Chapter 0

Introduction

Let $X, Y \subseteq \mathbf{CP}^2$ be smooth algebraic curves of degrees m and n in the complex projective plane $\mathbf{CP}^2$. If X and Y meet transversely, then the classical theorem of Bezout (see for example [71]) asserts that the intersection $X \cap Y$ has precisely mn points. This statement has a natural formulation in the language of cohomology. The curves X and Y have fundamental classes $[X], [Y] \in \mathrm{H}^2(\mathbf{CP}^2; \mathbf{Z})$. If C and C' meet transversely, then we have the formula

$$[X] \cup [Y] = [X \cap Y],$$

where the fundamental class $[X \cap Y] \in \mathrm{H}^4(\mathbf{CP}^2; \mathbf{Z}) \simeq \mathbf{Z}$ of the intersection $X \cap Y$ simply counts the number of points where X and Y meet. Of course, this should not be surprising: the cup product on cohomology classes is defined so as to encode the operation of intersection. However, it would be a mistake to regard the equation $[X] \cup [Y] = [X \cap Y]$ as obvious, because it is not always true. For example, if the curves X and Y meet nontransversely (but still in a finite number of points), then we always have a strict inequality

$$[X] \cup [Y] > [X \cap Y]$$

if the right hand side is again interpreted as counting the number of points in the set-theoretic intersection of X and Y.

If we want a formula which is valid for non-transverse intersections, then we must alter the definition of $[X \cap Y]$ so that it counts each intersection point with the appropriate multiplicity. In the situation described above, the multiplicity of an intersection point $p \in X \cap Y$ can be defined as the dimension of the tensor product

$$\mathscr{O}_{X,p} \otimes_{\mathscr{O}_{\mathbf{CP}^2,p}} \mathscr{O}_{Y,p}.$$

as a vector space over the complex numbers. This tensor product has a natural algebro-geometric interpretation: it is the local ring of the *scheme-theoretic* intersection $X \times_{\mathbf{CP}^2} Y$

at the point p. Consequently, the equation $[X] \cup [Y] = [X \cap Y]$ remains valid if the right hand side is properly interpreted: we must define the fundamental class of the intersection $[X \cap Y]$ in a way which takes into account the structure of $X \cap Y = X \times_{\mathbf{CP}^2} Y$ as a scheme.

In more complicated situations, the appropriate intersection multiplicities cannot always be determined from the scheme-theoretic intersection alone. Suppose that X and Y are singular subvarieties of a smooth algebraic variety Z having complementary dimension and intersecting in a finite number of points. In this case, the appropriate intersection multiplicity at a point $p \in X \cap Y$ is not always given by the complex dimension of the local ring

$$\mathscr{O}_{X \cap Y, p} = \mathscr{O}_{X,p} \otimes_{\mathscr{O}_{Z,p}} \mathscr{O}_{Y,p} .$$

The reason for this is easy to understand from the point of view of homological algebra. Since the tensor product functor $\otimes_{\mathscr{O}_{Z,p}}$ is not exact, it does not have good properties when considered alone. According to Serre's intersection formula, the correct intersection multiplicity is instead the Euler characteristic

$$\sum (-1)^m \dim_{\mathbf{C}} \operatorname{Tor}_m^{\mathscr{O}_{Z,p}}(\mathscr{O}_{X,p}, \mathscr{O}_{Y,p}).$$

This Euler characteristic contains the dimension of the local ring of the scheme-theoretic intersection as its leading term, but also higher-order corrections. We refer the reader to [188] for further discussion of this formula for the intersection multiplicity.

If we would like the equation $[X] \cup [Y] = [X \cap Y]$ to remain valid in the more complicated situations described above, then we need to interpret the right hand side in a more sophisticated way. It is not enough to contemplate the intersection $X \cap Y$ as a set or even as a scheme: we need to to remember *all* of the Tor-groups $\operatorname{Tor}_m^{\mathscr{O}_{Z,p}}(\mathscr{O}_{X,p}, \mathscr{O}_{Y,p})$, rather than simply the tensor product $\mathscr{O}_{X \cap Y, p} = \mathscr{O}_{X,p} \otimes_{\mathscr{O}_{Z,p}} \mathscr{O}_{Y,p} = \operatorname{Tor}_0^{\mathscr{O}_{Z,p}}(\mathscr{O}_{X,p}, \mathscr{O}_{Y,p})$.

Let us begin by recalling how these invariants are defined. Suppose that R is a commutative ring and that we are given R-modules A and B. We can then choose a projective resolution of A as an R-module: that is, an exact sequence of R-modules

$$\cdots \to P_2 \xrightarrow{d} P_1 \xrightarrow{d} P_0 \to A \to 0$$

where each P_m is projective. By definition, the groups $\operatorname{Tor}_m^R(A, B)$ are given by the homology groups of the chain complex

$$\cdots \to P_2 \otimes_R B \xrightarrow{d'} P_1 \otimes_R B \xrightarrow{d'} P_0 \otimes_R B,$$

whose differential d' is given by tensoring d with the identity map id_B.

In the situation of interest to us, A and B are not simply R-modules: they are commutative algebras over R. In this case, one can arrange that resolution (P_*, d) is compatible with the algebra structure on A in the following sense:

(*i*) There exist multiplication maps $P_m \otimes_R P_n \to P_{m+n}$ which endow the direct sum $\bigoplus_{n \geqslant 0} P_n$ with the structure of a graded ring which is commutative in the graded sense: that is, we have $xy = (-1)^{mn} yx$ for $x \in P_m$, $y \in P_n$.

(*ii*) The differential $d : P_* \to P_{*-1}$ satisfies the (graded) Leibniz rule $d(xy) = (dx)y + (-1)^m x(dy)$ for $x \in P_m$.

(*iii*) The surjection $P_0 \to A$ is a ring homomorphism.

Properties (*i*) and (*ii*) can be summarized by saying that (P_*, d) is a *commutative differential graded algebra* over R. If B is any commutative R-algebra, then the tensor product complex

$$\cdots \to P_2 \otimes_R B \xrightarrow{d'} P_1 \otimes_R B \xrightarrow{d'} P_0 \otimes_R B$$

inherits the structure of a commutative differential graded algebra over R (or even over B). We will denote this differential graded algebra by $A \otimes_R^L B$ and refer to it as the *derived tensor product of A and B over R.*

Warning 0.0.0.1. The definition of $A \otimes_R^L B$ depends on a choice of projective resolution of A by a differential graded algebra (P_*, d). However, the resulting commutative differential graded algebra turns out to be independent of (P_*, d) *up to quasi-isomorphism.* In particular, the homology groups of $A \otimes_R^L B$ are independent of the resolution chosen: these are simply the Tor-groups $\mathrm{Tor}_n^R(A, B)$.

Let R be a commutative ring. Then every commutative R-algebra R' can be regarded as a commutative differential graded R-algebra by identifying it with a chain complex which is concentrated in degree zero. We can therefore think of a commutative differential graded algebra as a generalized of ordinary commutative rings. In particular, the derived tensor product $A \otimes_R^L B$ bundles the information contained in the Tor-groups $\mathrm{Tor}_n^R(A, B)$ together into a single package which behaves, in some sense, like a commutative ring. The central idea of this book is that this heuristic can be taken seriously: objects like commutative differential graded algebras are, for many purposes, just as good as commutative rings and can be used equally well as the basic building blocks of algebraic geometry.

To fix ideas, let us introduce the a preliminary definition:

Definition 0.0.0.2. Let X be a topological space and let $\mathscr{O}_X$ be a sheaf of commutative differential graded $\mathbf{C}$-algebras on X. For each integer n, we let $\mathrm{H}_n(\mathscr{O}_X)$ denote sheaf of vector spaces given by the nth homology of $\mathscr{O}_X$, so that $\mathrm{H}_0(\mathscr{O}_X)$ is a sheaf of commutative rings on X and each $\mathrm{H}_n(\mathscr{O}_X)$ is a sheaf of $\mathrm{H}_0(\mathscr{O}_X)$-modules. We will say that $(X, \mathscr{O}_X)$ is a *differential graded* $\mathbf{C}$*-scheme* if the following conditions are satisfied:

(*a*) The pair $(X, \mathrm{H}_0(\mathscr{O}_X))$ is a scheme.

(*b*) Each $\mathrm{H}_n(\mathscr{O}_X)$ is a quasi-coherent sheaf on the scheme $(X, \mathrm{H}_0(\mathscr{O}_X))$.

(*c*) The sheaves $\mathrm{H}_n(\mathscr{O}_X)$ vanish for $n < 0$.

Warning 0.0.0.3. The notion of differential graded scheme has been studied by many authors (see [121], [41], [42], [19], [20]) using definitions which are different from (but closely related to) Definition 0.0.0.2.

Warning 0.0.0.4. Definition 0.0.0.2 captures the spirit of the kinds of objects that we will be studying in this book, at least when work over the field **C**. However, it does not really capture the spirit of *how* we will work with them. If $(X, \mathscr{O}_X)$ is a differential graded **C**-scheme, then one should think of the structure sheaf $\mathscr{O}_X$ as something that is well-defined only up to quasi-isomorphism, rather than "on the nose." This idea needs to be incorporated systematically into every aspect of the theory, beginning with the notion of morphism between differential graded **C**-scheme.

The theory of differential graded **C**-schemes has the following features:

- Every ordinary **C**-scheme $(X, \mathscr{O}_X)$ can be regarded as a differential graded **C**-scheme: we can simply regard the structure sheaf $\mathscr{O}_X$ as a sheaf of commutative differential graded algebras which is concentrated in degree zero.

- Every differential graded **C**-scheme $(X, \mathscr{O}_X)$ determines a **C**-scheme $(X, \mathrm{H}_0(\mathscr{O}_X))$, which we will refer to as the *underlying scheme* of $(X, \mathscr{O}_X)$.

- If $(X, \mathscr{O}_X)$ is a differential graded **C**-scheme, then the difference between $(X, \mathscr{O}_X)$ and its underlying scheme $(X, \mathrm{H}_0(\mathscr{O}_X))$ is measured by the quasi-coherent sheaves $\{\mathrm{H}_n(\mathscr{O}_X)\}_{n>0}$: if these sheaves vanish, then one should regard $(X, \mathscr{O}_X)$ and $(X, \mathrm{H}_0(\mathscr{O}_X))$ as equivalent data (see Warning 0.0.0.4).

- The theory of differential graded **C**-schemes has a good notion of fiber product. However, the inclusion of ordinary **C**-schemes into differential graded **C**-schemes does not preserve fiber products. In the setting affine schemes, the usual fiber product $\operatorname{Spec} A \times_{\operatorname{Spec} R} \operatorname{Spec} B$ is given by the spectrum of the tensor product $A \otimes_R B$. However, the same fiber product in the setting of differential graded **C**-schemes can be described as the spectrum (in a sense we will define later) of the *derived* tensor product $A \otimes_R^L B$.

Recall that a scheme $(X, \mathscr{O}_X)$ is said to be *reduced* if the structure sheaf $\mathscr{O}_X$ has no nonzero nilpotent sections. The relationship between differential graded **C**-schemes and ordinary **C**-schemes is analogous to the relationship between schemes and reduced schemes. Every scheme $(X, \mathscr{O}_X)$ determines a reduced scheme $(X, \mathscr{O}_X^{\mathrm{red}})$, where $\mathscr{O}_X^{\mathrm{red}}$ is the quotient of the structure sheaf $\mathscr{O}_X$ by the ideal sheaf of locally nilpotent sections. However, the passage from $(X, \mathscr{O}_X)$ to $(X, \mathscr{O}_X^{\mathrm{red}})$ loses information. Moreover, the lost information could be useful even if one is primarily interested in smooth algebraic varieties: recall that if $X, Y \subseteq \mathbf{CP}^2$ are smooth algebraic curves, then the (possibly non-reduced) scheme-theoretic intersection $X \times_{\mathbf{CP}^2} Y$ retains information about the multiplicity of each point $p \in X \cap Y$, but this information is lost by passing to the reduced scheme $(X \times_{\mathbf{CP}^2} Y)^{\mathrm{red}}$ (which remembers only the set-theoretic intersection of X and Y).

The situation for differential graded $\mathbf{C}$-schemes is similar: if X and Y are (possibly singular) subvarieties of a smooth algebraic variety Z which have complementary dimension and meet in a finite number of points, then Serre's formula for the intersection multiplicity of X and Y at a point p can be written $\sum (-1)^n \dim_{\mathbf{C}} \mathrm{H}_n(\mathscr{O}_{X \cap Y})_p$, where $\mathscr{O}_{X \cap Y}$ denotes structure sheaf of the fiber product $X \times_Z Y$ *in the setting of differential graded* $\mathbf{C}$*-schemes*. By passing to the underlying scheme of this fiber product $X \times_Z Y$, we lose information about all but the leading term of Serre's formula.

Remark 0.0.0.5. To get a feeling for the sort of information which is encoded by the fiber product $X \times_Z Y$ in the setting of differential graded $\mathbf{C}$-schemes, it is instructive to consider the case where $Z = \operatorname{Spec} R$ is an affine scheme and $X = \operatorname{Spec} R/I$, $Y = \operatorname{Spec} R/J$ are closed subschemes given by the vanishing loci of ideals $I, J \subseteq R$. In this case, the usual (scheme-theoretic) intersection of X and Y is the affine scheme $\operatorname{Spec} R/(I + J)$. The difference between $X \times_Z Y$ and this scheme-theoretic intersection is controlled by the groups $\{\mathrm{H}_n(R/I \otimes_R^L R/J) = \mathrm{Tor}_n^R(R/I, R/J)\}_{n>0}$. The group $\mathrm{Tor}_1^R(R/I, R/J)$ can be described concretely as the quotient $(I \cap J)/IJ$. Any element $f \in R$ which belongs to the intersection $I \cap J$ can be viewed as a regular function on Z which vanishes on *both* of the closed subschemes X and Y. Heuristically, such a function f might be said to vanish on the intersection $X \cap Y$ for *two* reasons, and we have $f \notin IJ$ if these reasons are "different" in some essential way. Consequently, the quotient $\mathrm{Tor}_1^R(R/I, R/J) = (I \cap J)/IJ$ is a measure of the redundancy of the equations defining the subschemes X and Y. Forming the fiber product $X \times_Z Y$ in differential graded $\mathbf{C}$-schemes retains information about this sort of redundancy: it remembers not only *which* functions vanish on the intersection of X and Y, but also *why* they vanish.

If X and Y are *smooth* subvarieties of a smooth complex algebraic variety Z, then some simplifications occur. As long as the intersection $X \cap Y$ has the "expected" dimension $\dim X + \dim Y - \dim Z$, the Tor-groups $\mathrm{Tor}_n^{\mathscr{O}_{Z,p}}(\mathscr{O}_{X,p}, \mathscr{O}_{Y,p})$ automatically vanish for each $p \in X \cap Y$. This means that the fiber product $X \times_Z Y$ in the setting of differential graded $\mathbf{C}$-schemes agrees with the usual scheme-theoretic intersection, so the theory of differential graded schemes has nothing new to tell us. However, the theory can be quite useful in the case where the intersection $X \cap Y$ does *not* have the expected dimension. We will say that a differential graded $\mathbf{C}$-scheme $(W, \mathscr{O}_W)$ is *quasi-smooth* if it is locally of the form $X \times_Z Y$, where X and Y are smooth subvarieties of a smooth complex algebraic variety Z. Then:

- Every quasi-smooth differential graded **C**-scheme $(W, \mathscr{O}_W)$ has a well-defined *virtual dimension* $\mathrm{vdim}_w(W) \in \mathbf{Z}$ at each point $w \in W$, which is a locally constant as a function of w.

- The integer $\mathrm{vdim}_w(W)$ can be thought of as the "expected dimension of W." When W is given as a fiber product $X \times_Z Y$ as above, its virtual dimension is given by the formula $\mathrm{vdim}_w(W) = \dim_w(X) + \dim_w(Y) - \dim_w(Z)$. Roughly speaking, the virtual dimension can be described as "the number of variables minus the number of equations."

- If $(W, \mathscr{O}_W)$ is quasi-smooth, then we always have $\mathrm{vdim}_w(W) \leqslant \dim_w(W)$, with equality if and only if $(W, \mathscr{O}_W)$ is an ordinary **C**-scheme in a neighborhood of w. Beware that unlike the actual dimension $\dim_w(W)$, the virtual dimension $\mathrm{vdim}_w(W)$ can be negative.

- Let $(W, \mathscr{O}_W)$ be a quasi-smooth differential graded **C**-scheme of virtual dimension d and let $W(\mathbf{C})$ denote the set of closed points of W, equipped with the complex-analytic topology. If the space $W(\mathbf{C})$ is compact, then there is a canonical element $[W] \in \mathrm{H}_{2d}(W(\mathbf{C}); \mathbf{Z})$ called the *virtual fundamental class* of $(W, \mathscr{O}_W)$ (this element can also be defined when W is not compact, in which case it lies in the Borel-Moore homology of $W(\mathbf{C})$). In the special case where W is a smooth ordinary **C**-scheme, the space $W(\mathbf{C})$ is a compact complex manifold of dimension d and $[W]$ is its usual fundamental class.

- Let Z be a smooth projective variety of dimension n over the complex numbers. Given a quasi-smooth differential graded **C**-scheme X of virtual dimension d and a map $X \hookrightarrow Z$ which is a closed embedding at the level of topological spaces, let us abuse notation by identifying the virtual fundamental class $[X] \in \mathrm{H}_{2d}(X(\mathbf{C}); \mathbf{Z})$ with its image under the canonical map

$$\mathrm{H}_{2d}(X(\mathbf{C}); \mathbf{Z}) \to \mathrm{H}_{2d}(Z(\mathbf{C}); \mathbf{Z}) \simeq \mathrm{H}^{2n-2d}(Z(\mathbf{C}); \mathbf{Z}),$$

where the isomorphism is provided by Poincare duality (note that when X is a smooth subvariety of Z, this recovers the usual interpretation of $[X]$ as an element in the cohomology ring $\mathrm{H}^*(Z(\mathbf{C}); \mathbf{Z})$). Then the equation $[X] \cup [Y] = [X \cap Y]$ holds in complete generality, provided that we interpret $X \cap Y$ as the fiber product $X \times_Z Y$ in the setting of differential graded **C**-schemes.

Example 0.0.0.6. Consider the easiest case of Bezout's theorem, where we are given a pair of lines $L, L' \subseteq \mathbf{CP}^2$ in the complex projective plane $\mathbf{CP}^2$. The lines L and L' *always* intersect transversely in exactly one point, except in the trivial case where the lines L and

L' are the same. In this degenerate case, the equation $[L] \cup [L'] = [L \cap L']$ seems to fail dramatically, because the naive intersection $L \cap L'$ (formed either in the set-theoretic or scheme-theoretic sense) does not even have the right dimension. However, the fiber product $(W, \mathscr{O}_W) = L \times_{\mathbf{CP}^2} L'$ in the differential graded setting is not equivalent to L as a differential graded $\mathbf{C}$-scheme: the homology sheaf $\mathrm{H}_1(\mathscr{O}_W)$ is a line bundle of degree -1 on W. This allows us to extract some useful information:

- The virtual dimension of W is 0, which differs from the dimension of the its underlying classical scheme L.
- As a topological space, $W(\mathbf{C})$ is a 2-sphere. However, in addition to its usual fundamental class in $\mathrm{H}_2(W(\mathbf{C}); \mathbf{Z})$, the space $W(\mathbf{C})$ also has a *virtual* fundamental class $[W] \in \mathrm{H}_0(W(\mathbf{C}); \mathbf{Z}) \simeq \mathbf{Z}$. One can show that this virtual fundamental class is given by the formula $[W] = \deg(\mathrm{H}_0(\mathscr{O}_W)) - \deg(\mathrm{H}_1(\mathscr{O}_W)) = 1$.

More informally, the structure sheaf $\mathscr{O}_W$ "knows" both that W is expected to be zero-dimensional and that it is expected to consist of exactly one point.

0.1 Why Spectral Algebraic Geometry?

Our goal in this book is to study algebro-geometric objects like the differential graded $\mathbf{C}$-schemes of Definition 0.0.0.2. However, this merits a warning: in the setting of Definition 0.0.0.2, we could replace $\mathbf{C}$ by an arbitrary field κ, but the resulting theory is not well-behaved if κ is of positive characteristic. To get a sensible theory in positive and mixed characteristic, we will replace the theory of differential graded commutative algebras by the more sophisticated theory of $\mathbb{E}_\infty$-*rings* (for the reader who is not familiar with the theory of $\mathbb{E}_\infty$-rings, we will give a brief review below; for the moment, it is enough to know that they are mathematical objects that are equivalent to commutative differential graded algebras when working over a field of characteristic zero, but better behaved in general). Among our basic objects of study in this book are *spectral schemes*: pairs $(X, \mathscr{O}_X)$ where X is a topological space and $\mathscr{O}_X$ is a sheaf of $\mathbb{E}_\infty$-rings on X which satisfies analogues of the hypotheses which appear in Definition 0.0.0.2. Every spectral scheme $(X, \mathscr{O}_X)$ has an *underlying scheme* which we will denote by $(X, \pi_0 \mathscr{O}_X)$.

A reader wanting to get a sense of the subject might ask the following:

(Q) What is the difference between spectral algebraic geometry and classical algebraic geometry? For example, what is the difference between a spectral scheme $(X, \mathscr{O}_X)$ and its underlying scheme $(X, \pi_0 \mathscr{O}_X)$?

A more skeptical reader might put the question in a more pointed way:

(Q') What use is the theory of spectral algebraic geometry? What can one do with a spectral scheme $(X, \mathscr{O}_X)$ that cannot already be done with the underlying scheme $(X, \pi_0 \mathscr{O}_X)$?

One answer to these questions was already sketched in the introduction: the language of spectral algebraic geometry provides a natural framework in which to understand issues of excess intersection and the theory of virtual fundamental classes. However, let us offer three more:

($A1$) The difference between spectral algebraic geometry and classical algebraic geometry lies in the nature of the structure sheaves considered: the structure sheaf of a spectral scheme $(X, \mathscr{O}_X)$ is a sheaf of $\mathbb{E}_\infty$-rings, while the structure sheaf of an ordinary scheme is a sheaf of commutative rings. Structured ring spectra (such as $\mathbb{E}_\infty$-rings) are ubiquitous in the study of stable homotopy theory and its applications. The language of spectral algebraic geometry provides a novel way of thinking about these objects, just as the language of classical algebraic geometry supplies geometric insights which are valuable in the study of commutative algebra.

($A2$) The difference between spectral algebraic geometry and classical algebraic geometry is analogous to the difference between triangulated categories and abelian categories. To every spectral scheme $(X, \mathscr{O}_X)$, one can assign a triangulated category $\mathrm{hQCoh}(X)$ whose objects we will refer to as *quasi-coherent sheaves on* X (this triangulated category arises as the homotopy category of a more fundamental invariant $\mathrm{QCoh}(X)$, which is a *stable* ∞*-category* rather than a triangulated category). The triangulated category $\mathrm{hQCoh}(X)$ contains, as a full subcategory, the abelian category $\mathcal{A}$ of quasi-coherent sheaves on the underlying scheme $(X, \pi_0 \mathscr{O}_X)$. Roughly speaking, the difference between the spectral scheme $(X, \mathscr{O}_X)$ and the ordinary scheme $(X, \pi_0 \mathscr{O}_X)$ is measured by the failure of $\mathrm{hQCoh}(X)$ to be the derived category of $\mathcal{A}$. In some situations, this failure is a feature rather than a bug: the triangulated category $\mathrm{hQCoh}(X)$ may be better suited to a particular application.

($A3$) The difference between spectral algebraic geometry and classical algebraic geometry can be understood in terms of deformation theory. One can think of a spectral scheme $(X, \mathscr{O}_X)$ as given by an ordinary scheme $X_0 = (X, \pi_0 \mathscr{O}_X)$ together with an "obstruction theory" for X_0 (of a somewhat elaborate type). In many cases, this obstruction theory is more natural and easier to work with than the obstruction theory which is intrinsic to X_0 itself.

We now briefly expand on each of these answers (we will discuss each one in much greater detail in the body of the text; ($A2$) and ($A3$) are, in some sense, the main themes of Parts III and **??**, respectively).

0.1.1 Homotopy Theory and $\mathbb{E}_\infty$-Rings

Algebraic topology can be described as the study of topological spaces by means of algebraic invariants. One of the main goals of the algebraic topologist is to answer questions of the following general form:

Question 0.1.1.1. Let X be an interesting topological space (perhaps a classifying space, a sphere, an Eilenberg-MacLane space, a compact Lie group, ...) and let E be an algebraic invariant of spaces (such as homology, cohomology, K-theory, stable or unstable homotopy, ...). What is $E(X)$?

Before attempting to answer a question of this kind, we would first need to decide what sort of answer we are looking for. For example, suppose that we are given a topological space X and asked to compute the cohomology groups $\mathrm{H}^*(X; \kappa)$ with coefficients in a field κ. These cohomology groups form a graded vector space over κ, so one could interpret Question 0.1.1.1 as follows:

(a) Give a basis for the cohomology $\mathrm{H}^*(X; \kappa)$ as a vector space over κ.

The invariants which arise in algebraic topology often have a very rich structure: for example, the cohomology $\mathrm{H}^*(X; \kappa)$ is not just a graded vector space over κ, it is a graded *algebra* over κ. Consequently, one can formulate Question 0.1.1.1 differently:

(*b*) Give a presentation of the ring $\mathrm{H}^*(X;\kappa)$ by generators and relations.

Remark 0.1.1.2. Problems (*a*) and (*b*) are not really the same. For example, it is possible to solve problem (*a*) without having any idea what the multiplication on $\mathrm{H}^*(X;\kappa)$ looks like. Conversely, the task of extracting a vector space basis from a presentation of $\mathrm{H}^*(X;\kappa)$ by generators and relations is nontrivial (but is at least a purely algebraic problem).

If the field κ is of characteristic 2 (or if the cohomology of X is concentrated in even degrees) then the cohomology ring $\mathrm{H}^*(X;\kappa)$ is *commutative*. In this case, we can reformulate (*b*) using the language of algebraic geometry:

(*c*) Describe the affine scheme $\operatorname{Spec}\mathrm{H}^*(X;\kappa)$ (for example, by specifying its functor of points).

The paradigm of (*c*) has turned out to be a surprisingly useful way of thinking about Question 0.1.1.1: ideas from algebraic geometry can be a powerful tool for organizing and understanding the results of many calculations in algebraic topology.

Example 0.1.1.3 (The Dual Steenrod Algebra)**.** Let $\mathcal{A}^\vee$ denote the dual Steenrod algebra: that is, the graded ring given by the direct limit

$$\mathcal{A}^\vee = \varinjlim \mathrm{H}^{\mathrm{red}}_{*+n}(K(\mathbf{F}_2,n);\mathbf{F}_2).$$

Then $\mathcal{A}^\vee$ is a graded Hopf algebra which is of central importance in algebraic topology by virtue of the fact that it controls the *co-operations* on $\mathbf{F}_2$-homology: for every topological space (or spectrum) X, the homology $\mathrm{H}_*(X;\mathbf{F}_2)$ has the structure of a comodule over $\mathcal{A}^\vee$.

The structure of $\mathcal{A}^\vee$ has a simple description (due to Milnor; see [152]): as an algebra, it is isomorphic to a polynomial ring $\mathbf{F}_2[\zeta_1,\zeta_2,\zeta_3,\ldots]$, where each variable ζ_n is homogeneous of degree 2^n-1 and the comultiplication $\Delta:\mathcal{A}^\vee\to\mathcal{A}^\vee\otimes_{\mathbf{F}_2}\mathcal{A}^\vee$ is given by the formula

$$\Delta(\zeta_n) = 1\otimes\zeta_n + \zeta_1\otimes\zeta_{n-1}^2 + \zeta_2\otimes\zeta_{n-2}^4 + \cdots + \zeta_{n-1}\otimes\zeta_1^{2^{n-1}} + \zeta_n\otimes 1.$$

Let $G=\operatorname{Spec}\mathcal{A}^\vee$ denote the associated affine scheme. For any commutative $\mathbf{F}_2$-algebra R, we can identify the set $G(R)$ of R-valued points of G with the subset of $R[[t]]$ consisting of those formal power series having the form $t+\zeta_1t^2+\zeta_2t^4+\zeta_3t^8+\cdots$; equivalently, we can describe $G(R)$ as the subset of $R[[t]]$ consisting of those power series $f(t)$ satisfying the conditions

$$f(t)\equiv t \mod t^2 \qquad f(t+t')=f(t)+f(t').$$

This supplies a conceptual way of thinking about co-operations on $\mathbf{F}_2$-homology: for any space X, we can regard the vector space $\mathrm{H}_*(X;\mathbf{F}_2)$ as an algebraic representation of the group scheme G (in fact, by taking into account the grading of $\mathrm{H}_*(X;\mathbf{F}_2)$, we can regard it as a representation of the larger group scheme G^+ parametrizing *all* power series f satisfying $f(t+t')=f(t)+f(t')$ which are invertible under composition).

Example 0.1.1.4 (Complex Bordism and Formal Group Laws)**.** For each $n \geqslant 0$, let MU_n denote the group of bordism classes of stably almost-complex manifolds of dimension n. The direct sum $\mathrm{MU}_* = \bigoplus \mathrm{MU}_n$ is a commutative ring, called the *complex bordism ring*. The structure of this ring was determined by Milnor ([153]): it is isomorphic to a polynomial ring $\mathbf{Z}[x_1, x_2, x_3, \ldots]$ where each variable x_i is homogeneous of degree $2i$. This result was refined by Quillen, who showed that there is a *canonical* isomorphism of MU_* with the Lazard ring L classifying 1-dimensional formal group laws ([169]). In other words, if X denotes the affine scheme $\operatorname{Spec} \mathrm{MU}_*$, then for any commutative ring R we can identify the set $X(R)$ of R-valued points of X with the set of power series $f(u,v) \in R[[u,v]]$ which satisfy the identities

$$f(u,0) = u \qquad f(u,v) = f(v,u) \qquad f(u, f(v,w)) = f(f(u,v), w).$$

Quillen's theorem is the starting point for the subject of *chromatic homotopy theory*, which has revealed a surprisingly tight connection between the study of cohomology theories and the study of formal groups and their arithmetic properties.

Examples 0.1.1.3 and 0.1.1.4 are concerned with algebraic structures that one sees at the level of homology and homotopy, respectively. For many applications, it is important to understand algebraic structures at a more primitive level: for example, at the level of chain complexes before passing to homology. To take a simple example, for *any* topological space M and *any* commutative ring R, the cohomology groups $\mathrm{H}^*(M;R)$ form a graded-commutative ring. However, when M is a smooth manifold and $R = \mathbf{R}$ is the field of real numbers, then $\mathrm{H}^*(M;R)$ can be described as the cohomology of the de Rham complex

$$\Omega^0_M \xrightarrow{d} \Omega^1_M \xrightarrow{d} \Omega^2_M \to \cdots .$$

One of the many convenient features of this description is it makes the graded-commutative ring structure on $\mathrm{H}^*(M;\mathbf{R})$ visible at the level of cochains: the de Rham complex (Ω^*_M, d) itself is a commutative differential graded algebra. Motivated by this observation, Sullivan introduced a construction which associates to an arbitrary topological space X a "polynomial de Rham complex" $C^*_{\mathrm{dR}}(X;\mathbf{Q})$, given by a mixture of singular and de Rham complexes. This construction is naturally quasi-isomorphic to the usual singular cochain complex $C^*(X;\mathbf{Q})$ but has the virtue of admitting a ring structure which is commutative at the level of cochains: $C^*_{\mathrm{dR}}(X;\mathbf{Q})$ is a commutative differential graded algebra over $\mathbf{Q}$. The result is a powerful algebraic invariant of X. For example, one has the following result:

Theorem 0.1.1.5 (Sullivan)**.** *Let X be a simply connected topological space whose rational cohomology groups $\mathrm{H}^n(X;\mathbf{Q})$ are finite-dimensional for every n. Then the rational homotopy type of X can be recovered from its polynomial de Rham complex $C^*_{\mathrm{dR}}(X;\mathbf{Q})$. More precisely, if we let $X_{\mathbf{Q}}$ denote the space of maps from $C^*_{\mathrm{dR}}(X;\mathbf{Q})$ into $\mathbf{Q}$ (in the homotopy theory of* *commutative differential graded algebras over* $\mathbf{Q}$*), then there is a canonical map* $X \to X_{\mathbf{Q}}$ *which is an isomorphism on rational cohomology.*

We refer to [?] for a more precise formulation and proof of Theorem 0.1.1.5 (we will discuss a version of Theorem 0.1.1.5 in §**??**).

Remark 0.1.1.6. It follows from Theorem 0.1.1.5 that the ring structure on the polynomial de Rham complex $C^*_{\mathrm{dR}}(X;\mathbf{Q})$ contains much more information than the ring structure on its homology $\mathrm{H}^*(X;\mathbf{Q})$. It is easy to give examples of finite CW complexes X and Y for which the cohomology rings $\mathrm{H}^*(X;\mathbf{Q})$ and $\mathrm{H}^*(Y;\mathbf{Q})$ are isomorphic, but much harder to give examples in which the polynomial de Rham complexes $C^*_{\mathrm{dR}}(X;\mathbf{Q})$ and $C^*_{\mathrm{dR}}(Y;\mathbf{Q})$ are quasi-isomorphic: if X and Y are simply connected, this can happen only if there exist maps of spaces $X \to Z \leftarrow Y$ which induce isomorphisms on rational cohomology (in this case, we say that X and Y are *rationally* homotopy equivalent).

Remark 0.1.1.7. The language of differential graded schemes suggests the possibility of formulating Theorem 0.1.1.5 in an algebro-geometric way. Let X be a topological space and let $C^*_{\mathrm{dR}}(X;\mathbf{Q})$ be its polynomial de Rham complex. One might try to form some sort of spectrum $\widehat{X} = \operatorname{Spec} C^*_{\mathrm{dR}}(X;\mathbf{Q})$ in the setting of differential graded $\mathbf{Q}$-schemes, so that the space $X_{\mathbf{Q}}$ appearing in Theorem 0.1.1.5 can be interpreted as a space of $\mathbf{Q}$-valued points of $\widehat{X}$. The object $\widehat{X}$ can be regarded as an algebro-geometric incarnation of the topological space X (in the terminology of [209], it is the *schematization* of X).

The geometric object $\widehat{X}$ does not quite fit into the framework of differential graded schemes introduced in Definition 0.0.0.2, because commutative differential graded algebra $C^*_{\mathrm{dR}}(X;\mathbf{Q})$ usually has nonzero homology in negative degrees (or, equivalently, nonzero cohomology in positive degrees). However, it is an example of a different sort of algebro-geometric object (a *coaffine stack*) which we will study in Chapter 9.

To define the polynomial de Rham complex $C^*_{\mathrm{dR}}(X;\mathbf{Q})$, it is necessary to work over $\mathbf{Q}$: if κ is a field of positive characteristic, then there is no canonical way to choose quasi-isomorphism of the singular cochain complex $C^*(X;\kappa)$ with a commutative differential graded algebra over κ. However, this should be regarded as a defect not of $C^*(X;\kappa)$, but of the notion of commutative differential graded algebra. The cochain complex $C^*(X;\kappa)$ is an example of an $\mathbb{E}_\infty$-algebra over κ: it can be equipped with a multiplication law

$$m : C^*(X;\kappa) \otimes_\kappa C^*(X;\kappa) \to C^*(X;\kappa)$$

which is "commutative and associative up to coherent homotopy": in other words, it satisfies every reasonable demand that can be formulated in a homotopy-invariant way (for example, m need not be commutative, but it is commutative up to a chain homotopy $h : C^*(X;\kappa) \otimes_\kappa C^*(X;\kappa) \to C^{*-1}(X;\kappa)$).

Remark 0.1.1.8. Any commutative differential graded algebra (A_*, d) over a field κ determines an $\mathbb{E}_\infty$-algebra over κ: a multiplication law which is commutative and associative "on the nose" is, in particular, commutative and associative up to coherent homotopy. If the field κ has characteristic zero, then every $\mathbb{E}_\infty$-algebra arises in this way, up to quasi-isomorphism. Over fields of positive characteristic, this is not true: there exists $\mathbb{E}_\infty$-algebras which are not quasi-isomorphic to commutative differential graded algebras. For example, if A is an $\mathbb{E}_\infty$-algebra over the field $\mathbf{F}_2$, then the homology groups of A (regarded as a cochain complex over $\mathbf{F}_2$) can be equipped with Steenrod operations $\mathrm{Sq}^n : \mathrm{H}^*(A) \to \mathrm{H}^{*+n}(A)$). If A is obtained from a commutative differential graded algebra over $\mathbf{F}_2$, then these operations automatically vanish for $* \neq n$. However, in the case $A = C^*(X; \mathbf{F}_2)$, they are usually nontrivial (and are a useful and important tool for studying the $\mathbf{F}_2$-cohomology of X).

Let X be a topological space. Just as the polynomial de Rham complex $C^*_{\mathrm{dR}}(X; \mathbf{Q})$ is a much more powerful invariant than the rational cohomology ring $\mathrm{H}^*(X; \mathbf{Q})$ (Remark 0.1.1.6), the structure of the cochain complex $C^*(X; \mathbf{F}_p)$ as an $\mathbb{E}_\infty$-algebra is a much more powerful invariant than the $\mathbf{F}_p$-cohomology ring $\mathrm{H}^*(X; \mathbf{F}_p)$. For example, the $\mathbb{E}_\infty$-structure on $C^*(X; \mathbf{F}_p)$ determines not only the ring structure on $\mathrm{H}^*(X; \mathbf{F}_p)$, but also the behavior of Steenrod operations. In fact, from the $\mathbb{E}_\infty$-structure on $C^*(X; \mathbf{F}_p)$ one can recover the entire p-adic homotopy type of X, thanks to the following analogue of Theorem 0.1.1.5:

Theorem 0.1.1.9 (Mandell)**.** *Let X be a simply connected space whose cohomology groups $\mathrm{H}^n(X; \mathbf{F}_p)$ are finite for every n, and let $X_p^\wedge$ denote the space of $\mathbb{E}_\infty$-algebra morphisms from $C^*(X; \mathbf{F}_p)$ to $\overline{\mathbf{F}}_p$ (here $\overline{\mathbf{F}}_p$ denotes an algebraic closure of $\mathbf{F}_p$). Then there is a canonical map $X \to X_p^\wedge$ which induces an isomorphism on $\mathbf{F}_p$-cohomology.*

Remark 0.1.1.10. In the situation of Theorem 0.1.1.9, the space $X_p^\wedge$ is a *p-adic completion of X*. This implies, for example, that each homotopy group $\pi_n X_p^\wedge$ an be identified with the p-adic completion of $\pi_n X$.

Remark 0.1.1.11. As with Theorem 0.1.1.5, it may be useful to think of Theorem 0.1.1.9 in algebro-geometric terms. If we view $C^*(X; \mathbf{F}_p)$ as a generalized commutative ring and form some kind of spectrum $\widehat{X} = C^*(X; \mathbf{F}_p)$, then we can view the p-adic completion $X_p^\wedge$ as the space $\widehat{X}(\overline{\mathbf{F}}_p)$ of $\overline{\mathbf{F}}_p$-valued points of $\widehat{X}$. The geometric perspective is a bit more useful here than in the rational case, because one can give an analogous description of the space $\widehat{X}(R)$ for any commutative $\mathbf{F}_p$-algebra R: it can be identified with the space of maps from the étale homotopy type of $\operatorname{Spec} R$ into $X_p^\wedge$. For more details, we refer the reader to Part IX.

If A is an $\mathbb{E}_\infty$-algebra over a field κ, then the multiplication on A (which is commutative up to homotopy) endows the homology $\mathrm{H}_*(A)$ with the structure of a graded-commutative ring. Many of the graded-commutative rings which arise naturally in algebraic topology (such as the cohomology rings of spaces) can be obtained in this way. However, there are many examples which are similar in spirit to which the formalism of chain complexes does not quite apply. For example, for each $n \geqslant 0$ let MSO_n denote the collection of bordism classes of closed oriented n-dimensional smooth manifolds. The collection $\{\mathrm{MSO}_n\}_{n \geqslant 0}$ forms a graded-commutative ring, where addition is given by the formation of disjoint unions and multiplication is given by the formation of Cartesian products. Heuristically, one can think of this graded ring as given by the homology of a "chain complex"

$$\cdots \xrightarrow{\partial} \Omega_3 \xrightarrow{\partial} \Omega_2 \xrightarrow{\partial} \Omega_1 \xrightarrow{\partial} \Omega_0$$

where Ω_n denotes the "collection" of compact oriented n-manifolds with boundary, and ∂ is given by forming the boundary. We have addition and multiplication operations

$$\coprod : \Omega_n \times \Omega_n \to \Omega_n \qquad \prod : \Omega_m \times \Omega_n \to \Omega_{m+n}$$

which are commutative and associative up to diffeomorphism. For many applications, it is important that we do *not* define Ω_n to simply be the set of diffeomorphism classes of compact oriented n-manifolds with boundary: passing to diffeomorphism classes loses important information about the behavior of addition and multiplication (for example, the natural action of the symmetric group Σ_2 on the manifolds $M \amalg M$ and $M \times M$). One can retain this information by regarding oriented bordism as an example of a more sophisticated object which we will refer to as an $\mathbb{E}_\infty$*-ring*. We will give an informal review of the theory of $\mathbb{E}_\infty$-rings in §0.2.3 (for a more detailed and precise account, see [139]). Let us summarize some of the features of this theory which are relevant to the present discussion:

- Every $\mathbb{E}_\infty$-ring A has an underlying cohomology theory $X \mapsto A^*(X)$. Roughly speaking, one can think of an $\mathbb{E}_\infty$-ring A as a cohomology theory equipped with a multiplicative structure which is commutative not only at the level of cohomology classes, but also at the level of representatives for cohomology classes (at least up to coherent homotopy).

- If A is an $\mathbb{E}_\infty$-ring and $n \in \mathbf{Z}$ is an integer, then we denote the cohomology group $A^{-n}(*)$ by $\pi_n A$ and refer to it as the *nth homotopy group of* A. The direct sum $\bigoplus_{n \in \mathbf{Z}} \pi_n A$ has the structure of a graded-commutative ring. In particular, $\pi_0 A$ is a commutative ring and each $\pi_n A$ has the structure of a module over $\pi_0 A$.

- Every commutative ring R can be regarded as an $\mathbb{E}_\infty$-ring: the corresponding cohomology theory is ordinary cohomology with coefficients in R. The $\mathbb{E}_\infty$-rings A which arise in this way are characterized by the fact that the homotopy groups $\pi_n A$ vanish for $n \neq 0$.

