Proof. The implication $(b) \Rightarrow (a)$ is trivial, and the converse follows from Proposition B.2.3.9. □

B.2.4 Quasi-Finite Morphisms

We now specialize to the study of ring homomorphism shaving relative dimension $\leqslant 0$.

Definition B.2.4.1. Let $\phi : A \to B$ be a homomorphism of commutative rings. We will say that ϕ is *quasi-finite* if it has relative dimension $\leqslant 0$: that is, if it exhibits B as a finitely generated A-algebra and, for each residue field κ of A, the tensor product $B_\kappa = \mathrm{Tor}_0^A(\kappa, B)$ has Krull dimension $\leqslant 0$.

Remark B.2.4.2. Let κ be a field and let R be a finitely generated algebra over κ. Then the following conditions are equivalent:

(a) The ring R has Krull dimension zero.

(b) The ring R has finite dimension as a vector space over κ.

(c) The Zariski spectrum $|\operatorname{Spec} R|$ is finite.

It follows that if $\phi : A \to B$ is a homomorphism of commutative rings that exhibits B as a finitely generated A-algebra, then ϕ is quasi-finite if and only if the map of Zariski spectra $|\operatorname{Spec} B| \to |\operatorname{Spec} A|$ has finite fibers (in this case, the fibers of the map $|\operatorname{Spec} B| \to |\operatorname{Spec} A|$ automatically inherit the discrete topology). Alternatively, ϕ is quasi-finite if and only if for every residue field κ of A, the tensor product $\mathrm{Tor}_0^A(\kappa, B)$ is a finite-dimensional vector space over κ.

Example B.2.4.3. Every étale homomorphism of commutative rings $\phi : A \to B$ is quasi-finite. In particular, every localization $A \to A[t^{-1}]$ is quasi-finite.

Example B.2.4.4. Let $\phi : A \to B$ be a homomorphism of commutative rings which exhibits B as a finitely generated A-module. Then ϕ is quasi-finite.

All quasi-finite ring homomorphisms can be obtained through some combination of Examples B.2.4.3 and B.2.4.4:

Theorem B.2.4.5. *[Zariski's Main Theorem, Affine Version] Let $\phi : A \to B$ be a quasi-finite map of commutative rings. Then there exists an A-subalgebra $B_0 \subseteq B$ which is finitely generated as an A-module for which the induced map $\operatorname{Spec} B \to \operatorname{Spec} B_0$ is an open immersion of schemes.*

We will deduce Theorem B.2.4.5 from the following local variant:

Theorem B.2.4.6. *Let $\phi : A \to B$ be a commutative ring homomorphism which exhibits B as a finitely generated A-algebra and let $\mathfrak{q}$ be a prime ideal of B which is an isolated point of the fiber $|\operatorname{Spec} B| \times_{|\operatorname{Spec} A|} \{\phi^{-1}(\mathfrak{q})\}$. Then there exists an A-subalgebra $B_0 \subseteq B$ with the following properties:*

(*i*) *The algebra B_0 is finitely generated as an A-module.*

(*ii*) *There exists an element $b \in B_0$ such that $b \notin \mathfrak{q}$ and the induced map $B_0[b^{-1}] \to B[b^{-1}]$ is an isomorphism.*

Proof. We use an argument of Grothendieck, borrowing some ideas from algebraic geometry. We first treat the case where A is Noetherian. Choose a surjection of A-algebras $A[x_1, \ldots, x_n] \to B$, which we can identify with a closed immersion of affine schemes $i : \operatorname{Spec} B \hookrightarrow \mathbf{A}^n_A$. Let $X \subseteq \mathbf{P}^n_A$ denote the scheme-theoretic image of i in the projective space $\mathbf{P}^n_A$, and let $f : X \to \operatorname{Spec} A$ denote the projection map. Then f admits a Stein factorization $X \xrightarrow{g} \operatorname{Spec} \overline{B} \xrightarrow{h} \operatorname{Spec} A$, where $\overline{B}$ is finitely generated as an A-module. Let $U \subseteq \operatorname{Spec} \overline{B}$ be the largest open subscheme for which the projection map $X \times_{\operatorname{Spec} \overline{B}} U \to U$ is an isomorphism, and set $V = \operatorname{Spec} B \times_{\operatorname{Spec} A} U$. Our assumption that $\mathfrak{q}$ is an isolated point of $|\operatorname{Spec} B| \times_{|\operatorname{Spec} A|} \{\phi^{-1}(\mathfrak{q})\}$ guarantees that $i(\mathfrak{q})$ is an isolated point of $f^{-1}\{\phi^{-1}\mathfrak{q}\}$, so that $\mathfrak{q}$ is contained in V (see Theorem 8.7.2.3). Consequently, there exists an element $\overline{b} \in \overline{B}$ whose image in B does not belong to $\mathfrak{q}$ such that $\operatorname{Spec} \overline{B}[\overline{b}^{-1}]$ is contained in the image of the open immersion $V \to U$. This guarantees that the natural map $\overline{B}[\overline{b}^{-1}] \to B[b^{-1}]$ is an isomorphism, where $b \in B$ denotes the image of $\overline{b}$. We now complete the proof by taking B_0 to be the image of the map $\overline{B} \to B$.

If we drop the assumption that A is Noetherian but still assume that B is finitely presented over A, then we can choose a finitely generated subalgebra $A' \subseteq A$, a finitely presented A'-algebra B', and an isomorphism of A-algebras $\operatorname{Tor}^{A'}_0(A, B') \simeq B$. Let $\mathfrak{q}'$ be the inverse image of $\mathfrak{q}$ in B'. Then $\mathfrak{q}'$ is an isolated point of the fiber $|\operatorname{Spec} B'| \times_{|\operatorname{Spec} A'|} \{\phi^{-1}(\mathfrak{q}')\}$. Applying the preceding argument, we deduce the existence of a subalgebra $B'_0 \subseteq B'$ which is finitely generated an A'-module and an element $b \in B'_0$ which is not contained in $\mathfrak{q}'$ such that $B'_0[b^{-1}] \simeq B'[b^{-1}]$. We now conclude by defining B_0 to be the A-subalgebra of B generated by the image of B'_0.

We now treat the general case. Let κ be the residue field of A at the point $\phi^{-1}(\mathfrak{q})$. Write B as a quotient $A[x_1, \ldots, x_n]/I$ for some ideal I, so that the tensor product $\operatorname{Tor}^A_0(\kappa, B)$ can be written as a quotient $\kappa[x_1, \ldots, x_n]/I_\kappa$ where I_κ is the ideal generated by the image of I. Since $\kappa[x_1, \ldots, x_n]$ is a Noetherian ring, the ideal I_κ is finitely generated. It follows that we can choose a finitely generated ideal $I' \subseteq I$ such that the quotient $B' = A[x_1, \ldots, x_n]/I'$ has the property that the natural map $\operatorname{Tor}^A_0(\kappa, B') \to \operatorname{Tor}^A_0(\kappa, B)$ is an isomorphism. Let $\mathfrak{q}'$ denote the inverse image of $\mathfrak{q}$ in B', so that $\mathfrak{q}'$ is an isolated point of the fiber $|\operatorname{Spec} B'| \times_{|\operatorname{Spec} A|} \{\phi^{-1}(\mathfrak{q}')\}$. Applying the preceding argument to $\mathfrak{q}'$, we deduce the existence of an A-algebra $B'_0 \to B'$ and an element $b' \in B'_0$ such that B'_0 is finitely generated as an A-module and $B'_0[b'^{-1}] \simeq B'[b'^{-1}]$. We conclude by defining B_0 to be the image of B'_0 in B, and b to be the image of b' in B. □

Warning B.2.4.7. The proof of Theorem B.2.4.6 given above depends on basic facts about

Stein factorizations (such as Zariski's connectedness theorem), which we will discuss in §8.7. On the other hand, much of the foundational material developed in Parts I and II depends on facts that are derived from Theorem B.2.4.6. A reader who is troubled by this circular reasoning can consult the literature for other approaches to either Theorem B.2.4.6 (for example, [172] contains a more elementary argument which avoids the use of algebraic geometry) or to developing the algebro-geometric tools needed for the proof given above (note that the proof above requires the theory of Stein factorizations only for projective morphisms).

Proof of Theorem B.2.4.5. Let $\phi : A \to B$ be a quasi-finite morphism of commutative rings. For each prime ideal $\mathfrak{q} \subseteq B$, we can use Theorem B.2.4.6 to choose an A-subalgebra $B(\mathfrak{q}) \subseteq B$ and an element $b_{\mathfrak{q}} \in B(\mathfrak{q})$ for which the induced map $B(\mathfrak{q})[b_{\mathfrak{q}}^{-1}] \to B[b_{\mathfrak{q}}^{-1}]$ is an isomorphism. The elements $b_{\mathfrak{q}}$ generate the unit ideal in B: we may therefore choose finitely many prime ideals $\mathfrak{q}_1, \ldots, \mathfrak{q}_n$ for which the elements $b_{\mathfrak{q}_i}$ generate the unit ideal. Let $B_0 \subseteq B$ be the A-subalgebra generated by $\{B(\mathfrak{q}_i)\}_{1 \leqslant i \leqslant n}$. Then B_0 is finitely generated as an A-algebra and integral over A, hence finitely generated as an A-module. By construction, each of the maps $B_0[b_{\mathfrak{q}_i}^{-1}] \to B[b_{\mathfrak{q}_i}^{-1}]$ is surjective (and is automatically injective, since localization is exact). It follows that the induced map $\operatorname{Spec} B \to \operatorname{Spec} B_0$ is an open immersion, complementary to the vanishing locus of the ideal $(b_{\mathfrak{q}_1}, \ldots, b_{\mathfrak{q}_n}) \subseteq B_0$. □

For later reference, we record another consequence of Theorem B.2.4.6:

Corollary B.2.4.8. *Let $\phi : A \to B$ be a commutative ring homomorphism which exhibits B as a finitely generated A-algebra, let $\mathfrak{q}$ be a prime ideal of A, and let $\mathfrak{p}$ be a prime ideal of B which is maximal among those prime ideals lying over $\mathfrak{q}$. Suppose that the local ring $B_{\mathfrak{p}}/\mathfrak{q}B_{\mathfrak{p}}$ has dimension $\leqslant d$. Then there exists an element $b \in B$ which does not belong to $\mathfrak{p}$ such that $B[b^{-1}]$ is of relative dimension d over A.*

Proof. Set $R = B_{\mathfrak{p}}/\mathfrak{q}B_{\mathfrak{p}}$. Since R has dimension $\leqslant d$, we can choose elements $r_1, \ldots, r_d$ which belong to the maximal ideal of R such that $R/(r_1, \ldots, r_d)$ has a unique maximal ideal. Multiplying each r_i by a unit if necessary, we may assume that each r_i is the image of an element $b_i \in B$. Let $\phi' : A[x_1, \ldots, x_d] \to B$ be the extension of ϕ given by $\phi'(x_i) = b_i$. Then $\mathfrak{p}$ is an isolated point of its fiber under the map $|\operatorname{Spec} B| \to |\operatorname{Spec} A[x_1, \ldots, x_d]|$. Theorem B.2.4.6 implies that we can choose a map $\rho : \overline{B} \to B$ of $A[x_1, \ldots, x_d]$-algebras where $\overline{B}$ is finitely generated as an $A[x_1, \ldots, x_d]$-module and ρ induces an isomorphism $\overline{B}[b^{-1}] \simeq B[b^{-1}]$ for some $b \in \overline{B} - \rho^{-1}\mathfrak{p}$. We now conclude by observing that the canonical map $A \to B[b^{-1}]$ factors as a composition

$$A \to A[x_1, \ldots, x_d] \to \overline{B} \to \overline{B}[b^{-1}] \simeq B[b^{-1}]$$

where the first map has relative dimension $\leqslant d$ (Example B.2.3.8) the second map is finite (hence of relative dimension $\leqslant 0$ by Example B.2.4.4), and the third map is étale (hence of relative dimension $\leqslant 0$ by Example B.2.4.3), so the composite map is of relative dimension $\leqslant d$ by Proposition B.2.3.7. □

B.3 Henselian Rings

In this section, we will review some basic facts about Henselian rings which will be needed in this book. For a more detailed exposition, we refer the reader to [172].

B.3.1 Henselian Pairs

Let R be a commutative ring. Suppose that we wish to find an element $t \in R$ which is a solution to a polynomial equation $f(t) = 0$, where where $f(x) \in R[x]$ is a polynomial. One approach to this problem is to begin with an approximate solution (an element $t_0 \in R$ such that $f(t_0) \equiv 0 \mod I$ for some ideal $I \subseteq R$) and to then find better approximations $\{t_n\}_{n \geqslant 0}$ using *Newton's method*: $t_{n+1} = t_n - \frac{f(t_n)}{f'(t_n)}$. Provided that these expressions are well-defined (that is, that each $f'(t_n) = \frac{\partial f(x)}{\partial x}|_{x=t_n}$ is an invertible element of R), an elementary calculation gives

$$f(t_n) \equiv 0 \mod I^{n+1} \qquad t_{n+1} \equiv t_n \mod I^{n+1}.$$

If the ring R is complete with respect to I (that is, if it is equivalent to the inverse limit of the tower $\cdots \to R/I^4 \to R/I^3 \to R/I^2 \to R/I$), then the sequence $\{t_n\}_{n \geqslant 0}$ converges I-adically to an element $t \in R$ satisfying $f(t) = 0$. The following definition is intended to capture the essence of this situation:

Definition B.3.1.1. Let R be a commutative ring and let $I \subseteq R$ be an ideal. We will say that (R, I) is a *Henselian pair* if it satisfies the following condition: for every étale ring homomorphism $R \to R'$ which induces an isomorphism $R/I \to R'/IR'$, there exists an R-algebra homomorphism $R' \to R$.

We say that a commutative ring R is *Henselian* it it is a local ring and the pair $(R, \mathfrak{m})$ is Henselian, where $\mathfrak{m}$ is the maximal ideal of R.

Warning B.3.1.2. Our terminology is not completely standard; many authors do not require a Henselian ring to be local.

Remark B.3.1.3. Let R be a commutative ring and let $I \subseteq J \subseteq R$ be ideals. If the pair (R, J) is Henselian, then the pair (R, I) is also Henselian. In particular, if R is a Henselian ring, then the pair (R, I) is Henselian for any ideal $I \subsetneq R$.

Definition B.3.1.1 is motivated by the following:

Proposition B.3.1.4 (Hensel's Lemma)**.** *Let R be a commutative ring which is I-adically complete for some ideal I. Then (R, I) is a Henselian pair.*

Proof. We apply Newton's method. Let R' be an étale R-algebra. Proposition B.1.1.1 implies the existence of an isomorphism $R' \simeq R[x_1, \ldots, x_n]/(f_1, \ldots, f_n)[\Delta^{-1}]$, where Δ denotes the determinant of the Jacobian matrix $[\frac{\partial f_i}{\partial x_j}]_{1 \leqslant i,j \leqslant n}$ (see Proposition B.1.1.3). We wish to show that every R-algebra homomorphism $\phi_0 : R' \to R/I$ can be lifted to a ring homomorphism $\phi : R' \to R$. Since R is complete with respect to I, it will suffice to construct a compatible sequence of R-algebra homomorphisms $\phi_a : R' \to R/I^{a+1}$. Assume that ϕ_a has already been constructed, and choose elements $\{y_j \in R\}_{1 \leqslant j \leqslant n}$ such that $\phi_a(x_j) \cong y_j$ modulo I^{a+1}. Since ϕ_a is a ring homomorphism, we have $f_i(\vec{y}) \in I^{a+1}$ for $1 \leqslant i \leqslant n$. Let $\Delta[\vec{x}]$ denote the determinant of the Jacobian matrix $M(\vec{x}) = [\frac{\partial f_i}{\partial x_j}]_{1 \leqslant i,j \leqslant n}$. Then $\Delta[\vec{y}]$ is invertible modulo I^{a+1} and therefore invertible (since I is contained in every maximal ideal of R, by Proposition B.3.2.2). It follows that $M(\vec{y})$ is an invertible matrix over R, so we can define $\vec{y}' = \vec{y} - M(\vec{y})^{-1} \vec{f}(\vec{y})$. A simple calculation gives shows that $f_i(\vec{y}') \in I^{2(a+1)}$, so that the assignment $x_i \mapsto y'_i$ determines a ring homomorphism $\phi_{a+1} : R' \to R/I^{a+2}$ compatible with ϕ_a. □

Corollary B.3.1.5. *Let R be a commutative ring and let $I \subseteq R$ be a nilpotent ideal. Then the pair (R, I) is Henselian.*

B.3.2 Lifting Idempotents

Let R be a commutative ring containing an ideal $I \subseteq R$. There are many equivalent ways to formulate the condition that (R, I) is a Henselian pair.

Notation B.3.2.1. If R is a commutative ring, we let $\mathrm{Idem}(R)$ denote the set of idempotent elements of R. Given a pair of commutative R-algebras A and B, we let $\mathrm{Hom}_R(A, B)$ denote the set of R-algebra homomorphisms from A to B.

Proposition B.3.2.2. *Let R be a commutative ring and let $I \subseteq R$ be an ideal. The following conditions are equivalent:*

(1) *The pair (R, I) is Henselian.*

(2) *For every étale R-algebra R', the reduction map $\theta_{R'} : \mathrm{Hom}_R(R', R) \to \mathrm{Hom}_R(R', R/I) \simeq \mathrm{Hom}_{R/I}(R'/IR', R/I)$ is bijective.*

(3) *The ideal I is contained in every maximal ideal $\mathfrak{m} \subseteq R$ and, for every R-algebra A which is a free R-module of finite rank, the reduction map $\mathrm{Idem}(A) \to \mathrm{Idem}(A/IA)$ is bijective.*

(4) *For every R-algebra A which is finitely generated as an R-module, the reduction map $\mathrm{Idem}(A) \to \mathrm{Idem}(A/IA)$ is bijective.*

Proof. We first show that (1) ⇒ (2). Assume that (R, I) is a Henselian pair. We first show that for every étale R-algebra R', the map $\theta_{R'}$ is surjective. Suppose we are given an R-algebra map $\phi_0 : R' \to R/I$. Then ϕ_0 extends to an R/I-algebra map $\overline{\phi}_0 : R'/IR' \to R/I$. Since R'/IR' is étale over R/I, the map $\overline{\phi}_0$ exhibits R/I as a direct factor of R"$/IR'$: that is, it induces an isomorphism $(R'/IR')[\overline{e}^{-1}] \simeq R/I$ for some idempotent element $\overline{e} \in R'/IR'$. Let $e \in R'$ be any element lying over $\overline{e}$. Then $R'[e^{-1}]$ is an étale R-algebra for which the unit map $R/I \to R'[e^{-1}]/IR'[e^{-1}]$ is an isomorphism. Applying our hypothesis that (R, I) is a Henselian pair, we deduce the existence of an R-algebra homomorphism $R'[e^{-1}] \to R$. Composing this with the evident map $R' \to R'[e^{-1}]$, we obtain an R-algebra map $\phi : R' \to R$ which is a preimage of ϕ_0 under the map $\theta_{R'}$.

To prove the injectivity of $\theta_{R'}$, suppose that we are given given two R-algebra maps $f, g : R' \to R$ with $\theta_{R'}(f) = \theta_{R'}(g)$. Since R' is étale over R, the multiplication map $m : R' \otimes_R R' \to R'$ induces an isomorphism $(R' \otimes_R R')[e^{-1}] \simeq R'$ for some idempotent element $e \in R' \otimes_R R'$. The maps f and g determine an R-algebra homomorphism $u : R' \otimes_R R' \to R$. Since $\theta(f) = \theta(g)$, the composite map $u' : R' \otimes_R R' \to R \to R/I$ factors through m, so that the image of $a = u(e) \in R$ under the quotient map $R \to R/I$ is an invertible element of R/I. Using the surjectivity of the map $\theta_{R[a^{-1}]} : \mathrm{Hom}_R(R[a^{-1}], R) \to \mathrm{Hom}_R(R[a^{-1}], R/I)$, we deduce that a is an invertible element of R. Then u factors through m, so that $f = g$.

We next show that (2) implies (3). Assume that the pair (R, I) satisfies (2). We first claim that I is contained in every maximal ideal $\mathfrak{m} \subseteq R$. Suppose otherwise: then the maximality of $\mathfrak{m}$ implies that $I + \mathfrak{m} = R$, so we can write $1 = a + b$ where $a \in I$ and $b \in \mathfrak{m}$. Then the image of b in R/I is invertible, so the mapping space $\mathrm{Hom}_R(R[b^{-1}], R/I)$ is nonempty. It follows from (2) that the mapping space $\mathrm{Hom}_R(R[b^{-1}], R)$ is nonempty, so that b is invertible in R. This is a contradiction, since b belongs to the maximal ideal $\mathfrak{m}$.

Now suppose that A is an R-algebra which is freely generated as an R-module by elements $a_1, \ldots a_n \in A$. The multiplication on A is then given by $a_i a_j = \sum_{1 \leqslant k \leqslant n} r^k_{i,j} a_k$ for some structure constants $r^k_{i,j} \in R$. Set $B = R[x_1, \ldots, x_n]/(f_1, \ldots, f_n)$ where $f_k(x_1, \ldots, x_n) = x_k - \sum_{i,j} r^k_{i,j} x_i x_j$. Unwinding the definitions, we see that for any R-algebra R', we have a canonical bijection $\mathrm{Hom}_R(B, R') \simeq \mathrm{Idem}(A \otimes_R R')$. From this description it follows that B is an étale R-algebra. Applying hypothesis (2), we deduce that the canonical map

$$\mathrm{Idem}(A) \simeq \mathrm{Hom}_R(B, R) \to \mathrm{Hom}_R(B, R/I) \simeq \mathrm{Idem}(A/IA)$$

is bijective, so that condition (3) is satisfied.

We now show that (3) implies (4). Assume (3) is satisfied and let A be an R-algebra which is generated as an R-module (not necessarily freely) by elements $a_1, \ldots, a_n \in R$. We wish to prove that the reduction map $\mathrm{Idem}(A) \to \mathrm{Idem}(A/IA)$ is bijective. We first show that it is injective. Let e and e' be idempotent elements of A with the same image in A/IA; we wish to prove that $e = e'$. Set $A' = A/(e - ee')$. Then A' is a finitely generated

R-module and the quotient A'/IA' vanishes (since the image of $e - ee'$ vanishes in A/IA). For every maximal ideal $\mathfrak{m}$ of R, assumption (3) guarantees that $I \subseteq \mathfrak{m}$, so that $A'/\mathfrak{m}A' \simeq 0$. Applying Nakayama's lemma, we deduce that the localization $A'_{\mathfrak{m}}$ vanishes. Since the maximal ideal $\mathfrak{m} \subseteq R$ was chosen arbitrarily, it follows that $A' \simeq 0$. Consequently, the idempotent $e - ee' \in A$ vanishes, so $e = ee'$. The same argument shows that $e' = ee'$, so that $e = e'$ by transitivity.

We now prove that the reduction map $\mathrm{Idem}(A) \to \mathrm{Idem}(A/IA)$ is surjective. Fix an idempotent element $\overline{e} \in A/IA$, and lift $\overline{e}$ to an element $e \in A$. The element e is not necessarily idempotent, but the difference $e - e^2$ belongs to the ideal I. Consequently, we can write

$$(e - e^2)a_i = \sum_{1 \leqslant j \leqslant n} c_{i,j} a_j$$

for some coefficients $c_{i,j} \in I \subseteq R$. Let $f(x) \in R[x]$ be the characteristic polynomial of the matrix $\left(c_{i,j}\right)$ and set $g(x) = f(x - x^2)$, so that $g(e) = f(e - e^2)$ vanishes in A. Set $A' = R[x]/(g(x))$, so that the construction $x \mapsto e$ determines an R-algebra homomorphism $A' \to A$. We have a commutative diagram

$$\begin{array}{ccc}
\mathrm{Idem}(A') & \longrightarrow & \mathrm{Idem}(A) \\
\downarrow & & \downarrow \\
\mathrm{Idem}(A'/IA') & \xrightarrow{\rho} & \mathrm{Idem}(A/IA)
\end{array}$$

where the left horizontal map is a bijection by virtue of assumption (2). Consequently, to prove that $\overline{e}$ lies in the image of the right vertical map, it will suffice to show that it lies in the image of the map $\rho : \mathrm{Idem}(A'/IA') \to \mathrm{Idem}(A/IA)$. Because the coefficients $c_{i,j}$ lies in the ideal I, we can identify A'/IA' with the quotient $(R/I)[x]/(x^n(1-x)^n)$. This is clear, since ρ factors as a composition

$$\mathrm{Idem}(A'/IA) \xrightarrow{\rho'} \mathrm{Idem}((R/I)[x]/(x - x^2)) \xrightarrow{\rho''} \mathrm{Idem}(A/IA),$$

where ρ' is bijective (since the ring homomorphism $(A'/IA' \to (R/I)[x]/(x - x^2)$ has nilpotent kernel) and the map ρ'' carries x to $\overline{e}$.

We now complete the proof by showing that (4) implies (1). Assume that condition (4) is satisfied, let R' be an étale R-algebra for which the unit map $R/I \to R'/IR'$ is an isomorphism. We wish to show that there exists an R-algebra homomorphism $\phi : R' \to R$. Since R' is étale over R, it is also quasi-finite over R. Applying Theorem B.2.4.5, we can choose an R-algebra homomorphism $\rho : A \to R'$, where A is finitely generated as an R-module and the induced map $j : \mathrm{Spec}\, R' \to \mathrm{Spec}\, A$ is an open immersion of affine schemes. Then the map $\overline{\rho} : A/IA \to R'/IR'$ also induces an open immersion of affine schemes $f : \mathrm{Spec}\, R'/IR' \to A/IA$. However, $\overline{\rho}$ is surjective (up to isomorphism, it is left inverse to the unit map $R/I \to A/IA$), so the map f is also a closed immersion. It follows that we can choose an idempotent element $\overline{e} \in A/IA$ for which $\overline{\rho}$ induces an isomorphism $(A/IA)[\overline{e}^{-1}] \to R'/IR'$. Using hypothesis (4), we can lift $\overline{e}$ to an idempotent element $e \in A$. Replacing A by $A[e^{-1}]$ and R' by $R'[\rho e^{-1}]$, we can reduce to the situation where $e = 1$: that is, the map $\overline{\rho}$ is an isomorphism.

We claim that ρ is an isomorphism. Suppose otherwise: then there exists some closed point of $x \in \operatorname{Spec} A$ which does not belong to the image of the open immersion j. Since A is finitely generated as an R-module, it follows that the image of x is a closed point of $\operatorname{Spec} R$, corresponding to a maximal ideal $\mathfrak{m} \subseteq R$. Hypothesis (4) implies that the map $\operatorname{Idem}(R/\mathfrak{m}) \to \operatorname{Idem}(R/(I + \mathfrak{m}))$ is bijective, so that $I \subseteq \mathfrak{m}$. It follows that x belongs to the closed subscheme $\operatorname{Spec} A/I \subseteq \operatorname{Spec} A$, contradicting the fact that $\overline{\rho}$ is an isomorphism.

For every maximal ideal $\mathfrak{m} \subseteq R$, the preceding argument shows that $I \subseteq \mathfrak{m}$ and therefore the natural map $R/\mathfrak{m} \to R'/\mathfrak{m}R'$ is an isomorphism. Since ρ is an isomorphism, the ring R' is finitely generated as an R-module. Applying Nakayama's lemma, we deduce that the map $R \to R'$ is surjective. Since R' is étale over R, we can write $R' = R/(e')$ for some idempotent element $e' \in R$. Then e' must belong the ideal I, and therefore to every maximal ideal $\mathfrak{m} \subseteq R$. It follows from the idempotence of e' that $e' = 0$. We conclude that the unit map $R \to R'$ is an isomorphism, so that there exists an R-algebra homomorphism $R' \to R$ as desired. □

B.3.3 Properties of Henselian Pairs

We now summarize some features of Henselian pairs which can be easily deduced from Proposition B.3.2.2.

Corollary B.3.3.1. *Let $\phi : R \to R'$ be a homomorphism of commutative rings which exhibits R' as a finitely generated R-module, and let $I \subseteq R$ be an ideal. If the pair (R, I) is Henselian, then the pair (R', IR') is Henselian.*

Proof. Use criterion (4) of Proposition B.3.2.2. □

Corollary B.3.3.2. *Let R be a Henselian commutative ring and let $I \subsetneq R$ be a proper ideal. Then the quotient R/I is also a Henselian ring.*

Corollary B.3.3.3. *Let R be a commutative ring containing ideals $I \subseteq J \subseteq R$. Suppose that the pairs (R, I) and $(R/I, J/I)$ are Henselian. Then the pair (R, J) is Henselian.*

Proof. Use criterion (2) of Proposition B.3.2.2. □

Corollary B.3.3.4. *Let $\phi : R \to R'$ be a homomorphism between local commutative rings. Suppose that R is Henselian and that ϕ exhibits R' as a finitely generated R-module. Then R' is Henselian.*

Proof. Let $\mathfrak{m}$ denote the maximal ideal of R and let $\mathfrak{m}'$ denote the maximal ideal of R'. Since R' is local, we have $R' \neq 0$. Invoking Nakayama's lemma, we deduce that $\mathfrak{m}R' \subseteq \mathfrak{m}'$. It follows from Corollary B.3.3.1 that the pair $(R', \mathfrak{m}R')$ is Henselian. By virtue of Corollary B.3.3.3, to prove that the pair $(R', \mathfrak{m}')$ is Henselian, it will suffice to show that the pair $(R'/\mathfrak{m}R', \mathfrak{m}'/\mathfrak{m}R')$ is Henselian. Note that the quotient $R'/\mathfrak{m}R'$ is a local ring which is finite-dimensional as a vector space over the field $R/\mathfrak{m}$, so that the maximal ideal of $R'/\mathfrak{m}R'$ is nilpotent. In particular, the ring $R'/\mathfrak{m}R'$ is complete with respect to its maximal ideal, so that the desired result follows from Proposition B.3.1.4. □

Corollary B.3.3.5. *Let $\phi : R \to R'$ be a homomorphism between commutative rings which exhibits R' as a finitely generated R-module. If R is isomorphic to a finite product of Henselian local rings, then R' is isomorphic to a finite product of Henselian local rings.*

Proof. Without loss of generality we may assume that R is a local ring with maximal ideal $\mathfrak{m}$. Then $A = R'/\mathfrak{m}R'$ is finite-dimensional algebra over the residue field $\kappa = R/\mathfrak{m}$, and therefore factors as a finite product $\prod A_i$ of local Artinian rings. Since R is Henselian, we can lift the factorization $A \simeq \prod_i A_i$ to a factorization $R' \simeq \prod R'_i$ (Proposition B.3.2.2). We now observe that each R'_i is a local commutative ring which is finitely generated as an R-module, and is therefore Henselian (Corollary B.3.3.4). □

Corollary B.3.3.6. *Let (R, I) be a Henselian pair and let A be a quasi-finite R-algebra with the property that A/IA is finite over R/I. Then A factors as a product $A' \times A''$, where A' is finite over R and $A''/IA'' \simeq 0$.*

Proof. Using Theorem B.2.4.5, we can factor ϕ as a composition $R \xrightarrow{\phi'} B \xrightarrow{\phi''} A$ where B is finite over R and ϕ'' induces an open immersion $j : \operatorname{Spec}(A) \to \operatorname{Spec}(B)$. Let $U \subseteq |\operatorname{Spec}(B)|$ denote the image of j and let $U_0 \subseteq |\operatorname{Spec}(B/IB)|$ denote its inverse image in $|\operatorname{Spec}(B/IB)|$. Since A/IA is finite over R/I, it is also finite over B/IB; it follows that U_0 is a closed and open subset of $|\operatorname{Spec}(B/IB)|$, and is therefore given as the vanishing locus of some idempotent element $\overline{e} \in B/IB$. Our assumption that (R, I) is a Henselian pair guarantees that we can lift e to an idempotent element $e \in B$. Let $V \subseteq |\operatorname{Spec}(B)|$ be the vanishing locus of e, so that V is a closed and open subset of $\operatorname{Spec} B$ whose intersection with $|\operatorname{Spec}(B/IB)|$ is equal to U_0. Then $V - U$ is a closed subset of $|\operatorname{Spec}(B)|$ whose image under the finite map $\operatorname{Spec}(B) \to \operatorname{Spec}(R)$ is also closed. By construction, this image does not intersect the vanishing locus of I, and is therefore empty (since (R, I) is a Henselian pair). It follows that V is contained in U, so that ϕ'' induces an isomorphism $B/(e) \simeq A/(\phi''(e))$. In particular, In particular, $A/(\phi''(e))$ is finitely generated as an R-module. We now complete the proof by taking $A' = A/(\phi''(e))$ and $A'' = A/(1 - \phi''(e))$. □

Corollary B.3.3.7. *Let (R, I) be a Henselian pair. Then the construction $A \mapsto A/IA$ induces an equivalence from the category of finite étale R-algebras to the category of finite étale R/I-modules.*

Proof. We first show that extension of scalars is fully faithful. Let A and B be finite étale R-algebras; we wish to show that the natural map

$$\mathrm{Hom}_{\mathrm{CAlg}_R^\heartsuit}(A, B) \to \mathrm{Hom}_{\mathrm{CAlg}_R^\heartsuit}(A, B/IB) \simeq \mathrm{Hom}_{\mathrm{CAlg}_{R/I}^\heartsuit}(A/IA, B/IB)$$

is bijective. This follows immediately from the fact that the pair (A, IA) is Henselian (Corollary B.3.3.1).

We now prove essential surjectivity. Let A_0 be a finite flat (R/I)-algebra. Using the structure theory of étale morphisms (see Proposition B.1.1.3), we can assume that $A_0 = A/IA$, where A is an étale R-algebra. Then A is quasi-finite over R, so we can use Corollary B.3.3.6 to split A as a product $A' \times A''$, where A' is finite (and therefore finite étale) over R and $A'/IA' \simeq A/IA \simeq A_0$. □

Corollary B.3.3.8. *Let R be a Henselian local ring with maximal ideal $\mathfrak{m}$ and let $\phi : R \to A$ be a quasi-finite ring homomorphism. Then we can write $A = A' \times A''$, where A' is finite over R and $A''/\mathfrak{m}A'' \simeq 0$.*

Proof. This is a special case of Corollary B.3.3.6, since the quasi-finite map $R/\mathfrak{m} \to A/\mathfrak{m}A$ is automatically finite. □

Corollary B.3.3.9. *Let R be a Henselian ring. Suppose we are given a faithfully flat étale map $R \to R'$. Then there exists an idempotent element $e \in R'$ such that $R'[e^{-1}]$ is local, faithfully flat over R, and finitely generated as an R-module.*

Proof. Since R' is étale over R, it is quasi-finite over R. Using Corollary B.3.3.8, we can reduce to the case where R' is finite over R. Let $\mathfrak{m}$ denote the maximal ideal of R, so that $R'/\mathfrak{m}R'$ is a nonzero étale algebra over the field $\kappa = R/\mathfrak{m}$. We can therefore choose an idempotent element $\overline{e}$ in $R'/\mathfrak{m}R'$ such that $(R'/\mathfrak{m}R')[\overline{e}^{-1}]$ is a finite separable extension of κ. Using Proposition B.3.2.2, we can lift $\overline{e}$ to an idempotent element $e \in R'$ having the desired properties. □

B.3.4 Henselization

Let R be a commutative ring and let $I \subseteq R$ be an ideal. If R is Noetherian, then the I-adic completion $\widehat{R} = \varprojlim \{R/I^n\}$ is complete with respect to the ideal $\widehat{I} = I\widehat{R}$, so that $(\widehat{R}, \widehat{I})$ is a Henselian pair by virtue of Hensel's Lemma (Proposition B.3.1.4). However, the passage from R to its completion $\widehat{R}$ is a fairly transcendental construction; in practice, it is often more convenient to work with a much more conservative enlargement of R having the same essential feature.

Proposition B.3.4.1. *Let R be a commutative ring and let $I \subseteq R$ be an ideal. Then there exists ring homomorphism $\phi : R \to A$ satisfying the following conditions:*

(a) *The pair (A, IA) is Henselian.*

(b) *For every R-algebra B, if the pair (B, IB) is Henselian, then there exists a unique R-algebra homomorphism $A \to B$.*

Moreover, the R-algebra A has the following additional property:

(c) *As an R-algebra, A can be written as a filtered colimit $\varinjlim R_\alpha$, where each R_α is an étale R-algebra for which the unit map $R/I \to R_\alpha/IR_\alpha$ is an isomorphism.*

In particular, the canonical map $R/I \to A/IA$ is an isomorphism.

Remark B.3.4.2. In the situation of Proposition B.3.4.1, the R-algebra A is uniquely determined (up to unique isomorphism) by the commutative ring R and the ideal $I \subseteq R$. We will refer to A as the *Henselization of R with respect to the ideal I*.

Proof of Proposition B.3.4.1. We define a category $\mathcal{C}$ as follows:

- The objects of $\mathcal{C}$ are étale R-algebras R' for which the natural map $R/I \to R'/IR'$ is an isomorphism.
- The morphisms of $\mathcal{C}$ are R-algebra homomorphisms.

The category $\mathcal{C}$ admits finite colimits and is therefore filtered. We let A denote the direct limit $\varinjlim_{R' \in \mathcal{C}} R'$. Then A satisfies condition (c) by construction. We will show that it also satisfies (a) and (b).

To prove (a), let B be an étale A-algebra for which the unit map $A/IA \to B/IB$ is an isomorphism. We wish to prove that there exists an A-algebra homomorphism $B \to A$. Since B is étale over A, it is finitely presented as an A-algebra. Using a direct limit argument, we can write $B = A \otimes_{R'} R''$, where R' is an object of $\mathcal{C}$ and R'' is an étale R'-algebra. Unwinding the definitions, we are reduced to proving that there exists an R'-algebra homomorphism from R'' to A. This is clear: the unit map $R'/IR' \to R''/IR''$ is an isomorphism, so we can regard $R' \to R''$ as a morphism in the category $\mathcal{C}$.

We now prove (b). Let B be an arbitrary R-algebra for which (B, IB) is a Henselian pair: we wish to prove that the map $\mathrm{Hom}_R(A, B)$ contains a single element. Using the definition of A as a direct limit, we are reduced to proving that the set $\mathrm{Hom}_R(R', B)$ has a single element for each $R' \in \mathcal{C}$. Since $B \otimes_R R'$ is étale over B and the pair (B, IB) is

Henselian, we have canonical bijections

$$\begin{aligned}\mathrm{Hom}_R(R', B) &\simeq \mathrm{Hom}_B(B \otimes_R R', B)\\ &\simeq \mathrm{Hom}_B(B \otimes_R R', B/IB)\\ &\simeq \mathrm{Hom}_R(R', B/I)\\ &\simeq \mathrm{Hom}_{R/I}(R'/IR', B/IB).\end{aligned}$$

These sets are singletons by virtue of our assumption that the unit map $R/I \to R'/IR'$ is an isomorphism. □

Remark B.3.4.3. The proof of Proposition B.3.4.1 shows that condition (b) follows from (a) and (c). Consequently, to prove that a ring homomorphism $\phi : R \to A$ exhibits A as the Henselization of R with respect to some ideal $I \subseteq R$, it suffices to show that ϕ satisfies conditions (a) and (c).

Remark B.3.4.4. Let $\phi : A \to B$ be a map which exhibits B as the Henselization of A with respect to an ideal I, and suppose we are given a pushout square

$$\begin{array}{ccc} A & \xrightarrow{\phi} & B \\ \downarrow{\scriptstyle\psi} & & \downarrow \\ A' & \xrightarrow{\phi'} & B' \end{array}$$

where ψ exhibits A' as a finitely generated A-module. Then ϕ' exhibits B' as the Henselization of A' with respect to the ideal IA'. This follows immediately from Remark B.3.4.3 and Corollary B.3.3.1.

Corollary B.3.4.5. *Let $\phi : R \to A$ be a quasi-finite map of commutative rings and let κ denote a residue field of R at some prime ideal $\mathfrak{p} \subseteq R$. Then there exists a factorization of the canonical map $R \to \kappa$ as a composition $R \to R' \to \kappa$, where R' is étale over R, and a decomposition of $R' \otimes_R A$ as a product $A' \times A''$, where A' is a finitely generated module over R' and $\kappa \otimes_{R'} A'' \simeq 0$.*

Proof. Suppose we are given an R-algebra R' equipped with a map $\rho : R' \to \kappa$. Let us say that R' is *good* if the tensor product $R' \otimes_R A$ (formed in the ordinary category of R-modules) decomposes as a Cartesian product $A' \times A''$, where A' is a finitely generated R'-module and $\kappa \otimes_{R'} A'' \simeq 0$. Note that ρ is good if and only if there exists an idempotent element $e \in R' \otimes_R A$ such that $(R' \otimes_R A)[e^{-1}]$ is finitely generated as an R'-module and the image of e vanishes in $\kappa \otimes_R A$. From this description, it is easy to see that if R' is given as a filtered colimit of R-algebra homomorphisms R'_α and R' is good, then some R'_α is also good.

Let S denote the Henselization of the local ring $R_{\mathfrak{p}}$ with respect to its maximal ideal. It follows from Corollary B.3.3.8 that S is good. Using Proposition B.3.4.1, we can write

S as a filtered colimit $\varinjlim S_\alpha$, where each S_α is an étale $R_{\mathfrak{p}}$-algebra. It follows that some S_α is good. Note that we can write S_α as a tensor product $R_{\mathfrak{p}} \otimes_R R'$ where R' is an étale R-algebra. Then S_α can be written as a filtered colimit of localizations $R'[a^{-1}]$ where $a \notin \mathfrak{p}$. It follows that some localization $R'[a^{-1}]$ is good and étale over R, as desired. □

Proposition B.3.4.6 (Transitivity of Henselizations)**.** *Suppose we are given homomorphisms of commutative rings $\phi : A \to B$ and $\psi : B \to C$ and ideals $I, J \subseteq A$ satisfying the following conditions:*

- (a) *The map ϕ exhibits B as the Henselization of A with respect to the ideal I.*
- (b) *The map ψ exhibits C as the Henselization of B with respect to the ideal JB.*

Then the composite map $(\psi \circ \phi) : A \to C$ exhibits C as the Henselization of A with respect to the ideal $I + J$.

Proof. Let D be an A-algebra for which the pair $(D, (I + J)D)$ is Henselian. Then the pairs (D, ID) and (D, JD) are also Henselian (Remark B.3.1.3). It follows from (b) that composition with ψ induces a bijection $\mathrm{Hom}_A(C, D) \to \mathrm{Hom}_A(B, D)$, and it follows from (a) that the set $\mathrm{Hom}_A(B, D)$ is a singleton. Consequently, there is a unique A-algebra homomorphism from C to D. To complete the proof, it will suffice to show that the pair $(C, (I + J)C)$ is Henselian. Using Corollary B.3.3.3, we are reduced to proving that the pairs (C, JC) and $(C/JC, (I + J)C/JC)$ are Henselian. The first follows from (b). To prove the second, we note that (b) implies that the canonical map $B/JB \to C/JC$ is an isomorphism. We are therefore reduced to proving that the pair $(B/JB, (I + J)B/JB)$ is Henselian. This follows from Corollary B.3.3.1, since the pair (B, IB) is Henselian by virtue of assumption (a). □

B.3.5 Strictly Henselian Rings

We now restrict our attention to a special class of Henselian rings.

Definition B.3.5.1. Let R be a commutative ring. We say that R is *strictly Henselian* if R is Henselian (Definition B.3.1.1) and the residue field $R/\mathfrak{m}$ is separably closed (where $\mathfrak{m}$ denotes the maximal ideal of R).

Example B.3.5.2. Let R be a strictly Henselian ring and let $I \subsetneq R$ be an ideal. Then the quotient R/I is Henselian (Corollary B.3.3.2) with the same residue field as R, and is therefore strictly Henselian.

Proposition B.3.5.3. *Let R be a commutative ring. The following conditions are equivalent:*

- (1) *The ring R is strictly Henselian.*

(2) *For every finite collection of étale maps* $\{\phi_\alpha : R \to R_\alpha\}$ *for which the induced map* $R \to \prod_\alpha R_\alpha$ *is faithfully flat, one of the maps* ϕ_α *admits a left inverse.*

Proof. Suppose first that condition (1) is satisfied, and let $\mathfrak{m}$ denote the maximal ideal of R. Let $\{\phi_\alpha : R \to R_\alpha\}$ be as in (2). Since the map $R \to \prod_\alpha R_\alpha$ is faithfully flat, there exists an index α such that $R_\alpha/\mathfrak{m}R_\alpha$ is nonzero. Since R_α is étale over R, $R_\alpha/\mathfrak{m}R_\alpha$ is a product of separable field extensions of $\kappa = R/\mathfrak{m}$. Since κ is separably closed, we can choose a map of R-algebras $\theta : R_\alpha/\mathfrak{m} \to R/\mathfrak{m}$. The assumption that R is Henselian implies that θ lifts to a map of R-algebras $R_\alpha \to R$, which is left inverse to ϕ_α.

Now suppose that (2) is satisfied; we wish to prove that R is strictly Henselian. We first observe that R is nonzero (otherwise the map from R to an empty product is faithfully flat, contradicting (2)). For every element $x \in R$, the map $R \to R[x^{-1}] \times R[(1-x)^{-1}]$ is faithfully flat, so condition (2) implies that either x or $1-x$ is invertible in R: that is, R is a local ring.

We now claim that R is Henselian. Let R' be an étale R-algebra and choose a map of R-algebras $\theta : R' \to R/\mathfrak{m}$. We wish to prove that θ can be lifted to an R-algebra map $R' \to R$. Let $\kappa = R/\mathfrak{m}$, so that $R'/\mathfrak{m}R'$ is a product of finite separable extensions of k. We proceed by induction on the dimension n of $R'/\mathfrak{m}R'$ as a κ-vector space. Note that $n > 0$, since θ induces a surjection $R'/\mathfrak{m}R' \to \kappa$. It follows that R' is faithfully flat over R, so condition (2) implies that there is a map of R-algebras $\phi : R' \to R$. Since R' is étale over R, the kernel of the map ϕ is generated by an idempotent element $e \in R'$. If $\theta(e) = 0$, then θ factors as a composition $R' \xrightarrow{\phi} R \to R/\mathfrak{m}$ so that ϕ is the desired lifting of θ. Assume otherwise. Then $\theta(e) = 1$ (since e is idempotent and κ is a field), so that θ factors through the quotient $R'' = R'/(1-e)$ of R'. The inductive hypothesis then implies that the induced map $R'' \to R/\mathfrak{m}$ lifts to a map of R-algebras $R'' \to R$, so that the composite map $R' \to R'' \to R$ is the desired lifting of θ.

To complete the proof, we must show that the field $\kappa = R/\mathfrak{m}$ is separably closed. Assume otherwise. Then we can choose a nontrivial finite separable extension field κ' of κ. Without loss of generality, κ' is generated by a single element; we may therefore write $\kappa' = \kappa[x]/(f(x))$ for some monic polynomial f with coefficients in κ. Let $\overline{f}(x)$ be a monic polynomial with coefficients in R which lifts f (and has the same degree as f), and let $R' = R[x]/(\overline{f}(x))$. Then R' is finite as an R-module. The derivative of $\overline{f}(x)$ is invertible in $R'/\mathfrak{m}R'$, and therefore (by Nakayama's lemma) invertible in R'. It follows that R' is faithfully flat and étale over R. Using condition (2), we deduce that there is a map of R-algebras $R' \to R$. Reducing modulo $\mathfrak{m}$, we obtain a map of κ-algebras $\kappa' \to \kappa$, contradicting our assumption that κ' is a proper extension of κ. □

It will be convenient to have the following relative formulation of Proposition B.3.5.3.

Corollary B.3.5.4. *Let $\phi : R \to A$ be a map of commutative rings. The following conditions are equivalent:*

(1) *The commutative ring A is strictly Henselian.*

(2) *For every finitely presented R-algebra R' and every finite collection of étale maps $\{R' \to R'_\alpha\}$ which induce a faithfully flat map $R' \to \prod_\alpha R'_\alpha$, every R-algebra map $R' \to A$ factors through some R'_α.*

Proof. Assume that (1) is satisfied, and let $\{R' \to R'_\alpha\}$ be as in (2). For any map $R' \to A$, we obtain a finite collection of étale maps $\{\phi_\alpha : A \to R'_\alpha \otimes_R A\}$ which induce a faithfully flat map $A \to \prod_\alpha (R'_\alpha \otimes_R A)$. Proposition B.3.5.3 implies that one of the maps ϕ_α admits a left inverse, which determines a map of R'-algebras from R'_α into A.

Now suppose that (2) is satisfied. We will show that A satisfies the criterion of Proposition B.3.5.3. Choose a finite collection of étale maps $\{A \to A_\alpha\}$ which induce a faithfully flat map $A \to \prod_\alpha A_\alpha$. Using the structure theory for étale morphisms (Proposition B.1.1.3), we may assume that there exists a finitely presented R-algebra R' and étale maps $R' \to R'_\alpha$ such that $A_\alpha \simeq R'_\alpha \otimes_R A$. Replacing R' by a product of localizations if necessary, we may suppose that the map $R' \to \prod_\alpha R'_\alpha$ is faithfully flat. Condition (2) then guarantees the existence of a map of R'-algebras $R'_\alpha \to A$ for some α, which we can identify with an A-algebra map from A_α into A. □

B.4 The Nisnevich Topology

In [162], Nisnevich introduced the *completely decomposed topology* (now called the *Nisnevich topology*) associated to a Noetherian scheme X of finite Krull dimension. The Nisnevich topology on X is intermediate between the Zariski and étale topologies, sharing some of the pleasant features of each. In this section, we will describe an analogue of the Nisnevich topology in the non-Noetherian setting. We will restrict our attention to the case of affine schemes; for a generalization to (spectral) algebraic spaces, see §3.7.

B.4.1 Nisnevich Coverings

In the setting of Noetherian schemes, one can define a Nisnevich covering to be a collection of étale maps $\{p_\alpha : U_\alpha \to X\}$ having the property that, for every point $x \in X$, there exists an index α and a point $\overline{x} \in U_\alpha$ such that $p_\alpha(\overline{x}) = x$ and p_α induces an isomorphism of residue fields $\kappa_x \to \kappa_{\overline{x}}$. To handle non-Noetherian situations, we need to adopt a more complicated definition.

Definition B.4.1.1. Let R be a commutative ring. We will say that a collection of étale ring homomorphisms $\{\phi_\alpha : R \to R_\alpha\}_{\alpha \in I}$ is a *Nisnevich covering* of R if there exists a finite sequence of elements $a_1, \ldots, a_n \in R$ with the following properties:

(1) The elements $a_1, \ldots, a_n$ generate the unit ideal in R.

(2) For $1 \leqslant i \leqslant n$, there exists an index α and a ring homomorphism ψ which fits into a commutative diagram

$$\begin{array}{ccc} & R_\alpha & \\ {}^{\phi_\alpha}\nearrow & & \searrow^{\psi} \\ R & \longrightarrow & R[a_i^{-1}]/(a_1, \ldots, a_{i-1}). \end{array}$$

Remark B.4.1.2. If the commutative ring R is Noetherian, then Definition B.4.1.1 recovers the standard definition of Nisnevich covering (see Proposition B.4.3.1).

Example B.4.1.3. For any commutative ring R, the one-element family of maps $\{\mathrm{id}_R : R \to R\}$ is a Nisnevich covering of R.

Example B.4.1.4. Let R be the zero ring. Then the empty collection $\varnothing$ is a Nisnevich covering of R (take $n = 0$ in Definition B.4.1.1).

Example B.4.1.5. Let R be a commutative ring and let $a_1, \ldots, a_n \in R$ be elements which generate the unit ideal. Then the collection of maps $\{R \to R[a_i^{-1}]\}_{1 \leqslant i \leqslant n}$ is a Nisnevich covering of R. In other words, every Zariski covering of R is also a Nisnevich covering.

Remark B.4.1.6. Let R be a commutative ring. Then any Nisnevich covering $\{R \to R_\alpha\}_{\alpha \in A}$ of R also an étale covering: that is, there exists a finite subset $A_0 \subseteq A$ for which the induced map $R \to \prod_{\alpha \in A_0} R_\alpha$ is (étale and) faithfully flat.

Remark B.4.1.7. Let $\{\phi_\alpha : R \to R_\alpha\}_{\alpha \in A}$ be a Nisnevich covering of a commutative ring R. Suppose we are given a family of étale maps $\{\psi_\beta : R \to R_\beta\}_{\beta \in B}$ with the following property: for each $\alpha \in A$, there exists $\beta \in B$ and a commutative diagram

$$\begin{array}{ccc} & R_\beta & \\ {}^{\psi_\beta}\nearrow & & \searrow \\ R & \xrightarrow{\phi_\alpha} & R_\alpha. \end{array}$$

Then $\{\psi_\beta : R \to R_\beta\}_{\beta \in B}$ is also a Nisnevich covering of R.

Remark B.4.1.8. Let $\{R \to R_\alpha\}_{\alpha \in A}$ be a Nisnevich covering of a commutative ring R. Then there exists a finite subset $A_0 \subseteq A$ such that $\{R \to R_\alpha\}_{\alpha \in A_0}$ is also a Nisnevich covering of R.

Remark B.4.1.9. Let $\{R \to R_\alpha\}_{\alpha \in A}$ be a Nisnevich covering of a commutative ring R, and suppose we are given a ring homomorphism $R \to R'$. Then the collection of induced maps $\{R' \to R' \otimes_R R_\alpha\}_{\alpha \in A}$ is a Nisnevich covering of R'.

B.4.2 The Nisnevich Site

Let R be a commutative ring. We let $\mathrm{CAlg}_R^{\text{ét}}$ denote the category whose objects are étale R-algebras and whose morphisms are R-algebra homomorphisms. The collection of Nisnevich coverings determines a Grothendieck topology on $\mathrm{CAlg}_R^{\text{ét}}$:

Theorem B.4.2.1. *Let R be a commutative ring. Then there exists a Grothendieck topology on the category $(\mathrm{CAlg}_R^{ét})^{\mathrm{op}}$ which can be described as follows: if A is an étale R-algebra, then a sieve $\mathcal{C} \subseteq (\mathrm{CAlg}_R^{ét})^{\mathrm{op}}_{/A} \simeq \mathrm{CAlg}_A^{ét}$ is covering if and only if it contains a collection of morphisms $\{A \to A_\alpha\}$ which comprise a Nisnevich covering of A, in the sense of Definition B.4.1.1.*

Definition B.4.2.2. Let R be a commutative ring. We will refer to the Grothendieck topology of Theorem B.4.2.1 as the *Nisnevich topology* on the category $(\mathrm{CAlg}_R^{\text{ét}})^{\mathrm{op}}$. We let $\mathcal{S}\mathrm{hv}_R^{\mathrm{Nis}}$ denote the full subcategory of $\mathrm{Fun}(\mathrm{CAlg}_R^{\text{ét}}, \mathcal{S})$ spanned by those functors which are sheaves with respect to the Nisnevich topology.

Unwinding the definitions, we see that Theorem B.4.2.1 follows from Example B.4.1.3, Remark B.4.1.9, and the following transitivity result:

Proposition B.4.2.3. *Let R be a commutative ring, and suppose we are given a Nisnevich covering $\{R \to R_\alpha\}_{\alpha \in A}$ of R. Assume furthermore that for each $\alpha \in A$, we are given a Nisnevich covering $\{R_\alpha \to R_{\alpha,\beta}\}$. Then the family of composite maps $\{R \to R_{\alpha,\beta}\}$ is a Nisnevich covering of R.*

The proof of Proposition B.4.2.3 will require some preliminaries.

Lemma B.4.2.4. *Let R be a commutative ring and let $\{R \to R_\alpha\}_{\alpha \in A}$ be a collection of étale maps. Suppose that there exists a nilpotent ideal $I \subseteq R$ such that the family of induced maps $\{R/I \to R_\alpha/IR_\alpha\}_{\alpha \in A}$ is a Nisnevich covering of R/I. Then $\{R \to R_\alpha\}_{\alpha \in A}$ is a Nisnevich covering of R.*

Proof. Choose a sequence of elements $a_1, \ldots, a_n \in R$ which generate the unit ideal in R/I and a collection of commutative diagrams

$$\begin{array}{ccc} & R_{\alpha_i} & \\ \nearrow & & \searrow^{\phi_i} \\ R & \longrightarrow & (R/I)[a_i^{-1}]/(a_1, \ldots, a_{i-1}). \end{array}$$

Since each R_{α_i} is étale over R and I is a nilpotent ideal, we can lift ϕ_i to an R-algebra map $\psi_i : R_{\alpha_i} \to R[a_i^{-1}]/(a_1, \ldots, a_{i-1})$. Let J denote the ideal $(a_1, \ldots, a_n)$; since the a_i generate the unit ideal in R/I, we have $I + J = R$. It follows that $R \subseteq (I+J)^m \subseteq I^m + J$ for every integer n. Choosing n sufficiently large, we have $I^m = 0$ so that $R = J$; this proves that $\{R \to R_\alpha\}_{\alpha \in A}$ is a Nisnevich covering of R. □

Lemma B.4.2.5. *Let R be a commutative ring containing an element x. A collection of étale maps $\{R \to R_\alpha\}_{\alpha \in A}$ is a Nisnevich cover of R if and only if the following conditions are satisfied:*

(1) *The maps $\{R/xR \to R_\alpha/xR_\alpha\}_{\alpha \in A}$ are a Nisnevich cover of the quotient ring R/xR.*

(2) *The maps $\{R[x^{-1}] \to R_\alpha[x^{-1}]\}_{\alpha \in A}$ are a Nisnevich cover of the commutative ring $R[x^{-1}]$.*

Proof. The necessity of conditions (1) and (2) follows from Remark B.4.1.9. For the converse, suppose that conditions (1) and (2) are satisfied. Using (2), we deduce that there exists a sequence of elements $\overline{a}_1, \overline{a}_2, \ldots, \overline{a}_n \in R[x^{-1}]$ which generates the unit ideal, a sequence of indices $\alpha_1, \ldots, \alpha_n \in A$, and a sequence of commutative diagrams

$$\begin{array}{ccc} & R_{\alpha_i}[x^{-1}] & \\ \nearrow & & \searrow^{\phi_i} \\ R[x^{-1}] & \longrightarrow & R[(xa_i)^{-1}]/(\overline{a}_1, \ldots, \overline{a}_{i-1}). \end{array}$$

Multiplying each $\overline{a}_i$ by a sufficiently large power of x, we may assume that $\overline{a}_i$ is the image of an element $a_i \in R$. Let J denote the ideal $(xa_1, \ldots, xa_n) \subseteq R$. Since the $\overline{a}_i$ generate the unit ideal in $R[x^{-1}]$, the ideal J contains x^k for $k \gg 0$. It follows that x generates a nilpotent ideal in R/J. Using (1) and Lemma B.4.2.4, we deduce that the maps $\{R/J \to R_\alpha/JR_\alpha\}_{\alpha \in A}$ determine a Nisnevich covering of R/J. We may therefore choose elements $b_1, \ldots, b_m \in R$ which generate the unit ideal in R/J together with commutative diagrams

$$\begin{array}{ccc} & R_{\beta_j}/JR_{\beta_j} & \\ \nearrow & & \searrow^{\psi_j} \\ R/J & \longrightarrow & R[_j^{-1}]/(J + (b_1, \ldots, b_{j-1})). \end{array}$$

Then the sequence $xa_1, xa_2, \ldots, xa_n, b_1, \ldots, b_m$ generates the unit ideal in R; using the maps $\{\phi_i\}_{1 \leq i \leq n}$ and $\{\psi_j\}_{1 \leq j \leq m}$, we see that the family of maps $\{R \to R_\alpha\}$ determines a Nisnevich covering of R. $\square$

Proof of Proposition B.4.2.3. Let $\{R \to R_\alpha\}_{\alpha \in A}$ be a Nisnevich covering of a commutative ring R, and suppose that for each $\alpha \in A$ we are given a Nisnevich covering $\{R_\alpha \to R_{\alpha,\beta}\}$. Choose a sequence $a_1, \ldots, a_n \in R$ which generate the unit ideal and commutative diagrams

$$\begin{array}{ccc} & R_{\alpha_i} & \\ \nearrow & & \searrow \\ R & \longrightarrow & R[a_i^{-1}]/(a_1, \ldots, a_{i-1}). \end{array}$$

We prove by induction on n that the maps $\{R \to R_{\alpha,\beta}\}$ form a Nisnevich covering of R. If $n = 0$, then the unit ideal and zero ideal of R coincide, so that $R \simeq 0$ and the result is obvious (Example B.4.1.4 and Remark B.4.1.7). Otherwise, we may assume by the inductive hypothesis that the family of maps $\{R/a_1R \to R_{\alpha,\beta}/a_1R_{\alpha,\beta}\}$ is a Nisnevich covering of R/a_1R. According to Lemma B.4.2.5, it will suffice to show that the maps $\{R[a_1^{-1}] \to R_{\alpha,\beta}[a_1^{-1}]\}$ are a Nisnevich covering of $R[a_1^{-1}]$. Using Remark B.4.1.9, we see that $\{R[a_1^{-1}] \to R[a_1^{-1}] \otimes_{R_{\alpha_1}} R_{\alpha_1,\beta}\}$ is a Nisnevich covering; the desired result now follows from Remark B.4.1.7. □

B.4.3 The Noetherian Case

For every commutative ring R, we let $|\operatorname{Spec} R|$ denote the Zariski spectrum of R: this is a topological space whose points are prime ideals $\mathfrak{p} \subset R$ (Example 1.1.1.2). For each point $\mathfrak{p} \in |\operatorname{Spec} R|$, we let $\kappa(\mathfrak{p})$ denote the fraction field of the quotient $R/\mathfrak{p}$.

Proposition B.4.3.1. *Let R be a Noetherian ring, and suppose we are given a collection of étale maps $\{\phi_\alpha : R \to R_\alpha\}_{\alpha \in A}$. The following conditions are equivalent:*

(1) *The maps $\{R \to R_\alpha\}_{\alpha \in A}$ determine a Nisnevich covering of R.*

(2) *For every $\mathfrak{p} \in |\operatorname{Spec} R|$, there exists an index $\alpha \in A$ and a prime ideal $\mathfrak{q} \in |\operatorname{Spec} R_\alpha|$ such that $\mathfrak{p} = \phi_\alpha^{-1}\mathfrak{q}$ and the induced map $\kappa(\mathfrak{p}) \to \kappa(\mathfrak{q})$ is an isomorphism.*

Proof. We first show that (1) ⇒ (2) (which does not require our assumption that R is Noetherian). Choose a sequence of elements $a_1, \ldots, a_n \in R$ which generate the unit ideal and a collection of commutative diagrams

$$\begin{array}{ccccc} & & R_{\alpha_i} & & \\ & \nearrow & & \searrow & \\ R & & \longrightarrow & & R[a_i^{-1}]/(a_1, \ldots, a_{i-1}). \end{array}$$

Let $\mathfrak{p}$ be a prime ideal of R. Since $\mathfrak{p} \neq R$, there exists an integer $i \leqslant n$ such that $a_1, \ldots, a_{i-1} \in \mathfrak{p}$ but $a_i \notin \mathfrak{p}$. Then $\mathfrak{p}$ is the inverse image of a prime ideal $\mathfrak{p}' \in R[a_i^{-1}]/(a_1, \ldots, a_{i-1})$, which also has an inverse image $\mathfrak{q} \in |\operatorname{Spec} R_{\alpha_i}|$. We have a commutative diagram of fields

$$\begin{array}{ccccc} & & \kappa(\mathfrak{q}) & & \\ & \nearrow & & \searrow & \\ \kappa(\mathfrak{p}) & & \longrightarrow & & \kappa(\mathfrak{p}'). \end{array}$$

Since the lower horizontal map is an isomorphism, we conclude that $\kappa(\mathfrak{p}) \simeq \kappa(\mathfrak{q})$.

Now suppose that (2) is satisfied; we will prove (1). Let X be the collection of all ideals $I \subseteq R$ for which the maps $\{R/I \to R_\alpha/IR_\alpha\}_{\alpha \in A}$ do not form a Nisnevich covering of R/I; we will prove that X is empty. Otherwise, X contains a maximal element I (since R is Noetherian). Replacing R by R/I, we may assume that X does not contain any nonzero ideal of R. Let J be the nilradical of R. Since R is Noetherian, J is nilpotent. If $J \neq 0$, then $J \notin X$ and assertion (1) follows from Lemma B.4.2.4. We may therefore assume that $J = 0$; that is, the ring R is reduced.

If $R = 0$ there is nothing to prove. Otherwise, since R is Noetherian, it contains finitely many associated primes $\eta_0, \eta_1, \ldots, \eta_k$. Reordering if necessary, we may assume that η_0 is not contained in η_i for $i > 0$. Choose an element $x \in R$ which belongs to $\eta_1 \cap \cdots \cap \eta_k$ but not to η_0. Then $x \neq 0$, so the principal ideal (x) does not belong to X. Using Lemma B.4.2.5, we can replace R by $R[x^{-1}]$ and thereby reduce to the case where R is a reduced ring with a unique associated prime, and therefore an integral domain.

Let κ denote the fraction field of R. Using assumption (2), we conclude that there exists an index $\alpha \in A$ and a prime ideal $\mathfrak{q} \subseteq R_\alpha$ such that $\phi_\alpha^{-1}\mathfrak{q} = (0) \subseteq R$ and $\kappa(\mathfrak{q}) \simeq \kappa$. In particular, we have an R-algebra map $R_\alpha \to \kappa(\mathfrak{q}) \to \kappa$. Since R_α is finitely presented as an R-algebra, this map factors through $R[y^{-1}] \subseteq \kappa$ for some nonzero element $y \in R$. It follows that the single map $\{R[y^{-1}] \to R_\alpha[y^{-1}]\}$ is a Nisnevich covering of $R[y^{-1}]$. Since the principal ideal (y) does not belong to X, Lemma B.4.2.5 implies that the maps $\{R \to R_\alpha\}_{\alpha \in A}$ is a Nisnevich covering of R, as desired. □

Remark B.4.3.2. Let $R = \varinjlim_\gamma R(\gamma)$ be a filtered colimit of commutative rings $R(\gamma)$, and suppose we are given a Nisnevich covering $\{R \to R_\alpha\}_{\alpha \in A}$ where the set A is finite (by virtue of Remark B.4.1.8, this assumption is harmless). Then there exists an index γ and a Nisnevich covering $\{R(\gamma) \to R(\gamma)_\alpha\}_{\alpha \in A}$ such that $R_\alpha \simeq R \otimes_{R(\gamma)} R(\gamma)_\alpha$ for each $\alpha \in A$.

Remark B.4.3.3. The theory of Nisnevich coverings (as set forth in Definition B.4.1.1) is uniquely determined by Remark B.4.3.2, Remark B.4.1.8, and Proposition B.4.3.1. That is, suppose we are given a commutative ring R and a collection of étale maps $\{R \to R_\alpha\}_{\alpha \in A}$. We can realize R as a filtered colimit of subrings which are finitely generated over $\mathbf{Z}$, and therefore Noetherian. It follows that $\{R \to R_\alpha\}_{\alpha \in A}$ is a Nisnevich covering of R if and only if there exists a finite subset $A_0 \subseteq A$, a subring $R' \subseteq R$ which is finitely generated over $\mathbf{Z}$, and a collection of étale maps $\{R' \to R'_\alpha\}_{\alpha \in A_0}$ satisfying condition (2) of Proposition B.4.3.1, such that $R_\alpha \simeq R \otimes_{R'} R'_\alpha$ for $\alpha \in A_0$.

B.4.4 Points of the Nisnevich Topology

Let R be a commutative ring and let $\mathcal{S}\mathrm{hv}_R^{\mathrm{Nis}}$ denote the associated ∞-category of Nisnevich sheaves (see Definition B.4.2.2). Our next goal is to describe the ∞-category $\mathrm{Fun}^*(\mathcal{S}\mathrm{hv}_R^{\mathrm{Nis}}, \mathcal{S})$ of points of the ∞-topos $\mathcal{S}\mathrm{hv}_R^{\mathrm{Nis}}$. First, we need to introduce some definitions.

Definition B.4.4.1. Let R be a commutative ring and let A be a commutative R-algebra. We will say that A is Ind-étale if it can be written as a filtered colimit $\varinjlim R_\alpha$, where each R_α is an étale R-algebra. We will say that A is a *Henselization of* R if it is Ind-étale over R and is a Henselian local ring. We let $\mathrm{CAlg}_R^{\mathrm{Hens}}$ denote the full subcategory of $\mathrm{CAlg}_R^{\heartsuit}$ spanned by the Henselizations of R.

Warning B.4.4.2. The terminologies of Definition B.4.4.1 and Remark **??** are not quite compatible. If R is a commutative ring and $I \subseteq R$ is an ideal, then the Henselization of R with respect to I (in the sense of Remark **??**) is an Ind-étale R-algebra, but usually not a Henselian ring unless the ideal $I \subseteq R$ is maximal. On the other hand, not every Henselization A of R (in the sense of Definition B.4.4.1) arises from the construction of Proposition B.3.4.1.

Remark B.4.4.3. Let R be a commutative ring. Every étale R-algebra A is finitely presented, and is therefore compact when viewed as an object of the category $\mathrm{CAlg}_R^{\heartsuit}$ of commutative R-algebras (or even the ∞-category CAlg_R of $\mathbb{E}_\infty$-algebras over R). It follows that the inclusion $\mathrm{CAlg}_R^{\text{ét}} \hookrightarrow \mathrm{CAlg}_R$ extends to a fully faithful embedding $\mathrm{Ind}(\mathrm{CAlg}_R^{\text{ét}}) \hookrightarrow \mathrm{CAlg}_R$, whose essential image is spanned by those R-algebras which are Ind-étale in the sense of Definition B.4.4.1.

Theorem B.4.4.4. *Let R be a commutative ring, and let $\mathscr{O}$ denote the commutative ring object of $\mathcal{S}\mathrm{hv}_R^{\mathrm{Nis}}$ given by $\mathscr{O}(A) = A$. Then evaluation on $\mathscr{O}$ induces an equivalence of ∞-categories $\mathrm{Fun}^*(\mathcal{S}\mathrm{hv}_R^{\mathrm{Nis}}, \mathcal{S}) \to \mathrm{CAlg}_R^{\mathrm{Hens}}$.*

The content of Theorem B.4.4.4 lies in the following analogue of Corollary B.3.5.4 for the Nisnevich topology:

Proposition B.4.4.5. *Let R be a commutative ring. The following conditions are equivalent:*

(1) *The ring R is Henselian.*

(2) *For every Nisnevich covering $\{\phi_\alpha : R \to R_\alpha\}$ of R, one of the morphisms ϕ_α admits a left inverse.*

Proof. We first show that (1) ⇒ (2). Assume that R is a local Henselian ring with maximal ideal $\mathfrak{m}$, and let $\kappa = R/\mathfrak{m}$ denote the residue field of R. Suppose we are given a Nisnevich covering $\{R \to R_\alpha\}$. We wish to prove that one of the spaces $\mathrm{Hom}_R(R_\alpha, R)$ is nonempty. Since R is Henselian, this is equivalent to showing that one of the mapping spaces

$$\mathrm{Hom}_R(R_\alpha, \kappa) \simeq \mathrm{Hom}_\kappa(R_\alpha \otimes_R \kappa, \kappa)$$

is nonempty. This follows immediately from Proposition B.4.3.1, since the collection of maps $\{\kappa \to R_\alpha \otimes_R \kappa\}$ form a Nisnevich covering of the field κ.

Now suppose that (2) is satisfied; we will prove (1). If $R = 0$, then the empty set is a Nisnevich covering of R, contradicting assumption (2). If $x \in R$, then the pair of maps $\{R \to A[x^{-1}], A \to A[(1-x)^{-1}]\}$ determines a Nisnevich covering of R. It then follows from (2) that either x or $1-x$ is invertible in R. This proves that R is a local ring; let $\mathfrak{m}$ denote its maximal ideal. Let A be an étale R-algebra and suppose we are given a R-algebra map $\phi_0 : A \to R/\mathfrak{m}$; we wish to show that ϕ_0 can be lifted to a R-algebra map $A \to R$. Replacing A by a localization if necessary, we may assume that ϕ_0 is the only R-algebra map from A to $R/\mathfrak{m}$. In this case, it suffices to show that the map $R \to A$ admits a left inverse. Since A is finitely presented as an R-algebra, we can lift ϕ_0 to a map $\phi_1 : A \to R/I$, where I is a proper ideal generated by finitely many elements $x_1, \ldots, x_n \in R$. By construction, the collection of maps $\{R \to R[x_i^{-1}], R \to A\}$ is a Nisnevich covering of R. Note that since $x_i \in I \subseteq \mathfrak{m}$, there cannot exist an R-algebra map $R[x_i^{-1}] \to A$. Using (2), we deduce the existence of an R-algebra map $A \to R$, as desired. □

Proof of Theorem B.4.4.4. Theorem HTT.5.1.5.6 and Proposition HTT.6.1.5.2 supply an equivalence of $\mathrm{Fun}^*(\mathrm{Fun}(\mathrm{CAlg}_R^{\text{ét}}, \mathcal{S}), \mathcal{S})$ with the ∞-category $\mathrm{Ind}(\mathrm{CAlg}_R^{\text{ét}})$, which we can identify with the full subcategory of CAlg_R spanned by those R-algebras which are Ind-étale over R (Remark B.4.4.3). Combining this observation with Proposition HTT.6.2.3.20 , we can identify $\mathrm{Fun}^*(\mathcal{S}\mathrm{hv}_R^{\mathrm{Nis}}, \mathcal{S})$ with the full subcategory of CAlg_R spanned by those Ind-étale R-algebras which satisfy condition (2) of Proposition B.4.4.5. By virtue of Proposition B.4.4.5, this full subcategory coincides with $\mathrm{CAlg}_R^{\mathrm{Hens}}$. □

B.4.5 Classification of Henselizations

Let R be a commutative ring. Using Theorem B.4.4.4, we can obtain a very explicit description of the Kan complex $\mathrm{Fun}^*(\mathcal{S}\mathrm{hv}_R^{\mathrm{Nis}}, \mathcal{S})^{\simeq}$ of points of the ∞-topos $\mathcal{S}\mathrm{hv}_R^{\mathrm{Nis}}$.

Notation B.4.5.1. Let R be a commutative ring. We define a subcategory $\mathrm{Field}_R^{\mathrm{sep}} \subseteq \mathrm{CAlg}_R^{\heartsuit}$ as follows:

- The objects of $\mathrm{Field}_R^{\mathrm{sep}}$ are ring homomorphisms $\phi : R \to \kappa$ which exhibit κ as a separable algebraic extension of some residue field of R.
- The morphisms in $\mathrm{Field}_R^{\mathrm{sep}}$ are given by isomorphisms of R-algebras.

Let R be commutative ring and let A be a Henselization of R (in the sense of Definition B.4.4.1). Then A is a local ring with maximal ideal $\mathfrak{m}$. Since A is Ind-etale over R, the residue field $A/\mathfrak{m}$ is a separable algebraic extension of the residue field $\kappa(\mathfrak{p})$ at some prime ideal $\mathfrak{p} \subseteq R$. The construction $A \mapsto A/\mathfrak{m}$ determines a functor $\Phi : (\mathrm{CAlg}_R^{\mathrm{Hens}})^{\simeq} \to \mathrm{Field}_R^{\mathrm{sep}}$.

Proposition B.4.5.2. *Let R be a commutative ring. Then the functor $\Phi : (\mathrm{CAlg}_R^{\mathrm{Hens}})^{\simeq} \to \mathrm{Field}_R^{\mathrm{sep}}$ is an equivalence of categories.*

Remark B.4.5.3. Let R be an $\mathbb{E}_\infty$-ring. Proposition B.4.5.2 asserts that every separable extension κ of every residue field of R has the form $A/\mathfrak{m}$, for some Henselian ring A which is Ind-étale over R. We will refer to A as the *Henselization of R at κ*.

Proof of Proposition B.4.5.2. We first prove that Φ is fully faithful. Let A and A' be Henselizations of R, let $\mathfrak{m} \subseteq A$ and $\mathfrak{m}' \subseteq A'$ denote maximal ideals, and set $\kappa = A/\mathfrak{m}$ and $\kappa' = A'/\mathfrak{m}'$. Unwinding the definitions, we must show that every R-algebra isomorphism of κ with κ' can be lifted uniquely to an R-algebra isomorphism of A with A'. Since A is Henselian, we have

$$\mathrm{Hom}_R(R', A) \simeq \mathrm{Hom}_A(R' \otimes_R A, A) \simeq \mathrm{Hom}_A(R' \otimes_R A, \kappa) \simeq \mathrm{Hom}_\kappa(R' \otimes_R \kappa, \kappa) \simeq \mathrm{Hom}_R(R', \kappa)$$

for every étale R-algebra R'. Passing to filtered colimits, we deduce that the restriction map $\mathrm{Hom}_R(R', A) \to \mathrm{Hom}_R(R', \kappa)$ is bijective whenever R' is Ind-etale over R. In particular, every R-algebra homomorphism $\phi_0 : \kappa' \to \kappa$ induces a map $A' \to \kappa' \xrightarrow{\phi_0} \kappa$, which lifts uniquely to an R-algebra homomorphism $\phi : A' \to A$. If ϕ_0 is invertible, the same argument shows that ϕ_0^{-1} lifts to an R-algebra map $\psi : A \to A'$. The compositions $\phi \circ \psi$ and $\psi \circ \phi$ lift the identity maps from κ and κ' to themselves; by uniqueness we deduce that $\phi \circ \psi = \mathrm{id}_A$ and $\psi \circ \phi = \mathrm{id}_{A'}$. It follows that ϕ is an isomorphism of R-algebras.

We now prove that Φ is essentially surjective. Let $\kappa \in \mathrm{Field}_R^{\mathrm{sep}}$, and let $\mathcal{C}$ denote the category whose objects are étale R-algebras R' equipped with an R-algebra homomorphism $\epsilon_{R'} : R' \to \kappa$. The category $\mathcal{C}$ admits finite colimits, and is therefore filtered. We let $A = \varinjlim_{(R', \epsilon_{R'}) \in \mathcal{C}} R'$, so that A is an Ind-étale R-algebra. By construction, we have a canonical map $\epsilon : A \to \kappa$. This implies in particular that $A \neq 0$. We next claim that A is a local ring with maximal ideal $\mathfrak{m} = \ker(\epsilon)$. To prove this, choose an arbitrary element $x \notin \mathfrak{m}$; we will show that x is invertible in A. To prove this, choose a representation of x as the image of an element $x_0 \in R'$, for some étale R-algebra R' equipped with a map $\epsilon_{R'} : R' \to \kappa$. Then $\epsilon_{R'}(x_0) = \epsilon(x) \neq 0$, so that $\epsilon_{R'}$ factors through $R'[x_0^{-1}]$. It follows that the map $R' \to A$ also factors through $R'[x_0^{-1}]$, so that the image of x_0 in A is invertible.

We now claim that ϵ induces an isomorphism $A/\mathfrak{m} \to \kappa$. This map is injective by construction. To prove the surjectivity, choose an arbitrary element $y \in \kappa$; we will prove that y belongs to the image of ϵ. Since κ is a separable algebraic extension of some residue field of R, the element y satisfies a polynomial equation $f(y) = 0$ where the coefficients of f lie in R, and the discriminant Δ of f invertible in κ. Then $R' = R[Y, \Delta^{-1}]/(f)$ is an étale R-algebra equipped with a map $R' \to \kappa$ given by $Y \mapsto y$. It follows that y belongs to the image of ϵ as desired.

To complete the proof, it will suffice to show that the local ring A is Henselian. Let B be an étale A-algebra equipped with an A-algebra homomorphism $f_0 : B \to \kappa$; we wish to prove that f_0 can be lifted to a map $f : B \to A$. Using the structure theory of étale morphisms (Proposition B.1.1.1), we can write $B = A \otimes_{R'} B_0$, where R' is an étale R-algebra equipped with a map $\epsilon_{R'} : R' \to \kappa$, and B_0 is étale over R'. Then f_0 determines a map $B_0 \to \kappa$ extending $\epsilon_{R'}$. It follows that the canonical map $R' \to A$ factors through B_0; this factorization determines a map $B \to A$ having the desired properties. □

B.5 Nisnevich Excision

Let R be a commutative ring and let $\mathcal{S}\mathrm{hv}_R^{\mathrm{Nis}}$ denote associated ∞-category of Nisnevich sheaves (see Definition B.4.2.2). In this section, we will prove a version of a result of Morel and Voevodsky (see [157]) which characterizes $\mathcal{S}\mathrm{hv}_R^{\mathrm{Nis}}$ as the full subcategory of $\mathrm{Fun}(\mathrm{CAlg}_R^{\text{ét}}, \mathcal{S})$ spanned by those functors $\mathscr{F}$ which possess a certain excision property (Theorem B.5.0.3). We will follow a particularly convenient formulation given by Asok, Hoyois, and Wendt ([7]), which allows us to stay entirely within the world of *affine* schemes.

Definition B.5.0.1. Let R be a commutative ring and let $\mathscr{F} : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{S}$ be a functor. We will say that $\mathscr{F}$ satisfies *Nisnevich excision* if the following conditions are satisfied:

(1) The space $\mathscr{F}(0)$ is contractible.

(2) Let $\phi : A \to A'$ be a morphism of étale R-algebras which induces an isomorphism $A/(a) \to A'/(a)$ for some element $a \in A$ (which, by abuse of notation, we will identify with its image in A'). Then the diagram of spaces

$$\begin{array}{ccc} \mathscr{F}(A) & \longrightarrow & \mathscr{F}(A') \\ \downarrow & & \downarrow \\ \mathscr{F}(A[a^{-1}]) & \longrightarrow & \mathscr{F}(A'[a^{-1}]) \end{array}$$

is a pullback square in $\mathcal{S}$.

Remark B.5.0.2. Let R be a commutative ring. The collection of all functors $\mathscr{F} : \mathrm{CAlg}_R^{\mathcal{S}} \to \mathcal{S}$ satisfying Nisnevich excision is closed under small limits and filtered colimits.

We can now state the main result of this section:

Theorem B.5.0.3 (Morel-Voevodsky, Asok-Hoyois-Wendt)**.** *Let R be a commutative ring and let $\mathscr{F} : \mathrm{CAlg}_R^{ét} \to \mathcal{S}$ be a functor. Then $\mathscr{F}$ is a sheaf with respect to the Nisnevich topology (Definition B.4.2.2) if and only if it satisfies Nisnevich excision.*

Corollary B.5.0.4. *Let R be a commutative ring. Then the full subcategory $\mathcal{S}\mathrm{hv}_R^{\mathrm{Nis}} \subseteq \mathrm{Fun}(\mathrm{CAlg}_R^{ét}, \mathcal{S})$ is closed under filtered colimits.*

Proof. Combine Theorem B.5.0.3 with Remark B.5.0.2. □

B.5.1 Non-Affine Excision

Let R be a commutative ring. We let $\mathrm{Sch}_R^{\text{ét}}$ denote the category of R-schemes which are quasi-compact, separated, and étale over R. For every object $X \in \mathrm{Sch}_R^{\text{ét}}$, we let $h_X : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{S}$ denote the functor given by $h_X(A) = \mathrm{Hom}_{\mathrm{Sch}_R^{\text{ét}}}(\operatorname{Spec} A, X)$. Note that h_X is a sheaf (of sets) with respect to the Nisnevich topology, and that h_X satisfies affine Nisnevich excision (Definition B.5.0.1). For any functor $\mathscr{F} : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{S}$, we will abuse notation by writing $\mathscr{F}(X)$ for the mapping space $\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}_R^{\text{ét}}, \mathcal{S})}(h_X, \mathscr{F})$. Note that $\mathscr{F}(X)$ can be regarded as a contravariant functor of X, and that $\mathscr{F}(\operatorname{Spec} A) \simeq \mathscr{F}(A)$ when A is an étale R-algebra (the value of $\mathscr{F}$ on more general R-schemes is obtained from the original functor $\mathscr{F} : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{S}$ by means of right Kan extension along the fully faithful embedding $\operatorname{Spec} : \mathrm{CAlg}_R^{\text{ét}} \to (\mathrm{Sch}_R^{\text{ét}})^{\mathrm{op}}$). The first step in the proof of Theorem B.5.0.3 is to show that this extension process behaves nicely with respect to excision:

Proposition B.5.1.1. *Let R be a commutative ring and let $\mathscr{F} : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{S}$ be a functor. The following conditions are equivalent:*

(1) *The functor $\mathscr{F}$ satisfies Nisnevich excision (Definition B.5.0.1).*

(2) *Suppose we are given a pullback diagram*

$$\begin{array}{ccc} U' & \longrightarrow & X' \\ \downarrow & & \downarrow{\scriptstyle p} \\ U & \xrightarrow{j} & X \end{array}$$

in $\mathrm{Sch}_R^{\text{ét}}$, where p is affine, j is an open immersion, and p induces an isomorphism $(X - U) \times_X X' \to (X - U)$, where $(X - U)$ denotes the complement of U (endowed with the reduced scheme structure). Then the diagram of spaces

$$\begin{array}{ccc} \mathscr{F}(U') & \longleftarrow & \mathscr{F}(X') \\ \uparrow & & \uparrow \\ \mathscr{F}(U) & \longleftarrow & \mathscr{F}(X) \end{array}$$

is a pullback square.

Remark B.5.1.2. In the statement of condition (2) of Proposition B.5.1.1, the hypothesis that p is affine is not important.

The proof of Proposition B.5.1.1 will require some preliminaries.

Lemma B.5.1.3. *[7] Let A be a commutative ring containing a pair of ideals I and J, and suppose we are given an étale ring homomorphism $\phi : A \to A'$ which induces an* *isomorphism* $A/(I+J) \to A'/(I+J)A'$. *Then there exists a commutative diagram of étale ring homomorphisms*

$$\begin{array}{ccc} A & \xrightarrow{\psi} & B \\ \downarrow{\scriptstyle\phi} & & \downarrow{\scriptstyle\phi'} \\ A' & \xrightarrow{\phi'} & B' \end{array}$$

where ψ *induces an isomorphism* $A/I \to B/IB$ *and* ϕ' *induces an isomorphism* $B/JB \to B'/JB'$.

Proof. Let $\overline{B}$ denote the Henselization of A with respect to the ideal I (see Proposition B.3.4.1 and Remark B.3.4.2) and let $\overline{B}'$ denote the Henselization of $\overline{B}$ with respect to the ideal $J\overline{B}$. Applying Proposition B.3.4.6, we can identify $\overline{B}$ with the Henselization of A with respect to the ideal $I+J$. Consequently, the assumption that the map $A/(I+J) \to A'/(I+J)A'$ is an isomorphism guarantees that there exists an A-algebra homomorphism $\rho : A' \to \overline{B}'$ (this follows from the construction of the Henselization given in the proof of Proposition B.3.4.1).

Since $\overline{B}'$ is the Henselization of $\overline{B}$ with respect to the ideal $J\overline{B}$, we can write $\overline{B}'$ as a filtered colimit $\varinjlim \overline{B}'_\alpha$, where each $\overline{B}'_\alpha$ is an étale $\overline{B}$-algebra for which the map $\overline{B}/J\overline{B} \to \overline{B}'_\alpha/J\overline{B}'_\alpha$ is an isomorphism. Because A' is finitely presented as an A-algebra, the map ρ factors through some map $\rho_\alpha : A' \to \overline{B}'_\alpha$.

Write $\overline{B}$ as the colimit of a diagram $\{\overline{B}_\beta\}_{\beta \in P}$ indexed by a direct partially ordered set P, where each $\overline{B}_\beta$ is an étale A-algebra for which the map $A/I \to \overline{B}_\beta/I\overline{B}_\beta$ is an isomorphism. Using the structure theory of étale morphisms (see Proposition B.1.1.3), we can write $\overline{B}'_\alpha = \overline{B} \otimes_{\overline{B}_\beta} \overline{B}'_{\alpha,\beta}$ for some $\beta \in P$, where $\overline{B}'_{\alpha,\beta}$ is étale over $\overline{B}_\beta$. Then we can write $\overline{B}'_\alpha$ as a filtered colimit $\varinjlim_{\beta' \geq \beta} \overline{B}_{\beta'} \otimes_{\overline{B}_\beta} \overline{B}'_{\alpha,\beta}$. Enlarging β if necessary, we may assume that ρ_α factors through an A-algebra map $\phi' : A' \to B'_{\alpha,\beta}$ and that the natural map $\overline{B}_\beta/J\overline{B}_\beta \to \overline{B}'_{\alpha,\beta}/J\overline{B}'_{\alpha,\beta}$ is an isomorphism. It follows that the commutative diagram

$$\begin{array}{ccc} A & \xrightarrow{\phi} & \overline{B}_\beta \\ \downarrow & & \downarrow \\ A' & \xrightarrow{\phi'} & \overline{B}'_{\alpha,\beta} \end{array}$$

has the desired properties. □

Proof of Proposition B.5.1.1. Note that condition (1) of Proposition B.5.1.1 can be identified with the special case of (2) where $X = \operatorname{Spec} A$ and $U = \operatorname{Spec} A[a^{-1}]$ for some element $a \in A$. Consequently, the implication (2) ⇒ (1) is immediate from the definitions. To prove the converse, let us assume that $\mathscr{F}$ satisfies Nisnevich excision. Let $p : X' \to X$ be an affine morphism in $\mathrm{Sch}_R^{\text{ét}}$, and let U be a quasi-compact open subscheme of X. We will say that p

is *U-good* if the diagram of spaces

$$\begin{array}{ccc} \mathscr{F}(X) & \longrightarrow & \mathscr{F}(X') \\ \downarrow & & \downarrow \\ \mathscr{F}(U) & \longrightarrow & \mathscr{F}(U \times_X X') \end{array}$$

is a pullback square. To establish (2), we must show that $p : X' \to X$ is U-good whenever the induced map $X' \times_X (X - U) \to X - U$ is an isomorphism. The proof proceeds in several steps.

(a) Let $p : X' \to X$ be an affine morphism in $\mathrm{Sch}_R^{\text{ét}}$ and let $U \subseteq X$ be a quasi-compact open subscheme. Suppose that, for every map $\operatorname{Spec} A \to X$ in $\mathrm{Sch}_R^{\text{ét}}$, the induced map $p_A : X' \times_X \operatorname{Spec} A \to \operatorname{Spec} A$ is $(U \times_X \operatorname{Spec} A)$-good. Then p is U-good. To prove this, write the functor $h_X : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{S}$ as a colimit $\varinjlim \mathscr{G}_\alpha$, where each $\mathscr{G}_\alpha : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{S}$ is corepresented by an object of $\mathrm{CAlg}_R^{\text{ét}}$. Set $\mathcal{X} = \mathrm{Fun}(\mathrm{CAlg}_R^{\text{ét}}, \mathcal{S})$. Unwinding the definitions, we see that p is U-good if and only if the diagram of spaces τ :

$$\begin{array}{ccc} \mathrm{Map}_{\mathcal{X}}(\varinjlim \mathscr{G}_\alpha, \mathscr{F}) & \longrightarrow & \mathrm{Map}_{\mathcal{X}}((\varinjlim \mathscr{G}_\alpha) \times_{h_X} h_U, \mathscr{F}) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathcal{X}}((\varinjlim \mathscr{G}_\alpha) \times_{h_X} h_{X'}, \mathscr{F}) & \longrightarrow & \mathrm{Map}_{\mathcal{X}}((\varinjlim \mathscr{G}_\alpha) \times_{h_X} h_{U'}, \mathscr{F}) \end{array}$$

is a pullback square, where $U' = U \times_X X'$. Because colimits in $\mathcal{X}$ are universal, we can write the preceding diagram as a limit of diagrams τ_α:

$$\begin{array}{ccc} \mathrm{Map}_{\mathcal{X}}(\mathscr{G}_\alpha, \mathscr{F}) & \longrightarrow & \mathrm{Map}_{\mathcal{X}}(\mathscr{G}_\alpha \times_{h_X} h_U, \mathscr{F}) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathcal{X}}(\mathscr{G}_\alpha \times_{h_X} h_{X'}, \mathscr{F}) & \longrightarrow & \mathrm{Map}_{\mathcal{X}}(\mathscr{G}_\alpha \times_{h_X} h_{U'}, \mathscr{F}). \end{array}$$

Choosing an object $A \in \mathrm{CAlg}_R^{\text{ét}}$ which corepresents the functor $\mathscr{G}_\alpha$, the desired result follows from our assumption that the map $p_A : X' \times_X \operatorname{Spec} A \to \operatorname{Spec} A$ is $(U \times_X \operatorname{Spec} A)$-good.

(b) Let $p : X' \to X$ be an affine morphism in $\mathrm{Sch}_R^{\text{ét}}$, let $a \in \Gamma(X; \mathcal{O}_X)$ be a global function on X, and let $U \subseteq X$ be the open subscheme on which the function a does not vanish. Suppose that p induces an isomorphism $X' \times_X (X - U) \to X - U$. Then p is U-good. To prove this, we can use (a) to reduce to the case where $X = \operatorname{Spec} A$ is affine, so that a can be regarded as an element of the ring A. Since p is affine, we can write

$X' = \operatorname{Spec} A'$. Unwinding the definitions, we wish to show that the diagram

$$\begin{array}{ccc} \mathscr{F}(A) & \longrightarrow & \mathscr{F}(A') \\ \downarrow & & \downarrow \\ \mathscr{F}(A[a^{-1}]) & \longrightarrow & \mathscr{F}(A'[a^{-1}]) \end{array}$$

is a pullback square, which follows from our assumption that $\mathscr{F}$ satisfies Nisnevich excision.

(c) Let $p : X' \to X$ be an affine morphism in $\mathrm{Sch}_R^{\text{ét}}$, let $U \subseteq V \subseteq X$ be quasi-compact open subschemes, set $U' = U \times_X X'$ and $V' = V \times_X X'$, and let $p_V : V' \to V$ be the projection map. Suppose that p_V is U-good. Then p is U-good if and only if p is V-good. To prove this, we note that there is a commutative diagram

$$\begin{array}{ccccc} \mathscr{F}(X) & \longrightarrow & \mathscr{F}(V) & \longrightarrow & \mathscr{F}(U) \\ \downarrow & & \downarrow & & \downarrow \\ \mathscr{F}(X') & \longrightarrow & \mathscr{F}(V') & \longrightarrow & \mathscr{F}(U'). \end{array}$$

Our assumption that p_V is U-good guarantees that the right square is a pullback, so that the left square is a pullback if and only if the outer square is a pullback.

(d) Let $\phi : A \to A'$ be a morphism of étale R-algebras. Let $U \subseteq \operatorname{Spec} A$ be the open subscheme complementary to the vanishing locus of a finitely generated ideal $I \subseteq A$. Suppose that there exists an element $a \in I$ for which ϕ induces an isomorphism $A/(a) \to A'/(a)$. It follows from (b) that the maps

$$\operatorname{Spec}(\phi) : \operatorname{Spec} A' \to \operatorname{Spec} A \qquad \operatorname{Spec}(\phi)_U : U \times_{\operatorname{Spec} A} \operatorname{Spec} A' \to U$$

are V-good, where $V = \operatorname{Spec} A[a^{-1}]$. Applying (c), we deduce that the map $\operatorname{Spec}(\phi) : \operatorname{Spec} A' \to \operatorname{Spec} A$ is U-good.

(e) Let $p : X'' \to X'$ and $q : X' \to X$ be affine morphisms in $\mathrm{Sch}_R^{\text{ét}}$ and let $U \subseteq X$ be a quasi-compact open subscheme. Suppose that p is $(U \times_X X')$-good. Then q is U-good if and only if $(q \circ p) : X'' \to X$ is U-good. To prove this, we observe that there is a commutative diagram

$$\begin{array}{ccc} \mathscr{F}(X) & \longrightarrow & \mathscr{F}(U) \\ \downarrow & & \downarrow \\ \mathscr{F}(X') & \longrightarrow & \mathscr{F}(U \times_X X') \\ \downarrow & & \downarrow \\ \mathscr{F}(X'') & \longrightarrow & \mathscr{F}(U \times_X X''), \end{array}$$

where the bottom square is a pullback by virtue of our assumption that p is $(U \times_X X')$-good. It follows that the upper square is a pullback if and only if the outer rectangle is a pullback.

(f) We now treat the general case. Let $p : X' \to X$ be an affine morphism in $\mathrm{Sch}_R^{\text{ét}}$ and let $U \subseteq X$ be a quasi-compact open subscheme for which p induces an isomorphism $X' \times_X (X - U) \to X - U$. We wish to prove that p is U-good. Using (a), we can reduce to the case where $X = \operatorname{Spec} A$ is affine, so that we can identify X' with $\operatorname{Spec} A'$ for some étale A-algebra A'. Since $U \subseteq \operatorname{Spec} A$ is quasi-compact, we can choose a finitely generated ideal $I \subseteq A$ such that U is the complement of the vanishing locus of I. Choose a set of generators $a_1, \ldots, a_n$ for the ideal I. Our assumption on p guarantees that the map $A/I \to A'/IA'$ is an isomorphism. Applying Lemma B.5.1.3 repeatedly, we deduce that there is a sequence of étale morphisms

$$A = A_0 \to A_1 \to \cdots \to A_n,$$

which induce isomorphisms $A_{i-1}/(a_i) \to A_i/(a_i)$ for $i \leqslant n$ and an A-algebra homomorphism $\rho : A' \to A_n$. It follows from (d) that each of the morphisms $\operatorname{Spec} A_{i+1} \to \operatorname{Spec} A_i$ is $(U \times_X \operatorname{Spec} A_i)$-good. Applying (e) repeatedly, we deduce that the composite map $q : \operatorname{Spec} A_n \to X$ is U-good. Set $A'_i = A' \otimes_A A_i$. Repeating the preceding argument, we deduce that the map $q' : \operatorname{Spec} A'_n \to X'$ is $(U \times_X X')$-good. We have a commutative diagram

$$\begin{array}{ccc} \operatorname{Spec} A'_n & \xrightarrow{q'} & X' \\ \downarrow{\scriptstyle p'} & & \downarrow{\scriptstyle p} \\ \operatorname{Spec} A_n & \xrightarrow{q} & X \end{array}$$

is a pullback. The ring homomorphism ρ determines a map $s : \operatorname{Spec} A_n \to \operatorname{Spec} A'_n$ which is a section of p' Since p' is étale, the map s is the inclusion of a direct summand: in particular, it induces an isomorphism from $\operatorname{Spec} A_n$ to the open subscheme $V \subseteq \operatorname{Spec} A'_n$ complementary to the vanishing locus of an idempotent element $e \in A'_n$. Since p' and s are isomorphisms away from the inverse image of U, we have $e \subseteq IA'_n$. Applying (d), we deduce that the map s is $(U \times_X A'_n)$-good. Since the identity map $\mathrm{id} : \operatorname{Spec} A_n \to \operatorname{Spec} A_n$ is $(U \times_X \operatorname{Spec} A_n)$-good, it follows from (e) that the map p' is $(U \times_X \operatorname{Spec} A_n)$-good. Applying (e) again, we deduce that the composition $(q \circ p') : \operatorname{Spec} A'_n \to X$ is U-good. Using the equality $q \circ p' = p \circ q'$, another application of (e) shows that p is U-good, as desired.

□

B.5.2 Weak Connectivity

Our strategy for proving Theorem B.5.0.3 is to use formal arguments to reduce to the following special case:

Proposition B.5.2.1. *Let R be a Noetherian ring of finite Krull dimension, let $X \in \mathrm{Sch}_R^{\acute{e}t}$, and let $\theta : \mathscr{F} \to h_X$ be a natural transformation of functors $\mathscr{F}, h_X : \mathrm{CAlg}_R^{\acute{e}t} \to \mathcal{S}$. Assume that $\mathscr{F}$ satisfies Nisnevich excision and that θ exhibits h_X as the sheafification of $\mathscr{F}$ with respect to the Nisnevich topology. Then θ admits a section.*

Our proof of Proposition B.5.2.1 involves some auxiliary considerations. We begin by introducing a "perverse" connectivity condition on $\mathcal{S}$-valued sheaves.

Notation B.5.2.2. Let X be a Noetherian scheme. For every point $x \in X$, we let $\mathrm{ht}(x)$ denote the dimension of the local ring $\mathcal{O}_{X,x}$. Note that if $X = \operatorname{Spec} R$ is the spectrum of a commutative ring R, then $\mathrm{ht}(x)$ is the height of the prime ideal $\mathfrak{p} \subseteq R$ corresponding to x.

Definition B.5.2.3. Let R be a Noetherian ring, let $X \in \mathrm{Sch}_R^{\text{ét}}$, and suppose are given a map $\theta : \mathscr{F} \to h_X$ in $\mathrm{Fun}(\mathrm{CAlg}_R^{\text{ét}}, \mathcal{S})$. For every morphism $f : U \to X$ in $\mathrm{Sch}_R^{\text{ét}}$, let $\mathscr{F}_f(U)$ denote the fiber product $\mathscr{F}(U) \times_{h_X(U)} \{f\}$. Let $n \geqslant -1$ be an integer. We will say that θ is *weakly n-connective* if if the following condition is satisfied:

- $(*)$ Let $f : U \to X$ be a morphism in $\mathrm{Sch}_R^{\text{ét}}$, let $x \in U$ be a point, and suppose we are given a map of spaces $S^k \to \mathscr{F}_f(U)$, where $-1 \leqslant k < n - \mathrm{ht}(x)$. Then there exists a map $g : U' \to U$ in $\mathrm{Sch}_R^{\text{ét}}$ and a point $x' \in U$ with $g(x') = x$ such that g induces an isomorphism of residue fields $\kappa(x) \to \kappa(x')$ and the composite map $S^k \to \mathscr{F}_f(U) \to \mathscr{F}_{f \circ g}(U')$ is nullhomotopic (when $k = -1$, this means that $\mathscr{F}_{f \circ g}(U')$ is nonempty).

Remark B.5.2.4. In the situation of Definition B.5.2.3, suppose that $\theta : \mathscr{F} \to h_X$ is weakly n-connective. For every morphism $U \to X$ in $\mathrm{Sch}_R^{\text{ét}}$, the pullback map $\mathscr{F} \times_{h_X} h_U \to h_U$ is also weakly n-connective.

We now summarize some of the features of Definition B.5.2.3 that will be used in the proof of Theorem B.5.0.3.

Lemma B.5.2.5. *Let R be a Noetherian ring, let $X \in \mathrm{Sch}_R^{\acute{e}t}$, let $\theta : \mathscr{F} \to h_X$ be a morphism in $\mathrm{Fun}(\mathrm{CAlg}_R^{\acute{e}t}, \mathcal{S})$, and let $n \geqslant 0$ be a nonnegative integer. Then θ is weakly n-connective if and only if the following conditions are satisfied:*

1. *For every map $f : U \to X$ in $\mathrm{Sch}_R^{\acute{e}t}$ and every point $x \in U$ of height $\leqslant n$, there exists a map $g : U' \to U$ in $\mathrm{Sch}_R^{\acute{e}t}$ and a point $x' \in U'$ such that $x = g(x')$, the map of residue fields $\kappa(x) \to \kappa(x')$ is an isomorphism, and $\mathscr{F}_{f \circ g}(U')$ is nonempty.*

(2) *If $n > 0$, then for every pair of maps $h_U \to \mathscr{F}$, $h_V \to \mathscr{F}$ in* $\mathrm{Fun}(\mathrm{CAlg}_R^{\acute{e}t}, \mathcal{S})$*, the induced map*

$$h_U \times_{\mathscr{F}} h_V \to h_U \times_{h_X} h_V \simeq h_{U \times_X V}$$

is $(n-1)$-connective.

Proof. Suppose first that θ is weakly n-connective. Condition (1) is obvious (take $k = -1$ in Definition B.5.2.3). To prove (2), assume that $n > 0$ and that we are given maps $\alpha : h_U \to \mathscr{F}$, $\beta : h_V \to \mathscr{F}$. We wish to show that the map $\theta' : h_U \times_{\mathscr{F}} h_V \to h_{U \times_X V}$ satisfies condition $(*)$ of Definition B.5.2.3. To this end, suppose we are given a map $f : W \to U \times_X V$ in $\mathrm{Sch}_R^{\text{ét}}$, a point $x \in W$, and a map of spaces $\eta : S^k \to \mathscr{F}'_f(W)$, where $\mathscr{F}' = h_U \times_{\mathscr{F}} h_V$ such that $-1 \leqslant k < n - 1 - \mathrm{ht}(x)$. Let f' be the induced map $W \to X$. Note that $\mathscr{F}'_f(W)$ can be identified with the space of paths joining the two points of $\mathscr{F}_{f'}(W)$ determined by α and β. Consequently, η determines a map $\eta_0 : S^{k+1} \to \mathscr{F}_{f'}(W)$. Using our assumption that θ is weakly n-connective, we can choose a map $g : W' \to W$ and a point $x' \in W'$ such that $g(x') = x$, $\kappa(x) \simeq \kappa(x')$, and the composite map

$$S^{k+1} \xrightarrow{\eta_0} \mathscr{F}_{f'}(W) \to \mathscr{F}_{f' \circ g}(W')$$

is nullhomotopic. Since $\mathscr{F}'_{f \circ g}(W')$ is homotopy equivalent to the space of paths in $\mathscr{F}_{f' \circ g}(W')$ joining the points determined by α and β, we deduce that the composite map $S^k \xrightarrow{\eta} \mathscr{F}'_f(W) \to \mathscr{F}'_{f \circ g}(W')$ is also nullhomotopic, as desired.

Now suppose that conditions (1) and (2) are satisfied. We must show that θ satisfies condition $(*)$ of Definition B.5.2.3. Choose a map $f : U \to X$ in $\mathrm{Sch}_R^{\text{ét}}$, a point $x \in U$, and a map of spaces $\eta : S^k \to \mathscr{F}_f(U)$, where $-1 \leqslant k < n - \mathrm{ht}(x)$. We wish to prove that there exists a map $g : U' \to U$ and a point $x' \in U'$ such that $g(x') = x$, $\kappa(x) \simeq \kappa(x')$, and the composite map $S^k \to \mathscr{F}_f(U) \to \mathscr{F}_{f \circ g}(U')$ is nullhomotopic. If $k = -1$, this follows from condition (1). Otherwise, we can write S^k as a homotopy pushout $* \coprod_{S^{k-1}} *$. Then η determines a pair of maps $\alpha, \beta : h_U \to \mathscr{F}$ such that $\theta \circ \alpha$ and $\theta \circ \beta$ are induced by f. Let $\mathscr{F}' = h_U \times_{\mathscr{F}} h_U$. The restriction of η to the equator of S^k gives a map $S^{k-1} \to \mathscr{F}'_\delta(U)$, where $\delta : U \to U \times_X U$ is the diagonal map. Using condition (2), we deduce the existence of a map $g : U' \to U$ and a point $x' \in U'$ such that $g(x') = x$, $\kappa(x) \simeq \kappa(x')$, and the induced map $S^{k-1} \to \mathscr{F}'_\delta(U) \to \mathscr{F}'_{\delta g}(U')$ is nullhomotopic. Unwinding the definitions, we deduce that $S^k \to \mathscr{F}_f(U) \to \mathscr{F}_{f \circ g}(U')$ is nullhomotopic, as desired. □

Lemma B.5.2.6. *Let R be a Noetherian ring, let $X \in \mathrm{Sch}_R^{\acute{e}t}$, and let $\theta : \mathscr{F} \to h_X$ be a morphism in* $\mathrm{Fun}(\mathrm{CAlg}_R^{\acute{e}t}, \mathcal{S})$*. Suppose that θ exhibits h_X as the sheafification of $\mathscr{F}$ with respect to the Nisnevich topology. Then θ is weakly n-connective for each $n \geqslant 0$.*

Proof. The proof proceeds by induction on n. We will show that θ satisfies the criteria of Lemma B.5.2.5. Condition (1) follows immediately from our assumption that θ is an effective epimorphism after Nisnevich sheafificiation. To verify (2), we may assume that $n > 0$. Choose maps $h_U \to \mathscr{F}$ and $h_V \to \mathscr{F}$. Since sheafification is left exact, the induced map $\theta' : h_U \times_{\mathscr{F}} h_V \to h_{U \times_X V}$ exhibits $h_{U \times_X V}$ as the sheafification of $h_U \times_{\mathscr{F}} h_V$ with respect to the Nisnevich topology. It follows from the inductive hypothesis that θ' is weakly $(n-1)$-connective, as desired. □

Lemma B.5.2.7. *Let R be a Noetherian ring, let $X \in \mathrm{Sch}_R^{\acute{e}t}$, and let $\theta : \mathscr{F} \to h_X$ be a weakly n-connective morphism in $\mathcal{C} = \mathrm{Fun}(\mathrm{CAlg}_R^{\mathrm{cn}}, \mathcal{S})$. Assume that $\mathscr{F}$ satisfies Nisnevich excision. Then there exists a finite set of points $x_1, \ldots, x_m \in X$ of height $> n$ and a commutative diagram*

$$\begin{array}{ccc} & \mathscr{F} & \\ \nearrow & & \searrow^{\theta} \\ h_U & \longrightarrow & h_X \end{array}$$

where $U = X - \bigcup_{1 \leqslant i \leqslant m} \overline{\{x_i\}}$.

Proof. The proof proceeds by induction on n. When $n = -1$, we take $x_1, \ldots, x_m$ to be the set of generic points of X, so that $U = \emptyset$ and the existence of the desired map $h_U \to \mathscr{F}$ follows from our assumption that $\mathscr{F}(0)$ is contractible. Assume now that $n \geqslant 0$ and that the result is known for the integer $n-1$, so that we can choose a commutative diagram

$$\begin{array}{ccc} & \mathscr{F} & \\ {}^{\phi}\nearrow & & \searrow^{\theta} \\ h_U & \longrightarrow & h_X \end{array}$$

where $U = X - \bigcup_{1 \leqslant i \leqslant m} \overline{\{x_i\}}$ where the points x_i have height $\geqslant n$. Reordering the points x_i if necessary, we may assume that $x_1, x_2, \ldots, x_k$ have height n while $x_{k+1}, \ldots, x_m$ have height $> n$. We assume that this data has been chosen so that k is as small as possible. We will complete the induction by showing that $k = 0$. Otherwise, the point x_1 has height n. Since θ is weakly n-connective, there exists a map $f : X' \to X$ and a point $x' \in X'$ such that $f(x') = x_1$, $\kappa(x) \simeq \kappa(x')$, and $\mathscr{F}_f(X')$ is nonempty. We may therefore choose a commutative diagram

$$\begin{array}{ccc} & \mathscr{F} & \\ {}^{\psi}\nearrow & & \searrow^{\theta} \\ h_{X'} & \xrightarrow{f} & h_X \end{array}$$

Replacing X' by an open subset if necessary, we may suppose that f induces an isomorphism from $f^{-1}\overline{\{x_1\}}$ to an open subset $V \subseteq \overline{\{x_1\}}$ (here we endow these closed subsets with the reduced scheme structure). Set $U' = U \times_X X'$. Our maps $\phi : h_U \to \mathscr{F}$ and $\psi : h_{X'} \to \mathscr{F}$ determine a map $\theta' : h_U \times_{\mathscr{F}} h_{X'} \to h_{U'}$. Using Lemma B.5.2.5, we see that θ' is weakly

$(n-1)$-connective. Applying the inductive hypothesis, we deduce that there exists a finite collection of points $y_1, \ldots, y_{m'} \in U'$ of height $\geqslant n$ and a commutative diagram

$$\begin{array}{ccccc} & & h_U \times_{\mathscr{F}} h_{X'} & & \\ & \nearrow & & \searrow & \\ h_W & & \longrightarrow & & h_{U'}, \end{array}$$

where W is the open subscheme $U' - \bigcup \overline{\{y_j\}}$ of U'. Replacing X' by the open subscheme $X' - \bigcup \overline{\{y_j\}}$ (which contains x', since x' is a point of height n and therefore cannot lie in the closure of any other point of height n), we may assume that $W = U'$, so that the maps $h_U \xrightarrow{\phi} \mathscr{F} \xleftarrow{\psi} h_{X'}$ induce homotopic maps from $h_{U'}$ into $\mathscr{F}$. Shrinking X' further if necessary, we may assume that X' is affine (so that the map $X' \to X$ is affine). Regard $U \cup V$ as an open subscheme of X; since $\mathscr{F}$ satisfies Nisnevich excision, the diagram

$$\begin{array}{ccc} \mathscr{F}(U \cup V) & \longrightarrow & \mathscr{F}(X') \\ \downarrow & & \downarrow \\ \mathscr{F}(U) & \longrightarrow & \mathscr{F}(U') \end{array}$$

is a pullback square in $\mathcal{S}$ (Proposition B.5.1.1). It follows that ϕ extends to a map ϕ' fitting into a commutative diagram

$$\begin{array}{ccccc} & & \mathscr{F} & & \\ & \overset{\phi'}{\nearrow} & & \overset{\theta}{\searrow} & \\ h_{U \cup V} & & \longrightarrow & & h_X, \end{array}$$

contradicting the minimality of k. □

Proof of Proposition B.5.2.1. Combine Lemmas B.5.2.6 and B.5.2.7. □

Remark B.5.2.8. Using Lemma B.5.2.7, one can show that if R is a Noetherian ring of Krull dimension $\leqslant n$, then the ∞-topos $\mathcal{S}\mathrm{hv}_R^{\mathrm{Nis}}$ has homotopy dimension $\leqslant n$. We will prove a more general version of this assertion in §3.7 (see Theorem 3.7.7.1).

B.5.3 The Proof of Theorem B.5.0.3

We now explain how to deduce Theorem B.5.0.3 from Proposition B.5.2.1. Our first step is to show that it suffices to treat the case where the commutative ring R is finitely generated over $\mathbf{Z}$ (and therefore a Noetherian ring of finite Krull dimension). This requires a brief digression about functoriality.

Notation B.5.3.1. Let $f : R' \to R$ be a homomorphism of commutative rings. Then f induces determines a pushforward functor $f_* : \mathrm{Fun}(\mathrm{CAlg}_R^{\text{ét}}, \mathcal{S}) \to \mathrm{Fun}(\mathrm{CAlg}_{R'}^{\text{ét}}, \mathcal{S})$, given by the formula $(f_* \mathscr{F})(A) = \mathscr{F}(R' \otimes_R A)$.

Lemma B.5.3.2. *Let R be a commutative ring and let $\mathscr{F} : \mathrm{CAlg}_R^{\acute{e}t} \to \mathcal{S}$ be a functor. The following conditions are equivalent:*

(1) *The functor $\mathscr{F}$ is a sheaf with respect to the Nisnevich topology.*

(2) *For every homomorphism of commutative rings $f : R' \to R$, the direct image $f_* \mathscr{F} \in \mathrm{Fun}(\mathrm{CAlg}_{R'}^{\acute{e}t}, \mathcal{S})$ is a sheaf for the Nisnevich topology.*

(3) *For every homomorphism of commutative rings $f : R' \to R$ where R' is finitely generated the direct image $f_* \mathscr{F} \in \mathrm{Fun}(\mathrm{CAlg}_{R'}^{\acute{e}t}, \mathcal{S})$ is a sheaf for the Nisnevich topology.*

Proof. The implications (1) ⇒ (2) ⇒ (3) are obvious. The implication (3) ⇒ (1) follows from the criterion of Proposition A.3.3.1, since for every étale ring homomorphism $R \to A$ which exhibits A as a Nisnevich covering of R, we can write $A = R \otimes_{R_0} A_0$ for some finitely generated subring $R_0 \subseteq R$, where A_0 is an étale R_0-algebra which is a Nisnevich covering of R_0. □

Lemma B.5.3.3. *Let R be a Noetherian ring of finite Krull dimension, let $X \in \mathrm{Sch}_R^{\acute{e}t}$, and let $\theta : \mathscr{F} \to h_X$ be a morphism in $\mathcal{C} = \mathrm{Fun}(\mathrm{CAlg}_R^{\acute{e}t}), \mathcal{S})$. Assume that $\mathscr{F}$ satisfies Nisnevich excision and that θ exhibits h_X as the Nisnevich sheafification of $\mathscr{F}$. Then the mapping space $\mathrm{Map}_{\mathcal{C}_{/h_X}}(h_X, \mathscr{F})$ is contractible.*

Proof. We will prove by induction on k that the mapping space $\mathrm{Map}_{\mathcal{C}_{/h_X}}(h_X, \mathscr{F})$ is k-connective. If $k > 0$, then it suffices to show that for every pair of maps $f, g : h_X \to \mathscr{F}$ in $\mathcal{C}_{/h_X}$, the mapping space $\mathrm{Map}_{\mathcal{C}_{/h_X}}(h_X, h_X \times_{\mathscr{F}} h_X)$ is $(k-1)$-connective, which follows from our inductive hypothesis (and the left exactness of sheafification). It will therefore suffice to treat the case $k = 0$, which follows from Proposition B.5.2.1. □

Proof of Theorem B.5.0.3. Suppose first that $\mathscr{F} : \mathrm{CAlg}_R^{\text{ét}}$ is a sheaf with respect to the Nisnevich topology: we claim that $\mathscr{F}$ satisfies Nisnevich excision. Using Example B.4.1.4, we see that the empty sieve is a covering of the zero ring $0 \in \mathrm{CAlg}_R^{\text{ét}}$, so that the space $\mathscr{F}(0)$ is contractible. To verify the second condition of Definition B.5.0.1, let us suppose we are given a morphism $\phi : A \to A'$ of étale R-algebras and an element $a \in A$ for which ϕ induces an isomorphism $A/(a) \to A'/(a)$. We wish to show that the diagram

$$\begin{array}{ccc} \mathscr{F}(A) & \longrightarrow & \mathscr{F}(A') \\ \downarrow & & \downarrow \\ \mathscr{F}(A[a^{-1}]) & \longrightarrow & \mathscr{F}(A'[a^{-1}]) \end{array}$$

is a pullback square.

Let $\mathcal{C} \subseteq \mathrm{CAlg}^{\text{ét}}_A$ be the sieve generated by the morphisms $A \to A'$ and $A \to A[a^{-1}]$. By assumption, this sieve is covering for the Nisnevich topology, so the assumption that $\mathscr{F}$ is a sheaf for the Nisnevich topology guarantees that the natural map $\mathscr{F}(A) \to \varprojlim \mathscr{F}|_{\mathcal{C}}$ is a homotopy equivalence.

Let $A^\bullet$ denote the augmented cosimplicial object of $\mathrm{CAlg}^{\text{ét}}_R$ given by the Čech nerve of ϕ, so that $A^{-1} \simeq A$ and $A^0 \simeq A'$. Localizing with respect to the element $a \in A = A^{-1}$ gives a map of augmented cosimplicial R-algebras $A^\bullet \to A^\bullet[a^{-1}]$, which we identify with a functor $\rho : \mathbf{\Delta}_+ \times \Delta^1 \to \mathrm{CAlg}^{\text{ét}}_R$. Let $\mathcal{J} \subseteq \mathbf{\Delta}_+ \times \Delta^1$ be the subcategory obtained by omitting the initial object, so that we can identify ρ with a functor $\rho' : \mathcal{J} \to \mathrm{CAlg}^{\text{ét}}_A$. Note that ρ' factors through $\mathcal{C}$. We claim that the map $\phi' : \mathcal{J} \to \mathcal{C}$ is right cofinal. We will prove this using the criterion of Theorem HTT.4.1.3.1 : it suffices to show that if B is an étale A-algebra which belongs to the sieve $\mathcal{C}$, then the ∞-category $\mathcal{J} \times_{\mathcal{C}} \mathcal{C}_{/B}$ is weakly contractible. Note that the projection map $\mathcal{J} \times_{\mathcal{C}} \mathcal{C}_{/B} \to \mathcal{J}$ is a right fibration which is classified by the functor $\psi : \mathcal{J}^{\mathrm{op}} \to \mathcal{S}$ given by the formula $\psi([n], i) = \mathrm{Map}_{\mathrm{CAlg}^{\text{ét}}_A}(\psi([n], i), B)$. By virtue of Proposition HTT.3.3.4.5 , the statement that $\mathcal{J} \times_{\mathcal{C}} \mathcal{C}_{/B}$ is weakly contractible is equivalent to the statement that the colimit $\varinjlim \psi \in \mathcal{S}$ is contractible. There are two cases to consider:

- (i) Suppose that the image of $a \in A$ is an invertible element of B. Then the canonical map $\mathrm{Map}_{\mathrm{CAlg}^{\text{ét}}_A}(A^n[a^{-1}], B) \to \mathrm{Map}_{\mathrm{CAlg}^{\text{ét}}_A}(A^n, B)$ is invertible for $n \geqslant 0$, so the functor ψ is a left Kan extension of its restriction to $(\mathbf{\Delta}_+ \times \{1\})^{\mathrm{op}} \subseteq \mathcal{J}^{\mathrm{op}}$. This subcategory has a final object $([-1], 1)$, so we can identify $\varinjlim \psi$ with the space $\psi([-1], 1) = \mathrm{Map}_{\mathrm{CAlg}^{\text{ét}}_A}(A[a^{-1}], B)$, which is contractible.
- (ii) Suppose that the image of $(*)$ in (b) is not invertible. Then the mapping space $\mathrm{Map}_{\mathrm{CAlg}^{\text{ét}}_A}(A^n[a^{-1}], B)$ is empty for each $n \geqslant 0$, so the functor ψ is a left Kan extension of its restriction to the subcategory $(\mathbf{\Delta} \times \{0\})^{\mathrm{op}} \subseteq \mathcal{J}^{\mathrm{op}}$. We can therefore identify $\varinjlim(\psi)$ with the geometric realization of the simplicial space $X_\bullet = \mathrm{Map}_{\mathrm{CAlg}^{\text{ét}}_A}(A^\bullet, B)$ Note that $X_\bullet$ is the Čech nerve of the map $\mathrm{Map}_{\mathrm{CAlg}^{\text{ét}}_A}(A', B) \to *$, and is therefore contractible (since the assumptions that $B \in \mathcal{C}$ and $\mathrm{Map}_{\mathrm{CAlg}^{\text{ét}}_A}(A[a^{-1}], B) = \varnothing$ guarantee that $\mathrm{Map}_{\mathrm{CAlg}^{\text{ét}}_A}(A', B)$ is nonempty).

Consider the maps $\mathscr{F}(A) \to \varprojlim_{J \in \mathcal{J}} \mathscr{F}(\rho(J)) \to \varprojlim_{B \in \mathcal{C}} \mathscr{F}(B)$. Since ρ is right cofinal, the second map is a homotopy equivalence. Since $\mathscr{F}$ is a Nisnevich sheaf, the composite map is a homotopy equivalence. It follows that $\mathscr{F} \circ \rho$ is a limit diagram in $\mathcal{S}$. We have a canonical isomorphism $\mathcal{J} \simeq (\mathbf{\Delta}^{\mathrm{op}} \times \Delta^1) \coprod_{\mathbf{\Delta}^{\mathrm{op}} \times \{0\}} (\mathbf{\Delta}^{\mathrm{op}}_+ \times \{0\})$. Applying the results of §HTT.4.2.3 to this decomposition, we obtain an equivalence

$$\varprojlim_{J \in \mathcal{J}} \mathscr{F}(\rho(J)) \simeq \mathscr{F}(A[a^{-1}]) \times_{\varprojlim \mathscr{F}(A^\bullet[a^{-1}])} \varprojlim \mathscr{F}(A^\bullet).$$

Consider the diagram

$$\begin{array}{ccccc} \mathscr{F}(A) & \longrightarrow & \varprojlim \mathscr{F}(A^\bullet) & \longrightarrow & \mathscr{F}(A') \\ \downarrow & & \downarrow & & \downarrow \\ \mathscr{F}(A[a^{-1}]) & \longrightarrow & \varprojlim \mathscr{F}(A^\bullet[a^{-1}]) & \longrightarrow & \mathscr{F}(A'[a^{-1}]). \end{array}$$

The above argument shows that the square on the left is a pullback. We wish to show that the outer square is a pullback. It will therefore suffice to show that the square on the right is a pullback. We can identify this square with a limit of diagrams σ_n :

$$\begin{array}{ccc} \mathscr{F}(A^n) & \longrightarrow & \mathscr{F}(A') \\ \downarrow & & \downarrow \\ \mathscr{F}(A^n[a^{-1}]) & \longrightarrow & \mathscr{F}(A'[a^{-1}]) \end{array}$$

induced by the multiplication $m : A^n \simeq A' \otimes_A \cdots \otimes_A A' \to A$. Since A' is étale over A, the map m exhibits A' as a direct factor of A^n: that is, we have a product decomposition $A^n \simeq A' \times B$ for some auxiliary factor B. Because $\mathscr{F}$ commutes with finite products (since it is Nisnevich sheaf; see Proposition A.3.3.1), we can identify σ_n with the diagram

$$\begin{array}{ccc} \mathscr{F}(A') \times \mathscr{F}(B) & \longrightarrow & \mathscr{F}(A') \\ \downarrow & & \downarrow \\ \mathscr{F}(A'[a^{-1}]) \times \mathscr{F}(B[a^{-1}]) & \longrightarrow & \mathscr{F}(A'[a^{-1}]) \end{array}$$

To show that this diagram is a pullback square, it will suffice to show that the localization map $B \to B[a^{-1}]$ is an isomorphism. This follows from our assumption that ϕ induces an isomorphism $A/(a) \to A'/(a)$ (which guarantees that m has the same property, so that $B/(a) \simeq 0$). This completes the proof that every Nisnevich sheaf satisfies Nisnevich excision.

We now prove the converse. Suppose that $\mathscr{F} : \mathrm{CAlg}_R^{\text{ét}}$ satisfies Nisnevich excision. We will prove that $\mathscr{F}$ is a sheaf for the Nisneivch topology. Using Lemma B.5.3.2, we can reduce to the case where the commutative ring R is finitely generated; in particular, we may assume that R is a Noetherian ring of finite Krull dimension. Let $\mathscr{F}'$ be the sheafification of $\mathscr{F}$ with respect to the Nisnevich topology. The first part of the proof shows that $\mathscr{F}'$ satisfies Nisnevich excision. We will show that for each $X \in \mathrm{Sch}_R^{\text{ét}}$, the map $\mathscr{F}(X) \to \mathscr{F}'(X)$ is a homotopy equivalence. Fix a point $\eta \in \mathscr{F}'(X)$, corresponding to a map $h_X \to \mathscr{F}'$. Then the homotopy fiber of $\mathscr{F}(X) \to \mathscr{F}'(X)$ over the point η can be identified with the space of sections of the induced map $\theta : \mathscr{F} \times_{\mathscr{F}'} h_X \to h_X$. Note that $\mathscr{F} \times_{\mathscr{F}'} h_X$ satisfies Nisnevich excision (Remark B.5.0.2) and that θ exhibits h_X as the Nisnevich sheafification of $\mathscr{F} \times_{\mathscr{F}'} h_X$ (since sheafification is left exact). The desired result now follows from Lemma B.5.3.3. $\square$

B.6 Topologies on Ring Spectra

In §A.3, we described a general paradigm for producing examples of Grothendieck topologies on ∞-categories. In this section, we will apply this paradigm to describe several different topologies on (the opposite of) the ∞-category CAlg of $\mathbb{E}_\infty$-rings.

B.6.1 The Flat Topology

Let $\phi : A \to B$ be a morphism of $\mathbb{E}_\infty$-rings. Recall that ϕ is said to be *flat* if the following conditions are satisfied:

(i) The underlying ring homomorphism $\pi_0 A \to \pi_0 B$ exhibits $\pi_0 B$ as a flat A-module.

(ii) The morphism ϕ induces an isomorphism of graded rings

$$(\pi_0 B) \otimes_{\pi_0 A} (\pi_* A) \to \pi_* B.$$

We refer the reader to §HA.7.2.2 for a more extensive discussion of flat morphisms of $\mathbb{E}_\infty$-rings (as well as several reformulations of the preceding definition).

Definition B.6.1.1. Let $\phi : A \to B$ be a morphism of $\mathbb{E}_\infty$-rings. We will say that f is *faithfully flat* if it satisfies the following conditions:

(i') The underlying map of commutative rings $\pi_0 A \to \pi_0 B$ is faithfully flat, in the sense of classical commutative algebra.

(ii) The morphism ϕ induces an isomorphism of graded rings

$$(\pi_0 B) \otimes_{\pi_0 A} (\pi_* A) \to \pi_* B.$$

Remark B.6.1.2. Let $f : A \to B$ be a faithfully flat morphism of $\mathbb{E}_\infty$-rings. A morphism $M \to N$ of A-modules is an equivalence if and only if the induced map $M \otimes_A B \to N \otimes_A B$ is an equivalence. This follows immediately from Corollary HA.7.2.1.22 .

Proposition B.6.1.3. *Let R be an $\mathbb{E}_\infty$-ring. Then there exists a Grothendieck topology on the ∞-category $\mathrm{CAlg}_R^{\mathrm{op}}$ which can be characterized as follows: if A is an $\mathbb{E}_\infty$-algebra over R, then a sieve $\mathcal{C} \subseteq (\mathrm{CAlg}_R^{\mathrm{op}})_{/A} \simeq \mathrm{CAlg}_A^{\mathrm{op}}$ is a covering if and only if it contains a finite collection of morphisms $\{A \to A_i\}_{1 \leqslant i \leqslant n}$ for which the induced map $A \to \prod_{1 \leqslant i \leqslant n} A_i$ is faithfully flat.*

Remark B.6.1.4. We will refer to the Grothendieck topology of Proposition B.6.1.3 as the *fpqc topology* on $\mathrm{CAlg}_R^{\mathrm{op}}$. We will often abuse terminology by referring to the fpqc topology on the ∞-category CAlg_R, rather than its opposite category.

Warning B.6.1.5. Let R be an $\mathbb{E}_\infty$-ring. Then the ∞-category $\mathrm{CAlg}_R^{\mathrm{op}}$ is not small. Consequently, though it makes sense to consider the ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{fpqc}}(\mathrm{CAlg}_R^{\mathrm{op}}) \subseteq \mathrm{Fun}(\mathrm{CAlg}_R, \mathcal{S})$ of $\mathcal{S}$-valued sheaves on $\mathrm{CAlg}_R^{\mathrm{op}}$, it is not clear that $\mathcal{S}\mathrm{hv}_{\mathrm{fpqc}}(\mathrm{CAlg}_R^{\mathrm{op}})$ is a localization of $\mathrm{Fun}(\mathrm{CAlg}_R, \mathcal{S})$. In concrete terms, the danger is that the process of sheafification with respect to the fpqc topology might produce spaces which are not essentially small.

Proof of Proposition B.6.1.3. Let S be the collection of faithfully flat morphisms in $\mathrm{CAlg}_R^{\mathrm{op}}$. We will show that S satisfies each of the hypotheses of Proposition A.3.2.1:

(a) The collection of faithfully flat morphisms in CAlg_R contains all equivalences and is stable under composition. The first assertion is obvious. To prove the second, consider a pair of faithfully flat morphisms $A \xrightarrow{f} B \xrightarrow{g} C$; we wish to prove that $g \circ f$ is faithfully flat. The underlying map $\pi_0 A \to \pi_0 C$ is a composition of faithfully flat morphisms of commutative rings, and therefore faithfully flat. The map $\mathrm{Tor}_0^{\pi_0 A}(\pi_0 C, \pi_i A) \to \pi_i C$ factors as a composition

$$\begin{aligned} \mathrm{Tor}_0^{\pi_0 A}(\pi_0 C, \pi_i A) &\simeq \mathrm{Tor}_0^{\pi_0 B}(\pi_0 C, \mathrm{Tor}_0^{\pi_0 A}(\pi_0 B, \pi_i A)) \\ &\xrightarrow{\alpha} \mathrm{Tor}_0^{\pi_0 B}(\pi_0 C, \pi_i B) \\ &\xrightarrow{\beta} \pi_i C. \end{aligned}$$

The map α is an isomorphism because f is faithfully flat, and the map β is an isomorphism because g is faithfully flat.

(b) It is clear that the ∞-category $\mathrm{CAlg}_R^{\mathrm{op}}$ admits pullbacks (the ∞-category CAlg_R of $\mathbb{E}_\infty$-rings is presentable and therefore admits all small limits and colimits). It therefore suffices to show that if we are given a diagram $A' \xleftarrow{g} A \xrightarrow{f} B$, where f is faithfully flat, then the induced map $A' \to B \otimes_A A'$ is faithfully flat. Since B is flat over A, Proposition HA.7.2.2.13 guarantees that the canonical maps $\gamma_i : \mathrm{Tor}_0^{\pi_0 A}(\pi_0 B, \pi_i A') \to \pi_i(B \otimes_A A')$ is an isomorphism. Taking $i = 0$, we deduce that $\pi_0(B \otimes_A A')$ is a pushout of $\pi_0 B$ and $\pi_0 A'$ over $\pi_0 A$, and therefore faithfully flat over $\pi_0 A'$. Moreover, the canonical map

$$\mathrm{Tor}_0^{\pi_0 A'}(\pi_0(B \otimes_A A'), \pi_i A') \to \pi_i(B \otimes_A A')$$

factors as a composition

$$\begin{aligned} \mathrm{Tor}_0^{\pi_0 A'}(\pi_0(B \otimes_A A'), \pi_i A') &\overset{\gamma_0^{-1}}{\simeq} \mathrm{Tor}_0^{\pi_0 A'}(\mathrm{Tor}_0^{\pi_0 A}(\pi_0 A', \pi_0 B), \pi_i A') \\ &\simeq \mathrm{Tor}_0^{\pi_0 A}(\pi_0 B, \pi_i A') \\ &\xrightarrow{\gamma_i} \pi_i(B \otimes_A A'). \end{aligned}$$

and is therefore an isomorphism.

(c) It is clear that the category $\mathrm{CAlg}_R^{\mathrm{op}}$ admits finite coproducts, which are given by products of the corresponding $\mathbb{E}_\infty$-algebras over R. We must show that if we are given a finite collection of faithfully flat morphisms $A_i \to B_i$ and we define $A = \prod_i A_i$ and $B = \prod_i B_i$, then the induced map $A \to B$ is also faithfully flat. We have $\pi_0 A = \prod_i \pi_0 A_i$ and $\pi_0 B \simeq \prod_i \pi_0 B_i$. Since a product of faithfully flat morphisms of commutative rings is faithfully flat, we deduce that the map $\pi_0 A \to \pi_0 B$ is faithfully flat. For the other homotopy groups, we have

$$\begin{aligned}
\pi_n B &\simeq \prod_i (\pi_n B_i) \\
&\simeq \prod_i \mathrm{Tor}_0^{\pi_0 A_i}(\pi_0 B_i, \pi_n A_i) \\
&\simeq \mathrm{Tor}_0^{\prod_i \pi_0 A_i}(\prod_i \pi_0 B_i, \prod_i \pi_n A_i) \\
&\simeq \mathrm{Tor}_0^{\pi_0 A}(\pi_0 B, \pi_n A)
\end{aligned}$$

as required.

(d) Given a finite collection of morphisms $A \to A_i$ and a morphism $A \to B$ in CAlg_R, we must show that the canonical map

$$(\prod_i A_i) \otimes_A B \to \prod_i (A_i \otimes_A B)$$

is an equivalence of $\mathbb{E}_\infty$-rings. We will show that this map is an equivalence in the ∞-category of B-modules. For this, it suffices to observe that the functor $F : \mathrm{Mod}_A \to \mathrm{Mod}_B$ given by $M \mapsto M \otimes_A B$ preserves finite limits. The functor F evidently preserves small colimits, and therefore also finite limits because the ∞-categories Mod_A and Mod_B are stable (Proposition HA.1.1.4.1).

□

Remark B.6.1.6. Let R be an $\mathbb{E}_\infty$-ring. The ∞-category $\mathrm{CAlg}_R^{\mathrm{op}}$ satisfies the additional hypothesis (e) (disjointness of coproducts) appearing in Proposition A.3.3.1. In other words, for any pair of $\mathbb{E}_\infty$-rings A and B, the relative tensor product $A \otimes_{A \times B} B$ is vanishes. To prove this, we observe that the identity element of $\pi_0(A \times B) \simeq \pi_0 A \times \pi_0 B$ can be written as a sum $e + e'$, where $e = (1, 0)$ and $e' = (0, 1)$. The image of e is trivial in $\pi_0 B$, and the image of e' is trivial in $\pi_0 A$. It follows that e and e' both have trivial image in the commutative ring $R = \pi_0(A \otimes_{A \times B} B)$, so that $1 = 0$ in R. Since every homotopy group of $A \otimes_{A \times B} B$ is a module over R, each of these groups is trivial.

Variant B.6.1.7. Let R be a *connective* $\mathbb{E}_\infty$-ring. Then Proposition B.6.1.3 has an obvious analogue for the ∞-category $\mathrm{CAlg}_R^{\mathrm{cn}}$ of *connective* $\mathbb{E}_\infty$-algebras over R, which can be proven in exactly the same way. We will refer to the resulting Grothendieck topology on $(\mathrm{CAlg}_R^{\mathrm{cn}})^{\mathrm{op}}$ also as the *fpqc topology*.

B.6.2 The (Small) Étale and Nisnevich Sites

Let R be an $\mathbb{E}_\infty$-ring. We let $\mathrm{CAlg}_R^{\text{ét}}$ denote the full subcategory of CAlg_R spanned by the étale R-algebras. We have the following analogue of Proposition B.6.1.3:

Proposition B.6.2.1. *Let R be an $\mathbb{E}_\infty$-ring. Then there exists a Grothendieck topology on the ∞-category $(\mathrm{CAlg}_R^{\acute{e}t})^{\mathrm{op}}$ which can be characterized as follows: if A is an $\mathbb{E}_\infty$-algebra over R, then a sieve $\mathcal{C} \subseteq (\mathrm{CAlg}_R^{\acute{e}t})^{\mathrm{op}}_{/A} \simeq (\mathrm{CAlg}_A^{\acute{e}t})^{\mathrm{op}}$ is a covering if and only if it contains a finite collection of morphisms $\{A \to A_i\}_{1 \leqslant i \leqslant n}$ for which the induced map $A \to \prod_{1 \leqslant i \leqslant n} A_i$ is faithfully flat.*

Proof. It will suffice to show that the collection of faithfully flat étale morphisms in $(\mathrm{CAlg}_R^{\text{ét}})^{\mathrm{op}}$ satisfies hypotheses (a) through (d) of Proposition A.3.2.1, which follows immediately from the proof of Proposition B.6.1.3 (together with the observation that the forgetful functor $\mathrm{CAlg}_R^{\text{ét}} \to \mathrm{CAlg}$ preserves pushouts and finite products). □

Definition B.6.2.2. Let R be an $\mathbb{E}_\infty$-ring. We will refer to the Grothendieck topology described in Proposition B.6.2.1 as the *étale topology* on $(\mathrm{CAlg}_R^{\text{ét}})^{\mathrm{op}}$. We let $\mathcal{S}\mathrm{hv}_R^{\text{ét}}$ denote the full subcategory of $\mathrm{Fun}(\mathrm{CAlg}_R^{\text{ét}}, \mathcal{S})$ spanned by those functors which are sheaves for the étale topology. We will refer to $\mathcal{S}\mathrm{hv}_R^{\text{ét}}$ as the *∞-topos of étale sheaves over R.*

Remark B.6.2.3. Let R be an $\mathbb{E}_\infty$-ring, let $\mathcal{C}$ be an ∞-category, and let $\mathscr{F} : \mathrm{CAlg}_R^{\mathrm{op}} \to \mathcal{C}$ be a functor. Suppose that $\mathscr{F}$ is a $\mathcal{C}$-valued sheaf for the fpqc topology of Proposition B.6.1.3. Then, for every $\mathbb{E}_\infty$-algebra A over R, the composite map

$$\mathscr{F}_A : \mathrm{CAlg}_A^{\text{ét}} \to \mathrm{CAlg}_R \xrightarrow{\mathscr{F}} \mathcal{C}$$

is a $\mathcal{C}$-valued sheaf for the étale topology of Proposition B.6.2.1. Moreover, if $\mathscr{F}$ is hypercomplete, then each $\mathscr{F}_R$ is hypercomplete. This follows immediately from the criteria given in Propositions A.3.3.1 and A.5.7.2.

Variant B.6.2.4. Let R be an $\mathbb{E}_\infty$-ring. Then there exists a Grothendieck topology on the ∞-category $(\mathrm{CAlg}_R^{\text{ét}})^{\mathrm{op}}$ which can be characterized as follows: if A is an $\mathbb{E}_\infty$-algebra over R, then a sieve $\mathcal{C} \subseteq (\mathrm{CAlg}_R^{\text{ét}})^{\mathrm{op}}_{/A} \simeq (\mathrm{CAlg}_A^{\text{ét}})^{\mathrm{op}}$ is a covering if and only if it contains a finite collection of morphisms $\{A \to A_i\}_{1 \leqslant i \leqslant n}$ for which the the underlying ring homomorphisms $\{\pi_0 A \to \pi_0 A_i\}$ form a Nisnevich covering (Definition B.4.1.1).

Proof. By virtue of Theorem HA.7.5.0.6 we can assume without loss of generality that R is discrete, in which case the desired result was established as Theorem **??**. □

Definition B.6.2.5. Let R be an $\mathbb{E}_\infty$-ring. We will refer to the Grothendieck topology described in Variant B.6.2.4 as the *Nisnevich topology* on $(\mathrm{CAlg}^{\text{ét}}_R)^{\mathrm{op}}$. We let $\mathcal{S}\mathrm{hv}^{\mathrm{Nis}}_R$ denote the full subcategory of $\mathrm{Fun}(\mathrm{CAlg}^{\text{ét}}_R, \mathcal{S})$ spanned by those functors which are sheaves for the Nisnevich topology. We will refer to $\mathcal{S}\mathrm{hv}^{\mathrm{Nis}}_R$ as the *∞-topos of Nisnevich sheaves over R*.

Remark B.6.2.6. For any $\mathbb{E}_\infty$-ring R, the étale topology on $(\mathrm{CAlg}^{\text{ét}}_R)^{\mathrm{op}}$ is a refinement of the Nisnevich topology on $(\mathrm{CAlg}^{\text{ét}}_R)^{\mathrm{op}}$ (see Remark B.4.1.6). In particular, we have $\mathcal{S}\mathrm{hv}^{\text{ét}}_R \subseteq \mathcal{S}\mathrm{hv}^{\mathrm{Nis}}_R$.

Remark B.6.2.7. Let R be an $\mathbb{E}_\infty$-ring. According to Theorem HA.7.5.0.6 , the functor $A \mapsto \pi_0 A$ determines an equivalence from the ∞-category $\mathrm{CAlg}^{\text{ét}}_R$ to the ordinary category $\mathrm{CAlg}^{\text{ét}}_{\pi_0 R}$ of étale algebras over the commutative ring $\pi_0 R$. Under this equivalence, the étale and Nisnevich topologies on $\mathrm{CAlg}^{\text{ét}}_R$ correspond to the étale and Nisnevich topologies on $\mathrm{CAlg}^{\text{ét}}_{\pi_0 R}$. We therefore have equivalences of ∞-categories $\mathcal{S}\mathrm{hv}^{\text{ét}}_R \simeq \mathcal{S}\mathrm{hv}^{\text{ét}}_{\pi_0 R}$ and $\mathcal{S}\mathrm{hv}^{\mathrm{Nis}}_R \simeq \mathcal{S}\mathrm{hv}^{\mathrm{Nis}}_{\pi_0 R}$. In particular, the ∞-topoi $\mathcal{S}\mathrm{hv}^{\text{ét}}_R$ and $\mathcal{S}\mathrm{hv}^{\mathrm{Nis}}_R$ are both 1-localic.

B.6.3 The Finite Flat Topology

We now study a variant of Definition B.6.2.2, where we impose descent only for morphisms which are *finite flat*.

Proposition B.6.3.1. *Let $f : A \to A'$ be a map of $\mathbb{E}_1$-rings which exhibits A' as a flat left A-module. The following conditions are equivalent:*

(1) *The map f exhibits $\pi_0 A'$ as a finitely presented left module over $\pi_0 A$.*

(2) *The map f exhibits $\pi_0 A'$ as a finitely generated projective left module over $\pi_0 A$.*

(3) *The map f exhibits $\tau_{\geqslant 0} A'$ as a finitely generated projective left module over $\tau_{\geqslant 0} A$.*

Proof. The equivalence (2) $\Leftrightarrow$ (3) follows from Proposition HA.7.2.2.18 . The implication (2) $\Rightarrow$ (1) is obvious. Conversely, suppose that $\pi_0 A'$ is finitely presented as a left $\pi_0 A$-module. Since $\pi_0 A'$ is flat over $\pi_0 A$, Lazard's theorem (Theorem HA.7.2.2.15) guarantees that $\pi_0 A'$ can be realized as a filtered colimit $\varinjlim M_\alpha$ of finitely generated free left modules over $\pi_0 A$. It follows that the isomorphism $\pi_0 A' \simeq \varinjlim M_\alpha$ factors through some M_α, so that $\pi_0 A'$ is a retract of M_α (as a left $\pi_0 A'$-module) and is therefore a finitely generated projective module. □

Definition B.6.3.2. We say that a morphism $f : A \to A'$ of $\mathbb{E}_\infty$-rings is *finite flat* if it satisfies the equivalent conditions of Proposition B.6.3.1. We say that f is *finite étale* if it is both finite flat and étale.

Warning B.6.3.3. The terminology of Definition B.6.3.2 is potentially misleading: in classical commutative algebra, a flat morphism $f : A \to A'$ which exhibits A' as a finitely generated A-module need not be finite flat. For example, suppose that X is a Stone space (Definition A.1.6.8) containing a point x, let A be the ring of locally constant $\mathbf{C}$-valued functions on X, and let $e : A \to \mathbf{C}$ be the map given by evaluation at x. Then e is surjective and flat, but is finite flat only if x is an isolated point of X.

Remark B.6.3.4. Let $f : A \to A'$ be an étale map of $\mathbb{E}_\infty$-rings. If f exhibits $\pi_0 A'$ as a finitely generated module over $\pi_0 A$, then it is finite étale. To prove this, it suffices to show that $\pi_0 A'$ is finitely presented as a module over $\pi_0 A$ (Proposition B.6.3.1). It follows from the structure of étale algebras (Proposition B.1.1.3) that there exists a finitely generated subring $R \subseteq \pi_0 A$ and an étale R-algebra R' such that $\pi_0 A' \simeq \pi_0 A \otimes_R R'$. Enlarging R if necessary, we can ensure that R' is a finitely generated R-module. Since R is Noetherian, the algebra R' is finitely presented as an R-module. It follows that $\pi_0 A'$ is finitely presented as a $\pi_0 A$-module.

We now summarize some of the permanence properties enjoyed by the class of finite flat morphisms:

Lemma B.6.3.5. (1) *Every equivalence $f : A \to A'$ of $\mathbb{E}_\infty$-rings is finite flat.*

(2) *The collection of finite flat morphisms in* CAlg *is closed under composition.*

(3) *Suppose we are given a pushout diagram of $\mathbb{E}_\infty$-rings*

$$\begin{array}{ccc} A & \xrightarrow{f} & A' \\ \downarrow & & \downarrow \\ B & \xrightarrow{g} & B'. \end{array}$$

If f is finite flat, then g is finite flat.

(4) *Given a finite collection $f_i : A_i \to A'_i$ of finite flat morphisms, the induced map $\prod_i A_i \to \prod_i A'_i$ is finite flat.*

Proposition B.6.3.6. *Let R be an $\mathbb{E}_\infty$-ring. Then there exists a Grothendieck topology on the ∞-category $(\mathrm{CAlg}_R^{\acute{e}t})^{\mathrm{op}}$ which can be characterized as follows: if A is an $\mathbb{E}_\infty$-algebra over R, then a sieve $\mathcal{C} \subseteq (\mathrm{CAlg}_R^{\acute{e}t})^{\mathrm{op}}_{/A} \simeq (\mathrm{CAlg}_A^{\acute{e}t})^{\mathrm{op}}$ is a covering if and only if it contains a finite collection of morphisms $\{A \to A_i\}_{1 \leqslant i \leqslant n}$ for which the induced map $A \to \prod_{1 \leqslant i \leqslant n} A_i$ is finite flat and faithfully flat.*

Proof. Let S be the collection of all morphisms in $\mathrm{CAlg}_R^{\text{ét}}$ which are finite flat and faithfully flat. To prove Proposition B.6.3.6, it will suffice to show that S satisfies conditions (a) through (d) of Proposition A.3.2.1. This follows immediately from Lemma B.6.3.5 and the proof of Proposition B.6.1.3. □

We will refer to the Grothendieck topology of Proposition B.6.3.6 as the *finite étale topology* on $(\mathrm{CAlg}_R^{\text{ét}})^{\mathrm{op}}$.

B.6.4 A Criterion for Étale Descent

We can now state the main result of this section:

Theorem B.6.4.1. *Let R be an $\mathbb{E}_\infty$-ring and let $\mathscr{F} : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{S}$ be a functor. Then $\mathscr{F}$ is a sheaf with respect to the étale topology if and only if the following conditions are satisfied:*

(1) *The functor $\mathscr{F}$ is a sheaf with respect to the Nisnevich topology.*

(2) *The functor $\mathscr{F}$ is a sheaf with respect to the finite étale topology.*

Remark B.6.4.2. Let R be an $\mathbb{E}_\infty$-ring, let $\mathcal{C} = (\mathrm{CAlg}_R^{\text{ét}})^{\mathrm{op}}$, and let $\mathcal{X}$ denote the full subcategory of $\mathcal{P}(\mathcal{C}) = \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ spanned by those functors $\mathscr{F} : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{S}$ which are sheaves with respect to the Nisnevich and finite étale topologies. It follows from Lemma HTT.6.3.3.4 that $\mathcal{X}$ is an accessible left exact localization of $\mathcal{P}(\mathcal{C})$. Since $\mathcal{X}$ can be obtained as $S^{-1}\mathcal{P}(\mathcal{C})$ where S consists of monomorphisms, we deduce from Proposition HTT.6.2.2.17 that $\mathcal{X} = \mathcal{S}\mathrm{hv}(\mathcal{C})$, where we regard $\mathcal{C}$ as endowed with the coarsest Grothendieck topology which is finer than both the Nisnevich and finite étale topologies.

Proof of Theorem B.6.4.1. The "only if" direction is obvious. To prove the converse, set $\mathcal{C} = (\mathrm{CAlg}_R^{\text{ét}})^{\mathrm{op}}$, and regard $\mathcal{C}$ as endowed with the coarsest Grothendieck topology which is finer than both the Nisnevich and finite étale topologies. We wish to show that $\mathcal{X} = \mathcal{S}\mathrm{hv}(\mathcal{C})$ is contained in the ∞-category of étale sheaves on $\mathcal{C}$. Let $L : \mathrm{Fun}(\mathrm{CAlg}_R^{\text{ét}}, \mathcal{S}) \to \mathcal{X}$ be a left adjoint to the inclusion, and let $j : (\mathrm{CAlg}_R^{\text{ét}})^{\mathrm{op}} \to \mathrm{Fun}(\mathrm{CAlg}_R^{\text{ét}}, \mathcal{S})$ be the Yoneda embedding. Since the fpqc topology on CAlg is subcanonical (Theorem D.6.3.5), the functor j takes values in $\mathcal{X}$. Using Proposition HTT.6.2.3.20 , we are reduced to proving the following: for every collection of morphisms $\{R' \to R_\alpha\}$ which generate a covering sieve with respect to the étale topology, the induced map $\theta : \coprod_\alpha j(R_\alpha) \to j(R')$ is an effective epimorphism in $\mathcal{X}$. Without loss of generality we may replace R by R', and thereby reduce to the case where $j(R')$ is a final object of $\mathcal{X}$.

Note that the Grothendieck topology on $\mathcal{C}$ is finitary (see Definition A.3.1.1); consequently, to prove that θ is an effective epimorphism in $\mathcal{X}$, it will suffice to prove that $\eta^*(\theta)$ is an effective epimorphism in $\mathcal{S}$, for every geometric morphism $\eta^* : \mathcal{X} \to \mathcal{S}$ (Theorem A.4.0.5). The map η^* determines a geometric morphism $\eta'^* : \mathcal{S}\mathrm{hv}((\mathrm{CAlg}_R^{\text{ét}})^{\mathrm{op}}) \to \mathcal{S}$. According to Corollary **??**, the point η'^* is determined by a Henselian R-algebra A which is a filtered colimit $\varinjlim A_\beta$ of étale R-algebras A_β. In particular, A is local. It follows that there exists an index α such that the induced map $A \to A \otimes_R R_\alpha$ is faithfully flat. We will complete the proof by showing that $\eta^* j(R_\alpha)$ is nonempty.

According to Corollary B.3.3.9, there exists an idempotent element $e \in \pi_0(A \otimes_R R_\alpha)$ such that $A' = (A \otimes_R R_\alpha)[e^{-1}]$ is a faithfully flat finite étale A-algebra. Consequently, there exists an index β and an idempotent $e_\beta \in \pi_0(A_\beta \otimes_R R_\alpha)$ such that $A'_\beta = (A_\beta \otimes_R R_\alpha)[e_\beta^{-1}]$ is a faithfully flat finite étale A_β-algebra. It follows that the map $j(A'_\beta) \to j(A_\beta)$ is an effective epimorphism in $\mathcal{X}$. Since $\eta^* j(A_\beta)$ can be identified with $\mathrm{Map}_{\mathrm{CAlg}_R}(A_\beta, A) \neq \emptyset$, we conclude that $\eta^* j(A'_\beta)$ is nonempty. The map $R_\alpha \to A'_\beta$ induces a map of spaces $\eta^* j(A'_\beta) \to \eta^* j(R_\alpha)$, so that $\eta^* j(R_\alpha)$ is nonempty as desired. □

We also have the following companion to Theorem B.6.4.1:

Theorem B.6.4.3. *Let R be an $\mathbb{E}_\infty$-ring, let $L_{\mathrm{Nis}} : \mathrm{Fun}(\mathrm{CAlg}_R^{\acute{e}t}, \mathcal{S}) \to \mathcal{S}\mathrm{hv}_R^{\mathrm{Nis}}$ be a left adjoint to the inclusion functor (given by sheafification with respect to the Nisnevich topology), and let $\mathscr{F} : \mathrm{CAlg}_R^{\acute{e}t} \to \mathcal{S}$ be a sheaf with respect to the finite étale topology. Assume that $\mathscr{F}$ is n-truncated for some $n \geqslant 0$. Then $L_{\mathrm{Nis}} \mathscr{F}$ is a sheaf with respect to the étale topology.*

Remark B.6.4.4. Let R be an $\mathbb{E}_\infty$-ring and let

$$L_{\mathrm{Nis}}, L_{\mathrm{f\acute{e}t}}, L_{\mathrm{\acute{e}t}} : \mathrm{Fun}(\mathrm{CAlg}_R^{\mathrm{\acute{e}t}}, \mathcal{S}) \to \mathrm{Fun}(\mathrm{CAlg}_R^{\mathrm{\acute{e}t}}, \mathcal{S})$$

denote the functors given by sheafification with respect to the Nisnevich, finite étale, and étale topologies, respectively. For any functor $\mathscr{F} : \mathrm{CAlg}_R^{\mathrm{\acute{e}t}} \to \mathcal{S}$, we have a canonical map $\rho : L_{\mathrm{Nis}}(L_{\mathrm{f\acute{e}t}} \mathscr{F}) \to L_{\mathrm{\acute{e}t}} \mathscr{F}$ (since the étale topology refines both the Nisnevich and finite étale topologies), which is an $L_{\mathrm{\acute{e}t}}$-equivalence. If $\mathscr{F}$ is truncated, then Theorem B.6.4.3 implies that the domain of ρ is an étale sheaf, so that ρ is an equivalence. In other words, to sheafify a (truncated) presheaf $\mathscr{F}$ with respect to the étale topology, we can first sheafify with respect to the finite étale topology and then with respect to the Nisnevich topology.

Warning B.6.4.5. In the situation of Remark B.6.4.4, we also have a natural map $\rho' : L_{\mathrm{f\acute{e}t}}(L_{\mathrm{Nis}} \mathscr{F}) \to L_{\mathrm{\acute{e}t}} \mathscr{F}$, but the map ρ' is generally not an equivalence (the functor $L_{\mathrm{f\acute{e}t}}$ usually does not preserve the class of Nisnevich sheaves).

We will deduce Theorem B.6.4.3 from the following general observation:

Lemma B.6.4.6. *Let $f : A \to B$ be a finite morphism of commutative rings, and let*

$$L_A : \mathrm{Fun}(\mathrm{CAlg}_A^{\acute{e}t}, \mathcal{S}) \to \mathcal{S}\mathrm{hv}_A^{\mathrm{Nis}} \qquad L_B : \mathrm{Fun}(\mathrm{CAlg}_B^{\acute{e}t}, \mathcal{S}) \to \mathcal{S}\mathrm{hv}_B^{\mathrm{Nis}}$$

be left adjoint to the inclusion functors. Suppose that $\mathscr{F} : \mathrm{CAlg}_B^{\acute{e}t} \to \mathcal{S}$ is a functor which commutes with finite products and that $\mathscr{F}$ is n-truncated for some $n \gg 0$. Then the Beck-Chevalley morphism $\rho : L_A(f_* \mathscr{F}) \to f_*(L_B \mathscr{F})$ is an equivalence in the ∞-category $\mathcal{S}\mathrm{hv}_A^{\mathrm{Nis}}$.

Proof of Lemma B.6.4.6. We will show that if $\mathscr{F} : \mathrm{CAlg}_B^{\mathrm{\acute{e}t}} \to \mathcal{S}$ is *any* functor which commutes with finite products, then the Beck-Chevalley morphism $\theta : L_A(f_* \mathscr{F}) \to f_*(L_B \mathscr{F})$

is ∞-connective. In the case where $\mathscr{F}$ is n-truncated, the domain and codomain of θ will also be n-truncated, so that θ will be an equivalence as desired.

Since the Nisnevich topology is finitary, the hypercompletion of the ∞-topos $\mathcal{S}\mathrm{hv}_A^{\mathrm{Nis}}$ has enough points (Theorem A.4.0.5). It will therefore suffice to show that $\eta^*(\theta)$ is a homotopy equivalence for every geometric morphism $\eta^* : \mathcal{S}\mathrm{hv}_A^{\mathrm{Nis}} \to \mathcal{S}$. Using Theorem B.4.4.4, we can identify the point $\eta^* \in \mathrm{Fun}^*(\mathcal{S}\mathrm{hv}_A^{\mathrm{Nis}}, \mathcal{S})$ with a Henselization $\overline{A}$ of A: that is, a local Henselian ring A which can be written as the colimit of a filtered diagram $\{A_\alpha\}$ in $\mathrm{CAlg}_A^{\text{ét}}$. Using Corollary B.3.3.5, we see that $\overline{B} = \overline{A} \otimes_A B$ factors as a finite product $\prod_i \overline{B}_i$, where each $\overline{B}_i$ is a local Henselian ring. Replacing A by an étale A-algebra if necessary, we may assume that this product decomposition exists already over A: that is, we have a factorization $B \simeq \prod B_i$ with $\overline{B}_i \simeq \overline{A} \otimes_A B_i$. Unwinding the definitions, we see that $\eta^*(\theta)$ can be identified with the natural map $\varinjlim \mathscr{F}(B \otimes_A A_\alpha) \to \prod_i \varinjlim \mathscr{F}(B_i \otimes_A A_\alpha)$, which is an equivalence by virtue of our assumption that $\mathscr{F}$ commutes with finite products. □

Remark B.6.4.7. In the statement of Lemma B.6.4.6, the hypothesis that $\mathscr{F}$ is n-truncated is not essential. For example, if A is a Noetherian ring of finite Krull dimension, then the ∞-topos $\mathcal{S}\mathrm{hv}_A^{\mathrm{Nis}}$ is hypercomplete (Corollary 3.7.7.3), so our proof of Lemma B.6.4.6 immediately shows that the map θ is an equivalence. One can treat the general case using a Noetherian approximation argument. We omit the details, since the truncated version of Lemma B.6.4.6 will be sufficient for our application.

Proof of Theorem B.6.4.3. Let R be an $\mathbb{E}_\infty$-ring and let $\mathscr{F} : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{S}$ be an n-truncated sheaf for the finite étale topology; we wish to show that $L_{\mathrm{Nis}}\,\mathscr{F}$ is a sheaf for the étale topology. By virtue of Theorem B.6.4.1, it will suffice to show that $L_{\mathrm{Nis}}\,\mathscr{F}$ is a sheaf with respect to the finite étale topology. Since $L_{\mathrm{Nis}}\,\mathscr{F}$ is a Nisnevich sheaf, it commutes with finite products. Using Proposition A.3.3.1, we are reduced to proving the following:

- $(*)$ Let $A \in \mathrm{CAlg}_R^{\text{ét}}$, let $u_0 : A \to A^0$ be a morphism which is finite étale and faithfully flat, and let $A^\bullet$ be the Čech nerve of u (formed in the opposite of the ∞-category $\mathrm{CAlg}_R^{\text{ét}}$). Then the canonical map $\rho : (L_{\mathrm{Nis}}\,\mathscr{F})(A) \to \mathrm{Tot}(L_{\mathrm{Nis}}\,\mathscr{F})(A^\bullet)$ is a homotopy equivalence.

Without loss of generality, we may assume that $A = R$. For each $n \geqslant 0$, let $u_n : A \to A^n$ be the canonical map, so that we have a pair of adjoint functors

$$\mathrm{Fun}(\mathrm{CAlg}_A^{\text{ét}}, \mathcal{S}) \underset{u_{n*}}{\overset{u_n^*}{\rightleftarrows}} \mathrm{Fun}(\mathrm{CAlg}_{A^n}^{\text{ét}}, \mathcal{S}).$$

Unwinding the definitions, we see that ρ is obtained from the composite map

$$\begin{aligned} L_{\mathrm{Nis}}\,\mathscr{F} &\xrightarrow{\rho'} L_{\mathrm{Nis}}(\mathrm{Tot}(u_*^\bullet u^{\bullet *}\,\mathscr{F})) \\ &\xrightarrow{\rho''} \mathrm{Tot}(L_{\mathrm{Nis}}(u_*^\bullet u^{\bullet *}\,\mathscr{F})) \\ &\xrightarrow{\rho'''} \mathrm{Tot}(u_*^\bullet u^{\bullet *}(L_{\mathrm{Nis}}\,\mathscr{F})). \end{aligned}$$

by evaluating at the object $A \in \mathrm{CAlg}^{\text{ét}}_A$. The morphism ρ' is an equivalence by virtue of our assumption that $\mathscr{F}$ is a sheaf for the finite étale topology, and the map ρ''' is an equivalence by virtue of Lemma B.6.4.6. The map ρ'' fits into a commutative diagram

$$\begin{array}{ccc} L_{\mathrm{Nis}}(\varprojlim_{[m]\in\mathbf{\Delta}} u^m_* u^{m*}\mathscr{F}) & \xrightarrow{\rho''} & \varprojlim_{[m]\in\mathbf{\Delta}}(L_{\mathrm{Nis}} u^m_* u^{m*}\mathscr{F}) \\ \downarrow & & \downarrow \\ L_{\mathrm{Nis}}(\varprojlim_{[m]\in\mathbf{\Delta}_{s,\leqslant n+1}} u^m_* u^{m*}\mathscr{F}) & \longrightarrow & \varprojlim_{[m]\in\mathbf{\Delta}_{s,\leqslant n+1}}(L_{\mathrm{Nis}} u^m_* u^{m*}\mathscr{F}). \end{array}$$

We conclude by observing that the vertical maps are equivalences when $\mathscr{F}$ is n-truncated, and the lower horizontal map is an equivalence because the sheafification functor L_{Nis} is left exact. □

B.6.5 The Henselian Case

We close this section with a few observations concerning finite étale morphisms in the Henselian setting.

Notation B.6.5.1. Let R be an $\mathbb{E}_\infty$-ring. We let $\mathrm{CAlg}^{\text{fét}}_R$ denote the full subcategory of CAlg_R spanned by the finite étale R-algebras.

Proposition B.6.5.2. *Let R be a Henselian $\mathbb{E}_\infty$-ring, let $\mathfrak{m} \subseteq \pi_0 R$ be the maximal ideal, and let κ denote the residue field $\pi_0 R/\mathfrak{m}$. Then the inclusion functor $\mathrm{CAlg}^{\text{fét}}_R \hookrightarrow \mathrm{CAlg}^{\text{ét}}_R$ admits a left adjoint. Moreover, the construction $A \mapsto (\pi_0 A)/\mathfrak{m}$ determines an equivalence of ∞-categories from $\mathrm{CAlg}^{\text{fét}}_R$ to $\mathrm{CAlg}^{\text{ét}}_\kappa$.*

Proof. We may assume without loss of generality that R is discrete. Let A be an étale R-algebra, and choose a factorization $A \simeq A' \times A''$ as in Corollary B.3.4.5. We claim that the projection map $A \to A'$ exhibits A' as a $\mathrm{CAlg}^{\text{fét}}_R$-localization of A. In other words, we claim that for every finite étale A-algebra B, every R-algebra homomorphism $\phi : A \to B$ factors (necessarily uniquely) through A'. Note that ϕ induces a decomposition $B \simeq B' \times B''$ and maps $\phi' : A' \to B'$, $\phi'' : A'' \to B''$. We wish to prove that $B'' \simeq 0$. Note that $B''/\mathfrak{m}B''$ is an algebra over $A''/\mathfrak{m}A'' \simeq 0$, so that $\mathfrak{m}B'' = B''$. Since B'' is a direct factor of B, it is a finite étale R-algebra. Using Nakayama's lemma, we conclude that $B'' \simeq 0$. The final assertion is a special case of Corollary B.3.3.7.

□

Proposition B.6.5.3. *Let R be a Henselian $\mathbb{E}_\infty$-ring, let $\mathfrak{m} \subseteq \pi_0 R$ be the maximal ideal, and let $\kappa = \pi_0 R/\mathfrak{m}$ denote the residue field. Let $\mathcal{X} = \mathcal{S}\mathrm{hv}^{\text{ét}}_R$ and let $\mathcal{X}_0$ denote the full subcategory of $\mathcal{X}$ spanned by those sheaves $X : \mathrm{CAlg}^{\text{ét}}_R \to \mathcal{S}$ which are right Kan extensions of their restriction to $\mathrm{CAlg}^{\text{fét}}_R$. Then $\mathcal{X}_0$ is an accessible left exact localization of $\mathcal{X}$. Moreover, the pullback functor $\mathcal{X} \simeq \mathcal{S}\mathrm{hv}^{\text{ét}}_{\tau_{\geqslant 0} R} \to \mathcal{S}\mathrm{hv}^{\text{ét}}_\kappa$ induces an equivalence of ∞-categories $\mathcal{X}_0 \to \mathcal{S}\mathrm{hv}^{\text{ét}}_\kappa$.*

Proof. We may assume without loss of generality that R is discrete. Let $T : \mathrm{CAlg}_R^{\text{ét}} \to \mathrm{CAlg}_R^{\text{fét}}$ be a left adjoint to the inclusion (see Proposition B.6.5.2). Then composition with T induces a left exact localization functor $L : \mathrm{Fun}(\mathrm{CAlg}_R^{\text{ét}}, \mathcal{S}) \to \mathrm{Fun}(\mathrm{CAlg}_R^{\text{ét}}, \mathcal{S})$, whose essential image is the collection of those functors $X : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{S}$ which are right Kan extensions of $X|_{\mathrm{CAlg}_R^{\text{fét}}}$. We will prove that $L\mathcal{X} \subseteq \mathcal{X}$, so that L induces a left exact localization on $\mathcal{X}$ whose essential image is $\mathcal{X} \cap L\,\mathrm{Fun}(\mathrm{CAlg}_R^{\text{ét}}, \mathcal{S}) = \mathcal{X}_0$. To prove this, suppose that $X \in \mathcal{S}\mathrm{hv}_R^{\text{ét}}$; we wish to show that LX is a sheaf with respect to the étale topology. Choose an étale R-algebra A and a covering sieve $\mathcal{C} \subseteq \mathrm{CAlg}_A^{\text{ét}}$; we wish to show that the canonical map $LX(A) \to \varprojlim_{B \in \mathcal{C}} LX(B)$ is an equivalence. Let $\mathcal{C}_0 \subseteq \mathcal{C}$ be the full subcategory spanned by those étale A-algebras which are finite étale over R. Then $LX|_{\mathcal{C}}$ is a right Kan extension of $LX|_{\mathcal{C}'}$. Using Lemma HTT.4.3.2.7 , we are reduced to proving that the map $\theta : LX(A) \to \varprojlim_{B \in \mathcal{C}_0} LX(B) \simeq \varprojlim_{B \in \mathcal{C}_0} X(B)$ is an equivalence.

Write $A = A' \times A''$ where A' is a finite étale R-algebra and $A''/\mathfrak{m}A'' \simeq 0$ (Corollary B.3.4.5). Let $\mathcal{C}' \subseteq \mathrm{CAlg}_{A'}^{\text{ét}}$ be the full subcategory spanned by those étale maps $A' \to B$ which factor as a composition $A' \to \overline{B} \to B$, where the composition $A \to A' \to \overline{B}$ belongs to $\mathcal{C}$ and $\overline{B}$ is finite étale over R. Since $\mathcal{C}$ is a covering sieve, it induces a covering sieve on A'. It follows that there exists a finite collection of étale maps $A' \to B_\alpha$ such that the induced map $A' \to \prod_\alpha B_\alpha$ is faithfully flat, and each of the composite maps $A \to A' \to B_\alpha$ belongs to $\mathcal{C}$. Using Corollary B.3.4.5, we can assume that each B_α is finite étale over R, so that $A' \to B_\alpha$ belongs to $\mathcal{C}'$. It follows that $\mathcal{C}'$ is a covering sieve on A', so that the map $X(A') \to \varprojlim_{B \in \mathcal{C}'} X(B)$ is a homotopy equivalence.

Note that we can identify $\mathcal{C}_0$ with a full subcategory of $\mathcal{C}'$, so that θ factors as a composition

$$LX(A) \simeq X(A') \to \varprojlim_{B \in \mathcal{C}'} X(B) \to \varprojlim_{B \in \mathcal{C}_0} X(B).$$

To prove that this map is a homotopy equivalence, it suffices to prove that the inclusion $\mathcal{C}_0 \to \mathcal{C}'$ is right cofinal. Using Corollary HTT.4.1.3.1 , we are reduced to proving the following: for every object $B \in \mathcal{C}'$, the ∞-category $\mathcal{C}'_{/B} \times_{\mathcal{C}'} \mathcal{C}_0$ is weakly contractible. In fact, the ∞-category $\mathcal{C}'_{/B} \times_{\mathcal{C}'} \mathcal{C}_0$ is filtered: it is nonempty by construction and admits pushouts.

We now show that the pullback map $i^* : \mathcal{X}_0 \to \mathcal{S}\mathrm{hv}_k^{\text{ét}}$ is an equivalence of ∞-categories. Proposition B.6.5.2 supplies an equivalence of ∞-categories $\mathrm{CAlg}_\kappa^{\text{ét}} \simeq \mathrm{CAlg}_R^{\text{fét}}$. This equivalence determines a Grothendieck topology on $\mathrm{CAlg}_R^{\text{fét}}$, which agrees with the finite étale topology introduced in Proposition B.6.3.6. It follows immediately from Proposition HTT.4.3.2.15 that i^* is fully faithful. To prove the essential surjectivity, we must show that if $Y_0 : \mathrm{CAlg}_R^{\text{fét}} \to \mathcal{S}$ is a sheaf with respect to the finite étale topology, then $Y = Y_0 \circ T$ is a sheaf with respect to the étale topology on $\mathrm{CAlg}_R^{\text{ét}}$. Let A be an étale R-algebra and let $\mathcal{C} \subseteq \mathrm{CAlg}_A^{\text{ét}}$ be a covering sieve on A. As above, we wish to show that the canonical map $Y(A) \to \varprojlim_{B \in \mathcal{C}} Y(B)$ is a homotopy equivalence. Write $A = A' \times A''$ as in Corollary B.3.4.5

and let $\mathcal{C}_0$ and $\mathcal{C}'$ be defined as. Once again, we see that $Y|_{\mathcal{C}}$ is a right Kan extension of $Y|_{\mathcal{C}_0}$, and are therefore reduced to showing that

$$Y(A) \simeq Y_0(A') \to \varprojlim_{B \in \mathcal{C}_0} Y_0(B) \simeq \varprojlim_{B \in \mathcal{C}_0} Y(B)$$

is a homotopy equivalence, which follows from the observation that $\mathcal{C}_0$ is a covering sieve on A' with respect to the finite étale topology. □

Let R be a connective Henselian $\mathbb{E}_\infty$-ring. Let $\mathfrak{m} \subseteq \pi_0 R$ be the maximal ideal, $\kappa = (\pi_0 R)/\mathfrak{m}$ the residue field, and let $\phi : R \to \kappa$ denote the evident map, so that ϕ induces a pair of adjoint functors

$$\mathcal{S}\mathrm{hv}_R^{\text{ét}} \underset{\phi_*}{\overset{\phi^*}{\rightleftarrows}} \mathcal{S}\mathrm{hv}_\kappa^{\text{ét}} .$$

Unwinding the definitions, we see that ϕ_* induces the equivalence of ∞-categories $\mathcal{S}\mathrm{hv}_\kappa^{\text{ét}} \to \mathcal{X}_0$ appearing in the statement of Proposition B.6.5.3. It follows that the localization functor $L : \mathcal{S}\mathrm{hv}_R^{\text{ét}} \to \mathcal{X}_0$ is given by the composition $\phi_* \phi^*$. For every sheaf $X \in \mathcal{S}\mathrm{hv}_R^{\text{ét}}$ and every *finite* étale R-algebra A, the unit map

$$X(A) \to (LX)(A) \simeq (\phi_* \phi^* X)(A) = (\phi^* X)(\pi_0 A / \mathfrak{m} \pi_0 A)$$

is a homotopy equivalence. Taking $A = R$, we obtain the following result:

Proposition B.6.5.4. *Let R be a connective Henselian $\mathbb{E}_\infty$-ring, $\mathfrak{m} \subseteq \pi_0 R$ the maximal ideal, and $\kappa = (\pi_0 R)/\mathfrak{m}$ the residue field. Let $\phi : R \to \kappa$ be the quotient map and $\phi^* : \mathcal{S}\mathrm{hv}_R^{\acute{e}t} \to \mathcal{S}\mathrm{hv}_\kappa^{\acute{e}t}$ the associated pullback functor. Let $\mathbf{1}$ denote the final object of $\mathcal{S}\mathrm{hv}_R^{\acute{e}t}$. Then the canonical map $\mathrm{Map}_{\mathcal{S}\mathrm{hv}_R^{\acute{e}t}}(\mathbf{1}, \mathscr{F}) \to \mathrm{Map}_{\mathcal{S}\mathrm{hv}_\kappa^{\acute{e}t}}(\phi^* \mathbf{1}, \phi^* \mathscr{F})$ is a homotopy equivalence for every object $\mathscr{F} \in \mathcal{S}\mathrm{hv}_R^{\acute{e}t}$.*

B.7 Galois Descent

Let R be an $\mathbb{E}_\infty$-ring. In §B.6, we proved that a presheaf $\mathscr{F} : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{S}$ satisfies descent for étale coverings if and only if it satisfies descent for both Nisnevich and finite étale coverings. The former condition is very concrete: it is equivalent to Nisnevich excision, by virtue of Theorem B.5.0.3. Our goal in this section is to obtain a concrete interpretation of the second condition as well (Theorem B.7.6.1). The main observation is that every finite étale covering can be refined to a Galois covering (Lemma B.7.6.4).

B.7.1 Free Actions of Finite Groups

We begin by reviewing the Galois theory of commutative rings. For a much more general discussion, we refer the reader to [50] (see in particular Expose 5, Theorem 4.1).

Proposition B.7.1.1. *Let G be a finite group acting on a commutative ring R. The following conditions are equivalent:*

(1) *For every nonzero commutative ring A, the group G acts freely on the set* $\mathrm{Hom}(R, A)$ *of ring homomorphisms from R to A.*

(2) *Let $\mathfrak{p}$ be a prime ideal of R and $G_{\mathfrak{p}} \subseteq G$ the stabilizer group of $\mathfrak{p}$. Then $G_{\mathfrak{p}}$ acts faithfully on the residue field $\kappa(\mathfrak{p})$.*

Proof. Assume first that (1) is satisfied. Choose a point $\mathfrak{p} \in |\operatorname{Spec} R|$ and let $\phi : R \to \kappa(\mathfrak{p})$ be the canonical map. For any $g \in G_{\mathfrak{p}}$, the action of g on $\mathrm{Hom}(R, \kappa(\mathfrak{p}))$ is given by the inverse of the action of g on $\kappa(\mathfrak{p})$. Since the action of G is free, we conclude that any nontrivial element $g \in G_{\mathfrak{p}}$ must act nontrivially on $\kappa(\mathfrak{p})$.

Conversely, suppose that condition (2) is satisfied, and let A be a nonzero commutative ring. We wish to prove that G acts freely on $\mathrm{Hom}(R, A)$. Choose a homomorphism $\psi : A \to \kappa$ where κ is a field; composition with ψ induces a G-equivariant map $\mathrm{Hom}(R, A) \to \mathrm{Hom}(R, k)$. It will therefore suffice to show that G acts freely on $\mathrm{Hom}(R, k)$. Let $\theta : R \to \kappa$ be a ring homomorphism which is invariant under an element $g \in G$. Then $g \in G_{\mathfrak{p}}$ for $\mathfrak{p} = \ker(\theta)$, and the map θ factors as a composition

$$R \xrightarrow{\theta'} \kappa(\mathfrak{p}) \xrightarrow{\theta''} k.$$

Since θ'' injective and θ is g-invariant, we conclude that g acts trivially on the field $\kappa(\mathfrak{p})$; condition (2) then guarantees that g is the identity element of G. □

Definition B.7.1.2. We will say that an action of a finite group G on a commutative ring R is *free* if it satisfies the equivalent conditions of Proposition B.7.1.1.

B.7.2 The Invariant Subring

Let R be a commutative ring equipped with an action of a finite group G. We let R^G denote the subring of R consisting of G-invariant elements. Our first goal is to show that if the action of G is free, then $R^G \hookrightarrow R$ is finite étale. In fact, we can make a more precise statement, for which we require a bit of notation.

Notation B.7.2.1. Let R be a commutative ring acted on by a finite group G and set $R' = \prod_{g \in G} R$. We define ring homomorphisms $\phi_0, \phi_1 : R \to R'$ by the formulae

$$\phi_0(r)_g = r \qquad \phi_1(r)_g = g(r).$$

Together these maps determine a ring homomorphism $\phi : \mathrm{Tor}_0^{R^G}(R, R) \to R'$, where $R^G \subseteq R$ denotes the ring of G-invariant elements of R.

Proposition B.7.2.2. *Let G be a finite group acting on freely on a commutative ring R, and let $R^G \subseteq R$ denote the subring consisting of G-invariant elements. Then:*

(1) *The inclusion $R^G \hookrightarrow R$ is finite étale.*

(2) *Let $R' = \prod_{g \in G} R$ be as in Notation B.7.2.1. Then the map $\phi : \mathrm{Tor}_0^{R^G}(R, R) \to R'$ is an isomorphism.*

The proof of Proposition B.7.2.2 depends on the following observation from the classical Galois theory of fields:

Lemma B.7.2.3. *Let G be a group of order n which acts faithfully on a field κ, and let $\phi_0, \phi_1 : \kappa \to \kappa'$ be as in Notation B.7.2.1. Then there exists a finite sequence $x_1, \ldots, x_n \in \kappa$ such that the images $\phi_1(x_i)$ form a basis for κ', regarded as a κ-vector space via the homomorphism ϕ_0.*

Proof. It is clear that κ' has dimension n over κ. Consequently, it will suffice to show that κ' is generated as a κ-vector space by elements of the form $\phi_1(x)$. In other words, we must show that the map $\phi : \mathrm{Tor}_0^{\kappa^G}(\kappa, \kappa) \to \kappa'$ is surjective. In the ring κ', we have a unique decomposition $1 = \sum_{g \in G} e_g$, where each e_g is a nonzero idempotent element corresponding to projection of $\kappa' = \prod_{g \in G} \kappa$ onto the gth factor. The elements e_g form a basis for κ' as a κ-vector space; it will therefore suffice to show that each e_g belongs to the image of ϕ. If $h \neq g$, then since $h^{-1}g$ acts nontrivially on κ we can choose an element $x \in \kappa$ such that $h(x) \neq g(x)$. Then

$$y_h = (\phi_0(h(x)) - \phi_1(x))\phi_0(\frac{1}{h(x) - g(x)})$$

belongs to the image of ϕ; note that the gth coordinate of y_h is equal to 1, and the hth coordinate vanishes. It follows that $e_g = \prod_{h \neq g} y_h$ also belongs to the image of ϕ, as desired. □

Proof of Proposition B.7.2.2. Consider the following weaker version of assertion (1):

(1′) The inclusion $R^G \hookrightarrow R$ is faithfully flat.

Since the diagonal inclusion $\phi_0 : R \to R'$ is finite étale, assertions (1′) and (2) imply (1) by faithfully flat descent. Assertions (1′) and (2) are local on $|\operatorname{Spec} R^G|$; we may therefore replace R^G by its localization at some prime and thereby reduce to the case where R^G is a local ring with a unique maximal ideal $\mathfrak{m}$.

Note that R integral over R^G: every element $x \in R$ is a solution to the polynomial equation $\prod_{g \in G}(X - g(x)) = 0$, whose coefficients are G-invariant. We may therefore write

R as a union of subalgebras R_α which are finitely generated as R^G-modules. It follows from Nakayama's lemma that each quotient $R_\alpha/\mathfrak{m}R_\alpha$ is nonzero, so that the direct limit $R/\mathfrak{m}R \simeq \varinjlim R_\alpha/\mathfrak{m}R_\alpha$ is nonzero. We conclude that $\mathfrak{m}$ is contained in a maximal ideal of R.

Choose a maximal ideal $\mathfrak{n} \subset R$ containing $\mathfrak{m}$. For each $g \in G$, let $\mathfrak{n}^g$ denote the inverse image of $\mathfrak{n}$ under the action of g on R. We next claim that R is a semi-local ring, whose maximal ideals are precisely those of the form $\mathfrak{n}^g$ for $g \in G$. To see this, it suffices to show that if $x \in R$ is an element which does not belong to any of the ideals $\mathfrak{n}^g$, then x is invertible in R. Note that for each $g \in G$, our assumption $x \notin \mathfrak{n}^g$ is equivalent to $g(x) \notin \mathfrak{n}$. Since $\mathfrak{n}$ is a prime ideal, we conclude that $y = \prod_{g \in G} g(x) \notin \mathfrak{n}$. Then y is a G-invariant element of R which does not belong to $\mathfrak{m}$, so that y is invertible in R^G and therefore x is invertible in R.

Let $H \subseteq G$ be the stabilizer of the ideal $\mathfrak{n} \subset R$ and let n be the order of H. Our assumption that G acts freely on R guarantees that H acts freely on the residue field $R/\mathfrak{n}$. Using Lemma B.7.2.3, we deduce the existence of elements $\overline{x}_1, \ldots, \overline{x}_n \in R/\mathfrak{n}$ whose images under the map ϕ_1 of Notation B.7.2.1 form a basis for $\prod_{h \in H}(R/\mathfrak{n})$ as a vector space over $R/\mathfrak{n}$. Choose elements $x_i \in \bigcap_{g \in G - H} \mathfrak{n}^g \subseteq R$ which reduce to the elements $\overline{x}_i$ modulo $\mathfrak{n}$, and let $g_1, \ldots, g_m \in G$ be a set of representatives for the set of right cosets G/H. For each maximal ideal $\mathfrak{n}'$ of R, the images $\phi_1(g_i(x_j))$ form a basis for the vector space $\prod_{g \in G} R/\mathfrak{n}'$. Using Nakayama's lemma, we conclude that the elements $\phi_1(g_i(x_j))$ form a basis of R' (viewed as an R-module via ϕ_0).

Let G act on R' via the formula $g(\{r_{g'}\}_{g' \in G}) = \{g(r_{g'g^{-1}})\}_{g' \in G}$. The map $\{r_{i,j}\} \mapsto \sum_{i,j} \phi_0(r_{i,j})\phi_1(g_i(x_j))$ determines a G-equivariant isomorphism $\bigoplus_{1 \leqslant i \leqslant m, 1 \leqslant j \leqslant n} R \simeq R'$. Passing to fixed points, we see that R is freely generated by the elements $g_i(x_j)$ as an R^G-module, which immediately implies both (1′) and (2). □

B.7.3 Descent

Let R be a commutative ring equipped with a free action of a finite group G. Proposition B.7.2.2 guarantees that R is faithfully flat over R^G. If $R^\bullet$ denotes the cosimplicial commutative ring obtained as the Čech nerve of the inclusion $R^G \hookrightarrow R$, then we have a canonical isomorphism $R^k \simeq \prod_{g_1, \ldots, g_k \in G} R$. Using faithfully flat descent, we obtain the following result:

Proposition B.7.3.1. *Let R be a commutative ring equipped with a free action of a finite group G. Then the construction $M \mapsto M \otimes_{R^G} R$ determines an equivalence of categories from the category of (discrete) R^G-modules to the category of (discrete) R-modules equipped with a compatible action of G. Moreover, if M is any R^G-module, the augmented cochain complex*

$$M \to R^0 \otimes_{R^G} M \to R^1 \otimes_{R^G} M \to \cdots$$

associated to the cosimplicial abelian group $R^\bullet \otimes_{R^G} M$ is acyclic.

Remark B.7.3.2. Let R be a commutative ring equipped with a free action of a finite group G, and let N be an R-module equipped with a compatible action of the group G. Unwinding the definitions, we see that the cochain complex appearing in Proposition B.7.3.1 is the standard complex for computing the group cohomology $\mathrm{H}^*(G; N)$. Proposition B.7.3.1 gives

$$\mathrm{H}^n(G; N) \simeq \begin{cases} 0 & \text{if } n > 0 \\ M & \text{if } n = 0. \end{cases}$$

where $M \simeq N^G$ is an R^G-module (unique up to canonical isomorphism) such that $M \otimes_{R^G} R \simeq N$.

B.7.4 Digression: Group Actions on Spectra

Let G be a discrete group. Then G is a monoid object in the category of sets, and therefore determines a simplicial set BG (see §HA.4.1.2). The simplicial set BG is a Kan complex with a unique vertex, and can therefore be viewed as an object of the ∞-category of pointed spaces $\mathcal{S}_*$. We refer to BG as the *classifying space* of G.

Remark B.7.4.1. The classifying space BG is determined up to equivalence by the requirements that BG is 1-connective, 1-truncated, and the fundamental group of BG (taken with respect to its base point) is isomorphic to G (see, for example, Proposition HTT.7.2.2.12).

Definition B.7.4.2. Let $\mathcal{C}$ be an ∞-category. A *G-equivariant object* of $\mathcal{C}$ is a map of simplicial sets $BG \to \mathcal{C}$.

Remark B.7.4.3. Evaluation at the base point of BG determines a forgetful functor $\theta : \mathrm{Fun}(BG, \mathcal{C}) \to \mathcal{C}$. We will generally abuse notation by identifying a G-equivariant object C of $\mathcal{C}$ with its image $\theta(C) \in \mathcal{C}$. In this situation, we will also say that the group G *acts on* the object $\theta(C) \in \mathcal{C}$ (the action itself is given by the object $C \in \mathrm{Fun}(BG, \mathcal{C})$).

Definition B.7.4.4. Let $\mathcal{C}$ be an ∞-category and let $F : BG \to \mathcal{C}$ be a functor which determines an action of G on the object $F(*) = X \in \mathcal{C}$. We let X^G denote a limit of the diagram F (if such a limit exists).

Remark B.7.4.5. The notation of Definition B.7.4.4 is abusive: the object X^G depends on the G-equivariant object $F : BG \to \mathcal{C}$, and not only on the underlying object $X \in \mathcal{C}$.

Let $\mathcal{C}$ be an ∞-category which admits small limits, let G be a discrete group, and suppose we are given a G-equivariant object $BG \to \mathcal{C}$, corresponding to an action of G on an object $X \in \mathcal{C}$. We can regard BG as a simplicial object in the category of sets: in particular, BG determines a simplicial space $S_\bullet$ with $S_n \simeq G^n$. According to Example HTT.A.2.9.31 , we can identify BG with the colimit of the diagram $S_\bullet : \mathbf{\Delta}^{\mathrm{op}} \to \mathcal{S}$. It follows that X^G can be identified with the limit of a cosimplicial object of $X^\bullet \in \mathcal{C}$, where each X^n is a limit of the induced diagram $S_n \to BG \to \mathcal{C}$. Since S_n is discrete, we obtain $X^n = \prod_{g_1,\ldots,g_n \in G} X$.

Now suppose that $\mathcal{C}$ is the ∞-category of spectra. Applying Variant HA.1.2.4.9 , we deduce the existence of a spectral sequence of abelian groups $\{E_r^{p,q}, d_r\}_{r \geqslant 1}$ with

$$E_1^{p,q} \simeq \prod_{g_1,\ldots,g_p \in G} \pi_{-q} X.$$

Note that each $\pi_{-q}X$ is an abelian group acted on by G; unwinding the definitions, we see that the differential d_1 is the standard differential in the cochain complex

$$\pi_{-q}X \to \prod_{g \in G} \pi_{-q}X \to \prod_{g,g' \in G} \pi_{-q}X \to \cdots$$

which computes the cohomology of the group G with coefficients in $\pi_{-q}X$. We therefore obtain a canonical isomorphism $E_2^{p,q} \simeq \mathrm{H}^p(G; \pi_{-q}X)$.

In good cases, the spectral sequence described above will converge to the homotopy groups $\pi_{-p-q}X^G$. For example, Corollary HA.1.2.4.12 yields the following result:

Proposition B.7.4.6. *Let G be a discrete group, and let $BG \to \mathrm{Sp}$ be a G-equivariant object of the ∞-category of spectra whose underlying spectrum is X. Assume that for every integer n and for each $k > 0$, the cohomology group $\mathrm{H}^k(G; \pi_n X)$ vanishes. Then for every integer n, the map $\pi_n(X^G) \to \pi_n X$ is injective and its image is the group of G-invariant elements of $\pi_n X$.*

B.7.5 Galois Extensions of $\mathbb{E}_\infty$-Rings

We now study actions of finite groups on $\mathbb{E}_\infty$-rings.

Definition B.7.5.1. Let G be a finite group acting on an $\mathbb{E}_\infty$-ring R. We will say that the action is *free* if the induced action of G on the commutative ring $\pi_0 R$ is free, in the sense of Definition B.7.1.2.

Let $f : R \to R'$ be a map of $\mathbb{E}_\infty$-rings and G a finite group. We will say that f is a *Galois extension* (with Galois group G) if there exists a free action of G on R' such that f factors as a composition $R \simeq R'^G \to R'$.

Warning B.7.5.2. Let $f : R \to R'$ be a Galois extension $\mathbb{E}_\infty$-rings. The Galois group G is not uniquely determined by f. For example, if $R' \simeq R^n$, then any group G of order n can appear as a Galois group for f.

Warning B.7.5.3. The notion of Galois extension introduced in Definition B.7.5.1 is very restrictive. For a much more general analogue of Galois theory in this context, we refer the reader to [175].

Remark B.7.5.4. Using Theorem HA.7.5.0.6 , we see that a map $f : R \to R'$ of $\mathbb{E}_\infty$-rings is a Galois extension if and only if the induced map of commutative rings $\pi_0 R \to \pi_0 R'$ is a Galois extension.

Proposition B.7.5.5. *Let R be an $\mathbb{E}_\infty$-ring equipped with a free action of a finite group G. Then:*

(1) *For every integer n, the map $\pi_n R^G \to \pi_n R$ is injective, and its image is the subgroup of G-invariant elements of $\pi_n R$.*

(2) *The map $R^G \to R$ is finite étale.*

(3) *The canonical map $R \otimes_{R^G} R \to \prod_{g \in G} R$ is an equivalence.*

Proof. Combine Propositions B.7.2.2, B.7.3.1, and B.7.4.6. □

B.7.6 Étale Descent and Galois Descent

Let R be an $\mathbb{E}_\infty$-ring and let $\mathscr{F} : \mathrm{CAlg}^{\text{ét}}_R \to \mathcal{S}$ be a functor. We will say that $\mathscr{F}$ *satisfies Galois descent* if, for every object $A \in \mathrm{CAlg}^{\text{ét}}_R$ equipped with a free action of a finite group G, the canonical map $\mathscr{F}(A^G) \to \mathscr{F}(A)^G$ is a homotopy equivalence.

We can now state the main result of this section.

Theorem B.7.6.1. *Let R be an $\mathbb{E}_\infty$-ring and let $\mathscr{F} : \mathrm{CAlg}^{\acute{e}t}_R \to \mathcal{S}$ be a functor. Then $\mathscr{F}$ is a sheaf with respect to the finite étale topology if and only if the following conditions are satisfied:*

(1) *The functor $\mathscr{F}$ satisfies Galois descent.*

(2) *The functor $\mathscr{F}$ commutes with finite products.*

Corollary B.7.6.2. *Let R be an $\mathbb{E}_\infty$-ring and let $\mathscr{F} : \mathrm{CAlg}^{\acute{e}t}_R \to \mathcal{S}$ be a functor. Then $\mathscr{F}$ is a sheaf with respect to the étale topology if and only if the following conditions are satisfied:*

(1) *The functor $\mathscr{F}$ satisfies Galois descent.*

(2) *The functor $\mathscr{F}$ is a sheaf with respect to the Nisnevich topology.*

Proof. Combine Theorem B.7.6.1 and Theorem B.6.4.1 (note that if $\mathscr{F} : \mathrm{CAlg}^{\text{ét}}_R \to \mathcal{S}$ is a sheaf for the Nisnevich topology, then $\mathscr{F}$ commutes with finite products). □

In order to prove Theorem B.7.6.1, we need to show that there is a sufficiently large supply of Galois extensions in the setting of $\mathbb{E}_\infty$-rings.

Lemma B.7.6.3. *Let $f : R \to R'$ be a finite étale map of $\mathbb{E}_\infty$-rings, and suppose that $\pi_0 R'$ is a projective $\pi_0 R$-module of rank n. Then there exists a map $R \to A$ which is finite étale and faithfully flat such that $R' \otimes_R A \simeq A^n$.*

Proof. We proceed by induction on n. If $n = 0$, we can take $A = R$. Assume $n > 0$. Then f is faithfully flat. Replacing R by R' and R' by $R' \otimes_R R'$, we can assume that f admits a left inverse $g : R' \to R$. Since f is étale, the map g determines a decomposition $R' \simeq R \times R''$. Then R'' is finite étale of rank $(n-1)$ over R. By the inductive hypothesis, we can choose a faithfully flat finite étale map $R \to A$ such that $R'' \otimes_R A \simeq A^{n-1}$. It follows that $R' \otimes_R A \simeq A^n$ as desired. □

Lemma B.7.6.4. *Let R be an $\mathbb{E}_\infty$-ring and let $f : R \to R'$ be a faithfully flat finite étale morphism. Then there exists a map $g : R' \to R''$ such that the composite map $R \to R''$ is a Galois extension.*

Proof. For each $i \geqslant 0$, there exists a largest open subset U_i of $|\operatorname{Spec} \pi_0 R|$ over which the localization of the module $\pi_0 R'$ has rank i. Then $|\operatorname{Spec} \pi_0 R|$ is the disjoint union of the open sets U_i, so each U_i is also closed and therefore has the form $|\operatorname{Spec}(\pi_0 R)[e_n^{-1}]|$ where e_i is some idempotent element of $\pi_0 R$. Since R' is faithfully flat over R, we have $e_0 = 0$. Let n be the least common multiple of the set $\{i : e_i \neq 0\}$. Replacing R' by $\prod_i R'[e_i^{-1}]^{\frac{n}{i}}$, we can assume that $\pi_0 R'$ has constant rank n over $\pi_0 R$.

Let $R'^{\otimes n}$ be the n-fold tensor power of R' over R. For every pair of integers $1 \leqslant i < j \leqslant n$, the multiplication on the ith and jth tensor factors induces a map of étale R-algebras $f_{i,j} : R'^{\otimes n} \to R'^{\otimes (n-1)}$. Since $f_{i,j}$ admits a section, it induces an equivalence $R'^{\otimes(n-1)} \simeq R'^{\otimes n}[\epsilon_{i,j}^{-1}]$ for some idempotent elements $\epsilon_{i,j} \in \pi_0 R'^{\otimes n}$. Let $R'' = R'^{\otimes n}[\prod_{i,j} \epsilon_{i,j}^{-1}]$. Then R'' carries an action of the symmetric group Σ_n (as one can see, for example, by reducing to the discrete case using Theorem HA.7.5.0.6) in the ∞-category CAlg_R. To complete the proof, it suffices to show that Σ_n acts freely on $\pi_0 R''$ and that the induced map $R \to R''^{\Sigma_n}$ is an equivalence. This assertion is local on R; we may therefore invoke Lemma B.7.6.3 to reduce to the case where $R' = R^n$. In this case, $R'' \simeq \prod_{\sigma \in \Sigma_n} R$ and the desired result is obvious. □

Proof of Theorem B.7.6.1. Let G be a finite group acting on an object $A \in \mathrm{CAlg}_R^{\text{ét}}$. Write BG as the colimit of simplicial space $S_\bullet$ (with $S_n \simeq G^n$) and let $A^\bullet$ be the cosimplicial $\mathbb{E}_\infty$-ring given by $A^n \simeq \varinjlim_{S_n} A \simeq \prod_{g_1,\ldots,g_n \in G} A$, so that $A^G \simeq \varprojlim A^\bullet$. Using Proposition B.7.5.5, we see that $A^\bullet$ can be identified with the Čech nerve of the map $A^G \to A$. Similarly, we see that $\mathscr{F}(A)^G$ can be identified with the limit of the cosimplicial space $[n] \mapsto \prod_{g_1,\ldots,g_n \in G} \mathscr{F}(A)$. If $\mathscr{F}$ commutes with finite products, then this cosimplicial object is given by $[n] \mapsto \mathscr{F}(A^n)$. We have proven:

- $(*)$ If $\mathscr{F}$ commutes with finite products, then $\mathscr{F}$ satisfies Galois descent if and only if, for every Galois extension $A^G \to A$ with Čech nerve $A^\bullet$ in $\mathrm{CAlg}_R^{\text{ét}}$, the induced map

$\mathscr{F}(A^G) \to \varprojlim \mathscr{F}(A^\bullet)$ is a homotopy equivalence.

If $\mathscr{F}$ is a sheaf with respect to the finite étale topology, then Proposition A.3.3.1 implies that $\mathscr{F}$ commutes with finite products and satisfies the criterion of $(*)$, and therefore satisfies Galois descent.

Conversely, suppose that $\mathscr{F}$ commutes with finite products and satisfies Galois descent. We wish to prove that $\mathscr{F}$ is a sheaf with respect to the finite étale topology. We proceed as in the proof of Proposition A.3.3.1. Let $A \in \mathrm{CAlg}_R^{\text{ét}}$ and let $\mathcal{C}^{(0)} \subseteq \mathrm{CAlg}_A^{\text{ét}}$ be a sieve on A; we wish to prove that the map $\mathscr{F}(A) \to \varprojlim \mathscr{F}|_{\mathcal{C}^{(0)}}$ is an equivalence. Suppose first that $\mathcal{C}^{(0)}$ is generated by a Galois extension $f : A \to A^0$. Let $A^\bullet$ be the Čech nerve of f. It follows from $(*)$ that the canonical map $\mathscr{F}(A) \to \varprojlim \mathscr{F}(A^\bullet)$. The desired result now follows follows from the observation that $A^\bullet$ is given by a right cofinal map $\mathbf{\Delta} \to \mathcal{C}^{(0)}$.

Suppose now that $\mathcal{C}^{(0)}$ is generated by a single map $f : A \to A'$ which is finite étale and faithfully flat. Using Lemma B.7.6.4, we see that there exists a map $A' \to A''$ such that A'' is a Galois extension of A. Let $\mathcal{C}^{(1)} \subseteq \mathcal{C}^{(0)}$ be the sieve generated by A'', so that $\mathscr{F}(A) \simeq \varprojlim \mathscr{F}|_{\mathcal{C}^{(1)}}$ by the above argument. By virtue of Lemma HTT.4.3.2.7 , it will suffice to show that $\mathscr{F}|_{\mathcal{C}^{(0)}}$ is a right Kan extension of $\mathscr{F}|_{\mathcal{C}^{(1)}}$. Choose a map $A' \to B$ and let $\mathcal{C}^{(2)}$ be the pullback of the sieve $\mathcal{C}^{(1)}$ to $\mathrm{CAlg}_B^{\text{ét}}$; we wish to prove that $\mathscr{F}(B) \simeq \varprojlim \mathscr{F}|_{\mathcal{C}^{(2)}}$. This follows from the above argument, since $\mathcal{C}^{(2)}$ is generated by the Galois extension $B \to B \otimes_A A''$.

Now suppose that $\mathcal{C}^{(0)}$ is generated by a finite collection of finite étale morphisms $\{A \to A_i\}_{1 \leqslant i \leqslant n}$ such that the induced map $A \to \prod_i A_i$ is faithfully flat. Let $A' = \prod_i A_i$ and let $\mathcal{C}^{(1)}$ denote the sieve generated by the the map $A \to A'$. The above argument shows that $\mathscr{F}(A) \simeq \varprojlim \mathscr{F}|_{\mathcal{C}^{(1)}}$. To prove that $\mathscr{F}(A) \simeq \varprojlim \mathscr{F}|_{\mathcal{C}^{(0)}}$, it will suffice to show that $\mathscr{F}|_{\mathcal{C}^{(1)}}$ is a right Kan extension of $\mathscr{F}|_{\mathcal{C}^{(0)}}$. Fix an object $g : A \to B$ in $\mathcal{C}^{(1)}$, and let $\mathcal{C}^{(2)}$ be the pullback of $\mathcal{C}^{(0)}$ to $\mathrm{CAlg}_B^{\text{ét}}$; we wish to prove that $\mathscr{F}(B) \simeq \varprojlim \mathscr{F}|_{\mathcal{C}^{(2)}}$. By construction, g factors through some map $g_0 : \prod_i A_i \to B$, so that g_0 determines a decomposition $B \simeq \prod_i B_i$. Let $T \subseteq \{1, \ldots, n\}$ denote the collection of indices i such that $B_i \neq 0$. Let $\mathcal{C}' \subseteq \mathcal{C}^{(2)}$ be the full subcategory spanned by those morphisms $B \to B'$ which factor through some B_i, where $B' \neq 0$. Note that in this case B_i is uniquely determined and the index i belongs to T; it follows that $\mathcal{C}'$ decomposes as a disjoint union of full subcategories $\coprod_{i \in T} \mathcal{C}'_i$. Each of the categories $\mathcal{C}'_i$ contains the projection $B \to B_i$ as an initial object, so the inclusion $\{B_i\}_{i \in T} \hookrightarrow \mathcal{C}'$ is right cofinal. We therefore obtain homotopy equivalences

$$\mathscr{F}(B) \simeq \mathscr{F}(\prod_{i \in T} B_i) \simeq \prod_{i \in T} \mathscr{F}(B_i) \simeq \varprojlim \mathscr{F}|_{\mathcal{C}'}.$$

By virtue of Lemma HTT.4.3.2.7 , we are reduced to proving that $\mathscr{F}|_{\mathcal{C}^{(2)}}$ is a right Kan extension of $\mathscr{F}|_{\mathcal{C}'}$. To see this, choose an object $B \to B'$ in $\mathcal{C}^{(2)}$; we wish to show that $\mathscr{F}(B') \simeq \varprojlim \mathscr{F}|_{\mathcal{C}'_{B'/}}$. Let $B'_i = B_i \otimes_B B'$ for $1 \leqslant i \leqslant n$, and let T' be the collection of indices

i for which $B'_i \neq 0$. Then $\mathcal{C}'_{B'/}$ decomposes as a disjoint union $\coprod_{i \in T'} (\mathcal{C}'_{B'/})_i$, each of which has a final object (given by the map $B' \to B'_i$). We therefore have homotopy equivalences

$$\varprojlim \mathscr{F}|_{\mathcal{C}'_{/B'}} \simeq \prod_{i \in T'} \mathscr{F}(B'_i) \simeq \mathscr{F}(\prod_{i \in T'} B'_i) \simeq \mathscr{F}(B'),$$

as desired.

