.2.

(b) The functor

$$T : \mathrm{RMod}_R^{\mathrm{proj}} \to \mathcal{X} \qquad T(M) = \Omega^\infty(\underline{M} \otimes_{\underline{R}} \mathscr{F})$$

is locally left exact.

Note that the ∞-category $\mathrm{RMod}_R^{\mathrm{cn}}$ is also projectively generated (Corollary HA.7.1.4.15), we have a fully faithful embedding $g : \mathrm{Mod}_R^{\mathrm{cn}} \hookrightarrow \mathcal{P}(\mathcal{G})$. Let f denote a left adjoint to g. The functor T admits an essentially unique extension to a functor $T^+ : \mathrm{RMod}_R^{\mathrm{cn}} \to \mathcal{X}$ which preserves sifted colimits; concretely, this extension is given by the same formula $T^+(M) = T(M) = \Omega^\infty(\underline{M} \otimes_{\underline{R}} \mathscr{F})$. Note that the composite functor $(T^+ \circ f) : \mathcal{P}(\mathcal{G}) \to \mathcal{X}$ is a colimit-preserving extension of the functor T. Consequently, assertion (b) is equivalent to the assertion that $T^+ \circ f$ is left exact.

Choose an essentially small full subcategory $\mathcal{C} \subseteq \mathrm{RMod}_R^{\mathrm{cn}}$ which is closed under finite limits and contains $\mathrm{RMod}_R^{\mathrm{proj}}$. Then $g(\mathcal{C}) \subseteq \mathcal{P}(\mathcal{G})$ contains the essential image of the Yoneda embedding and is therefore dense in $\mathcal{P}(\mathcal{G})$. It follows that $g|_{\mathcal{C}}$ induces a localization functor $L : \mathcal{P}(\mathcal{C}) \to \mathcal{P}(\mathcal{G})$. Let $T_{\mathcal{C}}$ denote the composite functor

$$\mathcal{P}(\mathcal{C}) \xrightarrow{L} \mathcal{P}(\mathcal{G}) \xrightarrow{f} \mathrm{RMod}_R^{\mathrm{cn}} \xrightarrow{T^+} \mathcal{X}\,.$$

Since g is left exact, this localization functor is left exact (Proposition HTT.6.1.5.2). Consequently, the left exactness of $T^+ \circ f$ is equivalent to the left exactness of $T_{\mathcal{C}}$. Using Proposition HTT.6.1.5.2 again, we see that this is equivalent to the left exactness of its composition with the Yoneda embedding $\mathcal{C} \hookrightarrow \mathcal{P}(\mathcal{C})$, which is the functor $T^+|_{\mathcal{C}}$. In other words, condition (b) can be reformulated as follows:

$(b_{\mathcal{C}})$ The functor $T^+|_{\mathcal{C}}$ is left exact.

Note that, if condition (b) is satisfied, then condition $(b_{\mathcal{C}})$ is satisfied for *every* essentially small full subcategory $\mathcal{C} \subseteq \mathrm{RMod}_R^{\mathrm{cn}}$ which is closed under finite limits and contains $\mathrm{RMod}_R^{\mathrm{proj}}$. It follows that (b) is equivalent to the following *a priori* stronger condition:

(c) The functor

$$T^+ : \mathrm{RMod}_R^{\mathrm{cn}} \to \mathcal{X} \qquad T^+(M) = \Omega^\infty(\underline{M} \otimes_{\underline{R}} \mathscr{F})$$

is left exact.

We now observe that (c) is equivalent to the left t-exactness of the functor $\underline{M} \mapsto \underline{M} \otimes_{\underline{R}} \mathscr{F}$. Since this functor is automatically right t-exact (by virtue of our assumption that $\mathscr{F}$ is connective; see Remark 21.2.3.3), we deduce that $(c) \Leftrightarrow (a)$ as desired. $\square$

21.2.4 Local Morphisms

Let $\mathcal{C}$ be a compactly generated ∞-category, and let $\mathcal{G} = \mathcal{C}_c^{\mathrm{op}}$ denote the opposite of the ∞-category of compact objects of $\mathcal{C}$. For any topological space X, Proposition 21.2.2.1 supplies an equivalence $\mathrm{Obj}_{\mathcal{G}}(X) \simeq \mathcal{S}\mathrm{hv}_{\mathcal{C}}(X)$. If the ∞-category $\mathcal{G}$ is equipped with a Grothendieck topology τ, then the full subcategory $\mathrm{Obj}_{\mathcal{G}}^{\tau}(X) \subseteq \mathrm{Obj}_{\mathcal{G}}(X)$ corresponds to a full subcategory of $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(X)$, whose objects might be referred to as "τ-local" $\mathcal{C}$-valued sheaves on X. In §21.2.5, we will show that when $\mathcal{C} = \mathrm{CAlg}^{\heartsuit}$ is the category of commutative rings and τ is the Zariski topology of Example 20.6.4.1, then this condition reduces to the usual notion of a sheaf of local rings on X (see Proposition 21.2.5.1). For algebro-geometric applications, we would like to restrict our attention further to the (non-full) subcategory where we allow only *local* maps between local sheaves of commutative rings. This requires an additional structure on $\mathcal{G}$.

Definition 21.2.4.1. Let $\mathcal{G}$ be an essentially small ∞-category equipped with an admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$ (see Definition **??**). Let $\mathcal{X}$ be an ∞-topos and suppose we are given a morphism $\alpha : \mathscr{O} \to \mathscr{O}'$ between $\mathcal{G}$-objects $\mathscr{O}, \mathscr{O}' \in \mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$. We will say that α is *local* if, for every morphism $U \to V$ in $\mathcal{G}^{\mathrm{ad}}$, the diagram

$$\begin{array}{ccc} \mathscr{O}^U & \xrightarrow{\alpha(U)} & \mathscr{O}'^U \\ \downarrow & & \downarrow \\ \mathscr{O}^V & \xrightarrow{\alpha(V)} & \mathscr{O}'^V \end{array}$$

is a pullback square in $\mathcal{X}$. We let $\mathrm{Obj}_{\mathcal{G}}^{\mathrm{loc}}(\mathcal{X})$ denote the (non-full) subcategory of $\mathrm{Fun}(\mathcal{G}, \mathcal{X})$ whose objects are locally left exact functors and whose morphisms are local natural transformations. If τ is a Grothendieck topology on $\mathcal{G}$, we let $\mathrm{Obj}_{\mathcal{G}}^{\tau,\mathrm{loc}}(\mathcal{X})$ denote the intersection $\mathrm{Obj}_{\mathcal{G}}^{\tau}(\mathcal{X}) \cap \mathrm{Obj}_{\mathcal{G}}^{\mathrm{loc}}(\mathcal{X})$.

Remark 21.2.4.2. In practice, we will use the notation $\mathrm{Obj}_{\mathcal{G}}^{\tau,\mathrm{loc}}$ only in situations where the Grothendieck topology τ is compatible with the admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$, in the sense of Definition 20.6.2.1. In this case, an object $\mathscr{O} \in \mathrm{Obj}_{\mathcal{G}}^{\mathrm{loc}}(\mathcal{X})$ belongs to the full subcategory $\mathrm{Obj}_{\mathcal{G}}^{\tau,\mathrm{loc}}(\mathcal{X})$ if and only if, for every collection of *admissible* morphisms $\{U_\alpha \to U\}$ in $\mathcal{G}$ which generate a τ-covering of U, the induced map $\amalg \mathscr{O}^{U_\alpha} \to \mathscr{O}^U$ is an effective epimorphism in $\mathcal{X}$.

Variant 21.2.4.3. In the situation of Definition 21.2.4.1, suppose that $\mathcal{X} = \mathcal{S}\mathrm{hv}(X)$ for some topological space X. Then we will denote the ∞-categories $\mathrm{Obj}_{\mathcal{G}}^{\mathrm{loc}}(\mathcal{X})$ and $\mathrm{Obj}_{\mathcal{G}}^{\tau,\mathrm{loc}}(\mathcal{X})$ by $\mathrm{Obj}_{\mathcal{G}}^{\mathrm{loc}}(X)$ and $\mathrm{Obj}_{\mathcal{G}}^{\tau,\mathrm{loc}}(X)$, respectively.

Definition 21.2.4.1 can be reformulated (and slightly generalized) using the language of fractured ∞-topoi developed in Chapter 20.

Definition 21.2.4.4. Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos, let $\mathcal{X}$ be an arbitrary ∞-topos, and let $\alpha : f^* \to g^*$ be a morphism in the ∞-category $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$. We will say that α is *local* if the following condition is satisfied: for every morphism $f : U \to V$ in the ∞-topos $\mathcal{E}^{\mathrm{corp}}$, the diagram

$$\begin{array}{ccc} f^*U & \xrightarrow{\alpha(U)} & g^*U \\ \downarrow & & \downarrow \\ f^*V & \xrightarrow{\alpha(V)} & g^*V \end{array}$$

is a pullback square in the ∞-topos $\mathcal{X}$. We let $\mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{X})$ denote the subcategory of $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$ containing all objects, whose morphisms are given by local natural transformations.

Remark 21.2.4.5. Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos and let $\mathcal{X}$ be an arbitrary ∞-topos. Then the collection of local morphisms in $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$ contains all equivalences and is closed under composition (which we have implicitly invoked by defining the subcategory $\mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{X}) \subseteq \mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$).

Warning 21.2.4.6. In the situation of Definition 21.2.4.4, the ∞-category $\mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{X})$ depends not only on $\mathcal{E}$ and $\mathcal{X}$, but on the choice of a fracture subcategory $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$.

Example 21.2.4.7 (The Trivial Case)**.** In the situation of Definition 21.2.4.4, suppose that $\mathcal{E}^{\mathrm{corp}} = \mathcal{E}$ (see Example 20.1.2.2). Then a natural transformation $\alpha : f^* \to g^*$ is local if and only if it is an equivalence. The "if" direction is obvious; to prove the converse, we note that $\mathcal{E}^{\mathrm{corp}}$ contains the projection map $U \to \mathbf{1}$ for every object $U \in \mathcal{E}$, so that the locality of α guarantees that the diagram

$$\begin{array}{ccc} f^*U & \xrightarrow{\alpha(U)} & g^*U \\ \downarrow & & \downarrow \\ f^*\mathbf{1} & \longrightarrow & g^*\mathbf{1} \end{array}$$

is a pullback square. Since the domain and codomain of the bottom horizontal map are final objects of $\mathcal{X}$ (by virtue of the left exactness of f^* and g^*), we conclude that the bottom horizontal map is an equivalence and therefore $\alpha(U) : f^*U \to g^*U$ is an equivalence as well.

Proposition 21.2.4.8. *Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos, let $\mathcal{X}$ be an arbitrary ∞-topos, and let $\alpha : f^* \to g^*$ be a morphism in the ∞-category $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$. The following conditions are equivalent:*

(a) *The morphism α is local, in the sense of Definition 21.2.4.4.*

(b) *For every $\mathcal{E}^{\mathrm{corp}}$-admissible morphism $f : U \to V$ in $\mathcal{E}$, the diagram*

$$\begin{array}{ccc} f^*U & \xrightarrow{\alpha(U)} & g^*U \\ \downarrow & & \downarrow \\ f^*V & \xrightarrow{\alpha(V)} & g^*V \end{array}$$

is a pullback square in the ∞-topos $\mathcal{X}$.

Proof. The implication $(b) \Rightarrow (a)$ is obvious. Converse, suppose that (a) is satisfied. Let S be the collection of all morphisms $U \to V$ in $\mathcal{E}$ for which the diagram

$$\begin{array}{ccc} f^*U & \xrightarrow{\alpha(U)} & g^*U \\ \downarrow & & \downarrow \\ f^*V & \xrightarrow{\alpha(V)} & g^*V \end{array}$$

is a pullback square. Then S is a local admissibility structure on $\mathcal{E}$ (Example 20.3.2.3). We wish to show that every $\mathcal{E}^{\mathrm{corp}}$-admissible morphism $f : U \to V$ is contained in S. This assertion is local on V, so we may assume without loss of generality that V is corporeal. In this case, the morphism f belongs to $\mathcal{E}^{\mathrm{corp}}$ (Example 20.3.1.2), so the desired result follows from assumption (a). □

Remark 21.2.4.9. Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos and let $\mathcal{X}$ be an arbitrary ∞-topos. The subcategory $\mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{X}) \subseteq \mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$ depends only on the collection of $\mathcal{E}^{\mathrm{corp}}$-admissible morphisms in $\mathcal{E}$. Consequently, replacing the fracture subcategory $\mathcal{E}^{\mathrm{corp}}$ by its completion (Remark 20.3.4.7) does not change the class of local morphisms in $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$.

Proposition 21.2.4.10. *Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos and let $h : \mathcal{G} \to \mathcal{E}$ be a presentation of $\mathcal{E}$ (see Definition 20.5.3.1). Then, for any ∞-topos $\mathcal{X}$, composition with h induces a fully faithful embedding*

$$\theta : \mathrm{Fun}^*(\mathcal{E}, \mathcal{X}) \hookrightarrow \mathrm{Obj}_{\mathcal{G}}(\mathcal{X}).$$

Moreover, a morphism in $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$ *is local (in the sense of Definition 21.2.4.4) if and only if its image under θ is local (in the sense of Definition 21.2.4.1). In particular, θ induces a fully faithful embedding*

$$\theta_{\mathrm{loc}} : \mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{X}) \hookrightarrow \mathrm{Obj}^{\mathrm{loc}}_{\mathcal{G}}(\mathcal{X}).$$

Proof. The functor h is dense and locally left exact (Remark 20.5.3.2), and therefore exhibits $\mathcal{E}$ as an accessible left exact localization of the presheaf ∞-category $\mathcal{P}(\mathcal{G})$. Consequently, to show that θ is fully faithful, we may assume without loss of generality that $\mathcal{E} = \mathcal{P}(\mathcal{G})$, in which case the functor θ is an equivalence of ∞-categories (by virtue of Theorem HTT.5.1.5.6 and the definition of local left exactness). To complete the proof, we must show a morphism $\alpha : f^* \to g^*$ in $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$ is local if and only if $\theta(\alpha)$ is local in $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$. The "only if" direction is obvious (since the functor h carries admissible morphisms in $\mathcal{G}$ to admissible morphisms in $\mathcal{E}$). Conversely, suppose that $\theta(\alpha)$ is local, and let $u : U \to V$ be an admissible morphism in $\mathcal{E}$; we wish to show that the diagram σ :

$$\begin{array}{ccc} f^*U & \xrightarrow{\alpha(U)} & g^*U \\ \downarrow & & \downarrow \\ f^*V & \xrightarrow{\alpha(V)} & g^*V \end{array}$$

is a pullback square in $\mathcal{X}$. Using Example 20.3.2.3, we see that this assertion can be tested locally on V. We may therefore assume without loss of generality that $V = h(V_0)$ for some object $V_0 \in \mathcal{G}$. Let us regard V and V_0 as fixed. The functor h induces a left exact localization $\mathcal{P}(\mathcal{G}^{\mathrm{ad}}) \to \mathcal{E}^{\mathrm{corp}}$, which therefore restricts to a left exact localization $\mathcal{P}(\mathcal{G}^{\mathrm{ad}}_{/V_0}) \to (\mathcal{E}^{\mathrm{corp}})_{/V}$. It follows that we can write U as a colimit (in the ∞-category $(\mathcal{X}^{\mathrm{corp}})_{/V}$) of objects of the form $h(U_0)$, for $U_0 \in \mathcal{G}^{\mathrm{ad}}_{/V_0}$. Using the fact that colimits are universal in the ∞-topos $\mathcal{X}$, we can reduce to the case where the map $U \to V$ is obtained by applying the functor h to some admissible morphism $U_0 \to V_0$ in $\mathcal{G}$, in which case the desired result follows from our assumption that $\theta(\alpha)$ is local. □

Example 21.2.4.11. Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site and let $h : \mathcal{G} \to \mathcal{S}\mathrm{hv}_\tau(\mathcal{G})$ be the sheafified Yoneda embedding (Definition 21.2.1.11). Then h is a presentation of the fractured ∞-topos $\mathcal{S}\mathrm{hv}_\tau(\mathcal{G})$, in the sense of Definition 20.5.3.1: that is the essential content of Proposition 20.6.3.2.

Corollary 21.2.4.12. *Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site (see Definition 20.6.2.1) and let $\mathcal{X}$ be an ∞-topos. Then composition with the sheafified Yoneda embedding $\mathcal{G} \to \mathcal{S}\mathrm{hv}_\tau(\mathcal{G})$ induces equivalences of ∞-categories*

$$\theta : \mathrm{Fun}^*(\mathcal{S}\mathrm{hv}_\tau(\mathcal{G}), \mathcal{X}) \hookrightarrow \mathrm{Obj}^{\tau}_{\mathcal{G}}(\mathcal{X}) \qquad \theta_{\mathrm{loc}} : \mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{S}\mathrm{hv}_\tau(\mathcal{G}), \mathcal{X}) \hookrightarrow \mathrm{Obj}^{\tau,\mathrm{loc}}_{\mathcal{G}}(\mathcal{X}).$$

Proof. Combine Proposition 21.2.1.13, Proposition 21.2.4.10, and Example 21.2.4.11. □

21.2.5 Examples: Sheaves of Rings

Let Aff denote the category whose objects are affine schemes of finite type over $\mathbf{Z}$ (that is, schemes of the form $\mathrm{Spec}\, R$, where R is a finitely presented commutative ring). We can then regard the category Aff as equipped with either the Zariski topology τ_{Zar} of Example 20.6.4.1, or the étale topology $\tau_{\text{ét}}$ of Example **??**. For any ∞-topos $\mathcal{X}$, we denote the corresponding ∞-categories of Aff-objects by $\mathrm{Obj}^{\mathrm{Zar}}_{\mathrm{Aff}}(\mathcal{X})$ and $\mathrm{Obj}^{\text{ét}}_{\mathrm{Aff}}(\mathcal{X})$, respectively, so that we have inclusion functors

$$\mathrm{Obj}^{\text{ét}}_{\mathrm{Aff}}(\mathcal{X}) \subseteq \mathrm{Obj}^{\mathrm{Zar}}_{\mathrm{Aff}}(\mathcal{X}) \subseteq \mathrm{Obj}_{\mathrm{Aff}}(\mathcal{X}).$$

These ∞-categories can be described more concretely as follows:

Proposition 21.2.5.1. *Let $\mathcal{X}$ be an ∞-topos. Then:*

(1) *There is a canonical equivalence of ∞-categories $\psi : \mathrm{Obj}_{\mathrm{Aff}}(\mathcal{X}) \simeq \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}^\heartsuit}(\mathcal{X})$, characterized informally by the formula $\mathrm{Map}_{\mathcal{X}}(U, \mathscr{O}^{\operatorname{Spec} R}) = \mathrm{Hom}_{\mathrm{CAlg}^\heartsuit}(R, \psi(\mathscr{O})(U))$.*

(2) *An object $\mathscr{O} \in \mathrm{Obj}_{\mathrm{Aff}}(\mathcal{X})$ belongs to the full subcategory $\mathrm{Obj}^{\mathrm{Zar}}_{\mathrm{Aff}}(\mathcal{X}) \subseteq \mathrm{Obj}_{\mathrm{Aff}}(\mathcal{X})$ if and only if $\psi(\mathscr{O})$ is local, when regarded as a commutative ring object of the topos $\mathcal{X}^\heartsuit$ (see Definition 1.2.1.4).*

(3) *A morphism $\alpha : \mathscr{O} \to \mathscr{O}'$ in the ∞-category $\mathrm{Obj}^{\mathrm{Zar}}_{\mathrm{Aff}}(\mathcal{X})$ is local (with respect to the admissibility structure of Example 20.6.4.1) if $\psi(\alpha) : \psi(\mathscr{O}) \to \psi(\mathscr{O}')$ is local when viewed as a morphism of commutative ring objects of $\mathcal{X}^\heartsuit$ (in the sense of Definition 1.2.1.4).*

(4) *An object $\mathscr{O} \in \mathrm{Obj}_{\mathrm{Aff}}(\mathcal{X})$ belongs to the full subcategory $\mathrm{Obj}^{\text{ét}}_{\mathrm{Aff}}(\mathcal{X}) \subseteq \mathrm{Obj}_{\mathrm{Aff}}(\mathcal{X})$ if and only if $\psi(\mathscr{O})$ is strictly Henselian, when regarded as a commutative ring object of the topos $\mathcal{X}^\heartsuit$ (see Definition 1.2.2.5).*

(5) *A morphism $\alpha : \mathscr{O} \to \mathscr{O}'$ in the ∞-category $\mathrm{Obj}^{\text{ét}}_{\mathrm{Aff}}(\mathcal{X})$ is local (with respect to the admissibility structure of Example **??**) if $\psi(\alpha) : \psi(\mathscr{O}) \to \psi(\mathscr{O}')$ is local when viewed as a morphism of commutative ring objects of $\mathcal{X}^\heartsuit$.*

Proof. Assertion (1) is a special case of Proposition 21.2.2.1 (and Remark 21.2.2.2), assertion (4) is immediate from the definitions, and assertion (5) follows from Proposition 1.2.2.12. We now prove (2). Let $\mathscr{O}$ be an object of $\mathrm{Obj}_{\mathrm{Aff}}(\mathcal{X})$ and set $\mathscr{A} = \psi(\mathscr{O})$, which we regard as a commutative ring object of the topos $\mathcal{X}^\heartsuit$. Unwinding the definitions, we see that $\mathscr{O}$ belongs to $\mathrm{Obj}^{\mathrm{Zar}}_{\mathrm{Aff}}(\mathcal{X})$ if and only if the following condition is satisfied:

($*$) For every finitely presented commutative ring R and every collection of elements $\{t_i\}_{1 \leqslant i \leqslant n}$ which generate the unit ideal in R, the induced map

$$\amalg_{1 \leqslant i \leqslant n} \mathscr{O}^{\operatorname{Spec} R[t_i^{-1}]} \to \mathscr{O}^{\operatorname{Spec} R}$$

is an effective epimorphism in $\mathcal{X}$.

On the other hand, $\mathscr{A}$ is local (when regarded as a commutative ring object of $\mathcal{X}^\heartsuit$) if and only if it satisfies the following pair of conditions:

(a) The sheaf $\mathscr{O}^{\varnothing}$ is an initial object of $\mathcal{X}$.

(b) The canonical map

$$\mathscr{O}^{\operatorname{Spec}\mathbf{Z}[x,x^{-1}]} \amalg \mathscr{O}^{\operatorname{Spec}\mathbf{Z}[x,(1-x)^{-1}]} \to \mathscr{O}^{\operatorname{Spec}\mathbf{Z}[x]}$$

is an effective epimorphism in $\mathcal{X}$.

We first note that conditions (a) and (b) follow immediately from ($*$) (condition (a) follows by applying ($*$) in the case where $R = 0$ and $n = 0$; condition (b) follows by applying ($*$) in the case $R = \mathbf{Z}[x]$ and $n = 2$). Conversely, suppose that conditions (a) and (b) are satisfied. We will establish ($*$) using induction on n. If $n = 0$, then the unit ideal of R coincides with the zero ideal, so that $R = 0$ and ($*$) follows from (a). To handle the inductive step, suppose that $n > 0$ and we are given a collection of elements $\{t_1, \ldots, t_n\}$ which generate the unit ideal in R. We can then choose elements $c_1, \ldots, c_n \in R$ satisfying $c_1t_1 + c_2t_2 + \cdots + c_nt_n = 1$. Set $x = c_1t_1 + \cdots + c_{n-1}t_{n-1}$, so that $1 - x = c_nt_n$. Since $\rho\,\mathscr{O}$ is left exact, we have a pullback diagram

$$\begin{array}{ccc} \mathscr{O}^{\operatorname{Spec} R[x^{-1}]} \amalg \mathscr{O}^{\operatorname{Spec} R[(1-x)^{-1}]} & \longrightarrow & \mathscr{O}^{\operatorname{Spec} R} \\ \downarrow & & \downarrow \\ \mathscr{O}^{\operatorname{Spec}\mathbf{Z}[x,x^{-1}]} \amalg \mathscr{O}^{\operatorname{Spec}\mathbf{Z}[x,(1-x)^{-1}])} & \longrightarrow & \mathscr{O}^{\operatorname{Spec}\mathbf{Z}[x]} . \end{array}$$

It follows from assumption (b) that the lower horizontal map is an effective epimorphism, so that the upper horizontal map is an effective epimorphism as well. Since the map $\operatorname{Spec} R[(1-x)^{-1}] \to \operatorname{Spec} R$ factors through $\operatorname{Spec} R[t_n^{-1}]$, it will suffice to show that the map

$$\amalg_{1 \leqslant i \leqslant n-1} \mathscr{O}^{\operatorname{Spec} R[x^{-1}]} \times_{\mathscr{O}^{\operatorname{Spec}\mathbf{Z}[x]}} \mathscr{O}^{\operatorname{Spec}\mathbf{Z}[x,x^{-1}]} \to \mathscr{O}^{\operatorname{Spec} R} \times_{\mathscr{O}^{\operatorname{Spec}\mathbf{Z}[x]}} \mathscr{O}^{\operatorname{Spec}\mathbf{Z}[x,x^{-1}]}$$

is an effective epimorphism. This follows from our inductive hypothesis (and the left exactness of the functor $\mathscr{O} : \operatorname{Aff} \to \mathcal{X}$), since the images of the elements $\{t_i\}_{1 \leqslant i \leqslant n-1}$ generate the unit ideal in the commutative ring $R[x^{-1}]$.

We now prove (3). Let $\alpha : \mathscr{O} \to \mathscr{O}'$ be a morphism in $\operatorname{Obj}^{\operatorname{Zar}}_{\operatorname{Aff}}(\mathcal{X})$. Unwinding the definitions, we see that α is local (in the sense of Definition 21.2.4.1) if and only if, for every finitely generated commutative ring R and every element $x \in R$, the upper square in the commutative diagram

$$\begin{array}{ccc} \mathscr{O}^{\operatorname{Spec} R[x^{-1}]} & \longrightarrow & \mathscr{O}^{\operatorname{Spec} R} \\ \downarrow & & \downarrow \\ \mathscr{O}'^{\operatorname{Spec} R[x^{-1}]} & \longrightarrow & \mathscr{O}'^{\operatorname{Spec} R} \\ \downarrow & & \downarrow \\ \mathscr{O}'^{\operatorname{Spec}\mathbf{Z}[x,x^{-1}]} & \longrightarrow & \mathscr{O}'^{\operatorname{Spec}\mathbf{Z}[x]} \end{array}$$

is a pullback. Since the bottom square is a pullback (by virtue of the left exactness of $\mathscr{O}'$), the locality of α is equivalent to the requirement that the outer rectangle of the diagram

$$\begin{array}{ccc} \mathscr{O}^{\operatorname{Spec} R[x^{-1}]} & \longrightarrow & \mathscr{O}^{\operatorname{Spec} R} \\ \downarrow & & \\ \mathscr{O}^{\operatorname{Spec} \mathbf{Z}[x,x^{-1}]} & \longrightarrow & \mathscr{O}^{\operatorname{Spec} \mathbf{Z}[x]} \\ \downarrow & & \downarrow \\ \mathscr{O}'^{\operatorname{Spec} \mathbf{Z}[x,x^{-1}]} & \longrightarrow & \mathscr{O}'^{\operatorname{Spec} \mathbf{Z}[x]} \end{array}$$

is a pullback square. Here the top square is automatically a pullback (by virtue of the left exactness of $\mathscr{O}$). Consequently, the morphism α is local if and only if the commutative diagram

$$\begin{array}{ccc} \mathscr{O}^{\operatorname{Spec} \mathbf{Z}[x,x^{-1}]} & \longrightarrow & \mathscr{O}^{\operatorname{Spec} \mathbf{Z}[x]} \\ \downarrow & & \downarrow \\ \mathscr{O}'^{\operatorname{Spec} \mathbf{Z}[x,x^{-1}]} & \longrightarrow & \mathscr{O}'^{\operatorname{Spec} \mathbf{Z}[x]} \end{array}$$

is a pullback square, which is equivalent to the assertion that $\psi(\alpha)$ is local (as a morphism of commutative ring objects of $\mathcal{X}^{\heartsuit}$). □

Warning 21.2.5.2. In part (3) of Proposition 21.2.5.1, the assumption that $\mathscr{O}$ and $\mathscr{O}'$ belong to $\operatorname{Obj}^{\operatorname{Zar}}_{\operatorname{Aff}}(\mathcal{X})$ is superfluous: the same assertion holds for *any* morphism $\alpha : \mathscr{O} \to \mathscr{O}'$ in $\operatorname{Obj}_{\operatorname{Aff}}(\mathcal{X})$. However, the analogous assertion for part (5) is false. For a general morphism $\alpha : \mathscr{O} \to \mathscr{O}'$ in $\operatorname{Obj}_{\operatorname{Aff}}(\mathcal{X})$ (or even in $\operatorname{Obj}^{\operatorname{Zar}}_{\operatorname{Aff}}(\mathcal{X})$), the condition of being local with respect to the admissibility structure of Example 20.6.4.1 (which has admissible morphisms of the form $\operatorname{Spec} R[t^{-1}] \hookrightarrow \operatorname{Spec} R$) is weaker than the condition of being local with respect to the admissibility structure of Example **??** (where every étale morphism in Aff is admissible).

We now formulate an analogue of Proposition 21.2.5.1, where we replace sheaves taking values in the ordinary category $\operatorname{CAlg}^{\heartsuit}$ of commutative rings with sheaves taking values in the ∞-category CAlg of *all* $\mathbb{E}_\infty$-rings. Let CAlg_c denote the full subcategory of CAlg spanned by the compact object, and let $\operatorname{Aff}_{\operatorname{Sp}}$ denote the opposite of the ∞-category CAlg_c; we denote the objects of $\operatorname{Aff}_{\operatorname{Sp}}$ by $\operatorname{Spec} R$, where R is a compact $\mathbb{E}_\infty$-ring. We can then regard the ∞-category $\operatorname{Aff}_{\operatorname{Sp}}$ as equipped with either the Zariski topology $\tau_{\operatorname{Zar}}$ of Example 20.6.4.4, or the étale topology $\tau_{\text{ét}}$ of Example **??**. For any ∞-topos $\mathcal{X}$, we denote the corresponding ∞-categories of $\operatorname{Aff}_{\operatorname{Sp}}$-objects by $\operatorname{Obj}^{\operatorname{Zar}}_{\operatorname{Aff}_{\operatorname{Sp}}}(\mathcal{X})$ and $\operatorname{Obj}^{\text{ét}}_{\operatorname{Aff}_{\operatorname{Sp}}}(\mathcal{X})$, respectively, so that we have inclusion functors

$$\operatorname{Obj}^{\text{ét}}_{\operatorname{Aff}_{\operatorname{Sp}}}(\mathcal{X}) \subseteq \operatorname{Obj}^{\operatorname{Zar}}_{\operatorname{Aff}_{\operatorname{Sp}}}(\mathcal{X}) \subseteq \operatorname{Obj}_{\operatorname{Aff}_{\operatorname{Sp}}}(\mathcal{X}).$$

We now have the following result:

Proposition 21.2.5.3. *Let $\mathcal{X}$ be an ∞-topos. Then:*

(1) *There is a canonical equivalence of ∞-categories $\psi : \mathrm{Obj}_{\mathrm{Aff}_{\mathrm{Sp}}}(\mathcal{X}) \simeq \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$, characterized informally by the formula $\mathrm{Map}_{\mathcal{X}}(U, \mathcal{O}^{\mathrm{Spec}\, R}) = \mathrm{Map}_{\mathrm{CAlg}^{\heartsuit}}(R, \psi(\mathcal{O})(U))$.*

(2) *An object $\mathcal{O} \in \mathrm{Obj}_{\mathrm{Aff}_{\mathrm{Sp}}}(\mathcal{X})$ belongs to the full subcategory $\mathrm{Obj}^{\mathrm{Zar}}_{\mathrm{Aff}_{\mathrm{Sp}}}(\mathcal{X}) \subseteq \mathrm{Obj}_{\mathrm{Aff}_{\mathrm{Sp}}}(\mathcal{X})$ if and only if the sheaf of $\mathbb{E}_\infty$-rings $\psi(\mathcal{O})$ is local (in the sense of Definition 1.4.2.1): that is, if and only if $\pi_0\psi(\mathcal{O})$ is local when regarded as a commutative ring object of the topos $\mathcal{X}^{\heartsuit}$.*

(3) *A morphism $\alpha : \mathcal{O} \to \mathcal{O}'$ in the ∞-category $\mathrm{Obj}^{\mathrm{Zar}}_{\mathrm{Aff}_{\mathrm{Sp}}}(\mathcal{X})$ is local (with respect to the admissibility structure of Example 20.6.4.4) if $\psi(\alpha) : \psi(\mathcal{O}) \to \psi(\mathcal{O}')$ is local when viewed as a morphism of* CAlg*-valued sheaves on $\mathcal{X}$ (in the sense of Definition 1.4.2.1).*

(4) *An object $\mathcal{O} \in \mathrm{Obj}_{\mathrm{Aff}_{\mathrm{Sp}}}(\mathcal{X})$ belongs to the full subcategory $\mathrm{Obj}^{\text{ét}}_{\mathrm{Aff}_{\mathrm{Sp}}}(\mathcal{X}) \subseteq \mathrm{Obj}_{\mathrm{Aff}_{\mathrm{Sp}}}(\mathcal{X})$ if and only if the sheaf of $\mathbb{E}_\infty$-rings $\psi(\mathcal{O})$ is strictly Henselian (in the sense of Definition 1.4.2.1): that is, if and only if $\pi_0\psi(\mathcal{O})$ is strictly Henselian when regarded as a commutative ring object of the topos $\mathcal{X}^{\heartsuit}$.*

(5) *A morphism $\alpha : \mathcal{O} \to \mathcal{O}'$ in the ∞-category $\mathrm{Obj}^{\text{ét}}_{\mathrm{Aff}_{\mathrm{Sp}}}(\mathcal{X})$ is local (with respect to the admissibility structure of Example* **??***) if $\psi(\alpha) : \psi(\mathcal{O}) \to \psi(\mathcal{O}')$ is local when viewed as a morphism of* CAlg*-valued sheaves on $\mathcal{X}$ (in the sense of Definition 1.4.2.1)*

Proof. Assertion (1) is a special case of Proposition 21.2.2.1 (and Remark 21.2.2.2), and assertion (4) and (5) follow from Lemma 1.4.3.9. Assertions (2) and (3) can be established by repeating the proof of Proposition 21.2.5.1, without essential change. □

Warning 21.2.5.4. Assertion (3) of Proposition 21.2.5.3 holds more generally for *any* morphism $\alpha : \mathcal{O} \to \mathcal{O}'$ in $\mathrm{Obj}_{\mathrm{Aff}_{\mathrm{Sp}}}(\mathcal{X})$, but assertion (5) requires that $\mathcal{O}$ and $\mathcal{O}'$ belong to $\mathrm{Obj}^{\text{ét}}_{\mathrm{Aff}_{\mathrm{Sp}}}(\mathcal{X})$ (as with Warning 21.2.5.2).

21.3 Factorization Systems and Fractured ∞-Topoi

As noted in the introduction to §20.2, every commutative ring homomorphism $\phi : A \to B$ factors canonically as a composition

$$A \xrightarrow{\phi'} A[S^{-1}] \xrightarrow{\phi''} B,$$

where the homomorphism ϕ'' is local (that is, it carries noninvertible elements of $A[S^{-1}]$ to noninvertible elements of B) and the map ϕ' is localizing; moreover, we can take S to be the set of elements $a \in A$ for which $\phi(a) \in B$ is invertible. More generally, if $\phi : \mathscr{A} \to \mathscr{B}$ is a map of *sheaves* of commutative rings on a topological space X, then f admits a factorization

$$\mathscr{A} \xrightarrow{\phi'} \mathscr{A}' \xrightarrow{\phi''} \mathscr{B},$$

which reduces to the previous factorization after passing to stalks at any point $x \in X$. Our goal in this section is to show that an analogous phenomenon occurs in the setting of $\mathcal{E}$-structured ∞-topoi, for any fractured ∞-topos $\mathcal{E}$. More precisely, we will prove the following:

Theorem 21.3.0.1. *Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos. Then:*

(1) *For every ∞-topos $\mathcal{X}$, there exists a factorization system $(S_L^{\mathcal{X}}, S_R^{\mathcal{X}})$ on the ∞-category $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$, where $S_R^{\mathcal{X}}$ is the collection of local morphisms in $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$ (Definition 21.2.4.4).*

(2) *The factorization system of (1) depends functorially on $\mathcal{X}$. In other words, for every geometric morphism of ∞-topoi $f^* : \mathcal{X} \to \mathcal{Y}$, composition with f^* carries $S_L^{\mathcal{X}}$ into $S_L^{\mathcal{Y}}$ and $S_R^{\mathcal{X}}$ into $S_R^{\mathcal{Y}}$.*

Remark 21.3.0.2. The functorial dependence of the factorization system $(S_L^{\mathcal{X}}, S_R^{\mathcal{X}})$ on the fractured ∞-topos $\mathcal{E}$ is more subtle; we will discuss it in §**??**.

Combining Theorem 21.3.0.1 with Proposition **??**, we obtain the following:

Corollary 21.3.0.3. *Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site (Definition 20.6.2.1). Then:*

(1) *For every ∞-topos $\mathcal{X}$, there exists a factorization system $(S_L^{\mathcal{X}}, S_R^{\mathcal{X}})$ on the ∞-category $\mathrm{Obj}_{\mathcal{G}}^{\tau}(\mathcal{X})$, where where $S_R^{\mathcal{X}}$ is the collection of local morphisms in $\mathrm{Obj}_{\mathcal{G}}^{\tau}(\mathcal{X})$ (Definition 21.2.4.1).*

(2) *The factorization system of (1) depends functorially on $\mathcal{X}$. In other words, for every geometric morphism of ∞-topoi $f^* : \mathcal{X} \to \mathcal{Y}$, composition with f^* carries $S_L^{\mathcal{X}}$ into $S_L^{\mathcal{Y}}$ and $S_R^{\mathcal{X}}$ into $S_R^{\mathcal{Y}}$.*

Our proof of Theorem 21.3.0.1 is quite involved, and will occupy our attention throughout this section. We will proceed in several steps:

(a) The first step was already carried out in §20.2.2: there we showed that for any admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$ determined a factorization system on the ∞-category of $\mathrm{Pro}(\mathcal{G})$ (Theorem 20.2.2.5). After passing to opposite ∞-categories, this recovers the factorization system described in Corollary 21.3.0.3 in the special case where $\mathcal{X} = \mathcal{S}$ is the ∞-topos of spaces and the topology τ on $\mathcal{G}$ is trivial.

(*b*) In §21.3.1, we show that Corollary 21.3.0.3 holds whenever the ∞-category $\mathcal{G}$ admits finite limits and the Grothendieck topology τ is trivial (Propositions 21.3.1.1 and 21.3.1.5). Our proof will proceed by reducing to the case where $\mathcal{X}$ is an ∞-topos of presheaves, in which case the desired result can be deduced from (*a*).

(*c*) In §**??**, we prove that Corollary 21.3.0.3 holds whenever the Grothendieck topology τ is trivial, without the assumption that $\mathcal{G}$ admits finite limits (Propositions 21.3.3.1 and 21.3.3.2). The proof proceeds by reduction to (*b*) using an embedding of $\mathcal{G}$ into an ∞-category which admits finite limits. In carrying out this reduction, we will use some general facts about ∞-topoi of paths, which we discuss in §21.3.2.

(*d*) In §**??**, we will show Theorem 21.3.0.1 (and therefore Corollary 21.3.0.3) holds in general. Our strategy is to use the existence of a presentation $h : \mathcal{G} \to \mathcal{E}$ (Theorem 20.5.3.4) to reduce to case where $\mathcal{E}$ has the form $\mathcal{P}(\mathcal{G})$, which is covered by case (*c*).

Remark 21.3.0.4. For the examples studied in this book, we do not need the full strength of Theorem 21.3.0.1: the fractured ∞-topoi of interest to us all have the form $\mathcal{S}\mathrm{hv}_\tau(\mathcal{G})$, where $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ is a geometric site for which the ∞-category $\mathcal{G}$ admits finite limits. At this level of generality, step (*c*) is superfluous and step (*d*) is slightly easier to handle.

21.3.1 The Case $\mathcal{G}$ Admits Finite Limits

We begin by establishing the following special case of Corollary 21.3.0.3.

Proposition 21.3.1.1. *Let $\mathcal{G}$ be an essentially small which admits finite limits and is equipped with an admissibility structure. Let $\mathcal{X}$ be an arbitrary ∞-topos. Then there exists a factorization system (S_L, S_R) on the ∞-category $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X}) = \mathrm{Fun}^{\mathrm{lex}}(\mathcal{G}, \mathcal{X})$ which is characterized by the following requirement: a morphism $\alpha : \mathscr{O} \to \mathscr{O}'$ in $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ belongs to S_R if and only if, for every admissible morphism $f : U \to V$ in $\mathcal{G}$, the diagram*

$$\begin{array}{ccc} \mathscr{O}^U & \longrightarrow & \mathscr{O}'^U \\ \downarrow & & \downarrow \\ \mathscr{O}^V & \longrightarrow & \mathscr{O}'^V \end{array}$$

is a pullback square in the ∞-topos $\mathcal{X}$.

Remark 21.3.1.2. In the situation of Proposition 21.3.1.1, Proposition 21.2.2.1 supplies an equivalence of ∞-categories $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X}) \simeq \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$, where $\mathcal{C} = \mathrm{Ind}(\mathcal{G}^{\mathrm{op}})$. Consequently, we can view Proposition 21.3.1.1 as supplying a factorization system on the ∞-category $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$ of $\mathcal{C}$-valued sheaves on $\mathcal{X}$.

The proof of Proposition 21.3.1.1 will require a few general remarks about factorization systems.

Lemma 21.3.1.3. *Let $\mathcal{C}$ be an ∞-category, $\mathcal{C}^0 \subseteq \mathcal{C}$ a localization of $\mathcal{C}$, and Y an object of $\mathcal{C}^0$. Then $\mathcal{C}^0_{/Y}$ is a localization of $\mathcal{C}_{/Y}$. Moreover, a morphism $f : X \to X'$ in $\mathcal{C}_{/Y}$ exhibits X' as a $\mathcal{C}^0_{/Y}$-localization of X if and only if f exhibits X' as a $\mathcal{C}^0$-localization of X in the ∞-category $\mathcal{C}$.*

Proof. We first prove the "if" direction of the last assertion. Choose a morphism $Y' \to Y$ in $\mathcal{C}$, where $Y' \in \mathcal{C}^0$. We have a map of homotopy fiber sequences

$$\begin{array}{ccc} \mathrm{Map}_{\mathcal{C}_{/Y}}(X', Y') & \xrightarrow{\phi} & \mathrm{Map}_{\mathcal{C}_{/Y}}(X, Y') \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathcal{C}}(X', Y') & \xrightarrow{\phi'} & \mathrm{Map}_{\mathcal{C}}(X, Y') \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathcal{C}}(X', Y) & \xrightarrow{\phi''} & \mathrm{Map}_{\mathcal{C}}(X, Y). \end{array}$$

Since the maps ϕ' and ϕ'' are homotopy equivalences, we conclude that ϕ is a homotopy equivalence as desired.

We now show that $\mathcal{C}^0_{/Y}$ is a localization of $\mathcal{C}_{/Y}$. In view of Proposition HTT.5.2.7.8 and the above argument, it will suffice to show that for every map $h : X \to Y$, there exists a factorization

$$\begin{array}{ccccc} & & X' & & \\ & \overset{f}{\nearrow} & & \overset{g}{\searrow} & \\ X & & \xrightarrow{h} & & Y \end{array}$$

where f exhibits X' as a $\mathcal{C}^0$-localization of X. The existence of f follows from Proposition HTT.5.2.7.8 (applied to the ∞-category $\mathcal{C}$), and the ability to complete the diagram follows from the assumption that $Y \in \mathcal{C}^0$.

To complete the proof, we observe that *any* $\mathcal{C}^0_{/Y}$-localization $X \to X''$ must be equivalent to the morphism $X \to X'$ constructed above, so that $X \to X''$ also exhibits X'' as a $\mathcal{C}^0$-localization of X. □

Recall that if $f : A \to B$ and $g : X \to Y$ are morphisms in an ∞-category $\mathcal{C}$, we write $f \perp g$ if, for every commutative diagram

$$\begin{array}{ccc} A & \longrightarrow & X \\ {\scriptstyle f}\downarrow & \nearrow & \downarrow{\scriptstyle g} \\ B & \longrightarrow & Y, \end{array}$$

the space $\mathrm{Map}_{\mathcal{C}_{A//Y}}(B, X)$ of dotted arrows rendering the diagram commutative is contractible (Definition HTT.5.2.8.1).

Lemma 21.3.1.4. *Let $\mathcal{C}$ be an ∞-category equipped with a factorization system (S_L, S_R), and let $L : \mathcal{C} \to \mathcal{C}$ be a localization functor such that $LS_R \subseteq S_R$. Then the full subcategory $L\mathcal{C} \subseteq \mathcal{C}$ admits a factorization system (S'_L, S'_R), where:*

(1) *A morphism f' in $L\mathcal{C}$ belongs to S'_L if and only if f' is a retract of Lf, for some $f \in S_L$.*

(2) *A morphism g in $L\mathcal{C}$ belongs to S'_R if and only if $g \in S_R$.*

Proof. Clearly S'_L and S'_R are stable under the formation of retracts. Let $h : X \to Z$ be a morphism in $L\mathcal{C}$; we wish to show that h factors as a composition $X \xrightarrow{f'} Y' \xrightarrow{g'} Z$ where $f' \in S'_L$ and $g' \in S'_R$. First, choose a factorization of h as a composition $X \xrightarrow{f} Y \xrightarrow{g} Z$. Then $Lf \in S'_L$, $Lg \in S'_R$, and $h \simeq Lh \simeq Lg \circ Lf$.

It remains to show that $f' \perp g'$, for $f' \in S'_L$ and $g' \in S'_R$. Without loss of generality, we may suppose $f' = Lf$ for some $f \in S_L$. Choose a commutative diagram

$$\begin{array}{ccccc} A & \longrightarrow & LA & \longrightarrow & X \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle Lf} & & \downarrow{\scriptstyle g'} \\ B & \longrightarrow & LB & \longrightarrow & Y. \end{array}$$

We wish to show that the mapping space $\mathrm{Map}_{\mathcal{C}_{LA//Y}}(LB, X)$ is weakly contractible. We have a commutative diagram of fiber sequences

$$\begin{array}{ccc} \mathrm{Map}_{\mathcal{C}_{LA//Y}}(LB, X) & \xrightarrow{\phi} & \mathrm{Map}_{\mathcal{C}_{A//Y}}(B, X) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathcal{C}_{/Y}}(LB, X) & \xrightarrow{\phi'} & \mathrm{Map}_{\mathcal{C}_{/Y}}(B, X) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathcal{C}_{/Y}}(LA, X) & \xrightarrow{\phi''} & \mathrm{Map}_{\mathcal{C}_{/Y}}(A, X). \end{array}$$

Using Lemma 21.3.1.3, we deduce that ϕ' and ϕ'' are homotopy equivalences. It follows that ϕ is also a homotopy equivalence. We are therefore reduced to proving that $\mathrm{Map}_{\mathcal{C}_{A//Y}}(B, X)$ is contractible, which follows from the orthogonality relation $f \perp g'$. □

Proof of Proposition 21.3.1.1. In the special case where $\mathcal{X} = \mathcal{S}$, the desired result follows immediately from Theorem 20.2.2.5. To treat the general case, we may assume without loss of generality that the ∞-topos $\mathcal{X}$ has the form $L\mathcal{P}(\mathcal{C})$, where $\mathcal{C}$ is a small ∞-category and L

is a left exact localization functor on the presheaf ∞-category $\mathcal{P}(\mathcal{C}) = \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$. Using Corollary HTT.5.2.8.18 , we deduce that the ∞-category $\mathrm{Obj}_{\mathcal{G}}(\mathcal{P}(\mathcal{C})) \simeq \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathrm{Obj}_{\mathcal{G}}(\mathcal{S}))$ admits a factorization system $(\overline{S}_L, \overline{S}_R)$, where a morphism α belongs to $\overline{S}_R$ if and only if, for every admissible morphism $U \to V$ in $\mathcal{G}$, the diagram

$$\begin{array}{ccc} \mathscr{O}^U & \longrightarrow & \mathscr{O}'^U \\ \downarrow & & \downarrow \\ \mathscr{O}^X & \longrightarrow & \mathscr{O}'^X \end{array}$$

is a pullback square in the ∞-category $\mathcal{P}(\mathcal{C})$.

Composition with L induces a localization functor from $\mathrm{Obj}_{\mathcal{G}}(\mathcal{P}(\mathcal{C}))$ to itself; since L is left exact, this functor carries $\overline{S}_R$ to itself. It follows from Lemma 21.3.1.4 that $(\overline{S}_L, \overline{S}_R)$ induces a factorization system (S_L, S_R) on the ∞-category $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ having the desired properties. □

We conclude this section with a discussion of the functorial behavior of the factorization systems described in Proposition 21.3.1.1.

Proposition 21.3.1.5. *Let $\mathcal{G}$ be an essentially small which admits finite limits and is equipped with an admissibility structure, let $\mathcal{X}$ and $\mathcal{Y}$ be ∞-topoi, and let $(S_L^{\mathcal{X}}, S_R^{\mathcal{Y}})$ and $(S_L^{\mathcal{X}}, S_R^{\mathcal{Y}})$ be the factorization systems on $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ and $\mathrm{Obj}_{\mathcal{G}}(\mathcal{Y})$ given by Proposition 21.3.1.1. For every geometric morphism $f^* \in \mathrm{Fun}^*(\mathcal{Y}, \mathcal{Z})$, composition with f^* carries $S_L^{\mathcal{X}}$ into $S_L^{\mathcal{Y}}$ and $S_R^{\mathcal{X}}$ into $S_R^{\mathcal{Y}}$.*

Our proof will use the following general fact, which is an immediate consequence of Remark HTT.5.2.8.7 and Proposition HTT.5.2.8.11 .

Lemma 21.3.1.6. *Suppose given a pair of adjoint functors*

$$\mathcal{C} \underset{G}{\overset{F}{\rightleftarrows}} \mathcal{D}.$$

Let (S_L, S_R) be a factorization system on $\mathcal{C}$, and (S'_L, S'_R) a factorization system on $\mathcal{D}$. The following conditions are equivalent:

(1) *The functor F carries S_L to S'_L.*

(2) *The functor G carries S'_R to S_R.*

Proof of Proposition 21.3.1.5. Let f_* be a right adjoint to f^*. Then composition with the functors f^* and f_* determines an adjunction

$$\mathrm{Obj}_{\mathcal{G}}(\mathcal{X}) \underset{f_*^{\mathcal{G}}}{\overset{f_{\mathcal{G}}^*}{\rightleftarrows}} \mathrm{Obj}_{\mathcal{G}}(\mathcal{Y});$$

see Remark 21.2.1.8. It follows immediately from the definitions that the functor $f^*_{\mathcal{G}}$ carries $S^{\mathcal{X}}_R$ into $S^{\mathcal{Y}}_R$, and that the functor $f^{\mathcal{G}}_*$ carries $S^{\mathcal{X}}_R$ into $S^{\mathcal{Y}}_R$. Applying Lemma 21.3.1.6, we deduce that $f^*_{\mathcal{G}}$ also carries $S^{\mathcal{X}}_L$ into $S^{\mathcal{Y}}_L$. □

21.3.2 Digression: ∞-Topoi of Paths

Let $\infty\mathcal{T}\mathrm{op}$ denote the ∞-category of ∞-topoi. Then $\infty\mathcal{T}\mathrm{op}$ is naturally *cotensored* over the ∞-category $\mathcal{C}\mathrm{at}_\infty$ of small ∞-categories. More precisely, for every ∞-topos $\mathcal{X}$ and any (small) simplicial set K, there exists another ∞-topos $\mathcal{X}^K$ and a map $\theta : K \to \mathrm{Fun}^*(\mathcal{X}, \mathcal{X}^K)$ with the following universal property: for every ∞-topos $\mathcal{Y}$, composition with θ induces an equivalence of ∞-categories

$$\mathrm{Fun}^*(\mathcal{X}^K, \mathcal{Y}) \to \mathrm{Fun}(K, \mathrm{Fun}^*(\mathcal{X}, \mathcal{Y}))$$

(see Proposition HTT.6.3.4.9). Note that $\mathcal{X}^K$ is determined up to (canonical) equivalence by $\mathcal{X}$ and K.

Warning 21.3.2.1. The ∞-topos $\mathcal{X}^K$ defined is *not* equivalent to the functor ∞-category $\mathrm{Fun}(K, \mathcal{X})$: the latter is instead characterized by the dual universal property property

$$\mathrm{Fun}^*(\mathcal{Y}, \mathrm{Fun}(K, \mathcal{X})) \simeq \mathrm{Fun}(K, \mathrm{Fun}^*(\mathcal{Y}, \mathcal{X})).$$

Remark 21.3.2.2 (Relationship with Exponentials)**.** Let K be a small simplicial set. For any ∞-topoi $\mathcal{X}$ and $\mathcal{Y}$, we have canonical equivalences

$$\begin{aligned}\mathrm{Fun}^*(\mathcal{X}^K, \mathcal{Y}) &\simeq \mathrm{Fun}(K, \mathrm{Fun}^*(\mathcal{X}, \mathcal{Y}))\\ &\simeq \mathrm{Fun}^*(\mathcal{X}, \mathrm{Fun}(K, \mathcal{Y}))\\ &\simeq \mathrm{Fun}^*(\mathcal{X}, \mathrm{Fun}(K, \mathcal{S}) \otimes \mathcal{Y}).\end{aligned}$$

It follows that $\mathcal{X}^K$ can be identified with an exponential of $\mathcal{Y}$ by the presheaf ∞-category $\mathrm{Fun}(K, \mathcal{S}) = \mathcal{P}(K^{\mathrm{op}})$, in the sense of Definition 21.1.6.4. Consequently, the existence of $\mathcal{X}^K$ (for an arbitrary ∞-topos $\mathcal{X}$) is equivalent to the exponentiability of the ∞-topos $\mathrm{Fun}(K, \mathcal{S})$. We may therefore regard this existence as a special case of Theorem 21.1.6.12 (note that the ∞-topos $\mathrm{Fun}(K, \mathcal{S})$ is compactly generated, and therefore compact assembled).

Definition 21.3.2.3. Let $\mathcal{X}$ be an ∞-topos. We will refer to $\mathcal{X}^{\Delta^1}$ as the *path ∞-topos* of $\mathcal{X}$.

Our goal in this section is to describe an explicit construction of the path ∞-topos $\mathcal{X}^{\Delta^1}$ in the special case where $\mathcal{X}$ is an ∞-topos of presheaves (Theorem 21.3.2.5).

Construction 21.3.2.4. Let $\mathcal{G}$ be a small ∞-category and let K be a simplicial set. Composition with the evaluation map $\mathrm{Fun}(K, \mathcal{G}) \times K \to \mathcal{G}$ induces a map

$$\begin{aligned} \mathcal{P}(\mathcal{G}) &= \mathrm{Fun}(\mathcal{G}^{\mathrm{op}}, \mathcal{S}) \\ &\to \mathrm{Fun}(\mathrm{Fun}(K, \mathcal{G})^{\mathrm{op}} \times K^{\mathrm{op}}, \mathcal{S}) \\ &\simeq \mathrm{Fun}(K^{\mathrm{op}}, \mathrm{Fun}(\mathrm{Fun}(K, \mathcal{G})^{\mathrm{op}}, \mathcal{S})) \\ &= \mathrm{Fun}(K^{\mathrm{op}}, \mathcal{P}(\mathrm{Fun}(K, \mathcal{G}))). \end{aligned}$$

This functor preserves all small limits and colimits and therefore determines a map

$$e : K^{\mathrm{op}} \to \mathrm{Fun}^*(\mathcal{P}(\mathcal{G}), \mathcal{P}(\mathrm{Fun}(K, \mathcal{G}))),$$

which we can identify with a geometric morphism of ∞-topoi $\pi_* : \mathcal{P}(\mathrm{Fun}(K, \mathcal{G})) \to \mathcal{P}(\mathcal{G})^{K^{\mathrm{op}}}$.

Our result can now be stated as follows:

Theorem 21.3.2.5. *Let $\mathcal{G}$ be a small ∞-category. Then the geometric morphism π_* : $\mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G})) \to \mathcal{P}(\mathcal{G})^{\Delta^1}$ is an equivalence of ∞-topoi. In other words, for any ∞-topos $\mathcal{Y}$, the natural map*

$$\mathrm{Fun}^*(\mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G})), \mathcal{Y}) \to \mathrm{Fun}(\Delta^1, \mathrm{Fun}^*(\mathcal{P}(\mathcal{G}), \mathcal{Y}))$$

is an equivalence of ∞-categories.

Remark 21.3.2.6. In the special case $\mathcal{Y} = \mathcal{S}$, Theorem 21.3.2.5 asserts that the canonical map $\mathrm{Pro}(\mathrm{Fun}(\Delta^1, \mathcal{G})) \to \mathrm{Fun}(\Delta^1, \mathrm{Pro}(\mathcal{G}))$ is an equivalence of ∞-categories, which is a special case of Proposition HTT.5.3.5.15 .

Warning 21.3.2.7. In general, the geometric morphism $\pi_* : \mathcal{P}(\mathrm{Fun}(K, \mathcal{G})) \to \mathcal{P}(\mathcal{G})^{K^{\mathrm{op}}}$ of Construction 21.3.2.4 is not an equivalence. For example, taking $\mathcal{S}$-valued points, π_* induces the natural map $\mathrm{Pro}(\mathrm{Fun}(K, \mathcal{G})) \to \mathrm{Fun}(K, \mathrm{Pro}(\mathcal{G}))$. This map need not be an equivalence, even when K is finite (see Warning HTT.5.3.5.16). However, our proof of Theorem 21.3.2.5 can be generalized to show that π_* is an equivalence whenever K is the nerve of a finite partially ordered set (this is a generalization of Proposition HTT.5.3.5.15).

Proof of Theorem 21.3.2.5. We define functors $e_0, e_1 : \mathcal{G} \to \mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G}))$ by the formulae

$$e_0(X)(f : Y_0 \to Y_1) = \mathrm{Map}_{\mathcal{G}}(Y_0, X) \qquad e_1(X)(f : Y_0 \to Y_1) = \mathrm{Map}_{\mathcal{G}}(Y_1, X).$$

There is an evident natural transformation of functors $e_1 \to e_0$, which we can identify with a map $e : \Delta^1 \times \mathcal{G} \to \mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G}))$. Choose a Cartesian fibration $\mathcal{M} \to \Delta^1$ with

$$\mathcal{M}_0 = \{0\} \times_{\Delta^1} \mathcal{M} = \mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G}))$$

$$\mathcal{M}_1 = \{1\} \times_{\Delta^1} \mathcal{M} = \Delta^1 \times \mathcal{G},$$

which is associated to the functor $e : \Delta^1 \times \mathcal{G} \to \mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G}))$. Let $\mathcal{M}^\circ$ denote the full subcategory of $\mathcal{M}$ spanned by the objects of $\mathcal{M}_1$ together with the essential image of the Yoneda embedding $\mathrm{Fun}(\Delta^1, \mathcal{G}) \to \mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G})) \simeq \mathcal{M}_0$. We will prove that, for a functor $F : \mathcal{M} \to \mathcal{Y}$, the following conditions are equivalent:

(a) The restriction $F|_{\mathcal{M}_0}$ belongs to $\mathrm{Fun}^*(\mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G})), \mathcal{Y})$ and F is a left Kan extension of $F|_{\mathcal{M}_0}$.

(b) The functor F is a left Kan extension of $F|_{\mathcal{M}^\circ}$, the functor $F|_{\mathcal{M}^\circ}$ is a right Kan extension of $F|_{\mathcal{M}_1}$, and the restriction of F to $\{i\} \times \mathcal{G} \subseteq \mathcal{M}_1$ is locally left exact for $i \in \{0, 1\}$.

Assume this for the moment. Let $\mathcal{C}$ denote the full subcategory of $\mathrm{Fun}(\mathcal{M}, \mathcal{Y})$ spanned by those functors which satisfy the equivalent conditions (a) and (b). Using Proposition HTT.4.3.2.15 and characterization (a), we see that restriction to the full subcategory $\mathcal{M}_0 \subseteq \mathcal{M}$ determines a trivial Kan fibration $\phi : \mathcal{C} \to \mathrm{Fun}^*(\mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G})), \mathcal{Y})$. Similarly, using characterization (b) and Proposition HTT.4.3.2.15 , we see that restriction to the full subcategory $\mathcal{M}_1 \subseteq \mathcal{M}$ determines a trivial Kan fibration $\psi : \mathcal{C} \to \mathrm{Fun}(\Delta^1, \mathrm{Fun}^{\mathrm{llex}}(\mathcal{G}, \mathcal{Y}))$.

Composition with j determines an equivalence of ∞-categories $\rho : \mathrm{Fun}^*(\mathcal{P}(\mathcal{G}), \mathcal{Y}) \to \mathrm{Fun}^{\mathrm{llex}}(\mathcal{G}, \mathcal{Y})$. It will therefore suffice to show that the composite map

$$\mathrm{Fun}^*(\mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G})), \mathcal{Y}) \xrightarrow{\alpha} \mathrm{Fun}(\Delta^1, \mathrm{Fun}^*(\mathcal{P}(\mathcal{G}), \mathcal{Y})) \xrightarrow{\rho} \mathrm{Fun}(\Delta^1, \mathrm{Fun}^{\mathrm{llex}}(\mathcal{G}, \mathcal{Y}))$$

is an equivalence of ∞-categories. We now complete the proof by observing that this composition is given by $\psi \circ s$, where $s : \mathrm{Fun}^*(\mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G})), \mathcal{Y}) \to \mathcal{C}$ is a section of the trivial Kan fibration ϕ.

It remains to prove that (a) and (b) are equivalent. Suppose first that F satisfies (a); we will prove that F also satisfies (b). For this, we must establish three things:

- To prove that F is a left Kan extension of $F|_{\mathcal{M}^\circ}$, it will suffice to show that $F_0 = F|_{\mathcal{M}_0}$ is a left Kan extension of its restriction to the essential image of the Yoneda embedding $j' : \mathrm{Fun}(\Delta^1, \mathcal{G}) \to \mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G}))$. This follows from our assumption that F_0 preserves small colimits (Lemma HTT.5.1.5.5).

- Fix an object of $\mathrm{Fun}(\Delta^1, \mathcal{G})$, which we can identify with a morphism $u : C \to D$ in the ∞-category $\mathcal{G}$. We will prove that the functor F is a right Kan extension of $F_1 = F|_{\mathcal{M}_1}$ at $j'(u) \in \mathcal{M}_0$. To prove this, let $\mathcal{D} = \mathcal{M}_1 \times_{\mathcal{M}} \mathcal{M}_{j'(u)/}$; we wish to show that the canonical map $F(j'(f)) \to \varprojlim F|_{\mathcal{D}}$ is an equivalence in $\mathcal{Y}$. Note that there is a right cofinal map $\Lambda^2_2 \to \mathcal{D}$, corresponding to the diagram

$$(1, C) \to (1, D) \leftarrow (0, D)$$

in the ∞-category $\Delta^1 \times \mathcal{G}$. It will therefore suffice to show that the diagram

$$\begin{array}{ccc} F_0(j'(u)) & \longrightarrow & F_1(1,C) \\ \downarrow & & \downarrow \\ F_1(0,D) & \longrightarrow & F_1(1,D) \end{array}$$

is a pullback square in $\mathcal{Y}$. Since F is a left Kan extension of F_0, we can write $F_1 = F_0 \circ e$. We are therefore reduced to proving that the diagram

$$\begin{array}{ccc} F_0(j'(u)) & \longrightarrow & F_0(e_0(C)) \\ \downarrow & & \downarrow \\ F_0(e_1(D)) & \longrightarrow & F_0(e_0(D)) \end{array}$$

is a pullback square in $\mathcal{Y}$. Since the functor F_0 is left exact, this follows from the observation that the diagram

$$\begin{array}{ccc} j'(u) & \longrightarrow & e_0(C) \\ \downarrow & & \downarrow \\ e_1(D) & \longrightarrow & e_0(D) \end{array}$$

is a pullback square in $\mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G}))$. (More concretely, this means that for every object $u' : C' \to D'$ in $\mathrm{Fun}(\Delta^1, \mathcal{G})$, the diagram

$$\begin{array}{ccc} \mathrm{Map}_{\mathrm{Fun}(\Delta^1,\mathcal{G})}(u', u) & \longrightarrow & \mathrm{Fun}_{\mathcal{G}}(C', C) \\ \downarrow & & \downarrow \\ \mathrm{Fun}_{\mathcal{G}}(D', D) & \longrightarrow & \mathrm{Fun}_{\mathcal{G}}(C', D) \end{array}$$

is a pullback square of spaces).

- We must show that for $i \in \{0, 1\}$, the restriction of F_1 to $\{i\} \times \mathcal{G}$ is locally left exact. This follows from the observation that this restriction factors as a composition

$$\mathcal{G} \xrightarrow{j} \mathcal{P}(\mathcal{G}) \xrightarrow{E^*_{1-i}} \mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G})) \xrightarrow{F} \mathcal{Y},$$

where j is locally left exact, E^*_i denotes the map of presheaf ∞ categories induced by composition with the functor $\mathrm{Fun}(\Delta^1, \mathcal{G}) \to \mathcal{G}$ given by evaluation on i (which preserves small limits and colimits), and $F|_{\mathcal{M}_0}$ is a left exact functor which preserves small colimits.

Now suppose that F satisfies (b). Let f_0 and f_1 denote the restrictions of F_1 to $\{0\} \times \mathcal{G}$ and $\{1\} \times \mathcal{G}$, respectively, so that $f_0, f_1 : \mathcal{G} \to \mathcal{Y}$ are locally left exact functors. We wish to show that F satisfies (a). Our proof breaks into three parts:

- We show that the functor F is a left Kan extension of F_0 at each object of $\Delta^1 \times \mathcal{G}$ having the form $(0, C)$. Equivalently, we must show that the canonical map $F_0(e_1(C)) \to f_0(C)$ is an equivalence. This is clear, since $e_1(C) \simeq j'(\mathrm{id}_C)$ belongs to the essential image of j', and the functor $F|_{\mathcal{M}^\circ}$ is a right Kan extension of $F|_{\mathcal{M}_1}$.

- We show that the functor F is a left Kan extension of F_0 at each object of $\Delta^1 \times \mathcal{G}$ having the form $(1, X)$. Equivalently, we must show that the canonical map $\beta : F_0(e_0(C)) \to f_1(C)$ is an equivalence in $\mathcal{Y}$. Since F is a left Kan extension of $F|_{\mathcal{M}^\circ}$, we can identify the domain of θ with the colimit of the composite map

$$\theta : \mathrm{Fun}(\Delta^1, \mathcal{G}) \times_{\mathrm{Fun}(\{0\}, \mathcal{G})} \mathcal{G}_{/C} \to \mathrm{Fun}(\Delta^1, \mathcal{G}) \xrightarrow{j'} \mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G})) \xrightarrow{F_0} \mathcal{Y}.$$

  Let us identify objects of the domain of θ with pairs (u, v), where $u : D \to C$ and $v : D \to E$ are morphisms in $\mathcal{G}$. Since $F|_{\mathcal{M}^\circ}$ is a right Kan extension of $F|_{\mathcal{M}_1}$, we see that the functor θ is given informally by the formula $\theta(u, v) = f_0(E) \times_{f_1(E)} f_1(D)$. Evaluation at the final vertex of Δ^1 determines a map $p : \mathrm{Fun}(\Delta^1, \mathcal{G}) \times_{\mathrm{Fun}(\{0\}, \mathcal{G})} \mathcal{G}_{/C} \to \mathcal{G}$. Note that p is a coCartesian fibration, whose fiber over an object $E \in \mathcal{G}$ is equivalent to the ∞-category $\mathcal{G}_{/C} \times_{\mathcal{G}} \mathcal{G}_{/E}$. Let $\theta' : \mathcal{G} \to \mathcal{Y}$ denote the functor given by $\theta'(E) = f_0(E) \times f_1(C)$, so that we have an evident natural transformation $\theta \to \theta' \circ p$. We claim that this natural transformation exhibits θ' as a left Kan extension of θ along p. To prove this, it suffices (since p is a coCartesian fibration) to show that the canonical map

$$\varinjlim_{D \in \mathcal{G}_{/C} \times_{\mathcal{G}} \mathcal{G}_{/E}} f_0(E) \times_{f_1(E)} f_(D) \to f_0(E) \times f_1(C)$$

  is an equivalence, for each $E \in \mathcal{E}$. Since colimits in $\mathcal{Y}$ are universal, it will suffice to prove that the map

$$\varinjlim_{D \in \mathcal{G}_{/C} \times_{\mathcal{G}} \mathcal{G}_{/E}} f_1(D) \to f_1(E) \times f_1(C)$$

  is an equivalence, which follows from our assumption that f_1 is locally left exact. It follows that we can identify β with the canonical map $\varinjlim_{E \in \mathcal{G}} \theta'(E) \to f_1(C)$. To prove that this map is an equivalence, it will suffice (again using the fact that colimits in $\mathcal{Y}$ are universal) to show that the colimit $\varinjlim_{E \in \mathcal{G}} f_0(E)$ is a final object of $\mathcal{Y}$. This follows from our assumption that f_0 is locally left exact.

- We show that the functor F_0 belongs to $\mathrm{Fun}^*(\mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G}), \mathcal{Y})$. First, our assumption that F is a left Kan extension of $F|_{\mathcal{M}^\circ}$ implies that F_0 is a left Kan extension of its restriction to the essential image of j', so that F_0 preserves small colimits (Lemma HTT.5.1.5.5). It will therefore suffice to show that the functor $g = F_0 \circ j'$ is a locally left exact functor from $\mathrm{Fun}(\Delta^1, \mathcal{G})$ into $\mathcal{Y}$. Note that g is given by the formula

$$g(u : C \to D) = f_0(D) \times_{f_1(D)} f_1(C).$$

We will show that the functor g satisfies the criterion of Proposition 20.4.3.1. Let K be a finite simplicial set and suppose that $q : K \to \mathrm{Fun}(\Delta^1, \mathcal{G})$ is a diagram; we wish to prove that the canonical map

$$\varinjlim g|_{\mathrm{Fun}(\Delta^1,\mathcal{G})_{/q}} \to \varprojlim g \circ q$$

is an equivalence in $\mathcal{Y}$. For $i \in \{0, 1\}$, let $q_i : K \to \mathcal{G}$ be the composition of q with the evaluation functor $\mathrm{Fun}(\Delta^1, \mathcal{G}) \to \mathrm{Fun}(\{i\}, \mathcal{G}) \simeq \mathcal{G}$. Then evaluation at $\{1\}$ determines a map $\rho : \mathrm{Fun}(\Delta^1, \mathcal{G})_{/q} \to \mathcal{G}_{/q_1}$. Let $h : \mathcal{G}_{/q_1} \to \mathcal{Y}$ be the functor given by

$$h(D) = f_0(D) \times_{\varprojlim(f_1 \circ q_1)} \varprojlim(f_1 \circ q_0),$$

so that we have an evident map $g \to h \circ \rho$. We claim that this map exhibits h as a left Kan extension of g along ρ. Since ρ is a coCartesian fibration, this is equivalent to the assertion that for each object $D \in \mathcal{G}_{/q_1}$, the canonical map

$$\varinjlim g|_{\mathrm{Fun}(\Delta^1,\mathcal{G})_{/q}} \times_{\mathrm{Fun}(\Delta^1,\mathcal{G})_{/q_1}} \mathrm{Fun}(\Delta^1, \mathcal{G})_{/C} \to h(D)$$

is an equivalence. Since colimits are universal in $\mathcal{Y}$, this follows from our assumption that the functor f_1 is locally left exact (Proposition 20.4.3.1). We are therefore reduced to proving that the canonical map

$$\varinjlim h \to \varprojlim(g \circ q) \simeq \varprojlim(f_0 \circ q_1) \times_{\varprojlim(f_1 \circ q_1)} \varprojlim(f_1 \circ q_0)$$

is an equivalence. Since colimits in $\mathcal{Y}$ are universal, we are reduced to proving that the canonical map $\varinjlim_{D \in \mathcal{G}_{/q_1}} f_0(D) \to \varprojlim(f_0 \circ q_1)$ is an equivalence in $\mathcal{Y}$, which follows from our assumption that f_0 is locally left exact (Proposition 20.4.3.1).

□

21.3.3 The Case of a General $\mathcal{G}$

Our next goal is to prove analogues of Propositions 21.3.1.1 and 21.3.1.5 in the case where the ∞-category $\mathcal{G}$ need not admit finite limits.

Proposition 21.3.3.1. *Let $\mathcal{G}$ be an essentially small ∞-category which is equipped with an admissibility structure $\mathcal{G}^{\mathrm{ad}} \subseteq \mathcal{G}$ and let $\mathcal{X}$ be an arbitrary ∞-topos. Then there exists a* *factorization system* (S_L, S_R) *on the* ∞*-category* $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X}) = \mathrm{Fun}^{\mathrm{llex}}(\mathcal{G}, \mathcal{X})$ *which is characterized by the following requirement: a morphism* $\alpha : \mathscr{O} \to \mathscr{O}'$ *in* $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ *belongs to* S_R *if and only if, for every admissible morphism* $f : U \to V$ *in* $\mathcal{G}$*, the diagram*

$$\begin{array}{ccc} \mathscr{O}^U & \longrightarrow & \mathscr{O}'^U \\ \downarrow & & \downarrow \\ \mathscr{O}^V & \longrightarrow & \mathscr{O}'^V \end{array}$$

is a pullback square in $\mathcal{X}$*.*

Proof. We first choose a functor $\theta : \mathcal{G} \to \mathcal{G}^+$ with the following universal property:

(*i*) The ∞-category $\mathcal{G}^+$ admits finite limits.

(*ii*) For every pullback diagram σ :

$$\begin{array}{ccc} U' & \longrightarrow & U \\ \downarrow & & \downarrow \\ X' & \longrightarrow & X \end{array}$$

in $\mathcal{G}$, where the vertical maps are admissible, the image $\theta(\sigma)$ is a pullback diagram in $\mathcal{G}^+$.

(*iii*) For any ∞-category $\mathcal{C}$ which admits finite limits, composition with θ induces a fully faithful embedding $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{G}^+, \mathcal{C}) \to \mathrm{Fun}(\mathcal{G}, \mathcal{C})$, whose essential image is spanned by those $\rho : \mathcal{G} \to \mathcal{C}$ such that $\rho(\sigma)$ is a pullback square for every pullback square σ :

$$\begin{array}{ccc} U' & \longrightarrow & U \\ \downarrow & & \downarrow \\ X' & \longrightarrow & X \end{array}$$

in $\mathcal{G}$ for which the vertical maps are admissible.

It follows from Proposition HTT.5.3.6.2 that there exists a functor $\theta : \mathcal{G} \to \mathcal{G}^+$ satisfying these conditions and that θ is fully faithful. Let Q be the smallest collection of morphisms in $\mathcal{G}^+$ which contains $\theta(f)$ for every admissible morphism f in $\mathcal{G}$ and satisfies the axioms of Definition 20.2.1.1 (so that Q determines an admissibility structure on $\mathcal{G}^+$).

Every locally left exact functor $\mathcal{G} \to \mathcal{X}$ preserves all pullback squares which exist in $\mathcal{G}$ (Remark 20.4.2.4). Using (*ii*), we obtain a fully faithful embedding $\rho : \mathrm{Fun}^{\mathrm{llex}}(\mathcal{G}, \mathcal{X}) \to \mathrm{Fun}^{\mathrm{lex}}(\mathcal{G}^+, \mathcal{X})$. Let (S_L^+, S_R^+) be the factorization system on $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{G}^+, \mathcal{X})$ given by Proposition 21.3.1.1. Let S_L and S_R be the inverse images of S_L^+ and S_R^+ under the functor ρ. To complete the proof, it will suffice to verify the following:

(a) The pair (S_L, S_R) is a factorization system on $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X}) = \mathrm{Fun}^{\mathrm{llex}}(\mathcal{G}, \mathcal{X})$.

(b) A morphism $\mathscr{O} \to \mathscr{O}'$ in $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ belongs to S_R if and only if every admissible morphism $f : U \to V$ in $\mathcal{G}$ determines a pullback square

$$\begin{array}{ccc} \mathscr{O}^U & \longrightarrow & \mathscr{O}'^U \\ \downarrow & & \downarrow \\ \mathscr{O}^V & \longrightarrow & \mathscr{O}'^V \end{array}$$

in the ∞-topos $\mathcal{X}$.

We first prove (b). The "only if" direction follows immediately from the definitions. To prove the converse, suppose that $\alpha : \mathscr{O} \to \mathscr{O}'$ is a morphism in $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ having the property that, for each admissible morphism $f : U \to V$ in $\mathcal{G}$, the diagram

$$\begin{array}{ccc} \mathscr{O}^U & \longrightarrow & \mathscr{O}'^U \\ \downarrow & & \downarrow \\ \mathscr{O}^V & \longrightarrow & \mathscr{O}'^V \end{array}$$

is a pullback square. Let Q' be the collection of all morphisms $U^+ \to V^+$ in $\mathcal{G}^+$ for which the diagram

$$\begin{array}{ccc} \mathscr{O}^{U^+} & \longrightarrow & \mathscr{O}'^{U^+} \\ \downarrow & & \downarrow \\ \mathscr{O}^{V^+} & \longrightarrow & \mathscr{O}'^{V^+} \end{array}$$

is a pullback square. Our hypothesis on α guarantees that Q' contains $\theta(f)$ for every admissible morphism f in $\mathcal{G}$. Using the left exactness of the functors $\mathscr{O}$ and $\mathscr{O}'$, we see that Q' determines an admissibility structure on $\mathcal{G}^+$ (Example 20.2.1.8). The minimality of Q implies that $Q \subseteq Q'$, so that $\alpha \in S_R$.

To prove (a), it will suffice to verify the following:

$(*)$ Let $\beta : \mathscr{O}' \to \mathscr{O}''$ be a morphism in $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{G}^+, \mathcal{X})$, so that β factors as a composition

$$\mathscr{O}' \xrightarrow{\beta_L} \mathscr{O} \xrightarrow{\beta_R} \mathscr{O}''$$

where $\beta_L \in S_L^+$ and $\beta_R \in S_R^+$. If $\mathscr{O}'$ and $\mathscr{O}''$ belong to the essential image of ρ, then $\mathscr{O}$ also belongs to the essential image of ρ.

To prove $(*)$, set $\mathscr{O}'_0 = \mathscr{O}' \circ \theta$ and $\mathscr{O}''_0 = \mathscr{O}'' \circ \theta$, so that β determines a map $\beta_0 : \mathscr{O}'_0 \to \mathscr{O}''_0$ in $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$. Using Theorem 21.3.2.5, we see that β_0 determines a geometric morphism of ∞-topoi $g^* : \mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G})) \to \mathcal{X}$, so that we can write $\beta_0 = g^*(\overline{\beta}_0)$ for some morphism $\overline{\beta}_0$

in $\mathrm{Fun}^{\mathrm{llex}}(\mathcal{G}, \mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G})))$. Using (iii), we can assume that $\overline{\beta}_0$ is the restriction of a map $\overline{\beta} : \overline{\mathscr{O}}' \to \overline{\mathscr{O}}''$ in $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{G}^+, \mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G})))$. Let $(\overline{S}_L, \overline{S}_R)$ denote the factorization system on $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{G}^+, \mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G})))$ given by Proposition 21.3.1.1, so that $\overline{\beta}$ factors as a composition $\overline{\mathscr{O}}' \xrightarrow{\overline{\beta}_L} \overline{\mathscr{O}} \xrightarrow{\overline{\beta}_R} \overline{\mathscr{O}}''$ with $\overline{\beta}_L \in \overline{S}_L$ and $\overline{\beta}_R \in \overline{S}_R$. Using Proposition 21.3.1.5, we can assume without loss of generality that the factorization described in $(*)$ is given by

$$\mathscr{O}' \xrightarrow{g^*\overline{\beta}_L} g^*\overline{\mathscr{O}} \xrightarrow{g^*\overline{\beta}_R} \mathscr{O}''.$$

It will therefore suffice to show that $g^*\overline{\mathscr{O}}$ belongs to the essential image of ρ: that is, that the composite functor $g^* \circ \overline{\mathscr{O}} \circ \theta : \mathcal{G} \to \mathcal{X}$ is locally left exact. To prove this, we are free to replace $\mathcal{X}$ by the ∞-topos $\mathcal{P}(\mathrm{Fun}(\Delta^1, \mathcal{G}))$. We may therefore assume without loss of generality that $\mathcal{X}$ has the form $\mathcal{P}(\mathcal{C})$, for some small ∞-category $\mathcal{C}$.

Let $\mathscr{O}$ be as in $(*)$; we wish to show that the functor $\mathscr{O} \circ \theta : \mathcal{G} \to \mathcal{P}(\mathcal{C})$ is locally left exact. Equivalently, we wish to show that for each object $C \in \mathcal{C}$, the composite functor

$$\mathcal{G} \xrightarrow{\theta} \mathcal{G}^+ \xrightarrow{\mathscr{O}} \mathcal{P}(\mathcal{C}) \xrightarrow{e_C} \mathcal{S}$$

is locally left exact, where e_C denotes the functor given by evaluation at C. Using Proposition 21.3.1.5 again, we are reduced to proving $(*)$ in the special case where $\mathcal{Y} = \mathcal{S}$. Let (S', S'') be the factorization system on $\mathrm{Obj}_{\mathcal{G}}(\mathcal{S})$ supplied by Theorem 20.2.2.5, so that β_0 factors as a composition

$$\mathscr{O}'_0 \xrightarrow{\beta'_0} \mathscr{O}_0 \xrightarrow{\beta''_0} \mathscr{O}''_0$$

where $\beta'_0 \in S'$ and $\beta''_0 \in S''$. To complete the proof, it will suffice to show that $\rho(\beta'_0) \in S^+_L$ and $\rho(\beta''_0) \in S^+_R$. The second of these assertions follows from (b) (and the description of the factorization system (S', S'') supplied by Theorem 20.2.2.5). To prove the first, it suffices to observe that the functor $\theta : \mathcal{G} \to \mathcal{G}^+$ induces a map $\mathrm{Pro}(\mathcal{G}) \to \mathrm{Pro}(\mathcal{G}^+)$ which carries proadmissible morphisms in $\mathrm{Pro}(\mathcal{G})$ to proadmissible morphisms in $\mathrm{Pro}(\mathcal{G}^+)$. □

We close this section by noting that the factorization system of Proposition 21.3.3.1 depends functorially on $\mathcal{X}$:

Proposition 21.3.3.2. *Let $\mathcal{G}$ be an essentially small ∞-category equipped with an admissibility structure, let $\mathcal{X}$ and $\mathcal{Y}$ be ∞-topoi, and let $(S^{\mathcal{X}}_L, S^{\mathcal{X}}_R)$ and $(S^{\mathcal{Y}}_L, S^{\mathcal{Y}}_R)$ denote the factorization systems on the ∞-categories $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ and $\mathrm{Obj}_{\mathcal{G}}(\mathcal{Y})$ given by Proposition 21.3.3.1. For every geometric morphism $f^* \in \mathrm{Fun}^*(\mathcal{X}, \mathcal{Y})$, composition with f^* carries $S^{\mathcal{X}}_L$ into $S^{\mathcal{Y}}_L$ and $S^{\mathcal{X}}_R$ into $S^{\mathcal{Y}}_R$.*

Proof. Let $\theta : \mathcal{G} \to \mathcal{G}^+$ be as in the proof of Proposition 21.3.3.1. Then we have a homotopy commutative diagram

$$\begin{array}{ccc} \mathrm{Obj}_{\mathcal{G}}(\mathcal{X}) & \xrightarrow{f^*} & \mathrm{Obj}_{\mathcal{G}}(\mathcal{Y}) \\ \downarrow \rho_{\mathcal{X}} & & \downarrow \rho_{\mathcal{Y}} \\ \mathrm{Obj}_{\mathcal{G}^+}(\mathcal{X}) & \xrightarrow{f^*} & \mathrm{Obj}_{\mathcal{G}^+}(\mathcal{Y}). \end{array}$$

We can then write

$$S_L^{\mathcal{X}} = \rho_{\mathcal{Y}}^{-1} S_L^{+,\mathcal{X}} \qquad S_R^{\mathcal{X}} = \rho_{\mathcal{X}}^{-1} S_R^{+,\mathcal{X}}$$

$$S_L^{\mathcal{Y}} = \rho_{\mathcal{Y}}^{-1} S_L^{+,\mathcal{Y}} \qquad S_R^{\mathcal{Y}} = \rho_{\mathcal{Y}}^{-1} S_R^{+,\mathcal{Y}},$$

where $(S_L^{+,\mathcal{X}}, S_R^{+,\mathcal{X}})$ and $(S_L^{+,\mathcal{Y}}, S_R^{+,\mathcal{Y}})$ are the factorization systems on $\mathrm{Obj}_{\mathcal{G}^+}(\mathcal{X})$ and $\mathrm{Obj}_{\mathcal{G}^+}(\mathcal{Y})$ supplied by Proposition 21.3.1.1. It will therefore suffice to show that composition with f^* carries $S_L^{+,\mathcal{X}}$ into $S_L^{+,\mathcal{Y}}$ and $S_R^{+,\mathcal{X}}$ into $S_R^{+,\mathcal{Y}}$, which follows from Proposition 21.3.1.5. □

21.3.4 The Case of a Fractured ∞-Topos

We now turn to the proof of Theorem 21.3.0.1 for a general fractured ∞-topos $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$. We will need the following:

Lemma 21.3.4.1. *Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos and let $h : \mathcal{G} \to \mathcal{E}$ be a presentation of $\mathcal{E}$ (see Definition 20.5.3.1). For any ∞-topos $\mathcal{X}$, let $\mathrm{LFun}(\mathcal{E}, \mathcal{X})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{E}, \mathcal{X})$ spanned by those functors which preserve small colimits, so that composition with h determines a fully faithful embedding $\iota : \mathrm{LFun}(\mathcal{E}, \mathcal{X}) \to \mathrm{Fun}(\mathcal{G}, \mathcal{X})$. Suppose we are given a natural transformation $\alpha : f \to g$ between functors $f, g : \mathcal{G} \to \mathcal{X}$ satisfying the following conditions:*

(∗) *For every admissible morphism $U \to V$ in $\mathcal{G}$, the diagram*

$$\begin{array}{ccc} f(U) & \longrightarrow & g(U) \\ \downarrow & & \downarrow \\ f(V) & \longrightarrow & g(V) \end{array}$$

is a pullback square in $\mathcal{X}$.

If g belongs to the essential image of ι, then so does f.

Proof. For each object $V \in \mathcal{G}$, let $F_V : \mathcal{P}(\mathcal{G}^{\mathrm{ad}}_{/V}) \to \mathcal{X}$ be the colimit-preserving extension of $f|_{\mathcal{G}^{\mathrm{ad}}_{/V}}$, and define $G_V : \mathcal{P}(\mathcal{G}^{\mathrm{ad}}_{/V}) \to \mathcal{X}$ similarly. The assumption that g belongs to the essential image of ι guarantees that G_V factors (up to homotopy) through the localization functor $\mathcal{P}(\mathcal{G}^{\mathrm{ad}}_{/V}) \to \mathcal{E}^{\mathrm{corp}}_{/hV}$, and we wish to show that F_V has the same property (for each $V \in \mathcal{G}$). This is clear, since assumption $(*)$ guarantees that F_V is given by the formula

$$F_V(\mathscr{F}) = G_V(\mathscr{F}) \times_{g(V)} f(V).$$

□

Proof of Theorem 21.3.0.1. Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos. Using Theorem 20.5.3.4, we can choose an essentially small full subcategory $\mathcal{G} \subseteq \mathcal{E}$ for which the inclusion $\mathcal{G} \hookrightarrow \mathcal{E}$ is a presentation of $\mathcal{E}$ (where a morphism in $\mathcal{G}$ is admissible if it is $\mathcal{E}^{\mathrm{corp}}$-admissible when regarded as a morphism in $\mathcal{E}$). The inclusion functor extends to a geometric morphism of ∞-topoi $H^* : \mathcal{P}(\mathcal{G}) \to \mathcal{E}$ whose right adjoint H_* is fully faithful. For every ∞-topos $\mathcal{X}$, composition with H^* induces a fully faithful embedding $\iota : \mathrm{Fun}^*(\mathcal{E}, \mathcal{X}) \hookrightarrow \mathrm{Fun}^*(\mathcal{P}(\mathcal{G}), \mathcal{X})$, whose essential image is spanned by those functors which carry H^*-equivalences in $\mathcal{P}(\mathcal{G})$ to equivalences in $\mathcal{X}$. Let (S_L, S_R) be the factorization system on $\mathrm{Fun}^*(\mathcal{P}(\mathcal{G}), \mathcal{X}) \simeq \mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ given by Proposition 21.3.3.1. To prove the first assertion of Theorem 21.3.0.1, it will suffice to verify the following:

(a) A morphism α in $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$ is local if and only if $\iota(\alpha)$ belongs to S_R.

(b) The factorization system (S_L, S_R) restricts to a factorization system on $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$. In other words, if we are given a morphism $\beta : \mathscr{O}' \to \mathscr{O}''$ in $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$ which factors as a composition
$$\iota\,\mathscr{O}' \xrightarrow{\beta_L} \mathscr{O} \xrightarrow{\beta_R} \iota\,\mathscr{O}''$$
where $\beta_L \in S_L$ and $\beta_R \in S_R$, then $\mathscr{O} \in \mathrm{Fun}^*(\mathcal{P}(\mathcal{G}), \mathcal{X})$ belongs to the essential image of ι.

Assertion (a) follows from Corollary 21.2.4.12 and (b) follows from Lemma 21.3.4.1.

We now complete the proof of Theorem 21.3.0.1 by showing that the factorization system constructed above depends functorially on the ∞-topos $\mathcal{X}$. Let $f^* : \mathcal{X} \to \mathcal{Y}$ be a geometric morphism of ∞-topoi and let $(S^{\mathcal{X}}_L, S^{\mathcal{X}}_R)$ and $(S^{\mathcal{Y}}_L, S^{\mathcal{Y}}_R)$ be the factorization systems constructed in the first part of the proof. We wish to show that composition with f^* carries $S^{\mathcal{X}}_L$ into $S^{\mathcal{Y}}_L$ and $S^{\mathcal{X}}_R$ into $S^{\mathcal{Y}}_R$. This follows from Proposition 21.3.3.2 by virtue of the commutativity of the diagram

$$\begin{array}{ccc} \mathrm{Fun}^*(\mathcal{E}, \mathcal{X}) & \longrightarrow & \mathrm{Fun}^*(\mathcal{E}, \mathcal{Y}) \\ \downarrow & & \downarrow \\ \mathrm{Obj}_{\mathcal{G}}(\mathcal{X}) & \longrightarrow & \mathrm{Obj}_{\mathcal{G}}(\mathcal{Y}). \end{array}$$

□

Corollary 21.3.4.2. *Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos and suppose that the collection of corporeal objects of $\mathcal{X}$ is closed under finite limits. Let $\mathcal{X}$ be an arbitrary ∞-topos and let $\mathscr{O} \in \mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$. Then the ∞-category $\mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{X})_{/\mathscr{O}}$ is presentable.*

Proof. Note that if we are given a commutative diagram

$$\begin{array}{ccc} \mathscr{O}'' & \xrightarrow{\alpha} & \mathscr{O}' \\ & \searrow \quad \swarrow & \\ & \mathscr{O} & \end{array}$$

in the ∞-category $\mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{X})$ where the vertical maps are local, then α is automatically local as well. We may therefore identify $\mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{X})_{/\mathscr{O}}$ with the full subcategory of $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})_{/\mathscr{O}}$ spanned by the local morphisms $\mathscr{O}' \to \mathscr{O}$.

Using Proposition 20.5.4.1, we can choose a presentation $h : \mathcal{G} \to \mathcal{E}$ where the ∞-category $\mathcal{G}$ admits finite limits. Then composition with h induces a fully faithful embedding $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X}) \to \mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$. Set $\mathscr{O}_0 = (\mathscr{O} \circ h) \in \mathrm{Obj}_{\mathcal{G}}(\mathcal{Y})$. Using Lemma 21.3.4.1, we can identify $\mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{X})_{/\mathscr{O}}$ with the full subcategory of $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})_{/\mathscr{O}_0}$ spanned by those maps $\mathscr{O}'_0 \to \mathscr{O}_0$ which satisfy condition $(*)$ of Lemma 21.3.4.1. This ∞-category is evidently accessible and Proposition 21.3.1.1 implies that it is a localization of $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})_{/\mathscr{O}_0}$. Since the collection of presentable ∞-categories is stable under accessible localization and passage to overcategories (Theorem HTT.5.5.1.1 and Proposition HTT.5.5.3.11), we are reduced to proving that $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ is a presentable ∞-category, which follows from the identification $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X}) \simeq \mathcal{S}\mathrm{hv}_{\mathrm{Ind}(\mathcal{G}^{\mathrm{op}})}(\mathcal{X})$ of Proposition 21.2.2.1 (alternatively, apply Lemmas HTT.5.5.4.17 , HTT.5.5.4.18 , and HTT.5.5.4.19). □

Remark 21.3.4.3. In the situation of Corollary 21.3.4.2, let $U \in \mathcal{E}$ be an object and let $\mathscr{O}^U \in \mathcal{X}$ denote the value of $\mathscr{O}$ on U. Then evaluation at U induces a functor

$$e_U : \mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{X})_{/\mathscr{O}} \to \mathcal{X}_{/\mathscr{O}^U}.$$

If $U \in \mathcal{E}$ is corporeal, then the functor e_U preserves limits. To prove this, it suffices to observe that we can choose a presentation $h : \mathcal{G} \to \mathcal{E}$ and an object $U_0 \in \mathcal{G}$ with $U = h(U_0)$; in this case, the functor e_U factors as a composition

$$\mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{X})_{/\mathscr{O}} \xrightarrow{\phi} \mathrm{Obj}_{\mathcal{G}}(\mathcal{X})_{/\mathscr{O}_0} \xrightarrow{e_{U_0}} \mathcal{X}_{/\mathscr{O}^U}$$

where e_{U_0} is given by evaluation at U_0 (which clearly preserves small limits) and the functor ϕ exhibits $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})_{/\mathscr{O}}$ as a localization of $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})_{/\mathscr{O}_0}$ (by the proof of Corollary 21.3.4.2).

Remark 21.3.4.4 (Representability of $\mathcal{X} \mapsto (S^{\mathcal{X}}_L, S^{\mathcal{X}}_R)$)**.** Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos and let $\mathcal{E}^{\Delta^1}$ be the path ∞-topos for $\mathcal{E}$ (Definition 21.3.2.3). Then the ∞-topos

$\mathcal{E}^{\Delta^1}$ represents a functor $U : \infty\mathcal{T}\mathrm{op} \to \widehat{\mathcal{S}}$, whose value on an ∞-topos $\mathcal{X}$ can be regarded as a classifying space for morphisms in the ∞-category $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$ (more precisely, we have a homotopy equivalence $U(\mathcal{X}) = \mathrm{Fun}(\Delta^1, \mathrm{Fun}^*(\mathcal{E}, \mathcal{X}))^{\simeq})$. For every ∞-topos $\mathcal{X}$, let $U_L(\mathcal{X}) \subseteq U(\mathcal{X})$ be the summand consisting of morphisms in $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$ which belong to $S_L^{\mathcal{X}}$, and define $U_R(\mathcal{X}) \subseteq U(\mathcal{X})$ similarly. It follows from Theorem 21.3.0.1 that we can regard U_L and U_R as functors from $\infty\mathcal{T}\mathrm{op}$ to the ∞-category $\widehat{\mathcal{S}}$.

Note that any morphism $u : f^* \to g^*$ in $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$ factors in an essentially unique way as a composition

$$f^* \xrightarrow{u'} h^* \xrightarrow{u''} g^*,$$

where $u' \in S_L^{\mathcal{X}}$ and $u'' \in S_R^{\mathcal{X}}$. Moreover, Theorem 21.3.0.1 guarantees that this factorization depends functorially on $\mathcal{X}$. It follows that the constructions $u \mapsto u'$ and $u \mapsto u''$ determine left homotopy inverses to the inclusions $U_L \hookrightarrow U$ and $U_R \hookrightarrow U$. In particular, the functors U_L and U_R are both retracts of U. Since the ∞-category $\infty\mathcal{T}\mathrm{op}$ of ∞-topoi is idempotent complete (it admits all small limits and colimits), it follows that the functors U_L and U_R are representable by ∞-topoi $\mathcal{E}_L^{\Delta^1}$ and $\mathcal{E}_R^{\Delta^1}$, respectively.

21.4 Structured Spaces

Recall that a *locally ringed space* is a pair $(X, \mathscr{O}_X)$, where X is a topological space and $\mathscr{O}_X$ is a local sheaf of commutative rings on X. The collection of locally ringed spaces can be organized into a category $\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}^{\heartsuit}}$, where a morphism from $(X, \mathscr{O}_X)$ to $(Y, \mathscr{O}_Y)$ in $\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}^{\heartsuit}}$ is given by a pair (f, α), where $f : X \to Y$ is a continuous map of topological spaces and $\alpha : f^* \mathscr{O}_Y \to \mathscr{O}_X$ is a local map between sheaves of commutative rings on X (Definition 1.1.5.1).

In Chapter 1, we considered several variants of the category $\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}^{\heartsuit}}$:

(*a*) Replacing the ordinary category of commutative rings by the ∞-category CAlg of $\mathbb{E}_\infty$-rings, we obtained the *∞-category of locally spectrally ringed spaces* $\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ (Definition 1.1.5.3).

(*b*) Replacing the ordinary category of topological spaces $\mathcal{T}\mathrm{op}$ by the ∞-category $\infty\mathcal{T}\mathrm{op}$ of ∞-topoi, we obtained the *∞-category of locally spectrally ringed ∞-topoi* $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ (Definition 1.4.2.1).

(*c*) Replacing the Zariski topology by the étale topology, we obtained a full subcategory $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}} \subseteq \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ of locally spectrally ringed ∞-topoi with strictly Henselian structure sheaves (Definition 1.4.2.1).

Our goal in this section is to develop a formalism which encompasses all of these examples and several variants thereof, and thereby lay a foundation for discussing variants of the theory of spectral algebraic geometry. We begin in §21.4.1 by associating to every geometric site $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ an ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ of *locally $\mathcal{G}$-structured ∞-topoi* (Construction 21.4.1.15), whose objects are pairs $(\mathcal{X}, \mathscr{O})$ where $\mathcal{X}$ is an ∞-topos and $\mathscr{O}$ is a τ-local $\mathcal{G}$-object of $\mathcal{X}$. The ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ specializes to the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ of locally spectrally ringed ∞-topoi when $\mathcal{G} = \mathrm{Aff}_{\mathrm{Sp}}$ is the spectral Zariski site of Example 20.6.4.4 (Example 21.4.1.19; see also Examples 21.4.1.17, 21.4.1.18, and 21.4.1.20 for related statements).

In general, many different geometric sites $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ can give rise to the same theory of (local) $\mathcal{G}$-objects: for any ∞-topos $\mathcal{X}$, the ∞-category $\mathrm{Obj}^{\tau}_{\mathcal{G}}(\mathcal{X})$ depends only on the ∞-topos $\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ and the subcategory $\mathrm{Obj}^{\tau,\mathrm{loc}}_{\mathcal{G}}(\mathcal{X}) \subseteq \mathrm{Obj}^{\tau}_{\mathcal{G}}(\mathcal{X})$ depends only on the tracture subcategory $\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})^{\mathrm{corp}} \subseteq \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ of Theorem 20.6.3.4. In §21.4.2, we adopt a more invariant perspective and introduce an ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ associated to any fractured ∞-topos $\mathcal{E}$ (Definition 21.4.2.6), which extends and (slightly) generalizes the constructions of §21.4.1.

The remainder of this section is devoted to studying formal properties enjoyed by the ∞-categories $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ and $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ of §21.4.1 and §21.4.2. In §21.4.3 we show that these ∞-categories admit small filtered limits (Theorem 21.4.3.1), and in §21.4.4 and 21.4.5 we show that they admit colimits for some restricted classes of diagrams (Propositions 21.4.4.9 and 21.4.5.1). One special case is particularly notable: in §21.4.6 we introduce subcategories $\infty\mathcal{T}\mathrm{op}^{\text{ét}}(\mathcal{G}) \subseteq \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ and $\infty\mathcal{T}\mathrm{op}^{\text{ét}}(\mathcal{E}) \subseteq \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ of *étale morphisms* (Variant 21.4.6.3 and Definition 21.4.6.1), which admit all small colimits (Proposition 21.4.6.4); these subcategories will play an important role in Chapter **??**.

To apply the formalism of this section in practice, one typically begins by choosing a geometric site $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ consisting of "simple" geometric objects of some kind (such as affine schemes of finite type over $\mathbf{Z}$), and obtains an ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ consisting of more general objects of the same type (such as locally ringed spaces, or more general ∞-topoi with a sheaf of local rings). In §21.4.7 we make this heuristic more precise by constructing a functor $\mathcal{G} \to \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$, which carries admissible morphisms in $\mathcal{G}$ to étale morphisms in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ (Remark 21.4.7.2). More generally, to any fractured ∞-topos $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$, we introduce a functor $\mathrm{Re} : \mathcal{E}_{\mathrm{corp}} \to \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ which we refer to as *corporeal realization* (Construction 21.4.7.1); here $\mathcal{E}_{\mathrm{corp}}$ denotes the full subcategory of $\mathcal{E}$ spanned by the corporeal objects. We show that the corporeal realization functor Re is always fully faithful (Proposition 21.4.7.10), and its value on a corporeal object $X \in \mathcal{E}$ can be characterized by a universal mapping property (Theorem 21.4.7.7).

21.4.1 The ∞-Category $\infty\mathcal{T}\mathrm{op}(\mathcal{G})$

Let $\mathcal{C}$ be an arbitrary ∞-category. In §1.1.2, we introduced the ∞-category $\mathcal{T}\mathrm{op}_{\mathcal{C}}$, whose objects are pairs $(X, \mathscr{F})$ where X is a topological space and $\mathscr{F}$ is a $\mathcal{C}$-valued sheaf on X

(Construction 1.1.2.2). We now consider some variants of this construction.

Construction 21.4.1.1 (The ∞-Category $\infty\mathcal{T}\mathrm{op}_{\mathcal{C}}$)**.** Let $\mathcal{C}$ be an arbitrary ∞-category. For every geometric morphism of ∞-topoi $f^* : \mathcal{X} \to \mathcal{Y}$, precomposition with f^* determines a direct image functor $f_*^{\mathcal{C}} : \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{Y}) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$ (see Remark 21.2.2.4). We can therefore view the construction $\mathcal{X} \mapsto \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$ as a functor $\infty\mathcal{T}\mathrm{op} \to \widehat{\mathcal{C}\mathrm{at}}_{\infty}$. We let $U : \infty\mathcal{T}\mathrm{op}_{\mathcal{C}} \to \infty\mathcal{T}\mathrm{op}$ be a coCartesian fibration classified by the functor $\mathcal{X} \mapsto \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})^{\mathrm{op}}$. We will refer to $\infty\mathcal{T}\mathrm{op}_{\mathcal{C}}$ as *the ∞-category of ∞-topoi with a $\mathcal{C}$-valued sheaf.*

Remark 21.4.1.2. Let $\mathcal{C}$ be an arbitrary ∞-category. We can describe the ∞-category $\infty\mathcal{T}\mathrm{op}_{\mathcal{C}}$ of Construction 21.4.1.1 more informally as follows:

(i) The objects of $\infty\mathcal{T}\mathrm{op}_{\mathcal{C}}$ are pairs $(\mathcal{X}, \mathscr{F})$, where $\mathcal{X}$ is an ∞-topos and $\mathscr{F}$ is a $\mathcal{C}$-valued sheaf on $\mathcal{X}$.

(ii) A morphism from $(\mathcal{X}, \mathscr{F})$ to $(\mathcal{Y}, \mathscr{G})$ in the ∞-category $\infty\mathcal{T}\mathrm{op}_{\mathcal{C}}$ is given by a geometric morphism of ∞-topoi $f_* : \mathcal{X} \to \mathcal{Y}$ together with a natural transformation $\beta : \mathscr{G} \to f_*^{\mathcal{C}} \mathscr{F} = \mathscr{F} \circ f^*$.

Remark 21.4.1.3 (Comparison with $\mathcal{T}\mathrm{op}_{\mathcal{C}}$)**.** Let $\mathcal{C}$ be an ∞-category which admits small limits. For any topological space X, Proposition 1.3.1.7 supplies an equivalence of ∞-categories $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{S}\mathrm{hv}(X)) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(X)$. This equivalence depends functorially on X, and therefore determines a pullback diagram of ∞-categories

$$\begin{array}{ccc} \mathcal{T}\mathrm{op}_{\mathcal{C}} & \longrightarrow & \infty\mathcal{T}\mathrm{op}_{\mathcal{C}} \\ \downarrow & & \downarrow \\ \mathcal{T}\mathrm{op} & \longrightarrow & \infty\mathcal{T}\mathrm{op}. \end{array}$$

Beware that this is generally false if $\mathcal{C}$ does not admit small limits.

Example 21.4.1.4 (Sheaves of $\mathbb{E}_\infty$-Rings)**.** Let $\mathcal{C} = \mathrm{CAlg}$ be the ∞-category of $\mathbb{E}_\infty$-rings. Then $\infty\mathcal{T}\mathrm{op}_{\mathcal{C}}$ is the ∞-category of spectrally ringed ∞-topoi (Construction 1.4.1.3), and $\mathcal{T}\mathrm{op}_{\mathcal{C}}$ is the ∞-category of spectrally ringed spaces (Definition 1.1.2.5).

We will be primarily interested in the ∞-category $\infty\mathcal{T}\mathrm{op}_{\mathcal{C}}$ in the case where the ∞-category $\mathcal{C}$ is compactly generated. In this case, we can reformulate Construction 21.4.1.1 using the ideas of §21.2.

Construction 21.4.1.5 (The ∞-Category $\infty\mathcal{T}\mathrm{op}(\mathcal{G})$)**.** Let $\mathcal{G}$ be an essentially small ∞-category. A *$\mathcal{G}$-structured ∞-topos* is a pair $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$, where $\mathcal{X}$ is an ∞-topos and $\mathscr{O}_{\mathcal{X}} : \mathcal{G} \to \mathcal{X}$ is a locally left exact functor (which we will denote by $(T \in \mathcal{G}) \mapsto (\mathscr{O}_{\mathcal{X}}^{T} \in \mathcal{X})$). In this case, we refer to $\mathscr{O}_{\mathcal{X}}$ as the *structure sheaf* of $\mathcal{X}$.

Note that if $f^* : \mathcal{X} \to \mathcal{Y}$ is a geometric morphism of ∞-topoi, then composition with f^* determines a functor $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X}) \to \mathrm{Obj}_{\mathcal{G}}(\mathcal{Y})$ (see Remark 21.2.2.4). We can therefore view the construction $\mathcal{X} \mapsto \mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ as a functor $\infty\mathcal{T}\mathrm{op}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$. We let $U : \infty\mathcal{T}\mathrm{op}(\mathcal{G}) \to \infty\mathcal{T}\mathrm{op}$ be a Cartesian fibration classified by the functor $\mathcal{X} \mapsto \mathrm{Obj}_{\mathcal{G}}(\mathcal{G})^{\mathrm{op}}$. We will refer to $\infty\mathcal{T}\mathrm{op}(\mathcal{G})$ as *the ∞-category of $\mathcal{G}$-structured ∞-topoi.*

Remark 21.4.1.6. Let $\mathcal{G}$ be an essentially small ∞-category. We can describe the ∞-category $\infty\mathcal{T}\mathrm{op}(\mathcal{G})$ of Construction 21.4.1.5 more informally as follows:

(*i*) The objects of $\infty\mathcal{T}\mathrm{op}(\mathcal{G})$ are $\mathcal{G}$-structured ∞-topoi $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$.

(*ii*) A morphism from $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ to $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ in the ∞-category $\infty\mathcal{T}\mathrm{op}(\mathcal{G})$ is given by a geometric morphism of ∞-topoi $f_* : \mathcal{X} \to \mathcal{Y}$ together with a natural transformation $\alpha : f^* \circ \mathscr{O}_{\mathcal{Y}} \to \mathscr{O}_{\mathcal{X}}$.

Here we can replace (*ii*) with the following variant:

(*ii'*) A morphism from $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ to $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ in the ∞-category $\infty\mathcal{T}\mathrm{op}(\mathcal{G})$ is given by a geometric morphism of ∞-topoi $f_* : \mathcal{X} \to \mathcal{Y}$ together with a natural transformation $\beta : \mathscr{O}_{\mathcal{Y}} \to f_* \circ \mathscr{O}_{\mathcal{X}}$.

Beware, however, that the functor $f_* \circ \mathscr{O}_{\mathcal{X}}$ appearing in (*ii'*) might fail to be locally left exact (unless we assume that $\mathcal{G}$ admits finite limits).

Variant 21.4.1.7. Let $\mathcal{G}$ be an essentially small ∞-category. A *$\mathcal{G}$-structured space* is a pair $(X, \mathscr{O}_X)$, where X is a topological space and $\mathscr{O}_X$ is a $\mathcal{G}$-object of the ∞-topos $\mathcal{S}\mathrm{hv}(X)$. The collection of all $\mathcal{G}$-structured spaces can be organized into an ∞-category $\mathcal{T}\mathrm{op}(\mathcal{G}) = \mathcal{T}\mathrm{op} \times_{\infty\mathcal{T}\mathrm{op}} \infty\mathcal{T}\mathrm{op}(\mathcal{G})$. We will refer to $\mathcal{T}\mathrm{op}(\mathcal{G})$ as *the ∞-category of $\mathcal{G}$-structured spaces.*

The relationship between Constructions 21.4.1.1 and 21.4.1.5 can be summarized by the following relative version of Proposition 21.2.2.1, whose proof we leave to the reader:

Proposition 21.4.1.8. *Let $\mathcal{G}$ be an essentially small ∞-category which admits finite limits and let $\mathcal{C} = \mathrm{Ind}(\mathcal{G}^{\mathrm{op}})$. Then there is a canonical equivalence of ∞-categories $\rho : \infty\mathcal{T}\mathrm{op}_{\mathcal{C}} \to \infty\mathcal{T}\mathrm{op}(\mathcal{G})$ given on objects by the construction $(\mathcal{X}, \mathscr{F}) \mapsto (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$, where $\mathscr{O}_{\mathcal{X}}$ is characterized by the formula $\mathrm{Map}_{\mathcal{X}}(X, \mathscr{O}^T_{\mathcal{X}}) \simeq \mathrm{Map}_{\mathcal{C}}(T, \mathscr{F}(X))$ for $X \in \mathcal{X}$ and $T \in \mathcal{G}$.*

Remark 21.4.1.9. Even without the assumption that $\mathcal{G}$ admits finite limits, we still have a fully faithful embedding $\infty\mathcal{T}\mathrm{op}_{\mathcal{C}} \hookrightarrow \infty\mathcal{T}\mathrm{op}(\mathcal{G})$.

Corollary 21.4.1.10. *Let $\mathcal{G}$ be an essentially small ∞-category which admits finite limits. Then the forgetful functor $\infty\mathcal{T}\mathrm{op}(\mathcal{G}) \to \infty\mathcal{T}\mathrm{op}$ is a coCartesian fibration.*

Proof. Apply Proposition 21.4.1.8 (noting that the forgetful functor $\infty\mathcal{T}\mathrm{op}_{\mathrm{Ind}(\mathcal{G}^{\mathrm{op}})} \to \infty\mathcal{T}\mathrm{op}$ is a coCartesian fibration by construction); alternatively, this follows directly from Remark 21.2.1.8. □

Corollary 21.4.1.11. *Let $\mathcal{C}$ be a compactly generated ∞-category. Then the forgetful functor $\infty\mathcal{T}\mathrm{op}_{\mathcal{C}} \to \infty\mathcal{T}\mathrm{op}$ is a Cartesian fibration.*

Proof. Apply Proposition 21.4.1.8 in the case where $\mathcal{G} = \mathcal{C}_c^{\mathrm{op}}$, noting that the forgetful functor $\infty\mathcal{T}\mathrm{op}(\mathcal{G}) \to \infty\mathcal{T}\mathrm{op}$ is a Cartesian fibration by construction. □

Corollary 21.4.1.12. *Let $\mathcal{G}$ be an essentially small ∞-category which admits finite limits and let $\mathcal{C} = \mathrm{Ind}(\mathcal{G}^{\mathrm{op}})$. Then there is a canonical equivalence of ∞-categories $\rho : \mathcal{T}\mathrm{op}_{\mathcal{C}} \to \mathcal{T}\mathrm{op}(\mathcal{G})$ given on objects by the construction $(X, \mathscr{F}) \mapsto (X, \mathscr{O}_X)$, where $\mathscr{O}_{\mathcal{X}}$ is characterized by the formula $\mathscr{O}_X^T(U) = \mathrm{Map}_{\mathcal{C}}(T, \mathscr{F}(U))$ for $U \subseteq X$ and $T \in \mathcal{G}$.*

Proof. Combine Proposition 21.4.1.8 with Remark **??**. □

Example 21.4.1.13 (Ringed Spaces)**.** Let Aff denote the category of affine schemes of finite type of over **Z**. Using Corollary 21.4.1.12, we obtain an equivalence $\mathcal{T}\mathrm{op}(\mathrm{Aff}) \simeq \mathcal{T}\mathrm{op}_{\mathrm{CAlg}^\heartsuit}$, where $\mathcal{T}\mathrm{op}_{\mathrm{CAlg}^\heartsuit}$ denotes the category of ringed spaces (Definition 1.1.1.1).