- If R is an $\mathbb{E}_\infty$-ring, we define an $\mathbb{E}_\infty$*-algebra over* R to be an $\mathbb{E}_\infty$-ring A equipped with a morphism of $\mathbb{E}_\infty$-rings $R \to A$. When R is an ordinary commutative ring, this reduces to the notion described informally earlier: one can identify A with a chain complex of R-modules equipped with a multiplication which is commutative and associative up to coherent homotopy. Under this identification, the homotopy groups of A (regarded as an abstract $\mathbb{E}_\infty$-ring) correspond to the homology groups of the associated chain complex.

There are many important examples of $\mathbb{E}_\infty$-rings A which do not arise as $\mathbb{E}_\infty$-algebras over any commutative ring R.

Example 0.1.1.12 (Complex K-Theory)**.** Let X be a finite CW complex. We define $K^0(X)$ to be the Grothendieck group of the commutative monoid

$$\{ \text{ Complex vector bundles on } X \ \}/ \text{ isomorphism } .$$

We refer to $K^0(X)$ as the *complex K-theory of X*. It is a commutative ring whose addition and multiplication arise from the operation of direct sum and tensor product on complex vector bundles, respectively.

One can extend the construction $X \mapsto K^0(X)$ to define invariants $K^n(X)$ for any integer n and any topological space X. These invariants determine a cohomology theory which we refer to as *complex K-theory*. This cohomology theory is represented by an $\mathbb{E}_\infty$-ring roughly speaking, the $\mathbb{E}_\infty$-structure reflects the fact that multiplication of K-theory classes can be arises concretely for the formation of tensor products of complex vector bundles, which is commutative and associative up to canonical isomorphism. Complex K-theory does not admit the structure of an $\mathbb{E}_\infty$-algebra over any commutative ring R.

Example 0.1.1.13 (Complex Bordism)**.** The complex bordism groups $\{\mathrm{MU}_n\}_{n \geqslant 0}$ of Example 0.1.1.4 can be identified with the homotopy groups of an $\mathbb{E}_\infty$-ring MU, called the *complex bordism spectrum*. In this case, the $\mathbb{E}_\infty$-structure reflects the fact the fact that the formation of Cartesian products of (stably almost) complex manifolds is commutative up to isomorphism. As in Example 0.1.1.12, MU is not an $\mathbb{E}_\infty$-algebra over any commutative ring R.

Example 0.1.1.14 (The Dual Steenrod Algebra)**.** The dual Steenrod algebra $\mathcal{A}^\vee$ of Example 0.1.1.3 can be defined by the formula

$$\mathcal{A}^\vee = \pi_*(\mathbf{F}_2 \wedge \mathbf{F}_2),$$

where $\mathbf{F}_2 \wedge \mathbf{F}_2$ denotes the $\mathbb{E}_\infty$-ring given by a coproduct of two copies of the ordinary commutative ring $\mathbf{F}_2$. This $\mathbb{E}_\infty$-ring does arise as an $\mathbb{E}_\infty$-algebra over $\mathbf{F}_2$, but in two *different* ways. In some situations, one might not want to choose between these (for example, if one wants to study the action of the symmetric group Σ_2 on $\mathbf{F}_2 \wedge \mathbf{F}_2$ given by permuting the factors), in which case it is better to view $\mathbf{F}_2 \wedge \mathbf{F}_2$ as an abstract $\mathbb{E}_\infty$-ring.

We can summarize the preceding discussion as follows:

(*i*) Many calculations in algebraic topology yield commutative (or graded-commutative) rings R. In these cases, it is sometimes easier to think about the affine scheme $\operatorname{Spec} R$ (see Examples 0.1.1.3 and 0.1.1.4).

(*ii*) Many of the graded-commutative rings which arise in algebraic topology can be described as $\pi_* A$ for some $\mathbb{E}_\infty$-ring A. Passage from A to $\pi_* A$ loses a lot of potentially useful information (see Theorems 0.1.1.5 and 0.1.1.9).

The theory of spectral algebraic geometry developed in this book can be described by the rough heuristic

$$\text{Spectral algebraic geometry} = \text{Algebraic Geometry} + \mathbb{E}_\infty\text{-Rings}.$$

One of the aims of this theory is to provide a setting which we can make use of insights (*i*) and (*ii*) simultaneously: given an $\mathbb{E}_\infty$-ring A, we might wish to contemplate the spectrum of A itself (regarded as a kind of generalized affine scheme), rather than the spectrum of some ordinary commutative ring extracted from A (such as $\pi_0 A$ or $\pi_* A$).

At this point, the reader might reasonably object that all of the schemes considered in this section are affine. If we are interested only in affine schemes, then the language of algebraic geometry is superfluous: the datum of an affine scheme is equivalent to the datum of a commutative ring, and the datum of an affine spectral scheme is equivalent to the datum of a (connective) $\mathbb{E}_\infty$-ring. However, there are also non-affine algebro-geometric objects which are relevant to algebraic topology. This is particularly true in the study of chromatic homotopy theory, where many non-affine objects arise naturally as parameter spaces for families of formal groups.

Example 0.1.1.15 (Elliptic Cohomology)**.** Let $\mathcal{M}_{1,1}$ denote the moduli stack of elliptic curves. It follows from the work of Goerss, Hopkins, and Miller that there an essentially unique sheaf $\mathscr{O}^+$ of $\mathbb{E}_\infty$-rings on (the étale site of) $\mathcal{M}_{1,1}$ with the following features:

($*$) Let $U = \operatorname{Spec} R$ be an affine scheme, let $\eta : U \to \mathcal{M}_{1,1}$ be an étale map which classifies an elliptic curve E over R, and set $A = \mathscr{O}^+(U)$. Then there is a canonical isomorphism of commutative rings $\pi_0 A \simeq R$ and a canonical isomorphism of the formal R-scheme $\operatorname{Spf} A^0(\mathbf{CP}^\infty)$ with the formal completion of E (compatible with the group structure on E). Moreover, the homotopy groups $\pi_n A$ vanish when n is odd, and the multiplication maps $\pi_2 A \otimes_R \pi_n A \simeq \pi_{n+2} A$ are isomorphisms for all n.

Passing to global sections, the sheaf $\mathscr{O}^+$ determines an $\mathbb{E}_\infty$-ring TMF called the *spectrum of topological modular forms*. The resulting cohomology theory manifests a rich interplay between ideas from algebraic topology, the arithmetic of modular forms, and mathematical physics.

The sheaf $\mathscr{O}^+$ has a natural interpretation in the language of spectral algebraic geometry. In the terminology of Part I, the pair $(\mathcal{M}_{1,1}, \mathscr{O}^+)$ is an example of a *nonconnective spectral Deligne-Mumford stack*, whose underlying classical Deligne-Mumford stack is the usual moduli stack of elliptic curves. Moreover, the pair $(\mathcal{M}_{1,1}, \mathscr{O}^+)$ can itself be interpreted as a moduli stack: it classifies elliptic curves (defined over $\mathbb{E}_\infty$-rings) which are equipped with an additional datum called an *orientation* (for an informal summary, we refer the reader to [140]). To make sense of this picture, it is important to have a theory of spectral algebraic geometry which includes non-affine objects: elliptic curves are not affine, and the moduli stack of elliptic curves is not even a scheme.

0.1.2 Derived Categories

Suppose that we are given some category $\mathcal{C}$ that we wish to understand (for example, the category of complex representations of a finite group G). One basic strategy is to first find some select some particularly simple objects $\{C_x \in \mathcal{C}\}_{x \in X}$ (for example, the collection of irreducible representations of the group G) and hope that an arbitrary object $C \in \mathcal{C}$ can be expressed as a combination or superposition of the objects $\{C_x\}_{x \in X}$. In many cases of interest, the "simple" objects $\{C_x\}$ admit an algebraic classification, meaning that they are parametrized by the points of some algebro-geometric object X.

Example 0.1.2.1. Let G be a finite flat commutative group scheme over a field κ. Then the one-dimensional (algebraic) representations of G can be identified with maps from G to the multiplicative group $\mathbf{G}_m$, which we can identify with the κ-valued points of the *Cartier dual* group scheme $G^\vee$. In this case, the category $\mathrm{Rep}(G)$ of algebraic representations of G can be identified with the category of quasi-coherent sheaves on $G^\vee$. In concrete terms, if we write $G = \operatorname{Spec} H$ for some finite-dimensional Hopf algebra H over κ, then $G^\vee$ is the spectrum of the dual Hopf algebra $H^\vee$, and the desired equivalence is given by

$$\begin{aligned}\{ \text{ Quasi-coherent sheaves on } G^\vee \ \} &\simeq \{ \ H^\vee\text{-modules } \} \\ &\simeq \{ \ H\text{-comodules } \} \\ &\simeq \{ \text{ Representations of } G \ \}.\end{aligned}$$

For every κ-valued point $\iota : \operatorname{Spec} \kappa \to G^\vee$, this equivalence carries the skyscraper sheaf $\iota_* \kappa$ (regarded as a quasi-coherent sheaf on $G^\vee$) to the one-dimensional representation of G classified by ι.

In Example 0.1.2.1, the identification of representations of G with quasi-coherent sheaves $G^\vee$ holds at the level of abelian categories. However, there are many examples in which one can apply essentially the same paradigm, but it only provides an equivalence at the level of *derived* categories. Recall that for any abelian $\mathcal{A}$, the *derived category* $D(\mathcal{A})$ is obtained from the category $K(\mathcal{A})$ of chain complexes with values in $\mathcal{A}$ by formally adjoining inverses to all quasi-isomorphisms (see [**?**]). If $\mathcal{A}$ is the abelian category of quasi-coherent sheaves on a scheme X, we will denote $D(\mathcal{A})$ simply by $D(X)$ and refer to it as the *derived category* of X.

Example 0.1.2.2 (The Fourier-Mukai Transform)**.** Let E be an elliptic curve defined over the field $\mathbf{C}$ of complex numbers. For every (closed) point $x \in E$, let $\mathscr{O}(x)$ denote the line bundle on E whose section are regular away from x and permitted to have a simple pole at the point x. If we fix a base point $e \in E$, then the construction

$$x \mapsto \mathscr{O}(x - e) = \mathscr{O}(x) \otimes \mathscr{O}(e)^{-1}$$

determines a bijection from the set of (closed) points of E to the set of isomorphism classes of line bundles of degree zero on E. The line bundles $\{\mathscr{O}(x-e)\}_{x \in E}$ are the fibers of a line bundle $\mathcal{P}$ on $E \times E$ corresponding to the Cartier divisor $\Delta - (\{e\} \times E) - (E \times \{e\})$, where Δ is the image of the diagonal map $E \to E \times E$. If we let $\pi_0, \pi_1 : E \times E \to E$ denote the projection maps, then the construction $\mathscr{F} \mapsto \pi_{1*}(\mathcal{P} \otimes \pi_0^* \mathscr{F})$ determines a functor from the abelian category of quasi-coherent sheaves on E to itself, which carries the skyscraper sheaf at a closed point $x \in E$ to the line bundle $\mathscr{O}(x-e)$. At the level of abelian categories, this functor is poorly behaved: it is neither exact nor faithful (for example, it annihilates any line bundle of degree $\leqslant 0$ on E). However, if we work instead at the level of derived categories, then the analogous construction $\mathscr{F} \mapsto R\pi_{1*}(\mathcal{P} \otimes \pi_0^* \mathscr{F})$ determines an equivalence from the category $D(E)$ to itself. Moreover, an analogous statement holds if we replace E by an abelian scheme over any commutative ring A (see [158]).

The derived category $D(X)$ of a scheme X is a fundamental invariant of X. In many cases it is even a *complete* invariant: if X is a smooth projective variety over a field κ whose canonical bundle is either ample or anti-ample, then a celebrated result of Bondal and Orlov asserts that X is determined (up to isomorphism in the category of schemes) by the full subcategory $D^b_{\mathrm{coh}}(X) \subseteq D(X)$ spanned by chain complexes with bounded coherent cohomology; see [163]. One of the main objects of study in this book is an extension of the construction $X \mapsto D(X)$ to the case where X is a spectral scheme. The main features of this extension can be summarized as follows:

- To every spectral scheme $(X, \mathscr{O}_X)$, we will associate a triangulated category $\mathrm{hQCoh}(X)$.
- If $(X, \mathscr{O}_X)$ is an ordinary scheme which is quasi-compact and separated, then $\mathrm{hQCoh}(X)$ can be identified with the derived category $D(X)$ (see Corollary 10.3.4.13).

- For a general spectral scheme $(X, \mathscr{O}_X)$, we can think of $\mathrm{hQCoh}(X)$ informally as the "derived category of X." However, this heuristic has the potential to cause confusion: in general, the triangulated category $\mathrm{hQCoh}(X)$ need not be equivalent to the derived category of *any* abelian category (however, it does arise as the homotopy category of a stable ∞-category $\mathrm{QCoh}(X)$, which is our actual object of interest).

- Let $(X, \mathscr{O}_X)$ be a spectral scheme and let $\mathcal{A}$ denote the abelian category of quasi-coherent sheaves on the underlying ordinary scheme $X_0 = (X, \pi_0 \mathscr{O}_X)$. Then the triangulated category $\mathrm{hQCoh}(X)$ contains the abelian category $\mathcal{A}$ as a full subcategory. Moreover, the inclusion $\mathcal{A} \hookrightarrow \mathrm{hQCoh}(X)$ extends to a triangulated functor $D(X_0) \to \mathrm{hQCoh}(X)$. Assuming that X is quasi-compact and separated, this functor is an equivalence if and only if $(X, \mathscr{O}_X)$ is an ordinary scheme (see Corollary 10.3.4.12).

- Let X_0 be a scheme and let $\mathcal{A}$ be the abelian category of quasi-coherent sheaves on X_0. Then the construction

$$\{\text{ spectral schemes with underlying ordinary scheme } X_0 \text{ }\} \downarrow \{\text{ triangulated categories containing } \mathcal{A} \text{ }\}$$

$$X \mapsto \mathrm{hQCoh}(X)$$

is not too far from being an equivalence (see Corollary 9.6.0.2). In other words, we have a rough heuristic

Spectral algebraic geometry = Algebraic Geometry + Triangulated Categories.

Extending the theory of derived categories to the setting of spectral schemes is not an empty theoretical exercise: it is often necessary when we wish to extend the paradigm of Examples 0.1.2.1 and 0.1.2.2 to more complicated situations. Given a triangulated category $\mathcal{C}$ and a family of objects $\{C_x\}_{x \in X_0}$ parametrized (in some sense) by a scheme X_0, there is often a canonical way to realize X_0 as the underlying ordinary scheme of a spectral scheme X in such a way that the construction $x \mapsto C_x$ extends to a triangulated equivalence $\mathrm{hQCoh}(X) \to \mathcal{C}$.

Example 0.1.2.3. Let G be a semisimple algebraic group defined over a field κ of characteristic $p > 0$, let $\mathfrak{g}$ be its Lie algebra, and let $U_0(\mathfrak{g})$ denote the restricted universal enveloping algebra of $\mathfrak{g}$. Let X denote the flag variety parametrizing choices of Borel subgroup $B \subseteq G$, let $X^{(1)}$ denote the pullback of X along the Frobenius map $\varphi : \operatorname{Spec} \kappa \to \operatorname{Spec} \kappa$, and let $\varphi_{\mathrm{geom}} : X \to X^{(1)}$ denote the geometric Frobenius map associated to X. For each κ-valued point $x \in X^{(1)}(\kappa)$, we can write the scheme-theoretic fiber $\varphi_{\mathrm{geom}}^{-1}\{x\}$ as the spectrum $\operatorname{Spec} A_x$, where A_x is a finite-dimensional κ-algebra. The action of G on X determines an action of the restricted universal enveloping algebra $U_0(\mathfrak{g})$ on A_x, and the construction $x \mapsto A_x$ extends to a functor of derived categories $T : D(X^{(1)}) \to D(U_0(\mathfrak{g}))$. The functor T is far from being an equivalence. However, if the prime number p is sufficiently large (with respect to the Dynkin diagram of G), then the functor T can be factored as a composition

$$D(X^{(1)}) = \mathrm{hQCoh}(X^{(1)}) \xrightarrow{\pi_*} \mathrm{hQCoh}(Y^{(1)}) \xrightarrow{T^+} D(A)$$

with the following features:

- The functor T^+ is a fully faithful embedding whose essential image is a direct summand (a "block") of the derived category $D(A)$.
- The spectral scheme $Y^{(1)}$ is the Frobenius pullback of the (spectral) fiber product $Y = \widetilde{\mathfrak{g}} \times_{\mathfrak{g}} \{0\}$, where $\widetilde{\mathfrak{g}} \subseteq X \times_{\operatorname{Spec} \kappa} \mathfrak{g}$ is the closed subscheme whose κ-valued points are pairs $(x, v) \in X(\kappa) \times \mathfrak{g}$ satisfying $v \in \mathfrak{b}_x$ (here we abuse notation by identifying $\mathfrak{g}$ with the affine scheme $\operatorname{Spec} \operatorname{Sym}^*_\kappa \mathfrak{g}^\vee$).
- The triangulated functor $\pi_* : \mathrm{hQCoh}(X^{(1)}) \to \mathrm{hQCoh}(Y^{(1)})$ is induced by pushforward along a map of spectral schemes $\pi : X^{(1)} \to Y^{(1)}$ which exhibits $X^{(1)}$ as the ordinary scheme underlying $Y^{(1)}$.

We refer the reader to [174] and [**?**] for more details.

Another motivation for the theory of spectral algebraic geometry is that the triangulated categories which appear have better formal properties than their classical counterparts.

Example 0.1.2.4. Suppose we are given a pullback diagram σ :

$$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow{g} & Y \end{array}$$

of quasi-compact separated schemes. To the morphisms f and f' we can associate (derived) pushforward functors

$$Rf_* : D(X) \to D(Y) \qquad Rf'_* : D(X') \to D(Y'),$$

to the morphisms g and g' we can associate (derived) pullback functors

$$Lg^* : D(Y) \to D(Y') \qquad Lg'^* : D(X) \to D(X'),$$

and there is an associated Beck-Chevalley transformation $\alpha : Lg^* \circ Rf_* \to Rf'_* \circ Lg'^*$. This natural transformation is an equivalence if either f or g is flat, but not in general. One can be more precise: the morphism α is an equivalence precisely when the diagram σ is *also* a pullback square in the setting of spectral schemes.

The situation in spectral algebraic geometry is simpler: for *any* pullback diagram σ :

$$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow{g} & Y \end{array}$$

of quasi-compact separated spectral schemes, the associated diagram of triangulated categories

$$\begin{array}{ccc} \mathrm{hQCoh}(X') & \xleftarrow{g'^*} & \mathrm{hQCoh}(X) \\ \downarrow{\scriptstyle f'_*} & & \downarrow{\scriptstyle f_*} \\ \mathrm{hQCoh}(Y') & \xleftarrow{g^*} & \mathrm{hQCoh}(Y) \end{array}$$

commutes up to canonical isomorphism (see Proposition 2.5.4.5).

Example 0.1.2.4 illustrates another general point: in classical algebraic geometry, the role of flatness hypotheses is often to guarantee that fiber products of ordinary schemes agree with the analogous fiber products in the setting of spectral schemes. If one extends the vocabulary of algebraic geometry to include spectral schemes, then flatness hypotheses are often superfluous (or can be substantially weakened).

Example 0.1.2.5 (Proper Descent)**.** Let $f : X \to S$ be a morphism of schemes which is quasi-compact and faithfully flat. Then f is of effective descent for quasi-coherent sheaves. More precisely, the abelian category $\mathcal{A}_S$ of quasi-coherent sheaves on S can be identified with the (homotopy) inverse limit $\varprojlim \mathcal{A}_{X_\bullet}$, where $X_\bullet$ denotes the simplicial scheme obtained from f (so that $X_n = X \times_S X \times_S \cdots \times_S X$ is the $(n+1)$-fold fiber product of X over S) and $\mathcal{A}_{X_\bullet}$ denotes the associated cosimplicial abelian category.

In the setting of spectral algebraic geometry, one can formulate and prove variants of this assumption without a flatness hypothesis. For example, if $f : X \to S$ is a map of Noetherian schemes which is proper, surjective, and of finite presentation and $X_\bullet$ is defined as above, then there is an associated equivalence $\mathrm{QCoh}(S) \to \varprojlim \mathrm{QCoh}(X_\bullet)$ of stable ∞-categories (see Theorem 5.6.6.1). One can even relax the hypothesis that f is surjective: in general, the inverse limit $\varprojlim \mathrm{QCoh}(X_\bullet)$ can be identified with $\mathrm{QCoh}(\widehat{S})$, where $\widehat{S}$ denotes the formal completion of S along the image of f. For example, suppose that S is a Noetherian scheme and let $\eta : \{s\} \hookrightarrow S$ be the inclusion of a closed point $s \in S$ (regarded as a reduced closed subscheme of S). Then, for any quasi-coherent sheaf $\mathscr{F}$ on S, the restriction of $\mathscr{F}$ to the formal completion $\widehat{S}$ can be recovered from the fiber $\eta^* \mathscr{F}$, together with "derived descent data" whose specification involves the iterated fiber products $X_n = \{s\} \times_S \{s\} \times_S \cdots \times_S \{s\}$.

Of course, it is essential here that these iterated fiber product are formed in the setting of spectral schemes (and therefore depend on the local structure of S near the point s, not only on the residue field of S at s).

0.1.3 Deformation Theory

Let X_0 be a smooth algebraic variety over the field $\mathbf{C}$ of complex numbers. One of the central aims of *deformation theory* is to understand the algebraic varieties which are "close to X_0" in some sense. For example, suppose that X_0 appears as the fiber of a morphism of schemes $f : X \to S$ at some point $s \in S$ (having residue field $\mathbf{C}$). One might hope that there is a close relationship between properties of the fiber X_0 and properties of other fibers $X_{s'} = X \times_S \{s'\}$, or of the scheme X itself. To guarantee this, one typically needs to make global assumptions about the morphism f (for example, that it is flat or proper) and also about base scheme S. For example, if $s, s' \in S$ are points belonging to different connected components of S, then there is no reason to expect any relationship between the fibers $X_0 = X \times_S \{s\}$ and $X_{s'} = X \times_S \{s'\}$. One way to avoid this concern is to restrict attention to the case where the scheme S has only one point: for example, the case where $S = \operatorname{Spec} R$ for some local Artinian ring R. This leads to the subject of *formal* deformation theory: the study of algebraic varieties which are, in some sense, "infinitesimally close" to X_0.

Let us begin by considering the simplest nontrivial case: let S denote the spectrum of the ring $\mathbf{C}[\epsilon]/(\epsilon^2)$ (sometimes referred to as the *ring of dual numbers*). If X_0 is an algebraic variety over $\mathbf{C}$, then a *first order deformation* of X_0 is pullback diagram of schemes

$$\begin{array}{ccc} X_0 & \longrightarrow & X \\ \downarrow & & \downarrow \\ \operatorname{Spec} \mathbf{C} & \longrightarrow & \operatorname{Spec} \mathbf{C}[\epsilon]/(\epsilon^2), \end{array}$$

where the vertical maps are flat. The following proposition summarizes some standard facts about first-order deformations:

Proposition 0.1.3.1. *Let X_0 be a smooth algebraic variety over $\mathbf{C}$. Then:*

(a) For every first-order deformation X of X_0, there is a canonical bijection

$$\{ \text{ Automorphisms of } X \text{ that restrict to the identity on } X_0 \ \} \simeq \mathrm{H}^0(X_0; T_{X_0}).$$

Here T_{X_0} denotes the tangent bundle of the smooth variety X_0.

(b) There is a canonical bijection

$$\{ \text{ Isomorphism classes of first-order deformations of } X_0 \ \} \simeq \mathrm{H}^1(X_0; T_{X_0}).$$

Many of the central ideas of spectral algebraic geometry originated from the desire to extend Proposition 0.1.3.1 to the case where X_0 is not smooth. To understand the issues involved, let us begin by how the tangent bundle is defined in the special case where $X_0 = \operatorname{Spec} B$ is an affine algebraic variety over $\mathbf{C}$. Recall that to any homomorphism of commutative rings $\phi : A \to B$, one can introduce a B-module $\Omega_{B/A}$ called the *module of Kähler differentials of B relative to A*: it is generated as an B-module by symbols $\{db\}_{b \in B}$ which are subject only to the relations

$$d(b+b') = db + db' \qquad d(bb') = bdb' + b'db \qquad d\phi(a) = 0.$$

In the special case where B is a *smooth* A-algebra, the B-module $\Omega_{B/A}$ is locally free of finite rank. In particular, if $X_0 = \operatorname{Spec} B$ is smooth affine algebraic variety over $\mathbf{C}$, then the B-module $\Omega_{B/\mathbf{C}}$ is locally free of finite rank, and therefore corresponds to an algebraic vector bundle $T^*_{X_0}$ on X_0 whose dual is (by definition) the tangent bundle T_{X_0}.

To a pair of ring homomorphisms $\phi : A \to B$ and $\psi : B \to C$, one can associate a short exact sequence of Kähler differentials

$$C \otimes_B \Omega_{B/A} \to \Omega_{C/A} \to \Omega_{C/B} \to 0. \tag{1}$$

This sequence is generally not exact on the left unless the ring homomorphism ψ is smooth. To remedy this defect, André and Quillen (independently) introduced the theory known as *André-Quillen homology* (generalizing earlier work of Lichtenbaum and Schlessinger), which has the following features:

- To every homomorphism of commutative rings $\phi : A \to B$ and every B-module M, one associates a sequence of B-modules $\{D_n(B/A; M)\}_{n \geqslant 0}$, called the *André-Quillen homology groups of B relative to A with coefficients in M*.

- The theory of André-Quillen homology generalizes the theory of Kähler differentials: for every homomorphism of commutative rings $\phi : A \to B$ and every B-module M, there is a canonical isomorphism $D_0(B/A; M) \simeq M \otimes_B \Omega_{B/A}$.

- If $\phi : A \to B$ is a smooth homomorphism of commutative rings, then the André-Quillen homology groups $D_n(B/A; M)$ vanish for $n > 0$ and any B-module M.

- To every composable pair of commutative ring homomorphisms $\phi : A \to B$ and $\psi : B \to C$ and every C-module M, one can associate a long exact sequence

  $$\cdots \to D_{n+1}(C/B; M) \to D_n(B/A; M) \to D_n(C/A; M) \to D_n(C/B; M) \to \cdots,$$

  extending the short exact sequence (1) in the special case $M = C$.

The André-Quillen homology groups $D_*(B/A; M)$ are obtained from a more fundamental invariant $L^{\mathrm{alg}}_{B/A}$, called the *cotangent complex of B over A*, a chain complex of (projective) B-modules which determines André-Quillen homology via the formula $D_*(B/A; M) = \mathrm{H}_*(M \otimes_B L^{\mathrm{alg}}_{B/A})$. This invariant was generalized in the work of Illusie (see [?] and [100]), which associates to every morphism $f : X \to S$ of schemes an object $L^{\mathrm{alg}}_{X/S}$ of the derived category $D(X)$, specializing to the chain complex $L^{\mathrm{alg}}_{B/A}$ in the case where $X = \operatorname{Spec} B$ and $S = \operatorname{Spec} A$ are affine. With this generalization, Proposition 0.1.3.1 extends as follows:

Proposition 0.1.3.2. *Let X_0 be an algebraic variety over $\mathbf{C}$ (not necessarily smooth). Then:*

(a) *For every first-order deformation X of X_0, there is a canonical bijection*

$$\{\textit{Automorphisms of } X \textit{ restricting to the identity on } X_0\} \simeq \mathrm{Ext}^0_{D(X_0)}(L^{\mathrm{alg}}_{X/\operatorname{Spec}\mathbf{C}}, \mathscr{O}_X).$$

(b) *There is a canonical bijection*

$$\{\textit{Isomorphism classes of first-order deformations of } X_0\} \simeq \mathrm{Ext}^1_{D(X_0)}(L^{\mathrm{alg}}_{X/\operatorname{Spec}\mathbf{C}}, \mathscr{O}_X).$$

Illusie's work on the cotangent complex was an important precursor to the theory of spectral algebraic geometry developed in this book. To understand this point, let us begin by recalling that the module of Kähler differentials $\Omega_{B/A}$ can be characterized by a universal property: for any B-module M, there is a canonical bijection

$$\begin{array}{c}\{\ B\text{-module homomorphisms } \Omega_{B/A} \to M\} \\ \downarrow \theta_0 \\ \{\ A\text{-algebra sections of the projection map } B \oplus M \to B\ \}\end{array}$$

which carries a map $\lambda : \Omega_{B/A} \to M$ to the A-algebra homomorphism $s_\lambda : B \to B \oplus M$ given by $s_\lambda(b) = b + \lambda(db)$. The entire cotangent complex $L^{\mathrm{alg}}_{B/A}$ can be characterized by an analogous universal property. To simplify the discussion, let us assume that A and B are $\mathbf{Q}$-algebras; in this case, we will denote the cotangent complex $L^{\mathrm{alg}}_{B/A}$ simply by $L_{B/A}$ (see Remark 0.1.3.7 below). If M is a chain complex of B-modules, then the direct sum $B \oplus M$ can be regarded as an $\mathbb{E}_\infty$-algebra over B, with homotopy groups given by

$$\pi_*(B \oplus M) = \begin{cases} B \oplus \mathrm{H}_0(M) & \text{if } * = 0 \\ \mathrm{H}_*(M) & \text{if } * \neq 0. \end{cases}$$

We then have a canonical bijection

$$\begin{array}{c}\{\ \text{Maps from } L_{B/A} \text{ into } M \text{ in the derived category } D(B)\ \} \\ \downarrow \theta \\ \{\text{Homotopy classes of sections of the projection } q : B \oplus M \to B\}\end{array}$$

where we interpret q as a map of $\mathbb{E}_\infty$-algebras over A. Note that $L_{B/A}$ is characterized by this universal property: that is, we can *define* $L_{B/A}$ to be an object which corepresents the functor

$$M \mapsto \{\text{Homotopy classes of sections of the projection } q : B \oplus M \to B\}.$$

This supplies a definition of $L_{B/A}$ which makes sense for *any* morphism of $\mathbb{E}_\infty$-rings $\phi : A \to B$. This leads to the theory of *topological* André-Quillen homology (see [145], [15], [16]). Like the theory of ordinary André-Quillen homology, it can be "relativized" to non-affine settings: to every morphism of spectral schemes $f : X \to S$, one can associate an object $L_{X/S}$ of the triangulated category $\mathrm{hQCoh}(X)$ called the *relative cotangent complex of f*. The construction $(f : X \to S) \mapsto L_{X/S}$ has the following features:

(1) Suppose that X and S are ordinary schemes over $\operatorname{Spec} \mathbf{Q}$. Then the relative cotangent complex $L_{X/S}$ (in the setting of spectral schemes) agrees with the cotangent complex $L^{\mathrm{alg}}_{X/S}$ of Illusie (for the case of positive and mixed characteristic, see Remark 0.1.3.7 below).

(2) Let $f : (X, \mathscr{O}_X) \to (S, \mathscr{O}_S)$ be a morphism of spectral schemes, let $X_0 = (X, \pi_0 \mathscr{O}_X)$ and $S_0 = (S, \pi_0 \mathscr{O}_S)$ be their underlying ordinary schemes, and let $\mathcal{A}$ be the abelian category of quasi-coherent sheaves on X_0. Then the "degree zero" part of $L_{X/S}$ agrees, as an object of $\mathcal{A}$, with the sheaf of Kähler differentials Ω_{X_0/S_0} of the underlying map $f_0 : X_0 \to S_0$.

One of the advantages of working in the setting of spectral algebraic geometry is that there is a much larger class of geometric objects for which the cotangent complex is well-behaved:

(i) If X is a spectral $\mathbf{C}$-scheme of finite presentation, then the cotangent complex $L_{X/\operatorname{Spec} \mathbf{C}} \in \mathrm{QCoh}(X)$ is perfect: that is, it is dualizable as an object of $\mathrm{QCoh}(X)$.

(ii) If X is an ordinary $\mathbf{C}$-scheme of finite presentation, then the cotangent complex $L_{X/\operatorname{Spec} \mathbf{C}}$ is a perfect complex if and only if X is a local complete intersection (see [**?**]).

To reconcile (i) and (ii), we remark that if X is an ordinary scheme, then the assumption that X is of finite presentation as a $\mathbf{C}$-scheme does not imply that it is of finite presentation as a spectral $\mathbf{C}$-scheme. However, the converse does hold: more generally, if $(X, \mathscr{O}_X)$ is a spectral scheme of finite presentation over $\mathbf{C}$ (as a spectral scheme), then the underlying ordinary scheme $X_0 = (X, \pi_0 \mathscr{O}_X)$ is of finite presentation over $\mathbf{C}$ (as a scheme). In this case, the cotangent complex $L_{X/\operatorname{Spec} \mathbf{C}}$ is often a much more natural and useful object than $L_{X_0/\operatorname{Spec} \mathbf{C}}$.

Example 0.1.3.3 (Quot Schemes)**.** Let X be a projective algebraic variety over $\mathbf{C}$ and let $\mathscr{F}$ be a quasi-coherent sheaf on X. For every commutative $\mathbf{C}$-algebra R, let X_R denote the fiber product $X \times_{\operatorname{Spec} \mathbf{C}} \operatorname{Spec} R$ and let $\mathscr{F}_R$ denote the pullback of $\mathscr{F}$ to X_R. We let $F(R)$ denote the collection of isomorphism classes of exact sequences

$$0 \to \mathscr{F}' \to \mathscr{F}_R \to \mathscr{F}'' \to 0$$

in the abelian category of quasi-coherent sheaves on X_R for which $\mathscr{F}''$ is flat over R. The construction $R \mapsto F(R)$ is representable by a $\mathbf{C}$-scheme Quot (see [**?**]). Given a $\mathbf{C}$-valued point $\eta \in F(\mathbf{C})$ classifying an exact sequence

$$0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0,$$

the Zariski cotangent space of Quot at the point η is the dual of the vector space $\operatorname{Hom}_{\mathcal{A}}(\mathscr{F}', \mathscr{F}'')$, where $\mathcal{A}$ is the abelian category of quasi-coherent sheaves on X. This vector space can be described as the 0th homology of the cotangent fiber $\eta^* L_{\operatorname{Quot} / \operatorname{Spec} \mathbf{C}}$. However, the scheme Quot is usually highly singular, so the entire cotangent fiber $\eta^* L_{\operatorname{Quot} / \operatorname{Spec} \mathbf{C}}$ can be difficult to describe.

The situation is better if we work in the setting of spectral algebraic geometry. The definitions of X_R, $\mathscr{F}_R$, and $F(R)$ make sense more generally when R is an $\mathbb{E}_\infty$-algebra over $\mathbf{C}$, and the resulting functor on $\mathbb{E}_\infty$-rings is representable by a spectral scheme Quot^+ having Quot is its underlying scheme (this object was introduced in [41]). The structure of the cotangent complex $L_{\operatorname{Quot}^+ / \operatorname{Spec} \mathbf{C}}$ has an immediate description in terms of the functor F (on $\mathbb{E}_\infty$-algebras). For example, if $\eta \in F(\mathbf{C})$ is as above, then the complex $\eta^* L_{\operatorname{Quot}^+ / \operatorname{Spec} \mathbf{C}}$ is dual to $\operatorname{RHom}(\mathscr{F}', \mathscr{F}'')$: in particular, the nth homology group of $\eta^* L_{\operatorname{Quot}^+ / \operatorname{Spec} \mathbf{C}}$ can be identified with the $\mathbf{C}$-linear dual of $\operatorname{Ext}^n_{\mathcal{A}}(\mathscr{F}', \mathscr{F}'')$.

Example 0.1.3.3 illustrates a general phenomenon: if Z_0 is a scheme representing which represents a functor F on the category of commutative rings, there is often a natural way to extend the definition of $F(R)$ to the case where R is an $\mathbb{E}_\infty$-ring in such a way that extended functor is representable by a spectral scheme Z. Roughly speaking, we can think of the specification of Z as given by "equipping Z_0 with a deformation theory" (we will make this idea precise in Part **??**; see Theorem 18.1.0.1), according to the rough heuristic

$$\text{Spectral algebraic geometry} = \text{Algebraic Geometry} + \text{Deformation Theory}.$$

From the above perspective, the subject of this book is a natural outgrowth of deformation theory, which allows us to think about invariants like the cotangent complex in a more flexible and general setting. However, the ideas of spectral algebraic geometry lead to new and useful ways to think about deformation-theoretic questions even for smooth algebraic varieties. For example, consider the following variant of Proposition 0.1.3.1:

Proposition 0.1.3.4. *Let X_0 be a smooth algebraic variety over $\mathbf{C}$. Then there is a canonical "obstruction class map"*

$$\rho : \{ \textit{ First order deformations of } X_0 \} \to \mathrm{H}^2(X_0; T_{X_0})$$

with the following property: if X is a first-order deformation of X_0, then the obstruction class $\rho(X) \in \mathrm{H}^2(X_0; T_{X_0})$ vanishes if and only if X can be extended to a second-order deformation of X_0: that is, if and only if there exists a pullback square of schemes

$$\begin{array}{ccc} X & \longrightarrow & \overline{X} \\ \downarrow & & \downarrow \\ \operatorname{Spec} \mathbf{C}[\epsilon]/(\epsilon^2) & \longrightarrow & \operatorname{Spec} \mathbf{C}[\epsilon]/(\epsilon^3) \end{array}$$

in which the vertical maps are flat.

Proposition 0.1.3.4 is very useful: it allows us to convert an *a priori* nonlinear problem (deforming an algebraic variety) into a linear one (checking that a certain cohomology class vanishes). This linear problem is often difficult, but in some cases it is trivial: for example, if X_0 is a smooth curve, then $\mathrm{H}^2(X_0; T_{X_0}) \simeq 0$, so Proposition 0.1.3.4 implies that *any* first-order deformation can be extended to a second-order deformation.

One might object that Proposition 0.1.3.4 is not as satisfying as Proposition 0.1.3.1. Note that Proposition 0.1.3.1 provides concrete geometric interpretations for the cohomology groups $\mathrm{H}^0(X_0; T_{X_0})$ and $\mathrm{H}^1(X_0; T_{X_0})$. Proposition 0.1.3.4 tells us that the cohomology group $\mathrm{H}^2(X_0; T_{X_0})$ is *related* to the problem of extending first-order deformations of X_0 to second-order deformations, but it does not tell us what a general element of $\mathrm{H}^2(X_0; T_{X_0})$ *is*. The language of spectral algebraic geometry provides a remedy for this situation. More precisely, it allows us to formulate a generalization of Proposition 0.1.3.1 which supplies a geometric interpretation for *all* of the cohomology groups $\mathrm{H}^n(X_0; T_{X_0})$ and which has Proposition 0.1.3.4 as a consequence.

Fix a smooth $\mathbf{C}$-scheme X_0 as in Proposition 0.1.3.4. For every commutative $\mathbf{C}$-algebra R equipped with an augmentation $\rho : R \to \mathbf{C}$, let us define a *deformation of X_0 over R* to be a flat R-scheme X_R together with an isomorphism $X_0 \simeq \operatorname{Spec} \mathbf{C} \times_{\operatorname{Spec} R} X_R$. The theory of spectral algebraic geometry allows us to consider a more general notion of deformation: if R is an $\mathbb{E}_\infty$-algebra over $\mathbf{C}$ (still equipped with an augmentation $\rho : R \to \mathbf{C}$), then we can contemplate *spectral schemes* X_R equipped with a flat map $X_R \to \operatorname{Spec} R$ and an equivalence $X_0 \simeq \operatorname{Spec} \mathbf{C} \times_{\operatorname{Spec} R} X_R$ (if R is an ordinary commutative ring, this reduces to the previous definition: the flatness of X_R over $\operatorname{Spec} R$ guarantees that X_R is an ordinary scheme). We then have the following generalization of Proposition 0.1.3.1, which we will discuss in Part V (see Proposition 19.4.3.1 and Corollary 19.4.3.3):

Proposition 0.1.3.5. *Let X_0 be a smooth algebraic variety over the field $\mathbf{C}$ of complex numbers and let R denote the direct sum $\mathbf{C} \oplus M$, where M is the chain complex of complex vector spaces which is concentrated in degree $n \geqslant 0$ and is isomorphic to $\mathbf{C}$ in degree n. Let us regard R as an $\mathbb{E}_\infty$-algebra over $\mathbf{C}$. Then:*

(a) If X_R is any deformation of X_0 over R, then there is a canonical bijection

$$\{\textit{Automorphisms of } X_R \textit{ that are the identity on } X_0\}/\textit{homotopy} \simeq \mathrm{H}^n(X_0; T_{X_0}).$$

(b) There is a canonical bijection

$$\{\textit{Deformations of } X_0 \textit{ over } R\}/\textit{homotopy equivalence} \simeq \mathrm{H}^{n+1}(X_0; T_{X_0}).$$

Remark 0.1.3.6. In the special case $n = 0$, the $\mathbb{E}_\infty$-ring $R = \mathbf{C} \oplus M$ can be identified with the ordinary ring of dual numbers $\mathbf{C}[\epsilon]/(\epsilon^2)$, and Proposition 0.1.3.5 reduces to Proposition 0.1.3.1. Proposition 0.1.3.5 implies that *all* of the cohomology groups $\mathrm{H}^m(X_0; T_{X_0})$ arise naturally when studying deformations of X_0 over "shifted" versions of the ring of dual numbers.

To relate Propositions 0.1.3.4 and 0.1.3.5, we note that the $\mathbf{C}[\epsilon]/(\epsilon^3)$ can be regarded as a an extension of $\mathbf{C}[\epsilon]/(\epsilon^2)$ by the square-zero ideal $(\epsilon^2) \simeq \mathbf{C}$. This implies that there is a pullback diagram of $\mathbb{E}_\infty$-algebras

$$\begin{array}{ccc} \mathbf{C}[\epsilon]/(\epsilon^3) & \longrightarrow & \mathbf{C} \\ \downarrow & & \downarrow \\ \mathbf{C}[\epsilon]/(\epsilon^2) & \xrightarrow{\phi} & R, \end{array}$$

where R is defined as in Proposition 0.1.3.5 in the special case $n = 1$. We can interpret this pullback square geometrically as supplying a pushout diagram of affine spectral schemes

$$\begin{array}{ccc} \operatorname{Spec} \mathbf{C}[\epsilon]/(\epsilon^3) & \longleftarrow & \operatorname{Spec} \mathbf{C} \\ \uparrow & & \uparrow \\ \operatorname{Spec} \mathbf{C}[\epsilon]/(\epsilon^2) & \longleftarrow & \operatorname{Spec} R. \end{array}$$

It follows that if X is a first-order deformation of X_0, then X extends to a second-order deformation if and only if the fiber product $X_R = X \times_{\operatorname{Spec} \mathbf{C}[\epsilon]/(\epsilon^2)} \operatorname{Spec} R$ is a trivial deformation of X_0 over R (that is, if and only if it is equivalent to $X_0 \times_{\operatorname{Spec} \mathbf{C}} \operatorname{Spec} R$). This is equivalent to the vanishing of a certain element $\rho(X) \in \mathrm{H}^2(X_0; T_{X_0})$, where ρ is the "obstruction map" given by the composition

$$\begin{aligned} \{ \text{ Deformations of } X_0 \text{ over } \mathbf{C}[\epsilon]/(\epsilon^2) \ \} \ &\to \ \{ \text{ Deformations of } X_0 \text{ over } R\} \\ &\simeq \ \mathrm{H}^2(X_0; T_{X_0}). \end{aligned}$$

where the first map is given by extension of scalars along ϕ and the second follows from the identification of Proposition 0.1.3.5.