We now treat the case of a general covering sieve $\mathcal{C}^{(0)} \subseteq \mathrm{CAlg}^{\text{ét}}_A$. By definition, there exists a finite collection of finite étale maps maps $f_i : A \to A_i$ which generate a covering sieve $\mathcal{C}^{(1)} \subseteq \mathcal{C}^{(0)}$. The above argument shows that $\mathscr{F}(A) \simeq \varprojlim \mathscr{F}|_{\mathcal{C}^{(1)}}$. To complete the proof, it will suffice (by Lemma HTT.4.3.2.7) to show that $\mathscr{F}|_{\mathcal{C}^{(0)}}$ is a right Kan extension of $\mathscr{F}|_{\mathcal{C}^{(1)}}$. Unwinding the definitions, we must show that for every map $g : A \to B$ in $\mathcal{C}^{(0)}$, we have $\mathscr{F}(A) \simeq \varprojlim \mathscr{F}|_{g^* \mathcal{C}^{(1)}}$. This is clear, since $g^* \mathcal{C}^{(1)}$ is a covering sieve on B generated by finitely many morphisms $B \to A_i \otimes_A B$. □

Appendix C

Prestable ∞-Categories

In §HA.1.1.1 , we introduced the notion of a *stable ∞-category* (Definition HA.1.1.1.9). The theory of stable ∞-categories can be regarded as an ∞-categorical analogue of the classical theory of abelian categories. To explicitly connect these theories, one can consider the data of a stable ∞-category $\mathcal{C}$ equipped with a t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$: from this data, one can extract an abelian category $\mathcal{C}^{\heartsuit} = \mathcal{C}_{\geqslant 0} \cap \mathcal{C}_{\leqslant 0}$ which appears as a full subcategory of $\mathcal{C}$. In good cases, one can reconstruct the entire ∞-category $\mathcal{C}$ (together with its t-structure) from the subcategory $\mathcal{C}_{\geqslant 0} \subseteq \mathcal{C}$: for example, if the t-structure on $\mathcal{C}$ is right complete, then we can identify $\mathcal{C}$ with the ∞-category $\mathrm{Sp}(\mathcal{C}_{\geqslant 0})$ of spectrum objects of $\mathcal{C}_{\geqslant 0}$. Our goal in this appendix is to develop a theory of *prestable* ∞-categories: that is, ∞-categories which behave like the "connective parts" of t-structures on stable ∞-categories.

We begin in §C.1 with an axiomatic approach: we define a prestable ∞-category $\mathcal{C}$ to be an ∞-category which satisfies a short list of conditions, analogous to (but slightly weaker than) the conditions defining a stable ∞-category (Definition C.1.2.1). Our first main result asserts the equivalence of this "intrinsic" definition with an "extrinsic" one: an ∞-category $\mathcal{C}$ is prestable if and only if it appears as a full subcategory of a stable ∞-category $\mathcal{D}$ which is closed under finite colimits and extensions (Corollary C.1.2.3). Under mild additional assumptions, one can arrange that $\mathcal{C}$ is the connective part of a (uniquely determined) t-structure on $\mathcal{D}$ (Proposition C.1.2.9). We will be primarily interested in the case where the stable ∞-category $\mathcal{D}$ is presentable and its t-structure is compatible with filtered colimits: in this case, we will say that $\mathcal{C}$ is a *Grothendieck prestable ∞-category* (Definition C.1.4.2). The collection of Grothendieck prestable ∞-categories can itself be organized into an ∞-category Groth_{∞}, which we will study in §C.3.

For any connective $\mathbb{E}_1$-ring A, the stable ∞-category RMod_A of right A-modules admits a t-structure which is compatible with filtered colimits, and the full subcategory $\mathrm{RMod}_A^{\mathrm{cn}} \subseteq \mathrm{RMod}_A$ of *connective* right A-modules is an example of a Grothendieck prestable ∞-category. The central result of this appendix is the following converse: every Grothendieck prestable

∞-category $\mathcal{C}$ can be obtained as a left exact localization of $\mathrm{RMod}_A^{\mathrm{cn}}$, for some connective $\mathbb{E}_1$-ring A (Theorem C.2.4.1). This can be regarded as a generalization of the classical Gabriel-Popescu theorem, which asserts that every Grothendieck abelian category arises as an exact localization of the abelian category $\mathrm{RMod}_A^{\heartsuit}$ for some associative ring A (see [75]). Like the classical Gabriel-Popescu theorem, Theorem C.2.4.1 is very useful: it supplies a mechanism for reducing questions about arbitrary Grothendieck prestable ∞-categories to questions about structured ring spectra. In §C.4, we will use this mechanism to construct a well-behaved tensor product on the ∞-category Groth_{∞}, which refines (and generalizes) the tensor product on presentable stable ∞-categories studied in §**??**.

Recall that an abelian category $\mathcal{A}$ is said to be *Grothendieck* if it admits exact filtered colimits and a small generator. The theory of Grothendieck prestable ∞-categories is closely related to the theory of Grothendieck abelian categories: every Grothendieck prestable ∞-category $\mathcal{C}$ determines a Grothendieck abelian category $\mathcal{C}^{\heartsuit}$ (which can be defined as the full subcategory of $\mathcal{C}$ spanned by the discrete objects), and every Grothendieck abelian category $\mathcal{A}$ arises in this way (though not uniquely). In §**??**, we will carry out a detailed study of this relationship and introduce a family of intermediate objects (which we refer to as *Grothendieck abelian n-categories* for $1 \leqslant n < \infty$) which interpolate between classical homological algebra and our theory of Grothendieck prestable ∞-categories.

Except in trivial cases, a Grothendieck prestable ∞-category $\mathcal{C}$ is never small: the definition requires that $\mathcal{C}$ admits arbitrary colimits (such as infinite direct sums). However, we can often select out an essentially small full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ by imposing some additional finiteness conditions on the objects of $\mathcal{C}$. In good cases, one might hope to recover the ∞-category $\mathcal{C}$ (up to equivalence) from the full subcategory $\mathcal{C}_0$. In §C.6, we will consider several variations on this theme, and give a detailed description of the mechanism relating $\mathcal{C}$ with $\mathcal{C}_0$.

Contents

C.1 Prestability

Recall that an ∞-category $\mathcal{C}$ is *stable* if it is pointed, admits finite colimits, and the suspension functor $\Sigma : \mathcal{C} \to \mathcal{C}$ is an equivalence of ∞-categories (Corollary HA.1.4.2.27). The collection of stable ∞-categories includes many, but not all, of the ∞-categories which are relevant to the study of homological algebra. For example, if R is a commutative ring, then the collection of chain complexes of R-modules can be organized into a stable ∞-category Mod_R whose homotopy category is the classical derived category of R (see §HA.1.3.2). The property of stability is not inherited by subcategories: for example, the full subcategory $\mathrm{Mod}_R^{\mathrm{cn}} \subseteq \mathrm{Mod}_R$ of *connective R-modules* (that is, chain complexes whose homology vanishes in negative degrees) is not stable. In this section, we will study a larger class of ∞-categories which we call *prestable ∞-categories*, which includes $\mathrm{Mod}_R^{\mathrm{cn}}$ and variants thereof.

C.1.1 The Spanier-Whitehead Construction

Recall that the Spanier-Whitehead category $\mathcal{SW}$ can be defined as follows (see Definition 0.2.3.1):

- The objects of $\mathcal{SW}$ are pairs (X, m), where X is a pointed finite space and m is an integer.
- Given a pair of objects $(X, m), (Y, n) \in \mathcal{SW}$, the set of morphisms from (X, m) to (Y, n) is given by the direct limit $\varinjlim_k [\Sigma^{m+k} X, \Sigma^{n+k} Y]$, where $[U, V]$ denotes the set of homotopy classes of pointed maps from U to V.

The Spanier-Whitehead category $\mathcal{SW}$ arises naturally as the homotopy category of the stable ∞-category $\mathrm{Sp}^{\mathrm{fin}}$ of finite spectra, which is obtained from the ∞-category $\mathcal{S}_*^{\mathrm{fin}}$ of pointed finite spaces by "inverting" the suspension functor. This is a special case of a more general construction.

Construction C.1.1.1 (Spanier-Whitehead)**.** Let $\mathcal{C}$ be a pointed ∞-category which admits finite colimits and let $\Sigma : \mathcal{C} \to \mathcal{C}$ denote the suspension functor (given by $\Sigma X = 0 \amalg_X 0 = \mathrm{cofib}(X \to 0)$). We let $\mathrm{SW}(\mathcal{C})$ denote the ∞-category given by the colimit of the sequence

$$\mathcal{C} \xrightarrow{\Sigma} \mathcal{C} \xrightarrow{\Sigma} \mathcal{C} \xrightarrow{\Sigma} \cdots$$

We will refer to $\mathrm{SW}(\mathcal{C})$ as the *Spanier-Whitehead ∞-category of $\mathcal{C}$*.

Remark C.1.1.2. In more concrete terms, we can identify the objects of $\mathrm{SW}(\mathcal{C})$ with pairs (C, m), where C is an object of the ∞-category $\mathcal{C}$ and m is an integer; morphism spaces in $\mathrm{SW}(\mathcal{C})$ are computed by the formula

$$\mathrm{Map}_{\mathrm{SW}(\mathcal{C})}((C, m), (D, n)) \simeq \varinjlim_k \mathrm{Map}_{\mathcal{C}}(\Sigma^{m+k} C, \Sigma^{n+k} D)$$

where the colimit is taken over $k \geqslant \max\{-m, -n\}$. Roughly speaking, we can think of (C, m) as an m-fold suspension of the object $C \in \mathcal{C}$ (which exists in the original ∞-category $\mathcal{C}$ for $m \geqslant 0$, but has otherwise been formally adjoined by passing from $\mathcal{C}$ to $\mathrm{SW}(\mathcal{C})$).

Remark C.1.1.3. The passage from an ∞-category $\mathcal{C}$ to its homotopy category $\mathrm{h}\mathcal{C}$ commutes with filtered colimits. Consequently, if $\mathcal{C}$ is a pointed ∞-category which admits finite colimits, then the homotopy category of $\mathrm{SW}(\mathcal{C})$ can be identified with the colimit of the diagram

$$\mathrm{h}\mathcal{C} \xrightarrow{\Sigma} \mathrm{h}\mathcal{C} \xrightarrow{\Sigma} \mathrm{h}\mathcal{C} \xrightarrow{\Sigma} \cdots .$$

In particular, it depends only on the homotopy category $\mathrm{h}\mathcal{C}$ and the suspension functor $\Sigma : \mathrm{h}\mathcal{C} \to \mathrm{h}\mathcal{C}$.

Example C.1.1.4. Let $\mathcal{C}$ be the ∞-category of pointed finite spaces. Then the homotopy category $\mathrm{hSW}(\mathcal{C})$ is the Spanier-Whitehead category $\mathcal{SW}$ of Definition 0.2.3.1.

Remark C.1.1.5. Let $\mathcal{C}$ be a pointed ∞-category which admits finite colimits. Then the suspension functor $\Sigma : \mathcal{C} \to \mathcal{C}$ preserves finite colimits. Consequently, we can regard $\mathrm{SW}(\mathcal{C})$ as the direct limit of the diagram

$$\mathcal{C} \xrightarrow{\Sigma} \mathcal{C} \xrightarrow{\Sigma} \mathcal{C} \xrightarrow{\Sigma} \cdots$$

both in the ∞-category $\mathcal{C}\mathrm{at}_\infty$ of ∞-categories, and in the subcategory $\mathcal{C}\mathrm{at}_\infty^{\mathrm{rex}}$ whose objects are ∞-categories which admits finite colimits and whose morphisms are functors which preserve finite colimits. In particular, each of the natural maps $\mathcal{C} \to \mathrm{SW}(\mathcal{C})$ preserves finite colimits.

Remark C.1.1.6. The construction $\mathcal{C} \mapsto \mathrm{Ind}(\mathcal{C})$ determines a functor $\mathrm{Ind} : \mathcal{C}\mathrm{at}_\infty^{\mathrm{rex}} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$, where $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ is the ∞-category of presentable stable ∞-categories (where the morphisms are given by functors which preserve small colimits). Moreover, the functor Ind commutes with colimits. Consequently, if $\mathcal{C}$ is a (small) ∞-category which admits finite colimits, then we can identify $\mathrm{Ind}(\mathrm{SW}(\mathcal{C}))$ with the direct limit of the sequence

$$\mathrm{Ind}(\mathcal{C}) \xrightarrow{\Sigma} \mathrm{Ind}(\mathcal{C}) \xrightarrow{\Sigma} \mathrm{Ind}(\mathcal{C}) \xrightarrow{\Sigma} \cdots$$

in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$. Using Corollary HTT.5.5.3.4 and Theorem HTT.5.5.3.18 , we can identify this colimit with the limit of the tower of right adjoint functors

$$\mathrm{Ind}(\mathcal{C}) \xleftarrow{\Omega} \mathrm{Ind}(\mathcal{C}) \xleftarrow{\Omega} \mathrm{Ind}(\mathcal{C}) \xleftarrow{\Omega} \cdots ;$$

that is, with the ∞-category $\mathrm{Sp}(\mathrm{Ind}(\mathcal{C}))$ of spectrum objects of $\mathrm{Ind}(\mathcal{C})$. Using an elaboration of this observation, we obtain a commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathcal{C}\mathrm{at}_\infty^{\mathrm{rex}} & \xrightarrow{\mathrm{SW}} & \mathcal{C}\mathrm{at}_\infty^{\mathrm{rex}} \\ \downarrow{\scriptstyle \mathrm{Ind}} & & \downarrow{\scriptstyle \mathrm{Ind}} \\ \mathcal{P}\mathrm{r}^{\mathrm{L}} & \xrightarrow{\mathrm{Sp}} & \mathcal{P}\mathrm{r}^{\mathrm{L}} . \end{array}$$

The construction $\mathcal{C} \mapsto \mathrm{SW}(\mathcal{C})$ can be characterized by a universal property:

Proposition C.1.1.7. *Let $\mathcal{C}$ be a pointed ∞-category which admits finite colimits. Then:*

- (a) *The ∞-category $\mathrm{SW}(\mathcal{C})$ is stable.*
- (b) *For any stable ∞-category $\mathcal{D}$, composition with the canonical map $\mathcal{C} \to \mathrm{SW}(\mathcal{C})$ induces an equivalence $\mathrm{Fun}^{\mathrm{rex}}(\mathrm{SW}(\mathcal{C}), \mathcal{D}) \to \mathrm{Fun}^{\mathrm{rex}}(\mathcal{C}, \mathcal{D})$; here $\mathrm{Fun}^{\mathrm{rex}}(\mathcal{C}, \mathcal{D})$ is the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ spanned by those functors which preserve finite colimits, and $\mathrm{Fun}^{\mathrm{rex}}(\mathrm{SW}(\mathcal{C}), \mathcal{D})$ is defined similarly.*

Proof. It follows immediately from Remark C.1.1.2 that the Spanier-Whitehead ∞-category $\mathrm{SW}(\mathcal{C})$ is also pointed (in fact, each of the natural maps $\mathcal{C} \to \mathrm{SW}(\mathcal{C})$ carries zero objects of $\mathcal{C}$ to zero objects of $\mathrm{SW}(\mathcal{C})$). Unwinding the definitions, we see that the suspension functor on $\mathrm{SW}(\mathcal{C})$ is induced by the solid arrows in the diagram

$$\begin{array}{ccccccc} \mathcal{C} & \xrightarrow{\Sigma} & \mathcal{C} & \xrightarrow{\Sigma} & \mathcal{C} & \xrightarrow{\Sigma} & \cdots \\ \downarrow{\scriptstyle\Sigma} & \nearrow^{\mathrm{id}} & \downarrow{\scriptstyle\Sigma} & \nearrow & \downarrow{\scriptstyle\Sigma} & \nearrow & \downarrow \\ \mathcal{C} & \xrightarrow{\Sigma} & \mathcal{C} & \xrightarrow{\Sigma} & \mathcal{C} & \longrightarrow & \cdots ; \end{array}$$

it follows by inspection that the dotted arrows provide a homotopy inverse to the suspension functor. Assertion (a) now follows from Proposition HA.1.4.2.11 .

We now prove (b). By virtue of Remark C.1.1.5, it will suffice to show that precomposition with the suspension functor on $\mathcal{C}$ induces an equivalence θ from $\mathrm{Fun}^{\mathrm{rex}}(\mathcal{C}, \mathcal{D})$ to itself. Since right exact functors commute with suspension, the functor θ is also given by postcomposition with the suspension functor on $\mathcal{D}$, and is therefore an equivalence (since $\mathcal{D}$ is assumed to be stable). □

C.1.2 Prestability

We now introduce our main objects of study in this section.

Definition C.1.2.1. Let $\mathcal{C}$ be an ∞-category. We will say that $\mathcal{C}$ is *prestable* if the following conditions are satisfied:

- (a) The ∞-category $\mathcal{C}$ is pointed and admits finite colimits.
- (b) The suspension functor $\Sigma : \mathcal{C} \to \mathcal{C}$ is fully faithful.
- (c) For every morphism $f : Y \to \Sigma Z$ in $\mathcal{C}$, there exists a pullback square σ :

$$\begin{array}{ccc} X & \xrightarrow{f'} & Y \\ \downarrow & & \downarrow{\scriptstyle f} \\ 0 & \longrightarrow & \Sigma Z \end{array}$$

in $\mathcal{C}$. Moreover, σ is also a pushout square.

If $\mathcal{C}$ is an ∞-category which satisfies conditions (a) of Definition C.1.2.1, then conditions (b) and (c) can be reformulated in terms of the Spanier-Whitehead ∞-category:

Proposition C.1.2.2. *Let $\mathcal{C}$ be a pointed ∞-category which admits finite colimits. Then the following conditions are equivalent:*

- (b) *The suspension functor $\Sigma : \mathcal{C} \to \mathcal{C}$ is fully faithful.*
- (b') *The canonical map $\mathcal{C} \to \mathrm{SW}(\mathcal{C})$ is fully faithful.*
- (b'') *There exists a fully faithful embedding $\rho : \mathcal{C} \to \mathcal{D}$, where $\mathcal{D}$ is a stable ∞-category and ρ preserves finite colimits.*

If these conditions are satisfied, then the following further conditions are equivalent:

- (c) *For every morphism $f : Y \to \Sigma Z$ in $\mathcal{C}$, there exists a pullback square σ :*

$$\begin{array}{ccc} X & \xrightarrow{f'} & Y \\ \downarrow & & \downarrow{\scriptstyle f} \\ 0 & \longrightarrow & \Sigma Z \end{array}$$

  in $\mathcal{C}$. Moreover, σ is also a pushout square.

- (c') *For every fully faithful embedding $\rho : \mathcal{C} \to \mathcal{D}$ which preserves finite colimits, if $\mathcal{D}$ is stable, then the essential image of ρ is closed under extensions in $\mathcal{D}$.*
- (c'') *The essential image of the canonical map $\mathcal{C} \to \mathrm{SW}(\mathcal{C})$ is closed under extensions.*
- (c''') *There exists a fully faithful embedding $\rho : \mathcal{C} \to \mathcal{D}$ which preserves finite colimits, the ∞-category $\mathcal{D}$ is stable, and the essential image of ρ is closed under extensions in $\mathcal{D}$.*

Proof. The implication $(b) \Rightarrow (b')$ follows immediately from the definition of $\mathrm{SW}(\mathcal{C})$ and the implication $(b') \Rightarrow (b'')$ is a tautology. To show that $(b'') \Rightarrow (b)$, suppose that $\rho : \mathcal{C} \to \mathcal{D}$ is a fully faithful embedding which commutes with finite colimits and that $\mathcal{D}$ is stable. We then have a commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{\rho} & \mathcal{D} \\ \downarrow{\scriptstyle \Sigma} & & \downarrow{\scriptstyle \Sigma} \\ \mathcal{C} & \xrightarrow{\rho} & \mathcal{D} \end{array}$$

where the horizontal maps and the right vertical map are fully faithful; it follows that the left vertical map is also fully faithful.

Assume now that (b), (b'), and (b'') are satisfied. We first show that (c) implies (c'). Let $\rho : \mathcal{C} \to \mathcal{D}$ be as above, and suppose we are given a fiber sequence

$$\rho(C') \to D \to \rho(C'')$$

in the stable ∞-category $\mathcal{D}$; we wish to show that D belongs to the essential image of ρ. Note that we can identify D with the fiber of a map $f : \rho(C'') \to \Sigma\rho(C') \simeq \rho(\Sigma C')$. Using our assumption that ρ is fully faithful, we can assume that $f = \rho(f_0)$ for some map $f_0 : C'' \to \Sigma C'$ in the ∞-category $\mathcal{C}$. It follows from assumption (c) that we can complete f_0 to a fiber sequence $C \to C'' \xrightarrow{f_0} \Sigma C'$ which is also a cofiber sequence. Since the functor ρ preserves finite colimits, we obtain a cofiber sequence $\rho(C) \to \rho(C'') \xrightarrow{f} \rho(\Sigma C)$ in the ∞-category $\mathcal{D}$. Because $\mathcal{D}$ is stable, we obtain $D \simeq \mathrm{fib}(f) \simeq \rho(C)$ so that D belongs to the essential image of ρ, as desired.

The implications $(c') \Rightarrow (c'') \Rightarrow (c''')$ are immediate. We will complete the proof by showing that $(c''') \Rightarrow (c)$. Assume that we have a functor $\rho : \mathcal{C} \to \mathcal{D}$ as above, and let $f : Y \to \Sigma Z$ be a morphism in $\mathcal{C}$. Set $D = \mathrm{fib}(\rho(f))$, so that we have a fiber sequence $\rho(Z) \to D \xrightarrow{g} \rho(Y)$ in the ∞-category $\mathcal{D}$. Since the essential image of ρ is closed under extensions, we can write $D = \rho(X)$ for some $X \in \mathcal{C}$. Because ρ is fully faithful and preserves finite colimits, the cofiber sequence $D \xrightarrow{g} \rho(Y) \xrightarrow{\rho(f)} \rho(\Sigma Z)$ can be lifted to a cofiber sequence $X \xrightarrow{g_0} Y \xrightarrow{f} \Sigma Z$ in the ∞-category $\mathcal{C}$. Note that this cofiber sequence is also a fiber sequence, since its essential image under the fully faithful embedding ρ is a fiber sequence. □

Corollary C.1.2.3. *Let $\mathcal{C}$ be an ∞-category. The following conditions are equivalent:*

- (i) *The ∞-category $\mathcal{C}$ is prestable.*
- (ii) *There exists a fully faithful embedding $\rho : \mathcal{C} \hookrightarrow \mathcal{D}$, where $\mathcal{D}$ is a stable ∞-category and the essential image of ρ is closed under finite colimits and extensions.*

Corollary C.1.2.4. *Let $\mathcal{C}$ be a prestable ∞-category and suppose we are given a cofiber sequence $C' \to C \to C''$ in $\mathcal{C}$. If any two of the objects $C, C', C'' \in \mathcal{C}$ vanishes, then so does the third.*

Corollary C.1.2.5. *Let $\mathcal{C}$ be a prestable ∞-category. If $u : C \to C'$ is a morphism in $\mathcal{C}$ satisfying* $\mathrm{cofib}(u) \simeq 0$*, then u is an equivalence.*

Corollary C.1.2.6. *Let $\mathcal{C}$ be a prestable ∞-category. Then every pushout square in $\mathcal{C}$ is also a pullback square.*

Proof. Choose a fully faithful embedding $\rho : \mathcal{C} \hookrightarrow \mathcal{D}$ which preserves finite colimits, where $\mathcal{D}$ is stable. If $\sigma \in \mathrm{Fun}(\Delta^1 \times \Delta^1, \mathcal{C})$ is a pushout square in $\mathcal{C}$, then $\rho(\sigma)$ is a pushout square in $\mathcal{D}$. Since $\mathcal{D}$ is stable, it follows that $\rho(\sigma)$ is also a pullback square in $\mathcal{D}$ (Proposition HA.1.1.3.4). Because ρ is fully faithful, we conclude that σ is a pullback square in $\mathcal{C}$. □

Example C.1.2.7. Any stable ∞-category is prestable.

Example C.1.2.8. Let $\mathcal{C}$ be a stable ∞-category equipped with a t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$. Then the full subcategory $\mathcal{C}_{\geqslant 0} \subseteq \mathcal{C}$ is prestable.

The prestable ∞-categories which arise from Example C.1.2.8 can be characterized as follows:

Proposition C.1.2.9. *Let $\mathcal{C}$ be an ∞-category. The following conditions are equivalent:*

- (a) *The ∞-category $\mathcal{C}$ is prestable and admits finite limits.*
- (b) *The ∞-category $\mathcal{C}$ is pointed and admits finite colimits, the canonical map $\rho : \mathcal{C} \to \mathrm{SW}(\mathcal{C})$ is fully faithful. Moreover, the stable ∞-category $\mathrm{SW}(\mathcal{C})$ admits a t-structure $(\mathrm{SW}(\mathcal{C})_{\geqslant 0}, \mathrm{SW}(\mathcal{C})_{\leqslant 0})$ where $\mathrm{SW}(\mathcal{C})_{\geqslant 0}$ is the essential image of ρ.*
- (c) *There exists a stable ∞-category $\mathcal{D}$ equipped with a t-structure $(\mathcal{D}_{\geqslant 0}, \mathcal{D}_{\leqslant 0})$ and an equivalence of ∞-categories $\mathcal{C} \simeq \mathcal{D}_{\geqslant 0})$.*

Proof. We first show that $(a) \Rightarrow (b)$. Assume that $\mathcal{C}$ is prestable and admits finite limits, and let $\mathrm{SW}(\mathcal{C})_{\geqslant 0}$ denote the full subcategory of $\mathrm{SW}(\mathcal{C})$ spanned by the essential image of the canonical map $\rho : \mathcal{C} \hookrightarrow \mathrm{SW}(\mathcal{C})$ (which is fully faithful by virtue of Proposition C.1.2.2). Let $\mathrm{SW}(\mathcal{C})_{\leqslant 0}$ denote the full subcategory of $\mathrm{SW}(\mathcal{C})$ spanned by those objects of the form $\Omega^n \rho(C)$, where C is an n-truncated object of $\mathcal{C}$. We will prove (b) by showing that the pair $(\mathrm{SW}(\mathcal{C})_{\geqslant 0}, \mathrm{SW}(\mathcal{C})_{\leqslant 0})$ is a t-structure on the stable ∞-category $\mathrm{SW}(\mathcal{C})$: that is, that it satisfies the conditions of Definition HA.1.2.1.1 :

(1) For each object $X \in \mathrm{SW}(\mathcal{C})_{\geqslant 0}$ and $Y \in \mathrm{SW}(\mathcal{C})_{\leqslant 0}$, every map $u : X \to \Omega Y$ is nullhomotopic. Write $X = \rho(C)$ and $Y = \Omega^n \rho(D)$ for some objects $C, D \in \mathcal{C}$ where D is n-truncated. Since ρ is fully faithful, the mapping space

$$\mathrm{Map}_{\mathrm{SW}(\mathcal{C})}(X, \Omega Y) \simeq \mathrm{Map}_{\mathrm{SW}(\mathcal{C})}(\rho(C), \Omega^{n+1} \rho(D)) \simeq \Omega^{n+1} \mathrm{Map}_{\mathcal{C}}(X, Y)$$

is contractible.

(2) We have $\Sigma\, \mathrm{SW}(\mathcal{C})_{\geqslant 0} \subseteq \mathrm{SW}(\mathcal{C})_{\geqslant 0}$ and $\Omega\, \mathrm{SW}(\mathcal{C})_{\leqslant 0} \subseteq \mathrm{SW}(\mathcal{C})_{\leqslant 0}$. The first inclusion follows from the observation that $\Sigma \rho(\mathcal{C}) = \rho(\Sigma\, \mathcal{C}) \subseteq \rho(\mathcal{C})$, and the second follows from the observation that every n-truncated object of $\mathcal{C}$ is also $(n+1)$-truncated.

(3) For every object $X \in \mathrm{SW}(\mathcal{C})$, there exists a fiber sequence $X' \to X \to X''$ where $X' \in \mathrm{SW}(\mathcal{C})_{\geqslant 0}$ and $X'' \in \mathrm{SW}(\mathcal{C})_{\leqslant -1}$. Write $X = \Omega^n \rho(C)$ for some object $C \in \mathcal{C}$, set $C' = \Sigma^n \Omega^n C$, and let C'' denote the cofiber of the canonical map $C' \to C$. Since the functor ρ preserves cofiber sequences, we obtain a cofiber sequence

$$\Omega^n \rho(C') \to \Omega^n \rho(C) \to \Omega^n \rho(C'').$$

The first term in this sequence can be rewritten as

$$\Omega^n \rho(\Sigma^n \Omega^n C) \simeq \Omega^n \Sigma^n \rho(\Omega^n C) \simeq \rho(\Omega^n C)$$

and therefore belongs to $\mathrm{SW}(\mathcal{C})_{\geqslant 0}$. It will therefore suffice to show that $\Omega^n \rho(C'')$ belongs to $\mathrm{SW}(\mathcal{C})_{\leqslant 0}$. We will prove this by verifying that the object $C'' \in \mathcal{C}$ is $(n-1)$-truncated. Fix an object $D \in \mathcal{C}$; we wish to show that the mapping space $\mathrm{Map}_{\mathcal{C}}(D, C'')$ is $(n-1)$-truncated. In other words, we wish to show that the homotopy groups of $\mathrm{Map}_{\mathcal{C}}(D, C'')$ vanish in degrees $\geqslant n$, for any choice of base point. Note that $\mathrm{Map}_{\mathcal{C}}(D, C'') \simeq \mathrm{Map}_{\mathrm{SW}(\mathcal{C})}(\rho(D), \rho(C''))$ is an infinite loop space; we may therefore assume without loss of generality that our base point is chosen to be the zero map $D \to C''$. In other words, it will suffice to show that for $m \geqslant n$, any map $u : \Sigma^m D \to C''$ is nullhomotopic. To prove this, set $Y = \Omega^n(\rho(\Sigma^m D) \times_{\rho(C'')} \rho(C)) \in \mathrm{SW}(\mathcal{D})$, so that we have a fiber sequence $\rho(\Omega^n C) \to Y \to \rho(\Sigma^{m-n} D)$. Because the essential image of ρ is closed under extensions, we can write $Y = \rho(E)$ for some object $E \in \mathcal{C}$. We then have a commutative diagram of cofiber sequences

$$\begin{array}{ccccc} \Sigma^n \Omega^n C & \longrightarrow & \Sigma^n E & \longrightarrow & \Sigma^m D \\ \downarrow & & \downarrow{\scriptstyle v} & & \downarrow{\scriptstyle u} \\ \Sigma^n \Omega^n C & \longrightarrow & C & \longrightarrow & C''. \end{array}$$

It follows from the adjointness of Σ^n and Ω^n that the map v factors through $\Sigma^n \Omega^n C$. It follows that u factors through C, and therefore (since $\Sigma^m D$ is an n-fold suspension) through the composite map $\Sigma^n \Omega^n C \to C \to C''$ which is nullhomotopic.

The implication $(b) \Rightarrow (c)$ is trivial. We complete the proof by showing that $(c) \Rightarrow (a)$. Let $\mathcal{D}$ be a stable ∞-category equipped with a t-structure $(\mathcal{D}_{\geqslant 0}, \mathcal{D}_{\leqslant 0})$; we wish to show that $\mathcal{D}_{\geqslant 0}$ is a prestable ∞-category which admits finite limits. The prestability of $\mathcal{D}_{\geqslant 0}$ follows from Example C.1.2.8, and the existence of finite limits follows from the fact that $\mathcal{D}_{\geqslant 0}$ is a colocalization of the stable ∞-category $\mathcal{D}$. □

Remark C.1.2.10. Let $\mathcal{C}$ be a prestable ∞-category which admits finite limits. It follows from Proposition C.1.2.9 that there exists a stable ∞-category $\mathcal{D}$ with a t-structure $(\mathcal{D}_{\geqslant 0}, \mathcal{D}_{\leqslant 0})$ and an equivalence $\mathcal{C} \simeq \mathcal{D}_{\geqslant 0}$. The stable ∞-category $\mathcal{D}$ is not uniquely determined. However, there are two canonical choices for $\mathcal{D}$:

(a) One can take $\mathcal{D}$ to be the Spanier-Whitehead ∞-category $\mathrm{SW}(\mathcal{C})$, as in the proof of Proposition C.1.2.9: that is, we can take $\mathcal{D}$ to be the colimit of the sequence

$$\mathcal{C} \xrightarrow{\Sigma} \mathcal{C} \xrightarrow{\Sigma} \mathcal{C} \to \cdots .$$

In this case, the t-structure on $\mathcal{D}$ is right bounded: that is, we have $\mathcal{D} = \bigcup \mathcal{D}_{\geqslant -n}$.

(*b*) One can take $\mathcal{D}$ to be the ∞-category $\mathrm{Sp}(\mathcal{C})$ of spectrum objects of $\mathcal{C}$, defined as the homotopy limit of the tower of ∞-categories

$$\cdots \to \mathcal{C} \xrightarrow{\Omega} \mathcal{C} \xrightarrow{\Omega} \mathcal{C}$$

which we can identify with

$$\cdots \to \mathrm{SW}(\mathcal{C})_{\geqslant -2} \xrightarrow{\tau_{\geqslant -1}} \mathrm{SW}(\mathcal{C})_{\geqslant -1} \xrightarrow{\tau_{\geqslant 0}} \mathrm{SW}(\mathcal{C})_{\geqslant 0}.$$

In other words, we can identify $\mathcal{D}$ with the right completion of the ∞-category $\mathrm{SW}(\mathcal{C})$ with respect to its t-structure; in particular, the t-structure on the ∞-category $\mathcal{D}$ is right complete.

An arbitrary stable ∞-category $\mathcal{D}$ with a t-structure $(\mathcal{D}_{\geqslant 0}, \mathcal{D}_{\leqslant 0})$ and an equivalence $\mathcal{C} \simeq \mathcal{D}_{\geqslant 0}$ lies somewhere between these two extremes: more precisely, one has functors

$$\varinjlim(\mathcal{C} \xrightarrow{\Sigma} \mathcal{C} \to \cdots) \simeq \bigcup_{n \geqslant 0} \mathcal{D}_{\geqslant -n} \subseteq \mathcal{D} \to \varprojlim_{n \geqslant 0} \mathcal{D}_{\geqslant -n} \simeq \mathrm{Sp}(\mathcal{C}).$$

Notation C.1.2.11. Let $\mathcal{C}$ be a prestable ∞-category. We let $\mathcal{C}^{\heartsuit}$ denote the full subcategory of $\mathcal{C}$ spanned by the discrete objects. We will refer to $\mathcal{C}^{\heartsuit}$ as the *heart* of $\mathcal{C}$. Note that if $\mathcal{C}$ admits finite limits, then Proposition C.1.2.9 implies that we can identify $\mathcal{C}^{\heartsuit}$ with the heart of a t-structure on the stable ∞-category $\mathrm{SW}(\mathcal{C})$. In particular, $\mathcal{C}^{\heartsuit}$ is an abelian category.

Definition C.1.2.12. Let $\mathcal{C}$ be a prestable ∞-category which admits finite limits. We will say that that an object $X \in \mathcal{C}$ is *∞-connective* if $\tau_{\leqslant n} X \simeq 0$ for every integer n. We will say that $\mathcal{C}$ is *separated* if every ∞-connective object of $\mathcal{C}$ is a zero object. We say that $\mathcal{C}$ is *complete* it is a homotopy limit of the tower of ∞-categories

$$\cdots \to \tau_{\leqslant 2}\,\mathcal{C} \xrightarrow{\tau_{\leqslant 1}} \tau_{\leqslant 1}\,\mathcal{C} \xrightarrow{\tau_{\leqslant 0}} \tau_{\leqslant 0}\,\mathcal{C} = \mathcal{C}^{\heartsuit}.$$

In other words, $\mathcal{C}$ is complete if it is Postnikov complete (in the sense of Definition A.7.2.1).

Remark C.1.2.13. If a prestable ∞-category $\mathcal{C}$ is complete, then it is separated.

Remark C.1.2.14. Let $\mathcal{C}$ be a stable ∞-category. Then $\mathcal{C}$ is separated in the sense of Definition C.1.2.12 (when regarded as a prestable ∞-category) if and only if $\mathcal{C} \simeq *$.

C.1.3 The Prestable Dold-Kan Correspondence

Let $\mathcal{C}$ be an ∞-category which admits finite colimits and let $X_\bullet \in \mathrm{Fun}(\boldsymbol{\Delta}^{\mathrm{op}}, \mathcal{C})$ be a simplicial object of $\mathcal{C}$. For each $n \geqslant 0$, we define the *n-skeleton* $\mathrm{sk}_n(X_\bullet)$ to be the colimit $\varinjlim_{[m] \in \boldsymbol{\Delta}^{\mathrm{op}}_{\leqslant n}} X_m$ (note that this colimit exists in $\mathcal{C}$, since it can be rewritten as a colimit over the subcategory $\mathbf{\Delta}^{\rm op}_{s,\leqslant n} \subseteq \mathbf{\Delta}^{\rm op}_{\leqslant n}$ having finite nerve; see Lemma HA.1.2.4.17). Note that$\mathbf{\Delta}_{\leqslant n}$ is contained in $\mathbf{\Delta}_{\leqslant n'}$ for $n \leqslant n'$, so that the skeleta of $X_\bullet$ can be arranged in a diagram

$$\mathrm{sk}_0(X_\bullet) \to \mathrm{sk}_1(X_\bullet) \to \mathrm{sk}_2(X_\bullet) \to \cdots .$$

The construction $X_\bullet \mapsto \{\mathrm{sk}_n(X_\bullet)\}_{n \geqslant 0}$ determines a functor

$$\mathrm{sk}_* : \mathrm{Fun}(\mathbf{\Delta}^{\rm op}, \mathcal{C}) \to \mathrm{Fun}(\mathrm{N}(\mathbf{Z}_{\geqslant 0}), \mathcal{C})$$

from simplicial objects of $\mathcal{C}$ to filtered objects of $\mathcal{C}$ (here $\mathbf{Z}_{\geqslant 0}$ denotes the set of nonnegative integers, endowed with its usual ordering). In §HA.1.2.4 , we proved that this functor is an equivalence when $\mathcal{C}$ is a stable ∞-category (see Theorem HA.1.2.4.1 and its proof). We now establish the following refinement:

Theorem C.1.3.1 (The Prestable Dold-Kan Correspondence)**.** *Let $\mathcal{C}$ be a prestable ∞-category. Then the functor*

$$\mathrm{sk}_* : \mathrm{Fun}(\mathbf{\Delta}^{\rm op}, \mathcal{C}) \to \mathrm{Fun}(\mathrm{N}(\mathbf{Z}_{\geqslant 0}), \mathcal{C})$$

is fully faithful. Moreover, the essential image of sk_* *is spanned by those diagrams*

$$X(0) \xrightarrow{f(1)} X(1) \xrightarrow{f(2)} X(2) \to \cdots$$

which possess the following property:

- $(*)$ *For each $n > 0$, the cofiber* $\mathrm{cofib}(f(n))$ *belongs to the essential image of the iterated suspension functor $\Sigma^n : \mathcal{C} \to \mathcal{C}$.*

Proof. Let $\mathrm{SW}(\mathcal{C})$ denote the Spanier-Whitehead category of $\mathcal{C}$ and let $\rho : \mathcal{C} \to \mathrm{SW}(\mathcal{C})$ be the canonical map. Since ρ commutes with finite colimits, we have a commutative diagram

$$\begin{array}{ccc} \mathrm{Fun}(\mathbf{\Delta}^{\rm op}, \mathcal{C}) & \xrightarrow{\mathrm{sk}_*} & \mathrm{Fun}(\mathrm{N}(\mathbf{Z}_{\geqslant 0}), \mathcal{C}) \\ \downarrow & & \downarrow \\ \mathrm{Fun}(\mathbf{\Delta}^{\rm op}, \mathrm{SW}(\mathcal{C})) & \xrightarrow{\mathrm{sk}_*} & \mathrm{Fun}(\mathrm{N}(\mathbf{Z}_{\geqslant 0}), \mathrm{SW}(\mathcal{C})), \end{array}$$

where the vertical maps are given by composition with ρ (and are therefore fully faithful). Since the bottom horizontal map is an equivalence of ∞-categories (Theorem HA.1.2.4.1), it follows immediately that the functor $\mathrm{sk}_* : \mathrm{Fun}(\mathbf{\Delta}^{\rm op}, \mathcal{C}) \to \mathrm{Fun}(\mathrm{N}(\mathbf{Z}_{\geqslant 0}), \mathcal{C})$ is fully faithful.

For each $n \geqslant 0$, consider the following hypotheses on a simplicial object $X_\bullet$ of $\mathrm{SW}(\mathcal{C})$:

- (a_n) The object X_n belongs to the essential image of the functor $\rho : \mathcal{C} \to \mathrm{SW}(\mathcal{C})$.
- (b_n) The cofiber of the map $\mathrm{sk}_{n-1}(X_\bullet) \to \mathrm{sk}_n(X_\bullet)$ belongs to the essential image of the functor $(\rho \circ \Sigma^n) : \mathcal{C} \to \mathrm{SW}(\mathcal{C})$ (here we adopt the convention that $\mathrm{sk}_{-1}(X_\bullet) \simeq 0$).

To complete the proof, it will suffice to show that a simplicial object $X_\bullet$ of $\mathrm{SW}(\mathcal{C})$ satisfies condition (a_n) for all $n \geqslant 0$ if and only if it satisfies condition (b_n) for all $n \geqslant 0$. We will prove this by showing that if $X_\bullet$ satisfies condition (a_m) for $0 \leqslant m < n$, then conditions (a_n) and (b_n) are equivalent.

Let us henceforth regard $n \geqslant 0$ as fixed. Let $X_{\leqslant n}$ denote the restriction of X to the full subcategory $\mathbf{\Delta}^{\mathrm{op}}_{\leqslant n} \subseteq \mathbf{\Delta}^{\mathrm{op}}$ and define $X_{\leqslant n-1}$ similarly. Let $\overline{X}', \overline{X} : \mathbf{\Delta}^{\mathrm{op}}_{+,\leqslant n} \to \mathrm{SW}(\mathcal{C})$ be left Kan extensions of $X_{\leqslant n-1}$ and $X_{\leqslant n}$, respectively, so that $\overline{X}'([-1]) \simeq \mathrm{sk}_{n-1} X$, $\overline{X}([-1]) \simeq \mathrm{sk}_n(X)$, and $\overline{X}'([n])$ can be identified with the nth latching object of X. The canonical identification $X_{\leqslant n-1} \simeq X_{\leqslant n}|_{\mathbf{\Delta}^{\mathrm{op}}_{\leqslant n-1}}$ induces a natural transformation of functors $\overline{X}' \to \overline{X}$. Let us denote the cofiber of this natural transformation by $\overline{X}''$, so that we have a cofiber sequence $\overline{X}' \to \overline{X} \to \overline{X}''$ in the ∞-category $\mathrm{Fun}(\mathbf{\Delta}^{\mathrm{op}}_{+,\leqslant n}, \mathrm{SW}(\mathcal{C}))$. Note that both $\overline{X}'$ and $\overline{X}$ are left Kan extensions of their restrictions to $\mathbf{\Delta}^{\mathrm{op}}_{\leqslant n}$, so that $\overline{X}''$ has the same property. Set $Z = \mathrm{cofib}(\mathrm{sk}_{n-1}(X_\bullet)\, \mathrm{sk}_n(X_\bullet)) \simeq \overline{X}''([-1])$. Since the objects $\overline{X}''([m])$ vanish for $0 \leqslant m < n$, Corollary HA.1.2.4.18 supplies an equivalence $Z \simeq \Sigma^n \overline{X}''([n])$. In other words, we have a cofiber sequence

$$\overline{X}'([n]) \to X_n \to \Sigma^{-n} Z.$$

Our hypothesis that $X_\bullet$ satisfies (a_m) for $m < n$ guarantees that $\overline{X}'([n])$ belongs to the essential image of ρ. Since the essential image of ρ is closed under cofibers and extensions, it follows that X_n belongs to the essential image of ρ if and only if $\Sigma^{-n} Z$ belongs to the essential image of ρ. We conclude that $(a_n) \Leftrightarrow (b_n)$, as desired. □

C.1.4 Grothendieck Prestable ∞-Categories

Let $\mathcal{A}$ be an abelian category. Recall that $\mathcal{A}$ is said to be *Grothendieck* if it is presentable and filtered colimits in $\mathcal{A}$ are exact. We now discuss an analogous condition in the setting of prestable ∞-categories.

Proposition C.1.4.1. *Let $\mathcal{C}$ be a presentable ∞-category. The following conditions are equivalent:*

- *(a) The ∞-category $\mathcal{C}$ is prestable and filtered colimits in $\mathcal{C}$ are left exact (see Definition HTT.7.3.4.2).*
- *(b) The ∞-category $\mathcal{C}$ is prestable and the functor $\Omega : \mathcal{C} \to \mathcal{C}$ commutes with filtered colimits.*
- *(c) The ∞-category $\mathcal{C}$ is prestable and the functor $\Omega^\infty : \mathrm{Sp}(\mathcal{C}) \to \mathcal{C}$ commutes with filtered colimits.*

(*d*) *There exists a presentable stable ∞-category $\mathcal{D}$, a t-structure $(\mathcal{D}_{\geqslant 0}, \mathcal{D}_{\leqslant 0})$ on $\mathcal{D}$ which is compatible with filtered colimits, and an equivalence $\mathcal{C} \simeq \mathcal{D}_{\geqslant 0}$.*

Definition C.1.4.2. Let $\mathcal{C}$ be a prestable ∞-category. We will say that $\mathcal{C}$ is *Grothendieck* if it presentable and satisfies the equivalent conditions of Proposition C.1.4.1.

Example C.1.4.3. Let $\mathcal{C}$ be a stable ∞-category. Then $\mathcal{C}$ is automatically a prestable ∞-category. It is a Grothendieck prestable ∞-category if and only if it is presentable (in this case, the functor $\Omega : \mathcal{C} \to \mathcal{C}$ automatically commutes with filtered colimits since it is an equivalence of ∞-categories).

Example C.1.4.4. Let $\mathcal{C}$ be a prestable ∞-category. If $\mathcal{C}$ is compactly generated (Definition HTT.5.5.7.1), then $\mathcal{C}$ is a Grothendieck prestable ∞-category (note that filtered colimits are left exact in any compactly generated ∞-category).

Example C.1.4.5. Let $\mathcal{A}$ be a Grothendieck abelian category and let $\mathcal{D}(\mathcal{A})$ be the derived ∞-category of $\mathcal{A}$ (see §HA.1.3.5). Then $\mathcal{D}(\mathcal{A})$ admits a t-structure $(\mathcal{D}(\mathcal{A})_{\geqslant 0}, \mathcal{D}(\mathcal{A})_{\leqslant 0})$ which is right complete and compatible with filtered colimits (Proposition HA.1.3.5.21). It follows that $\mathcal{D}(\mathcal{A})_{\geqslant 0}$ is a Grothendieck prestable ∞-category.

Remark C.1.4.6. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. Then the heart $\mathcal{C}^{\heartsuit}$ (see Notation C.1.2.11) is a Grothendieck abelian category (Remark HA.1.3.5.23). It follows from Example C.1.4.5 that every Grothendieck abelian category arises in this way. However, the correspondence is many-to-one. For example, if R is a commutative ring, then the Grothendieck abelian category $\mathrm{Mod}_R^{\heartsuit}$ can be identified with the heart of $\mathrm{Mod}_{\overline{R}}^{\mathrm{cn}}$ for *any* connective $\mathbb{E}_\infty$-ring $\overline{R}$ satisfying $\pi_0 \overline{R} \simeq R$. For a more detailed discussion about the relationship between a Grothendieck prestable ∞-category and its heart $\mathcal{C}^{\heartsuit}$, we refer the reader to §C.5.

Proof of Proposition C.1.4.1. The implication $(a) \Rightarrow (b)$ is trivial, the implication $(b) \to (c)$ follows from the observation that $\mathrm{Sp}(\mathcal{C})$ can be realized as the homotopy limit of the tower

$$\cdots \xrightarrow{\Omega} \to \mathcal{C} \xrightarrow{\Omega} \mathcal{C} \xrightarrow{\Omega} \to \mathcal{C} \xrightarrow{\Omega} \mathcal{C},$$

and the implication $(c) \Rightarrow (d)$ follows by taking $\mathcal{D} = \mathrm{Sp}(\mathcal{C})$ (see Remark C.1.2.10). We will complete the proof by showing that (d) implies (a). Suppose that $\mathcal{E}$ is a presentable stable ∞-category equipped with a t-structure $(\mathcal{D}_{\geqslant 0}, \mathcal{D}_{\leqslant 0})$ which is compatible with filtered colimits. Then $\mathcal{D}_{\geqslant 0}$ is prestable (Proposition C.1.2.9); we wish to show that filtered colimits in $\mathcal{D}_{\geqslant 0}$ are left exact. Let K be a finite simplicial set and let $F_{\geqslant 0} : \mathrm{Fun}(K, \mathcal{D}_{\geqslant 0}) \to \mathcal{D}_{\geqslant 0}$ be a right adjoint to the diagonal map; we wish to show that the functor $F_{\geqslant 0}$ commutes with filtered colimits. Unwinding the definitions, we can write $F_{\geqslant 0}$ as a composition

$$\mathrm{Fun}(K, \mathcal{D}_{\geqslant 0}) \hookrightarrow \mathrm{Fun}(K, \mathcal{D}) \xrightarrow{F} \mathcal{D} \xrightarrow{\tau_{\geqslant 0}} \mathcal{D}_{\geqslant 0},$$

where $F : \mathrm{Fun}(K, \mathcal{D}) \to \mathcal{D}$ is a right adjoint to the diagonal map. Since $\mathcal{D}$ is stable, the functor F preserves filtered colimits (in fact, it preserves all small colimits). It therefore suffices to observe that the truncation functor $\tau_{\geqslant 0}$ preserves filtered colimits, by virtue of our assumption that the t-structure $(\mathcal{D}_{\geqslant 0}, \mathcal{D}_{\leqslant 0})$ is compatible with filtered colimits. □

C.1.5 Additive ∞-Categories

Let $\mathcal{A}$ be a category. Recall that $\mathcal{A}$ is said to be *additive* if it satisfies the following three conditions:

(i) The category $\mathcal{A}$ is pointed: that is, there is an object $0 \in \mathcal{A}$ which is both initial and final.

Using (i), we can associate to every pair of objects $X, Y \in \mathcal{A}$ a *zero morphism* $0 \in \mathrm{Hom}_{\mathcal{A}}(X, Y)$, given by the composition $X \to 0 \to Y$.

(ii) The category $\mathcal{A}$ admits finite products and finite coproducts. Moreover, for every pair of objects $X, Y \in \mathcal{A}$, the canonical map

$$\begin{bmatrix} \mathrm{id}_X & 0 \\ 0 & \mathrm{id}_Y \end{bmatrix} : X \amalg Y \to X \times Y$$

is an isomorphism.

Using (ii), we can endow each $\mathrm{Hom}_{\mathcal{A}}(X, Y)$ with the structure of a commutative monoid, where the sum of morphisms $f, g : X \to Y$ is given by the composition

$$(f + g) : X \to X \times X \xrightarrow{(f,g)} Y \times Y \simeq Y \amalg Y \to Y.$$

(iii) For every pair of objects $X, Y \in \mathcal{A}$, the addition law defined above endows the set $\mathrm{Hom}_{\mathcal{A}}(X, Y)$ with the structure of an abelian group.

In this section, we will study the following ∞-categorical generalization of the notion of additive category:

Definition C.1.5.1. Let $\mathcal{C}$ be an ∞-category. We will say that $\mathcal{C}$ is *additive* if it satisfies the following conditions:

(a) The ∞-category $\mathcal{C}$ admits finite products.

(b) The ∞-category $\mathcal{C}$ admits finite coproducts.

(c) The homotopy category $\mathrm{h}\mathcal{C}$ is an additive category.

Remark C.1.5.2. Let $\mathcal{C}$ be an additive ∞-category. Then $\mathcal{C}$ is pointed. Moreover, for every pair of objects $X, Y \in \mathcal{C}$, the additivity of $\mathrm{h}\mathcal{C}$ implies that the canonical map

$$\begin{bmatrix} \mathrm{id}_X & 0 \\ 0 & \mathrm{id}_Y \end{bmatrix} : X \amalg Y \to X \times Y$$

is an equivalence. We will henceforth denote both the coproduct $X \amalg Y$ and the product $X \times Y$ by $X \oplus Y$, which we refer to as the *direct sum* of X and Y.

Remark C.1.5.3. Let $\mathcal{C}$ be an ∞-category. If $\mathcal{C}$ satisfies condition (a) of Definition C.1.5.1, then we can regard $\mathcal{C}$ as equipped with the Cartesian symmetric monoidal structure introduced in §HA.2.4.1 . Let $\mathrm{Mon}_{\mathrm{Comm}}(\mathcal{C})$ denote the ∞-category of commutative monoid objects of $\mathcal{C}$ (see §HA.2.4.2). If $\mathcal{C}$ satisfies also condition (b) of Definition C.1.5.1, then it can also be equipped with the coCartesian symmetric monoidal structure introduced in §**??**. If $\mathcal{C}$ satisfies condition (c) of Definition C.1.5.1, then the Cartesian and coCartesian symmetric monoidal structures on $\mathcal{C}$ are equivalent. In this case, Propositions HA.2.4.2.5 and HA.2.4.3.8 imply that the vertical maps in the diagram

$$\begin{array}{ccc} & \mathrm{CAlg}(\mathcal{C}) & \\ \swarrow & & \searrow \\ \mathrm{Mon}_{\mathrm{Comm}}(\mathcal{C}) & \longrightarrow & \mathcal{C} \end{array}$$

are equivalences of ∞-categories, so that the forgetful functor $\mathrm{Mon}_{\mathrm{Comm}}(\mathcal{C}) \to \mathcal{C}$ is also an equivalence of ∞-categories. In other words, every object of $\mathcal{C}$ admits the structure of a commutative monoid (with respect to the direct sum $\oplus$) in an essentially unique way.

Example C.1.5.4. Let $\mathcal{C}$ be an additive ∞-category, and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a full subcategory which is closed under finite coproducts. Then $\mathcal{C}_0$ is also an additive ∞-category.

Example C.1.5.5. Any stable ∞-category is additive (see Lemma HA.1.1.2.9).

Example C.1.5.6. Any prestable ∞-category is additive (this follows from Examples C.1.5.4 and C.1.5.5, together with Corollary C.1.2.3).

We now establish a converse to Example C.1.5.6: every (small) additive ∞-category $\mathcal{C}$ admits a canonical embedding into a (Grothendieck) prestable ∞-category, whose essential image is closed under finite coproducts.

Proposition C.1.5.7. *Let $\mathcal{C}$ be a small ∞-category which admits finite coproducts, let $\mathcal{P}_{\Sigma}(\mathcal{C}) \subseteq \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ be the full subcategory spanned by those functors which preserve finite products, and let $j : \mathcal{C} \to \mathcal{P}_{\Sigma}(\mathcal{C})$ be the Yoneda embedding. The following conditions are equivalent:*

(1) *The ∞-category $\mathcal{C}$ is additive.*

(2) *The ∞-category $\mathcal{P}_\Sigma(\mathcal{C})$ is prestable.*

Lemma C.1.5.8. *Let $\mathcal{C}$ be a small additive ∞-category. Then the ∞-category $\mathcal{P}_\Sigma(\mathcal{C})$ is also additive.*

Proof. Since $\mathcal{P}_\Sigma(\mathcal{C})$ is presentable, it admits finite limits and colimits. Let $j : \mathcal{C} \to \mathcal{P}_\Sigma(\mathcal{C})$ be the Yoneda embedding, so that j preserves finite products (Proposition HTT.5.1.3.2) and finite coproducts (Proposition HTT.5.5.8.10). In particular, if 0 is a zero object of $\mathcal{C}$, then $j(0)$ is a zero object of $\mathcal{P}_\Sigma(\mathcal{C})$. Consequently, for every pair of objects $X, Y \in \mathcal{P}_\Sigma(\mathcal{C})$, we obtain a canonical map $\theta_{X,Y} : X \amalg Y \to X \times Y$. We wish to prove that $\theta_{X,Y}$ is an equivalence for all $X, Y \in \mathcal{P}_\Sigma(\mathcal{C})$. Since $\mathcal{P}_\Sigma(\mathcal{C})$ is closed under sifted colimits in $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ and the formation of products in $\mathcal{S}$ commutes with small colimits in each variable, it follows that the construction $(X, Y) \mapsto X \times Y$ preserves sifted colimits separately in each variable. Consequently, the collection of those pairs (X, Y) for which $\theta_{X,Y}$ is an equivalence is closed under sifted colimits. We may therefore assume without loss of generality that X and Y belong to the essential image of j, in which case the desired result follows from the additivity of $\mathcal{C}$.

Arguing as in Remark C.1.5.3, we see that the forgetful functor $\mathrm{Mon}_{\mathrm{Comm}}(\mathcal{P}_\Sigma(\mathcal{C})) \to \mathcal{P}_\Sigma(\mathcal{C})$ is an equivalence of ∞-categories, so that we can regard each object $Y \in \mathcal{P}_\Sigma(\mathcal{C})$ as a commutative monoid object of $\mathcal{P}_\Sigma(\mathcal{C})$. In particular, if $X \in \mathcal{P}_\Sigma(\mathcal{C})$ is another object, then the mapping space $\mathrm{Map}_{\mathcal{P}_\Sigma}(X, Y)$ can be regarded as a commutative monoid object of the ∞-category $\mathcal{S}$, so that $\pi_0 \mathrm{Map}_{\mathcal{P}_\Sigma}(X, Y)$ inherits the structure of a commutative monoid. To complete the proof, it will suffice to show that each of the commutative monoids $\pi_0 \mathrm{Map}_{\mathcal{P}_\Sigma}(X, Y)$ is an abelian group: in other words, each of the mapping spaces $\mathrm{Map}_{\mathcal{P}_\Sigma}(X, Y)$ is *grouplike* commutative monoid object of $\mathcal{S}$, (see Definition **??**). Since the full subcategory of $\mathrm{Mon}_{\mathrm{Comm}}(\mathcal{S})$ spanned by the grouplike commutative monoids is closed under limits, the collection of those objects $X \in \mathcal{P}_\Sigma(\mathcal{C})$ for which $\pi_0 \mathrm{Map}_{\mathcal{P}_\Sigma}(X, Y)$ is an abelian group is closed under small colimits. We may therefore assume without loss of generality that X belongs to the essential image of j, so that X is a compact projective object of $\mathcal{P}_\Sigma$. Write Y as the geometric realization of a simplicial object $Y_\bullet$, where Y_0 is a coproduct of objects belonging to the essential image of j. Since X is projective, the map

$$\pi_0 \mathrm{Map}_{\mathcal{P}_\Sigma}(X, Y_0) \to \pi_0 \mathrm{Map}_{\mathcal{P}_\Sigma}(X, Y)$$

is surjective. We may therefore replace Y by Y_0 and thereby reduce to the case where Y has the form $\coprod_{\alpha \in A} j(Y_\alpha)$ for some objects $Y_\alpha \in \mathcal{C}$. Since X is compact, the commutative monoid $\pi_0 \mathrm{Map}_{\mathcal{P}_\Sigma}(X, Y)$ can be written as a filtered colimit of commutative monoids of the form $\pi_0 \mathrm{Map}_{\mathcal{P}_\Sigma}(X, \coprod_{\alpha \in A_0} j(Y_\alpha))$, where A_0 ranges over all finite subsets of A. We may therefore replace Y by $j(\coprod_{\alpha \in A_0} Y_\alpha)$ and thereby reduce to the case where Y also belongs to the essential image of j. In this case, the existence of inverses in the commutative monoid $\mathrm{Map}_{\mathcal{P}_\Sigma}(X, Y)$ follows from our assumption that $\mathcal{C}$ is additive. □

Proof of Proposition C.1.5.7. Let $\mathcal{C}$ be a small ∞-category which admits finite coproducts. Then the Yoneda embedding $j : \mathcal{C} \to \mathcal{P}_\Sigma(\mathcal{C})$ is fully faithful and preserves finite coproducts (Proposition HTT.5.5.8.10). Using Examples C.1.5.4 and C.1.5.6, we deduce that if $\mathcal{P}_\Sigma(\mathcal{C})$ is prestable, then $\mathcal{C}$ is additive. For the converse, assume that $\mathcal{C}$ is additive. Using Remark HA.5.2.6.26 , we can identify the ∞-category $\mathrm{Sp}^{\mathrm{cn}}$ of connective spectra with the full subcategory $\mathrm{Mon}^{\mathrm{gp}}_{\mathrm{Comm}}(\mathcal{S}) \subseteq \mathrm{Mon}_{\mathrm{Comm}}(\mathcal{S})$ spanned by the grouplike commutative monoid objects of $\mathcal{S}$. This identification furnishes an equivalence $\mathrm{Fun}^{\pi}(\mathcal{C}^{\mathrm{op}}, \mathrm{Sp}^{\mathrm{cn}}) \simeq \mathrm{Mon}^{\mathrm{gp}}_{\mathrm{Comm}}(\mathcal{P}_\Sigma(\mathcal{C}))$, where $\mathrm{Mon}^{\mathrm{gp}}_{\mathrm{Comm}}(\mathcal{P}_\Sigma(\mathcal{C}))$ denotes the full subcategory of $\mathrm{Mon}_{\mathrm{Comm}}(\mathcal{P}_\Sigma(\mathcal{C}))$ spanned by those commutative monoid objects X having the property that for each object $C \in \mathcal{C}$, the object $X(C) \simeq \mathrm{Map}_{\mathcal{P}_\Sigma(\mathcal{C})}(j(C), X) \in \mathrm{Mon}_{\mathrm{Comm}}(\mathcal{S})$ is grouplike. It follows from Lemma C.1.5.8 that $\mathcal{P}_\Sigma(\mathcal{C})$ is additive, so that the forgetful functor

$$\mathrm{Mon}^{\mathrm{gp}}_{\mathrm{Comm}}(\mathcal{P}_\Sigma(\mathcal{C})) = \mathrm{Mon}_{\mathrm{Comm}}(\mathcal{P}_\Sigma(\mathcal{C})) \to \mathcal{P}_\Sigma(\mathcal{C})$$

is an equivalence of ∞-categories. We therefore obtain an equivalence $\mathcal{P}_\Sigma(\mathcal{C}) \simeq \mathrm{Fun}^{\pi}(\mathcal{C}^{\mathrm{op}}, \mathrm{Sp}^{\mathrm{cn}})$. In particular, there is a fully faithful embedding $\mathcal{P}_\Sigma(\mathcal{C}) \hookrightarrow \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathrm{Sp})$ whose essential image is closed under finite colimits and extensions, so that $\mathcal{P}_\Sigma(\mathcal{C})$ is prestable by virtue of Corollary C.1.2.3. □

Remark C.1.5.9. Let $\mathcal{C}$ be a small additive ∞-category and let $\mathcal{E} = \mathcal{P}_\Sigma(\mathcal{C})$. It follows from Proposition C.1.5.7 that the ∞-category $\mathcal{E}$ is prestable. The proof of Proposition C.1.5.7 yields an equivalence $\mathcal{E} \simeq \mathrm{Fun}^{\pi}(\mathcal{C}^{\mathrm{op}}, \mathrm{Sp}^{\mathrm{cn}})$, which yields equivalences

$$\mathrm{Sp}(\mathcal{E}) \simeq \mathrm{Fun}^{\pi}(\mathcal{C}^{\mathrm{op}}, \mathrm{Sp}) \qquad \mathcal{E}^{\heartsuit} \simeq \mathrm{Fun}^{\pi}(\mathcal{C}^{\mathrm{op}}, \mathrm{Sp}^{\heartsuit}).$$

In particular, $\mathcal{E}$ is a Grothendieck prestable ∞-category and the canonical map $\mathcal{E} \to \varprojlim \tau_{\leqslant n} \mathcal{E}$ is an equivalence (that is, $\mathcal{E}$ is *complete* in the sense of Definition C.1.2.12).

Remark C.1.5.10. Let $\mathcal{E}$ be an ∞-category which is projectively generated (see Definition HTT.5.5.8.23). Then the following conditions are equivalent:

(a) The ∞-category $\mathcal{E}$ is additive.

(b) The ∞-category $\mathcal{E}$ is Grothendieck prestable.

(c) There exist a small additive ∞-category $\mathcal{C}$ and an equivalence $\mathcal{P}_\Sigma(\mathcal{C}) \simeq \mathcal{E}$.

The implication $(c) \Rightarrow (b)$ follows from Remark C.1.5.9, the implication $(b) \Rightarrow (a)$ follows from Example **??**. To show that $(a) \Rightarrow (c)$, take $\mathcal{C} \subseteq \mathcal{E}$ to be the full subcategory spanned by the compact projective objects. The assumption that $\mathcal{E}$ is projective generated guarantees the existence of an equivalence $\mathcal{P}_\Sigma(\mathcal{C}) \simeq \mathcal{E}$ (Proposition HTT.5.5.8.25). Since $\mathcal{C}$ is a full subcategory of $\mathcal{E}$ which is closed under finite coproducts, the additivity of $\mathcal{E}$ guarantees the additivity of $\mathcal{C}$ (Example **??**).

Example C.1.5.11. Let $\mathcal{C}$ be an additive ∞-category which is generated under finite coproducts by a single object $C \in \mathcal{C}$. Let $j : \mathcal{C} \to \mathcal{P}_\Sigma(\mathcal{C})$ be the Yoneda embedding, and let us abuse notation by identifying $\mathcal{P}_\Sigma(\mathcal{C})$ with a full subcategory of its stabilization $\mathrm{Sp}(\mathcal{P}_\Sigma(\mathcal{C}))$. Then $j(C)$ is a compact object of the stable $\mathrm{Sp}(\mathcal{P}_\Sigma(\mathcal{C}))$ whose desuspensions generate $\mathrm{Sp}(\mathcal{P}_\Sigma(\mathcal{C}))$ under small colimits. Applying Theorem **??** (and its proof), we deduce that there exists an $\mathbb{E}_1$-ring A and an equivalence of stable ∞-categories $\rho : \mathrm{RMod}_A \to \mathrm{Sp}(\mathcal{P}_\Sigma(\mathcal{C}))$ carrying A to $j(C)$. For each $n \geqslant 0$, we have a canonical homotopy equivalence

$$\Omega^{\infty-n} A \simeq \mathrm{Map}_{\mathcal{P}_\Sigma(\mathcal{C})}(j(C), \Sigma^n j(C)).$$

Since $j(C)$ is a projective object of $\mathcal{P}_\Sigma(\mathcal{C})$, it follows that $\Omega^{\infty-n}A$ is n-connective for each n: that is, the spectrum A is connective. Taking $n = 0$ and using the fact that j is fully faithful, we obtain a homotopy equivalence $\Omega^\infty A \simeq \mathrm{Map}_{\mathcal{C}}(C, C)$: more informally, we can regard A as the "endomorphism ring" of the object $C \in \mathcal{C}$. Since $\mathrm{RMod}_A^{\mathrm{cn}}$ is the smallest full subcategory of RMod_A which contains A and is closed under small colimits, the functor ρ restricts to an equivalence of Grothendieck prestable ∞-categories $\mathrm{RMod}_A^{\mathrm{cn}} \simeq \mathcal{P}_\Sigma(\mathcal{C})$.

C.2 The Gabriel-Popescu Theorem

Let $\mathcal{A}$ be a Grothendieck abelian category. Recall that an object $C \in \mathcal{A}$ is a *generator* of $\mathcal{A}$ if every object of $\mathcal{A}$ can be written as a quotient of a direct sum $\bigoplus C$ of copies of C.

Theorem C.2.0.12 (Gabriel-Popescu)**.** *Let $\mathcal{A}$ be a Grothendieck abelian category, let $C \in \mathcal{A}$ be a generator, let $A = \mathrm{Hom}_{\mathcal{A}}(C, C)$ be its endomorphism ring, and let $\mathrm{RMod}_A^\heartsuit$ denote the abelian category of right A-modules. Then the construction $D \mapsto \mathrm{Hom}_{\mathcal{A}}(C, D)$ determines a fully faithful embedding $G : \mathcal{A} \to \mathrm{RMod}_A^\heartsuit$. Moreover, the left adjoint of G (given by the construction $M \mapsto M \otimes_A C$) is an exact functor from $\mathrm{RMod}_A^\heartsuit$ to $\mathcal{A}$.*

Since every Grothendieck abelian category has a generator, Theorem C.2.0.12 implies that every Grothendieck abelian category can be realized as a left exact localization of the category of modules over a (possibly noncommutative) ring. This has many pleasant consequences: for example, it can be used to show that there is a well-behaved tensor product on Grothendieck abelian categories (see Theorem C.5.4.16).

Our goal in this section is to establish an analogue of Theorem C.2.0.12 for Grothendieck prestable ∞-categories (Theorem **??**), and to study some of its applications. For example, we will see that Theorem C.2.0.12 can be recovered from our result as a special case (Theorem C.2.2.1), and that every Grothendieck prestable ∞-category $\mathcal{C}$ can be obtained as a left exact localization of the ∞-category of $\mathrm{RMod}_A^{\mathrm{cn}}$, where A is a connective $\mathbb{E}_1$-ring (Theorem C.2.4.1).

C.2.1 The Gabriel-Popescu Theorem for Prestable ∞-Categories

We begin by introducing some terminology.

Definition C.2.1.1. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. A *generating subcategory* for $\mathcal{C}$ is a full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ with the following property: for every object $X \in \mathcal{C}$, there exists a collection of maps $\rho_\alpha : C_\alpha \to X$, where each C_α belongs to $\mathcal{C}_0$ and the induced map $\bigoplus_\alpha \pi_0 C_\alpha \to \pi_0 X$ is an epimorphism in the abelian category $\mathcal{C}^\heartsuit$.

When $\mathcal{C}_0$ is the full subcategory of $\mathcal{C}$ spanned by a single object C, then we say that C is a *generator* of $\mathcal{C}$ if $\mathcal{C}_0$ is a generating subcategory of $\mathcal{C}$.

Warning C.2.1.2. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. If $\mathcal{C}_0 \subseteq \mathcal{C}$ is a full subcategory which generates $\mathcal{C}$ under small colimits, then $\mathcal{C}_0$ is a generating subcategory of $\mathcal{C}$ in the sense of Definition C.2.1.1. However, the converse is not true in general. For example, if $\mathcal{C}$ is stable, then *any* full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ is a generating subcategory. However, we will show below that the converse does hold when $\mathcal{C}$ is separated (in the sense of Definition C.1.2.12); see Corollary C.2.1.7.

Remark C.2.1.3. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. Then $\mathcal{C}$ is presentable, so there exists an essentially full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ which generates $\mathcal{C}$ under small colimits. In particular, there exists an essentially small generating subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$.

Remark C.2.1.4. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. If $\mathcal{C}_0 \subseteq \mathcal{C}$ is a generating subcategory of $\mathcal{C}$ spanned by a small collection of objects $\{C_\alpha\}$, then the single object $C = \bigoplus_\alpha C_\alpha$ is a generator of $\mathcal{C}$. Combining this observation with Remark C.2.1.3, we see that every Grothendieck prestable ∞-category $\mathcal{C}$ admits a generator $C \in \mathcal{C}$.

Warning C.2.1.5. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $C \in \mathcal{C}$ be a generator. Then the truncation $\pi_0 C$ is a generator of the Grothendieck abelian category $\mathcal{C}^\heartsuit$. However, the converse is false in general. For example, $\mathbf{Z}$ is a generator for the Grothendieck abelian category $\mathrm{Sp}^\heartsuit$ of abelian groups, but is *not* a generator for the Grothendieck prestable ∞-category $\mathrm{Sp}^{\mathrm{cn}}$ (any map from $\mathbf{Z}$ to the sphere spectrum is nullhomotopic).

We can now formulate our main result:

Theorem C.2.1.6 (∞-Categorical Gabriel-Popescu Theorem)**.** *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be an essentially small generating subcategory. Assume that $\mathcal{C}$ is separated and that $\mathcal{C}_0$ is closed under finite coproducts in $\mathcal{C}$. Then:*

(1) *The inclusion functor $\mathcal{C}_0 \to \mathcal{C}$ extends to a left exact functor $F : \mathcal{P}_\Sigma(\mathcal{C}_0) \to \mathcal{C}$ which commutes with small colimits.*

(2) *The functor F admits a fully faithful right adjoint $G : \mathcal{C} \to \mathcal{P}_\Sigma(\mathcal{C}_0)$.*

We will give the proof of Theorem C.2.1.6 in §**??**. For the moment, let us enumerate some of its consequences.

Corollary C.2.1.7. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be an essentially small generating subcategory. If $\mathcal{C}$ is separated, then it is generated under small colimits by $\mathcal{C}_0$.*

Corollary C.2.1.8. *Let $\mathcal{C}$ be a separated Grothendieck prestable ∞-category and let $C \in \mathcal{C}$ be a generator. Then there exists a connective $\mathbb{E}_1$-ring A and a pair of adjoint functors $\mathrm{RMod}_A^{\mathrm{cn}} \underset{G}{\overset{F}{\rightleftarrows}} \mathcal{C}$, where $G(C) \simeq A$, the functor F is left exact, and the functor G is fully faithful.*

Proof. Let $\mathcal{C}_0 \subseteq \mathcal{C}$ denote the full subcategory spanned by the finite direct sums $C \oplus C \oplus \cdots \oplus C$. Example C.1.5.11 supplies a connective $\mathbb{E}_1$-ring A and an equivalence of ∞-categories $\mathcal{P}_\Sigma(\mathcal{C}_0) \simeq \mathrm{RMod}_A^{\mathrm{cn}}$. Applying Theorem C.2.1.6, we obtain the desired adjunction $\mathrm{RMod}_A^{\mathrm{cn}} \underset{G}{\overset{F}{\rightleftarrows}} \mathcal{C}$. □

Remark C.2.1.9. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. Then we can regard $\mathcal{C}$ as tensored over the ∞-category $\mathrm{Sp}^{\mathrm{cn}}$ of connective spectra (see Corollary C.4.1.2). It follows that for every object $C \in \mathcal{C}$, we can associate a connective spectrum $\mathrm{End}_{\mathcal{C}}(C)$ which is *universal* among connective spectra E equipped with a map $E \otimes C \to C$. In this case, we can regard $\mathrm{End}_{\mathcal{C}}(C)$ as a connective $\mathbb{E}_1$-ring and C as an $\mathrm{End}_{\mathcal{C}}(C)$-module object of $\mathcal{C}$. Suppose that $\mathcal{C}$ is separated and C is a generator of $\mathcal{C}$, and consider an adjunction $\mathrm{RMod}_A^{\mathrm{cn}} \underset{G}{\overset{F}{\rightleftarrows}} \mathcal{C}$ as in the statement of Corollary C.2.1.8. Then G is fully faithful and $G(C) \simeq A$, so we obtain a canonical equivalence

$$\mathrm{End}_{\mathcal{C}}(C) \simeq \mathrm{End}_{\mathrm{RMod}_A^{\mathrm{cn}}}(A) \simeq A.$$

In other words, we can identify A with the (connective) endomorphism ring $\mathrm{End}_{\mathcal{C}}(C)$. Under this identification, the functor F is given by $(M \in \mathrm{RMod}_A^{\mathrm{cn}}) \mapsto (M \otimes_A C \in \mathcal{C})$.

Corollary C.2.1.10. *Let $\mathcal{C}$ be presentable stable ∞-category equipped with a t-structure $(\mathcal{C}_{\geq 0}, \mathcal{C}_{\leq 0})$ which is left separated, right complete, and compatible with filtered colimits. Let $\mathcal{C}_0 \subseteq \mathcal{C}_{\geq 0}$ be a generating subcategory which is closed under finite direct sums. Then the functor $G : \mathcal{C} \to \mathrm{Fun}^\pi(\mathcal{C}_0^{\mathrm{op}}, \mathrm{Sp})$ given by $G(C)(C_0) = \underline{\mathrm{Map}}_{\mathcal{C}}(C_0, C)$ is fully faithful. Moreover, G admits a t-exact left adjoint $F : \mathrm{Fun}^\pi(\mathcal{C}_0^{\mathrm{op}}, \mathrm{Sp}) \to \mathcal{C}$.*

Proof. Applying Theorem C.2.1.6 to the inclusion $\mathcal{C}_0 \subseteq \mathcal{C}_{\geqslant 0}$ and identifying $\mathcal{P}_\Sigma(\mathcal{C}_0)$ with the ∞-category $\mathrm{Fun}(\mathcal{C}_0^{\mathrm{op}}, \mathrm{Sp}^{\mathrm{cn}})$ as in the proof of Proposition C.1.5.7, we obtain adjoint functors $\mathrm{Fun}^\pi(\mathcal{C}_0^{\mathrm{op}}, \mathrm{Sp}^{\mathrm{cn}}) \underset{g}{\overset{f}{\rightleftarrows}} \mathcal{C}_{\geqslant 0}$ where f is left exact and g is fully faithful. Passing to stabilizations, we obtain the desired adjunction $\mathrm{Fun}^\pi(\mathcal{C}_0^{\mathrm{op}}, \mathrm{Sp}) \underset{G}{\overset{F}{\rightleftarrows}} \mathcal{C}$. □

Corollary C.2.1.11. *Let $\mathcal{C}$ be presentable stable ∞-category equipped with a t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ which is left separated, right complete, and compatible with filtered colimits. Let C be a generator for the Grothendieck prestable ∞-category $\mathcal{C}_{\geqslant 0}$, and let $A \in \mathrm{Alg}^{\mathrm{cn}}$ denote the connective cover of the endomorphism ring $\underline{\mathrm{Map}}_{\mathcal{C}}(C, C)$. Then the construction $(D \in \mathcal{C}) \mapsto \underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$ induces a fully faithful embedding $G : \mathcal{C} \to \mathrm{RMod}_A$. Moreover, G admits a t-exact left adjoint F, given by $F(M) = M \otimes_A C$.*

C.2.2 The Gabriel-Popescu Theorem for Abelian Categories

We now show that the ∞-categorical Gabriel-Popescu theorem (Theorem C.2.1.6) implies the classical Gabriel-Popescu theorem (Theorem C.2.0.12). In fact, we can deduce a slightly stronger "many-object" version, due to Kuhn (see [126]).

Theorem C.2.2.1 (Kuhn)**.** *Let $\mathcal{A}$ be a Grothendieck abelian category, let $\mathcal{A}_0 \subseteq \mathcal{A}$ be an essentially small full subcategory which is closed under finite direct sums, and let $\mathrm{Fun}^\pi(\mathcal{A}_0^{\mathrm{op}}, \mathcal{S}\mathrm{et})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{A}_0^{\mathrm{op}}, \mathcal{S}\mathrm{et})$ spanned by those functors which preserve finite products. Suppose that, for every object $X \in \mathcal{A}$, there exists an epimorphism $\bigoplus C_\alpha \to X$, where each C_α belongs to $\mathcal{A}_0$. Then:*

- (a) *The construction $X \mapsto \mathrm{Hom}_{\mathcal{A}}(\bullet, X)$ determines a fully faithful embedding $g : \mathcal{A} \to \mathrm{Fun}^\pi(\mathcal{A}_0^{\mathrm{op}}, \mathcal{S}\mathrm{et})$.*
- (b) *The functor g admits an exact left adjoint $f : \mathrm{Fun}^\pi(\mathcal{A}_0^{\mathrm{op}}, \mathcal{S}\mathrm{et}) \to \mathcal{A}$.*

Example C.2.2.2 (The Case of a Single Generator)**.** Let $\mathcal{A}$ be a Grothendieck abelian category and let $C \in \mathcal{A}$ be a generator. Then the full subcategory $\mathcal{A}_0 \subseteq \mathcal{A}$ spanned by the objects $\{C^n\}_{n \geqslant 0}$ satisfies the hypotheses of Theorem C.2.2.1, and we can identify $\mathrm{Fun}^\pi(\mathcal{A}_0^{\mathrm{op}}, \mathcal{S}\mathrm{et})$ with the abelian category of (discrete) right modules over the endomorphism ring $A = \mathrm{Hom}_{\mathcal{A}}(C, C)$. Applying Theorem C.2.2.1, we obtain an adjunction $\mathrm{RMod}_A^\heartsuit \underset{g}{\overset{f}{\rightleftarrows}} \mathcal{A}$, where the functor f is exact and the functor $g = \mathrm{Hom}_{\mathcal{A}}(C, \bullet)$ is fully faithful: this proves Theorem C.2.0.12.

Proof of Theorem C.2.2.1. Let $\mathcal{D}(\mathcal{A})$ denote the derived ∞-category of $\mathcal{A}$ (see §HA.1.3.5). We regard $\mathcal{D}(\mathcal{A})$ as endowed with the t-structure $(\mathcal{D}(\mathcal{A})_{\geqslant 0}, \mathcal{D}(\mathcal{A})_{\leqslant 0})$ of Proposition HA.1.3.5.21 , so that $\mathcal{D}(\mathcal{A})_{\geqslant 0}$ is a separated Grothendieck prestable ∞-category (Example C.1.4.5). Let us abuse notation by identifying $\mathcal{A}$ with the heart of $\mathcal{D}(\mathcal{A})$.

Let X be an arbitrary object of $\mathcal{D}(\mathcal{A})$, which we can represent by a chain complex

$$\cdots \to I_2 \xrightarrow{d_2} I_1 \xrightarrow{d_1} I_0 \xrightarrow{d_0} I_{-1} \xrightarrow{d_{-1}} I_{-2} \to \cdots .$$

Our assumption on $\mathcal{A}_0$ guarantees that we can choose an epimorphism $\rho : \bigoplus C_\alpha \to \ker(d_0)$ in $\mathcal{A}$, where each C_α belongs to $\mathcal{A}_0$. Then we can regard ρ as a morphism from $\bigoplus C_\alpha$ to X in the ∞-category $\mathcal{D}(\mathcal{A})$ which induces an epimorphism on π_0. Allowing X to vary over all objects of $\mathcal{D}(\mathcal{A})_{\geqslant 0}$, we conclude that $\mathcal{A}_0 \subseteq \mathcal{A} \simeq \mathcal{D}(\mathcal{A})^\heartsuit \subseteq \mathcal{D}(\mathcal{A})_{\geqslant 0}$ is a generating subcategory of $\mathcal{D}(\mathcal{A})_{\geqslant 0}$. Applying the ∞-categorical Gabriel-Popescu theorem (Theorem C.2.1.6), we obtain an adjunction $\mathcal{P}_\Sigma(\mathcal{A}_0) \underset{G}{\overset{F}{\rightleftarrows}} \mathcal{D}(\mathcal{A})_{\geqslant 0}$ where F is left exact and G is fully faithful. Restricting to discrete objects, we obtain an adjunction $\tau_{\leqslant 0} \mathcal{P}_\Sigma(\mathcal{A}_0) \underset{g}{\overset{f}{\rightleftarrows}} \mathcal{A}$, where f is exact and g is fully faithful. It now suffices to observe that we have a canonical equivalence $\tau_{\leqslant 0} \mathcal{P}_\Sigma(\mathcal{A}_0) = \mathrm{Fun}^\pi(\mathcal{A}_0^{\mathrm{op}}, \mathcal{S}\mathrm{et})$, which carries g to the functor $X \mapsto \mathrm{Hom}_{\mathcal{A}}(\bullet, X)$. □

Corollary C.2.2.3. *Let $\mathcal{A}$ be a category. The following conditions are equivalent:*

(*a*) *The category $\mathcal{A}$ is a Grothendieck abelian category.*

(*b*) *There exists a Grothendieck abelian category $\mathcal{B}$ such that $\mathcal{A}$ is an accessible left exact localization of $\mathcal{B}$ (that is, there exists an accessible left exact functor $L : \mathcal{B} \to \mathcal{A}$ with a fully faithful right adjoint).*

(*c*) *There exists a (possibly noncommutative) ring A such that $\mathcal{A}$ is an accessible left exact localization of the abelian category $\mathcal{M}$ of right A-modules.*

Proof. The implication $(c) \Rightarrow (b)$ is obvious, and the implication $(a) \to (c)$ follows from Theorem C.2.0.12 (since every Grothendieck abelian category admits a generator). We complete the proof by showing that $(b) \Rightarrow (a)$. Let us identify $\mathcal{A}$ with a full subcategory of $\mathcal{B}$ via the left adjoint of the localization functor $L : \mathcal{B} \to \mathcal{A}$. Note that $\mathcal{A}$ is closed under small limits in $\mathcal{B}$, and in particular it is closed under finite products. Since $\mathcal{B}$ is an additive category, it follows that $\mathcal{A}$ is an additive category. Because $\mathcal{B}$ is a presentable category and the localization functor L is accessible, it follows that $\mathcal{A}$ is presentable: in particular, it admits kernels and cokernels. To complete the proof that $\mathcal{A}$ is abelian, it will suffice to show that for every morphism $f : C \to D$ in $\mathcal{A}$, the canonical map

$$\theta : \mathrm{coker}_{\mathcal{A}}(\ker_{\mathcal{A}}(f) \to C) \to \ker_{\mathcal{A}}(D \to \mathrm{coker}_{\mathcal{A}}(f))$$

is an isomorphism; here the subscript indicates that the relevant kernels and cokernels are computed in the category $\mathcal{A}$. Note that limits in the category $\mathcal{A}$ can be computed in $\mathcal{B}$ (that is, the inclusion $\mathcal{A} \hookrightarrow \mathcal{B}$ preserves limits) and that colimits in $\mathcal{A}$ are computed by forming colimits in $\mathcal{B}$ and then applying the localization functor L. We may therefore identify θ with the canonical map

$$L\,\mathrm{coker}_{\mathcal{B}}(\ker_{\mathcal{B}}(f) \to C) \to \ker_{\mathcal{B}}(D \to L\,\mathrm{coker}_{\mathcal{B}}(f)).$$

Since the functor L is left exact, the morphism θ is equivalent to the image under the functor L of the map

$$\mathrm{coker}_{\mathcal{B}}(\ker_{\mathcal{B}}(f) \to C) \to \ker_{\mathcal{B}}(D \to \mathrm{coker}_{\mathcal{B}}(f)),$$

which is an isomorphism since $\mathcal{B}$ is an abelian category.

We now complete the proof that $(b) \Rightarrow (a)$ by showing that the abelian category $\mathcal{A}$ is Grothendieck. Let $\{f_\alpha : C_\alpha \to D_\alpha\}$ be a filtered diagram of monomorphisms in $\mathcal{A}$ having colimit $f : C \to D$ in the category $\mathcal{B}$. Since filtered colimits in $\mathcal{B}$ are left exact, f is a monomorphism. Because the functor L is left exact, the induced map $Lf : LC \to LD$ (which we can identify with the colimit of $\{f_\alpha\}$ in the category $\mathcal{A}$) is also a monomorphism. This proves that filtered colimits in $\mathcal{A}$ are left exact. □

C.2.3 Localizations of Prestable ∞-Categories

Let $\mathcal{A}$ be a category. Then $\mathcal{A}$ is a Grothendieck abelian category if and only if it is equivalent to a left-exact localization of the abelian category of (right) modules over some associative ring A (Corollary C.2.2.3). In §C.2.4, we will prove an analogous result in the setting of Grothendieck prestable ∞-categories (Theorem C.2.4.1). The proof will require some general facts about localizations of prestable ∞-categories, which we review in this section.

Proposition C.2.3.1. *Let $\mathcal{C}$ be a prestable ∞-category which admits finite limits and let $\mathcal{D} \subseteq \mathcal{C}$ be a full subcategory. Suppose that the inclusion $\mathcal{D} \hookrightarrow \mathcal{C}$ admits a left adjoint $L : \mathcal{C} \to \mathcal{D}$ which is left exact. Then $\mathcal{D}$ is also a prestable ∞-category which admits finite limits. If $\mathcal{C}$ is a Grothendieck prestable ∞-category and L is accessible, then $\mathcal{D}$ is also a Grothendieck prestable ∞-category.*

Remark C.2.3.2. Let $L : \mathcal{C} \to \mathcal{D}$ be as in Proposition C.2.3.1. We will say that an object $C \in \mathcal{C}$ is *L-acyclic* if LC is a zero object of $\mathcal{D}$. For any morphism $\alpha : C' \to C$ in $\mathcal{C}$, the following conditions are equivalent:

(i) The morphism $L\alpha$ is an equivalence in $\mathcal{D}$.

(ii) The object $\mathrm{cofib}(\alpha) \in \mathcal{C}$ is L-acyclic.

The implication $(i) \Rightarrow (ii)$ follows from the observation $L(\mathrm{cofib}(\alpha)) = \mathrm{cofib}(L\alpha)$. To prove the converse, note that we have a cofiber sequence $LC' \xrightarrow{L\alpha} LC \to L\,\mathrm{cofib}(\alpha)$ which is also a fiber sequence by virtue of Corollary C.1.2.6, so the vanishing of $L\,\mathrm{cofib}(\alpha)$ guarantees that $L\alpha$ is an equivalence.

Proof of Proposition C.2.3.1. Since $\mathcal{D}$ is a localization of $\mathcal{C}$, it is closed under all limits which exist in $\mathcal{C}$; in particular, $\mathcal{D}$ admits finite limits. Moreover, since $\mathcal{C}$ admits finite colimits, the ∞-category $\mathcal{D}$ also admits finite colimits (which are given by forming the relevant colimits in $\mathcal{C}$ and then applying the functor L). Any final object of $\mathcal{D}$ is also final in $\mathcal{C}$ and therefore a zero object, so that $\mathcal{D}$ is pointed. Consider the adjunctions

$$\mathcal{C} \underset{\Omega_{\mathcal{C}}}{\overset{\Sigma_{\mathcal{C}}}{\rightleftarrows}} \mathcal{C} \qquad \mathcal{D} \underset{\Omega_{\mathcal{D}}}{\overset{\Sigma_{\mathcal{D}}}{\rightleftarrows}} \mathcal{D}.$$

For any object $D \in \mathcal{D}$, the unit map $u : D \to \Omega_{\mathcal{D}}\Sigma_{\mathcal{D}} D$ is given by the composition

$$D \xrightarrow{u'} \Omega_{\mathcal{C}}\Sigma_{\mathcal{C}} D \xrightarrow{u''} \Omega_{\mathcal{C}} L \Sigma_{\mathcal{C}} D \simeq \Omega_{\mathcal{D}}\Sigma_{\mathcal{D}} D.$$

The assumption that C is prestable guarantees that u' is an equivalence and the left exactness of L implies that u'' is an equivalence. It follows that u is an equivalence for every object $D \in \mathcal{D}$: that is, the suspension functor $\Sigma_{\mathcal{D}}$ is fully faithful.

To complete the proof that $\mathcal{D}$ is prestable, suppose that we are given a pullback diagram σ :

$$\begin{array}{ccc} X & \longrightarrow & X'' \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & \Sigma_{\mathcal{D}} X' \end{array}$$

in the ∞-category $\mathcal{D}$; we wish to show that σ is also a pushout square in $\mathcal{D}$. To prove this, we note that (by virtue of the left exactness of L) the diagram σ can be obtained by applying L to the pullback square

$$\begin{array}{ccc} X & \longrightarrow & \Sigma_{\mathcal{C}} X' \times_{\Sigma_{\mathcal{D}} X'} X'' \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & \Sigma_{\mathcal{C}} X', \end{array}$$

which is also a pushout square in $\mathcal{C}$ by virtue of our assumption that $\mathcal{C}$ is prestable. Since the functor L preserves finite colimits, it follows that σ is a pushout square in $\mathcal{D}$.

Now suppose that $\mathcal{C}$ is a Grothendieck prestable ∞-category and that the localization functor L is accessible. Then the ∞-category $\mathcal{D}$ is also presentable (Theorem HTT.5.5.1.1). To show that $\mathcal{D}$ is a Grothendieck prestable ∞-category, it will suffice to show that filtered colimits in $\mathcal{D}$ are left exact. Let $\mathcal{J}$ be a small filtered ∞-category and let

$$F_{\mathcal{C}} : \mathrm{Fun}(\mathcal{J}, \mathcal{C}) \to \mathcal{C} \qquad F_{\mathcal{D}} : \mathrm{Fun}(\mathcal{J}, \mathcal{D}) \to \mathcal{D}$$

be left adjoint to the diagonal maps. Then the functor $F_{\mathcal{C}}$ is left exact, and we wish to show that $F_{\mathcal{D}}$ is also left exact. This follows from the observation that $F_{\mathcal{D}}$ can be written as a composition $\mathrm{Fun}(\mathcal{J}, \mathcal{D}) \hookrightarrow \mathrm{Fun}(\mathcal{J}, \mathcal{C}) \xrightarrow{F_{\mathcal{C}}} \mathcal{C} \xrightarrow{L} \mathcal{D}$, since the functor L is left exact. □

We now classify the left exact localizations appearing in Proposition C.2.3.1.

Definition C.2.3.3. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. We will say that a full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ is *localizing* if it satisfies the following conditions:

(i) The ∞-category $\mathcal{C}_0$ is accessible and closed under small coproducts in $\mathcal{C}$.

(ii) Given a cofiber sequence $C' \to C \to C''$ in $\mathcal{C}$, if any two of the objects C, C', C'' belong to $\mathcal{C}_0$, then so does the third.

(iii) Given a cofiber sequence $C' \to C \to C''$ in $\mathcal{C}$ where $C \in \mathcal{C}_0$ and $C'' \in \mathcal{C}^{\heartsuit}$, we have $C' \in \mathcal{C}_0$.

Remark C.2.3.4. Let $\alpha : C' \to C$ be a morphism in a Grothendieck prestable ∞-category $\mathcal{C}$. Then the assertion $\mathrm{cofib}(\alpha) \in \mathcal{C}^{\heartsuit}$ is equivalent to the requirement that α exhibit C' as a (-1)-truncated object of $\mathcal{C}_{/C}$: that is, that it exhibits C' as a *subobject* of C. Consequently, assertion (iii) of Definition C.2.3.3 asserts that the full subcategory $\mathcal{C}_0$ is closed under the formation of subobjects.

Remark C.2.3.5. Condition (ii) of Definition C.2.3.3 guarantees that $\mathcal{C}_0$ is closed under the formation of cofibers in $\mathcal{C}$. Combined with condition (i), this implies that $\mathcal{C}_0$ is closed under all small colimits.

Example C.2.3.6. Let $\mathcal{C}$ be a presentable stable ∞-category. Then a full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ is localizing if and only if it is accessible and closed under small colimits and desuspensions.

Example C.2.3.7. Let $\mathcal{C}$ and $\mathcal{D}$ be Grothendieck prestable ∞-categories and let $F : \mathcal{C} \to \mathcal{D}$ be a functor which preserves small colimits and finite limits. If $\mathcal{D}_0 \subseteq \mathcal{D}$ is a localizing subcateegory, then the inverse image $F^{-1}(\mathcal{D}_0) \subseteq \mathcal{C}$ is also a localizing subcategory.

In particular, if we let $\mathcal{C}_0 \subseteq \mathcal{C}$ denote the full subcategory spanned by those objects C for which $FC \simeq 0$, then $\mathcal{C}_0$ is a localizing subcategory of $\mathcal{C}$.

Proposition C.2.3.8. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a full subcategory. The following conditions are equivalent:*

(a) *The full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ is localizing (see Definition C.2.3.3).*

(b) *There exists an accessible left exact localization $L : \mathcal{C} \to \mathcal{D}$ such that $\mathcal{C}_0$ is the full subcategory of $\mathcal{C}$ spanned by the L-acyclic objects.*

Proof of Proposition C.2.3.8. The implication $(b) \Rightarrow (a)$ is a special case of Example C.2.3.7. For the converse, suppose that (a) is satisfied. Let S be the collection of all morphisms $u : C \to D$ in $\mathcal{C}$ such that $\mathrm{cofib}(u) \in \mathcal{C}_0$. We first claim that S is strongly saturated (in the sense of Definition HTT.5.5.4.5). That is, it satisfies the following conditions:

(1) Given a pushout square

$$\begin{array}{ccc} C & \xrightarrow{u} & D \\ \downarrow & & \downarrow \\ C' & \xrightarrow{u'} & D' \end{array}$$

in $\mathcal{C}$, if u belongs to S then u' also belongs to S. This is clear, since $\mathrm{cofib}(u) \simeq \mathrm{cofib}(u')$.

(2) The full subcategory of $\mathrm{Fun}(\Delta^1, \mathcal{C})$ spanned by S is closed under small colimits. This follows from Remark C.2.3.5, since the construction $u \mapsto \mathrm{cofib}(u)$ preserves small colimits.

(3) Given a pair of composable morphisms $C \xrightarrow{f} D \xrightarrow{g} E$, if any two of the morphisms f, g, and $g \circ f$ belong to S, then so does the third. This follows by applying assumption (ii) of Definition C.2.3.3 to the cofiber sequence $\mathrm{cofib}(f) \to \mathrm{cofib}(g \circ f) \to \mathrm{cofib}(g)$.

Since $\mathcal{C}_0$ is an accessible category, it follows from Proposition HTT.5.4.6.6 that the full subcategory of $\mathrm{Fun}(\Delta^1, \mathcal{C})$ spanned by S is accessible. It follows that S is of small generation (Lemma HTT.5.5.4.14). Let $\mathcal{D} = S^{-1}\mathcal{C}$ be the full subcategory of $\mathcal{C}$ spanned by the S-local objects; applying Proposition HTT.5.5.4.15 we deduce that the inclusion $\mathcal{D} \hookrightarrow \mathcal{C}$ admits an accessible left adjoint $L : \mathcal{C} \to \mathcal{D}$. Note that an object $C \in \mathcal{C}$ satisfies $LC \simeq 0$ if and only if the canonical map $v : 0 \to C$ belongs to S: that is, if and only if $\mathrm{cofib}(v) \simeq C$ belongs to $\mathcal{C}_0$. To complete the proof of (a), it will suffice to show that the functor L is left exact. According to Proposition HTT.6.2.1.1 , it will suffice to show that for every pullback square σ :

$$\begin{array}{ccc} C & \xrightarrow{u} & D \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle g} \\ C' & \xrightarrow{u'} & D' \end{array}$$

in $\mathcal{C}$, if $u' \in S$, then $u \in S$. The condition that σ is a pullback square in $\mathcal{C}$ guarantees that it exhibits $\Sigma^\infty C$ as the connective cover of the fiber product $\Sigma^\infty D \times_{\Sigma^\infty D'} \Sigma^\infty C'$ in the stable ∞-category $\mathrm{Sp}(\mathcal{C})$. In particular, the total fiber of the diagram $\Sigma^\infty(\sigma)$ belongs to $\mathrm{Sp}(\mathcal{C})_{\leqslant -2}$, so the total cofiber of $\Sigma^\infty(\sigma)$ belongs to $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$. In other words, the cofiber of the map $\mathrm{cofib}(u) \to \mathrm{cofib}(u')$ is a discrete object of $\mathcal{C}$, so that $\mathrm{cofib}(u') \in \mathcal{C}_0$ implies $\mathrm{cofib}(u) \in \mathcal{C}_0$ by virtue of assumption (iii) of Definition C.2.3.3. □

Notation C.2.3.9. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a localizing subcategory. We let $\mathcal{C}/\mathcal{C}_0$ denote the full subcategory of $\mathcal{C}$ spanned by the S-local objects, where S is the collection of those morphisms in $\mathcal{C}$ whose cofiber belongs to $\mathcal{C}_0$. It follows from Remark C.2.3.2 that any functor $L : \mathcal{C} \to \mathcal{D}$ as in part (b) of Proposition C.2.3.8 is left adjoint to an equivalence of ∞-categories $\mathcal{D} \simeq \mathcal{C}/\mathcal{C}_0 \subseteq \mathcal{C}$.

The quotient category $\mathcal{C}/\mathcal{C}_0$ is characterized by the following universal property:

Proposition C.2.3.10. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category, let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a localizing subcategory, let $L : \mathcal{C} \to \mathcal{C}/\mathcal{C}_0$ be a left adjoint to the inclusion functor, and let $\mathcal{D}$ be any Grothendieck prestable ∞-category. Then composition with L induces a fully faithful embedding of ∞-categories $F : \mathrm{LFun}(\mathcal{C}/\mathcal{C}_0, \mathcal{D}) \to \mathrm{LFun}(\mathcal{C}, \mathcal{D})$, where $\mathrm{LFun}(\mathcal{C}, \mathcal{D})$ denotes the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ spanned by those functors which preserve small colimits, and $\mathrm{LFun}(\mathcal{C}/\mathcal{C}_0, \mathcal{D})$ is defined similarly; the essential image of F is spanned by those colimit-preserving functors $\mathcal{C} \to \mathcal{D}$ which annihilate each object of $\mathcal{C}_0$.*

Proof. Let S be the collection of morphisms u in $\mathcal{C}$ for which $\mathrm{cofib}(u) \in \mathcal{C}_0$. By virtue of Proposition HTT.**??** , it will suffice to show that a colimit-preserving functor $F : \mathcal{C} \to \mathcal{D}$ carries each morphism of S to an equivalence in $\mathcal{D}$ if and only if F annihilates each object of $\mathcal{C}_0$. The "only if" direction is obvious, and the "if" direction follows from Corollary C.1.2.5. □

Remark C.2.3.11. In the situation of Proposition C.2.3.10, a colimit-preserving functor $F : \mathcal{C}/\mathcal{C}_0 \to \mathcal{D}$ is left exact if and only if the composite functor $\mathcal{C} \xrightarrow{L} \mathcal{C}/\mathcal{C}_0 \xrightarrow{F} \mathcal{D}$ is left exact. The "if" direction is obvious (since we can identify F with the restriction of $F \circ L$ to the quotient $\mathcal{C}/\mathcal{C}_0$), and the converse follows from the left exactness of L (Proposition C.2.3.8).

C.2.4 Classification of Grothendieck Prestable ∞-Categories

We now extend the results of §C.2.3 to establish the following characterization for the class of Grothendieck prestable ∞-categories:

Theorem C.2.4.1. *Let $\mathcal{C}$ be an ∞-category. The following conditions are equivalent:*

(1) *The ∞-category $\mathcal{C}$ is prestable and Grothendieck.*

(2) *There exists a connective $\mathbb{E}_1$-ring A for which the ∞-category $\mathcal{C}$ is an accessible left exact localization of $\mathrm{RMod}_A^{\mathrm{cn}}$.*

The implication (2) ⇒ (1) of Theorem C.2.4.1 is an immediate consequence of Proposition C.2.3.1. If $\mathcal{C}$ is a *separated* Grothendieck prestable ∞-category, then assertion (2) follows from Corollary C.2.1.8: in this case, we can take A to be the (connective) endomorphism ring of any generator $C \in \mathcal{C}$. However, this strategy will not work in general: for example, if

$\mathcal{C}$ is stable, then the zero object $0 \in \mathcal{C}$ is a generator (see Warning C.2.1.2). Our proof will instead proceed in two steps: first, we write $\mathcal{C}$ as an (accessible) left-exact localization of a separated Grothendieck prestable ∞-category $\mathcal{C}'$. We will then deduce Theorem C.2.4.1 by applying Corollary C.2.1.8 to the ∞-category $\mathcal{C}'$.

We begin with some general remarks about t-structures and Ind-completions.

Proposition C.2.4.2. *Let $\mathcal{C}$ be a small stable ∞-category equipped with a t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$. Then the inclusion functor $\mathrm{Ind}(\mathcal{C}_{\geqslant 0}) \hookrightarrow \mathrm{Fun}^{\pi}(\mathcal{C}_{\geqslant 0}^{\mathrm{op}}, \mathcal{S})$ admits an exact left adjoint $L : \mathrm{Fun}^{\pi}(\mathcal{C}_{\geqslant 0}^{\mathrm{op}}, \mathcal{S}) \to \mathrm{Ind}(\mathcal{C}_{\geqslant 0})$.*

Lemma C.2.4.3. *Let $\mathcal{C}$ be a small stable ∞-category equipped with a t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$. Then $\mathrm{Ind}(\mathcal{C})$ inherits a t-structure $(\mathrm{Ind}(\mathcal{C})_{\geqslant 0}, \mathrm{Ind}(\mathcal{C})_{\leqslant 0})$, where $\mathrm{Ind}(\mathcal{C})_{\geqslant 0}$ is the essential image of the fully faithful functor $\mathrm{Ind}(\mathcal{C}_{\geqslant 0}) \to \mathrm{Ind}(\mathcal{C})$, and $\mathrm{Ind}(\mathcal{C})_{\leqslant 0}$ is defined similarly. If the t-structure on $\mathcal{C}$ is right bounded, then the t-structure on $\mathrm{Ind}(\mathcal{C})$ is right complete.*

Proof. The first assertion is straightforward. To prove the second, let us assume that the t-structure on $\mathcal{C}$ is right bounded. It is clear from the construction that $\mathrm{Ind}(\mathcal{C})_{\leqslant 0}$ is closed under filtered colimits in $\mathrm{Ind}(\mathcal{C})$. To prove that $\mathrm{Ind}(\mathcal{C})$ is right complete, it will suffice to show that the intersection $\bigcap_n \mathrm{Ind}(\mathcal{C})_{\leqslant -n}$ consists only of zero objects of $\mathrm{Ind}(\mathcal{C})$ (Proposition HA.1.2.1.19). To this end, let us suppose that $X \in \bigcap_n \mathrm{Ind}(\mathcal{C})_{\leqslant -n}$. Then $\mathrm{Map}_{\mathrm{Ind}(\mathcal{C})}(Y, X)$ is contractible for any $Y \in \bigcup_n \mathrm{Ind}(\mathcal{C})_{\geqslant -n}$, and therefore for any Y belonging to the essential image of the Yoneda embedding $j : \mathcal{C} \to \mathrm{Ind}(\mathcal{C})$. Since $\mathrm{Ind}(\mathcal{C})$ is generated under filtered colimits by the essential image of j, we conclude that $\mathrm{Map}_{\mathrm{Ind}(\mathcal{C})}(Y, X)$ is contractible for all Y and therefore X is a final object of $\mathrm{Ind}(\mathcal{C})$. □

Lemma C.2.4.4. *Let $\mathcal{C}$ and $\mathcal{D}$ be stable ∞-categories equipped with t-structures $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ and $(\mathcal{D}_{\geqslant 0}, \mathcal{D}_{\leqslant 0})$. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor which is exact and t-exact. Then the induced map $F|_{\mathcal{C}_{\geqslant 0}} : \mathcal{C}_{\geqslant 0} \to \mathcal{D}_{\geqslant 0}$ is left exact.*

Proof. Suppose we are given maps $X_0 \to X \leftarrow X_1$ in the ∞-category $\mathcal{C}_{\geqslant 0}$. Let $X_{01} = X_0 \times_X X_1$ denote the fiber product of X_0 with X_1 over X in the ∞-category $\mathcal{C}$, so that the truncation $\tau_{\geqslant 0} X_{01}$ is the fiber product of X_0 with X_1 over X in the smaller ∞-category $\mathcal{C}_{\geqslant 0}$. To show that $F|_{\mathcal{C}_{\geqslant 0}}$ is left exact, we wish to show that the diagram

$$\begin{array}{ccc} F(\tau_{\geqslant 0} X_{01}) & \longrightarrow & F(X_0) \\ \downarrow & & \downarrow \\ F(X_1) & \longrightarrow & F(X) \end{array}$$

is a pullback diagram in $\mathcal{D}_{\geqslant 0}$: in other words, that it induces an equivalence

$$\rho : F(\tau_{\geqslant 0} X_{01}) \to \tau_{\geqslant 0}(F(X_0) \times_{F(X)} F(X_1))$$

in the ∞-category $\mathcal{D}$. Using the exactness of F, we can rewrite the codomain of ρ as $\tau_{\geqslant 0}F(X_{01})$, so that the assertion that ρ is an equivalence follows because F is t-exact. $\square$

Proof of Proposition C.2.4.2. Without loss of generality, we can replace $\mathcal{C}$ by the union $\bigcup_n \mathcal{C}_{\geqslant -n}$ and thereby reduce to the case where the t-structure on $\mathcal{C}$ is right bounded, so that the pair of ∞-categories $(\mathrm{Ind}(\mathcal{C}_{\geqslant 0}), \mathrm{Ind}(\mathcal{C}_{\leqslant 0}))$ determines a right complete t-structure on $\mathrm{Ind}(\mathcal{C})$ (Lemma C.2.4.3). In this case, we can identify $\mathrm{Ind}(\mathcal{C})$ with the ∞-category of spectrum objects $\mathrm{Sp}(\mathrm{Ind}(\mathcal{C}_{\geqslant 0}))$, so that the inclusion $\mathrm{Ind}(\mathcal{C}_{\geqslant 0}) = \mathrm{Fun}^{\mathrm{lex}}(\mathcal{C}^{\mathrm{op}}_{\geqslant 0}, \mathcal{S}) \hookrightarrow \mathrm{Fun}^{\pi}(\mathcal{C}^{\mathrm{op}}_{\geqslant 0}, \mathcal{S})$ induces a functor

$$G : \mathrm{Ind}(\mathcal{C}) \to \mathrm{Sp}(\mathrm{Fun}^{\pi}(\mathcal{C}^{\mathrm{op}}_{\geqslant 0}, \mathcal{S})) \simeq \mathrm{Fun}^{\pi}(\mathcal{C}^{\mathrm{op}}_{\geqslant 0}, \mathrm{Sp}).$$

Set $\mathcal{E} = \mathrm{Fun}^{\pi}(\mathcal{C}^{\mathrm{op}}_{\geqslant 0}, \mathrm{Sp})$, and regard $\mathcal{E}$ as a stable ∞-category equipped with a t-structure (setting $\mathcal{E}_{\geqslant 0} = \mathrm{Fun}^{\pi}(\mathcal{C}^{\mathrm{op}}_{\geqslant 0}, \mathrm{Sp}_{\geqslant 0})$ and $\mathcal{E}_{\leqslant 0} = \mathrm{Fun}^{\pi}(\mathcal{C}^{\mathrm{op}}_{\geqslant 0}, \mathrm{Sp}_{\leqslant 0})$). The functor G preserves small limits and filtered colimits and therefore admits a left adjoint $F : \mathcal{E} \to \mathrm{Ind}(\mathcal{C})$; since G is left t-exact, the functor F is right t-exact. Note that the ∞-category $\mathcal{C}^{\mathrm{op}}_{\geqslant 0}$ is additive (since it is closed under finite products in the stable ∞-category $\mathcal{C}^{\mathrm{op}}$), so that we can identify $\mathrm{Fun}^{\pi}(\mathcal{C}^{\mathrm{op}}_{\geqslant 0}, \mathcal{S})$ with the full subcategory

$$\mathcal{E}_{\geqslant 0} = \mathrm{Fun}^{\pi}(\mathcal{C}^{\mathrm{op}}_{\geqslant 0}, \mathrm{Sp}_{\geqslant 0}) \subseteq \mathcal{E}$$

spanned by the connective objects. Under this identification, we see that L is given by the restriction of the functor $F : \mathcal{E} \to \mathrm{Ind}(\mathcal{C})$ to the full subcategory $\mathcal{E}_{\geqslant 0} \subseteq \mathcal{E}$. It will therefore suffice to show that F is left t-exact.

Let E be an object of $\mathcal{E}_{\leqslant 0}$; we wish to show that $F(E) \in \mathrm{Ind}(\mathcal{C})_{\leqslant 0}$. Writing E as the colimit of its truncations $\tau_{\geqslant -n}E$, we can reduce to the case where E belongs to $\mathcal{E}_{\geqslant -n}$ for some integer n. In this case, E can be written as as successive extension of shifts of objects belonging to the heart $\mathcal{E}^{\heartsuit}$. We may therefore assume without loss of generality that E belongs to the heart $\mathcal{E}^{\heartsuit}$: that is, that it is a discrete object of the ∞-category

$$\mathcal{E}_{\geqslant 0} \simeq \mathrm{Fun}^{\pi}(\mathcal{C}^{\mathrm{op}}_{\geqslant 0}, \mathcal{S}) = \mathcal{P}_{\Sigma}(\mathcal{C}_{\geqslant 0}).$$

Let $j : \mathcal{C}_{\geqslant 0} \to \mathcal{P}_{\Sigma}(\mathcal{C}_{\geqslant 0}) \simeq \mathcal{E}_{\geqslant 0}$ be the Yoneda embedding and let $J : \mathcal{C}_{\geqslant 0} \to \mathcal{E}^{\heartsuit}$ be the functor given by $J(C) = \pi_0 j(C)$. More concretely, we can identify $\mathcal{E}^{\heartsuit}$ with the abelian category of additive functors from the homotopy category $\mathrm{h}\mathcal{C}^{\mathrm{op}}_{\geqslant 0}$ to the category of abelian groups; for each object $C \in \mathcal{C}_{\geqslant 0}$, we can identify $J(C)$ with the functor

$$(C' \in \mathcal{C}^{\mathrm{op}}_{\geqslant 0}) \mapsto \mathrm{Ext}^0_{\mathcal{C}}(C', C)$$

represented by C.

Since $\mathcal{E}_{\geqslant 0}$ is generated (freely) under sifted colimits by the essential image of j, the abelian category $\mathcal{E}^{\heartsuit}$ is generated under colimits by the essential image of J. In particular, every object E of the abelian category $\mathcal{E}^{\heartsuit}$ can be written as the cokernel of a map

$$u : \bigoplus J(C_i) \to \bigoplus J(D_j)$$

whose domain and codomain are (possibly infinite) direct sums of objects belonging to the essential image of the functor J. We can therefore write E as a filtered colimit of objects $\{E_\alpha\}$, where each E_α is the cokernel (in the abelian category $\mathcal{E}^{\heartsuit}$) of a map $u_\alpha : \bigoplus J(C_i) \to \bigoplus J(D_j)$ whose domain and codomain are *finite* direct sums of objects belonging to the essential image of J. Since J commutes with finite direct sums, and the functor $F : \mathcal{E} \to \mathrm{Ind}(\mathcal{C})$ commutes with filtered colimits, it will suffice to show that $F(E) \in \mathrm{Ind}(\mathcal{C})_{\leqslant 0}$ in the special case where $E \in \mathcal{E}^{\heartsuit}$ is given as the cokernel of a single map $u : J(C) \to J(D)$ in $\mathcal{E}^{\heartsuit}$; here C and D are objects of $\mathcal{C}_{\geqslant 0}$. By virtue of Yoneda's lemma, we can identify u with a map from C to D in the ∞-category $\mathcal{C}_{\geqslant 0}$ (which is well-defined up to homotopy).

Let $\mathrm{im}(u)$ denote the image of the map u (formed in the abelian category $\mathcal{E}^{\heartsuit}$), so that we have an exact sequence $0 \to \mathrm{im}(u) \to J(D) \to E \to 0$ in the abelian category $\mathcal{E}^{\heartsuit}$ and therefore a fiber sequence

$$F(\mathrm{im}(u)) \to F(J(D)) \to F(E)$$

in the stable ∞-category $\mathrm{Ind}(\mathcal{C})$. Let X denote the fiber product $\mathrm{im}(u) \times_{J(D)} j(D)$, formed in the ∞-category $\mathcal{E}_{\geqslant 0}$. Since the functor F is exact, we have a pushout square

$$\begin{array}{ccc} F(X) & \longrightarrow & F(j(D)) \\ \downarrow & & \downarrow \\ F(\mathrm{im}(u)) & \longrightarrow & F(J(D)) \end{array}$$

in the stable ∞-category $\mathrm{Ind}(\mathcal{C})$; we may therefore identify $F(E)$ with the cofiber of the map $F(X) \to F(j(D))$. Let us identify objects of $\mathcal{E}_{\geqslant 0}$ with product-preserving functors $\mathcal{C}_{\geqslant 0}^{\mathrm{op}} \to \mathcal{S}$, so that $j(D)$ is identified with the functor represented by D. Unwinding the definitions, we see that X can be identified with the subfunctor of $j(D)$ which assigns to each object $C' \in \mathcal{C}_{\geqslant 0}$ the subspace $X(C') \subseteq j(D)(C') = \mathrm{Map}_{\mathcal{C}}(C', D)$ spanned by those maps $C' \to D$ which factor through C (the factorization itself is not specified). In other words, X is the *image* of the canonical map $v : j(C) \to j(D)$, formed in the ∞-topos $\mathrm{Fun}(\mathcal{C}_{\geqslant 0}^{\mathrm{op}}, \mathcal{S})$. It follows that X can be computed as the geometric realization of the simplicial object $X_\bullet$ of $\mathcal{E}_{\geqslant 0}$ given by the Čech nerve of v. Let $C_\bullet$ be the simplicial object of $\mathcal{C}$ given by the Čech nerve of the map $u : C \to D$. Since the functor $j : \mathcal{C}_{\geqslant 0} \to \mathcal{E}_{\geqslant 0}$ preserves finite limits, we can write $X_\bullet = j(\tau_{\geqslant 0} C_\bullet)$.

Let K be the cokernel of the map $\pi_0 C \to \pi_0 D$ determined by u (formed in the abelian category $\mathcal{C}^{\heartsuit}$ and let D' denote the fiber of the natural map $D \to K$. Unwinding the definitions, we see that $\tau_{\geqslant 0} C_\bullet$ can be identified with the Čech nerve of the natural map $C \to D'$. Let us abuse notation by identifying $\mathcal{C}$ with its essential image in $\mathrm{Ind}(\mathcal{C})$, so that the composite functor $F \circ j : \mathcal{C}_{\geqslant 0} \to \mathrm{Ind}(\mathcal{C})$ is simply the identity. Then $FX_\bullet = Fj(\tau_{\geqslant 0} C_\bullet)$ is the Čech nerve of the map $C \to D'$ in $\mathrm{Ind}(\mathcal{C})$. We therefore have $FX \simeq |FX_\bullet| \simeq FD'$, so that the cofiber of the map $FX \to D$ can be identified with K and therefore belongs to $\mathcal{C}^\heartsuit \subseteq \mathcal{C}_{\leqslant 0}$, as desired. □

Proof of Theorem C.2.4.1. It follows immediately from Proposition C.2.3.1 that if A is a connective $\mathbb{E}_1$-ring, then every accessible left exact localization of $\mathrm{RMod}_A^{\mathrm{cn}}$ is a Grothendieck prestable ∞-category. We wish to prove that every Grothendieck prestable ∞-category $\mathcal{C}$ arises in this way. Without loss of generality, we may assume that there exists a presentable stable ∞-category $\mathcal{E}$ equipped with a t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$ which is compatible with filtered colimits such that $\mathcal{C} = \mathcal{E}_{\geqslant 0}$. Since $\mathcal{E}$ is presentable, there exists a regular cardinal κ for which the inclusion $\mathcal{E}^\kappa \hookrightarrow \mathcal{E}$ extends to an equivalence of ∞-categories $\mathrm{Ind}_\kappa(\mathcal{E}^\kappa) \simeq \mathcal{E}$; here $\mathcal{E}^\kappa$ denotes the full subcategory of $\mathcal{E}$ spanned by the κ-compact objects and $\mathrm{Ind}_\kappa(\mathcal{E}^\kappa)$ is the full subcategory of $\mathrm{Fun}((\mathcal{E}^\kappa)^{\mathrm{op}}, \mathcal{S})$ spanned by those functors which preserve κ-small colimits (see §HTT.5.3.5). Enlarging κ if necessary, we may assume that the truncation functors $\tau_{\geqslant 0}$ and $\tau_{\leqslant 0}$ on $\mathcal{E}$ carry κ-compact objects to κ-compact objects. Then the t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$ on $\mathcal{E}$ induces a t-structure $(\mathcal{E}^\kappa_{\geqslant 0}, \mathcal{E}^\kappa_{\leqslant 0})$ on the stable ∞-category $\mathcal{E}^\kappa$, where $\mathcal{E}^\kappa_{\geqslant 0} = \mathcal{E}^\kappa \cap \mathcal{E}_{\geqslant 0}$ and $\mathcal{E}^\kappa_{\leqslant 0} = \mathcal{E}^\kappa \cap \mathcal{E}_{\leqslant 0}$. The inclusion $\mathcal{E}^\kappa \hookrightarrow \mathcal{E}$ admits an essentially unique extension to a functor $F : \mathrm{Ind}(\mathcal{E}^\kappa) \to \mathcal{E}$. Since the t-structure on $\mathcal{E}$ is compatible with filtered colimits, the functor F is t-exact. Moreover, the restriction $F|_{\mathrm{Ind}(\mathcal{E}^\kappa_{\geqslant 0})}$ admits a right adjoint which we can identify with the inclusion $\mathcal{E}_{\geqslant 0} \simeq \mathrm{Ind}_\kappa(\mathcal{E}^\kappa_{\geqslant 0}) \subseteq \mathrm{Ind}(\mathcal{E}_{\geqslant 0})$, and is therefore fully faithful. Consequently, $\mathcal{C} = \mathcal{E}_{\geqslant 0}$ is an accessible left exact localization of the Grothendieck prestable ∞-category $\mathrm{Ind}(\mathcal{E}^\kappa_{\geqslant 0})$. It follows from Proposition C.2.4.2 that $\mathrm{Ind}(\mathcal{E}^\kappa_{\geqslant 0})$ is an accessible left exact localization of the ∞-category $\mathcal{C}' = \mathrm{Fun}^\pi((\mathcal{E}^\kappa_{\geqslant 0})^{\mathrm{op}}), \mathcal{S})$. We may therefore replace $\mathcal{C}$ by $\mathcal{C}'$ and thereby reduce to the case where the Grothendieck prestable ∞-category $\mathcal{C}$ is complete. Replacing $\mathcal{E}$ by $\mathrm{Sp}(\mathcal{C})$, we may assume that the t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$ is both left and right complete. It follows from Remark C.2.1.4 that there exists an object $C \in \mathcal{E}_{\geqslant 0}$ which is a generator for $\mathcal{E}$. Let A be the connective cover of the endomorphism ring $\mathrm{End}_{\mathcal{E}}(C)$. Applying Theorem **??**, we deduce that $\mathcal{C} \simeq \mathcal{E}_{\geqslant 0}$ is an accessible left exact localization of the ∞-category $\mathrm{RMod}_A^{\mathrm{cn}}$ of connective right A-module spectra. □

C.2.5 Proof of the Gabriel-Popescu Theorem

Let $\mathcal{C}$ be a separated Grothendieck prestable ∞-category and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a generating subcategory. Theorem C.2.1.6 has two parts:

(1) The inclusion $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ extends to a functor $F : \mathcal{P}_\Sigma(\mathcal{C}_0) \to \mathcal{C}$ which preserves small colimits and finite limits.

(2) The functor F admits a fully faithful right adjoint $G : \mathcal{C} \to \mathcal{P}_\Sigma(\mathcal{C}_0)$.

For later applications, it will be convenient to have slightly stronger versions of both (1) and (2), where we loosen the requirement that $\mathcal{C}_0 \subseteq \mathcal{C}$ is a generating subcategory.

Notation C.2.5.1. Let $\mathcal{C}$ be an ∞-category and let $k \geqslant 0$ be an integer. Recall that we say an object $X \in \mathcal{C}$ is *k-truncated* if, for every object $Y \in \mathcal{C}$ and every point $\eta \in \mathrm{Map}_{\mathcal{C}}(Y, X)$, the homotopy groups $\pi_i(\mathrm{Map}_{\mathcal{C}}(Y, X), \eta)$ vanish for $i > k$. We let $\tau_{\leqslant k}\mathcal{C}$ denote the full subcategory of $\mathcal{C}$ spanned by the k-truncated objects.

In what follows, it will be convenient to extend the preceding definition to the case $k = \infty$. We therefore adopt the following convention: when $k = \infty$, every object of $\mathcal{C}$ is k-truncated, and $\tau_{\leqslant k}\mathcal{C} = \mathcal{C}$.

Proposition C.2.5.2. *Let $\mathcal{C}$ be a separated Grothendieck prestable ∞-category, let $\mathcal{C}_0 \subseteq \mathcal{C}$ be an essentially small full subcategory which is closed under finite coproducts, and let $0 \leqslant k \leqslant \infty$. Assume that the following condition is satisfied:*

$(*_k)$ *Every object $C \in \mathcal{C}_0$ is k-truncated. Moreover, for every k-truncated object $X \in \mathcal{C}$, there exists a collection of objects $\{C_i\}_{i \in I}$ in $\mathcal{C}_0$ and a map $\amalg_{i \in I} C_i \to X$ which induces an epimorphism $\pi_0(\amalg_{i \in I} C_i) \to \pi_0 X$ in the abelian category $\mathcal{C}^\heartsuit$.*

Then the inclusion map $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ extends to a left exact functor $F : \mathcal{P}_\Sigma(\mathcal{C}_0) \to \mathcal{C}$ which preserves small colimits.

Proposition C.2.5.3. *Let $\mathcal{C}$ be a separated Grothendieck prestable ∞-category, let $\mathcal{C}_0 \subseteq \mathcal{C}$ be an essentially small full subcategory which is closed under finite coproducts and satisfies condition $(*_k)$ of Proposition C.2.5.2, for some $0 \leqslant k \leqslant \infty$. Then the functor $F : \mathcal{P}_\Sigma(\mathcal{C}_0) \to \mathcal{C}$ admits a right adjoint $G : \mathcal{C} \to \mathcal{P}_\Sigma(\mathcal{C}_0)$ which restricts to a fully faithful embedding $\tau_{\leqslant k}\mathcal{C} \to \tau_{\leqslant k}\mathcal{P}_\Sigma(\mathcal{C}_0)$.*

Remark C.2.5.4. When $k = \infty$, condition $(*_k)$ of Proposition C.2.5.2 asserts that $\mathcal{C}_0 \subseteq \mathcal{C}$ is generating subcategory, in the sense of Definition C.2.1.1. Consequently, Theorem C.2.1.6 can be regarded as the special case of Propositions C.2.5.2 and C.2.5.3 where we take $k = \infty$. When $k = 0$, Propositions C.2.5.2 and C.2.5.3 are essentially equivalent to Theorem C.2.2.1. In general, we can regard Propositions C.2.5.2 and C.2.5.3 as "interpolating" between the classical and ∞-categorical versions of the Gabriel-Popescu theorem.

Proof of Proposition C.2.5.2. Let $\mathcal{C}$ be a separated Grothendieck prestable ∞-category and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be an essentially small generating subcategory which is closed under finite direct sums and satisfies condition $(*_k)$ for $0 \leqslant k \leqslant \infty$. The inclusion $\iota : \mathcal{C}_0 \hookrightarrow \mathcal{C}$ preserves finite coproducts, so ι admits an essentially unique extension to a functor $F : \mathcal{P}_\Sigma(\mathcal{C}_0) \to \mathcal{C}$ which commutes with small colimits (Proposition HTT.5.5.8.15). We wish to show that F is left exact. By virtue of Proposition C.3.2.1, it will suffice to show that for every discrete object $M \in \mathcal{P}_\Sigma(\mathcal{C}_0)$, the image $F(M) \in \mathcal{C}$ is discrete. Since $\mathcal{C}$ is separated, it will suffice to prove the following assertion for each $n > 0$:

(a_n) If M is a discrete object of $\mathcal{P}_\Sigma(\mathcal{C})$, then $\pi_n FM \simeq 0$.

Our proof of (a_n) will proceed by induction on n. Let us therefore assume that $n > 0$, and that (a_m) is satisfied for all $m < n$. Note that if M is an $(n-2)$-truncated object of $\mathcal{C}$, then M can be written as a successive extension of objects $\Sigma^i(\pi_i M)$ for $k \leqslant n-2$. The functor F preserves suspensions and cofiber sequences, so that FM can be written as a successive extension of objects of the form $\Sigma^i F(\pi_i M)$ for $0 \leqslant i \leqslant n-2$. Using assertions (a_m) for $m < n$, we obtain the following:

(a') Let M be an $(n-2)$-truncated object of $\mathcal{C}$. Then $\pi_{n-1}(FM) \simeq 0$.

We now turn to the proof of (a_n). Let $h : \mathcal{C}_0 \to \mathcal{P}_\Sigma(\mathcal{C}_0)$ be the Yoneda embedding. Then $\mathcal{P}_\Sigma(\mathcal{C}_0)$ is generated under small colimits by the essential image of h. Let M be a discrete object of $\mathcal{P}_\Sigma(\mathcal{C}_0)$, and choose a collection of objects $\{C_i\}_{i \in I}$ of $\mathcal{C}_0$ and a map $\rho : \amalg_{i \in I} h(C_i) \to M$ which induces an epimorphism on π_0. For every finite subset $I_0 \subseteq I$, let $M_{I_0} \subseteq M$ denote the image of $\amalg_{i \in I_0} \pi_0(h(C_i))$ in M. Then we can write M as a filtered colimit $\varinjlim M_{I_0}$. The functor F commutes with filtered colimits, so we have $\pi_n FM \simeq \varinjlim \pi_n FM_{I_0}$. It will therefore suffice to show that $\pi_n FM_{I_0} \simeq 0$ for each finite subset $I_0 \subseteq I$. Replacing M by M_{I_0} and setting $C = \amalg_{i \in I_0} C_i$, we can reduce to the case where there exists an object $C \in \mathcal{C}_0$ and a map $\rho : h(C) \to M$ which induces an epimorphism on π_0. Set $Q = \mathrm{fib}(\rho)$, so that we have a cofiber sequence $Q \to h(C) \to M$ in the ∞-category $\mathcal{P}_\Sigma(\mathcal{C}_0)$. Applying the functor F, we obtain a cofiber sequence $F(Q) \to C \to F(M)$ in the ∞-category $\mathcal{C}$, giving rise to a long exact sequence

$$\pi_n FQ \xrightarrow{\alpha} \pi_n C \to \pi_n FM \to \pi_{n-1} FQ \xrightarrow{\beta} \pi_{n-1} C$$

in the abelian category $\mathcal{C}^\heartsuit$. Assertion (a_n) is now reduced to the following pair of assertions:

(b) The map $\alpha : \pi_n FQ \to \pi_n C$ is an epimorphism in the abelian category $\mathcal{C}^\heartsuit$.

(c) The map $\beta : \pi_{n-1} FQ \to \pi_{n-1} C$ is a monomorphism in the abelian category $\mathcal{C}^\heartsuit$.

We first prove (b). Note that α is obtained by applying π_0 to a morphism $u : \Omega^n(FQ) \to \Omega^n(C)$ in $\mathcal{C}$. Using $(*_k)$, we deduce that $\Omega^n(C)$ is k-truncated, so that $\pi_0 \Omega^n(C)$ is generated by the images of maps $\pi_0(f)$, where $f : D \to \Omega^n C$ is a morphism in $\mathcal{C}$ whose domain D is contained in $\mathcal{C}_0$. It will therefore suffice to show that any such f factors through u. Note that f determines a map $h(f) : h(D) \to \Omega^n h(C)$ in $\mathcal{P}_\Sigma(\mathcal{C}_0)$. Since M is discrete, the map $\Omega^n Q \to \Omega^n h(C)$ is an equivalence; it follows that $h(f)$ factors as a composition $h(D) \to \Omega^n Q \to \Omega^n h(C)$. Applying the functor F, we obtain a map

$$D \simeq F(h(D)) \to F(\Omega^n Q) \to \Omega^n FQ$$

whose composition with u is homotopic to f.

The proof of (c) is a bit more involved. Set $Q' = \Omega^{n-1}Q$, so that we have a cofiber sequence $\Sigma^{n-1}Q' \to Q \to \tau_{\leqslant n-2}Q$ in the ∞-category $\mathcal{C}$. Applying the functor F and passing to homotopy, we obtain an exact sequence

$$\pi_0 FQ' \xrightarrow{\gamma} \pi_{n-1}FQ \to \pi_{n-1}F(\tau_{\leqslant n-2}Q)$$

in the abelian category $\mathcal{C}^{\heartsuit}$, where the third term vanishes by virtue of (a'). It follows that γ is an epimorphism in $\mathcal{C}^{\heartsuit}$. Choose a collection of objects $\{D_j\}_{j \in J}$ and a map $g : \amalg_{j \in J} h(D_j) \to Q'$ in $\mathcal{P}_{\Sigma}(\mathcal{C}_0)$ which is an epimorphism in π_0. Let γ_J denote the epimorphism given by the composition

$$\pi_0 \amalg_{j \in J} D_j \to \pi_0 FQ' \xrightarrow{\gamma} \pi_{n-1}FQ.$$

To show that β is a monomorphism, it will suffice to show that $\ker(\beta \circ \gamma_J)$ and $\ker(\gamma_J)$ coincide (as subobjects of $\pi_0 \amalg_{j \in J} D_j$). For every finite subset $J_0 \subseteq J$, let γ_{J_0} denote the restriction of γ_J to the finite coproduct $\pi_0(\amalg_{j \in J_0} F(D_j)$. Since filtered colimits in $\mathcal{C}$ are left exact, we can identify $\ker(\beta \circ \gamma_J)$ and $\ker(\gamma_J)$ with the filtered colimits $\varinjlim \ker(\beta \circ \gamma_{J_0})$ and $\varinjlim \ker(\gamma_{J_0})$. It will therefore suffice to show that for each finite subset $J_0 \subseteq J$, the kernels $\ker(\beta \circ \gamma_{J_0})$ and $\ker(\gamma_{J_0})$ coincide as subobjects of $\pi_0 D$, where $D = \amalg_{j \in J_0} D_j$. The restriction of g to $\amalg_{j \in J_0} h(D_j)$ is classified by an element $\xi \in \pi_0 Q'(D) = \pi_{n-1}Q(D)$. Let ξ' denote the image of ξ in $\pi_{n-1}h(C)(D)$, so that ξ' classifies a map $\overline{g} : D \to \Omega^{n-1}C$ in $\mathcal{C}$. The exactness of the sequence

$$\pi_0 \operatorname{fib}(\overline{g}) \xrightarrow{\delta} \pi_0 D \xrightarrow{\beta \circ \gamma_{J_0}} \pi_{n-1}C$$

shows that $\ker(\beta \circ \gamma_{J_0}) = \operatorname{im}(\delta)$. It will therefore suffice to show that $\operatorname{im}(\delta) \subseteq \ker(\gamma_J)$. Assumption $(*_k)$ ensures that C and D are k-truncated, so that $\operatorname{fib}(\overline{g})$ is k-truncated. Using $(*_k)$ again, we deduce that $\operatorname{im}(\delta)$ can be written as the union of the images of maps $\pi_0(f) : \pi_0 E \to \pi_0 D$, where $f : E \to D$ is a morphism in $\mathcal{C}_0$ which factors through $\operatorname{fib}(\overline{g})$. For any such map f, the composition $\overline{g} \circ f$ is nullhomotopic: that is, the image of ξ' in $\pi_{n-1}h(C)(E)$ vanishes. Using the exactness of the sequence $\pi_n M(E) \to \pi_{n-1}Q(E) \to \pi_{n-1}h(C)(E)$ (and the vanishing of $\pi_n M(E)$), we conclude that the image of ξ in $\pi_{n-1}Q(E) \simeq \pi_0 Q'(E)$ vanishes: that is, the composition $h(E) \xrightarrow{h(f)} h(D) \to \amalg_{j \in J} h(D_j) \xrightarrow{g} Q'$ is nullhomotopic. Applying F and passing to homotopy, we conclude that $\operatorname{im}(\pi_0(f)) \subseteq \ker(\gamma_{J_0})$, as desired. □

Proof of Proposition C.2.5.3. Let $F : \mathcal{P}_{\Sigma}(\mathcal{C}_0) \to \mathcal{C}$ be as in Proposition C.2.5.2. The functor F admits a right adjoint $G : \mathcal{C} \to \mathcal{P}_{\Sigma}(\mathcal{C}_0) \subseteq \operatorname{Fun}(\mathcal{C}_0^{\mathrm{op}}, \mathcal{S})$, given by the restricted Yoneda embedding $G(X)(C) = \mathrm{Map}_{\mathcal{C}}(C, X)$. Proposition C.2.5.2 implies that F is left exact, so it carries k-truncated objects to k-truncated objects. It follows that F and G restrict to adjoint functors

$$\tau_{\leqslant k}\,\mathcal{P}_{\Sigma}(\mathcal{C}_0) \underset{G_k}{\overset{F_k}{\rightleftarrows}} \tau_{\leqslant k}\,\mathcal{C}\,.$$

We wish to show that G_k is fully faithful. Equivalently, we wish to show that for each k-truncated object $X \in \mathcal{C}$, the counit map $v : (F \circ G)(X) \to X$ is an equivalence in $\mathcal{C}$. Since $\mathcal{C}$ is separated, it will suffice to show that the map $\pi_n(v) : \pi_n(F \circ G)(X) \to \pi_n X$ is an isomorphism in $\mathcal{C}^{\heartsuit}$ for each $n \geqslant 0$. Replacing X by $\Omega^n X$ (and using the left exactness of the functor F), we can assume without loss of generality that $n = 0$. Note that if $C \in \mathcal{C}_0$, then any morphism $C \to X$ factors through v. Since X is assumed to be k-truncated, assertion $(*_k)$ immediately implies that $\pi_0(v)$ is an epimorphism in $\mathcal{C}^{\heartsuit}$.

We now show that $\pi_0(v)$ is a monomorphism. Let $h : \mathcal{C}_0 \to \mathcal{P}_{\Sigma}(\mathcal{C}_0)$ denote the Yoneda embedding. Choose a collection of objects $\{C_i\}_{i \in I}$ of $\mathcal{C}_0$ and a morphism $f_I : \amalg_{i \in I} h(C_i) \to G(X)$ in $\mathcal{P}_{\Sigma}(\mathcal{C}_0)$ which induces an epimorphism on π_0. Then the induced map $\amalg_{i \in I} \pi_0 C_i \xrightarrow{\pi_0 F(f_I)} \pi_0(F \circ G)(X)$ is also an epimorphism. It will therefore suffice to show that $\ker(\pi_0(F(f_I)))$ and $\ker(\pi_0(v \circ F(f_I)))$ coincide (as subobjects of $\amalg_{i \in I} \pi_0 C_i$). For each finite subset $I_0 \subseteq I$, let f_{I_0} denote the restriction of f_I to $\amalg_{i \in I_0} h(C_i)$. Since filtered colimits in $\mathcal{C}$ are exact, we obtain isomorphisms

$$\ker(\pi_0(F(f_I))) \simeq \varinjlim_{I_0} \ker(\pi_0(F(f_{I_0}))) \qquad \ker(\pi_0(F(v \circ f_I))) \simeq \varinjlim_{I_0} \ker(\pi_0(F(v \circ f_{I_0}))).$$

It will therefore suffice to show that for each finite subset $I_0 \subseteq I$, the kernels $\ker(\pi_0(F(f_{I_0})))$ and $\ker(\pi_0(v \circ F(f_{I_0})))$ coincide (as subobjects of $\amalg_{i \in I_0} \pi_0 C_i$). Set $C = \amalg_{i \in I_0} C_i$ and $f_0 = f_{I_0}$, so that f_0 can be identified with $G(\rho)$, where $\rho : C \to X$ is the morphism in $\mathcal{C}$ given by the composition $v \circ F(f_0)$. We have a fiber sequence $\mathrm{fib}(\rho) \to C \xrightarrow{\rho} X$ in $\mathcal{C}$, hence a short exact sequence $\pi_0 \,\mathrm{fib}(F(f_0)) \xrightarrow{\alpha} \pi_0 C \xrightarrow{\pi_0 \rho} \pi_0 X$ in the abelian category $\mathcal{C}^{\heartsuit}$. It will therefore suffice to show that $\mathrm{im}(\alpha) \subseteq \ker(F(f_0))$ (as subobjects of $\pi_0 C$). Assumption $(*_k)$ guarantees that C is k-truncated, and X is k-truncated by assumption. It follows that $\mathrm{fib}(\rho)$ is k-truncated. Applying $(*_k)$, we are reduced to proving that for every object $D \in \mathcal{C}_0$ and every morphism $\phi : D \to C$ which factors through $\mathrm{fib}(\rho)$, we have $\mathrm{im}(\pi_0 \phi) \subseteq \ker(F(f_0))$. This is clear: if $\rho \circ \phi$ is nullhomotopic, then the induced map

$$D \simeq (F \circ G)(D) \xrightarrow{(F \circ G)(\phi)} (F \circ G)(C) \xrightarrow{(F \circ G)(\rho)} (F \circ G)(X)$$

is also nullhomotopic, and therefore vanishes after applying π_0. □

C.3 The ∞-Category of Grothendieck Prestable ∞-Categories

In §C.1, we introduced the notion of a Grothendieck prestable ∞-category (Definition C.1.4.2). The collection of Grothendieck prestable ∞-categories can itself be organized into a (very large) ∞-category Groth_∞:

Definition C.3.0.5. Let $\widehat{\mathcal{C}\mathrm{at}}_\infty$ denote the ∞-category of (not necessarily small) ∞-categories, and let $\mathcal{P}\mathrm{r}^{\mathrm{L}} \subseteq \widehat{\mathcal{C}\mathrm{at}}_\infty$ denote the subcategory whose objects are presentable ∞-categories and whose morphisms are functors which preserve small colimits (see Definition HTT.5.5.3.1). We let Groth_∞ denote the full subcategory of $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ whose objects are Grothendieck prestable ∞-categories (see Definition C.1.4.2).

C.3.1 Comparison with Stable ∞-Categories

The ∞-category Groth_∞ contains the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ of presentable stable ∞-categories as a full subcategory. Note that the inclusion functor $\mathcal{P}\mathrm{r}^{\mathrm{St}} \subseteq \mathcal{P}\mathrm{r}^{\mathrm{L}}$ admits a left adjoint, given by the construction $\mathcal{C} \mapsto \mathrm{Sp}(\mathcal{C})$ (see Proposition HA.4.8.2.18). When restricted to Groth_∞, this left adjoint is not far from being an equivalence of ∞-categories.

Proposition C.3.1.1. *Let $\mathcal{C}$ and $\mathcal{D}$ be Grothendieck prestable ∞-categories. Then the canonical map*

$$\theta : \mathrm{LFun}(\mathcal{C}, \mathcal{D}) \to \mathrm{LFun}(\mathrm{Sp}(\mathcal{C}), \mathrm{Sp}(\mathcal{D}))$$

is a fully faithful embedding, whose essential image consists of those functors $\mathrm{Sp}(\mathcal{C}) \to \mathrm{Sp}(\mathcal{D})$ which preserve small colimits and are right t-exact (with respect to the t-structure of Remark C.1.2.10).

Proof. Writing $\mathrm{Sp}(\mathcal{C})$ as the colimit of the diagram

$$\mathcal{C} \xrightarrow{\Sigma} \mathcal{C} \xrightarrow{\Sigma} \mathcal{C} \to \cdots$$

in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$, we can identify $\mathrm{LFun}(\mathrm{Sp}(\mathcal{C}), \mathrm{Sp}(\mathcal{D})$ with the homotopy limit of the tower

$$\cdots \to \mathrm{LFun}(\mathcal{C}, \mathrm{Sp}(\mathcal{D})) \to \mathrm{LFun}(\mathcal{C}, \mathrm{Sp}(\mathcal{D})).$$

where the transition maps are given by precomposition with the suspension functor $\Sigma : \mathcal{C} \to \mathcal{C}$. Since colimit-preserving functors commute with suspension, these transition maps can also be described as the functors given by postcomposition with the suspension functor on $\mathrm{Sp}(\mathcal{D})$, and are therefore equivalences. We can therefore identify θ with the map

$$\theta' : \mathrm{LFun}(\mathcal{C}, \mathcal{D}) \to \mathrm{LFun}(\mathcal{C}, \mathrm{Sp}(\mathcal{D}))$$

obtained by composing with the functor $\Sigma^\infty_{\mathcal{D}} : \mathcal{D} \to \mathrm{Sp}(\mathcal{D})$. It follows that θ is fully faithful, and that its essential image consists of those colimit-preserving functors $f : \mathrm{Sp}(\mathcal{C}) \to \mathrm{Sp}(\mathcal{D})$ such that $f \circ \Sigma^\infty_{\mathcal{C}}$ factors through the full subcategory $\mathrm{Sp}(\mathcal{D})_{\geqslant 0} \subseteq \mathrm{Sp}(\mathcal{D})$: that is, those functors which are right t-exact. □

Example C.3.1.2. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. It follows from Proposition C.3.1.1 that evaluation on the sphere spectrum $S \in \mathrm{Sp}^{\mathrm{cn}}$ induces an equivalence of ∞-categories $\mathrm{LFun}(\mathrm{Sp}^{\mathrm{cn}}, \mathcal{C}) \to \mathcal{C}$.

Remark C.3.1.3. Let $\mathcal{C}$ be a presentable stable ∞-category. Let us say that a full subcategory $\mathcal{C}_{\geqslant 0} \subseteq \mathcal{C}$ is a *core* if it is closed under small colimits and extensions. We let $\mathrm{Core}(\mathcal{C})$ denote the collection of all cores of $\mathcal{C}$, which we regard as a partially ordered set with respect to inclusions.

If $f : \mathcal{C} \to \mathcal{D}$ is a functor between presentable stable ∞-categories which preserves small colimits, then the construction

$$(\mathcal{D}_{\geqslant 0} \subseteq \mathcal{D}) \mapsto (f^{-1}\,\mathcal{D}_{\geqslant 0} \subseteq \mathcal{C})$$

carries cores of $\mathcal{D}$ to cores of $\mathcal{C}$. We can therefore view the construction $\mathcal{C} \mapsto \mathrm{Core}(\mathcal{C})$ as a contravariant functor from the homotopy category $\mathrm{h}\mathcal{P}\mathrm{r}^{\mathrm{St}}$ of presentable stable ∞-categories to the ordinary category of (large) partially ordered sets. Consequently, the construction $\mathcal{C} \mapsto \mathrm{Core}(\mathcal{C})$ can be regarded as a functor from the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ to the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty$. This functor classifies a Cartesian fibration $q : \mathsf{Groth}^+_\infty \to \mathcal{P}\mathrm{r}^{\mathrm{St}}$.

We will refer to Groth^+_∞ as the *∞-category of cored stable ∞-categories*. Unwinding the definitions, we see that the objects of Groth^+_∞ are pairs $(\mathcal{C}, \mathcal{C}_{\geqslant 0})$, where $\mathcal{C}$ is a presentable stable ∞-category and $\mathcal{C}_{\geqslant 0} \subseteq \mathcal{C}$ is a core; a morphism from $(\mathcal{C}, \mathcal{C}_{\geqslant 0})$ to $(\mathcal{D}, \mathcal{D}_{\geqslant 0})$ is given by a colimit preserving functor $f : \mathcal{C} \to \mathcal{D}$ satisfying $f(\mathcal{C}_{\geqslant 0}) \subseteq \mathcal{D}_{\geqslant 0}$.

If $\mathcal{C}$ is a Grothendieck prestable ∞-category, then the essential image of the functor $\Sigma^\infty : \mathcal{C} \to \mathrm{Sp}(\mathcal{C})$ determines a core $\mathrm{Sp}(\mathcal{C})_{\geqslant 0} \subseteq \mathrm{Sp}(\mathcal{C})$. Using Proposition C.3.1.1, we obtain the following:

Corollary C.3.1.4. *The construction $\mathcal{C} \mapsto (\mathrm{Sp}(\mathcal{C}), \mathrm{Sp}(\mathcal{C})_{\geqslant 0})$ determines a fully faithful embedding from the ∞-category Groth_∞ of Grothendieck prestable ∞-categories to the ∞-category Groth^+_∞ of cored stable ∞-categories.*

Remark C.3.1.5. Let $\mathcal{C}$ be a presentable stable ∞-category and let $\mathcal{C}_{\geqslant 0} \in \mathrm{Core}(\mathcal{C})$ be a core. According to Proposition HA.1.4.4.11 , the subcategory $\mathcal{C}_{\geqslant 0}$ can be extended to an accessible t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ on $\mathcal{C}$ if and only if $\mathcal{C}_{\geqslant 0}$ is generated (as a full subcategory of $\mathcal{C}$ closed under colimits and extensions) by a small collection of objects of $\mathcal{C}$. In this case, $(\mathcal{C}, \mathcal{C}_{\geqslant 0})$ belongs to the essential image of the fully faithful embedding of Corollary C.3.1.4 if and only if the t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ is compatible with filtered colimits and right complete. Assuming that $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ is compatible with filtered colimits, the right completeness is equivalent to the statement that the intersection $\bigcap_{n \geqslant 0} \mathcal{C}_{\leqslant -n}$ contains only zero objects of $\mathcal{C}$ (Proposition HA.**??**): in other words, that the objects $\{\Sigma^{-n} C : C \in \mathcal{C}_{\geqslant 0}\}$ generate the ∞-category $\mathcal{C}$ under small colimits. However, the hypothesis that the t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ be compatible with filtered colimits is difficult to formulate directly in terms of $\mathcal{C}_{\geqslant 0}$, unless $\mathcal{C}_{\geqslant 0}$ is generated by compact objects (a situation we will study in §C.6; see Proposition C.6.3.1).

Remark C.3.1.6. Let $f : \mathcal{C} \to \mathcal{D}$ be a colimit-preserving functor between Grothendieck prestable ∞-categories. Then the inverse image construction

$$f^{-1} : \mathrm{Core}(\mathcal{D}) \to \mathrm{Core}(\mathcal{C})$$

of Remark C.3.1.3 admits a left adjoint $f_+ : \mathrm{Core}(\mathcal{C}) \to \mathrm{Core}(\mathcal{D})$: for every core $\mathcal{C}_{\geqslant 0} \subseteq \mathcal{C}$, we can take $f_+(\mathcal{C}_{\geqslant 0})$ to be the smallest full subcategory of $\mathcal{D}$ which is closed under colimits and extensions and contains $f(C)$ for each object $C \in \mathcal{C}_{\geqslant 0}$. It follows that the Cartesian fibration $q : \mathsf{Groth}_{\infty}^{+} \to \mathcal{P}\mathrm{r}^{\mathrm{St}}$ of Corollary C.3.1.4 is also a coCartesian fibration.

Remark C.3.1.7. Let $\mathcal{C}$ be a presentable stable ∞-category. Then the collection of cores of $\mathcal{C}$ is closed under intersections. It follows that $\mathrm{Core}(\mathcal{C})$ is a complete lattice: when viewed as a category, it admits all limits and colimits. Combining this observation with Proposition HTT.4.3.1.5 and Corollary HTT.**??**, we deduce that the ∞-category $\mathsf{Groth}_{\infty}^{+}$ admits small limits and colimits, which are preserved by the forgetful functor $q : \mathsf{Groth}_{\infty}^{+} \to \mathcal{P}\mathrm{r}^{\mathrm{St}}$.

We regard the introduction of the ∞-category $\mathsf{Groth}_{\infty}^{+}$ as a technical device: we are not really interested in objects of $\mathsf{Groth}_{\infty}^{+}$ unless they arise from Grothendieck prestable ∞-categories by means of Corollary C.3.1.4. However, for certain constructions it is more convenient to work in the ∞-category $\mathsf{Groth}_{\infty}^{+}$ than in Groth_{∞} because the former admits arbitrary small limits and colimits (Remark C.3.1.7) but the latter does not.

Remark C.3.1.8. Let $\mathcal{C}$ and $\mathcal{D}$ be Grothendieck prestable ∞-categories and let $f : \mathcal{C} \to \mathcal{D}$ be a functor which preserves small colimits, so that f admits a right adjoint g (Corollary HTT.5.5.2.9). Then f is an equivalence if and only if the following conditions are satisfied:

(a) The induced map $F : \mathrm{Sp}(\mathcal{C}) \to \mathrm{Sp}(\mathcal{D})$ is an equivalence.

(b) The functor g does not annihilate any nonzero objects of $\mathcal{D}$.

The necessity of conditions (a) and (b) is obvious. Conversely, if condition (a) is satisfied, then we have a commutative diagram

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{f} & \mathcal{D} \\ \downarrow{\scriptstyle \Sigma^\infty_{\mathcal{C}}} & & \downarrow{\scriptstyle \Sigma^\infty_{\mathcal{D}}} \\ \mathrm{Sp}(\mathcal{C}) & \xrightarrow{F} & \mathrm{Sp}(\mathcal{D}), \end{array}$$

where the bottom horizontal map is an equivalence and the vertical maps are fully faithful. It follows immediately that f is fully faithful. Let G denote a homotopy inverse to F. In order to show that f is an equivalence, it will suffice to show that for each object $D \in \mathrm{Sp}(\mathcal{D})_{\geqslant 0}$, we have $GD \in \mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. Since the functor G is an equivalence, we can choose a fiber sequence $D' \to D \to D''$ in the stable ∞-category $\mathrm{Sp}(\mathcal{D})$ where $GD' \in \mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ and $GD'' \in \mathrm{Sp}(\mathcal{C})_{\leqslant -1}$. Then $D' \simeq (F \circ G)(D')$ belongs to $\mathrm{Sp}(\mathcal{D})_{\geqslant 0}$, so that $D'' \simeq \mathrm{cofib}(D' \to D)$ also belongs to $\mathrm{Sp}(\mathcal{D})_{\geqslant 0}$. The condition $GD'' \in \mathrm{Sp}(\mathcal{C})_{\leqslant -1}$ guarantees that the mapping space

$$\mathrm{Map}_{\mathcal{C}}(C, g(\Omega^\infty_{\mathcal{D}} D'')) \simeq \mathrm{Map}_{\mathcal{C}}(C, \Omega^\infty_{\mathcal{C}} GD'') \simeq \mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(\Sigma^\infty_{\mathcal{C}} C, GD'')$$

vanishes for every object $C \in \mathcal{C}$. Applying assumption (b), we deduce that $\Omega^\infty_{\mathcal{D}} D''$ vanishes, so that $D'' \simeq \Sigma^\infty_{\mathcal{D}} \Omega^\infty_{\mathcal{D}} D'' \simeq 0$. Thus $GD \simeq GD' \in \mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ as desired.

C.3.2 Left Exact Functors

We now restrict our attention to functors between Grothendieck prestable ∞-categories which preserve finite limits.

Proposition C.3.2.1. *Let $\mathcal{C}$ and $\mathcal{D}$ be Grothendieck prestable ∞-categories and let $f : \mathcal{C} \to \mathcal{D}$ be a colimit-preserving functor. Then the following conditions are equivalent:*

(1) *The functor f is left exact.*

(2) *The functor f carries discrete objects of $\mathcal{C}$ to discrete objects of $\mathcal{D}$.*

(3) *The induced map $F : \mathrm{Sp}(\mathcal{C}) \to \mathrm{Sp}(\mathcal{D})$ is left t-exact.*

Lemma C.3.2.2. *Let $\mathcal{C}$ and $\mathcal{D}$ be prestable ∞-categories which admit finite limits and let $f : \mathcal{C} \to \mathcal{D}$ be a right exact functor. The following conditions are equivalent:*

(1) *The functor f is left exact.*

(2) *The induced functor $\mathrm{SW}(f) : \mathrm{SW}(\mathcal{C}) \to \mathrm{SW}(\mathcal{D})$ is t-exact.*

Proof. Suppose first that (1) is satisfied. Let $X \in \mathrm{SW}(\mathcal{C})_{\leqslant n}$; we wish to show that $\mathrm{SW}(f)(X)$ belongs to $\mathrm{SW}(\mathcal{D})_{\leqslant n}$. Replacing X by a suspension if necessary, we may assume that X is the image of an object $X_0 \in \mathcal{C}$ under the identification $\mathcal{C} \simeq \mathrm{SW}(\mathcal{C})_{\geqslant 0}$. In this case, the object X_0 is n-truncated. Since f is left exact, the object $f(X_0) \in \mathcal{D}$ is n-truncated, so that $\mathrm{SW}(f)(X)$ belongs to $\mathrm{SW}(\mathcal{D})_{\leqslant n}$.

Now suppose that (2) is satisfied; we wish to show that the functor f preserves limits indexed by an arbitrary finite simplicial set K. Let $q_0 : K \to \mathcal{C}$ be an arbitrary diagram, so that q_0 can be identified with a diagram $q : K \to \mathrm{SW}(\mathcal{C})_{\geqslant 0}$. Extend q to a limit diagram $\overline{q} : K^{\triangleleft} \to \mathrm{SW}(\mathcal{C})$ in the ∞-category $\mathrm{SW}(\mathcal{C})$. Then $\tau_{\geqslant 0}\overline{q}$ is a limit diagram in the ∞-category $\mathrm{SW}(\mathcal{C})_{\geqslant 0} \simeq \mathcal{C}$. We wish to show that the image of $\tau_{\geqslant 0}\overline{q}$ under the functor $\mathrm{SW}(f) : \mathrm{SW}(\mathcal{C}) \to \mathrm{SW}(\mathcal{D})$ is a limit diagram in $\mathrm{SW}(\mathcal{D})_{\geqslant 0} \simeq \mathcal{D}$. Since $\mathrm{SW}(f)$ is t-exact, we can identify this image with $\tau_{\geqslant 0}\,\mathrm{SW}(f)(\overline{q})$. This is a limit diagram because the functors

$$\mathrm{SW}(f) : \mathrm{SW}(\mathcal{C}) \to \mathrm{SW}(\mathcal{D}) \qquad \tau_{\geqslant 0} : \mathrm{SW}(\mathcal{D}) \to \mathrm{SW}(\mathcal{D})_{\geqslant 0}$$

both preserve finite limits. □

Proof of Proposition C.3.2.1. The implication (1) ⇒ (2) is immediate. We next prove that (2) implies (3). Suppose that (2) is satisfied, and let $C \in \mathrm{Sp}(\mathcal{C})_{\leqslant 0}$; we wish to prove that $F(C) \in \mathrm{Sp}(\mathcal{D})_{\leqslant 0}$. Since $\mathrm{Sp}(\mathcal{C})$ is right complete, we can write $C = \varinjlim \tau_{\geqslant -n} C$. Because F commutes with filtered colimits, we have $F(C) = \varinjlim F(\tau_{\geqslant -n} C)$. Since $\mathrm{Sp}(\mathcal{D})_{\leqslant 0}$ is closed under filtered colimits, we are reduced to proving that each $F(\tau_{\geqslant -n} C)$ belongs to $\mathrm{Sp}(\mathcal{D})_{\leqslant 0}$. The proof proceeds by induction on n, the case $n < 0$ being trivial. To carry out the inductive step, we note that the exactness of F supplies a fiber sequence

$$F(\tau_{\geqslant 1-n} C) \to F(\tau_{\geqslant -n} C) \to F(\Sigma^{-n} \pi_n C).$$

The inductive hypothesis implies that $F(\tau_{\geqslant 1-n} C)$ belongs to $\mathrm{Sp}(\mathcal{D})_{\leqslant 0}$. Since $\mathrm{Sp}(\mathcal{D})_{\leqslant 0}$ is closed under extensions, we are reduced to proving that the object $F(\Sigma^{-n}\pi_n C) \simeq \Sigma^{-n} F(\pi_n C)$ belongs to $\mathrm{Sp}(\mathcal{D})_{\leqslant 0}$. In fact, it belongs to $\mathrm{Sp}(\mathcal{D})_{\leqslant -n}$: since $\pi_n C$ belongs to the heart $\mathrm{Sp}(\mathcal{C})^{\heartsuit}$, we can write $\pi_n C \simeq \Sigma^{\infty}_{\mathcal{C}} X$ for some discrete object $X \in \mathcal{C}$, so that $F(\pi_n C) \simeq \Sigma^{\infty}_{\mathcal{D}} F(X) \in \mathrm{Sp}(\mathcal{D})^{\heartsuit}$ by virtue of assumption (2).

We now complete the proof by showing that (3) implies (1). Let us identify $\mathrm{SW}(\mathcal{C})$ and $\mathrm{SW}(\mathcal{D})$ with the full subcategories

$$\bigcup_{n \geqslant 0} \mathrm{Sp}(\mathcal{C})_{\geqslant -n} \subseteq \mathrm{Sp}(\mathcal{C}) \qquad \mathrm{SW}(\mathcal{D}) \subseteq \bigcup_{n \geqslant 0} \mathrm{Sp}(\mathcal{D})_{\geqslant -n} \subseteq \mathrm{Sp}(\mathcal{D}).$$

It follows from (3) that the functor F_0 is t-exact, so that f is left exact by virtue of Lemma C.3.2.2. □

Notation C.3.2.3. Let $\mathsf{Groth}^{\mathrm{lex}}_{\infty}$ denote the subcategory of $\widehat{\mathcal{C}\mathrm{at}}_{\infty}$ whose objects are Grothendieck prestable ∞-categories and whose morphisms are functors $F : \mathcal{C} \to \mathcal{D}$ which preserve small colimits and finite limits.

Proposition C.3.2.4. *The ∞-category* $\mathsf{Groth}_\infty^{\mathrm{lex}}$ *admits small limits. Moreover, the forgetful functors*

$$\mathsf{Groth}_\infty^{\mathrm{lex}} \to \mathcal{P}\mathrm{r}^{\mathrm{L}} \qquad \mathsf{Groth}_\infty^{\mathrm{lex}} \to \mathsf{Groth}_\infty^{+}$$

preserve small limits.

Proof. Let $\{\mathcal{C}_\alpha\}$ be a small diagram of Grothendieck prestable ∞-categories where the transition maps preserve small colimits and finite limits, and let $\mathcal{C}$ denote a limit of $\{\mathcal{C}_\alpha\}$ in the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty$. It follows from Proposition **??** that the ∞-category $\mathcal{C}$ is presentable and that for any presentable ∞-category $\mathcal{D}$, a functor $f : \mathcal{D} \to \mathcal{C}$ preserves small colimits if and only if each of the maps $\mathcal{D} \to \mathcal{C} \to \mathcal{C}_\alpha$ preserves small colimits. Applying Proposition C.3.2.4, we see that $\mathcal{C}$ is a prestable ∞-category and that a functor $f : \mathcal{D} \to \mathcal{C}$ preserves finite limits if and only if each of the functors $\mathcal{D} \to \mathcal{C} \to \mathcal{C}_\alpha$ preserve small limits. To show that $\mathcal{C}$ is a limit of the diagram $\{\mathcal{C}_\alpha\}$ in Groth_∞, it will suffice to show that $\mathcal{C}$ is Grothendieck: that is, that the functor $\Omega_{\mathcal{C}} : \mathcal{C} \to \mathcal{C}$ commutes with filtered colimits (see Proposition C.1.4.1). This is equivalent to the statement that each of the composite maps $\mathcal{C} \xrightarrow{\Omega_{\mathcal{C}}} \mathcal{C} \to \mathcal{C}_\alpha$ commutes with filtered colimits. This is clear, since we can rewrite this composition as $\mathcal{C} \to \mathcal{C}_\alpha \xrightarrow{\Omega_{\mathcal{C}_\alpha}} \mathcal{C}_\alpha$, where $\Omega_{\mathcal{C}_\alpha}$ commutes with filtered colimits by virtue of our assumption that $\mathcal{C}_\alpha$ is a Grothendieck prestable ∞-category. This completes the proof that the ∞-category $\mathsf{Groth}_\infty^{\mathrm{lex}}$ admits small colimits which are preserved by the inclusion $\mathsf{Groth}_\infty^{\mathrm{lex}} \hookrightarrow \mathcal{P}\mathrm{r}^{\mathrm{L}}$.

We now complete the proof by showing that the functor $\mathsf{Groth}_\infty^{\mathrm{lex}} \to \mathsf{Groth}_\infty^{+}$ of Corollary C.3.1.4 preserves small limits. For any pointed presentable ∞-category $\mathcal{E}$, we can identify the ∞-category $\mathrm{Sp}(\mathcal{E})$ of spectrum objects of $\mathcal{E}$ with the homotopy limit of the diagram

$$\to \mathcal{E} \xrightarrow{\Omega} \mathcal{E} \xrightarrow{\Omega} \mathcal{E}$$

in the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty$. Moreover, this identification is functor with respect to *left exact* colimit-preserving functors. Consequently, if $\mathcal{C} \simeq \varprojlim \mathcal{C}_\alpha$ is as above, then we can identify $\mathrm{Sp}(\mathcal{C})$ with the limit of the diagram $\{\mathrm{Sp}(\mathcal{C}_\alpha)\}$ in the ∞-category of presentable stable ∞-categories. Each of the functors $\mathrm{Sp}(\mathcal{C}) \to \mathrm{Sp}(\mathcal{C}_\alpha)$ is t-exact, so that an object of $\mathrm{Sp}(\mathcal{C})$ belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ if and only if its image in each $\mathrm{Sp}(\mathcal{C}_\alpha)$ belongs to $\mathrm{Sp}(\mathcal{C}_\alpha)_{\geqslant 0}$; this proves that the object $(\mathrm{Sp}(\mathcal{C}), \mathrm{Sp}(\mathcal{C})_{\geqslant 0})$ is a limit of the diagram $\{(\mathrm{Sp}(\mathcal{C}_\alpha), \mathrm{Sp}(\mathcal{C}_\alpha)_{\geqslant 0})$ in $\mathsf{Groth}_\infty^{+}$. □

Corollary C.3.2.5. *The construction* $\mathcal{C} \mapsto \mathrm{Sp}(\mathcal{C})$ *determines a functor* $\mathsf{Groth}_\infty^{\mathrm{lex}} \to \mathcal{P}\mathrm{r}^{\mathrm{St}}$ *which preserves small limits.*

C.3.3 Filtered Colimits of Grothendieck Prestable ∞-Categories

Recall that the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable stable ∞-categories admits small limits (Proposition HTT.5.5.3.13) and small colimits (Theorem HTT.5.5.3.18). Our first goal is to show that the full subcategory $\mathsf{Groth}_\infty \subseteq \mathcal{P}\mathrm{r}^{\mathrm{L}}$ of Definition C.3.0.5 enjoys the following closure property:

Theorem C.3.3.1. *The full subcategory* $\mathsf{Groth}_\infty \subseteq \mathcal{P}\mathrm{r}^{\mathrm{L}}$ *is closed under small filtered colimits. Consequently, the* ∞*-category* Groth_∞ *admits filtered colimits, which are preserved by the inclusion* $\mathsf{Groth}_\infty \hookrightarrow \mathcal{P}\mathrm{r}^{\mathrm{L}}$.

To prove Theorem C.3.3.1, it will be convenient to first study *lax* (co)limits of Grothendieck prestable ∞-categories. Here, we do not need any requirements on the indexing ∞-category:

Proposition C.3.3.2. *Let* S *be a small simplicial set and let* $p : \mathcal{C} \to S$ *be a map of simplicial sets having the following properties:*

- (i) *The map* p *is both a Cartesian fibration and a coCartesian fibration.*
- (ii) *For each* $s \in S$*, the fiber* $\mathcal{C}_s = \mathcal{C} \times_S \{s\}$ *is a Grothendieck prestable* ∞*-category.*

Let $\mathcal{E} = \mathrm{Fun}_S(S, \mathcal{C}) = \mathrm{Fun}(S, \mathcal{C}) \times_{\mathrm{Fun}(S,S)} \{\mathrm{id}_S\}$ *denote the* ∞*-category of sections of* p*. Then* $\mathcal{E}$ *is a Grothendieck prestable* ∞*-category.*

Proof. Proposition HTT.5.5.3.17 implies that $\mathcal{E}$ is presentable. For each $s \in S$, let $e_s : \mathcal{E} \to \mathcal{C}_s$ denote the functor given by evaluation at s. Using Proposition HTT.5.1.2.2 , we see that the functors e_s preserve small limits and colimits. We next show that $\mathcal{E}$ is prestable: that is, it satisfies conditions (a) through (c) of Definition C.1.2.1:

- (a) We have already seen that $\mathcal{E}$ admits small colimits (and therefore finite colimits). Choose a morphism $g : \varnothing \to \mathbf{1}$ in $\mathcal{E}$, where $\varnothing \in \mathcal{E}$ is an initial object and $\mathbf{1} \in \mathcal{E}$ is a final object. For each vertex $s \in S$, the functor e_s carries g to a morphism from an initial object to a final object in the pointed ∞-category $\mathcal{C}_s$, so that $e_s(g)$ is an equivalence. It follows that g is an equivalence, so that $\mathcal{E}$ is pointed.
- (b) Fix an object $E \in \mathcal{E}$, and let $u : E \to \Omega_{\mathcal{E}}\Sigma_{\mathcal{E}} E$ be the unit map. For each $s \in S$, the evaluation functor $e_s : \mathcal{E} \to \mathcal{C}_s$ preserves finite limits and colimits and therefore carries u to the unit map $e_s(E) \to \Omega_{\mathcal{C}_s}\Sigma_{\mathcal{C}_s} e_s(E)$, which is an equivalence since $\mathcal{C}_s$ is prestable. It follows that u is an equivalence for each $E \in \mathcal{E}$, so that the suspension functor $\Sigma_{\mathcal{E}} : \mathcal{E} \to \mathcal{E}$ is fully faithful.
- (c) Suppose we are given a pullback square σ :

$$\begin{array}{ccc} X & \xrightarrow{f'} & Y \\ \downarrow & & \downarrow{\scriptstyle f} \\ 0 & \longrightarrow & \Sigma_{\mathcal{E}} Z \end{array}$$

  in $\mathcal{E}$; we wish to show that σ is also a pushout square. Since the functors $\{e_s\}_{s \in S}$ preserve finite limits and commute with suspension each $e_s(\sigma)$ is a pullback square in

$\mathcal{C}_s$ whose lower right-hand corner is a suspension (and whose lower left-hand corner is a zero object). The prestability of $\mathcal{C}_s$ guarantees that each $e_s(\sigma)$ is a pushout square in $\mathcal{C}_s$. Since the functors $\{e_s\}_{s \in S}$ preserve pushout squares and are mutually conservative, it follows that σ is a pushout square in $\mathcal{E}$.

To complete the proof, it will suffice to show that $\mathcal{E}$ is a *Grothendieck* prestable ∞-category: that is, that the functor $\Omega_{\mathcal{E}} : \mathcal{E} \to \mathcal{E}$ commutes with filtered colimits (see Proposition C.1.4.1). Since the evaluation functors $\{e_s\}_{s \in S}$ are mutually conservative and commute with filtered colimits, this is equivalent to the requirement that each composition $e_s \circ \Omega_{\mathcal{E}}$ commutes with filtered colimits. Because e_s is left exact, we have an equivalence $e_s \circ \Omega_{\mathcal{E}} \simeq \Omega_{\mathcal{C}_s} \circ e_s$; we are therefore reduced to showing that $\Omega_{\mathcal{C}_s}$ commutes with filtered colimits, which follows from our assumption that $\mathcal{C}_s$ is a Grothendieck prestable ∞-category. □

We will deduce Theorem C.3.3.1 from Proposition C.3.3.2, together with the following:

Proposition C.3.3.3. *Let A be a small filtered partially ordered set, let $p : \mathcal{C} \to \mathrm{N}(A)$ be a map of simplicial sets satisfying conditions (i) and (ii) of Proposition C.3.3.2. Let $\mathcal{E} = \mathrm{Fun}_{\mathrm{N}(A)}(\mathrm{N}(A), \mathcal{C})$ be the ∞-category of sections of $\mathcal{C}$, and let $\mathcal{E}^{\mathrm{cart}} \subseteq \mathcal{E}$ denote the full subcategory spanned by those sections $s : \mathrm{N}(A) \to \mathcal{C}$ which carry each edge of $\mathrm{N}(A)$ to a p-Cartesian morphism in $\mathcal{C}$. Then the inclusion $\mathcal{E}^{\mathrm{cart}} \hookrightarrow \mathcal{E}$ admits a left exact left adjoint $L : \mathcal{E} \to \mathcal{E}^{\mathrm{cart}}$.*

Proof of Theorem C.3.3.1 from Proposition C.3.3.3. Let $\mathcal{J}$ be a small filtered ∞-category and suppose we are given a diagram $f : \mathcal{J} \to \mathsf{Groth}_{\infty} \subseteq \mathcal{P}r^{\mathrm{L}}$. We wish to show that the colimit of f (formed in the ∞-category $\mathcal{P}r^{\mathrm{L}}$) is a Grothendieck prestable ∞-category. Using Proposition HTT.5.3.1.18 , we can choose a small filtered partially ordered set A and a left cofinal map $g : \mathrm{N}(A) \to \mathcal{J}$. Replacing f by $f \circ g$, we can reduce to the case where $\mathcal{J} = \mathrm{N}(A)$. Let $p : \mathcal{C} \to \mathrm{N}(A)$ be a presentable fibration classified by f (see Proposition HTT.5.5.3.3). Then p satisfies conditions (i) and (ii) of Proposition C.3.3.2, so that $\mathcal{E} = \mathrm{Fun}_{\mathrm{N}(A)}(\mathrm{N}(A), \mathcal{C})$ is a Grothendieck prestable ∞-category. Using Theorem HTT.5.5.3.18 and Proposition HTT.**??** , we can identify the colimit of f (formed in the ∞-category $\mathcal{P}r^{\mathrm{L}}$) with the full subcategory $\mathcal{E}^{\mathrm{cart}} \subseteq \mathcal{E}$ spanned by the Cartesian sections of p. It follows from Proposition C.3.3.3 that the inclusion $\mathcal{E}^{\mathrm{cart}} \subseteq \mathcal{E}$ admits a left exact left adjoint $L : \mathcal{E} \to \mathcal{E}^{\mathrm{cart}}$ (which is automatically accessible: see Proposition HTT.5.4.7.7). Applying Proposition C.2.3.1, we deduce that $\mathcal{E}^{\mathrm{cart}}$ is a Grothendieck prestable ∞-category. □

Proof of Proposition C.3.3.3. We proceed as in the proof of Proposition HTT.6.3.3.3 . For every cofinal subset $B \subseteq A$, let $\mathcal{E}_B$ denote the full subcategory of $\mathcal{E} = \mathrm{Fun}_{\mathrm{N}(A)}(\mathrm{N}(A), \mathcal{C})$ spanned by those sections s such that s is a p-right Kan extension of $s|_{\mathrm{N}(B)}$. By virtue of Lemma C.4.3.1, it will suffice to prove the following:

(a) For every cofinal subset $B \subseteq A$, the full subcategory $\mathcal{E}_B$ is an accessible left exact localization of $\mathcal{E}$.

(b) Let P be the set of all cofinal subsets of A. Then $\mathcal{E}^{\text{cart}} = \bigcap_{B \in P} \mathcal{E}_B$.

To prove (a), consider the restriction functor $\phi : \mathcal{E} \to \text{Fun}_{\text{N}(A)}(\text{N}(B), \mathcal{C})$. Using Proposition HTT.4.3.2.15, we deduce that ϕ restricts to a trivial Kan fibration $\phi_0 : \mathcal{E}_B \to \text{Fun}_{\text{N}(A)}(\text{N}(B), \mathcal{C})$. Any choice of section of ϕ_0 determines a fully faithful embedding $\text{Fun}_{\text{N}(A)}(\text{N}(B), \mathcal{C}) \to \mathcal{E}$ which is right adjoint to ϕ, having essential image $\mathcal{E}_B$. This proves that $\mathcal{E}_B$ is a localization of $\mathcal{E}$. Since $\text{Fun}_{\text{N}(A)}(\text{N}(B), \mathcal{C}) \simeq \text{Fun}_{\text{N}(B)}(\text{N}(B), \mathcal{C} \times_{\text{N}(A)} \text{N}(B))$ is a Grothendieck prestable ∞-category (Proposition C.3.3.2), it follows that $\mathcal{E}_B$ is also a Grothendieck prestable ∞-category (and, in particular, accessible). The left exactness of the localization $\mathcal{E} \to \mathcal{E}_B$ follows from the left exactness of ϕ (which is immediate from the fact that limits are computed levelwise; see Proposition HTT.5.1.2.2).

We now prove (b). Suppose first that $s : \text{N}(A) \to \mathcal{C}$ is a section of p which carries each edge of $\text{N}(A)$ to a p-Cartesian edge of $\mathcal{C}$. We claim that s belongs to $\mathcal{E}_B$ for every cofinal subset $B \subseteq A$. To prove this, it suffices to show that for each element $\alpha \in A$, the section s exhibits $s(\alpha)$ as a p-limit of the diagram $s|_{\text{N}(B_\alpha)}$, where $B_\alpha = \{\beta \in B : \beta \geqslant \alpha\}$. By assumption, s carries each edge of $\text{N}(A)$ to a p-Cartesian morphism in $\mathcal{C}$. Using Propositions HTT.4.3.1.9 , HTT.4.3.1.10 , and Corollary HTT.4.4.4.10 , we are reduced to proving that the simplicial set $\text{N}(B_\alpha)$ is weakly contractible. This is clear, since the cofinality of B in A guarantees that $\text{N}(B_\alpha)$ is filtered.

To complete the proof, it will suffice to show that every object $s \in \bigcap_{B \in P} \mathcal{C}_B$ belongs to $\mathcal{E}^{\text{cart}}$. Fix a pair of elements $\alpha \leqslant \beta$ in A; we wish to show that the map $s(\alpha) \to s(\beta)$ is p-Cartesian. To prove this, set $B = \{\gamma \in A : \gamma \geqslant \beta\}$. Since A is filtered, B is cofinal in A. Our assumption on s guarantees that s is a p-right Kan extension of $s|_{\text{N}(B)}$, so that $s(\alpha)$ is a p-limit of the diagram $s|_{\text{N}(B)}$. Since β is an initial object of $\text{N}(B)$, we conclude that the map $s(\alpha) \to s(\beta)$ is p-Cartesian, as desired. □

We now restrict our attention to the colimits of filtered diagrams in the subcategory $\mathsf{Groth}_\infty^{\text{lex}} \subseteq \mathsf{Groth}_\infty$ of Notation C.3.2.3.

Lemma C.3.3.4. *Let $\mathcal{J}$ be a small filtered ∞-category and suppose we are given a diagram $f : \mathcal{J} \to \mathsf{Groth}_\infty^{\text{lex}}$, which we will denote by $\{\mathcal{C}_\alpha\}_{\alpha \in \mathcal{J}}$. Let $\mathcal{C}$ denote the colimit $\varinjlim_{\alpha \in \mathcal{J}} \mathcal{C}_\alpha$ (formed in the ∞-category Groth_∞). For each $\alpha \in \mathcal{J}$, the tautological map $\rho_\alpha : \mathcal{C}_\alpha \to \mathcal{C}$ is left exact.*

Proof. Arguing as in the proof of Theorem C.3.3.1, we can use Proposition HTT.5.3.1.18 to reduce to the case where $\mathcal{J} = \text{N}(A)$ for some filtered partially ordered set A. Replacing A by the cofinal subset $\{\beta \in A : \beta \geqslant \alpha\}$, we can assume that α is a least element of A. Let $p : \mathcal{C} \to \text{N}(A)$ be a presentable fibration classified by f, let $\mathcal{E} = \text{Fun}_{\text{N}(A)}(\text{N}(A), \mathcal{C})$ be the

∞-category of sections of p, and let $\mathcal{E}^{\mathrm{cart}} \subseteq \mathcal{E}$ be as in Proposition C.3.3.3. Then we can identify the right adjoint to ρ_α with the functor $e_\alpha : \mathcal{E}^{\mathrm{cart}} \to \mathcal{C}_\alpha$ given by evaluation at α. It follows that ρ_α can be computed as the composition

$$\mathcal{C}_\alpha \xrightarrow{\overline{\rho}_\alpha} \mathcal{E} \xrightarrow{L} \mathcal{E}^{\mathrm{cart}},$$

where $\overline{\rho}_\alpha$ is given by p-left Kan extension along the inclusion $\{\alpha\} \hookrightarrow A$ and L is a left adjoint to the inclusion $\mathcal{E}^{\mathrm{cart}} \to \mathcal{E}$. Since the functor L is left exact (Proposition C.3.3.3), it will suffice to show that $\overline{\rho}_\alpha$ is left exact. Because the evaluation functors $\{e_\beta : \mathcal{E} \to \mathcal{C}_\beta\}_{\beta \in A}$ preserve small limits and are mutually conservative, this is equivalent to the assertion that each composition $e_\beta \circ \overline{\rho}_\alpha$ is left exact. Using the fact that α is a least element of A, we see that $e_\beta \circ \overline{\rho}_\alpha$ can be identified with the transition functor $\mathcal{C}_\alpha \to \mathcal{C}_\beta$ determined by the diagram $f : \mathrm{N}(A) \to \mathsf{Groth}_\infty^{\mathrm{lex}}$, and is therefore left exact by assumption. □

Proposition C.3.3.5. *The ∞-category $\mathsf{Groth}_\infty^{\mathrm{lex}}$ admits small filtered colimits, which are preserved by the inclusion functors $\mathsf{Groth}_\infty^{\mathrm{lex}} \hookrightarrow \mathsf{Groth}_\infty \hookrightarrow \mathcal{P}\mathrm{r}^{\mathrm{L}}$.*

Proof. By virtue of Theorem C.3.3.1, it will suffice to prove the following:

- $(*)$ Let $\mathcal{J}$ be an essentially small filtered ∞-category, let $\{\mathcal{C}_\alpha\}_{\alpha \in \mathcal{J}}$ be a diagram in the ∞-category $\mathsf{Groth}_\infty^{\mathrm{lex}}$ indexed by $\mathcal{J}$, let $\mathcal{C} \simeq \varinjlim_\alpha \mathcal{C}_\alpha$ be its colimit in the ∞-category Groth_∞, and for each $\alpha \in \mathcal{J}$ let $f_\alpha : \mathcal{C}_\alpha \to \mathcal{C}$ be the tautological map. Then a morphism $h : \mathcal{C} \to \mathcal{D}$ in Groth_∞ is left exact if and only if, for each $\alpha \in \mathcal{J}$, the composition $(h \circ f_\alpha) : \mathcal{C}_\alpha \to \mathcal{D}$ is left exact.

The "only if" direction of $(*)$ follows immediately from Lemma C.3.3.4. For each $\alpha \in \mathcal{J}$, let $g_\alpha : \mathcal{C} \to \mathcal{C}_\alpha$ denote a right adjoint to f_α. Using Lemma HTT.6.3.3.7 , we see that the identity functor $\mathrm{id}_{\mathcal{C}}$ can be written as a filtered colimit $\varinjlim_{\alpha \in \mathcal{J}} f_\alpha \circ g_\alpha$. It follows that any functor $h : \mathcal{C} \to \mathcal{D}$ which preserves small colimits can be written as a filtered colimit $\varinjlim_{\alpha \in \mathcal{J}} (h \circ f_\alpha \circ g_\alpha)$. The functors g_α are automatically left exact (since they are right adjoints). Consequently, if each $h \circ f_\alpha : \mathcal{C}_\alpha \to \mathcal{D}$ is left exact, then the composition $h \circ f_\alpha \circ g_\alpha$ is left exact. If $\mathcal{D}$ is a Grothendieck prestable ∞-category, then the formation of filtered colimits in $\mathcal{D}$ commutes with finite limits, so that $h \simeq \varinjlim_{\alpha \in \mathcal{J}} (h \circ f_\alpha \circ g_\alpha)$ is also left exact. □

C.3.4 Compact Functors

We now study a different class of functors between Grothendieck prestable ∞-categories, which we will refer to as *compact* functors.

Proposition C.3.4.1. *Let $\mathcal{C}$ and $\mathcal{D}$ be Grothendieck prestable ∞-categories, let $f : \mathcal{C} \to \mathcal{D}$ be a functor which preserves small colimits, and let $F : \mathrm{Sp}(\mathcal{C}) \to \mathrm{Sp}(\mathcal{D})$ be the right t-exact functor determined by f (see Proposition C.3.1.1). Then the functors f and F admit right adjoints $g : \mathcal{D} \to \mathcal{C}$ and $G : \mathrm{Sp}(\mathcal{D}) \to \mathrm{Sp}(\mathcal{C})$, and the following conditions are equivalent:*

(*a*) *The functor g commutes with small filtered colimits.*

(*b*) *The functor G commutes with small colimits.*

Definition C.3.4.2. Let $\mathcal{C}$ and $\mathcal{D}$ be a Grothendieck prestable ∞-categories. We will say that a colimit-preserving functor $f : \mathcal{C} \to \mathcal{D}$ is *compact* if it satisfies the equivalent conditions of Proposition C.3.4.1. We let $\mathsf{Groth}^{\mathrm{c}}_{\infty}$ denote the subcategory of Groth_{∞} whose objects are Grothendieck prestable ∞-categories and whose morphisms are compact functors.

Remark C.3.4.3. Let $f : \mathcal{C} \to \mathcal{D}$ be a morphism between Grothendieck prestable ∞-categories which preserves small colimits. If f is compact, then it carries compact objects of $\mathcal{C}$ to compact objects of $\mathcal{D}$. The converse holds if $\mathcal{C}$ is compactly generated (Proposition HTT.5.5.7.2).

Example C.3.4.4. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. According to Example C.3.1.2, evaluation on the sphere spectrum $S \in \mathrm{Sp}^{\mathrm{cn}}$ induces an equivalence of ∞-categories $\mathrm{LFun}(\mathrm{Sp}^{\mathrm{cn}}, \mathcal{C}) \to \mathcal{C}$. If $f : \mathrm{Sp}^{\mathrm{cn}} \to \mathcal{C}$ is a colimit-preserving functor, then the following conditions are equivalent:

(*a*) The functor f is compact (in the sense of Definition C.3.4.2).

(*b*) For every connective finite spectrum X, the object $f(X) \in \mathcal{C}$ is compact.

(*c*) The object $f(S) \in \mathcal{C}$ is compact.

The equivalence of (*a*) and (*b*) follows from Remark C.3.4.3, and the equivalence of (*b*) and (*c*) follows because every connective finite spectrum X can be build from the sphere spectrum S using finite colimits.

Proof of Proposition C.3.4.1. The existence of the functors g and G follows from the adjoint functor theorem. Unwinding the definitions, we see that the functor g can be identified with the composition

$$\mathcal{D} \xrightarrow{\Sigma^{\infty}_{\mathcal{D}}} \mathrm{Sp}(\mathcal{D}) \xrightarrow{G} \mathrm{Sp}(\mathcal{C}) \xrightarrow{\Omega^{\infty}_{\mathcal{C}}} \mathcal{C}\,.$$

Here the functor $\Sigma^{\infty}_{\mathcal{D}}$ commutes with small colimits (since it is a left adjoint) and the functor $\Omega^{\infty}_{\mathcal{C}}$ commutes with small filtered colimits (by virtue of our assumption that $\mathcal{C}$ is Grothendieck; see Proposition C.1.4.1). It follows immediately that (*b*) implies (*a*). Conversely, suppose that (*a*) is satisfied. The functor G is a right adjoint and is therefore left exact. Since the domain and codomain of G are stable ∞-categories, the functor G is also right exact. Consequently, to show that G preserves all small colimits, it will suffice to show that it preserves small filtered colimits.

For each integer n, let $G_n : \mathrm{Sp}(\mathcal{D}) \to \mathrm{Sp}(\mathcal{C})$ denote the functor given on objects by the formula $G_n(X) = G(\tau_{\geqslant -n} X)$. Since G is exact, for each $X \in \mathrm{Sp}(\mathcal{D})$ we have a canonical fiber sequence $G_n(X) \to G(X) \to G(\tau_{\leqslant -n-1}X)$. Since F is right t-exact, the functor G is left t-exact, so $G(\tau_{\leqslant -n-1}X)$ belongs to $\mathrm{Sp}(\mathcal{C})_{\leqslant -n-1}$. Using the right completeness of the t-structure on $\mathrm{Sp}(\mathcal{C})$, we deduce that the canonical map $\varinjlim_{n \geqslant 0} G_n(X) \to G(X)$ is an equivalence.

For each integer m, let $G_{n,m} : \mathrm{Sp}(\mathcal{D}) \to \mathrm{Sp}(\mathcal{C})$ denote the functor given by $\tau_{\geqslant -m} G(\tau_{\geqslant -n} X)$. Using the right completeness of $\mathrm{Sp}(\mathcal{C})$, we see that G_n can be written as a colimit of the diagram $\varinjlim_{m \geqslant 0} G_{n,m}$. We can therefore write the functor G as a direct limit

$$\varinjlim_{n \geqslant 0} \varinjlim_{m \geqslant 0} G_{n,m} \simeq \varinjlim_{n \geqslant 0} G_{n,n}.$$

It will therefore suffice to show that each of the functors $G_{n,n}$ commutes with filtered colimits. Unwinding the definitions, we have

$$G_{n,n} \simeq \Sigma^{-n}_{\mathrm{Sp}(\mathcal{C})} \circ G_{0,0} \circ \Sigma^{n}_{\mathrm{Sp}(\mathcal{D})}.$$

It will therefore suffice to show that the functor

$$\begin{aligned} G_{0,0} &= \tau_{\geqslant 0} \circ G \circ \tau_{\geqslant 0} \\ &\simeq \Sigma^{\infty}_{\mathcal{C}} \circ \Omega^{\infty}_{\mathcal{C}} \circ G \circ \Sigma^{\infty}_{\mathcal{D}} \circ \Omega^{\infty}_{\mathcal{D}} \\ &\simeq \Sigma^{\infty}_{\mathcal{C}} \circ g \circ \Omega^{\infty}_{\mathcal{D}} \end{aligned}$$

commutes with small filtered colimits. This follows from assumption (a), since the functor $\Sigma^{\infty}_{\mathcal{C}}$ preserves all small colimits and the functor $\Omega^{\infty}_{\mathcal{D}}$ preserves small filtered colimits (by virtue of our assumption that $\mathcal{D}$ is Grothendieck; see Proposition C.1.4.1). □

C.3.5 Colimits in $\mathsf{Groth}^{\mathrm{c}}_{\infty}$

In §C.3.3, we proved that the ∞-category Groth_{∞} of Grothendieck prestable ∞-categories admits filtered colimits (Theorem C.3.3.1). If we restrict our attention to diagrams where the transition maps are given by compact functors, then the analogous assertion holds even for non-filtered diagrams:

Proposition C.3.5.1. *The ∞-category* $\mathsf{Groth}^{\mathrm{c}}_{\infty}$ *admits small colimits.*

Proof. Let $\mathcal{P}\mathrm{r}^{\mathrm{R}}$ denote the ∞-category whose objects are presentable ∞-categories and whose morphisms are accessible functors which preserve small limits (see Definition HTT.5.5.3.1). According to Corollary HTT.5.5.3.4 , there is a canonical equivalence of ∞-categories $\mathcal{P}\mathrm{r}^{\mathrm{R}} \simeq (\mathcal{P}\mathrm{r}^{\mathrm{L}})^{\mathrm{op}}$ which is the identity on objects and replaces each morphism in $\mathcal{P}\mathrm{r}^{\mathrm{R}}$ with its left adjoint. Let $\mathcal{M} \subseteq \mathcal{P}\mathrm{r}^{\mathrm{R}}$ denote the subcategory given by the inverse image of $\mathsf{Groth}^{\mathrm{c}}_{\infty}$ under this equivalence. More concretely, $\mathcal{E}$ is the subcategory of $\widehat{\mathcal{C}\mathrm{at}}_{\infty}$ whose objects are Grothendieck prestable ∞-categories and whose morphisms are functors which preserve small limits and small filtered colimits. We will complete the proof by showing that the ∞-category $\mathcal{E}$ admits small limits.

Suppose we are given a diagram of Grothendieck prestable ∞-categories $\{\mathcal{C}_\alpha\}$, where each of the transition maps $g_{\alpha,\beta} : \mathcal{C}_\alpha \to \mathcal{C}_\beta$ preserves small limits and small filtered colimits. Let $\mathcal{C}$ denote the limit of the diagram $\{\mathcal{C}_\alpha\}$ in the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty$. It follows from Theorem HTT.5.5.3.18 that $\mathcal{C}$ is also the limit of the diagram $\{\mathcal{C}_\alpha\}$ in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{R}}$; in particular, $\mathcal{C}$ is presentable. Note that the ∞-category of spectrum objects $\mathrm{Sp}(\mathcal{C})$ can be identified with the limit $\varprojlim \mathrm{Sp}(\mathcal{C}_\alpha)$. Let $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ denote the full subcategory of $\mathrm{Sp}(\mathcal{C})$ given by the limit of the diagram of ∞-categories $\{\mathrm{Sp}(\mathcal{C}_\alpha)_{\leqslant 0}\}$. It follows from Theorem HTT.5.5.3.18 that $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ is a presentable ∞-category. Since the inclusion $\mathrm{Sp}(\mathcal{C})_{\leqslant 0} \hookrightarrow \mathrm{Sp}(\mathcal{C})$ preserves small limits and small filtered colimits, it admits a left adjoint $L : \mathrm{Sp}(\mathcal{C}) \to \mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ (Corollary HTT.5.5.2.9). Since $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ is closed under extensions in $\mathrm{Sp}(\mathcal{C})$, Proposition HA.1.2.1.16 implies that it extends to a t-structure $(\mathrm{Sp}(\mathcal{C})_{\geqslant 0}, \mathrm{Sp}(\mathcal{C})_{\leqslant 0})$ on $\mathrm{Sp}(\mathcal{C})$.

Since each $\mathcal{C}_\alpha$ is a Grothendieck prestable ∞-category, each of the loop functors $\Omega_{\mathcal{C}_\alpha} : \mathcal{C}_\alpha \to \mathcal{C}_\alpha$ preserves small filtered colimits. It follows that the loop functor $\Omega_{\mathcal{C}} : \mathcal{C} \to \mathcal{C}$ preserves small filtered colimits, so that the functor $\Omega^\infty_{\mathcal{C}} : \mathrm{Sp}(\mathcal{C}) \to \mathcal{C}$ preserves small filtered colimits and therefore restricts to a functor $U : \mathrm{Sp}(\mathcal{C})_{\geqslant 0} \to \mathcal{C}$ which preserves small filtered colimits. We claim that U preserves all small limits. To prove this, let K be a small simplicial set and let $q : K \to \mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ be a diagram having a limit $\overline{q} : K^{\triangleleft} \to \mathrm{Sp}(\mathcal{C})$ in $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$, so that $\tau_{\geqslant 0}\overline{q}$ is a limit of the diagram $\tau_{\geqslant 0} q \simeq q$ in the ∞-category $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. We wish to show that $U(\tau_{\geqslant 0}\overline{q})$ is a limit diagram in $\mathcal{C}$. Note that we have an evident fiber sequence of diagrams

$$U(\tau_{\geqslant 0}\overline{q}) \to \Omega^\infty_{\mathcal{C}}(\overline{q}) \to \Omega^\infty_{\mathcal{C}}(\tau_{\leqslant -1}\overline{q}).$$

It will therefore suffice to show that $\Omega^\infty_{\mathcal{C}}(\overline{q})$ and $\Omega^\infty_{\mathcal{C}}(\tau_{\leqslant -1}\overline{q})$ are limit diagrams in $\mathcal{C}$. The first assertion is clear (since the functor $\Omega^\infty_{\mathcal{C}}$ preserves limits) and the second follows from the observation that $\Omega^\infty_{\mathcal{C}}(\tau_{\leqslant -1}\overline{q})$ is equivalent to the constant diagram taking the value $0 \in \mathcal{C}$.

Since the t-structure $(\mathrm{Sp}(\mathcal{C})_{\geqslant 0}, \mathrm{Sp}(\mathcal{C})_{\leqslant 0})$ is compatible with filtered colimits, the ∞-category $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ is prestable and Grothendieck. We claim that the map $U : \mathrm{Sp}(\mathcal{C})_{\geqslant 0} \to \mathcal{C}$ exhibits $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ as a limit of the diagram $\{\mathcal{C}_\alpha\}$ in $\mathcal{E}$. For any presentable ∞-categories $\mathcal{D}$ and $\mathcal{D}'$, let $\mathrm{Fun}'(\mathcal{D}, \mathcal{D}')$ denote the full subcategory of $\mathrm{Fun}(\mathcal{D}, \mathcal{D}')$ spanned by those functors which preserve small limits and small filtered colimits. We wish to show that if $\mathcal{D}$ is a Grothendieck prestable ∞-category, then the composite map

$$\theta : \mathrm{Fun}'(\mathcal{D}, \mathrm{Sp}(\mathcal{C})_{\geqslant 0}) \xrightarrow{U\circ} \mathrm{Fun}'(\mathcal{D}, \mathcal{C}) \to \varprojlim_{\alpha} \mathrm{Fun}'(\mathcal{D}, \mathcal{C}_\alpha)$$

is an equivalence of ∞-categories. Let $\mathrm{Fun}''(\mathrm{Sp}(\mathcal{D}), \mathrm{Sp}(\mathcal{C}))$ denote the full subcategory of $\mathrm{Fun}(\mathrm{Sp}(\mathcal{D}), \mathrm{Sp}(\mathcal{C}))$ spanned by those functors which preserve small limits, small filtered colimits, and are left t-exact, and define $\mathrm{Fun}''(\mathrm{Sp}(\mathcal{D}), \mathrm{Sp}(\mathcal{C}_\alpha))$ similarly. Using Propositions **??** and C.3.4.1, we can identify θ with the natural map $\mathrm{Fun}''(\mathrm{Sp}(\mathcal{D}), \mathrm{Sp}(\mathcal{C})) \to$

$\varprojlim \mathrm{Fun}''(\mathrm{Sp}(\mathcal{D}), \mathrm{Sp}(\mathcal{C}_\alpha))$, which is an equivalence by virtue of our construction of $\mathcal{C}$ and the t-structure on $\mathrm{Sp}(\mathcal{C})$. □

Remark C.3.5.2. Let $\{\mathcal{C}_\alpha\}$ and $\mathcal{C}$ be as in the proof of Proposition C.3.5.1 and let X be an object of $\mathrm{Sp}(\mathcal{C})$. Then the following conditions are equivalent:

- The object X belongs to $\mathrm{Sp}(\mathcal{C})_{\leqslant -1}$.
- For every index α, the image of X under the forgetful functor $G_\alpha : \mathrm{Sp}(\mathcal{C}) \to \mathrm{Sp}(\mathcal{C}_\alpha)$ belongs to $\mathrm{Sp}(\mathcal{C}_\alpha)_{\leqslant -1}$.
- For each index α and each object $C \in \mathcal{C}_\alpha$, the mapping space $\mathrm{Map}_{\mathrm{Sp}(\mathcal{C}_\alpha)}(\Sigma^\infty_{\mathcal{C}_\alpha} C, G_\alpha(X))$ is contractible.
- For each index α and each object $C \in \mathcal{C}_\alpha$, the mapping space $\mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(\Sigma^\infty_{\mathcal{C}} f_\alpha(C), X)$ is contractible, where f_α denotes the tautological map from $\mathcal{C}_\alpha$ into the direct limit $\mathcal{C} \simeq \varinjlim \mathcal{C}_\alpha$.
- For each object $C \in \mathcal{C}$, the mapping space $\mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(\Sigma^\infty_{\mathcal{C}} C, X)$ is contractible (note that any object $C \in \mathcal{C}$ can be obtained as a colimit of objects belonging to the essential images of the functors f_α).

It follows that $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ can be identified with the smallest full subcategory of $\mathrm{Sp}(\mathcal{C})$ which contains the essential image of the functor $\Sigma^\infty_{\mathcal{C}} : \mathcal{C} \to \mathrm{Sp}(\mathcal{C})$ and is closed under small colimits and extensions (see Proposition HA.1.4.4.11). In other words, the composite functor

$$\mathsf{Groth}^{\mathrm{c}}_\infty \hookrightarrow \mathsf{Groth}_\infty \hookrightarrow \mathsf{Groth}^{+}_\infty$$

$$\mathcal{C} \mapsto (\mathrm{Sp}(\mathcal{C}), \mathrm{Sp}(\mathcal{C})_{\geqslant 0})$$

preserves small colimits.

The inclusion functor $\mathsf{Groth}^{\mathrm{c}}_\infty \hookrightarrow \mathcal{P}\mathrm{r}^{\mathrm{L}}$ does not preserve small colimits in general. In other words, the functor $U : \mathrm{Sp}(\mathcal{C})_{\geqslant 0} \to \mathcal{C}$ appearing in the proof of Proposition C.3.5.1 is generally not an equivalence of ∞-categories (because $\mathcal{C}$ is generally not a Grothendieck prestable ∞-category). However, Remark C.3.5.2 and Corollary C.3.1.4 immediately imply the following:

Proposition C.3.5.3. *The inclusion functor* $\mathsf{Groth}^{\mathrm{c}}_\infty \hookrightarrow \mathsf{Groth}_\infty$ *preserves small colimits.*

Remark C.3.5.4. Let $\{\mathcal{C}_\alpha\}$ be a small diagram in the ∞-category $\mathsf{Groth}^{\mathrm{c}}_\infty$, and suppose that the transition functors $f_{\alpha,\beta} : \mathcal{C}_\alpha \to \mathcal{C}_\beta$ admit right adjoints $g_{\alpha,\beta} : \mathcal{C}_\beta \to \mathcal{C}_\alpha$ which preserve *all* small colimits (in other words, the associated exact functors $G_{\alpha,\beta} : \mathrm{Sp}(\mathcal{C}_\beta) \to \mathrm{Sp}(\mathcal{C}_\alpha)$ are t-exact). In this case, the map $U : \mathrm{Sp}(\mathcal{C})_{\geqslant 0} \to \mathcal{C}$ can be identified with an inverse limit of equivalences

$$\mathrm{Sp}(\mathcal{C}_\alpha)_{\geqslant 0} \hookrightarrow \mathrm{Sp}(\mathcal{C}_\alpha) \xrightarrow{\Omega^\infty_{\mathcal{C}_\alpha}} \mathcal{C}_\alpha$$

and is therefore itself an equivalence. The proof of Proposition C.3.5.1 then shows that the colimit of the diagram $\{\mathcal{C}_\alpha\}$ in the ∞-category $\mathsf{Groth}^{\mathrm{c}}_\infty$ is also a colimit in the larger ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of all presentable ∞-categories. In this case, we can also describe $\mathcal{C}$ as the *limit* of the diagram in the ∞-category $\mathsf{Groth}^{\mathrm{lex}}_\infty$ determined by functors $g_{\alpha,\beta}$.

C.3.6 Separated and Complete Grothendieck Prestable ∞-Categories

We close this section with a few remarks about separated and complete Grothendieck prestable ∞-categories (see Definition C.1.2.12).