Example 21.4.1.14 (Spectrally Ringed Spaces)**.** Let $\mathrm{Aff}_{\mathrm{Sp}}$ denote the opposite of the ∞-category CAlg_c of compact $\mathbb{E}_\infty$-rings. Then Proposition 21.2.2.1 supplies an equivalence of $\infty\mathcal{T}\mathrm{op}(\mathrm{Aff}_{\mathrm{Sp}})$ with the ∞-category $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ of spectrally ringed ∞-topoi (Construction 1.4.1.3). Similarly, Corollary 21.4.1.12 supplies an equivalence of $\mathcal{T}\mathrm{op}(\mathrm{Aff}_{\mathrm{Sp}})$ with the ∞-category $\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ of spectrally ringed spaces (Definition 1.1.2.5).

We now consider a variant of Construction 21.4.1.5.

Construction 21.4.1.15. Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site (Definition 20.6.2.1). We let $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ denote the (non-full) subcategory of $\infty\mathcal{T}\mathrm{op}(\mathcal{G})$ described as follows:

- An object $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ of $\infty\mathcal{T}\mathrm{op}(\mathcal{G})$ belongs to $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ if and only if $\mathscr{O}_{\mathcal{X}}$ belongs to the full subcategory $\mathrm{Obj}_{\mathcal{G}}^{\tau}(\mathcal{X}) \subseteq \mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$ (see Definition 21.2.1.1).

- A morphism $(f, \alpha) : (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ in $\infty\mathcal{T}\mathrm{op}(\mathcal{G})$ belongs to $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ if and only if $\mathscr{O}_{\mathcal{X}}$ and $\mathscr{O}_{\mathcal{Y}}$ belong to $\mathrm{Obj}_{\mathcal{G}}^{\tau}(\mathcal{X})$ and $\mathrm{Obj}_{\mathcal{G}}^{\tau}(\mathcal{Y})$, and the morphism $\alpha : f^* \mathscr{O}_{\mathcal{Y}} \to \mathscr{O}_{\mathcal{X}}$ is local (in the sense of Definition 21.2.4.1).

We will refer to $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ as *the ∞-category of locally $\mathcal{G}$-structured ∞-topoi.* We let $\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ denote the fiber product $\mathcal{T}\mathrm{op} \times_{\infty\mathcal{T}\mathrm{op}} \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$, which we refer to as *the ∞-category of locally $\mathcal{G}$-structured spaces.*

In the case where $\mathcal{G}^{\mathrm{ad}} = \mathcal{G}^{\simeq}$ is the trivial admissibility structure on $\mathcal{G}$ (that is, only equivalences in $\mathcal{G}$ are admissible), then we will denote $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ and $\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ by $\infty\mathcal{T}\mathrm{op}^{\tau}(\mathcal{G})$ and $\mathcal{T}\mathrm{op}^{\tau}(\mathcal{G})$, respectively.

Remark 21.4.1.16. In the situation of Construction 21.4.1.15, the forgetful functor $U : \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G}) \to \infty\mathcal{T}\mathrm{op}$ is a Cartesian fibration, classified by the functor $\mathcal{X} \mapsto \mathrm{Obj}_{\mathcal{G}}^{\tau,\mathrm{loc}}(\mathcal{X})$. Beware that U is usually *not* a coCartesian fibration, even when $\mathcal{G}$ admits finite limits.

Example 21.4.1.17 (Algebraic Geometry: Zariski Topology)**.** Let $(\mathrm{Aff}, \mathrm{Aff}^{\mathrm{Zar}}, \tau_{\mathrm{Zar}})$ be the geometric site of Example 20.6.4.1, and set $\infty\mathcal{T}\mathrm{op}^{\mathrm{Zar}}(\mathrm{Aff}) = \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathrm{Aff})$. Using Propositions 21.2.5.1 and 21.4.1.8, we can identify the objects of $\infty\mathcal{T}\mathrm{op}^{\mathrm{Zar}}(\mathrm{Aff})$ with pairs $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$, where $\mathcal{X}$ is an ∞-topos and $\mathscr{O}_{\mathcal{X}}$ is a local commutative ring object of the underlying topos $\mathcal{X}^{\heartsuit}$. More precisely, we have a pullback diagram

$$\begin{array}{ccc} \infty\mathcal{T}\mathrm{op}^{\mathrm{Zar}}(\mathrm{Aff}) & \longrightarrow & 1\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}^{\heartsuit}} \\ \downarrow & & \downarrow \\ \infty\mathcal{T}\mathrm{op} & \xrightarrow{\heartsuit} & 1\mathcal{T}\mathrm{op} \end{array}$$

where $1\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}^{\heartsuit}}$ is the 2-category of locally ringed topoi (Definition 1.2.1.4). In particular, we can identify $\mathcal{T}\mathrm{op}^{\mathrm{Zar}}(\mathrm{Aff}) = \mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathrm{Aff})$ with the category $\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}^{\heartsuit}}$ of locally ringed spaces (see Definition 1.1.5.1).

Example 21.4.1.18 (Algebraic Geometry: Étale Topology)**.** Let $(\mathrm{Aff}, \mathrm{Aff}^{\text{ét}}, \tau_{\text{ét}})$ be the geometric site of Example **??** and set $\infty\mathcal{T}\mathrm{op}^{\text{ét}}(\mathrm{Aff}) = \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathrm{Aff})$. Using Propositions 21.2.5.1 and 21.4.1.8, we can identify the objects of $\infty\mathcal{T}\mathrm{op}^{\text{ét}}(\mathrm{Aff})$ with pairs $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$, where $\mathcal{X}$ is an ∞-topos and $\mathscr{O}_{\mathcal{X}}$ is a strictly Henselian commutative ring object of the underlying topos $\mathcal{X}^{\heartsuit}$. More precisely, we have a pullback diagram

$$\begin{array}{ccc} \infty\mathcal{T}\mathrm{op}^{\text{ét}}(\mathrm{Aff}) & \longrightarrow & 1\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}^{\heartsuit}} \\ \downarrow & & \downarrow \\ \infty\mathcal{T}\mathrm{op} & \xrightarrow{\heartsuit} & 1\mathcal{T}\mathrm{op} \end{array}$$

where $1\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}^{\heartsuit}}$ is the 2-category of locally ringed topoi with strictly Henselian structure sheaf (Definition 1.2.2.5).

Example 21.4.1.19 (Spectral Algebraic Geometry: Zariski Topology)**.** Let $(\mathrm{Aff}_{\mathrm{Sp}}, \mathrm{Aff}^{\mathrm{Zar}}_{\mathrm{Sp}}, \tau_{\mathrm{Zar}})$ be the geometric site of Example 20.6.4.4 and set $\infty\mathcal{T}\mathrm{op}^{\mathrm{Zar}}(\mathrm{Aff}_{\mathrm{Sp}}) = \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathrm{Aff}_{\mathrm{Sp}})$. Using Propositions 21.2.5.3 and 21.4.1.8, we can identify the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{Zar}}(\mathrm{Aff}_{\mathrm{Sp}})$ with the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ of locally spectrally ringed ∞-topoi (see Definition 1.4.2.1). In particular, we can identify $\mathcal{T}\mathrm{op}^{\mathrm{Zar}}(\mathrm{Aff}_{\mathrm{Sp}}) = \mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathrm{Aff}_{\mathrm{Sp}})$ with the ∞-category of locally spectrally ringed spaces (see Definition 1.1.5.3).

Example 21.4.1.20 (Spectral Algebraic Geometry: Étale Topology)**.** Let $(\mathrm{Aff}_{\mathrm{Sp}}, \mathrm{Aff}^{\text{ét}}_{\mathrm{Sp}}, \tau_{\text{ét}})$ be the geometric site of Example **??** and set $\infty\mathcal{T}\mathrm{op}^{\text{ét}}(\mathrm{Aff}_{\mathrm{Sp}}) = \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathrm{Aff}_{\mathrm{Sp}})$. Using

Propositions 21.2.5.3 and 21.4.1.8, we can identify the ∞-category $\infty\mathcal{T}\mathrm{op}^{\text{ét}}(\mathrm{Aff}_{\mathrm{Sp}})$ with the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$ of locally spectrally ringed ∞-topoi with strictly Henselian structure sheaf (see Definition 1.4.2.1).

21.4.2 The ∞-Category $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$

The constructions of §21.4.1 can be reformulated (and slightly generalized) by working directly with classifying ∞-topoi, rather than (geometric) sites.

Construction 21.4.2.1 (The ∞-Category $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$)**.** Let $\mathcal{E}$ be an ∞-topos. For every ∞-topos $\mathcal{X}$, we let $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{E}, \mathcal{X})$ whose objects are functors which preserve small colimits and finite limits. Note that if $f^* : \mathcal{X} \to \mathcal{Y}$ belongs to $\mathrm{Fun}^*(\mathcal{X}, \mathcal{Y})$, then composition with f^* determines a functor $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X}) \to \mathrm{Fun}^*(\mathcal{E}, \mathcal{Y})$. We can therefore view the construction $\mathcal{X} \mapsto \mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$ as a functor $\infty\mathcal{T}\mathrm{op}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_{\infty}$. We let $U : \infty\mathcal{T}\mathrm{op}(\mathcal{E}) \to \infty\mathcal{T}\mathrm{op}$ be a Cartesian fibration classified by the functor $\mathcal{X} \mapsto \mathrm{Fun}^*(\mathcal{E}, \mathcal{X})^{\mathrm{op}}$.

Warning 21.4.2.2. We notation $\infty\mathcal{T}\mathrm{op}(\mathcal{U})$ has now been assigned two different meanings: that of Construction 21.4.1.5 in the case where $\mathcal{U}$ is an essentially small ∞-category, and that of Construction 21.4.2.1 when $\mathcal{U}$ is an ∞-topos. There is some slight danger of confusion, because it is possible for an ∞-category $\mathcal{U}$ to satisfy both of these conditions. This happens only when $\mathcal{U}$ is a contractible Kan complex, and in this case Constructions 21.4.1.5 and 21.4.2.1 do not agree (the ∞-category $\infty\mathcal{T}\mathrm{op}(\mathcal{U})$ of Construction 21.4.1.5 is equivalent to $\infty\mathcal{T}\mathrm{op}$, while the ∞-category $\infty\mathcal{T}\mathrm{op}(\mathcal{U})$ is a contractible Kan complex).

Remark 21.4.2.3. Let $\mathcal{E}$ be an ∞-topos. Then the ∞-category $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$ can be viewed as a *lax* version of the overcategory $\infty\mathcal{T}\mathrm{op}_{/\mathcal{E}}$. The objects of $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$ can be identified with $\pi_* : \mathcal{X} \to \mathcal{E}$ in the ∞-category $\infty\mathcal{T}\mathrm{op}$, with morphisms from $\pi_* : \mathcal{X} \to \mathcal{E}$ to $\pi'_* : \mathcal{X}' \to \mathcal{E}$ given by diagrams

$$\begin{array}{ccc} \mathcal{X} & \xrightarrow{f_*} & \mathcal{X}' \\ & {\scriptstyle \pi_*}\searrow \quad \swarrow{\scriptstyle \pi'_*} & \\ & \mathcal{E} & \end{array}$$

which commute up to a possibly non-invertible natural transformation $\alpha : \pi_* \to \pi'_* \circ f_*$. In particular, the ∞-category $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$ contains the usual overcategory $\infty\mathcal{T}\mathrm{op}_{/\mathcal{E}}$ as a (non-full) subcategory; see Proposition 21.4.4.5 for more details.

Example 21.4.2.4. Let $\mathcal{G}$ be an essentially small ∞-category equipped with a Grothendieck topology τ, and let $\mathcal{E} = \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ be the associated ∞-topos. Then composition with the sheafified Yoneda embedding $h : \mathcal{G} \to \mathcal{E}$ induces an equivalence $\mathrm{Fun}^*(\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G}), \mathcal{X}) \to \mathrm{Obj}^{\tau}_{\mathcal{G}}(\mathcal{X})$ for every ∞-topos $\mathcal{X}$ (Proposition 21.2.1.13), which depends functorially on $\mathcal{X}$. It follows that h induces an equivalence of ∞-categories $\infty\mathcal{T}\mathrm{op}(\mathcal{E}) \to \infty\mathcal{T}\mathrm{op}^{\tau}(\mathcal{G})$, where $\infty\mathcal{T}\mathrm{op}^{\tau}(\mathcal{G})$ is defined as in Construction 21.4.1.15.

Example 21.4.2.5. Let $\mathcal{C}$ be a small ∞-category which admits finite colimits, and let $\mathcal{E} = \mathrm{Fun}(\mathcal{C}, \mathcal{S})$ denote the ∞-topos of presheaves on $\mathcal{C}^{\mathrm{op}}$. Combining Example 21.4.2.4 with Proposition 21.4.1.8, we obtain an equivalence of ∞-categories $\infty\mathcal{T}\mathrm{op}(\mathcal{E}) \simeq \infty\mathcal{T}\mathrm{op}_{\mathrm{Ind}(\mathcal{C})}$,

Definition 21.4.2.6. Let $\mathcal{E}$ be an ∞-topos equipped with a fracture subcategory $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$. We let $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ denote the (non-full) subcategory of $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$ whose morphisms are given by diagrams of ∞-topoi

$$\begin{array}{ccc} \mathcal{X} & \xrightarrow{f_*} & \mathcal{X}' \\ & {\scriptstyle \pi_*}\searrow \quad \swarrow{\scriptstyle \pi'_*} & \\ & \mathcal{E} & \end{array}$$

which commute up to a natural transformation $\pi_* \to \pi'_* \circ f_*$ for which the induced map of left adjoints $f^* \circ \pi'^* \to \pi^*$ is local, in the sense of Definition 21.2.4.4.

Remark 21.4.2.7. Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos. Then the Cartesian fibration $\infty\mathcal{T}\mathrm{op}(\mathcal{E}) \to \infty\mathcal{T}\mathrm{op}$ restricts to a Cartesian fibration $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E}) \to \infty\mathcal{T}\mathrm{op}$, which is classified by the functor

$$\infty\mathcal{T}\mathrm{op}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_{\infty} \qquad \mathcal{X} \mapsto \mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{X}).$$

Warning 21.4.2.8. In the situation of Construction 21.4.2.1, the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ depends not only on $\mathcal{E}$, but also on the choice of a fracture subcategory $\mathcal{E}^{\mathrm{corp}}$ (however, it depends only on the *completion* of $\mathcal{E}^{\mathrm{corp}}$, in the sense of Remark 20.3.4.7: see Remark 21.2.4.9.

Example 21.4.2.9. Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site (Definition 20.6.2.1) and regard $\mathcal{E} = \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ as equipped with the fracture subcategory $\mathcal{E}^{\mathrm{corp}} = \mathcal{S}\mathrm{hv}^{\mathrm{corp}}_{\tau}(\mathcal{G})$ of Theorem 20.6.3.4. Then composition with the sheafified Yoneda embedding $h : \mathcal{G} \to \mathcal{E}$ induces an equivalence $\mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G}), \mathcal{X}) \to \mathrm{Obj}^{\tau,\mathrm{loc}}_{\mathcal{G}}(\mathcal{X})$ for every ∞-topos $\mathcal{X}$ (Corollary 21.2.4.12), which depends functorially on $\mathcal{X}$. It follows that h induces an equivalence of ∞-categories $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E}) \to \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$, where $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ is defined as in Construction 21.4.1.15.

21.4.3 Filtered Limits in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$

Let $\infty\mathcal{T}\mathrm{op}$ be the ∞-category of ∞-topoi. Then the ∞-category $\infty\mathcal{T}\mathrm{op}$ admits all small limits (Corollary **??**). Moreover, *filtered* limits in the ∞-category $\infty\mathcal{T}\mathrm{op}$ are particularly easy to understand: they can be computed at the level of the underlying ∞-categories (in other words, the forgetful functor $\infty\mathcal{T}\mathrm{op} \hookrightarrow \widehat{\mathcal{C}\mathrm{at}}_{\infty}$ preserves filtered limits: see Theorem HTT.6.3.3.1). In this section, we will show that an analogous statement holds for the variants of $\infty\mathcal{T}\mathrm{op}$ described in §21.4.1 and §21.4.2. Our main result can be stated as follows:

Theorem 21.4.3.1. (1) *Let $\mathcal{E}$ be an ∞-topos. Then the ∞-category $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$ of Construction 21.4.2.1 admits small filtered limits, which are preserved by the forgetful functor $\infty\mathcal{T}\mathrm{op}(\mathcal{E}) \to \infty\mathcal{T}\mathrm{op}$.*

(2) *Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos. Then the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ of Definition 21.4.2.6 admits small filtered limits, which are preserved by the inclusion functor $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E}) \hookrightarrow \infty\mathcal{T}\mathrm{op}(\mathcal{E})$ (and therefore also by the forgetful functor $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E}) \to \infty\mathcal{T}\mathrm{op}$.*

(3) *Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site. Then the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ of Construction 21.4.1.15 admits small filtered limits, which are preserved by the forgetful functor $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G}) \to \infty\mathcal{T}\mathrm{op}$.*

(4) *Let $\mathcal{C}$ be a compactly generated ∞-category. Then the ∞-category $\infty\mathcal{T}\mathrm{op}_{\mathcal{C}}$ of Construction 21.4.1.1 admits small filtered limits, which are preserved by the forgetful functor $\infty\mathcal{T}\mathrm{op}_{\mathcal{C}} \to \infty\mathcal{T}\mathrm{op}$.*

We will deduce Theorem 21.4.3.1 from the following:

Proposition 21.4.3.2. *Let $\mathcal{E}$ and $\mathcal{X}$ be ∞-topoi. Then:*

(*i*) *The ∞-category $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$ admits small filtered colimits, which are preserved by the inclusion functor $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X}) \hookrightarrow \mathrm{Fun}(\mathcal{E}, \mathcal{X})$.*

(*ii*) *Suppose that $\mathcal{E}$ is equipped with a fracture subcategory $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$. Then the ∞-category $\mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{X})$ admits small filtered colimits, which are preserved by the inclusion $\mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{X}) \hookrightarrow \mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$.*

Let us assume Proposition 21.4.3.2 for the moment, and gather some consequences.

Corollary 21.4.3.3. *Let $\mathcal{E}$ be an ∞-topos. Then, for any geometric morphism of ∞-topoi $f^* : \mathcal{X} \to \mathcal{Y}$, composition with f^* induces a functor $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X}) \to \mathrm{Fun}^*(\mathcal{E}, \mathcal{Y})$ which preserves small filtered colimits. If $\mathcal{E}$ is equipped with a fracture subcategory $\mathcal{E}^{\mathrm{corp}}$, then the induced map $\mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{X}) \to \mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{Y})$ also preserves small filtered colimits.*

Warning 21.4.3.4. If $\mathcal{E}$ and $\mathcal{X}$ are ∞-topoi, then the ∞-category $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$ is always accessible (Proposition HTT.6.3.1.13). However, if $\mathcal{E}$ is equipped with a fracture subcategory $\mathcal{E}^{\mathrm{corp}}$, then the subcategory of local morphisms $\mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{X})$ need not be accessible. For example, if $\mathcal{E}^{\mathrm{corp}} = \mathcal{E}$, then $\mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{X}) \simeq \mathrm{Fun}^*(\mathcal{E}, \mathcal{X})^{\simeq}$ is accessible if and only if the ∞-category $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$ is essentially small.

Corollary 21.4.3.5. *Let $\mathcal{E}$ be an ∞-topos and let $\mathcal{I}$ be a small filtered ∞-category. Then:*

(1) *Every commutative diagram*

$$\begin{array}{ccc} \mathcal{I}^{\mathrm{op}} & \longrightarrow & \infty\mathcal{T}\mathrm{op}(\mathcal{E}) \\ \big\downarrow & \nearrow & \big\downarrow U \\ (\mathcal{I}^{\mathrm{op}})^{\triangleleft} & \longrightarrow & \infty\mathcal{T}\mathrm{op} \end{array}$$

admits a completion as indicated, where the dotted arrow is a U-limit diagram in $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$ (here U denotes the forgetful functor).

(2) *Suppose that $\mathcal{E}$ is equipped with a fracture subcategory $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$. Then every commutative diagram*

$$\begin{array}{ccc} \mathcal{I}^{\mathrm{op}} & \longrightarrow & \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E}) \\ \big\downarrow & \nearrow & \big\downarrow U^{\mathrm{loc}} \\ (\mathcal{I}^{\mathrm{op}})^{\triangleleft} & \longrightarrow & \infty\mathcal{T}\mathrm{op} \end{array}$$

admits a completion as indicated, where the dotted arrow is a U^{loc}-limit diagram in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$. Moreover, this completion is also a U-limit diagram.

Proof. Combine Proposition 21.4.3.2, Corollary 21.4.3.3, and Corollary HTT.4.3.1.11 . □

Proof of Theorem 21.4.3.1. Assertions (1) and (2) follow from Corollary 21.4.3.5, Theorem HTT.6.3.3.1 , and Proposition HTT.4.3.1.5 . The implication (2) ⇒ (3) follows from Example 21.4.2.9, and the implication (3) ⇒ (4) follows from Proposition **??**. □

Proof of Proposition 21.4.3.2. Let A be a (small) filtered partially ordered set and let $\{f^*_\alpha\}_{\alpha \in A}$ be a diagram in the ∞-category $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$ having colimit f^* in $\mathrm{Fun}(\mathcal{E}, \mathcal{X})$. To prove Proposition 21.4.3.2, we must establish the following:

(a) The functor f^* belongs to $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$.

(b) Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fracture subcategory and suppose that, for each $\alpha \leqslant \beta$ in A, the associated natural transformation $f^*_\alpha \to f^*_\beta$ is local. Then each of the natural transformations $f^*_\alpha \to f^*$ is local.

(c) In the situation of (b), suppose we are given a natural transformation $u : f^* \to g^*$, where $g^* \in \mathrm{Fun}^*(\mathcal{X}, \mathcal{Y})$. Suppose further that each of the induced transformations $u_\alpha : f^*_\alpha \to g^*$ is local. Then u is local.

Assertion (a) follows immediately from Lemma HTT.5.5.2.3 and Example HTT.7.3.4.7 . To prove (b), consider an arbitrary $U \to V$ in $\mathcal{E}^{\mathrm{corp}}$. We wish to show that the diagram σ :

$$\begin{array}{ccc} f^*_\alpha(U) & \longrightarrow & f^*(U) \\ \big\downarrow & & \big\downarrow \\ f^*_\alpha(V) & \longrightarrow & f^*(V) \end{array}$$

is a pullback square in $\mathcal{X}$. This is clear, since σ is a filtered colimit of pullback squares

$$\begin{array}{ccc} f_\alpha^*(U) & \longrightarrow & f_\beta^*(U) \\ \downarrow & & \downarrow \\ f_\alpha^*(V) & \longrightarrow & f_\beta^*(V) \end{array}$$

for $\beta \geqslant \alpha$. The proof of (c) is similar, using the fact that each diagram

$$\begin{array}{ccc} f^*(U) & \longrightarrow & g^*(U) \\ \downarrow & & \downarrow \\ f^*(V) & \longrightarrow & g^*(V) \end{array}$$

is a filtered colimit of diagrams of the form

$$\begin{array}{ccc} f_\alpha^*(U) & \longrightarrow & g^*(U) \\ \downarrow & & \downarrow \\ f_\alpha^*(V) & \longrightarrow & g^*(V) \end{array}$$

for $\alpha \in A$. □

21.4.4 Cartesian Colimits in $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$

We now consider the problem of constructing colimits of ∞-topoi equipped with structure sheaves. We begin with an easy observation.

Proposition 21.4.4.1. *Let K be a (small) simplicial set and let $\mathcal{C}$ be an ∞-category which admits K^{op}-indexed limits. Then the ∞-category $\infty\mathcal{T}\mathrm{op}_{\mathcal{C}}$ admits K-indexed colimits. Moreover, the forgetful functor $U : \infty\mathcal{T}\mathrm{op}_{\mathcal{C}} \to \infty\mathcal{T}\mathrm{op}$ preserves K-indexed colimits.*

Proof. Note that the ∞-category $\infty\mathcal{T}\mathrm{op}$ admits K-indexed colimits (Proposition HTT.6.3.2.3). By virtue of Proposition HTT.4.3.1.5 , it will suffice to show that for commutative diagram

$$\begin{array}{ccc} K & \longrightarrow & \infty\mathcal{T}\mathrm{op}_{\mathcal{C}} \\ \downarrow & \nearrow & \downarrow U \\ K^{\triangleright} & \longrightarrow & \infty\mathcal{T}\mathrm{op} \end{array}$$

admits an extension as indicated which is a U-colimit diagram. Using the criterion of Corollary HTT.4.3.1.11 , we are reduced to proving the following:

(i) For every ∞-topos $\mathcal{X}$, the ∞-category $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$ admits K^{op}-indexed limits.

(*ii*) For every geometric morphism of ∞-topoi $f_* : \mathcal{X} \to \mathcal{Y}$, the direct image functor $f_*^{\mathcal{C}} : \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{Y})$ (given by pointwise composition with f^*) preserves K^{op}-indexed limits.

Both assertions follow immediately from the observation that $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$ and $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{Y})$ are closed under K^{op}-indexed limits in the ∞-categories $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C})$ and $\mathrm{Fun}(\mathcal{Y}^{\mathrm{op}}, \mathcal{C})$, respectively. □

Let us review the proof of Proposition 21.4.4.1 in more informal language. To fix ideas, let us specialize to the case where $\mathcal{C} = \mathrm{CAlg}$ is the ∞-category of $\mathbb{E}_\infty$-rings. Suppose that we are given a diagram $\{(\mathcal{X}_I, \mathcal{O}_I)\}_{I \in \mathcal{I}}$ in the ∞-category $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ of spectrally ringed ∞-topoi, indexed by some (small) ∞-category $\mathcal{I}$. Then the underlying diagram $\{\mathcal{X}_I\}$ admits a colimit $\mathcal{X}$ in the ∞-category $\infty\mathcal{T}\mathrm{op}$. In particular, for each $I \in \mathcal{I}$ we have a tautological geometric morphism $f_{I*} : \mathcal{X}_I \to \mathcal{X}$. Then the colimit of the diagram $\{(\mathcal{X}_I, \mathcal{O}_I)\}_{I \in \mathcal{I}}$ is then given by the pair $(\mathcal{X}, \varprojlim_{I \in \mathcal{I}^{\mathrm{op}}} f_{I*} \mathcal{O}_I)$. Our analysis then depends on the following features of the theory of CAlg-valued sheaves:

(*a*) Every $\mathcal{C}$-valued sheaf $\mathcal{O}_I$ on $\mathcal{X}_I$ admits a direct image $f_{I*} \mathcal{O}_I$ on $\mathcal{X}$.

(*b*) The ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$ of CAlg-valued sheaves on $\mathcal{X}$ admits small limits (which are preserved by further direct image functors).

Beware that if we replace $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ by the subcategory $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ of *locally* spectrally ringed ∞-topoi, then the analogues of both (*a*) and (*b*) fail: local sheaves of $\mathbb{E}_\infty$-rings are not stable under either direct images or inverse limits. Consequently, it is not reasonable to expect to expect an analogue of Proposition 21.4.4.1 for the ∞-categories $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ and $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ introduced in §21.4.1 and §21.4.2. We will therefore restrict our attention to the study of a special class of diagrams, where in some sense the structure sheaf is not varying.

Definition 21.4.4.2. Let $\mathcal{E}$ be an ∞-topos and let $U : \infty\mathcal{T}\mathrm{op}(\mathcal{E}) \to \infty\mathcal{T}\mathrm{op}$ be the Cartesian fibration of Construction 21.4.2.1. We will say that a morphism in $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$ is *Cartesian* if it is U-Cartesian. We let $\infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{E})$ denote the (non-full) subcategory of $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$ spanned by the U-Cartesian morphisms.

Remark 21.4.4.3. Let $\mathcal{E}$ be an ∞-topos, and regard $\mathcal{E}$ as a fracture subcategory of itself (Example 20.1.2.2). Then the subcategory $\infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{E}) \subseteq \infty\mathcal{T}\mathrm{op}(\mathcal{E})$ of Definition 21.4.4.2 coincides with the subcategory $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E}) \subseteq \infty\mathcal{T}\mathrm{op}(\mathcal{E})$ of Definition 21.4.2.6.

Remark 21.4.4.4. Let $\mathcal{E}$ be an ∞-topos equipped with an arbitrary fracture subcategory $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$. Then we have an inclusion $\infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{E}) \subseteq \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$.

Proposition 21.4.4.5. *Let $\mathcal{E}$ be an ∞-topos. Then the forgetful functor $\infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{E}) \to \infty\mathcal{T}\mathrm{op}$ is a right fibration classified by the object $\mathcal{E} \in \infty\mathcal{T}\mathrm{op}$. In other words, there is an* *equivalence of ∞-categories $\infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{E}) \simeq \infty\mathcal{T}\mathrm{op}_{/\mathcal{E}}$ (compatible with the projection to $\infty\mathcal{T}\mathrm{op}$).*

Proof. The statement that the forgetful functor $\infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{E}) \to \infty\mathcal{T}\mathrm{op}$ is a right fibration is a special case of Corollary HTT.2.4.2.5 . To show that it is classified by the ∞-topos $\mathcal{E}$, it will suffices to observe that the object $(\mathcal{E}, \mathrm{id}_{\mathcal{E}})$ is a final object of $\infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{E})$ (see Proposition HTT.4.4.4.5), which follows easily from the definitions. □

Variant 21.4.4.6. Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site (Definition 20.6.2.1) and let $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ be the ∞-category of Construction 21.4.1.15. We let $\infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{G})$ denote the (non-full) subcategory of $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ spanned by the U-Cartesian morphisms, where $U : \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G}) \to \infty\mathcal{T}\mathrm{op}(\mathcal{G})$ is the forgetful functor.

Remark 21.4.4.7. Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site and let $\mathcal{E} = \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ be the associated ∞-topos. Then the equivalence $\infty\mathcal{T}\mathrm{op}(\mathcal{E}) \simeq \infty\mathcal{T}\mathrm{op}^{\tau}(\mathcal{G})$ of Example 21.4.2.4 restricts to an equivalence of ∞-categories $\infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{E}) \simeq \infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{G})$. In particular, the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{G})$ depends only on the ∞-category $\mathcal{G}$ and the Grothendieck topology τ, and not on the choice of admissibility structure $\mathcal{G}^{\mathrm{ad}}$.

Remark 21.4.4.8. In the situation of Variant 21.4.4.6, a morphism from $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ to $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ in the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ can be identified with a pair (f_*, α), where $f_* : \mathcal{X} \to \mathcal{Y}$ is a geometric morphism of ∞-topoi and $\alpha : f^* \mathscr{O}_{\mathcal{Y}} \to \mathscr{O}_{\mathcal{X}}$ is a local morphism of $\mathcal{G}$-objects. The pair (f_*, α) belongs to $\infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{G})$ if and only if the morphism α is an equivalence.

We can now state the main result of this section:

Proposition 21.4.4.9. *Let $\mathcal{E}$ be an ∞-topos. Then:*

(1) *The ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{E})$ admits small colimits.*

(2) *The forgetful functor $\infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{E}) \to \infty\mathcal{T}\mathrm{op}$ preserves small colimits.*

(3) *The inclusion functor $\infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{E}) \hookrightarrow \infty\mathcal{T}\mathrm{op}(\mathcal{E})$ preserves small colimits.*

(4) *For each fracture subcategory $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$, the inclusion $\infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{E}) \hookrightarrow \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ preserves small colimits.*

Warning 21.4.4.10. In the situation of Proposition 21.4.4.9, the ∞-categories $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$ and $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ need not admit small colimits.

Corollary 21.4.4.11. *Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site. Then the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{G})$ admits small colimits, which are preserved by the inclusion functors $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G}) \hookleftarrow \infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{G}) \hookrightarrow \infty\mathcal{T}\mathrm{op}^{\tau}(\mathcal{G})$ and by the forgetful functor $\infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{G}) \to \infty\mathcal{T}\mathrm{op}$.*

Proof. Combine Proposition 21.4.4.9 with Remark 21.4.4.7. □

We will deduce Proposition 21.4.4.9 from the following general categorical principle, whose proof we defer to the end of this section:

Lemma 21.4.4.12. *Let $p : X \to S$ be a coCartesian fibration of simplicial sets classified by a diagram $\chi : S \to \mathcal{C}\mathrm{at}_\infty$. Let $q : K^{\triangleleft} \to X$ be a diagram with the following properties:*

- (a) *The composition $\chi \circ p \circ q : K^{\triangleleft} \to \mathcal{C}\mathrm{at}_\infty$ is a limit diagram.*
- (b) *The diagram q carries each edge of $K^{\triangleleft}$ to a p-coCartesian morphism in X.*

Then q is a p-limit diagram.

Proof of Proposition 21.4.4.9. According to Proposition HTT.6.3.2.3 , the ∞-category $\infty\mathcal{T}\mathrm{op}$ admits small colimits. It follows that, for any ∞-topos $\mathcal{E}$, the ∞-category $\infty\mathcal{T}\mathrm{op}_{/\mathcal{E}}$ also admits small colimits, which are preserved by the forgetful functor $\infty\mathcal{T}\mathrm{op}_{/\mathcal{E}} \to \infty\mathcal{T}\mathrm{op}$ (see Proposition HTT.1.2.13.8). Assertions (1) and (2) of Proposition 21.4.4.9 now follow from Proposition 21.4.4.5. To prove (3) and (4), it will suffice (by virtue of Lemma 21.4.4.12) to establish the following:

- $(3')$ For any ∞-topos $\mathcal{E}$, the construction $\mathcal{X} \mapsto \mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$ determines a functor $\infty\mathcal{T}\mathrm{op}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ which preserves small limits.
- $(4')$ For any fractured subcategory $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$, the construction $\mathcal{X} \mapsto \mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{E}, \mathcal{X})$ determines a functor $\infty\mathcal{T}\mathrm{op}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ which preserves small limits.

Since the forgetful functor $\infty\mathcal{T}\mathrm{op}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ preserves small limits (Proposition HTT.6.3.2.1), it follows immediately from the definitions that the construction $\mathcal{X} \mapsto \mathrm{Fun}(\mathcal{E}, \mathcal{X})$ preserves small limits. We may therefore deduce $(3')$ and $(4')$ from the following elementary observations:

- $(3'')$ Let $\mathcal{X}$ be the colimit of a diagram $\{\mathcal{X}_\alpha\}$ in $\infty\mathcal{T}\mathrm{op}$. Then a functor $f^* : \mathcal{E} \to \mathcal{X}$ preserves small colimits and finite limits if and only if, for each index α, the composite functor
$$\mathcal{E} \xrightarrow{f^*} \mathcal{X} \to \mathcal{X}_\alpha$$
preserves small colimits and finite limits.
- $(4'')$ Let $\mathcal{X}$ be the colimit of a diagram $\{\mathcal{X}_\alpha\}$ in $\infty\mathcal{T}\mathrm{op}$, and let $u : f^* \to g^*$ be a morphism in $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$. Then u is local (with respect to some fracture subcategory $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$) if and only if, for each index α, the image of u in $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X}_\alpha)$ is local.

□

Proof of Lemma 21.4.4.12. Using Corollary HTT.3.3.1.2, we may reduce to the case where S is an ∞-category (so that X is also an ∞-category). Choose a categorical equivalence $K \to K'$ which is a monomorphism of simplicial sets, where K' is an ∞-category. Since X is an ∞-category, the map q factors through $K'^{\triangleleft}$. We may therefore replace K by K' and thereby reduce to the case where K is an ∞-category. In view of Corollary HTT.4.3.1.15, we may replace S by $K^{\triangleleft}$ (and X by the pullback $X \times_S K^{\triangleleft}$) and thereby reduce to the case where $p \circ q$ is an isomorphism.

Consider the map $\pi : K^{\triangleleft} \to (\Delta^0)^{\triangleleft} \simeq \Delta^1$. Since K is an ∞-category, the map π is a Cartesian fibration of simplicial sets. Let $p' : \mathcal{C} \to \Delta^1$ be the "pushforward" of the coCartesian fibration p, so that $\mathcal{C}$ is characterized by the universal mapping property

$$\mathrm{Hom}_{\Delta^1}(Y, \mathcal{C}) \simeq \mathrm{Hom}_{K^{\triangleleft}}(Y \times_{\Delta^1} K^{\triangleleft}, X).$$

Corollary HTT.3.2.2.12 implies that p' is a coCartesian fibration, associated to some functor f from $\mathcal{C}_0 = \mathcal{C} \times_{\Delta^1} \{0\}$ to $\mathcal{C}_1 = \mathcal{C} \times_{\Delta^1} \{1\}$. We can identify $\mathcal{C}_0$ with the fiber of p over the cone point of $K^{\triangleleft}$, and $\mathcal{C}_1$ with the ∞-category of sections of p over K. Let $\mathcal{C}'_1$ denote the full subcategory of $\mathcal{C}_1$ spanned by the coCartesian sections. Combining Corollary HTT.3.2.2.12, Proposition HTT.3.3.3.1, and assumption (a), we deduce that f determines an equivalence $\mathcal{C}_0 \to \mathcal{C}'_1$.

Let $q_0 = q|_K$. We can identify q_0 with an object $C \in \mathcal{C}_1$, and q with a morphism $\alpha : C' \to C$ in $\mathcal{C}$. We then have a commutative diagram

$$\begin{array}{ccc} \mathcal{C}_0 \times_X X_{/q} & \longrightarrow & \mathcal{C}_0 \times_X X_{/q_0} \\ \downarrow & & \downarrow \\ \mathcal{C}_0 \times_{\mathcal{C}} \mathcal{C}_{/\alpha} & \longrightarrow & \mathcal{C}_0 \times_{\mathcal{C}} \mathcal{C}_{/C}. \end{array}$$

We wish to show that the upper horizontal map is a categorical equivalence. Since the vertical maps are isomorphisms, it will suffice to show that the lower horizontal map is a categorical equivalence. In other words, we wish to show that for every object $C_0 \in \mathcal{C}_0$, composition with α induces a homotopy equivalence $\mathrm{Map}_{\mathcal{C}_0}(C_0, C') \to \mathrm{Map}_{\mathcal{C}}(C_0, C)$. We have a commutative diagram (in the homotopy category of spaces)

$$\begin{array}{ccc} \mathrm{Map}_{\mathcal{C}_0}(C_0, C') & \longrightarrow & \mathrm{Map}_{\mathcal{C}}(C_0, C) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathcal{C}_1}(fC_0, fC') & \longrightarrow & \mathrm{Map}_{\mathcal{C}}(fC_0, C). \end{array}$$

Here the right vertical map is a homotopy equivalence. Since f is fully faithful, the left vertical map is also a homotopy equivalence. It therefore suffices to show that the bottom horizontal map is a homotopy equivalence: in other words, that α induces an equivalence $fC' \to C$. This is simply a translation of condition (b). $\square$

21.4.5 Clutching for Structured Spaces

Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos. In §21.4.4, we proved that every small diagram in the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{Cart}}(\mathcal{E})$ admits a colimit in the larger ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ (Proposition 21.4.4.9). The existence of colimits for general diagrams in the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ is more subtle. However, we do have the following partial result:

Proposition 21.4.5.1. *Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos, and suppose we are given a diagram*

$$(\mathcal{X}_0, \mathcal{O}_0) \leftarrow (\mathcal{X}_{01}, \mathcal{O}_{01}) \rightarrow (\mathcal{X}_1, \mathcal{O}_1)$$

in the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$. Assume that the underlying geometric morphisms $\mathcal{X}_0 \xleftarrow{f_*} \mathcal{X}_{01} \xrightarrow{g_*} \mathcal{X}_1$ are closed immersions of ∞-topoi. Then there exists a pushout square σ :

$$\begin{array}{ccc} (\mathcal{X}_{01}, \mathcal{O}_{01}) & \longrightarrow & (\mathcal{X}_0, \mathcal{O}_0) \\ \downarrow & & \downarrow \\ (\mathcal{X}_1, \mathcal{O}_1) & \longrightarrow & (\mathcal{X}, \mathcal{O}) \end{array}$$

in the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$. Moreover:

(1) *The underlying diagram of ∞-topoi*

$$\begin{array}{ccc} \mathcal{X}_{01} & \xrightarrow{f_*} & \mathcal{X}_0 \\ \downarrow{\scriptstyle g_*} & & \downarrow{\scriptstyle g'_*} \\ \mathcal{X}_1 & \xrightarrow{f'_*} & \mathcal{X} \end{array}$$

is a pushout square in $\infty\mathcal{T}\mathrm{op}$; let us denote the diagonal composition by $h_* : \mathcal{X}_{01} \to \mathcal{X}$.

(2) *For every corporeal object $T \in \mathcal{E}$, the natural map*

$$\mathcal{O}^T \to g'_* \, \mathcal{O}_0^T \times_{h_* \, \mathcal{O}_{01}^T} f'_* \, \mathcal{O}_1^T$$

is an equivalence in the ∞-topos $\mathcal{X}$.

(3) *The diagram σ is also a pushout square in $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$.*

Corollary 21.4.5.2. *Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site and suppose we are given a diagram*

$$(\mathcal{X}_0, \mathcal{O}_0) \leftarrow (\mathcal{X}_{01}, \mathcal{O}_{01}) \rightarrow (\mathcal{X}_1, \mathcal{O}_1)$$

in the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$, where the underlying geometric morphisms $\mathcal{X}_0 \xleftarrow{f_*} \mathcal{X}_{01} \xrightarrow{g_*} \mathcal{X}_1$ are closed immersions. Then there exists a pushout square σ:

$$\begin{array}{ccc} (\mathcal{X}_{01}, \mathcal{O}_{01}) & \longrightarrow & (\mathcal{X}_0, \mathcal{O}_0) \\ \downarrow & & \downarrow \\ (\mathcal{X}_1, \mathcal{O}_1) & \longrightarrow & (\mathcal{X}, \mathcal{O}) \end{array}$$

in the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$. Moreover:

(1) *The underlying diagram of ∞-topoi*

$$\begin{array}{ccc} \mathcal{X}_{01} & \xrightarrow{f_*} & \mathcal{X}_0 \\ \downarrow{\scriptstyle g_*} & & \downarrow{\scriptstyle g'_*} \\ \mathcal{X}_1 & \xrightarrow{f'_*} & \mathcal{X} \end{array}$$

is a pushout square in $\infty\mathcal{T}\mathrm{op}$; let us denote the diagonal composition by $h_* : \mathcal{X}_{01} \to \mathcal{X}$.

(2) *For every object $T \in \mathcal{G}$, the natural map*

$$\mathscr{O}^T \to g'_* \mathscr{O}_0^T \times_{h_* \mathscr{O}_{01}^T} f'_* \mathscr{O}_1^T$$

is an equivalence in the ∞-topos $\mathcal{X}$.

(3) *The diagram σ is also a pushout square in $\infty\mathcal{T}\mathrm{op}(\mathcal{G})$.*

Proof. Set $\mathcal{E} = \mathcal{S}\mathrm{hv}_\tau(\mathcal{G})$, and regard $\mathcal{E}$ as equipped with the fracture subcategory described in Theorem 20.6.3.4. Then the sheafified Yoneda embedding $h : \mathcal{G} \to \mathcal{E}$ is a presentation of $\mathcal{E}$. Using Proposition 20.5.4.1, we deduce that the collection of corporeal objects of $\mathcal{E}$ is closed under finite limits. The desired result now follows from Proposition **??** and Example **??**. □

The rest of this section is devoted to the proof of Proposition 21.4.5.1. We begin by treating the special case where $\mathcal{X}_0 = \mathcal{X}_{01} = \mathcal{X}_1$.

Lemma 21.4.5.3. *Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos, let $h : \mathcal{G} \to \mathcal{E}$ be a presentation of $\mathcal{E}$ (Definition 20.5.3.1). Let $\mathcal{X}$ be an ∞-topos, so that composition with h determines a fully faithful embedding $\iota : \mathrm{Fun}^*(\mathcal{E}, \mathcal{X}) \to \mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$. Suppose we are given a diagram*

$$\mathscr{O}_0 \to \mathscr{O}_{01} \leftarrow \mathscr{O}_1$$

in the ∞-category $\mathrm{Obj}_{\mathcal{G}}^{\mathrm{loc}}(\mathcal{X})$, and set $\mathscr{O} = \mathscr{O}_0 \times_{\mathscr{O}_{01}} \mathscr{O}_1$ (where the fiber product is formed in the ∞-category $\mathrm{Fun}(\mathcal{G}, \mathcal{X})$). If $\mathscr{O}_0$, $\mathscr{O}_{01}$, and $\mathscr{O}_1$ belong to the essential image of ι, then so does ι. Moreover, the diagram

$$\begin{array}{ccc} \mathscr{O} & \longrightarrow & \mathscr{O}_0 \\ \downarrow & & \downarrow \\ \mathscr{O}_1 & \longrightarrow & \mathscr{O}_{01} \end{array}$$

is a pullback square in $\mathrm{Obj}_{\mathcal{G}}^{\mathrm{loc}}(\mathcal{X})$.

Proof. Since the map $\mathscr{O}_1 \to \mathscr{O}_{01}$ is local, the pullback map $\mathscr{O} \to \mathscr{O}_0$ satisfies the hypothesis of Lemma 21.3.4.1. It follows that $\mathscr{O}$ belongs to the essential image of ι and that the map $\mathscr{O} \to \mathscr{O}_0$ is local. Similarly, the projection map $\mathscr{O} \to \mathscr{O}_1$ is local. To complete the proof, it will suffice to show that for any other object $\mathscr{O}' \in \mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$, a natural transformation $\alpha : \mathscr{O}' \to \mathscr{O}$ is local if and only if composite maps

$$\alpha_0 : \mathscr{O}' \to \mathscr{O} \to \mathscr{O}_0 \qquad \alpha_1 : \mathscr{O}' \to \mathscr{O} \to \mathscr{O}_1$$

are both local. The "only if" direction is trivial. For the converse, note that if α_0 is local and $U \to T$ is an admissible morphism in $\mathcal{G}$, then we have a commutative diagram

$$\begin{array}{ccccc} \mathscr{O}'^U & \longrightarrow & \mathscr{O}^U & \longrightarrow & \mathscr{O}_0^U \\ \downarrow & & \downarrow & & \downarrow \\ \mathscr{O}'^T & \longrightarrow & \mathscr{O}^T & \longrightarrow & \mathscr{O}_0^T \end{array}$$

where the outer rectangle and the right square are pullbacks, so that the left square is a pullback as well. □

To reduce Proposition 21.4.5.1 to the situation of Lemma 21.4.5.3, we will need the following:

Lemma 21.4.5.4. *Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos, let $h : \mathcal{G} \to \mathcal{E}$ be a presentation of $\mathcal{E}$, and let $\mathcal{X}$ be an ∞-topos containing a (-1)-truncated object U. Let $i^* : \mathcal{X} \to \mathcal{X} \backslash U$ and $j^* : \mathcal{X} \to \mathcal{X}_{/U}$ be the closed and open immersions associated to U. Then composition with h determines fully faithful embeddings*

$$\iota : \mathrm{Fun}^*(\mathcal{E}, \mathcal{X}) \to \mathrm{Obj}_{\mathcal{G}}(\mathcal{X}) \quad \iota' : \mathrm{Fun}^*(\mathcal{E}, \mathcal{X} \backslash U) \to \mathrm{Obj}_{\mathcal{G}}(\mathcal{X} \backslash U) \quad \iota'' : \mathrm{Fun}^*(\mathcal{E}, \mathcal{X}_{/U}) \to \mathrm{Obj}_{\mathcal{G}}(\mathcal{X}_{/U}).$$

Then:

(1) *A functor $\mathscr{O} : \mathcal{G} \to \mathcal{X}$ belongs to the essential image of ι if and only if $i^* \mathscr{O}$ and $j^* \mathscr{O}$ belong to the essential images of ι' and ι'', respectively.*

(2) *Let $\alpha : \mathscr{O} \to \mathscr{O}'$ be a morphism in $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X})$. Then α is local if and only if $i^*\alpha$ is a local morphism of $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X} \backslash U)$ and $j^*\alpha$ is a local morphism of $\mathrm{Obj}_{\mathcal{G}}(\mathcal{X}_{/U})$.*

Proof. We will prove (1); the proof of (2) is similar. The "only if" direction is obvious. Conversely, assume that $i^* \mathscr{O}$ and $j^* \mathscr{O}$ belong to the essential images of ι' and ι'', respectively. Extend $\mathscr{O}$ to a colimit-preserving functor $F : \mathcal{P}(\mathcal{G}) \to \mathcal{X}$, and the presentation h to a colimit-preserving functor $H : \mathcal{P}(\mathcal{G}) \to \mathcal{E}$. Our assumption guarantees that the functors i^*F and j^*F are left exact, so that F is left exact by virtue of Lemma **??**. To complete the proof, it will suffice to show that the functor F factors (up to homotopy) through the localization functor H. In other words, we must show that if α is a morphism in $\mathcal{P}(\mathcal{G})$ for which $H(\alpha)$ is an equivalence, then $F(\alpha)$ is also an equivalence. By assumption, the functors i^*F and j^*F factor (up to homotopy) through H, so that $i^*F(\alpha)$ and $j^*F(\alpha)$ are equivalences. Applying Lemma **??**, we deduce that $F(\alpha)$ is an equivalence, as desired. □

Proof of Proposition 21.4.5.1. Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos. Using Theorem 20.5.3.4, we can choose a presentation $\rho : \mathcal{G} \to \mathcal{E}$. Suppose we are given a pushout diagram of ∞-topoi

$$(\mathcal{X}_0, \mathcal{O}_0) \leftarrow (\mathcal{X}_{01}, \mathcal{O}_{01}) \rightarrow (\mathcal{X}_1, \mathcal{O}_1)$$

in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$, where the underlying geometric morphisms $\mathcal{X}_0 \xleftarrow{f_*} \mathcal{X}_{01} \xrightarrow{g_*} \mathcal{X}_1$ are closed immersions with complementary open immersions $j_* : \mathcal{U}_0 \to \mathcal{X}_0$ and $j'_* : \mathcal{U}_1 \to \mathcal{X}_1$. Form a pushout diagram of ∞-topoi

$$\begin{array}{ccc} \mathcal{X}_{01} & \xrightarrow{f_*} & \mathcal{X}_0 \\ \downarrow{\scriptstyle g_*} & & \downarrow{\scriptstyle g'_*} \\ \mathcal{X}_1 & \xrightarrow{f'_*} & \mathcal{X} \end{array}$$

and denote the diagonal composition by $h_* : \mathcal{X}_{01} \to \mathcal{X}$. Set $\overline{\mathcal{O}}_0 = \mathcal{O}_0 \circ \rho \in \mathrm{Obj}_{\mathcal{G}}(\mathcal{X}_0)$, and define $\overline{\mathcal{O}}_1 \in \mathrm{Obj}_{\mathcal{G}}(\mathcal{X}_1)$ and $\overline{\mathcal{O}}_{01} \in \mathrm{Obj}_{\mathcal{G}}(\mathcal{X}_{01})$ similarly. Let $\overline{\mathcal{O}} : \mathcal{G} \to \mathcal{X}$ be the functor given by the formula

$$\overline{\mathcal{O}}^T = g'_* \overline{\mathcal{O}}_0^T \times_{h_* \overline{\mathcal{O}}_{01}^T} f'_* \overline{\mathcal{O}}_1^T.$$

It follows from Lemma 21.4.5.3 that the pullback

$$h^* \overline{\mathcal{O}} \simeq f^* \overline{\mathcal{O}}_0 \times_{\overline{\mathcal{O}}_{01}} g^* \overline{\mathcal{O}}_1$$

belongs to the essential image of the embedding $\mathrm{Fun}^*(\mathcal{E}, \mathcal{X}_{01}) \to \mathrm{Obj}_{\mathcal{G}}(\mathcal{X}_{01})$. Moreover, $j^* g'^* \overline{\mathcal{O}} \simeq j^* \overline{\mathcal{O}}_0$ and $j'^* f'^* \overline{\mathcal{O}} \simeq j'^* \overline{\mathcal{O}}_1$ belong to the essential images of the embeddings $\mathrm{Fun}^*(\mathcal{E}, \mathcal{U}) \to \mathrm{Obj}_{\mathcal{G}}(\mathcal{U})$ and $\mathrm{Fun}^*(\mathcal{E}, \mathcal{U}') \to \mathrm{Obj}_{\mathcal{G}}(\mathcal{U}')$. Applying Lemma 21.4.5.4 twice, we deduce that $\overline{\mathcal{O}} \simeq \mathcal{O} \circ \rho$ for some $\mathcal{O} \in \mathrm{Fun}^*(\mathcal{E}, \mathcal{X})$. By construction, we have a commutative diagram σ :

$$\begin{array}{ccc} (\mathcal{X}_{01}, \mathcal{O}_{01}) & \longrightarrow & (\mathcal{X}_0, \mathcal{O}_0) \\ \downarrow & & \downarrow \\ (\mathcal{X}_1, \mathcal{O}_1) & \longrightarrow & (\mathcal{X}, \mathcal{O}) \end{array}$$

in the ∞-category $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$.

We now claim that σ is a pushout square in $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$. To prove this, let $\mathsf{Y} = (\mathcal{Y}, \mathcal{O}')$ be an arbitrary object of $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$. Set $\mathsf{X} = (\mathcal{X}, \mathcal{O}) \in \infty\mathcal{T}\mathrm{op}(\mathcal{E})$, and define $\mathsf{X}_0, \mathsf{X}_1, \mathsf{X}_{01} \in \infty\mathcal{T}\mathrm{op}(\mathcal{E})$

similarly. We then have a commutative diagram of spaces τ :

$$\begin{array}{ccc} \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}(\mathcal{E})}(\mathsf{X},\mathsf{Y}) & \longrightarrow & \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}(\mathcal{E})}(\mathsf{X}_0,\mathsf{Y}) \times_{\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}(\mathcal{E})}(\mathsf{X}_{01},\mathsf{Y})} \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}(\mathcal{E})}(\mathsf{X}_1,\mathsf{Y}) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{X},\mathcal{Y}) & \longrightarrow & \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{X}_0,\mathcal{Y}) \times_{\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{X}_{01},\mathcal{Y})} \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{X}_1,\mathcal{Y}) \end{array}$$

and we wish to show that the upper horizontal map is a homotopy equivalence. The lower horizontal map is a homotopy equivalence by construction, so it will suffice to show that τ is a homotopy pullback square: that is, that τ induces a homotopy equivalence after passing to the vertical homotopy fibers over any point $\eta_*; \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{X},\mathcal{Y})$. Equivalently, we wish to show that the diagram of spaces τ':

$$\begin{array}{ccc} \mathrm{Map}_{\mathrm{Fun}^*(\mathcal{E},\mathcal{X})}(\eta^*\,\mathcal{O}',\mathcal{O}) & \longrightarrow & \mathrm{Map}_{\mathrm{Fun}^*(\mathcal{E},\mathcal{X}_0)}(g'^*\eta^*\,\mathcal{O}',\mathcal{O}) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathrm{Fun}^*(\mathcal{E},\mathcal{X}_1)}(f'^*\eta^*\,\mathcal{O}',\mathcal{O}) & \longrightarrow & \mathrm{Map}_{\mathrm{Fun}^*(\mathcal{E},\mathcal{X}_{01})}(h^*\eta^*\,\mathcal{O}',\mathcal{O}) \end{array}$$

is a pullback square. Set $\overline{\mathcal{O}}' = \mathcal{O}' \circ \rho \in \mathrm{Obj}_{\mathcal{G}}(\mathcal{Y})$. Using our assumption that $\rho : \mathcal{G} \to \mathcal{E}$ is a presentation, we can rewrite the diagram τ' as

$$\begin{array}{ccc} \mathrm{Map}_{\mathrm{Fun}(\mathcal{G},\mathcal{X})}(\eta^*\overline{\mathcal{O}}',\overline{\mathcal{O}}) & \longrightarrow & \mathrm{Map}_{\mathrm{Fun}(\mathcal{G},\mathcal{X})}(\eta^*\overline{\mathcal{O}}',g'_*\overline{\mathcal{O}}_0) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathrm{Fun}(\mathcal{G},\mathcal{X})}(\eta^*\overline{\mathcal{O}}',f'_*\overline{\mathcal{O}}_1) & \longrightarrow & \mathrm{Map}_{\mathrm{Fun}(\mathcal{G},\mathcal{X})}(\eta^*\overline{\mathcal{O}}',h_*\overline{\mathcal{O}}_{01}), \end{array}$$

which is a pullback square by assumption.

We now claim that the diagram σ is also a pullback square in the subcategory $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$. To prove this, it will suffice to show that a morphism $(\mathcal{X},\mathcal{O}) \to (\mathcal{Y},\mathcal{O}')$ in $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$ belongs to $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ if and only if the composite maps $(\mathcal{X}_i,\mathcal{O}_i) \to (\mathcal{X},\mathcal{O}) \to (\mathcal{Y},\mathcal{O}')$ belong to $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ for $i = 0$ and $i = 1$. This follows immediately from Lemmas 21.4.5.3 and 21.4.5.4.

We have now proven assertions (1) and (3) of Proposition **??**, along with the following weaker version of (2):

(2′) For every object $T \in \mathcal{E}$ which belongs to the essential image of $\rho : \mathcal{G} \to \mathcal{E}$, the natural map

$$\mathcal{O}^T \to g'_*\,\mathcal{O}_0^T \times_{h_*\,\mathcal{O}_{01}^T} f'_*\,\mathcal{O}_1^T$$

is an equivalence in the ∞-topos $\mathcal{X}$.

To conclude that assertion (2) holds in general, it suffices to observe that every corporeal object of $\mathcal{E}$ belongs to the essential image of *some* presentation $\rho' : \mathcal{G}' \to \mathcal{E}$ (see Remark 20.5.3.7).

□

21.4.6 Étale Morphisms of Structured ∞-Topoi

We now specialize our attention to a particularly useful class of Cartesian morphisms.

Definition 21.4.6.1. Let $\mathcal{E}$ be an ∞-topos. We will say that a morphism f in the ∞-category $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$ is *étale* if it is Cartesian (in the sense of Definition 21.4.4.2) and the image of f under the forgetful functor $\infty\mathcal{T}\mathrm{op}(\mathcal{E}) \to \infty\mathcal{T}\mathrm{op}$ is an étale morphism of ∞-topoi. We let $\infty\mathcal{T}\mathrm{op}^{\text{ét}}(\mathcal{E})$ denote the (non-full) subcategory of $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$ spanned by the étale morphisms.

Remark 21.4.6.2. Let $\mathcal{E}$ be an ∞-topos. Every étale morphism in $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$ is Cartesian (Remark 21.4.4.4), and therefore belongs to $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ for any fracture subcategory $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$.

Variant 21.4.6.3. Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site. We will say that a morphism $f : (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}) \to (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is *étale* if it is Cartesian (in the sense of Variant 21.4.4.6) and the underlying geometric morphism $\mathcal{Y} \to \mathcal{X}$ is étale. Equivalently, f is étale if it determines an equivalence $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}) \simeq (\mathcal{X}_{/X}, \mathscr{O}_{\mathcal{X}}|_X)$ for some object $X \in \mathcal{X}$ (see Notation 21.2.1.7). We let $\infty\mathcal{T}\mathrm{op}^{\text{ét}}(\mathcal{G})$ denote the (non-full) subcategory of $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ spanned by the étale morphisms.

Some of basic properties of the class of étale morphisms are summarized in the following result:

Proposition 21.4.6.4. *Let $\mathcal{E}$ be an ∞-topos. Then:*

(1) *Every equivalence in the ∞-category $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$ is étale.*

(2) *Suppose given a commutative diagram*

$$\begin{array}{ccccc} & & (\mathcal{X}', \mathscr{O}_{\mathcal{X}'}) & & \\ & \overset{f}{\nearrow} & & \overset{g}{\searrow} & \\ (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) & & \xrightarrow{\quad h \quad} & & (\mathcal{X}'', \mathscr{O}_{\mathcal{X}''}) \end{array}$$

in $\infty\mathcal{T}\mathrm{op}(\mathcal{E})$, where g is étale. Then f is étale if and only if h is étale.

(3) *The ∞-category $\infty\mathcal{T}\mathrm{op}^{\text{ét}}(\mathcal{E})$ admits small colimits.*

(4) *Small colimits in* $\infty\mathcal{T}\mathrm{op}^{\acute{e}t}(\mathcal{E})$ *are preserved by the forgetful functor* $\infty\mathcal{T}\mathrm{op}^{\acute{e}t}(\mathcal{E})$*, the inclusion functor* $\infty\mathcal{T}\mathrm{op}^{\acute{e}t}(\mathcal{E}) \hookrightarrow \infty\mathcal{T}\mathrm{op}(\mathcal{E})$*, and the inclusion functor* $\infty\mathcal{T}\mathrm{op}^{\acute{e}t}(\mathcal{E}) \hookrightarrow \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ *for any choice of fracture subcategory* $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$*.*

(5) *Fix an object* $(\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \in \infty\mathcal{T}\mathrm{op}(\mathcal{E})$*. Then the* ∞*-category* $(\infty\mathcal{T}\mathrm{op}^{\acute{e}t}(\mathcal{E}))_{/(\mathcal{X},\mathcal{O}_{\mathcal{X}})}$ *is canonically equivalent to* $\mathcal{X}$*.*

Proof. Assertion (1) is obvious. Assertion (2) follows from Proposition HTT.2.4.1.7 and Corollary HTT.6.3.5.9. Assertions (3) and (4) follow from Proposition 21.4.4.9 and Theorem HTT.6.3.5.13. Assertion (5) follows from Remark HTT.6.3.5.10. □

Remark 21.4.6.5. Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site and let $f : (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a morphism in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$. The condition that f is étale is local in the following sense: if the ∞-topos $\mathcal{Y}$ admits a covering by objects $U_\alpha \in \mathcal{Y}$ for which each of the induced maps $(\mathcal{Y}_{/U_\alpha}, \mathcal{O}_{\mathcal{Y}}|_{U_\alpha}) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is étale, then f is étale. To prove this, we let $\mathcal{Y}_0$ denote the full subcategory of $\mathcal{X}$ spanned by those objects U for which the map $(\mathcal{Y}_{/U}, \mathcal{O}_{\mathcal{Y}}|_U) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is étale. Proposition 21.4.6.4 implies that $\mathcal{Y}_0$ is stable under the formation of small colimits. In particular, $U_0 = \amalg U_\alpha$ belongs to $\mathcal{Y}_0$. Let $U_\bullet$ be the simplicial object of $\mathcal{Y}$ given by the Čech nerve of the effective epimorphism $U_0 \to \mathbf{1}_{\mathcal{Y}}$. Since $\mathcal{Y}_0$ is a sieve, we deduce that each $U_n \in \mathcal{Y}_0$. Then $|U_\bullet| \simeq \mathbf{1}_{\mathcal{Y}} \in \mathcal{Y}_0$, so that f is étale as desired.

Remark 21.4.6.6. Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site and let $f : (\mathcal{X}_{/X}, \mathcal{O}_{\mathcal{X}}|_X) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be an étale morphism in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$. Suppose we are given some other morphism $g : (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \in \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$. Combining the fact that f is U-Cartesian (where $U : \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G}) \to \infty\mathcal{T}\mathrm{op}$ is the forgetful functor) with the universal property of the ∞-topos $\mathcal{X}_{/X}$ given by Remark HTT.6.3.5.7, we deduce the existence of a canonical fiber sequence

$$\Gamma(\mathcal{Y}; g^*X) \to \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})}((\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}), (\mathcal{X}_{/U}, \mathcal{O}_{\mathcal{X}}|_U) \to \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})}((\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}), (\mathcal{X}, \mathcal{O}_{\mathcal{X}})),$$

where $\Gamma(\mathcal{Y}; \bullet) : \mathcal{Y} \to \mathcal{S}$ denotes the global sections functor.

Remark 21.4.6.7. Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site and let $g : (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a morphism in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$. For any object $X \in \mathcal{X}$, the diagram

$$\begin{array}{ccc} (\mathcal{Y}_{/g^*X}, \mathcal{O}_{\mathcal{Y}}|_{g^*X}) & \longrightarrow & (\mathcal{X}_{/X}, \mathcal{O}_{\mathcal{X}}|_X) \\ \downarrow & & \downarrow \\ (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) & \longrightarrow & (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \end{array}$$

is a pullback square in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{G})$ (whose vertical maps are étale). This follows immediately from the universal property of Remark 21.4.6.6.

21.4.7 Corporeal Realization

Let Aff denote the category of affine schemes of finite type over $\mathbf{Z}$ and let $\mathcal{S}\mathrm{hv}_{\mathrm{Zar}}(\mathrm{Aff})$ denote the ∞-topos of $\mathcal{S}$-valued sheaves with respect to the Zariski topology on Aff. Example 21.4.1.17 supplies a functor

$$\theta : \mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}^{\heartsuit}} \to \infty\mathcal{T}\mathrm{op}(\mathrm{Aff}),$$

where $\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}^{\heartsuit}}$ denotes the category of locally ringed topological spaces (Definition 1.1.5.1) and $\infty\mathcal{T}\mathrm{op}(\mathrm{Aff})$ denotes the ∞-category of $\mathcal{S}\mathrm{hv}_{\mathrm{Zar}}(\mathrm{Aff})$-structured ∞-topoi. Since every scheme X can be regarded as a locally ringed space, we can compose θ with the inclusion map $\mathrm{Aff} \hookrightarrow \mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}^{\heartsuit}}$ to obtain a functor $\mathrm{Aff} \hookrightarrow \infty\mathcal{T}\mathrm{op}(\mathrm{Aff})$. Our goal in this section is to show that a similar phenomenon occurs if we replace $\mathcal{S}\mathrm{hv}_{\mathrm{Zar}}(\mathrm{Aff})$ by an arbitrary fractured ∞-topos.

Construction 21.4.7.1 (Corporeal Realization)**.** Let $\mathcal{E}$ be a fractured ∞-topos. For each object $X \in \mathcal{E}$, we let $\mathscr{O}_X$ denote a right adjoint to the forgetful functor $\mathcal{E}^{\mathrm{ad}}_{/X} \to \mathcal{E}$. Note that the functor $\mathscr{O}_X$ factors as a composition

$$\mathcal{E} \xrightarrow{\times X} \mathcal{E}_{/X} \xrightarrow{\rho} \mathcal{E}^{\mathrm{ad}}_{/X},$$

where ρ_X is a right adjoint to the inclusion $\mathcal{X}^{\mathrm{ad}}_{/X} \hookrightarrow \mathcal{X}_{/X}$ (see Definition 20.3.3.1). Since colimits in $\mathcal{X}$ are universal, the functor $\mathcal{E} \xrightarrow{\times X} \mathcal{E}_{/X}$ always preserves small colimits. If $X \in \mathcal{E}$ is corporeal, then the functor ρ_X also preserves small colimits (Example 20.3.3.2), so that $\mathscr{O}_X : \mathcal{E} \to \mathcal{E}^{\mathrm{ad}}_{/X}$ preserves small colimits and can therefore be regarded as an object of the ∞-category $\mathrm{Fun}^*(\mathcal{E}, \mathcal{E}^{\mathrm{ad}}_{/X})$ (note that the functor $\mathscr{O}_X$ automatically preserves small limits, since it is defined as a right adjoint). We may therefore regard the pair $(\mathcal{E}^{\mathrm{ad}}_{/X}, \mathscr{O}_X)$ as an object of the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$. We will denote this object by $\mathrm{Re}(X)$ and refer to it as the *corporeal realization* of X.

Remark 21.4.7.2. Let $(\mathcal{G}, \mathcal{G}^{\mathrm{ad}}, \tau)$ be a geometric site (Definition 20.6.2.1) and let $h : \mathcal{G} \to \mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ be the sheafified Yoneda embedding. Then h carries each object $X \in \mathcal{G}$ to a corporeal object of $\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ (where we regard $\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})$ as a fractured ∞-topos via Theorem 20.6.3.4), and the ∞-topos $\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G})^{\mathrm{ad}}_{/X}$ can be identified with $\mathcal{S}\mathrm{hv}_{\tau^{\mathrm{ad}}}(\mathcal{G}^{\mathrm{ad}}_{/X})$ (see Proposition 20.6.3.2). According to Proposition 21.2.4.10, composition with the functor h induces an equivalence of ∞-categories

$$\mathrm{Fun}^*_{\mathrm{loc}}(\mathcal{S}\mathrm{hv}_{\tau}(\mathcal{G}), \mathcal{S}\mathrm{hv}_{\tau^{\mathrm{ad}}}(\mathcal{G}^{\mathrm{ad}}_{/X})) \simeq \mathrm{Obj}^{\mathrm{loc}}_{\mathcal{G}}(\mathcal{S}\mathrm{hv}_{\tau^{\mathrm{ad}}}(\mathcal{G}^{\mathrm{ad}}_{/X})).$$

Under this equivalence, the structure sheaf $\mathscr{O}_X$ of Construction 21.4.7.1 corresponds to the locally left exact functor $\mathcal{G} \to \mathcal{S}\mathrm{hv}_{\tau_X}(\mathcal{G}^{\mathrm{ad}}_{/X})$, which assigns to each $T \in \mathcal{G}$ the sheafification of the presheaf $(U \in \mathcal{G}^{\mathrm{ad}}_{/X}) \mapsto \mathrm{Map}_{\mathcal{G}}(U, T)$.

Example 21.4.7.3 (Algebraic Geometry: Étale Topology)**.** Let $(\mathrm{Aff}, \mathrm{Aff}^{\text{ét}}, \tau_{\text{ét}})$ denote the classical étale site (Example 20.6.4.2), and let $X = \operatorname{Spec} R$ be an object of Aff. It follows from Remark 21.4.7.2 that the corporeal realization $\mathrm{Re}(X)$ can be identified with the étale spectrum $\mathrm{Spét}\, R$ introduced in Definition 1.2.3.3.

Example 21.4.7.4 (Spectral Algebraic Geometry: Étale Topology)**.** Let $(\mathrm{Aff}_{\mathrm{Sp}}, \mathrm{Aff}^{\text{ét}}_{\mathrm{Sp}}, \tau_{\text{ét}})$ denote the spectral étale site (Example 20.6.4.5), and let $X = \operatorname{Spec} R$ be an object of $\mathrm{Aff}_{\mathrm{Sp}}$. It follows from Remark 21.4.7.2 that the corporeal realization $\mathrm{Re}(X)$ can be identified with the étale spectrum $\mathrm{Spét}\, R$ introduced in Definition 1.4.2.5.

Our main goal in this section is to show that for any fractured ∞-topos $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$, the construction $X \mapsto \mathrm{Re}(X)$ is functorial (Remark 21.4.7.8 and Proposition 21.4.7.10), and that a morphism $f : X \to Y$ between corporeal objects of $\mathcal{E}$ belongs to $\mathcal{E}^{\mathrm{corp}}$ if and only if the induced map $\mathrm{Re}(X) \to \mathrm{Re}(Y)$ is étale (Corollary 21.4.7.11). The main step will be to show that the corporeal realization $\mathrm{Re}(X)$ can be characterized by a universal property (Theorem 21.4.7.7).

Notation 21.4.7.5. [The Global Sections Functor] Let $\chi : \infty\mathcal{T}\mathrm{op} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ be the forgetful functor and let $Q : \overline{\infty\mathcal{T}\mathrm{op}}^{\mathrm{op}} \to \infty\mathcal{T}\mathrm{op}^{\mathrm{op}}$ be a Cartesian fibration classified by χ (so that the objects of $\overline{\infty\mathcal{T}\mathrm{op}}$ can be identified with pairs $(\mathcal{X}, X)$, where $\mathcal{X}$ is an ∞-topos and $X \in \mathcal{X}$ is an object). For each ∞-topos $\mathcal{X}$, we let $\mathbf{1}_{\mathcal{X}}$ denote a final object of $\mathcal{X}$. We let $\Gamma : \overline{\infty\mathcal{T}\mathrm{op}}^{\mathrm{op}} \to \mathcal{S}$ denote the functor represented by the object $(\mathcal{S}, \mathbf{1}_{\mathcal{S}}) \in \overline{\infty\mathcal{T}\mathrm{op}}$. We will denote the value of Γ on a pair $(\mathcal{X}, X)$ by $\Gamma(\mathcal{X}; X)$, given informally by the formula $\Gamma(\mathcal{X}; X) = \mathrm{Map}_{\mathcal{X}}(\mathbf{1}_{\mathcal{X}}, X)$. We will refer to Γ as the *global sections functor*.

Notation 21.4.7.6. Let $\mathcal{E}$ be an ∞-topos. For each $X \in \mathcal{E}$, evaluation at X determines a functor

$$e_X : \infty\mathcal{T}\mathrm{op}(\mathcal{E}) \to \overline{\infty\mathcal{T}\mathrm{op}}$$
$$e_X(f^* : \mathcal{E} \to \mathcal{Y}) = (\mathcal{Y}, f^* X).$$

We let $\Gamma^X : \infty\mathcal{T}\mathrm{op}(\mathcal{E})^{\mathrm{op}} \to \mathcal{S}$ denote the composition of e_X with the global sections functor Γ of Notation 21.4.7.5. If $\mathcal{E}$ is equipped with a fracture subcategory $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$, then we will abuse notation by identifying Γ^X with its restriction to the subcategory $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})^{\mathrm{op}} \subseteq \infty\mathcal{T}\mathrm{op}(\mathcal{E})^{\mathrm{op}}$.

We can now formulate the universal property enjoyed by the corporeal realization $\mathrm{Re}(X)$:

Theorem 21.4.7.7. *Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos and let $X \in \mathcal{E}^{\mathrm{corp}}$ be a corporeal object. Then the functor $\Gamma^X : \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})^{\mathrm{op}} \to \mathcal{S}$ is represented by the* $\mathrm{Re}(X) = (\mathcal{E}^{\mathrm{ad}}_{/X}, \mathcal{O}_X) \in \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$.

We postpone the proof of Theorem 21.4.7.7 for the moment; it will be deduced from a more general result (Theorem **??**) which we will prove in §**??**.

Remark 21.4.7.8 (Functoriality)**.** Let $\mathcal{E}$ be an ∞-topos and let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fracture subcategory. We let $\mathcal{E}_{\mathrm{corp}}$ denote the full subcategory of $\mathcal{E}$ spanned by the corporeal objects (that is, the essential image of the inclusion $\mathcal{E}^{\mathrm{corp}} \hookrightarrow \mathcal{E}$). Note that we always have $\mathcal{E}^{\mathrm{corp}} \subsetneq \mathcal{E}_{\mathrm{corp}} \subsetneq \mathcal{E}$, except in the trivial case where $\mathcal{E}^{\mathrm{corp}} = \mathcal{E}$ (see Warning 20.1.3.5).

Note that we can regard the map $\Gamma^X : \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})^{\mathrm{op}} \to \mathcal{S}$ of Notation 21.4.7.6 as a covariant functor of $X \in \mathcal{E}$. Using Theorem 21.4.7.7 (and the fact that the Yoneda embedding $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E}) \to \mathrm{Fun}(\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})^{\mathrm{op}}, \widehat{\mathcal{S}})$ is fully faithful) that we can regard the construction $X \mapsto \mathrm{Re}(X)$ as a functor $\mathrm{Re} : \mathcal{E}_{\mathrm{corp}} \to \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$. We will refer to Re as the *corporeal realization functor*.

In particular, every morphism $X \to Y$ in the ∞-category $\mathcal{E}_{\mathrm{corp}}$ induces a map

$$(\mathcal{E}^{\mathrm{ad}}_{/X}, \mathcal{O}_X) \to (\mathcal{E}^{\mathrm{ad}}_{/Y}, \mathcal{O}_Y)$$

in $\infty\mathcal{T}\mathrm{op}(\mathcal{X})$, whose underlying geometric morphism is right adjoint to the functor

$$\mathcal{E}^{\mathrm{ad}}_{/Y} \to \mathcal{E}^{\mathrm{ad}}_{/X} \qquad U \mapsto U \times_Y X.$$

Remark 21.4.7.9. Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos. Then the construction $(X \in \mathcal{E}) \mapsto \Gamma^X$ of Notation 21.4.7.6 preserves finite limits. It follows that the corporeal realization functor $\mathrm{Re} : \mathcal{E}_{\mathrm{corp}} \to \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ preserves all finite limits which exist in $\mathcal{E}_{\mathrm{corp}}$.

Proposition 21.4.7.10. *Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos. Then the corporeal realization functor $\mathrm{Re} : \mathcal{E}_{\mathrm{corp}} \to \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ is fully faithful.*

Proof. Let X and Y be corporeal objects of $\mathcal{E}$, and let $\rho_X : \mathcal{E}_{/X} \to \mathcal{E}^{\mathrm{ad}}_{/X}$ be a right adjoint to the inclusion. Using Theorem 21.4.7.7, we compute

$$\begin{aligned}
\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})}(\mathrm{Re}(X), \mathrm{Re}(Y)) &\simeq \Gamma^Y(\mathcal{E}^{\mathrm{ad}}_{/X}; \mathcal{O}_X) \\
&= \Gamma(\mathcal{X}^{\mathrm{ad}}_{/X}; \mathcal{O}_X(Y)) \\
&\simeq \Gamma(\mathcal{E}^{\mathrm{ad}}_{/X}; \rho_X(X \times Y)) \\
&\simeq \mathrm{Map}_{\mathcal{E}^{\mathrm{ad}}_{/X}}(X, \rho_X(X \times Y)) \\
&\simeq \mathrm{Map}_{\mathcal{E}_{/X}}(X, X \times Y) \\
&\simeq \mathrm{Map}_{\mathcal{E}}(X, Y).
\end{aligned}$$

□

Corollary 21.4.7.11. *Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos and let $f : X \to Y$ be a morphism between corporeal objects of $\mathcal{X}$. The following conditions are equivalent:*

(1) *The morphism f belongs to $\mathcal{E}^{\mathrm{corp}}$.*

(2) *The induced map of corporeal realizations* $\mathrm{Re}(X) \to \mathrm{Re}(Y)$ *is an étale morphism in* $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$.

Proof. The implication (1) ⇒ (2) follows from the description of the map $\mathrm{Re}(X) \to \mathrm{Re}(Y)$ given in Remark 21.4.7.8. Conversely, suppose that (2) is satisfied. Then there exists an object $U \in \mathcal{E}^{\mathrm{ad}}_{/Y}$ such that $\mathrm{Re}(X)$ is equivalent to $((\mathcal{E}^{\mathrm{ad}}_{/Y})_{/U}, \mathscr{O}_Y|_U) \simeq (\mathcal{E}^{\mathrm{ad}}_{/U}, \mathscr{O}_U) = \mathrm{Re}(U)$ as an object of $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})_{/\mathrm{Re}(Y)}$. Applying Proposition 21.4.7.10, we deduce that X and U are equivalent as objects of $\mathcal{E}_{/Y}$, so that $X \in \mathcal{E}^{\mathrm{ad}}_{/Y}$. Using Example 20.3.1.2, we deduce that f belongs to $\mathcal{E}^{\mathrm{corp}}$. □

The implication (1) ⇒ (2) of Corollary 21.4.7.11 can be generalized to the situation where X and Y are not necessarily corporeal:

Proposition 21.4.7.12. *Let* $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ *be a fractured* ∞*-topos and let* $f : X \to Y$ *be a* $\mathcal{E}^{\mathrm{corp}}$*-admissible morphism in* $\mathcal{X}$ *(Definition 20.3.1.1). If the functor* Γ^Y *of Notation 21.4.7.6 is representable by an object* $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}) \in \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$*, then* Γ^X *is representable by an object of* $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ *which is étale over* $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$.

Corollary 21.4.7.13. *Let* $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ *be a fractured* ∞*-topos and let* $f : X \to Y$ *be a morphism in* $\mathcal{E}$*. The following conditions are equivalent:*

(a) *The morphism* f *is* $\mathcal{E}^{\mathrm{corp}}$*-admissible.*

(b) *For every pullback diagram*

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow & & \downarrow f \\ Y' & \longrightarrow & Y \end{array}$$

in the ∞*-topos* $\mathcal{E}$*, if the functor* $\Gamma^{Y'} : \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})^{\mathrm{op}} \to \mathcal{S}$ *is representable by an object* $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}) \in \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$*, then* $\Gamma^{X'}$ *is representable by an object of* $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$ *which is étale over* $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$.

Proof. The implication (a) ⇒ (b) follows from Proposition 21.4.7.12. Conversely, suppose that (b) is satisfied. Choose a corporeal object $Y' \in \mathcal{X}$ equipped with an effective epimorphism $Y' \to Y$. To prove that f is $\mathcal{E}^{\mathrm{corp}}$-admissible, it will suffice to show that the projection map $Y' \times_Y X \to Y'$ is $\mathcal{E}^{\mathrm{corp}}$-admissible. Using Corollary 21.4.7.11, we are reduced to showing that the map of corporeal realizations $\mathrm{Re}(Y' \times_Y X) \to \mathrm{Re}(Y')$ is étale, which follows immediately from assumption (b). □

Remark 21.4.7.14. Let $\mathcal{E}^{\mathrm{corp}} \subseteq \mathcal{E}$ be a fractured ∞-topos. It follows from Corollary 21.4.7.13 that the admissibility structure $\mathcal{E}^{\mathrm{ad}} \subseteq \mathcal{E}$ of Proposition 20.3.1.3 can be recovered from the subcategory $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E}) \subseteq \infty\mathcal{T}\mathrm{op}(\mathcal{E})$ of Construction 21.4.2.1. Consequently, the subcategory $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E}) \subseteq \infty\mathcal{T}\mathrm{op}(\mathcal{E})$ determines the fracture subcategory $\mathcal{E}^{\mathrm{corp}}$ up to completion (see Remark 20.3.4.7).

Proof of Proposition 21.4.7.12. Suppose that $f : X \to Y$ is an $\mathcal{E}^{\mathrm{corp}}$-admissible morphism in $\mathcal{E}$ and that the functor $\Gamma^Y : \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E}) \to \mathcal{S}$ is representable by an object $(\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) \in \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$. In particular, we have a canonical point $\eta \in \Gamma^Y(\mathcal{Y}; \mathcal{O}_{\mathcal{Y}}) \simeq \Gamma(\mathcal{Y}; \mathcal{O}_{\mathcal{Y}}(Y))$. Let U denote the fiber product $\mathbf{1}_{\mathcal{Y}} \times_{\mathcal{O}_{\mathcal{Y}}(Y)} \mathcal{O}_{\mathcal{Y}}(X)$, so that η lifts to an element $\overline{\eta} \in \Gamma^X(\mathcal{Y}_{/U}; \mathcal{O}_{\mathcal{Y}}|_U)$. For any object $(\mathcal{Z}, \mathcal{O}_{\mathcal{Z}}) \in \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$, evaluation on $\overline{\eta}$ determines a map θ fitting into a commutative diagram

$$\begin{array}{ccc} \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})}((\mathcal{Z}, \mathcal{O}_{\mathcal{Z}}), (\mathcal{Y}_{/U}, \mathcal{O}_{\mathcal{Y}}|_U),) & \xrightarrow{\theta} & \Gamma^X(\mathcal{Z}; \mathcal{O}_{\mathcal{Z}}) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})}((\mathcal{Z}, \mathcal{O}_{\mathcal{Z}}), (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})) & \xrightarrow{\theta_0} & \Gamma^Y(\mathcal{Z}; \mathcal{O}_{\mathcal{Z}}). \end{array}$$

By assumption, the map θ_0 is a homotopy equivalence. Passing to vertical homotopy fibers over a point

$$(f^*, \alpha_0) \in \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})}((\mathcal{Z}, \mathcal{O}_{\mathcal{Z}}), (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}))$$

we obtain a map

$$\Gamma(\mathcal{Z}; f^*U) \simeq \Gamma(\mathcal{Z}; f^*\mathcal{O}_{\mathcal{Y}}(X)) \times_{\Gamma(\mathcal{Z}; f^*\mathcal{O}_{\mathcal{Y}}(Y))} \Gamma(\mathcal{Z}; f^*\mathbf{1}_{\mathcal{Y}}) \to \Gamma(\mathcal{Z}; \mathcal{O}_{\mathcal{Z}}(X)) \times_{\Gamma(\mathcal{Z}; \mathcal{O}_{\mathcal{Z}}(Y))} \Gamma(\mathcal{Z}; \mathbf{1}_{\mathcal{Z}}).$$

This map is a homotopy equivalence, since the $\mathcal{E}^{\mathrm{corp}}$-admissibility of f guarantees that the diagram

$$\begin{array}{ccc} f^*\mathcal{O}_{\mathcal{Y}}(X) & \longrightarrow & f^*\mathcal{O}_{\mathcal{Y}}(Y) \\ \downarrow & & \downarrow \\ \mathcal{O}_{\mathcal{Z}}(X) & \longrightarrow & \mathcal{O}_{\mathcal{Z}}(Y) \end{array}$$

is a pullback square in $\mathcal{Z}$ (see Proposition 21.2.4.8). It follows that θ is also a homotopy equivalence. Allowing $(\mathcal{Z}, \mathcal{O}_{\mathcal{Z}})$ to vary over all objects of $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}(\mathcal{E})$, we conclude that $\overline{\eta}$ exhibits Γ^X as the functor corepresented by the object $(\mathcal{Y}_{/U}, \mathcal{O}_{\mathcal{Y}}|_U)$. □

Chapter 25

Derived Algebraic Geometry

Associated to every commutative ring R, there are several candidates for a "homotopy theory" of commutative algebras over R:

(a) One can consider topological spaces (or simplicial sets) equipped with the structure of a commutative R-algebra, in which the commutative ring axioms are required to hold "on the nose."

(b) One can consider commutative differential graded algebras over R: that is, chain complexes over R which are equipped with a structure of a commutative R-algebra in which the commutative ring axioms are again required to hold "on the nose."

(c) One can consider $\mathbb{E}_\infty$-algebras over R. These can be viewed as chain complexes (or, in the connective case, as topological spaces) which are equipped with the structure of a commutative R-algebra "up to coherent homotopy."

If R contains the field $\mathbf{Q}$ of rational numbers, then (a), (b), and (c) give rise to essentially the same theory. More precisely, the category of simplicial commutative R-algebras and the category of commutative differential graded algebras over R admit model structures (Propositions HA.7.1.4.20 and HA.7.1.4.10), and the associated ∞-categories can be identified with $\mathrm{CAlg}_R^{\mathrm{cn}}$ and CAlg_R, respectively (Propositions 25.1.2.2 and HA.7.1.4.6); here CAlg_R denotes the ∞-category of $\mathbb{E}_\infty$-algebras over R and $\mathrm{CAlg}_R^{\mathrm{cn}} \subseteq \mathrm{CAlg}_R$ the full subcategory spanned by the connective $\mathbb{E}_\infty$-algebras over R.

If R does not contain the field $\mathbf{Q}$ of rational numbers, then the theory of commutative differential graded algebras over R is poorly behaved. However, one can still consider simplicial commutative algebra and $\mathbb{E}_\infty$-algebras over R, which give rise to *different* homotopy theories. The theory of spectral algebraic geometry developed earlier in this book can be loosely described as obtained from the theory of classical algebraic geometry by replacing commutative rings by $\mathbb{E}_\infty$-rings. In this section we will study a parallel (and closely related) theory which we call *derived* algebraic geometry, where we instead use simplicial commutative rings in place of ordinary commutative rings.

We begin in §25.1 with a review of the theory of simplicial commutative rings. Here we will indulge in a slight abuse of terminology: the term "simplicial commutative ring" is usually used in the literature to refer to a simplicial object of the ordinary category $\mathrm{CAlg}^{\heartsuit}$ of commutative rings, or (equivalently) to a commutative ring object in the ordinary category of simplicial sets. The collection of such objects can be organized into a simplicial model category $\mathbf{A}$. From our point of view, the real object of interest is the underlying ∞-category CAlg^{Δ}, which can be obtained as the homotopy coherent nerve of the full subcategory $\mathbf{A}^{\circ}$ of fibrant-cofibrant objects of $\mathbf{A}$. This ∞-category admits many different descriptions; for us, the most relevant of these is that it can be obtained from the category of finitely generated polynomial rings (over $\mathbf{Z}$) by freely adjoining sifted colimits. We will essentially take this universal property as our definition of CAlg^{Δ} (see Definition 25.1.1.1 and Remark 25.1.1.2); the relationship between this definition with the simplicial model category $\mathbf{A}$ can be deduced from some general results of [138] (Remark 25.1.1.3), but will not play an essential role in our exposition.

There is a close relationship between the theory of simplicial commutative rings and the theory of (connective) $\mathbb{E}_\infty$-rings. More precisely, we can associate to every simplicial commutative ring A an underlying connective $\mathbb{E}_\infty$-ring A°, which is an $\mathbb{E}_\infty$-algebra over $\mathbf{Z}$ (Construction 25.1.2.1). We therefore have forgetful functors

$$\mathrm{CAlg}^{\Delta} \to \mathrm{CAlg}^{\mathrm{cn}}_{\mathbf{Z}} \to \mathrm{CAlg}^{\mathrm{cn}}.$$

Heuristically, one can think of a connective $\mathbb{E}_\infty$-ring $R \in \mathrm{CAlg}^{\mathrm{cn}}$ as a space which is equipped with an addition and multiplication which satisfy the axiomatics for commutative rings "up to coherent homotopy," while a simplicial commutative ring $R \in \mathrm{CAlg}^{\Delta}$ is a space equipped with an addition and multiplication satisfying the commutative ring axioms "on the nose." In between these extremes lies the ∞-category $\mathrm{CAlg}^{\mathrm{cn}}_{\mathbf{Z}}$, whose objects R can be thought of as spaces equipped with an addition law which is strictly commutative and associative, and a compatible multiplication law which is commutative and associative only up to coherent homotopy. A precise consequence of this heuristic picture is that if for a simplicial commutative ring R, the space of units of the underlying $\mathbb{E}_\infty$-ring can be regarded as the 0th space of a $\mathbf{Z}$-module spectrum (Proposition 25.1.5.3).

Another important difference between the theory of $\mathbb{E}_\infty$-rings and the theory of simplicial commutative rings lies in the structure of free algebras. If A is an $\mathbb{E}_\infty$-ring and M is an A-module, then one can consider the free $\mathbb{E}_\infty$-algebra $\mathrm{Sym}^*_A(M)$ over A generated by M: as an A-module, it is given as an infinite direct sum $\bigoplus_{n \geq 0} \mathrm{Sym}^n_A()$, where each $\mathrm{Sym}^n_A(M)$ denotes the homotopy coinvariants for the action of the symmetric group Σ_n on the n-fold tensor power $M \otimes_A \cdots \otimes_A M$. In the setting of simplicial commutative rings, there is an analogous picture: given a simplicial commutative ring A and a connective A-module M, one can form a free algebra $\mathrm{LSym}^*_A(M)$ which decomposes as a direct sum $\bigoplus_{n \geqslant 0} \mathrm{LSym}^n_A(M)$ (see Construction 25.2.2.6). However, the symmetric powers $\mathrm{LSym}^n_A(M)$ which appear here *cannot* be defined as the homotopy coinvariants of symmetric group actions: instead, they are obtained as nonabelian left derived functors of the formation of symmetric powers in the setting of classical commutative algebra. In §25.2, we will analyze the derived symmetric power construction LSym^n_A as well as the analogous derived functors for exterior and divided powers (Constructions 25.2.2.1, 25.2.2.2, and 25.2.2.3) and study their behavior with respect to connectivity and finiteness properties of modules.

The theory of simplicial commutative rings was originally introduced as a tool for studying commutative algebra using techniques borrowed from algebraic topology. One of the motivating applications was to extend the theory of Kähler differentials $\Omega_{B/A}$ of a commutative ring homomorphism $A \to B$ to a homology theory (called *André-Quillen homology*), allowing the short exact sequence

$$\mathrm{Tor}^B_0(C, \Omega_{B/A}) \to \Omega_{C/A} \to \Omega_{C/B} \to 0$$

to be extended on the left. In §25.3, we study André-Quillen in the setting of *simplicial* commutative rings by assigning to each morphism $\phi : A \to B$ in CAlg^{Δ} a B-module spectrum $L^{\mathrm{alg}}_{B/A}$, which we will refer to as the *algebraic cotangent complex* of B over A (see Notation 25.3.2.1). This is generally different from the cotangent complex of the underlying morphism of $\mathbb{E}_\infty$-rings $A^\circ \to B^\circ$ considered elsewhere in this book, even when A and B are ordinary commutative rings (the algebraic cotangent complex $L^{\mathrm{alg}}_{B/A}$ computes André-Quillen homology, while the cotangent complex L_{B°/A° computes *topological* André-Quillen homology), but there is a close relationship between the two: there is an equivalence $L^{\mathrm{alg}}_{B/A} \simeq B^\circ \otimes_{B^+} L_{B^\circ/A^\circ}$ where B^+ is a certain (noncommutative) ring spectrum which acts on L_{B°/A° (see Remark 25.3.3.7). Using this description, we show that many of the pleasant features of the cotangent complexes of $\mathbb{E}_\infty$-ring can be extended to the algebraic setting; for example, a morphism of simplicial commutative rings $\phi : A \to B$ is an equivalence if and only if induces an isomorphism on π_0 and the algebraic cotangent complex $L^{\mathrm{alg}}_{B/A}$ vanishes (Corollary 25.3.6.6).

In §**??**, we study finiteness conditions on simplicial commutative rings (and on morphisms of simplicial commutative rings). If $\phi : A \to B$ is a morphism of simplicial commutative rings, we say that ϕ is *almost of finite presentation* if the functor $C \mapsto \mathrm{Map}_{\mathrm{CAlg}^{\Delta}_A}(B, C)$ commutes with filtered colimits when restricted to n-truncated objects of CAlg^{Δ}_A, for every nonnegative integer n (where $\mathrm{CAlg}^{\Delta}_A = (\mathrm{CAlg}^{\Delta})_{A/}$ denotes the ∞-category of simplicial commutative rings equipped with a map from A). Our main result is that this condition depends only the underlying morphism $\phi^\circ : A^\circ \to B^\circ$ of $\mathbb{E}_\infty$-rings (more precisely, it is equivalent to the requirement that ϕ° be almost of finite presentation, in the sense of Definition HA.7.2.4.26; see Proposition **??**), and that a similar phenomenon occurs for weaker finiteness conditions

(Theorem **??**). Note that this is not *a priori* obvious, because the analogous statement is false for stronger finiteness conditions such as compactness: the polynomial ring $\mathbf{Z}[x]$ is a compact object of the ∞-category CAlg^{Δ} of simplicial commutative rings, but is not compact when viewed as an $\mathbb{E}_\infty$-ring or as an $\mathbb{E}_\infty$-algebra over $\mathbf{Z}$ (see Warning **??**).

In §**??**, we study sheaves of simplicial commutative rings on a topological space X and, more generally, on an ∞-topos $\mathcal{X}$ (the former can be considered as a special case of the latter, since the datum of a sheaf on a topological space X is equivalent to the datum of a sheaf on the ∞-topos $\mathcal{S}\mathrm{hv}(X)$). In §**??**, we will use the language of CAlg^{Δ}-valued sheaves to introduce the notion of *derived scheme* (Definition **??**): namely, we define a derived scheme to be a pair $(X, \mathscr{O}_X)$ where X is a topological space and $\mathscr{O}_X$ is an CAlg^{Δ}-valued sheaf on X for which the underlying pair $(X, \mathscr{O}_X^{\circ})$ is a spectral scheme (in the sense of Definition 1.1.2.8). Our main result (Corollary **??**) is that this condition is equivalent to the requirement that the pair $(X, \mathscr{O}_X)$ is locally equivalent to the Zariski spectrum $\mathrm{Spec}(A)$ of some simplicial commutative ring A (see Notation **??**). In §**??**, we will prove an analogous result for Deligne-Mumford stacks (Corollary **??**), where the role of the Zariski spectrum $\mathrm{Spec}\, A$ is instead played by a suitable notion of étale spectrum $\mathrm{Sp\acute{e}t}(A)$ (Notation **??**).

The theory of derived algebraic geometry developed in this section is closely related to the theory of spectral algebraic geometry studied throughout this book. Every derived scheme $(X, \mathscr{O}_X)$ has an underlying spectral scheme $(X, \mathscr{O}_X^{\circ})$, and every derived Deligne-Mumford stack $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ has an underlying spectral Deligne-Mumford stack $(\mathcal{X}, \mathscr{O}_{\mathcal{X}}^{\circ})$. Consequently, many basic concepts and theorems can directly imported from spectral algebraic geometry to derived algebraic geometry. However, there is one important respect in which the theory of derived algebraic geometry is substantially simpler than the theory of spectral algebraic geometry. In the setting of spectral algebraic geometry, there are (at least) two *different* smoothness conditions one can consider on a morphism $f : \mathsf{X} \to \mathsf{Y}$: differential smoothness and fiber-smoothness (see Definition 11.2.5.5). One of the difficulties in working with spectral algebraic geometry is that these two notions are distinct from one another (unless we work in characteristic zero) and neither shares all of the pleasant features of smooth morphisms from classical algebraic geometry: differentially smooth morphisms need not be flat, and fiber-smooth morphisms need not satisfy an infinitesimal lifting criterion. In §**??**, we will see that the theory of derived algebraic geometry does not share this defect: we will introduce a smoothness condition on a morphism $f : \mathsf{X} \to \mathsf{Y}$ of derived Deligne-Mumford stacks (Variant 3.4.3.3) which entails both that f is flat *and* that it satisfies an infinitesimal lifting criterion. The notion of smooth morphism will play an important role in the theory of derived algebraic stacks which we will develop in Part VIII.

25.1 Simplicial Commutative Rings

Our goal in this section is to give a short introduction to the theory of simplicial commutative rings and its relationship to the theory of $\mathbb{E}_\infty$-rings which appears elsewhere in this book. Fix a commutative ring R. In §25.1.1, we introduce the ∞-category CAlg^{Δ}_R of *simplicial commutative R-algebras*, which is obtained from the category of polynomial rings over R by formally adjoining sifted colimits (Proposition 25.1.1.5). In §25.1.2, we study the relationship of ∞-category CAlg^{Δ}_R and the ∞-category $\mathrm{CAlg}^{\mathrm{cn}}_R$ of connective $\mathbb{E}_\infty$-algebras over R. There is a forgetful functor $\mathrm{CAlg}^{\Delta}_R \to \mathrm{CAlg}^{\mathrm{cn}}_R$, which we will denote by $A \mapsto A^\circ$; we show that this functor admits both left and right adjoints (Proposition 25.1.2.4), and that it is an equivalence when R contains the field $\mathbf{Q}$ of rational numbers (Proposition 25.1.2.2). For many purposes, it is convenient to identify a simplicial commutative R-algebra A with the underlying $\mathbb{E}_\infty$-algebra A°; for example, in §25.1.3 we define the homotopy groups of A to be the homotopy groups of A°

In §25.1.4, we study the dependence of the ∞-category CAlg^{Δ}_R on the commutative ring R. Every morphism of commutative rings $f : R \to R'$ induces a “restriction of scalars” functor $\mathrm{CAlg}^{\Delta}_{R'} \to \mathrm{CAlg}^{\Delta}_R$, and we show that this functor induces an equivalence of ∞-categories

$\mathrm{CAlg}^{\Delta}_{R'} \simeq (\mathrm{CAlg}^{\Delta}_{R})_{R'/}$ (Proposition 25.1.4.2). In particular, for any commutative ring R, we can identify $\mathrm{CAlg}^{\Delta}_{R}$ with the ∞-category $(\mathrm{CAlg}^{\Delta})_{R/}$, where $\mathrm{CAlg}^{\Delta} = \mathrm{CAlg}^{\Delta}_{\mathbf{Z}}$ denotes the ∞-category of simplicial commutative $\mathbf{Z}$-algebras.

Roughly speaking, the difference between objects of $\mathrm{CAlg}^{\Delta}_{R}$ and $\mathrm{CAlg}^{\mathrm{cn}}_{R}$ is that the multiplication on a simplicial commutative algebra is required to be "strictly" commutative, while the multiplication on an $\mathbb{E}_\infty$-algebra is only required to be commutative up to coherent homotopy. In §25.1.5, we give a precise articulation of this heuristic (Proposition 25.1.5.3) which will be applied in §25.3 to analyze the difference between the deformation theory of simplicial commutative algebras and their $\mathbb{E}_\infty$ counterparts.

25.1.1 The ∞-Category $\mathrm{CAlg}^{\Delta}_{R}$

We begin by introducing the principal objects of interest.

Definition 25.1.1.1. Let R be a commutative ring. We let Poly_R denote the category whose objects are polynomial rings $R[x_1, \ldots, x_n]$ over R, and whose morphisms are R-algebra homomorphisms. Note that the category Poly_R admits finite coproducts (given by the formation of tensor product over R).

We let $\mathrm{CAlg}^{\Delta}_{R}$ denote the full subcategory $\mathrm{Fun}^{\pi}(\mathrm{Poly}_R^{\mathrm{op}}, \mathcal{S}) \subseteq \mathrm{Fun}(\mathrm{Poly}_R^{\mathrm{op}}, \mathcal{S})$ spanned by those functors $\mathrm{Poly}_R^{\mathrm{op}} \to \mathcal{S}$ which preserve finite products. We will refer to $\mathrm{CAlg}^{\Delta}_{R}$ as the *∞-category of simplicial commutative R-algebras*. In the special case where R is the ring $\mathbf{Z}$ of integers, we will denote $\mathrm{CAlg}^{\Delta}_{R}$ simply by CAlg^{Δ}, and refer to it as the *∞-category of simplicial commutative rings*.

Remark 25.1.1.2. Let R be a commutative ring. By virtue of Proposition HTT.5.5.8.22 , the ∞-category $\mathrm{CAlg}^{\Delta}_{R}$ can be characterized up to equivalence by the following properties:

(1) The ∞-category $\mathrm{CAlg}^{\Delta}_{R}$ is presentable.

(2) There exists a coproduct-preserving, fully faithful functor $j : \mathrm{Poly}_R \hookrightarrow \mathrm{CAlg}^{\Delta}_{R}$.

(3) The essential image of j consists of compact projective objects of $\mathrm{CAlg}^{\Delta}_{R}$ which generate $\mathrm{CAlg}^{\Delta}_{R}$ under sifted colimits.

Remark 25.1.1.3. The terminology of Definition 25.1.1.1 is motivated by the following observation, which follows immediately from Corollary HTT.5.5.9.3 :

($*$) Let $\mathbf{A}_R$ be the ordinary category of simplicial commutative R-algebras, regarded as a simplicial model category in the usual way (see [167] or Proposition HTT.5.5.9.1), and let $\mathbf{A}^{\circ}$ denote the full subcategory spanned by the fibrant-cofibrant objects. Then there is a canonical equivalence of ∞-categories $\mathrm{N}(\mathbf{A}^{\circ}) \to \mathrm{CAlg}^{\Delta}_{R}$.

Remark 25.1.1.4. Using $(*)$, we deduce that the ∞-category of discrete objects of CAlg^{Δ}_R is canonically equivalent with (the nerve of) the category $\mathrm{CAlg}^{\heartsuit}_R$ of commutative R-algebras. We will generally abuse notation and not distinguish between commutative R-algebras and the corresponding discrete objects of CAlg^{Δ}_R. In particular, we will view the polynomial algebras $R[x_1, \ldots, x_n]$ as objects of CAlg^{Δ}_R (which we can regard as compact projective generators for CAlg^{Δ}_R, by virtue of Remark 25.1.1.2).

The following result is an immediate consequence of Proposition HTT.5.5.8.15 and its proof:

Proposition 25.1.1.5. *Let R be a commutative ring and let $j : \mathrm{Poly}_R \to \mathrm{CAlg}^{\Delta}_R$ denote the Yoneda embedding. Let $\mathcal{C}$ be an ∞-category which admits small sifted colimits, and $\mathrm{Fun}_{\Sigma}(\mathrm{CAlg}^{\Delta}_R, \mathcal{C})$ the full subcategory of $\mathrm{Fun}(\mathrm{CAlg}^{\Delta}_R, \mathcal{C})$ spanned by those functors which preserve sifted colimits. Then:*

(1) *Composition with j induces an equivalence of ∞-categories*

$$\mathrm{Fun}_{\Sigma}(\mathrm{CAlg}^{\Delta}_R, \mathcal{C}) \to \mathrm{Fun}(\mathrm{Poly}_R, \mathcal{C}).$$

(2) *A functor $F : \mathrm{CAlg}^{\Delta}_R \to \mathcal{C}$ belongs to $\mathrm{Fun}_{\Sigma}(\mathrm{CAlg}^{\Delta}_R, \mathcal{C})$ if and only if F is a left Kan extension of $F \circ j$ along j.*

(3) *Suppose $\mathcal{C}$ admits finite coproducts, and let $F : \mathrm{CAlg}^{\Delta}_R \to \mathcal{C}$ preserve sifted colimits. Then F preserves finite coproducts if and only if $F \circ j$ preserves finite coproducts.*

25.1.2 Comparison with $\mathbb{E}_\infty$-Algebras

We now study the relationship between simplicial commutative algebras and $\mathbb{E}_\infty$-algebras. We begin with an application of Proposition 25.1.1.5:

Construction 25.1.2.1. [The Underlying $\mathbb{E}_\infty$-Algebra] Let R be a commutative ring and let Poly_R denote the category of finitely generated polynomial rings over R, which we regard as a full subcategory of both the ∞-category CAlg^{Δ}_R of simplicial commutative R-algebras and the ∞-category $\mathrm{CAlg}^{\mathrm{cn}}_R$ of connective $\mathbb{E}_\infty$-algebras over R. By virtue of Proposition 25.1.1.5, there is an essentially unique functor

$$\Theta : \mathrm{CAlg}^{\Delta}_R \to \mathrm{CAlg}^{\mathrm{cn}}_R$$

which commutes with small sifted colimits and restricts to the identity on Poly_R. If A is an object of CAlg^{Δ}_R, we will $\Theta(A)$ by A° and refer to it as the *underlying $\mathbb{E}_\infty$-algebra of A.*

Proposition 25.1.2.2. *Let R be a commutative ring, and let $\Theta : \mathrm{CAlg}^{\Delta}_R \to \mathrm{CAlg}^{\mathrm{cn}}_R$ be the forgetful functor of Construction 25.1.2.1. Then:*

(1) *The functor* Θ *preserves small limits and colimits.*

(2) *The functor* Θ *is conservative.*

(3) *If* R *contains the field* $\mathbf{Q}$*, then* Θ *is an equivalence of* ∞*-categories.*

Proof. We first prove (1). To prove that Θ preserves small colimits, it will suffice to show that the inclusion $\mathrm{Poly}_R \hookrightarrow \mathrm{CAlg}_R^{\mathrm{cn}}$ of Construction 25.1.2.1 preserves finite coproducts (Proposition 25.1.1.5). Since coproducts in $\mathrm{CAlg}_R^{\mathrm{cn}}$ are computed by relative tensor products over R, this follows from the fact that every polynomial algebra $R[x_1, \ldots, x_n]$ is flat as a R-module.

Consider the functor $\phi : \mathrm{CAlg}_R^{\mathrm{cn}} \to \mathcal{S}$ defined by the composition

$$\mathrm{CAlg}_R^{\mathrm{cn}} \simeq \mathrm{CAlg}(\mathrm{Mod}_R^{\mathrm{cn}}) \to \mathrm{Mod}_R^{\mathrm{cn}} \to (\mathrm{Sp})_{\geqslant 0} \xrightarrow{\Omega^\infty} \mathcal{S}.$$

Using Corollary HA.3.2.2.5 and Corollary HA.4.2.3.3, we deduce that ϕ is conservative and preserves small limits. Let $\psi, \psi' : \mathrm{CAlg}_R^{\Delta} \to \mathcal{S}$ be the functors given by $\psi(A) = \phi(A^\circ)$ and $\psi'(A) = A(R[x])$. The functor ψ' obviously preserves small limit, and it is conservative since every object of Poly_k can be written as a coproduct of finitely many copies of $R[x]$. To complete the proofs of (1) and (2), it will suffice to show that the functors ψ and ψ' are equivalent. The functor ψ' obviously preserves small sifted colimits. Combining Proposition HA.1.4.3.9, Corollary HA.4.2.3.5, and Corollary HA.3.2.3.2, we conclude that $\psi : \mathrm{CAlg}_k^{\Delta} \to \mathcal{S}$ preserves small sifted colimits as well. By virtue of Proposition 25.1.1.5, it will suffice to show that the composite functors $\psi \circ j, \psi' \circ j : \mathrm{Poly}_R \to \mathcal{S}$ are equivalent. We now simply observe that both of these compositions can be identified with the functor which associates to each polynomial ring $R[x_1, \ldots, x_n]$ its underlying set of elements, regarded as a discrete space.

Let us now prove (3). Suppose that R is a $\mathbf{Q}$-algebra. Then, for every $n \geqslant 0$, every flat R-module M, and every $i > 0$, the homology group $\mathrm{H}_i(\Sigma_n; M^{\otimes n})$ vanishes, where Σ_n denotes the symmetric group on n letters. It follows that the symmetric power $\mathrm{Sym}_R^n(M) \in \mathrm{Mod}_R^{\mathrm{cn}}$ is discrete, so that the $\mathbb{E}_\infty$-algebra $\mathrm{Sym}_R^*(R^m)$ can be identified with the (discrete) polynomial ring $R[x_1, \ldots, x_m]$. Using Proposition HA.7.2.4.27, we conclude that the essential image of θ_0 consists of compact projective objects of $\mathrm{CAlg}_R^{\mathrm{cn}}$ which generate $\mathrm{CAlg}_R^{\mathrm{cn}}$ under colimits, so that Θ is an equivalence by Proposition HTT.5.5.8.25. □

Notation 25.1.2.3. [Tensor Products] Let R be a commutative ring, and suppose we are given a diagram

$$A_0 \leftarrow A \to A_1,$$

in the ∞-category CAlg_R^{Δ}. We will denote the pushout of this diagram by $A_0 \otimes_A A_1$. This notation is justified by the fact that the forgetful functor $B \mapsto B^\circ$ preserves small colimits

(Proposition 25.1.2.2), so that we have a canonical equivalence

$$(A_0 \otimes_A A_1)^\circ \simeq A_0^\circ \otimes_{A^\circ} A_1^\circ$$

in $\mathrm{CAlg}_R^{\mathrm{cn}}$.

Proposition 25.1.2.4. *Let R be a commutative ring. Then the forgetful functor $\Theta : \mathrm{CAlg}_R^\Delta \to \mathrm{CAlg}_R^{\mathrm{cn}}$ admits left and right adjoints*

$$\Theta^L : \mathrm{CAlg}_R^{\mathrm{cn}} \to \mathrm{CAlg}_R^\Delta \qquad \Theta^R : \mathrm{CAlg}_R^{\mathrm{cn}} \to \mathrm{CAlg}_R^\Delta .$$

Moreover, the functor Θ is both monadic and comonadic: that is, we can identify CAlg_R^Δ with the ∞-category of algebras for the monad $\Theta \circ \Theta^L$ on $\mathrm{CAlg}_R^{\mathrm{cn}}$, or with the ∞-category of coalgebras for the comonad $\Theta \circ \Theta^R$ on $\mathrm{CAlg}_R^{\mathrm{cn}}$.

Proof. Since the functor Θ preserves small limits and colimits, the existence of the functors Θ^L and Θ^R follows from Corollary HTT.5.5.2.9 . Since Θ is conservative and preserves geometric realizations of simplicial objects, the monadicity of Θ follows from the Barr-Beck theorem (Theorem HA.4.7.0.3). Similarly, the comonadicity of Θ follows from the fact that it is conservative and preserves totalizations of cosimplicial objects. □

Remark 25.1.2.5. Let R be a commutative ring, and let $\Theta^R : \mathrm{CAlg}_k^\Delta \to \mathrm{CAlg}_k^{\mathrm{cn}}$ be as in Proposition 25.1.2.4. Let A be a connective $\mathbb{E}_\infty$-algebra over R. The underlying space of the simplicial commutative k-algebra $\Theta^R(A)$ can be identified with

$$\mathrm{Map}_{\mathrm{CAlg}_k^\Delta}(R[x], \Theta^R(A)) \simeq \mathrm{Map}_{\mathrm{CAlg}_R^{\mathrm{cn}}}(R[x], A).$$

Note that this is generally *different* from the underlying space $\Omega^\infty(A) \in \mathcal{S}$, because the discrete R-algebra $R[x]$ generally does not agree with the free $\mathbb{E}_\infty$-algebra $R\{x\} \in \mathrm{CAlg}_R$ (though they do coincide whenever R is a $\mathbf{Q}$-algebra). We can think of $\mathrm{Map}_{\mathrm{CAlg}_R}(R[x], A)$ as the space of "very commutative" points A, which generally differs from the underlying space $\Omega^\infty(A) \simeq \mathrm{Map}_{\mathrm{CAlg}_R}(R\{x\}, A)$of A. The difference between these spaces can be regarded either as a measure of the failure of the polynomial $R[x]$ to be free as an $\mathbb{E}_\infty$-algebra over R, or as a measure of the failure of free $\mathbb{E}_\infty$-algebra $R\{x\}$ to be flat over R.