Remark 0.1.3.7. Let $\phi : A \to B$ be a homomorphism of commutative rings, which we can also regard as a morphism of $\mathbb{E}_\infty$-rings. In general, the algebraic André-Quillen homology of ϕ (denoted by $L^{\mathrm{alg}}_{B/A}$ in the above discussion and throughout this book) is different from the topological André-Quillen homology of ϕ (denoted by $L_{B/A}$ in the above discussion and throughout this book), though they are rationally equivalent (and therefore coincide whenever B is a $\mathbf{Q}$-algebra). The deformation theory of spectral schemes is controlled by topological André-Quillen homology. For applications in positive and mixed characteristic, it is often more appropriate to use the theory of *derived algebraic geometry*, in which deformations are controlled by algebraic André-Quillen homology. We will give a detailed exposition of derived algebraic geometry and its relationship to spectral algebraic geometry in Part VII.

0.2 Prerequisites

Throughout this book, we will make extensive use of the language of ∞-categories developed in [138] and [139]. The reader will also need some familiarity with stable homotopy theory and the theory of structured ring spectra, which are developed from the ∞-categorical perspective in [139] (for a different approach to the same material, see [60]). For the reader's convenience, we include a brief (and incomplete) expository account of some of the relevant material below. For a more detailed account (which includes precise definitions and proofs), we refer the reader to [138] and [139]. Since we will need to refer to these texts frequently in this book, we adopt the following conventions:

(HTT) We will indicate references to [138] using the letters HTT.

(HA) We will indicate references to [139] using the letters HA.

For example, Theorem HTT.6.1.0.6 refers to Theorem 6.1.0.6 of [138].

The other main prerequisite for reading this book is some familiarity with classical algebraic geometry. To some extent, this is logically unnecessary: the theory of spectral algebraic geometry is developed "from scratch" in this book, and most of our references to the classical theory are purely for motivation. Moreover, we have made an effort to keep this book as self-contained as possible as far as algebraic geometry and commutative algebra are concerned: we have generally opted to include proofs of standard results (particularly in cases where the use of "derived" methods can shed some additional light) except in a few cases which would take us too far afield. Nevertheless, a reader who is not familiar with the classical theory of schemes will almost surely find this book impenetrable (if he or she has even made it this far).

0.2.1 Homotopy Theory and Simplicial Sets

For every integer $n \geqslant 0$, let $|\Delta^n|$ denote the topological n-simplex, given by

$$|\Delta^n| = \{(x_0, \ldots, x_n) \in \mathbf{R}^{n+1}_{\geqslant 0} : x_0 + x_1 + \cdots + x_n = 1\}.$$

If X is a topological space, we let $\mathrm{Sing}_n(X)$ denote the set of continuous maps from $|\Delta^n|$ into X. These sets play a role in defining many important invariants of X: for example, the singular homology groups of X are obtained from the chain complex of free abelian groups

$$\cdots \to \mathbf{Z}[\mathrm{Sing}_2 X] \xrightarrow{d_0 - d_1 + d_2} \mathbf{Z}[\mathrm{Sing}_1 X] \xrightarrow{d_0 - d_1} \mathbf{Z}[\mathrm{Sing}_0 X]$$

where each $d_k : \mathrm{Sing}_n X \to \mathrm{Sing}_{n-1} X$ is the map which assigns to a simplex the face opposite its kth vertex. To describe the structure given by the sets $\{\mathrm{Sing}_n(X)\}_{n \geqslant 0}$ and the face maps d_k in a more systematic way, it will be useful to introduce a bit of terminology.

Definition 0.2.1.1. For each integer $n \geqslant 0$, we let $[n]$ denote the finite linearly ordered set $\{0 < 1 < \cdots < n\}$. We define a category $\mathbf{\Delta}$ as follows:

- The objects of $\mathbf{\Delta}$ are sets of the form $[n]$ for $n \geqslant 0$.
- A morphism from $[m]$ to $[n]$ in $\mathbf{\Delta}$ consists of a nondecreasing function $\alpha : [m] \to [n]$.

We will refer to $\mathbf{\Delta}$ as the *category of combinatorial simplices*. A *simplicial set* is a functor $S_\bullet : \mathbf{\Delta}^{\mathrm{op}} \to \mathcal{S}\mathrm{et}$, where $\mathcal{S}\mathrm{et}$ denotes the category of sets. In this case, we will denote the value of $S_\bullet$ on the object $[n] \in \mathbf{\Delta}$ by S_n, and refer to it as the *set of n-simplices of S*. We let $\mathcal{S}\mathrm{et}_\Delta$ denote the category $\mathrm{Fun}(\mathbf{\Delta}^{\mathrm{op}}, \mathcal{S}\mathrm{et})$ of simplicial sets.

For each $n \geqslant 0$, it is useful to think of the set $[n] = \{0 < 1 < \cdots < n\}$ as the set of vertices of the topological n-simplex $|\Delta^n|$. Every map of sets $\alpha : [m] \to [n]$ extends uniquely to a linear map $\rho : |\Delta^m| \to |\Delta^n|$, given in coordinates by the construction

$$(x_0, \ldots, x_m) \mapsto (\sum_{\alpha(i)=0} x_i, \ldots, \sum_{\alpha(i)=n} x_i).$$

If X is a topological space, then composition with ρ determines a map $\mathrm{Sing}_n X \to \mathrm{Sing}_m X$. In particular, we can regard the construction $([n] \in \mathbf{\Delta}) \mapsto (\mathrm{Sing}_n X \in \mathcal{S}\mathrm{et})$ as a simplicial set. We refer to this simplicial set as the *singular simplicial set* of X and denote it by $\mathrm{Sing}_\bullet X$.

The construction $X \mapsto \mathrm{Sing}_\bullet X$ determines a functor $\mathrm{Sing}_\bullet$ from the category $\mathcal{T}\mathrm{op}$ of topological spaces to the category $\mathcal{S}\mathrm{et}_\Delta$ of simplicial sets. This functor admits a left adjoint

$$\mathcal{S}\mathrm{et}_\Delta \to \mathcal{T}\mathrm{op}$$

$$S_\bullet \mapsto |S_\bullet|$$

which we refer to as *geometric realization.* If X is a topological space which has the homotopy type of a CW complex, then the counit map $|\operatorname{Sing}_\bullet X| \to X$ is a homotopy equivalence (the assumption that X has the homotopy type of a CW complex is necessary here: for any simplicial set $S_\bullet$, the geometric realization $|S_\bullet|$ is a CW complex). Consequently, from the perspective of homotopy theory, no information is lost by discarding the original space X in favor of the simplicial set $\operatorname{Sing}_\bullet X$ (see Remark 0.2.1.5 below). In fact, it is possible to develop the theory of algebraic topology in entirely combinatorial terms, using simplicial sets as surrogates for topological spaces. Moreover, this approach has many advantages:

- Many of the most important algebraic invariants of a topological space X (such as homotopy groups, homology, and cohomology) are obtained by studying maps from n-simplices (and their boundaries) into X. Consequently, these invariants can be extracted more directly from the singular simplicial set $\operatorname{Sing}_\bullet X$ itself.

- Working with simplicial sets rather than topological spaces avoids many of the technicalities and pathologies of point-set topology.

- When applying homotopy-theoretic methods to areas of mathematics outside of topology (a major theme of this book), the association between homotopy theory and topological spaces can be an unnecessary distraction.

We will assume throughout this book that the reader is familiar with the homotopy theory of simplicial sets. We devote the remainder of this section to giving a quick review of some basic definitions and notations; for a more thorough introduction, we refer the reader to the texts [81] and [151].

Notation 0.2.1.2. For each $n \geqslant 0$, we let $\Delta^n \in \mathcal{S}\mathrm{et}_\Delta = \operatorname{Fun}(\mathbf{\Delta}^{\mathrm{op}}, \mathcal{S}\mathrm{et})$ denote the simplicial set which is represented by the object $[n] \in \mathbf{\Delta}$, so that the m-simplices of Δ^n are given by nondecreasing maps $[m] \to [n]$. We will refer to Δ^n as the *standard n-simplex.* For any simplicial set $S_\bullet$, Yoneda's lemma provides a canonical bijection $S_n \simeq \operatorname{Hom}_{\mathcal{S}\mathrm{et}_\Delta}(\Delta^n, S_\bullet)$. We will often abuse notation by using this bijection to identify elements of S_n with the corresponding maps $\sigma : \Delta^n \to S_\bullet$, referring to either datum as an *n-simplex* of $S_\bullet$.

We let $\partial \Delta^n$ denote the simplicial subset of Δ^n whose m-simplices are nondecreasing maps $\alpha : [m] \to [n]$ which are not surjective. For $0 < i < n$, we let Λ^n_i denote the simplicial subset of $\partial \Delta^n \subset \Delta^n$ whose m-simplices are nondecreasing maps $\alpha : [m] \to [n]$ having the property that $\alpha([m]) \cup \{i\} \subsetneq [n]$. We will refer to $\partial \Delta^n$ as the *boundary* of Δ^n and to Λ^n_i as the *ith horn* of Δ^n.

If $S_\bullet$ is a simplicial set, we will refer to the element of S_0 as the *vertices* of S and the elements of S_1 as the *edges* of S. Each vertex $v \in S_0$ can be identified with a map $\Delta^0 \to S_\bullet$. We will generally abuse notation by denoting the domain of this map by $\{v\}$.

Taking $S_\bullet$ to be the standard n-simplex, we see that each element $0 \leqslant i \leqslant n$ determines a map $\{i\} \simeq \Delta^0 \to \Delta^n$, which we will refer to as the *ith vertex of* Δ^n.

Remark 0.2.1.3. For each $n \geqslant 0$, the geometric realization of the standard n-simplex $\Delta^n \in \mathcal{S}\mathrm{et}_\Delta$ can be identified with the topological n-simplex

$$|\Delta^n| = \{(x_0, \dots, x_n) \in \mathbf{R}^{n+1} : x_0 + x_1 + \cdots + x_n = 1\}.$$

Under this identification, the geometric realization of $\partial \Delta^n$ corresponds to the subset of $|\Delta^n|$ consisting of those n-tuples $(x_0, \dots, x_n)$ for which at least one coordinate x_j vanishes. The ith horn Λ^n_i corresponds to the subset of $|\Delta^n|$ consisting of those tuples $(x_0, \dots, x_n)$ satisfying $x_j = 0$ for some $j \neq i$. More informally: $|\partial \Delta^n|$ is obtained from the topological n-simplex $|\Delta^n|$ by deleting its interior, while $|\Lambda^n_i|$ is obtained from $|\Delta^n|$ by deleting its interior together with the face opposite the ith vertex.

Definition 0.2.1.4. Let $S_\bullet$ be a simplicial set. We will say that $S_\bullet$ is a *Kan complex* if, for every pair of integers $0 \leqslant i \leqslant n$, every map $\sigma_0 : \Lambda^n_i \to S_\bullet$ can be extended to an n-simplex $\sigma : \Delta^n \to S_\bullet$. We let $\mathcal{K}\mathrm{an}$ denote the full subcategory of $\mathcal{S}\mathrm{et}_\Delta$ spanned by the Kan complexes; we will refer to $\mathcal{K}\mathrm{an}$ as the *category of Kan complexes*.

Let $S_\bullet$ and $T_\bullet$ be simplicial sets. Given a pair of maps $f, g : S_\bullet \to T_\bullet$, a *simplicial homotopy* from f to g is a map of simplicial sets $h : S_\bullet \times \Delta^1 \to T_\bullet$ such that $h|_{S_\bullet \times \{0\}} = f$ and $h|_{S_\bullet \times \{1\}} = g$. We will say that f and g are *simplicially homotopic* if there exists a simplicial homotopy from f to g. If $T_\bullet$ is a Kan complex, then this is an equivalence relation. We let $\mathrm{h}\mathcal{K}\mathrm{an}$ denote the category whose objects are Kan complexes, where the morphisms from $S_\bullet$ to $T_\bullet$ in $\mathrm{h}\mathcal{K}\mathrm{an}$ are the simplicial homotopy classes of maps from $S_\bullet$ to $T_\bullet$. We will refer to $\mathrm{h}\mathcal{K}\mathrm{an}$ as the *homotopy category of Kan complexes*.

Remark 0.2.1.5. The homotopy category of Kan complexes is equivalent to the homotopy category of CW complexes. More precisely, one can prove the following:

- For every topological space X, the singular simplicial set $\mathrm{Sing}_\bullet X$ is a Kan complex (this follows from the observation that each horn $|\Lambda^n_i|$ is a retract of the corresponding n-simplex $|\Delta^n|$; see Remark 0.2.1.3). Moreover, if $f, g : X \to Y$ are homotopic maps between topological spaces X and Y, then the induced maps $\mathrm{Sing}_\bullet(f), \mathrm{Sing}_\bullet(g) : \mathrm{Sing}_\bullet(X) \to \mathrm{Sing}_\bullet(Y)$ are simplicially homotopic. Consequently, construction $X \mapsto \mathrm{Sing}_\bullet X$ determines a functor $\mathrm{h}\mathcal{T}\mathrm{op} \to \mathrm{h}\mathcal{K}\mathrm{an}$, where $\mathrm{h}\mathcal{T}\mathrm{op}$ is the homotopy category of topological spaces.

- For every simplicial set $S_\bullet$, the geometric realization $|S_\bullet|$ is a CW complex. Moreover, if $f, g : S_\bullet \to T_\bullet$ are maps of simplicial sets which are simplicially homotopic, then the induced maps of topological spaces $|f|, |g| : |S_\bullet| \to |T_\bullet|$ are homotopic. Consequently, the construction $S_\bullet \mapsto |S_\bullet|$ determines a functor $\mathrm{h}\mathcal{K}\mathrm{an} \to \mathrm{h}\mathcal{T}\mathrm{op}^{\mathrm{CW}}$, where $\mathrm{h}\mathcal{T}\mathrm{op}^{\mathrm{CW}}$ denotes the homotopy category of CW complexes.

- For any CW complex X, the counit map $v : |\operatorname{Sing}_\bullet X| \to X$ is a homotopy equivalence. For any Kan complex $S_\bullet$, the unit map $S_\bullet \to \operatorname{Sing}_\bullet |S_\bullet|$ is a simplicial homotopy equivalence. Consequently, the functors

$$\mathrm{h}\mathcal{T}\mathrm{op}^{\mathrm{CW}} \underset{\operatorname{Sing}_\bullet}{\overset{|\,|}{\rightleftarrows}} \mathrm{h}\mathcal{K}\mathrm{an}$$

are mutually inverse equivalences of categories.

Remark 0.2.1.6. From a spectral scheme $(X, \mathscr{O}_X)$, one can extract topological spaces of two very different types:

(a) The underlying topological space X. This space will typically be non-Hausdorff and therefore very far from the type of spaces which are usually studied in algebraic topology. Consequently, we will not be interested in the homotopy type of such a space: it is primarily a device that allows us to talk about sheaves.

(b) The underlying spaces of the $\mathbb{E}_\infty$-rings $\mathscr{O}_X(U)$. These spaces should really be regarded as only well-defined up to homotopy equivalence: in other words, *all* that we care about is their homotopy type. For example, we would never want to consider sheaves on such a space (other than locally constant sheaves), because the notion of sheaf is not homotopy invariant.

To distinguish between these possibilities, we will usually regard objects of type (b) as Kan complexes rather than as topological spaces. Unless otherwise specified, we use the term "space" to refer to a Kan complex. When we wish to refer to a set equipped with a topology, we will use the term "topological space."

0.2.2 Higher Category Theory

For a reader trained in classical algebraic geometry, the most exotic feature of spectral algebraic geometry is likely to be that all of its basic objects come equipped with an "internal" homotopy theory. To fix ideas, let us introduce a bit of terminology:

Definition 0.2.2.1. Let $\mathcal{C}$ be a category. For every pair of objects $X, Y \in \mathcal{C}$, let $\operatorname{Map}_{\mathcal{C}}(X, Y)$ denote the set of morphisms from X to Y. We will say that $\mathcal{C}$ is a *topological category* if each of the sets $\operatorname{Map}_{\mathcal{C}}(X, Y)$ has been equipped with a topology for which the composition maps

$$\operatorname{Map}_{\mathcal{C}}(Y, Z) \times \operatorname{Map}_{\mathcal{C}}(X, Y) \to \operatorname{Map}_{\mathcal{C}}(X, Z)$$

are continuous (for every triple of objects $X, Y, Z \in \mathcal{C}$).

The collection of spectral schemes (and other more general geometric objects that we study in this book) can be organized into a topological category SpSch. In particular, if X and Y are spectral schemes, then there is a notion of a *homotopy* from a morphism $f : X \to Y$ to another morphism $g : X \to Y$: namely, a path in the topological space $\mathrm{Map}_{\mathrm{SpSch}}(X, Y)$. Consequently, there is an associated notion of *homotopy equivalence*: we say that spectral schemes X and Y are *equivalent* if there exist morphisms $f : X \to Y$ and $g : Y \to X$ such that $f \circ g$ is homotopic to the identity map id_Y and $g \circ f$ is homotopic to the identity map id_X.

Warning 0.2.2.2. Let X be a spectral scheme over the field $\mathbf{C}$ of complex numbers. Then we can associate to X its set $X(\mathbf{C})$ of $\mathbf{C}$-valued points (which is the same as the set of $\mathbf{C}$-valued points of the underlying ordinary scheme of X). The set $X(\mathbf{C})$ inherits the structure of a topological space (from the usual topology on $\mathbf{C}$), which we will refer to as the *complex-analytic topology*. This topology is completely unrelated to the structure of SpSch as a topological category. If $f, g : X \to Y$ are homotopic morphisms between spectral schemes over $\mathbf{C}$, then they induce the same map at the level of underlying schemes, so that the induced maps $X(\mathbf{C}) \to Y(\mathbf{C})$ are the same. In particular, if $f : X \to Y$ is an equivalence of spectral schemes over $\mathbf{C}$, then the induced map on $\mathbf{C}$-valued points $X(\mathbf{C}) \to Y(\mathbf{C})$ is a homeomorphism (not merely a homotopy equivalence). In more informal terms: the "internal" homotopy theory of a spectral scheme X is a purely infinitesimal datum, and is invisible to all classical invariants of X (like the space $X(\mathbf{C})$ with its complex-analytic topology, or the underlying topological space of X with its Zariski topology).

The notion of homotopy plays a central role in the theory in the theory of spectral algebraic geometry: all meaningful properties of spectral schemes are invariant under equivalence, and all meaningful properties of morphisms between spectral schemes are invariant under homotopy. This motivates the following definition:

Definition 0.2.2.3. Let $\mathcal{C}$ be a topological category. The *homotopy category* $\mathrm{h}\mathcal{C}$ is defined as follows:

- The objects of $\mathrm{h}\mathcal{C}$ are the objects of $\mathcal{C}$.
- For every pair of objects $X, Y \in \mathrm{h}\mathcal{C}$, the set $\mathrm{Hom}_{\mathrm{h}\mathcal{C}}(X, Y)$ of morphisms from X to Y in $\mathrm{h}\mathcal{C}$ is the set of path components $\pi_0 \mathrm{Map}_{\mathcal{C}}(X, Y)$ of morphisms from X to Y in $\mathcal{C}$.
- For every triple of objects $X, Y, Z \in \mathcal{C}$, the composition law $\circ : \mathrm{Hom}_{\mathrm{h}\mathcal{C}}(Y, Z) \times \mathrm{Hom}_{\mathrm{h}\mathcal{C}}(X, Y) \to \mathrm{Hom}_{\mathrm{h}\mathcal{C}}(X, Z)$ is the unique map for which the diagram

$$\begin{array}{ccc} \mathrm{Map}_{\mathcal{C}}(Y, Z) \times \mathrm{Map}_{\mathcal{C}}(X, Y) & \xrightarrow{\circ} & \mathrm{Map}_{\mathcal{C}}(X, Z) \\ \downarrow & & \downarrow \\ \mathrm{Hom}_{\mathrm{h}\mathcal{C}}(Y, Z) \times \mathrm{Hom}_{\mathrm{h}\mathcal{C}}(X, Y) & \xrightarrow{\circ} & \mathrm{Hom}_{\mathrm{h}\mathcal{C}}(X, Z) \end{array}$$

commutes.

By definition, two morphisms of spectral schemes $f, g : X \to Y$ are homotopic if and only if they induce the same morphism in the homotopy category hSpSch, and a morphism $f : X \to Y$ is an equivalence if and only if it induces an isomorphism in hSpSch. Consequently, one way to enforce the philosophy that all constructions should be homotopy invariant is to restrict attention to constructions which can be described entirely in terms of hSpSch. However, this turns out to be too restrictive:

Example 0.2.2.4. Let $\mathcal{C}$ be a topological category. By definition, commutative diagrams in the homotopy category $\mathrm{h}\mathcal{C}$ correspond to diagrams in $\mathcal{C}$ which commute *up to homotopy*. For example, a diagram

$$\begin{array}{ccc} X' & \xrightarrow{f'} & X \\ \downarrow{\scriptstyle g'} & & \downarrow{\scriptstyle g} \\ Y' & \xrightarrow{f} & Y \end{array}$$

in $\mathrm{h}\mathcal{C}$ is specified by giving maps $\overline{f}, \overline{f}', \overline{g}$, and $\overline{g}'$ (well-defined up to homotopy) for which there exists a path α joining $\overline{g} \circ \overline{f}'$ to $\overline{f} \circ \overline{g}'$ in the topological space $\mathrm{Map}_{\mathcal{C}}(X', Y)$. In practice, we are often interested not only in knowing that α exists, but in *specifying* a particular choice of α. A choice of homotopy is not something that can be described in terms of the homotopy category $\mathrm{h}\mathcal{C}$ alone.

Example 0.2.2.5. Let $f_0 : X_0 \to X$ and $f_1 : X_1 \to X$ be morphisms of spectral schemes. To the pair (f_0, f_1), one can canonically associate a new spectral scheme which we will denote by $X_0 \times_X X_1$ and refer to as the *fiber product of* X_0 *with* X_1 *over* X. However, this object is usually *not* a fiber product of X_0 with X_1 over X in the homotopy category hSpSch. In the language of topological categories, it is a *homotopy* fiber product, which can be characterized as follows: there is a diagram of spectral schemes

$$\begin{array}{ccc} X_{01} & \xrightarrow{p_0} & X_0 \\ \downarrow{\scriptstyle p_1} & & \downarrow{\scriptstyle f_0} \\ X_1 & \xrightarrow{f_1} & X \end{array}$$

and a path α from $f_0 \circ p_0$ to $f_1 \circ p_1$ in the topological space $\mathrm{Map}_{\mathrm{SpSch}}(X_{01}, X)$ which enjoys the following universal property: for every spectral scheme Y, the induced map from $\mathrm{Map}_{\mathrm{SpSch}}(Y, X_{01})$ to the fiber product

$$\mathrm{Map}_{\mathrm{SpSch}}(Y, X_0) \times_{\mathrm{Map}_{\mathrm{SpSch}}(Y,X)} \mathrm{Map}_{\mathrm{SpSch}}(Y, X)^{[0,1]} \times_{\mathrm{Map}_{\mathrm{SpSch}}(Y,X)} \mathrm{Map}_{\mathrm{SpSch}}(Y, X_1)$$

is a (weak) homotopy equivalence. In other words, the datum of a morphism from Y to X_{01} is equivalent to the data of a pair of morphisms $g_0 : Y \to X_0$ and $g_1 : Y \to X_1$ together with a homotopy β from $g_0 \circ f_0$ to $g_1 \circ f_1$. In general, different choices for the homotopy β give rise to different morphisms $Y \to X_{01}$ (even up to homotopy). Consequently, X_{01} is usually *not* a fiber product of X_0 with X_1 over X in the homotopy category hSpSch (such a fiber product usually does not exist). It enjoys an analogous universal property, but one which cannot be formulated in terms of the homotopy category hSpSch alone.

Examples 0.2.2.4 and 0.2.2.5 illustrate that passage from a topological category $\mathcal{C}$ to its homotopy category $\mathrm{h}\mathcal{C}$ loses essential information about diagrams even of very simple shape (indexed by a square). For more complicated diagrams, the situation is worse. To fix ideas, let us suppose that we are given some index category $\mathcal{J}$ and a functor $F : \mathcal{J} \to \mathrm{h}\mathcal{C}$, which we interpret as a commutative diagram in $\mathrm{h}\mathcal{C}$. In practice, this is often not good enough: many basic constructions require that we promote F to a *homotopy coherent* diagram $\overline{F}$ in $\mathcal{C}$. This involves supplying the following sort of data:

(D_1) For every morphism $v : X \to Y$ in $\mathcal{J}$, a choice of point $\overline{F}(v) \in \mathrm{Map}_{\mathcal{C}}(F(X), F(Y))$ belonging to the path component $F(v) \in \mathrm{Hom}_{\mathrm{h}\mathcal{C}}(F(X), F(Y)) = \pi_0 \mathrm{Map}_{\mathcal{C}}(F(X), F(Y))$.

(D_2) For every composable pair of morphisms $X \xrightarrow{v} Y \xrightarrow{w} Z$ in $\mathcal{C}$, a choice of path

$$\alpha_{w,v} : [0,1] \to \mathrm{Map}_{\mathcal{C}}(F(X), F(Z))$$

which begins at the point $\overline{F}(w \circ v)$ and ends at the point $\overline{F}(w) \circ \overline{F}(v)$. Note that such a path always exist, since

$$F(w \circ v) = F(w) \circ F(v) \in \mathrm{Hom}_{\mathrm{h}\mathcal{C}}(F(X), F(Z)) = \pi_0 \mathrm{Map}_{\mathcal{C}}(X, Z).$$

(D_3) For every triple of composable morphisms

$$W \xrightarrow{u} X \xrightarrow{v} Y \xrightarrow{w} Z,$$

a continuous map of topological spaces $[0,1]^2 \to \mathrm{Map}_{\mathcal{C}}(W, Z)$ whose restriction to the boundary of the square $[0,1]^2$ is as indicated in the diagram

$$\begin{array}{ccc} \overline{F}(w \circ v \circ u) & \xrightarrow{\alpha_{w, v \circ u}} & \overline{F}(w) \circ \overline{F}(v \circ u) \\ \downarrow{\scriptstyle \alpha_{w \circ v, u}} & & \downarrow{\scriptstyle \overline{F}(w) \circ \alpha_{v,u}} \\ \overline{F}(w \circ v) \circ \overline{F}(u) & \xrightarrow{\alpha_{w,v} \circ \overline{F}(u)} & \overline{F}(w) \circ \overline{F}(v) \circ \overline{F}(u). \end{array}$$

Beware that the existence of such a map might depend on the choices made in (D_2).

(D_n) An analogous datum for every n-tuple of composable morphisms

$$X_0 \xrightarrow{u_1} X_1 \xrightarrow{u_2} \cdots \xrightarrow{u_{n-1}} X_{n-1} \xrightarrow{u_n} X_n,$$

taking the form of a map of topological spaces $[0,1]^{n-1} \to \mathrm{Map}_{\mathcal{C}}(X_0, X_n)$ whose restriction to the boundary $\partial[0,1]^{n-1}$ is determined by the data (D_m) for $m < n$.

To give a precise and succinct formulation of (D_n), it is useful to introduce a bit of terminology.

Construction 0.2.2.6. Let $n \geqslant 0$ be an integer and let $[n]$ denote the linearly ordered set $\{0 < 1 < \ldots < n\}$. We define a topological category $\mathcal{T}_n$ as follows:

- The objects of $\mathcal{T}_n$ are the elements of $[n]$.
- Given a pair of objects $i, j \in \mathcal{T}_n$, the space of maps from i to j is given by

$$\mathrm{Map}_{\mathcal{T}_n}(i,j) = \begin{cases} \varnothing & \text{if } i > j \\ \{f \in [0,1]^{\{i,i+1,\ldots,j\}} : f(i) = f(j) = 1\} & \text{if } i \leqslant j. \end{cases}$$

- For $0 \leqslant i \leqslant j \leqslant k \leqslant n$, the composition law

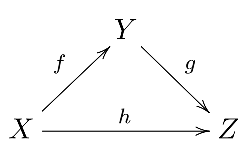
$$\circ : \mathrm{Map}_{\mathcal{T}_n}(j,k) \times \mathrm{Map}_{\mathcal{T}_n}(i,j) \to \mathrm{Map}_{\mathcal{T}_n}(i,k)$$

is given by the formula $(f \circ g)(t) = \begin{cases} f(t) & \text{if } j \leqslant t \leqslant k \\ g(t) & \text{if } i \leqslant t \leqslant j. \end{cases}$

If $\mathcal{C}$ is a topological category, we let $\mathrm{N}(\mathcal{C})_n$ denote the collection of all functors $F : \mathcal{T}_n \to \mathcal{C}$ which are continuous (meaning that the induced map $\mathrm{Map}_{\mathcal{T}_n}(i,j) \to \mathrm{Map}_{\mathcal{C}}(F(i), F(j))$ is continuous for $i, j \in [n]$.

Example 0.2.2.7. Let $\mathcal{C}$ be a topological category. Then:

- An element of $\mathrm{N}(\mathcal{C})_0$ is given by an object X of $\mathcal{C}$.
- An element of $\mathrm{N}(\mathcal{C})_1$ is given by a morphism $f : X \to Y$ in $\mathcal{C}$.
- An element of $\mathrm{N}(\mathcal{C})_2$ is given by a (non-commuting) diagram



in $\mathcal{C}$ together with a path α from h to $g \circ f$ (which "witnesses" that the diagram commutes up to homotopy).

Remark 0.2.2.8. For each $n \geqslant 0$, the topological category $\mathcal{T}_n$ appearing in Construction 0.2.2.6 can be regarded as a "thickened version" of the partially ordered set $[n] = \{0 < 1 < \cdots < n\}$ (regarded as a category): each of the nonempty mapping spaces in $\mathcal{T}_n$ is contractible, and the homotopy category of $\mathcal{T}_n$ can be identified with $[n]$.

Construction 0.2.2.9 (Homotopy Coherent Nerve: [45], [44])**.** Let $m, n \geqslant 0$ be integers and suppose we are given a nondecreasing map $\rho : [m] \to [n]$. Then we can extend ρ to a (continuous) functor $\mathcal{T}_m \to \mathcal{T}_n$, which is given on morphisms by the construction

$$(f \in \mathrm{Map}_{\mathcal{T}_m}(i,j)) \mapsto (\rho(f) \in \mathrm{Map}_{\mathcal{T}_n}(\rho(i), \rho(j)))$$

$$\rho(f)(t) = \sup(\{0\} \cup \{f(\bar{t})\}_{\rho(\bar{t})=t}).$$

If $\mathcal{C}$ is a topological category, then composition with ρ induces a map $\mathrm{N}(\mathcal{C})_n \to \mathrm{N}(\mathcal{C})_m$. Using this construction, we can regard the construction $[n] \mapsto \mathrm{N}(\mathcal{C})_n$ as a simplicial set. We will denote this simplicial set by $\mathrm{N}(\mathcal{C})_\bullet$ and refer to it as the *homotopy coherent nerve* of $\mathcal{C}$.

Example 0.2.2.10. Let $\mathcal{C}$ be any category. Then we can regard $\mathcal{C}$ as a topological category by equipping each of the morphism sets $\mathrm{Hom}_{\mathcal{C}}(X, Y)$ with the discrete topology. In this case, we will refer to the homotopy coherent nerve $\mathrm{N}(\mathcal{C})_\bullet$ simply as the *nerve* of $\mathcal{C}$. Unwinding the definitions, we see that for each $n \geqslant 0$, the set $\mathrm{N}(\mathcal{C})_n$ can be identified with the set of all diagrams

$$X_0 \xrightarrow{f_1} X_1 \xrightarrow{f_2} X_2 \to \cdots \xrightarrow{f_n} X_n$$

consisting of n-tuples of composable morphisms in $\mathcal{C}$.

Using Construction 0.2.2.9, one can formulate the notion of a homotopy coherent diagram in a very simple way:

Definition 0.2.2.11. Let $\mathcal{J}$ and $\mathcal{C}$ be topological categories. A *homotopy coherent diagram in $\mathcal{C}$ indexed by $\mathcal{J}$* is a map of simplicial sets $\mathrm{N}(\mathcal{J})_\bullet \to \mathrm{N}(\mathcal{C})_\bullet$.

Remark 0.2.2.12. When $\mathcal{J}$ is an ordinary category (regarded as a topological category with the discrete topology), Definition 0.2.2.11 supplies a precise formulation of the incomplete definition sketched earlier (note that Definition 0.2.2.11 incorporates some additional requirements regarding identity morphisms that we did not mention earlier: for example, a homotopy coherent diagram should send each identity morphism in $\mathcal{J}$ to an identity morphism in $\mathcal{C}$).

Definition 0.2.2.11 illustrates a general phenomenon. Working with a topological category $\mathcal{C}$ in a homotopy-invariant way often requires us to introduce definitions which seem complicated because they involve a bottomless hierarchy of coherences (conditions which hold up to homotopy, which must be specified and which must satisfy further conditions, but only up to homotopy, which must also be specified, and so forth). However, these definitions can often be expressed in a simple and efficient way in terms of the homotopy coherent nerve $\mathrm{N}(\mathcal{C})_\bullet$, using the language of simplicial sets. For many purposes, it is convenient to discard the topological category $\mathcal{C}$ and work directly with the simplicial set $\mathrm{N}(\mathcal{C})$. It turns out that passage to the homotopy coherent nerve does not lose any essential information. For ordinary categories, it does not lose *any* information:

Example 0.2.2.13. Let $\mathcal{C}$ be an ordinary category. Then $\mathcal{C}$ can be recovered (up to canonical isomorphism) from its nerve $\mathrm{N}(\mathcal{C})_\bullet$. For example, the objects of $\mathcal{C}$ are just the 0-simplices of $\mathrm{N}(\mathcal{C})_\bullet$, and the morphisms of $\mathcal{C}$ are just the 1-simplices of $\mathrm{N}(\mathcal{C})_\bullet$. Given a pair of composable morphisms $X \xrightarrow{f} Y \xrightarrow{g} Z$ in $\mathcal{C}$, the composition $g \circ f$ is the unique morphism $h : X \to Z$ for which there exists a 2-simplex in $\mathrm{N}(\mathcal{C})$ whose boundary is given by

$$\begin{array}{ccccc} & & Y & & \\ & \overset{f}{\nearrow} & & \overset{g}{\searrow} & \\ X & & \xrightarrow{\quad h \quad} & & Z. \end{array}$$

Elaborating on Example 0.2.2.13, one can prove the following:

Proposition 0.2.2.14. *The construction $\mathcal{C} \mapsto \mathrm{N}(\mathcal{C})_\bullet$ determines a fully faithful embedding from the category $\mathcal{C}\mathrm{at}$ of small categories to the category $\mathcal{S}\mathrm{et}_\Delta$ of simplicial sets. The essential image of this embedding consists of those simplicial sets $S_\bullet$ with the following property:*

($*$) *For every pair of integers $0 < i < n$ and every map $\sigma_0 : \Lambda^n_i \to S_\bullet$, there is a unique map $\sigma : \Delta^n \to S_\bullet$ extending σ_0.*

Remark 0.2.2.15. In the special case $i = 1$ and $n = 2$, condition ($*$) of Proposition 0.2.2.14 corresponds to the assertion that every composable pair of morphisms $f : X \to Y$ and $g : Y \to Z$ uniquely determine a commutative diagram

$$\begin{array}{ccccc} & & Y & & \\ & \overset{f}{\nearrow} & & \overset{g}{\searrow} & \\ X & & \xrightarrow{\quad h \quad} & & Z. \end{array}$$

Note that condition ($*$) of Proposition 0.2.2.14 bears a striking resemblance to the definition of a Kan complex (Definition 0.2.1.4). However, there are two important differences: in the definition of a Kan complex, one requires that horns $\sigma_0 : \Lambda^n_i \to S_\bullet$ can be extended to simplices $\sigma : \Delta^n \to S_\bullet$ whenever $0 \leqslant i \leqslant n$, not only for the "inner" horns where $0 < i < n$. On the other hand, the definition of a Kan complex only requires the existence of σ, not its uniqueness. Neither of these conditions implies the other: the nerve of a category $\mathcal{C}$ is not a Kan complex if there are non-invertible morphisms in $\mathcal{C}$, and the singular complex of a topological space X is not the nerve of a category if there are nonconstant paths in X. However, these definitions admit a common generalization:

Definition 0.2.2.16. Let $S_\bullet$ be a simplicial set. We will say that $S_\bullet$ is an ∞-*category* if it satisfies the following condition:

($\star$) For every pair of integers $0 < i < n$ and every map $\sigma_0 : \Lambda^n_i \to S_\bullet$, there exists a map $\sigma : \Delta^n \to S_\bullet$ extending σ_0.

Definition 0.2.2.16 was introduced originally by Boardman and Vogt in their work on homotopy invariant algebraic structures (see [?]). They referred to condition $(\star)$ as the *weak Kan condition* and to simplicial sets $S_\bullet$ satisfying $(\star)$ as *weak Kan complexes*. The theory was developed more extensively by Joyal, who refers to simplicial sets satisfying $(\star)$ as *quasicategories* (see, for example, [106], [107], and [108]).

Example 0.2.2.17. Every Kan complex is an ∞-category. In particular, if X is a topological space, then the singular simplicial set $\mathrm{Sing}_\bullet X$ is an ∞-category. More informally, this means any topological space X can be regarded as an ∞-category (by passing to its singular simplicial set), so that the theory of ∞-categories subsumes the classical homotopy theory of spaces.

Example 0.2.2.18. For every ordinary category $\mathcal{C}$, the nerve $\mathrm{N}(\mathcal{C})_\bullet$ is an ∞-category. More informally, this means that any category $\mathcal{C}$ can be regarded as an ∞-category (by passing to its nerve). By virtue of Proposition 0.2.2.14, this involves no loss of information. We will sometimes abuse terminology by not distinguishing between a category $\mathcal{C}$ and the corresponding ∞-category $\mathrm{N}(\mathcal{C})_\bullet$.

We will make extensive use of the theory of ∞-categories in this book. For the reader's convenience, we include a brief account of some of the most important definitions and notations; for a much more extensive discussion (which includes proofs of all of the assertions made in this section), we refer the reader to [138].

Notation 0.2.2.19. We will typically denote ∞-categories by caligraphic letters like $\mathcal{C}$ and $\mathcal{D}$, emphasizing the perspective that an ∞-category is a kind of generalized category. If $\mathcal{C}$ is an ∞-category, we will refer to the 0-simplices of $\mathcal{C}$ as *objects* and to the 1-morphisms of $\mathcal{C}$ as *morphisms*. If $e : \Delta^1 \to \mathcal{C}$ is a 1-simplex of $\mathcal{C}$, then $X = e|_{\{0\}}$ and $Y = e|_{\{1\}}$ are 0-simplices of $\mathcal{C}$, and we will say that *e is a morphism from X to Y* and write $e : X \to Y$. For every object $X \in \mathcal{C}$, we let id_X denote the 1-simplex of $\mathcal{C}$ given by the composition $\Delta^1 \to \Delta^0 \xrightarrow{X} \mathcal{C}$. Then id_X is a morphism from X to itself, which we will refer to as *the identity morphism*.

If $\mathcal{C}$ is an ∞-category, then one can associate to every pair of objects $X, Y \in \mathcal{C}$ a space of map $\mathrm{Map}_{\mathcal{C}}(X, Y)$, which we will regard as a Kan complex. In fact, there are several natural constructions of this space which yield homotopy equivalent (but nonisomorphic) results. Perhaps the easiest is this: one can define $\mathrm{Map}_{\mathcal{C}}(X, Y)$ as the Kan complex whose n-simplices are maps $\Delta^n \times \Delta^1$ to $\mathcal{C}$ which carry $\Delta^n \times \{0\}$ to the vertex X and $\Delta^n \times \{1\}$ to the vertex Y. By definition, a vertex of $\mathrm{Map}_{\mathcal{C}}(X, Y)$ is a morphism $f : X \to Y$ in $\mathcal{C}$. We wil say that two morphisms $f, g : X \to Y$ are *homotopic* if the belong to the same path component of $\mathrm{Map}_{\mathcal{C}}(X, Y)$.

Let σ be a 2-simplex in an ∞-category $\mathcal{C}$ whose boundary is given as follows:

$$\begin{array}{ccccc} & & Y & & \\ & \overset{f}{\nearrow} & & \overset{g}{\searrow} & \\ X & & \xrightarrow{h} & & Z. \end{array}$$

In this case, we will say that σ *exhibits* h *as a composition of* g *with* f and write $h = g \circ f$. This is an abuse of notation: neither the 2-simplex σ nor the morphism h are uniquely determined by f and g. However, one can show that h is determined uniquely up to homotopy (and that the homotopy class of h depends only on the homotopy classes of f and g).

To every ∞-category $\mathcal{C}$ one can associate an ordinary category $\mathrm{h}\mathcal{C}$, called the *homotopy category* of $\mathcal{C}$. The objects of $\mathrm{h}\mathcal{C}$ are the objects of $\mathcal{C}$, and a morphism from X to Y in $\mathrm{h}\mathcal{C}$ is a homotopy class of morphisms from X to Y in $\mathcal{C}$. There is a canonical map of simplicial sets $\mathcal{C} \to \mathrm{N}(\mathrm{h}\mathcal{C})_\bullet$, and the homotopy category $\mathrm{h}\mathcal{C}$ is universal with respect to this property. We will say that a morphism in $\mathcal{C}$ is an *equivalence* if its image in $\mathrm{h}\mathcal{C}$ is an isomorphism. We say that two objects $X, Y \in \mathcal{C}$ are *equivalent* if there exists an equivalence from X to Y.