Proposition C.3.6.1. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category, and let $\mathcal{C}^{\mathrm{sep}} \subseteq \mathcal{C}$ be the full subcategory spanned by those objects C with the following property: for every ∞-connective object $D \in \mathcal{C}$, the mapping space $\mathrm{Map}_{\mathcal{C}}(D, C)$ is contractible. Then:*

- (a) *The inclusion functor $\mathcal{C}^{\mathrm{sep}} \hookrightarrow \mathcal{C}$ admits a left adjoint $L : \mathcal{C} \to \mathcal{C}^{\mathrm{sep}}$ which is left exact.*
- (b) *The ∞-category $\mathcal{C}^{\mathrm{sep}}$ is a separated Grothendieck prestable ∞-category.*
- (c) *For any separated Grothendieck prestable ∞-category $\mathcal{D}$, composition with L induces an equivalence of ∞-categories $\mathrm{LFun}(\mathcal{C}^{\mathrm{sep}}, \mathcal{D}) \to \mathrm{LFun}(\mathcal{C}, \mathcal{D})$.*

Proof. We first prove (b). Without loss of generality, we may assume that $\mathcal{C} = \mathcal{E}_{\geqslant 0}$ for some presentable stable ∞-category $\mathcal{E}$ equipped with a t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$ which is compatible with filtered colimits. Then the ∞-category of ∞-connective objects of $\mathcal{C}$ can be identified with the intersection $\mathcal{E}_{\geqslant\infty} = \bigcap_{n \geqslant 0} \mathcal{E}_{\geqslant n}$. The subcategory $\mathcal{E}_{\geqslant\infty}$ is presentable and closed under colimits and extensions in $\mathcal{E}$. It follows from Proposition HA.1.4.4.11 that $\mathcal{E}$ admits an accessible t-structure $(\mathcal{E}_{\geqslant\infty}, \mathcal{E}')$. Since $\mathcal{E}_{\geqslant\infty}$ is closed under desuspensions, the subcategory $\mathcal{E}' \subseteq \mathcal{E}$ is closed under suspensions and is therefore a stable subcategory of $\mathcal{E}$. Unwinding the definitions, we see that $\mathcal{E}'$ can be identified with the full subcategory of $\mathcal{E}$ spanned by those objects C for which the mapping space $\mathrm{Map}_{\mathcal{E}}(D, C)$ is contractible for every ∞-connective object $D \in \mathcal{C}$. In particular we have

$$\mathcal{E}_{\leqslant 0} \subseteq \mathcal{E}' \qquad \mathcal{C}^{\mathrm{sep}} = \mathcal{E}_{\geqslant 0} \cap \mathcal{E}' .$$

It follows that the pair of subategories $(\mathcal{C}^{\mathrm{sep}}, \mathcal{E}_{\leqslant 0})$ determines a t-structure on $\mathcal{E}'$. Since $\mathcal{E}_{\leqslant 0}$ is closed under the formation of filtered colimits in $\mathcal{E}$, it is also closed under the formation of filtered colimits in $\mathcal{E}' \subseteq \mathcal{E}$: that is, the t-structure $(\mathcal{C}^{\mathrm{sep}}, \mathcal{E}_{\leqslant 0})$ is compatible with filtered colimits. It follows that $\mathcal{C}^{\mathrm{sep}}$ is a Grothendieck prestable ∞-category. Moreover, if $C \in \mathcal{C}^{\mathrm{sep}}$

is ∞-connective as an object of $\mathcal{C}^{\mathrm{sep}}$, then it is ∞-connective as an object of $\mathcal{C}$. It then follows from the definition of $\mathcal{C}^{\mathrm{sep}}$ that the identity map $\mathrm{id} : C \to C$ is nullhomotopic so that $C \simeq 0$. This proves that $\mathcal{C}^{\mathrm{sep}}$ is separated.

By construction, the inclusion $\mathcal{E}' \hookrightarrow \mathcal{E}$ admits a left adjoint $\overline{L} : \mathcal{E} \to \mathcal{E}'$. Since $\mathcal{E}_{\leqslant 0}$ is contained in $\mathcal{E}'$, the functor $\overline{L}$ is equivalent to the identity on $\mathcal{E}_{\leqslant 0}$ and is therefore left t-exact. If $E \in \mathcal{E}_{\geqslant 0}$, then $\overline{L}E$ is an extension of an object of $\mathcal{E}_{\geqslant \infty}$ by E, and therefore also belong to $\mathcal{E}_{\geqslant 0}$: this proves that L is also left t-exact. It follows that $\overline{L}$ restricts to a left exact localization functor $L : \mathcal{C} \to \mathcal{C}_0$, which proves (a).

We now prove (c). Let $\mathcal{D}$ be a Grothendieck prestable ∞-category. It follows from (a) that the canonical map $\mathrm{LFun}(\mathcal{C}^{\mathrm{sep}}, \mathcal{D}) \to \mathrm{LFun}(\mathcal{C}, \mathcal{D})$ is a fully faithful embedding whose essential image consists of those colimit-preserving functors $F : \mathcal{C} \to \mathcal{D}$ for which the right adjoint $G : \mathcal{D} \to \mathcal{C}$ factors through $\mathcal{C}^{\mathrm{sep}}$. This is equivalent to the condition that the mapping space $\mathrm{Map}_{\mathcal{C}}(C, GD) \simeq \mathrm{Map}_{\mathcal{D}}(FC, D)$ is contractible whenever $C \in \mathcal{C}$ is ∞-connective and $D \in \mathcal{D}$ is arbitrary. The assumption that C is ∞-connective guarantees that it belongs to the essential image of the iterated suspension functor $\Sigma^n_{\mathcal{C}}$ for every $n \geqslant 0$, so that FC belongs to the essential image of the iterated suspension functor $\Sigma^n_{\mathcal{D}}$ for each $n \geqslant 0$. If $\mathcal{D}$ is separated, then $FC \simeq 0$ and the contractibility of $\mathrm{Map}_{\mathcal{D}}(FC, D)$ is automatic. □

In the situation of Proposition C.3.6.1, we will refer to $\mathcal{C}^{\mathrm{sep}}$ as the *separated quotient* of $\mathcal{C}$.

Corollary C.3.6.2. *Let* $\mathsf{Groth}^{\mathrm{sep}}_{\infty}$ *denote the full subcategory of* Groth_{∞} *spanned by the separated Grothendieck prestable* ∞*-categories. Then the inclusion functor* $\mathsf{Groth}^{\mathrm{sep}}_{\infty} \hookrightarrow \mathsf{Groth}_{\infty}$ *admits a left adjoint, given on objects by the construction* $\mathcal{C} \mapsto \mathcal{C}^{\mathrm{sep}}$*.*

Proposition C.3.6.3. *Let* $\mathcal{C}$ *be a Grothendieck prestable* ∞*-category and let* $\widehat{\mathcal{C}}$ *denote the homotopy limit of the tower of* ∞*-categories*

$$\cdots \to \tau_{\leqslant 2}\, \mathcal{C} \to \tau_{\leqslant 1}\, \mathcal{C} \to \tau_{\leqslant 0}\, \mathcal{C}\,.$$

Then:

- (a) *The natural map* $f : \mathcal{C} \to \widehat{\mathcal{C}}$ *preserves small colimits and finite limits.*
- (b) *The* ∞*-category* $\widehat{\mathcal{C}}$ *is a complete Grothendieck prestable* ∞*-category.*
- (c) *For every complete Grothendieck prestable* ∞*-category* $\mathcal{D}$*, composition with* f *induces an equivalence of* ∞*-categories* $\mathrm{LFun}(\widehat{\mathcal{C}}, \mathcal{D}) \to \mathrm{LFun}(\mathcal{C}, \mathcal{D})$*.*

In the situation of Proposition C.3.6.3, we will refer to $\widehat{\mathcal{C}}$ as the *completion* of the prestable ∞-category $\mathcal{C}$.

Proof of Proposition **??**. Without loss of generality, we may assume that $\mathcal{C} = \mathcal{E}_{\geqslant 0}$ for some presentable stable ∞-category $\mathcal{E}$ equipped with a t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$ which is compatible with filtered colimits. Let $\widehat{\mathcal{E}}$ denote the left completion of $\mathcal{E}$ with respect to the t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$: that is, the homotopy inverse limit of the tower

$$\cdots \to \mathcal{E}_{\leqslant 2} \xrightarrow{\tau_{\leqslant 1}} \mathcal{E}_{\leqslant 1} \xrightarrow{\tau_{\leqslant 0}} \mathcal{E}_{\leqslant 0}.$$

It follows from Proposition HA.1.2.1.17 that $\widehat{\mathcal{E}}$ is a stable ∞-category which inherits a t-structure $(\widehat{\mathcal{E}}_{\geqslant 0}, \widehat{\mathcal{E}}_{\leqslant 0})$ and a t-exact functor $F : \mathcal{E} \to \widehat{\mathcal{E}}$ which induces equivalences $\mathcal{E}_{\leqslant n} \simeq \widehat{\mathcal{E}}_{\leqslant n}$ for every integer n. Note that the ∞-category $\mathcal{E}$ is presentable (Proposition **??**). Since the t-structure on $\mathcal{E}$ is compatible with filtered colimits, each of the functors in the diagram

$$\cdots \to \mathcal{E}_{\leqslant 2} \xrightarrow{\tau_{\leqslant 1}} \mathcal{E}_{\leqslant 1} \xrightarrow{\tau_{\leqslant 0}} \mathcal{E}_{\leqslant 0}.$$

commutes with filtered colimits. It follows that the projection map $\widehat{\mathcal{E}} \to \mathcal{E}_{\leqslant 0}$ commutes with filtered colimits, so that the t-structure on $\widehat{\mathcal{E}}$ is also compatible with filtered colimits.

Unwinding the definitions, we can identify $\widehat{\mathcal{C}}$ with $\widehat{\mathcal{E}}_{\geqslant 0}$ so that $\widehat{\mathcal{C}}$ is a Grothendieck prestable ∞-category. Since the t-structure on $\widehat{\mathcal{E}}$ is left complete, the prestable ∞-category $\widehat{\mathcal{C}}$ is complete; this proves (b), and assertion (a) follows from the t-exactness of F. We will complete the proof by establishing (c). Let $\mathcal{D}$ be a complete Grothendieck prestable ∞-category, so that $\mathcal{D}$ can be identified with the homotopy limit of the tower

$$\cdots \to \tau_{\leqslant 2}\mathcal{D} \xrightarrow{\tau_{\leqslant 1}} \tau_{\leqslant 1}\mathcal{D} \xrightarrow{\tau_{\leqslant 0}} \tau_{\leqslant 0}\mathcal{D} \simeq \mathcal{D}^{\heartsuit}.$$

in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$. It follows that the canonical map $\theta : \mathrm{LFun}(\widehat{\mathcal{C}}, \mathcal{D}) \to \mathrm{LFun}(\mathcal{C}, \mathcal{D})$ can be identified with the homotopy limit of a tower of maps

$$\theta_n : \mathrm{LFun}(\widehat{\mathcal{C}}, \tau_{\leqslant n}\mathcal{D}) \to \mathrm{LFun}(\mathcal{C}, \tau_{\leqslant n}\mathcal{D}).$$

Let $g : \widehat{\mathcal{C}} \to \mathcal{C}$ be a right adjoint to f. Passing to right adjoints we can identify θ_n with the functor $\mathrm{RFun}(\tau_{\leqslant n}\mathcal{D}, \widehat{\mathcal{C}})^{\mathrm{op}} \to \mathrm{RFun}(\tau_{\leqslant n}\mathcal{D}, \mathcal{C})^{\mathrm{op}}$ given by composition with g; here $\mathrm{RFun}(\tau_{\leqslant n}\mathcal{D}, \widehat{\mathcal{C}})$ denotes the full subcategory of $\mathrm{Fun}(\tau_{\leqslant n}\mathcal{D}, \widehat{\mathcal{C}})$ spanned by those accessible functors which preserve small limits and $\mathrm{RFun}(\tau_{\leqslant n}\mathcal{D}, \mathcal{C})$ is defined similarly. Since any left exact functor carries n-truncated objects to n-truncated objects, it will suffice to show that the functor g restricts to an equivalence of ∞-categories $g_{\leqslant n} : \tau_{\leqslant n}\widehat{\mathcal{C}} \to \tau_{\leqslant n}\mathcal{C}$. This is clear: the left exactness of f guarantees that $g_{\leqslant n}$ is right adjoint to the functor $f|_{\tau_{\leqslant n}\mathcal{C}} : \tau_{\leqslant n}\mathcal{C} \to \tau_{\leqslant}\, n\widehat{\mathcal{C}}$, which is an equivalence by virtue of Proposition HA.1.2.1.17. □

Corollary C.3.6.4. *Let* $\mathsf{Groth}_{\infty}^{\mathrm{comp}}$ *denote the full subcategory of* Groth_{∞} *spanned by the separated Grothendieck prestable ∞-categories. Then the inclusion functor* $\mathsf{Groth}_{\infty}^{\mathrm{comp}} \hookrightarrow \mathsf{Groth}_{\infty}$ *admits a left adjoint, given at the level of objects by the construction* $\mathcal{C} \mapsto \widehat{\mathcal{C}}$.

C.4 Tensor Products of Prestable ∞-Categories

Let $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ denote the ∞-category whose objects are presentable ∞-categories and whose morphisms are functors which preserve small colimits (see Definition HTT.5.5.3.1). In §HA.4.8.1 , we constructed a symmetric monoidal structure on the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$: given a pair of presentable ∞-categories $\mathcal{C}$ and $\mathcal{D}$, the tensor product $\mathcal{C} \otimes \mathcal{D} \in \mathcal{P}\mathrm{r}^{\mathrm{L}}$ is universal among ∞-categories $\mathcal{E}$ which admit small colimits and are equipped with a functor $\mathcal{C} \times \mathcal{D} \to \mathcal{E}$ which preserve small colimits separately in each variable. Our goal in this section is to show that the symmetric monoidal structure on $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ induces a symmetric monoidal structure on the full subcategory $\mathsf{Groth}_\infty \subseteq \mathcal{P}\mathrm{r}^{\mathrm{L}}$ spanned by the Grothendieck prestable ∞-categories (Theorem **??**).

C.4.1 Additive ∞-Categories

Recall that an ∞-category $\mathcal{C}$ is *additive* if $\mathcal{C}$ admits finite products and coproducts and the homotopy category $\mathrm{h}\mathcal{C}$ is additive (see Definition C.1.5.1). Our starting point is the following characterization of presentable additive ∞-categories:

Theorem C.4.1.1. *Let $\mathcal{C}$ be a presentable ∞-category. The following conditions are equivalent:*

(a) *The ∞-category $\mathcal{C}$ is additive.*

(b) *The functor $\Sigma^\infty_+ : \mathcal{S} \to \mathrm{Sp}^{\mathrm{cn}}$ induces an equivalence of ∞-categories $\mathcal{C} \simeq \mathcal{S} \otimes \mathcal{C} \to \mathrm{Sp}^{\mathrm{cn}} \otimes \mathcal{C}$. Here the tensor products are formed in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable ∞-categories.*

Corollary C.4.1.2. *The functor $\Sigma^\infty_+ : \mathcal{S} \to \mathrm{Sp}^{\mathrm{cn}}$ exhibits $\mathrm{Sp}^{\mathrm{cn}}$ as an idempotent object of the symmetric monoidal ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ (see Definition HA.4.8.2.1). In other words, the functor Σ^∞_+ induces equivalences*

$$\mathrm{Sp}^{\mathrm{cn}} \simeq \mathrm{Sp}^{\mathrm{cn}} \otimes \mathcal{S} \to \mathrm{Sp}^{\mathrm{cn}} \otimes \mathrm{Sp}^{\mathrm{cn}} \leftarrow \mathcal{S} \otimes \mathrm{Sp}^{\mathrm{cn}} \simeq \mathrm{Sp}^{\mathrm{cn}} .$$

Proof. This is an immediate consequence of Theorem C.4.1.1, since the ∞-category $\mathrm{Sp}^{\mathrm{cn}}$ is additive. □

Corollary C.4.1.3. *The ∞-category $\mathrm{Sp}^{\mathrm{cn}}$ of connective spectra admits an essentially unique symmetric monoidal structure for which the unit object is the sphere spectrum $S \in \mathrm{Sp}^{\mathrm{cn}}$. Moreover, the forgetful functor*

$$G : \mathrm{Mod}_{\mathrm{Sp}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$$

is fully faithful, and its essential image consists of the additive presentable ∞-categories.

Proof. The first two assertions follow from Corollary C.4.1.2, Proposition HA.4.8.2.9 , and Proposition HA.4.8.2.10 . Let $F : \mathcal{P}\mathrm{r}^{\mathrm{L}} \to \mathrm{Mod}_{\mathrm{Sp}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ be right adjoint to G; then a presentable ∞-category $\mathcal{C}$ belongs to the essential image of G if and only if the unit map

$$\mathcal{C} \to (G \circ F)(\mathcal{C}) \simeq \mathrm{Sp}^{\mathrm{cn}} \otimes \mathcal{C}$$

is an equivalence. By virtue of Theorem C.4.1.1, this is equivalent to the requirement that $\mathcal{C}$ is additive. □

Corollary C.4.1.4. *Let $\mathcal{P}\mathrm{r}^{\mathrm{Add}}$ denote the full subcategory of $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ whose objects are additive presentable ∞-categories. Then:*

(*a*) *The inclusion functor $\mathcal{P}\mathrm{r}^{\mathrm{Add}} \hookrightarrow \mathcal{P}\mathrm{r}^{\mathrm{L}}$ admits a left adjoint $L : \mathcal{P}\mathrm{r}^{\mathrm{L}} \to \mathcal{P}\mathrm{r}^{\mathrm{Add}}$, given on the level of objects by $\mathcal{C} \mapsto \mathrm{Sp}^{\mathrm{cn}} \otimes \mathcal{C}$.*

(*b*) *The localization functor L is compatible with the symmetric monoidal structure on $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ (in the sense of Definition HA.2.2.1.6). Consequently, there is an essentially unique symmetric monoidal structure on $\mathcal{P}\mathrm{r}^{\mathrm{Add}}$ for which the functor $L : \mathcal{P}\mathrm{r}^{\mathrm{L}} \to \mathcal{P}\mathrm{r}^{\mathrm{Add}}$ is symmetric monoidal.*

(*c*) *The inclusion functor $\mathcal{P}\mathrm{r}^{\mathrm{Add}} \hookrightarrow \mathcal{P}\mathrm{r}^{\mathrm{L}}$ preserves tensor products.*

Remark C.4.1.5. The inclusion functor $\mathcal{P}\mathrm{r}^{\mathrm{Add}} \hookrightarrow \mathcal{P}\mathrm{r}^{\mathrm{L}}$ is lax symmetric monoidal (since it is right adjoint to the symmetric monoidal functor L) and preserves tensor products, but it is not a symmetric monoidal functor because it fails to preserve unit objects. The unit object of the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ is the ∞-category $\mathcal{S}$ of spaces, while the unit object of $\mathcal{P}\mathrm{r}^{\mathrm{Add}} \simeq \mathrm{Mod}_{\mathrm{Sp}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ is the ∞-category $\mathrm{Sp}^{\mathrm{cn}}$ of connective spectra.

Proof of Corollary C.4.1.4. Assertions (*a*) and (*b*) follow from Corollary C.4.1.3 and Proposition HA.4.8.2.7 . To prove (*c*), it suffices to observe that if $\mathcal{C}$ and $\mathcal{D}$ are additive presentable ∞-categories, then the tensor product $\mathcal{C} \otimes \mathcal{D}$ (formed in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$) is again additive (since it admits the structure of a $\mathrm{Sp}^{\mathrm{cn}}$-module). □

The proof of Theorem C.4.1.1 will require some preliminaries. First, we prove an analogue of Theorem C.4.1.1 for $\mathbb{E}_\infty$-spaces which need not be grouplike.

Definition C.4.1.6. Let $\mathcal{C}$ be an ∞-category. We will say that $\mathcal{C}$ is *semiadditive* if it satisfies the following conditions:

(*a*) The ∞-category $\mathcal{C}$ admits finite products and finite coproducts.

(*b*) The ∞-category $\mathcal{C}$ admits a zero object 0. In particular, to every pair of objects X and Y we can associate a *zero morphism* (well-defined up to homotopy) given by the composition $X \to 0 \to Y$.

(c) For every pair of objects X and Y, the canonical map $X \amalg Y \to X \times Y$ represented by the matrix $\begin{bmatrix} \mathrm{id}_X & 0 \\ 0 & \mathrm{id}_Y \end{bmatrix}$ is an equivalence in $\mathcal{C}$.

Remark C.4.1.7. Let $\mathcal{C}$ be an ∞-category which admits finite sums and finite products. Then $\mathcal{C}$ is semiadditive if and only if the homotopy category of $\mathcal{C}$ is semiadditive.

Remark C.4.1.8. Let $\mathcal{C}$ be an ∞-category which admits finite sums and finite products. Then we can regard $\mathcal{C}$ as endowed with the *Cartesian* symmetric monoidal structure (given by the formation of products) or with the *coCartesian* symmetric monoidal structure (given by the formation of coproducts). The ∞-category $\mathcal{C}$ is semiadditive if and only if these two symmetric monoidal structures on $\mathcal{C}$ are the same.

Let us regard the ∞-category $\mathcal{S}$ as endowed with the symmetric monoidal structure given by the Cartesian product and let $\mathrm{CAlg}(\mathcal{S})$ denote the ∞-category of commutative algebra objects of $\mathcal{S}$: that is, the ∞-category of $\mathbb{E}_\infty$-spaces. We then have the following analogue of Theorem C.4.1.1:

Proposition C.4.1.9. *Let $\mathcal{C}$ be a presentable ∞-category. The following conditions are equivalent:*

(a) *The ∞-category $\mathcal{C}$ is semiadditive (Definition C.4.1.6).*

(b) *The free functor $\mathrm{Sym}^*_{\mathcal{S}} : \mathcal{S} \to \mathrm{CAlg}(\mathcal{S})$ induces an equivalence of ∞-categories*

$$\theta : \mathcal{C} \simeq \mathcal{S} \otimes \mathcal{C} \to \mathrm{CAlg}(\mathcal{S}) \otimes \mathcal{C}.$$

Here the tensor products are formed in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable ∞-categories.

Proof. Let us regard $\mathcal{C}$ as endowed with the Cartesian symmetric monoidal structure. We then have

$$\begin{aligned} \mathrm{CAlg}(\mathcal{S}) \otimes \mathcal{C} &\simeq \mathrm{Fun}'(\mathcal{C}^{\mathrm{op}}, \mathrm{CAlg}(\mathcal{S})) \\ &\simeq \mathrm{CAlg}(\mathrm{Fun}'(\mathcal{C}^{\mathrm{op}}, \mathcal{S})) \\ &\simeq \mathrm{CAlg}(\mathcal{C}), \end{aligned}$$

where $\mathrm{Fun}'(\mathcal{C}^{\mathrm{op}}, \mathrm{CAlg}(\mathcal{S}))$ denotes the full subcategory of $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ spanned by those functors which preserve small limits and $\mathrm{Fun}'(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ is defined similarly. Unwinding the definitions, we see that θ can be identified with the forgetful functor $\mathrm{CAlg}(\mathcal{C}) \to \mathcal{C}$. Note that the symmetric monoidal structure on $\mathrm{CAlg}(\mathcal{C})$ (given by the formation of Cartesian products) is always coCartesian (Proposition HA.3.2.4.7). If the functor θ is an equivalence of ∞-categories, then the Cartesian symmetric monoidal structure on $\mathcal{C}$ is also coCartesian so that $\mathcal{C}$ is semiadditive by virtue of Remark C.4.1.8. Conversely, if the Cartesian symmetric monoidal structure on $\mathcal{C}$ is coCartesian, then the forgetful functor $\mathrm{CAlg}(\mathcal{C}) \to \mathcal{C}$ is an equivalence of ∞-categories by virtue of Proposition HA.2.4.3.9 . □

Construction C.4.1.10. Let $I = \{x, y\}$ be a set with two elements and let M be the free $\mathbb{E}_\infty$-space generated by I (concretely, M can be identified with a product of two copies of the nerve of the groupoid $\mathcal{F}\mathrm{in}^{\simeq}$ of finite sets). Then $\pi_0 M$ can be identified with the commutative monoid freely generated by x and y. The construction

$$x \mapsto x \qquad y \mapsto x + y$$

determines a map of sets $I \to \pi_0 M$ which we can lift to a morphism of $\mathbb{E}_\infty$-spaces $\sigma : M \to M$, which we will refer to as the *shearing map.*

For any $\mathbb{E}_\infty$-space Z, composition with σ induces a map of spaces

$$Z^2 \simeq \mathrm{Map}_{\mathrm{CAlg}(\mathcal{S})}(M, Z) \xrightarrow{\circ\sigma} \mathrm{Map}_{\mathrm{CAlg}(\mathcal{S})}(M, Z) \simeq Z^2$$

which induces the homomorphism of commutative monoids

$$\pi_0 Z^2 \to \pi_0 Z^2 \qquad (a, b) \mapsto (a, a + b).$$

It follows that the commutative monoid $\pi_0 Z$ is a group if and only if Z is local with respect to the single map $\{\sigma\}$.

According to Remark HA.5.2.6.26 , we can identify the ∞-category $\mathrm{Sp}^{\mathrm{cn}}$ of connective spectra with the full subcategory of $\mathrm{CAlg}(\mathcal{S})$ spanned by those $\mathbb{E}_\infty$-spaces Z for which $\pi_0 Z$ is a group. In other words, the ∞-category of connective spectra can be obtained as the localization of $\mathrm{CAlg}(\mathcal{S})$ with respect to the single morphism σ. In particular, there exists a functor $L : \mathrm{CAlg}(\mathcal{S}) \to \mathrm{Sp}^{\mathrm{cn}}$ with the following universal property: for any ∞-category $\mathcal{C}$ which admits small colimits, composition with L induces an equivalence $\mathrm{LFun}(\mathrm{Sp}^{\mathrm{cn}}, \mathcal{C}) \to \mathrm{LFun}(\mathrm{CAlg}(\mathcal{S}), \mathcal{C})$ whose essential image is spanned by those functors $F \in \mathrm{LFun}(\mathrm{CAlg}(\mathcal{S}), \mathcal{C})$ for which $F(\sigma)$ is an equivalence in $\mathcal{C}$.

Proof of Theorem C.4.1.1. Let $\mathcal{C}$ be a presentable ∞-category. Using Proposition HA.4.8.1.17 , we can identify the tensor product $\mathrm{Sp}^{\mathrm{cn}} \otimes \mathcal{C}$ with the full subcategory of $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathrm{Sp}^{\mathrm{cn}})$ spanned by those functors which are accessible and preserve small limits. In particular, the ∞-category $\mathrm{Sp}^{\mathrm{cn}} \otimes \mathcal{C}$ admits a fully faithful embedding into the ∞-category $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathrm{Sp})$ whose essential image is closed under finite products. Since $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathrm{Sp})$ is a stable ∞-category, it is additive. It follows that $\mathrm{Sp}^{\mathrm{cn}} \otimes \mathcal{C}$ is additive. If condition (b) is satisfied, then $\mathcal{C}$ is equivalent to $\mathrm{Sp}^{\mathrm{cn}} \otimes \mathcal{C}$ and is therefore also additive.

We now prove the converse. Suppose that $\mathcal{C}$ is additive; we wish to show that the canonical map $F : \mathcal{C} \to \mathrm{Sp}^{\mathrm{cn}} \otimes \mathcal{C}$ is an equivalence of ∞-categories. Unwinding the definitions, we see that F is left adjoint to the functor $G : \mathrm{LFun}(\mathrm{Sp}^{\mathrm{cn}}, \mathcal{C}^{\mathrm{op}})^{\mathrm{op}} \to \mathcal{C}$ given by evaluation at the sphere spectrum S. Let $L : \mathrm{CAlg}(\mathcal{S}) \to \mathrm{Sp}^{\mathrm{cn}}$ be the localization functor appearing in Construction C.4.1.10. Then the functor G factors as a composition

$$\mathrm{LFun}(\mathrm{Sp}^{\mathrm{cn}}, \mathcal{C}^{\mathrm{op}})^{\mathrm{op}} \xrightarrow{G'} \mathrm{LFun}(\mathrm{CAlg}(\mathcal{S}), \mathcal{C}^{\mathrm{op}})^{\mathrm{op}} \xrightarrow{G''} \mathcal{C},$$

where the functor G'' is given by evaluation on the free $\mathbb{E}_\infty$-space on a single generator and is therefore an equivalence of ∞-categories by virtue of Proposition C.4.1.9 (since any additive ∞-category is also semiadditive). It will therefore suffice to show that the functor G' is an equivalence of ∞-categories. For this, it will suffice to show that for every colimit-preserving functor $H : \mathrm{CAlg}(\mathcal{S}) \to \mathcal{C}^{\mathrm{op}}$, the map $H(\sigma)$ is an equivalence in $\mathcal{C}$, where $\sigma : \mathrm{Sym}^*_{\mathcal{S}}(I) \to \mathrm{Sym}^*_{\mathcal{S}}(I)$ is the shearing map appearing in Construction C.4.1.10. Note that if $G''(H)$ is an object $C \in \mathcal{C}$, then $H(\sigma)$ can be identified with the map from $C \oplus C$ to itself represented by the matrix $\begin{bmatrix} \mathrm{id}_C & 0 \\ \mathrm{id}_C & \mathrm{id}_C \end{bmatrix}$, which is an equivalence by virtue of our assumption that the homotopy category $\mathrm{h}\mathcal{C}$ is an additive category. □

C.4.2 Tensor Products

Every prestable ∞-category is additive, so we can regard the ∞-category Groth_∞ of Grothendieck prestable ∞-categories as a full subcategory of the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{Add}}$ of presentable additive ∞-categories. The main result of this section can be formulated as follows:

Theorem C.4.2.1. *Let $\mathsf{Groth}_\infty \subseteq \mathcal{P}\mathrm{r}^{\mathrm{Add}}$ denote the ∞-category of Grothendieck prestable ∞-categories (see Definition C.3.0.5). Then Groth_∞ contains the unit object of $\mathcal{P}\mathrm{r}^{\mathrm{Add}}$ and is closed under tensor products. Consequently, Groth_∞ inherits the structure of a symmetric monoidal ∞-category for which the inclusion $\mathsf{Groth}_\infty \hookrightarrow \mathcal{P}\mathrm{r}^{\mathrm{Add}}$ is symmetric monoidal.*

Remark C.4.2.2. Let $\mathcal{C}$ and $\mathcal{D}$ be presentable stable ∞-categories equipped with t-structures $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ and $(\mathcal{D}_{\geqslant 0}, \mathcal{D}_{\leqslant 0})$ which are compatible with filtered colimits. Then $\mathcal{C}_{\geqslant 0}$ and $\mathcal{D}_{\geqslant 0}$ are Grothendieck prestable ∞-categories. Choose a functor $H : \mathcal{C} \times \mathcal{D} \to \mathcal{E}$ which exhibits $\mathcal{E}$ as a tensor product of $\mathcal{C}$ with $\mathcal{D}$ in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$. Let $\mathcal{E}_{\geqslant 0}$ be the smallest full subcategory of $\mathcal{E}$ which is closed under small colimits and contains the essential image of the restriction $h = H|_{\mathcal{C}_{\geqslant 0} \times \mathcal{D}_{\geqslant 0}}$. Since the formation of stabilizations commutes with tensor products, we can identify $\mathcal{E}_{\geqslant 0}$ with the smallest full subcategory of

$$\mathcal{E} \simeq \mathrm{Sp}(\mathcal{C}_{\geqslant 0}) \otimes \mathrm{Sp}(\mathcal{D}_{\geqslant 0}) \simeq \mathrm{Sp}(\mathcal{C}_{\geqslant 0} \otimes \mathcal{D}_{\geqslant 0})$$

which contains the essential image of the functor

$$\Sigma^\infty : \mathcal{C}_{\geqslant 0} \otimes \mathcal{D}_{\geqslant 0} \to \mathrm{Sp}(\mathcal{C}_{\geqslant 0} \otimes \mathcal{D}_{\geqslant 0}).$$

The content of Theorem C.4.2.1 is that the tensor product $\mathcal{C}_{\geqslant 0} \otimes \mathcal{D}_{\geqslant 0}$ is also a Grothendieck prestable ∞-category. Unwinding the definitions, this translates into the following assertions:

(*a*) The functor $\Sigma^\infty : \mathcal{C}_{\geqslant 0} \otimes \mathcal{D}_{\geqslant 0} \to \mathrm{Sp}(\mathcal{C}_{\geqslant 0} \otimes \mathcal{D}_{\geqslant 0})$ is fully faithful. In other words, the functor $h : \mathcal{C}_{\geqslant 0} \times \mathcal{D}_{\geqslant 0} \to \mathcal{E}_{\geqslant 0}$ exhibits $\mathcal{E}_{\geqslant 0}$ as a tensor product of $\mathcal{C}_{\geqslant 0}$ with $\mathcal{D}_{\geqslant 0}$ in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$.

(b) The full subcategory $\mathcal{E}_{\geqslant 0}$ is closed under extensions in $\mathcal{E}$, and therefore determines a t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$ on $\mathcal{E}$.

(c) The full subcategory $\mathcal{E}_{\leqslant 0} \subseteq \mathcal{E}$ is closed under filtered colimits.

Remark C.4.2.3. Let $\mathcal{C}$ and $\mathcal{D}$ be presentable stable ∞-categories, and let

$$m : \mathcal{C} \times \mathcal{D} \to \mathcal{C} \otimes \mathcal{D}$$

be a functor which exhibits $\mathcal{C} \otimes \mathcal{D}$ as a tensor product of $\mathcal{C}$ with $\mathcal{D}$ in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$. Let $\mathrm{Core}(\mathcal{C})$, $\mathrm{Core}(\mathcal{D})$, and $\mathrm{Core}(\mathcal{C} \otimes \mathcal{D})$ be the partially ordered sets described in Remark C.3.1.3. Then m induces a map of partially ordered sets

$$m_! : \mathrm{Core}(\mathcal{C}) \times \mathrm{Core}(\mathcal{D}) \to \mathrm{Core}(\mathcal{C} \otimes \mathcal{D}),$$

which we can describe explicitly as follows: given cores $\mathcal{C}_{\geqslant 0} \subseteq \mathcal{C}$ and $\mathcal{D}_{\geqslant 0} \subseteq \mathcal{D}$, we define $m_!(\mathcal{C}_{\geqslant 0}, \mathcal{D}_{\geqslant 0})$ to be the smallest full subcategory of $\mathcal{C} \otimes \mathcal{D}$ which is closed under colimits and extensions and contains the objects $m(C, D)$ for each $C \in \mathcal{C}_{\geqslant 0}$, $D \in \mathcal{D}_{\geqslant 0}$. It is not difficult to see that this construction exhibits the construction $\mathcal{C} \mapsto \mathrm{Core}(\mathcal{C})$ as a (covariant) lax symmetric monoidal functor from the homotopy category $\mathrm{h}\mathcal{P}\mathrm{r}^{\mathrm{St}}$ to the category of partially ordered sets. Equivalently, the construction $\mathcal{C} \mapsto \mathrm{Core}(\mathcal{C})$ can be regarded as a lax symmetric monoidal functor from the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ to the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_{\infty}$. It follows that the coCartesian fibration $q : \mathsf{Groth}_{\infty}^{+} \to \mathcal{P}\mathrm{r}^{\mathrm{St}}$ of Remark C.3.1.6 can be regarded as a symmetric monoidal functor. In more concrete terms, the symmetric monoidal structure on $\mathsf{Groth}_{\infty}^{+}$ is given by the construction

$$(\mathcal{C}, \mathcal{C}_{\geqslant 0}) \otimes (\mathcal{D}, \mathcal{D}_{\geqslant 0}) = (\mathcal{C} \otimes \mathcal{D}, m_!(\mathcal{C}_{\geqslant 0}, \mathcal{D}_{\geqslant 0}))$$

described above.

Now suppose that $\mathcal{C}$ and $\mathcal{D}$ are Grothendieck prestable ∞-categories. Theorem C.4.2.1 asserts that the tensor product $\mathcal{C} \otimes \mathcal{D}$ (formed in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$) is again a Grothendieck prestable ∞-category. Since the stabilization functor $\mathrm{Sp}(\bullet) : \mathcal{P}\mathrm{r}^{\mathrm{L}} \to \mathcal{P}\mathrm{r}^{\mathrm{St}}$ is symmetric monoidal, we can identify the ∞-category $\mathrm{Sp}(\mathcal{C} \otimes \mathcal{D})$ with the tensor product $\mathrm{Sp}(\mathcal{C}) \otimes \mathrm{Sp}(\mathcal{D})$. Moreover, we have a commutative diagram

$$\begin{array}{ccc} \mathcal{C} \times \mathcal{D} & \xrightarrow{m} & \mathcal{C} \otimes \mathcal{D} \\ \downarrow{\scriptstyle \Sigma^{\infty}_{\mathcal{C}} \times \Sigma^{\infty}_{\mathcal{D}}} & & \downarrow{\scriptstyle \Sigma^{\infty}_{\mathcal{C} \otimes \mathcal{D}}} \\ \mathrm{Sp}(\mathcal{C}) \times \mathrm{Sp}(\mathcal{D}) & \xrightarrow{m'} & \mathrm{Sp}(\mathcal{C}) \otimes \mathrm{Sp}(\mathcal{D}) \end{array}$$

where the vertical maps are fully faithful embeddings. Since $\mathcal{C} \otimes \mathcal{D}$ is generated under small colimits by the essential image of m, the functor $\Sigma^{\infty}_{\mathcal{C} \otimes \mathcal{D}}$ identifies $\mathcal{C} \otimes \mathcal{D}$ with the smallest full subcategory of $\mathrm{Sp}(\mathcal{C}) \otimes \mathrm{Sp}(\mathcal{D})$ which contains the image of functor $m'|_{\mathrm{Sp}(\mathcal{C})_{\geqslant 0} \times \mathrm{Sp}(\mathcal{D})_{\geqslant 0}}$ and is closed under small colimits. One consequence of Theorem C.4.2.1 is that this full subcategory is *also* closed under extensions: that is, it can be identified with the core $m'_!(\mathrm{Sp}(\mathcal{C})_{\geqslant 0}, \mathrm{Sp}(\mathcal{D})_{\geqslant 0})$ defined above. It follows that we can regard the construction $\mathcal{C} \mapsto (\mathrm{Sp}(\mathcal{C}), \mathrm{Sp}(\mathcal{C})_{\geqslant 0})$ of Corollary C.3.1.4 as a *symmetric monoidal* functor from the ∞-category Groth_∞ to the ∞-category Groth_∞^+.

C.4.3 The Proof of Theorem C.4.2.1

The proof of Theorem C.4.2.1 will require the following generalization of Lemma HTT.6.3.3.4:

Lemma C.4.3.1. *Let $\mathcal{X}$ be a presentable ∞-category equipped with a small collection of full subcategories $\{\mathcal{X}_\alpha \subseteq \mathcal{X}\}_{\alpha \in A}$. Assume the following:*

(1) *Each of the ∞-categories $\mathcal{X}_\alpha$ is presentable.*

(2) *Each of the inclusion functors $\mathcal{X}_\alpha \hookrightarrow \mathcal{X}$ admits a left exact left adjoint $L_\alpha : \mathcal{X} \to \mathcal{X}_\alpha$.*

(3) *Filtered colimits in the ∞-category $\mathcal{X}$ are left exact.*

Then the intersection $\bigcap \mathcal{X}_\alpha$ is presentable, and the inclusion functor $\bigcap \mathcal{X}_\alpha \hookrightarrow \mathcal{X}$ admits a left exact left adjoint L.

Proof. Without loss of generality, we may assume that A is an initial segment of the ordinals: that is, $A = \{\alpha : \alpha < \beta\}$, for some ordinal β. Choose a regular cardinal κ such that each of the functors L_α commutes with κ-filtered colimits (when regarded as a functor from the ∞-category $\mathcal{X}$ to itself). Let $\beta\kappa$ denote the ordinal product of α with κ, and let $[\beta\kappa]$ denote the linearly ordered set of ordinals $\leqslant \beta\kappa$. We will construct a map $\mathrm{N}[\beta\kappa] \to \mathrm{Fun}(\mathcal{X}, \mathcal{X})$, which we view as a transfinite sequence of functors $\{F_\gamma : \mathcal{X} \to \mathcal{X}\}_{\gamma \leqslant \beta\kappa}$. Let $F_0 = \mathrm{id}_{\mathcal{X}}$ and $F_\gamma = \varinjlim_{\delta < \gamma} F_\delta$ when γ is a nonzero limit ordinal. To complete the construction, it will suffice to define $F_{\gamma+1}$ assuming that F_γ has already been defined. Writing $\gamma = \beta\delta + \alpha$ for $\alpha < \beta$, we set $F_{\gamma+1} = L_\alpha \circ F_\gamma$.

Since each L_α is an accessible left exact functor and filtered colimits in $\mathcal{X}$ are left exact (see Example **??**), it follows by induction on γ that each of the functors F_γ is left exact and accessible. Set $L = F_{\beta\kappa}$. We claim that L is a localization functor with essential image $\bigcap_{\alpha \in A} \mathcal{X}_\alpha$. To prove this, it suffices to verify the following:

(a) For each $X \in \mathcal{X}$ and each $Y \in \bigcap_{\alpha \in A} \mathcal{X}_\alpha$, the canonical map $X \to L(X)$ induces a homotopy equivalence $\mathrm{Map}_{\mathcal{X}}(L(X), Y) \to \mathrm{Map}_{\mathcal{X}}(X, Y)$. More generally, we claim that each of the maps

$$\mathrm{Map}_{\mathcal{X}}(F_\gamma(X), Y) \to \mathrm{Map}_{\mathcal{X}}(F_0(X), Y) = \mathrm{Map}_{\mathcal{X}}(X, Y)$$

is a homotopy equivalence. The proof proceeds by induction on γ, the case $\gamma = 0$ being trivial. If γ is a nonzero limit ordinal, we invoke the fact that $F_\gamma \simeq \varinjlim_{\delta<\gamma} F_\delta$. To handle the case of successor ordinals, it suffices to show that $\mathrm{Map}_{\mathcal{X}}(F_{\gamma+1}(X), Y) \to \mathrm{Map}_{\mathcal{X}}(F_\gamma(X), Y)$ is a homotopy equivalence for each ordinal γ. Writing $\gamma = \beta\delta + \alpha$, we have $F_{\gamma+1}(X) = L_\alpha F_\gamma(X)$. The desired result now follows from our assumption that Y belongs to the subcategory $\mathcal{X}_\alpha \subseteq \mathcal{X}$.

(b) For each $X \in \mathcal{X}$, we must show that the object $L(X)$ belongs to $\bigcap \mathcal{X}_\alpha$. Fix $\alpha \in A$; we wish to show that $L(X) \in \mathcal{X}_\alpha$. Note that the collection of ordinals of the form $\beta\delta + \alpha + 1$, where $\delta < \kappa$ is cofinal in the set $\{\gamma : \gamma < \beta\kappa\}$. It follows that

$$L(X) \simeq \varinjlim_{\delta<\kappa} F_{\beta\delta+\alpha+1}(X) = \varinjlim_{\delta<\kappa} L_\alpha F_{\beta\delta+\alpha}(X)$$

is a κ-filtered colimit of objects belonging to $\mathcal{X}_\alpha$. Since the functor L_α commutes with κ-filtered colimits, we conclude that $L(X) \in \mathcal{X}_\alpha$ as desired.

□

Proof of Theorem C.4.2.1. It is clear that the unit object $\mathrm{Sp}^{\mathrm{cn}} \in \mathcal{P}\mathrm{r}^{\mathrm{Add}}$ is a Grothendieck prestable ∞-category. It will therefore suffice to show that if $\mathcal{C}$ and $\mathcal{C}'$ are Grothendieck prestable ∞-categories, then the tensor product $\mathcal{C} \otimes \mathcal{C}'$ is also a Grothendieck prestable ∞-category. Using Theorem C.2.4.1, we may assume without loss of generality that there exist inclusions

$$\mathcal{C} \subseteq \mathcal{D} \qquad \mathcal{C}' \subseteq \mathcal{D}'$$

which admit left exact left adjoints

$$L : \mathcal{D} \to \mathcal{C} \qquad L' : \mathcal{D}' \to \mathcal{C}',$$

where $\mathcal{D} = \mathrm{RMod}_A^{\mathrm{cn}}$ and $\mathcal{D}' = \mathrm{RMod}_{A'}^{\mathrm{cn}}$ for some connective $\mathbb{E}_1$-rings A and A'.

We first note that L induces a functor $F : \mathcal{D} \otimes \mathcal{D}' \to \mathcal{C} \otimes \mathcal{D}'$. Using Corollary C.4.1.3, we can view $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{D}'$ as ∞-categories tensored over $\mathrm{Sp}^{\mathrm{cn}}$, the functor L with a $\mathrm{Sp}^{\mathrm{cn}}$-linear functor, and F with the induced map

$$\mathcal{D} \otimes_{\mathrm{Sp}^{\mathrm{cn}}} \mathcal{D}' \to \mathcal{C} \otimes_{\mathrm{Sp}^{\mathrm{cn}}} \mathcal{D}'.$$

Applying Theorem HA.4.8.4.6 , we can identify F with the map $\mathrm{RMod}_A(\mathcal{D}) \to \mathrm{RMod}_A(\mathcal{C})$ determined by L, which is left adjoint to the inclusion $\mathrm{RMod}_A(\mathcal{C}) \hookrightarrow \mathrm{RMod}_A(\mathcal{D})$. It follows that the functor F admits a fully faithful right adjoint $G : \mathcal{C} \otimes \mathcal{D}' \to \mathcal{D} \otimes \mathcal{D}'$. Let $\mathcal{E} \subseteq \mathcal{D} \otimes \mathcal{D}'$ denote the essential image of G and let $\overline{L} = (G \circ F) : \mathcal{D} \otimes \mathcal{D}' \to \mathcal{E}$ be a left adjoint to the inclusion of $\mathcal{E}$ into $\mathcal{D} \otimes \mathcal{D}'$. Note that we can identify $\overline{L}$ with the upper horizontal map in the commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{RMod}_A(\mathcal{D}) & \longrightarrow & \mathrm{RMod}_A(\mathcal{C}) \\ \downarrow & & \downarrow \\ \mathcal{D} & \xrightarrow{L} & \mathcal{C}. \end{array}$$

Since the vertical maps are conservative and preserve finite limits (Corollary HA.4.2.3.3) and the functor L is left exact, the functor $\overline{L}$ is also left exact.

Let $F' : \mathcal{D} \otimes \mathcal{D}' \to \mathcal{D} \otimes \mathcal{C}'$ be the functor determined by L'. Repeating the above reasoning, we deduce that F' admits a fully faithful right adjoint $G' : \mathcal{D} \otimes \mathcal{C}' \to \mathcal{D} \otimes \mathcal{D}'$ whose essential image is a full subcategory $\mathcal{E}'$ of $\mathcal{D} \otimes \mathcal{D}'$, and that the inclusion $\mathcal{E}' \hookrightarrow \mathcal{D} \otimes \mathcal{D}'$ admits a left exact left adjoint $\overline{L}' : \mathcal{D} \otimes \mathcal{D}' \to \mathcal{E}'$.

For every pair of presentable ∞-categories $\mathcal{X}$ and $\mathcal{Y}$, let $\mathrm{Fun}'(\mathcal{X}^{\mathrm{op}} \times \mathcal{Y}^{\mathrm{op}}, \mathcal{S})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}} \times \mathcal{Y}^{\mathrm{op}}, \mathcal{S})$ spanned by those functors which preserve small limits separately in each variable; it then follows from Proposition HTT.5.5.2.2 that we can identify $\mathrm{Fun}'(\mathcal{X}^{\mathrm{op}} \times \mathcal{Y}^{\mathrm{op}}, \mathcal{S})$ with the tensor product $\mathcal{X} \otimes \mathcal{Y}$ in $\mathcal{P}\mathrm{r}^{\mathrm{L}}$. Since L and L' are localization functors, composition with the functor $L \times L'$ induces a fully faithful embedding

$$\mathrm{Fun}'(\mathcal{C}^{\mathrm{op}} \times \mathcal{C}'^{\mathrm{op}}, \mathcal{S}) \to \mathrm{Fun}'(\mathcal{D}^{\mathrm{op}} \times \mathcal{D}'^{\mathrm{op}}, \mathcal{S})$$

whose essential image consists of those functors $H : \mathcal{D}^{\mathrm{op}} \times \mathcal{D}'^{\mathrm{op}} \to \mathcal{S}$ which carry each $(L \times L')$-equivalence in $\mathcal{D} \times \mathcal{D}'$ to a homotopy equivalence in $\mathcal{S}$. Since every $(L \times L')$-equivalence can be written as a composition of an $(L \times \mathrm{id})$-equivalence with an $(\mathrm{id} \times L')$-equivalence, it follows that $\mathrm{Fun}'(\mathcal{C}^{\mathrm{op}} \times \mathcal{C}'^{\mathrm{op}}, \mathcal{S})$ can be identified with the fiber product

$$\mathrm{Fun}'(\mathcal{C}^{\mathrm{op}} \times \mathcal{D}'^{\mathrm{op}}, \mathcal{S}) \times_{\mathrm{Fun}'(\mathcal{D}^{\mathrm{op}} \times \mathcal{D}'^{\mathrm{op}}, \mathcal{S})} \mathrm{Fun}'(\mathcal{D}^{\mathrm{op}} \times \mathcal{C}'^{\mathrm{op}}, \mathcal{S}).$$

In other words, the tensor product $\mathcal{C} \otimes \mathcal{C}'$ is equivalent to the intersection of the full subcategories $\mathcal{E}, \mathcal{E}' \subseteq \mathcal{D} \otimes \mathcal{D}'$. It follows from Theorem HA.4.8.5.16 that we can identify $\mathcal{D} \otimes \mathcal{D}'$ with the ∞-category $\mathrm{RMod}^{\mathrm{cn}}_{A \otimes A'}$, and it follows from Lemma C.4.3.1 that the intersection $\mathcal{E} \cap \mathcal{E}'$ is an accessible left exact localization of $\mathcal{D} \otimes \mathcal{D}'$. Applying Theorem C.2.4.1, we conclude that $\mathcal{C} \otimes \mathcal{C}' \simeq \mathcal{E} \cap \mathcal{E}'$ is a Grothendieck prestable ∞-category, as desired. □

Remark C.4.3.2. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor between presentable ∞-categories. Suppose that F admits a fully faithful right adjoint G. Then, for any presentable ∞-category $\mathcal{E}$, the induced map $(F \otimes \mathrm{id}_{\mathcal{E}}) : \mathcal{C} \otimes \mathcal{E} \to \mathcal{D} \otimes \mathcal{E}$ admits a fully faithful right adjoint. This is clear, since a right adjoint to $(F \otimes \mathrm{id}_{\mathcal{E}})$ is given by the composition

$$\mathcal{D} \otimes \mathcal{E} \simeq \mathrm{Fun}'(\mathcal{E}^{\mathrm{op}}, \mathcal{D}) \xrightarrow{G \circ} \mathrm{Fun}'(\mathcal{E}^{\mathrm{op}}, \mathcal{C}) \simeq \mathcal{C} \otimes \mathcal{E};$$

here $\mathrm{Fun}'(\mathcal{E}^{\mathrm{op}}, \mathcal{D})$ denotes the full subcategory of $\mathrm{Fun}(\mathcal{E}^{\mathrm{op}}, \mathcal{D})$ spanned by those functors which preserve small limits and $\mathrm{Fun}'(\mathcal{E}^{\mathrm{op}}, \mathcal{C})$ is defined similarly.

C.4.4 Left Exact and Compact Functors

We now study properties of functors between prestable ∞-categories which are preserved by the tensor product of Theorem C.4.2.1.

Proposition C.4.4.1. *Let $f : \mathcal{C} \to \mathcal{D}$ be a functor between Grothendieck prestable ∞-categories which preserves small colimits. If f is left exact, then for any Grothendieck prestable ∞-category $\mathcal{E}$ the induced map $(f \otimes \mathrm{id}_{\mathcal{E}}) : \mathcal{C} \otimes \mathcal{E} \to \mathcal{D} \otimes \mathcal{E}$ is also left exact.*

Proof. Using Theorem C.2.4.1, we can assume that there is a connective $\mathbb{E}_1$-ring A and an inclusion $\mathcal{E} \hookrightarrow \mathrm{RMod}_A^{\mathrm{cn}}$ which admits a left exact left adjoint $L : \mathrm{RMod}_A^{\mathrm{cn}} \to \mathcal{E}$. The proof of Theorem C.4.2.1 shows that L induces left exact functors

$$L_{\mathcal{C}} : \mathrm{RMod}_A(\mathcal{C}) \simeq \mathcal{C} \otimes \mathrm{RMod}_A^{\mathrm{cn}} \to \mathcal{C} \otimes \mathcal{E}$$

$$L_{\mathcal{D}} : \mathrm{RMod}_A(\mathcal{D}) \simeq \mathcal{D} \otimes \mathrm{RMod}_A^{\mathrm{cn}} \to \mathcal{D} \otimes \mathcal{E}$$

which admit fully faithful right adjoints $G_{\mathcal{C}}$ and $G_{\mathcal{D}}$. We then have

$$\begin{aligned} f \otimes \mathrm{id}_{\mathcal{E}} &\simeq (f \otimes \mathrm{id}_{\mathcal{E}}) \circ L_{\mathcal{C}} \circ G_{\mathcal{E}} \\ &\simeq L_{\mathcal{D}} \circ (f \otimes \mathrm{id}_{\mathrm{RMod}_A^{\mathrm{cn}}}) \\ &\simeq G_{\mathcal{E}}. \end{aligned}$$

The functor $L_{\mathcal{D}}$ is left exact, the functor $G_{\mathcal{E}}$ preserves all small colimits, and $f \otimes \mathrm{id}_{\mathrm{RMod}_A^{\mathrm{cn}}}$ can be identified with the functor $\mathrm{RMod}_A(\mathcal{C}) \to \mathrm{RMod}_A(\mathcal{D})$ induced by f (by virtue of Theorem HA.4.8.4.6). This functor is left exact by virtue of our assumption that f is left exact. □

Corollary C.4.4.2. *The symmetric monoidal structure on the ∞-category Groth_∞ restricts to a symmetric monoidal structure on the subcategory $\mathsf{Groth}_\infty^{\mathrm{lex}}$ of Notation C.3.2.3.*

Proposition C.4.4.3. *Let $f : \mathcal{C} \to \mathcal{D}$ be a compact functor between Grothendieck presentable ∞-categories. Then, for any Grothendieck prestable ∞-category $\mathcal{E}$, the induced map $(f \otimes \mathrm{id}_{\mathcal{E}}) : \mathcal{C} \otimes \mathcal{E} \to \mathcal{D} \otimes \mathcal{E}$ is compact.*

Proof. Let $F : \mathrm{Sp}(\mathcal{C}) \to \mathrm{Sp}(\mathcal{D})$ be the functor obtained from f by applying the stabilization construction $\mathcal{P}\mathrm{r}^{\mathrm{L}} \to \mathcal{P}\mathrm{r}^{\mathrm{St}}$. Using Proposition C.3.4.1, we see that F admits a right adjoint $G : \mathrm{Sp}(\mathcal{D}) \to \mathrm{Sp}(\mathcal{C})$ which commutes with small colimits. Then F and G induce adjoint functors

$$\mathrm{Sp}(\mathcal{C}) \otimes \mathrm{Sp}(\mathcal{E}) \underset{(G \otimes \mathrm{id})}{\overset{(F \otimes \mathrm{id})}{\rightleftarrows}} \mathrm{Sp}(\mathcal{D}) \otimes \mathrm{Sp}(\mathcal{E})$$

which commute with small colimits. We now observe that the functor $F \otimes \mathrm{id}$ can be identified with the image of the map $f \otimes \mathrm{id}_{\mathcal{E}} : \mathcal{C} \otimes \mathcal{E} \to \mathcal{D} \otimes \mathcal{E}$ under the stabilization functor $\mathcal{P}\mathrm{r}^{\mathrm{L}} \to \mathcal{P}\mathrm{r}^{\mathrm{St}}$, so that $f \otimes \mathrm{id}_{\mathcal{E}}$ is compact (see Proposition C.3.4.1). □

Corollary C.4.4.4. *The symmetric monoidal structure on the* ∞*-category* Groth_∞ *restricts to a symmetric monoidal structure on the subcategory* $\mathsf{Groth}^{\mathrm{c}}_\infty \subseteq \mathsf{Groth}_\infty$ *of Definition C.3.4.2.*

Remark C.4.4.5. In the situation of Proposition C.4.4.3, suppose that the functor f admits a right adjoint g which preserves *all* small colimits. Then the adjunction between f and g determines a pair of adjoint functors

$$\mathcal{C} \otimes \mathcal{E} \underset{(g \otimes \mathrm{id}_{\mathcal{E}}),}{\overset{(f \otimes \mathrm{id}_{\mathcal{E}})}{\rightleftarrows}} \mathcal{D} \otimes \mathcal{E}$$

so that the functor $f \otimes \mathrm{id}_{\mathcal{E}}$ also admits a right adjoint which preserves small colimits.

C.4.5 Tensor Products and Colimits

The symmetric monoidal structure on the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ is closed: that is, for every presentable ∞-category $\mathcal{C}$, the tensor product functor $\mathcal{D} \mapsto \mathcal{C} \otimes \mathcal{D}$ admits a right adjoint, given by the construction $\mathcal{E} \mapsto \mathrm{LFun}(\mathcal{C}, \mathcal{E})$. It follows that the tensor product on $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ preserves small colimits separately in each variable. Our next goal is to prove an analogous assertion for the ∞-category $\mathsf{Groth}^{\mathrm{c}}_\infty$:

Proposition C.4.5.1. *The tensor product*

$$\otimes : \mathsf{Groth}^{\mathrm{c}}_\infty \times \mathsf{Groth}^{\mathrm{c}}_\infty \to \mathsf{Groth}^{\mathrm{c}}_\infty$$

of Corollary C.4.4.4 preserves small colimits separately in each variable.

Warning C.4.5.2. Proposition C.4.5.1 does not follow from the corresponding assertion concerning the tensor product on $\mathcal{P}\mathrm{r}^{\mathrm{L}}$, since the inclusion functor $\mathsf{Groth}^{\mathrm{c}}_\infty \hookrightarrow \mathcal{P}\mathrm{r}^{\mathrm{L}}$ does not preserve small colimits.

Proposition C.4.5.1 is an immediate consequence of Remarks C.3.5.2, C.4.2.3, and the following stronger result:

Proposition C.4.5.3. *The tensor product*

$$\otimes : \mathsf{Groth}^{+}_\infty \times \mathsf{Groth}^{+}_\infty \to \mathsf{Groth}^{+}_\infty$$

of Remark C.4.2.3 preserves small colimits separately in each variable.

Proof. Let $q : \mathsf{Groth}^{+}_\infty \to \mathcal{P}\mathrm{r}^{\mathrm{St}}$ be the forgetful functor given by $(\mathcal{C}, \mathcal{C}_{\geqslant 0}) \mapsto \mathcal{C}$. Note that a small diagram $p : K^{\triangleright} \to \mathsf{Groth}^{+}_\infty$ is a colimit diagram if and only $q \circ p$ is a colimit diagram in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ and p is a q-colimit diagram (Proposition HTT.4.3.1.5). Since the tensor product on the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ preserves small colimits separately in each variable, it will suffice to show that for each object $(\mathcal{C}, \mathcal{C}_{\geqslant 0})$, the formation of tensor product with $(\mathcal{C}, \mathcal{C}_{\geqslant 0})$ determines a functor $T : \mathsf{Groth}^{+}_\infty \to \mathsf{Groth}^{+}_\infty$ which preserves q-colimit diagrams. Using Propositions HTT.4.3.1.9 and HTT.4.3.1.10 , we are reduced to proving the following more concrete assertions:

(a) For every presentable stable ∞-category $\mathcal{D}$, the functor T induces a map of partially ordered sets $\mathrm{Core}(\mathcal{D}) \to \mathrm{Core}(\mathcal{C} \otimes \mathcal{D})$ which preserves colimits (in other words, the formation of suprema).

(b) The functor T carries q-coCartesian morphisms in Groth_∞^+ to q-coCartesian morphisms in Groth_∞^+.

We first prove (a). Let $m : \mathcal{C} \times \mathcal{D} \to \mathcal{E}$ be a functor which exhibits $\mathcal{E}$ as a tensor product of $\mathcal{C}$ with $\mathcal{D}$, and let $m_! : \mathrm{Core}(\mathcal{C}) \times \mathrm{Core}(\mathcal{D}) \to \mathrm{Core}(\mathcal{E})$ be as in Remark C.4.2.3. Let $\{\mathcal{D}^\alpha_{\geqslant 0}\}$ be a collection of cores of $\mathcal{D}$ having supremum $\mathcal{D}_{\geqslant 0} \in \mathrm{Core}(\mathcal{D})$. We wish to show that $m_!(\mathcal{C}_{\geqslant 0}, \mathcal{D}_{\geqslant 0})$ is a supremum of the set $\{m_!(\mathcal{C}_{\geqslant 0}, \mathcal{D}^\alpha_{\geqslant 0})\}$ in the partially ordered set $\mathrm{Core}(\mathcal{E})$. To prove this, suppose that $\mathcal{E}_{\geqslant 0} \subseteq \mathcal{E}$ is any core which contains each $m_!(\mathcal{C}_{\geqslant 0}, \mathcal{D}^\alpha_{\geqslant 0})$. Let $\mathcal{D}' \subseteq \mathcal{D}$ be the full subcategory spanned by those objects $D \in \mathcal{D}$ which satisfy $m(C, D) \in \mathcal{E}_{\geqslant 0}$ for each $C \in \mathcal{C}_{\geqslant 0}$. Since the functor m preserves small colimits separately in each variable, it follows that $\mathcal{D}' \subseteq \mathcal{D}$ is a core. By construction, it contains each $\mathcal{D}^\alpha_{\geqslant 0}$ and therefore contains the supremum $\mathcal{D}_{\geqslant 0}$, which proves that $m_!(\mathcal{C}_{\geqslant 0}, \mathcal{D}_{\geqslant 0}) \subseteq \mathcal{E}_{\geqslant 0}$ as desired.

Let us now prove (b). Suppose we are given a colimit preserving functor between presentable stable ∞-categories $f : \mathcal{D} \to \mathcal{D}'$, and form a commutative diagram

$$\begin{array}{ccc} \mathcal{C} \times \mathcal{D} & \xrightarrow{m} & \mathcal{E} \\ \downarrow{\scriptstyle \mathrm{id} \times f} & & \downarrow{\scriptstyle g} \\ \mathcal{C} \times \mathcal{D}' & \xrightarrow{m'} & \mathcal{E}' \end{array}$$

where the horizontal maps exhibit $\mathcal{E}$ and $\mathcal{E}'$ as tensor products of $\mathcal{D}$ and $\mathcal{D}'$ with $\mathcal{C}$, respectively. Define

$$m_! : \mathrm{Core}(\mathcal{C}) \times \mathrm{Core}(\mathcal{D}) \to \mathrm{Core}(\mathcal{E}) \qquad m'_! : \mathrm{Core}(\mathcal{C}) \times \mathrm{Core}(\mathcal{D}') \to \mathrm{Core}(\mathcal{E}')$$

as in Remark C.4.2.3. Unwinding the definitions, we wish to show for every core $\mathcal{D}_{\geqslant 0} \subseteq \mathcal{D}$, if $\mathcal{D}'_{\geqslant 0} \subseteq \mathcal{D}'$ is the smallest core containing $f(\mathcal{D}_{\geqslant 0})$, then $m'_!(\mathcal{C}_{\geqslant 0}, \mathcal{D}'_{\geqslant 0})$ is the smallest core containing $g(m_!(\mathcal{C}_{\geqslant 0}, \mathcal{D}_{\geqslant 0}))$. Let $\mathcal{E}'_{\geqslant 0} \in \mathrm{Core}(\mathcal{E}')$ be any core satisfying $m(\mathcal{C}_{\geqslant 0}, \mathcal{D}_{\geqslant 0}) \subseteq g^{-1} \mathcal{E}'_{\geqslant 0}$, and let $\mathcal{D}''$ be the full subcategory of $\mathcal{D}'$ spanned by those objects D' which satisfy $m'(\mathcal{C}_{\geqslant 0} \times \{D'\}) \subseteq \mathcal{E}'_{\geqslant 0}$. Then $\mathcal{D}''$ is a core containing $f(\mathcal{D}_{\geqslant 0})$, so we have $\mathcal{D}'_{\geqslant 0} \subseteq \mathcal{D}''$ and therefore $m'_!(\mathcal{C}_{\geqslant 0}, \mathcal{D}'_{\geqslant 0}) \subseteq \mathcal{E}'_{\geqslant 0}$ as desired. □

C.4.6 Completed Tensor Products

We now consider the interaction between the tensor product on Grothendieck prestable ∞-categories and the separatedness and completeness conditions introduced in Definition C.1.2.12.

Proposition C.4.6.1. *Let* $\mathsf{Groth}_\infty^{\mathrm{comp}} \subseteq \mathsf{Groth}_\infty^{\mathrm{sep}} \subseteq \mathsf{Groth}_\infty$ *denote the full subcategories of* Groth_∞ *spanned by the complete and separated Grothendieck prestable ∞-categories, and let*

$$L : \mathsf{Groth}_\infty \to \mathsf{Groth}_\infty^{\mathrm{sep}} \qquad L' : \mathsf{Groth}_\infty \to \mathsf{Groth}_\infty^{\mathrm{comp}}$$

denote left adjoints to the inclusion maps. Suppose that $F : \mathcal{C} \to \mathcal{D}$ *is a functor between Grothendieck prestable ∞-categories which preserves small colimits, and let* $\mathcal{E}$ *be an arbitrary Grothendieck prestable ∞-categories. Then:*

- *If* LF *is an equivalence in the ∞-category* $\mathsf{Groth}_\infty^{\mathrm{sep}}$*, then* $L(F \otimes \mathrm{id}_{\mathcal{E}})$ *is also an equivalence in the ∞-category* $\mathsf{Groth}_\infty^{\mathrm{sep}}$*.*
- *If* $L'F$ *is an equivalence in the ∞-category* $\mathsf{Groth}_\infty^{\mathrm{comp}}$*, then* $L'(F \otimes \mathrm{id}_{\mathcal{E}})$ *is also an equivalence in the ∞-category* $\mathsf{Groth}_\infty^{\mathrm{comp}}$*.*

In other words, the localization functors L *and* L' *are compatible with the symmetric monoidal structure on* Groth_∞*, in the sense of Definition HA.2.2.1.6.*

Proof. We will prove the assertion for the localization functor L; the proof for L' is similar. Assume that LF is an equivalence. We wish to prove that $L(F \otimes \mathrm{id}_{\mathcal{E}})$ is also an equivalence. In other words, we wish to prove that for every separated Grothendieck presentable ∞-category $\mathcal{X}$, composition with the functor $F \otimes \mathrm{id}_{\mathcal{E}}$ induces an equivalence of ∞-categories

$$\theta : \mathrm{LFun}(\mathcal{D} \otimes \mathcal{E}, \mathcal{X}) \to \mathrm{LFun}(\mathcal{C} \otimes \mathcal{E}, \mathcal{X}).$$

This is clear, because θ can be identified with the natural map

$$\mathrm{LFun}(\mathcal{E}, \mathrm{LFun}(\mathcal{D}, \mathcal{X})) \to \mathrm{LFun}(\mathcal{E}, \mathrm{LFun}(\mathcal{C}, \mathcal{X}))$$

obtained by composition with the equivalence $\mathrm{LFun}(\mathcal{D}, \mathcal{X}) \xrightarrow{\circ F} \mathrm{LFun}(\mathcal{C}, \mathcal{X})$. □

Corollary C.4.6.2. *The ∞-categories* $\mathsf{Groth}_\infty^{\mathrm{sep}}$ *and* $\mathsf{Groth}_\infty^{\mathrm{comp}}$ *admit essentially unique symmetric monoidal structures for which the localization functors*

$$L : \mathsf{Groth}_\infty \to \mathsf{Groth}_\infty^{\mathrm{sep}} \qquad L' : \mathsf{Groth}_\infty \to \mathsf{Groth}_\infty^{\mathrm{comp}}$$

are symmetric monoidal.

Warning C.4.6.3. If we equip the ∞-categories $\mathsf{Groth}_\infty^{\mathrm{sep}}$ and $\mathsf{Groth}_\infty^{\mathrm{comp}}$ with the symmetric monoidal structures described in Corollary C.4.6.2, then the inclusion functors

$$\mathsf{Groth}_\infty^{\mathrm{comp}} \hookrightarrow \mathsf{Groth}_\infty^{\mathrm{sep}} \hookrightarrow \mathsf{Groth}_\infty$$

are lax symmetric monoidal, but not symmetric monoidal. We will denote the tensor product on $\mathsf{Groth}_\infty^{\mathrm{comp}}$ by

$$\widehat{\otimes} : \mathsf{Groth}_\infty^{\mathrm{comp}} \times \mathsf{Groth}_\infty^{\mathrm{comp}} \to \mathsf{Groth}_\infty^{\mathrm{comp}}$$

and refer to it as the *completed tensor product* on $\mathsf{Groth}_\infty^{\mathrm{comp}}$. Unwinding the definitions, we see that the completed tensor product is given on objects by the formula $\mathcal{C} \widehat{\otimes} \mathcal{D} = \widehat{\mathcal{C} \otimes \mathcal{D}}$, where $\mathcal{C} \mapsto \widehat{\mathcal{C}}$ denotes the completion functor of Proposition C.3.6.3 (that is, the localization functor L' of Corollary C.4.6.2).

C.5 Grothendieck Abelian Categories

In §C.1, we introduced the notion of a *Grothendieck prestable ∞-category* (Definition C.1.4.2). In this section, we will investigate the relationship between the theory of Grothendieck prestable ∞-categories and the more classical theory of Grothendieck abelian categories. Recall that if $\mathcal{C}$ is a Grothendieck prestable ∞-category, then the full subcategory $\mathcal{C}^{\heartsuit} \subseteq \mathcal{C}$ spanned by the discrete objects is a Grothendieck abelian category (Remark C.1.4.6). We now consider the converse:

Question C.5.0.4. Given a Grothendieck abelian category $\mathcal{A}$, is there a canonical way to construct a Grothendieck prestable ∞-category $\mathcal{C}$ and an equivalence $\mathcal{A} \simeq \mathcal{C}^{\heartsuit}$?

We have already given an affirmative answer to Question C.5.0.4: if $\mathcal{A}$ is a Grothendieck prestable ∞-category, then the derived ∞-category $\mathcal{D}(\mathcal{A})$ can be endowed with the t-structure $(\mathcal{D}(\mathcal{A})_{\geqslant 0}, \mathcal{D}(\mathcal{A})_{\leqslant 0})$ of Proposition HA.1.3.5.21 , and the ∞-category $\mathcal{D}(\mathcal{A})_{\geqslant 0}$ is a Grothendieck prestable ∞-category whose heart is equivalent to $\mathcal{A}$ (Example C.1.4.5). However, there are (at least) two other ways to answer Question C.5.0.4:

- If $\mathcal{A}$ is a Grothendieck abelian category, then t-structure on $\mathcal{D}(\mathcal{A})$ need not be left complete. Consequently, we can consider the left completion of $\mathcal{D}(\mathcal{A})$, which we will denote by $\widehat{\mathcal{D}}(\mathcal{A})$ and refer to as the *completed derived ∞-category of* $\mathcal{A}$. This completion inherits a t-structure $(\widehat{\mathcal{D}}(\mathcal{A})_{\geqslant 0}, \widehat{\mathcal{D}}(\mathcal{A})_{\leqslant 0})$, and $\widehat{\mathcal{D}}(\mathcal{A})_{\geqslant 0}$ is another Grothendieck prestable ∞-category whose heart can be identified with $\mathcal{A}$.

- Let $\mathcal{A}$ be a Grothendieck abelian category and let $\mathrm{Ch}(\mathcal{A})$ be the (differential graded) category of chain complexes with values in $\mathcal{A}$. Then $\mathrm{Ch}(\mathcal{A})$ admits a model structure, where the cofibrations are monomorphisms of chain complexes and the weak equivalences are quasi-isomorphisms of chain complexes (Proposition HA.1.3.5.3). The ∞-category $\mathcal{D}(\mathcal{A})$ is defined as the differential graded nerve of the full subcategory $\mathrm{Ch}(\mathcal{A})^{\circ} \subseteq \mathrm{Ch}(\mathcal{A})$ spanned by the fibrant objects (Definition HA.1.3.5.8). If $A_\bullet$ is a fibrant object of $\mathrm{Ch}(\mathcal{A})$, then each A_n is an injective object of $\mathcal{A}$: that is, we have $\mathrm{Ch}(\mathcal{A})^{\circ}) \subseteq \mathrm{Ch}(\mathcal{A}^{\mathrm{inj}})$, where $\mathcal{A}^{\mathrm{inj}} \subseteq \mathcal{A}$ denotes the full subcategory spanned by the injective objects of $\mathcal{A}$. In general, this inclusion is strict: an unbounded chain complex of injective objects of $\mathcal{A}$ need not be a fibrant object of $\mathrm{Ch}(\mathcal{A})$. We let $\check{\mathcal{D}}(\mathcal{A})$ denote the differential graded nerve of the category $\mathrm{Ch}(\mathcal{A}^{\mathrm{inj}})$ of *all* chain complexes of injective objects of $\mathcal{A}$. Then $\check{\mathcal{D}}(\mathcal{A})$ admits a t-structure $(\check{\mathcal{D}}(\mathcal{A})_{\geqslant 0}, \check{\mathcal{D}}(\mathcal{A})_{\leqslant 0})$, where $\check{\mathcal{D}}(\mathcal{A})_{\geqslant 0}$ is a Grothendieck prestable ∞-category whose heart is $\mathcal{A}$. We will refer to $\check{\mathcal{D}}(\mathcal{A})$ as the *unseparated derived ∞-category of $\mathcal{A}$*.

If $\mathcal{A}$ is a Grothendieck abelian, then the ∞-categories described above are related by functors

$$\check{\mathcal{D}}(\mathcal{A})_{\geqslant 0} \to \mathcal{D}(\mathcal{A})_{\geqslant 0} \to \widehat{\mathcal{D}}(\mathcal{A})_{\geqslant 0}$$

which preserve small colimits and finite limits. Each can be characterized by a universal property:

- The unseparated derived ∞-category $\check{\mathcal{D}}(\mathcal{A})_{\geqslant 0}$ is universal among Grothendieck prestable ∞-categories $\mathcal{E}$ equipped with a functor $\mathcal{A} \to \mathcal{E}^{\heartsuit}$ which preserves small colimits and finite limits (Corollary C.5.8.9).
- The derived ∞-category $\mathcal{D}(\mathcal{A})_{\geqslant 0}$ is universal among *separated* Grothendieck prestable ∞-categories $\mathcal{E}$ equipped with a functor $\mathcal{A} \to \mathcal{E}^{\heartsuit}$ which preserves small colimits and finite limits (Theorem C.5.4.9).
- The completed derived ∞-category $\widehat{\mathcal{D}}(\mathcal{A})_{\geqslant 0}$ is universal among *complete* Grothendieck prestable ∞-categories $\mathcal{E}$ equipped with a functor $\mathcal{A} \to \mathcal{E}^{\heartsuit}$ which preserves small colimits and finite limits (Corollary C.5.9.5).

The relationship between Grothendieck prestable ∞-categories and Grothendieck abelian categories is analogous to the relationship between ∞-topoi and ordinary (Grothendieck) topoi. Another of our goals in this section is to pursue this analogy by introducing "linear" versions of some useful concepts from the study of higher topoi, as summarized in the following table:

Nonlinear Concept	Linear Concept
∞-topos	Grothendieck prestable ∞-category
Hypercomplete ∞-topos	Separated Grothendieck prestable ∞-category
Postnikov-complete ∞-topos	Complete Grothendieck prestable ∞-category
Bounded ∞-topos	Anticomplete Grothendieck prestable ∞-category
$(n+1)$-localic ∞-topos	Anticomplete, n-complicial Grothendieck prestable ∞-category
$(n+1)$-topos	Grothendieck abelian n-category

cc

C.5.1 Localizing Subcategories of Abelian Categories

In §C.2, we introduced the notion of a *localizing subcategory* of a Grothendieck prestable ∞-category $\mathcal{C}$ (Definition C.2.3.3). We now review the analogous localization theory of Grothendieck abelian categories. We begin by establishing a 1-categorical analogue of Proposition C.2.3.1.

Proposition C.5.1.1. *Let $\mathcal{A}$ be an abelian category and let $\mathcal{B} \subseteq \mathcal{A}$ be a full subcategory. Suppose that the inclusion $\mathcal{B} \hookrightarrow \mathcal{A}$ admits a left adjoint $L : \mathcal{A} \to \mathcal{B}$ which is left exact. Then $\mathcal{B}$ is an abelian category and L is exact (when viewed as a functor from $\mathcal{A}$ to $\mathcal{B}$).*

Proof. Since $\mathcal{B}$ is a localization of $\mathcal{A}$, it is closed under all limits which exist in $\mathcal{A}$. In particular, it contains the zero object of $\mathcal{A}$ and is closed under finite direct sums, and is therefore an additive category. Moreover, every morphism $f : X \to Y$ in $\mathcal{B}$ has a kernel (which can be computed in the abelian category $\mathcal{A}$) and a cokernel (which can be computed by first taking the cokernel in the abelian category $\mathcal{A}$ and then applying the localization functor L). To complete the proof that $\mathcal{B}$ is abelian, it will suffice to show that for every f as above, the canonical map $\alpha : L\,\mathrm{coker}(\ker(f) \to X) \to \ker(Y \to L\,\mathrm{coker}(f))$ is an isomorphism (where the kernels and cokernals are formed in the abelian category $\mathcal{A}$). Using the left exactness of L, we see that α is obtained by applying the functor L to the natural map $\alpha_0 : \mathrm{coker}(\ker(f) \to X) \to \ker(Y \to \mathrm{coker}(f))$, which is an isomorphism by virtue of our assumption that $\mathcal{A}$ is an abelian category. The functor $L : \mathcal{A} \to \mathcal{B}$ is left exact by assumption and right exact by virtue of the fact that it is left adjoint to the inclusion, and is therefore exact. □

In the situation of Proposition C.5.1.1, the category $\mathcal{B}$ can be obtained (up to equivalence) from $\mathcal{A}$ by formally inverting the L-equivalences: that is, the morphisms $f : X \to Y$ in the category $\mathcal{A}$ such that Lf is an isomorphism. Since $L : \mathcal{A} \to \mathcal{B}$ is an exact functor, the morphism Lf is an isomorphism if and only if $\mathrm{coker}(Lf) = L\,\mathrm{coker}(f)$ and $\ker(Lf) = L\ker(f)$ both vanish: that is, if and only if the functor L annihilates $\ker(f)$ and $\mathrm{coker}(f)$. Consequently, the category $\mathcal{B}$ can be recovered from $\mathcal{A}$ together with the full subcategory $\mathcal{A}_0 = \{X \in \mathcal{A} : LX \simeq 0\}$. One can then ask: which full subcategories $\mathcal{A}_0 \subseteq \mathcal{A}$ can arise in this way? When $\mathcal{A}$ is a Grothendieck abelian category, this is answered by the following:

Definition C.5.1.2. Let $\mathcal{A}$ be a Grothendieck abelian category. We will say that a full subcategory $\mathcal{A}_0 \subseteq \mathcal{A}$ is *localizing* if it satisfies the following conditions:

(*a*) For every exact sequence $0 \to X' \to X \to X'' \to 0$ in $\mathcal{A}$, the object X belongs to $\mathcal{A}_0$ if and only if both X' and X'' belong to $\mathcal{A}_0$. In other words, the full subcategory $\mathcal{A}_0$ is closed under the formation of subobjects, quotient objects, and extensions.

(*b*) The full subcategory $\mathcal{A}_0 \subseteq \mathcal{A}$ is closed under the formation of (small) coproducts.

Remark C.5.1.3. If $\mathcal{A}$ is an arbitrary abelian category, then a full subcategory $\mathcal{A}_0 \subseteq \mathcal{A}$ satisfying condition (a) of Definition C.5.1.2 is often called a *Serre subcategory* of $\mathcal{A}$.

Definition C.5.1.4. Let $\mathcal{A}$ be a Grothendieck abelian category and let $\mathcal{A}_0 \subseteq \mathcal{A}$ be a localizing subcategory. We will say that a morphism $f : X \to Y$ in $\mathcal{A}$ is a $\mathcal{A}_0$*-equivalence* if the kernel and cokernel of f belong to $\mathcal{A}_0$. We will say that an object $Z \in \mathcal{A}$ is $\mathcal{A}_0$*-local* if, for every $\mathcal{A}_0$-equivalence $f : X \to Y$, the induced map $\mathrm{Hom}_{\mathcal{A}}(Y, Z) \to \mathrm{Hom}_{\mathcal{A}}(X, Z)$ is bijective. We let $\mathcal{A}/\mathcal{A}_0$ denote the full subcategory of $\mathcal{A}$ spanned by the $\mathcal{A}_0$-local objects.

Remark C.5.1.5. Let $\mathcal{A}$ be a Grothendieck abelian category and let $\mathcal{A}_0 \subseteq \mathcal{A}$ be a localizing subcategory. Every morphism $f : X \to Y$ in $\mathcal{A}$ admits an essentially unique factorization $X \xrightarrow{f'} W \xrightarrow{f''} Y$, where f' is an epimorphism and f'' is a monomorphism. Note that f is a $\mathcal{A}_0$-equivalence if and only if f' and f'' are $\mathcal{A}_0$-equivalences. Consequently, an object $Z \in \mathcal{A}$ is $\mathcal{A}_0$-local if only if the induced map $\mathrm{Hom}_{\mathcal{A}}(Y, Z) \to \mathrm{Hom}_{\mathcal{A}}(X, Z)$ is bijective for any $\mathcal{A}_0$-equivalence $X \to Y$ which is either an epimorphism or a monomorphism. This is equivalent to the following pair of conditions:

- (a) For every exact sequence $0 \to A \to X \xrightarrow{f} Y \to 0$ in $\mathcal{A}$ where $A \in \mathcal{A}_0$, the induced map $\mathrm{Hom}_{\mathcal{A}}(Y, Z) \to \mathrm{Hom}_{\mathcal{A}}(X, Z)$ is surjective (note that it is automatically injective, since f is an epimorphism).
- (b) For every exact sequence $0 \to X \xrightarrow{f} Y \to A \to 0$ in $\mathcal{A}$ where $A \in \mathcal{A}_0$, the induced map $\mathrm{Hom}_{\mathcal{A}}(Y, Z) \to \mathrm{Hom}_{\mathcal{A}}(X, Z)$ is bijective.

Note that condition (a) is equivalent to the requirement that $\mathrm{Hom}_{\mathcal{A}}(A, Z) \simeq 0$ for each $A \in \mathcal{A}_0$. Moreover, if this condition is satisfied, then the map appearing in (b) is automatically injective. Unwinding the definitions, we see that the surjectivity is equivalent to the requirement that every exact sequence $0 \to Z \to \widetilde{Z} \to A \to 0$ in $\mathcal{A}$ splits provided that $A \in \mathcal{A}_0$: that is, to the condition that $\mathrm{Ext}^1_{\mathcal{A}}(A, Z) \simeq 0$ for $A \in \mathcal{A}_0$. Consequently, an object $Z \in \mathcal{A}$ is $\mathcal{A}_0$-local if and only if we have $\mathrm{Hom}_{\mathcal{A}}(A, Z) \simeq \mathrm{Ext}^1_{\mathcal{A}}(A, Z) \simeq 0$ for all $A \in \mathcal{A}_0$: that is, if and only if every extension of A by Z admits a *unique* splitting.

The relevance of Definition C.5.1.2 is explained by the next result:

Proposition C.5.1.6. *Let $\mathcal{A}$ be a Grothendieck abelian category and let $\mathcal{A}_0 \subseteq \mathcal{A}$ be a full subcategory. The following conditions are equivalent:*

- (1) *The full subcategory $\mathcal{A}_0 \subseteq \mathcal{A}$ is localizing.*
- (2) *There exists a full subcategory $\mathcal{B} \subseteq \mathcal{A}$ for which the inclusion functor admits a left exact left adjoint $L : \mathcal{A} \to \mathcal{B}$, where $\mathcal{A}_0 = \{A \in \mathcal{A} : LA \simeq 0\}$.*

Moreover, if these conditions are satisfied, then $\mathcal{B}$ is a Grothendieck abelian category.

Remark C.5.1.7. In the situation of Proposition C.5.1.6, let $f : A \to A'$ be a morphism in $\mathcal{A}$. Then Lf is an isomorphism in $\mathcal{B}$ if and only if the objects $\ker(Lf) \simeq L\ker(f)$ and $\mathrm{coker}(Lf) \simeq L\,\mathrm{coker}(f)$ vanish: that is, if and only if f is a $\mathcal{A}_0$-equivalence, in the sense of Definition **??**. It follows that the essential image of the inclusion $\mathcal{B} \hookrightarrow \mathcal{A}$ can be identified with the full subcategory $\mathcal{A}/\mathcal{A}_0 \subseteq \mathcal{A}$ spanned by the $\mathcal{A}_0$-local objects.

Proof of Proposition C.5.1.6. Suppose first that (2) is satisfied. Then $L : \mathcal{A} \to \mathcal{B}$ is an exact functor between abelian categories (Proposition C.5.1.1), so the full subcategory $\mathcal{A}_0 = \{A \in \mathcal{A} : LA \simeq 0\}$ is closed under the formation of subobjects, quotient objects, and extensions. Since L preserves small colimits, the full subcategory $\mathcal{A}_0 \subseteq \mathcal{A}$ is closed under small colimits and therefore under small coproducts. This proves that (2) ⇒ (1).

Now suppose that (1) is satisfied. Then the full subcategory $\mathcal{A}_0 \subseteq \mathcal{A}$ is closed under quotients and direct sums, and is therefore closed under all small colimits. Let $E \in \mathcal{A}$ be a generator for the Grothendieck abelian category $\mathcal{A}$, so that every object $X \in \mathcal{A}$ can be written as a filtered colimit of subobjects X_α, each of which can be described as a quotient of E^n for $n \geqslant 0$. Note that if $X \in \mathcal{A}_0$, then each X_α belongs to $\mathcal{A}_0$. It follows that $\mathcal{A}_0$ is generated under filtered colimits by the (essentially small) subcategory of $\mathcal{A}_0$ spanned by objects which appear as quotients of some E^n. Every such quotient is small as an object of $\mathcal{A}$ and therefore also as an object of $\mathcal{A}_0$, so that the category $\mathcal{A}_0$ is accessible. Let S denote the collection of all $\mathcal{A}_0$-equivalences in $\mathcal{A}$; it follows from Proposition HTT.5.4.6.6 that S spans an accessible subcategory of $\mathrm{Fun}(\Delta^1, \mathcal{A})$.

Let $\mathcal{D}(\mathcal{A})$ denote the derived ∞-category of $\mathcal{A}$ (see §**??**), let $\mathcal{D}_{\mathcal{A}_0}(\mathcal{A})$ denote the full subcategory of $\mathcal{D}(\mathcal{A})$ spanned by those chain complexes in $\mathcal{A}$ whose homologies lie in the subcategory $\mathcal{A}_0 \subseteq \mathcal{A}$. Using the assumption that $\mathcal{A}_0$ is a Serre subcategory of $\mathcal{A}$, we immediately deduce that $\mathcal{D}_{\mathcal{A}_0}(\mathcal{A})$ is a stable subcategory of $\mathcal{D}(\mathcal{A})$. Since $\mathcal{A}_0$ is closed under direct sums, the full subcategory $\mathcal{D}_{\mathcal{A}_0}(\mathcal{A}) \subseteq \mathcal{D}(\mathcal{A})$ is closed under coproducts and therefore under all small colimits. Set $\mathcal{D}_{\mathcal{A}_0}(\mathcal{A})_{\geqslant 0} = \mathcal{D}(\mathcal{A})_{\geqslant 0} \cap \mathcal{D}_{\mathcal{A}_0}(\mathcal{A})$. We claim that $\mathcal{D}_{\mathcal{A}_0}(\mathcal{A})_{\geqslant 0}$ is a localizing subcategory of the Grothendieck prestable ∞-category $\mathcal{D}(\mathcal{A})_{\geqslant 0}$: that is, that it satisfies conditions (i), (ii), and (iii) of Definition C.2.3.3. Since $\mathcal{D}_{\mathcal{A}_0}(\mathcal{A})$ and $\mathcal{D}(\mathcal{A})_{\geqslant 0}$ are both closed under small colimits in $\mathcal{D}(\mathcal{A})$, it is clear that $\mathcal{D}_{\mathcal{A}_0}(\mathcal{A})_{\geqslant 0}$ is closed under colimits in $\mathcal{D}(\mathcal{A})$. Using Proposition HTT.5.4.6.6 , we see that the accessibility of the subcategory $\mathcal{A}_0 \subseteq \mathcal{A}$ implies the accessibility of the subcategory $\mathcal{D}_{\mathcal{A}_0}(\mathcal{A})_{\geqslant 0} \subseteq \mathcal{D}(\mathcal{A})$.

Let $\mathcal{C}$ denote the quotient $\mathcal{D}(\mathcal{A})_{\geqslant 0}/\mathcal{D}_{\mathcal{A}_0}(\mathcal{A})_{\geqslant 0}$ (see Notation C.2.3.9). Then $\mathcal{C}$ is a Grothendieck prestable ∞-category, so the full subcategory $\mathcal{C}^\heartsuit \subseteq \mathcal{C}$ of discrete objects is a Grothendieck abelian category (Remark C.1.4.6). Since the localization functor $\mathcal{D}(\mathcal{A})_{\geqslant 0} \to \mathcal{D}(\mathcal{A})_{\geqslant 0}/\mathcal{D}_{\mathcal{A}_0}(\mathcal{A})_{\geqslant 0}$ and its right adjoint are left exact, they determine adjoint functors $\mathcal{D}(\mathcal{A})^\heartsuit \underset{G}{\overset{F}{\rightleftarrows}} \mathcal{C}^\heartsuit$ which exhibit $\mathcal{C}^\heartsuit$ as an exact localization of the Grothendieck abelian category $\mathcal{D}(\mathcal{A})^\heartsuit \simeq \mathcal{A}$. By construction, an object $A \in \mathcal{A}$ is annihilated by F if and only if it belongs to the full subcategory $\mathcal{A}_0 \subseteq \mathcal{A}$. We conclude by taking $\mathcal{B} \subseteq \mathcal{A}$ to be the essential image of the functor G. □

Remark C.5.1.8. Let $\mathcal{A}$ be a Grothendieck abelian category, let $\mathcal{A}_0 \subseteq \mathcal{A}$ be a localizing subcategory, and let $\mathcal{B}$ be an arbitrary category which admits small colimits. Let $\mathrm{LFun}(\mathcal{A}, \mathcal{B})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{A}, \mathcal{B})$ spanned by those functors which preserve small colimits and define $\mathrm{LFun}(\mathcal{A} / \mathcal{A}_0, \mathcal{B})$ similarly. It follows from Proposition HTT.5.5.4.20 that composition with the localization functor $L : \mathcal{A} \to \mathcal{A} / \mathcal{A}_0$ induces a fully faithful embedding $\mathrm{LFun}(\mathcal{A} / \mathcal{A}_0, \mathcal{B}) \hookrightarrow \mathrm{LFun}(\mathcal{A}, \mathcal{B})$, whose essential image is spanned by those functors which carry $\mathcal{A}_0$-equivalences in $\mathcal{A}$ to isomorphisms in $\mathcal{B}$. In particular, if $F : \mathcal{A} \to \mathcal{B}$ is a colimit-preserving functor which carries $\mathcal{A}_0$-equivalences to isomorphisms, then F admits an essentially unique factorization through the quotient $\mathcal{A} / \mathcal{A}_0$. Note that if $\mathcal{B}$ is an abelian category and F is exact, then the condition that F preserves $\mathcal{A}_0$-equivalences is equivalent to the requirement that F annihilates the objects of $\mathcal{A}_0$. In this case, the induced map $\mathcal{A} / \mathcal{A}_0 \to \mathcal{B}$ is also an exact functor.

C.5.2 Comparison of Localizing Subcategories

Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $\mathcal{C}^{\heartsuit}$ denote the full subcategory of $\mathcal{C}$ spanned by the discrete objects. Then $\mathcal{C}^{\heartsuit}$ is a Grothendieck abelian category. We study the relationship between localizing subcategories of $\mathcal{C}$ (in the sense of Definition C.2.3.3) and localizing subcategories of $\mathcal{C}^{\heartsuit}$ (in the sense of Definition C.5.1.2).

Proposition C.5.2.1. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a localizing subcategory (in the sense of Definition C.2.3.3). Then:*

(*a*) *The ∞-category $\mathcal{C}_0$ is Grothendieck prestable.*

(*b*) *An object of $\mathcal{C}_0$ is discrete if and only if it is discrete when viewed as an object of $\mathcal{C}$: that is, we have $\mathcal{C}_0^{\heartsuit} = \mathcal{C}_0 \cap \mathcal{C}^{\heartsuit}$.*

(*c*) *The full subcategory $\mathcal{C}_0^{\heartsuit} \subseteq \mathcal{C}^{\heartsuit}$ is a localizing subcategory of the Grothendieck abelian category $\mathcal{C}^{\heartsuit}$ (in the sense of Definition C.5.1.2).*

(*d*) *There is a canonical equivelence of Grothendieck abelian categories $(\mathcal{C} / \mathcal{C}_0)^{\heartsuit} \simeq \mathcal{C}^{\heartsuit} / \mathcal{C}_0^{\heartsuit}$.*

Proof. Assertion (*a*) follows immediately from the definitions. To prove (*b*), suppose that X is a discrete object of $\mathcal{C}_0$. Let $\pi_0 X$ denote the 0-truncation of X in the Grothendieck prestable ∞-category $\mathcal{C}$, so that we have a fiber sequence $X' \to X \to \pi_0 X$. Using condition (*iii*) of Proposition C.2.3.3, we deduce that $X' \in \mathcal{C}_0$. Since $\pi_0 X' \simeq 0$, we can write $X' = \Sigma Y$ for some object $Y \in \mathcal{C}$. We then have a fiber sequence $Y \to 0 \to X'$ in $\mathcal{C}$, so that condition (*ii*) of Definition C.2.3.3 gives $Y \in \mathcal{C}_0$. Since X is discrete, we deduce that

$\pi_1 \operatorname{Map}_{\mathcal{C}}(Y, X) \simeq \pi_0 \operatorname{Map}_{\mathcal{C}}(X', X) \simeq \pi_0 \operatorname{Map}_{\mathcal{C}}(X', X') \simeq 0$. In particular, the identity map $\mathrm{id} : X' \to X'$ is nullhomotopic, so that $X' \simeq 0$ and therefore $X \simeq \pi_0 X$ is a discrete object of $\mathcal{C}$.

To prove (c) and (d), we note that the functors appearing in the adjunction $\mathcal{C} \underset{G}{\overset{F}{\rightleftarrows}} \mathcal{C} / \mathcal{C}_0$ are left exact, and therefore induce an adjunction between Grothendieck abelian categories $\mathcal{C}^{\heartsuit} \underset{G^{\heartsuit}}{\overset{F^{\heartsuit}}{\rightleftarrows}} (\mathcal{C} / \mathcal{C}_0)^{\heartsuit}$. Unwinding the definitions, we see that an object $C \in \mathcal{C}^{\heartsuit}$ is annihilated by $F^{\heartsuit}$ if and only if it belongs to $\mathcal{C}_0 \cap \mathcal{C}^{\heartsuit} = \mathcal{C}_0^{\heartsuit}$. It follows from Proposition C.5.1.6 that $\mathcal{C}_0^{\heartsuit}$ is a localizing subcategory of $\mathcal{C}^{\heartsuit}$, and that the quotient $\mathcal{C}^{\heartsuit} / \mathcal{C}_0^{\heartsuit}$ can be identified with the essential image of the fully faithful embedding $G^{\heartsuit}$. □

Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. It follows from Proposition C.5.2.1 that the construction $\mathcal{C}_0 \mapsto \mathcal{C}_0^{\heartsuit}$ determines a map

$$\{\text{Localizing subcategories of } \mathcal{C}\} \to \{\text{Localizing subcategories of } \mathcal{C}^{\heartsuit}\}.$$

We will see in a moment that this map is surjective: that is, given a localizing subcategory $\mathcal{A}_0 \subseteq \mathcal{C}^{\heartsuit}$, we can always find a localizing subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ satisfying $\mathcal{C}_0^{\heartsuit} = \mathcal{A}_0$. The localizing subcategory $\mathcal{C}_0$ is generally not unique. However, there are (at least) two natural choices for the subcategory $\mathcal{C}_0$: one which is as large as possible (Proposition C.5.2.7), and one which is as small as possible (Proposition C.5.2.8).

Proposition C.5.2.2. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a localizing subcategory. For each object $C \in \mathcal{C}_0$, we have $\pi_n C \in \mathcal{C}_0^{\heartsuit}$ for $n \geqslant 0$.*

Proof. Since the localization functor $L : \mathcal{C} \to \mathcal{C} / \mathcal{C}_0$ is left exact, we have $L(\pi_n C) \simeq \pi_n(LC) \simeq 0$ for $n \geqslant 0$. □

The converse of Proposition C.5.2.2 is not necessary true: in general, we cannot test whether or not an object $C \in \mathcal{C}$ belongs to $\mathcal{C}_0$ by studying the homotopy groups $\pi_n C \in \mathcal{C}^{\heartsuit}$.

Definition C.5.2.3. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a localizing subcategory. We will say that $\mathcal{C}_0$ is *separating* if, for every object $C \in \mathcal{C}$ which satisfies $\pi_n C \in \mathcal{C}_0^{\heartsuit}$ for $n \geqslant 0$, we have $C \in \mathcal{C}_0$.

Remark C.5.2.4. Unwinding the definitions, we see that a localizing subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ is separating (in the sense of Definition C.5.2.3) if and only if the Grothendieck prestable ∞-category $\mathcal{C} / \mathcal{C}_0$ is separated (in the sense of Definition C.1.2.12).

Remark C.5.2.5. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. Suppose we are given localizing subcategories $\mathcal{C}_0, \mathcal{C}_1 \subseteq \mathcal{C}$, where $\mathcal{C}_1$ is separating. Then $\mathcal{C}_0 \subseteq \mathcal{C}_1$ if and only if $\mathcal{C}_0^{\heartsuit} \subseteq \mathcal{C}_1^{\heartsuit}$. The "only if" direction is obvious, and the "if" direction follows from Proposition C.5.2.2.

Remark C.5.2.6. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category, let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a separated localizing subcategory, and let $\mathcal{A}_0 = \mathcal{C}_0^{\heartsuit}$. It follows from Remark C.5.2.5 that $\mathcal{C}_0$ is the largest localizing subcategory of $\mathcal{C}$ whose heart is $\mathcal{A}_0$.

Proposition C.5.2.7. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. Then the construction $\mathcal{C}_0 \mapsto \mathcal{C}_0^{\heartsuit}$ induces a bijection*

$$\theta : \{\textit{Separating localizing subcategories of } \mathcal{C}\} \to \{\textit{Localizing subcategories of } \mathcal{C}^{\heartsuit}\}.$$

Proof. The injectivity of θ follows from Remark C.5.2.6. To prove surjectivity, let $\mathcal{A}_0 \subseteq \mathcal{C}^{\heartsuit}$ be a localizing subcategory of $\mathcal{C}^{\heartsuit}$ and define $\mathcal{C}_0 \subseteq \mathcal{C}$ be the full subcategory of $\mathcal{C}$ spanned by those objects C satisfying $\pi_n C \in \mathcal{A}_0$ for $n \geqslant 0$. We must show that $\mathcal{C}_0$ is a localizing subcategory of $\mathcal{C}$: that is, that it satisfies the requirements of Definition C.2.3.3:

- (i) The full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ is accessible and closed under small coproducts. The accessibility of $\mathcal{C}_0$ follows from the accessibility of $\mathcal{A}_0$ (established in the proof of Proposition C.5.1.6) using Proposition HTT.5.4.6.6 . Since $\mathcal{A}_0 \subseteq \mathcal{C}^{\heartsuit}$ is closed under the formation of coproducts and each of the functors $\pi_n : \mathcal{C} \to \mathcal{C}^{\heartsuit}$ commutes with coproducts, we conclude that $\mathcal{C}_0 \subseteq \mathcal{C}$ is closed under coproducts.

- (ii) Suppose we are given a cofiber sequence $X' \to X \to X''$ in $\mathcal{C}$. We must show that if any two of the objects X, X', and X'' belongs to $\mathcal{C}_0$, then so does the third. For simplicity, let us assume that X' and X'' belong to $\mathcal{C}_0$; the proofs in the other two cases differ only by minor changes in notation. For each $n \geqslant 0$, we have an exact sequence $\pi_n X' \to \pi_n X \to \pi_n X''$ in the abelian category $\mathcal{C}^{\heartsuit}$. It follows that we can write $\pi_n X$ as an extension of a subobject of $\pi_n X''$ by a quotient object of $\pi_n X'$. Since X' and X'' belong to $\mathcal{C}_0$, the objects $\pi_n X'$ and $\pi_n X''$ belong to $\mathcal{A}_0$. Since $\mathcal{A}_0$ is a localizing subcategory of $\mathcal{C}^{\heartsuit}$, it follows that any subobject of $\pi_n X''$ and any quotient object of $\pi_n X'$ belong to $\mathcal{A}_0$, so that $\pi_n X \in \mathcal{A}_0$ by virtue of the fact that $\mathcal{A}_0$ is closed under extensions. Allowing n to vary, we deduce that $X \in \mathcal{C}_0$.

- (iii) Suppose we are given a cofiber sequence $X' \to X \to X''$ in $\mathcal{C}$ where $X \in \mathcal{C}_0$ and $X'' \in \mathcal{C}^{\heartsuit}$; we wish to show that $X' \in \mathcal{C}_0$. The canonical map $\pi_n X' \to \pi_n X$ is a monomorphism for $n \geqslant 0$ (and an isomorphism for $n > 0$). Our assumption that $X \in \mathcal{C}_0$ guarantees that each $\pi_n X$ belongs to $\mathcal{A}_0$, so that $\pi_n X' \in \mathcal{A}_0$ by virtue of the fact that $\mathcal{A}_0$ is closed under the formation of subobjects. Allowing n to vary, we deduce that $X' \in \mathcal{C}_0$ as desired.

□

We now consider localizing subcategories which are, in some sense, as far as possible from being separating.

Proposition C.5.2.8. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category, let $\mathrm{Sp}(\mathcal{C})$ denote the ∞-category of spectrum objects of $\mathcal{C}$, and regard $\mathrm{Sp}(\mathcal{C})$ as equipped with the t-structure of Remark C.1.2.10. Let $\mathcal{A}_0$ be a localizing subcategory of the Grothendieck abelian category $\mathrm{Sp}(\mathcal{C})^{\heartsuit} \simeq \mathcal{C}^{\heartsuit}$, and let $\mathcal{E} \subseteq \mathrm{Sp}(\mathcal{C})$ denote the full subcategory spanned by those objects X with the property that $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(A, X)$ vanishes for each object $A \in \mathcal{A}_0$ and every integer n. Then:*

- (a) *The ∞-category $\mathcal{E}$ is presentable, and the inclusion functor $\mathcal{E} \hookrightarrow \mathrm{Sp}(\mathcal{C})$ admits a left adjoint $L : \mathrm{Sp}(\mathcal{C}) \to \mathcal{E}$.*
- (b) *There is a unique t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$ on $\mathcal{E}$ for which $\mathcal{E}_{\leqslant 0} = \mathrm{Sp}(\mathcal{C})_{\leqslant 0} \cap \mathcal{E}$.*
- (c) *The functor L is t-exact.*
- (d) *The t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$ is right complete and compatible with filtered colimits.*
- (e) *The full subcategory $\mathcal{E}_{\geqslant 0} \subseteq \mathcal{E}$ is a Grothendieck prestable ∞-category.*
- (f) *Let $\mathcal{C}_0$ denote the full subcategory of $\mathcal{C}$ spanned by those objects which are annihilated by the functor $\mathcal{C} \simeq \mathrm{Sp}(\mathcal{C})_{\geqslant 0} \xrightarrow{L} \mathcal{E}_{\geqslant 0}$. Then $\mathcal{C}_0$ is a localizing subcategory of $\mathcal{C}$ satisfying $\mathcal{C}_0^{\heartsuit} = \mathcal{A}_0$.*
- (g) *The full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ is the smallest localizing subcategory of $\mathcal{C}$ which contains $\mathcal{A}_0$.*

Proof. Choose a small collection of objects $\{A_\alpha\}$ of $\mathcal{A}_0$ which generate $\mathcal{A}_0$ under filtered colimits. Unwinding the definitions, we see that an object $X \in \mathrm{Sp}(\mathcal{C})$ belongs to $\mathcal{E}$ if and only if it is S-local, where S denotes the collection of all morphisms of the form $0 \to \Sigma^n A_\alpha$. Assertion (a) now follows from Proposition HTT.5.5.4.15 .

Choose a small collection of objects $\{C_\beta\}$ of $\mathcal{C}$ which generate $\mathcal{C}$ under small colimits. Let $\mathcal{E}_{\geqslant 0}$ denote the smallest full subcategory of $\mathcal{E}$ which is closed under small colimits and extensions and contains every object of the form $L(\Sigma^\infty C_\beta)$. Applying Proposition HA.1.4.4.11 , we see that $\mathcal{E}_{\geqslant 0}$ can be extended to an accessible t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$ on $\mathcal{E}$. Unwinding the definitions, we see that an object $X \in \mathcal{E}$ belongs to $\mathcal{E}_{\leqslant 0}$ if and only if each of the mapping spaces

$$\mathrm{Map}_{\mathcal{E}}(L\Sigma^\infty C_\beta, \Omega X) \simeq \mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(\Sigma^\infty C_\beta, \Omega X)$$

is discrete. It follows that $\mathcal{E}_{\leqslant 0} = \mathcal{E} \cap \mathrm{Sp}(\mathcal{C})_{\leqslant 0}$, which proves (b).

Let $\mathcal{D}$ denote the full subcategory of $\mathrm{Sp}(\mathcal{C})$ spanned by those objects X such that $LX \simeq 0$, and let $\overline{\mathcal{D}}$ be the full subcategory of $\mathrm{Sp}(\mathcal{C})$ spanned by those objects X such that $\pi_n X \in \mathcal{A}_0$ for every integer n. We next prove:

- $(*)$ There are inclusions $\overline{\mathcal{D}} \cap \mathrm{Sp}(\mathcal{C})_{\leqslant 0} \subseteq \mathcal{D} \subseteq \overline{\mathcal{D}}$.

Note that $\mathcal{D}$ is generated under small colimits by the collection of objects $\{\Sigma^n A_\alpha\}$. Since each of these objects belongs to $\overline{\mathcal{D}}$ and $\overline{\mathcal{D}}$ is closed under small colimits, it follows that $\mathcal{D} \subseteq \overline{\mathcal{D}}$. To prove the other inclusion, we note that the t-structure on $\mathrm{Sp}(\mathcal{C})$ is right complete, so that every object $X \in \mathrm{Sp}(\mathcal{C})$ can be obtained as a colimit $\varinjlim \tau_{\geqslant -n} X$. If X belongs to $\overline{\mathcal{D}} \cap \mathrm{Sp}(\mathcal{C})_{\leqslant 0}$, then each truncation $\tau_{\geqslant -n} X$ can be written as a finite extension of desuspensions of objects of $\mathcal{A}_0$, and is therefore annihilated by L. Since L preserves small colimits, it follows that $LX \simeq 0$.

Let X be any object of $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ and form a fiber sequence $X' \xrightarrow{u} X \to LX$. Then X' is annihilated by the functor L, so that $(*)$ implies that the homotopy groups $\pi_n X'$ belong to $\mathcal{A}_0$ for every integer n. Our assumption that X belong to $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ guarantees that we can factor the map u as a composition $X' \xrightarrow{u'} X'' \xrightarrow{u''} X$, where $X'' \in \mathrm{Sp}(\mathcal{C})_{\leqslant 0}$, the maps $\pi_n X' \to \pi_n X''$ are isomorphisms for $n < 0$, the map $\pi_0 X' \to \pi_0 X''$ is an epimorphism, and the map $\pi_0 X'' \to \pi_0 X$ is a monomorphism. It follows that the objects $\pi_n X''$ belong to $\mathcal{A}_0$ for all $n \in \mathbf{Z}$. Applying $(*)$ again, we see that $X'' \in \mathcal{D}$. By construction, X' is a final object of $\mathcal{D} \times_{\mathrm{Sp}(\mathcal{C})} \mathrm{Sp}(\mathcal{C})_{/X}$, so that X' is a retract of X'' in the ∞-category $\mathrm{Sp}(\mathcal{C})_{/X}$. It follows $X' \in \mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ and that the map $\pi_0(u) : \pi_0 X' \to \pi_0 X$ is a monomorphism in $\mathrm{Sp}(\mathcal{C})^{\heartsuit}$, from which we conclude that $LX \simeq \mathrm{cofib}(u)$ also belongs to $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$. This proves that the functor $L : \mathrm{Sp}(\mathcal{C}) \to \mathcal{E}$ is left t-exact. The right t-exactness of L follows immediately from the fact that L is left adjoint to the left t-exact inclusion functor $\mathcal{E} \hookrightarrow \mathrm{Sp}(\mathcal{C})$. This completes the proof of (c).

We now prove (d). Let $\{X_\alpha\}$ be a small filtered diagram in the ∞-category $\mathcal{E}_{\leqslant 0}$, and let $X = \varinjlim X_\alpha$ be its colimit in the ∞-category $\mathrm{Sp}(\mathcal{C})$. Then X belongs to $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ (since the t-structure on $\mathrm{Sp}(\mathcal{C})$ is compatible with filtered colimits). It follows from (c) that $LX \in \mathcal{E}_{\leqslant 0}$. Note that LX can be identified with the colimit of the diagram $\{X_\alpha\}$ in the ∞-category $\mathcal{E}$, so that the t-structure on $\mathcal{E}$ is compatible with filtered colimits. The right completeness of $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$ now follows from Proposition **??**, since the intersection $\bigcap_{n \geqslant 0} \mathcal{E}_{\leqslant -n} \subseteq \bigcap_{n \geqslant 0} \mathrm{Sp}(\mathcal{C})_{\leqslant -n}$ contains only zero objects of $\mathrm{Sp}(\mathcal{C})$.

Assertion (e) follows from (a), (b), and (d) (see Proposition C.1.4.1). We now prove (f). It follows from (c) that L restricts to a functor $L_{\geqslant 0} : \mathrm{Sp}(\mathcal{C})_{\geqslant 0} \to \mathcal{E}_{\geqslant 0}$. Unwinding the definitions, we see that $L_{\geqslant 0}$ is left adjoint to the composite functor

$$\mathcal{E}_{\geqslant 0} \hookrightarrow \mathcal{E} \hookrightarrow \mathrm{Sp}(\mathcal{C}) \xrightarrow{\tau_{\geqslant 0}} \mathrm{Sp}(\mathcal{C})_{\geqslant 0}.$$

We claim that this composite functor is fully faithful. To prove this, choose an arbitrary object $X \in \mathcal{E}$, and consider the fiber sequence

$$\tau_{\geqslant 0} X \to X \to \tau_{\leqslant -1} X$$

where the truncations are formed with respect to the t-structure on $\mathrm{Sp}(\mathcal{C})$. Applying the functor L (and invoking our assumption that $X \in \mathcal{E}$), we obtain a fiber sequence

$$L(\tau_{\geqslant 0} X) \xrightarrow{u_X} X \to L(\tau_{\leqslant -1} X)$$

in the ∞-category $\mathcal{E}$. It follows from (c) that the map u_X exhibits $L(\tau_{\geqslant 0}X)$ as the connective cover of X with respect to the t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$. In particular, if X belongs to $\mathcal{E}_{\geqslant 0}$, then the map u is an equivalence. Allowing X to vary, we conclude that the functor $\tau_{\geqslant 0} : \mathcal{E}_{\geqslant 0} \to \mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ is fully faithful. That is, $L_{\geqslant 0} : \mathrm{Sp}(\mathcal{C})_{\geqslant 0} \to \mathcal{E}_{\geqslant 0}$ exhibits $\mathcal{E}_{\geqslant 0}$ as an accessible left exact localization of $\mathcal{C} \simeq \mathrm{Sp}(\mathcal{C})_{\geqslant 0}$, so that $\mathcal{C}_0$ is a localizing subcategory of $\mathcal{C}$ (Proposition C.2.3.8). By construction, an object $C \in \mathcal{C}$ belongs to $\mathcal{C}_0$ if and only if $\Sigma^{\infty} C$ belongs to $\mathcal{D} \subseteq \mathrm{Sp}(\mathcal{C})$, so the equality $\mathcal{C}_0^{\heartsuit} = \mathcal{A}_0$ is a special case of $(*)$.

We now prove (g). Let $\mathcal{C}_1$ be any localizing subcategory of $\mathcal{C}$ which contains $\mathcal{A}_0$. The inclusion $\mathcal{C}/\mathcal{C}_1 \hookrightarrow \mathcal{C}$ extends to a fully faithful embedding $g : \mathrm{Sp}(\mathcal{C}/\mathcal{C}_1) \hookrightarrow \mathrm{Sp}(\mathcal{C})$. To show that $\mathcal{C}_0 \subseteq \mathcal{C}_1$, it will suffice to show that the essential image of g is contained in $\mathrm{Sp}(\mathcal{C}/\mathcal{C}_0) \simeq \mathcal{E} \subseteq \mathrm{Sp}(\mathcal{C})$. This is equivalent to the requirement that the left adjoint of g annihilates the subcategory $\mathcal{A}_0 \subseteq \mathrm{Sp}(\mathcal{C})^{\heartsuit}$, which follows from our assumption that $\mathcal{C}_1$ contains $\mathcal{A}_0$. □

C.5.3 Complicial Prestable ∞-Categories

We now study a class of Grothendieck prestable ∞-categories $\mathcal{C}$ which are "controlled" by their n-truncated objects, for some $n \geqslant 0$.

Definition C.5.3.1. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $n \geqslant 0$ be an integer. We will say that $\mathcal{C}$ is *n-complicial* if, for every object $X \in \mathcal{C}$, there exists a morphism $f : \overline{X} \to X$ where $\overline{X}$ is n-truncated and the induced map $\pi_0 \overline{X} \to \pi_0 X$ is an epimorphism in the abelian category $\mathcal{C}^{\heartsuit}$.

The terminology of Definition C.5.3.1 is motivated by the following observation:

Proposition C.5.3.2. *Let $\mathcal{A}$ be a Grothendieck abelian category, let $\mathcal{D}(\mathcal{A})$ denote the (unbounded) derived ∞-category of $\mathcal{A}$ (see §HA.**??**), and regard $\mathcal{D}(\mathcal{A})$ as equipped with the t-structure $(\mathcal{D}(\mathcal{A})_{\geqslant 0}, \mathcal{D}(\mathcal{A})_{\leqslant 0})$ of Proposition HA.1.3.5.21 . Then $\mathcal{D}(\mathcal{A})_{\geqslant 0}$ is a 0-complicial Grothendieck prestable ∞-category.*

Proof. We have already seen that $\mathcal{D}(\mathcal{A})_{\geqslant 0}$ is a Grothendieck prestable ∞-category (Example C.1.4.5). We claim that it is 0-complicial. To prove this, choose an object $X_\bullet \in \mathcal{D}(\mathcal{A})_{\geqslant 0}$, which we can identify with a chain complex

$$\cdots X_2 \xrightarrow{d_2} X_1 \xrightarrow{d_1} X_0 \xrightarrow{d_0} X_{-1} \xrightarrow{d_{-1}} X_{-2} \to \cdots$$

in the abelian category $\mathcal{A}$. Let $\overline{X} = \ker(d_0) \in \mathcal{A}$. Then there is an evident map $\overline{X} \to X$ in $\mathcal{D}(\mathcal{A})_{\geqslant 0}$ (where we abuse notation by identifying $\overline{X}$ with its image under the equivalence $\mathcal{A} \simeq \mathcal{D}(\mathcal{A})^{\heartsuit}$) which induces an epimorphism on homology in degree zero. □

Our first goal is to show that n-complicial Grothendieck prestable ∞-categories exist in abundance.

Proposition C.5.3.3. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a localizing subcategory. If $\mathcal{C}$ is n-complicial, then $\mathcal{C}/\mathcal{C}_0$ is n-complicial.*

Proof. Let us regard $\mathcal{C}/\mathcal{C}_0$ as a full subcategory of $\mathcal{C}$, and let $L : \mathcal{C} \to \mathcal{C}/\mathcal{C}_0$ be a left adjoint to the inclusion. For any object $X \in \mathcal{C}/\mathcal{C}_0$, we can choose a morphism $\alpha : \overline{X} \to X$, where $\overline{X}$ is an n-truncated object of $\mathcal{C}$ and the induced map $\pi_0\overline{X} \to \pi_0 X$ is an epimorphism in the abelian category $\mathcal{C}^{\heartsuit}$. Since X belongs to $\mathcal{C}/\mathcal{C}_0$, the morphism α factors as a composition $\overline{X} \to L\overline{X} \xrightarrow{\alpha'} X$. Because L is left exact, the object $L\overline{X} \in \mathcal{C}/\mathcal{C}_0$ is also n-truncated. The induced map $\pi_0 L\overline{X} \to \pi_0 X$ is the image of $\pi_0(\alpha)$ under the exact functor $L^{\heartsuit} : \mathcal{C}^{\heartsuit} \to (\mathcal{C}/\mathcal{C}_0)^{\heartsuit}$, and is therefore an epimorphism the abelian category $(\mathcal{C}/\mathcal{C}_0)^{\heartsuit}$. □

Proposition C.5.3.4. *Let $\mathcal{A}$ be an essentially small additive ∞-category. Suppose that, for every pair of objects $X, Y \in \mathcal{A}$, the mapping space $\mathrm{Map}_{\mathcal{A}}(X,Y)$ is n-truncated. Then $\mathcal{P}_{\Sigma}(\mathcal{A}) = \mathrm{Fun}^{\pi}(\mathcal{A}^{\mathrm{op}}, \mathcal{S})$ is an n-complicial Grothendieck prestable ∞-category.*

Proof. It follows from Remark C.1.5.10 that $\mathrm{Fun}^{\pi}(\mathcal{A}^{\mathrm{op}}, \mathcal{S})$ is Grothendieck prestable ∞-category. Let $j : \mathcal{A} \to \mathrm{Fun}^{\pi}(\mathcal{A}^{\mathrm{op}}, \mathcal{S})$ be the Yoneda embedding. Since $\mathrm{Fun}^{\pi}(\mathcal{A}^{\mathrm{op}}, \mathcal{S})$ is generated under small colimits by the essential image of j, for every object $X \in \mathrm{Fun}^{\pi}(\mathcal{A}^{\mathrm{op}}, \mathcal{S})$ we can choose a map $\overline{X} \to X$ which is an epimorphism on π_0, where $\overline{X}$ is a small coproduct of objects belonging to the essential image of j. Our assumption that the mapping spaces in $\mathcal{A}$ are n-truncated guarantees that j takes values in $\tau_{\leqslant n} \mathrm{Fun}^{\pi}(\mathcal{A}^{\mathrm{op}}, \mathcal{S})$, so that $\overline{X}$ is n-truncated. □

Example C.5.3.5. Let A be an $\mathbb{E}_1$-ring which is connective and n-truncated. Then the Grothendieck prestable ∞-category $\mathrm{LMod}_A^{\mathrm{cn}}$ is n-complicial.

Any Grothendieck prestable ∞-category $\mathcal{C}$ which both separated and n-complicial can be obtained by combining Propositions C.5.3.4 and C.5.3.3:

Proposition C.5.3.6. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $n \geqslant 0$. The following conditions are equivalent:*

- (a) *The Grothendieck prestable ∞-category $\mathcal{C}$ is separated and n-complicial.*
- (b) *There exists an essentially small additive $(n+1)$-category $\mathcal{A}$, a separating localizing subcategory $\mathcal{E} \subseteq \mathcal{P}_{\Sigma}(\mathcal{A})$, and an equivalence $\mathcal{C} \simeq \mathcal{P}_{\Sigma}(\mathcal{A})/\mathcal{E}$.*

Proof. The implication $(b) \Rightarrow (a)$ follows immediately from Propositions C.5.3.3 and C.5.3.4. For the converse, we note that if $\mathcal{C}$ is n-complicial then we can choose an an essentially small generating subcategory $\mathcal{A} \subseteq \mathcal{C}$ (in the sense of Definition C.2.1.1) which consists of n-truncated objects. Enlarging $\mathcal{A}$ if necessary, we may assume that $\mathcal{A}$ is closed under finite direct sums. If $\mathcal{C}$ is separated, then Theorem C.2.1.6 implies that the inclusion $\mathcal{A} \hookrightarrow \mathcal{C}$

extends to a left exact localization functor $\mathcal{P}_\Sigma(\mathcal{A}) \to \mathcal{C}$, so that $\mathcal{C}$ can be identified with $\mathcal{P}_\Sigma(\mathcal{A})/\mathcal{E}$ for some localizing subcategory $\mathcal{E} \subseteq \mathcal{P}_\Sigma(\mathcal{A})$ (Proposition C.2.3.8); since $\mathcal{C}$ is separated, the localizing subcategory $\mathcal{E}$ is separating. □

Notation C.5.3.7. For Grothendieck prestable ∞-categories $\mathcal{C}$ and $\mathcal{D}$, we let $\mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ spanned by those functors which are left exact and preserve small colimits. Note that if $F \in \mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}, \mathcal{D})$, then F induces a functor $F_{\leqslant n} : \tau_{\leqslant n}\,\mathcal{C} \to \tau_{\leqslant n}\,\mathcal{D}$, for each $n \geqslant 0$. We will say that F is an *n-equivalence* if the functor $F_{\leqslant n}$ is an equivalence of ∞-categories.

Proposition C.5.3.8. *Let $\mathcal{C}$ be a separated Grothendieck prestable ∞-category and let $n \geqslant 0$. Then there exists a separated, n-complicial Grothendieck prestable ∞-category $\mathcal{C}'$ and an n-equivalence $\lambda \in \mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}', \mathcal{C})$.*

Proof. Choose an essentially small full subcategory $\mathcal{A} \subseteq \tau_{\leqslant n}\,\mathcal{C}$ with the property that, for every object $C \in \tau_{\leqslant n}\,\mathcal{C}$, there exists a map $\bigoplus_{i \in I} A_i \to C$ which induces an epimorphism $\bigoplus_{i \in I} \pi_0 A_i \to \pi_0 C$ in $\mathcal{C}^{\heartsuit}$, where each A_i belongs to $\mathcal{A}$ (for example, we choose a regular cardinal κ such that $\tau_{\leqslant n}\,\mathcal{C}$ is κ-accessible, and take $\mathcal{A}$ to be the full subcategory of $\tau_{\leqslant n}\,\mathcal{C}$ spanned by the κ-compact objects). Enlarging $\mathcal{A}$ if necessary, we may assume that $\mathcal{A}$ is closed under finite direct sums. Set $\overline{\mathcal{C}} = \mathcal{P}_\Sigma(\mathcal{A}) = \mathrm{Fun}^{\pi}(\mathcal{A}^{\mathrm{op}}, \mathcal{S})$. Using Proposition C.2.5.2, we see that the inclusion functor $\mathcal{A} \hookrightarrow \tau_{\leqslant n}\,\mathcal{C} \hookrightarrow \mathcal{C}$ extends to a left exact functor $F : \overline{\mathcal{C}} \to \mathcal{C}$ (Proposition C.2.5.2). Let $\overline{\mathcal{C}}_0$ be the full subcategory of $\overline{\mathcal{C}}$ spanned by those objects which are annihilated by F. Then $\overline{\mathcal{C}}_0$ is a localizing subcategory of $\overline{\mathcal{C}}$ (see Example C.2.3.7). Set $\mathcal{C}' = \overline{\mathcal{C}}/\overline{\mathcal{C}}_0$, so that the functor F factors (up to homotopy) as a composition

$$\overline{\mathcal{C}} \to \overline{\mathcal{C}}/\overline{\mathcal{C}}_0 = \mathcal{C}' \xrightarrow{\lambda} \mathcal{C},$$

where λ is a functor preserving small colimits and finite limits (Remark C.2.3.11). We claim that λ has the desired properties. To see this, we first note that $\overline{\mathcal{C}}$ is n-complicial (Proposition C.5.3.4), so the quotient $\mathcal{C}' \simeq \overline{\mathcal{C}}/\overline{\mathcal{C}}_0$ is also n-complicial (Proposition C.5.3.3). The functor λ is conservative by construction. Since λ is left exact, the separatedness of $\mathcal{C}$ implies the separatedness of $\mathcal{C}'$.

We now complete the proof by showing that λ restricts to an equivalence of ∞-categories $\lambda_n : \tau_{\leqslant n}\,\mathcal{C}' \to \tau_{\leqslant n}\,\mathcal{C}$. Let $G : \mathcal{C} \to \overline{\mathcal{C}}$ be a right adjoint to F. By construction, the functor G factors through the full subcategory $\overline{\mathcal{C}}/\overline{\mathcal{C}}_0$; moreover, when regarded as a functor from $\mathcal{C}$ to $\overline{\mathcal{C}}/\overline{\mathcal{C}}_0 = \mathcal{C}'$, the functor G is right adjoint to λ. It follows that λ and G determine adjoint functors $\tau_{\leqslant n}\,\mathcal{C}' \underset{G_n}{\overset{\lambda_n}{\rightleftarrows}} \tau_{\leqslant n}\,\mathcal{C}$. Proposition C.2.5.3 implies that the functor G_n is fully faithful. Since the functor λ is conservative, it follows that λ_n and G_n are mutually inverse equivalences of ∞-categories. □

Our next goal is to show that for any separated Grothendieck prestable ∞-category $\mathcal{C}$, the functor $\lambda : \mathcal{C}' \to \mathcal{C}$ of Proposition C.5.3.8 is unique (up to canonical equivalence). We will deduce this from the following universal property of n-complicial Grothendieck prestable ∞-categories:

Proposition C.5.3.9. *Let $\mathcal{C}$ and $\mathcal{D}$ be Grothendieck prestable ∞-categories and let $n \geqslant 0$ be an integer. Suppose that $\mathcal{C}$ is n-complicial and that $\mathcal{D}$ is separated. Then the restriction functor $\phi : \mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}, \mathcal{D}) \to \mathrm{Fun}(\tau_{\leqslant n}\,\mathcal{C}, \tau_{\leqslant n}\,\mathcal{D})$ is a fully faithful embedding, whose essential image is spanned by those functors $f : \tau_{\leqslant n}\,\mathcal{C} \to \tau_{\leqslant n}\,\mathcal{D}$ which are left exact and commute with small colimits.*

Proof. Consider first the special case where $\mathcal{C} = \mathcal{P}_{\Sigma}(\mathcal{A})$, where $\mathcal{A}$ is an essentially small additive $(n+1)$-category. Using Proposition HTT.5.5.8.15 , we see that composition with the Yoneda embedding $j : \mathcal{A} \to \mathcal{C}$ induces equivalences of ∞-categories

$$\mathrm{LFun}(\mathcal{C}, \mathcal{D}) \xrightarrow{\mu} \mathrm{Fun}^{\pi}(\mathcal{A}, \mathcal{D}) \qquad \mathrm{LFun}(\tau_{\leqslant n}\,\mathcal{C}, \tau_{\leqslant n}\,\mathcal{D}) \simeq \mathrm{LFun}(\mathcal{C}, \tau_{\leqslant n}\,\mathcal{D}) \to \mathrm{Fun}^{\pi}(\mathcal{A}, \tau_{\leqslant n}\,\mathcal{D}).$$

Note that the functor j takes values in the full subcategory $\tau_{\leqslant n}\,\mathcal{C}$. Consequently, the functor μ carries $\mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}, \mathcal{D}) \subseteq \mathrm{LFun}(\mathcal{C}, \mathcal{D})$ to the full subcategory $\mathrm{Fun}^{\pi}(\mathcal{A}, \tau_{\leqslant n}\,\mathcal{D})$. These identifications fit into a commutative diagram

$$\begin{array}{ccc} \mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}, \mathcal{D}) & \xrightarrow{\phi} & \mathrm{LFun}(\tau_{\leqslant n}\,\mathcal{C}, \tau_{\leqslant n}\,\mathcal{D}) \\ \downarrow{\scriptstyle \mu} & & \downarrow{\scriptstyle \sim} \\ \mathrm{Fun}^{\pi}(\mathcal{A}, \tau_{\leqslant n}\,\mathcal{D}) & \xrightarrow{\mathrm{id}} & \mathrm{Fun}^{\pi}(\mathcal{A}, \tau_{\leqslant n}\,\mathcal{D}) \end{array}$$

To complete the proof, it will suffice to show that if $F : \mathcal{C} \to \mathcal{D}$ is a colimit-preserving functor such that $F(\mathcal{A}) \subseteq \tau_{\leqslant n}\,\mathcal{D}$ and the composite functor

$$\tau_{\leqslant n}\,\mathcal{C} \hookrightarrow \mathcal{C} \xrightarrow{F} \mathcal{D} \xrightarrow{\tau_{\leqslant n}} \tau_{\leqslant n}\,\mathcal{D}$$

is left exact, then F is left exact. For this, it will suffice to show that for each discrete object $C \in \mathcal{C}^{\heartsuit}$, the image $F(C) \in \mathcal{D}$ is also discrete (Proposition C.3.2.1). Since $(\tau_{\leqslant n} F) : \tau_{\leqslant n}\,\mathcal{C} \to \tau_{\leqslant n}\,\mathcal{D}$ is left exact, it is automatic that $\tau_{\leqslant n} F(C)$ is a discrete object of $\mathcal{D}$. We will complete the proof by showing that $F(C)$ is n-truncated. This is a special case of the following more general assertion:

$(*)$ For each n-truncated object $Z \in \mathcal{C}$, the object $F(Z) \in \mathcal{D}$ is also n-truncated.

Since $\mathcal{D}$ is separated, $(*)$ is equivalent to the assertion that for each n-truncated object $C \in \mathcal{C}$, the homotopy groups $\pi_m F(Z) \in \mathcal{D}^{\heartsuit}$ vanish for $m > n$. We prove this by induction on m. Let Z be an n-truncated object of $\mathcal{C}$, and choose a map $Y \to Z$, where Y is a coproduct of objects belonging to $\mathcal{A}$ and the induced map $\pi_0 Y \twoheadrightarrow \pi_0 Z$ is an epimorphism in the abelian category $\mathcal{C}^{\heartsuit}$. We then have a cofiber sequence $X \to Y \to Z$, where X and Y are also n-truncated. The cofiber sequence $FX \to FY \to FZ$ yields a long exact sequence of homotopy groups

$$\pi_m FY \to \pi_m FZ \to \pi_{m-1} FX \xrightarrow{\beta} \pi_{m-1} FY.$$

The functor F commutes with coproducts and carries $\mathcal{A}$ into $\tau_{\leqslant n}\mathcal{D}$, so that FY is n-truncated. It follows that $\pi_m FY$ vanishes for $m > n$. Consequently, to show that $\pi_m FZ$ vanishes, it will suffice to show that the map β is a monomorphism in the abelian category $\mathcal{D}^{\heartsuit}$. For $m > n+1$, our inductive hypothesis implies that $\pi_{m-1} FX$ vanishes, and there is nothing to prove. When $m = n+1$, we note that the n-truncatedness of Z implies that the morphism $X \to Y$ is $(n-1)$-truncated. Since the functor $\tau_{\leqslant n} F$ is left exact, the map $\tau_{\leqslant n} FX \to \tau_{\leqslant n} FY$ is also $(n-1)$-truncated, which guarantees that β is injective as desired. This completes the proof of Proposition C.5.3.9 in the special case $\mathcal{C} = \mathcal{P}_{\Sigma}(\mathcal{C})$.

We now treat the general case. Let $\mathcal{C}$ be any n-complicial Grothendieck prestable ∞-category, and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be the full subcategory consisting of objects which are n-connective for all n. Since $\mathcal{D}$ is separated, any colimit-preserving functor $\mathcal{C} \to \mathcal{D}$ must annihilate $\mathcal{C}_0$. We may therefore replace $\mathcal{C}$ by $\mathcal{C} / \mathcal{C}_0$ and thereby reduce to the case where $\mathcal{C}$ is also separated. Applying Proposition C.5.3.6, we obtain an equivalence $\mathcal{C} \simeq \mathcal{P}_{\Sigma}(\mathcal{A}) / \mathcal{E}$ for some essentially small additive $(n+1)$-category $\mathcal{A}$ and some separating localizing subcategory $\mathcal{E} \subseteq \mathcal{P}_{\Sigma}(\mathcal{A})$. This equivalence determines a commutative diagram

$$\begin{array}{ccc} \mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}, \mathcal{D}) & \xrightarrow{\phi} & \mathrm{LFun}(\tau_{\leqslant n}\mathcal{C}, \tau_{\leqslant n}\mathcal{D}) \\ \downarrow & & \downarrow \\ \mathrm{LFun}^{\mathrm{lex}}(\mathcal{P}_{\Sigma}(\mathcal{A}), \mathcal{D}) & \longrightarrow & \mathrm{LFun}(\tau_{\leqslant n}\mathcal{P}_{\Sigma}(\mathcal{A}), \tau_{\leqslant n}\mathcal{D}) \end{array}$$

where the vertical maps are fully faithful. It follows from the first part of the proof that the functor ϕ must also be fully faithful. To complete the proof, it will suffice (by virtue of Proposition C.2.3.10 and Remark C.2.3.11) to show that if $F : \mathcal{P}_{\Sigma}(\mathcal{A}) \to \mathcal{D}$ is functor which is left exact and preserves small colimits for which the composite functor $\mathcal{P}_{\Sigma}(\mathcal{A}) \xrightarrow{F} \mathcal{D} \xrightarrow{\tau_{\leqslant m}} \mathcal{D}$ factors through $\mathcal{C}$, then the functor F annihilates $\mathcal{E}$. This is clear: since $\mathcal{D}$ is separated and F is left exact, the functor F annihilates $\mathcal{E}$ if and only if it annihilates the abelian category $\mathcal{E}^{\heartsuit}$. $\square$

C.5.4 Grothendieck Abelian n-Categories

Let $\mathcal{A}$ be a category. According to Remark C.1.4.6, $\mathcal{A}$ is a Grothendieck abelian category if and only if there exists a Grothendieck prestable ∞-category $\mathcal{C}$ and an equivalence $\mathcal{A} \simeq \mathcal{C}^{\heartsuit}$. We now consider a mild generalization:

Definition C.5.4.1. Let $\mathcal{A}$ be an ∞-category and let $n \geqslant 0$. We will say that $\mathcal{A}$ is a *Grothendieck abelian* $(n+1)$*-category* if there exists an equivalence $\mathcal{A} \simeq \tau_{\leqslant n} \mathcal{C}$, where $\mathcal{C}$ is a Grothendieck prestable ∞-category. We let Groth_n denote the subcategory of $\widehat{\mathcal{C}\mathrm{at}}_\infty$ whose objects are Grothendieck abelian $(n+1)$-categories and whose morphisms are functors which preserve small colimits. We let $\mathsf{Groth}_n^{\mathrm{lex}}$ denote the subcategory of $\widehat{\mathcal{C}\mathrm{at}}_\infty$ whose objects are Grothendieck abelian $(n+1)$-categories and whose morphisms are functors which preserve small colimits and finite limits. In the special case $n = 0$, we will denote Groth_n and $\mathsf{Groth}_n^{\mathrm{lex}}$ by $\mathsf{Groth}_{\mathrm{ab}}$ and $\mathsf{Groth}_{\mathrm{ab}}^{\mathrm{lex}}$, respectively.

Remark C.5.4.2. Every Grothendieck abelian n-category is a presentable ∞-category. Consequently, for each $n \geqslant 0$, we can regard Groth_n as a full subcategory of the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable ∞-categories.

Remark C.5.4.3. For each $n \geqslant 0$, the ∞-category Groth_n is actually an $(n+2)$-category: that is, for every pair of objects $\mathcal{A}, \mathcal{B} \in \mathsf{Groth}_n$, the mapping space $\mathrm{Map}_{\mathsf{Groth}_n}(\mathcal{A}, \mathcal{B})$ is $(n+1)$-truncated. (it is the underlying Kan complex of the ∞-category $\mathrm{LFun}(\mathcal{A}, \mathcal{B})$ of colimit-preserving functors from $\mathcal{A}$ to $\mathcal{B}$).

Example C.5.4.4. Let $F : \mathcal{C} \to \mathcal{D}$ be a colimit-preserving functor between Grothendieck prestable ∞-categories. Tensoring with $\tau_{\leqslant n} \mathcal{S}$, we obtain a colimit-preserving functor

$$F_{\leqslant n} : \tau_{\leqslant n} \mathcal{C} \simeq \mathcal{C} \otimes \tau_{\leqslant n} \mathcal{S} \xrightarrow{F \otimes \mathrm{id}} \mathcal{D} \otimes \tau_{\leqslant n} \mathcal{S} \simeq \tau_{\leqslant n} \mathcal{D},$$

given concretely by the formula $F_{\leqslant n}(C) = \tau_{\leqslant n} F(C)$. This construction determines a functor $\mathsf{Groth}_\infty \to \mathsf{Groth}_n$, given on objects by $\mathcal{C} \mapsto \tau_{\leqslant n} \mathcal{C}$.

Note that if F is left exact, then we can identify the functor $F_{\leqslant n} : \tau_{\leqslant n} \mathcal{C} \to \tau_{\leqslant n} \mathcal{D}$ with the restriction $F|_{\tau_{\leqslant n} \mathcal{C}}$. It follows that $F_{\leqslant n}$ is also left exact, so that the construction $\mathcal{C} \mapsto \tau_{\leqslant n} \mathcal{C}$ determines a functor $\mathsf{Groth}_\infty^{\mathrm{lex}} \to \mathsf{Groth}_n^{\mathrm{lex}}$.

Every Grothendieck abelian category $\mathcal{A}$ admits a *canonical* realization as the heart of a Grothendieck prestable ∞-category $\mathcal{C}$: we can take $\mathcal{C}$ to be the ∞-category $\mathcal{D}(\mathcal{A})_{\geqslant 0}$ of connective objects of the derived ∞-category $\mathcal{D}(\mathcal{A})$. Using the results of §C.5.3, we can provide an analogous realization for Grothendieck abelian n-categories:

Proposition C.5.4.5. *Let $\mathsf{Groth}_\infty^{\mathrm{lex,sep}}$ denote the subcategory of Groth_∞ whose objects are separated Grothendieck prestable ∞-categories and whose morphisms are left exact functors which preserve small colimits. Let $n \geqslant 0$, and let $L : \mathsf{Groth}_\infty^{\mathrm{lex,sep}} \to \mathsf{Groth}_n^{\mathrm{lex}}$ be the functor $\mathcal{C} \mapsto \tau_{\leqslant n} \mathcal{C}$ of Example C.5.4.4 (restricted to separated prestable ∞-categories). Then L admits a fully faithful left adjoint $\mathsf{Groth}_n^{\mathrm{lex}} \hookrightarrow \mathsf{Groth}_\infty^{\mathrm{lex,sep}}$, whose essential image is spanned by those Grothendieck prestable ∞-categories $\mathcal{C}$ which are separated and n-complicial.*

Proof. Let $\mathcal{E} \subseteq \mathsf{Groth}_{\infty}^{\mathrm{lex,sep}}$ denote the full subcategory spanned by those separated Grothendieck prestable ∞-categories which are n-complicial. We first claim that $\mathcal{E}$ is a colocalization of $\mathsf{Groth}_{\infty}^{\mathrm{lex,sep}}$. In other words, for every object $\mathcal{C} \in \mathsf{Groth}_{\infty}^{\mathrm{lex,sep}}$, we claim that there exists a morphism $\lambda : \mathcal{C}' \to \mathcal{C}$ in $\mathsf{Groth}_{\infty}^{\mathrm{lex,sep}}$ where $\mathcal{C}'$ is n-complicial and, for every n-complicial separated Grothendieck prestable ∞-category $\mathcal{C}''$, composition with λ induces a homotopy equivalence

$$\mathrm{Map}_{\mathsf{Groth}_{\infty}^{\mathrm{lex,sep}}}(\mathcal{C}'', \mathcal{C}') \to \mathrm{Map}_{\mathsf{Groth}_{\infty}^{\mathrm{lex,sep}}}(\mathcal{C}'', \mathcal{C}).$$

By virtue of Proposition C.5.3.9, to guarantee the latter property it suffices to arrange that λ is an n-equivalence, which is always possible by virtue of Proposition C.5.3.8.

Note that the functor L carries n-equivalences in $\mathsf{Groth}_{\infty}^{\mathrm{lex,sep}}$ to equivalences in $\mathsf{Groth}_{n}^{\mathrm{lex}}$, and therefore factors as a composition

$$\mathsf{Groth}_{\infty}^{\mathrm{lex,sep}} \xrightarrow{L'} \mathcal{E} \xrightarrow{L''} \mathsf{Groth}_{n}^{\mathrm{lex}}$$

where L' is right adjoint to the inclusion $\mathcal{E} \hookrightarrow \mathsf{Groth}_{\infty}^{\mathrm{lex,sep}}$, and L'' is the restriction $L|_{\mathcal{E}}$. To complete the proof, it will suffice to show that the functor L'' is an equivalence of ∞-categories. The assertion that L'' is fully faithful follows immediately from Proposition C.5.3.9. We will complete the proof by showing that L'' is essentially surjective. Let $\mathcal{A}$ be a Grothendieck abelian $(n+1)$-category, so that $\mathcal{A} \simeq \tau_{\leqslant n}\mathcal{C}$ for some Grothendieck prestable ∞-category $\mathcal{C}$. We wish to show that we can arrange that $\mathcal{C}$ is separated and n-complicial. To prove this, we first replace $\mathcal{C}$ by its separated quotient (see Proposition C.3.6.1) to arrange that $\mathcal{C}$ is separated, and then apply Proposition C.5.3.8. □

Remark C.5.4.6. Let $\mathcal{C}$ be a separated Grothendieck prestable ∞-category. The proof of Proposition C.5.4.5 shows that the functor $\lambda : \mathcal{C}' \to \mathcal{C}$ appearing in Proposition C.5.3.8 is determined uniquely (up to equivalence) by $\mathcal{C}$.

Warning C.5.4.7. In the statement of Proposition C.5.4.5, the left exactness assumption is essential. The construction $\mathcal{C} \mapsto \tau_{\leqslant n}\mathcal{C}$ determines a functor $\mathsf{Groth}_{\infty}^{\mathrm{sep}} \to \mathsf{Groth}_{n}$ (see Example C.5.4.4) which does *not* have a fully faithful right adjoint: for example, if $\mathcal{C}$ is any separated Grothendieck prestable ∞-category, then the suspension functor $\Sigma^n : \mathcal{C} \to \mathcal{C}$ is a morphism in $\mathsf{Groth}_{\infty}^{\mathrm{sep}}$ whose image in Groth_{n} is nullhomotopic.

Arguing as in Example C.5.4.4, we see that the construction $\mathcal{C} \mapsto \tau_{\leqslant m}\mathcal{C}$ determines a forgetful functor $\mathsf{Groth}_{n} \to \mathsf{Groth}_{m}$ for all $m \leqslant n$. We therefore obtain a tower of ∞-categories

$$\mathsf{Groth}_{\infty} \to \cdots \to \mathsf{Groth}_{2} \to \mathsf{Groth}_{1} \to \mathsf{Groth}_{0} = \mathsf{Groth}_{\mathrm{ab}},$$

which determines a functor $\mathsf{Groth}_{\infty} \to \varprojlim \mathsf{Groth}_{n}$.

Theorem C.5.4.8. *The functor $\theta : \mathsf{Groth}_{\infty} \to \varprojlim \mathsf{Groth}_{n}$ described above restricts to an equivalence of ∞-categories $\theta^{\mathrm{comp}} : \mathsf{Groth}_{\infty}^{\mathrm{comp}} \to \varprojlim \mathsf{Groth}_{n}$.*

Proof. We first show that θ^{comp} is fully faithful. Let $\mathcal{C}$ and $\mathcal{D}$ be Grothendieck prestable ∞-categories. Unwinding the definitions, we have canonical homotopy equivalences

$$\begin{aligned} \mathrm{Map}_{\varprojlim \mathsf{Groth}_n}(\theta(\mathcal{C}), \theta(\mathcal{D})) &\simeq \varprojlim \mathrm{Map}_{\mathsf{Groth}_n}(\tau_{\leqslant n}\,\mathcal{C}, \tau_{\leqslant n}\,\mathcal{D}) \\ &\simeq \varprojlim \mathrm{LFun}(\tau_{\leqslant n}\,\mathcal{C}, \tau_{\leqslant n}\,\mathcal{D})^{\simeq} \\ &\simeq \varprojlim \mathrm{LFun}(\mathcal{C}, \tau_{\leqslant n}\,\mathcal{D})^{\simeq} \\ &\simeq \mathrm{LFun}(\mathcal{C}, \widehat{\mathcal{D}})^{\simeq} \end{aligned}$$

Using these equivalences, we can identify the natural map $\mathrm{Map}_{\mathsf{Groth}_\infty}(\mathcal{C}, \mathcal{D}) \to \mathrm{Map}_{\varprojlim \mathsf{Groth}_n}(\theta(\mathcal{C}), \theta(\mathcal{D}))$ with the map $\mathrm{LFun}(\mathcal{C}, \mathcal{D})^{\simeq} \to \mathrm{LFun}(\mathcal{D}, \widehat{\mathcal{D}})^{\simeq}$ given by composition with the functor $\mathcal{D} \to \widehat{\mathcal{D}}$. In particular, this map is an equivalence whenever $\mathcal{D}$ is complete.

We now prove essential surjectivity. Suppose we are given an object of the inverse limit $\varprojlim \mathsf{Groth}_n$, which we will identify with a sequence of objects $\mathcal{C}_n \in \mathsf{Groth}_n$ together with equivalences $\alpha_n : \mathcal{C}_n \simeq \tau_{\leqslant n}\,\mathcal{C}_{n+1}$. For each $n \geqslant 0$, Proposition C.5.4.5 guarantees the existence of a separated n-complicial Grothendieck prestable ∞-category $\mathcal{D}_n$ and an equivalence $\mathcal{C}_n \simeq \tau_{\leqslant n}\,\mathcal{D}_n$. Applying Proposition C.5.4.5, we see that each of the functors α_n admits an essentially unique extension to a functor $\beta_n : \mathcal{D}_n \to \mathcal{D}_{n+1}$ which preserves small colimits and finite limits. Let $\mathcal{D}$ denote the colimit $\varinjlim \mathcal{D}_n$, formed in the ∞-category Groth_∞ (see Theorem C.3.3.1). The underlying ∞-category of $\mathcal{D}$ can be described as the inverse limit of the tower

$$\cdots \to \mathcal{D}_3 \xrightarrow{\gamma_2} \mathcal{D}_2 \xrightarrow{\gamma_1} \mathcal{D}_1 \xrightarrow{\gamma_0} \mathcal{D}_0,$$

where γ_n denotes a right adjoint to β_n. In particular, for each $m \geqslant 0$, we can identify $\tau_{\leqslant m}\,\mathcal{D}$ with the limit of the tower

$$\cdots \to \tau_{\leqslant m}\,\mathcal{D}_3 \xrightarrow{\gamma_2} \tau_{\leqslant m}\,\mathcal{D}_2 \xrightarrow{\gamma_1} \tau_{\leqslant m}\,\mathcal{D}_1 \xrightarrow{\gamma_0} \tau_{\leqslant m}\,\mathcal{D}_0\,.$$

By construction, this tower is eventually equivalent to the constant tower with value $\mathcal{C}_n$. We therefore have canonical equivalences $\tau_{\leqslant m}\,\mathcal{D} \simeq \mathcal{C}_m$ which are easily seen to be compatible with the maps α_n, so that $\mathcal{D}$ is a preimage of the object $\{\mathcal{C}_n\} \in \varprojlim \mathsf{Groth}_n$ under the functor θ. It follows that the completion $\widehat{\mathcal{D}}$ is a preimage of the object $\{\mathcal{C}_n\}$ under the functor θ^{comp}. □

It follows from Proposition C.5.3.2 that in the special case $n = 0$, the fully faithful embedding $\mathsf{Groth}^{\mathrm{lex}}_{\mathrm{ab}} = \mathsf{Groth}^{\mathrm{lex}}_0 \hookrightarrow \mathsf{Groth}^{\mathrm{lex,sep}}_\infty$ of Proposition C.5.4.5 carries a Grothendieck abelian category $\mathcal{A}$ to the Grothendieck prestable ∞-category $\mathcal{D}(\mathcal{A})_{\geqslant 0}$. We therefore have the following:

Theorem C.5.4.9. *Let $\mathcal{A}$ be a Grothendieck abelian category and let $\mathcal{C}$ be a separated Grothendieck prestable ∞-category. Then restriction to the heart induces a fully faithful embedding*

$$\mathrm{LFun}^{\mathrm{lex}}(\mathcal{D}(\mathcal{A})_{\geqslant 0}, \mathcal{C}) \to \mathrm{Fun}(\mathcal{A}, \mathcal{C}^{\heartsuit}),$$

whose essential image is spanned by those exact functors $\mathcal{A} \to \mathcal{C}^{\heartsuit}$ which preserve small colimits.

Remark C.5.4.10. It follows from Proposition C.5.4.5 that we can regard the construction $\mathcal{A} \mapsto \mathcal{D}(\mathcal{A})_{\geqslant 0}$ as a fully faithful embedding from the ∞-category $\mathsf{Groth}_{\mathrm{ab}}^{\mathrm{lex}}$ to the ∞-category $\mathsf{Groth}_{\infty}^{\mathrm{lex,sep}} \subseteq \mathsf{Groth}_{\infty}$: that is, the formation of derived ∞-categories is functorial (at least with respect to exact functors which preserve small colimits).

Remark C.5.4.11. Let $\mathcal{A}$ be a Grothendieck abelian category. Using Propositions C.5.3.2 and C.5.4.5, we see that the derived ∞-category $\mathcal{D}(\mathcal{A})$ (together with its t-structure) is determined uniquely up to equivalence by the following properties:

(a) The ∞-category $\mathcal{D}(\mathcal{A})$ is presentable and stable.

(b) The t-structure $(\mathcal{D}(\mathcal{A})_{\geqslant 0}, \mathcal{D}(\mathcal{A})_{\leqslant 0})$ is right complete, left separated, and compatible with filtered colimits.

(c) The Grothendieck prestable ∞-category $\mathcal{D}(\mathcal{A})_{\geqslant 0}$ is 0-complicial.

(d) The heart $\mathcal{D}(\mathcal{A})^{\heartsuit}$ is equivalent to $\mathcal{A}$.

In order to study Grothendieck abelian $(n+1)$-categories, it will be convenient to work with a larger class of objects (in which colimit and tensor product constructions will be *a priori* well-defined).

Notation C.5.4.12. For each $n \geqslant 0$, let $\mathcal{P}r_n^{Add}$ denote the full subcategory of $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ spanned by those presentable ∞-categories $\mathcal{A}$ which satisfy satisfy the following conditions:

(a) The ∞-category $\mathcal{A}$ is additive.

(b) The ∞-category $\mathcal{A}$ is (equivalent to) an $(n+1)$-category: that is, the mapping spaces $\mathrm{Map}_{\mathcal{A}}(X, Y)$ are n-truncated, for every pair of objects $X, Y \in \mathcal{A}$.

Note that we can regard Groth_n as a full subcategory of $\mathcal{P}r_n^{Add}$.

Proposition C.5.4.13. *Let $n \geqslant 0$ be an integer. Then:*

(a) *The functor*

$$\mathcal{S} \to \tau_{\leqslant n}\,\mathrm{Sp}^{\mathrm{cn}} \qquad X \mapsto \tau_{\leqslant n}\Sigma^{\infty}_{+} X$$

exhibits $\tau_{\leqslant n}\,\mathrm{Sp}^{\mathrm{cn}}$ as an idempotent object of the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable ∞-categories (see Definition **??***).*

(*b*) *The forgetful functor* $\pi : \mathrm{Mod}_{\tau_{\leqslant n}\,\mathrm{Sp}}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ *is a fully faithful embedding, whose essential image is the full subcategory* $\mathcal{P}r_n^{Add} \subseteq \mathcal{P}\mathrm{r}^{\mathrm{L}}$.

In particular, any Grothendieck abelian $(n+1)$*-category* $\mathcal{A}$ *admits an essentially unique action of the* ∞*-category* $\tau_{\leqslant n}\,\mathrm{Sp}^{\mathrm{cn}}$.

Proof. It follows from Proposition HA.4.8.2.15 that the functor $\tau_{\leqslant n} : \mathcal{S} \to \tau_{\leqslant n}\,\mathcal{S}$ exhibits $\tau_{\leqslant n}\,\mathcal{S}$ as an idempotent object of the symmetric monoidal ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$. In particular, the forgetful functor $\mathrm{Mod}_{\tau_{\leqslant n}\,\mathcal{S}}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ is fully faithful, and Proposition HA.4.8.2.15 also implies that its essential image consists of those presentable ∞-categories which are equivalent to $(n+1)$-categories. Consequently, for any presentable ∞-category $\mathcal{C}$, the tensor product $(\tau_{\leqslant n}\,\mathcal{S}) \otimes \mathcal{C}$ is universal among presentable ∞-categories $\mathcal{E}$ which are equivalent to $(n+1)$-categories and receive a functor $\mathcal{C} \to \mathcal{E}$. We can therefore identify $(\tau_{\leqslant n}\,\mathcal{S}) \otimes \mathcal{C}$ with the ∞-category $\tau_{\leqslant n}\,\mathcal{C}$ of n-truncated objects of $\mathcal{C}$. In particular, we can identify the tensor product $(\tau_{\leqslant n}\,\mathcal{S}) \otimes \mathrm{Sp}^{\mathrm{cn}}$ with the ∞-category $\tau_{\leqslant n}\,\mathrm{Sp}^{\mathrm{cn}}$ of n-truncated connective spectra. Since the suspension functor $\Sigma^{\infty}_{+} : \mathcal{S} \to \mathrm{Sp}^{\mathrm{cn}}$ and the truncation functor $\tau_{\leqslant n} : \mathcal{S} \to \tau_{\leqslant n}\,\mathcal{S}\,\mathrm{Sp}^{\mathrm{cn}}$ and $\tau_{\leqslant n}\,\mathcal{S}$ as idempotent objects of $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ (Proposition HA.4.8.2.15 and Corollary C.4.1.2), their tensor product

$$\mathcal{S} \simeq \mathcal{S} \otimes \mathcal{S} \xrightarrow{\tau_{\leqslant n} \otimes \Sigma^{\infty}_{+}} (\tau_{\leqslant n}\,\mathcal{S}) \otimes \mathrm{Sp}^{\mathrm{cn}} \simeq \tau_{\leqslant n}\,\mathrm{Sp}^{\mathrm{cn}}$$

$$X \mapsto \tau_{\leqslant n}(\Sigma^{\infty}_{+} X)$$

exhibits $\tau_{\leqslant n}\,\mathrm{Sp}^{\mathrm{cn}}$ as an idempotent object of $\mathcal{P}\mathrm{r}^{\mathrm{L}}$. This proves (a).

It follows from (a) that there exists an essentially unique commutative algebra structure on the object $\tau_{\leqslant n}\,\mathrm{Sp}^{\mathrm{cn}} \in \mathcal{P}\mathrm{r}^{\mathrm{L}}$ for which the functor $\tau_{\leqslant n}\Sigma^{\infty}_{+} : \mathcal{S} \to \tau_{\leqslant n}\,\mathrm{Sp}^{\mathrm{cn}}$ is the unit map (see Proposition HA.4.8.2.9). It follows from the uniqueness that the multiplication on $\tau_{\leqslant n}\,\mathrm{Sp}^{\mathrm{cn}}$ corresponds to the symmetric monoidal structure given by $(X, Y) \mapsto \tau_{\leqslant n}(X \otimes Y)$; in particular, when $n = 0$, it is given by the classical tensor product of abelian groups. Using Proposition HA.4.8.2.10 , we see that the forgetful functor $\mathrm{Mod}_{\tau_{\leqslant n}\,\mathrm{Sp}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ is a fully faithful embedding, whose essential image consists of those presentable ∞-categories $\mathcal{A}$ for which the canonical map

$$e : \mathcal{A} \to (\tau_{\leqslant n}\,\mathrm{Sp}^{\mathrm{cn}}) \otimes \mathcal{A} \simeq (\tau_{\leqslant n}\,\mathcal{S}) \otimes \mathrm{Sp}^{\mathrm{cn}} \otimes \mathcal{A}$$

is an equivalence. If $\mathcal{A}$ satisfies this condition, then it can be regarded as a module over both $\mathrm{Sp}^{\mathrm{cn}}$ and $\tau_{\leqslant n}\,\mathcal{S}$, and is therefore both additive and equivalent to an $(n+1)$-category (Corollary C.4.1.3 and Proposition HA.4.8.2.15). Conversely, if $\mathcal{A}$ is additive and equivalent to an $(n+1)$-category, then e factors as a composition of equivalences

$$\mathcal{A} \xrightarrow{\sim} (\tau_{\leqslant n}\,\mathcal{S}) \otimes \mathcal{A} \xrightarrow{\sim} (\tau_{\leqslant n}\,\mathcal{S}) \otimes (\mathrm{Sp}^{\mathrm{cn}} \otimes \mathcal{A})$$

and is therefore an equivalence, which proves (b). $\square$

Remark C.5.4.14. It follows from Proposition C.5.4.13 that the $\mathcal{P}r_n^{Add} \hookrightarrow \mathcal{P}\mathrm{r}^{\mathrm{L}}$ admits a left adjoint L, given by the construction $\mathcal{C} \mapsto (\tau_{\leqslant n} \mathrm{Sp}^{\mathrm{cn}}) \otimes \mathcal{C}$. Moreover, the localization functor L is compatible with the symmetric monoidal structure on $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ (see Definition HA.2.2.1.6). Consequently, there is an essentially unique symmetric monoidal structure on the ∞-category $\mathcal{P}r_n^{Add}$ with respect to which the localization functor L is symmetric monoidal. The tensor product on $\mathcal{P}r_n^{Add}$ agrees with the tensor product on $\mathcal{P}\mathrm{r}^{\mathrm{L}}$, but the unit object is different (the unit object of $\mathcal{P}r_0^{Add}$ is given $\tau_{\leqslant n} \mathrm{Sp}^{\mathrm{cn}}$), rather than the ∞-category $\mathcal{S}$ of spaces).

Corollary C.5.4.15. *Let $n \geqslant 0$ be an integer. Then the inclusion functor $\iota : \mathcal{P}r_n^{Add} \subseteq \mathcal{P}\mathrm{r}^{\mathrm{Add}}$ admits a left adjoint, which assigns to each presentable additive ∞-category $\mathcal{C}$ the full subcategory $\tau_{\leqslant n} \mathcal{C} \subseteq \mathcal{C}$ spanned by the n-truncated objects.*

Proof. Using Proposition C.5.4.13 and Corollary C.4.1.3, we can identify ι with the forgetful functor $\mathrm{Mod}_{\tau_{\leqslant n} \mathrm{Sp}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \rightarrow \mathrm{Mod}_{\mathrm{Sp}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$. This functor has a left adjoint given by the construction

$$\mathcal{C} \mapsto (\tau_{\leqslant n} \mathrm{Sp}^{\mathrm{cn}}) \otimes_{\mathrm{Sp}^{\mathrm{cn}}} \mathcal{C} \simeq (\tau_{\leqslant n} \mathcal{S}) \otimes \mathcal{C} \simeq \tau_{\leqslant n} \mathcal{C} .$$

□

In §C.4, we showed that the collection of Grothendieck prestable ∞-categories is closed under tensor products (Theorem C.4.2.1). We now prove an analogue for Grothendieck abelian categories:

Theorem C.5.4.16. *Let $\mathcal{A}$ and $\mathcal{B}$ be Grothendieck abelian $(n+1)$-categories for some $n \geqslant 0$. Then the tensor product $\mathcal{A} \otimes \mathcal{B}$ (formed in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$) is also a Grothendieck abelian $(n+1)$-category.*

Remark C.5.4.17. In the case where $n = 0$ and the abelian categories $\mathcal{A}$ and $\mathcal{B}$ are compactly generated, Theorem C.5.4.16 was proven by Schäppi in [179]; in this case, the tensor product $\mathcal{A} \otimes \mathcal{B}$ is again compactly generated.

Proof of Theorem C.5.4.16. Let $\mathcal{A}$ and $\mathcal{B}$ be Grothendieck abelian $(n+1)$-categories; we wish to show that the tensor product $\mathcal{A} \otimes \mathcal{B}$ is also a Grothendieck abelian $(n+1)$-category. Choose Grothendieck prestable ∞-categories $\mathcal{C}$ and $\mathcal{D}$ satisfying $\mathcal{A} \simeq \tau_{\leqslant n} \mathcal{C}$ and $\mathcal{B} \simeq \tau_{\leqslant n} \mathcal{D}$. It follows from Theorem C.4.2.1 that the tensor product $\mathcal{C} \otimes \mathcal{D}$ is again a Grothendieck prestable ∞-category. In the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$, we have equivalences

$$\begin{aligned} \mathcal{A} \otimes \mathcal{B} &\simeq (\tau_{\leqslant n} \mathcal{S} \otimes \mathcal{C}) \otimes (\tau_{\leqslant n} \mathcal{S} \otimes \mathcal{D}) \\ &\simeq (\tau_{\leqslant n} \mathcal{S} \otimes \tau_{\leqslant n} \mathcal{S}) \otimes (\mathcal{C} \otimes \mathcal{D}) \\ &\simeq \tau_{\leqslant n} \mathcal{S} \otimes (\mathcal{C} \otimes \mathcal{D}) \\ &\simeq \tau_{\leqslant n} (\mathcal{C} \otimes \mathcal{D}), \end{aligned}$$

so that $\mathcal{A} \otimes \mathcal{B}$ is also a Grothendieck abelian $(n+1)$-category. □

Remark C.5.4.18. Theorem C.4.2.1 can be regarded as an ∞-categorical analogue of Theorem C.5.4.16, and the preceding argument shows that it immediately implies Theorem C.5.4.16. When $n = 0$, one can also prove Theorem C.5.4.16 directly (without appeal to higher category theory) by mimicking our earlier proof of Theorem C.4.2.1, using the classical Gabriel-Popescu theorem in place of its ∞-categorical analogue.

Since the ∞-category Groth_n contains the unit object $\tau_{\leqslant n}\,\mathrm{Sp}^{\mathrm{cn}}$ of $\mathcal{P}r_n^{Add}$, Theorem C.5.4.16 implies the following:

Corollary C.5.4.19. *For each $n \geqslant 0$, the symmetric monoidal structure on the ∞-category $\mathcal{P}r_n^{Add} \simeq \mathrm{Mod}_{\tau_{\leqslant n}\mathrm{Sp}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ restricts to a symmetric monoidal structure on the full subcategory $\mathsf{Groth}_n \subseteq \mathcal{P}r_n^{Add}$. In other words, there is an essentially unique symmetric monoidal structure on the ∞-category Groth_n for which the inclusion functor $\mathsf{Groth}_n \hookrightarrow \mathcal{P}r_n^{Add}$ is symmetric monoidal.*

Remark C.5.4.20. Since the localization functor

$$\mathcal{P}\mathrm{r}^{\mathrm{Add}} \simeq \mathrm{Mod}_{\mathrm{Sp}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \xrightarrow{\tau_{\leqslant}\mathrm{Sp}^{\mathrm{cn}} \otimes_{\mathrm{Sp}^{\mathrm{cn}}}} \mathrm{Mod}_{\tau_{\leqslant n}\mathrm{Sp}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \simeq \mathcal{P}r_n^{Add}$$

of Remark C.5.4.14 is symmetric monoidal, it follows that the functor

$$\mathsf{Groth}_\infty \to \mathsf{Groth}_n \qquad \mathcal{C} \mapsto \tau_{\leqslant n}\,\mathcal{C}$$

of Warning C.5.4.7 is also symmetric monoidal.

We next prove an analogue of Proposition C.3.2.4:

Proposition C.5.4.21. *Let $n \geqslant 0$ be an integer. Then the ∞-category $\mathsf{Groth}_n^{\mathrm{lex}}$ admits small limits, which are preserved by the inclusion functors*

$$\mathsf{Groth}_n^{\mathrm{lex}} \hookrightarrow \mathsf{Groth}_n \hookrightarrow \mathcal{P}\mathrm{r}^{\mathrm{L}} \hookrightarrow \widehat{\mathcal{C}\mathrm{at}}_\infty.$$

Proof. Let $\{\mathcal{C}_\alpha\}$ be a small diagram in $\mathsf{Groth}_n^{\mathrm{lex}}$. Using Proposition C.5.4.5, we can lift $\{\mathcal{C}_\alpha\}$ to a diagram $\{\overline{\mathcal{C}}_\alpha\}$ in $\mathsf{Groth}_\infty^{\mathrm{lex}}$, where each $\overline{\mathcal{C}}_\alpha$ is separated and n-complicial. Set $\overline{\mathcal{C}} = \varprojlim\{\overline{\mathcal{C}}_\alpha\}$ (formed in the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty$). It follows from Proposition C.3.2.4 that $\overline{\mathcal{C}}$ is a Grothendieck prestable ∞-category, which is also a limit for the diagram $\{\overline{\mathcal{C}}\}_\alpha$ in the ∞-categories Groth_∞ and $\mathsf{Groth}_\infty^{\mathrm{lex}}$. It follows that $\mathcal{C} = \tau_{\leqslant n}\overline{\mathcal{C}}$ is a Grothendieck abelian $(n+1)$-category. Moreover, since the transition functors $\overline{\mathcal{C}}_\alpha \to \overline{\mathcal{C}}_\beta$ are left exact, an object of $\overline{\mathcal{C}}$ is n-truncated if and only if its image in each $\overline{\mathcal{C}}_\alpha$ is n-truncated. We can therefore identify $\mathcal{C}$ with a limit of the diagram $\{\mathcal{C}_\alpha\}$ in $\widehat{\mathcal{C}\mathrm{at}}_\infty$. For any presentable ∞-category $\mathcal{D}$, a functor $\mathcal{D} \to \mathcal{C}$ preserves small colimits and finite limits if and only if each of the composite maps $\mathcal{D} \to \mathcal{C} \to \mathcal{C}_\alpha$ preserves small colimits and finite limits (this is a formal consequence of our assumption that the transition maps $\mathcal{C}_\alpha \to \mathcal{C}_\beta$ preserve small colimits and finite limits). It follows that $\mathcal{C}$ is also a limit of the diagram $\{\mathcal{C}_\alpha\}$ in the ∞-categories $\mathsf{Groth}_n^{\mathrm{lex}}$ and $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ (hence also in the full subcategory $\mathsf{Groth}_n \subseteq \mathcal{P}\mathrm{r}^{\mathrm{L}}$). □

C.5.5 Anticomplete Prestable ∞-Categories

Recall that a Grothendieck prestable ∞-category $\mathcal{C}$ is said to be *complete* if it is Postnikov-complete: that is, if it is equivalent to the limit of the tower of ∞-categories

$$\cdots \to \tau_{\leqslant 3}\,\mathcal{C} \xrightarrow{\tau_{\leqslant 2}} \tau_{\leqslant 2}\,\mathcal{C} \xrightarrow{\tau_{\leqslant 1}} \tau_{\leqslant 1}\,\mathcal{C} \xrightarrow{\tau_{\leqslant 0}} \tau_{\leqslant 0}\,\mathcal{C} = \mathcal{C}^{\heartsuit}.$$

We now study Grothendieck prestable ∞-categories $\mathcal{C}$ which are, in some sense, as far as possible from being complete. First, we need to introduce some terminology.

Proposition C.5.5.1. *Let $\mathcal{C}$ and $\mathcal{D}$ be Grothendieck prestable ∞-categories, let $f : \mathcal{C} \to \mathcal{D}$ be a colimit-preserving functor, and let $n \geqslant 0$ be an integer. The following conditions are equivalent:*

- (a) *For every discrete object $C \in \mathcal{C}$, the object $f(C) \in \mathcal{D}$ is n-truncated.*
- (b) *For every k-truncated object $C \in \mathcal{C}$, the object $f(C) \in \mathcal{D}$ is $(n+k)$-truncated.*

Proof. The implication $(b) \Rightarrow (a)$ is obvious. To prove the converse, we note that a k-truncated object $C \in \mathcal{C}$ can be written as a successive extension of the objects $\Sigma^i(\pi_i C)$ for $0 \leqslant i \leqslant k$. If (a) is satisfied, then $f(C)$ can be written as a successive extension of the objects $\Sigma^i f(\pi_i C) \in \tau_{\leqslant n+i}\,\mathcal{D} \subseteq \tau_{\leqslant n+k}\,\mathcal{D}$, so that $f(C)$ belongs to $\tau_{\leqslant n+k}\,\mathcal{D}$. □

Definition C.5.5.2. Let $\mathcal{C}$ and $\mathcal{D}$ be Grothendieck prestable ∞-categories and let $f : \mathcal{C} \to \mathcal{D}$ be a colimit-preserving functor. We will say that *f has amplitude $\leqslant n$* if the equivalent conditions of Proposition C.5.5.1 are satisfied. We will say that *f has bounded amplitude* if f has amplitude $\leqslant n$ for some $n \geqslant 0$. We let $\mathrm{LFun}^b(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\mathrm{LFun}(\mathcal{C}, \mathcal{D})$ spanned by those functors which are of bounded amplitude.

Example C.5.5.3. Let $f : \mathcal{C} \to \mathcal{D}$ be a colimit-preserving functor between Grothendieck prestable ∞-categories. Then f has amplitude $\leqslant 0$ if and only if f is left exact (Proposition C.3.2.1).

Definition C.5.5.4. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. We will say that $\mathcal{C}$ is *anticomplete* if it satisfies the following condition:

- $(*)$ Let $\mathcal{D}$ be a Grothendieck prestable ∞-category and let $\widehat{\mathcal{D}}$ be its completion. Then the canonical map
$$\mathrm{LFun}^b(\mathcal{C}, \mathcal{D}) \to \mathrm{LFun}^b(\mathcal{C}, \widehat{\mathcal{D}})$$
is an equivalence of ∞-categories.

We now consider some examples of anticomplete Grothendieck prestable ∞-categories.

Proposition C.5.5.5. *Let $\mathcal{C}$ be an ∞-category. The following conditions are equivalent:*

(a) *The ∞-category $\mathcal{C}$ is a compactly generated prestable ∞-category, the functor $\Omega : \mathcal{C} \to \mathcal{C}$ preserves compact objects, and every compact object of $\mathcal{C}$ is n-truncated for $n \gg 0$.*

(b) *There exist an essentially small stable ∞-category $\mathcal{E}$ equipped with a bounded t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$ and an equivalence $\mathcal{C} \simeq \mathrm{Ind}(\mathcal{E}_{\geqslant 0})$.*

Moreover, if $\mathcal{C}$ satisfies these conditions, then $\mathcal{C}$ is anticomplete.

Remark C.5.5.6. For a refinement of Proposition C.5.5.5, we refer the reader to Theorem C.6.7.1.

Proof of Proposition C.5.5.5. We first show that (b) implies (a). Let $\mathcal{E}$ be an essentially small stable ∞-category equipped with a bounded t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$. Then $\mathcal{C} = \mathrm{Ind}(\mathcal{E}_{\geqslant 0})$ is a prestable ∞-category (see the proof of Proposition C.2.4.2) which is compactly generated, and therefore a Grothendieck prestable ∞-category. Let $j : \mathcal{E}_{\geqslant 0} \to \mathcal{C}$ be the Yoneda embedding, so that an object $C \in \mathcal{C}$ is compact if and only if C is a direct summand of $j(E)$ for some $E \in \mathcal{E}_{\geqslant 0}$. Since the t-structure on $\mathcal{E}$ is bounded, the object $E \in \mathcal{E}_{\geqslant 0}$ is n-truncated for $n \gg 0$, so that $j(E) \in \mathcal{C}$ is also n-truncated and therefore C is n-truncated. Finally, we note that ΩC is a direct summand of $j(\tau_{\geqslant 0}\Omega E)$ and is therefore also a compact object of $\mathcal{C}$.

We now prove the converse. Suppose that $\mathcal{C}$ is a compactly generated prestable ∞-category and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be the full subcategory spanned by the compact objects. Then $\mathcal{C}_0$ is an essentially small prestable ∞-category (Proposition C.6.1.1). Let $\mathcal{E} = \mathrm{SW}(\mathcal{C}_0)$ denote the Spanier-Whitehead ∞-category of $\mathcal{C}_0$ (Construction C.1.1.1). If $\Omega : \mathcal{C} \to \mathcal{C}$ preserves compact objects, then $\mathcal{C}_0$ is closed under finite limits in $\mathcal{C}$. Applying Proposition C.1.2.9, we deduce that $\mathcal{E}$ admits a t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$, where $\mathcal{E}_{\geqslant 0} \simeq \mathcal{C}_0$. This t-structure is always right-bounded, and is left-bounded if and only if every compact object $C \in \mathcal{C}$ is n-truncated for some $n \gg 0$. In this case, we have $\mathcal{C} \simeq \mathrm{Ind}(\mathcal{C}_0) \simeq \mathrm{Ind}(\mathcal{E}_{\geqslant 0})$, so that $\mathcal{C}$ satisfies condition (b).

We now complete the proof by showing that if $\mathcal{C} = \mathrm{Ind}(\mathcal{E}_{\geqslant 0})$ as above, then $\mathcal{C}$ is anticomplete. Let $\mathcal{D}$ be a Grothendieck prestable ∞-category and let $\widehat{\mathcal{D}}$ denote its completion; we wish to show that the canonical map

$$\rho : \mathrm{LFun}^b(\mathrm{Ind}(\mathcal{E}_{\geqslant 0}), \mathcal{D}) \to \mathrm{LFun}^b(\mathrm{Ind}(\mathcal{E}_{\geqslant 0}), \widehat{\mathcal{D}})$$

is an equivalence of ∞-categories. The proof of Proposition C.2.4.2 supplies a t-exact equivalence $\mathrm{Sp}(\mathrm{Ind}(\mathcal{E}_{\geqslant 0})) \simeq \mathrm{Ind}(\mathcal{E})$. Using Proposition C.3.1.1, we can identify ρ with the canonical map

$$\rho' : \mathrm{Fun}'(\mathrm{Ind}(\mathcal{E}), \mathrm{Sp}(\mathcal{D})) \to \mathrm{Fun}'(\mathrm{Ind}(\mathcal{E}), \mathrm{Sp}(\widehat{\mathcal{D}})).$$

Here $\mathrm{Fun}'(\mathrm{Ind}(\mathcal{E}), \mathrm{Sp}(\mathcal{D}))$ denotes the full subcategory of $\mathrm{Fun}(\mathrm{Ind}(\mathcal{E}), \mathrm{Sp}(\mathcal{D}))$ spanned by those functors which preserve small colimits, are right t-exact, and carry $\mathrm{Ind}(\mathcal{E})_{\leqslant 0}$ into

$\mathrm{Sp}(\mathcal{D})_{\leqslant n}$ for some $n \gg 0$, and the ∞-category $\mathrm{Fun}'(\mathrm{Ind}(\mathcal{E}), \mathrm{Sp}(\widehat{\mathcal{D}}))$ is defined similarly. The map ρ' fits into a commutative diagram

$$\begin{array}{ccc} \mathrm{Fun}'(\mathrm{Ind}(\mathcal{E}), \mathrm{Sp}(\mathcal{D})) & \xrightarrow{\rho'} & \mathrm{Fun}'(\mathrm{Ind}(\mathcal{C}), \mathrm{Sp}(\widehat{\mathcal{D}})) \\ \downarrow & & \downarrow \\ \mathrm{Fun}''(\mathcal{E}, \mathrm{Sp}(\mathcal{D})) & \xrightarrow{\rho''} & \mathrm{Fun}''(\mathcal{E}, \mathrm{Sp}(\widehat{\mathcal{D}})) \end{array}$$

where $\mathrm{Fun}''(\mathcal{E}, \mathrm{Sp}(\mathcal{D}))$ denote the full subcategory of $\mathrm{Fun}(\mathcal{E}, \mathrm{Sp}(\mathcal{D}))$ spanned by those functors which are exact, right t-exact, and carries $\mathcal{E}_{\leqslant 0}$ into $\mathrm{Sp}(\mathcal{D})_{\leqslant n}$ for some $n \gg 0$, the ∞-category $\mathrm{Fun}''(\mathcal{E}, \mathrm{Sp}(\widehat{\mathcal{D}}))$ is defined similarly, and the vertical maps are equivalences of ∞-categories. We now observe that ρ'' is an equivalence of ∞-categories, since the t-structure on $\mathcal{E}$ is left bounded and the map $\mathrm{Sp}(\mathcal{D}) \to \mathrm{Sp}(\widehat{\mathcal{D}})$ induces an equivalence $\mathrm{Sp}(\mathcal{D})_{\leqslant n} \to \mathrm{Sp}(\widehat{\mathcal{D}})_{\leqslant n}$ for every integer n. □

Proposition C.5.5.7. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category with heart $\mathcal{A} = \mathcal{C}^{\heartsuit}$, let $\mathcal{A}_0 \subseteq \mathcal{A}$ be a localizing subcategory of $\mathcal{A}$, and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be the smallest localizing subcategory of $\mathcal{C}$ which contains $\mathcal{A}_0$ (see Proposition C.5.2.8). If $\mathcal{C}$ is anticomplete, then $\mathcal{C} / \mathcal{C}_0$ is also anticomplete.*

Proof. Let $\mathcal{D}$ be a Grothendieck prestable ∞-category with completion $\widehat{\mathcal{D}}$. We wish to show that the canonical map $\rho : \mathrm{LFun}^b(\mathcal{C} / \mathcal{C}_0, \mathcal{D}) \to \mathrm{LFun}^b(\mathcal{C} / \mathcal{C}_0, \widehat{\mathcal{D}})$ is an equivalence of ∞-categories. Note that the functor ρ fits into a commutative diagram of ∞-categories σ :

$$\begin{array}{ccc} \mathrm{LFun}^b(\mathcal{C} / \mathcal{C}_0, \mathcal{D}) & \xrightarrow{\rho} & \mathrm{LFun}^b(\mathcal{C} / \mathcal{C}_0, \widehat{\mathcal{D}}) \\ \downarrow & & \downarrow \\ \mathrm{LFun}^b(\mathcal{C}, \mathcal{D}) & \xrightarrow{\overline{\rho}} & \mathrm{LFun}^b(\mathcal{C}, \widehat{\mathcal{D}}), \end{array}$$

where the map $\overline{\rho}$ is an equivalence of ∞-categories (by virtue of our assumption that $\mathcal{C}$ is anticomplete) and the vertical maps are fully faithful embeddings. It will therefore suffice to show that the diagram σ is a pullback square. Using Proposition C.2.3.10 and Remark C.2.3.11, we are reduced to proving the following:

(∗) Let $F : \mathcal{C} \to \mathcal{D}$ be a functor which preserves small colimits and has bounded amplitude. If the composite functor $\mathcal{C} \xrightarrow{F} \mathcal{D} \to \widehat{\mathcal{D}}$ annihilates $\mathcal{C}_0$, then F annihilates $\mathcal{C}_0$.

To prove this, let $\mathcal{C}_1$ denote the full subcategory of $\mathcal{C}$ spanned by those objects $C \in \mathcal{C}$ satisfying $F(C) \simeq 0$. Note that if $X \in \mathcal{A}_0$ and F has amplitude $\leqslant n$, then $F(X) \in \tau_{\leqslant n} \mathcal{D}$ is annihilated by the completion functor $\mathcal{D} \to \widehat{\mathcal{D}}$, so that $F(X) \simeq 0$ (since the completion functor $\mathcal{D} \to \widehat{\mathcal{D}}$ is an equivalence on discrete objects). It follows that $\mathcal{A}_0 \subseteq \mathcal{C}_1$. Since $\mathcal{C}_1$ is a localizing subcategory of $\mathcal{C}$ (Example C.2.3.7), we have $\mathcal{C}_0 \subseteq \mathcal{C}_1$, so that F annihilates $\mathcal{C}_0$ as desired. □

Lemma C.5.5.8. *Let $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{E}$ be Grothendieck prestable ∞-categories, and suppose we are given functors $f \in \mathrm{LFun}^b(\mathcal{C}, \mathcal{D})$ and $g \in \mathrm{LFun}^{\mathrm{lex}}(\mathcal{D}, \mathcal{E})$. If g induces a conservative functor $\mathcal{D}^{\heartsuit} \to \mathcal{E}^{\heartsuit}$ and $(g \circ f)$ has amplitude $\leqslant n$, then f has amplitude $\leqslant n$.*

Proof. Note that our assumption that f has bounded amplitude guarantees that the conclusion of Lemma C.5.5.8 is satisfied for $n \gg 0$. We now proceed by descending induction on n. To carry out the inductive step, let us suppose that f has amplitude $\leqslant n+1$ and that $g \circ f$ has amplitude $\leqslant n$; we wish to show that f has amplitude $\leqslant n$. Let $C \in \mathcal{C}$ be a discrete object; then $f(C) \in \mathcal{D}$ is $(n+1)$-truncated and we wish to show that it is n-truncated. Because g is left exact, we have $g(\pi_{n+1} f(C)) \simeq \pi_{n+1}(g \circ f)(C) \simeq 0$. Since $g|_{\mathcal{D}^{\heartsuit}}$ is conservative, it follows that $\pi_{n+1} f(C) \simeq 0$, so that $f(C)$ is n-truncated as desired. □

Proposition C.5.5.9. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. Then there exists an anticomplete Grothendieck prestable ∞-category $\check{\mathcal{C}}$ and a functor $\lambda \in \mathrm{LFun}^{\mathrm{lex}}(\check{\mathcal{C}}, \mathcal{C})$ which induces an equivalence of completions.*

Proof. Let $\widehat{\mathcal{C}}$ be the completion of $\mathcal{C}$. For each $n \geqslant 0$, the ∞-category $\tau_{\leqslant n}\widehat{\mathcal{C}}$ is presentable. We can therefore choose an essentially small dense subcategory $\mathcal{K}_n \subseteq \tau_{\leqslant n}\widehat{\mathcal{C}}$ (see Definition 20.4.1.1). Let us abuse notation by identifying $\widehat{\mathcal{C}}$ with its essential image in $\mathrm{Sp}(\widehat{\mathcal{C}})$. Let $\mathcal{E}$ be the smallest stable subcategory of $\mathrm{Sp}(\widehat{\mathcal{C}})$ which contains each $\mathcal{K}_n$ and is closed under truncation (so that the t-structure on $\mathrm{Sp}(\widehat{\mathcal{C}})$ induces a t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$ on $\mathcal{E}$). Note that the t-structure on $\mathcal{E}$ is bounded. The inclusion $\mathcal{E} \hookrightarrow \mathrm{Sp}(\widehat{\mathcal{C}})$ extends to a t-exact functor $\mathrm{Ind}(\mathcal{E}) \to \mathrm{Sp}(\widehat{\mathcal{C}})$ which preserves small colimits, and therefore determines a functor of Grothendieck prestable ∞-categories $F : \mathrm{Ind}(\mathcal{E}_{\geqslant 0}) \to \widehat{\mathcal{C}}$ which preserves small colimits and finite limits. Note that the heart of $\mathrm{Ind}(\mathcal{E}_{\geqslant 0})$ can be identified with $\mathrm{Ind}(\mathcal{E}^{\heartsuit})$, so that F induces an exact functor of abelian categories $F^{\heartsuit} : \mathrm{Ind}(\mathcal{E}^{\heartsuit}) \to \widehat{\mathcal{C}}^{\heartsuit}$. Let $\mathcal{A}_0 \subseteq \mathrm{Ind}(\mathcal{E}^{\heartsuit})$ be the full subcategory spanned by those objects which are annihilated by $F^{\heartsuit}$, and let $\mathcal{A}_0^+ \subseteq \mathrm{Ind}(\mathcal{E}_{\geqslant 0})$ be the smallest localizing subcategory of $\mathrm{Ind}(\mathcal{E}_{\geqslant 0})$ which contains $\mathcal{A}_0$ (Proposition C.5.2.8). We define $\check{\mathcal{C}}$ to be the quotient $\mathrm{Ind}(\mathcal{E}_{\geqslant 0})/\mathcal{A}_0^+$. It follows from Propositions C.5.5.5 and C.5.5.7 that the $\check{\mathcal{C}}$ is an anticomplete Grothendieck prestable ∞-category. The functor F annihilates $\mathcal{A}_0$ and therefore also annihilates $\mathcal{A}_0^+$ (Example C.2.3.7). It follows from Proposition C.2.3.10 and Remark C.2.3.11 that F factors as a composition

$$\mathrm{Ind}(\mathcal{E}_{\geqslant 0}) \to \check{\mathcal{C}} \xrightarrow{\overline{F}} \widehat{\mathcal{C}},$$

where $\overline{F}$ preserves small colimits and finite limits. Since $\check{\mathcal{C}}$ is anticomplete, the functor $\overline{F}$ factors as a composition $\mathcal{C}' \xrightarrow{\lambda} \mathcal{C} \to \widehat{\mathcal{C}}$ where λ preserves small colimits and has bounded amplitude. Applying Lemma C.5.5.8, we see that λ is left exact.. We will complete the proof by showing that λ induces an equivalence of completions. To prove this, it will suffice to show that the functor $\overline{F}$ induces an equivalence $\tau_{\leqslant n}\check{\mathcal{C}} \to \tau_{\leqslant n}\widehat{\mathcal{C}}$, for each $n \geqslant 0$.

Let $G : \widehat{\mathcal{C}} \to \mathrm{Ind}(\mathcal{E}_{\geqslant 0})$ be a right adjoint to F. By construction, G factors through $\mathcal{C}' = \mathrm{Ind}(\mathcal{E}_{\geqslant 0})/\mathcal{A}_0^+$ (which we regard as a full subcategory of $\mathrm{Ind}(\mathcal{E}_{\geqslant 0})$. Moreover, when regarded as a functor from $\widehat{\mathcal{C}}$ to $\check{\mathcal{C}}$, the functor G is right adjoint to $\overline{F}$. By construction, the intersection $\mathcal{E}_{\geqslant 0} \cap \tau_{\leqslant n}\widehat{\mathcal{C}}$ contains $\mathcal{K}_n$, and is therefore dense in $\tau_{\leqslant n}\widehat{\mathcal{C}}$ (Remark 20.4.1.10). It follows that the functor G is fully faithful when restricted to $\tau_{\leqslant n}\widehat{\mathcal{C}}$. To complete the proof, it will suffice to show that $\overline{F}|_{\tau_{\leqslant n}\check{\mathcal{C}}}$ is conservative. Let $\alpha : X \to Y$ be a morphism of n-truncated objects of $\check{\mathcal{C}}$ such that $\overline{F}(\alpha)$ is an equivalence. Let Z denote the cofiber of α, formed in the ∞-category $\mathrm{Ind}(\mathcal{E}_{\geqslant 0})$. Since $\overline{F}(\alpha)$ is an equivalence, we have $F(Z) \simeq 0$. The functor F is left exact, so we have $F(\pi_i Z) \simeq \pi_i F(Z) \simeq 0$ for all $i \geqslant 0$. In other words, the homotopy groups $\pi_i Z$ belong to $\mathcal{A}_0$. Since X and Y are n-truncated, the object Z is $(n+1)$-truncated, and can therefore be written as a *finite* extension of objects of the form $\Sigma^i(\pi_i Z)$. It follows that $Z \in \mathcal{A}_0^+$, so that α is an equivalence as desired. □

Corollary C.5.5.10. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. The following conditions are equivalent:*

- (a) *The Grothendieck prestable ∞-category $\mathcal{C}$ is anticomplete.*
- (b) *For every Grothendieck prestable ∞-category $\mathcal{D}$, the canonical map* $\mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}, \mathcal{D}) \to \mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}, \widehat{\mathcal{D}})$ *is an equivalence of ∞-categories.*

Proof. The implication $(a) \Rightarrow (b)$ follows from Lemma C.5.5.8. Conversely, suppose that (b) is satisfied. Choose a map $\lambda : \check{\mathcal{C}} \to \mathcal{C}$ satisfying the hypotheses of Proposition C.5.5.9. We then have a commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}, \check{\mathcal{C}}) & \longrightarrow & \mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}, \mathcal{C}) \\ \downarrow & & \downarrow \\ \mathrm{LFun}^{\mathrm{lex}}(\check{\mathcal{C}}, \check{\mathcal{C}}) & \longrightarrow & \mathrm{LFun}^{\mathrm{lex}}(\check{\mathcal{C}}, \mathcal{C}), \end{array}$$

where the horizontal maps are given by postcomposition with λ and the vertical maps are given by precomposition with λ. Since $\mathcal{C}$ satisfies (b), the upper horizontal map is an equivalence of ∞-categories. We can therefore choose a functor $\mu \in \mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}, \check{\mathcal{C}})$ for which $\lambda \circ \mu$ is homotopic to the identity $\mathrm{id}_{\mathcal{C}}$. It follows that $\lambda \circ \mu \circ \lambda$ is homotopic to λ. Since $\check{\mathcal{C}}$ is anticomplete, the implication $(a) \Rightarrow (b)$ shows that the lower horizontal map is also an equivalence of ∞-categories, so that $\mu \circ \lambda$ is also homotopic to the identity $\mathrm{id}_{\check{\mathcal{C}}}$. It follows that λ is an equivalence of ∞-categories, so that $\mathcal{C} \simeq \check{\mathcal{C}}$ is anticomplete. □

In the situation of Proposition C.5.5.9, the map $\lambda : \check{\mathcal{C}} \to \mathcal{C}$ depends functorially on $\mathcal{C}$. More precisely, we have the following:

Corollary C.5.5.11. *Let* $\mathsf{Groth}_\infty^{\mathrm{ch,lex}}$ *denote the full subcategory of* $\mathsf{Groth}_\infty^{\mathrm{lex}}$ *spanned by the anticomplete Grothendieck prestable* ∞*-categories. Then* $\mathsf{Groth}_\infty^{\mathrm{ch,lex}}$ *is a colocalization of* $\mathsf{Groth}_\infty^{\mathrm{lex}}$*: that is, the inclusion functor* $\mathsf{Groth}_\infty^{\mathrm{ch,lex}} \hookrightarrow \mathsf{Groth}_\infty^{\mathrm{lex}}$ *admits a right adjoint.*

Proof. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $\lambda : \check{\mathcal{C}} \to \mathcal{C}$ be as in the statement of Proposition C.5.5.9. We claim that λ exhibits $\check{\mathcal{C}}$ as a $\mathsf{Groth}_\infty^{\mathrm{ch,lex}}$-colocalization of $\mathcal{C}$. To prove this, it will suffice to show that for any anticomplete Grothendieck prestable ∞-category $\mathcal{D}$, the upper horizontal map in the diagram

$$\begin{array}{ccc} \mathrm{LFun}^{\mathrm{lex}}(\mathcal{D}, \check{\mathcal{C}}) & \longrightarrow & \mathrm{LFun}^{\mathrm{lex}}(\mathcal{D}, \mathcal{C}) \\ \downarrow & & \downarrow \\ \mathrm{LFun}^{\mathrm{lex}}(\mathcal{D}, \widehat{\mathcal{C}}) & \longrightarrow & \mathrm{LFun}^{\mathrm{lex}}(\mathcal{D}, \widehat{\mathcal{C}}) \end{array}$$

is an equivalence of ∞-categories. This is clear: the vertical maps are equivalences because $\mathcal{D}$ is anticomplete, and the lower horizontal map is an equivalence because the functor $\widehat{\lambda} : \widehat{\mathcal{C}}' \to \widehat{\mathcal{C}}$ is an equivalence. □

We close by noting the following consequence of the proof of Proposition C.5.5.9:

Proposition C.5.5.12. *Let* $\mathcal{C}$ *be an anticomplete Grothendieck prestable* ∞*-category. Then:*

- (a) *There is an equivalence* $\mathcal{C} \simeq \mathcal{D} / \mathcal{D}_0$*, where* $\mathcal{D}$ *is an anticomplete Grothendieck prestable* ∞*-category satisfying the hypotheses of Proposition C.5.5.5 and* $\mathcal{D}_0$ *is the smallest localizing subcategory of* $\mathcal{D}$ *which contains some localizing subcategory of* $\mathcal{D}^{\heartsuit}$*.*
- (b) *There exists an essentially small generating subcategory* $\mathcal{C}_0 \subseteq \mathcal{C}$ *having that every object* $C \in \mathcal{C}_0$ *is* n*-truncated for some* $n \gg 0$ *(where* n *might depend on* C*).*

Proof. The proof of Proposition C.5.5.9 shows that there exists a left exact, colimit-preserving functor $\lambda : \mathcal{C}' \to \mathcal{C}$, where $\mathcal{C}'$ has the form described in (a) and λ induces an equivalence after passing to completions. Since $\mathcal{C}$ and $\mathcal{C}'$ are both anticomplete, it follows that λ is an equivalence (see Proposition C.5.9.2), which proves (a). To prove (b), we note that the essential image of the composite functor

$$\mathcal{D}^c \hookrightarrow \mathcal{D} \to \mathcal{D} / \mathcal{D}_0 \simeq \mathcal{C}$$

is a generating subcategory of $\mathcal{C}$, where $\mathcal{D}^c$ denotes the full subcategory of $\mathcal{D}$ spanned by the compact objects. □

Using the theory of anticomplete Grothendieck prestable ∞-categories, we can eliminate the separatedness restrictions from several of the results of §C.5.3.

Definition C.5.5.13. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $n \geqslant 0$ be an integer. We will say that $\mathcal{C}$ is *weakly n-complicial* if, for every truncated object $X \in \mathcal{C}$, there exists a morphism $f : \overline{X} \to X$ where $\overline{X}$ is n-truncated and the induced map $\pi_0 \overline{X} \to \pi_0 X$ is an epimorphism in the abelian category $\mathcal{C}^{\heartsuit}$.

Remark C.5.5.14. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. The hypothesis that $\mathcal{C}$ is weakly n-complicial depends only the full subcategory $\bigcup_{n \geqslant 0} \tau_{\leqslant n} \mathcal{C}$ of truncated objects of $\mathcal{C}$. Consequently, $\mathcal{C}$ is weakly n-complicial if and only if the completion $\widehat{\mathcal{C}}$ is weakly n-complicial. Note that if we were to replace "weakly n-complicial" by "n-complicial", then the analogous statement would be false: if $\mathcal{C}$ is a Grothendieck prestable ∞-category which is n-complicial and separated but not complete, then $\widehat{\mathcal{C}}$ cannot be n-complicial (see Proposition C.5.4.5).

Proposition C.5.5.15. *Let R be a connective $\mathbb{E}_1$-ring. The following conditions are equivalent:*

(1) *The $\mathbb{E}_1$-ring R is n-truncated.*

(2) *The Grothendieck prestable ∞-category $\mathrm{LMod}_R^{\mathrm{cn}}$ is n-complicial.*

(3) *The Grothendieck prestable ∞-category $\mathrm{LMod}_R^{\mathrm{cn}}$ is weakly n-complicial.*

Proof. For any R-module M, we can choose a free R-module P and a morphism $f : P \to M$ which induces a surjection $\pi_0 P \to \pi_0 M$. If R is n-truncated, then P is also n-truncated. This proves that (1) $\Rightarrow$ (2). The implication (2) $\Rightarrow$ (3) is obvious. We will complete the proof by showing that (3) $\Rightarrow$ (1). Assume that $\mathrm{LMod}_R^{\mathrm{cn}}$ is weakly n-complicial. Then, for every integer $m \geqslant 0$, we can choose a map of connective R-modules $f : N \to \tau_{\leqslant m} R$ which is surjective on π_0, where N is n-truncated. Then the tautological map $R \to \tau_{\leqslant m} R$ factors through f, and therefore factors as a composition $R \to \tau_{\leqslant n} R \to \tau_{\leqslant m} R$. It follows that the homotopy groups $\pi_i R$ must vanish for $n < i \leqslant m$. Since m is arbitrary, we conclude that R is n-truncated. □

Proposition C.5.5.16. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. Then:*

(i) *If $\mathcal{C}$ is n-complicial, then it is weakly n-complicial.*

(ii) *If $\mathcal{C}$ is anticomplete and weakly n-complicial, then $\mathcal{C}$ is n-complicial.*

Proof. Assertion (i) follows immediately from the definitions. Let us prove (ii). Assume that $\mathcal{C}$ is anticomplete and weakly n-complicial, and let X be an object of $\mathcal{C}$. Since $\mathcal{C}$ is anticomplete, Proposition C.5.5.12 implies that there exists a map $\bigoplus_{i \in I} X_i \to X$ which induces an epimorphism $\bigoplus_{i \in I} \pi_0 X_i \to \pi_0 X$ in the abelian category $\mathcal{C}^{\heartsuit}$, where each X_i is a truncated object of $\mathcal{C}$. Since $\mathcal{C}$ is weakly n-complicial, we can choose maps $\overline{X}_i \to X_i$ which induce epimorphisms $\pi_0 \overline{X}_i \to \pi_0 X_i$, where each $\overline{X}_i$ is n-truncated. Then $\overline{X} = \bigoplus_{i \in I} \overline{X}_i$ is an n-truncated object of $\mathcal{C}$ equipped with a map $\overline{X} \to X$ which is an epimorphism on π_0. □

Corollary C.5.5.17. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $n \geqslant 0$. The following conditions are equivalent:*

(*i*) *The Grothendieck prestable ∞-category $\mathcal{C}$ is weakly n-complicial.*

(*ii*) *There exists an n-complicial Grothendieck prestable ∞-category $\mathcal{C}'$ and a functor $\lambda \in \mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}', \mathcal{C})$ which induces an equivalence of completions $\widehat{\lambda} : \widehat{\mathcal{C}}' \xrightarrow{\sim} \widehat{\mathcal{C}}$.*

Proof. Let $\lambda : \mathcal{C}' \to \mathcal{C}$ be as in (*ii*). If $\mathcal{C}'$ is n-complicial, then it is weakly n-complicial, so that $\mathcal{C}$ is also weakly n-complicial (Remark C.5.5.14). Conversely, assume that $\mathcal{C}$ is weakly n-complicial and let $\lambda : \mathcal{C}' \to \mathcal{C}$ be as in Proposition C.5.5.9. Then $\mathcal{C}'$ is weakly n-complicial (Remark C.5.5.14) and anticomplete, hence n-complicial (Proposition C.5.5.16). □

Proposition C.5.5.18. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $n \geqslant 0$. Then there exists an anticomplete, n-complicial Grothendieck prestable ∞-category $\mathcal{C}'$ and an n-equivalence $\lambda \in \mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}', \mathcal{C})$.*

Proof. Let $\widehat{\mathcal{C}}$ be the completion of $\mathcal{C}$. Then $\widehat{\mathcal{C}}$ is separated. Applying Proposition C.5.3.8, we can choose an n-complicial Grothendieck prestable ∞-category $\mathcal{C}'$ and an n-equivalence $\mu \in \mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}', \mathcal{C})$. Using Proposition C.5.5.9, we can choose an anticomplete Grothendieck prestable ∞-category $\mathcal{C}''$ and a functor $\nu \in \mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}'', \mathcal{C}')$ which induces an equivalence $\widehat{\mathcal{C}}'' \to \widehat{\mathcal{C}}'$. Since $\mathcal{C}'$ is n-complicial, it is weakly n-complicial. Applying Remark C.5.5.14, we see that $\mathcal{C}''$ is also weakly n-complicial. Since $\mathcal{C}''$ is anticomplete, it is n-complicial (Proposition C.5.5.16). Replacing $\mathcal{C}'$ by $\mathcal{C}''$ (and μ by the composite functor $\mu \circ \nu$), we may reduce to the case where $\mathcal{C}'$ is anticomplete. It follows that μ factors as a composition $\mathcal{C}' \xrightarrow{\lambda} \mathcal{C} \to \widehat{\mathcal{C}}$. Since μ is an n-equivalence, the map λ is also an n-equivalence. □

Proposition C.5.5.19. *Let $\mathcal{C}$ and $\mathcal{D}$ be Grothendieck prestable ∞-categories and let $n \geqslant 0$ be an integer. Suppose that $\mathcal{C}$ is anticomplete and n-complicial. Then the restriction functor $\phi : \mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}, \mathcal{D}) \to \mathrm{Fun}(\tau_{\leqslant n}\mathcal{C}, \tau_{\leqslant n}\mathcal{D})$ is a fully faithful embedding, whose essential image is spanned by those functors $f : \tau_{\leqslant n}\mathcal{C} \to \tau_{\leqslant n}\mathcal{D}$ which are left exact and commute with small colimits.*

Proof. Since $\mathcal{C}$ is anticomplete, we can replace $\mathcal{D}$ by its completion $\widehat{\mathcal{D}}$ and thereby reduce where $\mathcal{D}$ is complete. In particular, $\mathcal{D}$ is separated, so the desired result follows from Proposition C.5.3.9. □

Proposition C.5.5.20. *Let $n \geqslant 0$, let $\mathsf{Groth}_n^{\mathrm{lex}}$ be as in Definition C.5.4.1, and let $L : \mathsf{Groth}_\infty^{\mathrm{lex}} \to \mathsf{Groth}_n^{\mathrm{lex}}$ be the functor given by $L(\mathcal{C}) = \tau_{\leqslant n}\mathcal{C}$. Then L admits a fully faithful left adjoint $\mathsf{Groth}_n^{\mathrm{lex}} \hookrightarrow \mathsf{Groth}_\infty^{\mathrm{lex}}$, whose essential image is spanned by those Grothendieck prestable ∞-categories $\mathcal{C}$ which are anticomplete and n-complicial.*

Proof. Let $\mathcal{E} \subseteq \mathsf{Groth}_{\infty}^{\mathrm{lex}}$ denote the full subcategory spanned by those Grothendieck prestable ∞-categories which are anticomplete and n-complicial. We first claim that $\mathcal{E}$ is a colocalization of $\mathsf{Groth}_{\infty}^{\mathrm{lex}}$. In other words, for every object $\mathcal{C} \in \mathsf{Groth}_{\infty}^{\mathrm{lex}}$, we claim that there exists a morphism $\lambda : \mathcal{C}' \to \mathcal{C}$ in $\mathsf{Groth}_{\infty}^{\mathrm{lex}}$ where $\mathcal{C}'$ is anticomplete and n-complicial and, for every anticomplete n-complicial Grothendieck prestable ∞-category $\mathcal{D}$, composition with λ induces a homotopy equivalence

$$\mathrm{Map}_{\mathsf{Groth}_{\infty}^{\mathrm{lex}}}(\mathcal{D}, \mathcal{C}') \to \mathrm{Map}_{\mathsf{Groth}_{\infty}^{\mathrm{lex}}}(\mathcal{D}, \mathcal{C}).$$

By virtue of Proposition C.5.5.19, to guarantee the latter property it suffices to arrange that λ is an n-equivalence, which is always possible by virtue of Proposition C.5.5.18.

Note that the functor L carries n-equivalences in $\mathsf{Groth}_{\infty}^{\mathrm{lex}}$ to equivalences in $\mathsf{Groth}_{n}^{\mathrm{lex}}$, and therefore factors as a composition

$$\mathsf{Groth}_{\infty}^{\mathrm{lex}} \xrightarrow{L'} \mathcal{E} \xrightarrow{L''} \mathsf{Groth}_{n}^{\mathrm{lex}}$$

where L' is right adjoint to the inclusion $\mathcal{E} \hookrightarrow \mathsf{Groth}_{\infty}^{\mathrm{lex}}$, and L'' is the restriction $L|_{\mathcal{E}}$. To complete the proof, it will suffice to show that the functor L'' is an equivalence of ∞-categories. The assertion that L'' is fully faithful follows immediately from Proposition C.5.5.19, and essential surjectivity follows from Proposition C.5.5.18. □

Remark C.5.5.21. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $n \geqslant 0$. The proof of Proposition C.5.5.20 shows that the functor $\lambda : \mathcal{C}' \to \mathcal{C}$ appearing in Proposition C.5.5.18 is determined uniquely (up to equivalence) by $\mathcal{C}$.