We can interpret the situation as follows. The affine line $\mathrm{Spec}(R[x])$ can be regarded as a commutative R-algebra in the category of R-schemes. Since the functor $\theta : \mathrm{Poly}_R \to \mathrm{CAlg}_R^{\mathrm{cn}}$ preserves finite coproducts, we can also view $R[x]$ as a commutative k-algebra object (in an appropriate sense) of the ∞-category $(\mathrm{CAlg}_R^{\mathrm{cn}})^{\mathrm{op}}$. In other words, the functor $\mathrm{CAlg}_R^{\mathrm{cn}} \to \mathcal{S}$ corepresented by $R[x]$ can naturally be lifted to a functor taking values in a suitable ∞-category of "commutative R-algebras in $\mathcal{S}$": this is the ∞-category CAlg_R^Δ of simplicial commutative R-algebras, and the lifting is provided by the functor Θ^R.

Proposition 25.1.2.4 allows us to identify the ∞-category CAlg_R^{Δ} with the ∞-category of coalgebras for the comonad $T = \Theta \circ \Theta^R$ on the ∞-category $\mathrm{CAlg}_R^{\mathrm{cn}}$. In other words, the ∞-category CAlg_R^{Δ} arises naturally when we attempt to correct the difference between the $\mathbb{E}_\infty$-algebras $R[x]$ and $R\{x\}$ (which measures the failure of T to agree with the identity functor on $\mathrm{CAlg}_R^{\mathrm{cn}}$). In the ∞-category CAlg_R^{Δ}, the polynomial ring $R[x]$ is both flat over R *and* free (see Remark 25.1.3.6).

25.1.3 Homotopy Groups and Truncation

Let R be a commutative ring and let A be an object of CAlg_R^{Δ}. For each integer $n \in \mathbf{Z}$, we let $\pi_n(A)$ denote the nth homotopy group of the $\mathbb{E}_\infty$-ring A°. Then $\pi_*(A)$ is a graded R-algebra which is commutative in the graded sense (that is, for homogeneous elements $x \in \pi_m(A)$ and $y \in \pi_n(A)$, we have $xy = (-1)^{mn} yx \in \pi_{m+n}(A)$). Since the functor $A \mapsto A^\circ$ is conservative, a morphism $f : A \to B$ of simplicial commutative R-algebras is an equivalence if and only if each of the induced maps $\pi_n(A) \to \pi_n(B)$ is an isomorphism.

Remark 25.1.3.1. Let R be a commutative ring, and suppose we are given a diagram

$$A_0 \leftarrow A \rightarrow A_1$$

in the ∞-category CAlg_R^{Δ}, having pushout $A_0 \otimes_A A_1$. Then Proposition HA.7.2.1.19 supplies a convergent spectral sequence

$$E_2^{s,t} = \mathrm{Tor}_s^{\pi_*(A)}(\pi_*(A_0), \pi_*(A_1))_t \Rightarrow \pi_{s+t}(A_0 \otimes_A A_1).$$

Example 25.1.3.2. Let $\phi : R \to R'$ be any homomorphism of commutative rings, and let us identify R' with the corresponding discrete object of CAlg_R^{Δ}. Then for each $n \geqslant 0$, we have a canonical equivalence

$$R' \otimes_R R[x_1, \ldots, x_n] \simeq R'[x_1, \ldots, x_n]$$

in CAlg_R^{Δ}.

Remark 25.1.3.3. Let R be a commutative ring, let A be an object of CAlg_R^{Δ}, and let $n \geqslant 0$ be an integer. The following conditions are equivalent:

(1) The $\mathbb{E}_\infty$-ring A° is n-truncated.

(2) The homotopy groups $\pi_m(A)$ vanish for $m > n$.

(3) For every object $B \in \mathrm{CAlg}_R^{\Delta}$, the mapping space $\mathrm{Map}_{\mathrm{CAlg}_R^{\Delta}}(B, A)$ is n-truncated.

We will say that A is *n-truncated* if it satisfies these equivalent conditions. We let $\tau_{\leqslant n} \mathrm{CAlg}_R^{\Delta}$ denote the full subcategory of CAlg_R^{Δ} spanned by the n-truncated objects.

Remark 25.1.3.4. Let k be a commutative ring and let $n \geqslant 0$ be an integer. Then the inclusion functor $\tau_{\leqslant n} \operatorname{CAlg}_R^{\Delta} \hookrightarrow \operatorname{CAlg}_R^{\Delta}$ admits a left adjoint $\tau_{\leqslant n} : \operatorname{CAlg}_R^{\Delta} \to \tau_{\leqslant n} \operatorname{CAlg}_R^{\Delta}$, given concretely by the formula

$$(\tau_{\leqslant n} A)(P) = \tau_{\leqslant n}(A(P)).$$

for $P \in \operatorname{Poly}_R$. Note that the forgetful functor $A \mapsto A^{\circ}$ commutes with the formation of n-truncations.

Remark 25.1.3.5. For each $n \geqslant 0$, the forgetful functor

$$\Theta : \operatorname{CAlg}_R^{\Delta} \to \operatorname{CAlg}_R^{\mathrm{cn}} \qquad A \mapsto A^{\circ}$$

restricts to a functor $\Theta_{\leqslant n} : \tau_{\leqslant n} \operatorname{CAlg}_R^{\Delta} \to \tau_{\leqslant n} \operatorname{CAlg}_R^{\mathrm{cn}}$. When $n = 0$, this functor is an equivalence of categories (in this case, both sides can be identified with the ordinary category $\operatorname{CAlg}_R^{\heartsuit}$ of commutative algebras over R).

Remark 25.1.3.6. Let R be a commutative ring and let A be an object of $\operatorname{CAlg}_R^{\Delta}$. The homotopy groups $\pi_*(A)$ can be identified with the homotopy groups of the mapping space $\operatorname{Map}_{\operatorname{CAlg}_R^{\Delta}}(R[x], A)$. In particular, we have a canonical bijection $\operatorname{Hom}_{\operatorname{hCAlg}_R^{\Delta}}(R[x], A) \simeq \pi_0(A)$. More generally, evaluation separately on each variable induces a homotopy equivalence

$$\operatorname{Map}_{\operatorname{CAlg}_R^{\Delta}}(R[x_1, \ldots, x_n], A) \simeq \operatorname{Map}_{\operatorname{CAlg}_R^{\Delta}}(R[x], A)^n$$

and a bijection $\operatorname{Hom}_{\operatorname{hCAlg}_R^{\Delta}}(R[x_1, \ldots, x_n], A) \simeq \pi_0(A)^n$.

Remark 25.1.3.7. Let $f : R[x_1, \ldots, x_n] \to R[y_1, \ldots, y_m]$ be a homomorphism of polynomial rings over R, given by $x_i \mapsto f_i(y_1, \ldots, y_m)$. For every object $A \in \operatorname{CAlg}_k^{\Delta}$, composition with f induces a map of spaces

$$\operatorname{Map}_{\operatorname{CAlg}_R^{\Delta}}(R[y_1, \ldots, y_m], A) \to \operatorname{Map}_{\operatorname{CAlg}_R^{\Delta}}(R[x_1, \ldots, x_n], A).$$

Passing to homotopy groups at some point $\eta \in \operatorname{Map}_{\operatorname{CAlg}_R^{\Delta}}(R[y_1, \ldots, y_m], A)$, we get a map $\pi_*(A)^m \to \pi_*(A)^n$. For $* = 0$, this map is given by

$$(a_1, \ldots, a_m) \mapsto (f_1(a_1, \ldots, a_m), \ldots, f_n(a_1, \ldots, a_m)).$$

For $* > 0$, it is given instead by the action of the Jacobian matrix $[\frac{\partial f_i}{\partial y_j}]$ (which we regard as a matrix taking values in $\pi_0(A)$ using the morphism η).

25.1.4 Change of Base Ring

We now study the behavior of the ∞-category CAlg^{Δ}_R as we vary the commutative ring R.

Construction 25.1.4.1 (Restriction and Extension of Scalars)**.** Let $\varphi : R \to R'$ be a homomorphism of commutative rings. Then extension of scalars along φ determines a functor $f : \mathrm{Poly}_R \to \mathrm{Poly}_{R'}$. Using Proposition 25.1.1.5, we see that there is an essentially unique functor $F : \mathrm{CAlg}^{\Delta}_k \to \mathrm{CAlg}^{\Delta}_{k'}$ which preserves sifted colimits and fits into a commutative diagram

$$\begin{array}{ccc} \mathrm{Poly}_R & \xrightarrow{f} & \mathrm{Poly}_{R'} \\ \downarrow{\scriptstyle j} & & \downarrow{\scriptstyle j} \\ \mathrm{CAlg}^{\Delta}_R & \xrightarrow{F} & \mathrm{CAlg}^{\Delta}_{R'} . \end{array}$$

In this case, we will say that $F : \mathrm{CAlg}^{\Delta}_R \to \mathrm{CAlg}^{\Delta}_{R'}$ is the functor of *extension of scalars along* φ.

Since the functor f preserves finite coproducts, the functor F preserves small colimits and therefore admits a right adjoint $G : \mathrm{CAlg}^{\Delta}_{R'} \to \mathrm{CAlg}^{\Delta}_R$. Concretely, if we identify $\mathrm{CAlg}^{\Delta}_{R'}$ with the full subcategory of $\mathrm{Fun}(\mathrm{Poly}^{\mathrm{op}}_{R'}, \mathcal{S})$ spanned by those functors which preserve finite products, then the functor G is given by precomposition with f. In particular, we have a canonical isomorphism $\pi_*(G(A)) \simeq \pi_*(A)$. We will refer to G as the functor of *restriction of scalars along* φ.

In the situation of Construction 25.1.4.1, the canonical isomorphism $\pi_*(G(R')) \simeq R'$ shows that $G(R')$ is a discrete object of CAlg^{Δ}_R which can be identified with R' (as a commutative algebra over R).

Proposition 25.1.4.2. *Let $\varphi : R \to R'$ be a homomorphism of commutative rings. Then the restriction of scalars functor of Construction 25.1.4.1 induces an equivalence of ∞-categories*

$$\overline{G} : \mathrm{CAlg}^{\Delta}_{R'} \simeq (\mathrm{CAlg}^{\Delta}_{R'})_{R'/} \to (\mathrm{CAlg}^{\Delta}_R)_{G(R')/} \simeq (\mathrm{CAlg}^{\Delta}_R)_{R'/}.$$

Proof. Note that the equivalence $R' \simeq G(R')$ in CAlg^{Δ}_R induces a map $F(R') \to R'$ in the ∞-category $\mathrm{CAlg}^{\Delta}_{R'}$. Unwinding the definitions, we see that the functor $\overline{G}$ admits a left adjoint $\overline{F}$, given on objects by the formula $\overline{F}(A) = F(A) \otimes_{F(R')} R'$. We will show that the unit map $u : \mathrm{id}_{\mathrm{CAlg}^{\Delta}_R} \to \overline{G} \circ \overline{F}$ is an equivalence, so that the functor $\overline{F}$ is fully faithful. To complete the proof, it will then suffice to show that $\overline{G}$ is conservative, which follows immediately from the observation that the homotopy groups of $\overline{G}(B)$ can be identified with the homotopy groups of B.

Fix an object $A \in \mathrm{CAlg}^{\Delta}_R$; we wish to show that the unit map $u_A : A \to (\overline{G} \circ \overline{F})(A)$ is an equivalence in CAlg^{Δ}_R. Since the functor F preserves compact projective objects, the functor

G commutes with sifted colimits. It follows that the functor $A \mapsto u_A$ preserves sifted colimits. Since the ∞-category CAlg^{Δ}_R has compact projective generators given by the polynomial rings $R[x_1, \ldots, x_n]$, the ∞-category $(\mathrm{CAlg}^{\Delta}_R)_{R'/}$ has compact projective generators of the form $R[x_1, \ldots, x_n] \otimes_R R'$. It will therefore suffice to show that u_A is an equivalence when A has the form $A_0 \otimes_R R'$ for some $A_0 \simeq R[x_1, \ldots, x_n] \in \mathrm{CAlg}^{\Delta}_R$. In this case, a simple calculation shows that the map

$$\begin{aligned} \pi_*(A) &\to \pi_*(\overline{G} \circ \overline{F})(A) \\ &\simeq \pi_*(\overline{F}(A)) \\ &\simeq \pi_*(F(A) \otimes_{F(R')} R') \\ &\simeq \pi_*(F(A_0) \otimes_{F(R)} F(R') \otimes_{F(R')} R') \\ &\simeq \pi_*(F(A_0) \otimes_{F(R)} R') \\ &\simeq \pi_*(F(A_0)) \\ &\simeq R'[x_1, \ldots, x_n] \end{aligned}$$

is the identity. □

Corollary 25.1.4.3. *Let R be a commutative ring. Then the Construction 25.1.4.1 induces an equivalence of ∞-categories* $\mathrm{CAlg}^{\Delta}_R \simeq (\mathrm{CAlg}^{\Delta})_{R/}$.

Notation 25.1.4.4. For the remainder of this book, we will abuse notation by not distinguishing between the ∞-categories CAlg^{Δ}_R and $(\mathrm{CAlg}^{\Delta})_{R/}$: that is, we will think of objects of CAlg^{Δ}_R as simplicial commutative rings A equipped with a map $R \to A$.

More generally, if R is a simplicial commutative ring, we let CAlg^{Δ}_R denote the ∞-category $(\mathrm{CAlg}^{\Delta})_{R/}$. By virtue of Corollary 25.1.4.3, this agrees with Definition 25.1.1.1 (up to canonical equivalence) in the case where R is an ordinary commutative ring.

Note that every morphism $\varphi : R \to R'$ of simplicial commutative rings induces a pair of adjoint functors $\mathrm{CAlg}^{\Delta}_R \rightleftarrows \mathrm{CAlg}^{\Delta}_{R'}$, given by

$$(A \in \mathrm{CAlg}^{\Delta}_R) \mapsto (A \otimes_R R' \in \mathrm{CAlg}^{\Delta}_{R'}) \qquad (B \in \mathrm{CAlg}^{\Delta}_{R'}) \mapsto (B \in \mathrm{CAlg}^{\Delta}_R).$$

When R and R' are ordinary commutative rings, these constructions recover (up to canonical equivalence) the functors described in Construction 25.1.4.1.

25.1.5 Strictness of Multiplication

Let A be a connective $\mathbb{E}_\infty$-ring. Then we can think of A as consisting of an "underlying space" $\Omega^\infty A$ which is equipped with an addition and multiplication which satisfy the axioms of commutative algebra "up to coherent homotopy." Under this heuristic, the difference between objects of $\mathrm{CAlg}^{\mathrm{cn}}$ and objects of $\mathrm{CAlg}^{\mathrm{cn}}_{\mathbf{Z}}$ is that in the latter case, we require addition to be commutative "on the nose" rather than up to coherent homotopy. Remark 25.1.2.5 expresses a similar heuristic: the difference between objects of $\mathrm{CAlg}^{\mathrm{cn}}_{\mathbf{Z}}$ and objects of CAlg^{Δ} is that for the latter, we also require multiplication to be commutative "on the nose" rather than up to coherent homotopy. Our final goal in this section is to make this idea more precise.

Notation 25.1.5.1. The functor $\Sigma^{\infty}_{+} : \mathcal{S} \to \mathrm{Sp}^{\mathrm{cn}}$ is symmetric monoidal, where we regard $\mathcal{S}$ as equipped with the Cartesian symmetric monoidal structure and $\mathrm{Sp}^{\mathrm{cn}}$ as equipped with the symmetric monoidal structure given by the smash product. In particular, composition with Σ^{∞}_{+} induces a functor

$$\mathrm{CAlg}^{\mathrm{gp}}(\mathcal{S}) \subseteq \mathrm{CAlg}(\mathcal{S}) \to \mathrm{CAlg}(\mathrm{Sp}^{\mathrm{cn}}) = \mathrm{CAlg}^{\mathrm{cn}};$$

here $\mathrm{CAlg}^{\mathrm{gp}}(\mathcal{S})$ denotes the full subcategory of $\mathrm{CAlg}(\mathcal{S})$ spanned by the grouplike $\mathbb{E}_{\infty}$-spaces. For any connective $\mathbb{E}_{\infty}$-ring R, we can compose with the base change functor $\mathrm{CAlg}^{\mathrm{cn}} \to \mathrm{CAlg}^{\mathrm{cn}}_{R}$ to obtain a functor

$$\Psi : \mathrm{CAlg}^{\mathrm{gp}}(\mathcal{S}) \to \mathrm{CAlg}^{\mathrm{cn}}_{k}$$

$$X \mapsto R[X],$$

where $R[X]$ denotes the spectrum $R \otimes \Sigma^{\infty}_{+}(X)$ whose homotopy groups are the R-homology groups of X.

Proposition 25.1.5.2. *Let R be a commutative ring. Then the composite functor*

$$\mathrm{Mod}^{\mathrm{cn}}_{\mathbf{Z}} \xrightarrow{\Omega^{\infty}} \mathrm{CAlg}^{\mathrm{gp}}(\mathcal{S}) \xrightarrow{\Psi} \mathrm{CAlg}^{\mathrm{cn}}_{R}$$

admits an essentially unique factorization as a composition

$$\mathrm{Mod}^{\mathrm{cn}}_{\mathbf{Z}} \xrightarrow{\Psi^{\mathrm{alg}}} \mathrm{CAlg}^{\Delta}_{R} \xrightarrow{\Theta} \mathrm{CAlg}^{\mathrm{cn}}_{R},$$

where Ψ^{alg} commutes with sifted colimits. Here Θ denotes the forgetful functor of Proposition 25.1.2.4 and Ψ is the group algebra functor of Notation 25.1.5.1. Moreover, the functor Ψ^{alg} commutes with all small colimits.

Proof. Let $\mathcal{C}$ denote the full subcategory of $\mathrm{Mod}^{\mathrm{cn}}_{\mathbf{Z}}$ spanned by those modules of the form $\mathbf{Z}^{k}$. Then $\mathrm{Mod}^{\mathrm{cn}}_{\mathbf{Z}}$ is freely generated by $\mathcal{C}$ under sifted colimits (Corollary HA.7.1.4.15). Consequently, it will suffice to show that the composite functor

$$\mathcal{C} \subseteq \mathrm{Mod}^{\mathrm{cn}}_{\mathbf{Z}} \xrightarrow{\Omega^{\infty}} \mathrm{CAlg}^{\mathrm{gp}}(\mathcal{S}) \xrightarrow{\Psi} \mathrm{CAlg}^{\mathrm{cn}}_{k}$$

$$\mathbf{Z}^{k} \mapsto R[\mathbf{Z}^{k}]$$

admits an essentially unique factorization through the forgetful functor $\Theta : \mathrm{CAlg}_k^{\Delta} \to \mathrm{CAlg}_k^{\mathrm{cn}}$. This follows from the observation that Θ is an equivalence when restricted to discrete objects. To prove that Ψ^{alg} commutes with all small colimits, it suffices to observe that the functor

$$\mathcal{C} \to \mathrm{CAlg}_R^{\Delta} \qquad \mathbf{Z}^k \mapsto R[\mathbf{Z}^k]$$

preserves finite coproducts; see Proposition HTT.5.5.8.15 . □

Proposition 25.1.5.3. *Let R be a commutative ring, and let σ :*

$$\begin{array}{ccc} \mathrm{Mod}_{\mathbf{Z}}^{\mathrm{cn}} & \xrightarrow{\Psi^{\mathrm{alg}}} & \mathrm{CAlg}_R^{\Delta} \\ \downarrow \Omega^{\infty} & & \downarrow \Theta \\ \mathrm{CAlg}^{\mathrm{gp}}(\mathcal{S}) & \xrightarrow{\Psi} & \mathrm{CAlg}_R^{\mathrm{cn}} \end{array}$$

be the commutative diagram of ∞-categories supplied by Proposition 25.1.5.2. Then σ is left adjointable (Definition **??***).*

Lemma 25.1.5.4. *Let R be a commutative ring. For every object $A \in \mathrm{CAlg}_k^{\Delta}$, the canonical map*

$$\mathrm{Map}_{\mathrm{CAlg}_R^{\Delta}}(R[x^{\pm 1}], A) \to \mathrm{Map}_{\mathrm{CAlg}_R^{\Delta}}(R[x], A) \simeq \Omega^{\infty} A^{\circ}$$

induces a homotopy equivalence from $\mathrm{Map}_{\mathrm{CAlg}_R^{\Delta}}(R[x^{\pm 1}], A)$ to the union of those connected components of $\Omega^{\infty} A^{\circ}$ which correspond to invertible elements of the commutative ring $\pi_0(A)$.

Proof. It follows from Notation 25.1.2.3 that the diagram

$$\begin{array}{ccc} R[x] & \longrightarrow & R[x^{\pm 1}] \\ \downarrow & & \downarrow \\ R[x^{\pm 1}] & \longrightarrow & R[x^{\pm 1}] \end{array}$$

is a pushout square in CAlg_R^{Δ}, which implies that the map $\rho : \mathrm{Map}_{\mathrm{CAlg}_R^{\Delta}}(R[x^{\pm 1}], A) \to \mathrm{Map}_{\mathrm{CAlg}_R^{\Delta}}(R[x], A)$ has (-1)-truncated homotopy fibers: that is, it induces a homotopy equivalence from $\mathrm{Map}_{\mathrm{CAlg}_R^{\Delta}}(R[x^{\pm 1}], A)$ to some union of connected components of $\mathrm{Map}_{\mathrm{CAlg}_R^{\Delta}}(R[x], A) \simeq \Omega^{\infty} A^{\circ}$. Notation 25.1.2.3 also shows that the diagram

$$\begin{array}{ccc} R[t] & \xrightarrow{t \mapsto 1} & R \\ \downarrow t \mapsto xy & & \downarrow \\ R[x, y] & \xrightarrow{y \mapsto x^{-1}} & R[x^{\pm 1}] \end{array}$$

is a pushout square in CAlg_R^{Δ}, so that a point of $\Omega^{\infty} A^{\circ}$ belongs to the essential image of ρ if and only if its homotopy class is an invertible element in $\pi_0(A)$. □

Proof of Proposition 25.1.5.3. The functor Ψ preserves small colimits by construction and the functor Ψ^{alg} preserves small colimits by virtue of Proposition 25.1.5.2. It follows from Corollary HTT.5.5.2.9 that the functors Ψ and Ψ^{alg} admit right adjoints

$$\mathrm{GL}_1 : \mathrm{CAlg}_R^{\mathrm{cn}} \to \mathrm{CAlg}^{\mathrm{gp}}(\mathcal{S}) \qquad \mathbf{G}_m : \mathrm{CAlg}_R^{\Delta} \to \mathrm{Mod}_{\mathbf{Z}}^{\mathrm{cn}}.$$

To complete the proof, it will suffice to show that for each object $A \in \mathrm{CAlg}_R^{\Delta}$, the canonical map

$$\rho : \Omega^{\infty}(\mathbf{G}_m(A)) \to \mathrm{GL}_1(A^{\circ})$$

is a homotopy equivalence of grouplike $\mathbb{E}_{\infty}$-spaces. Unwinding the definitions, we can identify the domain of ρ with the mapping space $\mathrm{Map}_{\mathrm{CAlg}_R^{\Delta}}(R[x^{\pm 1}], A)$ and the codomain of ρ with the union of those connected components of $\Omega^{\infty} A^{\circ} \simeq \mathrm{Map}_{\mathrm{CAlg}_R^{\Delta}}(R[x], A)$ which correspond to invertible elements of $\pi_0(A)$. The desired result now follows from Lemma 25.1.5.4. □

Remark 25.1.5.5. It follows from Proposition 25.1.5.3 that we have a commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{CAlg}_R^{\Delta} & \xrightarrow{\mathbf{G}_m} & \mathrm{Mod}_{\mathbf{Z}}^{\mathrm{cn}} \\ \downarrow{\scriptstyle \Theta} & & \downarrow{\scriptstyle \Omega^{\infty}} \\ \mathrm{CAlg}_R^{\mathrm{cn}} & \xrightarrow{\mathrm{GL}_1} & \mathrm{CAlg}^{\mathrm{gp}}(\mathcal{S}). \end{array}$$

In other words, any realization of an object $A \in \mathrm{CAlg}_R^{\mathrm{cn}}$ as the underlying $\mathbb{E}_{\infty}$-algebra of a simplicial commutative ring determines a realization of the space of units $\mathrm{GL}_1(A)$ as the 0th space of a $\mathbf{Z}$-module spectrum. This can be regarded as an expression of the heuristic idea that the multiplication on a simplicial commutative ring is "strictly" commutative.

25.2 Symmetric Powers of Modules

To every $\mathbb{E}_1$-ring A, one can associate the ∞-category LMod_A of (left) A-module spectra. Conversely, from the ∞-category LMod_A together with the distinguished object $\mathbf{1} = A \in \mathrm{LMod}_A$, one can recover A: it can be identified with the endomorphism algebra of $\mathbf{1}$ (see Theorem HA.7.1.2.1).

One can think of an $\mathbb{E}_{\infty}$-ring A as consisting of an underlying $\mathbb{E}_1$-ring (which we will also denote by A) together with some additional structure (encoding the commutativity of A). By virtue of Theorem HA.7.1.2.1 , the underlying $\mathbb{E}_1$-ring is determined by the the ∞-category $\mathrm{Mod}_A \simeq \mathrm{LMod}_A$ (together with its unit object). We can therefore view the commutativity of A as an additional structure *on* the ∞-category Mod_A. In fact, we can be much more precise: according to Proposition HA.7.1.2.6 , we can recover the $\mathbb{E}_{\infty}$-structure on A from the symmetric monoidal structure on the ∞-category Mod_A (and vice versa).

Now suppose that A is a simplicial commutative ring. Then A has an underlying $\mathbb{E}_\infty$-ring (and therefore also an underlying $\mathbb{E}_1$-ring) which we will denote by A° (Construction 25.1.2.1). As an $\mathbb{E}_1$-ring, the ring spectrum A° is determined by the ∞-category Mod_{A° (together with its unit object). By analogy with the preceding discussion, it is natural to expect the fact that A° arises from a simplicial commutative ring to be reflected in some additional structure on the ∞-category Mod_{A°. For example, the $\mathbb{E}_\infty$-structure on A° determines a symmetric monoidal structure on Mod_{A°. If we are working over the field $\mathbf{Q}$, then we can recover the simplicial commutative ring A from its underlying $\mathbb{E}_\infty$-ring A° (Proposition 25.1.2.2), so there is nothing more to say. However, if we are working in positive or mixed characteristics, then the ∞-category of modules over a simplicial commutative ring has additional features that are not determined by its symmetric monoidal structure. Our goal in this section is to describe some of these features more explicitly.

We begin in §25.2.1 by describing a general paradigm. Suppose that, for every polynomial ring $A = \mathbf{Z}[x_1, \ldots, x_n]$ and every free A-module M of finite rank, we have a procedure for producing another A-module $F(M)$. In this case, the construction $(A, M) \mapsto F(M)$ admits a canonical extension to a functor defined on pairs (A, M), where R is *any* simplicial commutative ring and M is *any* connective A-module structure; this extension is characterized up to equivalence by the requirement that it commutes with sifted colimits (Corollary 25.2.1.3). We will be particularly interested in the case where $F(M) = \mathrm{CSym}^n_A(M)$ is the *classical nth symmetric power* of the module M; in this case, we will denote the extended construction by $M \mapsto \mathrm{LSym}^n_A(M)$ and refer to $\mathrm{LSym}^n_A(M)$ as the *nth derived symmetric power* of M (Construction **??**). Most of this section is devoted to the study of these derived symmetric power functors (and several variant constructions which we introduce in §25.2.2). We begin in §25.2.3 by establishing some elementary properties of derived symmetric powers: for example, they are compatible with base change in A (Proposition **??**) and carry flat modules to flat modules (Corollary 25.2.3.3).

In §25.2.4 and §25.2.5, we study the connectivity and finiteness properties of the derived symmetric power $\mathrm{LSym}^n_A(M)$. We prove an essentially connectivity estimate which asserts that if M is m-connective for $m \geqslant 2$, then $\mathrm{LSym}^n_A(M)$ is $(m+2n-2)$-connective (Proposition 25.2.4.1). The proof is based on a result of Illusie, which allows us to relate the derived symmetric powers of M to derived *divided* powers of the shift $\Sigma^{-2}(M)$ (Proposition 25.2.4.2). We also show that if M is perfect or almost perfect as an A-module, then $\mathrm{LSym}^n_A(M)$ has the same property (Proposition 25.2.5.3 and Corollary 25.2.5.2).

We refer to $\mathrm{LSym}^n_A(M)$ as the nth *derived* symmetric power of M to distinguish it from R-module given by the homotopy coinvariants for the symmetric group Σ_n on the nth tensor power $M \otimes_A \cdots \otimes_A M$. We will denote the latter by $\mathrm{Sym}^n_A(M)$ and refer to it simply as the *nth symmetric power of M*. In §25.2.6, we study the relationship between these constructions. In particular, we show that there is a canonical map $\rho : \mathrm{Sym}^n_A(M) \to \mathrm{LSym}^n_A(M)$ which is an equivalence if A is an algebra over the field $\mathbf{Q}$ of rational numbers (Proposition 25.2.6.1). Beware that it is not an equivalence in general: roughly speaking, the failure of ρ to be an equivalence can be regarded as a measure of the information that is lost in passing from the simplicial commutative ring A to its underlying $\mathbb{E}_\infty$-ring A° (note that the definition of $\mathrm{LSym}^n_A(M)$ depends on A, while $\mathrm{Sym}^n_A(M)$ depends only on A°).

25.2.1 Modules over Simplicial Commutative Rings

We begin by introducing some definitions.

Notation 25.2.1.1. Let A be a simplicial commutative ring and let A° denote its underlying $\mathbb{E}_\infty$-ring (see Construction 25.1.2.1). We let Mod_A denote the ∞-category Mod_{A°. We will refer to objects of Mod_A as *A-modules* and to Mod_A as the *∞-category of A-modules.* We will say that an A-module M is *connective* if $\pi_n M \simeq 0$ for $n < 0$ and *discrete* if $\pi_n M \simeq 0$ for $n \neq 0$; we let $\mathrm{Mod}^{\mathrm{cn}}_A$ and $\mathrm{Mod}^{\heartsuit}_A$ denote the full subcategories of Mod_A spanned by those A-modules which are connective and discrete, respectively.

Let $\mathrm{Mod}(\mathrm{Sp})$ denote the ∞-category whose objects are pairs (A, M) where A is an $\mathbb{E}_\infty$-ring and M is an A-module spectrum (Notation 2.2.1.1). We let SCRMod denote the fiber product $\mathrm{CAlg}^\Delta \times_{\mathrm{CAlg}(\mathrm{Sp})} \mathrm{Mod}(\mathrm{Sp})$ whose objects are pairs (A, M), where A is a simplicial commutative ring and M is an A-module. We let $\mathrm{SCRMod}^{\mathrm{cn}}$ denote the full subcategory of SCRMod spanned by those pairs (A, M) where M is a connective A-module.

Proposition 25.2.1.2. *Let $\mathcal{C} \subseteq \mathrm{SCRMod}^{\mathrm{cn}}$ denote the full subcategory spanned by those pairs (A, M) where A is equivalent to a polynomial ring $\mathbf{Z}[x_1, \ldots, x_m]$ for some $m \geqslant 0$ and M is equivalent to A^n for some $n \geqslant 0$. Then the objects of $\mathcal{C}$ form compact projective generators for $\mathrm{SCRMod}^{\mathrm{cn}}$: that is, the inclusion $\mathcal{C} \hookrightarrow \mathrm{SCRMod}^{\mathrm{cn}}$ extends to an equivalence of ∞-categories $\mathcal{P}_\Sigma(\mathcal{C}) = \mathrm{Fun}^\pi(\mathcal{C}^{\mathrm{op}}, \mathcal{S}) \to \mathrm{SCRMod}^{\mathrm{cn}}$.*

Proof. Note that $\mathcal{C}$ consists of those objects of $\mathrm{SCRMod}^{\mathrm{cn}}$ which can be obtained as coproduct of finitely many copies of the objects $C = (\mathbf{Z}[x], 0)$ and $D = (\mathbf{Z}, \mathbf{Z})$. Unwinding the definitions, we see that C and D corepresent functors $\mathrm{SCRMod}^{\mathrm{cn}} \to \mathcal{S}$ given by

$$(A, M) \mapsto \Omega^\infty A^\circ \qquad (A, M) \mapsto \Omega^\infty M.$$

Since both of these functors preserve sifted colimits, the objects C and D are compact and projective, so that $\mathcal{C}$ consists of compact projective objects of $\mathrm{SCRMod}^{\mathrm{cn}}$. It follows from Proposition HTT.?? that the inclusion $f : \mathcal{C} \hookrightarrow \mathrm{SCRMod}^{\mathrm{cn}}$ extends to a fully faithful embedding $F : \mathcal{P}_\Sigma(\mathcal{C}) \to \mathrm{SCRMod}^{\mathrm{cn}}$ which commutes with sifted colimits. Since f preserves finite coproducts, the functor F preserves small colimits (Proposition **??**) and therefore admits a right adjoint G (Corollary HTT.5.5.2.9). To prove that F is an equivalence of

∞-categories, it will suffice to show that the functor G is conservative. This is clear, since the conservative functor

$$((A, M) \in \mathrm{SCRMod}^{\mathrm{cn}}) \mapsto ((\Omega^{\infty} A^{\circ}, \Omega^{\infty} M) \in \mathcal{S} \times \mathcal{S})$$

factors through G. □

Corollary 25.2.1.3. *Let $\mathcal{C} \subseteq \mathrm{SCRMod}^{\mathrm{cn}}$ be as in Proposition 25.2.1.2, let $\mathcal{E}$ be an arbitrary ∞-category which admits small sifted colimits, and let $\mathrm{Fun}_{\Sigma}(\mathrm{SCRMod}_k^{\mathrm{cn}}, \mathcal{E})$ denote the full subcategory of $\mathrm{Fun}(\mathrm{SCRMod}^{\mathrm{cn}}, \mathcal{E})$ spanned by those functors which preserve sifted colimits. Then the restriction functor*

$$\mathrm{Fun}_{\Sigma}(\mathrm{SCRMod}^{\mathrm{cn}}, \mathcal{E}) \to \mathrm{Fun}(\mathcal{C}, \mathcal{E})$$

is an equivalence of ∞-categories.

Proof. Compare Proposition HTT.5.5.8.15 with Proposition 25.2.1.2. □

25.2.2 Derived Symmetric Powers

We can state Corollary 25.2.1.3 more informally as follows: to construct a functor $F : \mathrm{SCRMod}^{\mathrm{cn}} \to \mathcal{E}$ which commutes with sifted colimits, it suffices to specify the values of F on pairs (A, M) where A is a polynomial ring and M is a finitely generated free module over A. This is very convenient, since the collection of such pairs (A, M) forms an *ordinary* category rather than an ∞-category (by virtue of the fact that the higher homotopy groups of A and M vanish). We can use this to construct many examples of such functors "by hand":

Construction 25.2.2.1 (Derived Symmetric Powers)**.** Let A be a commutative ring, let $n \geqslant 0$ be an integer, and let M be a discrete A-module. We let $\mathrm{CSym}^n_A M$ denote the *discrete* A-module given by the nth symmetric power of A of M: that is, the quotient of the n-fold tensor product $\pi_0(M \otimes_A \cdots \otimes_A M)$ by the action of the symmetric group Σ_n given by permuting the factors

$$\sigma(x_1 \otimes \cdots \otimes x_n) = x_{\sigma(1)} \otimes \cdots \otimes x_{\sigma(n)}.$$

Note that if M is a free A-module of rank m with basis $\{x_1, \ldots, x_m\}$, then $\mathrm{CSym}^n_A M$ is also a free A-module of rank $\binom{n+m-1}{n}$, with basis given by the set of monomials $x_1^{d_1} \cdots x_m^{d_m}$ satisfying $d_1 + \cdots + d_m = n$. In particular, the construction $(A, M) \mapsto (A, \mathrm{CSym}^n_A M)$ determines a functor $f : \mathcal{C} \to \mathcal{C}$, where $\mathcal{C} \subseteq \mathrm{SCRMod}^{\mathrm{cn}}$ is defined as in Proposition

25.2.1.2. It follows from Corollary 25.2.1.3 that f admits an essentially unique extension $F : \mathrm{SCRMod}^{\mathrm{cn}} \to \mathrm{SCRMod}^{\mathrm{cn}}$ which commutes with sifted colimits and that the diagram

$$\begin{array}{ccc} \mathrm{SCRMod}^{\mathrm{cn}} & \xrightarrow{F} & \mathrm{SCRMod}^{\mathrm{cn}} \\ \downarrow & & \downarrow \\ \mathrm{CAlg}^{\Delta} & \xrightarrow{\mathrm{id}} & \mathrm{CAlg}^{\Delta} \end{array}$$

commutes up to canonical equivalence. We can therefore write $F(A, M) = (A, \mathrm{LSym}^n_A M)$ for some object $\mathrm{LSym}^n_A(M) \in \mathrm{Mod}^{\mathrm{cn}}_A$. We will refer to $\mathrm{LSym}^n_A(M)$ as the *derived nth symmetric power of M over A*.

Construction 25.2.2.2 (Derived Exterior Powers)**.** Let A be a polynomial ring, let $n \geqslant 0$ be an integer, and let M be a free A-module of finite rank. We let $\bigwedge^n_A(M)$ denote the nth exterior power of A of M: that is, the quotient of the n-fold tensor product $M^{\otimes n}$ by the action of the symmetric group Σ_n by signed permutations

$$\sigma(x_1 \otimes \cdots \otimes x_n) = \mathrm{sgn}(\sigma) x_{\sigma(1)} \otimes \cdots \otimes x_{\sigma(n)};$$

here $\mathrm{sgn}(\sigma) \in \{\pm 1\}$ denotes the sign of the permutation σ. Note that if M is a free A-module of rank m with basis $\{x_1, \ldots, x_m\}$, then $\bigwedge^n_A(M)$ is also a free A-module of rank $\binom{m}{n}$, with basis given the images of $x_{i_1} \otimes \cdots \otimes x_{i_n}$ where $1 \leqslant i_1 < i_2 < \cdots < i_n \leqslant m$. In particular, the construction $(A, M) \mapsto (A, \bigwedge^n_A(M))$ determines a functor $f : \mathcal{C} \to \mathcal{C}$, where $\mathcal{C} \subseteq \mathrm{SCRMod}^{\mathrm{cn}}$ is defined as in Proposition 25.2.1.2. It follows from Corollary 25.2.1.3 that f admits an essentially unique extension $F : \mathrm{SCRMod}^{\mathrm{cn}} \to \mathrm{SCRMod}^{\mathrm{cn}}$ which commutes with sifted colimits and that the diagram

$$\begin{array}{ccc} \mathrm{SCRMod}^{\mathrm{cn}} & \xrightarrow{F} & \mathrm{SCRMod}^{\mathrm{cn}} \\ \downarrow & & \downarrow \\ \mathrm{CAlg}^{\Delta} & \xrightarrow{\mathrm{id}} & \mathrm{CAlg}^{\Delta} \end{array}$$

commutes up to canonical equivalence. We can therefore write $F(A, M) = (A, \bigwedge^n_A(M))$ for some object $\bigwedge^n_A(M) \in \mathrm{Mod}^{\mathrm{cn}}_A$. We will refer to $\bigwedge^n_A(M)$ as the *derived nth exterior power of M over A*.

Construction 25.2.2.3 (Derived Divided Powers)**.** Let A be a polynomial ring, let $n \geqslant 0$ be an integer, and let M be a free A-module. We let $\Gamma^n_A(M)$ denote the nth divided power of A of M: that is, the submodule of $\pi_0(M \otimes_A \cdots \otimes_A M)$ given by taking invariants for the action of the symmetric group Σ_n given by permuting the factors. Note that if M is a free A-module of rank m, then $\Gamma^n_A(M)$ is also a free A-module of rank $\binom{n+m-1}{n}$. In particular, the construction $(A, M) \mapsto (A, \Gamma^n_A M)$ determines a functor $f : \mathcal{C} \to \mathcal{C}$, where

$\mathcal{C} \subseteq \mathrm{SCRMod}^{\mathrm{cn}}$ is defined as in Proposition 25.2.1.2. It follows from Corollary 25.2.1.3 that f admits an essentially unique extension $F : \mathrm{SCRMod}^{\mathrm{cn}} \to \mathrm{SCRMod}^{\mathrm{cn}}$ which commutes with sifted colimits and that the diagram

$$\begin{array}{ccc} \mathrm{SCRMod}^{\mathrm{cn}} & \xrightarrow{F} & \mathrm{SCRMod}^{\mathrm{cn}} \\ \downarrow & & \downarrow \\ \mathrm{CAlg}^{\Delta} & \xrightarrow{\mathrm{id}} & \mathrm{CAlg}^{\Delta} \end{array}$$

commutes up to canonical equivalence. We can therefore write $F(A, M) = (A, \Gamma^n_A(M))$ for some object $\Gamma^n_A(M) \in \mathrm{Mod}^{\mathrm{cn}}_A$. We will refer to $\Gamma^n_A(M)$ as the *derived nth divided power of M over A.*

Remark 25.2.2.4. Construction 25.2.2.3 can be regarded as dual to Construction 25.2.2.1 in the sense that if M is a free module of finite rank over a commutative ring A, then there is a canonical isomorphism

$$\Gamma^n_A(M^\vee) \simeq (\mathrm{CSym}^n_A(M))^\vee.$$

Similarly, one can contemplate a "dual" version of Construction 25.2.2.2, but this does not lead to anything new: the formation of exterior powers $M \mapsto \bigwedge^n_A(M)$ is already self-dual in the sense that there is a canonical isomorphism $\bigwedge^n_A(M^\vee) \simeq (\bigwedge^n_A(M))^\vee$ when M is a free A-module of finite rank.

Example 25.2.2.5. Let A be a simplicial commutative ring and let M be an A-module. When $n = 0$, we have $\mathrm{LSym}^n_A(M) \simeq \bigwedge^n_A(M) \simeq \Gamma^n_A(M) \simeq A$. When $n = 1$, we have $\mathrm{LSym}^n_A(M) \simeq \bigwedge^n_A(M) \simeq \Gamma^n_A(M) \simeq M$.

Construction 25.2.2.6. [Derived Symmetric Algebras] For every morphism of simplicial commutative rings $\phi : A \to B$, the underlying map of $\mathbb{E}_\infty$-rings $A^\circ \to B^\circ$ allows us to regard B° as a connective A-module. This observation determines a forgetful functor

$$G : \mathrm{Fun}(\Delta^1, \mathrm{CAlg}^{\Delta}) \to \mathrm{SCRMod}^{\mathrm{cn}}$$

$$(\phi : A \to B) \mapsto (A, B^\circ).$$

The functor G preserves small limits and filtered colimits and therefore admits a left adjoint $F : \mathrm{SCRMod}^{\mathrm{cn}} \to \mathrm{Fun}(\Delta^1, \mathrm{CAlg}^{\Delta})$. Unwinding the definitions, we see that the functor F carries a pair $(A, M) \in \mathrm{SCRMod}$ to a morphism of simplicial commutative rings whose domain can be identified with A, and whose codomain we will denote by $\mathrm{LSym}^*_A(M)$ and refer to as the *derived symmetric algebra on M*. The composite functor $G \circ F : \mathrm{SCRMod}^{\mathrm{cn}} \to \mathrm{SCRMod}^{\mathrm{cn}}$ preserves sifted colimits and is therefore determined (up to equivalence) by its restriction to the full subcategory $\mathcal{C} \subseteq \mathrm{SCRMod}^{\mathrm{cn}}$ of Proposition 25.2.1.2. Note that if $A = \mathbf{Z}[x_1, \ldots, x_m]$ is a polynomial ring over $\mathbf{Z}$ and if M is a free A-module on generators $y_1, \ldots, y_n$, then $F(A, M)$ can be identified with the map of polynomial rings $\mathbf{Z}[x_1, \ldots, x_m] \to \mathbf{Z}[x_1, \ldots, x_m, y_1, \ldots, y_n]$, so that $(G \circ F)(A, M)$ can be identified with the pair $(A, \bigoplus_{k \geqslant 0} \mathrm{CSym}^k_A(M))$. Applying Corollary 25.2.1.3, we see that for *any* connective module M over *any* simplicial commutative ring A, we have a canonical equivalence of A-modules

$$\mathrm{LSym}^*_A(M) \simeq \bigoplus_{n \geqslant 0} \mathrm{LSym}^n_A(M),$$

where the right hand side is defined as in Construction 25.2.2.1.

25.2.3 Properties of Derived Functors

Let $\phi : A \to B$ be any morphism of simplicial commutative rings. Then the forgetful functor $\mathrm{Mod}_B \to \mathrm{Mod}_A$ admits a left adjoint, which we will denote by $M \mapsto B \otimes_A M$.

Proposition 25.2.3.1. *Let $q : \mathrm{SCRMod}^{\mathrm{cn}} \to \mathrm{CAlg}^{\Delta}$ denote the forgetful functor, let $n \geqslant 0$ be an integer, and let $F : \mathrm{SCRMod}^{\mathrm{cn}} \to \mathrm{SCRMod}^{\mathrm{cn}}$ be as in Construction 25.2.2.1, 25.2.2.2, or 25.2.2.3. Then F carries q-coCartesian morphisms to q-coCartesian morphisms. In other words, for every morphism $\phi : A \to B$ of simplicial commutative rings and every connective A-module M, the canonical maps*

$$B \otimes_A \mathrm{LSym}^n_A(M) \to \mathrm{LSym}^n_B(B \otimes_A M)$$

$$B \otimes_A {\bigwedge}^n_A(M) \to {\bigwedge}^n_B(B \otimes_A M)$$

$$B \otimes_A \Gamma^n_A(M) \to \Gamma^n_B(B \otimes_A M)$$

are equivalences.

Proof. We will prove that the map $\alpha_M : B \otimes_A \mathrm{LSym}^n_A M \to \mathrm{LSym}^n_B(B \otimes_A M)$; the proof in the remaining cases differs only by a change of notation. Note that the construction $M \mapsto \alpha_M$ commutes with sifted colimits. Consequently, it will suffice to prove that α_M is an equivalence in the special case where M is a free A-module of finite rank. In particular, we may assume that $M = A \otimes_{\mathbf{Z}} M_0$ where $M_0 \simeq \mathbf{Z}^m$ is a free $\mathbf{Z}$-module of finite rank. We then have a commutative diagram

$$\begin{array}{ccc} & B \otimes_A A \otimes_{\mathbf{Z}} \mathrm{LSym}^n_{\mathbf{Z}} M_0 & \\ \swarrow & & \searrow \\ B \otimes_A \mathrm{LSym}^n_A(A \otimes_{\mathbf{Z}} M_0) & \xrightarrow{\alpha_M} & \mathrm{LSym}^n_B(B \otimes_A A \otimes_{\mathbf{Z}} M_0). \end{array}$$

Consequently, it will suffice to prove that α_M is an equivalence in the special case where $A = \mathbf{Z}$ is the ring of integers. Let us therefore regard A and M as fixed, and regard the morphism α_M as a functor of $B \in \mathrm{CAlg}^{\Delta}$. Since this functor commutes with sifted colimits, it will suffice to prove that α_M is an equivalence in the special case where $B \simeq \mathbf{Z}[x_1, \ldots, x_k]$ is a polynomial ring on finitely many generators. Unwinding the definitions, we are reduced to proving that the map

$$B \otimes_{\mathbf{Z}} \mathrm{CSym}^n_{\mathbf{Z}}(\mathbf{Z}^m) \to \mathrm{CSym}^n_B(B^m)$$

is an equivalence. This follows immediately from the explicit description of CSym^n_B on free B-modules given in Construction 25.2.2.1. □

Corollary 25.2.3.2. *Let A be a simplicial commutative ring, let $n \geqslant 0$, and let M be an A-module which is (locally) free of some finite rank r. Then the A-modules $\mathrm{LSym}^n_A(M)$, $\bigwedge^n_A(M)$, and $\Gamma^n_A(M)$ are (locally) free of ranks $\binom{n+r-1}{n}$, $\binom{r}{n}$, and $\binom{n+r-1}{n}$, respectively.*

Proof. Using Proposition 25.2.3.1, we can reduce to the case where M is a free A-module of rank r. In this case, we can write $M = A \otimes_{\mathbf{Z}} \mathbf{Z}^r$. Using Proposition 25.2.3.1 again, we can reduce to the case where $A = \mathbf{Z}$ and $M = \mathbf{Z}^r$, in which case the desired results follow from explicit calculation. □

Corollary 25.2.3.3. *Let A be a simplicial commutative ring, let $n \geqslant 0$ be an integer, and let M be a flat A-module. Then the A-modules $\mathrm{LSym}^n_A(M)$, $\bigwedge^n_A(M)$, and $\Gamma^n_A(M)$ are also flat.*

Proof. Combine Corollary 25.2.3.2 with Theorem HA.7.2.2.15 . □

It follows from Corollary 25.2.3.3 that if A is a commutative ring and M is a flat A-module, then the modules $\mathrm{LSym}^n_A(M)$, $\bigwedge^n_A(M)$, and $\Gamma^n_A(M)$ are discrete. In fact, we can be more precise:

Proposition 25.2.3.4. *Let A be a commutative ring (regarded as a discrete object of CAlg^{Δ}) and let M be a flat A-module. Then:*

(1) *There is a canonical isomorphism $\alpha : \mathrm{LSym}^n_A(M) \simeq \mathrm{CSym}^n_A(M)$.*

(2) *There is a canonical isomorphism $\beta : \bigwedge^n_A(M) \simeq \bigwedge'^n_A(M)$, where $\bigwedge'^n_A(M)$ denotes the quotient of the nth tensor power $M^{\otimes n}$ by the action of the symmetric group Σ_n by signed permutations*

$$\sigma(x_1 \otimes \cdots \otimes x_n) = \mathrm{sgn}(\sigma) x_{\sigma(1)} \otimes \cdots \otimes x_{\sigma(n)}.$$

(3) *There is a canonical isomorphism $\gamma : \Gamma^n_A(M) \simeq \Gamma'^n_A(M)$, where $\Gamma'^n_A(M)$ denotes the submodule of $M^{\otimes n}$ spanned by the elements which invariant under the action of Σ_n.*

Proof. We will prove (1); the proofs of (2) and (3) are similar. Let $\mathcal{E} \subseteq \mathrm{SCRMod}^{\mathrm{cn}}$ denote the full subcategory of $\mathrm{SCRMod}^{\mathrm{cn}}$ spanned by those objects of the form (A, M), where A is an ordinary commutative ring and M is a discrete A-module. Define functors

$$F, F' : \mathcal{E} \to \mathrm{SCRMod}^{\mathrm{cn}}$$

by setting $F(A, M) = (A, \mathrm{LSym}^n_A(M))$ and $F'(A, M) = (A, \mathrm{CSym}^n_A(M))$. By definition, the functors F and F' agree on the subcategory $\mathcal{C} \subseteq \mathcal{E}$ defined in Proposition 25.2.1.2, and F is a left Kan extension of its restriction $F|_{\mathcal{C}}$. It follows that there is an essentially unique natural transformation $\alpha : F \to F'$ which is the identity on objects of $\mathcal{C}$. For every object $(A, M) \in \mathcal{E}$, this natural transformation determines a map $\alpha_{A,M} : \mathrm{LSym}^n_A(M) \to \mathrm{CSym}^n_A(M)$. We claim that $\alpha_{A,M}$ is an equivalence when M is a flat A-module. To prove this, we first note that for fixed A, both sides commute with filtered colimits in M. Using Theorem HA.7.2.2.15 , we can reduce to the case where M is a free A-module of finite rank. In this case, M is obtained from a free $\mathbf{Z}$-module by extension of scalars, so the desired result follows from Proposition 25.2.3.1. □

Warning 25.2.3.5. Let A be a commutative ring and let M be a discrete A-module. If M is not flat, then the A-modules $\mathrm{LSym}^n_A(M)$, $\bigwedge^n_A(M)$, and $\Gamma^n_A(M)$ are not necessarily discrete. In particular, $\bigwedge^n_A(M)$ and $\Gamma^n_A(M)$ need not coincide with the usual nth exterior power and nth divided power module of M, in the sense of commutative algebra (however, the usual algebraic constructions can be recovered from $\bigwedge^n_A(M)$ and $\Gamma^n_A(M)$ by passing to connected components).

25.2.4 Connectivity of Derived Symmetric Powers

Our next goal is to prove the following:

Proposition 25.2.4.1. *Let A be a simplicial commutative ring, let M be a connective A-module, and let $n > 0$. If M is 1-connective, then $\mathrm{LSym}^n_A(M)$ is n-connective. If M is m-connective for $m \geqslant 2$, then $\mathrm{LSym}^n_A(M)$ is $(m + 2n - 2)$-connective.*

Our proof is based on the following result, which relates the functors defined in Constructions 25.2.2.1, 25.2.2.2, and 25.2.2.3:

Proposition 25.2.4.2 (Illusie)**.** *For every simplicial commutative ring A, every connective A-module M, and every nonnegative integer n, there are canonical equivalences*

$$\mathrm{LSym}^n_A(\Sigma M) \simeq \Sigma^n \bigwedge\nolimits^n_A(M) \qquad \bigwedge\nolimits^n_A(\Sigma M) \simeq \Sigma^n \Gamma^n_A(M)$$

in the ∞-category Mod_A.

Before giving the proof of Proposition 25.2.4.2, let us show that it implies Proposition 25.2.4.1.

Lemma 25.2.4.3. *Let A be a simplicial commutative ring and let M be an A-module which is m-connective for some $m \geqslant 0$. Then, for each $n > 0$, the derived divided power $\Gamma^n_A(M)$ is also m-connective.*

Proof. We proceed by induction on m, the case $m = 0$ being trivial. To carry out the inductive step, suppose that M is m-connective for $m > 0$, and let $N_\bullet$ denote the simplicial object of Mod_A given by the Čech nerve of the map $0 \to M$. Then each N_k is equivalent to $(\Sigma^{-1} M)^k$ and is therefore $(m-1)$-connective. It that $(\Gamma^n_A M) \simeq |\Gamma^n_A(N_\bullet)|$ is $(m-1)$-connective and that $\pi_{m-1} \Gamma^n_A(M)$ is a quotient of $\pi_{m-1}(\Gamma^n_A(N_0)) \simeq 0$, so that $\Gamma^n_A(M)$ is m-connective as desired. □

Proof of Proposition 25.2.4.1. If M is 1-connective, then $\Sigma^{-1}(M)$ is connective, so that $\bigwedge^n_A(\Sigma^{-1}(M))$ is a well-defined connective A-module. The first assertion now follows from the equivalence

$$\mathrm{LSym}^n_A(M) \simeq \Sigma^n \bigwedge\nolimits^n_A(\Sigma^{-1}(M))$$

provided by Proposition 25.2.4.2.

If M is m-connective for $m \geqslant 2$, then $\Sigma^{-2}(M)$ is connective. Proposition 25.2.4.2 then supplies an equivalence $\mathrm{LSym}^n_A(M) \simeq \Sigma^{2n} \Gamma^n_A(\Sigma^{-2}(M))$. We are therefore reduced to proving that A-module $\Gamma^n_A(\Sigma^{-2}(M))$ is $(m-2)$-connective, which follows from Lemma 25.2.4.3. □

Proof of Proposition 25.2.4.1. Let us first suppose that R is a discrete commutative ring and that we are given a short exact sequence

$$0 \to M' \xrightarrow{\rho} M \to M'' \to 0$$

between free R-modules of finite rank. Let $\mathrm{CSym}^*_R(M)$ denote the (discrete) symmetric algebra over R generated by M, and let $\mathrm{CSym}^*_R(M'')$ be defined similarly. Then We can regard $\mathrm{CSym}^*_R(M'')$ as the quotient of $\mathrm{CSym}^*_R(M)$ by a regular sequence given by a set of generators for M'. We therefore have a Koszul complex which resolves $\mathrm{CSym}^*_R(M'')$ by free $\mathrm{CSym}^*_R(M)$-modules of finite rank, given by

$$\cdots \to (\bigwedge\nolimits^1_R M') \otimes_R (\mathrm{CSym}^*_R M) \to (\bigwedge\nolimits^0_R M') \otimes_R (\mathrm{CSym}^*_R M) \to (\mathrm{LSym}^*_R M') \to 0.$$

Restricting to our attention to terms which are homogeneous of degree n, we obtain an exact sequence

$$0 \to (\bigwedge\nolimits^n_R M') \otimes_R (\mathrm{CSym}^0_R M) \xrightarrow{d_n} \cdots \to (\bigwedge\nolimits^0_R M') \otimes_R (\mathrm{CSym}^n_R M) \xrightarrow{d_0} \mathrm{CSym}^n_R M'' \to 0.$$

Applying the same construction to the dual exact sequence

$$0 \to M''^{\vee} \to M^{\vee} \to M'^{\vee} \to 0$$

and dualizing (using Remark 25.2.2.4), we obtain another exact sequence

$$0 \to \Gamma^n_R(M') \xrightarrow{d'_0} (\bigwedge^0_R M'') \otimes_R (\Gamma^n_R M) \to \cdots \xrightarrow{d'_n} (\bigwedge^n_R M'') \otimes_R (\Gamma^0_R M) \to 0.$$

Let $f_i(R, \rho)$ denote the image of the differential d_i and let $g_i(R, \rho)$ denote the image of the differential d'_i, so that we have equivalences

$$f_0(R, \rho) \simeq \mathrm{CSym}^n_R(M'') \qquad g_0(R, \rho) \simeq \Gamma^n_R(M')$$

$$f_n(R, \rho) \simeq \bigwedge^n_R(M') \qquad g_n(R, \rho) \simeq \bigwedge^n_R(M'')$$

and short exact sequence

$$0 \to f_{i+1}(R, \rho) \to (\bigwedge^i_R(M')) \otimes_R (\mathrm{CSym}^{n-i}_R(M)) \to f_i(R, \rho) \to 0$$

$$0 \to g_i(R, \rho) \to (\bigwedge^i_R(M'')) \otimes_R (\Gamma^{n-i}_R(M)) \to g_{i+1}(R, \rho) \simeq 0.$$

Let $\mathcal{E}$ denote the ∞-category $\mathrm{Fun}(\Delta^1, \mathrm{SCRMod}^{\mathrm{cn}}) \times_{\mathrm{Fun}(\Delta^1, \mathrm{CAlg}^{\Delta})} \mathrm{CAlg}^{\Delta}$ whose objects are pairs $(A, \rho : M' \to M)$, where A is a simplicial commutative ring and ρ is a morphism of connective A-modules. Let $\mathcal{E}_0 \subseteq \mathcal{E}$ be the full subcategory spanned by those pairs $(A, \rho : M' \to M)$ where A is a polynomial ring $\mathbf{Z}[x_1, \ldots, x_k]$ and ρ fits into a short exact sequence

$$0 \to M' \xrightarrow{\rho} M \to M'' \to 0$$

of finitely generated free modules over A. Equivalently, we can describe $\mathcal{E}_0$ as the full subcategory of $\mathcal{E}$ generated under coproducts by the objects

$$C = (\mathbf{Z}[x], \mathrm{id} : 0 \to 0) \qquad D = (\mathbf{Z}, \mathrm{id} : \mathbf{Z} \to \mathbf{Z}) \qquad E = (\mathbf{Z}, \rho_0 : 0 \to \mathbf{Z}).$$

Note that the objects C, D, and E corepresent functors $\mathcal{E} \to \mathcal{S}$ given by

$$(A, \rho) \mapsto \Omega^{\infty} A^{\circ} \qquad (A, \rho) \mapsto \Omega^{\infty} M' \qquad (A, \rho) \mapsto \Omega^{\infty} M,$$

which preserve sifted colimits and are jointly conservative. It follows that the inclusion $\mathcal{E}_0 \hookrightarrow \mathcal{E}$ extends to an equivalence of ∞-categories $\mathcal{P}_{\Sigma}(\mathcal{E}_0) \simeq \mathcal{E}$, so that any functor $u : \mathcal{E} \to \mathrm{SCRMod}^{\mathrm{cn}}$ admits an essentially unique extension to a functor $U : \mathcal{E} \to \mathrm{SCRMod}^{\mathrm{cn}}$ which commutes with sifted colimits. Applying this observation to the functors

$$(R, \rho : M' \to M) \mapsto (R, f_i(R, \rho)) \qquad (R, \rho : M' \to M) \mapsto (R, g_i(R, \rho)),$$

we obtain functors $\mathcal{E} \to \mathrm{SCRMod}^{\mathrm{cn}}$ which we will denote by

$$(A, \rho) \mapsto (A, F_i(A, \rho)) \qquad (A, \rho) \mapsto (A, G_i(A, \rho)).$$

We have canonical equivalences

$$F_0(A, \rho : M' \to M) \simeq \mathrm{LSym}^n_A \operatorname{cofib}(\rho) \qquad f_n(A, \rho : M' \to M) \simeq \bigwedge\nolimits^n_A M'$$

$$G_0(A, \rho : M' \to M) \simeq \Gamma^n_A M' \qquad G_n(A, \rho : M' \to M) \simeq \bigwedge\nolimits^n_A \operatorname{cofib}(\rho)$$

and fiber sequences

$$F_{i+1}(A, \rho : M' \to M) \to (\bigwedge\nolimits^i_A M') \otimes_A (\mathrm{CSym}^{n-i}_A M) \to F_i(A, \rho : M' \to M)$$

$$G_i(A, \rho : M' \to M) \to (\bigwedge\nolimits^i_A \operatorname{cofib}(\rho)) \otimes_A (\Gamma^{n-i}_A M) \to G_{i+1}(A, \rho : M' \to M).$$

In the special case where $M = 0$, the middle terms of these fiber sequences vanish, so we obtain the desired equivalences

$$\mathrm{LSym}^n_A(\Sigma M') \simeq F_0(A, \rho : M' \to 0) \simeq \cdots \simeq \Sigma^n F_n(A, \rho : M' \to 0) \simeq \Sigma^n \bigwedge\nolimits^n_A (M')$$

$$\bigwedge\nolimits^n_A (\Sigma M') \simeq G_n(A, \rho : M' \to 0) \simeq \cdots \simeq \Sigma^n G_0(A, \rho : M' \to 0) \simeq \Sigma^n \Gamma^n_A(M').$$

□

By virtue of Proposition 25.2.4.2, the derived exterior power functor and derived divided power functor of Constructions 25.2.2.2 and 25.2.2.3 are completely determined by the derived symmetric power functor of Construction 25.2.2.1. Consequently, we will mainly confine our discussion to derived symmetric powers in what follows.

25.2.5 Finiteness of Derived Symmetric Powers

We now study finiteness properties of the derived symmetric powers $\mathrm{LSym}^n_A(M)$ (note that, by virtue of Proposition 25.2.4.1, this subsumes also the study of finiteness properties of the constructions $\bigwedge^n_A(M)$ and $\Gamma^n_A(M)$).

Proposition 25.2.5.1. *Let A be a simplicial commutative ring and let M be a connective A-module which is perfect to order m for some $m \geqslant 0$. Then, for every $n \geqslant 0$, the A-modules $\mathrm{LSym}^n_A(M)$ is perfect to order n.*

Proof. Since M is perfect to order n, Corollary 2.7.2.4 implies that we can write M as the geometric realization of a simplicial object $M_\bullet$ of $\mathrm{Mod}^{\mathrm{cn}}_A$ where M_k is a free A-module of finite rank for $0 \leqslant k \leqslant m$. Since the functor LSym^n_A commutes with sifted colimits, we can write $\mathrm{LSym}^n_A(M)$ as the geometric realization of the simplicial object $\mathrm{LSym}^n_A(M_\bullet)$. It follows from Corollary 25.2.3.2 that $\mathrm{LSym}^n_A(M_k)$ is free of finite rank for $0 \leqslant k \leqslant m$, so that $\mathrm{LSym}^n_A(M) \simeq |\mathrm{LSym}^n_A(M_\bullet)|$ is perfect to order m by virtue of Corollary 2.7.2.4. □

Corollary 25.2.5.2. *Let A be a simplicial commutative ring, let $n \geqslant 0$, and let M be an A-module which is connective and almost perfect. Then the A-module $\mathrm{LSym}^n_A(M)$ is almost perfect.*

We now prove the analogous statement for perfect modules.

Proposition 25.2.5.3. *Let A be a simplicial commutative ring, let M be a connective perfect A-module, and let $n \geqslant 0$ be an integer. Then the derived symmetric power is $\mathrm{LSym}^n_A(M)$ is a perfect A-module.*

The proof of Proposition 25.2.5.3 will require an auxiliary construction.

Construction 25.2.5.4. Let R be a discrete commutative ring and suppose we are given a short exact sequence of finitely generated free R-modules

$$0 \to M' \xrightarrow{\rho} M \to M'' \to 0.$$

For each $d \geqslant 0$, let $\overline{F}^d(\rho)$ denote the $\mathrm{CSym}^*_R(M')$-submodule of $\mathrm{CSym}^*_R(M)$ generated by the symmetric powers $\mathrm{CSym}^{d'}_R(M)$ for $0 \leqslant d' \leqslant d$. Passing to homogeneous elements of some degree $n \geqslant 0$, we obtain a finite filtration

$$0 = \overline{F}^{-1,n}(\rho) \subseteq \overline{F}^{0,n}(\rho) \subseteq \overline{F}^{1,n}(\rho) \subseteq \cdots \subseteq \overline{F}^{n,n}(\rho) = \mathrm{CSym}^n_R(M)$$

whose successive quotients $\overline{F}^{d,n}(\rho)/\overline{F}^{d-1,n}(\rho)$ are canonically isomorphic to $\mathrm{CSym}^d_R(M'') \otimes_R \mathrm{CSym}^{n-d}_R(M')$. Let $\mathcal{E}_0 \subseteq \mathcal{E}$ be as in the proof of Proposition 25.2.4.2, so that the construction

$$(R, \rho) \mapsto (R, \overline{F}^{0,n}(\rho) \to \cdots \to \overline{F}^{n,n}(\rho))$$

determines a functor from $\mathcal{E}_0$ to the ∞-category

$$\mathrm{Fun}(\Delta^n, \mathrm{SCRMod}^{\mathrm{cn}}) \times_{\mathrm{Fun}(\Delta^n, \mathrm{CAlg}^{\Delta})} \mathrm{CAlg}^{\Delta}.$$

Arguing as in the proof of Proposition 25.2.4.2, we see that this functor admits an essentially unique extension to a functor

$$\mathcal{E} \to \mathrm{Fun}(\Delta^n, \mathrm{SCRMod}^{\mathrm{cn}}) \times_{\mathrm{Fun}(\Delta^n, \mathrm{CAlg}^{\Delta})} \mathrm{CAlg}^{\Delta}.$$

$$(R, \rho : M' \to M) \mapsto (R, F^{0,n}(\rho) \to \cdots \to F^{n,n}(\rho)),$$

where we have

$$F^{0,n}(\rho) \simeq \mathrm{LSym}^n_R(M') \qquad F^{n,n}(\rho) = \mathrm{LSym}^n_R(M)$$

$$\mathrm{cofib}(F^{d-1,n}(\rho) \to F^{d,n}(\rho)) \simeq \mathrm{LSym}^d_R(M'') \otimes_R \mathrm{LSym}^{n-d}_R(M').$$

Proof of Proposition 25.2.5.3. Let A be a simplicial commutative ring and let M be a connective perfect A-module; we wish to show that $\mathrm{LSym}^n_A(M)$ is also perfect. Choose an integer $m \geqslant 0$ such that M has Tor-amplitude $\leqslant m$. We proceed by induction on m. If $m = 0$, then M is a projective A-module of finite rank and the desired result follows from Corollary 25.2.3.2 (and Proposition 25.2.3.1). Let us therefore assume that $m > 0$. Our proof now proceeds also by induction on n. Since M is perfect and connective, the group $\pi_0 M$ is finitely generated as a module over $\pi_0 A$; we can therefore choose a fiber sequence $M' \xrightarrow{\rho} A^k \to M$ where M' is a connective perfect A-module having Tor-amplitude $< m$. Applying Construction 25.2.5.4, we deduce the existence of a finite sequence of maps

$$\mathrm{LSym}^n_A(M') \simeq F^{0,n}(\rho) \to F^{1,n}(\rho) \to \cdots \to F^{n,n}(\rho) \simeq \mathrm{LSym}^n_A(A^k),$$

where each of the successive quotients is given by

$$\mathrm{cofib}(F^{d-1,n}(\rho) \to F^{d,n}(\rho)) \simeq \mathrm{LSym}^d(M) \otimes_A \mathrm{LSym}^{n-d}(M').$$

Using our inductive hypotheses, we see that these cofibers are perfect for $d < n$, so that $F^{n-1,n}(\rho)$ is perfect. The fiber sequence

$$F^{n-1,n}(\rho) \to \mathrm{LSym}^n_A(A^k) \to \mathrm{LSym}^n_A(M)$$

now proves that $\mathrm{LSym}^n_A(M)$ is perfect, as desired. □

25.2.6 Comparison with Sym^*_A

Let A be an $\mathbb{E}_\infty$-ring. For any A-module M, let $\mathrm{Sym}^n_A(M)$ denote the nth symmetric power of M in the sense of Construction HA.3.1.3.9: that is, the A-module obtained by taking the (homotopy) coinvariants for the action of the symmetric group Σ_n on the n-fold tensor power $M \otimes_A \cdots \otimes_A M$. Note that if A and M are connective, then we have a canonical isomorphism

$$\pi_0(\mathrm{Sym}^n_A(M)) \simeq \mathrm{CSym}^n_{\pi_0(A)}(\pi_0(M)).$$

In particular, if A is a polynomial ring over $\mathbf{Z}$ and M is a finitely generated free module over A, then there is a canonical map $\rho : \mathrm{Sym}^n_A(M) \to \mathrm{CSym}^n_A(M)$ which exhibits $\mathrm{CSym}^n_A(M)$ as the 0-truncation of $\mathrm{Sym}^n_A(M)$. Since the functor $(A, M) \mapsto \mathrm{Sym}^n_A(M)$ commutes with sifted colimits, we can use Corollary 25.2.1.3 to extend ρ to a map $\mathrm{Sym}^n_A(M) \to \mathrm{LSym}^n_A(M)$ defined for all simplicial commutative rings A and all connective A-modules M. This map is generally *not* an equivalence. For example, when $A = M = \mathbf{Z}$, the symmetric power $\mathrm{LSym}^n_A(M)$ is discrete, but the homotopy groups of $\mathrm{Sym}^n_A(M)$ are the integral homology groups of Σ_n.

Proposition 25.2.6.1. *Let A be a simplicial commutative ring and suppose that there exists a morphism $\mathbf{Q} \to A$. Then, for every connective A-module M and every integer $n \geqslant 0$, the map $\rho_M : \mathrm{Sym}^n_A(M) \to \mathrm{LSym}^n_A(M)$ described above is an equivalence.*

Proof. The construction $M \mapsto \rho_M$ commutes with sifted colimits. Consequently, to prove that ρ_M is an equivalence for all connective A-modules M, it will suffice to prove that it is an equivalence in the special case where M is a free A-module of finite rank. In this case, we can write $M = A \otimes_{\mathbf{Q}} V$ where V is a finite-dimensional vector space over $\mathbf{Q}$. Using Proposition 25.2.3.1 (and the observation that the symmetric monoidal, colimit-preserving functor $\mathrm{Mod}_{\mathbf{Q}} \to \mathrm{Mod}_A$ commutes with the formation of symmetric powers), we can reduce to the case $A = \mathbf{Q}$. In this case, Proposition 25.2.3.4 allows us to identify $\mathrm{LSym}^n_{\mathbf{Q}} V$ with the classical symmetric power $\mathrm{CSym}^n_{\mathbf{Q}}(V) \simeq \pi_0 \mathrm{Sym}^n_{\mathbf{Q}}(V)$. We are therefore reduced to proving that the homotopy groups $\pi_i \mathrm{Sym}^n_{\mathbf{Q}}(V)$ vanish for $i > 0$. In other words, we wish to prove that the homology groups $\mathrm{H}_i(\Sigma_n; V^{\otimes n})$ vanish for $i > 0$, which follows from the fact that Σ_n is a finite group and $V^{\otimes n}$ is a vector space over the rational numbers. □

Remark 25.2.6.2. Proposition 25.2.6.1 shows that if we are working rationally, the derived symmetric powers LSym^n_A of Construction 25.2.2.1 can be recovered from the symmetric monoidal structure on the ∞-category Mod_A, and therefore depend only on the underlying $\mathbb{E}_\infty$-ring A°. Of course this is to be expected, since the forgetful functor $\mathrm{CAlg}^{\Delta}_{\mathbf{Q}} \to \mathrm{CAlg}^{\mathrm{cn}}_{\mathbf{Q}}$ is an equivalence of ∞-categories (Proposition 25.1.2.2).

25.3 The Algebraic Cotangent Complex

Let A be an $\mathbb{E}_\infty$-ring. For any A-module M, the direct sum $A \oplus M$ can be regarded as an $\mathbb{E}_\infty$-algebra over A. One can then define a *derivation* of A into M to be a section of the projection map $e : A \oplus M \to A$. Recall that sections of e are classified by A-module morphisms $L_A \to M$, where L_A is a certain A module which we refer to as the *cotangent complex* of A (see §HA.7.3.5).

In §25.3.1, we will show that if A is the underlying $\mathbb{E}_\infty$-ring of a simplicial commutative ring and the module M is connective, the direct sum $A \oplus M$ is also the underlying $\mathbb{E}_\infty$-algebra of a simplicial commutative ring (Construction 25.3.1.1). We can then consider a *different* notion of derivation from A into M: namely, a section of the projection map $e : A \oplus M \to A$ in the ∞-category of simplicial commutative rings. Such sections can also be classified by A-module morphisms $L^{\mathrm{alg}}_A \to M$, where is an A-module that we will refer to as the *algebraic cotangent complex of* A (Definition 25.3.1.6).

Our main objective in this section is to understand the relationship between the A-modules L_A and L^{alg}_A. We begin in §25.3.3 by observing that when A admits the structure of a simplicial commutative ring, the relative cotangent complex $L_{A/\mathbf{Z}}$ can be endowed with additional structure: namely, can be regarded as a left module over a certain $\mathbb{E}_1$-ring A^+ (Remark 25.3.3.5). The ring spectrum A^+ is equipped with a canonical map $\gamma : A^+ \to A$, and the algebraic cotangent complex L^{alg}_A can be obtained from $L_{A/\mathbf{Z}}$ by extending scalars along γ (Remark 25.3.3.7). Consequently, to analyze the difference between $L_{A/\mathbf{Z}}$ and L^{alg}_A, we would like understand how far γ is from being an equivalence of ring spectra. We address this question in §25.3.4 by showing that there are canonical maps of $\mathbb{E}_1$-rings $A \to A^+ \leftarrow \mathbf{Z}$ which induce, via the multiplication on A^+, an equivalence of spectra $A \otimes_S \mathbf{Z} \to A^+$ (Proposition 25.3.4.2). Beware that this is not an equivalence of *ring* spectra; the actions of A and $\mathbf{Z}$ on A^+ generally do not commute with one another (Warning **??**). Nevertheless, the equivalence $A \otimes_S \mathbf{Z} \simeq A^+$ gives us good control the difference between A and A^+. In 25.3.5, we translate this into information about the relationship between the cotangent complexes $L_{A/\mathbf{Z}}$ and L_A^{alg}.

For many applications, it is useful to consider not only the absolute algebraic cotangent complex L_A^{alg}, but also the *relative* algebraic cotangent complex $L_{B/A}^{\mathrm{alg}}$ associated to a morphism of simplicial commutative rings $\varphi : A \to B$. In §25.3.6, we introduce a canonical map of A-modules $\mathrm{cofib}(\varphi) \to L_{B/A}^{\mathrm{alg}}$ and study its connectivity properties, which will play a key role in understanding finiteness properties of simplicial commutative rings in §**??**.

Remark 25.3.0.1. The $\mathbb{E}_1$-ring A^+ was introduced by Schwede in [185], where it is denoted by DA.

25.3.1 Derivations

Let A be a commutative ring and let M be a (discrete) A-module. Then the direct sum $A \oplus M$ admits the structure of a commutative ring, with multiplication given by

$$(a, m)(a', m') = (aa', am' + a'm).$$

We will refer to $A \oplus M$ as the *trivial square-zero extension of A by M*. Using the paradigm described in §25.2.1, we can extend this construction to the setting of simplicial commutative rings:

Construction 25.3.1.1 (Trivial Square-Zero Extensions)**.** Let $\mathcal{C} \subseteq \mathrm{SCRMod}^{\mathrm{cn}}$ be the category appearing in Proposition 25.2.1.2, whose objects are pairs (A, M) where A is a polynomial ring and M is a free A-module of finite rank. The construction $(A, M) \mapsto A \oplus M$ determines a functor from $\mathcal{C}$ to the category of commutative rings, which we regard as a full subcategory of the ∞-category CAlg^{Δ} of simplicial commutative rings. Applying Corollary 25.2.1.3, we deduce that there is an essentially unique functor $F : \mathrm{SCRMod}^{\mathrm{cn}} \to \mathrm{CAlg}^{\Delta}$ which commutes with sifted colimits and is given by $(A, M) \mapsto A \oplus M$ on the subcategory $\mathcal{C}$. We will denote the value of the functor F on a pair (A, M) by $A \oplus M$, and refer to it as the *trivial square zero extension of A by M*.

Remark 25.3.1.2. The constructions

$$(A, M) \mapsto (A \oplus M)^{\circ} \qquad (A, M) \mapsto A^{\circ} \oplus M$$

determine functors from the ∞-category $\mathrm{SCRMod}^{\mathrm{cn}}$ to the ∞-category $\mathrm{CAlg}^{\mathrm{cn}}_{\mathbf{Z}}$ of connective $\mathbb{E}_\infty$-algebras over $\mathbf{Z}$. These functors are canonically equivalent when restricted to the full subcategory $\mathcal{C} \subseteq \mathrm{SCRMod}^{\mathrm{cn}}$ and both commute with small sifted colimits. It follows from Corollary 25.2.1.3 that they are equivalent: that is, the underlying $\mathbb{E}_\infty$-algebra of a trivial square-zero extension $A \oplus M$ in the sense of Construction 25.3.1.1 is a trivial square-zero extension of $\mathbb{E}_\infty$-algebras in the sense of Remark **??**. In particular, when A and M are discrete, then the simplicial commutative ring $A \oplus M$ of Construction 25.3.1.1 can be identified with the usual trivial square-zero extension of A by M.

Remark 25.3.1.3. In the situation of Construction 25.3.1.1, we can restrict the construction $(A, M) \mapsto A \oplus M$ to the full subcategory $\mathcal{E} \subseteq \mathrm{SCRMod}^{\mathrm{cn}}$ spanned by those pairs (A, M) where $M \simeq 0$. This restricted functor commutes with sifted colimits and agrees with the forgetful functor $(A, M) \mapsto A$ when A is a polynomial ring over $\mathbf{Z}$, and therefore agree with the forgetful functor in general: that is, whenever $M \simeq 0$, we have a canonical equivalence $A \oplus M \simeq A$.

If M is an arbitrary connective A-module, we have essentially unique maps $0 \to M \to 0$ in Mod_A, which determine maps of simplicial commutative rings $A \to A \oplus M \to A$. In other words, we can regard the trivial square-zero extension $A \oplus M$ as an object of the pointed ∞-category $(\mathrm{CAlg}^{\Delta}_A)_{/A}$.

Definition 25.3.1.4. Let A be a simplicial commutative ring and let M be a connective A-module. We let $\mathrm{Der}(A, M)$ denote the mapping space $\mathrm{Map}_{\mathrm{CAlg}^{\Delta}_{/A}}(A, A \oplus M)$. We will refer to $\mathrm{Der}(A, M)$ as the *space of derivations of A into M*.

Note that the construction $M \mapsto \mathrm{Der}(A, M)$ is functorial. In particular, given a point $\eta \in \mathrm{Der}(A, M_0)$, evaluation on η determines a map

$$\mathrm{Map}_{\mathrm{Mod}_A}(M_0, M) \to \mathrm{Der}(A, M)$$

for every connective A-module M. If this map is a homotopy equivalence for each $M \in \mathrm{Mod}^{\mathrm{cn}}_A$, then we will say that η is a *universal derivation*.

Proposition 25.3.1.5. *Let A be a simplicial commutative ring. Then there exists a connective A-module M_0 and a universal derivation $\eta \in \mathrm{Der}(A, M_0)$.*

Proof. The construction $M \mapsto \mathrm{Der}(A, M)$ determines an accessible functor

$$\mathrm{Mod}^{\mathrm{cn}}_A \to \mathcal{S}$$

which preserves small limits. We wish to show that this functor is corepresentable, which follows from Proposition HTT.5.5.2.7 . □

Construction 25.3.1.6 (The Algebraic Cotangent Complex)**.** Let A be a simplicial commutative ring. Proposition 25.3.1.5 implies that there exists a connective A-module L_A^{alg} and a universal derivation $\eta \in \mathrm{Der}(A, L_A^{\mathrm{alg}})$. It follows from general nonsense that the pair $(L_A^{\mathrm{alg}}, \eta)$ is uniquely determined up to equivalence. We will refer to L_A^{alg} as the *algebraic cotangent complex* of A.

Example 25.3.1.7. Let A be a polynomial ring $\mathbf{Z}[x_s]$ generated by a possibly infinite set of variables $\{x_s\}_{s \in S}$. Let $\Omega_{A/\mathbf{Z}}$ denote the module of Kähler differentials of A (regarded as a module over $\mathbf{Z}$, so that $\Omega_{A/\mathbf{Z}}$ is the A-module freely generated by the symbols $\{dx_s\}_{s \in S}$. The construction

$$(f \in A) \mapsto (f, \sum \frac{\partial f}{\partial x_s} dx_s)$$

determines a derivation η of A into $\Omega_{A/\mathbf{Z}}$. Moreover, for every connective A-module M, evaluation on η determines a homotopy equivalence

$$\mathrm{Map}_{\mathrm{Mod}_A}(\Omega_{A/\mathbf{Z}}, M) \to \mathrm{Der}(A, M) \simeq \mathrm{Map}_{\mathrm{CAlg}^{\Delta}_{/A}}(A, A \oplus M),$$

since both sides can be identified with the space $\prod_{s \in S} \Omega^{\infty} M$. It follows that η is a universal derivation, and therefore determines an identification $L_A^{\mathrm{alg}} \simeq \Omega_{A/\mathbf{Z}}$; in particular, L_A^{alg} is a *discrete* A-module.

Example 25.3.1.8. Let A be a commutative ring. When regarded as an object of the ∞-category CAlg^{Δ}, the commutative ring A can be written as the geometric realization of a simplicial object $P_\bullet$ where each P_n is a polynomial ring over $\mathbf{Z}$ (possibly with an infinite set of generators). It follows from Remark **??** that we can identify the algebraic cotangent complex L_A^{alg} with the geometric realization of the simplicial A-module $A \otimes_{P_\bullet} L_{P_\bullet}^{\mathrm{alg}}$. It follows from Example 25.3.1.7 that this simplicial A-module is levelwise free, given by $A \otimes_{P_\bullet} \Omega_{P_\bullet/\mathbf{Z}}$. We can therefore identify L_A^{alg} with the B-module represented by the normalized chain complex

$$\cdots \to A \otimes_{P_2} \Omega_{P_2/\mathbf{Z}} \to A \otimes_{P_1} \Omega_{P_1/\mathbf{Z}} \to A \otimes_{P_0} \Omega_{P_0/\mathbf{Z}}.$$

This chain complex is often referred to as the *cotangent complex of* A; its homology is called the *André-Quillen homology of* A and has been studied by many authors (see for example [1], [132], and [167]). We refer to it instead as the *algebraic* cotangent complex to distinguish it from the complex L_A which computes the *topological* André-Quillen homology of A (which plays a larger role throughout most of this book).

25.3.2 The Relative Algebraic Cotangent Complex

The construction $A \mapsto (A, L_A^{\mathrm{alg}})$ determines a functor from the ∞-category of simplicial commutative rings to the ∞-category $\mathrm{SCRMod}^{\mathrm{cn}}$. In particular, every map of simplicial commutative rings $\phi : A \to B$ induces a morphism of B-modules

$$B \otimes_A L_A^{\mathrm{alg}} \to L_B^{\mathrm{alg}}.$$

Notation 25.3.2.1. Let $f : A \to B$ be a morphism of simplicial commutative rings. We let $L_{B/A}^{\mathrm{alg}}$ denote the cofiber of the induced map $B \otimes_A L_A^{\mathrm{alg}} \to L_B^{\mathrm{alg}}$. We will refer to $L_{B/A}^{\mathrm{alg}}$ as the *relative algebraic cotangent complex of B over A*.

Example 25.3.2.2. Let A be a simplicial commutative ring, let M be a connective A-module, and let $B = \mathrm{LSym}_A^*(M)$ be the derived symmetric algebra on M (see Construction 25.2.2.6). The universal property of B then supplies a canonical equivalence

$$L_{B/A}^{\mathrm{alg}} \simeq B \otimes_A M.$$

In the special case where $A = \mathbf{Z}$ and M is a free A-module, this recovers the description of the absolute algebraic cotangent complex L_B^{alg} given in Example 25.3.1.7.

Remark 25.3.2.3. Fix a simplicial commutative ring B. Then the construction

$$A \mapsto B \otimes_A L_A^{\mathrm{alg}}$$

determines a functor $F : \mathrm{CAlg}_{/B}^{\Delta} \to \mathrm{Mod}_B^{\mathrm{cn}}$. Unwinding the definitions, we see that this functor is left adjoint to the square-zero extension functor

$$G : \mathrm{Mod}_B^{\mathrm{cn}} \to \mathrm{CAlg}_B^{\Delta} \qquad M \mapsto B \oplus M.$$

In particular, the functor F preserves small colimits.

Remark 25.3.2.4. Let $\phi : A \to B$ be a morphism of simplicial commutative rings. For every connective B-module M, we have a canonical homotopy equivalence

$$\mathrm{Map}_{\mathrm{Mod}_B}(L_{B/A}^{\mathrm{alg}}, M) \simeq \mathrm{Map}_{(\mathrm{CAlg}_A^{\Delta})_{/B}}(B, B \oplus M).$$

It follows that for every pushout diagram of simplicial commutative rings

$$\begin{array}{ccc} A' & \longrightarrow & B' \\ \downarrow & & \downarrow \\ A & \longrightarrow & B, \end{array}$$

there is a canonical equivalence of B-modules $L_{B/A}^{\mathrm{alg}} \simeq B \otimes_{B'} L_{B'/A'}^{\mathrm{alg}}$.

Remark 25.3.2.5. For every composable pair of morphisms between simplicial commutative rings $A \to B \to C$, there is a canonical cofiber sequence

$$C \otimes_B L_{B/A}^{\mathrm{alg}} \to L_{C/A}^{\mathrm{alg}} \to L_{C/B}^{\mathrm{alg}}$$

in the stable ∞-category Mod_C.

25.3.3 Spectrum Objects of $\mathrm{CAlg}^{\Delta}_{/A}$

Let A be an $\mathbb{E}_\infty$-ring and let M be an A-module spectrum. In §HA.7.3.4 , we equipped the direct sum $A \oplus M$ with the structure of an $\mathbb{E}_\infty$-algebra (see Remark **??**). Let $\mathrm{CAlg}^{\mathrm{aug}}_A$ denote the ∞-category of augmented $\mathbb{E}_\infty$-algebras over A, whose objects are pairs (B, ϵ) where $B \in \mathrm{CAlg}_A$ and $\epsilon : B \to A$ is an augmentation. The construction $(B, \epsilon) \mapsto \mathrm{fib}(\epsilon)$ determines a functor $\rho : \mathrm{CAlg}^{\mathrm{aug}}_A \to \mathrm{Mod}_A$. This functor commutes with finite limits, and therefore induces a functor on spectrum objects

$$\overline{\rho} : \mathrm{Sp}(\mathrm{CAlg}^{\mathrm{aug}}_A) \to \mathrm{Sp}(\mathrm{Mod}_A) \simeq \mathrm{Mod}_A .$$

According to Corollary HA.7.3.4.14 , the functor $\overline{\rho}$ is an equivalence of ∞-categories; the direct sum $A \oplus M$ is then defined as the image of M under the composition

$$\mathrm{Mod}_A \xrightarrow{\overline{\rho}^{-1}} \mathrm{Sp}(\mathrm{CAlg}^{\mathrm{aug}}_A) \xrightarrow{\Omega^\infty} \mathrm{CAlg}^{\mathrm{aug}}_A .$$

Phrased differently, the functor $M \mapsto A \oplus M$ can be characterized (up to contractible choice) by the requirement that there is a canonical equivalence $M \simeq \rho(A \oplus M)$.

In §25.3.1, we gave an analogous definition in the situation where A is a simplicial commutative ring and M is a connective A-module. However, our approach was somewhat different: in essence, we gave a direct construction of the functor $(A, M) \mapsto A \oplus M$, rather than characterizing it by a universal property. It is also possible to apply the abstract formalism of §HA.7.3.4 in the setting of simplicial commutative rings. However, this yields a slightly different notion of square-zero extension.

Notation 25.3.3.1. Let A be a simplicial commutative ring and let $\mathrm{CAlg}^{\Delta}_{/A}$ denote the ∞-category whose objects are pairs (B, ϵ), where B is a simplicial commutative ring equipped with a map $\epsilon : B \to A$ (here we do not require that B is equipped with the structure of a simplicial commutative algebra over A). The construction

$$(\epsilon : B \to A) \mapsto \mathrm{fib}(\epsilon^\circ : B^\circ \to A^\circ)$$

determines a functor of ∞-categories $\psi_0 : \mathrm{CAlg}^{\Delta}_{/A} \to \mathrm{Sp}$. This functor preserves small limits, and therefore induces a functor between spectrum objects

$$\psi : \mathrm{Sp}(\mathrm{CAlg}^{\Delta}_{/A}) \to \mathrm{Sp}(\mathrm{Sp}) \simeq \mathrm{Sp} .$$

Proposition 25.3.3.2. *Let A be a simplicial commutative ring. Then:*

(1) *The functor $\psi : \mathrm{Sp}(\mathrm{CAlg}^{\Delta}_{/A}) \to \mathrm{Sp}$ admits a left adjoint φ.*

(2) *The adjunction $\mathrm{Sp} \underset{\psi}{\overset{\varphi}{\rightleftarrows}} \mathrm{Sp}(\mathrm{CAlg}^{\Delta}_{/A})$ is monadic.*

(3) *The underlying monad* $(\psi \circ \varphi) : \mathrm{Sp} \to \mathrm{Sp}$ *is a functor which preserves small colimits.*

Proof. The functor $\psi_0 : \mathrm{CAlg}^{\Delta}_{/A} \to \mathrm{Sp}$ preserves small limits and filtered colimits, so the functor $\psi : \mathrm{Sp}(\mathrm{CAlg}^{\Delta}_{/A}) \to \mathrm{Sp}$ has the same properties. Assertion (1) now follows from the adjoint functor theorem (Corollary HTT.5.5.2.9). Note that ψ is a left exact functor between stable ∞-categories and therefore right exact. It follows that ψ preserves all small colimits, which proves (3). In particular, ψ preserves geometric realizations. Since it is also conservative, assertion (2) follows from the Barr-Beck theorem (Theorem HA.4.7.0.3). □

Corollary 25.3.3.3. *Let* A *be a simplicial commutative ring. Then the functor*

$$\psi : \mathrm{Sp}(\mathrm{CAlg}^{\Delta}_{/A}) \to \mathrm{Sp}$$

factors canonically as a composition

$$\mathrm{Sp}(\mathrm{CAlg}^{\Delta}_{/A}) \simeq \mathrm{LMod}_{A^+} \xrightarrow{u} \mathrm{Sp}$$

for some $\mathbb{E}_1$*-algebra* A^+*; here* $u : \mathrm{LMod}_{A^+} \to \mathrm{Sp}$ *denotes the forgetful functor.*

Proof. Let $\psi \circ \varphi$ be the monad of Proposition 25.3.3.2, and take A^+ to be the image of $\psi \circ \varphi$ under the equivalence of monoidal ∞-categories $\mathrm{LFun}(\mathrm{Sp}, \mathrm{Sp}) \simeq \mathrm{Sp}$. □

Remark 25.3.3.4. Let A be a simplicial commutative ring and let A° denote its underlying $\mathbb{E}_\infty$-ring. Note that the construction $B \mapsto B^\circ$ determines a forgetful functor $\mathrm{CAlg}^{\Delta}_{/A} \to (\mathrm{CAlg}^{\mathrm{cn}}_{\mathbf{Z}})_{/A^\circ}$. Passing to spectrum objects, we obtain a functor $u : \mathrm{Sp}(\mathrm{CAlg}^{\Delta}_{/A}) \to \mathrm{Sp}((\mathrm{CAlg}^{\mathrm{cn}}_{\mathbf{Z}})_{/A^\circ})$. Note that the map ψ of Notation 25.3.3.1 factors as a composition

$$\mathrm{Sp}(\mathrm{CAlg}^{\Delta}_{/A}) \xrightarrow{u} \mathrm{Sp}((\mathrm{CAlg}^{\mathrm{cn}}_{\mathbf{Z}})_{/A^\circ}) \simeq \mathrm{Mod}_{A^\circ} \xrightarrow{v} \mathrm{Sp},$$

where v is the forgetful functor. It follows that there is an essentially unique map of $\mathbb{E}_1$-rings $\alpha : A^\circ \to A^+$ for which the diagram

$$\begin{array}{ccc} \mathrm{Sp}(\mathrm{CAlg}^{\Delta}_{/A}) & \xrightarrow{u} & \mathrm{Sp}((\mathrm{CAlg}^{\mathrm{cn}}_{\mathbf{Z}})_{/A^\circ}) \\ \downarrow{\sim} & & \downarrow{\sim} \\ \mathrm{LMod}_{A^+} & \longrightarrow & \mathrm{Mod}_{A^\circ} \end{array}$$

commutes up to homotopy, where the bottom horizontal map is given by restriction of scalars along α.

Remark 25.3.3.5. Let A be a simplicial commutative ring and let A° be the underlying $\mathbb{E}_\infty$-algebra over $\mathbf{Z}$. Then the cotangent complex $L_{A^\circ/\mathbf{Z}}$ can be described as the image of A under the composite functor

$$\mathrm{CAlg}^{\Delta}_{/A} \xrightarrow{\Sigma^\infty_+} \mathrm{Sp}(\mathrm{CAlg}^{\Delta}_{/A}) \to \mathrm{Sp}((\mathrm{CAlg}^{\mathrm{cn}}_{\mathbf{Z}})_{/A^\circ}) \simeq \mathrm{Mod}_{A^\circ}.$$

In particular, we see that L_{A° has a canonical preimage under the functor $\mathrm{LMod}_{A^+} \to \mathrm{Mod}_{A^\circ}$ given by restriction of scalars along the map $\alpha : A^\circ \to A^+$ of Remark 25.3.3.4.

We can summarize the situation more informally as follows: if A° is the underlying $\mathbb{E}_\infty$-ring of a simplicial commutative ring A, then the relative cotangent complex $L_{A^\circ/\mathbf{Z}}$ is endowed with additional structure: it carries a left action of the $\mathbb{E}_1$-ring A^+ of Corollary 25.3.3.3 (which restricts to the tautological action of A° on $L_{A^\circ/\mathbf{Z}}$ along $\alpha : A^\circ \to A^+$).

Let us now return to the construction of square-zero extensions given in §**??**.

Construction 25.3.3.6. Fix a simplicial commutative ring A. The construction $M \mapsto A \oplus M$ then determines a functor $\theta_0 : \mathrm{Mod}^{\mathrm{cn}}_{A^\circ} \to \mathrm{CAlg}^{\Delta}_{/A}$ which commutes with small limits. Passing to spectrum objects, we obtain a functor

$$\theta : \mathrm{Mod}_{A^\circ} \simeq \mathrm{Sp}(\mathrm{Mod}_{A^\circ}) \to \mathrm{Sp}(\mathrm{CAlg}^{\Delta}_{/A}).$$

By virtue of Remark 25.3.1.2, the composition of this functor with the forgetful map

$$\mathrm{Sp}(\mathrm{CAlg}^{\Delta}_{/A}) \to \mathrm{Sp}((\mathrm{CAlg}^{\mathrm{cn}}_{\mathbf{Z}})_{/A^\circ}) \simeq \mathrm{Mod}_{A^\circ}$$

is naturally equivalent to the identity functor Mod_{A°. It follows that there is an essentially unique map of $\mathbb{E}_1$-rings $\gamma : A^+ \to A^\circ$ for which the composition

$$\mathrm{Mod}_{A^\circ} \xrightarrow{\theta} \mathrm{Sp}(\mathrm{CAlg}^{\Delta}_{/A}) \simeq \mathrm{LMod}_{A^+}$$

is given by restriction of scalars along γ. Moreover, the composition $A^\circ \xrightarrow{\alpha} A^+ \xrightarrow{\gamma} A^\circ$ is homotopic to the identity.

Remark 25.3.3.7. Let A be a simplicial commutative ring. The algebraic cotangent complex L^{alg}_A is characterized by the requirement that, for any connective A-module M, we have canonical homotopy equivalences

$$\begin{aligned} \mathrm{Map}_{\mathrm{Mod}_{A^\circ}}(L^{\mathrm{alg}}_A, M) &\simeq \mathrm{Map}_{\mathrm{CAlg}^{\Delta}_{/A}}(A, A \oplus M) \\ &\simeq \mathrm{Map}_{\mathrm{Sp}(\mathrm{CAlg}^{\Delta}_{/A})}(\Sigma^\infty_+(A), \theta(M)) \\ &\simeq \mathrm{Map}_{\mathrm{LMod}_{A^+}}(L_{A^\circ/\mathbf{Z}}, M) \end{aligned}$$

where we regard $L_{A^\circ/\mathbf{Z}}$ as a left A^+-module as in Remark 25.3.3.4, and we regard M as a left A^+-module by restricting scalars along the map $\gamma : A^+ \to A^\circ$ of Construction 25.3.3.6. It follows that we have a canonical equivalence of A-modules $L^{\mathrm{alg}}_A \simeq A^\circ \otimes_{A^+} L_{A^\circ/\mathbf{Z}}$.

More generally, if we are given a morphism $B \to A$ of simplicial commutative rings, then we can identify the relative algebraic cotangent complex $L^{\mathrm{alg}}_{A/B}$ with $A^\circ \otimes_{A^+} L_{A^\circ/B^\circ}$.

25.3.4 Calculation of the Ring Spectrum A^+

Let A be a simplicial commutative ring. Our goal in this section is to describe the $\mathbb{E}_1$-ring A^+ appearing in the statement of Corollary 25.3.3.3. This ring spectrum is essentially characterized by the requirement that the ∞-category LMod_{A^+} is equivalent to the ∞-category of spectrum objects $\mathrm{CAlg}^{\Delta}_{/A}$. Suppose we are given an object $X \in \mathrm{Sp}(\mathrm{CAlg}^{\Delta}_{/A})$. Then the image $\widetilde{A}$ of X under the forgetful functor $\Omega^\infty : \mathrm{Sp}(\mathrm{CAlg}^{\Delta}_{/A}) \to \mathrm{CAlg}^{\Delta}_{/A}$ as a kind of "generalized trivial square-zero extension of A." Any such extension determines a trivial square-zero extension of the underlying $\mathbb{E}_\infty$-ring A°, which is automatically of the form $A^\circ \oplus M$ for some connective A°-module M. However, to promote the $\mathbb{E}_\infty$-ring $A^\circ \oplus M$ to a simplicial commutative ring A°, we also need to make the multiplication of $A^\circ \oplus M$ *strictly commutative*. We now show that this can be used to endow M with the structure of a $\mathbf{Z}$-module spectrum, which is *a priori* unrelated to its A°-module structure.

Construction 25.3.4.1. Let A be a simplicial commutative ring and let A° denote its underlying $\mathbb{E}_\infty$-ring. Then Remark 25.1.5.5 supplies a commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{CAlg}^{\Delta}_{/A} & \xrightarrow{\mathbf{G}_m} & (\mathrm{Mod}^{\mathrm{cn}}_{\mathbf{Z}})_{/\mathbf{G}_m(A)} \\ \downarrow{\scriptstyle\Theta} & & \downarrow \\ (\mathrm{CAlg}^{\mathrm{cn}}_{\mathbf{Z}})_{/A^\circ} & \xrightarrow{\mathrm{GL}_1} & \mathrm{CAlg}^{\mathrm{gp}}(\mathcal{S})_{/\,\mathrm{GL}_1(A^\circ)} \end{array}$$

Passing to spectrum objects and using the equivalences

$$\mathrm{CAlg}^{\Delta}_{/A} \simeq \mathrm{LMod}_{A^+} \qquad \mathrm{Sp}((\mathrm{Mod}^{\mathrm{cn}}_{\mathbf{Z}})_{/\mathbf{G}_m(A)}) \simeq \mathrm{Mod}_{\mathbf{Z}}$$

$$\mathrm{Sp}((\mathrm{CAlg}^{\mathrm{cn}}_{\mathbf{Z}})_{/A^\circ}) \simeq \mathrm{Mod}_{A^\circ} \qquad \mathrm{Sp}((\mathrm{CAlg}^{\mathrm{gp}}(\mathcal{S}))_{/\,\mathrm{GL}_1(A^\circ)}) \simeq \mathrm{Sp},$$

we obtain a commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{LMod}_{A^+} & \longrightarrow & \mathrm{Mod}_{\mathbf{Z}} \\ \downarrow & & \downarrow \\ \mathrm{Mod}_{A^\circ} & \longrightarrow & \mathrm{Sp} \end{array}$$

where the bottom horizontal map and right vertical maps are the forgetful functors, and the left vertical map is given by restriction of scalars along the map $\alpha : A^\circ \to A^+$ of Remark 25.3.3.4. It follows that the upper horizontal map is given by restriction of scalars along an essentially unique morphism of $\mathbb{E}_1$-rings $\beta : \mathbf{Z} \to A^+$.

We now use Construction 25.3.4.1 to describe the structure of the ring spectrum A^+ (see [185] for another proof):

Proposition 25.3.4.2 (Schwede). *Let A be a simplicial commutative ring and let $\alpha : A^{\circ} \to A^{+}$ and $\beta : \mathbf{Z} \to A^{+}$ be the morphisms of $\mathbb{E}_1$-rings given in Remark 25.3.3.4 and Construction 25.3.4.1, respectively. Then the multiplication on A^{+} induces a homotopy equivalence of spectra*

$$A^{\circ} \otimes_S \mathbf{Z} \xrightarrow{\alpha \otimes \beta} A^{+} \otimes_S A^{+} \to A^{+}.$$

Warning 25.3.4.3. Let A be a simplicial commutative ring. In general, the $\mathbb{E}_1$-ring A^{+} is not commutative (in fact, the graded ring $\pi_* A^{+}$ need not even be graded-commutative). Consequently, the homotopy equivalence $A^{\circ} \otimes_S \mathbf{Z} \simeq A^{+}$ is generally not compatible with ring structures. More informally, the issue is that the $\mathbb{E}_1$-ring morphisms $f : \mathbf{Z} \to A^{+}$ and $f' : A^{\circ} \to A^{+}$ do not "commute" with one another. Beware also that the order of the multiplication is important: we can also consider the multiplication map

$$\mathbf{Z} \otimes_S A^{+} \xrightarrow{\beta \otimes \alpha} A^{+} \otimes_S A^{+} \to A^{+},$$

but this map is generally not a homotopy equivalence of spectra.

Proof of Proposition 25.3.4.2. We have a commutative diagram of $\mathbb{E}_1$-rings

$$\begin{array}{ccc} A^{+} & \xleftarrow{\beta} & \mathbf{Z} \\ \uparrow{\scriptstyle \alpha} & & \uparrow \\ A^{\circ} & \longleftarrow & S \end{array}$$

which induces a commutative diagram of module ∞-categories σ :

$$\begin{array}{ccc} \mathrm{LMod}_{A^{+}} & \longrightarrow & \mathrm{Mod}_{\mathbf{Z}} \\ \downarrow & & \downarrow \\ \mathrm{Mod}_{A^{\circ}} & \longrightarrow & \mathrm{Mod}_{\mathrm{Sp}} \end{array}$$

Unwinding the definitions, we see that the multiplication map $A^{\circ} \otimes_S \mathbf{Z} \to A^{+}$ is an equivalence if and only if the diagram σ is left adjointable. By construction, the diagram σ arises by applying the stabilization construction to a diagram of ∞-categories σ_0:

$$\begin{array}{ccc} \mathrm{CAlg}^{\Delta}_{/A} & \xrightarrow{\mathbf{G}_m} & (\mathrm{Mod}^{\mathrm{cn}}_{\mathbf{Z}})_{/\mathbf{G}_m(A)} \\ \downarrow{\scriptstyle \Theta} & & \downarrow \\ (\mathrm{CAlg}^{\mathrm{cn}}_{\mathbf{Z}})_{/A^{\circ}} & \xrightarrow{\mathrm{GL}_1} & \mathrm{CAlg}^{\mathrm{gp}}(\mathcal{S})_{/\mathrm{GL}_1(A^{\circ})} \end{array}$$

We are therefore reduced to showing that the diagram σ_0 is left adjointable, which follows from Proposition 25.1.5.3. $\square$

25.3.5 Comparison with the Topological Cotangent Complex

Let $\phi : A \to B$ be a morphism of simplicial commutative rings. Then there exists a "universal A-linear derivation" $B \to B \oplus L^{\mathrm{alg}}_{B/A}$ in the ∞-category $(\mathrm{CAlg}^{\Delta}_{A})_{/B}$. Passing to the underlying $\mathbb{E}_\infty$-rings, we obtain a morphism $B^\circ \to B^\circ \oplus L^{\mathrm{alg}}_{B/A}$ in the ∞-category $\mathrm{CAlg}_{A^\circ//B^\circ}$, which is classified by a morphism of B-modules

$$\rho_{B/A} : L_{B^\circ/A^\circ} \to L^{\mathrm{alg}}_{B/A}.$$

Proposition 25.3.5.1. *Let $\phi : A \to B$ be a morphism of simplicial commutative rings. Suppose that $\mathrm{fib}(\phi)$ is m-connective for some $m \geqslant -1$: that is, the underlying map $\pi_n A \to \pi_n B$ is surjective when $n = m$ and an isomorphism for $n < m$. Then the comparison map $\rho_{B/A} : L_{B^\circ/A^\circ} \to L^{\mathrm{alg}}_{B/A}$ has $(m+3)$-connective fiber. In other words, the map $\pi_n L_{B^\circ/A^\circ} \to \pi_n L^{\mathrm{alg}}_{B/A}$ is surjective when $n = m+3$ and an isomorphism for $n < m+3$.*

Proof. Under the identification $L^{\mathrm{alg}}_{B/A} \simeq B^\circ \otimes_{B^+} L_{B^\circ/A^\circ}$ supplied by Remark 25.3.3.7, the comparison map $\rho_{B/A}$ is given by

$$L_{B^\circ/A^\circ} \to B^\circ \otimes_{B^+} L_{B^\circ/A^\circ}.$$

Since $\mathrm{fib}(\phi)$ is m-connective, the relative cotangent complex L_{B°/A° is $(m+1)$-connective (this is trivial when $m = -1$ and follows from Corollary HA.7.4.3.2 if $m \geqslant 0$). It will therefore suffice to show that the map of $\mathbb{E}_1$-rings $\gamma : B^+ \to B^\circ$ appearing in Remark 25.3.3.5 has 2-connective fiber. Since γ is a left homotopy inverse to the map $\alpha : B^\circ \to B^+$ of Remark 25.3.3.4, we have $\mathrm{fib}\,\gamma) \simeq \Sigma\,\mathrm{fib}(\alpha)$. We are therefore reduced to proving that $\mathrm{fib}(\alpha)$ is 1-connective. We conclude by observing that the identification $B^+ \simeq B^\circ \otimes_S \mathbf{Z}$ induces an equivalence $\mathrm{fib}(\alpha) \simeq B^\circ \otimes_S (\tau_{\geqslant 1} S)$, where S is the sphere spectrum. □

Variant 25.3.5.2. Let A be a simplicial commutative ring. Then the universal derivation $A \to A \oplus L^{\mathrm{alg}}_{A}$ in $\mathrm{CAlg}^{\Delta}_{A}$ determines a map of $\mathbb{E}_\infty$-rings which is classified by a comparison map $\rho : L_{A^\circ} \to L^{\mathrm{alg}}_{A}$. The map ρ also has 2-connective fiber: this follows from the observation that ρ factors as a composition

$$L_{A^\circ} \xrightarrow{\rho'} L_{A^\circ/\mathbf{Z}} \xrightarrow{\rho''} L^{\mathrm{alg}}_{A/\mathbf{Z}},$$

where γ'' has 2-connective fiber by Proposition 25.3.5.1 and $\mathrm{fib}(\gamma') \simeq A \otimes_{\mathbf{Z}} L_{\mathbf{Z}}$ is 2-connective by virtue of the fact that the cofiber of the unit map $S \to \mathbf{Z}$ is 2-connective (here S denotes the sphere spectrum).

The connectivity estimate given in Proposition 25.3.5.1 is in some sense optimal: in general, the map $\pi_2 L_{B^\circ/A^\circ} \to \pi_2 L^{\mathrm{alg}}_{B/A}$ need not be injective (for example, it is not injective if $A = \mathbf{Z}$ and $B = \mathbf{Z}[x]$. However, we do have the following:

Proposition 25.3.5.3. *Let $\phi : A \to B$ be a morphism of simplicial commutative rings. Then the comparison map $\rho_{B/A} : L_{B^\circ/A^\circ} \to L^{\mathrm{alg}}_{B/A}$ is a rational equivalence. In other words, for every integer n, the map of abelian groups $\pi_n L_{B^\circ/A^\circ} \to \pi_n L^{\mathrm{alg}}_{B/A}$ becomes an isomorphism after tensoring with the rational numbers.*

Corollary 25.3.5.4. *Let $\phi : A \to B$ be a morphism of simplicial commutative rings, and suppose that the commutative ring $\pi_0 B$ is a $\mathbf{Q}$-algebra. Then the comparison map $\rho_{B/A} : L_{B^\circ/A^\circ} \to L^{\mathrm{alg}}_{B/A}$ is an equivalence of B-modules.*

Proof of Proposition 25.3.5.3. By virtue of Remark 25.3.3.7, it will suffice to show that the morphism of $\mathbb{E}_1$-rings $\gamma : B^+ \to B^\circ$ appearing in Remark 25.3.3.5 is a rational equivalence. Note that γ is left inverse to the map $\alpha : B^\circ \to B^+$ of Remark 25.3.3.4, so we are reduced to showing that α is a rational equivalence. It follows from Proposition 25.3.4.2 that as a map of spectra, α can be obtained by smashing the identity on B° with the unit map $S \to \mathbf{Z}$, where S is the sphere spectrum. We are therefore reduced to proving that the unit map $S \to \mathbf{Z}$ is a rational equivalence, which follows from the fact that the stable homotopy groups of spheres are torsion in nonzero degrees. □

25.3.6 The Hurewicz Map

Let $\phi : A \to B$ be a morphism of simplicial commutative rings. Recall that the underlying morphism of $\mathbb{E}_\infty$-rings $A^\circ \to B^\circ$ determines a map

$$\epsilon^\circ_\phi : B \otimes_A \mathrm{cofib}(\phi) \to L_{B^\circ/A^\circ}$$

(see Theorem HA.7.4.3.1). Composing with the comparison map $\gamma_{B/A}$, we obtain a map

$$\epsilon_\phi : B \otimes_A \mathrm{cofib}(\phi) \to L^{\mathrm{alg}}_{B/A}.$$

We will refer to ϵ_ϕ as the *Hurewicz map associated to ϕ.*

Proposition 25.3.6.1. *Let $\phi : A \to B$ be a morphism of simplicial commutative rings and suppose that the fiber of ϕ. Then the map*

$$\epsilon_\phi : B \otimes_A \mathrm{cofib}(\phi) \to L^{\mathrm{alg}}_{B/A}$$

is surjective on π_0. If the fiber of ϕ is connective, then the fiber of ϵ_ϕ is 2-connective. If the fiber of ϕ is m-connective for $m > 0$, then the fiber of ϵ_ϕ is $(m+3)$-connective.

Warning 25.3.6.2. The analogue of Proposition 25.3.6.1 in the setting of $\mathbb{E}_\infty$-rings is somewhat stronger: it asserts that if the fiber of ϕ is m-connective, then the fiber of ϵ°_ϕ is $(2m+2)$-connective. In the setting of simplicial commutative rings, we have a weaker statement because the derived symmetric powers $\mathrm{LSym}^n_A(M)$ are only slightly more connected than M (see Proposition 25.2.4.1).