If $\mathcal{C}$ and $\mathcal{D}$ are ∞-categories, then a *functor* from $\mathcal{C}$ to $\mathcal{D}$ is a map of simplicial sets $F : \mathcal{C} \to \mathcal{D}$. For every pair of simplicial sets $\mathcal{C}$ and $\mathcal{D}$, we let $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ denote the simplicial set parametrizing maps from $\mathcal{C}$ to $\mathcal{D}$: that is, $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ is characterized by the existence of a canonical bijection $\mathrm{Hom}_{\mathcal{S}\mathrm{et}_\Delta}(S, \mathrm{Fun}(\mathcal{C}, \mathcal{D})) \simeq \mathrm{Hom}_{\mathcal{S}\mathrm{et}_\Delta}(S \times \mathcal{C}, \mathcal{D})$. If $\mathcal{D}$ is an ∞-category, then $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ is also an ∞-category. If $\mathcal{C}$ and $\mathcal{D}$ are both ∞-categories, then we will refer to $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ as the *∞-category of functors from $\mathcal{C}$ to $\mathcal{D}$*.

Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of ∞-categories. We say that F is an *equivalence of ∞-categories* if there exists a functor $G : \mathcal{D} \to \mathcal{C}$ such that $G \circ F$ is equivalent to $\mathrm{id}_\mathcal{C}$ in the ∞-category $\mathrm{Fun}(\mathcal{C}, \mathcal{C})$ and $F \circ G$ is equivalent to $\mathrm{id}_\mathcal{D}$ in the ∞-category $\mathrm{Fun}(\mathcal{D}, \mathcal{D})$. In this case, the functor G is also an equivalence of ∞-categories, and we will say that the functors F and G are *mutually inverse*.

The construction of homotopy coherent nerves establishes a close connection between the theory of ∞-categories and the theory of topological categories. One can show that the construction $\mathcal{C} \mapsto \mathrm{N}(\mathcal{C})$ admits a left adjoint $S_\bullet \mapsto |\mathfrak{C}(S_\bullet)|$ (modulo a slight technicality: one needs to adjust Definition 0.2.2.1 to work in the setting of compactly generated topological spaces, rather than arbitrary topological spaces). Moreover, one has the following:

(*i*) For every ∞-category $\mathcal{D}$, the unit map $\mathcal{D} \to \mathrm{N}(|\mathfrak{C}(\mathcal{D})|)$ is an equivalence of ∞-categories.

(*ii*) For any topological category $\mathcal{C}$, the counit map $v : |\mathfrak{C}(\mathcal{C})| \to \mathcal{C}$ is a weak equivalence of topological categories. More precisely, it is bijective on objects, and for each pair of maps $X, Y \in \mathcal{C}$ the induced map

$$v_{X,Y} : \mathrm{Map}_{|\mathfrak{C}(\mathcal{C})|}(X, Y) \to \mathrm{Map}_\mathcal{C}(X, Y)$$

is a weak homotopy equivalence (that is, it induces isomorphisms on all homotopy groups). If $\mathrm{Map}_{\mathcal{C}}(X, Y)$ has the homotopy type of a CW complex, then $v_{X,Y}$ is a homotopy equivalence.

Assertions (i) and (ii) imply that the notions of topological category and ∞-category are, in some sense, equivalent. However, the latter theory is often much simpler to work with in practice. For example, if $\mathcal{C}$ and $\mathcal{D}$ are ∞-categories, then the ∞-category $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ of functors from $\mathcal{C}$ to $\mathcal{D}$ is very easy to define, but the corresponding construction in the setting of topological categories is much more involved.

We close this section by mentioning some of the most important examples of ∞-categories:

Example 0.2.2.20. The collection of all Kan complexes can be organized into an ∞-category, which we will denote by $\mathcal{S}$ and refer to as *the ∞-category of spaces*. It is obtained by applying a variant of Construction 0.2.2.9 to the category $\mathcal{K}\mathrm{an}$ of Kan complexes (which is enriched in simplicial sets). In low degrees, it can be described explicitly as follows:

- A 0-simplex of $\mathcal{S}$ is a Kan complex X.
- A 1-simplex of $\mathcal{S}$ is a map of simplicial sets $f : X \to Y$, where X and Y are Kan complexes.
- A 2-simplex of $\mathcal{S}$ is given by a (non-commuting) diagram of Kan complexes

$$\begin{array}{ccc} & Y & \\ {}^{f}\nearrow & & \searrow^{g} \\ X & \xrightarrow{h} & Z \end{array}$$

  together with a simplicial homotopy from h to $g \circ f$.

One can obtain an equivalent (but nonisomorphic) ∞-category by applying the homotopy coherent nerve to the (topological) category $\mathcal{T}\mathrm{op}^{\mathrm{CW}}$ of CW complexes.

Example 0.2.2.21. The collection of all (small) ∞-categories can be organized into an ∞-category, which we will denote by $\mathcal{C}\mathrm{at}_\infty$ and refer to as *the ∞-category of ∞-categories*. In low degrees, it can be described explicitly as follows:

- A 0-simplex of $\mathcal{C}\mathrm{at}_\infty$ is an ∞-category $\mathcal{C}$.
- A 1-simplex of $\mathcal{C}\mathrm{at}_\infty$ is a functor of ∞-categories $F : \mathcal{C} \to \mathcal{D}$.
- A 2-simplex of $\mathcal{C}\mathrm{at}_\infty$ is given by a (non-commuting) diagram of ∞-categories

$$\begin{array}{ccc} & \mathcal{D} & \\ {}^{F}\nearrow & & \searrow^{G} \\ \mathcal{C} & \xrightarrow{H} & \mathcal{E} \end{array}$$

  together with an equivalence $u : H \to G \circ F$ in the ∞-category $\mathrm{Fun}(\mathcal{C}, \mathcal{E})$.

0.2.3 Stable Homotopy Theory and Structured Ring Spectra

Let X and Y be finite CW complexes equipped with base points $x \in X$ and $y \in Y$. One of the primary aims of algebraic topology is to describe the set $[X, Y]$ of homotopy classes of pointed maps from X to Y. This is generally quite difficult, even in the case where X and Y are relatively simple spaces (such as spheres). A more reasonable (but still difficult) problem is to determine the set $[X, Y]_s$ of *stable* homotopy classes of maps from X to Y, which is defined as the direct limit $\varinjlim [\Sigma^n X, \Sigma^n Y]$; here $\Sigma^n X$ and $\Sigma^n Y$ denote the n-fold suspensions of X and Y, respectively. To study these invariants systematically, it is convenient to introduce the following definition:

Definition 0.2.3.1. The *Spanier-Whitehead category* $\mathcal{SW}$ is defined as follows:

- An object of the category $\mathcal{SW}$ consists of a pair (X, m), where X is a pointed finite CW complex and $m \in \mathbf{Z}$ is an integer.
- Given a pair of objects $(X, m), (Y, n) \in \mathcal{SW}$, the set of morphisms from (X, m) to (Y, n) is given by the direct limit $\varinjlim_k [\Sigma^{m+k} X, \Sigma^{n+k} Y]$ (note that the set $[\Sigma^{m+k} X, \Sigma^{n+k} Y]$ is well-defined as soon as $m + k$ and $n + k$ are both nonnegative).

Given a pointed finite CW complex X and an integer $m \in \mathbf{Z}$, one should think of the object $(X, m) \in \mathcal{SW}$ as playing the role of the suspension $\Sigma^m X$. Note that m is allowed to be negative: the Spanier-Whitehead category enlarges the homotopy category of pointed finite CW complexes by allowing "formal desuspensions."

Example 0.2.3.2. For each integer $n \in \mathbf{Z}$, we let S^n denote the object of the Spanier-Whitehead category given by (S^0, n), where S^0 is the 0-sphere. We will refer to S^n as the *n-sphere*. Note that for $n \geqslant 0$, the object S^n can be identified with the pair $(S^n, 0)$.

Remark 0.2.3.3. Let X and Y be pointed finite CW complexes, and let us abuse notation by identifying X and Y with the objects $(X, 0), (Y, 0) \in \mathcal{SW}$. Then we have $\mathrm{Hom}_{\mathcal{SW}}(X, Y)$ is the set $[X, Y]_s$ of stable homotopy classes of maps from X to Y.

Remark 0.2.3.4. For any pair of objects $(X, m), (Y, n) \in \mathcal{SW}$, it follows from the Freudenthal suspension theorem that the diagram of sets $\{[\Sigma^{m+k} X, \Sigma^{n+k} Y]\}$ is eventually constant: that is, the natural map

$$[\Sigma^{m+k} X, \Sigma^{n+k} Y] \to [\Sigma^{m+k+1} X, \Sigma^{n+k+1} Y]$$

is bijective for $k \gg 0$.

Let $\mathcal{H}$ denote the category whose objects are pointed finite CW complexes and whose morphisms are homotopy classes of pointed maps. Then the construction $X \mapsto \Sigma X$

determines a functor Σ from the category $\mathcal{H}$ to itself. Unwinding the definitions, the Spanier-Whitehead category can be described as the direct limit of the sequence of categories

$$\cdots \to \mathcal{H} \xrightarrow{\Sigma} \mathcal{H} \xrightarrow{\Sigma} \mathcal{H} \xrightarrow{\Sigma} \mathcal{H} \xrightarrow{\Sigma} \mathcal{H} \to \cdots .$$

The category $\mathcal{H}$ arises naturally as the homotopy category of an ∞-category: namely, the ∞-category $\mathcal{S}_*^{\mathrm{fin}}$ whose objects are pointed Kan complexes X for which the geometric realization $|X|$ has the homotopy type of a finite CW complex. Moreover, the suspension functor $\Sigma : \mathcal{H} \to \mathcal{H}$ is obtained from a functor from $\mathcal{S}_*^{\mathrm{fin}}$ to itself, which we will also denote by Σ. It follows that the Spanier-Whitehead category $\mathcal{SW}$ can also be described as the homotopy category of an ∞-category: namely, the direct limit of the sequence

$$\cdots \to \mathcal{S}_*^{\mathrm{fin}} \xrightarrow{\Sigma} \mathcal{S}_*^{\mathrm{fin}} \xrightarrow{\Sigma} \mathcal{S}_*^{\mathrm{fin}} \xrightarrow{\Sigma} \mathcal{S}_*^{\mathrm{fin}} \xrightarrow{\Sigma} \mathcal{S}_*^{\mathrm{fin}} \to \cdots .$$

We will denote this direct limit by $\mathrm{Sp}^{\mathrm{fin}}$ and refer to it as the *∞-category of finite spectra*.

The set $[X, Y]_s$ of stable homotopy classes of maps from X to Y is generally easier to compute than the set $[X, Y]$. This is in part because the problem is more structured: for example, the set $[X, Y]_s$ has the structure of an abelian group. In fact, one can say much more: the Spanier-Whitehead category $\mathcal{SW}$ is an example of a *triangulated category* in the sense of Verdier (see [**?**]). The next definition axiomatizes those features of the ∞-category $\mathrm{Sp}^{\mathrm{fin}}$ that are responsible for this phenomenon:

Definition 0.2.3.5. Let $\mathcal{C}$ be an ∞-category. We will say that $\mathcal{C}$ is *stable* if it satisfies the following axioms:

(a) The ∞-category $\mathcal{C}$ admits finite colimits.

(b) The ∞-category $\mathcal{C}$ has an object which is both initial and final (we will refer to such an object as a *zero object* of $\mathcal{C}$ and denote it by $0 \in \mathcal{C}$).

(c) The suspension functor $\Sigma : \mathcal{C} \to \mathcal{C}$ (given by the formula $\Sigma X = 0 \amalg_X 0$) is an equivalence of ∞-categories.

Example 0.2.3.6. The ∞-category $\mathcal{S}_*^{\mathrm{fin}}$ satisfies axioms (a) and (b) of Definition 0.2.3.5: axiom (b) follows from the fact that we are working with *pointed* spaces (so that the one-point space is both initial and final), and axiom (a) follows from from the observation that the pointed finite spaces are precisely those that can be built from the 0-sphere S^0 by means of finite colimits. However, the ∞-category $\mathcal{S}_*^{\mathrm{fin}}$ does not satisfy (c): for example, the 0-sphere S^0 cannot be obtained as the suspension of another space. The ∞-category $\mathrm{Sp}^{\mathrm{fin}}$ of finite spectra can be regarded as remedy for the fact that $\mathcal{S}_*^{\mathrm{fin}}$ does not satisfy (c): it satisfies property (c) by construction, and inherits properties (a) and (b) from $\mathcal{S}_*^{\mathrm{fin}}$. Consequently, $\mathrm{Sp}^{\mathrm{fin}}$ is a stable ∞-category.

Remark 0.2.3.7. If $\mathcal{C}$ is a stable ∞-category, then its homotopy category $\mathrm{h}\mathcal{C}$ inherits the structure of a triangulated category. Moreover, essentially all of the triangulated categories which arise naturally can be described as the homotopy category of a stable ∞-category.

Remark 0.2.3.8. Suppose we are given a commutative diagram σ :

$$\begin{array}{ccc} X & \longrightarrow & Y \\ \downarrow & & \downarrow \\ W & \longrightarrow & Z \end{array}$$

in a stable ∞-category $\mathcal{C}$. Then σ is a pullback square if and only if it is a pushout square.

Remark 0.2.3.9. Let $\mathcal{C}$ be an ∞-category with a zero object 0, and suppose we are given a commutative diagram σ :

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ \downarrow & & \downarrow{\scriptstyle g} \\ 0 & \longrightarrow & Z \end{array}$$

in $\mathcal{C}$. If σ is a pullback square, we abuse terminology by saying that the diagram

$$X \xrightarrow{f} Y \xrightarrow{g} Z$$

is a *fiber sequence* (here we are implicitly referring to the entire diagram σ, which we can think of as supplying the morphisms f and g together with a nullhomotopy of the composition $g \circ f$). Similarly, if σ is a pushout square, then we abuse terminology by saying that the diagram

$$X \xrightarrow{f} Y \xrightarrow{g} Z$$

is a cofiber sequence. If the ∞-category $\mathcal{C}$ is stable, then the fiber sequence and cofiber sequences in $\mathcal{C}$ are the same.

For many purposes, the ∞-category $\mathrm{Sp}^{\mathrm{fin}}$ of finite spectra is too small: it admits finite limits and colimits, but does not admit many other categorical constructions such as infinite products. One can remedy this by passing to a larger ∞-category.

Construction 0.2.3.10. Let $\mathcal{C}$ be a small ∞-category. Then one can form a new ∞-category $\mathrm{Ind}(\mathcal{C})$, called *the ∞-category of* Ind-*objects of* $\mathcal{C}$. This ∞-category admits two closely related descriptions:

(a) It is obtained from $\mathcal{C}$ by formally adjoining filtered colimits. In particular, every object of $\mathrm{Ind}(\mathcal{C})$ can be written as the colimit $\varinjlim C_\alpha$ of some filtered diagram $\{C_\alpha\}$ in $\mathcal{C}$, and the mapping spaces in $\mathrm{Ind}(\mathcal{C})$ can be described informally by the formula

$$\mathrm{Map}_{\mathrm{Ind}(\mathcal{C})}(\varinjlim C_\alpha, \varinjlim D_\beta) \simeq \varprojlim_\alpha \varinjlim_\beta \mathrm{Map}_{\mathcal{C}}(C_\alpha, D_\beta).$$

(*b*) If $\mathcal{C}$ admits finite colimits, then $\mathrm{Ind}(\mathcal{C})$ can be described as the full subcategory of $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ spanned by those functors which preserve finite limits.

We let Sp denote the ∞-category $\mathrm{Ind}(\mathrm{Sp}^{\mathrm{fin}})$. We will refer to Sp as the *∞-category of spectra*. A *spectrum* is an object of the ∞-category Sp.

Remark 0.2.3.11. If $\mathcal{C}$ is a stable ∞-category, then the ∞-category $\mathrm{Ind}(\mathcal{C})$ is also stable. In particular, the ∞-category Sp is stable, so the homotopy category $\mathrm{h}\mathcal{C}$ is triangulated.

Definition 0.2.3.12. For each $n \in \mathbf{Z}$, let $S^n \in \mathrm{CW}$ be defined as in Example 0.2.3.2 and regard S^n as an object of the ∞-category Sp. In the special case $n = 0$, we will denote S^n simply by S and refer to it as the *sphere spectrum*.

Let E be an arbitrary spectrum and let $n \in \mathbf{Z}$ be an integer. Since the homotopy category hSp is additive, the set $\mathrm{Hom}_{\mathrm{hSp}}(S^n, E) = \pi_0 \mathrm{Map}_{\mathrm{Sp}}(S^n, E)$ has the structure of an abelian group. We will denote this group by $\pi_n E$ and refer to it as the *nth homotopy group of E*. We say that a spectrum E is *connective* if the homotopy groups $\pi_n E$ vanish for $n < 0$. We let $\mathrm{Sp}^{\mathrm{cn}}$ denote the full subcategory of Sp spanned by the connective spectra.

There are many different ways of looking at the notion of a spectrum (most of which lead to alternative definitions of the ∞-category Sp). Let us summarize a few of the most useful:

Spectra are infinite loop spaces: Let E be a spectrum. For each integer $n \in \mathbf{Z}$, we let $\Omega^{\infty-n} E$ denote the mapping space $\mathrm{Map}_{\mathrm{Sp}}(S^{-n}, E)$. We refer to $\Omega^{\infty-n}E$ as the *nth space of E*. Note that each $\Omega^{\infty-n}E$ can be identified with the loop space of $\Omega^{\infty-n-1}E$. Consequently, the construction $E \mapsto \{\Omega^{\infty-n}E\}_{n \in \mathbf{Z}}$ determines a functor from the ∞-category Sp to the inverse limit of the tower of ∞-categories

$$\cdots \xrightarrow{\Omega} \mathcal{S}_* \xrightarrow{\Omega} \mathcal{S}_* \xrightarrow{\Omega} \mathcal{S}_* \xrightarrow{\Omega} \mathcal{S}_* \xrightarrow{\Omega} \cdots .$$

One can show that this functor is an equivalence of ∞-categories. In other words, the data of a spectrum E is equivalent to the data of an *infinite loop space*: that is, a sequence of pointed spaces $\{E(n)\}_{n \in \mathbf{Z}}$ which are equipped with homotopy equivalences $E(n) \simeq \Omega E(n+1)$.

Spectra are cohomology theories: Let E be a spectrum. For every space X, let $E^n(X)$ denote the set $\pi_0 \mathrm{Map}_{\mathcal{S}}(X, \Omega^{\infty-n}E)$ of homotopy classes of (unpointed) maps from X into the nth space of E. We will refer to $E^n(X)$ as the *nth cohomology group of X with coefficients in E*. One can show that the construction $X \mapsto \{E^n(X)\}_{n \in \mathbf{Z}}$ (which extends in a canonical way to an invariant of pairs of spaces $A \subseteq X$) is a *generalized cohomology theory*: that is, it satisfies all of the Eilenberg-Steenrod axioms characterizing singular cohomology, with the exception of the dimension axiom. Moreover, the converse is true as well: according to the Brown representability theorem, every generalized cohomology theory arises in this way. More precisely, this construction yields a bijection

$$\{ \text{ Spectra } \}/\text{ equivalence } \simeq \{ \text{ Cohomology theories } \}/\text{ isomorphism } .$$

Spectra are generalized abelian groups: Let E be a spectrum. Then the 0th space $\Omega^\infty E$ is an example of an $\mathbb{E}_\infty$*-space*: that is, it can be equipped with an addition law

$$+ : \Omega^\infty E \times \Omega^\infty E \to \Omega^\infty E$$

which is unital, commutative, and associative up to *coherent* homotopy. Moreover, the construction $E \mapsto \Omega^\infty E$ restricts to an equivalence from the ∞-category $\mathrm{Sp}^{\mathrm{cn}}$ of connective spectra to the ∞-category $\mathrm{CAlg}^{\mathrm{gp}}(\mathcal{S})$ of *grouplike* $\mathbb{E}_\infty$-spaces (an $\mathbb{E}_\infty$-space A is said to be *grouplike* if the addition on A exhibits the set of connected components $\pi_0 A$ as an abelian group).

Spectra are the universal stable ∞-category: The ∞-category Sp is stable, admits small colimits, and contains a distinguished object S (the sphere spectrum). Moreover, it is *universal* with respect to these properties: if $\mathcal{C}$ is any stable ∞-category which admits small colimits and $\mathrm{LFun}(\mathrm{Sp}, \mathcal{C})$ denotes the full subcategory of $\mathrm{Fun}(\mathrm{Sp}, \mathcal{C})$ spanned by those functors which preserve small colimits, then the construction $F \mapsto F(S)$ induces an equivalence of ∞-categories $e : \mathrm{LFun}(\mathrm{Sp}, \mathcal{C}) \to \mathcal{C}$. In particular, for each object $C \in \mathcal{C}$, there is an essentially unique functor $F : \mathrm{Sp} \to \mathcal{C}$ which preserves small colimits and satisfies $F(S) = C$.

Let X be a spectrum. We will say that X is *discrete* if the homotopy groups $\pi_n X$ vanish for $n \neq 0$. In this case, X is determined (up to canonical equivalence) by the abelian group $\pi_0 X$. More precisely, the construction $X \mapsto \pi_0 X$ induces an equivalence from the full subcategory $\mathrm{Sp}^\heartsuit \subseteq \mathrm{Sp}$ spanned by the discrete spectra to the ordinary category of abelian groups (which we can regard as an ∞-category by taking its nerve). We can use an inverse of this equivalence to identify the category of abelian groups with the full subcategory $\mathrm{Sp}^\heartsuit \subseteq \mathrm{Sp}$. If A is an abelian group, then the image of A under this identification is called the *Eilenberg-MacLane spectrum of* A. As an infinite loop space, it is given by the sequence $\{K(A,n)\}$; here $K(A,n)$ denotes the Eilenberg-MacLane space characterized by the formula

$$\pi_* K(A,n) = \begin{cases} A & \text{if } * = n \\ 0 & \text{otherwise.} \end{cases}$$

The corresponding cohomology theory is ordinary cohomology with coefficients in A. Throughout this book, we will will often abuse notation by identifying an abelian group A with its corresponding Eilenberg-MacLane spectrum.

It follows from the universal property of the ∞-category Sp that there is an essentially unique functor $\otimes : \mathrm{Sp} \times \mathrm{Sp} \to \mathrm{Sp}$ which preserves small colimits separately in each variable and satisfies $S \otimes S = S$. We will refer to this functor as the *smash product*. Using the universal property of the ∞-category Sp, one can show that the smash product functor endows Sp with the structure of a *symmetric monoidal* ∞-category: that is, the functor $\otimes$ is commutative, associative, and unital up to coherent homotopy.

Definition 0.2.3.13. For any symmetric monoidal ∞-category $\mathcal{C}$, we let $\mathrm{CAlg}(\mathcal{C})$ denote the ∞-category of commutative algebra objects of $\mathcal{C}$. Roughly speaking, an object of $\mathrm{CAlg}(\mathcal{C})$ is given by an object $A \in \mathcal{C}$ equipped with a multiplication $m : A \otimes A \to A$ which is commutative, associative, and unital *up to coherent homotopy*. In the special case where $\mathcal{C}$ is the ∞-category of spectra (equipped with the symmetric monoidal structure given by the smash product), we will denote $\mathrm{CAlg}(\mathcal{C})$ simply by CAlg. We will refer to the objects of CAlg as $\mathbb{E}_\infty$*-rings* and to the ∞-category $\mathcal{C}$ as *the* ∞*-category of* $\mathbb{E}_\infty$*-rings*.

Remark 0.2.3.14. Let E be a spectrum, so that E determines a cohomology theory which assigns to each space X a graded abelian group $E^*(X)$. If E is an $\mathbb{E}_\infty$-ring, then the associated cohomology theory is *multiplicative*: that is, it assigns to each space X a graded ring $E^*(X)$ which is commutative in the graded sense (meaning that $xy = (-1)^{mn} yx$ for $x \in E^m(X)$ and $y \in E^n(X)$). However, the converse fails dramatically: there are many examples of multiplicative cohomology theories which cannot be represented by $\mathbb{E}_\infty$-rings. Roughly speaking, one expects a cohomology theory E^* to be represented by an $\mathbb{E}_\infty$-ring if it is can be equipped with a multiplicative structure for which commutativity and associativity can be seen (at least up to coherent homotopy) at the level of cochains, rather than merely at the level of cohomology.

Let E be an $\mathbb{E}_\infty$-ring. Then the collection of homotopy groups $\pi_* E = E^{-*}(\{x\})$ has the structure of a graded-commutative ring. In particular, $\pi_0 E$ is a commutative ring and each $\pi_n E$ can be regarded as a module over $\pi_0 E$. We will say that E is *connective* if it is connective when regarded as a spectrum (that is, the homotopy groups $\pi_n E$ vanish for $n < 0$) and we will say that E is *discrete* if it is discrete when regarded as a spectrum (that is, the homotopy groups $\pi_n E$ vanish for $n \neq 0$). We let $\mathrm{CAlg}^{\mathrm{cn}}$ denote the full subcategory of CAlg spanned by the connective $\mathbb{E}_\infty$-rings, and we let $\mathrm{CAlg}^{\heartsuit}$ denote the full subcategory of CAlg spanned by the discrete $\mathbb{E}_\infty$-rings.

Remark 0.2.3.15. The construction $A \mapsto \Omega^\infty A$ induces an equivalence from the ∞-category of connective spectra to the ∞-category of grouplike $\mathbb{E}_\infty$-spaces. We can phrase this more informally as follows: giving a connective spectrum is equivalent to giving a space X which behaves like an abelian group *up to coherent homotopy*. This heuristic can be extended to $\mathbb{E}_\infty$-rings: a connective $\mathbb{E}_\infty$-ring A can be thought of as a space X which behaves like a commutative ring up to coherent homotopy.

Remark 0.2.3.16. The construction $A \mapsto \pi_0 A$ determines an equivalence from the ∞-category $\mathrm{CAlg}^{\heartsuit}$ to the ordinary category of commutative rings (regarded as an ∞-category via its nerve). We will generally abuse notation by using this equivalence to identify $\mathrm{CAlg}^{\heartsuit}$ with the category of commutative rings, so that every commutative ring R is regarded as an $\mathbb{E}_\infty$-ring. In terms of the heuristic of Remark 0.2.3.15, this corresponds to regarding R as a space equipped with the discrete topology.

By virtue of Remark 0.2.3.16, we can regard the theory of $\mathbb{E}_\infty$-rings as a generalization of classical commutative algebra. Moreover, it is a robust generalization: all of the basic results, constructions, and ideas that are needed to set up the foundations of classical algebraic geometry have analogues in the setting of $\mathbb{E}_\infty$-rings, which we will make use of throughout this book.

0.3 Overview

This book is divided into nine parts, each of which is devoted to exploring some facet of the relationship between algebraic geometry and structured ring spectra. Our first goal is to establish foundations for the subject. We begin in Part I by introducing "spectral" versions of various algebro-geometric objects (such as schemes, algebraic spaces, and Deligne-Mumford stacks) and studying how these objects are related to their classical counterparts. We also explain how to associate to every spectral scheme X (or, more generally, any spectral Deligne-Mumford stack) a stable ∞-category $\mathrm{QCoh}(X)$ of *quasi-coherent sheaves on* X, which is closely related to the abelian categories of quasi-coherent sheaves which appear in classical algebraic geometry.

Part II is concerned with proper morphisms in the setting of spectral algebraic geometry. In some sense, there is very little to say here: a morphism $f : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ of spectral schemes is proper if and only if the underlying morphism of ordinary schemes $f_0 : (X, \pi_0 \mathscr{O}_X) \to (Y, \pi_0 \mathscr{O}_Y)$ is proper. However, some aspects of the theory work more smoothly in the spectral setting. For example, many important foundational results about proper morphisms between Noetherian schemes (for example, the direct image theorem, the theorem on formal functions, the Grothendieck existence theorem, and Grothendieck's formal GAGA principle) admit generalizations to the setting of spectral algebraic geometry which do not require any Noetherian assumptions (see Theorem 5.6.0.2, Lemma 8.5.1.1, Theorem 8.5.0.3, and Corollary 8.5.3.4).

The subject of Part III is the following general question: to what extent can an algebro-geometric object X can be recovered from the stable ∞-category $\mathrm{QCoh}(X)$? We address this question by proving several "Tannaka reconstruction" type results which assert that, in many circumstances, we can recover X as a kind of "spectrum" of $\mathrm{QCoh}(X)$ (much like an affine scheme $(Y, \mathscr{O}_Y)$ can be recovered as the spectrum of its coordinate ring $\Gamma(Y; \mathscr{O}_Y)$). We also show that there is a close relationship between stable ∞-categories $\mathcal{C}$ equipped with an action of $\mathrm{QCoh}(X)$ and *sheaves* of stable ∞-categories on X (categorifying the relationship between quasi-coherent sheaves on an affine scheme $(Y, \mathscr{O}_Y)$ and modules over the coordinate ring $\Gamma(Y; \mathscr{O}_Y)$.

A standard heuristic principle of deformation theory asserts that over a field κ of characteristic zero, one can describe a formal neighborhood of any algebro-geometric object X near a point $x \in X$ in terms of a differential graded Lie algebra. In Part IV, we will formulate this principle precisely by introducing an ∞-category Moduli_κ of *formal moduli problems* over κ and constructing an equivalence of Moduli_κ with an ∞-category of differential graded Lie algebras over κ. We also study variants of this principle in the setting of noncommutative geometry (which are valid in any characteristic). Part IV is mostly independent of the first three parts (they are relevant mainly because they provide examples of formal moduli problems which can be analyzed using the formalism of Part IV).

In Part **??** we study representability problems in the setting of spectral algebraic geometry. Suppose we are given a functor $h : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, where $\mathrm{CAlg}^{\mathrm{cn}}$ denotes the ∞-category of connective $\mathbb{E}_\infty$-rings and $\mathcal{S}$ denotes the ∞-category of spaces. We might then ask if there exists a spectral scheme X (or some other sort of algebro-geometric object) which *represents* the functor h, in the sense that there exist homotopy equivalences $h(A) \simeq \mathrm{Map}(\mathrm{Spec}\, A, X)$ depending functorially on A (such an X is uniquely determined up to equivalence, as we will see in Part I). In the setting of classical algebraic geometry, this sort of question can often be addressed using Artin's representability theorem, which gives necessary and sufficient conditions for a functor to be representable by an algebraic stack which is locally of finite presentation over a (sufficiently nice) commutative ring R. The main goal of Part **??** is to formulate and prove an analogous statement in the spectral setting.

The basic objects of study in classical and spectral algebraic geometry can be described in a very similar way: they are given by pairs $(X, \mathscr{O}_X)$, where X is a topological space (or some variant thereof: in the theory of Deligne-Mumford stacks, it is convenient to allow X to be a topos; when studying higher Deligne-Mumford stacks, it is convenient to allow X to be an ∞-topos) and $\mathscr{O}_X$ is a "structure sheaf" on X. The difference between classical and spectral algebraic geometry lies in what sort of sheaf $\mathscr{O}_X$ is: in the classical case, $\mathscr{O}_X$ is a sheaf of commutative rings; in the spectral case, it is a sheaf of $\mathbb{E}_\infty$-rings. In Part VI, we introduce general formalism of "∞-topoi with structure sheaves" which is intended to capture the spirit of these types of definitions in a broad degree of generality. Part VI does not depend on any of the earlier parts of this book (logically, it could precede Part I; however, most readers will probably find it easier to digest the theory of CAlg-valued sheaves than the general sheaf theory of Part VI).

In Part VII, we study several variants of spectral algebraic geometry:

- *derived differential topology*, whose basic objects (*derived manifolds*) are analogous to smooth manifolds in the same way that spectral schemes are analogous to smooth algebraic varieties.

- *derived complex analytic geometry*, whose basic objects (*derived complex-analytic spaces*) are analogous to complex-analytic manifolds in the same way that spectral schemes are analogous to smooth algebraic varieties.

- *derived algebraic geometry*, a variant of spectral algebraic geometry which uses simplicial commutative rings in place of $\mathbb{E}_\infty$-rings. The resulting theory is equivalent to spectral algebraic geometry in characteristic zero, but is quite different (and more closely connected to classical algebraic geometry) in positive and mixed characteristic.

Each of these variants can be regarded as an instance of the general paradigm of Part VI. However, we give an exposition in each instance which can be read independently, referring occasionally to the formalism of Part VI for the verification of some routine details.

The term "derived algebraic geometry" is meant to evoke an analogy with the theory of derived categories, which perhaps merits some explanation. To fix ideas, suppose that we are given a commutative ring A and an A-module M. Then:

- The construction $N \mapsto \mathrm{Hom}_A(M, N)$ determines a functor from the category of A-modules to itself which is left exact but generally not right exact. In order to account for the failure of right exactness, it is often useful to consider the right derived functors $\{N \mapsto \mathrm{Ext}^n_A(M, N)\}_{n \geqslant 0}$.

- The construction $N \mapsto M \otimes_A N$ determines a functor from the category of A-modules to itself which is right exact but generally not left exact. In order to account for the failure of left exactness, it is often useful to consider the left derived functors $\{N \mapsto \mathrm{Tor}^A_n(M, N)\}_{n \geqslant 0}$.

To study either of these derived functors, it is useful to consider the *derived category* $D(A)$ which obtained from the category of chain complexes of A-modules by formally inverting all quasi-isomorphisms. Let $D(A)_{\geqslant 0}$ denote the subcategory of $D(A)$ consisting of those chain complexes whose homology groups are concentrated in nonnegative degrees, and define $D(A)_{\leqslant 0}$ similarly. One can then consider *total derived functors*

$$\mathrm{RHom}_A(M, \bullet) : D(A)_{\leqslant 0} \to D(A)_{\leqslant 0} \qquad M \otimes^L_A \bullet : D(A)_{\geqslant 0} \to D(A)_{\geqslant 0}$$

which, when restricted to an ordinary A-module N (regarded as chain complexes concentrated in degree zero), yield chain complexes whose (co)homology groups recover the invariants $\mathrm{Ext}^n_A(M, N)$ and $\mathrm{Tor}^n_A(M, N)$, respectively.

The relationship between the theory of derived schemes and the classical theory of schemes is somewhat analogous to the relationship between the derived category $D(A)_{\leqslant 0}$

and the abelian category of A-modules. The ∞-category of derived schemes can be regarded as an enlargement of the category of schemes, and certain left exact constructions on schemes (such as the formation of fiber products) admit refinements in the setting of derived schemes in a way that retains additional (and often useful) information. The theory of algebraic stacks provides another enlargement of the category of schemes which is quite different, but in some sense formally dual. The 2-category of algebraic stacks is an enlargement of the category of schemes in which one has improved versions of certain right exact constructions, such as the formation of quotients by group actions (such quotients sometimes do not exist in the category of schemes, and when they do exist they are often badly behaved). In this respect, the relationship between the theory of algebraic stacks and the theory of schemes is somewhat analogous to the relationship between the derived category $D(A)_{\geqslant 0}$ and the abelian category of A-modules (to make the analogy stronger, one can further enlarge the category of schemes by considering algebraic n-stacks for $n > 1$).

In Part VIII we will discuss the theory of *derived stacks*, an extension of classical algebraic geometry which provides a common generalization of the theory of derived schemes and the theory of (higher) algebraic stacks (in much the same way that the full derived category $D(A)$ contains both $D(A)_{\leqslant 0}$ and $D(A)_{\geqslant 0}$ as full subcategories). Many important foundational results concerning ordinary algebraic stacks can be extended to the setting of derived stacks. In particular, we will prove a version of Artin's representability theorem, which establishes necessary and sufficient conditions for a functor to be representable by a derived stack (Theorem **??**) and which can be used to produce many examples of geometric objects which fit into the framework of this book.

In [170], Quillen showed that the homotopy theory of simply connected spaces whose homotopy groups are rational vector spaces is equivalent to the theory of *connected* differential graded Lie algebras over $\mathbf{Q}$. Quillen's work provided an early clue to the significance of differential graded Lie algebras, and partially inspired the study of their applications to deformation theory. In Part IX we will reverse this logic, explaining how Quillen's result is related to (and can be deduced from) the theory developed in Part IV. We also discuss Mandell's p-adic analogue of rational homotopy theory and describe a natural extension which makes use of algebro-geometric ideas. Part IX is primarily self-contained, and can be read independently of the rest of this book.

This book includes several appendices discussing background material needed in the body of the text. In Appendix A, we review of the theory of Grothendieck sites and sheaves in the setting of higher category theory, introduce the notion of a *coherent* ∞-topos (and prove an ∞-categorical analogue of Deligne's completeness theorem: for every coherent ∞-topos $\mathcal{X}$, the hypercompletion $\mathcal{X}^{\mathrm{hyp}}$ has enough points). In Appendix B we discuss several specific examples of Grothendieck topologies which arise in spectral algebraic geometry (such as the Nisnevich and étale topologies associated to a commutative ring) and their relationship to one another, reviewing some of the requisite commutative algebra along the way. Appendix C introduces the theory of *prestable ∞-categories*, a generalization of the notion of stable ∞-category which will play an important role in Part III. In Appendix D, we study the notion of an *R-linear* (pre)stable ∞-category, where R is a ring spectrum, and combine the results of Appendices B and C to prove several descent theorems (both for objects of R-linear ∞-categories and for R-linear ∞-categories themselves). Finally, Appendix E contains an exposition of profinite homotopy theory, which is needed for the discussion of p-adic homotopy theory in Part IX.

0.4 What is not in this book?

Even in a book as long as this, we could not hope to give a comprehensive account of the various ways in which homotopy theoretic ideas have influenced algebraic geometry. In this section, we present an (incomplete) list of ideas which are thematically related to the subject of spectral algebraic geometry, but which will not make an appearance in this book (at least in its present form).

Virtual fundamental classes: One of the primary motivations for developing the language of spectral algebraic geometry is to provide a natural setting for the theory of virtual fundamental classes described in the introduction. In this book, we will discuss some of the relevant formal ingredients (we discuss quasi-smoothness in §**??** and virtual dimension in §**??**). However, we will not discuss virtual fundamental classes (or the cohomological framework in which they naturally reside) here. The subject has been treated in the literature from a variety of perspectives: see, for example, [120], [18], [131], and [191].

Elliptic cohomology: The theory of spectral algebraic geometry plays a central role in understanding the moduli-theoretic interpretation of the theory of topological modular forms (see Example 0.1.1.15) and other related constructions in the setting of chromatic homotopy theory. We will discuss these applications in a sequel to this book. For an informal outline in the case of elliptic cohomology we refer the reader to [140]; see also [21] for a discussion of the more general theory of topological *automorphic* forms.

Higher stacks outside of derived algebraic geometry: Part VIII of this book is devoted to the theory of higher algebraic stacks in the setting of derived algebraic geometry. One can develop an analogous theory in any setting where one has a good notion of smooth morphism, including the theory of spectral algebraic geometry (using the notion of *differential smoothness* that we discuss in §11.2). However, we will not consider such objects in this book. A general framework which incorporates the theory of derived algebraic stacks and many other variants has been developed by Toën and Vezzosi; see [214].

Separated Deligne-Mumford stacks: Throughout this book, we will say an algebro-geometric object X is *separated* if the diagonal map $\delta : X \to X \times X$ is a closed immersion. This convention means that X is forbidden to exhibit any "stacky" behavior: an algebraic stack for which δ is a closed immersion is automatically an algebraic space. Many basic results about separated (spectral) algebraic spaces can be generalized to larger classes of (spectral) Deligne-Mumford stacks. We generally ignore such generalizations, except in cases where they require no additional effort to prove.

Global deformation theory: Let X be an algebro-geometric object (such as a scheme or a spectral scheme) defined over the field $\mathbf{C}$ of complex numbers. In Part IV of this book, we study the formal completion of X at a $\mathbf{C}$-valued point $x \in X(\mathbf{C})$ and show that it is determined by a differential graded Lie algebra. One could ask for something more ambitious: suppose we are given instead an arbitrary closed embedding $\iota : X_0 \hookrightarrow X$: how can one describe the formal completion of X along the image of ι in a manner that is completely intrinsic to X_0? We refer the reader to [77] for an approach this problem, using a theory of "derived" Lie algebroids.

Ind-Coherent Sheaves and Grothendieck Duality: Let $f : X \to Y$ a morphism between schemes of finite type over a field. To f, one can associate an *exceptional inverse image functor* $f^! : D^+(Y) \to D^+(X)$ which is a right adjoint to the (derived) pushforward f_* in the case where f is proper, and is left adjoint to f_* in the case where f is étale. Here $D^+(X)$ and $D^+(Y)$ denote the (cohomologically) "bounded below" derived categories of X and Y, respectively. The theory of Grothendieck duality can be generalized to the setting of spectral algebraic geometry. However, the assumption that objects be "cohomologically bounded below" objects is particularly annoying in the spectral setting (for example, it need not be satisfied by the structure sheaves of X and Y). To eliminate this assumption (and achieve a more robust theory), one needs to replace the stable ∞-category $\mathrm{QCoh}(X)$ of quasi-coherent sheaves studied in this book by the closely related ∞-category $\mathrm{Ind}(\mathrm{Coh}(X))$ of Ind-*coherent sheaves on* X. For a discussion these issues (over fields of characteristic zero) we refer the reader to [76].

Shifted symplectic structures: One feature of spectral algebraic geometry that distinguishes it from classical algebraic geometry is that finiteness conditions on spectral schemes are more strongly reflected in their deformation theory. For example, if X is a spectral scheme of finite presentation over $\mathbf{C}$, then the cotangent complex $L_{X/\operatorname{Spec}\mathbf{C}}$ is perfect: that is, it is a dualizable object of $\mathrm{QCoh}(X)$ (the analogous statement for ordinary **C**-schemes holds only when X is a local complete intersection). There are some cases in which the cotangent complex $L_{X/\operatorname{Spec}\mathbf{C}}$ is not only dualizable, but *self-dual* (up to a shift). An antisymmetric identification of $L_{X/\operatorname{Spec}\mathbf{C}}$ with its shifted dual $\Sigma^n L^{\vee}_{X/\operatorname{Spec}\mathbf{C}}$ can be viewed as a kind of "shifted 2-form on X." When this 2-form is closed (in a suitable sense), we say that X has a *n-shifted symplectic structure*. The theory of shifted symplectic structures is still in its infancy (at the time of this writing), but seems to capture an essential feature which is common to many interesting moduli spaces (once they have been appropriately "derived"). For more details, see [164], [37], [166], [34].

0.5 Notation and Terminology

We will assume general familiarity with the terminology of [138] and [139]. For the reader's convenience, we now review some cases in which the conventions of this book differ from those [138], [139], or the established mathematical literature.