C.5.6 Digression: Injective Objects of Grothendieck Abelian Categories

Let $\mathcal{A}$ be an abelian category. Recall that an object $Q \in \mathcal{A}$ is said to be *injective* if the functor $X \mapsto \mathrm{Hom}_{\mathcal{A}}(X, Q)$ is exact. In this section, we review some standard facts about injective objects in Grothendieck abelian categories which will be needed elsewhere in this book. For a more detailed exposition, we refer the reader to [74]. We begin by recalling a theorem of Grothendieck (for a proof, see [87] or Corollary HA.1.3.5.7):

Proposition C.5.6.1 (Grothendieck)**.** *Let $\mathcal{A}$ be a Grothendieck abelian category. Then $\mathcal{A}$ has enough injectives. In other words, for every object $X \in \mathcal{A}$, there exists a monomorphism $X \hookrightarrow Q$, where Q is injective.*

In the situation of Proposition C.5.6.1, the injective object Q is not uniquely determined. However, there is a choice of Q which is, in some sense, as small as possible: the *injective hull* of M.

Notation C.5.6.2. Let $\mathcal{A}$ be a Grothendieck abelian category containing an object X. We let $\mathrm{Sub}(X)$ denote the partially ordered set of isomorphism classes of subobjects of X. In what follows, we will abuse notation by identifying elements of $\mathrm{Sub}(X)$ with monomorphisms $i : Y \hookrightarrow X$ in the category $\mathcal{A}$ (or simply with the domains of those elements). We will also write $Y \subseteq X$ to indicate that Y is an element of $\mathrm{Sub}(X)$ (or that Y is the domain of a monomorphism $Y \hookrightarrow X$, which we will often not specify explicitly).

Definition C.5.6.3. Let $\mathcal{A}$ be a Grothendieck abelian category, let X be an object of $\mathcal{A}$, and let $X_0 \subseteq X$ be a subobject of X. We say that X is an *essential extension* of X_0 if, for every nonzero subobject $X' \subseteq X$, the intersection $X' \times_X X_0 \in \mathrm{Sub}(X')$ is nonzero.

Lemma C.5.6.4. *Let $\mathcal{A}$ be a Grothendieck abelian category, let Q be an object of $\mathcal{A}$, and let $X \subseteq Q$ be a subobject of Q. Then:*

(a) *Let $S \subseteq \mathrm{Sub}(Q)$ be the collection of subobjects of Q which contain X and are essential extensions of X. Then there exists a maximal element $E \in S$.*

(b) *If Q is injective, then E is also injective.*

Proof. To prove (a), it will suffice to show that S satisfies the hypotheses of Zorn's lemma. It is clear that S is nonempty (since $X \in S$). If $\{Y_\alpha\}$ is a filtered subset of S, then $Y = \varinjlim_\alpha Y_\alpha$ can be identified with a subobject of Q containing X. Any subobject $Y' \subseteq Y$ can be identified with the colimit $\varinjlim_\alpha (Y' \times_Y Y_\alpha)$. If Y' is nonzero, then some intersection $Y' \times_Y Y_\alpha$ must also be nonzero. The assumption $Y_\alpha \in S$ then implies that $Y' \times_Y X \simeq (Y' \times_Y Y_\alpha) \times_{Y_\alpha} X$ is nonzero. It follows that Y is an essential extension of X and is therefore an upper bound for $\{Y_\alpha\}$ in the partially ordered set S.

We now prove (b). Assume that Q is injective; we wish to show that E is injective. Let M be an object of $\mathcal{A}$, let M_0 be a subobject of M, and let $f_0 : M_0 \to E$ be a morphism; we wish to show that f_0 can be extended to a morphism $f : M \to E$. To prove this, we let T be the collection of all pairs (M_1, f_1), where M_1 is a subobject of M containing M_0 and $f_1 : M_1 \to E$ is an extension of f_0. The set T satisfies the hypotheses of Zorn's Lemma, and therefore contains a maximal element (M_1, f_1). Using our assumption that Q is injective, we can extend f_1 to a map $g : M \to Q$. If g factors through E, then we can complete the proof by setting $f = g$. Otherwise, g induces a map $\overline{g} : E \amalg_{M_1} M \to Q$ whose image is strictly larger than E. The maximality of E then implies that $\mathrm{im}(\overline{g})$ cannot be an essential extension of X: that is, there exists a subobject $K \subseteq \mathrm{im}(\overline{g})$ such that $K \times_Q X \simeq 0$. We then must also have $K \times_Q E \simeq 0$ (since E is an essential extension of X), so that we can identify $K \oplus E$ with a subobject of $\mathrm{im}(\overline{g})$. It follows that $M_2 = M \times_{\mathrm{im}(g)} (K \oplus E)$ is strictly larger that M_1. Let $f_2 : M_2 \to E$ be the map given by composing the projections

$$M_2 = M \times_{\mathrm{im}(g)} (K \oplus E) \to K \oplus E \qquad K \oplus E \to E.$$

Then $(M_2, f_2) \in T$ is a proper extension of (M_1, f_1), contrary to our maximality assumption. □

Definition C.5.6.5. Let $\mathcal{A}$ be a Grothendieck abelian category and let $f : X \to Q$ be a morphism in $\mathcal{A}$. We will say that f *exhibits Q as an injective hull of X* if Q is injective, f is a monomorphism, and f exhibits Q as an essential extension of X.

In any Grothendieck abelian category, injective hulls exist and are well-defined up to isomorphism:

Proposition C.5.6.6. *Let $\mathcal{A}$ be a Grothendieck abelian category and let X be an object of $\mathcal{A}$. Then:*

(1) *There exists a morphism $f : X \hookrightarrow Q$ which exhibits Q as an injective hull of X.*

(2) *Let $f : X \hookrightarrow Q$ be a monomorphism, where Q is injective. Then, for every essential extension $g : X \hookrightarrow Y$, there exists a monomorphism $h : Y \hookrightarrow Q$ extending f. In other words, Q contains every essential extension of X.*

(3) *Let $f : X \hookrightarrow Q$ be a monomorphism, where Q is injective. If $g : X \hookrightarrow Q'$ exhibits Q' as an injective hull of X, then f factors as a composition $X \xrightarrow{g} Q' \hookrightarrow Q' \oplus Q'' \simeq Q$ for some injective object $Q'' \in \mathcal{A}$. In other words, Q is isomorphic (in the category $\mathcal{A}_{X/}$) to the direct sum of Q' with an auxiliary (injective) object.*

(4) *Let $f : X \hookrightarrow Q$ and $g : X \hookrightarrow Q'$ be morphisms which exhibit Q and Q' as injective hulls of X. Then there exists an isomorphism $h : Q' \to Q$ such that $f = h \circ g$.*

Warning C.5.6.7. In part (4) of Proposition C.5.6.6, the isomorphism $h : Q' \to Q$ need not be unique. In other words, injective hulls are unique up to isomorphism but *not* up to unique (or canonical) isomorphism.

Proof of Proposition C.5.6.6. Assertion (1) follows from Lemma C.5.6.4. To prove (2), suppose we are given morphisms $f : X \to Q$ and $g : X \to Y$. If Q is injective and g is a monomorphism, then we can write $f = h \circ g$ for some morphism $h : Y \to Q$. Then $X \times_Y \ker(h) \simeq \ker(f) \simeq 0$. If Y is an essential extension of X, then it follows that h is a monomorphism.

We now prove (3). Suppose we are given a monomorphism $f : X \hookrightarrow Q$ and a morphism $g : X \hookrightarrow Q'$, where Q is injective and g exhibits Q' as an injective hull of X. It follows from (2) that there exists a monomorphism $h : Q' \hookrightarrow Q$ such that $f = h \circ g$. Using the injectivity of Q', we see that the monomorphism h splits: that is, we can write Q as a direct sum $Q' \oplus Q''$. Since Q'' is a retract of Q, it is also an injective object of $\mathcal{C}$.

Assertion (4) is an immediate consequence of (3). □

Proposition C.5.6.8 (Krause [124])**.** *Let $\mathcal{A}$ be a Grothendieck abelian category and let Q_* be a chain complex of injective objects of $\mathcal{A}$. Then Q_* splits as a direct sum $Q'_* \oplus Q''_*$, where:*

- (a) *The complex Q'_* is homotopically minimal: that is, for every integer n, the object Q'_n is an injective hull of $\ker(d'_n : Q'_n \to Q'_{n-1})$; here d'_* denote the differential on the chain complex Q'_*.*
- (b) *The chain complex Q''_* is contractible: that is, there is a chain homotopy $h : Q''_* \to Q''_{*+1}$ from 0 to $\mathrm{id}_{Q''_*}$.*

Proof. For each integer n, let $d_n : Q_n \to Q_{n-1}$ denote the differential on Q_*. Choose a subobject $E_n \subseteq Q_n$ which is maximal among essential extensions of $\ker(d_n)$. Since Q_n is injective, Lemma C.5.6.4 implies that E_n is also injective. Consequently, the inclusion $E_n \hookrightarrow Q_n$ is a split monomorphism; we can therefore choose another subobject $A_n \subseteq Q_n$ such that $Q_n \simeq A_n \oplus E_n$.

The differential

$$d_{n+1} : Q_{n+1} \to \ker(d_n) \subseteq E_n \subseteq Q_n$$

is injective when restricted to A_{n+1}, and therefore induces an isomorphism $\phi_{n+1} : A_{n+1} \to B_n$ for some subobject $B_n \subseteq E_n$. Since A_{n+1} is a direct summand of Q_{n+1}, it is an injective object of $\mathcal{A}$. It follows that B_n is also injective, so the inclusion $B_n \hookrightarrow E_n$ splits. We can therefore choose another subobject $Q'_n \subseteq E_n$ such that $E_n \simeq Q'_n \oplus E_n$.

Let us write the composition

$$Q'_n \hookrightarrow Q_n \xrightarrow{d_n} \ker(d_{n-1}) \subseteq E_{n-1} \simeq Q'_{n-1} \oplus B_{n-1}$$

as (d'_n, ψ_n) for some pair of maps

$$d'_n : Q'_n \to Q'_{n-1} \qquad \psi_n : Q'_n \to B_{n-1}.$$

Set $Q''_n = A_n \oplus B_n$, and let $d''_n : Q''_n \to Q''_{n-1}$ denote the map given by the composition

$$Q''_n = A_n \oplus B_n \to A_n \xrightarrow{\phi_n} B_{n-1} \to A_{n-1} \oplus B_{n-1} = Q''_{n-1}.$$

Then (Q'_*, d'_*) and (Q''_*, d''_*) are chain complexes satisfying conditions (a) and (b), and the maps

$$Q'_n \oplus Q''_n \simeq Q'_n \oplus A_n \oplus B_n \xrightarrow{\mathrm{id} - \rho_n} Q'_n \oplus A_n \oplus B_n \simeq Q_n$$

determine an isomorphism of chain complexes $(Q_*, d_*) \simeq (Q'_*, d'_*) \oplus (Q''_*, d''_*)$, where ρ_n is given by the composition

$$Q'_n \oplus A_n \oplus B_n \to Q'_n \xrightarrow{\psi_n} B_{n-1} \xrightarrow{\phi_n^{-1}} A_n \to Q'_n \oplus A_n \oplus B_n.$$

□

Definition C.5.6.9. Let $\mathcal{A}$ be a Grothendieck abelian category and let X be an object of $\mathcal{A}$.

(a) We say that X is *indecomposable* if it is nonzero and cannot be written as a direct sum $X_0 \oplus X_1$, where X_0 and X_1 are nonzero subobjects of X.

(b) We say that X is *coirreducible* if it is nonzero and, for every pair of nonzero subobjects $X_0, X_1 \subseteq X$, the intersection $X_0 \times_X X_1$ is also nonzero.

Proposition C.5.6.10. *Let $\mathcal{A}$ be a Grothendieck abelian category. Then:*

(a) *Every coirreducible object $X \in \mathcal{A}$ is indecomposable.*

(b) *Let Q be an injective object of $\mathcal{A}$. If Q is indecomposable, then Q is an injective hull of each nonzero subobject $X \subseteq Q$.*

(c) *Every indecomposable injective object $Q \in \mathcal{A}$ is coirreducible.*

(d) *Let $f : X \hookrightarrow Y$ be a monomorphism in $\mathcal{A}$. If Y is coirreducible and X is nonzero, then X is coirreducible.*

(e) *Let $f : X \hookrightarrow Y$ be a monomorphism in $\mathcal{A}$ which exhibits Y as an essential extension of X. If X is coirreducible, then Y is coirreducible.*

(f) *Let $f : X \hookrightarrow Q$ be a morphism in $\mathcal{C}$ which exhibits Q as an injective hull of X. Then X is coirreducible if and only if Q is indecomposable.*

Proof. Assertion (a) follows immediately from the definitions. To prove (b), suppose that Q is an indecomposable injective object of $\mathcal{A}$ and let $X \subseteq Q$ be a nonzero subobject. It follows from Proposition C.5.6.6 that Q splits as a direct sum $Q' \oplus Q''$, where Q' is an injective hull of X. The indecomposability of Q implies that $Q'' \simeq 0$, so that Q is an injective hull of X.

Assertion (c) is a reformulation of (b). Assertion (d) follows immediately from the definitions. To prove (e), suppose that Y is an essential extension of X and that we are given nonzero subobjects $Y_0, Y_1 \subseteq Y$. Then the intersections $X_0 = Y_0 \times_Y X$ and $X_1 = Y_1 \times_Y X$ are also nonzero. If X is coirreducible, then $X_0 \times_X X_1$ is nonzero, so that $Y_0 \times_Y Y_1$ is also nonzero.

We now prove (f). Let $f : X \hookrightarrow Q$ exhibit Q as an injective hull of X. It follows from (d) and (e) that X is coirreducible if and only if Q is coirreducible. Since Q is injective, it follows from (a) and (c) that Q is coirreducible if and only if it is indecomposable. □

Corollary C.5.6.11. *Let R be a Noetherian commutative ring and let $Q \in \mathrm{Mod}_R^{\heartsuit}$. The following conditions are equivalent:*

(1) *The R-module Q is indecomposable and injective.*

(2) *The R-module Q is an injective hull some residue field κ of R.*

Proof. The implication (2) $\Rightarrow$ (1) follows immediately from Proposition C.5.6.10, since every residue field κ of R is coirreducible as an R-module. For the converse, suppose that (1) is satisfied. Since Q is a nonzero module over a Noetherian ring R, it has an associated prime: that is, there exists a monomorphism $\iota : R/\mathfrak{p} \hookrightarrow Q$ for some prime ideal $\mathfrak{p}$ of R. Let κ be the fraction field of $R/\mathfrak{p}$. The injectivity of Q guarantees that ι extends to a map $\bar{\iota} : \kappa \to Q$. Since $\ker(\bar{\iota}) \cap (R/\mathfrak{p}) \simeq 0$, we have $\ker(\bar{\iota}) \simeq 0$: that is, the map ι is injective. Assertion (b) of Proposition C.5.6.10 guarantees that $\bar{\iota}$ exhibits Q as an injective hull of κ. □

Recall that an abelian category $\mathcal{A}$ is said to be *locally Noetherian* if it is a Grothendieck abelian category and every object $X \in \mathcal{A}$ can be written as a union of its Noetherian subobjects (see Definition C.6.8.5).

Proposition C.5.6.12. *Let $\mathcal{A}$ be a locally Noetherian abelian category and let Q be an object of $\mathcal{A}$. The following conditions are equivalent:*

(a) *The object $Q \in \mathcal{A}$ is injective.*

(b) *For every Noetherian object $X \in \mathcal{A}$ and every subobject $X' \subseteq X$, the restriction map $\mathrm{Hom}_{\mathcal{A}}(X, Q) \to \mathrm{Hom}_{\mathcal{A}}(X', Q)$ is surjective.*

Proof. The implication $(a) \Rightarrow (b)$ is immediate. Conversely, suppose that (b) is satisfied. To show that Q is injective, it will suffice to show that for *every* object $X \in \mathcal{A}$ and every subobject $X' \subseteq X$, the restriction map $\mathrm{Hom}_{\mathcal{A}}(X, Q) \to \mathrm{Hom}_{\mathcal{A}}(X', Q)$ is surjective. To prove this, fix a map $f' : X' \to Q$, and let P be the partially ordered set of equivalence classes of pairs (X_0, f_0), where X_0 is a subobject of X containing X' and $f_0 : X_0 \to Q$ is a morphism satisfying $f_0|_{X'} = f'$. It is easy to see that P satisfies the hypotheses of Zorn's Lemma and therefore admits a maximal element (X_0, f_0). Replacing X' by X_0 and f' by f_0, we may reduce to the case where the morphism f' cannot be extended to any subobject of X properly containing X'. If Y is a Noetherian subobject of X and we set $Y' = X' \times_X Y$, then assumption (b) implies that $f'|_{Y'}$ can be extended to a map $Y \to Q$, so that f' can be extended to a map $Y \amalg_{Y'} X' \to Q$. The maximality of f' guarantees that $Y' \simeq Y$: that is, the Noetherian subobject Y is contained in X'. Allowing Y to vary, we deduce that X' contains every Noetherian subobject $Y \subseteq X$, and therefore coincides with X by virtue of our assumption that $\mathcal{A}$ is locally Noetherian. □

Corollary C.5.6.13. *Let $\mathcal{A}$ be a locally Noetherian abelian category. Then the collection of injective objects of $\mathcal{A}$ is closed under filtered colimits.*

Proof. Let $\{Q_\alpha\}$ be a filtered diagram of injective objects of $\mathcal{A}$ having colimit Q; we wish to show that Q is injective. By virtue of Proposition C.5.6.12, it will suffice to show that for every monomorphism $f : X' \hookrightarrow X$ where X is Noetherian, the induced map $\rho : \mathrm{Hom}_{\mathcal{A}}(X, Q) \to \mathrm{Hom}_{\mathcal{A}}(X', Q)$ is surjective. Since X and X' are compact objects of $\mathcal{A}$ (see Proposition C.6.8.7), we can write ρ as a filtered colimit of maps $\rho_\alpha : \mathrm{Hom}_{\mathcal{A}}(X, Q_\alpha) \to \mathrm{Hom}_{\mathcal{A}}(X', Q_\alpha)$, each of which is surjective by virtue of our assumption that Q_α is injective. □

Lemma C.5.6.14. *Let $\mathcal{A}$ be a locally Noetherian abelian category and let Q be a nonzero injective object of $\mathcal{A}$. Then there exists subobject $X \subseteq Q$ which is Noetherian and coirreducible.*

Proof. Since Q is nonzero and $\mathcal{A}$ is locally Noetherian, there exists a Noetherian object $Y \in \mathcal{A}$ and a nonzero map $f : Y \to Q$. Let $S \subseteq \mathrm{Sub}(Y)$ be the collection of all subobjects $Y' \subseteq Y$ for which there exists a nonzero map $g : Y \to Q$ which annihilates Y'. The existence of f shows that S is nonempty. Since Y is Noetherian, we can choose a maximal element $Y' \in S$. Let $g : Y \to Q$ be a nonzero map which annihilates Y', and set $X = \mathrm{im}(g)$. Then X is nonzero and Noetherian (Proposition C.6.8.2). We will complete the proof by showing that X is coirreducible. Suppose otherwise: then there exist nonzero subobjects $X_0, X_1 \subseteq X$ such that $X_0 \times_X X_1$ is nonzero. It follows that we can identify $X_0 \oplus X_1$ with a subobject of Q. Let $q : X_0 \oplus X_1 \to X_0$ be the projection map onto the first factor. It follows from the injectivity of Q that we can extend q to a map $\overline{q} : Q \to Q$. The map $(\overline{q} \circ g) : Y \to Q$ is nonzero (since its image contains X_0), and the kernel $\ker(\overline{q} \circ g)$ is strictly larger than Y' (since it contains the fiber product $Y \times_X X_1$). This contradicts the maximality of Y'. □

Lemma C.5.6.15. *Let $\mathcal{A}$ be a locally Noetherian abelian category and let Q be a nonzero injective object of $\mathcal{A}$. Then Q splits as a direct sum $Q' \oplus Q''$, where Q' is indecomposable.*

Proof. Applying Lemma C.5.6.14, we can choose a subobject $X \subseteq Q$ which is coirreducible. Using Proposition C.5.6.6, we can decompose Q as a direct sum $Q' \oplus Q''$, where Q' is an injective hull of X. It follows from Proposition C.5.6.10 that Q' is indecomposable. □

Proposition C.5.6.16. *Let $\mathcal{A}$ be a locally Noetherian abelian category and let Q be an object of $\mathcal{A}$. The following conditions are equivalent:*

(1) *The object Q is injective.*

(2) *There exists an isomorphism $Q \simeq \bigoplus_\alpha Q_\alpha$, where each Q_α is an injective object of $\mathcal{A}$.*

(3) *There exists an isomorphism $Q \simeq \bigoplus_\alpha Q_\alpha$, where each Q_α is an indecomposable injective object of $\mathcal{A}$.*

Proof. The implication (3) ⇒ (2) is obvious and the implication (2) ⇒ (1) follows from Corollary C.5.6.13. We will complete the proof by showing that (1) implies (3). Suppose that Q is injective. Let S denote the collection of all subsets $\mathcal{J} \subseteq \mathrm{Sub}(Q)$ with the following properties:

(*i*) Each element of $\mathcal{J}$ is an indecomposable injective object of $\mathcal{A}$.

(*ii*) The canonical map $\bigoplus_{Q_0 \in \mathcal{J}} Q_0 \to Q$ is a monomorphism.

Note that S is nonempty (since it contains the empty set). Moreover, since the collection of monomorphisms in $\mathcal{A}$ is closed under filtered colimits, the set S is closed under directed unions. Applying Zorn's Lemma, we deduce that S contains a maximal element $\mathcal{J}$. Set $Q' = \bigoplus_{Q_0 \in \mathcal{J}} Q_0$, so that the canonical map $Q' \to Q$ is a monomorphism. Since Q is injective, it follows that Q splits as a direct sum $Q' \oplus Q''$ for some auxiliary subobject $Q'' \subseteq Q$. If Q'' is nonzero, then Lemma C.5.6.15 implies that there exists an indecomposable direct summand $Q''_0 \subseteq Q''$. In this case, we would have $\mathcal{J} \cup \{Q''_0\} \in S$, contradicting the maximality of $\mathcal{J}$. It follows that $Q'' \simeq 0$, so that $Q \simeq \bigoplus_{Q_0 \in \mathcal{J}} Q_0$ satisfies condition (3). □

C.5.7 Injective Objects of Stable ∞-Categories

Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $\mathrm{Sp}(\mathcal{C})$ denote the ∞-category of spectrum objects of $\mathcal{C}$. We will regard $\mathrm{Sp}(\mathcal{C})$ as equipped with the t-structure $(\mathrm{Sp}(\mathcal{C})_{\geqslant 0}, \mathrm{Sp}(\mathcal{C})_{\leqslant 0})$ of Remark C.1.2.10. In this section, we will introduce the notion of *injective object* of the ∞-category $\mathrm{Sp}(\mathcal{C})$ (Definition C.5.7.2) and describe its relationship with the theory of injective objects of the abelian category $\mathcal{C}^{\heartsuit}$.

Proposition C.5.7.1. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let Q be an object of $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$. The following conditions are equivalent:*

(1) *The object Q is projective when viewed as an object of $\mathrm{Sp}(\mathcal{C})^{\mathrm{op}}_{\leqslant 0}$: in other words, for every cosimplicial object $X^\bullet$ of $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$, the map*

$$|\operatorname{Map}_{\mathrm{Sp}(\mathcal{C})}(X^\bullet, Q)| \to \operatorname{Map}_{\mathrm{Sp}(\mathcal{C})}(\operatorname{Tot} X^\bullet, Q)$$

is a homotopy equivalence.

(2) *For every $X \in \mathrm{Sp}(\mathcal{C})_{\leqslant 0}$, the abelian group $\operatorname{Ext}^1_{\mathcal{C}}(X, Q)$ vanishes.*

(3) *For every object $X \in \mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ and every integer $n > 0$, the abelian group $\operatorname{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X, Q)$ vanishes.*

(4) *For every object $X \in \mathcal{C}^{\heartsuit}$ and every integer $i > 0$, the abelian group $\operatorname{Ext}^i_{\mathrm{Sp}(\mathcal{C})}(X, Q)$ vanishes.*

(5) *Given a fiber sequence*

$$X' \to X \to X'',$$

where $X', X, X'' \in \mathrm{Sp}(\mathcal{C})_{\leqslant 0}$, the induced map $\operatorname{Ext}^0_{\mathrm{Sp}(\mathcal{C})}(X', Q) \to \operatorname{Ext}^0_{\mathrm{Sp}(\mathcal{C})}(X, Q)$ is surjective.

Proof. Apply Proposition HA.?? to the ∞-category $\mathrm{Sp}(\mathcal{C})^{\mathrm{op}}$. □

Definition C.5.7.2. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $Q \in \mathrm{Sp}(\mathcal{C})$. We will say that Q is *injective* if it belongs to $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ and satisfies the equivalent conditions of Proposition C.5.7.1.

Proposition C.5.7.3. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let Q be an object of $\mathrm{Sp}(\mathcal{C})$. The following conditions are equivalent:*

- (a) *The object Q is injective.*
- (b) *For every object $X \in \mathrm{Sp}(\mathcal{C})$, the canonical map $\mathrm{Ext}^0_{\mathrm{Sp}(\mathcal{C})}(X, Q) \to \mathrm{Hom}_{\mathcal{C}^\heartsuit}(\pi_0 X, \pi_0 Q)$ is an isomorphism.*

Moreover, if these conditions are satisfied, then $\pi_0 Q$ is an injective object of the abelian category $\mathcal{C}^\heartsuit$.

Proof. Suppose first that (a) is satisfied, and let X be an object of $\mathrm{Sp}(\mathcal{C})$; we wish to show that the canonical map $\rho : \mathrm{Ext}^0_{\mathrm{Sp}(\mathcal{C})}(X, Q) \to \mathrm{Hom}_{\mathcal{C}^\heartsuit}(\pi_0 X, \pi_0 Q)$ is an isomorphism. Using the fact that Q belongs to $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$, we can identify $\mathrm{Hom}_{\mathcal{C}^\heartsuit}(\pi_0 X, \pi_0 Q)$ with $\mathrm{Ext}^0_{\mathrm{Sp}(\mathcal{C})}(\tau_{\geqslant 0} X, Q)$. Using this identification, we can fit ρ into a short exact sequence of abelian groups

$$\mathrm{Ext}^0_{\mathrm{Sp}(\mathcal{C})}(\tau_{\leqslant -1} X, Q) \to \mathrm{Ext}^0_{\mathrm{Sp}(\mathcal{C})}(X, Q) \xrightarrow{\rho} \mathrm{Ext}^0_{\mathrm{Sp}(\mathcal{C})}(\tau_{\geqslant 0} X, Q) \to \mathrm{Ext}^1_{\mathrm{Sp}(\mathcal{C})}(\tau_{\leqslant -1} X, Q).$$

If Q is injective, then the first and last terms of this short exact sequence vanish (Proposition C.5.7.1), so that ρ is an isomorphism.

Now suppose that (b) is satisfied. Applying (b) in the case $X = \tau_{\geqslant 1} Q$, we deduce that the group $\mathrm{Ext}^0_{\mathrm{Sp}(\mathcal{C})}(\tau_{\geqslant 1} Q, Q)$ vanishes. In particular, the canonical map $\tau_{\geqslant 1} Q \to Q$ is nullhomotopic, so that Q belongs to $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$. Applying (b) in the case $X = \Sigma^{-n} C$ for $C \in \mathcal{C}^\heartsuit$, we deduce that $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(C, Q)$ vanishes for $n \neq 0$. Using criterion (3) of Proposition C.5.7.1, we deduce that Q is injective.

Now suppose that Q satisfies (a) and (b). For any short exact sequence $0 \to X' \to X \to X'' \to 0$ in the abelian category $\mathcal{C}^\heartsuit$, we have a short exact sequence of abelian groups

$$\mathrm{Ext}^0_{\mathrm{Sp}(\mathcal{C})}(X, Q) \xrightarrow{\theta} \mathrm{Ext}^0_{\mathrm{Sp}(\mathcal{C})}(X', \pi_0 Q) \to \mathrm{Ext}^1_{\mathrm{Sp}(\mathcal{C})}(X'', Q)$$

where the third term vanishes by virtue of the injectivity of Q. It follows that the map θ is surjective, so that condition (b) shows that $\mathrm{Hom}_{\mathcal{C}^\heartsuit}(X, \pi_0 Q) \to \mathrm{Hom}_{\mathcal{C}^\heartsuit}(X', \pi_0 Q)$ is surjective. It follows that $\pi_0 Q$ is an injective object of the abelian category $\mathcal{C}^\heartsuit$. □

If R is a connective $\mathbb{E}_1$-ring, then Corollary HA.7.2.2.19 asserts that the homotopy category of the ∞-category of projective left R-modules is equivalent to the ordinary category of projective modules over $\pi_0 R$. Our next goal is to prove an analogous result for injective modules:

Theorem C.5.7.4. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $\mathrm{Sp}(\mathcal{C})^{\mathrm{inj}}$ denote the full subcategory of $\mathrm{Sp}(\mathcal{C})$ spanned by the injective objects. Let $\mathcal{A} = \mathcal{C}^{\heartsuit}$ and let $\mathcal{A}^{\mathrm{inj}}$ denote the full subcategory of $\mathcal{A}$ spanned by the injective objects. Then the construction Then the construction $Q \mapsto \pi_0 Q$ determines an equivalence of categories $\theta : \mathrm{hSp}(\mathcal{C})^{\mathrm{inj}} \to \mathcal{A}^{\mathrm{inj}}$.*

Warning C.5.7.5. In the situation of Theorem C.5.7.4, the domain of the equivalence $\theta : \mathrm{hSp}(\mathcal{C})^{\mathrm{inj}} \simeq \mathcal{A}^{\mathrm{inj}}$ is the *homotopy* category of $\mathrm{Sp}(\mathcal{C})^{\mathrm{inj}}$. In general, the mapping spaces in $\mathrm{Sp}(\mathcal{C})^{\mathrm{inj}}$ are not discrete (and contain information which is not seen by the abelian category $\mathcal{A} = \mathcal{C}^{\heartsuit}$).

The proof of Theorem C.5.7.4 will require some preliminaries.

Lemma C.5.7.6. *Let α be an ordinal and let $(\alpha) = \{\beta : \beta < \alpha\}$ be the collection of ordinals smaller than α. Let $F : \mathrm{N}(\alpha) \to \mathcal{S}$ be a functor with the following property: for every ordinal $\beta < \alpha$, the map $F(\beta) \to \varprojlim_{\gamma < \beta} F(\gamma)$ has connected homotopy fibers. Then $\varprojlim_{\beta < \alpha} F(\beta)$ is connected.*

Proof. Using Proposition HTT.4.2.4.4 , we may assume without loss of generality that F arises from a diagram $X : (\alpha) \to \mathcal{S}\mathrm{et}_{\Delta}$ which is fibrant with respect to the injective model structure. Then $\varprojlim_{\beta < \alpha} F(\beta)$ is represented by the Kan complex $\varprojlim_{\beta < \alpha} X(\beta)$ (Theorem HTT.4.2.4.1). The assumption that X is fibrant is equivalent to the requirement that each of the maps $\theta_\beta : X(\beta) \to \varprojlim_{\gamma < \beta} X(\gamma)$ is a Kan fibration, and we are given that each of the maps θ_β has connected homotopy fibers. Let x and y be vertices of $\varprojlim_{\beta < \alpha} X(\beta)$, and let x_β and y_β denote the images of x and y in $X(\beta)$ for $\beta < \alpha$. To show that x and y belong to the same path component of $\varprojlim_{\beta < \alpha} X(\beta)$, we must construct a compatible system of edges $\{e_\beta : x_\alpha \to y_\beta\}$ in $X(\beta)$. The construction proceeds by induction on β. Assume that the edges $\{e_\gamma\}_{\gamma < \beta}$ have been constructed, thereby determining an edge $e' : x' \to y'$ in $\varprojlim_{\gamma < \beta} X(\gamma)$. Since θ_β is a Kan fibration, we can choose an edge $\overline{e}' : x_\beta \to \overline{y}'$ in $X(\beta)$ lying over e'. Since the fiber $X(\beta)_{y'}$ is path connected, we can choose a path $\overline{e}'' : \overline{y}' \to y_\beta$ in $X(\beta)_{y'}$. Using the fact that θ_β is a Kan fibration again, we conclude that there exists a 2-simplex σ:

$$\begin{array}{ccccc} & & \overline{y}' & & \\ & \overset{\overline{e}'}{\nearrow} & & \overset{\overline{e}''}{\searrow} & \\ x_\beta & & \xrightarrow{e_\beta} & & y_\beta \end{array}$$

lying over the degenerate 2-simplex associated to e', which produces the desired edge e_β lying over e'. $\square$

Lemma C.5.7.7. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. Then there exists a small collection of objects $\{X_i \in \mathcal{C}^{\heartsuit}\}_{i \in I}$ such that an object $Q \in \mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ is injective if and only if the abelian groups $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X_i, Q)$ vanish for all $i \in I$ and $n > 0$.*

Proof. Choose a set of objects $\{Y_j\}_{j \in J}$ which generates the abelian category $\mathrm{h}\mathcal{C}^{\heartsuit}$ under small colimits, and let $\{X_i\}_{i \in I}$ be a collection of representatives for all isomorphism classes of quotients of the objects $\{Y_j\}_{j \in J}$. Since $\mathcal{C}^{\heartsuit}$ is a Grothendieck abelian category, the collection I is small (see the proof of Proposition HA.1.3.5.3). We claim that this collection of objects has the desired property.

Let Q be an object of $\mathcal{C}_{\leqslant 0}$ such that $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X_i, Q) \simeq 0$ for $i \in I$ and $n > 0$; we wish to prove that Q is injective. To prove this, consider an arbitrary object $Z \in \mathcal{C}^{\heartsuit}$ and integer $n > 0$; we will show that $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(Z, Q) \simeq 0$. To this end, we first construct a transfinite sequence of subobjects $Z_\alpha \subseteq Z$ as follows. Assume that α is an ordinal that the subobjects $\{Z_\beta \subseteq Z\}_{\beta < \alpha}$ have been constructed. If the induced map $\phi : \varinjlim Z_\beta \to Z$ is not an isomorphism, then there exists an index $j \in J$ and a map $Y_j \to Z$ which does not factor through ϕ. We define Z_α to be the image of the map $Y_j \oplus (\varinjlim_{\beta < \alpha} Z_\beta) \to Z$.

The proof of Proposition HA.1.3.5.3 shows that the collection of isomorphism classes of subobjects of Z is small, so this process must eventually stop: that is, we have $\varinjlim_{\beta<\alpha} Z_\beta \simeq Z$ for some ordinal α. Then $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(Z, Q) \simeq \pi_0 \varprojlim_{\beta < \alpha} \mathrm{Map}_{\mathcal{C}}(\Sigma^{-n} Z_\beta, Q)$. To prove that this group vanishes, it suffices (by Lemma C.5.7.6) to show that for each $\beta < \alpha$, the map

$$\theta : \mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(\Sigma^{-n} Z_\beta, Q) \to \mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(\varinjlim_{\gamma<\beta} \Sigma^{-n} Z_\gamma, Q)$$

has connected homotopy fibers. By construction, the map $\varinjlim_{\gamma<\beta} Z_\gamma \to Z_\beta$ is a monomorphism in $\mathcal{C}^{\heartsuit}$ whose cokernel is given by X_i for some $i \in I$. We then have a fiber sequence

$$\Sigma^{n-1} X_i \to \varinjlim_{\gamma<\beta} \Sigma^{-n} Z_\gamma \to \Sigma^{-n} Z_\beta$$

so that θ is a pullback of the map $\theta' : * \to \mathrm{Map}_{\mathcal{C}}(\Sigma^{-n-1} X_i, Q)$. It therefore suffices to show that θ' has connected homotopy fibers: that is, that the homotopy group $\pi_1 \mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(\Sigma^{-n-1} X_i, Q) \simeq \mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X_i, Q)$ vanishes, which follows from our assumption on I. □

Proposition C.5.7.8. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let Q_0 be an injective object of the abelian category $\mathcal{C}^{\heartsuit}$. Then there exists a map $\phi : Q_0 \to Q$ in $\mathcal{C}_{\leqslant 0}$, where Q is an injective object of $\mathcal{C}$ and ϕ induces an equivalence $Q_0 \simeq \pi_0 Q$.*

Proof. Let $\{X_i\}_{i \in I}$ be as in Lemma C.5.7.7. Since the ∞-category $\mathrm{Sp}(\mathcal{C})$ is presentable, we can choose a regular cardinal κ such that each of the objects X_i is κ-compact. We will extend the object Q_0 to a transfinite sequence of objects $\{Q_\alpha \in \mathrm{Sp}(\mathcal{C})_{\leqslant 0}\}_{\alpha<\kappa}$ with the following properties:

(*a*) If $\lambda < \kappa$ is a nonzero limit ordinal, then $Q_\lambda \simeq \varinjlim_{\alpha<\lambda} Q_\lambda$.

(*b*) The map $Q_0 \to Q_\alpha$ induces an equivalence $Q_0 \to \pi_0 Q_\alpha$ for each $\alpha < \kappa$.

(c) Let $\alpha < \kappa$ and let $\eta \in \mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X_i, Q_\alpha)$ for some $i \in I$ and some $n > 0$. Then the image of η vanishes in $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X_i, Q_{\alpha+1})$.

Assuming that such a construction is possible, let $Q = \varinjlim_{\alpha<\kappa} Q_\alpha$. Then the natural map $Q_0 \to Q$ induces an equivalence $Q_0 \simeq \pi_0 Q$ by virtue of (b). We claim that Q is injective. To prove this, consider an arbitrary class $\eta \in \mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X_i, Q)$ for $i \in I$ and $n > 0$. Since X_i is κ-compact, η is the image of a class $\eta_0 \in \mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X_i, Q_\alpha)$ for some $\alpha < \kappa$. The image of η_0 in $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X_i, Q_{\alpha+1})$ vanishes by (c), so that $\eta = 0$ as desired.

It remains to construct the sequence Q_α. We proceed by induction on α, the case where α is a limit ordinal being prescribed by condition (a). Let us therefore suppose that Q_α has been defined. Let S be the set of all triples (n, i, η), where $\eta \in \mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X_i, Q_\alpha)$. Choose a well-ordering of the set S having order type β. For each $\gamma < \beta$, let $\eta_\gamma \in \mathrm{Ext}^{n_\gamma}_{\mathcal{C}}(X_{i_\gamma}, Q_\alpha)$ denote the corresponding class. We will construct a transfinite sequence of objects $\{P_\gamma\}_{\gamma \leqslant \beta+1}$ of $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ with the following properties:

(a′) We have $P_0 = Q_\alpha$. If $\lambda \leqslant \beta + 1$ is a limit ordinal, then $P_\lambda \simeq \varinjlim_{\gamma<\lambda} P_\gamma$.

(b′) For each $\gamma \leqslant \beta + 1$, the map $Q_0 \to P_\gamma$ induces an equivalence $Q_0 \simeq \pi_0 P_\gamma$.

(c′) For each $\gamma \leqslant \beta$, the image of η_γ in $\mathrm{Ext}^{n_\gamma}(X_{i_\gamma}, P_{\gamma+1})$ vanishes.

Assuming that this construction is possible, we can complete the proof by setting $Q_{\alpha+1} = P_{\beta+1}$.

The construction of the objects P_γ proceeds by induction on γ. When γ is a limit ordinal, the definition of P_γ is determined by (a′). Let us therefore assume that P_γ has been constructed. Let $n = n_\gamma$ and $i = i_\gamma$, and let η denote the image of η_γ in $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X_i, P_\gamma)$. Then η determines a map $\phi : \Sigma^{-n} X_i \to P_\gamma$. If $n > 1$, we define $Q_{\gamma+1}$ to be the cofiber of ϕ; it is then clear that $P_{\gamma+1}$ has the desired properties. Let us therefore assume that $n = 1$, so that ϕ induces a map $\psi : X_i \to \pi_{-1} P_\gamma$ in the abelian category $\mathcal{C}^\heartsuit$. Let K denote the fiber of ψ, so that the composite map

$$\Sigma^{-1} K \to \Sigma^{-1} X_i \to \pi_{-1} P_\gamma \to \tau_{\leqslant -1} P_\gamma$$

is nullhomotopic. It follows that the map $\Sigma^{-1} K \to \Sigma^{-1} X_i \xrightarrow{\phi} P_\gamma$ factors through some map $\xi : \Sigma^{-1} K \to \pi_0 P_\gamma \simeq Q_0$. The map ξ determines an extension

$$0 \to Q_0 \to E \to K \to 0$$

in the abelian category $\mathcal{C}^\heartsuit$. Since Q_0 is an injective object of $\mathcal{C}^\heartsuit$, this extension splits so that $\xi = 0$. Let X_i/K denote the cofiber of the map $K \to X_i$, so that ϕ factors as a composition

$$\Sigma^{-1} X_i \to \Sigma^{-1}(X_i/K) \xrightarrow{\phi'} P_\gamma.$$

We now define $P_{\gamma+1}$ to be the cofiber of ϕ'. Then $P_{\gamma+1}$ satisfies condition (c') by construction. To verify (b'), we observe that there is an exact sequence

$$0 \to \pi_0 Q_\gamma \to \pi_0 Q_{\gamma+1} \to X_i/K \xrightarrow{\psi'} \pi_{-1} Q_\gamma,$$

where ψ' is the map induced by ψ. Since K is the fiber of ψ, the map ψ' is injective so that $\pi_0 Q_{\gamma+1} \simeq \pi_0 Q_\gamma \simeq Q_0$ as desired. □

Proof of Theorem C.5.7.4. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and set $\mathcal{A} = \mathcal{C}^\heartsuit$. It follows from Proposition C.5.7.3 that the functor $\pi_0 : \mathrm{Sp}(\mathcal{C})^{\mathrm{inj}} \to \mathcal{A}^{\mathrm{inj}}$ is fully faithful, and from Proposition C.5.7.8 that it is essentially surjective. □

Example C.5.7.9 (Injective Hulls)**.** Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. We will say that a morphism $f : X \to Q$ in $\mathrm{Sp}(\mathcal{C})$ *exhibits Q as an injective hull of X* if it satisfies the following conditions:

(i) The object $Q \in \mathrm{Sp}(\mathcal{C})$ is injective.

(ii) The induced map $\pi_0(f) : \pi_0 X \to \pi_0 Q$ is a monomorphism in the abelian category $\mathcal{C}^\heartsuit$.

(iii) The map $\pi_0(f)$ exhibits $\pi_0 Q$ as an essential extension of $\pi_0 X$ (see Definition C.5.6.3).

Note that for any object $X \in \mathrm{Sp}(\mathcal{C})$, we can choose a morphism $f : X \to Q$ which exhibits Q as an injective hull of X. To prove this, we first observe that there exists a morphism $f_0 : \pi_0 X \to Q_0$ in the abelian category $\mathcal{C}^\heartsuit$ which exhibits Q_0 as an injective hull of $\pi_0 X$ (Proposition C.5.6.6). Using Proposition C.5.7.8, we can assume that $Q_0 = \pi_0 Q$ for some injective object $Q \in \mathrm{Sp}(\mathcal{C})$, and Proposition C.5.7.3 implies that we can lift f_0 to a morphism $f : X \to Q$ satisfying conditions (i), (ii), and (iii).

Note that if $f : X \to Q$ and $g : X \to Q'$ are morphisms in $\mathrm{Sp}(\mathcal{C})$ which exhibit Q and Q' are injective hulls of X, then Theorem C.5.6.6 guarantees that there exists an isomorphism $h_0 : \pi_0 Q' \simeq \pi_0 Q$ such that $(\pi_0 f) = h_0 \circ (\pi_0 g)$ in the abelian category $\mathcal{C}^\heartsuit$. Using Proposition C.5.7.3, we see that h_0 can be lifted to an equivalence $h : Q' \to Q$ such that $f \simeq h \circ g$. In other words, any two injective hulls of X are equivalent (though the equivalence is not uniquely determined).

Example C.5.7.10. [Brown-Comenetz Duality] Let Sp denote the ∞-category of spectra, endowed with the t-structure described in Proposition **??**. Then the heart $\mathrm{Sp}^\heartsuit$ is equivalent to the category of abelian groups. An abelian group A is injective if and only if it *divisible*: that is, if and only if the multiplication map $A \xrightarrow{n} A$ is surjective for every integer n. Theorem C.5.7.4 implies that for every injective abelian group A, there is an injective spectrum I_A with $\pi_0 I_A \simeq A$. Moreover, the spectrum I_A is determined uniquely (up to a connected space of choices). In particular, there exists an injective spectrum I with $\pi_0 I \simeq \mathbf{Q}/\mathbf{Z}$, which is unique up to equivalence. The spectrum I is called the *Brown-Comenetz dual of the sphere spectrum.* It is characterized up to homotopy equivalence by the following universal property in the stable homotopy category hSp: for every spectrum X, there is a canonical isomorphism $\mathrm{Ext}^n_{\mathrm{Sp}}(X, I) \simeq \mathrm{Hom}(\pi_n X, \mathbf{Q}/\mathbf{Z})$, where the latter Hom is computed in the category of abelian groups. In particular, the homotopy groups of I are dual to the stable homotopy groups of spheres.

Proposition C.5.7.11. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $n \geqslant 0$ be an integer. The following conditions are equivalent:*

(a) *The ∞-category $\mathcal{C}$ is weakly n-complicial.*

(b) *Every injective object of $\mathrm{Sp}(\mathcal{C})$ belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant -n}$.*

Proof. Suppose first that (a) is satisfied, and let $Q \in \mathrm{Sp}(\mathcal{C})$ be an injective object. Then $Q \in \mathrm{Sp}(\mathcal{C})_{\leqslant 0}$. It follows that for each $m \geqslant 0$, the object $\Omega^{\infty - m} Q$ is an m-truncated object of $\mathcal{C}$. Assumption (a) then implies that there exists a map $\rho : X \to \Omega^{\infty-m} Q$ which induces an epimorphism

$$\pi_0 X \to \pi_0(\Omega^{\infty-m} Q) \simeq \pi_{-m} Q$$

in the abelian category $\mathcal{C}^{\heartsuit}$, where X is n-truncated. If $m > n$, then the injectivity of Q implies that $\mathrm{Ext}^m_{\mathrm{Sp}(\mathcal{C})}(\Sigma^{\infty} X, Q) \simeq 0$, so that ρ is nullhomotopic and therefore $\pi_{-m} Q \simeq 0$. Since the t-structure on $\mathrm{Sp}(\mathcal{C})$ is right separated, we conclude that $Q \in \mathrm{Sp}(\mathcal{C})_{\geqslant -n}$.

We now prove the converse. Suppose that (b) is satisfied, and let X be an m-truncated object of $\mathcal{C}$. We wish to show that there exists an n-truncated object $\overline{X} \in \mathcal{C}$ and a morphism $\overline{X} \to X$ which induces an epimorphism on π_0. The proof proceeds by induction on m. If $m \leqslant n$, we can take $\overline{X} = X$. We will therefore assume that $m > n$. Choose a morphism $f : \Sigma^{\infty-m} X \to Q$ in $\mathrm{Sp}(\mathcal{C})$ which exhibits Q as an injective hull of $\Sigma^{\infty-m} X$ (see Example C.5.7.9). Then f induces a map $g : X \to \Omega^{\infty-m} Q$ in the ∞-category $\mathcal{C}$. Note that g is a morphism between m-truncated objects of $\mathcal{C}$ and induces a monomophism on π_m, so the fiber $\mathrm{fib}(g)$ is $(m-1)$-truncated. Applying our inductive hypothesis, we deduce that there exists an n-truncated object $\overline{X} \in \mathcal{C}$ and a morphism $h : \overline{X} \to \mathrm{fib}(g)$ which is an epimorphism on π_0. We will complete the proof by showing that the composite map $\overline{X} \xrightarrow{h} \mathrm{fib}(g) \to X$ is also an epimorphism on π_0. This follows from the exactness of the sequence $\pi_0 \mathrm{fib}(g) \to \pi_0 X \to \pi_{-m} Q$, since the third term vanishes by virtue of assumption (b). □

C.5.8 Chain Complexes of Injectives

Let $\mathcal{A}$ be a Grothendieck abelian category. It follows from Proposition C.5.5.20 that there exists an essentially unique Grothendieck prestable ∞-category $\mathcal{C}$ which is 0-complicial, anticomplete, and satisfies $\mathcal{C}^{\heartsuit} = \mathcal{A}$. In this section, we will describe an explicit construction of $\mathcal{C}$: its stabilization $\mathrm{Sp}(\mathcal{C})$ can be obtained as the differential graded nerve of the category of chain complexes of injective objects of $\mathcal{A}$.

Remark C.5.8.1. For further discussion of chain complexes of injective objects of Grothendieck abelian categories, we refer the reader to the work of Krause (see [124] and [125]) and Neeman ([161]); the results of this section are essentially a translation of [125]).

Definition C.5.8.2. Let $\mathcal{A}$ be a Grothendieck abelian category and let $\mathcal{A}^{\mathrm{inj}}$ denote the full subcategory of $\mathcal{A}$ spanned by the injective objects. We let $\mathrm{Ch}(\mathcal{A}^{\mathrm{inj}})$ denote the category of chain complexes with values in $\mathcal{A}^{\mathrm{inj}}$, which we regard as a differential graded category. We let $\check{\mathcal{D}}(\mathcal{A})$ denote the differential graded nerve $\mathrm{N}_{\mathrm{dg}}(\mathrm{Ch}(\mathcal{A}^{\mathrm{inj}}))$ (see Construction HA.1.3.1.6). We will refer to $\check{\mathcal{D}}(\mathcal{A})$ as the *unseparated derived ∞-category of* $\mathcal{A}$.

Remark C.5.8.3. In the situation of Definition C.5.8.2, the derived ∞-category $\mathcal{D}(\mathcal{A})$ is defined as the differential graded nerve of the full subcategory $\mathrm{Ch}(\mathcal{A})^{\circ} \subseteq \mathrm{Ch}(\mathcal{A}^{\mathrm{inj}})$ spanned by those chain complexes which are fibrant with respect to the model structure of Proposition HA.1.3.5.3 . Consequently, we can regard $\mathcal{D}(\mathcal{A})$ as a full subcategory of $\check{\mathcal{D}}(\mathcal{A})$.

Notation C.5.8.4. Let $\mathcal{A}$ is a Grothendieck abelian category. We let $\check{\mathcal{D}}(\mathcal{A})_{\geqslant 0}$ denote the full subcategory of $\check{\mathcal{D}}(\mathcal{A})$ spanned by those chain complexes $Q_{\bullet}$ satisfying $\mathrm{H}_n(Q_{\bullet}) \simeq 0$ for $n < 0$. We set $\check{\mathcal{D}}(\mathcal{A})_{\leqslant 0} = \mathcal{D}(\mathcal{A})_{\leqslant 0}$ be the subcategory of $\check{\mathcal{D}}(\mathcal{A})$ spanned by those chain complexes $Q_{\bullet}$ which are fibrant (with respect to the model structure of Proposition HA.1.3.5.3) and satisfy $\mathrm{H}_n(Q_{\bullet}) \simeq 0$ for $n > 0$.

Proposition C.5.8.5. *Let $\mathcal{A}$ be a Grothendieck abelian category. Then $\check{\mathcal{D}}(\mathcal{A})$ is a stable ∞-category. Moreover, the pair of full subcategories $(\check{\mathcal{D}}(\mathcal{A})_{\geqslant 0}, \check{\mathcal{D}}(\mathcal{A})_{\leqslant 0})$ is a t-structure on $\check{\mathcal{D}}(\mathcal{A})$.*

Proof. The first assertion follows from Proposition HA.1.3.2.10 , and the second from Proposition HA.1.3.5.18 . □

To compute morphisms in the ∞-category $\check{\mathcal{D}}(\mathcal{A})$, the following observation is useful.

Lemma C.5.8.6. *Let $\mathcal{A}$ be a Grothendieck abelian category, let $i : M'_* \to M_*$ be a quasi-isomorphism in $\mathrm{Ch}_{\leqslant 0}(\mathcal{A})$, and let Q_* be a complex of injective objects of $\mathcal{A}$. Then composition with i induces a quasi-isomorphism of chain complexes of abelian groups*

$$\mathrm{Map}_{\mathrm{Ch}(\mathcal{A})}(M_*, Q_*) \to \mathrm{Map}_{\mathrm{Ch}(\mathcal{A})}(M'_*, Q_*).$$

Proof. Since Q_* is levelwise injective, we have a short exact sequence of chain complexes

$$0 \to \mathrm{Map}_{\mathrm{Ch}(\mathcal{A})}(M_*/M'_*, Q_*) \to \mathrm{Map}_{\mathrm{Ch}(\mathcal{A})}(M_*, Q_*) \to \mathrm{Map}_{\mathrm{Ch}(\mathcal{A})}(M'_*, Q_*) \to 0.$$

It will therefore suffice to show that the chain complex of abelian groups $\mathrm{Map}_{\mathrm{Ch}(\mathcal{A})}(M_*/M'_*, Q_*)$ is acyclic. In other words, we must show that for every integer n, every chain map $M_*/M'_* \to Q_*[n]$ is nullhomotopic. To prove this, we are free to replace Q_* by the chain complex

$$\cdots \to 0 \to Q_{1-n} \to Q_{-n} \to \cdots$$

In this case, Q_* is fibrant with respect to the model structure of Proposition HA.1.3.5.3 (see Proposition HA.1.3.5.6), so the desired result follows from Proposition HA.1.3.5.11 (since the quotient M_*/M'_* is acyclic). □

Example C.5.8.7. Let $\mathcal{A}$ be a Grothendieck abelian category and let X be an object of $\mathcal{A}$, and let $X^{\heartsuit}$ denote the image of X under the equivalence $\mathcal{A} \simeq \mathcal{D}(\mathcal{A})^{\heartsuit} \simeq \check{\mathcal{D}}(\mathcal{A})^{\heartsuit}$. As a chain complex, we can identify $X^{\heartsuit}$ with any choice of injective resolution of X. Applying Lemma C.5.8.6, we see that for any object $Q_\bullet \in \check{\mathcal{D}}(\mathcal{A})$, we can identify the groups $\mathrm{Ext}^*_{\check{\mathcal{D}}(\mathcal{A})}(Y^{\heartsuit}, Q_\bullet)$ with the cohomology groups of the chain complex

$$\cdots \to \mathrm{Hom}_{\mathcal{A}}(X, Q_2) \to \mathrm{Hom}_{\mathcal{A}}(X, Q_1) \to \mathrm{Hom}_{\mathcal{A}}(X, Q_0) \to \mathrm{Hom}_{\mathcal{A}}(X, Q_{-1}) \to \mathrm{Hom}_{\mathcal{A}}(X, Q_{-2}) \to \cdots .$$

The main result of this section can be stated as follows:

Theorem C.5.8.8. *Let $\mathcal{A}$ be a Grothendieck abelian category. Then:*

(a) The unseparated derived ∞-category $\check{\mathcal{D}}(\mathcal{A})$ is presentable and stable.

(b) The t-structure $(\check{\mathcal{D}}(\mathcal{A})_{\geq 0}, \check{\mathcal{D}}(\mathcal{A})_{\leq 0})$ is right complete and compatible with filtered colimits. Equivalently, $\check{\mathcal{D}}(\mathcal{A})_{\geq 0}$ is a Grothendieck prestable ∞-category and $\check{\mathcal{D}}(\mathcal{A})$ is equivalent to the stabilization $\mathrm{Sp}(\check{\mathcal{D}}(\mathcal{A})_{\geq 0})$.

(c) The Grothendieck prestable ∞-category $\check{\mathcal{D}}(\mathcal{A})_{\geq 0}$ is anticomplete and 0-complicial.

(d) The construction $Q_\bullet \to \mathrm{H}_0(Q_\bullet)$ induces an equivalence of categories $\check{\mathcal{D}}(\mathcal{A})^{\heartsuit} \to \mathcal{A}$.

It follows from Proposition C.5.5.20 that the ∞-category $\check{\mathcal{D}}(\mathcal{A})$ and its t-structure are characterized uniquely (up to canonical equivalence) by the assertions of Theorem C.5.8.8. Moreover, Proposition C.5.5.20 supplies the following analogue of Theorem C.5.4.9:

Corollary C.5.8.9. *Let $\mathcal{A}$ be a Grothendieck abelian category and let $\mathcal{C}$ be any Grothendieck prestable ∞-category. Then restriction to the heart induces a fully faithful embedding*

$$\mathrm{LFun}^{\mathrm{lex}}(\check{\mathcal{D}}(\mathcal{A})_{\geq 0}, \mathcal{C}) \to \mathrm{Fun}(\mathcal{A}, \mathcal{C}^{\heartsuit}),$$

whose essential image is spanned by those exact functors $\mathcal{A} \to \mathcal{C}^{\heartsuit}$ which preserve small colimits.

Remark C.5.8.10. It follows from Proposition C.5.5.20 (or from the universal property of Corollary C.5.8.9) that the construction $\mathcal{A} \mapsto \breve{\mathcal{D}}(\mathcal{A})$ is functorial: if $f : \mathcal{A} \to \mathcal{A}'$ is an exact functor between Grothendieck abelian categories which preserves small colimits, then f induces a functor $F : \breve{\mathcal{D}}(\mathcal{A}) \to \breve{\mathcal{D}}(\mathcal{A}')$. The functor F is determined (up to equivalence) by the requirements that it is t-exact, preserves small colimits, and that the composite functor

$$\mathcal{A} \simeq \breve{\mathcal{D}}(\mathcal{A})^{\heartsuit} \xrightarrow{F} \breve{\mathcal{D}}(\mathcal{A}')^{\heartsuit} \simeq \mathcal{A}'$$

is equivalent to the original functor f.

Corollary C.5.8.11. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $\mathcal{A} = \mathcal{C}^{\heartsuit}$. Then the inclusion functor $\mathcal{A} \hookrightarrow \mathcal{C}$ admits an essentially unique extension to a functor $\lambda : \breve{\mathcal{D}}(\mathcal{A})_{\geqslant 0} \to \mathcal{C}$ which preserves small colimits and finite limits. The following conditions are equivalent:*

- (a) *The functor λ is an equivalence of ∞-categories.*
- (b) *The Grothendieck prestable ∞-category $\mathcal{C}$ is anticomplete and 0-complicial.*
- (c) *The Grothendieck prestable ∞-category $\mathcal{C}$ is anticomplete and weakly 0-complicial.*
- (d) *The Grothendieck prestable ∞-category $\mathcal{C}$ is anticomplete and every injective object of $\mathrm{Sp}(\mathcal{C})$ belongs to the heart of $\mathrm{Sp}(\mathcal{C})$.*

Proof. The existence (and essential uniqueness) of λ follows from Corollary **??**. The implication $(a) \Rightarrow (b)$ follows from Theorem C.5.8.8, and the converse follows from Proposition C.5.5.20. The equivalence $(b) \Leftrightarrow (c)$ follows from Proposition C.5.5.16, and the equivalence $(c) \Leftrightarrow (d)$ from Proposition C.5.7.11. □

We now turn to the proof of Theorem C.5.8.8, following [125]. We first consider the following special case:

Proposition C.5.8.12. *Let $\mathcal{A}_0$ be a small abelian category. Assume that every object $X \in \mathcal{A}_0$ admits a finite resolution*

$$0 \to P_n \to P_{n-1} \to \cdots \to P_0 \to X \to 0,$$

where each P_i is a projective object of $\mathcal{A}_0$. Set $\mathcal{A} = \mathrm{Ind}(\mathcal{A}_0)$. Then:

- (i) *An object $X \in \mathcal{D}(\mathcal{A})$ is compact if and only if the homotopy groups $\pi_n X$ are compact objects of $\mathcal{D}(\mathcal{A})$ for every $n \in \mathbf{Z}$, and vanish for all but finitely many n.*
- (ii) *The derived ∞-category $\mathcal{D}(\mathcal{A})$ is compactly generated.*
- (iii) *The Grothendieck prestable ∞-category $\mathcal{D}(\mathcal{A})_{\geqslant 0}$ is anticomplete.*

(*iv*) *The ∞-categories $\check{\mathcal{D}}(\mathcal{A})$ and $\mathcal{D}(\mathcal{A})$ are the same. That is, every chain complex Q_* of injective objects of $\mathcal{A}$ is a fibrant object of* $\mathrm{Ch}(\mathcal{A})$ *(with respect to the model structure of Proposition HA.1.3.5.3).*

Proof. Let us abuse notation by identifying $\mathcal{A}$ with the full subcategory $\mathcal{D}(\mathcal{A})^{\heartsuit} \subseteq \mathcal{D}(\mathcal{A})$ and $\mathcal{A}_0$ with its essential image in $\mathcal{A} = \mathrm{Ind}(\mathcal{A}_0)$. Let P be a projective object of $\mathcal{A}_0$ and let Ab denote the category of abelian groups, so that the construction $Y \mapsto \mathrm{Hom}_{\mathcal{A}}(P, Y)$ determines an exact functor $e : \mathcal{A} \to \mathrm{Ab}$. The induced map $\mathrm{Ch}(e) : \mathrm{Ch}(\mathcal{A}) \to \mathrm{Ch}(\mathrm{Ab})$ carries quasi-isomorphisms to quasi-isomorphisms. Let $\{Q^j_*\}_{j \in J}$ be any collection of objects of $\mathcal{D}(\mathcal{A})$, which we will identify with fibrant objects of the category $\mathrm{Ch}(\mathcal{A})$. Choose a trivial cofibration $u : \bigoplus_{j \in J} Q^j_* \to Q_*$, where Q_* is another fibrant object of $\mathrm{Ch}(\mathcal{A})$. Then u is a quasi-isomorphism of chain complexes and the chain complex Q_* represents the coproduct of the objects Q^j_* in the ∞-category $\mathcal{D}(\mathcal{A})$. Using Example C.5.8.7, we see that composition with u induces isomorphisms of abelian groups

$$\begin{aligned}
\bigoplus_{j \in J} \pi_0 \mathrm{Map}_{\mathcal{D}(\mathcal{A})}(P, Q^j_*) &\simeq \bigoplus_{j \in J} \mathrm{H}_0(\mathrm{Ch}(e)(Q^j_*)) \\
&\simeq \mathrm{H}_0(\bigoplus_{j \in J} \mathrm{Ch}(e)(Q^j_*)) \\
&\simeq \mathrm{H}_0(\mathrm{Ch}(e)(\bigoplus_{j \in J} Q^j_*)) \\
&\xrightarrow{u} \mathrm{H}_0(\mathrm{Ch}(e)(Q_*)) \\
&\simeq \pi_0 \mathrm{Map}_{\mathcal{D}(\mathcal{A})}(P, Q_*).
\end{aligned}$$

Applying Proposition **??**, we deduce that P is a compact object of $\mathcal{D}(\mathcal{A})$.

By assumption, every object $X \in \mathcal{A}_0$ admits a finite resolution

$$0 \to P_n \to P_{n-1} \to \cdots \to P_0 \to X \to 0,$$

where each $P_i \in \mathcal{A}_0$ is projective and therefore compact as an object of $\mathcal{D}(\mathcal{A})$. It follows that X is also compact when viewed as an object of $\mathcal{D}(\mathcal{A})$. Every compact object of $\mathcal{A} = \mathrm{Ind}(\mathcal{A}_0)$ is a retract of an object belonging to $\mathcal{A}_0$, and is therefore also a compact object of $\mathcal{D}(\mathcal{A})$.

Let $\mathcal{C} \subseteq \mathcal{D}(\mathcal{A})$ denote the full subcategory spanned by those objects X such that $\pi_n X$ is a compact object of $\mathcal{D}(\mathcal{A})$ for every integer n which vanishes for all but finitely many n. Note that $\mathcal{C}$ is a stable subcategory of $\mathcal{D}(\mathcal{A})$. Each $X \in \mathcal{C}$ can be written as a finite extension of the objects $\Sigma^n(\pi_n X)$, and is therefore also compact when viewed as an object of $\mathcal{D}(\mathcal{A})$. It follows that the inclusion $\mathcal{C} \hookrightarrow \mathcal{D}(\mathcal{A})$ extends to a fully faithful embedding $f : \mathrm{Ind}(\mathcal{C}) \hookrightarrow \mathcal{D}(\mathcal{A})$. Applying Corollary HTT.5.5.2.9 , we see that f admits a right adjoint $g : \mathcal{D}(\mathcal{A}) \to \mathrm{Ind}(\mathcal{C})$. Note that if Q_* is fibrant object of $\mathrm{Ch}(\mathcal{A})$ such that $g(Q_*)$ vanishes as an object of $\mathcal{C}$, then for every projective object $P \in \mathcal{A}_0$ we have

$$\mathrm{H}_n(\mathrm{Ch}(e)(Q_*)) \simeq \mathrm{Map}_{\mathcal{D}(\mathcal{A})}(\Sigma^n P, Q_*) \simeq 0$$

where e is defined as above. It follows that the chain complex Q_* is acyclic, and therefore vanishes when viewed as an object of $\mathcal{D}(\mathcal{A})$. Applying this argument to $Q_* = \mathrm{fib}(v)$ for some morphism v in $\mathcal{D}(\mathcal{A})$, we deduce that v is an equivalence if and only if $g(v)$ is an equivalence: that is, the functor g is conservative, so that f and g are mutually inverse equivalence of ∞-categories. This proves (ii), and shows that an object of $\mathcal{D}(\mathcal{A})$ is compact if and only if it is a retract of an object of $\mathcal{C}$. Assertion (i) now follows from the observation that $\mathcal{C}$ is closed under the formation of retracts. Assertion (iii) follows from (i) and (ii) together with Proposition C.5.5.5.

We will deduce (iv) from the following assertion:

$(*)$ Let Q_* be an acyclic chain complex of injective objects of $\mathcal{A}$ and let X be any object of $\mathcal{A}$. Then the chain complex of abelian groups

$$\cdots \to \mathrm{Hom}_{\mathcal{A}}(X, Q_2) \to \mathrm{Hom}_{\mathcal{A}}(X, Q_1) \to \mathrm{Hom}_{\mathcal{A}}(X, Q_0) \to \mathrm{Hom}_{\mathcal{A}}(X, Q_{-1}) \to \mathrm{Hom}_{\mathcal{A}}(X, Q_{-2}) \to \cdots$$

is also acyclic.

Let us assume $(*)$ for the moment, and see how it leads to a proof of $(*)$. Suppose that Q'_* is any chain complex of injective objects of $\mathcal{A}$. Choose a trivial cofibration $f_* : Q'_* \to Q_*$ in $\mathrm{Ch}(\mathcal{A})$, where Q_* is fibrant. Then each of the maps $f_k : Q'_k \to Q_k$ is a monomorphism whose domain Q'_k is injective. It follows that each f_k is a split monomorphism. Set $Q''_* = Q_*/Q'_*$. Each of the projection maps $Q_k \to Q''_k$ admits a section s_k which exhibits Q''_k as a direct summand of Q_k, so that Q''_k is an injective object of $\mathcal{A}$ (Proposition HA.1.3.5.6). Since f_* is a quasi-isomorphism, the chain complex Q''_* is acyclic. For each integer k, let Z_k denote the kernel of the differential $Q''_k \to Q''_{k-1}$. Applying $(*)$ in the case $X = Z_k$, we deduce that the sequence

$$\mathrm{Hom}_{\mathcal{A}}(Z_k, Q''_{k+1}) \to \mathrm{Hom}_{\mathcal{A}}(Z_k, Q''_k) \to \mathrm{Hom}_{\mathcal{A}}(Z_k, Q''_{k-1})$$

is exact. Consequently, the inclusion $Z_k \hookrightarrow Q''_k$ lifts to a map Q''_{k+1}: in other words, the chain complex Q''_* is split exact. It follows that there exists a contracting homotopy $h : Q''_* \to Q''_{*+1}$. Let $\overline{h}$ denote the composite map $Q_* \to Q''_* \xrightarrow{h} Q''_{*+1} \xrightarrow{s} Q_*$. Then $\overline{h}$ determines a chain homotopy from the identity id_{Q_*} to a retraction $r : Q_* \to Q'_*$. In particular, we see that Q'_* is a retract of Q_*, and is therefore a fibrant object of $\mathrm{Ch}(\mathcal{A})$.

It remains to prove $(*)$. Fix an acyclic chain complex Q_* consisting of injective objects of $\mathcal{A}$. For each object $X \in \mathcal{A}$, let $T_*(X)$ denote the chain complex of abelian groups given by $T_k(X) = \mathrm{Hom}_{\mathcal{A}}(X, Q_k)$. Let us say an object $X \in \mathcal{A}$ is *good* if the chain complex $T_*(X)$ is acyclic. We now proceed in several steps.

(a) Every projective object $P \in \mathcal{A}$ is good (since the acyclicity of Q_* immediately implies the acyclicity of the chain complex $T_*(P) = \mathrm{Hom}_{\mathcal{A}}(P, Q_*)$ when P is projective).

(*b*) Suppose we are given a short exact sequence $0 \to X' \to X \to X'' \to 0$. Then the diagram of chain complexes

$$0 \to T_*(X'') \to T_*(X) \xrightarrow{\rho} T_*(X') \to 0$$

is also exact (this follows from the injectivity of the objects Q_k). In particular, we see that if any two of the objects X, X', and X'' is good, then so is the third. Moreover, the map ρ is surjective: that is, it is a fibration with respect to the projective model structure on the category Ch(Ab) of chain complexes of abelian groups.

(*c*) Let X be an object of $\mathcal{A}$ which admits a finite projective resolution

$$0 \to P_n \to \cdots \to P_0 \to X \to 0.$$

Then X is good. This follows from (*a*) and (*b*), using induction on n.

(*d*) Every object of $\mathcal{A}_0$ is good. This follows from (*c*) together with our assumption that every object of $\mathcal{A}_0$ admits a finite projective resolution (note that any projective object of $\mathcal{A}_0$ is also injective as an object of $\mathcal{A} = \mathrm{Ind}(\mathcal{A}_0)$).

(*e*) Let I be a well-ordered set and let $\{X_i\}_{i \in I}$ be a diagram in $\mathcal{A}$ with the property that, for each $i \in I$, the map $\varinjlim_{j<i} X_j \to X_i$ is a monomorphism in $\mathcal{A}$. If each X_i is good, then the colimit $\varinjlim X_i$ is good (this follows from (*a*) together with Corollary HTT.A.2.9.25).

(*f*) Let X be an object of $\mathcal{A}_0$ and let X' be a subobject of X (in the abelian category $\mathcal{A}$). We claim that X' is good. To prove this, choose an epimorphism $\bigoplus_{i \in I} Y_i \to X'$, where each Y_i belongs to $\mathcal{A}_0$. We proceed by (transfinite) induction on the cardinality of the set I. If I is finite, then $X' \in \mathcal{A}_0$ and the desired result follows from (*d*). Otherwise, we can choose a well-ordering of the set I for which each initial segment $I_{\leqslant j} = \{i \in I : i \leqslant j\}$ has cardinality smaller than I. For each $j \in I$, let X'_j be the subobject of X' given by the image of the composite map $\bigoplus_{i \in I_j} Y_i \to \bigoplus_{i \in I} Y_i \to X'$. It follows from our inductive hypothesis that each X'_j is good, so that (*e*) guarantees that $X' \simeq \varinjlim_{j \in I} X'_j$ is also good.

(*g*) Let X'' be an object of $\mathcal{A}$ and suppose there exists an epimorphism $u : X \to X''$, where $X \in \mathcal{A}_0$. Then X'' is good. This follows by applying (*b*) to the short exact sequence $0 \to X' \to X \xrightarrow{u} X'' \to 0$, since X is good by virtue of (*d*) and $X' \simeq \ker(u)$ is good by virtue of (*f*).

Now suppose that X is an arbitrary object of $\mathcal{A}$; we will show that X is good. Choose an epimorphism $\bigoplus_{i \in I} Y_i \to X$ where each Y_i belongs to $\mathcal{A}_0$. We proceed by induction on the cardinality of I. If I is finite, then the desired result follows from (g). Otherwise, we can choose a well-ordering of the set I for which each initial segment $I_{\leqslant j} = \{i \in I : i \leqslant j\}$ has cardinality smaller than I. For each $j \in J$, let X_j denote the image of the composite map $\bigoplus_{i \in I_j} Y_i \to \bigoplus_{i \in I} Y_i \to X$. Our inductive hypothesis guarantees that each X_j is good, so that $X \simeq \varinjlim_{j \in I} X_j$ is also good (by virtue of (e)). □

We will prove the general case Theorem C.5.8.8 by reducing to the situation of Proposition C.5.8.12, using the following observation:

Proposition C.5.8.13. *Let $\mathcal{A}$ be a Grothendieck abelian category. Then there exists an essentially small abelian category $\mathcal{B}_c$ in which every object admits a projective resolution of length* 2*, such that $\mathcal{A}$ is a left exact localization of the Grothendieck abelian category* $\mathrm{Ind}(\mathcal{B}_c)$.

Proof. Choose an essentially small subcategory $\mathcal{A}_0 \subseteq \mathcal{A}$ which contains a set of generators for $\mathcal{A}$ and is closed under finite limits. Let $\mathcal{B} = \mathrm{Fun}^{\pi}(\mathcal{A}_0^{\mathrm{op}}, \mathcal{S}\mathrm{et})$ be the full subcategory of $\mathrm{Fun}(\mathcal{A}_0^{\mathrm{op}}, \mathcal{S}\mathrm{et})$ spanned by the product-preserving functors. It follows from the Gabriel-Popescu theorem (Theorem C.2.2.1) that the construction $X \mapsto \mathrm{Hom}_{\mathcal{A}}(*, X)$ induces a fully faithful embedding $G : \mathcal{A} \to \mathcal{B}$ and that the left adjoint to G is left exact (in other words, G exhibits $\mathcal{A}$ as a left-exact localization of $\mathcal{B}$). The objects $\{G(A)\}_{A \in \mathcal{A}_0}$ form compact projective generators for the abelian category $\mathcal{B}$. In particular, the category $\mathcal{B}$ is compactly generated: that is, we have an equivalence $\mathcal{B} \simeq \mathrm{Ind}(\mathcal{B}_c)$, where $\mathcal{B}_c$ denotes the full subcategory of $\mathcal{B}$ spanned by the compact objects. To complete the proof, it will suffice to establish the following:

- (a) The full subcategory $\mathcal{B}_c \subseteq \mathcal{B}$ is abelian.
- (b) Every object of $\mathcal{B}_c$ admits a projective resolution of length 2.

Unwinding the definitions, we see that an object $X \in \mathcal{B}$ is compact if and only if it admits a resolution

$$G(A') \xrightarrow{e} G(A) \to X \to 0$$

for some objects $A', A \in \mathcal{A}_0$. In this case, the fact that G is fully faithful guarantees that we can write $e = G(e_0)$ for some map $e_0 : A' \to A$ in the category $\mathcal{A}_0$. In this case, the left exactness of G supplies an isomorphism $\ker(e) \simeq G(\ker(e_0))$; the resulting exact sequence

$$0 \to G(\ker(e_0)) \to G(A') \to G(A) \to X \to 0$$

is a projective resolution of X having length 2, which proves (b).

Note that the full subcategory $\mathcal{B}_c \subseteq \mathcal{B}$ of compact objects is closed under finite colimits; in particular, it is closed under finite direct sums and the formation of cokernels. To prove (a), it will suffice to show that $\mathcal{B}_c$ is closed under kernels. Suppose that we are given a morphism $f : X \to Y$ in $\mathcal{B}_c$; we wish to show that the kernel $\ker(f)$ also belongs to $\mathcal{B}_c$. Choosing projective resolutions as above, we can arrange that f fits into a commutative diagram

$$\begin{array}{ccccccc} G(A') & \longrightarrow & G(A) & \longrightarrow & X & \longrightarrow & 0 \\ \downarrow & & \downarrow & & \downarrow f & & \\ G(A') & \longrightarrow & G(A) & \longrightarrow & Y. & \longrightarrow & 0. \end{array}$$

A simple diagram chase then yields an exact sequence

$$G(A') \times_{G(B)} G(B') \to G(A) \times_{G(B)} G(B') \to \ker(f) \to 0.$$

Using the fact that G is fully faithful and left exact, we can rewrite this sequence as $G(A' \times_B B') \to G(A \times_B B') \to \ker(f) \to 0$, so that $\ker(f)$ is a compact object of $\mathcal{B}$ as desired. □

Remark C.5.8.14. Let $\mathcal{A}$ be a Grothendieck abelian category and let Q_* be chain complex of injective objects of $\mathcal{A}$. Assume that Q_* is homotopically minimal (in the sense of Proposition C.5.6.8). Then the following conditions are equivalent:

(1) The objects Q_n vanish for $n > 0$.

(2) The object Q_* belongs to $\check{\mathcal{D}}(\mathcal{A})_{\leq 0}$.

(3) For every object $X \in \mathcal{A} \simeq \check{\mathcal{D}}(\mathcal{A})^{\heartsuit}$, the groups $\mathrm{Ext}^n_{\check{\mathcal{D}}(\mathcal{A})}(X, Q_*)$ vanish for $n < 0$.

The implications (1) ⇒ (2) ⇒ (3) are evident (and do not require the assumption that Q_* is homotopically minimal). Assume that (3) is satisfied and let $n > 0$; we wish to show that $Q_n \simeq 0$. Suppose otherwise. Then the homotopical minimality of Q_* guarantees that $Z = \ker(d_n : Q_n \to Q_{n-1})$ is nonzero. Using Example C.5.8.7, we see that the inclusion $\iota : Z \hookrightarrow Q_n$ represents a class $\eta \in \mathrm{Ext}^{-n}_{\check{\mathcal{D}}(\mathcal{A})}(Z, Q_*)$. Assumption (3) guarantees that $\eta = 0$, so that ι factors as a composition $Z \xrightarrow{\bar{\iota}} Q_{n+1} \xrightarrow{d_{n+1}} Q_n$. Then d_{n+1} is injective when restricted to $\mathrm{im}(\bar{\iota})$, contradicting the homotopical minimality of Q_*.

Proposition C.5.8.15. *Let $\mathcal{A}$ be a Grothendieck abelian category, let $\mathcal{A}_0 \subseteq \mathcal{A}$ be a localizing subcategory, and let $\mathcal{A}/\mathcal{A}_0$ be the full subcategory of $\mathcal{A}$ spanned by the $\mathcal{A}_0$-local objects (see Definition* **??***). Then:*

(a) *Every injective object of $\mathcal{A}/\mathcal{A}_0$ is also injective when regarded as an object of $\mathcal{A}$. Consequently, we can regard $\check{\mathcal{D}}(\mathcal{A}/\mathcal{A}_0)$ as a full subcategory of $\check{\mathcal{D}}(\mathcal{A})$.*

(b) *Let Q_* be an object of $\check{\mathcal{D}}(\mathcal{A})$. Then Q_* belongs to the essential image of the inclusion $\check{\mathcal{D}}(\mathcal{A}/\mathcal{A}_0) \hookrightarrow \check{\mathcal{D}}(\mathcal{A})$ if and only if, for every object $Y \in \mathcal{A}_0$, the groups $\mathrm{Ext}^n_{\check{\mathcal{D}}(\mathcal{A})}(X, Q_*)$ vanish for every integer n (here we abuse notation by identifying X with its image under the equivalence $\mathcal{A} \simeq \check{\mathcal{D}}(\mathcal{A})^{\heartsuit}$).*

(c) *We have* $\check{\mathcal{D}}(\mathcal{A}/\mathcal{A}_0)_{\leqslant 0} = \check{\mathcal{D}}(\mathcal{A}/\mathcal{A}_0) \cap \check{\mathcal{D}}(\mathcal{A})_{\leqslant 0}$.

Proof. Assertion (a) follows from the fact that the inclusion $\mathcal{A}/\mathcal{A}_0 \hookrightarrow \mathcal{A}$ admits an exact left adjoint (Proposition C.5.1.6). The inclusion

$$\check{\mathcal{D}}(\mathcal{A}/\mathcal{A}_0)_{\leqslant 0} \subseteq \check{\mathcal{D}}(\mathcal{A}/\mathcal{A}_0) \cap \check{\mathcal{D}}(\mathcal{A})_{\leqslant 0}$$

follows immediately from the definitions, and the reverse inclusion follows from Proposition C.5.6.8 and Remark C.5.8.14.

The "only if" direction of (b) follows immediately from Example C.5.8.7. To prove the converse, suppose that Q_* is a chain complex of injective objects of $\mathcal{A}$ and that the groups $\mathrm{Ext}^n_{\check{\mathcal{D}}(\mathcal{A})}(X, Q_*)$ vanish for all n and all $X \in \mathcal{A}_0$. We wish to prove that Q_* belongs to the essential image of the inclusion $\check{\mathcal{D}}(\mathcal{A}/\mathcal{A}_0) \hookrightarrow \check{\mathcal{D}}(\mathcal{A})$. Using Proposition C.5.6.8, we can reduce to the case where Q_* is homotopically minimal. We will prove in this case that $Q_* \in \check{\mathcal{D}}(\mathcal{A}/\mathcal{A}_0)$: that is, each of the objects Q_n is $\mathcal{A}_0$-local. By virtue of Remark C.5.1.5, this is equivalent to the requirement that the groups $\mathrm{Ext}^i_{\mathcal{A}}(X, Q_n)$ vanish for all $X \in \mathcal{A}_0$ and $i = 0, 1$. For $i = 1$, the vanishing is automatic (since Q_n is an injective object of $\mathcal{A}$). To handle the case $i = 0$, suppose (for a contradiction) that there exists some nonzero map $f : X \to Q_n$ in the abelian category $\mathcal{A}$. Replacing X by $\mathrm{im}(f)$, we may suppose that f is a monomorphism. Since Q_* is homotopically minimal, there exists a nonzero subobject $X' \subseteq X$ for which the composite map

$$X' \hookrightarrow X \xrightarrow{f} Q_n \xrightarrow{d_n} Q_{n-1}$$

vanishes. Using Example C.5.8.7, we see that this composite map represents an element $\eta \in \mathrm{Ext}^{-n}_{\check{\mathcal{D}}(\mathcal{A})}(X', Q_*)$. By assumption, η must vanish, so that $f|_{X'}$ factors as a composition $X' \xrightarrow{g} Q_{n+1} \xrightarrow{d_{n+1}} Q_n$. Invoking our assumption that Q_* is homotopically minimal, we deduce that the fiber product $X' \times_{Q_{n+1}} \ker(d_{n+1})$ is nonzero, contradicting our assumption that f is a monomorphism. □

Proof of Theorem C.5.8.8. Let $\mathcal{A}$ be a Grothendieck abelian category. Applying Proposition C.5.8.13, we can write $\mathcal{A}$ as a quotient $\mathcal{B}/\mathcal{B}_0$ where $\mathcal{B} \simeq \mathrm{Ind}(\mathcal{B}_c)$ is a compactly generated Grothendieck abelian category, the full subcategory $\mathcal{B}_c \subseteq \mathcal{B}$ of compact objects is abelian, every object of $\mathcal{B}_c$ admits a projective resolution of length 2, and $\mathcal{B}_0 \subseteq \mathcal{B}$ is a localizing subcategory. Applying Propositions C.5.8.12 and C.5.3.2, we see that $\check{\mathcal{D}}(\mathcal{B})$ is a presentable stable ∞-category, the t-structure $(\check{\mathcal{D}}(\mathcal{B})_{\geqslant 0}, \check{\mathcal{D}}(\mathcal{B})_{\leqslant 0})$ is right complete and compatible with filtered colimits, and the Grothendieck prestable ∞-category $\check{\mathcal{D}}(\mathcal{B})_{\geqslant 0}$ is anticomplete and 0-complicial. Combining Propositions C.5.8.15 and C.5.2.8, we deduce that $\check{\mathcal{D}}(\mathcal{A})$ is a presentable stable ∞-category, that the t-structure $(\check{\mathcal{D}}(\mathcal{A})_{\geqslant 0}, \check{\mathcal{D}}(\mathcal{A})_{\leqslant 0})$ is right complete and compatible with filtered colimits, and that the Grothendieck prestable ∞-category $\check{\mathcal{D}}(\mathcal{A})_{\geqslant 0}$

can be identified with the quotient $\breve{\mathcal{D}}(\mathcal{B})_{\geqslant 0}/\mathcal{C}_0$, where $\mathcal{C}_0 \subseteq \breve{\mathcal{D}}(\mathcal{B})_{\geqslant 0}$ is the smallest localizing subcategory which contains $\mathcal{A}_0$. Applying Proposition C.5.5.7, we deduce that $\breve{\mathcal{D}}(\mathcal{A})_{\geqslant 0}$ is also anticomplete. Proposition C.5.3.3 guarantees that $\breve{\mathcal{D}}(\mathcal{A})_{\geqslant 0}$ is 0-complicial. □

C.5.9 Completed Derived ∞-Categories

We now observe that the theory of anticomplete Grothendieck prestable ∞-categories is closely related to the theory of complete Grothendieck prestable ∞-categories.

Notation C.5.9.1. Let $\mathsf{Groth}_{\infty}^{\mathrm{lex,comp}}$ denote the subcategory of Groth_{∞} whose objects are complete Grothendieck prestable ∞-categories and whose morphisms are left exact functors which preserve small colimits.

Proposition C.5.9.2. *Let $\mathsf{Groth}_{\infty}^{\mathrm{lex,comp}}$ denote the full subcategory of $\mathsf{Groth}_{\infty}^{\mathrm{lex}}$ spanned by the complete Grothendieck prestable ∞-categories. Then the construction $\mathcal{C} \mapsto \widehat{\mathcal{C}}$ determines an equivalence of ∞-categories $\mathsf{Groth}_{\infty}^{\mathrm{ch,lex}} \to \mathsf{Groth}_{\infty}^{\mathrm{lex,comp}}$.*

Proof. Let $\mathcal{C}$ and $\mathcal{D}$ be Grothendieck prestable ∞-categories. It follows immediately from the definitions that if $\mathcal{C}$ is anticomplete, then the canonical map

$$\mathrm{Map}_{\mathsf{Groth}_{\infty}^{\mathrm{lex}}}(\mathcal{C}, \mathcal{D}) \to \mathrm{Map}_{\mathsf{Groth}_{\infty}^{\mathrm{lex}}}(\widehat{\mathcal{C}}, \widehat{\mathcal{D}})$$

is a homotopy equivalence. This proves that the completion functor $\mathsf{Groth}_{\infty}^{\mathrm{ch,lex}} \to \mathsf{Groth}_{\infty}^{\mathrm{lex,comp}}$ is fully faithful. Essential surjectivity follows from Proposition C.5.5.9. □

Let $\mathcal{C}$ be an anticomplete Grothendieck prestable ∞-category and let $\widehat{\mathcal{C}}$ be its completion. Using Remark C.5.5.14 and Proposition C.5.5.16, we deduce that $\mathcal{C}$ is n-complicial if and only if $\widehat{\mathcal{C}}$ is weakly n-complicial. Combining this observation with Propositions C.5.9.2 and C.5.5.20, we obtain the following variant of Proposition C.5.4.5:

Proposition C.5.9.3. *Let n be a nonnegative integer and let $L : \mathsf{Groth}_{\infty}^{\mathrm{lex,comp}} \to \mathsf{Groth}_{n}^{\mathrm{lex}}$ be the functor given by $L(\mathcal{C}) = \tau_{\leqslant n}\mathcal{C}$ (see Example C.5.4.4). Then L admits a fully faithful left adjoint, whose essential image is spanned by those Grothendieck prestable ∞-categories $\mathcal{C}$ which are complete and weakly n-complicial.*

We now specialize Proposition C.5.9.3 to the case $n = 0$.

Definition C.5.9.4. Let $\mathcal{A}$ be a Grothendieck abelian category and let $\mathcal{D}(\mathcal{A})$ be the derived ∞-category of $\mathcal{A}$. We let $\widehat{\mathcal{D}}(\mathcal{A})$ denote the left completion of $\mathcal{D}(\mathcal{A})$ with respect to its t-structure (see §HA.1.2.1): that is, the limit of the tower

$$\cdots \mathcal{D}(\mathcal{A})_{\leqslant 3} \xrightarrow{\tau_{\leqslant 2}} \mathcal{D}(\mathcal{A})_{\leqslant 2} \xrightarrow{\tau_{\leqslant 1}} \mathcal{D}(\mathcal{A})_{\leqslant 1} \xrightarrow{\tau_{\leqslant 0}} \mathcal{D}(\mathcal{A})_{\leqslant 0}.$$

We will refer to $\widehat{\mathcal{D}}(\mathcal{A})$ as the *completed derived ∞-category* of $\mathcal{A}$. It is equipped with a t-structure $(\widehat{\mathcal{D}}(\mathcal{A})_{\geqslant 0}, \widehat{\mathcal{D}}(\mathcal{A})_{\leqslant 0})$, where $\widehat{\mathcal{D}}(\mathcal{A})_{\geqslant 0}$ is the completion of the Grothendieck prestable ∞-category $\mathcal{D}(\mathcal{A})_{\geqslant 0}$ (in the sense of Proposition C.3.6.3) and $\widehat{\mathcal{D}}(\mathcal{A})_{\leqslant 0}$ is equivalent to $\mathcal{D}(\mathcal{A})_{\leqslant 0}$.

If $\mathcal{A}$ is a Grothendieck abelian category, then we can identify $\widehat{\mathcal{D}}(\mathcal{A})_{\geqslant 0}$ with the image of $\mathcal{A}$ under the functor $\mathsf{Groth}^{\mathrm{lex}}_{\mathrm{ab}} = \mathsf{Groth}^{\mathrm{lex}}_{0} \to \mathsf{Groth}^{\mathrm{lex,comp}}_{\infty}$ of Proposition C.5.9.3. We therefore obtain the following analogue of Theorem C.5.4.9:

Corollary C.5.9.5. *Let $\mathcal{A}$ be a Grothendieck abelian category and let $\mathcal{C}$ be a Grothendieck prestable ∞-category. If $\mathcal{C}$ is complete, then the restriction functor $\mathrm{LFun}^{\mathrm{lex}}(\widehat{\mathcal{D}}(\mathcal{A})_{\geqslant 0}, \mathcal{C}) \to \mathrm{Fun}(\mathcal{A}, \mathcal{C}^{\heartsuit})$ is a fully faithful embedding, whose essential image consists of those functors $F : \mathcal{A} \to \mathcal{C}^{\heartsuit}$ which are left exact and preserve small colimits (here we abuse notation by identifying $\mathcal{A}$ with the heart $\widehat{\mathcal{D}}(\mathcal{A})^{\heartsuit}_{\geqslant 0}$).*

Corollary C.5.9.6. *The construction $\mathcal{A} \mapsto \widehat{\mathcal{D}}(\mathcal{A})_{\geqslant 0}$ determines a fully faithful embedding $\mathsf{Groth}^{\mathrm{lex}}_{\mathrm{ab}} \hookrightarrow \mathsf{Groth}^{\mathrm{lex,comp}}_{\infty}$, which is left adjoint to the heart functor*

$$\mathsf{Groth}^{\mathrm{lex,comp}}_{\infty} \to \mathsf{Groth}^{\mathrm{lex}}_{\mathrm{ab}} \qquad \mathcal{C} \mapsto \mathcal{C}^{\heartsuit}.$$

We also have the following variant of Corollary C.5.8.11:

Corollary C.5.9.7. *Let $\mathcal{C}$ be a complete Grothendieck prestable ∞-category and let $\mathcal{A} = \mathcal{C}^{\heartsuit}$. Then the inclusion functor $\mathcal{A} \hookrightarrow \mathcal{C}$ admits an essentially unique extension to a functor $\lambda : \widehat{\mathcal{D}}(\mathcal{A})_{\geqslant 0} \to \mathcal{C}$ which preserves small colimits and finite limits. The following conditions are equivalent:*

(a) The functor λ is an equivalence of ∞-categories.

(b) The Grothendieck prestable ∞-category $\mathcal{C}$ is weakly 0-complicial.

(c) Every injective object of $\mathrm{Sp}(\mathcal{C})$ belongs to the heart of $\mathrm{Sp}(\mathcal{C})$.

Proof. The existence (and essential uniqueness) of λ follows from Corollary C.5.9.5. The equivalence $(a) \Leftrightarrow (b)$ follows from Proposition C.5.9.3 and the equivalence $(b) \Leftrightarrow (c)$ follows from Proposition C.5.7.11. □

C.6 Finiteness Conditions on Prestable ∞-Categories

Let $\mathcal{C}$ be a presentable ∞-category. Recall that $\mathcal{C}$ is said to be *compactly generated* if every object $C \in \mathcal{C}$ can be written as the colimit of a filtered diagram $\varinjlim \{C_\alpha\}$, where each C_α is a compact object of $\mathcal{C}$. In this case, the ∞-category $\mathcal{C}$ is equivalent to $\mathrm{Ind}(\mathcal{C}_0)$, where $\mathcal{C}_0 \subseteq \mathcal{C}$ is the full subcategory spanned by the compact objects. Moreover, the construction $\mathcal{C}_0 \mapsto \mathrm{Ind}(\mathcal{C}_0)$ establishes an equivalence between the following data:

(*a*) Essentially small ∞-categories $\mathcal{C}_0$ which are idempotent complete and admit finite colimits.

(*b*) Compactly generated ∞-categories $\mathcal{C}$.

In this section, we will consider several variants of the equivalence between (*a*) and (*b*) which arise in the study of prestable ∞-categories. We begin in §C.6.1 by showing that in the situation above, the ∞-category $\mathcal{C} = \mathrm{Ind}(\mathcal{C}_0)$ is prestable if and only if $\mathcal{C}_0$ is prestable (Proposition C.6.1.1). Consequently, the equivalence between (*a*) and (*b*) persists when we restrict our attention to prestable ∞-categories (Corollary C.6.1.5). Moreover, the theory of compactly generated ∞-categories simplifies (to some extent) when we work in the prestable setting: in §C.6.3, we supply a simple criterion which can be used to verify that a Grothendieck prestable ∞-category $\mathcal{C}$ is compactly generated (Corollary C.6.3.3).

Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. If $C \in \mathcal{C}$ is a compact object, then $\pi_0 C$ is a compact object of the Grothendieck abelian category $\mathcal{C}^{\heartsuit}$. However, the converse is false: for example, a compact object of the abelian category $\mathcal{C}^{\heartsuit}$ need not be compact when viewed as an object of $\mathcal{C}$. For a prototypical example, we can take $\mathcal{C} = \mathrm{Mod}_R^{\mathrm{cn}}$ to be the ∞-category of connective modules over a commutative ring R. If $M \in \mathrm{Mod}_R^{\heartsuit}$ is a discrete R-module, then M is compact as an object of $\mathrm{Mod}_R^{\heartsuit}$ if and only if it is finitely presented, but is compact as an object of $\mathrm{Mod}_R^{\mathrm{cn}}$ if and only if it is perfect (that is, if and only if it admits a finite resolution by finitely generated projective R-modules). In general, the second condition is much stronger than the first. However, if R is a Noetherian ring (or, more generally, a coherent ring), then the difference is smaller: in this case, every finitely presented R-module M admits a resolution

$$\cdots \to P_3 \to P_2 \to P_1 \to P_0 \to M$$

where each P_n is a projective R-module of finite rank, but we might not be able to arrange that $P_n \simeq 0$ for $n \gg 0$. In this case, we cannot conclude that M is perfect, but we can conclude that it is *almost compact*: that is, that it is compact when viewed as an object of $\tau_{\leqslant n} \mathrm{Mod}_R^{\mathrm{cn}}$, for each $n \geqslant 0$. In §C.6.5, we generalize this observation by introducing the notion of a *coherent* Grothendieck prestable ∞-category: that is, a Grothendieck prestable ∞-category $\mathcal{C}$ which has "enough" almost compact objects (Definition C.6.5.1). We then study two situations in which a coherent Grothendieck stable ∞-category $\mathcal{C}$ can be recovered from its almost compact objects:

- In §C.6.6, we show that a Grothendieck prestable ∞-category $\mathcal{C}$ which is separated and coherent can be functorially recovered from the full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ spanned by its almost compact objects (Theorem C.6.6.14).

- In §C.6.7, we show that Grothendieck prestable ∞-category $\mathcal{C}$ which is anticomplete and coherent is also compactly generated, so that $\mathcal{C}$ can be recovered from the full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ of compact objects (Corollary C.6.7.3); moreover, an object $C \in \mathcal{C}$ is compact if and only if it is truncated and almost compact.

In many cases of interest, one has even stronger finiteness conditions. Recall that a Grothendieck abelian category $\mathcal{A}$ is said to be *locally Noetherian* if every object $X \in \mathcal{A}$ can be written as a (filtered) colimit of its Noetherian subobjects (Definition C.6.8.5). In §C.6.9, we will consider an analogous condition in the setting of Grothendieck prestable ∞-categories (Definition C.6.9.1) and study some of its consequences.

Remark C.6.0.8. The theory of coherent Grothendieck prestable ∞-categories presented here can be regarded as a "linear" version of the theory of coherent ∞-topoi presented in Appendix A. In particular, Theorem C.6.6.14 and Corollary C.6.7.3 are directly analogous to Theorems A.6.6.5 and A.7.5.3, respectively.

C.6.1 Prestability and Ind-Completion

Our starting point is the following result:

Proposition C.6.1.1. *Let $\mathcal{C}$ be a small idempotent-complete ∞-category which admits finite colimits. Then $\mathcal{C}$ is prestable if and only if $\operatorname{Ind}(\mathcal{C})$ is prestable.*

Remark C.6.1.2. Every compactly generated prestable ∞-category $\mathcal{C}$ is a Grothendieck prestable ∞-category: filtered colimits in $\mathcal{C}$ are left exact by virtue of Remark HA.**??**.

Lemma C.6.1.3. *Let $\mathcal{C}$ be a compact generated prestable ∞-category. Then an object $C \in \mathcal{C}$ is compact if and only if $\Sigma^{\infty} C$ is a compact object of $\operatorname{Sp}(\mathcal{C})$.*

Proof. The "only if" direction follows from the fact that the functor $\Sigma^{\infty} : \mathcal{C} \to \operatorname{Sp}(\mathcal{C})$ is fully faithful and preserves filtered colimits. The converse follows from the fact that $\Omega^{\infty} : \operatorname{Sp}(\mathcal{C}) \to \mathcal{C}$ preserves filtered colimits (Remark C.6.1.2 and Proposition C.1.4.1). ☐

Proof of Proposition C.6.1.1. Assume first that $\operatorname{Ind}(\mathcal{C})$ is prestable. Let $j : \mathcal{C} \to \operatorname{Ind}(\mathcal{C})$ be the Yoneda embedding. Since $\mathcal{C}$ is idempotent-complete, the functor j induces an equivalence from $\mathcal{C}$ to the full subcategory of $\operatorname{Ind}(\mathcal{C})$ spanned by the compact objects. Since j preserves finite colimits, the diagram of ∞-categories

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{j} & \operatorname{Ind}(\mathcal{C}) \\ \downarrow{\scriptstyle \Sigma_{\mathcal{C}}} & & \downarrow{\scriptstyle \Sigma_{\operatorname{Ind}(\mathcal{C})}} \\ \mathcal{C} & \xrightarrow{j} & \operatorname{Ind}(\mathcal{C}) \end{array}$$

commutes up to homotopy. Since $\Sigma_{\operatorname{Ind}(\mathcal{C})}$ and j are fully faithful, it follows that $\Sigma_{\mathcal{C}}$ is also fully faithful. To complete the proof that $\mathcal{C}$ is prestable, it will suffice to show that for every cofiber sequence $X \to X'' \to \Sigma X'$ in $\mathrm{Ind}(\mathcal{C})$, if both X'' and X' are compact, then X is compact. This follows immediately from Lemma C.6.1.3.

Now suppose that $\mathcal{C}$ is prestable. Then there exists a fully faithful embedding $f : \mathcal{C} \hookrightarrow \mathcal{D}$, where $\mathcal{D}$ is stable and the essential image of f is closed under colimits and extensions (Corollary C.1.2.3). Without loss of generality, we may assume that $\mathcal{D}$ is idempotent complete. The functor f induces a fully faithful embedding $\mathrm{Ind}(f) : \mathrm{Ind}(\mathcal{C}) \hookrightarrow \mathrm{Ind}(\mathcal{D})$ which preserves small colimits, and the functor $\mathrm{Ind}(\mathcal{D})$ is stable by virtue of Proposition HA.1.1.3.6 . To show that $\mathrm{Ind}(\mathcal{C})$ is prestable, it will suffice to show that the essential image of $\mathrm{Ind}(f)$ is closed under extensions (Corollary C.1.2.3). Let us abuse notation by identifying $\mathcal{D}$ with the full subcategory of $\mathrm{Ind}(\mathcal{D})$ spanned by the compact objects. Suppose we are given a fiber sequence $X' \to X \to X''$ in $\mathrm{Ind}(\mathcal{D})$, where the objects X' and X'' are the images of diagrams $\{C'_\alpha\}_{\alpha \in A}$ and $\{C''_\beta\}_{\beta \in B}$ in the ∞-category $\mathcal{C}$ indexed by filtered partially ordered sets A and B. We wish to show that X has the same property. Writing X as a filtered colimit of the fiber products $X \times_{X''} f(C''_\beta)$, we can assume that X" belongs to the essential image of $\mathcal{C}$. In particular, X'' is a compact object of $\mathrm{Ind}(\mathcal{D})$, so that the natural map $X'' \to \Sigma X'$ factors through some C'_α. In this case, we can write X as a filtered colimit $\varinjlim_{\gamma \geqslant \alpha} X_\gamma$, where X_γ denotes the fiber of the induced map $X'' \to \Sigma X'_\gamma$. We are therefore reduced to showing that each X_γ belongs to the essential image of $\mathcal{C}$. Note X_γ is a compact object of $\mathrm{Ind}(\mathcal{D})$ (since it is an extension of compact objects), and can therefore be identified with an object of $\mathcal{D}$. Since the essential image of f is closed under extensions, it follows that X_γ belongs to the essential image of $\mathcal{C}$ as desired. □

Notation C.6.1.4. We let $\mathcal{C}\mathrm{at}_\infty^{\mathrm{PSt}}$ denote the subcategory of $\mathcal{C}\mathrm{at}_\infty$ whose objects are small prestable ∞-categories and whose morphisms are right exact functors. We will refer to $\mathcal{C}\mathrm{at}_\infty^{\mathrm{PSt}}$ as *the ∞-category of prestable ∞-categories.*

Let $\mathcal{C}\mathrm{at}_\infty^{\star}$ denote the subcategory of $\mathcal{C}\mathrm{at}_\infty$ whose objects are small idempotent-complete ∞-categories which admit finite colimits and whose morphisms are functors which preserve finite colimits. According to Lemma HA.5.3.2.9 , the construction $\mathcal{C} \mapsto \mathrm{Ind}(\mathcal{C})$ induces an equivalence from $\mathcal{C}\mathrm{at}_\infty^{\star}$ to the subcategory of $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ whose objects are compactly generated ∞-categories and whose morphisms are functors which preserve small colimits and compact objects. Combining that observation with Proposition C.6.1.1 and Remark C.3.4.3, we obtain the following:

Corollary C.6.1.5. *Let $\mathcal{C}\mathrm{at}_\infty^{\mathrm{PSt},\star}$ denote the full subcategory of $\mathcal{C}\mathrm{at}_\infty^{\mathrm{PSt}}$ whose objects are small idempotent-complete prestable ∞-categories. Then the construction $\mathcal{C} \mapsto \mathrm{Ind}(\mathcal{C})$ determines a fully faithful embedding $\mathrm{Ind} : \mathcal{C}\mathrm{at}_\infty^{\mathrm{PSt},\star} \hookrightarrow \mathsf{Groth}_\infty^{\mathrm{c}}$, whose essential image is spanned by the compactly generated prestable ∞-categories.*

Warning C.6.1.6. To obtain the equivalence of Corollary C.6.1.5, it is essential that our definition of a prestable ∞-category $\mathcal{C}$ does not require that $\mathcal{C}$ admits finite limits. For example, if R is an arbitrary connective $\mathbb{E}_\infty$-ring, then the ∞-category $\mathrm{Mod}_R^{\mathrm{cn}}$ of connective R-modules is a compactly generated prestable ∞-category, whose full subcategory of compact objects is given by the intersection $\mathrm{Mod}_R^{\mathrm{perf,cn}} = \mathrm{Mod}_R^{\mathrm{cn}} \cap \mathrm{Mod}_R^{\mathrm{perf}}$ spanned by the connective perfect R-modules. This ∞-category almost never admits finite limits (according to Proposition C.1.2.9, it admits finite limits if and only if the stable ∞-category $\mathrm{Mod}_R^{\mathrm{perf}} \simeq \mathrm{SW}(\mathrm{Mod}_R^{\mathrm{perf,cn}})$ admits a t-structure $(\mathrm{Mod}_R^{\mathrm{perf,cn}}, (\mathrm{Mod}_R^{\mathrm{perf}})_{\leqslant 0})$: in other words, if and only if the collection of perfect R-modules is stable under the formation of truncations).

C.6.2 Tensor Products of Compactly Generated Prestable ∞-Categories

We let $\mathsf{Groth}_\infty^{\mathrm{cg}}$ denote the subcategory of $\widehat{\mathcal{C}\mathrm{at}}_\infty$ whose objects are compactly generated prestable ∞-categories and whose morphisms are compact functors $f : \mathcal{C} \to \mathcal{D}$. We regard $\mathsf{Groth}_\infty^{\mathrm{cg}}$ as a full subcategory of the ∞-category $\mathsf{Groth}_\infty^{\mathrm{c}}$ introduced in Definition C.3.4.2 (namely, the essential image of the functor Ind of Corollary C.6.1.5).

Proposition C.6.2.1. *The ∞-category $\mathsf{Groth}_\infty^{\mathrm{cg}}$ admits small colimits and the inclusion functors*

$$\mathsf{Groth}_\infty^{\mathrm{cg}} \hookrightarrow \mathsf{Groth}_\infty^{\mathrm{c}} \qquad \mathsf{Groth}_\infty^{\mathrm{cg}} \hookrightarrow \mathsf{Groth}_\infty$$

preserve small colimits.

Proof. By virtue of Proposition C.3.5.1, it will suffice to show that if $\{\mathcal{C}_\alpha\}$ is a diagram in $\mathsf{Groth}_\infty^{\mathrm{c}}$ having colimit $\mathcal{C}$ and each $\mathcal{C}_\alpha$ is compactly generated, then $\mathcal{C}$ is compactly generated. For each index α, let $f_\alpha : \mathcal{C}_\alpha \to \mathcal{C}$ be the tautological map and $G_\alpha : \mathrm{Sp}(\mathcal{C}) \to \mathrm{Sp}(\mathcal{C}_\alpha)$ the stabilization of the right adjoint to f_α. Each of the functors f_α is a morphism in $\mathsf{Groth}_\infty^{\mathrm{c}}$ and therefore carries compact objects of $\mathcal{C}_\alpha$ to compact objects of $\mathcal{C}$. Moreover, an object $X \in \mathrm{Sp}(\mathcal{C})$ belongs to $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ if and only if the groups

$$\mathrm{Ext}^*_{\mathrm{Sp}(\mathcal{C}_\alpha)}(\Sigma^\infty_{\mathcal{C}_\alpha} C, G_\alpha X) \simeq \mathrm{Ext}^*_{\mathrm{Sp}(\mathcal{C})}(\Sigma^\infty_{\mathcal{C}} f_\alpha(C), X)$$

vanish for each $* < 0$ and every compact object $C \in \mathcal{C}_\alpha$. It follows that the collection of objects $\{\Sigma^\infty_{\mathcal{C}} f_\alpha C\}$ where $C \in \mathcal{C}_\alpha$ is compact satisfy the hypotheses of Proposition C.6.3.1, so that $\mathcal{C} \simeq \mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ is a compactly generated prestable ∞-category. □

Proposition C.6.2.2. *Let $\mathcal{C}$ and $\mathcal{D}$ be compactly generated prestable ∞-categories. Then the tensor product $\mathcal{C} \otimes \mathcal{D}$ (formed in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$) is a compactly generated prestable ∞-category.*

Proof. The prestability of $\mathcal{C} \otimes \mathcal{D}$ follows from Theorem C.4.2.1 and the existence of compact generators follows because the functor $\mathrm{Ind} : \mathcal{C}\mathrm{at}_\infty^{\mathrm{rex}} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ is symmetric monoidal, where $\mathcal{C}\mathrm{at}_\infty^{\mathrm{rex}}$ denotes the ∞-category whose objects are small ∞-categories which admit finite colimits and whose morphisms are functors which preserve finite colimits. □

Since the unit object $\mathrm{Sp}^{\mathrm{cn}} \in \mathsf{Groth}_\infty^{\mathrm{c}}$ is compactly generated, Propositions C.6.2.2, **??**, and C.6.2.1 yield the following:

Corollary C.6.2.3. *The symmetric monoidal structure on $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ induces a symmetric monoidal structure on the ∞-category $\mathsf{Groth}_\infty^{\mathrm{cg}}$ for which the inclusion $\mathsf{Groth}_\infty^{\mathrm{cg}} \hookrightarrow \mathsf{Groth}_\infty^{\mathrm{c}}$ is symmetric monoidal functor. Moreover, the tensor product $\otimes : \mathsf{Groth}_\infty^{\mathrm{cg}} \times \mathsf{Groth}_\infty^{\mathrm{cg}} \to \mathsf{Groth}_\infty^{\mathrm{cg}}$ preserves small colimits separately in each variable.*

C.6.3 Digression: A Criterion for Compact Generation

We close this section by establishing a result which is useful for constructing examples of compactly generated prestable ∞-categories.

Proposition C.6.3.1. *Let $\mathcal{C}$ be a presentable stable ∞-category, and let $\{C_\alpha\}_{\alpha \in A}$ be a collection of compact objects of $\mathcal{C}$. Suppose that for every nonzero object $D \in \mathcal{C}$, there exists $\alpha \in A$ for which the graded abelian group $\mathrm{Ext}^*_{\mathcal{C}}(C_\alpha, D)$ is nonzero. Then:*

- (a) *Let $\mathcal{C}_{\leqslant 0}$ be the full subcategory of $\mathcal{C}$ spanned by those objects D for which the groups $\mathrm{Ext}^*_{\mathcal{C}}(C_\alpha, D)$ vanish for all $\alpha \in A$ and $* < 0$. Then $\mathcal{C}_{\leqslant 0}$ can be extended to a t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ on $\mathcal{C}$.*
- (b) *The t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ is right complete and compatible with filtered colimits.*
- (c) *Let $\mathcal{E} \subseteq \mathcal{C}$ be the smallest full subcategory which contains the objects C_α and is closed under finite colimits and extensions. Then the inclusion $\mathcal{E} \hookrightarrow \mathcal{C}$ extends to an equivalence of ∞-categories $\mathrm{Ind}(\mathcal{E}) \simeq \mathcal{C}_{\geqslant 0}$.*
- (d) *The ∞-category $\mathcal{C}_{\geqslant 0}$ is compactly generated and prestable.*
- (e) *Let D be an object of $\mathcal{C}_{\geqslant 0}$. Then D is compact as an object of $\mathcal{C}_{\geqslant 0}$ if and only if it is compact as an object of $\mathcal{C}$.*

Proof. The existence of the t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ follows immediately from Proposition HA.1.4.4.11 . Since each C_α is a compact object of $\mathcal{C}$, it follows immediately that the full subcategory $\mathcal{C}_{\leqslant 0} \subseteq \mathcal{C}$ is closed under filtered colimits. In particular, it is closed under arbitrary coproducts. Any object $D \in \bigcap_{n \geqslant 0} \mathcal{C}_{\leqslant -n}$ satisfies $\mathrm{Ext}^*_{\mathcal{C}}(C_\alpha, D) \simeq 0$ for all $\alpha \in A$ and is therefore a zero object of $\mathcal{C}$. The right completeness of $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ is therefore a consequence of Proposition HA.1.2.1.19 . This proves (a) and (b).

Since the collection of compact objects of $\mathcal{C}$ is closed under finite colimits and extensions, every object of $\mathcal{E}$ is compact when viewed as an object of $\mathcal{C}$. Note that the full subcategory $\mathcal{C}_{\geqslant 0} \subseteq \mathcal{C}$ is also closed under finite colimits and extensions and therefore contains $\mathcal{E}$. In particular, every object of $\mathcal{E}$ is compact when viewed as an object of $\mathcal{C}_{\geqslant 0}$, so the inclusion $\mathcal{E} \hookrightarrow \mathcal{C}_{\geqslant 0}$ extends to a fully faithful embedding $\theta : \mathrm{Ind}(\mathcal{E}) \to \mathcal{C}_{\geqslant 0}$ which commutes with small colimits. Let $\mathcal{C}' \subseteq \mathcal{C}_{\geqslant 0}$ be the essential image of θ. To prove (c), we must show that $\mathcal{C}' = \mathcal{C}_{\geqslant 0}$. The proof of Proposition HA.1.4.4.11 shows that $\mathcal{C}_{\geqslant 0}$ is the smallest full subcategory of $\mathcal{C}$ which contains the objects C_α and is closed under small colimits and extensions. Consequently, to establish the inclusion $\mathcal{C}_{\geqslant 0} \subseteq \mathcal{C}'$, it will suffice to show that the ∞-category $\mathcal{C}'$ is closed under extensions in $\mathcal{C}$. Suppose we are given a fiber sequence

$$C' \to C \to C''$$

where $C', C'' \in \mathcal{C}'$; we wish to prove that $C \in \mathcal{C}'$. Write C'' as a filtered colimit $\varinjlim C''_\beta$, where each C''_β belongs to $\mathcal{E}$. It follows that C can be written as a filtered colimit of objects of the form $C \times_{C''} C''_\beta$. Since $\mathcal{C}'$ is closed under filtered colimits in $\mathcal{C}$, it will suffice to show that each $C \times_{C''} C''_\beta$ belongs to $\mathcal{C}'$. Replacing C'' by C''_β, we may reduce to the case where $C''_\beta \in \mathcal{E}$. In this case, we can realize C as the fiber of a map $\eta : C'' \to \Sigma C'$. Write C' as a filtered colimit $\varinjlim C'_\gamma$, where each C'_γ belongs to $\mathcal{E}$. Since C'' is a compact object of $\mathcal{C}$, it follows that η factors through $\Sigma C'_{\gamma_0}$ for some index γ_0. We may therefore write C as a filtered colimit of objects of the form $\mathrm{fib}(C'' \to \Sigma C'_\gamma)$, which are extensions of objects of $\mathcal{E}$ and therefore belong to $\mathcal{E}$. This proves (c).

Assertion (d) is an immediate consequence of (b) and (c). To prove (e), it suffices to observe that any compact object of $\mathcal{C}_{\geqslant 0} \simeq \mathrm{Ind}(\mathcal{E})$ is a retract of an object of $\mathcal{E}$, and is therefore compact when viewed as an object of $\mathcal{C}$. □

Remark C.6.3.2. Let $\mathcal{D}$ be a compactly generated prestable ∞-category, and choose a collection of compact objects $\{D_\alpha\}_{\alpha \in A}$ which generate $\mathcal{D}$ under small colimits. Set $\mathcal{C} = \mathrm{Sp}(\mathcal{D})$. Then the objects $\{\Sigma^\infty D_\alpha \in \mathcal{C}\}$ satisfy the hypotheses of Proposition C.6.3.1, and the t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ of Proposition C.6.3.1 agrees with the one determined by the prestability of $\mathcal{D}$ (that is, $\mathcal{C}_{\geqslant 0}$ can be identified with the essential image of the functor $\Sigma^\infty : \mathcal{C} \to \mathrm{Sp}(\mathcal{C}) = \mathcal{D}$). Consequently, *every* compactly generated prestable ∞-category $\mathcal{D}$ can be obtained from the construction of Proposition C.6.3.1.

Corollary C.6.3.3. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. The following conditions are equivalent:*

(a) *The ∞-category $\mathcal{C}$ is compactly generated.*

(b) *For every nonzero object $C \in \mathcal{C}$, there exists a morphism $\alpha : C_0 \to C$, where C_0 is compact and α is not nullhomotopic.*

Proof. Suppose first that (a) is satisfied, and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be the full subcategory spanned by the compact objects. Then the composition of the Yoneda embedding $j : \mathcal{C} \to \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ with the restriction functor $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}) \to \mathrm{Fun}(\mathcal{C}_0^{\mathrm{op}}, \mathcal{S})$ is fully faithful. Consequently, if $C \in \mathcal{C}$ is nonzero, then $j(C)|_{\mathcal{C}_0^{\mathrm{op}}}$ cannot be a final object of $\mathrm{Fun}(\mathcal{C}_0^{\mathrm{op}}, \mathcal{S})$: that is, there exists a compact object $C_0 \in \mathcal{C}_0$ such that the mapping space $\mathrm{Map}_{\mathcal{C}}(C_0, C)$ is not contractible. It follows that for some integer n, the homotopy group $\pi_n \mathrm{Map}_{\mathcal{C}}(C_0, C)$ is nontrivial. Replacing C_0 by the suspension $\Sigma^n C_0$, it follows that there exists a map $C_0 \to C$ which is not nullhomotopic.

Now suppose that (b) is satisfied. If X is a nonzero object of $\mathrm{Sp}(\mathcal{C})$, then $\Omega^{\infty-n} X$ is a nonzero object of $\mathcal{C}$ for some $n \gg 0$, so condition (b) guarantees that there is compact object $C_0 \in \mathcal{C}$ such that $\pi_0 \mathrm{Map}_{\mathcal{C}}(C_0, \Omega^{\infty-n} X) \simeq \mathrm{Ext}^n_{\mathcal{C}}(\Sigma^\infty C_0, X) \neq 0$. Consequently, the collection of objects $\{\Sigma^\infty C_0\}_{C_0 \in \mathcal{C}_0}$ satisfies the hypotheses of Proposition C.6.3.1. We conclude that there exists a t-structure $(\mathrm{Sp}(\mathcal{C})_{\geqslant 0}, \mathrm{Sp}(\mathcal{C})_{\leqslant 0})$ on $\mathrm{Sp}(\mathcal{C})$, where $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ is a compactly generated prestable ∞-category and $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ is the full subcategory spanned by those objects X for which the groups

$$\mathrm{Ext}^{-n}_{\mathrm{Sp}(\mathcal{C})}(\Sigma^\infty C_0, X) \simeq \pi_0 \mathrm{Map}_{\mathcal{C}}(\Sigma^n C, \Omega^\infty X)$$

vanish for $C_0 \in \mathcal{C}_0$ and $n > 0$. Applying (b) again, we deduce that $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ is spanned by those objects $X \in \mathrm{Sp}(\mathcal{C})$ satisfying $\Omega^{\infty+1} X \simeq 0$, so that $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ is the essential image of the fully faithful embedding $\Sigma^\infty : \mathcal{C} \to \mathrm{Sp}(\mathcal{C})$. □

C.6.4 Almost Compact Objects

Let $\mathcal{C}$ be an ∞-category which admits filtered colimits. Recall that an object $C \in \mathcal{C}$ is said to be *compact* if the functor $D \mapsto \mathrm{Map}_{\mathcal{C}}(C, D)$ commutes with filtered colimits. In practice, it is often useful to consider a slightly weaker condition (see Definition HA.7.2.4.8):

Definition C.6.4.1. Let $\mathcal{C}$ be a presentable ∞-category. We say that an object $C \in \mathcal{C}$ is *almost compact* if, for every integer $n \geqslant 0$, the construction $D \mapsto \mathrm{Map}_{\mathcal{C}}(C, D)$ determines a functor $\tau_{\leqslant n} \mathcal{C} \to \mathcal{S}$ which commutes with filtered colimits.

Remark C.6.4.2. Let $\mathcal{C}$ be a presentable ∞-category. An object $C \in \mathcal{C}$ is almost compact if and only if, for every $n \geqslant 0$, the truncation $\tau_{\leqslant n} C$ is compact when viewed as an object of $\tau_{\leqslant n} \mathcal{C}$.

Example C.6.4.3. Let $\mathcal{C}$ be a presentable ∞-category. Every compact object of $\mathcal{C}$ is almost compact.

Proposition C.6.4.4. *Let $\mathcal{C}$ be a presentable ∞-category and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be the full subcategory spanned by those objects which are almost compact. Then $\mathcal{C}_0$ is closed under finite colimits and under geometric realizations of simplicial objects.*

Proof. Closure under finite colimits follows immediately from Remark C.6.4.2 and the closure of compact objects of $\tau_{\leqslant n} \mathcal{C}$ under finite colimits (Corollary HTT.5.3.4.15). Similarly, to show that $\mathcal{C}_0$ is closed under geometric realizations of simplicial objects, it will suffice to show that for every simplicial object $X_\bullet$ of $\tau_{\leq n}\mathcal{C}$, if each X_k is a compact object of $\tau_{\leq n}\mathcal{C}$, then the geometric realization $|X_\bullet|$ (formed in the ∞-category $\tau_{\leq n}\mathcal{C}$) is also compact. This follows from the fact that $\tau_{\leq n}\mathcal{C}$ is equivalent to an $(n+1)$-category, so that the geometric realization $|X_\bullet|$ can be identified with the finite colimit $\varinjlim_{[k]\in\mathbf{\Delta}^{\mathrm{op}}_{s,\leq n+1}} X_k$. □

Proposition C.6.4.5. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $\mathcal{C}^{\mathrm{ac}} \subseteq \mathcal{C}$ be the full subcategory spanned by the almost compact objects. The following conditions are equivalent:*

- (a) *The loop functor $\Omega : \mathcal{C} \to \mathcal{C}$ carries $\mathcal{C}^{\mathrm{ac}}$ to itself.*
- (b) *For every morphism $f : X \to Y$ in $\mathcal{C}^{\mathrm{ac}}$, the fiber $\mathrm{fib}(f)$ belongs to $\mathcal{C}^{\mathrm{ac}}$.*
- (c) *The full subcategory $\mathcal{C}^{\mathrm{ac}} \subseteq \mathcal{C}$ is closed under finite limits.*
- (d) *For every object $X \in \mathcal{C}^{\mathrm{ac}}$, the object $\pi_0 X$ also belongs to $\mathcal{C}^{\mathrm{ac}}$.*

Proof. We first prove that (a) implies (b). Let $f : X \to Y$ be a morphism in $\mathcal{C}$, where X and Y are almost compact. Applying Proposition C.6.4.4, we deduce that the cofiber $\mathrm{cofib}(f)$ is almost compact. From assumption (a) (and the prestability of $\mathcal{C}$) we deduce that $\mathrm{fib}(f) \simeq \Omega\,\mathrm{cofib}(f)$ is almost compact.

We next show that (b) implies (c). By virtue of Corollary HTT.4.4.2.4 , it will suffice to show that $\mathcal{C}^{\mathrm{ac}}$ contains the final object of $\mathcal{C}$ (which is clear) and is closed under fiber products. This follows from (b): if $f_0 : X_0 \to X$ and $f_1 : X_1 \to X$ are morphisms in $\mathcal{C}^{\mathrm{ac}}$, then we can identify the fiber product $X_0 \times_X X_1$ with the fiber of the induced map $X_0 \oplus X_1 \xrightarrow{f_0 - f_1} X$.

The implication $(c) \Rightarrow (a)$ is obvious. We complete the proof by showing that (a) and (d) are equivalent. Suppose that (a) is satisfied and that $X \in \mathcal{C}^{\mathrm{ac}}$. Then $\Omega X \in \mathcal{C}^{\mathrm{ac}}$. Since the collection of almost compact objects of $\mathcal{C}$ is closed under finite colimits, it follows that $\pi_0 X \simeq \mathrm{cofib}(\Sigma\Omega X \to X)$ also belongs to $\mathcal{C}^{\mathrm{ac}}$.

Conversely, suppose that (d) is satisfied. For every object $X \in \mathcal{C}^{\mathrm{ac}}$, the cofiber sequence $X \to \pi_0 X \to \Sigma^2 \Omega X$ shows that $\Sigma^2\Omega X$ is almost compact. Since the double suspension functor Σ^2 induces a fully faithful embedding $\tau_{\leq n}\mathcal{C} \to \tau_{\leq n+2}\mathcal{C}$ which commutes with filtered colimits for each $n \geq 0$, it follows that $\Omega X \in \mathcal{C}$ is also almost compact. □

Corollary C.6.4.6. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category which satisfies the equivalent conditions of Proposition C.6.4.5, and let $C \in \mathcal{C}$ be an object. The following conditions are equivalent:*

- (i) *The object C is almost compact.*
- (ii) *For each $n \geq 0$, the truncation $\tau_{\leq n} C$ is almost compact.*

(*iii*) *For each $n \geqslant 0$, the object $\pi_n C \in \mathcal{C}^{\heartsuit}$ is almost compact (when viewed as an object of $\mathcal{C}$).*

Proof. The implication $(i) \Rightarrow (ii)$ follows from the existence of a cofiber sequence $\Sigma^{n+1}\Omega^{n+1}C \to C \to \tau_{\leqslant n} C$, and the implication $(ii) \Rightarrow (iii)$ from the existence of an equivalence $\pi_n C \simeq \Omega^n(\tau_{\leqslant n} C)$. We will complete the proof by showing that $(iii) \Rightarrow (i)$. Assume that (iii) is satisfied; we wish to show that C is almost compact. Equivalently, we wish to show that $\tau_{\leqslant m} C$ is compact when viewed as an object of $\tau_{\leqslant m}\mathcal{C}$, for each $m \geqslant 0$. In fact, we will a stronger assertion: for each $m \geqslant 0$, the truncation $\tau_{\leqslant m} C$ is almost compact (when viewed as an object of $\mathcal{C}$). The proof proceeds by induction on m, the case $m = -1$ being trivial. To carry out the inductive step, we observe that there exists a fiber sequence

$$\tau_{\leqslant m} C \to \tau_{\leqslant m-1} C \to \Sigma^{m+1}(\pi_m C).$$

The object $\tau_{\leqslant m-1} C$ is almost compact by our inductive hypothesis, and $\Sigma^{m+1}(\pi_m C)$ is almost compact by virtue of assumption (iii). Invoking assumption (b) of Proposition C.6.4.5, we conclude that $\tau_{\leqslant m} C$ is almost compact. □

C.6.5 Coherent Grothendieck Prestable ∞-Categories

We now turn our attention to Grothendieck prestable ∞-categories which have "enough" almost compact objects.

Definition C.6.5.1. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be the full subcategory spanned by the almost compact objects. We will say that $\mathcal{C}$ is *coherent* if it satisfies the following conditions:

(a) The full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ is closed under finite limits.

(b) The full subcategory $\mathcal{C}_0$ is a generating subcategory of $\mathcal{C}$, in the sense of Definition C.2.1.1. That is, for every object $X \in \mathcal{C}$, there exists a morphism $\bigoplus C_\alpha \to X$ which induces an epimorphism on π_0, where each C_α is almost compact.

We will say that $\mathcal{C}$ is *weakly coherent* if it satisfies condition (a) and the following weaker version of (b):

(b') For every truncated object $X \in \mathcal{C}$, there exists a morphism $\bigoplus C_\alpha \to X$ which induces an epimorphism on π_0, where each C_α is almost compact.

Warning C.6.5.2. Let $\mathcal{C}$ be a compactly generated prestable ∞-category. Then $\mathcal{C}$ automatically satisfies condition (b) of Definition C.6.5.1, but need not satisfy condition (a).

Example C.6.5.3. Let R be a connective $\mathbb{E}_1$-ring and let $\mathcal{C} = \mathrm{LMod}_R^{\mathrm{cn}}$ denote the ∞-category of connective left R-modules. Using Proposition HA.7.2.4.18 , we see that the following assertions are equivalent:

(i) The $\mathbb{E}_1$-ring R is left coherent.

(ii) The Grothendieck prestable ∞-category $\mathcal{C}$ is coherent.

(iii) The Grothendieck prestable ∞-category $\mathcal{C}$ is weakly coherent.

We now discuss some criteria which can be used to recognize weakly coherent Grothendieck prestable ∞-categories.

Proposition C.6.5.4. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. The following conditions are equivalent:*

(1) *The ∞-category $\mathcal{C}$ is weakly coherent.*

(2) *For each $n \geqslant 0$, the ∞-category $\tau_{\leqslant n}\mathcal{C}$ is compactly generated and the collection of compact objects of $\tau_{\leqslant n}\mathcal{C}$ is closed under finite limits.*

Proof. Suppose first that (1) is satisfied. Chose $n \geqslant 0$, and let $\mathcal{E} \subseteq \tau_{\leqslant n}\mathcal{C}$ be the full subcategory spanned by those objects which are almost compact (when viewed as objects of $\mathcal{C}$). Since the collection of almost compact objects of $\mathcal{C}$ is closed under finite colimits (Proposition C.6.4.4) and under the truncation functor $\tau_{\leqslant n}$ (Corollary C.6.4.6), it follows that $\mathcal{E}$ is closed under finite colimits in $\tau_{\leqslant n}\mathcal{C}$. Applying Propositions HTT.5.3.5.11 and HTT.5.5.1.9 , we see that the inclusion $\mathcal{E} \hookrightarrow \tau_{\leqslant n}\mathcal{C}$ extends to a fully faithful embedding $F : \mathrm{Ind}(\mathcal{E}) \to \tau_{\leqslant n}\mathcal{C}$ which commutes with small colimits.

Let $G : \tau_{\leqslant n}\mathcal{C} \to \mathrm{Ind}(\mathcal{E})$ be a right adjoint to F. Note that if $X \in \tau_{\leqslant n}\mathcal{C}$ satisfies $GX \simeq 0$, then the mapping space $\mathrm{Map}_{\mathcal{C}}(C, X) \simeq \mathrm{Map}_{\mathcal{C}}(\tau_{\leqslant n}C, X)$ is contractible for all almost compact objects $C \in \mathcal{C}$ (Corollary C.6.4.6). If $\mathcal{C}$ is weakly coherent, this implies that $\pi_0 X \simeq 0$. Applying the same argument to $\Omega^i X$, we deduce that $\pi_i X \simeq 0$ for $0 \leqslant i \leqslant n$ and therefore $X \simeq 0$.

Now let X be any object of $\tau_{\leqslant n}\mathcal{C}$ and let $v : (F \circ G)(X) \to X$ be the counit map. Since F is fully faithful, the map $G(v)$ is an equivalence in $\mathrm{Ind}(\mathcal{E})$. The functor G is left exact (since it is a right adjoint), so we have $G(\mathrm{fib}(v)) = \mathrm{fib}\, G(v) \simeq 0$. It follows from the preceding argument that $\mathrm{fib}(v) = 0$. For every almost compact object $C \in \mathcal{C}$, every map $C \to X$ factors through v. Our assumption that $\mathcal{C}$ is weakly coherent ensures that v induces an epimorphism on π_0, so that the fiber sequence $\mathrm{fib}(v) \to (F \circ G)(X) \to X$ is also a cofiber sequence. The vanishing of $\mathrm{fib}(v)$ now shows that v is an equivalence. Allowing X to vary, we conclude that F is an equivalence of ∞-categories so that the ∞-category $\tau_{\leqslant n}\mathcal{C}$ is compactly generated.

It follows immediately from the definitions that each object of $\mathcal{E}$ is compact when viewed as an object of $\tau_{\leqslant n}\mathcal{C}$. Conversely, since F is an equivalence, every compact object of $\tau_{\leqslant n}\mathcal{C}$

is a retract of an object of $\mathcal{E}$. Since $\mathcal{E}$ is evidently closed under retracts, it follows that an object of $\tau_{\leqslant n}\mathcal{C}$ is compact if and only if it belongs to $\mathcal{E}$. Since the collections of n-truncated objects and almost compact objects of $\mathcal{C}$ are both closed under finite limits, it follows that the collection of compact objects of $\tau_{\leqslant n}\mathcal{C}$ is closed under finite limits. Allowing n to vary, we deduce that (2) is satisfied.

We now prove the converse. Assume that $\mathcal{C}$ satisfies (2); we will prove that $\mathcal{C}$ is weakly coherent. We first show that the collection of almost compact objects of $\mathcal{C}$ is closed under finite limits. By virtue of Proposition C.6.4.5, it will suffice to show that if $X \in \mathcal{C}$ is almost compact, then $\Omega X \in \mathcal{C}$ is also almost compact. For this, we must prove that for each $n \geqslant 0$, the object $\tau_{\leqslant n}(\Omega X) \simeq \Omega(\tau_{\leqslant n+1} X)$ is a compact object of $\tau_{\leqslant n}\mathcal{C}$. This is clear: our hypothesis that X is almost compact guarantees that $\tau_{\leqslant n+1} X$ is a compact object of $\tau_{\leqslant n+1}\mathcal{C}$, so that assumption (2) shows that $\Omega(\tau_{\leqslant n+1} X)$ is compact when viewed as an object of $\tau_{\leqslant n+1}\mathcal{C}$ (and therefore also when viewed as an object of the smaller ∞-category $\tau_{\leqslant n}\mathcal{C}$).

We now claim that if $n \geqslant 0$ and C is a compact object of $\tau_{\leqslant n}\mathcal{C}$, then C is almost compact when viewed as an object of $\mathcal{C}$. In other words, the object C is compact when viewed as an object of $\tau_{\leqslant m}\mathcal{C}$ for any $m \geqslant n$. To prove this, we invoke assumption (2) to write C as the colimit of a filtered diagram $\{C_\alpha\}$, where each C_α is a compact object of $\tau_{\leqslant m}\mathcal{C}$. Since truncation in $\mathcal{C}$ commutes with filtered colimits, we have $C \simeq \varinjlim_\alpha \tau_{\leqslant n} C_\alpha$. Using the compactness of C in $\tau_{\leqslant n}\mathcal{C}$, we deduce that C is a retract of $\tau_{\leqslant n} C_\alpha$. We are therefore reduced to proving that $\tau_{\leqslant n} C_\alpha$ is a compact object of $\tau_{\leqslant m}\mathcal{C}$, which follows by inspecting the cofiber sequence

$$\Sigma^{n+1}\Omega^{n+1} C_\alpha \to C_\alpha \to \tau_{\leqslant n} C_\alpha.$$

If X is any n-truncated object of $\mathcal{C}$, then assumption (2) guarantees that we can write X as the colimit of a filtered diagram $\{C_\alpha\}$, where each C_α is a compact object of $\tau_{\leqslant n}\mathcal{C}$ (and therefore an almost compact object of $\mathcal{C}$). Since the map $\bigoplus C_\alpha \to X$ is an epimorphism on π_0, we see that $\mathcal{C}$ satisfies condition (b') of Definition C.6.5.1 and is therefore weakly coherent, as desired. □

Corollary C.6.5.5. *Let $F : \mathcal{C} \to \mathcal{D}$ be a functor between Grothendieck prestable ∞-categories which induces an equivalence $\tau_{\leqslant n}\mathcal{C} \to \tau_{\leqslant n}\mathcal{D}$ for all $n \geqslant 0$. Then $\mathcal{C}$ is weakly coherent if and only if $\mathcal{D}$ is weakly coherent.*

Proposition C.6.5.6. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. Then $\mathcal{C}$ is weakly coherent if and only if the following conditions are satisfied:*

(i) The collection of almost compact objects of $\mathcal{C}$ is closed under finite limits.

(ii) Every object $D \in \mathcal{C}^\heartsuit$ can be written as a filtered colimit $\varinjlim D_\alpha$, where each D_α is an almost compact object of $\mathcal{C}$ which belongs to $\mathcal{C}^\heartsuit$.

Proof. The necessity of (i) is obvious, and the necessity of (ii) follows from the proof of Proposition C.6.5.4. Conversely, suppose that (i) and (ii) are satisfied. To prove that $\mathcal{C}$ is weakly coherent, we must show that for every n-truncated object $X \in \mathcal{C}$, there exists a map $u : \coprod C_i \to X$ which is an epimorphism on π_0, where each C_i is an almost compact object of $\mathcal{C}$. We proceed by induction on n. In the case $n = 0$, the desired result follows immediately from (ii). Let us therefore assume that $n > 0$. Set $\overline{X} = \tau_{\leqslant n-1} X$, so that our inductive hypothesis guarantees the existence of a map $\overline{u} : \bigoplus \overline{C}_i \to \overline{X}$ which is an epimorphism on π_0, where each $\overline{C}_i$ is an almost compact object of $\mathcal{C}$. Using (ii), we can write $\pi_n X$ as a filtered colimit $\varinjlim D_\alpha$, where each D_α is an almost compact object of $\mathcal{C}$ which belongs to $\mathcal{C}^\heartsuit$. We then have a fiber sequence $X \to \overline{X} \xrightarrow{v} \varinjlim \Sigma^{n+1} D_\alpha$ in the ∞-category $\mathcal{C}$. For each index i, the assumption that $\overline{C}_i$ is almost compact guarantees that the composite map

$$\overline{C}_i \to \bigoplus \overline{C}_i \xrightarrow{\overline{u}} \overline{X} \xrightarrow{v} \varinjlim \Sigma^{n+1} D_\alpha$$

factors through some $\Sigma^{n+1} D_{\alpha(i)}$ for some index $\alpha(i)$. Choose such a factorization and set $C_i = \operatorname{fib}(\overline{C}_i) \to \Sigma^{n+1} D_{\alpha(i)}$. It follows from (i) that C_i is an almost compact object of $\mathcal{C}$. We now complete the proof by observing that $\overline{u}$ fits into a commutative diagram

$$\begin{array}{ccc} \bigoplus C_i & \xrightarrow{u} & X \\ \downarrow & & \downarrow \\ \bigoplus \overline{C}_i & \xrightarrow{\overline{u}} & \overline{X}, \end{array}$$

where u is also an epimorphism on π_0 (since the vertical maps induce isomorphisms on π_0). □

In the setting of weakly n-complicial Grothendieck prestable ∞-categories, the criterion of Proposition C.6.5.4 can be sharpened.

Proposition C.6.5.7. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category which is weakly n-complicial for some $n \geqslant 0$. The following conditions are equivalent:*

(1) *The Grothendieck prestable ∞-category $\mathcal{C}$ is weakly coherent.*

(2) *The ∞-category $\tau_{\leqslant n} \mathcal{C}$ is compactly generated and the collection of compact objects of $\tau_{\leqslant n} \mathcal{C}$ is closed under finite limits.*

Proof. The implication (1) $\Rightarrow$ (2) follows from Proposition C.6.5.4 (and does not require our assumption that $\mathcal{C}$ is weakly n-complicial). Assume that (2) is satisfied, and let $\mathcal{A}$ be the full subcategory of $\mathcal{C}^\heartsuit$ spanned by those objects which are compact when viewed as objects of $\tau_{\leqslant n} \mathcal{C}$. Assumption (2) implies that $\mathcal{A}$ is closed under the formation of kernels and cokernels in $\mathcal{C}^\heartsuit$ and is therefore an abelian category. Let $\mathcal{E} \subseteq \operatorname{Sp}(\mathcal{C})$ be the full subcategory spanned by those objects X having the following properties:

- The object X is truncated: that is, $X \in \mathrm{Sp}(\mathcal{C})_{\leqslant m}$ for $m \gg 0$.
- For every integer m, the object $\pi_m X \in \mathrm{Sp}(\mathcal{C})^{\heartsuit} \simeq \mathcal{C}^{\heartsuit}$ belongs to $\mathcal{A}$.
- The object X belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant -k}$ for $k \gg 0$ (since the t-structure on $\mathrm{Sp}(\mathcal{C})$ is right complete, this is equivalent to the requirement that $\pi_{-k} X$ vanishes for $k \gg 0$).

Then $\mathcal{E}$ is an essentially small stable subcategory of $\mathrm{Sp}(\mathcal{C})$ which is closed under truncations, so that the t-structure on $\mathrm{Sp}(\mathcal{C})$ induces a bounded t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$ on $\mathcal{E}$. Set $\mathcal{C}' = \mathrm{Ind}(\mathcal{E}_{\geqslant 0})$. Then the inclusion functor $\iota : \mathcal{E}_{\geqslant 0} \hookrightarrow \mathrm{Sp}(\mathcal{C})_{\geqslant 0} \simeq \mathcal{C}$ extends to a functor $\lambda \in \mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}', \mathcal{C})$. We next prove:

(*i*) For every cofiber sequence $C' \to C \to C''$ in $\mathcal{C}$, if C' and C'' are compact objects of $\tau_{\leqslant n} \mathcal{C}$, then C is also a compact object of $\tau_{\leqslant n} \mathcal{C}$.

To prove (*i*), we invoke assumption (2) to write C as the colimit of a filtered diagram $\{C_\alpha\}$, where each C_α is a compact object of $\tau_{\leqslant n} \mathcal{C}$. Using the compactness of C'', we deduce that there exists an index α for which the composite map $C_\alpha \to C \to C''$ induces an epimorphism on π_0. Set $C'_\alpha = C' \times_C C_\alpha \simeq \mathrm{fib}(C_\alpha \to C'')$. Since the collection of compact objects of $\tau_{\leqslant n} \mathcal{C}$ is closed under finite limits, C'_α is compact in $\tau_{\leqslant n} \mathcal{C}$. We now observe that the pullback diagram

$$\begin{array}{ccc} C'_\alpha & \longrightarrow & C_\alpha \\ \downarrow & & \downarrow \\ C' & \longrightarrow & C \end{array}$$

is also a pushout square (in both $\mathcal{C}$ and $\tau_{\leqslant n} \mathcal{C}$), so that C is also a compact object of $\tau_{\leqslant n} \mathcal{C}$. We now show:

(*ii*) An object $C \in \tau_{\leqslant n} \mathcal{C}$ is compact (when viewed as an object of $\tau_{\leqslant n} C$) if and only if $\pi_i C$ in $\mathcal{A}$ for $0 \leqslant i \leqslant n$.

The "if" direction follows immediately from (*i*) (since C can be written as a successive extension of objects of the form $\Sigma^i(\pi_i C)$) To prove the converse, we observe that $\pi_i C$ fits into a cofiber sequence

$$\Sigma(\Omega^{i+1} C) \to \Omega^i C \to \pi_i C$$

in the ∞-category $\tau_{\leqslant n} \mathcal{C}$.

Combining (*ii*) with our assumption that $\tau_{\leqslant n} \mathcal{C}$ is compactly generated, we deduce:

(*iii*) The functor λ induces an equivalence $\tau_{\leqslant n} \mathcal{C}' \to \tau_{\leqslant n} \mathcal{C}$.

We now prove:

(*iv*) The ∞-category $\mathcal{C}'$ is n-complicial.

Fix an object $X \in \mathcal{C}'$; we wish to prove that there exists a map $\overline{X} \to X$ in $\mathcal{C}'$ which is an epimorphism on π_0, where $\overline{X}$ is n-truncated. Write X as a filtered colimit $\varinjlim\{X_\alpha\}$, where each X_α is an object of $\mathcal{E}_{\geqslant 0}$. We can then view each X_α as a truncated object of ∞-category $\mathcal{C}$. Since $\mathcal{C}$ is weakly n-complicial, we can choose morphisms $\overline{X}_\alpha \to X_\alpha$ in $\mathcal{C}$ which induce epimorphisms on π_0, where each $\overline{X}_\alpha$ is an n-truncated object of $\mathcal{C}$. Using our assumption that $\tau_{\leqslant n}\mathcal{C}$ is compactly generated, we can write each $\overline{X}_\alpha$ as the colimit of a filtered diagram $\{\overline{X}_{\alpha,\beta}\}$ where each $\overline{X}_{\alpha,\beta}$ is a compact object of $\tau_{\leqslant n}\mathcal{C}$. Then we can view each $\overline{X}_{\alpha,\beta}$ as an n-truncated object of $\mathcal{E}_{\geqslant 0}$. Taking $\overline{X} = \bigoplus_{\alpha,\beta}\overline{X}_{\alpha,\beta}$, we obtain a proof of (iv).

Combining (iii), (iv), and Proposition C.5.9.3, we deduce that the functor $\lambda : \mathcal{C}' \to \mathcal{C}$ induces an equivalence on completions: that is, it restricts to an equivalence $\tau_{\leqslant m}\mathcal{C}' \to \tau_{\leqslant m}\mathcal{C}$ for all $m \leqslant 0$. Identifying $\tau_{\leqslant m}\mathcal{C}'$ with $\mathrm{Ind}(\mathcal{E}_{\geqslant 0} \cap \mathcal{E}_{\leqslant m})$, we see that an object $X \in \tau_{\leqslant m}\mathcal{C}$ is compact if and only if $\pi_i X \in \mathcal{A}$ for $0 \leqslant i \leqslant m$. Allowing m to vary, we conclude that an object $X \in \mathcal{C}$ is almost compact if and only if $\pi_i X \in \mathcal{A}$ for all $i \geqslant 0$. From this description, we immediately deduce that $\mathcal{C}$ satisfies the equivalent conditions of Proposition C.6.4.5. To complete the proof that $\mathcal{C}$ is weakly coherent, it will suffice to show that for each truncated object $X \in \mathcal{C}$, there exists a map $\bigoplus_\alpha C_\alpha \to X$ which is an epimorphism on π_0, where each C_α is almost compact. Using our assumption that $\mathcal{C}$ is weakly n-complicial, we can reduce to the case where X belongs to $\tau_{\leqslant n}\mathcal{C}$, in which case the desired result follows immediately from (iii). □

Corollary C.6.5.8. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category which is n-complicial for some $n \geqslant 0$. The following conditions are equivalent:*

(1) *The Grothendieck prestable ∞-category $\mathcal{C}$ is coherent.*

(2) *The ∞-category $\tau_{\leqslant n}\mathcal{C}$ is compactly generated and the collection of compact objects of $\tau_{\leqslant n}\mathcal{C}$ is closed under finite limits.*

Proof. The implication (1) ⇒ (2) follows immediately from Proposition C.6.5.7. Conversely, suppose that condition (2) is satisfied and let X be an object of $\mathcal{C}$; we wish to show that there exists a map $\bigoplus C_\alpha \to X$ which is an epimorphism on π_0, where each C_α is almost compact. Using our assumption that $\mathcal{C}$ is n-complicial, we can reduce to the case where X is n-truncated, in which case the desired result follows from Proposition C.6.5.7. □

Let $\mathcal{A}$ be a Grothendieck abelian category. Then the following conditions are equivalent:

- The category $\mathcal{A}$ is compactly generated and the collection of compact objects of $\mathcal{A}$ is closed under finite limits.
- There is an equivalence $\mathcal{A} \simeq \mathrm{Ind}(\mathcal{A}_0)$ for some essentially small abelian category $\mathcal{A}_0$.

Specializing Proposition **??** to the case $n = 0$, we obtain the following:

Corollary C.6.5.9. *Let $\mathcal{A}_0$ be an essentially small abelian category and set $\mathcal{A} = \mathrm{Ind}(\mathcal{A}_0)$. Then the Grothendieck prestable ∞-categories $\check{\mathcal{D}}(\mathcal{A})_{\geqslant 0}$ and $\mathcal{D}(\mathcal{A})_{\geqslant 0}$ are coherent, and the Grothendieck prestable ∞-category $\widehat{\mathcal{D}}(\mathcal{A})_{\geqslant 0}$ is weakly coherent.*

C.6.6 Separated Coherent Grothendieck Prestable ∞-Categories

Let $\mathcal{C}$ be a coherent Grothendieck prestable ∞-category. Our next goal is to articulate a precise sense in which $\mathcal{C}$ is "controlled" by its almost compact objects. We begin with an elementary observation.

Proposition C.6.6.1. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category which is separated and coherent and let $\mathcal{C}^{\mathrm{ac}} \subseteq \mathcal{C}$ be the full subcategory spanned by the almost compact objects. Then $\mathcal{C}^{\mathrm{ac}}$ is essentially small.*

Warning C.6.6.2. The conclusion of Proposition C.6.6.1 is false if $\mathcal{C}$ is not separated: if X is a nonzero object of $\mathcal{C}$ whose truncations $\tau_{\leqslant n} X$ vanish for all n, then taking a coproduct of any number of copies of X yields an almost compact object of $\mathcal{C}$.

We will deduce Proposition C.6.6.1 from the following more precise assertion:

Lemma C.6.6.3. *Let $\mathcal{C}$ be a coherent separated Grothendieck prestable ∞-category and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a generating subcategory which is closed under finite colimits and extensions and consists of almost compact objects of $\mathcal{C}$. Then every almost compact object $X \in \mathcal{C}$ can be obtained as the geometric realization of a simplicial object $X_\bullet$, where each X_n belongs to $\mathcal{C}_0$.*

Proof. Let X be an object of $\mathcal{C}$ which is almost compact. We will construct a sequence of cofiber sequences
$$X(n) \to X \to \Sigma^n Y(n),$$
where each $X(n)$ belongs to $\mathcal{C}_0$. The construction proceeds by induction. In the case $n = 0$, we take $X(n) = 0$ and $Y(n) = X$. To carry out the inductive step, let us assume that we have constructed a cofiber sequence $X(n) \xrightarrow{u} X \to \Sigma^n Y(n)$ with $X(n) \in \mathcal{C}_0$. Then X and $X(n)$ are both almost compact, so that $Y(n) \simeq \Omega^n \operatorname{cofib}(u)$ is also almost compact. Using our assumption that $\mathcal{C}_0$ is a generating subcategory of $\mathcal{C}$, we can choose a map $\bigoplus_{i \in I} C_i \to Y(n)$ which induces an epimorphism $\bigoplus \pi_0 C_i \to \pi_0 Y(n)$, where each C_i belongs to $\mathcal{C}_0$. Since $Y(n)$ is almost compact, the truncation $\pi_0 Y(n)$ is a compact object of the abelian category $\mathcal{C}^{\heartsuit}$, so we can choose a finite subset $I_0 \subseteq I$ for which the induced map $v : \bigoplus_{i \in I_0} C_i \to Y(n)$ also induces an epimorphism on π_0. Set $C = \bigoplus_{i \in I_0} C_i$, so that C is an object of $\mathcal{C}_0$. We now define $X(n+1) = X \times_{\Sigma^n Y(n)} \Sigma^n C$, so that we have $\operatorname{cofib}(X(n+1) \to X) \simeq \Sigma^{n+1}(\operatorname{fib}(v))$. By construction, we have a cofiber sequence
$$X(n) \to X(n+1) \to \Sigma^n C$$

so that $X(n+1)$ also belongs to $\mathcal{C}_0$. Note that each of the maps $X(n) \to X$ induces an isomorphism $\pi_i X(n) \to \pi_i X$ for $i \leqslant n-2$. Invoking our assumption that $\mathcal{C}$ is separated, we see that X can be identified with the direct limit $\varinjlim X(n)$.

By construction, the cofiber of each map $X(n) \to X(n+1)$ is an n-fold suspension of an object of $\mathcal{C}_0$. Applying Theorem C.1.3.1, we deduce the existence of an equivalence $\{X(n+1)\}_{n \geqslant 0} \simeq \{\mathrm{sk}_n(E_\bullet)\}_{n \geqslant 0}$ for some simplicial object $X_\bullet$ of $\mathcal{C}_0$, so that $X \simeq |X_\bullet|$. □

Remark C.6.6.4. In the situation of Lemma C.6.6.3, the closure properties of $\mathcal{C}_0$ can be weakened: all we really need is that $\mathcal{C}_0$ is closed under finite direct sums.

Proof of Proposition C.6.6.1. Since $\mathcal{C}$ is presentable, there exists a small collection of objects $\{C_\alpha\}$ which span a generating subcategory of $\mathcal{C}$ (in the sense of Definition C.2.1.1). Using our assumption that $\mathcal{C}$ is coherent, we can arrange that each C_α is almost compact. Let $\mathcal{C}_0$ denote the smallest full subcategory of $\mathcal{C}$ which contains each C_α and is closed under finite colimits, geometric realizations, and extensions. Then $\mathcal{C}_0$ is essentially small, and Lemma C.6.6.3 shows that every almost compact object of $\mathcal{C}$ belongs to $\mathcal{C}_0$. □

Theorem C.6.6.5. *Let $\mathcal{C}$ and $\mathcal{D}$ be separated Grothendieck prestable ∞-categories and let $\mathcal{C}^{\mathrm{ac}} \subseteq \mathcal{C}$ denote the full subcategory spanned by the almost compact objects. If $\mathcal{C}$ is coherent, then the restriction functor $\mathrm{LFun}(\mathcal{C}, \mathcal{D}) \to \mathrm{Fun}(\mathcal{C}^{\mathrm{ac}}, \mathcal{D})$ is fully faithful, and its essential image is spanned by those functors $\mathcal{C}^{\mathrm{ac}} \to \mathcal{D}$ which preserve finite colimits.*

Proof. Since $\mathcal{C}^{\mathrm{ac}}$ is closed under finite limits and colimits in $\mathcal{C}$, the inclusion functor $\mathcal{C}^{\mathrm{ac}} \hookrightarrow \mathcal{C}$ extends to a functor $F : \mathrm{Ind}(\mathcal{C}^{\mathrm{ac}}) \to \mathcal{C}$ which preserves small colimits and finite limits. Let $G : \mathcal{C} \to \mathrm{Ind}(\mathcal{C}^{\mathrm{ac}})$ be a right adjoint to F. Let us identify $\mathrm{Ind}(\mathcal{C}^{\mathrm{ac}})$ with the full subcategory of $\mathrm{Fun}((\mathcal{C}^{\mathrm{ac}})^{\mathrm{op}}, \mathcal{S})$ spanned by the left exact functors, so that G is given by the formula $G(C)(D) = \mathrm{Map}_{\mathcal{C}}(D, C)$. If $\mathcal{C}$ is coherent, then $\mathcal{C}^{\mathrm{ac}} \subseteq \mathcal{C}$ is a generating subcategory of $\mathcal{C}$, so that Theorem C.2.1.6 implies that G is fully faithful.

It follows from Proposition C.6.6.1 that $\mathcal{C}^{\mathrm{ac}}$ is an essentially small prestable ∞-category so that $\mathrm{Ind}(\mathcal{C}^{\mathrm{ac}})$ is a Grothendieck prestable ∞-category (Proposition C.6.1.1). Applying Proposition C.2.3.8, we see that G restricts to an equivalence $\mathcal{C} \to \mathrm{Ind}(\mathcal{C}^{\mathrm{ac}})/\mathcal{E}$, where $\mathcal{E} \subseteq \mathrm{Ind}(\mathcal{C}^{\mathrm{ac}})$ is the localizing subcategory spanned by those objects of $\mathrm{Ind}(\mathcal{C}^{\mathrm{ac}})$ which are annihilated by F.

It follows from Proposition C.6.5.7 that the functor F induces an equivalence $\tau_{\leqslant n} \mathrm{Ind}(\mathcal{C}^{\mathrm{ac}}) \to \tau_{\leqslant n} \mathcal{C}$ for each $n \geqslant 0$. Consequently, if $X \in \mathrm{Ind}(\mathcal{C}^{\mathrm{ac}})$ is annihilated by F, then we must have $\tau_{\leqslant n} X \simeq 0$ for all $n \geqslant 0$: that is, X belongs to the essential image of the suspension functor $\Sigma^m : \mathrm{Ind}(\mathcal{C}^{\mathrm{ac}}) \to \mathrm{Ind}(\mathcal{C}^{\mathrm{ac}})$ for each $m \geqslant 0$. It follows that any colimit-preserving functor $H : \mathrm{Ind}(\mathcal{C}^{\mathrm{ac}}) \to \mathcal{D}$ must carry X into the essential image of the functor $\Sigma^m : \mathcal{D} \to \mathcal{D}$ for each $m \geqslant 0$. Since $\mathcal{D}$ is separated, we must have $HX \simeq 0$. That is, any colimit-preserving functor $\mathrm{Ind}(\mathcal{C}^{\mathrm{ac}}) \to \mathcal{D}$ automatically annihilates the localizing subcategory $\mathcal{E} \subseteq \mathrm{Ind}(\mathcal{C}^{\mathrm{ac}})$.

Applying Proposition C.2.3.10, we deduce that composition with F induces an equivalence of ∞-categories $\mathrm{LFun}(\mathcal{C}, \mathcal{D}) \to \mathrm{LFun}(\mathrm{Ind}(\mathcal{C}^{\mathrm{ac}}), \mathcal{D})$. It now suffices to observe that composition with the Yoneda embedding $\mathcal{C}^{\mathrm{ac}} \hookrightarrow \mathrm{Ind}(\mathcal{C}^{\mathrm{ac}})$ determines a fully faithful embedding $\mathrm{LFun}(\mathrm{Ind}(\mathcal{C}^{\mathrm{ac}}), \mathcal{D}) \hookrightarrow \mathrm{Fun}(\mathcal{C}^{\mathrm{ac}}, \mathcal{D})$, whose essential image is spanned by those functors which preserve finite colimits (Propositions HTT.5.3.5.11 and HTT.5.5.1.9). □

Remark C.6.6.6. In the situation of Theorem C.6.6.5, let $f : \mathcal{C} \to \mathcal{D}$ be a functor which preserves small colimits. Then the following conditions are equivalent:

(i) The functor f is left exact.

(ii) The composite functor $\mathrm{Ind}(\mathcal{C}^{\mathrm{ac}}) \to \mathcal{C} \xrightarrow{f} \mathcal{D}$ is left exact.

(iii) The restriction $f|_{\mathcal{C}^{\mathrm{ac}}}$ is left exact.

The equivalence of (i) and (ii) follows from Remark C.2.3.11, and the equivalence of (ii) and (iii) from the fact that filtered colimits in $\mathcal{D}$ are left exact.

Remark C.6.6.7. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category which is coherent and separated, and let $\mathcal{C}^{\mathrm{ac}} \subseteq \mathcal{C}$ denote the full subcategory spanned by the almost compact objects. Then $\mathcal{C}^{\mathrm{ac}}$ has the following properties:

(a) The ∞-category $\mathcal{C}^{\mathrm{ac}}$ is prestable (since it is a full subcategory of the prestable ∞-category $\mathcal{C}$ which is closed under finite colimits and extensions).

(b) The ∞-category $\mathcal{C}^{\mathrm{ac}}$ admits finite limits (since $\mathcal{C}$ is assumed to be coherent).

(c) The ∞-category $\mathcal{C}^{\mathrm{ac}}$ admits geometric realizations of simplicial objects (since the collection of almost compact objects of $\mathcal{C}$ is closed under geometric realizations, by virtue of Proposition C.6.4.4).

(d) The ∞-category $\mathcal{C}^{\mathrm{ac}}$ is essentially small (Proposition C.6.6.1).

(e) The ∞-category $\mathcal{C}^{\mathrm{ac}}$ is separated (since $\mathcal{C}$ is separated).

Our next goal is to show that every ∞-category $\mathcal{E}$ satisfying conditions (a) through (e) of Remark C.6.6.7 has the form $\mathcal{C}^{\mathrm{ac}}$, where $\mathcal{C}$ is a Grothendieck prestable ∞-category which is separated and coherent (Theorem C.6.6.14). The main ingredient we will need is the following:

Proposition C.6.6.8. *Let $\mathcal{E}$ be an essentially small separated prestable ∞-category which admits finite limits and geometric realizations. Let X be an object of $\mathrm{Ind}(\mathcal{E})$, and let us view X as a left exact functor $\mathcal{E}^{\mathrm{op}} \to \mathcal{S}$. The following conditions are equivalent:*

(a) *For every simplicial object* $E_\bullet$ *of* $\mathcal{E}$*, the canonical map* $X(|E_\bullet|) \to \operatorname{Tot} X(E_\bullet)$ *is a homotopy equivalence.*

(b) *For every simplicial object* $E_\bullet$ *of* $\mathcal{E}$ *which satisfies* $|E_\bullet| \simeq 0$*, the totalization* $\operatorname{Tot} X(E_\bullet)$ *is contractible.*

(c) *For every diagram* $E(0) \to E(1) \to E(2) \to \cdots$ *in* $\mathcal{E}$*, where each* $E(n)$ *belongs to the essential image of* $\Sigma^n : \mathcal{E} \to \mathcal{E}$*, the limit* $\varprojlim X(E(n))$ *is contractible.*

(d) *The object* X *belongs to the separated quotient* $\operatorname{Ind}(\mathcal{E})/\operatorname{Ind}(\mathcal{E})_{\geqslant\infty}$*; here* $\operatorname{Ind}(\mathcal{E})_{\geqslant\infty}$ *denotes the localizing subcategory of* $\operatorname{Ind}(\mathcal{E})$ *spanned by those objects* Y *for which* $\tau_{\leqslant n} Y \simeq 0$ *for all* $n \geqslant 0$*.*

Proof. The implication $(a) \Rightarrow (b)$ is obvious. Conversely, suppose that $E_\bullet$ is an arbitrary simplicial object of $\mathcal{E}$. Let $E''_\bullet$ denote the constant simplicial object of $\mathcal{E}$ with the value $|E_\bullet|$, and form a fiber sequence $E'_\bullet \to E_\bullet \to E''_\bullet$. It is easy to see that each of the maps $E_n \to E''_n = |E_\bullet|$ induces an epimorphism on π_0, so that the fiber sequence $E'_\bullet \to E_\bullet \to E''_\bullet$ is also a cofiber sequence. Passing to geometric realizations, we obtain a cofiber sequence $|E'_\bullet| \to |E_\bullet| \xrightarrow{u} |E''_\bullet|$ where u is an equivalence, so that $|E'_\bullet| \simeq 0$. Since the functor X is left exact, applying the functor X yields a fiber sequence of cosimplicial (pointed) spaces

$$X(E''_\bullet) \to X(E_\bullet) \to X(E'_\bullet)$$

and therefore a fiber sequence of totalizations

$$\operatorname{Tot} X(E''_\bullet) \xrightarrow{v} \operatorname{Tot} X(E_\bullet) \to \operatorname{Tot} X(E'_\bullet).$$

Note that the cosimplicial space $X(E''_\bullet)$ is constant with value $X(|E_\bullet|)$ and that v can be dentified with the tautological map $X(|E_\bullet|) \to \operatorname{Tot} X(E_\bullet)$. If assumption (b) is satisfied, then $\operatorname{Tot} X(E'_\bullet)$ is contractible and the map v is a homotopy equivalence; this proves $(b) \Rightarrow (a)$.

Now let $E_\bullet$ be a simplicial object of $\mathcal{E}$, and consider its diagram of partial skeleta

$$\operatorname{sk}_0(E_\bullet) \to \operatorname{sk}_1(E_\bullet) \to \operatorname{sk}_2(E_\bullet) \to \cdots$$

Since $\tau_{\leqslant n} \mathcal{E}$ is equivalent to an $(n+1)$-category, the canonical map $\tau_{\leqslant n} \operatorname{sk}_{n+1}(E_\bullet) \to \tau_{\leqslant n}|E_\bullet|$ is an equivalence for every n. Using the separatedness of $\mathcal{E}$, we see that $|E_\bullet| \simeq 0$ if and only if $\operatorname{sk}_n(E_\bullet)$ belongs to the essential image of the functor $\Sigma^n : \mathcal{E} \to \mathcal{E}$ for every $n \geqslant 0$. Conversely, given any diagram

$$E(0) \to E(1) \to E(2) \to \cdots$$

in $\mathcal{E}$ where each $E(n)$ belongs to the essential image of $\Sigma^n : \mathcal{E} \to \mathcal{E}$, each cofiber $\operatorname{cofib}(E(n-1) \to E(n))$ is an extension of $\Sigma E(n-1)$ by $E(n)$, and therefore also belongs to the essential image of $\Sigma^n : \mathcal{E} \to \mathcal{E}$. It then follows from Theorem C.1.3.1 that we have an equivalence $\{E(n)\}_{n \geqslant 0} \simeq \{\mathrm{sk}_n(E_\bullet)\}_{n \geqslant 0}$ for an essentially unique simplicial object $E_\bullet$ of $\mathcal{E}$. The left exactness of X then gives equivalences $X(E(n)) = X(\mathrm{sk}_n(E_\bullet)) \simeq \mathrm{Tot}^n X(E_\bullet)$, so that $\varprojlim \{X(E(n))\}_{n \geqslant 0} \simeq \varprojlim \{\mathrm{Tot}^n X(E_\bullet)\}_{n \geqslant 0} \simeq \mathrm{Tot}\, X(E_\bullet)$. This shows that conditions (*b*) and (*c*) are equivalent.

We now show that (*d*) implies (*c*). Let $j : \mathcal{E} \to \mathrm{Ind}(\mathcal{E})$ denote the Yoneda embedding. If $\{E(n)\}_{n \geqslant 0}$ is a diagram in $\mathcal{E}$ which each $E(n)$ is an n-fold suspension, then $\{j(E(n))\}_{n \geqslant 0}$ is a diagram in $\mathrm{Ind}(\mathcal{E})$ where each $j(E(n))$ is also an n-fold suspension. It follows that the direct limit $\varinjlim j(E(n))$ belongs to the full subcategory $\mathrm{Ind}(\mathcal{E})_{\geqslant \infty}$. Assumption (*d*) then implies that the space

$$\varprojlim X(E(n)) \simeq \varprojlim \mathrm{Map}_{\mathrm{Ind}(\mathcal{E})}(j(E(n)), X) \simeq \mathrm{Map}_{\mathrm{Ind}(\mathcal{E})}(\varinjlim j(E(n)), X)$$

is contractible.

We now complete the proof by showing that (*c*) implies (*d*). Suppose that X satisfies (*c*); we wish to show that X belongs to the quotient $\mathrm{Ind}(\mathcal{E}) / \mathrm{Ind}(\mathcal{E})_{\geqslant \infty}$. In other words, we wish to show that if we are given any cofiber sequence $Y' \to Y \to Y''$ with $Y'' \in \mathrm{Ind}(\mathcal{E})_{\geqslant \infty}$, then the induced map $\theta : \mathrm{Map}_{\mathrm{Ind}(\mathcal{E})}(Y, X) \to \mathrm{Map}_{\mathrm{Ind}(\mathcal{E})}(Y', X)$ is a homotopy equivalence. Since $\pi_0 Y'' \simeq 0$, we also have a cofiber sequence $\Omega Y'' \to Y' \to Y$, so that θ fits into a fiber sequence

$$\mathrm{Map}_{\mathrm{Ind}(\mathcal{E})}(Y, X) \xrightarrow{\theta} \mathrm{Map}_{\mathrm{Ind}(\mathcal{E})}(Y', X) \to \mathrm{Map}_{\mathrm{Ind}(\mathcal{E})}(\Omega Y'', X).$$

It will therefore suffice to prove the contractibility of the space $\mathrm{Map}_{\mathrm{Ind}(\mathcal{E})}(\Omega Y'', X)$.

Let $\mathcal{C}_0$ denote the full subcategory of $\mathrm{Ind}(\mathcal{E})$ spanned by those objects of the form $\varinjlim j(E(n))$, where $\{E(n)\}_{n \geqslant 0}$ is a diagram in $\mathcal{E}$ for which each $E(n)$ is an n-fold suspension. Let $\mathcal{C}$ denote the smallest full subcategory of $\mathrm{Ind}(\mathcal{E})$ which contains $\mathcal{C}_0$ and is closed under small colimits and extensions. Note that the collection of those objects $Z \in \mathrm{Ind}(\mathcal{E})$ for which $\mathrm{Map}_{\mathrm{Ind}(\mathcal{E})}(Z, X)$ is contractible is closed under small colimits and extensions. Consequently, if (*c*) is satisfied, then $\mathrm{Map}_{\mathrm{Ind}(\mathcal{E})}(Z, X)$ is contractible for each $Z \in \mathcal{C}$. Similarly, $\mathrm{Ind}(\mathcal{E})_{\geqslant \infty}$ contains $\mathcal{C}_0$ and is closed under small colimits and extensions, so we have $\mathcal{C} \subseteq \mathrm{Ind}(\mathcal{E})_{\geqslant \infty}$. We will complete the proof by showing that $\mathcal{C} = \mathrm{Ind}(\mathcal{E})_{\geqslant \infty}$. To this end, we first prove the following:

- $(*)$ Let Z be a nonzero object of $\mathrm{Ind}(\mathcal{E})_{\geqslant \infty}$. Then there exists a morphism $e : C \to Z$ which is not nullhomotopic, where $C \in \mathcal{C}_0$.

To prove $(*)$, we first note that our assumption that Z is nonzero guarantees that there exists an object $E(0) \in \mathcal{E}$ and a morphism $e_0 : j(E(0)) \to Z$ which is not nullhomotopic. To prove $(*)$, it will suffice to show that we can extend e_0 to a compatible sequence of maps $\{e_n : j(E(n)) \to Z\}_{n \geqslant 0}$, where each $E(n) \in \mathcal{E}$ is an n-fold suspension. The construction proceeds by induction. Let us therefore suppose that $n > 0$ and that $e_n : j(E(n)) \to Z$ has been constructed. Let us represent Z by a diagram $\{Z_\alpha\}_{\alpha \in A}$ in $\mathcal{E}$, indexed by a filtered partially ordered set A. It follows that there exists some index α such that e_n is represented by a map $\overline{e}_n : E(n-1) \to Z_\alpha$ in the ∞-category $\mathcal{E}$. Since $\tau_{\leqslant n} Z$ vanishes, there exists $\beta \geqslant \alpha$ for which the map $\tau_{\leqslant n} Z_\alpha \to \tau_{\leqslant n} Z_\beta$ is nullhomotopic. It follows that the composite map

$$E(n) \xrightarrow{\overline{e}_n} Z_\alpha \to Z_\beta$$

factors through $E(n+1) = \tau_{\geqslant n+1} Z_\beta$, which provides the desired extension of e_n.

We now use $(*)$ to show that $\mathcal{C} = \mathrm{Ind}(\mathcal{E})_{\geqslant \infty}$. It follows from Proposition HA.1.4.4.11 that $\mathcal{C}$ is a presentable ∞-category. Applying Corollary HTT.5.5.2.9 , we deduce that the inclusion $\mathcal{C} \hookrightarrow \mathrm{Ind}(\mathcal{E})$ admits a right adjoint G. Let Z be an object of $\mathrm{Ind}(\mathcal{E})_{\geqslant \infty}$ and let $v : G(Z) \to Z$ be the counit map; we wish to show that v is an equivalence. Suppose otherwise: then $\mathrm{cofib}(v)$ is a nonzero object of $\mathrm{Ind}(\mathcal{E})_{\geqslant \infty}$, so assertion $(*)$ implies that there exists an object $C \in \mathcal{C}_0$ and a morphism $e : C \to \mathrm{cofib}(v)$ which is not nullhomotopic. Let Z_C denote the fiber product $Z \times_{\mathrm{cofib}(v)} C$, so that we have a diagram of cofiber sequences

$$\begin{array}{ccccc} G(Z) & \longrightarrow & Z_C & \longrightarrow & C \\ \downarrow & \swarrow & \downarrow & & \downarrow e \\ G(Z) & \xrightarrow{v} & Z & \longrightarrow & \mathrm{cofib}(v). \end{array}$$

Since $\mathcal{C}$ is closed under extensions, the object Z_C belongs to $\mathcal{C}$. The universal property of $G(Z)$ then guarantees the existence of a dotted arrow as indicated in the diagram. This shows that e is nullhomotopic, contrary to our assumption. $\square$

Proposition C.6.6.9. *Let $\mathcal{E}$ be an essentially small separated prestable ∞-category which admits finite limits and geometric realizations. Let $\mathcal{C}$ be the full subcategory of* $\mathrm{Fun}(\mathcal{E}^{\mathrm{op}}, \mathcal{S})$ *spanned by those functors which preserve finite limits and totalizations of cosimplicial objects. Then $\mathcal{C}$ is a separated coherent Grothendieck prestable ∞-category, and the Yoneda embedding $j : \mathcal{E} \hookrightarrow \mathcal{C}$ induces an equivalence from $\mathcal{E}$ to the full subcategory $\mathcal{C}^{\mathrm{ac}} \subseteq \mathcal{C}$ spanned by the almost compact objects.*

Proof. The ∞-category $\mathrm{Ind}(\mathcal{E})$ is Grothendieck prestable by virtue of Proposition C.6.1.1. Using Proposition C.6.6.8, we see that $\mathcal{C}$ can be identified with the separated quotient $\mathrm{Ind}(\mathcal{E}) / \mathrm{Ind}(\mathcal{E})_{\geqslant \infty}$ of $\mathrm{Ind}(\mathcal{E})$, so that $\mathcal{C}$ is a separated Grothendieck prestable ∞-category. For each $n \geqslant 0$, we have an equivalence

$$\tau_{\leqslant n} \mathcal{C} \simeq \tau_{\leqslant n}(\mathrm{Ind}(\mathcal{E}) / \mathrm{Ind}(\mathcal{E})_{\geqslant \infty}) = \tau_{\leqslant n} \mathrm{Ind}(\mathcal{E}) \simeq \mathrm{Ind}(\tau_{\leqslant n} \mathcal{E}).$$

It follows immediately that the Yoneda embedding $j : \mathcal{E} \to \mathcal{C}$ carries each object of $\mathcal{E}$ to an almost compact object of $\mathcal{C}$. Using the criterion of Proposition C.6.5.4, we see that $\mathcal{C}$

is weakly coherent. Since $\mathcal{C}$ is a localization of $\mathrm{Ind}(\mathcal{E})$, the essential image of $j : \mathcal{E} \to \mathcal{C}$ is a generating subcategory of $\mathcal{C}$ (in the sense of Definition C.2.1.1) which consists of almost compact objects, so that $\mathcal{C}$ is coherent. To complete the proof, it will suffice to show that every almost compact object of $\mathcal{C}$ belongs to the essential image of j. To see this, we first observe that the essential image of j is closed under finite limits and colimits, and is therefore also closed under extensions. Applying Lemma C.6.6.3, we see that every almost compact object $C \in \mathcal{C}$ can be written as a geometric realization $|C_\bullet|$, where each C_k belongs to the essential image of j. By construction, the functor j preserves geometric realizations, so that every almost compact object of $\mathcal{C}$ belongs to the essential image of j. □

Proposition C.6.6.9 shows that every ∞-category $\mathcal{E}$ which satisfies the conditions of Remark C.6.6.7 has the form $\mathcal{C}^{\mathrm{ac}}$, for some separated coherent Grothendieck prestable ∞-category $\mathcal{C}$. It follows from Theorem C.6.6.5 that the ∞-category $\mathcal{C}$ is uniquely determined up to equivalence. In fact, the ∞-category $\mathcal{C}$ depends functorially on $\mathcal{E}$. To articulate this more precisely, it will be convenient to introduce a variant of Definition C.3.4.2.

Definition C.6.6.10. Let $\mathcal{C}$ and $\mathcal{D}$ be Grothendieck prestable ∞-categories and let $F : \mathcal{C} \to \mathcal{D}$ be a functor which preserves small colimits. Let $G : \mathcal{D} \to \mathcal{C}$ be a right adjoint to F (which exists by virtue of Corollary HTT.5.5.2.9). We will say that F is *almost compact* if, for each $n \geqslant 0$, the functor

$$G|_{\tau_{\leqslant n}\mathcal{D}} : \tau_{\leqslant n}\mathcal{D} \to \tau_{\leqslant n}\mathcal{C}$$

commutes with filtered colimits.

Example C.6.6.11. Let $\mathcal{C}$ and $\mathcal{D}$ be Grothendieck prestable ∞-categories. Then every functor $F : \mathcal{C} \to \mathcal{D}$ which is compact (in the sense of Definition C.3.4.2) is almost compact (in the sense of Definition C.6.6.10).

Example C.6.6.12. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $f : \mathrm{Sp}^{\mathrm{cn}} \to \mathcal{C}$ be a colimit-preserving functor. Then f is almost compact (in the sense of Definition C.6.6.10) if and only if the object $f(S) \in \mathcal{C}$ is almost compact (in the sense of Definition C.6.4.1).

Proposition C.6.6.13. *Let $\mathcal{C}$ and $\mathcal{D}$ be Grothendieck prestable ∞-categories and let $F : \mathcal{C} \to \mathcal{D}$ be a functor which preserves small colimits. Then:*

(1) *If F is almost compact, then F carries almost compact objects of $\mathcal{C}$ to almost compact objects of $\mathcal{D}$.*

(2) *If $\mathcal{C}$ is weakly coherent and F carries almost compact objects of $\mathcal{C}$ to almost compact objects of $\mathcal{D}$, then F is almost compact.*

Proof. Assume that F is almost compact and that $C \in \mathcal{C}$ is almost compact. For each $n \geqslant 0$, the functor $\tau_{\leqslant n}\,\mathcal{D} \to \mathcal{S}$ given by $D \mapsto \mathrm{Map}_{\mathcal{D}}(FC, D)$ can be expressed as a composition of functors

$$\tau_{\leqslant n}\,\mathcal{D} \xrightarrow{G} \tau_{\leqslant n}\,\mathcal{C} \xrightarrow{\mathrm{Map}_{\mathcal{C}}(C,\bullet)} \mathcal{S}$$

which commute with filtered colimits. Allowing n to vary, we deduce that FC is a compact object of $\mathcal{D}$, which proves (1).

Now suppose that $\mathcal{C}$ is weakly coherent. Then for each $n \geqslant 0$, the ∞-category $\tau_{\leqslant n}\,\mathcal{C}$ is compactly generated (Proposition C.6.5.7). It follows that the functor $G|_{\tau_{\leqslant n}\,\mathcal{D}}$ commutes with filtered colimits if and only if, for each compact object C of $\tau_{\leqslant n}\,\mathcal{C}$, the composite functor

$$\tau_{\leqslant n}\,\mathcal{D} \xrightarrow{G} \tau_{\leqslant n}\,\mathcal{C} \xrightarrow{\mathrm{Map}_{\mathcal{C}}(C,\bullet)} \mathcal{S}$$

commutes with filtered colimits. Note that in this case, C is almost compact when viewed as an object of $\mathcal{C}$. Consequently, if the functor F preserves almost compact objects, then FC is an almost compact object of $\mathcal{D}$, so that the construction $D \mapsto \mathrm{Map}_{\mathcal{C}}(C, GD) \simeq \mathrm{Map}_{\mathcal{D}}(FC, D)$ commutes with filtered colimits when restricted to $\tau_{\leqslant n}\,\mathcal{D}$, as desired. □

We can now formulate our main result.

Theorem C.6.6.14. *Let $\mathsf{Groth}_{\infty}^{\mathrm{coh}}$ denote the subcategory of $\widehat{\mathcal{C}\mathrm{at}}_{\infty}$ whose objects are coherent separated Grothendieck prestable ∞-categories and whose morphisms are almost compact functors. For each object $\mathcal{C} \in \mathsf{Groth}_{\infty}^{\mathrm{coh}}$, let $\mathcal{C}^{\mathrm{ac}}$ denote the full subcategory of $\mathcal{C}$ spanned by the almost compact objects. Then the construction $\mathcal{C} \mapsto \mathcal{C}^{\mathrm{ac}}$ determines a fully faithful embedding $\rho : \mathsf{Groth}_{\infty}^{\mathrm{coh}} \to \mathcal{C}\mathrm{at}_{\infty}^{\mathrm{PSt}}$, whose essential image is spanned by those prestable ∞-categories which are separated and admit finite limits and geometric realizations.*

Proof. It follows from Proposition C.6.6.13 that the functor ρ is well-defined and from Theorem C.6.6.5 (together with Proposition C.6.6.13) that ρ is fully faithful. Essential surjectivity follows from Proposition C.6.6.9. □

We conclude this section with another observation about the relationship between separatedness and coherence.

Proposition C.6.6.15. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let $\mathcal{C}_{\geqslant\infty} \subseteq \mathcal{C}$ be the localizing subcategory spanned by those objects $X \in \mathcal{C}$ satisfying $\pi_n X \simeq 0$ for $n \geqslant 0$. Then $\mathcal{C}$ is coherent if and only if the quotient $\mathcal{C}\,/\,\mathcal{C}_{\geqslant\infty}$ is coherent.*

Proof. Let us regard $\mathcal{C}\,/\,\mathcal{C}_{\geqslant\infty}$ as a full subcategory of $\mathcal{C}$, and let $L : \mathcal{C} \to \mathcal{C}\,/\,\mathcal{C}_{\geqslant\infty}$ denote a left adjoint to the inclusion. Note that $\mathcal{C}\,/\,\mathcal{C}_{\geqslant\infty}$ contains every truncated object of $\mathcal{C}$ (so that L is equivalent to the identity when restricted to $\tau_{\leqslant n}\,\mathcal{C}$, for any $n \geqslant 0$). From this, we deduce:

(*i*) An object of $\mathcal{C}/\mathcal{C}_{\geqslant\infty}$ is almost compact if and only if it is almost compact when regarded as an object of $\mathcal{C}$.

(*ii*) An object $X \in \mathcal{C}$ is almost compact if and only if $LX \in \mathcal{C}/\mathcal{C}_{\geqslant\infty}$ is almost compact.

Suppose first that $\mathcal{C}$ is coherent. Then the collection of almost compact objects of $\mathcal{C}$ is closed under finite limits. Applying (*i*), we deduce that the collection of almost compact objects of $\mathcal{C}/\mathcal{C}_{\geqslant\infty}$ is closed under finite limits. For every object $X \in \mathcal{C}/\mathcal{C}_{\geqslant\infty}$, our assumption that $\mathcal{C}$ is coherent guarantees that we can find a morphism $u : \bigoplus C_\alpha \to X$ in $\mathcal{C}$, where each C_α is an almost compact object of $\mathcal{C}$ and u induces an epimorphism on π_0. Then $L(u)$ is a morphism in $\mathcal{C}/\mathcal{C}_{\geqslant\infty}$ which is also an epimorphism on π_0, whose domain $L(\bigoplus C_\alpha)$ can be identified with a coproduct in the ∞-category $\mathcal{C}/\mathcal{C}_{\geqslant\infty}$ of objects LC_α, which are almost compact by virtue of (*ii*). Allowing X to vary, we conclude that $\mathcal{C}/\mathcal{C}_{\geqslant\infty}$ is coherent.

We now prove the converse. Suppose that $\mathcal{C}/\mathcal{C}_{\geqslant\infty}$ is coherent. Then the collection of almost compact objects of $\mathcal{C}/\mathcal{C}_{\geqslant\infty}$ is closed under finite limits. Using (*ii*) and the left exactness of L, we deduce that the collection of almost compact objects of $\mathcal{C}$ is closed under finite limits. For every object $X \in \mathcal{C}$, our assumption that $\mathcal{C}/\mathcal{C}_{\geqslant\infty}$ is coherent guarantees that we can find a map $u : \bigoplus C_\alpha \to LX$ which is surjective on π_0, where each C_α is an almost compact object of $\mathcal{C}/\mathcal{C}_{\geqslant\infty}$. For each index α, set $\overline{C}_\alpha = C_\alpha \times_{LX} X$. Since L is left exact, each of the projection maps $\overline{C}_\alpha \to C_\alpha$ induces an equivalence $L\overline{C}_\alpha \simeq C_\alpha$. Using (*ii*), we see that each $\overline{C}_\alpha$ is an almost compact object of $\mathcal{C}$. Amalgamating the projection maps $\overline{C}_\alpha \to X$, we obtain a morphism $\overline{u} : \bigoplus \overline{C}_\alpha \to X$. Since $\overline{u}$ and u are equivalent after applying the functor L, our assumption that u induces an epimorphism on π_0 guarantees that $\overline{u}$ also induces an epimorphism on π_0. Allowing X to vary, we conclude that $\mathcal{C}$ is coherent, as desired. □

C.6.7 Anticomplete Coherent Grothendieck Prestable ∞-Categories

In the setting of anticomplete Grothendieck prestable ∞-categories, coherence takes a particularly simple form.

Theorem C.6.7.1. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. The following conditions are equivalent:*

(*a*) *The ∞-category $\mathcal{C}$ is a compactly generated, the functor $\Omega : \mathcal{C} \to \mathcal{C}$ preserves compact objects, and every compact object of $\mathcal{C}$ is truncated.*

(*b*) *There exist an essentially small stable ∞-category $\mathcal{E}$ equipped with a bounded t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$ and an equivalence $\mathcal{C} \simeq \operatorname{Ind}(\mathcal{E}_{\geqslant 0})$.*

(*c*) *The Grothendieck prestable ∞-category $\mathcal{C}$ is anticomplete and coherent.*

(*d*) *The Grothendieck prestable ∞-category $\mathcal{C}$ is anticomplete and weakly coherent.*

Proof. The equivalence $(a) \Leftrightarrow (b)$ follows from Proposition C.5.5.5. We next show that $(b) \Rightarrow (c)$. Assume that there is an equivalence $f : \mathrm{Ind}(\mathcal{E}_{\geqslant 0}) \simeq \mathcal{C}$ for some essentially small stable ∞-category $\mathcal{E}$ equipped with a bounded t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$. Proposition C.5.5.5 implies that $\mathcal{C}$ is anticomplete. Let us abuse notation by identifying $\mathcal{E}_{\geqslant 0}$ with its essential image under the fully faithful embedding

$$\mathcal{E}_{\geqslant 0} \hookrightarrow \mathrm{Ind}(\mathcal{E}_{\geqslant 0}) \xrightarrow{f} \mathcal{C}.$$

For each $n \geqslant 0$, the functor f induces an equivalence $\mathrm{Ind}(\mathcal{E}_{\geqslant 0} \cap \mathcal{E}_{\leqslant n}) \simeq \tau_{\leqslant n}\mathcal{C}$. It follows that an object $X \in \mathcal{C}$ is almost compact if and only if each truncation $\tau_{\leqslant n}X$ belongs to $\mathcal{E}_{\geqslant 0}$. From this description, it follows immediately that the functor $\Omega : \mathcal{C} \to \mathcal{C}$ carries almost compact objects to almost compact objects. Moreover, the collection of almost compact objects of $\mathcal{C}$ contains $\mathcal{E}_{\geqslant 0}$ and is therefore a generating subcategory of $\mathcal{C} \simeq \mathrm{Ind}(\mathcal{E}_{\geqslant 0})$. This proves that $\mathcal{C}$ is coherent, and Proposition C.5.5.5 implies that $\mathcal{C}$ is anticomplete.

The implication $(c) \Rightarrow (d)$ is obvious. We will complete the proof by showing that (d) implies (b). Assume that $\mathcal{C}$ is anticomplete and weakly coherent. Let $\mathcal{E}_{\geqslant 0}$ be the full subcategory of $\mathcal{C}$ spanned by those objects which are truncated and almost compact. Then $\mathcal{E}_{\geqslant 0}$ is closed under finite colimits in $\mathcal{C}$ and is therefore a prestable ∞-category. Since $\mathcal{C}$ is weakly coherent, the ∞-category $\mathcal{E}_{\geqslant 0}$ is also closed under finite limits in $\mathcal{C}$. Let $\mathcal{E} = \mathrm{SW}(\mathcal{E}_{\geqslant 0})$ be the Spanier-Whitehead ∞-category of $\mathcal{E}_{\geqslant 0}$ and let us abuse notation by identifying $\mathcal{E}_{\geqslant 0}$ with its image in $\mathcal{E}$, so that $\mathcal{E}$ admits a right-bounded t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$ (see Proposition C.1.2.9). By construction, every object of $\mathcal{E}_{\geqslant 0}$ is truncated, so this t-structure is also left-bounded. Set $\mathcal{C}' = \mathrm{Ind}(\mathcal{E}_{\geqslant 0})$, so that the inclusion $\mathcal{E}_{\geqslant 0} \hookrightarrow \mathcal{C}$ extends to functor $\lambda : \mathcal{C}' \to \mathcal{C}$ which preserves small colimits and finite limits. Using Proposition C.6.5.4, we see that λ induces an equivalence

$$\tau_{\leqslant n}\mathcal{C}' \simeq \mathrm{Ind}(\mathcal{E}_{\geqslant 0} \cap \mathcal{E}_{\leqslant n}) \to \tau_{\leqslant n}\mathcal{C}$$

for each $n \geqslant 0$. The ∞-category $\mathcal{C}'$ is anticomplete (by virtue of the implication $(b) \Rightarrow (c)$) and the ∞-category $\mathcal{C}$ is anticomplete by assumption. Applying Proposition C.5.9.2, we deduce that λ is an equivalence of ∞-categories. □

Corollary C.6.7.2. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. The following conditions are equivalent:*

(*i*) *The Grothendieck prestable ∞-category $\mathcal{C}$ is weakly coherent.*

(*ii*) *There exists a coherent Grothendieck prestable ∞-category $\mathcal{C}'$ and a functor $\lambda \in \mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}', \mathcal{C})$ which induces an equivalence of completions $\widehat{\mathcal{C}}' \simeq \widehat{\mathcal{C}}$.*

Proof. The implication $(ii) \Rightarrow (i)$ follows immediately from Corollary C.6.5.5. Conversely, suppose that (i) is satisfied. Using Proposition C.5.5.9, we can choose a map $\lambda \in \mathrm{LFun}^{\mathrm{lex}}(\mathcal{C}', \mathcal{C})$ which induces an equivalence of completions $\widehat{\mathcal{C}}' \to \widehat{\mathcal{C}}$, where $\mathcal{C}'$ is anticomplete. Since $\mathcal{C}$ is weakly coherent, the Grothendieck prestable ∞-category $\mathcal{C}'$ is also weakly coherent (Corollary C.6.5.5) and therefore coherent (Theorem C.6.7.1). □

Combining Theorem C.6.7.1 with Corollary C.6.1.5, we obtain the following:

Corollary C.6.7.3. *Let $\mathcal{C}\mathrm{at}_\infty^{\mathrm{PSt},b}$ denote the full subcategory of $\mathcal{C}\mathrm{at}_\infty^{\mathrm{PSt}}$ spanned by those small prestable ∞-categories $\mathcal{C}$ satisfying the following conditions:*

(i) *The ∞-category $\mathcal{C}$ admits finite limits.*

(ii) *Every object of $\mathcal{C}$ is truncated.*

Then the construction $\mathcal{C} \mapsto \mathrm{Ind}(\mathcal{C})$ determines a fully faithful embedding $\mathrm{Ind} : \mathcal{C}\mathrm{at}_\infty^{\mathrm{PSt},b} \hookrightarrow \mathsf{Groth}_\infty^{\mathrm{c}}$, whose essential image is spanned by those Grothendieck prestable ∞-categories which are coherent and anticomplete.

Remark C.6.7.4. An ∞-category $\mathcal{C}$ which satisfies conditions (i) and (ii) of Corollary C.6.7.3 is automatically idempotent complete (since $\mathcal{C} = \bigcup_{n \geqslant 0} \tau_{\leqslant n} \mathcal{C}$, and each $\tau_{\leqslant n} \mathcal{C}$ is an $(n+1)$-category which admits finite limits).

Remark C.6.7.5. Let $\mathcal{C}$ and $\mathcal{D}$ be prestable ∞-categories satisfying conditions (i) and (ii) of Corollary C.6.7.3. Then a functor $f : \mathcal{C} \to \mathcal{D}$ is left exact if and only if the induced map $\mathrm{Ind}(f) : \mathrm{Ind}(\mathcal{C}) \to \mathrm{Ind}(\mathcal{D})$ is left exact (this follows from the left exactness of filtered colimits in $\mathcal{D}$). Restricting to left exact functors on both sides, the equivalence of Corollary C.6.7.3 can be regarded a "linear analogue" of Theorem A.7.5.3.

C.6.8 Locally Noetherian Abelian Categories

We now give a brief review of the classical theory of locally Noetherian abelian categories. For a more complete exposition, we refer the reader to [74].

Definition C.6.8.1. Let $\mathcal{A}$ be an abelian category. For every object $X \in \mathcal{A}$, we let $\mathrm{Sub}(X)$ denote the partially ordered set of (isomorphism classes of) subobjects of X. We say that an object $X \in \mathcal{A}$ is *Noetherian* if the partially ordered set $\mathrm{Sub}(X)$ satisfies the ascending chain condition: that is, if every increasing sequence

$$X_0 \subseteq X_1 \subseteq X_2 \subseteq X_3 \subseteq \cdots$$

in $\mathrm{Sub}(X)$ eventually stabilizes.

Proposition C.6.8.2. *Let $\mathcal{A}$ be an abelian category containing an exact sequence $0 \to X' \to X \to X'' \to 0$. Then X is Noetherian if and only if X' and X'' are Noetherian. In other words, the collection of Noetherian objects of $\mathcal{A}$ is closed under the formation of subobjects, quotient objects, and extensions.*

Proof. It is easy to see that if X is Noetherian, then X' and X'' must be Noetherian (note that we can identify $\mathrm{Sub}(X')$ and $\mathrm{Sub}(X'')$ with partially ordered subsets of $\mathrm{Sub}(X)$). To prove the converse, assume that X' and X'' are Noetherian, and suppose we are given an ascending sequence $X_0 \subseteq X_1 \subseteq X_2 \subseteq \cdots$ of subobjects of X. For each $n \geqslant 0$, let X'_n and X''_n denote the kernel and image of the composite map $X_n \hookrightarrow X \to X''$, respectively. Then we can identify $\{X'_n\}_{n \geqslant 0}$ as an ascending chain of subobjects of X', and $\{X''_n\}_{n \geqslant 0}$ as an ascending chain of subobjects of X''. Using our assumption that X' and X'' are Noetherian, we deduce that there is an integer n_0 for which the inclusions $X'_{n_0} \hookrightarrow X'_n$ and $X''_{n_0} \hookrightarrow X''_n$ are isomorphisms for $n \geqslant n_0$. Applying the Snake Lemma to the commutative diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & X'_{n_0} & \longrightarrow & X_{n_0} & \longrightarrow & X''_{n_0} & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & X'_n & \longrightarrow & X_n & \longrightarrow & X''_n & \longrightarrow & 0, \end{array}$$

we deduce that the chain $\{X_n\}_{n \geqslant 0}$ is constant for $n \geqslant n_0$. □

Corollary C.6.8.3. *Let $\mathcal{A}$ be an abelian category containing an exact sequence $X' \to X \to X''$. If X' and X'' are Noetherian, then X is Noetherian.*

Proposition C.6.8.4. *Let $\mathcal{A}$ be a Grothendieck abelian category containing an object X. The following conditions are equivalent:*

(1) *The object X is the colimit of its Noetherian subobjects.*

(2) *The object X can be written as the colimit of a small filtered diagram $\{X_\alpha\}$, where each X_α is a Noetherian object of $\mathcal{A}$.*

(3) *There exists an epimorphism $\bigoplus_\alpha X_\alpha \to X$, where each X_α is a Noetherian object of $\mathcal{A}$.*

Proof. It follows from Proposition C.6.8.2 that the Noetherian subobjects of X form a filtered partially ordered set, which shows that (1) ⇒ (2). The implication (2) ⇒ (3) is immediate. To show that (3) implies (1), we note that the existence of an epimorphism $\bigoplus_{\alpha \in A} X_\alpha \to X$ implies that X can be identified with the colimit of the subobjects given by the images of the maps $\bigoplus_{\alpha \in A_0} X_\alpha \to X$, where A_0 ranges over the finite subsets of A; each of these images is a Noetherian subobject of X by virtue of Proposition C.6.8.2. □

Definition C.6.8.5. Let $\mathcal{A}$ be an abelian category. We will say that $\mathcal{A}$ is *locally Noetherian* if it is a Grothendieck abelian category and every object $X \in \mathcal{A}$ satisfies the equivalent conditions of Proposition C.6.8.4.

Example C.6.8.6. Let R be an associative ring. Then the abelian category $\mathrm{LMod}_R^{\heartsuit}$ of (discrete) left R-modules is locally Noetherian if and only if the ring R is left Noetherian (that is, if and only if every left ideal $I \subseteq R$ is finitely generated).

Proposition C.6.8.7. *Let $\mathcal{A}$ be a locally Noetherian abelian category and let $X \in \mathcal{A}$ be a Noetherian object. Then X is compact: that is, the functor $Y \mapsto \mathrm{Hom}_{\mathcal{A}}(X, Y)$ commutes with filtered colimits.*

Proof. Suppose we are given a diagram $\{Y_\alpha\}_{\alpha \in A}$ in the category $\mathcal{A}$ which is indexed by a filtered partially ordered set A. We wish to show that the canonical map $\theta : \varinjlim_{\alpha \in A} \mathrm{Hom}_{\mathcal{A}}(X, Y_\alpha) \to \mathrm{Hom}_{\mathcal{A}}(X, Y)$ is an isomorphism. We first show that θ is injective. Suppose that we are given an element $f \in \ker(\theta)$, which we can represent by a morphism $f_\alpha : X \to Y_\alpha$ for some $\alpha \in A$. For each $\beta \geqslant \alpha$, let $K_\beta \subseteq X$ denote the kernel of the composite map $X \xrightarrow{f_\alpha} Y_\alpha \to Y_\beta$. Since $\mathcal{A}$ is a Grothendieck abelian category, the vanishing of the map $\theta(f) : X \to Y$ guarantees that X is the direct limit of the subobjects $\{K_\beta\}_{\beta \geqslant \alpha}$. Our assumption that X is Noetherian guarantees that $X = K_\beta$ for some $\beta \geqslant \alpha$, so that the composite map $X \xrightarrow{f_\alpha} Y_\alpha \to Y_\beta$ vanishes and therefore $f = 0$, as desired.

We now verify the surjectivity of the map θ. Fix a map $g : X \to Y$. For each $\alpha \in A$, let X_α denote the fiber product $X \times_Y Y_\alpha$. Let $q_\alpha : X_\alpha \to X$ denote the projection onto the first factor. To prove that g belongs to the image of θ, it will suffice to show that q_α admits a section for some $\alpha \in A$. Since $\mathcal{A}$ is a Grothendieck abelian category, the canonical map $\varinjlim X_\alpha \to X$ is an isomorphism. In particular, X is the direct limit of the the diagram of subobjects $\{\mathrm{im}\, q_\alpha\}_{\alpha \in A}$. Since X is Noetherian, it follows that there exists an index $\alpha \in A$ such that q_α is an epimorphism. Write X_α as a filtered colimit of Noetherian subobjects $\{X_{\alpha,i}\}_{i \in I}$. Then X is the colimit of the diagram of subobjects $\{\mathrm{im}\, q_\alpha|_{X_{\alpha,i}}\}_{i \in I}$, so there exists an index $i \in I$ such that $q_\alpha|_{X_{\alpha,i}}$ is an epimorphism. Let $K = \ker(q_\alpha|_{X_{\alpha,i}}$. Then K is Noetherian (Proposition C.6.8.2), and the composite map $K \hookrightarrow X_\alpha \to \varprojlim_{\beta \geqslant \alpha} X_\beta \simeq X$ vanishes. It follows from the first part of the proof that there exists $\beta \geqslant \alpha$ for which the composite map $K \hookrightarrow X_\alpha \to X_\beta$ vanishes. It follows that the map q_β admits a section (given by composing the induced map $X_{\alpha,i}/K \to X_\beta$ with the inverse of the canonical isomorphism $X_{\alpha,i}/K \xrightarrow{\sim} X$). □

Corollary C.6.8.8. *Let $\mathcal{A}$ be a locally Noetherian abelian category, and let $\mathcal{A}_0 \subseteq \mathcal{A}$ be the full subcategory spanned by the Noetherian objects. Then the inclusion $\mathcal{A}_0 \hookrightarrow \mathcal{A}$ extends to an equivalence of ∞-categories $F : \mathrm{Ind}(\mathcal{A}_0) \to \mathcal{A}$.*

Proof. There exists an essentially unique functor $F : \mathrm{Ind}(\mathcal{A}_0) \to \mathcal{A}$ which extends the inclusion map and commutes with filtered colimits. It follows from Proposition C.6.8.7 that F is fully faithful and from Definition C.6.8.5 that F is essentially surjective. □

Corollary C.6.8.9. *Let $\mathcal{A}$ be a locally Noetherian abelian category. Then $\mathcal{A}$ is compactly generated, and an object $X \in \mathcal{A}$ is compact if and only if it is Noetherian.*

Remark C.6.8.10. Suppose that $\mathcal{A}_0$ is a small abelian category in which every object is Noetherian. Then $\mathrm{Ind}(\mathcal{A}_0)$ is a locally Noetherian abelian category, and an object of $\mathrm{Ind}(\mathcal{A}_0)$ is Noetherian if and only if it belongs to the essential image of the fully faithful embedding $j : \mathcal{A}_0 \hookrightarrow \mathrm{Ind}(\mathcal{A}_0)$. To prove this, we first note that $\mathrm{Ind}(\mathcal{A}_0)$ compactly generated. It follows that filtered colimits in $\mathrm{Ind}(\mathcal{A}_0)$ are left exact and therefore $\mathrm{Ind}(\mathcal{A}_0)$ is a Grothendieck abelian category. We next claim that if $M \in \mathrm{Ind}(\mathcal{A}_0)$ belongs to the essential image of j, then every subobject of M belongs to the essential image of j. To prove this, write $M = j(N)$ for some $N \in \mathcal{A}_0$. Let M' be a subobject of M, and write $M' \simeq \varinjlim_{\alpha \in A} j(N_\alpha)$ where the colimit is taken over some filtered partially ordered set A. Then $M' \simeq \varinjlim_{\alpha \in A} j(\mathrm{im}(N_\alpha \to N))$. Since N is Noetherian, we deduce that there exists $\alpha \in A$ such that $M' \simeq \mathrm{im}(N_\alpha \to N)$, so that M' belongs to the image of j.

The above argument shows that for each object $N \in \mathcal{A}_0$, the partially ordered set of isomorphism classes of subobjects of N is isomorphic to the partially ordered set of isomorphism classes of subobjects of $j(N)$. Since $N \in \mathcal{A}_0$ is Noetherian, we conclude that $j(N) \in \mathrm{Ind}(\mathcal{A}_0)$ is Noetherian. Now suppose that $M \simeq \varinjlim_{\alpha \in A} j(N_\alpha)$ is an arbitrary object of $\mathrm{Ind}(\mathcal{A}_0)$. Then M is equivalent to the filtered colimit of subobjects $\varinjlim_{\alpha \in A} \mathrm{im}(j(N_\alpha) \to M)$. Each of these subobjects is a quotient of $j(N_\alpha)$, and therefore Noetherian. This proves that the abelian category $\mathrm{Ind}(\mathcal{A}_0)$ is locally Noetherian. If the object M above is Noetherian, then there exists an index $\alpha \in A$ such that $M \simeq \mathrm{im}(j(N_\alpha) \to M)$. Then M is a quotient of $j(N_\alpha)$. Since $\ker(j(N_\alpha) \to M)$ is a subobject of $j(N_\alpha)$, it belongs to the essential image of j. It follows that every Noetherian object $M \in \mathrm{Ind}(\mathcal{A}_0)$ belongs to the essential image of j.

The collection of locally Noetherian abelian categories is closed under passage to left exact localization:

Proposition C.6.8.11. *Let $\mathcal{A}$ be a locally Noetherian abelian category and let $\mathcal{A}_0 \subseteq \mathcal{A}$ be a localizing subcategory. Then $\mathcal{A}_0$ and $\mathcal{A}/\mathcal{A}_0$ are locally Noetherian.*

Proof. It follows immediately from the definitions that $\mathcal{A}_0$ is locally Noetherian. Let $L : \mathcal{A} \to \mathcal{A}/\mathcal{A}_0$ be a left adjoint to the inclusion. For each object $X \in \mathcal{A}$, let $\mathrm{Sub}_{\mathcal{A}}(X)$ denote the set of isomorphism classes of subobjects of X, and for $Y \in \mathcal{A}/\mathcal{A}_0$ define $\mathrm{Sub}_{\mathcal{A}/\mathcal{A}_0}(Y)$ similarly. For each object $X \in \mathcal{A}$, the construction $(Y_0 \in \mathrm{Sub}_{\mathcal{A}/\mathcal{A}_0}(LX)) \mapsto (Y_0 \times_{LX} X \in \mathrm{Sub}_{\mathcal{A}}(X))$ determines an order-preserving map $\rho : \mathrm{Sub}_{\mathcal{A}/\mathcal{A}_0}(LX) \to \mathrm{Sub}_{\mathcal{A}}(X)$. It follows from the left exactness of L that this map is injective (it has a left inverse, given by the construction

$(X_0 \in \mathrm{Sub}_{\mathcal{A}}(X)) \mapsto (LX_0 \in \mathrm{Sub}_{\mathcal{A}/\mathcal{A}_0}(LX)))$. Consequently, if X is a Noetherian object of $\mathcal{A}$, then LX is a Noetherian object of $\mathcal{A}/\mathcal{A}_0$. Every object $X \in \mathcal{A}$ can be written as a union of its Noetherian subobjects, so that $LX \in \mathcal{A}/\mathcal{A}_0$ can be written as a filtered colimit of subobjects which are Noetherian in $\mathcal{A}/\mathcal{A}_0$. Since the functor L is essentially surjective, it follows that $\mathcal{A}/\mathcal{A}_0$ is locally Noetherian as desired. □

C.6.9 Locally Noetherian Prestable ∞-Categories

We now introduce an ∞-categorical analogue of Definition C.6.8.5.