Proof of Proposition 25.3.6.1. By construction, the map ϵ_ϕ is given by a composition

$$B \otimes_A \mathrm{cofib}(\phi) \xrightarrow{\epsilon^\circ_\phi} L_{B^\circ/A^\circ} \xrightarrow{\gamma_{B/A}} L^{\mathrm{alg}}_{B/A}.$$

If the fiber $\mathrm{fib}(\phi)$ is m-connective for $m \geqslant -1$, then the fiber of ϵ°_ϕ is $(2m+2)$-connective (Theorem HA.7.4.3.1) and the fiber of $\gamma_{B/A}$ is $(m+3)$-connective (Proposition 25.3.5.1). □

Corollary 25.3.6.3. *Let $\phi : A \to B$ be a morphism of simplicial commutative rings, so that the universal derivation $B \to B \oplus L^{\mathrm{alg}}_{B/A}$ induces a morphism of A-modules $\beta : \mathrm{cofib}(\phi) \to L^{\mathrm{alg}}_{B/A}$.*

(a) *If the fiber $\mathrm{fib}(\phi)$ is connective, then the fiber $\mathrm{fib}(\beta)$ is 1-connective.*

(b) *If the fiber $\mathrm{fib}(\phi)$ is 1-connective, then the fiber $\mathrm{fib}(\beta)$ is 3-connective.*

(c) *If the fiber $\mathrm{fib}(\phi)$ is m-connective for $m \geqslant 2$, then the fiber $\mathrm{fib}(\beta)$ is $(m+3)$-connective.*

Proof. The map β factors as a composition

$$\mathrm{cofib}(\phi) \xrightarrow{\beta_0} B \otimes_A \mathrm{cofib}(\phi) \xrightarrow{\epsilon_\phi} L^{\mathrm{alg}}_{B/A}.$$

If $\mathrm{fib}(\phi)$ is m-connective, then $\mathrm{fib}(\beta) \simeq \mathrm{fib}(\phi) \otimes_A \mathrm{cofib}(\phi)$ is $(2m+1)$-connective. It follows from Proposition 25.3.6.1 that the map ϵ_ϕ is 2-connective when $m = 0$ and $(m+3)$-connective when $m > 0$. It follows that $\mathrm{fib}(\beta)$ is 1-connective when $m = 0$, 3-connective when $m = 1$, and $(m+3)$-connective for $m > 1$. □

Corollary 25.3.6.4. *Let $\phi : A \to B$ be a morphism of simplicial commutative rings. If the fiber $\mathrm{fib}(\phi)$ is m-connective for $m \geqslant 0$, then the algebraic cotangent complex $L^{\mathrm{alg}}_{B/A}$ is $(m+1)$-connective.*

Remark 25.3.6.5. Let $\phi : A \to B$ be a morphism of simplicial commutative rings, and suppose that $\mathrm{fib}(\phi)$ is m-connective for $m \geqslant 0$: that is, the map $\pi_n A \to \pi_n B$ is surjective when $n = m$ and an isomorphism for $n < m$. It follows from Corollary 25.3.6.4 that the homotopy groups $\pi_n L^{\mathrm{alg}}_{B/A}$ vanish for $n \leqslant m$. We can restate Corollary 25.3.6.3 as follows:

(a') If $m = 0$, then the universal derivation induces a surjection $\pi_1 \mathrm{cofib}(\phi) \to \pi_1 L^{\mathrm{alg}}_{B/A}$.

(b') If $m = 1$, then the universal derivation induces an isomorphism $\pi_2 \mathrm{cofib}(\phi) \to \pi_2 L^{\mathrm{alg}}_{B/A}$ and a surjection $\pi_3 \mathrm{cofib}(\phi) \to \pi_3 L^{\mathrm{alg}}_{B/A}$.

(c') If $m \geqslant 2$, then the universal derivation induces isomorphisms

$$\pi_{m+1} \mathrm{cofib}(\phi) \to \pi_{m+1} L^{\mathrm{alg}}_{B/A} \qquad \pi_{m+2} \mathrm{cofib}(\phi) \to \pi_{m+2} L^{\mathrm{alg}}_{B/A}$$

and a surjection $\pi_{m+3} \mathrm{cofib}(\phi) \to \pi_{m+3} L^{\mathrm{alg}}_{B/A}$.

Corollary 25.3.6.6. *Let $\phi : A \to B$ be a morphism of simplicial commutative rings. Then ϕ is an equivalence if and only if it induces an isomorphism of commutative rings $\pi_0 A \to \pi_0 B$ and the algebraic cotangent complex $L^{\mathrm{alg}}_{B/A}$ vanishes.*

Proof. The "only if" direction is clear. Suppose, conversely, that ϕ induces an isomorphism of $\pi_0 A$ with $\pi_0 B$. If ϕ is not an equivalence, then $\mathrm{cofib}(\phi)$ is a nonzero connective A-module, so there exists some smallest integer $n \geqslant 0$ such that $\pi_n \mathrm{cofib}(\phi) \neq 0$. Then $\pi_n(B \otimes_A \mathrm{cofib}(\phi)) \neq 0$. It follows from Proposition 25.3.6.1 that the fiber of the map

$$\epsilon_\phi : B \otimes_A \mathrm{cofib}(\phi) \to L^{\mathrm{alg}}_{B/A}$$

is $(n+1)$-connective (and even $(n+2)$-connective if $n \geqslant 2$). In particular, it induces an isomorphism $\pi_n(B \otimes_A \mathrm{cofib}(\phi)) \to \pi_n L^{\mathrm{alg}}_{B/A}$, contradicting our assumption that $L^{\mathrm{alg}}_{B/A} \simeq 0$. □

Coherent ∞-Topoi

Recall that a scheme $(X, \mathscr{O}_X)$ is said to be *quasi-compact* if the topological space X is quasi-compact: that is, every open covering of X admits a finite subcovering. We say that $(X, \mathscr{O}_X)$ is *quasi-separated* if the collection of quasi-compact open subsets of X is closed under pairwise intersections. Throughout this book, we study algebro-geometric objects which behave like schemes, but whose "underlying topology" is encoded by an ∞-topos rather than a topological space. Our primary goal in this appendix is to describe finiteness hypotheses on ∞-topoi which are analogous the the hypotheses of quasi-compactness and quasi-separatedness on ordinary topological spaces.

We begin in §A.1 with a discussion of the theory of *coherent* topological spaces: that is, sober topological spaces X for which the quasi-compact open subsets form a basis for the topology of X and are stable under finite intersections. If X is a coherent topological space, then the collection of quasi-compact open subsets of X forms a distributive lattice Λ. A version of the classical *Stone duality theorem* asserts that the lattice Λ determines X up to homeomorphism (Proposition A.1.5.10). This result provides an appealing algebraic approach to the theory of coherent topological spaces: we can describe such a space X by specifying a collection of well-behaved open subsets, rather than by specifying its points.

In §A.2, we introduce an ∞-categorical counterpart of the notion of coherent topological space: the notion of *coherent* ∞-topos. We say that an ∞-topos $\mathcal{X}$ is *locally coherent* if there exists a full subcategory $\mathcal{X}_0 \subseteq \mathcal{X}$ of quasi-compact objects which is stable under fiber products, such that every object $X \in \mathcal{X}$ admits a covering $\{U_\alpha \rightarrow X\}$ by objects of $\mathcal{X}_0$. If this condition is satisfied, then there exists a largest subcategory with these properties, which we denote by $\mathcal{X}^{\mathrm{coh}}$ and refer to as the *∞-category of coherent objects of $\mathcal{X}$*. We will say that a locally coherent ∞-topos $\mathcal{X}$ is *coherent* if $\mathcal{X}^{\mathrm{coh}}$ contains the final object of $\mathcal{X}$. Coherent ∞-topoi exist in great abundance: in §A.3, we show that if $\mathcal{C}$ is an ∞-category which admits finite limits and is equipped with a *finitary* Grothendieck topology (that is, a Grothendieck topology which is generated by finite coverings), then the ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is both coherent and locally coherent (Proposition A.3.1.3). In particular, most of the ∞-topoi that we will encounter in this book are coherent.

Most of this appendix is devoted to answering the following:

Question A.0.6.7. Let $\mathcal{X}$ be an ∞-topos which is coherent and locally coherent. To what extent can $\mathcal{X}$ be recovered from its full subcategory $\mathcal{X}^{\mathrm{coh}} \subseteq \mathcal{X}$ of coherent objects?

Before we can properly discuss Question A.0.6.7, we first need to ask something more basic:

Question A.0.6.8. Let $\mathcal{X}$ be an ∞-topos which is coherent and locally coherent. What sort of mathematical object is $\mathcal{X}^{\mathrm{coh}}$?

In §A.6, we address Question A.0.6.8 by introducing the notion of an *∞-pretopos* (Definition A.6.1.1). Roughly speaking, an ∞-pretopos is an ∞-category having the exactness properties of an ∞-topos, but which is not required to admit "infinitary" categorical constructions (such as infinite products and coproducts). If $\mathcal{X}$ is a coherent ∞-topos, then its full subcategory $\mathcal{X}^{\mathrm{coh}}$ of coherent objects is an ∞-pretopos. Conversely, if $\mathcal{C}$ is an essentially small ∞-pretopos, then $\mathcal{C}$ can be equipped with a finitary Grothendieck topology (Definition A.6.2.4) from which we can construct a coherent ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})$. Unfortunately, these constructions are not quite inverse to one another (in contrast with the analogous situation in classical topos theory), due to technicalities related to failure of Whitehead's theorem in a general ∞-topos. However, we can obtain a good dictionary by imposing additional restrictions on both sides. This can be accomplished in (at least) two different ways:

(*a*) An ∞-topos $\mathcal{X}$ is said to be *hypercomplete* if every ∞-connective morphism $f : X \to Y$ in $\mathcal{X}$ is an equivalence (in other words, if Whitehead's theorem is valid for $\mathcal{X}$). In §A.6, we will introduce the more general notion of a *hypercomplete ∞-pretopos* (Definition A.6.5.3) and establish an equivalence

$$\{ \text{ Small hypercomplete } \infty\text{-pretopoi } \}$$
$$\Updownarrow$$
$$\{ \text{ Hypercomplete, coherent, locally coherent } \infty\text{-topoi } \}$$

(see Theorem A.6.6.5).

(*b*) We will say that an ∞-topos $\mathcal{X}$ is *bounded* if it can be written as a limit of n-localic ∞-topoi (Definition A.7.1.2) and that an ∞-pretopos $\mathcal{C}$ is bounded if it is essentially small and each object $C \in \mathcal{C}$ is truncated (Definition A.7.4.1). In §A.7, we establish an equivalence

$$\{ \text{ Bounded } \infty\text{-pretopoi } \}$$
$$\Updownarrow$$
$$\{ \text{ Bounded coherent } \infty\text{-topoi } \}$$

(see Theorem A.7.5.3).

Both (*a*) and (*b*) provide useful contexts in which to work. In §A.4, we will show that an ∞-topos $\mathcal{X}$ which is hypercomplete and locally coherent has enough points (Theorem A.4.0.5): this can be regarded as an ∞-categorical generalization of a classical result of Deligne on coherent Grothendieck topoi (Corollary A.4.0.6). This result is useful because it provides a general mechanism for reducing certain types of questions about arbitrary ∞-topoi to more concrete questions about the homotopy theory of spaces. We will apply this mechanism in §A.5 to show that in any ∞-topos $\mathcal{X}$, the homotopy theory of simplicial objects of $\mathcal{X}$ behaves to a large extent like the classical homotopy theory of simplicial sets (see Theorems **??**, A.5.4.1, and A.5.6.1). On the other hand, the theory of bounded ∞-pretopoi has the virtue that it admits a completely finitary description (in other words, it can be axiomatized without referring to infinite limits and colimits), and seems to provide a good language for extending concepts of first-order logic to the ∞-categorical setting. We offer some evidence for this last assertion in §A.9 by proving an ∞-categorical generalization of the "conceptual completeness" theorem of Makkai-Reyes (see [143]), asserting that a morphism of bounded ∞-pretopoi $f^* : \mathcal{C} \to \mathcal{D}$ is an equivalence if and only if $\mathcal{C}$ and $\mathcal{D}$ have the same "models" (see Theorem A.9.3.1 for a precise statement). The proof relies on a study of Pro-objects of bounded ∞-pretopoi which we carry out in §A.8 which may be of some independent interest (and will be useful for our study of profinite homotopy theory in Appendix E).

Contents

A.1 Stone Duality

Let X be a topological space. We will say that X is *coherent* if it satisfies the following conditions:

(a) The space X is *sober*: that is, every irreducible closed subset of X has a unique generic point (see Definition 1.5.3.1).

(b) The collection of quasi-compact open subsets of X forms a basis for the topology of X.

(c) The space X is quasi-compact and quasi-separated. In other words, the collection of quasi-compact open subsets of X is closed under finite intersections.

Warning A.1.0.9. Some authors do not include condition (a) in the definition of a coherent topological space. This does not matter very much: for every topological space X, one can construct a sober topological space X' having the same lattice of open sets (concretely, X' can be described as the set of irreducible closed subsets of X). Then X' is coherent if and only if X satisfies conditions (b) and (c).

Our goal in this section is to review the theory of Stone duality, which establishes an equivalence of the theory of coherent topological spaces and the theory of distributive lattices (Proposition A.1.5.10). We will also record a few facts about the relationship between Boolean algebras and distributive lattices, which are useful for working with constructible sets in algebraic geometry (see §4.3). For a much more extensive discussion of Stone duality, we refer the reader to [105].

A.1.1 Upper Semilattices

We begin by reviewing some definitions.

Definition A.1.1.1. An *upper semilattice* is a partially ordered set Λ such that every finite subset $S \subseteq \Lambda$ has a supremum $\bigvee S$.

For partially ordered set Λ to be an upper semilattice, it is necessary and sufficient that Λ has least element $\bot$ and every pair of elements $x, y \in \Lambda$ has a least upper bound. We denote this least upper bound by $x \vee y$, and refer to it as the *join* of x and y.

Remark A.1.1.2. Let Λ be an upper semilattice. Then the join operation $\vee : \Lambda \times \Lambda \to \Lambda$ endows Λ with the structure of a commutative monoid (with identity element given by $\perp$). Moreover, every element $x \in \Lambda$ is idempotent: that is, we have $x = x \vee x$. Conversely, if M is a commutative monoid in which every element is idempotent, then we can introduce a partial ordering of M by writing $x \leqslant y$ if and only if $xy = y$. This partial ordering exhibits M as an upper semilattice.

Definition A.1.1.3. Let Λ and Λ' be upper semilattices. A *distributor* from Λ to Λ' is a subset $D \subseteq \Lambda \times \Lambda'$ satisfying the following conditions:

(*i*) If $(x, x') \in D$, $y \leqslant x$, and $x' \leqslant y'$, then $(y, y') \in D$.

(*ii*) Let $S = \{y_i\}$ be a finite subset of Λ', let $y = \bigvee S$, and let $x \in \Lambda$. Then $(x, y) \in D$ if and only if we can write $x = \bigvee\{x_i\}$ for some finite collection of elements $\{x_i\} \subseteq \Lambda$ such that $(x_i, y_i) \in D$ for every index i.

(*iii*) Let $S = \{y_i\}$ be a finite subset of Λ' and let $x \in \Lambda$ be such that $(x, y_i) \in D$ for every index i. Then there exists an element $y \in \Lambda'$ such that $(x, y) \in D$, and $y \leqslant y_i$ for every index i.

We say that an upper semilattice Λ is *distributive* if the set $\{(x, y) \in \Lambda \times \Lambda : x \leqslant y\}$ is a distributor from Λ to itself.

Remark A.1.1.4. Let Λ be an upper semilattice. The set $\{(x, y) \in \Lambda \times \Lambda : x \leqslant y\}$ automatically satisfies conditions (*i*) and (*iii*) of Definition A.1.1.3. Consequently, Λ is distributive if and only if for every inequality $x \leqslant \bigvee\{y_i\}$, we can write $x = \bigvee\{x_i\}$ for some collection of elements x_i satisfying $x_i \leqslant y_i$. This is obvious if the set $\{y_i\}$ is empty. Using induction on the size of the set $\{y_i\}$, we see that Λ is distributive if and only if the following condition is satisfied:

($*$) For every inequality $x \leqslant y \vee z$ in Λ, we can write $x = y_0 \vee z_0$, where $y_0 \leqslant y$ and $z_0 \leqslant z$.

Construction A.1.1.5. Let Λ, Λ', and Λ'' be upper semilattices, and suppose we are given distributors $D \subseteq \Lambda \times \Lambda'$ and $D' \subseteq \Lambda' \times \Lambda''$. We define the *composition* D' with D to be the relation

$$D'D = \{(x, z) \in \Lambda \times \Lambda'' : (\exists y \in \Lambda')[(x, y) \in D \text{ and } (y, z) \in D']\}.$$

Then $D'D$ is a distributor from Λ to Λ''. The composition of distributors is associative. Moreover, if Λ is a distributive upper semilattice and we let id_Λ denote the distributor $\{(x, y) \in \Lambda \times \Lambda : x \leqslant y\}$, then $\mathrm{id}_P D = D$ for any distributor R from Λ' to Λ, and $D' \mathrm{id}_P = D'$ for any distributor D' from Λ to Λ'. We therefore obtain a category SLat whose objects are distributive upper semilattices, where the morphisms from Λ to Λ' are given by distributors from Λ to Λ'.

Example A.1.1.6. Let X be a topological space, and let $\Lambda(X)$ denote the collection of all quasi-compact open subsets of X. Then $\Lambda(X)$ is an upper semilattice (when regarded as a partially ordered set with respect to inclusion). The empty set $\emptyset \subseteq X$ is a least element of $\Lambda(X)$, and the join operation $\vee : \Lambda(X) \times \Lambda(X) \to \Lambda(X)$ is given by $(U, V) \mapsto U \cup V$.

A.1.2 The Spectrum of an Upper Semilattice

Example A.1.1.6 has a converse: every upper semilattice Λ is isomorphic to the partially ordered set of quasi-compact open subsets of some topological space X. In fact, there is a canonical choice for the topological space X, which we will refer to as the *spectrum* of Λ and denote by $\mathrm{Spec}(\Lambda)$.

Definition A.1.2.1. Let Λ be an upper semilattice. We say that a subset $I \subseteq \Lambda$ is an *ideal* if it is closed downwards and closed under finite joins. We say that a subset $F \subseteq \Lambda$ is a *filter* if it is closed upwards and every finite subset $S \subseteq F$ has a lower bound in F. We say that an ideal I is *prime* if $\Lambda - I$ is a filter.

Remark A.1.2.2. Any ideal $I \subseteq \Lambda$ contains the least element $\bot \in \Lambda$. Note that I is prime if and only if the following pair of conditions holds:

- (i) The empty set $\emptyset \subseteq \Lambda - I$ has a lower bound in $\Lambda - I$: that is, $I \neq \Lambda$.
- (ii) For every pair of elements $x, y \in \Lambda$ such that $x, y \notin I$, there exists $z \leqslant x, y$ such that $z \notin I$.

Construction A.1.2.3. Let Λ be a distributive upper semilattice. We let $\mathrm{Spec}(\Lambda)$ denote the collection of all prime ideals of Λ. We will refer to $\mathrm{Spec}(\Lambda)$ as the *spectrum* of Λ.

Notation A.1.2.4. Let Λ be a distributive upper semilattice. If $I \subseteq \Lambda$ is an ideal, we let $\mathrm{Spec}(\Lambda)_I$ denote the collection of those prime ideals $\mathfrak{p} \subseteq \Lambda$ such that $I \nsubseteq \mathfrak{p}$. If $x \in \Lambda$, we let $\mathrm{Spec}(\Lambda)_x = \{\mathfrak{p} \in \mathrm{Spec}(\Lambda) : x \notin \mathfrak{p}\}$.

Proposition A.1.2.5. *Let Λ be a distributive upper semilattice and let $\mathrm{Spec}(\Lambda)$ be the spectrum of Λ. Then:*

1. *There exists a topology on the set $\mathrm{Spec}(\Lambda)$, for which the open sets are those of the form $\mathrm{Spec}(\Lambda)_I$, where I ranges over the ideals of Λ.*
2. *The construction $I \mapsto \mathrm{Spec}(\Lambda)_I$ determines an isomorphism from the partially ordered set of ideals of Λ and the partially ordered set of open subsets of $\mathrm{Spec}(\Lambda)$.*
3. *For each $x \in \Lambda$, the subset $\mathrm{Spec}(\Lambda)_x \subseteq \mathrm{Spec}(\Lambda)$ is open. Moreover, the collection of sets of the form $\mathrm{Spec}(\Lambda)_x$ form a basis for the topology of $\mathrm{Spec}(\Lambda)$.*

(4) *For every finite subset* $S \subseteq \Lambda$ *having join* $\bigvee S = x$*, the open set* $\mathrm{Spec}(\Lambda)_x$ *is given by the union* $\bigcup_{y \in S} \mathrm{Spec}(\Lambda)_y$*.*

(5) *Each of the open sets* $\mathrm{Spec}(\Lambda)_x$ *is quasi-compact. Conversely, every quasi-compact open subset of* $\mathrm{Spec}(\Lambda)$ *has the form* $\mathrm{Spec}(\Lambda)_x$ *for some uniquely determined* $x \in \Lambda$*.*

(6) *The topological space* $\mathrm{Spec}(\Lambda)$ *is sober: that is, every irreducible closed subset of* $\mathrm{Spec}(\Lambda)$ *has a unique generic point.*

The proof of Proposition A.1.2.5 depends on the following basic observation:

Lemma A.1.2.6. *Let* Λ *be a distributive upper semilattice containing an element* x*. For every ideal* $I \subseteq \Lambda$ *which does not contain* x*, there exists a prime ideal* $\mathfrak{p} \subseteq \Lambda$ *which contains* I *but does not contain* x*.*

Proof. Using Zorn's lemma, we can choose an ideal $\mathfrak{p} \subseteq \Lambda$ which is maximal among those ideals which contain I and do not contain x. We will complete the proof by showing that $\mathfrak{p}$ is prime. Since $x \notin \mathfrak{p}$, it is clear that $\Lambda - \mathfrak{p}$ is nonempty. It will therefore suffice to show that every pair of elements $y, z \in \Lambda - \mathfrak{p}$ have a lower bound in $\Lambda - \mathfrak{p}$. The maximality of $\mathfrak{p}$ implies that x belongs to the ideal generated by $\mathfrak{p}$ and y. It follows that $x \leqslant y \vee y'$ for some $y' \in \mathfrak{p}$. Since Λ is distributive, we can write $x = y_0 \vee y_0'$ for some $y_0 \leqslant y$ and some $y_0' \in \mathfrak{p}$. The same argument shows that $x \leqslant z \vee z'$ for some $z' \in \mathfrak{p}$. Then $y_0 \leqslant z \vee z'$, so that $y_0 = z_0 \vee z_0'$ for some $z_0 \leqslant z$ and some $z_0' \in \mathfrak{p}$. Then z_0 is a lower bound for y and z. We claim that $z_0 \notin \mathfrak{p}$: otherwise, we deduce that $y_0 = z_0 \vee z_0' \in \mathfrak{p}$, so that $x = y_0 \vee y_0' \in \mathfrak{p}$, a contradiction. □

Proof of Proposition A.1.2.5. We first prove (1). Suppose first that we are given a finite collection of open subsets $\mathrm{Spec}(\Lambda)_{I_\alpha}$ of $\mathrm{Spec}(\Lambda)$, and let $I = \bigcap_\alpha I_\alpha$. To prove that $\bigcap_\alpha \mathrm{Spec}(\Lambda)_{I_\alpha}$ is open, it will suffice to show that $\bigcap_\alpha \mathrm{Spec}(\Lambda)_{I_\alpha} = \mathrm{Spec}(\Lambda)_I$. That is, we must show that a prime ideal $\mathfrak{p} \subseteq \Lambda$ contains I if and only if it contains some I_α. The "if" direction is obvious. For the converse, suppose that each I_α contains an element $x_\alpha \in \Lambda - \mathfrak{p}$. Since $\mathfrak{p}$ is a prime ideal, the finite collection of elements $\{x_\alpha\}$ have a lower bound $x \in \Lambda - \mathfrak{p}$. Since each I_α is closed downwards, we deduce that $x \in I = \bigcap_\alpha I_\alpha$.

Now suppose we are given an arbitrary collection of open subsets $\mathrm{Spec}(\Lambda)_{I_\beta}$ of $\mathrm{Spec}(\Lambda)$; we wish to show that $\bigcup_\beta \mathrm{Spec}(\Lambda)_{I_\beta}$ is open. Let I smallest ideal containing each I_β. Then a prime ideal $\mathfrak{p}$ contains I if and only if it contains each I_β; so that $\bigcup_\beta \mathrm{Spec}(\Lambda)_{I_\beta} = \mathrm{Spec}(\Lambda)_I$. This completes the proof of (1).

We now prove (2). Consider two ideals $I, J \subseteq \Lambda$; we wish to show that $I \subseteq J$ if and only if $\mathrm{Spec}(\Lambda)_I \subseteq \mathrm{Spec}(\Lambda)_J$. Let $K = I \cap J$, so that $\mathrm{Spec}(\Lambda)_K = \mathrm{Spec}(\Lambda)_I \cap \mathrm{Spec}(\Lambda)_J$ (by the argument given above). Then $K \subseteq I$. We wish to show that $K = I$ if and only if $\mathrm{Spec}(\Lambda)_K = \mathrm{Spec}(\Lambda)_I$. The "only if" direction is obvious. For the converse, we must show that if $I \neq K$, then there is a prime ideal $\mathfrak{p}$ such that $K \subseteq \mathfrak{p}$ but $I \nsubseteq \mathfrak{p}$.

To prove (3), we note that $\mathrm{Spec}(\Lambda)_x = \mathrm{Spec}(\Lambda)_I$ where I is the ideal $\{y \in \Lambda : y \leqslant x\}$; this proves that $\mathrm{Spec}(\Lambda)_x$ is open. For any ideal $J \subseteq \Lambda$, we have $\mathrm{Spec}(\Lambda)_J = \bigcup_{x \in J} \mathrm{Spec}(\Lambda)_x$, so that the open sets of the form $\mathrm{Spec}(\Lambda)_x$ form a basis for the topology of $\mathrm{Spec}(\Lambda)$. Assertion (4) follows immediately from the definition of a prime ideal.

We now prove (5). Let $x \in \Lambda$, and suppose that $\mathrm{Spec}(\Lambda)_x$ admits a covering by open sets of the form $\mathrm{Spec}(\Lambda)_{I_\alpha} \subseteq \mathrm{Spec}(\Lambda)_x$. Let J be the smallest ideal containing each I_α. It follows from the proof of (1) that $\mathrm{Spec}(\Lambda)_J = \bigcup_\alpha \mathrm{Spec}(\Lambda)_{I_\alpha} = \mathrm{Spec}(\Lambda)_x$. Invoking (2), we deduce that $J = \{y \in \Lambda : y \leqslant x\}$. In particular, $x \in J$. It follows that $x \leqslant x_1 \vee \ldots \vee x_n$ for some elements $x_i \in I_{\alpha(i)}$, from which we deduce that $\mathrm{Spec}(\Lambda)_x = \bigcup_{1 \leqslant i \leqslant n} \mathrm{Spec}(\Lambda)_{I_{\alpha(i)}}$. This proves that $\mathrm{Spec}(\Lambda)_x$ is quasi-compact. Conversely, suppose that $U \subseteq \mathrm{Spec}(\Lambda)$ is any quasi-compact open set. Then U has a finite covering by basic open sets of the form $\mathrm{Spec}(\Lambda)_{y_1}, \ldots, \mathrm{Spec}(\Lambda)_{y_n}$. It follows from (4) that $U = \mathrm{Spec}(\Lambda)_y$, where $y = y_1 \vee \ldots \vee y_n$.

We now prove (6). Suppose that $K \subseteq \mathrm{Spec}(\Lambda)$ is an irreducible closed subset. Then $K = \mathrm{Spec}(\Lambda) - \mathrm{Spec}(\Lambda)_I$ for some ideal $I \subseteq \Lambda$, which is uniquely determined by condition (2). By definition, a prime ideal $\mathfrak{p} \in \mathrm{Spec}(\Lambda)$ is a generic point for K if K is the smallest closed subset containing $\mathfrak{p}$. According to condition (2), this is equivalent to the requirement that I be the largest ideal such that $I \subseteq \mathfrak{p}$. That is, $\mathfrak{p}$ is a generic point for K if and only if $\mathfrak{p} = I$. This proves the uniqueness of $\mathfrak{p}$. For existence, it suffices to show that I is a prime ideal. Since K is nonempty, $I \neq \Lambda$. It will therefore suffice to show that every pair of elements $x, y \in \Lambda - I$ have a lower bound in $\Lambda - I$. Since $x, y \notin I$, the open sets $\mathrm{Spec}(\Lambda)_x$ and $\mathrm{Spec}(\Lambda)_y$ have nonempty intersection with K. Because K is irreducible, we conclude that $\mathrm{Spec}(\Lambda)_x \cap \mathrm{Spec}(\Lambda)_y \cap K \neq \emptyset$. That is, there exists a prime ideal $\mathfrak{q}$ such that $x, y \notin \mathfrak{q}$ while $I \subseteq \mathfrak{q}$. Since $\mathfrak{q}$ is prime, x and y have a lower bound $z \in \Lambda - \mathfrak{q}$. Then z is a lower bound for x and y in $\Lambda - I$. □

A.1.3 Stone Duality for Upper Semilattices

It follows from Proposition A.1.2.5 that every distributive upper semilattice Λ can be recovered as the partially ordered set of quasi-compact open subsets of $\mathrm{Spec}(\Lambda)$. Our next goal is to prove a refinement of this observation: the construction $\Lambda \mapsto \mathrm{Spec}(\Lambda)$ determines a fully faithful embedding from the category SLat of distributive upper semilattices (Construction A.1.1.5) to the category of topological spaces (Proposition A.1.3.3).

Construction A.1.3.1. Let Λ and Λ' be distributive upper semilattices, and let $D \subseteq \Lambda \times \Lambda'$ be a distributor from Λ to Λ'. We define a map $\mathrm{Spec}(D) : \mathrm{Spec}(\Lambda) \to \mathrm{Spec}(\Lambda')$ by the formula

$$\mathrm{Spec}(D)(\mathfrak{p}) = \{y \in \Lambda' : (\forall x \in \Lambda)[(x, y) \in D \Rightarrow x \in \mathfrak{p}]\}.$$

We claim that, for every prime ideal $\mathfrak{p} \subseteq \Lambda$, the subset $\mathrm{Spec}(D)(\mathfrak{p})$ is a prime ideal in Λ'. It is clear that $\mathrm{Spec}(D)(\mathfrak{p})$ is closed downwards. If $\{y_1, \ldots, y_n\} \subseteq P' - \mathrm{Spec}(D)(\mathfrak{p})$ is a finite subset, then we can choose a finite subset $\{x_1, \ldots, x_n\} \subseteq P - \mathfrak{p}$ such that $(x_i, y_i) \in D$ for $1 \leqslant i \leqslant n$. Since $\mathfrak{p}$ is prime, the elements x_i have a lower bound $x \in \Lambda - \mathfrak{p}$. Then $(x, y_i) \in D$ for $1 \leqslant i \leqslant n$. Since D is a distributor, we deduce that $(x, y) \in D$ for some lower bound y for $\{y_1, \ldots, y_n\}$. Noting that $y \notin \mathrm{Spec}(D)(\mathfrak{p})$, we see that $\Lambda' - \mathrm{Spec}(D)(\mathfrak{p})$ is a filter. To show that $\mathrm{Spec}(D)(\mathfrak{p})$ is an ideal, suppose we are given a finite collection of elements $\{y'_1, \ldots, y'_m\} \subseteq \mathrm{Spec}(D)(\mathfrak{p})$. If the join $y'_1 \vee \cdots \vee y'_m$ does not belong to $\mathrm{Spec}(D)(\mathfrak{p})$, then $(x', y'_1 \vee \cdots \vee y'_m) \in D$ for some $x \in \mathfrak{p}$. We can therefore write $x' = x'_1 \vee \cdots \vee x'_m$ where $(x'_i, y'_i) \in D$ for every index i. Since each $y'_i \in \mathrm{Spec}(D)(\mathfrak{p})$, we conclude that $x'_i \in \mathfrak{p}$, so that $x' = x'_1 \vee \cdots x'_n \in \mathfrak{p}$, a contradiction.

Remark A.1.3.2. In the situation of Construction A.1.3.1, the map $\mathrm{Spec}(D) : \mathrm{Spec}(\Lambda) \to \mathrm{Spec}(\Lambda')$ is continuous. To prove this, we note that if $I \subseteq P'$ is an ideal, then $\mathrm{Spec}(D)^{-1} \mathrm{Spec}(\Lambda')_I = \mathrm{Spec}(\Lambda)_J$, where J is the ideal $\{x \in \Lambda : (\exists y \in I)[(x, y) \in D]\}$.

It follows from Remark A.1.3.2 that we can view Spec as a functor from the category SLat of distributive upper semilattices (with morphisms given by distributors) to the category $\mathcal{T}\mathrm{op}$ of topological spaces.

We can now formulate the first main result of this section.

Proposition A.1.3.3 (Duality for Distributive Upper Semilattices)**.** *The functor* Spec : SLat $\to \mathcal{T}\mathrm{op}$ *is fully faithful. Moreover, a topological space X belongs to the essential image of* Spec *if and only if it is sober and has a basis consisting of quasi-compact open sets.*

Proof. Let Λ and Λ' be distributive upper semilattices, let $f : \mathrm{Spec}(\Lambda) \to \mathrm{Spec}(\Lambda')$ be a continuous map, and let $D \subseteq \Lambda \times \Lambda'$ be a distributor. We first prove the following:

$(*)$ We have $f = \mathrm{Spec}(D)$ if and only if $D = \{(x, y) \in \Lambda \times \Lambda' : \mathrm{Spec}(\Lambda)_x \subseteq f^{-1} \mathrm{Spec}(\Lambda')_y\}$.

This shows in particular that D is uniquely determined by f, so that the functor Spec is faithful. We begin by proving the "only if" direction of $(*)$. Suppose that $f = \mathrm{Spec}(D)$. If $(x, y) \in D$, then for every prime ideal $\mathfrak{p} \subseteq \Lambda$ not containing x, we have $y \in \mathrm{Spec}(D)(\mathfrak{p}) = f(\mathfrak{p})$, so that $\mathrm{Spec}(\Lambda)_x \subseteq f^{-1} \mathrm{Spec}(\Lambda')_y$. Conversely, suppose $(x, y) \notin D$. Then $I = \{x' \in \Lambda : (x', y) \in D\}$ is an ideal of Λ which does not contain the element x. Using Lemma A.1.2.6, we can choose a prime ideal $\mathfrak{p}$ containing I and not containing x. Then $\mathfrak{p} \in \mathrm{Spec}(\Lambda)_x$ but $f(F) = \mathrm{Spec}(D)(\mathfrak{p}) \notin \mathrm{Spec}(\Lambda')_y$, so that $\mathrm{Spec}(\Lambda)_x \nsubseteq f^{-1} \mathrm{Spec}(\Lambda')_y$.

We next prove the "if" direction of $(*)$. Assume that $D = \{(x, y) \in \Lambda \times \Lambda' : \mathrm{Spec}(\Lambda)_x \subseteq f^{-1} \mathrm{Spec}(\Lambda')_y\}$, and let $\mathfrak{p} \subseteq \Lambda$ be a prime ideal. We wish to show that $f(F) = \mathrm{Spec}(D)(\mathfrak{p})$.

We have

$$\begin{aligned} y \notin f(\mathfrak{p}) &\Leftrightarrow f(F) \in \operatorname{Spec}(\Lambda')_y \\ &\Leftrightarrow F \in f^{-1} \operatorname{Spec}(\Lambda')_y \\ &\Leftrightarrow (\exists x \in \Lambda)[F \in \operatorname{Spec}(\Lambda)_x \subseteq f^{-1} \operatorname{Spec}(\Lambda')_y] \\ &\Leftrightarrow (\exists x \in \Lambda)[(x \in F) \wedge (x, y) \in D] \\ &\Leftrightarrow y \notin \operatorname{Spec}(D)(\mathfrak{p}). \end{aligned}$$

We now prove that the functor Spec is full. Let $f : \operatorname{Spec}(\Lambda) \to \operatorname{Spec}(\Lambda')$ be a continuous map, and set $D = \{(x, y) \in \Lambda \times \Lambda' : \operatorname{Spec}(\Lambda)_x \subseteq f^{-1} \operatorname{Spec}(\Lambda')_y\}$. We will show that D is a distributor, so that assertion $(*)$ immediately implies that $f = \operatorname{Spec}(D)$. Let us verify the conditions of Definition A.1.1.3:

(*i*) It is clear that if $(x, y) \in D$, $x' \leqslant x$, and $y \leqslant y'$, then $(x', y') \in D$.

(*ii*) Let $S = \{y_i\}$ be a finite subset of Λ', let $y = \bigvee S$, and let $x \in \Lambda$. Then $(x, y) \in D$ if and only if $\operatorname{Spec}(\Lambda)_x \subseteq \bigcup_i f^{-1} \operatorname{Spec}(\Lambda')_{y_i}$. In this case, $\operatorname{Spec}(\Lambda)_x$ admits a covering by quasi-compact open sets $U_{i,j}$ such that $U_{i,j} \subseteq f^{-1} \operatorname{Spec}(\Lambda')_{y_i}$. Since $\operatorname{Spec}(\Lambda)_x$ is quasi-compact, we can assume that this covering is finite. Let $U_i = \bigcup_j U_{i,j}$. Then each U_i is a quasi-compact open subset of $\operatorname{Spec}(\Lambda)$, and is therefore of the form $\operatorname{Spec}(\Lambda)_{x_i}$ for some $x_i \in \Lambda$. Since $\operatorname{Spec}(\Lambda)_x = \bigcup U_i$, we have $x = x_1 \vee \cdots \vee x_n$. Moreover, the containment $U_i \subseteq f^{-1} \operatorname{Spec}(\Lambda')_{y_i}$ implies that $(x_i, y_i) \in D$ for $1 \leqslant i \leqslant n$.

(*iii*) Let $S = \{y_i\}$ be a finite subset of Λ' and let $x \in \Lambda$ be such that $(x, y_i) \in D$ for every index i. Then $U = \bigcap \operatorname{Spec}(\Lambda')_{y_i}$ is an open subset of $\operatorname{Spec}(\Lambda')$ containing $f(\operatorname{Spec}(\Lambda)_x)$. Since f is continuous, $\operatorname{Spec}(\Lambda)_x$ is quasi-compact. We may therefore choose a finite covering of $f(\operatorname{Spec}(\Lambda)_x)$ by quasi-compact open subsets of $\operatorname{Spec}(\Lambda')$ which are contained in U. Let V be the union of these quasi-compact open sets, so that $V = \operatorname{Spec}(\Lambda)_y$ for some $y \in Y$. Then $\operatorname{Spec}(\Lambda)_x \subseteq f^{-1}V$, so that $(x, y) \in D$ and $y \leqslant y_i$ for each i.

We now describe the essential image of the functor Spec. Proposition A.1.2.5 implies that for every distributive upper semilattice Λ, the spectrum $\operatorname{Spec}(\Lambda)$ is a sober topological space having a basis of quasi-compact open sets. Conversely, suppose that X is any sober topological space having a basis of quasi-compact open sets. Let Λ be the collection of all quasi-compact open subsets of X, partially ordered by inclusion. Since the collection of quasi-compact open subsets of X is closed under finite unions, we see that Λ is an upper semilattice. We next claim that Λ is distributive. Let U, V, and W be quasi-compact open subsets of X such that $U \subseteq V \cup W$. Then $U \cap V$ and $U \cap W$ is an open covering of U. Since X has a basis of quasi-compact open sets, this covering admits a refinement $\{U_\alpha\}$ where each U_α is quasi-compact. Since U is quasi-compact, we may assume that the set of indices

α is finite. Then $U = V_1 \cup \cdots \cup V_m \cup W_1 \cup \cdots \cup W_{m'}$, where $V_i \subseteq V$, $W_i \subseteq W$, and each of the open sets V_i and W_i is quasi-compact. Let $V' = \bigcup_i V_i$ and $W' = \bigcup_i W_i$. Then V' and W' are quasi-compact open subsets of X satisfying $U = V' \cup W'$, $V' \subseteq V$, and $W' \subseteq W$.

We now define a map $\Phi : X \to \operatorname{Spec}(\Lambda)$ by the formula $\Phi(x) = \{U \in \Lambda : x \notin U\}$. To prove that ϕ is well-defined, we must show that for every point $x \in X$, the subset $\Phi(x) \subseteq \Lambda$ is a prime ideal. It is easy to see that $\Phi(x)$ is an ideal. If we are given a finite collection of elements $U_1, \ldots, U_n \in \Lambda - \Phi(x)$, then $x \in \bigcap_i U_i$. Since X has a basis of quasi-compact open sets, we can choose a quasi-compact open set $V \subseteq \bigcap_i U_i$ containing x, so that V is a lower bound for the subset $\{U_i\} \subseteq \Phi(x)$. This proves that $\Lambda - \Phi(x)$ is a filter, so that $\Phi(x)$ is prime.

For each $U \in \Lambda$, we have

$$\Phi^{-1} \operatorname{Spec}(\Lambda)_U = \{x \in X : \Phi(x) \in \operatorname{Spec}(\Lambda)_U\} = \{x \in X : x \in U\} = U.$$

Since the open sets of the form $\operatorname{Spec}(\Lambda)_U$ form a basis for the topology of $\operatorname{Spec}(\Lambda)$ (Proposition A.1.2.5), we deduce that Φ is continuous. We next show that Φ is bijective. Let $\mathfrak{p} \subseteq \Lambda$ be a prime ideal; we wish to show that there is a unique point $x \in X$ such that $F = \Phi(x)$. Let $V = \bigcup_{U \in \mathfrak{p}} U$. Note that if $\mathfrak{p} = \Phi(x)$, then V is the union of all those quasi-compact open subsets of X which do not contain the point x. It follows that x is a generic point of $X - V$. Since X is sober, we conclude that the point x is unique if it exists. To prove the existence, we will show that the closed set $K = X - V$ is irreducible. Since $\mathfrak{p}$ is prime, there exists a quasi-compact open set $W \subseteq X$ which is not contained in $\mathfrak{p}$. We claim that $W \cap K \neq \varnothing$. Assume otherwise; then $W \subseteq V = \bigcup_{U \notin F} U$. Since W is quasi-compact, it is contained in a finite union $U_1 \cup \cdots \cup U_n$ where each U_i belongs to $\mathfrak{p}$. Since $\mathfrak{p}$ is an ideal, we conclude that $U_1 \cup \cdots \cup U_n \in \mathfrak{p}$, contradicting our assumption that $U \notin \mathfrak{p}$. To complete the proof that K is irreducible, it will suffice to show that if W and W' are open subsets of X such that $W \cap K \neq \varnothing$ and $W' \cap K \neq \varnothing$, then $W \cap W' \cap K \neq \varnothing$. Since X has a basis of quasi-compact open sets, we may assume without loss of generality that W and W' are quasi-compact. The definition of V then guarantees that W and W' belong to the filter $\Lambda - \mathfrak{p}$. It follows that W and W' have a lower bound $W'' \in \Lambda - \mathfrak{p}$. Since $\mathfrak{p}$ is an ideal, W'' is not contained in any finite union of open sets belonging to $\mathfrak{p}$. The quasi-compactness of W'' then implies that W'' is not contained in $\bigcup_{U \in \mathfrak{p}} U = V$, so that $\varnothing \neq W'' \cap K \subseteq W \cap W' \cap K$.

To complete the proof, it will suffice to show that the continuous bijection $\Phi : X \to \operatorname{Spec}(\Lambda)$ is an open map. Since X has a basis consisting of quasi-compact open sets, it will suffice to show that for every quasi-compact open set $U \subseteq X$, the set $\Phi(U) \subseteq \operatorname{Spec}(\Lambda)$ is open. In fact, we claim that $\Phi(U) = \operatorname{Spec}(\Lambda)_U$. The containment $\Phi(U) \subseteq \operatorname{Spec}(\Lambda)_U$ was established above. To verify the reverse inclusion, let $\mathfrak{p} \subseteq \Lambda$ be a prime ideal not containing U. The bijectivity of Φ implies that $\mathfrak{p} = \Phi(x)$ for some point $x \in X$. It now suffices to observe that $x \in U$ (since this is equivalent to the condition that $U \notin \mathfrak{p} = \Phi(x)$). □

A.1.4 Distributive Lattices

We now give a brief review of the theory of distributive lattices.

Definition A.1.4.1. Let Λ be a partially ordered set. We say that Λ is a *lattice* if both Λ and Λ^{op} are upper semilattices: that is, if every finite subset $S \subseteq \Lambda$ has both a greatest lower bound and a least upper bound.

Notation A.1.4.2. If Λ is a lattice and we are given a finite subset $S \subseteq \Lambda$, we will denote its greatest lower bound by $\bigwedge S$. We will refer to $\bigwedge S$ as the *meet* of S. We denote the greatest element of S by $\top$, and the join of set $S = \{x, y\}$ by $x \wedge y$.

Remark A.1.4.3. Let Λ be a lattice. Then the opposite partially ordered set Λ^{op} is also a lattice. Moreover, a subset $I \subseteq \Lambda$ is an ideal if and only if it is a filter when regarded as a subset of Λ^{op}. In particular, I is a prime ideal of Λ if and only if $\Lambda - I$ is a prime ideal of Λ^{op}.

Proposition A.1.4.4. *Let Λ be a lattice. The following conditions are equivalent:*

(1) *The lattice Λ is distributive when regarded as an upper semilattice (see Definition A.1.1.3).*

(2) *For every triple of elements $x, y, z \in \Lambda$, we have $x \wedge (y \vee z) = (x \wedge y) \vee (x \wedge z)$.*

(3) *The lattice Λ^{op} is distributive when regarded as an upper semilattice.*

(4) *For every triple of elements $x, y, z \in \Lambda$, we have $x \vee (y \wedge z) = (x \vee y) \wedge (x \vee z)$.*

Definition A.1.4.5. We say that a lattice Λ is *distributive* if it satisfies the equivalent conditions of Proposition A.1.4.4.

Proof of Proposition A.1.4.4. We first prove that (1) ⇒ (2). Let x, y, and z be elements of a lattice Λ. Since $x \wedge y \leqslant x \wedge (y \vee z) \geqslant x \wedge z$, we automatically have

$$x \wedge (y \vee z) \geqslant (x \wedge y) \vee (x \wedge z).$$

Suppose that Λ is distributive as an upper semilattice. Then the inequality $x \wedge (y \vee z) \leqslant y \vee z$ implies that we can write $x \wedge (y \vee z) = y' \vee z'$, where $y' \leqslant y$ and $z' \leqslant z$. Then $y', z' \leqslant x$, so that $y' \leqslant x \wedge y$ and $z' \leqslant x \wedge z$. It follows that

$$x \wedge (y \vee z) = y' \vee z' \leqslant (x \wedge y) \vee (x \wedge z).$$

Conversely, suppose that (2) holds. We will prove that Λ is distributive as an upper semilattice. Suppose we have an inequality $x \leqslant y \vee z$ in Λ. Then

$$x = x \wedge (y \vee z) = (x \wedge y) \vee (x \wedge z),$$

where $x \wedge y \leqslant y$ and $x \wedge z \leqslant z$. This completes the proof that (1) $\Leftrightarrow$ (2), and the equivalence (3) $\Leftrightarrow$ (4) follows by the same argument.

We now prove that (2) $\Leftrightarrow$ (4). By symmetry, it will suffice to show that (2) $\Rightarrow$ (4). Let $x, y, z \in \Lambda$. If assumption (2) is satisfied, we have

$$\begin{aligned}(x \vee y) \wedge (x \vee z) &= (x \wedge (x \vee z)) \vee (y \wedge (x \vee z)) \\ &= x \vee ((y \wedge x) \vee (y \wedge z)) \\ &= (x \vee (y \wedge x)) \vee (y \wedge z) \\ &= x \vee (y \wedge z).\end{aligned}$$

□

Combining Remark A.1.4.3 with Lemma A.1.2.6, we obtain the following:

Proposition A.1.4.6. *Let Λ be a distributive lattice containing an element x and let $F \subseteq \Lambda$ be a filter which does not contain x. Then there exists a prime ideal $\mathfrak{p} \subseteq \Lambda$ which contains x such that $\mathfrak{p} \cap F = \varnothing$.*

A.1.5 Stone Duality for Distributive Lattices

We now study the restriction of the fully faithful embedding $\mathrm{Spec} : \mathrm{SLat} \hookrightarrow \mathcal{T}\mathrm{op}$ to distributive lattices.

Definition A.1.5.1. Let X be a topological space having a basis of quasi-compact open sets. We say that X is *quasi-separated* if, for every pair of quasi-compact open sets $U, V \subseteq X$, the intersection $U \cap V$ is quasi-compact.

Proposition A.1.5.2. *Let Λ be a distributive upper semilattice. The following conditions are equivalent:*

(1) *The partially ordered set Λ is a distributive lattice.*

(2) *The topological space $\mathrm{Spec}(\Lambda)$ is quasi-compact and quasi-separated.*

Proof. Suppose first that condition (2) is satisfied. Let us identify Λ with the collection of quasi-compact open subsets of $\mathrm{Spec}(\Lambda)$. For any finite collection $\{U_i\}$ of such subsets, condition (2) guarantees that $U = \bigcup U_i$ is quasi-compact, so that U is a greatest lower bound for $\{U_i\}$ in Λ. Conversely, suppose that (1) is satisfied. Let $\{U_i\}_{1 \leqslant i \leqslant n}$ be a finite collection of quasi-compact open subsets of $\mathrm{Spec}(\Lambda)$, and let U be their greatest lower bound in Λ. Then U is the largest quasi-compact open subset contained in $\bigcap U_i$. Since $\mathrm{Spec}(\Lambda)$ has a basis of quasi-compact open sets, we must have $U = \bigcap U_i$, so that $\bigcap U_i$ is quasi-compact. Taking $n = 0$, we learn that $\mathrm{Spec}(\Lambda)$ is quasi-compact; taking $n = 2$, we learn that $\mathrm{Spec}(\Lambda)$ is quasi-separated. □

Definition A.1.5.3. Let Λ and Λ' be lattices. A *lattice homomorphism* from Λ to Λ' is a map $\lambda : \Lambda \to \Lambda'$ such that, for every finite subset $S \subseteq \Lambda$, we have

$$\lambda(\bigvee S) = \bigvee \lambda(S) \qquad \lambda(\bigwedge S) = \bigwedge \lambda(S).$$

We let Lat denote the category whose objects are distributive lattices and whose morphisms are lattice homomorphisms.

Remark A.1.5.4. A map of lattices $\lambda : \Lambda \to \Lambda'$ is a lattice homomorphism if and only if λ satisfies

$$\lambda(\bot) = \bot \qquad \lambda(x \vee y) = \lambda(x) \vee \lambda(y)$$
$$\lambda(\top) = \top \qquad \lambda(x \wedge y) = \lambda(x) \wedge \lambda(y).$$

Here $\bot$ and $\top$ denote the least and greatest elements of Λ and Λ'.

Construction A.1.5.5. Let Λ and Λ' be distributive lattices, and let $\lambda : \Lambda' \to \Lambda$ be a lattice homomorphism. We let $D_\lambda \subseteq \Lambda \times \Lambda'$ denote the subset $\{(x, y) \in \Lambda \times \Lambda' : x \leqslant \lambda(y)\}$. Then D_λ is a distributor from Λ to Λ'. The construction $\lambda \mapsto D_\lambda$ determines a functor $\mathrm{Lat}^{\mathrm{op}} \to \mathrm{SLat}$.

Remark A.1.5.6. The functor $\mathrm{Lat}^{\mathrm{op}} \to \mathrm{SLat}$ of Construction A.1.5.5 is faithful. That is, we can recover a lattice homomorphism $\lambda : \Lambda' \to \Lambda$ from the underlying distributor D_λ. For each $y \in \Lambda'$, $\lambda(y)$ can be characterized as the largest element of x such that $(x, y) \in D_\lambda$.

Notation A.1.5.7. Let Λ be a distributive lattice. We let $\mathrm{Spec}(\Lambda)$ denote the spectrum of Λ, regarded as an upper semilattice (Construction A.1.2.3). If $\lambda : \Lambda \to \Lambda'$ is a lattice homomorphism, we let $\mathrm{Spec}(\lambda) : \mathrm{Spec}(\Lambda') \to \mathrm{Spec}(\Lambda)$ denote the map associated to the distributor D_λ of Construction A.1.5.5. The construction $\Lambda \mapsto \mathrm{Spec}(\Lambda)$ determines a functor $\mathrm{Lat}^{\mathrm{op}} \to \mathcal{T}\mathrm{op}$. We will abuse notation by denoting this functor by Spec.

Remark A.1.5.8. The definition of the spectrum $\mathrm{Spec}(\Lambda)$ can be simplified a bit if we work in the setting of distributive lattices. Note than an ideal $\mathfrak{p} \subseteq \Lambda$ is prime if and only if it satisfies the following pair of conditions:

(*i*) The greatest element $\top \in \Lambda$ is not contained in $\mathfrak{p}$.

(*ii*) If $x \wedge y \in \mathfrak{p}$, then either x or y belongs to $\mathfrak{p}$.

Definition A.1.5.9. Let X and Y be coherent topological spaces. We will say that a morphism $f : X \to Y$ is *quasi-compact* if, for every quasi-compact open subset $U \subseteq Y$, the inverse image $f^{-1}(U)$ is a quasi-compact open subset of X. We let $\mathcal{T}\mathrm{op}_{\mathrm{coh}}$ denote the category whose objects are coherent topological spaces and whose morphisms are quasi-compact, continuous maps.

Proposition A.1.5.10. *The functor* Spec : $\mathrm{Lat}^{\mathrm{op}} \to \mathcal{T}\mathrm{op}$ *induces an equivalence of categories* $\mathrm{Lat}^{\mathrm{op}} \to \mathcal{T}\mathrm{op}_{\mathrm{coh}}$. *In other words,* Spec *is a faithful functor with the following properties:*

(1) *A topological space* X *lies in the essential image of* Spec *if and only if it is coherent.*

(2) *Let* Λ *and* Λ' *be distributive lattices. Then a continuous map* $f : \mathrm{Spec}(\Lambda) \to \mathrm{Spec}(\Lambda')$ *arises from a lattice homomorphism* $\lambda : \Lambda' \to \Lambda$ *(necessarily unique) if and only if* f *is quasi-compact.*

Proof. The faithfulness follows from Proposition A.1.3.3 and Remark A.1.5.6. Assertion (1) follows from Propositions A.1.3.3 and A.1.5.2. We now prove (2). Suppose first that $\lambda : \Lambda' \to \Lambda$ is a lattice homomorphism, let D_λ be the corresponding distributor, and $f : \mathrm{Spec}(\Lambda) \to \mathrm{Spec}(\Lambda')$ the induced map. For each $y \in \Lambda'$, we have

$$f^{-1}\,\mathrm{Spec}(\Lambda')_y = \bigcup_{\mathrm{Spec}(\Lambda)_x \subseteq f^{-1}\,\mathrm{Spec}(\Lambda')_y} \mathrm{Spec}(\Lambda)_x = \bigcup_{(x,y)\in D_\lambda} \mathrm{Spec}(\Lambda)_x = \bigcup_{x \leqslant \lambda(y)} \mathrm{Spec}(\Lambda)_x = \mathrm{Spec}(\Lambda)_{\lambda(y)},$$

so that f^{-1} carries quasi-compact open subsets of $\mathrm{Spec}(\Lambda')$ to quasi-compact open subsets of $\mathrm{Spec}(\Lambda)$. Conversely, suppose that $f : \mathrm{Spec}(\Lambda) \to \mathrm{Spec}(\Lambda')$ is a continuous map such that $f^{-1}U$ is quasi-compact whenever $U \subseteq \mathrm{Spec}(\Lambda')$ is quasi-compact. We then have $f^{-1}\,\mathrm{Spec}(\Lambda')_y = \mathrm{Spec}(\Lambda)_{\lambda(y)}$ for some map $\lambda : \Lambda' \to \Lambda$. Since the formation of inverse images commutes with unions and intersections, we conclude that λ is a lattice homomorphism. Note that $\mathrm{Spec}(\Lambda)_x \subseteq f^{-1}\,\mathrm{Spec}(\Lambda')_y$ if and only if $x \leqslant \lambda(y)$, so that the underlying distributor of the continuous map f is given by D_λ. □

Remark A.1.5.11. Let X be a coherent topological space and let $\{U_\alpha\}$ be a collection of nonempty quasi-compact open subsets of X which are closed under finite intersections. Then $\bigcap U_\alpha \neq \varnothing$. This follows from Proposition A.1.4.6.

Remark A.1.5.12. Let Λ be a distributive lattice which is given as a filtered colimit of distributive lattices Λ_α. Then the canonical map $\mathrm{Spec}(\Lambda) \simeq \varprojlim \mathrm{Spec}(P_\alpha)$ is a homeomorphism.

A.1.6 Boolean Algebras

Let Λ be a distributive lattice containing a least element $\perp$ and a greatest element $\top$. Let $x \in \Lambda$ be an element. A *complement* of x is an element $x^c \in \Lambda$ such that

$$x \wedge x^c = \perp \qquad x \vee x^c = \top.$$

We will say that x is *complemented* if there exists a complement for x.

Remark A.1.6.1. Let Λ be a distributive lattice containing an element x. If x' and x'' are complements of x, then $x' = x''$. To see this, we note that

$$x' = x' \wedge \top = x' \wedge (x \vee x'') = (x' \wedge x) \vee (x' \wedge x'') = \perp \vee (x' \wedge x'') = x' \wedge x''$$

so that $x' \leqslant x''$. The same argument shows that $x'' \leqslant x'$.

Remark A.1.6.2. Let Λ be a distributive lattice containing elements x, x^c. Then x^c is a complement of x if and only if x is a complement of x^c. In this case, we will simply say that x and x^c are *complementary*.

Remark A.1.6.3. Let $\lambda : \Lambda' \to \Lambda$ be a homomorphism of distributive lattices. Suppose that $y, y^c \in \Lambda'$ are complementary. Then $\lambda(y), \lambda(y^c) \in \Lambda$ are complementary.

Definition A.1.6.4. A *Boolean algebra* is a distributive lattice Λ for which every element $x \in \Lambda$ has a complement. We let BAlg denote the full subcategory of Lat spanned by the Boolean algebras.

Proposition A.1.6.5. *Let Λ be a distributive upper semilattice. The following conditions are equivalent:*

(1) *The partially ordered set Λ is a Boolean algebra.*

(2) *The spectrum* $\mathrm{Spec}(\Lambda)$ *is compact and Hausdorff.*

Proof. Suppose first that (1) is satisfied. Let $\mathfrak{p}$ and $\mathfrak{q}$ be distinct prime ideals of Λ. We may assume without loss of generality that there exists an element $x \in \mathfrak{p}$ which does not belong to $\mathfrak{q}$. Let x^c be a complement of x. Since $x \vee x^c = \top \notin \mathfrak{p}$, we conclude that $x^c \notin \mathfrak{p}$. Since $x \wedge x^c \in \mathfrak{q}$, we conclude that $x^c \in \mathfrak{q}$. Then $\mathrm{Spec}(\Lambda)_{x^c}$ and $\mathrm{Spec}(\Lambda)_x$ are disjoint open subsets of $\mathrm{Spec}(\Lambda)$ containing $\mathfrak{p}$ and $\mathfrak{q}$, respectively.

We now show that (2) $\Rightarrow$ (1). Let $x \in \Lambda$, so that $\mathrm{Spec}(\Lambda)_x$ is a quasi-compact open subset of $\mathrm{Spec}(\Lambda)$. Since $\mathrm{Spec}(\Lambda)$ is Hausdorff, the subset $\mathrm{Spec}(\Lambda)_x$ is also closed. Let U be the complement of $\mathrm{Spec}(\Lambda)_x$. Then U is a closed subset of $\mathrm{Spec}(\Lambda)$ and therefore compact. Since it is also an open subset of $\mathrm{Spec}(\Lambda)$, it has the form $\mathrm{Spec}(\Lambda)_y$ for some $y \in \Lambda$. We now observe that y is a complement to x. □

Corollary A.1.6.6. *Let Λ be a distributive lattice, let Λ' be a Boolean algebra, and let $D \subseteq \Lambda \times \Lambda'$ be a distributor. Then $D = D_\lambda$ for some lattice homomorphism $\lambda : \Lambda' \to \Lambda$ (necessarily unique, by Remark A.1.5.6).*

Remark A.1.6.7. Corollary A.1.6.6 implies that we can regard the category BAlg of Boolean algebras as a full subcategory of *both* the category of Lat of distributive lattices (where the morphisms are lattice homomorphisms) and the category $\mathrm{SLat}^{\mathrm{op}}$ of distributive upper semilattices (where the morphisms are distributors). Beware that the embedding $\mathrm{Lat} \hookrightarrow \mathrm{SLat}^{\mathrm{op}}$ is not full.

Proof of Corollary A.1.6.6. Using Propositions A.1.3.3 and A.1.5.10, we are reduced to proving that if $f : \mathrm{Spec}(\Lambda) \to \mathrm{Spec}(\Lambda')$ is a continuous map and $U \subseteq \mathrm{Spec}(\Lambda')$ is a quasi-compact open subset, then $f^{-1}U$ is a quasi-compact open subset of $\mathrm{Spec}(\Lambda)$. Since $\mathrm{Spec}(\Lambda')$ is Hausdorff (Proposition A.1.6.5), the subset $U \subseteq \mathrm{Spec}(\Lambda')$ is closed. The continuity of f guarantees that $f^{-1}U$ is a closed subset of $\mathrm{Spec}(\Lambda)$, hence quasi-compact (since $\mathrm{Spec}(\Lambda)$ is quasi-compact). □

Definition A.1.6.8. Let X be a topological space. We say that X is a *Stone space* if it is compact, Hausdorff, and has a basis of closed and open sets. We let $\mathcal{T}\mathrm{op}_{\mathrm{St}}$ denote the category whose objects are Stone spaces and whose morphisms are continuous maps.

Remark A.1.6.9. The category of Stone spaces admits several other descriptions, which we will discuss in §E.1 (see Proposition E.1.3.1).

Remark A.1.6.10. Let X be a Hausdorff space. Then X is automatically sober (every irreducible closed subset of X is a singleton). Moreover, an open set $U \subseteq X$ is quasi-compact if and only if it is also closed. It follows that the collection of quasi-compact open subsets of X is closed under finite intersections. It follows that a topological space X is a Stone space if and only if X is both Hausdorff and coherent.

Theorem A.1.6.11 (Stone Duality)**.** *The construction* $\Lambda \mapsto \mathrm{Spec}(\Lambda)$ *induces a fully faithful embedding* $\mathrm{Spec} : \mathrm{BAlg}^{\mathrm{op}} \to \mathcal{T}\mathrm{op}$*, whose essential image is the full subcategory* $\mathcal{T}\mathrm{op}_{\mathrm{St}}$ *spanned by the Stone spaces.*

Proof. Combine Proposition A.1.6.5, Proposition A.1.5.10, Corollary A.1.6.6, and Remark A.1.6.10. □

A.2 Coherent ∞-Topoi

Let $\mathcal{X}$ be a Grothendieck topos. We say that $\mathcal{X}$ is *coherent* if it is equivalent to a category of the form $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathcal{C})$, where $\mathcal{C}$ is a small category which admits finite limits, and is equipped with a finitary Grothendieck topology (see Definition A.3.1.1). The theory of coherent topoi can be regarded as a generalization of the theory of coherent topological spaces described in §A.1. In this section, we will study a further generalization: the theory of *coherent ∞-topoi*.

Definition A.2.0.12. Let $\mathcal{X}$ be an ∞-topos. We will say that $\mathcal{X}$ is *quasi-compact* if every covering of $\mathcal{X}$ has a finite subcovering: that is, for every effective epimorphism $\amalg_{i \in I} U_i \to \mathbf{1}$ in $\mathcal{X}$ (where $\mathbf{1}$ is the final object of $\mathcal{X}$), there exists a finite subset $I_0 \subseteq I$ such that the map $\amalg_{i \in I} U_i \to \mathbf{1}$ is also an effective epimorphism. We say that an object $X \in \mathcal{X}$ is *quasi-compact* if the ∞-topos $\mathcal{X}_{/X}$ is quasi-compact.

Let $n \geqslant 0$ be an integer. We will define the notion of an *n-coherent ∞-topos* using induction on n. We say that an ∞-topos $\mathcal{X}$ is 0-*coherent* if it is quasi-compact. Assume that we have defined the notion of an n-coherent ∞-topos for some $n \geqslant 0$. We will say that an object $U \in \mathcal{X}$ of an ∞-topos $\mathcal{X}$ is *n-coherent* if the ∞-topos $\mathcal{X}_{/U}$ is n-coherent. We say that $\mathcal{X}$ is *locally n-coherent* if, for every object $X \in \mathcal{X}$, there exists an effective epimorphism $\amalg_i U_i \to X$, where each U_i is n-coherent. We say that $\mathcal{X}$ is *$(n+1)$-coherent* if it is locally n-coherent and the collection of n-coherent objects of $\mathcal{X}$ is closed under finite products.

Remark A.2.0.13. Let $\mathcal{X}$ be an ∞-topos. Then $\mathcal{X}$ is quasi-compact if and only if, for every collection of (-1)-truncated objects $\{U_i \in \mathcal{X}\}_{i \in I}$ such that $\tau_{\leqslant -1}(\amalg_{i \in I} U_i)$ is a final object of $\mathcal{X}$, there exists a finite subset $I_0 \subseteq I$ such that $\tau_{\leqslant -1}(\amalg_{i \in I_0} U_i)$ is a final object of $\mathcal{X}$. In particular, the condition that $\mathcal{X}$ is quasi-compact depends only on the underlying locale of (-1)-truncated objects of $\mathcal{X}$.

Remark A.2.0.14. Let $\mathcal{X}$ be an n-coherent ∞-topos for $n > 0$. The collection of $(n-1)$-coherent objects of $\mathcal{X}$ is stable under finite products. In particular, the final object of $\mathcal{X}$ is $(n-1)$-coherent, so that $\mathcal{X}$ is $(n-1)$-coherent. It follows that an n-coherent ∞-topos is also m-coherent for each $m \leqslant n$.

Remark A.2.0.15. Let $\mathcal{X}$ be a locally n-coherent ∞-topos. Then $\mathcal{X}_{/U}$ is locally n-coherent for any object $U \in \mathcal{X}$. In this case, an object $X \in \mathcal{X}$ is $(n+1)$-coherent if and only if it is n-coherent and, for every pullback diagram

$$\begin{array}{ccc} U \times_X V & \longrightarrow & U \\ \downarrow & & \downarrow \\ V & \longrightarrow & X \end{array}$$

in $\mathcal{X}$, if U and V are n-coherent, then $U \times_X V$ is also n-coherent.

Remark A.2.0.16. Suppose that $\mathcal{X} = \prod_{1 \leqslant i \leqslant k} \mathcal{X}_i$ is a product of finitely many ∞-topoi (corresponding to a *coproduct* in the ∞-category $\infty\mathcal{T}\mathrm{op}$). Then $\mathcal{X}$ is n-coherent if and only if each $\mathcal{X}_i$ is n-coherent. It follows that if $\mathcal{Y}$ is any ∞-topos, then a finite coproduct $U = \amalg_{1 \leqslant i \leqslant k} U_i$ in $\mathcal{Y}$ is n-coherent if and only if each U_i is n-coherent.

Remark A.2.0.17. Let $\mathcal{X}$ be a locally n-coherent ∞-topos and let $X \in \mathcal{X}$ be a quasi-compact object. The assumption that $\mathcal{X}$ is locally n-coherent guarantees the existence of an effective epimorphism $\amalg_{i \in I} U_i \to X$, where each U_i is n-coherent. Since X is quasi-compact, we may assume that the index set I is finite. Then $U = \amalg_{i \in I} U_i$ is n-coherent by Remark A.2.0.16. It follows that there exists an effective epimorphism $U \to X$, where U is n-coherent.

A.2.1 Coherence of Morphisms

We now introduce a relative version of Definition A.2.0.12.

Definition A.2.1.1. Let $\mathcal{X}$ be an ∞-topos which is locally n-coherent. We will say that a morphism $f : X' \to X$ in $\mathcal{X}$ is *relatively n-coherent* if, for every n-coherent object $U \in \mathcal{X}$ and every morphism $U \to X$, the fiber product $U \times_X X'$ is also n-coherent.

Example A.2.1.2. Let $\mathcal{X}$ be a locally n-coherent ∞-topos. If $f : X' \to X$ is a morphism such that X' is n-coherent and X is $(n+1)$-coherent, then f is relatively n-coherent.

Proposition A.2.1.3. *Let $n \geqslant 0$ be an integer and $\mathcal{X}$ an ∞-topos, and let $f : X_0 \to X$ be a morphism in $\mathcal{X}$. Assume that if $n > 0$, then $\mathcal{X}$ is locally $(n-1)$-coherent and that f is relatively $(n-1)$-coherent. Then:*

(1) *The map f is relatively m-coherent for each $m < n$.*

(2) *Assume that f is an effective epimorphism and that X_0 is n-coherent. Then X is n-coherent.*

Proof. The proof proceeds by induction on n. Suppose first that $n = 0$; we must show that if f is an effective epimorphism and X_0 is quasi-compact, then X is quasi-compact. Choose an effective epimorphism $\amalg_{i \in I} X_i \to X$. Then the induced map $\amalg_{i \in I}(X_i \times_X X_0) \to X_0$ is also an effective epimorphism. Since X_0 is quasi-compact, there exists a finite subset $I_0 \subseteq I$ such that the map $\amalg_{i \in I_0}(X_i \times_X X_0) \to X_0$ is an effective epimorphism. Since f is an effective epimorphism, we conclude that the composite map $\amalg_{i \in I_0}(X_i \times_X X_0) \to X_0 \to X$ is an effective epimorphism. This map factors through $\phi : \amalg_{i \in I_0} X_i \to X$, so that ϕ is an effective epimorphism as desired.

Now suppose that $n > 0$. We begin by proving (1). Choose a morphism $U \to X$, where U is m-coherent; we must show that $U_0 = U \times_X X_0$ is m-coherent. Remark A.2.0.17 guarantees the existence of an effective epimorphism $g : V \to U$, where V is $(n-1)$-coherent. It follows from Example A.2.1.2 that g is relatively $(m-1)$-coherent. Let $V_0 = V \times_X X_0$ and $g_0 : V_0 \to U_0$ the induced map, so that g_0 is also relatively $(m-1)$-coherent. Our assumption that f is relatively $(n-1)$-coherent guarantees that V_0 is $(n-1)$-coherent, and therefore m-coherent (Remark A.2.0.14). Since g_0 is an effective epimorphism, the inductive hypothesis guarantees that U_0 is m-coherent, as desired.

We now prove (2). We will show that X satisfies the criterion for n-coherence described in Remark A.2.0.15. The inductive hypothesis guarantees that X is $(n-1)$-coherent. Choose maps $U \to X$ and $V \to X$, where U and V are $(n-1)$-coherent; we wish to show that $U \times_X V$ is $(n-1)$-coherent. Let $U_0 = U \times_X X_0$ and $V_0 = V \times_X X_0$. Since f is relatively $(n-1)$-coherent, U_0 and V_0 are $(n-1)$-coherent. Since X_0 is n-coherent, we deduce that $U_0 \times_{X_0} V_0$ is $(n-1)$-coherent. The map $f' : U_0 \times_{X_0} V_0 \to U \times_X V$ is a pullback of f and therefore relatively $(n-2)$-coherent by (1). Since f' is an effective epimorphism, the inductive hypothesis guarantees that $U \times_X V$ is $(n-1)$-coherent, as desired. □

Corollary A.2.1.4. *Let $\mathcal{X}$ be an ∞-topos and suppose we are given a full subcategory $\mathcal{X}_0 \subseteq \mathcal{X}$ with the following properties:*

(*a*) *Every object $U \in \mathcal{X}_0$ is an n-coherent object of $\mathcal{X}$*

(*b*) *For every object $X \in \mathcal{X}$, there exists an effective epimorphism $\amalg U_i \to X$, where each U_i belongs to $\mathcal{X}_0$.*

Then:

(1) *A morphism $f : X' \to X$ in $\mathcal{X}$ is relatively n-coherent if and only if, for every morphism $U \to X$ where $U \in \mathcal{X}_0$, the fiber product $U' = U \times_X X'$ is n-coherent.*

(2) *An object $X \in \mathcal{X}$ is $(n+1)$-coherent if and only if it is quasi-compact and, for every pair of maps $U \to X$, $V \to X$ where $U, V \in \mathcal{X}_0$, the fiber product $U \times_X V$ is n-coherent.*

Proof. We first prove (1). The "only if" direction is obvious. For the converse, choose a map $V \to X$ where V is n-coherent; we wish to show that $V' = V \times_X X'$ is n-coherent. Condition (*b*) and the quasi-compactness of V guarantee the existence of an effective epimorphism $g : \amalg_{i \in I} U_i \to V$, where each U_i belongs to $\mathcal{X}_0$ and the index set I is finite. Let $g' : \amalg_{i \in I}(U_i \times_X X') \to V'$ be the induced map. Using our hypothesis together with Remark A.2.0.16, we see that $\amalg_{i \in I}(U_i \times_X X')$ is n-coherent. The map g is relatively $(n-1)$-coherent by Example A.2.1.2, so that g' is relatively $(n-1)$-coherent. Applying Proposition A.2.1.3, we deduce that V' is n-coherent as desired.

We now prove (2) using induction on n. The "only if" direction is again obvious. Assume therefore that X is quasi-compact and that $U \times_X V$ is n-coherent whenever $U, V \in \mathcal{X}_0$. We note that X is n-coherent: this follows from the inductive hypothesis if $n > 0$, or by assumption if $n = 0$. Using (1), we see that the map $U \to X$ is relatively n-coherent whenever $U \in \mathcal{X}_0$. Consequently, if V is an arbitrary n-coherent object of $\mathcal{X}$ and we are given a map $g : V \to X$, then $U \times_X V$ is n-coherent for each $U \in \mathcal{X}_0$. Applying (1) again, we deduce that g is relatively n-coherent. It follows that the fiber product $U \times_X V$ is n-coherent whenever U and V are n-coherent, so that X is $(n+1)$-coherent by Remark A.2.0.15. □

Corollary A.2.1.5. *Let $\mathcal{X}$ be a locally n-coherent ∞-topos, and let $f : X' \to X$ be a morphism in $\mathcal{X}$. Suppose that there exists an effective epimorphism $U \to X$ such that the induced map $f' : U' \to U$ is relatively n-coherent, where $U' = X' \times_X U$. Then f is relatively n-coherent.*

Proof. Suppose we are given a map $Y \to X$, where Y is n-coherent. We wish to prove that $Y' = X' \times_X Y$ is n-coherent. Replacing X by Y and U by $Y \times_X U$, we are reduced to proving that if X is n-coherent, then X' is also n-coherent.

Since $\mathcal{X}$ is locally n-coherent, there exists an effective epimorphism $\amalg_{i \in I} U_i \to U$, where each U_i is n-coherent. The composite map $\amalg_{i \in I} U_i \to U \to X$ is also an effective epimorphism.

Since X is quasi-compact, there exists a finite subset $I_0 \subseteq I$ such that the map $\amalg_{i \in I_0} U_i \to X$ is an effective epimorphism. The coproduct $\amalg_{i \in I_0} U_i$ is n-coherent (Remark A.2.0.16). Replacing U by $\amalg_i U_i$, we can reduce to the case where U is n-coherent. Since f' is relatively n-coherent, we deduce that U' is n-coherent. Since X is n-coherent and U is $(n-1)$-coherent, the map $U \to X$ is relatively $(n-1)$-coherent (if $n > 0$), so the induced map $U' \to X'$ is an effective epimorphism which is $(n-1)$-coherent (if $n > 0$). Proposition A.2.1.3 now implies that X' is n-coherent as desired. □

Definition A.2.1.6. Let $\mathcal{X}$ be an ∞-topos. We will say that $\mathcal{X}$ is *coherent* if it is n-coherent for every integer n. We will say that an object $U \in \mathcal{X}$ is *coherent* if the ∞-topos $\mathcal{X}_{/U}$ is coherent. We will say that $\mathcal{X}$ is *locally coherent* if, for every object $X \in \mathcal{X}$, there exists an effective epimorphism $\amalg_i U_i \to X$ where each U_i is coherent.

Example A.2.1.7. Let $\mathcal{X} = \mathcal{S}$ be the ∞-category of spaces. Then $\mathcal{X}$ is coherent and locally coherent. An object $X \in \mathcal{X}$ is n-coherent if and only if the homotopy sets $\pi_i(X, x)$ are finite for every point $x \in X$ and all $i \leqslant n$.

Remark A.2.1.8. Let $\mathcal{X}$ be an ∞-topos. The collection of coherent objects of $\mathcal{X}$ is closed under finite coproducts (Remark A.2.0.16) and under fiber products. In particular, if $\mathcal{X}$ is coherent, then the collection of coherent objects of $\mathcal{X}$ is closed under finite limits.

A.2.2 Coherence and Hypercompletion

We now show that, to some extent, the coherence of an ∞-topos $\mathcal{X}$ depends only on the hypercompletion $\mathcal{X}^{\mathrm{hyp}}$.

Lemma A.2.2.1. *Let $\mathcal{X}$ be an ∞-topos and $f^* : \mathcal{X} \to \mathcal{Y}$ a geometric morphism, which exhibits $\mathcal{Y}$ as a cotopological localization of $\mathcal{X}$ (see Definition HTT.6.5.2.17). Let $n \geqslant 0$ be an integer, and assume either that $n = 0$ or that $\mathcal{X}$ is locally $(n-1)$-coherent.*

(1) *An object $X \in \mathcal{X}$ is n-coherent if and only if $f^* X \in \mathcal{Y}$ is n-coherent.*

(2) *An object $Y \in \mathcal{Y}$ is n-coherent if and only if $f_* Y \in \mathcal{X}$ is n-coherent.*

(3) *If $n > 0$, the ∞-topos $\mathcal{Y}$ is locally $(n-1)$-coherent.*

Proof. Since f^* is a localization functor, the counit map $f^* f_* Y \to Y$ is an equivalence for each $Y \in \mathcal{Y}$. Consequently, assertion (2) follows from (1), applied to $X = f_* Y$. We prove (1) by induction on n. We first note that the inductive hypothesis implies (3). To see this, assume that $n > 0$ and let $Y \in \mathcal{Y}$, so that $Y \simeq f^* X$ for $X = f_* Y \in \mathcal{X}$. Since $\mathcal{X}$ is locally $(n-1)$-coherent, there exists an effective epimorphism $\amalg V_i \to X$ where each V_i is $(n-1)$-coherent. This induces an effective epimorphism $\amalg f^* V_i \to Y$ in $\mathcal{Y}$, and each $f^* V_i$ is $(n-1)$-coherent by the inductive hypothesis.

We now prove (1) in the case $n = 0$. Suppose that $X \in \mathcal{X}$ is quasi-compact; we wish to show that $f^*X \in \mathcal{Y}$ is quasi-compact. Choose an effective epimorphism $u : \amalg_{i \in I} U_i \to f^*X$ in $\mathcal{Y}$. For $i \in I$, let $V_i = f_* U_i \times_{f_* f^* X} X$, so that $u \simeq f^* v$ for some map $v : \amalg_{i \in I} V_i \to X$. Since f^* is a cotopological localization, the map v is an effective epimorphism. Since X is quasi-compact, there exists a finite subset $I_0 \subseteq I$ such that the induced map $v' : \amalg_{i \in I_0} V_i \to X$ is an effective epimorphism. It follows that $f^*(v') = u' : \amalg_{i \in I_0} U_i \to f^* X$ is an effective epimorphism as well.

Now suppose that f^*X is quasi-compact. We wish to prove that X is quasi-compact. Choose an effective epimorphism $v : \amalg_{i \in I} V_i \to X$, so that $u = f^* v$ is an effective epimorphism $\mathcal{Y}$. Since f^*X is quasi-compact, there exists a finite subset $I_0 \subseteq I$ such that the induced map $\amalg_{i \in I_0} f^* V_i \to f^* X$ is an effective epimorphism. Since f^* is a cotopological localization, we conclude that the map $\amalg_{i \in I_0} V_i \to X$ is an effective epimorphism.

It remains to prove (1) in the case $n > 0$. Suppose first that X is n-coherent. Using the inductive hypothesis, we deduce that f^*X is $(n-1)$-coherent; moreover, we have already seen that $\mathcal{Y}$ is locally $(n-1)$-coherent. To show that f^*X is n-coherent, it suffices to show that for every pair of maps $U \to f^*X$ and $U' \to f^*X$ where $U, U' \in \mathcal{Y}$ are $(n-1)$-coherent, the fiber product $U \times_{f^*X} U'$ is $(n-1)$-coherent (Remark A.2.0.15). Let $V = f_* U \times_{f_* f^* X} X$ and $V' = f_* U' \times_{f_* f^* X} X$. It follows from the inductive hypothesis that V and V' are $(n-1)$-coherent objects of $\mathcal{X}$, so that $V \times_X V'$ is $(n-1)$-coherent. Applying the inductive hypothesis again, we conclude that $U \times_{f^*X} U' \simeq f^*(V \times_X V')$ is $(n-1)$-coherent.

For the converse, suppose that f^*X is n-coherent. Using the inductive hypothesis, we conclude that X is $(n-1)$-coherent. To show that X is n-coherent, it suffices to show that if we are given morphisms $V \to X$, $V' \to X$ where $V, V' \in \mathcal{X}$ are $(n-1)$-coherent, then $V \times_X V'$ is $(n-1)$-coherent. By the inductive hypothesis, it suffices to show that $f^*(V \times_X V') \simeq f^* \times_{f^*X} f^* V'$ is $(n-1)$-coherent, which follows from our assumption that f^*X is n-coherent. □

Taking $\mathcal{Y}$ be the hypercompletion of $\mathcal{X}$ and allowing n to vary, we immediately obtain the following conssequence:

Proposition A.2.2.2. *Let $\mathcal{X}$ be an ∞-topos which is locally n-coherent for all $n \geqslant 0$, let $\mathcal{X}^{\mathrm{hyp}}$ be the full subcategory of $\mathcal{X}$ spanned by the hypercomplete objects, and let $L : \mathcal{X} \to \mathcal{X}^{\mathrm{hyp}}$ be a left adjoint to the inclusion. Then:*

(1) *The ∞-topos $\mathcal{X}^{\mathrm{hyp}}$ is locally n-coherent for all $n \geqslant 0$.*

(2) *An object of $\mathcal{X}^{\mathrm{hyp}}$ is coherent if and only if it is coherent when viewed as an object of $\mathcal{X}$.*

(3) *An object $X \in \mathcal{X}$ is coherent if and only if LX is coherent.*

In particular, if $\mathcal{X}$ is locally coherent, then $\mathcal{X}^{\mathrm{hyp}}$ is also locally coherent.

A.2.3 Coherence and Compactness

Let $\mathcal{X}$ be an ∞-topos. The hypothesis that an object $X \in \mathcal{X}$ be n-coherent can be regarded as a finiteness condition on X. Our next result relates this finiteness condition to the compactness properties of X.

Proposition A.2.3.1. *Let $\mathcal{X}$ be an n-coherent ∞-topos for some $n \geqslant 0$, and let $\Gamma : \mathcal{X} \to \mathcal{S}$ be the global sections functor (that is, Γ is the functor corepresented by the final object $\mathbf{1} \in \mathcal{X}$). Then the restriction of Γ to $\tau_{\leqslant n-1}\mathcal{X}$ commutes with filtered colimits.*

Corollary A.2.3.2. *Let $\mathcal{X}$ be a locally n-coherent ∞-topos. Then:*

(1) *If $U \in \mathcal{X}$ is an n-coherent object, then $\tau_{\leqslant n-1}U$ is a compact object of $\tau_{\leqslant n-1}\mathcal{X}$.*

(2) *The ∞-category $\tau_{\leqslant n-1}\mathcal{X}$ is generated, under small colimits, by objects of the form $\tau_{\leqslant n-1}U$, where $U \in \mathcal{X}$ is n-coherent.*

(3) *The ∞-category $\tau_{\leqslant n-1}\mathcal{X}$ is compactly generated.*

Proof. Assertion (1) follows immediately from Proposition A.2.3.1. Consider an arbitrary object $X \in \mathcal{X}$. Since $\mathcal{X}$ is locally coherent, we can choose a hypercovering $X_\bullet$ of X such that each X_m is a coproduct of n-coherent objects of $\mathcal{X}$. If we assume that $X \in \tau_{\leqslant n-1}\mathcal{X}$, then the map $\tau_{\leqslant n-1}|X_\bullet| \to \tau_{\leqslant n-1}X \simeq X$ is an equivalence. Consequently, X is the geometric realization of a simplicial object of $\tau_{\leqslant n-1}\mathcal{X}$, each term of which is a coproduct of objects having the form $\tau_{\leqslant n-1}U$, where U is n-coherent. This proves (2). Assertion (3) follows immediately from (1) and (2). □

Remark A.2.3.3. Let $\mathcal{X}$ be a locally $(n+1)$-coherent ∞-topos. Let $\mathcal{C}$ be the smallest full subcategory of $\tau_{\leqslant n}\mathcal{X}$ which is closed under finite colimits and contains $\tau_{\leqslant n}U$ for every $(n+1)$-coherent object $U \in \mathcal{X}$. Then $\mathcal{C}$ is the full subcategory of $\tau_{\leqslant n}\mathcal{X}$ spanned by the compact objects. To see this, we first note that every object of $\mathcal{C}$ is compact in $\tau_{\leqslant n}\mathcal{X}$. It follows from Proposition HTT.5.3.5.11 that the inclusion $\mathcal{C} \hookrightarrow \tau_{\leqslant n}\mathcal{X}$ extends to a fully faithful embedding $\phi : \mathrm{Ind}(\mathcal{C}) \to \tau_{\leqslant n}\mathcal{X}$. Proposition HTT.5.5.1.9 implies that ϕ preserves small colimits, so that ϕ is an equivalence of ∞-categories by Corollary A.2.3.2. It follows that the ∞-category of compact objects of $\tau_{\leqslant n}\mathcal{X}$ can be identified with an idempotent completion of $\mathcal{C}$. Since $\mathcal{C}$ is an $(n+1)$-category which admits finite colimits, it is already idempotent complete (Proposition HTT.**??**), so that every compact object of $\tau_{\leqslant n}\mathcal{X}$ belongs to $\mathcal{C}$.

The proof of Proposition A.2.3.1 depends on the following:

Lemma A.2.3.4. *Let $n \geqslant 0$ be an integer, and let $\mathcal{X}$ be an ∞-topos which we assume to be locally $(n-1)$-coherent if $n > 0$. Let $f : U \to X$ be a morphism in $\mathcal{X}$. If f is $(n-2)$-truncated, X is n-coherent, and U is $(n-1)$-coherent, then U is n-coherent.*

Proof. We proceed by induction on n. In the case $n = 0$, the map f is an equivalence and the n-coherence of U follows from the n-coherence of X. Assume therefore that $n > 0$, so that U is quasi-compact. We wish to show that if we are given maps $V_1 \to U$, $V_2 \to U$, where V_1 and V_2 are $(n-1)$-coherent objects of $\mathcal{X}$, then the fiber product $V_1 \times_U V_2$ is also $(n-1)$-coherent. Since U is $(n-1)$-coherent, the fiber product $V_1 \times_U V_2$ is automatically $(n-2)$-coherent. The map $V_1 \times_U V_2 \to V_1 \times_X V_2$ is a pullback of the diagonal map $U \to U \times_X U$ and therefore $(n-3)$-truncated. Since X is n-coherent, the fiber product $V_1 \times_X V_2$ is $(n-1)$-coherent, and the desired result follows from the inductive hypothesis. □

Remark A.2.3.5. Let $\mathcal{X}$ be a coherent ∞-topos and let $U \in \mathcal{X}$ be an n-truncated object. Then U is coherent if and only if it is $(n+1)$-coherent. This follows by applying Lemma A.2.3.4 in the case where X is a final object of $\mathcal{X}$.

Proof of Proposition A.2.3.1. We proceed by induction on n. In the case $n = 0$, our assumption guarantees that $\mathcal{X}$ is quasi-compact and the desired result follows immediately from the definition. Let us therefore assume that $n > 0$. Let $\mathcal{J}$ be a small filtered ∞-category, let $U, U' : \mathrm{Fun}(\mathcal{J}, \tau_{\leq n-1}\mathcal{X}) \to \mathcal{S}$ be given by

$$U(F) = \varinjlim_{J \in \mathcal{J}} \Gamma(F(J)) \qquad U'(F) = \Gamma(\varinjlim_{J \in \mathcal{J}} F(J)).$$

There is an evident natural transformation $\beta_F : U(F) \to U'(F)$; we wish to show that β_F is a homotopy equivalence. Assume for the moment that β_F is surjective on connected components. It then suffices to show that for every pair of points $\eta, \eta' \in U(F)$, the map β_F induces a homotopy equivalence of path spaces $\phi : \{\eta\} \times_{U(F)} \{\eta'\} \to \{\eta\} \times_{U'(F)} \{\eta'\}$. Since $\mathcal{J}$ is filtered, we may assume without loss of generality that η and η' are the images of points $\eta_0, \eta'_0 \in \Gamma(F(J))$. Since $\mathcal{J}$ is filtered, the map $\mathcal{J}_{J/} \to \mathcal{J}$ is left cofinal; we may therefore replace $\mathcal{J}$ by $\mathcal{J}_{J/}$ and thereby assume that J is a final object of $\mathcal{J}$. In this case, η_0 and η'_0 determine natural transformations $* \to F$, where $*$ denotes the constant functor $\mathcal{J} \to \mathcal{X}$ taking the value $\mathbf{1}$. Let $F' = * \times_F *$. Unwinding the definitions, we see that ϕ can be identified with the map $\beta_{F'}$. The desired result then follows from the inductive hypothesis, since $\mathcal{X}$ is $(n-1)$-truncated and F' takes values in $\tau_{\leq n-2}\mathcal{X}$.

It remains to prove that β_F is surjective on connected components. Choose a point $\eta \in U'(F)$, corresponding to a map $\alpha : \mathbf{1} \to \varinjlim_{J \in \mathcal{J}} F(J)$. We wish to show that α factors (up to homotopy) through $F(J)$ for some $J \in \mathcal{J}$. Note that the map $\amalg_{J \in \mathcal{J}} F(J) \to \varinjlim_{J \in \mathcal{J}} F(J)$ is an effective epimorphism. Since $\mathcal{X}$ is locally $(n-1)$-coherent, there exists a collection of $(n-1)$-coherent objects $\{U_i \in \mathcal{X}\}_{i \in I}$ such that $\amalg_{i \in I} U_i \to \mathbf{1}$ is an effective epimorphism and each of the composite maps $U_i \to \mathbf{1} \to \varinjlim_{J \in \mathcal{J}} F(J)$ factors through $F(J_i)$, for some $J_i \in \mathcal{J}$. Since $\mathcal{X}$ is quasi-compact, we can assume that the set I is finite. Let $U = \amalg_{i \in I} U_i$. Since $\mathcal{J}$ is filtered, there exists an object $J_0 \in \mathcal{J}$ and maps $J_i \to J_0$ for $i \in I$, so that the composite map $U \to \mathbf{1} \xrightarrow{\alpha} \varinjlim_{J \in \mathcal{J}} F(J)$ factors through $F(J_0)$. Since $\mathcal{J}$ is filtered, the map

$\mathcal{J}_{J_0/} \to \mathcal{J}$ is left cofinal; we may therefore replace $\mathcal{J}$ by $\mathcal{J}_{J_0/}$ and thereby reduce to the case where J_0 is an initial object of $\mathcal{J}$. Let $F_0 : \mathcal{J} \to \mathcal{X}$ be the constant functor taking the value $F(\mathcal{J}_0)$, and let $F_\bullet$ be the simplicial object of $\mathrm{Fun}(\mathcal{J}, \mathcal{X})$ given by the Čech nerve of the map $F_0 \to F$. Let $U_\bullet$ be the Čech nerve of the map $U \to \mathbf{1}$, so that we obtain a map of simplicial objects of $\mathcal{X}$ $\gamma : U_\bullet \to \varinjlim_{J \in \mathcal{J}} F_\bullet(J)$. We will prove the following assertion by induction on $m \geqslant 0$:

(∗) Let $\mathbf{\Delta}_{s,\leqslant m}$ denote the subcategory of $\mathbf{\Delta}$ whose objects are linearly ordered sets $[j]$ for $j \leqslant m$, and whose morphisms are given by injective maps $[j] \to [j']$. Let $U_\bullet^{\leqslant m}$ be the restriction of $U_\bullet$ to $\mathbf{\Delta}^{\mathrm{op}}_{s,\leqslant m}$, define $F_\bullet^{\leqslant m}$ similarly, and let $\gamma^{\leqslant m} : U_\bullet^{\leqslant m} \to \varinjlim_{J \in \mathcal{J}} F_\bullet^{\leqslant m}(J)$ be the map induced by γ. Then there exists an object $J_m \in \mathcal{J}$ such that $\gamma^{\leqslant m}$ factors through $F_\bullet^{\leqslant m}(J_m)$.

Assertion (∗) is obvious when $m = 0$, since the functor F_0 is constant. Assume that $\gamma^{\leqslant m-1}$ factors through $F_\bullet^{\leqslant m-1}(J_{m-1})$ for some $J_{m-1} \in \mathcal{J}$. Replacing $\mathcal{J}$ by $\mathcal{J}_{J_{m-1}/}$, we may assume that J_{m-1} is an initial object of $\mathcal{J}$, so that we have a canonical map $\delta_J : U_\bullet^{\leqslant m-1} \to F_\bullet^{\leqslant m-1}(J)$ for all $J \in \mathcal{J}$. Let $M(J) \in \mathcal{X}$ denote the mth matching object of $F_\bullet(J)$, for each $j \in J$, so that δ_J determines a map $\theta : U_m \to M(J)$. Using Proposition HTT.A.2.9.14 , we see that promoting δ_J to a natural transformation $U_\bullet^{\leqslant m} \to F_\bullet^{\leqslant m}(J)$ is equivalent to choosing a point of the mapping space

$$\mathrm{Map}_{\mathcal{X}_{/M(J)}}(U_m, F_m(J)) \simeq \mathrm{Map}_{\mathcal{X}_{/U_m}}(U_m, F_m(J) \times_{M(J)} U_m).$$

Consequently, to prove (∗), it suffices to show that the map

$$\varinjlim \mathrm{Map}_{\mathcal{X}_{/U_m}}(U_m, F_m(J) \times_{M(J)} U_m) \to \mathrm{Map}_{\mathcal{X}_{/U_m}}(U_m, \varinjlim F_m(J) \times_{M(J)} U_m)$$

is a homotopy equivalence. Since $\mathcal{X}$ is n-coherent and $U \in \mathcal{X}$ is $(n-1)$-coherent, the ∞-topos $\mathcal{X}_{/U_m}$ is $(n-1)$-coherent. By the inductive hypothesis, it suffices to show that the the objects $F_m(J) \times_{M(J)} U_m$ are $(n-2)$-truncated objects of $\mathcal{X}_{/U_m}$. For this, it suffices to show that the map $F_m(J) \to M(J)$ is $(n-2)$-truncated. This map is a pullback of the diagonal $F(J) \to F(J)^{\partial \Delta^m}$, and therefore $(n-m-1)$-truncated (since $F(J)$ is assumed to be $(n-1)$-truncated). This completes the proof of (∗).

Applying (∗) in the case $m = n$ and composing with the natural map $\varinjlim F_\bullet^{\leqslant n} \to F$, we deduce the existence of an object $J_n \in \mathcal{J}$ and a commutative diagram σ :

$$\begin{array}{ccc} \varinjlim U_\bullet^{\leqslant n} & \longrightarrow & F(J_n) \\ \downarrow & & \downarrow \\ \mathbf{1} & \xrightarrow{\eta} & \varinjlim_{J \in \mathcal{J}} F(J). \end{array}$$

Since the map $U \to \mathbf{1}$ is an effective epimorphism, we deduce that $\tau_{\leqslant n-1} \varinjlim U_{\bullet}^{\leqslant n} \simeq |U_{\bullet}| \simeq \mathbf{1}$. Applying the truncation functor $\tau_{\leqslant n-1}$ to the diagram σ, we conclude that η factors through $F(J_n)$. □

A.2.4 Coherence and Truncations

We now study the behavior of coherent objects under truncation.

Proposition A.2.4.1. *Let $\mathcal{X}$ be an ∞-topos and let $f : X \to Y$ be a morphism of $\mathcal{X}$, and let $n \geqslant 0$. Then:*

(a_n) *If X is n-coherent and f is n-connective, then Y is n-coherent.*

(b_n) *If Y is n-coherent and f is $(n+1)$-connective, then X is n-coherent.*

Proof. We proceed by induction on n. We begin by treating the case $n = 0$. To prove (a_0), assume that X is quasi-compact and that f is an effective epimorphism; we wish to show that Y is also quasi-compact. Fix an effective epimorphism $\amalg_{i \in I} Y_i \to Y$ and for each $i \in I$ set $X_i = Y_i \times_Y X$. Then the induced map $\amalg_{i \in I} X_i \to X$ is also an effective epimorphism. Since X is quasi-compact, we can choose a finite subset $I_0 \subseteq I$ for which the upper horizontal map in the diagram

$$\begin{array}{ccc} \amalg_{i \in I_0} X_i & \longrightarrow & X \\ \downarrow & & \downarrow f \\ \amalg_{i \in I_0} Y_i & \longrightarrow & Y \end{array}$$

is an effective epimorphism. Since f is an effective epimorphism by assumption, it follows from the commutativity of the diagram that the lower horizontal map is also an effective epimorphism.

We now prove (b_0). Assume that f is 1-connective and that Y is quasi-compact. Suppose we are given an effective epimorphism $\rho : \amalg_{i \in I} X_i \to X$. Then the composite map $\amalg_{i \in I} X_i \to X \xrightarrow{f} Y$ is also an effective epimorphism. Using the quasi-compactness of Y, we deduce that there exists a finite subset $I_0 \subseteq I$ for which the composite map $\phi : \amalg_{i \in I_0} X_i \to X \xrightarrow{f} Y$ is also an effective epimorphism. We claim that $\rho_0 = \rho|_{\amalg_{i \in I_0} X_i}$ is also an effective epimorphism. To prove this, we note that ρ_0 factors as a composition

$$\amalg_{i \in I_0} X_i \xrightarrow{g} \amalg_{i \in I_0} X_i \times_Y X \xrightarrow{h} X$$

where g is the coproduct of maps $g_i : X_i \to X_i \times_Y X$ and h is the amalgam of maps $h_i : X_i \times_Y X \to X$ given by projection onto the second factor. Each g_i is a pullback of the diagonal map $X \to X \times_Y X$, and is therefore an effective epimorphism by virtue of our assumption that f is 1-connective. The map h is a pullback of ϕ, and is therefore an effective epimorphism. It follows that ρ_0 is also an effective epimorphism, as desired.

We now carry out the inductive step. Assume that $n > 0$ and that assertions (a_m) and (b_m) are valid for $m < n$. We begin by establishing (a_n). Suppose that X is n-coherent and that f is n-connective; we wish to show that Y is n-coherent. For each object $Y' \in \mathcal{X}_{/Y}$, we can regard the fiber product $X' = X \times_Y Y'$ as an object of $\mathcal{X}_{/X}$. Since X is n-coherent, the ∞-topos $\mathcal{X}_{/X}$ is locally $(n-1)$-coherent: in particular, we can choose an effective epimorphism $\amalg X_i \to X'$, where each X_i is an $(n-1)$-coherent object of $\mathcal{X}$. Since f is an effective epimorphism, the composite map $\amalg X_i \to X' \to Y'$ is also an effective epimorphism. Allowing Y' to vary, we deduce that the ∞-topos $\mathcal{X}_{/Y}$ is locally $(n-1)$-coherent. To complete the proof of (a_n), we must show that for every pair of $(n-1)$-coherent objects $Y_0, Y_1 \in \mathcal{X}_{/Y}$, the fiber product $Y_{01} = Y_0 \times_Y Y_1$ is also $(n-1)$-coherent. Set $X_0 = X \times_Y Y_0$ and $X_1 = X \times_Y Y_1$. Then f induces n-connective maps $X_0 \to Y_0$ and $X_1 \to Y_1$, it follows from our inductive hypothesis (b_{n-1}) that X_0 and X_1 are $(n-1)$-coherent. Using the n-coherence of X, we deduce that $X_{01} = X_0 \times_X X_1$ is $(n-1)$-coherent. The natural map $X_{01} \to Y_{01}$ is a pullback of f, and therefore n-connective. Applying (a_{n-1}), we deduce that Y_{01} is $(n-1)$-coherent, as desired.

We now prove (b_n). Assume that Y is n-coherent and that f is $(n+1)$-connective; we wish to show that X is n-coherent. Since $\mathcal{X}_{/Y}$ is locally $(n-1)$-coherent, it follows immediately from the definitions that $\mathcal{X}_{/X}$ is locally $(n-1)$-coherent. It will therefore suffice to show that if $X_0, X_1 \in \mathcal{X}_{/X}$ are $(n-1)$-coherent, then the fiber product $X_0 \times_X X_1$ are $(n-1)$-coherent. Unwinding the definitions, we have a pullback diagram

$$\begin{array}{ccc} X_0 \times_X X_1 & \xrightarrow{\delta'} & X_0 \times_Y X_1 \\ \downarrow & & \downarrow \\ X & \xrightarrow{\delta} & X \times_Y X. \end{array}$$

Our assumption that f is $(n+1)$-connective guarantees that δ is n-connective, so that δ' is also n-connective. The n-coherence of Y guarantees that $X_0 \times_Y X_1$ is $(n-1)$-coherent. Applying (b_{n-1}), we deduce that $X_0 \times_X X_1$ is also $(n-1)$-coherent, as desired. □

Corollary A.2.4.2. *Let $\mathcal{X}$ be an ∞-topos containing a morphism $f : X \to Z$. Let $n \geqslant 0$ be an integer, so that f factors as a composition $X \xrightarrow{f'} Y \xrightarrow{f''} Z$ where f' is n-connective and f'' is $(n-1)$-truncated. If X is n-coherent and Z is m-coherent for $m \geqslant n$, then Y is m-coherent.*

Proof. We proceed by induction on m. If $m = n$, the desired result follows from Proposition A.2.4.1 (together with the n-coherence of X and the n-connectivity of f'). The inductive step follows from Lemma A.2.3.4 (since f'' is $(n-1)$-truncated and therefore also $(m-2)$-truncated for $m > n$). □

Corollary A.2.4.3. *Let $\mathcal{X}$ be an ∞-topos containing an n-coherent object X. For each $m \geqslant n$, if the ∞-topos $\mathcal{X}$ is m-coherent, then the object $\tau_{\leqslant n-1}X$ is m-coherent.*

Proof. Apply Corollary A.2.4.2 in the case where Z is a final object of $\mathcal{X}$. □

Corollary A.2.4.4. *Let $\mathcal{X}$ be a coherent ∞-topos. If $X \in \mathcal{X}$ is an n-coherent object for $n \geqslant 0$, then the truncation $\tau_{\leqslant n-1}X$ is a coherent object of $\mathcal{X}$.*

A.3 ∞-Topoi of Sheaves

In §A.2, we introduced the notion of a *coherent ∞-topos* (Definition A.2.1.6). In this section, we will describe a large class of coherent ∞-topoi. More precisely, we will show that if $\mathcal{C}$ is a small ∞-category which admits finite limits and its equipped with a *finitary* Grothendieck topology (Definition A.3.1.1), then the ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is coherent (Proposition A.3.1.3). It would be too optimistic to expect the converse to hold in the ∞-categorical setting: just as not every ∞-topos $\mathcal{X}$ can be obtained as an ∞-category of sheaves on a Grothendieck site, not every coherent ∞-topos $\mathcal{X}$ can be obtained as an ∞-category of sheaves on a finitary Grothendieck site. However, we will show that something slightly weaker is true: every ∞-topos $\mathcal{X}$ which is coherent, locally coherent, and hypercomplete can be realized as the ∞-category of hypercomplete sheaves on a finitary Grothendieck site (Theorem A.3.4.1). In fact, there is even a canonical choice for the site $\mathcal{C}$ (which we will study in §A.6).

A.3.1 Finitary Grothendieck Topologies

Let $\mathcal{C}$ be an ∞-category. Recall that a *sieve* on an object $C \in \mathcal{C}$ is a full subcategory $\mathcal{C}^{(0)}_{/C} \subseteq \mathcal{C}_{/C}$ with the following property: for any commutative diagram

$$\begin{array}{ccc} C_0 & \longrightarrow & C_1 \\ & {\scriptstyle \phi_0}\searrow \quad \swarrow{\scriptstyle \phi_1} & \\ & C & \end{array}$$

in $\mathcal{C}$, if ϕ_1 belongs to $\mathcal{C}^{(0)}_{/C}$, then ϕ_0 also belongs to $\mathcal{C}^{(0)}_{/C}$. A *Grothendieck topology* on $\mathcal{C}$ consists of the specification, for each object $C \in \mathcal{C}$, of a special class of sieves on C, called *covering sieves*, which satisfy the following axioms:

(a) For every object $C \in \mathcal{C}$, the category $\mathcal{C}_{/C}$ is a covering sieve on C.

(b) Let $\phi : C \to D$ be a morphism in $\mathcal{C}$, $\mathcal{C}^{(0)}_{/D}$ a sieve on D, and $\phi^* \mathcal{C}^{(0)}_{/D}$ the full subcategory of $\mathcal{C}^{(0)}_{/C}$ spanned by those maps $\psi : C_0 \to C$ for which the composite map $\phi \circ \psi$ belongs to $\mathcal{C}^{(0)}_{/D}$. If $\mathcal{C}^{(0)}_{/D}$ is a covering sieve on D, then $\mathcal{C}^{(0)}_{/C}$ is a covering sieve on C.

(c) Let $D \in \mathcal{C}$ be an object, and suppose we are given sieves $\mathcal{C}^{(0)}_{/D}, \mathcal{C}^{(1)}_{/D} \subseteq \mathcal{C}_{/D}$. Suppose that $\mathcal{C}^{(0)}_{/D}$ is a covering sieve, and that for each morphism $\phi : C \to D$ belonging to $\mathcal{C}^{(0)}_{/D}$, the sieve $\phi^* \mathcal{C}^{(1)}_{/D}$ is a covering sieve on C. Then $\mathcal{C}^{(1)}_{/D}$ is a covering sieve on D.

Definition A.3.1.1. Let $\mathcal{C}$ be an ∞-category which admits pullbacks. We will say that a Grothendieck topology on $\mathcal{C}$ is *finitary* if it satisfies the following condition:

(∗) For every object $C \in \mathcal{C}$ and every covering sieve $\mathcal{C}^{(0)}_{/C} \subseteq \mathcal{C}_{/C}$, there exists a finite collection of morphisms $\{C_i \to C\}_{1 \leqslant i \leqslant n}$ in $\mathcal{C}^{(0)}_{/C}$ which generate a covering of C (in other words, the smallest sieve $\mathcal{C}^{(1)}_{/C}$ containing each C_i is also a covering sieve on C).

Remark A.3.1.2. Let $\mathcal{C}$ be an ∞-category which admits pullbacks, and suppose that $\mathcal{C}$ is equipped with an arbitrary Grothendieck topology. Let $\mathcal{D}$ denote the same ∞-category $\mathcal{C}$, and let us say that a sieve $\mathcal{D}^{(0)}_{/D} \subseteq \mathcal{D}_{/D}$ is *covering* if it contains a finite collection of morphisms $\{D_i \to D\}$ which generate a covering sieve in $\mathcal{C}$. This collection of covering sieves determines a Grothendieck topology on $\mathcal{D}$. This Grothendieck topology is the finest finitary topology on $\mathcal{D}$ which is coarser than the original topology on $\mathcal{C}$.

Proposition A.3.1.3. *Let $\mathcal{C}$ be a small ∞-category which admits pullbacks which is equipped with a finitary Grothendieck topology. Then:*

(1) *If $j : \mathcal{C} \to \mathcal{S}\mathrm{hv}(\mathcal{C})$ denotes the composition of the Yoneda embedding $\mathcal{C} \to \mathcal{P}(\mathcal{C})$ with the sheafification function $\mathcal{P}(\mathcal{C}) \to \mathcal{S}\mathrm{hv}(\mathcal{C})$, the functor j carries each object $C \in \mathcal{C}$ to a coherent object of $\mathcal{S}\mathrm{hv}(\mathcal{C})$.*

(2) *The ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is locally coherent.*

(3) *If $\mathcal{C}$ has a final object, then $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is coherent.*

Proof. Since $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is generated by $j(\mathcal{C})$ under small colimits, assertion (2) follows immedaitely from (1). Since j preserves finite limits, it carries final objects of $\mathcal{C}$ to final objects of $\mathcal{S}\mathrm{hv}(\mathcal{C})$, so assertion (3) also follows from (1). We will prove the following assertions by induction on n:

(1′) The functor j carries each object $C \in \mathcal{C}$ to an n-coherent object of $\mathcal{S}\mathrm{hv}(\mathcal{C})$.

(2′) The ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is locally n-coherent.

It is clear that (1′) implies (2′). To prove (1′), let us first assume that $n = 0$. We must show that for $C \in \mathcal{C}$, the object $j(C) \in \mathcal{S}\mathrm{hv}(\mathcal{C})$ is quasi-compact. Choose an effective epimorphism $\amalg_{i \in I} U_i \to j(C)$ in $\mathcal{S}\mathrm{hv}(\mathcal{C})$. It follows that there exists a covering $\{C_\alpha \to C\}$ in $\mathcal{C}$ such that each of the induced maps $j(C_\alpha) \to j(C)$ factors through U_i for some i. Since the topology on $\mathcal{C}$ is finitary, we may assume that this covering is finite; then we may assume that all of this indices $i \in I$ which are used belong to some finite subset $I_0 \subseteq I$, so that $\amalg_{i \in I_0} U_i \to j(C)$ is an effective epimorphism, as desired.

Now suppose that $n > 0$. Using the inductive hypothesis, we may assume that $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is locally $(n-1)$-coherent and that $j(C)$ is $(n-1)$-coherent for $C \in \mathcal{C}$. We wish to show that $j(C)$ is n-coherent. Without loss of generality, we may replace $\mathcal{C}$ by $\mathcal{C}_{/C}$ and $\mathcal{S}\mathrm{hv}(\mathcal{C})$ by $\mathcal{S}\mathrm{hv}(\mathcal{C})_{/j(C)} \simeq \mathcal{S}\mathrm{hv}(\mathcal{C}_{/C})$. We wish to show that the collection of $(n-1)$-coherent objects of $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is closed under finite products. Using Corollary A.2.1.4, we are reduced to showing that $j(C') \times j(C'')$ is $(n-1)$-coherent, for every pair of objects $C', C'' \in \mathcal{C}$. This is clear, since $j(C') \times j(C'') = j(C' \times C'')$. □

A.3.2 Examples of Grothendieck Topologies

The theory of Grothendieck topologies is quite flexible and can be applied in a great deal of generality. However, for many applications, it is convenient to work not with covering *sieves*, but instead with covering *morphisms*: that is, morphisms $\phi : C \to D$ which generate a covering sieve on D. We now describe a general procedure for constructing Grothendieck topologies which are "generated" by their covering morphisms. Most of the Grothendieck topologies of interest to us in this book can be constructed using this procedure.

Proposition A.3.2.1. *Let $\mathcal{C}$ be an ∞-category and let S be a collection of morphisms in $\mathcal{C}$. Assume that:*

(a) The collection of morphisms S is contains all equivalences and is stable under composition (in particular, if $f, g : C \to D$ are homotopic morphisms in $\mathcal{C}$, then $f \in S$ if and only if $g \in S$).

(b) The ∞-category $\mathcal{C}$ admits pullbacks. Moreover, the class of morphisms S is stable under pullback: for every pullback diagram

$$\begin{array}{ccc} C' & \longrightarrow & C \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ D' & \longrightarrow & D \end{array}$$

such that $f \in S$, the morphism f' also belongs to S.

(c) The ∞-category $\mathcal{C}$ admits finite coproducts. Moreover, the collection of morphisms S is stable under finite coproducts: if $f_i : C_i \to D_i$ is a finite collection of morphisms in $\mathcal{C}$ which belong to S, then the induced map $\coprod_i C_i \to \coprod_i D_i$ also belongs to S.

(d) Finite coproducts in $\mathcal{C}$ are universal. That is, given a diagram $\coprod_{1 \leqslant i \leqslant n} C_i \to D \leftarrow D'$, the canonical map $\coprod_{1 \leqslant i \leqslant n}(C_i \times_D D') \to (\coprod_{1 \leqslant i \leqslant n} C_i) \times_D D'$ is an equivalence in $\mathcal{C}$.

Then there exists a Grothendieck topology on $\mathcal{C}$ which can be described as follows: a sieve $\mathcal{C}^{(0)}_{/C} \subseteq \mathcal{C}_{/C}$ on an object $C \in \mathcal{C}$ is covering if and only if it contains a finite collection of morphisms $\{C_i \to C\}_{1 \leqslant i \leqslant n}$ such that the induced map $\coprod C_i \to C$ belongs to S.

Remark A.3.2.2. The Grothendieck topologies described in Proposition A.3.2.1 are finitary.

Proof of Proposition A.3.2.1. We show that the collection of covering sieves satisfies the conditions of Definition HTT.6.2.2.1 :

(1) For every object $C \in \mathcal{C}$, the sieve $\mathcal{C}_{/C}$ covers C. This is clear, since $\mathcal{C}_{/C}$ contains the identity map $\mathrm{id}_C : C \to C$, which belongs to S by (a).