- We will generally not distinguish between a category $\mathcal{C}$ and its nerve $\mathrm{N}(\mathcal{C})$. In particular, we regard every category $\mathcal{C}$ as an ∞-category.

- We will generally abuse terminology by not distinguishing between an abelian group M and the associated Eilenberg-MacLane spectrum: that is, we view the ordinary category of abelian groups as a full subcategory of the ∞-category Sp of spectra. Similarly, we regard the ordinary category of commutative rings as a full subcategory of the ∞-category CAlg of $\mathbb{E}_\infty$-rings.

- Let A be an $\mathbb{E}_\infty$-ring. We will refer to A-module spectra simply as *A-modules*. The collection of A-modules can be organized into a stable ∞-category which we will denote by Mod_A and refer to as *the ∞-category of A-modules*. This convention has an unfortunate feature: when A is an ordinary commutative ring, it does not reduce to the usual notion of A-module. In this case, Mod_A is not the abelian category of A-modules but is closely related to it: the homotopy category hMod_A is equivalent to the derived category $D(A)$. *Unless otherwise specified, the term "A-module" will be used to refer to an object of* Mod_A*, even when A is an ordinary commutative ring.* When we wish to consider an A-module M in the usual sense, we will say that M is a *discrete* A-module or an *ordinary* A-module.

- Let A be a commutative ring and let $M \in \mathrm{Mod}_A$ be an A-module. Using the equivalence of categories $\mathrm{hMod}_A \simeq D(A)$, we can identify M with a chain complex of A-modules. This identification has the potential to lead to confusion: beware that the *homotopy groups* of M (if we regard M as a spectrum) correspond to the *homology groups* of

M (if we regard M as a chain complex). We will usually denote these groups by $\{\pi_n M\}_{n \in \mathbf{Z}}$ and refer to them as the homotopy groups of M: that is, we favor the perspective that M is a spectrum with an action of A, rather than a chain complex.

- Unless otherwise specified, all algebraic constructions we consider in this book should be understood in the "derived" sense. For example, if we are given discrete modules M and N over a commutative ring A, then the tensor product $M \otimes_A N$ denotes the *derived* tensor product $M \otimes_A^L N$. This may not be a discrete A-module: its homotopy groups are given by $\pi_n(M \otimes_A N) \simeq \mathrm{Tor}_n^A(M, N)$. When we wish to consider the usual tensor product of M with N over A, we will denote it by $\mathrm{Tor}_0^A(M, N)$ or by $\pi_0(M \otimes_A N)$.

- If M and N are spectra, we will denote the smash product of M with N by $M \otimes N$, rather than $M \wedge N$. More generally, if M and N are modules over an $\mathbb{E}_\infty$-ring A, then we will denote the smash product of M with N over A by $M \otimes_A N$, rather than $M \wedge_A N$. Note that when A is an ordinary commutative ring and the modules M and N are discrete, this agrees with the preceding convention.

- If $\mathcal{C}$ is a triangulated category (such as the homotopy category of a stable ∞-category), we will denote the shift functor on $\mathcal{C}$ by $X \mapsto \Sigma X$, rather than $X \mapsto X[1]$.

- If $\mathcal{C}$ and $\mathcal{D}$ are ∞-categories which admit finite limits, we let $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ spanned by those functor which are *left exact*: that is, those functors which preserve finite limits. If instead $\mathcal{C}$ and $\mathcal{D}$ admits finite colimits, we let $\mathrm{Fun}^{\mathrm{rex}}(\mathcal{C}, \mathcal{D}) = \mathrm{Fun}^{\mathrm{lex}}(\mathcal{C}^{\mathrm{op}}, \mathcal{D}^{\mathrm{op}})^{\mathrm{op}}$ denote the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ spanned by the *right exact* functors: that is, those functors which preserve finite colimits.

- If $\mathcal{C}$ is an ∞-category, we let $\mathcal{C}^{\simeq}$ denote the largest Kan complex contained in $\mathcal{C}$: that is, the ∞-category obtained from $\mathcal{C}$ by discarding all non-invertible morphisms.

- We will say that a functor $f : \mathcal{C} \to \mathcal{D}$ between ∞-categories is *left cofinal* if, for every object $D \in \mathcal{D}$, the ∞-category $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{D/}$ is weakly contractible (this differs from the convention of [138], which refers to a functor with this property simply as *cofinal*; see Theorem HTT.4.1.3.1). We will say that f is *right cofinal* if the induced map $\mathcal{C}^{\mathrm{op}} \to \mathcal{D}^{\mathrm{op}}$ is left cofinal, so that f is right cofinal if and only if the ∞-category $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{/D}$ is weakly contractible for each $D \in \mathcal{D}$.

- We let $\mathcal{T}\mathrm{op}$ denote the category whose objects are topological spaces X, with maps given by continuous functions $f : X \to Y$. We let $\infty\mathcal{T}\mathrm{op}$ denote the ∞-category whose objects are ∞-topoi $\mathcal{X}$ (in the sense of [138]) and whose morphisms are geometric morphisms $f_* : \mathcal{X} \to \mathcal{Y}$ (that is, functors which admit a left adjoint f^* which preserves finite limits). This notation is intended to suggest that $\infty\mathcal{T}\mathrm{op}$ be viewed as an enlargement of $\mathcal{T}\mathrm{op}$ (which is roughly correct; see §1.5).

- If $\mathcal{X}$ is an ∞-topos, we will say that a collection of objects $\{U_\alpha \in \mathcal{X}\}$ is a *covering* of $\mathcal{X}$ if the coproduct $\amalg U_\alpha$ is 0-connective: that is, if the map $\amalg U_\alpha \to \mathbf{1}$ is an effective epimorphism, where $\mathbf{1}$ denotes a final object of $\mathcal{X}$.

- If $\mathcal{C}$ is an ∞-category, we will often write $\mathcal{C}^\heartsuit$ to denote some full subcategory of $\mathcal{C}$ which forms an ordinary category. We will mainly use this notation in the following three (closely related) cases:

  - If $\mathcal{X}$ is an ∞-topos, then we let $\mathcal{X}^\heartsuit$ denote the full subcategory of $\mathcal{X}$ spanned by the discrete objects of $\mathcal{X}$. This is an ordinary Grothendieck topos, which we will refer to as the *underlying topos of* $\mathcal{X}$.
  - If $\mathcal{C}$ is a stable ∞-category equipped with a t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$, then we let $\mathcal{C}^\heartsuit$ denote the intersection $\mathcal{C}_{\geqslant 0} \cap \mathcal{C}_{\leqslant 0}$. This is an abelian category, which we refer to as the *heart of* $\mathcal{C}$.
  - If R is an $\mathbb{E}_\infty$-ring, we let CAlg_R denote the ∞-category of $\mathbb{E}_\infty$-algebras over R. When R is connective, we let $\mathrm{CAlg}_R^\heartsuit$ denote the full subcategory of CAlg_R spanned by the discrete objects, so that $\mathrm{CAlg}_R^\heartsuit$ can be identified with the ordinary category of commutative rings A equipped with a ring homomorphism $\pi_0 R \to A$.

- If $\mathcal{C}$ is an essentially small ∞-category, we let $\mathrm{Ind}(\mathcal{C})$ denote the ∞-category of Ind-objects of $\mathcal{C}$ introduced in §HTT.5.3.5 . We will generally regard $\mathrm{Ind}(\mathcal{C})$ as a full subcategory of the ∞-category $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ by identifying each Ind-object of $\mathcal{C}$ with the functor that it represents on $\mathcal{C}$. Note that the Yoneda embedding $j : \mathcal{C} \to \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ factors through the full subcategory $\mathrm{Ind}(\mathcal{C}) \subseteq \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$. By slight abuse of terminology, we will refer to the induced map $j : \mathcal{C} \to \mathrm{Ind}(\mathcal{C})$ also as the *Yoneda embedding*.

- If $\mathcal{C}$ is an essentially small ∞-category, we let $\mathrm{Pro}(\mathcal{C})$ denote the ∞-category $\mathrm{Ind}(\mathcal{C}^{\mathrm{op}})^{\mathrm{op}}$. We will refer to $\mathrm{Pro}(\mathcal{C})$ as the *∞-category of* Pro-*objects of* $\mathcal{C}$. We will view $\mathrm{Pro}(\mathcal{C})$ as a full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{S})^{\mathrm{op}}$. As in the case of Ind-objects, there is a canonical map $\mathcal{C} \hookrightarrow \mathrm{Pro}(\mathcal{C})$ which we will (by slight abuse of terminology) refer to as the Yoneda embedding.

- Let R be a commutative ring. In classical algebraic geometry, the notation $\mathrm{Spec}\, R$ is often used to refer to several different (but closely related) mathematical objects:

  (i) The topological space X whose points are prime ideals $\mathfrak{p} \subseteq R$, equipped with the *Zariski topology* having a basis consisting of open sets of the form $U_f = \{\mathfrak{p} \subseteq R : f \notin \mathfrak{p}\}$.

(ii) The affine scheme $(X, \mathscr{O}_X)$, where X is the topological space defined above and $\mathscr{O}_X$ is the sheaf of commutative rings given on basic open sets by the formula $\mathscr{O}_X(U_f) = R[f^{-1}]$.

(iii) The functor { commutative rings } → { sets } repesented by the affine scheme $(X, \mathscr{O}_X)$, which assigns to each commutative ring A the set $\mathrm{Hom}(R, A)$ of ring homomorphisms from R to A.

Note that (ii) and (iii) are equivalent data, and we will often abuse terminology by not distinguishing between them. To avoid confusing (i) and (ii), we denote the affine scheme $(X, \mathscr{O}_X)$ by $\operatorname{Spec} R$ and its underlying topological space X by $|\operatorname{Spec} R|$. More generally, we sometimes use the notation $|Y|$ to denote the "underlying topological space" of some geometric object Y (such as a scheme, algebraic space, or some variant thereof).

0.6 Acknowledgements

This book has been shaped by discussions with friends, colleagues, and collaborators over several years. I would like to thank David Ben-Zvi, Bhargav Bhatt, Roman Bezrukavnikov, David Carchedi, Brian Conrad, Vladimir Drinfeld, John Francis, Dennis Gaitsgory, Daniel Halpern-Leistner, David Nadler, Tony Pantev, Mauro Porta, and Carlos Simpson for many enlightening conversations on the subject matter of this book. I would also like to thank Benjamin Antieau, Anthony Blanc, Kestutis Cesnavicius, Adeel Khan, and David Roberts for offering suggestions and pointing out errors in earlier versions of this manuscript.

Special thanks are due to Bertrand Toën and Gabriele Vezzosi, who initiated the study of spectral algebraic geometry: much of this book is based on their writings and on ideas that they have generously shared over the years. Special thanks are due also to my advisor, Mike Hopkins: this book grew out of a doctoral dissertation written under his direction. Finally, I would also like to thank all of my students, past and present: Lukas Brantner, Omar Antolin Camarena, Dustin Clausen, Gijs Heuts, Akhil Mathew, Anatoly Preygel, and Nick Rozenblyum. With each I have had enlightening conversations about algebraic geometry, homotopy theory and their interaction, and many of the resulting insights have made their way into this book.

Part I

Fundamentals of Spectral Algebraic Geometry

Our goal in Part I is to set up foundations for the theory of spectral algebraic geometry that we will develop in this book. We begin in Chapter 1 by introducing the central definitions. After a brief review of Grothendieck's theory of schemes, we describe two of its extensions: the theory of *spectral schemes* (obtained from the classical theory by replacing ordinary commutative rings by $\mathbb{E}_\infty$-rings) and the theory of *Deligne-Mumford stacks* (obtained from the classical theory by replacing the Zariski topology with the étale topology). These extensions admit a common generalization: the theory of *spectral Deligne-Mumford stacks*, which are our principal objects of interest in this book. By definition, a spectral Deligne-Mumford stack X is a pair $(\mathcal{X}, \mathscr{O}_\mathcal{X})$, where $\mathcal{X}$ is an ∞-topos (in the sense of [138]) and $\mathscr{O}_\mathcal{X}$ is a sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$, which is required to satisfy a certain local condition (namely, we require that the pair $(\mathcal{X}, \mathscr{O}_\mathcal{X})$ can be described locally as the *étale spectrum* of a connective $\mathbb{E}_\infty$-ring: see Definition 1.4.2.5). The resulting theory has the following features:

- The collection of spectral Deligne-Mumford stacks can be organized into an ∞-category SpDM, which we will refer to as the *∞-category of spectral Deligne-Mumford stacks*.
- The ∞-category SpDM of spectral Deligne-Mumford stacks contains the 2-category DM of ordinary Deligne-Mumford stacks as a full subcategory (see Remark 1.4.8.3). In particular, it contains the ordinary category Sch of schemes as a full subcategory.
- To every spectral Deligne-Mumford stack $\mathsf{X} = (\mathcal{X}, \mathscr{O}_\mathcal{X})$, one can associate an ordinary Deligne-Mumford stack $(\mathcal{X}^\heartsuit, \pi_0 \mathscr{O}_\mathcal{X})$, which we all the *underlying Deligne-Mumford stack* of X (Remark 1.4.8.2). This construction determines a forgetful functor SpDM $\rightarrow$ DM, which is left homotopy inverse to the inclusion DM $\hookrightarrow$ SpDM).

In Chapter 2, we study quasi-coherent sheaves in spectral algebraic geometry. To each spectral Deligne-Mumford stack $\mathsf{X} = (\mathcal{X}, \mathscr{O}_\mathcal{X})$, we associate a stable ∞-category $\mathrm{QCoh}(\mathsf{X})$ whose objects we will refer to as *quasi-coherent sheaves* (Definition 2.2.2.1). The stable ∞-category $\mathrm{QCoh}(\mathsf{X})$ comes equipped with a t-structure whose heart $\mathrm{QCoh}(\mathsf{X})^\heartsuit$ can be identified with the abelian category of quasi-coherent sheaves on the ordinary Deligne-Mumford stack $(\mathcal{X}^\heartsuit, \pi_0 \mathscr{O})$. In some sense, the distinction between $\mathrm{QCoh}(\mathsf{X})$ and its heart $\mathrm{QCoh}(\mathsf{X})^\heartsuit$ measures the difference between classical and spectral algebraic geometry: when X arises from a "classical" geometric object (like a quasi-compact separated scheme), the stable ∞-category $\mathrm{QCoh}(\mathsf{X})$ can be obtained from the abelian category $\mathrm{QCoh}(\mathsf{X})^\heartsuit$ by passing to the derived ∞-category of §**??** (see Proposition **??**, or Corollary **??** for a closely related assertion).

Let X be a scheme. If R is a commutative ring, then we define an *R-valued point* of X to be a map of schemes $\mathrm{Spét}\, R \rightarrow X$. The collection of R-valued points of X forms a set $X(R) = \mathrm{Hom}_{\mathrm{Sch}}(\operatorname{Spec} R, X)$, and the construction $R \mapsto X(R)$ determines a functor from the category of commutative rings to the category of sets. The situation in spectral algebraic geometry is analogous. To every connective $\mathbb{E}_\infty$-ring R, one can associate a spectral Deligne-Mumford stack $\operatorname{Sp\acute{e}t} R$ which we call the *étale spectrum of* R (in the case where R is an ordinary commutative ring, this is simply the image of the affine scheme $\operatorname{Spec} R$ under the fully faithful embedding $\iota : \mathrm{Sch} \hookrightarrow \mathrm{SpDM}$). If X is a spectral Deligne-Mumford stack, then we define an *R-valued point* of X to be a morphism of spectral Deligne-Mumford stacks $\operatorname{Sp\acute{e}t} R \to \mathsf{X}$. However, there is a vital difference between classical and spectral algebraic geometry: the collection of spectral Deligne-Mumford stacks forms an ∞-category, rather than an ordinary category. Consequently, the collection of R-valued points of a spectral Deligne-Mumford stack X forms a space $\mathrm{Map}_{\mathrm{SpDM}}(\operatorname{Sp\acute{e}t} R, \mathsf{X})$, rather than a set. In Chapter 3, we will study the situation where the mapping space $\mathrm{Map}_{\mathrm{SpDM}}(\operatorname{Sp\acute{e}t} R, \mathsf{X})$ is discrete whenever R is an ordinary commutative ring; in this case, we say that X is a *spectral algebraic space*. Roughly speaking, this condition means that X is forbidden to exhibit any "stacky" behavior (beware, however, that the space $\mathrm{Map}_{\mathrm{SpDM}}(\operatorname{Sp\acute{e}t} R, \mathsf{X})$ will usually have a nontrivial homotopy type if R is not discrete, even if X arises from an ordinary scheme).

Remark 0.6.0.1. Our theory of spectral algebraic geometry is closely related to the theory of homotopical algebraic geometry introduced by Toën and Vezzosi, and the material presented here has substantial overlap with their work (see [202], [213], [214], and [215]). The primary difference in our exposition is that we stick closely to the classical view of scheme as a kind of ringed space, while Toën and Vezzosi put more emphasis on the "functor of points" philosophy described above.

Chapter 1

Schemes and Deligne-Mumford Stacks

In this section, we will introduce the basic objects of study in this book: spectral Deligne-Mumford stacks. The collection of spectral Deligne-Mumford stacks can be organized into an ∞-category SpDM, which contains the usual category of schemes as a full subcategory. Recall that a scheme is defined to be a topological space X together with a sheaf of commutative rings $\mathscr{O}$ on X for which the pair $(X, \mathscr{O})$ is isomorphic, locally on X, to the spectrum $\operatorname{Spec} R$ of a commutative ring R. Our definition of spectral Deligne-Mumford stack is similar in spirit, but differs in three significant ways:

(a) Rather than working with sheaves of ordinary commutative rings, we work with sheaves taking values in the larger ∞-category CAlg of $\mathbb{E}_\infty$-rings (see §HA.7 for an introduction to the theory of $\mathbb{E}_\infty$-rings, and Definition 1.3.1.4 for the definition of a CAlg-valued sheaf).

(b) In place of a topological space X, we consider an arbitrary ∞-topos $\mathcal{X}$. This affords us a great deal of flexibility in forming certain categorical constructions, like quotients by group actions, which can be useful for some applications (such as studying the moduli of objects which admit nontrivial symmetries).

(c) Rather than requiring $(\mathcal{X}, \mathscr{O})$ to be locally equivalent to an affine model of the form $\operatorname{Spec} R$, where R is a commutative ring, we consider instead models of the form $\operatorname{Spét} A$, where A is an $\mathbb{E}_\infty$-ring and $\operatorname{Spét} A$ is its *étale spectrum* (see Definitions 1.2.3.3 and 1.4.2.5). In other words, we will consistently work locally with respect to the étale topology, rather than the Zariski topology.

The ideas required to carry out modification (a) are logically independent from those required to carry out modifications (b) and (c), so we will first discuss them separately from one another. We will begin in §1.1 by considering (a) alone. This leads us to the notion of a *spectral scheme*: that is, a topological space X equipped with a sheaf of $\mathbb{E}_\infty$-rings $\mathscr{O}$ for which $(X, \mathscr{O})$ is locally equivalent to $\operatorname{Spec} A$, where A is a connective $\mathbb{E}_\infty$-ring (see Definition 1.1.2.8 and Corollary 1.1.6.2). We will show that the collection of spectral schemes can be organized into an ∞-category SpSch, which contains the usual category of schemes as a full subcategory (Proposition 1.1.8.4).

In §1.2, we will discuss a completely different enlargement of the category of schemes: the 2-category of Deligne-Mumford stacks. We will view Deligne-Mumford stacks as ringed topoi $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$, which are locally equivalent to the étale spectrum of an affine scheme (Definition 1.2.4.1).

To adapt the notion of Deligne-Mumford stack to the setting of spectral algebraic geometry, we will need a theory of sheaves of $\mathbb{E}_\infty$-rings on topoi (or, more generally, on ∞-topoi). In §1.3, we will show how to associate to every ∞-topos $\mathcal{X}$ another ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$, whose objects are *sheaves of spectra* on $\mathcal{X}$ (or, equivalently, *spectrum objects* of $\mathcal{X}$). The ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ is symmetric monoidal, and the commutative algebra objects of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ form an ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$. We will refer to the objects of $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$ as *sheaves of* $\mathbb{E}_\infty$*-rings on* $\mathcal{X}$. We then define a *spectrally ringed* ∞*-topos* to be a pair $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$, where $\mathcal{X}$ is an ∞-topos and $\mathscr{O}_{\mathcal{X}}$ is a sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$.

In §1.4, we will introduce the notion of a *spectral Deligne-Mumford stack*: that is, a spectrally ringed ∞-topos $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ which is locally equivalent to the étale spectrum of a (connective) $\mathbb{E}_\infty$-ring. The collection of spectral Deligne-Mumford stacks can be organized into an ∞-category SpDM, which we show to be an enlargement of the usual 2-category of Deligne-Mumford stacks (Remark 1.4.8.3).

In this book, we adopt the point of view that a Deligne-Mumford stack is a ringed topos $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ satisfying certain local assumptions. Another perspective (which is more common in the literature) is to view a Deligne-Mumford stack as a groupoid-valued functor on the category of commutative rings (or a certain type of fibered category). We will establish the equivalence of these perspectives in §1.2 (see Theorem 1.2.5.9). In §1.6, we will describe a similar approach to the theory of spectral Deligne-Mumford stack. To every spectral Deligne-Mumford stack (or spectral scheme) X, one can assign a $\mathcal{S}$-valued functor h_{X} on the ∞-category $\mathcal{S}$ of $\mathbb{E}_\infty$-rings. We will show that the construction $\mathsf{X} \mapsto h_{\mathsf{X}}$ is fully faithful (Proposition 1.6.4.2). Combining this fact with some elementary observations about the relationship between topological spaces and ∞-topoi (which we review in §1.5), we show that the ∞-category of spectral schemes can be identified with a full subcategory of the ∞-category of spectral Deligne-Mumford stacks. For this reason, we will primarily focus our attention on spectral Deligne-Mumford stacks throughout the rest of this book.

1.1 Spectral Schemes

1.1.1 Review of Scheme Theory

Our primary objective in this book is to develop the theory of *spectral algebraic geometry*: a variant of algebraic geometry which uses structured ring spectra in the place of ordinary commutative rings. Before we begin this undertaking, it will be helpful to review some of the foundational definitions of the classical theory.

Definition 1.1.1.1. A *ringed space* is a pair $(X, \mathscr{O}_X)$, where X is a topological space and $\mathscr{O}_X$ is a sheaf of commutative rings on X. In this case, we will say that $\mathscr{O}_X$ is the *structure sheaf* of X. We will regard the collection of all ringed spaces as the objects of a category $\mathcal{T}\mathrm{op}_{\mathrm{CAlg}^\heartsuit}$, where a morphism from $(X, \mathscr{O}_X)$ to $(Y, \mathscr{O}_Y)$ in $\mathcal{T}\mathrm{op}_{\mathrm{CAlg}^\heartsuit}$ consists of a pair (π, ϕ), where $\pi : X \to Y$ is a continuous map of topological spaces and $\phi : \mathscr{O}_Y \to \pi_* \mathscr{O}_X$ is a map between sheaves of commutative rings on Y.

Example 1.1.1.2. Let R be a commutative ring. We let $|\operatorname{Spec} R|$ denote the set of all prime ideals of R. For every ideal $I \subseteq R$, we set $V_I = \{\mathfrak{p} \in |\operatorname{Spec} R| : I \subseteq \mathfrak{p}\}$, and refer to V_I as the *vanishing locus* of I. We will regard $|\operatorname{Spec} R|$ as a topological space, where a subset of $|\operatorname{Spec} R|$ is closed if and only if it has the form V_I for some ideal $I \subseteq R$. We will refer to the resulting topology on $|\operatorname{Spec} R|$ as the *Zariski topology*.

For each element $x \in R$, let $U_x = \{\mathfrak{p} \in |\operatorname{Spec} R| : x \notin \mathfrak{p}\}$ denote the complement of the vanishing locus of the principal ideal (x). We will say that an open set $U \subseteq |\operatorname{Spec} R|$ is *elementary* if it has the form U_x, for some element $x \in R$. The collection of elementary open sets forms a basis for the topology of $|\operatorname{Spec} R|$.

The *structure sheaf* of $|\operatorname{Spec} R|$ is a sheaf of commutative rings $\mathscr{O}$ on $|\operatorname{Spec} R|$ with the following properties:

(a) There is a ring homomorphism $\phi : R \to \Gamma(|\operatorname{Spec} R|; \mathscr{O}) = \mathscr{O}(|\operatorname{Spec} R|)$.

(b) For each element $x \in R$, the composite map $R \xrightarrow{\phi} \mathscr{O}(|\operatorname{Spec} R|) \to \mathscr{O}(U_x)$ carries x to an invertible element of $\mathscr{O}(U_x)$, and induces an isomorphism of commutative rings $R[x^{-1}] \simeq \mathscr{O}(U_x)$. In particular, the map α itself is an isomorphism.

Since the open sets U_x form a basis for the topology of R, property (b) determines the structure sheaf $\mathscr{O}$ up to unique isomorphism, once the map $\alpha : R \to \mathscr{O}(|\operatorname{Spec} R|)$ has been fixed (for the existence of $\mathscr{O}$, see Example 1.1.4.7 below).

Remark 1.1.1.3. It is customary to abuse notation by identifying the spectrum $\operatorname{Spec} R$ of a commutative ring R with its underlying topological space $|\operatorname{Spec} R|$. However, we will avoid this abuse of notation for the time being.

Definition 1.1.1.4. Let $(X, \mathscr{O}_X)$ be a ringed space. For every open subset $U \subseteq X$, we let $\mathscr{O}_X|_U$ denote the restriction of $\mathscr{O}_X$ to open subsets of U (which we regard as a sheaf of commutative rings on U). Then $(X, \mathscr{O}_X|_U)$ is itself a locally ringed space.

We say that $(X, \mathscr{O}_X)$ is a *scheme* if, for every point $x \in X$, there exists an open subset $U \subseteq X$ containing x such that $(U, \mathscr{O}_X|_U)$ is isomorphic to $\operatorname{Spec} R$ for some commutative ring R (in the category of ringed spaces). We say that a scheme $(X, \mathscr{O}_X)$ is *affine* if it is isomorphic (in the category $\mathcal{T}\mathrm{op}_{\mathrm{CAlg}^\heartsuit}$ of ringed spaces) to $\operatorname{Spec} R$, for some commutative ring R.

1.1.2 Spectrally Ringed Spaces

Our goal in this section is to introduce an ∞-categorical generalization of the theory of schemes, which we will refer to as the theory of *spectral schemes*. For this, we will need to work with topological spaces equipped with a sheaf of $\mathbb{E}_\infty$-rings, rather than a sheaf of ordinary commutative rings.

Definition 1.1.2.1. Let X be a topological space and let $\mathcal{U}(X)$ denote the partially ordered set of all open subsets of X (which we will regard as a category). For any ∞-category $\mathcal{C}$, a *$\mathcal{C}$-valued presheaf* on X is a functor $\mathscr{F} : \mathcal{U}(X)^{\mathrm{op}} \to \mathcal{C}$. We will say that a $\mathcal{C}$-valued presheaf $\mathscr{F}$ is a *sheaf* if it satisfies the following condition:

- Let $\{U_\alpha\}$ be a collection of open subsets of X having union U, and let $\mathcal{U}' = \{V \in \mathcal{U}(X) : (\exists \alpha)[V \subseteq U_\alpha]\}$. Then the functor $\mathscr{F}$ exhibits $\mathscr{F}(U)$ as a limit of the diagram $\mathscr{F}|_{\mathcal{U}'^{\mathrm{op}}}$ (in other words, $\mathscr{F}$ induces an equivalence $\mathscr{F}(U) \simeq \varprojlim_{V \in \mathcal{U}'} \mathscr{F}(V)$ in the ∞-category $\mathcal{C}$).

We let $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(X)$ denote the full subcategory of $\operatorname{Fun}(\mathcal{U}(X)^{\mathrm{op}}, \mathcal{C})$ spanned by those functors which are $\mathcal{C}$-valued sheaves on X..

Construction 1.1.2.2. Let $\mathcal{C}$ be an ∞-category, and let $\pi : X \to Y$ be a continuous map of topological spaces. Let $\mathscr{F} : \mathcal{U}(X)^{\mathrm{op}} \to \mathcal{C}$ be a $\mathcal{C}$-valued presheaf on X. Then we can define another $\mathcal{C}$-valued presheaf $(\pi_* \mathscr{F}) : \mathcal{U}(Y)^{\mathrm{op}} \to \mathcal{C}$, given on objects by the formula $(\pi_* \mathscr{F})(U) = \mathscr{F}(\pi^{-1}U)$. If $\mathscr{F}$ is a $\mathcal{C}$-valued sheaf on X, then $\pi_* \mathscr{F}$ is a $\mathcal{C}$-valued sheaf on Y. Moreover, the construction $\mathscr{F} \mapsto \pi_* \mathscr{F}$ determines a functor $\pi_* : \mathcal{S}\mathrm{hv}_{\mathcal{C}}(X) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(Y)$, given by precomposition with the map of partially ordered sets $\pi^{-1} : \mathcal{U}(Y) \to \mathcal{U}(X)$. We will refer to π_* as the *pushforward* functor associated to π.

We can regard the construction $X \mapsto \mathcal{S}\mathrm{hv}_{\mathcal{C}}(X)^{\mathrm{op}}$ as a functor from the category $\mathcal{T}\mathrm{op}$ of topological spaces to the category of simplicial sets, which carries a continuous map map $\pi : X \to Y$ to the pushforward functor $\pi_* : \mathcal{S}\mathrm{hv}_{\mathcal{C}}(X)^{\mathrm{op}} \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(Y)^{\mathrm{op}}$. We let $\mathcal{T}\mathrm{op}_{\mathcal{C}}$ denote the relative nerve of this functor, in the sense of Definition HTT.3.2.5.2 . Then $\mathcal{T}\mathrm{op}_{\mathcal{C}}$ is an ∞-category equipped with a coCartesian fibration $\mathcal{T}\mathrm{op}_{\mathcal{C}} \to \mathcal{T}\mathrm{op}$, having the property that each fiber $\mathcal{T}\mathrm{op}_{\mathcal{C}} \times_{\mathcal{T}\mathrm{op}} \{X\}$ is canonically isomorphic to the ∞-category $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(X)^{\mathrm{op}}$.

Remark 1.1.2.3. Let $\mathcal{C}$ be an ∞-category. Then the objects of $\mathcal{T}\mathrm{op}_{\mathcal{C}}$ are given by pairs $(X, \mathscr{O}_X)$, where X is a topological space and $\mathscr{O}_X$ is a $\mathcal{C}$-valued sheaf on X. A morphism from $(X, \mathscr{O}_X)$ to $(Y, \mathscr{O}_Y)$ in $\mathcal{T}\mathrm{op}_{\mathcal{C}}$ is given by a pair (π, α), where $\pi : X \to Y$ is a continuous map of topological spaces and $\alpha : \mathscr{O}_Y \to \pi_* \mathscr{O}_X$ is a morphism in the ∞-category $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(Y)$.

Example 1.1.2.4. Let $\mathrm{CAlg}^{\heartsuit}$ denote the category of commutative rings (regarded as an ∞-category). Then $\mathcal{T}\mathrm{op}_{\mathrm{CAlg}^{\heartsuit}}$ is equivalent to the category of ringed spaces.

Definition 1.1.2.5. Let CAlg denote the ∞-category of $\mathbb{E}_\infty$-rings. A *spectrally ringed space* is a pair $(X, \mathscr{O}_X)$, where X is a topological space and $\mathscr{O}_X$ is a CAlg-valued sheaf on X. In this case, we will refer to $\mathscr{O}_X$ as the *structure sheaf* of X. We will refer to $\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ as the *∞-category of spectrally ringed spaces.*

Notation 1.1.2.6. Let X be a topological space, and let $\mathscr{F}$ be a sheaf on X with values in the ∞-category Sp of spectra. For each integer n, the construction $U \mapsto \pi_n(\mathscr{F}(U))$ determines a presheaf of abelian groups on X. We let $\pi_n \mathscr{F}$ denote the sheafification of this presheaf. If $\mathscr{O}_X$ is a sheaf of $\mathbb{E}_\infty$-rings on X, then $\pi_0 \mathscr{O}_X$ is a sheaf of commutative rings on X, and each $\pi_n \mathscr{O}_X$ can be regarded as a sheaf of $\pi_0 \mathscr{O}_X$-modules on X.

The construction $(X, \mathscr{O}_X) \mapsto (X, \pi_0 \mathscr{O}_X)$ determines a functor from the ∞-category $\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ of spectrally ringed spaces to the category of ringed spaces. We will refer to $(X, \pi_0 \mathscr{O}_X)$ as the *underlying ringed space* of $(X, \mathscr{O}_X)$.

Warning 1.1.2.7. Let $(X, \mathscr{O}_X)$ be a spectrally ringed space. For every integer n and every open set $U \subseteq X$, there is a canonical map of abelian groups

$$\pi_n(\mathscr{O}_X(U)) \to (\pi_n \mathscr{O}_X)(U),$$

which is generally *not* an isomorphism.

We are now ready to introduce our main objects of interest.

Definition 1.1.2.8. A *spectral scheme* is a spectrally ringed space $(X, \mathscr{O}_X)$ which satisfies the following conditions:

(1) The underlying ringed space $(X, \pi_0 \mathscr{O}_X)$ is a scheme.

(2) Each of the sheaves $\pi_n \mathscr{O}_X$ is quasi-coherent (when viewed as a sheaf of $\pi_0 \mathscr{O}_X$-modules on X).

(3) Let U be an open subset of X for which the scheme $(U, (\pi_0 \mathscr{O}_X)|_U)$ is affine. Then, for each integer n, the canonical map $\pi_n(\mathscr{O}_X(U)) \to (\pi_n \mathscr{O}_X)(U)$ is an isomorphism.

(4) The sheaves $\pi_n \mathscr{O}_X$ vanish when $n < 0$.

Variant 1.1.2.9. We will say that a spectrally ringed space $(X, \mathscr{O}_X)$ is a *nonconnective spectral scheme* if it satisfies conditions (1), (2), and (3) of Definition 1.1.2.8.

Remark 1.1.2.10. If $(X, \mathscr{O}_X)$ is a nonconnective spectral scheme, then the ringed space $(X, \pi_0 \mathscr{O}_X)$ is a scheme. We will refer to $(X, \pi_0 \mathscr{O}_X)$ as the *underlying scheme* of $(X, \mathscr{O}_X)$.

1.1.3 Digression: Hypercompleteness

We next show that condition (3) of Definition 1.1.2.8 admits an alternate formulation, and is automatically satisfied in many cases of interest (see Corollary 1.1.3.6).

Definition 1.1.3.1. Let $\mathscr{F}$ be a spectrum-valued sheaf on a topological space X. We will say that $\mathscr{F}$ is *hypercomplete* if the functor $U \mapsto \Omega^\infty \mathscr{F}(U)$ determines a hypercomplete object of the ∞-topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(X)$ (see §HTT.6.5.2).

Remark 1.1.3.2. Let X be a topological space. Then the collection of hypercomplete objects of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(X)$ is closed under small limits and under suspensions (see Proposition 1.3.3.3). Moreover, the condition that an object $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(X)$ be hypercomplete can be tested locally on X (Corollary 1.3.3.8).

Remark 1.1.3.3. Let $u : \mathscr{F} \to \mathscr{F}'$ be a morphism of hypercomplete spectrum-valued sheaves on a topological space X. Then u is an equivalence if and only if it induces an isomorphism $\pi_n \mathscr{F} \to \pi_n \mathscr{F}'$ (in the category of sheaves of abelian groups) for every integer n. The "only if" direction is obvious. To prove the converse, it suffices to show that the map $u_n : \Omega^\infty(\Sigma^n \mathscr{F}) \to \Omega^\infty(\Sigma^n \mathscr{F}')$ is an equivalence in the ∞-topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(X)$ for every integer n. This is clear, since u_n is a morphism between hypercomplete objects of $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(X)$ which induces an isomorphism on homotopy sheaves.

Proposition 1.1.3.4. *Let $(X, \mathscr{O}_X)$ be a spectrally ringed space satisfying the following conditions:*

(1) *The underlying ringed space* $(X, \pi_0 \mathscr{O}_X)$ *is a scheme.*

(2) *Each of the sheaves* $\pi_n \mathscr{O}_X$ *is quasi-coherent (when viewed as a sheaf of* $\pi_0 \mathscr{O}_X$*-modules on* X*).*

(3′) *The structure sheaf* $\mathscr{O}_X$ *is hypercomplete.*

Then $(X, \mathscr{O}_X)$ *is a nonconnective spectral scheme.*

Proof. For each integer n, let $\tau_{\leqslant n} \mathscr{O}_X$ denote the n-truncation of $\mathscr{O}_X$ with respect to the natural t-structure on the ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(X)$ (see Proposition 1.3.2.7). We then have fiber sequences

$$\Sigma^n(\pi_n \mathscr{O}_X) \to \tau_{\leqslant n} \mathscr{O}_X \to \tau_{\leqslant n-1} \mathscr{O}_X,$$

where we abuse notation by identifying the sheaf of abelian groups $\pi_n \mathscr{O}_X$ with the corresponding object in the heart of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(X)$. Passing to global sections and extracting homotopy groups, we obtain a long exact sequence

$$\mathrm{H}^{n-m}(U; (\pi_n \mathscr{O}_X)|_U) \to \pi_m(\tau_{\leqslant n} \mathscr{O}_X)(U) \to \pi_m(\tau_{\leqslant n-1} \mathscr{O}_X(U)) \to \mathrm{H}^{n-m+1}(U; (\pi_n \mathscr{O}_X)|_U)$$

for each open subset $U \subseteq X$. Assumption (2) implies that the cohomology groups $\mathrm{H}^i(U; (\pi_n \mathscr{O}_X)|_U)$ vanish whenever U is affine and $i > 0$. Moreover, for an open subset $U \subseteq X$, the spectra $(\tau_{\leqslant n} \mathscr{O}_X)(U)$ and $(\tau_{\leqslant n-1} \mathscr{O}_X)(U)$ are n-truncated and $(n-1)$-truncated, respectively. It follows that if U is affine, our long exact sequence degenerates to supply isomorphisms

$$\pi_m(\tau_{\leqslant n} \mathscr{O}_X)(U) \simeq \begin{cases} 0 & \text{if } m > n \\ (\pi_n \mathscr{O}_X)(U) & \text{if } m = n \\ (\tau_{\leqslant n-1} \mathscr{O}_X)(U) & \text{if } m < n. \end{cases}$$

Set $\mathscr{O}'_X = \varprojlim_n \tau_{\leqslant n} \mathscr{O}_X \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(X)$. We have an evident map $u : \mathscr{O}_X \to \mathscr{O}'_X$, and the above calculation shows that this map induces an equivalence $(\pi_n \mathscr{O}_X)(U) \to \pi_n(\mathscr{O}'_X(U))$ for every affine open subset $U \subseteq X$. In particular, u induces an isomorphism of sheaves $\pi_n \mathscr{O}_X \to \pi_n \mathscr{O}'_X$ for every integer n. The $\mathcal{S}$-valued sheaf $\Omega^\infty \mathscr{O}'_X$ is hypercomplete by construction, and the $\mathcal{S}$-valued sheaf $\Omega^\infty \mathscr{O}_X$ is hypercomplete by virtue of assumption (3′). It follows that the map u is an equivalence, so that $(\pi_n \mathscr{O}_X)(U) \simeq \pi_n(\mathscr{O}_X(U))$ for each affine open subset $U \subseteq X$. That is, $(X, \mathscr{O}_X)$ satisfies condition (3) of Definition 1.1.2.8, and is therefore a nonconnective spectral scheme. □

Remark 1.1.3.5. The converse of Proposition 1.1.3.4 is also true: if $(X, \mathscr{O}_X)$ is a nonconnective spectral scheme, then the structure sheaf $\mathscr{O}_X$ is hypercomplete (see Corollary 1.1.6.2).

Corollary 1.1.3.6. *Let $(X, \mathscr{O}_X)$ be a spectrally ringed space, and suppose that X is a Noetherian topological space of finite Krull dimension. Then $(X, \mathscr{O}_X)$ is a nonconnective spectral scheme if and only if $(X, \pi_0 \mathscr{O}_X)$ is a scheme and each homotopy group $\pi_n \mathscr{O}_X$ is a quasi-coherent sheaf on $(X, \pi_0 \mathscr{O}_X)$.*

Proof. If X is a Noetherian topological space of finite Krull dimension, then the ∞-topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(X)$ has finite homotopy dimension, so that every object of $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(X)$ is hypercomplete (see §HTT.7.2.4 ; we will prove a generalization of this statement in §3.7). The desired result now follows from Proposition 1.1.3.4. □

Remark 1.1.3.7. Let $(X, \mathscr{O}_X)$ be a spectrally ringed ∞-topos which satisfies conditions (1) and (2) of Definition 1.1.2.8. Then we can obtain a nonconnective spectral scheme by replacing the sheaf $\mathscr{O}_X$ with its hypercompletion. This replacement does not change the underlying scheme $(X, \pi_0 \mathscr{O}_X)$ or any of the quasi-coherent sheaves $\pi_n \mathscr{O}_X$.

1.1.4 The Spectrum of an $\mathbb{E}_\infty$-Ring

Our next goal is to produce some examples of spectral schemes.

Definition 1.1.4.1. Let A be an $\mathbb{E}_\infty$-ring. We let $|\operatorname{Spec} A|$ denote the Zariski spectrum of the underlying commutative ring $R = \pi_0 A$. We will say that an open subset $U \subseteq |\operatorname{Spec} A|$ is *affine* if it is affine when regarded as an open subset of the affine scheme $\operatorname{Spec} R$.

Let A be an $\mathbb{E}_\infty$-ring. We wish to construct a CAlg-valued sheaf on the topological space $|\operatorname{Spec} A|$, analogous to the structure sheaf on the spectrum of an ordinary commutative ring. First, we review the theory of localizations in the setting of $\mathbb{E}_\infty$-rings.

Remark 1.1.4.2. Let $f : A \to B$ be a map of $\mathbb{E}_\infty$-rings, and let $a \in \pi_0 A$. We will say that *f exhibits B as a localization of A by $a \in \pi_0 A$* if the map f is étale and f induces an isomorphism of commutative rings $(\pi_0 A)[a^{-1}] \simeq \pi_0 B$. In this case, we will denote B by $A[a^{-1}]$. Theorem HA.7.5.0.6 guarantees that $A[a^{-1}]$ exists and is well-defined up to equivalence (in fact, up to a contractible space of choices). The localization map $A \to A[a^{-1}]$ can be characterized by either of the following conditions (see Corollary HA.7.5.4.6):

(1) The map $A \to A[a^{-1}]$ induces an isomorphism of graded rings $(\pi_* A)[a^{-1}] \to \pi_* A[a^{-1}]$.