Definition C.6.9.1. Let $\mathcal{C}$ be prestable ∞-category. We will say that $\mathcal{C}$ is *locally Noetherian* if it is a weakly coherent Grothendieck prestable ∞-category (Definition C.6.5.1) and the abelian category $\mathcal{C}^{\heartsuit}$ is locally Noetherian.

Remark C.6.9.2. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. The condition that $\mathcal{C}$ is locally Noetherian depends only on the completion of $\mathcal{C}$. In particular, if $F : \mathcal{C} \to \mathcal{D}$ is a functor of Grothendieck prestable ∞-categories which induces an equivalence $\tau_{\leqslant n}\mathcal{C} \simeq \tau_{\leqslant n}\mathcal{D}$ for $n \geqslant 0$, then $\mathcal{C}$ is locally Noetherian if and only if $\mathcal{D}$ is locally Noetherian (see Corollary C.6.5.5).

Proposition C.6.9.3. *Let $\mathcal{C}$ be a locally Noetherian prestable ∞-category and let X be an object of $\mathcal{C}$. Then X is almost compact if and only if $\pi_n X$ is a Noetherian object of $\mathcal{C}^{\heartsuit}$ for each $n \geqslant 0$.*

Proof. Combine Corollaries C.6.4.6 and C.6.8.9. □

Example C.6.9.4. Let R be a connective $\mathbb{E}_1$-ring. Then R is left Noetherian if and only if the Grothendieck prestable ∞-category $\mathrm{LMod}_R^{\mathrm{cn}}$ is locally Noetherian (this follows from Examples C.6.5.3 and C.6.8.6.

Example C.6.9.5. Let $\mathcal{A}$ be a locally Noetherian abelian category. Then the Grothendieck prestable ∞-categories $\check{\mathcal{D}}(\mathcal{A})_{\geqslant 0}$, $\mathcal{D}(\mathcal{A})_{\geqslant 0}$, and $\widehat{\mathcal{D}}(\mathcal{A})_{\geqslant 0}$ are locally Noetherian (this follows immediately from Corollary C.6.5.9).

Warning C.6.9.6. It follows immediately from the definition that if $\mathcal{C}$ is a locally Noetherian prestable ∞-category, then the heart $\mathcal{C}^{\heartsuit}$ is a locally Noetherian abelian category. However, the converse is not true in general. For a counterexample, take $\mathcal{C} = \mathrm{Mod}_R^{\heartsuit}$, where R is a connective $\mathbb{E}_\infty$-ring for which $\pi_0 R$ is Noetherian but some homotopy group $\pi_n R$ is not finitely generated as a module over $\pi_0 R$).

Proposition C.6.9.7. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. The following conditions are equivalent:*

(a) *The prestable ∞-category $\mathcal{C}$ is locally Noetherian.*

(b) *For every integer $n \geqslant 0$, the ∞-category $\tau_{\leqslant n}\mathcal{C}$ is compactly generated. Moreover, if $C \in \tau_{\leqslant n}\mathcal{C}$ is a compact object, then $\pi_n C$ is a Noetherian object of $\mathcal{C}^{\heartsuit}$.*

Proof. The implication $(a) \Rightarrow (b)$ follows from Proposition C.6.9.3. Conversely, suppose that (b) is satisfied. We will prove the following:

$(*)$ For $n \geqslant 0$, an object $C \in \tau_{\leqslant n}\mathcal{C}$ is compact if and only if $\pi_m C$ is a Noetherian object of $\mathcal{C}^{\heartsuit}$ for $0 \leqslant m \leqslant n$.

Assume $(*)$ for the moment. Since the collection of Noetherian objects of $\mathcal{C}^{\heartsuit}$ is closed under finite direct sums (Proposition C.6.8.2), it follows that the collection of compact objects of $\tau_{\leqslant n}\mathcal{C}$ is also closed under finite direct sums, for each $n \geqslant 0$. Moreover, if $f : C \to D$ is a morphism between compact objects of $\tau_{\leqslant n}\mathcal{C}$, then we have exact sequences $\pi_{m+1} D \to \pi_m \operatorname{fib}(f) \to \pi_m C$ in the abelian category $\mathcal{C}^{\heartsuit}$ where the outer terms are Noetherian (by virtue of $(*)$). It follows from Corollary C.6.8.3 that $\pi_m \operatorname{fib}(f)$ is Noetherian for $0 \leqslant m \leqslant n$, so that $\operatorname{fib}(f)$ is also a compact object of $\tau_{\leqslant n}\mathcal{C}$ (by virtue of $(*)$). It follows that the collection of compact objects of $\tau_{\leqslant n}\mathcal{C}$ is closed under finite limits, so that $\mathcal{C}$ is weakly coherent (Proposition C.6.5.4). Applying (b) in the case $n = 0$, we see that $\mathcal{C}^{\heartsuit}$ is a compactly generated abelian category in which every compact object is Noetherian, so that $\mathcal{C}^{\heartsuit}$ is locally Noetherian and therefore $\mathcal{C}$ is locally Noetherian.

It remains to prove $(*)$. The "only if" direction follows immediately from (b) (note that if C is a compact object of $\tau_{\leqslant n}\mathcal{C}$, then $\tau_{\leqslant m} C$ is a compact object of $\tau_{\leqslant m}\mathcal{C}$ for $0 \leqslant m \leqslant n$). To prove the converse, let us consider the following more refined statement:

$(*_k)$ Let $0 \leqslant k \leqslant n$ and let C be an object of $\tau_{\leqslant n}\mathcal{C}$ such that $\pi_m C$ is Noetherian for $0 \leqslant m \leqslant k$. Then there exists a compact object $D \in \tau_{\leqslant n}\mathcal{C}$ and a map $f : D \to C$ such that the cofiber $\operatorname{cofib}(f)$ (formed in the ∞-category $\mathcal{C}$) satisfies $\pi_m \operatorname{cofib}(f) \simeq 0$ unless $k < m \leqslant n$.

Note that the "if" direction of (b) is an immediate consequence of $(*_n)$. Let us regard n as fixed; we will prove assertion $(*_k)$ using induction on k. The case $k = -1$ is trivial (in this case, we can take $C' = 0$). Let us therefore assume that $k \geqslant 0$ and that C is an n-truncated object of $\mathcal{C}$ such that $\pi_m C$ is Noetherian for $0 \leqslant m \leqslant k$. Applying assumption (b), we can write C as the colimit of a filtered diagram $\{C_\alpha\}$, where each C_α is a compact object of $\tau_{\leqslant n}\mathcal{C}$. It follows from our assumption that $\pi_0 C$ is Noetherian that we can choose some index α for which the map $u : C_\alpha \to C$ induces an epimorphism on π_0. For every integer m, we have a short exact sequence $\pi_{m+1} C \to \pi_m \operatorname{fib}(u) \to \pi_m C_\alpha$. Using assumption (b) and Proposition C.6.8.2, we see that $\pi_m \operatorname{fib}(u)$ is a Noetherian object of $\mathcal{C}^{\heartsuit}$ for $m < k$. Applying our inductive hypothesis, we deduce that there exists a compact object $E \in \tau_{\leqslant n}\mathcal{C}$ and a morphism $g : E \to \operatorname{fib}(u)$ such that $\pi_m \operatorname{cofib}(g)$ vanishes unless $k \leqslant m \leqslant n$. Let D' denote the cofiber of the composite map $E \xrightarrow{g} \operatorname{fib}(u) \to C_\alpha$, so that we have a cofiber sequence $\operatorname{cofib}(g) \to D' \xrightarrow{f'} C$. It follows that D' is an n-truncated object of $\mathcal{C}$. Moreover, it is a compact object of $\tau_{\leqslant n} \mathcal{C}$ (since both E and C_α are compact objects of $\tau_{\leqslant n} \mathcal{C}$).

Let K denote the kernel of the map $(\pi_n f') : \pi_n D' \to \pi_n C$, and let D be the cofiber of the canonical map

$$\Sigma^n K = \Sigma^n \Omega^n \operatorname{fib}(f') \to \operatorname{fib}(f') \to D'.$$

Since D' is a compact object of $\tau_{\leqslant n} \mathcal{C}$, assumption (b) implies that $\pi_n D'$ is a Noetherian object of $\mathcal{C}^{\heartsuit}$, so the subobject $K \subseteq \pi_n D'$ is also Noetherian. In particular, K is a compact object of $\mathcal{C}^{\heartsuit}$ (Proposition C.6.8.7), so that $\Sigma^n K$ is a compact object of $\tau_{\leqslant n} \mathcal{C}$. It follows that $D = \operatorname{cofib}(K \to D')$ is also a compact object of $\tau_{\leqslant n} \mathcal{C}$. The map f' admits an essentially unique factorization $D' \to D \xrightarrow{f} C$. Unwinding the definitions, we have isomorphisms $\pi_m \operatorname{cofib}(f) \xleftarrow{\sim} \pi_m \operatorname{cofib}(f') \simeq \pi_{m-1} \operatorname{cofib}(g)$ for $m \neq n+1$ and $\pi_{n+1} \operatorname{cofib}(f) \simeq 0$. It follows that $\pi_m \operatorname{cofib}(f)$ vanishes unless $k < m \leqslant n$, so that f satisfies the requirements of $(*_k)$. $\square$

Proposition C.6.9.8. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. Then $\mathcal{C}$ is locally Noetherian if and only if it satisfies the following conditions:*

(i) The abelian category $\mathcal{C}^{\heartsuit}$ is locally Noetherian.

(ii) Each Noetherian object $C \in \mathcal{C}^{\heartsuit}$ is almost compact when viewed as an object of $\mathcal{C}$.

Proof. The necessity of condition (i) is immediate, and the necessity of (ii) follows from Proposition C.6.9.3. Conversely, suppose that conditions (i) and (ii) are satisfied; we wish to show that $\mathcal{C}$ is locally Noetherian. We will show that $\mathcal{C}$ satisfies condition (b) of Proposition C.6.9.7. Fix an integer $n \geqslant 0$, and let $\mathcal{E} \subseteq \tau_{\leqslant n} \mathcal{C}$ be the full subcategory spanned by those objects $C \in \tau_{\leqslant n} \mathcal{C}$ for which the objects $\pi_m C \in \mathcal{C}^{\heartsuit}$ are Noetherian for $0 \leqslant m \leqslant n$. It follows from (ii) that each object of $\mathcal{E}$ is an almost compact object of $\mathcal{C}$, and in particular a compact object of $\tau_{\leqslant n} \mathcal{C}$. It follows that the inclusion $\mathcal{E} \hookrightarrow \tau_{\leqslant n} \mathcal{C}$ extends to a fully faithful embedding $f : \operatorname{Ind}(\mathcal{E}) \to \tau_{\leqslant n} \mathcal{C}$ which commutes with filtered colimits. To complete the proof, it will suffice to show that f is essentially surjective. When $n = 0$, this follows from Corollary C.6.8.8. We now proceed by induction on n. Assume therefore that $n > 0$ and that we are given an object $C \in \tau_{\leqslant n} \mathcal{C}$; we wish to show that C belongs to the essential image of f. Note that we have a fiber sequence

$$C \to \tau_{\leqslant n-1} C \xrightarrow{\eta} \Sigma^{n+1}(\pi_n C)$$

in the prestable ∞-category $\mathcal{C}$. Using our inductive hypothesis, we see that $\tau_{\leqslant n-1} C$ can be written as the colimit of a filtered diagram $\{D_\alpha\}$, where each D_α is an $(n-1)$-truncated object of $\mathcal{E}$. For each index α, let η_α denote the composite map $D_\alpha \to \tau_{\leqslant n-1} \to \Sigma^{n+1}(\pi_n C)$, so that $C \simeq \varinjlim \mathrm{fib}(\eta_\alpha)$. Since the essential image of f is closed under filtered colimits, it will suffice to show that each fiber $\mathrm{fib}(\eta_\alpha)$ belongs to the essential image of f. Using assumption (i) (and Corollary C.6.8.8), we can write $\pi_n C$ as a union of Noetherian subobjects. Since D_α is an almost compact object of $\mathcal{C}$, the map $\eta_\alpha : D_\alpha \to \Sigma^{n+1}(\pi_n C)$ factors through $\Sigma^{n+1} E$ for some Noetherian subobject $E \subseteq \pi_n C$. For every Noetherian subobject $E' \subseteq \pi_n C$ containing E, let $\eta_{E'}$ denote the composite map $D_\alpha \to \Sigma^{n+1}(E) \to \Sigma^{n+1}(E')$, so that we can identify $\mathrm{fib}(\eta_\alpha)$ with the colimit $\varinjlim_{E \subseteq E' \subseteq \pi_n C} \mathrm{fib}(\eta_{E'})$. We now complete the proof by observing that each $\mathrm{fib}(\eta_{E'})$ belongs to $\mathcal{E}$. □

Proposition C.6.9.9. *Let $\mathcal{C}$ be a locally Noetherian prestable ∞-category, let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a localizing subcategory, and let $L : \mathcal{C} \to \mathcal{C} / \mathcal{C}_0$ be a left adjoint to the inclusion. Then:*

(1) *The functor L is almost compact (Definition C.6.6.10).*

(2) *The quotient $\mathcal{C} / \mathcal{C}_0$ is locally Noetherian.*

Proof. Let $\mathcal{A}_0 = \mathcal{C}_0 \cap \mathcal{C}^\heartsuit$, and let $\mathcal{C}_1$ be the smallest localizing subcategory of $\mathcal{C}$ which contains $\mathcal{A}_0$. Then L factors as a composition $\mathcal{C} \xrightarrow{L'} \mathcal{C} / \mathcal{C}_1 \xrightarrow{L''} \mathcal{C} / \mathcal{C}_0$, where L' is a left adjoint to the inclusion $\iota : \mathcal{C} / \mathcal{C}_1 \hookrightarrow \mathcal{C}$ and the functor L'' induces an equivalence on completions. By virtue of Proposition C.5.2.8, an object $X \in \mathcal{C}$ is $\mathcal{C}_1$-local if and only if $\mathrm{Ext}^*_{\mathrm{Sp}(\mathcal{C})}(A, X)$ vanishes for each object $A \in \mathcal{A}_0$. Since $\mathcal{C}$ is locally Noetherian, every object $A \in \mathcal{A}_0$ can be written as a union of Noetherian subobjects. Consequently, an object $X \in \mathcal{C}$ is $\mathcal{C}_1$-local if and only if $\mathrm{Ext}^*_{\mathrm{Sp}(\mathcal{C})}(A, X)$ vanishes for every Noetherian object $A \in \mathcal{A}_0$. Fix an integer $n \geqslant 0$. Since every Noetherian object of $\mathcal{C}^\heartsuit$ is compact when viewed as an object of $\tau_{\leqslant n} \mathcal{C}$ (Proposition C.6.9.8), it follows that the collection of n-truncated $\mathcal{C}_1$-local objects of $\mathcal{C}$ is closed under filtered colimits. Allowing n to vary, we deduce that the functor L' is almost compact. Since L'' induces an equivalence on completions, it follows that the functor $L \simeq L'' \circ L'$ is also almost compact.

We now claim that $\mathcal{C} / \mathcal{C}_0$ is locally Noetherian. It follows from Proposition C.6.8.11 that the abelian category $(\mathcal{C} / \mathcal{C}_0)^\heartsuit \simeq \mathcal{C}^\heartsuit / \mathcal{A}_0$ is locally Noetherian. Moreover, using (1) (or the proof of Proposition C.6.8.11), we see that the functor L carries Noetherian objects of $\mathcal{C}^\heartsuit$ to Noetherian objects of $(\mathcal{C} / \mathcal{C}_0)^\heartsuit$. Every object $X \in \mathcal{C}^\heartsuit$ can be written as a filtered union of its Noetherian subobjects $\{X_\alpha\}$, so that $LX \in (\mathcal{C} / \mathcal{C}_0)^\heartsuit$ is a filtered union of Noetherian subobjects $\{LX_\alpha\}$. If LX is a Noetherian object of $(\mathcal{C} / \mathcal{C}_0)^\heartsuit$, we must have $LX \simeq LX_\alpha$ for some α. In this case, X_α is an almost compact object of $\mathcal{C}$ (Proposition C.6.9.8), so that (1) implies that $LX \simeq LX_\alpha$ is an almost compact object of $\mathcal{C} / \mathcal{C}_0$. In particular, every Noetherian object of $(\mathcal{C} / \mathcal{C}_0)^\heartsuit$ is an almost compact object of $\mathcal{C} / \mathcal{C}_0$, so that $\mathcal{C} / \mathcal{C}_0$ is locally Noetherian by virtue of Proposition C.6.9.8. □

C.6.10 Injective Objects in the Locally Noetherian Setting

Let $\mathcal{A}$ be a locally Noetherian abelian category. It follows from Proposition C.5.6.12 that an object $Q \in \mathcal{A}$ is injective if and only if the group $\mathrm{Ext}^1_{\mathcal{A}}(X, Q)$ vanishes for every Noetherian object $X \in \mathcal{A}$. We now establish an ∞-categorical analogue:

Proposition C.6.10.1. *Let $\mathcal{C}$ be a locally Noetherian prestable ∞-category and let $Q \in \mathrm{Sp}(\mathcal{C})_{\leqslant 0}$. The following conditions are equivalent:*

- (a) *The object Q is injective: that is, for each object $X \in \mathcal{C}^{\heartsuit}$, the groups $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X, Q)$ vanish for $n > 0$ (see Definition HA.**??**).*
- (b) *For each Noetherian object $X \in \mathcal{C}^{\heartsuit}$, the groups $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X, Q)$ vanish for $n > 0$.*

Proof. The implication $(a) \Rightarrow (b)$ is immediate. Conversely, suppose that (b) is satisfied. Choose an object $X \in \mathcal{C}^{\heartsuit}$ and an element $\eta \in \mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X, Q)$ for $n > 0$, which we can identify with a morphism $f : X \to \Sigma^n Q$. We wish to show that f is nullhomotopic. Define a transfinite sequence of subobjects $\{X_\alpha \subseteq X\}$ as follows:

- If $\alpha = 0$, we set $X_\alpha = 0$.
- If α is a nonzero limit ordinal, we set $X_\alpha = \varinjlim_{\beta < \alpha} X_\beta$.
- If $\alpha = \beta + 1$ is a successor ordinal, we take X_α to be the preimage in X of a nonzero Noetherian subobject $Y_\alpha \subseteq X/X_\beta$, provided that such an object exists: otherwise, we take $Y_\alpha = 0$ and set $X_\alpha = X_\beta$.

For each ordinal α, let K_α denote the homotopy fiber product $\{f\} \times_{\mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(X_\alpha, \Sigma^n Q)} \{0\}$ (in other words, the classifying space for nullhomotopies of $f|_{X_\alpha}$). Note that K_0 is contractible, that $K_\alpha \simeq \varprojlim_{\beta < \alpha} K_\beta$ when α is a nonzero limit ordinal, and that we have canonical fiber sequences $K_\alpha \xrightarrow{\rho_\beta} K_\beta \to \mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(Y_\alpha, \Sigma^n Q)$ when $\alpha = \beta + 1$ is a successor ordinal. Since each Y_α is Noetherian, assumption (b) guarantees that the mapping spaces $\mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(Y_\alpha, \Sigma^n Q)$ are connected. It follows that each of the maps ρ_β is surjective on connected components, so that each of the spaces K_α is nonempty. Because X has a bounded number of isomorphism classes of subobjects, we must have $X_\alpha \simeq X$ for $\alpha \gg 0$, so the fact that K_α is nonempty guarantees that the map $f : X \to \Sigma^n Q$ is nullhomotopic as desired. □

Proposition C.6.10.2. *Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. Then $\mathcal{C}$ is locally Noetherian if and only if it satisfied the following conditions:*

- (i) *The abelian category $\mathcal{C}^{\heartsuit}$ is locally Noetherian.*
- (ii) *The collection of injective objects of $\mathrm{Sp}(\mathcal{C})$ is closed under small filtered colimits.*

Proof. The necessity of condition (i) is obvious, and the necessity of (ii) follows from Proposition C.6.10.1. Conversely, suppose that $\mathcal{C}$ satisfies conditions (i) and (ii); we wish to show that $\mathcal{C}$ is locally Noetherian. By virtue of Proposition C.6.9.8, it will suffice to show that every Noetherian object $X \in \mathcal{C}^{\heartsuit}$ is compact when viewed as an object of $\mathrm{Sp}(\mathcal{C})_{\leqslant n}$, for every integer $n \geqslant 0$. Our proof proceeds by induction on n; when $n = 0$, the desired result follows from Proposition C.6.8.7. To carry out the inductive step, it will suffice to show that the construction $(Y \in \mathrm{Sp}(\mathcal{C})_{\leqslant n}) \mapsto (\mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(X, Y) \in \mathcal{S})$ commutes with colimits indexed by $\mathrm{N}(A)$ for every filtered partially ordered set A. Set $\mathcal{C}' = \mathrm{Fun}(\mathrm{N}(A), \mathcal{C})$ and let $\vec{Y}$ be an object of $\mathrm{Sp}(\mathcal{C}')_{\leqslant n} \simeq \mathrm{Fun}(\mathrm{N}(A), \mathrm{Sp}(\mathcal{C})_{\leqslant n})$. Choose a morphism $f : \vec{Y} \to \Sigma^n \vec{Q}$ in $\mathrm{Sp}(\mathcal{C}')$ which exhibits $\vec{Q}$ as an injective hull of $\vec{Y}$ (Example C.5.7.9), so that $\vec{Y}' = \mathrm{fib}(f)$ belongs to $\mathrm{Sp}(\mathcal{C}')_{\leqslant n-1}$. We then have a commutative diagram of fiber sequences

$$\begin{array}{ccccc} \varinjlim \mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(X, \vec{Y}'(\alpha)) & \longrightarrow & \varinjlim \mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(X, \vec{Y}(\alpha)) & \longrightarrow & \varinjlim \mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(X, \Sigma^n \vec{Q}(\alpha)) \\ \downarrow{\scriptstyle \rho'} & & \downarrow{\scriptstyle \rho} & & \downarrow{\scriptstyle \rho''} \\ \mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(X, \varinjlim \vec{Y}'(\alpha)) & \longrightarrow & \mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(X, \varinjlim \vec{Y}(\alpha)) & \longrightarrow & \mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(X, \Sigma^n \varinjlim \vec{Q}(\alpha)). \end{array}$$

Note that for each $\alpha \in A$, evaluation at α determines a functor $e_\alpha : \mathrm{Sp}(\mathcal{C}') \to \mathrm{Sp}(\mathcal{C})$ with a t-exact left adjoint (given by left Kan extension along the inclusion $\{\alpha\} \hookrightarrow A$). It follows that e_α carries injective objects of $\mathrm{Sp}(\mathcal{C}')$ to injective objects of $\mathrm{Sp}(\mathcal{C})$. In particular, the objects $\vec{Q}(\alpha)$ are injective for each $\alpha \in A$, so the mapping spaces $\mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(X, \Sigma^n \vec{Q}(\alpha))$ are n-connective Assumption (ii) guarantees that $\varinjlim \vec{Q}(\alpha)$ is also an injective object of $\mathrm{Sp}(\mathcal{C})$, so that the codomain of ρ'' is also n-connective. It follows that the map

$$\pi_m(\rho'') : \pi_m \varinjlim \mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(X, \Sigma^n \vec{Q}(\alpha)) \to \pi_m \mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(X, \Sigma^n \varinjlim \vec{Q}(\alpha))$$

is an isomorphism for every integer m: if $m \neq n$, then both sides vanish; if $m = n$, then we invoke the fact that X is compact as an object of the abelian category $\mathcal{C}^{\heartsuit}$, by virtue of Proposition C.6.8.7. It follows that ρ'' is a homotopy equivalence between connected spaces. Consequently, to show that ρ is a homotopy equivalence, it will suffice to show that ρ' is a homotopy equivalence, which follows from our inductive hypothesis. □

Corollary C.6.10.3. *Let $\mathcal{C}$ be a locally Noetherian prestable ∞-category. Then the collection of injective objects of* $\mathrm{Sp}(\mathcal{C})$ *is closed under (possibly infinite) coproducts.*

Definition C.6.10.4. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let Q be a nonzero object of $\mathrm{Sp}(\mathcal{C})$. We will say that Q is *indecomposable* if it cannot be written as a direct sum $Q' \oplus Q''$, where Q' and Q'' are nonzero objects of $\mathrm{Sp}(\mathcal{C})$.

Remark C.6.10.5. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category and let Q be an injective object of $\mathrm{Sp}(\mathcal{C})$. Then Q is indecomposable if and only if $\pi_0 Q$ is an indecomposable injective object of the abelian category $\mathcal{C}^{\heartsuit}$:this is an immediate consequence of Theorem C.5.7.4.

We have the following analogue of Proposition C.5.6.16:

Proposition C.6.10.6. *Let $\mathcal{C}$ be a locally Noetherian prestable ∞-category and let Q be an object of $\mathrm{Sp}(\mathcal{C})$. The following conditions are equivalent:*

(1) *The object Q is injective.*

(2) *There exists an equivalence $Q \simeq \bigoplus_\alpha Q_\alpha$, where each Q_α is an injective object of $\mathrm{Sp}(\mathcal{C})$.*

(3) *There exists an equivalence $Q \simeq \bigoplus_\alpha Q_\alpha$, where each Q_α is an indecomposable injective object of $\mathrm{Sp}(\mathcal{C})$.*

Proof. The implication (3) ⇒ (2) is obvious and the implication (2) ⇒ (1) follows from Corollary C.6.10.3. We will show that (1) ⇒ (3). Let Q be an injective object of $\mathrm{Sp}(\mathcal{C})$. Then $\pi_0 Q$ is an injective object of the abelian category $\mathcal{C}^\heartsuit$. Using Proposition C.5.6.16, we can choose an equivalence $u_0 : \amalg_\alpha Q_{0\alpha} \simeq \pi_0 Q$, where each $Q_{0\alpha}$ is an indecomposable injective object of $\mathcal{C}^\heartsuit$. Using Proposition C.5.7.8, we can lift each $Q_{0\alpha}$ to an injective object $Q_\alpha \in \mathrm{Sp}(\mathcal{C})$ (which is indecomposable by virtue of Remark C.6.10.5). Applying Proposition C.5.7.3 (and the injectivity of Q), we can lift u_0 to a morphism $u : \bigoplus Q_\alpha \to Q$ in $\mathrm{Sp}(\mathcal{C})$. It follows from Corollary C.6.10.3 that the domain of u is injective. Since u_0 is an isomorphism, Theorem C.5.7.4 guarantees that u is an equivalence. □

Example C.6.10.7. Let R be a Noetherian $\mathbb{E}_\infty$-ring. Using Corollary C.5.6.11 and Theorem C.5.7.4, we see that the following conditions on an R-module Q are equivalent:

(1) The R-module Q is indecomposable and injective.

(2) The R-module Q is an injective hull (in the sense of Example C.5.7.9) of some residue field κ of R.

Appendix D

Descent for Modules and Linear ∞-Categories

Let $f : U \to X$ be a map of schemes, and let $p, q : U \times_X U \to U$ denote the two projection maps. A *descent datum* is a pair $(\mathscr{F}, \alpha)$, where $\mathscr{F}$ is a quasi-coherent sheaf on U and $\alpha : p^* \mathscr{F} \to q^* \mathscr{F}$ is an isomorphism of quasi-coherent sheaves on $U \times_X U$ which satisfies a suitable cocycle condition. There is a functor from the category of quasi-coherent sheaves on X to the category of descent data, given by $\mathscr{F}_0 \mapsto (f^* \mathscr{F}_0, \alpha)$, where α denotes the evident isomorphism

$$p^*(f^* \mathscr{F}_0) \simeq (f \circ p)^* \mathscr{F}_0 = (f \circ q)^* \mathscr{F}_0 \simeq q^*(f^* \mathscr{F}_0).$$

The classical theory of *faithfully flat descent* guarantees that this functor is an equivalence of categories whenever the map f is faithfully flat and quasi-compact. This is the basis for an important technique in algebraic geometry: one can often reduce questions about X (or about quasi-coherent sheaves on X) to questions about U, which may be easier to answer.

In the special case where the schemes $X = \operatorname{Spec} A$ and $U = \operatorname{Spec} B$ are affine, the theory of faithfully flat descent can be phrased entirely in the language of commutative algebra: it asserts that if B is faithfully flat over A, then the category of (discrete) A-modules can be identified with the category whose objects are pairs (M_B, α), where M_B is a (discrete) B-module and $\alpha : B \otimes_A M_B \to M_B \otimes_A B$ is an isomorphism of $(B \otimes_A B)$-modules satisfying a cocycle condition. Our goal in this appendix is to discuss some analogous statements in a higher-categorical setting, which differs in three important respects:

(a) In place of the ordinary category $\operatorname{Mod}_A^{\heartsuit}$ of discrete A-modules, we study the ∞-category Mod_A of *A-module spectra*. This necessitates working with a more elaborate notion of descent datum: to recover an A-module M from the tensor product $M_B = B \otimes_A M$, one needs more than just the equivalence $\alpha : B \otimes_A M_B \simeq M_B \otimes_A B$. Instead, we should ask that M_B be promoted to an object of the totalization of the cosimplicial ∞-category

$$\mathrm{Mod}_B \rightrightarrows \mathrm{Mod}_{B \otimes_A B} \rightrightarrows \mathrm{Mod}_{B \otimes_A B \otimes_A B} \rightrightarrows \cdots .$$

More informally, this amounts to the requirement that M_B is equipped with an equivalence $\alpha : B \otimes_A M_B \simeq M_B \otimes_A B$ satisfying a *cocycle condition up to coherent homotopy*.

(*b*) In order for the theory developed in this appendix to be useful for the study of spectral algebraic geometry, it is important that we do not require that A and B are ordinary commutative rings: the theory of faithfully flat descent makes sense more generally for modules over $\mathbb{E}_\infty$-rings (in fact, many of the results of this appendix make sense more generally for $\mathbb{E}_2$-rings).

(*c*) If A is an ordinary commutative ring, then one can study A-modules in any additive category $\mathcal{A}$ (the usual theory of discrete A-modules is obtained by taking $\mathcal{A}$ to be the category of abelian groups). More generally, if A is a (connective) $\mathbb{E}_\infty$-ring, one can study A-modules in any additive ∞-category $\mathcal{C}$. Much of the basic apparatus of descent theory makes sense in this more general setting (under some mild assumptions on $\mathcal{C}$).

We begin our study of descent in §D.1 by introducing the notion of an *additive A-linear ∞-category*, where A is a connective $\mathbb{E}_\infty$-ring (Definition D.1.2.1). Roughly speaking, an additive A-linear ∞-category is a presentable ∞-category $\mathcal{C}$ in which each mapping space $\mathrm{Map}_{\mathcal{C}}(C, D)$ can be regarded as (the 0th space of) a connective A-module spectrum. We will be primarily interested in the situations where $\mathcal{C}$ is a stable ∞-category (in which case we can drop the connectivity assumption on A; see Variant D.1.5.1), but the cases where $\mathcal{C}$ is a prestable ∞-category or an ordinary abelian category are also of considerable interest.

Let A be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be an additive A-linear ∞-category. Then every object $X \in \mathcal{C}$ can be regarded as an A-module in a canonical way. If $\phi : A \to B$ is a morphism of connective $\mathbb{E}_\infty$-rings, then one can consider *B-modules* in $\mathcal{C}$: that is, objects $X \in \mathcal{C}$ which are equipped with an action of B which is compatible with the tautological action of A. The collection of such B-modules forms an ∞-category that we will denote $\mathrm{LMod}_B(\mathcal{C})$. In §D.2, we will see that the ∞-category $\mathrm{LMod}_B(\mathcal{C})$ is naturally an additive B-linear ∞-category, which we can think of as obtained from $\mathcal{C}$ by *extension of scalars* along the morphism ϕ (to emphasize this perspective, we will often denote $\mathrm{LMod}_B(\mathcal{C})$ by $B \otimes_A \mathcal{C}$).

To every additive A-linear ∞-category $\mathcal{C}$ and every morphism $\phi : A \to B$ as above, one can form a cosimplicial ∞-category

$$\mathrm{LMod}_B(\mathcal{C}) \rightrightarrows \mathrm{LMod}_{B \otimes_A B}(\mathcal{C}) \rightrightarrows \mathrm{LMod}_{B \otimes_A B \otimes_A B}(\mathcal{C}) \rightrightarrows \cdots$$

whose inverse limit can be thought of as B-modules in $\mathcal{C}$ equipped with descent data. The fundamental question of this appendix can be formulated as follows: under what conditions is this ∞-category equivalent to $\mathcal{C}$? In §D.3, we supply a partial answer to this question by introducing the notion of a *universal descent morphism* of $\mathbb{E}_\infty$-rings. Roughly speaking, a morphism $\phi : A \to B$ is a universal descent morphism if every *stable* A-linear ∞-category $\mathcal{C}$ is equivalent to the totalization of the cosimplicial ∞-category above. This condition can be reformulated in more concrete terms and verified for a large class of morphisms of $\mathbb{E}_\infty$-rings (including, for example, all morphisms which are faithfully flat and étale).

In §D.4, we study the problem of descent in the setting of a *prestable* A-linear ∞-category $\mathcal{C}$ which is not necessarily stable. In this case, one still has a descent theorem under a the slightly more restrictive hypothesis that $\phi : A \to B$ is a faithfully flat universal descent morphism (see Theorem D.4.1.6); this result applies in particular if ϕ is faithfully flat and étale. In this case, there is a close relationship between properties of the ∞-category $\mathcal{C}$ and properties of the ∞-category $\mathrm{LMod}_B(\mathcal{C})$, which we will explore in detail in §D.5.

Unfortunately, we do not know if an arbitrary faithfully flat morphism of $\mathbb{E}_\infty$-rings $\phi : A \to B$ is an universal descent morphism (this is true under some mild assumptions regarding the cardinality of A and B, however: see Proposition D.3.3.1). Nevertheless, we will show in §D.6 that many of the descent theorems established in §D.3 for universal descent morphisms are valid for arbitrary faithfully flat morphisms under some mild additional restrictions (see Theorem D.6.3.1).

Contents

D.1 Ring Actions on ∞-Categories

Let $\mathcal{A}$ be an additive category. Then $\mathcal{A}$ is enriched over the category of abelian groups: for every pair of objects $X, Y \in \mathcal{A}$, the set $\mathrm{Hom}_{\mathcal{A}}(X, Y)$ of morphisms from X to Y admits the structure of an abelian group, and for every triple of objects $X, Y, Z \in \mathcal{A}$ the composition map $\mathrm{Hom}_{\mathcal{A}}(Y, Z) \times \mathrm{Hom}_{\mathcal{A}}(X, Y) \to \mathrm{Hom}_{\mathcal{A}}(X, Z)$ is bilinear and is therefore classified by a group homomorphism

$$\mathrm{Hom}_{\mathcal{A}}(Y, Z) \otimes \mathrm{Hom}_{\mathcal{A}}(X, Y) \to \mathrm{Hom}_{\mathcal{A}}(X, Y)$$

(here the tensor product is formed in the category of abelian groups).

Many additive categories $\mathcal{A}$ which arise in practice come equipped with additional structure. If R is a commutative ring, then the following data are equivalent:

(a) An enrichment of $\mathcal{A}$ over the category of R-modules: that is, an R-module structure on each of sets $\mathrm{Hom}_{\mathcal{A}}(X, Y)$ for which the composition maps $\mathrm{Hom}_{\mathcal{A}}(Y, Z) \times \mathrm{Hom}_{\mathcal{A}}(X, Y) \to \mathrm{Hom}_{\mathcal{A}}(X, Z)$ are R-bilinear (and therefore classifies by R-module homomorphisms $\mathrm{Hom}_{\mathcal{A}}(Y, Z) \otimes_R \mathrm{Hom}_{\mathcal{A}}(X, Y) \to \mathrm{Hom}_{\mathcal{A}}(X, Y)$).

(b) An action of R on each object $X \in \mathcal{A}$ via a ring homomorphism $\phi_X : R \to \mathrm{Hom}_{\mathcal{A}}(X, X)$, which depends functorially on X in the following sense: for every morphism $f : X \to Y$ in $\mathcal{A}$ and every element $a \in R$, the diagram

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ \downarrow{\scriptstyle \phi_X(a)} & & \downarrow{\scriptstyle \phi_Y(a)} \\ X & \xrightarrow{f} & Y \end{array}$$

commutes.

(c) An action of R on the identity functor $\mathrm{id}_{\mathcal{A}}$: that is, a ring homomorphism $\phi : R \to \mathrm{Hom}_{\mathrm{Fun}(\mathcal{A},\mathcal{A})}(\mathrm{id}_{\mathcal{A}}, \mathrm{id}_{\mathcal{A}})$.

(d) A monoidal functor $\Phi : \mathrm{Mod}_R^{\mathrm{ff}} \to \mathrm{Fun}(\mathcal{A}, \mathcal{A})$ which commutes with finite direct sums; here $\mathrm{Mod}_R^{\mathrm{ff}}$ denotes the category of free R-modules of finite rank and we regard $\mathrm{Fun}(\mathcal{A}, \mathcal{A})$ as a monoidal category with respect to composition.

We will refer to any of these equivalent data as an *action of R on the additive category $\mathcal{A}$*.

In this section, we will introduce an ∞-categorical generalization of the preceding definition, where we allow $\mathcal{A}$ to be an additive ∞-category and R to be a (connective) ring spectrum. In this book, we will be primarily interested in the case where R is an $\mathbb{E}_\infty$-ring. However, the definition below makes sense whenever R is an $\mathbb{E}_2$-ring, and working in this greater generality has some advantages.

D.1.1 Ring Actions on Additive ∞-Categories

Let R be a connective $\mathbb{E}_2$-ring. We let $\mathrm{LMod}_R^{\mathrm{ff}}$ denote the full subcategory of LMod_R spanned by those left R-modules which are free of finite rank over R. The full subcategory $\mathrm{LMod}_R^{\mathrm{ff}}$ contains the unit object $R \in \mathrm{LMod}_R$ and is closed under the tensor product $\otimes_R$, and therefore inherits the structure of a monoidal ∞-category.

Definition D.1.1.1. Let $\mathcal{A}$ be an additive ∞-category and let R be a connective $\mathbb{E}_2$-ring. An *action of R on $\mathcal{A}$* is a monoidal functor $\mathrm{LMod}_R^{\mathrm{ff}} \to \mathrm{Fun}(\mathcal{A}, \mathcal{A})$ which commutes with finite direct sums.

Remark D.1.1.2. Let $\mathcal{A}$ be an additive ∞-category, let R be a connective $\mathbb{E}_2$-ring, and let $\phi : \mathrm{LMod}_R^{\mathrm{ff}} \to \mathrm{Fun}(\mathcal{A}, \mathcal{A})$. be an action of R on $\mathcal{A}$. Then ϕ carries each object of $\mathrm{LMod}_R^{\mathrm{ff}}$ to a direct sum of finitely many copies of the identity functor $\mathrm{id}_{\mathcal{A}}$. Consequently, if $\mathrm{Fun}'(\mathcal{A}, \mathcal{A})$ is any full subcategory of $\mathrm{Fun}(\mathcal{A}, \mathcal{A})$ which is closed under finite direct sums, then ϕ automatically factors through $\mathrm{Fun}'(\mathcal{A}, \mathcal{A})$. For example, we can take $\mathrm{Fun}'(\mathcal{A}, \mathcal{A})$ to be the full subcategory $\mathrm{Fun}^{\pi}(\mathcal{A}, \mathcal{A}) \subseteq \mathrm{Fun}(\mathcal{A}, \mathcal{A})$ spanned by those functors which preserve finite products.

Remark D.1.1.3. Let $\mathcal{A}$ be an additive ∞-category. Giving an action of a connective $\mathbb{E}_2$-ring on $\mathcal{A}$ is equivalent to exhibiting $\mathcal{A}$ as an ∞-category which is left-tensored over the monoidal ∞-category $\mathrm{LMod}_R^{\mathrm{ff}}$ via an action $a : \mathrm{LMod}_R^{\mathrm{ff}} \times \mathcal{A} \to \mathcal{A}$ which preserves finite direct sums in the first variable. By virtue of Remark **??**, it follows automatically that a preserves finite direct sums in the second variable as well.

Remark D.1.1.4. Let $\mathcal{A}$ be a small additive ∞-category. Then the ∞-category $\mathrm{Ind}(\mathcal{A})$ is also additive. Let us abuse notation by identifying $\mathcal{A}$ with its essential image under the Yoneda embedding $j : \mathcal{A} \to \mathrm{Ind}(\mathcal{A})$, and let $\mathrm{Fun}'(\mathrm{Ind}(\mathcal{A}), \mathrm{Ind}(\mathcal{A}))$ denote the full subcategory of $\mathrm{Fun}(\mathrm{Ind}(\mathcal{A}), \mathrm{Ind}(\mathcal{A}))$ spanned by those functors which preserve small filtered colimits and carry $\mathcal{A}$ into itself. Then the restriction functor $\mathrm{Fun}'(\mathrm{Ind}(\mathcal{A}), \mathrm{Ind}(\mathcal{A})) \to \mathrm{Fun}(\mathcal{A}, \mathcal{A})$ is an equivalence of ∞-categories.

Let R be a connective $\mathbb{E}_2$-ring. Invoking Remark D.1.1.2, we see that giving an action of R on $\mathrm{Ind}(\mathcal{A})$ is equivalent to giving an action of R on $\mathcal{A}$ itself. Using a similar argument (using sifted colimits in place of filtered colimits), we see that giving an action of R on $\mathcal{A}$ is equivalent to giving an action of R on the presentable additive ∞-category $\mathcal{P}_{\Sigma}(\mathcal{A}) = \mathrm{Fun}^{\pi}(\mathcal{A}^{\mathrm{op}}, \mathcal{S})$.

In what follows, we will generally restrict our attention to the study of actions on *presentable* additive ∞-categories $\mathcal{A}$ (by virtue of Remark D.1.1.4, this does not really involve any loss of generality).

Remark D.1.1.5. Let R be a connective $\mathbb{E}_2$-ring. Then the objects $\{R^n \in \mathrm{LMod}_R^{\mathrm{cn}}\}_{n \geqslant 0}$ form a set of compact projective generators for $\mathrm{LMod}_R^{\mathrm{cn}}$ which is closed under the formation fo finite coproducts (Corollary HA.7.1.4.15). It follows that we can identify $\mathrm{LMod}_R^{\mathrm{cn}}$ with the ∞-category $\mathcal{P}_\Sigma(\mathrm{LMod}_R^{\mathrm{ff}})$ obtained by freely adjoining sifted colimits to $\mathrm{LMod}_R^{\mathrm{ff}}$.

Suppose that $\mathcal{C}$ is a presentable ∞-category equipped with a monoidal structure for which the tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves small colimits separately in each variable, let $\mathrm{Fun}^{\otimes}(\mathrm{LMod}_R^{\mathrm{cn}}, \mathcal{C})$ denote the ∞-category of monoidal functors from $\mathrm{LMod}_R^{\mathrm{cn}}$ to $\mathcal{C}$, and define $\mathrm{Fun}^{\otimes}(\mathrm{LMod}_R^{\mathrm{ff}}, \mathcal{C})$ similarly. It follows from the formalism of §HA.4.8.1 that the restriction functor $\mathrm{Fun}^{\otimes}(\mathrm{LMod}_R^{\mathrm{cn}}, \mathcal{C}) \to \mathrm{Fun}^{\otimes}(\mathrm{LMod}_R^{\mathrm{ff}}, \mathcal{C})$ induces an equivalence from the full subcategory of $\mathrm{Fun}^{\otimes}(\mathrm{LMod}_R^{\mathrm{cn}}, \mathcal{C})$ spanned by those monoidal functors which preserve small colimits to the full subategory of $\mathrm{Fun}^{\otimes}(\mathrm{LMod}_R^{\mathrm{ff}}, \mathcal{C})$ spanned by those functors which preserve finite coproducts.

D.1.2 R-Linear ∞-Categories

Let R be a connective $\mathbb{E}_2$-ring. Applying Remark D.1.1.5 in the special case where $\mathcal{C} = \mathrm{LFun}(\mathcal{A}, \mathcal{A})$ for some presentable additive ∞-category $\mathcal{A}$, we see that the following data are equivalent:

- (i) Actions of R on $\mathcal{A}$: that is, monoidal functors $\mathrm{LMod}_R^{\mathrm{ff}} \to \mathrm{Fun}(\mathcal{A}, \mathcal{A})$ which preserve finite coproducts.
- (ii) Monoidal functors $\mathrm{LMod}_R^{\mathrm{ff}} \to \mathrm{LFun}(\mathcal{A}, \mathcal{A})$ which preserve finite coproducts (see Remark D.1.1.2).
- (iii) Monoidal functors $\mathrm{LMod}_R^{\mathrm{cn}} \to \mathrm{LFun}(\mathcal{A}, \mathcal{A})$ which preserve small colimits.
- (iv) Left actions of $\mathrm{LMod}_R^{\mathrm{cn}}$ (regarded as an algebra object of the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$) on $\mathcal{A}$ (regarded as an object of $\mathcal{P}\mathrm{r}^{\mathrm{L}}$).

This motivates the following definition:

Definition D.1.2.1. Let R be a connective $\mathbb{E}_2$-ring, and regard the monoidal ∞-category $\mathrm{LMod}_R^{\mathrm{cn}}$ as an algebra object of the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable ∞-categories. We let $\mathrm{LinCat}_R^{\mathrm{Add}}$ denote the ∞-category $\mathrm{LMod}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$. We will refer to the objects of $\mathrm{LinCat}_R^{\mathrm{Add}}$ as *additive R-linear ∞-categories*, and to $\mathrm{LinCat}_R^{\mathrm{Add}}$ itself as the *∞-category of R-linear ∞-categories*.

Remark D.1.2.2. Let R be a connective $\mathbb{E}_2$-ring and let $\mathcal{A} \in \mathrm{LinCat}_R^{\mathrm{Add}}$ be a presentable ∞-category equipped with an action of $\mathrm{LMod}_R^{\mathrm{cn}}$. Then $\mathcal{A}$ can also be regarded as a module over the ∞-category $\mathrm{LMod}_S^{\mathrm{cn}} = \mathrm{Sp}^{\mathrm{cn}}$, and is therefore automatically additive (Corollary C.4.1.3). Conversely, if $\mathcal{A}$ is a presentable additive ∞-category, then the preceding discussion shows that promoting $\mathcal{A}$ to an object of $\mathrm{LinCat}_R^{\mathrm{Add}}$ is equivalent to giving an action of R on $\mathcal{A}$ (in the sense of Definition D.1.1.1).

Remark D.1.2.3. If R is a discrete commutative ring, then the theory of additive R-linear ∞-categories is closely related to the theory of *differential graded categories* over R (see §HA.1.3.1).

Notation D.1.2.4. Let R be an $\mathbb{E}_2$-ring and let $\mathcal{A}$ be an additive R-linear ∞-category. The action of R on $\mathcal{A}$ determines a functor $a : \mathrm{LMod}_R^{\mathrm{cn}} \times \mathcal{A} \to \mathcal{A}$. Given a connective left R-module M and an object $X \in \mathcal{A}$, we will denote the image of (M, X) under this functor by $M \otimes_R X$.

Warning D.1.2.5. Let R be a connective $\mathbb{E}_2$-ring. We have defined an additive R-linear ∞-category to be a presentable ∞-category $\mathcal{A}$ equipped with a left action of the presentable monoidal ∞-category $\mathrm{LMod}_R^{\mathrm{cn}}$. There are several obvious variants:

(a) We can consider right actions of $\mathrm{LMod}_R^{\mathrm{cn}}$ on $\mathcal{A}$.

(b) We can consider left actions of $\mathrm{RMod}_R^{\mathrm{cn}}$ on $\mathcal{A}$.

(c) We can consider right actions of $\mathrm{RMod}_R^{\mathrm{cn}}$ on $\mathcal{A}$.

Using the fact that the matrix $\begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}$ belongs to the identity component of the orthogonal group $\mathrm{O}(2)$ (which acts on the $\mathbb{E}_2$-operad), we see that datum (c) is (noncanonically) equivalent to the datum of an action of R on $\mathcal{A}$, and the data (a) and (b) are (noncanonically) equivalent to one another (both are equivalent to giving an action of the $\mathbb{E}_2$-ring R^{rev} on $\mathcal{A}$, where R^{rev} denotes the reverse of R in the sense of Construction HA.5.2.5.18). Note that this somewhat technical point is relevant only when R is not fully commutative: if R is a connective $\mathbb{E}_\infty$-ring, then the data (a), (b), and (c) are all *canonically* equivalent to supplying an action of R on $\mathcal{A}$, and we can identify the $\mathrm{LinCat}_R^{\mathrm{Add}}$ with the (symmetrically defined) ∞-category $\mathrm{Mod}_{\mathrm{Mod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$.

Warning D.1.2.6. The definition of additive R-linear ∞-category $\mathcal{A}$ supplied by Definition D.1.2.1 is perhaps unnecessarily restrictive, because we require $\mathcal{A}$ to be a presentable ∞-category. A more liberal definition might encompass *any* additive ∞-category $\mathcal{A}$ which equipped with an action of R, in the sense of Definition D.1.1.1. Our choice of terminology is motivated by the desire to avoid awkward language, since most of the actions we wish to study in this book are on *presentable* ∞-categories.

D.1.3 The Center of an Additive ∞-Category

Let $\mathcal{A}$ be an additive category. Then the endomorphism ring $E = \mathrm{Hom}_{\mathrm{Fun}(\mathcal{A},\mathcal{A})}(\mathrm{id}_{\mathcal{A}}, \mathrm{id}_{\mathcal{A}})$ is a commutative ring. For any commutative ring R, equipping $\mathcal{A}$ with the structure of an R-linear category is equivalent to choosing a ring homomorphism $\phi : R \to E$. In the ∞-categorical setting, there is a similar picture with one important difference: the endomorphism ring E is an $\mathbb{E}_2$-ring, rather than an $\mathbb{E}_\infty$-ring.

Notation D.1.3.1. For every connective $\mathbb{E}_1$-ring R, we can regard $\mathrm{LMod}_R^{\mathrm{cn}}$ as a presentable additive ∞-category with a distinguished object (given by R, regarded as a left module over itself). The construction $R \mapsto (\mathrm{LMod}_R^{\mathrm{cn}}, R)$ determines a functor

$$\Theta_* : \mathrm{Alg}(\mathrm{Sp}^{\mathrm{cn}}) \to \mathrm{Alg}_{\mathbb{E}_0}(\mathcal{P}\mathrm{r}^{\mathrm{Add}}) \simeq \mathrm{Alg}_{\mathbb{E}_0}(\mathrm{Mod}_{\mathrm{Sp}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})).$$

According to Theorem HA.4.8.5.11 , the functor Θ_* admits a right adjoint G which carries a presentable ∞-category $\mathcal{C}$ with a distinguished object $X \in \mathcal{C}$ to its endomorphism algebra $\mathrm{End}(X) \in \mathrm{Alg}(\mathrm{Sp}^{\mathrm{cn}})$, a connective $\mathbb{E}_1$-ring satisfying $\Omega^\infty \mathrm{End}(X) \simeq \mathrm{Map}_{\mathcal{C}}(X, X)$.

According to Theorem HA.4.8.5.16 , the functor Θ_* is symmetric monoidal. It follows that the functor G is lax symmetric monoidal. Suppose that $\mathcal{C}$ is an associative algebra object of $\mathcal{P}\mathrm{r}^{\mathrm{Add}}$: that is, a monoidal presentable ∞-category for which tensor product functor $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves small colimits separately in each variable. Then we can regard $(\mathcal{C}, \mathbf{1})$ as an algebra object of $\mathrm{Alg}_{\mathbb{E}_0}(\mathcal{P}\mathrm{r}^{\mathrm{Add}})$, where $\mathbf{1}$ denotes the unit object of $\mathcal{C}$. It follows that $\mathrm{End}(\mathbf{1}) = G(\mathcal{C}, \mathbf{1})$ can be regarded as an object of $\mathrm{Alg}(\mathrm{Alg}(\mathrm{Sp}^{\mathrm{cn}})) \simeq \mathrm{Alg}_{\mathbb{E}_2}(\mathrm{Sp}^{\mathrm{cn}})$. In other words, we can regard $\mathrm{End}(\mathbf{1})$ as an $\mathbb{E}_2$-ring.

Remark D.1.3.2. Let $\mathcal{C}$ be a monoidal ∞-category with unit object $\mathbf{1}$. Assume that $\mathcal{C}$ is additive and presentable and that the tensor product $\otimes : \mathcal{C} \times \mathcal{C}$ preserves small colimits separately in each variable. For any connective $\mathbb{E}_2$-ring R, we have a canonical homotopy equivalence $\mathrm{Map}_{\mathrm{Alg}_{\mathbb{E}_2}}(R, \mathrm{End}(\mathbf{1})) \simeq \mathrm{Map}_{\mathrm{Alg}(\mathcal{P}\mathrm{r}^{\mathrm{L}})}(\mathrm{LMod}_R^{\mathrm{cn}}, \mathcal{C})$.

Construction D.1.3.3 (The Connective Center)**.** Let $\mathcal{A}$ be a presentable additive ∞-category. Then the ∞-category $\mathrm{LFun}(\mathcal{A}, \mathcal{A})$ of colimit-preserving functors from $\mathcal{A}$ to itself is also an additive presentable ∞-category, and the composition map

$$\circ : \mathrm{LFun}(\mathcal{A}, \mathcal{A}) \times \mathrm{LFun}(\mathcal{A}, \mathcal{A}) \to \mathrm{LFun}(\mathcal{A}, \mathcal{A})$$

preserves small colimits separately in each variable and determines a monoidal structure on $\mathrm{LFun}(\mathcal{A}, \mathcal{A})$ (in fact, it is *strictly* associative: it exhibits $\mathrm{LFun}(\mathcal{A}, \mathcal{A})$ as a simplicial monoid). We let $\mathfrak{Z}^{\mathrm{cn}}(\mathcal{A})$ denote the connective $\mathbb{E}_2$-ring given by $\mathrm{End}(\mathrm{id}_{\mathcal{A}})$ (see Notation D.1.3.1). Then $\mathfrak{Z}^{\mathrm{cn}}(\mathcal{A})$ is a connective $\mathbb{E}_2$-ring which we will refer to as the *connective center* of $\mathcal{A}$.

Remark D.1.3.4. Let $\mathcal{A}$ be a presentable additive ∞-category. For every connective $\mathbb{E}_2$-ring R, Remark D.1.3.2 supplies a homotopy equivalence

$$\mathrm{Map}_{\mathrm{Alg}_{\mathbb{E}_2}(\mathrm{Sp}^{\mathrm{cn}})}(R, \mathfrak{Z}^{\mathrm{cn}}(\mathcal{A})) \simeq \mathrm{Map}_{\mathrm{Alg}(\mathcal{P}\mathrm{r}^{\mathrm{L}})}(\mathrm{LMod}_R^{\mathrm{cn}}, \mathrm{LFun}(\mathcal{A}, \mathcal{A})).$$

In other words, giving an action of R on $\mathcal{A}$ is equivalent to giving a morphism of $\mathbb{E}_2$-rings $R \to \mathfrak{Z}^{\mathrm{cn}}(A)$.

Remark D.1.3.5. Let $\mathcal{A}$ be a presentable additive ∞-category. Then we have a canonical homotopy equivalence $\Omega^{\infty} \mathfrak{Z}^{\mathrm{cn}}(\mathcal{A}) \simeq \mathrm{Map}_{\mathrm{Fun}(\mathcal{A},\mathcal{A})}(\mathrm{id}_{\mathcal{A}}, \mathrm{id}_{\mathcal{A}})$. In particular, for every nonnegative integer n, we have a canonical isomorphism $\pi_n \mathfrak{Z}^{\mathrm{cn}}(\mathcal{A}) \simeq \mathrm{Map}_{\mathrm{Fun}(\mathcal{A},\mathcal{A})}(\mathrm{id}_{\mathcal{A}}, \Omega^n_{\mathcal{A}})$.

Example D.1.3.6. Let $\mathcal{A}$ be a presentable additive ∞-category, and suppose that $\mathcal{A}$ is equivalent to an m-category for some $m \geqslant 1$. Then the functor $\Omega^n_{\mathcal{A}} : \mathcal{A} \to \mathcal{A}$ vanishes for $n \geqslant m$. It follows that the homotopy groups $\pi_n \mathfrak{Z}^{\mathrm{cn}}(\mathcal{A})$ vanish for $n \geqslant m$.

In particular, if $\mathcal{A}$ is (equivalent to) an ordinary category, then the connective center $\mathfrak{Z}^{\mathrm{cn}}(\mathcal{A})$ is discrete. It follows that for every connective $\mathbb{E}_2$-ring R, giving an action of R on $\mathcal{A}$ is equivalent to giving an action of the commutative ring $\pi_0 R$ on $\mathcal{A}$.

Example D.1.3.7 (Linearity over $\mathbf{F}_p$)**.** Let p be a prime number and let $\mathbf{F}_p$ denote the finite field $\mathbf{Z}/p\mathbf{Z}$ with p elements. A theorem of Hopkins and Mahowald asserts that, when regarded as an $\mathbb{E}_2$-ring, the field $\mathbf{F}_p$ is obtained from the sphere spectrum by attaching a single 1-cell to "kill p": more precisely, if $A = \mathrm{Sym}^*_{\mathbb{E}_2}(S)$ denotes the free $\mathbb{E}_2$-ring on a single generator x of degree zero, then there is a pushout diagram of $\mathbb{E}_2$-rings

$$\begin{array}{ccc} A & \xrightarrow{x \mapsto 0} & S \\ \downarrow{\scriptstyle x \mapsto p} & & \downarrow \\ S & \longrightarrow & \mathbf{F}_p. \end{array}$$

It follows that if $\mathcal{A}$ is any presentable additive ∞-category, then the mapping space $\mathrm{Map}_{\mathrm{Alg}_{\mathbb{E}_2}(\mathrm{Sp}^{\mathrm{cn}}}(\mathbf{F}_p, \mathfrak{Z}^{\mathrm{cn}}(A))$ can be identified with the homotopy fiber product

$$\{0\} \times_{\mathrm{Map}_{\mathrm{Fun}(\mathcal{A},\mathcal{A})}(\mathrm{id}_{\mathcal{A}}, \mathrm{id}_{\mathcal{A}})} \{p\}.$$

In particular, a presentable additive ∞-category $\mathcal{A}$ admits an action of $\mathbf{F}_p$ if and only if the map $p : \mathrm{id}_{\mathcal{A}} \to \mathrm{id}_{\mathcal{A}}$ is nullhomotopic.

Example D.1.3.8 (Linearity over $\mathbf{Q}$)**.** Let $\mathcal{A}$ be a presentable additive ∞-category. Suppose that $n > 0$ and that every object $X \in \mathcal{A}$, the map $n\,\mathrm{id}_X : X \to X$ is an equivalence. It follows that multiplication by n induces an equivalence from the identity functor $\mathrm{id}_{\mathcal{A}}$ to itself, so that n is invertible in the commutative ring $\pi_0 \mathfrak{Z}^{\mathrm{cn}}(\mathcal{A})$. If this condition is satisfied for *every* positive integer n, then $\pi_0 \mathfrak{Z}^{\mathrm{cn}}(\mathcal{A})$ is an algebra over the field $\mathbf{Q}$ of rational numbers and therefore the mapping space $\mathrm{Map}_{\mathrm{Alg}_{\mathbb{E}_2}(\mathrm{Sp}^{\mathrm{cn}})}(\mathbf{Q}, \mathfrak{Z}^{\mathrm{cn}}(\mathcal{A}))$ is contractible. It follows that $\mathcal{A}$ admits an essentially unique action of the field $\mathbf{Q}$ of rational numbers. Conversely, if $\mathcal{A}$ is an additive $\mathbf{Q}$-linear ∞-category, then the multiplication map $n\,\mathrm{id}_X : X \to X$ is an equivalence for each $X \in \mathcal{A}$ and every positive integer n.

Example D.1.3.9. Let $\mathcal{A}$ be a Grothendieck abelian category, let $\mathcal{D}(\mathcal{A})$ denote the derived ∞-category of $\mathcal{A}$, and let $\mathcal{C} = \mathcal{D}(\mathcal{A})_{\geqslant 0}$ be the associated Grothendieck prestable ∞-category.

It follows from Theorem C.5.4.9 that restriction to the heart induces a homotopy equivalence

$$\mathrm{Map}_{\mathrm{Fun}(\mathcal{C},\mathcal{C})}(\mathrm{id}_{\mathcal{C}}, \mathrm{id}_{\mathcal{C}}) \simeq \mathrm{Map}_{\mathrm{Fun}(\mathcal{A},\mathcal{A})}(\mathrm{id}_{\mathcal{A}}, \mathrm{id}_{\mathcal{A}}),$$

hence an equivalence of connective $\mathbb{E}_2$-rings $\mathfrak{Z}^{\mathrm{cn}}(\mathcal{C}) \to \mathfrak{Z}^{\mathrm{cn}}(\mathcal{A})$ (Remark D.1.3.5). In particular, we deduce the following:

- The connective center $\mathfrak{Z}^{\mathrm{cn}}(\mathcal{C})$ is discrete (see Example D.1.3.6).
- For every connective $\mathbb{E}_2$-ring R, giving an action of R on $\mathcal{C}$ is equivalent to giving an action of R on the abelian category $\mathcal{A}$ (and any such action factors through the discrete commutative ring $\pi_0 R$).

The same reasoning applies if we take $\mathcal{C}$ to be the complete Grothendieck prestable ∞-category $\widehat{\mathcal{D}}(\mathcal{A})_{\geqslant 0}$ (see Corollary C.5.9.5), or either of the stable ∞-categories $\mathcal{D}(\mathcal{A})$ and $\widehat{\mathcal{D}}(\mathcal{A})$.

D.1.4 Special Classes of R-Linear ∞-Categories

In this book, we will generally be interested in studying an additive R-linear ∞-categories which satisfy some additional conditions.

Definition D.1.4.1. Let R be a connective $\mathbb{E}_2$-ring and let $\mathcal{C} \in \mathrm{LinCat}_R^{\mathrm{Add}}$ be an additive R-linear ∞-category.

(*a*) We say that $\mathcal{C}$ is a *stable R-linear ∞-category* if the underlying ∞-category of $\mathcal{C}$ is stable.

(*b*) We say that $\mathcal{C}$ is a *prestable R-linear ∞-category* if the underlying ∞-category of $\mathcal{C}$ is a Grothendieck prestable ∞-category.

(*c*) We say that $\mathcal{C}$ is an *abelian R-linear ∞-category* if the underlying ∞-category of $\mathcal{C}$ is (equivalent to) a Grothendieck abelian category.

We let $\mathrm{LinCat}_R^{\mathrm{St}}$ denote the full subcategory of $\mathrm{LinCat}_R^{\mathrm{Add}}$ spanned by the stable R-linear ∞-categories, $\mathrm{LinCat}_R^{\mathrm{PSt}} \subseteq \mathrm{LinCat}_R^{\mathrm{Add}}$ the full subcategory spanned by the prestable R-linear ∞-categories, and $\mathrm{LinCat}_R^{\mathrm{Ab}} \subseteq \mathrm{LinCat}_R^{\mathrm{Add}}$ the full subcategory spanned by the abelian R-linear ∞-categories.

Warning D.1.4.2. As with Definition D.1.2.1, the terminology of Definition D.1.4.1 is potentially misleading. Throughout this book, if we say that a stable ∞-category $\mathcal{C}$ is R-linear, we are implicitly asserting that $\mathcal{C}$ is a *presentable* stable ∞-category. Likewise, if we say that a prestable ∞-category (or abelian category) $\mathcal{C}$ is R-linear, we are implicitly asserting that $\mathcal{C}$ is a Grothendieck prestable ∞-category (or Grothendieck abelian category).

Of course, it is possible to adopt more liberal definitions which could be applied to more general stable ∞-categories, prestable ∞-categories, or abelian categories. However, the conventions of Definition D.1.4.1 are better suited to our undertakings in this book.

Remark D.1.4.3. Every presentable stable ∞-category $\mathcal{C}$ is a Grothendieck prestable ∞-category. Consequently, for any connective $\mathbb{E}_2$-ring R, we can regard $\mathrm{LinCat}_R^{\mathrm{St}}$ as a full subcategory of $\mathrm{LinCat}_R^{\mathrm{PSt}}$.

Example D.1.4.4. Let S denote the sphere spectrum, which we regard as a connective $\mathbb{E}_2$-ring. Then the forgetful functor $\mathrm{LinCat}_S^{\mathrm{Add}} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ determines an equivalence of ∞-categories $\mathrm{LinCat}_S^{\mathrm{Add}} \simeq \mathcal{P}\mathrm{r}^{\mathrm{Add}}$, which restricts to give equivalences

$$\mathrm{LinCat}_S^{\mathrm{St}} \simeq \mathcal{P}\mathrm{r}^{\mathrm{St}} \qquad \mathrm{LinCat}_S^{\mathrm{PSt}} \simeq \mathsf{Groth}_\infty \qquad \mathrm{LinCat}_S^{\mathrm{Ab}} \simeq \mathsf{Groth}_{\mathrm{ab}}.$$

Remark D.1.4.5. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. Then $\mathrm{Sp}(\mathcal{C}) \simeq \mathrm{Sp} \otimes \mathcal{C}$ is a presentable stable ∞-category and $\mathcal{C}^\heartsuit \simeq \mathrm{Ab} \otimes \mathcal{C}$ is a Grothendieck abelian category. If $\mathcal{C}$ is equipped with a left action of $\mathrm{LMod}_R^{\mathrm{cn}}$ for some connective $\mathbb{E}_2$-ring R, then $\mathrm{Sp} \otimes \mathcal{C}$ and $\mathrm{Ab} \otimes \mathcal{C}$ inherit left actions of $\mathrm{LMod}_R^{\mathrm{cn}}$. We therefore obtain forgetful functors

$$\begin{array}{ccccc} \mathrm{LinCat}_R^{\mathrm{St}} & \leftarrow & \mathrm{LinCat}_R^{\mathrm{PSt}} & \rightarrow & \mathrm{LinCat}_R^{\mathrm{Ab}} \\ \mathrm{Sp}(\mathcal{C}) & \leftarrow\!\shortmid & \mathcal{C} & \mapsto & \mathcal{C}^\heartsuit. \end{array}$$

In other words, if $\mathcal{C}$ is a prestable R-linear ∞-category, then $\mathrm{Sp}(\mathcal{C})$ is a stable R-linear ∞-category and $\mathcal{C}^\heartsuit$ is an abelian R-linear ∞-category.

Remark D.1.4.6. Let $\mathcal{A}$ be a Grothendieck abelian category and let R be a connective $\mathbb{E}_2$-ring. Then any colimit-preserving (monoidal) functor from the ∞-category $\mathrm{LMod}_R^{\mathrm{cn}}$ to the category $\mathrm{LFun}(\mathcal{A}, \mathcal{A})$ automatically factors through the ∞-category $\tau_{\leqslant 0} \mathrm{LMod}_R^{\mathrm{cn}} \simeq \mathrm{LMod}_R^\heartsuit$ of discrete left R-modules, which depends only on the underlying commutative ring $\pi_0 R$. It follows that the natural map $R \to \pi_0 R$ induces an equivalence of ∞-categories $\mathrm{LinCat}_{\pi_0 R}^{\mathrm{Ab}} \to \mathrm{LinCat}_R^{\mathrm{Ab}}$.

D.1.5 The Stable Case

Let R be a connective $\mathbb{E}_2$-ring. The inclusion functor $\mathrm{LMod}_R^{\mathrm{cn}} \hookrightarrow \mathrm{LMod}_R$ can be regarded as a morphism between algebra objects of $\mathcal{P}\mathrm{r}^{\mathrm{L}}$, and therefore induces a forgetful functor

$$\theta : \mathrm{LMod}_{\mathrm{LMod}_R}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \to \mathrm{LMod}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \simeq \mathrm{LinCat}_R^{\mathrm{Add}}.$$

This functor admits a left adjoint, given by the construction

$$\begin{aligned} \mathcal{A} \mapsto\ & \mathrm{LMod}_R \otimes_{\mathrm{LMod}_R^{\mathrm{cn}}} \mathcal{A} \\ \simeq\ & \mathrm{Sp}(\mathrm{LMod}_R^{\mathrm{cn}}) \otimes_{\mathrm{LMod}_R^{\mathrm{cn}}} \mathcal{A} \\ \simeq\ & (\mathrm{Sp} \otimes \mathrm{LMod}_R^{\mathrm{cn}}) \otimes_{\mathrm{LMod}_R^{\mathrm{cn}}} \mathcal{A} \\ \simeq\ & \mathrm{Sp} \otimes \mathcal{A}; \end{aligned}$$

here the unit for the adjunction is provided by the canonical map

$$\mathcal{A} \simeq \mathcal{S} \otimes \mathcal{A} \xrightarrow{\Sigma^{\infty}_{+}} \mathrm{Sp} \otimes \mathcal{A}.$$

Since the functor $\Sigma^{\infty}_{+} : \mathcal{S} \to \mathrm{Sp}$ exhibits the ∞-category of spectra as an idempotent object of $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ (see Proposition HA.4.8.2.18), it follows that the functor θ is fully faithful. Moreover, the essential image of θ is spanned by those additive R-linear ∞-categories $\mathcal{A}$ for which the unit map $\mathcal{A} \to \mathrm{Sp} \otimes \mathcal{A}$ is an equivalence of ∞-categories: by virtue of Proposition **??**, this is the full subcategory $\mathrm{LinCat}^{\mathrm{St}}_{R} \subseteq \mathrm{LinCat}^{\mathrm{Add}}_{R}$ of *stable* R-linear ∞-categories. This motivates the following variant of Definition D.1.4.1:

Variant D.1.5.1. Let R be an $\mathbb{E}_2$-ring (not necessarily connective). We let $\mathrm{LinCat}^{\mathrm{St}}_{R}$ denote the ∞-category $\mathrm{LMod}_{\mathrm{LMod}_R}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$. We will refer to the objects of $\mathrm{LinCat}^{\mathrm{St}}_{R}$ as *stable R-linear ∞-categories*, and to $\mathrm{LinCat}^{\mathrm{St}}_{R}$ as the *∞-category of stable R-linear ∞-categories*.

Warning D.1.5.2. If R is a connective $\mathbb{E}_2$-ring, then the definition of a stable R-linear ∞-category $\mathcal{C}$ given in Definition D.1.4.1 is equivalent (but not identical) to the definition given in Variant D.1.5.1: in the first case, we require that $\mathcal{C}$ is equipped with a left action of the monoidal ∞-category $\mathrm{LMod}^{\mathrm{cn}}_{R}$ of connective R-modules, and in the second we require that it is equipped with a left action of the monoidal ∞-category LMod_R of *all* R-modules. It follows from the argument supplied above that if $\mathcal{C}$ is stable, then any action of $\mathrm{LMod}^{\mathrm{cn}}_{R}$ on $\mathcal{C}$ admits an essentially unique extension to an action of the larger ∞-category LMod_R.

In what follows, we will abuse terminology by not distinguishing between the notions of stable R-linear ∞-category given in Definition D.1.4.1 and Variant D.1.5.1. The advantage of the former is that it makes sense without the assumption that $\mathcal{C}$ is stable, and the advantage of the latter is that it makes sense without the assumption that R is connective.

Remark D.1.5.3. Let R be an $\mathbb{E}_2$-ring and let $\mathcal{C}$ and $\mathcal{C}'$ be stable R-linear ∞-categories. We will refer to the morphisms from $\mathcal{C}$ to $\mathcal{C}'$ in $\mathrm{LinCat}^{\mathrm{St}}_{R}$ as *R-linear functors* from $\mathcal{C}$ to $\mathcal{C}'$. Every R-linear functor $F : \mathcal{C} \to \mathcal{C}'$ determines a colimit-preserving functor between the underlying (presentable) ∞-categories of $\mathcal{C}$ and $\mathcal{C}'$, which therefore admits a right adjoint G (Corollary HTT.5.5.2.9). If the functor G commutes with small colimits, then it inherits the structure of an R-linear functor: this is a special case of Remark D.7.4.4.

In the stable setting, we have the following variant of Construction D.1.3.3:

Construction D.1.5.4 (The Center)**.** For every $\mathbb{E}_1$-ring R, we can regard LMod_R as a presentable stable ∞-category with a distinguished object (given by R, regarded as a left module over itself). The construction $R \mapsto (\mathrm{LMod}_R, R)$ determines a functor $\Theta_* : \mathrm{Alg}(\mathrm{Sp}) \to \mathrm{Alg}_{\mathbb{E}_0}(\mathrm{Mod}_{\mathrm{Sp}}(\mathcal{P}\mathrm{r}^{\mathrm{L}}))$. According to Theorem HA.4.8.5.11 , the functor Θ_* admits a right adjoint G which carries a presentable stable ∞-category $\mathcal{C}$ with a distinguished object $X \in \mathcal{C}$

to its endomorphism algebra $\underline{\mathrm{End}}(X) \in \mathrm{Alg}(\mathrm{Sp})$, an $\mathbb{E}_1$-ring satisfying $\Omega^{\infty-n}\,\mathrm{End}(X) \simeq \mathrm{Map}_{\mathcal{C}}(X, \Sigma^n X)$ for each $n \in \mathbf{Z}$.

According to Theorem HA.4.8.5.16 , the functor Θ_* is symmetric monoidal. It follows that the functor G is lax symmetric monoidal. Suppose that $\mathcal{C}$ is an associative algebra object of $\mathrm{Mod}_{\mathrm{Sp}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$: that is, a monoidal presentable stable ∞-category for which tensor product functor $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves small colimits separately in each variable. Then we can regard $(\mathcal{C}, \mathbf{1})$ as an algebra object of $\mathrm{Alg}_{\mathbb{E}_0}(\mathrm{Mod}_{\mathrm{Sp}}(\mathcal{P}\mathrm{r}^{\mathrm{L}}))$, where $\mathbf{1}$ denotes the unit object of $\mathcal{C}$. It follows that $\underline{\mathrm{End}}(\mathbf{1}) = G(\mathcal{C}, \mathbf{1})$ can be regarded as an object of $\mathrm{Alg}(\mathrm{Alg}(\mathrm{Sp})) \simeq \mathrm{Alg}_{\mathbb{E}_2}(\mathrm{Sp})$. In other words, we can regard $\underline{\mathrm{End}}(\mathbf{1})$ as an $\mathbb{E}_2$-ring.

Suppose that $\mathcal{C}$ is an arbitrary presentable stable ∞-category. Then the ∞-category $\mathrm{LFun}(\mathcal{C}, \mathcal{C})$ of colimit-preserving functors from $\mathcal{A}$ to itself is also a presentable stable ∞-category ∞-category, and the composition map

$$\circ : \mathrm{LFun}(\mathcal{C}, \mathcal{C}) \times \mathrm{LFun}(\mathcal{C}, \mathcal{C}) \to \mathrm{LFun}(\mathcal{C}, \mathcal{C})$$

preserves small colimits separately in each variable and determines a monoidal structure on $\mathrm{LFun}(\mathcal{C}, \mathcal{C})$. We let $\mathfrak{Z}(\mathcal{C})$ denote the $\mathbb{E}_2$-ring given by $\underline{\mathrm{End}}(\mathrm{id}_{\mathcal{C}}) = G(\mathrm{LFun}(\mathcal{C}, \mathcal{C}), \mathrm{id}_{\mathcal{C}})$. Then $\mathfrak{Z}(\mathcal{C})$ is an $\mathbb{E}_2$-ring which we will refer to as the *center* of $\mathcal{C}$.

Remark D.1.5.5. Let $\mathcal{C}$ be a presentable stable ∞-category. For every $\mathbb{E}_2$-ring R, there is a canonical homotopy equivalence

$$\mathrm{Map}_{\mathrm{Alg}_{\mathbb{E}_2}(\mathrm{Sp})}(R, \mathfrak{Z}(\mathcal{C})) \simeq \mathrm{Map}_{\mathrm{Alg}(\mathcal{P}\mathrm{r}^{\mathrm{L}})}(\mathrm{LMod}_R, \mathrm{LFun}(\mathcal{C}, \mathcal{C})).$$

In other words, promoting $\mathcal{C}$ to a stable R-linear ∞-category (in the sense of Variant D.1.5.1) is equivalent to providing a morphism of $\mathbb{E}_2$-rings $R \to \mathfrak{Z}(\mathcal{C})$. Using Remark D.1.3.4 and Warning D.1.5.2, we deduce that the connective center $\mathfrak{Z}^{\mathrm{cn}}(\mathcal{C})$ of Construction D.1.3.3 can be identified with the connective cover of the center $\mathfrak{Z}(\mathcal{C})$.

Remark D.1.5.6. Let $\mathcal{C}$ be a presentable stable ∞-category. For every integer n, we have a canonical homotopy equivalence $\Omega^{\infty-n}\,\mathfrak{Z}(\mathcal{C}) \simeq \mathrm{Map}_{\mathrm{Fun}(\mathcal{C},\mathcal{C})}(\mathrm{id}_{\mathcal{C}}, \mathrm{id}_{\mathcal{C}})$, and therefore a canonical isomorphism of abelian groups $\pi_n\,\mathfrak{Z}(\mathcal{C}) \simeq \mathrm{Ext}^{-n}_{\mathrm{Fun}(\mathcal{C},\mathcal{C})}(\mathrm{id}_{\mathcal{C}}, \mathrm{id}_{\mathcal{C}})$.

Remark D.1.5.7. If $\mathcal{C}$ is a presentable stable ∞-category, then the $\mathbb{E}_2$-ring $\mathfrak{Z}(\mathcal{C})$ can be regarded as an incarnation of the *topological Hochschild cohomology* of the ∞-category $\mathcal{C}$.

D.1.6 Limits and Colimits

We close this section with a few remarks about limits and colimits of R-linear ∞-categories. Note that the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ admits small limits and colimits (see §HTT.5.5.3). Consequently, for any connective $\mathbb{E}_2$-ring R, the ∞-category $\mathrm{LinCat}_R^{\mathrm{Add}} = \mathrm{LMod}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ of additive R-linear ∞-categories admits small limits and colimits. However, when we restrict our attention to additive R-linear ∞-categories which satisfy additional requirements, then the matter becomes more delicate.

Remark D.1.6.1 (Limits of Prestable R-Linear ∞-Categories)**.** Let R be a connective $\mathbb{E}_2$-ring, and let $\mathrm{LinCat}_R^{\mathrm{PSt,lex}}$ denote the subcategory of $\mathrm{LinCat}_R^{\mathrm{PSt}}$ whose objects are prestable R-linear ∞-categories and whose morphisms are R-linear functors which preserve small colimits and finite limits. We have an evident forgetful functor

$$q : \mathrm{LinCat}_R^{\mathrm{PSt,lex}} \to \mathrm{LinCat}_S^{\mathrm{PSt,lex}} \simeq \mathsf{Groth}_\infty^{\mathrm{lex}}.$$

It follows from Proposition C.3.2.4 that for every small diagram $p : K \to \mathrm{LinCat}_R^{\mathrm{PSt,lex}}$, the composite map $(q \circ p) : K \to \mathsf{Groth}_\infty^{\mathrm{lex}}$ can be extended to a limit diagram which is preserved by the inclusions $\mathsf{Groth}_\infty^{\mathrm{lex}} \hookrightarrow \mathsf{Groth}_\infty \hookrightarrow \mathcal{P}\mathrm{r}^{\mathrm{L}}$. Combining this observation with Corollary HA.4.2.3.3 , we deduce that the diagram p admits a limit in $\mathrm{LinCat}_R^{\mathrm{PSt,lex}}$ which is preserved by the inclusion functors $\mathrm{LinCat}_R^{\mathrm{PSt,lex}} \hookrightarrow \mathrm{LinCat}_R^{\mathrm{PSt}} \hookrightarrow \mathrm{LinCat}_R^{\mathrm{Add}}$.

Remark D.1.6.2 (Filtered Colimits of Prestable R-Linear ∞-Categories)**.** Let R be a connective $\mathbb{E}_2$-ring. It follows from Theorem C.3.3.1 that the full subcategory $\mathrm{LinCat}_R^{\mathrm{PSt}} \subseteq \mathrm{LinCat}_R^{\mathrm{Add}}$ is closed under small filtered colimits. In particular, $\mathrm{LinCat}_R^{\mathrm{PSt}}$ admits small filtered colimits, which are preserved by the forgetful functors

$$\mathrm{LinCat}_R^{\mathrm{PSt}} \hookrightarrow \mathrm{LinCat}_R^{\mathrm{Add}} \to \mathcal{P}\mathrm{r}^{\mathrm{Add}} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}.$$

Moreover, the subcategory $\mathrm{LinCat}_R^{\mathrm{PSt,lex}} \subseteq \mathrm{LinCat}_R^{\mathrm{PSt}}$ also admits small filtered colimits, which are preserved by the inclusion $\mathrm{LinCat}_R^{\mathrm{PSt,lex}} \hookrightarrow \mathrm{LinCat}_R^{\mathrm{PSt}}$ (Proposition C.3.3.5).

Remark D.1.6.3 (Colimits of Prestable R-Linear ∞-Categories along Compact Functors)**.** Let R be a connective $\mathbb{E}_2$-ring and let $\mathrm{LinCat}_R^{\mathrm{PSt},c}$ denote the subcategory of $\mathrm{LinCat}_R^{\mathrm{PSt}}$ whose objects are prestable R-linear ∞-categories and whose morphisms are compact R-linear functors (see Definition C.3.4.2). We have an evident forgetful functor

$$q : \mathrm{LinCat}_R^{\mathrm{PSt},c} \to \mathrm{LinCat}_S^{\mathrm{PSt},c} \simeq \mathsf{Groth}_\infty^{\mathrm{c}}.$$

It follows from Proposition C.3.5.1 that for every small diagram $p : K \to \mathrm{LinCat}_R^{\mathrm{PSt},c}$, the composite map $(q \circ p) : K \to \mathsf{Groth}_\infty^{\mathrm{c}}$ can be extended to a colimit diagram which is preserved by the inclusion $\mathsf{Groth}_\infty^{\mathrm{c}} \hookrightarrow \mathsf{Groth}_\infty$. Moreover, this colimit is also preserved by the formation of tensor product with any Grothendieck prestable ∞-category $\mathcal{C}$ (Proposition C.4.5.1). Combining this observation with Corollary HA.4.2.3.5 , we deduce that the diagram p admits a colimit in $\mathrm{LinCat}_R^{\mathrm{PSt},c}$ which is preserved by the inclusion $\mathrm{LinCat}_R^{\mathrm{PSt},c} \hookrightarrow \mathrm{LinCat}_R^{\mathrm{PSt}}$.

Remark D.1.6.4 (Limits and Colimits of Stable R-Linear ∞-Categories)**.** Let R be an arbitrary $\mathbb{E}_2$-ring. Then the ∞-category $\mathrm{LinCat}_R^{\mathrm{St}} = \mathrm{LMod}_{\mathrm{LMod}_R}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ of stable R-linear

∞-categories admits small limits and colimits. In the special case where R is connective, we can identify $\mathrm{LinCat}_R^{\mathrm{St}}$ with a full subcategory of $\mathrm{LinCat}_R^{\mathrm{PSt,lex}}$ (since every right exact functor between stable ∞-categories is also left exact) and the inclusion $\mathrm{LinCat}_R^{\mathrm{St}} \hookrightarrow \mathrm{LinCat}_R^{\mathrm{PSt,lex}}$ preserves small limits.

Remark D.1.6.5 (Limits of Abelian R-Linear ∞-Categories)**.** Let R be a connective $\mathbb{E}_2$-ring, and let $\mathrm{LinCat}_R^{\mathrm{Ab,lex}}$ denote the subcategory of $\mathrm{LinCat}_R^{\mathrm{Ab}}$ whose objects are abelian R-linear ∞-categories and whose morphisms are R-linear functors which preserve small colimits and finite limits. We have an evident forgetful functor $q : \mathrm{LinCat}_R^{\mathrm{Ab,lex}} \to \mathsf{Groth}_{\mathrm{ab}}^{\mathrm{lex}}$. It follows from Proposition C.5.4.21 that for $p : K \to \mathrm{LinCat}_R^{\mathrm{Ab,lex}}$, the composite map $(q \circ p) : K \to \mathsf{Groth}_{\mathrm{ab}}^{\mathrm{lex}}$ can be extended to a limit diagram which is preserved by the inclusions $\mathsf{Groth}_{\mathrm{ab}}^{\mathrm{lex}} \hookrightarrow \mathsf{Groth}_{\mathrm{ab}} \hookrightarrow \mathcal{P}\mathrm{r}^{\mathrm{L}}$. Combining this observation with Corollary HA.4.2.3.3 , we deduce that the diagram p admits a limit in $\mathrm{LinCat}_R^{\mathrm{Ab,lex}}$ which is preserved by the inclusion functors $\mathrm{LinCat}_R^{\mathrm{Ab,lex}} \hookrightarrow \mathrm{LinCat}_R^{\mathrm{Ab}} \hookrightarrow \mathrm{LinCat}_R^{\mathrm{Add}}$.

Remark D.1.6.6 (Filtered Colimits of Abelian R-Linear ∞-Categories)**.** Let R be a connective $\mathbb{E}_2$-ring. Then the ∞-category $\mathrm{LinCat}_R^{\mathrm{Ab}}$ is closed under filtered colimits in $\mathrm{LinCat}_R^{\mathrm{Add}}$: this can be deduced from a suitable 1-categorical analogue of Theorem C.3.3.1. In particular, $\mathrm{LinCat}_R^{\mathrm{Ab}}$ admits small filtered colimits, which are preserved by the forgetful functors

$$\mathrm{LinCat}_R^{\mathrm{Ab}} \hookrightarrow \mathrm{LinCat}_R^{\mathrm{Add}} \to \mathcal{P}\mathrm{r}^{\mathrm{Add}} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}.$$

Moreover, the subcategory $\mathrm{LinCat}_R^{\mathrm{Ab,lex}} \subseteq \mathrm{LinCat}_R^{\mathrm{Ab}}$ also admits small filtered colimits, which are preserved by the inclusion $\mathrm{LinCat}_R^{\mathrm{Ab,lex}} \hookrightarrow \mathrm{LinCat}_R^{\mathrm{Ab}}$.

Remark D.1.6.7. Let R be a connective $\mathbb{E}_2$-ring. Then the functors

$$\begin{array}{ccccc} \mathrm{LinCat}_R^{\mathrm{St}} & \leftarrow & \mathrm{LinCat}_R^{\mathrm{PSt}} & \to & \mathrm{LinCat}_R^{\mathrm{Ab}} \\ \mathrm{Sp}(\mathcal{C}) & \mapsfrom & \mathcal{C} & \mapsto & \mathcal{C}^{\heartsuit} \end{array}$$

preserve small filtered colimits (since they are given by tensoring with the objects $\mathrm{Sp}, \tau_{\leqslant 0}\,\mathrm{Sp}^{\mathrm{cn}}$ in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{Add}}$).

Remark D.1.6.8. Let R be a connective $\mathbb{E}_2$-ring. Then the functors

$$\begin{array}{ccccc} \mathrm{LinCat}_R^{\mathrm{St}} & \leftarrow & \mathrm{LinCat}_R^{\mathrm{PSt,lex}} & \to & \mathrm{LinCat}_R^{\mathrm{Ab,lex}} \\ \mathrm{Sp}(\mathcal{C}) & \mapsfrom & \mathcal{C} & \mapsto & \mathcal{C}^{\heartsuit} \end{array}$$

preserve small limits: this follows from Proposition C.5.5.20 and Corollary C.3.2.5.

Warning D.1.6.9. Let R be a connective $\mathbb{E}_2$-ring. The stabilization construction $\mathcal{C} \mapsto \mathrm{Sp}(\mathcal{C})$ determines a functor $\mathrm{LinCat}_R^{\mathrm{PSt},c} \to \mathrm{LinCat}_R^{\mathrm{St}}$ which preserves small colimits. However, the construction

$$\mathrm{LinCat}_R^{\mathrm{PSt},c} \to \mathrm{LinCat}_R^{\mathrm{Ab}} \qquad \mathcal{C} \mapsto \mathcal{C}^{\heartsuit}$$

does *not* preserve small colimits in general. However, it does preserve all colimits in $\mathrm{LinCat}_R^{\mathrm{PSt},c}$ which remain colimits in the larger ∞-category $\mathrm{LinCat}_R^{\mathrm{Add}}$: for example, colimits of diagrams which satisfy the hypothesis described in Remark C.3.5.4.

D.2 Tensor Products and Extension of Scalars

Let R be a connective $\mathbb{E}_2$-ring. In §D.1, we introduced the the ∞-category $\mathrm{LinCat}_R^{\mathrm{Add}}$ of *additive R-linear ∞-categories* (Definition D.1.2.1), as well as the full subcategories

$$\mathrm{LinCat}_R^{\mathrm{St}}, \mathrm{LinCat}_R^{\mathrm{PSt}}, \mathrm{LinCat}_R^{\mathrm{Ab}} \subseteq \mathrm{LinCat}_R^{\mathrm{Add}}$$

of stable, prestable, and abelian R-linear ∞-categories. Note that these ∞-categories can be regarded as *contravariant* functors of R: if $\phi : R \to R'$ is a morphism of connective $\mathbb{E}_2$-rings, then extension of scalars along ϕ determines a monoidal functor $\mathrm{LMod}_R^{\mathrm{cn}} \to \mathrm{LMod}_{R'}^{\mathrm{cn}}$ and therefore a forgetful functor

$$\mathrm{LinCat}_{R'}^{\mathrm{Add}} = \mathrm{LMod}_{\mathrm{LMod}_{R'}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \to \mathrm{LMod}_{\mathrm{LMod}_{R}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) = \mathrm{LinCat}_{R}^{\mathrm{Add}},$$

which we will refer to as *restriction of scalars along ϕ*. In other words, every additive R'-linear ∞-category $\mathcal{A}$ can be regarded as an additive R-linear ∞-category. Note that the underlying ∞-category $\mathcal{A}$ does not change, so if $\mathcal{A}$ is stable, prestable, or abelian as an R'-linear ∞-category, then it is also stable, prestable or abelian as an R-linear ∞-category. In other words, restriction of scalars induces forgetful functors

$$\mathrm{LinCat}_{R'}^{\mathrm{St}} \to \mathrm{LinCat}_{R}^{\mathrm{St}} \qquad \mathrm{LinCat}_{R'}^{\mathrm{PSt}} \to \mathrm{LinCat}_{R}^{\mathrm{PSt}} \qquad \mathrm{LinCat}_{R'}^{\mathrm{Ab}} \to \mathrm{LinCat}_{R}^{\mathrm{Ab}}.$$

In this section, we will study left adjoints to these forgetful functors, given by *extension of scalars* along the morphism $\phi : R \to R'$.

D.2.1 The Bar Construction

We begin with a general discussion of relative tensor products in the setting of presentable ∞-categories.

Construction D.2.1.1. Let $\mathcal{C}$ be a monoidal ∞-category, let $\mathcal{M}$ be an ∞-category which is right-tensored over $\mathcal{C}$, and let $\mathcal{N}$ be an ∞-category which is left-tensored over $\mathcal{C}$. Assume that $\mathcal{C}$, $\mathcal{M}$, and $\mathcal{N}$ are presentable, and that the tensor product functors

$$\mathcal{M} \times \mathcal{C} \to \mathcal{M} \qquad \mathcal{C} \times \mathcal{C} \to \mathcal{C} \qquad \mathcal{C} \times \mathcal{N} \to \mathcal{N}$$

preserve small colimits separately in each variable. Then we can regard $\mathcal{C}$ as an algebra object in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable ∞-categories, and we can regard $\mathcal{M}$ and $\mathcal{N}$

as right and left modules over $\mathcal{C}$, respectively. We let $\mathcal{M} \otimes_{\mathcal{C}} \mathcal{N}$ denote the relative tensor product of $\mathcal{M}$ with $\mathcal{N}$ over $\mathcal{C}$ in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$: that is, the geometric realization of the two-sided bar construction $\mathrm{Bar}_{\mathcal{C}}(\mathcal{M}, \mathcal{N})_{\bullet}$ of Construction HA.4.4.2.7 .

Let us now specialize to the case where $\mathcal{C} = \mathrm{LMod}_R^{\mathrm{cn}}$ for some connective $\mathbb{E}_2$-ring R. In this case, the left action of $\mathcal{C}$ on $\mathcal{N}$ exhibits $\mathcal{N}$ as an additive R-linear ∞-category, and the right action of $\mathcal{C}$ on $\mathcal{M}$ exhibits $\mathcal{M}$ as an additive R^{rev}-linear ∞-category, where R^{rev} denotes the reverse of R (see Warning D.1.2.5). In this case, we will denote the tensor product $\mathcal{M} \otimes_{\mathcal{C}} \mathcal{N}$ by $\mathcal{M} \otimes_R \mathcal{N}$, and refer to it as the *tensor product of $\mathcal{M}$ with $\mathcal{N}$ over R.*

Remark D.2.1.2 (Tensor Products of Ordinary Categories)**.** Let R be an $\mathbb{E}_2$-ring and let $\mathcal{M} \in \mathrm{RMod}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ and $\mathcal{N} \in \mathrm{LMod}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ be as Construction D.2.1.1. Suppose that $\mathcal{M}$ and $\mathcal{N}$ are (equivalent to the nerves of) ordinary categories. Then the right and left actions of $\mathrm{LMod}_R^{\mathrm{cn}}$ on $\mathcal{M}$ and $\mathcal{N}$ factor through the monoidal functor $\pi_0 : \mathrm{LMod}_R^{\mathrm{cn}} \to \mathrm{LMod}_R^{\heartsuit}$. Moreover, the induced map of two-sided bar constructions $\mathrm{Bar}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{M}, \mathcal{N})_{\bullet} \to \mathrm{Bar}_{\mathrm{LMod}_R^{\heartsuit}}(\mathcal{M}, \mathcal{N})_{\bullet}$ induces an equivalence in each degree, and therefore an equivalence

$$\mathcal{M} \otimes_R \mathcal{N} = |\mathrm{Bar}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{M}, \mathcal{N})_{\bullet}| \simeq |\mathrm{Bar}_{\mathrm{LMod}_R^{\heartsuit}}(\mathcal{M}, \mathcal{N})| = \mathcal{M} \otimes_{\mathrm{LMod}_R^{\heartsuit}} \mathcal{N}.$$

Remark D.2.1.3. For every presentable ∞-category $\mathcal{C}$, let $\mathcal{C}^{\heartsuit}$ denote the full subcategory of $\mathcal{C}$ spanned by the discrete objects. The construction $\mathcal{C} \mapsto \mathcal{C}^{\heartsuit}$ determines a functor from the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable ∞-categories to the ∞-category $\mathrm{Mod}_{\mathcal{S}\mathrm{et}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ of presentable 1-categories. This functor is symmetric monoidal and commutes with small colimits, and therefore commutes with the formation of tensor products. Consequently, if R is a connective $\mathbb{E}_2$-ring and we are given objects $\mathcal{M} \in \mathrm{RMod}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ and $\mathcal{N} \in \mathrm{LMod}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ as in Construction D.2.1.1, then we have canonical equivalences

$$\begin{aligned} (\mathcal{M} \otimes_R \mathcal{N})^{\heartsuit} &= (\mathcal{M} \otimes_{\mathrm{Mod}_R^{\mathrm{cn}}} \mathcal{N})^{\heartsuit} \\ &\simeq \mathcal{M}^{\heartsuit} \otimes_{\mathrm{Mod}_R^{\heartsuit}} \mathcal{N}^{\heartsuit} \\ &\simeq \mathcal{M}^{\heartsuit} \otimes_R \mathcal{N}^{\heartsuit} \end{aligned}$$

where the final equivalence is provided by Remark D.2.1.2.

Remark D.2.1.4 (Tensor Products of Stable Categories)**.** Let R be a connective $\mathbb{E}_2$-ring and let $\mathcal{M} \in \mathrm{RMod}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ and $\mathcal{N} \in \mathrm{LMod}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ be as Construction D.2.1.1. Suppose that $\mathcal{M}$ and $\mathcal{N}$ are stable. Then the right and left actions of $\mathrm{LMod}_R^{\mathrm{cn}}$ on $\mathcal{M}$ and $\mathcal{N}$ factor through the monoidal inclusion functor $\mathrm{LMod}_R^{\mathrm{cn}} \hookrightarrow \mathrm{LMod}_R$. As in Remark D.2.1.2, the induced map of two-sided bar constructions $\mathrm{Bar}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{M}, \mathcal{N})_{\bullet} \to \mathrm{Bar}_{\mathrm{LMod}_R}(\mathcal{M}, \mathcal{N})_{\bullet}$ induces an equivalence in each degree, and therefore an equivalence

$$\mathcal{M} \otimes_R \mathcal{N} = |\mathrm{Bar}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{M}, \mathcal{N})_{\bullet}| \simeq |\mathrm{Bar}_{\mathrm{LMod}_R}(\mathcal{M}, \mathcal{N})| = \mathcal{M} \otimes_{\mathrm{LMod}_R} \mathcal{N}.$$

Variant D.2.1.5. Let R be an arbitrary $\mathbb{E}_2$-ring, and let $\mathcal{N}$ be a stable R-linear ∞-category in the sense of Variant D.1.5.1: that is, a presentable stable ∞-category equipped with a left action of the monoidal ∞-category LMod_R. Similarly, let $\mathcal{M}$ be a presentable stable ∞-category equipped with a right action of the monoidal ∞-category LMod_R. We let $\mathcal{M} \otimes_R \mathcal{N}$ denote the relative tensor product $\mathcal{M} \otimes_{\mathrm{LMod}_R} \mathcal{N} = |\mathrm{Bar}_{\mathrm{LMod}_R}(\mathcal{M}, \mathcal{N})_\bullet|$ in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ (or, equivalently, in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ of presentable stable ∞-categories). It follows from Remark D.2.1.4 that when R is connective, this construction is canonically equivalent to the relative tensor product given in Construction D.2.1.1.

Remark D.2.1.6. The construction $\mathcal{C} \mapsto \mathrm{Sp}(\mathcal{C})$ determines a symmetric monoidal functor from the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable ∞-categories to the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}} \simeq \mathrm{Mod}_{\mathrm{Sp}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ of presentable stable ∞-categories. Consequently, if R is a connective $\mathbb{E}_2$-ring and we are given objects $\mathcal{M} \in \mathrm{RMod}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ and $\mathcal{N} \in \mathrm{LMod}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ as in Construction D.2.1.1, then we have canonical equivalences

$$\begin{aligned}
\mathrm{Sp}(\mathcal{M} \otimes_R \mathcal{N}) &= \mathrm{Sp}(\mathcal{M} \otimes_{\mathrm{Mod}_R^{\mathrm{cn}}} \mathcal{N}) \\
&\simeq \mathrm{Sp}(\mathcal{M}) \otimes_{\mathrm{Mod}_R} \mathrm{Sp}(\mathcal{N}) \\
&\simeq \mathrm{Sp}(\mathcal{M}) \otimes_R \mathrm{Sp}(\mathcal{N})
\end{aligned}$$

where the final equivalence is provided by Remark D.2.1.4.

D.2.2 Closure Properties of $\otimes_R$

We now study the closure properties under tensor product of the special classes of R-linear ∞-categories introduced in Definition D.1.4.1.

Proposition D.2.2.1. *Let R be a connective $\mathbb{E}_2$-ring, and suppose we are given ∞-categories*

$$\mathcal{M} \in \mathrm{RMod}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \qquad \mathcal{N} \in \mathrm{LMod}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}}).$$

Then:

- (a) *The relative tensor product $\mathcal{M} \otimes_R \mathcal{N}$ is an additive presentable ∞-category.*
- (b) *If either $\mathcal{M}$ or $\mathcal{N}$ is stable, then the relative tensor product $\mathcal{M} \otimes_R \mathcal{N}$ is stable.*
- (c) *If $\mathcal{M}$ and $\mathcal{N}$ are Grothendieck prestable ∞-categories, then the tensor product $\mathcal{M} \otimes_R \mathcal{N}$ is also a Grothendieck prestable ∞-category.*
- (d) *If $\mathcal{M}$ and $\mathcal{N}$ are (equivalent to) Grothendieck abelian categories, then the relative tensor product $\mathcal{M} \otimes_R \mathcal{N}$ is (equivalent to) a Grothendieck abelian category.*

Remark D.2.2.2. In the special case where R is the sphere spectrum, assertion (c) fo Proposition D.2.2.1 reduces to Theorem C.4.2.1, and assertion (d) reduces to Theorem C.5.4.16.

Proof of Proposition D.2.2.1. Since $\mathcal{M}$ is additive, it can be regarded as a module over the commutative algebra object $\mathrm{Sp}^{\mathrm{cn}} \in \mathrm{CAlg}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ (Corollary C.4.1.3), so that $\mathcal{M} \otimes_R \mathcal{N}$ is also a module over $\mathrm{Sp}^{\mathrm{cn}}$ and therefore additive (Corollary C.4.1.3). This proves (a). Similarly, if $\mathcal{M}$ or $\mathcal{N}$ is stable, then it can be regarded as a module over $\mathrm{Sp} \in \mathrm{CAlg}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ by virtue of Proposition HA.4.8.2.18 , so that $\mathcal{M} \otimes_R \mathcal{N}$ is also a module over Sp and therefore a stable ∞-category. This proves (b).

We now prove (c). Let us identify $\mathcal{M} \otimes_R \mathcal{N}$ with the geometric realization of a simplicial object $\mathcal{E}_\bullet$ of $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ given by the two-sided bar construction $\mathrm{Bar}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{M}, \mathcal{N})_\bullet$ of Construction **??**. By virtue of Lemma HTT.6.5.3.7 , this is equivalent to the colimit of the underlying semisimplicial object

$$([n] \in \mathbf{\Delta}_s^{\mathrm{op}}) \mapsto \mathcal{E}_n = \mathcal{M} \otimes (\mathrm{LMod}_R^{\mathrm{cn}})^{\otimes n} \otimes \mathcal{N}.$$

Note that each $\mathcal{E}_n$ is a Grothendieck prestable ∞-category by virtue of Theorem C.4.2.1. To show that the colimit (formed in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$) is again a Grothendieck prestable ∞-category, it will suffice to show that the semisimplicial object $\mathcal{E}_\bullet$ satisfies the hypotheses of Remark C.3.5.4: that is, for every injective map $\alpha : [m] \hookrightarrow [n]$, the associated functor $f_\alpha : \mathcal{E}_n \to \mathcal{E}_m$ admits a right adjoint which preserves small colimits. Factoring α as a composition, we may reduce to the case $m = n - 1$, so that f_α is one of the face maps of the simplicial object $\mathcal{E}_\bullet$. Unwinding the definitions, we see that f_α is obtained from one of the maps

$$a : \mathcal{M} \otimes \mathrm{LMod}_R^{\mathrm{cn}} \to \mathcal{M} \qquad m : \mathrm{LMod}_R^{\mathrm{cn}} \otimes \mathrm{LMod}_R^{\mathrm{cn}} \to \mathrm{LMod}_R^{\mathrm{cn}} \qquad a' : \mathrm{LMod}_R^{\mathrm{cn}} \otimes \mathcal{N} \to \mathcal{N}$$

by tensoring with some auxiliary object of Groth_∞; here the functor a is given by the right action of $\mathrm{LMod}_R^{\mathrm{cn}}$ on $\mathcal{M}$, the functor m is given by the monoidal structure on $\mathrm{LMod}_R^{\mathrm{cn}}$, and the functor a' is given by the left action of $\mathrm{LMod}_R^{\mathrm{cn}}$ on $\mathcal{N}$. By virtue of Remark C.4.4.5, it will suffice to show that the functors a, m, and a' admit right adjoints which preserve small colimits. We will prove this for the functor a; the proof in the other cases differs by a slight change in notation. We first note that a admits a right homotopy inverse f, given by the natural map $\mathcal{M} \simeq \mathcal{M} \otimes \mathrm{Sp}^{\mathrm{cn}} \to \mathcal{M} \otimes \mathrm{LMod}_R^{\mathrm{cn}}$. Let $g : \mathcal{M} \otimes \mathrm{LMod}_R \to \mathcal{M}$ be a right adjoint to f, so that g is a left homotopy inverse to the right adjoint of a. Consequently, to show that the right adjoint of a preserves small colimits, it will suffice to show that g is conservative and preserves small colimits. Using Theorem HA.4.8.4.6 , we can identify g with the forgetful functor $\mathrm{RMod}_R(\mathcal{M}) \to \mathcal{M}$, so that the desired result is a special case of Corollary HA.4.2.3.5 .

We now prove (d). Let us abuse notation by identifying $\mathcal{M}$ and $\mathcal{N}$ with their homotopy categories (which are Grothendieck abelian categories). Define

$$\mathcal{M}_+ = \mathcal{D}(\mathcal{M})_{\geqslant 0} \qquad \mathcal{N}_+ = \mathcal{D}(\mathcal{N})_{\geqslant 0},$$

so that $\mathcal{M}_+$ and $\mathcal{N}_+$ are Grothendieck prestable ∞-categories whose hearts can be identified with $\mathcal{M}$ and $\mathcal{N}$, respectively. It follows from Example D.1.3.9 that the action of R on $\mathcal{N}$ admits an essentially unique lift to an action of determines an action of R on $\mathcal{N}_+$; similarly, the action of R^{rev} on $\mathcal{M}$ admits an essentially unique lift to an action of R^{rev} on $\mathcal{M}_+$. Applying Remark D.2.1.3, we compute

$$\begin{aligned}\mathcal{M} \otimes_R \mathcal{N} &\simeq \mathcal{M}_+^{\heartsuit} \otimes_R \mathcal{N}_+^{\heartsuit} \\ &\simeq (\mathcal{M}_+ \otimes_R \mathcal{N}_+)^{\heartsuit}.\end{aligned}$$

It follows from part (c) that the tensor product $\mathcal{M}_+ \otimes_R \mathcal{N}_+$ is a Grothendieck prestable ∞-category, so that its heart $(\mathcal{M}_+ \otimes_R \mathcal{N}_+)^{\heartsuit}$ is a Grothendieck abelian category. □

D.2.3 The Commutative Case

Let us now specialize to the study of additive ∞-categories equipped with actions of $\mathbb{E}_\infty$-rings.

Remark D.2.3.1. Let R be a connective $\mathbb{E}_\infty$-ring. Then $\mathrm{Mod}_R^{\mathrm{cn}}$ is a symmetric monoidal ∞-category which we can regard as a *commutative* algebra object of the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$. In this case, the ∞-category

$$\mathrm{LinCat}_R^{\mathrm{Add}} = \mathrm{LMod}_{\mathrm{LMod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \simeq \mathrm{Mod}_{\mathrm{Mod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$$

of additive R-linear ∞-categories inherits the structure of a symmetric monoidal ∞-category, and the symmetric monoidal structure on $\mathrm{LinCat}_R^{\mathrm{Add}}$ is given (at the level of the underlying ∞-categories) by the relative tensor product $\otimes_R$ of Construction D.2.1.1 (see Theorem HA.4.5.2.1).

Note that the full subcategory $\mathrm{LinCat}_R^{\mathrm{PSt}} \subseteq \mathrm{LinCat}_R^{\mathrm{Add}}$ of prestable R-linear ∞-categories contains the unit object $\mathrm{Mod}_R^{\mathrm{cn}} \in \mathrm{LinCat}_R^{\mathrm{Add}}$ and is closed under tensor products (by virtue of Proposition D.2.2.1). It follows that $\mathrm{LinCat}_R^{\mathrm{PSt}}$ inherits the structure of a symmetric monoidal ∞-category.

Variant D.2.3.2. Let R be a connective $\mathbb{E}_\infty$-ring. Then the abelian category $\mathrm{Mod}_R^{\heartsuit}$ of discrete R-modules can be regarded as a commutative algebra object of $\mathcal{P}\mathrm{r}^{\mathrm{L}}$. Consequently, the ∞-category $\mathrm{Mod}_{\mathrm{Mod}_R^{\heartsuit}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ inherits the structure of a symmetric monoidal ∞-category. Note that we can identify $\mathrm{Mod}_{\mathrm{Mod}_R^{\heartsuit}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ with the full subcategory of $\mathrm{LinCat}_R^{\mathrm{Add}}$ spanned by the additive R-linear ∞-categories which are equivalent to their homotopy categories. It follows from Remark D.2.1.2 that under this identification, the tensor product on $\mathrm{Mod}_{\mathrm{Mod}_R^{\heartsuit}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ corresponds to the relative tensor product $(\mathcal{M}, \mathcal{N}) \mapsto \mathcal{M} \otimes_R \mathcal{N}$ of Construction D.2.1.1. Let us identify ∞-category $\mathrm{Mod}_R^{\mathrm{Ab}}$ of abelian R-linear ∞-categories with a full subcategory of $\mathrm{Mod}_{\mathrm{Mod}_R^{\heartsuit}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$. This subcategory contains the unit object $\mathrm{Mod}_R^{\heartsuit}$ and is closed under tensor products (by virtue of Proposition D.2.2.1), and therefore inherits the structure of a symmetric monoidal ∞-category.

Variant D.2.3.3. Let R be an arbitrary $\mathbb{E}_\infty$-ring. Then Mod_R is a symmetric monoidal ∞-category which we can regard as commutative algebra object of the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$. In this case, the ∞-category

$$\mathrm{LinCat}_R^{\mathrm{St}} = \mathrm{LMod}_{\mathrm{LMod}_R}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \simeq \mathrm{Mod}_{\mathrm{Mod}_R}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$$

of stable R-linear ∞-categories (as defined in Variant D.1.5.1) inherits a symmetric monoidal structure whose tensor product is given (at the level of the underlying stable ∞-categories) by the the construction $(\mathcal{M}, \mathcal{N}) \mapsto \mathcal{M} \otimes_R \mathcal{N}$ of Variant D.2.1.5 (which agrees with Construction D.2.1.1 whenever R is connective).

Remark D.2.3.4. Let R be a connective $\mathbb{E}_\infty$-ring. Then the constructions

$$\begin{array}{ccccc} \mathrm{LinCat}_R^{\mathrm{St}} & \leftarrow & \mathrm{LinCat}_R^{\mathrm{PSt}} & \rightarrow & \mathrm{LinCat}_R^{\mathrm{Ab}} \\ \mathrm{Sp}(\mathcal{C}) & \leftarrow\!\shortmid & \mathcal{C} & \mapsto & \mathcal{C}^{\heartsuit} \end{array}$$

are symmetric monoidal (with respect to the symmetric monoidal structures described in Remark D.2.3.1, Variant D.2.3.2, and Variant D.2.3.3). Note that on all three ∞-categories, the tensor product functor $\otimes_R$ is given by Construction D.2.1.1. However, the unit objects are different: the unit object of $\mathrm{LinCat}_R^{\mathrm{St}}$ is the stable ∞-category Mod_R, the unit object of $\mathrm{LinCat}_R^{\mathrm{PSt}}$ is the prestable ∞-category $\mathrm{Mod}_R^{\mathrm{cn}}$, and the unit object of $\mathrm{LinCat}_R^{\mathrm{Ab}}$ is the abelian category $\mathrm{Mod}_R^{\heartsuit}$.

Remark D.2.3.5. If κ is a field, the tensor product

$$\otimes_\kappa : \mathrm{LinCat}_\kappa^{\mathrm{Ab}} \times \mathrm{LinCat}_\kappa^{\mathrm{Ab}} \rightarrow \mathrm{LinCat}_\kappa^{\mathrm{Ab}}$$

is closely related to Deligne's tensor product for (small) κ-linear abelian categories (see [48]). The restriction to the setting of small abelian categories is technically inconvenient, since Deligne's tensor product is only well-defined (at least as an abelian category) under somewhat restrictive assumptions. We refer the reader to [65] for further discussion.

D.2.4 Extension of Scalars

We now return to the setting of $\mathbb{E}_2$-rings.

Construction D.2.4.1 (Extension of Scalars)**.** Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_2$-rings. For every additive R-linear ∞-category $\mathcal{C}$, we let $R' \otimes_R \mathcal{C}$ denote the additive R'-linear ∞-category given by the relative tensor product

$$\mathrm{Mod}^{\mathrm{cn}}_{R'} \otimes_R \mathcal{C} = \mathrm{Mod}^{\mathrm{cn}}_{R'} \otimes_{\mathrm{Mod}^{\mathrm{cn}}_R} \mathcal{C} = |\,\mathrm{Bar}_{\mathrm{Mod}^{\mathrm{cn}}_R}(\mathrm{Mod}^{\mathrm{cn}}_{R'}, \mathcal{C})_\bullet|.$$

We will say that $R' \otimes_R \mathcal{C}$ is obtained from $\mathcal{C}$ by *extension of scalars* along the morphism ϕ.

Remark D.2.4.2. If $\phi : R \to R'$ is a morphism of connective $\mathbb{E}_2$-rings, then extension of scalars along ϕ determines a functor $\mathrm{LinCat}^{\mathrm{Add}}_R \to \mathrm{LinCat}^{\mathrm{Add}}_{R'}$ which is left adjoint to the forgetful functor $\mathrm{LinCat}^{\mathrm{Add}}_{R'} \to \mathrm{LinCat}^{\mathrm{Add}}_R$ given by restriction of scalars along ϕ.

Variant D.2.4.3. Let $\phi : R \to R'$ be an arbitrary morphism of $\mathbb{E}_2$-rings. If $\mathcal{C}$ is a stable R-linear ∞-category, we let $R' \otimes_R \mathcal{C}$ denote the relative tensor product

$$\mathrm{LMod}_{R'} \otimes_R \mathcal{C} = \mathrm{LMod}_{R'} \otimes_{\mathrm{LMod}_R} \mathcal{C} = |\,\mathrm{Bar}_{\mathrm{LMod}_R}(\mathrm{LMod}_{R'}, \mathcal{C})_\bullet|.$$

Then $R' \otimes_R \mathcal{C}$ is a stable R'-linear ∞-category which we will say is obtained from $\mathcal{C}$ by extension of scalars along ϕ.

If R and R' are connective, then the assumption that $\mathcal{C}$ is stable guarantees that the inclusion maps

$$\mathrm{LMod}^{\mathrm{cn}}_R \hookrightarrow \mathrm{LMod}_R \qquad \mathrm{LMod}^{\mathrm{cn}}_{R'} \hookrightarrow \mathrm{LMod}_{R'}$$

induce a levelwise equivalence of two-sided bar constructions $\mathrm{Bar}_{\mathrm{LMod}^{\mathrm{cn}}_R}(\mathrm{LMod}^{\mathrm{cn}}_{R'}, \mathcal{C})_\bullet \to \mathrm{Bar}_{\mathrm{LMod}_R}(\mathrm{LMod}_{R'}, \mathcal{C})_\bullet$. Consequently, as an additive R'-linear ∞-category, the extension of scalars $R' \otimes_R \mathcal{C}$ agrees with the one given by Construction D.2.4.1.

Remark D.2.4.4. Let R be a connective $\mathbb{E}_2$-ring and let $\mathcal{C}$ be an additive R-linear ∞-category. Let A be a connective $\mathbb{E}_1$-algebra over R (that is, an algebra object of the monoidal ∞-category $\mathrm{LMod}^{\mathrm{cn}}_R$) and let $\mathrm{LMod}_A(\mathcal{C})$ denote the ∞-category of A-module objects of $\mathcal{C}$. Then Theorem HA.4.8.4.6 supplies an equivalence of ∞-categories $\mathrm{LMod}_A(\mathcal{C}) \simeq \mathrm{LMod}^{\mathrm{cn}}_A \otimes_{\mathrm{LMod}^{\mathrm{cn}}_R} \mathcal{C}$. In particular, if $\phi : R \to R'$ is a morphism of connective $\mathbb{E}_2$-rings, then the extension of scalars $R' \otimes_R \mathcal{C}$ can be identified with the ∞-category $\mathrm{LMod}_{R'}(\mathcal{C})$.

If the ∞-category $\mathcal{C}$ is stable, then the same reasoning applies without any connectivity assumptions on R and R'.

Proposition D.2.4.5. *Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_2$-rings. Then:*

(a) *If $\mathcal{C}$ is a stable R-linear ∞-category, then the extension of scalars $R' \otimes_R \mathcal{C}$ is a stable R-linear ∞-category.*

(b) *If $\mathcal{C}$ is a prestable R-linear ∞-category, then the extension of scalars $R' \otimes_R \mathcal{C}$ is a prestable R'-linear ∞-category.*

(c) *If $\mathcal{C}$ is an abelian R-linear ∞-category, then the extension of scalars $R' \otimes_R \mathcal{C}$ is an abelian R'-linear ∞-category.*

Proof. Assertions (a) and (b) follow immediately from Proposition D.2.2.1. To prove (c), we observe that $\mathcal{C}$ can be regarded as an Ab-module object of $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ (Proposition C.5.4.13), so that $R' \otimes_R \mathcal{C}$ inherits the structure of an Ab-module and is therefore equivalent to its homotopy category. We therefore have equivalences

$$\begin{aligned} R' \otimes_R \mathcal{C} &\simeq (R' \otimes_R \mathcal{C})^{\heartsuit} \\ &\simeq (\mathrm{Mod}^{\mathrm{cn}}_{R'} \otimes_{\mathrm{Mod}^{\mathrm{cn}}_R} \mathcal{C})^{\heartsuit} \\ &\simeq \mathrm{Mod}^{\heartsuit}_{R'} \otimes_{\mathrm{Mod}^{\heartsuit}_R} \mathcal{C}^{\heartsuit} \\ &\simeq \mathrm{Mod}^{\heartsuit}_{R'} \otimes_R \mathcal{C} \end{aligned}$$

so that the desired result again follows from Proposition D.2.2.1. □

Remark D.2.4.6. One can deduce Proposition D.2.4.5 directly (without use of Proposition D.2.2.1) from the description of the extension of scalars functor supplied by Remark D.2.4.4.

Remark D.2.4.7. Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_2$-rings and let $\mathcal{C}$ be a prestable R-linear ∞-category. Then the stabilization $\mathrm{Sp}(\mathcal{C})$ inherits a t-structure $(\mathrm{Sp}(\mathcal{C})_{\geqslant 0}, \mathrm{Sp}(\mathcal{C})_{\leqslant 0})$, where $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ is the essential image of the functor $\Sigma^{\infty} : \mathcal{C} \to \mathrm{Sp}(\mathcal{C})$. Similarly, the ∞-category

$$\mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C})) = R' \otimes_R \mathrm{Sp}(\mathcal{C}) \simeq \mathrm{Sp}(R' \otimes_R \mathcal{C})$$

inherits a t-structure, where $\mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$ is the essential image of the functor

$$\Sigma^{\infty} : (R' \otimes_R \mathcal{C}) \to \mathrm{Sp}(R' \otimes_R \mathcal{C}).$$

We claim that this t-structure can be described explicitly as follows:

(a) An object $X \in \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))$ belongs to $\mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$ if and only if its image in $\mathrm{Sp}(\mathcal{C})$ belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$.

(b) An object $X \in \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))$ belongs to $\mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))_{\leqslant 0}$ if and only if its image in $\mathrm{Sp}(\mathcal{C})$ belongs to $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$.

To prove the "only if" directions of (a) and (b), we observe that the forgetful functor $G : \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C})) \to \mathrm{Sp}(\mathcal{C})$ is right adjoint to the stabilization of the natural map $\mathcal{C} \simeq R \otimes_R \mathcal{C} \to R' \otimes_R \mathcal{C}$, and therefore t-exact by the proof of Proposition D.2.2.1. The "if" directions of (a) and (b) then follow from the additional observation that the functor G is conservative.

D.3 Universal Descent Morphisms

Let $f : A \to B$ be a faithfully flat map of commutative rings. A classical theorem of Grothendieck asserts that the category of A-modules is equivalent to the category $\mathcal{C}$ whose objects are pairs (M, η), where M is a B-module and η is a "descent datum" for M: that is, an automorphism of $B \otimes_A M$ which is compatible with the evident involution of $B \otimes_A B$ and satisfies a suitable cocycle condition. Our goal in this section is to prove an analogue of Grothendieck's result in the ∞-categorical setting. More precisely, we will introduce the notion of a *universal descent morphism* of ring spectra (Definition D.3.1.1) and show that, if $f : A \to B$ is a universal descent morphism, then the ∞-category Mod_A can be identified with a suitably defined ∞-category of "B-modules equipped with descent data" (Corollary D.3.4.2). Moreover, an analogous statement holds for any arbitrary stable A-linear ∞-category (Theorem D.3.4.1).

The collection of universal descent morphisms is fairly robust: for example, it includes all faithfully flat morphisms $f : A \to B$ for which $\pi_0 B$ admits a countable (or even mildly uncountable) presentation as a $\pi_0 A$-module (Proposition D.3.3.1).

Remark D.3.0.8. Most of the results of this section (including the definition of universal descent morphism) were explained to us by Akhil Mathew. We refer the reader to [**?**] for further discussion.

D.3.1 Propagating Modules

Definition D.3.1.1. Let A be an $\mathbb{E}_2$-ring, let M be a left A-module spectrum, and let $\mathcal{C}$ denote the smallest stable subcategory of LMod_A which contains all A-modules of the form $N \otimes_A M$ and is closed under retracts. We will say that M is a *propagating module* for A if $\mathcal{C} = \mathrm{LMod}_A$. We will say that a morphism $f : A \to B$ of $\mathbb{E}_2$-rings is a *universal descent morphism* if it exhibits B as a propagating module for A.

Warning D.3.1.2. In the situation of Definition D.3.1.1, the monoidal structure on LMod_A is generally not symmetric. Consequently, the notion of propagating module is *a priori* asymmetric as well: it might be more appropriate to refer to an object $M \in \mathrm{LMod}_A$ as a *left propagating* module if it satisfies the requirements of Definition D.3.1.1, and a *right propagating module* if the ∞-category LMod_A is generated (under finite colimits and retracts) by objects of the form $M \otimes_A N$. However, we will see in a moment that an $\mathbb{E}_1$-algebra $B \in \mathrm{Alg}_A$ is left propagating as an A-module if and only if it is right propagating (Remark D.3.2.2). In practice, we will primarily be interested in universal descent morphisms between $\mathbb{E}_\infty$-rings, in which case the potential asymmetry disappears.

Remark D.3.1.3. Let A be an $\mathbb{E}_2$-ring and let $M \in \mathrm{LMod}_A$. Then the full subcategory $\mathcal{C} \subseteq \mathrm{LMod}_A$ appearing in Definition D.3.1.1 is closed under the operation $\bullet \mapsto N \otimes_A \bullet$, for each object $N \in \mathrm{LMod}_A$. It follows that M is a propagating module for A if and only if $A \in \mathcal{C}$.

Remark D.3.1.4. Let $\{A_i\}_{1 \leqslant i \leqslant n}$ be a finite collection of $\mathbb{E}_2$-rings with product A, and let M be a left A-module which we can write as a product $\prod_{1 \leqslant i \leqslant n} M_i$, where each M_i is a left A_i-module (see Lemma D.3.5.5). Then M is a propagating A-module if and only if each M_i is a propagating A_i-module.

Remark D.3.1.5. Let $\phi : A \to A'$ be a morphism of $\mathbb{E}_2$-rings, let $M \in \mathrm{LMod}_A$, and set $M' = A' \otimes_A M \in \mathrm{LMod}_{A'}$. Let $\mathcal{C} \subseteq \mathrm{LMod}_A$ be the subcategory appearing in Definition D.3.1.1, and let $\mathcal{C}' \subseteq \mathrm{LMod}_{A'}$ be defined in an analogous way. Then the extension of scalars functor

$$\mathrm{LMod}_A \to \mathrm{LMod}_{A'} \qquad N \mapsto A' \otimes_A N$$

carries $\mathcal{C}$ into $\mathcal{C}'$. In particular, if M is a propagating module for A, then $A' = A' \otimes_A A \in \mathcal{C}'$, so that M' is a propagating module for A' (Remark D.3.1.3).

Proposition D.3.1.6. (1) *Every equivalence of $\mathbb{E}_2$-rings is a universal descent morphism.*

(2) *Let $f : A \to B$ and $g : B \to C$ be universal descent morphisms in $\mathrm{Alg}^{(2)}$. Then $g \circ f : A \to C$ is a universal descent morphism.*

(3) *Let*

$$\begin{array}{ccc} A & \xrightarrow{f} & B \\ \downarrow & & \downarrow \\ A' & \xrightarrow{f'} & B' \end{array}$$

be a pushout diagram of $\mathbb{E}_\infty$-rings. If f is a universal descent morphism, then so is f'.

(4) *The collection of universal descent morphisms is closed under finite products.*

Proof. Assertion (1) is obvious, assertion (3) follows immediately from Remark D.3.1.3, and assertion (4) follows immediately from Remark D.3.1.4. To prove (2), let $\mathcal{C} \subseteq \mathrm{LMod}_A$ denote the smallest stable subcategory of LMod_A which contains the essential image of the forgetful functor $\mathrm{LMod}_C \to \mathrm{LMod}_A$ and is closed under retracts. By virtue of Variant D.3.2.3, it will suffice to show that $\mathcal{C} = \mathrm{LMod}_A$. Since f is a universal descent morphism, we are reduced to proving that $\mathcal{C}$ contains the essential image of the forgetful functor $\mathrm{LMod}_B \to \mathrm{LMod}_A$. Let $\mathcal{D} \subseteq \mathrm{LMod}_B$ be the inverse image of $\mathcal{C}$; we wish to show that $\mathcal{D} = \mathrm{LMod}_B$. Using our assumption that g is a universal descent morphism, we are reduced to showing that $\mathcal{D}$ contains the essential image of the forgetful functor $\mathrm{LMod}_C \to \mathrm{LMod}_B$, which follows immediately from our construction. □

Remark D.3.1.7. Let A be an $\mathbb{E}_\infty$-ring, and let S be the collection of all universal descent morphisms in the ∞-category $\mathrm{CAlg}_A^{\mathrm{op}}$. Then Proposition D.3.1.6 implies that S satisfies the hypotheses of Proposition A.3.2.1, and therefore determines a Grothendieck topology on the (large) ∞-category $\mathrm{CAlg}_A^{\mathrm{op}}$. We will refer to this Grothendieck topology as the *universal descent topology*.

D.3.2 The Adams Tower

Let A be an $\mathbb{E}_2$-ring and let $B \in \mathrm{Alg}_A$ be an $\mathbb{E}_1$-algebra over A. Then we can associate to B a cosimplicial object $B^\bullet$ of LMod_A, given levelwise by the formula

$$[n] \mapsto B^n = B \otimes_A \cdots \otimes_A B.$$

We let $\mathrm{Tot}^\bullet(B/A)$ denote the Tot-tower of this cosimplicial object: that is, the sequence of morphisms

$$\cdots \to \mathrm{Tot}^2(B/A) \to \mathrm{Tot}^1(B/A) \to \mathrm{Tot}^0(B/A) \simeq B$$

where $\mathrm{Tot}^n(B/A) \simeq \varprojlim_{[m] \in \mathbf{\Delta}_{\leqslant n}} B^m$. We will abuse notation by identifying $\mathrm{Tot}^\bullet(B/A)$ with the corresponding Pro-object of LMod_A.

Proposition D.3.2.1. *Let A be an $\mathbb{E}_2$-ring and let $B \in \mathrm{Alg}_A$ be an $\mathbb{E}_1$-algebra over A. The following conditions are equivalent:*

(1) *The image of B in LMod_A is a propagating module for A.*

(2) *The unit map $f : A \to B$ induces an equivalence*

$$A \simeq \{\mathrm{Tot}^\bullet(A/A)\} \to \{\mathrm{Tot}^\bullet(B/A)\}$$

in the ∞-category $\mathrm{Pro}(\mathrm{LMod}_A)$.

Proof. We first prove that (1) $\Rightarrow$ (2). Let $\mathcal{C}$ denote the full subcategory of LMod_A spanned by those objects M for which the canonical map $\theta_M : \{M \otimes_A \mathrm{Tot}^\bullet(A/A)\} \to \{M \otimes_A \mathrm{Tot}^\bullet(B/A)\}$ is an equivalence in $\mathrm{Pro}(\mathrm{LMod}_A)$. Since the construction $M \mapsto \theta_M$ is an exact functor, the ∞-category $\mathcal{C}$ is a stable subcategory of LMod_A which is closed under retracts. It follows immediately from the definitions that if $M \in \mathcal{C}$, then $N \otimes_A M \in \mathcal{C}$. Consequently, to prove (2), it will suffice to show $\mathcal{C}$ contains a propagating module for A. By virtue of (1), it will suffice to show that $B \in \mathcal{C}$. This is clear, since $\{B \otimes \mathrm{Tot}^\bullet(B/A)\}$ can be identified with the Tot-tower associated to the split cosimplicial object $B^{\bullet+1}$.

Now suppose that (2) is satisfied. Let $\mathcal{D}$ denote the smallest stable subcategory of LMod_A which contains all objects of the form $N \otimes_A B$ and is closed under retracts. Then $B^\bullet$ is a cosimplicial object of $\mathcal{D}$. Since each term in the tower $\mathrm{Tot}^\bullet(B/A)$ can be written as a finite limit of objects of the form B^n, it follows that $\{\mathrm{Tot}^\bullet(B/A)\}$ can be identified with a

Pro-object of $\mathcal{D}$. Assumption (2) implies that A is equivalent to a retract of $\mathrm{Tot}^n(B/A)$ for some integer n, so that $A \in \mathcal{D}$. Invoking Remark D.3.1.3, we see that $\mathcal{D} = \mathrm{LMod}_A$, so that condition (1) is satisfied. □

Remark D.3.2.2. It follows from Proposition D.3.2.1 that if $B \in \mathrm{Alg}_A$ is an $\mathbb{E}_1$-algebra over A, then B is left propagating if and only if it is right propagating, in the sense of Warning D.3.1.2.

Variant D.3.2.3. Let $f : A \to B$ be a morphism of $\mathbb{E}_2$-rings. The following conditions are equivalent:

(1) The map f is a universal descent morphism.

(2) Let $\mathcal{C} \subseteq \mathrm{LMod}_A$ be the smallest stable subcategory which contains the essential image of the forgetful functor $\mathrm{LMod}_B \to \mathrm{LMod}_A$ and is closed under retracts. Then $\mathcal{C} = \mathrm{LMod}_A$.

Proof. Let $\mathcal{C}$ be as in (2). Then $\mathcal{C}$ contains all objects of the form $M \otimes_A B$, so that the implication (1) ⇒ (2) follows immediately from the definitions. Conversely, suppose that (2) is satisfied. Let $\mathcal{D} \subseteq \mathrm{LMod}_A$ be the full subcategory spanned by those objects M for which the canonical map

$$\theta_M : \{M \otimes_A \mathrm{Tot}^\bullet(A/A)\} \to \{M \otimes_A \mathrm{Tot}^\bullet(B/A)\}$$

is an equivalence in $\mathrm{Pro}(\mathrm{LMod}_A)$. Then $\mathcal{D}$ is a stable subcategory of LMod_A which is closed under retracts, and we wish to show that $A \in \mathcal{D}$. By virtue of (2), it will suffice to show that $\mathcal{D}$ contains the essential image of the forgetful functor $\mathrm{LMod}_B \to \mathrm{LMod}_A$. This follows from the observation that for $M \in \mathrm{LMod}_B$, the simplicial object $M \otimes_A B^\bullet \simeq M \otimes_B B^{\bullet+1}$ is a split cosimplicial object with limit M. □

D.3.3 Faithfully Flat Morphisms

Our next result supplies a large class of universal descent morphisms.

Proposition D.3.3.1. *Let $\phi : A \to B$ be a faithfully flat morphism of $\mathbb{E}_2$-rings. Suppose that, as a left module over $\pi_0 A$, the commutative ring $\pi_0 B$ admits a presentation using fewer than $\aleph_\omega$ generators and relations (here $\aleph_\omega$ denotes the first infinite singular cardinal). Then ϕ is a universal descent morphism.*

Remark D.3.3.2. The technical cardinality assumption appearing in Proposition D.3.3.1 is automatically satisfied if the commutative rings $\pi_0 A$ and $\pi_0 B$ have cardinality $< \aleph_\omega$. Assuming the generalized continuum hypothesis, this condition is satisfied for all commutative rings which arise in ordinary mathematical practice.

Remark D.3.3.3. There exist many examples of universal descent morphisms which are not faithfully flat. For example, the canonical map from the real K-theory spectrum KO to the complex K-theory spectrum KU is a universal descent morphism.

Remark D.3.3.4. We do not know if every faithfully flat morphism of ring spectra is a universal descent morphism. However, many of the descent theorems in this section can be proven for arbitrary faithfully flat morphisms as well; see §D.6 for more details.

Corollary D.3.3.5. *Every faithfully flat étale morphism of $\mathbb{E}_2$-rings is a universal descent morphism.*

The proof of Proposition D.3.3.1 is based on a theorem of Mitchell on vanishing of derived functors of the inverse limit for filtered diagrams of small cofinality. We formulate a version of this result as follows:

Lemma D.3.3.6. *Let n be a nonnegative integer, let J be a filtered partially ordered set of cardinality $\leqslant \aleph_n$, and let $\{X_j\}_{j \in J}$ be a diagram of spaces indexed by J^{op}. If each of the spaces X_j is m-connective for some integer m, then the inverse limit $\varprojlim_{j \in J} X_j$ is $(m-n)$-connective.*

Proof. We proceed by induction on n. Note that if J has cardinality $< \aleph_n$, the desired result follows from the inductive hypothesis (note that if J is finite, there is nothing to prove). We may therefore assume that the cardinality of J is exactly $\aleph_n$.

We now proceed by induction on m. If $m < n$ then there is nothing to prove. If $m > n$, then to show that $X = \varprojlim_{j \in J} X_j$ is $(m-n)$-connective, it will suffice to show that it is nonempty and that the fiber product $\{x\} \times_X \{y\}$ is $(m-n-1)$-connective for every pair of points $x, y \in X$. This follows from the inductive hypothesis, applied to the diagram $\{\{x\} \times_{X_j} \{y\}\}_{j \in J}$. It will therefore suffice to treat the case $m = n$: that is, we must show that if each X_j is n-connective, then the limit X is nonempty.

Since the cardinality of J is $\aleph_n$, we can choose a bijection $\mu : \aleph_n \to J$. We define a sequence of subsets $J_\alpha \subseteq J$ for $\alpha < \aleph_n$, each having cardinality $< \aleph_n$, using transfinite induction on α. Assuming that J_β has been constructed for $\beta < \alpha$, we take J_α to be any filtered subset of J having cardinality $< \aleph_n$ which contains $\mu(\alpha)$ and the union $\bigcup_{\beta < \alpha} J_\beta$. Then we can write $\mathrm{N}(J)$ as a filtered colimit of simplicial sets $\varinjlim_{\alpha < \aleph_n} \mathrm{N}(J_\alpha)$. It follows that we can write X as the limit of a diagram $\{Y_\alpha\}_{\alpha < \aleph_n}$, where $Y_\alpha = \varprojlim_{j \in J_\alpha} X_j$ (see §HTT.4.2.3).

Without loss of generality, we can assume that the diagram $\{Y_\alpha\}_{\alpha < \aleph_n}$ is given by a map $\mathrm{N}(\aleph_n)^{\mathrm{op}} \to \mathcal{S}$ which is obtained as the nerve of a functor of ordinary categories $\rho : \aleph_n^{\mathrm{op}} \to \mathcal{S}\mathrm{et}_\Delta$ (Proposition HTT.4.2.4.4). Moreover, we may assume that ρ is fibrant with respect to the injective model structure on $\mathrm{Fun}(\aleph_n^{\mathrm{op}}, \mathcal{S}\mathrm{et}_\Delta)$. In this case, the limit Y of the diagram $\{Y_\alpha\}_{\alpha < \aleph_n}$ in the ∞-category $\mathcal{S}$ coincides with its limit in the ordinary category of simplicial sets (Theorem HTT.4.2.4.1). We wish to prove that Y is nonempty. Since the diagram $\{Y_\alpha\}$ is indexed by a well-ordered set, it will suffice to show that for each $\alpha < \aleph_n$, the canonical map $\theta : Y_\alpha \to \varprojlim_{\beta<\alpha} Y_\beta$ is surjective on vertices. Because ρ is a fibrant diagram, the map θ is a Kan fibration. It will therefore suffice to show that the spaces

$$Y_\alpha = \varprojlim_{j \in J_\alpha} X_j \qquad \text{and} \qquad \varprojlim_{\beta<\alpha} Y_\beta \simeq \varprojlim_{j \in \bigcup_{\beta<\alpha} J_\beta} X_j$$

are connected. This follows from our inductive hypothesis, since the filtered partially ordered sets J_α and $\bigcup_{\beta<\alpha} J_\beta$ have cardinality $< \aleph_n$. □

Lemma D.3.3.7. *Let A be a connective $\mathbb{E}_1$-ring, let M be a flat left A-module, and let N be a connective left A-module. Assume that $\pi_0 M$ is an $\aleph_n$-compact object of the category of discrete $\pi_0 A$-modules. Then $\mathrm{Ext}^m_A(M, N) \simeq 0$ for $m > n$.*

Proof. Let us identify N with the limit of its Postnikov tower

$$\cdots \to \tau_{\leqslant 2} N \to \tau_{\leqslant 1} N \to \tau_{\leqslant 0} N,$$

so that we have a Milnor exact sequence

$$\lim{}^1 \{\mathrm{Ext}^{m-1}_A(M, \tau_{\leqslant k} N)\} \to \mathrm{Ext}^m_A(M, N) \to \lim{}^0 \{\mathrm{Ext}^m_A(M, \tau_{\leqslant k} N)\}.$$

It will therefore suffice to show that the abelian groups $\lim^1\{\mathrm{Ext}^{m-1}_A(M, \tau_{\leqslant k} N)\}$ and $\lim^0\{\mathrm{Ext}^m_A(M, \tau_{\leqslant k} N)\}$ are trivial for $m > n$. To prove this, we will show that the maps $\mathrm{Ext}^{m-1}_A(M, \tau_{\leqslant k} N) \to \mathrm{Ext}^{m-1}_A(M, \tau_{\leqslant k-1} N)$ are surjective for $k \geqslant 1$, and that the groups $\mathrm{Ext}^m(M, \tau_{\leqslant k} N)$ vanish for all k. Using the exact sequences

$$\mathrm{Ext}^{m-1}_A(M, \tau_{\leqslant k} N) \to \mathrm{Ext}^{m-1}_A(M, \tau_{\leqslant k-1} N) \to \mathrm{Ext}^{m+k}_A(M, \pi_k N)$$

$$\mathrm{Ext}^{m+k}_A(M, \pi_k N) \to \mathrm{Ext}^m_A(M, \tau_{\leqslant k} N) \to \mathrm{Ext}^m_A(M, \tau_{\leqslant k-1} N),$$

we are reduced to proving that the groups $\mathrm{Ext}^{m+k}_A(M, \pi_k N)$ vanish. Replacing m by $m+k$ and N by $\pi_k N$, we can further reduce to the case where N is discrete. In this case, we have a canonical isomorphism $\mathrm{Ext}^m_A(M, N) \simeq \mathrm{Ext}^m_{\pi_0 A}(\pi_0 A \otimes_A M, N)$. We may therefore replace A by $\pi_0 A$ (and M by $\pi_0 A \otimes_A M$) and thereby reduce to the case where A is discrete. Since M is flat over A, it follows that M is also discrete.

Since M is flat over A, it can be written as the colimit of a diagram $\{M_\alpha\}_{\alpha \in P}$ indexed by a filtered partially ordered set P, where each M_α is a free left A-module of finite rank (Theorem HA.7.2.2.15). For each $\aleph_n$-small filtered subset $P' \subseteq P$, let $M_{P'}$ denote the colimit $\varinjlim_{\alpha \in P'} M_\alpha$. Then M can be written as a filtered colimit of the diagram $\{M_{P'}\}$, where P' ranges over all $\aleph_n$-small filtered subsets of P. Since M is $\aleph_n$-compact, the identity map $\mathrm{id}_M : \varinjlim_{P'} M_{P'} \to M$ factors through some $M_{P'}$, so that M is a retract of $M_{P'}$. We may therefore replace M by $M_{P'}$ and P by P', and thereby reduce to the case where P is $\aleph_n$-small. We have a canonical isomorphism

$$\mathrm{Ext}^m_A(M,N) \simeq \pi_0 \mathrm{Map}_{\mathrm{Mod}_A}(M, \Sigma^m N) \simeq \pi_0 \varprojlim_{\alpha \in P} \mathrm{Map}_{\mathrm{Mod}_A}(M_\alpha, \Sigma^m N)$$

To show that this group vanishes, it will suffice (by virtue of Lemma D.3.3.6) to show that the mapping spaces $\mathrm{Map}_{\mathrm{Mod}_A}(M_\alpha, \Sigma^m N)$ are n-connective for each $\alpha \in P$. This is clear, since M_α is a free left A-module of finite rank and $\Sigma^m N$ is n-connective. □

Proof of Proposition D.3.3.1. Since B is flat over A, we can identify B with the image of its connective cover $\tau_{\geqslant 0} B$ under the base change functor $\mathrm{LMod}_{\tau_{\geqslant 0} A} \to \mathrm{LMod}_A$. By virtue of Remark D.3.1.3, to prove that B is propagating as a left A-module, it will suffice to show that $\tau_{\geqslant 0} B$ is propagating as a left $\tau_{\geqslant 0} A$-module. We may therefore replace ϕ by the induced map $\tau_{\geqslant 0} A \to \tau_{\geqslant 0} B$ and thereby reduce to the case where A is connective.

Let $\mathcal{C}$ denote the smallest stable subcategory of LMod_A which contains all objects of the form $M \otimes_A B$ and is closed under retracts. By virtue of Remark D.3.1.3, it will suffice to show that A belongs to $\mathcal{C}$. Let K be the fiber of the map $\phi : A \to B$, and let $\rho : K \to A$ be the canonical map. For each integer $m \geqslant 0$, let $\rho(m) : K^{\otimes m} \to A^{\otimes m} \simeq A$ be the the mth tensor power of ρ, formed in the monoidal ∞-category LMod_A. Then $\rho(m+1)$ is given by the composition $K^{\otimes m+1} \xrightarrow{\mathrm{id}_{K^{\otimes m}}} K^{\otimes m} \xrightarrow{\rho(m)} A$, so we have a fiber sequence

$$K^{\otimes m} \otimes_A B \to \mathrm{cofib}(\rho(m+1)) \to \mathrm{cofib}(\rho(m)).$$

It follows by induction on m that each $\mathrm{cofib}(\rho(m))$ belongs to $\mathcal{C}$. Consequently, to prove that $A \in \mathcal{C}$, it will suffice to show that A is a retract of $\mathrm{cofib}(\rho(m))$ for some $m \geqslant 0$. This condition holds whenever the homotopy class of $\rho(m)$ vanishes (when regarded as an element of $\mathrm{Ext}^0_A(K^{\otimes m}, A) \simeq \mathrm{Ext}^m_A((\Sigma K)^{\otimes m}, A)$. Our assumptions imply that $\Sigma K \simeq \mathrm{cofib}(\phi)$ is a flat A-module, and that $\pi_0 \mathrm{cofib}(K)$ admits a presentation using fewer than $\aleph_n$ generators and relations for some integer $n \geqslant 0$. It follows that $(\Sigma K)^{\otimes m}$ has the same properties for each $m > 0$, so that $\mathrm{Ext}^m_A((\Sigma K)^{\otimes m}, A)$ vanishes for $m > n$ by virtue of Lemma D.3.3.7. □

D.3.4 Comonadicity

Suppose that we are given a pair of adjoint functors $\mathcal{C} \underset{G}{\overset{F}{\rightleftarrows}} \mathcal{D}$ between ∞-categories. Let $U = F \circ G : \mathcal{D} \to \mathcal{D}$. Then the functor U admits the structure of a comonad: that is, it is an associative coalgebra object of the monoidal ∞-category $\mathrm{Fun}(\mathcal{D}, \mathcal{D})$ (see §HA.4.7). Equivalently, we can regard U as an associative algebra in the monoidal ∞-category $\mathrm{Fun}(\mathcal{D}^{\mathrm{op}}, \mathcal{D}^{\mathrm{op}})$, which has a left action on the ∞-category $\mathcal{D}^{\mathrm{op}}$. We can regard $\mathrm{LMod}_U(\mathcal{D}^{\mathrm{op}})$ as (the opposite of) the ∞-category of *U-comodule objects* of $\mathcal{D}$: that is, objects

$D \in \mathcal{D}$ equipped with a map $\alpha : D \to U(D)$ together with additional coherence data. The functor F factors canonically as a composition $\mathcal{C} \xrightarrow{F'} \mathrm{LMod}_U(\mathcal{D}^{\mathrm{op}})^{\mathrm{op}} \xrightarrow{F''} \mathcal{D}$. More informally: for every object $C \in \mathcal{C}$, the image $F(C) \in \mathcal{D}$ is naturally equipped with the structure of a U-comodule (given by the unit map $F(C) \to F(GF(C)) \simeq (F \circ G)(F(C)) = U(F(C))$). We may therefore think of a U-comodule structure on an object $D \in \mathcal{D}$ as a kind of descent data for D: it is a structure whose presence indicates that the object D might lift to an object of C.

We say that a functor $F : \mathcal{C} \to \mathcal{D}$ is *comonadic* if F admits a right adjoint $G : \mathcal{D} \to \mathcal{C}$, and the functor $F' : \mathcal{C} \to \mathrm{LMod}_U(\mathcal{D}^{\mathrm{op}})^{\mathrm{op}}$ described above is an equivalence of ∞-categories. In other words, F is comonadic if $\mathcal{C}$ can be identified with the ∞-category of objects of $\mathcal{D}$ equipped with descent data.

Theorem D.3.4.1. *Let $f : A \to B$ be a universal descent morphism of $\mathbb{E}_2$-rings, and let $\mathcal{C}$ be a stable A-linear ∞-category. Then the extension-of-scalars functor $F : \mathcal{C} \to \mathrm{LMod}_B(\mathcal{C})$ (given by tensoring with B) is comonadic.*

Corollary D.3.4.2. *Let $f : A \to B$ be a universal descent morphism of $\mathbb{E}_2$-rings. Then the base-change functor $\mathrm{LMod}_A \to \mathrm{LMod}_B$ is comonadic.*

Proof. Apply Theorem **??** in the case $\mathcal{C} = \mathrm{LMod}_A$. □

Proof of Theorem D.3.4.1. According to Theorem HA.4.7.3.5 , it will suffice to verify that F satisfies the following conditions:

(1) The functor F is conservative.

(2) For every F-split cosimplicial object $C^\bullet$ of $\mathcal{C}$, the canonical map $F(\varprojlim C^\bullet) \to \varprojlim F(C^\bullet)$ is an equivalence in $\mathrm{LMod}_B(\mathcal{C})$.

We first prove (1). Since F is an exact functor between stable ∞-categories, it will suffice to show that if $C \in \mathcal{C}$ is an object for which $F(C) \simeq 0$, then $C \simeq 0$. To prove this, let $\mathcal{E}$ denote the full subcategory of LMod_A spanned by those A-modules M for which the tensor product $M \otimes_A C$ vanishes. Then $\mathcal{E}$ is a stable subcategory of LMod_A which is closed under retracts. We wish to prove that $A \in \mathcal{E}$. Since f is a universal descent morphism, it will suffice to show that $\mathcal{E}$ contains the essential image of the forgetful functor $\mathrm{LMod}_B \to \mathrm{LMod}_A$ (see Variant D.3.2.3). This is clear: if $M \in \mathrm{LMod}_B(\mathcal{C})$, then our assumption that $F(C) \simeq 0$ implies that

$$M \otimes_A C \simeq M \otimes_B F(C) \simeq 0.$$

We now prove (2). Let $C^\bullet$ be an F-split cosimplicial object of $\mathcal{C}$. For each object $M \in \mathrm{LMod}_A$, let us regard $M \otimes_A C^\bullet$ as another cosimplicial object of $\mathcal{C}$, so that we have a canonical map $\theta_M : F(\varprojlim(M \otimes_A C^\bullet)) \to \varprojlim(M \otimes_A C^\bullet)$ in $\mathrm{LMod}_B(\mathcal{C})$. Let $\mathcal{E}'$ denote the full subcategory of LMod_A spanned by those objects M for which θ_M is an equivalence. Then $\mathcal{E}'$ is a stable subcategory of LMod_A which is closed under retracts. We wish to prove that $A \in \mathcal{E}'$. Since f is a universal descent morphism, it will suffice to show that $\mathcal{E}$ contains the essential image of the forgetful functor $\mathrm{LMod}_B \to \mathrm{LMod}_A$ (see Variant D.3.2.3). To prove this, we observe that for $M \in \mathrm{LMod}_B$, we can identify $M \otimes_A C^\bullet$ with $M \otimes_B F(C^\bullet)$. Since $F(C^\bullet)$ is a split cosimplicial object of $\mathrm{LMod}_B(\mathcal{C})$, it follows that $M \otimes_A C^\bullet$ is a split cosimplicial object of $\mathcal{C}$, and therefore θ_M is an equivalence as desired. □

Theorem D.3.4.1 admits a converse:

Proposition D.3.4.3. *Let $f : A \to B$ be a morphism of $\mathbb{E}_2$-rings. Suppose that for every A-linear ∞-category $\mathcal{C}$, the base change functor $F_{\mathcal{C}} : \mathcal{C} \to \mathrm{LMod}_B(\mathcal{C})$ is comonadic. Then f is a universal descent morphism.*

Proof. Let $B^\bullet$ be the cosimplicial object of Alg_A appearing in the discussion preceeding Proposition D.3.2.1. We first prove the following:

- $(*)$ Let $\mathcal{C}$ be a locally small stable ∞-category which is left-tensored over LMod_A. Suppose that $\mathcal{C}$ admits small colimits and that the action $\otimes_A : \mathrm{LMod}_A \times \mathcal{C} \to \mathcal{C}$ preserves small colimits separately in each variable. Then, for each object $C \in \mathcal{C}$, the canonical map $A \to \mathrm{Tot}(B^\bullet)$ exhibits C as a totalization of the cosimplicial object $B^\bullet \otimes_A C$ in $\mathcal{C}$.

Note that if $\mathcal{C}$ presentable (and therefore an A-linear ∞-category), then assertion $(*)$ follows immediately from the comonadicity of the base change functor $\mathcal{C} \to \mathrm{LMod}_B(\mathcal{C})$. To treat the general case, fix a regular cardinal κ and let LMod_A^κ denote the full subcategory of LMod_A spanned by the κ-compact objects. Note that LMod_A^κ contains the unit object of LMod_A and is closed under tensor products, and therefore inherits the structure of a monoidal ∞-category. Fix objects $C, C' \in \mathcal{C}$; we wish to show that the canonical map

$$\mathrm{Map}_{\mathcal{C}}(C', C) \to \varprojlim \mathrm{Map}_{\mathcal{C}}(C', B^\bullet \otimes_A C)$$

is a homotopy equivalence. Choose an essentially small stable subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ containing C and C' which is closed under κ-small colimits. Then we can regard $\mathcal{C}_0$ as an ∞-category tensored over LMod_A^κ, and the tensor product functor $\otimes_A : \mathrm{LMod}_A^\kappa \times \mathcal{C}_0 \to \mathcal{C}_0$ preserves κ-small colimits separately in each variable. Using Lemma HA.5.3.2.11 , we see that $\mathrm{Ind}_\kappa(\mathcal{C}_0)$ inherits the structure of an ∞-category left-tensored over $\mathrm{Ind}_\kappa(\mathrm{LMod}_A^\kappa) \simeq \mathrm{LMod}_A$. Let $j : \mathcal{C}_0 \to \mathrm{Ind}_\kappa(\mathcal{C}_0)$ denote the Yoneda embedding. Since $\mathrm{Ind}_\kappa(\mathcal{C}_0)$ is presentable, the base change functor $\mathrm{Ind}_\kappa(\mathcal{C}_0) \to \mathrm{LMod}_B(\mathrm{Ind}_\kappa(\mathcal{C}_0))$ is comonadic, so that $j(C) \simeq \varprojlim B^\bullet \otimes_A j(C)$ and therefore the canonical map

$$\begin{aligned} \mathrm{Map}_{\mathrm{Ind}_\kappa(\mathcal{C}_0)}(j(C'), j(C)) &\to \varprojlim \mathrm{Map}_{\mathrm{Ind}_\kappa(\mathcal{C})}(j(C'), B^\bullet \otimes_A j(C)) \\ &\simeq \varprojlim \mathrm{Map}_{\mathrm{Ind}_\kappa(\mathcal{C})}(j(C'), j(B^\bullet \otimes_A C)). \end{aligned}$$

is a homotopy equivalence. Assertion $(*)$ now follows because the Yoneda embedding j is fully faithful.

For each object $M \in \mathrm{LMod}_A$, the construction $N \mapsto N \otimes_A M$ determines a functor $r_M : \mathrm{LMod}_A \to \mathrm{LMod}_A$ which preserves small colimits and therefore admits a right adjoint. Let us indicate this right adjoint by the notation $K \mapsto {}^M K$, which we regard as a functor from $\mathrm{LMod}_A^{\mathrm{op}}$ to itself (so that $\mathrm{Map}_{\mathrm{LMod}_A}(N \otimes_A M, K) \simeq \mathrm{Map}_{\mathrm{LMod}_A}(N, {}^M K)$). This construction exhibits $\mathrm{LMod}_A^{\mathrm{op}}$ as an ∞-category which is left-tensored over LMod_A. Moreover, the action map

$$\mathrm{LMod}_A \times \mathrm{LMod}_A^{\mathrm{op}} \to \mathrm{LMod}_A^{\mathrm{op}} \qquad (M, K) \mapsto {}^M K$$

preserves small colimits separately in each variable. Applying $(*)$, we deduce that for each object $N \in \mathrm{LMod}_A$, the canonical map $|{}^{B^\bullet} N| \to N$ is an equivalence in LMod_A. Applying Ω^∞, we obtain a homotopy equivalence

$$\begin{aligned}
\varinjlim_{n \geqslant 0} \mathrm{Map}_{\mathrm{LMod}_A}(\mathrm{Tot}^n(B/A), N) &\simeq \varinjlim_{n \geqslant 0} \Omega^\infty({}^{\mathrm{Tot}^n(B/A)} N) \\
&\simeq \Omega^\infty \varinjlim_{n \geqslant 0} ({}^{\mathrm{Tot}^n(B/A)} N) \\
&\simeq \Omega^\infty |{}^{B^\bullet} N| \\
&\to \Omega^\infty N \\
&\simeq \mathrm{Map}_{\mathrm{LMod}_A}(A, N),
\end{aligned}$$

where $\{\mathrm{Tot}^n(B/A)\}_{n \geqslant 0}$ is the Tot-tower defined in the discussion preceding Proposition D.3.2.1. It follows that the Tot-tower is equivalent to A as an object of $\mathrm{Pro}(\mathrm{LMod}_A)$, so that Proposition D.3.2.1 implies that B is a propagating object of LMod_A and therefore $f : A \to B$ is a universal descent morphism. □

D.3.5 Effective Descent for Objects

If we restrict our attention to $\mathbb{E}_\infty$-rings, then we can reformulate Theorem D.3.4.1 using the language of sheaves. For this, we need to introduce a bit of notation.

Notation D.3.5.1. Fix a $\mathbb{E}_\infty$-ring A and a stable A-linear ∞-category $\mathcal{C}$. We let $\mathrm{Mod}(\mathcal{C})$ denote the fiber product $\mathrm{CAlg}(\mathrm{Mod}_A) \times_{\mathrm{Alg}(\mathrm{Mod}_A)} \mathrm{LMod}(\mathcal{C})$ whose objects are pairs (B, M), where $B \in \mathrm{CAlg}(\mathrm{Mod}_A) \simeq \mathrm{CAlg}_A$ is an $\mathbb{E}_\infty$-algebra over A and M is a left B-module object of $\mathcal{C}$. We will denote the fiber of $\mathrm{Mod}(\mathcal{C})$ over an object $B \in \mathrm{CAlg}_A$ by $\mathrm{Mod}_B(\mathcal{C})$.

In the situation of Notation D.3.5.1, the coCartesian fibration $q : \mathrm{Mod}(\mathcal{C}) \to \mathrm{CAlg}(\mathrm{Mod}_A)$ is classified by a functor $\mathrm{CAlg}_A \to \widehat{\mathcal{C}\mathrm{at}}_\infty$: in other words, the construction $B \mapsto \mathrm{Mod}_B(\mathcal{C})$ can be regarded as a functor of B.

Theorem D.3.5.2. *Let A be an $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a stable A-linear ∞-category. Then the construction $B \mapsto \mathrm{Mod}_B(\mathcal{C})$ determines a $\mathcal{P}\mathrm{r}^{\mathrm{L}}$-valued sheaf with respect to the universal descent topology on the ∞-category $\mathrm{CAlg}_A^{\mathrm{op}}$ (see Remark D.3.1.7).*

Remark D.3.5.3. Let A be an $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a stable A-linear ∞-category. It follows from Theorem D.3.5.2 and Corollary D.3.3.5 that the construction $B \mapsto \mathrm{LMod}_B(\mathcal{C})$ is a sheaf with respect to the étale topology on the ∞-category $\mathrm{CAlg}_A^{\text{ét}}$. In fact, this is true more generally when A is an $\mathbb{E}_2$-ring (the proof in this case requires only slight modification).

Remark D.3.5.4. It follows from Proposition D.3.4.3 that the universal descent topology is the *finest* Grothendieck topology for which Theorem D.3.5.2 holds.

Lemma D.3.5.5. *Let R be an $\mathbb{E}_2$-ring and let $\mathcal{C}$ be a stable R-linear ∞-category. Then the construction $A \mapsto \mathrm{LMod}_A(\mathcal{C})$ commutes with finite products (when regarded as a functor $\mathrm{Alg}_R \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$).*

Proof. Let $\{A_i\}_{1 \leqslant i \leqslant n}$ be a finite collection of $\mathbb{E}_1$-algebras over R and let $A = \prod_{1 \leqslant i \leqslant n} A_i$. We wish to show that the canonical functor

$$\theta : \mathrm{LMod}_A(\mathcal{C}) \to \prod_{1 \leqslant i \leqslant n} \mathrm{LMod}_{A_i}(\mathcal{C})$$

is an equivalence of ∞-categories. By virtue of Proposition HA.5.2.2.36 , it will suffice to verify the following assertions:

(*a*) The functor θ is conservative. That is, if $\alpha : M \to N$ is a morphism in $\mathrm{LMod}_A(\mathcal{C})$ is such that each of the induced maps $\alpha_i : A_i \otimes_A M \to A_i \otimes_A M$ is an equivalence, then α is an equivalence. It suffices to show that the image of α is an equivalence in the ∞-category $\mathcal{C}$. This is clear, since α is equivalent to the product of the morphisms α_i in the ∞-category $\mathcal{C}$.

(*b*) Suppose we are given objects $M_i \in \mathrm{LMod}_{A_i}(\mathcal{C})$, and let $M \simeq \prod_{1 \leqslant i \leqslant n} M_i$ (regarded as an A-module). Then the canonical map $\phi : A_i \otimes_A M \to M_i$ is an equivalence for $1 \leqslant i \leqslant n$. To prove this, we see that the domain of ϕ is given by the product $\prod_{1 \leqslant j \leqslant n} (A_i \otimes_A A_j) \otimes_{A_j} M_j$. To prove that ϕ is an equivalence, it suffices to show that $A_i \otimes_A A_j \simeq 0$ for $i \neq j$, and that the canonical map $A_i \to A_i \otimes_A A_i$ is an equivalence. Since each A_j is flat as a left A-module, we have $\pi_*(A_i \otimes_A A_j) \simeq (\pi_* A_i) \otimes_{\pi_* A} (\pi_* A_j)$, so the desired result follows from a simple algebraic calculation.

□

Lemma D.3.5.6. *Let $\mathcal{C}$ be a symmetric monoidal ∞-category, let $\mathcal{M}$ be an ∞-category left-tensored over $\mathcal{C}$, and suppose we are given a pushout diagram of commutative algebra objects of $\mathcal{C}$:*

$$\begin{array}{ccc} A & \longleftarrow & B \\ \uparrow & & \uparrow \\ A' & \longleftarrow & B' \end{array}$$

Then the diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{LMod}_A(\mathcal{M}) & \longrightarrow & \mathrm{LMod}_B(\mathcal{M}) \\ \downarrow & & \downarrow \\ \mathrm{LMod}_{A'}(\mathcal{M}) & \longrightarrow & \mathrm{LMod}_{B'}(\mathcal{M}) \end{array}$$

is right adjointable.

Proof. This follows immediately from Proposition HA.4.6.2.17. □

Lemma D.3.5.7. *Let $f : A \to B$ be a morphism of $\mathbb{E}_\infty$-rings, let $B^\bullet$ be the Čech nerve of f (formed in the ∞-category $\mathrm{CAlg}^{\mathrm{op}}$), and let $\mathcal{C}$ be a stable A-linear ∞-category. The following conditions are equivalent:*

(1) *The base change functor $\mathcal{C} \to \mathrm{Mod}_B(\mathcal{C})$ is comonadic.*

(2) *The canonical map $\mathcal{C} \to \varprojlim \mathrm{Mod}_{B^\bullet}(\mathcal{C})$ is an equivalence of ∞-categories.*

Proof. It follows from Lemma D.3.5.6 that the augmented cosimplicial ∞-category $\mathcal{C}^\bullet$ satisfies the (dual) Beck-Chevalley condition: that is, for every morphism $\alpha : [m] \to [n]$ in $\mathbf{\Delta}$, the diagram

$$\begin{array}{ccc} \mathcal{C}^m & \xrightarrow{d^0} & \mathcal{C}^{m+1} \\ \downarrow & & \downarrow \\ \mathcal{C}^n & \xrightarrow{d^0} & \mathcal{C}^{n+1} \end{array}$$

is right adjointable. The desired result now follows from Corollary HA.4.7.5.3. □

Lemma D.3.5.8. *Let $f : A \to B$ be a universal descent morphism of $\mathbb{E}_\infty$-rings and let $B^\bullet$ be the Čech nerve of f (formed in the ∞-category $\mathrm{CAlg}^{\mathrm{op}}$). For any A-linear ∞-category $\mathcal{C}$, the canonical map $\mathcal{C} \to \varprojlim \mathrm{Mod}_{B^\bullet}(\mathcal{C})$ is an equivalence of ∞-categories.*

Proof. Combine Lemma D.3.5.7 with Theorem D.3.4.1. □

Proof of Theorem D.3.5.2. Combine Proposition A.3.3.1, Lemma D.3.5.5, and Lemma D.3.5.8. □

D.3.6 Effective Descent for ∞-Categories

Our next goal is to formulate and prove a categorification of Theorem D.3.5.2.

Remark D.3.6.1. Let $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ denote the ∞-category whose objects are presentable ∞-categories and whose morphisms are colimit preserving functors. We let $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ denote the full subcategory of $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ spanned by the stable ∞-categories. We can identify the ∞-category Sp of spectra with a commutative algebra object of $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ and $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ with the ∞-category $\mathrm{Mod}_{\mathrm{Sp}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ (see Proposition HA.4.8.2.18). According to Theorem HA.4.8.5.16 , the construction $A \mapsto \mathrm{LMod}_A(\mathrm{Sp})$ determines a symmetric monoidal functor $\mathrm{Alg}(\mathrm{Sp}) \to \mathcal{P}\mathrm{r}^{\mathrm{St}}$. Passing to algebra objects (and using Theorem HA.5.1.2.2), we obtain a functor

$$\mathrm{Alg}_{\mathbb{E}_2}(\mathrm{Sp}) \simeq \mathrm{Alg}(\mathrm{Alg}(\mathrm{Sp})) \to \mathrm{Alg}(\mathcal{P}\mathrm{r}^{\mathrm{St}}) \to \mathrm{Alg}(\mathcal{P}\mathrm{r}^{\mathrm{L}}).$$

We let $\mathrm{LinCat}^{\mathrm{St}}$ denote the fiber product $\mathrm{Alg}_{\mathbb{E}_2}(\mathrm{Sp}) \times_{\mathrm{Alg}(\mathcal{P}\mathrm{r}^{\mathrm{L}})} \mathrm{LMod}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$. We will refer to $\mathrm{LinCat}^{\mathrm{St}}$ as the *∞-category of stable linear ∞-categories.*

There is an evident categorical fibration $\theta : \mathrm{LinCat}^{\mathrm{St}} \to \mathrm{Alg}_{\mathbb{E}_2}(\mathrm{Sp})$. By construction, the fiber of θ over an $\mathbb{E}_2$-ring A can be identified with the ∞-category $\mathrm{LinCat}^{\mathrm{St}}_A$ of stable A-linear ∞-categories introduced in Variant D.1.5.1. We may therefore think of $\mathrm{LinCat}^{\mathrm{St}}$ as an ∞-category whose objects are pairs $(A, \mathcal{C})$, where A is an $\mathbb{E}_2$-ring and $\mathcal{C}$ is a stable A-linear ∞-category.

The forgetful functor $\theta : \mathrm{LinCat}^{\mathrm{St}} \to \mathrm{Alg}_{\mathbb{E}_2}(\mathrm{Sp})$ is both a Cartesian fibration and a coCartesian fibration. In particular, as a coCartesian fibration, θ is classified by a functor $\mathrm{Alg}_{\mathbb{E}_2}(\mathrm{Sp}) \to \widehat{\mathcal{C}\mathrm{at}}_\infty$. This functor assigns to each $\mathbb{E}_2$-ring A the ∞-category $\mathrm{LinCat}^{\mathrm{St}}_A$ of stable A-linear ∞-categories, and to each morphism $\phi : A \to B$ of $\mathbb{E}_2$-rings the extension of scalars functor

$$\mathrm{LinCat}^{\mathrm{St}}_A \to \mathrm{LinCat}^{\mathrm{St}}_B \qquad \mathcal{C} \mapsto B \otimes_A \mathcal{C} \simeq \mathrm{LMod}_B(\mathcal{C})$$

described in Variant D.2.4.3.

Theorem D.3.6.2. *The construction $A \mapsto \mathrm{LinCat}^{\mathrm{St}}_A$ of Remark D.3.6.1 determines a functor $\mathrm{CAlg} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ which is a sheaf with respect to the universal descent topology of Remark D.3.1.7.*

The proof of Theorem D.3.6.2 will require some preliminaries.

Lemma D.3.6.3. *Let $\{A_i\}_{1 \leqslant i \leqslant n}$ be a finite collection of $\mathbb{E}_2$-rings having product A. Then the canonical map $\phi : \mathrm{LinCat}^{\mathrm{St}}_A \to \prod_{1 \leqslant i \leqslant n} \mathrm{LinCat}^{\mathrm{St}}_{A_i}$ is an equivalence of ∞-categories.*

Proof. We will prove that ϕ satisfies the hypotheses of Proposition HA.5.2.2.36 :

(*a*) Let $F : \mathcal{C} \to \mathcal{D}$ be a morphism in $\mathrm{LinCat}^{\mathrm{St}}_A$ whose image in each $\mathrm{LinCat}^{\mathrm{St}}_{A_i}$ is an equivalence. We wish to show that F is an equivalence. Using Lemma D.3.5.5, we deduce that $\mathcal{C}$ and $\mathcal{D}$ can be identified with the products $\prod_i \mathrm{LMod}_{A_i}(\mathcal{C})$ and $\prod_i \mathrm{LMod}_{A_i}(\mathcal{D})$, respectively. Since the induced map $\mathrm{LMod}_{A_i}(\mathcal{C}) \to \mathrm{LMod}_{A_i}(\mathcal{D})$ is an equivalence for each index i, we conclude that F induces an equivalence of ∞-categories $f : \mathcal{C} \to \mathcal{D}$.

(b) Suppose we are given a finite collection of objects $(A_i, \mathcal{C}_i)$ in $\mathrm{LinCat}^{\mathrm{St}}$. For each index i, let $\mathcal{D}_i$ denote the A-linear ∞-category obtained from $\mathcal{C}_i$ by restriction of scalars and set $\mathcal{D} = \prod_i \mathcal{D}_i$. We wish to prove that for each index i, the canonical map $\mathrm{LMod}_{A_i} \otimes_{\mathrm{LMod}_A} \mathcal{D} \to \mathcal{C}_i$ is an equivalence. We have

$$\mathrm{LMod}_{A_i}(\mathcal{D}) \simeq \mathrm{LMod}_{A_i}(\prod_j \mathcal{D}_j) \simeq \prod_j \mathrm{LMod}_{A_i}(\mathcal{D}_j) \simeq \prod_j \mathrm{LMod}_{A_i \otimes_A A_j}(\mathcal{C}_j).$$

For $i \neq j$, the tensor product $A_i \otimes_A A_j$ is trivial, so that $\mathrm{LMod}_{A_i \otimes_A A_j}(\mathcal{C}_j)$ is a contractible Kan complex. For $i = j$, the tensor product $A_i \otimes_A A_j$ is equivalent to A_i, so that the forgetful functor $\mathrm{LMod}_{A_i \otimes_A A_j}(\mathcal{C}_j) \to \mathcal{C}_j$ is an equivalence. Passing to the product over i, we obtain the desired result.

$\square$

Proof of Theorem D.3.6.2. It follows from Lemma D.3.6.3 that the construction $A \mapsto \mathrm{LinCat}^{\mathrm{St}}_A$ preserves finite products. By virtue of Proposition A.3.3.1, it will suffice to show that if $f : A \to A^0$ is a universal descent morphism in CAlg with Čech nerve $A^\bullet$, then the canonical map $\mathrm{LinCat}^{\mathrm{St}}_A \to \varprojlim \mathrm{LinCat}^{\mathrm{St}}_{A^\bullet}$ is an equivalence of ∞-categories. We proceed by showing that this functor satisfies the conditions of Proposition HA.5.2.2.36:

(a) Fix an morphism $F : \mathcal{C} \to \mathcal{D}$ in $\mathrm{LinCat}^{\mathrm{St}}_A$ whose image in $\mathrm{LinCat}^{\mathrm{St}}_{A^0}$ is an equivalence. It follows that F induces an equivalence of cosimplicial ∞-categories $\mathrm{LMod}_{A^\bullet}(\mathcal{C}) \to \mathrm{LMod}_{A^\bullet}(\mathcal{D})$. We have a commutative diagram

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{F} & \mathcal{D} \\ \downarrow & & \downarrow \\ \varprojlim \mathrm{LMod}_{A^\bullet}(\mathcal{C}) & \longrightarrow & \varprojlim \mathrm{LMod}_{A^\bullet}(\mathcal{D}), \end{array}$$

where the vertical maps are equivalences of ∞-categories by Theorem D.3.5.2. It follows that F is an equivalence of ∞-categories.

(b) Let $\theta : \mathrm{LinCat}^{\mathrm{St}} \to \mathrm{Alg}_{\mathbb{E}_2}(\mathrm{Sp})$ be the forgetful functor. Suppose we are given a diagram $X^\bullet : \mathbf{\Delta} \to \mathrm{LinCat}^{\mathrm{St}}$ lying over the cosimplicial $\mathbb{E}_\infty$-ring $A^\bullet$, and write $X^\bullet = (A^\bullet, \mathcal{C}^\bullet)$. Then $X^\bullet$ can be extended to a θ-limit diagram $\overline{X}^\bullet$ with $\overline{X}^{-1} = (A, \mathcal{C})$. We must show that if $X^\bullet$ carries every morphism in $\mathbf{\Delta}$ to a θ-coCartesian morphism in $\mathrm{LinCat}^{\mathrm{St}}$, then $\overline{X}$ has the same property. This follows from the calculation

$$\begin{aligned} \mathrm{LMod}_{A^0}(\mathcal{C}) &\simeq \mathrm{LMod}_{A^0}(\varprojlim \mathcal{C}^\bullet) \\ &\simeq \varprojlim \mathrm{LMod}_{A^0}(\mathcal{C}^\bullet) \\ &\simeq \varprojlim \mathcal{C}^{\bullet+1} \\ &\simeq \mathcal{C}^0 . \end{aligned}$$

□

D.4 Étale Descent for Prestable ∞-Categories

In §D.3, we showed that the construction $A \mapsto \mathrm{LinCat}^{\mathrm{St}}_A$ determines a functor $\mathrm{CAlg} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ which is a sheaf with respect to the universal descent topology of Remark D.3.1.7 (Theorem D.3.6.2). In particular, it is a sheaf with respect to the étale topology (since every faithfully flat étale map of $\mathbb{E}_\infty$-rings is a universal descent morphism; see Corollary D.3.3.5). Our goal in this section is to prove an analogous result for *prestable* A-linear ∞-categories (Theorem D.4.1.2).

D.4.1 Formulation of the Theorem

It follows from Theorem HA.4.8.5.16 that the construction $A \mapsto \mathrm{LMod}_A(\mathrm{Sp}^{\mathrm{cn}})$ determines a symmetric monoidal functor from the ∞-category $\mathrm{Alg}^{\mathrm{cn}} = \mathrm{Alg}(\mathrm{Sp}^{\mathrm{cn}})$ of connective $\mathbb{E}_1$-rings to the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{Add}} \simeq \mathrm{Mod}_{\mathrm{Sp}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ of presentable additive ∞-categories. Passing to algebra objects (and using Theorem HA.5.1.2.2), we obtain a functor $\mathrm{Alg}_{\mathbb{E}_2}(\mathrm{Sp}^{\mathrm{cn}}) \simeq \mathrm{Alg}(\mathrm{Alg}^{\mathrm{cn}}) \to \mathrm{Alg}(\mathcal{P}\mathrm{r}^{\mathrm{Add}}) \to \mathrm{Alg}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$.

Construction D.4.1.1. We let $\mathrm{LinCat}^{\mathrm{PSt}}$ denote the ∞-category

$$\mathrm{Alg}_{\mathbb{E}_2}(\mathrm{Sp}^{\mathrm{cn}}) \times_{\mathrm{Alg}(\mathcal{P}\mathrm{r}^{\mathrm{L}})} \mathrm{LMod}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \times_{\mathcal{P}\mathrm{r}^{\mathrm{L}}} \mathsf{Groth}_\infty$$

whose objects are pairs $(A, \mathcal{C})$, where A is a connective $\mathbb{E}_2$-ring and $\mathcal{C}$ is a prestable A-linear ∞-category. There is an evident Cartesian fibration $\theta : \mathrm{LinCat}^{\mathrm{PSt}} \to \mathrm{Alg}_{\mathbb{E}_2}(\mathrm{Sp}^{\mathrm{cn}})$ whose fiber over a connective $\mathbb{E}_2$-ring A can be identified with the ∞-category $\mathrm{LinCat}^{\mathrm{PSt}}_A$ of prestable A-linear ∞-categories introduced in Definition D.1.4.1. It follows from Proposition D.2.4.5 (and Corollary HTT.5.2.2.5) that θ is also a coCartesian fibration: it associates to every morphism $\phi : A \to B$ of connective $\mathbb{E}_2$-rings the functor

$$\mathrm{LinCat}^{\mathrm{PSt}}_A \to \mathrm{LinCat}^{\mathrm{PSt}}_B \qquad \mathcal{C} \mapsto B \otimes_A \mathcal{C} \simeq \mathrm{LMod}_B(\mathcal{C})$$

given by extension of scalars along ϕ (see Construction D.2.4.1). As a coCartesian fibration, the map θ is classified by a functor $\mathrm{Alg}_{\mathbb{E}_2}(\mathrm{Sp}^{\mathrm{cn}}) \to \widehat{\mathcal{C}\mathrm{at}}_\infty$, given at the level of objects by $A \mapsto \mathrm{LinCat}_A^{\mathrm{PSt}}$.

We can now state our main result of this section:

Theorem D.4.1.2 (Étale Descent for Prestable ∞-categories)**.** *The construction $R \mapsto \mathrm{LinCat}_R^{\mathrm{PSt}}$ determines a functor $\mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ which is a sheaf with respect to the étale topology.*

Remark D.4.1.3. In the statement of Theorem D.4.1.2, the restriction to to $\mathbb{E}_\infty$-rings is not essential: for any connective $\mathbb{E}_2$-ring A, the construction $R \mapsto \mathrm{LinCat}_R^{\mathrm{PSt}}$ determines a $\widehat{\mathcal{C}\mathrm{at}}_\infty$-valued sheaf on the ∞-category $\mathrm{Alg}_R^{\text{ét}}$ of étale R-algebras. This can be established using minor modifications of the proof of Theorem D.4.1.2 we present below.

We will deduce Theorem D.4.1.2 from a somewhat stronger statement (Theorem D.4.1.6). To formulate it, we need a variant of Remark D.3.1.7.

Construction D.4.1.4 (Flat Universal Descent Topology)**.** Let S be the collection of morphisms $f : A \to B$ between connective $\mathbb{E}_\infty$-rings which are flat universal descent morphisms (see Definition D.3.1.1). It follows from Propositions D.3.1.6 and B.6.1.3 that S satisfies the hypotheses of Proposition A.3.2.1, and therefore determines a Grothendieck topology on the (large) ∞-category $(\mathrm{CAlg}^{\mathrm{cn}})^{\mathrm{op}}$. We will refer to this Grothendieck topology as the *flat universal descent topology.*

Remark D.4.1.5. Let $f : A \to B$ be a flat universal descent morphism of connective $\mathbb{E}_\infty$-rings. Then f is faithfully flat: the assumption that f is a universal descent morphism guarantees that the extension of scalars functor $M \mapsto B \otimes_A M$ cannot annihilate any nonzero A-modules. It follows that the fpqc topology is a refinement of the flat universal descent topology. We do not know if these topologies are the same.

Every faithfully flat étale morphism of $\mathbb{E}_\infty$-rings $f : A \to B$ is also universal descent morphism (Corollary D.3.3.5). Consequently, the flat universal descent topology is a refinement of the étale topology. Theorem D.4.1.2 is therefore a consequence of the following:

Theorem D.4.1.6. *The construction $R \mapsto \mathrm{LinCat}_R^{\mathrm{PSt}}$ determines a functor $\mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ which is a sheaf with respect to the flat universal descent topology of Construction D.4.1.4.*

D.4.2 Comparison of Stable and Prestable ∞-Categories

We would like to deduce Theorem D.4.1.6 from the analogous result for the construction $R \mapsto \mathrm{LinCat}_R^{\mathrm{St}}$ (which satisfies descent for the universal descent topology, by virtue of Theorem D.3.6.2). For this, we need to compare a prestable ∞-category $\mathcal{C}$ with its stabilization $\mathrm{Sp}(\mathcal{C})$.

Lemma D.4.2.1. *Let R be a connective $\mathbb{E}_2$-ring. Then the diagram of ∞-categories*

$$\begin{array}{ccc} \mathrm{LinCat}_R^{\mathrm{PSt}} & \xrightarrow{\mathrm{Sp}(\bullet)} & \mathrm{LinCat}_R^{\mathrm{St}} \\ \downarrow & & \downarrow \\ \mathsf{Groth}_\infty & \xrightarrow{\mathrm{Sp}(\bullet)} & \mathcal{P}\mathrm{r}^{\mathrm{St}} \end{array}$$

is a pullback square.

Remark D.4.2.2. More informally, Lemma **??** asserts that the data of a prestable R-linear ∞-category $\mathcal{C}$ is equivalent to the data of a stable R-linear ∞-category $\mathcal{D}$ (given by the stabilization $\mathrm{Sp}(\mathcal{C})$) together with a t-structure $(\mathcal{D}_{\geqslant 0}, \mathcal{D}_{\leqslant 0})$ which is right complete and compatible with filtered colimits. In particular, if $\mathcal{C}$ is a Grothendieck prestable ∞-categories, then giving an action of R on $\mathcal{C}$ is equivalent to giving an action of R on the associated stable ∞-category $\mathrm{Sp}(\mathcal{C})$.

Proof of Lemma D.4.2.1. We first show that natural map

$$\theta : \mathrm{LinCat}_R^{\mathrm{PSt}} \to \mathrm{LinCat}_R^{\mathrm{St}} \times_{\mathcal{P}\mathrm{r}^{\mathrm{St}}} \mathsf{Groth}_\infty$$

is fully faithful. Let $\mathcal{C}$ and $\mathcal{D}$ be prestable R-linear ∞-categories. We wish to show that the diagram $\sigma_{\mathcal{C},\mathcal{D}}$:

$$\begin{array}{ccc} \mathrm{Map}_{\mathrm{LinCat}_R^{\mathrm{PSt}}}(\mathcal{C}, \mathcal{D}) & \longrightarrow & \mathrm{Map}_{\mathrm{LinCat}_R^{\mathrm{St}}}(\mathrm{Sp}(\mathcal{C}), \mathrm{Sp}(\mathcal{D})) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathcal{P}\mathrm{r}^{\mathrm{St}}}(\mathrm{Sp}(\mathcal{C}), \mathrm{Sp}(\mathcal{D})) & \longrightarrow & \mathrm{Map}_{\mathsf{Groth}_\infty}(\mathcal{C}, \mathcal{D}) \end{array}$$

is a pullback square in $\mathcal{S}$. Let us regard the prestable R-linear ∞-category $\mathcal{D}$ as fixed, and write

$$\mathcal{C} \simeq \mathrm{LMod}_R^{\mathrm{cn}} \otimes_{\mathrm{LMod}_R^{\mathrm{cn}}} \mathcal{C} \simeq |\, \mathcal{C}_\bullet \,|$$

where $\mathcal{C}_\bullet$ is the simplicial prestable R-linear ∞-category given by the two-sided bar construction $[n] \mapsto (\mathrm{LMod}_R^{\mathrm{cn}})^{\otimes n+1} \otimes \mathcal{C}$. Then $\sigma_{\mathcal{C},\mathcal{D}}$ is the totalization of the cosimplicial diagram $\sigma_{\mathcal{C}_\bullet,\mathcal{D}}$. It will therefore suffice to show that $\sigma_{\mathcal{C},\mathcal{D}}$ is a homotopy equivalence in the special case where $\mathcal{C} \simeq \mathrm{LMod}_R^{\mathrm{cn}} \otimes \mathcal{C}'$ is freely generated by a Grothendieck prestable ∞-category $\mathcal{C}'$. Unwinding the definitions, we wish to show that the diagram

$$\begin{array}{ccc} \mathrm{Map}_{\mathsf{Groth}_\infty}(\mathcal{C}', \mathcal{D}) & \longrightarrow & \mathrm{Map}_{\mathcal{P}\mathrm{r}^{\mathrm{St}}}(\mathrm{Sp}(\mathcal{C}'), \mathrm{Sp}(\mathcal{D})) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathsf{Groth}_\infty}(\mathcal{C}, \mathcal{D}) & \longrightarrow & \mathrm{Map}_{\mathcal{P}\mathrm{r}^{\mathrm{St}}}(\mathrm{Sp}(\mathcal{C}), \mathrm{Sp}(\mathcal{D})) \end{array}$$

is a homotopy pullback square. By virtue of Proposition C.3.1.1, this is equivalent to the following:

(∗) Let $F : \mathrm{Sp}(\mathcal{C}) \to \mathrm{Sp}(\mathcal{D})$ be a functor which preserves small colimits. Then F is right t-exact if and only if the composite map $\mathrm{Sp}(\mathcal{C}') \to \mathrm{Sp}(\mathcal{C}) \xrightarrow{F} \mathrm{Sp}(\mathcal{D})$ is right t-exact.

Since $\mathrm{LMod}_R^{\mathrm{cn}}$ is generated under small colimits by its unit object, the ∞-category $\mathcal{C} \simeq \mathrm{LMod}_R^{\mathrm{cn}} \otimes \mathcal{C}'$ is generated under small colimits by the essential image of the natural map $\mathcal{C}' \to \mathcal{C}$, from which assertion (∗) follows immediately. This completes the proof that θ is fully faithful.

We now prove that θ is essentially surjective. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category, and suppose that $\mathrm{Sp}(\mathcal{C})$ has the structure of a stable R-linear ∞-category, encoded by a colimit-preserving monoidal functor

$$\phi : \mathrm{LMod}_R \to \mathrm{LFun}(\mathrm{Sp}(\mathcal{C}), \mathrm{Sp}(\mathcal{C})).$$

Using Proposition C.3.1.1, we can identify $\mathrm{LFun}(\mathcal{C}, \mathcal{D})$ with the full subcategory of $\mathrm{LFun}(\mathrm{Sp}(\mathcal{C}), \mathrm{Sp}(\mathcal{D}))$ spanned by the right t-exact functors. Let $\mathcal{E}$ be denote the fiber product

$$\mathrm{LMod}_R \times_{\mathrm{LFun}(\mathrm{Sp}(\mathcal{C}), \mathrm{Sp}(\mathcal{C}))} \mathrm{LFun}(\mathcal{C}, \mathcal{C}),$$

which we can identify with a monoidal full subcategory of LMod_R. Then $\mathcal{E}$ contains the unit object of LMod_R and is closed under small colimits, and therefore contains all connective R-modules. It follows that ϕ restricts to a colimit-preserving monoidal functor $\mathrm{LMod}_R^{\mathrm{cn}} \hookrightarrow \mathcal{E} \to \mathrm{LFun}(\mathcal{C}, \mathcal{C})$, so we can regard $\mathcal{C}$ as a prestable R-linear ∞-category. □

D.4.3 Sheaves of ∞-Categories

We now collection some formal categorical observations which are relevant to the proof of Theorem D.4.1.6.

Lemma D.4.3.1. *The ∞-category $\mathcal{C}\mathrm{at}_\infty$ is generated (under small colimits) by the objects $\Delta^0, \Delta^1 \in \mathcal{C}\mathrm{at}_\infty$.*

Proof. Let $\mathcal{C}$ be the smallest full subcategory of $\mathcal{C}\mathrm{at}_\infty$ which contains Δ^0 and Δ^1 and is closed under small colimits. Let $\overline{\mathcal{C}} \subseteq \mathcal{S}\mathrm{et}_\Delta$ be the full subcategory spanned by those simplicial sets K which are categorically equivalent to ∞-categories belonging to $\mathcal{C}$. We wish to prove that $\mathcal{C} = \mathcal{C}\mathrm{at}_\infty$, or equivalently that $\overline{\mathcal{C}} = \mathcal{S}\mathrm{et}_\Delta$. Since $\overline{\mathcal{C}}$ is stable under filtered colimits in $\mathcal{S}\mathrm{et}_\Delta$, it will suffice to show that $\overline{\mathcal{C}}$ contains every finite simplicial set K. We proceed by induction on dimension n of K and the number of nondegenerate n-simplices of K. If $K = \varnothing$, then there is nothing to prove. Otherwise, we have a homotopy pushout diagram

$$\begin{array}{ccc} \partial\,\Delta^n & \longrightarrow & \Delta^n \\ \downarrow & & \downarrow \\ K_0 & \longrightarrow & K \end{array}$$

where $\partial \Delta^n$ and K_0 belong to $\overline{\mathcal{C}}$ by the inductive hypothesis. Since $\mathcal{C}$ is stable under pushouts, $\overline{\mathcal{C}}$ is stable under homotopy pushouts; consequently, to show that $K \in \overline{\mathcal{C}}$, it will suffice to show that $\Delta^n \in \overline{\mathcal{C}}$. If $n > 2$, then the inclusion $\Lambda^n_1 \subseteq \Delta^n$ is a categorical equivalence. It therefore suffices to show that $\Lambda^n_1 \in \overline{\mathcal{C}}$, which follows from the inductive hypothesis. We are therefore reduced to the case $n \leqslant 1$: that is, we must show that $\Delta^0, \Delta^1 \in \overline{\mathcal{C}}$, which is clear. □

Lemma D.4.3.2. *Let $\mathcal{C}$ be a small ∞-category equipped with a Grothendieck topology, and let $\alpha : \mathscr{F} \to \mathscr{F}'$ be a natural transformation of functors $\mathscr{F}, \mathscr{F}' : \mathcal{C}^{\mathrm{op}} \to \mathcal{S}$. For every object $C \in \mathcal{C}$ and every point $\eta \in \mathscr{F}'(C)$, we define a functor $\mathscr{F}_\eta : \mathcal{C}_{/C} \to \mathcal{S}$ by taking the fiber of the induced transformation $\mathscr{F}|_{\mathcal{C}_{/C}} \to \mathscr{F}'|_{\mathcal{C}_{/C}}$ (over the point determined by η).*

Assume that $\mathscr{F}'$ is a sheaf on $\mathcal{C}$. Then the following conditions are equivalent:

1. *The functor $\mathscr{F}$ is a sheaf on $\mathcal{C}$.*
2. *For every object $C \in \mathcal{C}$ and every point $\eta \in \mathscr{F}'(C)$, the functor $\mathscr{F}_\eta$ is a sheaf on $\mathcal{C}_{/C}$ (with respect to the induced Grothendieck topology).*

Moreover, if $\mathscr{F}'$ is hypercomplete, then $\mathscr{F}$ is hypercomplete if and only if each $\mathscr{F}_\eta$ is hypercomplete.

Proof. The implication (1) ⇒ (2) is obvious, since the full subcategory $\mathcal{S}\mathrm{hv}(\mathcal{C}_{/C}) \subseteq \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}_{/C}, \mathcal{S})$ is closed under small limits. Suppose that (2) is satisfied. Fix an object $C \in \mathcal{C}$ and a covering sieve $\mathcal{C}^{(0)}_{/C} \subseteq \mathcal{C}_{/C}$; we wish to prove that the canonical map $\theta : \mathscr{F}(C) \to \varprojlim \mathscr{F}|_{\mathcal{C}^{(0)}_{/C}}$ is a homotopy equivalence. We have a commutative diagram

$$\begin{array}{ccc} \mathscr{F}(C) & \xrightarrow{\theta} & \varprojlim \mathscr{F}|_{\mathcal{C}^{(0)}_{/C}} \\ \downarrow & & \downarrow \\ \mathscr{F}'(C) & \xrightarrow{\theta'} & \varprojlim \mathscr{F}'|_{\mathcal{C}^{(0)}_{/C}}, \end{array}$$

where the map θ' is a homotopy equivalence. Consequently, to show that θ is a homotopy equivalence, it will suffice to show that θ induces a homotopy equivalence after passing to the homotopy fiber over any point $\eta \in \mathscr{F}'(C)$; this is precisely the content of assumption (2).

Now suppose that $\mathscr{F}'$ is hypercomplete. Since the collection of hypercomplete sheaves on $\mathcal{C}_{/C}$ is closed under limits, it is easy to see that $\mathscr{F}$ is hypercomplete only if each $\mathscr{F}_\eta$ is hypercomplete. Conversely, suppose that each $\mathscr{F}_\eta$ is hypercomplete; we wish to prove that $\mathscr{F}$ is hypercomplete. Choose an ∞-connective morphism $\beta : \mathscr{F} \to \mathscr{G}$, where $\mathscr{G}$ is hypercomplete; we wish to prove that β induces an equivalence $\beta_C : \mathscr{F}(C) \to \mathscr{G}(C)$ for each $C \in \mathcal{C}$. Since $\mathscr{F}'$ is hypercomplete, the map α factors through β; it will therefore suffice to show that β_C induces a homotopy equivalence after passing to the homotopy fiber over every point $\eta \in \mathscr{F}'(C)$. For this, it suffices to show that the induced map $\beta_\eta : \mathscr{F}_\eta \to \mathscr{G}_\eta$ is an equivalence. This is clear, since β_η is ∞-connective and both $\mathscr{F}_\eta$ and $\mathscr{G}_\eta$ are hypercomplete objects of $\mathcal{S}\mathrm{hv}(\mathcal{C}_{/C})$. □

Corollary D.4.3.3. *Let $\mathcal{C}$ be a small ∞-category equipped with a Grothendieck topology and let $X : \mathcal{C}^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty$ be a $\mathcal{C}\mathrm{at}_\infty$-valued presheaf on $\mathcal{C}$. Then X is a sheaf if and only if it satisfies the following conditions:*

(a) *The $\mathcal{S}$-valued functor $C \mapsto X(C)^{\simeq}$ is a $\mathcal{S}$-valued sheaf on $\mathcal{C}$.*

(b) *For every object $C \in \mathcal{C}$ and every pair of objects $x, y \in X(C)$, the construction*

$$(D \in \mathcal{C}_{/C}) \mapsto \mathrm{Map}_{X(D)}(x_D, y_D)$$

determines a $\mathcal{S}$-valued sheaf on $\mathcal{C}_{/C}$ (with respect to the induced Grothendieck topology); here x_D and y_D denote the images of x and y under the functor $X(C) \to X(D)$.

Proof. For every ∞-category $\mathcal{J}$, let $X^{\mathcal{J}} : \mathcal{C}^{\mathrm{op}} \to \mathcal{S}$ be the functor given by

$$C \mapsto \mathrm{Map}_{\mathcal{C}\mathrm{at}_\infty}(\mathcal{J}, X(C)) \simeq \mathrm{Fun}(\mathcal{J}, X(C))^{\simeq}.$$

Then X is a $\mathcal{C}\mathrm{at}_\infty$-valued sheaf on $\mathcal{C}$ if and only if each $X^{\mathcal{J}}$ is a $\mathcal{S}$-valued sheaf on $\mathcal{C}$. If this condition is satisfied, then condition (a) follows by taking $\mathcal{J} = \Delta^0$ and condition (b) follows by applying Lemma D.4.3.2 to the map $X^{\Delta^1} \to X^{\partial \Delta^1}$. Conversely, suppose that (a) and (b) are satisfied, and let $\mathcal{E} \subseteq \mathcal{C}\mathrm{at}_\infty$ be the full subcategory spanned by those ∞-categories $\mathcal{J}$ for which $X^{\mathcal{J}}$ is a sheaf. Since the construction $\mathcal{J} \mapsto X^{\mathcal{J}}$ carries colimits in $\mathcal{C}\mathrm{at}_\infty$ to limits in $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$, we deduce that $\mathcal{E}$ is closed under small colimits in $\mathcal{C}\mathrm{at}_\infty$. Condition ($a$) implies that $\mathcal{E}$ contains Δ^0, and therefore also contains the coproduct $\Delta^0 \amalg \Delta^0 \simeq \partial \Delta^1$. Applying Lemma D.4.3.2 to the map $X^{\Delta^1} \to X^{\partial \Delta^1}$, we see that condition (b) implies that $\Delta^1 \in \mathcal{J}$. It follows from Lemma D.4.3.1 that $\mathcal{E} = \mathcal{C}\mathrm{at}_\infty$, so that X is a $\mathcal{C}\mathrm{at}_\infty$-valued sheaf on $\mathcal{C}$ as desired. □

D.4.4 Faithful Flatness

We now collect some facts about faithfully flat morphisms between $\mathbb{E}_1$-ring spectra. Here, we must be careful to distinguish between left and right flatness.

Definition D.4.4.1. Let $\phi : A \to B$ be a morphism of connective $\mathbb{E}_1$-rings. We will say that B is *left faithfully flat* over A if the following conditions are satisfied:

(a) The morphism ϕ exhibits B as a flat left A-module, in the sense of Definition HA.7.2.2.10 .

(b) For every nonzero right A-module M, the tensor product $M \otimes_A B$ is also nonzero.

We say that B is *right faithfully flat* if the following dual conditions are satisfied:

(a') The morphism ϕ exhibits B as a flat right A-module, in the sense of Definition HA.7.2.2.10.

(b') For every nonzero left A-module M, the tensor product $B \otimes_A M$ is also nonzero.

Remark D.4.4.2. Let $\phi : A \to B$ be a morphism of connective $\mathbb{E}_k$-rings for $2 \leqslant k \leqslant \infty$. Then ϕ is right faithfully flat if and only if it is left faithfully flat. In this case, we will simply say that ϕ is *faithfully flat*.

Lemma D.4.4.3. *Let $f : A \to B$ be a morphism of connective $\mathbb{E}_1$-rings. The following conditions are equivalent:*

(1) *The map f is left faithfully flat.*

(2) *The cofiber* $\mathrm{cofib}(f)$ *is flat when regarded as a left A-module.*

Proof. Suppose first that (2) is satisfied. We have a fiber sequence of left A-modules $A \to B \to \mathrm{cofib}(f)$. Since A and $\mathrm{cofib}(f)$ are flat as left modules over A, B is also flat as a left A-module. Applying Theorem HA.7.2.2.15, we can write $\mathrm{cofib}(f)$ as a filtered colimit $\varinjlim N_\alpha$, where each N_α is free of finite rank as a left A-module. Then, as a left A-module, B can be realized as a filtered colimit of left modules $B_\alpha = B \times_{\mathrm{cofib}(f)} N_\alpha$, each of which fits into a fiber sequence $A \to B_\alpha \to N_\alpha$. Since A is connective and N_α is free, this fiber sequence splits. Consequently, for any right A-module M, the canonical map $M \simeq M \otimes_A A \to M \otimes_A N_\alpha$ admits a left homotopy inverse and therefore induces an injective map $\pi_* M \to \pi_*(M \otimes_A N_\alpha)$. Passing to the colimit over α, we deduce that the map $\pi_* M \to \pi_*(M \otimes_A B)$ is injective. Consequently, if $M \otimes_A B$ vanishes, then so does M.

Now suppose that (1) is satisfied. Since A and B are connective, $\mathrm{cofib}(f)$ is connective. We wish to show that $\mathrm{cofib}(f)$ is flat (as a left A-module). By virtue of Theorem HA.7.2.2.15, it will suffice to show that for every discrete right A-module M, the relative tensor product $M \otimes_A \mathrm{cofib}(f)$ is discrete. We have a fiber sequence of spectra $M \to M \otimes_A B \to M \otimes_A \mathrm{cofib}(f)$. Since B is flat as a left A-module, the spectrum $M \otimes_A B$ is discrete. Consequently, to prove that $M \otimes_A \mathrm{cofib}(f)$ is discrete, it suffices to show that the map $\theta : \pi_0 M \to \pi_0(M \otimes_A B) \simeq \mathrm{Tor}_0^{\pi_0 A}(\pi_0 M, \pi_0 B)$ is a monomorphism. Let $K \subseteq \pi_0 M$ denote the kernel of θ. Since $\pi_0 B$ is flat over $\pi_0 A$, we can identify $\mathrm{Tor}_0^{\pi_0 A}(K, \pi_0 B)$ with a submodule of $\mathrm{Tor}_0^{\pi_0 A}(\pi_0 M, \pi_0 B)$. This submodule is generated by $\theta(K) = 0$ as a module over $\pi_0 B$, and therefore vanishes. It follows that $K \otimes_A B \simeq 0$, contradicting our assumption that ϕ is left faithfully flat. □

Proposition D.4.4.4. *Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_2$-rings, let $\mathcal{C}$ be a prestable R-linear ∞-category, and let X be an object of* $\mathrm{Sp}(\mathcal{C})$.

(a) *If ϕ is faithfully flat, then X belongs to* $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ *if and only if* $R' \otimes_R X \in \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))$ *belongs to* $\mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0} \subseteq \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))$.

(b) *If ϕ is a flat universal descent morphism, then X belongs to* $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ *if and only if* $R' \otimes_R X \in \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))$ *belongs to* $\mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))_{\leqslant 0} \subseteq \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))$.

Proof. We first prove (a). It follows immediately from the definitions (making no assumptions on ϕ) that if X belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$, then $R' \otimes_R X$ belongs to $\mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$. Conversely, suppose that $R' \otimes_R X$ belongs to $\mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$ and that ϕ is faithfully flat. We wish to prove that X belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. Since the t-structure on $\mathrm{Sp}(\mathcal{C})$ is right complete, this is equivalent to the assertion that $\pi_n X \simeq 0$ for $n < 0$. To prove this, it will suffice to show that the canonical map $\rho : \pi_n X \to \pi_n(R' \otimes_R X)$ is a monomorphism in the abelian category $\mathcal{C}^{\heartsuit}$. By virtue of Lemma D.4.4.3, the cofiber $\mathrm{cofib}(\phi)$ is flat as a right R-module and can therefore (by Proposition HA.7.2.2.15) be realized as the colimit of a filtered diagram $\{M_\alpha\}$ of *free* right R-modules. For each index α, set $R'_\alpha = R' \times_{\mathrm{cofib}(\phi)} M_\alpha$. Since the t-structure on $\mathrm{Sp}(\mathcal{C})$ is compatible with filtered colimits, the map ρ is a filtered colimit of morphisms

$$\rho_\alpha : \pi_n X \to \pi_n(R'_\alpha \otimes_R X).$$

The abelian category $\mathcal{C}^{\heartsuit}$ is Grothendieck, so it will suffice to show that each ρ_α is a monomorphism in $\mathcal{C}^{\heartsuit}$. In fact, ρ_α is a split monomorphism, since the fiber sequence of right R-modules $R \to R'_\alpha \to M_\alpha$ splits (because M_α is free and R is connective).

We now prove (b). If R' is flat over R, then (using Proposition HA.7.2.2.15) we can write R' as the colimit of a filtered diagram $\{N_\beta\}$ of finitely generated free right R-modules. If $X \in \mathrm{Sp}(\mathcal{C})_{\leqslant 0}$, then $R' \otimes_R X \simeq \varinjlim_\beta N_\beta \otimes_R X$ also belongs to $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$, since the t-structure on $\mathrm{Sp}(\mathcal{C})$ is compatible with filtered colimits and each $N_\beta \otimes_R X$ is a direct sum of finitely many copies of X.

Conversely, suppose that $R' \otimes_R X \in \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))_{\leqslant 0}$. Choose a fiber sequence $X' \to X \to X''$ in the ∞-category $\mathrm{Sp}(\mathcal{C})$, where $X' \in \mathrm{Sp}(\mathcal{C})_{\geqslant 1}$ and $X'' \in \mathrm{Sp}(\mathcal{C})_{\leqslant 0}$. If R' is flat over R, then the preceding arguments show that

$$R' \otimes_R X' \in \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 1} \qquad R' \otimes_R X'' \in \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))_{\leqslant 0}.$$

Consequently, the assumption that $R' \otimes_R X$ belongs to $\mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))_{\leqslant 0}$ guarantees that $R' \otimes_R X' \simeq 0$. If ϕ is a universal descent morphism, it follows from Theorem D.3.4.1 that $X' \simeq 0$, so that $X \simeq X'' \in \mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ as desired. $\square$

Corollary D.4.4.5. *Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ and $\mathcal{D}$ be prestable R-linear ∞-categories and let $F : \mathrm{Sp}(\mathcal{C}) \to \mathrm{Sp}(\mathcal{D})$ be an R-linear functor. Suppose that there exists a faithfully flat map $R \to R'$ of connective $\mathbb{E}_2$-rings for which the induced functor $R' \otimes_R \mathrm{Sp}(\mathcal{C}) \to R' \otimes_R \mathrm{Sp}(\mathcal{D})$ is right t-exact. Then F is right t-exact.*

D.4.5 The Proof of Theorem D.4.1.6

We wish to show that the construction $R \mapsto \mathrm{LinCat}_R^{\mathrm{PSt}}$ determines a $\widehat{\mathcal{C}\mathrm{at}}_\infty$-valued sheaf with respect to the flat universal descent topology on $(\mathrm{CAlg}^{\mathrm{cn}})^{\mathrm{op}}$. We will prove this by verifying conditions (a) and (b) of Corollary D.4.3.3. We begin by verifying condition (b). Let A be a connective $\mathbb{E}_\infty$-ring and suppose that we are given prestable A-linear ∞-categories $\mathcal{C}$ and $\mathcal{D}$. We wish to show that the functor $\mathscr{F} : \mathrm{CAlg}_A^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, given by the formula $\mathscr{F}(B) = \mathrm{Map}_{\mathrm{LinCat}_B^{\mathrm{PSt}}}(B \otimes_A \mathcal{C}, B \otimes_A \mathcal{D})$, is a sheaf with respect to the flat universal descent topology. Define $\mathscr{F}' : \mathrm{CAlg}_A^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ by the formula

$$\mathscr{F}'(B) = \mathrm{Map}_{\mathrm{LinCat}_B}(B \otimes_A \mathrm{Sp}(\mathcal{C}), B \otimes_A \mathrm{Sp}(\mathcal{D})).$$

We have an evident natural transformation $\alpha : \mathscr{F} \to \mathscr{F}'$. Using Lemma D.4.2.1, we see that α identifies each $\mathscr{F}(B)$ with the summand of $\mathscr{F}'(B)$ consisting of those B-linear functors $B \otimes_A \mathrm{Sp}(\mathcal{C}) \to B \otimes_A \mathrm{Sp}(\mathcal{D})$ which are right t-exact. Since $\mathscr{F}'$ is a sheaf for the universal descent topology (Theorem D.3.5.2) and the condition of right t-exactness is local with respect to the fpqc topology (Corollary D.4.4.5), it follows that $\mathscr{F}$ is a sheaf with respect to the flat universal descent topology.