(2) If $\mathcal{C}^{(0)}_{/C}$ is a covering sieve on an object $C \in \mathcal{C}$ and $f : C' \to C$ is a morphism in $\mathcal{C}$, then the pullback sieve $f^* \mathcal{C}^{(0)}_{/C}$ covers C'. To prove this, we observe that there exists a finite collection of morphisms $C_i \to C$ belonging to $\mathcal{C}^{(0)}_{/C}$ such that the induced map $\coprod_i C_i \to C$ belongs to S. Assumption (b) guarantees that the induced map $(\coprod_i C_i) \times_C C' \to C'$ also belongs to S, and assumption (d) gives an identification $(\coprod_i C_i) \times_C C' \simeq \coprod_i (C_i \times_C C')$. It now suffices to observe that each of the morphisms $C_i \times_C C' \to C'$ belongs to the sieve $f^* \mathcal{C}^{(0)}_{/C}$.

(3) Let $\mathcal{C}^{(0)}_{/C}$ be a covering sieve on an object $C \in \mathcal{C}$, and let $\mathcal{C}^{(1)}_{/C}$ be an arbitrary sieve on C. Suppose that, for each morphism $f : C' \to C$ belonging to $\mathcal{C}^{(0)}_{/C}$, the pullback sieve $f^* \mathcal{C}^{(1)}_{/C}$ covers C'. We must show that $\mathcal{C}^{(1)}_{/C}$ covers C. Since $\mathcal{C}^{(0)}_{/C}$ is a covering sieve, there exists a finite collection of morphisms $f_i : C_i \to C$ belonging to $\mathcal{C}^{(0)}_{/C}$ such that the induced map $\coprod_i C_i \to C$ belongs to S. Each $f_i^* \mathcal{C}^{(1)}_{/C}$ is a covering sieve on C_i, so there exists a finite collection of morphisms $C_{i,j} \to C_i$ belonging to $f^* \mathcal{C}^{(1)}_{/C}$ such that the induced map $\coprod_j C_{i,j} \to C_i$ belongs to S. It follows that each of the composite maps $C_{i,j} \to C_i \to C$ belongs to the sieve $\mathcal{C}^{(1)}_{/C}$. To prove that $\mathcal{C}^{(1)}_{/C}$ is covering, it suffices to show that the map $g : \coprod_{i,j} C_{i,j} \to C$ belongs to S. To prove this, we factor g as a composition

$$\coprod_{i,j} C_{i,j} \xrightarrow{g'} \coprod_i C_i \xrightarrow{g''} C.$$

The map g'' belongs to S by assumption, and the map g' is a finite coproduct of maps belonging to S and therefore belongs to S by virtue of (c). It follows from (a) that $g \simeq g'' \circ g'$ belongs to S, as required.

□

A.3.3 Čech Descent

Recall that if $\mathcal{C}$ is an ∞-category equipped with a Grothendieck topology and $\mathscr{F} : \mathcal{C}^{\mathrm{op}} \to \mathcal{D}$ is a functor, we say that $\mathscr{F}$ is a *sheaf* if, for every covering sieve $\mathcal{C}^{(0)}_{/C} \subseteq \mathcal{C}_{/C}$ on an object $C \in \mathcal{C}$, the functor $\mathscr{F}$ exhibits $\mathscr{F}(C)$ as a limit of the diagram $\mathscr{F}|_{(\mathcal{C}^{(0)}_{/C})^{\mathrm{op}}}$. For Grothendieck topologies which arise from the construction of Proposition A.3.2.1, we can formulate this condition in a more concrete way:

Proposition A.3.3.1. *Let $\mathcal{C}$ be an ∞-category and S a collection of morphisms in $\mathcal{C}$. Assume that $\mathcal{C}$ and S satisfy the hypotheses of Proposition A.3.2.1, together with the following additional hypothesis:*

(e) *Coproducts in the ∞-category $\mathcal{C}$ are disjoint. That is, if C and C' are objects of $\mathcal{C}$, then the fiber product $C \times_{C \amalg C'} C'$ is an initial object of $\mathcal{C}$ (see §HTT.6.1.1).*

Let $\mathcal{D}$ be an arbitrary ∞-category and let $\mathscr{F} : \mathcal{C}^{\mathrm{op}} \to \mathcal{D}$ be a functor. Then $\mathscr{F}$ is a $\mathcal{D}$-valued sheaf on $\mathcal{C}$ if and only if the following conditions are satisfied:

(1) *The functor $\mathscr{F}$ preserves finite products.*

(2) *Let $f : U_0 \to X$ be a morphism in $\mathcal{C}$ which belongs to S and let $U_\bullet$ be a Čech nerve of f (see §HTT.6.1.2), regarded as an augmented simplicial object of $\mathcal{C}$. Then the composite map $\mathbf{\Delta}_+ \xrightarrow{U_\bullet} \mathcal{C}^{\mathrm{op}} \xrightarrow{\mathscr{F}} \mathcal{D}$ is a limit diagram. In other words, $\mathscr{F}$ exhibits $\mathscr{F}(X)$ as a totalization of the cosimplicial object $[n] \mapsto \mathscr{F}(U_n)$.*

Proof. For every object $D \in \mathcal{D}$, let $h^D : \mathcal{D} \to \mathcal{S}$ be the functor corepresented by D. Using Proposition HTT.5.1.3.2 , we deduce that $\mathscr{F}$ is a sheaf $\mathcal{D}$-valued sheaf on $\mathcal{C}$ if and only if each composite map $h^D \circ \mathscr{F}$ is a $\mathcal{S}$-valued sheaf on $\mathcal{C}$, and that $\mathscr{F}$ satisfies conditions (1) and (2) if and only if each $h^D \circ \mathscr{F}$ satisfies the same condition. We may therefore replace $\mathscr{F}$ by $h^D \circ \mathscr{F}$ and thereby reduce to the case where $\mathcal{D} = \mathcal{S}$.

Suppose first that $\mathscr{F}$ is a sheaf; we will prove that $\mathscr{F}$ satisfies conditions (1) and (2). We begin with (1). Let $\{C_i\}_{1 \leqslant i \leqslant n}$ be a finite collection of objects in $\mathcal{C}$ and let $C = \coprod_i C_i$ be their coproduct. We wish to prove that the canonical map $\mathscr{F}(C) \to \prod_i \mathscr{F}(C_i)$ is an equivalence. The proof proceeds by induction on n. If $n = 0$, then C is an initial object of $\mathcal{C}$ so that the empty sieve is a covering of C. Since $\mathscr{F}$ is a sheaf, we deduce that $\mathscr{F}(C)$ is a final object of $\mathcal{S}$, as required. If $n = 1$, there is nothing to prove. If $n > 2$, we let $D = \coprod_{1 \leqslant i < n} C_i$, so that $C = D \amalg C_n$. The natural map $\mathscr{F}(C) \to \prod_i \mathscr{F}(C_i)$ then factors as a composition of maps

$$\mathscr{F}(C) \to \mathscr{F}(D) \times \mathscr{F}(C_n) \to (\prod_{1 \leqslant i < n} \mathscr{F}(C_i)) \times \mathscr{F}(C_n) \simeq \prod_{1 \leqslant i \leqslant n} \mathscr{F}(C_n),$$

each of which is an equivalence by the inductive hypothesis. It remains to treat the case $n = 2$. Let $\mathcal{C}^{(0)}_{/C} \subseteq \mathcal{C}_{/C}$ be the sieve generated by C_1 and C_2. This sieve is evidently a covering of C, so that $\mathscr{F}(C) \simeq \varprojlim \mathscr{F}|_{(\mathcal{C}^{(0)}_{/C})^{\mathrm{op}}}$. To complete the proof, it suffices to show that the canonical map $\varprojlim \mathscr{F}|_{(\mathcal{C}^{(0)}_{/C})^{\mathrm{op}}} \to \mathscr{F}(C_1) \times \mathscr{F}(C_2)$ is an equivalence. Let $p : \Lambda^2_0 \to \mathcal{C}^{(0)}_{/C}$ be the map corresponding to the pullback diagram

$$\begin{array}{ccc} C_1 \times_C C_2 & \longrightarrow & C_1 \\ \downarrow & & \downarrow \\ C_2 & \longrightarrow & C \end{array}$$

in $\mathcal{C}$. Since $C_1 \times_C C_2$ is initial in $\mathcal{C}$, the above argument shows that $\mathscr{F}(C_1 \times_C C_2)$ is final in $\mathcal{D}$: that is, $\mathscr{F}|_{(\Lambda^2_0)^{\mathrm{op}}}$ is a right Kan extension of $\mathscr{F}|_{\{1,2\}^{\mathrm{op}}}$, so that $\varprojlim \mathscr{F}|_{(\Lambda^2_0)^{\mathrm{op}}} \simeq \mathscr{F}(C_1) \times \mathscr{F}(C_2)$ by Lemma HTT.4.3.2.7 . To complete the proof of (1), we will show that p is left cofinal. According to Theorem HTT.4.1.3.1 , it will suffice to show that for every object $(f : D \to C) \in \mathcal{C}^{(0)}_{/C}$, the ∞-category $S = \Lambda^2_0 \times_{\mathcal{C}^{(0)}_{/C}} (\mathcal{C}^{(0)}_{/C})_{f/}$ is weakly contractible. If $D \in \mathcal{C}$ is initial, then the projection map $S \to \Lambda^2_0$ is a trivial Kan fibration and the result is obvious. If D is not initial, then condition (d) guarantees that there do not exist any maps from D to an initial object of $\mathcal{C}$. Using (e), we deduce that there do not exist any maps from D into $C_1 \times_C C_2$. It follows that f factors through either the map $C_1 \to C$ or $C_2 \to C$, but not both. Without loss of generality, we may assume that f factors through $C_1 \to C$. In this case, we can identify S with the simplicial set $\{C_1\} \times_{\mathcal{C}_{/C}} \mathcal{C}_{D//C}$, which is the homotopy fiber of the composition map $q : \mathrm{Map}_{\mathcal{C}}(D, C_1) \to \mathrm{Map}_{\mathcal{C}}(D, C)$ over f. We wish to show that this homotopy fiber is contractible. By assumption, it is nonempty; it will therefore suffice to show that the morphism q is (-1)-truncated. To prove this, we need only verify that $C_1 \to C$ is a monomorphism; that is, that the diagonal map $C_1 \to C_1 \times_C C_1$ is an equivalence. Using (d), we obtain equivalences

$$C_1 \simeq C_1 \times_C C \simeq C_1 \times_C (C_1 \amalg C_2) \simeq (C_1 \times_C C_1) \amalg (C_1 \times_C C_2),$$

and the first summand maps by an equivalence to $C_1 \times_C C_1$. The second summand is trivial, by virtue of (e).

We now prove (2). Let $f : U_0 \to X$ be a morphism of S and let f be its Čech nerve, so that f generates a covering sieve $\mathcal{C}^{(0)}_{/X} \subseteq \mathcal{C}_{/X}$. We can regard $U_\bullet$ as determining a simplicial object $V : \mathbf{\Delta}^{\mathrm{op}} \to \mathcal{C}^{(0)}_{/X}$. Our assumption that $\mathscr{F}$ is a sheaf guarantees that $\mathscr{F}(X) \simeq \varprojlim \mathscr{F}|_{(\mathcal{C}^{(0)}_{/X})^{\mathrm{op}}}$. To prove (2), it suffices to prove that the map V is left cofinal. According to Theorem HTT.4.1.3.1 , it suffices to show that for every map $f : X' \to X$ belonging to $\mathcal{C}^{(0)}_{/X}$, the ∞-category $\mathcal{X} = \mathbf{\Delta}^{\mathrm{op}} \times_{\mathcal{C}^{(0)}_{/X}} (\mathcal{C}^{(0)}_{/X})_{f/}$ is weakly contractible. The projection map $\mathcal{X} \to \mathbf{\Delta}^{\mathrm{op}}$ is a left fibration, classified by a functor $\chi : \mathbf{\Delta}^{\mathrm{op}} \to \mathcal{S}$. According to Proposition HTT.3.3.4.5 , it will suffice to show that $\varinjlim(\chi)$ is contractible. Note that χ can be identified with the underlying simplicial object of the Čech nerve of the map of spaces $q : \mathrm{Map}_{\mathcal{C}_{/X}}(X', U_0) \to \Delta^0$. Since f belongs to the sieve $\mathcal{C}^{(0)}_{/X}$, the space $\mathrm{Map}_{\mathcal{C}_{/X}}(X', U_0)$ is nonempty so that q is an effective epimorphism. Since $\mathcal{S}$ is an ∞-topos, we conclude that $\varinjlim(\chi) \simeq \Delta^0$ as required.

Now suppose that $\mathscr{F}$ satisfies (1) and (2); we will show that $\mathscr{F}$ is a sheaf on $\mathcal{C}$. Choose an object $X \in \mathcal{C}$ and a covering sieve $\mathcal{C}^{(0)}_{/X}$; we wish to prove that $\mathscr{F}(X) \simeq \varprojlim \mathscr{F}|_{(\mathcal{C}^{(0)}_{/X})^{\mathrm{op}}}$. We first treat the case where $\mathcal{C}^{(0)}_{/X}$ is generated by a single morphism $f : U_0 \to X$ which belongs to S. Let $U_\bullet$ be a Čech nerve of f, so that $\mathscr{F}(X)$ can be identified with the totalization of the cosimplicial space $[n] \mapsto \mathscr{F}(U_n)$ by virtue of (2). To complete the proof, we invoke the fact (established above) that $U_\bullet$ determines a left cofinal map $\mathbf{\Delta}^{\mathrm{op}} \to \mathcal{C}^{(0)}_{/X}$.

Now suppose that $\mathcal{C}^{(0)}_{/X}$ is generated by a finite collection of morphisms $\{C_i \to X\}_{1 \leqslant i \leqslant n}$ such that the induced map $\coprod C_i \to X$ belongs to S. Let $C = \coprod_i C_i$ and let $\mathcal{C}^{(1)}_{/X}$ denote the sieve generated by the induced map $C \to X$. Then $\mathcal{C}^{(1)}_{/X}$ contains $\mathcal{C}^{(0)}_{/X}$ and is therefore a covering sieve; the above argument shows that $\mathscr{F}(X) \simeq \varprojlim \mathscr{F}|_{(\mathcal{C}^{(1)}_{/X})^{\mathrm{op}}}$. To complete the proof in this case, it will suffice to show that $\mathscr{F}|_{(\mathcal{C}^{(1)}_{/X})^{\mathrm{op}}}$ is a right Kan extension of $\mathscr{F}|_{(\mathcal{C}^{(0)}_{/X})^{\mathrm{op}}}$.

Fix an object $f : U \to X$ of the sieve $\mathcal{C}^{(1)}_{/X}$, and let $\mathcal{E}$ denote the full subcategory of $(\mathcal{C}^{(1)}_{/X})_{/U} \simeq \mathcal{C}_{/U}$ spanned by those objects whose image in $\mathcal{C}_{/X}$ belongs to $\mathcal{C}^{(0)}_{/X}$. We wish to prove that the canonical map $\mathscr{F}(U) \to \varprojlim \mathscr{F}|_{\mathcal{E}^{\mathrm{op}}}$ is an equivalence. By construction, the map f factors through some map $f_0 : U \to C$. Invoking (b), we have $U \simeq U \times_C C \simeq \coprod_i U \times_C C_i$, so that U can be obtained as a coproduct of objects U_i belonging to $\mathcal{C}^{(0)}_{/X}$. Let $T \subseteq \{1, \ldots, n\}$ denote the collection of indices for which U_i is not initial. We let $\mathcal{E}' \subseteq \mathcal{E}$ denote the full subcategory spanned by morphisms $U' \to U$ which factor through some U_i and such that $U' \in \mathcal{C}$ is not initial. For $i \neq j$, the fiber product $U_i \times_U U_j$ is initial (by (e)) and therefore receives no morphisms from non-initial objects of $\mathcal{C}$ (by (d)); it follows that $\mathcal{E}'$ can be decomposed as a disjoint union $\coprod_{i \in T} \mathcal{E}'_i$ where each $\mathcal{E}'_i$ denotes the full subcategory of $\mathcal{E}'$ spanned by those morphisms $U' \to U$ which factor through U_i. Since the map $U_i \to U$ is a monomorphism, each $\mathcal{E}'_i$ contains the map $U_i \to U$ as a final object, so that the inclusion $\{U_i\}_{i \in T} \to \mathcal{E}'$ is left cofinal. Condition (1) implies that $\mathscr{F}(U) \simeq \prod_{i \in T} \mathscr{F}(U_i)$, so that $\mathscr{F}(U)$ is a limit of the diagram $\mathscr{F}|_{(\mathcal{E}')^{\mathrm{op}}}$. We will prove that $\mathscr{F}|_{\mathcal{E}^{\mathrm{op}}}$ is a right Kan extension of $\mathscr{F}|_{\mathcal{E}'^{\mathrm{op}}}$, so that $\varprojlim \mathscr{F}|_{\mathcal{E}^{\mathrm{op}}} \simeq \varprojlim \mathscr{F}|_{\mathcal{E}'^{\mathrm{op}}} \simeq \mathscr{F}(U)$ by Lemma HTT.4.3.2.7. To see this, choose an object $U' \to U$ in $\mathcal{E}$; we wish to show that $\mathscr{F}(U')$ is a limit of the diagram $\mathscr{F}|_{(\mathcal{E}'_{/U'})^{\mathrm{op}}}$. Let $U'_i = U' \times_U U_i$, and let T' be the collection of indices i for which U'_i is not initial. Then $\mathcal{E}'_{/U'}$ decomposes as a disjoint union $\coprod_{i \in T'} (\mathcal{E}'_{/U'})_i$, each of which has a final object (given by the map $U'_i \to U'$). It follows that $\varprojlim \mathscr{F}|_{(\mathcal{E}'_{/U'})^{\mathrm{op}}}$ is equivalent to $\prod_{i \in T'} \mathscr{F}(U'_i)$, which is equivalent to $\mathscr{F}(U')$ by virtue of (1).

We now treat the case of a general covering sieve $\mathcal{C}^{(0)}_{/X} \subseteq \mathcal{C}_{/X}$. By definition, there exists a finite collection of morphisms $f_i : C_i \to X$ belonging to $\mathcal{C}^{(0)}_{/X}$ such that the induced map $\coprod_i C_i \to X$ belongs to S. Let $\mathcal{C}^{(1)}_{/X} \subseteq \mathcal{C}^{(0)}_{/X}$ be the sieve generated by the maps f_i. The above argument shows that $\mathscr{F}(X) \simeq \varprojlim \mathscr{F}|_{(\mathcal{C}^{(1)}_{/X})^{\mathrm{op}}}$. To prove that $\mathscr{F}(X) \simeq \varprojlim(\mathcal{C}^{(0)})_{/X})^{\mathrm{op}}$, it will suffice to show that $\mathscr{F}|_{(\mathcal{C}^{(0)}_{/X})^{\mathrm{op}}}$ is a right Kan extension of $\mathscr{F}|_{(\mathcal{C}^{(1)}_{/X})^{\mathrm{op}}}$ (Lemma HTT.4.3.2.7). Unwinding the definitions, we must show that for every $f : U \to X$ belonging to the sieve $\mathcal{C}^{(0)}_{/X}$, we have $\mathscr{F}(U) \simeq \varprojlim \mathscr{F}|_{f^* \mathcal{C}^{(1)}_{/X}}$. This is clear, since $f^* \mathcal{C}^{(1)}_{/X}$ is generated by the pullback maps $C_i \times_X U \to U$, and the induced map $\coprod_i (C_i \times_X U) \to U$ factors as a composition

$$\coprod_i (C_i \times_X U) \xrightarrow{\alpha} (\coprod_i C_i) \times_X U \xrightarrow{\beta} U,$$

where α is an equivalence by assumption (d) and the map β belongs to S by assumption (b). □

Corollary A.3.3.2. *Let $\mathcal{C}$ be an ∞-category and let S be a collection of morphisms of $\mathcal{C}$ satisfying the hypotheses of Proposition A.3.3.1. Suppose that we are given functors $\chi, \chi' : \mathcal{C}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ and a natural transformation $\rho : \chi \to \chi'$ satisfying the following conditions:*

(1) *For each object $C \in \mathcal{C}$, the ∞-category $\chi(C)$ admits finite products and totalizations of cosimplicial objects.*

(2) *For each object $C \in \mathcal{C}$, the functor $\rho(C) : \chi(C) \to \chi'(C)$ is conservative and preserves finite products and totalizations of cosimplicial objects.*

(3) *For every morphism $C \to D$ in $\mathcal{C}$, the diagram*

$$\begin{array}{ccc} \chi(C) & \longrightarrow & \chi(D) \\ \downarrow & & \downarrow \\ \chi'(C) & \longrightarrow & \chi'(D) \end{array}$$

is right adjointable.

If χ' is a $\mathcal{C}\mathrm{at}_\infty$-valued sheaf on $\mathcal{C}$, then χ is also a $\mathcal{C}\mathrm{at}_\infty$-valued sheaf on $\mathcal{C}$.

Proof. Combine Proposition A.3.3.1 with Corollary HA.5.2.2.37 . □

A.3.4 Classification of Hypercomplete Locally Coherent ∞-Topoi

We now apply the preceding results to give an "extrinsic" characterization of the class of hypercomplete locally coherent ∞-topoi.

Theorem A.3.4.1. *Let $\mathcal{X}$ be an ∞-topos. The following conditions are equivalent:*

(1) *The ∞-topos $\mathcal{X}$ is locally coherent and hypercomplete.*

(2) *There exists a small ∞-category $\mathcal{C}$ which admits fiber products, a finitary Grothendieck topology on $\mathcal{C}$, and an equivalence $\mathcal{X} \simeq \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$.*

Moreover, if these conditions are satisfied, then we may assume that $\mathcal{C}$ admits finite coproducts and that the topology on $\mathcal{C}$ is subcanonical. If $\mathcal{X}$ is coherent, we may assume that $\mathcal{C}$ admits finite limits.

We will deduce Theorem A.3.4.1 from the following more precise result:

Proposition A.3.4.2. *Let $\mathcal{X}$ be an ∞-topos which is hypercomplete, and let $\mathcal{C} \subseteq \mathcal{X}$ be a full subcategory which satisfies the following conditions:*

(a) *The ∞-category $\mathcal{C}$ is essentially small.*

(b) *Each object of $\mathcal{C}$ is a coherent object of $\mathcal{X}$.*

(c) *The ∞-category $\mathcal{C}$ is closed under finite coproducts and fiber products.*

(d) *For every object $X \in \mathcal{X}$, there exists an effective epimorphism $\amalg U_\alpha \to X$ where each U_α belongs to $\mathcal{C}$.*

Then the ∞-category $\mathcal{C}$ admits a finitary Grothendieck topology which can be characterized as follows: a collection of morphisms $\{f_\alpha : U_\alpha \to X\}$ generates a covering sieve on $X \in \mathcal{C}$ if and only if the induced map $\amalg U_\alpha \to X$ is an effective epimorphism in $\mathcal{X}$. For each $X \in \mathcal{X}$, let $h_X : \mathcal{C}^{\mathrm{op}} \to \mathcal{S}$ denote the functor given by $h_X(Y) = \mathrm{Map}_{\mathcal{X}}(Y, X)$. Then the construction $X \mapsto h_X$ induces an equivalence of ∞-categories $\mathcal{X} \to \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$.

Proof of Theorem A.3.4.1. The implication (2) ⇒ (1) of Theorem A.3.4.1 follows immediately from Propositions A.3.1.3 and A.2.2.2. To prove the converse, suppose that $\mathcal{X}$ is locally coherent. Choose a small collection of objects $\{X_\alpha\}$ which generates $\mathcal{X}$ under small colimits. Since $\mathcal{X}$ is locally coherent, for each index α we can choose an effective epimorphism $\amalg_\beta U_{\alpha,\beta} \to X_\alpha$ where $U_{\alpha,\beta}$ is coherent. Let $\mathcal{C}$ denote an essentially small full subcategory of $\mathcal{X}$ such that each object of $\mathcal{C}$ is coherent in $\mathcal{X}$, and each $U_{\alpha,\beta}$ belongs to $\mathcal{C}$. Enlarging this collection if necessary, we may assume that it is closed under pullbacks, finite coproducts, and that it contains the a final object of $\mathcal{X}$ if $\mathcal{X}$ is coherent (see Remark **??**) Then Proposition A.3.4.2 supplies a finitary Grothendieck topology on $\mathcal{C}$ and an equivalence $\mathcal{X} \simeq \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$. □

Remark A.3.4.3. In the situation of Theorem A.3.4.1, we can take $\mathcal{C}$ to be the full subcategory of $\mathcal{X}$ spanned by the coherent object of $\mathcal{X}$: see Remark A.6.6.3.

The proof of Proposition A.3.4.2 depends on the following:

Lemma A.3.4.4. *Let $\mathcal{X}$ be an ∞-topos containing a collection of objects $\{X_i\}_{i \in I}$. For every subset $J \subseteq I$, let $X_J \simeq \amalg_{i \in J} X_i$. If $C \in \mathcal{X}$ is quasi-compact, then the canonical map*

$$\varinjlim_{J \subseteq I} \operatorname{Map}_{\mathcal{X}}(C, X_J) \to \operatorname{Map}_{\mathcal{X}}(C, X_I)$$

is a homotopy equivalence, where the colimit is taken over all finite subsets $J \subseteq I$.

Proof. Let J be any subset of I and let $\phi : C \to X_J$ be a morphism in $\mathcal{X}$. Since colimits in $\mathcal{X}$ are universal, this morphism determines a decomposition $C \simeq \amalg_{i \in J} C_i$, where $C_i = C \times_{X_J} X_i$. We define the *support* of ϕ to be the subset of J consisting of those indices $i \in J$ such that C_i is not an initial object of $\mathcal{X}$.

Let $\phi : C \to X_J$ be any morphism. Since C is quasi-compact, there is a finite subset $J_0 \subseteq J$ such that the map $\amalg_{i \in J_0} C_i \to C$ is an effective epimorphism. For $i' \in J$, we have an effective epimorphism $\amalg_{i \in J_0} C_i \times_C C_{i'} \to C_{i'}$. If $i' \notin J_0$, then the left hand side is an initial object of $\mathcal{X}$ (since coproducts in $\mathcal{X}$ are disjoint), so that $C_{i'}$ is likewise initial object of $\mathcal{X}$. It follows that the support of ϕ is contained in J_0, and is therefore finite.

For each $J \subseteq I$, we can decompose the mapping space $\operatorname{Map}_{\mathcal{X}}(C, X_J)$ as a coproduct $\amalg_S \operatorname{Map}^S_{\mathcal{X}}(C, X_J)$, where S ranges over finite subsets of I and $\operatorname{Map}^S_{\mathcal{X}}(C, X_J)$ is the summand of $\operatorname{Map}^S_{\mathcal{X}}(C, X_J)$ given by maps $\phi : C \to X_J$ with support S (by convention, this summand is empty unless $S \subseteq J$). It will therefore suffice to prove that for every finite set S, the map

$$\varinjlim_{J \subseteq I} \operatorname{Map}^S_{\mathcal{X}}(C, X_J) \to \operatorname{Map}^S_{\mathcal{X}}(C, X_I)$$

is a homotopy equivalence. To prove this, we observe that $\operatorname{Map}^S_{\mathcal{X}}(C, X_J) \simeq \operatorname{Map}^S_{\mathcal{X}}(C, X_I)$ whenever $S \subseteq J$. □

Proof of Proposition A.3.4.2. The existence of desired the Grothendieck topology on $\mathcal{C}$ follows by applying Proposition A.3.2.1 to the class of effective epimorphisms between morphisms in $\mathcal{C}$. It follows from Proposition 20.4.5.1 that the functor $h : \mathcal{X} \to \operatorname{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ is fully faithful and from Remark 20.4.5.2 that h admits a left exact left adjoint $F : \operatorname{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}) \to \mathcal{X}$. Using Proposition A.3.3.1, we see that h factors through the full subcategory $\mathcal{S}\mathrm{hv}(\mathcal{C}) \subseteq \operatorname{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$, and therefore through the full subcategory $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ (since $\mathcal{X}$ is assumed to be hypercomplete). It follows that the functor F factors as a composition

$$\operatorname{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}) \xrightarrow{L} \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}} \xrightarrow{f^*} \mathcal{X}$$

where L is a left adjoint to the inclusion and f^* is a geometric morphism of ∞-topoi. Let $f_* : \mathcal{X} \to \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ denote the right adjoint to f^* (which coincides with the functor h). We wish to show that f_* and f^* are mutually inverse equivalence of ∞-categories.

We first show that the functor f_* is conservative: that is, if $u : X \to Y$ is a morphism in $\mathcal{X}$ such that $f_*(u)$ is an equivalence, then u is an equivalence. Since $\mathcal{X}$ is hypercomplete, it will suffice to show that u is n-connective for every integer n. We proceed by induction on n. When $n = 0$, we must show that u is an effective epimorphism. Choose an object $Z \in \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ and an effective epimorphism $v : f^*Z \to Y$. Then v is adjoint to a map $v' \in \mathrm{Map}_{\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}}(Z, f_*Y)$. Since $f_*(u)$ is an equivalence, the map v' factors through f_*X; it follows that v factors as a composition $f^*Z \to X \xrightarrow{u} Y$ so that u is also an effective epimorphism as desired If $n > 0$, then (since u is an effective epimorphism) we are reduced to proving that the induced map $\delta : X \to X \times_Y X$ is $(n-1)$-connective. This follows from our inductive hypothesis, since $f_*(\delta)$ is also an equivalence. This completes the proof that the functor f_* is conservative.

We next prove:

$(*)$ For each $n \geqslant 0$, the functor f_* carries n-connective morphisms in $\mathcal{X}$ to n-connective morphisms in $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$.

The proof proceeds by induction on n. We begin by treating the case $n = 0$. Fix an effective epimorphism $u : X \to Y$ in $\mathcal{X}$; we wish to show that $f_*(u)$ is an effective epimorphism in $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$. Unwinding the definitions, we must show that for every object $C \in \mathcal{C}$ and every morphism $\eta : C \to Y$, there exists a covering sieve on $\{C_i \to C\}$ such that each of the composite maps $C_i \to C \to Y$ factors through g. To prove this, it suffices to choose an effective epimorphism $\amalg C_i \to C \times_Y X$, where each $C_i \in \mathcal{C}$; our assumption that u is an effective epimorphism guarantees that the composite map $\amalg C_i \to C \times_Y X \to C$ is also an effective epimorphism, so that the maps $\{C_i \to C\}$ generate a covering sieve in $\mathcal{C}$.

Now suppose $n > 0$ and that $u : X \to Y$ is an n-connective morphism in $\mathcal{X}$; we wish to show that $f_*(u)$ is an n-connective morphism in $\mathcal{S}\mathrm{hv}(\mathcal{C})$. The above argument shows that $f_*(u)$ is an effective epimorphism; it will therefore suffice to show that the diagonal map $f_*X \to f_*X \times_{f_*Y} f_*X = f_*(X \times_Y X)$ is a $(n-1)$-connective. This follows from our inductive hypothesis.

To complete the proof that f_* is an equivalence, it will suffice to show that the unit map $u_{\mathscr{F}} : \mathscr{F} \to f_*f^*\mathscr{F}$ is an equivalence for each $\mathscr{F} \in \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$. We first prove that $u_{\mathscr{F}}$ is an equivalence in the special case where $\mathscr{F}$ can be written as a coproduct $\amalg_{i \in I} h_{C_i}$ for some objects $C_i \in \mathcal{C} \subseteq \mathcal{X}$. For every subset $J \subseteq I$, let $\mathscr{F}_J \in \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ denote the coproduct $\amalg_{i \in J} h_{C_i}$ and let u_J denote the unit map $\mathscr{F}_J \to f_*f^*\mathscr{F}_J$. We wish to show that u_I is an equivalence. We first show that u_J is an equivalence when $J \subseteq I$ is finite. Write $C = \amalg_{i \in J} C_i$, so we have equivalences

$$f_*f^*\mathscr{F}_J \simeq f_*(f^* \amalg_{i \in J} h_{C_i}) \simeq f_*(\amalg_{i \in J} f^* h_{C_i}) \simeq f_*(\amalg_{i \in J} C_i) \simeq h_C$$

(where the last equivalence is a consequence of the subcanonicality of the topology on $\mathcal{C}$). Consequently, we can identify u_J with the canonical map $\amalg_{i \in J} h_{C_i} \to h_C$. Note that the fiber product

$$\amalg_{i \in J} h_{C_i} \times_{h_C} \amalg_{i \in J} h_{C_i}$$

is given by $\amalg_{i,j \in J} h_{C_i \times_C C_j}$. For $i \neq j$, the fiber product $C_i \times_C C_j$ is an initial object $\emptyset \in \mathcal{C}$. The empty sieve is a covering of $C_i \times_C C_j$, so we have an effective epimorphism from the initial object to $h_{C_i \times_C C_j}$ in the ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$, so that $h_{C_i \times_C C_j}$ is also initial in $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$. It follows that $\amalg_{i \in J} h_{C_i} \times_{h_C} \amalg_{i \in J} h_{C_i}$ is equivalent to $\amalg_{i \in J} h_{C_i \times_C C_i} \simeq \amalg_{i \in J} h_{C_i}$: that is, the map u_J becomes an equivalence after pullback along u_J. To complete the proof that u_J is an equivalence, it suffices to show that u_J is an effective epimorphism. This follows from the observation that the collection of maps $\{C_i \to C\}_{i \in J}$ generates a covering sieve.

To complete the proof that u_I is an equivalence, it will suffice to show that the canonical map $\varinjlim_{J \subseteq I} u_J \to u_I$ is an equivalence in $\mathrm{Fun}(\Delta^1, \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}})$; here the colimit is taken over all finite subsets $J \subseteq I$. It is easy to see that $\mathscr{F}_I \simeq \varinjlim_{J \subseteq I} \mathscr{F}_J$ in $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$. We will complete the proof by showing that $f_* f^* \mathscr{F}_I$ is a colimit of the diagram $\{f_* f^* \mathscr{F}_J\}_{J \subseteq I}$ in the ∞-category $\mathcal{P}(\mathcal{C})$ (and therefore also in the full subcategory $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}} \subseteq \mathcal{P}(\mathcal{C})$). In other words, we claim that for each object $C \in \mathcal{C}$, the canonical map $\varinjlim_{J \subseteq I} \mathrm{Map}_{\mathcal{X}}(C, \amalg_{i \in J} C_i) \to \mathrm{Map}_{\mathcal{X}}(C, \amalg_{i \in I} C_i)$ is a homotopy equivalence. This is a special case of Lemma A.3.4.4.

We now prove that the unit map $u_{\mathscr{F}} : \mathscr{F} \to f_* f^* \mathscr{F}$ is an equivalence for an arbitrary hypercomplete sheaf $\mathscr{F} \in \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$. Since $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ is hypercomplete, it will suffice to verify the following:

($*'$) For every object $\mathscr{F} \in \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ and every $n \geqslant 0$, the unit map $u_X : \mathscr{F} \to f_* f^* \mathscr{F}$ is n-connective.

The proof of ($*'$) proceeds by induction on n. We begin with the casen $n = 0$. Fix $\mathscr{F} \in \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$; we wish to show that the unit map $u_{\mathscr{F}} : \mathscr{F} \to f_* f^* \mathscr{F}$ is an effective epimorphism. Since $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ is generated under colimits by the essential image of the Yoneda embedding $j : \mathcal{C} \to \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$, we can choose an effective epimorphism $v : \mathscr{F}' \to \mathscr{F}$ in $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$, where $\mathscr{F}'$ is a coproduct of objects belonging to the essential image of j. We have a commutative diagram

$$\begin{array}{ccc} \mathscr{F}' & \longrightarrow & f_* f^* \mathscr{F}' \\ \downarrow & & \downarrow \\ \mathscr{F} & \longrightarrow & f_* f^* \mathscr{F} . \end{array}$$

It will therefore suffice to show that the composite map $\mathscr{F}' \to f_* f^* \mathscr{F}' \to f_* f^* \mathscr{F}$ is an effective epimorphism. We established above that the first map is an equivalence, and are therefore reduced to showing that the map $f_* f^*(v)$ is an effective epimorphism. This follows from ($*$) (since the pullback functor f^* preserves effective epimorphisms).

We now prove $(*')$ in the case $n > 0$. Fix an object $\mathscr{F} \in \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$; we wish to prove that $u_{\mathscr{F}}$ is n-connective. The argument above shows that $u_{\mathscr{F}}$ is an effective epimorphism; it will therefore suffice to show that the diagonal map $\beta : \mathscr{F} \to \mathscr{F} \times_{f_* f^* \mathscr{F}} \mathscr{F}$ is $(n-1)$-connective. Let $\mathscr{F}'$ be as above so that we have a pullback diagram

$$\begin{array}{ccc} \mathscr{F}' \times_{\mathscr{F}} \mathscr{F}' & \xrightarrow{\beta'} & \mathscr{F}' \times_{f_* f^* \mathscr{F}} \mathscr{F}' \\ \downarrow & & \downarrow \\ \mathscr{F} & \xrightarrow{\beta} & \mathscr{F} \times_{f_* f^* \mathscr{F}} \mathscr{F}. \end{array}$$

Since the vertical maps are effective epimorphisms, it will suffice to show that β' is $(n-1)$-connective. To prove this, it suffices to observe that the composition of β' with the equivalence $\mathscr{F}' \times_{f_* f^* \mathscr{F}} \mathscr{F}' \to (f_* f^* \mathscr{F}') \times_{f_* f^* \mathscr{F}} (f_* f^* \mathscr{F}')$ can be identified with the unit map $u_{\mathscr{F}' \times_{\mathscr{F}} \mathscr{F}'}$, which is $(n-1)$-connective by virtue of our inductive hypothesis. □

A.4 Deligne's Completeness Theorem

Let $\mathcal{X}$ be a Grothendieck topos. We say that $\mathcal{X}$ has *enough points* if the following condition holds:

$(*)$ Let $\alpha : X \to Y$ be a morphism in $\mathcal{X}$ which is not an isomorphism. Then there exists a geometric morphism $f^* : \mathcal{X} \to \mathcal{S}\mathrm{et}$ such that $f^*(\alpha)$ is not bijective.

A useful theorem of Deligne asserts that every coherent topos has enough points. Our goal in this section is to prove an ∞-categorical version of this result. We will follow the proof of Deligne's theorem given in [142], with minor modifications.

Theorem A.4.0.5 (∞-Categorical Deligne Completeness Theorem)**.** *Let $\mathcal{X}$ be an ∞-topos which is locally coherent and hypercomplete. Then $\mathcal{X}$ has enough points. In other words, given a morphism $\alpha : X \to Y$ in $\mathcal{X}$ which is not an equivalence, there exists a geometric morphism $f^* : \mathcal{X} \to \mathcal{S}$ such that $f^*(\alpha)$ is not an equivalence.*

Note that Theorem A.4.0.5 recovers the classical version of Deligne's completeness theorem:

Corollary A.4.0.6 (Deligne)**.** *Let $\mathcal{X}$ be a coherent topos. Then $\mathcal{X}$ has enough points.*

Proof. Since $\mathcal{X}$ is a coherent topos, it can be realized as the category $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathcal{C})$ of $\mathcal{S}$et-valued sheaves on a small category $\mathcal{C}$ which admits finite limits which is equipped with a finitary Grothendieck topology. Let $\overline{\mathcal{X}}$ be the ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})$, so that $\mathcal{X}$ can be identified with the full subcategory of $\overline{\mathcal{X}}$ spanned by the discrete objects. Let $\alpha : X \to Y$ be a morphism in

$\mathcal{X}$ which is not an isomorphism. Then α can be regarded as a morphism in $\overline{\mathcal{X}}^{\mathrm{hyp}}$ which is not an equivalence. According to Theorem A.4.0.5, there exists a geometric morphism $\overline{f}^* : \overline{\mathcal{X}}^{\mathrm{hyp}} \to \mathcal{S}$ such that $\overline{f}^*(\alpha)$ is not an equivalence in $\mathcal{S}$. Restricting to discrete objects, we get a geometric morphism $f^* : \mathcal{X} \to \mathcal{S}\mathrm{et}$ such that $f^*(\alpha)$ is not an equivalence. □

A.4.1 Digression: Sheaves on Complete Boolean Algebras

Let Λ be a Boolean algebra (see Definition A.1.6.4). We say that Λ is *complete* if every subset $S \subseteq \Lambda$ has a least upper bound $\bigvee S$ in Λ.

Remark A.4.1.1. If Λ is a Boolean algebra, then the formation of complements $x \mapsto x^c$ determines an isomorphism of Λ with the opposite partially ordered set Λ^{op}. It follows that Λ is complete if and only if every subset $S \subseteq \Lambda$ has a greatest lower bound $\bigwedge S$ in Λ.

Remark A.4.1.2. Let Loc denote the category of locales (Definition 1.5.1.5). The construction $\mathcal{X} \mapsto \mathrm{Sub}(\mathcal{X})$ of Definition 1.5.4.1 admits a fully faithful right adjoint $\mathrm{Loc} \to \infty\mathcal{T}\mathrm{op}$ (see §HTT.6.4.2) and §HTT.6.4.5). This equivalence is given concretely by assigning to each locale Λ the full subcategory $\mathcal{S}\mathrm{hv}(\Lambda) \subseteq \mathrm{Fun}(\Lambda^{\mathrm{op}}, \mathcal{S})$ spanned by those functors $\mathscr{F}$ which satisfy the following condition: for every subset $S \subseteq \Lambda$ which is closed downwards, the canonical map $\mathscr{F}(\bigvee S) \to \varprojlim_{U \in S} \mathscr{F}(U)$ is a homotopy equivalence.

Every complete Boolean algebra Λ is a locale. The completeness of Λ immediately implies that that Λ satisfies condition (1), and the inequality $(\bigvee U_\alpha) \wedge V \geqslant \bigvee (U_\alpha \wedge V)$ follows immediately from the definitions. To verify the reverse inequality $(\bigvee U_\alpha) \wedge V \leqslant \bigvee (U_\alpha \wedge V)$, choose a complement V^c of V, so that we can write each U_α as a join $(U_\alpha \wedge V) \vee (U_\alpha \wedge V^c)$. We therefore have

$$\begin{aligned}
(\bigvee U_\alpha) \wedge V &= (\bigvee ((U_\alpha \wedge V) \vee (U_\alpha \wedge V^c)) \wedge V \\
&= (\bigvee (U_\alpha \wedge V) \vee \bigvee U(_\alpha \wedge V^c)) \wedge V \\
&\leqslant (\bigvee (U_\alpha \wedge V) \vee V^c) \wedge V \\
&= ((\bigvee (U_\alpha \wedge V)) \wedge V) \vee (V^c \wedge V) \\
&= (\bigvee (U_\alpha \wedge V)) \wedge V \\
&\leqslant \bigvee (U_\alpha \wedge V).
\end{aligned}$$

It follows that every complete Boolean algebra Λ determines a 0-localic ∞-topos $\mathcal{S}\mathrm{hv}(\Lambda) \subseteq \mathrm{Fun}(\Lambda^{\mathrm{op}}, \mathcal{S})$.

The ∞-topos of sheaves on a complete Boolean algebra Λ has many pleasant features.

Proposition A.4.1.3. *Let Λ be a complete Boolean algebra. Then the ∞-topos $\mathcal{S}\mathrm{hv}(\Lambda)$ has homotopy dimension $\leqslant 0$: that is, every 0-connective object $X \in \mathcal{S}\mathrm{hv}(\Lambda)$ admits a global section.*

Proof. Let $X \in \mathcal{S}\mathrm{hv}(\Lambda)$ be a 0-connective object which does not admit a global section. For every ordinal α, we let (α) denote the well-ordered set of ordinals $\{\beta : \beta < \alpha\}$. We will construct a compatible sequence of functors $\phi_\alpha : \mathrm{N}(\alpha) \to \mathcal{X}_{/X}$ with the following property:

- $(*)$ The composite functor $\mathrm{N}(\alpha) \xrightarrow{\phi_\alpha} \mathcal{X}_{/X} \to \mathcal{X}$ takes values in the full subcategory of $\mathcal{X}$ spanned by the (-1)-truncated objects, and determines a strictly increasing map $[\alpha] \to \Lambda$.

This leads to a contradiction for α sufficiently large (namely, for any ordinal α such that $[\alpha]$ has cardinality greater than that of Λ).

The construction of the maps ϕ_α proceeds by induction on α. If α is a limit ordinal, we let ϕ_α be the amalgamation of the functors $\{\phi_\beta\}_{\beta<\alpha}$. To complete the construction, it suffices to show that every map $\phi_\alpha : \mathrm{N}(\alpha) \to \mathcal{X}_{/X}$ can be extended to a map $\phi_{\alpha+1} : \mathrm{N}(\alpha+1) \to \mathcal{X}_{/X}$ satisfying $(*)$. The colimit of ϕ_α can be identified with a map $\psi : U \to X$ in $\mathcal{X}$, where U is (-1)-truncated. Let us identify U with an element of the Boolean algebra Λ, and ψ with a point of the space $X(U)$. Since X does not admit a global section, U is not a maximal element of Λ. Because Λ is a Boolean algebra, the object U has a complement $U' \in \Lambda$, which is not a minimal element of Λ. Since $X \in \mathcal{S}\mathrm{hv}(\Lambda)$ is 0-connective, the object U' can be written as a join $\bigvee U'_i$ where each $X(U'_i)$ is nonempty. For some index i, the element $U'_i \in \Lambda$ is nontrivial. Since $U'_i \wedge U = \emptyset$, the canonical map $X(U'_i \vee U) \to X(U'_i) \to X(U)$ is a homotopy equivalence; it follows that ψ can be lifted (up to homotopy) to a point of $X(U'_i \vee U)$. This point gives an extension $\phi_{\alpha+1}$ of ϕ_α, with $\phi_{\alpha+1}(\alpha)$ given by a map $V \to X$ where V is a (-1)-truncated object corresponding to the element $U'_i \vee U$. of Λ. □

Corollary A.4.1.4. *Let Λ be a complete Boolean algebra. Then the ∞-topos $\mathcal{S}\mathrm{hv}(\Lambda)$ is locally of homotopy dimension $\leqslant 0$.*

Proof. For each $U \in \Lambda$, let $\chi_U \in \mathcal{S}\mathrm{hv}(\Lambda)$ be the sheaf given by the formula

$$\chi_U(V) = \begin{cases} \Delta^0 & \text{if } V \leqslant U \\ \emptyset & \text{otherwise.} \end{cases}$$

The objects χ_U generate $\mathcal{S}\mathrm{hv}(\Lambda)$ under colimits. Consequently, it suffices to show that each of the ∞-topoi $\mathcal{S}\mathrm{hv}(\Lambda)_{/\chi_U}$ has homotopy dimension $\leqslant 0$. We complete the proof by observing that $\mathcal{S}\mathrm{hv}(\Lambda)_{/\chi_U}$ is equivalent to $\mathcal{S}\mathrm{hv}(\Lambda_U)$, where Λ_U denotes the complete Boolean algebra $\{V \in \Lambda : V \leqslant U\}$, and therefore has homotopy dimension $\leqslant 0$ by Proposition A.4.1.3. □

Corollary A.4.1.5. *Let Λ be a complete Boolean algebra. Then the ∞-topos $\mathcal{S}\mathrm{hv}(\Lambda)$ is hypercomplete.*

Proof. Combine Corollary A.4.1.4 with Corollary HTT.7.2.1.12 . □

The next result shows that complete Boolean algebras are in abundant supply.

Proposition A.4.1.6. *Let $\mathcal{X}$ be a 0-localic ∞-topos. Assume that $\mathcal{X}$ is not a contractible Kan complex. Then there exists a nontrivial complete Boolean algebra Λ and a geometric morphism $f^* : \mathcal{X} \to \mathcal{S}\mathrm{hv}(\Lambda)$.*

Proof. Let $\mathcal{U}$ be the underlying locale of $\mathcal{X}$: that is, the partially ordered set of subobjects of the unit object $\mathbf{1}_{\mathcal{X}}$. Then $\mathcal{U}$ is a complete lattice: in particular, every set of elements $\{U_\alpha \in \mathcal{U}\}$ has a greatest lower bound $\wedge_\alpha U_\alpha$ and a least upper bound $\vee_\alpha U_\alpha$. In particular, $\mathcal{U}$ has a least element (which we will denote by $\varnothing$) and a greatest element (which we will denote by $\mathbf{1}$). For each element $U \in \mathcal{U}$, we let U' denote the least upper bound of the set $\{V \in \mathcal{U} : U \wedge V = \varnothing\}$. Let $\Lambda = \{U \in \mathcal{U} : U = U''\}$. We will prove:

- (a) The map $U \mapsto U''$ determines a retraction from $\mathcal{U}$ onto Λ, which commutes with finite meets and infinite joins.
- (b) As a partially ordered set, Λ is a complete Boolean algebra.

Assertion (a) implies that Λ is a left exact localization of $\mathcal{U}$, and is therefore itself a locale; moreover, the proof of Proposition HTT.6.4.5.7 gives a geometric morphism $f^* : \mathcal{X} \to \mathcal{S}\mathrm{hv}(\Lambda)$. We begin by proving ($a$). Note that the construction $U \mapsto U'$ is order-reversing. It follows that $U \leqslant V$ implies that $U'' \leqslant V''$. Moreover, we have an evident inequality $U \leqslant U''$ which guarantees that $U''' = U'$. In particular, $U' \in \Lambda$ for each $U \in \mathcal{U}$. We next claim that the construction $U \mapsto U''$ is a left adjoint to the inclusion $\Lambda \subseteq \mathcal{U}$. In other words, we claim that for $V \in \mathcal{U}$, we have $U \leqslant V$ if and only if $U'' \leqslant V$. The "if" direction is clear (since $U \leqslant U''$), and the "only if" direction follows from the implications

$$(U \leqslant V) \Rightarrow (V' \leqslant U') \Rightarrow (U'' \leqslant V'') \Rightarrow (U'' \leqslant V),$$

since $V = V''$. It follows immediately that $U \mapsto U''$ is a retraction onto Λ which preserves infinite joins.

We now show that the construction $U \mapsto U''$ preserves finite meets (note that, since the inclusion $\Lambda \hookrightarrow \mathcal{U}$ admits a left adjoint, Λ is closed under meets in $\mathcal{U}$). The inequality $U \leqslant U''$ shows that $\mathbf{1} = \mathbf{1}''$. It therefore suffices to show that $U \mapsto U''$ preserves pairwise meets. The construction $U \mapsto U'$ is an order-reversing bijection from Λ to itself, and therefore carries finite joins in Λ to finite meets in Λ. It will therefore suffice to show that the construction $U \mapsto U'$ carries pairwise meets in $\mathcal{U}$ to pairwise joins in Λ. In other words, we must show that for $U, V \in \mathcal{U}$, the element $(U \wedge V)'$ is a join of U' and V' in Λ. It is clear that $U', V' \leqslant (U \wedge V)'$; it therefore suffices to show that if $W = W''$ is any upper bound for U' and V' in Λ, then $(U \wedge V)' \leqslant W = W''$. In other words, we must show that $(U \wedge V)' \wedge W' = \varnothing$: that is, if $X \in \mathcal{U}$ is any object such that $X \wedge W = \varnothing$ and $X \wedge (U \wedge V) = \varnothing$, then $X = \varnothing$.

We have $X \wedge U \leqslant V' \leqslant W'' = W$, so that $(X \wedge U) \leqslant X \wedge W = \varnothing$. This shows that $X \leqslant U' \leqslant W$, so that $X = X \wedge W = \varnothing$ as desired. This completes the proof of (a).

The proof of (a) shows that Λ is a locale; in particular, it is a distributive lattice. To prove (b), it suffices to show that Λ is complemented: that is, for every $U \in \Lambda$ there exists $V \in \Lambda$ such that $U \wedge V = \varnothing$ and $U \vee V = \mathbf{1}$. For this, we take $V = U'$, so that the equation $U \wedge V = \varnothing$ is obvious. To prove $U \vee V = \mathbf{1}$, it suffices to show that if U and U' are bounded by an element $W \in B$, then $W = \mathbf{1}$. In fact, the inequalities $U \leqslant W$ and $U' \leqslant W$ guarantee that $W' \leqslant U' \wedge U'' = \varnothing$, so that $W = W'' = \varnothing' = \mathbf{1}$. □

A.4.2 Surjective Geometric Morphisms

As a first step towards the proof of Theorem A.4.0.5, we discuss various formulations of the hypothesis that the hypercompletion of an ∞-topos $\mathcal{X}$ has enough points.

Proposition A.4.2.1. *Let $\mathcal{X}$ be an ∞-topos, and suppose we are given a collection of geometric morphisms $\{f_\alpha^* : \mathcal{X} \to \mathcal{X}_\alpha\}$. The following conditions are equivalent:*

(1) *A monomorphism $u : X \to Y$ in $\mathcal{X}$ is an equivalence if and only if each $f_\alpha^*(u)$ is an equivalence in $\mathcal{X}_\alpha$.*

(2) *A morphism $u : X \to Y$ in $\mathcal{X}$ is an effective epimorphism if and only if each $f_\alpha^*(u)$ is an effective epimorphism in $\mathcal{X}_\alpha$.*

(3) *For each $n \geqslant 0$, a morphism $u : X \to Y$ in $\mathcal{X}$ is n-connective if and only if each $f_\alpha^*(u)$ is n-connective.*

(4) *A morphism $u : X \to Y$ in $\mathcal{X}$ is ∞-connective if and only if each $f_\alpha^*(u)$ is ∞-connective.*

Proof. We will prove that $(1) \Rightarrow (2) \Rightarrow (3) \Rightarrow (4) \Rightarrow (1)$. Suppose first that (1) is satisfied, and let $u : X \to Y$ be a morphism in $\mathcal{X}$. Then u factors as a composition $X \xrightarrow{u'} X' \xrightarrow{u''} Y$, where u' is an effective epimorphism and u'' is a monomorphism. If each $f_\alpha^*(u)$ is an effective epimorphism, then each $f_\alpha^*(u'')$ is an equivalence, so that (1) implies that u'' is an equivalence. It follows that $u \simeq u'$ is an effective epimorphism as desired.

Now suppose that (2) is satisfied; we prove (3) using induction on n, the case $n = -1$ being vacuous. Suppose that $u : X \to Y$ is a morphism in $\mathcal{X}$ such that each $f_\alpha^*(u)$ is n-connective. Let $v : X \to X \times_Y X$ be the diagonal map; then each $f_\alpha^*(v)$ is $(n-1)$-connective. The inductive hypothesis guarantees that v is $(n-1)$-connective, and assumption (2) guarantees that u is an effective epimorphism. It follows that u is n-connective as desired.

The implication $(3) \Rightarrow (4)$ is obvious, and the implication $(4) \Rightarrow (1)$ follows from the observation that a monomorphism $u : X \to Y$ is an equivalence if and only if it is ∞-connective. □

Definition A.4.2.2. We will say that a collection of geometric morphisms of ∞-topoi $\{f^*_\alpha : \mathcal{X} \to \mathcal{X}_\alpha\}$ is *jointly surjective* if it satisfies the equivalent conditions of Proposition A.4.2.1. We will say that a geometric morphism $f^* : \mathcal{X} \to \mathcal{Y}$ is *surjective* if the one-element collection $\{f^* : \mathcal{X} \to \mathcal{Y}\}$ is jointly surjective.

Warning A.4.2.3. Let $f : X \to Y$ be a continuous map of topological spaces, so that f determines a geometric morphism $f^* : \mathcal{S}\mathrm{hv}(Y) \to \mathcal{S}\mathrm{hv}(X)$. If f is surjective, then the geometric morphism f^* is surjective. However, the converse fails in general.

Example A.4.2.4. Let $\mathcal{X}$ be an ∞-topos, and let $f^* : \mathcal{X} \to \mathcal{X}^{\mathrm{hyp}}$ be a left adjoint to the inclusion. Then f^* is surjective.

Example A.4.2.5. Let $\mathcal{X}$ be an ∞-topos containing an object U. Then the étale geometric morphism $f^* : \mathcal{X} \to \mathcal{X}_{/U}$ is surjective if and only if the object U is 0-connective: that is, if and only if the map $U \to \mathbf{1}$ is an effective epimorphism, where $\mathbf{1}$ denotes a final object of $\mathcal{X}$. If this condition is satisfied, then we will say that $f^* : \mathcal{X} \to \mathcal{X}_{/U}$ is an *étale surjection*.

Remark A.4.2.6. Let $\mathcal{X}$ be an arbitrary ∞-topos. Since the ∞-topos $\mathcal{S}$ is hypercomplete, composition with the localization functor $\mathcal{X} \to \mathcal{X}^{\mathrm{hyp}}$ induces an equivalence between the ∞-category of points of $\mathcal{X}^{\mathrm{hyp}}$ and the ∞-category of points of $\mathcal{X}$. Note if $\mathcal{X}$ is locally foherent, then $\mathcal{X}^{\mathrm{hyp}}$ is also locally coherent (Proposition A.2.2.2). Consequently, Theorem A.4.0.5 can be reformulated as follows: if $\mathcal{X}$ is a coherent ∞-topos, then there exists a jointly surjective collection of points $\{f^*_\alpha : \mathcal{X} \to \mathcal{S}\}$.

Proposition A.4.2.7. *Let $\mathcal{X}$ be a* 0*-localic ∞-topos. Then there exists a surjective geometric morphism $f^* : \mathcal{X} \to \mathcal{S}\mathrm{hv}(\Lambda)$, where Λ is a complete Boolean algebra.*

Proof. Let $\mathcal{U}$ be the locale of equivalence classes of (-1)-truncated objects of $\mathcal{X}$. For every proper inclusion $U \subset V$ in $\mathcal{U}$, Proposition A.4.1.6 supplies a nontrivial complete Boolean algebra $\Lambda_{U,V}$ and a left exact, join-preserving map $f_{U,V} : \mathcal{U} \to \Lambda_{U,V}$. Let Λ be the product of the Boolean algebras $\Lambda_{U,V}$, and let $f : \mathcal{U} \to \Lambda$ be the product functor; then f induces a geometric morphism $f^* : \mathcal{X} \to \mathcal{S}\mathrm{hv}(\Lambda)$. We claim that this geometric morphism is surjective.

Let $u : X \to Y$ be a monomorphism in $\mathcal{X}$ such that $f^*(u)$ is an equivalence; we wish to prove that u is an equivalence. For each $V \in \mathcal{U}$, let $\chi_V \in \mathcal{S}\mathrm{hv}(U)$ be the sheaf given by the formula

$$\chi_V(W) = \begin{cases} \Delta^0 & \text{if } W \subseteq V \\ \varnothing & \text{otherwise.} \end{cases}$$

The ∞-category $\mathcal{S}\mathrm{hv}(\mathcal{U})$ is generated under colimits by the objects χ_V. In particular, there exists an effective epimorphism $\amalg_\alpha \chi_{V_\alpha} \to Y$. It therefore suffices to show that the induced map

$$(\amalg_\alpha \chi_{V_\alpha}) \times_Y X \to \amalg_\alpha \chi_{V_\alpha}$$

is an equivalence. This map is a coproduct of morphisms

$$u_\alpha : \chi_{V_\alpha} \times_Y X \to \chi_{V_\alpha}.$$

To complete the proof, it suffices to show that each u_α is an equivalence. We may therefore replace u by u_α, and thereby reduce to the case where Y has the form χ_V for some object $V \in \mathcal{U}$.

Since u is a monomorphism, we can identify X with χ_U for some $U \subseteq V$. We wish to show that $U = V$. Suppose otherwise, so that the geometric morphism $f^*_{U,V} : \mathcal{X} \to \mathcal{S}\mathrm{hv}(\Lambda) \to \mathcal{S}\mathrm{hv}(\Lambda_{U,V})$ is well-defined. We note that the image of χ_U in $\mathcal{S}\mathrm{hv}(\Lambda_{U,V})$ is the initial object, while the image of χ_V in $\mathcal{S}\mathrm{hv}(\Lambda_{U,V})$ is the final object. Consequently, $f^*_{U,V}(u)$ is an equivalence in $\mathcal{S}\mathrm{hv}(\Lambda_{U,V})$ between the initial and final objects, contradicting the nontriviality of $\Lambda_{U,V}$. □

A.4.3 The Diaconescu Cover

Our proof of Theorem A.4.0.5 will proceed by reducing to a more concrete statement about locales. The mechanism for this reduction is the following result:

Proposition A.4.3.1. *Let $\mathcal{C}$ be an ∞-category equipped with a Grothendieck topology. Then there exists a surjective geometric morphism $f^* : \mathcal{S}\mathrm{hv}(\mathcal{C}) \to \mathcal{X}$, where $\mathcal{X}$ is a 0-localic ∞-topos.*

Proof. Let $\mathcal{D}$ be an ∞-category equipped with a functor $g : \mathcal{D} \to \mathcal{C}$. We will say that a sieve $\mathcal{D}^{(0)}_{/D} \subseteq \mathcal{D}_{/D}$ on an object $D \in \mathcal{D}$ is *covering* if the following condition is satisfied:

- $(*)$ For every morphism $\alpha : D' \to D$ in $\mathcal{D}$, the collection of morphisms $g(\beta) : g(D'') \to g(D')$ such that the composition $(\alpha \circ \beta) : D'' \to D$ belongs to $\mathcal{D}^{(0)}_{/D}$ generates a covering sieve on $g(D') \in \mathcal{C}$.

It is not difficult to see that this defines a Grothendieck topology on $\mathcal{D}$. Let $L_{\mathcal{C}} : \mathcal{P}(\mathcal{C}) \to \mathcal{S}\mathrm{hv}(\mathcal{C})$ and $L_{\mathcal{D}} : \mathcal{P}(\mathcal{D}) \to \mathcal{S}\mathrm{hv}(\mathcal{D})$ be left adjoints to the inclusions, and consider the composite functor $\overline{f}^* : \mathcal{P}(\mathcal{C}) \xrightarrow{\circ g} \mathcal{P}(\mathcal{D}) \xrightarrow{L_{\mathcal{D}}} \mathcal{S}\mathrm{hv}(\mathcal{D})$. It is clear that $\overline{f}^*$ is a geometric morphism.

We now suppose that the functor g has the following property:

- (a) For every object $D \in \mathcal{D}$ and every morphism $\beta : C \to g(D)$ in $\mathcal{D}$, there exists a morphism $\overline{\beta} : \overline{C} \to D$ in $\mathcal{D}$ such that $\beta = g(\overline{\beta})$.

We claim that $\overline{f}^*$ carries $L_{\mathcal{C}}$-equivalences to equivalences in $\mathcal{S}\mathrm{hv}(\mathcal{D})$. To prove this, it suffices to show that if we are given a collection of morphisms $\alpha_i : C_i \to C$ which generate a covering sieve on $C \in \mathcal{C}$, then the induced map $\phi : \amalg \overline{f}^* j(C_i) \to \overline{f}^* j(C)$ is an effective epimorphism in $\mathcal{S}\mathrm{hv}(\mathcal{D})$; here $j : \mathcal{C} \to \mathcal{P}(\mathcal{C})$ denotes the Yoneda embedding (see Proposition HTT.6.2.3.20).

Let $e : \mathcal{D} \to \mathcal{S}\mathrm{hv}(\mathcal{D})$ be the composition of the Yoneda embedding $\mathcal{D} \to \mathcal{P}(\mathcal{D})$ with the sheafification functor $L_{\mathcal{D}}$. Then $\mathcal{S}\mathrm{hv}(\mathcal{D})$ is generated under colimits by the essential image of e. Consequently, to prove that ϕ is an effective epimorphism, it suffices to show that for every morphism $u : e(D) \to \overline{f}^* j(C)$, the induced map

$$\phi_u : \amalg(\overline{f}^* j(C_i) \times_{\overline{f}^* j(C)} e(D)) \to e(D)$$

is an effective epimorphism in $\mathcal{S}\mathrm{hv}(\mathcal{D})$. Passing to a covering of D, we may reduce to the case where u is induced by a morphism in $\mathcal{P}(\mathcal{D})$, corresponding to a map $\overline{u} : g(D) \to C$ in $\mathcal{C}$. Let $\mathcal{D}^{(0)}_{/D}$ denote the full subcategory of $\mathcal{D}_{/D}$ spanned by those morphisms $D_0 \to D$ such that the induced map $g(D_0) \to g(D) \xrightarrow{\overline{u}} C$ belongs to the sieve generated by the collection of morphisms $\{\alpha_i\}$. It is clear that $\mathcal{D}^{(0)}_{/D}$ is a sieve on D. For every morphism $D_0 \to D$ in $\mathcal{D}^{(0)}_{/D}$, the induced map $e(D_0) \to e(D)$ factors through ϕ_u. Consequently, to show that ϕ_u is an effective epimorphism, it will suffice to show that $\mathcal{D}^{(0)}_{/D}$ is a covering sieve on D: that is, that it satisfies condition $(*)$. Choose a morphism $D' \to D$ in $\mathcal{D}$. Since the collection of covering sieves in $\mathcal{C}$ forms a Grothendieck topology, there exists a collection of morphisms $\beta_j : C'_j \to g(D')$ which generate a covering sieve, each of which fits into a commutative diagram

$$\begin{array}{ccc} C'_j & \xrightarrow{\beta_j} & g(D') \\ \downarrow & & \downarrow \\ C_i & \xrightarrow{\alpha_i} & C. \end{array}$$

Condition (a) guarantees that each β_j can be lifted to a morphism $\overline{\beta}_j : \overline{C}'_j \to D'$ in $\mathcal{D}$, which belongs to the pullback of the sieve $\mathcal{D}^{(0)}_{/D}$. It follows that $\mathcal{D}^{(0)}_{/D}$ satisfies condition $(*)$ and is therefore a covering sieve on D, as required.

Since $\overline{f}^*$ carries $L_{\mathcal{C}}$-equivalences to equivalences in $\mathcal{S}\mathrm{hv}(\mathcal{D})$, it factors up to homotopy as a composition $\mathcal{P}(\mathcal{C}) \xrightarrow{L_{\mathcal{C}}} \mathcal{S}\mathrm{hv}(\mathcal{C}) \xrightarrow{f^*} \mathcal{S}\mathrm{hv}(\mathcal{D})$ where f^* is a colimit-preserving functor which (since it is equivalent to $\overline{f}^*|_{\mathcal{S}\mathrm{hv}(\mathcal{C})}$) preserves finite limits. We now make the following additional assumption:

(b) The functor g is surjective on objects.

We claim that condition (b) implies that f^* is surjective in the sense of Definition A.4.2.2. We will show that if $u : X \to Y$ is a morphism $\mathcal{S}\mathrm{hv}(X)$ such that $f^*(u)$ is an effective epimorphism in $\mathcal{S}\mathrm{hv}(\mathcal{D})$, then u is an effective epimorphism in $\mathcal{S}\mathrm{hv}(X)$. Choose an object $C \in \mathcal{C}$ and a point $\eta \in Y(C)$, and let $\mathcal{C}^{(0)}_{/C}$ be the full subcategory of $\mathcal{C}_{/C}$ spanned by those morphisms $C' \to C$ such that the image of η in $\pi_0 Y(C')$ can be lifted to $\pi_0 X(C')$; we wish to prove that $\mathcal{C}^{(0)}_{/C}$ is covering. Assumption (b) implies we can write $C = g(D)$ for some object

$D \in \mathcal{D}$. Then η determines a point $\overline{\eta} \in (f^*Y)(D)$. Let $\mathcal{D}^{(0)}_{/D} \subseteq \mathcal{D}_{/D}$ be the sieve consisting of morphisms $D' \to D$ such that the image of $\overline{\eta}$ in $\pi_0(f^*Y)(D')$ lifts to $\pi_0(f^*X)(D)$, and let $\mathcal{D}^{(1)}_{/D} \subseteq \mathcal{D}_{/D}$ be the sieve consisting of morphisms $\beta : D' \to D$ such that the image of η in $\pi_0 Y(g(D'))$ lifts to $\pi_0 X(g(D'))$. The functor g carries $\mathcal{D}^{(1)}_{/D}$ into $\mathcal{C}^{(0)}_{/C}$. Consequently, to prove that $\mathcal{C}^{(0)}_{/C}$ is a covering sieve on $C \in \mathcal{C}$, it suffices to show that $\mathcal{D}^{(1)}_{/D}$ is a covering sieve on $D \in \mathcal{D}$. Since $f^*(u)$ is an effective epimorphism, the sieve $\mathcal{D}^{(0)}_{/D}$ is covering. It therefore suffices to show that for each $\beta : D' \to D$ in $\mathcal{D}^{(0)}_{/D}$, the pullback $\beta^* \mathcal{D}^{(1)}_{/D} \subseteq \mathcal{D}_{/D'}$ is a covering sieve on D'. Replacing D by D' (and C by $g(D')$), we may assume that $\overline{\eta}$ lifts to a point $\overline{\eta}' \in (f^*X)(D)$. Note that f^*X is the sheafification of the functor $\mathcal{D} \xrightarrow{g} \mathcal{C} \xrightarrow{X} \mathcal{S}$. It follows that there exists a covering sieve $\mathcal{D}^{(2)}_{/D}$ on D such that for each morphism $D' \to D$ in $\mathcal{D}^{(2)}_{/D}$, the image of $\overline{\eta}'$ in $(f^*X)(D')$ belongs to the image of $X(g(D'))$. We clearly have a containment $\mathcal{D}^{(2)}_{/D} \subseteq \mathcal{D}^{(1)}_{/D}$, so that $\mathcal{D}^{(1)}_{/D}$ is also a covering sieve.

We now add the following further assumption:

(c) The ∞-category $\mathcal{D}$ is (the nerve of) a partially ordered set.

In this case, the ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{D})$ is 0-localic, so that the geometric morphism $f^* : \mathcal{S}\mathrm{hv}(\mathcal{C}) \to \mathcal{S}\mathrm{hv}(\mathcal{D})$ satisfies the requirements of Proposition A.4.3.1.

It remains to prove that there exists a functor $g : \mathcal{D} \to \mathcal{C}$ satisfying conditions (a), (b), and (c). For this, we let A denote the partially ordered set of pairs (n, σ), where $n \geqslant 0$ and $\sigma : \Delta^n \to \mathcal{C}^{\mathrm{op}}$ is an n-simplex of $\mathcal{C}^{\mathrm{op}}$. We write $(n, \sigma) \leqslant (n', \sigma')$ if $n \leqslant n'$ and $\sigma = \sigma'|_{\Delta^{\{0,\ldots,n\}}}$. A k-simplex of the nerve $\mathrm{N}(A)$ consists of a sequence τ :

$$(n_0, \sigma_0) \leqslant \cdots \leqslant (n_k, \sigma_k).$$

Let $g(\tau)$ denote the k-simplex of $\mathcal{C}^{\mathrm{op}}$ given by the composition

$$\Delta^k \xrightarrow{\gamma} \Delta^{n_k} \xrightarrow{\sigma_k} \mathcal{C}^{\mathrm{op}},$$

where γ is given on vertices by the formula $\gamma(i) = n_i$. Then the construction $\tau \mapsto g(\tau)$ determines a map of simplicial sets $g : \mathrm{N}(A)^{\mathrm{op}} \to \mathcal{C}$. It is easy to see that this map satisfies conditions (a), (b), and (c). $\square$

Corollary A.4.3.2. *Let $\mathcal{X}$ be an ∞-topos. Then there exists a complete Boolean algebra Λ and a surjective geometric morphism $f^* : \mathcal{X} \to \mathcal{S}\mathrm{hv}(\Lambda)$*

Proof. Using Proposition HTT.6.5.2.19 , we deduce that there exists a small ∞-category $\mathcal{C}$ equipped with a Grothendieck topology such that $\mathcal{X}$ is a cotopological localization of $\mathcal{S}\mathrm{hv}(\mathcal{C})$. Proposition A.4.3.1 gives a surjective geometric morphism $g^* : \mathcal{S}\mathrm{hv}(\mathcal{C}) \to \mathcal{Y}$, where $\mathcal{Y}$ is 0-localic. Proposition A.4.2.7 guarantees a surjective geometric morphism $h^* : \mathcal{Y} \to \mathcal{S}\mathrm{hv}(\Lambda)$, where $\mathcal{S}\mathrm{hv}(\Lambda)$ is a complete Boolean algebra. Since $\mathcal{S}\mathrm{hv}(\Lambda)$ is hypercomplete (Corollary A.4.1.5), the functor $h^* \circ g^*$ carries ∞-connective morphisms in $\mathcal{S}\mathrm{hv}(\mathcal{C})$ to equivalences in $\mathcal{S}\mathrm{hv}(\Lambda)$, and therefore factors as a composition

$$\mathcal{S}\mathrm{hv}(\mathcal{C}) \to \mathcal{X} \xrightarrow{f^*} \mathcal{S}\mathrm{hv}(\Lambda)$$

for some surjective geometric morphism f^*. □

A.4.4 The Proof of Deligne's Theorem

If Λ is an arbitrary Boolean algebra, we let $\mathrm{Spec}(\Lambda)$ denote the spectrum of Λ (Construction A.1.2.3), so that $\mathrm{Spec}(\Lambda)$ is a compact Hausdorff space with a basis of closed and open sets (Theorem A.1.6.11). Let $\mathcal{U}(\mathrm{Spec}(\Lambda))$ denote the collection of *all* open subsets $\mathrm{Spec}(\Lambda)$. For each $\lambda \in \Lambda$, let $U_\lambda = \{\mathfrak{p} \in \mathrm{Spec}(\Lambda) : \lambda \notin \mathfrak{p}\}$, so that the construction $\lambda \mapsto U_\lambda$ determines an injective map of partially ordered sets $\iota : \Lambda \hookrightarrow \mathcal{U}(\mathrm{Spec}(\Lambda))$, whose image is the collection of closed and open subsets of $\mathrm{Spec}(\Lambda)$. If Λ is complete, then the inclusion map ι admits a left adjoint $\phi : \mathcal{U}(\mathrm{Spec}(\Lambda)) \to \Lambda$, given by the formula $\phi(U) = \bigvee\{\lambda \in \Lambda : U_\lambda \subseteq U\}$. It is easy to see that the map ϕ preserves finite meets and arbitrary joins, and can therefore be regarded as a morphism of locales. In particular, it induces a geometric morphism of ∞-topoi $f^* : \mathcal{S}\mathrm{hv}(\mathrm{Spec}(\Lambda)) \to \mathcal{S}\mathrm{hv}(\Lambda)$.

Lemma A.4.4.1. *Let Λ be a complete Boolean algebra, and let $f^* : \mathcal{S}\mathrm{hv}(\mathrm{Spec}(\Lambda)) \to \mathcal{S}\mathrm{hv}(\Lambda)$ be the geometric morphism constructed above. Then:*

(1) *The right adjoint f_* to f^* is fully faithful. In other words, the composition $f^* f_*$ is equivalent to the identity on $\mathcal{S}\mathrm{hv}(\Lambda)$.*

(2) *For every finite collection of objects $\{X_i\}_{1 \leqslant i \leqslant n}$ and effective epimorphism $\amalg X_i \to Y$ in $\mathcal{S}\mathrm{hv}(\Lambda)$, the induced map $\amalg f_* X_i \to f_* Y$ is an effective epimorphism in $\mathcal{S}\mathrm{hv}(\mathrm{Spec}(\Lambda))$.*

Proof. Let $\iota : \Lambda \hookrightarrow \mathcal{U}(\mathrm{Spec}(\Lambda))$ be the inclusion described above. The functor $f_* : \mathcal{S}\mathrm{hv}(\Lambda) \to \mathcal{S}\mathrm{hv}(\mathrm{Spec}(\Lambda))$ is given by right Kan extension along the inclusion ι, and is fully faithful by Proposition HTT.4.3.2.15 . This proves (1). To prove (2), we note that $\mathcal{S}\mathrm{hv}(\mathrm{Spec}(\Lambda))$ is generated under colimits by objects of the form $f_* \chi_U$ for $U \in \Lambda$ (see the proof of Corollary A.4.1.4; consequently, we may assume without loss of generality that Y has the form χ_U. Each of the maps $X_i \to Y$ factors as a composition

$$X_i \xrightarrow{u_i} \chi_{U_i} \to \chi_U,$$

where u_i is an effective epimorphism. Applying Proposition A.4.1.3 (to the complete Boolean algebra $\{V \in \Lambda : V \leqslant U_i\}$), we deduce that u_i admits a section s_i. We have a commutative

diagram

$$\begin{array}{ccc} & \amalg f_* X_i & \\ {\scriptstyle \amalg s_i}\nearrow & & \searrow \\ \amalg f_* \chi_{U_i} & \xrightarrow{\psi} & f_* \chi_U . \end{array}$$

Consequently, to prove (2), it suffices to show that ψ is an effective epimorphism. For this, it suffices to observe that for each $V \in \Lambda$, the functor f_* carries χ_V to the sheaf represented by the open set $i(V) \subseteq \operatorname{Spec}(\Lambda)$, and the map $V \mapsto i(V)$ preserves finite joins. □

Lemma A.4.4.2. *Let $\mathcal{C}$ be a small ∞-category which admits finite limits and which is equipped with a finitary Grothendieck topology. Let Λ be a complete Boolean algebra, and let $g^* : \mathcal{S}\mathrm{hv}(\mathcal{C}) \to \mathcal{S}\mathrm{hv}(\Lambda)$ be a geometric morphism. Then g^* is homotopic to a composition*

$$\mathcal{S}\mathrm{hv}(\mathcal{C}) \xrightarrow{h^*} \mathcal{S}\mathrm{hv}(\operatorname{Spec}(\Lambda)) \xrightarrow{f^*} \mathcal{S}\mathrm{hv}(\Lambda),$$

where f^* is the geometric morphism of Lemma A.4.4.1.

Proof. For every ∞-topos $\mathcal{Y}$, the ∞-category of geometric morphisms from $\mathcal{S}\mathrm{hv}(\mathcal{C})$ to $\mathcal{Y}$ can be identified with the ∞-category of left-exact functors $u : \mathcal{C} \to \mathcal{Y}$ with the following property: for every every collection of morphisms $\{C_i \to C\}$ which generate a covering sieve on an object $C \in \mathcal{C}$, the induced map $\amalg u(C_i) \to u(C)$ is an effective epimorphism in $\mathcal{Y}$ (Proposition HTT.6.2.3.20). In particular, g^* is classified by a functor $u : \mathcal{C} \to \mathcal{S}\mathrm{hv}(\Lambda)$. Let f_* denote a right adjoint to f^*, and let $u' : \mathcal{C} \to \mathcal{S}\mathrm{hv}(\operatorname{Spec}(\Lambda))$ be the composition $f_* \circ u$. It follows from Lemma A.4.4.1 that u' determines a geometric morphism $h^* : \mathcal{S}\mathrm{hv}(\mathcal{C}) \to \mathcal{S}\mathrm{hv}(\operatorname{Spec}(\Lambda))$ such that $f^* \circ h^* \simeq g^*$. □

Lemma A.4.4.3. *Let $\mathcal{C}$ be a small ∞-category which admits finite limits and which is equipped with a finitary Grothendieck topology. Then there exists a surjective geometric morphism $h^* : \mathcal{S}\mathrm{hv}(\mathcal{C}) \to \mathcal{S}\mathrm{hv}(X)$, where X is a Stone space.*

Proof. Corollary A.4.3.2 guarantees the existence of a surjective geometric morphism $g^* : \mathcal{S}\mathrm{hv}(\mathcal{C}) \to \mathcal{S}\mathrm{hv}(\Lambda)$, where Λ is a complete Boolean algebra. Let X be the spectrum of Λ. Lemma A.4.4.2 guarantees that g^* factors through a geometric morphism $h^* : \mathcal{X} \to \mathcal{S}\mathrm{hv}(X)$, which is clearly surjective. □

Proof of Theorem A.4.0.5. Let $\mathcal{X}$ be an ∞-topos which is locally coherent; we wish to show that the ∞-topos $\mathcal{X}^{\mathrm{hyp}}$ has enough points. Without loss of generality, we may assume that $\mathcal{X}$ is coherent and hypercomplete (see Remark A.4.2.6). Using Theorem A.3.4.1, we can assume that $\mathcal{X} = \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ for some small ∞-category $\mathcal{C}$ which admits finite limits and is equipped with a finitary Grothendieck topology. Choose a surjective geometric morphism $h^* : \mathcal{S}\mathrm{hv}(\mathcal{C}) \to \mathcal{S}\mathrm{hv}(X)$ as in Lemma A.4.4.3. For each point $x \in X$, let f_x^* denote the composite map $\mathcal{S}\mathrm{hv}(\mathcal{C}) \xrightarrow{h^*} \mathcal{S}\mathrm{hv}(X) \to \mathcal{S}\mathrm{hv}(\{x\}) \simeq \mathcal{S}$. It is easy to see that the collection of geometric morphisms $\{f_x^*\}_{x \in X}$ is jointly surjective, so that $\mathcal{X} \simeq \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ has enough points as desired (see Remark A.4.2.6). □

A.5 Application: Homotopy Theory of Simplicial Objects

Theorem A.4.0.5 is very useful: it can be used to reduce many questions about a general ∞-topos $\mathcal{X}$ to questions about the ∞-topos $\mathcal{S}$ of spaces, which can then be attacked using methods of classical homotopy theory. In this section, we will illustrate this principle by using Theorem A.4.0.5 to study extension conditions on simplicial (and semisimplicial) objects of an arbitrary ∞-topos $\mathcal{X}$.

A.5.1 Semisimplicial Objects

We begin by reviewing some terminology.

Notation A.5.1.1. We let $\mathbf{\Delta}$ denote the category of simplices: the objects of $\mathbf{\Delta}$ are the finite linearly ordered sets $[n] = \{0 < 1 < \cdots < n\}$ for $n > 0$, and the morphisms in $\mathbf{\Delta}$ are nondecreasing functions. We let $\mathbf{\Delta}_s$ denote the subcategory of $\mathbf{\Delta}$ containing all objects, where a morphism from $[m]$ to $[n]$ in $\mathbf{\Delta}_s$ is a strictly increasing function $\alpha : [m] \to [n]$.

A *simplicial object* of an ∞-category $\mathcal{C}$ is a functor $\mathbf{\Delta}^{\mathrm{op}} \to \mathcal{S}$, and a *semisimplicial object* of $\mathcal{C}$ is a a functor $\mathbf{\Delta}_s^{\mathrm{op}} \to \mathcal{S}$. We will typically denote either a simplicial or semisimplicial object of $\mathcal{C}$ by $X_\bullet$, and indicate its value on an object $[n] \in \mathbf{\Delta}$ by X_n.

Remark A.5.1.2. Let $X_\bullet : \mathbf{\Delta}^{\mathrm{op}} \to \mathcal{C}$ be a simplicial object of an ∞-category $\mathcal{C}$. Then the composition

$$\mathbf{\Delta}_s^{\mathrm{op}} \hookrightarrow \mathbf{\Delta}^{\mathrm{op}} \xrightarrow{X_\bullet} \mathcal{C}$$

is a semisimplicial object of $\mathcal{C}$, which we will refer to as the *underlying semisimpicial object of* $X_\bullet$. We will typically abuse notation by not distinguishing between $X_\bullet$ and its underlying semisimplicial object.

Notation A.5.1.3. Let $X_\bullet$ be a semisimplicial object of an ∞-category $\mathcal{C}$. We let $|X_\bullet|$ denote a colimit of the diagram $X_\bullet$, provided that such a colimit exists. In this case, we will refer to $|X_\bullet|$ as the *geometric realization* of $X_\bullet$.

Remark A.5.1.4. The inclusion $\mathbf{\Delta}_s \hookrightarrow \mathbf{\Delta}$ is right cofinal (Lemma HTT.6.5.3.7). Consequently, if $X_\bullet$ is a simplicial object of an ∞-category $\mathcal{C}$, then a geometric realization of (the underlying semsimplicial object of) $X_\bullet$ can be identified with a colimit of the diagram $X_\bullet : \mathbf{\Delta}^{\mathrm{op}} \to \mathcal{C}$.

Notation A.5.1.5. Let K be a simplicial set. We say that K is *nonsingular* if every nondegenerate simplex $\sigma : \Delta^n \to K$ is a monomorphism of simplicial sets. For any simplicial set K, we let $\mathbf{\Delta}_K$ denote the category of simplices of K: that is, the category whose objects are simplices $\sigma : \Delta^m \to K$, where a morphism from $\sigma : \Delta^m \to K$ to $\tau : \Delta^n \to K$ is given by a commutative diagram of simplicial sets

$$\begin{array}{ccc} \Delta^m & \longrightarrow & \Delta^n \\ & {\scriptstyle\sigma}\searrow \quad \swarrow{\scriptstyle\tau} & \\ & K. & \end{array}$$

For any simplicial set K, we let $\mathbf{\Delta}_K^{\mathrm{nd}}$ denote the full subcategory of $\mathbf{\Delta}_K$ spanned by the nondegenerate simplices $\sigma : \Delta^m \to K$. In this case where K is nonsingular, this construction has several pleasant features:

- The category $\mathbf{\Delta}_K^{\mathrm{nd}}$ is (equivalent to) a partially ordered set.
- The inclusion $\mathbf{\Delta}_K^{\mathrm{nd}} \hookrightarrow \mathbf{\Delta}_K$ is left cofinal.
- The nerve of the category $\mathbf{\Delta}_K^{\mathrm{nd}}$ can be identified with the subdivision of the simplicial set K.

Construction A.5.1.6. Let $X_\bullet$ be a semisimplicial object of an ∞-category $\mathcal{C}$ and let K be a nonsingular simplicial set. We let $X_\bullet[K]$ denote the limit of the diagram

$$(\mathbf{\Delta}_K^{\mathrm{nd}})^{\mathrm{op}} \to \mathbf{\Delta}_s^{\mathrm{op}} \xrightarrow{X_\bullet} \mathcal{C},$$

provided that such a limit exists (otherwise, we will say that $X_\bullet[K]$ *does not exist*).

Example A.5.1.7. Let $K = \Delta^n$. For any semisimplicial object $X_\bullet$ of an ∞-category $\mathcal{C}$, the object $X_\bullet[K]$ can be identified with $X_n \in \mathcal{C}$.

Example A.5.1.8. Let $\mathcal{C}$ be an ∞-category which admits finite limits and let $X_\bullet$ be a semisimplicial object of $\mathcal{C}$. Then for any finite nonsingular simplicial set K, the object $X_\bullet[K] \in \mathcal{C}$ is well-defined.

Proposition A.5.1.9. *Let $\mathcal{C}$ be an ∞-category which admits fiber products and let $X_\bullet$ be a semisimplicial object of $\mathcal{C}$. Then, for any $n > 0$ and any $0 \leqslant i \leqslant n$, the object $X_\bullet[\Lambda^n_i] \in \mathcal{C}$ is well-defined.*

Proof. Let $\mathcal{J} \subseteq \mathbf{\Delta}^{\mathrm{nd}}_{\Lambda^n_i}$ be the full subcategory spanned by those simplices which contain the ith vertex. Then the inclusion $\mathcal{J} \hookrightarrow \mathbf{\Delta}^{\mathrm{nd}}_{\Lambda^n_i}$ is left cofinal. Then we can identify $\mathcal{J}$ with $\mathcal{J}_0^{\triangleleft}$, where $\mathcal{J}_0$ is the full subcategory spanned by those of positive dimension which contain the ith vertex. We are therefore reduced to showing that the diagram

$$(\mathcal{J}_0^{\mathrm{op}})^{\triangleleft} \simeq \mathcal{J}^{\mathrm{op}} \to \mathbf{\Delta}_s^{\mathrm{op}} \xrightarrow{X_\bullet} \mathcal{C}$$

admits a limit, which is equivalent to the existence of a limit of a diagram $\mathcal{J}_0^{\mathrm{op}} \to \mathcal{C}_{/X_0}$. It now suffices to observe that because $\mathcal{C}$ admits fiber products, the ∞-category $\mathcal{C}_{/X_0}$ admits all finite limits. □

Variant A.5.1.10. Let $X_\bullet$ be a *simplicial* object of an ∞-category $\mathcal{C}$. Then for any simplicial set K, we can contemplate the existence of a limit for the diagram

$$\mathbf{\Delta}_K^{\mathrm{op}} \to \mathbf{\Delta}^{\mathrm{op}} \xrightarrow{X_\bullet} \mathcal{C};$$

if such a limit exists, we will denote it by $X_\bullet[K]$. In the special case where K is a nonsingular simplicial set, the left cofinality of the inclusion $\mathbf{\Delta}_K^{\mathrm{nd}} \hookrightarrow \mathbf{\Delta}_K$ implies that this definition agrees with that of Construction A.5.1.6 (and therefore depends only on the underlying semisimplicial object of $X_\bullet$).

Remark A.5.1.11. Let L be a nonsingular simplicial set and let $K \subseteq L$ be a simplicial subset. Then K is also nonsingular. Moreover, the inclusion $K \hookrightarrow L$ induces a functor $\iota : \mathbf{\Delta}_K^{\mathrm{nd}} \to \mathbf{\Delta}_L^{\mathrm{nd}}$. If $X_\bullet$ is a semisimplicial object of an ∞-category $\mathcal{C}$ for which both $X_\bullet[K]$ and $X_\bullet[L]$ exist, then ι induces a restriction map $X_\bullet[L] \to X_\bullet[K]$.

Variant A.5.1.12. If $X_\bullet$ is a simplicial object of an ∞-category $\mathcal{C}$, then one can define a $X_\bullet[L] \to X_\bullet[K]$ for *any* map of simplicial sets $K \to L$ (provided that $X_\bullet[K]$ and $X_\bullet[L]$ are defined). However, this generality will not be very important for what follows (in practice, we will generally be interested in the case where K and L are simplicial subsets of a standard simplex).

Remark A.5.1.13. Let $X_\bullet$ be a semisimplicial object of an ∞-category $\mathcal{C}$, let K be a nonsingular simplicial set, and suppose that K is a union of simplicial subsets $K_0, K_1 \subseteq K$ having intersection $K_{01} = K_0 \cap K_1$. Then we have a pushout diagram of simplicial sets

$$\begin{array}{ccc} \mathrm{N}(\mathbf{\Delta}^{\mathrm{nd}}_{K_{01}}) & \longrightarrow & \mathrm{N}(\mathbf{\Delta}^{\mathrm{nd}}_{K_0}) \\ \downarrow & & \downarrow \\ \mathrm{N}(\mathbf{\Delta}^{\mathrm{nd}}_{K_1}) & \longrightarrow & \mathrm{N}(\mathbf{\Delta}^{\mathrm{nd}}_{K}). \end{array}$$

Assume that the objects $X_\bullet[K_0], X_\bullet[K_1], X_\bullet[K_{01}] \in \mathcal{C}$ are well-defined. Using the results of §HTT.4.2.3 , we deduce that the object $X_\bullet[K]$ can be identified with the fiber product $X_\bullet[K_0] \times_{X_\bullet[K_{01}]} X_\bullet[K_1]$ (in particular, this fiber product exists in $\mathcal{C}$ if and only if $X_\bullet[K]$ is well-defined).

Remark A.5.1.14. Let $\mathcal{C}$ be an ∞-category which admits finite limits, let X be an object of $\mathcal{C}$, and let $\rho : \mathcal{C}_{/X} \to \mathcal{C}$ denote the forgetful functor. Let $U_\bullet$ be a semisimplicial object of $\mathcal{C}_{/X}$ (so that we can identify $U_\bullet$ with an *augmented* semisimplicial object of the ∞-category $\mathcal{C}$) and let $\rho U_\bullet$ denote the underlying semisimplicial object of $\mathcal{C}$. For any nonsingular simplicial set K, we have a canonical map $u : \rho(U_\bullet[K]) \to (\rho U_\bullet)[K]$ in the ∞-category $\mathcal{C}$. If K is weakly contractible, then the subdivision $\mathrm{N}(\mathbf{\Delta}_K)$ is also weakly contractible, so the comparison map u is an equivalence (Proposition HTT.4.4.2.9).

A.5.2 Kan Fibrations

We now study semisimplicial objects of an ∞-topos $\mathcal{X}$.

Definition A.5.2.1. Let $\mathcal{X}$ be an ∞-topos and let $f : X_\bullet \to Y_\bullet$ be a morphism of semisimplicial objects of $\mathcal{X}$. We will say that f is a *Kan fibration* if, for each $n > 0$ and each $0 \leqslant i \leqslant n$, the induced map

$$X_\bullet[\Delta^n] \to Y_\bullet[\Delta^n] \times_{Y_\bullet[\Lambda^n_i]} X_\bullet[\Lambda^n_i]$$

is an effective epimorphism in $\mathcal{X}$. We will say that f is a *trivial Kan fibration* if, for each $n \geqslant 0$, the natural map

$$X_\bullet[\Delta^n] \to Y_\bullet[\Delta^n] \times_{Y_\bullet[\partial\,\Delta^n]} X_\bullet[\partial\,\Delta^n]$$

is an effective epimorphism.

If $f : X_\bullet \to Y_\bullet$ is a morphism between simplicial objects of $\mathcal{X}$, we will say that f is a *Kan fibration* (*trivial Kan fibration*) if the underlying morphism of semisimplicial objects is a Kan fibration (trivial Kan fibration).

Example A.5.2.2. Let $f : X_\bullet \to Y_\bullet$ be a morphism of simplicial sets. Then f can be regarded as a morphism between simplicial objects of the ∞-topos $\mathcal{S}$ (which are levelwise discrete). The morphism f is a Kan fibration (trivial Kan fibration) in the sense of Definition A.5.2.1 if and only if it is a Kan fibration (trivial Kan fibration) in the usual sense.

Definition A.5.2.3. Let $\mathcal{X}$ be an ∞-topos and let $X_\bullet$ be a semisimplicial object of $\mathcal{X}$. We will say that $X_\bullet$ *satisfies the Kan condition* if, for each $n \geqslant 1$ and each $0 \leqslant i \leqslant n$, the map $X_n = X_\bullet[\Delta^n] \to X_\bullet[\Lambda^n_i]$ is an effective epimorphism in $\mathcal{X}$. We will say that $X_\bullet$ is a *hypercovering of* $\mathcal{X}$ if, for each $n \geqslant 0$, the canonical map $X_n = X_\bullet[\Delta^n] \to X_\bullet[\partial\,\Delta^n]$ is an effective epimorphism. More generally, if $X_\bullet$ is a semisimplicial object of the ∞-topos $\mathcal{X}_{/X}$ which is a hypercovering of $\mathcal{X}_{/X}$, then we will say that $X_\bullet$ is a *hypercovering of* X.

Remark A.5.2.4. Let $X_\bullet$ be a semisimplicial object of an ∞-topos $\mathcal{X}$. Then there is an essentially unique map $f : X_\bullet \to \mathbf{1}_\bullet$, where $\mathbf{1}_\bullet$ denotes the constant semisimplicial object whose value is a final object of $\mathcal{X}$. The morphism f is a Kan fibration if and only if $X_\bullet$ satisfies the Kan condition, and f is a trivial Kan fibration if and only if $X_\bullet$ is a hypercovering.

Example A.5.2.5. Let $\mathcal{X}$ be an ∞-topos and let $X_\bullet$ be a simplicial object of $\mathcal{X}$. Then $X_\bullet$ is a groupoid object of $\mathcal{X}$ (in the sense of Definition HTT.6.1.2.7) if and only if, for each $0 \leqslant i \leqslant n$, the natural map $X_n = X_\bullet[\Delta^n] \to X_\bullet[\Lambda^n_i]$ is an equivalence in $\mathcal{X}$. In particular, every groupoid object of $\mathcal{X}$ satisfies the Kan condition.

Remark A.5.2.6. Let $\mathcal{X}$ be an ∞-topos, let $X \in \mathcal{X}$ be an object, and let $\rho : \mathcal{X}_{/X} \to \mathcal{X}$ denote the forgetful functor. Let $U_\bullet$ be a semisimplicial object of $\mathcal{X}_{/X}$. Then $U_\bullet$ satisfies the Kan condition if and only if $\rho(U_\bullet)$ satisfies the Kan condition. This follows immediately from Remark A.5.1.14.

We now summarize some of the elementary properties of Definition A.5.2.1:

Proposition A.5.2.7. *Let $\mathcal{X}$ be an ∞-topos and suppose we are given a pullback diagram*

$$\begin{array}{ccc} X'_\bullet & \longrightarrow & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y'_\bullet & \longrightarrow & Y_\bullet \end{array}$$

of semisimplicial objects of $\mathcal{X}$. If f is a Kan fibration, then f' is a Kan fibration. If f is a trivial Kan fibration, then f' is a trivial Kan fibration.

Proof. The desired result follows immediately from the fact that the class of effective epimorphisms in $\mathcal{X}$ is stable under the formation of pullback. □

Proposition A.5.2.8. *Let $\mathcal{X}$ be an ∞-topos and let $f : X_\bullet \to Y_\bullet$ be a trivial Kan fibration between semisimplicial objects of $\mathcal{X}$. For every finite nonsingular simplicial set L and every simplicial subset $K \subseteq L$, the natural map the induced map $\theta_{L,K} : X_\bullet[L] \to Y_\bullet[L] \times_{Y_\bullet[K]} X_\bullet[K]$ is an effective epimorphism in $\mathcal{X}$.*

Proof. Working by induction on the number of simplices of L which do not belong to K, we can reduce to the case where L is obtained from K by adding a single nondegenerate n-simplex whose boundary is contained in K. In this case, the map $\theta_{L,K}$ is a pullback of the map $\theta_{\Delta^n, \partial \Delta^n}$, which is an effective epimorphism by virtue of our assumption that f is a trivial Kan fibration. □

Corollary A.5.2.9. *Let $f : X_\bullet \to Y_\bullet$ be a morphism between semisimplicial objects of an ∞-topos $\mathcal{X}$. If f is a Kan fibration, then it is a trivial Kan fibration.*

Corollary A.5.2.10. *Let $X_\bullet$ be a semisimplicial object of an ∞-topos $\mathcal{X}$. If $X_\bullet$ is a hypercovering, then $X_\bullet$ satisfies the Kan condition.*

Proposition A.5.2.11. *Let $f : X_\bullet \to Y_\bullet$ and $g : Y_\bullet \to Z_\bullet$ be morphisms between semisimplicial objects of an ∞-topos $\mathcal{X}$. Then:*

(1) *If f and g are Kan fibrations, then $g \circ f$ is a Kan fibration.*

(1′) *If f is a trivial Kan fibration and $g \circ f$ is a Kan fibration, then g is a Kan fibration.*

(2) *If f and g are trivial Kan fibrations, then $g \circ f$ is a trivial Kan fibration.*

(2′) *If f and $g \circ f$ are trivial Kan fibrations, then g is a trivial Kan fibration.*

Proof. We will prove (2) and (2′); the proofs of (1) and (1′) are similar. Assume that f is a trivial Kan fibration; we wish to show that g is a trivial Kan fibration if and only if $g \circ f$ is a trivial Kan fibration. Let $n \geqslant 0$ be an integer.

Since f is a trivial Kan fibration, the natural map $X_\bullet[\partial\,\Delta^n] \to Y_\bullet[\partial\,\Delta^n]$ is an effective epimorphism in $\mathcal{X}$. Consequently, the map $Y_\bullet[\Delta^n] \to Z_\bullet[\Delta^n] \times_{Z_\bullet[\partial\,\Delta^n]} Y_\bullet[\partial\,\Delta^n]$ is an effective epimorphism if and only if the projection map $Y_\bullet[\Delta^n] \times_{Y_\bullet[\partial\,\Delta^n]} X_\bullet[\partial\,\Delta^n] \to Z_\bullet[\Delta^n] \times_{Z_\bullet[\partial\,\Delta^n]} X_\bullet[\partial\,\Delta^n]$ is an effective epimorphism. Inspecting the diagram

$$\begin{array}{ccc} X_\bullet[\Delta^n] & \longrightarrow & Y_\bullet[\Delta^n] \times_{Y_\bullet[\partial\,\Delta^n]} X_\bullet[\partial\,\Delta^n] \\ & \searrow \quad \swarrow & \\ & Z_\bullet[\Delta^n] \times_{Z_\bullet[\partial\,\Delta^n]} X_\bullet[\partial\,\Delta^n] & \end{array}$$

(in which the upper horizontal map is an effective epimorphism by virtue of our assumption on f), we deduce that the left vertical map is an effective epimorphism if and only if the right vertical map is an effective epimorphism. Allowing n to vary, we deduce that g is a trivial Kan fibration if and only if $g \circ f$ is a trivial Kan fibration. □

Corollary A.5.2.12. *Let $\mathcal{X}$ be an ∞-topos and let $f : X_\bullet \to Y_\bullet$ be a trivial Kan fibration between semisimplicial objects of $\mathcal{X}$. Then:*

(1) *The semisimplicial object $X_\bullet$ satisfies the Kan condition if and only if $Y_\bullet$ satisfies the Kan condition.*

(2) *The semisimplicial object $X_\bullet$ is a hypercovering of $\mathcal{X}$ if and only if $Y_\bullet$ is a hypercovering of $\mathcal{X}$.*

A.5.3 Connectivity of Trivial Kan Fibrations

We are now ready to state our first main result of this section:

Theorem A.5.3.1. *Let $f : X_\bullet \to X'_\bullet$ be a trivial Kan fibration between semisimplicial objects of an ∞-topos $\mathcal{X}$. Assume that one of the following conditions holds:*

(i) The morphism f can be promoted to a morphism between simplicial objects of $\mathcal{X}$.

(ii) The semisimplicial object $X'_\bullet$ satisfies the Kan condition.

Then f induces an ∞-connective map $|X_\bullet| \to |X'_\bullet|$.

Warning A.5.3.2. If $f : X_\bullet \to X'_\bullet$ does not satisfy either of the conditions (i) or (ii), then the conclusion of Theorem A.5.3.1 need not be valid. For example, suppose that $X'_\bullet$ is the semisimplicial set represented by the object $[1] \in \mathbf{\Delta}_s$ (so the simplices of $X'_\bullet$ are the *nondegenerate* simplices of Δ^1). Then the data of a map of semisimplicial sets $f : X_\bullet \to X'_\bullet$ is equivalent to the data of a bipartite graph: that is, a pair of sets V_0, V_1 (which can be defined as the inverse images of the two vertices of $X'_\bullet$) and another set E equipped with maps $V_0 \xleftarrow{d_0} E \xrightarrow{d_1} V_1$. The hypothesis that f is a trivial Kan fibration is equivalent to the requirement that the map $(d_0, d_1) : E \to V_0 \times V_1$ is surjective. If both V_0 and V_1 have more than one element, then the geometric realization $|X_\bullet|$ is *never* contractible.

Specializing Theorem A.5.3.1 to the case where $Y_\bullet$ is final we obtain the following:

Corollary A.5.3.3. *Let $X_\bullet$ be a semisimplicial object of an ∞-topos $\mathcal{X}$ which is a hypercovering. Then $|X_\bullet|$ is an ∞-connective object of $\mathcal{X}$.*

Let us now outline our strategy for proving Theorem A.5.3.1, which we will use to prove many other results in this section. The first observation is that we can reduce to proving Theorem A.5.3.1 in a single example: namely, we can assume that the ∞-topos $\mathcal{X}$ is *freely* generated by a Kan fibration (satisfying condition (i) or condition (ii)). We then observe that in this universal example, the ∞-topos $\mathcal{X}$ is locally coherent. It then follows from Deligne's theorem (Theorem A.4.0.5) that the hypercompletion $\mathcal{X}^{\mathrm{hyp}}$ has enough points, which allows us to reduce to the case $\mathcal{X} = \mathcal{S}$. In this case, we will "resolve" $X_\bullet$ and $X'_\bullet$ by semisimplicial sets, for which the desired result can be proven by combinatorial methods.

To handle case (ii) of Theorem A.5.3.1, we need the following result:

Proposition A.5.3.4. *Let $f : X_\bullet \to Y_\bullet$ be a Kan fibration between semisimplicial sets. Suppose that $Y_\bullet$ is the underlying semisimplicial set of a simplicial set $\overline{Y}_\bullet$. Then f can be lifted to a Kan fibration of simplicial sets $\overline{f} : \overline{X}_\bullet \to \overline{Y}_\bullet$.*

Taking $\overline{Y}_\bullet = \Delta^0$ in Proposition A.5.3.4, we obtain the following result of Rourke-Sanderson (see [176]):

Corollary A.5.3.5. *Let $X_\bullet$ be a semisimplicial set. If $X_\bullet$ satisfies the Kan condition, then $X_\bullet$ can be promoted to a simplicial set.*

We will prove Proposition A.5.3.4 using a slight variant of the proof of Corollary A.5.3.5 given in [113]. The key point is the following:

Lemma A.5.3.6. *Let $K_\bullet$ denote the semisimplicial subset of Δ^n given by the union of $\partial\,\Delta^n$ with the unique nondegenerate n-simplex of Δ^n (so that a k-simplex $\sigma : \Delta^k \to \Delta^n$ belongs to $X_\bullet$ if and only if σ is either an isomorphism or is not surjective). Then the inclusion $K_\bullet \hookrightarrow \Delta^n$ has the left lifting property with respect to all Kan fibrations between semisimplicial sets.*

Proof. For every nonsingular simplicial set $L_\bullet$, let $L_\bullet^{\mathrm{nd}}$ denote the semisimplicial subset of $L_\bullet$ spanned by the nondegenerate simplices. Let us say that a map of semisimplicial sets $A_\bullet \hookrightarrow B_\bullet$ is *anodyne* if it has the left lifting property with respect to all Kan fibrations. Using the small object argument (see Proposition HTT.A.1.2.5), we see that the collection of anodyne morphisms of semisimplicial sets is the smallest collection of morphisms which is closed under pushouts, retracts, transfinite composition, and contains all horn inclusions $(\Lambda^m_i)^{\mathrm{nd}} \hookrightarrow (\Delta^m)^{\hookrightarrow}$. We wish to prove that the inclusion

$$(\Delta^n)^{\mathrm{nd}} \amalg_{(\partial\,\Delta^n)^{\mathrm{nd}}} \partial\,\Delta^n \hookrightarrow \Delta^n$$

is anodyne. Our proof will proceed by induction on n.

For every semisimplicial set $A_\bullet$, let $A_\bullet^+$ denote the cone on $A_\bullet$: that is, the semisimplicial set given by

$$A_m = \begin{cases} \{\sigma \in A_m\} \amalg \{v\} & \text{if } m = 0 \\ \{\sigma \in A_m\} \amalg \{\sigma^+ | \sigma \in A_{m-1}\} & \text{if } m > 0, \end{cases}$$

whose face maps determined by the fact that they extend the face maps on $A_\bullet$ and are otherwise given by the formula

$$d_i\sigma^+ = \begin{cases} (d_i\sigma)^+ & \text{if } \sigma \in A_m \text{ and } 0 \leqslant i \leqslant m, m > 0 \\ \sigma & \text{if } \sigma \in A_m \text{ and } i = m+1 \\ v & \text{if } \sigma \in A_m \text{ and } 0 = i = m. \end{cases}$$

Let us say that a semisimplicial set $A_\bullet$ is *good* if the inclusion $A_\bullet \hookrightarrow A_\bullet^+$ is anodyne.

Our proof proceeds in several steps:

(*a*) For any monomorphism of semisimplicial sets $\iota : A_\bullet \hookrightarrow B_\bullet$, the induced map $\iota^+ : A_\bullet^+ \to B_\bullet^+$ is anodyne. Writing ι as a transfinite composition of simplex attachments, we can reduce to checking this in the case $B = (\Delta^m)^{\mathrm{nd}}$ and $A = (\partial\,\Delta^m)^{\mathrm{nd}}$, in which case a simple calculation shows that ι^+ can be identified with the horn inclusion $(\Lambda^{m+1}_{m+1})^{\mathrm{nd}} \hookrightarrow (\Delta^{m+1})^{\mathrm{nd}}$.

(b) Suppose we are given a monomorphism of semisimplicial sets $\iota : A_\bullet \hookrightarrow B_\bullet$, where $A_\bullet$ is good and there exists a retraction $r : B_\bullet^+ \to B_\bullet$ (this condition is satisfied, for example, when $B_\bullet = \Delta^n$). Then ι is a retract of the composite map $A_\bullet \to A_\bullet^+ \xrightarrow{\iota^+} B_\bullet^+$, and is therefore anodyne (by virtue of (a) and our assumption that $A_\bullet$ is good).

(c) Suppose that $\iota : A_\bullet \hookrightarrow B_\bullet$ is a monomorphism of semisimplicial sets. If ι is anodyne, then the induced map $\iota' : A_\bullet^+ \amalg_{A_\bullet} B_\bullet \to B_\bullet^+$ is also anodyne. To prove this, we can use Proposition HTT.A.1.2.5 to reduce to the case where ι is a horn inclusion $(\Lambda^m_i)^{\mathrm{nd}} \hookrightarrow (\Delta^m)^{\mathrm{nd}}$, in which case ι' can be identified with the horn inclusion $(\Lambda^{m+1}_i)^{\mathrm{nd}} \hookrightarrow (\Delta^{m+1})^{\mathrm{nd}}$.

(d) Let $\iota : A_\bullet \hookrightarrow B_\bullet$ be an anodyne morphism of simplicial sets. It follows from (c) that if $A_\bullet$ is good, then $B_\bullet$ is also good.

(e) For each $m \geqslant 0$, the simplex $B_\bullet = (\Delta^m)^{\mathrm{nd}})$ is good. To prove this, we use induction on m. When $m = 0$, the natural map $B_\bullet \hookrightarrow B_\bullet^+$ can be identified with the horn inclusion $(\Lambda^1_0)^{\mathrm{nd}} \hookrightarrow (\Delta^1)^{\mathrm{nd}}$, and is therefore anodyne. For $m > 0$, we can write $B_\bullet = A_\bullet^+$ where $A_\bullet = (\Delta^{m-1})^{\mathrm{nd}}$. It follows from our inductive hypothesis that $A_\bullet$ is good, so that the inclusion $A_\bullet \hookrightarrow B_\bullet$ is anodyne and therefore $B_\bullet$ is good by virtue of (c).

(f) Let $L_\bullet$ be a simplicial subset of $(\partial\,\Delta^n)$. We claim that the semisimplicial set $L_\bullet \amalg_{L_\bullet^{\mathrm{nd}}} (\Delta^n)^{\mathrm{nd}}$ is good. The proof proceeds by induction on the number of nondegenerate simplices of L. If $L = \varnothing$, the desired result follows from (e). Otherwise, we can write $L_\bullet$ as the union of a simplicial subset $L'_\bullet$ with a nondegenerate m-simplex of $\partial\,\Delta^n$ whose boundary belongs to $L'_\bullet$. We then have an inclusion

$$\iota : L'_\bullet \amalg_{L'^{\mathrm{nd}}_\bullet} (\Delta^n)^{\mathrm{nd}} \hookrightarrow L_\bullet \amalg_{L^{\mathrm{nd}}_\bullet} (\Delta^n)^{\mathrm{nd}}.$$

The domain of ι is good by our inductive hypothesis. Consequently, to show that the codomain of ι is good, it will suffice to show that ι is anodyne (by virtue of (d)). For this, we observe that ι is a pushout of the inclusion

$$\partial\,\Delta^m \amalg_{(\partial\,\Delta^m)^{\mathrm{nd}}} (\Delta^m)^{\mathrm{nd}} \hookrightarrow \Delta^m.$$

Since $m < n$, this map is anodyne by virtue of our (other) inductive hypothesis.

Applying (f) in the case $L_\bullet = \partial\,\Delta^n$, we deduce that the semisimplicial set $(\Delta^n)^{\mathrm{nd}} \amalg_{(\partial\,\Delta^n)^{\mathrm{nd}}} \partial\,\Delta^n$ is good. Combining this observation with (b), we conclude that the inclusion $(\Delta^n)^{\mathrm{nd}} \amalg_{(\partial\,\Delta^n)^{\mathrm{nd}}} \partial\,\Delta^n \hookrightarrow \Delta^n$ is anodyne, as desired. □

Proof of Proposition A.5.3.4. Let $\mathcal{C}$ denote the category whose objects are triples $(\overline{S}_\bullet, \overline{\alpha}, \beta)$ where $\overline{S}_\bullet$ is a simplicial set whose underlying semisimplicial set we will denote by $S_\bullet$,

$\overline{\alpha} : \overline{S}_\bullet \to \overline{Y}_\bullet$ is a map of simplicial sets whose underlying map of semisimplicial sets we denote by α, and $\beta : S_\bullet \to X_\bullet$ is a monomorphism of semisimplicial sets for which the diagram

$$\begin{array}{ccc} S_\bullet & \xrightarrow{\beta} & X_\bullet \\ & {\scriptstyle\alpha}\searrow \quad \swarrow{\scriptstyle f} & \\ & Y_\bullet & \end{array}$$

commutes. A morphism from $(\overline{S}_\bullet, \overline{\alpha}, \beta)$ to $(\overline{S}'_\bullet, \overline{\alpha}', \overline{\beta}')$ in the category $\mathcal{C}$ is a map $\overline{g} : \overline{S}_\bullet \to \overline{S}'_\bullet$ satisfying $\overline{\alpha} = \overline{\alpha}' \circ \overline{g}$ and $\beta = \beta' \circ g$ (where g denotes the map of semisimplicial sets underlying $\overline{g}$). Since a map of simplicial sets is determined by the underlying map of semisimplicial sets, the morphism $\overline{g}$ is unique if it exists; it follows that the category $\mathcal{C}$ is equivalent to a partially ordered set P (which we can identify with the set of isomorphism classes of objects of $\mathcal{C}$). Note that P is nonempty (since $\mathcal{C}$ contains an object $(\overline{S}_\bullet, \overline{\alpha}, \beta)$ where $\overline{S}_\bullet$ is empty) and that every directed subset of P has a least upper bound (since the category $\mathcal{C}$ admits filtered colimits). It follows from Zorn's lemma that P has a maximal element, which is represented by an object $(\overline{S}_\bullet, \overline{\alpha}, \beta) \in \mathcal{C}$. To complete the proof, it will suffice to show that $\beta : S_\bullet \hookrightarrow X_\bullet$ is an isomorphism of simplicial sets. Suppose otherwise: then there exists an n-simplex $\sigma \in X_n$ which does not belong to the image of β. Let us assume that n is chosen as small as possible, so that each face of σ belongs to the image of β.