(2) For every $\mathbb{E}_\infty$-ring B, the induced map $\operatorname{Map}_{\mathrm{CAlg}}(A[a^{-1}], B) \to \operatorname{Map}_{\mathrm{CAlg}}(A, B)$ restricts to a homotopy equivalence of $\operatorname{Map}_{\mathrm{CAlg}}(A[a^{-1}], B)$ with the summand of $\operatorname{Map}_{\mathrm{CAlg}}(A, B)$ spanned by those maps $A \to B$ which carry $a \in \pi_0 A$ to an invertible element of $\pi_0 B$.

Proposition 1.1.4.3. *Let A be an $\mathbb{E}_\infty$-ring and let $R = \pi_0 A$ be its underlying commutative ring. Then there exists a* CAlg*-valued sheaf $\mathscr{O}$ on the topological space $|\operatorname{Spec} A|$ and a morphism $\phi : A \to \mathscr{O}(|\operatorname{Spec} A|)$ of $\mathbb{E}_\infty$-rings which satisfies the following conditions:*

(a) *For every element $x \in R$ defining an elementary open subset $U_x = \{\mathfrak{p} \in |\operatorname{Spec} A| : x \notin \mathfrak{p}\}$, the composite map $A \xrightarrow{\phi} \mathscr{O}(|\operatorname{Spec} A|) \to \mathscr{O}(U_x)$ induces an equivalence of $\mathbb{E}_\infty$-rings $A[x^{-1}] \simeq \mathscr{O}(U_x)$.*

(b) *The canonical map*

$$R = \pi_0 A \xrightarrow{\alpha} \pi_0(\mathscr{O}(|\operatorname{Spec} A|)) \to (\pi_0 \mathscr{O})(|\operatorname{Spec} A|)$$

induces an isomorphism of $\pi_0 \mathscr{O}$ with the structure sheaf of the affine scheme $\operatorname{Spec} R$*.*

(c) *The pair $(|\operatorname{Spec} A|, \mathscr{O})$ is a nonconnective spectral scheme. If A is connective, then $(|\operatorname{Spec} A|, \mathscr{O})$ is a spectral scheme.*

We will deduce the existence of the sheaf $\mathscr{O}$ from the following general principle:

Proposition 1.1.4.4. *Let X be a topological space, let $\mathcal{C}$ be an ∞-category which admits small limits, and let $\mathcal{U}_e$ denote a collection of open subsets of X satisfying the following conditions:*

(i) *The sets belonging to $\mathcal{U}_e$ form a basis for the topology of X. That is, for every point $x \in X$ and every open set U containing x, there exists an open set $V \in \mathcal{U}_e$ such that $x \in V \subseteq U$.*

(ii) *For every pair of open sets $U, V \in \mathcal{U}_e$, the intersection $U \cap V$ belongs to $\mathcal{U}_e$.*

(iii) *Each of the open sets $U \in \mathcal{U}_e$ is quasi-compact.*

Then a functor $\mathscr{F} : \mathcal{U}(X)^{\mathrm{op}} \to \mathcal{C}$ is a $\mathcal{C}$-valued sheaf on X if and only if the following conditions are satisfied:

(1) *The functor $\mathscr{F}$ is a right Kan extension of $\mathscr{F}|_{\mathcal{U}_e^{\mathrm{op}}}$.*

(2) *Let $U_1, U_2, \ldots, U_n \in \mathcal{U}_e$ be a finite collection of open sets whose union $U = \bigcup U_i$ also belongs to $\mathcal{U}_e$. For each $S \subseteq \{1, \ldots, n\}$, let $U_S = \bigcap_{i \in S} U_i$. Then $\mathscr{F}$ induces an equivalence $\mathscr{F}(U) \to \varprojlim_{\emptyset \neq S} \mathscr{F}(U_S)$, where the limit is taken over the partially ordered set of all nonempty subsets $S \subseteq \{1, \ldots, n\}$.*

Corollary 1.1.4.5. *Under the hypotheses of Proposition 1.1.4.4, the restriction map*

$$\mathcal{S}\mathrm{hv}_{\mathcal{C}}(X) \to \operatorname{Fun}(\mathcal{U}_e^{\mathrm{op}}, \mathcal{C})$$

is a fully faithful embedding, whose essential image is the collection of those functors $\mathcal{U}_e^{\mathrm{op}} \to \mathcal{C}$ which satisfy condition (2) of Proposition 1.1.4.4.

Proof. Combine Propositions 1.1.4.4 and HTT.4.3.2.15. □

Before proving Proposition 1.1.4.4, let us describe some of its applications.

Example 1.1.4.6. Let X be a topological space and let $\mathcal{U}_e$ be a collection of open subsets of X satisfying conditions (i), (ii), and (iii) of Proposition 1.1.4.4. Applying Proposition 1.1.4.4 in the special case $\mathcal{C} = \mathcal{S}$, we obtain an equivalence of ∞-topoi $\mathcal{S}\mathrm{hv}(X) \simeq \mathcal{S}\mathrm{hv}(\mathcal{U}_e)$, where we regard $\mathcal{U}_e$ as equipped with the Grothendieck topology given by those sieves $\{U_\alpha \subseteq U\}$ for which $U = \bigcup U_\alpha$.

Example 1.1.4.7. Let R be a commutative ring, let $X = |\operatorname{Spec} R|$, let $\mathcal{U}_e$ denote the collection of all elementary open subsets of X, and let $\mathcal{C}$ be the category of commutative rings. Using Corollary 1.1.4.5, we see that the structure sheaf $\mathscr{O}$ of the affine scheme $\operatorname{Spec} R$ is essentially unique, and its existence reduces to the following basic assertion of commutative algebra: if $x_1, \ldots, x_n$ is a collection of elements of R which generate the unit ideal in R, then we have an equalizer diagram

$$R \longrightarrow \prod_{1 \leqslant i \leqslant n} R[x_i^{-1}] \rightrightarrows \prod_{1 \leqslant i < j \leqslant n} R[x_i^{-1}, x_j^{-1}]$$

in the category of commutative rings.

Proof of Proposition 1.1.4.3. Let $X = |\operatorname{Spec} A|$, let $\mathcal{U}_e$ denote the collection of open affine subsets of X, and let $\overline{\mathscr{O}}$ denote the structure sheaf of the affine scheme $\operatorname{Spec} R$. For every affine open subset $U \subseteq X$, the commutative ring $\overline{\mathscr{O}}(U)$ is étale as an R-algebra. Let $\overline{\mathscr{O}}_e$ denote the restriction of the sheaf $\overline{\mathscr{O}}$ to the partially ordered set $\mathcal{U}_e$, so that we can regard $\overline{\mathscr{O}}_e$ as a functor from $\mathcal{U}_e^{\mathrm{op}}$ to the category of étale R-algebras. Applying Theorem HA.7.5.0.6 , we see that there is an essentially unique functor $\mathscr{O}_e : \mathcal{U}_e^{\mathrm{op}} \to \mathrm{CAlg}_A$ such that $\overline{\mathscr{O}}_e(U) = \pi_0 \mathscr{O}_e(U)$, and each of the A-algebras $\mathscr{O}_e(U)$ is flat over A.

Let $\mathscr{O} : \mathcal{U}(X)^{\mathrm{op}} \to \mathrm{CAlg}$ be a right Kan extension of the functor $\mathscr{O}_e$. We claim that $\mathscr{O}$ is a CAlg-valued sheaf on X. To prove this, it will suffice to show that the functor $\mathscr{O}$ satisfies condition (2) of Proposition 1.1.4.4. Let $U_1, \ldots, U_n$ be a collection of open affine subsets of X whose union $U = \bigcup_{1 \leqslant i \leqslant n} U_i$ is also open. For each $S \subseteq \{1, \ldots, n\}$, let U_S denote the intersection $\bigcap_{i \in S} U_i$. We wish to show that the canonical map

$$\mu : \mathscr{O}(U) \to \varprojlim_{S \neq \varnothing} \mathscr{O}(U_S)$$

is an equivalence.

Since the open sets U_i form an affine open covering of U, the map $\overline{\mathscr{O}}(U) \to \prod_{1 \leqslant i \leqslant n} \overline{\mathscr{O}}(U_i)$ is faithfully flat. It follows that $\prod_{1 \leqslant i \leqslant n} \mathscr{O}(U_i)$ is faithfully flat over $\mathscr{O}(U)$. Consequently, to prove that μ is an equivalence, it will suffice to show that μ induces an equivalence

$$\mu_i : \mathscr{O}(U_i) \to \mathscr{O}(U_i) \otimes_{\mathscr{O}(U)} \varprojlim_{S \neq \varnothing} \mathscr{O}(U_S),$$

for $1 \leqslant i \leqslant n$. The operation $M \mapsto \mathscr{O}(U_i) \otimes_{\mathscr{O}(U)} M$ is an exact functor between stable ∞-categories, and therefore preserves finite limits. Consequently, we may identify μ_i with the canonical map

$$\mathscr{O}(U_i) \to \varprojlim_{S \neq \varnothing} (\mathscr{O}(U_i) \otimes_{\mathscr{O}(U)} \mathscr{O}(U_S)) \simeq \varprojlim_{S \neq \varnothing} \mathscr{O}(U_{S \cup \{i\}}).$$

Note that the functor $S \mapsto \mathscr{O}(U_{S \cup \{i\}})$ is a right Kan extension of its restriction to the partially ordered set $P = \{S \subseteq \{1, \ldots, n\} : i \in S\}$, so that μ_i is equivalent to the map $\mathscr{O}(U_i) \to \varprojlim_{S \in P} \mathscr{O}(U_S)$. This map is an equivalence, since the partially ordered set P contains $\{i\}$ as a least element. This completes the proof of (a).

By construction, the functor $U \mapsto \pi_0(\mathscr{O}(U))$ determines a presheaf of commutative rings on $|\operatorname{Spec} A|$ which agrees with $\overline{\mathscr{O}}$ on every affine open subset of $|\operatorname{Spec} A|$. Since the affine open subsets of $|\operatorname{Spec} A|$ form a basis for the topology of $|\operatorname{Spec} A|$, we obtain an isomorphism $\overline{\mathscr{O}} \simeq \pi_0 \mathscr{O}$ of sheaves of commutative rings on $|\operatorname{Spec} A|$. This proves (b).

We now prove (c). Let m be an integer, and let $M = \pi_m A$. Then we can regard M as a (discrete) R-module. Let $\mathscr{F}$ be the associated quasi-coherent sheaf on the affine scheme $\operatorname{Spec} R$, so that $\mathscr{F}(U) \simeq \overline{\mathscr{O}}(U) \otimes_R M$ for every affine open subset $U \subseteq |\operatorname{Spec} A|$. Since $\mathscr{O}(U)$ is flat over A, we obtain isomorphisms

$$\mathscr{F}(M) \simeq \overline{\mathscr{O}}(U) \otimes_R M \simeq \pi_0 \mathscr{O}(U) \otimes_{\pi_0 A} \pi_m A \simeq \pi_m \mathscr{O}(U),$$

depending functorially on $U \in \mathcal{U}_e$. Since $\mathcal{U}_e$ forms a basis for the topology of $|\operatorname{Spec} A|$, it follows that the sheaf $\pi_m \mathscr{O}$ is isomorphic to $\mathscr{F}$ (as a sheaf of $\overline{\mathscr{O}}$-modules), and is therefore quasi-coherent. Condition (3) of Definition 1.1.2.8 follows immediately from our construction, so that $(|\operatorname{Spec} A|, \mathscr{O})$ is a nonconnective spectral scheme. If A is connective, then the above calculation gives $\pi_m \mathscr{O} \simeq \mathscr{F} \simeq 0$ for $m < 0$, so that $(|\operatorname{Spec} A|, \mathscr{O})$ is a spectral scheme. □

Definition 1.1.4.8. Let A be an $\mathbb{E}_\infty$-ring, and let $\mathscr{O}$ be the sheaf of $\mathbb{E}_\infty$-rings on $|\operatorname{Spec} A|$ constructed in the proof of Proposition 1.1.4.3. We will refer to $\mathscr{O}$ as the *structure sheaf* of $|\operatorname{Spec} A|$. The pair $(|\operatorname{Spec} A|, \mathscr{O})$ is a spectrally ringed space, which we will denote by $\operatorname{Spec} A$ and refer to as the *spectrum* of A. We will say that a nonconnective spectral scheme $(X, \mathscr{O}_X)$ is *affine* if it is equivalent to $\operatorname{Spec} A$ for some $\mathbb{E}_\infty$-ring A.

Warning 1.1.4.9. Let R be a commutative ring. Then we can regard R as a discrete $\mathbb{E}_\infty$-ring. In this case, the notation introduced in Definition 1.1.4.8 is potentially ambiguous: we write $\operatorname{Spec} R$ to denote both the affine scheme $(|\operatorname{Spec} R|, \mathscr{O}_0)$ of Example 1.1.1.2 and the spectral scheme $(|\operatorname{Spec} R|, \mathscr{O})$ of Proposition 1.1.4.3. These two objects are not quite the same: $\mathscr{O}_0$ is a sheaf of commutative rings on $X = |\operatorname{Spec} R|$, while $\mathscr{O}$ is a sheaf of $\mathbb{E}_\infty$-rings on X. However, they are interchangeable data: the sheaf of commutative rings $\mathscr{O}_0$ isomorphic to $\pi_0 \mathscr{O}$, and the sheaf of $\mathbb{E}_\infty$-rings $\mathscr{O}$ can be recovered as the sheafification of $\mathscr{O}_0$ (regarded as a presheaf of $\mathbb{E}_\infty$-rings on X). Moreover, we have an equivalence $\mathscr{O}_0(U) \simeq \mathscr{O}(U)$ whenever U is an affine subset of X, which extends to an isomorphism $\mathscr{O}_0(U) \simeq \pi_0 \mathscr{O}(U)$ for every open subset $U \subseteq X$. However, the $\mathbb{E}_\infty$-rings $\mathscr{O}(U)$ are generally not discrete: we have canonical isomorphisms

$$\pi_{-n} \mathscr{O}(U) \simeq \mathrm{H}^n(U; \mathscr{O}_0|_U).$$

Proof of Proposition 1.1.4.4. Suppose first that $\mathscr{F}$ is a $\mathcal{C}$-valued sheaf on X. Let $\{U_\alpha\}_{\alpha \in A}$ be any collection of open subsets of X, and set $U = \bigcup_\alpha U_\alpha$, and let $\mathcal{U}'$ denote the subset of $\mathcal{U}(X)$ given by those open sets V which are contained in U_α for some $\alpha \in A$. Let $P(A)$ denote the partially ordered set of all nonempty finite subsets of A. For each $S \in P(A)$, we set $U_S = \bigcap_{\alpha \in S} U_\alpha$. The construction $S \mapsto U_S$ determines a right cofinal map $P(A) \to \mathcal{U}'^{\mathrm{op}}$. Invoking our hypothesis that $\mathscr{F}$ is a sheaf, we deduce that the canonical maps

$$\mathscr{F}(U) \to \varprojlim_{V \in \mathcal{U}'} \mathscr{F}(V) \to \varprojlim_{S \in P(A)} \mathscr{F}(U_S)$$

are equivalences in the ∞-category $\mathcal{C}$. This immediately implies condition (2).

To verify condition (1), we must show that for any open subset $U \subseteq X$, the canonical map

$$\mathscr{F}(U) \to \varprojlim_{V \in \mathcal{U}_e \cap \mathcal{U}(U)} \mathscr{F}(V)$$

is an equivalence. Since $\mathcal{U}_e$ forms a basis for the topology of X, we can write $U = \bigcup_{\gamma \in A} U_\gamma$ where each γ belongs to $\mathcal{U}_e$. Let $\mathcal{U}'$ be defined as above, so that we have a commutative diagram

$$\begin{array}{ccc} \mathscr{F}(U) & \longrightarrow & \varprojlim_{V \in \mathcal{U}_e \cap \mathcal{U}(U)} \mathscr{F}(V) \\ \downarrow & & \downarrow \\ \varprojlim_{V \in \mathcal{U}'} \mathscr{F}(V) & \longrightarrow & \varprojlim_{V \in \mathcal{U}_e \cap \mathcal{U}'} \mathscr{F}(V). \end{array}$$

The left vertical map is an equivalence by virtue of our assumption that $\mathscr{F}$ is a $\mathcal{C}$-valued sheaf. Similarly, the assumption that $\mathscr{F}$ is a sheaf implies that the functor $\mathscr{F}|_{(\mathcal{U}_e \cap \mathcal{U}(U))^{\mathrm{op}}}$ is a right Kan extension of $\mathscr{F}|_{(\mathcal{U}_e \cap \mathcal{U}')^{\mathrm{op}}}$, which shows that the right vertical map is also an equivalence. We are therefore reduced to proving that the bottom horizontal map an equivalence. For this, it suffices to show that the inclusion of simplicial sets $\mathcal{U}_e \cap \mathcal{U}' \hookrightarrow \mathcal{U}'$ is left cofinal. This is equivalent to the assertion that for each $V \in \mathcal{U}'$, the partially ordered set $T = \{W \in \mathcal{U}_e \cap \mathcal{U}' : V \subseteq W\}$ has weakly contractible nerve. This is clear, since T is nonempty and closed under finite intersections.

Now suppose that $\mathscr{F}$ satisfies conditions (1) and (2); we will show that $\mathscr{F}$ is a $\mathcal{C}$-valued sheaf on X. Fix an open set $U \subseteq X$ and an open covering $\{U_\gamma\}_{\gamma \in A}$ of U. Let $\mathcal{U}'$ be as above; we wish to show that the canonical map $\mathscr{F}(U) \to \varprojlim_{V \in \mathcal{U}'} \mathscr{F}(V)$ is an equivalence in $\mathcal{C}$.

Since $\mathscr{F}$ satisfies condition (1), the functor $\mathscr{F}|_{\mathcal{U}'^{\mathrm{op}}}$ is a right Kan extension of $\mathscr{F}|_{(\mathcal{U}_e \cap \mathcal{U}')^{\mathrm{op}}}$. It will therefore suffice to show that the composite map

$$\mathscr{F}(U) \to \varprojlim_{V \in \mathcal{U}'} \mathscr{F}(V) \to \varprojlim_{V \in \mathcal{U}_e \cap \mathcal{U}'} \mathscr{F}(V)$$

is an equivalence. Since assumption (1) supplies an equivalence $\mathscr{F}(U) \simeq \varprojlim_{V \in \mathcal{U}_e \cap \mathcal{U}(U)} \mathscr{F}(V)$, it will suffice to show that $\mathscr{F}|_{(\mathcal{U}_e \cap \mathcal{U}(U))^{\mathrm{op}}}$ is a right Kan extension of $\mathscr{F}|_{(\mathcal{U}_e \cap \mathcal{U}')}{}^{\mathrm{op}}$. For this, let us fix an open set $V \in \mathcal{U}_e$ with $V \subseteq U$; we wish to show that the map

$$\theta : \mathscr{F}(V) \to \varprojlim_{W \in \mathcal{U}_e \cap \mathcal{U}', W \subseteq V} \mathscr{F}(W)$$

is an equivalence.

It follows from assumption (iii) that V is quasi-compact, so we can write V as a finite union $V_1 \cup \cdots \cup V_n$ where each V_i belongs to $\mathcal{U}' \cap \mathcal{U}_e$. Let $\mathcal{U}''$ denote the collection of all open subsets of X which belong to $\mathcal{U}_e$ and are contained in one of the open sets V_i. We will prove:

$(*)$ The functor $\mathscr{O}|_{(\mathcal{U}_e \cap \mathcal{U}(V))^{\mathrm{op}}}$ is a right Kan extension of $\mathscr{O}|_{\mathcal{U}''^{\mathrm{op}}}$.

Assuming $(*)$, the map θ fits into a commutative diagram

$$\begin{array}{ccc} \mathscr{O}(V) & \xrightarrow{\theta} & \varprojlim_{W \in \mathcal{U}_e \cap \mathcal{U}', W \subseteq V} \mathscr{O}(W) \\ & \searrow \quad \swarrow & \\ & \varprojlim_{V \in \mathcal{U}''} \mathscr{O}(V) & \end{array}$$

where the vertical maps are equivalences, so that θ is an equivalence. To prove $(*)$, we must show that for every open set $W \in \mathcal{U}_e$ with $W \subseteq V$, the canonical map

$$\phi : \mathscr{F}(W) \to \varprojlim_{W' \subseteq W, W' \in \mathcal{U}''} \mathscr{F}(W')$$

is an equivalence. Let Q denote the partially ordered set of all nonempty subsets of $\{1, \ldots, n\}$. For each subset $S \subseteq \{1, \ldots, n\}$, let W_S denote the intersection $W \cap \bigcap_{i \in S} V_i$. Since the construction $S \mapsto W_S$ induces a right cofinal functor $S \to \mathcal{U}(W) \cap \mathcal{U}''$, we can identify ϕ with the map

$$\mathscr{F}(W) \to \varprojlim_{\varnothing \neq S} \mathscr{F}(W_S),$$

which is an equivalence by virtue of assumption (2). $\square$

1.1.5 The Universal Property of Spec A

If R is a commutative ring, then the affine scheme $\operatorname{Spec} R$ can be characterized by a universal mapping property. To formulate it, we need to work in the setting of *locally* ringed spaces.

Definition 1.1.5.1. Let X be a topological space and let $\mathscr{O}_X$ be a sheaf of commutative rings on X. We say that $\mathscr{O}_X$ is *local* if, for every point $x \in X$, the stalk $\pi_0 \mathscr{O}_{X,x}$ is a local ring (we will give a quick review of the theory of local rings in §1.4). We say that a ringed space $(X, \mathscr{O}_X)$ is *locally ringed* if $\mathscr{O}_X$ is local.

The collection of locally ringed spaces can be organized into a category $\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}^\heartsuit}$, where a map of locally ringed spaces $(X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ is given by a continuous map $\pi : X \to Y$ together with a map of sheaves $\mathscr{O}_Y \to \pi_* \mathscr{O}_X$ satisfying the following locality condition: for every point $x \in X$, the induced ring homomorphism $\mathscr{O}_{Y,f(x)} \to \mathscr{O}_{X,x}$ is local (that is, it carries noninvertible elements of $\mathscr{O}_{Y,f(x)}$ to noninvertible elements of $\mathscr{O}_{X,x}$).

Example 1.1.5.2. Every scheme $(X, \mathscr{O}_X)$ is a locally ringed space. To prove this, we may work locally on X and thereby reduce to the case where $(X, \mathscr{O}_X) = \operatorname{Spec} R$ for some commutative ring R. In this case, the stalk of the structure sheaf $\mathscr{O}_X$ at a point $\mathfrak{p} \in |\operatorname{Spec} R|$ can be identified with the local ring $R_{\mathfrak{p}}$.

Definition 1.1.5.1 has an obvious generalization to the setting of CAlg-valued sheaves:

Definition 1.1.5.3. Let $(X, \mathscr{O}_X)$ be a spectrally ringed space. We will say that $(X, \mathscr{O}_X)$ is a *locally spectrally ringed space* if the underlying ringed space $(X, \pi_0 \mathscr{O}_X)$ is locally ringed. We let $\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ denote the subcategory of $\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ whose objects are locally spectrally ringed spaces $(X, \mathscr{O}_X)$, and whose morphisms are maps $(X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ for which the underlying map $(X, \pi_0 \mathscr{O}_X) \to (Y, \pi_0 \mathscr{O}_Y)$ is morphism in the category of locally ringed spaces.

Every spectral scheme $(X, \mathscr{O}_X)$ is a locally spectrally ringed space. This allows us to organize the collection of spectral schemes into an ∞-category:

Definition 1.1.5.4. Let $(X, \mathscr{O}_X)$ and $(Y, \mathscr{O}_Y)$ be nonconnective spectral schemes. A *morphism of nonconnective spectral schemes* from $(X, \mathscr{O}_X)$ to $(Y, \mathscr{O}_Y)$ is a map $(X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ in the category $\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ of locally spectrally ringed spaces. In other words, a morphism from $(X, \mathscr{O}_X)$ to $(Y, \mathscr{O}_Y)$ consists of a pair (f, α), where $f : X \to Y$ is a continuous map of topological spaces and $\alpha : \mathscr{O}_Y \to f_* \mathscr{O}_X$ is a morphism in $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(Y)$ which induces a local homomorphism of commutative rings $(\pi_0 \mathscr{O}_Y)_{f(x)} \to (\pi_0 \mathscr{O}_X)_x$ for each $x \in X$.

Let $\mathrm{SpSch}^{\mathrm{nc}}$ denote the subcategory of $\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ whose objects are nonconnective spectral schemes and whose morphisms are morphisms of nonconnective spectral schemes. Let

SpSch denote the full subcategory of $\mathrm{SpSch}^{\mathrm{nc}}$ spanned by the spectral schemes. We will refer to SpSch as the *∞-category of spectral schemes*, and to $\mathrm{SpSch}^{\mathrm{nc}}$ as the *∞-category of nonconnective spectral schemes*.

If $(X, \mathscr{O}_X)$ is a locally ringed space and R is a commutative ring, then there is a canonical bijection

$$\mathrm{Hom}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}^{\heartsuit}}}((X, \mathscr{O}_X), \operatorname{Spec} R) \simeq \mathrm{Hom}_{\mathrm{CAlg}^{\heartsuit}}(R, \mathscr{O}_X(X)).$$

In the setting of spectral algebraic geometry, we have an analogous statement:

Proposition 1.1.5.5. *Let $(X, \mathscr{O}_X)$ be a locally spectrally ringed space, let A be an $\mathbb{E}_\infty$-ring, and write $\operatorname{Spec}(A) = (|\operatorname{Spec} A|, \mathscr{O})$. Then composition with the canonical map $\phi : A \to \mathscr{O}(|\operatorname{Spec} A|)$ induces a homotopy equivalence*

$$\mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}((X, \mathscr{O}_X), \operatorname{Spec} A) \to \mathrm{Map}_{\mathrm{CAlg}}(A, \mathscr{O}_X(X)).$$

Proof. Let $\phi : A \to \mathscr{O}_X(X)$ be a morphism of $\mathbb{E}_\infty$-rings; we wish to show that the homotopy fiber

$$Z = \mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}((X, \mathscr{O}_X), \operatorname{Spec} A) \times_{\mathrm{Map}_{\mathrm{CAlg}}(A, \mathscr{O}_X(X))} \{\phi\}$$

is contractible. Let R denote the commutative ring $\pi_0 R$. For each point $x \in X$, let $\kappa(x)$ denote the residue field of the local ring $(\pi_0 \mathscr{O}_X)_x$, so that ϕ determines a ring homomorphism $R \to \kappa(x)$ whose kernel is a prime ideal $\mathfrak{p}_x \subseteq R$. Let $f : X \to |\operatorname{Spec} A|$ be the map given by $f(x) = \mathfrak{p}_x$. We first claim that f is continuous. To prove this, it will suffice to show that for every element $r \in R$, the set $U = \{x \in X : r \notin \mathfrak{p}_x\}$ is an open subset of X. Suppose that $x \in U$, so that ϕ carries r to an invertible element of the local ring $(\pi_0 \mathscr{O}_X)_x$. Let $s \in (\pi_0 \mathscr{O}_X)_x$ denote the multiplicative inverse of this element. Then there exists an open set $V \subseteq X$ containing x and an element $\overline{s} \in \pi_0(\mathscr{O}_X(V))$ lifting s. Shrinking V if necessary, we may suppose that $\overline{s}$ is a multiplicative inverse of the image of r under the composite map $R \xrightarrow{\phi} \pi_0 \mathscr{O}_X(X) \to \pi_0 \mathscr{O}_X(V)$. This implies that $V \subseteq U$, so that U contains an open neighborhood of x.

Suppose we are given a map of spectrally ringed spaces from $(X, \mathscr{O}_X)$ to $\operatorname{Spec} A$, given by a map of topological spaces $g : X \to |\operatorname{Spec} A|$ and a morphism $\gamma : \mathscr{O} \to g_* \mathscr{O}_X$. For each $x \in X$, the composite map $R \to \pi_0 \mathscr{O}_X(X) \to (\pi_0 \mathscr{O}_X)_x \to \kappa(x)$ factors through $R_{g(x)}$, so that $f(x) \subseteq g(x)$ (as prime ideals of the commutative ring R). Moreover, (g, γ) is a morphism of locally spectrally ringed spaces if and only if equality holds for each $x \in X$. We may therefore identify Z with the homotopy fiber of the map $\mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(|\operatorname{Spec} A|)}(\mathscr{O}, g_* \mathscr{O}_X) \to \mathrm{Map}_{\mathrm{CAlg}}(A, \mathscr{O}_X(X))$ over the point ϕ.

Let $\mathcal{U}_e$ denote the collection of all elementary open subsets of $|\operatorname{Spec} A|$ and define $\mathcal{C} = \mathrm{Fun}(\mathcal{U}_e^{\mathrm{op}}, \mathrm{CAlg})$. It follows from Corollary 1.1.4.5 that the restriction functor $T : \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(|\operatorname{Spec} A|) \to \mathcal{C}$ is a fully faithful embedding. We may therefore identify Z with the homotopy fiber of the map $\mathrm{Map}_{\mathcal{C}}(T\mathscr{O}, Tg_* \mathscr{O}_X) \to \mathrm{Map}_{\mathrm{CAlg}}(A, \mathscr{O}_X(X))$ over the point ϕ. Let $\mathrm{CAlg}_R^{\heartsuit}$ denote the category of commutative R-algebras. Since $\mathscr{O}(U)$ is a localization of A for each $U \in \mathcal{U}_e$, we can use Theorem HA.7.5.4.2 to identify Z with the set of maps

$$\mathrm{Hom}_{\mathrm{Fun}(\mathcal{U}_e^{\mathrm{op}}, \mathrm{CAlg}_R^{\heartsuit})}(\pi_0 T\mathscr{O}, \pi_0 Tg_* \mathscr{O}_X).$$

For each element $r \in R$, let U_r denote the elementary open subset $\{\mathfrak{p} \in |\operatorname{Spec} A| : r \notin \mathfrak{p}\} \subseteq |\operatorname{Spec} A|$, so that $\pi_0 \mathscr{O}(U_r) \simeq R[r^{-1}]$. Consequently, to prove that Z is contractible, it will suffice to show that for each $r \in R$, the image of r is invertible in the commutative ring $\pi_0(g_* \mathscr{O}_X)(U_r)$.

Let $\phi(r)$ denote the image of r under the map $R \to \pi_0 \mathscr{O}_X(X)$, so that multiplication by r induces a map m_r from $\mathscr{O}_X$ to itself (as a Sp-valued sheaf on X). Let $U = g^{-1} U_r$. For each point $x \in U$, the image of r in the local ring $(\pi_0 \mathscr{O}_X)_x$ is invertible. We may therefore choose an open set $V \subseteq X$ containing x such that the image of r in $\pi_0 \mathscr{O}_X(V)$ is invertible, so that m_r induces an equivalence from $\mathscr{O}_X|_V$ to itself. It follows that $\mathrm{fib}(m_r)$ vanishes on U, so that multiplication by r induces an isomorphism from $\pi_0 \mathscr{O}_X(U)$ to itself. It follows that the image of r in $\pi_0(g_* \mathscr{O}_X)(U_r)$ is invertible, as desired. □

Remark 1.1.5.6. The global sections functor $(X, \mathscr{O}_X) \mapsto \mathscr{O}_X(X)$ determines a forgetful functor $\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}^{\mathrm{loc}} \to \mathrm{CAlg}^{\mathrm{op}}$. It follows from Proposition 1.1.5.5 that this functor admits a right adjoint, given on objects by $A \mapsto \operatorname{Spec} A$. In particular, the spectrally ringed space $\operatorname{Spec} A$ depends functorially on A.

Remark 1.1.5.7. Let A and B be $\mathbb{E}_\infty$-rings. Using the universal property of $\operatorname{Spec} B$, we obtain a homotopy equivalence $\mathrm{Map}_{\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}^{\mathrm{loc}}}(\operatorname{Spec} A, \operatorname{Spec} B) \simeq \mathrm{Map}_{\mathrm{CAlg}}(B, \mathscr{O}(|\operatorname{Spec} A|))$, where $\mathscr{O}$ denotes the structure sheaf of $\operatorname{Spec} A$. Under this homotopy equivalence, the canonical map $\mathrm{Map}_{\mathrm{CAlg}}(B, A) \to \mathrm{Map}_{\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}^{\mathrm{loc}}}(\operatorname{Spec} A, \operatorname{Spec} B)$ is given by composition with the equivalence $\alpha : A \to \mathscr{O}(|\operatorname{Spec} A|)$ appearing in Proposition 1.1.4.3. It follows that the functor $\operatorname{Spec} : \mathrm{CAlg}^{\mathrm{op}} \to \mathrm{SpSch}^{\mathrm{nc}}$ is fully faithful.

1.1.6 Characterization of Affine Spectral Schemes

Let $(X, \mathscr{O}_X)$ be a locally spectrally ringed space. Proposition 1.1.5.5 asserts that every map of $\mathbb{E}_\infty$-rings $\alpha : A \to \mathscr{O}_X(X)$ induces a map $f : (X, \mathscr{O}_X) \to \operatorname{Spec} A$ in the ∞-category $\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}^{\mathrm{loc}}$. Our next result gives a criterion for this map to be an equivalence:

Proposition 1.1.6.1. *Let $(X, \mathscr{O}_X)$ be a locally spectrally ringed space, let A be an $\mathbb{E}_\infty$-ring, and let $f : (X, \mathscr{O}_X) \to \operatorname{Spec} A$ be a morphism of locally spectrally ringed spaces. Assume that:*

(a) The map f induces an equivalence of $\mathbb{E}_\infty$-rings $\alpha : A \to \mathscr{O}_X(X)$.

(b) *The underlying ringed space* $(X, \pi_0 \mathscr{O}_X)$ *is an affine scheme.*

(c) *For each integer* n*, the sheaf* $\pi_n \mathscr{O}_X$ *is quasi-coherent.*

Then the following conditions are equivalent:

(1) *The map* f *is an equivalence.*

(2) *The sheaf* $\mathscr{O}_X$ *is hypercomplete.*

(3) *The spectrally ringed space* $(X, \mathscr{O}_X)$ *is a nonconnective spectral scheme.*

Corollary 1.1.6.2. *Let* $(X, \mathscr{O}_X)$ *be a spectrally ringed space. Suppose that the ringed space* $(X, \pi_0 \mathscr{O}_X)$ *is a scheme, and that* $\pi_n \mathscr{O}_X$ *is a quasi-coherent sheaf of* $(\pi_0 \mathscr{O}_X)$*-modules on* X *for every integer* n*. The following conditions are equivalent:*

(1) *The structure sheaf* $\mathscr{O}_X$ *is hypercomplete.*

(2) *The pair* $(X, \mathscr{O}_X)$ *is a nonconnective spectral scheme.*

(3) *For each point* $x \in X$*, there exists an open set* $U \subseteq X$ *containing* x *such that the spectrally ringed space* $(U, \mathscr{O}_X|_U)$ *is an affine nonconnective spectral scheme (that is, there exists an equivalence* $(U, \mathscr{O}_X|_U) \simeq \operatorname{Spec} A$ *for some* $\mathbb{E}_\infty$*-ring* A*).*

Proof. The implication (1) $\Rightarrow$ (2) follows from Proposition 1.1.3.4. We next show that (2) $\Rightarrow$ (3). Assume that $(X, \mathscr{O}_X)$ is a nonconnective spectral scheme, and let $x \in X$. Since the ringed space $(X, \pi_0 \mathscr{O}_X)$ is a scheme, we can choose an open subset $U \subseteq X$ containing X such that $(U, (\pi_0 \mathscr{O}_X)|_U)$ is an affine scheme. Set $A = \mathscr{O}_X(U)$, so that Proposition 1.1.5.5 supplies a map of locally spectrally ringed spaces $f : (U, \mathscr{O}_X|_U) \to \operatorname{Spec} A$. Using condition (1) and Proposition 1.1.6.1, we conclude that f is an equivalence.

We now complete the proof by showing that (3) $\Rightarrow$ (1). The assertion that $\mathscr{O}_X$ is hypercomplete can be tested locally on X (see Corollary 1.3.3.8). Using (3), we are reduced to proving that $\mathscr{O}_X$ is hypercomplete in the special case where $(X, \mathscr{O}_X) \simeq \operatorname{Spec} A$ for some $\mathbb{E}_\infty$-ring A, which follows from Proposition 1.1.6.1. □

Corollary 1.1.6.3. *Let* $(X, \mathscr{O}_X)$ *be a nonconnective spectral scheme. Then* $(X, \mathscr{O}_X)$ *is affine if and only if the underlying scheme* $(X, \pi_0 \mathscr{O}_X)$ *is affine.*

Corollary 1.1.6.4. *Let* $(X, \mathscr{O}_X)$ *be a spectrally ringed space. Then the condition that* X *is a nonconnective spectral scheme can be tested locally on* X*. That is, if each point* $x \in X$ *has an open neighborhood* $U \subseteq X$ *such that* $(U, \mathscr{O}_X|_U)$ *is a nonconnective spectral scheme, then* $(X, \mathscr{O}_X)$ *is a nonconnective spectral scheme.*

Proof of Proposition 1.1.6.1. Let $\mathscr{O}$ denote the structure sheaf of the nonconnective spectral scheme $\operatorname{Spec} A$. To prove that (1) implies (2), it will suffice to show that $\mathscr{O}$ is hypercomplete. We will prove this by exhibiting $\mathscr{O}$ as an inverse limit $\varprojlim_n \mathscr{O}_n$, where each $\mathscr{O}_n$ is a sheaf of spectra on $|\operatorname{Spec} A|$ taking values in the full subcategory $\mathrm{Sp}_{\leqslant n} \subseteq \mathrm{Sp}$ of n-truncated spectra.

Let $\tau_{\geqslant 0} A$ denote the connective cover of A, and let $\mathscr{O}'$ denote the structure sheaf of $\operatorname{Spec}(\tau_{\geqslant 0} A)$ (which we also regard as a sheaf of $\mathbb{E}_\infty$-rings on the topological space $|\operatorname{Spec} A|$). Let $\mathcal{U}_e$ denote the collection of all affine open subsets of X, and define functors $\mathscr{F}^\circ_n : \mathcal{U}_e^{\mathrm{op}} \to \mathrm{Sp}$ by the formula $\mathscr{F}^\circ_n(U) = \tau_{\leqslant n} \mathscr{O}(U)$. We claim that each $\mathscr{F}^\circ_n$ satisfies hypothesis (2) of Proposition 1.1.4.4. To prove this, it suffices to observe that we have a canonical equivalence $\mathscr{F}^\circ_n(U) \simeq (\tau_{\leqslant n} A) \otimes_{\tau_{\geqslant 0} A} \mathscr{O}'(U)$, and that the $N \mapsto (\tau_{\leqslant n} A) \otimes_{\tau_{\geqslant 0} A} N$ commutes with finite limits. Let $\mathscr{F}_n : \mathcal{U}(|\operatorname{Spec} A|)^{\mathrm{op}} \to \mathrm{Sp}$ be a right Kan extension of $\mathscr{F}^\circ_n$, so that $\mathscr{F}_n$ is a Sp-valued sheaf on $|\operatorname{Spec} A|$ (by Proposition 1.1.4.4). By construction, we have a canonical map $\mathscr{O} \to \varprojlim_n \mathscr{F}_n$, which is an equivalence when evaluated on each affine open subset of X and therefore an equivalence (since the functors $\mathscr{O}$ and $\varprojlim_n \mathscr{F}_n$ are right Kan extensions of their restrictions to $\mathcal{U}_e^{\mathrm{op}}$, by Proposition 1.1.4.4). By construction, the spectrum $\mathscr{F}_n(U)$ is n-truncated for any affine open subset $U \subseteq X$. Since the collection of n-truncated spectra is closed under small limits, it follows that $\mathscr{F}_n(U)$ is n-truncated for all $U \subseteq X$, so that $\mathscr{F}_n$ is an n-truncated object of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(|\operatorname{Spec} A|)$. This completes the proof of the implication (1) $\Rightarrow$ (2).

The implication (2) $\Rightarrow$ (3) follows from Proposition 1.1.3.4. We will complete the proof by showing that (3) $\Rightarrow$ (1). Suppose that $(X, \mathscr{O}_X)$ is a nonconnective spectral scheme. Using (b), we can write $(X, \pi_0 \mathscr{O}_X) \simeq \operatorname{Spec} R$ for some commutative ring R. For each integer n, set $\mathcal{M}_n = \pi_n \mathscr{O}_X$. It follows from ($c$) that $\mathcal{M}_n$ is a quasi-coherent sheaf on the scheme $(X, \pi_0 \mathscr{O}_X)$. We may therefore choose a discrete R-module M_n such that $\mathcal{M}_n(U) = (\pi_0 \mathscr{O}_X)(U) \otimes_R M_n$ for each affine open subset $U \subseteq X$. Using (2), we deduce that the canonical map $\pi_n(\mathscr{O}_X(U)) \to \mathcal{M}_n(U)$ is an isomorphism whenever U is affine. Using (a), we obtain isomorphisms

$$\pi_n A \overset{\alpha}{\simeq} \pi_n \mathscr{O}_X(X) \simeq M_n.$$

Taking $n = 0$, we conclude that the canonical map $\pi_0 A \to R$ is an isomorphism, so that f induces a homeomorphism $X \to |\operatorname{Spec} R|$. Let $\mathscr{O}$ denote the structure sheaf of $\operatorname{Spec} A$; let us abuse notation by identifying $\mathscr{O}$ with a CAlg-valued sheaf on X. To complete the proof, it will suffice to show that f induces an equivalence $\mathscr{O} \to \mathscr{O}_X$ in $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(X)$. Using Corollary 1.1.4.5, we are reduced to proving that the map $\mathscr{O}(U) \to \mathscr{O}_X(U)$ is an equivalence for each open subset $U \subseteq X$. Equivalently, we must show that each of the maps $\theta_n : \pi_n \mathscr{O}(U) \to \pi_n \mathscr{O}_X(U)$ is an isomorphism. This is clear, since θ_n fits into a commutative

diagram

$$\begin{array}{ccc} & (\pi_0 \mathscr{O}_X)(U) \otimes_R M_n & \\ \swarrow & & \searrow \\ \pi_n \mathscr{O}(U) & \longrightarrow & \pi_n \mathscr{O}_X(U). \end{array}$$

where the vertical maps are isomorphisms. □

1.1.7 Truncations of Spectral Schemes

The difference between an $\mathbb{E}_\infty$-ring A and the ordinary commutative ring $\pi_0 A$ is controlled by the remaining homotopy groups $\{\pi_n A\}_{n \neq 0}$: if these vanish, then the data of A and $\pi_0 A$ are interchangeable. We now make some analogous remarks for *sheaves* of $\mathbb{E}_\infty$-rings.