We now prove (a). Define $\widehat{\mathcal{S}}$-valued functors $\mathscr{G}, \mathscr{G}' : \mathscr{G}_R^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ by the formulae

$$\mathscr{G}(A) = (\mathrm{LinCat}_A^{\mathrm{PSt}})^{\simeq} \qquad \mathscr{G}'(A) = (\mathrm{LinCat}_A^{\mathrm{St}})^{\simeq}.$$

The construction $\mathcal{C} \mapsto \mathrm{Sp}(\mathcal{C})$ determines a map $\beta : \mathscr{G} \to \mathscr{G}'$ and the functor $\mathscr{G}'$ is a sheaf with respect to the universal descent topology (Theorem D.3.5.2). To conclude that $\mathscr{G}$ is a sheaf with respect to the flat universal descent topology, it will suffice to show that the morphism β satisfies the hypotheses of Lemma D.4.3.2. Fix a connective $\mathbb{E}_\infty$-ring A and a stable A-linear ∞-category $\mathcal{C}$, and let $\mathscr{H} : \mathscr{G}_A^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be the functor given by $\mathscr{H}(B) = \mathscr{G}(B) \times_{\mathscr{G}'(B)} \{\mathcal{C}\}$. Using Lemma D.4.2.1, we see that $\mathscr{H}(B)$ can be identified with the discrete (but large) collection of t-structures on the stable ∞-category $B \otimes_A \mathcal{C}$ which are right complete and compatible with filtered colimits. It follows from (b) that this $\mathscr{H}$ is a separated set-valued presheaf on $\mathscr{G}_A^{\mathrm{cn}}$ and we wish to prove that it is actually a sheaf. Let us therefore fix a connective A-algebra B and a finite collection of morphisms $\{B \to B_i\}_{i \in I}$ for which the map $B \to \prod B_i$ is a flat universal descent morphism, and suppose we are given a collection of elements $\eta_i \in \mathscr{H}(B_i)$ which are compatible (in the sense that η_i and η_j have the same image in $\mathscr{H}(B_i \amalg_B B_j)$ for every pair of elements $i, j \in I$); we wish to show that the element $\{\eta_i\}_{i \in I} \in \prod \mathscr{H}(B_i)$ can be lifted to an element $\eta \in \mathscr{H}(B)$.

Set $B^0 = \prod_{i \in I} B_i$ and let $B^\bullet$ denote the cosimplicial object of $\mathrm{CAlg}_B^{\mathrm{cn}}$ given by the Čech nerve of the map $B \to B^0$. Then we can regard $\mathrm{LMod}_{B^\bullet}(\mathcal{C})$ as a cosimplicial object of the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$, and the elements of η_i determine a lifting of $\mathrm{LMod}_{B^\bullet}(\mathcal{C})$ to the ∞-category Groth_∞, which we will denote by $\mathrm{LMod}_{B^\bullet}(\mathcal{C})_{\geqslant 0}$. Note that for every injective map $[m] \hookrightarrow [n]$

the transition maps $B^m \to B^n$ is flat, so the associated functor $\mathrm{LMod}_{B^m}(\mathcal{C}) \to \mathrm{LMod}_{B^n}(\mathcal{C})$ is left t-exact. It follows that the totalization $\mathcal{E} = \mathrm{Tot}(\mathrm{LMod}_{B^\bullet}(\mathcal{C})_{\geqslant 0})$ is again a Grothendieck prestable ∞-category (see Proposition C.3.2.4). Moreover, we have a canonical equivalence

$$\begin{aligned} \mathrm{Sp}(\mathcal{E}) &\simeq \mathrm{Tot}\,\mathrm{Sp}(\mathrm{LMod}_{B^\bullet}(\mathcal{C}))_{\geqslant 0}) \\ &\simeq \mathrm{Tot}\,\mathrm{LMod}_{B^\bullet}(\mathcal{C}) \\ &\simeq \mathrm{LMod}_B(\mathcal{C}), \end{aligned}$$

where the last equivalence is a consequence of Theorem **??**. In other words, the ∞-category $\mathrm{LMod}_B(\mathcal{C})$ admits a t-structure $(\mathrm{LMod}_B(\mathcal{C})_{\geqslant 0}, \mathrm{LMod}_B(\mathcal{C})_{\leqslant 0})$ which is right t-exact and compatible with filtered colimits which is characterized by the following property:

- $(*)$ An object $X \in \mathrm{LMod}_B(\mathcal{C})$ belongs to $\mathrm{LMod}_B(\mathcal{C})_{\geqslant 0}$ if and only if each of the tensor products $B^n \otimes_B X$ belongs to $\mathrm{LMod}_{B^n}(\mathcal{C})_{\geqslant 0}$ (moreover, it suffices to check this condition in the special case $n = 0$).

This t-structure determines an element $\eta \in \mathscr{H}(B)$. To complete the proof, we wish to show that η is a preimage of the collection $\{\eta_i\} \in \prod_{i \in I} \mathscr{H}(B_i)$. By virtue of Remark D.2.4.7, this can be restated as follows:

- $(*')$ An object $Y \in \mathrm{LMod}_{B^0}(\mathcal{C})$ belongs to $\mathrm{LMod}_{B^0}(\mathcal{C})_{\geqslant 0}$ if and only if its image under the forgetful functor $\mathrm{LMod}_{B^0}(\mathcal{C}) \to \mathrm{LMod}_B(\mathcal{C})$ belongs to $\mathrm{LMod}_B(\mathcal{C})_{\geqslant 0}$.

By virtue of $(*)$ together with the left adjointability of the diagram of forgetful functors

$$\begin{array}{ccc} \mathrm{LMod}_{B^1}(\mathcal{C}) & \longrightarrow & \mathrm{LMod}_{B^0}(\mathcal{C}) \\ \downarrow & & \downarrow \\ \mathrm{LMod}_{B^0}(\mathcal{C}) & \longrightarrow & \mathrm{LMod}_B(\mathcal{C}), \end{array}$$

we can restate $(*')$ as follows:

- $(*'')$ An object $Y \in \mathrm{LMod}_{B^0}(\mathcal{C})$ belongs to $\mathrm{LMod}_{B^0}(\mathcal{C})_{\geqslant 0}$ if and only if its image under the composite functor $\mathrm{LMod}_{B^0}(\mathcal{C}) \xrightarrow{\phi} \mathrm{LMod}_{B^1}(\mathcal{C}) \xrightarrow{\psi} \mathrm{LMod}_{B^0}(\mathcal{C})$ belongs to $\mathrm{LMod}_{B^0}(\mathcal{C})_{\geqslant 0}$. (Here ϕ and ψ are induced by the two B^0-algebra structures on B^1.)

Assertion $(*'')$ now follows from Proposition D.4.4.4 and Remark D.2.4.7. This completes the proof of Theorem D.4.1.6.

D.5 Local Properties of R-Linear ∞-Categories

Let P be some property of Grothendieck prestable ∞-categories. In this section, we will study the following closely related questions:

Question D.5.0.1. Under what conditions is the property P stable under base change? That is, if we are given a morphism $\phi : R \to R'$ of connective $\mathbb{E}_\infty$-rings and a prestable R-linear ∞-category $\mathcal{C}$ which has the property P, then when can we conclude that the prestable R'-linear ∞-category $R' \otimes_R \mathcal{C}$ also has the property P?

Question D.5.0.2. Under what conditions can the property P be tested locally? That is, if we are given a morphism $\phi : R \to R'$ of connective $\mathbb{E}_\infty$-rings which is a “covering” in some sense (for example, a faithfully flat morphism) and a prestable R-linear ∞-category $\mathcal{C}$ for which $R' \otimes_R \mathcal{C}$ has the property P, then when can we conclude that $\mathcal{C}$ also has the property P?

Our goal in this section is to provide partial answers to Questions D.5.0.1 and D.5.0.2 in a variety of circumstances. Our main results can be summarized as follows:

- The properties of being stable, separated, and complete are compatible with arbitrary base change and can be tested locally with respect to the flat universal descent topology (Propositions D.5.1.1, D.5.1.2, and D.5.1.3).

- The property that an R-linear functor $F : \mathcal{C} \to \mathcal{D}$ is compact (left exact) is stable under arbitrary base change and can be tested locally with respect to the (flat) universal descent topology (Propositions D.5.2.1 and D.5.2.2).

- The property of being compactly generated is stable under arbitrary base change and can be tested locally with respect to the étale topology (Theorem D.5.3.1).

- The property of being anticomplete is stable under fiber-smooth base change (Theorem D.5.4.1) and can be tested locally with respect to the étale topology (Theorem D.5.4.9).

- The property of being weakly coherent is stable under base base change along quasi-finite morphisms which are almost of finite presentation (Theorem D.5.5.1) and can be tested locally with respect to the étale topology (Corollary D.5.5.11).

- The property of being locally Noetherian is stable under base change along morphisms which are almost of finite presentation and can be tested locally with respect to the flat topology (Propositions D.5.6.1 and D.5.6.4).

- For each $n \geqslant 0$, the properties of being n-complicial and weakly n-complicial are stable under flat base change. Moreover, the property of being weakly n-complicial can be tested locally with respect to the flat universal descent topology (Proposition D.5.7.1).

D.5.1 Stable, Separated, and Complete Prestable ∞-Categories

We with some easy cases of Questions D.5.0.1 and D.5.0.2.

Proposition D.5.1.1. *Let R be a connective $\mathbb{E}_2$-ring and let $\mathcal{C}$ be a prestable R-linear ∞-category. Then:*

- (a) *Assume that $\mathcal{C}$ is stable (see Definition C.1.2.12). Then for any connective $\mathbb{E}_1$-algebra R' over R, the Grothendieck prestable ∞-category $\mathrm{LMod}_{R'}(\mathcal{C})$ is also stable.*
- (b) *If there exists a flat universal descent morphism $R \to R'$ of connective $\mathbb{E}_2$-rings (for example, a morphism which is étale and faithfully flat) such that $R' \otimes_R \mathcal{C}$ is stable, then $\mathcal{C}$ is stable.*

Proof. Assertion (a) is trivial. To prove (b), suppose that $R' \otimes_R \mathcal{C}$ is stable. We wish to prove that the functor $\Sigma^\infty : \mathcal{C} \simeq \mathrm{Sp}(\mathcal{C})_{\geqslant 0} \subseteq \mathrm{Sp}(\mathcal{C})$ is an equivalence of ∞-categories. Equivalently, we wish to show that every object $C \in \mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ is zero. Since R' is flat over R, the tensor product $R' \otimes_R C \in \mathrm{LMod}_{R'}(\mathcal{C})$ belongs to $\mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))_{\leqslant 0}$, and therefore vanishes (by virtue of the stability of $R' \otimes_R \mathcal{C}$). Since $R \to R'$ is a universal descent morphism, it follows that $C \simeq 0$ as desired. □

Proposition D.5.1.2. *Let R be a connective $\mathbb{E}_2$-ring and let $\mathcal{C}$ be a prestable R-linear ∞-category. Then:*

- (a) *Assume that $\mathcal{C}$ is separated (see Definition C.1.2.12). Then for any connective $\mathbb{E}_1$-algebra R' over R, the Grothendieck prestable ∞-category $\mathrm{LMod}_{R'}(\mathcal{C})$ is also separated.*
- (b) *If there exists a universal descent morphism $R \to R'$ of connective $\mathbb{E}_2$-rings (for example, a morphism which is étale and faithfully flat) such that $R' \otimes_R \mathcal{C}$ is separated, then $\mathcal{C}$ is separated.*

Proof. We first prove (a). Assume that $\mathcal{C}$ is separated and let X be an object of the ∞-category $\bigcap_{n \geqslant 0} \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))_{\geqslant n}$. Then the image of X under the forgetful functor $\theta : \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C})) \to \mathrm{Sp}(\mathcal{C})$ belongs to $\bigcap \mathrm{Sp}(\mathcal{C})_{\geqslant n}$ (see Remark D.2.4.7). The assumption that $\mathcal{C}$ is separated then gives $\theta(X) \simeq 0$. Since the functor θ is conservative, we conclude that $X \simeq 0$. Allowing X to vary, we deduce that $\mathrm{LMod}_{R'}(\mathcal{C})$ is separated.

We now prove (b). Assume that $R' \otimes_R \mathcal{C}$ is separated and let $X \in \bigcap_{n \geqslant 0} \mathrm{Sp}(\mathcal{C})_{\geqslant n}$. Then the tensor product $R' \otimes_R X$ belongs to $\bigcap_{n \geqslant 0} \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))_{\geqslant n}$. It follows that $R' \otimes_R X \simeq 0$. If $R \to R'$ is a universal descent morphism, this implies that $X \simeq 0$. □

Proposition D.5.1.3. *Let R be a connective $\mathbb{E}_2$-ring and let $\mathcal{C}$ be a prestable R-linear ∞-category. Then:*

(a) *Assume that $\mathcal{C}$ is complete (see Definition C.1.2.12). Then for any connective $\mathbb{E}_1$-algebra R' over R, the Grothendieck prestable ∞-category $\mathrm{LMod}_{R'}(\mathcal{C})$ is also complete.*

(b) *If there exists a flat universal descent morphism $R \to R'$ of connective $\mathbb{E}_2$-rings (for example, a morphism which is étale and faithfully flat) such that $R' \otimes_R \mathcal{C}$ is complete, then $\mathcal{C}$ is complete.*

Proof. If $\mathcal{C}$ is complete, then the canonical map $\mathrm{Sp}(\mathcal{C}) \to \varprojlim_{n \geq 0} \mathrm{Sp}(\mathcal{C})_{\leq n}$ is an equivalence of ∞-categories left-tensored over $\mathrm{LMod}_R^{\mathrm{cn}}$. It follows that, for every algebra object $R' \in \mathrm{LMod}_R^{\mathrm{cn}}$, the induced functor

$$\mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C})) \to \varprojlim \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C})_{\leq n}) \simeq \varprojlim \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))_{\leq n}$$

is also an equivalence, so that $R' \otimes_R \mathcal{C}$ is also complete. This proves (a).

We now prove (b). Assume that $\phi : R \to R'$ is a universal descent morphism of connective $\mathbb{E}_2$-rings and that $R' \otimes_R \mathcal{C}$ is complete. We then have a pair of adjoint functors

$$\mathrm{Sp}(\mathcal{C}) \underset{G}{\overset{F}{\rightleftarrows}} \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C})).$$

Since ϕ is a universal descent morphism, this adjunction is comonadic: that is, it exhibits $\mathrm{Sp}(\mathcal{C})$ as the ∞-category of coalgebras over the comonad

$$U = F \circ G : \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C})) \to \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C})),$$

given at the level of objects by $X \mapsto R' \otimes_R X$. If the map ϕ is flat, then an object $X \in \mathrm{Sp}(\mathcal{C})$ belongs to $\mathrm{Sp}(\mathcal{C})_{\leq n}$ if and only if $R' \otimes_R X$ belongs to $\mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))_{\leq n}$ (Proposition D.4.4.4). Note that the comonad U commutes with truncations. It follows that the canonical map $\mathrm{Sp}(\mathcal{C}) \to \varprojlim_{n \geq 0} \mathrm{Sp}(\mathcal{C})_{\leq n}$ can be identified with the opposite of the composition of equivalences

$$\begin{aligned}
\mathrm{Sp}(\mathcal{C})^{\mathrm{op}} &\simeq \mathrm{RMod}_U(\mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))^{\mathrm{op}}) \\
&\simeq \mathrm{RMod}_U(\varprojlim \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))^{\mathrm{op}}_{\leq n}) \\
&\simeq \varprojlim \mathrm{RMod}_U(\mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{C}))^{\mathrm{op}}_{\leq n}) \\
&\simeq \varprojlim \mathrm{Sp}(\mathcal{C})^{\mathrm{op}}_{\leq n},
\end{aligned}$$

and is therefore an equivalence of ∞-categories. □

D.5.2 Left Exact and Compact Functors

We now consider a slight variant of Questions D.5.0.1 and D.5.0.2. Suppose we are given a connective $\mathbb{E}_2$-ring R and an R-linear functor $f : \mathcal{C} \to \mathcal{D}$, where $\mathcal{C}$ and $\mathcal{D}$ are prestable

R-linear ∞-categories. What is the relationship between properties of the functor f and properties of the induced map $\mathrm{LMod}_{R'}(\mathcal{C}) \to \mathrm{LMod}_{R'}(\mathcal{D})$, where R' is an $\mathbb{E}_1$-algebra over R?

Proposition D.5.2.1. *Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ and $\mathcal{D}$ be prestable R-linear ∞-categories, and let $f : \mathcal{C} \to \mathcal{D}$ be an R-linear functor. Then:*

- (a) *If the functor f is left exact, then for any connective $\mathbb{E}_1$-algebra R' over R, the induced functor $f_{R'} : \mathrm{LMod}_{R'}(\mathcal{C}) \to \mathrm{LMod}_{R'}(\mathcal{C})$ is also left exact.*
- (b) *If there exists a flat universal descent morphism $R \to R'$ of connective $\mathbb{E}_2$-rings (for example, a morphism which is étale and faithfully flat) for which the map $f_{R'}$ is left exact, then f is left exact.*

Proof. Assertion (a) follows from the commutativity of the diagram

$$\begin{array}{ccc} \mathrm{LMod}_{R'}(\mathcal{C}) & \xrightarrow{f_{R'}} & \mathrm{LMod}_{R'}(\mathcal{D}) \\ \downarrow & & \downarrow \\ \mathcal{C} & \xrightarrow{f} & \mathcal{D}, \end{array}$$

since the vertical maps (given by the forgetful functors) are conservative and preserve finite limits (Corollary HA.4.2.3.3). To prove (b), we note that there is also a commutative diagram

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{f} & \mathcal{D} \\ \downarrow{\scriptstyle R'\otimes_R} & & \downarrow{\scriptstyle R'\otimes_R} \\ \mathrm{LMod}_{R'}(\mathcal{C}) & \xrightarrow{f_{R'}} & \mathrm{LMod}_{R'}(\mathcal{D}). \end{array}$$

If $R \to R'$ is a flat universal descent morphism, then Proposition D.4.4.4 (together with Proposition C.3.2.1) guarantee that the vertical maps in this diagram are conservative and left exact. Consequently, the left exactness of f follows from the left exactness of $f_{R'}$. □

Proposition D.5.2.2. *Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ and $\mathcal{D}$ be prestable R-linear ∞-categories, and let $f : \mathcal{C} \to \mathcal{D}$ be an R-linear functor. Then:*

- (a) *Suppose that f is compact. Then, for any connective $\mathbb{E}_1$-algebra R' over R, the induced functor $f_{R'} : \mathrm{LMod}_{R'}(\mathcal{C}) \to \mathrm{LMod}_{R'}(\mathcal{D})$ is compact.*
- (b) *If there exists a universal descent morphism $R \to R'$ of connective $\mathbb{E}_2$-rings (for example, a morphism which is étale and faithfully flat) for which the induced map $f_{R'} : R' \otimes_R \mathcal{C} \to R' \otimes_R \mathcal{D}$ is compact, then f is compact.*

Proof. To prove (a), let g and $g_{R'}$ denote right adjoints to f and $f_{R'}$, so that we have a commutative diagram σ :

$$\begin{array}{ccc} \mathrm{LMod}_{R'}(\mathcal{D}) & \xrightarrow{g_{R'}} & \mathrm{LMod}_{R'}(\mathcal{D}) \\ \downarrow & & \downarrow \\ \mathcal{D} & \xrightarrow{g} & \mathcal{C}\,. \end{array}$$

where the vertical maps are conservative and preserve small colimits (Corollary HA.4.2.3.5). It follows immediately that if g commutes with filtered colimits, then so does $g_{R'}$.

We now prove (b). Passing to stabilizations in the diagram σ, we obtain a commutative diagram of stable ∞-categories τ :

$$\begin{array}{ccc} \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{D})) & \xrightarrow{G_{R'}} & \mathrm{LMod}_{R'}(\mathrm{Sp}(\mathcal{D})) \\ \downarrow & & \downarrow \\ \mathrm{Sp}(\mathcal{D}) & \xrightarrow{G} & \mathrm{Sp}(\mathcal{C}). \end{array}$$

For every left R-module M, let $G_M : \mathrm{Sp}(\mathcal{D}) \to \mathrm{Sp}(\mathcal{C})$ denote the functor given on objects by $G_M(X) = G(M \otimes_R X)$. By virtue of Proposition C.3.2.4, to show that the functor g commutes with filtered colimits it will suffice to show that G_R commutes with all colimits. In fact, we will prove that the functor G_M commutes with colimits for *all* left R-modules M.

Let $\mathcal{E} \subseteq \mathrm{LMod}_R$ denote the full subcategory spanned by those left R-modules M for which the functor G_M commutes with small colimits. We wish to show that $\mathcal{E} = \mathrm{LMod}_R$. Since the construction $M \mapsto G_M$ commutes with finite limits, the ∞-category $\mathcal{E}$ is a stable subcategory of LMod_R which is closed under retracts. Since $R \to R'$ is a universal descent morphism, it will suffice to show that $\mathcal{E}$ contains the essential image of the forgetful functor $\mathrm{LMod}_{R'} \to \mathrm{LMod}_R$ (see Variant D.3.2.3). In other words, we are reduced to proving that the functor G_M commutes with small colimits in the special case where M admits the structure of a left R'-module. In this case, the commutativity of the diagram τ allows us to identify G_M with the composition of colimit-preserving functors

$$\mathcal{D} \xrightarrow{R' \otimes_R} \mathrm{LMod}_{R'}(\mathcal{D}) \xrightarrow{M \otimes_{R'}} \mathrm{LMod}_{R'}(\mathcal{D}) \xrightarrow{G_{R'}} \mathrm{LMod}_{R'}(\mathcal{C}) \to \mathcal{C}\,.$$

□

Remark D.5.2.3. Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a prestable R-linear ∞-category, and let $C \in \mathcal{C}$ be an object. Then C determines an R-linear functor $\lambda : \mathrm{LMod}_R^{\mathrm{cn}} \to \mathcal{C}$, given by $\lambda(M) = M \otimes_R C$, and the object $C \in \mathcal{C}$ is compact if and only if the functor λ is compact (in the sense of Definition C.3.5.1). Applying Proposition D.5.2.2, we deduce:

- (a) If C is compact, then for any $\mathbb{E}_1$-algebra A over R, the tensor product $A \otimes_R C$ is a compact object of $\mathrm{LMod}_A(\mathcal{C})$.

(b) If there exists a universal descent morphism of $\mathbb{E}_2$-rings $R \to R'$ (for example, a morphism that is étale and faithfully flat) and $R' \otimes_R C$ is a compact object of $\mathrm{LMod}_{R'}(\mathcal{C})$, then C is compact.

D.5.3 Compactly Generated Prestable ∞-Categories

Recall that a stable ∞-category $\mathcal{C}$ is said to be *compactly generated* if is equivalent to an ∞-category of the form $\mathrm{Ind}(\mathcal{C}_0)$, where $\mathcal{C}_0$ is an essentially small stable ∞-category. In the case where $\mathcal{C}$ is equipped with an action of a commutative ring R, a theorem of Toën asserts that the hypothesis that $\mathcal{C}$ is compactly generated can be tested locally with respect to the étale topology on R ([211]). This was generalized to the setting of $\mathbb{E}_\infty$-rings by Antieau and Gepner ([2]). Our goal in this section is to prove the following analogous result in the setting of prestable ∞-categories:

Theorem D.5.3.1. *Let R be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a prestable R-linear ∞-category. Then:*

(a) *If $\mathcal{C}$ is compactly generated, then $\mathrm{LMod}_{R'}(\mathcal{C})$ is compactly generated for any connective $\mathbb{E}_1$-algebra R' over R.*

(b) *If there exists a faithfully flat étale morphism $R \to R'$ such that $R' \otimes_R \mathcal{C}$ is compactly generated, then $\mathcal{C}$ is compactly generated.*

Remark D.5.3.2. Theorem D.5.3.1 is valid also when R is a connective $\mathbb{E}_2$-ring; the proof we give in this section requires only minor modifications.

Part (a) of Theorem D.5.3.1 is a special case of the following:

Lemma D.5.3.3. *Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a Grothendieck prestable ∞-category equipped with a right action of $\mathrm{LMod}_R^{\mathrm{cn}}$, and let $\mathcal{D}$ be a Grothendieck prestable ∞-category equipped with a left action of $\mathrm{LMod}_R^{\mathrm{cn}}$. Assume that $\mathcal{C}$ and $\mathcal{D}$ are compactly generated. Then:*

(a) *The tensor product $\mathcal{C} \otimes_R \mathcal{D} = \mathcal{C} \otimes_{\mathrm{LMod}_R^{\mathrm{cn}}} \mathcal{D}$ is compactly generated.*

(b) *Let $\mathcal{E} \subseteq \mathcal{C} \otimes_R \mathcal{D}$ be the smallest full subcategory which is closed under cofibers and contains every object of the form $C \otimes_R D$, where C is a compact object of $\mathcal{C}$ and D is a compact object of $\mathcal{D}$. Then every compact object of $\mathcal{C} \otimes_R \mathcal{D}$ is a retract of an object of $\mathcal{E}$.*

Proof. Let $\mathcal{E}$ be as in (b). It is easy to see that $\mathcal{E}$ is closed under finite coproducts and is therefore closed under finite colimits in $\mathcal{C} \otimes_R \mathcal{D}$. As in the proof of Proposition D.2.2.1, we can identify $\mathcal{C} \otimes_R \mathcal{D}$ with the geometric realization of a semisimplicial object ($[n] \in$

$\mathbf{\Delta}_s^{op}) \mapsto \mathrm{Bar}\,\mathrm{LMod}_R^{cn}(\mathcal{C},\mathcal{D})_n$ of the ∞-category Groth_∞^c of Definition C.3.4.2. It follows that the natural map $\mathcal{C}\otimes\mathcal{D}\to\mathcal{C}\otimes_R\mathcal{D}$ preserves compact objects. Since the collection of compact objects of $\mathcal{C}\otimes_R\mathcal{D}$ is closed under finite colimits, each object of $\mathcal{E}$ is compact in $\mathcal{C}\otimes_R\mathcal{D}$. It follows that the inclusion $\mathcal{E}\hookrightarrow\mathcal{C}\otimes_R\mathcal{D}$ extends to a fully faithful embedding $f:\mathrm{Ind}(\mathcal{E})\to\mathcal{C}\otimes_R\mathcal{D}$ which commutes with small colimits. Let g be a right adjoint to f. Since we can identify $\mathcal{C}\otimes_R\mathcal{D}$ with the totalization of $\mathrm{Bar}_{\mathrm{LMod}_R^{cn}}(\mathcal{C},\mathcal{D})_\bullet$ in the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty$, the functor g is conservative. It follows that f is an equivalence of ∞-categories, which proves (a) and (b). □

Let $\mathcal{C}$ be an R-linear prestable ∞-category, for some connective $\mathbb{E}_2$-ring R. If $\mathcal{C}$ is compactly generated, then there is a close relationship between compact objects of $\mathcal{C}$ and compact objects of the localization $\mathcal{C}[a^{-1}]=R[a^{-1}]\otimes_R\mathcal{C}$ (where a is an element of $\pi_0 R$):

Proposition D.5.3.4 (Thomason's Trick)**.** *Let R be a connective $\mathbb{E}_2$-ring and let $\mathcal{C}$ be a compactly generated prestable R-linear ∞-category. Let a be an element of $\pi_0 R$ and let D be a compact object of $\mathcal{C}[a^{-1}]$. Then there exists a compact object $C\in\mathcal{C}$ and an equivalence $R[a^{-1}]\otimes_R C\simeq D\oplus\Sigma D$ in the ∞-category $\mathcal{C}[a^{-1}]$.*

Proof. For each object $C\in\mathcal{C}$, let $C[a^{-1}]$ denote the tensor product $R[a^{-1}]\otimes_R C\in\mathcal{C}[a^{-1}]$. Note that, as an object of $\mathcal{C}$, we can identify $C[a^{-1}]$ with the colimit of the filtered diagram

$$C\xrightarrow{a}C\xrightarrow{a}C\xrightarrow{a}C\xrightarrow{a}\cdots.$$

Consequently, for objects $C,C'\in\mathcal{C}$, if C is compact then we have a canonical isomorphism of abelian groups

$$\pi_0\,\mathrm{Map}_{\mathcal{C}[a^{-1}]}(C[a^{-1}],C'[a^{-1}])\simeq\pi_0\,\mathrm{Map}_{\mathcal{C}}(C,C'[a^{-1}])\simeq(\pi_0\,\mathrm{Map}_{\mathcal{C}}(C,C'))[a^{-1}].$$

Let $\mathcal{E}$ denote the full subcategory $R[a^{-1}]\otimes_R\mathcal{C}$ spanned by those objects of the form $R[a^{-1}]\otimes_R C$, where $C\in\mathcal{C}$ is compact. The above argument shows that for any morphism $f:C[a^{-1}]\to C'[a^{-1}]$ between objects of $\mathcal{E}$, there exists an integer $n\gg 0$ such that $a^n f$ is induced by a map $f_0:C\to C'$ in $\mathcal{C}$. We then have $\mathrm{cofib}(f)\simeq\mathrm{cofib}(a^n f)\simeq\mathrm{cofib}(f_0)[a^{-1}]$. In particular, the ∞-category $\mathcal{E}$ is closed under the formation of cofibers. A similar argument (replacing C' by $\Sigma C'$ and fibers in place of cofibers) shows that $\mathcal{E}$ is closed under extensions.

Let X be any nonzero object of $\mathcal{C}[a^{-1}]$. Then the image of X in $\mathcal{C}$ is nonzero, so our assumption that $\mathcal{C}$ is compactly generated guarantees that there is a nonzero morphism $f_0:C\to X$ in $\mathcal{C}$, where $C\in\mathcal{C}$ is compact (Corollary C.6.3.3). The map f_0 induces a nonzero map $f:C[a^{-1}]\to X$ in $\mathcal{C}[a^{-1}]$, whose domain lies in the full subcategory $\mathcal{E}$. Arguing as in Proposition C.6.3.1, we see that $\mathcal{E}$ is a set of compact generators for $\mathcal{C}[a^{-1}]$. In particular, every compact object $D\in\mathcal{C}[a^{-1}]$ can be obtained as a direct summand of an object $E\in\mathcal{E}$. Write $E\simeq D\oplus D'$, and let $q:E\to E$ be the direct sum of the zero map $0:D\to D$ with the identity map $\mathrm{id}_{D'} : D' \to D$. Then $D \oplus \Sigma D \simeq \mathrm{cofib}(q)$ belongs to $\mathcal{E}$, and can therefore be written as $C[a^{-1}]$ for some compact object $C \in \mathcal{C}$. □

Proof of Part (*b*) *of Theorem D.5.3.1.* Let R be a connective $\mathbb{E}_\infty$-ring, let $\mathcal{C}$ be a prestable R-linear ∞-category, and let $\mathrm{CAlg}_R^{\text{ét}}$ denote the ∞-category of étale R-algebras. We define a functor $\chi : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{S}$ by the formula

$$\chi(R') = \begin{cases} \Delta^0 & \text{if } R' \otimes_R \mathcal{C} \text{ is compactly generated} \\ \varnothing & \text{otherwise.} \end{cases}$$

To prove Theorem **??**, it will suffice to show that the functor χ is a sheaf with respect to the étale topology. By virtue of Theorem B.6.4.1, it will suffice to show that χ is a sheaf with respect to both the finite étale topology and the Nisnevich topology.

We begin by showing that χ is a sheaf with respect to the Nisnevich topology. By virtue of Theorem B.5.0.3, it will suffice to show that χ satisfies affine Nisnevich excision. Note that if $R' \simeq 0$, then the ∞-category $R' \otimes_R \mathcal{C}$ is a contractible Kan complex and therefore compactly generated, so that $\chi(R') \simeq \Delta^0$. To complete the proof, it will suffice to show that if $\phi : A \to A'$ is a morphism of étale R-algebras which induces an isomorphism $(\pi_0 A)/(a) \to (\pi_0 A')/(a)$ for some element $a \in \pi_0 A$, then the diagram

$$\begin{array}{ccc} \chi(A) & \longrightarrow & \chi(A') \\ \downarrow & & \downarrow \\ \chi(A[a^{-1}]) & \longrightarrow & \chi(A'[a^{-1}]) \end{array}$$

is a pullback square. In other words, we must show that if $A' \otimes_R \mathcal{C}$ and $A[a^{-1}] \otimes_R \mathcal{C}$ are compactly generated, then $A \otimes_R \mathcal{C}$ is compactly generated. To prove this, we can assume without loss of generality that $R = A$. We will show that $\mathcal{C}$ is compactly generated by verifying that it satisfies the requirements of Corollary C.6.3.3. Let $C \in \mathcal{C}$ be a nonzero object; we wish to show that there is a compact object $C_0 \in \mathcal{C}$ and a nonzero map $f : C_0 \to C$. There are two cases to consider:

(i) Suppose that the object $C[a^{-1}] = A[a^{-1}] \otimes_A C$ vanishes. Let $\mathcal{D} \subseteq \mathcal{C}$ be the full subcategory spanned by those objects $D \in \mathcal{C}$ satisfying $D[a^{-1}] \simeq 0$, and define $\mathcal{D}' \subseteq (A' \otimes_A \mathcal{C})$ similarly. Using Theorem D.3.5.2 and Proposition D.4.4.4, we see that the construction $B \mapsto (B \otimes_A \mathcal{C})$ is a $\widehat{\mathcal{C}\mathrm{at}}_\infty$-valued sheaf with respect to the étale topology. In particular, it satisfies Nisnevich excision (Theorem B.5.0.3), so the diagram of ∞-categories

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{A[a^{-1}]\otimes_A} & A[a^{-1}] \otimes_A \mathcal{C} \\ \downarrow{\scriptstyle A'\otimes_A} & & \downarrow{\scriptstyle A'[a^{-1}]\otimes_{A[a^{-1}]}} \\ A' \otimes_A \mathcal{C} & \xrightarrow{A'[a^{-1}]\otimes_{A'}} & A'[a^{-1}] \otimes_A \mathcal{C} \end{array}$$

is a pullback square. Passing to homotopy fibers in the horizontal direction, we conclude that the functor $D \mapsto A' \otimes_A D$ induces an equivalence of ∞-categories $\mathcal{D} \to \mathcal{D}'$. By assumption, the ∞-category $A' \otimes_A \mathcal{C}$ is compactly generated. It follows from Proposition 7.1.1.12 that $\mathcal{D}'$ is compactly generated, so that $\mathcal{D}$ is also compactly generated. Our assumption that $C[a^{-1}]$ vanishes guarantees that C belongs to the full subcategory $\mathcal{D} \subseteq \mathcal{C}$. Since $\mathcal{D}$ is compactly generated, Corollary C.6.3.3 guarantees that there exists a nonzero map $C_0 \to C$, where C_0 is a compact object of $\mathcal{D}$. Note that the tensor product $A' \otimes_A C_0 \in \mathcal{D}'$ is a compact object of $A' \otimes_A \mathcal{C}$ (by virtue of Proposition 7.1.1.12) and the tensor product $A[a^{-1}] \otimes_A C_0$ is a compact object of $A[a^{-1}] \otimes_A \mathcal{C}$ (since it vanishes). Applying Remark D.5.2.3, we deduce that C_0 is a compact object of $\mathcal{C}$, as desired.

(ii) Suppose that the object $C[a^{-1}] = A[a^{-1}] \otimes_A C$ does not vanish. Since $A[a^{-1}] \otimes_A \mathcal{C}$ is a compactly generated prestable ∞-category, Corollary C.6.3.3 guarantees that there exists a compact object $D_0 \in A[a^{-1}] \otimes_A \mathcal{C}$ and a nonzero map $f : D_0 \to C[a^{-1}]$. Let D'_0 denote the tensor product $A'[a^{-1}] \otimes_{A[a^{-1}]} D_0$, which we regard as a compact object of the ∞-category $A'[a^{-1}] \otimes_A \mathcal{C}$. Replacing D_0 by $D_0 \oplus \Sigma D_0$ if necessary, we can assume that D'_0 has the form $D'[a^{-1}]$ for some compact object $D' \in (A' \otimes_A \mathcal{C})$ (Proposition D.5.3.4). Since the diagram of ∞-categories

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{A[a^{-1}]\otimes_A} & A[a^{-1}] \otimes_A \mathcal{C} \\ \downarrow{\scriptstyle A'\otimes_A} & & \downarrow{\scriptstyle A'[a^{-1}]\otimes_{A[a^{-1}]}} \\ A' \otimes_A \mathcal{C} & \xrightarrow{A'[a^{-1}]\otimes_{A'}} & A'[a^{-1}] \otimes_A \mathcal{C} \end{array}$$

is a pullback square, we can choose an object $D \in \mathcal{C}$ satisfying $D_0 \simeq D[a^{-1}]$ and $D' \simeq A' \otimes_A D$. It follows from Remark D.5.2.3 that the object D is compact. As in the proof of Proposition 7.1.1.12, we have a canonical isomorphism

$$(\pi_0 \operatorname{Map}_{\mathcal{C}}(D, C))[a^{-1}] \simeq \pi_0 \operatorname{Map}_{\mathcal{C}[a^{-1}]}(D_0, C[a^{-1}]) \neq 0.$$

In particular, the group $\pi_0 \operatorname{Map}_{\mathcal{C}}(D, C)$ must be nonzero, so there exists a nonzero map $f : D \to C$.

We now argue that χ is a sheaf with respect to the finite étale topology. Since χ is a sheaf for the Nisnevich topology, it commutes with finite products. It will therefore suffice to show that if $\phi : A \to B$ is a finite étale faithfully flat morphism in $\mathrm{CAlg}^{\text{ét}}_R$ for which $B \otimes_R \mathcal{C}$ is compactly generated, then $A \otimes_R \mathcal{C}$ is also compactly generated. As before, we may assume without loss of generality that $R = A$.

Let $F : \mathcal{C} \to \mathrm{LMod}_B(\mathcal{C})$ denote the functor given by $F(C) = B \otimes_A C$. Note that since B is finitely generated and projective as an A-module, the composite functor $\mathcal{C} \xrightarrow{F} \mathrm{LMod}_B(\mathcal{C}) \to \mathcal{C}$

is a retract of a product of finitely many copies of the identity functor, and therefore preserves small limits. It follows that the functor f also preserves small limits. Applying Corollary HTT.5.5.2.9 , we deduce that F admits a left adjoint $F^L : \mathrm{LMod}_B(\mathcal{C}) \to \mathcal{C}$.

If C is any nonzero object of $\mathcal{C}$, then $f(C)$ is a nonzero object of $\mathrm{LMod}_B(\mathcal{C})$. Since $\mathrm{LMod}_B(\mathcal{C})$ is compactly generated, Corollary C.6.3.3 implies that there exists a compact object $D \in \mathrm{LMod}_B(\mathcal{C})$ and a nonzero map $\alpha : D \to F(C)$. Then α determines a nonzero map $F^L(D) \to C$, and the object $F^L(D) \in \mathcal{C}$ is compact by virtue of Proposition HTT.5.5.7.2 (since the functor F commutes with filtered colimits). Applying Corollary C.6.3.3, we deduce that $\mathcal{C}$ is compactly generated. □

D.5.4 Anticomplete Prestable ∞-Categories

We now study descent questions for the class of anticomplete prestable R-linear ∞-categories. Our starting point is the following result:

Theorem D.5.4.1. *Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_\infty$-rings which satisfies the following conditions:*

- (i) *The morphism ϕ is flat.*
- (ii) *The $\mathbb{E}_\infty$-ring R' has finite* Tor*-amplitude when regarded as a module over $R' \otimes_R R'$.*

Let $\mathcal{C}$ be a prestable R-linear ∞-category. If $\mathcal{C}$ is anticomplete, then $R' \otimes_R \mathcal{C}$ is anticomplete.

Remark D.5.4.2. Hypotheses (i) and (ii) of Theorem D.5.4.1 are satisfied when the morphism $\phi : R \to R'$ is étale. More generally, they are satisfies if ϕ is *fiber-smooth*, in the sense of Definition 11.2.3.1 (see Proposition 11.3.3.1).

Remark D.5.4.3. Theorem D.5.4.1 is valid more generally in the setting of $\mathbb{E}_2$-rings; we leave the requisite modifications to the reader.

Warning D.5.4.4. In the setting of Theorem D.5.4.1, hypothesis (ii) is essential. For example, suppose that $\phi : R \to R'$ is a morphism of Noetherian rings of finite Krull dimension. If R is regular, then the prestable ∞-category $\mathrm{Mod}_R^{\mathrm{cn}}$ is anticomplete. However, the tensor product $R' \otimes_R \mathrm{Mod}_R^{\mathrm{cn}} \simeq \mathrm{Mod}_{R'}^{\mathrm{cn}}$ is anticomplete only if R' is also regular.

Before giving the proof of Theorem D.5.4.1, we need a few observations about the class of anticomplete prestable R-linear ∞-categories.

Lemma D.5.4.5. *Let $\mathcal{C}$ be a compactly generated monoidal prestable ∞-category (where the tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves small colimits separately in each variable), and suppose that the ∞-category $\mathrm{Sp}(\mathcal{C})$ is locally rigid (see Definition D.7.4.1). Let $\mathrm{LMod}_{\mathcal{C}}^{\mathrm{lex}}(\mathsf{Groth}_\infty)$*

be the subcategory of $\mathrm{LMod}_{\mathcal{C}}(\mathsf{Groth}_\infty)$ *whose objects are* $\mathcal{C}$*-linear Grothendieck prestable* ∞*-categories* $\mathcal{M}$ *and whose morphisms are* $\mathcal{C}$*-linear functors which preserve small colimits and finite limits, and let* $\mathrm{LMod}^{\mathrm{ch}}_{\mathcal{C}}(\mathsf{Groth}_\infty)$ *denote the full subcategory of* $\mathrm{LMod}^{\mathrm{lex}}_{\mathcal{C}}(\mathsf{Groth}_\infty)$ *spanned by the anticomplete prestable* $\mathcal{C}$*-linear* ∞*-categories. Then:*

(1) *The* ∞*-category* $\mathrm{LMod}^{\mathrm{ch}}_{\mathcal{C}}(\mathsf{Groth}_\infty)$ *is a colocalization of* $\mathrm{LMod}^{\mathrm{lex}}_{\mathcal{C}}(\mathsf{Groth}_\infty)$*: that is, the inclusion functor* $\mathrm{LMod}^{\mathrm{ch}}_{\mathcal{C}}(\mathsf{Groth}_\infty) \hookrightarrow \mathrm{LMod}^{\mathrm{lex}}_{\mathcal{C}}(\mathsf{Groth}_\infty)$ *admits a right adjoint* $\mathcal{M} \mapsto \breve{\mathcal{M}}$*.*

(2) *For every* $\mathcal{C}$*-linear Grothendieck prestable* ∞*-category* $\mathcal{M}$*, the canonical map* $\breve{\mathcal{M}} \to \mathcal{M}$ *induces an equivalence of completions.*

Remark D.5.4.6. Let $\mathcal{C}$ be as in Lemma D.5.4.5 and let $\mathcal{M}$ be a $\mathcal{C}$-linear Grothendieck prestable ∞-category. Then Lemma D.5.4.5 implies that there exists a $\mathcal{C}$-linear functor $\lambda : \breve{\mathcal{M}} \to \mathcal{M}$ which exhibits $\breve{\mathcal{M}}$ as a $\mathrm{LMod}^{\mathrm{ch}}_{\mathcal{C}}(\mathsf{Groth}_\infty)$-colocalization of $\mathcal{M}$. In particular, the Grothendieck prestable ∞-category $\breve{\mathcal{M}}$ is anticomplete. Moreover, part (2) of Lemma D.5.4.5 guarantees that λ induces an equivalence on completions, so that the image of λ under the forgetful functor $\mathrm{LMod}_{\mathcal{C}}(\mathsf{Groth}_\infty) \to \mathsf{Groth}_\infty$ can be identified with the functor appearing in Proposition C.5.5.9. We can summarize the situation more informally as follows:

(i) If $\mathcal{M}$ is a Grothendieck prestable ∞-category equipped which is equipped with a left action of $\mathcal{C}$ and $\lambda : \breve{\mathcal{M}} \to \mathcal{M}$ is as in Proposition C.5.5.9, then the ∞-category $\breve{\mathcal{M}}$ inherits a left action of $\mathcal{C}$.

(ii) The ∞-category $\breve{\mathcal{M}}$ of (i) is universal among anticomplete prestable $\mathcal{C}$-linear ∞-categories equipped with a left exact $\mathcal{C}$-linear functor to $\mathcal{M}$.

Applying Lemma D.5.4.5 in the case $\mathcal{C} = \mathrm{LMod}^{\mathrm{cn}}_R$, where R is a connective $\mathbb{E}_2$-ring, we obtain the following:

Corollary D.5.4.7. *Let* R *be a connective* $\mathbb{E}_2$*-ring and let* $\mathcal{M}$ *be a prestable* R*-linear* ∞*-category. The following conditions are equivalent:*

(a) *The prestable* ∞*-category* $\mathcal{M}$ *is anticomplete.*

(b) *For every prestable* R*-linear* ∞*-category* $\mathcal{N}$ *with completion* $\widehat{\mathcal{N}}$*, the canonical map* $\theta : \mathrm{Map}_{\mathrm{LinCat}^{\mathrm{PSt,lex}}_R}(\mathcal{M}, \mathcal{N}) \to \mathrm{Map}_{\mathrm{LinCat}^{\mathrm{PSt,lex}}_R}(\mathcal{M}, \widehat{\mathcal{N}})$ *is a homotopy equivalence.*

Proof of Lemma D.5.4.5. In what follows, we will assume that the reader is familiar with the formalism of ∞-operads. Let us regard the ∞-category Groth_∞ of Grothendieck prestable ∞-categories as equipped with symmetric monoidal structure described in §C.4. This symmetric monoidal structure is encoded by a coCartesian fibration $q : \mathsf{Groth}^{\otimes}_\infty \to \mathcal{F}\mathrm{in}_*$. Let $\mathcal{LM}^{\otimes}$ denote the ∞-operad of Definition HA.4.2.1.7 (so that $\mathcal{LM}^{\otimes}$-algebras are given by pairs (A, M), where A is an associative algebra and M is a left A-module) and set $\mathcal{O}^{\otimes} = \mathsf{Groth}^{\otimes}_\infty \times_{\mathcal{F}\mathrm{in}_*} \mathcal{LM}^{\otimes}$. The ∞-operad $\mathcal{O}^{\otimes}$ can be described more concretely as follows:

- Objects of $\mathcal{O}$ are given by pairs $(\mathcal{E}, \sigma)$, where $\mathcal{E}$ is a Grothendieck prestable ∞-category and $\sigma \in \{\mathfrak{a}, \mathfrak{m}\}$ is a formal symbol.

- Given a finite collection of objects $\{(\sigma_i, \mathcal{E}_i)\}_{i \in I}$ $(\sigma, \mathcal{E})$ of $\mathcal{O}$, a morphism $\phi \in \mathrm{Mul}_{\mathcal{O}}(\{(\sigma_i, \mathcal{E}_i)\}_{i \in I}, (\sigma, \mathcal{E}))$ consists of the following data:

  - A functor $\prod_{i \in I} \mathcal{E}_i \to \mathcal{E}$ which preserves small colimits separately in each variable.
  - A linear ordering $\leqslant$ on the set I.

  This data is required to satisfy the following condition:

  - If $\sigma = \mathfrak{a}$, then $\sigma_i = \mathfrak{a}$ for all $i \in I$. If $\sigma = \mathfrak{m}$, then there is a unique element $i \in I$ such that $\sigma_i = \mathfrak{m}$, and i is a maximal element of $(I, \leqslant)$.

Consider the subcategory $\mathcal{O}_1^{\otimes} \subseteq \mathcal{O}^{\otimes}$ which defines an ∞-operad admitting the following description:

- An object $(\sigma, \mathcal{E})$ of $\mathcal{O}$ belongs to $\mathcal{O}_1$ if either $\sigma = \mathfrak{m}$ or $\sigma = \mathfrak{a}$ and $\mathcal{E}$ is compactly generated.

- Let $\phi \in \mathrm{Mul}_{\mathcal{O}}(\{(\sigma_i, \mathcal{E}_i)\}_{i \in I}, (\sigma, \mathcal{E}))$ classify a functor $f : \prod_{i \in I} \mathcal{E}_i \to \mathcal{E}$ which preserves small colimits separately in each variables. Then ϕ belongs to $\mathrm{Mul}_{\mathcal{O}_1}(\{(\sigma_i, \mathcal{E}_i)\}_{i \in I}, (\sigma, \mathcal{E}))$ if one of the following conditions is satisfied:

  - We have $\sigma = \mathfrak{a}$ and $f(\{E_i\})$ is a compact object of $\mathcal{E}$ whenever each E_i is a compact object of $\mathcal{E}_i$.
  - We have $\sigma = \mathfrak{m}$, so that there is a unique element $i \in I$ such that $\sigma_i = \mathfrak{m}$. Moreover, for every collection of compact objects $\{E_j \in \mathcal{E}_j\}_{j \in I - \{i\}}$, the functor

    $$\mathcal{E}_i \simeq \mathcal{E}_i \times \prod_{j \neq i} \{E_j\} \hookrightarrow \prod_{j \in I} \mathcal{E}_j \xrightarrow{f} \mathcal{E}$$

    has bounded amplitude, in the sense of Definition C.5.5.2.

Unwinding the definitions, we can identify objects of $\mathrm{Alg}_{/\mathcal{LM}}(\mathcal{O})$ with pairs $(\mathcal{C}, \mathcal{M})$, where $\mathcal{C}$ is a monoidal Grothendieck prestable ∞-category, $\mathcal{M}$ is a Grothendieck prestable ∞-category which is left-tensored over $\mathcal{C}$, and the action maps

$$\mathcal{C} \times \mathcal{C} \to \mathcal{C} \qquad \mathcal{C} \times \mathcal{M} \to \mathcal{M}$$

preserve small colimits separately in each variable. Under this identification, $\mathrm{Alg}_{/\mathcal{LM}}(\mathcal{O}_1)$ corresponds to the subcategory of $\mathrm{Alg}_{/\mathcal{LM}}(\mathcal{O})$ which can be described as follows:

- An object $(\mathcal{C}, \mathcal{M}) \in \mathrm{Alg}_{/\mathcal{LM}}(\mathcal{O})$ belongs to $\mathrm{Alg}_{/\mathcal{LM}}(\mathcal{O}_1)$ if and only if $\mathcal{C}$ is compactly generated, the collection of compact objects of $\mathcal{C}$ contains the unit object and is stable under tensor products, and for each compact object $C \in \mathcal{C}$ the functor $M \mapsto C \otimes M$ has bounded amplitude.

- A morphism from $(\mathcal{C}, \mathcal{M})$ to $(\mathcal{C}', \mathcal{M}')$ in $\mathrm{Alg}_{/\mathcal{LM}}(\mathcal{O})$ is a morphism of $\mathrm{Alg}_{/\mathcal{LM}}(\mathcal{O}_1)$ if and only if its domain and codomain belong to $\mathrm{Alg}_{/\mathcal{LM}}(\mathcal{O}_1)$, the underlying monoidal functor $\mathcal{C} \to \mathcal{C}'$ preserves compact objects, and the underlying functor $\mathcal{M} \to \mathcal{M}'$ has bounded amplitude.

Now suppose that we are given an object $(\mathcal{C}, \mathcal{M}) \in \mathrm{Alg}_{/\mathcal{LM}}(\mathcal{O})$ having the property that $\mathcal{C}$ is compactly generated and $\mathrm{Sp}(\mathcal{C})$ is locally rigid. If C is a compact object of $\mathcal{C}$, then $\Sigma^\infty C$ is a compact object of $\mathrm{Sp}(\mathcal{C})$. It follows that $\Sigma^\infty C$ is a dualizable object of $\mathrm{Sp}(\mathcal{C})$, whose dual $D = (\Sigma^\infty C)^\vee$ is also compact. We therefore have $D \in \mathrm{Sp}(\mathcal{C})_{\geqslant -n}$ for some $n \gg 0$. Let $\mathcal{M}$ be any left $\mathcal{C}$-module in the ∞-category Groth_∞. For $M \in \mathrm{Sp}(\mathcal{M})_{\leqslant k}$ and $N \in \mathrm{Sp}(\mathcal{M})_{\geqslant n+k+1}$, the mapping space

$$\mathrm{Map}_{\mathrm{Sp}(\mathcal{M})}(N, (\Sigma^\infty C) \otimes M) \simeq \mathrm{Map}_{\mathrm{Sp}(\mathcal{M})}(D \otimes N, M)$$

is contractible. Allowing N to vary, we deduce that tensor product with $\Sigma^\infty C$ carries $\mathrm{Sp}(\mathcal{M})_{\leqslant k}$ into $\mathrm{Sp}(\mathcal{M})_{\leqslant n+k}$. It follows that tensor product with C induces a functor $\mathcal{M} \to \mathcal{M}$ of bounded amplitude. Allowing C to vary, we conclude that $(\mathcal{C}, \mathcal{M})$ belongs to the subcategory $\mathrm{Alg}_{/\mathcal{LM}}(\mathcal{O}_1) \subseteq \mathrm{Alg}_{/\mathcal{LM}}(\mathcal{O}_0)$. This proves the following:

$(*)$ Suppose we are given a monoidal Grothendieck prestable ∞-category $\mathcal{C}$ (where the tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves small colimits separately in each variable), which we regard as an associative algebra object of the ∞-category Groth_∞. If $\mathcal{C}$ is compactly generated and $\mathrm{Sp}(\mathcal{C})$ is locally rigid, then the inclusion

$$\{\mathcal{C}\} \times_{\mathrm{Alg}(\mathsf{Groth}_\infty)} \mathrm{Alg}_{/\mathcal{LM}}(\mathcal{O}_1) \hookrightarrow \{\mathcal{C}\} \times_{\mathrm{Alg}(\mathsf{Groth}_\infty)} \mathrm{Alg}_{/\mathcal{LM}}(\mathcal{O}) \simeq \mathrm{LMod}_{\mathcal{C}}(\mathsf{Groth}_\infty)$$

is an equivalence onto the subcategory of $\mathrm{LMod}_{\mathcal{C}}(\mathsf{Groth}_\infty)$ whose morphisms are $\mathcal{C}$-linear functors of bounded amplitude.

Consider the full subcategory $\mathcal{O}_0^\otimes \subseteq \mathcal{O}_1^\otimes$ which defines an ∞-operad admitting the following description:

- An object $(\sigma, \mathcal{E})$ of $\mathcal{O}_1$ belongs to $\mathcal{O}_0$ if either $\sigma = \mathfrak{a}$ or $\sigma = \mathfrak{m}$ and $\mathcal{E}$ is anticomplete.

Then we can identify $\mathrm{Alg}_{/\mathcal{LM}}(\mathcal{O}_0)$ with the full subcategory of $\mathrm{Alg}_{/\mathcal{LM}}(\mathcal{O}_1)$ spanned by those pairs $(\mathcal{C}, \mathcal{M})$ where $\mathcal{M}$ is anticomplete.

Fix an object $X \in \mathcal{O}_1^\otimes$, given by a sequence $\{(\sigma_i, \mathcal{E}_i)\}_{1 \leqslant i \leqslant n}$. For each $1 \leqslant i \leqslant n$ satisfying $\sigma_i = \mathfrak{m}$, choose a functor $\lambda_i : \mathcal{E}'_i \to \mathcal{E}_i$ satisfying the requirements of Proposition C.5.5.9. For

$1 \leqslant i \leqslant n$ satisfying $\sigma_i = \mathfrak{a}$, set $\mathcal{E}'_i = \mathcal{E}_i$ and let $\lambda_i : \mathcal{E}'_i \to \mathcal{E}_i$ be the identity map. Define $X' = \{(\sigma_i, \mathcal{E}'_i)\}_{1 \leqslant i \leqslant n} \in \mathcal{O}_0^{\otimes}$, so that $\{\lambda_i\}_{1 \leqslant i \leqslant n}$ determines a map $\lambda : X' \to X$ in $\mathcal{O}_1^{\otimes}$. We will prove the following:

$(*')$ For each $X \in \mathcal{O}_1^{\otimes}$ as above, the map $\lambda : X' \to X$ exhibits X' as a $\mathcal{O}_0^{\otimes}$-colocalization of X.

Assume $(*')$ for the moment. Allowing X to vary over all objects of $\mathcal{O}_1^{\otimes}$, we deduce that the inclusion functor $\mathcal{O}_0^{\otimes} \hookrightarrow \mathcal{O}_1^{\otimes}$ admits a right adjoint G, given by $X \mapsto X'$. Then G is a functor of ∞-operads, which induces a functor $\mathrm{Alg}_{/\mathcal{LM}}(\mathcal{O}_1) \to \mathrm{Alg}_{/\mathcal{LM}}(\mathcal{O}_0)$ which is right adjoint to the inclusion, given on objects by the construction $(\mathcal{C}, \mathcal{M}) \mapsto (\mathcal{C}, \breve{\mathcal{M}})$, where the counit map determines a $\mathcal{C}$-linear functor $\breve{\mathcal{M}} \to \mathcal{M}$ which is an equivalence on completions. Combining this observation with $(*)$, we obtain the following:

$(*'')$ Let $\mathcal{C} \in \mathrm{Alg}(\mathsf{Groth}_\infty)$ be as in $(*)$, let $\mathrm{LMod}'_{\mathcal{C}}(\mathsf{Groth}_\infty)$ be the subcategory of $\mathrm{LMod}_{\mathcal{C}}(\mathsf{Groth}_\infty)$ whose morphisms are $\mathcal{C}$-linear functors of bounded amplitude, and let $\mathrm{LMod}''_{\mathcal{C}}(\mathsf{Groth}_\infty) \subseteq \mathrm{LMod}'_{\mathcal{C}}(\mathsf{Groth}_\infty)$ be the full subcategory spanned by those $\mathcal{C}$-modules which are anticomplete. Then the inclusion $\mathrm{LMod}''_{\mathcal{C}}(\mathsf{Groth}_\infty) \hookrightarrow \mathrm{LMod}'_{\mathcal{C}}(\mathsf{Groth}_\infty)$ admits a right adjoint $\mathrm{LMod}'_{\mathcal{C}}(\mathsf{Groth}_\infty) \to \mathrm{LMod}''_{\mathcal{C}}(\mathsf{Groth}_\infty)$, which we will denote by $\mathcal{M} \to \breve{\mathcal{M}}$. Moreover, the counit map $\breve{\mathcal{M}} \to \mathcal{M}$ induces an equivalence of completions.

Note that in the situation of $(*'')$, a $\mathcal{C}$-linear functor $f : \mathcal{M} \to \mathcal{N}$ is left exact if and only if the composite map $\breve{\mathcal{M}} \to \mathcal{M} \xrightarrow{f} \mathcal{N}$ is left exact (Proposition C.3.2.1). It follows that the construction $\mathcal{M} \to \breve{\mathcal{M}}$ restricts to a functor $\mathrm{LMod}^{\mathrm{lex}}_{\mathcal{C}}(\mathsf{Groth}_\infty) \to \mathrm{LMod}^{\mathrm{ch}}_{\mathcal{C}}(\mathsf{Groth}_\infty)$ which is right adjoint to the inclusion, which completes the proof of Lemma D.5.4.5.

It remains to prove $(*')$. Let $\lambda : X' \to X$ be as in $(*')$, and let Y be any object of $\mathcal{O}_0^{\otimes}$; we wish to show that composition with λ induces a homotopy equivalence $\mathrm{Map}_{\mathcal{O}_1^{\otimes}}(Y, X) \to \mathrm{Map}_{\mathcal{O}_1^{\otimes}}(Y, X)$. Using the fact that $\mathcal{O}_1^{\otimes}$ is an ∞-operad, we can reduce to the case where $X = (\sigma, \mathcal{E}) \in \mathcal{O}_1$. If $\sigma = \mathfrak{a}$, then λ is an equivalence and there is nothing to prove. Let us therefore assume that $\sigma = \mathfrak{m}$, and let $\lambda : \breve{\mathcal{E}} \to \mathcal{E}$ be as in Proposition C.5.5.9. Unwinding the definitions, we wish to prove the following:

$(*''')$ Suppose we are given Grothendieck prestable ∞-categories $\mathcal{D}_1, \ldots, \mathcal{D}_k$ and $\mathcal{D}$, where $\mathcal{D}_i$ is compactly generated for $1 \leqslant i \leqslant k$ and $\mathcal{D}$ is anticomplete. Let $\mathrm{Fun}^{\rho}(\mathcal{D}_1 \times \cdots \times \mathcal{D}_k \times \mathcal{D}, \mathcal{E})$ be the full subcategory of $\mathrm{Fun}(\mathcal{D}_1 \times \cdots \times \mathcal{D}_k \times \mathcal{D}, \mathcal{E})$ spanned by those functors f which preserve small colimits separately in each variable and have the property that, for every sequence of compact objects $\{D_i \in \mathcal{D}_i\}_{1 \leqslant i \leqslant k}$, the induced map $f(D_1, \ldots, D_k, \bullet) : \mathcal{D} \to \mathcal{E}$ has bounded amplitude. Define $\mathrm{Fun}^{\rho}(\mathcal{D}_1 \times \cdots \times \mathcal{D}_k \times \mathcal{D}, \breve{\mathcal{E}})$ similarly. Then composition with λ induces a homotopy equivalence

$$\mathrm{Fun}^{\rho}(\mathcal{D}_1 \times \cdots \times \mathcal{D}_k \times \mathcal{D}, \breve{\mathcal{E}})^{\simeq} \to \mathrm{Fun}^{\rho}(\mathcal{D}_1 \times \cdots \times \mathcal{D}_k \times \mathcal{D}, \mathcal{E})^{\simeq}.$$

In fact, in the situation of $(*''')$, we will show that λ induces an equivalence of ∞-categories

$$\mathrm{Fun}^{\rho}(\mathcal{D}_1 \times \cdots \times \mathcal{D}_k \times \mathcal{D}, \breve{\mathcal{E}}) \to \mathrm{Fun}^{\rho}(\mathcal{D}_1 \times \cdots \times \mathcal{D}_k \times \mathcal{D}, \mathcal{E}).$$

To prove this, we let $\mathcal{D}_i^c$ denote the full subcategory of $\mathcal{D}_i$ spanned by the compact objects for $1 \leqslant i \leqslant k$, let $\mathrm{LFun}^b(\mathcal{D}, \mathcal{E})$ be the full subcategory of $\mathrm{LFun}(\mathcal{D}, \mathcal{E})$ spanned by the functors of bounded amplitude, and define $\mathrm{LFun}^b(\mathcal{D}, \breve{\mathcal{E}})$ similarly. Restriction to compact objects then yields a commutative diagram

$$\begin{array}{ccc} \mathrm{Fun}^{\rho}(\mathcal{D}_1 \times \cdots \times \mathcal{D}_k \times \mathcal{D}, \breve{\mathcal{E}}) & \longrightarrow & \mathrm{Fun}^{\rho}(\mathcal{D}_1 \times \cdots \times \mathcal{D}_k \times \mathcal{D}, \mathcal{E}) \\ \downarrow & & \downarrow \\ \mathrm{Fun}^{\mathrm{rex}}(\mathcal{D}_1^c \times \cdots \times \mathcal{D}_k^c, \mathrm{LFun}^b(\mathcal{D}, \breve{\mathcal{E}})) & \longrightarrow & \mathrm{Fun}^{\mathrm{rex}}(\mathcal{D}_1^c \times \cdots \times \mathcal{D}_k^c, \mathrm{LFun}^b(\mathcal{D}, \mathcal{E})) \end{array}$$

where $\mathrm{Fun}^{\mathrm{rex}}(\mathcal{D}_1^c \times \cdots \times \mathcal{D}_k^c, \mathrm{LFun}^b(\mathcal{D}, \mathcal{E}))$ denotes the full subcategory of $\mathrm{Fun}(\mathcal{D}_1^c \times \cdots \times \mathcal{D}_k^c, \mathrm{LFun}^b(\mathcal{D}, \mathcal{E}))$ spanned by those functors which preserve finite colimits separately in each variable, and $\mathrm{Fun}^{\mathrm{rex}}(\mathcal{D}_1^c \times \cdots \times \mathcal{D}_k^c, \mathrm{LFun}^b(\mathcal{D}, \breve{\mathcal{E}}))$ is defined similarly. Since each $\mathcal{D}_i$ is compactly generated, the vertical maps are equivalences of ∞-categories. We now complete the proof of $(*''')$ by observing that the bottom horizontal map is also an equivalence, since composition with λ induces an equivalence $\mathrm{LFun}(\mathcal{D}, \breve{\mathcal{E}}) \to \mathrm{LFun}(\mathcal{D}, \mathcal{E})$ by virtue of our assumption that $\mathcal{D}$ is anticomplete. □

Lemma D.5.4.8. *Let R be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a prestable R-linear ∞-category. Suppose that $M \in \mathrm{Mod}_R^{\mathrm{cn}}$ has* Tor*-amplitude $\leqslant m$ and that $C \in \mathcal{C}$ is n-truncated. Then the tensor product $M \otimes_R C$ is $(m+n)$-truncated.*

Proof. We proceed by induction on m. If $m = 0$, then M is a flat R-module. Applying Theorem HA.7.2.2.15 , we can write M as a filtered colimit $\varinjlim_\alpha M_\alpha$, where each M_α is a free R-module of finite rank. Each of the tensor products $M_\alpha \otimes_R C$ is a direct sum of finitely many copies of C, and is therefore n-truncated. Since $\mathcal{C}$ is a Grothendieck prestable ∞-category, it follows that the $M \otimes_R C \simeq \varinjlim (M_\alpha \otimes_R C)$ is also n-truncated.

We now carry out the inductive step. Assume that $m > 0$, and choose a free R-module F and a map $\alpha : F \to M$ which is surjective on π_0. Then we have a cofiber sequence $\mathrm{fib}(\alpha) \to F \to M$ in the ∞-category $\mathrm{Mod}_R^{\mathrm{cn}}$, where $\mathrm{fib}(\alpha)$ and F have Tor-amplitude $\leqslant m-1$. Tensoring with the object C, we obtain a cofiber sequence

$$\mathrm{fib}(\alpha) \otimes_R C \to F \otimes_R C \to M \otimes_R C$$

in the ∞-category $\mathcal{C}$. Our inductive hypothesis implies that the first two terms of this sequence are $(m+n-1)$-truncated, so the third term must be $(m+n)$-truncated. □

Proof of Theorem D.5.4.1. Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_\infty$-rings for which R' is flat over R and of finite Tor-amplitude over $R' \otimes_R R'$, and let $\mathcal{C}$ be a anticomplete prestable R-linear ∞-category. We wish to show that $\mathcal{C}' = R' \otimes_R \mathcal{C}$ is also anticomplete. We will prove this by verifying that $R' \otimes_R \mathcal{C}$ satisfies condition (b) of Corollary D.5.4.7. Let $\mathcal{D}$ be a prestable R'-linear ∞-category and let $\widehat{\mathcal{D}}$ be its completion; we wish to show that the canonical map

$$\theta : \mathrm{Map}_{\mathrm{LinCat}_{R'}^{\mathrm{PSt,lex}}}(\mathcal{C}', \mathcal{D}) \to \mathrm{Map}_{\mathrm{LinCat}_{R'}^{\mathrm{PSt,lex}}}(\mathcal{C}', \widehat{\mathcal{D}})$$

is a homotopy equivalence.

Let $\lambda : \mathcal{C} \to \mathcal{C}'$ denote the R-linear functor given by $\lambda(C) = R' \otimes_R C$, so that precomposition with λ induces a homotopy equivalence $\rho : \mathrm{Map}_{\mathrm{LinCat}_{R'}^{\mathrm{PSt}}}(\mathcal{C}', \mathcal{D}) \simeq \mathrm{Map}_{\mathrm{LinCat}_{R}^{\mathrm{PSt}}}(\mathcal{C}, \mathcal{D})$. Since R' is flat over R, the functor λ is left exact, so that ρ restricts to a fully faithful embedding $\rho^{\mathrm{lex}} : \mathrm{Map}_{\mathrm{LinCat}_{R'}^{\mathrm{PSt,lex}}}(\mathcal{C}', \mathcal{D}) \simeq \mathrm{Map}_{\mathrm{LinCat}_{R}^{\mathrm{PSt,lex}}}(\mathcal{C}, \mathcal{D})$. Similarly, we have a fully faithful embedding $\widehat{\rho}^{\mathrm{lex}} : \mathrm{Map}_{\mathrm{LinCat}_{R'}^{\mathrm{PSt,lex}}}(\mathcal{C}', \widehat{\mathcal{D}}) \simeq \mathrm{Map}_{\mathrm{LinCat}_{R}^{\mathrm{PSt,lex}}}(\mathcal{C}, \widehat{\mathcal{D}})$. These maps fit into a commutative diagram σ :

$$\begin{array}{ccc} \mathrm{Map}_{\mathrm{LinCat}_{R'}^{\mathrm{PSt,lex}}}(\mathcal{C}', \mathcal{D}) & \xrightarrow{\theta} & \mathrm{Map}_{\mathrm{LinCat}_{R'}^{\mathrm{PSt,lex}}}(\mathcal{C}', \widehat{\mathcal{D}}) \\ \downarrow{\scriptstyle \rho^{\mathrm{lex}}} & & \downarrow{\scriptstyle \widehat{\rho}^{\mathrm{lex}}} \\ \mathrm{Map}_{\mathrm{LinCat}_{R}^{\mathrm{PSt,lex}}}(\mathcal{C}, \mathcal{D}) & \longrightarrow & \mathrm{Map}_{\mathrm{LinCat}_{R}^{\mathrm{PSt,lex}}}(\mathcal{C}, \widehat{\mathcal{D}}), \end{array}$$

where the bottom horizontal map is a homotopy equivalence by virtue of our assumption that $\mathcal{C}$ is anticomplete (Corollary D.5.4.7). To complete the proof, it will suffice to show that σ is a pullback square. Unwinding the definitions, this is equivalent to the following assertion:

$(*)$ Let $F : \mathcal{C}' \to \mathcal{D}$ be an R'-linear functor. If both of the composite functors

$$\mathcal{C} \xrightarrow{\lambda} \mathcal{C}' \xrightarrow{F} \mathcal{D} \qquad \mathcal{C}' \xrightarrow{F} \mathcal{D} \to \widehat{\mathcal{D}}$$

are left exact, then F is left exact.

To show that the functor $F : \mathcal{C}' \to \mathcal{D}$ appearing in $(*)$ is left exact, it is enough to show that for each discrete object $C \in \mathcal{C}'$, the image $F(C) \in \mathcal{D}$ is also discrete (Proposition C.3.2.1). Set $A = R' \otimes_R R'$ so that we have two natural maps $\iota_0, \iota_1 : R' \to A$. Extension of scalars along ι_0 determines an exact functor $\mu : \mathrm{LMod}_{R'}(\mathcal{C}) \to \mathrm{LMod}_A(\mathcal{C})$ and restriction of scalars along ι_1 determines an exact functor $\nu : \mathrm{LMod}_A(\mathcal{C}) \to \mathrm{LMod}_{R'}(\mathcal{C})$, and the composition $\nu \circ \mu$ is homotopic to the composition $\mathrm{LMod}_{R'}(\mathcal{C}) \to \mathcal{C} \xrightarrow{\lambda} \mathrm{LMod}_{R'}(\mathcal{C})$. Consequently, if $F \circ \lambda$ is left exact, then $F \circ \nu \circ \mu$ is left exact. It follows that $(F \circ \nu \circ \mu)(C) = F(A \otimes_R C)$ is a discrete A-module object of $\mathcal{D}$. Applying Lemma D.5.4.8 (and our assumption that R

has finite Tor-amplitude as an A-module), we conclude that $F(C) \simeq R \otimes_A F(A \otimes_R C)$ is a truncated object of $\mathcal{D}$. Since the completion map $\mathcal{D} \to \widehat{\mathcal{D}}$ is an equivalence when restricted to truncated objects and the image of $F(C)$ in $\widehat{\mathcal{D}}$ belongs to the heart of $\widehat{\mathcal{D}}$, it follows that $F(C) \in \mathcal{D}^{\heartsuit}$, as desired. □

We now prove a converse to Theorem D.5.4.1:

Theorem D.5.4.9. *Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_\infty$-rings which satisfies the following conditions:*

(i) The morphism ϕ is flat.

(ii) The $\mathbb{E}_\infty$-ring R' has finite Tor*-amplitude when regarded as a module over $R' \otimes_R R'$.*

(iii) The map ϕ is a universal descent morphism.

Let $\mathcal{C}$ be a prestable R-linear ∞-category. If $R' \otimes_R \mathcal{C}$ is anticomplete, then $\mathcal{C}$ is anticomplete.

Remark D.5.4.10. Hypotheses (i), (ii) and (iii) of Theorem D.5.4.9 are satisfied if ϕ is étale and faithfully flat, or more generally if ϕ is fiber-smooth and faithfully flat (Proposition 11.3.3.1 and Remark 11.2.3.3).

Proof of Theorem D.5.4.9. We will prove that $\mathcal{C}$ is anticomplete by showing that it satisfies criterion (b) of Corollary D.5.4.7. Let $\mathcal{D}$ be a prestable R-linear ∞-category and let $\widehat{\mathcal{D}}$ denote its completion; we wish to show that the canonical map

$$\theta : \mathrm{Map}_{\mathrm{LinCat}_R^{\mathrm{PSt,lex}}}(\mathcal{C}, \mathcal{D}) \to \mathrm{Map}_{\mathrm{LinCat}_R^{\mathrm{PSt,lex}}}(\mathcal{C}, \widehat{\mathcal{D}})$$

is a homotopy equivalence. Let $R^\bullet$ denote the Čech nerve of the morphism ϕ (formed in the ∞-category $\mathrm{CAlg}^{\mathrm{op}}$). Using hypotheses (i) and (iii), Theorem D.4.1.6, and Proposition D.5.2.1, we conclude that θ can be obtained as the totalization of a map of cosimplicial spaces

$$\theta^\bullet : \mathrm{Map}_{\mathrm{LinCat}_{R^\bullet}^{\mathrm{PSt,lex}}}(\mathrm{LMod}_{R^\bullet}(\mathcal{C}), \mathrm{LMod}_{R^\bullet}(\mathcal{D})) \to \mathrm{Map}_{\mathrm{LinCat}_R^{\mathrm{PSt,lex}}}(\mathrm{LMod}_{R^\bullet}(\mathcal{C}), \mathrm{LMod}_{R^\bullet}(\widehat{\mathcal{D}}))$$

We will complete the proof by showing that each θ^k is a homotopy equivalence. By virtue of Corollary D.5.4.7, it will suffice to show that the Grothendieck prestable ∞-category $\mathrm{LMod}_{R^k}(\mathcal{C})$ is anticomplete. This follows from Theorem D.5.4.1, since R^k is flat over R and of finite Tor-amplitude over $R^k \otimes_R R^k$. □

D.5.5 Weakly Coherent Prestable ∞-Categories

We now consider descent for the property of weak coherence (see Definition C.6.5.1).

Theorem D.5.5.1. *Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_\infty$-rings which is almost of finite presentation, and suppose that the underlying ring homomorphism $\pi_0 R \to \pi_0 R'$ is quasi-finite (Definition B.2.4.1). Let $\mathcal{C}$ be an R-linear prestable ∞-category. If $\mathcal{C}$ is weakly coherent, then $R' \otimes_R \mathcal{C}$ is weakly coherent.*

The proof of Theorem D.5.5.1 will require a number of preliminaries. We begin by studying the special case where $R' \simeq R[t^{-1}]$ is a localization of R.

Lemma D.5.5.2. *Let R be a connective $\mathbb{E}_\infty$-ring and let t be an element of $\pi_0 R$. Let $\mathcal{C}$ be an additive R-linear ∞-category which is compactly generated and let $\mathcal{C}[t^{-1}]$ denote the ∞-category $R[t^{-1}] \otimes_R \mathcal{C} \simeq \mathrm{LMod}_{R[t^{-1}]}(\mathcal{C})$. Then:*

- *(a) The ∞-category $\mathcal{C}[t^{-1}]$ is compactly generated.*
- *(b) An object $C \in \mathcal{C}[t^{-1}]$ is compact if and only if it is a direct summand of an object of the form $C_0[t^{-1}]$, for some compact object $C_0 \in \tau_{\leqslant n} \mathcal{C}$.*

Proof. Let $\mathcal{E} \subseteq \mathcal{C}[t^{-1}]$ be the full subcategory spanned by objects of the form $C_0[t^{-1}]$, where C_0 is a compact object of $\mathcal{C}$. By virtue of Lemma D.5.3.3, it will suffice to show that $\mathcal{E}$ is closed under the formation of cofibers. To prove this, let $f : C_0[t^{-1}] \to D_0[t^{-1}]$ be a morphism in $\mathcal{E}$. The compactness of C_0 guarantees that, for $k \gg 0$, the map $t^k f : C_0[t^{-1}] \to D_0[t^{-1}]$ is obtained by localizing a map $f_0 : C_0 \to D_0$ in $\mathcal{C}$, so that $\mathrm{cofib}(f) \simeq \mathrm{cofib}(t^k f) \simeq \mathrm{cofib}(f_0)[t^{-1}]$. □

Remark D.5.5.3. In the situation of Lemma D.5.5.2, suppose that $\mathcal{C}$ is an n-category for some $n < \infty$. Then every compact object of $\mathcal{C}[t^{-1}]$ has the form $C_0[t^{-1}]$, where C_0 is a compact object of $\mathcal{C}$; see Proposition HTT.**??**.

Lemma D.5.5.4. *Let R be a connective $\mathbb{E}_\infty$-ring and let t be an element of $\pi_0 R$. Let $\mathcal{C}$ be a weakly coherent prestable R-linear ∞-category. Then $\mathcal{C}[t^{-1}]$ is also weakly coherent.*

Proof. For each integer n, the ∞-category $\tau_{\leqslant n} \mathcal{C}$ is compactly generated. It follows from Lemma D.5.5.2 that the ∞-category $\tau_{\leqslant n} \mathcal{C}[t^{-1}]$ is also compactly generated. Moreover, Remark D.5.5.3 shows that an object of $\tau_{\leqslant n} \mathcal{C}[t^{-1}]$ is compact if and only if it has the form $C_0[t^{-1}]$, where C_0 is a compact object of $\tau_{\leqslant n} \mathcal{C}$. Arguing as in the proof of Lemma D.5.5.2, we see that every morphism $f : C \to D$ between compact objects of $\tau_{\leqslant n} \mathcal{C}[t^{-1}]$ is obtained from a morphism $f_0 : C_0 \to D_0$ between compact objects of $\tau_{\leqslant n} \mathcal{C}$ by applying the localization functor $M \mapsto M[t^{-1}]$. Our assumption that $\mathcal{C}$ is weakly coherent guarantees that $\mathrm{fib}(f_0)$ is a compact object of $\tau_{\leqslant n} \mathcal{C}$, so that $\mathrm{fib}(f) \simeq \mathrm{fib}(f_0)[t^{-1}]$ is a compact object of $\tau_{\leqslant n} \mathcal{C}[t^{-1}]$. It follows that the collection of compact objects of $\tau_{\leqslant n} \mathcal{C}[t^{-1}]$ is closed under finite limits. Applying Proposition C.6.5.4, we deduce that $\mathcal{C}[t^{-1}]$ is weakly coherent. □

Lemma D.5.5.5. *Let R be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a prestable R-linear ∞-category which satisfies the following conditions:*

(a) *For every integer n, the ∞-category $\tau_{\leqslant n}\mathcal{C}$ is compactly generated.*

(b) *There exists a collection of elements $t_1, t_2, \ldots, t_k \in \pi_0 R$ which generate the unit ideal such that each $\mathcal{C}[t_i^{-1}]$ is weakly coherent.*

Then $\mathcal{C}$ is weakly coherent.

Proof. By virtue of Proposition C.6.5.4, it will suffice to show that for each $n \geqslant 0$, the collection of compact objects of $\tau_{\leqslant n}\mathcal{C}$ is closed under finite limits. Fix a morphism $f : C \to D$ between compact objects of $\tau_{\leqslant n}\mathcal{C}$; we wish to show that $\mathrm{fib}(f)$ is compact. By virtue of Remark D.5.2.3, it will suffice to show that the localization $\mathrm{fib}(f)[t_i^{-1}]$ is a compact object of $\tau_{\leqslant n}\mathcal{C}[t_i^{-1}]$ for $1 \leqslant i \leqslant k$, which follows from the weak coherence of $\mathcal{C}[t_i^{-1}]$. □

We now consider a special case of Theorem D.5.5.1 which lies at the opposite extreme.

Lemma D.5.5.6. *Let R be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a prestable R-linear ∞-category. Let M be a connective R-module and let $C \in \mathcal{C}$. If M is almost perfect and C is almost compact, then the object $M \otimes_R C$ is almost compact.*

Proof. Using Proposition HA.**??** , we can write M as the geometric realization of a simplicial object $P_\bullet$ of Mod_R where each P_m is a free R-module of finite rank. Then $M \otimes_R C$ can be identified with the geometric realization $|P_\bullet \otimes_R C|$, which is almost compact by virtue of Proposition C.6.4.4. □

Lemma D.5.5.7. *Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_\infty$-rings which exhibits R' as an almost perfect module over R. Then:*

(a) *If $C \in \mathrm{LMod}_{R'}(\mathcal{C})$ is an object whose image under the forgetful functor $\mathrm{LMod}_{R'}(\mathcal{C}) \to \mathcal{C}$ is an almost compact object of $\mathcal{C}$, then C is an almost compact as an object of $\mathrm{LMod}_{R'}(\mathcal{C})$.*

(b) *Suppose that $\tau_{\leqslant n}\mathcal{C}$ is compactly generated ∞-category for each $n \geqslant 0$. If $C \in \mathrm{LMod}_{R'}(\mathcal{C})$ is almost compact, then the image of C under the forgetful functor $\mathrm{LMod}_{R'}(\mathcal{C}) \to \mathcal{C}$ is almost compact.*

Proof. To prove (a), we note that $C \simeq R' \otimes_{R'} C$ can be written as the geometric realization of two-sided bar construction $\mathrm{Bar}_{R'}(R', C)_\bullet$. By virtue of Proposition C.6.4.4, it will suffice to show that each $\mathrm{Bar}_{R'}(R', C)_k$ is an almost compact object of $\mathrm{LMod}_{R'}(\mathcal{C})$. The extension of scalars functor $\mathcal{C} \to \mathrm{LMod}_{R'}(\mathcal{C})$ is compact, and therefore sends almost compact objects to almost compact objects. It will therefore suffice to show that each iterated tensor product

$R' \otimes_R R' \otimes_R \cdots \otimes_R C$ is an almost compact object of $\mathcal{C}$, which follows from Lemma D.5.5.6 provided that C is almost compact when viewed as an object of $\mathcal{C}$.

We will deduce (b) from the following more precise assertions:

(b_n) Suppose that $\tau_{\leqslant n}\mathcal{C}$ is compactly generated ∞-category for some $n \geqslant 0$. If C is a compact object of $\tau_{\leqslant n}\operatorname{LMod}_{R'}(\mathcal{C})$, then the image of C in $\tau_{\leqslant n}\mathcal{C}$ is compact.

To prove (b_n), let $\mathcal{E}$ be the full subcategory of $\tau_{\leqslant n}\operatorname{LMod}_{R'}(\mathcal{C})$ spanned by those objects C whose image in $\tau_{\leqslant n}\mathcal{C}$ is compact; we wish to show that $\mathcal{E}$ contains all compact objects of $\tau_{\leqslant n}\operatorname{LMod}_{R'}(\mathcal{C})$. Since $\mathcal{E}$ is evidently closed under retracts and cofibers (formed in the ∞-category $\tau_{\leqslant n}\operatorname{LMod}_{R'}(\mathcal{C})$), it will suffice to show that $\mathcal{E}$ contains every object of the form $\tau_{\leqslant n}(R' \otimes_R C_0)$, where C_0 is a compact object of $\tau_{\leqslant n}\mathcal{C}$ (see Lemma D.5.3.3). This is clear, since $\tau_{\leqslant n}(R' \otimes_R C_0)$ can be built from C_0 using finite colimits. □

Lemma D.5.5.8. *Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_\infty$-rings which exhibits R' as an almost perfect module over R, and let $\mathcal{C}$ be a prestable R-linear ∞-category. If $\mathcal{C}$ is weakly coherent, then $\operatorname{LMod}_{R'}(\mathcal{C})$ is weakly coherent.*

Proof. We show that $\operatorname{LMod}_{R'}(\mathcal{C})$ satisfies the requirements of Definition C.6.5.1. It follows from Lemma D.5.5.7 that an object $C \in \operatorname{LMod}_{R'}(\mathcal{C})$ is almost compact if and only if its image in $\mathcal{C}$ is almost compact. Using the weak coherence of $\mathcal{C}$, we see that the collection of almost compact objects of $\operatorname{LMod}_{R'}(\mathcal{C})$ is closed under finite limits. If X is a truncated object of $\operatorname{LMod}_{R'}(\mathcal{C})$, then the weak coherence of $\mathcal{C}$ implies that there exists a morphism $\bigoplus C_\alpha \to X$ in the ∞-category $\mathcal{C}$ which is an epimorphism on π_0, where each C_α is an almost compact object of $\mathcal{C}$. Then the induced map $\bigoplus(R' \otimes_R C_\alpha) \to X$ is a morphism in the ∞-category $\operatorname{LMod}_{R'}(\mathcal{C})$ which induces an epimorphism on π_0, where each $R' \otimes_R C_\alpha$ is an almost compact object of $\operatorname{LMod}_{R'}(\mathcal{C})$. □

We will need the following weak converse:

Lemma D.5.5.9. *Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_\infty$-rings and let $\mathcal{C}$ be a prestable R-linear ∞-category. Assume that:*

(i) For each $n \geqslant 0$, the ∞-category $\tau_{\leqslant n}\mathcal{C}$ is compactly generated.

(ii) The morphism ϕ exhibits R' as an almost perfect R-module.

(iii) The morphism ϕ induces an isomorphism of commutative rings $\pi_0 R \to \pi_0 R'$.

(iv) The Grothendieck prestable ∞-category $\operatorname{LMod}_{R'}(\mathcal{C})$ is weakly coherent.

Then $\mathcal{C}$ is weakly coherent.

Proof. Let X be an almost compact object of $\mathcal{C}$. Then $R' \otimes_R X$ is an almost compact object of $\mathrm{LMod}_{R'}(\mathcal{C})$. Using assumption (iv), we deduce that $\pi_0(R' \otimes_R X)$ is an almost compact object of $\mathrm{LMod}_{R'}(\mathcal{C})$. Using (i), (ii), and Lemma D.5.5.7, we see that $\pi_0(R' \otimes_R X)$ is almost compact when viewed as an object of $\mathcal{C}$. Using (iii), we see that the canonical map $\pi_0(R' \otimes_R X) \to \pi_0 X$ is an isomorphism in $\mathcal{C}^{\heartsuit}$, so that $\pi_0 X$ is an almost compact object of $\mathcal{C}$. Invoking Proposition C.6.4.5, we deduce that the collection of almost compact objects of $\mathcal{C}$ is closed under finite limits. To complete the proof, it will suffice (by virtue of Proposition C.6.5.6) to show that every object $C \in \mathcal{C}^{\heartsuit}$ can be written as a filtered colimit $\varinjlim C_\alpha$, where each $C_\alpha \in \mathcal{C}^{\heartsuit}$ is almost compact when viewed as an object of $\mathcal{C}$. Assumption (iii) implies that C admits an essentially unique R'-module structure, so that the weak coherence of $\mathrm{LMod}_{R'}(\mathcal{C})$ implies that we can choose such an equivalence $C \simeq \varinjlim C_\alpha$ where each C_α is almost compact when viewed as an object of $\mathrm{LMod}_{R'}(\mathcal{C})$. It follows from (i), (ii), and Lemma D.5.5.7 that each C_α is also almost compact when viewed as an object of $\mathcal{C}$. □

Proof of Theorem D.5.5.1. Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_\infty$-rings and let $\mathcal{C}$ be a weakly coherent prestable R-linear ∞-category. Assume that ϕ is almost of finite presentation and that the underlying homomorphism of commutative rings $R \to R'$ is quasi-finite. We wish to show that $\mathrm{LMod}_{R'}(\mathcal{C})$ is also weakly coherent.

Since $\pi_0 R'$ is finitely generated as an algebra over $\pi_0 R$, we can extend ϕ to a map $R\{x_1, \ldots, x_n\} \to R'$ which induces a surjection

$$\pi_0(R\{x_1, \ldots, x_n\}) \simeq (\pi_0 R)[x_1, \ldots, x_n] \xrightarrow{\rho} \pi_0 R';$$

here $R\{x_1, \ldots, x_n\}$ denotes the free $\mathbb{E}_\infty$-algebra over R on n generators. Since $\pi_0 R'$ is finitely presented over $\pi_0 R$, the kernel of ρ is generated by finitely many polynomials $\{g_i(x_1, \ldots, x_n)\}_{1 \leqslant i \leqslant m}$. These polynomials classify a morphism $\vec{g} : R\{y_1, \ldots, y_m\} \to R\{x_1, \ldots, x_n\}$ of $\mathbb{E}_\infty$-algebras over R. Let $\overline{R} = R\{x_1, \ldots, x_n\} \otimes_{R\{y_1, \ldots, y_m\}} R$ denote the $\mathbb{E}_\infty$-algebra over R obtained from $R\{x_1, \ldots, x_n\}$ by "killing" the polynomials $g_i(x_1, \ldots, x_m)$, so that ϕ factors as a composition

$$R \xrightarrow{\phi'} \overline{R} \xrightarrow{\phi''} R'.$$

By construction, ϕ' is almost of finite presentation and ϕ'' induces an isomorphism on π_0. Since ϕ is almost of finite presentation, it follows that ϕ'' is also locally almost of finite presentation. Using Corollary 5.2.2.2, we see that ϕ'' exhibits R' as an almost perfect $\overline{R}$-module. Consequently, in order to show that $R' \otimes_R \mathcal{C}$ is weakly coherent, it will suffice to show that $\overline{R} \otimes_R \mathcal{C}$ is weakly coherent (Lemma D.5.5.8). We may therefore replace R' by $\overline{R}$

and thereby reduce to the case where the morphism ϕ fits into a pushout diagram σ :

$$\begin{array}{ccc} R\{y_1,\ldots,y_m\} & \longrightarrow & R \\ \downarrow{\scriptstyle \vec{g}} & & \downarrow{\scriptstyle \phi} \\ R\{x_1,\ldots,x_n\} & \longrightarrow & R'; \end{array}$$

here the upper horizontal map is given by $y_i \to 0$.

Write R as the colimit of a diagram $\{R_\alpha\}_{\alpha \in A}$ indexed by a filtered partially ordered set A, where each R_α is a compact object of $\mathrm{CAlg}^{\mathrm{cn}}$. For α sufficiently large, we can arrange that all of the coefficients of the polynomials $g_i(x_1,\ldots,x_n)$ can be lifted to elements of $\pi_0 R_\alpha$, so that σ can be lifted to a pushout square σ_α :

$$\begin{array}{ccc} R_\alpha\{y_1,\ldots,y_m\} & \longrightarrow & R_\alpha \\ \downarrow & & \downarrow{\scriptstyle \phi_\alpha} \\ R_\alpha\{x_1,\ldots,x_n\} & \longrightarrow & R'_\alpha. \end{array}$$

Enlarging α further, we can assume that the ring homomorphism $\pi_0 R_\alpha \to \pi_0 R'_\alpha$ is quasi-finite. In this case, we have a canonical equivalence $R' \otimes_R \mathcal{C} \simeq R'_\alpha \otimes_{R_\alpha} \mathcal{C}$. We may therefore replace ϕ by ϕ_α and thereby reduce to the case where R is Noetherian (so that R' is also Noetherian).

The assumption that R' is Noetherian guarantees that the commutative ring $\pi_0 R'$ is almost perfect when viewed as an R'-module (Proposition HA.7.2.4.17). By virtue of Lemma D.5.5.9, to show that $R' \otimes_R \mathcal{C}$ is weakly coherent, it will suffice to show that $(\pi_0 R') \otimes_R \mathcal{C}$ is weakly coherent. We may therefore replace R' by $\pi_0 R'$ and thereby reduce to the case where R' is discrete.

Applying the affine version of Zariski's main theorem (in the form of Theorem B.2.4.5), we see that the map $\pi_0 R \to R'$ factors as a composition $\pi_0 R \to B \xrightarrow{\psi} R'$ where B is a commutative ring which is finitely generated as a module over $\pi_0 R$ and the map ψ induces an open immersion of affine schemes $j : \operatorname{Spec} R' \to \operatorname{Spec} B$. Because R is Noetherian, Proposition HA.7.2.4.17 implies that B is almost perfect when viewed as an R-module, so that Lemma D.5.5.8 guarantees that $B \otimes_R \mathcal{C}$ is weakly coherent. The complement of the image of j is a closed subset of $\operatorname{Spec} B$, which we can identify with the vanishing locus of a finitely generated ideal $(b_1,\ldots,b_k)$. Applying Lemma D.5.5.4, we deduce that each of the ∞-categories $B[b_i^{-1}] \otimes_R \mathcal{C} \simeq R'[b_i^{-1}] \otimes_R \mathcal{C}$ is weakly coherent. Since the elements b_i generate the unit ideal in R', Lemma D.5.5.5 guarantees that $R' \otimes_R \mathcal{C}$ is also weakly coherent, as desired. □

Let us now list some consequences of Theorem D.5.5.1.

Corollary D.5.5.10. *Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_\infty$-rings which is almost of finite presentation, and suppose that the underlying ring homomorphism $\pi_0 R \to \pi_0 R'$ is quasi-finite (Definition B.2.4.1). Let $\mathcal{C}$ be an R-linear prestable ∞-category. If $\mathcal{C}$ is coherent, then $R' \otimes_R \mathcal{C}$ is coherent.*

Proof. It follows from Theorem D.5.5.1 that $R' \otimes_R \mathcal{C}$ is weakly coherent. Let X be an object of $R' \otimes_R \mathcal{C} \simeq \mathrm{LMod}_{R'}(\mathcal{C})$. Since $\mathcal{C}$ is coherent, we can choose a morphism $u : \bigoplus C_\alpha \to X$ in $\mathcal{C}$, where each C_α is an almost compact object of $\mathcal{C}$ and $\pi_0(u)$ is an epimorphism in the abelian category $\mathcal{C}^\heartsuit$. Extending scalars, we see that u classifies a morphism $u_{R'} : \bigoplus (R' \otimes_R C_\alpha) \to X$ in $\mathrm{LMod}_{R'}(\mathcal{C})$ The map $u_{R'}$ is also an epimorphism on π_0 (since this can be checked after applying the forgetful functor $\mathrm{LMod}_{R'}(\mathcal{C}) \to \mathcal{C}$), and each $R' \otimes_R C_\alpha$ is an almost compact object $\mathrm{LMod}_{R'}(\mathcal{C})$ (since the restriction-of-scalars functor $\mathrm{LMod}_{R'}(\mathcal{C}) \to \mathcal{C}$ commutes with filtered colimits). Allowing X to vary, we deduce that $R' \otimes_R \mathcal{C}$ is coherent. □

We also have the following stronger version of Lemma D.5.5.5:

Corollary D.5.5.11. *Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_\infty$-rings which is étale and faithfully flat, and let $\mathcal{C}$ be a prestable R-linear ∞-category. If $R' \otimes_R \mathcal{C}$ is weakly coherent, then $\mathcal{C}$ is weakly coherent.*

Proof. Applying Lemma D.5.4.5, we can choose a anticomplete prestable R-linear ∞-category $\breve{\mathcal{C}}$ and a left exact R-linear functor $\lambda : \breve{\mathcal{C}} \to \mathcal{C}$ which induces an equivalence of completions. Then λ induces an R'-linear functor $\lambda_{R'} : R' \otimes_R \breve{\mathcal{C}} \to R' \otimes_R \mathcal{C}$. Note that the functor $\lambda_{R'}$ is also left exact and induces an equivalence of completions. Applying Corollary C.6.5.5, we see that $R' \otimes_R \breve{\mathcal{C}}$ is weakly coherent. Using Theorem D.5.4.1, we see that $R' \otimes_R \breve{\mathcal{C}}$ is anticomplete. Applying Theorem C.6.7.1, we see that $R' \otimes_R \breve{\mathcal{C}}$ is compactly generated, that every compact object of $R' \otimes_R \breve{\mathcal{C}}$ is truncated, and that the collection of compact objects of $R' \otimes_R \breve{\mathcal{C}}$ is closed under finite limits. Theorem D.5.3.1 then guarantees that $\breve{\mathcal{C}}$ is compactly generated, and Remark D.5.2.3 implies that an object $C \in \breve{\mathcal{C}}$ is compact if and only if the object $R' \otimes_R C \in \mathrm{LMod}_{R'}(\breve{\mathcal{C}})$ is compact. Since the extension-of-scalars functor $\breve{\mathcal{C}} \to \mathrm{LMod}_{R'}(\breve{\mathcal{C}})$ is left exact and conservative, it follows the collection of compact objects of $\breve{\mathcal{C}}$ is closed under finite limits and that every compact object of $\breve{\mathcal{C}}$ is truncated. Using Theorem C.6.7.1 again, we conclude that $\breve{\mathcal{C}}$ is weakly coherent, so that $\mathcal{C}$ is also weakly coherent (Corollary C.6.5.5). □

Remark D.5.5.12. We do not know if the analogue of Corollary D.5.5.11 holds for coherent prestable ∞-categories.

Corollary D.5.5.13. *Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_\infty$-rings which is étale and faithfully flat. If R' is coherent, then R is coherent.*

Proof. Combine Corollary D.5.5.11 with Example C.6.5.3. □

D.5.6 Locally Noetherian Prestable ∞-Categories

Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_\infty$-rings which is almost of finite presentation. It follows from Proposition HA.7.2.4.31 that if R is Noetherian, then R' is Noetherian. We establish a relative version of this assertion:

Proposition D.5.6.1. *Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_\infty$-rings and let $\mathcal{C}$ be a prestable R-linear ∞-category. If $\mathcal{C}$ is locally Noetherian and ϕ is almost of finite presentation, then $R' \otimes_R \mathcal{C}$ is also locally Noetherian.*

Our starting point is the following variant of the Hilbert basis theorem.

Lemma D.5.6.2. *Let $\mathcal{A}$ be a Grothendieck abelian category containing an object X, let $\mathcal{B} = \mathrm{LMod}_{\mathbf{Z}[t]}(\mathcal{A})$ denote the category of $\mathbf{Z}[t]$-modules in $\mathcal{A}$, and set $X[t] = \mathbf{Z}[t] \otimes_{\mathbf{Z}} X \in \mathcal{B}$. If X is a Noetherian object of $\mathcal{A}$, then $X[t]$ is a Noetherian object of $\mathcal{B}$.*

Proof. For each $n \geqslant 0$, let $\mathbf{Z}[t]_{\leqslant n}$ denote the subset of the polynomial ring $\mathbf{Z}[t]$ consisting of polynomials having degree $\leqslant n$, and let $e_n : \mathbf{Z}[t]_{\leqslant n} \to \mathbf{Z}$ be the map given by $e_n(c_0 + c_1 t + \cdots + c_n t^n) = a_n$. We let $X[t]_{\leqslant n}$ denote the tensor product $\mathbf{Z}[t]_{\leqslant n} \otimes_{\mathbf{Z}} X$, which we will identify with a subobject of $X[t]$ (in the abelian category $\mathcal{A}$).

Let Y be a subobject of $X[t]$ in the abelian category $\mathcal{B}$. For each $n \geqslant 0$, let $Y_{\leqslant n}$ denote the fiber product $Y \times_{X[t]} X[t]_{\leqslant n}$ (formed in the abelian category $\mathcal{A}$). Then e_n induces a map $e_n^Y : Y_{\leqslant n} \to X$ whose kernel can be identified with $Y_{\leqslant n-1}$. Let $S_n(Y)$ denote the image of e_n^Y, which we regard as a subobject of X.

Now suppose we are given an nondecreasing sequence

$$Y(0) \subseteq Y(1) \subseteq Y(2) \subseteq Y(3) \subseteq \cdots$$

of subobjects of $X[t]$ in the abelian category $\mathcal{B}$. Then $\{S_n(Y(n))\}_{n \geqslant 0}$ is a nondecreasing sequence of subobject of X in the abelian category $\mathcal{A}$. Since X is Noetherian, this sequence must eventually stabilize: that is, we can choose an integer $n_0 \gg 0$ such that $S_n(Y(n)) = S_{n_0}(Y(n_0))$ for $n \geqslant n_0$. For each $k < n_0$, the sequence of subobjects $\{S_k(Y(n))\}_{n \geqslant 0}$ must also stabilize. We can therefore choose $n_1 \gg n_0$ such that $S_k(Y(n)) = S_k(Y(n_1))$ for $n \geqslant n_1$ and $k < n_0$. We will complete the proof by showing that $Y(n) = Y(n_1)$ for $n \geqslant n_1$. To prove this, it will suffice to show that we have $Y(n)_{\leqslant k} = Y(n_1)_{\leqslant k}$ for every integer k. This follows by induction on k, by inspecting the diagram of short exact sequences

$$\begin{array}{ccccccccc} 0 & \longrightarrow & Y(n_1)_{\leqslant k-1} & \longrightarrow & Y(n_1)_{\leqslant k} & \longrightarrow & S_k(Y(n_1)) & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & Y(n)_{\leqslant k-1} & \longrightarrow & Y(n)_{\leqslant k} & \longrightarrow & S_k(Y(n)) & \longrightarrow & 0. \end{array}$$

□

Lemma D.5.6.3. *Let R be a commutative ring and let $\mathcal{C}$ be a prestable R-linear ∞-category. If $\mathcal{C}$ is locally Noetherian, then $R[t_1, \ldots, t_m] \otimes_R \mathcal{C}$ is also locally Noetherian for each $m \geqslant 0$.*

Proof. Working by induction on m, we can reduce to the case where $m = 0$. We first note that if $\mathcal{C}$ is locally Noetherian, then $\tau_{\leqslant n} \mathcal{C}$ is compactly generated for each $n \geqslant 0$, so that $\tau_{\leqslant n}(R[t] \otimes_R \mathcal{C})$ is also compactly generated (Lemma D.5.3.3). Let $\mathcal{E} \subseteq \tau_{\leqslant n}(R[t] \otimes_R \mathcal{C})$ be the full subcategory spanned by those objects X for which the homotopy groups $\pi_k X$ are Noetherian objects of the abelian category $\mathrm{LMod}_{R[t]}(\mathcal{C}^{\heartsuit})$ for $0 \leqslant k \leqslant m$. For each compact object $C \in \tau_{\leqslant n} \mathcal{C}$, the objects $\pi_k C \in \mathcal{C}^{\heartsuit}$ are Noetherian for $0 \leqslant k \leqslant n$, so that Lemma D.5.6.2 guarantees that $R[t] \otimes_R C$ belongs to $\mathcal{E}$. The ∞-category $\mathcal{E}$ is clearly closed under retracts, and Corollary C.6.8.3 shows that $\mathcal{E}$ is closed under the formation of cofibers. Applying Lemma D.5.3.3, we see that every compact object of $\tau_{\leqslant n}(R[t] \otimes_R \mathcal{C})$ belongs to $\mathcal{E}$. Applying Proposition C.6.9.7, we deduce that $R[t] \otimes_R \mathcal{C}$ is locally Noetherian. □

Proof of Proposition D.5.6.1. Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_\infty$-rings which is almost of finite presentation and let $\mathcal{C}$ be locally Noetherian R-linear prestable ∞-category; we wish to show that $R' \otimes_R \mathcal{C}$ is also locally Noetherian. Since $\pi_0 R'$ is finitely generated as an algebra over $\pi_0 R$, we can factor ϕ as a composition $R \xrightarrow{\phi'} R\{t_1, \ldots, t_n\} \xrightarrow{\phi''} R'$, where $R\{t_1, \ldots, t_n\}$ denotes the free $\mathbb{E}_\infty$-algebra over R on generators $t_1, \ldots, t_n$ and the morphism ϕ'' is surjective on π_0.

Let S denote the sphere spectrum. The canonical map $S \to \pi_0 S \simeq \mathbf{Z}$ exhibits $\mathbf{Z}$ as an almost perfect S-module (Proposition HA.7.2.4.17). Applying Lemma D.5.5.8, we deduce that $\mathbf{Z} \otimes_S \mathcal{C}$ is weakly coherent. Since $(\mathbf{Z} \otimes_S \mathcal{C})^{\heartsuit} \simeq \mathcal{C}^{\heartsuit}$ is a locally Noetherian abelian category, it follows that $\mathbf{Z} \otimes_S \mathcal{C}$ is a locally Noetherian Grothendieck prestable ∞-category. Applying Lemma D.5.6.3, we deduce that $\mathbf{Z}[t_1, \ldots, t_n] \otimes_S \mathcal{C}$ is also locally Noetherian. Note that $S\{t_1, \ldots, t_n\}$ is a Noetherian $\mathbb{E}_\infty$-ring (Proposition HA.7.2.4.31) so that the canonical map $S\{t_1, \ldots, t_n\} \to \pi_0 S\{t_1, \ldots, t_n\} \simeq \mathbf{Z}[t_1, \ldots, t_n]$ exhibits $\mathbf{Z}[t_1, \ldots, t_n]$ as an almost perfect module over $S\{t_1, \ldots, t_n\}$. Applying Lemma D.5.5.9, we conclude that $S\{t_1, \ldots, t_n\} \otimes_S \mathcal{C}$ is weakly coherent. Using the equivalence of hearts $(S\{t_1, \ldots, t_n\} \otimes_S \mathcal{C})^{\heartsuit} \simeq (\mathbf{Z}[t_1, \ldots, t_n] \otimes_S \mathcal{C})^{\heartsuit}$, we conclude that $S\{t_1, \ldots, t_n\} \otimes_S \mathcal{C} \simeq R\{t_1, \ldots, t_n\} \otimes_R \mathcal{C}$ is locally Noetherian. We may therefore replace ϕ by ϕ'' and thereby reduce to the case where the map $\phi : R \to R'$ is surjective on π_0. In this case, the weak coherence of $R' \otimes_R \mathcal{C}$ follows from Theorem D.5.5.1.

To complete the proof, it will suffice to show that every compact object X of $(R' \otimes_R \mathcal{C})^{\heartsuit}$ is also Noetherian. Note that since $R' \otimes_R \mathcal{C}$ is weakly coherent, the object X is almost compact as an object of $R' \otimes_R \mathcal{C}$, and therefore also as an object of $\mathcal{C}$ (Lemma D.5.5.7). Our assumption that $\mathcal{C}$ is locally Noetherian then guarantees that X is Noetherian when viewed as an object of the abelian category $\mathcal{C}^{\heartsuit}$, and therefore also as an object of the abelian category $(R' \otimes_R \mathcal{C})^{\heartsuit}$. □

We now consider the problem of descent.

Proposition D.5.6.4. *Let $\phi : R \to R'$ be morphism of connective $\mathbb{E}_\infty$-rings and let $\mathcal{C}$ be a prestable R-linear ∞-category. If ϕ is faithfully flat and $R' \otimes_R \mathcal{C}$ is locally Noetherian, then $\mathcal{C}$ is locally Noetherian.*

We first establish the analogue of Proposition D.5.6.4 for abelian categories.

Lemma D.5.6.5. *Let $\phi : R \to R'$ be a homomorphism of commutative rings and let $\mathcal{A}$ be an R-linear abelian category. If ϕ is faithfully flat and $R' \otimes_R \mathcal{A}$ is locally Noetherian, then $\mathcal{A}$ is locally Noetherian.*

Proof. Let X be an object of $\mathcal{A}$ and set $X' = R' \otimes_R X$. Since $R' \otimes_R \mathcal{A} \simeq \mathrm{LMod}_{R'}(\mathcal{A})$ is locally Noetherian, we can write X' as a union of subobjects $\{X'_\alpha\}$ which are Noetherian when regarded as objects of $\mathrm{LMod}_{R'}(\mathcal{A})$. For each index α, set $X_\alpha = X \times_{X'} X'_\alpha$. Since filtered colimits in $\mathcal{A}$ are left exact, we have $X \simeq \varinjlim X_\alpha$. We will show that each X_α is a Noetherian object of $\mathcal{A}$, so that X can be written as a union of Noetherian subobjects. To prove this, we first observe that each tensor product $R' \times_R X_\alpha$ can be identified with a subobject of $X' = R' \otimes_R X$ (since R' is flat over R) which is contained in X'_α. The faithful flatness of R' over R implies that the construction

$$(Y \hookrightarrow X_\alpha) \mapsto (R' \otimes_R Y \hookrightarrow X'_\alpha)$$

induces an injection from the set of isomorphism classes of subobjects of X_α in the abelian category $\mathcal{A}$ to the set of isomorphism classes of subobjects of X'_α in the abelian category $\mathrm{LMod}_{R'}(\mathcal{A})$. Since the latter set satisfies the ascending chain condition (by virtue of our assumption that X'_α is a Noetherian object of $\mathrm{LMod}_{R'}(\mathcal{A})$), the former set must also satisfy the ascending chain condition. □

Proof of Proposition D.5.6.4. Let $\phi : R \to R'$ be a faithfully flat morphism of connective $\mathbb{E}_\infty$-rings, let $\mathcal{C}$ be a prestable R-linear ∞-category, and assume that $\mathcal{C}' = R' \otimes_R \mathcal{C}$ is locally Noetherian. We wish to show that $\mathcal{C}$ is locally Noetherian. It follows from Lemma D.5.6.5 that the abelian category $\mathcal{C}^\heartsuit$ is locally Noetherian. It will therefore suffice to show that for every Noetherian object $C \in \mathcal{C}^\heartsuit$ is compact when viewed as an object of $\tau_{\leqslant n} \mathcal{C}$ for each $n \geqslant 0$ (Proposition C.6.9.8).

Fix a filtered diagram $\{D_\alpha\}$ of n-truncated objects of $\mathcal{C}$ having colimit D; we wish to show that the canonical map $\rho : \varinjlim \mathrm{Map}_{\mathcal{C}}(C, D_\alpha) \to \mathrm{Map}_{\mathcal{C}}(C, D)$ is a homotopy equivalence. We will prove that the homotopy fibers of ρ are m-truncated for every integer $m \geqslant -2$. Note that this is trivial when $m = n$ (since the domain and codomain of ρ are both n-truncated). We will handle the general case using descending induction on m. For each index α, set $D'_\alpha = R' \otimes_R D_\alpha$, and set $D' = \varinjlim D'_\alpha \simeq R' \otimes_R D$. Let D'_α / D_α denote the cofiber of the canonical map $D_\alpha \to D'_\alpha$, and define D'/D similarly. Note that our hypothesis that R' is faithfully flat over R guarantees that each D'_α/D_α is also n-truncated. We have a commutative diagram of fiber sequences

$$\begin{array}{ccccc} \varinjlim \mathrm{Map}_{\mathcal{C}}(C, D_\alpha) & \longrightarrow & \varinjlim \mathrm{Map}_{\mathcal{C}}(C, D'_\alpha) & \longrightarrow & \varinjlim \mathrm{Map}_{\mathcal{C}}(C, D'_\alpha/D_\alpha) \\ \downarrow{\scriptstyle \rho} & & \downarrow{\scriptstyle \rho'} & & \downarrow{\scriptstyle \rho''} \\ \mathrm{Map}_{\mathcal{C}}(C, D) & \longrightarrow & \mathrm{Map}_{\mathcal{C}}(C, D') & \longrightarrow & \mathrm{Map}_{\mathcal{C}}(C, D'/D). \end{array}$$

It follows from our inductive hypothesis that the map ρ'' has $(m+1)$-truncated homotopy fibers. Consequently, to show that the homotopy fibers of ρ are m-truncated, it will suffice to show that ρ' is a homotopy equivalence. Set $C' = R' \otimes_R C$, so that ρ' can be identified with the canonical map $\varinjlim \mathrm{Map}_{\mathcal{C}'}(C', D'_\alpha) \to \mathrm{Map}_{\mathcal{C}'}(C', D')$. To show that this map is a homotopy equivalence, it will suffice to show that C' is compact when viewed as an object of $\tau_{\leqslant n} \mathcal{C}'$. Using our assumption that $\mathcal{C}'$ is locally Noetherian (together with Proposition C.6.9.3), we are reduced to showing that C' is a Noetherian object of the abelian category $\mathcal{C}'^{\heartsuit}$. By virtue of Corollary C.6.8.9, this is equivalent to the assertion that C' is a compact object of $\mathcal{C}'^{\heartsuit}$. Since the forgetful functor $\mathcal{C}'^{\heartsuit} \to \mathcal{C}^{\heartsuit}$ commutes with filtered colimits, this follows from the fact that C is a compact object of $\mathcal{C}^{\heartsuit}$ (Proposition C.6.8.7). □

D.5.7 Complicial Prestable ∞-Categories

We now consider descent properties for the class of n-complicial Grothendieck prestable ∞-categories.

Proposition D.5.7.1. *Let R be a connective $\mathbb{E}_2$-ring, let R' be an $\mathbb{E}_1$-algebra over R which is flat when regarded as a right R-module, and let $\mathcal{C}$ be a prestable R-linear ∞-category. Then:*

- *(a) If $\mathcal{C}$ is n-complicial for some $n \geqslant 0$, then $\mathrm{LMod}_{R'}(\mathcal{C})$ is also n-complicial.*
- *(b) If $\mathcal{C}$ is weakly n-complicial for some $n \geqslant 0$, then $\mathrm{LMod}_{R'}(\mathcal{C})$ is also weakly n-complicial.*
- *(c) If R' is faithfully flat as a right R-module and $\mathrm{LMod}_{R'}(\mathcal{C})$ is weakly n-complicial for some $n \geqslant 0$, then $\mathcal{C}$ is also weakly n-complicial.*

Warning D.5.7.2. Proposition **??** is not true if we drop the flatness hypothesis on ϕ.

Proof of Proposition D.5.7.1. We first prove (b). Suppose that $\mathcal{C}$ is weakly n-complicial; we wish to show that $\mathrm{LMod}_{R'}(\mathcal{C})$ is also weakly n-complicial. Fix a truncated object $X \in \mathrm{LMod}_{R'}(\mathcal{C})$. Let us abuse notation by identifying X with its image under the forgetful functor $\mathrm{LMod}_{R'}(\mathcal{C}) \to \mathcal{C}$. Since $\mathcal{C}$ is weakly n-complicial, we can choose a morphism $\alpha : \overline{X} \to X$ in $\mathcal{C}$, where $\overline{X}$ is n-truncated and the induced map $\pi_0 \overline{X} \to \pi_0 X$ is an epimorphism in $\mathcal{C}^{\heartsuit}$. Extending scalars, we obtain a morphism $\alpha' : R' \otimes_R \overline{X} \to X$ in $\mathrm{LMod}_{R'}(\mathcal{C})$. Note that if we regard α' as a morphism of $\mathcal{C}$, then α factors through α'. It follows that α' induces an epimorphism $\pi_0(R' \otimes_R \overline{X}) \to \pi_0 X$ in the abelian category $\mathcal{C}^{\heartsuit}$, hence also in the abelian category $\mathrm{LMod}_{R'}(\mathcal{C})^{\heartsuit}$. We conclude by observing that our flatness assumption on R' guarantees that as a right R-module, R' can be written as a filtered colimit of free R-modules of finite rank. Since the collection of n-truncated objects of $\mathcal{C}$ is closed under filtered colimits, it follows that $R' \otimes_R \overline{X}$ is n-truncated. Allowing X to vary, we conclude that $\mathrm{LMod}_{R'}(\mathcal{C})$ is weakly n-complicial, as desired.

Assertion (a) follows from exactly the same argument, where we now drop the assumption that X is truncated. We will complete the proof by establishing (c). Assume that R' is faithfully flat over R and that $\mathrm{LMod}_{R'}(\mathcal{C})$ is weakly n-complicial; we will show that $\mathcal{C}$ is weakly n-complicial. By virtue of Proposition C.5.7.11, it will suffice to show that every injective object $Q \in \mathrm{Sp}(\mathcal{C})$ belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant -n}$. The injectivity of Q guarantees that Q belongs to $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$. Using the flatness of R' as a right R-module, we deduce that $R' \otimes_R Q$ belongs to $\mathrm{Sp}(\mathrm{LMod}_{R'}(\mathcal{C}))_{\leqslant 0}$. Since $\mathrm{LMod}_{R'}(\mathcal{C})^{\heartsuit}$ is a Grothendieck abelian category, we can choose a monomorphism $\phi : \pi_0(R' \otimes_R Q) \hookrightarrow Q'_0$ in $\mathrm{LMod}_{R'}(\mathcal{C})^{\heartsuit}$, where $Q'_0 \in \mathrm{LMod}_{R'}(\mathcal{C})^{\heartsuit}$ is injective. Using Propositon HA.**??** , we can lift Q'_0 to an injective object $Q' \in \mathrm{Sp}(\mathrm{LMod}_{R'}(\mathcal{C}))$. The injectivity of Q' then guarantees that we can lift ϕ to a map $\overline{\phi} : R' \otimes_R Q \to Q'$. Let ψ denote the composite map

$$Q \to R' \otimes_R Q \xrightarrow{\overline{\phi}} Q'.$$

Since ϕ is a monomorphism by construction and R' is faithfully flat over R, the morphism ψ induces a monomorphism $\pi_0 Q \to \pi_0 Q'$ in the abelian category $\mathcal{C}^{\heartsuit}$. In other words, the cofiber $\mathrm{cofib}(\psi)$ belongs to $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$. Using the exactness of the sequence

$$\mathrm{Ext}^0_{\mathrm{Sp}(\mathcal{C})}(Q', Q) \to \mathrm{Ext}^0_{\mathrm{Sp}(\mathcal{C})}(Q, Q) \to \mathrm{Ext}^1_{\mathrm{Sp}(\mathcal{C})}(\mathrm{cofib}(\psi), Q),$$

and the injectivity of Q, we deduce that ψ admits a left homotopy inverse: that is, Q is a direct summand of Q' (when we regard Q' as an object of $\mathcal{C}$). Since $\mathrm{LMod}_{R'}(\mathcal{C})$ is weakly n-complicial, Q' belongs to $\mathrm{Sp}(\mathrm{LMod}_{R'}(\mathcal{C}))_{\geqslant -n}$ (Proposition C.5.7.11), so that Q belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant -n}$ as desired. □

We do not know if it is possible to replace “weakly n-complicial” by “n-complicial” in part (c) of Proposition D.5.7.1. However, we do have the following weaker result:

Corollary D.5.7.3. *Let $\phi : R \to R'$ be a flat universal descent morphism of connective $\mathbb{E}_\infty$-rings which exhibits R' as a module of finite* Tor*-amplitude over $R' \otimes_R R'$. Let $\mathcal{C}$ be a prestable R-linear ∞-category, and let $n \geqslant 0$. Then:*

(1) *If $R' \otimes_R \mathcal{C}$ is anticomplete and n-complicial, then $\mathcal{C}$ is anticomplete and n-complicial.*

(2) *If $R' \otimes_R \mathcal{C}$ is separated and n-complicial, then $\mathcal{C}$ is separated and n-complicial.*

Proof. Assume first that $R' \otimes_R \mathcal{C}$ is anticomplete and n-complicial. It follows from Theorem D.5.4.9 that $\mathcal{C}$ is anticomplete and from Proposition D.5.7.1 that $\mathcal{C}$ is weakly n-complicial. Applying Proposition C.5.5.16, we deduce that $\mathcal{C}$ is n-complicial.

Now suppose that $R' \otimes_R \mathcal{C}$ is separated and n-complicial. Using Propositions D.5.7.1 and D.5.1.2, we deduce that $\mathcal{C}$ is separated and weakly n-complicial. Using Lemma D.5.4.5, we can choose a left exact R-linear functor $\lambda : \breve{\mathcal{C}} \to \mathcal{C}$ where $\breve{\mathcal{C}}$ is anticomplete and λ induces an equivalence of completions. Applying Remark C.5.5.14, we deduce that $\breve{\mathcal{C}}$ is also weakly n-complicial. Proposition C.5.5.16 then implies that $\breve{\mathcal{C}}$ is n-complicial. Let $\breve{\mathcal{C}}^{\mathrm{sep}}$ denote the separated quotient of $\breve{\mathcal{C}}$ (see Proposition C.3.6.1. Then $\breve{\mathcal{C}}^{\mathrm{sep}}$ inherits the structure of an R-linear prestable ∞-category, and Proposition C.5.3.3 implies that $\breve{\mathcal{C}}^{\mathrm{sep}}$ is n-complicial. The functor λ factors as a composition $\breve{\mathcal{C}} \to \breve{\mathcal{C}}^{\mathrm{sep}} \xrightarrow{\mu} \mathcal{C}$, where μ is left exact and induces an equivalence of completions. It follows that the induced map $\mu_{R'} : R' \otimes_R \breve{\mathcal{C}}^{\mathrm{sep}} \to R' \otimes_R \mathcal{C}$ is also left exact and induces an equivalence on completions. It follows from Proposition D.5.1.2 that $R' \otimes_R \breve{\mathcal{C}}^{\mathrm{sep}}$ is separated and from Proposition D.5.7.1 that it is n-complicial. Applying Proposition C.5.3.9, we deduce that $\mu_{R'}$ is an equivalence. Applying Theorem D.4.1.6, we conclude that μ is also an equivalence, so that $\mathcal{C} \simeq \breve{\mathcal{C}}^{\mathrm{sep}}$ is n-complicial as desired. □

We now specialize to the case $n = 0$.

Corollary D.5.7.4. *Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_\infty$-rings, let $\mathcal{C}$ be a prestable R-linear ∞-category, and let $\mathcal{A} = \mathcal{C}^\heartsuit$ be its heart. Then:*

(a) *Assume that the inclusion $\mathcal{A} \hookrightarrow \mathcal{C}$ extends to an equivalence $\breve{\mathcal{D}}(\mathcal{A})_{\geqslant 0} \simeq \mathcal{C}$ and the morphism ϕ is flat and exhibits R' as a module of finite* Tor*-amplitude over $R' \otimes_R R'$. Then the inclusion $\mathrm{LMod}_{R'}(\mathcal{A}) \hookrightarrow \mathrm{LMod}_{R'}(\mathcal{C})$ extends to an equivalence $\breve{\mathcal{D}}(\mathrm{LMod}_{R'}(\mathcal{A})) \to \mathrm{LMod}_{R'}(\mathcal{C})$.*

(a′) *If the inclusion $\mathcal{A} \hookrightarrow \mathcal{C}$ extends to an equivalence $\mathcal{D}(\mathcal{A})_{\geqslant 0} \simeq \mathcal{C}$ and the morphism ϕ is flat, then the inclusion $\mathrm{LMod}_{R'}(\mathcal{A}) \hookrightarrow \mathrm{LMod}_{R'}(\mathcal{C})$ extends to an equivalence $\mathcal{D}(\mathrm{LMod}_{R'}(\mathcal{A})) \to \mathrm{LMod}_{R'}(\mathcal{C})$.*

(a″) *If the inclusion $\mathcal{A} \hookrightarrow \mathcal{C}$ extends to an equivalence $\widehat{\mathcal{D}}(\mathcal{A})_{\geqslant 0} \simeq \mathcal{C}$ and the morphism ϕ is flat, then the inclusion $\mathrm{LMod}_{R'}(\mathcal{A}) \hookrightarrow \mathrm{LMod}_{R'}(\mathcal{C})$ extends to an equivalence $\widehat{\mathcal{D}}(\mathrm{LMod}_{R'}(\mathcal{A})) \to \mathrm{LMod}_{R'}(\mathcal{C})$.*

(b) *If the inclusion $\mathrm{LMod}_{R'}(\mathcal{A}) \hookrightarrow \mathrm{LMod}_{R'}(\mathcal{C})$ extends to an equivalence $\breve{\mathcal{D}}(\mathrm{LMod}_{R'}(\mathcal{A})) \to \mathrm{LMod}_{R'}(\mathcal{C})$ and ϕ is flat universal descent morphism which exhibits R' as a module of finite* Tor*-amplitude over $R' \otimes_R R'$, then the inclusion $\mathcal{A} \hookrightarrow \mathcal{C}$ extends to an equivalence $\breve{\mathcal{D}}(\mathcal{A})_{\geqslant 0} \simeq \mathcal{C}$.*

(b′) *If the inclusion $\mathrm{LMod}_{R'}(\mathcal{A}) \hookrightarrow \mathrm{LMod}_{R'}(\mathcal{C})$ extends to an equivalence $\mathcal{D}(\mathrm{LMod}_{R'}(\mathcal{A})) \to \mathrm{LMod}_{R'}(\mathcal{C})$ and ϕ is flat universal descent morphism which exhibits R' as a module of* *finite* Tor*-amplitude over* $R' \otimes_R R'$*, then the inclusion* $\mathcal{A} \hookrightarrow \mathcal{C}$ *extends to an equivalence* $\mathcal{D}(\mathcal{A})_{\geqslant 0} \simeq \mathcal{C}$*.*

(b'') *If the inclusion* $\mathrm{LMod}_{R'}(\mathcal{A}) \hookrightarrow \mathrm{LMod}_{R'}(\mathcal{C})$ *extends to an equivalence* $\widehat{\mathcal{D}}(\mathrm{LMod}_{R'}(\mathcal{A})) \to \mathrm{LMod}_{R'}(\mathcal{C})$ *and* ϕ *is flat universal descent morphism, then the inclusion* $\mathcal{A} \hookrightarrow \mathcal{C}$ *extends to an equivalence* $\widehat{\mathcal{D}}(\mathcal{A})_{\geqslant 0} \simeq \mathcal{C}$*.*

Proof. Assertion (a) follows from Corollary C.5.8.11, Proposition D.5.7.1, and Theorem D.5.4.1. Assertion (a') follows from Remark C.5.4.11, Proposition D.5.7.1, and Proposition D.5.1.2. Assertion (a'') follows from Corollary C.5.9.7, Proposition D.5.7.1, and Proposition D.5.1.3. Assertion (b) follows from Corollaries C.5.8.11 and D.5.7.3. Assertion (b') follows from Corollary D.5.7.3 and Remark C.5.4.11. Assertion (b'') follows from Corollary C.5.9.7, Proposition D.5.7.1, and Proposition D.5.1.3. □

D.6 Descent for the Flat Topology

Let A be a Noetherian local ring with maximal ideal $\mathfrak{m}$, and let $\widehat{A} = \varprojlim A/\mathfrak{m}^n$ denote its completion. Then the natural map $A \to \widehat{A}$ is a faithfully flat map of commutative rings. It follows from the theory of faithfully flat descent that the category of A-modules is equivalent to the category of $\widehat{A}$-modules equipped with descent data. Using this fact, one can reduce many questions about A (and the category of A-modules) to questions about $\widehat{A}$ (and the category of $\widehat{A}$-modules).

In §D.3, we introduced the notion of an universal descent morphism of $\mathbb{E}_\infty$-rings (Definition D.3.1.1) and proved that if $f : A \to B$ is a universal descent morphism, then the base change functor $\mathrm{Mod}_A \to \mathrm{Mod}_B$ is comonadic (that is, we can identify A-module spectra with objects of Mod_B equipped with suitable descent data). This result applies in particular when $f : A \to B$ is faithfully flat and $\pi_0 B$ is countably presented over $\pi_0 A$ (Proposition D.3.3.1). However, this countable presentation assumption is typically not satisfied for $B = \widehat{A}$ (if A is a local Noetherian ring as above), and we do not know if it is true that all faithfully flat morphisms are universal descent morphisms. Consequently, the results of §D.3 are inadequate for many of the applications of the theory of descent. Our goal in this section is to remedy the situation by proving an analogue of Theorem D.3.5.2 for the fpqc topology.

D.6.1 Flat Descent for Stable ∞-Categories

We begin with a few general remarks.

Remark D.6.1.1. Let CAlg denote the ∞-category of $\mathbb{E}_\infty$-rings. In §A.3, we introduced the *fpqc topology* on the ∞-category $\mathrm{CAlg}^{\mathrm{op}}$. If A is an $\mathbb{E}_\infty$-ring, then a sieve on A is covering with respect to the fpqc topology if and only if it contains a finite collection of maps $\{\phi_\alpha : A \to A_\alpha\}$ which induces a faithfully flat morphism $A \to \prod_\alpha A_\alpha$.

For every $\mathbb{E}_\infty$-ring A, the fpqc topology on $\mathrm{CAlg}^{\mathrm{op}}$ determines a Grothendieck topology on the ∞-category $\mathrm{CAlg}_A^{\mathrm{op}}$ of $\mathbb{E}_\infty$-algebras over A. If A is connective, we also obtain a Grothendieck topology on the ∞-category $(\mathrm{CAlg}_A^{\mathrm{cn}})^{\mathrm{op}}$ of connective $\mathbb{E}_\infty$-algebras over A. We will refer to both of these topologies as the *fpqc topology*.

Definition D.6.1.2. Let A be an $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a stable A-linear ∞-category. We will say that $\mathcal{C}$ *satisfies flat descent* if the functor

$$\chi : \mathrm{CAlg}_A \to \widehat{\mathcal{C}\mathrm{at}}_\infty \qquad B \mapsto B \otimes_A \mathcal{C}$$

is a $\widehat{\mathcal{C}\mathrm{at}}_\infty$-valued sheaf with respect to the fpqc topology on $\mathrm{CAlg}_A^{\mathrm{op}}$. We will say that $\mathcal{C}$ *satisfies flat hyperdescent* if the functor χ is a hypercomplete sheaf with respect to the fpqc topology.

In the situation of Definition D.6.1.2, if the $\mathbb{E}_\infty$-ring A is connective, then it suffices to restrict our attention to $\mathbb{E}_\infty$-algebras over A which are also connective:

Proposition D.6.1.3. *Let A be a connective $\mathbb{E}_\infty$-ring, let $\mathcal{C}$ be a stable A-linear ∞-category, and let $\chi : \mathrm{CAlg}_A \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ be the functor given by $\chi(B) = B \otimes_A \mathcal{C}$. Then:*

1. *The functor χ is a sheaf for the fpqc topology on the ∞-category $\mathrm{CAlg}_A^{\mathrm{op}}$ if the restriction $\chi|_{\mathrm{CAlg}_A^{\mathrm{cn}}}$ is a sheaf with respect to the fpqc topology on $(\mathrm{CAlg}_A^{\mathrm{cn}})^{\mathrm{op}}$.*
2. *The functor χ is a hypercomplete sheaf for the fpqc topology on the ∞-category $\mathrm{CAlg}_A^{\mathrm{op}}$ if the restriction $\chi|_{\mathrm{CAlg}_A^{\mathrm{cn}}}$ is a hypercomplete sheaf with respect to the fpqc topology on $(\mathrm{CAlg}_A^{\mathrm{cn}})^{\mathrm{op}}$.*

Before giving the proof of Proposition D.6.1.3, let us introduce a bit of useful terminology:

Definition D.6.1.4. Let $R^\bullet$ be an augmented cosemisimplicial object of CAlg. We will say that $R^\bullet$ is a *flat hypercovering* if it determines an S-hypercovering in the ∞-category $\mathrm{CAlg}^{\mathrm{op}}$ in the sense of Definition A.5.7.1, where S is the collection of faithfully flat morphisms in CAlg. In other words, $R^\bullet$ is a flat hypercovering if each of the maps $L_n(R^\bullet) \to R^n$ is faithfully flat, where $L_n(R^\bullet)$ denotes the nth latching object of the cosemisimplicial $\mathbb{E}_\infty$-ring $R^\bullet$. In this case, we will also say that the underlying semisimplicial $\mathbb{E}_\infty$-ring of $R^\bullet$ is a *flat hypercovering* of R^{-1}.

Proof of Proposition D.6.1.3. We will prove (1); the proof of (2) is similar. The "only if" direction is obvious. Conversely, suppose that $\chi|_{\mathrm{CAlg}_A^{\mathrm{cn}}}$ is a sheaf with respect to the flat topology on $\mathrm{CAlg}_A^{\mathrm{cn}}$. We wish to show that χ is a sheaf with respect to the fpqc topology. Using Proposition A.3.3.1 and Lemma D.3.5.5, we are reduced to proving the following:

$(*)$ Let $f : B \to B^0$ be a faithfully flat morphism of A-algebras, and let $B^\bullet : \mathbf{\Delta}_+ \to \mathrm{CAlg}_A$ be the Čech nerve of f (regarded as a morphism in the ∞-category $\mathrm{CAlg}_A^{\mathrm{op}}$). Then $\chi(B^\bullet)$ is a limit diagram in $\widehat{\mathcal{C}\mathrm{at}}_\infty$.

According to Proposition HA.5.2.2.36 , it will suffice to verify the following:

(a) The extension of scalars functor $\phi : \mathrm{LMod}_B(\mathcal{C}) \to \mathrm{LMod}_{B^0}(\mathcal{C})$ is conservative. To prove this, we let $\tau_{\geqslant 0}B$ and $\tau_{\geqslant 0}B^0$ be the connective covers of B and B^0, respectively. Since f is flat, the canonical map $B \otimes_{\tau_{\geqslant 0}B} \tau_{\geqslant 0}B^0 \to B^0$ is an equivalence. It follows from Lemma D.3.5.6 that ϕ fits into a homotopy commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{LMod}_B(\mathcal{C}) & \xrightarrow{\phi} & \mathrm{LMod}_B(\mathcal{C}) \\ \downarrow & & \downarrow \\ \mathrm{LMod}_{\tau_{\geqslant 0}B}(\mathcal{C}) & \xrightarrow{\phi_0} & \mathrm{LMod}_{\tau_{\geqslant 0}B^0}(\mathcal{C}). \end{array}$$

Here the vertical maps are the evident forgetful functors (and therefore conservative). Consequently, to show that ϕ is conservative, it suffices to show that ϕ_0 is conservative, which follows from our assumption that $\chi|_{\mathrm{CAlg}_A^{\mathrm{cn}}}$ is a sheaf with respect to the fpqc topology.

(b) Let $M^\bullet$ be a cosimplicial object of $\mathcal{C}$ which is a module over the underlying cosimplicial algebra of $B^\bullet$ such that each of the maps $B^p \otimes_{B^q} M^q \to M^p$ is an equivalence. Let $M = \varprojlim M^\bullet$, regarded as a B-module object of $\mathcal{C}$. Then we must show that the canonical map $B^p \otimes_B M \to M^p$ is an equivalence for each $p \geqslant 0$. To prove this, we note that since f is flat, the map $\tau_{\geqslant 0}B^p \otimes_{\tau_{\geqslant 0}B^q} B^q \to B^p$ is an equivalence for every morphism $[p] \to [q]$ in $\mathbf{\Delta}_+$. Let us regard $M^\bullet$ as a cosimplicial module over the underlying cosimplicial algebra of $\tau_{\geqslant 0}B^\bullet$. Using Lemma D.3.5.6, we conclude that each of the maps $\tau_{\geqslant 0}B^p \otimes_{\tau_{\geqslant 0}B^q} M^q \to M^p$ is an equivalence. Combining our assumption that $\chi|_{\mathrm{CAlg}_A^{\mathrm{cn}}}$ is a sheaf with respect to the fpqc topology and Proposition HA.5.2.2.36 , we conclude that each of the maps $\tau_{\geqslant 0}B^p \otimes_{\tau_{\geqslant 0}B} M \to M^p$ is an equivalence for $p \geqslant 0$. The desired result now follows from Lemma D.3.5.6.

□

D.6.2 Flat Descent for Prestable ∞-Categories

The criterion of Proposition D.6.1.3 has the virtue of making sense at the level of *prestable* ∞-categories:

Definition D.6.2.1. Let A be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a prestable A-linear ∞-category. We will say that $\mathcal{C}$ *satisfies flat descent* if the functor

$$\chi : \mathrm{CAlg}_A^{\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty \qquad B \mapsto B \otimes_A \mathcal{C}$$

is a $\widehat{\mathcal{C}\mathrm{at}}_\infty$-valued sheaf with respect to the fpqc topology on $(\mathrm{CAlg}^{\mathrm{cn}}_A)^{\mathrm{op}}$. We will say that $\mathcal{C}$ *satisfies flat hyperdescent* if the functor χ is a hypercomplete sheaf with respect to the fpqc topology.

Remark D.6.2.2. Let A be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be an stable A-linear ∞-category. It follows from Proposition D.6.1.3 that $\mathcal{C}$ satisfies flat (hyper)descent when regarded as a stable A-linear ∞-category (in the sense of Definition D.6.1.2) if and only if it satisfies flat (hyper)descent when regarded as an additive A-linear ∞-category (in the sense of Definition D.6.2.1).

Proposition D.6.2.3. *Let A be connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a prestable A-linear ∞-category. Then:*

(1) *If $\mathcal{C}$ satisfies flat descent, then the stable A-linear ∞-category* $\mathrm{Sp}(\mathcal{C})$ *satisfies flat descent.*

(2) *If $\mathcal{C}$ satisfies flat hyperdescent, then the stable A-linear ∞-category* $\mathrm{Sp}(\mathcal{C})$ *satisfies flat hyperdescent.*

Proof. We will prove (2); the proof of (1) is similar. Assume that $\mathcal{C}$ satisfies flat hyperdescent; we wish to show that $\mathrm{Sp}(\mathcal{C})$ has the same property. By virtue of Proposition D.6.1.3, it will suffice to show that the construction

$$\mathrm{CAlg}^{\mathrm{cn}}_A \to \widehat{\mathcal{C}\mathrm{at}}_\infty \qquad B \mapsto B \otimes_A \mathrm{Sp}(\mathcal{C}) \simeq \mathrm{Sp}(\mathrm{LMod}_B(\mathcal{C}))$$

is a hypercomplete sheaf with respect to the fpqc topology. We will show that this functor satisfies the hypotheses of Proposition A.5.7.2. It is easy to see that the construction $B \mapsto \mathrm{Sp}(\mathrm{LMod}_B(\mathcal{C}))$ commutes with finite products. Let B be a connective A-algebra and let $B^\bullet$ be a semicosimplicial object of $\mathrm{CAlg}^{\mathrm{cn}}_B$ which is a flat hypercovering of B; we wish to show that the canonical map $\theta : \mathrm{Sp}(\mathrm{LMod}_B(\mathcal{C})) \to \varprojlim \mathrm{Sp}(\mathrm{LMod}_{B^\bullet}(\mathcal{C}))$ is an equivalence of ∞-categories. The functor θ factors as a composition

$$\mathrm{Sp}(\mathrm{LMod}_B(\mathcal{C})) \xrightarrow{\theta'} \mathrm{Sp}(\varprojlim \mathrm{LMod}_{B^\bullet}(\mathcal{C})) \xrightarrow{\theta''} \varprojlim \mathrm{Sp}(\mathrm{LMod}_{B^\bullet}(\mathcal{C})),$$

where θ' is an equivalence of ∞-categories by virtue of our assumption that the prestable B-linear ∞-category $\mathcal{C}$ satisfies flat hyperdescent. It will therefore suffice to show that the functor θ'' is also an equivalence of ∞-categories. By virtue of Remark C.3.2.5, it will suffice to show that the cosimplicial ∞-category $\mathrm{LMod}_{B^\bullet}(\mathcal{C})$ is given by a diagram in $\mathsf{Groth}^{\mathrm{lex}}_\infty$: that is, that for each morphism $[m] \to [n]$ in $\mathbf{\Delta}_+$, the associated functor $\mathrm{LMod}_{B^m}(\mathcal{C}) \to \mathrm{LMod}_{B^n}(\mathcal{C})$ (given by extension of scalars) is left exact. Since the forgetful functor $\mathrm{LMod}_{B^n}(\mathcal{C}) \to \mathcal{C}$ is both conservative and left exact, we are reduced to proving the left exactness of the composite functor

$$\mathrm{LMod}_{B^m}(\mathcal{C}) \to \mathrm{LMod}_{B^n}(\mathcal{C}) \to \mathcal{C} \qquad C \mapsto B^n \otimes_{B^m} C.$$

To prove this, let $\mathcal{E} \subseteq \mathrm{RMod}^{\mathrm{cn}}_{B^m}$ be the full subcategory spanned by those connective right B^m-modules M for which the functor

$$\mathrm{LMod}_{B^m}(\mathcal{C}) \to \mathcal{C} \qquad C \mapsto M \otimes_{B^m} C$$

is left exact. Since filtered colimits in $\mathcal{C}$ are left exact, the ∞-category $\mathcal{E}$ is closed under filtered colimits. We wish to show that $B^n \in \mathcal{E}$. Our assumption that $B^\bullet$ is a flat hypercovering of B guarantees that B^n is flat as a module over B^m and can therefore be obtained as a filtered colimit of free B^m-modules of finite rank (Theorem HA.7.2.2.15). It will therefore suffice to show that $\mathcal{E}$ contains all free B^m-modules of finite rank. Since $\mathcal{E}$ is closed under the formation of direct sums, we are reduced to proving that $\mathcal{E}$ contains the module B^m itself, which is equivalent to the left exactness of the forgetful functor $\mathrm{LMod}_{B^m}(\mathcal{C}) \to \mathcal{C}$. □

D.6.3 The Descent Theorem

We can now state the main result of this section:

Theorem D.6.3.1. *Let A be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a prestable A-linear ∞-category. If $\mathcal{C}$ is complete (see Definition C.1.2.12), then $\mathcal{C}$ satisfies flat hyperdescent.*

We will give the proof Theorem D.6.3.1 later in this section. For the moment, let us describe some of its consequences.

Corollary D.6.3.2. *Let A be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{A}$ be an abelian A-linear ∞-category. Then $\mathcal{A}$ satisfies flat hyperdescent.*

Proof. We will show that $\mathcal{C}$ satisfies the hypotheses of Proposition A.5.7.2. Since the functor $B \mapsto \mathrm{LMod}_B(\mathcal{A})$ commutes with finite products, it will suffice to show that for every flat hypercovering $B^\bullet$ of an object $B \in \mathrm{CAlg}^{\mathrm{cn}}_A$, the canonical map $\theta : \mathrm{LMod}_B(\mathcal{A}) \to \varprojlim \mathrm{LMod}_{B^\bullet}(\mathcal{A})$ is an equivalence of ∞-categories.

Let $\mathcal{C}$ be a complete prestable A-linear ∞-category satisfying $\mathcal{C}^\heartsuit \simeq \mathcal{A}$ (the existence of $\mathcal{C}$ follows from Example D.1.3.9). It follows from Theorem D.6.3.1 that $\mathcal{C}$ satisfies flat hyperdescent, so that the canonical map $\mathrm{LMod}_B(\mathcal{C}) \to \varprojlim \mathrm{LMod}_{B^\bullet}(\mathcal{C})$ is an equivalence. Here it suffices to take the limit of the underlying cosemisimplicial ∞-category of $\mathrm{LMod}_{B^\bullet}(\mathcal{C})$, in which the transition functors are left exact. Passing to hearts, we deduce that the map θ is an equivalence, as desired. □

Corollary D.6.3.3. *Let A be an $\mathbb{E}_\infty$-ring. Then the stable A-linear ∞-category Mod_A satisfies flat hyperdescent.*

Proof. Without loss of generality, we may assume that A is the sphere spectrum. Then A is connective. By virtue of Proposition D.6.2.3, it will suffice to show that the prestable ∞-category $\mathrm{Mod}^{\mathrm{cn}}_A$ satisfies flat hyperdescent, which follows immediately from Theorem D.6.3.1. □

Corollary D.6.3.4. *Let $R^{\bullet} : \mathbf{\Delta}_{s,+} \to \mathrm{CAlg}$ be a flat hypercovering of an $\mathbb{E}_{\infty}$-ring $R = R^{-1}$, let M be an R-module spectrum, and let $M^{\bullet}$ be the cosemisimplicial $R^{\bullet}|_{\mathbf{\Delta}_s}$-module spectrum given levelwise by the formula $M^n = M \otimes_R R^n$. Then the canonical map $M \to \varprojlim M^{\bullet}$ is an equivalence.*

Proof. Combine Proposition A.5.7.2, Proposition HA.5.2.2.36 , and Corollary D.6.3.3. □

Theorem D.6.3.5. *The identity functor* CAlg → CAlg *is a hypercomplete* CAlg*-valued sheaf on* $\mathrm{CAlg}^{\mathrm{op}}$ *(with respect to the fpqc topology).*

Remark D.6.3.6. Theorem D.6.3.5 implies that the fpqc topology on the ∞-category $\mathrm{CAlg}^{\mathrm{op}}$ is *subcanonical*.

Proof of Theorem D.6.3.5. We will show that the identity functor id : CAlg → CAlg satisfies the hypotheses of Proposition A.5.7.2. Since the functor id clearly preserves finite products, it will suffice to show that every hypercovering $R^{\bullet} : \mathbf{\Delta}_{s,+} \to \mathrm{CAlg}$ is a limit diagram in CAlg. This is an immediate consequence of Corollary D.6.3.4. □

D.6.4 Digression: Faithfully Flat Monads

We now introduce an auxiliary notion which will be useful in the proof of Theorem D.6.3.1.

Definition D.6.4.1. Let $\mathcal{C}$ be a prestable ∞-category which admits finite limits, let $T : \mathcal{C} \to \mathcal{C}$ be a monad, and let $T_{\mathrm{red}} : \mathcal{C} \to \mathcal{C}$ be the cofiber of the unit map $\mathrm{id} \to T$ (formed in the ∞-category $\mathrm{Fun}(\mathcal{C}, \mathcal{C})$). We will say that T is *faithfully flat* if the functor T is right exact and the functor T_{red} is left exact.

Remark D.6.4.2. In the situation of Definition D.6.4.1, the right exactness of T guarantees the right exactness of T_{red}, and the left exactness of T_{red} guarantees the left exactness of T.

Remark D.6.4.3. Let $\mathcal{C}$ be a prestable ∞-category which admits finite limits and let $T : \mathcal{C} \to \mathcal{C}$ be a faithfully flat monad. For each object $C \in \mathcal{C}$ and each integer $n \geqslant 0$, let $\pi_n C \in \mathcal{C}^{\heartsuit}$ denote the nth homotopy object of $\Sigma^{\infty}(C)$ taken with respect to the natural t-structure on the Spanier-Whitehead ∞-category $\mathrm{SW}(\mathcal{C})$ of Construction C.1.1.1. The cofiber sequence $C \to TC \to T_{\mathrm{red}} C$ determines a long exact sequence

$$\cdots \to \pi_{n+1} T_{\mathrm{red}} C \xrightarrow{\delta_n} \pi_n C \to \pi_n TC \to \pi_n T_{\mathrm{red}} C \xrightarrow{\delta_{n-1}} \pi_{n-1} C,$$

depending functorially on the object C. We therefore have a commutative diagram

$$\begin{array}{ccc} \pi_{n+1} T_{\mathrm{red}} C & \xrightarrow{\delta_n} & \pi_n C \\ \downarrow & & \downarrow \\ \pi_{n+1} T_{\mathrm{red}}(\tau_{\leqslant n} C) & \longrightarrow & \pi_n(\tau_{\leqslant n} C), \end{array}$$

where the lower right corner vanishes (by virtue of our assumption that the functor T_{red} is left exact) and the right horizontal map is an isomorphism. It follows that each boundary map δ_n vanishes: that is, we have short exact sequences $0 \to \pi_n C \to \pi_n TC \to \pi_n T_{\mathrm{red}} C \to 0$ for each $n \geqslant 0$.

Remark D.6.4.4. Let A be a connective $\mathbb{E}_2$-ring and let $\mathcal{C}$ be a prestable A-linear ∞-category. For every connective $\mathbb{E}_1$-algebra B over A, we have a pair of adjoint functors

$$\mathcal{C} \underset{G}{\overset{F}{\rightleftarrows}} \mathrm{LMod}_B(\mathcal{C})$$

which determines a monad $T \simeq G \circ F$ on $\mathcal{C}$, given on objects by the formula $M \mapsto B \otimes_A M$. Since the functor G is conservative and preserves small colimits, Theorem HA.4.7.3.5 implies that $\mathrm{LMod}_B(\mathcal{C})$ can be identified with the ∞-category $\mathrm{LMod}_T(\mathcal{C})$ of T-modules in $\mathcal{C}$.

Lemma D.6.4.5. *Let A be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ prestable A-linear ∞-category, and let $B \in \mathrm{Alg}_A$ be an $\mathbb{E}_1$-algebra over A which is right faithfully flat over A (Definition D.4.4.1). Then the monad T of Remark D.6.4.4 is faithfully flat.*

Proof. It is clear that the monad T is right t-exact. Let B/A denote the cofiber of the map of A-modules $A \to B$. For each object $C \in \mathcal{C}$, the cofiber of the unit map $C \to TC$ can be identified with $(B/A) \otimes_A C$. We wish to prove that the functor $C \mapsto (B/A) \otimes_A C$ is left exact. We now argue as in the proof of Proposition D.6.2.3. Let $\mathcal{E} \subseteq \mathrm{RMod}_A^{\mathrm{cn}}$ be the full subcategory spanned by those connective right A-modules M for which the construction $C \mapsto M \otimes_A C$ is left exact. It is easy to see that $\mathcal{E}$ contains all free A-modules of finite rank. Since filtered colimits in $\mathcal{C}$ are left exact, the ∞-category $\mathcal{E}$ is closed under filtered colimits in $\mathrm{RMod}_A^{\mathrm{cn}}$, and therefore contains all flat right A-modules (Theorem HA.7.2.2.15). It now suffices to observe that the right faithful flatness of B over A guarantees that B/A is flat as a right A-module (Lemma D.4.4.3). □

Proposition D.6.4.6. *Let $\mathcal{C}$ be a prestable ∞-category, let T be a faithfully flat monad on $\mathcal{C}$, and let $F : \mathcal{C} \to \mathrm{LMod}_T(\mathcal{C})$ be a left adjoint to the forgetful functor $G : \mathrm{LMod}_T(\mathcal{C}) \to \mathcal{C}$. If $\mathcal{C}$ is complete (in the sense of Definition C.1.2.12), then the functor F is comonadic.*

Proof. According to Theorem HA.4.7.3.5 , it will suffice to show that the functor F is conservative and preserves totalizations of F-split cosimplicial objects of $\mathcal{C}$. For each $n \geqslant 0$, define $\pi_n : \mathcal{C} \to \mathcal{C}^{\heartsuit}$ as in Remark D.6.4.3. We first show that F is conservative. Let $\alpha : X \to Y$ be a morphism in $\mathcal{C}$ such that $F(\alpha)$ is an equivalence. Then $T \operatorname{cofib}(\alpha) \simeq GF(\operatorname{cofib}(\alpha)) \simeq G \operatorname{cofib}(F(\alpha)) \simeq 0$. Applying Remark D.6.4.3, we see that the natural map $\pi_n \operatorname{cofib}(\alpha) \to \pi_n T \operatorname{cofib}(\alpha)$ is a monomorphism (in the abelian category $\mathcal{C}^{\heartsuit}$) for each $n \geqslant 0$, so that each $\pi_n \operatorname{cofib}(\alpha)$ vanishes. Since $\mathcal{C}$ is left complete, we conclude that $\operatorname{cofib}(\alpha) \simeq 0$ and therefore α is an equivalence.

Let $X^\bullet$ be an F-split cosimplicial object of $\mathcal{C}$; we wish to show that $X^\bullet$ admits a totalization in $\mathcal{C}$ which is preserved by the functor T. Since the monad T is faithfully flat, it induces an exact functor $T^\heartsuit$ from the abelian category $\mathcal{C}^\heartsuit$ to itself. Note that for every object $C \in \mathcal{C}^\heartsuit$, there exists a monomorphism $C \hookrightarrow T^\heartsuit C$; in particular, the functor $T^\heartsuit$ does not annihilate any nonzero objects of $\mathcal{C}^\heartsuit$. For every object $Y \in \mathcal{C}$, we have canonical isomorphisms $\pi_n TY \simeq T^\heartsuit \pi_n Y$. Since $X^\bullet$ is F-split, it follows that $T^\heartsuit \pi_n X^\bullet$ is a split cosimplicial object of $\mathcal{C}^\heartsuit$ for each $n \geqslant 0$. Let

$$A(n)^0 \xrightarrow{d(n)} A(n)^1 \longrightarrow A(n)^2 \longrightarrow \cdots$$

be the unnormalized chain complex (in $\mathcal{C}^\heartsuit$) associated to the cosimplicial object $\pi_n X^\bullet$. It follows that $T^\heartsuit(A(n)^*)$ is split exact: in particular, we have an exact sequence

$$0 \to K \to T^\heartsuit A(n)^0 \to T^\heartsuit A(n)^1 \to \cdots .$$

Since the functor $T^\heartsuit$ is exact, we can write $K = \ker(T^\heartsuit d(n)) \simeq T^\heartsuit \ker d(n)$. Since $T^\heartsuit$ is exact and does not annihilate any nonzero objects of $\mathcal{C}^\heartsuit$, we deduce the exactness of the sequence

$$0 \to \ker d(n) \to A(n)^0 \to A(n)^1 \to \cdots .$$

Applying Corollary **??** (in the stable ∞-category $\mathrm{Sp}(\mathcal{C})$), we deduce that $X^\bullet$ admits a totalization $X \in \mathcal{C}$ and that the natural map $X \to X^0$ induces isomorphisms $\pi_n X \simeq \ker d(n) \subseteq \pi_n X^0$ for every integer $n \geqslant 0$. Using the exactness of $T^\heartsuit$ and the identification $T^\heartsuit \pi_n X \simeq \pi_n TX$, we see that the natural map $\alpha : TX \to \varprojlim TX^\bullet$ determines an exact sequence

$$0 \to \pi_n TX \to T^\heartsuit A(n)^0 \to T^\heartsuit A(n)^1 \to \cdots$$

so that α is an equivalence (again by virtue of Corollary HA.1.2.4.12). □

D.6.5 The Proof of Theorem D.6.3.1

We now turn to the proof of Theorem D.6.3.1. We begin by giving a concrete criterion for flat descent, which follows easily from the Barr-Beck theorem:

Proposition D.6.5.1. *Let A be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a prestable A-linear ∞-category. Then $\mathcal{C}$ satisfies flat descent if and only if, for every faithfully flat map of connective A-algebras $B \to B^0$, the base-change functor $\mathrm{LMod}_B(\mathcal{C}) \to \mathrm{LMod}_{B^0}(\mathcal{C})$ is comonadic.*

Proof. Using Proposition A.3.3.1 and Lemma D.3.5.5, we see that $\mathcal{C}$ satisfies flat descent if and only if, for every faithfully flat morphism of connective A-algebras $f : B \to B^0$, the following condition is satisfied:

($*'$) Let $B^\bullet : \mathbf{\Delta}_+ \to \mathrm{CAlg}_A$ be the Čech nerve of f (regarded as a morphism in $\mathrm{CAlg}_A^{\mathrm{op}}$, and let $\mathcal{C}^\bullet$ be the augmented cosimplicial ∞-category given by the formula $\mathcal{C}^\bullet = \mathrm{LMod}_{B^\bullet}(\mathcal{C})$. Then $\mathcal{C}^\bullet$ is a limit diagram in $\widehat{\mathcal{C}\mathrm{at}}_\infty$.

The desired result now follows from Lemma D.3.5.8. □

Proof of Theorem D.6.3.1. Let A be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a prestable A-linear ∞-category; we wish to show that $\mathcal{C}$ satisfies flat hyperdescent. We first prove that $\mathcal{C}$ satisfies flat descent. By virtue of Proposition D.6.5.1, it will suffice to show that for every faithfully flat morphism between connective A-algebras $B \to B^0$, the base-change functor $F : \mathrm{LMod}_B(\mathcal{C}) \to \mathrm{LMod}_{B^0}(\mathcal{C})$ is comonadic. It follows from Remark D.6.4.4 that we can identify $\mathrm{LMod}_{B^0}(\mathcal{C})$ with the ∞-category $\mathrm{LMod}_T(\mathrm{LMod}_B(\mathcal{C}))$, where T denotes the monad given by $C \mapsto B^0 \otimes_B C$. The faithful flatness of B^0 over B guarantees that the monad T is faithfully flat (Lemma D.6.4.5), so that the comonadicity of F is a consequence of Proposition D.6.4.6.

For each integer $n \geqslant 0$, let $\chi_n : \mathrm{CAlg}_A^{\mathrm{cn}} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ denote the functor given by

$$\chi_n(B) = (\tau_{\leqslant n}\,\mathcal{S}) \otimes \mathrm{Mod}_B^{\mathrm{cn}} \otimes_{\mathrm{Mod}_A^{\mathrm{cn}}} \mathcal{C} \simeq \tau_{\leqslant n}\,\mathrm{LMod}_B(\mathcal{C}),$$

which assigns to each connective A-algebra B the ∞-category of n-truncated B-module objects of $\mathcal{C}$. We claim that χ_n is an $\mathcal{P}\mathrm{r}^{\mathrm{L}}$-valued sheaf with respect to the fpqc topology. To prove this, it will suffice to show that for every faithfully flat map between connective A-algebras $B \to B^0$ as above having Čech nerve $B^\bullet$, the upper horizontal map in the commutative diagram of ∞-categories

$$\begin{array}{ccc} \tau_{\leqslant n}\,\mathrm{LMod}_B(\mathcal{C}) & \longrightarrow & \varprojlim \tau_{\leqslant n}\,\mathrm{LMod}_{B^\bullet}(\mathcal{C}) \\ \downarrow & & \downarrow \\ \mathrm{LMod}_B(\mathcal{C}) & \longrightarrow & \varprojlim \mathrm{LMod}_{B^\bullet}(\mathcal{C}) \end{array}$$

is an equivalence of ∞-categories (beware that the vertical maps do not preserve small colimits). It follows from the first part of the proof that the lower horizontal map preserves small colimits, and the vertical maps are fully faithful embeddings. Unwinding the definitions, we are reduced to proving that an object $C \in \mathrm{LMod}_B(\mathcal{C})$ is n-truncated whenever $B^0 \otimes_B C$ is n-truncated. This is clear: the prestable ∞-category $\mathcal{C}$ is complete and therefore also separated, so that an object $C \in \mathrm{LMod}_B(\mathcal{C})$ is n-truncated if and only if the homotopy objects $\pi_m C$ vanish for $m > n$, and we have monomorphisms $\pi_m C \to \pi_m(B^0 \otimes_B C)$ in the abelian category $\mathcal{C}^\heartsuit$ by virtue of Remark D.6.4.3.

Note that for each $n \geqslant 0$, the functor χ_n takes values in the full subcategory of $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ spanned by the presentable $(n+1)$-categories. Since this subcategory is itself an $(n+2)$-category, the functor χ_n is automatically $(n+1)$-truncated and in particular hypercomplete.

The completeness of $\mathcal{C}$ implies that each of the prestable ∞-categories $\mathrm{LMod}_B(\mathcal{C})$ is also complete (Proposition D.5.1.3), so that the functor $B \mapsto \mathrm{LMod}_B(\mathcal{C})$ is given by the inverse limit $\varprojlim_{n \geqslant 0} \chi_n(B)$ in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ and is therefore also hypercomplete. □

D.6.6 Effective Descent for Complete Prestable ∞-Categories

We now discuss a categorification of Theorem D.6.3.1, where our attention is focused not on objects of A-linear ∞-categories, but on the A-linear ∞-categories themselves.

Notation D.6.6.1. For every connective $\mathbb{E}_2$-ring A, let $\mathrm{LinCat}_A^{\mathrm{comp}}$ denote the full subcategory of $\mathrm{LinCat}_A^{\mathrm{PSt}}$ spanned by those prestable A-linear ∞-categories which are complete (in the sense of Definition C.1.2.12). It follows from Proposition D.5.1.3 that for any morphism $\phi : A \to B$ of connective $\mathbb{E}_2$-rings, the extension of scalars functor $\mathcal{C} \mapsto B \otimes_A \mathcal{C}$ carries $\mathrm{LinCat}_A^{\mathrm{comp}}$ into $\mathrm{LinCat}_B^{\mathrm{comp}}$. Consequently, we can regard the construction $A \mapsto \mathrm{LinCat}_A^{\mathrm{comp}}$ as a functor from the ∞-category $\mathrm{Alg}_{\mathbb{E}_2}^{\mathrm{cn}}$ of connective $\mathbb{E}_2$-rings to the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty$.

Proposition D.6.6.2. *The functor*

$$\mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty \qquad A \mapsto \mathrm{LinCat}_A^{\mathrm{comp}}$$

is a $\widehat{\mathcal{C}\mathrm{at}}_\infty$-valued sheaf with respect to the fpqc topology on $(\mathrm{CAlg}^{\mathrm{cn}})^{\mathrm{op}}$.

Remark D.6.6.3. We will see in a moment that the sheaf $A \mapsto \mathrm{LinCat}_A^{\mathrm{comp}}$ is hypercomplete (Theorem D.6.8.1).

Proof of Proposition D.6.6.2. We will show that the construction $A \mapsto \mathrm{LinCat}_A^{\mathrm{comp}}$ satisfies the hypotheses of Proposition A.3.3.1. Note that since the construction $A \mapsto \mathrm{LinCat}_A^{\mathrm{comp}}$ satisfies descent for the étale topology (Remark D.6.8.2), it commutes with finite products. It will therefore suffice to verify condition (2) of Proposition A.3.3.1. Suppose we are given a faithfully flat map of $\mathbb{E}_\infty$-rings $f : A \to A^0$ having Čech nerve $A^\bullet$. We wish to show that the induced map $\mathrm{LinCat}_A^{\mathrm{comp}} \to \varprojlim \mathrm{LinCat}_{A^\bullet}^{\mathrm{comp}}$ is an equivalence of ∞-categories. We proceed by showing that this functor satisfies the conditions of Proposition HA.5.2.2.36 :

(a) Fix an morphism $F : \mathcal{C} \to \mathcal{D}$ in the ∞-category $\mathrm{LinCat}_A^{\mathrm{comp}}$ whose image in $\mathrm{LinCat}_{A^0}^{\mathrm{comp}}$ is an equivalence. It follows that F induces an equivalence of cosimplicial ∞-categories $\mathrm{LMod}_{A^\bullet}(\mathcal{C}) \to \mathrm{LMod}_{A^\bullet}(\mathcal{D})$. We have a commutative diagram

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{F} & \mathcal{D} \\ \downarrow & & \downarrow \\ \varprojlim \mathrm{LMod}_{A^\bullet}(\mathcal{C}) & \longrightarrow & \varprojlim \mathrm{LMod}_{A^\bullet}(\mathcal{D}) \end{array}$$

where the vertical maps are equivalences of ∞-categories (since $\mathcal{C}$ and $\mathcal{D}$ satisfy flat descent by virtue of Theorem D.6.3.1). It follows that F is an equivalence of ∞-categories.

(b) Let $q : \mathcal{E} \to \mathrm{CAlg}^{\mathrm{cn}}$ be a coCartesian fibration classified by the functor $A \mapsto \mathrm{LinCat}_A^{\mathrm{comp}}$: more informally, $\mathcal{E}$ is the ∞-category whose objects are pairs $(A, \mathcal{C})$ where A is a connective $\mathbb{E}_\infty$-ring and $\mathcal{C}$ is a complete prestable A-linear ∞-category. Suppose we are given a diagram $X^\bullet : \mathbf{\Delta} \to \mathcal{E}$ which carries each morphism in $\mathbf{\Delta}$ to a q-coCartesian morphism of $\mathcal{E}$ and satisfies $q(X^\bullet) = A^\bullet$. We must show that $X^\bullet$ can be extended to a q-limit diagram $\overline{X}^\bullet : \mathbf{\Delta}_+ \to \mathcal{E}$ which also carries each morphism of $\mathbf{\Delta}_+$ to a q-coCartesian morphism in $\mathcal{E}$. Write $X^\bullet = (A^\bullet, \mathcal{C}^\bullet)$. To prove the existence of the q-limit diagram $\overline{X}^\bullet$, we must show that the cosimplicial object $\mathcal{C}^\bullet$ admits a totalization $\mathcal{C}$ in the ∞-category $\mathrm{LinCat}_A^{\mathrm{PSt}}$ of prestable A-linear ∞-categories, and that $\mathcal{C}$ is complete. Note that the completeness of $\mathcal{C}$ is automatic, since the ∞-category of complete prestable ∞-categories is a localization of Groth_∞ and is therefore closed under small limits (Proposition C.3.6.3). To prove that $\mathcal{C}^\bullet$ admits a totalization, it will suffice to show that the underlying cosemisimplicial object $([n] \in \mathbf{\Delta}_s) \mapsto \mathcal{C}^n$ admits a totalization in the ∞-category Groth_∞. This is a special case of Proposition **??**, since the flatness of A^0 over A guarantees that the transition functors $\mathcal{C}^m \to \mathcal{C}^n \simeq \mathrm{LMod}_{A^n}(\mathcal{C}^m)$ associated to injective maps $[m] \hookrightarrow [n]$ are left exact.

To complete the proof, we must show that the diagram $\overline{X}^\bullet$ carries each morphism $\alpha : [m] \to [n]$ in $\mathbf{\Delta}_+$ to a q-coCartesian morphism in $\mathcal{E}$. If $m \neq -1$, then this follows from the analogous assumption on $X^\bullet$. If $m = -1$, then we can factor α as a composition $[-1] \to [0] \to [n]$ and thereby reduce to the case $n = 0$. In this case, the desired result follows from the calculation

$$\mathrm{LMod}_{A^0}(\mathcal{C}) \simeq \mathrm{LMod}_{A^0}(\varprojlim \mathcal{C}^\bullet) \simeq \varprojlim \mathrm{LMod}_{A^0}(\mathcal{C}^\bullet) \simeq \varprojlim \mathcal{C}^{\bullet+1} \simeq \mathcal{C}^0 .$$

□

D.6.7 Digression on Hypercompleteness

Our next goal is to show that the sheaf $A \mapsto \mathrm{LinCat}_A^{\mathrm{comp}}$ of Proposition D.6.6.2 is hypercomplete. We begin with some general remarks about hypercomplete objects of ∞-topoi.

Lemma D.6.7.1. *Let $\mathcal{X}$ be an ∞-topos containing an object X. The following conditions are equivalent:*

(1) *The object $X \in \mathcal{X}$ is hypercomplete.*

(2) *For every ∞-connective morphism $E \to E'$ in $\mathcal{X}$, the map $\mathrm{Map}_{\mathcal{X}}(E', X) \to \mathrm{Map}_{\mathcal{X}}(E, X)$ is surjective on connected components.*

Proof. The implication (1) ⇒ (2) is obvious. Suppose that (2) is satisfied. We wish to prove that for every ∞-connective morphism $\alpha : E \to E'$, the map $\theta_\alpha : \mathrm{Map}_{\mathcal{X}}(E', X) \to \mathrm{Map}_{\mathcal{X}}(E, X)$ is a homotopy equivalence. We will prove that θ_α is n-connective using induction on n, the case $n = -1$ being vacuous. Since θ_α is surjective on connected components (by (2)), it will suffice to show that the diagonal map

$$\mathrm{Map}_{\mathcal{X}}(E', X) \to \mathrm{Map}_{\mathcal{X}}(E', X) \times_{\mathrm{Map}_{\mathcal{X}}(E,X)} \mathrm{Map}_{\mathcal{X}}(E', X) \simeq \mathrm{Map}_{\mathcal{X}}(E' \amalg_E E', X)$$

is $(n-1)$-connected. This follows from the inductive hypothesis, since the codiagonal $E' \amalg_E E' \to E'$ is also ∞-connective. □

Lemma D.6.7.2. *Let $\mathcal{X}$ be an ∞-topos. Then the collection of hypercomplete objects of $\mathcal{X}$ is closed under small coproducts.*

Proof. Suppose we are given a collection of hypercomplete objects $\{X_\alpha\}_{\alpha \in A}$ having coproduct $X \in \mathcal{X}$. We wish to prove that X is hypercomplete. According to Lemma D.6.7.1, it will suffice to show that if $\phi : E \to E'$ is an ∞-connective morphism in $\mathcal{X}$, then the induced map $\mathrm{Map}_{\mathcal{X}}(E', X) \to \mathrm{Map}_{\mathcal{X}}(E, X)$ is surjective on connected components. Fix a morphism $f : E \to X$. For each index α, let E_α denote the fiber product $X_\alpha \times_X E$, so that the induced map $E_\alpha \to E'$ admits a factorization

$$E_\alpha \xrightarrow{g_\alpha} E'_\alpha \xrightarrow{h_\alpha} E'$$

where g_α is an effective epimorphism and h_α is a monomorphism. Let $E'' = \amalg_\alpha E'_\alpha$, so that the maps h_α induce a map $\psi : E'' \to E'$. We claim that ψ is an equivalence. Since ϕ factors through ψ, we deduce that ψ is an effective epimorphism. It will therefore suffice to show that the diagonal map

$$\amalg_\alpha E'_\alpha E'' \to E'' \times_{E'} E'' \simeq \amalg_{\alpha,\beta} E'_\alpha \times_{E'} E'_\beta$$

is an equivalence. Because each h_α is a monomorphism, each of the diagonal maps $E'_\alpha \to E'_\alpha \times_{E'} E'_\alpha$ is an equivalence; we are therefore reduced to proving that $E'_\alpha \times_{E'} E'_\beta \simeq \varnothing$ for $\alpha \neq \beta$. This follows from the existence of an effective epimorphism

$$\varnothing \simeq E_\alpha \times_E E_\beta \to E_\alpha \times_{E'} E_\beta \to E'_\alpha \times_{E'} E'_\beta.$$

This completes the proof that ψ is an equivalence, so that we can identify ϕ with the coproduct of morphisms $\phi_\alpha : E_\alpha \to E'_\alpha$. To prove that f factors through ϕ, it suffices to show that each restriction $f|_{E_\alpha}$ factors through ϕ_α. This follows from our assumption that X_α is hypercomplete, since ϕ_α is a pullback of ϕ and therefore ∞-connective. □

Lemma D.6.7.3. *Let $\mathcal{X}$ be an ∞-topos, and let $f : U \to X$ be an effective epimorphism in $\mathcal{X}$. Assume that U is hypercomplete. Then the following conditions are equivalent:*

(1) *The object X is hypercomplete.*

(2) *The fiber product $U \times_X U$ is hypercomplete.*

Proof. The implication (1) ⇒ (2) is obvious, since the full subcategory $\mathcal{X}^{\mathrm{hyp}} \subseteq \mathcal{X}$ spanned by the hypercomplete objects is closed under small limits. We will prove that (2) ⇒ (1). Let $L : \mathcal{X} \to \mathcal{X}^{\mathrm{hyp}}$ be a left adjoint to the inclusion, so that L is left exact (see §HTT.6.5.2). Let $U_\bullet$ be a Čech nerve of the map $U \to X$, so that $LU_\bullet$ is a Čech nerve of the induced map $LU \to LX$. Using assumption (2) and our assumption that U is hypercomplete, we deduce that U_0 and U_1 are both hypercomplete, so that $U_n \simeq U_1 \times_{U_0} \cdots \times_{U_0} U_1$ is hypercomplete for all $n \geqslant 0$. It follows that the canonical map $U_\bullet \to LU_\bullet$ is an equivalence. We therefore obtain equivalences $X \simeq |U_\bullet| \simeq |LU_\bullet| \simeq LX$, so that X is also hypercomplete (the last equivalence here results from the observation that $LU \to LX$ is an effective epimorphism, since it can be identified with the composition of f with the ∞-connective map $X \to LX$). □

Proposition D.6.7.4. *Let $\mathcal{C}$ be an ∞-category which admits finite limits and is equipped with a Grothendieck topology. Assume that every object $C \in \mathcal{C}$ represents a functor $e_C : \mathcal{C}^{\mathrm{op}} \to \mathcal{S}$ which is a hypercomplete sheaf on $\mathcal{C}$. Let $\mathscr{F} : \mathcal{C}^{\mathrm{op}} \to \mathcal{S}$ be a sheaf on $\mathcal{C}$. The following conditions are equivalent:*

(1) *The sheaf $\mathscr{F}$ is hypercomplete.*

(2) *For every pair of objects $C, C' \in \mathcal{C}$ and maps $\eta : e_C \to \mathscr{F}$, $\eta' : e_{C'} \to \mathscr{F}$, the fiber product $e_C \times_{\mathscr{F}} e_{C'}$ is hypercomplete.*

(3) *For every object $C \in \mathcal{C}$ and every pair of maps $\eta, \eta' : e_C \to \mathscr{F}$, the equalizer of the diagram*

$$e_C \underset{\eta'}{\overset{\eta}{\rightrightarrows}} \mathscr{F}$$

is hypercomplete.

Proof. The implication (1) ⇒ (3) is clear, since the collection of hypercomplete objects of $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is stable under small limits. The implication (3) ⇒ (2) follows from the observation that $e_C \times_{\mathscr{F}} e_{C'}$ can be identified with the equalizer of the pair of maps

$$\mathscr{F} \leftarrow e_C \leftarrow e_{C \times C'} \to e_{C'} \to \mathscr{F} .$$

We will prove that (2) ⇒ (1). Let $\mathscr{F}' = \amalg_{\eta \in \mathscr{F}(C)} e_C$, so we have an effective epimorphism $\mathscr{F}' \to \mathscr{F}$. Lemma D.6.7.2 implies that $\mathscr{F}'$ is hypercomplete. By virtue of Lemma D.6.7.3, it will suffice to prove that the fiber product $\mathscr{F}' \times_{\mathscr{F}} \mathscr{F}'$ is hypercomplete. This fiber product can be identified with the coproduct

$$\amalg_{\eta \in \mathscr{F}(C), \eta' \in \mathscr{F}(C')} e_C \times_{\mathscr{F}} e_{C'}$$

which is hypercomplete by virtue of assumption (2) and Lemma D.6.7.2. □

D.6.8 Effective Hyperdescent for Complete Prestable ∞-Categories

Our final goal in this section is to establish a slightly stronger form of Proposition D.6.6.2:

Theorem D.6.8.1. *The functor*

$$\mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty \qquad A \mapsto \mathrm{LinCat}_A^{\mathrm{comp}}$$

is a hypercomplete $\widehat{\mathcal{C}\mathrm{at}}_\infty$*-valued sheaf with respect to the fpqc topology on* $(\mathrm{CAlg}^{\mathrm{cn}})^{\mathrm{op}}$.

Remark D.6.8.2. Theorem D.6.8.1 can be regarded as an analogue for the fpqc topology of some of the results of §D.4: it follows from Theorem D.4.1.2 and Proposition D.5.1.3 that the construction $A \mapsto \mathrm{LinCat}_A^{\mathrm{comp}}$ satisfies descent for the étale topology.

Remark D.6.8.3. In the statement of Theorem D.6.8.1, the restriction to the setting of *complete* prestable ∞-categories is needed only to guarantee that the prestable ∞-categories $\mathcal{C}$ in question satisfy flat hyperdescent. Several variants are possible: for example, if we let $\mathrm{LinCat}_A^{\flat}$ denote the full subcategory of $\mathrm{LinCat}_A^{\mathrm{PSt}}$ spanned by those prestable ∞-categories which satisfy flat (hyper)descent, then the same argument shows that the construction $A \mapsto \mathrm{LinCat}_A^{\flat}$ is a (hypercomplete) sheaf with respect to the fpqc topology.

Corollary D.6.8.4. *The functor*

$$\mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty \qquad A \mapsto \mathrm{LinCat}_A^{\mathrm{Ab}}$$

is a hypercomplete $\widehat{\mathcal{C}\mathrm{at}}_\infty$*-valued sheaf with respect to the fpqc topology on* $(\mathrm{CAlg}^{\mathrm{cn}})^{\mathrm{op}}$.

Remark D.6.8.5. The sheaf $A \mapsto \mathrm{LinCat}_A^{\mathrm{Ab}}$ is automatically hypercomplete, since it is 2-truncated.

Proof of Corollary D.6.8.4. We will show that the construction $A \mapsto \mathrm{LinCat}_A^{\mathrm{Ab}}$ satisfies hypothesis (2) of Proposition A.3.3.1 (hypothesis (1) is easy and left to the reader). Suppose we are given a faithfully flat map of $\mathbb{E}_\infty$-rings $f : A \to A^0$ having Čech nerve $A^\bullet$. We wish to show that the induced map $\theta : \mathrm{LinCat}_A^{\mathrm{Ab}} \to \varprojlim \mathrm{LinCat}_{A^\bullet}^{\mathrm{Ab}}$ is an equivalence of ∞-categories. We first claim that θ is fully faithful. Let $\mathcal{C}$ and $\mathcal{D}$ be abelian A-linear ∞-categories. Unwinding the definitions, we wish to prove that the canonical map

$$\begin{aligned} \mathrm{Map}_{\mathrm{LinCat}_A^{\mathrm{Ab}}}(\mathcal{C}, \mathcal{D}) &\to \varprojlim \mathrm{Map}_{\mathrm{LinCat}_{A^\bullet}^{\mathrm{Ab}}}(A^\bullet \otimes_A \mathcal{C}, A^\bullet \otimes_A \mathcal{D}) \\ &\simeq \varprojlim \mathrm{Map}_{\mathrm{LinCat}_A^{\mathrm{Ab}}}(\mathcal{C}, A^\bullet \otimes_A \mathcal{D}) \end{aligned}$$

is a homotopy equivalence. To prove this, it suffice to show that the canonical map $\mathcal{D} \to \varprojlim A^\bullet \otimes_A \mathcal{D}$ is an equivalence, which follows from Corollary D.6.3.2 and Proposition C.5.4.21.

To show that θ is essentially surjective, it will suffice to show that θ induces a homotopy equivalence $\theta^{\simeq} : (\mathrm{LinCat}_A^{\mathrm{Ab}})^{\simeq} \to \varprojlim(\mathrm{LinCat}_{A^\bullet}^{\mathrm{Ab}})^{\simeq}$. Let $X^\bullet$ denote the augmented cosimplicial space given by $X^n = (\mathrm{LinCat}_{A^n}^{\mathrm{Ab}})^{\simeq}$ (where, by convention, we set $A^{-1} = A$). For each $n \geqslant -1$, let Y^n denote the full subcategory of $(\mathrm{LinCat}_{A^n}^{\mathrm{comp}})^{\simeq}$ spanned by the complicial prestable A^n-linear ∞-categories. According to Proposition D.5.7.1, the condition that a complete prestable ∞-category be complicial is stable under base change along flat morphisms and can be tested locally for the fpqc topology. Consequently, we can regard the construction $[n] \mapsto Y^n$ as a functor $\mathbf{\Delta}_{s,+} \to \widehat{\mathcal{S}}$. For each $n \geqslant -1$, the construction

$$(\mathcal{C} \in \mathrm{LinCat}_{A^n}^{\mathrm{comp}}) \mapsto (\mathcal{C}^{\heartsuit} \in \mathrm{LinCat}_{A^n}^{\mathrm{Ab}})$$

determines a map of spaces $Y^n \to X^n$, which is a homotopy equivalence by virtue of Example D.1.3.9 and Corollary C.5.9.5. This map depends functorially on n, and therefore exhibits $Y^\bullet$ as the underlying augmented cosemisimplicial space of the augmented cosimplicial space $X^\bullet$. By virtue of Lemma **??**, to show that $X^\bullet$ is a limit diagram in $\widehat{\mathcal{S}}$, it will suffice to show that $Y^\bullet$ is a limit diagram in $\widehat{\mathcal{S}}$. This follows immediately from Theorem D.6.8.1 and Proposition D.5.7.1. □

The proof of Theorem D.6.8.1 will require a brief digression. Suppose that $\mathcal{C}$ is a small ∞-category, and let $\mathscr{F} : \mathcal{C}^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty$ be a presheaf of ∞-categories on $\mathcal{C}$, classified by a Cartesian fibration $p : \widetilde{\mathcal{C}} \to \mathcal{C}$. According to Proposition HTT.3.3.3.1 , we can identify $\varprojlim \mathscr{F}$ with the full subcategory of $\mathrm{Fun}_{\mathcal{C}}(\mathcal{C}, \widetilde{\mathcal{C}})$ spanned by the Cartesian sections of p. Let $X, Y \in \varprojlim \mathscr{F} \subseteq \mathrm{Fun}_{\mathcal{C}}(\mathcal{C}, \widetilde{\mathcal{C}})$ so that the pair (X, Y) determines a functor $\mathcal{C} \to \mathcal{C}' = \mathrm{Fun}(\partial\,\Delta^1, \widetilde{\mathcal{C}}) \times_{\mathrm{Fun}(\partial\,\Delta^1, \mathcal{C})} \mathcal{C}$. We let $\mathcal{D}$ denote the fiber product $\mathrm{Fun}(\Delta^1, \widetilde{\mathcal{C}}) \times_{\mathcal{C}'} \mathcal{C}$. The projection $\mathcal{D} \to \mathcal{C}$ is a right fibration, whose fiber over an object $C \in \mathcal{C}$ can be identified with the Kan complex $\mathrm{Hom}_{\widetilde{\mathcal{C}}_C}(X(C), Y(C))$ (see §HTT.1.2.2). This right fibration is classified by a functor $\underline{\mathrm{Hom}}_{\mathscr{F}}(X, Y) : \mathcal{C}^{\mathrm{op}} \to \mathcal{S}$, given informally by the formula $\underline{\mathrm{Hom}}_{\mathscr{F}}(X, Y)(C) = \mathrm{Map}_{\mathscr{F}(C)}(X(C), Y(C))$. Let $\mathcal{D}_0$ be the full subcategory of $\mathcal{D}$ whose fiber over an object $C \in \mathcal{C}$ is given by the full subcategory of $\mathrm{Hom}_{\widetilde{\mathcal{C}}_C}(X(C), Y(C))$ spanned by the equivalences in $\widetilde{\mathcal{C}}_C$. The projection $\mathcal{D}_0 \to \mathcal{C}$ is also a right fibration, classified by a functor $\underline{\mathrm{Hom}}^{\simeq}_{\mathscr{F}}(X, Y) : \mathcal{C}^{\mathrm{op}} \to \mathcal{S}$.

Proposition D.6.8.6. *Let $\mathcal{C}$ be an ∞-category which admits finite limits and is equipped with a Grothendieck topology. Assume that for every object $C \in \mathcal{C}$, the functor $e_C : \mathcal{C}^{\mathrm{op}} \to \mathcal{S}$ represented by C is a hypercomplete sheaf on $\mathcal{C}$. Let $\mathscr{F} : \mathcal{C}^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty$ be a $\mathcal{C}\mathrm{at}_\infty$-valued sheaf on $\mathcal{C}$. The following conditions are equivalent:*

(1) *The sheaf $\mathscr{F}$ is hypercomplete.*

(2) *For every object $C \in \mathcal{C}$ and every pair of objects $X, Y \in \mathscr{F}(C) \simeq \varprojlim \mathscr{F}|_{\mathcal{C}^{\mathrm{op}}_{/C}}$, the functor $\underline{\mathrm{Hom}}_{\mathscr{F}}(X, Y) : (\mathcal{C}_{/C})^{\mathrm{op}} \to \mathcal{S}$ is a hypercomplete sheaf on $\mathcal{C}_{/C}$.*

Proof. Suppose first that (1) is satisfied; we will prove (2). Replacing $\mathcal{C}$ by $\mathcal{C}_{/C}$, we may suppose that $X, Y \in \varprojlim \mathscr{F}$. For every simplicial set K, let $\mathscr{F}^K$ denote the composition

$$\mathcal{C}^{\mathrm{op}} \xrightarrow{\mathscr{F}} \mathcal{C}\mathrm{at}_\infty \xrightarrow{\mathrm{Fun}(K,\bullet)} \mathcal{C}\mathrm{at}_\infty .$$

and let $*$ denote the constant functor $\mathscr{F}^{\varnothing} : \mathcal{C}^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty$ taking the value Δ^0. Then the pair (X, Y) determines a natural transformation $* \to \mathscr{F}^{\partial \Delta^0}$, and $\underline{\mathrm{Hom}}_{\mathscr{F}}(X, Y)$ can be identified with the fiber product $* \times_{\mathscr{F}^{\partial \Delta^1}} \mathscr{F}^{\Delta^1}$. Since $\mathscr{F}$ is hypercomplete, we deduce that $\mathscr{F}^{\Delta^1}$, $\mathscr{F}^{\partial \Delta^1}$, and $* \simeq \mathscr{F}^{\varnothing}$ are hypercomplete. It follows that $\underline{\mathrm{Hom}}_{\mathscr{F}}(X, Y)$ is a hypercomplete $\mathcal{C}\mathrm{at}_\infty$-valued sheaf on $\mathcal{C}$, and therefore a hypercomplete $\mathcal{S}$-valued sheaf on $\mathcal{C}$ (since the inclusion $\mathcal{S} \subseteq \mathcal{C}\mathrm{at}_\infty$ preserves small limits).

Now assume (2). Fix an object $C \in \mathcal{C}$, and let $f : x \to y$ be a morphism in $\mathscr{F}(C)$. Since $\mathscr{F}$ is a sheaf, we deduce that f is an equivalence if and only if there exists a covering sieve $\{C_\alpha \to C\}$ on C such that the image of f under each of the induced functors $\mathscr{F}(C) \to \mathscr{F}(C_\alpha)$ is an equivalence. Combining this observation with (2) and Lemma D.4.3.2, we deduce:

(∗) For every object $C \in \mathcal{C}$ and every pair of objects $X, Y \in \mathscr{F}(C) \simeq \varprojlim \mathscr{F}|_{\mathcal{C}^{\mathrm{op}}_{/C}}$, the functor $\underline{\mathrm{Hom}}^{\simeq}_{\mathscr{F}}(X, Y) : (\mathcal{C}_{/C})^{\mathrm{op}} \to \mathcal{S}$ is a hypercomplete sheaf on $\mathcal{C}_{/C}$.

For every ∞-category $\mathcal{D}$, let $\chi_{\mathcal{D}} : \mathcal{C}\mathrm{at}_\infty \to \mathcal{S}$ be the functor corepresented by $\mathcal{D}$. Let $\mathcal{C}\mathrm{at}'_\infty$ denote the full subcategory of $\mathcal{C}\mathrm{at}_\infty$ spanned by those ∞-categories $\mathcal{D}$ for which the composite functor

$$\mathscr{F}_{\mathcal{D}} : \mathcal{C}^{\mathrm{op}} \xrightarrow{\mathscr{F}} \mathcal{C}\mathrm{at}_\infty \xrightarrow{\chi_{\mathcal{D}}} \mathcal{S}$$

is a hypercomplete sheaf on $\mathcal{C}$. We wish to prove that $\mathcal{C}\mathrm{at}'_\infty = \mathcal{C}\mathrm{at}_\infty$. Since the collection of hypercomplete sheaves is stable under small limits in $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ and the construction $\mathcal{D} \mapsto \mathscr{F}_{\mathcal{D}}$ carries colimits to limits, we conclude that $\mathcal{C}\mathrm{at}'_\infty \subseteq \mathcal{C}\mathrm{at}_\infty$ is stable under small colimits. By virtue of Lemma D.4.3.1, it will suffice to show that $\Delta^0, \Delta^1 \in \mathcal{C}\mathrm{at}'_\infty$. The inclusion $\Delta^0 \in \mathcal{C}\mathrm{at}'_\infty$ follows from (∗) together with Proposition D.6.7.4. It follows that $\partial \Delta^1 \in \mathcal{C}\mathrm{at}'_\infty$, so that $\mathscr{F}_{\partial \Delta^1}$ is a hypercomplete sheaf on $\mathcal{C}$. Applying Lemma D.4.3.2 to the restriction map $\mathscr{F}_{\Delta^1} \to \mathscr{F}_{\partial \Delta^1}$, we deduce that $\mathscr{F}_{\Delta^1}$ is hypercomplete so that $\Delta^1 \in \mathcal{C}\mathrm{at}'_\infty$ as desired (the hypotheses of Lemma D.4.3.2 are satisfied by virtue of assumption (2)). □

Proof of Theorem D.6.8.1. Proposition D.6.6.2 shows that the functor $A \mapsto \mathrm{LinCat}^{\mathrm{comp}}_A$ is a sheaf with respect to the fpqc topology. We wish to show show that this sheaf is hypercomplete. Note that every object of $\mathrm{CAlg}^{\mathrm{cn}}$ corepresents a hypercomplete sheaf on $(\mathrm{CAlg}^{\mathrm{cn}})^{\mathrm{op}}$ (this follows from Theorem D.6.3.5). We will complete the proof by showing that the construction $A \mapsto \mathrm{LinCat}^{\mathrm{comp}}_A$ satisfies the criterion of Proposition D.6.8.6. For this, we must show that for every connective $\mathbb{E}_\infty$-ring A and every pair of objects $\mathcal{C}, \mathcal{D} \in \mathrm{LinCat}^{\mathrm{comp}}_A$, the functor

$$\mathrm{CAlg}^{\mathrm{cn}}_A \to \widehat{\mathcal{S}} \qquad B \mapsto \mathrm{Map}_{\mathrm{LinCat}^{\mathrm{comp}}_B}(B \otimes_A \mathcal{C}, B \otimes_A \mathcal{D})$$

is a hypercomplete sheaf with respect to the fpqc topology on $(\mathrm{CAlg}_A^{\mathrm{cn}})^{\mathrm{op}}$. This is clear, since the prestable A-linear ∞-category $\mathcal{D}$ satisfies flat hyperdescent (Theorem D.6.3.1). $\square$

D.7 Duality for Stable ∞-Categories

Let R be an $\mathbb{E}_\infty$-ring and let $\mathrm{LinCat}_R^{\mathrm{St}}$ denote the ∞-category of stable R-linear ∞-categories (see Variant D.1.5.1). Then $\mathrm{LinCat}_R^{\mathrm{St}}$ is a symmetric monoidal ∞-category with respect to the R-linear tensor product $\otimes_R$ (see Variant D.2.3.3). In particular, one can consider dualizable objects of $\mathrm{LinCat}_R^{\mathrm{St}}$, in the sense of §HA.4.6.1 . Our goal in this section is to prove the following result:

Theorem D.7.0.7. *Let R be an $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a stable R-linear ∞-category. Then $\mathcal{C}$ is dualizable (as an object of the symmetric monoidal ∞-category $\mathrm{LinCat}_R^{\mathrm{St}}$) if and only if it is compactly assembled (see Definition 21.1.2.1). In particular, if $\mathcal{C}$ is compactly generated, then it is dualizable.*

Our proof of Theorem D.7.0.7 has three essentially disjoint steps. We begin by showing that a compactly generated stable ∞-category $\mathcal{C}$ is always dualizable when viewed as an object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ (Proposition D.7.2.3). We then apply this result to give a precise characterization of the dualizable objects of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ (Proposition D.7.3.1). We then complete the proof by showing that an object of $\mathrm{LinCat}_R^{\mathrm{St}}$ is dualizable if and only if its image under the forgetful functor $\mathrm{LinCat}_R^{\mathrm{St}} \to \mathcal{P}\mathrm{r}^{\mathrm{St}}$ is dualizable (Corollary D.7.7.6).

D.7.1 Digression: Mapping Spectra

We begin by introducing some terminology which is useful for studying R-linear ∞-categories in general.

Notation D.7.1.1. Let $\mathcal{C}$ be an ∞-category which is left tensored over a monoidal ∞-category $\mathcal{E}$. Given a pair of objects $C, D \in \mathcal{C}$, we let $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$ denote an object of $\mathcal{E}$ which classifies morphisms from C to D (if such an object exists). That is, $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$ is an object of $\mathcal{E}$ equipped with a map $\alpha : \underline{\mathrm{Map}}_{\mathcal{C}}(C, D) \otimes C \to D$ with the following universal property: for every object $E \in \mathcal{E}$, composition with α induces a homotopy equivalence $\mathrm{Map}_{\mathcal{E}}(E, \underline{\mathrm{Map}}_{\mathcal{C}}(C, D)) \to \mathrm{Map}_{\mathcal{C}}(E \otimes C, D)$. Note that if such a pair $(\underline{\mathrm{Map}}_{\mathcal{C}}(C, D), \alpha)$ exists, then it is well-defined up to a contractible space of choices. Moreover $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$ is contravariantly functorial in C, and covariantly functorial in D.

Example D.7.1.2. Let R be an $\mathbb{E}_2$-ring and let $\mathcal{C}$ be a stable R-linear ∞-category. For every pair of objects $C, D \in \mathcal{C}$, the construction $(M \in \mathrm{LMod}_R) \mapsto \mathrm{Map}_{\mathcal{C}}(M \otimes_R C, D)$ determines a functor $\mathrm{LMod}_R^{\mathrm{op}} \to \mathcal{S}$ which preserves small limits, and is therefore representable by an object of LMod_R which we will denote by $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$.

Example D.7.1.3. Let $\mathcal{C}$ be a presentable stable ∞-category. Then there is an (essentially unique) action of the ∞-category Sp of spectra on $\mathcal{C}$ for which the underlying map $\mathrm{Sp} \times \mathcal{C} \to \mathcal{C}$ preserves small colimits separately in each variable. It follows from Example D.7.1.2 (in the special case $R = S$) that for every pair of objects $C, D \in \mathcal{C}$, the mapping object $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D) \in \mathrm{Sp}$ is well-defined.

Warning D.7.1.4. Notation D.7.1.1 is somewhat abusive, because the object $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$ depends not only on the pair $C, D \in \mathcal{C}$ but also on the left action of an auxiliary ∞-category $\mathcal{E}$ on $\mathcal{C}$. This poses some danger of confusion. For example, let R be a connective $\mathbb{E}_2$-ring and let $\mathcal{C}$ be a stable R-linear ∞-category. Then $\mathcal{C}$ is left tensored over both the monoidal ∞-category LMod_R of left R-modules and the full subcategory $\mathrm{LMod}_R^{\mathrm{cn}} \subseteq \mathrm{LMod}_R$ of connective left R-modules. Notation D.7.1.1 then assigns two different meanings to the expression $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$: we can consider a classifying object for morphisms from C to D in either LMod_R or $\mathrm{LMod}_R^{\mathrm{cn}}$. We will follow the convention of Example D.7.1.2: unless otherwise specified, the expression $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$ indicates an object of LMod_R which classifies morphisms from C to D. The analogous classifying object in $\mathrm{LMod}_R^{\mathrm{cn}}$ can be identified with the connective cover $\tau_{\geq 0}\underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$.

Remark D.7.1.5. Let $\phi : R' \to R$ be a morphism of $\mathbb{E}_2$-rings and let $\mathcal{C}$ be an R-linear stable ∞-category. Then we can also regard $\mathcal{C}$ as an R'-linear stable ∞-category (by neglect of structure). For every pair of objects $C, D \in \mathcal{C}$, the classifying object $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$ does not depend on whether we view $\mathcal{C}$ as an R-linear stable ∞-category or an R'-linear stable ∞-category. More precisely, if we let $\underline{\mathrm{Map}}^R_{\mathcal{C}}(C, D) \in \mathrm{LMod}_R$ and $\underline{\mathrm{Map}}^{R'}_{\mathcal{C}}(C, D) \in \mathrm{LMod}_{R'}$ denote the relevant classifying objects, then $\underline{\mathrm{Map}}^{R'}_{\mathcal{C}}(C, D)$ can be identified with the image of $\underline{\mathrm{Map}}^R_{\mathcal{C}}(C, D)$ under the restriction-of-scalars functor $\mathrm{LMod}_R \to \mathrm{LMod}_{R'}$.

D.7.2 Duality for Compactly Generated ∞-Categories

Let $\mathcal{C}$ be a compactly generated stable ∞-category, so that there exists an equivalence $\mathcal{C} \simeq \mathrm{Ind}(\mathcal{C}_c)$ where $\mathcal{C}_c$ denotes the full subcategory of $\mathcal{C}$ spanned by the compact objects. Our goal in this section is to show that $\mathcal{C}$ is a dualizable object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$, whose dual can be identified with the compactly generated ∞-category $\mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}})$. This is a consequence of a more precise statement (Proposition D.7.2.3) which we prove below.

Construction D.7.2.1. Let $\mathcal{C}$ be a compactly generated stable ∞-category and let $\mathcal{C}_c$ denote the full subcategory of $\mathcal{C}$ spanned by the compact objects. Then the construction $(C, D) \mapsto \underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$ of Example D.7.1.3 determines a functor $\underline{\mathrm{Map}}_{\mathcal{C}} : \mathcal{C}^{\mathrm{op}} \times \mathcal{C} \to \mathrm{Sp}$, which we can identify with a map $\rho : \mathcal{C}^{\mathrm{op}} \to \mathrm{Fun}(\mathcal{C}, \mathrm{Sp})$. Let ρ_c denote the restriction of ρ to the full subcategory $\mathcal{C}_c^{\mathrm{op}} \subseteq \mathcal{C}^{\mathrm{op}}$. Note that the functor ρ preserves small limits, so that ρ_c is left exact and therefore (by virtue of the fact that the domain and codomain of ρ_c are stable) also right exact. Using Propositions HTT.5.3.5.10 and HTT.5.5.1.9, we deduce that this functor admits an essentially unique extension $\widehat{\rho}_c : \mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}}) \to \mathrm{Fun}(\mathcal{C}, \mathrm{Sp})$ which preserves small colimits. We will identify this extension with a bifunctor

$$\Phi_{\mathcal{C}} : \mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}}) \times \mathcal{C} \to \mathrm{Sp}.$$

Lemma D.7.2.2. *Let $\mathcal{C}$ be a compactly generated stable ∞-category and let $\Phi_{\mathcal{C}} : \mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}}) \times \mathcal{C} \to \mathrm{Sp}$ be defined as in Construction D.7.2.1. Then the functor $\Phi_{\mathcal{C}}$ preserves small colimits separately in each variable.*

Proof. By construction, the functor $\Phi_{\mathcal{C}}$ preserves small colimits in the first variable. It will therefore suffice to show that for each object $X \in \mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}})$, the functor $C \mapsto \Phi_{\mathcal{C}}(X, C) \in \mathrm{Sp}$ preserves small colimits. The collection of those objects $X \in \mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}})$ which satisfy this condition is evidently closed under small colimits; we may therefore assume that X is the image of some object $D \in \mathcal{C}_c^{\mathrm{op}}$. We are therefore reduced to showing that the functor $C \mapsto \underline{\mathrm{Map}}_{\mathcal{C}}(D, C)$ preserves small colimits. This functor evidently preserves small limits, and is therefore exact. We are therefore reduced to showing that the functor $C \mapsto \underline{\mathrm{Map}}_{\mathcal{C}}(D, C)$ preserves filtered colimits: that is, that for every integer n, the construction $C \mapsto \Omega^{\infty+n}\underline{\mathrm{Map}}_{\mathcal{C}}(D, C)$ determines a functor $\mathcal{C} \to \mathcal{S}$ which preserves filtered colimits. This is clear, since this functor is corepresentable by the compact object $\Sigma^n D \in \mathcal{C}$. □

Let $\mathcal{C}$ be a compactly generated stable ∞-category and let $\mathcal{C}_c$ denote the full subcategory of $\mathcal{C}$ spanned by the compact objects. Using Lemma D.7.2.2, we see that the functor $\Phi_{\mathcal{C}}$ of Construction D.7.2.1 induces a colimit-preserving functor $e_{\mathcal{C}} : \mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}}) \otimes \mathcal{C} \to \mathrm{Sp}$, where the tensor product is taken in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ of presentable stable ∞-categories.

Proposition D.7.2.3. *Let $\mathcal{C}$ be a compactly generated stable ∞-category. Then the functor $e_{\mathcal{C}} : \mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}}) \otimes \mathcal{C} \to \mathrm{Sp}$ constructed above is a duality datum in the symmetric monoidal ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ (see Definition HA.4.6.1.1). In particular, $\mathcal{C}$ is a dualizable object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$, and its dual can be identified with $\mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}})$.*

Proof. According to Lemma HA.4.6.1.6, it will suffice to show that for every pair of presentable stable ∞-categories $\mathcal{D}$ and $\mathcal{E}$, the composite map

$$\theta : \mathrm{Map}_{\mathcal{P}\mathrm{r}^{\mathrm{L}}}(\mathcal{D}, \mathcal{C} \otimes \mathcal{E}) \to \mathrm{Map}_{\mathcal{P}\mathrm{r}^{\mathrm{L}}}(\mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}}) \otimes \mathcal{D}, \mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}}) \otimes \mathcal{C} \otimes \mathcal{E}) \to \mathrm{Map}_{\mathcal{P}\mathrm{r}^{\mathrm{L}}}(\mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}}) \otimes \mathcal{D}, \mathcal{E})$$

is a homotopy equivalence. Proposition HTT.5.5.1.9 and the definition of the tensor product on $\mathcal{P}\mathrm{r}^{\mathrm{St}}$, we can identify $\mathrm{Map}_{\mathcal{P}\mathrm{r}^{\mathrm{L}}}(\mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}}) \otimes \mathcal{D}, \mathcal{E})$ with the subcategory of $\mathrm{Fun}(\mathcal{C}_c^{\mathrm{op}} \times \mathcal{D}, \mathcal{E})$ whose objects are functors which are exact in the first argument and colimit-preserving in the second, and whose morphisms are equivalences. Under this identification, θ corresponds to the map

$$\mathrm{Map}_{\mathcal{P}\mathrm{r}^{\mathrm{L}}}(\mathcal{D}, \mathcal{C} \otimes \mathcal{E}) \to \mathrm{Map}_{\mathcal{P}\mathrm{r}^{\mathrm{L}}}(\mathcal{D}, \mathrm{Fun}^{\mathrm{lex}}(\mathcal{C}_c^{\mathrm{op}}, \mathcal{E}))$$

given by composition with the equivalence

$$\mathcal{C} \otimes \mathcal{E} \simeq \mathrm{RFun}(\mathcal{C}^{\mathrm{op}}, \mathcal{E}) \simeq \mathrm{Fun}^{\mathrm{lex}}(\mathcal{C}_c^{\mathrm{op}}, \mathcal{E})$$

of Proposition HA.4.8.1.17 . □

D.7.3 Duality for Compactly Assembled ∞-Categories

We now extend Proposition D.7.2.3 to the setting of compactly assembled stable ∞-categories.