Let $A_\bullet \subseteq \partial\,\Delta^n$ denote the semisimplicial subset consisting of the nondegenerate simplices of $\partial\,\Delta^n$, so that σ determines a map of semisimplicial sets $A_\bullet \to X_\bullet$ which factors uniquely as a composition $A_\bullet \xrightarrow{\rho} S_\bullet \xrightarrow{\beta} X_\bullet$. The map ρ extends uniquely to a map of simplicial sets $\overline{\rho}^+ : \partial\,\Delta^n \to \overline{S}_\bullet$. Let $\overline{S}'_\bullet$ denote the pushout $\overline{S}_\bullet \amalg_{\partial\,\Delta^n} \Delta^n$. The map $\overline{\alpha}$ and the n-simplex $f(\sigma) \in Y_n$ determine a map of simplicial sets $\overline{\alpha}^+ : \overline{S}'_\bullet \to \overline{Y}_\bullet$. Let $S'_\bullet$ denote the underlying semisimplicial subset of $\overline{S}'_\bullet$, which can be described as a pushout $S_\bullet \amalg_{\partial\,\Delta^n} \Delta^n$ in the category of semisimplicial sets. We claim that β can be extended to a map of semisimplicial sets $\beta' : S'_\bullet \to X_\bullet$ which carries the nondegenerate n-simplex of Δ^n to σ and fits into a commutative diagram

$$\begin{array}{ccc} S'_\bullet & \xrightarrow{\beta'} & X_\bullet \\ & {\scriptstyle\alpha'}\searrow \quad \swarrow{\scriptstyle f} & \\ & Y_\bullet. & \end{array}$$

To prove this, it suffices to solve a lifting problem of the form

$$\begin{array}{ccc} K_\bullet & \longrightarrow & X_\bullet \\ \downarrow & \nearrow & \downarrow{\scriptstyle f} \\ \Delta^n & \longrightarrow & Y_\bullet, \end{array}$$

where $K_\bullet$ is as in Lemma A.5.3.6; this is possibly by virtue of our assumption that f is a Kan fibration.

It follows from the maximality of $(\overline{S}_\bullet, \overline{\alpha}, \beta) \in \mathcal{C}$ that the triple $(\overline{S}'_\bullet, \overline{\alpha}', \beta')$ cannot be an object of $\mathcal{C}$: in other words, the map β' cannot be a monomorphism of semisimplicial sets. We can therefore choose a pair of k-simplices $\tau, \tau' \in S'_k$ such that $\tau \neq \tau'$ but $\beta'(\tau) = \beta'(\tau')$. Let us assume that k is chosen as small as possible, so that the 0th faces of τ and τ' are the same. Since β is injective, the simplices τ and τ' cannot both belong to S_k. We may therefore assume without loss of generality that τ is the image of a k-simplex Δ^n which does not belong to $\partial \Delta^n$. In this case, the nondegenerate n-simplex of Δ^n appears as a facet of τ, so that $\sigma \in X_n$ appears as a facet of $\beta'(\tau) = \beta'(\tau')$. It follows that τ' also cannot belong to S_k, so that we can identify τ' also with a k-simplex of Δ^n which does not belong to $\partial \Delta^n$. Then we can identify β and β' with surjective nondecreasing functions

$$\beta, \beta' : \{0 < 1 < \cdots < k-1 < k\} \to \{0 < 1 < \cdots < n-1 < n\}.$$

Since the 0th faces of β and β' agree, we have $\beta(i) = \beta'(i)$ for $i > 0$. However, the surjectivity of β and β' guarantees that $\beta(0) = 0 = \beta'(0)$. It follows that $\beta = \beta'$, contrary to our assumption. □

We now use Proposition A.5.3.4 to prove Theorem A.5.3.1 in the special case $\mathcal{X} = \mathcal{S}$:

Lemma A.5.3.7. *Let $f : X_\bullet \to X'_\bullet$ be a trivial Kan fibration between semisimplicial objects of $\mathcal{S}$ which satisfies one of the following conditions:*

(i) The morphism f can be promoted to a morphism between simplicial objects of $\mathcal{S}$.

(ii) The semisimplicial object $X'_\bullet$ satisfies the Kan condition.

Then the induced map $\theta : |X_\bullet| \to |X'_\bullet|$ is a homotopy equivalence.

Proof. Using Proposition HTT.4.2.4.4 , we may assume without loss of generality that f is obtained from a morphism $\overline{f} : \overline{X}_\bullet \to \overline{X}'_\bullet$ between semisimplicial objects of the ordinary category $\mathcal{S}\mathrm{et}_\Delta$ of simplicial sets. Moreover, in case (i), we may even assume that this is a morphism between *simplicial* objects of $\mathcal{S}\mathrm{et}_\Delta$. Without loss of generality, we may assume that $\overline{X}'_\bullet$ is Reedy fibrant and that $\overline{f}$ is a Reedy fibration: that is, for each $n \geqslant 0$, the natural maps

$$\overline{X}_\bullet[\Delta^n] \to \overline{X}_\bullet[\partial \Delta^n] \times_{\overline{X}'_\bullet[\partial \Delta^n]} \overline{X}'_\bullet[\Delta^n] \qquad \overline{X}'_\bullet[\Delta^n] \to \overline{X}'_\bullet[\partial \Delta^n]$$

are Kan fibrations of simplicial sets. It follows that for every nonsingular simplicial set K, the simplicial sets $\overline{X}_\bullet[K]$ and $\overline{X}'_\bullet[K]$ are Kan complexes that represent the objects $X_\bullet[K], X'_\bullet[K] \in \mathcal{S}$. It follows that for $n \geqslant 0$, the map of simplicial sets

$$\overline{X}_\bullet[\Delta^n] \to \overline{X}_\bullet[\partial \Delta^n] \times_{\overline{X}'_\bullet[\partial \Delta^n]} \overline{X}'_\bullet[\Delta^n]$$

is a Kan fibration which is surjective on connective components, and therefore surjective on m-simplices for all $m \geqslant 0$. In case (ii), the same argument shows that the maps $\overline{X}'_\bullet[\Delta^n] \to \overline{X}'_\bullet[\Lambda^n_i]$ are surjective on m-simplices for all $n > 0$ and $0 \leqslant i \leqslant n$.

Let $\overline{X}_{\bullet m}$ and $\overline{X}'_{\bullet m}$ denote the semisimplicial sets obtained by evaluating $\overline{X}_\bullet$ and $\overline{X}'_\bullet$ on the object $[m] \in \mathbf{\Delta}^{\mathrm{op}}$. Then we can identify θ with a homotopy colimit of the maps $\theta_m : |\overline{X}_{\bullet m}| \to |\overline{X}'_{\bullet m}|$; it will therefore suffice to show that each θ_m is a homotopy equivalence. The above argument shows that the map of semisimplicial sets $\overline{f}_m : \overline{X}_{\bullet m} \to \overline{X}'_{\bullet m}$ is a trivial Kan fibration. To show that $\overline{f}_m$ induces a homotopy equivalence of geometric realizations, it will suffice to show that $\overline{f}_m$ can be promoted to a map of simplicial sets. In case (i), this follows from our construction; in case (ii), it follows by from Corollary A.5.3.5 (applied to the semisimplicial set $\overline{X}'_{\bullet m}$) and Proposition A.5.3.4.

□

Lemma A.5.3.8. *Let $f : X_\bullet \to X'_\bullet$ be a trivial Kan fibration between semisimplicial objects of an ∞-topos $\mathcal{X}$. Then there exists a ∞-topos $\mathcal{Y}$ which is coherent and locally coherent, a trivial Kan fibration $g : Y_\bullet \to Y'_\bullet$ between semisimplicial objects of $\mathcal{Y}$, and a geometric morphism $\phi^* : \mathcal{Y} \to \mathcal{X}$ such that f is equivalent to $\phi^*(g)$. Moreover, if f satisfies condition (i) or (ii) of Theorem A.5.3.1, then we can arrange that g has the same property.*

Proof. Let $\mathcal{C}$ be an ∞-category freely generated by $\mathbf{\Delta}_s^{\mathrm{op}} \times \Delta^1$ under finite limits. More precisely, we choose a functor $u : \mathbf{\Delta}_s^{\mathrm{op}} \times \Delta^1 \to \mathcal{C}$, where $\mathcal{C}$ admits finite limits, which has the following universal property: for any ∞-category $\mathcal{D}$ which admits finite limits, composition with u induces an equivalence of ∞-categories $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{C}, \mathcal{D}) \to \mathrm{Fun}(\mathbf{\Delta}_s^{\mathrm{op}} \times \Delta^1, \mathcal{D})$, where $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{C}, \mathcal{D})$ denotes the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ spanned by those functors which preserve finite limits. The existence of u follows from Remark HTT.5.3.5.9 . Let us identify u with a morphism $Z_\bullet \to Z'_\bullet$ of the ∞-category $\mathcal{C}$. We will regard $\mathcal{C}$ as equipped with the coarsest Grothendieck topology τ for which each of the natural maps $Z_\bullet[\Delta^n] \to Z'_\bullet[\Delta^n] \times_{Z'_\bullet[\partial \Delta^n]} Z_\bullet[\partial \Delta^n]$ generates a covering sieve. It follows from Remark A.3.1.2 that the Grothendieck topology τ is finitary, so that $\mathcal{Y} = \mathcal{S}\mathrm{hv}(\mathcal{C})$ is a coherent and locally coherent ∞-topos (Proposition A.3.1.3). Let $g : Y_\bullet \to Y'_\bullet$ be the morphism of semisimplicial objects of $\mathcal{Y}$ which is obtained from u by applying the sheafified Yoneda embedding $\mathcal{C} \to \mathcal{S}\mathrm{hv}(\mathcal{C})$. We can regard f as a functor $\mathbf{\Delta}_s^{\mathrm{op}} \times \Delta^1 \to \mathcal{X}$. Invoking the universal property of u, we can assume that f is given by the composition $\mathbf{\Delta}_s^{\mathrm{op}} \times \Delta^1 \xrightarrow{u} \mathcal{C} \xrightarrow{f'} \mathcal{X}$ where the functor f' preserves finite limits. Using Proposition HTT.6.2.3.20 , we see that f' induces a geometric morphism $\phi^* : \mathcal{Y} \to \mathcal{X}$ satisfying $\phi^*(g) \simeq f$. This proves the first assertion.

If f satisfies condition (i) of Theorem **??**, then we can arrange that g has the same property using a variant of the above construction where we replace $\mathbf{\Delta}_s^{\mathrm{op}} \times \Delta^1$ by $\mathbf{\Delta}^{\mathrm{op}} \times \Delta^1$. If f satisfies condition (ii) of Theorem **??**, then we can arrange that g has the same property by replacing τ by a slightly finer (but still finitary) topology, where the morphisms

$Z'_\bullet[\Delta^n] \to Z'_\bullet[\Lambda^n_i]$ are also coverings. □

Proof of Theorem A.5.3.1. Let $f : X_\bullet \to X'_\bullet$ be a trivial Kan fibration between semisimplicial objects of ∞-topos $\mathcal{X}$ which satisfies condition (i) or (ii) of Theorem A.5.3.1; we wish to prove that the induced map $|f| : |X_\bullet| \to |X'_\bullet|$ is ∞-connective. Using Lemma A.5.3.8, we can reduce to the case where the ∞-topos $\mathcal{X}$ is locally coherent. In this case, it follows from Theorem A.4.0.5 that the map $|f|$ is ∞-connective if and only if $\phi^*|f|$ is a homotopy equivalence for every geometric morphism $\phi^* : \mathcal{X} \to \mathcal{S}$. We may therefore assume without loss of generality that $\mathcal{X} = \mathcal{S}$, in which case the desired result follows from Lemma A.5.3.7. □

A.5.4 Pullbacks and Geometric Realizations

We now state our next main result:

Theorem A.5.4.1. *Let $\mathcal{X}$ be a hypercomplete ∞-topos. Suppose we are given a pullback square of semisimplicial objects σ :*

$$\begin{array}{ccc} X'_\bullet & \xrightarrow{g'} & X_\bullet \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y'_\bullet & \xrightarrow{g} & Y_\bullet \end{array}$$

satisfying one of the following conditions:

(i) *The morphism f is a Kan fibration and σ can be promoted to a pullback square of simplicial objects of $\mathcal{X}$.*

(ii) *The morphisms f and g are Kan fibrations and $Y_\bullet$ satisfies the Kan condition.*

Then the diagram of geometric realizations

$$\begin{array}{ccc} |X'_\bullet| & \longrightarrow & |X_\bullet| \\ \downarrow & & \downarrow \\ |Y'_\bullet| & \longrightarrow & |Y_\bullet| \end{array}$$

is a pullback square in $\mathcal{X}$.

Warning A.5.4.2. In the statement of Theorem A.5.4.1, it is not enough to assume merely that f is a Kan fibration: for example, the geometric realization of the fiber of a Kan fibration f between semisimplicial sets need not be equivalent to the homotopy fiber of geometric realization of f (see Warning A.5.3.2).

Our proof of Theorem A.5.4.1 will follow the same basic outline as our proof of Theorem A.5.3.1: we will use Theorem A.4.0.5 to reduce to a statement about the homotopy theory of semisimplicial spaces, and then reduce further to a statement about the homotopy theory of semisimplicial sets. To carry out the second step, our basic mechanism is the following:

Lemma A.5.4.3. *Let $Y_\bullet$ be a simplicial (semisimplicial) object of $\mathcal{S}$. Then there exists a trivial Kan fibration $f : X_\bullet \to Y_\bullet$ of simplicial (semisimplicial) objects of $\mathcal{S}$, where $X_\bullet$ is levelwise discrete: that is, $X_\bullet$ is a simplicial (semisimplicial) set.*

Proof. We will prove Theorem A.5.4.3 for simplicial objects of $\mathcal{S}$; the proof in the semisimplicial case is analogous (and slightly easier). We will produce $X_\bullet$ as the union of a compatible sequence of functors $F_{\leqslant n} : \mathbf{\Delta}^{\mathrm{op}}_{\leqslant n} \to \mathcal{S}\mathrm{et} \subseteq \mathcal{S}$ and f as the limit of a compatible sequence of natural transformations $\alpha_n : F_{\leqslant n} \to Y_\bullet|_{\mathbf{\Delta}^{\mathrm{op}}_{\leqslant n}}$. Let us assume that $n \geqslant 0$ and that we have constructed the a functor $F_{\leqslant n-1} : \mathbf{\Delta}^{\mathrm{op}}_{\leqslant n} \to \mathcal{S}\mathrm{et} \subseteq \mathcal{S}$ satisfying the following additional condition:

($*_{n-1}$) For each $m \leqslant n$, let L_m denote the mth latching object of $F_{\leqslant n-1}$: that is, the colimit $\varinjlim_{[k] \hookrightarrow [m], k<m} F_{\leqslant n-1}([k])$. For $m < n$, the natural map $L_m \to F_{\leqslant n-1}([m])$ is injective, so we can write $F_{\leqslant n-1}([m])$ as a disjoint union of L_m with an auxiliary set A_m.

It follows from ($*_{n-1}$) that the nth latching object of $F_{\leqslant n-1}$ can be identified with the disjoint union $\amalg_{[m] \hookrightarrow [n], m<n} A_m$, and is therefore discrete. Let M_n denote the nth matching object of $F_{\leqslant n-1}$. According to Corollary HTT.A.2.9.15 , to produce a functor $F_{\leqslant n}$ extending $F_{\leqslant n-1}$ and a natural transformation α_n extending α_{n-1}, it suffices to supply a commutative diagram

$$\begin{array}{ccc} & X_n & \\ \nearrow & & \searrow^{\phi} \\ L_n & \longrightarrow & Y_n \times_{Y_\bullet[\partial \Delta^n]} M_n \end{array}$$

where the bottom vertical maps is determined by $F_{\leqslant n-1}$ and α_{n-1}. This can be achieved by taking X_n to be the disjoint union of L_n with an auxiliary set A_n, and choosing the map ϕ so that $\phi|_{A_n}$ is surjective on connected components. By construction, we see that $F_{\leqslant n}$ satisfies ($*_n$) and that the maps $\{\alpha_n\}_{n \geqslant 0}$ induce a trivial Kan fibration $f : X_\bullet \to Y_\bullet$. □

Lemma A.5.4.4. *Let $\mathcal{X}$ be a hypercomplete ∞-topos and suppose we are given a pullback diagram σ :*

$$\begin{array}{ccc} X'_\bullet & \xrightarrow{g'} & X_\bullet \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y'_\bullet & \xrightarrow{g} & Y_\bullet \end{array}$$

of semisimplicial objects of $\mathcal{X}$. Then there exists an equivalence $\sigma = \phi^* \widetilde{\sigma}$, where $\phi^* : \mathcal{Y} \to \mathcal{X}$ is a geometric morphism of ∞-topoi, $\widetilde{\sigma}$ is a pullback diagram of semisimplicial objects of $\mathcal{Y}$, and the ∞-topos $\mathcal{Y}$ is locally coherent and hypercomplete. Moreover, if σ satisfies condition (i) or (ii) of Theorem A.5.4.1, then we can arrange that $\widetilde{\sigma}$ has the same property.

Proof. To fix ideas, let us assume that σ satisfies condition (ii) of Theorem A.5.4.1; we will show that we can choose an equivalence $\sigma \simeq \phi^* \widetilde{\sigma}$ where $\widetilde{\sigma}$ also satisfies (ii) (the proof for the case where σ satisfies (i) is similar). We proceed as in the proof of Lemma A.5.3.8. Let $\mathcal{C}$ be an ∞-category which is freely generated by $\mathbf{\Delta}_s^{\mathrm{op}} \times \Lambda^2_2$ under finite limits, so that there is a functor $u : \mathbf{\Delta}_s^{\mathrm{op}} \times \Lambda^2_2 \to \mathcal{C}$ having the following universal property: for any ∞-category $\mathcal{D}$ which admits finite limits, composition with u induces an equivalence of ∞-categories $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{C}, \mathcal{D}) \to \mathrm{Fun}(\mathbf{\Delta}_s^{\mathrm{op}} \times \Lambda^2_2, \mathcal{D})$, where $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{C}, \mathcal{D})$ denotes the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ spanned by those functors which preserve finite limits. The existence of u follows from Remark HTT.5.3.5.9 . The map u can be identified with a diagram $\overline{Y}'_\bullet \xrightarrow{\overline{g}} \overline{Y}_\bullet \xleftarrow{\overline{f}} \overline{X}_\bullet$ of semisimplicial objects of $\mathcal{C}$ which we can complete to a pullback diagram $\overline{\sigma}$:

$$\begin{array}{ccc} \overline{X}'_\bullet & \xrightarrow{\overline{g}'} & \overline{X}_\bullet \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle \overline{f}} \\ \overline{Y}'_\bullet & \xrightarrow{\overline{g}} & \overline{Y}_\bullet . \end{array}$$

Let us regard $\mathcal{C}$ as equipped with the coarsest Grothendieck topology for which the natural maps

$$\overline{X}_\bullet[\Delta^n] \to \overline{X}_\bullet[\Lambda^n_i] \times_{\overline{Y}_\bullet[\Lambda^n_i]} \overline{Y}_\bullet[\Delta^n] \quad \overline{Y}_\bullet[\Delta^n] \to \overline{Y}_\bullet[\Lambda^n_i] \quad \overline{Y}'_\bullet[\Delta^n] \to \overline{Y}'_\bullet[\Lambda^n_i] \times_{\overline{Y}_\bullet[\Lambda^n_i]} \overline{Y}_\bullet[\Delta^n]$$

are coverings. It follows from Remark A.3.1.2 that this Grothendieck topology is finitary, so Propositions A.3.1.3 and A.2.2.2 guarantee that the ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ is coherent.

Let $j : \mathcal{C} \to \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ denote the composition of the Yoneda embedding $\mathcal{C} \hookrightarrow \mathcal{P}(\mathcal{C})$ with a left adjoint to the inclusion $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}} \subseteq \mathcal{P}(\mathcal{C})$. It follows from the universal property of u that there is an essentially unique left exact functor $\rho : \mathcal{C} \to \mathcal{X}$ satisfying $\rho(\overline{\sigma}) \simeq \sigma$. Since $\mathcal{X}$ is hypercomplete and σ satisfies condition (ii) of Theorem A.5.4.1, Proposition HTT.6.2.3.20 shows that ρ admits an essentially unique factorization as a composition $\mathcal{C} \xrightarrow{j} \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}} \xrightarrow{\phi^*} \mathcal{X}$ where ϕ^* is a geometric morphism. We now complete the proof by taking $\widetilde{\sigma} = j(\overline{\sigma})$. □

Proof of Theorem A.5.4.1. Let $\mathcal{X}$ be a hypercomplete ∞-topos and suppose we are given a commutative diagram of semisimplicial objects

$$\begin{array}{ccc} X'_\bullet & \xrightarrow{g'} & X_\bullet \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y'_\bullet & \xrightarrow{g} & Y_\bullet \end{array}$$

which satisfies either (i) or (ii); we wish to show that the diagram of geometric realizations

$$\begin{array}{ccc} |X'_\bullet| & \longrightarrow & |X_\bullet| \\ \downarrow & & \downarrow \\ |Y'_\bullet| & \longrightarrow & |Y_\bullet| \end{array}$$

is a pullback square in $\mathcal{X}$. Using Lemma A.5.4.4, we can reduce to the case where $\mathcal{X}$ is locally coherent. Using Theorem A.4.0.5, we can reduce further to the case where $\mathcal{X} = \mathcal{S}$.

Applying Lemma A.5.4.3, we can choose a semisimplicial set $\overline{Y}_\bullet$ and a trivial Kan fibration $\overline{Y}_\bullet \to Y_\bullet$. Applying Lemma A.5.4.3 two more times, we can choose semisimplicial sets $\overline{X}_\bullet$ and $\overline{Y}'_\bullet$ equipped with trivial Kan fibrations

$$\overline{X}_\bullet \to \overline{Y}_\bullet \times_{Y_\bullet} X_\bullet \qquad \overline{Y}'_\bullet \to \overline{Y}_\bullet \times_{Y_\bullet} Y'_\bullet.$$

Set $\overline{X}'_\bullet = \overline{X}_\bullet \times_{\overline{Y}_\bullet} \overline{Y}'_\bullet$, so that we have a pullback square $\overline{\sigma}$:

$$\begin{array}{ccc} \overline{X}'_\bullet & \xrightarrow{\overline{g}'} & \overline{X}_\bullet \\ \downarrow{\scriptstyle \overline{f}'} & & \downarrow{\scriptstyle \overline{f}} \\ \overline{Y}'_\bullet & \xrightarrow{\overline{g}} & \overline{Y}_\bullet \end{array}$$

of semisimplicial sets. Note that if σ satisfies (i), then we can arrange that $\overline{\sigma}$ is a diagram of simplicial sets.

Applying Propositions A.5.2.11 and A.5.2.7, we see that the natural map $\overline{\sigma} \to \sigma$ induces trivial Kan fibrations

$$\overline{X}'_\bullet \to X'_\bullet \qquad \overline{X}_\bullet \to X_\bullet$$
$$\overline{Y}'_\bullet \to Y'_\bullet \qquad \overline{Y}_\bullet \to Y_\bullet$$

and therefore induces an equivalence on geometric realizations (Lemma A.5.3.7). We are therefore reduced to showing that the diagram of spaces

$$\begin{array}{ccc} |\overline{X}'_\bullet| & \longrightarrow & |\overline{X}_\bullet| \\ \downarrow & & \downarrow \\ |\overline{Y}'_\bullet| & \longrightarrow & |\overline{Y}_\bullet| \end{array}$$

is a pullback square in $\mathcal{S}$. To prove this, it will suffice to show that $\overline{\sigma}$ can be promoted to a diagram of simplicial sets :such a promotion is automatically a homotopy pullback square of simplicial sets, since the model structure on $\mathcal{S}\mathrm{et}_\Delta$ is right proper (the map $\overline{f}$ is a Kan fibration, since it is the composition of a trivial Kan fibration with a pullback of f). In case (i), this promotion is automatic; in case (ii), it can be obtained by first applying Corollary A.5.3.5 to the semisimplicial set $\overline{Y}_\bullet$, and then applying Proposition A.5.3.4 to the morphisms $\overline{f}$ and $\overline{g}$. □

A.5.5 Coherence and the Kan Condition

Let $X_\bullet$ be a simplicial set. If $X_\bullet$ satisfies the Kan condition and each of the sets X_n is finite, then the homotopy groups $\pi_k(X_\bullet, x)$ are finite for all $k \geqslant 0$ and all $x \in X_0$. In other words, the geometric realization $|X_\bullet|$ is a coherent object of the ∞-topos $\mathcal{S}$. We now generalize this observation to semisimplicial objects of an arbitrary ∞-topos:

Theorem A.5.5.1. *Let $X_\bullet$ be a semisimplicial object of an ∞-topos $\mathcal{X}$. Assume that $\mathcal{X}$ is locally n-coherent for all $n \geqslant 0$, that $X_\bullet$ satisfies the Kan condition, and that each X_k is a coherent object of $\mathcal{X}$. Then the geometric realization $|X_\bullet|$ is also a coherent object of $\mathcal{X}$.*

The proof of Theorem A.5.5.1 will require some preliminaries.

Notation A.5.5.2. Let $X_\bullet$ be a semisimplicial object of an ∞-category $\mathcal{C}$. We let $X_\bullet^+$ denote the semisimplicial object of $\mathcal{C}$ obtained by composing $X_\bullet$ with the translation functor

$$s_+ : \mathbf{\Delta}_s \to \mathbf{\Delta}_s \qquad [n] \mapsto [n] \star [0] \simeq [n+1].$$

Similarly, we let $X_\bullet^-$ denote the semisimplicial object of $\mathcal{C}$ given by composing $X_\bullet$ with the functor

$$s_- : \mathbf{\Delta}_s \to \mathbf{\Delta}_s \qquad [n] \mapsto [0] \star [n] \simeq [n+1].$$

Note that the inclusion maps $[0] \star [n] \hookleftarrow [n] \hookrightarrow [n] \star [0]$ determine maps of semisimplicial objects $X_\bullet^- \to X_\bullet \leftarrow X_\bullet^+$. Similarly, the inclusions $[0] \star [n] \hookleftarrow [0] \hookrightarrow [n] \star [0]$ induce maps $|X_\bullet^-| \to X_0 \leftarrow |X_\bullet^+|$ in the ∞-category $\mathcal{C}$ (provided that the geometric realizations $|X_\bullet^-|$ and $|X_\bullet^+|$ are well-defined).

Lemma A.5.5.3. *Let $\mathcal{X}$ be an ∞-topos and let $X_\bullet$ be a semisimplicial object of $\mathcal{X}$. If $X_\bullet$ satisfies the Kan condition, then the natural maps $X_\bullet^- \to X_\bullet \leftarrow X_\bullet^+$ are Kan fibrations.*

Proof. Let $n > 0$ and $0 \leqslant i \leqslant n$. Using Remark A.5.1.13, we can identify the canonical map

$$X_\bullet^-[\Delta^n] \to X_\bullet^-[\Lambda^n_i] \times_{X_\bullet[\Lambda^n_i]} X_\bullet[\Delta^n]$$

with the restriction map $X_\bullet[\Delta^{n+1}] \to X_\bullet[\Lambda^{n+1}_{i+1}]$, which is an effective epimorphism by virtue of our assumption that $X_\bullet$ satisfies the Kan condition. The proof for $X_\bullet^+$ is similar. □

Lemma A.5.5.4. *Let $\mathcal{X}$ be an ∞-topos and let $X_\bullet$ be a semisimplicial object of $\mathcal{X}$ which satisfies the Kan condition. Then the natural maps $|X_\bullet^-| \to X_0 \leftarrow |X_\bullet^+|$ are ∞-connective.*

Proof. We will show that the natural map $\theta : |X_\bullet^-| \to X_0$ is ∞-connective; the proof for $X_\bullet^+$ is similar. Applying Lemma A.5.3.8 to the identity map $\mathrm{id} : X_\bullet \to X_\bullet$, we can reduce to the case where the ∞-topos $\mathcal{X}$ is coherent. Using Theorem A.4.0.5, we can further reduce to the case $\mathcal{X} = \mathcal{S}$. In this case, Proposition HTT.4.2.4.4 implies that we can obtain $X_\bullet$ from a semisimplicial object $\overline{X}_\bullet$ in the ordinary category $\mathcal{S}\mathrm{et}_\Delta$ of simplicial sets. Without loss of generality, we may assume that $\overline{X}_\bullet$ is Reedy fibrant. It follows that for every nonsingular simplicial set K, the simplicial set $\overline{X}_\bullet[K]$ is a Kan complex which represents the object $X_\bullet[K] \in \mathcal{S}$. Since $X_\bullet$ satisfies the Kan condition, we conclude that each of the maps $\overline{X}_\bullet[\Delta^n] \to \overline{X}_\bullet[\Lambda^n_i]$ is a Kan fibration of simplicial sets which is surjective on connective components, and is therefore surjective on m-simplices for each $m \geqslant 0$.

For $m \geqslant 0$, let $\overline{X}_{\bullet m}$ denote the semisimplicial set obtained by evaluating $\overline{X}_\bullet$ on the object $[m] \in \mathbf{\Delta}^{\mathrm{op}}$. The preceding argument shows that each $\overline{X}_{\bullet m}$ satisfies the Kan condition. The map θ can be written as a homotopy colimit of maps $\theta_m : |\overline{X}^-_{\bullet m}| \to \overline{X}_{0m}$. It will therefore suffice to show that each θ_m is a homotopy equivalence. In other words, we may replace $X_\bullet$ with $\overline{X}_{\bullet m}$ and thereby reduce to the case where $X_\bullet$ is a semisimplicial set. Using Corollary A.5.3.5, we can promote $X_\bullet$ to a simplicial set, in which case the desired result follows from the fact that the augmented simplicial set $\mathbf{\Delta}_+ \xrightarrow{[n] \mapsto [0] \star [n]} \mathbf{\Delta} \xrightarrow{X_\bullet} \mathcal{S}\mathrm{et}$ is split. □

Proof of Theorem A.5.5.1. Let $\mathcal{X}$ be an ∞-topos which is locally n-coherent for all $n \geqslant 0$, let $X_\bullet$ be a semisimplicial object of $\mathcal{X}$ which satisfies the Kan condition, and assume that each X_k is a coherent object of $\mathcal{X}$. We wish to prove that the geometric realization $|X_\bullet|$ is also a coherent object of $\mathcal{X}$. Using Proposition A.2.2.2, we can replace $\mathcal{X}$ by its hypercompletion and thereby reduce to the case where $\mathcal{X}$ is hypercomplete.

We will show that $|X_\bullet|$ is n-coherent for each $n \geqslant 0$. The proof proceeds by induction on n. In the case $n = 0$, we must show that $|X_\bullet|$ is quasi-compact. This follows from the fact that there exists an effective epimorphism $X_0 \to |X_\bullet|$, where X_0 is quasi-compact. We now carry out the inductive step. Let $X_\bullet^+$ and $X_\bullet^-$ be defined as in Notation A.5.5.2. Combining Lemma A.5.5.3 with Theorem A.5.4.1, we deduce that the diagram σ :

$$\begin{array}{ccc} |X_\bullet^- \times_{X_\bullet} X_\bullet^+| & \xrightarrow{f} & |X_\bullet^-| \\ \downarrow & & \downarrow g \\ |X_\bullet^+| & \xrightarrow{f'} & |X_\bullet| \end{array}$$

is a pullback diagram in $\mathcal{X}$. It follows from Lemma A.5.5.3 that $X_\bullet^- \times_{X_\bullet} X_\bullet^+$ satisfies the Kan condition. Applying our inductive hypothesis, we deduce that upper left corner of the diagram σ is an $(n-1)$-coherent object of $\mathcal{X}$. The upper right corner is equivalent to

X_0 (Lemma A.5.5.4) and is therefore n-coherent. Applying Example A.2.1.2, we deduce that the morphism f is relatively $(n-1)$-coherent. Since g is an effective epimorphism, it follows that f' is also relatively $(n-1)$-coherent (Corollary A.2.1.5). Applying Proposition A.2.1.3 to the morphism f' (and using the n-coherence of $|X^+_\bullet| \simeq X_0$), we deduce that $|X_\bullet|$ is n-coherent, as desired. □

A.5.6 Triviality of Kan Fibrations

We now formulate a refinement of Theorem A.5.3.1:

Theorem A.5.6.1. *Let $f : X_\bullet \to Y_\bullet$ be a morphism of semisimplicial objects of an ∞-topos $\mathcal{X}$, where $Y_\bullet$ satisfies the Kan condition. The following conditions are equivalent:*

(1) *The morphism f is a trivial Kan fibration.*

(2) *The morphism f is a Kan fibration and the induced map $|X_\bullet| \to |Y_\bullet|$ is ∞-connective.*

Remark A.5.6.2. One can show that the conclusion of Theorem A.5.6.1 remains valid if we replace the assumption that $Y_\bullet$ satisfies the Kan condition by the assumption that f can be promoted to a morphism of simplicial objects. However, this variant of Theorem A.5.6.1 requires a proof which is somewhat different from the one we give below.

Applying Theorem A.5.6.1 in the case where $Y_\bullet$ is a final object of $\mathrm{Fun}(\mathbf{\Delta}_s^{\mathrm{op}}, \mathcal{S})$, we obtain the following:

Corollary A.5.6.3. *Let $X_\bullet$ be a semisimplicial object of an ∞-topos $\mathcal{X}$. The following conditions are equivalent:*

(1) *The semisimplicial object $X_\bullet$ is a hypercovering of $\mathcal{X}$.*

(2) *The semisimplicial object $X_\bullet$ satisfies the Kan condition and the geometric realization $|X_\bullet|$ is ∞-connective.*

Combining Corollary A.5.6.3 with Remark A.5.2.6, we obtain the following:

Corollary A.5.6.4. *Let $X_\bullet$ be a semisimplicial object of an ∞-topos $\mathcal{X}$. Then $X_\bullet$ satisfies the Kan condition if and only if it is a hypercovering of its geometric realization $|X_\bullet|$.*

The proof of Theorem A.5.6.1 will again proceed by reduction to the case $\mathcal{X} = \mathcal{S}$ by means of Deligne's theorem.

Lemma A.5.6.5. *Let $f : X_\bullet \to X'_\bullet$ be a morphism of semisimplicial objects of a hypercomplete ∞-topos $\mathcal{X}$. Assume that $X'_\bullet$ satisfies the Kan condition, f is a Kan fibration, and the geometric realization $|f| : |X_\bullet| \to |X'_\bullet|$ is an equivalence. Then we can write $f = \phi^*(g)$, where $\phi^* : \mathcal{Y} \to \mathcal{X}$ is a geometric morphism of ∞-topoi, $g : Y_\bullet \to Y'_\bullet$ is a Kan fibration between semisimplicial objects of $\mathcal{Y}$, where $Y'_\bullet$ satisfies the Kan condition and $|g|$ is an equivalence.*

Proof. We begin as in Lemma A.5.3.8. Choose a functor $u : \mathbf{\Delta}_s^{\mathrm{op}} \times \Delta^1 \to \mathcal{C}$ which freely generates $\mathcal{C}$ under finite limits, and regard u as a morphism $Z_\bullet \to Z'_\bullet$ between semisimplicial objects of $\mathcal{C}$. Let us regard $\mathcal{C}$ as equipped with the coarsest Grothendieck topology for which each of the natural maps

$$Z_\bullet[\Delta^n] \to Z'_\bullet[\Delta^n] \times_{Z'_\bullet[\Lambda^n_i]} Z_\bullet[\Lambda^n_i] \qquad Z'_\bullet[\Delta^n] \to Z'_\bullet[\Lambda^n_i]$$

is a covering. Let $j : \mathcal{C} \to \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ denote the composition of the Yoneda embedding with a left adjoint to the inclusion $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}} \hookrightarrow \mathcal{P}(\mathcal{C})$. The universal property of u implies that we can write f as a composition $\mathbf{\Delta}_s^{\mathrm{op}} \times \Delta^1 \xrightarrow{u} \mathcal{C} \xrightarrow{f'} \mathcal{X}$ where the functor f' preserves finite limits. Since f is a Kan fibration and $X'_\bullet$ satisfies the Kan condition, it follows from Proposition HTT.6.2.3.20 (together with the hypercompleteness of $\mathcal{X}$) that f' induces a geometric morphism $\psi^* : \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}} \to \mathcal{X}$ satisfying $f \simeq \psi^*(j(u))$.

Since the Grothendieck topology on $\mathcal{C}$ is finitary (Remark A.3.1.2), it follows from Propositions A.3.1.3 and A.2.2.2 that the ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ is locally coherent and that the essential image of j consists of coherent objects of $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$. Using Theorem A.5.5.1, we deduce that the geometric realizations $D = |jZ_\bullet|$ and $D' = |jZ'_\bullet|$ are coherent objects of $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$. Choose a full subcategory $\mathcal{D} \subseteq \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ containing D and D' which satisfies hypotheses (a) through (d) of Proposition A.3.4.2. Let τ denote the (finitary) Grothendieck topology described in Proposition A.3.4.2, so that the inclusion $\iota : \mathcal{D} \hookrightarrow \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ extends to an equivalence $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}} \simeq \mathcal{S}\mathrm{hv}_\tau(\mathcal{D})^{\mathrm{hyp}}$. For each $n \geqslant -1$, we let $\delta_n : D \to D' \times_{D'^{S^n}} D^{S^n}$ denote the $(n+1)$st iterated diagonal of the canonical map $D \to D'$. Let τ' denote the coarsest Grothendieck topology on $\mathcal{D}$ which refines τ and has the property that each of the morphisms δ_n generates a covering sieve. Then τ' is also a finitary Grothendieck topology (Remark A.3.1.2) so the full subcategory $\mathcal{S}\mathrm{hv}_{\tau'}(\mathcal{D})^{\mathrm{hyp}} \subseteq \mathcal{S}\mathrm{hv}_\tau(\mathcal{D})^{\mathrm{hyp}}$ is again a locally coherent ∞-topos (Propositions A.3.1.3 and A.2.2.2). Since f induces an equivalence of geometric realizations, it follows that the functor ψ^* carries each δ_n to an equivalence in $\mathcal{X}$ and therefore factors through the localization functor $L : \mathcal{S}\mathrm{hv}_\tau(\mathcal{D})^{\mathrm{hyp}} \to \mathcal{S}\mathrm{hv}_{\tau'}(\mathcal{D})^{\mathrm{hyp}}$. By construction, L carries each δ_n to an effective epimorphism in $\mathcal{S}\mathrm{hv}_{\tau'}(\mathcal{D})^{\mathrm{hyp}}$. It follows that the induced map $LD \to LD'$ is ∞-connective and therefore an equivalence (since $\mathcal{S}\mathrm{hv}_{\tau'}(\mathcal{D})^{\mathrm{hyp}}$ is hypercomplete). We now complete the proof by setting $\mathcal{Y} = \mathcal{S}\mathrm{hv}_{\tau'}(\mathcal{D})^{\mathrm{hyp}}$ and $g = L(j(u))$. □

Proof of Theorem A.5.6.1. The implication (1) ⇒ (2) follows from Theorem A.5.3.1 and Corollary A.5.2.9. We will prove the converse. Suppose that $f : X_\bullet \to Y_\bullet$ is a Kan fibration between semisimplicial objects of $\mathcal{X}$, that $Y_\bullet$ satisfies the Kan condition, and that the induced map $|f| : |X_\bullet| \to |Y_\bullet|$ is ∞-connective; we wish to show that f is a trivial Kan fibration. Replacing $\mathcal{X}$ by its hypercompletion, we can assume that $\mathcal{X}$ is hypercomplete and that $|f|$ is an equivalence. By virtue of Lemma A.5.3.8, we may assume without loss of generality that $\mathcal{X}$ is a coherent ∞-topos. By virtue of Theorem A.4.0.5, we may further reduce to the case where $\mathcal{X} = \mathcal{S}$.

Using Lemma A.5.4.3, we can choose a trivial Kan fibration $u : Y'_\bullet \to Y_\bullet$ where $Y'_\bullet$ is a semisimplicial set. Applying Lemma A.5.4.3 again, we can choose a trivial Kan fibration $X'_\bullet \to X_\bullet \times_{Y_\bullet} Y'_\bullet$ where $X'_\bullet$ is a semisimplicial set. We then have a commutative diagram

$$\begin{array}{ccc} X'_\bullet & \xrightarrow{f'} & Y'_\bullet \\ \downarrow{\scriptstyle v} & & \downarrow{\scriptstyle u} \\ X_\bullet & \xrightarrow{f} & Y_\bullet. \end{array}$$

Each term in this diagram satisfies the Kan condition and the vertical maps are trivial Kan fibrations. It follows from Theorem A.5.3.1 that the induced maps $|v| : |X'_\bullet| \to |X_\bullet|$ and $|u| : |Y'_\bullet| \to |Y_\bullet|$ are homotopy equivalences. Since the geometric realization of f is a homotopy equivalence, it follows that the geometric realization of f' is a homotopy equivalence. Using Corollary A.5.3.5, we can promote $Y'_\bullet$ to a simplicial set. The map f' is the composition of a trivial Kan fibration with a pullback of f, and is therefore a Kan fibration of semisimplicial sets. Applying Proposition A.5.3.4, we can promote f' to a map of simplicial sets $X'_\bullet \to Y'_\bullet$. Since this map induces a homotopy equivalence of geometric realizations, it is a trivial Kan fibration. It follows that the the composition $u \circ f' \simeq f \circ v$ is also a trivial Kan fibration. Since v is a trivial Kan fibration, Proposition A.5.2.11 implies that f is also a trivial Kan fibration. □

A.5.7 Hypercompleteness

We now describe an application of Theorem **??** to the problem of recognizing *hypercomplete* sheaves in the setting of §A.3. First, we need a bit more terminology.

Definition A.5.7.1. Let $\mathbf{\Delta}_{s,+}$ denote the category whose objects are linearly ordered sets of the form $[n] = \{0 < 1 < \ldots < n\}$ for $n \geqslant -1$, and whose morphisms are strictly increasing functions. If $\mathcal{C}$ is an ∞-category, we will refer to a functor $X_\bullet : \mathbf{\Delta}_{s,+}^{\mathrm{op}} \to \mathcal{C}$ as an *augmented semisimplicial object* of $\mathcal{C}$. If $\mathcal{C}$ admits finite limits, then for each $n \geqslant 0$ we can associate to $X_\bullet$ an nth matching object

$$M_n(X) = \varprojlim_{[m] \hookrightarrow [n]} X_m,$$

where the limit is taken over all injective maps $[m] \to [n]$ such that $m < n$.

Let S be a collection of morphisms in $\mathcal{C}$. We will say that an augmented semisimplicial object $X_\bullet : \mathbf{\Delta}_{s,+}^{\mathrm{op}} \to \mathcal{C}$ is an *S-hypercovering* if, for each $n \geqslant 0$, the canonical map $X_n \to M_n(X)$ belongs to S.

Proposition A.5.7.2. *Let $\mathcal{C}$ be an ∞-category and S a collection of morphisms in $\mathcal{C}$. Assume that $\mathcal{C}$ and S satisfy the conditions of Proposition A.3.2.1 and condition (e) of Proposition A.3.3.1. Let $\mathcal{D}$ be an arbitrary ∞-category and $\mathscr{F} : \mathcal{C}^{\mathrm{op}} \to \mathcal{D}$ a functor. Then $\mathscr{F}$ is a hypercomplete $\mathcal{D}$-valued sheaf on $\mathcal{C}$ if and only if the following conditions are satisfied:*

(1) *The functor $\mathscr{F}$ preserves finite products.*

(2) *Let $X_\bullet : \mathbf{\Delta}^{\mathrm{op}}_{s,+} \to \mathcal{C}$ be an S-hypercovering. Then the composite map*

$$\mathbf{\Delta}_{s,+} \xrightarrow{X_\bullet} \mathcal{C}^{\mathrm{op}} \xrightarrow{\mathscr{F}} \mathcal{D}$$

is a limit diagram.

Proof of Proposition A.5.7.2. As in the proof of Proposition A.3.3.1, we may assume without loss of generality that $\mathcal{D} = \mathcal{S}$. We first prove the "only if" direction. Assume that $\mathscr{F}$ is a hypercomplete sheaf. Condition (1) follows from Proposition A.3.3.1. To prove (2), let $F : \mathcal{C} \to \mathcal{S}\mathrm{hv}(\mathcal{C})$ denote the composition of the Yoneda embedding $\mathcal{C} \to \mathcal{P}(\mathcal{C})$ with the sheafification functor $\mathcal{P}(\mathcal{C}) \to \mathcal{S}\mathrm{hv}(\mathcal{C})$, and let $L : \mathcal{S}\mathrm{hv}(\mathcal{C}) \to \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ be a left adjoint to the inclusion. It will suffice to show that $L \circ F \circ X_\bullet$ is a colimit diagram in $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$: in other words, that $X_\bullet$ exhibits $LF(X_{-1})$ as a colimit of the diagram $\{LFX_n\}_{n \geqslant 0}$. This follows immediately from Theorem A.5.3.1, applied in the ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})_{/FX_{-1}}$.

Now suppose that (1) and (2) are satisfied. Proposition A.3.3.1 guarantees that $\mathscr{F}$ is a sheaf on $\mathcal{C}$; we wish to prove that $\mathcal{C}$ is hypercomplete. Choose an ∞-connective morphism $\alpha : \mathscr{F} \to \mathscr{G}$ in $\mathcal{S}\mathrm{hv}(\mathcal{C})$, where $\mathscr{G}$ is hypercomplete (and therefore satisfies conditions (1) and (2)). We wish to show that α is an equivalence. To prove this, it will suffice to verify the following:

(∗) Let $\alpha : \mathscr{F} \to \mathscr{G}$ be an ∞-connective morphism in $\mathcal{S}\mathrm{hv}(\mathcal{C})$, where $\mathscr{F}$ and $\mathscr{G}$ both satisfy (2). Then α is an equivalence.

To prove (∗), we will show that for every object $C \in \mathcal{C}$ and each $n \geqslant 0$, the map of spaces $\alpha_C : \mathscr{F}(C) \to \mathscr{G}(C)$ is n-connective. The proof proceeds by induction on n. If $n > 0$, then the inductive hypothesis guarantees that α_C is 0-connective; it therefore suffices to show that the diagonal map $\mathscr{F}(C) \to \mathscr{F}(C) \times_{\mathscr{G}(C)} \mathscr{F}(C)$ is $(n-1)$-connective, which also follows from the inductive hypothesis. It therefore suffices to treat the case $n = 0$: that is, we must show that the map $\mathscr{F}(C) \to \mathscr{G}(C)$ is surjective on connected components. Replacing $\mathcal{C}$ by $\mathcal{C}_{/C}$, we may assume that C is a final object of $\mathcal{C}$, so that a point $\eta \in \mathscr{G}(C)$ determines a map $\mathbf{1} \to \mathscr{G}$, where $\mathbf{1}$ denotes the final object of $\mathcal{S}\mathrm{hv}(\mathcal{C})$. Replacing $\mathscr{F}$ by $\mathscr{F} \times_{\mathscr{G}} \mathbf{1}$, we are reduced to proving the following:

(∗′) Let $\mathscr{F}$ be an ∞-connective object of $\mathcal{S}\mathrm{hv}(\mathcal{C})$ satisfying condition (2), and let $C \in \mathcal{C}$ be a final object. Then $\mathscr{F}(C)$ is nonempty.

To prove $(*')$, let $\widetilde{\mathcal{C}} \to \mathcal{C}$ be the right fibration classified by the functor $\mathscr{F} : \mathcal{C}^{\mathrm{op}} \to \mathcal{S}$. We wish to show that $\widetilde{\mathcal{C}} \times_{\mathcal{C}} \{C\}$ is nonempty. We will construct an S-hypercovering $X_\bullet : \mathbf{\Delta}_{s,+}^{\mathrm{op}} \to \mathcal{C}$ with $X_{-1} = C$ together with a lifting $Y_\bullet : \mathbf{\Delta}_s^{\mathrm{op}} \to \widetilde{\mathcal{C}}$ of $X_\bullet|_{\mathbf{\Delta}_s^{\mathrm{op}}}$. Condition (2) and Corollary HTT.3.3.3.3 guarantee that $Y_\bullet$ extends (in an essentially unique fashion) to a map $\overline{Y}_\bullet : \mathbf{\Delta}_{s,+}^{\mathrm{op}} \to \widetilde{\mathcal{C}}$ lifting $X_\bullet$, so that $\overline{Y}_{-1}$ is the required point of $\widetilde{\mathcal{C}} \times_{\mathcal{C}} \{C\}$.

The construction of $X_\bullet$ and $Y_\bullet$ proceeds in stages. Let $\mathbf{\Delta}_{s,\leqslant m}$ denote the full subcategory of $\mathbf{\Delta}_s$ spanned by the objects $[k]$ for $k \leqslant m$, and define $\mathbf{\Delta}_{s,+,\leqslant m} \subseteq \mathbf{\Delta}_{s,+}$ similarly. We define $X_\bullet^{\leqslant m} : \mathbf{\Delta}_{s,+,\leqslant m}^{\mathrm{op}} \to \mathcal{C}$ and $Y_\bullet^{\leqslant m} : \mathbf{\Delta}_{s,\leqslant m}^{\mathrm{op}} \to \widetilde{\mathcal{C}}$ by induction on m, the case $m = -1$ being trivial. Assuming that $X_\bullet^{\leqslant m-1}$ has been defined, we can define the matching object $M_m(X) \in \mathcal{C}$. The lifting $Y_\bullet^{\leqslant m-1}$ determines a map $\partial \Delta^m \to \mathscr{F}(M_m(X))$. Since $\mathscr{F}$ is ∞-connective, there exists a collection of morphisms $\{D_i \to M_m(X)\}$ which generate a covering sieve, such that each composite map $\partial \Delta^m \to \mathscr{F}(M_m(X)) \to \mathscr{F}(D_i)$ is nullhomotopic. Without loss of generality, we may assume that the set of indices D_i is finite, and that the map $\amalg D_i \to M_m(X)$ belongs to S. Let $D = \amalg D_i$. Using condition (1), we see that the composite map $\gamma : \partial \Delta^m \to \mathscr{F}(M_m(X)) \to \mathscr{F}(D)$ is nullhomotopic. We can now define the extension $X_\bullet^{\leqslant m}$ by setting $X_m = D$, and the extension $Y_\bullet^{\leqslant m}$ using the nullhomotopy γ. □

A.6 Pretopoi in Higher Category Theory

Let $\mathcal{X}$ be a locally coherent ∞-topos (see Definition A.2.1.6). Then the structure of $\mathcal{X}$ is largely determined by the full subcategory $\mathcal{X}_0 \subseteq \mathcal{X}$ spanned by the coherent objects of $\mathcal{X}$. The full subcategory $\mathcal{X}_0$ is not an ∞-topos (for example, it does not admit small colimits unless $\mathcal{X}$ is trivial), but nevertheless shares many of the defining categorical features of ∞-topoi (for example, the effectivity of groupoid objects). In this section, we will axiomatize these features by introducing the notion of a *∞-pretopos* (Definition A.6.1.1). The class of ∞-pretopoi includes all ∞-topoi $\mathcal{X}$ and is closed under passage to well-behaved full subcategories, like the full subcategory of coherent objects of a coherent ∞-topos $\mathcal{X}$ (Corollary A.6.1.7). Conversely, every ∞-pretopos $\mathcal{X}_0$ can be equipped with a finitary Grothendieck topology from which one can extract a coherent topos $\mathcal{S}\mathrm{hv}(\mathcal{X}_0)$. These processes are *approximately* inverse to one another: for a more precise statement, see Theorems **??** or **??**.

A.6.1 ∞-Pretopoi

We begin by introducing some terminology.

Definition A.6.1.1. Let $\mathcal{C}$ be an ∞-category. We will say that $\mathcal{C}$ is a *local ∞-pretopos* if it satisfies the following axioms:

(a) The ∞-category $\mathcal{C}$ admits fiber products. That is, for every pair of morphisms $f : X \to Y$ and $f' : X' \to Y$ with common codomain, there exists a fiber product

$X \times_Y X'$.

(b) The ∞-category $\mathcal{C}$ admits finite coproducts. In particular, $\mathcal{C}$ has an initial object.

(b′) The formation of finite coproducts in $\mathcal{C}$ is universal. That is, for every collection finite collection of morphisms $\{X_\alpha \to X\}$ and every map $Y \to X$, the induced map

$$\amalg_\alpha (X_\alpha \times_X Y) \to (\amalg_\alpha X_\alpha) \times_X Y$$

is an equivalence in $\mathcal{C}$.

(c) Coproducts in $\mathcal{C}$ are disjoint: that is, for every pair of objects $X, Y \in \mathcal{C}$, the fiber product $X \times_{X \amalg Y} Y$ is an initial object of $\mathcal{C}$.

(d) Every groupoid object of $\mathcal{C}$ is effective. That is, if $X_\bullet : \mathbf{\Delta}^{\mathrm{op}} \to \mathcal{C}$ is a groupoid object of $\mathcal{C}$ (see Definition HTT.6.1.2.7), then there exists a geometric realization $|X_\bullet| \in \mathcal{C}$, and the canonical diagram

$$\begin{array}{ccc} X_1 & \xrightarrow{d_0} & X_0 \\ \downarrow{\scriptstyle d_1} & & \downarrow \\ X_0 & \longrightarrow & |X_\bullet| \end{array}$$

is a pullback square in $\mathcal{C}$ (here $d_0, d_1 : X_1 \to X_0$ denote the face maps).

(d′) The formation of geometric realizations of groupoids in $\mathcal{C}$ is universal. In other words, given a morphism $f : X \to Y$ in $\mathcal{C}$ and a groupoid object $Y_\bullet$ of $\mathcal{C}_{/Y}$, the induced map $|X \times_Y Y_\bullet| \to X \times_Y |Y_\bullet|$ is an equivalence in $\mathcal{C}$.

We will say that $\mathcal{C}$ is an *∞-pretopos* if it is a local ∞-pretopos which admits a final object.

Remark A.6.1.2. In the situation of Definition A.6.1.1, it suffices to check condition (b′) in the case $X = \amalg X_\alpha$ and it suffices to check condition (d′) in the special case $X = |X_\bullet|$.

Remark A.6.1.3. Let $\mathcal{C}$ be a local ∞-pretopos. Then for every object $X \in \mathcal{C}$, the ∞-category $\mathcal{C}_{/X}$ is a local ∞-pretopos which admits a final object, and therefore an ∞-pretopos. Conversely, if $\mathcal{C}$ is an ∞-category which admits finite coproducts and $\mathcal{C}_{/X}$ is an ∞-pretopos for each $X \in \mathcal{C}$, then $\mathcal{C}$ is a local ∞-pretopos.

Remark A.6.1.4. Let $\mathcal{C}$ be a local ∞-pretopos and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a full subcategory of $\mathcal{C}$. If $\mathcal{C}_0$ is closed under fiber products, finite coproducts, and the formation of geometric realizations of groupoid objects, then $\mathcal{C}_0$ is also a local ∞-pretopos. If, in addition, $\mathcal{C}$ is an ∞-pretopos and $\mathcal{C}_0$ contains the final object of $\mathcal{C}$, then $\mathcal{C}_0$ is also an ∞-pretopos.

Example A.6.1.5. Every ∞-topos is an ∞-pretopos (Theorem HTT.6.1.0.6).

Proposition A.6.1.6. *Let $\mathcal{X}$ be an ∞-topos and let $\mathcal{X}^{\mathrm{coh}} \subseteq \mathcal{X}$ be the full subcategory spanned by the coherent objects of $\mathcal{X}$. Then $\mathcal{X}^{\mathrm{coh}}$ is a local ∞-pretopos.*

Corollary A.6.1.7. *Let $\mathcal{X}$ be a coherent ∞-topos and let $\mathcal{X}^{\mathrm{coh}} \subseteq \mathcal{X}$ be the full subcategory spanned by the coherent objects of $\mathcal{X}$. Then $\mathcal{X}^{\mathrm{coh}}$ is an ∞-pretopos.*

Proof of Proposition A.6.1.6. The ∞-topos $\mathcal{X}$ itself is a local ∞-pretopos (Example A.6.1.5). Consequently, to show that the full subcategory $\mathcal{X}^{\mathrm{coh}} \subseteq \mathcal{X}$ is a local ∞-pretopos, it will suffice to show that $\mathcal{X}^{\mathrm{coh}}$ is closed under finite coproducts, fiber products, and the geometric realization of groupoid objects (Remark A.6.1.4). The first two assertions follow from Remark A.2.1.8. To prove the third, suppose that $X_\bullet$ is a groupoid object of $\mathcal{X}^{\mathrm{coh}}$, and set $X = |X_\bullet|$ (where the geometric realization is formed in $\mathcal{X}$). Since groupoid objects of $\mathcal{X}$ are effective, we have a pullback square

$$\begin{array}{ccc} X_1 & \longrightarrow & X_0 \\ \downarrow & & \downarrow \\ X_0 & \longrightarrow & X \end{array}$$

in the ∞-topos $\mathcal{X}$. Since X_0 and X_1 are coherent objects of $\mathcal{X}$, the upper horizontal morphism in this diagram is n-coherent for each integer n (Example A.2.1.2). Since the vertical maps in this diagram are effective epimorphisms, it follows that the lower horizontal map is also n-coherent for every integer n (Corollary A.2.1.5). Applying Proposition A.2.1.3 (and the coherence of X_0), we deduce that X is $(n+1)$-coherent. Allowing n to vary, we deduce that X is coherent, as desired. $\square$

A.6.2 The Effective Epimorphism Topology

Let $\mathcal{C}$ be an ∞-category which admits fiber products. For each morphism $f : U \to X$ in $\mathcal{C}$, the *Čech nerve* of f is the simplicial object $U_\bullet$ of $\mathcal{C}_{/X}$ depicted in the diagram

$$\cdots \substack{\longrightarrow\\\longrightarrow\\\longrightarrow} U \times_X U \rightrightarrows U,$$

so that U_n is the $(n+1)$-fold fiber product of U with itself over X. We will say that f is an *effective epimorphism* if the above diagram exhibits X as a geometric realization of $U_\bullet$ in the ∞-category $\mathcal{C}$. When $\mathcal{C}$ is a local ∞-pretopos, the class of effective epimorphisms has many good properties.

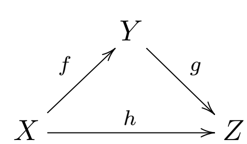
Proposition A.6.2.1. *Let $\mathcal{C}$ be a local ∞-pretopos. Then $\mathcal{C}$ admits a factorization system (see Definition HTT.5.2.8.8) (S_L, S_R), where S_L is the collection of effective epimorphisms in $\mathcal{C}$ and S_R is the collection of (-1)-truncated morphisms of $\mathcal{C}$.*

Proof. It is easy to see that S_L and S_R are closed under retracts. We next claim that every morphism $f : U \to X$ belonging to S_L is left orthogonal to every morphism $g : V \to Y$ belonging to S_R. To prove this, we can replace $\mathcal{C}$ by $\mathcal{C}_{/Y}$ and thereby reduce to the case where Y is a final object of $\mathcal{C}$. We wish to show that the canonical map $\theta : \mathrm{Map}_{\mathcal{C}}(X, V) \to \mathrm{Map}_{\mathcal{C}}(U, V)$ is a homotopy equivalence. Let $U_\bullet$ be the Čech nerve of f; our assumption that f is an effective epimorphism guarantees that we can identify X with the geometric realization $|U_\bullet|$, so that the domain of θ can be identified with the totalization of the cosimplicial space $\mathrm{Map}_{\mathcal{C}}(U_\bullet, V)$. Note that our assumption that g is (-1)-truncated guarantees that each of the spaces $\mathrm{Map}_{\mathcal{C}}(U_n, V)$ is either empty or contractible. Since there exist morphisms $[m] \to [n]$ in $\mathbf{\Delta}$ for every pair of integers $m, n \geqslant 0$, either $\mathrm{Map}_{\mathcal{C}}(U_n, V)$ is empty for all $n \geqslant 0$ (in which case θ is a map between empty spaces) or $\mathrm{Map}_{\mathcal{C}}(U_n, V)$ is contractible for all $n \geqslant 0$ (in which case θ is a morphism between contractible spaces). In either case, the map θ is automatically a homotopy equivalence.

To complete the proof that (S_L, S_R) is a factorization system on $\mathcal{C}$, it will suffice to show that every morphism $f : U \to X$ in $\mathcal{C}$ admits a factorization $U \xrightarrow{f_L} V \xrightarrow{f_R} X$ where f_L is an effective epimorphism and f_R is (-1)-truncated. To prove this, we let $U_\bullet$ denote the Čech nerve of f and $V = |U_\bullet|$. Since $\mathcal{C}$ is a local ∞-pretopos, the groupoid $U_\bullet$ is effective and therefore f_L is an effective epimorphism. It remains to show that f_R is (-1)-truncated: that is, that the diagonal map $V \simeq V \times_V V \xrightarrow{\delta} V \times_X V$ is an equivalence. Because $\mathcal{C}$ is a local ∞-pretopos, the formation of geometric realizations of groupoid objects of $\mathcal{C}$ commutes with pullbacks, so we can identify δ with the geometric realization of a map of bisimplicial objects $\delta_{\bullet\bullet} : U_\bullet \times_V U_\bullet \to U_\bullet \times_X U_\bullet$. We now observe that each δ_{mn} is the pullback of the map $\delta_{00} : U \times_V U \to U \times_X U \simeq U_1$, which is an equivalence by virtue of the fact that $U_\bullet$ is an effective groupoid object of $\mathcal{C}$. □

Corollary A.6.2.2. *Let $\mathcal{C}$ be a local ∞-pretopos.*

(a) Suppose we are given a commutative diagram



in $\mathcal{C}$ where f is an effective epimorphism. Then g is an effective epimorphism if and only if h is an effective epimorphism. In particular, the collection of effective epimorphisms is closed under composition.

(*b*) *Suppose we are given a pullback square*

$$\begin{array}{ccc} U' & \xrightarrow{g'} & U \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ X' & \xrightarrow{g} & X \end{array}$$

in the ∞-category $\mathcal{C}$. If f is an effective epimorphism, then so is f'. The converse holds if g is an effective epimorphism.

(*c*) *Let $\{f_\alpha : U_\alpha \to X_\alpha\}$ be a finite collection of effective epimorphisms in $\mathcal{C}$. Then the induced map $\amalg f_\alpha : \amalg U_\alpha \to \amalg X_\alpha$ is an effective epimorphism.*

Proof. Assertions (a) and (c) follow from Propositions A.6.2.1 and HTT.5.2.8.6. Let us prove (b). Suppose we are given a pullback square

$$\begin{array}{ccc} U' & \xrightarrow{g'} & U \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ X' & \xrightarrow{g} & X. \end{array}$$

in the ∞-category $\mathcal{C}$. Let $U_\bullet$ be the Čech nerve of f, so that $X' \times_X U_\bullet$ can be identified with the Čech nerve of f'. Since the formation of geometric realizations of groupoid objects in $\mathcal{C}$ commutes with pullback, we have a pullback square

$$\begin{array}{ccc} |X' \times_X U_\bullet| & \longrightarrow & |U_\bullet| \\ \downarrow & & \downarrow \\ X' & \xrightarrow{g'} & X. \end{array}$$

Consequently, if f is an effective epimorphism, then so is f'. Conversely, suppose that g and f' are effective epimorphisms. Then the preceding argument shows that g' is an effective epimorphism. It follows from (a) that $g \circ f' = f \circ g'$ is an effective epimorphism, so that f is an effective epimorphism by a second application of (a). □

Corollary A.6.2.3. *Let $\mathcal{C}$ be a local ∞-pretopos. Then $\mathcal{C}$ admits a Grothendieck topology which can be described as follows: a collection of morphisms $\{f_\alpha : U_\alpha \to X\}_{\alpha \in A}$ in $\mathcal{C}$ generate a covering sieve if and only if there exists a finite subset $A_0 \subseteq A$ such that the induced map $\amalg_{\alpha \in A_0} U_\alpha \to X$ is an effective epimorphism.*

Proof. It suffices to show that the collection of effective epimorphisms satisfies conditions (a) through (d) of Proposition A.3.2.1. Conditions (a) through (c) follow from Corollary A.6.2.2, while condition (d) follows from our assumption that $\mathcal{C}$ is a local ∞-pretopos. □

Definition A.6.2.4. Let $\mathcal{C}$ be a local ∞-pretopos. We will refer to the Grothendieck topology of Corollary A.6.2.3 as the *effective epimorphism topology*. We let $\mathcal{S}\mathrm{hv}(\mathcal{C})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ spanned by those functors which are sheaves with respect to the effective epimorphism topology.

Applying Proposition A.3.3.1, we immediately obtain the following:

Proposition A.6.2.5. *Let $\mathcal{C}$ be a local ∞-pretopos and let $\mathscr{F} : \mathcal{C}^{\mathrm{op}} \to \mathcal{S}$ be a functor. Then $\mathscr{F}$ is a sheaf (with respect to the effective epimorphism topology) if and only if it satisfies the following conditions:*

(1) *For every finite collection of objects $\{X_\alpha\}_{\alpha \in A}$ in $\mathcal{C}$, the canonical map $\mathscr{F}(\amalg X_\alpha) \to \prod \mathscr{F}(X_\alpha)$ is a homotopy equivalence.*

(2) *For every effective epimorphism $f : U \to X$ in $\mathcal{C}$ having Čech nerve $U_\bullet$, the induced map $\mathscr{F}(X) \to \mathrm{Tot}\, \mathscr{F}(U_\bullet)$ is a homotopy equivalence.*

Corollary A.6.2.6. *Let $\mathcal{C}$ be a local ∞-pretopos. Then the effective epimorphism topology on $\mathcal{C}$ is subcanonical: that is, the Yoneda embedding $j : \mathcal{C} \hookrightarrow \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ factors through $\mathcal{S}\mathrm{hv}(\mathcal{C})$.*

A.6.3 Subobjects

We now describe explicate one relationship between our theory of ∞-pretopoi (Definition A.6.1.1) and the classical theory of distributive lattices (Definition A.1.4.5).

Notation A.6.3.1. Let X be an object of an ∞-category $\mathcal{C}$. Recall that a *subobject of* X is a (-1)-truncated morphism $\iota : U \to X$ in $\mathcal{C}$. We will often abuse terminology by referring to the object $U \in \mathcal{C}$ as a *subobject of* X (in which case we implicitly assume that a (-1)-truncated morphism $U \to X$ has been specified). If U and V are subobjects of X, we write $U \subseteq V$ if there exists a commutative diagram

$$\begin{array}{ccc} U & \xrightarrow{f} & V \\ & \searrow \quad \swarrow & \\ & X. & \end{array}$$

Note that since the map $V \to X$ is (-1)-truncated, the morphism f is unique up to a contractible space of choices (provided that f exists).

If U and V are subobjects of an object $X \in \mathcal{C}$, we say that U and V are *equivalent* if they are equivalent when viewed as objects of $\mathcal{C}_{/X}$ (in other words, if $U \subseteq V$ and $V \subseteq U$). We let $\mathrm{Sub}(X)$ denote the collection of equivalence classes of subobjects of X. We will generally abuse notation by identifying a subobject U of X with the corresponding element of $\mathrm{Sub}(X)$.

We regard $\mathrm{Sub}(X)$ as a partially ordered set with respect to the inclusion relation $\subseteq$ defined above.

Remark A.6.3.2. Let X be an object of an ∞-category $\mathcal{C}$. Then the partially ordered set $\mathrm{Sub}(X)$ can be regarded as an ∞-category, which is equivalent to the full subcategory of $\mathcal{C}_{/X}$ spanned by the (-1)-truncated objects. This equivalence determines a fully faithful embedding $\mathrm{Sub}(X) \hookrightarrow \mathcal{C}_{/X}$. If $\mathcal{C}$ is a local ∞-pretopos, then Proposition A.6.2.1 implies that this fully faithful embedding admits a left adjoint $L : \mathcal{C}_{/X} \to \mathrm{Sub}(X)$. For each object $U \in \mathcal{C}_{/X}$, the underlying map $f : U \to X$ admits an essentially unique factorization $U \xrightarrow{f'} LU \xrightarrow{f''} X$, where f' is an effective epimorphism and f'' is (-1)-truncated. Consequently, the object LU can be described explicitly as the geometric realization $|U_\bullet|$, where $U_\bullet$ is the groupoid object of $\mathcal{C}$ given by the Čech nerve of f (which is the same as the Čech nerve of f', by virtue of the fact that f'' is (-1)-truncated).

Proposition A.6.3.3. *Let $\mathcal{C}$ be a local ∞-pretopos. Then, for each $X \in \mathcal{C}$, the partially ordered set* $\mathrm{Sub}(X)$ *is a distributive lattice.*

Proof. Let us abuse notation by identifying $\mathrm{Sub}(X)$ with the full subcategory of $\mathcal{C}_{/X}$ spanned by the (-1)-truncated objects. Let $L : \mathcal{C}_{/X} \to \mathrm{Sub}(X)$ be a left adjoint to the inclusion (see Remark A.6.3.2). Note that $\mathrm{Sub}(X)$ is closed under all limits which exist in $\mathcal{C}_{/X}$. Since $\mathcal{C}$ admits pullbacks, the ∞-category $\mathcal{C}_{/X}$ admits finite products so that $\mathrm{Sub}(X)$ is a lower semilattice. Since $\mathcal{C}$ admits finite coproducts, the partially ordered set $\mathrm{Sub}(X)$ admits finite joins which are given by the formula $\bigvee_{i \in I} U_i = L(\bigwedge_{i \in I} U_i)$. This proves that the partially ordered set $\mathrm{Sub}(X)$ is a lattice. To show that this lattice is distributive, it will suffice to show that for every triple of subobjects $U, V, W \in \mathrm{Sub}(X)$, the inclusion $(U \wedge V) \vee (U \wedge W) \subseteq U \wedge (V \vee W)$ is an equality. Unwinding the definitions, we see that this is equivalent to the requirement that the composite map

$$(U \times_X V) \amalg (U \times_X W) \xrightarrow{f} U \times_X (V \amalg W) \xrightarrow{g} U \times_X L(V \amalg W)$$

is an effective epimorphism. Our assumption that $\mathcal{C}$ is a local ∞-pretopos guarantees that f is an equivalence, and the morphism g is a pullback of the natural map $V \amalg W \to L(V \amalg W)$ and is therefore an effective epimorphism by virtue of Corollary A.6.2.2. □

Remark A.6.3.4 (Functoriality)**.** Let $\mathcal{C}$ be a local ∞-pretopos and let $f : X \to Y$ be a morphism in $\mathcal{C}$. Then the construction $U \mapsto U \times_Y X$ determines a functor $f^* : \mathcal{C}_{/Y} \to \mathcal{C}_{/X}$. This functor is left exact (since it is right adjoint to the functor $f_! : \mathcal{C}_{/X} \to \mathcal{C}_{/Y}$ given by composition with f) and therefore carries (-1)-truncated objects to (-1)-truncated objects. It therefore induces a map of partially ordered sets $f^* : \mathrm{Sub}(Y) \to \mathrm{Sub}(X)$. We claim that $f^* : \mathrm{Sub}(Y) \to \mathrm{Sub}(X)$ is a homomorphism of distributive lattices (Definition A.1.5.3): that is, it preserves finite joins and finite meets. The preservation of finite meets follows from left exactness. For the case of joins, we must show that for every finite collection of objects $\{U_i\}_{i \in I}$ of $\mathrm{Sub}(Y)$, the inclusion $\bigvee_{i \in I} f^* U_i \subseteq f^*(\bigvee_{i \in I} U_i)$ is an equality. Unwinding the definitions, this is equivalent to the requirement that the composite map

$$\amalg_{i \in I} f^* U_i \xrightarrow{\rho} f^*(\amalg_{i \in I} U_i) \xrightarrow{\rho'} f^*(\bigvee_{i \in I} U_i)$$

is an effective epimorphism in $\mathcal{C}$. The map ρ is an equivalence (since finite coproducts in $\mathcal{C}$ are universal) and the map ρ' is a pullback of the effective epimorphism $\amalg_{i \in I} U_i \to \bigvee_{i \in I} U_i$, hence an effective epimorphism by virtue of Corollary A.6.2.2.

Proposition A.6.3.5. *Let $\mathcal{C}$ be a local ∞-pretopos and let $f : X \to Y$ be an effective epimorphism in $\mathcal{C}$. The following conditions are equivalent:*

(a) *The morphism f is an effective epimorphism.*

(b) *The induced map of distributive lattices $f^* : \mathrm{Sub}(Y) \to \mathrm{Sub}(X)$ is injective.*

Proof. We first show that (a) implies (b). Suppose that f is an effective epimorphism and that we are given subobjects $U, V \in \mathrm{Sub}(Y)$ satisfying $f^* U = f^* V$ in $\mathrm{Sub}(X)$; we wish to show that $U = V$. We will show that the projection maps $U \leftarrow U \times_X V \to V$ are equivalences in $\mathcal{C}$. Since both projections are (-1)-truncated morphisms, it will suffice to show that they are effective epimorphisms. By virtue of Corollary A.6.2.2, we are reduced to proving that the induced maps

$$U \times_X Y \leftarrow U \times_X V \times_X Y \to V \times_X Y$$

are effective epimorphisms. However, both of these maps are equivalences, since assumption (a) gives

$$f^* U = (f^* U) \wedge (f^* V) = f^*(U \wedge V) = (f^* U) \wedge (f^* V) = f^* V$$

in the partially ordered set $\mathrm{Sub}(X)$.

Now suppose that (b) is satisfied. It follows from Proposition A.6.2.1 that the morphism f factors as a composition $X \xrightarrow{f'} U \xrightarrow{f''} Y$ where f' is an effective epimorphism and f'' is (-1)-truncated. Then $f^* U = f^* Y$ in $\mathrm{Sub}(X)$, so condition (b) implies that $U = Y$ in $\mathrm{Sub}(Y)$: that is, the morphism f'' is an equivalence. It follows that $f \simeq f'' \circ f'$ is a composition of effective epimorphisms, and therefore an effective epimorphism as desired. □

Remark A.6.3.6. Let $\mathcal{C}$ be an ∞-pretopos containing an object X, and suppose we are given a pair of (-1)-truncated morphisms $U \to X \leftarrow V$. The following conditions are equivalent:

(i) The induced map $U \amalg V \to X$ is (-1)-truncated.

(ii) The fiber product $U \times_X V$ is an initial object of $\mathcal{C}$.

To prove this, we note that since coproducts in $\mathcal{C}$ are universal, assertion (i) is equivalent to statement that the composite map

$$\begin{aligned} U \amalg V &\simeq (U \times_X U) \amalg (V \times_X V) \\ &\to (U \times_X U) \amalg (V \times_X U) \amalg (U \times_X V) \amalg (V \times_X V) \\ &\simeq (U \amalg V) \times_X (U \times_X V) \end{aligned}$$

is an equivalence. The equivalence of this statement with (ii) follows from the disjointness of coproducts in $\mathcal{C}$.

Remark A.6.3.7. Let $f : U \to X$ be a morphism in a local ∞-pretopos $\mathcal{C}$. Using Remark A.6.3.6, we deduce that the following conditions are equivalent:

(i) The morphism f is (-1)-truncated and exhibits U as a complemented element of the distributive lattice $\mathrm{Sub}(X)$ (in other words, there exists an subobject $V \in \mathrm{Sub}(X)$ satisfying $U \wedge V = \emptyset$ and $U \vee V = X$).

(ii) There exists a morphism $g : V \to X$ such that f and g induce an equivalence $U \amalg V \xrightarrow{(f,g)} X$ (note that since coproducts in $\mathcal{C}$ are disjoint, this automatically guarantees that f and g are (-1)-truncated).

If these conditions are satisfied, then the morphism $g : V \to X$ appearing in (ii) is essentially unique (see Remark A.1.6.1).

Definition A.6.3.8. Let $\mathcal{C}$ be a local ∞-pretopos. We will say that $\mathcal{C}$ is *Boolean* if, for every object $X \in \mathcal{C}$, the distributive lattice $\mathrm{Sub}(X)$ is a Boolean algebra.

Remark A.6.3.9. Let $\mathcal{C}$ be a local ∞-pretopos. If $\mathcal{C}$ is Boolean, then every (-1)-truncated morphism $f : U \to X$ in $\mathcal{C}$ determines an essentially unique decomposition of $X \simeq U \amalg V$ in $\mathcal{C}$ (Remark A.6.3.7).

A.6.4 The Universal Property of $\mathcal{S}\mathrm{hv}(\mathcal{C})$

The collection of all ∞-pretopoi can be organized into an ∞-category.

Definition A.6.4.1. Let $\mathcal{C}$ and $\mathcal{C}'$ be ∞-pretopoi. We let $\mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{C}')$ denote the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{C}')$ spanned by those functors $f : \mathcal{C} \to \mathcal{C}'$ which preserve finite limits, finite coproducts, and carry effective epimorphisms in $\mathcal{C}$ to effective epimorphisms in $\mathcal{C}'$. We will refer to $\mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{C}')$ as the *∞-category of ∞-pretopos morphisms from $\mathcal{C}$ to $\mathcal{C}'$*.

We let $\infty\widehat{\mathcal{T}\text{op}}^{\text{pre}}$ denote the subcategory of $\widehat{\mathcal{C}\text{at}}_\infty$ whose objects are (not necessarily small) ∞-pretopoi and whose morphisms are functors which preserve finite limits, finite coproducts, and effective epimorphisms, and we let $\infty\mathcal{T}\text{op}^{\text{pre}}$ denote the full subcategory of $\infty\widehat{\mathcal{T}\text{op}}^{\text{pre}}$ spanned by those ∞-pretopoi which are essentially small.

Example A.6.4.2. Let $f^* : \mathcal{X} \to \mathcal{Y}$ be a geometric morphism of ∞-topoi. Then f^* is a morphism of ∞-pretopoi: it preserves finite limits and small colimits by definition, and preserves effective epimorphisms by virtue of Remark HTT.6.2.3.6 . Consequently, we can regard the ∞-category $\infty\mathcal{T}\text{op}^{\text{op}}$ as a (non-full) subcategory of $\infty\widehat{\mathcal{T}\text{op}}^{\text{pre}}$.

Example A.6.4.3. Let $\mathcal{C}$ be a local ∞-pretopos and let $f : C \to D$ be a morphism in $\mathcal{C}$. Then the construction $(D' \in \mathcal{C}_{/D}) \mapsto (C \times_D D' \in \mathcal{C}_{/C})$ determines an ∞-pretopos morphism from $\mathcal{C}_{/D}$ to $\mathcal{C}_{/C}$.

Proposition A.6.4.4. *Let $\mathcal{C}$ be an essentially small ∞-pretopos and let $\mathcal{X}$ be an ∞-topos. Then composition with the Yoneda embedding $j : \mathcal{C} \to \mathcal{S}\text{hv}(\mathcal{C})$ induces an equivalence of ∞-categories* $\text{Fun}^*(\mathcal{S}\text{hv}(\mathcal{C}), \mathcal{X}) \to \text{Fun}^{\text{pre}}(\mathcal{C}, \mathcal{X})$*; here* $\text{Fun}^*(\mathcal{S}\text{hv}(\mathcal{C}), \mathcal{X})$ *denotes the full subcategory of* $\text{Fun}(\mathcal{S}\text{hv}(\mathcal{C}), \mathcal{X})$ *spanned by those functors which preserve small colimits and finite limits.*

Remark A.6.4.5. Proposition A.6.4.4 implies that we can regard the construction $\mathcal{C} \mapsto \mathcal{S}\text{hv}(\mathcal{C})$ as a *partially defined* left adjoint to the inclusion functor $\infty\mathcal{T}\text{op}^{\text{op}} \hookrightarrow \infty\widehat{\mathcal{T}\text{op}}^{\text{pre}}$. It is not quite a left adjoint because Proposition A.6.4.4 requires the ∞-pretopos $\mathcal{C}$ to be essentially small, but the ∞-topos $\mathcal{X}$ will almost never be essentially small.

Proof of Proposition A.6.4.4. By virtue of Proposition HTT.6.2.3.20 , composition with j induces a fully faithful embedding $\text{Fun}^*(\mathcal{S}\text{hv}(\mathcal{C}), \mathcal{X}) \to \text{Fun}(\mathcal{C}, \mathcal{X})$ whose essential image is spanned by those left exact functors $f : \mathcal{C} \to \mathcal{X}$ which satisfy the following additional condition:

$(*)$ For every collection of morphisms $\{u_\alpha : U_\alpha \to V\}_{\alpha \in A}$ in $\mathcal{C}$ which generate a covering sieve with respect to the effective epimorphism topology, the induced map $\rho : \amalg f(U_\alpha) \to f(V)$ is an effective epimorphism in the ∞-topos $\mathcal{X}$.

Note that in verifying $(*)$, we may assume without loss of generality that the set A is finite, so that the maps u_α determine an effective epimorphism $u : \amalg U_\alpha \to V$ in the ∞-pretopos $\mathcal{C}$. If f commutes with finite coproducts, then we can identify ρ with $f(u)$. Consequently, if f is a morphism of ∞-pretopoi, then f satisfies $(*)$. We now prove the converse. Suppose that f is a left exact functor which satisfies $(*)$. Applying $(*)$ in the case where A is a singleton, we deduce that f preserves effective epimorphisms. Applying $(*)$ in the case where A is empty, we deduce that f preserves initial objects. To complete the proof, it will suffice to show that f preserves pairwise coproducts. Let U and U' be objects of $\mathcal{C}$. Since coproducts in $\mathcal{C}$ are disjoint, we have a pullback square

$$\begin{array}{ccc} \emptyset & \longrightarrow & U \\ \downarrow & & \downarrow \\ U' & \longrightarrow & U \amalg U' \end{array}$$

in the ∞-category $\mathcal{C}$, where $\emptyset$ is an initial object of $\mathcal{C}$. Note that each of the morphisms in this diagram is (-1)-truncated. Applying the left exact functor f, we obtain a pullback square

$$\begin{array}{ccc} f(\emptyset) & \longrightarrow & f(U) \\ \downarrow & & \downarrow \\ f(U') & \longrightarrow & f(U \amalg U') \end{array}$$

in the ∞-topos $\mathcal{X}$, where each morphism is (-1)-truncated. Since $f(\emptyset)$ is an initial object of $\mathcal{X}$, the induced map $f(U) \amalg f(U') \to f(U \amalg U')$ is (-1)-truncated. To show that this map is an equivalence, it suffices to show that it is an effective epimorphism, which follows by applying $(*)$ to the pair of maps $\{U \to U \amalg U', U' \to U \amalg U'\}$. □

A.6.5 Hypercomplete ∞-Pretopoi

Let $\mathcal{C}$ be a small local ∞-pretopos. Then the Yoneda embedding $j : \mathcal{C} \to \mathcal{S}\mathrm{hv}(\mathcal{C})$ is fully faithful. We now describe some additional conditions on $\mathcal{C}$ which guarantee that the essential image of j admits a simple description.

Definition A.6.5.1. Let $\mathcal{C}$ be a local ∞-pretopos. We will say that a semisimplicial object $X_\bullet$ of $\mathcal{C}$ *satisfies the Kan condition* if, for $n > 0$ and $0 \leqslant i \leqslant n$, the natural map $X_n = X_\bullet[\Delta^n] \to X_\bullet[\Lambda^n_i]$ is an effective epimorphism (note that $X_\bullet[\Lambda^n_i]$ is well-defined by virtue of the assumption that $\mathcal{C}$ admits fiber products: see Proposition A.5.1.9).

If $\mathcal{C}$ is an ∞-pretopos, we will say that a semisimplicial object $X_\bullet$ of $\mathcal{C}$ is a *hypercovering* if the natural map $X_n = X_\bullet[\Delta^n] \to X_\bullet[\partial\,\Delta^n]$ is an effective epimorphism for $n \geqslant 0$. More generally, if $\mathcal{C}$ is a local ∞-pretopos containing an object X, then we will say that a semisimplicial object $X_\bullet$ of $\mathcal{C}_{/X}$ is a *hypercovering of* X if it is a hypercovering of the ∞-pretopos $\mathcal{C}_{/X}$.

Remark A.6.5.2. In the special case where $\mathcal{C}$ is an ∞-topos, Definition A.6.5.1 recovers the notions of Kan condition and hypercover given in Definition A.5.2.3.

Definition A.6.5.3. Let $\mathcal{C}$ be a local ∞-pretopos. We will say that $\mathcal{C}$ is *hypercomplete* if it satisfies the following conditions:

(a) Every simplicial object $X_\bullet$ of $\mathcal{C}$ which satisfies the Kan condition, there exists an object $X \in \mathcal{C}$ such that $X_\bullet$ can be lifted to a simplicial object of $\mathcal{C}_{/X}$ which is a hypercovering of X.

(b) If $X \in \mathcal{C}$ and $X_\bullet$ is a simplicial object of $\mathcal{C}_{/X}$ which is a hypercovering of X, then X is a colimit of the diagram $\mathbf{\Delta}^{\mathrm{op}} \xrightarrow{X_\bullet} \mathcal{C}_{/X} \to \mathcal{C}$.

Remark A.6.5.4. In the situation of Definition A.6.5.3, the converse of assertion (a) is always true: if $X_\bullet$ is a hypercovering of an object $X \in \mathcal{C}$, then the image of $X_\bullet$ under the forgetful functor $\mathcal{C}_{/X} \to \mathcal{C}$ satisfies the Kan condition (see Remark A.5.2.6).

Remark A.6.5.5. Let $\mathcal{C}$ be a local ∞-pretopos. If $\mathcal{C}$ satisfies condition (b) of Definition A.6.5.3 and $X_\bullet$ is a simplicial object of $\mathcal{C}$ which satisfies the Kan condition, then the object X appearing in condition (a) is determined uniquely up to equivalence: condition (b) supplies an equivalence $X \simeq |X_\bullet|$.

Proposition A.6.5.6. *Let $\mathcal{X}$ be an ∞-topos. Then $\mathcal{X}$ is hypercomplete as an ∞-topos (in the sense of Definition HTT.6.5.2) if and only if it is hypercomplete as an ∞-pretopos (in the sense of Definition A.6.5.3).*

Proof. If $\mathcal{X}$ satisfies condition (b) of Definition A.6.5.3, then it is hypercomplete as an ∞-topos by virtue of Theorem HTT.6.5.3.12 . Conversely, suppose that $\mathcal{X}$ is hypercomplete as an ∞-topos. If $X_\bullet$ is a semisimplicial object of $\mathcal{X}$ which is a hypercovering of an object $X \in \mathcal{X}$, then the canonical map $|X_\bullet| \to X$ is ∞-connective (Theorem A.5.3.1) and therefore an equivalence (since $\mathcal{X}$ is hypercomplete). This verifies condition (b) of Definition A.6.5.3. If $X_\bullet$ is a semisimplicial object of $\mathcal{X}$ which satisfies the Kan condition, then Corollary A.5.6.4 shows that $X_\bullet$ is a hypercovering of its geometric realization, which verifies condition (a). □

Proposition A.6.5.7. *Let $\mathcal{X}$ be an ∞-topos and let $\mathcal{X}_0 \subseteq \mathcal{X}$ be a full subcategory which satisfies the following conditions:*

(a) *The full subcategory $\mathcal{X}_0 \subseteq \mathcal{X}$ is closed under finite coproducts.*

(b) *The full subcategory $\mathcal{X}_0 \subseteq \mathcal{X}$ is closed under fiber products.*

(c) *Every object $X \in \mathcal{X}_0$ is quasi-compact.*

(d) *For every object $X \in \mathcal{X}$, there exists an effective epimorphism $\amalg U_\alpha \to X$, where each U_α belongs to X.*

(e) *For every object $X \in \mathcal{X}$ and every simplicial object $U_\bullet$ of $\mathcal{X}_{/X}$ which is a hypercovering of X, if each U_n belongs to $\mathcal{X}_0$, then X belongs to $\mathcal{X}_0$.*

Then $\mathcal{X}_0$ is the full subcategory of $\mathcal{X}$ spanned by the coherent objects.

Proof. We first prove by induction on k that each each $X \in \mathcal{X}_0$ is a k-coherent object of $\mathcal{X}$. In the case $k = 0$, this follows from (c). Suppose that $k > 0$. It follows from (d) and our inductive hypothesis that the ∞-topos $\mathcal{X}_{/X}$ is locally k-coherent. Let U and V be $(k-1)$-coherent objects of $\mathcal{X}_{/X}$; we wish to show that $U \times_X V$ is $(k-1)$-coherent. Since $k > 0$, the objects U and V are quasi-compact. Using (a) and (d), we can choose effective epimorphisms $u : U' \to U$ and $v : V' \to V$ where $U', V' \in \mathcal{X}_0$. Then U' and V' are $(k-1)$-coherent by our inductive hypothesis, so the morphisms u and v are relatively $(k-1)$-coherent (Example A.2.1.2). It follows that the induced map $U' \times_X V' \to U \times_X V$ is an effective epimorphism which is relatively $(k-1)$-coherent. It follows from (b) that the fiber product $U' \times_X V'$ belongs to $\mathcal{X}_0$ and is therefore $(k-1)$-coherent by our inductive hypothesis, so that $U \times_X V$ is $(k-1)$-coherent by virtue of Proposition A.2.1.3. Allowing k to vary, we deduce that each object of $\mathcal{X}_0$ is coherent.

We now prove the converse. Let $X \in \mathcal{X}$ be a coherent object; we wish to prove that $X \in \mathcal{X}_0$. By virtue of (e), it will suffice to show that there exists simplicial object $U_\bullet$ of $\mathcal{X}_{/X}$ which is a hypercovering of X, such that $U_n \in \mathcal{X}_0$ for all $n \geqslant 0$. We will construct $U_\bullet$ as the union of a compatible sequence of functors $F_{\leqslant n} : \mathbf{\Delta}^{\mathrm{op}}_{\leqslant n} \to \mathcal{X}_0 \times_{\mathcal{X}} \mathcal{X}_{/X}$ which have the following additional property:

$(*_n)$ For $m \leqslant n+1$, let L_m denote the mth latching object of $F_{\leqslant n}$: that is, the colimit $\varinjlim_{[k] \hookrightarrow [m], k<m} F_{\leqslant n}([k])$. Then the natural map $L_m \to F_{\leqslant n}([m])$ exhiibits L_m as a summand of $F_{\leqslant n}([m])$: that is, we have an equivalence $F_{\leqslant n}([m]) \simeq L_m \amalg A_m$ for some auxiliary object $A_m \in \mathcal{X}_0$.

Let us assume that we have already constructed the diagram $F_{\leqslant n-1}$ satisfying $(*_{n-1})$. It follows that the latching object L_n can be identified with the finite coproduct $\amalg_{[m] \hookrightarrow [n], m<n} A_m$ and therefore belongs to $\mathcal{X}_0$. Let M_n denote the matching object $\varprojlim_{[m] \hookrightarrow [n], m<n} F_{\leqslant n-1}([m])$ (where the limit is formed in the ∞-category $\mathcal{X}_{/X}$). Each $F_{\leqslant n-1}([m])$ belongs to $\mathcal{X}_0$ and is therefore coherent, so that M_n is a coherent object of $\mathcal{X}$. In particular, M_n is quasi-compact, so assumptions (a) and (d) guarantee the existence of an effective epimorphism $v : Y \to M_n$ where $Y \in \mathcal{X}_0$. Using Corollary HTT.A.2.9.15 , we see that the data of a functor $F_{\leqslant n}$ extending $F_{\leqslant n-1}$ is equivalent to the data of a commutative diagram

$$\begin{array}{ccc} & X_n & \\ \nearrow & & \searrow^{\phi} \\ L_n & \xrightarrow{\phi_0} & M_n \end{array}$$

where the map ϕ_0 prescribed by $F_{\leqslant n-1}$. We complete the construction by taking X_n to be the coproduct $L_n \amalg Y$ and ϕ to be the amalgam of ϕ_0 with v. It is easy to see that resulting functor $X_\bullet : \mathbf{\Delta}^{\mathrm{op}} \to \mathcal{X}_{/X}$ has the desired properties. □

Our next result points to the relevance of Definition A.6.5.3:

Proposition A.6.5.8. *Let $\mathcal{C}$ be an essentially small local ∞-pretopos. If $\mathcal{C}$ is hypercomplete, then the Yoneda embedding $j : \mathcal{C} \hookrightarrow \mathcal{S}\mathrm{hv}(\mathcal{C})$ factors through the full subcategory $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ spanned by the hypercomplete objects of $\mathcal{S}\mathrm{hv}(\mathcal{C})$. Moreover, an object of $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ belongs to the essential image of j if and only if it is coherent.*

Proof. Let $X \in \mathcal{C}$ be an object; we wish to show that $j(X) \in \mathcal{S}\mathrm{hv}(\mathcal{C})$ is hypercomplete. Using Proposition A.5.7.2, we are reduced to proving that if $Y_\bullet$ is a hypercovering of an object $Y \in \mathcal{C}$, then the canonical map $\mathrm{Map}_{\mathcal{C}}(Y, X) \to \varprojlim \mathrm{Map}_{\mathcal{C}}(Y_\bullet, X)$ is a homotopy equivalence. This follows from the second assumption of Definition A.6.5.3. This proves that j factors through $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$. To complete the proof, it will suffice to show that the essential image of j satisfies conditions (a) through (e) of Proposition A.6.5.7. Conditions (b) and (d) are obvious, condition (a) follows from the proof of Proposition A.6.4.4, condition (c) from Proposition A.3.1.3. To prove (e), suppose that $\mathscr{F}_\bullet$ is a simplicial hypercovering of an object $\mathscr{F} \in \mathcal{S}\mathrm{hv}(\mathcal{X})^{\mathrm{hyp}}$ where each $\mathscr{F}_k$ belongs to the essential image of j. Since j is fully faithful, the image of $\mathscr{F}_\bullet$ in $\mathcal{S}\mathrm{hv}(\mathcal{X})^{\mathrm{hyp}}$ can be identified with $j(U_\bullet)$ for some simplicial object $U_\bullet$ of $\mathcal{C}$. Since $\mathscr{F}_\bullet$ is a hypercovering of $\mathscr{F}$, it satisfies the Kan condition (Remark A.6.5.4), so that the simplicial object $U_\bullet$ also satisfies the Kan condition. Our assumption that $\mathcal{C}$ is hypercomplete guarantees the existence of an object $X \in \mathcal{C}$ such that $U_\bullet$ can be lifted to a hypercovering of X. It follows that $j(U_\bullet)$ is a hypercovering of $j(X)$ in $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$. Since $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$ is hypercomplete, we conclude that that both $\mathscr{F}$ and $j(X)$ can be identified with the geometric realization $|j(U_\bullet)$, so that $\mathscr{F} \simeq j(X)$ belongs to the essential image of j as desired. □

Corollary A.6.5.9. *Let $\mathcal{C}$ be a local ∞-pretopos. If $\mathcal{C}$ is hypercomplete, then $\mathcal{C}$ is idempotent-complete.*

Proof. Enlarging the universe if necessary, we may assume that $\mathcal{C}$ is small. In this case, Proposition A.6.5.8 shows that the essential image of the Yoneda embedding $j : \mathcal{C} \hookrightarrow \mathcal{S}\mathrm{hv}(\mathcal{C})$ is closed under retracts. Since the ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is idempotent-complete, it follows that $\mathcal{C}$ is idempotent-complete. □

A.6.6 The ∞-Category of Hypercomplete ∞-Pretopoi

We now show that the datum of a hypercomplete ∞-pretopos is essentially the same as the datum of a hypercomplete ∞-topos which is coherent and locally coherent (Theorem **??**).

Proposition A.6.6.1. *Let $\mathcal{X}$ be an ∞-topos which is locally coherent and hypercomplete, and let $\mathcal{X}^{\mathrm{coh}}$ denote the full subcategory of $\mathcal{X}$ spanned by the coherent objects. Then:*

(1) *The ∞-category $\mathcal{X}^{\mathrm{coh}}$ is a local ∞-pretopos.*

(2) *The ∞-category $\mathcal{X}^{\mathrm{coh}}$ is essentially small.*

(3) *If $X_\bullet$ is a semisimplicial object of $\mathcal{X}^{\mathrm{coh}}$ which satisfies the Kan condition, then the geometric realization $|X_\bullet|$ belongs to $\mathcal{X}^{\mathrm{coh}}$ and $X_\bullet$ is a hypercovering of $|X_\bullet|$.*

(4) *If $X \in \mathcal{X}^{\mathrm{coh}}$ is an object and $X_\bullet : \mathbf{\Delta}_s^{\mathrm{op}} \to \mathcal{X}_{/X}$ is a hypercovering of X, then the induced map $|X_\bullet| \to X$ is an equivalence.*

In particular, $\mathcal{X}^{\mathrm{coh}}$ is a hypercomplete local ∞-pretopos.

Proof. Assertion (a) follows from Proposition A.6.1.6, assertion (c) from Theorem A.5.5.1, and assertion (d) from Theorem A.5.3.1 (and the hypercompleteness of $\mathcal{X}$). We now prove (b). Since $\mathcal{X}$ is a presentable ∞-category, there exists an essentially small full subcategory $\mathcal{X}_0 \subseteq \mathcal{X}$ such that every object $X \in \mathcal{X}$ admits an effective epimorphism $\amalg U_\alpha \to X$, where each U_α belongs to $\mathcal{X}_0$. Because $\mathcal{X}$ is locally coherent, we may assume without loss of generality that each object of $\mathcal{X}_0$ is coherent. Enlarging $\mathcal{X}_0$ if necessary, we may assume that $\mathcal{X}_0$ is closed under fiber products, finite coproducts (Remark A.2.1.8), and that for every simplicial object $U_\bullet$ of $\mathcal{X}_0$ which satisfies the Kan condition, the geometric realization $|U_\bullet|$ belongs to $\mathcal{X}$ (Theorem A.5.5.1). Then $\mathcal{X}_0$ satisfies the hypotheses of Proposition A.6.5.7, so that $\mathcal{X}^{\mathrm{coh}} = \mathcal{X}_0$ is essentially small. □

Warning A.6.6.2. Using a more refined argument, one can show that the ∞-category $\mathcal{X}^{\mathrm{coh}}$ is essentially small for *any* hypercomplete ∞-topos $\mathcal{X}$: the local coherence of $\mathcal{X}$ is not necessary. However, the hypothesis that $\mathcal{X}$ is hypercomplete cannot be eliminated.

Remark A.6.6.3. Let $\mathcal{X}$ be an ∞-topos which is hypercomplete and locally coherent. Combining Propositions A.6.6.1 and A.3.4.2, we see that the Yoneda embedding of $\mathcal{X}$ induces an equivalence of ∞-categories $\mathcal{X} \to \mathcal{S}\mathrm{hv}(\mathcal{X}^{\mathrm{coh}})^{\mathrm{hyp}}$.

Corollary A.6.6.4. *Let $\mathcal{C}$ be a local ∞-pretopos which is essentially small. The following conditions are equivalent:*

(1) *The ∞-pretopos $\mathcal{C}$ is hypercomplete (in the sense of Definition A.6.5.3).*

(2) *There exists an ∞-topos $\mathcal{X}$ which is hypercomplete and locally coherent and an equivalence of ∞-categories $\mathcal{C} \simeq \mathcal{X}^{\mathrm{coh}}$.*

(3) *The ∞-pretopos $\mathcal{C}$ satisfies the following stronger version of the requirements of Definition A.6.5.3:*

   (a') *Every semisimplicial object $X_\bullet$ of $\mathcal{C}$ which satisfies the Kan condition, there exists an object $X \in \mathcal{C}$ such that $X_\bullet$ can be lifted to a semisimplicial object of $\mathcal{C}_{/X}$ which is a hypercovering of X.*

(b') *If $X \in \mathcal{C}$ and $X_\bullet$ is a semisimplicial object of $\mathcal{C}_{/X}$ which is a hypercovering of X, then X is a colimit of the diagram $\mathbf{\Delta}_s^{\mathrm{op}} \xrightarrow{X_\bullet} \mathcal{C}_{/X} \to \mathcal{C}$.*

Proof. The implication (1) ⇒ (2) follows from Proposition A.6.5.8, the implication (2) ⇒ (3) from Proposition A.6.6.1, and the implication (3) ⇒ (1) is trivial. □

Theorem A.6.6.5. *Let $\mathcal{E}$ denote the subcategory of $\infty\mathcal{T}\mathrm{op}$ whose objects are ∞-topoi $\mathcal{X}$ which are hypercomplete, coherent, and locally coherent and whose morphisms are functors $f^* : \mathcal{X} \to \mathcal{Y}$ which preserve small colimits, finite limits, and carry coherent objects of $\mathcal{X}$ to coherent objects of $\mathcal{Y}$. Then the construction $\mathcal{X} \mapsto \mathcal{X}^{\mathrm{coh}}$ induces a fully faithful functor $\rho : \mathcal{E}^{\mathrm{op}} \to \infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}$, whose essential image is spanned by the ∞-pretopoi which are hypercomplete and essentially small.*

Proof. It follows from Proposition A.6.6.1 that if $\mathcal{X}$ is an ∞-topos which is hypercomplete, coherent, and locally coherent, then the full subcategory $\mathcal{X}^{\mathrm{coh}} \subseteq \mathcal{X}$ of coherent objects is a hypercomplete ∞-pretopos which is essentially small. This proves that the functor ρ is well-defined. We next claim that ρ is fully faithful. Let $\mathcal{X}$ and $\mathcal{Y}$ be ∞-topoi which are hypercomplete, coherent, and locally coherent; we wish to show that the canonical map

$$\theta : \mathrm{Map}_{\mathcal{E}}(\mathcal{X}, \mathcal{Y}) \to \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}}(\mathcal{Y}^{\mathrm{coh}}, \mathcal{X}^{\mathrm{coh}}) \simeq \mathrm{Fun}^{\mathrm{pre}}(\mathcal{Y}^{\mathrm{coh}}, \mathcal{X}^{\mathrm{coh}})^{\simeq}$$

is a homotopy equivalence. Using Remark A.6.6.3, we can identify $\mathcal{Y}$ with the hypercomplete ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{Y}^{\mathrm{coh}})^{\mathrm{hyp}}$. Since the ∞-pretopos $\mathcal{Y}^{\mathrm{coh}}$ is hypercomplete (Proposition A.6.6.1), an object of $\mathcal{S}\mathrm{hv}(\mathcal{Y}^{\mathrm{coh}})^{\mathrm{hyp}}$ is coherent if and only if it belongs to the essential image of the Yoneda embedding $j : \mathcal{Y}^{\mathrm{coh}} \to \mathcal{S}\mathrm{hv}(\mathcal{Y}^{\mathrm{coh}})^{\mathrm{hyp}}$ (Proposition A.6.5.8). Unwinding the definitions, we see the map θ fits into a pullback diagram of spaces

$$\begin{array}{ccc} \mathrm{Map}_{\mathcal{E}}(\mathcal{X}, \mathcal{Y}) & \xrightarrow{\theta} & \mathrm{Fun}^{\mathrm{pre}}(\mathcal{Y}^{\mathrm{coh}}, \mathcal{X}^{\mathrm{coh}})^{\simeq} \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{X}, \mathcal{Y}) & \xrightarrow{\theta'} & \mathrm{Fun}^{\mathrm{pre}}(\mathcal{Y}^{\mathrm{coh}}, \mathcal{X})^{\simeq}. \end{array}$$

It will therefore suffice to show that the map θ' is a homotopy equivalence. This follows from the observation that we can write θ' as a composition

$$\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{X}, \mathcal{Y}) \xrightarrow{\phi} \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{S}\mathrm{hv}(\mathcal{X}^{\mathrm{coh}}), \mathcal{Y}) \xrightarrow{\psi} \mathrm{Fun}^{\mathrm{pre}}(\mathcal{Y}^{\mathrm{coh}}, \mathcal{X})^{\simeq},$$

where ϕ is a homotopy equivalence by virtue of our assumption that $\mathcal{X}$ is hypercomplete and ψ is a homotopy equivalence by virtue of Proposition A.6.4.4. This shows that ρ is fully faithful. The description of the essential image of ρ follows from Corollary A.6.6.4. □

A.6.7 Truncations in ∞-Pretopoi

Let $\mathcal{C}$ be an arbitrary ∞-category. Recall that an object $C \in \mathcal{C}$ is said to be *n-truncated* if the mapping space $\mathrm{Map}_{\mathcal{C}}(C', C)$ is n-truncated for each $C' \in \mathcal{C}$. We say that a morphism $u : C \to D$ *exhibits D as an n-truncation of C* if the object D is n-truncated and, for every n-truncated object $E \in \mathcal{C}$, composition with u induces a homotopy equivalence $\mathrm{Map}_{\mathcal{C}}(D, E) \to \mathrm{Map}_{\mathcal{C}}(C, E)$. In this case, the morphism u (and the object $D \in \mathcal{C}$) are uniquely determined by C (up to canonical equivalence). Our next goal is to show that truncations exist in any ∞-pretopos:

Proposition A.6.7.1. *Let $\mathcal{C}$ be an ∞-pretopos and let $n \geqslant -2$ be an integer. Then:*

(a) *For every object $C \in \mathcal{C}$, there exists a morphism $u : C \to D$ which exhibits D as an n-truncation of C.*

(b) *Let $\mathcal{C}'$ be another ∞-pretopos and let $f \in \mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{C}')$ be a morphism of ∞-pretopoi (see Definition A.6.4.1). If $u : C \to D$ is a morphism in $\mathcal{C}$ which exhibits D as an n-truncation of C, then $f(u) : f(C) \to f(D)$ is a morphism in $\mathcal{C}'$ which exhibits $f(D)$ as an n-truncation of $f(C)$.*

Corollary A.6.7.2. *Let $\mathcal{C}$ be an ∞-pretopos, let $n \geqslant -2$ be an integer, and let $\mathcal{C}_{\leqslant n}$ be the full subcategory of $\mathcal{C}$ spanned by the n-truncated objects. Then the inclusion functor $\mathcal{C}_{\leqslant n} \hookrightarrow \mathcal{C}$ admits a left adjoint $\tau_{\leqslant n} : \mathcal{C} \to \mathcal{C}_{\leqslant n}$.*

Corollary A.6.7.3. *Let $\mathcal{C}$ and $\mathcal{C}'$ be ∞-pretopoi and let $f \in \mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{C}')$ be an ∞-pretopos morphism from $\mathcal{C}$ to $\mathcal{C}'$. Then the diagram of ∞-categories*

$$\begin{array}{ccc} \mathcal{C}_{\leqslant n} & \longrightarrow & \mathcal{C} \\ \downarrow{\scriptstyle f|_{\mathcal{C}_{\leqslant n}}} & & \downarrow{\scriptstyle f} \\ \mathcal{C}'_{\leqslant n} & \longrightarrow & \mathcal{C}' \end{array}$$

is left adjointable. In particular, the diagram of ∞-categories

$$\begin{array}{ccc} \mathcal{C}_{\leqslant n} & \xleftarrow{\tau_{\leqslant n}} & \mathcal{C} \\ \downarrow{\scriptstyle f|_{\mathcal{C}_{\leqslant n}}} & & \downarrow{\scriptstyle f} \\ \mathcal{C}'_{\leqslant n} & \xleftarrow{\tau_{\leqslant n}} & \mathcal{C}' \end{array}$$

commutes up to (canonical) homotopy.

We will deduce Proposition A.6.7.1 from the following:

Proposition A.6.7.4. *Let $\mathcal{C}$ be a small local ∞-pretopos, which we regard as equipped with the effective epimorphism topology of Corollary A.6.2.3. Let $n \geqslant -2$ be an integer and suppose we are given a pair of morphisms $\mathscr{F} \xrightarrow{f} \mathscr{G} \xrightarrow{g} \mathscr{H}$ in $\mathcal{S}\mathrm{hv}(\mathcal{C})$, where f is $(n+1)$-connective and g is n-truncated. If $\mathscr{F}$ and $\mathscr{H}$ belong to the essential image of the Yoneda embedding $j : \mathcal{C} \to \mathcal{S}\mathrm{hv}(\mathcal{C})$, then so does $\mathscr{G}$.*

Proof. We proceed by induction on n. If $n = -2$, the g is an equivalence and there is nothing to prove. Let us therefore assume that $n > -2$. Let $\mathscr{F}_\bullet$, $\mathscr{G}_\bullet$, and $\mathscr{H}_\bullet$ denote the simplicial objects of $\mathcal{C}$ given by the Čech nerves of the morphisms $\mathrm{id}_{\mathscr{F}}$, f, and $g \circ f$, respectively. We then have a diagram of simplicial objects

$$\mathscr{F}_\bullet \xrightarrow{f_\bullet} \mathscr{G}_\bullet \xrightarrow{g_\bullet} \mathscr{H}_\bullet .$$

For each $k \geqslant 0$, the map f_k fits into a commutative diagram

$$\begin{array}{ccccc} & & \mathscr{G}_k & & \\ & \overset{f_k}{\nearrow} & & \overset{h}{\searrow} & \\ \mathscr{F}_k & & \xrightarrow{\mathrm{id}} & & \mathscr{F} \end{array}$$

where h is a composition of pullbacks of f, and is therefore an $(n+1)$-connective morphism in $\mathcal{S}\mathrm{hv}(\mathcal{G})$. It follows that f_k is n-connective. Note that g_k is a pullback of the diagonal map $\mathscr{G} \to \mathscr{H} \times_{\mathscr{H}^{k+1}} \mathscr{G}^{k+1}$; since g is n-truncated, we conclude that g_k is $(n-1)$-truncated. Since the functor j is fully faithful and left exact, the essential image of j is closed under finite limits; it follows that $\mathscr{F}_k$ and $\mathscr{H}_k$ belong to the image of j. Applying our inductive hypothesis, we deduce that $\mathscr{G}_k$ also belongs to the image of j. Using the fact that j is fully faithful, we can identify $\mathcal{G}_\bullet$ with the image under j of a groupoid object $X_\bullet$ of $\mathcal{C}$. Since $\mathcal{C}$ is a local ∞-pretopos, we can identify $X_\bullet$ with the Čech nerve of the induced map $u : X_0 \to |X_\bullet|$ in $\mathcal{C}$. Because the functor j is left exact, it follows that $\mathcal{G}_\bullet \simeq j(X_\bullet)$ is the Čech nerve of the induced map $j(u) : j(X_0) \to j|X_\bullet|$. The map u is an effective epimorphism in $\mathcal{C}$ and therefore generates a covering with respect to the effective epimorphism topology, so that $j(u)$ is an effective epimorphism in the ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})$. It follows that we can identify $j|X_\bullet|$ with the geometric realization $|\mathcal{G}_\bullet|$. Our assumption that $n > -2$ guarantees that f is an effective epimorphism so that the natural map $|\mathcal{G}_\bullet| \to \mathcal{G}$ is an equivalence, and therefore $\mathcal{G} \simeq j|X_\bullet|$ belongs to the essential image of j as desired. □

Proof of Proposition A.6.7.1. We first prove (a). Let $\mathcal{C}$ be an ∞-pretopos, let $n \geqslant -2$ be an integer, and let C be an object of $\mathcal{C}$. We wish to show that there exists a morphism $u : C \to D$ in $\mathcal{C}$ which exhibits D as an n-truncation of $\mathcal{C}$. Passing to a larger universe if necessary, we may assume that $\mathcal{C}$ is small. Let $j : \mathcal{C} \to \mathcal{S}\mathrm{hv}(\mathcal{C})$ be the Yoneda embedding. Since $\mathcal{C}$ has a final object, the final object $\mathbf{1} \in \mathcal{S}\mathrm{hv}(\mathcal{C})$ belongs to the essential image of

j. Applying Proposition A.6.7.4 to the diagram $j(C) \xrightarrow{u'} \tau_{\leqslant n} j(C) \to \mathbf{1}$ in $\mathcal{S}\mathrm{hv}(\mathcal{C})$, we can assume that $\tau_{\leqslant n} j(C)$ can be written as $j(D)$ for some object $D \in \mathcal{C}$. Since j is fully faithful, we can further assume that $u' = j(u)$ for some morphism $u : C \to D$ in $\mathcal{C}$. We claim that u has the desired property. Since $j(D) = \tau_{\leqslant n} j(C)$ is n-truncated, we immediately deduce that the object $D \in \mathcal{C}$ is n-truncated. To complete the proof of (a), it suffices to observe that for any n-truncated object $E \in \mathcal{C}$, the object $j(E) \in \mathcal{S}\mathrm{hv}(\mathcal{C})$ is n-truncated so that the canonical map

$$\mathrm{Map}_{\mathcal{C}}(D, E) \simeq \mathrm{Map}_{\mathcal{S}\mathrm{hv}(\mathcal{C})}(\tau_{\leqslant n} j(C), j(E)) \to \mathrm{Map}_{\mathcal{S}\mathrm{hv}(\mathcal{C})}(j(C), j(E)) \simeq \mathrm{Map}_{\mathcal{C}}(C, E)$$

is a homotopy equivalence.