Definition 1.1.7.1. Let X be a topological space and let $\mathscr{O}_X$ be a sheaf of $\mathbb{E}_\infty$-rings on X. We will say that $\mathscr{O}_X$ is *connective* if the sheaves $\pi_n \mathscr{O}_X$ vanish for $n < 0$. We let $\mathcal{S}\mathrm{hv}^{\mathrm{cn}}_{\mathrm{CAlg}}(X)$ denote the full subcategory of $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(X)$ spanned by the connective sheaves of $\mathbb{E}_\infty$-rings on X.

If $\mathscr{O}_X$ is a sheaf of $\mathbb{E}_\infty$-rings on X and n is an integer, then we will say that $\mathscr{O}_X$ is *n-truncated* if the $\mathbb{E}_\infty$-ring $\mathscr{O}_X(U)$ is n-truncated, for every open subset $U \subseteq X$. We let $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(X)^{\leqslant n}$ denote the full subcategory of $\mathcal{S}\mathrm{hv}^{\mathrm{cn}}_{\mathrm{CAlg}}(X)$ spanned by the n-truncated sheaves of $\mathbb{E}_\infty$-rings on X, and $\mathcal{S}\mathrm{hv}^{\mathrm{cn}}_{\mathrm{CAlg}}(X)^{\leqslant n}$ the intersection $\mathcal{S}\mathrm{hv}^{\mathrm{cn}}_{\mathrm{CAlg}}(X) \cap \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(X)^{\leqslant n}$.

Warning 1.1.7.2. Let $\mathscr{O}_X$ be a sheaf of $\mathbb{E}_\infty$-rings on a topological space X. The condition that $\mathscr{O}_X$ is connective does *not* imply that the $\mathbb{E}_\infty$-rings $\mathscr{O}_X(U)$ are connective for $U \subseteq X$. Nevertheless, there is an equivalence of ∞-categories $\rho : \mathcal{S}\mathrm{hv}^{\mathrm{cn}}_{\mathrm{CAlg}}(X) \to \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}^{\mathrm{cn}}}(X)$, given on objects by the formula $(\rho \mathscr{O})(U) = \tau_{\geqslant 0}(\mathscr{O}(U))$; see Proposition 1.3.5.7.

Remark 1.1.7.3. Let $(X, \mathscr{O}_X)$ be a nonconnective spectral scheme. Then $(X, \mathscr{O}_X)$ is a spectral scheme if and only if the structure sheaf $\mathscr{O}_X$ is connective.

Remark 1.1.7.4. Let $(X, \mathscr{O}_X)$ be a spectrally ringed space. If $\mathscr{O}_X$ is n-truncated for some integer n, then the sheaves $\pi_m \mathscr{O}_X$ are trivial for $m > n$. The converse holds provided that $\mathscr{O}_X$ is hypercomplete. In particular, if $(X, \mathscr{O}_X)$ is a nonconnective spectral scheme, then $\mathscr{O}_X$ is n-truncated if and only if $\pi_m \mathscr{O}_X \simeq 0$ for $m > n$.

Our next goal is to describe the relationship between the ∞-category SpSch of spectral schemes and the larger ∞-category $\mathrm{SpSch}^{\mathrm{nc}}$ of nonconnective spectral schemes. For this, we will need a few general remarks about CAlg-valued sheaves on topological space. We will defer the proofs until §1.3, where we will give a more systematic treatment of spectrum-valued sheaves.

Fix a topological space X. Then:

$(T1)$ The inclusion functor $\mathcal{S}\mathrm{hv}^{\mathrm{cn}}_{\mathrm{CAlg}}(X) \hookrightarrow \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(X)$ admits a right adjoint, which we will denote by $\mathscr{O}_X \mapsto \tau_{\geqslant 0} \mathscr{O}_X$ (see Remark 1.3.5.4). Moreover, a map $\alpha : \mathscr{O}_X \to \mathscr{O}'_X$ induces an equivalence $\tau_{\geqslant 0} \mathscr{O}_X \to \tau_{\geqslant 0} \mathscr{O}'_X$ if and only if α induces an equivalence of $\mathrm{CAlg}^{\mathrm{cn}}$-valued sheaves on X (that is, if and only if the induced map $\tau_{\geqslant 0} \mathscr{O}_X(U) \to \tau_{\geqslant 0} \mathscr{O}'_X(U)$ is an equivalence, for each open set $U \subseteq X$; see Proposition 1.3.5.10). In particular, the canonical map $\tau_{\geqslant 0} \mathscr{O}_X \to \mathscr{O}_X$ induces isomorphisms $\pi_m(\tau_{\geqslant 0} \mathscr{O}_X) \to \pi_m \mathscr{O}_X$ for $m \geqslant 0$.

$(T2)$ For each $n \geqslant 0$, the inclusion functor $\mathcal{S}\mathrm{hv}^{\mathrm{cn}}_{\mathrm{CAlg}}(X)^{\leqslant n} \hookrightarrow \mathcal{S}\mathrm{hv}^{\mathrm{cn}}_{\mathrm{CAlg}}(X)$ admits a left adjoint, which we will denote by $\mathscr{O}_X \mapsto \tau_{\leqslant n} \mathscr{O}_X$. Moreover, for every connective CAlg-valued sheaf $\mathscr{O}_X$ on X, the canonical map $\pi_m \mathscr{O}_X \to \pi_m(\tau_{\leqslant n} \mathscr{O}_X)$ is an isomorphism for $m \leqslant n$ (see Remark 1.3.5.6).

$(T3)$ The construction $\mathscr{O}_X \mapsto \pi_0 \mathscr{O}_X$ induces an equivalence of the ∞-category $\mathcal{S}\mathrm{hv}^{\mathrm{cn}}_{\mathrm{CAlg}}(X)^{\leqslant 0}$ with the ordinary category of sheaves of commutative rings on X (see Remark 1.3.5.6).

Proposition 1.1.7.5. *Let $(X, \mathscr{O}_X)$ be a nonconnective spectral scheme, and let $\tau_{\geqslant 0} \mathscr{O}_X$ denote a connective cover of $\mathscr{O}_X$ in the ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(X)$. Then $(X, \tau_{\geqslant 0} \mathscr{O}_X)$ is a spectral scheme. Moreover, it has the following universal property: for every spectrally ringed ∞-topos $(Y, \mathscr{O}_Y)$ where $\mathscr{O}_Y$ is connective, the canonical map*

$$\theta : \mathrm{Map}_{\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}}((X, \tau_{\leqslant 0} \mathscr{O}_X), (Y, \mathscr{O}_Y)) \to \mathrm{Map}_{\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}}((X, \mathscr{O}_X), (Y, \mathscr{O}_Y))$$

is a homotopy equivalence. If $(Y, \mathscr{O}_Y)$ is locally spectrally ringed, then the map θ restricts to a homotopy equivalence

$$\mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}((X, \tau_{\leqslant 0} \mathscr{O}_X), (Y, \mathscr{O}_Y)) \to \mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}((X, \mathscr{O}_X), (Y, \mathscr{O}_Y)).$$

Corollary 1.1.7.6. *The inclusion functor* $\mathrm{SpSch} \hookrightarrow \mathrm{SpSch}^{\mathrm{nc}}$ *admits a left adjoint, given by* $(X, \mathscr{O}_X) \mapsto (X, \tau_{\geqslant 0} \mathscr{O}_X)$.

Proof of Proposition 1.1.7.5. Let $(X, \mathscr{O}_X)$ be an arbitrary spectrally ringed space, and let $(Y, \mathscr{O}_Y)$ be a spectrally ringed space where $\mathscr{O}_Y$ is connective. The canonical map $\tau_{\geqslant 0} \mathscr{O}_X \to \mathscr{O}_X$ is an equivalence after applying the functor $\Omega^\infty : \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(X) \to \mathcal{S}\mathrm{hv}_{\mathcal{S}}(X)$. It follows that the canonical map $\alpha : f_*(\tau_{\geqslant 0} \mathscr{O}_X) \to f_* \mathscr{O}_X$ is an equivalence after applying the functor $\Omega^\infty : \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(Y) \to \mathcal{S}\mathrm{hv}_{\mathcal{S}}(Y)$. In particular, α induces an equivalence of connective covers, so that composition with α induces a homotopy equivalence

$$\mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(Y)}(\mathscr{O}_Y, f_*(\tau_{\geqslant 0} \mathscr{O}_X)) \to \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(Y)}(\mathscr{O}_Y, f_* \mathscr{O}_X).$$

Passing to the disjoint union over all continuous maps $f : X \to Y$, we conclude that the map

$$\theta : \mathrm{Map}_{\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}}((X, \tau_{\geqslant 0} \mathscr{O}_X), (Y, \mathscr{O}_Y)) \to \mathrm{Map}_{\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}}((X, \mathscr{O}_X), (Y, \mathscr{O}_Y)).$$

If $\mathscr{O}_X$ and $\mathscr{O}_Y$ are local, then $\tau_{\geqslant 0}\,\mathscr{O}_X$ is also local (since we have an isomorphism $\pi_0(\tau_{\geqslant 0}\,\mathscr{O}_X) \to \pi_0\,\mathscr{O}_X$), and it follows immediately from the definitions that θ restricts to a homotopy equivalence

$$\mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}((X, \tau_{\geqslant 0}\,\mathscr{O}_X), (Y, \mathscr{O}_Y)) \to \mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}((X, \mathscr{O}_X), (Y, \mathscr{O}_Y)).$$

To complete the proof, it will suffice to show that if $(X, \mathscr{O}_X)$ is a nonconnective spectral scheme, then $(X, \tau_{\geqslant 0}\,\mathscr{O}_X)$ is a spectral scheme. This assertion can be tested locally on X: we may therefore assume without loss of generality that $(X, \mathscr{O}_X) = \operatorname{Spec} A$ for some $\mathbb{E}_\infty$-ring A. Let $B = \tau_{\geqslant 0}A$. Then $\operatorname{Spec} B$ is a spectral scheme, so the canonical map $(X, \mathscr{O}_X) \to \operatorname{Spec} B$ factors as a composition $(X, \mathscr{O}_X) \to (X, \tau_{\geqslant 0}\,\mathscr{O}_X) \xrightarrow{\phi} \operatorname{Spec} B$. The natural map $B \to A$ induces an isomorphism of commutative rings and therefore a homeomorphism $f : |\operatorname{Spec} A| \to |\operatorname{Spec} B|$. Let $\mathscr{O}'$ denote the structure sheaf of $\operatorname{Spec} B$; we wish to show that ϕ induces a map $\mathscr{O}' \to f_*\,\mathscr{O}_X$ which exhibits $\mathscr{O}'$ as a connective cover of $f_*\,\mathscr{O}_X$. Since B is connective, $\mathscr{O}'$ is connective (Proposition 1.1.4.3); by virtue of $(T1)$, it will suffice to show that the map $\mathscr{O}' \to f_*\,\mathscr{O}_X$ induces an equivalence of $\mathrm{CAlg}^{\mathrm{cn}}$-valued sheaves on X (after composing pointwise with the truncation functor $\tau_{\geqslant 0} : \mathrm{CAlg} \to \mathrm{CAlg}^{\mathrm{cn}}$). Using Proposition 1.1.4.4, we are reduced to showing that the map $\tau_{\geqslant 0}\,\mathscr{O}'(U) \to \tau_{\geqslant 0}\,\mathscr{O}_X(f^{-1}U)$ is an equivalence for every elementary open subset $U \subseteq |\operatorname{Spec} B|$. In other words, we must show that the map $\tau_{\geqslant 0}B[a^{-1}] \to \tau_{\geqslant 0}A[a^{-1}]$ is an equivalence for each $a \in \pi_0 A$, which is clear. □

Remark 1.1.7.7. The proof of Proposition 1.1.7.5 shows that if $(X, \mathscr{O}_X)$ is an affine nonconnective spectral scheme, then the associated spectral scheme $(X, \tau_{\geqslant 0}\,\mathscr{O}_X)$ is the spectrum of a connective $\mathbb{E}_\infty$-ring. In particular, if A is an $\mathbb{E}_\infty$-ring and $\operatorname{Spec} A$ is a spectral scheme, then A must be connective.

Definition 1.1.7.8. Let $(X, \mathscr{O}_X)$ be a spectral scheme, and let $n \geqslant 0$ be an integer. We will say that $(X, \mathscr{O}_X)$ is *n-truncated* if the structure sheaf $\mathscr{O}_X$ is n-truncated (when regarded as a connective CAlg-valued sheaf on X). We let $\mathrm{SpSch}^{\leqslant n}$ denote the full subcategory of SpSch spanned by the n-truncated spectral schemes.

Example 1.1.7.9. Let A be a connective $\mathbb{E}_\infty$-ring and write $\operatorname{Spec} A = (X, \mathscr{O}_X)$. For every elementary open subset $U \subseteq X$, the $\mathbb{E}_\infty$-ring $\mathscr{O}_X(U)$ has the form $A[a^{-1}]$ for some $a \in \pi_0 A$. It follows that if A is n-truncated, then $\mathscr{O}_X(U)$ is n-truncated for each elementary open subset $U \subseteq X$ (and therefore for every open subset $U \subseteq X$ by virtue of Proposition 1.1.4.4), so that $(X, \mathscr{O}_X)$ is an n-truncated spectral scheme. Conversely, if $(X, \mathscr{O}_X)$ is an n-truncated spectral scheme, then $A \simeq \mathscr{O}_X(X)$ is an n-truncated connective $\mathbb{E}_\infty$-ring.

Proposition 1.1.7.10. *Let $(X, \mathscr{O}_X)$ be a spectral scheme. For each $n \geqslant 0$, the truncation $(X, \tau_{\leqslant n}\,\mathscr{O}_X)$ is also a spectral scheme. Moreover, it has the following universal property: for* *every spectrally ringed space $(Y, \mathscr{O}_Y)$ for which $\mathscr{O}_Y$ is n-truncated, the canonical map*

$$\theta : \mathrm{Map}_{\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}}((Y, \mathscr{O}_Y), (X, \tau_{\leqslant n}\, \mathscr{O}_X)) \to \mathrm{Map}_{\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}}((Y, \mathscr{O}_Y), (X, \mathscr{O}_X))$$

is a homotopy equivalence. Moreover, if $(Y, \mathscr{O}_Y)$ is locally spectrally ringed, then θ restricts to a homotopy equivalence

$$\mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}((Y, \mathscr{O}_Y), (X, \tau_{\leqslant n}\, \mathscr{O}_X)) \to \mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}((Y, \mathscr{O}_Y), (X, \mathscr{O}_X)).$$

Corollary 1.1.7.11. *For each integer $n \geqslant 0$, the inclusion* $\mathrm{SpSch}^{\leqslant n} \hookrightarrow \mathrm{SpSch}$ *admits a right adjoint, given on objects by $(X, \mathscr{O}_X) \mapsto (X, \tau_{\leqslant n}\, \mathscr{O}_X)$.*

Proof of Proposition 1.1.7.10. Suppose first that $(X, \mathscr{O}_X)$ and $(Y, \mathscr{O}_Y)$ are arbitrary spectrally ringed space for which $\mathscr{O}_X$ is connective and $\mathscr{O}_Y$ is n-truncated. For every continuous map $f : Y \to X$, we have a commutative diagram

$$\begin{array}{ccc} \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(X)}(\tau_{\leqslant n}\, \mathscr{O}_X, \tau_{\geqslant 0} f_*\, \mathscr{O}_Y) & \longrightarrow & \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(X)}(\mathscr{O}_X, \tau_{\geqslant 0} f_*\, \mathscr{O}_Y) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(X)}(\tau_{\leqslant n}\, \mathscr{O}_X, f_*\, \mathscr{O}_Y) & \longrightarrow & \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(X)}(\mathscr{O}_X, f_*\, \mathscr{O}_Y). \end{array}$$

Here the vertical maps are homotopy equivalences since $\mathscr{O}_X$ and $\tau_{\leqslant n}\, \mathscr{O}_X$ are connective, and the universal property of $\tau_{\leqslant n}\, \mathscr{O}_X$ guarantees that the upper horizontal map is a homotopy equivalence. It follows that the lower horizontal map is a homotopy equivalence. Passing to a disjoint union over all continuous maps $f : Y \to X$, we conclude that the map

$$\theta : \mathrm{Map}_{\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}}((Y, \mathscr{O}_Y), (X, \tau_{\leqslant n}\, \mathscr{O}_X)) \to \mathrm{Map}_{\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}}((Y, \mathscr{O}_Y), (X, \mathscr{O}_X))$$

is a homotopy equivalence, from which we immediately deduce that θ restricts to a homotopy equivalence

$$\mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}((Y, \mathscr{O}_Y), (X, \tau_{\leqslant n}\, \mathscr{O}_X)) \to \mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}((Y, \mathscr{O}_Y), (X, \mathscr{O}_X)).$$

We now complete the proof by showing that if $(X, \mathscr{O}_X)$ is a spectral scheme, then $(X, \tau_{\leqslant n}\, \mathscr{O}_X)$ is a spectral scheme. The assertion The assertion is local on X. We may therefore assume without loss of generality that $(X, \mathscr{O}_X)$ is affine, hence of the form $\mathrm{Spec}\, A$ for some $\mathbb{E}_\infty$-ring A. It follows from Remark 1.1.7.7 that A is connective. Let $B = \tau_{\leqslant n} A$. Then $\mathrm{Spec}\, B$ is an n-truncated spectral scheme (Example 1.1.7.9), so the canonical map $\mathrm{Spec}\, B \to \mathrm{Spec}\, A \simeq (X, \mathscr{O}_X)$ factors as a composition

$$\mathrm{Spec}\, B \xrightarrow{\phi} (X, \tau_{\leqslant n}\, \mathscr{O}_X) \to (X, \mathscr{O}_X).$$

To complete the proof, it will suffice to show that ϕ is an equivalence. We will prove this by showing that for every locally spectrally ringed space $(Y, \mathscr{O}_Y)$ where $\mathscr{O}_Y$ is connective and n-truncated, the horizontal map in the diagram

$$\begin{array}{ccc} \mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}((Y, \mathscr{O}_Y), \operatorname{Spec} B) & \longrightarrow & \mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}((Y, \mathscr{O}_Y), (X, \tau_{\leqslant n} \mathscr{O}_X)) \\ & \searrow \quad \swarrow & \\ & \mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}((Y, \mathscr{O}_Y), (X, \mathscr{O}_X)) & \end{array}$$

is a homotopy equivalence. Here the right vertical map is a homotopy equivalence by the first part of the proof, and we can use Proposition 1.1.5.5 to identify the left horizontal map with the map ψ appearing in the diagram

$$\begin{array}{ccc} \mathrm{Map}_{\mathrm{CAlg}}(B, \tau_{\geqslant 0}(\mathscr{O}_Y(Y))) & \xrightarrow{\psi'} & \mathrm{Map}_{\mathrm{CAlg}}(A, \tau_{\geqslant 0}(\mathscr{O}_Y(Y))) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathrm{CAlg}}(B, \mathscr{O}_Y(Y)) & \xrightarrow{\psi} & \mathrm{Map}_{\mathrm{CAlg}}(A, \mathscr{O}_Y(Y)) \end{array}$$

Here the universal property of B ensures that ψ' is a homotopy equivalence (since $\tau_{\geqslant 0} \mathscr{O}_Y(Y)$ is n-truncated), and the vertical maps are homotopy equivalences because A and B are connective. □

1.1.8 Comparing Spectral Schemes with Schemes

We now consider the relationship between our theory of spectral schemes and the classical theory of schemes.

Proposition 1.1.8.1. *Let $(X, \mathscr{O}_X)$ and $(Y, \mathscr{O}_Y)$ be spectrally ringed spaces. Suppose that $\mathscr{O}_X$ is 0-truncated and $\mathscr{O}_Y$ is connective. Then the canonical map*

$$\mathrm{Map}_{\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}}((X, \mathscr{O}_X), (Y, \mathscr{O}_Y)) \to \mathrm{Hom}((X, \pi_0 \mathscr{O}_X), (Y, \pi_0 \mathscr{O}_Y))$$

is a homotopy equivalence, where right hand side denotes the (discrete) set of morphisms from $(X, \pi_0 \mathscr{O}_X)$ to $(Y, \pi_0 \mathscr{O}_Y)$ in the category of ringed spaces.

Proof. Let $\mathcal{C}$ denote the category of sheaves of commutative rings on Y. Fix a continuous map $f : X \to Y$; we wish to show that the map

$$\mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(Y)}(\mathscr{O}_Y, f_* \mathscr{O}_X) \to \mathrm{Hom}_{\mathcal{C}}(\pi_0 \mathscr{O}_Y, f_* \pi_0 \mathscr{O}_X).$$

Since $\mathscr{O}_X$ is 0-truncated, the presheaf of commutative rings $U \mapsto \pi_0(\mathscr{O}_X(U))$ is a sheaf, so that the canonical map $\pi_0(\mathscr{O}_X(U)) \to (\pi_0 \mathscr{O}_X)(U)$ is an isomorphism for every open subset $U \subseteq X$. For each open subset $V \subseteq Y$, we the canonical map

$$\pi_0((f_* \mathscr{O}_X)(V)) = \pi_0(\mathscr{O}_X(f^{-1}V)) \simeq (\pi_0 \mathscr{O}_X)(f^{-1}V) = (f_*(\pi_0 \mathscr{O}_X))(V)$$

is an isomorphism. It will therefore suffice to show that the canonical map

$$\theta_{\mathscr{A}} : \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(Y)}(\mathscr{O}_Y, \mathscr{A}) \to \mathrm{Hom}_{\mathcal{C}}(\pi_0 \mathscr{O}_Y, \pi_0 \mathscr{A})$$

is a homotopy equivalence, where $\mathscr{A} = f_* \mathscr{O}_X$. In fact, we will prove more generally that the map $\theta_{\mathscr{A}}$ is an equivalence whenever $\mathscr{A}$ is a 0-truncated object of $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(Y)$. Since $\mathscr{O}_Y$ is connective, we can use $(T1)$ to replace $\mathscr{A}$ by its connective cover $\tau_{\geqslant 0} \mathscr{A}$ and thereby reduce to the case where $\mathscr{A}$ is connective. We can then use $(T2)$ to identify the mapping space $\mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(Y)}(\mathscr{O}_Y, \mathscr{A})$ with $\mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(Y)}(\tau_{\leqslant 0} \mathscr{O}_Y, \mathscr{A})$, which is equivalent to $\mathrm{Hom}_{\mathcal{C}}(\pi_0 \mathscr{O}_Y, \pi_0 \mathscr{A})$ by $(T3)$. □

Corollary 1.1.8.2. *Let $\mathcal{C}$ denote the full subcategory of $\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ spanned by those spectrally ringed spaces $(X, \mathscr{O}_X)$ where $\mathscr{O}_X$ is connective and 0-truncated. Then the construction $(X, \mathscr{O}_X) \mapsto (X, \pi_0 \mathscr{O}_X)$ induces an equivalence from $\mathcal{C}$ to the category of ringed spaces.*

Proof. It follows from Proposition 1.1.8.1 that the construction $(X, \mathscr{O}_X) \mapsto (X, \pi_0 \mathscr{O}_X)$ is fully faithful when restricted to spectrally ringed spaces $(X, \mathscr{O}_X)$ for which $\mathscr{O}_X$ is connective and 0-truncated. To verify the essential surjectivity, it will suffice to show that for every topological space X and every sheaf of commutative rings $\mathscr{A}$ on X, there exists a connective 0-truncated object $\mathscr{O}_X \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(X)$ such that $\mathscr{A}$ is isomorphic to $\pi_0 \mathscr{O}_X$. This follows from assertion $(T3)$. □

Corollary 1.1.8.3. *Let $\mathcal{C}^{\mathrm{loc}}$ denote the full subcategory of $\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ spanned by those locally spectrally ringed spaces $(X, \mathscr{O}_X)$ where $\mathscr{O}_X$ is connective and 0-truncated. Then the construction $(X, \mathscr{O}_X) \mapsto (X, \pi_0 \mathscr{O}_X)$ induces an equivalence from $\mathcal{C}^{\mathrm{loc}}$ to the ordinary category of locally ringed spaces.*

Let Sch denote the category of schemes.. Passage to the underlying scheme determines a functor from $\mathrm{SpSch}^{\mathrm{nc}} \to \mathrm{Sch}$, given on objects by $(X, \mathscr{O}_X) \mapsto (X, \pi_0 \mathscr{O}_X)$.

Proposition 1.1.8.4. *The construction $(X, \mathscr{O}_X) \mapsto (X, \pi_0 \mathscr{O}_X)$ induces an equivalence of ∞-categories $\mathrm{SpSch}^{\leqslant 0} \to \mathrm{Sch}$.*

Proof. Corollary 1.1.8.3 implies that the functor $(X, \mathscr{O}_X) \mapsto (X, \pi_0 \mathscr{O}_X)$ is fully faithful when restricted to $\mathrm{SpSch}^{\leqslant 0}$. Moreover, it implies that for every scheme $(X, \mathscr{O})$, we can write $\mathscr{O} = \pi_0 \mathscr{O}_X$ for some object $\mathscr{O}_X \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(X)$ which is connective and 0-truncated. To complete the proof, it will suffice to show that $(X, \mathscr{O}_X)$ is a spectral scheme. Since $\mathscr{O}_X$ is connective, it will suffice to show that $(X, \mathscr{O}_X$ is a nonconnective spectral scheme. We will prove this by verifying the hypotheses of Proposition 1.1.3.4. The ringed space $(X, \pi_0 \mathscr{O}_X) \simeq (X, \mathscr{O})$ is a scheme by construction. The sheaves $\pi_n \mathscr{O}_X$ either vanish (if $n \neq 0$) or are isomorphic to $\mathscr{O}$ (if $n = 0$), and are therefore quasi-coherent. Finally, the assumption that $\mathscr{O}_X$ is 0-truncated immediately implies that $\mathscr{O}_X$ is hypercomplete. □

Remark 1.1.8.5. We can regard a homotopy inverse to the equivalence $\mathrm{SpSch}^{\leqslant 0} \to \mathrm{Sch}$ as supplying a fully faithful functor $\mathrm{Sch} \to \mathrm{SpSch}$. In other words, we can identify the category of schemes with a full subcategory of the ∞-category of spectral schemes: namely, the full subcategory spanned by the 0-truncated spectral schemes.

1.2 Deligne-Mumford Stacks

Let E be an elliptic curve over the field $\mathbf{C}$ of complex numbers. Then E is classified up to isomorphism by its *j-invariant* $j(E) \in \mathbf{C}$. The theory of the j-invariant supplies a complete classification of elliptic curves over $\mathbf{C}$: two elliptic curves E and E' are isomorphic if and only if $j(E) = j(E')$, and every complex number arises as the j-invariant of some curve over $\mathbf{C}$.

If we wish to classify *families* of elliptic curves, the situation becomes more complicated. Suppose that X is an algebraic variety over $\mathbf{C}$ and that E is a family of elliptic curves over X (in other words, we have a proper smooth morphism $\pi : E \to X$ equipped with a section, whose fibers are elliptic curves). For each point $x \in X(\mathbf{C})$, let E_x denote the fiber product $\operatorname{Spec} \mathbf{C} \times_X E$, so that E_x is an elliptic curve over $\mathbf{C}$. The construction $x \mapsto j(E_x)$ is a regular function on X, which we can view as a map of algebraic varieties $j_E : X \to \mathbf{A}^1$. However, the function j_E *does not* determine E up to isomorphism in general.

Example 1.2.0.1. Let E be an elliptic curve over $\mathbf{C}$, let $\widetilde{X}$ be an algebraic variety over $\mathbf{C}$ equipped with a fixed-point free involution σ, and let X denote the quotient of $\widetilde{X}$ by the action of σ. Then σ determines involutions σ_+ and σ_- on the product $\widetilde{X} \times_{\operatorname{Spec} \mathbf{C}} E$, given on $\mathbf{C}$-points by the formulae

$$\sigma_+(\widetilde{x}, y) = (\sigma(\widetilde{x}), y) \qquad \sigma_-(\widetilde{x}, y) = (\sigma(\widetilde{x}), -y).$$

Let E_+ denote the quotient of $\widetilde{X} \times_{\operatorname{Spec} \mathbf{C}} E$ by the action of the involution σ_+, and define E_- similarly. We have obvious projection maps $\pi_\pm : E_\pm \to X$, each fiber of which is isomorphic to the original elliptic curve E. It follows that E_+ and E_- determine the same j-invariant

$$X \to \{j(E)\} \hookrightarrow \mathbf{A}^1 .$$

However, E_+ and E_- are *never* isomorphic as elliptic curves over X unless the variety $\widetilde{X}$ is disconnected.

It follows from Example 1.2.0.1 that there can be no *fine moduli space* of elliptic curves: that is, there cannot exist a scheme M such that elliptic curves over an arbitrary scheme X are classified up isomorphism by maps from X into M. In fact, this phenomenon is ubiquitous: a similar problem arises whenever we wish to classify objects which admit nontrivial symmetries. To address this issue, Deligne and Mumford introduced a new type of algebro-geometric object which now bears their names: the *Deligne-Mumford stack*. The collection of Deligne-Mumford stacks can be organized into a 2-category DM, which contains the usual category of schemes as a full subcategory. Moreover, it also contains more exotic objects such as the moduli stack of elliptic curves $\mathcal{M}_{1,1}$, which has the property that for any scheme X, the category $\mathrm{Hom}_{\mathrm{DM}}(X, \mathcal{M}_{1,1})$ can be identified with the category of elliptic curves $\pi : E \to X$ (with morphisms given by *isomorphisms* of elliptic curves).

Our goal in this section is to give a brief overview of the classical theory of Deligne-Mumford stacks. In §1.4, we will explain how the ideas presented here can be generalized to the setting of spectral algebraic geometry and thereby obtain a notion of *spectral Deligne-Mumford stack* (Definition 1.4.4.2), which will play a central role throughout this book.

Remark 1.2.0.2. For a detailed introduction to the theory of algebraic stacks, we refer the reader to [129].

Warning 1.2.0.3. Our presentation of the theory of Deligne-Mumford stacks differs from the presentation given in [129] (and most others in the literature) in two major respects:

(i) We will define a Deligne-Mumford stack to be a ringed topos $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ satisfying a "local affineness" condition which parallels the usual definition of a scheme (Definition 1.1.1.4). The equivalence of this perspective with the "functor-of-points" approach will be established at the end of this section (Theorem 1.2.5.9).

(ii) We do not include any separatedness hypotheses in our definition of Deligne-Mumford stack (so that we allow, for example, classifying stacks for infinite discrete groups).

Roughly speaking, the definition of a Deligne-Mumford stacks is obtained by modifying the definition of a scheme $(X, \mathscr{O}_X)$ in two ways:

(a) In place of the topological space X, we allow an arbitrary Grothendieck topos $\mathcal{X}$.

(b) In place of the requirement that $(X, \mathscr{O}_X)$ be locally isomorphic to the spectrum of a commutative ring, we require that $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be locally equivalent to $\mathrm{Spét}\, A$, where A is an $\mathbb{E}_\infty$-ring and $\mathrm{Spét}\, A$ denotes its spectrum with respect to the étale topology (see Construction 1.2.3.3).

1.2.1 Local Rings in a Topos

We begin by reviewing the theory of locally ringed topoi.

Definition 1.2.1.1. A *ringed topos* consists of a pair $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$, where $\mathcal{X}$ is a Grothendieck topos and $\mathscr{O}_{\mathcal{X}}$ is a commutative ring object of $\mathcal{X}$. Given a pair of ringed topoi $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ and $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$, we define a category $\mathrm{Map}_{1\mathcal{T}\mathrm{op}_{\mathrm{CAlg}^\heartsuit}}((\mathcal{X}, \mathscr{O}_{\mathcal{X}}), (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}))$ as follows:

- The objects of $\mathrm{Hom}_{1\mathcal{T}\mathrm{op}_{\mathrm{CAlg}^\heartsuit}}((\mathcal{X}, \mathscr{O}_{\mathcal{X}}), (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}))$ are pairs (f_*, α), where $f_* : \mathcal{X} \to \mathcal{Y}$ is a geometric morphism of topoi (in other words, f_* is a functor which admits a left adjoint f^* which preserves finite limits) and $\alpha : \mathscr{O}_Y \to f_* \mathscr{O}_X$ is a morphism of commutative ring objects of $\mathcal{Y}$.

- A morphism from (f_*, α) to (f'_*, α') in $\mathrm{Hom}_{1\mathcal{T}\mathrm{op}_{\mathrm{CAlg}^\heartsuit}}((\mathcal{X}, \mathscr{O}_{\mathcal{X}}), (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}))$ is a natural transformation of functors $\beta : f'_* \to f_*$ for which the diagram

$$\begin{array}{ccc} & \mathscr{O}_{\mathcal{Y}} & \\ {}^{\alpha'}\swarrow & & \searrow^{\alpha} \\ f'_* \mathscr{O}_{\mathcal{X}} & \xrightarrow{\beta(\mathscr{O}_{\mathcal{X}})} & f_* \mathscr{O}_{\mathcal{X}} \end{array}$$

  commutes.

We will regard the collection of all ringed topoi as a (strict) 2-category $1\mathcal{T}\mathrm{op}_{\mathrm{CAlg}^\heartsuit}$, with the categories of morphisms defined above and the evident composition law.

Example 1.2.1.2. Let X be a topological space and let $\mathscr{O}_X$ be a sheaf of commutative rings on X. Then we can regard $\mathscr{O}_X$ as a commutative ring object of the topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(X)$ of set-valued sheaves on X. The pair $(\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(X), \mathscr{O}_X)$ is a ringed topos.

Notation 1.2.1.3. Let $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a ringed topos, and let $U \in \mathcal{X}$ be an object. We let $\mathscr{O}_{\mathcal{X}}|_U$ denote the product $U \times \mathscr{O}_{\mathcal{X}}$, which we view as a commutative ring object of the topos $\mathcal{X}_{/U}$. Then $(\mathcal{X}_{/U}, \mathscr{O}_{\mathcal{X}}|_U)$ is another ringed topos, equipped with an evident morphism $(\mathcal{X}_{/U}, \mathscr{O}_{\mathcal{X}}|_U) \to (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$.

We now review what it means for a commutative ring object of a topos $\mathcal{X}$ to be *local*. Let R be a commutative ring. For every element $r \in R$, we let (r) denote the principal ideal generated by r. If r is not a unit, then $(r) \neq R$, so (by Zorn's lemma) (r) is contained in a maximal ideal $\mathfrak{m} \subset R$. We say that R is *local* if it contains a unique maximal ideal $\mathfrak{m}_R$. In this case, the above reasoning shows that $\mathfrak{m}_R$ can be described as the collection of non-invertible elements of R. The ring R is local if and only if the collection of non-units $R - R^\times$ forms an ideal in R. Since $R - R^\times$ is clearly closed under multiplication by elements of R, this is equivalent to the requirement that $R - R^\times$ is an additive subgroup of R. That is, R is local if and only if the following pair of conditions is satisfied:

(a) The element 0 belongs to $R - R^\times$. In other words, 0 is not a unit in R: this is equivalent to the requirement that $0 \neq 1$ in R.

(b) If $r, r' \in R - R^\times$, then $r + r' \in R - R^\times$. Equivalently, if $r + r'$ is a unit, then either r or r' is a unit. This is equivalent to the following apparently weaker condition: if $s \in R$, then either s or $1 - s$ is a unit in R (to see this, take $s = \frac{r}{r+r'}$, so that s is invertible if and only if r is invertible and $1 - s \simeq \frac{r'}{r+r'}$ is invertible if and only if r' is invertible).

If R and R' are local commutative rings, then we say that a ring homomorphism $f : R \to R'$ is *local* if it carries $\mathfrak{m}_R$ into $\mathfrak{m}_{R'}$: that is, if an element $x \in R$ is invertible if and only if its image $f(x) \in R'$ is invertible.

All of these notions admit generalizations to the setting of commutative ring objects of an arbitrary Grothendieck topos:

Definition 1.2.1.4. Let $\mathcal{X}$ be a topos with final object $\mathbf{1}$, and let $\mathscr{O}$ be a commutative ring object of $\mathcal{X}$. Let $\mathscr{O}^{\times}$ denote the group object of $\mathcal{X}$ given by the units of $\mathscr{O}$, so that we have a pullback diagram

$$\begin{array}{ccc} \mathscr{O}^{\times} & \longrightarrow & \mathscr{O} \times \mathscr{O} \\ \downarrow & & \downarrow m \\ \mathbf{1} & \xrightarrow{1} & \mathscr{O} \end{array}$$

where m denotes the multiplication on $\mathscr{O}$,

We will say that $\mathscr{O}$ is *local* if the following conditions are satisfied:

(a) The sheaf $\mathscr{O}_{\mathcal{X}}$ is locally nontrivial. That is, if $0 : \mathbf{1} \to \mathscr{O}$ denotes the zero section of $\mathscr{O}$, then the fiber product $\mathbf{1} \times_{\mathscr{O}} \mathscr{O}^{\times}$ is an initial object of $\mathcal{X}$.

(b) Let $e : \mathscr{O}^{\times} \hookrightarrow \mathscr{O}$ denote the inclusion map. Then the maps e and $1 - e$ determine an effective epimorphism $\mathscr{O}^{\times} \amalg \mathscr{O}^{\times} \to \mathscr{O}$ in the topos $\mathcal{X}$.

If $\alpha : \mathscr{O} \to \mathscr{O}'$ is a map between commutative ring objects of $\mathcal{X}$, then we say that α is *local* if the diagram

$$\begin{array}{ccc} \mathscr{O}^{\times} & \longrightarrow & \mathscr{O}'^{\times} \\ \downarrow & & \downarrow \\ \mathscr{O} & \longrightarrow & \mathscr{O}' \end{array}$$

is a pullback square in $\mathcal{X}$.

We let $1\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}^{\heartsuit}}$ denote the subcategory of $1\mathcal{T}\mathrm{op}_{\mathrm{CAlg}^{\heartsuit}}$ whose objects are ringed topoi $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ where $\mathscr{O}_{\mathcal{X}}$ is local, and whose morphisms maps $(f_*, \alpha) : (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ for which α classifies a local map $f^* \mathscr{O}_{\mathcal{Y}} \to \mathscr{O}_{\mathcal{X}}$. We will refer to $1\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}^{\heartsuit}}$ as the *2-category of locally ringed topoi.*

Example 1.2.1.5. Let $(X, \mathscr{O}_X)$ be a ringed space. Then $\mathscr{O}_X$ is local (in the sense of Definition 1.2.1.4) if and only if $(X, \mathscr{O}_X)$ is a locally ringed space (in the sense of Definition 1.1.5.1): that is, if and only if each stalk $\mathscr{O}_{X,x}$ is a local ring. Moreover, if $(X, \mathscr{O}_X)$ and $(Y, \mathscr{O}_Y)$ are locally ringed spaces, then a map of ringed spaces $(X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ is a map of locally ringed spaces (in the sense of Definition 1.1.5.1) if and only if the induced map of ringed topoi $(\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(X), \mathscr{O}_X) \to (\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(Y), \mathscr{O}_Y)$ is local (in the sense of Definition 1.2.1.4).

Remark 1.2.1.6. Let $\mathscr{O}$ be a commutative ring object of a topos $\mathcal{X}$, and let $U = \mathbf{1} \times_{\mathscr{O}} \mathscr{O}^{\times}$ be the fiber product appearing in condition (a) of Definition 1.2.1.4. Then U is a subobject of the final object $\mathbf{1} \in \mathcal{X}$ and is maximal among those subobjects $V \subseteq \mathbf{1}$ for which the restriction $\mathscr{O}|_V$ is trivial. If $f_* : \mathcal{Y} \to \mathcal{X}$ is a geometric morphism of topoi, then:

(i) The pullback $f^* \mathscr{O}$ is trivial (as a commutative ring object of $\mathcal{Y}$) if and only if the geometric morphism f_* factors through the open immersion of topoi $\mathcal{X}_{/U} \to \mathcal{X}$ determined by U.

(ii) The pullback $f^* \mathscr{O}$ satisfies condition (a) of Definition 1.2.1.4 if and only if the geometric morphism f_* factors through the closed subtopos of $\mathcal{X}$ complementary to U.

Remark 1.2.1.7. Let $\mathcal{X}$ be a topos and suppose we are given a commutative diagram

$$\begin{array}{ccccc} & & \mathscr{O}' & & \\ & \overset{\alpha}{\nearrow} & & \overset{\beta}{\searrow} & \\ \mathscr{O} & & \xrightarrow{\gamma} & & \mathscr{O}'' \end{array}$$

of commutative ring objects of $\mathcal{X}$. Then:

(a) If α and β are local, then γ is local.

(b) If β and γ are local, then α is local.

(c) If α and γ are local and α is an effective epimorphism, then β is local.

Proposition 1.2.1.8. *Let $\mathcal{X}$ be a topos and let $\alpha : \mathscr{O} \to \mathscr{O}'$ be a morphism between commutative ring objects of $\mathcal{X}$. Then:*

(1) *If $\mathscr{O}'$ is local and α is local, then $\mathscr{O}$ is local.*

(2) *If $\mathscr{O}$ is local and α is an effective epimorphism, then the following conditions are equivalent:*

   (a) *The commutative ring object $\mathscr{O}'$ is local.*

   (b) *The commutative ring object $\mathscr{O}'$ satisfies condition (a) of Definition 1.2.1.4.*

   (c) *The morphism α is local.*

Proof. Consider first the commutative diagram σ :

$$\begin{array}{ccc} \mathscr{O}^{\times} \amalg \mathscr{O}^{\times} & \longrightarrow & \mathscr{O}'^{\times} \amalg \mathscr{O}'^{\times} \\ \downarrow{\scriptstyle v} & & \downarrow{\scriptstyle v'} \\ \mathscr{O} & \xrightarrow{\alpha} & \mathscr{O}' \end{array}$$

where the vertical maps are defined as condition (b) of Definition 1.2.1.4. If α is local, then σ is a pullback square. If, in addition, the commutative ring object $\mathscr{O}'$ is local, then v' is an effective epimorphism. It follows that v is also an effective epimorphism. Since $\mathbf{1} \times_{\mathscr{O}'} \mathscr{O}'^{\times}$ is an initial object of $\mathcal{X}$, the existence of a morphism

$$\mathbf{1} \times_{\mathscr{O}} \mathscr{O}^{\times} \to \mathbf{1} \times_{\mathscr{O}} \mathscr{O}^{\times}$$

shows that $\mathbf{1} \times_{\mathscr{O}} \mathscr{O}^{\times}$ is also initial in $\mathcal{X}$. This completest the proof of (1).