Proposition D.7.3.1. *Let $\mathcal{C}$ be a presentable stable ∞-category. The following conditions are equivalent:*

(1) *The ∞-category $\mathcal{C}$ is dualizable as an object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$.*

(2) *Let $F : \overline{\mathcal{D}} \to \mathcal{D}$ be a functor between presentable stable ∞-categories which admits a fully faithful right adjoint G. Then every colimit-preserving functor $U : \mathcal{C} \to \mathcal{D}$ is equivalent to $F \circ \overline{U}$ for some colimit-preserving functor $\overline{U} : \mathcal{C} \to \overline{\mathcal{D}}$.*

(3) *Let $F : \overline{\mathcal{C}} \to \mathcal{C}$ be a functor between presentable stable ∞-categories which admits a fully faithful right adjoint G. Then F admits a colimit-preserving section $G' : \mathcal{C} \to \overline{\mathcal{C}}$.*

(4) *The ∞-category $\mathcal{C}$ is a retract (in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ of presentable stable ∞-categories) of a compactly generated stable ∞-category.*

(5) *The ∞-category $\mathcal{C}$ is compactly assembled (in the sense of Definition 21.1.2.1).*

Proof. We first show that (1) ⇒ (2). Let $F : \overline{\mathcal{D}} \to \mathcal{D}$ be as in (2). Then F exhibits $\mathcal{D}$ as a quotient $\overline{\mathcal{D}}/\overline{\mathcal{D}}_0$, where $\overline{\mathcal{D}}_0$ is the localizing subcategory of $\overline{\mathcal{D}}$ spanned by objects which are annihilated by F. In particular, for any presentable stable ∞-category $\mathcal{E}$, composition with F induces a fully faithful embedding

$$\mathrm{LFun}(\mathcal{D}, \mathcal{C} \otimes \mathcal{E}) \to \mathrm{LFun}(\overline{\mathcal{D}}, \mathcal{C} \otimes \mathcal{E})$$

whose essential image is spanned by those functors which annihilate $\overline{\mathcal{D}}_0$. Let $\mathcal{C}^\vee$ denote a dual of $\mathcal{C}$, and let $\mathcal{A}$ denote the smallest localizing subcategory of $\mathcal{C}^\vee \otimes \overline{\mathcal{D}}$ which contains the essential image of $\mathcal{C}^\vee \otimes \overline{\mathcal{D}}_0$. Then, for any presentable stable ∞-category $\mathcal{E}$, the natural map $\mathrm{LFun}(\mathcal{C}^\vee \otimes \mathcal{D}, \mathcal{E}) \to \mathrm{LFun}(\mathcal{C}^\vee \otimes \overline{\mathcal{D}}, \mathcal{E})$ is a fully faithful embedding, whose essential image consists of those colimit-preserving functors $\mathcal{C}^\vee \otimes \overline{\mathcal{D}} \to \mathcal{E}$ which annihilate $\mathcal{A}$. It follows that the functor F exhibits $\mathcal{C}^\vee \otimes \mathcal{D}$ as the quotient of $\mathcal{C}^\vee \otimes \overline{\mathcal{D}}$ by the localizing subcategory $\mathcal{A}$. In particular, the functor $\mathcal{C}^\vee \otimes \overline{\mathcal{D}} \to \mathcal{C}^\vee \otimes \mathcal{D}$ is essentially surjective, which proves (2).

The implication (2) ⇒ (3) is trivial. We now prove (3) ⇒ (4). Let $\mathcal{C}_0 \subseteq \mathcal{C}$ be an essentially small dense full subcategory. Enlarging $\mathcal{C}_0$ if necessary, we may assume that $\mathcal{C}_0$ is a stable subcategory of $\mathcal{C}$. Then the inclusion $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ extends to a colimit-preserving functor $F : \mathrm{Ind}(\mathcal{C}_0) \to \mathcal{C}$, and the density of $\mathcal{C}_0$ in $\mathcal{C}$ guarantees that F has a fully faithful right adjoint G. Invoking assumption (3), we deduce that F admits a section $G' : \mathcal{C} \to \mathrm{Ind}(\mathcal{C}_0)$ which preserves small colimits. Then F and G' exhibit $\mathcal{C}$ as a retract of $\mathrm{Ind}(\mathcal{C}_0)$.

Note that since the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ is idempotent complete, the collection of dualizable objects of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ is closed under retracts. Consequently, the implication (4) $\Rightarrow$ (1) follows from Proposition D.7.2.3. The implication (4) $\Rightarrow$ (5) is trivial. We now complete the proof by showing that (5) $\Rightarrow$ (1). We proceed as in the proof of Theorem 21.1.2.10. Let $G : \mathrm{Ind}(\mathcal{C}) \to \mathcal{C}$ be the Ind-extension of the identity functor $\mathrm{id}_{\mathcal{C}}$, and let $F : \mathcal{C} \to \mathrm{Ind}(\mathcal{C})$ be a left adjoint to G (whose existence is guaranteed by our assumption that $\mathcal{C}$ is compactly assembled; see Theorem 21.1.2.10). If $\mathcal{C}_0 \subseteq \mathcal{C}$ is an essentially small full subcategory, we will abuse notation by identifying $\mathrm{Ind}(\mathcal{C}_0)$ with its essential image in $\mathrm{Ind}(\mathcal{C})$. Since $\mathcal{C}$ is accessible, there exists a small collection of objects $\{X_\alpha\}$ which generates $\mathcal{C}$ under small filtered colimits. Choose an essentially small stable subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ for which each $F(X_\alpha)$ belongs to the subcategory $\mathrm{Ind}(\mathcal{C}_0) \subseteq \mathrm{Ind}(\mathcal{C})$. Since the functor F commutes with small filtered colimits, it follows that F factors through a functor $F_0 : \mathcal{C} \to \mathrm{Ind}(\mathcal{C}_0)$. Let $G_0 = G|_{\mathrm{Ind}(\mathcal{C}_0)}$. Then $G_0 \circ F_0$ is equivalent to the identity functor $\mathrm{id}_{\mathcal{C}}$, so that F_0 and G_0 exhibit $\mathcal{C}$ as a retract of $\mathrm{Ind}(\mathcal{C}_0)$ in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$. □

D.7.4 Locally Rigid Monoidal ∞-Categories

In order to deduce Theorem D.7.0.7 from Proposition D.7.2.3, we will need to compare the condition of dualizability in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ with the *a priori* unrelated condition of dualizability in the ∞-category $\mathrm{LinCat}_R^{\mathrm{St}} = \mathrm{Mod}_{\mathrm{Mod}_R}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$, where R is an $\mathbb{E}_\infty$-ring. The comparison rests on some features of the monoidal ∞-category Mod_R which we now axiomatize.

Definition D.7.4.1. Let $\mathcal{C}$ be a monoidal stable ∞-category. We will say that $\mathcal{C}$ is *locally rigid* if it satisfies the following conditions:

(1) The ∞-category $\mathcal{C}$ is compactly generated.

(2) The tensor product functor $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves small colimits separately in each variable.

(3) The unit object $\mathbf{1} \in \mathcal{C}$ is compact.

(4) Every compact object of $\mathcal{C}$ admits a left dual and a right dual.

Example D.7.4.2. Let R be an $\mathbb{E}_2$-ring. Then LMod_R is a locally rigid stable monoidal ∞-category. That is, every perfect R-module is both left and right dualizable as an object of LMod_R. This is clear, since the collection of left and right dualizable objects of LMod_R is a stable subcategory which contains the unit object $R \in \mathrm{LMod}_R$.

Remark D.7.4.3. Let $\mathcal{C}$ be a locally rigid stable monoidal ∞-category and suppose that $X \in \mathcal{C}$ is an object which admits a right dual $X^\vee$. Then for any object $Y \in \mathcal{C}$, we have a canonical homotopy equivalence $\mathrm{Map}_{\mathcal{C}}(X, Y) \simeq \mathrm{Map}_{\mathcal{C}}(\mathbf{1}, Y \otimes X^\vee)$. Since the operation $Y \mapsto Y \otimes X^\vee$ commutes with filtered colimits and the unit object $\mathbf{1}$ is compact, we deduce that the functor $Y \mapsto \mathrm{Map}_{\mathcal{C}}(X, Y)$ commutes with filtered colimits: that is, X Is a compact object of $\mathcal{C}$. The same argument shows that every left dualizable object of $\mathcal{C}$ is compact. Consequently, the following conditions on an object $X \in \mathcal{C}$ are equivalent:

(a) The object $X \in \mathcal{C}$ is compact.

(b) The object X admits a left dual.

(c) The object X admits a right dual.

Remark D.7.4.4. Let $\mathcal{C}$ be a locally rigid monoidal ∞-category, let $\mathcal{M}$ and $\mathcal{N}$ be presentable ∞-categories which are left-tensored over $\mathcal{C}$, and suppose that the action maps

$$\otimes : \mathcal{C} \times \mathcal{M} \to \mathcal{M} \qquad \mathcal{C} \times \mathcal{N} \to \mathcal{N}$$

preserves small colimits separately in each variable. Let $F : \mathcal{M} \to \mathcal{N}$ be a $\mathcal{C}$-linear functor which commutes with small colimits and let $G : \mathcal{N} \to \mathcal{M}$ be a right adjoint to F. For every pair of objects $C \in \mathcal{C}$ and $N \in \mathcal{N}$, the counit map $(F \circ G)(N) \to N$ induces a map

$$F(C \otimes G(N)) \to C \otimes (F \circ G)(N) \to C \otimes N,$$

which is adjoint to a morphism $\theta_{C,N} : C \otimes G(N) \to G(C \otimes N)$ in $\mathcal{C}$.

Suppose that the functor G preserves small colimits. We claim that each of the maps $\theta_{C,N}$ is an equivalence. Note that the construction $C \mapsto \theta_{C,N}$ commutes with filtered colimits. We can therefore reduce to the case where C is compact, and therefore right dualizable. We claim that for each object $M \in \mathcal{M}$, composition with $\theta_{C,N}$ induces a homotopy equivalence $\mathrm{Map}_{\mathcal{M}}(M, C \otimes G(N)) \to \mathrm{Map}_{\mathcal{M}}(M, G(C \otimes N))$. Unwinding the definitions, we see that this map is given by a composition of homotopy equivalences

$$\begin{aligned} \mathrm{Map}_{\mathcal{M}}(M, C \otimes G(N)) &\simeq \mathrm{Map}_{\mathcal{M}}(C^\vee \otimes M, G(N)) \\ &\simeq \mathrm{Map}_{\mathcal{N}}(F(C^\vee \otimes M), N) \\ &\simeq \mathrm{Map}_{\mathcal{N}}(C^\vee \otimes F(M), N) \\ &\simeq \mathrm{Map}_{\mathcal{N}}(F(M), C \otimes N) \\ &\simeq \mathrm{Map}_{\mathcal{M}}(M, G(C \otimes N)). \end{aligned}$$

Applying Remark **??**, we see that G can be regarded as a $\mathcal{C}$-linear functor from $\mathcal{N}$ to $\mathcal{M}$.

Example D.7.4.5. Let $\mathcal{C}$ and $\mathcal{D}$ be locally rigid stable monoidal ∞-categories, and let $F : \mathcal{C} \to \mathcal{D}$ be a monoidal functor which preserves small colimits. Then F carries (left or right) dualizable objects of $\mathcal{C}$ to (left or right) dualizable objects of $\mathcal{D}$, and therefore carries compact objects of $\mathcal{C}$ to compact objects of $\mathcal{D}$ (Remark D.7.4.3). Applying Proposition HTT.5.5.7.2 , we deduce that the functor F admits a right adjoint G which commutes with filtered colimits. Using Remark D.1.5.3, we conclude that G has the structure of a $\mathcal{C}$-linear functor.

D.7.5 Frobenius Algebras in $\mathcal{P}\mathrm{r}^{\mathrm{St}}$

Let $\mathcal{C}$ be a stable monoidal ∞-category. If $\mathcal{C}$ is presentable and the tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves small colimits separately in each variable, then we can identify $\mathcal{C}$ with an associative algebra object of the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ of presentable stable ∞-categories. When $\mathcal{C}$ is locally rigid (Definition D.7.4.1), we can say more:

Proposition D.7.5.1. *Let $\mathcal{C}$ be a locally rigid monoidal stable ∞-category, and let $\lambda : \mathcal{C} \to \mathrm{Sp}$ denote the functor given by $\lambda(C) = \underline{\mathrm{Map}}_{\mathcal{C}}(\mathbf{1}, C)$. Then $(\mathcal{C}, \lambda)$ is a Frobenius algebra object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$. In other words, the composite map $u : \mathcal{C} \otimes \mathcal{C} \to \mathcal{C} \xrightarrow{\lambda} \mathrm{Sp}$ is a duality datum in the symmetric monoidal ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$.*

Proof. The map u classifies a bifunctor $\beta : \mathcal{C} \times \mathcal{C} \to \mathrm{Sp}$, given by the formula $\beta(C, D) = \underline{\mathrm{Map}}_{\mathcal{C}}(\mathbf{1}, C \otimes D)$. Let $\Phi_{\mathcal{C}}$ be as in Construction D.7.2.1. Using Proposition D.7.2.3, we deduce that there exists an essentially unique functor $F : \mathcal{C} \to \mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}})$ which is equipped with an equivalence $\beta \simeq \Phi_{\mathcal{C}} \circ (F \times \mathrm{id}_{\mathcal{C}})$. We wish to show that F is an equivalence of ∞-categories. Note that for every compact object $C \in \mathcal{C}$, the functor $\beta(C, \bullet)$ carries $D \in \mathcal{C}$ to the spectrum

$$\beta(C, D) = \underline{\mathrm{Map}}_{\mathcal{C}}(\mathbf{1}, C \otimes D) \simeq \underline{\mathrm{Map}}_{\mathcal{C}}(C^{\vee}, D),$$

so that $\beta(C, \bullet)$ is representable by the object $C^{\vee} \in \mathcal{C}_c$. Let us abuse notation by identifying $\mathcal{C}_c^{\mathrm{op}}$ with its essential image in $\mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}})$. Unwinding the definitions, we see that F carries $\mathcal{C}_c$ into $\mathcal{C}_c^{\mathrm{op}}$, and is given on $\mathcal{C}_c$ by the formula $C \mapsto C^{\vee}$. If $C, C' \in \mathcal{C}$ are compact, then the canonical map

$$\mathrm{Map}_{\mathcal{C}}(C, C') \to \mathrm{Map}_{\mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}})}(F(C), F(C')) \simeq \mathrm{Map}_{\mathcal{C}_c}(C'^{\vee}, C^{\vee})$$

is a homotopy equivalence. It follows that $F|_{\mathcal{C}_c}$ is fully faithful. Since F commutes with filtered colimits and carries compact objects of $\mathcal{C}$ to compact objects of $\mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}})$, we conclude that F is fully faithful. Since every object of $\mathcal{C}_c$ admits a left dual, the essential image of F contains $\mathcal{C}_c^{\mathrm{op}}$ and is closed under filtered colimits. It follows that F is essentially surjective and is therefore an equivalence of ∞-categories. □

Remark D.7.5.2. [Serre Automorphism] Let $\mathcal{C}$ be a locally rigid stable monoidal ∞-category, let $\lambda : \mathcal{C} \to \mathrm{Sp}$ be defined as in Proposition D.7.5.1, and regard $(\mathcal{C}, \lambda)$ as a Frobenius algebra object of the symmetric monoidal ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$. Let $\sigma : \mathcal{C} \to \mathcal{C}$ denote the Serre automorphism of the Frobenius algebra object $(\mathcal{C}, \lambda)$ (see Remark HA.4.6.5.4). Then σ is a monoidal equivalence from $\mathcal{C}$ to itself. Moreover, if $m, m' : \mathcal{C} \otimes \mathcal{C} \to \mathcal{C}$ classify the tensor product on $\mathcal{C}$ and its opposite, then we have a commutative diagram of ∞-categories

$$\begin{array}{ccccc} \mathcal{C}\otimes\mathcal{C} & & \xrightarrow{\mathrm{id}\otimes\sigma} & & \mathcal{C}\otimes\mathcal{C} \\ \downarrow{\scriptstyle m} & & & & \downarrow{\scriptstyle m'} \\ \mathcal{C} & & & & \mathcal{C} \\ & \searrow^{\lambda} & & \swarrow^{\lambda} & \\ & & \mathrm{Sp}. & & \end{array}$$

In other words, for every pair of objects $C, D \in \mathcal{C}$, we have a canonical equivalence of spectra

$$\underline{\mathrm{Map}}_{\mathcal{C}}(\mathbf{1}, C \otimes D) \simeq \underline{\mathrm{Map}}_{\mathcal{C}}(\mathbf{1}, D \otimes \sigma(C)).$$

If C is a compact object of $\mathcal{C}$, we can rewrite the left hand side of this equivalence as

$$\underline{\mathrm{Map}}_{\mathcal{C}}(\mathbf{1}, C \otimes D) \simeq \underline{\mathrm{Map}}_{\mathcal{C}}(C^{\vee}, D) \simeq \underline{\mathrm{Map}}_{\mathcal{C}}(\mathbf{1}, D \otimes (C^{\vee})^{\vee}).$$

We can informally summarize the situation as follows: if $\mathcal{C}$ is a locally rigid stable monoidal ∞-category, then the double duality functor $C \mapsto (C^{\vee})^{\vee}$ extends to a monoidal equivalence of $\mathcal{C}$ with itself.

Example D.7.5.3. Let R be an $\mathbb{E}_2$-ring. Then the ∞-category LMod_R is locally rigid (Example D.7.4.2). According to Remark D.7.5.2, double duality determines a monoidal equivalence $\sigma : \mathrm{LMod}_R \to \mathrm{LMod}_R$. Using Propositon HA.7.1.2.6 , we see that σ arises from an equivalence from R to itself in the ∞-category $\mathrm{Alg}_{\mathbb{E}_2}(\mathrm{Sp})$ of $\mathbb{E}_2$-rings. One can show that this equivalence is induced by the homotopy from the identity map from the ∞-operad $\mathbb{E}_2^{\otimes}$ to itself which is determined by the action of the circle group SO(2) on the $\mathbb{E}_2^{\otimes}$ (see Example HA.5.4.2.18).

D.7.6 A Recognition Criterion

Let $\mathcal{M}$ be a presentable stable ∞-category. If there exists a compact generator $M \in \mathcal{M}$, then we can identify $\mathcal{M}$ as the ∞-category RMod_A of right A-modules, where $A = \mathrm{End}_{\mathcal{M}}(M) = \underline{\mathrm{Map}}_{\mathcal{M}}(M, M)$ is the $\mathbb{E}_1$-ring of endomorphisms of M (see Theorem HA.7.1.2.1). We now establish a mild generalization of this statement:

Proposition D.7.6.1. *Let $\mathcal{C}$ be a locally rigid stable monoidal ∞-category and let $\mathcal{M}$ be an ∞-category which is left-tensored over $\mathcal{C}$. Assume that $\mathcal{M}$ is presentable and that the tensor product $\otimes : \mathcal{C} \times \mathcal{M} \to \mathcal{M}$ preserves small colimits separately in each variable. Let $A \in \mathrm{Alg}(\mathcal{C})$ be an algebra object of $\mathcal{C}$, and let $M \in \mathrm{LMod}_A(\mathcal{M})$, so that tensor product with M determines a $\mathcal{C}$-linear functor $\lambda : \mathrm{RMod}_A(\mathcal{C}) \to \mathcal{M}$ (see Theorem HA.4.8.4.1). Then λ is an equivalence if and only if the following conditions are satisfied:*

(1) *The object $M \in \mathcal{M}$ is compact.*

(2) *The object $A \in \mathcal{C}$ classifies endomorphisms of M in $\mathcal{C}$. That is, for every object $C \in \mathcal{C}$, the action of A on M induces a homotopy equivalence*

$$\mathrm{Map}_{\mathcal{C}}(C, A) \to \mathrm{Map}_{\mathcal{M}}(C \otimes M, M).$$

(3) *The ∞-category $\mathcal{M}$ is generated under small colimits by objects of the form $C \otimes M$, where $C \in \mathcal{C}$.*

Proof. To prove that conditions (1), (2), and (3) are necessary, it suffices to show that they are satisfied when $\mathcal{M} = \mathrm{RMod}_A(\mathcal{C})$ and $M = A$ (regarded as a right module over itself). In this case, M corepresents the composite functor $\mathrm{RMod}_A(\mathcal{C}) \to \mathcal{C} \xrightarrow{\phi} \mathcal{S}$, where $\phi : \mathcal{C} \to \mathcal{S}$ is the functor corepresented by the unit object $\mathbf{1}$. Since $\mathcal{C}$ is locally rigid, $\mathbf{1}$ is a compact object of $\mathcal{C}$, and condition (1) follows. Condition (2) follows from Proposition HA.4.2.4.2 , and condition (3) follows because every right A-module N can be written as $N \otimes_A A$, which is computed as the geometric realization of the simplicial object with entries of the form $N \otimes A^{\otimes k}$ for $k > 0$.

Conversely, suppose that conditions (1), (2), and (3) are satisfied. We first claim that the functor λ is fully faithful. To prove this, it will suffice to show that for every pair of objects $N, N' \in \mathrm{RMod}_A(\mathcal{C})$, the functor λ induces a homotopy equivalence

$$\theta_{N,N'} : \mathrm{Map}_{\mathrm{RMod}_A(\mathcal{C})}(N, N') \to \mathrm{Map}_{\mathcal{M}}(N \otimes_A M, N' \otimes_A M).$$

Let us first regard N' as fixed. The collection of those $N \in \mathrm{RMod}_A(\mathcal{C})$ for which $\theta_{N,N'}$ is an equivalence is closed under small colimits in $\mathrm{RMod}_A(\mathcal{C})$. Since $\mathrm{RMod}_A(\mathcal{C})$ is generated under small colimits by objects of the form $C \otimes A$, we may assume that $N = C \otimes A$ for some $C \in \mathcal{C}$. Since $\mathcal{C}$ is compactly generated, we may further reduce to the case where C is a compact object of $\mathcal{C}$. Then C admits a left dual ${}^{\vee}C$. Replacing N' by ${}^{\vee}C \otimes N'$, we may reduce to the case where $C = \mathbf{1}$, so that $N = A$. In this case, we can identify θ with the canonical map $\phi_{N'} : \mathrm{Map}_{\mathcal{C}}(\mathbf{1}, N') \to \mathrm{Map}_{\mathcal{M}}(M, N' \otimes_A M)$.

Let $\mathcal{E} \subseteq \mathrm{RMod}_A(\mathcal{C})$ denote the full subcategory spanned by those objects N' satisfying the following condition: for every integer d, the map $\phi_{\Sigma^d N'}$ is a homotopy equivalence. Since the construction $N' \mapsto \phi_{N'}$ preserves finite limits, $\mathcal{E}$ is a stable subcategory of

$\mathrm{RMod}_A(\mathcal{C})$, and therefore closed under finite colimits in $\mathrm{RMod}_A(\mathcal{C})$. Using condition (1), we deduce that $\mathcal{E}$ is closed under filtered colimits, and therefore closed under small colimits in $\mathrm{RMod}_A(\mathcal{C})$. Consequently, to show that $\mathcal{E} = \mathrm{RMod}_A(\mathcal{C})$, it will suffice to show that $\mathcal{E}$ contains every right A-module of the form $C' \otimes A$, where C' is a compact object of $\mathcal{C}$. In this case, C' is right dualizable, so we can identify $\phi_{N'}$ with the canonical map $\mathrm{Map}_{\mathcal{C}}(C'^{\vee}, A) \to \mathrm{Map}_{\mathcal{M}}(C'^{\vee} \otimes M, M)$. This map is a homotopy equivalence by virtue of assumption (2). This completes the proof that λ is fully faithful.

Since λ is a fully faithful functor which preserves small colimits, the essential image of λ is closed under small colimits in $\mathcal{M}$. Since this essential image contains every object of the form $C \otimes M$, where $C \in \mathcal{C}$, assumption (3) guarantees that λ is essentially surjective. □

Combining Proposition D.7.6.1 with the results of §HA.4.7.1 , we obtain the following:

Corollary D.7.6.2. *Let $\mathcal{C}$ be a locally rigid stable monoidal ∞-category and let $\mathcal{M}$ be an ∞-category which is left-tensored over $\mathcal{C}$. Let $M \in \mathcal{M}$ be an object. Then the following conditions are equivalent:*

1. *There exists an algebra object $A \in \mathrm{Alg}(\mathcal{C})$ and a $\mathcal{C}$-linear equivalence of ∞-categories $\lambda : \mathrm{RMod}_A(\mathcal{C}) \to \mathcal{M}$ with $\lambda(A) \simeq M$.*
2. *The ∞-category $\mathcal{M}$ is presentable, the tensor product $\otimes : \mathcal{C} \times \mathcal{M} \to \mathcal{M}$ preserves small colimits separately in each variable, M is a compact object of $\mathcal{M}$, and $\mathcal{M}$ is generated under small colimits by objects of the form $C \otimes M$, where $C \in \mathcal{C}$.*

Corollary D.7.6.3. *Let R be an $\mathbb{E}_2$-ring, let $\mathcal{M}$ be an R-linear ∞-category, and let $M \in \mathcal{M}$ be an object. The following conditions are equivalent:*

1. *There exists an R-algebra $A \in \mathrm{Alg}_R$ and an R-linear equivalence of ∞-categories $\lambda : \mathrm{RMod}_A \simeq \mathcal{M}$ with $\lambda(A) \simeq M$.*
2. *The object $M \in \mathcal{M}$ is compact, and the suspensions $\{\Sigma^k M\}_{k \in \mathbf{Z}}$ generate $\mathcal{M}$ under small colimits.*

Corollary D.7.6.4. *Let $\mathcal{C}$ be a locally rigid stable monoidal ∞-category, and let $\mathcal{M} \in \mathrm{LMod}_{\mathcal{C}}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$. Suppose that there exists a compact object $M \in \mathcal{M}$ such that $\mathcal{M}$ is generated under small colimits by objects of the form $C \otimes M$, where $C \in \mathcal{C}$. Then:*

1. *There exists an algebra object $A \in \mathrm{Alg}(\mathcal{C})$ and a $\mathcal{C}$-linear equivalence $\mathcal{M} \simeq \mathrm{RMod}_A(\mathcal{C})$.*
2. *As a left $\mathcal{C}$-module object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$, $\mathcal{M}$ admits a left dual ${}^{\vee}\mathcal{M} \in \mathrm{RMod}_{\mathcal{C}}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$.*

Proof. Assertion (1) follows immediately from Corollary D.7.6.2, and (2) follows from (1) and Remark HA.4.8.4.8 . □

D.7.7 Smoothness of Locally Rigid Stable ∞-Categories

We now turn to the proof of Theorem D.7.0.7. The main point is to establish the following:

Proposition D.7.7.1. *Let $\mathcal{C}$ be a locally rigid stable monoidal ∞-category. Then $\mathcal{C}$ is smooth when viewed as an algebra object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$: that is, it is dualizable as module over $\mathcal{C}^{\mathrm{op}} \otimes \mathcal{C}$ (see Definition HA.4.6.4.13).*

Lemma D.7.7.2. *Let $\mathcal{C}$ and $\mathcal{C}'$ be locally rigid stable monoidal ∞-categories, which we regard as algebra objects of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$. Then the tensor product $\mathcal{C} \otimes \mathcal{C}' \in \mathrm{Alg}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$ is also locally rigid.*

Proof. For every pair of objects $C \in \mathcal{C}$, $C' \in \mathcal{C}'$, we let $C \boxtimes C'$ denote the image of (C, C') under the tautological map $\mathcal{C} \times \mathcal{C}' \to \mathcal{C} \otimes \mathcal{C}'$. If C and C' are compact, then $C \boxtimes C'$ is a compact object of $\mathcal{C} \otimes \mathcal{C}'$. Note that the unit object of $\mathcal{C} \otimes \mathcal{C}'$ can be written as $\mathbf{1}_{\mathcal{C}} \boxtimes \mathbf{1}_{\mathcal{C}'}$, where $\mathbf{1}_{\mathcal{C}}$ and $\mathbf{1}_{\mathcal{C}'}$ denote the unit objects of $\mathcal{C}$ and $\mathcal{C}'$, respectively. It follows that the unit object of $\mathcal{C} \otimes \mathcal{C}'$ is compact. We also note that if $C \in \mathcal{C}$ and $C' \in \mathcal{C}'$ are both left dualizable (right dualizable), then $C \boxtimes C'$ is left dualizable (right dualizable). Consequently, the collection of left (right) dualizable objects of $\mathcal{C} \boxtimes \mathcal{C}'$ forms a stable subcategory which contains all objects of the form $C \boxtimes C'$, where C and C' are compact. It follows that every compact object of $\mathcal{C} \otimes \mathcal{C}'$ is (left and right) dualizable. □

Proof of Proposition D.7.7.1. Let $\mathcal{C}$ be a locally rigid stable monoidal ∞-category, and regard $\mathcal{C}$ as an associative algebra object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$. Let $\mathcal{C}^{\mathrm{rev}}$ denote the opposite algebra (so that $\mathcal{C}^{\mathrm{rev}}$ agrees with $\mathcal{C}$ as an ∞-category, but is equipped with the opposite tensor product), and let $\mathcal{C}^{e} \in \mathrm{LMod}_{\mathcal{C} \otimes \mathcal{C}^{\mathrm{rev}}}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$ denote the evaluation module of $\mathcal{C}$ (see Construction HA.4.6.3.7). We wish to show that $\mathcal{C}^{e}$ is left dualizable. Note that $\mathcal{C} \otimes \mathcal{C}^{\mathrm{rev}}$ is locally rigid (Lemma D.7.7.2). The desired result now follows immediately from Corollary D.7.6.4, since the unit object $\mathbf{1} \in \mathcal{C}$ is compact, and $\mathcal{C}$ is generated under small colimits by objects of the form $C \otimes \mathbf{1} \otimes D$ where $C, D \in \mathcal{C}$. □

Corollary D.7.7.3. *Let $\mathcal{C}$ be a locally rigid stable monoidal ∞-category, and let $\mathcal{M} \in \mathrm{LMod}_{\mathcal{C}}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$. The following conditions are equivalent:*

(1) *The ∞-category $\mathcal{M}$ admits a right dual $\mathcal{M}^{\vee}$ (that is, $\mathcal{M}$ is dualizable as an object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$).*

(2) *The ∞-category $\mathcal{M}$ admits a left dual ${}^{\vee}\mathcal{M}$ (that is, $\mathcal{M}$ is dualizable as a $\mathcal{C}$-module).*

Proof. It follows from Propositions D.7.5.1 and D.7.7.1 that $\mathcal{C}$ is smooth and proper when regarded as an algebra object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$. The equivalence of (1) and (2) now follows from Propositions HA.4.6.4.4 and HA.4.6.4.12. □

Theorem D.7.0.7 is a special case of the following more general result:

Corollary D.7.7.4. *Let $\mathcal{C}$ be a locally rigid stable monoidal ∞-category, and let $\mathcal{M} \in \mathrm{LMod}_{\mathcal{C}}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$. If $\mathcal{M}$ is compactly assembled, then $\mathcal{M}$ admits a left dual ${}^{\vee}\mathcal{M} \in \mathrm{RMod}_{\mathcal{C}}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$.*

Proof. Combine Corollary D.7.7.3 with Proposition D.7.3.1. □

Warning D.7.7.5. Let $\mathcal{C}$ be a locally rigid stable monoidal ∞-category, and let $\mathcal{M} \in \mathrm{LMod}_{\mathcal{C}}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$ be an ∞-category left-tensored over $\mathcal{C}$ which satisfies the equivalent conditions of Corollary D.7.7.3. Then $\mathcal{M}$ admits left and right duals ${}^{\vee}\mathcal{M}, \mathcal{M}^{\vee} \in \mathrm{RMod}_{\mathcal{C}}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$. These duals are canonically equivalent to one another as ∞-categories, but are generally *not* equivalent as ∞-categories right-tensored over $\mathcal{C}$. Instead, the actions of $\mathcal{C}$ on ${}^{\vee}\mathcal{M}$ and $\mathcal{M}^{\vee}$ differ by composition with the Serre automorphism of $\mathcal{C}$ described in Remark D.7.5.2 (see Remark HA.4.6.5.13). However, this automorphism is trivial whenever the monoidal structure on $\mathcal{C}$ is symmetric (Remark HA.4.6.5.15): for example, if $\mathcal{C} = \mathrm{Mod}_R$ where R is an $\mathbb{E}_{\infty}$-ring.

Remark D.7.7.6. Let R be an $\mathbb{E}_{\infty}$-ring and let $\mathcal{C}$ be a compactly generated stable R-linear ∞-category. Then:

(1) The ∞-category $\mathcal{C}$ is dualizable as an object of $\mathrm{LinCat}_R^{\mathrm{St}}$ (this follows from Corollary D.7.7.4).

(2) Let $e : \mathcal{C}^{\vee} \otimes_R \mathcal{C} \to \mathrm{Mod}_R$ be a duality datum in LinCat_R, and let $\lambda : \mathrm{Mod}_R \to \mathrm{Sp}$ denote the forgetful functor. Then the composite map

$$\mathcal{C}^{\vee} \otimes \mathcal{C} \to \mathcal{C}^{\vee} \otimes_R \mathcal{C} \xrightarrow{e} \mathrm{Mod}_R \xrightarrow{\lambda} \mathrm{Sp}$$

is a duality datum in $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ (combine (1) with Proposition D.7.5.1, Proposition D.7.6.1, and Corollary HA.4.6.5.14).

(3) Let $\mathcal{C}_c$ denote the full subcategory of $\mathcal{C}$ spanned by the compact objects. Then $\mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}})$ admits the structure of a stable R-linear ∞-category. Moreover, the functor $e_{\mathcal{C}} : \mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}}) \otimes \mathcal{C} \to \mathrm{Sp}$ is homotopic to a composition

$$\mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}}) \otimes \mathcal{C} \to \mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}}) \otimes_R \mathcal{C} \xrightarrow{\overline{e}_{\mathcal{C}}} \mathrm{Mod}_R \xrightarrow{\lambda} \mathrm{Sp},$$

where $\overline{e}_{\mathcal{C}}$ exhibits $\mathrm{Ind}(\mathcal{C}_c^{\mathrm{op}})$ as the dual of $\mathcal{C}$ in the ∞-category $\mathrm{LinCat}_R^{\mathrm{St}}$ (combine (2) with Proposition D.7.2.3).

Corollary D.7.7.7. *Let R be an $\mathbb{E}_{\infty}$-ring and let $\mathcal{C}$ be a compactly assembled stable R-linear ∞-category. Then $\mathcal{C}$ satisfies flat hyperdescent (see Definition D.6.1.2).*

Proof. Using Lemma D.3.5.5 and Proposition A.5.7.2, we are reduced to proving the following:

(∗) Let $A^{\bullet} : \mathbf{\Delta}_s \rightarrow \mathrm{CAlg}_{R/}$ be a flat hypercovering of an R-algebra A. Then the canonical map $\theta : \mathrm{Mod}_A \otimes_{\mathrm{Mod}_R} \mathcal{C} \rightarrow \varprojlim(\mathrm{Mod}_{A^{\bullet}} \otimes_{\mathrm{Mod}_R} \mathcal{C})$ is an equivalence of R-linear ∞-categories.

Let $\mathcal{D}$ be another R-linear ∞-category; we wish to show that θ induces a homotopy equivalence

$$\phi : \mathrm{Map}_{\mathrm{LinCat}_R}(\mathcal{D}, \mathrm{Mod}_A \otimes_{\mathrm{Mod}_R} \mathcal{C}) \rightarrow \varprojlim \mathrm{Map}_{\mathrm{LinCat}_R}(\mathcal{D}, \mathrm{Mod}_{A^{\bullet}} \otimes_{\mathrm{Mod}_R} \mathcal{C}).$$

Corollary D.7.7.4 implies that $\mathcal{C}$ is a dualizable object of LinCat_R. Let us denote its dual by $\mathcal{C}^{\vee}$. Then ϕ can be identified with the canonical map

$$\mathrm{Map}_{\mathrm{LinCat}_R}(\mathcal{D} \otimes_{\mathrm{Mod}_R} \mathcal{C}^{\vee}, \mathrm{Mod}_A) \rightarrow \varprojlim \mathrm{Map}_{\mathrm{LinCat}_R}(\mathcal{D} \otimes_{\mathrm{Mod}_R} \mathcal{C}^{\vee}, \mathrm{Mod}_{A^{\bullet}}).$$

We are therefore reduced to proving that $\mathrm{Mod}_A \simeq \varprojlim \mathrm{Mod}_{A^{\bullet}}$, which follows from Corollary D.6.3.3. □

Appendix E

Profinite Homotopy Theory

Let X be a simply connected space. Using rational homotopy theory (see §**??**), one can associate to X another simply connected space $X_{\mathbf{Q}}$ called the *rationalization of* X, whose homotopy $\pi_n X_{\mathbf{Q}} \simeq \mathbf{Q} \otimes_{\mathbf{Z}} (\pi_n X)$. The space $X_{\mathbf{Q}}$ captures all "rational information" about the homotopy type of the space X, while completely ignoring torsion. In this appendix, we give an overview of the subject of *profinite* homotopy theory which takes the opposite approach: emphasizing the role of "torsion information" (while completely neglecting rational information).

Definition E.0.7.8. Let X be a space. We will say that X is π*-finite* if it satisfies the following conditions:

(1) The space X is n-truncated for some integer n.

(2) The set $\pi_0 X$ is finite.

(3) For each vertex $x \in X$ and each integer $m \geqslant 1$, the group $\pi_m(X, x)$ is finite.

Let $\mathcal{S}_\pi$ denote the full subcategory of $\mathcal{S}$ spanned by the π-finite spaces.

Remark E.0.7.9. A space X is π-finite if and only if it is a truncated coherent object of the ∞-topos $\mathcal{S}$ (see Example A.2.1.7). In particular, the ∞-category $\mathcal{S}_\pi$ is a bounded ∞-pretopos (Example A.7.4.4).

Remark E.0.7.10. The full subcategory $\mathcal{S}_\pi \subseteq \mathcal{S}$ is closed under finite coproducts, finite limits, and retracts. In particular, $\mathcal{S}_\pi$ is an idempotent-complete ∞-category which admits finite limits. Note also that $\mathcal{S}_\pi$ is essentially small (and therefore accessible).

Definition E.0.7.11. A *profinite space* is a Pro-object of the ∞-category $\mathcal{S}_\pi$ (see Definition A.8.1.1): that is, a functor $U : \mathcal{S}_\pi \to \mathcal{S}$ which preserves finite limits. We let $\mathcal{S}_\pi^\wedge = \mathrm{Pro}(\mathcal{S}_\pi)$ denote the full subcategory of $\mathrm{Fun}(\mathcal{S}_\pi, \mathcal{S})^{\mathrm{op}}$ spanned by the profinite spaces. We will refer to $\mathcal{S}_\pi^\wedge$ as the ∞*-category of profinite spaces.*

Example E.0.7.12. Let X be a space. We let $X_{\pi}^{\wedge} : \mathcal{S}_{\pi} \to \mathcal{S}$ denote the functor given by $T \mapsto \mathrm{Map}_{\mathcal{S}}(X, T)$. Then $X_{\pi}^{\wedge}$ is a profinite space, which we will refer to as the *profinite completion* of X.

Under the dictionary of Remark **??**, the profinite completion $X_{\pi}^{\wedge}$ can be identified with the diagram $(\mathcal{S}_{/X} \times_{\mathcal{S}} \mathcal{S}_{\pi}) \to \mathcal{S}_{\pi}$: that is, the filtered system $\{T_{\alpha}\}$ indexed by all maps $X \to T_{\alpha}$, where T_{α} is π-finite.

Our main goal in this section is to address the following (closely related) questions:

(a) To what extent does the homotopy theory of profinite spaces approximate the classical homotopy theory of spaces?

(b) To what extent does the profinite completion of a space X approximate the space X itself?

Let us now outline the contents of this section. We begin in §E.1 by considering a simplified variant of the ∞-category $\mathcal{S}_{\pi}^{\wedge}$, where we consider Pro-objects not of the ∞-category $\mathcal{S}_{\pi}$ of π-finite spaces, but instead of the ordinary category $\mathcal{S}\mathrm{et}^{\mathrm{fin}}$ of finite sets. The category $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})$ is well-understood: it is equivalent to the category of *Stone spaces*: that is, topological spaces which are compact, Hausdorff, and totally disconnected (Theorem E.1.4.1). In §E.2, we study an analogous fully faithful embedding from the ∞-category $\mathcal{S}_{\pi}^{\wedge}$ of profinite spaces to the ∞-category $\infty\mathcal{T}\mathrm{op}$ of ∞-topoi (Theorem E.2.4.1). We say that an ∞-topos $\mathcal{X}$ is *profinite* if it belongs to the essential image of the embedding $\mathcal{S}_{\pi}^{\wedge} \hookrightarrow \infty\mathcal{T}\mathrm{op}$. The class of profinite ∞-topoi admits several different descriptions, whose equivalence will be established in §E.3 (see in particular Proposition E.3.1.1, Theorem E.3.2.8, and Theorem E.3.4.1).

The category $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})$ of profinite sets can be regarded as a full subcategory of the ∞-category $\mathcal{S}_{\pi}^{\wedge}$ of profinite spaces: namely, the full subcategory spanned by those profinite spaces which are 0-*truncated*. In §E.4, we study the general notion of an n-truncated map of profinite spaces for $n \geqslant 0$, together with the dual notion of an n-connective map. Our main result (Theorem E.4.1.2) asserts that just as in classical homotopy theory, any map of profinite spaces $f : X \to Z$ admits an essentially unique factorization $X \xrightarrow{f'} Y \xrightarrow{f''} Z$ where f' is $(n+1)$-connective f'' is n-truncated.

Let X be a profinite space, represented by a filtered diagram $\{X_{\alpha}\}$ of π-finite spaces. Then we can form the inverse limit $\varprojlim_{\alpha} X_{\alpha}$ in the ∞-category of spaces. This inverse limit depends functorially on X: we will denote it by $\mathrm{Mat}(X)$, and refer to it as the *materialization* of X. If we choose a base point $x \in \mathrm{Mat}(X)$, then the fiber product $\Omega X = \{x\} \times_X \{x\}$ is a group object in the ∞-category of profinite spaces. In §E.5, we will prove a converse to this assertion: every group object G in the ∞-category of profinite spaces arises as the loop space of a (connected) profinite space, which we will denote by BG and refer to as the *classifying* *space* of G (Theorem E.5.0.4). This can be regarded as homotopy-theoretic analogue of the classical fact that every group object in the category of profinite sets can be written as a filtered inverse limit of finite groups (Proposition E.5.1.3).

One of the most important structural features of the classical homotopy theory of spaces is that colimits are universal in the ∞-category of spaces: that is, the formation of colimits in $\mathcal{S}$ commutes with pullback (Lemma HTT.6.1.3.14). The analogous statement for profinite spaces is not true in complete generality (Warning E.6.0.9). Nevertheless, in §E.6, we will see that it is approximately true: arbitrary colimits are preserved by pullback along maps of π-finite spaces (Corollary E.6.0.8), and many colimits (such as pushouts and geometric realizations) are preserved by pullback along arbitrary maps of profinite spaces (Theorem E.6.3.1).

In §E.7, we will study finiteness conditions on profinite spaces. For a simply connected profinite space X, we show that the following conditions are equivalent (see Theorem E.7.0.5):

(a) For every prime number p and every integer $n \geqslant 2$, the map $\pi_n X \xrightarrow{p} \pi_n X$ has finite cokernel.

(b) For every prime number p and every integer $n \geqslant 2$, the cohomology group $\mathrm{H}^n(X; \mathbf{F}_p)$ is finite.

If these conditions are satisfied, we say that the profinite space X has *finite type*. In §E.8, we show that the materialization functor $X \mapsto \mathrm{Mat}(X)$ is fully faithful when restricted to profinite spaces of finite type (Theorem E.8.2.1). An important special case occurs when X is the profinite completion $Y_\pi^\wedge$ of a simply connected space Y with finitely generated homotopy groups. In this case, X is of finite type (so that passage from X to $\mathrm{Mat}(X)$ involves no loss of information), and the canonical map $Y \to \mathrm{Mat}(X)$ exhibits the homotopy groups of X as the profinite completion of the homotopy groups of Y (Proposition E.8.2.4).

If X is a simply connected space, then we can think of its rationalization $X_{\mathbf{Q}}$ as an invariant which records rational data about X (for example, its homology and cohomology with rational coefficients) while discarding integral and torsion information, while its profinite completion $X_\pi^\wedge$ records "p-adic" data for each prime number p, but discards all information about how these data are related for different values of p. In good cases, one can recover X by "attaching" its rationalization $X_{\mathbf{Q}}$ to its profinite completion $X_\pi^\wedge$ by means of a map of rational spaces $X_{\mathbf{Q}} \to \mathrm{Mat}(X_\pi^\wedge)_{\mathbf{Q}}$. In §E.9 we will describe this reconstruction procedure in detail, following the work of Sullivan in [196].

Remark E.0.7.13. In [219], Quick develops another approach to the homotopy theory of profinite spaces, using the formalism of simplicial profinite sets. For a discussion of the relationship of Definition E.0.7.11 with Quick's theory, we refer the reader to the work of Barnea-Harpaz-Horel ([13]); see also Theorem E.1.5.3.

Contents

E.1 Profinite Sets and Stone Spaces

Recall that a topological space X is a *Stone space* if it is compact, Hausdorff, and has a basis consisting of closed and open sets (Definition A.1.6.8). The category $\mathcal{T}\mathrm{op}_{\mathrm{St}}$ of Stone spaces admits many different descriptions:

(*a*) According to the Stone duality theorem (Theorem A.1.6.11), a topological space X is a Stone space if and only if it is homeomorphic to the spectrum $\mathrm{Spec}(\Lambda)$ of a Boolean algebra Λ. Moreover, the construction $\Lambda \mapsto \mathrm{Spec}(\Lambda)$ determines a (contravariant) equivalence from the category of Boolean algebras to the category $\mathcal{T}\mathrm{op}_{\mathrm{St}}$ of Stone spaces.

(b) For any filtered inverse system of finite sets $\{S_\alpha\}$, the inverse limit $\varprojlim S_\alpha$ is a Stone space (when endowed with the inverse limit topology). This construction determines an equivalence from the category of profinite sets to the category of Stone spaces (Theorem E.1.4.1).

(c) Let p be a prime number. We say that a commutative ring B is an $\mathbf{F}_p$-*Boolean algebra* if $p = 0$ in B and every element $x \in B$ satisfies the equation $x^p = x$. For any $\mathbf{F}_p$-Boolean algebra B, the Zariski spectrum $|\operatorname{Spec} B|$ is a Stone space. Moreover, the construction $B \mapsto |\operatorname{Spec} B|$ induces a (contravariant) equivalence from the category of $\mathbf{F}_p$-Boolean algebras to the category of Stone spaces (Theorem **??**). When $p = 2$, this reduces to the equivalence described in (a) (see Proposition **??**).

Our goal in this section is to give a detailed explanation of (b) (we discuss (a) in §A.1 and (c) in §**??**). Let $\mathcal{S}\mathrm{et}^{\mathrm{fin}}$ denote the category of finite sets. We will refer to Pro-objects of $\mathcal{S}\mathrm{et}^{\mathrm{fin}}$ as *profinite sets*. In this section, we will review some of the basic facts about the category $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})$ of profinite sets and construct the equivalence of categories $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}}) \simeq \mathcal{T}\mathrm{op}_{\mathrm{St}}$. We will then discuss the relationship between the ordinary category $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})$ of profinite sets and the ∞-category $\mathcal{S}_\pi^\wedge = \mathrm{Pro}(\mathcal{S}_\pi)$ of profinite spaces.

E.1.1 Finite Sets and Inverse Limits

Our starting point is the following fundamental fact about profinite sets:

Proposition E.1.1.1. *Let A be a filtered partially ordered set, and suppose we are given a functor $X : A^{\mathrm{op}} \to \mathcal{S}\mathrm{et}$. If the set $X(\alpha)$ is finite for each $\alpha \in A$, then the inverse limit $\varprojlim_{\alpha \in A} X(\alpha)$ is nonempty.*

Proof. Let S denote the collection of all subfunctors $X_0 \subseteq X$ such that the set $X_0(\alpha)$ is nonempty for each $\alpha \in A$. We regard S as a linearly ordered set with respect to inclusions. Note that any linearly ordered subset of S has an infimum in S, since the intersection of any chain of nonempty finite subsets of a finite set is again nonempty. It follows from Zorn's lemma that S has a minimal element $X_0 \subseteq X$. We will show that for each $\alpha \in A$, the set $X_0(\alpha)$ has a single element, so that $\varprojlim_{\alpha \in A} X_0(\alpha)$ consists of a single element. The desired result will then follow from the existence of a map $\varprojlim_{\alpha \in A} X_0(\alpha) \to \varprojlim_{\alpha \in A} X(\alpha)$.

Let $\alpha \in A$ and choose elements $x, y \in X_0(\alpha)$; we will prove that $x = y$. For $\beta \geqslant \alpha$, let $\phi_\beta : X_0(\beta) \to X_0(\alpha)$ be the corresponding map of finite sets, and define subfunctors $X_x, X_y \subseteq X_0$ by the formulae

$$X_x(\beta) = \begin{cases} \phi_\beta^{-1}(X_0(\alpha) - \{x\}) & \text{if } \beta \geqslant \alpha \\ X_0(\beta) & \text{otherwise.} \end{cases}$$

$$X_y(\beta) = \begin{cases} \phi_\beta^{-1}(X_0(\alpha) - \{y\}) & \text{if } \beta \geqslant \alpha \\ X_0(\beta) & \text{otherwise.} \end{cases}$$

Since X_0 was chosen to be a minimal element of S, we must have $X_x, X_y \notin S$. It follows that there exist elements $\beta, \gamma \in A$ such that the sets $X_x(\beta)$ and $X_y(\gamma)$ are empty. Since A is filtered, we may assume without loss of generality that $\beta = \gamma$. Note also that we must have $\beta \geqslant \alpha$, since otherwise $X_x(\beta) = X_0(\beta) \neq \varnothing$. Since $X_x(\beta) = \varnothing$, the map ϕ_β must be the constant map taking the value $x \in X_0(\alpha)$. The same argument shows that ϕ_β takes the constant value y. Since $X_0(\beta) \neq \varnothing$, this proves that $x = y$ as desired. □

E.1.2 The Topology of a Profinite Set

Let $\mathcal{S}\text{et}$ denote the category of sets. We will abuse notation by identifying $\mathcal{S}\text{et}$ with the full subcategory of $\mathcal{T}\text{op}$ spanned by those topological spaces which are endowed with the discrete topology. Since the category $\mathcal{T}\text{op}$ admits filtered inverse limits, the inclusion $\mathcal{S}\text{et} \subseteq \mathcal{T}\text{op}$ extends to a functor $\psi : \text{Pro}(\mathcal{S}\text{et}^{\text{fin}}) \to \mathcal{T}\text{op}$ which preserves filtered inverse limits (moreover, this extension is unique up to unique isomorphism).

Proposition E.1.2.1. *The functor* $\psi : \text{Pro}(\mathcal{S}\text{et}^{\text{fin}}) \to \mathcal{T}\text{op}$ *described above is fully faithful.*

Proof. Let us identify $\text{Pro}(\mathcal{S}\text{et}^{\text{fin}})$ with the category of left exact functors $F : \mathcal{S}\text{et}^{\text{fin}} \to \mathcal{S}\text{et}$. The functor ψ admits a left adjoint ϕ, which carries a topological space X to the left exact functor $\phi(X)$ given by the formula

$$\phi(X)(J) = \text{Hom}_{\mathcal{T}\text{op}}(X, J).$$

To prove that ψ is fully faithful, it will suffice to show that if S is a profinite set and $X = \psi(S)$, then the adjoint map $\phi(X) \to S$ is an isomorphism of profinite sets.

Choose a filtered partially ordered set A and an isomorphism of profinite sets $S \simeq \varprojlim_{\alpha \in A} S_\alpha$ in $\text{Pro}(\mathcal{S}\text{et}^{\text{fin}})$, where each S_α is a finite set. Then $X = \psi(S)$ can be identified with the inverse limit of the diagram $\{S_\alpha\}$ in the category $\mathcal{T}\text{op}$ of topological spaces. Unwinding the definitions, we must show that for every finite set T, the natural map

$$\theta : \varinjlim \text{Hom}_{\mathcal{S}\text{et}}(S_\alpha, T) \to \text{Hom}_{\mathcal{T}\text{op}}(X, T)$$

is a bijection. We first show that θ is injective. Suppose we are given a pair of maps $f_0, f_1 : S_\alpha \to T$ such that the composite maps $X \xrightarrow{\phi_\alpha} S_\alpha \to T$ coincide. We wish to show that there exists $\beta \geqslant \alpha$ such that the composite maps $S_\beta \to S_\alpha \to T$ coincide. Let $S' = \{s \in S_\alpha : f_0(s) \neq f_1(s)\}$. For each $s \in S'$, the inverse image $\phi_\alpha^{-1}\{s\} \subseteq X$ is empty. Using Proposition E.1.1.1, we deduce that the inverse image of $\{s\}$ in S_{β_s} is empty for some $\beta_s \geqslant \alpha$. Since S' is finite, we may choose $\beta \in A$ such that $\beta \geqslant \beta_s$ for all $s \in S'$. Then the inverse image of S' in S_β is empty, so that β has the desired property.

We now show that θ is surjective. Suppose we are given a continuous map $f : X \to T$. We wish to show that f factors through $\phi_\alpha : X \to S_\alpha$ for some index $\alpha \in A$. If T is empty, then X is empty and so (by Proposition E.1.1.1) the set S_α is empty for some $\alpha \in A$, and therefore f factors through S_α. Let us therefore assume that T is nonempty. Fix $t \in T$ and let $X_t = f^{-1}\{t\}$. Note that X_t is both open and closed in X. Since X is compact, X_t is also compact. By construction, the topological space X has a basis consisting of sets of the form $\phi_\alpha^{-1}\{s\}$, where $s \in S_\alpha$. In particular, for every point $x \in X_t$, we can choose a $\alpha_x \in A$ and a point $s_x \in S_{\alpha_x}$ such that $x \in \phi_{\alpha_x}^{-1}\{s_x\} \subseteq X_t$. The sets $U_x = \phi_{\alpha_x}^{-1}\{s_x\}$ form an open covering of X_t. Since X_t is compact, there exist finitely many points $x_1, \ldots, x_n \in X_t$ such that $X_t = \bigcup_{1 \leqslant i \leqslant n} U_{x_i}$. Since A is filtered, we can choose an index $\alpha_t \in A$ such that $\alpha_t \geqslant \alpha_{x_i}$ for $1 \leqslant i \leqslant n$. Because T is finite, we may further choose α such that $\alpha \geqslant \alpha_t$ for all $t \in T$. Let $S_t = \{s \in S_\alpha : \varnothing \neq \phi_\alpha^{-1}\{s\} \subseteq X_t\}$. Then

$$X_t \subseteq \bigcup_{1 \leqslant i \leqslant n} U_{x_i} \subseteq \phi_\alpha^{-1} S_t \subseteq X_t.$$

Note that the subsets $S_t \subseteq S_\alpha$ are disjoint. Since T is nonempty, there exists a map of finite sets $f' : S_\alpha \to T$ such that $S_t \subseteq f'^{-1}\{t\}$ for each $t \in T$. Then $f = f' \circ \phi_\alpha$ as desired. □

E.1.3 Stone Spaces

Our next goal is to describe the essential image of the fully faithful embedding $\psi : \mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}}) \to \mathcal{T}\mathrm{op}$ appearing in Proposition E.1.2.1. First, let us review a bit of classical point-set topology.

Proposition E.1.3.1. *Let X be a compact Hausdorff space. The following conditions are equivalent:*

- (a) *There exists a basis for the topology of X consisting of sets which are both closed and open.*
- (b) *Every connected subset of X is a singleton.*

Proof. Suppose first that (a) is satisfied, and let $S \subseteq X$ be connected. Then S is nonempty; we wish to show that it contains only a single element. Suppose otherwise, and choose distinct points $x, y \in S$. Since X is Hausdorff, there exists an open set $U \subseteq X$ containing x but not y. Using condition (a), we can assume that the set U is also closed. Then $U \cap S$ and $(X - U) \cap S$ is a decomposition of S into nonempty closed and open subsets, contradicting the connectedness of S.

To prove the converse, we need the following fact:

- $(*)$ Let $x, y \in X$. Assume that, for every closed and open subset $U \subseteq X$, if x belongs to U then y also belongs to U. Then there is a connected subset of X containing both x and y.

To prove $(*)$, consider the collection S of all closed subsets $Y \subseteq X$ which contain both x and y, having the property that any closed and open subset $U \subseteq Y$ containing x also contains y. Then S is nonempty (since $X \in S$). We claim that every linearly ordered subset of S has a lower bound in S. Suppose we are given such a linearly ordered set $\{Y_\alpha\}$, and let $Y = \bigcap Y_\alpha$. Then Y contains the points x and y. If $Y \notin S$, then we can decompose Y as the disjoint union of (closed and open) subsets $Y_-, Y_+ \subseteq Y$, with $x \in Y_-$ and $y \in Y_+$. Let us regard Y_- and Y_+ as compact subsets of X. Since X is Hausdorff, we can choose disjoint open sets $U_-, U_+ \subseteq X$ with $Y_- \subseteq U_-$ and $Y_+ \subseteq U_+$. The intersection

$$(X - U_-) \cap (X - U_+) \cap \bigcap_\alpha Y_\alpha$$

is empty. Since X is compact, we conclude that there exists an index α such that $(X - U_-) \cap (X - U_+) \cap Y_\alpha = \varnothing$. Then $Y_\alpha \cap U_-$ and $Y_\alpha \cap U_+$ are disjoint closed and open subsets of Y_α containing x and y respectively, contradicting our assumption that $Y_\alpha \in S$. This completes the proof that $Y \in S$, so that S satisfies the hypotheses of Zorn's lemma. We may therefore choose a minimal element $Z \in S$.

To complete the proof of $(*)$, it will suffice to show that Z is connected. Assume otherwise: then there exists a decomposition of Z into closed and open nonempty subsets $Z', Z'' \subseteq Z$. Since $Z \in S$, we have either $x, y \in Z'$ or $x, y \in Z''$; let us suppose that $x, y \in Z'$. The minimality of Z implies that $Z' \notin S$, so that Z' can be further decomposed into closed and open subsets $Z'_-, Z'_+ \subseteq Z'$ containing x and y, respectively. Then Z'_- and $Z'_+ \cup Z''$ are closed and open subsets of Z containing x and y, respectively, contradicting our assumption that $Z \in S$. This completes the proof of $(*)$.

Now suppose that (b) is satisfied; we wish to prove (a). It follows from condition $(*)$ that for every pair of distinct points $x, y \in X$, there exists a closed and open subset $V_{x,y}$ which contains y but does not contain x. Let $U \subseteq X$ be an open set; we wish to show that U contains a closed and open neighborhood of each point $x \in U$. Then $X - U$ is covered by the open sets $\{V_{x,y}\}_{y \in X-U}$. Since $X - U$ is compact, we can choose a finite subset $\{y_1, \ldots, y_n\} \subseteq X - U$ such that $X - U \subseteq \bigcup_{1 \leqslant i \leqslant n} V_{x,y_i}$. It follows that $X - \bigcup_{1 \leqslant i \leqslant n} V_{x,y_i}$ is a closed and open subset of X which contains x and is contained in U. □

Definition E.1.3.2. Let X be a topological space. We say that X is a *Stone space* if it is compact, Hausdorff, and satisfies the equivalent conditions of Proposition E.1.3.1. We let $\mathcal{T}\mathrm{op}$ denote the category of topological spaces, and $\mathcal{T}\mathrm{op}_{\mathrm{St}}$ the full subcategory of $\mathcal{T}\mathrm{op}$ spanned by the Stone spaces.

Remark E.1.3.3. Let X be a compact Hausdorff space. The collection of closed and open subsets of X is closed under finite intersections. Consequently, to show that the X is a Stone space, it suffices to verify that the collection of closed and open sets forms a subbasis for the topology of X.

Remark E.1.3.4. Let X be a Stone space. Then every closed subset $Y \subseteq X$ is also a Stone space (with the induced topology).

E.1.4 The Stone Duality Theorem

We now establish a refinement of Proposition E.1.2.1:

Theorem E.1.4.1 (Stone Duality)**.** *The functor $\psi : \mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}}) \to \mathcal{T}\mathrm{op}$ of Proposition E.1.2.1 induces an equivalence of categories $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}}) \simeq \mathcal{T}\mathrm{op}_{\mathrm{St}}$.*

Lemma E.1.4.2. *The category $\mathcal{T}\mathrm{op}_{\mathrm{St}}$ of Stone spaces is closed under the formation of projective limits (in the larger category $\mathcal{T}\mathrm{op}$ of topological spaces).*

Proof. Suppose we are given an arbitrary diagram $\{X_\alpha\}$ of Stone spaces; we wish to show that $\varprojlim X_\alpha$ is also a Stone space. Note that $\varprojlim_\alpha X_\alpha$ can be identified with a closed subspace of the product $\prod_\alpha X_\alpha$. It will therefore suffice to show that $\prod_\alpha X_\alpha$ is a Stone space (Remark E.1.3.4). This product is obviously Hausdorff, compact by virtue of Tychanoff's theorem, and has a subbasis consisting of inverse images of open subsets of the spaces X_α. Since each X_α has a basis of closed and open sets, we conclude that $\prod_\alpha X_\alpha$ has a subbasis consisting of closed and open sets, and is therefore a Stone space by Remark E.1.3.3. □

Proof of Theorem E.1.4.1. Using Proposition E.1.2.1 and Lemma E.1.4.2, we see that the functor ψ is a fully faithful embedding $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}}) \to \mathcal{T}\mathrm{op}_{\mathrm{St}}$. To complete the proof, it will suffice to show that this map is essentially surjective.

Fix a Stone space X, and let $\mathcal{C}$ be the category whose objects are pairs (T, f), where T is a finite set (which we regard as a discrete topological space) and $f : X \to T$ is a surjection. Let $Y = \varprojlim_{(T,f)\in\mathcal{C}} T$, so that Y is a Stone space belonging to the essential image of ψ. To show that X belongs to the essential image of ψ, it will suffice to show that the canonical map $f : X \to Y$ is a homeomorphism.

Note that Y has a basis of open sets consisting of inverse images of points under the maps $Y \to T$, where $(T, f) \in \mathcal{C}$. It follows that the image of f is dense in Y. Since X is compact and Y is Hausdorff, the map f is closed and therefore surjective. To complete the proof that f is a homeomorphism, it will suffice to show that f is injective. To this end, suppose we are given two distinct points $x, y \in X$. Since X is a Stone space, we can choose a continuous map $u : X \to \{0, 1\}$ such that $u(x) = 0$ and $u(y) = 1$. By construction, this map factors through Y, so that $u(x) \neq u(y)$. □

Corollary E.1.4.3. *Let $f : \{X_\alpha\} \to \{Y_\beta\}$ be a map in the category $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})$. If f induces a bijection of sets $\varprojlim X_\alpha \to \varprojlim Y_\beta$, then f is an isomorphism in $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})$.*

Proof. According to Theorem E.1.4.1, it will suffice to show that F is a homeomorphism of Stone spaces. This is clear, since it is continuous bijection between compact Hausdorff spaces. □

Remark E.1.4.4. Since the functor $\psi : \mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}}) \to \mathcal{T}\mathrm{op}$ admits a left adjoint (see the proof of Proposition E.1.2.1), it follows from Theorem E.1.4.1 that the inclusion functor $\mathcal{T}\mathrm{op}_{\mathrm{St}} \hookrightarrow \mathcal{T}\mathrm{op}$ also admits a left adjoint. Unwinding the definitions, we see that this left adjoint carries a topological space X to $\varprojlim_E X/E$, where the inverse limit is taken over all equivalence relations E on X for which X/E is finite and the map $X \to X/E$ is continuous. In the special case where X has the discrete topology, we will denote this inverse limit by βX, and refer to it as the *Stone-Čech compactification* of X.

Warning E.1.4.5. The Stone-Čech compactification of an arbitrary topological space X can be defined as an initial object in the category of compact Hausdorff spaces Y equipped with a map $X \to Y$. If the topology on X is discrete, then the Stone-Čech compactification of X is a Stone space, and is therefore homeomorphic to the space βX of Remark E.1.4.4. However, this need not be true if X is not discrete.

E.1.5 Profinite Kan Complexes

Our goal for the remainder of this section is to describe a concrete model for the ∞-category $\mathcal{S}_{\pi}^{\wedge}$ of profinite spaces. First, we need to introduce a bit of notation.

Definition E.1.5.1. Let $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_{\Delta}$ denote the category $\mathrm{Fun}(\mathbf{\Delta}^{\mathrm{op}}, \mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}}))$ of simplicial objects of $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})$. We will refer to the objects of $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_{\Delta}$ as *simplicial profinite sets.*

If X is a simplicial set with only finitely many vertices in each degree, then we can regard X as simplicial profinite set (by means of the full faithful embedding $\mathcal{S}\mathrm{et}^{\mathrm{fin}} \hookrightarrow \mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})$). We will regard $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_{\Delta}$ as a simplicial category, with mapping spaces given by

$$\mathrm{Hom}(\Delta^n, \mathrm{Map}_{\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_{\Delta}}(X, Y)) \simeq \mathrm{Hom}_{\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_{\Delta}}(\Delta^n \times X, Y).$$

Definition E.1.5.2. Let X be a simplicial profinite set. We will say that X is *well-presented* if it can be written as the inverse limit of a diagram $\{X_\alpha\}_{\alpha \in A}$ indexed by a partially ordered set A satisfying the following conditions:

(1) The partially ordered set A is filtered. Moreover, for every element $\alpha \in A$, the set $\{\beta \in A : \beta \leqslant \alpha\}$ is finite.

(2) Each X_α is a simplicial set with only finitely many simplices of each dimension, regarded as a simplicial profinite set as in Definition E.1.5.1.

(3) The diagram $\{X_\alpha\}_{\alpha \in A}$ is fibrant with respect to the injective model structure on $\mathrm{Fun}(A^{\mathrm{op}}, \mathcal{S}\mathrm{et}_{\Delta})$. In particular, each X_α is a Kan complex.

(4) For each index $\alpha \in A$, there exists an integer $n \geqslant 0$ such that the Kan complex X_α is n-coskeletal.

In this case, we will also say that $\{X_\alpha\}_{\alpha \in A}$ is a *good presentation* of X. We let $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})^{\mathrm{wp}}_{\Delta}$ denote the full subcategory of $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_{\Delta}$ spanned by the well-presented simplicial profinite sets.

Theorem E.1.5.3. *The simplicial category $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})^{\mathrm{wp}}_{\Delta}$ is fibrant. That is, for every pair of well-presented simplicial profinite sets X and Y, the mapping space $\mathrm{Map}_{\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_{\Delta}}(X, Y)$ is a Kan complex. Moreover, there is a canonical equivalence of ∞-categories*

$$\mathrm{N}(\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})^{\mathrm{wp}}_{\Delta}) \simeq \mathcal{S}^{\wedge}_{\pi} .$$

Remark E.1.5.4. For a refinement of Theorem E.1.5.3, we refer the reader to [13].

E.1.6 Preliminaries

We now collect some auxiliary results which will be needed in our proof of Theorem E.1.5.3.

Lemma E.1.6.1. *Let S be a well-founded partially ordered set, and let $u : X \to Y$ be a morphism in the category $\mathrm{Fun}(S^{\mathrm{op}}, \mathcal{S}\mathrm{et}_{\Delta})$. Then u is a fibration with respect to the injective model structure on $\mathrm{Fun}(S^{\mathrm{op}}, \mathcal{S}\mathrm{et}_{\Delta})$ if and only if, for every index $s \in S$, the induced map*

$$\theta_s : X(s) \to Y(s) \times_{\varprojlim_{t<s} Y(t)} \varprojlim_{t<s} X(t)$$

is a Kan fibration.

Proof. We first prove the "only if" direction. For every simplicial set K and each $s \in S$, define functors $\underline{K}_{\leqslant s}$ and $\underline{K}_{<s}$ by the formulae

$$\underline{K}_{\leqslant s}(t) = \begin{cases} K & \text{if } t \leqslant s \\ \varnothing & \text{otherwise} \end{cases} \qquad \underline{K}_{<s}(t) = \begin{cases} K & \text{if } t < s \\ \varnothing & \text{otherwise.} \end{cases}$$

Note that the map θ_s is a Kan fibration if and only if, for every trivial cofibration of simplicial sets $K \to L$, the induced map $v^s_{K,L} : \underline{K}_{\leqslant s} \amalg_{\underline{K}_{<s}} \underline{L}_{<s} \to \underline{L}_{\leqslant s}$ has the left lifting property with respect to u. Since each of these maps is a trivial cofibration with respect to the injective model structure on $\mathrm{Fun}(A^{\mathrm{op}}, \mathcal{S}\mathrm{et}_{\Delta})$, the "only if" direction of the assertion follows immediately.

Conversely, suppose that each of the maps θ_s is a Kan fibration. Using our assumption that S is well-founded, we can choose an ordinal α and an enumeration $S = \{s_\beta\}_{\beta < \alpha}$ such that $s_\beta \leqslant s_\gamma$ implies $\beta \leqslant \gamma$. Let $i : U \to V$ be a trivial cofibration in $\mathrm{Fun}(S^{\mathrm{op}}, \mathcal{S}\mathrm{et}_{\Delta})$. For each $\beta \leqslant \alpha$, define $U_\beta \in \mathrm{Fun}(S^{\mathrm{op}}, \mathcal{S}\mathrm{et}_{\Delta})$ by the formula

$$U_\beta(s_\gamma) = \begin{cases} V(s_\gamma) & \text{if } \gamma < \beta \\ U(s_\gamma) & \text{if } \gamma \geqslant \beta. \end{cases}$$

Then i is a transfinite composition of the morphisms $U_\beta \to U_{\beta+1}$, each of which is a pushout of the morphism $v^s_{U(s),V(s)}$ where $s = s_\beta$. If each θ_s is a Kan fibration, then u has the right lifting property with respect to each of the maps $v^s_{U(s),V(s)}$, and therefore also with respect to the morphism i. □

Lemma E.1.6.2. *Let S be a partially ordered set. Suppose that for each $s \in S$, the set $\{t \in S : t \leqslant s\}$ is finite. Then the collection of fibrations in $\mathrm{Fun}(S^{\mathrm{op}}, \mathcal{S}\mathrm{et}_\Delta)$ (which we regard as endowed with the injective model structure) is closed under filtered colimits.*

Proof. This follows immediately from the description of the fibrations in $\mathrm{Fun}(S^{\mathrm{op}}, \mathcal{S}\mathrm{et}_\Delta)$ supplied by Lemma E.1.6.1. □

Lemma E.1.6.3. *Let Y be a simplicial set which has only finitely many simplices of each dimension and which is n-coskeletal for some integer n. Then Y is compact when viewed as an object of the category $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})^{\mathrm{op}}_\Delta$.*

Proof. For every simplicial profinite set X, we can write $\mathrm{Hom}_{\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_\Delta}(X, Y)$ as an inverse limit

$$\varprojlim_{[a]\to[b]} \mathrm{Hom}_{\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})}(X_b, Y_a),$$

where the limit is taken over all morphisms $[b] \to [a]$ in $\mathbf{\Delta}$. Since Y is n-coskeletal, we can replace this limit by the limit over the category of all maps $[b] \to [a]$ where $a, b \leqslant n$. Since each Y_a is finite, the construction $X \mapsto \mathrm{Hom}_{\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})}(X_b, Y_a)$ carries filtered inverse limits in $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_\Delta$ to filtered colimits of sets. It follows that the construction

$$X \mapsto \mathrm{Hom}_{\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_\Delta}(X, Y)$$

also carries filtered limits in $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_\Delta$ to filtered colimits of sets. □

Lemma E.1.6.4. *Let A be a filtered partially ordered set. Then there exists a cofinal map of partially ordered sets $f : A' \to A$, where A' is a filtered partially ordered set having the property that for every element $\alpha \in A'$, the set $\{\beta \in A' : \beta \leqslant \alpha\}$ is finite.*

Proof. Take A' to be the collection of all finite subsets of A which contain a largest element, and $f : A' \to A$ to be the function which assigns to every such subset its largest element. □

Lemma E.1.6.5. *Let X be a Kan complex. The following conditions are equivalent:*

(a) *There exists a homotopy equivalence of Kan complexes $X \simeq X'$, where X' has finitely many simplices of each dimension.*

(b) *The set $\pi_0 X$ is finite, and the group $\pi_n(X, x)$ is finite for each integer $n \geqslant 1$ and each vertex $x \in X$.*

Proof. Suppose first that (a) is satisfied. Replacing X by X', we may suppose that X has finitely many simplices of each dimension. It follows immediately that $\pi_0 X$ is finite (since it is a quotient of the set of 0-simplices of X) and that each homotopy group $\pi_n(X, x)$ is finite (since it can be realized as a quotient of a subset of the set of n-simplices of X).

Now suppose that (b) is satisfied. We wish to show that there exists a homotopy equivalence $X \to X'$, where X' has finitely many simplices of each dimension. Writing X as a disjoint union of its connected components, we can reduce to the case where X is connected. We will construct X' as the inverse limit of a tower of Kan complexes

$$\cdots \to X'(3) \to X'(2) \to X'(1)$$

with the following properties:

(i) For every integer $n \geqslant 1$, the map $X \to X'(n)$ exhibits $X'(n)$ as an n-truncation of X.

(ii) For each integer $n \geqslant 1$, the Kan complex $X'(n)$ has only finitely many simplices of each dimension.

(iii) The maps $X'(n) \to X'(n-1)$ are bijective on simplices of dimension $< n$.

The construction proceeds by induction on n. To begin, choose a base point $x \in X$, and let $G = \pi_1(X, x)$. Let EG denote the simplicial set whose n-simplices are maps from $\{0, \ldots, n\}$ into G. Then we can take $X'(1)$ to be the quotient $BG = EG/G$.

To carry out the inductive step, suppose that $X'(n-1)$ has been constructed, and set $A = \pi_n(X, x)$. Let $A[n+1]$ denote the chain complex of abelian groups given by A concentrated in degree $n+1$, and let C_* denote the chain complex of abelian groups

$$\cdots \to 0 \to A \xrightarrow{\text{id}} A \to 0 \to \cdots$$

which is concentrated in degrees n and $n+1$, so that we have a surjection of chain complexes $u : C_* \to A[n+1]$. Let $v : Y \to Z$ be the map of simplicial abelian groups associated to u by the Dold-Kan correspondence. Note that the map $\tau_{\leqslant n} X \to X'(n-1)$ is an n-gerbe banded by A (regarded as a local system of abelian groups on $X'(n-1)$, so that there exists a pullback diagram

$$\begin{array}{ccc} \tau_{\leqslant n} X & \longrightarrow & (Y \times EG)/G \\ \downarrow & & \downarrow \\ X'(n-1) & \longrightarrow & (Z \times EG)/G \end{array}$$

in the ∞-category $\mathcal{S}$. Since the right vertical map in this diagram is a Kan fibration, the fiber product

$$X'(n) = X'(n-1) \times_{(Z \times EG)/G} (Y \times EG)/G$$

satisfies all of our requirements. □

Lemma E.1.6.6. *Let S be a partially ordered set with the property that for each $s \in S$, the set $\{t \in S : t < s\}$ is finite, and suppose that we are given a diagram $X : \mathrm{N}(S)^{\mathrm{op}} \to \mathcal{S}_{\pi}$. Then X is equivalent to the map induced by a functor of ordinary categories $Y : S^{\mathrm{op}} \to \mathcal{S}\mathrm{et}_{\Delta}$ satisfying the following conditions:*

(a) *The diagram Y is fibrant with respect to the injective model structure on the category $\mathrm{Fun}(S^{\mathrm{op}}, \mathcal{S}\mathrm{et}_{\Delta})$.*

(b) *For each $s \in S$, the simplicial set $Y(s)$ is a Kan complex with finitely many simplices in each dimension.*

(c) *For each $s \in S$, there exists an integer n such that the simplicial set $Y(s)$ is n-coskeletal.*

Proof. Since S is well-founded, we can choose an ordinal α and a transfinite enumeration $S = \{s_\beta\}_{\beta < \alpha}$ such that $s_\beta \leqslant s_\gamma$ implies $\beta \leqslant \gamma$. For each $\beta \leqslant \alpha$, let $S_\beta = \{s_\gamma\}_{\gamma < \beta} \subseteq S$. We will construct Y as the amalgam of a compatible family of diagrams $Y_\beta : S_\beta^{\mathrm{op}} \to \mathcal{S}\mathrm{et}_{\Delta}$, satisfying the analogues of conditions (a), (b), and (c). The construction proceeds by induction. Assume that $\beta < \alpha$ and that Y_β has been constructed as a fibrant diagram $S_\beta^{\mathrm{op}} \to \mathcal{S}\mathrm{et}_{\Delta}$. Using Lemma E.1.6.1, we deduce that the restriction of Y_β to $\{t \in S : t < s_\beta\}$ is a fibrant diagram. Let K denote the inverse limit $\varprojlim_{t < s_\beta} Y_\beta(t)$, calculated in the ordinary category of simplicial sets. Then K is also the homotopy limit of the diagram $\{Y_\beta(t)\}_{t < s_\beta}$. It follows that K is a Kan complex which is equivalent to $\varprojlim_{t < s_\beta} X(t)$. Consequently, the natural map $X(s_\beta) \to \varprojlim_{t < s_\beta}$ determines a map of Kan complexes $X(s_\beta) \to K$. Since $X(s_\beta)$ is π-finite, Lemma E.1.6.5 implies that there exists a homotopy equivalence of Kan complexes $K' \to X(s_\beta)$, where Y has finitely many simplices of each dimension. Replacing K' by a suitably truncation, we may suppose that K' is n-coskeletal for $n \geqslant 0$. Let f denote the composite map $K' \to X(s_\beta) \to K$. Set $K'' = \mathrm{Fun}(\{0\}, K') \times_{\mathrm{Fun}(\{0\}, K)} \mathrm{Fun}(\Delta^1, K)$. Then evaluation at $\{1\} \subseteq \Delta^1$ determines a Kan fibration $K'' \to K$, which is equivalent to the projection map $X(s_\beta) \to \varprojlim_{t < s_\beta} X(t)$. We complete the proof by taking $Y_{\beta+1}$ to be the functor given on objects by the formula

$$Y_{\beta+1}(t) = \begin{cases} K'' & \text{if } t = s_\beta \\ Y_\beta(t) & \text{otherwise.} \end{cases}$$

□

E.1.7 The Proof of Theorem E.1.5.3

We now turn to the proof of Theorem E.1.5.3. Our first goal is to show that the simplicial category $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})^{\mathrm{wp}}_{\Delta}$ is fibrant. Let X and Y be well-presented simplicial profinite spaces;

we wish to show that the simplicial set $\mathrm{Map}_{\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_\Delta}(X, Y)$ is a Kan complex. Choose good presentations

$$X \simeq \varprojlim_{\alpha \in A} X_\alpha \qquad Y \simeq \varprojlim_{\beta \in B} Y_\beta.$$

Since the diagram $\{Y_\beta\}_{\beta \in B}$ is fibrant (with respect to the injective model structure on $\mathrm{Fun}(B^{\mathrm{op}}, \mathcal{S}\mathrm{et}_\Delta)$), it follows that the diagram of simplicial sets $\{\mathrm{Fun}(X_\alpha, Y_\beta)\}_{\beta \in B}$ is fibrant for each $\alpha \in A$. Applying Lemma E.1.6.2, we deduce that the diagram $\{\varinjlim_{\alpha \in A} \mathrm{Fun}(X_\alpha, Y_\beta)_{\beta \in B}$ is fibrant. Using Lemma E.1.6.3, we can identify this with the diagram of simplicial sets

$$\{\mathrm{Map}_{\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_\Delta}(X, Y_\beta)\}_{\beta \in B}.$$

It follows that

$$\mathrm{Map}_{\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_\Delta}(X, Y) \simeq \varprojlim_{\beta \in B} \mathrm{Map}_{\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_\Delta}(X, Y_\beta)$$

is a Kan complex, as desired. Moreover, the above argument also proves the following:

- $(*)$ If $\{Y_\beta\}_{\beta \in B}$ is a good presentation of Y, then Y is a homotopy limit of the diagram $\{Y_\beta\}_{\beta \in B}$ in the simplicial category $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_\Delta^{\mathrm{wp}}$.

Let $\mathcal{C}$ denote the simplicial nerve of $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_\Delta^{\mathrm{wp}}$. Using $(*)$ and Theorem HTT.4.2.4.1 , we deduce:

- $(*')$ If $\{Y_\beta\}_{\beta \in B}$ is a good presentation of $Y \in \mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_\Delta$, then Y is a limit of the diagram $\{Y_\beta\}$ in the ∞-category $\mathcal{C}$.

Choose a fully faithful embedding $f : \mathcal{C} \to \overline{\mathcal{C}}$, where $\overline{\mathcal{C}}$ admits small limits, and the functor f preserves all small limits which exist in $\mathcal{C}$ (for example, we can take f to be the Yoneda embedding $\mathcal{C} \to \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$).

Let $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_\Delta^0 \subseteq \mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_\Delta$ denote the full subcategory spanned by those Kan complexes which have only finitely many simplices in each degree, which are n-truncated for some integer n (regarded as simplicial profinite sets as in Definition E.1.5.1). Let $\mathcal{C}^0$ denote the simplicial nerve of $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_\Delta^0$. Since $\overline{\mathcal{C}}$ admits small filtered limits, the composite functor $\mathcal{C}^0 \hookrightarrow \mathcal{C} \xrightarrow{f} \overline{\mathcal{C}}$ admits an essentially unique extension to a functor $F : \mathrm{Pro}(\mathcal{C}^0) \to \overline{\mathcal{C}}$. We will prove the following:

- $(\star)$ The functor F is fully faithful, and its essential image coincides with the essential image of f.

It follows from Lemma E.1.6.5 that a Kan complex X is homotopy equivalent to an object of $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_\Delta^0$ if and only if X is π-finite, so that the inclusion $\mathcal{C}^0 \hookrightarrow \mathcal{S}_\pi$ is an equivalence of ∞-categories. Assuming $(\star)$, we obtain equivalences

$$\mathcal{S}_\pi^\wedge = \mathrm{Pro}(\mathcal{S}_\pi) \leftarrow \mathrm{Pro}(\mathcal{C}^0) \simeq \mathcal{C},$$

thereby completing the proof.

It remains to prove ($\star$). We first show that the essential image of F is contained in the essential image of f. Let X be a profinite space. Then we can write X as the limit of a diagram $\{X_\alpha\}_{\alpha \in A}$ indexed by a filtered partially ordered set A, where each X_α is π-finite. Using Lemma E.1.6.4, we can assume that for each $\alpha \in A$, the set $\{\beta \in A : \beta \leqslant \alpha\}$ is finite. Using Lemma E.1.6.6, we can assume that $\{X_\alpha\}_{\alpha \in A}$ is a diagram in the ordinary category of simplicial sets, which is a good presentation for some simplicial profinite set $\overline{X} \in \mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_\Delta$. Using ($*'$), we deduce that $\overline{X}$ is a limit of the diagram $\{X_\alpha\}_{\alpha \in A}$ in the ∞-category $\mathcal{C}$. Since f preserves small limits, it follows that $f(\overline{X})$ is a limit of the diagram $\{f(X_\alpha)\}_{\alpha \in A}$. Since the functor F preserves small filtered limits, we have

$$F(X) \simeq \varprojlim F(X_\alpha) = \varprojlim f(X_\alpha) \simeq f(\overline{X}),$$

so that $F(X)$ belongs to the essential image of f.

We next prove that F is fully faithful. Fix objects $X, Y \in \mathcal{S}_\pi^\wedge$; we wish to show that the canonical map

$$\theta_{X,Y} : \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(X,Y) \to \mathrm{Map}_{\overline{\mathcal{C}}}(F(X), F(Y))$$

is a homotopy equivalence. Since F preserves small filtered limits, the construction $Y \mapsto \theta_{X,Y}$ is compatible with filtered limits. It will therefore suffice to show that $\theta_{X,Y}$ is an equivalence in the special case where Y is π-finite. Using Lemma E.1.6.5, we may assume without loss of generality that Y is n-truncated and has finitely many simplices in each dimension. Write $X = \varprojlim_{\alpha \in A} X_\alpha$ as above. We then have a commutative diagram

$$\begin{array}{ccc} \varinjlim_\alpha \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(X_\alpha, Y) & \longrightarrow & \varinjlim_\alpha \mathrm{Map}_{\overline{\mathcal{C}}}(F(X_\alpha), Y) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(X, Y) & \longrightarrow & \mathrm{Map}_{\overline{\mathcal{C}}}(F(X), F(Y)). \end{array}$$

The upper horizontal map is a homotopy equivalence because the functor F is fully faithful when restricted to $\mathcal{C}^0$ (where it agrees with f). The left vertical map is a homotopy equivalence because Y is π-finite, and the right vertical map can be identified with the map

$$\varinjlim_{\alpha} \mathrm{Map}_{\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_\Delta}(X_\alpha, Y) \to \mathrm{Map}_{\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})_\Delta}(\overline{X}, Y),$$

which is an isomorphism by Lemma E.1.6.3.

To complete the proof of Theorem E.1.5.3, it will suffice to show that for every object $X \in \mathcal{C}$, the object $f(X) \in \overline{\mathcal{C}}$ belongs to the essential image of F. To prove this, choose a good presentation $\{X_\alpha\}_{\alpha \in A}$ for X. It follows from ($*'$) that X is a limit of the diagram $\{X_\alpha\}_{\alpha \in A}$ in $\mathcal{C}$, so that $f(X) \simeq \varprojlim_\alpha f(X_\alpha)$. Since F is a fully faithful embedding which preserves small filtered limits, the essential image of F is closed under small filtered limits. It will therefore suffice to show that $f(X_\alpha)$ belongs to the essential image of F for each $\alpha \in A$. This is clear, since $f(X_\alpha) \simeq F(X_\alpha)$.

E.2 Shape Theory

The ∞-category $\mathcal{S}_\pi$ of π-finite spaces is a bounded ∞-pretopos, whose associated ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{S}_\pi)$ can be identified with the ∞-category $\mathcal{S}$. Using Theorem A.7.5.3 (and the fact that the ∞-topos $\mathcal{S}$ is a final object of $\infty\mathcal{T}\mathrm{op}$, we deduce the existence of a fully faithful embedding

$$\Psi_\pi : \mathcal{S}_\pi^\wedge = \mathrm{Pro}(\mathcal{S}_\pi) \hookrightarrow \infty\mathcal{T}\mathrm{op}_{/\mathcal{S}} \simeq \infty\mathcal{T}\mathrm{op}\,.$$

In this section, we will see that the functor Ψ_π embedding has a very natural interpretation in the language of shape theory: it appears as the right adjoint to the *profinite shape functor* $\mathrm{Sh}_\pi : \infty\mathcal{T}\mathrm{op} \to \mathcal{S}_\pi^\wedge$ (Variant E.2.2.2). It follows that the essential image of Ψ_π ∞-topoi can be regarded as a localization of the ∞-category $\infty\mathcal{T}\mathrm{op}$ of all ∞-topoi. Our main goal is to obtain an explicit description of the associated localization functor $\Psi_\pi \circ \mathrm{Sh}_\pi$, which we will denote by $\mathcal{X} \mapsto \mathcal{X}^{\mathrm{pf}}$ and refer to as *profinite reflection*. As we will see, the ∞-topos $\mathcal{X}^{\mathrm{pf}}$ can be regarded as a "best approximation" to $\mathcal{X}$ that can be recovered from the locally constant constructible objects of $\mathcal{X}$ (for a precise statement, see Theorem E.2.3.2).

E.2.1 Pro-Spaces

We begin with some general remarks about Pro-objects of the ∞-category of spaces.

Definition E.2.1.1. A Pro-*space* is a Pro-object of the ∞-category of spaces: that is, an accessible left-exact functor from the ∞-category $\mathcal{S}$ to itself. We will refer to $\mathrm{Pro}(\mathcal{S}) \subseteq \mathrm{Fun}(\mathcal{S},\mathcal{S})^{\mathrm{op}}$ as the *∞-category of* Pro-*spaces.*.

Remark E.2.1.2. The collection of accessible left-exact functors from $\mathcal{S}$ to itself is closed under composition. Consequently, we can regard the full subcategory $\mathrm{Pro}(\mathcal{S}) \subseteq \mathrm{Fun}(\mathcal{S},\mathcal{S})^{\mathrm{op}}$ as a simplicial monoid (and, in particular, a monoidal ∞-category). We will denote the resulting product on $\mathrm{Pro}(\mathcal{S})$ by

$$\circ : \mathrm{Pro}(\mathcal{S}) \times \mathrm{Pro}(\mathcal{S}) \to \mathrm{Pro}(\mathcal{S}).$$

Note that the unit object $\mathrm{id} \in \mathrm{Pro}(\mathcal{S})$ is also a final object. In particular, for every pair of objects $U, V \in \mathrm{Pro}(\mathcal{S})$, we have a canonical map $U \circ V \to (U \circ \mathrm{id}) \times (\mathrm{id} \circ V) \simeq U \times V$. Beware that this map is generally not an equivalence.

Remark E.2.1.3. Composition with the inclusion functor $i : \mathcal{S}_\pi \hookrightarrow \mathcal{S}$ induces a forgetful functor $\mathrm{Pro}(\mathcal{S}) \to \mathcal{S}_\pi^\wedge$. According to Example A.8.1.8, this forgetful functor is left adjoint to the map $\mathrm{Pro}(i) : \mathcal{S}_\pi^\wedge = \mathrm{Pro}(\mathcal{S}_\pi) \to \mathrm{Pro}(\mathcal{S})$, which is a fully faithful embedding (Proposition A.8.1.9). We can summarize the situation by saying that the forgetful functor $\mathrm{Pro}(\mathcal{S}) \to \mathcal{S}_\pi^\wedge$ exhibits the ∞-category of profinite spaces as a localization of the ∞-category of Pro-spaces. We will sometimes abuse terminology by identifying $\mathcal{S}_\pi^\wedge$ with its essential image in $\mathrm{Pro}(\mathcal{S})$.

Remark E.2.1.4. Since the ∞-category $\mathcal{S}$ of spaces is presentable, Example A.8.1.7 implies that the Yoneda embedding $\mathcal{S} \to \mathrm{Pro}(\mathcal{S})$ admits a right adjoint, given on objects by $\{X_\alpha\} \mapsto \varprojlim X_\alpha$. We will denote this right adjoint by $\mathrm{Mat} : \mathrm{Pro}(\mathcal{S}) \to \mathcal{S}$, and refer to it as the *materialization functor*.

Remark E.2.1.5. The profinite completion functor $X \mapsto X_\pi^\wedge$ factors as a composition

$$\mathcal{S} \xrightarrow{j} \mathrm{Pro}(\mathcal{S}) \xrightarrow{r} \mathrm{Pro}(\mathcal{S}_\pi) = \mathcal{S}_\pi^\wedge,$$

where j denotes the Yoneda embedding and r denotes the restriction functor. Note that j admits a right adjoint (given by the materialization functor $\mathrm{Mat} : \mathrm{Pro}(\mathcal{S}) \to \mathcal{S}$) and that r admits a right adjoint (given by the fully faithful embedding $\mathcal{S}_\pi^\wedge \hookrightarrow \mathrm{Pro}(\mathcal{S})$ of Remark E.2.1.3). It follows that the right adjoint to profinite completion is given by the composition $\mathcal{S}_\pi^\wedge \hookrightarrow \mathrm{Pro}(\mathcal{S}) \xrightarrow{\mathrm{Mat}} \mathcal{S}$, which we will denote also by Mat.

E.2.2 Shape and Profinite Shape

Let $\mathcal{X}$ be an ∞-topos. Then $\mathcal{X}$ admits an essentially unique geometric morphism $q_* : \mathcal{X} \to \mathcal{S}$, which has a left adjoint $q^* : \mathcal{S} \to \mathcal{X}$. The composition $q_* q^* : \mathcal{S} \to \mathcal{S}$ is an accessible left exact functor from the ∞-category $\mathcal{S}$ to itself, which we can identify with a Pro-space $\mathrm{Sh}(\mathcal{X}) \in \mathrm{Pro}(\mathcal{S})$ which we refer to as the *shape* of $\mathcal{X}$ (see §HTT.7.1.6 .

Proposition E.2.2.1. *Let $\Psi : \mathrm{Pro}(\mathcal{S}) \to \infty\mathcal{T}\mathrm{op}$ be the (essentially unique) functor which preserves small filtered limits whose composition with the Yoneda embedding $\mathcal{S} \hookrightarrow \mathrm{Pro}(\mathcal{S})$ is given by $X \mapsto \mathcal{S}_{/X}$ (see Proposition A.8.1.6). Then the functor Ψ admits a left adjoint, given on objects by $\mathcal{X} \mapsto \mathrm{Sh}(\mathcal{X})$.*

Proof. Let $\mathcal{X}$ be an ∞-topos and let Y be a Pro-space; we wish to show that there is a homotopy equivalence $\mathrm{Map}_{\mathrm{Pro}(\mathcal{S})}(\mathrm{Sh}(\mathcal{X}), Y) \simeq \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{X}, \Psi(Y))$ which depends functorially on Y. Since both sides commute with filtered limits in Y, we may assume without loss of generality that Y belongs to $\mathcal{S}$ (which, by abuse of notation, we identify with its essential image in $\mathrm{Pro}(\mathcal{S})$). Let $q_* : \mathcal{X} \to \mathcal{S}$ be a geometric morphism of ∞-topoi and let $q^* : \mathcal{S} \to \mathcal{X}$ be its left adjoint. Invoking the universal property of $\Psi(Y) = \mathcal{S}_{/Y}$ given by Proposition **??**, we obtain canonical homotopy equivalences

$$\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{X}, \Psi(Y)) = \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{X}, \mathcal{S}_{/Y}) \simeq \Gamma(\mathcal{X}; q^* Y) = \mathrm{Sh}(\mathcal{X})(Y) \simeq \mathrm{Map}_{\mathrm{Pro}(\mathcal{S})}(\mathrm{Sh}(\mathcal{X}), Y).$$

□

It follows from Proposition E.2.2.1 that we can regard the construction $\mathcal{X} \mapsto \mathrm{Sh}(\mathcal{X})$ as a functor from the ∞-category $\infty\mathcal{T}\mathrm{op}$ of ∞-topoi to the ∞-category $\mathrm{Pro}(\mathcal{S})$ of Pro-spaces. Moreover, this functor preserves small colimits.

Variant E.2.2.2. Composing the shape functor $\mathrm{Sh} : \infty\mathcal{T}\mathrm{op} \to \mathrm{Pro}(\mathcal{S})$ with the forgetful functor $\mathrm{Pro}(\mathcal{S}) \to \mathrm{Pro}(\mathcal{S}_\pi) = \mathcal{S}_\pi^\wedge$, we obtain a functor $\mathrm{Sh}_\pi : \infty\mathcal{T}\mathrm{op} \to \mathcal{S}_\pi^\wedge$. If $\mathcal{X}$ is an ∞-topos, we will refer to the profinite space $\mathrm{Sh}_\pi(\mathcal{X})$ as the *profinite shape* of $\mathcal{X}$.

Example E.2.2.3. The construction $X \mapsto \mathcal{S}_{/X}$ determines a fully faithful embedding from the ∞-category of spaces to the ∞-category $\mathcal{T}\mathrm{op}_\infty$ of ∞-topoi (Remark HTT.6.3.5.10). Consequently, for any space X, the profinite shape $\mathrm{Sh}_\pi(\mathcal{S}_{/X})$ of the ∞-topos $\mathcal{S}_{/X}$ can be identified with the profinite completion $X_\pi^\wedge$ of X. In other words, the notion of profinite completion (introduced in Example E.0.7.12) can be regarded as a special case of the notion of profinite shape (introduced in Variant E.2.2.2).

E.2.3 Profinite Reflection

Let $\infty\mathcal{T}\mathrm{op}$ denote the ∞-category of ∞-topoi, and let $\infty\mathcal{T}\mathrm{op}^{\mathrm{pf}}$ denote the full subcategory of $\infty\mathcal{T}\mathrm{op}$ spanned by the profinite ∞-topoi (Definition E.2.4.3). It follows from Theorem E.2.4.1 that $\infty\mathcal{T}\mathrm{op}^{\mathrm{pf}}$ is a localization of $\infty\mathcal{T}\mathrm{op}$: that is, the inclusion functor $\infty\mathcal{T}\mathrm{op}^{\mathrm{pf}} \hookrightarrow \infty\mathcal{T}\mathrm{op}$ admits a left adjoint. We will denote this left adjoint by $\mathcal{X} \mapsto \mathcal{X}^{\mathrm{pf}}$, and we will refer to the profinite ∞-topos $\mathcal{X}^{\mathrm{pf}}$ as the *profinite reflection* of an ∞-topos $\mathcal{X}$.

Example E.2.3.1. Let $X \in \mathcal{S}$ be a space. Then the profinite reflection of the ∞-topos $\mathcal{X}_{/X}$ can be identified with the profinite ∞-topos $\Psi_\pi(X_\pi^\wedge)$ (see Example E.2.2.3), where $X_\pi^\wedge$ denotes the profinite completion of X. In other words, we can regard profinite reflections of ∞-topoi as a generalization of profinite completions of spaces.

We can now state the main result of this section:

Theorem E.2.3.2. *Let $\mathcal{X}$ be an ∞-topos and let $\mathcal{X}^{\mathrm{lcc}}$ denote the full subcategory of $\mathcal{X}$ spanned by the locally constant constructible objects. Then:*

(1) *The ∞-category $\mathcal{X}^{\mathrm{lcc}}$ is a bounded ∞-pretopos (see Definition A.7.4.1).*

(2) *The inclusion functor $\iota : \mathcal{X}^{\mathrm{lcc}} \to \mathcal{X}$ is an ∞-pretopos morphism (Definition A.6.4.1) .*

(3) *The functor ι induces a geometric morphism of ∞-topoi $\iota_* : \mathcal{X} \to \mathcal{S}\mathrm{hv}(\mathcal{X}^{\mathrm{lcc}})$.*

(4) *The geometric morphism ι_* exhibits $\mathcal{S}\mathrm{hv}(\mathcal{X}^{\mathrm{lcc}})$ as a profinite reflection of $\mathcal{X}$.*

Theorem E.2.3.2 immediately implies the following stronger form of Proposition E.2.7.1:

Corollary E.2.3.3. *Let $f_* : \mathcal{X} \to \mathcal{Y}$ be a geometric morphism of ∞-topoi. Then f_* induces an equivalence of profinite spaces $\mathrm{Sh}_\pi(\mathcal{X}) \to \mathrm{Sh}_\pi(\mathcal{Y})$ if and only if the pullback functor f^* restricts to an equivalence of ∞-categories $\mathcal{Y}^{\mathrm{lcc}} \to \mathcal{X}^{\mathrm{lcc}}$.*

Proof of Theorem E.2.3.2. Let $\mathcal{X}^{\mathrm{pf}}$ be the profinite reflection of $\mathcal{X}$. There is an evident geometric morphism $u_* : \mathcal{X} \to \mathcal{X}^{\mathrm{pf}}$ which induces an equivalence of profinite shapes. Applying Proposition E.2.7.1, we deduce that the associated pullback functor u^* induces an equivalence of ∞-categories $(\mathcal{X}^{\mathrm{pf}})^{\mathrm{lcc}} \to \mathcal{X}^{\mathrm{lcc}}$. Since $\mathcal{X}^{\mathrm{pf}}$ is profinite, Proposition **??** implies that we can identify $(\mathcal{X}^{\mathrm{pf}})^{\mathrm{lcc}}$ with the full subcategory of $\mathcal{X}^{\mathrm{pf}}$ spanned by the truncated coherent objects, which is a bounded ∞-pretopos (Example A.7.4.4). This proves (1). Assertion (2) follows from from Proposition E.2.6.1 and assertion (3) from (2) and Proposition A.6.4.4. To prove (4), we observe that there is a commutative diagram of ∞-topoi and geometric morphisms

$$\begin{array}{ccc} \mathcal{X} & \xrightarrow{u_*} & \mathcal{X}^{\mathrm{pf}} \\ \downarrow{\scriptstyle \iota_*} & & \downarrow{\scriptstyle \iota_*^{\mathrm{pf}}} \\ \mathcal{S}\mathrm{hv}(\mathcal{X}^{\mathrm{lcc}}) & \longrightarrow & \mathcal{S}\mathrm{hv}((\mathcal{X}^{\mathrm{pf}})^{\mathrm{lcc}}). \end{array}$$

The lower horizontal map is an equivalence by virtue of Proposition E.2.7.1 and the right vertical map is an equivalence by virtue of Corollary E.2.5.7 (since the ∞-topos $\mathcal{X}^{\mathrm{pf}}$ is profinite). Since u_* exhibits $\mathcal{X}^{\mathrm{pf}}$ as a profinite reflection of $\mathcal{X}$ by construction, it follows that the functor ι_* also exhibits $\mathcal{S}\mathrm{hv}(\mathcal{X}^{\mathrm{lcc}})$ as a profinite reflection of $\mathcal{X}$. □

E.2.4 Profinite ∞-Topoi

We now introduce a higher-categorical generalization of the theory of Stone spaces.

Theorem E.2.4.1. *The profinite shape functor* $\mathrm{Sh}_\pi : \infty\mathcal{T}\mathrm{op} \to \mathcal{S}^{\wedge}_{\pi}$ *admits a fully faithful right adjoint* $\Psi_\pi : \mathcal{S}^{\wedge}_{\pi} \to \infty\mathcal{T}\mathrm{op}$.

Proof. The functor Ψ_π can be obtained by composing the fully faithful embedding $\mathcal{S}^{\wedge}_{\pi} = \mathrm{Pro}(\mathcal{S}_\pi) \hookrightarrow \mathrm{Pro}(\mathcal{S})$ with the functor $\Psi : \mathrm{Pro}(\mathcal{S}) \to \infty\mathcal{T}\mathrm{op}$. More concretely, if X is a profinite space given as the limit of a filtered diagram of π-finite spaces $\{X_\alpha\}$, then $\Psi_\pi(X)$ is the limit of the diagram of ∞-topoi $\{\mathcal{S}_{/X_\alpha}\}$. It follows from Theorem **??** (and the observation that $\Psi_\pi(*) \simeq \mathcal{S}$ is a final object of $\infty\mathcal{T}\mathrm{op}$) that the functor Ψ_π is fully faithful. □

Warning E.2.4.2. In the statement of Theorem **??**, the restriction to profinite spaces is essential: the functor $\Psi : \mathrm{Pro}(\mathcal{S}) \to \infty\mathcal{T}\mathrm{op}$ is not fully faithful.

Definition E.2.4.3. We will say that an ∞-topos $\mathcal{X}$ is *profinite* if it belongs to the essential image of the functor $\Psi_\pi : \mathcal{S}^{\wedge}_{\pi} \to \infty\mathcal{T}\mathrm{op}$ of Theorem **??**. We let $\infty\mathcal{T}\mathrm{op}^{\mathrm{pf}}$ denote the full subcategory of $\infty\mathcal{T}\mathrm{op}$ spanned by the profinite ∞-topoi.

Remark E.2.4.4. An ∞-topos $\mathcal{X}$ is profinite if and only if it can be obtained as a limit of a filtered diagram $\{\mathcal{X}_\alpha\}$ in $\infty\mathcal{T}\mathrm{op}$, where each $\mathcal{X}_\alpha$ is equivalent to $\mathcal{S}_{/X_\alpha}$ for some π-finite space X_α.

Remark E.2.4.5. Every profinite ∞-topos $\mathcal{X}$ is bounded and coherent (see Corollary A.8.3.3).

Example E.2.4.6. Let X be a Stone space (Definition A.1.6.8). Then the ∞-topos $\mathcal{S}\mathrm{hv}(X)$ is profinite. To prove this, we first use Theorem E.1.4.1 to write X as the inverse limit of a filtered diagram of finite sets $\{X_\alpha\}$. Let $\mathcal{X}$ denote the profinite ∞-topos $\varprojlim \mathcal{S}_{/X_\alpha}$. Since the collection of 0-localic ∞-topoi is closed under small limits, we see that $\mathcal{X}$ is 0-localic. We may therefore write $\mathcal{X} = \mathcal{S}\mathrm{hv}(\mathcal{U})$, where $\mathcal{U}$ is a locale (Corollary HTT.6.4.2.6). Unwinding the definitions, we can identify X with the topological space of points of $\mathcal{U}$. Since $\mathcal{X}$ is a profinite ∞-topos, it is locally coherent (Remark E.2.4.5), so that the hypercompletion $\mathcal{X}^{\mathrm{hyp}}$ has enough points (Theorem A.4.0.5). It follows that $\mathcal{U}$ is a spatial locale, hence isomorphic to the collection of open subsets of X. We therefore have an equivalence $\mathcal{X} \simeq \mathcal{S}\mathrm{hv}(X)$, so that $\mathcal{S}\mathrm{hv}(X)$ is profinite as desired.

Example E.2.4.7. Let G be a profinite group, and let $BG \in \mathcal{S}_\pi^\wedge$ be its (profinite) classifying space (see §E.5). Arguing as in Example E.2.4.6, we see that the associated profinite ∞-topos $\rho(BG)$ is 1-localic, and that its topos of discrete objects can be identified with the category of sets equipped with a continuous action of G. It is therefore natural to think of $\rho(BG)$ as the ∞-category of spaces equipped with a continuous action of G. Beware that this is potentially misleading: the ∞-topos $\rho(BG)$ need not be hypercomplete (see Warning HTT.7.2.2.31), so that the fiber functor $\eta^* : \rho(BG) \to \mathcal{S}$ associated to a base point $\eta \in BG$ (which "forgets the action of G") need not be conservative.

Example E.2.4.8. Let κ be a field, and let $\overline{\kappa}$ denote a separable closure of κ. Then the ∞-category $\mathcal{S}\mathrm{hv}_\kappa^{\text{ét}}$ is 1-localic, and its underlying topos of discrete objects can be identified with the category of sets equipped with a continuous action of the Galois group $G = \mathrm{Gal}(\overline{\kappa}/\kappa)$. It follows that $\mathcal{S}\mathrm{hv}_\kappa^{\text{ét}}$ is a profinite ∞-topos, associated the profinite space BG.

E.2.5 Locally Constant Constructible Sheaves

Every profinite ∞-topos $\mathcal{X}$ is bounded and coherent (Remark E.2.4.5). However, the converse is generally false. For example, if X is a coherent topological space, then $\mathcal{S}\mathrm{hv}(X)$ is a coherent ∞-topos, but $\mathcal{S}\mathrm{hv}(X)$ is profinite if and only if X is a Stone space. To guarantee that an ∞-topos $\mathcal{X}$ is profinite, it is not enough to assume the existence of a large class of coherent objects of $\mathcal{X}$: one needs to assume in addition that such objects are *locally constant* in the following sense:

Definition E.2.5.1. Let $\mathcal{X}$ be an ∞-topos, so that there is an essentially unique geometric morphism $q^* : \mathcal{S} \to \mathcal{X}$. We will say that an object $X \in \mathcal{X}$ is *locally constant constructible* if there exists a finite collection of objects $\{U_i \in \mathcal{X}\}_{1 \leqslant i \leqslant n}$ which cover $\mathcal{X}$, a collection of π-finite spaces $\{Y_i\}_{1 \leqslant i \leqslant n}$, and equivalences equivalences $X \times U_i \simeq q^* Y_i \times U_i$ in the ∞-topos

$\mathcal{X}_{/U_i}$ for $1 \leqslant i \leqslant n$. We let $\mathcal{X}^{\mathrm{lcc}}$ denote the full subcategory of $\mathcal{X}$ spanned by the locally constant constructible objects.

Remark E.2.5.2. Let $\mathcal{X}$ be an ∞-topos. Then the collection of locally constant constructible objects of $\mathcal{X}$ is closed under finite coproducts.

Remark E.2.5.3. Let $\mathcal{X}$ and $\mathcal{Y}$ be ∞-topoi, and let $f_* : \mathcal{X} \to \mathcal{Y}$ be a geometric morphism. Then the pullback functor $f^* : \mathcal{Y} \to \mathcal{X}$ carries locally constant constructible objects of $\mathcal{Y}$ to locally constant constructible objects of $\mathcal{X}$.

Warning E.2.5.4. Let $\mathcal{X}$ be an ∞-topos. Then the condition that an object $X \in \mathcal{X}$ be locally constant constructible is *not* local on $\mathcal{X}$. For example, suppose that $\mathcal{X} = \mathcal{S}_{/Y}$, for some Kan complex Y. Then we can identify objects $X \in \mathcal{X}$ with functors $\chi : Y \to \mathcal{S}$. If χ takes values in the full subcategory $\mathcal{S}_\pi \subseteq \mathcal{S}$ spanned by the π-finite spaces, then there exists a covering of $\mathcal{X}$ by objects U_α such that each $X \times U_\alpha$ is a locally constant constructible object of $\mathcal{X}_{/U_\alpha}$ (take the U_α to be the connected components of Y). However, X is not locally constant constructible unless the essential image of χ has only finitely many homotopy equivalence classes of objects.

Proposition E.2.5.5. *Let $\mathcal{X}$ be a coherent ∞-topos and let X be an object of $\mathcal{X}$. If X is locally constant constructible, then X is coherent.*

Proof. Fix an integer $n \geqslant 0$; we will show that X is n-coherent. Let $q^* : \mathcal{S} \to \mathcal{X}$ be a geometric morphism of ∞-topoi. Choose a finite covering $\{U_i\}_{1 \leqslant i \leqslant m}$ of $\mathcal{X}$ and equivalences $X \times U_i \simeq f^* Y_i \times U_i$ in $\mathcal{X}_{/U_i}$, where each Y_i is a π-finite space. Choose an integer k such that each Y_i is k-truncated. Using Corollary A.2.1.5, can reduce to the problem of showing that each of the maps $X \times U_i \simeq q^* Y_i \times U_i \to U_i$ is relatively n-coherent. For this, it will suffice to show that $q^* Y \in \mathcal{X}$ is coherent for each $Y \in \mathcal{S}_\pi$.

Choose an integer k such that Y is k-truncated; we proceed by induction on k. Since the collection of coherent objects of $\mathcal{X}$ is closed under finite coproducts, we may assume that Y is connected. Choose a base point $y \in Y$, so that y induces an effective epimorphism $f : U_i \to f^* Y \times U_i$ in the ∞-topos $\mathcal{X}_{/U_i}$. Note that the fiber product $U_i \times_{f^* Y \times U_i} U_i$ can be identified with $q^*(\{y\} \times_Y \{y\}) \times U_i$, and is therefore an coherent object of $\mathcal{X}$ by our inductive hypothesis. Using Corollary A.2.1.5, we deduce that the map $f : \mathbf{1} \to X$ is relatively coherent, so that X is coherent by virtue of Proposition A.2.1.3. □

For profinite ∞-topoi, Proposition E.2.5.5 admits a converse:

Proposition E.2.5.6. *Let $\mathcal{X}$ be a profinite ∞-topos. Then an object $X \in \mathcal{X}$ is locally constant constructible if and only if it is coherent and n-truncated for some $n \gg 0$.*

Proof. The "only if" direction follows from Proposition E.2.5.5. To prove the converse, write $\mathcal{X}$ as the limit of a filtered diagram of ∞-topoi $\{\mathcal{X}_\alpha\}$, where each $\mathcal{X}_\alpha$ has the form $\mathcal{S}_{/Y}$ for some π-finite space Y. It follows from Proposition A.8.3.2 that the full subcategory $\mathcal{X}^{\mathrm{coh}}_{<\infty} \subseteq \mathcal{X}$ spanned by the truncated coherent objects can be written as a filtered colimit of the subcategories $\mathcal{X}^{\mathrm{coh}}_{\alpha<\infty} \subseteq \mathcal{X}_\alpha$. In particular, every truncated coherent object of $\mathcal{X}$ can obtained as the pullback of a bounded coherent object of some $\mathcal{X}_\alpha$. Using Remark E.2.5.3, we can replace $\mathcal{X}$ by $\mathcal{X}_\alpha$ and thereby reduce to the case where $\mathcal{X} = \mathcal{S}_{/Y}$ for some π-finite space Y.

Unwinding the definitions, we see that a truncated coherent object $X \in \mathcal{X}$ can be identified with a π-finite space X equipped with a map $f : X \to Y$. Since Y is π-finite, the set $\pi_0 Y$ is finite. We can therefore choose a finite collection of points $y_1, \ldots, y_k \in Y$ which represent every connected component of Y, so that objects $\{y_1\}, \ldots, \{y_k\} \in \mathcal{S}_{/Y}$ form a covering of the ∞-topos $\mathcal{S}_{/Y}$. It now suffices to observe that each of the homotopy fibers $X \times_Y \{y_i\} \in \mathcal{S}_{/\{y_i\}} \simeq \mathcal{S}$ is π-finite. □

Corollary E.2.5.7. *Let $\mathcal{X}$ be a profinite ∞-topos. Then:*

(1) *The ∞-category $\mathcal{X}^{\mathrm{lcc}}$ is a bounded ∞-pretopos (see Definition A.7.4.1).*

(2) *The inclusion functor $\iota : \mathcal{X}^{\mathrm{lcc}} \to \mathcal{X}$ is an ∞-pretopos morphism (Definition A.6.4.1) .*

(3) *The functor ι induces an equivalence of ∞-topoi $\iota_* : \mathcal{X} \to \mathcal{S}\mathrm{hv}(\mathcal{X}^{\mathrm{lcc}})$ (where we regard $\mathcal{X}^{\mathrm{lcc}}$ as equipped with the effective epimorphism topology of Definition A.6.2.4).*

Proof. Since every profinite ∞-topos $\mathcal{X}$ is bounded and coherent (Remark E.2.4.5), Theorem A.7.5.3 supplies an equivalence of ∞-categories $\mathcal{X} \simeq \mathcal{S}\mathrm{hv}(\mathcal{X}^{\mathrm{coh}}_{<\infty})$. The desired result now follows from Proposition E.2.5.6. □

E.2.6 Closure Properties of $\mathcal{X}^{\mathrm{lcc}}$

Our next goal is to show that the ∞-category $\mathcal{X}^{\mathrm{lcc}}$ of locally constant constructible sheaves on an ∞-topos $\mathcal{X}$ behaves well even when $\mathcal{X}$ is not coherent.

Proposition E.2.6.1. *Let $\mathcal{X}$ be an ∞-topos. Then the full subcategory $\mathcal{X}^{\mathrm{lcc}} \subseteq \mathcal{X}$ is an ∞-pretopos. Moreover, the inclusion $\mathcal{X}^{\mathrm{lcc}} \hookrightarrow \mathcal{X}$ is a morphism of ∞-pretopoi.*

The proof will require some preliminaries.

Notation E.2.6.2. Let $\mathcal{X}$ be an ∞-topos. For every pair of objects $X, Y \in \mathcal{X}$, the functor $Z \mapsto \mathrm{Map}_{\mathcal{X}}(Z \times X, Y)$ carries small colimits in $\mathcal{X}$ to limits in the ∞-category of spaces, and is therefore representable by an object of $\mathcal{X}$. We will denote this object by $\underline{\mathrm{Map}}_{\mathcal{X}}(X, Y)$.

Let $q_* : \mathcal{X} \to \mathcal{S}$ be the global sections functor (corepresented by a final object of $\mathcal{X}$) and let $q^* : \mathcal{S} \to \mathcal{X}$ be a left adjoint to q_*. Then the functor q^* preserves finite products. Consequently, for every pair of Kan complexes K and L, the canonical map $\mathrm{Fun}(K,L) \times K \to L$ determines a morphism $q^* \mathrm{Fun}(K,L) \times q^* K \to q^* L$, which is adjoint to a map $\phi_{K,L} : q^* \mathrm{Fun}(K,L) \to \underline{\mathrm{Map}}_{\mathcal{X}}(q^* K, q^* L)$.

Lemma E.2.6.3. *Let $\mathcal{X}$ be an ∞-topos, and let $q^* : \mathcal{S} \to \mathcal{X}$ and $\phi_{K,L} : q^* \mathrm{Fun}(K,L) \to \underline{\mathrm{Map}}_{\mathcal{X}}(q^* K, q^* L)$ be defined as above. If K is π-finite and L is truncated, then $\phi_{K,L}$ is an equivalence in $\mathcal{X}$.*

Proof. Since K is π-finite, there exists an integer n such that K is n-truncated. We proceed by induction on n. If $n = 0$, then K is a finite discrete set and both sides can be identified with a product of finitely many copies of $q^* L$. To carry out the inductive step, assume that $n > 0$. Let U_0 be a finite set consisting of one vertex from each connected component of K, and let $U_\bullet$ denote the Čech nerve of the map $U_0 \to K$, so that we have a homotopy equivalence $|U_\bullet| \simeq K$. Then we can identify $\phi_{K,L}$ with the composite map

$$q^* \varprojlim_{[d] \in \mathbf{\Delta}} \mathrm{Fun}(U_d, L) \xrightarrow{\phi'} \varprojlim_{[d] \in \mathbf{\Delta}} q^* \mathrm{Fun}(U_d, L) \xrightarrow{\phi''} \varprojlim_{[d] \in \mathbf{\Delta}} \underline{\mathrm{Map}}_{\mathcal{X}}(q^* U_d, q^* L).$$

The map ϕ'' is an equivalence by virtue of the inductive hypothesis. For each integer m, the map ϕ' fits into a commutative diagram

$$\begin{array}{ccc} q^* \varprojlim_{[d] \in \mathbf{\Delta}} \mathrm{Fun}(U_d, L) & \xrightarrow{\phi'} & \varprojlim_{[d] \in \mathbf{\Delta}} q^* \mathrm{Fun}(U_d, L) \\ \downarrow & & \downarrow \\ q^* \varprojlim_{[d] \in \mathbf{\Delta}_{s, \leq m}} \mathrm{Fun}(U_d, L) & \longrightarrow & \varprojlim_{[d] \in \mathbf{\Delta}_{s, \leq m}} q^* \mathrm{Fun}(U_d, L). \end{array}$$

Since L is truncated, the vertical maps are equivalences for $m \gg 0$, and the lower horizontal map is an equivalence because q^* is left-exact. It follows that ϕ' is an equivalence, as desired. □

Remark E.2.6.4. The hypotheses of Lemma E.2.6.3 are satisfied whenever the Kan complexes K and L are both π-finite. Note that in this case, the Kan complex $\mathrm{Fun}(K,L)$ is also π-finite.

Remark E.2.6.5. Passing to global sections, we see that if K and L are π-finite Kan complexes, then the canonical map $\beta : \mathrm{Map}_{\mathcal{X}}(\mathbf{1}, q^* \mathrm{Map}_{\mathcal{S}}(K,L)) \to \mathrm{Map}_{\mathcal{X}}(q^* K, q^* L)$ is a homotopy equivalence. Note that the map β restricts to a homotopy equivalence $\beta_0 : \mathrm{Map}_{\mathcal{X}}(\mathbf{1}, q^* \mathrm{Map}_{\mathcal{S}^{\simeq}}(K,L)) \to \mathrm{Map}_{\mathcal{X}^{\simeq}}(q^* K, q^* L)$.

It follows from Lemma E.2.6.3 that any finite diagram of locally constant constructible objects of $\mathcal{X}$ can be "made constant" after passing to a finite covering of $\mathcal{X}$:

Proposition E.2.6.6. *Let $\mathcal{X}$ be an ∞-topos, let $q^* : \mathcal{S} \to \mathcal{X}$ be a geometric morphism, let K be a finite simplicial set, and let $\rho : K \to \mathcal{X}^{\mathrm{lcc}}$ be a diagram. Then there exists a finite collection of objects $\{U_i\}_{1 \leqslant i \leqslant n}$ which cover $\mathcal{X}$ and a finite collection of diagrams $\{\rho_i : K \to \mathcal{S}_\pi\}_{1 \leqslant i \leqslant n}$ such that, for $1 \leqslant i \leqslant n$, there is an equivalence $U_i \times \rho \simeq U_i \times q^*(\rho_i)$ in the ∞-category* $\mathrm{Fun}(K, \mathcal{X}_{/U_i})$.

Proof. We proceed by induction on the number of nondegenerate simplices of K. If $K = \varnothing$ there is nothing to prove. Otherwise, we can write K as a coproduct $K_0 \amalg_{\partial \Delta^n} \Delta^n$ for some simplicial subset $K_0 \subseteq K$ and some $n \geqslant 0$. Using our inductive hypothesis, we may assume (after passing to a finite covering of $\mathcal{X}$ if necessary) that $\rho|_{K_0}$ is homotopic to a composition $K_0 \xrightarrow{\rho'_0} \mathcal{S}_\pi \xrightarrow{q^*} \mathcal{X}$ for some functor $\rho'_0 : K_0 \to \mathcal{S}_\pi$; we wish to show that (after passing to a further covering of $\mathcal{X}$ if necessary) that the functor ρ admits a similar factorization. If $n = 0$, this follows immediately from the definition of $\mathcal{X}^{\mathrm{lcc}}$. Let us therefore assume that $n > 0$. Let $L, L' \in \mathcal{S}_\pi$ denote the images under ρ'_0 of the initial and final vertices of $\partial \Delta^n$, so that ρ'_0 and ρ determine a commutative diagram of spaces

$$\begin{array}{ccc} S^{n-2} & \xrightarrow{u_0} & \mathrm{Map}_{\mathcal{S}}(L, L') \\ \downarrow & & \downarrow \\ * & \longrightarrow & \mathrm{Map}_{\mathcal{X}}(q^* L, q^* L'). \end{array}$$

Using Lemma E.2.6.3, we can identify this diagram with a global section of the object

$$\mathrm{fib}(q^* \mathrm{Map}_{\mathcal{S}}(L, L') \xrightarrow{\delta} q^* \mathrm{Map}_{\mathcal{S}}(L, L')^{S^{n-2}}) \simeq q^* T,$$

where $T \simeq \mathrm{Map}_{\mathcal{S}}(L, L') \times_{\mathrm{Map}_{\mathcal{S}}(L,L')^{S^{n-2}}} \{u_0\}$ is the space of nullhomotopies of u_0. To compete the proof, it suffices to observe that, after passing to a finite covering of $\mathcal{X}$, we can assume that this global section is constant: that is, it is homotopic to the global section determined by some point $t \in T$. This follows from the observation that $\pi_0 T$ is finite. $\square$

Corollary E.2.6.7. *Let $\mathcal{X}$ be an ∞-topos. Then the ∞-pretopos $\mathcal{X}^{\mathrm{lcc}}$ is Boolean (Definition A.6.3.8): that is, for every object $X \in \mathcal{X}^{\mathrm{lcc}}$, the distributive lattice* $\mathrm{Sub}(X)$ *of subobjects of X (in the ∞-category $\mathcal{X}^{\mathrm{lcc}}$) is a Boolean algebra.*

Proof. Let $i : U \hookrightarrow X$ be a (-1)-truncated morphism in $\mathcal{X}^{\mathrm{lcc}}$; we wish to show that U admits a complement in the distributive lattice $\mathrm{Sub}(X)$. Choose a geometric morphism $q^* : \mathcal{S} \to \mathcal{X}$. Using Proposition E.2.6.6, we can assume (after passing to a finite covering of $\mathcal{X}$ if necessary) that $i = q^*(i_0)$ for some map of π-finite spaces $i_0 : U_0 \to X_0$. Replacing U_0 by its essential image in X_0, we may assume that X_0 decomposes as a disjoint union $U_0 \amalg V_0$ for some π-finite space V_0. We now observe that $V = q^* V_0$ is a complement of U in $\mathrm{Sub}(X)$. $\square$

Corollary E.2.6.8. *Let $\mathcal{X}$ be an ∞-topos. Then the full subcategory $\mathcal{X}^{\mathrm{lcc}} \subseteq \mathcal{X}$ is closed under finite limits.*

Proof. Let K be a finite simplicial set and let $p : K \to \mathcal{X}^{\mathrm{lcc}}$ be a diagram; we wish to show that $\varprojlim(p)$ is locally constant constructible. Using Proposition E.2.6.6, we may assume (after passing to a finite cover of $\mathcal{X}$) that the diagram p factors as a composition

$$K \xrightarrow{p_0} \mathcal{S}_\pi \hookrightarrow \mathcal{S} \xrightarrow{q^*} \mathcal{X},$$

where q^* is a geometric morphism. In this case, the left exactness of q^* implies that $\varprojlim(p) \simeq q^*(\varprojlim(p_0))$ is the image under q^* of a π-finite space. □

Corollary E.2.6.9. *Let $\mathcal{X}$ be an ∞-topos and let $X_\bullet$ be a groupoid object of $\mathcal{X}$. If each $X_k \in \mathcal{X}$ is locally constant constructible, then then the geometric realization $|X_\bullet| \in \mathcal{X}$ is locally constant constructible.*

Proof. Choose an integer $n \gg 0$ so that X_0 and X_1 are n-truncated. It follows that each X_k is n-truncated: that is, we can identify $X_\bullet$ with a groupoid object of $\tau_{\leqslant n}\mathcal{X}$. Let K denote the $(n+2)$-skeleton of $\mathrm{N}(\mathbf{\Delta}^{\mathrm{op}}_{\leqslant n+3})$, so that the simplicial object $X_\bullet$ restricts to a diagram $p : K \to \mathcal{X}^{\mathrm{lcc}}$. Since the simplicial set K is finite, we may assume (after passing to a finite covering of $\mathcal{X}$ if necessary) that p factors as a composition

$$K \xrightarrow{p_0} \mathcal{S}_\pi \hookrightarrow \mathcal{S} \xrightarrow{q^*} \mathcal{X}$$

where q^* is a geometric morphism. Replacing p_0 by its composition with the truncation functor $\tau_{\leqslant n} : \mathcal{S}_\pi \to \mathcal{S}_\pi$ if necessary, we may assume that p_0 takes values in the full subcategory of $\mathcal{S}_\pi$ spanned by the n-truncated objects. Since this full subcategory is equivalent to an n-category, the map p_0 extends to a functor $\overline{p}_0 : \mathbf{\Delta}^{\mathrm{op}}_{\leqslant n+3} \to \mathcal{S}_\pi$. Since $X_\bullet$ is a groupoid object, it follows that either the ∞-topos $\mathcal{X}$ is a contractible Kan complex (in which case there is nothing to prove) or the diagram $\overline{p}_0$ is an $(n+3)$-skeletal category object of $\mathcal{S}_\pi$. In the latter case, Theorem A.8.2.3 allows us to extend $\overline{p}_0$ to a category object $X'_\bullet$ of $\mathcal{S}_\pi$, which is easily seen to be a groupoid object. Since $\mathcal{S}_\pi$ is an ∞-pretopos (Remark E.0.7.9), the geometric realization $|X'_\bullet|$ is also π-finite. Note that the simplicial objects $q^* X'_\bullet$ and $X_\bullet$ have equivalent $(n+3)$-skeleta and are therefore equivalent (since they are category objects of $\tau_{\leqslant n}\mathcal{X}$; see Theorem A.8.2.3), so that $|X_\bullet| \simeq |q^* X'_\bullet| \simeq q^*|X'_\bullet|$ lies in the essential image of $q^*|_{\mathcal{S}_\pi}$. □

Proof of Proposition E.2.6.1. Let $\mathcal{X}$ be an ∞-topos. Then the full subcategory $\mathcal{X}^{\mathrm{lcc}} \subseteq \mathcal{X}$ is closed under the formation of finite coproducts (Remark E.2.5.2), finite limits (Corollary E.2.6.8), and geometric realizations of groupoid objects (Corollary E.2.6.9). It follows that $\mathcal{X}^{\mathrm{lcc}}$ is an ∞-pretopos and that the inclusion $\mathcal{X}^{\mathrm{lcc}} \hookrightarrow \mathcal{X}$ is a morphism of ∞-pretopoi (see Remark A.6.1.4). □

E.2.7 Profinite Shape and Locally Constant Sheaves

Our next goal is to show that the process of profinite completion does not lose any information about locally constant constructible sheaves.

Proposition E.2.7.1. *Let $f_* : \mathcal{X} \to \mathcal{Y}$ be a geometric morphism of ∞-topoi. If f_* induces an equivalence of profinite shapes $\mathrm{Sh}_\pi(\mathcal{X}) \to \mathrm{Sh}_\pi(\mathcal{Y})$, then the pullback functor f^* induces an equivalence $\mathcal{Y}^{\mathrm{lcc}} \to \mathcal{X}^{\mathrm{lcc}}$.*

In order to prove Proposition E.2.7.1, it will be convenient to introduce a variant of Definition E.2.5.1.

Definition E.2.7.2. Let $\mathcal{X}$ be an ∞-topos, let $q^* : \mathcal{S} \to \mathcal{X}$ be a geometric morphism, let $\mathcal{K}$ be a full subcategory of $\mathcal{S}$, and let $X \in \mathcal{X}$ be an object. We will say that X is *$\mathcal{K}$-constructible* if there exists a finite collection of objects $\{U_i \in \mathcal{X}\}_{1 \leqslant i \leqslant n}$ which cover $\mathcal{X}$, a finite collection of objects $Y_i \in \mathcal{K}$, and equivalences $X \times U_i \simeq (q^* Y_i) \times U_i$ in $\mathcal{X}_{/U_i}$ for $1 \leqslant i \leqslant n$.

Remark E.2.7.3. In the situation of Definition E.2.7.2, suppose that $\mathcal{K}$ is spanned by finitely many Kan complexes $\{Y_1, \ldots, Y_m\}$. In this case, an object $X \in \mathcal{X}$ is $\mathcal{K}$-constructible if and only if there exists a collection of objects $\{U_\alpha \in \mathcal{X}\}_{\alpha \in A}$ such that $\amalg U_\alpha \to \mathbf{1}$ is an effective epimorphism, and equivalences $X \times U_\alpha \simeq q^* Y_{i(\alpha)} \times U_\alpha$ for some function $i : A \to \{1, \ldots, m\}$ (if this condition is satisfied, we can always arrange that $A = \{1, \ldots, m\}$ by replacing the objects $\{Y_\alpha\}$ by the finite collection $\{\amalg_{i(\alpha)=j} Y_\alpha\}_{1 \leqslant j \leqslant m}$). Consequently, the condition that an object $X \in \mathcal{X}$ be $\mathcal{K}$-constructible can be tested locally on $\mathcal{X}$ (in contrast with Warning **??**).

Remark E.2.7.4. Let $\mathcal{X}$ be an ∞-topos. Then an object $X \in \mathcal{X}$ is locally constant constructible (in the sense of Definition E.2.5.1) if and only if it is $\mathcal{S}_\pi$-constructible (in the sense of Definition E.2.7.2)

Remark E.2.7.5. Let $f^* : \mathcal{X} \to \mathcal{Y}$ be a geometric morphism of ∞-topoi and let $\mathcal{K} \subseteq \mathcal{S}$ be a full subcategory. Then the functor f^* carries $\mathcal{K}$-constructible objects of $\mathcal{X}$ to $\mathcal{K}$-constructible objects of $\mathcal{Y}$.

Example E.2.7.6. Let $\mathcal{K}$ be a full subcategory of $\mathcal{S}$ which is spanned by finitely many Kan complexes $\{Y_1, \ldots, Y_m\}$. Let $\iota_{\mathcal{K}} : \mathcal{K}^{\simeq} \hookrightarrow \mathcal{S}$ denote the inclusion map, which we regard as an object of the ∞-topos $\mathrm{Fun}(\mathcal{K}^{\simeq}, \mathcal{S})$. Then $\iota_{\mathcal{K}}$ is $\mathcal{K}$-constructible: for $1 \leqslant i \leqslant m$, we have $\iota_{\mathcal{K}} \times U_i \simeq (q^* Y_i) \times U_i$, where $q^* : \mathcal{S} \to \mathrm{Fun}(\mathcal{K}^{\simeq}, \mathcal{S})$ is the diagonal inclusion and $U_i : \mathcal{K}^{\simeq} \to \mathcal{S}$ denotes the functor represented by $Y_i \in \mathcal{K}^{\simeq}$.

We will need the following result:

Proposition E.2.7.7. *Let $\mathcal{K}$ be a full subcategory of $\mathcal{S}$ which is spanned by finitely many π-finite spaces and let let $\iota : \mathcal{K}^{\simeq} \hookrightarrow \mathcal{S}$ be the inclusion map. For any ∞-topos $\mathcal{X}$, evaluation on ι induces a fully faithful embedding $e : \mathrm{Fun}^*(\mathrm{Fun}(\mathcal{K}^{\simeq}, \mathcal{S}), \mathcal{X}) \to \mathcal{X}^{\simeq}$ whose essential image is the full subcategory of $\mathcal{X}$ spanned by the $\mathcal{K}$-constructible objects.*

Proof. We first show that e is fully faithful. Suppose we are given geometric morphisms $f^*, g^* : \mathrm{Fun}(\mathcal{K}^{\simeq}, \mathcal{S}) \to \mathcal{X}$; we wish to show that the functor e induces a homotopy equivalence

$$\theta : \mathrm{Map}_{\mathrm{Fun}^*(\mathrm{Fun}(\mathcal{K}^{\simeq}, \mathcal{S}), \mathcal{X})}(f^*, g^*) \to \mathrm{Map}_{\mathcal{X}^{\simeq}}(f^*(\iota), g^*(\iota)).$$

Let us identify the ∞-topos $\mathrm{Fun}(\mathcal{K}^{\simeq}, \mathcal{S})$ with $\mathcal{S}_{/\mathcal{K}^{\simeq}}$, so that Corollary HTT.6.3.5.6 supplies an equivalence of ∞-categories $\mathrm{Fun}^*(\mathrm{Fun}(\mathcal{K}^{\simeq}, \mathcal{S}), \mathcal{X}) \simeq \mathrm{Map}_{\mathcal{X}}(\mathbf{1}, q^* \mathcal{K}^{\simeq})$, where $q^* : \mathcal{S} \to \mathcal{X}$ is a geometric morphism and $\mathbf{1}$ denotes a final object of $\mathcal{X}$. Under this identification, the geometric morphisms f^* and g^* correspond to maps $f, g : \mathbf{1}_{\mathcal{X}} \to q^* \mathcal{K}^{\simeq}$. Since the assertion that θ is a homotopy equivalence can be tested locally on $\mathcal{X}$, we may assume (after passing to a covering of $\mathcal{X}$ if necessary) that the maps f and g are constant: that is, that they are obtained by applying the functor q^* to inclusions $\{K\} \hookrightarrow \mathcal{K}^{\simeq}$ and $\{L\} \hookrightarrow \mathcal{K}^{\simeq}$ for some π-finite Kan complexes K and L. In this case, the map θ can be identified with the homotopy equivalence $\mathrm{Map}_{\mathcal{X}}(\mathbf{1}, \mathrm{Map}_{\mathcal{S}^{\simeq}}(K, L)) \to \mathrm{Map}_{\mathcal{X}^{\simeq}}(q^*L, q^*K)$ of Remark E.2.6.5.

It remains to prove that the functor e is essentially surjective. Let X be a $\mathcal{K}$-constructible object of $\mathcal{X}$; we wish to show that X belongs to the essential image of e. The first part of the proof shows that this assertion is local on $\mathcal{X}$ (see Remark E.2.7.3). We may therefore assume without loss of generality that $X = q^*K$ for some Kan complex $K \in \mathcal{K}$, in which case the result is obvious. □

Proof of Proposition E.2.7.1. Let $f_* : \mathcal{X} \to \mathcal{Y}$ be a geometric morphism of ∞-topoi. Suppose that f_* induces an equivalence of profinite spaces $\mathrm{Sh}_\pi(\mathcal{X}) \to \mathrm{Sh}_\pi(\mathcal{Y})$. We wish to prove that the pullback functor $f^* : \mathcal{Y}^{\mathrm{lcc}} \to \mathcal{X}^{\mathrm{lcc}}$ is an equivalence of ∞-categories. Note that we can regard $f^* : \mathcal{Y}^{\mathrm{lcc}} \to \mathcal{X}^{\mathrm{lcc}}$ can be regarded as a morphism of ∞-pretopoi (see Proposition E.2.6.1) in which every object is truncated. To show that f^* is an equivalence, it will suffice to show that it satisfies conditions (a) and (b) of Proposition A.9.2.1:

(a) We will show that the functor $f^* : \mathcal{Y}^{\mathrm{lcc}} \to \mathcal{X}^{\mathrm{lcc}}$ is essentially surjective. Fix an object $X \in \mathcal{X}^{\mathrm{lcc}}$. Then we can choose a full subcategory $\mathcal{K} \subseteq \mathcal{S}$ spanned by finitely many π-finite Kan complexes such that X is $\mathcal{K}$-constructible. Let $\iota \in \mathrm{Fun}(\mathcal{K}^{\simeq}, \mathcal{S})$ denote the inclusion functor. It follows from Proposition E.2.7.7 that there exists an (essentially unique) geometric morphism $g_* : \mathcal{X} \to \mathrm{Fun}(\mathcal{K}^{\simeq}, \mathcal{S})$ such that $X \simeq g^*(\iota)$. Since $\mathcal{K}^{\simeq}$ is a π-finite Kan complex, our assumption that $\mathrm{Sh}_\pi(f_*)$ is an equivalence guarantees that the geometric morphism g_* is equivalent to a composition $\mathcal{X} \xrightarrow{f_*} \mathcal{Y} \xrightarrow{g'_*} \mathrm{Fun}(\mathcal{K}^{\simeq}, \mathcal{S})$. It follows that $X \simeq g^*(\iota) \simeq f^*(g'^*\iota) \in f^* \mathcal{Y}^{\mathrm{lcc}}$.

(b) Let $\phi : U \to Y$ be a morphsim in $\mathcal{Y}^{\mathrm{lcc}}$ such that $f^*(\phi)$ is an equivalence; we wish to show that ϕ is an equivalence. Using Corollary E.2.6.7, we see that Y decomposes as a coproduct $U \amalg V$ for some auxiliary object $V \in \mathcal{Y}^{\mathrm{lcc}}$. Since $f^*(\phi)$ is an equivalence, the object $f^*(V)$ is initial in $\mathcal{X}$. Set $V' = \tau_{\leqslant -1} V$. Then V' is a (-1)-truncated object of $\mathcal{Y}^{\mathrm{lcc}}$. Applying Corollary E.2.6.7 again, we deduce that V' is complemented: that is, the final object $\mathbf{1}$ of $\mathcal{Y}$ decomposes as a coproduct $V' \amalg W$. Let T denote the topological space $\{v, w\}$ with the discrete topology, so that the decomposition $\mathbf{1} \simeq V' \amalg W$ is classified by a geometric morphism $g_* : \mathcal{Y} \to \mathcal{S}\mathrm{hv}(T)$. Our assumption $f^* V' \simeq \varnothing$ guarantees that the composite map $\mathcal{X} \xrightarrow{f_*} \mathcal{Y} \xrightarrow{g_*} \mathcal{S}\mathrm{hv}(T)$ factors through the inclusion $i_* : \mathcal{S}\mathrm{hv}(\{w\}) \hookrightarrow \mathcal{S}\mathrm{hv}(T)$. Since the ∞-topoi $\mathcal{S}\mathrm{hv}(T)$ and $\mathcal{S}\mathrm{hv}(\{w\}) \simeq \mathcal{S}$ are profinite, it follows from our assumption that $\mathrm{Sh}_\pi(f_*)$ is an equivalence that the geometric morphism g_* also factors through i_*. In other words, the object $V' \in \mathcal{Y}$ is initial, so that $V \in \mathcal{Y}$ is also initial and the morphism $\phi : U \to U \amalg V \simeq Y$ is an equivalence, as desired.

□

E.3 ∞-Categorical Stone Duality

The theory of Stone duality (Theorems A.1.6.11 and E.1.4.1) supplies equivalences between the following categories:

(*a*) The category $\mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}})$ of profinite sets.

(*b*) The category $\mathcal{T}\mathrm{op}_{\mathrm{St}}$ of Stone spaces (a full subcategory of the category $\mathcal{T}\mathrm{op}$ of topological spaces).

(*c*) The opposite of the category BAlg of Boolean algebras (a full subcategory of the category Lat of distributive lattices).

Theorem E.2.4.1 supplies an equivalence between the ∞-category $\mathcal{S}^{\wedge}_{\pi}$ of profinite spaces and the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{pf}}$ of profinite ∞-topoi, which we can regard as an ∞-categorical generalization of the equivalence $(a) \Leftrightarrow (b)$. Our goal in this section is to establish an ∞-categorical version of the equivalence $(b) \Leftrightarrow (c)$. The relevant analogies can be summarized as follows:

Classical Stone Duality	∞-Categorical Stone Duality
Finite Set	π-Finite Space
Profinite Set	Profinite Space
Topological Space	∞-Topos
Coherent Topological Space	Bounded Coherent ∞-Topos
Stone Space	Profinite ∞-Topos
Distributive Lattice	Bounded ∞-Pretopos

Remark E.3.0.8. In the preceding table of analogies, each of the mathematical concepts appearing on the right can be regarded as a generalization of the classical concept which appears on the left. In particular:

- Every finite set S can be regarded as a π-finite space, by equipping S with the discrete topology.
- Every profinite set can be regarded as a profinite space (Remark E.4.1.4).
- Every topological space X determines an ∞-topos $\mathcal{S}\mathrm{hv}(X)$. Moreover, this construction does not lose any information if X is sober (Proposition 1.5.3.5). If X is a Stone space, then $\mathcal{S}\mathrm{hv}(X)$ is a profinite ∞-topos; moreover, the diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{Pro}(\mathcal{S}\mathrm{et}^{\mathrm{fin}}) & \longrightarrow & \mathcal{T}\mathrm{op} \\ \downarrow & & \downarrow{\scriptstyle \mathcal{S}\mathrm{hv}} \\ \mathcal{S}_{\pi}^{\wedge} & \longrightarrow & \infty\mathcal{T}\mathrm{op} \end{array}$$

  commutes up to equivalence, where the upper horizontal map is given by classical Stone duality and the lower horizontal map is the fully faithful embedding of Theorem E.2.4.1 (see Example E.2.4.6).

To complete the picture, we need to determine the ∞-categorical analogue of a Boolean algebra. More precisely, we need to answer the following:

Question E.3.0.9. Let $\mathcal{C}$ be a bounded ∞-pretopos. Under what conditions is the associated ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})$ profinite?

We will supply three answers to Question E.3.0.9:

(*i*) The ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is profinite if and only if every truncated coherent object of $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is locally constant constructible (Proposition E.3.1.1).

(*ii*) The ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is profinite if and only if $\mathcal{C}$ is Boolean and of finite breadth (Theorem E.3.2.8).

(*iii*) The ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is profinite if and only if the ∞-category of points $\mathrm{Fun}^*(\mathcal{S}\mathrm{hv}(\mathcal{C}), \mathcal{S}) \simeq \mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{S})$ is a Kan complex (Theorem E.3.4.1).

E.3.1 Profinite ∞-Topoi

Our first characterization of the class of profinite ∞-topoi is an easy consequence of Theorem E.2.3.2:

Proposition E.3.1.1. *Let $\mathcal{X}$ be an ∞-topos. Then $\mathcal{X}$ is profinite if and only if it satisfies the following conditions:*

(*a*) *The ∞-topos $\mathcal{X}$ is coherent.*

(*b*) *The ∞-topos $\mathcal{X}$ is bounded.*

(*c*) *Every truncated coherent object of $\mathcal{X}$ is locally constant constructible.*

Proof. The necessity was established by Proposition **??**. For sufficiency, we note that conditions (*a*) and (*b*) imply that the canonical map $u_* : \mathcal{X} \to \mathcal{S}\mathrm{hv}(\mathcal{X}^{\mathrm{coh}}_{<\infty})$ is an equivalence (Theorem A.7.5.3). If condition (*c*) is satisfied, then Theorem E.2.3.2 implies that the geometric morphism u_* also exhibits $\mathcal{S}\mathrm{hv}(\mathcal{X}^{\mathrm{coh}}_{<\infty})$ as a profinite reflection of $\mathcal{X}$, so that $\mathcal{X} \simeq \mathcal{S}\mathrm{hv}(\mathcal{X}^{\mathrm{coh}}_{<\infty})$ is profinite. □

Corollary E.3.1.2. *Let $\mathcal{X}$ and $\mathcal{Y}$ be coherent ∞-topoi, and let $f^* : \mathcal{Y} \to \mathcal{X}$ be a geometric morphism. If the ∞-topos $\mathcal{Y}$ is profinite, then the functor f^* carries coherent objects of $\mathcal{Y}$ to coherent objects of $\mathcal{X}$.*

Proof. Let $Y \in \mathcal{Y}$ be a coherent object; we wish to show that $f^*Y \in \mathcal{X}$ is coherent. In other words, we wish to show that f^*Y is n-coherent for each integer $n \geqslant 0$. By virtue of Proposition A.2.4.1, it will suffice to show that $\tau_{\leqslant n+1} f^*Y \simeq f^*(\tau_{\leqslant n+1} Y)$ is n-coherent. Using Corollary A.2.4.4, we can replace Y by $\tau_{\leqslant n+1} Y$ and thereby reduce to the case where Y is truncated. In this case, our assumption that $\mathcal{Y}$ is profinite guarantees that Y is locally constant constructible (Proposition **??**), so that $f^*Y \in \mathcal{X}$ is locally constant constructible (Remark E.2.5.3) and therefore a coherent object of $\mathcal{X}$ by virtue of Proposition E.2.5.5. □

Remark E.3.1.3. It follows from Corollary E.3.1.2 that the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{pf}}$ of profinite ∞-topoi can be regarded as a full subcategory of both the ∞-category $\infty\mathcal{T}\mathrm{op}$ (whose morphisms are all geometric morphisms) and the ∞-category $\infty\mathcal{T}\mathrm{op}_{\mathrm{coh}}$ of Construction A.7.5.2 (where we require pullback functors to preserve coherent objects). This can be regarded as an ∞-categorical analogue of Remark A.1.6.7.

Proposition E.3.1.4. *Let $\mathcal{X}$ and $\mathcal{Y}$ be ∞-topoi. If $\mathcal{X}$ is profinite, then the ∞-category* $\mathrm{Fun}^*(\mathcal{X}, \mathcal{Y})$ *of geometric morphisms from $\mathcal{X}$ to $\mathcal{Y}$ is an (essentially small) Kan complex.*

Proof. Let us regard $\mathcal{Y}$ as fixed. The collection of those ∞-topoi $\mathcal{X}$ for which $\mathrm{Fun}^*(\mathcal{X}, \mathcal{Y})$ is an essentially small Kan complex is closed under small limits in $\infty\mathcal{T}\mathrm{op}$. We may therefore assume without loss of generality that $\mathcal{X} = \mathcal{S}_{/X}$ for some π-finite space X (Remark E.2.4.4), in which case the desired result follows from Corollary HTT.6.3.5.6 . □

Example E.3.1.5. Taking $\mathcal{Y} = \mathcal{S}$ in the statement of Proposition E.3.1.4, we deduce that for any profinite ∞-topos $\mathcal{X}$, the ∞-category $\mathrm{Fun}^*(\mathcal{X}, \mathcal{S})$ is a Kan complex. If $\mathcal{X} = \Psi_\pi(X)$ is the profinite ∞-topos associated to a profinite space X, then this Kan complex can be identified with

$$\mathrm{Fun}^*(\mathcal{X}, \mathcal{S}) \simeq \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{S}, \Psi_\pi(X)) \simeq \mathrm{Map}_{\mathcal{S}^\wedge_\pi}(*, X) \simeq \mathrm{Mat}(X).$$

Theorem E.3.1.6 (Whitehead's Theorem for Profinite Spaces)**.** *The materialization functor* $\mathrm{Mat} : \mathcal{S}^\wedge_\pi \to \mathcal{S}$ *is conservative. That is, if $f : X \to Y$ is a map of profinite spaces, then the following conditions are equivalent:*

(1) *The map f is an equivalence of profinite spaces.*

(2) *The map f induces a homotopy equivalence of spaces* $\mathrm{Mat}(X) \to \mathrm{Mat}(Y)$.

Proof. The implication (1) ⇒ (2) is obvious. Conversely, suppose that $\mathrm{Mat}(f) : \mathrm{Mat}(X) \to \mathrm{Mat}(Y)$ is a homotopy equivalence. Let $\mathcal{X}$ and $\mathcal{Y}$ denote the profinite ∞-topoi associated to X and Y, respectively, so that f induces a geometric morphism $f^* : \mathcal{Y} \to \mathcal{X}$. Combining (2) with Example E.3.1.5, we deduce that f^* induces an equivalence of ∞-categories $\mathrm{Fun}^*(\mathcal{X}, \mathcal{S}) \to \mathrm{Fun}^*(\mathcal{Y}, \mathcal{S})$. Because $\mathcal{X}$ and $\mathcal{Y}$ are bounded coherent ∞-topoi (Remark **??**) and the functor f^* preserves coherent objects (Corollary E.3.1.2), it follows from conceptual completeness (Theorem A.9.0.6) that f^* is an equivalence of ∞-topoi. Since from a profinite space to the associated profinite ∞-topos is fully faithful (Theorem E.2.4.1), it follows that f is an equivalence of profinite spaces. □

E.3.2 ∞-Pretopoi of Finite Breadth

Our next goal is to give a more intrinsic formulation of the criterion of Proposition E.3.1.1. First, we need to introduce some terminology.

Definition E.3.2.1. Let $\mathcal{C}$ be an ∞-pretopos containing an object X and suppose we are given integers $0 \leqslant i < j \leqslant n$. We let $\delta_{i,j} : X^n \to X^{n+1}$ denote the morphism in $\mathcal{C}$ induced by the map of finite sets

$$\{0 < 1 < \cdots < n\} \to \{1 < \cdots < n\} \qquad m \mapsto \begin{cases} m+1 & \text{if } m < i \\ j & \text{if } m = i \\ m & \text{if } m > i. \end{cases}$$

For fixed $n \geqslant 0$, we will say that X has *breadth* $\leqslant n$ if the maps $\{\delta_{i,j} : X^n \to X^{n+1}\}_{0 \leqslant i < j \leqslant n}$ determine a covering for the effective epimorphism topology (Definition A.6.2.4). More generally, we will say that a morphism $u : X \to Y$ in $\mathcal{C}$ has *breadth* $\leqslant n$ if it exhibits X as an object of breadth $\leqslant n$ in the ∞-pretopos $\mathcal{C}_{/Y}$. We will say that $\mathcal{C}$ has *finite breadth* if every morphism in $\mathcal{C}$ has breadth $\leqslant n$ for some integer n.

Example E.3.2.2. Let $\mathcal{C}$ be an ∞-pretopos. A morphism $u : X \to Y$ has breadth $\leqslant 0$ if and only if X is an initial object of $\mathcal{C}$.

Example E.3.2.3. Let $\mathcal{C}$ be an ∞-pretopos. A morphism $u : X \to Y$ has breadth $\leqslant 1$ if and only if the diagonal map $\delta : X \to X \times_Y X$ is an effective epimorphism.

Example E.3.2.4. A morphism $u : X \to Y$ in $\mathcal{S}$ has breadth $\leqslant n$ if and only if, for every point $y \in Y$, the homotopy fiber $X \times_Y \{y\}$ has at most n path components.

Remark E.3.2.5. Let $\mathcal{C}$ be an ∞-pretopos and let $n \geqslant 0$ be an integer. Then an object $C \in \mathcal{C}$ has breadth $\leqslant n$ if and only if the 0-truncation $\tau_{\leqslant 0} C$ has breadth $\leqslant n$.

Remark E.3.2.6. Let $\mathcal{C}$ be an ∞-topos and let $m \geqslant 0$ be an integer. If $u : X \to Y$ is a morphism in $\mathcal{C}$ If an object $C \in \mathcal{C}$ has breadth $\leqslant m$, then it also has breadth $\leqslant n$ whenever $n > m$.

Remark E.3.2.7. Let $f^* : \mathcal{C} \to \mathcal{D}$ be a morphism of ∞-pretopoi. If $u : X \to Y$ is a morphism in $\mathcal{C}$ having breadth $\leqslant n$, then $f^*(u) : f^* X \to f^* Y$ is a morphism in $\mathcal{D}$ having breadth $\leqslant n$.

Definition E.3.2.1 was motivated by the following:

Theorem E.3.2.8. *Let $\mathcal{C}$ be a bounded ∞-pretopos and let $\mathcal{X} = \mathcal{S}\mathrm{hv}(\mathcal{C})$ be the corresponding ∞-topos. The following conditions are equivalent:*

(1) *Every truncated coherent object of $\mathcal{X}$ is locally constant constructible.*

(2) *The ∞-topos $\mathcal{X}$ is profinite.*

(3) *The ∞-pretopos $\mathcal{C}$ is Boolean (Definition A.6.3.8) and of finite breadth.*

Corollary E.3.2.9. *Let $\mathcal{X}$ be an ∞-topos. Then $\mathcal{X}$ is profinite if and only if has the form $\mathcal{S}\mathrm{hv}(\mathcal{C})$, where $\mathcal{C}$ is an ∞-pretopos which is bounded, Boolean, and of finite breadth.*

Proof. Combine Proposition E.3.1.1 with Theorem E.3.2.8. □

Proof of Theorem E.3.2.8. The equivalence of (1) $\Leftrightarrow$ (2) follows from Proposition E.3.1.1. We next show that (1) implies (3). Note that if (1) is satisfied, then the Yoneda embedding $\mathcal{C} \hookrightarrow \mathcal{S}\mathrm{hv}(\mathcal{C}) \simeq \mathcal{X}$ induces an equivalence from $\mathcal{C}$ to the full subcategory $\mathcal{X}^{\mathrm{lcc}} \subseteq \mathcal{X}$, so that $\mathcal{C}$ is Boolean by virtue of Corollary E.2.6.7. To complete the proof of (3), it will suffice to show that every morphism $u : X \to Y$ in $\mathcal{X}^{\mathrm{lcc}}$ has finite breadth. Let $q^* : \mathcal{S} \to \mathcal{X}$ be a geometric morphism. Using Proposition E.2.6.6, we can assume (after passing to a finite covering of $\mathcal{X}$ if necessary) that $u = q^*(u_0)$ for some morphism $u_0 : X_0 \to Y_0$ in $\mathcal{S}_\pi$. It will therefore suffice to show that u_0 has finite breadth (Remark E.3.2.7), which follows immediately from Example E.3.2.4.

We now complete the proof by showing that (3) $\Rightarrow$ (1). Assume that (3) is satisfied, let $j : \mathcal{C} \to \mathcal{S}\mathrm{hv}(\mathcal{C}) = \mathcal{X}$ be the Yoneda embedding, and let $\mathcal{C}_0 = j^{-1}(\mathcal{X}^{\mathrm{lcc}}) \subseteq \mathcal{C}$ be the full subcategory of $\mathcal{C}$ spanned by those object $X \in \mathcal{C}$ for which $j(X) \in \mathcal{X}$ is locally constant constructible. We wish to prove that $\mathcal{C}_0 = \mathcal{C}$. Since $\mathcal{C}_0$ every object of $\mathcal{C}$ is truncated, this is an immediate consequence of the following:

$(*_m)$ Let $u : X \to Y$ be an m-truncated morphism in $\mathcal{C}$. Then $j(X) \in \mathcal{S}\mathrm{hv}(\mathcal{C})_{/j(Y)}$ is locally constant constructible.

The proof of $(*_m)$ proceeds by induction on m. If $m = -2$, then $u : X \to Y$ is an equivalence and there is nothing to prove. Let us therefore assume that $m > -2$. It follows from assumption (3) that the morphism u has breadth $\leqslant k$ for some integer $k \gg 0$; we proceed by induction on k. We first apply Proposition A.6.2.1 to factor u as a composition $X \xrightarrow{u'} Y_0 \xrightarrow{u''} Y$ where u' is an effective epimorphism and u'' is (-1)-truncated. Since $\mathcal{C}$ is Boolean, the morphism u'' determines a splitting $Y \simeq Y_0 \amalg Y_1$. It follows that $j(Y_0)$ is a summand of $j(Y)$, so that $j(X)$ is locally constant constructible as an object of $\mathcal{S}\mathrm{hv}(\mathcal{C})_{/j(Y)}$ if and only if it is locally constant constructible as an object of $\mathcal{S}\mathrm{hv}(\mathcal{C})_{/j(Y_0)}$. We may therefore replace Y by Y_0 and thereby reduce to the case where u is an effective epimorphism in $\mathcal{C}$. In this case, $j(u)$ is an effective epimorphism in $\mathcal{S}\mathrm{hv}(\mathcal{C})_{/j(Y)}$, so that $j(X) \in \mathcal{S}\mathrm{hv}(\mathcal{C})_{/j(Y)}$ is locally constant constructible if and only if $j(X \times_Y X) \in \mathcal{S}\mathrm{hv}(\mathcal{C})_{/j(X)}$ is locally constant constructible. We may therefore replace u by the projection map $u_X : X \times_Y X \to X$ and thereby reduce to the case where u admits a section $s : Y \to X$.

Applying Proposition A.6.2.1, we see that the map s factors as a composition $Y \xrightarrow{s'} U \xrightarrow{s''} X$, where s' is an effective epimorphism and s'' is (-1)-truncated. Since $\mathcal{C}$ is Boolean, the map s'' determines a decomposition $X \simeq U \amalg V$. Because u has breadth $\leqslant k$ and the restriction $u|_U : U \to Y$ admits a section s', the map $u|_V : V \to Y$ has breadth $< k$. It follows from our inductive hypothesis that $j(V) \in \mathcal{S}\mathrm{hv}(\mathcal{C})_{/j(Y)}$ is locally constant constructible. Consequently, to show that $j(X) \simeq j(U) \amalg j(V) \in \mathcal{S}\mathrm{hv}(\mathcal{C})_{/j(Y)}$ is locally constant constructible, it will suffice to show that $j(U)$ is locally constant constructible.

Let $Z_\bullet$ denote the groupoid object of $\mathcal{C}_{/Y}$ given by the Čech nerve of the morphism $s' : Y \to U$. Since U is a subobject of X, it is m-truncated as an object of $\mathcal{C}_{/Y}$. It follows that $Z_a \in \mathcal{C}_{/Y}$ is $(m-1)$-truncated for each $a \geqslant 0$. Applying our inductive hypothesis $(*_{m-1})$, we deduce that $j(Z_a)$ is a locally constant constructible object of $\mathcal{S}\mathrm{hv}(\mathcal{C})_{/j(Y)}$. Applying Corollary E.2.6.9, we conclude that $j(U) \simeq j(|Z_\bullet|) = |j(Z_\bullet)| \in \mathcal{S}\mathrm{hv}(\mathcal{C})_{/j(Y)}$ is also locally constant constructible. □

E.3.3 Digression: Ultraproducts

Before giving our final characterization of the class of profinite ∞-topoi, we need a few facts about ultraproducts and ultrapowers in the ∞-categorical setting.

Definition E.3.3.1. Let S be a set. We let $P(S)$ denote the power set of S: that is, the collection of all subsets of S. An *ultrafilter* on S is a subset $\mathcal{U} \subseteq P(S)$ with the following properties:

- (a) The subset $\mathcal{U} \subseteq P(S)$ is a filter: that is, it is closed upward and stable under finite intersections.
- (b) For every subset $I \subseteq S$, exactly one of the sets I and $S - I$ belongs to $\mathcal{U}$.

Example E.3.3.2. Let S be a set containing an element s. Then the set $\mathcal{U}_s = \{I \in P(S) : s \in I\} \subseteq P(S)$ is an ultrafilter on S. We say that an ultrafilter $\mathcal{U} \subseteq P(S)$ is *principal* if it has the form $\mathcal{U}_s$ for some element $s \in S$.

Remark E.3.3.3. Let S be a set. A subset $\mathcal{U} \subseteq P(S)$ is an ultrafilter if and only if its complement $P(S) - \mathcal{U}$ is a prime ideal, in the sense of Definition A.1.2.1. Consequently, we can identify the set of ultrafilters on S with the spectrum $X = \operatorname{Spec} P(S)$ of the Boolean algebra $P(S)$. For each $s \in S$, the principal ultrafilter $\mathcal{U}_s$ is an isolated point of X, and the construction $s \mapsto \mathcal{U}_s$ determines a homeomorphism from S to a subspace of X. For this reason, X is often referred to as the *Stone-Čech compactification of* X. Note that if S is infinite, then it is not compact when endowed with the discrete topology, so there must exist a nonprincipal ultrafilter on S.

Construction E.3.3.4 (Ultraproducts)**.** Let $\mathcal{E}$ be an ∞-category which admits products and filtered colimits. Suppose we are given a collection of objects $\{E_s\}_{s \in S}$ of $\mathcal{E}$ which is indexed by a set S. This collection of objects determines a functor $F : P(S)^{\mathrm{op}} \to \mathcal{E}$, given on objects by the formula $F(I) = \prod_{s \in I} E_s$ (more precisely, we can regard the collection of objects $\{E_s\}_{s \in S}$ as $F_0 : S \to \mathcal{E}$, where we regard S as a category having only identity morphisms, and we define $F : P(S)^{\mathrm{op}} \to \mathcal{E}$ to be a right Kan extension of F_0). If $\mathcal{U} \subseteq P(S)$ is an ultrafilter, then we can regard $\mathcal{U}^{\mathrm{op}}$ as a direct subset of the partially ordered set $P(S)^{\mathrm{op}}$. We let $\prod_{\mathcal{U}} E_s$ denote the colimit $\varinjlim_{I \in \mathcal{U}^{\mathrm{op}}} F(I)$. We will refer to $\prod_{\mathcal{U}} E_s$ as the *ultraproduct of $\{E_s\}_{s \in S}$ with respect to $\mathcal{U}$.*

Example E.3.3.5. Let $\{E_s\}_{s \in S}$ be a collection of sets indexed by a set S, and suppose that each E_s is nonempty. For every ultrafilter $\mathcal{U} \subseteq P(S)$, the ultraproduct $\prod_{\mathcal{U}} E_s$ (formed in the category $\mathcal{S}$et of sets) can be identified with the quotient of the product $\prod_{s \in S} E_s$ by the equivalence relation $\equiv$ defined as follows:

$$\{x_s\}_{s \in S} \equiv \{y_s\}_{s \in S} \text{ if } \{s \in S : x_s = y_s\} \in \mathcal{U}.$$

Example E.3.3.6. Let $\mathcal{E}$ be an ∞-category which admits products and filtered colimits, let $\{E_s\}_{s \in S}$ be a collection of objects of $\mathcal{E}$ indexed by a set S, and let $\mathcal{U}_t$ be the principal ultrafilter determined by an element $t \in S$. Then the inclusion $\{\{t\}\} \hookrightarrow \mathcal{U}$ is right cofinal, so the ultraproduct $\prod_{\mathcal{U}_t} E_s$ can be identified with E_t.

Remark E.3.3.7. Let $\mathcal{E}$ and $\mathcal{E}'$ be ∞-categories which admit products and filtered colimits. If $F : \mathcal{E} \to \mathcal{E}'$ is any functor which preserves products and filtered colimits, then F commutes with ultraproducts: in other words, for every collection of objects $\{E_s\}_{s \in S}$ of $\mathcal{E}$ and every ultrafilter $\mathcal{U}$ on S, we have a canonical equivalence $F(\prod_{\mathcal{U}} E_s) \simeq \prod_{\mathcal{U}} F(E_s)$ in the ∞-category $\mathcal{E}'$.

Note that Construction E.3.3.4 is functorial: if we fix the ∞-category $\mathcal{E}$, the set S, and the ultrafilter $\mathcal{U} \subseteq P(S)$, then the construction $\{E_s\}_{s \in S} \mapsto \prod_{\mathcal{U}} E_s$ determines a functor $\prod_{\mathcal{U}} : \mathcal{E}^S \to \mathcal{E}$. We will need the following elementary properties of this functor:

Proposition E.3.3.8. *Let S be a set and let $\mathcal{U} \subseteq P(S)$ be an ultrafilter. Then the ultraproduct functor $\prod_{\mathcal{U}} : \mathcal{S}^S \to \mathcal{S}$ is a morphism of ∞-pretopoi. In other words, the functor $\prod_{\mathcal{U}}$ preserves finite limits, finite coproducts, and effective epimorphisms.*

Proof. For each $I \subseteq S$, let $F_I : \mathcal{S}^S \to \mathcal{S}$ denote the functor given by $F_I(\{X_s\}_{s \in S}) = \prod_{s \in I} X_s$. Each of the functors F_I is left exact, and $\prod_{\mathcal{U}}$ can be obtained as a filtered colimit $\varinjlim_{I \in \mathcal{U}^{\mathrm{op}}} F_I$. Since filtered colimits in $\mathcal{S}$ are left exact, it follows that the functor $\prod_{\mathcal{U}}$ is left exact. Each of the functors F_I preserves effective epimorphisms (since the collection of effective epimorphisms in $\mathcal{S}$ is closed under small products), so the functor $\prod_{\mathcal{U}}$ also preserves effective epimorphisms (since the collection of effective epimorphisms in $\mathcal{S}$ is closed under filtered colimits). We will complete the proof by showing that the functor $\prod_{\mathcal{U}}$ preserves finite coproducts. We first observe that $\prod_{\mathcal{U}}$ preserves initial objects: in fact, the functor $F_I : \mathcal{S}^S \to \mathcal{S}$ preserves initial objects for all nonempty subsets $I \subseteq P(S)$, and therefore for all subsets I which belong to the ultrafilter $\mathcal{U}$ (note that the empty set $\varnothing \in P(S)$ is not contained in $\mathcal{U}$).

To complete the proof, it will suffice to show that the functor $\prod_{\mathcal{U}}$ preserves pairwise coproducts. Let $\{X_s\}_{s \in S}$ and $\{Y_s\}_{s \in S}$ be objects of $\mathcal{S}^S$. Since the functor $\prod_{\mathcal{U}}$ is left exact, the natural maps

$$\prod_{\mathcal{U}} X_s \xrightarrow{i} \prod_{\mathcal{U}} (X_s \amalg Y_s) \xleftarrow{j} \prod_{\mathcal{U}} Y_s$$

are (-1)-truncated, and we have

$$\prod_{\mathcal{U}} X_s \times_{\prod_{\mathcal{U}}(X_s \amalg Y_s)} \prod_{\mathcal{U}} Y_s \simeq \prod_{\mathcal{U}} (X_s \times_{X_s \amalg Y_s} Y_s) \simeq \prod_{\mathcal{U}} \varnothing \simeq \varnothing.$$

It follows that the natural map $\rho : (\prod_{\mathcal{U}} X_s) \amalg (\prod_{\mathcal{U}} Y_s) \to \prod_{\mathcal{U}} (X_s \amalg Y_s)$ is (-1)-truncated. To complete the proof, it will suffice to show that ρ is surjective on connected components. Note that every path component of $\prod_{\mathcal{U}} (X_s \amalg Y_s)$ belongs to the image of the natural map $\phi_I : \prod_{s \in I} (X_s \amalg Y_s) \to \prod_{\mathcal{U}} (X_s \amalg Y_s)$ for some $I \in \mathcal{U}$. Decomposing the domain of ϕ_I as a coproduct $\amalg_{I = I_0 \amalg I_1} (\prod_{s \in I_0} X_s) \times (\prod_{s \in I_1} Y_s)$, we see that every path component of $\prod_{\mathcal{U}} (X_s \amalg Y_s)$ belongs to the essential image of the natural map

$$\phi_{I_0, I_1} : (\prod_{s \in I_0} X_s) \times (\prod_{s \in I_1} Y_s) \to \prod_{\mathcal{U}} (X_s \amalg Y_s)$$

for some pair of disjoint subsets $I_0, I_1 \in P(S)$ satisfying $I_0 \amalg I_1 \in \mathcal{U}$. Since $\mathcal{U}$ is an ultrafilter, either I_0 or I_1 belongs to $\mathcal{U}$. We conclude by observing that if $I_0 \in \mathcal{U}$, then ϕ_{I_0, I_1} factors through the map i; if I_1 belongs to $\mathcal{U}$, then the map ϕ_{I_0, I_1} factors through j. □

Corollary E.3.3.9 (Łos's Theorem). *Let $\mathcal{C}$ be an ∞-pretopos and let $\mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{S})$ be the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{S})$ spanned by those functors which preserve finite limits, finite coproducts, and effective epimorphisms (Definition A.6.4.1). Then the $\mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{S})$ is closed under the formation of ultraproducts. That is, for every set S and every ultrafilter $\mathcal{U} \subseteq P(S)$, the ultraproduct functor $\prod_{\mathcal{U}} : \mathrm{Fun}(\mathcal{C}, \mathcal{S})^S \to \mathrm{Fun}(\mathcal{C}, \mathcal{S})$ carries $\mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{S})^S$ into $\mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{S})$.*

Let $\mathcal{E}$ be an ∞-category which admits products and filtered colimits, and let S be a set equipped with an ultrafilter $\mathcal{U} \subseteq P(S)$. Composing the ultraproduct functor $\prod_{\mathcal{U}} : \mathcal{E}^S \to \mathcal{E}$ of Construction E.3.3.4 with the diagonal map $\delta : \mathcal{E} \to \mathcal{E}^S$, we obtain a functor $\mathcal{E} \to \mathcal{E}$, which we will denote by $E \mapsto E^S / \mathcal{U}$. For each object $E \in \mathcal{E}$, we will refer to $E^S / \mathcal{U}$ as the *ultrapower of E by $\mathcal{U}$*.

Remark E.3.3.10. Let $\mathcal{E}$ and $\mathcal{U} \subseteq P(S)$ be as above. Unwinding the definitions, we see that the ultrapower $E^S / \mathcal{U}$ can be described as the filtered colimit $\varinjlim_{I \in \mathcal{U}^{\mathrm{op}}} F(I)$, where $F : P(S)^{\mathrm{op}} \to \mathcal{E}$ is the right Kan extension of the constant functor $F_0 : S \to \mathcal{E}$ taking the value E. Let $F' : P(S)^{\mathrm{op}} \to \mathcal{E}$ denote the constant functor with the value E. Since F is a right Kan extension of $F|_S$, the equality $F'|_S = F|_S$ extends uniquely to a natural transformation $F' \to F$, which induces a map $\gamma : E \simeq \varinjlim_{I \in \mathcal{U}^{\mathrm{op}}} F'(I) \to \varinjlim_{I \in \mathcal{U}^{\mathrm{op}}} F(I) = E^S / \mathcal{U}$.

E.3.4 Profiniteness and Points

We now combine the theory of ultraproducts with the criterion of Theorem E.3.2.8 to establish the following profiniteness criterion:

Theorem E.3.4.1. *Let $\mathcal{X}$ be an ∞-topos. Then $\mathcal{X}$ is profinite if and only if it satisfies the following conditions:*

(a) *The ∞-topos $\mathcal{X}$ is coherent.*

(b) *The ∞-topos $\mathcal{X}$ is bounded.*

(c) *The ∞-category $\operatorname{Fun}^*(\mathcal{X}, \mathcal{S})$ of points of $\mathcal{X}$ is a Kan complex.*

Note that the necessity of conditions (a), (b), and (c) follows from Remark E.2.4.5 and Proposition E.3.1.4. By virtue of Theorem A.7.5.3 and Remark A.9.1.4, the converse is equivalent to the following:

Proposition E.3.4.2. *Let $\mathcal{C}$ be a bounded ∞-pretopos. If the ∞-category $\operatorname{Fun}^*(\mathcal{C}, \mathcal{S})$ is a Kan complex, then the ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is profinite.*

Proof. Let $\mathcal{C}$ be a bounded ∞-pretopos having the property that $\operatorname{Fun}^*(\mathcal{C}, \mathcal{S})$ is a Kan complex. We wish to show that the ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{C})$ is profinite. By virtue of Theorem E.3.2.8, it will suffice to show that $\mathcal{C}$ is Boolean and of finite breadth. We begin by showing that $\mathcal{C}$ is Boolean. Fix an object $X \in \mathcal{C}$ and a subobject $U \in \operatorname{Sub}(X)$; we wish to show that U is complemented. Let $j : \mathcal{C} \to \mathcal{S}\mathrm{hv}(\mathcal{C})$ denote the Yoneda embedding and let V be the largest subobject of $j(X)$ which is disjoint from $j(U)$. Note that if the canonical map $j(U) \amalg V \to j(X)$ is an equivalence, then V is a truncated coherent object of $\mathcal{S}\mathrm{hv}(\mathcal{C})$ and is therefore of the form $j(V_0)$ for some $V_0 \in \operatorname{Sub}(X)$ complementary to U. Assume otherwise. Applying Theorem A.4.0.5 to the hypercompletion $\mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}}$, we deduce that there exists a point $\eta^* : \mathcal{S}\mathrm{hv}(\mathcal{C})^{\mathrm{hyp}} \to \mathcal{S}$ and a point $x \in \eta^* j(X)$ which cannot be lifted to either $\eta^* j(U)$ or $\eta^* V$. Set $M = \eta^* \circ j$, and view M as an object of $\operatorname{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{S}) \subseteq \operatorname{Pro}(\mathcal{C})^{\mathrm{op}}$, so that we can view x as a morphism $M \to X$ in $\operatorname{Pro}(\mathcal{C})$. Write M as the limit of a filtered diagram $\{M_\alpha\}$ in $\mathcal{C}_{/X}$. Note that if $U \times_X M_\alpha$ were initial in $\mathcal{C}$ for any index $\alpha \in A$, then the map $x : M_\alpha \to X$ would factor through some subobject $V_0 \in \operatorname{Sub}(X)$ disjoint from U, contradicting our assumption that x cannot be lifted to V. It follows that $U \times_X M$ is not initial in $\operatorname{Pro}(\mathcal{C})^{\mathrm{cc}}_{/M}$. Applying Theorem A.4.0.5 again, we deduce that the ∞-topos $\mathcal{S}\mathrm{hv}(\operatorname{Pro}(\mathcal{C})^{\mathrm{cc}}_{/M})^{\mathrm{hyp}}$ has a point μ^* for which the composite map $\operatorname{Pro}(\mathcal{C})^{\mathrm{cc}}_{/M} \hookrightarrow \mathcal{S}\mathrm{hv}(\operatorname{Pro}(\mathcal{C})^{\mathrm{cc}}_{/M})^{\mathrm{hyp}} \xrightarrow{\mu^*} \mathcal{S}$ carries $U \times_X M$ to a nonempty space. Unwinding the definitions, we can identify this composite map with an object $N \in \operatorname{Pro}(\operatorname{Pro}(\mathcal{C})^{\mathrm{cc}}_{/M}) \simeq \operatorname{Pro}(\mathcal{C})_{/M}$ for which the composite map $N \xrightarrow{\pi} M \xrightarrow{x} X$ factor through U. Since the map x itself does not factor through U, the map π cannot be an equivalence, which contradicts our assumption that $\mathrm{Fun}^*(\mathcal{C}, \mathcal{S}) \simeq \mathrm{Pro}(\mathcal{C})^{\mathrm{op}}_{\circ}$ is a Kan complex.

We now show that the ∞-pretopos $\mathcal{C}$ of finite breadth. Fix a morphism $f : X \to Y$ in $\mathcal{C}$; we wish to show that f has breadth $\leqslant n$ for some integer n. Replacing $\mathcal{C}$ by $\mathcal{C}_{/Y}$, we can assume that Y is a final object of $\mathcal{C}$. Note that if the object X does not have breadth $\leqslant n$, then we can use Theorem A.4.0.5 to produce an object $M_n \in \mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{S})$ such that $\pi_0 M_n(X)$ has cardinality $> n$. Assume (for a contradiction) that such an object exists for all $n \geqslant 0$. Let $\mathcal{U}$ be a nonprincipal ultrafilter on the set $\mathbf{Z}_{\geqslant 0}$, and set $M = \prod_{\mathcal{U}} M_n$. Then M is an object of $\mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{S})$, and we can identify $\pi_0 M(X)$ with the ultraproduct $\prod_{\mathcal{U}} \pi_0 M_n(X)$ (Remark E.3.3.7). It follows that the set $S = \pi_0 M(X)$ is infinite. Let $\mathcal{V}$ be a nonprincipal ultrafilter on S and let $N = M^S/\mathcal{V}$ be the corresponding ultrapower of M, so that the natural map $\gamma : M \to N$ of Remark E.3.3.10 can be regarded as a morphism in the ∞-category $\mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{S})$. Our assumption that $\mathrm{Fun}^{\mathrm{pre}}(\mathcal{C}, \mathcal{S})$ is a Kan complex guarantees that γ is an equivalence, and therefore induces a bijection of sets $\gamma_0 : \pi_0 M(X) \to \pi_0 N(X)$. Using Remark E.3.3.7, we can identify γ_0 with the diagonal map $S \to S^S/\mathcal{V}$. This is a contradiction: the equivalence class of the identity map $\mathrm{id}_S : S \to S$ does not belong to the image of the map γ_0 (otherwise, the ultrafilter $\mathcal{V}$ would be principal). □

E.4 Truncations of Profinite Spaces

Let $f : X \to Y$ be a map of spaces, and let $n \geqslant -2$ be an integer. Recall that f is said to be *n-truncated* if, for each $y \in Y$, the homotopy fiber $X_y = X \times_Y \{y\}$ is an n-truncated space: that is, if the truncation map $X_y \to \tau_{\leqslant n} X_y$ is an equivalence. We say that f is *$(n+1)$-connective* if each homotopy fiber X_y of f is $(n+1)$-connective: that is, if the truncation $\tau_{\leqslant n} X_y$ is contractible. According to Example HTT.5.2.8.16 , every map of spaces $f : X \to Y$ admits an essentially unique factorization $X \xrightarrow{f'} Z \xrightarrow{f''} Y$, where the map f' is $(n+1)$-connective and f'' is n-truncated. Our goal in this section is to construct an analogous factorization in the case where f is a map of profinite spaces.

E.4.1 Connective and Truncated Morphisms

Throughout this section, we will abuse notation by identifying the ∞-category $\mathcal{S}_\pi$ of π-finite spaces with its essential image in the ∞-category $\mathcal{S}^\wedge_\pi$ of profinite spaces.

Definition E.4.1.1. Let $n \geqslant -2$ be an integer. We will say that a map $f : X \to Y$ of profinite spaces is *n-truncated* if it is given as a filtered limit of morphisms $f_\alpha : X_\alpha \to Y_\alpha$, where each f_α is an n-truncated map of π-finite spaces. If $n \geqslant -1$, we say that f is *n-connective* if it is given as a filtered limit of morphisms $f_\beta : X_\beta \to Y_\beta$, where each f_β is an n-connective map of π-finite spaces.

Let $*$ denote a final object of $\mathcal{S}_\pi^\wedge$. We say that a π-profinite space X is *n-connective* if the constant map $X \to *$ is n-connective, and *n-truncated* if the constant map $X \to *$ is n-truncated. We say that X is *connected* if it is 1-connective, and *simply connected* if it is 2-connective.

Recall that a *factorization system* on an ∞-category $\mathcal{C}$ is a pair (S_L, S_R) with the following properties (Definition HTT.5.2.8.8):

(1) Both S_L and S_R are collections of morphisms of $\mathcal{C}$ which are closed under the formation of retracts.

(2) Every morphism in S_L is left orthogonal to every morphism in S_R (see Definition HTT.5.2.8.1).

(3) Every morphism $f : X \to Y$ in $\mathcal{C}$ can be obtained as a composition $X \xrightarrow{f'} Z \xrightarrow{f''} Y$, where $f' \in S_L$ and $f'' \in S_R$.

We refer the reader to §HTT.5.2.8 for a general discussion of factorization systems in ∞-categories. We can now state the first main result of this section:

Theorem E.4.1.2. *Let $n \geqslant -2$ be an integer. Let $\hat{S}_L$ denote the collection of $(n+1)$-connective morphisms in $\mathcal{S}_\pi^\wedge$, and let $\hat{S}_R$ denote the collection of n-truncated morphisms in $\mathcal{S}_\pi^\wedge$. Then the pair $(\hat{S}_L, \hat{S}_R)$ is a factorization system on the ∞-category $\mathcal{S}_\pi^\wedge$.*

Example E.4.1.3. Let X be a profinite space and let $n \geqslant -2$ be an integer. Theorem E.4.1.2 implies that there is an essentially unique map $f : X \to \tau_{\leqslant n} X$, where f is $(n+1)$-connective and $\tau_{\leqslant n} X$ is n-truncated. The construction $X \mapsto \tau_{\leqslant n} X$ determines a functor from the ∞-category $\mathcal{S}_\pi^\wedge$ to itself, which is left adjoint to the inclusion of n-truncated profinite spaces into $\mathcal{S}_\pi^\wedge$. Alternatively, we can describe $\tau_{\leqslant n}$ as the essentially unique extension of the usual truncation functor on π-finite spaces which commutes with filtered limits.

Remark E.4.1.4. Every finite set can be regarded as a π-finite space. We therefore obtain an inclusion of ∞-categories $\mathcal{S}\mathrm{et}^{\mathrm{fin}} \hookrightarrow \mathcal{S}_\pi$, which induces a fully faithful embedding

$$\mathrm{Pro}(\mathcal{S}^{\mathrm{fin}}) \to \mathrm{Pro}(\mathcal{S}_\pi) = \mathcal{S}_\pi^\wedge$$

whose essential image is the full subcategory of $\mathrm{Pro}(\mathcal{S}_\pi^\wedge)$ spanned by the 0-truncated profinite spaces.

E.4.2 Construction of the Factorization System

Theorem E.4.1.2 is an immediate consequence of the following pair of results:

Proposition E.4.2.1. *Let $n \geqslant -2$ be an integer. Let S_L be the collection of $(n+1)$-connective morphisms between π-finite spaces and let S_R be the collection of n-truncated morphisms between π-finite spaces. Then the pair (S_L, S_R) is a factorization system on the ∞-category $\mathcal{S}_\pi$ of π-finite spaces.*

Proposition E.4.2.2. *Let $\mathcal{C}$ be an essentially small ∞-category which is equipped with a factorization system (S_L, S_R). Let $\mathcal{C}_L$ denote the full subcategory of $\mathrm{Fun}(\Delta^1, \mathcal{C})$ spanned by those morphisms belonging to S_L, and $\mathcal{C}_R$ the full subcategory of $\mathrm{Fun}(\Delta^1, \mathcal{C})$ spanned by those morphisms belonging to S_R. Then the inclusions $\mathcal{C}_L \hookrightarrow \mathrm{Fun}(\Delta^1, \mathcal{C}) \hookleftarrow \mathcal{C}_R$ determine fully faithful embeddings*

$$\mathrm{Ind}(\mathcal{C}_L) \hookrightarrow \mathrm{Ind}(\mathrm{Fun}(\Delta^1, \mathcal{C})) \simeq \mathrm{Fun}(\Delta^1, \mathrm{Pro}(\mathcal{C})) \hookleftarrow (\mathcal{C}_R)$$

(see Proposition HTT.5.3.5.15). Let $\hat{S}_L$ and $\hat{S}_R$ denote the collections of morphisms in $\mathrm{Ind}(\mathcal{C})$ which belong to the essential images of these embeddings. Then $(\hat{S}_L, \hat{S}_R)$ is a factorization system on $\mathrm{Ind}(\mathcal{C})$.

Proof of Proposition E.4.2.1. According to Example HTT.5.2.8.16 , the collections of $(n+1)$-connective and n-truncated morphisms in $\mathcal{S}$ determine a factorization system on $\mathcal{S}$. The only nontrivial point is to show that if $f : X \to Y$ is a map of π-finite spaces and we factor f as a composition $X \xrightarrow{f'} Z \xrightarrow{f''} Y$ where f' is $(n+1)$-connective and f'' is n-truncated, then the space Z is also π-finite. Since Y is π-finite, it will suffice to show that for each $y \in Y$, the homotopy fiber $Z_y = Z \times_Y \{y\}$ is π-finite. For this, we observe that Z_y is given by the truncation $\tau_{\leqslant n} X_y$, where X_y denotes the homotopy fiber $X \times_Y \{y\}$. □

Proof of Proposition E.4.2.2. Since ∞-categories $\mathrm{Ind}(\mathcal{C}_L)$ and $\mathrm{Ind}(\mathcal{C}_R)$ are idempotent complete, the sets $\hat{S}_L$ and $\hat{S}_R$ are clearly stable under retracts. Let $\mathcal{D}$ denote the full subcategory of $\mathrm{Fun}(\Delta^2, \mathcal{C})$ spanned by those diagrams

$$\begin{array}{ccc} & Z & \\ {}^{f'}\nearrow & & \searrow^{f''} \\ X & \xrightarrow{f} & Y \end{array}$$

where $f' \in S_L$ and $f'' \in S_R$. According to Proposition HTT.5.2.8.17 , the inclusion $\Delta^1 \simeq \Delta^{\{0,2\}} \hookrightarrow \Delta^2$ induces an equivalence of ∞-categories $\mathcal{D} \to \mathrm{Fun}(\Delta^1, \mathcal{C})$. It follows that the induced map $\mathrm{Ind}(\mathcal{D}) \to \mathrm{Ind}(\mathrm{Fun}(\Delta^1, \mathcal{C})) \simeq \mathrm{Fun}(\Delta^1, \mathrm{Ind}(\mathcal{C}))$ is an equivalence. From this, we conclude that every morphism $f : X \to Y$ in $\mathrm{Ind}(\mathcal{C})$ factors as a composition $X \xrightarrow{f'} Z \xrightarrow{f''} Y$, where $f' \in \hat{S}_L$ and $f'' \in \hat{S}_R$.

It remains to prove that every morphism in $\hat{S}_L$ is left orthogonal to every morphism in $\hat{S}_R$. To prove this, suppose we are given a filtered diagram $\{f_\alpha : A_\alpha \to B_\alpha\}$ in $\mathcal{C}_L$ and a filtered diagram $\{g_\beta : X_\beta \to Y_\beta\}$ in $\mathcal{C}_R$, having limits given by morphisms $f : A \to B$ and $g : X \to Y$ in $\mathrm{Ind}(\mathcal{C})$. We wish to show that the diagram

$$\begin{array}{ccc} \mathrm{Map}_{\mathrm{Ind}(\mathcal{C})}(B, X) & \longrightarrow & \mathrm{Map}_{\mathrm{Ind}(\mathcal{C})}(A, X) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathrm{Ind}(\mathcal{C})}(B, Y) & \longrightarrow & \mathrm{Map}_{\mathrm{Ind}(\mathcal{C})}(B, X) \end{array}$$

is a pullback square of spaces. Since the collection of pullback diagrams in $\mathcal{S}$ is closed under filtered colimits and small limits, it suffices to prove that for every pair of indices α and β, the diagram of spaces

$$\begin{array}{ccc} \mathrm{Map}_{\mathrm{Ind}(\mathcal{C})}(B_\alpha, X_\beta) & \longrightarrow & \mathrm{Map}_{\mathrm{Ind}(\mathcal{C})}(A_\alpha, X_\beta) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathrm{Ind}(\mathcal{C})}(B_\alpha, Y_\beta) & \longrightarrow & \mathrm{Map}_{\mathrm{Ind}(\mathcal{C})}(B_\alpha, X_\beta) \end{array}$$

is a pullback square. This follows because f_α is left orthogonal to g_β in the ∞-category $\mathcal{C}$. □

E.4.3 Connectivity of Profinite Completions

We now study the relationship between the connectivity properties of a morphism $f : X \to Y$ of spaces and the induced map of profinite completions $X^\wedge_\pi \to Y^\wedge_\pi$.

Proposition E.4.3.1. *Let $f : X \to Y$ be a map of spaces. If f is n-connective, then the induced map $X^\wedge_\pi \to Y^\wedge_\pi$ is an n-connective map of profinite spaces.*

Proof. By virtue of Theorem E.4.1.2, it will suffice to show that the map $X^\wedge_\pi \to Y^\wedge_\pi$ has the left lifting property with respect to every $(n-1)$-truncated map of profinite space $g : U \to V$. Then g can be written as a filtered limit of $(n-1)$-truncated maps $g_\alpha : U_\alpha \to V_\alpha$. Replacing g by g_α, we can reduce to the case where U and V are π-finite. In this case, the desired property follows immediately from our assumption that f has the left lifting property with respect to g (in the ∞-category of spaces). □

Corollary E.4.3.2. *Let X be an n-connective space. Then the profinite completion $X^\wedge_\pi$ is an n-connective profinite space.*

Corollary E.4.3.2 has a counterpart for truncatedness:

Proposition E.4.3.3. *Let X be a discrete space. Then the profinite completion $X^\wedge_\pi$ is 0-truncated.*

Proof. Set $S = \pi_0 X$. Let $\mathcal{E}$ denote the set of all equivalence relations E on S such that S/E is finite. Then $\{S/E\}_{E \in \mathcal{E}}$ represents a Pro-object in the category of finite sets, and therefore determines a 0-truncated profinite space. We will show that $\{S/E\}_{E \in \mathcal{E}}$ is a profinite completion of X. In other words, we show that for every π-finite space T, the composite map

$$\varinjlim_{E \in \mathcal{E}} \mathrm{Fun}(S/E, T) \xrightarrow{\phi} \mathrm{Fun}(S, T) \xrightarrow{\psi} \mathrm{Fun}(X, T)$$

is a homotopy equivalence. By virtue of Lemma E.1.6.5, we may assume without loss of generality that T has finitely many simplices of each dimension, from which it follows that ϕ is an isomorphism of simplicial sets. The map ψ is a homotopy equivalence by virtue of our assumption that X is discrete. □

Warning E.4.3.4. It is not true in general that if X is an n-truncated space, then the profinite completion $X^{\wedge}_{\pi}$ is n-truncated. For example, suppose that $X = BG$ is the classifying space of a discrete group G (so that X is 1-truncated). Then $\tau_{\leqslant 1} X^{\wedge}_{\pi}$ can be identified with the classifying space for the profinite completion $G^{\wedge}$ of G. The profinite completion $X^{\wedge}_{\pi}$ is 1-truncated if and only if, for every finite abelian group A with an action of G and every integer $m \geqslant 0$, the map of cohomology groups $\mathrm{H}^m_c(G^{\wedge}; M) \to \mathrm{H}^m(G; M)$ is an isomorphism, where the left hand side indicates the profinite group cohomology of $G^{\wedge}$.

E.4.4 Materialization

For applications of Theorem E.4.1.2, it is useful to have some alternate descriptions of the classes of n-connective and n-truncated morphisms in $\mathcal{S}^{\wedge}_{\pi}$. For this, we need a slight digression.

Proposition E.4.4.1. *Let $F : \mathcal{S} \to \mathcal{S}^{\wedge}_{\pi}$ denote the profinite completion functor $F(X) = X^{\wedge}_{\pi}$. Then F admits a right adjoint.*

Proof. Proposition HTT.5.1.3.2 implies that F preserves small colimits. Since the ∞-category $\mathcal{S}$ is presentable, it follows that F admits a right adjoint (Corollary HTT.5.5.2.9 and Remark HTT.5.5.2.10). □

Notation E.4.4.2. The profinite completion functor $X \mapsto X^{\wedge}_{\pi}$ is fully faithful when restricted to the ∞-category $\mathcal{S}_{\pi}$ of π-finite spaces. If X is π-finite, we will generally abuse notation by not distinguishing between X and its profinite completion. In particular, we let $*$ denote the profinite space given by the profinite completion of a one-point space (as an object of $\mathcal{S}^{\wedge}_{\pi} \subseteq \mathrm{Fun}(\mathcal{S}_{\pi}, \mathcal{S})^{\mathrm{op}}$, we can identify $*$ with the inclusion functor $\mathcal{S}_{\pi} \hookrightarrow \mathcal{S}$).

Remark E.4.4.3. For every profinite space X, we have a canonical homotopy equivalence

$$\mathrm{Mat}(X) \simeq \mathrm{Map}_{\mathcal{S}}(*, \mathrm{Mat}(X)) \simeq \mathrm{Map}_{\mathcal{S}^{\wedge}_{\pi}}(*, X).$$

Remark E.4.4.4. Let X and Y be profinite spaces, represented by filtered diagrams of π-finite spaces $\{X_\alpha\}_{\alpha \in A}$, $\{Y_\beta\}_{\beta \in B}$. Then the coproduct $X \amalg Y$ is represented by the filtered diagram $\{X_\alpha \amalg Y_\beta\}_{(\alpha,\beta) \in A \times B}$. It follows that the materialization $\mathrm{Mat}(X \amalg Y)$ is given by

$$\begin{aligned} \mathrm{Mat}(X \amalg Y) &\simeq \varprojlim_{\alpha,\beta} (X_\alpha \amalg Y_\beta) \\ &\simeq (\varprojlim_{\alpha} X_\alpha) \amalg (\varprojlim_{\beta} Y_\beta) \\ &\simeq \mathrm{Mat}(X) \amalg \mathrm{Mat}(Y). \end{aligned}$$

In other words, the materialization functor commutes with finite coproducts.

E.4.5 Connectivity of Materializations

We will see later that a map of profinite spaces $f : X \to Y$ is n-truncated if and only if $\mathrm{Mat}(f)$ is n-truncated (Proposition E.4.6.1), and n-connective if and only if $\mathrm{Mat}(f)$ is n-connective (Corollary E.4.6.3). As a first step, we prove the following:

Proposition E.4.5.1. *Let $f : X \to Y$ be an n-connective map of profinite spaces. Then the induced map $\mathrm{Mat}(X) \to \mathrm{Mat}(Y)$ is also n-connective.*

Remark E.4.5.2. In the special case where $Y = *$, X is discrete, and $n = 0$, we can Proposition E.4.5.1 reduces to Proposition E.1.1.1.

Lemma E.4.5.3. *Let $\mathcal{J}$ be a filtered ∞-category and let $X : \mathcal{J}^{\mathrm{op}} \to \mathcal{S}$ be a diagram of spaces indexed by $\mathcal{J}^{\mathrm{op}}$. Assume that:*

(a) For every object $J \in \mathcal{J}$, the set $\pi_0 X(J)$ is nonempty and finite.

(b) For every object $J \in \mathcal{J}$, every point $\eta \in X(J)$, and every integer $n \geq 1$, the group $\pi_n(X(J), \eta)$ is finite.

Then the limit $\varprojlim_{J \in \mathcal{J}^{\mathrm{op}}} X(J)$ is nonempty.

Proof. According to Proposition HTT.5.3.1.18 , there exists a filtered partially ordered set A and a left cofinal map $\mathrm{N}(A) \to \mathcal{J}$. We may therefore replace $\mathcal{J}$ by $\mathrm{N}(A)$ and thereby assume that $\mathcal{J}$ is the nerve of a filtered partially ordered set.

If $n \geq 0$, we will say that X is *n-truncated* if the space $X(\alpha)$ is n-truncated for each $\alpha \in A$. We first prove that $\varprojlim_{\alpha \in A^{\mathrm{op}}} X(\alpha)$ is nonempty under the additional assumption that X is n-truncated. Our proof proceeds by induction on n; the case $n = 0$ follows from Proposition E.1.1.1.

Suppose that X is n-truncated for $n > 0$. Let $X' : \mathrm{N}(A)^{\mathrm{op}} \to \mathcal{S}$ denote the composition of X with the truncation functor $\tau_{\leq n-1} : \mathcal{S} \to \mathcal{S}$. Our inductive hypothesis implies that the limit $\varprojlim_{\alpha\in A^{\mathrm{op}}} X'(\alpha)$ is nonempty. We will prove that X is nonempty by showing that the map $\theta : \varprojlim_{\alpha\in A^{\mathrm{op}}} X(\alpha) \to \varprojlim_{\alpha\in A^{\mathrm{op}}} X'(\alpha)$ is surjective on connected components. To this end, suppose we are given a point $\eta \in \varprojlim_{\alpha\in A^{\mathrm{op}}} X'(\alpha)$, so that η determines a natural transformation $X'_0 \to X'$, where X'_0 denotes the constant functor $\mathrm{N}(A)^{\mathrm{op}} \to \mathcal{S}$ taking the value Δ^0. Let $X_0 = X \times_{X'} X'_0$. To prove that the homotopy fiber of θ over η is nonempty, we must show that $\varprojlim_{\alpha\in A^{\mathrm{op}}} X_0(\alpha)$ is nonempty. Note that for each $\alpha \in A$, the space $X_0(\alpha)$ is an n-gerbe: that is, it is both n-truncated and n-connective. In particular, since $n > 0$, each of the spaces $X_0(\alpha)$ is connected.

Let $\mathcal{B}$ denote the collection of all finite subsets $B \subseteq A$ which contain a largest element. Let K denote the simplicial subset of $\mathrm{N}(A)$ given by the union of all the vertices. For each $B \in \mathcal{B}$, let $K_B \subseteq \mathrm{N}(A)$ denote the union $K \cup \mathrm{N}(B)$. Regard $\mathcal{B}$ as a partially ordered set with respect to inclusions, and define a functor $Y : \mathrm{N}(\mathcal{B})^{\mathrm{op}} \to \mathcal{S}$ by the formula $Y(B) = \varprojlim(X_0|_{K_B^{\mathrm{op}}})$ (see §HTT.4.2.3). Using Proposition HTT.4.2.3.8 , we obtain a homotopy equivalence $\varprojlim_{B\in\mathcal{B}^{\mathrm{op}}} Y(B) \simeq \varprojlim_{\alpha\in A} X_0(\alpha)$. It will therefore suffice to show that $\varprojlim_{B\in\mathcal{B}^{\mathrm{op}}} Y(B)$ is nonempty. Let $M = \varprojlim(X_0|_K) = \prod_{\alpha\in A} X_0(\alpha)$ and let $Z : \mathrm{N}(\mathcal{B}^{\mathrm{op}}) \to \mathcal{S}$ be the constant functor taking the value M. Note that $\mathcal{B}$ is filtered, so that $\varprojlim_{B\in\mathcal{B}^{\mathrm{op}}} Z(B) \simeq M$. We have an evident natural transformation of functors $Y \to Z$ which induces a map $\theta' : \varprojlim_{B\in\mathcal{B}^{\mathrm{op}}} Y(B) \to \varprojlim_{B\in\mathcal{B}^{\mathrm{op}}} Z(B) \simeq M$. Since M is nonempty, it will suffice to show that the homotopy fibers of θ' are nonempty.

Choose a point $\zeta \in M$, corresponding to a collection of points $\{\zeta_\alpha \in X_0(\alpha)\}_{\alpha\in A}$. The point ζ determines a natural transformation of functors $Z_0 \to Z$, where $Z_0 : \mathrm{N}(\mathcal{B})^{\mathrm{op}} \to \mathcal{S}$ is the constant functor taking the value Δ^0. Let $Y_0 = Y \times_Z Z_0$, so that the homotopy fiber of θ' over the point ζ is given by $\varprojlim_{B\in\mathcal{B}^{\mathrm{op}}} Y_0(B)$. Fix an element $B \in \mathcal{B}$, so that B is a subset of A which contains a largest element β. We have homotopy equivalences $Y(B) \simeq X_0(\beta) \times \prod_{\alpha\notin B} X_0(\alpha)$ and $Z(B) \simeq \prod_{\alpha\in A} X_0(\alpha)$. For each $\alpha \in B$, let ζ'_α denote the image of ζ_β under the map $X_0(\beta) \to X_0(\alpha)$. Unwinding the definitions, we see that $Y_0(B)$ can be identified with the product over all $\alpha \in B - \{\alpha\}$ of the space of paths joining ζ_α with ζ'_α in $X_0(\alpha)$. Since each $X_0(\alpha)$ is a connected n-truncated space with finite homotopy groups, we conclude that $Y_0(B)$ is a nonempty $(n-1)$-truncated space with finite homotopy groups. Since $\mathcal{B}$ is filtered, it follows from the inductive hypothesis that $\varprojlim_{B\in\mathcal{B}^{\mathrm{op}}} Y_0(B)$ is nonempty.

We now treat the case of a general functor $X : \mathrm{N}(A)^{\mathrm{op}} \to \mathcal{S}$. For each integer n, let $\tau_{\leqslant n}X$ denote the composition of X with the truncation functor $\tau_{\leqslant n} : \mathcal{S} \to \mathcal{S}$. Then X is the limit of the tower

$$\cdots \to \tau_{\leqslant 2}X \to \tau_{\leqslant 1}X \to \tau_{\leqslant 0}X,$$

so that $\varprojlim_{\alpha\in A^{\mathrm{op}}} X(\alpha)$ is given by the limit of the tower of spaces $\{\varprojlim_{\alpha\in A^{\mathrm{op}}} \tau_{\leqslant n}X(\alpha)\}_{n\geqslant 0}$. The above arguments show that $\varprojlim_{\alpha\in A^{\mathrm{op}}} \tau_{\leqslant 0}X(\alpha)$ is nonempty and that each of the transition maps $\varprojlim_{\alpha\in A^{\mathrm{op}}} \tau_{\leqslant n}X(\alpha) \to \varprojlim_{\alpha\in A^{\mathrm{op}}} \tau_{\leqslant n-1}X(\alpha)$ has nonempty homotopy fibers, from which it immediately follows that the tower $\{\varprojlim_{\alpha \in A^{\mathrm{op}}} \tau_{\leqslant n} X(\alpha)\}_{n \geqslant 0}$ has nonempty limit. $\square$

Corollary E.4.5.4. *Let $\mathcal{J}$ and X be as in Lemma E.4.5.3, and let $n \geqslant 0$ be an integer such that each $X(J)$ is n-connective. Then $X = \varprojlim_{J \in \mathcal{J}} X(J)$ is n-connective.*

Proof. We proceed by induction on n. If $n = 0$, the desired result follows from Lemma E.4.5.3. Assume therefore that $n > 0$. The inductive hypothesis implies that X is nonempty. It will therefore suffice to show that, for every pair of points $\eta, \eta' \in X$, the path space $\{\eta\} \times_X \{\eta'\}$ is $(n-1)$-connective. Let $X_0, X_1 : \mathcal{J}^{\mathrm{op}} \to \mathcal{S}$ denote the constant functor taking the value Δ^0, so that η and η' determine natural transformations $X_0 \to X \leftarrow X_1$ and we have a homotopy equivalence $\{\eta\} \times_X \{\eta'\} \simeq \varprojlim_{J \in \mathcal{J}^{\mathrm{op}}} (X_0 \times_X X_1)(J)$. Since $X_0 \times_X X_1$ takes $(n-1)$-connective values, the inductive hypothesis implies that $\{\eta\} \times_X \{\eta'\}$ is $(n-1)$-connective. $\square$

Remark E.4.5.5. Let X be a profinite space, let $n \geqslant 0$ be an integer, and let $f : X \to \tau_{\leqslant n} X$ be an n-truncation of X. Then $\mathrm{Mat}(f) : \mathrm{Mat}(X) \to \mathrm{Mat}(\tau_{\leqslant n} X)$ is a map from $\mathrm{Mat}(X)$ to an n-truncated space. Since f is $(n+1)$-connective, Corollary E.4.5.4 implies that $\mathrm{Mat}(f)$ is $(n+1)$-connective: that is, $\mathrm{Mat}(f)$ induces an equivalence $\tau_{\leqslant n} \mathrm{Mat}(X) \simeq \mathrm{Mat}(\tau_{\leqslant n} X)$.

Proof of Proposition E.4.5.1. Write f as a filtered limit of n-connective maps $f_\alpha : X_\alpha \to Y_\alpha$ between p-finite spaces. Let $\eta \in \mathrm{Mat}(Y)$, so that η determines a compatible family of points $\eta_\alpha \in Y_\alpha$. We wish to prove that the homotopy fiber $\mathrm{Mat}(X)_\eta = \mathrm{Mat}(X) \times_{\mathrm{Mat}(Y)} \{\eta\}$ is n-connective. This homotopy fiber is given as the limit of a filtered system n-connective, p-finite spaces $X_\alpha \times_{Y_\alpha} \{\eta_\alpha\}$, and is therefore n-connective by Corollary E.4.5.4. $\square$

E.4.6 Truncatedness of Materializations

We now prove an analogue of Proposition E.4.5.1 for truncated morphisms of profinite spaces.