We now prove (b). Let $u : C \to D$ be as above and let $f : \mathcal{C} \to \mathcal{C}'$ be a morphism of ∞-pretopoi. We then have a commutative diagram of ∞-pretopoi

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{f} & \mathcal{C}' \\ \downarrow{\scriptstyle j} & & \downarrow{\scriptstyle j'} \\ \mathcal{S}\mathrm{hv}(\mathcal{C}) & \xrightarrow{f^*} & \mathcal{S}\mathrm{hv}(\mathcal{C}'), \end{array}$$

where f^* is a geometric moprhism of ∞-topoi. Since $j(u)$ exhibits $j(D)$ as an n-truncation of $j(C)$, it follows that $(f^* \circ j)(u) = (j' \circ f)(u)$ exhibits $(j' \circ f)(D)$ as an n-truncation of $(j' \circ f)(C)$. Since j' is left exact and fully faithful, it follows that $f(u)$ exhibits $f(D)$ as an n-truncation of $f(C)$, as desired. □

Corollary A.6.7.5. *Let $\mathcal{X}$ be a coherent ∞-topos. If X is a coherent object of $\mathcal{X}$, then every truncation $\tau_{\leqslant n} X$ is also a coherent object of $\mathcal{X}$.*

A.7 Bounded ∞-Topoi

For each $0 \leqslant n \leqslant \infty$, let $\mathcal{T}\mathrm{op}_n$ denote the $(n+1)$-category of n-topoi (see Definition HTT.6.4.5.1). For $m \leqslant n$, the construction $\mathcal{X} \mapsto \tau_{\leqslant m-1} \mathcal{X}$ determines a forgetful functor $\mathcal{T}\mathrm{op}_n \to \mathcal{T}\mathrm{op}_m$; these forgetful functors determine a tower of ∞-categories

$$\cdots \to \mathcal{T}\mathrm{op}_3 \to \mathcal{T}\mathrm{op}_2 \to \mathcal{T}\mathrm{op}_1 \to \mathcal{T}\mathrm{op}_0 \,.$$

The canonical map $\infty\mathcal{T}\mathrm{op} \to \varprojlim \{\mathcal{T}\mathrm{op}_n\}_{n \geqslant 0}$ is not an equivalence: for example, if $\mathcal{X}$ is any ∞-topos and $\mathcal{X}^{\mathrm{hyp}} \subseteq \mathcal{X}$ is the full subcategory spanned by the hypercomplete objects, then the inclusion map $\iota_* : \mathcal{X}^{\mathrm{hyp}} \hookrightarrow \mathcal{X}$ is a morphism in $\infty\mathcal{T}\mathrm{op}$ whose image in each $\mathcal{T}\mathrm{op}_n$ is an equivalence (since truncated objects of $\mathcal{X}$ are automatically hypercomplete). Our goal in this section is to describe the relationship between $\infty\mathcal{T}\mathrm{op}$ and $\varprojlim \{\mathcal{T}\mathrm{op}_n\}_{n \geqslant 0}$ in more detail: in particular, we will show that it has both a right adjoint (Theorem **??**) and a left adjoint (Theorem **??**), both of which are fully faithful.

A.7.1 Boundedness

Fix an integer $n \geqslant 0$. Recall that an ∞-topos $\mathcal{X}$ is said to be *n-localic* if it has the form $\mathcal{S}\mathrm{hv}(\mathcal{C})$, where $\mathcal{C}$ is a small $(n-1)$-category which admits finite limits and is equipped with a Grothendieck topology (see the proof of Proposition HTT.6.4.5.9). We let $\infty\mathcal{T}op^{\leqslant n}$ denote the full subcategory of $\infty\mathcal{T}\mathrm{op}$ spanned by the n-localic ∞-topoi. It follows from Proposition HTT.6.4.5.7 that the forgetful functor $\infty\mathcal{T}\mathrm{op} \rightarrow \mathcal{T}\mathrm{op}_n$ admits a fully faithful right adjoint whose essential image is the full subcategory $\infty\mathcal{T}op^{\leqslant n} \subseteq \infty\mathcal{T}\mathrm{op}$. In particular, the ∞-category $\infty\mathcal{T}op^{\leqslant n}$ is a localization of $\infty\mathcal{T}\mathrm{op}$; we let $L_n : \infty\mathcal{T}\mathrm{op} \rightarrow \infty\mathcal{T}op^{\leqslant n}$ denote a right adjoint to the inclusion.

Proposition A.7.1.1. *Let $\mathcal{X}$ be an ∞-topos. The following conditions are equivalent:*

(a) *The ∞-topos $\mathcal{X}$ can be obtained as written as a limit of a small filtered diagram $\{\mathcal{X}_\alpha\}$ in the ∞-category $\infty\mathcal{T}\mathrm{op}$, where each of the ∞-topoi $\mathcal{X}_\alpha$ is n-localic for some integer n (which might depend on α).*

(b) *The canonical map $\theta_* : \mathcal{X} \rightarrow \varprojlim L_n \mathcal{X}$ is an equivalence in $\infty\mathcal{T}\mathrm{op}$.*

Definition A.7.1.2. Let $\mathcal{X}$ be an ∞-topos. We will say that $\mathcal{X}$ is *bounded* if it satisfies the equivalent conditions of Proposition A.7.1.1. We let $\infty\mathcal{T}\mathrm{op}^{\mathrm{b}}$ denote the full subcategory of $\infty\mathcal{T}\mathrm{op}$ spanned by the bounded ∞-topoi.

Example A.7.1.3. Let $\mathcal{X}$ be an ∞-topos which is n-localic for some integer n. Then $\mathcal{X}$ is bounded.

The essential content of Proposition A.7.1.1 is contained in the following observation:

Lemma A.7.1.4. *For each $n \geqslant 0$, the functor $L_n : \infty\mathcal{T}\mathrm{op} \rightarrow \infty\mathcal{T}\mathrm{op}$ preserves small filtered limits.*

Proof. Suppose we are given a diagram of ∞-topoi

$$\mathcal{J}^{\mathrm{op}} \rightarrow \infty\mathcal{T}\mathrm{op} \qquad (\alpha \in \mathcal{J}) \mapsto \mathcal{X}_\alpha,$$

indexed by a small filtered ∞-category $\mathcal{J}$. We wish to show that the canonical map $\rho_* : L_n(\varprojlim_{\alpha \in \mathcal{J}^{\mathrm{op}}} \mathcal{X}_\alpha) \rightarrow \varprojlim_{\alpha \in \mathcal{J}^{\mathrm{op}}} L_n \mathcal{X}_\alpha$ is an equivalence of ∞-topoi. Since the domain and codomain of ρ_* are n-localic, it will suffice to show that ρ_* induces an equivalence when restricted to $(n-1)$-truncated objects. In other words, we are reduced to showing that the map $\rho'_* : \varprojlim_{\alpha \in \mathcal{J}^{\mathrm{op}}} \mathcal{X}_\alpha \rightarrow \varprojlim_{\alpha \in \mathcal{J}^{\mathrm{op}}} L_n \mathcal{X}_\alpha$ is an equivalence when restricted to $(n-1)$-truncated objects. Because $\mathcal{J}$ is filtered, the domain and codomain of ρ'_* can be identified with the corresponding limits in the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty$ (Theorem HTT.6.3.3.1). In particular, we see that an object of $\varprojlim_{\alpha \in \mathcal{J}^{\mathrm{op}}} \mathcal{X}_\alpha$ (or of $\varprojlim_{\alpha \in \mathcal{J}^{\mathrm{op}}} L_n \mathcal{X}_\alpha$) is $(n-1)$-truncated if and only if its image in each $\mathcal{X}_\alpha$ (or $L_n \mathcal{X}_\alpha$) is $(n-1)$-truncated. We are therefore reduced to showing that the natural map

$$\varprojlim_{\alpha \in \mathcal{J}^{\mathrm{op}}} \tau_{\leqslant n-1} \mathcal{X}_\alpha \to \varprojlim_{\alpha \in \mathcal{J}^{\mathrm{op}}} \tau_{\leqslant n-1} L_n \mathcal{X}_\alpha$$

is an equivalence of ∞-categories. This is clear, since it is given as a limit of equivalences $\tau_{\leqslant n-1} \mathcal{X}_\alpha \to \tau_{\leqslant n-1} L_n \mathcal{X}_\alpha$. □

Proof of Proposition A.7.1.1. The implication $(b) \Rightarrow (a)$ is trivial. We will prove the converse. Suppose that $\mathcal{J}$ is a small filtered ∞-category and that $\mathcal{X}$ is given as the limit of a diagram

$$\mathcal{J}^{\mathrm{op}} \to \infty\mathcal{T}\mathrm{op} \qquad (\alpha \in \mathcal{J}) \mapsto \mathcal{X}_\alpha,$$

where each of the ∞-topoi $\mathcal{X}_\alpha$ is n_α-localic for some integer $n_\alpha \geqslant 0$. We have a commutative diagram

$$\begin{array}{ccc} \mathcal{X} & \xrightarrow{\sim} & \varprojlim_{\alpha \in \mathcal{J}^{\mathrm{op}}} \mathcal{X}_\alpha \\ \downarrow{\scriptstyle \theta_*} & & \downarrow{\scriptstyle \varprojlim \theta_{\alpha *}} \\ \varprojlim_n L_n \mathcal{X} & \longrightarrow & \varprojlim_{\alpha \in \mathcal{J}^{\mathrm{op}}} \varprojlim_n L_n \mathcal{X}_\alpha . \end{array}$$

For each $\alpha \in \mathcal{J}^{\mathrm{op}}$, the tower $\{L_n \mathcal{X}_\alpha\}_{n \geqslant 0}$ is essentially constant (with value $\mathcal{X}_\alpha$) for $n \geqslant n_\alpha$, so the canonical map $\theta_{\alpha *} : \mathcal{X}_\alpha \to \varprojlim_n L_n \mathcal{X}_\alpha$ is an equivalence. Consequently, to show that θ_* is an equivalence, it will suffice to show that the lower horizontal map in the preceding diagram is an equivalence. For this, it will suffice to show that for each $n \geqslant 0$, the natural map $\rho_* : L_n \mathcal{X} \to \varprojlim_{\alpha \in \mathcal{J}^{\mathrm{op}}} L_n \mathcal{X}_\alpha$ is an equivalence, which follows from Lemma A.7.1.4. □

Proposition A.7.1.5. *The canonical map $\infty\mathcal{T}\mathrm{op} \to \varprojlim_n \mathcal{T}\mathrm{op}_n$ admit a fully faithful right adjoint, whose essential image is the full subcategory $\infty\mathcal{T}\mathrm{op}^{\mathrm{b}} \subseteq \infty\mathcal{T}\mathrm{op}$ spanned by the bounded ∞-topoi.*

Proof. Using Proposition HTT.6.4.5.7 , we can identify $\varprojlim_n \mathcal{T}\mathrm{op}_n$ with the limit of the tower of ∞-categories

$$\cdots \to \infty\mathcal{T}op^{\leqslant 3} \xrightarrow{L_2} \infty\mathcal{T}op^{\leqslant 2} \xrightarrow{L_1} \infty\mathcal{T}op^{\leqslant 1} \xrightarrow{L_0} \infty\mathcal{T}op^{\leqslant 0}.$$

We can therefore identify the objects of $\varprojlim_n \mathcal{T}\mathrm{op}_n$ with towers of ∞-topoi

$$\cdots \to \mathcal{X}_3 \xrightarrow{\phi(2)_*} \mathcal{X}_2 \xrightarrow{\phi(1)_*} \mathcal{X}_1 \xrightarrow{\phi(0)_*} \mathcal{X}_0$$

where each $\phi(n)_*$ is a geometric morphism which exhibits $\mathcal{X}_n$ as an n-localic reflection of $\mathcal{X}_{n+1}$ (so that each $\mathcal{X}_n$ is n-localic). The natural map $F : \infty\mathcal{T}\mathrm{op} \to \varprojlim_n \mathcal{T}\mathrm{op}_n$ admits a right adjoint $G : \varprojlim_n \mathcal{T}\mathrm{op}_n \to \infty\mathcal{T}\mathrm{op}$, which carries a tower $\{\mathcal{X}_n\}_{n \geqslant 0}$ as above to the limit $\varprojlim \mathcal{X}_n$ (formed in the ∞-category $\infty\mathcal{T}\mathrm{op}$ of ∞-topoi). Note that for any such tower $\{\mathcal{X}_n\}_{n\geqslant 0}$, Lemma A.7.1.4 implies that the canonical map $L_m \varprojlim_n \mathcal{X}_n \to \varprojlim_n L_m \mathcal{X}_n \simeq \mathcal{X}_m$ is an equivalence. In other words, the counit $v : F \circ G \to \mathrm{id}$ is an equivalence, so that the functor G is fully faithful. To complete the proof, it suffices to observe that the full subcategory $\infty\mathcal{T}\mathrm{op}^{\mathrm{b}} \subseteq \infty\mathcal{T}\mathrm{op}$ is the essential image of G: in other words, that an ∞-topos $\mathcal{X}$ is bounded if and only if the unit map $\mathcal{X} \to (G \circ F)(\mathcal{X}) = \varprojlim_n L_n \mathcal{X}$ is an equivalence. □

Example A.7.1.6. Let $\mathcal{C}$ be a small ∞-category which admits finite limits and let S be a collection of morphisms in $\mathcal{C}$ which satisfies conditions (a) through (d) of Proposition A.3.2.1 and therefore determines a Grothendieck topology on $\mathcal{C}$. Suppose further that coproducts in $\mathcal{C}$ are disjoint and that every object $C \in \mathcal{C}$ is n-truncated for some integer $n \geqslant 0$ (which might depend on $\mathcal{C}$). For each $n \geqslant 0$, let $\mathcal{C}_{\leqslant n}$ denote the full subcategory of $\mathcal{C}$ spanned by the n-truncated objects, and let $S_{\leqslant n}$ denote the collection of morphisms in $\mathcal{C}_{\leqslant n}$ which belong to S. Since coproducts in $\mathcal{C}$ are disjoint, the collection of n-truncated objects of $\mathcal{C}$ is closed under coproducts for $n \geqslant 0$, so that the collection of morphisms $S_{\leqslant n}$ also satisfies the hypotheses of Proposition A.3.2.1 and therefore determines a Grothendieck topology on $\mathcal{C}_{\leqslant n}$. The equality $\mathcal{C} = \bigcup_{n\geqslant 0} \mathcal{C}_{\leqslant n}$ induces an equivalence of ∞-categories $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}) \simeq \varprojlim_n \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}_{\leqslant n}, \mathcal{S})$. Using the criterion of Proposition A.3.3.1, we see that this equivalence restricts to an equivalence $\mathcal{S}\mathrm{hv}(\mathcal{C}) \simeq \varprojlim_{n\geqslant 0} \mathcal{S}\mathrm{hv}(\mathcal{C}_{\leqslant n})$ in the ∞-category $\infty\mathcal{T}\mathrm{op}$. By construction, each of the ∞-topoi $\mathcal{S}\mathrm{hv}(\mathcal{C}_{\leqslant n})$ is n-localic. It follows that the ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is bounded.

A.7.2 Postnikov Completeness

Let $\mathcal{C}$ be a presentable ∞-category. For each $n \geqslant 0$, we let $\tau_{\leqslant n}\mathcal{C}$ denote the full subcategory of $\mathcal{C}$ spanned by the n-truncated objects. The inclusion functor $\tau_{\leqslant n}\mathcal{C} \hookrightarrow \mathcal{C}$ has a left adjoint, which we will denote by $\tau_{\leqslant n}$. We have a tower of ∞-categories

$$\cdots \to \tau_{\leqslant 3}\mathcal{C} \xrightarrow{\tau_{\leqslant 2}} \tau_{\leqslant 2}\mathcal{C} \xrightarrow{\tau_{\leqslant 1}} \tau_{\leqslant 1}\mathcal{C} \xrightarrow{\tau_{\leqslant 0}} \tau_{\leqslant 0}\mathcal{C}.$$

Definition A.7.2.1. Let $\mathcal{C}$ be a presentable ∞-category. We will say that $\mathcal{C}$ is *Postnikov complete* if the canonical map

$$\mathcal{C} \to \varprojlim_n \tau_{\leqslant n}\mathcal{C} \qquad C \mapsto \{\tau_{\leqslant n} C\}_{n\geqslant 0}$$

is an equivalence of ∞-categories. We let $\infty\mathcal{T}\mathrm{op}^{\mathrm{c}}$ denote the full subcategory of $\infty\mathcal{T}\mathrm{op}$ spanned by those ∞-topoi which are Postnikov complete.

Warning A.7.2.2. The terminology of Definition A.7.2.1 is slightly different from that of [138], where we said that *Postnikov towers in $\mathcal{C}$ are convergent* if $\mathcal{C}$ satisfies the requirement of Definition A.7.2.1.

Remark A.7.2.3. Let $\mathcal{X}$ be an ∞-topos. If $\mathcal{X}$ is Postnikov complete, then every object $X \in \mathcal{X}$ can be recovered as the limit of its Postnikov tower $\{\tau_{\leqslant n} X\}_{n \geqslant 0}$. It follows that every Postnikov complete ∞-topos is hypercomplete. However, the converse is false.

The failure of an ∞-topos $\mathcal{X}$ to be Postnikov complete can always be corrected by passing to a suitable modification of $\mathcal{X}$:

Theorem A.7.2.4. *Let $\mathcal{X}$ be an ∞-topos, and let $\widehat{\mathcal{X}}$ denote the limit of the tower of ∞-categories*

$$\cdots \to \tau_{\leqslant 3}\,\mathcal{X} \xrightarrow{\tau_{\leqslant 2}} \tau_{\leqslant 2}\,\mathcal{X} \xrightarrow{\tau_{\leqslant 1}} \tau_{\leqslant 1}\,\mathcal{X} \xrightarrow{\tau_{\leqslant 0}} \tau_{\leqslant 0}\,\mathcal{X} = \mathcal{X}^{\heartsuit}.$$

Then:

- (a) *The ∞-category $\widehat{\mathcal{X}}$ is an ∞-topos.*
- (b) *The canonical map $e^* : \mathcal{X} \to \widehat{\mathcal{X}}$ is a geometric morphism (that is, it preserves small colimits and finite limits).*
- (c) *For each $n \geqslant 0$, the map $e^* : \mathcal{X} \to \widehat{\mathcal{X}}$ induces an equivalence when restricted to n-truncated objects.*
- (d) *The ∞-topos $\widehat{\mathcal{X}}$ is Postnikov complete.*
- (e) *If $\mathcal{Y}$ is a Postnikov complete ∞-topos, then composition with e^* induces an equivalence of ∞-categories* $\mathrm{Fun}^*(\widehat{\mathcal{X}}, \mathcal{Y}) \to \mathrm{Fun}^*(\mathcal{X}, \mathcal{Y})$.

Definition A.7.2.5. Let $\mathcal{X}$ be an ∞-topos. We will refer to the ∞-topos $\widehat{\mathcal{X}} = \varprojlim \{\tau_{\leqslant n}\,\mathcal{X}\}_{n \geqslant 0}$ of Theorem A.7.2.4 as the *Postnikov completion* of $\mathcal{X}$.

Before giving the proof of Theorem A.7.2.4, let us describe some of its consequences.

Corollary A.7.2.6. *The inclusion functor $\infty\mathcal{T}\mathrm{op}^{\mathrm{c}} \hookrightarrow \infty\mathcal{T}\mathrm{op}$ admits a right adjoint, which carries each ∞-topos $\mathcal{X}$ to its Postnikov completion $\widehat{\mathcal{X}}$.*

Corollary A.7.2.7. *The natural map $\rho : \infty\mathcal{T}\mathrm{op} \to \varprojlim_n \mathcal{T}\mathrm{op}_n$ admits a fully faithful left adjoint, whose essential image is the full subcategory of $\infty\mathcal{T}\mathrm{op}^{\mathrm{c}} \subseteq \infty\mathcal{T}\mathrm{op}$.*

Proof. Let $\infty\mathcal{T}\mathrm{op}^{\mathrm{b}}$ denote the full subcategory of $\infty\mathcal{T}\mathrm{op}$ spanned by the bounded ∞-pretopoi (Definition A.7.1.2). Using Proposition A.7.1.5, we deduce that there is an equivalence of ∞-categories $\varprojlim_n \mathcal{T}\mathrm{op}_n \simeq \infty\mathcal{T}\mathrm{op}^{\mathrm{b}}$ whose composition with ρ yields a functor $L : \infty\mathcal{T}\mathrm{op} \to \infty\mathcal{T}\mathrm{op}^{\mathrm{b}}$ which is left adjoint to the inclusion $\infty\mathcal{T}\mathrm{op}^{\mathrm{b}} \hookrightarrow \infty\mathcal{T}\mathrm{op}$. Using Corollary A.7.2.6, we can regard the formation of Postnikov completions $\mathcal{X} \mapsto \widehat{\mathcal{X}}$ as a functor from the ∞-category $\infty\mathcal{T}\mathrm{op}$ to itself. To complete the proof of Corollary A.7.2.7, it will suffice to verify the following:

(i) The construction $\mathcal{X} \mapsto \widehat{\mathcal{X}}$ determines a functor $\infty\mathcal{T}\mathrm{op}^{\mathrm{b}} \to \infty\mathcal{T}\mathrm{op}$ which is left adjoint to L.

(ii) An ∞-topos $\mathcal{Y}$ is Postnikov complete if and only if it has the form $\widehat{\mathcal{X}}$ for some $\mathcal{X} \in \infty\mathcal{T}\mathrm{op}^{\mathrm{b}}$.

To prove (i), we must establish the existence of a homotopy equivalence $\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\widehat{\mathcal{X}}, \mathcal{Y}) \simeq \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{X}, L\,\mathcal{Y})$ depending functorially on $\mathcal{X} \in \infty\mathcal{T}\mathrm{op}^{\mathrm{b}}$ and $\mathcal{Y} \in \infty\mathcal{T}\mathrm{op}$. We obtain this homotopy equivalence by inspecting the commutative diagram

$$\begin{array}{ccccc}
 & & \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\widehat{\mathcal{X}}, \mathcal{Y}) & \longleftarrow & \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\widehat{\mathcal{X}}, \widehat{\mathcal{Y}}) \\
 & & \downarrow & & \downarrow{\scriptstyle \alpha} \\
\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{X}, L\,\mathcal{Y}) & \longrightarrow & \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\widehat{\mathcal{X}}, L\,\mathcal{Y}) & \longleftarrow & \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\widehat{\mathcal{X}}, \widehat{L\,\mathcal{Y}}) \\
\uparrow & & \uparrow & & \\
\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(L\,\mathcal{X}, L\,\mathcal{Y}) & \xrightarrow{\beta} & \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(L\widehat{\mathcal{X}}, L\,\mathcal{Y}). & &
\end{array}$$

We claim that each of the maps in this diagram is a homotopy equivalence. Here the lower vertical maps are homotopy equivalences because $L\,\mathcal{Y}$ is bounded, and the right horizontal maps are homotopy equivalences by virtue of Corollary A.7.2.6 (since $\widehat{\mathcal{X}}$ is Postnikov complete). We are therefore reduced to proving that α and β are homotopy equivalences. This follows from the observations that the geometric morphisms $\mathcal{Y} \to L\,\mathcal{Y}$ and $\widehat{\mathcal{X}} \to \mathcal{X}$ are equivalences on n-truncated objects for each $n \geqslant 0$ (and therefore induce equivalences $\widehat{\mathcal{Y}} \to \widehat{L\,\mathcal{Y}}$ and $L\widehat{\mathcal{X}} \to L\,\mathcal{X}$, respectively). This completes the proof of (i). The "if" direction of (ii) follows from assertion (d) of Theorem A.7.2.4, and the "only if" direction follows from the observation that for any Postnikov complete ∞-topos $\mathcal{X}$, we have equivalences $\mathcal{X} \leftarrow \widehat{\mathcal{X}} \to \widehat{L\,\mathcal{X}}$ in the ∞-category $\infty\mathcal{T}\mathrm{op}$. □

Corollary A.7.2.8. *The formation of Postnikov completions induces an equivalence of ∞-categories $\infty\mathcal{T}\mathrm{op}^{\mathrm{b}} \to \infty\mathcal{T}\mathrm{op}^{\mathrm{c}}$ (with homotopy inverse given by the functor $L : \infty\mathcal{T}\mathrm{op}^{\mathrm{c}} \to \infty\mathcal{T}\mathrm{op}^{\mathrm{b}}$ appearing in the proof of Corollary A.7.2.7).*

Warning A.7.2.9. Corollary A.7.2.8 asserts that the datum of a bounded ∞-topos $\mathcal{X}$ is equivalent to the datum of a Postnikov complete ∞-topos $\mathcal{Y}$. Beware that the $\mathcal{X}$ and $\mathcal{Y}$ are usually not equivalent as ∞-topoi (though they are related by a geometric morphism $\mathcal{Y} \to \mathcal{X}$ which induces an equivalence on n-truncated objects for each $n \geqslant 0$). In other words, the condition that an ∞-topos $\mathcal{Z}$ is bounded is *not* equivalent to the condition that $\mathcal{Z}$ is Postnikov complete. Both of these conditions assert that $\mathcal{Z}$ can be recovered from its truncated objects, but not in the same way:

- The ∞-topos $\mathcal{Z}$ is Postnikov complete if and only if it can be recovered as the limit of the tower of ∞-categories

$$\cdots \to \tau_{\leqslant 3}\,\mathcal{Z} \xrightarrow{\tau_{\leqslant 2}} \tau_{\leqslant 2}\,\mathcal{Z} \xrightarrow{\tau_{\leqslant 1}} \tau_{\leqslant 1}\,\mathcal{Z} \xrightarrow{\tau_{\leqslant 0}} \tau_{\leqslant 0}\,\mathcal{Z}$$

- The ∞-topos $\mathcal{Z}$ is bounded if and only if it can be recovered as the limit of its tower of geometric morphisms

$$\cdots \to \mathcal{Z}_3 \xrightarrow{\phi(2)_*} \mathcal{Z}_2 \xrightarrow{\phi(1)_*} \mathcal{Z}_1 \xrightarrow{\phi(0)_*} \mathcal{Z}_0;$$

here $\mathcal{Z}_n$ denotes the n-localic ∞-topos corresponding to the n-topos $\tau_{\leqslant n-1}\,\mathcal{Z}$.

To put the difference in another way: the hypothesis that $\mathcal{Z}$ is Postnikov complete guarantees that every object $Z \in \mathcal{Z}$ can be recovered as the limit of its Postnikov tower $\{\tau_{\leqslant n} Z\}$ *in the ∞-category* $\mathcal{Z}$ (and that conversely, every Postnikov tower arises in this way), while the hypothesis of boundedness asserts that the ∞-topos $\mathcal{Z}$ can itself be recovered as the limit of its "localic Postnikov tower" $\{\mathcal{Z}_n\}_{n \geqslant 0}$ *in the ∞-category* $\infty\mathcal{T}\mathrm{op}$.

A.7.3 The Proof of Theorem A.7.2.4

The proof of Theorem A.7.2.4 will require some auxiliary constructions.

Notation A.7.3.1. Let $f : X \to Y$ be a morphism in an ∞-topos $\mathcal{X}$ and let $n \geqslant -1$ be an integer. We let $\tau_{\leqslant n}(f)$ denote an n-truncation of X regarded as an object of $\mathcal{X}_{/Y}$, so that the map f factors canonically as a composition $X \xrightarrow{f'} \tau_{\leqslant n}(f) \xrightarrow{f''} Y$ where f' is $(n+1)$-connective and f'' is n-truncated.

Fix an ∞-topos $\mathcal{X}$. For each $n \geqslant 0$, we let $\mathcal{E}_n$ denote the full subcategory of $\mathrm{Fun}(\Delta^1, \mathcal{X})$ spanned by those morphisms $f : X \to Y$ where the object Y is n-truncated and the morphism f is $(n-1)$-truncated. We have inclusions of ∞-categories

$$\mathcal{E}_0 \hookrightarrow \mathrm{Fun}(\Delta^1, \tau_{\leqslant 0}\,\mathcal{X}) \hookrightarrow \mathcal{E}_1 \hookrightarrow \mathrm{Fun}(\Delta^1, \tau_{\leqslant 1}\,\mathcal{X}) \hookrightarrow \mathcal{E}_2 \hookrightarrow \mathrm{Fun}(\Delta^1, \tau_{\leqslant 2}\,\mathcal{X}) \hookrightarrow \cdots.$$

Note that each of these inclusion functors admits a left adjoint:

- For $n \geqslant 0$, the inclusion $\mathcal{E}_n \hookrightarrow \mathrm{Fun}(\Delta^1, \tau_{\leqslant 0}\,\mathcal{X})$ admits a left adjoint which carries a morphism $f : X \to Y$ to the induced map $\tau_{\leqslant n-1}(f) \to Y$.

- For $n \geqslant 0$, the inclusion $\mathrm{Fun}(\Delta^1, \tau_{\leqslant n}\,\mathcal{X}) \hookrightarrow \mathcal{E}_{n+1}$ admits a left adjoint which carries a morphism $f : X \to Y$ to the induced map $\tau_{\leqslant n} X \to \tau_{\leqslant n} Y$.

In particular, each of the inclusion functors $\mathcal{E}_n \hookrightarrow \mathcal{E}_{n+1}$ admits a left adjoint $\rho_n : \mathcal{E}_{n+1} \to \mathcal{E}_n$. Let $\widehat{\mathcal{X}} = \varprojlim\{\tau_{\leqslant n}\mathcal{X}\}$ be the Postnikov completion of $\mathcal{X}$. The towers of ∞-categories $\{\mathrm{Fun}(\Delta^1, \tau_{\leqslant n}\mathcal{X})\}_{n \geqslant 0}$ and $\{\mathcal{E}_n\}_{n\geqslant 0}$ are both right cofinal in the tower

$$\mathcal{E}_0 \leftarrow \mathrm{Fun}(\Delta^1, \tau_{\leqslant 0}\mathcal{X}) \leftarrow \mathcal{E}_1 \leftarrow \mathrm{Fun}(\Delta^1, \tau_{\leqslant 1}\mathcal{X}) \leftarrow \mathcal{E}_2 \leftarrow \mathrm{Fun}(\Delta^1, \tau_{\leqslant 2}\mathcal{X}) \leftarrow \cdots,$$

and therefore have the same limit. This proves the following:

Lemma A.7.3.2. *Let $\mathcal{X}$ be an ∞-topos and let $\widehat{\mathcal{X}}$ be its Postnikov completion. Then the ∞-category $\mathrm{Fun}(\Delta^1, \widehat{\mathcal{X}})$ can be identified with a limit of the tower of ∞-categories*

$$\mathcal{E}_0 \xleftarrow{\rho_0} \mathcal{E}_1 \xleftarrow{\rho_1} \mathcal{E}_2 \xleftarrow{\rho_2} \mathcal{E}_3 \leftarrow \cdots$$

constructed above.

Remark A.7.3.3. Let $\mathcal{X}$ be an ∞-topos and let $X = \{X_n\}_{n\geqslant 0}$ be an object of the Postnikov completion $\widehat{\mathcal{X}}$. Then the identification $\mathrm{Fun}(\Delta^1, \widehat{\mathcal{X}}) \simeq \varprojlim\{\mathcal{E}_n\}$ of Lemma A.7.3.2 induces an identification of the ∞-category $\widehat{\mathcal{X}}_{/X}$ with the limit of a tower of ∞-categories

$$\tau_{\leqslant -1}\mathcal{X}_{/X_0} \leftarrow \tau_{\leqslant 0}\mathcal{X}_{/X_1} \leftarrow \tau_{\leqslant 1}\mathcal{X}_{/X_2} \leftarrow \tau_{\leqslant 2}\mathcal{X}_{/X_3} \leftarrow \cdots.$$

Unwinding the definitions, we see that each of the transition maps in this diagram can be identified with the composition

$$\tau_{\leqslant n}\mathcal{X}_{/X_{n+1}} \xrightarrow{\tau_{\leqslant n-1}} \tau_{\leqslant n-1}\mathcal{X}_{/X_{n+1}} \simeq \tau_{\leqslant n-1}\mathcal{X}_{/X_n},$$

where the equivalence is supplied by the fact that the map $X_{n+1} \to X_n$ is $(n+1)$-connective (see Lemma HTT.7.2.1.13). It follows that each of these transition maps preserves finite products (Lemma HTT.6.5.1.2), so that each of the induced maps $\widehat{\mathcal{X}}_{/X} \to \tau_{\leqslant n-1}\mathcal{X}_{/X_n}$ also preserves finite products.

Proposition A.7.3.4. *Let $\mathcal{X}$ be an ∞-topos. Then the Postnikov completion $\widehat{\mathcal{X}}$ is also an ∞-topos.*

Proof. We first prove that colimits in $\widehat{\mathcal{X}}$ are universal. Fix a morphism $f : X \to Y$ in $\widehat{\mathcal{X}}$, which we can identify with a compatible family of maps $f_n : X_n \to Y_n$ in $\tau_{\leqslant n}\mathcal{X}$. We wish to show that the associated pullback functor $\widehat{\mathcal{X}}_{/Y} \to \widehat{\mathcal{X}}_{/X}$ preserves small colimits. Using Lemma A.7.3.2, we can identify this pullback functor with an inverse limit of pullback functors $\tau_{\leqslant n-1}\mathcal{X}_{/Y_n} \to \tau_{\leqslant n-1}\mathcal{X}_{/X_n}$, which preserve small colimits by virtue of the fact that colimits are universal in $\mathcal{X}$.

The evaluation functor $\mathrm{Fun}(\Delta^1, \widehat{\mathcal{X}}) \to \mathrm{Fun}(\{1\}, \widehat{\mathcal{X}}) \simeq \widehat{\mathcal{X}}$ is Cartesian fibration which is classified by a functor $\chi : \widehat{\mathcal{X}}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$. To complete the proof that $\mathcal{X}$ is an ∞-topos, it will suffice to show that the functor χ commutes with small limits (Theorem HTT.6.1.3.9).

Using Lemma A.7.3.2, we can identify χ with a limit of functors $\widehat{\mathcal{X}}^{\mathrm{op}} \to (\tau_{\leqslant n}\,\mathcal{X})^{\mathrm{op}} \xrightarrow{\chi_n} \widehat{\mathcal{C}\mathrm{at}}_\infty$, where each χ_n classifies the Cartesian fibration $\mathcal{E}_n \to \tau_{\leqslant n}\,\mathcal{X}$. It will therefore suffice to show that each of the functors χ_n preserves small limits, which follows from Theorem HTT.6.4.4.5 (applied to the $(n+1)$-topos $\tau_{\leqslant n+1}\,\mathcal{X}$). □

Proposition A.7.3.5. *Let $\mathcal{X}$ be an ∞-topos. Then the canonical map $e^* : \mathcal{X} \to \widehat{\mathcal{X}}$ (given on objects by the construction $X \mapsto \{\tau_{\leqslant n} X\}_{n \geqslant 0}$) preserves small colimits and finite limits.*

Proof. Each of the truncation functors $\tau_{\leqslant n} : \mathcal{X} \to \tau_{\leqslant n}\,\mathcal{X}$ preserves small colimits and final objects, so that the functor e^* preserves small colimits and final objects. To complete the proof that e^* is a geometric morphism, it will suffice to show that it preserves pullbacks. In other words, it will suffice to show that for each object $X \in \mathcal{X}$, the induced map $\mathcal{X}_{/X} \to \widehat{\mathcal{X}}_{/e^*X}$ preserves finite products. By virtue of Remark A.7.3.3, this is equivalent to the requirement that each of the composite functors $\mathcal{X}_{/X} \to \widehat{\mathcal{X}}_{/e^*X} \to \tau_{\leqslant n-1}\,\mathcal{X}_{/\tau_{\leqslant n} X}$ preserves finite products. Unwinding the definitions, we see that each of these functors can be rewritten as a composition $\mathcal{X}_{/X} \xrightarrow{\tau_{\leqslant n-1}} \tau_{\leqslant n-1}\,\mathcal{X}_{/X} \simeq \tau_{\leqslant n-1}\,\mathcal{X}_{/\tau_{\leqslant n} X}$, where the truncation functor $\tau_{\leqslant n-1}$ preserves finite products by virtue of Lemma HTT.6.5.1.2 and the equivalence is provided by Lemma HTT.7.2.1.13 . □

Remark A.7.3.6. The functor $e^* : \mathcal{X} \to \widehat{\mathcal{X}}$ of Proposition A.7.3.5 admits a right adjoint e_*, which carries an object $\{X_n\}_{n \geqslant 0}$ of $\widehat{\mathcal{X}}$ to the limit $\varprojlim X_n$ in the ∞-category $\mathcal{X}$. In particular, the composite functor $e_* e^* : \mathcal{X} \to \mathcal{X}$ associates to each object $X \in \mathcal{X}$ the limit $\varprojlim \tau_{\leqslant n} X$ of its Postnikov tower. Beware that that the natural map $X \to e_* e^* X$ need not be an equivalence. However, it is always an equivalence when the object $X \in \mathcal{X}$ is m-truncated for some integer m.

Proposition A.7.3.7. *Let $\mathcal{X}$ be an ∞-topos, let $\widehat{\mathcal{X}}$ be its Postnikov completion, and let $n \geqslant 0$ be an integer. Then the canonical map $e^* : \mathcal{X} \to \widehat{\mathcal{X}}$ is an equivalence when restricted to n-truncated objects.*

Proof. The functor e^* and its right adjoint e_* are both left exact, and therefore restrict to adjoint functors

$$\tau_{\leqslant n}\,\mathcal{X} \underset{e_{n*}}{\overset{e_n^*}{\rightleftarrows}} \tau_{\leqslant n}\widehat{\mathcal{X}}.$$

It follows from Remark A.7.3.6 that the functor e_n^* is fully faithful. It will therefore suffice to show that the functor e_n^* is essentially surjective. Let X be an n-truncated object of $\widehat{\mathcal{X}}$, given by a compatible sequence of objects $X_m \in \tau_{\leqslant m}\,\mathcal{X}$. We will show that if X is n-truncated, then the canonical map $X \to e^* X_n$ is an equivalence in $\widehat{\mathcal{X}}$. This is equivalent to the following:

(∗) For each $m \geqslant n$, the canonical map $X_m \to X_n$ is an equivalence in $\mathcal{X}$.

We prove $(*)$ by induction on m, the case $m = n$ being trivial. To carry out the inductive step, it will suffice to show that for $m > n$, the map $\rho : X_m \to X_{m-1}$ is an equivalence. Since ρ exhibits X_{m-1} as an $(m-1)$-truncation of X_m, this is equivalent to the statement that X_m is $(m-1)$-truncated: that is, that the diagonal map $\delta : X_m \to X_m^{S^m}$ is an equivalence. Note that δ is automatically (-1)-truncated (since X_m is m-truncated); consequently, it will suffice to show that δ is an effective epimorphism. Observe that the map δ factors as a composition

$$X_m \simeq \tau_{\leqslant m} X_{2m} \xrightarrow{\delta'} \tau_{\leqslant m}(X_{2m}^{S^m}) \xrightarrow{\delta''} (\tau_{\leqslant m} X_{2m})^{S^m} \simeq X_m^{S^m}.$$

Because S^m has dimension $\leqslant m$, the natural map $X_{2m}^{S^m} \to (\tau_{\leqslant m} X_{2m})^{S^m}$ is an effective epimorphism. This map factors through δ'', so that δ'' is an effective epimorphism. Consequently, to complete the proof, it will suffice to show that δ' is an effective epimorphism. In fact, the map δ' is an equivalence: it is the image under the tautological map $\widehat{\mathcal{X}} \to \tau_{\leqslant m} \mathcal{X}$ of the diagonal $X \to X^{S^m}$, which is an equivalence by virtue of our assumptions that X is n-truncated and $m > n$. □

Corollary A.7.3.8. *Let $\mathcal{X}$ be an ∞-topos and let $\widehat{\mathcal{X}} = \varprojlim\{\tau_{\leqslant n} \mathcal{X}\}$ be its Postnikov completion. Then, for each integer $n \geqslant 0$, the tautological map $F_n : \widehat{\mathcal{X}} \to \tau_{\leqslant n} \mathcal{X}$ admits a fully faithful right adjoint $G_n : \tau_{\leqslant n} \mathcal{X} \to \widehat{\mathcal{X}}$, whose essential image is the full subcategory of $\widehat{\mathcal{X}}$ spanned by the n-truncated objects.*

Proof. The existence of the right adjoint G_n follows from Corollary HTT.5.5.2.9 . Since G_n preserves finite limits, it carries n-truncated objects to n-truncated objects and therefore takes values in the full subcategory $\tau_{\leqslant n}\widehat{\mathcal{X}}$. Let $e^* : \mathcal{X} \to \widehat{\mathcal{X}}$ denote the canonical map, so that the composition $F_n \circ e^*$ can be identified with the n-truncation functor $\tau_{\leqslant n} : \mathcal{X} \to \tau_{\leqslant n} \mathcal{X}$. Passing to right adjoints, we deduce that the composite functor $\tau_{\leqslant n} \mathcal{X} \xrightarrow{G_n} \widehat{\mathcal{X}} \xrightarrow{e_*} \mathcal{X}$ is homotopic to the inclusion map. Since the functor e_* restricts to an equivalence $\tau_{\leqslant n}\widehat{\mathcal{X}} \to \tau_{\leqslant n} \mathcal{X}$ (Proposition A.7.3.7), it follows that G_n induces an equivalence $\tau_{\leqslant n} \mathcal{X} \simeq \tau_{\leqslant n}\widehat{\mathcal{X}}$. □

Proposition A.7.3.9. *Let $\mathcal{X}$ be an ∞-topos and let $\widehat{\mathcal{X}}$ denote its Postnikov completion. Then $\widehat{\mathcal{X}}$ is Postnikov complete.*

Proof. By construction, the Postnikov completion $\widehat{\mathcal{X}}$ can be identified with the limit of the tower of ∞-categories

$$\cdots \to \tau_{\leqslant 3} \mathcal{X} \to \tau_{\leqslant 2} \mathcal{X} \to \tau_{\leqslant 1} \mathcal{X} \to \tau_{\leqslant 0} \mathcal{X}.$$

Using Corollary A.7.3.8, we can identify this tower with

$$\cdots \to \tau_{\leqslant 3}\widehat{\mathcal{X}} \to \tau_{\leqslant 2}\widehat{\mathcal{X}} \to \tau_{\leqslant 1}\widehat{\mathcal{X}} \to \tau_{\leqslant 0}\widehat{\mathcal{X}}$$

(as a diagram in $(\mathcal{P}\mathrm{r}^{\mathrm{L}})_{\widehat{\mathcal{X}}/}$), so that $\widehat{\mathcal{X}}$ is Postnikov complete as desired. □

Proposition A.7.3.10. *Let $\mathcal{X}$ and $\mathcal{Y}$ be ∞-topoi. If $\mathcal{Y}$ is Postnikov complete, then composition with the natural map $e^* : \mathcal{X} \to \widehat{\mathcal{X}}$ induces an equivalence of ∞-categories* $\mathrm{Fun}^*(\widehat{\mathcal{X}}, \mathcal{Y}) \to \mathrm{Fun}^*(\mathcal{X}, \mathcal{Y})$.

Proof. For every pair of presentable ∞-categories $\mathcal{Z}$ and $\mathcal{Z}'$, let $\mathrm{LFun}(\mathcal{Z}, \mathcal{Z}')$ denote the full subcategory of $\mathrm{Fun}(\mathcal{Z}, \mathcal{Z}')$ spanned by those functors which preserve small colimits. We first show that composition with e^* induces an equivalence of ∞-categories $\theta : \mathrm{LFun}(\widehat{\mathcal{X}}, \mathcal{Y}) \to \mathrm{LFun}(\mathcal{X}, \mathcal{Y})$. Using our assumption that $\mathcal{Y}$ is Postnikov complete, we can identify θ with the limit of a tower of functors $\theta_n : \mathrm{LFun}(\widehat{\mathcal{X}}, \tau_{\leqslant n} \mathcal{Y}) \to \mathrm{LFun}(\mathcal{X}, \tau_{\leqslant n} \mathcal{Y})$, each of which is an equivalence by virtue of Proposition A.7.3.7.

To complete the proof, it will suffice to show that a colimit-preserving functor $f^* : \widehat{\mathcal{X}} \to \mathcal{Y}$ is left exact if and only if the composite functor $f^* \circ e^* : \mathcal{X} \to \mathcal{Y}$ is left exact. The "only if" direction follows from Proposition A.7.3.5. To prove the converse, suppose that $f'^* = f^* \circ e^*$ preserves finite limits. It is then clear that the functor f^* preserves final objects. To show that f^* is left exact, it will suffice to show that for each object $X = \{X_n\}_{n \geqslant 0}$ in $\widehat{\mathcal{X}}$, the induced map $\widehat{\mathcal{X}}_{/X} \to \mathcal{Y}_{/f^* X}$ preserves finite products. Using Remark A.7.3.3 (and the Postnikov completeness of $\mathcal{Y}$), we can write the ∞-category $\mathcal{Y}_{/f^* X}$ as the limit of a tower of ∞-categories $\{\tau_{\leqslant n-1} \mathcal{Y}_{/f'^* X_n}\}$ where the transition maps preserve finite products. We are therefore reduced to showing that each of the composite maps $\widehat{\mathcal{X}}_{/X} \to \mathcal{Y}_{/f^* X} \to \tau_{\leqslant n-1} \mathcal{Y}_{/f'^* X_n}$ preserves finite products. Unwinding the definitions, we see that each of these maps can be described as a composition $\widehat{\mathcal{X}}_{/X} \xrightarrow{u} \tau_{\leqslant n-1} \mathcal{X}_{/X_n} \xrightarrow{v} \tau_{\leqslant n-1} \mathcal{Y}_{/f'^* X_n}$, where the functor v preserves finite products because f'^* is left exact, and the functor u preserves finite products by virtue of Remark A.7.3.3. □

Proof of Theorem A.7.2.4. Combine Propositions A.7.3.4, A.7.3.5, A.7.3.7, A.7.3.9, and A.7.3.10. □

A.7.4 Bounded ∞-Pretopoi

We now discuss an analogue of Definition A.7.1.2 in the setting of ∞-pretopoi.

Definition A.7.4.1. Let $\mathcal{C}$ be an ∞-pretopos. We will say that $\mathcal{C}$ is *bounded* if it is essentially small and every object $X \in \mathcal{C}$ is n-truncated for $n \gg 0$. We let $\infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}_{<\infty}$ denote the full subcategory of $\infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}$ spanned by the bounded ∞-pretopoi.

Warning A.7.4.2. The terminology of Definition A.7.4.1 is slightly abusive. Any ∞-topos $\mathcal{X}$ can be regarded as an ∞-pretopos (Example A.6.1.5), but the condition that $\mathcal{X}$ is bounded as an ∞-topos (in the sense of Definition A.7.1.2) is not equivalent to the condition that $\mathcal{X}$ is bounded as an ∞-pretopos (in the sense of Definition A.7.4.1). In practice, there is unlikely to be any confusion: an ∞-topos $\mathcal{X}$ will *never* be bounded as an ∞-pretopos except in the trivial case where $\mathcal{X} \simeq \mathcal{S}\mathrm{hv}(\varnothing)$ is an initial object of $\infty\mathcal{T}\mathrm{op}$.

The next result implies that that bounded ∞-pretopoi exist in great abundance:

Proposition A.7.4.3. *Let $\mathcal{C}$ be an ∞-pretopos and let $\mathcal{C}_{<\infty}$ denote the full subcategory of $\mathcal{C}$ spanned by those objects which are n-truncated for some $n \gg 0$. Then:*

(a) *The full subcategory $\mathcal{C}_{<\infty} \subseteq \mathcal{C}$ is closed under finite limits, finite coproducts, and geometric realizations of groupoid objects.*

(b) *The ∞-category $\mathcal{C}_{<\infty}$ is an ∞-pretopos.*

(c) *If $\mathcal{C}_{<\infty}$ is essentially small, then it is a bounded ∞-pretopos.*

Proof. We will prove (a); assertion (b) then follows from Remark A.6.1.4 and (c) is an immediate consequence of (b). Enlarging the universe if necessary, we may assume that $\mathcal{C}$ is small. Let $j : \mathcal{C} \to \mathcal{S}\mathrm{hv}(\mathcal{C})$ denote the Yoneda embedding, so that an object of $\mathcal{C}$ is n-truncated if and only if its image in $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is n-truncated. We may therefore replace $\mathcal{C}$ by $\mathcal{S}\mathrm{hv}(\mathcal{C})$ and thereby reduce to the case where $\mathcal{C}$ is an ∞-topos (at the cost of dropping our assumption that $\mathcal{C}$ is small). In this case, the result is clear: the collection of n-truncated objects of $\mathcal{C}$ is closed under all limits, closed under coproducts if $n \geqslant 0$, and if $X_\bullet$ is a groupoid object of $\mathcal{C}$ for which X_0 and X_1 are n-truncated, then the geometric realization $|X_\bullet|$ is $(n+1)$-truncated. $\square$

Example A.7.4.4. Let $\mathcal{X}$ be a coherent ∞-topos. We let $\mathcal{X}^{\mathrm{coh}}_{<\infty}$ denote the full subcategeory of $\mathcal{X}$ spanned by the bounded coherent objects. Note that every n-truncated object coherent object of $\mathcal{X}$ is a compact object of $\tau_{\leqslant n}\mathcal{X}$ (Corollary A.2.3.2). It follows that the ∞-category $\mathcal{X}^{\mathrm{coh}}_{<\infty}$ is essentially small. Combining this observation with Propositions A.7.4.3 and A.6.1.6, we deduce that $\mathcal{X}^{\mathrm{coh}}_{<\infty}$ is a bounded ∞-pretopos.

A.7.5 Boundedness and Coherence

Let $\mathcal{X}$ be a hypercomplete ∞-topos which is coherent and locally coherent. According to Theorem A.6.6.5, we can recover $\mathcal{X}$ from its full subcategory $\mathcal{X}^{\mathrm{coh}}$ of coherent objects, which is a hypercomplete ∞-pretopos. Our goal in this section is to prove an analogous result, where the hypercompleteness hypothesis on $\mathcal{X}$ is replaced by boundedness. We begin with a simple observation:

Proposition A.7.5.1. *Let $\mathcal{X}$ be an ∞-topos which is bounded and coherent. Then $\mathcal{X}$ is locally coherent.*

Proof. Fix an object $X \in \mathcal{X}$. We wish to show that there exists an effective epimorphism $\amalg X_i \to X$, where each $X_i \in \mathcal{X}$ is coherent. Write $\mathcal{X}$ as the limit of a filtered diagram $\{\mathcal{X}_\alpha\}$ in $\infty\mathcal{T}\mathrm{op}$, where each $\mathcal{X}_\alpha$ is n_α-localic for some integer $n_\alpha \geqslant 0$. For each index α, let $f^*_\alpha : \mathcal{X}_\alpha \to \mathcal{X}$ be the corresponding geometric morphism. Then $\mathcal{X}$ is generated under small colimits by objects which lie in the essential image of some $\mathcal{X}_\alpha$. In particular, there exists an effective epimorphism $\amalg f_\alpha^* Y_\alpha \to X$ for some objects Y_α in $\mathcal{X}_\alpha$. Since $\mathcal{X}_\alpha$ is n_α-localic, we can choose effective epimorphisms $Z_\alpha \to Y_\alpha$ in $\mathcal{X}_\alpha$, where each Z_α is $(n_\alpha - 1)$-truncated. Replacing X by $f_\alpha^* Z_\alpha$, we can reduce to the case where X is n-truncated for some integer $n \gg 0$.

Since the ∞-topos $\mathcal{X}$ is coherent, it is $(n+2)$-coherent and therefore locally $(n+1)$-coherent. We may therefore choose an effective epimorphism $\rho' : \amalg X_i' \to X$, where each X_i' is $(n+1)$-coherent. Using our assumption that X is n-truncated, we deduce that ρ factors as a composition $\amalg X_i' \to \amalg(\tau_{\leqslant n} X_i') \xrightarrow{\rho} X$. We conclude by observing that ρ is an effective epimorphism and that each of the objects $\tau_{\leqslant n} X_i'$ is a coherent object of $\mathcal{X}$ by virtue of Corollary A.2.4.4. □

Construction A.7.5.2. Let $\infty\mathcal{T}\mathrm{op}_{\mathrm{coh}}$ denote the subcategory of $\infty\mathcal{T}\mathrm{op}$ whose objects are coherent ∞-topoi and whose morphisms are functors $f^* : \mathcal{X} \to \mathcal{Y}$ which preserve small colimits, finite limits, and carry coherent objects of $\mathcal{X}$ to coherent objects of $\mathcal{Y}$. Then the construction $\mathcal{X} \mapsto \mathcal{X}^{\mathrm{coh}}_{<\infty}$ induces a functor $\infty\mathcal{T}\mathrm{op}_{\mathrm{coh}}^{\mathrm{op}} \to \infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}_{<\infty}$.

Theorem A.7.5.3. *The forgetful functor*

$$\infty\mathcal{T}\mathrm{op}_{\mathrm{coh}}^{\mathrm{op}} \to \infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}_{<\infty} \qquad \mathcal{X} \mapsto \mathcal{X}^{\mathrm{coh}}_{<\infty}$$

of Construction A.7.5.2 admits a fully faithful left adjoint, given at the level of objects by the construction $\mathcal{C} \mapsto \mathcal{S}\mathrm{hv}(\mathcal{C})$. The essential image of this right adjoint is the full subcategory of $\infty\mathcal{T}\mathrm{op}_{\mathrm{coh}}^{\mathrm{op}}$ spanned by the bounded coherent ∞-topoi.

Proof. Let $\mathcal{C}$ be a bounded ∞-pretopos and let $\mathcal{X}$ be a coherent ∞-topos. For any geometric morphism $f^* : \mathcal{S}\mathrm{hv}(\mathcal{C}) \to \mathcal{X}$, let $\mathcal{E}(f^*)$ denote the full subcategory of $\mathcal{S}\mathrm{hv}(\mathcal{C})$ spanned by those coherent objects $\mathscr{F} \in \mathcal{S}\mathrm{hv}(\mathcal{C})$ for which $f^* \mathscr{F}$ is a coherent object of $\mathcal{X}$. Using Theorem A.5.5.1 and Remark A.2.1.8, we see that $\mathcal{E}(f^*)$ satisfies conditions (a), (b), (c), and (e) of Proposition A.6.5.7. If $\mathcal{E}(f^*)$ contains the essential image of the Yoneda embedding $j : \mathcal{C} \to \mathcal{S}\mathrm{hv}(\mathcal{C})$, then it also satisfies condition (d) and therefore contains all coherent objects of $\mathcal{S}\mathrm{hv}(\mathcal{C})$. This proves the following:

- $(*)$ A geometric morphism $f^* : \mathcal{S}\mathrm{hv}(\mathcal{C}) \to \mathcal{X}$ belongs to $\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}_{\mathrm{coh}}}(\mathcal{X}, \mathcal{S}\mathrm{hv}(\mathcal{C}))$ if and only if $f^* \circ j$ factors through the full subcategory $\mathcal{X}^{\mathrm{coh}} \subseteq \mathcal{X}$.

It follows from $(*)$ that we have a homotopy pullback square

$$\begin{array}{ccc} \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}_{\mathrm{coh}}}(\mathcal{X}, \mathcal{S}\mathrm{hv}(\mathcal{C})) & \longrightarrow & \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}_{<\infty}}(\mathcal{C}, \mathcal{X}^{\mathrm{coh}}_{<\infty}) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{X}, \mathcal{S}\mathrm{hv}(\mathcal{C})) & \longrightarrow & \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}}(\mathcal{C}, \mathcal{X}), \end{array}$$

where the horizontal maps are given by composition with j. Proposition A.6.4.4 implies that the bottom horizontal map is a homotopy equivalence, so the upper horizontal map is a homotopy equivalence as well. It follows that the construction $\mathcal{C} \mapsto \mathcal{S}\mathrm{hv}(\mathcal{C})$ induces a left adjoint to the forgetful functor $\mathcal{X} \mapsto \mathcal{X}^{\mathrm{coh}}_{<\infty}$ of Construction A.7.5.2.

We wish to show that this left adjoint is fully faithful. Equivalently, we wish to show that for each bounded ∞-pretopos $\mathcal{C}$, the unit map $\mathcal{C} \to \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{coh}}_{<\infty}$ is an equivalence of ∞-categories. For this, we must show that that a sheaf $\mathscr{F} \in \mathcal{S}\mathrm{hv}(\mathcal{C})$ is representable by an object of $\mathcal{C}$ if and only if it is truncated and coherent. This is a special case of the following assertion:

$(*')$ Let X be an object of $\mathcal{S}\mathrm{hv}(\mathcal{C})$ and let $\mathscr{F}$ be a coherent object of $\mathcal{S}\mathrm{hv}(\mathcal{C})$ equipped with an n-truncated morphism $f : \mathscr{F} \to j(X)$. Then $\mathscr{F}$ belongs to the essential image of j.

We will prove $(*')$ using induction on n. In the special case $n = -2$, the morphism f is an equivalence and there is nothing to prove. Let us therefore assume that $n > -2$. Since $\mathscr{F}$ is coherent, it is quasi-compact. We can therefore choose an effective epimorphism $g : \amalg_{i \in I} j(Y_i) \to \mathscr{F}$ where the index set I is finite. Set $Y = \amalg_{i \in I} Y_i \in \mathcal{C}$, so that we can identify g with a map $j(Y) \to \mathscr{F}$. Let $\mathscr{G}_\bullet$ denote the Čech nerve of g and let $\mathscr{H}_\bullet$ denote the Čech nerve of the composite map $(f \circ g)$, so that we can write $\mathscr{H}_\bullet = j(U_\bullet)$ where $U_\bullet$ is the Čech nerve of the associated map $Y \to X$ in the ∞-category $\mathcal{C}$. Our assumption that f is n-truncated guarantees that each of the induced maps $\mathcal{G}_k \to \mathcal{H}_k$ is $(n-1)$-truncated. Applying our inductive hypothesis, we deduce that each $\mathcal{G}_k$ belongs to the essential image of j. Since j is fully faithful, we can write $\mathcal{G}_\bullet = j(V_\bullet)$ for some groupoid object $V_\bullet$ of $\mathcal{C}$. Because j preserves effective epimorphisms, we conclude that $\mathscr{F} \simeq |\mathcal{G}_\bullet| \simeq j(|V_\bullet|)$ belongs to the essential image of j, as desired.

To complete the proof, we must show that a coherent ∞-topos $\mathcal{X} \in \infty\mathcal{T}\mathrm{op}_{\mathrm{coh}}$ belongs to the essential image of the construction $\mathcal{C} \mapsto \mathcal{S}\mathrm{hv}(\mathcal{C})$ if and only if $\mathcal{X}$ is bounded. The "only if" direction follows immediately from Example A.7.1.6. To prove the converse, we must show that if $\mathcal{X}$ is bounded and coherent then the inclusion $\mathcal{X}^{\mathrm{coh}}_{<\infty} \hookrightarrow \mathcal{X}$ extends to a geometric morphism $f^* : \mathcal{S}\mathrm{hv}(\mathcal{X}^{\mathrm{coh}}_{<\infty}) \to \mathcal{X}$ which is an equivalence of ∞-topoi. The domain and codomain of f^* are both bounded ∞-topoi (for the domain, this follows from Example A.7.1.6). It will therefore suffice to show that the functor f^* restricts to an equivalence on truncated objects. Applying Proposition A.9.2.1 (after passing to a larger universe), we are reduced to proving the following:

(a) For every truncated object $\mathscr{F} \in \mathcal{S}\mathrm{hv}(\mathcal{X}^{\mathrm{coh}}_{<\infty})$ and every morphism $u : X \to f^* \mathscr{F}$ between truncated objects of $\mathcal{X}$, there exists a morphism $v : \mathscr{G} \to \mathscr{F}$ between truncated objects of $\mathcal{S}\mathrm{hv}(\mathcal{X}^{\mathrm{coh}}_{<\infty})$ and a commutative diagram

$$\begin{array}{ccc} f^*\mathscr{G} & \xrightarrow{w} & X \\ & {\scriptstyle f^*v}\searrow \quad \swarrow{\scriptstyle u} & \\ & f^*\mathscr{F} & \end{array}$$

in $\mathcal{X}$, where w is an effective epimorphism.

(*b*) For every (-1)-truncated morphism $u : \mathscr{F} \to \mathscr{F}'$ between truncated object of $\mathcal{S}\mathrm{hv}(\mathcal{X}^{\mathrm{coh}}_{<\infty})$, if $f^*(u)$ is an equivalence, then u is an equivalence.

We begin with the proof of (a). Choose an effective epimorphism $\amalg \mathscr{F}_i \to \mathscr{F}$, where each $\mathscr{F}_i$ is representable by an object of $\mathcal{X}^{\mathrm{coh}}_{<\infty}$. Replacing X by $X \times_{f^*\mathscr{F}} f^*\mathscr{F}_i$, we can reduce to the case where $\mathscr{F}$ is representable by an object $Y \in \mathcal{X}^{\mathrm{coh}}_{<\infty}$. Then we can regard X is an object of the bounded coherent ∞-topos $\mathcal{X}_{/Y}$. Using the proof of Proposition A.7.5.1, we can find an effective epimorphism $\amalg Y_j \to X$ where each Y_j is a truncated coherent object of $\mathcal{X}_{/Y}$, and therefore also a truncated coherent object of $\mathcal{X}$. Assertion (a) now follows from the observation that $\amalg Y_j$ belongs to the essential image of the functor f^*.

We now prove (b). Let $u : \mathscr{F} \to \mathscr{F}'$ be a (-1)-truncated morphism in $\mathcal{S}\mathrm{hv}(\mathcal{X}^{\mathrm{coh}}_{<\infty})$ such that f^*u is an equivalence in $\mathcal{X}$; we wish to show that u is an equivalence. Writing $\mathscr{F}'$ as a colimit of representable sheaves, we can assume without loss of generality that $\mathscr{F}'$ is representable by a truncated coherent object $X \in \mathcal{X}$. Choose an effective epimorphism $\amalg_{i \in I} \mathscr{F}_i \to \mathscr{F}$, where each $\mathscr{F}_i$ is representable by an object $X_i \in (\mathcal{X}^{\mathrm{coh}}_{<\infty})_{/X}$. Since f^*u is an equivalence, the induced map

$$\amalg_{i \in I} X_i \simeq f^*(\amalg_{i \in I} \mathscr{F}_i) \to f^*\mathscr{F} \to f^*\mathscr{F}' \simeq X$$

is an effective epimorphism in $\mathcal{X}$. Because X is quasi-compact, we can choose a finite subset $I_0 \subseteq I$ for which the induced map $\amalg_{i \in I_0} X_i \to X$ is also an effective epimorphism. Note that $\amalg_{i \in I_0} X_i$ is a truncated coherent object of $\mathcal{X}$ which represents the sheaf $\amalg_{i \in I_0} \mathscr{F}_i \in \mathcal{S}\mathrm{hv}(\mathcal{X}^{\mathrm{coh}}_{<\infty})$. It follows that the composite map

$$\amalg_{i \in I_0} \mathscr{F}_i \to \amalg_{i \in I} \mathscr{F}_i \to \mathscr{F} \xrightarrow{u} \mathscr{F}'$$

is an effective epimorphism, so that u is also an effective epimorphism. Since u is also (-1)-truncated, it follows that u is an equivalence. □

Corollary A.7.5.4. *Let $\mathcal{C}$ be a bounded ∞-pretopos. Then $\mathcal{C}$ is idempotent-complete.*

Proof. Using Theorem A.7.5.3, one can identify $\mathcal{C}$ with the full subcategory of $\mathcal{S}\mathrm{hv}(\mathcal{C})$ spanned by the truncated coherent objects. In particular, there is a fully faithful embedding $j : \mathcal{C} \to \mathcal{S}\mathrm{hv}(\mathcal{C})$ whose essential image is closed under retracts. Since the ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is idempotent-complete, it follows that $\mathcal{C}$ is idempotent-complete. □

A.8 Pro-Objects of ∞-Pretopoi

Let $\mathcal{C}$ be a bounded ∞-pretopos (Definition A.7.4.1). Let us regard $\mathcal{C}$ as equipped with the effective epimorphism topology (Definition A.6.2.4) and let $j : \mathcal{C} \to \mathcal{S}\mathrm{hv}(\mathcal{C})$ be the Yoneda embedding. The construction $(C \in \mathcal{C}) \mapsto \mathcal{S}\mathrm{hv}(\mathcal{C})_{/C}$ determines a functor ρ_0 from $\mathcal{C}$ to the ∞-category $\infty\mathcal{T}\mathrm{op}_{/\mathcal{S}\mathrm{hv}(\mathcal{C})}$ of ∞-topoi equipped with a geometric morphism to $\mathcal{S}\mathrm{hv}(\mathcal{C})$. Let $\mathrm{Pro}(\mathcal{C})$ denote the ∞-category of Pro-objects of $\mathcal{C}$ (see Definition A.8.1.1). Since the ∞-category $\infty\mathcal{T}\mathrm{op}$ admits filtered limits, the functor ρ_0 admits an essentially unique extension $\rho : \mathrm{Pro}(\mathcal{C}) \to \infty\mathcal{T}\mathrm{op}_{/\mathcal{S}\mathrm{hv}(\mathcal{C})}$ which commutes with filtered limits. The main result of this section can be formulated as follows:

Theorem A.8.0.5. *Let $\mathcal{C}$ be a bounded ∞-pretopos. Then the functor $\rho : \mathrm{Pro}(\mathcal{C}) \to \infty\mathcal{T}\mathrm{op}_{/\mathcal{S}\mathrm{hv}(\mathcal{C})}$ is fully faithful.*

The proof of Theorem A.8.0.5 will occupy our attention throughout this section. Roughly speaking, our strategy is to give a more direct construction of the functor ρ (realizing the value of ρ on each Pro-object of $\mathcal{C}$ with the ∞-category of sheaves on a suitable bounded ∞-pretopos) which will allow us compute the relevant mapping spaces in the ∞-category $\infty\mathcal{T}\mathrm{op}_{/\mathcal{S}\mathrm{hv}(\mathcal{C})}$.

A.8.1 ∞-Categories of Pro-Objects

We begin by reviewing the theory of Pro-objects in the setting of ∞-categories. Let $\mathcal{C}$ be an essentially small ∞-category. In §HTT.5.3.5 , we introduced an ∞-category $\mathrm{Ind}(\mathcal{C})$ of Ind-*objects of* $\mathcal{C}$, which is obtained from $\mathcal{C}$ by formally adjoining filtered direct limits. In this section, we will need the categorical dual of this construction, which associates to $\mathcal{C}$ an ∞-category $\mathrm{Pro}(\mathcal{C}) = \mathrm{Ind}(\mathcal{C}^{\mathrm{op}})^{\mathrm{op}}$ of Pro-*objects* of $\mathcal{C}$. For the discussion of shape theory in §**??**, it will be convenient work in a slightly different context.

Definition A.8.1.1. Let $\mathcal{C}$ be an accessible ∞-category which admits finite limits. A Pro-*object* of $\mathcal{C}$ is a functor $U : \mathcal{C} \to \mathcal{S}$ which is accessible and preserves finite limits. We let $\mathrm{Pro}(\mathcal{C})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{S})^{\mathrm{op}}$ spanned by the Pro-objects of $\mathcal{C}$. We will refer to $\mathrm{Pro}(\mathcal{C})$ as the ∞-*category of* Pro-*objects of* $\mathcal{C}$.

Remark A.8.1.2. Let $\mathcal{C}$ be an essentially small idempotent complete ∞-category which admits finite limits (so that $\mathcal{C}$ is accessible: see Corollary HTT.5.4.3.6). Then $\mathcal{C}^{\mathrm{op}}$ admits finite colimits, so that $\mathrm{Ind}(\mathcal{C}^{\mathrm{op}})$ is the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{S})$ spanned by those functors which preserve finite limits. It follows that we have a canonical isomorphism $\mathrm{Pro}(\mathcal{C}) \simeq \mathrm{Ind}(\mathcal{C}^{\mathrm{op}})^{\mathrm{op}}$ (note that since $\mathcal{C}$ is essentially small, every functor $\mathcal{C} \to \mathcal{S}$ is automatically accessible).

Remark A.8.1.3. Let $\mathcal{C}$ be an accessible ∞-category which admits finite limits. Then the Yoneda embedding determines a fully faithful functor $j : \mathcal{C} \to \mathrm{Pro}(\mathcal{C})$. We will often abuse notation by not distinguishing between an object $C \in \mathcal{C}$ and the Pro-object $j(C) \in \mathrm{Pro}(\mathcal{C})$ corepresented by C.

Remark A.8.1.4. Let $\mathcal{C}$ be an accessible ∞-category which admits finite limits. The collection of left-exact, accessible functors from $\mathcal{C}$ to $\mathcal{S}$ is closed under small filtered colimits. It follows that the ∞-category $\mathrm{Pro}(\mathcal{C})$ admits filtered limits. Moreover, these limits are computed pointwise, so the essential image of the Yoneda embedding $\mathcal{C} \to \mathrm{Pro}(\mathcal{C})$ consists of compact objects of $\mathrm{Pro}(\mathcal{C})^{\mathrm{op}}$.

Remark A.8.1.5. Let $\mathcal{C}$ be an accessible ∞-category which admits finite limits. For every regular cardinal κ, let $\mathcal{C}^{\kappa}$ denote the full subcategory of $\mathcal{C}$ spanned by the κ-compact objects. If $U : \mathcal{C} \to \mathcal{S}$ is an accessible functor, then there exists a regular cardinal κ such that $\mathcal{C}^{\kappa}$ is closed under finite limits in $\mathcal{C}$ and U is a left Kan extension of its restriction to $\mathcal{C}^{\kappa}$. Then the restriction $U_0 = U|_{\mathcal{C}^{\kappa}}$ can be regarded as a Pro-object of $\mathcal{C}^{\kappa}$, and can therefore be written as a filtered colimit of functors represented by objects of $\mathcal{C}^{\kappa}$. It follows that U can be written as a filtered colimit of functors represented by objects of $\mathcal{C}$. Consequently, every object U of $\mathrm{Pro}(\mathcal{C})$ can be written as the limit of a filtered diagram $\{U_{\alpha}\}$, where each U_{α} belongs to the essential image of the Yoneda embedding $\mathcal{C} \to \mathrm{Pro}(\mathcal{C})$. We will generally abuse notation by identifying the diagram $\{U_{\alpha}\}$ with its limit in $\mathrm{Pro}(\mathcal{C})$. Using Remarks A.8.1.3 and A.8.1.4, we see that mapping spaces in $\mathrm{Pro}(\mathcal{C})$ can be described by the usual formula

$$\begin{aligned} \mathrm{Map}_{\mathrm{Pro}(\mathcal{C})}(\{C_{\alpha}\}, \{D_{\beta}\}) &\simeq \varprojlim_{\beta} \mathrm{Map}_{\mathrm{Pro}(\mathcal{C})}(\{C_{\alpha}\}, j(D_{\beta})) \\ &\simeq \varprojlim_{\beta} \varinjlim_{\alpha} \mathrm{Map}_{\mathrm{Pro}(\mathcal{C})}(j(C_{\alpha}), j(D_{\beta})) \\ &\simeq \varprojlim_{\beta} \varinjlim_{\alpha} \mathrm{Map}_{\mathcal{C}}(C_{\alpha}, D_{\beta}). \end{aligned}$$

Our interest in Definition A.8.1.1 is justified by the following universal property:

Proposition A.8.1.6. *Let $\mathcal{C}$ be an accessible ∞-category which admits finite limits, let $\mathcal{D}$ be an ∞-category which admits small filtered limits, and let $\mathrm{Fun}'(\mathrm{Pro}(\mathcal{C}), \mathcal{D})$ denote the full subcategory of $\mathrm{Fun}(\mathrm{Pro}(\mathcal{C}), \mathcal{D})$ spanned by those functors which preserve small filtered limits. Then composition with the Yoneda embedding restricts to an equivalence of ∞-categories*

$$\mathrm{Fun}'(\mathrm{Pro}(\mathcal{C}), \mathcal{D}) \to \mathrm{Fun}(\mathcal{C}, \mathcal{D}).$$

We can state Proposition A.8.1.6 more informally as follows: the ∞-category $\mathrm{Pro}(\mathcal{C})$ is obtained from $\mathcal{C}$ by freely adjoining small filtered limits.

Proof of Proposition A.8.1.6. Let $\widehat{\mathcal{S}}$ denote the ∞-category of spaces which are not necessarily small, let $\mathcal{E}$ denote the smallest full subcategory of $\mathrm{Fun}(\mathcal{C}, \widehat{\mathcal{S}})$ which contains the essential image of the Yoneda embedding and is closed under small filtered colimits, and let $\mathrm{Fun}'(\mathcal{E}^{\mathrm{op}}, \mathcal{D})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{E}^{\mathrm{op}}, \mathcal{D})$ spanned by those functors which preserve small filtered limits. Using Remark HTT.5.3.5.9 , we see that composition with the Yoneda embedding induces an equivalence of ∞-categories $\mathrm{Fun}'(\mathcal{E}^{\mathrm{op}}, \mathcal{D}) \to \mathrm{Fun}(\mathcal{C}, \mathcal{D})$. It will therefore suffice to show that $\mathcal{E}$ is equivalent to $\mathrm{Pro}(\mathcal{C})^{\mathrm{op}}$ (as subcategories of $\mathrm{Fun}(\mathcal{C}, \widehat{\mathcal{S}})$. Using Remark A.8.1.4, we see that $\mathcal{E}$ is contained in the essential image of $\mathrm{Pro}(\mathcal{C})^{\mathrm{op}}$. We will complete the proof by verifying the following:

- $(*)$ Let $F : \mathcal{C} \to \mathcal{S}$ be an accessible functor which preserves finite limits. Then F can be written as a small filtered colimit $\varinjlim F_\alpha$, where each of the functors $F_\alpha : \mathcal{C} \to \mathcal{S}$ is corepresentable by an object of $\mathcal{C}$.

To prove $(*)$, choose a regular cardinal κ such that $\mathcal{C}$ is κ-accessible and the functor $F : \mathcal{C} \to \mathcal{S}$ preserves κ-filtered colimits. Let $\mathcal{C}^\kappa$ denote the full subcategory of $\mathcal{C}$ spanned by the κ-compact objects. Enlarging κ if necessary, we may assume $\mathcal{C}^\kappa$ is closed under finite limits. Let F^κ denote the restriction of F to $\mathcal{C}^\kappa$. Since $\mathcal{C}^\kappa$ is essentially small and F^κ is left-exact, we can write F^κ as a filtered colimit of functors F^κ_α, where each F^κ_α is corepresentable by an object of $\mathcal{C}^\kappa$ (Corollary HTT.5.3.5.4). Since the Yoneda embedding $h^\kappa : (\mathcal{C}^\kappa)^{\mathrm{op}} \to \mathrm{Fun}(\mathcal{C}^\kappa, \mathcal{S})$ is fully faithful, we can write $F^\kappa_\alpha = h^\kappa(C_\alpha)$ for some filtered diagram $\{C_\alpha\}$ in $(\mathcal{C}^\kappa)^{\mathrm{op}}$. Let $h : \mathcal{C}^{\mathrm{op}} \to \mathrm{Fun}(\mathcal{C}, \mathcal{S})$ denote the Yoneda embedding for $\mathcal{C}$, and let $F' = \varinjlim_\alpha h(C_\alpha)$. We will complete the proof of $(*)$ by showing that $F' \simeq F$. By construction, F and F' have the same restriction to $\mathcal{C}^\kappa$. Since $\mathcal{C}$ is κ-accessible, it will suffice to show that the functors F and F' preserve small κ-filtered colimits (Proposition HTT.5.3.5.10). For the functor F, this follows by assumption. To show that F' commutes with κ-filtered colimits, it will suffice to show that each $h(C_\alpha)$ commutes with κ-filtered colimits; this follows because each C_α is κ-compact. □

Example A.8.1.7. Let $\mathcal{C}$ be a presentable ∞-category, and let $F : \mathcal{C} \to \mathrm{Pro}(\mathcal{C})$ be the Yoneda embedding. It follows from Proposition HTT.5.1.3.2 that the functor j preserves small colimits. Applying Corollary HTT.5.5.2.9 , we deduce that F admits a right adjoint $G : \mathrm{Pro}(\mathcal{C}) \to \mathcal{C}$. Since G is a right adjoint, it preserves small filtered limits. Because F is fully faithful, the unit map $\mathrm{id}_{\mathcal{C}} \to G \circ F$ is an equivalence. It follows from Proposition A.8.1.6 that the functor G is uniquely determined (up to a contractible space of choices) by these conditions: that is, $G : \mathrm{Pro}(\mathcal{C}) \to \mathcal{C}$ is the unique extension of the identity functor on $\mathcal{C}$ which preserves small filtered limits. If X is an object of $\mathrm{Pro}(\mathcal{C})$ given by an inverse system $\{X_\alpha\}$ of objects of $\mathcal{C}$, then $G(X)$ is given by the limit $\varprojlim X_\alpha$.

Example A.8.1.8. Let $f : \mathcal{C} \to \mathcal{D}$ be a functor between accessible ∞-categories which admit small limits. Then the composite functor $\mathcal{C} \xrightarrow{f} \mathcal{D} \to \mathrm{Pro}(\mathcal{D})$ induces a map $\mathrm{Pro}(f) :$

$\operatorname{Pro}(\mathcal{C}) \to \operatorname{Pro}(\mathcal{D})$, which commutes with small filtered limits. If f is accessible and preserves finite limits, then composition with f induces a functor $F : \operatorname{Pro}(\mathcal{D}) \to \operatorname{Pro}(\mathcal{C})$. It is not difficult to see that the functor F (when defined) is a left adjoint to $\operatorname{Pro}(f)$.

Proposition A.8.1.9. *Let $\mathcal{C}$ be an accessible ∞-category which admits finite limits, let $\mathcal{C}_0 \subseteq \mathcal{C}$ be an accessible full subcategory which is closed under finite limits, and let $f : \mathcal{C}_0 \to \mathcal{C}$ denote the inclusion map (so that f is accessible). Then the induced map $\operatorname{Pro}(f) : \operatorname{Pro}(\mathcal{C}_0) \to \operatorname{Pro}(\mathcal{C})$ is fully faithful. Moreover, the essential image of $\operatorname{Pro}(f)$ is spanned by those* Pro*-objects $X \in \operatorname{Pro}(\mathcal{C}) \subseteq \operatorname{Fun}(\mathcal{C}, \mathcal{S})^{\mathrm{op}}$ for which X is a left Kan extension of $X|_{\mathcal{C}_0}$.*

Proof. Let $\mathcal{D}$ denote the full subcategory of $\operatorname{Fun}(\mathcal{C}, \mathcal{S})^{\mathrm{op}}$ spanned by those functors which are left Kan extensions of their restrictions to $\mathcal{C}_0$. Then $\mathcal{D}^{\mathrm{op}} \subseteq \operatorname{Fun}(\mathcal{C}, \mathcal{S})$ is closed under small colimits, so that $\mathcal{D}$ is closed under small limits in $\operatorname{Fun}(\mathcal{C}, \mathcal{S})$. Using Remark A.8.1.4, we see that the intersection $\mathcal{D} \cap \operatorname{Pro}(\mathcal{C})$ is closed under small filtered limits in $\operatorname{Pro}(\mathcal{C})$. Note that the Yoneda embedding $j : \mathcal{C} \to \operatorname{Fun}(\mathcal{C}, \mathcal{S})^{\mathrm{op}}$ carries $\mathcal{C}_0$ into $\mathcal{D}$. It follows that $\operatorname{Pro}(f)$ carries $\operatorname{Pro}(\mathcal{C}_0)$ into $\operatorname{Pro}(\mathcal{C}) \cap \mathcal{D}$. Let $U : \operatorname{Pro}(\mathcal{C}) \cap \mathcal{D} \to \operatorname{Pro}(\mathcal{C}_0)$ denote the functor given by composition with the inclusion $\mathcal{C}_0 \subseteq \mathcal{C}$. Then U preserves small filtered limits (Remark A.8.1.4), and the diagram

$$\begin{array}{ccc} \mathcal{C}_0 & \xrightarrow{\mathrm{id}} & \mathcal{C}_0 \\ \downarrow & & \downarrow \\ \operatorname{Pro}(\mathcal{C}_0) & \xrightarrow{U \circ \operatorname{Pro}(f)} & \operatorname{Pro}(\mathcal{C}_0) \end{array}$$

commutes up to homotopy. It follows that that $U \circ \operatorname{Pro}(f)$ is homotopic to the identity. Since U is fully faithful (Proposition HTT.4.3.2.15), we deduce that $\operatorname{Pro}(f)$ is an equivalence of ∞-categories. □

A.8.2 Digression: Truncated Category Objects

Let $\mathcal{C}$ be an ∞-category which admits finite limits. Recall that a *category object* of $\mathcal{C}$ is a simplicial object $C_\bullet$ of $\mathcal{C}$ satisfying the following "Segal condition": for each $n \geqslant 0$, the diagram of linearly ordered sets

$$\begin{array}{ccccccccc} & \{0,1\} & & \cdots & & \{n-1,n\} & \\ \nearrow & & \nwarrow \quad \nearrow & & \nwarrow \quad \nearrow & & \nwarrow \\ \{0\} & & \{1\} & \cdots & \{n-1\} & & \{n\} \end{array}$$

induces an equivalence

$$C_n \to C_1 \times_{C_0} \cdots \times_{C_0} C_1.$$

Example A.8.2.1. Let $C_\bullet$ be a simplicial set. Then $C_\bullet$ is a category object of the category $\mathcal{S}\mathrm{et}$ of sets if and only if $C_\bullet$ is isomorphic to the nerve of a small category $\mathcal{E}$. Moreover, the category $\mathcal{E}$ is determined up to canonical isomorphism: the objects of $\mathcal{E}$ are the elements of the set C_0, the morphisms of $\mathcal{E}$ are the elements of the set C_1, and the composition of morphisms is determined by the map

$$C_1 \times_{C_0} C_1 \simeq C_2 \xrightarrow{\rho} C_1,$$

where ρ is induced by the inclusion of linearly ordered sets $[1] \simeq \{0, 2\} \hookrightarrow [2]$.

We now call attention to two phenomena visible in Example A.8.2.1:

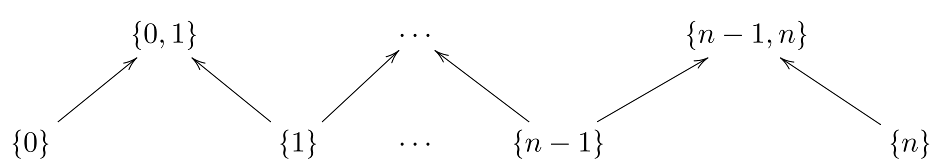
- Let $C_\bullet$ be a category object in sets, so that $C_\bullet \simeq \mathrm{N}(\mathcal{E})$ for some small category $\mathcal{E}$. To recover the category $\mathcal{E}$ (and therefore the entire simplicial set $C_\bullet$), we only need to know the sets C_0, C_1, C_2, and the maps between them.

- When reconstructing the category $\mathcal{E}$ from the simplicial set $C_\bullet$, the main step is to prove that composition of morphisms is associative. The proof of this involves studying the set C_3 and the bijection $C_3 \to C_1 \times_{C_0} C_1 \times_{C_0} C_1$. In particular, it does not make any reference to the sets C_n for $n \geqslant 4$.

Our goal in this section is to generalize these observations. We begin by introducing some terminology.

Definition A.8.2.2. Let $\mathcal{C}$ be an ∞-category which admits finite limits, and let $m \geqslant 1$ be an integer. We let $\mathbf{\Delta}_{\leqslant m}$ denote the category whose objects are the sets $[n] = \{0 < 1 < \ldots < n\}$ for $0 \leqslant n \leqslant m$, and whose morphisms are nondecreasing maps of linearly ordered sets. An *m-skeletal simplicial object* of $\mathcal{C}$ is a functor $\mathbf{\Delta}^{\mathrm{op}}_{\leqslant m} \to \mathcal{C}$. If C is an m-skeletal simplicial object and $n \leqslant m$, we let C_n denote the image in $\mathcal{C}$ of the object $[n] \in \mathbf{\Delta}_{\leqslant m}$.

An *m-skeletal category object* is a functor $\mathbf{\Delta}^{\mathrm{op}}_{\leqslant m} \to \mathcal{C}$ with the following property: for each $n \leqslant m$, the diagram of linearly ordered sets



induces an equivalence $C_n \to C_1 \times_{C_0} \cdots \times_{C_0} C_1$.

We let $\mathrm{CObj}(\mathcal{C})$ denote the full subcategory of $\mathrm{Fun}(\mathbf{\Delta}^{\mathrm{op}}, \mathcal{C})$ spanned by the category objects, and $\mathrm{CObj}_{\leqslant m}(\mathcal{C})$ the full subcategory of $\mathrm{Fun}(\mathbf{\Delta}^{\mathrm{op}}_{\leqslant m}, \mathcal{C})$ spanned by the m-skeletal category objects.

We can now state our main result.

Theorem A.8.2.3. *Let $\mathcal{C}$ be an ∞-category which is equivalent to an n-category for some $n \geqslant -1$ (see Definition HTT.2.3.4.1) and admits finite limits. Then the restriction functor $\mathrm{CObj}(\mathcal{C}) \to \mathrm{CObj}_{\leqslant m}(\mathcal{C})$ is fully faithful when $m = n+1$ and an equivalence of ∞-categories when $m \geqslant n+2$.*

Corollary A.8.2.4. *Let $\mathcal{C}$ be an ∞-category which is given as a filtered colimit $\varinjlim \mathcal{C}_\alpha$, where each $\mathcal{C}_\alpha$ admits finite limits and each of the transition maps $\mathcal{C}_\alpha \to \mathcal{C}_\beta$ preserves finite limits. Suppose further that there exists an integer n such that each $\mathcal{C}_\alpha$ is equivalent to an n-category. Then the canonical map $\varinjlim \mathrm{CObj}(\mathcal{C}_\alpha) \to \mathrm{CObj}(\mathcal{C})$ is an equivalence of ∞-categories.*

Proof. Note that $\mathcal{C}$ is also equivalent to an n-category. Let K denote the $(n+1)$-skeleton of the simpicial set $\mathrm{N}(\mathbf{\Delta}^{\mathrm{op}}_{\leqslant n+2})$. We have a commutative diagram

$$\begin{array}{ccc}
\varinjlim_\alpha \mathrm{CObj}(\mathcal{C}_\alpha) & \longrightarrow & \mathrm{CObj}(\mathcal{C}) \\
\downarrow & & \downarrow \\
\varinjlim_\alpha \mathrm{CObj}_{\leqslant n+2}(\mathcal{C}_\alpha) & \longrightarrow & \mathrm{CObj}_{\leqslant n+2}(\mathcal{C}) \\
\downarrow & & \downarrow \\
\varinjlim_\alpha \mathrm{Fun}(\mathbf{\Delta}^{\mathrm{op}}_{\leqslant n+2}, \mathcal{C}_\alpha) & \longrightarrow & \mathrm{Fun}(\mathbf{\Delta}^{\mathrm{op}}_{\leqslant n+2}, \mathcal{C}) \\
\downarrow & & \downarrow \\
\varinjlim_\alpha \mathrm{Fun}(K, \mathcal{C}_\alpha) & \longrightarrow & \mathrm{Fun}(K, \mathcal{C}).
\end{array}$$

The upper vertical maps are equivalences by virtue of Theorem A.8.2.3, the lower vertical maps are equivalences by virtue of our assumption that the ∞-categories $\mathcal{C}$ and $\mathcal{C}_\alpha$ are equivalent to n-categories, and the middle square is a (homotopy) pullback. We are therefore reduced to showing that the canonical map $\varinjlim_\alpha \mathrm{Fun}(K, \mathcal{C}_\alpha) \to \mathrm{Fun}(K, \mathcal{C})$ is an equivalence, which follows from the observation that K is a finite simplicial set. □

Corollary A.8.2.5. *Let $\mathcal{C}$ be an ∞-category which is given as a filtered colimit $\varinjlim \mathcal{C}_\alpha$, where each $\mathcal{C}_\alpha$ admits finite limits and each of the transition maps $\mathcal{C}_\alpha \to \mathcal{C}_\beta$ preserves finite limits. Then the induced map $\varinjlim_\alpha \mathcal{G}\mathrm{pd}(\mathcal{C}_\alpha) \to \mathcal{G}\mathrm{pd}(\mathcal{C})$ is an equivalence of ∞-categories. Here $\mathcal{G}\mathrm{pd}(\mathcal{E})$ denotes the ∞-category of groupoid objects of $\mathcal{E}$ (see Definition HTT.6.1.2.7).*

Theorem A.8.2.3 is an immediate consequence of the following more precise assertions (and Proposition HTT.4.3.2.15).

Proposition A.8.2.6. *Let $\mathcal{C}$ be an ∞-category which admits finite limits, and let $C_\bullet$ be a category object of $\mathcal{C}$. Assume that the map $C_1 \to C_0 \times C_0$ is $(n-2)$-truncated for some integer $n \geqslant 0$. Then $C_\bullet$ is a right Kan extension of its restriction to $\mathbf{\Delta}^{\mathrm{op}}_{\leqslant n}$.*

Proposition A.8.2.7. *Let $\mathcal{C}$ be an ∞-category which admits finite limits, let $n \geqslant 1$, and let $C_\bullet$ be an n-skeletal category object of $\mathcal{C}$. Assume that the map $C_1 \to C_0 \times C_0$ is $(n-3)$-truncated. Then $C_\bullet$ can be extended to a category object $\overline{C}_\bullet$ of $\mathcal{C}$ (this extension is necessarily a right Kan extension, by virtue of Proposition A.8.2.6).*

The proofs of Propositions A.8.2.6 and A.8.2.7 will require some preliminaries. First, we need a slight modification of Construction A.5.1.6:

Notation A.8.2.8. Let $\mathcal{C}$ be an ∞-category which admits finite limits and let $C_\bullet$ be an m-skeletal simplicial object of $\mathcal{C}$. Let K be a finite nonsingular simplicial set of dimension $\leqslant m$ (meaning that every nondegenerate simplex of K has dimension $\leqslant m$), and let $\mathbf{\Delta}_K^{\mathrm{nd}}$ denote the category of nondegenerate simplices of K (see Notation A.5.1.5). We let $C_\bullet[K]$ denote a limit of the induced diagram $(\mathbf{\Delta}_K^{\mathrm{nd}})^{\mathrm{op}} \to \mathbf{\Delta}_{\leqslant m}^{\mathrm{op}} \xrightarrow{C_\bullet} \mathcal{C}$.

Lemma A.8.2.9. *Let $\mathcal{C}$ be an ∞-category which admits finite limits, let $C_\bullet$ be an m-skeletal category object of $\mathcal{C}$ for some $m \geqslant 1$. Then:*

(1) *Let $n \leqslant m+1$, let $0 < j < n$, and let $A \subseteq \Delta^n$ be the simplicial subset spanned by the edges $\{\Delta^{\{i-1,i\}}\}_{1 \leqslant i \leqslant n}$. Then the restriction map $C_\bullet[\Lambda^n_j] \to C_\bullet[A]$ is an equivalence.*

(2) *For $0 < j < n \leqslant m$, the map $C_\bullet[\Delta^n] \to C_\bullet[\Lambda^n_j]$ is an equivalence.*

Proof. We prove (1) and (2) by a simultaneous induction on n. Note that if $n \leqslant m$ and K is defined as in (1), then the composite map $C_\bullet[\Delta^n] \to C_\bullet[\Lambda^n_j] \to C_\bullet[A]$ is an equivalence by virtue of our assumption that $C_\bullet$ is an n-skeletal category object. Consequently, assertion (2) follows from (1) and the two-out-of-three property.

We now prove (1). Let S be the collection of all nondegenerate simplices σ of Δ^n which contain the vertex j together with additional vertices i and k such that $i < j < k$. Write $S = \{\sigma_1, \sigma_2, \ldots, \sigma_b\}$, where $a < a'$ whenever σ_a has dimension larger than $\sigma_{a'}$; in particular, we have $\sigma_1 = \Delta^n$. For $1 \leqslant a \leqslant b$, let τ_a be the face of σ_a obtained by the removing the vertex j, and let K_a denote the simplicial subset obtained from Δ^n by removing the simplices $\{\sigma_{a'}, \tau_{a'}\}_{a' \leqslant a}$. We have a chain of simplicial subsets

$$\Delta^{\{0,\ldots,j\}} \coprod_{\{j\}} \Delta^{\{j,j+1,\ldots,n\}} = K_b \subseteq K_{b-1} \subseteq \cdots \subseteq K_1 = \Lambda^n_j.$$

For $1 \leqslant a < b$, the inclusion $K_{a+1} \subseteq K_a$ is a pushout of an inner horn inclusion $\Lambda^{n'}_{j'} \subseteq \Delta^{n'}$ for some $0 < j' < n' < n$, so we have a pullback diagram

$$\begin{array}{ccc} C_\bullet[K_a] & \longrightarrow & C_\bullet[K_{a+1}] \\ \downarrow & & \downarrow \\ C_\bullet[\Delta^{n'}] & \longrightarrow & C_\bullet[\Lambda^{n'}_{j'}] \end{array}$$

The inductive hypothesis implies that the bottom horizontal map is an equivalence, so that $C_\bullet[K_a] \simeq C_\bullet[K_{a+1}]$ for $1 \leqslant a < b$. It follows that the restriction map

$$C_\bullet[\Lambda^n_j] \to C_\bullet[K_b] \simeq C_\bullet[\Delta^{\{0,\ldots,j\}}] \times_{C_\bullet[\{j\}]} C_\bullet[\Delta^{\{j,\ldots,n\}}]$$

is an equivalence. Let A_- be the simplicial subset of Δ^n spanned by the edges $\Delta^{\{i-1,i\}}$ for $1 \leqslant i \leqslant j$, and let A_+ be the simplicial subset of Δ^n spanned by the edges $\Delta^{\{i-1,i\}}$ for $j < i \leqslant n$. Since $C_\bullet$ is an m-coskeletal category object, the restriction maps

$$C_\bullet[\Delta^{\{0,\ldots,j\}}] \to C_\bullet[A_-] \qquad C_\bullet[\Delta^{\{j,j+1,\ldots,n\}}] \to C_\bullet[A_+]$$

are equivalences. It follows that the map

$$C_\bullet[\Lambda^n_j] \to C_\bullet[A] \simeq C_\bullet[A_-] \times_{C_\bullet[\{j\}]} C_\bullet[A_+]$$

is an equivalence. □

Proof of Proposition A.8.2.6. Let $C_\bullet$ be a category object of $\mathcal{C}$ such that the map $C_1 \to C_0 \times C_0$ is $(n-2)$-truncated. We wish to show that $C_\bullet$ is a right Kan extension of its restriction to $\mathbf{\Delta}^{\mathrm{op}}_{\leqslant n}$. It will suffice to show that for each $m \geqslant n$, the restriction $C_\bullet|_{\mathbf{\Delta}^{\mathrm{op}}_{\leqslant m}}$ is a right Kan extension of $C_\bullet|_{\mathbf{\Delta}^{\mathrm{op}}_{\leqslant n}}$. Using Proposition HTT.4.3.2.8 repeatedly, we are reduced to showing that $C_\bullet|_{\mathbf{\Delta}^{\mathrm{op}}_{\leqslant m}}$ is a right Kan extension of $C_\bullet|_{\mathbf{\Delta}^{\mathrm{op}}_{\leqslant m-1}}$ for $m > n$. In other words, we must show that if $m > n$, then the map $C_m \to M_m(C)$ is an equivalence, where $M_m(C)$ denotes the mth matching object of $C_\bullet$ (see Notation HTT.A.2.9.7). We will show more generally that the map $\beta_m : C_m \to M_m(C)$ is $(n-m-1)$-truncated for each $m \geqslant 1$. If $m > n$, this implies that β_m is an equivalence. We proceed by induction on m: the case $m = 1$ follows from our hypothesis that $C_1 \to C_0 \times C_0$ is $(n-2)$-truncated. Assume therefore that $m \geqslant 2$, and choose $0 < j < m$. Lemma A.8.2.9 implies that the composite map

$$C_\bullet[\Delta^m] \simeq C_m \to M_m(C) \simeq C_\bullet[\partial\,\Delta^m] \to C_\bullet[\Lambda^m_j]$$

is an equivalence. It will therefore suffice to show that the map $\gamma : C_\bullet[\partial\,\Delta^m] \to C_\bullet[\Lambda^m_j]$ is $(n-m)$-truncated. This follows from the inductive hypothesis, since γ is a pullback of the map $C_{m-1} \to M_{m-1}(C)$. □

Proof of Proposition A.8.2.7. Let $C_\bullet$ be an n-skeletal category object of $\mathcal{C}$ and assume that the map $C_1 \to C_0 \times C_0$ is $(n-3)$-truncated. Since $\mathcal{C}$ admits finite limits, there exists a simplicial object $\overline{C}_\bullet$ which is a right Kan extension of $C_\bullet$. We wish to show that $\overline{C}_\bullet$ is a category object of $\mathcal{C}$. It will suffice to show that the restriction $\overline{C}_\bullet|_{\mathbf{\Delta}^{\mathrm{op}}_{\leqslant m}}$ is an m-skeletal category object for each $m \geqslant n$. We proceed by induction on m, the case $m = n$ being trivial. Let $A \subseteq \Delta^m$ be the simplicial subset given by the union of the edges $\{\Delta^{\{i-1,i\}}\}_{1 \leqslant i \leqslant m}$; we wish to show that the map $\overline{C}_\bullet[\Delta^m] \to \overline{C}_\bullet[A]$ is an equivalence. Since $m > n \geqslant 1$, we can choose $0 < j < m$. Using the inductive hypothesis and Lemma A.8.2.9, we deduce that $\overline{C}_\bullet[\Lambda^m_j] \to \overline{C}_\bullet[A]$ is an equivalence. It will therefore suffice to show that the restriction map $\beta : \overline{C}_\bullet[\Delta^m] \to \overline{C}_\bullet[\Lambda^m_j]$ is an equivalence. Note that β is a pullback of the map $\beta' : \overline{C}_\bullet[\Delta^{m-1}] \to \overline{C}_\bullet[\partial\,\Delta^{m-1}]$. We will show that β' is an equivalence. For this, it suffices to prove the more general claim that for $1 \leqslant k < m$, the map $\beta'_k : \overline{C}_\bullet[\Delta^k] \to \overline{C}_\bullet[\partial\,\Delta^k]$ is $(n-k-2)$-truncated.

As in the proof of Proposition A.8.2.6, we proceed by induction on k, the case $k = 1$ being true by virtue of our hypothesis. Assume therefore that $k \geqslant 2$, and choose $0 < i < k$. Since $k < m$, the restriction $\overline{C}_\bullet|_{\mathbf{\Delta}_{\leqslant k}}$ is a k-skeletal category object so that Lemma A.8.2.9 implies that the composite map $\overline{C}_\bullet[\Delta^k] \xrightarrow{\beta'_k} \overline{C}_\bullet[\partial\,\Delta^k] \xrightarrow{\gamma} \overline{C}_\bullet[\Lambda^k_i]$ is an equivalence. It is therefore sufficient to show that γ is $(n-k-1)$-truncated. This follows from the inductive hypothesis, since γ is a pullback of β'_{k-1}. □

A.8.3 Filtered Colimits of ∞-Pretopoi

In §A.7, we introduced the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}_{<\infty}$ whose objects are bounded ∞-pretopoi and whose morphisms are functors which preserve finite limits, finite coproducts, and effective epimorphisms (Definition A.7.4.1). We now make the following observation:

Proposition A.8.3.1. *The ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}_{<\infty}$ admits small filtered colimits. Moreover, the inclusion $\infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}_{<\infty} \hookrightarrow \widehat{\mathcal{C}\mathrm{at}}_\infty$ preserves small filtered colimits.*

Proof. Let $\{\mathcal{C}_\alpha\}_{\alpha \in A}$ be a diagram in the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}_{<\infty}$ indexed by a filtered partially ordered set A, and set $\mathcal{C} = \varinjlim_{\alpha \in A} \mathcal{C}_\alpha$. For each index $\alpha \in A$, let $f^*_\alpha : \mathcal{C}_\alpha \to \mathcal{C}$ be the canonical map. Unwinding the definitions, we must prove the following:

- (i) The ∞-category $\mathcal{C}$ is a bounded ∞-pretopos.
- (ii) For every bounded ∞-pretopos $\mathcal{E}$, a functor $g^* : \mathcal{C} \to \mathcal{E}$ is a morphism in $\infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}_{<\infty}$ if and only if the composition $(g^* \circ f^*_\alpha) : \mathcal{C}_\alpha \to \mathcal{E}$ is a morphism in $\infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}_{<\infty}$ for each $\alpha \in A$.

We first prove (i). By assumption, each of the ∞-categories $\mathcal{C}_\alpha$ admits finite limits and finite coproducts and each of the transition maps $\mathcal{C}_\alpha \to \mathcal{C}_\beta$ preserves finite limits and finite colimits. It follows that the ∞-category $\mathcal{C}$ admits finite limits and finite coproducts and that each of the functors f^*_α preserves finite limits and finite coproducts. In particular, each of the functors f^*_α carries n-truncated objects of $\mathcal{C}_\alpha$ to n-truncated objects of $\mathcal{C}$. Since every object $C \in \mathcal{C}$ lies in the essential image of one of the functors f^*_α, it follows immediately that C is n-truncated for some integer n. Conversely, suppose that $C \in \mathcal{C}$ is n-truncated, and write $C = f^*_\alpha C_0$ for some index α and some object $C_0 \in \mathcal{C}_\alpha$. Since the diagonal map $\delta : C \to C^{S^{n+1}}$ is an equivalence, it follows that the map $\delta_0 : C_0 \to C_0^{S^{n+1}}$ is a morphism in $\mathcal{C}_\alpha$ whose image under f_α^* is an equivalence. We may therefore arrange (after enlarging α) that the map δ_0 is an equivalence, so that the object $C_0 \in \mathcal{C}_\alpha$ is n-truncated. It follows that we have $\mathcal{C}^{\leqslant n} \simeq \varinjlim \mathcal{C}_\alpha^{\leqslant n}$, where $\mathcal{C}^{\leqslant n}$ denotes the full subcategory of $\mathcal{C}$ spanned by the n-truncated objects and $\mathcal{C}_\alpha^{\leqslant n} \subseteq \mathcal{C}_\alpha$ is defined similarly.

To complete the proof of (i), it will suffice to show that $\mathcal{C}$ is an ∞-pretopos. We first show that coproducts in $\mathcal{C}$ are universal. Suppose we are given a finite collection of morphisms $\phi_i : X_i \to X$ in $\mathcal{C}$ and a morphism $\psi : Y \to X$ in $\mathcal{C}$; we wish to prove that the induced map $\theta : \amalg(X_i \times_X Y) \to (\amalg X_i) \times_X Y$ is an equivalence. Without loss of generality, we may assume that $\psi = f_\alpha^* \psi_0$ for some morphism $\psi_0 : Y_0 \to X_0$ in $\mathcal{C}_\alpha$. Enlarging α if necessary, we may further assume that each ϕ_i is given by $f_\alpha^*(\phi_{i0})$ for some morphism $\phi_{i0} X_{i0} \to X_0$ in $\mathcal{C}_\alpha$. Then $\theta = f_\alpha^* \theta_0$, where θ_0 denotes the canonical map $\amalg(X_{i0} \times_{X_0} Y_0) \to (\amalg X_{i0}) \times_{X_0} Y_0$ in the ∞-category $\mathcal{C}_\alpha$. Since $\mathcal{C}_\alpha$ is an ∞-pretopos, the morphism θ_0 is an equivalence, so that $\theta \simeq f_\alpha^*(\theta_0)$ is an equivalence in $\mathcal{C}$.

We now claim that coproducts in $\mathcal{C}$ are disjoint. Fix objects $X, Y \in \mathcal{C}$; we wish to show that the fiber product $Z = X \times_{X \amalg Y} Y$ is an initial object of $\mathcal{C}$. Without loss of generality, we may assume that there exists an index α such that $X = f_\alpha^* X_0$ and $Y = f_\alpha^* Y_0$ for some objects $X_0, Y_0 \in \mathcal{C}_\alpha$. In this case, we have $Z = f_\alpha^*(Z_0)$, where $Z_0 = X_0 \times_{X_0 \amalg Y_0} Y_0$. Since $\mathcal{C}_\alpha$ is an ∞-pretopos, the object $Z_0 \in \mathcal{C}_\alpha$ is initial, so that $Z = f_\alpha^* Z_0$ is an initial object of $\mathcal{C}$.

We next show that for each index $\alpha \in A$, the functor $f_\alpha^* : \mathcal{C}_\alpha \to \mathcal{C}$ preserves effective epimorphisms. Fix an effective epimorphism $u : C_0 \to C$ in $\mathcal{C}_\alpha$ and let $C_\bullet$ denote the Čech nerve of u. Since f_α^* is left exact, the simplicial object $f_\alpha^* C_\bullet$ is the Čechnerve of $f_\alpha^*(u)$. To show that $f_\alpha^*(u)$ is an effective epimorphism, we must show that $f_\alpha^* C$ is a geometric realization of $f_\alpha^* C_\bullet$. In other words, we must show that for each object $D \in \mathcal{C}$, the canonical map $\rho : \operatorname{Map}_{\mathcal{C}}(f_\alpha^* C, D) \to \operatorname{Tot} \operatorname{Map}_{\mathcal{C}}(f_\alpha^* C_\bullet, D)$ is a homotopy equivalence. Enlarging α if necessary, we may assume that $D = f_\alpha^* D_0$ for some object $D_0 \in \mathcal{C}_\alpha$. For $\beta \geqslant \alpha$, let $f_{\alpha\beta}^* : \mathcal{C}_\alpha \to \mathcal{C}_\beta$ denote the transition map. Unwinding the definitions, we see that the map ρ factors as a composition

$$\varinjlim_{\beta \geqslant \alpha} \operatorname{Map}_{\mathcal{C}_\beta}(f_{\alpha\beta}^* C, f_{\alpha\beta}^* D_0) \xrightarrow{\rho'} \varinjlim_{\beta \geqslant \alpha} \operatorname{Tot} \operatorname{Map}_{\mathcal{C}_\beta}(f_{\alpha\beta}^* C_\bullet, f_{\alpha\beta}^* D_0) \xrightarrow{\rho''} \operatorname{Tot} \varinjlim_{\beta \geqslant \alpha} \operatorname{Map}_{\mathcal{C}_\beta}(f_{\alpha\beta}^* C_\bullet, f_{\alpha\beta}^* D_0).$$

The map ρ' is a filtered colimit of homotopy equivalences $\rho'_\beta : \operatorname{Map}_{\mathcal{C}_\beta}(f_{\alpha\beta}^* C, f_{\alpha\beta}^* D_0) \to \operatorname{Tot} \operatorname{Map}_{\mathcal{C}_\beta}(f_{\alpha\beta}^* C_\bullet, f_{\alpha\beta}^* D_0)$, each of which is a homotopy equivalence because the functor $f_{\alpha\beta}^*$ is left exact and preserves effective epimorphisms. Since the ∞-pretopos $\mathcal{C}_\alpha$ is bounded, there exists an integer m such that $D_0 \in \mathcal{C}_\alpha$ is m-truncated. It follows that each of the mapping spaces $\operatorname{Map}_{\mathcal{C}_\beta}(f_{\alpha\beta}^* C_\bullet, f_{\alpha\beta}^* D_0)$ is also m-truncated, so that the map ρ'' is also a homotopy equivalence. This completes the proof that ρ is a homotopy equivalence, so that f_α^* preserves effective epimorphisms.

We now claim that every groupoid object of $\mathcal{C}$ is effective. Let $C_\bullet$ be a groupoid object of $\mathcal{C}$. Choose $n \gg 0$ for which the objects $C_0, C_1 \in \mathcal{C}$ are n-truncated. Since the collection of

n-truncated objects of $\mathcal{C}$ is closed under finite limits, it follows that each C_k is n-truncated: that is, we can regard $C_\bullet$ as a groupoid object of the subcategory $\mathcal{C}^{\leqslant n} \subseteq \mathcal{C}$. Corollary A.8.2.5 implies that the canonical map $\varinjlim_\alpha \mathrm{Gpd}(\mathcal{C}_\alpha^{\leqslant n}) \to \mathcal{C}^{\leqslant n}$ is an equivalence of ∞-categories, so we can assume without loss of generality that $C_\bullet = f_\alpha^* C'_\bullet$ for some index α and some groupoid object $C'_\bullet$ in $\mathcal{C}_\alpha^{\leqslant n}$. Since $\mathcal{C}_\alpha$ is an ∞-pretopos, we can assume that $C'_\bullet$ is the Čech nerve of an effective epimorphism $u : C'_0 \to C'$ in $\mathcal{C}_\alpha$. It follows that $C_\bullet$ can be identified with the Čech nerve of the induced map $f_\alpha^*(u) : C_0 \to f_\alpha^* C'$. Because the functor f_α^* preserves effective epimorphisms, the morphism $f_\alpha^*(u)$ is an effective epimorphism, so that $f_\alpha^* C'$ is a geometric realization of the groupoid $C_\bullet$ in the ∞-category $\mathcal{C}$.

To complete the proof of (i), it will suffice to show that the formation of geometric realizations in $\mathcal{C}$ is universal. In other words, let $C_\bullet$ be a groupoid object of $\mathcal{C}$ having geometric realization $C = |C_\bullet|$, and suppose we are given a map $g : D \to C$; we wish to show that the induced map $|D \times_C C_\bullet| \to D$ is an equivalence. Since the groupoid object $C_\bullet$ is effective, it can be identified with the Čech nerve of the map $v : C_0 \to C$. It follows that $D \times_C C_\bullet$ can be identified with the Čechnerve of the induced map $v_D : D \times_C C_0 \to D$. We are therefore reduced to proving that v is an effective epimorphism. The argument of the preceding paragraph shows that we can can assume that $v = f_\alpha^*(u)$ for some $\alpha \in A$ and some effective epimorphism $u : C'_0 \to C'$ in $\mathcal{C}_\alpha$. Enlarging α if necessary, we can assume that $g = f_\alpha^*(g_0)$ for some map $g_0 : D' \to C'$ in $\mathcal{C}_\alpha$. Then $v_D = f_\alpha^* u_D$, where $u_D : D' \times_{C'} C'_0 \to D'$ is the projection onto the first factor. Since $\mathcal{C}_\alpha$ is an ∞-pretopos, the morphism u_D is an effective epimorphism in $\mathcal{C}_\alpha$ (Corollary A.6.2.2) and therefore $v_D = f_\alpha^* u_D$ is an effective epimorphism in $\mathcal{C}$. This completes the proof of (i).

We now prove (ii). The arguments above show that each of the functors $f_\alpha^* : \mathcal{C}_\alpha \to \mathcal{C}$ preserves finite limits, finite coproducts, and effective epimorphisms. This proves the "only if" direction of (ii). To prove the converse, suppose we are given an ∞-pretopos $\mathcal{E}$ and a functor $g^* : \mathcal{C} \to \mathcal{E}$ such that each composition $g^* \circ f_\alpha^*$ is a morphism of ∞-pretopoi. We claim that g^* is a morphism of ∞-pretopoi. Note that if K is a finite simplicial set and $p : K \to \mathcal{C}$ is any diagram, then we can assume that $p = f_\alpha^* \circ p_0$ for some diagram $p_0 : K \to \mathcal{C}_\alpha$. Since the functors f_α^* and $g^* \circ f_\alpha^*$ preserve K-indexed limits, it follows that the canonical map $g^* \varinjlim(p) \to \varinjlim g^*(p)$ is an equivalence in $\mathcal{E}$. Allowing p and K to vary, we deduce that the functor g^* preserves finite limits. A similar argument shows that g^* preserves finite coproducts. To show that g^* preserves effective epimorphisms, it suffices to note that our preceding arguments every effective epimorphism in $\mathcal{C}$ is equivalent to the image under f_α^* of some effective epimorphism in $\mathcal{C}_\alpha$, for some $\alpha \in A$. □

We now describe the significance of Proposition A.8.3.1 at the level of bounded coherent ∞-topoi.

Proposition A.8.3.2. *Let $\{\mathcal{C}_\alpha\}$ be a small filtered diagram of bounded ∞-pretopoi having colimit $\mathcal{C} \in \infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}_{<\infty}$. Then the induced map $\mathcal{S}\mathrm{hv}(\mathcal{C}) \to \varprojlim_\alpha \mathcal{S}\mathrm{hv}(\mathcal{C}_\alpha)$ is an equivalence in*

$\infty\mathcal{T}\mathrm{op}$.

Corollary A.8.3.3. *Let $\infty\mathcal{T}\mathrm{op}_{\mathrm{coh}}$ denote the ∞-category of bounded coherent ∞-topoi (see Construction A.7.5.2). Then the ∞-category $\infty\mathcal{T}\mathrm{op}_{\mathrm{coh}}$ admits small filtered limits, and the inclusion functor $\infty\mathcal{T}\mathrm{op}_{\mathrm{coh}} \hookrightarrow \infty\mathcal{T}\mathrm{op}$ preserves small filtered limits.*

Proof. Combine Proposition A.8.3.2 with Theorem A.7.5.3. □

Proof of Proposition A.8.3.2. Since the inclusion functor $\infty\mathcal{T}\mathrm{op} \hookrightarrow \widehat{\mathcal{C}\mathrm{at}}_\infty$ preserves small filtered limits (Theorem HTT.6.3.3.1), it will suffice to show that $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is a limit of the diagram $\{\mathcal{S}\mathrm{hv}(\mathcal{C}_\alpha)\}$ in the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty$. We have a commutative diagram

$$\begin{array}{ccc} \mathcal{S}\mathrm{hv}(\mathcal{C}) & \longrightarrow & \varprojlim \mathcal{S}\mathrm{hv}(\mathcal{C}_\alpha) \\ \downarrow & & \downarrow \\ \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}) & \longrightarrow & \varprojlim \mathrm{Fun}(\mathcal{C}_\alpha^{\mathrm{op}}, \mathcal{S}), \end{array}$$

where the vertical maps are fully faithful embeddings and the bottom horizontal map is an equivalence by virtue of our assumption that $\mathcal{C}$ is a colimit of the diagram $\{\mathcal{C}_\alpha\}$ in $\mathcal{C}\mathrm{at}_\infty$ (Proposition A.8.3.1). This immediately implies that the upper horizontal map is fully faithful. To verify essential surjectivity, we must show that if $\mathscr{F} : \mathcal{C}^{\mathrm{op}} \to \mathcal{S}$ is a functor having the property that $\mathscr{F}|_{\mathcal{C}_\alpha^{\mathrm{op}}}$ belongs to $\mathcal{S}\mathrm{hv}(\mathcal{C}_\alpha)$ for each index α, then $\mathscr{F}$ is a sheaf on $\mathcal{C}$. This follows immediately from the criterion of Proposition A.6.2.5 (note that the proof of Proposition A.8.3.1 shows that every effective epimorphism in $\mathcal{C}$ is equivalent to the image of an effective epimorphism in $\mathcal{C}_\alpha$ for some index α). □

A.8.4 The Proof of Theorem A.8.0.5

We now have most of the ingredients needed to assemble a proof of Theorem A.8.0.5.

Definition A.8.4.1. Let $\mathcal{E}$ be an ∞-category which admits small limits. We will say that an object $X \in \mathcal{E}$ is *cocompact* if it is compact when viewed as an object of $\mathcal{E}^{\mathrm{op}}$: that is, if the functor $\mathrm{Map}_{\mathcal{E}}(\bullet, X)$ carries filtered limits in $\mathcal{E}$ to filtered colimits in $\mathcal{S}$. More generally, we will say that a morphism $X \to Y$ in $\mathcal{E}$ is *cocompact* if it exhibits X as a cocompact object of the ∞-category $\mathcal{E}_{/Y}$. We let $\mathcal{E}_{/Y}^{\mathrm{cc}}$ denote the full subcategory of $\mathcal{E}_{/Y}$ spanned by the cocompact objects.

Suppose that $\mathcal{C}$ is an essentially small ∞-category which admits finite limits. Then the ∞-category $\mathrm{Ind}(\mathcal{C}^{\mathrm{op}}) \simeq \mathrm{Pro}(\mathcal{C})^{\mathrm{op}}$ is compactly generated. Moreover, if $\mathcal{C}$ is idempotent-complete, then an object of $\mathrm{Pro}(\mathcal{C})^{\mathrm{op}}$ is compact if and only if it belongs to the essential image of the Yoneda embedding $j : \mathcal{C}^{\mathrm{op}} \to \mathrm{Pro}(\mathcal{C})^{\mathrm{op}}$. Applying Proposition 4.4.1.2, we obtain the following:

Proposition A.8.4.2. *Let $\mathcal{C}$ be an essentially small idempotent-complete ∞-category which admits finite limits, and let $j : \mathcal{C} \to \operatorname{Pro}(\mathcal{C})$ be the Yoneda embedding. Then:*

(1) *A morphism $f : X \to Y$ in $\operatorname{Pro}(\mathcal{C})$ is cocompact if and only if there exists a pullback square*

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ \downarrow & & \downarrow \\ j(X_0) & \xrightarrow{f_0} & j(Y_0) \end{array}$$

for some objects $X_0, Y_0 \in \mathcal{C}$.

(2) *For each object $Y \in \operatorname{Pro}(\mathcal{C})$, the inclusion $\operatorname{Pro}(\mathcal{C})^{\mathrm{cc}}_{/Y} \hookrightarrow \operatorname{Pro}(\mathcal{C})_{/Y}$ extends to an equivalence of ∞-categories $\operatorname{Pro}(\operatorname{Pro}(\mathcal{C})^{\mathrm{cc}}_{/Y}) \simeq \operatorname{Pro}(\mathcal{C})_{/Y}$.*

(3) *The construction $Y \mapsto \operatorname{Pro}(\mathcal{C})^{\mathrm{cc}}_{/Y}$ determines a functor $\operatorname{Pro}(\mathcal{C})^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ which commutes with filtered colimits.*

Lemma A.8.4.3. *Let $\mathcal{C}$ be a bounded ∞-pretopos. Then:*

(a) *For each object $X \in \operatorname{Pro}(\mathcal{C})$, the ∞-category $\operatorname{Pro}(\mathcal{C})^{\mathrm{cc}}_{/X}$ is a bounded ∞-pretopos.*

(b) *For each morphism $f : X \to Y$ in $\operatorname{Pro}(\mathcal{C})$, the pullback functor $Y' \mapsto X \times_Y Y'$ induces a morphism of ∞-pretopoi $\operatorname{Pro}(\mathcal{C})^{\mathrm{cc}}_{/Y} \to \operatorname{Pro}(\mathcal{C})^{\mathrm{cc}}_{/X}$.*

(c) *The construction $Y \mapsto \operatorname{Pro}(\mathcal{C})^{\mathrm{cc}}_{/Y}$ determines a functor $\operatorname{Pro}(\mathcal{C})^{\mathrm{op}} \to \infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}_{<\infty}$ which commutes with filtered colimits.*

Proof. Let $\chi : \operatorname{Pro}(\mathcal{C})^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ be the functor given by $\chi(X) = \operatorname{Pro}(\mathcal{C})^{\mathrm{cc}}_{/X}$ (see Proposition A.8.4.2) and let $j : \mathcal{C} \to \operatorname{Pro}(\mathcal{C})$ denote the Yoneda embedding. It follows from assertion (1) of Proposition A.8.4.2 that for each object $C \in \mathcal{C}$, the functor j induces an equivalence of ∞-categories $\mathcal{C}_{/C} \to \operatorname{Pro}(\mathcal{C})^{\mathrm{cc}}_{/j(C)}$. The ∞-category $\mathcal{C}_{/C}$ is an ∞-pretopos (Remark A.6.1.3) which is evidently bounded, so that $\operatorname{Pro}(\mathcal{C})^{\mathrm{cc}}_{/j(C)}$ is also a bounded ∞-pretopos. Moreover, if $f : C \to D$ is a morphism in $\mathcal{C}$, then the associated pullback functor $\operatorname{Pro}(\mathcal{C})^{\mathrm{cc}}_{/j(D)} \to \operatorname{Pro}(\mathcal{C})^{\mathrm{cc}}_{/j(C)}$ can be identified with the pullback map $\mathcal{C}_{/D} \to \mathcal{C}_{/C}$, and is therefore a morphism of ∞-pretopoi (Example A.6.4.3). It follows that the composite functor

$$\mathcal{C}^{\mathrm{op}} \xrightarrow{j} \operatorname{Pro}(\mathcal{C})^{\mathrm{op}} \xrightarrow{\chi} \widehat{\mathcal{C}\mathrm{at}}_\infty$$

factors through the subcategory $\infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}_{<\infty} \subseteq \widehat{\mathcal{C}\mathrm{at}}_\infty$. Proposition A.8.4.2 implies that the functor χ commutes with filtered limits. Using Proposition A.8.3.1, we deduce that χ also factors through $\infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}_{<\infty}$, which proves ($a$) and ($b$). Assertion ($c$) follows from the fact that χ preserves filtered colimits, since the inclusion $\infty\mathcal{T}\mathrm{op}^{\mathrm{pre}}_{<\infty} \hookrightarrow \widehat{\mathcal{C}\mathrm{at}}_\infty$ is conservative and preserves filtered colimits. □

Lemma A.8.4.4. *Let $\mathcal{C}$ be a bounded ∞-pretopos. For each object $X \in \mathrm{Pro}(\mathcal{C})$, let us regard the ∞-pretopos $\mathrm{Pro}(\mathcal{C})^{\mathrm{cc}}_{/X}$ as equipped with the effective epimorphism topology (Definition A.6.2.4). Then:*

(a) *For each $X \in \mathrm{Pro}(\mathcal{C})$, the ∞-topos $\mathcal{S}\mathrm{hv}(\mathrm{Pro}(\mathcal{C})^{\mathrm{cc}}_{/X})$ is bounded and coherent.*

(b) *The construction $X \mapsto \mathcal{S}\mathrm{hv}(\mathrm{Pro}(\mathcal{C})^{\mathrm{cc}}_{/X})$ determines a functor $\mathrm{Pro}(\mathcal{C}) \to \infty\mathcal{T}\mathrm{op}$ which preserves filtered limits.*

Proof. Combine Lemma A.8.4.3 with Proposition A.8.3.2. □

Proof of Theorem A.8.0.5. Let $\mathcal{C}$ be a bounded ∞-pretopos and let $\overline{\rho} : \mathrm{Pro}(\mathcal{C}) \to \infty\mathcal{T}\mathrm{op}$ be the functor given on objects by $X \mapsto \mathcal{S}\mathrm{hv}(\mathrm{Pro}(\mathcal{C})^{\mathrm{cc}}_{/X})$. Note that $\overline{\rho}$ carries the initial object $\mathbf{1} \in \mathrm{Pro}(\mathcal{C})$ to the ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})$, and therefore induces a functor $\rho : \mathrm{Pro}(\mathcal{C}) \simeq \mathrm{Pro}(\mathcal{C})_{/\mathbf{1}} \to \infty\mathcal{T}\mathrm{op}_{/\mathcal{S}\mathrm{hv}(\mathcal{C})}$. By construction, the composition of ρ with the Yoneda embedding $\mathcal{C} \hookrightarrow \mathrm{Pro}(\mathcal{C})$ can be identified with the composition

$$\mathcal{C} \hookrightarrow \mathcal{S}\mathrm{hv}(\mathcal{C}) \simeq \infty\mathcal{T}\mathrm{op}^{\text{ét}}_{/\mathcal{S}\mathrm{hv}(\mathcal{C})} \subseteq \infty\mathcal{T}\mathrm{op}_{/\mathcal{S}\mathrm{hv}(\mathcal{C})},$$

and the functor ρ commutes with filtered limits by virtue of Lemma A.8.4.4. Consequently, the content of Theorem A.8.0.5 is that the functor ρ is fully faithful: that is, that it induces a homotopy equivalence $\theta_{X,Y} : \mathrm{Map}_{\mathrm{Pro}(\mathcal{C})}(X, Y) \to \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}_{/\mathcal{S}\mathrm{hv}(\mathcal{C})}}(\rho(X), \rho(Y))$ for every pair of objects $X, Y \in \mathrm{Pro}(\mathcal{C})$.

Let us abuse notation by identifying $\mathcal{C}$ with its essential image under the fully faithful embedding $\mathcal{C} \hookrightarrow \mathrm{Pro}(\mathcal{C})$. Regard the object $X \in \mathrm{Pro}(\mathcal{C})$ as fixed. Since the functor ρ commutes with small filtered limits, the construction $Y \mapsto \theta_{X,Y}$ commutes with small filtered limits. Consequently, the collection of those objects $Y \in \mathrm{Pro}(\mathcal{C})$ for which $\theta_{X,Y}$ is a homotopy equivalence is closed under small filtered limits. We may therefore assume without loss of generality that Y is an object of $\mathcal{C}$. Let $\mathscr{F} \in \mathcal{S}\mathrm{hv}(\mathcal{C})$ denote the image of Y under the Yoneda embedding $\mathcal{C} \hookrightarrow \mathcal{S}\mathrm{hv}(\mathcal{C})$, so that we can identify $\rho(Y)$ with the overcategory $\mathcal{S}\mathrm{hv}(\mathcal{C})_{/\mathscr{F}}$. Set $\mathcal{X} = \rho(X)$, which we regard as an object of $\infty\mathcal{T}\mathrm{op}_{/\mathcal{S}\mathrm{hv}(\mathcal{C})}$ via a geometric morphism $e_* : \mathcal{X} \to \mathcal{S}\mathrm{hv}(\mathcal{C})$ with left adjoint $e^* : \mathcal{S}\mathrm{hv}(\mathcal{C}) \to \mathcal{X}$. Invoking the universal property of $\mathcal{S}\mathrm{hv}(\mathcal{C})_{/\mathscr{F}}$ (see Proposition HTT.6.3.5.5), we can identify the mapping space $\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}_{/\mathcal{S}\mathrm{hv}(\mathcal{C})}}(\rho(X), \rho(Y))$ with the mapping space $\mathrm{Map}_{\mathcal{X}}(\mathbf{1}_{\mathcal{X}}, e^*\mathscr{F})$, where $\mathbf{1}_{\mathcal{X}}$ denotes a final object of $\mathcal{X}$. By construction, we can identify $\mathcal{X}$ with the ∞-category $\mathcal{S}\mathrm{hv}(\mathrm{Pro}(\mathcal{C})^{\mathrm{cc}}_{/X})$, and the objects $\mathbf{1}_{\mathcal{X}}$ and $e^*\mathscr{F}$ are the images under the Yoneda embedding $\mathrm{Pro}(\mathcal{C})^{\mathrm{cc}}_{/X} \hookrightarrow \mathcal{S}\mathrm{hv}(\mathrm{Pro}(\mathcal{C})^{\mathrm{cc}}_{/X}) = \mathcal{X}$ of the objects X and $X \times Y$, respectively. Under this identification, the map $\theta_{X,Y}$ corresponds to the evident homotopy equivalence $\mathrm{Map}_{\mathrm{Pro}(\mathcal{C})}(X, Y) \simeq \mathrm{Map}_{\mathrm{Pro}(\mathcal{C})_{/X}}(X, X \times Y)$. □

A.9 Conceptual Completeness

Let $\mathcal{X}$ be an ∞-topos. Recall that a *point* of $\mathcal{X}$ is a geometric morphism $\eta^* : \mathcal{X} \to \mathcal{S}$. We let $\mathrm{Fun}^*(\mathcal{X}, \mathcal{S})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{X}, \mathcal{S})$ spanned by the points of $\mathcal{X}$. It is natural to ask the following:

Question A.9.0.5. To what extent can an ∞-topos $\mathcal{X}$ be recovered from its ∞-category of points $\mathrm{Fun}^*(\mathcal{X}, \mathcal{S})$?

In §A.4, we took a first step toward answering Question A.9.0.5: according to Theorem A.4.0.5, if $\mathcal{X}$ is hypercomplete and locally coherent, then $\mathcal{X}$ has enough points (that is, the points $\eta^* : \mathcal{X} \to \mathcal{S}$ are mutually conservative). Our goal in this section is to prove the following closely related result:

Theorem A.9.0.6. *Let $\mathcal{X}$ and $\mathcal{Y}$ be bounded coherent ∞-topoi and let $f^* : \mathcal{X} \to \mathcal{Y}$ be a geometric morphism. Then f^* is an equivalence if and only if the following conditions are satisfied:*

(a) *The functor f^* carries coherent objects of $\mathcal{X}$ to coherent objects of $\mathcal{Y}$.*

(b) *Composition with f^* induces an equivalence of ∞-categories $\mathrm{Fun}^*(\mathcal{Y}, \mathcal{S}) \to \mathrm{Fun}^*(\mathcal{X}, \mathcal{S})$.*

Remark A.9.0.7. Theorem A.9.0.6 can be regarded as an ∞-categorical generalization of the conceptual completeness theorem of Makkai-Reyes; see [143].

Warning A.9.0.8. In the statement of Theorem A.9.0.6, one cannot replace (b) by the weaker statement that f_* induces a homotopy equivalence $\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{S}, \mathcal{Y}) \to \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{S}, \mathcal{X})$. For example, let X be a coherent topological space and let Y be the Stone space obtained by equipping X with the constructible topology (see Notation 4.3.1.3). Then the canonical map $f : Y \to X$ induces a geometric morphism $f^* : \mathcal{S}\mathrm{hv}(X) \to \mathcal{S}\mathrm{hv}(Y)$ satisfying condition (a) of Theorem A.9.0.6. The ∞-categories $\mathrm{Fun}_*(\mathcal{S}, \mathcal{S}\mathrm{hv}(X))$ and $\mathrm{Fun}_*(\mathcal{S}, \mathcal{S}\mathrm{hv}(Y))$ can be identified with X and Y respectively, where we regard X and Y as partially ordered sets with respect to the specialization ordering. The underlying map $\rho : \mathrm{Fun}^*(\mathcal{S}\mathrm{hv}(Y), \mathcal{S}) \to \mathrm{Fun}^*(\mathcal{S}\mathrm{hv}(X), \mathcal{S})$ induces a homotopy equivalence of the underlying Kan complexes (since f is bijective), but is generally not an equivalence of ∞-categories (since the specialization ordering on Y is trivial but the specialization ordering on X need not be).

A.9.1 Points and Pro-Objects

Let $\mathcal{C}$ be an bounded ∞-pretopos. In §A.8, we saw that the ∞-category $\mathrm{Pro}(\mathcal{C})$ of Pro-objects of $\mathcal{C}$ admits a "topological" incarnation: it can be identified with a full subcategory of the ∞-category $\infty\mathcal{T}\mathrm{op}_{/\mathcal{S}\mathrm{hv}(\mathcal{C})}$ of ∞-topoi with a geometric morphism to $\mathcal{S}\mathrm{hv}(\mathcal{C})$ (see Theorem A.8.0.5). We now describe a slightly different relationship between Pro-objects of $\mathcal{C}$ and the geometry of $\mathcal{S}\mathrm{hv}(\mathcal{C})$.

Proposition A.9.1.1. *Let $\mathcal{C}$ be an ∞-pretopos and let $X : \mathcal{C} \to \mathcal{S}$ be a left exact functor. The following conditions are equivalent:*

(1) *The functor X is an ∞-pretopos morphism (Definition A.6.4.1).*

(2) *For every finite collection of objects $\{U_i\}_{\in I}$ of $\mathcal{C}$ and every effective epimorphism $\amalg_{i\in I} U_i \to V$, the induced map $\amalg_{i\in I} X(U_i) \to X(V)$ is surjective on connected components.*

Proof. If (1) is satisfied, then the functor X preserves coproducts and effective epimorphisms, so condition (2) follows. Conversely, suppose that (2) is satisfied. Applying (2) in the case where I is a singleton, we deduce that X preserves effective epimorphisms. Taking $I = \varnothing$, we deduce that X preserves initial objects. Since X is left exact by assumption, it will suffice to prove X preserves pairwise coproducts. Let U and V be objects of $\mathcal{C}$ and let $i : U \to U \amalg V$ and $j : V \to U \amalg V$ denote the canonical maps. We wish to show that $X(i)$ and $X(j)$ exhibit $X(U \amalg V)$ as a coproduct of $X(U)$ with $X(V)$. Because $\mathcal{C}$ is an ∞-pretopos, coproducts in $\mathcal{C}$ are disjoint. It follows that the maps i and j are (-1)-truncated and that the fiber product $U \times_{U\amalg V} V$ is initial in $\mathcal{C}$. Using the left exactness of X, we deduce that $X(i)$ and $X(j)$ are (-1)-truncated and that the fiber product $X(U) \times_{X(U\amalg V)} X(V)$ is empty. It follows that the natural map $\rho : X(U) \amalg X(V) \to X(U \amalg V)$ is (-1)-truncated. To complete the proof, it suffices to show that ρ is surjective on connected components, which follows from (2). □

Corollary A.9.1.2. *Let $\mathcal{C}$ be an essentially small ∞-pretopos. Then composition with the Yoneda embedding $j : \mathcal{C} \to \mathcal{S}\mathrm{hv}(\mathcal{C})$ induces an equivalence of ∞-categories $\mathrm{Fun}^*(\mathcal{S}\mathrm{hv}(\mathcal{C}), \mathcal{S}) \to \mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{S})$.*

Proof. Combine Propositions A.9.1.1 and HTT.6.2.3.20 . □

Definition A.9.1.3. Let $\mathcal{C}$ be an essentially small ∞-pretopos, and let us abuse notation by identifying $\mathcal{C}$ with its essential image in the ∞-category $\mathrm{Pro}(\mathcal{C})$. We will say that an object $X \in \mathrm{Pro}(\mathcal{C})$ is *prime* if it satisfies the following condition:

($*$) For every finite collection of objects $\{U_i\}_{i\in I}$ of $\mathcal{C}$ and every effective epimorphism $\amalg_{i\in I} U_i \to V$, the induced map $\amalg_{i\in I} \mathrm{Map}_{\mathrm{Pro}(\mathcal{C})}(X, U_i) \to \mathrm{Map}_{\mathrm{Pro}(\mathcal{C})}(X, V)$ is surjective on connected components.

Let $\mathrm{Pro}(\mathcal{C})_\circ$ denote the full subcategory of $\mathrm{Pro}(\mathcal{C})$ spanned by those objects which satisfy condition ($*$).

Remark A.9.1.4. Let $\mathcal{C}$ be an essentially small ∞-pretopos. It follows from Proposition A.9.1.1 that the equality $\mathrm{Pro}(\mathcal{C}) = \mathrm{Fun}^{\mathrm{lex}}(\mathcal{C}, \mathcal{S})^{\mathrm{op}}$ restricts to an equality $\mathrm{Pro}(\mathcal{C})_\circ = \mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{S})^{\mathrm{op}}$. Using Corollary A.9.1.2, we can identify $\mathrm{Pro}(\mathcal{C})_\circ$ with the opposite of the ∞-category $\mathrm{Fun}^*(\mathcal{S}\mathrm{hv}(\mathcal{C}), \mathcal{S})$ of points of $\mathcal{S}\mathrm{hv}(\mathcal{C})$.

Remark A.9.1.5. Let Λ be a distributive lattice (Definition A.1.4.5), which we regard as a category (where there is a unique morphism from λ to μ if $\lambda \leqslant \mu$). There is a bijective correspondence between isomorphism classes of Pro-objects of Λ and filters $F \subseteq \Lambda$ (see Definition A.1.2.1), which carries an object $X \in \mathrm{Pro}(\Lambda)$ to the filter $F_X = \{\lambda \in \Lambda : \mathrm{Hom}_{\mathrm{Pro}(\Lambda)}(X, \lambda) \neq \varnothing\}$. Let us say that the Pro-object X is *prime* if it satisfies the following analogue of condition $(*)$ of Definition A.9.1.3:

($\star$) For every finite subset $\{\lambda_i\}_{i \in I}$ of Λ, the map $\amalg_{i \in I} X(\lambda_i) \to X(\bigvee_{i \in I} \lambda_i)$ is surjective.

Unwinding the definitions, we see that a Pro-object X satisfies ($\star$) if and only if the complement of $F_X \subseteq \Lambda$ is an ideal. Consequently, the construction $X \mapsto \mathfrak{p}_X = \Lambda - F_X$ determines a bijection from the set of isomorphism classes of prime objects of $\mathrm{Pro}(\Lambda)$ to the set $\mathrm{Spec}(\Lambda)$ of prime ideals in Λ (in fact, we can be more precise: the construction $X \mapsto \mathfrak{p}_X$ determines an equivalence from the full subcategory of $\mathrm{Pro}(\Lambda)$ spanned by the prime Pro-objects to the partially ordered set of prime ideals in Λ).

Warning A.9.1.6. Let $\mathcal{C}$ be a bounded ∞-pretopos and let $X \in \mathrm{Pro}(\mathcal{C})$ be a Pro-object. Then X potentially has two different incarnations in the ∞-category $\infty\mathcal{T}\mathrm{op}_{/\mathcal{S}\mathrm{hv}(\mathcal{C})}$:

(*a*) We can consider the image of X under the fully faithful embedding $\rho : \mathrm{Pro}(\mathcal{C}) \hookrightarrow \infty\mathcal{T}\mathrm{op}_{/\mathcal{S}\mathrm{hv}(\mathcal{C})}$ of Theorem A.8.0.5: by virtue of Lemma A.8.4.4, this image can be identified with the ∞-topos $\mathcal{S}\mathrm{hv}(\mathrm{Pro}(\mathcal{C})^{\mathrm{cc}}_{/X})$.

(*b*) If X is prime, then the image of X under the equivalence of ∞-categories $\mathrm{Pro}(\mathcal{C})_\circ \simeq \mathrm{Fun}^*(\mathcal{S}\mathrm{hv}(\mathcal{C}), \mathcal{S})^{\mathrm{op}}$ of Remark A.9.1.4 is a geometric morphism $\eta_{X*} : \mathcal{S} \to \mathcal{S}\mathrm{hv}(\mathcal{C})$, which exhibits the ∞-topos $\mathcal{S}$ as an object of $\infty\mathcal{T}\mathrm{op}_{/\mathcal{S}\mathrm{hv}(\mathcal{C})}$.

These objects are usually not the same. However, they are closely related: if X is prime, then the geometric morphism $\eta_{X*} : \mathcal{S} \to \mathcal{S}\mathrm{hv}(\mathcal{C})$ admits a factorization $\mathcal{S} \xrightarrow{\eta'_{X*}} \mathcal{S}\mathrm{hv}(\mathrm{Pro}(\mathcal{C})^{\mathrm{cc}}_{/X}) \to \mathcal{S}\mathrm{hv}(\mathcal{C})$. Beware that if $u : X \to Y$ is a morphism in $\mathrm{Pro}(\mathcal{C})_\circ$, then the diagram of ∞-topoi

$$\begin{array}{ccc} \mathcal{S} & \xrightarrow{\eta'_{X*}} & \mathcal{S}\mathrm{hv}(\mathrm{Pro}(\mathcal{C})^{\mathrm{cc}}_{/X}) \\ \downarrow{\scriptstyle \mathrm{id}} & & \downarrow{\scriptstyle \rho(u)} \\ \mathcal{S} & \xrightarrow{\eta'_{Y*}} & \mathcal{S}\mathrm{hv}(\mathrm{Pro}(\mathcal{C})^{\mathrm{cc}}_{/Y}) \end{array}$$

commutes only up to a natural transformation $\rho(u) \circ \eta'_{X*} \to \eta'_{Y*}$, which is an equivalence if and only if u is an equivalence.

A.9.2 Detecting Equivalences of ∞-Pretopoi

Our proof Theorem A.9.0.6 rests on the following recognition criterion for equivalences of (bounded) ∞-pretopoi (which we used already in our proof of Theorem A.7.5.3):

Proposition A.9.2.1. *Let $\mathcal{C}$ and $\mathcal{D}$ be bounded ∞-pretopoi and let $f^* : \mathcal{C} \to \mathcal{D}$ be a functor which preserves coproducts, finite limits, and effective epimorphisms. Then f^* is an equivalence if and only if the following conditions are satisfied:*

(a) *For every object $C \in \mathcal{C}$ and every morphism $u : D \to f^*C$ in $\mathcal{D}$, there exists a morphism $v : C' \to C$ in $\mathcal{C}$ and a commutative diagram*

$$\begin{array}{ccc} f^*C' & \xrightarrow{w} & D \\ & {\scriptstyle f^*v} \searrow \quad \swarrow {\scriptstyle u} & \\ & f^*C & \end{array}$$

in $\mathcal{D}$, where w is an effective epimorphism.

(b) *For every (-1)-truncated morphism $u : C' \to C$ in $\mathcal{C}$, if $f^*(u)$ is an equivalence in $\mathcal{D}$, then u is an equivalence.*

Proof. The necessity of conditions (a) and (b) is obvious. For the converse, assume that (a) and (b) are satisfied; we wish to prove that the functor f^* is an equivalence of ∞-categories. We begin by showing that f^* is conservative. Let $u : C' \to C$ be a morphism in $\mathcal{C}$ such that $f^*(u)$ is an equivalence; we wish to show that u is an equivalence. Because $\mathcal{C}$ is bounded, we may assume that the morphism u is n-truncated for some integer n; we proceed by induction on n. If $n = -2$, there is nothing to prove. If $n > -2$, then the diagonal map $\delta : C' \to C' \times_C C'$ is $(n-1)$-truncated and the left exactness of f^* guarantees that $f^*(\delta)$ is an equivalence. Applying our inductive hypothesis, we deduce that δ is an equivalence: that is, the morphism u is (-1)-truncated. In this case, the desired result follows from assumption (b).

We will prove that the functor f^* is an equivalence of ∞-categories by establishing the following assertions for $n \geqslant -2$:

(1_n) For every pair of objects $C, C' \in \mathcal{C}$ where C' is n-truncated, the functor f^* induces a homotopy equivalence $\mathrm{Map}_{\mathcal{C}}(C, C') \to \mathrm{Map}_{\mathcal{D}}(f^*C, f^*C')$.

(2_n) Every n-truncated object of $\mathcal{D}$ belongs to the essential image of f^*.

Since $\mathcal{C}$ is bounded, it follows from (1_n) (for all $n \geqslant -2$) that the functor f^* is fully faithful; since $\mathcal{D}$ is bounded, it follows from (2_n) (for all $n \geqslant -2$) that the functor f^* is essentially surjective.

We will prove (1_n) and (2_n) by a simultaneous induction on n. Let us begin with the case $n = -2$. If $C' \in \mathcal{C}$ is (-2)-truncated, then it is a final object of $\mathcal{C}$, so (since the functor f^* preserves finite limits) we conclude that f^*C' is a final object of $\mathcal{D}$. This proves (2_n). Assertion (1_n) follows from the observation that for any object $C \in \mathcal{C}$, the natural map

$\mathrm{Map}_{\mathcal{C}}(C, C') \to \mathrm{Map}_{\mathcal{D}}(f^*C, f^*C')$ has contractible domain and codomain and is therefore automatically a homotopy equivalence.

We now prove (1_n) for $n > -2$. Fix objects $C, C' \in \mathcal{C}$ where C' is n-truncated; we wish to prove that the natural map $\rho : \mathrm{Map}_{\mathcal{C}}(C, C') \to \mathrm{Map}_{\mathcal{D}}(f^*C, f^*C')$ is a homotopy equivalence. Fix $k \geqslant -1$ and suppose we are given a map $S^k \to \mathrm{Map}_{\mathcal{C}}(C, C')$; we wish to show that the induced map

$$\mathrm{fib}(\mathrm{Map}_{\mathcal{C}}(C, C') \to \mathrm{Map}_{\mathcal{C}}(C, C'^{S^k})) \to \mathrm{fib}(\mathrm{Map}_{\mathcal{D}}(f^*C, f^*C') \to \mathrm{Map}_{\mathcal{D}}(f^*C, f^*C'^{S^k}))$$

is surjective on connected components. Replacing $\mathcal{C}$ by $\mathcal{C}_{/C'^{S^k}}$ and $\mathcal{D}$ by $\mathcal{D}_{/f^*C'^{S^k}}$, we are reduced to proving that the map ρ is surjective on connected components. Let us therefore fix a map $\alpha : f^*C \to f^*C'$ in the ∞-category $\mathcal{D}$; we wish to show that α belongs to the essential image of ρ. Note that the pair

$$(\mathrm{id}, \alpha) : f^*C \to f^*C \times f^*C' \simeq f^*(C \times C')$$

is a pullback of the diagonal map $f^*C' \to f^*(C' \times C')$. Since C' is n-truncated, the map (id, α) exhibits f^*C as an $(n-1)$-truncated object of the ∞-pretopos $\mathcal{D}_{/f^*(C \times C')}$. Applying our inductive hypothesis (2_{n-1}) to the map $\mathcal{C}_{/C \times C'} \to \mathcal{D}_{/f^*(C \times C')}$, we deduce that there exists an object $E \in \mathcal{C}_{/C \times C'}$ and an equivalence $f^*E \simeq f^*C$ in the ∞-category $\mathcal{D}_{/f^*(C \times C')}$. Let us regard E as an object of $\mathcal{C}$ equipped with a pair of maps $\beta : E \to C$ and $\beta' : E \to C'$. Then $f^*(\beta)$ is an equivalence and therefore β is an equivalence (by virtue of the fact that f^* is conservative). We now observe that α is homotopic to the composition $f^*(\beta') \circ f^*(\beta)^{-1} \simeq f^*(\beta' \circ \beta^{-1})$ and therefore belongs to the essential image of ρ as desired. This completes the proof of (1_n).

We now verify (2_n). Let $D \in \mathcal{D}$ be an n-truncated object. Using (a), we can choose an effective epimorphism $u : D_0 \to D$, where D_0 belongs to the essential image of f^*. Since the essential image of f^* is stable under n-truncation, we may assume without loss of generality that D_0 is n-truncated. Let $D_\bullet$ denote the Čech nerve of u. Note that for $k > 0$, we have an equivalence

$$D_k \simeq D_{k-1} \times_D D_0 \simeq (D_{k-1} \times D_0) \times_{D \times D} D.$$

Since D is n-truncated, it follows that the projection map $D_k \to D_{k-1} \times D_0$ is $(n-1)$-truncated. It follows from inductive hypothesis (2_{n-1}) and induction on k that each D_k belongs to the essential image of f^*. Since each D_k is n-truncated and the functor f^* is fully faithful when restricted to n-truncated objects (by virtue of (1_n)), we can write $D_\bullet = f^*C_\bullet$ for some groupoid object $C_\bullet$ in $\mathcal{C}$. Set $C = |C_\bullet|$, and let $v : C_0 \to C$ be the canonical map. Then f^*v factors as a composition

$$f^*C_0 \simeq D_0 \xrightarrow{u} D = |f^*C_\bullet| \xrightarrow{w} f^*|C_\bullet| = f^*C.$$

where w is (-1)-truncated. Since the functor f^* preserves effective epimorphisms, the map f^*v is an effective epimorphism. It follows that $w : D \to f^*C$ is an equivalence, so that D belongs to the essential image of f^* as desired. □

A.9.3 The Proof of Theorem A.9.0.6

We now turn to the proof of Theorem A.9.0.6. It is clear that if $f^* : \mathcal{X} \to \mathcal{Y}$ is an equivalence of bounded coherent ∞-topoi, then f^* carries coherent objects of $\mathcal{X}$ to coherent objects of $\mathcal{Y}$ and that composition with f^* induces an equivalence $\mathrm{Fun}^*(\mathcal{Y}, \mathcal{S}) \to \mathrm{Fun}^*(\mathcal{X}, \mathcal{S})$. By virtue of Theorem A.7.5.3 and Corollary A.9.1.2, the converse can be reformulated as follows:

Theorem A.9.3.1. *Let $f^* : \mathcal{C} \to \mathcal{D}$ be a morphism between bounded ∞-pretopoi, and suppose that composition with f^* induces an equivalence* $\mathrm{Fun}^{\mathrm{pre}}(\mathcal{D}, \mathcal{S}) \to \mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{S})$*. Then f^* is an equivalence of ∞-categories.*

Proof. We will show that the functor f^* satisfies conditions (a) and (b) of Proposition A.9.2.1. We begin with condition (b). Let $i : U \to X$ be a (-1)-truncated morphism in $\mathcal{C}$ such that $f^*(i)$ is an equivalence in $\mathcal{D}$; we wish to show that i is an equivalence. To prove this, it will suffice to show that the image of i under the Yoneda embedding $j_{\mathcal{C}} : \mathcal{C} \hookrightarrow \mathcal{S}\mathrm{hv}(\mathcal{C})$ is an equivalence. Since $\mathcal{C}$ is bounded, the functor j takes values in the full subcategory $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}} \subseteq \mathcal{S}\mathrm{hv}(\mathcal{C})$, which has enough points by virtue of Theorem A.4.0.5. It will therefore suffice to show that for every geometric morphism $\eta^* : \mathcal{S}\mathrm{hv}(\mathcal{C}) \to \mathcal{S}$, the image $\eta^*(j_{\mathcal{C}}(i))$ is a homotopy equivalence. Equivalently, we wish to show that the functor $(\eta^* \circ j_{\mathcal{C}}) \in \mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{S})$ carries i to an equivalence. The essential surjectivity of the functor $\mathrm{Fun}^{\mathrm{pre}}(\mathcal{D}, \mathcal{S}) \to \mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{S})$ guarantees that $\eta^* \circ j$ factors through f^*, so the desired result follows from our assumption that $f^*(i)$ is an equivalence.

We can break condition (a) of Proposition A.9.2.1 into the following family of assertions:

(a_n) For every object $E \in \mathcal{C}$ and every n-truncated morphism $u : D \to f^*E$ in $\mathcal{D}$, there exists a morphism $v : C \to E$ in $\mathcal{C}$ and a commutative diagram

$$\begin{array}{ccc} f^*C & \xrightarrow{w} & D \\ & {\scriptstyle f^*v} \searrow \quad \swarrow {\scriptstyle u} & \\ & f^*E & \end{array}$$

in $\mathcal{D}$, where w is an effective epimorphism.

Our proof of (a_n) will proceed by induction on n. If $n = -2$, then u is an equivalence and there is nothing to prove. Let us therefore assume that $n > -2$. Replacing $\mathcal{C}$ by $\mathcal{C}_{/E}$ and $\mathcal{D}$ by $\mathcal{D}_{/f^*E}$, we may reduce to the case where E is a final object of $\mathcal{C}$, so that $D \in \mathcal{D}$ is

n-truncated. Let us say that an object $D' \in \mathcal{D}_{/D}$ is *good* if there exists an $(n-1)$-truncated map $D' \to f^* C$ for some object $C \in \mathcal{C}$. Suppose that the collection of good objects $D' \in \mathcal{D}_{/D}$ generate a covering sieve with respect to the effective epimorphism topology: that is, there exists a finite collection of good objects $\{D'_i\}_{i \in I}$ for which the induced map $\amalg_{i \in I} D'_i \to D$ is an effective epimorphism. By definition, each of the objects D'_i admits an $(n-1)$-truncated morphism $D'_i \to f^* C_i$ for some object $C_i \in \mathcal{C}_{/C}$. Applying the inductive hypothesis (a_{n-1}), we deduce the existence of effective epimorphisms $f^* C'_i \to D'_i$ for some objects $C'_i \in \mathcal{C}_{/C_i}$. We can then complete the verification of (a_n) by observing that the composite map

$$f^*(\amalg_{i \in I} C'_i) \simeq \amalg_{i \in I} f^* C'_i \to \amalg_{i \in I} D'_i \to D$$

is an effective epimorphism.

Let us now treat the case where the good objects of $\mathcal{D}_{/D}$ do *not* generate a covering sieve with respect to the effective epimorphism topology. Applying Theorem A.4.0.5 to the ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{D})^{\mathrm{hyp}}$ and using the identifications $\mathrm{Fun}^*(\mathcal{S}\mathrm{hv}(\mathcal{D})^{\mathrm{hyp}}, \mathcal{S}) \simeq \mathrm{Fun}^*(\mathcal{S}\mathrm{hv}(\mathcal{D}), \mathcal{S}) \simeq \mathrm{Fun}^{\mathrm{pre}}(\mathcal{D}, \mathcal{S})$, we deduce that there exists an object $M \in \mathrm{Fun}^{\mathrm{pre}}(\mathcal{D}, \mathcal{S})$ together with a point $x \in M(D)$ which cannot be lifted to a point of $M(D')$ for any good object $D' \in \mathcal{D}_{/D}$.

In what follows, let us abuse notation by identifying $\mathcal{C}$ and $\mathcal{D}$ with their essential images in the ∞-categories $\mathrm{Pro}(\mathcal{C})$ and $\mathrm{Pro}(\mathcal{D})$. Note that precomposition with the functor f^* determines a functor $F : \mathrm{Pro}(\mathcal{D}) \to \mathrm{Pro}(\mathcal{C})$, and the functor F admits a right adjoint $G : \mathrm{Pro}(\mathcal{C}) \to \mathrm{Pro}(\mathcal{D})$ (which can be described as the essentially unique extension of f^* which commutes with filtered limits). Let us view M as an object of the ∞-category $\mathrm{Pro}(\mathcal{D})$ and x as a morphism from M to D in $\mathrm{Pro}(\mathcal{D})$. Set $X = M^{S^n} \times_{(F \circ G)(M)^{S^n}} (F \circ G)(M)$, where the fiber product is computed in the ∞-category $\mathrm{Pro}(\mathcal{D})$, and consider the composite map $X \to M^{S^n} \xrightarrow{x} D^{S^n}$. Since the object D is n-truncated, the diagonal map $\delta : D \to D^{S^n}$ is (-1)-truncated. Set $X_0 = D \times_{D^{S^n}} X$, so that projection onto the second factor gives a (-1)-truncated, cocompact morphism $\iota : X_0 \to X$ in $\mathrm{Pro}(\mathcal{D})$. We consider two cases:

(*i*) Suppose that the morphism ι is an equivalence. Let us write the object $M \in \mathrm{Pro}(\mathcal{D})_{/D}$ as the limit of a filtered diagram $\{M_\alpha\}_{\alpha \in A}$ in $\mathcal{D}_{/D}$. For each index $\alpha \in A$, set $X_\alpha = M_\alpha^{S^n} \times_{(F \circ G)(M_\alpha)^{S^n}} (F \circ G)(M_\alpha)$ and $X_{\alpha 0} = D \times_{D^{S^n}} X_\alpha$. Since $\mathrm{Pro}(\mathcal{D})^{\mathrm{cc}}_{/X}$ is the filtered colimit of the ∞-categories $\mathrm{Pro}(\mathcal{D})^{\mathrm{cc}}_{/X_\alpha}$ (Proposition A.8.4.2), there exists an index $\alpha \in A$ for which the projection map $X_{\alpha 0} \to X_\alpha$ is an equivalence. Let us write $G(M_\alpha)$ as the limit of a filtered diagram $\{C_\beta\}_{\beta \in B}$ in $\mathcal{C}$, and for each index $\beta \in B$ set

$$Y_\beta = M_\alpha^{S^n} \times_{f^* C_\beta^{S^n}} f^* C_\beta \qquad Y_{\beta 0} = D \times_{D^{S^n}} Y_\beta.$$

Using Proposition A.8.4.2 again, we deduce that $\mathrm{Pro}(\mathcal{D})^{\mathrm{cc}}_{/X_\alpha}$ can be identified with the filtered colimit of the diagram of ∞-categories $\{\mathrm{Pro}(\mathcal{D})^{\mathrm{cc}}_{/Y_\beta}\}_{\beta \in B}$, so that there exists an index $\beta \in B$ such that the projection $\iota_\beta : Y_{\beta 0} \to Y_\beta$ is an equivalence. The map

$M_\alpha \to D \times f^* C_\beta$ factors as a composition $M_\alpha \xrightarrow{e} D' \xrightarrow{(g,h)} D \times f^* C_\beta$, where the morphism e is n-connective and the morphism (g,h) is $(n-1)$-truncated. Unwinding the definitions, we have a pullback diagram

$$\begin{array}{ccc} M_\alpha^{S^n} \times_{(D \times f^* C_\beta)^{S^n}} (X \times f^* C_\beta) & \xrightarrow{\iota_\beta} & M_\alpha^{S^n} \times_{f^* C_\beta^{S^n}} f^* C_\beta \\ \downarrow & & \downarrow \\ D'^{S^n} \times_{(D \times f^* C_\beta)^{S^n}} (X \times f^* C_\beta) & \xrightarrow{\iota'} & D'^{S^n} \times_{f^* C_\beta^{S^n}} f^* C_\beta \end{array}$$

in the ∞-pretopos $\mathcal{D}$. Since e is n-connective, the vertical maps are effective epimorphisms. Since the map ι_β is an equivalence, we deduce that ι' is an equivalence. Because the morphism (g,h) is $(n-1)$-truncated, the diagonal map $D' \to D'^{S^n} \times_{(D \times f^* C_\beta)^{S^n}} (X \times f^* C_\beta)$ is an equivalence, so the composite map

$$D' \to D'^{S^n} \times_{(D \times f^* C_\beta)^{S^n}} (X \times f^* C_\beta) \xrightarrow{\iota'} D'^{S^n} \times_{f^* C_\beta^{S^n}} f^* C_\beta$$

is also an equivalence. In other words, the map $h : D' \to f^* C_\beta$ is $(n-1)$-truncated. It follows that g exhibits D' as a good object of $\mathcal{D}_{/D}$. This is a contradiction, since the morphism $x : M \to D$ factors through D'.

(ii) Suppose that the morphism ι is not an equivalence. Applying Theorem A.4.0.5 to the hypercompletion of the ∞-topos $\mathcal{S}\mathrm{hv}(\mathrm{Pro}(\mathcal{D})^{\mathrm{cc}}_{/X})$, we deduce that there exists a geometric morphism $\nu^* : \mathcal{S}\mathrm{hv}(\mathrm{Pro}(\mathcal{D})^{\mathrm{cc}}_{/X}) \to \mathcal{S}$ such that the image of X_0 under the composite map

$$\mathrm{Pro}(\mathcal{D})^{\mathrm{cc}}_{/X} \hookrightarrow \mathcal{S}\mathrm{hv}(\mathrm{Pro}(\mathcal{D})^{\mathrm{cc}}_{/X}) \xrightarrow{\nu^*} \mathcal{S}$$

is empty. Using Corollary A.9.1.2, we can identify η^* with a prime Pro-object $N \in \mathrm{Pro}(\mathrm{Pro}(\mathcal{D})^{\mathrm{cc}}_{/X}) \simeq \mathrm{Pro}(\mathcal{D})_{/X}$. By construction, the Pro-object N fits into a commutative diagram

$$\begin{array}{ccc} N & \longrightarrow & (G \circ F)(M) \\ \downarrow{\scriptstyle \phi} & & \downarrow \\ M^{S^n} & \longrightarrow & (G \circ F)(M)^{S^n} \end{array}$$

in the ∞-category $\mathrm{Pro}(\mathcal{D})$, and the composite map $N \xrightarrow{\phi} M^{S^n} \xrightarrow{x} D^{S^n}$ does not factor through the diagonal map $D \to D^{S^n}$. Unwinding the definitions, we see that ϕ classifies a map of spaces $S^n \to \mathrm{Map}_{\mathrm{Fun}^{\mathrm{pre}}(\mathcal{D},\mathcal{S})}(M, N)$, and the commutativity of the diagram σ shows that the composite map

$$S^n \to \mathrm{Map}_{\mathrm{Fun}^{\mathrm{pre}}(\mathcal{D},\mathcal{S})}(M, N) \to \mathrm{Map}_{\mathrm{Fun}^{\mathrm{pre}}(\mathcal{C},\mathcal{S})}(FM, FN)$$

is nullhomotopic. By assumption, precomposition with f^* induces an equivalence of ∞-categories $\mathrm{Fun}^{\mathrm{pre}}(\mathcal{D}, \mathcal{S}) \to \mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{S})$, so the map $S^n \to \mathrm{Map}_{\mathrm{Fun}^{\mathrm{pre}}(\mathcal{D},\mathcal{S})}(M, N)$ must already be nullhomotopic: that is, the map ϕ factors through the diagonal $M \to M^{S^n}$. It follows that the composite map $N \xrightarrow{\phi} M^{S^n} \xrightarrow{x} D^{S^n}$ factors through the diagonal $D \to D^{S^n}$: that is, the projection map $N \to X$ factors through X_0. This is a contradiction, since the mapping space $\mathrm{Map}_{\mathrm{Pro}(\mathcal{D})_{/X}}(N, X_0) = \emptyset$ by construction.

□

Appendix B

Grothendieck Topologies in Commutative Algebra

Let Aff denote the category of affine schemes. We will say that a collection of morphisms $\{f_\alpha : U_\alpha \to X\}$ in Aff is *jointly surjective* if the map $\coprod U_\alpha \to X$ is surjective as a map of topological spaces. There are several Grothendieck topologies on the category Aff which are useful in the study of classical algebraic geometry. For example:

- The *Zariski topology*, whose coverings are generated by collections of maps $\{\operatorname{Spec} R_\alpha \to \operatorname{Spec} R\}$ which are jointly surjective and have the property that each R_α is isomorphic to $R[x_\alpha^{-1}]$ for some element $x_\alpha \in R$ (in this case, the condition of joint surjectivity is equivalent to the condition that the elements x_α generate the unit ideal in R).
- The *étale topology*, whose coverings generated by collections of maps $\{\operatorname{Spec} R_\alpha \to \operatorname{Spec} R\}$ which are jointly surjective and have the property that each R_α is an étale R-algebra.
- The *fpqc topology*, whose coverings are generated by finite collections of maps $\{\operatorname{Spec} R_\alpha \to \operatorname{Spec} R\}$ which are jointly surjective and have the property that each R_α is flat over R.

In this appendix, we will study some Grothendieck topologies which play an analogous role in the theory of spectral algebraic geometry. For our purposes, the most important of the topologies listed above is the étale topology. We therefore begin in §B.1 by reviewing the theory of étale morphisms between $\mathbb{E}_\infty$-rings (relying heavily on the more extensive discussion given in §HA.7.5). Our main result is a structure theorem for étale morphisms (Proposition B.1.1.3), which parallels (and generalizes) the classification of étale morphisms of ordinary commutative rings (Proposition B.1.1.1).

If R is an $\mathbb{E}_\infty$-ring, we let CAlg_R denote the ∞-category of $\mathbb{E}_\infty$-algebras over R and $\mathrm{CAlg}_R^{\text{ét}} \subseteq \mathrm{CAlg}_R$ the full subcategory of étale R-algebras. This ∞-category can be equipped with a Grothendieck topology which we refer to as *the étale topology* (see Definition B.6.2.2). Most of this appendix is devoted to developing some tools for answering the following:

Question B.0.3.1. Let R be an $\mathbb{E}_\infty$-ring and let $\mathscr{F} : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{C}$ be a functor with values in an ∞-category $\mathcal{C}$. How can one tell if $\mathscr{F}$ is a sheaf for the étale topology?

Remark B.0.3.2. For any $\mathbb{E}_\infty$-ring R, the ∞-category $\mathrm{CAlg}_R^{\text{ét}}$ is actually (equivalent to) an ordinary category: more precisely, it is equivalent to the ordinary category $\mathrm{CAlg}_{\pi_0 R}^{\text{ét}}$ of étale algebras over the ordinary commutative ring $\pi_0 R$ (Theorem HA.7.5.0.6). Consequently, to understand general features of the theory of étale sheaves over R, there is no loss of generality in assuming that R is discrete. However, the sheaves which arise *in practice* often depend on the $\mathbb{E}_\infty$-ring R itself, and not only on the commutative ring $\pi_0 R$. For example, the forgetful functor $\mathscr{O} : \mathrm{CAlg}_R^{\text{ét}} \to \mathrm{CAlg}$ plays the role of the structure sheaf of the étale spectrum $\mathrm{Spét}\, R$ (see Proposition 1.4.2.4), and we can recover R as the value of $\mathscr{O}$ on the initial object of $\mathrm{CAlg}_R^{\text{ét}}$.

To address Question B.0.3.1, it will be convenient to introduce some auxiliary Grothendieck topologies: the *Nisnevich topology* (which we study in §B.4) and the *finite étale topology* (see Proposition **??**). In §B.6, we will show that a functor $\mathscr{F} : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{S}$ is a sheaf for the étale topology if and only if it is a sheaf for both the Nisnevich topology and the finite étale topology (Theorem B.6.4.1). This result is useful because the class of sheaves with respect to the Nisnevich and finite étale topologies admit more concrete characterizations. In §B.5, we will prove a result a Morel and Voevodsky (Theorem B.5.0.3) which characterizes Nisnevich sheaves as those functors $\mathscr{F} : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{S}$ which satisfy a certain excision property (see Theorem B.5.0.3). In §B.7, we will show that a functor $\mathscr{F} : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{S}$ is a sheaf for the finite étale topology if and only if it satisfies a version of Galois descent (Theorem B.7.6.1).

Our discussion of the Nisnevich topology (and of its relationship with the étale topology) will require some familiarity with the theory of commutative rings. Some of the early sections of this appendix are devoted to giving brief expository accounts of some of the requisite commutative algebra: in §B.2 we discuss the dimension theory of Noetherian rings, and in §B.3 we review the theory of Henselian rings (and the construction of the *Henselization* of a commutative ring R with respect to an ideal $I \subseteq R$).

Remark B.0.3.3. Another important Grothendieck topology on the category of (affine) schemes is the *fppf topology*, whose coverings are generated by finite collections of maps $\{\mathrm{Spec}\, R_\alpha \to \mathrm{Spec}\, R\}$ which are jointly surjective and have the property that each R_α is flat and of finite presentation over R. We will discuss analogues of the fppf topology in §**??**.

Contents

B.1 Étale Morphisms of Ring Spectra

Let $\phi : A \to B$ be a homomorphism of commutative rings. The morphism ϕ is said to be *étale* if the following conditions are satisfied:

(i) The morphism ϕ is flat: that is, it exhibits B as a flat A-module.

(ii) The multiplication map $B \otimes_A B \to B$ exhibits B as a localization $(B \otimes_A B)[e^{-1}]$ for some idempotent element $e \in B \otimes_A B$.

(iii) The commutative ring B is finitely presented as an A-algebra.

In §HA.7.5 , we studied a generalization of the theory of étale ring homomorphisms to the setting of $\mathbb{E}_\infty$-rings. Recall that if $\phi : A \to B$ is a morphism of $\mathbb{E}_\infty$-rings, then we say that ϕ is *étale* if the underlying ring homomorphism $\pi_0 A \to \pi_0 B$ is étale and ϕ induces an isomorphism of graded rings $\pi_0 B \otimes_{\pi_0 A} \pi_* A \to \pi_* B$. Note that if A is discrete, then ϕ is étale if and only if B is also discrete and ϕ is étale when regarded as a morphism of commutative rings (that is, it satisfies conditions (i), (ii) and (iii) above).

B.1.1 Structure Theory of Étale Morphisms

In the setting of classical commutative algebra, the collection of étale ring homomorphisms admits the following "extrinsic" characterization:

Proposition B.1.1.1. *Let A be a commutative ring. Then a ring homomorphism $\phi : A \to B$ is étale if and only if it exhibits B as isomorphic to an A-algebra of the form*

$$(A[y_1, \ldots, y_n]/(f_1, \ldots, f_n))[\Delta^{-1}],$$

where Δ denotes the determinant of the Jacobian matrix $[\frac{\partial f_i}{\partial y_j}]_{1 \leqslant i,j \leqslant n}$.

We would like to generalize Proposition B.1.1.1 to the setting of $\mathbb{E}_\infty$-rings. First, we need to introduce some terminology.

Notation B.1.1.2. Let A be an $\mathbb{E}_\infty$-ring, and let x be an arbitrary symbol. We let $A\{x\}$ denote the free $\mathbb{E}_\infty$-algebra over A on one generator. More precisely, we let $A\{x\}$ denote an object CAlg_A equipped with a point $\eta \in \Omega^\infty A\{x\}$ have the following universal property: for every object $B \in \mathrm{CAlg}_A$, evaluation on η induces a homotopy equivalence $\mathrm{Map}_{\mathrm{CAlg}_A}(A\{x\}, B) \to \Omega^\infty B$. We can describe $A\{x\}$ more explicitly as the symmetric algebra $\mathrm{Sym}^*_A(A)$ on A (regarded as a module over itself), so that $A\{x\}$ is equivalent to the infinite direct sum $\bigoplus_{n \geqslant 0} A_{\Sigma_n}$, where A_{Σ_n} denotes the spectrum of coinvariants with respect to the trivial action of the symmetric group Σ_n on A (see §HA.3.1.3).

More generally, given a finite collection of symbols $x_1, \ldots, x_m$, we let $A\{x_1, \ldots, x_m\}$ denote the free $\mathbb{E}_\infty$-algebra over A on m generators, which can either be described inductively by the formula $A\{x_1, \ldots, x_m\} \simeq (A\{x_1, \ldots, x_{m-1}\})\{x_m\}$, or as the symmetric algebra $\mathrm{Sym}^*_A(A^m)$. We note that if A is connective, then the commutative ring $\pi_0 A\{x_1, \ldots, x_m\}$ can be identified with the polynomial algebra $(\pi_0 A)[x_1, \ldots, x_m]$.

We can now formulate the main result of this section.

Proposition B.1.1.3. *Let R be a connective $\mathbb{E}_\infty$-ring, and let $\phi : A \to B$ be a morphism between R-algebras. The following conditions are equivalent:*

(1) *The map ϕ is étale.*

(2) *There exists a pushout diagram of R-algebras*

$$\begin{array}{ccc} R\{x_1, \ldots, x_n\} & \longrightarrow & A \\ \downarrow{\scriptstyle \phi_0} & & \downarrow{\scriptstyle \phi} \\ R\{y_1, \ldots, y_n\}[\Delta^{-1}] & \longrightarrow & B, \end{array}$$

where $\phi_0(x_i) = f_i(y_1, \ldots, y_n) \in (\pi_0 R)[y_1, \ldots, y_n]$ and $\Delta \in (\pi_0 R)[y_1, \ldots, y_n]$ denotes the determinant of the Jacobian matrix $[\frac{\partial f_i}{\partial y_j}]_{1 \leqslant i,j \leqslant n}$.

B.1.2 The Proof of Proposition B.1.1.1

Proposition B.1.1.3 can be regarded as a generalization of Proposition B.1.1.1, since every étale ring homomorphism is also étale when regarded as a morphism of $\mathbb{E}_\infty$-rings. Nevertheless, we give a proof of Proposition B.1.1.1 first, since it will be needed in the proof of Proposition B.1.1.3.

Lemma B.1.2.1. *Let $f : A \to B$ be a map of connective $\mathbb{E}_\infty$-rings. Assume that:*

(1) *The map f induces a surjection $f_0 : \pi_0 A \to \pi_0 B$.*

(2) *The commutative ring $\pi_0 B$ is finitely presented over $\pi_0 A$ (that is, the kernel of f_0 is a finitely generated ideal in $\pi_0 A$).*

(3) *The abelian group $\pi_1 L_{B/A}$ vanishes.*

Then there exists an element $a \in \pi_0 A$ such that $\pi_0 B \simeq (\pi_0 A)[a^{-1}]$.

Proof. Let I denote the kernel of f_0, and let $R = (\pi_0 A)/I^2$. It follows from Corollary HA.7.4.1.27 that, in the ∞-category CAlg_A, we have a commutative diagram

$$\begin{array}{ccc} R & \longrightarrow & \pi_0 B \\ \downarrow & & \downarrow \\ \pi_0 B & \longrightarrow & (\pi_0 B) \oplus \Sigma(I/I^2). \end{array}$$

Since $\pi_i L_{B/A} \simeq 0$ for $i \leqslant 1$, the canonical map

$$\mathrm{Map}_{\mathrm{CAlg}_A}(B, \pi_0 B) \to \mathrm{Map}_{\mathrm{CAlg}_A}(B, \pi_0 B \oplus \Sigma(I/I^2))$$

is a homotopy equivalence, so that $\mathrm{Map}_{\mathrm{CAlg}_R}(B, R) \to \mathrm{Map}_{\mathrm{CAlg}_R}(B, \pi_0 B)$ is also a homotopy equivalence. In particular, the truncation map $B \to \pi_0 B$ lifts (in an essentially unique fashion) to a map $B \to R$. Passing to connected components, we deduce that the quotient map of commutative algebras $\phi : (\pi_0 A)/I^2 \to (\pi_0 A)/I$ admits a section (in the category of $\pi_0 A$-algebras). This implies that ϕ is an isomorphism: that is, that $I = I^2$.

Because $\pi_0 B$ is finitely presented over $\pi_0 A$, the ideal I is generated by finitely elements $y_1, \ldots, y_m$. Since $I = I^2$, we can write $y_i = \sum_j z_{i,j} y_j$ for some elements $z_{i,j} \in I$. Let Z denote the matrix $\{z_{i,j}\}_{1 \leqslant i,j \leqslant m}$. Then $\mathrm{id} - Z$ annihilates the vector $(y_1, \ldots, y_m) \in (\pi_0 A)^m$. Let $a \in \pi_0 A$ denote the determinant of $\mathrm{id} - Z$. Since the entries of Z belong to I, D is congruent to 1 modulo I and is therefore invertible in $\pi_0 B$. It follows that we have a canonical map $g : A[a^{-1}] \to B$. We claim that g induces an isomorphism $g_0 : \pi_0 A[a^{-1}] \to \pi_0 B$. The surjectivity of g is clear, and the injectivity follows from the observation that multiplication by a annihilates every element of I. □

Lemma B.1.2.2. *Let κ be a field and suppose we are given a homomorphism of polynomial rings $\psi : \kappa[x_1, \ldots, x_n] \to \kappa[y_1, \ldots, y_n]$, given by $\psi(x_i) = f_i(y_1, \ldots, y_n)$. Let $\Delta \in \kappa[y_1, \ldots, y_n]$ denote the determinant of the Jacobian matrix $[\frac{\partial f_i}{\partial y_j}]_{1 \leqslant i,j \leqslant n}$. Then $\kappa[y_1, \ldots, y_n][\Delta^{-1}]$ is flat over $\kappa[x_1, \ldots, x_n]$.*

Proof. Without loss of generality, we may suppose that κ is algebraically closed. It will suffice to show that for each maximal ideal $\mathfrak{m} \subseteq \kappa[y_1, \ldots, y_n]$ not containing Δ, the induced map of localizations $\kappa[x_1, \ldots, x_n]_{\mathfrak{n}} \to \kappa[y_1, \ldots, y_n]_{\mathfrak{m}}$ is flat, where $\mathfrak{n} = \psi^{-1}\mathfrak{m}$. Using Hilbert's Nullstellensatz, we conclude that $\mathfrak{m}$ is generated by $y_j - \lambda_j$ for some scalars $\lambda_j \in \kappa$. Making a change of coordinates if necessary, we may assume that $\mathfrak{m} = (y_1, \ldots, y_n)$. Similarly, we may assume that the polynomials f_i satisfy $f_i(0, \ldots, 0) = 0$, so that $\mathfrak{n} = (x_1, \ldots, x_n)$. In this case, we have a commutative diagram

$$\begin{array}{ccc} \kappa[x_1, \ldots, x_n]_{\mathfrak{n}} & \longrightarrow & \kappa[y_1, \ldots, y_n]_{\mathfrak{m}} \\ \downarrow & & \downarrow \\ \kappa[[x_1, \ldots, x_n]] & \xrightarrow{\psi^\wedge} & \kappa[[y_1, \ldots, y_n]], \end{array}$$

where the vertical maps are faithfully flat (Corollary 7.3.6.9). It will therefore suffice to show that $\psi^\wedge$ is flat. In fact, we claim that $\psi^\wedge$ is an isomorphism. To prove this, we note that $\psi^\wedge$ is an inverse limit of maps of the form

$$\psi_d : \kappa[x_1, \ldots, x_n]/\mathfrak{n}^d \to \kappa[y_1, \ldots, y_n]/\mathfrak{m}^d.$$

Since ψ_d is a map between vector spaces of the same dimension over κ, we are reduced to proving that ψ_d is surjective. Using induction on d, we can reduce to the case $d = 2$, in which case the desired result follows from our assumption that $\Delta \notin \mathfrak{m}$. □

Proof of Proposition B.1.1.1. Suppose first that $B = (A[y_1, \ldots, y_n]/(f_1, \ldots, f_n))[\Delta^{-1}]$; we will prove that B is étale over A. It is clear that B is finitely presented as an A-algebra. We next prove that B is flat over A. For this, let us abuse notation by identifying Δ with the determinant of the Jacobian matrix $[\frac{\partial f_i}{\partial y_j}]_{1 \leqslant i,j \leqslant n}$ in the polynomial ring $A[y_1, \ldots, y_n]$, so that we have a pushout diagram of commutative rings

$$\begin{array}{ccc} A[x_1, \ldots, x_n] & \longrightarrow & A \\ \downarrow{\scriptstyle \psi} & & \downarrow \\ A[y_1, \ldots, y_n][\Delta^{-1}] & \longrightarrow & B \end{array}$$

where $\psi(x_i) = f_i$. It will therefore suffice to show that the map ψ is flat. Writing A as a direct limit of finitely generated subrings, we may reduce to the case A is Noetherian, so that $A[y_1, \ldots, y_n][\Delta^{-1}]$ is locally almost of finite presentation as an $\mathbb{E}_\infty$-algebra over $A[x_1, \ldots, x_n]$. Using the fiberwise flatness criterion (see Corollary 11.3.10 of [90] or Proposition **??**), we can reduce to the case where A is a field, in which case the desired result follows from Lemma B.1.2.2.

Let $B' = B \otimes_A B$. To complete the proof that B is étale over A, it will suffice to show that the multiplication map $m : B' \to B$ exhibits B as a localization $B'[e^{-1}]$ for some element $e \in B$ (since m is surjective, this will prove that the map of affine schemes $\operatorname{Spec} B \to \operatorname{Spec} B'$ is both a closed and open immersion, so that we can choose e to be idempotent if desired). By virtue of Lemma B.1.2.1, it will suffice to show that the abelian group $\pi_1 L_{B/B'}$ vanishes. Using the exactness of the sequence $\pi_1 L_{B/B} \to \pi_1 L_{B/B'} \to \pi_0(B \otimes_{B'} L_{B'/B}$, we are reduced to proving that the group

$$\pi_0(B \otimes_{B'} L_{B'/B}) \simeq \pi_0(B \otimes_{B'} B' \otimes_B L_{B/A}) \simeq \pi_0 L_{B/A} \simeq \Omega_{B/A}$$

vanishes. This is clear, since $\Omega_{B/A}$ can be computed as the cokernel of the map $B^n \to B^n$ given by the Jacobian matrix $[\frac{\partial f_i}{\partial y_j}]_{1 \leqslant i,j \leqslant n}$, which is invertible in B by assumption.

We now prove the converse. Suppose that $\phi : A \to B$ is an étale homomorphism of commutative rings. Since B is finitely generated as an A-algebra, we can choose a surjective ring homomorphism $\phi' : A' \to B$, where $A' = A[y_1, \ldots, y_n]$ is a polynomial algebra over A. Let $I \subseteq A'$ denote the kernel of ϕ'. We have a fiber sequence of cotangent complexes $B \otimes_{A'} L_{A'/A} \to L_{B/A} \to L_{B/A'}$. Since B is étale over A, the relative cotangent complex $L_{B/A}$ vanishes. It follows that the boundary map $\delta : \pi_1 L_{B/A'} \to \pi_0(B \otimes_{A'} L_{A'/A})$ is an isomorphism. Using Theorem HA.7.4.3.1 and Proposition HA.7.4.3.9 , we obtain isomorphisms

$$\pi_1 L_{B/A'} \simeq I/I^2 \qquad \pi_0(B \otimes_{A'} L_{A'/A}) \simeq B \otimes_{A'} \Omega_{A/A} \simeq B^n.$$

Under these isomorphisms, δ carries an element $\overline{f} \in I/I^2$ to the image in B^n of the vector of partial derivatives $[\frac{\partial f}{\partial y_j}]_{1 \leqslant j \leqslant n}$, where $f \in I$ is any representative of $\overline{f}$. It follows that we can choose a sequence of functionrs $f_1, f_2, \ldots, f_n \in I$ such that the Jacobian matrix $[\frac{\partial f_i}{\partial y_j}]_{1 \leqslant i,j \leqslant n}$ has invertible image in B. Set $A'' = (A[y_1, \ldots, y_n]/(f_1, \ldots, f_n))[\Delta^{-1}]$, where Δ denotes the determinant of $[\frac{\partial f_i}{\partial y_j}]_{1 \leqslant i,j \leqslant n}$. Then ϕ' factors through a ring homomorphism $\phi'' : A'' \to B$. The first part of the proof shows that A'' is étale over A, and the map ϕ'' induces a surjection $\pi_0 A'' \to \pi_0 B$ by construction. We have a fiber sequence of B-modules $B \otimes_{A''} L_{A''/A} \to L_{B/A} \to L_{B/A''}$. Since B and A'' are both étale over A, the first two terms of this fiber sequence vanish. It follows in particular that $\pi_1 L_{B/A''} \simeq 0$. Applying Lemma B.1.2.1, we deduce that $B \simeq A''[a^{-1}]$ for some element $a \in A''$. Multiplying a by a power of Δ if necessary, we may assume that a is the image of some polynomial $g \in A'$. In this case, we have an isomorphism

$$B \simeq A[y_1, \ldots, y_n, y_{n+1}]/(f_1, \ldots, f_n, f_{n+1})[\Delta'^{-1}],$$

where $f_{n+1} = 1 - g y_{n+1}$ and Δ' denotes the determinant of the Jacobian matrix $[\frac{\partial f_i}{\partial y_j}]_{1 \leqslant i,j \leqslant n+1}$. □

B.1.3 The Proof of Proposition B.1.1.3

We now study the structure of étale morphisms between $\mathbb{E}_\infty$-rings.

Lemma B.1.3.1. *Let $f : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings. The following conditions are equivalent:*

(1) *The abelian group $\pi_0 L_{B/A}$ vanishes, and $\pi_0 B$ is finitely generated as an algebra over $\pi_0 A$.*

(2) *There exist finitely many elements $x_1, \ldots, x_n \in \pi_0 B$ which generate the unit ideal, such that each of the induced maps $A \to B[x_i^{-1}]$ factors as a composition $A \xrightarrow{f'} A_i \xrightarrow{f''} B[x_i^{-1}]$ where f' is étale and f'' induces a surjection $\pi_0 A_i \to \pi_0 B[x_i^{-1}]$.*

Proof. Suppose first that (2) is satisfied. Each of the commutative rings $\pi_0 B[x_i^{-1}]$ is a quotient of an étale $\pi_0 A$-algebra, and therefore finitely generated over $\pi_0 A$. Let $B_0 \subseteq \pi_0 B$

be a finitely generated $\pi_0 A$-subalgebra containing each x_i, such that $B_0[x_i^{-1}] \to \pi_0 B[x_i^{-1}]$ is surjective for each i. Since the x_i generate the unit ideal in B, we deduce that $\pi_0 B = B_0$ is finitely generated over $\pi_0 A$.

It remains to prove that $\pi_0 L_{B/A} \simeq 0$. Since the elements x_i generate the unit ideal, it will suffice to show that $(\pi_0 L_{B/A})[x_i^{-1}] \simeq \pi_0(L_{B/A} \otimes_B B[x_i^{-1}]) \simeq \pi_0 L_{B[x_i^{-1}]/A}$ vanishes for each index i. Choose a factorization $A \xrightarrow{f'} A_i \xrightarrow{f''} B[x_i^{-1}]$ as in (2). We have a short exact sequence of abelian groups

$$\pi_0(B[x_i^{-1}] \otimes_{A'} L_{A_i/A}) \to \pi_0 L_{B[x_i^{-1}]/A} \to \pi_0 L_{B[x_i^{-1}]/A_i}.$$

Here $L_{A_i/A}$ vanishes since f' is étale (Corollary HA.7.5.4.5) and $\pi_0 L_{B[x_i^{-1}]/A_i}$ can be identified with the relative Kähler differentials $\Omega_{\pi_0 B[x_i^{-1}]/\pi_0 A_i}$ (Proposition HA.7.4.3.9), which vanishes because f'' is surjective on connected components. It follows that $\pi_0 L_{B[x_i^{-1}]/A} \simeq 0$ as desired.

Now suppose that (1) is satisfied. Let $R = \pi_0 B$. Since R is finitely generated over $\pi_0 A$, we can choose a presentation $R \simeq (\pi_0 A)[x_1, \ldots, x_n]/I$ for some ideal $I \subseteq (\pi_0 A)[x_1, \ldots, x_n]$. Then $\pi_0 L_{B/A}$ is the module of Kähler differentials of R over $\pi_0 A$ (Proposition HA.7.4.3.9). That is, $\pi_0 L_{B/A}$ is the quotient of the free R-module generated by elements $\{dx_i\}_{1 \leqslant i \leqslant n}$ by the submodule generated by elements $\{df\}_{f \in I}$. Since $\pi_0 L_{B/A} \simeq 0$, we can choose a finite collection of elements $\{f_j \in I\}_{1 \leqslant j \leqslant m}$ such that the Jacobian matrix $M = \{\frac{\partial f_j}{\partial x_i}\}$ has rank n. Let $\{a_k\}$ be the collection of determinants of n-by-n submatrices of the matrix M, so that the elements a_k generate the unit ideal in R. We will prove that each of the composite maps $A \to B[a_k^{-1}]$ factors as a composition $A \xrightarrow{f'} A_k \xrightarrow{f''} B[a_k^{-1}]$, where f' is étale and f'' is surjective on connected components. Reordering the f_j if necessary, we may suppose that $m \geqslant n$ and that a_k is the determinant of the matrix $\{\frac{\partial f_j}{\partial x_i}\}_{1 \leqslant i,j \leqslant n}$. Set

$$R' = (\pi_0 R)[x_1, \ldots, x_n, a_k^{-1}]/(f_1, \ldots, f_m),$$

so that R is an étale algebra over $\pi_0 A$ (Proposition B.1.1.1). It follows from Theorem HA.7.5.0.6 that R' can be lifted (in an essentially unique fashion) to an étale A-algebra A_k. Moreover, Corollary HA.7.5.4.6 implies that the surjective map $R' \to R[a_k^{-1}] = \pi_0 B[a_k^{-1}]$ lifts to a map $A_k \to B[a_k^{-1}]$, thereby supplying the desired factorization. □

Recall that if $\phi : A \to B$ is an étale morphism of $\mathbb{E}_\infty$-rings, then the relative cotangent complex $L_{B/A}$ vanishes (Corollary HA.7.5.4.5). We will need the following partial converse:

Lemma B.1.3.2. *Let $f : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings and let $1 \leqslant n \leqslant \infty$ be an integer. The following conditions are equivalent:*

(1) *The commutative ring $\pi_0 B$ is finitely presented over $\pi_0 A$, and $\pi_i L_{B/A} \simeq 0$ for $i \leqslant n$.*

(2) *The map f factors as a composition $A \xrightarrow{f'} A_i \xrightarrow{f''} B$ where f' is étale, f'' induces an isomorphism $\pi_i A' \to \pi_i B$ for $i < n$, and f'' induces a surjection $\pi_n A' \to \pi_n B$.*

Proof. Suppose first that (2) is satisfied. Then $\pi_0 B \simeq \pi_0 A'$ is étale over $\pi_0 A$, and therefore finitely presented as a $\pi_0 A$-algebra. We have a fiber sequence of B-modules $B \otimes_{A'} L_{A'/A} \to L_{B/A} \to L_{B/A'}$. Since A' is étale over A, we deduce that $L_{A'/A} \simeq 0$. Since f'' is n-connective, Corollary HA.7.4.3.2 implies that $L_{B/A} \simeq L_{B/A'}$ is $(n+1)$-connective, thereby completing the proof of (1).

Now assume that condition (1) holds. We first prove that $\pi_0 B$ is étale over $\pi_0 A$. Using Lemma B.1.3.1, we can choose a finite collection of elements $x_i \in \pi_0 B$ generating the unit ideal such that each of the induced maps $A \to B[x_i^{-1}]$ factors as a composition $A \xrightarrow{g'} A_i \xrightarrow{g''} B[x_i^{-1}]$ where g' is étale and g'' is surjective on connected components. Note that $\pi_1 L_{B[x_i^{-1}]/A_i} \simeq (\pi_1 L_{B/A})[x_i^{-1}] \simeq 0$. Using Lemma B.1.2.1, we deduce that $\pi_0 B[x_i^{-1}]$ is étale over $\pi_0 A_i$ and therefore over $\pi_0 A$, from which it follows that $\pi_0 B$ is étale over $\pi_0 A$.

Using Theorem HA.7.5.0.6 , we can choose an étale A-algebra A' and an isomorphism of $\pi_0 A$-algebras $\alpha : \pi_0 A' \simeq \pi_0 B$. Theorem HA.7.5.4.2 implies that we can lift α to a map of A-algebras $f'' : A' \to B$. To complete the proof, it will suffice to show that f'' is n-connective; this follows from Corollary HA.7.4.3.2 . □

Lemma B.1.3.3. *Let $A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings, and assume that the relative cotangent complex $L_{B/A}$ vanishes. The following conditions are equivalent:*

(1) *The commutative ring $\pi_0 B$ is finitely presented over $\pi_0 A$.*

(2) *The algebra B is of finite presentation over A.*

(3) *The algebra B is almost of finite presentation over A.*

(4) *The map $A \to B$ is étale.*

Proof. The implication (4) ⇒ (1) is obvious, the equivalences (1) ⇔ (2) ⇔ (3) follow from Theorem HA.7.4.3.18 , and the implication (1) ⇒ (4) is a special case of Lemma B.1.3.2. □

Proof of Proposition B.1.1.3. To prove that (2) implies (1), it suffices to show that the map ϕ_0 appearing in the diagram is étale. Note that the relative cotangent complex of ϕ_0 can be identified with the cofiber of the map $L_{A\{x_1,\ldots,x_n\}/A} \otimes_{A\{x_1,\ldots,x_n\}} A\{y_1,\ldots,y_n\}[\Delta^{-1}] \to L_{A\{y_1,\ldots,y_n\}[\Delta^{-1}]/A}$. This is a map of free modules of rank n, which is given on π_0 by the Jacobian matrix $[\frac{\partial f_i}{\partial y_j}]_{1 \leqslant i,j \leqslant n}$. Since this matrix is invertible in $\pi_0 A\{y_1,\ldots,y_n\}[\Delta^{-1}]$, we deduce that the relative cotangent complex of ϕ_0 vanishes, so that ϕ_0 is étale by Lemma B.1.3.3.

We now prove that (1) ⇒ (2). Suppose that ϕ is étale. Then B is flat over A, so we have a pushout diagram of $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc} \tau_{\geqslant 0} A & \longrightarrow & A \\ \downarrow & & \downarrow \\ \tau_{\geqslant 0} B & \longrightarrow & B. \end{array}$$

We may therefore replace A and B by their connective covers, and thereby reduce to the case where A and B are connective. Proposition B.1.1.1 implies that there exists an isomorphism of commutative rings $\pi_0 B \simeq (\pi_0 A)[y_1, \ldots, y_m]/(f_1, \ldots, f_m)[\overline{\Delta}^{-1}]$, where $\overline{\Delta}$ denotes the determinant of the Jacobian matrix $[\frac{\partial f_i}{\partial y_j}]_{1 \leqslant i,j \leqslant m}$ is invertible in $\pi_0 B$. Let $\{a_i \in \pi_0 A\}_{1 \leqslant i \leqslant k}$ be the nonzero coefficients appearing in the polynomials f_i. Choose a commutative diagram

$$\begin{array}{ccc} A\{x_1, \ldots, x_k\} & \xrightarrow{g_0} & A \\ \downarrow & & \downarrow{\scriptstyle \phi} \\ A\{x_1, \ldots, x_k, y_1, \ldots, y_m\} & \xrightarrow{g_1} & B \end{array}$$

where g_0 carries each x_i to $a_i \in \pi_0 A$. For each $1 \leqslant i \leqslant m$, choose a polynomial $\overline{f}_i \in (\pi_0 A)[y_1, \ldots, y_m, x_1, \ldots, x_k]$ lying over f_i, so that we have $g_1(\overline{f}_i) = 0 \in \pi_0 B$. Let $\Delta \in (\pi_0 A)[y_1, \ldots, y_m, x_1, \ldots, x_k]$ denote the determinant of the Jacobian matrix $[\frac{\partial \overline{f}_i}{\partial y_j}]_{1 \leqslant i,j \leqslant m}$.

Using Corollary HA.7.5.4.6 , we deduce the existence of a commutative diagram

$$\begin{array}{ccccc} A\{x_1, \ldots, x_k, z_1, \ldots, z_m\} & \xrightarrow{\epsilon} & A\{x_1, \ldots, x_k\} & \longrightarrow & A \\ \downarrow{\scriptstyle h} & & & & \downarrow{\scriptstyle \phi} \\ A\{x_1, \ldots, x_k, y_1, \ldots, y_m\}[\Delta^{-1}] & & \xrightarrow{\quad g_1 \quad} & & B \end{array}$$

where $h(z_i) = \overline{f}_i$ and $\epsilon(z_i) = 0$ for $1 \leqslant i \leqslant m$. We claim that the outer square appearing in this diagram is a pushout. To see this, form a pushout diagram

$$\begin{array}{ccc} A\{x_1, \ldots, x_k, z_1, \ldots, z_m\} & \longrightarrow & A \\ \downarrow{\scriptstyle \phi_0} & & \downarrow \\ A\{x_1, \ldots, x_k, y_1, \ldots, y_m\}[\Delta^{-1}] & \longrightarrow & B' \end{array}$$

so that we have a canonical map $\psi : B' \to B$; we wish to show that ψ is an equivalence. By construction, $\psi : B' \to B$ induces an isomorphism on connected components. The first part of the proof shows that B' is étale over A, so that $L_{B'/A} \simeq 0$. Since $L_{B/A} \simeq 0$, we conclude that $L_{B/B'} \simeq 0$, so that $B \simeq B'$ by Corollary HA.7.4.3.2 . □

B.1.4 Descent for the Flat Topology

We close this section with a simple observation concerning the relationship between flat and étale morphisms of $\mathbb{E}_\infty$-rings. We will assume that the reader is familiar with the notion of a *faithfully flat* morphism of $\mathbb{E}_\infty$-rings (see Definition B.6.1.1).

Proposition B.1.4.1. *Suppose we are given morphisms of $\mathbb{E}_\infty$-rings $A \xrightarrow{f} B \xrightarrow{g} C$, where g is étale and faithfully flat. Then f is étale if and only if $g \circ f$ is étale.*

The proof of Proposition **??** requires the following:

Lemma B.1.4.2. *Let $f : A \to B$ and $g : B \to C$ be morphisms of $\mathbb{E}_\infty$-rings. Then:*

(1) *If f and g are flat, then $g \circ f$ is flat.*

(2) *If $g \circ f$ is flat and g is faithfully flat, then f is flat.*

Proof. We first prove (1). The map $\pi_0 A \to \pi_0 C$ is a composition of two flat maps between commutative rings, and therefore a flat map. It therefore suffices to show that for each integer n, the map of abelian groups $\mathrm{Tor}_0^{\pi_0 A}(\pi_n A, \pi_0 C) \to \pi_n C$ is an isomorphism. We can factor this map as a composition

$$\begin{aligned} \mathrm{Tor}_0^{\pi_0 A}(\pi_n A, \pi_0 C) &\simeq \mathrm{Tor}_0^{\pi_0 B}(\mathrm{Tor}_0^{\pi_0 A}(\pi_n A, \pi_0 B), \pi_0 C) \\ &\xrightarrow{\phi} \mathrm{Tor}_0^{\pi_0 B}(\pi_n B, \pi_0 C) \\ &\xrightarrow{\psi} \pi_n C. \end{aligned}$$

We conclude by observing that ϕ is an isomorphism because f is assumed to be flat, and the map ψ is an isomorphism because g is assumed to be flat.

We now prove (2). We first claim that f induces a flat map of commutative rings $\pi_0 A \to \pi_0 B$. To prove this, choose a monomorphism $M \to N$ of (discrete) $\pi_0 A$-modules, and let K be the kernel of the induced map $\mathrm{Tor}_0^{\pi_0 A}(M, \pi_0 B) \to \mathrm{Tor}_0^{\pi_0 A}(N, \pi_0 B)$; we wish to prove that $K = 0$. Since $\pi_0 B \to \pi_0 C$ is faithfully flat, it suffices to show that $\mathrm{Tor}_0^{\pi_0 C}(K, \pi_0 B)$ is zero. Using the flatness of $\pi_0 B \to \pi_0 C$, we can identify $\mathrm{Tor}_0^{\pi_0 C}(K, \pi_0 B)$ with the kernel of the map

$$\begin{aligned} \mathrm{Tor}_0^{\pi_0 B}(\mathrm{Tor}_0^{\pi_0 A}(M, \pi_0 B), \pi_0 C) &\simeq \mathrm{Tor}_0^{\pi_0 A}(M, \pi_0 C) \\ &\to \mathrm{Tor}_0^{\pi_0 A}(N, \pi_0 C) \\ &\simeq \mathrm{Tor}_0^{\pi_0 B}(\mathrm{Tor}_0^{\pi_0 A}(N, \pi_0 B), \pi_0 C). \end{aligned}$$

This map is a monomorhism, since $g \circ f$ is assumed to be flat.

To complete the proof that f is flat, we must show that for each integer n, the map $\mathrm{Tor}_0^{\pi_0 A}(\pi_n A, \pi_0 B) \to \pi_n B$ is an isomorphism. Since g is faithfully flat, we reduce to proving that the map ϕ above is an isomorphism. By a two-out-of-three argument, we are reduced to proving that the maps $\psi \circ \phi$ and ψ are isomorphisms. This follows from our assumption that g and $g \circ f$ are flat. □

Corollary B.1.4.3. *Suppose we are given a pushout diagram of $\mathbb{E}_\infty$-rings*

$$\begin{array}{ccc} A & \xrightarrow{\psi} & A' \\ \downarrow{\scriptstyle \phi} & & \downarrow{\scriptstyle \phi'} \\ B & \xrightarrow{\psi'} & B', \end{array}$$

where ψ is faithfully flat. If B' is flat over A', then B is flat over A.

Proof. Since ψ is faithfully flat flat, the morphism ψ' is also faithfully flat. By virtue of Lemma B.1.4.2, it will suffice to show that the composition $\psi' \circ \phi \simeq \phi' \circ \psi$ is flat. This follows from Lemma B.1.4.2, since ψ and ϕ' are both flat.

□

Proof of Proposition B.1.4.1. The "only if" direction is obvious. For the converse, assume that $g \circ f$ is étale. Lemma B.1.4.2 implies that f is flat. It will therefore suffice to show that the commutative ring $\pi_0 B$ is étale over $\pi_0 A$. Replacing A, B, and C by their connective covers, we can reduce to the case where A, B, and C are connective. We have a fiber sequence $C \otimes_B L_{B/A} \to L_{C/A} \to L_{C/B}$. Since C is étale over both A and B, we have $L_{C/A} \simeq L_{C/B} \simeq 0$. It follows that $C \otimes_B L_{B/A} \simeq 0$. Since C is faithfully flat over B, this implies that $L_{B/A} \simeq 0$ (Remark B.6.1.2). To complete the proof that B is étale over A, it will suffice to show that $\pi_0 B$ is finitely presented as a commutative algebra over $\pi_0 A$ (Lemma B.1.3.3). We first prove that $\pi_0 B$ is finitely generated over $\pi_0 A$. Since g is étale, the commutative algebra $\pi_0 C$ is finitely presented over $\pi_0 B$. We may therefore choose a finitely generated $\pi_0 A$-subalgebra $R \subseteq \pi_0 B$ and an étale morphism $R \to R'$ such that $\pi_0 C \simeq (\pi_0 B) \otimes_R R'$. Since $\pi_0 C$ is finitely generated over $\pi_0 A$, we may assume (after enlarging R if necessary) that the map $R' \to \pi_0 C$ is surjective. Since $\pi_0 C$ is faithfully flat over $\pi_0 B$, we conclude that the inclusion $R \hookrightarrow \pi_0 B$ is surjective, so that $\pi_0 B = R$ is finitely generated over $\pi_0 A$. Choose a surjection $S \to \pi_0 B$, where S is finitely presented over $\pi_0 A$. Let I denote the kernel of ϕ; we wish to show that I is a finitely generated ideal. Using Proposition B.1.1.3, we can choose an étale morphism $S \to S'$ and an isomorphism $\pi_0 C \simeq \pi_0 B \otimes_S S'$. Replacing S by the quotient S/J for some finitely generated ideal $J \subseteq I$, we can assume that S' is faithfully flat over S. It follows that the canonical map $S'' \to \pi_0 C$ is surjection with kernel $S' \otimes_S I$. Since $\pi_0 C$ is finitely presented over $\pi_0 A$, the ideal $S' \otimes_S I$ is finitely generated as a module over S'. Because S' is faithfully flat over S, the ideal I is finitely generated as an S-module, as desired. □

B.2 Dimension Theory of Commutative Rings

In this section, we will review the dimension theory of Noetherian commutative rings (more complete accounts can be found in many standard texts on commutative algebra, such as [8] or [59]).

B.2.1 Dimension of a Local Noetherian Ring

Let A be a local Noetherian ring. Then the maximal ideal $\mathfrak{m} \subseteq A$ is finitely generated: that is, we can choose finitely many elements $a_1, \ldots, a_d \in A$ such that $\mathfrak{m} = (a_1, \ldots, a_d)$.

Definition B.2.1.1. Let A be a local Noetherian ring with maximal ideal $\mathfrak{m}$. The *dimension* of A is the smallest integer $d \geqslant 0$ for which there exists elements $a_1, \ldots, a_d \in \mathfrak{m}$ for which the ideal $(a_1, \ldots, a_d)$ contains some power of $\mathfrak{m}$.

The dimension of a local Noetherian ring admits several other characterizations:

Theorem B.2.1.2. *Let A be a local Noetherian ring with maximal ideal $\mathfrak{m}$ and let $d \geqslant 0$ be an integer. The following conditions are equivalent:*

(a) *Every chain of prime ideals $\mathfrak{p}_0 \subsetneq \mathfrak{p}_1 \subsetneq \cdots \subsetneq \mathfrak{p}_k$ in A has length $k \leqslant d$.*

(b) *The local ring A has Krull dimension $\leqslant d$ (in the sense of Definition B.2.1.1): that is, there exist elements $a_1, \ldots, a_d \in \mathfrak{m}$ such that $(a_1, \ldots, a_d)$ contains $\mathfrak{m}^n$ for $n \gg 0$.*

(c) *There exists a constant c such that for each $n \geqslant 0$, the quotient $A/\mathfrak{m}^n$ has length $\leqslant cn^d$ as an A-module.*

Remark B.2.1.3. In the situation of Theorem B.2.1.2, there exists a polynomial $P(t) \in \mathbf{Q}[t]$ such the quotient $A/\mathfrak{m}^n$ has length $P(n)$ for all sufficiently large integers n. The polynomial $P(t)$ is called the *Hilbert-Samuel polynomial* of A, and its degree is the dimension of A.

Proof of Theorem B.2.1.2. We first show that (a) implies (b) using induction on d. If $d = 0$, then condition (a) guarantees that $\mathfrak{m}$ is the unique prime ideal of A, and therefore coincides with the nilradical of A. Since A is Noetherian, the maximal ideal $\mathfrak{m}$ is finitely generated, so we have $\mathfrak{m}^n \simeq 0$ for $n \gg 0$, which proves (b). Suppose that $d > 0$. The ring A is Noetherian and therefore contains finitely many minimal prime ideals. The assumption $d > 0$ implies that each of these minimal prime ideals is properly contained in $\mathfrak{m}$. We can therefore choose an element $x \in \mathfrak{m}$ which is not contained in any minimal prime ideal of A. For any sequence of prime ideals $\mathfrak{q}_0 \subsetneq \mathfrak{q}_1 \subsetneq \cdots \subsetneq \mathfrak{q}_k$ in the quotient ring $A/(x)$, their inverse images in A form a sequence of prime ideals which does not contain any minimal prime ideal of A, and can therefore be extended to a chain of prime ideals in A having length $k+1$. It follows from assumption (a) that $k < d$, so our inductive hypothesis implies that $A/(x)$ has dimension $< d$. That is, we can choose elements $\overline{y}_1, \ldots, \overline{y}_{d_1} \in \overline{\mathfrak{m}}$ such that $(\overline{y}_1, \ldots, \overline{y}_{d-1})$ contains $\overline{\mathfrak{m}}^n$ for $n \gg 0$, where $\overline{\mathfrak{m}}$ denotes the image of $\mathfrak{m}$ in $A/(x)$. Writing each $\overline{y}_i$ as the image of an element $y_i \in \mathfrak{m}$, we obtain $\mathfrak{m}^n \subseteq (x, y_1, \ldots, y_{d-1})$ so that A has dimension $\leqslant d$.

We next prove that (b) implies (c). Choose elements $x_1, \ldots, x_d \in \mathfrak{m}$ for which the ideal $(x_1, \ldots, x_d)$ contains some power of $\mathfrak{m}$. It follows that that $A/(x_1, \ldots, x_d)$ appears as a quotient of $A/\mathfrak{m}^k$ for $k \gg 0$ and is therefore an A-module of finite length. Let c be the length of $A/(x_1, \ldots, x_d)$. An easy induction shows that for every sequence of integers $n_1, \ldots, n_d \geqslant 0$, the quotient $A/(x_1^{n_1}, \ldots, x_d^{n_d})$ has length $\leqslant c \prod_{1 \leqslant i \leqslant d} n_i$. For $n \geqslant 0$, the ideal $\mathfrak{m}^n$ contains each x_i^n, so that $A/\mathfrak{m}^n$ is a quotient of $A/(x_1^n, \ldots, x_d^n)$ and therefore has length $\leqslant cd^n$.

We now show that (c) implies (a). For each A-module M of finite length, let $\ell(M)$ denote the length of M as an A-module. Suppose that there exists a chain of prime ideals $\mathfrak{p}_0 \subsetneq \cdots \subsetneq \mathfrak{p}_k$ in A having length k. We will prove that there exists a positive real number e such that $\ell(A/\mathfrak{m}^n) \geqslant en^k$ for $n \gg 0$. If (c) is satisfied, then this claim guarantees that $k \leqslant d$, so that (a) is also satisfied. Our proof proceeds by induction on k, the case $k = 0$ being trivial. Let us therefore assume that $k > 0$. Replacing A by $A/\mathfrak{p}_0$, we may assume that $\mathfrak{p}_0 = (0)$ so that A is an integral domain. Choose a nonzero element $x \in \mathfrak{p}_1$. Applying the Artin-Rees lemma to the ideal $(x) \subseteq A$, we deduce that there exists an integer r such that $\mathfrak{m}^n \cap (x) \subseteq \mathfrak{m}^{n-r}(x)$ for $n \geqslant r$. Set $\overline{A} = A/(x)$ and let $\overline{\mathfrak{m}}$ be the image of $\mathfrak{m}$ in $\overline{A}$. Applying our inductive hypothesis to $\overline{A}$, we deduce that there exists constant $\overline{e} > 0$ and $a_0 \geqslant r$ such that $\ell(\overline{A}/\mathfrak{m}^a) \geqslant \overline{e}a^{k-1}$ for $a \geqslant a_0$. For $n \geqslant a_0$, there is a unique integer $n' > 0$ such that $a_0 - r \leqslant n - rn' < a_0$. We then have

$$\begin{aligned}
\ell(A/\mathfrak{m}^n) &\geqslant \sum_{0 \leqslant i < n'} \ell((x^i) + \mathfrak{m}^n/(x^{i+1}) + \mathfrak{m}^n) \\
&= \sum_{0 \leqslant i < n'} \ell(A/(x) + \{y \in A : x^i y \in \mathfrak{m}^n\}) \\
&\geqslant \sum_{0 \leqslant i < n'} \ell(\overline{A}/\overline{\mathfrak{m}}^{n-ir}) \\
&\geqslant \sum_{0 \leqslant i < n'} \overline{e}(n - ir)^{k-1} \\
&\geqslant \int_0^{n'} \overline{e}(n - tr)^{k-1} dt \\
&= \frac{\overline{e}}{rk}(n^k - (n - rn')^k) \\
&> \frac{\overline{e}}{rk}(n^k - a_0^k).
\end{aligned}$$

It follows that for any constant $e < \frac{\overline{e}}{rk}$, we have $\ell(A/\mathfrak{m}^n) \geqslant en^k$ for $n \gg 0$. □

Remark B.2.1.4. Let A be a local Noetherian ring. It follows from characterization (c) of Theorem B.2.1.2 that the dimension of A is the same as the dimension of the completion $\widehat{A}$ of A at its maximal ideal $\mathfrak{m}$.

Definition B.2.1.5. Let A be a Noetherian ring and let $\mathfrak{p}$ be a prime ideal of A. The *height* of $\mathfrak{p}$ is the dimension of the local ring $A_{\mathfrak{p}}$. We say that A has *Krull dimension* $\leqslant d$ if each prime ideal $\mathfrak{p}$ in A has height $\leqslant d$.

Remark B.2.1.6. Let $\mathfrak{p}$ be a prime ideal in a Noetherian ring A. It follows from criterion (a) of Theorem B.2.1.2 that the height of $\mathfrak{p}$ is the largest integer h for which there exists a chain of prime ideals $\mathfrak{q}_0 \subsetneq \mathfrak{q}_1 \subsetneq \cdots \subsetneq \mathfrak{q}_h = \mathfrak{p}$ ending in $\mathfrak{p}$.

Remark B.2.1.7. If A is a local Noetherian ring of dimension d and $I \subsetneq A$ is an ideal, then the quotient A/I is a local Noetherian ring of dimension $\leqslant d$. More generally, if A is a Noetherian ring of Krull dimension $\leqslant d$, then any quotient ring of A has Krull dimension $\leqslant d$.

B.2.2 Flat Morphisms

We now discuss the relationship between the Krull dimensions of commutative rings A and B which are related by a ring homomorphism $\phi : A \to B$. In the case where ϕ is flat, we have the following:

Theorem B.2.2.1. *Let $\phi : A \to B$ be a flat homomorphism of commutative rings. Let $\mathfrak{p}$ be a prime ideal of B, and let $\mathfrak{q}$ be a prime ideal of A which is contained in $\phi^{-1}\mathfrak{p}$. Then we can write $\mathfrak{q} = \phi^{-1}\mathfrak{p}_0$ for some prime ideal $\mathfrak{p}_0 \subseteq \mathfrak{p} \subseteq B$.*

Proof. Replacing A by $A/\mathfrak{q}$ and B by $B/\mathfrak{q}B$, we may assume that A is an integral domain and that $\mathfrak{q}$ is the zero ideal. Replacing B by $B_{\mathfrak{p}}$, we may reduce to the case where B is a local ring with maximal ideal $\mathfrak{p}$. In this case, it will suffice to show that there exists any prime ideal $\mathfrak{p}_0 \subseteq B$ such that $\phi^{-1}\mathfrak{p}_0 = (0)$. Let K denote the fraction field of A, so that we have an injective map $A \hookrightarrow K$. Since B is flat over A, the induced map $B \to K \otimes_A B$ is also injective. It follows that $K \otimes_A B$ is nonzero, so that there there exists a maximal ideal $\mathfrak{m}$ in the ring $K \otimes_A B$. We let $\mathfrak{p}_0$ denote the inverse image of $\mathfrak{m}$ in B; it follows from the commutativity of the diagram

$$\begin{array}{ccc} |\operatorname{Spec}(K \otimes_A B)| & \longrightarrow & |\operatorname{Spec} B| \\ \downarrow & & \downarrow \\ |\operatorname{Spec} K| & \longrightarrow & |\operatorname{Spec} A| \end{array}$$

that $\phi^{-1}\mathfrak{p}_0 = (0)$, as desired. □

Corollary B.2.2.2. *Let $\phi : A \to B$ be a flat morphism of Noetherian rings, let $\mathfrak{p}$ be a prime ideal of B, and let $\mathfrak{q} = \phi^{-1}\mathfrak{p}$. If $\mathfrak{p}$ has height $\leqslant d$, then $\mathfrak{q}$ has height $\leqslant d$.*

Proof. If $\mathfrak{q}$ does not have height $\leqslant d$, then there exists a chain of prime ideals $\mathfrak{q}_0 \subsetneq \mathfrak{q}_1 \subsetneq \cdots \subsetneq \mathfrak{q}_{d+1} = \mathfrak{q}$ in A having length $d+1$. Applying Theorem B.2.2.1 repeatedly, we see that this chain can be lifted to a chain of prime ideals $\mathfrak{p}_0 \subsetneq \mathfrak{p}_1 \subsetneq \cdots \subsetneq \mathfrak{p}_{d+1} = \mathfrak{p}$ in B, contradicing our asusumption that $\mathfrak{p}$ has height $\leqslant d$. □

Corollary B.2.2.3. *Let $\phi : A \to B$ be a faithfully flat morphism of commutative rings. If B has Krull dimension $\leqslant d$, then A has Krull dimension $\leqslant d$.*

Variant B.2.2.4. Let $\phi : A \rightarrow B$ be an étale homomorphism between Noetherian rings, let $\mathfrak{p}$ be a prime ideal in B, and let $\mathfrak{q} = \phi^{-1}\mathfrak{p}$. Then $\mathfrak{p}$ and $\mathfrak{q}$ have the same height.

Proof. The map ϕ induces an isomorphism between the completions of the local rings $A_{\mathfrak{q}}$ and $B_{\mathfrak{p}}$, so the desired result follows from Remark B.2.1.4. □

For later use, we record another consequence of Theorem B.2.2.1:

Corollary B.2.2.5. *Let $\phi : A \rightarrow B$ be homomorphism of commutative rings which is flat and of finite presentation (for example, an étale morphism). Then the induced map of topological spaces $f : |\operatorname{Spec} B| \rightarrow |\operatorname{Spec} A|$ is open.*

Proof. Let U be an open subset of $|\operatorname{Spec} B|$; we wish to prove that $f(U)$ is an open subset of $|\operatorname{Spec} A|$. Without loss of generality, we may assume that U is a basic open set of the form $|\operatorname{Spec} B[b^{-1}]|$. Replacing B by $B[b^{-1}]$, we are reduced to proving that the image of f is open. Since ϕ is of finite presentation, Chevalley's constructibility theorem (Theorem 4.3.3.1) implies that the image of f is a constructible subset of $|\operatorname{Spec} B|$. To show that this image is open, it will suffice to show that it is stable under generalization (Proposition 4.3.2.1), which follows immediately from Theorem B.2.2.1. □

B.2.3 Relative Dimension

We will need the following relative version of Definition B.2.1.1:

Definition B.2.3.1. Let $\phi : A \rightarrow B$ be a homomorphism of commutative rings and let $d \geqslant 0$ be an integer. We will say that ϕ is *of relative dimension* $\leqslant d$ if it exhibits B as a finitely generated A-algebra and, for every ring homomorphism $A \rightarrow \kappa$ where κ is a field, the tensor product $\operatorname{Tor}_0^A(\kappa, B)$ has Krull dimension $\leqslant d$ (in the sense of Definition B.2.1.1).

Remark B.2.3.2. In the situation of Definition B.2.4.1, the assumption that B is finitely generated as an A-algebra guarantees that any tensor product $\operatorname{Tor}_0^A(\kappa, B)$ is a finitely generated algebra over the field κ, and is therefore automatically Noetherian.

Remark B.2.3.3. In the situation of Definition B.2.3.1, it suffices to consider the case where κ is a residue field of A: see Corollary B.2.3.10 below.

Remark B.2.3.4. Let $\phi : A \rightarrow B$ and $\psi : B \rightarrow C$ be homomorphisms of commutative rings. If $\psi \circ \phi : A \rightarrow C$ has relative dimension $\leqslant d$, then ψ has relative dimension $\leqslant d$. It is clear that if C is finitely generated over A, then it is also finitely generated over B. We complete the proof by observing that for any ring homomorphism from B to a field κ, the tensor product $\operatorname{Tor}_0^B(\kappa, C)$ is a quotient of $\operatorname{Tor}_0^A(\kappa, C)$ and therefore has Krull dimension $\leqslant d$ (Remark B.2.1.7).

We now summarize some of the formal properties of Definition B.2.3.1.

Proposition B.2.3.5. *Suppose we are given a pushout diagram of commutative rings*

$$\begin{array}{ccc} A & \xrightarrow{\phi} & B \\ \downarrow{\scriptstyle\psi} & & \downarrow \\ A' & \xrightarrow{\phi'} & B'. \end{array}$$

If ϕ is of relative dimension $\leqslant d$, then so is ϕ'. The converse holds if ψ is faithfully flat.

Proof. The first assertion follows immediately from the definitions. To prove the second, suppose that ϕ' is of relative dimension d and that ψ is faithfully flat. Then B' is finitely generated over A', so we can choose finitely many elements $b_1, \ldots, b_n \in B$ whose images generate B' as an A'-algebra. Let $B_0 \subseteq B$ be the A-subalgebra generated by $b_1, \ldots, b_n$. Then the inclusion $\iota : B_0 \hookrightarrow B$ induces a surjection

$$A' \otimes_A B_0 \to A' \otimes_A B \simeq B'.$$

Since A' is faithfully flat over A, it follows that ι is surjective so that $B = B_0$ is finitely generated as an A-algebra. To complete the proof, choose a ring homomorphism $A \to \kappa$ where κ is a field and set $B_\kappa = \mathrm{Tor}_0^A(\kappa, B)$. We wish to show that B_κ has Krull dimension $\leqslant d$. Since ϕ' is faithfully flat, there exists an extension field κ' of κ for which the composite map $A \to \kappa \hookrightarrow \kappa'$ factors through A'. Our assumption that ϕ' has relative dimension $\leqslant d$ then implies that $B_{\kappa'} \simeq \kappa' \otimes_\kappa B_\kappa$ has Krull dimension $\leqslant d$. Since $B_{\kappa'}$ is faithfully flat over B_κ, it follows that B_κ also has Krull dimension $\leqslant d$ (Corollary B.2.2.3). □

Proposition B.2.3.6. *Let $\phi : A \to B$ be a homomorphism of commutative rings which has relative dimension $\leqslant d$. Suppose that A is a Noetherian ring of Krull dimension $\leqslant n$. Then B is a Noetherian ring of Krull dimension $\leqslant n + d$.*

Proof. Since B is finitely generated as an A-algebra, it is Noetherian by virtue of the Hilbert basis theorem. Fix a prime ideal $\mathfrak{p} \subseteq B$; we will show that the local ring $B_\mathfrak{p}$ has dimension $\leqslant n+d$. Set $\mathfrak{q} = \phi^{-1}\mathfrak{p} \subseteq A$. Replacing A by the localization $A_\mathfrak{q}$ and B by the tensor product $A_\mathfrak{q} \otimes_A B$, we may assume that A is a local ring with maximal ideal $\mathfrak{q}$. Since A has Krull dimension $\leqslant n$, we can choose elements $a_1, \ldots, a_n$ for which the ideal $(a_1, \ldots, a_n)$ contains $\mathfrak{q}^k$ for some integer k. Similarly, the condition that ϕ has relative dimension $\leqslant d$ guarantees that we can choose elements $\overline{b}_1, \ldots, \overline{b}_d$ in $B_\mathfrak{p}/\mathfrak{q}B_\mathfrak{p}$ such that the ideal $(\overline{b}_1, \ldots, \overline{b}_d)$ contains the image of $\mathfrak{p}^{k'}$ for some $k' > 0$. For each $1 \leqslant i \leqslant d$, choose an element $b_i \in B_\mathfrak{p}$ representing $\overline{b}_i$, and let $I \subseteq B_\mathfrak{p}$ denote the ideal $(\phi(a_1), \ldots, \phi(a_n), b_1, \ldots, b_d)$. By construction, we have

$$\mathfrak{p}^{kk'} \subseteq (\mathfrak{q}B_\mathfrak{p} + I)^k \subseteq \mathfrak{q}^k B_\mathfrak{p} + I \subseteq I$$

so that $B_\mathfrak{p}$ has dimension $\leqslant n + d$, as desired. □

Proposition B.2.3.7. *Let $\phi : A \to B$ an $\psi : B \to C$ be homomorphisms of commutative rings. If ϕ has relative dimension $\leqslant d$ and ψ has relative dimension $\leqslant d'$, then $\psi \circ \phi$ has relative dimension $\leqslant d + d'$.*

Proof. Since B is finitely generated as an A-algebra and C is finitely generated as a B-algebra, we immediately see that C is finitely generated as an A-algebra. Choose a field κ and a ring homomorphism $A \to \kappa$ and set

$$B_\kappa = \mathrm{Tor}_0^A(\kappa, B) \qquad C_\kappa = \mathrm{Tor}_0^A(\kappa, C).$$

Since ϕ has relative dimension $\leqslant d$, the ring B_κ has Krull dimension $\leqslant d$. Since ψ has relative dimension $\leqslant d'$, the map $B_\kappa \to C_\kappa$ has relative dimension $\leqslant d'$ (Proposition B.2.3.5). Applying Proposition B.2.3.6, we deduce that C_κ has Krull dimension $\leqslant d + d'$. □

Example B.2.3.8. Let A be a commutative ring. Then the polynomial ring $A[x_1, \ldots, x_d]$ has relative dimension $\leqslant d$ over A. To prove this, we may use Proposition B.2.3.7 to reduce to the case where $d = 1$. Since $A[x]$ is finitely generated as an A-algebra, it will suffice to show that for every field κ, the polynomial ring $\kappa[x]$ has Krull dimension $\leqslant 1$. This is clear, since every ideal in $\kappa[x]$ (or any localization of $\kappa[x]$) is principal.

Proposition B.2.3.9. *Let A be a finitely generated algebra over a field κ, let κ' be an extension field of κ, and set $A' = \kappa' \otimes_\kappa A$. Then A and A' have the same Krull dimension.*

Proof. Let d be the Krull dimension of A (which is finite by virtue of Example B.2.3.8 and Remark B.2.1.7). Since A' is faithfully flat over A, it follows from Corollary B.2.2.3 that the Krull dimension of A' is $\geqslant d$. We wish to prove the reverse inequality. We first treat the case where κ' is a finitely generated field extension of κ. Proceeding by induction on the number of generators, we may assume that κ' is generated (as an extension field of κ) by a single element x. There are two cases to consider:

- Suppose that x is algebraic over κ. Then κ' is a finite algebraic extension of κ. From this, it follows immediately that the inclusion $\kappa \hookrightarrow \kappa'$ has relative dimension 0, so that the inclusion $A \hookrightarrow A'$ also has relative dimension 0 (Proposition B.2.3.5) and therefore A' has Krull dimension $\leqslant d$ by virtue of Proposition B.2.3.6.

- Suppose that x is transcendental over κ, so that κ' is the fraction field of the polynomial ring $\kappa[x]$. It follows that A' is obtained from $A[x]$ by inverting all nonzero polynomials $f(x)$ whose coefficients lie in the field κ. Suppose we are given a chain of prime ideals $\mathfrak{p}_0 \subsetneq \mathfrak{p}_1 \subsetneq \cdots \subsetneq \mathfrak{p}_k$ in A'; we wish to show that $k \leqslant d$. Set $\mathfrak{q}_i = \mathfrak{p}_i \cap A[x]$. Note that the residue field of $A[x]$ at $\mathfrak{q}_k$ is not algebraic over κ, so (by virtue of Hilbert's Nullstellensatz) the prime ideal $\mathfrak{q}_k \subseteq A[x]$ is not maximal. Choose a maximal ideal $\mathfrak{m} \subseteq A[x]$ containing $\mathfrak{q}_k$, so that $\mathfrak{m}$ has height $\geqslant k + 1$. Since A has Krull dimension

$\leqslant d$, it follows from Example B.2.3.8 and Proposition B.2.3.6 that $A[x]$ has Krull dimension $\leqslant d+1$, so that $k+1 \leqslant d+1$ and therefore $k \leqslant d$ as desired.

We now treat the general case, where κ' is not assumed to be a finitely generated field extension of κ. Fix a prime ideal $\mathfrak{m} \subseteq A'$; we wish to show that $\mathfrak{p}$ has height $\leqslant d$. Without loss of generality, we may assume that the prime ideal $\mathfrak{m}$ is maximal. Since A' is a finitely generated algebra over κ', it is a Noetherian ring; in particular, the ideal $\mathfrak{m}$ is generated by finitely many elements $x_1, \ldots, x_n \in \mathfrak{m}$. We can therefore choose a subfield $\kappa'' \subseteq \kappa'$ which is a finitely generated extension field of κ such that each x_i is defined over κ'': that is, it belongs to the image of the natural map $A \otimes_\kappa \kappa'' \hookrightarrow A'$. It follows from the first part of the proof that $A \otimes_\kappa \kappa''$ has Krull dimension d. We may therefore replace κ by κ'' (and A by $A \otimes_\kappa \kappa''$) and thereby reduce to the case where each x_i belongs to the image of the inclusion $A \hookrightarrow A'$. Let $\mathfrak{n}$ be the ideal in A generated by the elements x_i, so that $A'/\mathfrak{m} = (A/\mathfrak{n}) \otimes_\kappa \kappa'$. Hilbert's Nullstellensatz implies that $A'/\mathfrak{m}$ is finite-dimensional as a vector space over κ', so that $A/\mathfrak{n}$ is finitely generated as a vector space over κ. Since $A/\mathfrak{n}$ can be identified with a subring of $A'/\mathfrak{m}$, it is an integral domain and therefore a finite extension field of κ. It follows that $\mathfrak{n}$ is a maximal ideal of A.

Our assumption that A has Krull dimension $\leqslant d$ implies that the local ring $A_\mathfrak{n}$ has dimension $\leqslant d$. We can therefore choose elements $y_1, \ldots, y_d \in \mathfrak{n}$ such that $\mathfrak{n}^k A_\mathfrak{n}$ is contained in $y_1 A_\mathfrak{n} + y_2 A_\mathfrak{n} + \cdots + y_d A_\mathfrak{n}$ for some integer $k \gg 0$. Replacing A by a localization $A[a^{-1}]$ for $a \notin \mathfrak{n}$, we may assume that $\mathfrak{n}^k \subseteq y_1 A + y_2 A + \cdots + y_d A$ Extending scalars to A', we deduce that $\mathfrak{m}^k$ is contained in the ideal $(y_1, \ldots, y_d) = y_1 A' + \cdots + y_d A'$, so that the local ring $A'_\mathfrak{m}$ has dimension $\leqslant d$ as desired. □

Corollary B.2.3.10. *Let $\phi : A \to B$ be a homomorphism of commutative rings which exhibits B as a finitely generated algebra over A. The following conditions are equivalent:*

- (a) *The map ϕ has relative dimension $\leqslant d$: that is, for every ring homomorphism $A \to \kappa$ where κ is a field, the tensor product $\mathrm{Tor}_0^A(\kappa, B)$ has Krull dimension $\leqslant d$.*

- (b) *For every residue field κ of A, the tensor product $\mathrm{Tor}_0^A(\kappa, B)$ has Krull dimension $\leqslant d$.*

Corollary B.2.3.11. *Let κ be a field, let A be a finitely generated κ-algebra, and let $d \geqslant 0$ be an integer. The following conditions are equivalent:*

- (a) *The commutative ring A has Krull dimension $\leqslant d$ (in the sense of Definition B.2.1.1).*

- (b) *The unit map $\kappa \to A$ has relative dimension $\leqslant d$ (in the sense of Definition B.2.3.1).*