Proposition E.4.6.1. *Let $f : X \to Y$ be a morphism of profinite spaces and let $n \geqslant -2$ be an integer. The following conditions are equivalent:*

(1) *The morphism f is n-truncated, in the sense of Definition E.4.1.1.*

(2) *The morphism f exhibits X as an n-truncated object of the ∞-category $(\mathcal{S}_\pi^\wedge)_{/Y}$: that is, for every profinite space Z, the map of spaces $\mathrm{Map}_{\mathcal{S}_\pi^\wedge}(Z, X) \to \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(Z, Y)$ is n-truncated.*

(3) *The induced map of materializations $\mathrm{Mat}(X) \to \mathrm{Mat}(Y)$ is n-truncated.*

Proof. Suppose first that condition (1) is satisfied: that is, f is given as the limit of a filtered diagram of n-truncated morphisms $f_\alpha : X_\alpha \to Y_\alpha$ between π-finite spaces. We will prove that (2) is satisfied. Let Z be an arbitrary π-profinite space. Then the map $\theta : \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(Z, X) \to \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(Z, Y)$ is a filtered limit of maps

$$\theta_\alpha : \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(Z, X_\alpha) \to \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(Z, Y_\alpha).$$

Consequently, to prove that θ is n-truncated, it will suffice to show that each θ_α is n-truncated. Write Z as a filtered limit of π-finite spaces Z_β, so that θ_α is a filtered colimit of maps

$$\theta_{\alpha,\beta} : \mathrm{Map}_{\mathcal{S}}(Z_\beta, X_\alpha) \to \mathrm{Map}_{\mathcal{S}}(Z_\beta, Y_\alpha).$$

It will therefore suffice to show that each $\theta_{\alpha,\beta}$ is n-truncated, which follows immediately from our assumption that f_α is n-truncated.

The implication (2) ⇒ (3) is obvious. We will complete the proof by showing that (3) ⇒ (1). Using Theorem E.4.1.2, we can factor f as a composition $X \xrightarrow{f'} Z \xrightarrow{f''} Y$ where f' is $(n+1)$-connective and f'' is n-truncated. The first part of the proof shows that the map of materializations $\mathrm{Mat}(Z) \to \mathrm{Mat}(Y)$ is n-truncated, so that f' induces an n-truncated map $\mathrm{Mat}(X) \to \mathrm{Mat}(Z)$. Proposition E.4.5.1 implies that $\mathrm{Mat}(X) \to \mathrm{Mat}(Z)$ is $(n+1)$-connective. It follows that the map from $\mathrm{Mat}(X)$ to $\mathrm{Mat}(Z)$ is a homotopy equivalence. Using Theorem E.3.1.6, we deduce that f' is an equivalence of profinite spaces, so that f is n-truncated as desired. □

Corollary E.4.6.2. *Let $n \geqslant -2$ be an integer, and let $X \in \mathcal{S}_\pi^\wedge$ be a profinite space. The following conditions are equivalent:*

(1) *The profinite space X belongs to the essential image of the localization functor $\tau_{\leqslant n} : \mathcal{S}_\pi^\wedge \to \mathcal{S}_\pi^\wedge$ of Example E.4.1.3.*

(2) *The profinite space X is n-truncated, in the sense of Definition E.4.1.1.*

(3) *For every profinite space Y, the mapping space $\mathrm{Map}_{\mathcal{S}_\pi^\wedge}(Y, X)$ is n-truncated.*

(4) *The space $\mathrm{Mat}(X)$ is n-truncated.*

Corollary E.4.6.3. *Let $f : X \to Y$ be a morphism of profinite spaces, and let $n \geqslant -1$ be an integer. The following conditions are equivalent:*

(1) *The morphism f is n-connective, in the sense of Definition E.4.1.1.*

(2) *The induced map of materializations $\mathrm{Mat}(X) \to \mathrm{Mat}(Y)$ is n-connective.*

Proof. The implication (1) ⇒ (2) follows from Proposition E.4.5.1. Assume that (2) is satisfied; we will prove (1). Using Theorem E.4.1.2, we can factor f as a composition

$$X \xrightarrow{f'} Z \xrightarrow{f''} Y$$

where f' is n-connective and f'' is $(n-1)$-truncated. Using Propositions E.4.6.1 and E.4.5.1, we conclude that $\mathrm{Mat}(f')$ is n-connective and $\mathrm{Mat}(f'')$ is $(n-1)$-truncated. Since $\mathrm{Mat}(f)$ is n-connective, we conclude that $\mathrm{Mat}(f'')$ is an equivalence. Applying Theorem E.3.1.6, we deduce that f'' is an equivalence, so that $f \simeq f'' \circ f'$ is n-connective. □

E.5 Profinite Classifying Spaces

Let X be a space equipped with a base point $x \in X$, and let ΩX denote the loop space of X (based at the point x). Then composition of loops determines a multiplication map $\Omega X \times \Omega X \to \Omega X$, which is unital and associative up to coherent homotopy. We can summarize the situation by saying that the construction $X \mapsto \Omega X$ determines a functor from the ∞-category $\mathcal{S}_*$ of pointed spaces to the ∞-category $\mathcal{G}\mathrm{rp}(\mathcal{S})$ of group objects in the ∞-category $\mathcal{S}$ of spaces. This functor restricts to an equivalence of ∞-categories $\mathcal{S}_*^{\geqslant 1} \simeq \mathcal{G}\mathrm{rp}(\mathcal{S})$, where $\mathcal{S}_*^{\geqslant 1}$ denotes the full subcategory of $\mathcal{S}_*$ spanned by the connected pointed spaces (Lemma HTT.7.2.2.10). Our goal in this section is to prove the following:

Theorem E.5.0.4. *The functor $\Omega : (\mathcal{S}_\pi^\wedge)_* \to \mathcal{G}\mathrm{rp}(\mathcal{S}_\pi^\wedge)$ induces an equivalence of ∞-categories $(\mathcal{S}_\pi^\wedge)_*^{\geqslant 1} \simeq \mathcal{G}\mathrm{rp}(\mathcal{S}_\pi^\wedge)$.*

E.5.1 Profinite Groups

It is not difficult to show that $(\mathcal{S}_\pi^\wedge)_*$ can be identified with the ∞-category of Pro-objects of $(\mathcal{S}_\pi)_*^{\geqslant 1}$, which (by Lemma HTT.7.2.2.10) can be identified with the ∞-category of group objects of $\mathcal{S}_\pi$. Consequently, Theorem E.5.0.4 is equivalent to the assertion that the canonical map $\mathrm{Pro}(\mathcal{G}\mathrm{rp}(\mathcal{S}_\pi)) \to \mathcal{G}\mathrm{rp}(\mathrm{Pro}(\mathcal{S}_\pi))$ is an equivalence of ∞-categories. This can be regarded as a generalization of a classical fact about profinite groups, which we now review.

Definition E.5.1.1. A *profinite group* is a topological group G whose underlying topological space is a Stone space (see Definition E.1.3.2). We let $\mathrm{Grp}_{\mathrm{St}}$ denote the category whose objects are profinite groups and whose morphisms are continuous group homomorphisms.

Example E.5.1.2. Every finite group G can be regarded as a profinite group (when endowed with the discrete topology). That is, we can regard the category $\mathrm{Grp}_{\mathrm{fin}}$ of finite groups as a full subcategory of $\mathrm{Grp}_{\mathrm{St}}$.

Proposition E.5.1.3. *The inclusion $\mathrm{Grp}_{\mathrm{fin}} \hookrightarrow \mathrm{Grp}_{\mathrm{St}}$ extends to an equivalence of categories*

$$\mathrm{Pro}(\mathrm{Grp}_{\mathrm{fin}}) \simeq \mathrm{Grp}_{\mathrm{St}} .$$

Proof. Since the category of Stone spaces is closed under limits (in the larger category of all topological spaces; see Lemma E.1.4.2), the category $\mathrm{Grp}_{\mathrm{St}}$ is closed under limits in the category of all topological groups. It follows that $\mathrm{Grp}_{\mathrm{St}}$ admits small limits, so that the inclusion $\mathrm{Grp}_{\mathrm{fin}} \hookrightarrow \mathrm{Grp}_{\mathrm{St}}$ extends to a functor $F : \mathrm{Pro}(\mathrm{Grp}_{\mathrm{fin}}) \to \mathrm{Grp}_{\mathrm{St}}$ which commutes with filtered limits (Proposition HTT.5.3.5.10). We first claim that F is fully faithful. According to Proposition HTT.5.3.5.11 , it will suffice to show that every finite group G is compact when viewed as an object of $\mathrm{Grp}_{\mathrm{St}}{}^{\mathrm{op}}$. In other words, we claim that if we are given a filtered system of profinite groups H_α having limit H, then the canonical map

$$\varinjlim \mathrm{Hom}_{\mathrm{Grp}_{\mathrm{St}}}(H_\alpha, G) \to \mathrm{Hom}_{\mathrm{Grp}_{\mathrm{St}}}(H, G)$$

is bijective. Theorem E.1.4.1 implies that G is compact when viewed as an object of the category $\mathcal{T}\mathrm{op}_{\mathrm{St}}^{\mathrm{op}}$. Consequently, every continuous group homomorphism $f : H \to G$ factors as a composition $H \to H_\alpha \xrightarrow{f'} G$, for some index α. We must show that it is possible to choose α so that f' is a group homomorphism. To prove this, we consider the pair of maps

$$u, v : H_\alpha \times H_\alpha \to G$$

given by $u(x, y) = f'(xy)$, $v(x, y) = f'(x)f'(y)$. Then u and v induce the same map from $H \times H$ into G. Using Theorem E.1.4.1 we conclude that there exists a map of indices $\beta \to \alpha$ such that u and v agree on $H_\beta \times H_\beta$. Replacing α by β, we may assume that $u = v$ so that f' is a group homomorphism, as desired.

It remains to prove that the functor F is essentially surjective. Fix a profinite group G, and let S be the partially ordered set of open normal subgroups $G_0 \subseteq G$. Then S^{op} is filtered (since the collection of open normal subgroups is closed under finite intersections). We may therefore view the inverse system $\{G/G_0\}_{G_0 \in A}$ as an object $\overline{G} \in \mathrm{Pro}(\mathrm{Grp}_{\mathrm{fin}})$. We will complete the proof by showing that the natural map $\phi : G \to F(\overline{G})$ is an isomorphism of profinite groups.

Note that every nonempty open subset of $F(\overline{G})$ contains the inverse image of some element of G/G_0, where G_0 is an open normal subgroup of G. From this we immediately deduce that ϕ has dense image. Since G is compact and $F(\overline{G})$ is Hausdorff, it follows that ϕ is a quotient map: that is, ϕ induces an isomorphism of profinite groups $G/\ker(\phi) \to F(\overline{G})$. We will complete the proof by showing that $\ker(\phi)$ is trivial.

Choose a non-identity element $x \in G$; we wish to show that there exists an open normal subgroup of G which does not contain x. Since G is a Stone space, there exists a closed and open subset $Y \subseteq G$ which contains the identity element but does not contain x. Let $Y^+ = \{gyg^{-1} : g \in G, y \in Y\}$. Then Y^+ image of a continuous map $G \times Y \to G$. Since G is compact, we conclude that Y^+ is compact and therefore a closed subset of G. As a union of conjugates of Y, Y^+ is also an open subset of G. Let $G_0 = \{g \in G : gY^+ = Y^+\}$. Then G_0 is a subgroup of G which does not contain x. Since Y^+ is conjugation-invariant, the subgroup G_0 is normal. Moreover, the complement of G_0 is given by the image of $(G - Y^+) \times Y^+$ under the continuous map $(g, h) \mapsto (gh^{-1})$. Since the product is a compact set, we conclude that $G - G_0$ is compact, so that G_0 is an open subgroup of G. □

E.5.2 Homotopy Groups of Profinite Spaces

Profinite groups arise naturally when studying algebraic invariants of profinite spaces.

Definition E.5.2.1. Let X be a profinite space. We let $\pi_0 X$ denote the set $\pi_0 \operatorname{Mat}(X)$ of path components of the materialization $\operatorname{Mat}(X)$. For each integer $n \geqslant 1$ and each point $x \in \operatorname{Mat}(X)$, we let $\pi_n(X, x)$ denote the homotopy group $\pi_n(\operatorname{Mat}(X), x)$. We will refer to the groups $\pi_n(X, x)$ as the *homotopy groups of* X (with base point x).

The next result enables us to compute the homotopy groups of a profinite space:

Proposition E.5.2.2. *The construction $X \mapsto \pi_0 X$ determines a functor $\mathcal{S}_\pi^\wedge \to \mathcal{S}\mathrm{et}$ which preserves filtered limits.*

Proof. Let $F : \mathcal{S}_\pi^\wedge \to \mathcal{S}\mathrm{et}$ be the functor given by $F(X) = \pi_0 X$. Let us abuse notation by identifying the ∞-category $\mathcal{S}_\pi$ of π-finite spaces with a full subcategory of the ∞-category $\mathcal{S}_\pi^\wedge$ of profinite spaces, so that $F_0 = F|_{\mathcal{S}_\pi}$ is the functor given by $F_0(T) = \pi_0 T$. Let $F' : \mathcal{S}_\pi^\wedge \to \mathcal{S}\mathrm{et}$ be a right Kan extension of F_0, so that the identification $F'|_{\mathcal{S}_\pi} = F|_{\mathcal{S}_\pi}$ extends to a natural transformation $u : F \to F'$. Since F' commutes with filtered limits, it will suffice to show that u is an equivalence. To this end, consider a profinite space K, which we can assume is given by the limit of a diagram $X : \mathcal{J}^{\mathrm{op}} \to \mathcal{S}_\pi$ for some filtered ∞-category $\mathcal{J}$. We wish to show that the canonical map

$$\theta : \pi_0(\varprojlim_{J \in \mathcal{J}^{\mathrm{op}}} X(J)) \to \varprojlim_{J \in \mathcal{J}^{\mathrm{op}}} \pi_0 X(J)$$

is a bijection. Choose a point $\eta \in \varprojlim_{J \in \mathcal{J}^{\mathrm{op}}} \pi_0 X(J)$. Then η determines, for each $J \in \mathcal{J}$, a connected component $X_\eta(J)$ of $X(J)$. We can regard X_η itself as a functor $\mathcal{J}^{\mathrm{op}} \to \mathcal{S}_\pi$. Note that $\theta^{-1}\{\eta\}$ can be identified with the set of path components of the limit $V_\eta = \varprojlim_{J \in \mathcal{J}^{\mathrm{op}}} X_\eta(J)$. To prove that θ is a bijection, it will suffice to show that each of the spaces V_η is connected. This follows from Corollary E.4.5.4, since each $X_\eta(J)$ is connected by construction. □

We now use Proposition E.5.2.2 to deduce an analogous statement for homotopy groups π_n for $n > 0$.

Definition E.5.2.3. Let X be a profinite space. A *point* of X is a point of the materialization $\operatorname{Mat}(X)$. By virtue of Remark E.4.4.3, we can identify points of X with maps $* \to X$ in the ∞-category $\mathcal{S}_\pi^\wedge$ of profinite spaces. We let $(\mathcal{S}_\pi^\wedge)_*$ denote the ∞-category of pointed objects of $\mathcal{S}_\pi^\wedge$: that is, the ∞-category of profinite spaces X equipped with a point $* \to X$.

Corollary E.5.2.4. *For each integer $n \geqslant 1$, let $\pi_n : (\mathcal{S}_\pi^\wedge)_*$ denote the functor which carries a pointed profinite space (X, x) to the homotopy group $\pi_n(X, x)$. Then the functor π_n commutes with filtered limits.*

Proof. This follows from Proposition E.5.2.2, since the functor $X \mapsto \Omega(X)$ preserves limits. □

Remark E.5.2.5. Let X be a profinite space. Then we can write X as the limit of a diagram $\{X_\alpha\}$, where each X_α is π-finite. Using Proposition E.5.2.2, we deduce that $\pi_0 X$ can be identified with the Stone space associated to the profinite set given by the diagram $\{\pi_0 X_\alpha\}$. In particular, the inverse limit topology endows $\pi_0 X$ with the structure of a Stone space.

Let x be a point of X, which we can identify with a compatible family of points $x_\alpha \in X_\alpha$. For each integer $n \geqslant 1$, Corollary E.5.2.4 supplies an isomorphism $\pi_n(X, x) \simeq \varprojlim_\alpha \pi_n(X_\alpha, x_\alpha)$, so that we can view $\pi_n(X, x)$ as a profinite group.

Remark E.5.2.6. Let X be a space, and let $X_\pi^\wedge$ be its profinite completion (Example E.0.7.12). Then $\pi_0 X_\pi^\wedge$ can be identified with the Stone-Čech compactification of the set $\pi_0 X$ (Remark E.1.4.4). In particular, for every space X, we have a canonical map of profinite spaces

$$X_\pi^\wedge \to \beta(\pi_0 X)$$

(where we identify the Stone-Čech compactification of $\pi_0 X$ with the corresponding profinite space, under the fully faithful embedding of Remark E.4.1.4). If X is discrete, then this map is an equivalence (Proposition E.4.3.3).

E.5.3 Digression: Strong n-Truncations

We now introduce a technical notion which will play an important role in our proof of Theorem E.5.0.4.

Definition E.5.3.1. Let X be a space and let $n \geqslant 1$ be an integer. We will say that X is *strongly n-truncated* if it satisfies the following conditions:

- (a) The space X is n-truncated. That is, the groups $\pi_m(X, x)$ are trivial for every base point $x \in X$ and every integer $m > n$.
- (b) For every choice of base point $x \in X$, the group $\pi_1(X, x)$ acts trivially on $\pi_n(X, x)$.

Remark E.5.3.2. For every integer $n \geqslant 1$, the inclusion from the ∞-category of strongly n-truncated spaces to the ∞-category of spaces admits a left adjoint $\tau^s_{\leqslant n}$. To every space X, this left adjoint assigns another space $\tau^s_{\leqslant n} X$, which we will refer to as the *strong n-truncation of X*. It is characterized up to equivalence by the requirement that there is a map $f : X \to \tau^s_{\leqslant n} X$ which is bijective on connected components, and the homotopy groups of $\tau^s_{\leqslant n} X$ are given by

$$\pi_m(\tau^s_{\leqslant n} X, f(x)) \simeq \begin{cases} \pi_m(X,x) & \text{if } m < n \\ \pi_n(X,x)_{\pi_1(X,x)} & \text{if } m = n \\ 0 & \text{if } m > n. \end{cases}$$

Here $\pi_n(X,x)_{\pi_1(X,x)}$ denotes the group of coinvariants for the action of $\pi_1(X,x)$ on $\pi_n(X,x)$ (if $n = 1$, this is the abelianization of $\pi_1(X,x)$).

Remark E.5.3.3. Let $n \geqslant 1$ be an integer. The strong truncation functor $\tau^s_{\leqslant n}$ of Remark E.5.3.2 carries π-finite spaces to π-finite spaces. It therefore admits an essentially unique extension to a functor $\mathcal{S}^\wedge_\pi \to \mathcal{S}^\wedge_\pi$ which commutes with filtered limits. We will abuse notation by denoting this functor also by $\tau^s_{\leqslant n}$.

Let X be a profinite space, and write X as the limit of a filtered diagram of π-finite spaces X_α. By definition, $\tau^s_{\leqslant n} X$ is given by the limit of the diagram $\{\tau^s_{\leqslant n} X_\alpha\}$ (in the ∞-category $\mathcal{S}^\wedge_\pi$ of profinite spaces).

Proposition E.5.3.4. *Let X be a profinite space, let $n \geqslant 1$ be an integer, and let $\theta : X \to \tau^s_{\leqslant n} X$ be the canonical map. Then:*

- (a) *The map θ induces a bijection $\pi_0 X \to \pi_0 \tau^s_{\leqslant n} X$.*
- (b) *For each point $x \in X$, the map $\pi_m(X,x) \to \pi_m(\tau^s_{\leqslant n} X, \theta(x))$ is an isomorphism for $m < n$.*
- (c) *For each point $x \in X$, let K denote the kernel of the canonical map $\pi_n(X,x) \to \pi_n(X,x)_{\pi_1(X,x)}$, and let $\overline{K}$ denote the closure of K in $\pi_n(X,x)$ (with respect to the profinite topology described in Remark E.5.2.5). Then θ induces a surjection $\pi_n(X,x) \to \pi_n(\tau^s_{\leqslant n} X, \theta(x))$ with kernel $\overline{K}$.*
- (d) *For each point $x \in X$ and each $m > n$, the group $\pi_m(\tau^s_{\leqslant n} X, \theta(x))$ vanishes.*

Proof. Write X as the limit of a diagram of π-finite spaces $\{X_\alpha\}_{\alpha \in A}$ indexed by a filtered partially ordered set A. Since each of the maps $X_\alpha \to \tau^s_{\leqslant n} X_\alpha$ is bijective on connected components, assertion (a) follows from Proposition E.5.2.2. Similarly, (b) and (d) follow from Corollary E.5.2.4. It remains to prove (c). Let x be a point of X, given by a compatible family of points $x_\alpha \in X_\alpha$. For each $\alpha \in A$, let M_α denote the coinvariants for the action of $\pi_1(X_\alpha, x_\alpha)$ on $\pi_n(X_\alpha, x_\alpha)$, and set $M = \varprojlim_\alpha M_\alpha$. Then Corollary E.5.2.4 supplies an isomorphism $\pi_n(\tau^s_{\leqslant n} X, \theta(x)) \simeq M$. The natural map $\nu : \pi_n(X,x) \to M$ is an inverse limit of surjective homomorphisms of finite groups $\nu_\alpha : \pi_n(X_\alpha, x_\alpha) \to M_\alpha$, and therefore a surjection (Proposition E.1.1.1). It remains to prove that $\ker(\nu) = \overline{K}$. It is clear that $\ker(\nu)$ is a closed subgroup of $\pi_n(X,x)$ which contains K. To complete the proof, it will suffice to show that K is dense in $\ker(\nu)$. To this end, choose an element $u \in \ker(\nu) \subseteq \pi_n(X,x)$, given by a compatible family of elements $u_\alpha \in \pi_n(X_\alpha, x_\alpha)$. We wish to show that for each $\alpha \in A$, u_α belongs to the image of the map $K \to \pi_n(X_\alpha, x_\alpha)$.

For each index $\beta \in A$, the action of $\pi_1(X_\beta, x_\beta)$ on $\pi_n(X_\beta, x_\beta)$ is given by a map

$$a_\beta : \pi_1(X_\beta, x_\beta) \times \pi_n(X_\beta, x_\beta) \to \pi_n(X_\beta, x_\beta).$$

The inverse limit of these maps determines an action map

$$a : \pi_1(X,x) \times \pi_n(X,x) \to \pi_n(X,x).$$

Let K_β denote the kernel of the map $\pi_n(X_\beta, x_\beta) \to M_\beta$. Let $K_\beta^{(1)} \subseteq K_\beta$ denote the subset of $\pi_n(X_\beta, x_\beta)$ consisting of elements of the form $a_\beta(g,h)h^{-1}$. Then $K_\beta^{(1)}$ generates the group K_β. For each integer $m \geqslant 1$, let $K_\beta^{(m)}$ denote the subset of $\pi_n(X_\beta, x_\beta)$ consisting of m-fold products of elements of $K_\beta^{(1)}$. Since $\pi_n(X_\beta, x_\beta)$ is finite, we have $K_\beta = K_\beta^{(m)}$ for m sufficiently large (depending on β).

For each $\beta \geqslant \alpha$ and each integer $m > 0$, let $L_\beta^{(m)}$ denote the image of $K_\beta^{(m)}$ in $\pi_n(X_\alpha, x_\alpha)$. Then $L_\beta^{(m)}$ is the subset of $\pi_n(X_\alpha, x_\alpha)$ generated by all m-fold products of elements of $L_\beta^{(1)}$. Let m_0 denote the order of the finite group $\pi_n(X_\alpha, x_\alpha)$, so that $L_\beta^{(m)} = L_\beta^{(m_0)}$ for $m \geqslant N$. Since $u_\beta \in K_\beta = \bigcup_m K_\beta^{(m)}$, we have $u_\alpha \in \bigcup_m L_\beta^{(m)} = L_\beta^{(m_0)}$.

For each $\beta \geqslant \alpha$, let $S_\beta \subseteq \pi_1(X_\beta, x_\beta)^{m_0} \times \pi_n(X_\beta, x_\beta)^{m_0}$ denote the subset consisting of those tuples $(g_1, \ldots, g_{m_0}, h_1, \ldots, h_{m_0})$ such that

$$a_\beta(g_1,h_1)h_1^{-1} a_\beta(g_2,h_2)h_2^{-1} \cdots a_\beta(g_{m_0}, h_{m_0})h_{m_0}^{-1}$$

is a preimage of u_α under the map $\pi_n(X_\beta, x_\beta) \to \pi_n(X_\alpha, x_\alpha)$. It follows from the above reasoning that each of the sets S_β is nonempty. Applying Proposition E.1.1.1, we deduce that $\varprojlim_{\beta \geqslant \alpha} S_\beta$ is nonempty. Using Corollary E.5.2.4, we can identify an element of the inverse limit with a tuple $(g_1, \ldots, g_{m_0}, h_1, \ldots, h_{m_0}) \in \pi_1(X,x)^{m_0} \times \pi_n(X,x)^{m_0}$. Set

$$v = a(g_1,h_1)h_1^{-1} \cdots a(g_{m_0}, h_{m_0})h_{m_0}^{-1}.$$

By construction, v is an element of K whose image in $\pi_n(X_\alpha, x_\alpha)$ coincides with u_α. □

Corollary E.5.3.5. *Let X be a profinite space and let $n \geqslant 1$ be an integer such that* $\mathrm{Mat}(X)$ *is strongly n-truncated. Then the canonical map $\theta : X \to \tau^s_{\leqslant n} X$ is an equivalence in $\mathcal{S}^\wedge_\pi$.*

Proof. It follows from Proposition E.5.3.4 that $\mathrm{Mat}(\theta)$ is a homotopy equivalence. Applying Theorem E.3.1.6, we deduce that θ is an equivalence of profinite spaces. □

E.5.4 Families of Abelian Groups

Let X be a space which is strongly n-truncated (Definition E.5.3.1). Then, for any base point $x \in X$, the fundamental group $\pi_1(X, x)$ acts trivially on the homotopy group $\pi_n(X, x)$. It follows that $\pi_n(X, x)$ is an abelian group which depends only on the image of x in $\pi_0 X$. We now axiomatize this structure.

Definition E.5.4.1. A *family of abelian groups* consists of the following data:

(a) A map of sets $\phi : A \to S$.

(b) An abelian group structure on each fiber $A_s = \phi^{-1}\{s\}$.

We will generally abuse notation and indicate a family of abelian groups simply as a map $\phi : A \to S$. We will say that a family of abelian groups $\phi : A \to S$ is *finite* if A and S are finite.

If $\phi : A \to S$ and $\phi' : A' \to S'$ are families of abelian groups, then a *morphism of families of abelian groups* from ϕ to ϕ' is a commutative diagram of sets

$$\begin{array}{ccc} A & \xrightarrow{\phi} & S \\ \downarrow{\scriptstyle F} & & \downarrow{\scriptstyle f} \\ A' & \xrightarrow{\phi'} & S' \end{array}$$

such that, for every element $s \in S$, the induced map $F_s : A_s \to A'_{f(s)}$ is a group homomorphism.

We let Fam denote the category whose objects are families of abelian groups, and $\mathrm{Fam}_{\mathrm{fin}}$ the full subcategory of Fam spanned the finite families of abelian groups.

Remark E.5.4.2. Let $\phi : A \to S$ be a family of abelian groups. For every element $s \in S$, let $e(s)$ denote the identity element of the abelian group A_s. Then the construction $s \mapsto e(s)$ determines a map from S to A, which we will refer to as the *zero section* of ϕ.

Notation E.5.4.3. If $\phi : A \to S$ is a family of abelian groups, then we can identify A with an abelian group object of the topos $\mathcal{S}\mathrm{et}_{/S}$. For each $n \geqslant 0$, we let $K(\phi, n)$ denote the associated Eilenberg-MacLane object of the ∞-topos $\mathcal{S}_{/S}$. More concretely, we have $K(\phi, n) = \amalg_{s \in S} K(A_s, n)$, where A_s denotes the abelian group $\phi^{-1}\{s\}$. Note that if $\phi : A \to S$ is a finite family of abelian groups, then the space $K(\phi, n)$ is π-finite.

Example E.5.4.4. Let X be a strongly n-truncated space. For each path component $\eta \in \pi_0 X$, let $\pi_n(X, \eta)$ denote the homotopy group $\pi_n(X, x)$, where $x \in X$ is a representative of η. Our assumption that $\pi_1(X, x)$ acts trivially on $\pi_n(X, x)$ guarantees that the abelian group $\pi_n(X, \eta)$ is independent of the choice of x, up to *canonical* isomorphism. Then the map $\amalg_{\eta \in \pi_0 X} \pi_n(X, \eta) \to \pi_0 X$ is a family of abelian groups, in the sense of Definition E.5.4.1. Let us denote this family by $\pi_n X$.

The map $X \to \tau_{\leqslant n-1} X$ is n-connective and n-truncated. In the terminology of §HTT.7.2.2 , we can regard X as an n-gerbe over $\tau_{\leqslant n-1} X$, banded by a local system of abelian groups on $\tau_{\leqslant n-1} X$. By assumption, this local system is trivial: that is, it can be written (canonically) as the pullback of $\pi_n(X)$, which we regard as a local system of abelian groups on $\pi_0(X)$. We therefore have a pullback diagram of spaces σ_X :

$$\begin{array}{ccc} X & \longrightarrow & \pi_0 X \\ \downarrow & & \downarrow \\ \tau_{\leqslant n-1} X & \longrightarrow & K(\pi_n(X), n+1). \end{array}$$

Note that σ_X depends functorially on X, and that the construction $X \mapsto \sigma_X$ commutes with products.

The category $\mathrm{Fam}_{\mathrm{fin}}$ admits finite products, so it makes sense to consider group objects in $\mathrm{Fam}_{\mathrm{fin}}$. The collection of group objects in $\mathrm{Fam}_{\mathrm{fin}}$ forms a category, which we will denote by $\mathcal{G}\mathrm{rp}(\mathrm{Fam}_{\mathrm{fin}})$. We will need the following fact, whose proof we defer until the end of this section:

Proposition E.5.4.5. *Every group object of* $\mathrm{Pro}(\mathrm{Fam}_{\mathrm{fin}})$ *can be written as a filtered inverse limit of group objects of* $\mathrm{Fam}_{\mathrm{fin}}$.

E.5.5 Digression: Effective Epimorphisms of Profinite Spaces

Recall that if $f : U \to X$ is a map of spaces which is surjective on connected components, then f is an effective epimorphism: that is, we can recover X as the geometric realization of the simplicial space $U_\bullet$ given as the Čech nerve of f. We now establish an analogous statement in the setting of profinite homotopy theory.

Notation E.5.5.1. Let $\mathbf{\Delta}_+$ denote the augmented simplex category. We have fully faithful embeddings $\mathbf{\Delta}^{\mathrm{op}} \overset{j}{\hookrightarrow} \mathbf{\Delta}_+^{\mathrm{op}} \overset{i}{\hookleftarrow} \Delta^1$ where i carries Δ^1 to the morphism $[0] \to [-1]$ in $\mathbf{\Delta}_+^{\mathrm{op}}$.

For any ∞-category $\mathcal{C}$, the embeddings i and j determine restriction functors

$$\mathrm{Fun}(\mathbf{\Delta}^{\mathrm{op}}, \mathcal{C}) \overset{j^*}{\leftarrow} \mathrm{Fun}(\mathbf{\Delta}_+^{\mathrm{op}}, \mathcal{C}) \overset{i^*}{\to} \mathrm{Fun}(\Delta^1, \mathcal{C}).$$

If $\mathcal{C}$ admits fiber products, then the functor i^* admits a right adjoint i_*, which carries a morphism $f : U \to X$ in $\mathcal{C}$ to the augmented simplicial object of $\mathcal{C}$ given by the Čech nerve of f. If the ∞-category $\mathcal{C}$ admits a geometric realizations of simplicial objects, then the functor j^* admits a left adjoint $j_!$, given by $(j_! X_\bullet)_{-1} = |X_\bullet|$. Note that if $\mathcal{C}$ admits finite limits, then the functor i_* takes values in the ∞-category $\mathcal{G}\mathrm{pd}(\mathcal{C})$ of groupoid objects of

$\mathcal{C}$ (see Proposition HTT.6.1.2.11). If $\mathcal{C}$ admits finite limits and geometric realizations, we obtain a pair of adjoint functors

$$\mathcal{G}\mathrm{pd}(\mathcal{C}) \underset{j^* i_*}{\overset{i^* j_!}{\rightleftarrows}} \mathrm{Fun}(\Delta^1, \mathcal{C}).$$

Remark E.5.5.2. Let $\mathcal{C}$ be an ∞-category which admits finite limits and geometric realizations of simplicial objects. Recall that a *group object* of $\mathcal{C}$ is a groupoid object $U_\bullet$ of $\mathcal{C}$ such that U_0 is a final object of $\mathcal{C}$. We let $\mathcal{G}\mathrm{rp}(\mathcal{C}) \subseteq \mathrm{Fun}(\mathbf{\Delta}^{\mathrm{op}}, \mathcal{C})$ denote the full subcategory spanned by the group objects of $\mathcal{C}$, and $\mathcal{C}_* \subseteq \mathrm{Fun}(\Delta^1, \mathcal{C})$ the ∞-category of pointed objects of $\mathcal{C}$ (that is, the full subcategory $\mathrm{Fun}(\Delta^1, \mathcal{C})$ spanned by those morphisms $U \to X$ where U is a final object of $\mathcal{C}$). Then the adjunction of Notation E.5.5.1 restricts to a pair of adjoint functors

$$\mathcal{G}\mathrm{rp}(\mathcal{C}) \underset{\Omega}{\overset{B}{\rightleftarrows}} \mathcal{C}_*.$$

Proposition E.5.5.3. *Let $\mathcal{E}$ denote the full subcategory of $\mathrm{Fun}(\Delta^1, \mathcal{S}_\pi^\wedge)$ spanned by those morphisms $f : U \to X$ of profinite spaces which induce a surjection $\pi_0 U \to \pi_0 X$. Then the functor $j^* i_* : \mathrm{Fun}(\Delta^1, \mathcal{S}_\pi^\wedge) \to \mathcal{G}\mathrm{pd}(\mathcal{S}_\pi^\wedge)$ of Notation E.5.5.1 is fully faithful when restricted to $\mathcal{C}$.*

Corollary E.5.5.4. *Let $(\mathcal{S}_\pi^\wedge)_*$ denote the ∞-category of pointed objects of $\mathcal{S}_\pi^\wedge$, and let $(\mathcal{S}_\pi^\wedge)_*^{\geqslant 1}$ denote the full subcategory of $(\mathcal{S}_\pi^\wedge)_*$ spanned by the pointed connected profinite spaces. Then the functor Ω of Remark E.5.5.2 restricts to a fully faithful embedding $(\mathcal{S}_\pi^\wedge)_*^{\geqslant 1} \hookrightarrow \mathcal{G}\mathrm{rp}(\mathcal{S}_\pi^\wedge)$.*

Warning E.5.5.5. In §E.5, we will show that the functor $\Omega : (\mathcal{S}_\pi^\wedge)_*^{\geqslant 1} \to \mathcal{G}\mathrm{rp}(\mathcal{S}_\pi^\wedge)$ is an equivalence of ∞-categories: that is, every group object in the ∞-category of profinite spaces can be identified with the loop space of a profinite space (Theorem E.5.0.4). However, the fully faithful embedding $\mathcal{E} \hookrightarrow \mathcal{G}\mathrm{pd}(\mathcal{S}_\pi^\wedge)$ of Proposition E.5.5.3 is not essentially surjective. To see this, let X be an arbitrary compact Hausdorff space, and let U be a Stone space equipped with a surjective map $f : U \to X$. Then the Čech nerve $U_\bullet$ of f is a groupoid object in the category of Stone spaces, which we can view as a groupoid object in the ∞-category of discrete objects of $\mathcal{S}_\pi^\wedge$. However, this groupoid is not effective unless X is also a Stone space.

Proof of Proposition E.5.5.3. In what follows, we will abuse notation by identifying $\mathcal{S}_\pi$ with its essential image in $\mathcal{S}_\pi^\wedge$. Let $f : U \to X$ be a map of profinite spaces which induces a surjection $\pi_0 U \to \pi_0 X$, and let $U_\bullet$ denote the Čech nerve of U. We wish to prove that the canonical map $|U_\bullet| \to X$ is an equivalence in the ∞-category of profinite spaces. Equivalently, we wish to show that the canonical map

$$\phi : \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(X, T) \to \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(|U_\bullet|, T) \simeq \varprojlim \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(U_\bullet, T)$$

is a homotopy equivalence.

Using Proposition HTT.5.3.5.15 , we can write f as a limit of maps $\{f_\alpha : U_\alpha \to X_\alpha\}_{\alpha \in A}$ indexed by a filtered partially ordered set A, where each U_α and X_α is π-finite. For each index α, let $X^0_\alpha \subseteq X_\alpha$ denote the union of those connected components of X_α which contain vertices in the image of f_α. We first claim that the canonical map $\varprojlim X^0_\alpha \to \varprojlim X_\alpha$ is an equivalence in $\mathcal{S}^\wedge_\pi$. Note that we have a pullback diagram

$$\begin{array}{ccc} \varprojlim X^0_\alpha & \longrightarrow & \varprojlim X_\alpha \\ \downarrow & & \downarrow \\ \varprojlim \pi_0 X^0_\alpha & \xrightarrow{\theta} & \varprojlim \pi_0 X_\alpha. \end{array}$$

It will therefore suffice to show that θ is an equivalence in $\mathcal{S}^\wedge_\pi$. According to Corollary E.1.4.3, it will suffice to show that θ induces a bijection on the underlying sets. It is clear that θ is injective (since it is an inverse limit of injections). The surjectivity follows from our assumption that the composite map

$$\pi_0 U \simeq \varprojlim \pi_0 U_\alpha \to \varprojlim \pi_0 X^0_\alpha \to \varprojlim \pi_0 X_\alpha \simeq \pi_0 X$$

is surjective. We may therefore replace each X_α with X^0_α, and thereby reduce to the case where each of the maps f_α is surjective on connected components.

For each index $\alpha \in A$, let $U_{\alpha\bullet}$ denote the Čech nerve of f_α, so that $U_\bullet \simeq \varprojlim_\alpha U_{\alpha\bullet}$. It follows that we can identify ϕ with the composition

$$\varinjlim_{\alpha \in A} \mathrm{Map}_{\mathcal{S}_\pi}(X_\alpha, T) \xrightarrow{\phi'} \varinjlim_{\alpha \in A} \varprojlim_{[n] \in \mathbf{\Delta}} \mathrm{Map}_{\mathcal{S}_\pi}(U_{\alpha n}, T) \xrightarrow{\phi''} \varprojlim_{[n] \in \mathbf{\Delta}} \varinjlim_{\alpha \in A} \mathrm{Map}_{\mathcal{S}_\pi}(U_{\alpha n}, T).$$

Since each f_α is an effective epimorphism, the canonical maps $|U_{\alpha\bullet}| \to X_\alpha$ are homotopy equivalences, so that ϕ' is a homotopy equivalence. We will complete the proof by showing that ϕ'' is a homotopy equivalence. To this end, we note that for every integer $m \geqslant 0$, the map ϕ'' fits into a commutative diagram

$$\begin{array}{ccc} \varinjlim_{\alpha \in A} \varprojlim_{[n] \in \mathbf{\Delta}} \mathrm{Map}_{\mathcal{S}_\pi}(U_{\alpha n}, T) & \longrightarrow & \varprojlim_{[n] \in \mathbf{\Delta}} \varinjlim_{\alpha \in A} \mathrm{Map}_{\mathcal{S}_\pi}(U_{\alpha n}, T) \\ \downarrow & & \downarrow \\ \varinjlim_{\alpha \in A} \varprojlim_{[n] \in \mathbf{\Delta}_{s, \leqslant m}} \mathrm{Map}_{\mathcal{S}_\pi}(U_{\alpha n}, T) & \xrightarrow{\psi_m} & \varprojlim_{[n] \in \mathbf{\Delta}_{s, \leqslant m}} \varinjlim_{\alpha \in A} \mathrm{Map}_{\mathcal{S}_\pi}(U_{\alpha n}, T); \end{array}$$

here $\mathbf{\Delta}_{s, \leqslant m}$ denotes the subcategory of $\mathbf{\Delta}$ whose objects have the form $[n]$ for $n \leqslant m$ and whose morphisms are required to be injective. Since the simplicial sets $\mathrm{N}(\mathbf{\Delta}_{\leqslant m})$ are finite and A is filtered, the maps ψ_m are homotopy equivalences. The space T is π-finite and therefore truncated. It follows that the vertical maps are homotopy equivalences for $m \gg 0$ (see the proof of Lemma HA.1.3.3.10), so that ϕ'' is a homotopy equivalence as desired. $\square$

E.5.6 The Proof of Theorem E.5.0.4

We now explain how to deduce Theorem E.5.0.4 from Proposition E.5.4.5. Let G be a group object of $\mathcal{S}_\pi^\wedge$; we wish to show that G belongs to the essential image of the functor $\Omega : (\mathcal{S}_\pi^\wedge)_*^{\geqslant 1} \to \mathcal{G}\mathrm{rp}(\mathcal{S}_\pi^\wedge)$. Note that $(\mathcal{S}_\pi^\wedge)_*^{\geqslant 1}$ is closed under filtered limits in $(\mathcal{S}_\pi^\wedge)_*$ (Proposition E.5.2.2). Since the functor Ω is fully faithful (Corollary E.5.5.4) and commutes with filtered limits, it follows that the essential image of Ω is closed under filtered limits in $\mathcal{G}\mathrm{rp}(\mathcal{S}_\pi^\wedge)$. Writing G as the inverse limit of its Postnikov towe

$$\cdots \to \tau_{\leqslant 2} G \to \tau_{\leqslant 1} G \to \tau_{\leqslant 0} G,$$

we can reduce to the case where G is n-truncated for some integer n.

We now proceed by induction on n. In the case where $n = 0$, we can identify G with a group object in the ordinary category of profinite sets. Using Proposition E.5.1.3, we deduce that G can be written as a filtered limit of group objects in the category of finite sets. Since the essential image of Ω is closed under filtered limits, we can assume that G is a finite group. Then the classifying space BG is π-finite, and we have $G \simeq \Omega(BG)$.

Suppose now that $n \geqslant 1$, and assume that $\tau_{\leqslant n-1} G$ belongs to the essential image of Ω. Note that $\mathrm{Mat}(G)$ can be regarded as a group object of the ∞-category of spaces. It follows that for each point $x \in G$, the fundamental group $\pi_1(G, x)$ acts trivially on the homotopy groups $\pi_m(G, x)$. In particular, $\mathrm{Mat}(G)$ is strongly n-truncated. Applying Corollary E.5.3.5, we deduce that the canonical map $G \to \tau^s_{\leqslant n} G$ is an equivalence.

Let $U : \mathrm{Fam}_{\mathrm{fin}} \to \mathcal{S}_\pi$ be the functor given by $U(\phi : A \to S) = K(\phi, n+1)$ (see Notation E.5.4.3). Then U admits an essentially unique extension to a functor $\widehat{U} : \mathrm{Pro}(\mathrm{Fam}_{\mathrm{fin}}) \to \mathcal{S}_\pi^\wedge$ which commutes with filtered limits.

Let $\mathcal{C}$ denote the full subcategory of $\mathcal{S}$ spanned by those π-finite spaces which are strongly n-truncated. For each object $X \in \mathcal{C}$, define $\pi_n X \in \mathrm{Fam}_{\mathrm{fin}}$ as in Example E.5.4.4. The construction $X \mapsto \pi_n X$ admits an essentially unique extension to a functor $\mathrm{Pro}(\mathcal{C}) \to \mathrm{Pro}(\mathrm{Fam}_{\mathrm{fin}})$ which commutes with filtered limits. We will denote this functor also by $X \mapsto \pi_n X$.

For each $X \in \mathcal{C}$, let σ_X denote the pullback diagram

$$\begin{array}{ccc} X & \longrightarrow & \pi_0 X \\ \downarrow & & \downarrow \\ \tau_{\leqslant n-1} X & \longrightarrow & K(\pi_n X, n+1) \end{array}$$

appearing in Example E.5.4.4. Then the construction $X \mapsto \sigma_X$ admits an essentially unique extension to a functor $\widehat{\sigma} : \mathrm{Pro}(\mathcal{C}) \to \mathrm{Fun}(\Delta^1 \times \Delta^1, \mathcal{S}_\pi^\wedge)$ which commutes with filtered limits. In particular, it carries group objects of $\mathrm{Pro}(\mathcal{C})$ to pullback diagrams $\mathcal{G}\mathrm{rp}(\mathcal{S}_\pi^\wedge)$. Applying this functor to G, we obtain a pullback square

$$\begin{array}{ccc} G & \longrightarrow & \tau_{\leqslant 0}G \\ \downarrow & & \downarrow f \\ \tau_{\leqslant n-1}G & \xrightarrow{f'} & \widehat{U}(\pi_n G). \end{array}$$

Since the functor $\pi_n : \mathrm{Pro}(\mathcal{C}) \to \mathrm{Pro}(\mathrm{Fam}_{\mathrm{fin}})$ commutes with finite products, we can regard $\pi_n G$ as a group object of $\mathrm{Pro}(\mathrm{Fam}_{\mathrm{fin}})$. Applying Proposition E.5.4.5, we can write $\pi_n G$ as a filtered limit of objects $\phi_\alpha \in \mathcal{G}\mathrm{rp}(\mathrm{Fam}_{\mathrm{fin}})$. Then each $\widehat{U}(\phi_\alpha) = K(\phi_\alpha, n+1)$ is a group object of $\mathcal{S}_\pi$, and therefore belongs to the essential image of Ω. It follows that $\widehat{U}(\pi_n G)$ belongs to the essential image of Ω. Write $\widehat{U}(\pi_n G) \simeq \Omega(X)$, where X is a pointed connected profinite space. By the inductive hypothesis, we can also write

$$\tau_{\leqslant 0}G \simeq \Omega(Y) \qquad \tau_{\leqslant n-1}G \simeq \Omega(Z)$$

for some pointed profinite spaces Y and Z. Using Proposition E.5.5.3, we see that f and f' are induced by pointed maps $\overline{f} : Y \to X$ and $\overline{f}' : Z \to X$. It follows from Proposition E.5.2.2 that the map f induces an isomorphism on connected components, so that $\overline{f}$ is an isomorphism on fundamental groups. Consequently, the fiber product $Y \times_X Z$ is also connected. It follows that $G \simeq \Omega(Y \times_X Z)$ belongs to the essential image of Ω, as desired.

E.5.7 The Proof of Proposition E.5.4.5

The proof of Proposition E.5.4.5 will require some preliminaries.

Definition E.5.7.1. A *topological family of abelian groups* is a family of abelian groups $\phi : A \to S$, together with topologies on the sets A and S, for which the map ϕ is continuous, the zero section $S \to A$ is continuous, and the addition on each A_s is given by a continuous map $a : A \times_S A \to A$. We let $\mathrm{Fam}_{\mathcal{T}\mathrm{op}}$ denote the category whose objects are topological families of abelian groups, and whose morphisms are maps of families of abelian groups

$$\begin{array}{ccc} A & \xrightarrow{\phi} & S \\ \downarrow & & \downarrow \\ A' & \xrightarrow{\phi'} & S' \end{array}$$

where the vertical maps are continuous.

Remark E.5.7.2. We can obtain a variant of Definition E.5.7.1 by requiring also that the inverse maps on the groups A_s be given by a continuous map $A \to A$ (so that each A_s has the structure of a topological group). This additional condition will automatically be satisfied in cases of interest to us here (for example, if A and S are Stone spaces, or if ϕ is a group object of $\mathrm{Fam}_{\mathcal{T}\mathrm{op}}$).

If $\phi : A \to S$ is a finite family of abelian groups, we will view ϕ as a topological family of abelian groups where A and S are equipped with the discrete topology. This construction determines a fully faithful embedding $\iota : \mathrm{Fam}_{\mathrm{fin}} \hookrightarrow \mathrm{Fam}_{\mathcal{T}\mathrm{op}}$. Since the category $\mathrm{Fam}_{\mathcal{T}\mathrm{op}}$ admits filtered limits, ι admits an essentially unique extension to a functor $\widehat{\iota} : \mathrm{Pro}(\mathrm{Fam}_{\mathrm{fin}}) \to \mathrm{Fam}_{\mathcal{T}\mathrm{op}}$ which commutes with filtered limits.

Lemma E.5.7.3. *The functor* $\widehat{\iota} : \mathrm{Pro}(\mathrm{Fam}_{\mathrm{fin}}) \to \mathrm{Fam}_{\mathcal{T}\mathrm{op}}$ *is fully faithful.*

Proof. Suppose we are given a pair of objects $\phi, \psi \in \mathrm{Pro}(\mathrm{Fam}_{\mathrm{fin}})$, which are given as limits of finite families of abelian groups

$$\{\phi_\alpha : A_\alpha \to S_\alpha\} \qquad\qquad \{\psi_\beta : B_\beta \to T_\beta\}$$

indexed by filtered partially ordered sets. We wish to prove that the canonical map $\theta : \mathrm{Hom}_{\mathrm{Pro}(\mathrm{Fam}_{\mathrm{fin}})}(\phi, \psi) \to \mathrm{Hom}_{\mathrm{Fam}_{\mathcal{T}\mathrm{op}}}(\widehat{\iota}(\phi), \widehat{\iota}(\psi))$ is a bijection. Unwinding the definitions, we can write θ as an inverse limit of maps $\theta_\beta : \mathrm{Hom}_{\mathrm{Pro}(\mathrm{Fam}_{\mathrm{fin}})}(\phi, \psi_\beta) \to \mathrm{Hom}_{\mathrm{Fam}_{\mathcal{T}\mathrm{op}}}(\widehat{\iota}(\phi), \iota(\psi_\beta))$. Replacing ψ by ψ_β, we may reduce to the case where $\psi \in \mathrm{Fam}_{\mathrm{fin}}$. In this case, θ can be identified with the canonical map $\varinjlim_\alpha \mathrm{Hom}_{\mathrm{Fam}}(\phi_\alpha, \psi) \to \mathrm{Hom}_{\mathrm{Fam}_{\mathcal{T}\mathrm{op}}}(\varprojlim \phi_\alpha, \psi)$. We first show that θ is injective. Suppose we are given an index α and a pair of maps $u, v : \phi_\alpha \to \psi$ which induce the same map from $\varprojlim \phi_\alpha$ to ψ. Let $E \subseteq A_\alpha$ be the subset consisting of elements on which u and v do not agree. Then E is a finite set which is disjoint from the image of the map $\varprojlim_{\alpha' \geqslant \alpha} A_{\alpha'} \to A_\alpha$. Using Proposition E.1.1.1, we see that E is disjoint from the image of the map $A_{\alpha'} \to A_\alpha$ for some $\alpha' \geqslant \alpha$. Then u and v have the same image in $\mathrm{Hom}_{\mathrm{Fam}}(\phi_{\alpha'}, \psi)$, hence the same image in $\mathrm{Hom}_{\mathrm{Pro}(\mathrm{Fam})}(\phi, \psi)$.

Set $A = \varprojlim A_\alpha$ and $S = \varprojlim S_\alpha$, so that $\widehat{\iota}(\phi)$ is a topological family of abelian groups $A \to S$. Let $\psi : B \to T$ be a finite family of abelian groups, and let $u \in \mathrm{Hom}_{\mathrm{Fam}_{\mathcal{T}\mathrm{op}}}(\widehat{\iota}(\phi), \iota(\psi))$, given by a diagram of continuous maps

$$\begin{array}{ccc} A & \longrightarrow & S \\ \downarrow{\scriptstyle u'} & & \downarrow{\scriptstyle u''} \\ B & \longrightarrow & T. \end{array}$$

Applying Theorem E.1.4.1, we deduce that there exists an index α such that u' and u'' factor through maps $u'_\alpha : A_\alpha \to B$ and $u''_\alpha : S_\alpha \to T$. For each $\alpha' \geqslant \alpha$, let $u'_{\alpha'} : A_{\alpha'} \to B$ and $u''_{\alpha'} : S_{\alpha'} \to T$ denote the compositions of u'_α and u''_α with the projection maps $A_{\alpha'} \to A_\alpha$ and $S_{\alpha'} \to S_\alpha$.

Enlarging α if necessary, we may suppose that the diagram

$$\begin{array}{ccc} A_\alpha & \longrightarrow & S \\ \downarrow{\scriptstyle u'_\alpha} & & \downarrow{\scriptstyle u''_\alpha} \\ B & \longrightarrow & T. \end{array}$$

commutes. Let $E \subseteq A_\alpha \times_{S_\alpha} A_\alpha$ be the set consisting of those pairs (a, b) such that $u'_\alpha(a+b) \neq u'_\alpha(a) + u'_\alpha(b)$. Since u is a map of families of abelian groups, E does not intersect the image of the projection map $A \times_S A \to A_\alpha \times_{S_\alpha} A_\alpha$. Using Proposition E.1.1.1, we conclude that there exists $\alpha' \geqslant \alpha$ such that E does not intersect the image of the projection map $A_{\alpha'} \times_{S_{\alpha'}} A_{\alpha'} \to A_\alpha \times_{S_\alpha} A_\alpha$. Replacing α by α', we may suppose that $E = \emptyset$. In this case, each of the maps $A_\alpha \times_{S_\alpha} \{s\} \to B \times_T \{u'_\alpha(s)\}$ is a function between finite abelian groups which preserves addition, and therefore a group homomorphism. It follows that (u'_α, u''_α) is a morphism from ϕ_α to ψ in the category Fam, so that u belongs to the image of θ. □

Example E.5.7.4. Let G be a group, and let M be an abelian group equipped with a (right) action of G, given by $(x \in M, g \in G) \mapsto x^g$. Let $G \ltimes M$ denote the semidirect product of G and A: that is, the product $G \times M$, equipped with the group structure given by $(g, x)(g', x') = (gg', x^{g'} + x')$. Each fiber of the projection map $\phi : G \ltimes M \to G$ can be identified with the abelian group M, so we can view ϕ as a family of abelian groups. Moreover, the multiplication on the groups $G \ltimes M$ and G exhibit ϕ as a group object in the category Fam.

Remark E.5.7.5. Suppose that $\phi : A \to S$ is a group object in the category Fam. In particular, we can regard A and S as groups, so that the map ϕ and the zero section $e : S \to A$ are group homomorphisms. For each $s \in S$, let A_s denote the abelian group $\phi^{-1}\{s\}$. Then the multiplication on ϕ determines group homomorphisms $A_s \times A_{s'} \to A_{ss'}$. Let 1 denote the identity element of S. Then $e(1)$ is the identity element of A, and also the unit element of A_1. Since the multiplication on A induces a group homomorphism $A_1 \times A_1 \to A_1$, it follows that the inclusion $A_1 \hookrightarrow A$ is a group homomorphism: that is, we can identify A_1 with the kernel $\ker(\phi)$ not only as a set, but as a group. We have an exact sequence

$$0 \to A_1 \to A \xrightarrow{\phi} S \to 0.$$

Since A_1 is abelian, the group S acts on A_1 by conjugation. Moreover, this sequence is split by the map $e : S \to A$, so we obtain an isomorphism of groups $S \ltimes A_1 \simeq A$, given by $(s, x) \mapsto e(s)x$. We can summarize the situation as follows: every group object of Fam has the form $G \ltimes M \to G$, where G is a group and M is an abelian group with an action of G, as in Example E.5.7.4.

If ϕ is a group object in the category $\mathrm{Fam}_{\mathcal{T}\mathrm{op}}$ of topological families of abelian groups, the same argument shows that we can write ϕ as the projection map $\phi : G \ltimes M \to G$, where G is a topological group and M is a topological abelian group equipped with a continuous action of G.

Lemma E.5.7.6. *Let M be a profinite group equipped with a continuous action of a profinite group G. Then the collection of open G-invariant normal subgroups of M forms a neighborhood basis for the identity element of M.*

Proof. Let U be an open subset of M containing the identity element. We wish to show that U contains an open G-invariant normal subgroup of M. It follows from Proposition E.5.1.3 that U contains an open normal subgroup of M. Shrinking U if necessary, we may suppose that U is an open normal subgroup.

For each $g \in G$, let U^g denote the image of U under the group homomorphism from M to itself determined by g, and set $V = \bigcap_{g \in G} U^g$. Then V is a G-invariant normal subgroup of M which is contained in U. We will complete the proof by showing that V is open. This is clear, since the complement of V is the image of a continuous map $G \times (M - U) \to M$ whose domain is compact. □

Proof of Proposition E.5.4.5. Suppose that ϕ is a group object of $\mathrm{Pro}(\mathrm{Fam}_{\mathrm{fin}})$. Let $\widehat{\iota} : \mathrm{Pro}(\mathrm{Fam}_{\mathrm{fin}}) \to \mathrm{Fam}_{\mathcal{T}\mathrm{op}}$ be the fully faithful embedding of Lemma E.5.7.3. Then $\widehat{\iota}(\phi)$ is a group object of $\mathrm{Fam}_{\mathcal{T}\mathrm{op}}$. According to Remark E.5.7.5, $\widehat{\iota}(\phi)$ has the form $G \ltimes M \to M$, where G is a topological group and M is a topological abelian group equipped with an action of G. Note that each of these groups is profinite.

Let A denote the set of all pairs (G_0, M_0), where M_0 is an open G-invariant subgroup of M and G_0 is an open normal subgroup of G which acts trivially on the quotient M/M_0. We regard A as a partially ordered set by reverse inclusion. Since the set of such pairs (G_0, M_0) is closed under finite intersections, A is a filtered partially ordered set. For each pair $(G_0, M_0) \in A$, let ϕ_{G_0, M_0} denote the projection map

$$G/G_0 \ltimes M/M_0 \to M/M_0,$$

regarded as a group object of $\mathrm{Fam}_{\mathrm{fin}}$ (see Example E.5.7.4). We claim that ϕ is represented by the inverse limit of the system $\{\phi_{(G_0,M_0)}\}_{(G_0,M_0) \in A}$. To prove this, it will suffice (by virtue of Lemma E.5.7.3) to show that the map

$$\widehat{\iota}(\phi) \to \varprojlim_{(G_0,M_0) \in A} \phi_{(G_0,M_0)}$$

is an isomorphism of topological families of abelian groups. Equivalently, we must show that the maps

$$\alpha : G \to \varprojlim_{(G_0,M_0) \in A} G/G_0 \qquad \beta : M \to \varprojlim_{(G_0,M_0) \in A} M/M_0$$

are isomorphisms of profinite groups. By construction, these maps have dense image and are therefore surjective. We will complete the proof by showing that α and β are injective.

We first show that α is injective. Let g be a nontrivial element of G. It follows from Proposition E.5.1.3 that there exists an open normal subgroup $G_0 \subseteq G$ which does not contain g. Then (G_0, M) is an element of A, and the image of g in G/G_0 is nontrivial. It follows that $\alpha(g)$ is nontrivial.

We now show that β is injective. Let x be a nonzero element of M. It follows from Lemma E.5.7.6 that there exists a G-invariant open subgroup $M_0 \subseteq M$ which does not contain x. Then G acts continuously on the finite set M/M_0. Let $G_0 \subseteq G$ be the kernel of this action. Then (G_0, M_0) is an element of A, and x has nonzero image in M/M_0. It follows that $\beta(x)$ is nonzero. □

E.6 Universality of Colimits

Recall that an ∞-category $\mathcal{X}$ is an ∞-*topos* if it satisfies the ∞-categorical version of Giraud's axioms (see Theorem HTT.6.1.0.6):

(*i*) The ∞-category $\mathcal{X}$ is presentable.

(*ii*) Coproducts in $\mathcal{X}$ are disjoint.

(*iii*) Every groupoid object of $\mathcal{X}$ is effective.

(*iv*) Colimits in $\mathcal{X}$ are universal.

Roughly speaking, these axioms assert that the homotopy theory of $\mathcal{X}$ behaves much like the classical homotopy theory of spaces. In this section, we will investigate the extent to which these axioms are satisfied by the ∞-category $\mathcal{S}_\pi^\wedge$ of profinite spaces. We can summarize the situation as follows:

(*i'*) The ∞-category $\mathcal{S}_\pi^\wedge$ of profinite spaces is not presentable (in fact, it has no small objects other than the initial object). However, the opposite ∞-category $(\mathcal{S}_\pi^\wedge)^{\mathrm{op}}$ is presentable. In particular, the ∞-category $\mathcal{S}_\pi^\wedge$ admits all small limits and colimits.

(*ii'*) Coproducts are disjoint in the ∞-category $\mathcal{S}_\pi^\wedge$ of profinite spaces. To see this, suppose we are given a pair of profinite spaces X and Y, represented by filtered diagrams of π-finite spaces $\{X_\alpha\}_{\alpha \in A}, \{Y_\beta\}_{\beta \in B}$. Then the diagram of profinite spaces σ :

$$\begin{array}{ccc} \emptyset & \longrightarrow & X \\ \downarrow & & \downarrow \\ Y & \longrightarrow & X \amalg Y \end{array}$$

can be written as a filtered limit of diagrams $\sigma_{\alpha,\beta}$:

$$\begin{array}{ccc} \emptyset & \longrightarrow & X_\alpha \\ \downarrow & & \downarrow \\ Y_\beta & \longrightarrow & X_\alpha \amalg Y_\beta. \end{array}$$

Since coproducts are disjoint in the ∞-category $\mathcal{S}$ of spaces, each of the diagrams $\sigma_{\alpha,\beta}$ is a pullback square. It follows immediately that σ is also a pullback square.

(iii') Not every groupoid object of $\mathcal{S}_\pi^\wedge$ is effective (see Warning E.5.5.5). Nevertheless, in §E.5, we proved that every group object of $\mathcal{S}_\pi^\wedge$ can be recovered as the loop space of its classifying space (Theorem E.5.0.4). In other words, every group object G of $\mathcal{S}_\pi^\wedge$ is effective when viewed as a groupoid object of $\mathcal{S}_\pi^\wedge$.

(iv') Colimits are generally not universal in the ∞-category $\mathcal{S}_\pi^\wedge$ of profinite spaces (see Warning E.6.0.9). Nevertheless, we will prove in this section that colimits indexed by finite diagrams are universal, and that geometric realizations are universal (Theorem E.6.3.1).

Before discussing (iv') in more detail, let us consider another fundamental feature of classical homotopy theory. If $\mathcal{X}$ is an ∞-category satisfying axioms (i) and (iv), then conditions (ii) and (iii) are equivalent to the following:

(v) The construction $(X \in \mathcal{X}) \mapsto \mathcal{X}_{/X}$ determines a functor $\mathcal{X}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ which commutes with small limits.

In the particular case where $\mathcal{X} = \mathcal{S}$ is the ∞-category of spaces, axiom (v) supplies an equivalence of ∞-categories $\mathrm{Fun}(X, \mathcal{S}) \simeq \mathcal{S}_{/X}$ for any space X. We can describe the inverse equivalence informally as follows: it assigns to a map of spaces $Y \to X$ the functor $X \to \mathcal{S}$ which carries a point $x \in X$ to the homotopy fiber $Y_x = Y \times_X \{x\}$. Our first goal will be to show that an analogous statement holds in the profinite setting, provided that the space X is π-finite:

Theorem E.6.0.7. *Let X be a π-finite space, and let $\varinjlim : \mathrm{Fun}(X, \mathcal{S}_\pi^\wedge) \to \mathcal{S}_\pi^\wedge$ be the colimit functor (a left adjoint to the diagonal embedding $\mathcal{S}_\pi^\wedge \to \mathrm{Fun}(X, \mathcal{S}_\pi^\wedge)$). Then:*

(1) *Let e_0 denote a final object of $\mathrm{Fun}(X, \mathcal{S}_\pi^\wedge)$ (that is, the constant functor from X to $\mathcal{S}_\pi^\wedge$ taking the value $* \in \mathcal{S}_\pi^\wedge$). Then there is a canonical equivalence $\varinjlim(e_0) \simeq X$ in $\mathcal{S}_\pi^\wedge$.*

(2) *The functor $\varinjlim$ induces an equivalence of ∞-categories*

$$F : \mathrm{Fun}(X, \mathcal{S}_\pi^\wedge) \simeq \mathrm{Fun}(X, \mathcal{S}_\pi^\wedge)_{/e_0} \to (\mathcal{S}_\pi^\wedge)_{/X}.$$

Corollary E.6.0.8. *Let $f : X \to Y$ be a map of π-finite spaces, and let $f^* : (\mathcal{S}_\pi^\wedge)_{/Y} \to (\mathcal{S}_\pi^\wedge)_{/X}$ be the functor given by $f^*Z = X \times_Y Z$. Then f^* preserves small colimits.*

Proof. Using Theorem E.6.0.7, we can identify f^* with the functor $\mathrm{Fun}(Y, \mathcal{S}_\pi^\wedge) \to \mathrm{Fun}(X, \mathcal{S}_\pi^\wedge)$ given by composition with f. □

Warning E.6.0.9. The conclusion of Corollary E.6.0.8 generally fails if we allow f to be a map of profinite spaces, rather than a map of π-finite spaces. For example, suppose we are given a pair of set A and B, which we regard as discrete spaces. Let $X = A^{\wedge}_{\pi}$ be the profinite completion of A: then X is a 0-truncated profinite space, and set $Y = *$. Then the canonical map $\amalg_{b \in B}(X \times \{b\}) \rightarrow X \times \amalg_{b \in B}\{b\}$ is generally not an equivalence of profinite spaces. Using Remark E.5.2.6, we can identify the left hand side with the Stone-Čech compactification of $A \times B$ and the right hand side with product of the Stone-Čech compactifications of A and B. These are not isomorphic unless either A or B is finite.

E.6.1 Diagrams Indexed by π-Finite Spaces

Let X be a Kan complex. We will say that X is *almost π-finite* if, for each vertex $x \in X$ and each $n \geqslant 0$, the set $\pi_n(X, x)$ is finite (by virtue of Lemma E.1.6.5, this is equivalent to the requirement that there exists a homotopy equivalence of Kan complexes $X \simeq X'$, where X' has finitely many simplices of each dimension). We now summarize some elementary facts about diagrams indexed by almost π-finite Kan complexes which will be needed in the proof of Theorem E.6.0.7.

Lemma E.6.1.1. *Let X be a Kan complex which is almost π-finite, let $\mathcal{C}$ be an essentially small ∞-category which admits finite limits, and suppose that every object of $\mathcal{C}$ is truncated. Then:*

(1) *Every functor $X \rightarrow \mathcal{C}$ admits a limit in $\mathcal{C}$.*

(2) *The Yoneda embedding $j : \mathcal{C} \hookrightarrow \mathrm{Pro}(\mathcal{C})$ preserves X-indexed limits.*

Proof. Fix a diagram $q : X \rightarrow \mathcal{C}$. Since X has only finitely many connected components, it follows that there exists an integer n such that $q(x)$ is n-truncated, for each point $x \in X$. Let $\mathcal{C}_0 \subseteq \mathcal{C}$ denote the full subcategory spanned by the n-truncated objects, so that q factors through $\mathcal{C}_0$. Replacing $\mathcal{C}$ by $\mathcal{C}_0$, we may reduce to the case where $\mathcal{C}$ is equivalent to an $(n+1)$-category.

Since $\mathcal{C}$ admits finite limits, $\mathrm{Pro}(\mathcal{C})$ admits all small limits. Consequently, the diagram $j \circ q$ admits a limit $C \in \mathrm{Pro}(\mathcal{C})$. To complete the proof, it will suffice to show that C belongs to the essential image of j. Without loss of generality we can assume that X has only finitely many simplices of each dimension. Let K be the $(n+1)$-skeleton of X. Since $\mathrm{Pro}(\mathcal{C})$ is equivalent to an $(n+1)$-category, the restriction map $\varprojlim(j \circ q) \rightarrow \varprojlim(j \circ q|_K)$ is an equivalence in $\mathrm{Pro}(\mathcal{C})$. It will therefore suffice to show that $\varprojlim(j \circ q|_K)$ belongs to the essential image of j, which follows because j preserves finite limits (Proposition HTT.5.3.5.14). □

Lemma E.6.1.2. *Let $\mathcal{C}$ be an essentially small ∞-category which admits finite limits and let X be a Kan complex which is almost π-finite. If every object of $\mathcal{C}$ is truncated, then the canonical map $\theta : \mathrm{Pro}(\mathrm{Fun}(X, \mathcal{C})) \to \mathrm{Fun}(X, \mathrm{Pro}(\mathcal{C}))$ is fully faithful.*

Proof. Suppose we are given objects $\mu, \nu \in \mathrm{Pro}(\mathrm{Fun}(X, \mathcal{C}))$, represented by filtered diagrams

$$\{\mu_\alpha \in \mathrm{Fun}(X, \mathcal{C})\}_{\alpha \in A} \qquad \{\nu_\beta \in \mathrm{Fun}(X, \mathcal{C})\}_{\beta \in B}.$$

We wish to show that the canonical map

$$\theta_{\mu,\nu} : \mathrm{Map}_{\mathrm{Pro}(\mathrm{Fun}(X,\mathcal{C}))}(\mu, \nu) \to \mathrm{Map}_{\mathrm{Fun}(X,\mathrm{Pro}(\mathcal{C}))}(\theta(\mu), \theta(\nu))$$

is a homotopy equivalence. Unwinding the definitions, we can identify $\theta_{\mu,\nu}$ with the map

$$\varprojlim_{\beta \in B} \varinjlim_{\alpha \in A} \varprojlim_{x \in X} \mathrm{Map}_{\mathcal{C}}(\mu_\alpha(x), \mu_\beta(x)) \to \varprojlim_{x \in X} \varprojlim_{\beta \in B} \varinjlim_{\alpha \in A} \mathrm{Map}_{\mathcal{C}}(\mu_\alpha(x), \mu_\beta(x)).$$

Without loss of generality, we may suppose that X has only finitely many simplices of each dimension. For each pair of indices $\alpha \in A$, $\beta \in B$, let $u_{\alpha,\beta} : X \to \mathcal{S}$ denote the diagram given by $v \mapsto \mathrm{Map}_{\mathcal{C}}(\mu_\alpha(x), \mu_\beta(x))$. We are then reduced to proving that for each index $\beta \in B$, the canonical map

$$\varinjlim_{\alpha \in A} \varprojlim_{x \in X} (u_{\alpha,\beta}(x)) \to \varprojlim_{x \in X} (\varinjlim_{\alpha \in A} u_{\alpha,\beta}(x))$$

is a homotopy equivalence. Since every object of $\mathcal{C}$ is truncated, we can choose an integer n such that $\mu_\beta(x)$ is n-truncated for every vertex $x \in X$. In this case, each of the diagrams $u_{\alpha,\beta}$ takes values in the full subcategory $\tau_{\leq n} \mathcal{S}$. Let K be the $(n+1)$-skeleton of X, so that we have a commutative diagram

$$\begin{array}{ccc} \varinjlim_{\alpha \in A} \varprojlim (u_{\alpha,\beta}) & \longrightarrow & \varprojlim (\varinjlim_{\alpha \in A} u_{\alpha,\beta}) \\ \downarrow & & \downarrow \\ \varinjlim_{\alpha \in A} \varprojlim (u_{\alpha,\beta}|_K) & \longrightarrow & \varprojlim (\varinjlim_{\alpha \in A} u_{\alpha,\beta}|_K) \end{array}$$

where the vertical maps are homotopy equivalences. It will therefore suffice to show that the bottom horizontal map is a homotopy equivalence, which follows because filtered colimits in the ∞-category $\mathcal{S}$ are left exact. □

Lemma E.6.1.3. *Let X be a Kan complex which is almost π-finite. Then the canonical map $\theta : \mathrm{Pro}(\mathrm{Fun}(X, \mathcal{S}_\pi)) \to \mathrm{Fun}(X, \mathcal{S}_\pi^\wedge)$ is an equivalence of ∞-categories.*

Proof. It follows from Lemma E.6.1.2 that θ is fully faithful. Let $\mathcal{E} \subseteq \mathrm{Fun}(X, \mathcal{S}_\pi^\wedge)$ denote the essential image of θ. Since θ preserves small limits, the full subcategory $\mathcal{E}$ is closed under small limits in $\mathrm{Fun}(X, \mathcal{S}_\pi^\wedge)$. Fix a functor $\lambda : X \to \mathcal{S}_\pi^\wedge$; we wish to prove that $\lambda \in \mathcal{E}$. For each integer n, let $\lambda_n : X \to \mathcal{S}_\pi^\wedge$ be the functor given by $\lambda_n(x) = \tau_{\leqslant n}\lambda(x)$. Then λ is a limit of the diagram $\{\lambda_n\}_{n \geqslant 0}$. It will therefore suffice to show that each λ_n belongs to $\mathcal{E}$. Replacing λ by λ_n, we may suppose that λ takes values in the full subcategory $\tau_{\leqslant n}\mathcal{S}_\pi^\wedge$.

Without loss of generality, we can assume that X has only finitely many simplices of each dimension. Let K be the $(n+1)$-skeleton of X. Using Variant HTT.4.2.3.16 , we can choose a right cofinal map $\mathrm{N}(A) \to K$, where A is a finite partially ordered set. Let f denote the composite map $\mathrm{N}(A) \to K \subseteq X$. Let $f^* : \mathrm{Fun}(X, \mathcal{S}_\pi^\wedge) \to \mathrm{Fun}(\mathrm{N}(A), \mathcal{S}_\pi^\wedge)$ denote the functor given by composition with f, and let $f_* : \mathrm{Fun}(\mathrm{N}(A), \mathcal{S}_\pi^\wedge) \to \mathrm{Fun}(X, \mathcal{S}_\pi^\wedge)$ denote a right adjoint to f^*, given by right Kan extension along f. For each point $x \in X$, let $\mathrm{N}(A)_{x/}$ denote the fiber product $\mathrm{N}(A) \times_X X_{x/}$, so that we have

$$(f_* f^* \lambda)(x) = \varprojlim_{a \in \mathrm{N}(A)_{x/}} \lambda(f(a)).$$

Since X is a Kan complex, the diagram

$$\begin{array}{ccc} \mathrm{N}(A)_{x/} & \longrightarrow & X_{x/} \\ \downarrow & & \downarrow \\ \mathrm{N}(A) & \longrightarrow & X \end{array}$$

is a homotopy pullback square with respect to the usual model structure on the category of simplicial sets. Since $\mathrm{N}(A)$ is weakly homotopy equivalent to the $(n+1)$-skeleton of X, it follows that (a fibrant replacement for) $\mathrm{N}(A)_{x/}$ is $(n+1)$-connective. Because λ takes values in n-truncated objects of $\mathcal{S}_\pi^\wedge$, we deduce that the unit map $\lambda \to (f_* f^* \lambda)$ is an equivalence. We may therefore identify λ with $f_*\mu$, where $\mu : \mathrm{N}(A) \to \mathcal{S}_\pi^\wedge$ is a functor taking n-truncated values.

Using Proposition HTT.5.3.5.15 , we can write μ as a filtered limit of functors $\{\mu_\beta : \mathrm{N}(A) \to \mathcal{S}_\pi\}$. It follows that $\lambda \simeq \varprojlim_\beta f_*\mu_\beta$. Since $\mathcal{E}$ is closed under small limits, it will suffice to prove that each of the functors $f_*\mu_\beta$ belongs to $\mathcal{E}$. In fact, we claim that each of the functors $f_*\mu_\beta$ belongs to $\mathrm{Fun}(X, \mathcal{S}_\pi)$. To prove this, it will suffice to show that for each point $x \in X$, the limit $\varprojlim_{a \in \mathrm{N}(A)_{x/}} \mu_\beta(a)$ belongs to the full subcategory $\mathcal{S}_\pi \subseteq \mathcal{S}_\pi^\wedge$. Let $\overline{\mu}_\beta$ denote the restriction of μ_β to $\mathrm{N}(A)_{x/}$, and let ν be a right Kan extension of $\overline{\mu}_\beta$ along the projection $\mathrm{N}(A)_{x/} \to \mathrm{N}(A)$. Since $\mathcal{S}_\pi$ is closed under finite limits in $\mathcal{S}_\pi^\wedge$, it will suffice to show that ν takes values in $\mathcal{S}_\pi$. Unwinding the definitions, we see that for each $a \in A$, $\nu(a)$ is given by the limit of the constant diagram $\{x\} \times_X \{f(a)\} \to \mathcal{S}_\pi^\wedge$ taking the value $\mu_\beta(a)$. This follows from Lemma E.6.1.1, since the path space $\{x\} \times_X \{f(a)\}$ satisfies the requirement of Lemma E.6.1.1. $\square$

E.6.2 The Proof of Theorem E.6.0.7

Let X be a π-finite space and let $e_0 \in \mathrm{Fun}(X, \mathcal{S}_\pi^\wedge)$ be the constant functor taking the value $*$. Since the Yoneda embedding $j : \mathcal{S}_\pi \hookrightarrow \mathcal{S}_\pi^\wedge$ preserves all colimits which exist in $\mathcal{S}_\pi$ (Proposition HTT.5.1.3.2), we have a canonical identification $X \simeq \varinjlim e_0$, which induces a functor

$$F : \mathrm{Fun}(X, \mathcal{S}_\pi^\wedge) \simeq \mathrm{Fun}(X, \mathcal{S}_\pi^\wedge)_{/e_0} \xrightarrow{\varinjlim} (\mathcal{S}_\pi^\wedge)_{/X}.$$

We wish to show that F is an equivalence of ∞-categories. We begin by showing that the functor F preserves filtered limits. Let $\{\mu_\alpha\}_{\alpha \in A}$ be a filtered diagram in $\mathrm{Fun}(X, \mathcal{S}_\pi^\wedge)$; we wish to show that the canonical map $F(\varprojlim_{\alpha \in A} \mu_\alpha) \to \varprojlim_{\alpha \in A} F(\mu_\alpha)$ is an equivalence of profinite spaces. Equivalently, we wish to show that for every π-finite space T, the canonical map

$$\theta : \varinjlim_{\alpha} \varprojlim_{x \in X} \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(\mu_\alpha(x), T) \to \varprojlim_{x \in X} \varinjlim_{\alpha} \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(\mu_\alpha(x), T)$$

is a homotopy equivalence. Using Lemma E.1.6.5, we may assume without loss of generality that X has finitely many simplices of each dimension. Choose an integer n such that T is n-truncated, and let K denote the $(n+1)$-skeleton of X. Then θ can be identified with the upper horizontal map in the diagram

$$\begin{array}{ccc} \varprojlim_{x \in X} \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(\mu_\alpha(x), T) & \longrightarrow & \varprojlim_{x \in X} \varinjlim_{\alpha} \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(\mu_\alpha(x), T) \\ \downarrow & & \downarrow \\ \varprojlim_{x \in K} \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(\mu_\alpha(x), T) & \longrightarrow & \varprojlim_{x \in K} \varinjlim_{\alpha} \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(\mu_\alpha(x), T) \end{array}$$

where the vertical maps are homotopy equivalences. It therefore suffices to show that the bottom horizontal map is a homotopy equivalence, which follows because filtered colimits in $\mathcal{S}$ are left exact.

We next prove that F is fully faithful. Using Lemma E.6.1.3 and Proposition HTT.5.3.5.11 , we are reduced to proving that the restriction $F_0 = F|_{\mathrm{Fun}(X, \mathcal{S}_\pi)}$ is fully faithful, and that F_0 takes values in the full subcategory of $(\mathcal{S}_\pi^\wedge)_{/X}$ spanned by the cocompact objects (that is, the full subcategory spanned by those objects which are compact in the opposite ∞-category $(\mathcal{S}_\pi^\wedge)_{/X}^{\mathrm{op}}$). Let $\mu, \nu : X \to \mathcal{S}_\pi \subseteq \mathcal{S}$ be functors, classifying Kan fibrations $Y_\mu \to X \leftarrow Y_\nu$ with essentially small fibers. Then $F(\mu)$ and $F(\nu)$ can be identified with the objects of $(\mathcal{S}_\pi)_{/X} \subseteq (\mathcal{S}_\pi^\wedge)_{/X}$ given by Y_μ and Y_ν (see Proposition HTT.3.3.4.5). From this description it is easy to see that the canonical map

$$\mathrm{Map}_{\mathrm{Fun}(X, \mathcal{S}_\pi^\wedge)}(\mu, \nu) \to \mathrm{Map}_{(\mathcal{S}_\pi^\wedge)_{/X}}(F(\mu), F(\nu))$$

is a homotopy equivalence (both sides can be identified with the mapping space $\mathrm{Fun}_X(Y_\mu, Y_\nu)$), and that $F(\mu)$ and $F(\nu)$ are cocompact.

Note that the functor F admits a right adjoint G, which carries a map of profinite spaces $Y \to X$ to the functor $G(Y) \in \operatorname{Fun}(X, \mathcal{S}_{\pi}^{\wedge})$ given on objects by the formula $G(Y)(x) = \{x\} \times_X Y$. To complete the proof that F is an equivalence of ∞-categories, it will suffice to show that G is conservative. That is, we must show that if we are given a diagram of profinite spaces

$$\begin{array}{ccc} Y & \xrightarrow{g} & Y' \\ & \searrow \quad \swarrow & \\ & X & \end{array}$$

which induces an equivalence $\{x\} \times_X Y \to \{x\} \times_X Y'$ for every point $x \in X$, then g is an equivalence. This follows immediately from the characterization of equivalences in $\mathcal{S}_{\pi}^{\wedge}$ supplied by Theorem E.3.1.6.

E.6.3 Universality of Colimits

Using Theorem **??**, we can establish the universality of a large class of colimits in the ∞-category $\mathcal{S}_{\pi}^{\wedge}$ of profinite spaces.

Theorem E.6.3.1. *Let $f : X \to Y$ be a map of profinite spaces, and let $f^* : (\mathcal{S}_{\pi}^{\wedge})_{/Y} \to (\mathcal{S}_{\pi}^{\wedge})_{/X}$ be the functor given by $f^*(Y') = X \times_Y Y'$. Let K be a simplicial set having only finitely many simplices of each dimension. Then the functor f^* preserves K-indexed colimits.*

Corollary E.6.3.2. *Let $f : X \to Y$ be a map of profinite spaces, and let $f^* : (\mathcal{S}_{\pi}^{\wedge})_{/Y} \to (\mathcal{S}_{\pi}^{\wedge})_{/X}$ be the functor given by $f^*(Y') = X \times_Y Y'$. Then f preserves geometric realizations of simplicial objects.*

Corollary E.6.3.3. *Let K be a simplicial set with only finitely many simplices in each degree. Then the Cartesian product functor $\mathcal{S}_{\pi}^{\wedge} \times \mathcal{S}_{\pi}^{\wedge} \to \mathcal{S}_{\pi}^{\wedge}$ preserves K-indexed colimits separately in each variable. In particular, it preserves geometric realizations of simplicial objects.*

The proof of Theorem E.6.3.1 will require some preliminaries.

Lemma E.6.3.4. *Let K be a simplicial set with only finitely many simplices of each dimension, and let $\varinjlim : \operatorname{Fun}(K, \mathcal{S}_{\pi}^{\wedge}) \to \mathcal{S}_{\pi}^{\wedge}$ denote the colimit functor. Then $\varinjlim$ commutes with filtered limits.*

Proof. Let $\{\mu_\alpha : K \to \mathcal{S}_{\pi}^{\wedge}\}_{\alpha \in A}$ be a filtered diagram in $\operatorname{Fun}(K, \mathcal{S}_{\pi}^{\wedge})$. We wish to show that the canonical map $\varinjlim(\varprojlim_{\alpha \in A} \mu_\alpha) \to \varprojlim_{\alpha \in A}(\varinjlim \mu_\alpha)$ is an equivalence of profinite spaces. Equivalently, we wish to show that for every π-finite space T, the canonical map

$$\theta : \varinjlim_{\alpha \in A} \varprojlim_{v \in K} \operatorname{Map}_{\mathcal{S}_{\pi}^{\wedge}}(\mu_\alpha(v), T) \to \varprojlim_{v \in K} \varinjlim_{\alpha \in A} \operatorname{Map}_{\mathcal{S}_{\pi}^{\wedge}}(\mu_\alpha(v), T)$$

is a homotopy equivalence. Choose an integer n such that T is n-truncated, and let K_0 denote the $(n+1)$-skeleton of K. Then the vertical maps in the diagram

$$\begin{array}{ccc} \varinjlim_{\alpha \in A} \varprojlim_{v \in K} \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(\mu_\alpha(v), T) & \xrightarrow{\theta} & \varprojlim_{v \in K} \varinjlim_{\alpha \in A} \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(\mu_\alpha(v), T) \\ \downarrow & & \downarrow \\ \varinjlim_{\alpha \in A} \varprojlim_{v \in K_0} \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(\mu_\alpha(v), T) & \xrightarrow{\theta'} & \varprojlim_{v \in K_0} \varinjlim_{\alpha \in A} \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(\mu_\alpha(v), T) \end{array}$$

are homotopy equivalences. We are therefore reduced to proving that θ' is a homotopy equivalence, which follows because filtered colimits are left exact in the ∞-category $\mathcal{S}$. □

We are now in a position to prove a weak form of Theorem E.6.3.1:

Lemma E.6.3.5. *Let $f : X \to Y$ be a map of profinite spaces, and let $f^* : (\mathcal{S}_\pi^\wedge)_{/Y} \to (\mathcal{S}_\pi^\wedge)_{/X}$ be the functor given by $f^*(Y') = X \times_Y Y'$. Then the functor f^* preserves finite colimits.*

Proof. Since the functor f^* preserves initial objects, it will suffice to show that f^* preserves pushout squares (Corollary HTT.4.4.2.5). To prove this, suppose we are given a diagram σ :

$$\begin{array}{ccccc} & & W & & \\ & \swarrow & & \searrow & \\ & X & & Y & \\ & & \searrow & \swarrow & \\ Z' & \longrightarrow & Z & & \end{array}$$

in the ∞-category $\mathcal{S}_\pi^\wedge$. We wish to prove that the canonical map

$$\theta : (Z' \times_Z X) \amalg_{Z' \times_Z W} (Z' \times_Z Y) \to Z' \times_Z (X \amalg_W Y)$$

is an equivalence of profinite spaces. Using Proposition HTT.5.3.5.15 , we can write σ as a filtered limit of diagrams σ_α:

$$\begin{array}{ccccc} & & W_\alpha & & \\ & \swarrow & & \searrow & \\ & X_\alpha & & Y_\alpha & \\ & & \searrow & \swarrow & \\ Z'_\alpha & \longrightarrow & Z_\alpha & & \end{array}$$

of π-finite spaces. Using Lemma E.6.3.4, we see that θ can be written as a filtered limit of maps

$$\theta_\alpha : (Z'_\alpha \times_{Z_\alpha} X_\alpha) \amalg_{(Z'_\alpha \times_{Z_\alpha} W_\alpha)} (Z'_\alpha \times_{Z_\alpha} Y_\alpha) \to Z'_\alpha \times_{Z_\alpha} (X_\alpha \amalg_{W_\alpha} Y_\alpha).$$

Each of these maps is an equivalence by virtue of Corollary E.6.0.8. □

Proof of Theorem E.6.3.1. Let K be a simplicial set with only finitely many vertices of each dimension, and suppose we are given a diagram $q : K \to (\mathcal{S}_{\pi}^{\wedge})_{/X}$. We wish to show that the canonical map $\varinjlim_{v \in K} Y \times_X q(v) \to Y \times_X \varinjlim_{v \in K} q(v)$ is an equivalence of profinite spaces. For this, it will suffice to show that for each integer $n \geqslant 0$, the induced map $\tau_{\leqslant n}(\varinjlim_{v \in K} Y \times_X q(v)) \to \tau_{\leqslant n}(Y \times_X \varinjlim_{v \in K} q(v))$ is an equivalence. Let K_0 denote the $(n+2)$-skeleton of K, so that we have a commutative diagram

$$\begin{array}{ccc} \tau_{\leqslant n}(\varinjlim_{v \in K_0} Y \times_X q(v)) & \longrightarrow & \tau_{\leqslant n}(Y \times_X \varinjlim_{v \in K_0} q(v)) \\ \downarrow \phi & & \downarrow \psi \\ \tau_{\leqslant n}(\varinjlim_{v \in K} Y \times_X q(v)) & \longrightarrow & \tau_{\leqslant n}(Y \times_X \varinjlim_{v \in K} q(v)). \end{array}$$

It follows from Lemma E.6.3.5 that the lower horizontal map in this diagram is an equivalence. It will therefore suffice to show that the the maps ϕ and ψ are equivalences. For ϕ, this is clear: the ∞-category of n-truncated objects of $\mathcal{S}_{\pi}^{\wedge}$ is equivalent to an $(n+1)$-category, so the colimit of a K-indexed diagram in $\tau_{\leqslant n} \mathcal{S}_{\pi}^{\wedge}$ is equivalent to the colimit of its restriction to K_0. The same argument shows that the map $\tau_{\leqslant n+1} \varinjlim_{v \in K_0} q(v) \to \tau_{\leqslant n+1} \varinjlim_{v \in K} q(v)$ is an equivalence, so the the map $\varinjlim_{v \in K_0} q(v) \to \varinjlim_{v \in K} q(v)$ is $(n+1)$-connective. It follows that the map $Y \times_X \varinjlim_{v \in K_0} q(v) \to Y \times_X \varinjlim_{v \in K} q(v)$ is also $(n+1)$-connective, so that ψ is an equivalence as desired. □

E.6.4 Digression: Bar Constructions

Let Y be a connected profinite space with a base point $y \in Y$. According to Theorem E.5.0.4, Y can be functorially recovered from its loop space $G = \Omega Y$, regarded as a group object of $\mathcal{S}_{\pi}^{\wedge}$. We will prove below that the ∞-category $(\mathcal{S}_{\pi}^{\wedge})_{/Y}$ of profinite spaces over Y can be identified with the ∞-category of profinite spaces equipped with an action of G (Theorem E.6.5.1). First, we need some general remarks about group actions in the ∞-categorical setting.

Notation E.6.4.1. Let $\mathcal{C}$ be an ∞-category which admits finite limits and geometric realizations of simplicial objects, and suppose that Cartesian product functor $\mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves geometric realizations separately in each variable. We will regard $\mathcal{C}$ as endowed with the Cartesian symmetric monoidal structure, so that every group object G of $\mathcal{C}$ can be identified with an associative algebra object of $\mathcal{C}$. In this case, we can think of $\mathrm{LMod}_G(\mathcal{C})$ as the ∞-category of objects of $\mathcal{C}$ equipped with a left action of G, $\mathrm{RMod}_G(\mathcal{C})$ as the ∞-category of spaces equipped with a right action of G. It follows from Theorem HA.4.4.2.8 the relative tensor product functor $\otimes_G : \mathrm{RMod}_G(\mathcal{C}) \times \mathrm{LMod}_G(\mathcal{C}) \to \mathcal{C}$ is well-defined, and is computed by the two-sided bar construction

$$X \otimes_G Y = |\mathrm{Bar}_G(X, Y)_\bullet| \qquad \mathrm{Bar}_G(X, Y)_n = X \times G^n \times Y.$$

Example E.6.4.2. Let $\mathcal{C}$ be an ∞-category satisfying the hypotheses of Notation E.6.4.1, and let G be a group object of $\mathcal{C}$. Using Corollary HA.4.2.3.3 , we see that the final object $* \in \mathcal{C}$ can be regarded as a (left or right) G-module in an essentially unique way. We let BG denote the relative tensor product $* \otimes_G *$. Unwinding the definitions, we see that the two-sided bar construction $\mathrm{Bar}_G(*, *)_\bullet$ agrees with G (as a simplicial object of $\mathcal{C}$), so that the construction $G \mapsto BG$ is left adjoint to the functor $\Omega : \mathcal{C}_* \to \mathcal{G}\mathrm{rp}(\mathcal{C})$ of Remark E.5.5.2. We will refer to BG as the *classifying space* of G.

Construction E.6.4.3. Let $\mathcal{C}$ be an ∞-category satisfying the hypotheses of Notation E.6.4.1, and let G be a group object of $\mathcal{C}$. The construction $X \mapsto X \otimes_G *$ determines a functor $\mathrm{RMod}_G(\mathcal{C}) \to \mathcal{C}$, which carries the final object of $\mathrm{RMod}_G(\mathcal{C})$ to the classifying space BG. It therefore induces a functor $\mathrm{RMod}_G(\mathcal{C}) \simeq \mathrm{RMod}_G(\mathcal{C})_{/*} \to \mathcal{C}_{/BG}$, which we will denote by $X \mapsto X/G$. We will refer to X/G as the *quotient of X by G*.

Proposition E.6.4.4. *Let $\mathcal{C}$ be an ∞-category which admits finite limits and geometric realizations of simplicial objects, and assume that the Cartesian product functor $\mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves geometric realizations of simplicial objects. Let G be a group object of $\mathcal{C}$, and let $U : \mathrm{RMod}_G(\mathcal{C}) \to \mathcal{C}_{/BG}$ be the functor given by $X \mapsto X/G$. Then U admits a right adjoint V. Moreover, the composite functor $\mathcal{C}_{/BG} \xrightarrow{V} \mathrm{RMod}_G(\mathcal{C}) \to \mathcal{C}$ is given on objects by $V(f : Y \to BG) = \mathrm{fib}(f)$.*

Proof. Let $\mathcal{E}_0$ denote the full subcategory of $\mathrm{Fun}(\mathbf{\Delta}^{\mathrm{op}} \times \Delta^1, \mathcal{C}) \times_{\mathrm{Fun}(\mathbf{\Delta}^{\mathrm{op}} \times \{1\}, \mathcal{C})} \{G\}$ spanned by those morphisms $Z \to G$ between simplicial objects of $\mathcal{C}$ which satisfy the following condition:

($*$) For each $n \geqslant 0$, the inclusion $\{0\} \hookrightarrow [n]$ induces a map $Z_n \to Z_0$ which exhibits Z_n as a product of Z_0 with G_n.

Proposition HA.4.2.2.9 supplies an equivalence of ∞-categories $\mathrm{RMod}_G(\mathcal{C}) \to \mathcal{E}_0$ which carries a right G-module X to the map $\mathcal{C}$ given by the two-sided bar construction $\mathrm{Bar}_G(X, *)_\bullet$, where $*$ denotes the final object of $\mathcal{C}$, which we regard as a left G-module (together with the evident map of simplicial objects $\mathrm{Bar}_G(X, *)_\bullet \to \mathrm{Bar}\, G(*, *)_\bullet \simeq G$).

Let $\overline{G} : \mathbf{\Delta}_+^{\mathrm{op}} \to \mathcal{C}$ be a colimit of the simplicial object G of $\mathcal{C}$ (so that $\overline{G}$ is an augmented simplicial object of $\mathcal{C}$ with $\overline{G}_{-1} = BG$). Let $K_+ \subseteq \mathbf{\Delta}_+^{\mathrm{op}} \times \Delta^1$ denote the full subcategory obtained by removing the objects $([n], 0)$ for $n \geqslant 0$. Let $\mathcal{E}_-$ denote the full subcategory of $\mathrm{Fun}(K_-, \mathcal{C}) \times_{\mathrm{Fun}(\mathbf{\Delta}_+^{\mathrm{op}} \times \{1\}, \mathcal{C})} \{\overline{G}\}$ spanned by those functors which satisfy ($*$), let $\mathcal{E}$ denote the inverse image of $\mathcal{E}_-$ in $\mathrm{Fun}(\mathbf{\Delta}_+^{\mathrm{op}} \times \Delta^1, \mathcal{C})$, and let $\mathcal{E}_+$ denote the fiber product $\mathrm{Fun}(K_+, \mathcal{C}) \times_{\mathrm{Fun}(\mathbf{\Delta}_+^{\mathrm{op}} \times \{1\}, \mathcal{C})} \{\overline{G}\}$.

We have evident restriction maps $\mathcal{E}_- \xleftarrow{u^*} \mathcal{E} \xrightarrow{v^*} \mathcal{E}_+$. Note that the diagram of ∞-categories

$$\begin{array}{ccc} \mathbf{\Delta}^{\mathrm{op}} \times \{1\} & \longrightarrow & \mathbf{\Delta}_+^{\mathrm{op}} \times \{1\} \\ \downarrow & & \downarrow \\ \mathbf{\Delta}^{\mathrm{op}} \times \Delta^1 & \longrightarrow & \mathcal{E}_- \end{array}$$

is a homotopy pushout square. The restriction map $\mathcal{E}_- \to \mathcal{E}_0$ is trivial Kan fibration, so that we have an equivalence of ∞-categories $\mathcal{E}_- \simeq \mathrm{RMod}_G(\mathcal{C})$. The ∞-category $\mathcal{E}_+$ is isomorphic as a simplicial set to $\mathcal{C}^{/BG}$, hence equivalent to $\mathcal{C}_{/BG}$.

Since $\mathcal{C}$ admits geometric realizations of simplicial objects, the functor u^* admits a left adjoint $u_!$, given by left Kan extension along the inclusion $\mathcal{E}_- \hookrightarrow \mathcal{E}$. Unwinding the definitions, we see that the composite functor see that the composite functor

$$\mathrm{RMod}_G(\mathcal{C}) \simeq \mathcal{E}_- \xrightarrow{u_!} \mathcal{E} \xrightarrow{v^*} \mathcal{E}_+ \simeq \mathcal{C}_{/BG}$$

$$(X \in \mathrm{RMod}_G(\mathcal{C})) \mapsto |\operatorname{Bar}_G(X, *)_\bullet| = X/G.$$

Since $\mathcal{C}$ admits finite limits, the functor v^* admits a right adjoint v_* given by right Kan extension along the inclusion $\mathcal{E}_+ \hookrightarrow \mathcal{E}$. It follows that U admits a right adjoint V, given by the composition

$$\mathcal{C}_{/BG} \simeq \mathcal{E}_+ \xrightarrow{v_*} \mathcal{E} \xrightarrow{u^*} \mathcal{E}_- \simeq \mathrm{RMod}_G(\mathcal{C}).$$

More concretely, this functor is given by

$$(f : Y \to \overline{G}_{-1}) \mapsto \overline{G}_0 \times_{\overline{G}_{-1}} Y = \operatorname{fib}(f)$$

(endowed with appropriate action of G). □

E.6.5 Bar Construction

According to Corollary E.6.3.3, the formation of Cartesian products of profinite spaces determines a functor

$$\mathcal{S}_\pi^\wedge \times \mathcal{S}_\pi^\wedge \to \mathcal{S}_\pi^\wedge \qquad (X, Y) \mapsto X \times Y$$

which preserves preserves geometric realizations of simplicial object. It follows that the ∞-category $\mathcal{S}_\pi^\wedge$ of profinite spaces satisfies the hypotheses of Notation E.6.4.1. In particular, if G is a group object of the ∞-category $\mathcal{S}_\pi^\wedge$ and X is a profinite space equipped with a right action of G, then we can define the quotient X/G as in Construction E.6.4.3. We can now formulate our main result:

Theorem E.6.5.1. *Let G be a group object of the ∞-category $\mathcal{S}_\pi^\wedge$. Then the construction $X \mapsto X/G$ determines an equivalence of ∞-categories $U : \mathrm{RMod}_G(\mathcal{S}_\pi^\wedge) \to (\mathcal{S}_\pi^\wedge)_{/BG}$.*

Proof. According to Proposition E.6.4.4, the functor U admits a right adjoint V. We first claim that V is fully faithful: that is, for every object $Y \in (\mathcal{S}^{\wedge}_{\pi})_{/BG}$, the counit map $v : (U \circ V)(Y) \to Y$ is an equivalence of profinite spaces. Let us identify G with a simplicial object $K_{\bullet}$ of $\mathcal{C}$. The proof of Proposition E.6.4.4 shows that v can be identified with the composite map $|K_{\bullet} \times_{BG} Y| \xrightarrow{v'} |K_{\bullet}| \times_{BG} Y \xrightarrow{v''} Y$. The map v'' is evidently an equivalence, and v' is an equivalence by virtue of Corollary E.6.3.2 (the statement that v is an equivalence can also be deduced directly from Proposition E.5.5.3).

We now complete the proof by showing that the functor V is essentially surjective. Using Corollaries E.6.3.3 and HA.4.2.3.5 , we see that the forgetful functor $f : \mathrm{RMod}_G(\mathcal{S}^{\wedge}_{\pi}) \to \mathcal{S}^{\wedge}_{\pi}$ preserves geometric realizations of simplicial objects. Corollary E.6.3.2 and Proposition E.6.4.4 imply that the composite functor $fV : (\mathcal{S}^{\wedge}_{\pi})_{/BG} \to \mathcal{S}^{\wedge}_{\pi}$ also preserves geometric realizations of simplicial objects. Because f is conservative, this implies that V preserves geometric realizations of simplicial objects. Since V is fully faithful, the essential image of V is closed under geometric realizations in $\mathrm{RMod}_G(\mathcal{S}^{\wedge}_{\pi})$. By virtue of Proposition HA.4.7.3.14 , we are reduced to proving that the essential image of V contains all *free* right G-modules: that is, right G-modules of the form $Y \times G$, where Y is a profinite space. This is clear, since $Y \times G$ can be identified with $V(Y)$, where $Y \to BG$ is nullhomotopic. □

Remark E.6.5.2. Let X and Y be connected pointed profinite spaces, with loop spaces $G = \Omega X$ and $H = \Omega Y$. Then we can regard the ∞-categories

$$(\mathcal{S}^{\wedge}_{\pi})_{/X} \simeq \mathrm{RMod}_G(\mathcal{S}^{\wedge}_{\pi}) \qquad (\mathcal{S}^{\wedge}_{\pi})_{/Y} \simeq \mathrm{RMod}_H(\mathcal{S}^{\wedge}_{\pi})$$

as tensored over $\mathcal{S}^{\wedge}_{\pi}$ (which we regard as a symmetric monoidal ∞-category via the Cartesian product). Let $\mathrm{LinFun}_{\mathcal{S}^{\wedge}_{\pi}}(\mathcal{S}^{\wedge}_{\pi}, (\mathcal{S}^{\wedge}_{\pi})_{/X})(\mathcal{S}^{\wedge}_{\pi})_{/Y}$ denote the ∞-category of $\mathcal{S}^{\wedge}_{\pi}$-linear functors from $(\mathcal{S}^{\wedge}_{\pi})_{/X}$ to $(\mathcal{S}^{\wedge}_{\pi})_{/Y}$ which commute with geometric realizations of simplicial objects. Then Theorem HA.4.8.4.1 supplies an equivalence of ∞-categories

$$\mathrm{LinFun}^{\mathcal{S}^{\wedge}_{\pi}}_{\mathcal{S}^{\wedge}_{\pi}}((\mathcal{S}^{\wedge}_{\pi})_{/X}, (\mathcal{S}^{\wedge}_{\pi})_{/Y}) \simeq {}_G\mathrm{BMod}_H(\mathcal{S}^{\wedge}_{\pi}).$$

Using Theorem E.6.5.1, we can identify the left hand side with the ∞-category $(\mathcal{S}^{\wedge}_{\pi})_{/X \times Y}$. We can describe this equivalence more concretely as follows: it associates to each correspondence $M \to X \times Y$ the functor $(\mathcal{S}^{\wedge}_{\pi})_{/X} \to (\mathcal{S}^{\wedge}_{\pi})_{/Y}$ given by $X' \mapsto M \times_X X'$.

E.7 Profinite Spaces of Finite Type

In this section, we will study the following finiteness condition in profinite homotopy theory:

Definition E.7.0.3. Let X be a profinite space. We will say that X is of *finite type* if, for every π-finite space Y, the mapping space $\mathrm{Map}_{\mathcal{S}^{\wedge}_{\pi}}(X, Y)$ is π-finite.

Remark E.7.0.4. Let X be a profinite space. If X is of finite type, then $\pi_0 X$ is finite. It follows that a profinite space is of finite type if and only if it can be written as a disjoint union of finitely many connected profinite spaces of finite type.

Our main result asserts that for simply connected profinite spaces, Definition E.7.0.3 admits a number of reformulations:

Theorem E.7.0.5. *Let X be a simply connected profinite space. The following conditions are equivalent:*

(1) *The profinite space X is of finite type.*

(2) *For every prime number p and every integer $n \geqslant 0$, the cohomology group $\mathrm{H}^n(X; \mathbf{F}_p)$ is finite (see Definition E.7.1.1).*

(3) *For every prime number p and every integer $n \geqslant 2$, the cokernel of the map $\pi_n X \xrightarrow{p} \pi_n X$ is finite.*

E.7.1 Cohomology of Profinite Spaces

Our first step is to introduce the definitions of the cohomology groups $\mathrm{H}^n(X; \mathbf{F}_p)$ which appear in the statement of Theorem E.7.0.5. We begin by reviewing the definition of cohomology groups in classical homotopy theory.

Definition E.7.1.1. If X is a Kan complex and M is an abelian group, we let $C^*(X; M)$ denote the chain complex of M-valued cochains on X. The construction $X \mapsto C^*(X; M)$ carries homotopy equivalences of Kan complexes to quasi-isomorphisms of chain complexes, and therefore induces a functor of ∞-categories $\mathcal{S}^{\mathrm{op}} \to \mathrm{Mod}_{\mathbf{Z}}$ which we will denote by $C^*(\bullet, M)$.

Applying Proposition HTT.5.3.5.10 , we deduce that there is an essentially unique functor $(\mathcal{S}_\pi^\wedge)^{\mathrm{op}} \to \mathrm{Mod}_{\mathbf{Z}}$ which commutes with filtered colimits and coincides with $C^*(\bullet; M)$ on the full subcategory $\mathcal{S}_\pi \subseteq \mathcal{S}_\pi^\wedge$ of π-finite spaces. We will abuse notation by denoting this functor also by $X \mapsto C^*(X; M)$.

If X is a profinite space and $n \geqslant 0$ is an integer, we let $\mathrm{H}^n(X; M)$ denote the homotopy group $\pi_{-n} C^*(X; M)$. We will refer to $\mathrm{H}^n(X; M)$ as the *nth cohomology group of X with coefficients in M*.

Remark E.7.1.2. Let M be an abelian group, and let X be a profinite space represented by a filtered diagram of π-finite spaces $\{X_\alpha\}$. By definition, $C^*(X; M)$ is given by the filtered colimit $\varinjlim C^*(X_\alpha; M)$. In particular, we have canonical isomorphisms $\mathrm{H}^n(X; M) = \varinjlim \mathrm{H}^n(X_\alpha; M)$.

Example E.7.1.3. Let X be a profinite space and let M be an abelian group. Using Remark E.7.1.2 and Proposition E.5.2.2, we see that $\mathrm{H}^0(X; M)$ can be identified with the set of locally constant M-valued functions on $\pi_0 X$.

Example E.7.1.4. Let G be a profinite group, and let $BG \in \mathcal{S}_{\pi}^{\wedge}$ be the classifying space of G (Example E.6.4.2). For each integer n, we can identify $\mathrm{H}^n(BG; M)$ with the profinite group cohomology of G with coefficients in M (see, for example, [189]).

Remark E.7.1.5. Let M be an abelian group. Then the functor $(\mathcal{S}_{\pi}^{\wedge})^{\mathrm{op}} \to \mathrm{Mod}_{\mathbf{Z}}$ $\quad X \mapsto C^*(X; M)$ is a left Kan extension of its restriction to the full subcategory $\mathcal{S}_{\pi}^{\mathrm{op}} \subseteq (\mathcal{S}_{\pi}^{\wedge})^{\mathrm{op}}$. Because the functor $X \mapsto C^*(\mathrm{Mat}(X); M)$ agrees with $X \mapsto C^*(X; M)$ when X is π-finite, we obtain a comparison map $C^*(X; M) \to C^*(\mathrm{Mat}(X); M)$, depending functorially on X and M. In particular, we obtain natural maps $\mathrm{H}^n(X; M) \to \mathrm{H}^n(\mathrm{Mat}(X); M)$. If X is a profinite space, we can think of $\mathrm{H}^n(X; M)$ as a continuous version of the usual cohomology of the materialization $\mathrm{Mat}(X)$. For example, $\mathrm{H}^0(\mathrm{Mat}(X); M)$ can be identified with the set of all M-valued functions on the set $\pi_0 X$, while $\mathrm{H}^0(X; M)$ can be identified with the set of M-valued functions on $\pi_0 X$ which are continuous with respect to the Stone space topology on $\pi_0 X$ (Example E.7.1.3).

Remark E.7.1.6. Let M be a finite abelian group and let $n \geqslant 0$ be an integer, so that the Eilenberg-MacLane space $K(M, n)$ is π-finite. Then the functor $X \mapsto \pi_0 \mathrm{Map}_{\mathcal{S}_{\pi}^{\wedge}}(X, K(M, n))$ agrees with with the functor $X \mapsto \mathrm{H}^n(X; M)$ on π-finite spaces and commutes with filtered colimits, and therefore agrees with the functor $X \mapsto \mathrm{H}^n(X; M)$ on all profinite spaces. In other words, the functor $X \mapsto \mathrm{H}^n(X; M)$ is representable (in the homotopy category of profinite spaces) by the Eilenberg-MacLane space $K(M, n)$.

Remark E.7.1.7. Let M be an abelian group, let X be a space, and let $X_{\pi}^{\wedge}$ be the profinite completion of X. Composing the map $C^*(X_{\pi}^{\wedge}; M) \to C^*(\mathrm{Mat}(X_{\pi}^{\wedge}); M)$ of Remark E.7.1.5 with pullback along the unit map $X \to \mathrm{Mat}(X_{\pi}^{\wedge})$, we obtain a canonical map $C^*(X_{\pi}^{\wedge}; M) \to C^*(X; M)$. If the abelian group M is finite, then this map is an equivalence. To prove this, it suffices to show that for each $n \geqslant 0$, the induced map $\mathrm{H}^n(X_{\pi}^{\wedge}; M) \to \mathrm{H}^n(X; M)$ is an isomorphism. This is clear: both sides can be identified with the set of homotopy classes of maps from X into the Eilenberg-MacLane space $K(M, n)$ (see Remark E.7.1.6).

E.7.2 The Künneth Formula

Let κ be a commutative ring. Then we can regard the construction $X \mapsto C^*(X; \kappa)$ as a functor from $\mathcal{S}^{\mathrm{op}}$ to the ∞-category of $\mathbb{E}_{\infty}$-algebras over κ. Consequently, the construction Definition E.7.1.1 can be refined to obtain a functor $C^*(\bullet; \kappa) : (\mathcal{S}_{\pi}^{\wedge})^{\mathrm{op}} \to \mathrm{CAlg}_{\kappa}$.

Proposition E.7.2.1. *Let κ be a field, and suppose we are given a pullback diagram*

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow & & \downarrow \phi \\ Y' & \longrightarrow & Y \end{array}$$

of profinite spaces. If Y is simply connected, then the diagram σ :

$$\begin{array}{ccc} C^*(X';\kappa) & \longleftarrow & C^*(X;\kappa) \\ \uparrow & & \uparrow \\ C^*(Y';\kappa) & \longleftarrow & C^*(Y;\kappa) \end{array}$$

is a pushout square in CAlg_κ.

Proof. Using Proposition HTT.5.3.5.15 , we can write the diagram $X \xrightarrow{\phi} Y \xleftarrow{\psi} Y'$ as a filtered limit of diagrams $X_\alpha \xrightarrow{\phi_\alpha} Y_\alpha \xleftarrow{\psi_\alpha} Y'_\alpha$ of π-finite spaces. Since Y is simply connected, we may assume without loss of generality that each Y_α is simply connected. It follows that σ is a filtered colimit of diagrams σ_α :

$$\begin{array}{ccc} C^*(X_\alpha \times_{Y_\alpha} Y'_\alpha;\kappa) & \longleftarrow & C^*(X_\alpha;\kappa) \\ \uparrow & & \uparrow \\ C^*(Y'_\alpha;\kappa) & \longleftarrow & C^*(Y_\alpha;\kappa). \end{array}$$

We may therefore reduce to the case where X, Y, and Y' (and therefore also X') are π-finite. For each $y \in Y$, let X_y denote the homotopy fiber of ϕ over the point y. Using Corollary **??** (and the simple-connectivity of Y), we are reduced to proving that the cohomology groups $\mathrm{H}^n(X_y;\kappa)$ are finite-dimensional as vector spaces over κ, for each $n \geqslant 0$. Using Lemma E.1.6.5, we may assume that X_y has only finitely many simplices of each dimension, in which case the result is obvious. □

Corollary E.7.2.2. *Let X and Y be simply connected profinite spaces. For every field κ, the canonical map*

$$C^*(X;\kappa) \otimes_\kappa C^*(Y;\kappa) \to C^*(X \times Y;\kappa)$$

is an equivalence. In particular, we have a canonical isomorphism

$$\mathrm{H}^*(X;\kappa) \otimes_\kappa \mathrm{H}^*(Y;\kappa) \to \mathrm{H}^*(X \times Y;\kappa).$$

Remark E.7.2.3. Let κ be a field, and suppose we are given a pullback diagram of profinite spaces

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow & & \downarrow \phi \\ Y' & \longrightarrow & Y \end{array}$$

where Y is simply connected. Combining Propositions E.7.2.1 and HA.7.2.1.19 , we obtain a spectral sequence $\{E_r^{p,q}, d_r\}_{r \geqslant 2}$ converging to $\mathrm{H}^*(X'; \kappa)$, whose second page is given by $\mathrm{Tor}_*^{\mathrm{H}^*(Y;\kappa)}(\mathrm{H}^*(Y'; \kappa), \mathrm{H}^*(X; \kappa))$; when Y is a point, this spectral sequence degenerates and yields the isomorphism of Corollary E.7.2.2.

E.7.3 Singular Elements of Profinite Abelian Groups

We now discuss the finiteness condition that appears in condition (3) of Theorem E.7.0.5.

Definition E.7.3.1. Let M be a finite abelian group, and let p be a prime number. We will say that an element $x \in M$ is *p-singular* if $p^d x = 0$ for $d \gg 0$. If M is a profinite abelian group, we will say that an element $x \in M$ is *topologically p-singular* if the sequence $x, px, p^2x, \ldots$ converges to the identity element of M.

Remark E.7.3.2. Let M be a profinite abelian group. An element $x \in M$ is topologically p-singular if and only if, for every open subgroup $N \subseteq M$, the image of x is a p-singular element of the finite abelian group M/N. In particular, the collection of topologically p-singular elements of M forms a closed subgroup $M_p \subseteq M$.

Remark E.7.3.3. Let M be a finite abelian group. Then M is isomorphic to the product $\prod_p M_p$, where p ranges over all prime numbers and M_p denotes the subgroup of M consisting of p-singular elements.

Remark E.7.3.4. Let M be a profinite abelian group. Combining Remarks E.7.3.2 and E.7.3.3, we deduce that M factors canonically as a product $\prod_p M_p$, where p ranges over all prime numbers and M_p denotes the subgroup of p consisting of topologically p-singular elements. Note that each factor M_p can be regarded as a module over the ring $\mathbf{Z}_p = \varprojlim_{d \geqslant 0} \mathbf{Z} / p^d \mathbf{Z}$ of p-adic integers.

Proposition E.7.3.5. *Let M be a profinite abelian group. The following conditions are equivalent:*

(1) *For every prime number p, the subgroup $M_p \subseteq M$ of topologically p-singular elements is finitely generated as a module over the ring $\mathbf{Z}_p$ of p-adic integers.*

(2) *For every prime number p, the subgroup $M_p \subseteq M$ of topologically p-singular elements is isomorphic (as an abstract group) to a finite product of groups of the form $\mathbf{Z}_p$ and $\mathbf{Z}_p / p^d \mathbf{Z}_p$.*

(3) *For every prime number p, there are only finitely many group homomorphisms from M to $\mathbf{F}_p$.*

(4) *For each prime number p, there are only finitely many continuous group homomorphisms from M to $\mathbf{F}_p$.*

(5) *For every prime number p, the quotient M/pM is finite.*

(6) *For every prime number p, the multiplication map $p : M \to M$ has open image.*

Definition E.7.3.6. Let M be a profinite abelian group. We will say that M is *of finite type* if it satisfies the equivalent conditions of Proposition E.7.3.5. If X is a simply connected profinite space, then we will say that X is *of finite type* if the homotopy groups $\{\pi_m X\}_{m \geqslant 2}$ are of finite type (when regarded as profinite abelian groups).

Remark E.7.3.7. Let M be a profinite abelian group. We will say that M is *topologically finitely generated* if there exists a finitely generated subgroup of M which is dense in M. In this case, M can be written as a quotient of $\widehat{\mathbf{Z}}^d$ for some $d \geqslant 0$, where $\widehat{\mathbf{Z}} \simeq \varprojlim \mathbf{Z}/n\mathbf{Z}$ denotes the profinite completion of $\mathbf{Z}$. It follows that if M is topologically finitely generated, then M is of finite type. However, the converse fails. For example, the profinite group $\prod_p (\mathbf{Z}/p\mathbf{Z})^p$ is of finite type, but is not topologically finitely generated.

Proof of Proposition E.7.3.5. The implication (1) $\Rightarrow$ (2) follows from the structure theory of finitely generated modules over the discrete valuation ring $\mathbf{Z}_p$. Since the inclusion $M_p \hookrightarrow M$ induces an isomorphism $M_p/pM_p \simeq M/pM$, the implications (2) $\Rightarrow$ (3) $\Rightarrow$ (4) are obvious. Note that the maps $p : M \to M$ are closed, so that each the quotient M/pM inherits the structure of a compact Hausdorff topological group. In particular, M/pM is finite if and only if the identity element comprises an open subset of M/pM, which is equivalent to the requirement that pM is open in M. This proves (5) $\Leftrightarrow$ (6).

We next prove that (4) $\Rightarrow$ (5). Write M as an inverse limit $\varprojlim M_\alpha$, where each M_α is a finite abelian group. Let $\mathrm{Vect}^{\mathrm{fin}}_{\mathbf{F}_p}$ denote the category of finite-dimensional vector spaces over the finite field $\mathbf{F}_p$. Then we can identify M/pM with the inverse limit of the diagram $\{M_\alpha/pM_\alpha\}$ in $\mathrm{Vect}^{\mathrm{fin}}_{\mathbf{F}_p}$, representing a pro-object of $\mathrm{Vect}^{\mathrm{fin}}_{\mathbf{F}_p}$. Vector space duality determines an equivalence of categories $(\mathrm{Vect}^{\mathrm{fin}}_{\mathbf{F}_p})^{\mathrm{op}} \simeq \mathrm{Vect}^{\mathrm{fin}}_{\mathbf{F}_p}$, which extends to an equivalence $\mathrm{Pro}(\mathrm{Vect}^{\mathrm{fin}}_{\mathbf{F}_p})^{\mathrm{op}} \simeq \mathrm{Ind}(\mathrm{Vect}^{\mathrm{fin}}_{\mathbf{F}_p}) \simeq \mathrm{Vect}_{\mathbf{F}_p}$. The image of the diagram $\{M_\alpha/pM_\alpha\}$ under this equivalence can be identified with the set $\mathrm{Hom}_c(M, \mathbf{F}_p)$ of continuous group homomorphisms from M to $\mathbf{F}_p$. Condition (4) implies that $\mathrm{Hom}_c(M, \mathbf{F}_p) \in \mathrm{Vect}^{\mathrm{fin}}_{\mathbf{F}_p} \subseteq \mathrm{Vect}_{\mathbf{F}_p}$: that is, the Ind-object obtained by applying vector space duality to $\{M_\alpha/pM_\alpha\}$ is constant. It follows that the Pro-system $\{M_\alpha/pM_\alpha\}$ is also constant, so that M/pM is a retract of some M_α/pM_α, and is in particular finite.

We now complete the proof by showing that (5) $\Rightarrow$ (1). Replacing M by M_p, we may suppose that M is a p-profinite abelian group (see Definition **??**). Choose a basis $\{\overline{x}_i\}_{1 \leqslant i \leqslant n}$ for the $\mathbf{F}_p$-vector space M/pM. Each $\overline{x}_i$ can be lifted to an element $x_i \in M$, which determines a group homomorphism $\phi_i : \mathbf{Z} \to M$. Since M is a profinite p-group, the map ϕ_i factors through the p-profinite completion $\mathbf{Z}_p$ of $\mathbf{Z}$. We therefore obtain a sequence of continuous maps $\overline{\phi}_i : \mathbf{Z}_p \to M$. Since M is abelian, we can add these homomorphisms to obtain a continuous group homomorphism $\overline{\phi} : \mathbf{Z}_p^n \to M$. We claim that $\overline{\phi}$ is surjective. Since $\mathbf{Z}_p^n$ is compact, it will suffice to show that the image of $\overline{\phi}$ is dense. In other words, we must show that if $\psi : M \to N$ is a continuous surjection for some finite group N, then the composite map $\psi \circ \overline{\phi} : \mathbf{Z}_p^n \to N$ is surjective. Since the action of p is nilpotent on N, it suffices to show that the composite map $\theta : \mathbf{Z}_p^n \to N/pN$ is surjective (by Nakayama's lemma). This is clear, since θ is a composition of surjections $\mathbf{Z}_p^n \to \mathbf{F}_p^n \simeq M/pM \to N/pN$. □

E.7.4 The Hurewicz Theorem

We now begin to connect Definition E.7.3.6 with finiteness hypotheses on profinite spaces.

Proposition E.7.4.1. *Let X be a profinite space which is n-connective for some $n \geqslant 1$, and let M be an abelian group. There are canonical isomorphisms*

$$\mathrm{H}^m(X; M) \simeq \begin{cases} M & \text{if } m = 0 \\ 0 & \text{if } 0 < m < n \\ \mathrm{Hom}_c(\pi_n X, M) & \text{if } m = n. \end{cases}$$

Here $\mathrm{Hom}_c(\pi_n X, M)$ denotes the collection of continuous group homomorphisms from $\pi_n(X, x)$ to M (where we regard M as endowed with the discrete topology), where x is an arbitrarily chosen base point of X.

Corollary E.7.4.2. *Let X be a profinite space which is n-connective for some $n \geqslant 2$. The following conditions are equivalent:*

(1) *The profinite abelian group $\pi_n X$ is of finite type.*

(2) *The cohomology group $\mathrm{H}^n(X; \mathbf{F}_p)$ is finite, for every prime number p.*

Proof of Proposition E.7.4.1. Choose a point $x \in X$. Since X is n-connective, we can write X as the limit of a filtered diagram $\{X_\alpha\}$ of n-connective π-finite spaces. Let x_α denote the image of x in X_α, and let $\pi_n X_\alpha$ denote the finite group $\pi_n(X_\alpha, x_\alpha)$. Since each X_α is n-connective, the Hurewicz and universal coefficient theorems of classical homotopy theory supply isomorphisms

$$\mathrm{H}^m(X_\alpha; M) \simeq \begin{cases} M & \text{if } m = 0 \\ 0 & \text{if } 0 < m < n \\ \mathrm{Hom}(\pi_n X_\alpha, M) & \text{if } m = n. \end{cases}$$

Since $\mathrm{H}^*(X; M) \simeq \varinjlim \mathrm{H}^*(X_\alpha; M)$, we obtain canonical isomorphisms

$$\mathrm{H}^m(X; M) \simeq \begin{cases} M & \text{if } m = 0 \\ 0 & \text{if } 0 < m < n \\ \varinjlim \mathrm{Hom}(\pi_n X_\alpha, \mathbf{F}_p) & \text{if } m = n. \end{cases}$$

It now suffices to observe that the profinite group $\pi_n X$ is given as the limit of the filtered system of finite groups $\pi_n X$, so that $\mathrm{Hom}_c(\pi_n X, M) \simeq \varinjlim \mathrm{Hom}(\pi_n X_\alpha, M)$. □

E.7.5 A Convergence Theorem

The main ingredient in our proof of Theorem E.7.0.5 is the following technical result, which will also play an important role in §E.8:

Proposition E.7.5.1. *Let $n \geqslant 1$, let p be a prime number, and consider the tower of spaces $\{K(\mathbf{Z}/p^a\mathbf{Z}, n)\}_{a \geqslant 0}$ having limit $K(\mathbf{Z}_p, n) \in \mathcal{S}$. For every integer $m \geqslant 0$, the pro-system of abelian groups $\mathrm{H}_m(K(\mathbf{Z}/p^a\mathbf{Z}, n); \mathbf{F}_p)$ is equivalent to the constant pro-system with value $\mathrm{H}_m(K(\mathbf{Z}_p, n); \mathbf{F}_p)$.*

Remark E.7.5.2. If M is a finite abelian group, then the Eilenberg-MacLane spaces $K(M, n)$ can be represented by Kan complexes having only finitely many simplices of each dimension. It follows immediately that the groups $\mathrm{H}_m(K(M, n); \mathbf{F}_p)$ are finite for every prime number p and every integer $m \geqslant 0$. Proposition E.7.5.1 implies that the tower of abelian groups $\{\mathrm{H}_m(K(\mathbf{Z}/p^d\mathbf{Z}, n); \mathbf{F}_p)\}_{d \geqslant 0}$ is equivalent (as a Pro-abelian group) to the abelian group $\mathrm{H}_m(K(\mathbf{Z}_p, n); \mathbf{F}_p)$. It follows that the group $\mathrm{H}_m(K(\mathbf{Z}_p, n); \mathbf{F}_p)$ is isomorphic to a retract of $K(\mathbf{Z}/p^d\mathbf{Z}, n); \mathbf{F}_p)$ for $d \gg 0$. In particular, $\mathrm{H}_m(K(\mathbf{Z}_p, n); \mathbf{F}_p)$ is a finite group.

For the proof of Proposition E.7.5.1, we will need the following standard fact:

Lemma E.7.5.3. *Let M be an abelian group, and let p be a prime number for which the map $p : M \to M$ is an isomorphism. Then, for every integer $n \geqslant 1$, the augmentation map $C_*(K(M, n); \mathbf{F}_p) \to \mathbf{F}_p$ is an equivalence.*

Proof. For every abelian group N, the classifying space BN can be constructed as a simplicial abelian group, so that the homology $\mathrm{H}_*(BN; \mathbf{F}_p)$ inherits the structure of a graded commutative ring. Note that we have canonical isomorphisms $\mathrm{H}_1(BN; \mathbf{F}_p) \simeq (\pi_1 BN)/p(\pi_1 BN) \simeq N/pN$. If N is a free abelian group of finite rank, an elementary calculation shows that this extends to an isomorphism of $\mathrm{H}_*(BN; \mathbf{F}_p)$ with an exterior algebra (over $\mathbf{F}_p$) on the vector space N/pN. More generally, if N is a torsion-free abelian group, then writing N as a union of its finitely generated submodules, we obtain an isomorphism $\mathrm{H}_*(BN; \mathbf{F}_p) \simeq \bigwedge^*(N/pN)$.

Choose an exact sequence of $\mathbf{Z}[p^{-1}]$-modules $0 \to Q \to P \to M \to 0$, where P is a free $\mathbf{Z}[p^{-1}]$-module. Then P and Q are torsion-free, and the quotients P/pP and Q/pQ are trivial. It follows from the above arguments that $C_*(BP; \mathbf{F}_p) \simeq C_*(BQ; \mathbf{F}_p) \simeq \kappa$. Note that we can identify BM with the quotient of BP by the action of BQ, so that

$$C_*(BM; \mathbf{F}_p) \simeq C_*(BP; \mathbf{F}_p) \otimes_{C_*(BQ; \mathbf{F}_p)} \mathbf{F}_p \simeq \mathbf{F}_p \otimes_{\mathbf{F}_p} \mathbf{F}_p \simeq \mathbf{F}_p.$$

This completes the proof in the special case $n = 1$.

We handle the general case using induction on n. Assume that the counit map $C_*(K(M,n);\mathbf{F}_p) \to \mathbf{F}_p$ is an equivalence. We can regard $K(M,n)$ as a simplicial abelian group, whose classifying space can be identified with $K(M,n+1)$. We therefore have a canonical equivalence

$$C_*(K(M,n+1);\mathbf{F}_p) \simeq \mathbf{F}_p \otimes_{C_*(K(M,n);\mathbf{F}_p)} \mathbf{F}_p \simeq F_p \otimes_{\mathbf{F}_p} \mathbf{F}_p \simeq \mathbf{F}_p,$$

as desired. □

Proof of Proposition E.7.5.1. We first treat the case $n = 1$. We have a fiber sequence of simply connected spaces $K(\mathbf{Z},1) \to K(\mathbf{Z}_p,1) \to K(\mathbf{Z}_p/\mathbf{Z},1)$. Since multiplication by p is invertible on $\mathbf{Z}_p/\mathbf{Z}$, we have $\mathrm{H}_m(K(\mathbf{Z}_p/\mathbf{Z},1);\mathbf{F}_p) \simeq 0$ for $m > 0$. Using the Serre spectral sequence, we deduce that the map $K(\mathbf{Z},1) \to K(\mathbf{Z}_p,1)$ induces an isomorphism on homology groups with coefficients in $\mathbf{F}_p$. It will therefore suffice to show that, for each $m \geqslant 0$, the pro-system $\{\mathrm{H}_m(K(\mathbf{Z}/p^a\mathbf{Z},1);\mathbf{F}_p)\}_{a \geqslant 0}$ is equivalent to the constant pro-system taking the value

$$\mathrm{H}_m(K(\mathbf{Z},1);\mathbf{F}_p) \simeq \begin{cases} \mathbf{F}_p & \text{if } m \in \{0,1\} \\ 0 & \text{otherwise.} \end{cases}$$

For each $a \geqslant 1$, let $\epsilon_a \in \mathrm{H}^1(K(\mathbf{Z}/p^a\mathbf{Z},1);\mathbf{F}_p)$ classify the unit map $\mathbf{Z}/p^a\mathbf{Z} \to \mathbf{Z}/p\mathbf{Z} \simeq \mathbf{F}_p$, and let $\eta_a \in \mathrm{H}^2(K(\mathbf{Z}/p^a\mathbf{Z},1);\mathbf{F}_p)$ classify the central extension $0 \to \mathbf{F}_p \to \mathbf{Z}/p^{a+1}\mathbf{Z} \to \mathbf{Z}/p^a\mathbf{Z} \to 0$. Then $\mathrm{H}^*(K(\mathbf{Z}/p^a\mathbf{Z},1);\mathbf{F}_p)$ has a basis given by the products η^i and $\epsilon_a\eta_a^i$ for $i \geqslant 0$. Note that the image of η_a in $\mathrm{H}^2(K(\mathbf{Z}/p^{a+1}\mathbf{Z},1);\mathbf{F}_p)$ is zero (since the central extension classified by η_a splits over $\mathbf{Z}/p^{a+1}\mathbf{Z}$), and the image of ϵ_a in $\mathrm{H}^1(K(\mathbf{Z}/p^{a+1}\mathbf{Z},1))$ is ϵ_{a+1}. It follows that the maps

$$\mathrm{H}^m(K(\mathbf{Z}/p\mathbf{Z},1);\mathbf{F}_p) \to \mathrm{H}^m(K(\mathbf{Z}/p^2\mathbf{Z},1);\mathbf{F}_p) \to \mathrm{H}^m(K(\mathbf{Z}/p^3\mathbf{Z},1);\mathbf{F}_p) \to \cdots$$

are isomorphisms for $m \leqslant 1$ and zero for $m > 1$. Passing to dual spaces, we conclude that the tower

$$\cdots \to \mathrm{H}_m(K(\mathbf{Z}/p^3\mathbf{Z},1);\mathbf{F}_p) \to \mathrm{H}_m(K(\mathbf{Z}/p^2\mathbf{Z},1);\mathbf{F}_p) \to \mathrm{H}_m(K(\mathbf{Z}/p\mathbf{Z},1);\mathbf{F}_p)$$

consists of isomorphisms for $m \leqslant 1$ and zero maps for $m > 1$. We now complete the proof (in the case $n = 1$) by observing that the maps $\mathrm{H}_m(K(\mathbf{Z},1);\mathbf{F}_p) \to \mathrm{H}_m(K(\mathbf{Z}/p\mathbf{Z},1);\mathbf{F}_p)$ are isomorphisms for $m \leqslant 1$.

We now treat the general case. Since $\mathrm{Mod}_{\mathbf{F}_p}$ is a presentable symmetric monoidal ∞-category, there is a unique colimit-preserving symmetric monoidal functor $\mathcal{S} \to \mathrm{Mod}_{\mathbf{F}_p}$. Let us denote this functor by $X \mapsto C_*(X)$. Note that the homology groups of a space X are given by the formula $\mathrm{H}_m(X;\mathbf{F}_p) = \pi_m C_*(X)$. It will therefore suffice to prove the following:

($*$) For every integer m, the Pro-object $\{\tau_{\leqslant m} C_*(K(\mathbf{Z}/p^a\mathbf{Z}, n))\}_{a \geqslant 0}$ of $\mathrm{Mod}_{\mathbf{F}_p}$ is equivalent to the constant $\mathbf{F}_p$-module spectrum $\tau_{\leqslant m} C_*(K(\mathbf{Z}_p, n))$.

Since the functor $X \mapsto \tau_{\leqslant m} C_*(X)$ is a successive extension of the functors $X \mapsto \mathrm{H}_a(X; \mathbf{F}_p)$ for $0 \leqslant a \leqslant m$, the proof given above shows that ($*$) holds when $n = 1$. To prove ($*$) in general, we proceed by induction on n. Suppose that $n > 1$. Let $X_\bullet$ be a Čech nerve of the map $* \to K(\mathbf{Z}_p, n)$, so that $X_\bullet$ is a group object of $\mathcal{S}$. Since C_* is a symmetric monoidal functor, we deduce that $C_*(X_1)$ is an associative algebra object of $\mathrm{Mod}_{\mathbf{F}_p}$; here $X_1 = * \times_{K(\mathbf{Z}_p, n)} * \simeq K(\mathbf{Z}_p, n-1)$. Since $K(\mathbf{Z}_p, n)$ is connected, the canonical map $|X_\bullet| \to K(\mathbf{Z}_p, n)$ is an equivalence. Because C_* preserves colimits, we deduce that $C_*(K(\mathbf{Z}_p, n))$ is given by $|C_*(X_\bullet)|$. Unwinding the definitions, we see that this geometric realization corresponds to the bar construction $\mathbf{F}_p \otimes_{C_*(K(\mathbf{Z}_p, n-1))} \mathbf{F}_p$. Similar reasoning yields an equivalence $C_*(K(\mathbf{Z}/p^a\mathbf{Z}, n)) \simeq \mathbf{F}_p \otimes_{C_*(K(\mathbf{Z}/p^a\mathbf{Z}, n-1))} \mathbf{F}_p$ for each $a \geqslant 0$. We have a commutative diagram of Pro-objects

$$\begin{array}{ccc}
\mathbf{F}_p \otimes_{C_*(K(\mathbf{Z}_p, n-1))} \mathbf{F}_p & \longrightarrow & \{\mathbf{F}_p \otimes_{C_*(K(\mathbf{Z}/p^a\mathbf{Z}, n-1))} \mathbf{F}_p\} \\
\downarrow & & \downarrow \\
C_*(K(\mathbf{Z}_p, n)) & \longrightarrow & \{C_*(K(\mathbf{Z}/p^a\mathbf{Z}, n))\}
\end{array}$$

where the vertical maps are equivalences. Using the inductive hypothesis, we deduce that upper horizontal map becomes an equivalence after applying the truncation functor $\tau_{\leqslant m}$. It follows that the lower horizontal map becomes an equivalence after applying the truncation functor $\tau_{\leqslant m}$ as well, which proves ($*$). □

E.7.6 Profinite Eilenberg-MacLane Spaces

We now discuss Eilenberg-MacLane spaces in the setting of profinite homotopy theory.

Notation E.7.6.1. Let $n \geqslant 1$ be an integer, and let G be a profinite group (which we assume to be abelian if $n \geqslant 2$). We let $\widehat{K}(G, n)$ denote the profinite space represented by the filtered diagram $\{K(G/U, n)\}$, where U ranges over all open normal subgroups of G.

Suppose that X is a simply connected profinite space, so that X can be represented by a filtered diagram $\{X_\alpha\}$ of simply connected π-finite spaces X_α. Choosing a base point $x \in X$, we obtain a collection of fiber sequences $\tau_{\leqslant n} X_\alpha \to \tau_{\leqslant n-1} X_\alpha \to K(\pi_n X_\alpha, n+1)$, depending functorially on α. Using Remark E.5.2.5, we see that the filtered diagram $\{\pi_n X_\alpha\}$ is isomorphic (as a Pro-object) to the diagram $\{\pi_n X/U\}$, where U ranges over all open subgroups of $\pi_n X$. Passing to the inverse limit over α, we obtain a fiber sequence of profinite spaces $\tau_{\leqslant n} X \to \tau_{\leqslant n-1} X \to \widehat{K}(\pi_n X, n+1)$.

Proposition E.7.6.2. *Let M be a profinite abelian group, let p be a prime number, and let $M_p \subseteq M$ be the subgroup consisting of topologically p-singular elements (see Definition E.7.3.1). For every integer $n \geqslant 1$, the canonical map*

$$C^*(\widehat{K}(M,n); \mathbf{F}_p) \to C^*(\widehat{K}(M_p,n); \mathbf{F}_p)$$

is an equivalence.

Proof. Writing M as an inverse limit of finite abelian groups, we can reduce to the case where M is finite. In this case, we can write $M = M_p \times M'$, where M' is a subgroup of M on which p acts invertibly. We then have an equivalence

$$C_*(K(M,n); \mathbf{F}_p) \simeq C_*(K(M_p,n); \mathbf{F}_p) \otimes_{\mathbf{F}_p} C_*(K(M',n); \mathbf{F}_p),$$

so that the desired result follows from Lemma E.7.5.3. □

Proposition E.7.6.3. *Let X be a simply connected profinite space, and suppose that the profinite groups $\pi_m X$ are of finite type for $m \geqslant 2$. Then the cohomology groups $\mathrm{H}^n(X; M)$ are finite for every integer $n \geqslant 0$ and every finite abelian group M.*

Proof. Every exact sequence of abelian groups $0 \to M' \to M \to M'' \to 0$ determines a fiber sequence $C^*(X; M') \to C^*(X; M) \to C^*(X; M'')$, hence a long exact sequence of cohomology groups

$$\cdots \to \mathrm{H}^{n-1}(X; M'') \to \mathrm{H}^n(X; M') \to \mathrm{H}^n(X; M) \to \mathrm{H}^n(X; M'') \to \mathrm{H}^{n+1}(X; M') \to \cdots$$

It will therefore suffice to prove finiteness after replacing M by M' and M''. Choosing an appropriate filtration of M, we can reduce to the case where $M = \mathbf{F}_p$ for some prime number p.

Note that the canonical map $\mathrm{H}^n(\tau_{\leqslant n} X; \mathbf{F}_p) \to \mathrm{H}^n(X; \mathbf{F}_p)$ is an isomorphism for every integer n. Consequently, to prove the finiteness of $\mathrm{H}^n(X; \mathbf{F}_p)$, we may replace X by $\tau_{\leqslant n} X$, and thereby reduce to the case where X is n-truncated. We proceed by induction on n, the case $n \leqslant 1$ being trivial (since X is assumed to be simply connected). To carry out the inductive step, set $M = \pi_n X$, so that Notation E.7.6.1 supplies a fiber sequence

$$X \to \tau_{\leqslant n-1} X \to \widehat{K}(M, n+1).$$

Applying Proposition E.7.2.1, we obtain a pushout diagram

$$\begin{array}{ccc} C^*(\widehat{K}(M,n+1); \mathbf{F}_p) & \longrightarrow & \mathbf{F}_p \\ \downarrow & & \downarrow \\ C^*(\tau_{\leqslant n-1} X; \mathbf{F}_p) & \longrightarrow & C^*(X; \mathbf{F}_p) \end{array}$$

of $\mathbb{E}_\infty$-algebras over $\mathbf{F}_p$. Using the inductive hypothesis and Lemma **??**, we are reduced to proving that $C^*(\widehat{K}(M, n+1); \mathbf{F}_p)$ is locally finite. Using Proposition E.7.6.2, we see that this is equivalent to the local finiteness of $C^*(\widehat{K}(M_p, n+1); \mathbf{F}_p)$. Since X is of finite type, we can write M_p as product of finitely many factors isomorphic to $\mathbf{Z}_p$ or $\mathbf{Z}/p^d\mathbf{Z}$. Using Proposition E.7.2.1 again, we are reduced to proving that the $\mathbb{E}_\infty$-algebras $C^*(\widehat{K}(\mathbf{Z}_p, n+1); \mathbf{F}_p)$ and $C^*(K(\mathbf{Z}/p^d\mathbf{Z}, n+1); \mathbf{F}_p)$ are locally finite, which follows from Remark E.7.5.2. □

E.7.7 The Proof of Theorem E.7.0.5

Let X be a simply connected profinite space. We wish to prove that the following conditions are equivalent:

(1) The profinite space X is of finite type.

(2) For every prime number p and every integer $n \geqslant 0$, the cohomology group $\mathrm{H}^n(X; \mathbf{F}_p)$ is finite.

(3) For every prime number p and every integer $n \geqslant 2$, the cokernel of the map $\pi_n X \xrightarrow{p} \pi_n X$ is finite.

The implicatoin (1) ⇒ (2) follows from Remark E.7.1.6. We next show that (2) implies (1). Assume that X satisfies (2) and let Y be a π-finite space; We wish to show that the mapping space $\mathrm{Map}_{\mathcal{S}_\pi^\wedge}(X, Y)$ is π-finite. Since X is simply connected, the diagonal embedding $\tau_{\leqslant 1} Y \to \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(X, \tau_{\leqslant 1} Y)$ is a homotopy equivalence. It follows that $\mathrm{Map}_{\mathcal{S}_\pi^\wedge}(X, \tau_{\leqslant 1} Y)$ is π-finite. Consequently, we are reduced to proving that the homotopy fibers of the map $\mathrm{Map}_{\mathcal{S}_\pi^\wedge}(X, Y) \to \mathrm{Map}_{\mathcal{S}_\pi^\wedge}(X, \tau_{\leqslant 1} Y)$ are π-finite. Since X is simply-connected, every map $X \to \tau_{\leqslant 1} Y$ is homotopic to a constant map. We may therefore replace Y by one of the homotopy fibers of the map $Y \to \tau_{\leqslant 1} Y$, and thereby reduce to the case where Y is simply connected.

Since Y is π-finite, it is n-truncated for some integer n. We proceed by induction on n, the case $n \leqslant 1$ being trivial. Since Y is simply connected, there exists a fiber sequence $Y \to \tau_{\leqslant n-1} Y \to K(M, n+1)$, where $M = \pi_n Y$. The inductive hypothesis implies that the mapping space $\mathrm{Map}_{\mathcal{S}_\pi^\wedge}(X, \tau_{\leqslant n-1} Y)$ is π-finite. It will therefore suffice to show that the mapping space $\mathrm{Map}_{\mathcal{S}_\pi^\wedge}(X, K(M, n+1))$ is π-finite. Using Remark E.7.1.6, we are reduced to proving that the cohomology groups $\mathrm{H}^d(X; M)$ are finite for every integer d. The collection of finite abelian groups M which satisfy this condition are closed under extension. We may therefore reduce to the case where M is a cyclic group of prime order, in which case the desired result follows from (2). This completes the proof that (2) ⇒ (1).

The implication (3) ⇒ (2) follows from Proposition E.7.6.3. We will complete the proof of Theorem E.7.0.5 by showing that (2) ⇒ (3). Let X be a simply connected profinite space, and suppose that the cohomology group $\mathrm{H}^n(X; \mathbf{F}_p)$ is finite for every integer n and every prime number p. We wish to prove that each homotopy group $\pi_m X$ is of finite type as a profinite abelian group. We proceed by induction on m, the case $m \leqslant 1$ being trivial. To carry out the inductive step, assume that $\pi_d X$ is of finite type for $d < m$. Choose a base point $x \in X$, and form a fiber sequence of profinite spaces

$$Y \to X \to \tau_{\leqslant m-1} X.$$

For every prime number p, Proposition E.7.2.1 supplies a pushout diagram of $\mathbb{E}_\infty$-algebras

$$\begin{array}{ccc} C^*(\tau_{\leqslant m-1}X; \mathbf{F}_p) & \longrightarrow & \mathbf{F}_p \\ \downarrow & & \downarrow \\ C^*(X; \mathbf{F}_p) & \longrightarrow & C^*(Y; \mathbf{F}_p). \end{array}$$

Since the homotopy groups of $\tau_{\leqslant m-1} X$ are of finite type, Proposition E.7.6.3 guarantees that the $\mathbb{E}_\infty$-algebra $C^*(\tau_{\leqslant m-1}X; \mathbf{F}_p)$ is locally finite. Because $C^*(X; \mathbf{F}_p)$ is also locally finite, Lemma **??** implies that $C^*(Y; \mathbf{F}_p)$ is locally finite. In particular, the group $\mathrm{H}^m(Y; \mathbf{F}_p)$ is finite. Proposition E.7.4.1 supplies an isomorphism

$$\mathrm{H}^m(Y; \mathbf{F}_p) \simeq \mathrm{Hom}_c(\pi_m Y; \mathbf{F}_p) \simeq \mathrm{Hom}_c(\pi_m X; \mathbf{F}_p).$$

It follows that $\mathrm{Hom}_c(\pi_m X; \mathbf{F}_p)$ is finite for every prime number p, so that the profinite abelian group $\pi_m X$ is of finite type as desired(Proposition E.7.3.5).

We close this section by mentioning a simple consequence of Theorem E.7.0.5:

Corollary E.7.7.1. *Let X be a simply connected space, and suppose that the cohomology groups $\mathrm{H}^n(X; \mathbf{F}_p)$ are finite for every integer $n \geqslant 2$ and every prime number p. Then the profinite completion $X^\wedge_\pi$ is a simply connected profinite space of finite type.*

Proof. Combine Theorem E.7.0.5 with Remark E.7.1.7 and Corollary E.4.3.2. □

E.8 Materialization

In §E.3, we proved that the materialization functor $\mathrm{Mat} : \mathcal{S}^\wedge_\pi \to \mathcal{S}$ is conservative (Theorem E.3.1.6). In this section, we will show that the materialization functor is fully faithful when restricted to profinite spaces which are simply connected and of finite type. Moreover, we show that the essential image of this restriction admits a simple algebraic description (Theorem E.8.2.1). Moreover, a space Y belongs to the essential image of this restriction if and only if the homotopy groups of Y satisfy a purely algebraic condition (Theorem E.8.2.1).

E.8.1 Congruence Completion of Abelian Groups

We begin by reviewing some elementary algebra.

Definition E.8.1.1. Let M be an abelian group. We will say that M is *congruence-finite* if, for every positive integer d, the kernel and cokernel of the map $M \xrightarrow{d} M$ are finite abelian groups. If M is a congruence-finite abelian group, we let $\widehat{M}$ denote the inverse limit $\varprojlim_d M/dM$, where d ranges over all positive integers. We will refer to $\widehat{M}$ as the *congruence completion* of M. We will say that M is *congruence-separated* if it is congruence-finite, and the canonical map $\theta : M \to \widehat{M}$ is injective. We will say that M is *congruence-complete* if M is congruence-finite and θ is an isomorphism.

Remark E.8.1.2. For every congruence-finite abelian group M, we will regard the congruence-completion $\widehat{M} = \varprojlim M/dM$ as a profinite abelian group, equipped with the inverse limit topology.

Remark E.8.1.3. Let M be an abelian group. Then M is congruence-finite if and only if, for every prime number p, the kernel and cokernel of the map $M \xrightarrow{p} M$ are finite abelian groups.

Remark E.8.1.4. The group $\mathbf{Z}$ is congruence-separated. Its congruence completion $\widehat{\mathbf{Z}} = \varprojlim \mathbf{Z}/N\mathbf{Z}$ is a commutative ring, which is isomorphic to the product $\prod_p \mathbf{Z}_p$.

Example E.8.1.5. Let M be a finitely generated abelian group. Then M is congruence-separated. Moreover, the congruence-completion of M is isomorphic to the tensor product $\widehat{\mathbf{Z}} \otimes_{\mathbf{Z}} M$.

The relevance of Definition E.8.1.1 to our investigation stems from the following characterization of the class of congruence-complete abelian groups:

Proposition E.8.1.6. *Let* Ab *denote the category of abelian groups, and let* $\mathcal{C}$ *denote the category of profinite abelian groups of finite type. Then the forgetful functor* $\theta : \mathcal{C} \to \mathrm{Ab}$ *is fully faithful, and its essential image consists of those abelian groups which are congruence-complete.*

Proof. Let M and N be profinite abelian groups. To prove that θ is fully faithful, it will suffice to show that if M is of finite type, then every group homomorphism $f : M \to N$ is continuous. Let $N' \subseteq N$ be an open subgroup, so that N/N' is finite. Choose an integer $d > 0$ which annihilates N/N'. Then $f^{-1}(N')$ contains the subgroup $dM \subseteq M$. Since M has finite type, Proposition E.7.3.5 implies that dM is a closed subgroup of finite index in M, hence open. It follows that $f^{-1}(N')$ is also an open subgroup of M. Allowing N' to vary over all open subgroups of N, we deduce that f is continuous. This completes the proof that θ is fully faithful.

We next prove that if M is a profinite abelian group of finite type, then M is congruence-complete (when regarded as an abstract abelian group). We first claim that M is congruence-finite. For this, it will suffice to show that for every prime number p, the map $M \xrightarrow{p} M$ has finite kernel and cokernel (Remark E.8.1.3). Without loss of generality, we may replace M by the subgroup $M_p \subseteq M$ of topologically p-singular elements. In this case, M is a finitely generated module over $\mathbf{Z}_p$ (Proposition E.7.3.5) and the result is obvious.

Arguing as above, we see that the subgroup $dM \subseteq M$ is open for each $d > 0$, so that the projection maps $M \to M/dM$ are continuous. It follows that the natural map $f : M \to \widehat{M}$ is continuous. The image of f is evidently dense in $\widehat{M}$. Since M is compact, we conclude that f is surjective. To prove the injectivity of M, it will suffice to show that every element $x \in \bigcap_d dM$ is zero. Since M is a profinite abelian group, it will suffice to show that the image of x vanishes in each quotient M/M', where M' is an open subgroup of M. The group M/M' is finite, hence annihilated by some integer $d > 0$. Then $dM \subseteq M'$, so that $x \mapsto 0 \in M/M'$ as desired.

Conversely, suppose we are given a congruence-complete abelian group N; we wish to show that N belongs to the essential image of θ. Since N is congruence-complete, we have an isomorphism of abstract groups $u : N \simeq \widehat{N}$. It will therefore suffice to show that the profinite abelian group $\widehat{N}$ has finite type. Using Proposition E.7.3.5, we are reduced to proving that $\widehat{N}/p\widehat{N}$ is finite for every prime number p. This is clear, since u induces an isomorphism $\widehat{N}/p\widehat{N} \simeq N/pN$. □

E.8.2 Materialization for Profinite Spaces of Finite Type

We can now formulate the main result of this section:

Theorem E.8.2.1. *Let $(\mathcal{S}^{\wedge}_{\pi})_{\mathrm{ft}}$ denote the full subcategory of $\mathcal{S}^{\wedge}_{\pi}$ spanned by those profinite spaces which are simply connected and of finite type. Then the materialization functor $\mathrm{Mat} : \mathcal{S}^{\wedge}_{\pi} \to \mathcal{S}$ restricts to a fully faithful embedding $\mathrm{Mat}_{\mathrm{ft}} : \mathcal{S}^{\wedge}_{\pi})_{\mathrm{ft}} \to \mathcal{S}$. Moreover, a space X belongs to the essential image of $\mathrm{Mat}_{\mathrm{ft}}$ if and only if it is simply connected and each homotopy group $\pi_n X$ is congruence-complete.*

Remark E.8.2.2. Theorem E.8.2.1 can be regarded as a homotopy-theoretic analogue of Proposition E.8.1.6.

We will deduce Theorem E.8.2.1 from the following pair of assertions, which we prove later in this section:

Proposition E.8.2.3. *Let X be a profinite space. If X is simply connected and of finite type, then the counit map $v : \mathrm{Mat}(X)^{\wedge}_{\pi} \to X$ is an equivalence of profinite spaces (that is, X can be recovered as the profinite completion of its materialization).*

Proposition E.8.2.4. *Let X be a simply connected space, and suppose that each homotopy group $\pi_n X$ is congruence-separated. Then:*

(a) *For every prime number p and every integer $n \geqslant 0$, the cohomology group $\mathrm{H}^n(X; \mathbf{F}_p)$ is finite.*

(b) *The unit map $X \to \mathrm{Mat}(X^{\wedge}_{\pi})$ induces maps $\pi_n X \to \pi_n X^{\wedge}_{\pi}$ which exhibit each $\pi_n X^{\wedge}_{\pi}$ as a congruence-completion of $\pi_n X$.*

Proof of Theorem E.8.2.1. Let X and Y be profinite spaces. Then the canonical map

$$\mathrm{Map}_{\mathcal{S}^{\wedge}_{\pi}}(X, Y) \to \mathrm{Map}_{\mathcal{S}}(\mathrm{Mat}(X), \mathrm{Mat}(Y)) \simeq \mathrm{Map}_{\mathcal{S}^{\wedge}_{\pi}}(\mathrm{Mat}(X)^{\wedge}_{\pi}, Y)$$

is given by composition with the counit map $v : \mathrm{Mat}(X)^{\wedge}_{\pi} \to X$. If X is simply connected and of finite type, then v is an equivalence (Proposition E.8.2.3). It follows that Mat is fully faithful when restricted to $(\mathcal{S}^{\wedge}_{\pi})_{\mathrm{ft}}$.

It remains to describe the essential image of the functor $\mathrm{Mat}|_{(\mathcal{S}^{\wedge}_{\pi})_{\mathrm{ft}}}$. Note that if X is a simply connected profinite space of finite type, then each homotopy group $\pi_n X$ is a profinite abelian group of finite type (Theorem E.7.0.5), so that $\pi_n \mathrm{Mat}(X)$ is congruence-complete when viewed as an abstract abelian group (Proposition E.8.1.6). Conversely, suppose that Z is a simply connected space whose homotopy groups are congruence-complete; we wish to show that there exists a simply connected profinite space X of finite type and an equivalence $Z \simeq \mathrm{Mat}(X)$. Let $X = Z^{\wedge}_{\pi}$ be the profinite completion of Z. Then X is simply connected (Corollary E.4.3.2). Using Proposition E.8.2.4 and Remark E.7.1.7, we deduce that the cohomology groups $\mathrm{H}^n(X; \mathbf{F}_p)$ are finite, so that X is of finite type (Theorem E.7.0.5). To complete the proof, it will suffice to show that the unit map $u : Z \to \mathrm{Mat}(X)$ is a homotopy equivalence. Since the domain and codomain of u are simply connected, this is equivalent to the assertion that u induces isomorphisms $\pi_n Z \to \pi_n \mathrm{Mat}(X)$ for $n \geqslant 2$. This follows from Proposition E.8.2.4, since the homotopy groups of Z are assumed to be congruence-complete. □

E.8.3 The Proof of Proposition E.8.2.3

We will deduce Proposition E.8.2.3 from the following:

Lemma E.8.3.1. *Let X be a simply connected profinite space of finite type. Then, for every prime number p, the map of cohomology rings $\theta : \mathrm{H}^*(X; \mathbf{F}_p) \to \mathrm{H}^*(\mathrm{Mat}(X); \mathbf{F}_p)$ is an isomorphism.*

Proof. We will say that a profinite space X is *p-good* if the map $\theta : \mathrm{H}^*(X; \mathbf{F}_p) \to \mathrm{H}^*(\mathrm{Mat}(X); \mathbf{F}_p)$ of Remark E.7.1.5 is an isomorphism. Suppose we are given a pullback diagram of profinite spaces σ :

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow & & \downarrow \\ Y' & \longrightarrow & Y. \end{array}$$

Choose a base point $y \in Y$, and let X_y denote the fiber product $X \times_Y \{y\}$. If Y is simply connected and $C^*(\mathrm{Mat}(X_y); \mathbf{F}_p)$ is locally finite, then Corollary **??** implies that the induced diagram

$$\begin{array}{ccc} C^*(\mathrm{Mat}(X'); \mathbf{F}_p) & \longleftarrow & C^*(\mathrm{Mat}(X); \mathbf{F}_p) \\ \uparrow & & \uparrow \\ C^*(\mathrm{Mat}(Y'); \mathbf{F}_p) & \longleftarrow & C^*(\mathrm{Mat}(Y); \mathbf{F}_p) \end{array}$$

is a pushout square of $\mathbb{E}_\infty$-algebras over $\mathbf{F}_p$. Similarly, Proposition E.7.2.1 implies that the diagram

$$\begin{array}{ccc} C^*(X'; \mathbf{F}_p) & \longleftarrow & C^*(X; \mathbf{F}_p) \\ \uparrow & & \uparrow \\ C^*(Y'; \mathbf{F}_p) & \longleftarrow & C^*(Y; \mathbf{F}_p) \end{array}$$

is a pushout square of $\mathbb{E}_\infty$-algebras over $\mathbf{F}_p$. This proves the following:

$(*)$ If the profinite spaces X, Y, and Y' are p-good, the cochain complex $C^*(\mathrm{Mat}(X_y); \mathbf{F}_p)$ is locally finite, and the profinite space Y is simply connected, then X' is also p-good.

Note that for $n \geqslant 1$, the profinite space $\widehat{K}(\mathbf{Z}_p, n)$ is p-good (Proposition E.7.5.1) and that the $\mathbb{E}_\infty$-algebra $C^*(\widehat{K}(\mathbf{Z}_p, n); \mathbf{F}_p)$ is locally finite (Remark E.7.5.2). Taking $X = \widehat{K}(\mathbf{Z}_p, n)$ for $n \geqslant 1$ and $Y = *$, we conclude that if a simply connected profinite space Z is p-good, then the product $Z \times \widehat{K}(\mathbf{Z}_p, n)$ is also p-good for $n \geqslant 2$. Similarly, if Z is simply connected and p-good, then the product $Z \times K(\mathbf{Z}/p^d \mathbf{Z}, n)$ is p-good for any $n \geqslant 2$ and any $d \geqslant 0$. Combining these observations with Proposition E.7.3.5, we deduce that $\widehat{K}(M, n)$ is p-good for $n \geqslant 2$ and any finitely generated $\mathbf{Z}_p$-module M. More generally, if M is any profinite abelian group, then Lemma E.7.5.3 and Proposition E.7.6.3 supply isomorphisms

$$\mathrm{H}^*(K(M, n); \mathbf{F}_p) \simeq \mathrm{H}^*(K(M_p, n); \mathbf{F}_p) \qquad \mathrm{H}^*(\widehat{K}(M, n); \mathbf{F}_p) \simeq \mathrm{H}^*(\widehat{K}(M_p, n); \mathbf{F}_p),$$

where M_p denotes the closed subgroup of topologically p-singular elements of M. It follows that $\widehat{K}(M, n)$ is p-good if and only if $\widehat{K}(M_p, n)$ is p-good. In particular, if M is a profinite abelian group of finite type, then $\widehat{K}(M, n)$ is p-good for all $n \geqslant 2$.

Let X be a simply connected profinite space, and write $X = \varprojlim \{\tau_{\leqslant n} X\}$. The canonical map $\mathrm{Mat}(X) \to \mathrm{Mat}(\tau_{\leqslant n} X)$ has $(n+1)$-connective homotopy fibers, and therefore induces isomorphisms

$$\mathrm{H}^m(\mathrm{Mat}(\tau_{\leqslant n} X); \mathbf{F}_p) \simeq \mathrm{H}^m(\mathrm{Mat}(X); \mathbf{F}_p)$$

for $m \leqslant n$. We therefore have a commutative diagram

$$\begin{array}{ccc} \varinjlim \mathrm{H}^*(\tau_{\leqslant n} X; \mathbf{F}_p) & \longrightarrow & \varinjlim \mathrm{H}^*(\mathrm{Mat}(\tau_{\leqslant n} X); \mathbf{F}_p) \\ \downarrow & & \downarrow \\ \mathrm{H}^*(X; \mathbf{F}_p) & \longrightarrow & \mathrm{H}^*(\mathrm{Mat}(X); \mathbf{F}_p). \end{array}$$

where the vertical maps are isomorphisms. Consequently, to prove that X is p-good, it suffices to show that each truncation $\tau_{\leqslant n} X$ is p-good.

Assume now that X has finite type. We prove by induction on n that the truncation $\tau_{\leqslant n} X$ is good, the case $n = 1$ being trivial. If $n > 1$, then Notation E.7.6.1 supplies a pullback diagram of profinite spaces

$$\begin{array}{ccc} \tau_{\leqslant n} X & \longrightarrow & * \\ \downarrow & & \downarrow \phi \\ \tau_{\leqslant n-1} X & \longrightarrow & \widehat{K}(M, n+1) \end{array}$$

where $M = \pi_n X$ is a profinite abelian group of finite type. Since $\tau_{\leqslant n-1} X$ and $\widehat{K}(M, n+1)$ are p-good, we are reduced to proving that the fiber $F = \mathrm{fib}(\phi) \simeq \widehat{K}(M, n)$ has the property that $C^*(\mathrm{Mat}(F); \mathbf{F}_p)$ is of finite type. Equivalently, we must show that the homology groups $\mathrm{H}_*(K(M, n); \mathbf{F}_p)$ are finite in each degree. Since M is of finite type, it can be written as a finite product of factors which are isomorphic to $\mathbf{Z}_p$, $\mathbf{Z}/p^d\,\mathbf{Z}$, and abelian groups on which p acts by an isomorphism. Using the Künneth formula and Lemma E.7.5.3, we are reduced to proving that the homology groups

$$\mathrm{H}_*(K(\mathbf{Z}_p, n); \mathbf{F}_p) \qquad \mathrm{H}_*(K(\mathbf{Z}/p^d\,\mathbf{Z}, n); \mathbf{F}_p)$$

are finite in each degree, which follows from Remark E.7.5.2. □

Proof of Proposition E.8.2.3. Since X and $\mathrm{Mat}(X)^\wedge_\pi$ are simply connected, it will suffice to show that composition with v induces a homotopy equivalence

$$\theta_Y : \mathrm{Map}_{\mathcal{S}^\wedge_\pi}(X, Y) \to \mathrm{Map}_{\mathcal{S}^\wedge_\pi}(\mathrm{Mat}(X)^\wedge_\pi, Y)$$

for every simply connected profinite space Y. Writing Y as the limit of a filtered diagram of simply connected π-finite spaces, we can reduce to the case where Y is π-finite. Then Y is n-truncated for some integer n. We proceed by induction on n, the case $n \leqslant 1$ being trivial. In general, we have a fiber sequence $Y \to \tau_{\leqslant n-1} Y \to K(M, n+1)$ where $M = \pi_n Y$. Since $\theta_{\tau_{\leqslant n-1} Y}$ is a homotopy equivalence by the inductive hypothesis, we are reduced to proving that $\theta_{K(M,n+1)}$ is an homotopy equivalence. For this, it suffices to show that v induces an isomorphism $\mathrm{H}^*(X; M) \to \mathrm{H}^*(\mathrm{Mat}(X)^\wedge_\pi; M)$ (see Remark E.7.1.6). Since M

is finite, Remark E.7.1.7 allows us to identify this with the canonical map $\mathrm{H}^*(X; M) \to \mathrm{H}^*(\mathrm{Mat}(X); M)$. The collection of those finite abelian groups M for which this map is an isomorphism is closed under extension (as in the proof of Proposition E.7.6.3). We may therefore reduce to the case where $M = \mathbf{F}_p$ for some prime number p, in which case the desired result follows from Lemma E.8.3.1. □

Remark E.8.3.2. Let X be a simply connected space, and suppose that the cohomology group $\mathrm{H}^n(X; \mathbf{F}_p)$ is finite for every prime number p and every integer $n \geqslant 0$. Then the canonical map $\theta : X \to \mathrm{Mat}(X^\wedge_\pi)$ exhibits $\mathrm{Mat}(X^\wedge_\pi)$ as a localization of X with respect to the family of homology theories $\{\mathrm{H}_*(\bullet; \mathbf{F}_p)\}$, in the ∞-category $\mathcal{S}^{\geqslant 2}$ of simply connected spaces. More precisely, we have the following:

- (a) The map θ induces an isomorphism on homology groups $\mathrm{H}_*(X; \mathbf{F}_p) \to \mathrm{H}_*(\mathrm{Mat}(X^\wedge_\pi); \mathbf{F}_p)$ for every prime number p.

- (b) Let $f : Y \to Z$ be a map of simply connected spaces which induces an isomorphism $\mathrm{H}_*(Y; \mathbf{F}_p) \to \mathrm{H}_*(Z; \mathbf{F}_p)$ for every prime number p. Then composition with f induces a homotopy equivalence $\mathrm{Map}_{\mathcal{S}}(Z, \mathrm{Mat}(X^\wedge_\pi)) \to \mathrm{Map}_{\mathcal{S}}(Y, \mathrm{Mat}(X^\wedge_\pi))$.

Assertion (a) is an immediate consequence of Lemma E.8.3.1 and Remark E.7.1.7. To prove (b), it suffices to show that f induces an equivalence of simply connected profinite spaces $Y^\wedge_\pi \to Z^\wedge_\pi$. Equivalently, we must show that for every simply connected π-finite space T, composition with f induces a homotopy equivalence $\mu_T : \mathrm{Map}_{\mathcal{S}}(Z, T) \to \mathrm{Map}_{\mathcal{S}}(Y, T)$. Choose an integer n such that T is n-truncated. We proceed by induction on n, the case $n \geqslant 1$ being trivial. To handle the inductive step, we note that there is a fiber sequence $T \to \tau_{\leqslant n-1} T \to K(M, n+1)$ where $M = \pi_n T$. Since the inductive hypothesis guarantees that $\mu_{\tau_{\leqslant n-1} T}$ is a homotopy equivalence, we are reduced to proving that $\mu_{K(M,n+1)}$ is a homotopy equivalence. For this, it suffices to show that f induces an isomorphism $\mathrm{H}^*(Z; M) \to \mathrm{H}^*(Y; M)$. The collection of those finite abelian groups M which satisfy this condition is closed under extension; we may therefore reduce to the case where $M = \mathbf{F}_p$ for some prime number p, in which case the desired result follows immediately from our hypothesis that f induces an isomorphism on $\mathbf{F}_p$-homology.

E.8.4 The Proof of Proposition E.8.2.4

We begin with some auxiliary algebraic results.

Lemma E.8.4.1. *Let M be a congruence-finite abelian group, let d be a positive integer, and let x be an element of the kernel of the projection map $\widehat{M} \to M/dM$. Then we can write $x = dy$ for some $y \in \widehat{M}$.*

Proof. For every positive integer d', let x_d denote the image of x in $\ker(M/dd'M \to M/dM)$, and let $S_{d'}$ denote the preimage of x under the surjection $M/d'M \xrightarrow{d} \ker(M/dd'M \to M/dM)$. Then $\{S_{d'}\}_{d'>0}$ is a filtered diagram of nonempty finite sets. Applying Proposition E.1.1.1, we deduce that $\varprojlim S_{d'}$ is nonempty. □

Lemma E.8.4.2. *Let M be a congruence-finite abelian group, let d be a positive integer, and let $x \in \widehat{M}$ be an element satisfying $dx = 0$. Then x is the image of an element $y \in M$ satisfying $dy = 0$.*

Proof. For every positive integer d', let $S_{d'}$ denote the collection of those elements $y \in M$ such that $dy = 0$ and y represents the image of x in $M/dd'M$. We wish to show that the inverse limit $\varprojlim S_{d'}$ is nonempty. Since the map $M \xrightarrow{d} M$ has finite kernel, each $S_{d'}$ is a finite set. By virtue of Proposition E.1.1.1, it will suffice to show that each $S_{d'}$ is nonempty. To prove this, choose an arbitrary element $y \in M$ representing the image of x in $M_{dd'}M$. Since $dx = 0$, we can write $dy = dd'z$ for some $z \in M$. Then $y - d'z$ belongs to $S_{d'}$. □

Lemma E.8.4.3. *Let M be an abelian group. The following conditions are equivalent:*

(1) *The group M is congruence-separated.*

(2) *The group M is congruence-finite, and the canonical map $u : M \to \widehat{M}$ is an injection whose cokernel is a rational vector space.*

(3) *There exists an exact sequence of abelian groups $0 \to M \to N \to V \to 0$ where N is congruence-complete and V is a rational vector space.*

Proof. Suppose first that (1) is satisfied. Then M is congruence-finite and the map $u : M \to \widehat{M}$ is injective. Let $V = \operatorname{coker}(u)$. We claim that V is a rational vector space. To prove this, it will suffice to show that for every positive integer d, the map $d : V \to V$ is bijective. To prove surjectivity, fix an element $\overline{x} \in V$, represented by an element $x \in \widehat{M}$. Let x_d denote the image of x in M/dM, and let $x' \in M$ be a representative of x_d. Replacing x by $x - u(x')$, we may assume that $x_d = 0$. Applying Lemma E.8.4.1, we can write $x = dy$ for some $y \in \widehat{M}$, so that $\overline{x}$ belongs to the image of the map $d : V \to V$.

To prove injectivity, suppose that $\overline{x} \in V$ satisfies $d\overline{x} = 0$. Let $x \in \widehat{M}$ be a representative of $\overline{x}$, so that $dx = u(y)$ for some $y \in M$. Note that dx belongs to the kernel of the map $\widehat{M} \to M/dM$, so that $y \in dM$. Write $y = dx'$ for some $x' \in M$. Replacing x by $x - u(x')$, we can reduce to the case where $dx = 0$. Applying Lemma E.8.4.2, we deduce that x belongs to the image of u, so that $\overline{x} = 0$. This completes the proof that (1) $\Rightarrow$ (2).

To prove that (2) $\Rightarrow$ (3), we will show the congruence completion $\widehat{M}$ is congruence-complete. For this, it suffices to show that $\widehat{M}$ is a profinite abelian group of finite type (Proposition E.8.1.6). Let p be a prime number; we wish to show that $\widehat{M}/p\widehat{M}$ is finite (see

Proposition E.7.3.5). This is clear, since there exists an exact sequence of abelian groups $M/pM \to \widehat{M}/p\widehat{M} \to V/pV$ where M/pM is finite and $V/pV \simeq 0$.

We now show that (3) $\Rightarrow$ (1). Choose an exact sequence $0 \to M \xrightarrow{\phi} N \to V \to 0$ where N is congruence-complete and V is a rational vector space. For every positive integer d, we have $\mathrm{Tor}_0(V, \mathbf{Z}/d\mathbf{Z}) \simeq \mathrm{Tor}_1(V, \mathbf{Z}/d\mathbf{Z}) \simeq 0$, so that ϕ induces an isomorphism $M/dM \to N/dN$. It follows that the lower horizontal map in the diagram

$$\begin{array}{ccc} M & \xrightarrow{\phi} & N \\ \downarrow{\scriptstyle\psi} & & \downarrow \\ \widehat{M} & \longrightarrow & \hat{N} \end{array}$$

is an isomorphism. Since N is congruence-complete, the right vertical map is also an isomorphism. Since ϕ is injective, we conclude that ψ is also injective: that is, M is congruence-separated. □

Remark E.8.4.4. The proof of the implication (3) $\Rightarrow$ (1) in Lemma E.8.4.3 shows that if M is a congruence-finite abelian group and we are given any injection $u : M \hookrightarrow N$, where N is congruence-complete and N/M is a rational vector space, then u induces an isomorphism of N with the congruence-completion of M.

Lemma E.8.4.5. *Let M be a congruence-separated abelian group, and let p be a prime number. Then the cohomology groups $\mathrm{H}^m(K(M,n); \mathbf{F}_p)$ are finite for $n \geqslant 2$.*

Proof. Lemma E.8.4.3 supplies an exact sequence $0 \to M \to \widehat{M} \to V \to 0$, where V is a rational vector space. We therefore have a fiber sequence of Eilenberg-MacLane spaces $K(V, n-1) \to K(M,n) \to K(\widehat{M}, n)$. Since $\mathrm{H}^d(K(V, n-1); \mathbf{F}_p) \simeq 0$ for $d > 0$ (Lemma E.7.5.3), the map $\mathrm{H}^*(K(\widehat{M}, n); \mathbf{F}_p) \to \mathrm{H}^*(K(M,n); \mathbf{F}_p)$ is an isomorphism. It will therefore suffice to show that $\mathrm{H}^*(K(\widehat{M}, n); \mathbf{F}_p)$ is finite dimensional in each degree. Let us regard $\widehat{M}$ as a profinite abelian group, and let $\widehat{K}(\widehat{M}, n)$ be the profinite space introduced in Notation E.7.6.1. Since $\widehat{M}$ has finite type, Lemma E.8.3.1 supplies an isomorphism $\mathrm{H}^*(\widehat{K}(\widehat{M}, n); \mathbf{F}_p) \simeq \mathrm{H}^*(K(\widehat{M}, n); \mathbf{F}_p)$. We are therefore reduced to proving that $\mathrm{H}^*(K(\widehat{M}, n); \mathbf{F}_p)$ is finite-dimensional in each degree, which is a special case of Proposition E.7.6.3. □

Lemma E.8.4.6. *Let X be a simply connected space, and suppose that each homotopy group $\pi_m X$ is congruence-separated. Then for every prime number p and every $n \geqslant 0$, the cohomology group $\mathrm{H}^n(X; \mathbf{F}_p)$ is finite.*

Proof. Replacing X by $\tau_{\leqslant n} X$, we may assume that X is m-truncated for some integer m. We proceed by induction on m, the case $m \leqslant 1$ being trivial. To carry out the inductive step, we note that there is a pullback diagram

$$\begin{array}{ccc} X & \longrightarrow & * \\ \downarrow & & \downarrow u \\ \tau_{\leqslant m-1}X & \longrightarrow & K(\pi_m X, m+1). \end{array}$$

The homotopy fibers of u can be identified with $K(\pi_m X, m)$, so that $C^*(\mathrm{fib}(u); \mathbf{F}_p)$ is locally finite by virtue of Lemma E.8.4.5. Applying Corollary **??**, we obtain an equivalence

$$C^*(X; \mathbf{F}_p) \simeq C^*(\tau_{\leqslant m-1}X; \mathbf{F}_p) \otimes_{C^*(K(\pi_m X, m+1); \mathbf{F}_p)} \mathbf{F}_p.$$

Using the inductive hypothesis and Lemma **??**, we are reduced to proving that $C^*(K(\pi_m X, m+1); \mathbf{F}_p)$ is locally finite, which follows from Lemma E.8.4.5. □

Lemma E.8.4.7. *Let M be a congruence-separated abelian group, and let V be a rational vector space. Then every group homomorphism $V \to M$ is trivial.*

Proof. Since M is congruence-separated, the natural map from M to its congruence-completion $\widehat{M}$ is injective. It will therefore suffice to show that every map $f : V \to \widehat{M}$ is trivial. Writing $\widehat{M}$ as the inverse limit $\varprojlim M/dM$, we are reduced to proving that every map $V \to M/dM$ is trivial. This is clear (since d acts invertibly on V). □

Lemma E.8.4.8. *Let X be a connected space with base point $x \in X$. Assume that $\pi_1(X, x)$ is abelian, and that for each $n \geqslant 2$ the action of $\pi_1(X, x)$ on $\pi_n(X, x)$ is nilpotent (that is, $\pi_n(X, x)$ admits a finite filtration by $\pi_1(X, x)$-invariant submodules whose successive quotients are acted on trivially by $\pi_1(X, x)$). Let p be a prime number. Then the following conditions are equivalent:*

- (a) *Each homotopy group $\pi_n(X, x)$ is a module over $\mathbf{Z}[p^{-1}]$.*
- (b) *The cohomology groups $\mathrm{H}^n(X; \mathbf{F}_p)$ vanish for $n > 0$.*

Proof. Suppose first that (a) is satisfied. We wish to prove that $\mathrm{H}^n(X; \mathbf{F}_p) \simeq 0$ for $n > 0$. Replacing X by $\tau_{\leqslant n}X$, we can reduce to the case where X is m-truncated for some integer m. We proceed by induction on m, the case $m = 0$ being trivial. To carry out the inductive step, we observe that there is a fiber sequence $K(\pi_m(X, x), m) \to X \to \tau_{\leqslant m-1}X$. Using assumption (a) and Lemma E.7.5.3, we deduce that $\mathrm{H}^d(K(\pi_m(X, x), m); \mathbf{F}_p) \simeq 0$ for $d > 0$, so that the restriction map $\mathrm{H}^*(\tau_{\leqslant m-1}X; \mathbf{F}_p) \to \mathrm{H}^*(X; \mathbf{F}_p)$ is an isomorphism. The desired vanishing now follows from the inductive hypothesis.

We now prove that $(b) \Rightarrow (a)$. Suppose, for a contradiction, that (a) is not satisfied. Then there exists some smallest integer n such that the action of p on $\pi_n(X, x)$ is not invertible. Let $Y = \tau_{\leqslant n-1}X$, let $y \in Y$ denote the image of the point x, and let F denote the homotopy fiber of the map $X \to Y$ over the point y. Then Y satisfies condition (a). The first part of the proof shows that $\mathrm{H}^m(Y; \mathbf{F}_p) \simeq 0$ for $m > 0$. Using the Serre spectral sequence, we deduce the following:

(a) The cohomology group $\mathrm{H}^n(X; \mathbf{F}_p)$ can be identified with the group of invariants for the action of $\pi_1(Y, y)$ on $\mathrm{H}^n(F; \mathbf{F}_p)$.

(b) There is a surjection from $\mathrm{H}^{n+1}(X; \mathbf{F}_p)$ to the group of invariants for the action of $\pi_1(Y, y)$ on $\mathrm{H}^{n+1}(F; \mathbf{F}_p)$.

Since F is n-connective, we have $\mathrm{H}^n(F; \mathbf{F}_p) \simeq \mathrm{Hom}(\pi_n F; \mathbf{F}_p) \simeq \mathrm{Hom}(\pi_n(X, x); \mathbf{F}_p)$. It follows that the action of $\pi_1(Y, y)$ on $\mathrm{H}^n(F; \mathbf{F}_p)$ is nilpotent. Since $\mathrm{H}^n(X; \mathbf{F}_p) \simeq 0$, assertion (a) implies that $\mathrm{H}^n(F; \mathbf{F}_p) \simeq 0$. It follows that the map $\pi_n(X, x) \xrightarrow{p} \pi_n(X, x)$ is surjective.

We have a fiber sequence $F' \to F \to K(\pi_n(X, x), n)$. Since F' is $(n+1)$-connective, the induced map

$$\mathrm{Ext}^1_{\mathbf{Z}}(\pi_n(X, x); \mathbf{F}_p) \simeq \mathrm{H}^{n+1}(K(\pi_n(X, x), n); \mathbf{F}_p) \to \mathrm{H}^{n+1}(F; \mathbf{F}_p)$$

is injective. Using (b) and our assumption that $\mathrm{H}^{n+1}(X; \mathbf{F}_p) \simeq 0$, we conclude that $\mathrm{Ext}^1_{\mathbf{Z}}(\pi_n(X, x); \mathbf{F}_p)$ does not contain any nonzero elements which are invariant under the action of $\pi_1(Y, y) \simeq \pi_1(X, x)$. Since the action of $\pi_1(X, x)$ on $\mathrm{Ext}^1_{\mathbf{Z}}(\pi_n(X, x); \mathbf{F}_p)$ is nilpotent, we conclude that $\mathrm{Ext}^1_{\mathbf{Z}}(\pi_n(X, x); \mathbf{F}_p) \simeq 0$: that is, the multiplication map $\pi_n(X, x) \xrightarrow{p} \pi_n(X, x)$ is injective. □

Proof of Proposition E.8.2.4. Let X be a simply connected space, and suppose that each homotopy group of X is congruence-separated. Choose a base point $x \in X$. Let $X^\wedge_\pi$ be the profinite completion of X. Using Lemma E.8.4.6 and Remark E.7.1.7, we deduce that each cohomology group $\mathrm{H}^n(X^\wedge_\pi; \mathbf{F}_p)$ is finite, so that $X^\wedge_\pi$ is of finite type (Theorem E.7.0.5). Let u denote the unit map $X \to \mathrm{Mat}(X^\wedge_\pi)$, and let F denote the homotopy fiber of u (taken over the image of x), and let $\overline{x}$ denote the base point of F determined by x. Since the domain and codomain of u are simply-connected, F is a connected space with abelian fundamental group $\pi_1(F, \overline{x})$, and the action of $\pi_1(F, \overline{x})$ on the higher homotopy groups $\pi_n(F, \overline{x})$ is nilpotent.

Let p be a prime number, and let κ denote the finite field $\mathbf{F}_p$. Using Remark E.7.1.7 and Lemma E.8.3.1, we conclude that u induces an isomorphism $\mathrm{H}^*(\mathrm{Mat}(X^\wedge_\pi; \kappa) \to \mathrm{H}^*(X; \kappa)$. Let $\mathscr{F} \in \mathrm{Fun}(\mathrm{Mat}(X^\wedge_\pi); \mathrm{Mod}_\kappa)$ denote the direct image of the constant local system $\underline{\kappa}_X$, and let $\theta : \underline{\kappa}_{\mathrm{Mat}(X^\wedge_\pi)} \to \mathscr{F}$ be the unit map. Then θ induces an equivalence

$$C^*(\mathrm{Mat}(X^\wedge_\pi); \kappa) \to C^*(\mathrm{Mat}(X^\wedge_\pi); \mathscr{F}) \simeq C^*(X; \kappa).$$

It follows that $C^*(\mathrm{Mat}(X^\wedge_\pi); \mathrm{cofib}(\theta)) \simeq 0$. Since $\mathrm{Mat}(X^\wedge_\pi)$ is simply connected, we conclude that $\mathrm{cofib}(\theta)$ is an equivalence. It follows that $\mathrm{H}^m(F; \kappa) \simeq 0$ for $m > 0$. Applying Lemma E.8.4.8, we conclude that each homotopy group of F is a module over $\mathbf{Z}[p^{-1}]$. Since this holds for every prime number p, we conclude that the homotopy groups of F are rational vector spaces.

We have a long exact sequence of homotopy groups

$$\cdots \to \pi_n(F, \overline{x}) \xrightarrow{\phi} \pi_n(X, x) \to \pi_n(\mathrm{Mat}(X_\pi^\wedge), u(x)) \to \pi_{n-1}(F, \overline{x}) \xrightarrow{\psi} \pi_{n-1}(X, x) \to \cdots$$

Using Lemma E.8.4.7, we see that the maps ϕ and ψ are trivial, so that we have a short exact sequence

$$0 \to \pi_n(X, x) \to \pi_n(\mathrm{Mat}(X_\pi^\wedge), u(x)) \to \pi_{n-1}(F, \overline{x}) \to 0.$$

Applying Remark E.8.4.4, we deduce that u exhibits $\pi_n(\mathrm{Mat}(X_\pi^\wedge), u(x))$ as the congruence-completion of $\pi_n(X, x)$. □

E.9 The Arithmetic Square

Let M be a finitely generated abelian group, let $\widehat{M} \simeq \widehat{\mathbf{Z}} \otimes_{\mathbf{Z}} M$ denote the congruence completion of M (Definition E.8.1.1), and let $M_{\mathbf{Q}} \simeq \mathbf{Q} \otimes_{\mathbf{Z}} M$ denote the rational vector space obtained by tensoring M with the field of rational numbers. Then there is a pullback diagram of abelian groups

$$\begin{array}{ccc} M & \longrightarrow & \widehat{M} \\ \downarrow & & \downarrow \\ M_{\mathbf{Q}} & \xrightarrow{\phi} & \widehat{M}_{\mathbf{Q}}. \end{array}$$

Consequently, we can recover M (up to canonical isomorphism) from its congruence completion $\widehat{M}$, the rational vector space $M_{\mathbf{Q}}$, and the map ϕ. Our goal in this section is to establish the following homotopy-theoretic analogue:

Theorem E.9.0.9 (Sullivan's Arithmetic Square)**.** *Let X be a simply connected space, and assume that the cohomology group $\mathrm{H}^n(X; \mathbf{F}_p)$ is finite for each prime number p and each $n \geqslant 0$. Then the diagram of spaces*

$$\begin{array}{ccc} X & \longrightarrow & \mathrm{Mat}(X_\pi^\wedge) \\ \downarrow & & \downarrow \\ X_{\mathbf{Q}} & \longrightarrow & \mathrm{Mat}(X_\pi^\wedge)_{\mathbf{Q}} \end{array}$$

is a pullback square in the ∞-category $\mathcal{S}$.

Remark E.9.0.10. In the statement of Theorem E.9.0.9, the symbols $X_{\mathbf{Q}}$ and $\mathrm{Mat}(X_\pi^\wedge)_{\mathbf{Q}}$ denote rationalizations of the space X and $\mathrm{Mat}(X_\pi^\wedge)$, respectively. We refer the reader to §**??** for a review of rational homotopy theory.

E.9.1 Example: Spaces with Finitely Generated Homotopy Groups

Let us first consider the special case of Theorem E.9.0.9 in which X is a simply connected space whose homotopy groups are finitely generated (note that any such space satisfies the hypotheses of Theorem E.9.0.9: see Example E.8.1.5 and Proposition E.8.2.4). Form a pullback diagram

$$\begin{array}{ccc} Y & \longrightarrow & \mathrm{Mat}(X_{\pi}^{\wedge}) \\ \downarrow & & \downarrow \\ X_{\mathbf{Q}} & \longrightarrow & \mathrm{Mat}(X_{\pi}^{\wedge})_{\mathbf{Q}}. \end{array}$$

To prove Theorem E.9.0.9, we must show that the canonical map $\rho : X \to Y$ is a homotopy equivalence. This can be established by direct calculation. Fix an integer $n \geqslant 1$, a base point $x \in X$, and let $y = \rho(x)$ be the image of x in Y. Set $M = \pi_n X$ and $N = \pi_{n+1} X$, and let $\widehat{M}$ and $\widehat{N}$ denote the congruence-completions of M and N. We then have canonical isomorphisms

$$\pi_n \mathrm{Mat}(X_{\pi}^{\wedge}) \simeq \widehat{M} \qquad \pi_n \mathrm{Mat}(X_{\pi}^{\wedge})_{\mathbf{Q}} \simeq \widehat{M}_{\mathbf{Q}} \qquad \pi_n X_{\mathbf{Q}} \simeq M_{\mathbf{Q}}$$

$$\pi_{n+1} \mathrm{Mat}(X_{\pi}^{\wedge}) \simeq \widehat{N} \qquad \pi_{n+1} \mathrm{Mat}(X_{\pi}^{\wedge})_{\mathbf{Q}} \simeq \widehat{N}_{\mathbf{Q}} \qquad \pi_{n+1} X_{\mathbf{Q}} \simeq N_{\mathbf{Q}}.$$

It follows that the homotopy group $\pi_n(Y, y)$ fits into a long exact sequence

$$\widehat{N} \oplus N_{\mathbf{Q}} \xrightarrow{\phi} \widehat{N}_{\mathbf{Q}} \to \pi_n(Y, y) \to \widehat{M} \oplus M_{\mathbf{Q}} \xrightarrow{\psi} \widehat{M}_{\mathbf{Q}}.$$

Since M and N are finitely generated abelian groups, an elementary calculation shows that ϕ is surjective, so that the diagram

$$\begin{array}{ccc} \pi_n(Y, y) & \longrightarrow & \pi_n \mathrm{Mat}(X_{\pi}^{\wedge}) \\ \downarrow & & \downarrow \\ \pi_n X_{\mathbf{Q}} & \longrightarrow & \pi_n \mathrm{Mat}(X_{\pi}^{\wedge})_{\mathbf{Q}}. \end{array}$$

is a pullback square. Consequently, to show that the map ρ induces an isomorphism $\pi_n(X, x) \to \pi_n(Y, y)$, it will suffice to show that the diagram

$$\begin{array}{ccc} \pi_n(X, x) & \longrightarrow & \pi_n \mathrm{Mat}(X_{\pi}^{\wedge}) \\ \downarrow & & \downarrow \\ \pi_n X_{\mathbf{Q}} & \longrightarrow & \pi_n \mathrm{Mat}(X_{\pi}^{\wedge})_{\mathbf{Q}} \end{array}$$

is also a pullback square. In other words, we are reduced to showing that the diagram

$$\begin{array}{ccc} M & \longrightarrow & \widehat{M} \\ \downarrow & & \downarrow \\ M_{\mathbf{Q}} & \longrightarrow & \widehat{M}_{\mathbf{Q}} \end{array}$$

is a pullback, which is a purely algebraic consequence of our assumption that M is a finitely generated abelian group.

E.9.2 The Main Lemma

There are many examples of spaces X which satisfy the hypotheses of Theorem E.9.0.9 but whose homotopy groups are *not* finitely generated: for example, we can take $X = \mathrm{Mat}(Y)$ for any simply connected profinite space Y of finite type (Proposition E.8.2.3). To establish Theorem E.9.0.9 in general, we will need a slightly more sophisticated argument. First, let us introduce a bit of terminology.

Definition E.9.2.1. Let M be an abelian group, and let $M_{\mathbf{Q}} = \mathbf{Q} \otimes_{\mathbf{Z}} M$ denote its rationalization. We will say that a subset $U \subseteq M_{\mathbf{Q}}$ is *congruence-open* if, for every element $x \in U$, there exists an integer $n > 0$ such that $x + nM \subseteq U$. The collection of congruence-open sets determines a topology on $M_{\mathbf{Q}}$, which we will refer to as the *congruence topology.*

The main ingredient in our proof of Theorem E.9.0.9 is the following:

Lemma E.9.2.2. *Let Y be a simply connected profinite space of finite type, let Z be a simply connected rational space, and let $\phi : Z \to \mathrm{Mat}(Y)_{\mathbf{Q}}$ be a map satisfying the following technical condition:*

$(*)$ *The image of the map $\pi_2 Z \to \pi_2 \mathrm{Mat}(Y)_{\mathbf{Q}} \simeq (\pi_2 Y)_{\mathbf{Q}}$ is dense with respect to the congruence topology of Definition E.9.2.1.*

Form a pullback diagram σ :

$$\begin{array}{ccc} \overline{Z} & \xrightarrow{\psi} & \mathrm{Mat}(Y) \\ \downarrow{\scriptstyle \psi'} & & \downarrow \\ Z & \xrightarrow{\phi} & \mathrm{Mat}(Y)_{\mathbf{Q}}. \end{array}$$

Then:

(a) *The space $\overline{Z}$ is simply connected.*

(b) *The map ψ induces isomorphisms $\mathrm{H}^*(\mathrm{Mat}(Y); \mathbf{F}_p) \to \mathrm{H}^*(\overline{Z}; \mathbf{F}_p)$ for every prime number p.*

(c) *The cohomology group $\mathrm{H}^n(\overline{Z}; \mathbf{F}_p)$ is finite for every integer $n \geqslant 0$ and every prime number p.*

(d) *The map ψ' induces an isomorphism $\mathrm{H}^*(Z; \mathbf{Q}) \to \mathrm{H}^*(\overline{Z}; \mathbf{Q})$.*

Proof. Since $\mathrm{Mat}(Y)$ and Z are connected and $\mathrm{Mat}(Y)_{\mathbf{Q}}$ is simply connected, we immediately see that $\overline{Z}$ is connected. Choose a base point $z \in \overline{Z}$, so that we have an exact sequence

$$\pi_2(Z, \psi'(z)) \oplus \pi_2(Y, \psi(z)) \xrightarrow{\mu} \pi_2(\mathrm{Mat}(Y)_{\mathbf{Q}}, (\phi\psi')(z)) \to \pi_1(\overline{Z}, z) \to 0.$$

To prove (a), it suffices to show that the map μ is surjective. This is equivalent to the surjectivity of the map $\pi_2 Z \to \mathrm{coker}(\pi_2 Y \to (\pi_2 Y)_{\mathbf{Q}})$, which is a reformulation of assumption $(*)$.

Let κ denote the finite field $\mathbf{F}_p$ for some prime number p, let $\underline{\kappa}_Z$ denote the constant local system on Z with value κ, and let $\mathscr{F} \in \mathrm{Fun}(\mathrm{Mat}(Y)_{\mathbf{Q}}; \mathrm{Mod}_\kappa)$ denote the direct image of $\underline{\kappa}_Z$ under the map ϕ. We have a fiber sequence of local systems $\underline{\kappa}_{\mathrm{Mat}(Y)_{\mathbf{Q}}} \xrightarrow{u} \mathscr{F} \to \mathscr{F}'$. Since Z and $\mathrm{Mat}(Y)_{\mathbf{Q}}$ are simply connected rational spaces, Lemma E.8.4.8 implies that the map ϕ induces an equivalence

$$C^*(\mathrm{Mat}(Y)_{\mathbf{Q}}; \kappa) \to C^*(Z; \kappa) \simeq C^*(\mathrm{Mat}(Y)_{\mathbf{Q}}; \mathscr{F}),$$

so that $C^*(\mathrm{Mat}(Y)_{\mathbf{Q}}; \mathscr{F}') \simeq 0$. Note that $\pi_n \mathscr{F}' \simeq 0$ for $n > 0$. Consequently, if $\mathscr{F}' \neq 0$, there is a largest integer m such that $\pi_m \mathscr{F}' \neq 0$. Since $\mathrm{Mat}(Y)_{\mathbf{Q}}$ is simply connected, it would then follow that $\pi_m C^*(\mathrm{Mat}(Y)_{\mathbf{Q}}; \mathscr{F}') \neq 0$, and we would obtain a contradiction. It follows that $\mathscr{F}' \simeq 0$: that is, the unit map u is an equivalence of local systems on $\mathrm{Mat}(Y)_{\mathbf{Q}}$. Since the diagram σ is a pullback square, it follows that $\underline{\kappa}_{\mathrm{Mat}(Y)}$ is the direct image of the constant local system $\underline{\kappa}_{\overline{Z}}$, so that ψ' induces an isomorphism $\mathrm{H}^*(\mathrm{Mat}(Y); \kappa) \to \mathrm{H}^*(\overline{Z}; \kappa)$ as desired. This proves (b). Assertion (c) follows from (b), Lemma E.8.3.1, and Theorem E.7.0.5.

We now prove (d). Let $\mathscr{G} \in \mathrm{Fun}(\mathrm{Mat}(Y)_{\mathbf{Q}}; \mathrm{Mod}_{\mathbf{Q}})$ denote the direct image of the constant local system $\underline{\mathbf{Q}}_{\mathrm{Mat}(Y)}$ along the map $\nu : \mathrm{Mat}(Y) \to \mathrm{Mat}(Y)_{\mathbf{Q}}$, and let $u' : \underline{\mathbf{Q}}_{\mathrm{Mat}(Y)_{\mathbf{Q}}} \to \mathscr{G}$ denote the unit map. Since ν is a rational homotopy equivalence, the map u' induces an equivalence

$$C^*(\mathrm{Mat}(Y)_{\mathbf{Q}}; \mathbf{Q}) \to C^*(\mathrm{Mat}(Y); \mathbf{Q}) \simeq C^*(\mathrm{Mat}(Y)_{\mathbf{Q}}; \mathscr{G}).$$

It follows that $C^*(\mathrm{Mat}(Y)_{\mathbf{Q}}; \mathrm{cofib}(u')) \simeq 0$. Arguing as above, we conclude that $\mathrm{cofib}(u') \simeq 0$ so that u' is an equivalence. Since σ is a pullback square, we conclude that $\underline{\mathbf{Q}}_Z$ is the direct image of the constant local system $\underline{\mathbf{Q}}_{\overline{Z}}$ along ψ', so that ψ' induces an isomorphism $\mathrm{H}^*(Z; \mathbf{Q}) \to \mathrm{H}^*(\overline{\mathbf{Z}}; \mathbf{Q})$. □

E.9.3 The Proof of Theorem E.9.0.9

In the proof of Theorem E.9.0.9, we will need the following standard homotopy-theoretic fact:

Lemma E.9.3.1. *Let $f : X \to Y$ be a map of simply connected spaces, and suppose that f satisfies the following conditions:*

(1) *For every prime number p, the map f induces an isomorphism* $\mathrm{H}^*(Y;\mathbf{F}_p) \to \mathrm{H}^*(X;\mathbf{F}_p)$.

(2) *The map f induces an isomorphism* $\mathrm{H}^*(Y;\mathbf{Q}) \to \mathrm{H}^*(X;\mathbf{Q})$.

Then f is a homotopy equivalence.

Proof. Since X and Y are simply connected, it will suffice to show that the natural map $\phi_{\mathbf{Z}} : \mathrm{H}_*(X;\mathbf{Z}) \to \mathrm{H}_*(Y;\mathbf{Z})$ is an isomorphism. Using the exact sequence of abelian groups $0 \to \mathbf{Z} \to \mathbf{Q} \to \mathbf{Q}/\mathbf{Z} \to 0$, we are reduced to showing that the maps

$$\phi_{\mathbf{Q}} : \mathrm{H}_*(X;\mathbf{Q}) \to \mathrm{H}_*(Y;\mathbf{Q}) \qquad \phi_{\mathbf{Q}/\mathbf{Z}} : \mathrm{H}_*(X;\mathbf{Q}/\mathbf{Z}) \to \mathrm{H}_*(Y;\mathbf{Q}/\mathbf{Z})$$

are isomorphisms. For the map $\phi_{\mathbf{Q}}$, this follows immediately from assumption (2). For the map $\phi_{\mathbf{Q}/\mathbf{Z}}$, we can write $\mathbf{Q}/\mathbf{Z}$ as a direct limit of finite abelian groups and thereby reduce to the problem of showing that the map $\phi_M : \mathrm{H}_*(X;M) \to \mathrm{H}_*(Y;M)$ is an equivalence when M is finite. Writing M as a successive extension of cyclic groups of prime order, we can reduce to the case $M = \mathbf{F}_p$, in which case the desired result follows from assumption (1). □

Proof of Theorem E.9.0.9. Let X be a simply connected space such that each cohomology group $\mathrm{H}^n(X;\mathbf{F}_p)$ is finite. Using Remark E.7.1.7 and Proposition E.7.3.5, we deduce that the profinite completion $X_\pi^\wedge$ has finite type. Note that for every finite abelian group M, we have

$$\mathrm{Hom}_c(\pi_2 X_\pi^\wedge; M) \simeq \mathrm{H}^2(X_\pi^\wedge; M) \simeq \mathrm{H}^2(X;M) \simeq \mathrm{Hom}(\pi_2 X; M),$$

so that the map $\pi_2 X \to \pi_2 X_\pi^\wedge$ has dense image. It follows that the map $\pi_2 X_{\mathbf{Q}} \to \pi_2 \mathrm{Mat}(X_\pi^\wedge)_{\mathbf{Q}}$ also has dense image (where we endow $\pi_2 \mathrm{Mat}(X_\pi^\wedge)_{\mathbf{Q}}$ with the congruence topology): that is, the map $\phi : X_{\mathbf{Q}} \to \mathrm{Mat}(X_\pi^\wedge)_{\mathbf{Q}}$ satisfies hypothesis $(*)$ of Lemma E.9.2.2. Set $Y = X_{\mathbf{Q}} \times_{\mathrm{Mat}(X_\pi^\wedge)_{\mathbf{Q}}} \mathrm{Mat}(X_\pi^\wedge)$. Applying Lemma E.9.2.2, we deduce the following:

(a) The space Y is simply connected.

(b) For every prime number p, the canonical map $\mathrm{H}^*(\mathrm{Mat}(X_\pi^\wedge);\mathbf{F}_p) \to \mathrm{H}^*(Y;\mathbf{F}_p)$ is an isomorphism.

(d) The map $\mathrm{H}^*(X_{\mathbf{Q}};\mathbf{Q}) \to \mathrm{H}^*(Y;\mathbf{Q})$ is an isomorphism.

The commutative diagram

$$\begin{array}{ccc} X & \longrightarrow & \mathrm{Mat}(X_\pi^\wedge) \\ \downarrow & & \downarrow \\ X_{\mathbf{Q}} & \longrightarrow & \mathrm{Mat}(X_\pi^\wedge)_{\mathbf{Q}} \end{array}$$

determines a map of spaces $f : X \to Y$. The composite map

$$\mathrm{H}^*(X_{\mathbf{Q}}; \mathbf{Q}) \to \mathrm{H}^*(Y; \mathbf{Q}) \to \mathrm{H}^*(X; \mathbf{Q})$$

is an isomorphism by construction, and the composite map

$$\mathrm{H}^*(\mathrm{Mat}(X^{\wedge}_{\pi}); \mathbf{F}_p) \to \mathrm{H}^*(Y; \mathbf{F}_p) \to \mathrm{H}^*(X; \mathbf{F}_p)$$

is an isomorphism for every prime number p by virtue of Lemma E.8.3.1 and Remark E.7.1.7. Combining these observations with (b) and (d), we conclude that f induces isomorphisms

$$\mathrm{H}^*(Y; \mathbf{Q}) \to \mathrm{H}^*(X; \mathbf{Q}) \qquad \mathrm{H}^*(Y; \mathbf{F}_p) \to \mathrm{H}^*(X; \mathbf{F}_p),$$

so that Lemma E.9.3.1 guarantees that f is a homotopy equivalence. □

Remark E.9.3.2. The construction $Y \mapsto \mathrm{Mat}(Y)_{\mathbf{Q}}$ determines a functor $\mathcal{S}^{\wedge}_{\pi} \to \mathcal{S}$. Let $\mathcal{C}$ denote the full subcategory of the fiber product $\mathrm{Fun}(\Delta^1, \mathcal{S}) \times_{\mathrm{Fun}(\{1\}, \mathcal{S})} \mathcal{S}^{\wedge}_{\pi}$ spanned by those triples $(Y, Z, \phi : Z \to \mathrm{Mat}(Y)_{\mathbf{Q}})$ where Y is a simply connected profinite space of finite type, Z is a simply connected rational space, and ϕ is a map satisfying hypothesis $(*)$ of Lemma E.9.2.2. Let $\mathcal{C}'$ denote the full subcategory of $\mathcal{S}$ spanned by the simply connected spaces X for which the cohomology groups $\mathrm{H}^n(X; \mathbf{F}_p)$ are finite dimensional for all prime numbers p and all $n \geqslant 0$. It follows from Lemma E.9.2.2 that the construction $(Y, Z, \phi) \mapsto Z \times_{\mathrm{Mat}(Y)_{\mathbf{Q}}} \mathrm{Mat}(Y)$ determines a functor $G : \mathcal{C} \to \mathcal{C}'$. The proof of Theorem E.9.0.9 shows that the construction $X \mapsto (X^{\wedge}_{\pi}, X_{\mathbf{Q}}, \phi : X_{\mathbf{Q}} \to \mathrm{Mat}(X^{\wedge}_{\pi})_{\mathbf{Q}})$ determines a functor $F : \mathcal{C}' \to \mathcal{C}$, which is easily seen to be left adjoint to G. Theorem E.9.0.9 shows that the unit map $u : \mathrm{id}_{\mathcal{C}'} \to G \circ F$ is an equivalence of functors from $\mathcal{C}'$ to itself. We claim that the counit map $v : F \circ G \to \mathrm{id}_{\mathcal{C}}$ is also an equivalence. In other words, we claim that for every object $(Y, Z, \phi) \in \mathcal{C}$, the canonical maps

$$f : (Z \times_{\mathrm{Mat}(Y)_{\mathbf{Q}}} \mathrm{Mat}(Y))^{\wedge}_{\pi} \to Y \qquad g : (Z \times_{\mathrm{Mat}(Y)_{\mathbf{Q}}} \mathrm{Mat}(Y))_{\mathbf{Q}} \to Z$$

are equivalences. This follows from assertions (b) and (d) of Lemma E.9.2.2, respectively. It follows that F and G are mutually inverse equivalences of ∞-categories.