To prove (2), assume that $\mathscr{O}$ is local and that α is an effective epimorphism. The implication $(a) \Rightarrow (b)$ is trivial, and the implication $(b) \Rightarrow (a)$ follows by inspecting the commutative diagram σ (if v and α are effective epimorphisms, it follows that v' is an effective epmorphism as well). We next prove that $(c) \Rightarrow (b)$. Assume that α is local. Then the induced map

$$\beta : \mathbf{1} \times_{\mathscr{O}} \mathscr{O}^{\times} \to \mathbf{1} \times_{\mathscr{O}'} \mathscr{O}'^{\times}$$

is a pullback of α, and therefore an effective epimorphism. Our assumption that $\mathscr{O}$ is local guarantees that the domain of β is an initial object of $\mathcal{X}$. It follows that the codomain of β is also an initial object of $\mathcal{X}$, so that assertion (b) is satisfied.

We now complete the proof by showing that (b) implies (c). Fix an object $X \in \mathcal{X}$ and a morphism $f : X \to \mathscr{O}$, which we regard as an element of the commutative ring $\mathrm{Hom}_{\mathcal{X}}(X, \mathscr{O})$. Let $\alpha_X : \mathrm{Hom}_{\mathcal{X}}(X, \mathscr{O}) \to \mathrm{Hom}_{\mathcal{X}}(X, \mathscr{O}')$ be the homomorphism of commutative rings determined by α. We wish to show that if $\alpha_X(f)$ is invertible, then f is invertible. Let $\overline{g} : X \to \mathscr{O}'$ be a multiplicative inverse of $\alpha_X(f)$ in the commutative ring $\mathrm{Hom}_{\mathcal{X}}(X, \mathscr{O}')$. Since α is an effective epimorphism, we can (after passing to a covering of X) assume without loss of generality that $\overline{g} = \alpha_X(g)$ for some $g : X \to \mathscr{O}$. Since $\mathscr{O}$ is local, we can (after passing to a further covering of X) assume that either fg or $1 - fg$ is invertible in the commutative ring $\mathrm{Hom}_{\mathcal{X}}(X, \mathscr{O})$. In the first case, we conclude that f is invertible as desired. In the second case, it follows that $\alpha_X(1 - fg) = 0$ is invertible in the commutative ring $\mathrm{Hom}_{\mathcal{X}}(X, \mathscr{O}')$, so that condition (b) guarantees that X is an initial object of $\mathcal{X}$. In this case, $\mathrm{Hom}_{\mathcal{X}}(X, \mathscr{O})$ is the zero ring (so that f is tautologically invertible). □

1.2.2 Strictly Henselian Rings in a Topos

To develop the theory of Deligne-Mumford stacks, we will need to work with ringed topoi satisfying stronger locality requirements, related to the étale topology rather than the Zariski topology.

Notation 1.2.2.1. Let $\mathcal{X}$ be a topos, let $\mathscr{O}_{\mathcal{X}}$ be a commutative ring object of $\mathcal{X}$, and let $\mathrm{CAlg}^{\heartsuit}$ denote the category of commutative rings. For every commutative ring R, let $\mathcal{S}\mathrm{ol}_R(\mathscr{O}_{\mathcal{X}})$ denote an object of $\mathcal{X}$ having the following universal property: for every object

$U \in \mathcal{X}$, there is a canonical bijection

$$\mathrm{Hom}_{\mathcal{X}}(U, \mathcal{S}\mathrm{ol}_R(\mathscr{O}_{\mathcal{X}})) \simeq \mathrm{Hom}_{\mathrm{CAlg}^{\heartsuit}}(R, \mathrm{Hom}_{\mathcal{X}}(U, \mathscr{O}_{\mathcal{X}})).$$

Remark 1.2.2.2. Let $f : (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ be a map of ringed topoi and let R be a commutative ring. Then we have a canonical map $f^* \mathcal{S}\mathrm{ol}_R(\mathscr{O}_{\mathcal{Y}}) \to \mathcal{S}\mathrm{ol}_R(\mathscr{O}_{\mathcal{X}})$ in the topos $\mathcal{X}$, which is an isomorphism if $\mathscr{O}_{\mathcal{X}} \simeq f^* \mathscr{O}_{\mathcal{Y}}$ and R is finitely generated as a commutative ring.

Example 1.2.2.3. Let $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be as in Notation 1.2.2.1 and let R be the zero ring. Then $\mathcal{S}\mathrm{ol}_R(\mathscr{O}_{\mathcal{X}})$ can be identified with the fiber product $U = \mathbf{1} \times_{\mathscr{O}_{\mathcal{X}}} \mathscr{O}_{\mathcal{X}}^{\times}$ in Remark 1.2.1.6. In particular, if $\mathscr{O}_{\mathcal{X}}$ is local, then $\mathcal{S}\mathrm{ol}_R(\mathscr{O}_{\mathcal{X}})$ is an initial object of $\mathcal{X}$.

Example 1.2.2.4. Let $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be as in Notation 1.2.2.1 and let R be a commutative ring which factors as a Cartesian product $R_0 \times R_1$. The projection maps $R_0 \leftarrow R \to R_1$ induce morphisms

$$\mathcal{S}\mathrm{ol}_{R_0}(\mathscr{O}_{\mathcal{X}}) \to \mathcal{S}\mathrm{ol}_R(\mathscr{O}_{\mathcal{X}}) \leftarrow \mathcal{S}\mathrm{ol}_{R_1}(\mathscr{O}_{\mathcal{X}}).$$

Unwinding the definitions, we have

$$\begin{aligned} \mathcal{S}\mathrm{ol}_{R_i}(\mathscr{O}_{\mathcal{X}}) \times_{\mathcal{S}\mathrm{ol}_R(\mathscr{O}_{\mathcal{X}})} \mathcal{S}\mathrm{ol}_{R_j}(\mathscr{O}_{\mathcal{X}}) &\simeq \mathcal{S}\mathrm{ol}_{R_i \otimes_R R_j}(\mathscr{O}_{\mathcal{X}}) \\ &\simeq \begin{cases} \mathcal{S}\mathrm{ol}_{R_i}(\mathscr{O}_{\mathcal{X}}) & \text{if } i = j \\ \mathcal{S}\mathrm{ol}_0(\mathscr{O}_{\mathcal{X}}) & \text{if } i \neq j. \end{cases} \end{aligned}$$

In particular, if $\mathscr{O}_{\mathcal{X}}$ satisfies condition (a) of Definition 1.2.1.4, then the $\mathcal{S}\mathrm{ol}_{R_i}(\mathscr{O}_{\mathcal{X}})$ are disjoint subobjects of $\mathcal{S}\mathrm{ol}_R(\mathscr{O}_{\mathcal{X}})$, so we have a monomorphism

$$\mathcal{S}\mathrm{ol}_{R_0}(\mathscr{O}_{\mathcal{X}}) \amalg \mathcal{S}\mathrm{ol}_{R_1}(\mathscr{O}_{\mathcal{X}}) \to \mathcal{S}\mathrm{ol}_R(\mathscr{O}_{\mathcal{X}}).$$

If $\mathscr{O}_{\mathcal{X}}$ satisfies condition (b) of Definition 1.2.1.4, then this map is an epimorphism. Consequently, if $\mathscr{O}_{\mathcal{X}}$ is local, then the construction $R \mapsto \mathcal{S}\mathrm{ol}_R(\mathscr{O}_{\mathcal{X}})$ carries finite products in the category of commutative rings to finite coproducts in the topos $\mathcal{X}$.

Definition 1.2.2.5. Let $\mathcal{X}$ be a topos and let $\mathscr{O}_{\mathcal{X}}$ be a commutative ring object of $\mathcal{X}$. We will say that $\mathscr{O}_{\mathcal{X}}$ is *strictly Henselian* if the following condition is satisfied:

$(*)$ For every commutative ring R and every finite collection of étale maps $R \to R_\alpha$ which induce a faithfully flat map $R \to \prod_\alpha R_\alpha$, the induced map

$$\coprod_\alpha \mathcal{S}\mathrm{ol}_{R_\alpha}(\mathscr{O}_{\mathcal{X}}) \to \mathcal{S}\mathrm{ol}_R(\mathscr{O}_{\mathcal{X}})$$

is an effective epimorphism.

We let $1\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}^{\heartsuit}}$ denote the full subcategory of $1\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}^{\heartsuit}}$ spanned by those ringed topoi $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ where $\mathscr{O}_{\mathcal{X}}$ is strictly Henselian.

Remark 1.2.2.6. In the situation of Definition 1.2.2.5, it suffices to verify condition $(*)$ in the case where the commutative ring R is finitely generated (this follows immediately from the structure theory of étale ring homomorphisms; see Proposition B.1.1.1).

Remark 1.2.2.7. Let $f_* : \mathcal{X} \to \mathcal{Y}$ be a geometric morphism of topoi, and let $\mathscr{O}_{\mathcal{Y}}$ be a commutative ring object of $\mathcal{Y}$. If $\mathscr{O}_{\mathcal{Y}}$ is strictly Henselian, then $f^* \mathscr{O}_{\mathcal{Y}}$ is a strictly Henselian commutative ring object of $\mathcal{X}$. This follows immediately from Remarks 1.2.2.2 and 1.2.2.6.

Example 1.2.2.8. Let $\mathcal{X} = \mathcal{S}\mathrm{et}$ be the category of sets, and let $\mathscr{O}_{\mathcal{X}}$ be a commutative ring object of $\mathcal{X}$, which we can identify with a commutative ring A. For every finitely generated commutative ring R, we can identify $\mathcal{S}\mathrm{ol}_R(\mathscr{O}_{\mathcal{X}})$ with the set $\mathrm{Hom}(R, A)$ of ring homomorphisms from R to A. Applying Corollary B.3.5.4, we deduce that $\mathscr{O}_{\mathcal{X}}$ is strictly Henselian (in the sense of Definition B.3.5.1) if and only if the commutative ring A is strictly Henselian (in the sense of Definition B.3.5.1).

Remark 1.2.2.9. Let $\mathcal{X}$ be a topos, and let $\mathscr{O}_{\mathcal{X}}$ be a commutative ring object of $\mathcal{X}$. If $\mathscr{O}_{\mathcal{X}}$ is strictly Henselian, then $\mathscr{O}_{\mathcal{X}}$ is local. Conversely, if $\mathscr{O}_{\mathcal{X}}$ is local, then (by virtue of Example 1.2.2.4) it is strictly Henselian if and only if it satisfies the following *a priori* weaker version of condition $(*)$:

$(*')$ For every commutative ring R and every faithfully flat étale map $R \to R'$, the induced map $\mathcal{S}\mathrm{ol}_{R'}(\mathscr{O}_{\mathcal{X}}) \to \mathcal{S}\mathrm{ol}_R(\mathscr{O}_{\mathcal{X}})$ is an effective epimorphism in the topos $\mathcal{X}$.

Remark 1.2.2.10. Let $\mathcal{X}$ be a topos, and suppose that $\mathcal{X}$ has enough points. If $\mathscr{O}_{\mathcal{X}}$ is a commutative ring object of $\mathcal{X}$, then $\mathscr{O}_{\mathcal{X}}$ is strictly Henselian if and only if, for each point $x^* : \mathcal{X} \to \mathcal{S}\mathrm{et}$ of $\mathcal{X}$, the pullback $x^* \mathscr{O}_{\mathcal{X}}$ is a strictly Henselian commutative ring. In particular, if X is a topological space and $\mathscr{O}_X$ is a sheaf of commutative rings on X, then $\mathscr{O}_X$ is strictly Henselian (as a commutative ring object of the topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(X)$) if and only if each stalk $\mathscr{O}_{X,x}$ is a strictly Henselian ring.

Example 1.2.2.11. Let $(X, \mathscr{O}_X)$ be a complex analytic space. Then $\mathscr{O}_X$ is strictly Henselian (when viewed as a commutative ring object of the topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(X)$).

Proposition 1.2.2.12. *Let $f : (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ be a morphism of locally ringed topoi and let $v : A \to B$ be an étale morphism of commutative rings. If $\mathscr{O}_{\mathcal{Y}}$ is strictly Henselian and $\mathscr{O}_{\mathcal{X}}$ is local, then the induced diagram σ :*

$$\begin{array}{ccc} f^* \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{Y}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{X}}) \\ \downarrow & & \downarrow \\ f^* \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{Y}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{X}}) \end{array}$$

is a pullback square in the topos $\mathcal{X}$.

Proof. Using Proposition B.1.1.1, we can choose a pushout diagram

$$\begin{array}{ccc} A_0 & \longrightarrow & A \\ \downarrow{\scriptstyle v_0} & & \downarrow{\scriptstyle v} \\ B_0 & \longrightarrow & B \end{array}$$

in the category of commutative rings, where v_0 is étale and A_0 is finitely generated (so that B_0 is also finitely generated). In this case, σ fits into a commutative diagram

$$\begin{array}{ccccc} f^* \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{Y}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{X}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_{B_0}(\mathscr{O}_{\mathcal{X}}) \\ \downarrow & & \downarrow & & \downarrow \\ f^* \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{Y}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{X}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_{A_0}(\mathscr{O}_{\mathcal{X}}) \end{array}$$

where the square on the right is a pullback. It will therefore suffice to show that the outer rectangle in the diagram

$$\begin{array}{ccccc} f^* \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{Y}}) & \longrightarrow & f^* \mathcal{S}\mathrm{ol}_{B_0}(\mathscr{O}_{\mathcal{Y}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_{B_0}(\mathscr{O}_{\mathcal{X}}) \\ \downarrow & & \downarrow & & \downarrow \\ f^* \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{Y}}) & \longrightarrow & f^* \mathcal{S}\mathrm{ol}_{A_0}(\mathscr{O}_{\mathcal{Y}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_{A_0}(\mathscr{O}_{\mathcal{X}}) \end{array}$$

is a pullback square. Since the square on the left is a pullback, we are reduced to showing that the square on the right is a pullback. Using Remark 1.2.2.2, we can rewrite this diagram as

$$\begin{array}{ccc} \mathcal{S}\mathrm{ol}_{B_0}(f^* \mathscr{O}_{\mathcal{Y}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_{B_0}(\mathscr{O}_{\mathcal{X}}) \\ \downarrow & & \downarrow \\ \mathcal{S}\mathrm{ol}_{A_0}(f^* \mathscr{O}_{\mathcal{Y}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_{A_0}(\mathscr{O}_{\mathcal{X}}). \end{array}$$

Replacing v by v_0 and $\mathscr{O}_{\mathcal{Y}}$ by $f^* \mathscr{O}_{\mathcal{Y}}$, we are reduced to proving Proposition 1.2.2.12 in the special case where $\mathcal{X} = \mathcal{Y}$ (and f_* is the identity map).

For each point $x \in |\operatorname{Spec} A|$, let $\kappa(x)$ denote the residue field of A at x and let $d(x) = \dim_{\kappa(x)}(\kappa(x) \otimes_A B)$. Note that there exists an integer $n \geqslant 0$ such that $d(x) \leqslant n$ for each $x \in |\operatorname{Spec} A|$. Our proof will proceed by induction on n. Note that if $n = 0$, then $B \simeq A[0^{-1}]$ and the desired result follows from our assumption that f is local. We now treat the case $n = 0$. The ring homomorphism v induces a map of Zariski spectra $u : |\operatorname{Spec} B| \to |\operatorname{Spec} A|$. Let $U \subseteq |\operatorname{Spec} A|$ be the image of u, so that U is quasi-compact and open (Corollary B.2.2.5). Write $U = \bigcup_{1 \leqslant i \leqslant n} |\operatorname{Spec} A[\frac{1}{a_i}]|$ for some elements $a_1, \ldots, a_n \in A$. Since U contains the image of $|\operatorname{Spec} B|$, the elements $v(a_i)$ generate the unit ideal in B. Since $\mathscr{O}_{\mathcal{X}}$ is local, it follows that the map

$$\coprod_{1 \leqslant i \leqslant n} \mathcal{S}\mathrm{ol}_{B[v(a_i)^{-1}]}(\mathscr{O}_{\mathcal{X}}) \to \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{X}})$$

is an effective epimorphism in $\mathcal{X}$. It will therefore suffice to show that each of the induced maps

$$\theta_i : \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{Y}}) \times_{\mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{X}}} \mathcal{S}\mathrm{ol}_{B[f(a_i)^{-1}]}(\mathscr{O}_{\mathcal{X}}) \to \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{Y}}) \times_{\mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{X}})} \mathcal{S}\mathrm{ol}_{B[f(a_i)^{-1}]}(\mathscr{O}_{\mathcal{X}})$$

is an isomorphism. We have a commutative diagram

$$\begin{array}{ccc} \mathcal{S}\mathrm{ol}_{B[f(a_i)^{-1}]}(\mathscr{O}_{\mathcal{Y}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{Y}}) \times_{\mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{X}})} \mathcal{S}\mathrm{ol}_{B[f(a_i)^{-1}]}(\mathscr{O}_{\mathcal{X}}) \\ \downarrow{\theta'_i} & & \downarrow{\theta_i} \\ \mathcal{S}\mathrm{ol}_{A[a_i^{-1}]}(\mathscr{O}_{\mathcal{Y}}) \times_{\mathcal{S}\mathrm{ol}_{A[a_i^{-1}]}(\mathscr{O}_{\mathcal{X}})} \mathcal{S}\mathrm{ol}_{B[f(a_i)^{-1}]}(\mathscr{O}_{\mathcal{X}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{Y}}) \times_{\mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{X}})} \mathcal{S}\mathrm{ol}_{B[f(a_i)^{-1}]}(\mathscr{O}_{\mathcal{X}}), \end{array}$$

where the horizontal maps are isomorphisms by virtue of our assumption that the map $\mathscr{O}_{\mathcal{Y}} \to \mathscr{O}_{\mathcal{X}}$ is local. It will therefore suffice to show that each of the maps θ'_i is an isomorphism. Replacing A by $A[a_i^{-1}]$ and B by $B[f(a_i)^{-1}]$, we are reduced to the case where the map $u : |\operatorname{Spec} B| \to |\operatorname{Spec} A|$ is surjective. In this case, B is étale and faithfully flat over A. Since $\mathscr{O}_{\mathcal{Y}}$ is strictly Henselian, the map $\mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{Y}}) \to \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{Y}})$ is an effective epimorphism. We are therefore reduced to proving that the pullback map

$$\begin{aligned} \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{Y}}) \times_{\mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{Y}})} \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{Y}}) &\xrightarrow{\psi} \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{Y}}) \times_{\mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{Y}})} (\mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{Y}}) \times_{\mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{X}})} \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{X}})) \\ &\simeq \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{Y}}) \times_{\mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{X}})} (\mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{X}}) \times_{\mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{X}})} \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{X}})) \end{aligned}$$

is an isomorphism. We may therefore replace v by the induced map $B \to B \otimes_A B$, and thereby reduce to proving Proposition 1.2.2.12 in the special case where v admits a left inverse $B \to A$. Set $C = B \otimes_A B$, so that ψ can be identified with the canonical map

$$\mathcal{S}\mathrm{ol}_C(\mathscr{O}_{\mathcal{Y}}) \to \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{Y}}) \times_{\mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{X}})} \mathcal{S}\mathrm{ol}_C(\mathscr{O}_{\mathcal{X}}).$$

Our assumption that v is étale guarantees that C factors as a direct product $B \times C'$ in the category $\mathrm{CAlg}_B^{\heartsuit}$. Since both $\mathscr{O}_{\mathcal{Y}}$ and $\mathscr{O}_{\mathcal{X}}$ is local, we can factor ψ as a direct product of maps

$$\psi_0 : \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{Y}}) \to \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{Y}}) \times_{\mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{X}})} \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{X}})$$

$$\psi_1 : \mathcal{S}\mathrm{ol}_{C'}(\mathscr{O}_{\mathcal{Y}}) \to \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{Y}}) \times_{\mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{X}})} \mathcal{S}\mathrm{ol}_{C'}(\mathscr{O}_{\mathcal{X}}).$$

Here the map ψ_0 is obviously an equivalence, and the map ψ_1 is an equivalence by virtue of our inductive hypothesis (note that $\dim_{\kappa(x)}(\kappa(x) \otimes_B C') = \dim_{\kappa(x)}(\kappa(x) \otimes_B C) - 1 < n$ for each $x \in |\operatorname{Spec} B|$). □

Remark 1.2.2.13. In the statement of Proposition 1.2.2.12, we do not need the full strength of our assumption that $\mathscr{O}_{\mathcal{X}}$ is local: for example, if $\mathcal{X}$ has enough points, it is enough to assume that each stalk $\mathscr{O}_{\mathcal{X},x}$ has the property that the Zariski spectrum $|\operatorname{Spec} \mathscr{O}_{\mathcal{X},x}|$ is connected.

Proposition 1.2.2.14. *Let $\mathcal{X}$ be a topos and let $\alpha : \mathscr{O} \to \mathscr{O}'$ be an effective epimorphism between local commutative ring objects of $\mathcal{X}$. If $\mathscr{O}$ is strictly Henselian, then $\mathscr{O}'$ is strictly Henselian.*

Proof. By virtue of Remark 1.2.2.9, it will suffice to show that for every faithfully flat étale morphism $\phi : A \to B$ of commutative rings, the induced map $\rho : \mathcal{S}\mathrm{ol}_B(\mathscr{O}') \to \mathcal{S}\mathrm{ol}_A(\mathscr{O}')$ is an effective epimorphism in $\mathcal{X}$. Using the structure theory of étale morphisms (see Proposition B.1.1.3) we can choose a pushout diagram of commutative rings

$$\begin{array}{ccc} A_0 & \longrightarrow & A \\ \downarrow{\scriptstyle \phi_0} & & \downarrow{\scriptstyle \phi} \\ B_0 & \longrightarrow & B \end{array}$$

where ϕ_0 is étale and $A_0 \simeq \mathbf{Z}[x_1, \ldots, x_n]$ is a polynomial ring over $\mathbf{Z}$. Let $U \subseteq |\operatorname{Spec} A_0|$ denote the (open) image of the map $|\operatorname{Spec} B_0| \to |\operatorname{Spec} A_0|$ and choose elements $\{f_i \in A_0\}_{1 \leqslant i \leqslant m}$ such that $U = \bigcup_{1 \leqslant i \leqslant m} |\operatorname{Spec} A_0[f_i^{-1}]|$. Then the images of f_i in A generate the unit ideal. Since $\mathscr{O}'$ is local, the bottom horizontal map in the diagram

$$\begin{array}{ccc} \coprod_{1 \leqslant i \leqslant m} \mathcal{S}\mathrm{ol}_{B[f_i^{-1}]}(\mathscr{O}') & \longrightarrow & \mathcal{S}\mathrm{ol}_B(\mathscr{O}') \\ \downarrow & & \downarrow{\scriptstyle \rho} \\ \coprod_{1 \leqslant i \leqslant m} \mathcal{S}\mathrm{ol}_{A[f_i^{-1}]}(\mathscr{O}') & \longrightarrow & \mathcal{S}\mathrm{ol}_A(\mathscr{O}') \end{array}$$

is an effective epimorphism. Consequently, to show that ρ is an effective epimorphism, it will suffice to show that each of the induced maps $\mathcal{S}\mathrm{ol}_{B[f_i^{-1}]}(\mathscr{O}') \to \mathcal{S}\mathrm{ol}_{A[f_i^{-1}]}(\mathscr{O}')$ is an effective epimorphism. Using the existence of a pullback square

$$\begin{array}{ccc} \mathcal{S}\mathrm{ol}_{B[f_i^{-1}]}(\mathscr{O}') & \longrightarrow & \mathcal{S}\mathrm{ol}_{A[f_i^{-1}]}(\mathscr{O}') \\ \downarrow & & \downarrow \\ \mathcal{S}\mathrm{ol}_{B_0[f_i^{-1}]}(\mathscr{O}') & \longrightarrow & \mathcal{S}\mathrm{ol}_{A_0[f_i^{-1}]}(\mathscr{O}'), \end{array}$$

we can replace A by $A_0[f_i^{-1}]$ (note that the map $A_0[f_i^{-1}] \to B_0[f_i^{-1}]$ is faithfully flat because $|\operatorname{Spec} A_0[f_i^{-1}]|$ is contained in U).

Consider the diagram

$$\begin{array}{ccccc} \mathcal{S}\mathrm{ol}_B(\mathscr{O}) & \xrightarrow{\overline{\rho}} & \mathcal{S}\mathrm{ol}_A(\mathscr{O}) & \longrightarrow & \mathcal{S}\mathrm{ol}_{A_0}(\mathscr{O}) \\ \downarrow & & \downarrow u & & \downarrow v \\ \mathcal{S}\mathrm{ol}_B(\mathscr{O}') & \xrightarrow{\rho} & \mathcal{S}\mathrm{ol}_A(\mathscr{O}') & \longrightarrow & \mathcal{S}\mathrm{ol}_{A_0}(\mathscr{O}'). \end{array}$$

Since A_0 is isomorphic to the polynomial ring $\mathbf{Z}[x_1, \ldots, x_n]$, we can identify v with the map $\alpha^n : \mathscr{O}^n \to \mathscr{O}'^n$. Our assumption that α is an effective epimorphism now guarantees that v is an effetive epimorphism. Since α is local, the right square in this diagram is a pullback, so that u is also an effective epimorphism. Our assumption that $\mathscr{O}$ is strictly Henselian guarantees that $\overline{\rho}$ is an effective epimorphism. It now follows by inspection of the above diagram that ρ is an effective epimorphism as desired. □

1.2.3 The Étale Spectrum of a Commutative Ring

Let R be a commutative ring and let $\operatorname{Spec} R = (X, \mathscr{O}_X)$ be the associated affine scheme. Then we can regard $\mathscr{O}_X$ as a commutative ring object of the topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(X)$. This commutative ring object is local, but is usually not strictly Henselian. To remedy this, one can replace the Zariski spectrum $\operatorname{Spec} R$ by a slightly more sophisticated object, which we will refer to as the *étale spectrum* of R.

Definition 1.2.3.1 (The Étale Topos of a Commutative Ring)**.** Let R be a commutative ring. We let $\mathrm{CAlg}^{\heartsuit}_R$ denote the category of commutative R-algebras, and $\mathrm{CAlg}^{\text{ét}}_R$ the full subcategory of CAlg_R spanned by the étale R-algebras. The (opposite of) the ∞-category $\mathrm{CAlg}^{\text{ét}}_R$ is equipped with a Grothendieck topology, where a family of maps $\{A \to A_\alpha\}$ generates a covering sieve if and only if there exists some finite collection of indices $\alpha_1, \alpha_2, \ldots, \alpha_n$ such that the map $A \to \prod_{1 \leqslant i \leqslant n} A_{\alpha_i}$ is faithfully flat (this is an immediate consequence of Proposition A.3.2.1). We will refer to this Grothendieck topology as the *étale topology.*

We let $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}^{\text{ét}}_R)$ denote the full subcategory of $\mathrm{Fun}(\mathrm{CAlg}^{\text{ét}}_R, \mathcal{S}\mathrm{et})$ spanned by those functors which are sheaves with respect to the étale topology. We will refer to $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}^{\text{ét}}_R)$ as the *étale topos* of R.

Proposition 1.2.3.2. *Let R be a commutative ring, and let $\mathscr{O} : \mathrm{CAlg}^{\text{ét}}_R \to \mathcal{S}\mathrm{et}$ be the forgetful functor (which assigns to each étale R-algebra A its underlying set). Then $\mathscr{O}$ is a sheaf for the étale topology, and can therefore be identified with a commutative ring object of the topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}^{\text{ét}}_R)$. Moreover, $\mathscr{O}$ is strictly Henselian.*

Proof. The assertion that $\mathscr{O}$ is an étale sheaf is equivalent to the assertion that for every étale R-algebra R' and every faithfully flat étale map $R' \to R''$, the diagram

$$R' \to R'' \rightrightarrows R'' \otimes_{R'} R''$$

is an equalizer in the category of sets (see Proposition A.3.3.1). We now show that $\mathscr{O}$ is strictly Henselian. Suppose we are given a commutative ring A and a faithfully flat étale map $A \to \prod_{1 \leqslant i \leqslant n} A_i$. We wish to show that the induced map $\theta : \coprod_{1 \leqslant i \leqslant n} \mathcal{S}\mathrm{ol}_{A_i}(\mathscr{O}) \to \mathcal{S}\mathrm{ol}_A(\mathscr{O})$ is an epimorphism in the topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}_R^{\text{ét}})$. To prove this, suppose we are given an étale R-algebra R' and a point $\eta \in \mathcal{S}\mathrm{ol}_A(\mathscr{O})(R')$, which we can identify with an algebra homomorphism $A \to R'$. For $1 \leqslant i \leqslant n$, let $R'_i = A_i \otimes_A R'$, and let η_i denote the image of η in $\mathcal{S}\mathrm{ol}_A(\mathscr{O})(R'_i)$. Then $\prod_{1 \leqslant i \leqslant n} R'_i$ is faithfully flat and étale over R, and is therefore generates a covering sieve on the object $R' \in (\mathrm{CAlg}_R^{\text{ét}})^{\mathrm{op}}$. Moreover, each of the points η_i can be lifted to a point $\overline{\eta}_i \in \mathcal{S}\mathrm{ol}_{A_i}(\mathscr{O})(R'_i)$, so that θ is an epimorphism as desired. $\square$

Definition 1.2.3.3. Let R be a commutative ring, and let $\mathscr{O}$ be as in Proposition 1.2.3.2. We will denote the ringed topos $(\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}_R^{\text{ét}}), \mathscr{O})$ by $\mathrm{Spét}\, R$, and refer to it as the *étale spectrum* of the commutative ring R.

If $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is a ringed topos, we let $\Gamma(\mathcal{X}; \mathscr{O}_{\mathcal{X}})$ denote the commutative ring $\mathrm{Hom}_{\mathcal{X}}(\mathbf{1}, \mathscr{O}_{\mathcal{X}})$, where $\mathbf{1}$ denotes a final object of $\mathcal{X}$. We will refer to the construction $(\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \mapsto \Gamma(\mathcal{X}; \mathscr{O}_{\mathcal{X}})$ as the *global sections functor.*.

Proposition 1.2.3.4. *Let $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a ringed topos for which $\mathscr{O}_{\mathcal{X}}$ is strictly Henselian, and let R be a commutative ring. Then the global sections functor induces an equivalence of categories*

$$\mathrm{Map}_{1\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}^\heartsuit}}((\mathcal{X}, \mathscr{O}_{\mathcal{X}}), \mathrm{Spét}\, R) \to \mathrm{Hom}_{\mathrm{CAlg}^\heartsuit}(R, \Gamma(\mathcal{X}; \mathscr{O}_{\mathcal{X}}))$$

(where the set on the right hand side is interpreted as a discrete category, having only identity morphisms).

Corollary 1.2.3.5. *The global sections functor*

$$1\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}^\heartsuit} \to (\mathrm{CAlg}^\heartsuit)^{\mathrm{op}}$$

$$(\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \mapsto \Gamma(\mathcal{X}; \mathscr{O}_{\mathcal{X}})$$

admits a right adjoint, given on objects by $R \mapsto \mathrm{Spét}\, R$.

Remark 1.2.3.6. If R is a commutative ring and $\mathrm{Spét}\, R = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$, then the unit map $R \to \Gamma(\mathcal{X}; \mathscr{O}_{\mathcal{X}})$ is an equivalence. It follows that the construction $R \mapsto \mathrm{Spét}\, R$ determines a fully faithful functor from (the opposite of) the category of commutative rings to the 2-category $1\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}^\heartsuit}$.

In particular, we can regard the construction $R \mapsto \mathrm{Spét}\, R$ as a contravariant functor from the category of commutative rings to the 2-category $1\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}^\heartsuit} \subseteq 1\mathcal{T}\mathrm{op}_{\mathrm{CAlg}^\heartsuit}$.

Remark 1.2.3.7. Let R be a commutative ring, and let $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ denote the étale spectrum $\operatorname{Spét} R$. For every étale R-algebra A, let $h^A : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{S}\mathrm{et}$ denote the functor corepresented by A, which we regard as an object of the topos $\mathcal{X}$. Then there is a canonical equivalence of ringed topoi

$$(\mathcal{X}_{/h^A}, \mathcal{O}_\mathcal{X}|_{h^A}) \simeq \operatorname{Spét} A.$$

This can be deduced either from the universal properties of $\operatorname{Spét} R$ and $\operatorname{Spét} A$ (Proposition 1.2.3.4), or directly from the construction of the étale spectra.

Proof of Proposition 1.2.3.4. Fix a ring homomorphism $\phi : R \to \Gamma(\mathcal{X}; \mathcal{O}_\mathcal{X})$, and let $\mathcal{C}$ denote the fiber product

$$\mathrm{Map}_{1\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}^\heartsuit}}((\mathcal{X}, \mathcal{O}_\mathcal{X}), \operatorname{Spét} R) \times_{\mathrm{Hom}_{\mathrm{CAlg}^\heartsuit}(R, \Gamma(\mathcal{X}; \mathcal{O}_\mathcal{X}))} \{\phi\}.$$

We will show that the category $\mathcal{C}$ is trivial (that is, it is equivalent to the category having a single object and a single morphism).

Write $\operatorname{Spét} R = (\mathcal{Y}, \mathcal{O}_\mathcal{Y})$. Let $\mathbf{1}_\mathcal{X}$ and $\mathbf{1}_\mathcal{Y}$ denote final objects of the topoi $\mathcal{X}$ and $\mathcal{Y}$, respectively. For every étale R-algebra A, let $h^A \in \mathcal{Y} \subseteq \mathrm{Fun}(\mathrm{CAlg}_R^{\text{ét}}, \mathcal{S}\mathrm{et})$ denote the functor corepresented by A, so that h^A fits into a pullback diagram σ_A:

$$\begin{array}{ccc} h^A & \longrightarrow & \mathcal{S}\mathrm{ol}_A(\mathcal{O}_\mathcal{Y}) \\ \downarrow & & \downarrow \\ \mathbf{1}_\mathcal{Y} & \longrightarrow & \mathcal{S}\mathrm{ol}_R(\mathcal{O}_\mathcal{Y}). \end{array}$$

We also define an object $X_A \in \mathcal{X}$ so that we have a pullback diagram τ_A :

$$\begin{array}{ccc} X_A & \longrightarrow & \mathcal{S}\mathrm{ol}_A(\mathcal{O}_\mathcal{X}) \\ \downarrow & & \downarrow \\ \mathbf{1}_\mathcal{X} & \longrightarrow & \mathcal{S}\mathrm{ol}_R(\mathcal{O}_\mathcal{X}), \end{array}$$

where the bottom horizontal map is determined by the ring homomorphism $\phi : R \to \mathrm{Hom}_\mathcal{X}(\mathbf{1}_\mathcal{X}, \mathcal{O}_\mathcal{X})$.

Let $f = (f_*, \alpha)$ be a map of ringed topoi from $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ to $(\mathcal{Y}, \mathcal{O}_\mathcal{Y})$ which induces the ring homomorphism ϕ upon passage to global sections. For every étale R-algebra A, the map α determines a natural transformation of diagrams $f^*\sigma_A \to \tau_A$, which gives in particular a map $\nu_{f,A} : f^* h^A \to X_A$. If (f_*, α) belongs to $\mathcal{C}$, then the maps $\nu_{f,A}$ are isomorphisms (Proposition 1.2.2.12). In particular, if we are given two objects (f_*, α) and (f'_*, α') in $\mathcal{C}$, then for each $A \in \mathrm{CAlg}_R^{\text{ét}}$ there is a unique isomorphism $\theta_A : f^* h^A \simeq f'^* h^A$ for which the

diagram

$$\begin{array}{ccc} f^* h^A & \xrightarrow{\theta_A} & f'^* h^A \\ & {\scriptstyle \nu_{f,A}} \searrow \quad \swarrow {\scriptstyle \nu_{f',A}} & \\ & X_A & \end{array}$$

commutes. In particular, for each $X \in \mathcal{X}$, we have bijections

$$\begin{aligned} (f'_* X)(A) &\simeq \mathrm{Hom}_{\mathcal{Y}}(h^A, f'_* X) \\ &\simeq \mathrm{Hom}_{\mathcal{X}}(f'^* h^A, X) \\ &\simeq \mathrm{Hom}_{\mathcal{X}}(f^* h^A, X) \\ &\simeq \mathrm{Hom}_{\mathcal{Y}}(h^A, f_* X) \\ &\simeq (f_* X)(A). \end{aligned}$$

These bijections depend functorially on X and A, and therefore supply an isomorphism γ between the functors f'_* and f_*. We claim that γ is the unique morphism from (f_*, α) to (f'_*, α') in the category $\mathcal{C}$. Uniqueness is clear from the definition. To prove that γ is a morphism in $\mathcal{C}$, let us abuse notation by identifying γ with the adjoint natural transformation $f^* \to f'^*$; we must show that the diagram

$$\begin{array}{ccc} f^* \mathscr{O}_{\mathcal{Y}} & \xrightarrow{\gamma(\mathscr{O}_{\mathcal{Y}})} & f'^* \mathscr{O}_{\mathcal{Y}} \\ & \searrow \quad \swarrow & \\ & \mathscr{O}_{\mathcal{X}} & \end{array}$$

commutes. Writing $\mathscr{O}_{\mathcal{Y}}$ as a colimit of representable functors, we are reduced to proving that for each map $h^A \to \mathscr{O}_{\mathcal{Y}}$ in the topos $\mathcal{Y}$ (classified by an element $a \in A$), the diagram

$$\begin{array}{ccc} f^* h^A & \xrightarrow{\gamma(h^A)} & f'^* h^A \\ \downarrow & & \downarrow \\ f^* \mathscr{O}_{\mathcal{Y}} & & f'^* \mathscr{O}_{\mathcal{Y}} \\ & \searrow \quad \swarrow & \\ & \mathscr{O}_{\mathcal{X}} & \end{array}$$

commutes. This is because the vertical compositions can be identified (using the maps $\nu_{f,A}$ and $\nu_{f',A}$) with the composite map $X_A \hookrightarrow \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{X}}) \xrightarrow{a} \mathscr{O}_{\mathcal{X}}$.

It follows from the above argument that for every pair of objects $C, C' \in \mathcal{C}$, the set $\mathrm{Hom}_{\mathcal{C}}(C, C')$ contains a unique element (which is also an isomorphism in $\mathcal{C}$). To complete the proof, it will suffice to show that the category $\mathcal{C}$ is nonempty. To this end, we define a functor $f_* : \mathcal{X} \to \mathrm{Fun}(\mathrm{CAlg}^{\text{ét}}_R, \mathcal{S}\mathrm{et})$ by the formula $f_*(X)(A) = \mathrm{Hom}_{\mathcal{X}}(X_A, X)$. The assumption that $\mathscr{O}_{\mathcal{X}}$ is strictly Henselian implies that f_* factors through the full subcategory $\mathcal{Y} \subseteq \mathrm{Fun}(\mathrm{CAlg}^{\text{ét}}_R, \mathcal{S}\mathrm{et})$. We claim that f_* is a geometric morphism of topoi: that is, it admits a left adjoint f^* which commutes with finite limits. The existence of a left adjoint f^* follows from the adjoint functor theorem (since f_* is an accessible functor which preserves small limits). By construction, we have a canonical isomorphism $f^* h^A \simeq X_A$ for each $A \in \mathrm{CAlg}^{\text{ét}}_R$. To prove that f^* preserves finite limits, it suffices to show that the construction $A \mapsto f^* h^A \simeq X_A$ carries finite colimits in $\mathrm{CAlg}^{\text{ét}}_A$ to finite limits in $\mathcal{X}$ (see Lemma HTT.6.4.5.6), which follows immediately from the construction.

Unwinding the definitions, we obtain for each $A \in \mathrm{CAlg}^{\text{ét}}_R$ a canonical ring homomorphism

$$A \to \mathrm{Hom}_{\mathcal{X}}(\mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{X}}), \mathscr{O}_{\mathcal{X}}) \to \mathrm{Hom}_{\mathcal{X}}(X_A, \mathscr{O}_{\mathcal{X}}) = (f_* \mathscr{O}_{\mathcal{X}})(A).$$

These ring homomorphisms depend functorially on R, and therefore give rise to a homomorphism $\alpha : \mathscr{O}_{\mathcal{Y}} \to f_* \mathscr{O}_{\mathcal{X}}$ of commutative ring objects of $\mathcal{Y}$. We may therefore regard (f_*, α) as a map of ringed topoi from $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ to $\mathrm{Spét}\, R$. It is clear from the construction that the induced ring homomorphism $R \simeq \Gamma(\mathcal{Y}; \mathscr{O}_{\mathcal{Y}}) \to \Gamma(\mathcal{X}; \mathscr{O}_{\mathcal{X}})$ coincides with ϕ. To complete the proof that (f_*, α) is an object of the category $\mathcal{C}$, it will suffice to show that the underlying map $f^* \mathscr{O}_{\mathcal{Y}} \to \mathscr{O}_{\mathcal{X}}$ is local. To prove this, fix an object $X \in \mathcal{X}$ and an element ζ of the commutative ring $\mathrm{Hom}_{\mathcal{X}}(X, f^* \mathscr{O}_{\mathcal{Y}})$; we wish to show that if the image of ζ in $\mathrm{Hom}_{\mathcal{X}}(X, \mathscr{O}_{\mathcal{X}})$ is invertible, then ζ is invertible. This assertion can be tested locally on X: we may therefore assume that the map ζ factors as a composition

$$X \xrightarrow{\zeta_0} X_A \simeq f^* h^A \xrightarrow{f^* \zeta_1} f^* \mathscr{O}_{\mathcal{Y}},$$

for some étale R-algebra A. In this case, we can identify ζ_1 with an element $a \in A$ and ζ_0 with a map of R-algebras $\phi_X : A \to \mathrm{Hom}_{\mathcal{X}}(X, \mathscr{O}_{\mathcal{X}})$, in which case the image of ζ in $\mathrm{Hom}_{\mathcal{X}}(X, \mathscr{O}_{\mathcal{X}})$ can be identified with $\phi_X(r)$. If this element of $\mathrm{Hom}_{\mathcal{X}}(X, \mathscr{O}_{\mathcal{X}})$ is invertible, then ϕ_X extends to an R-algebra homomorphism $\overline{\phi}_X : A[a^{-1}] \to \mathrm{Hom}_{\mathcal{X}}(X, \mathscr{O}_{\mathcal{X}})$. In this case, ζ_0 factors through the subobject $X_{A[a^{-1}]} \subseteq X_A$. We are therefore reduced to proving that the composite map $X_{A[a^{-1}]} \to X_A \simeq f^* h^A \xrightarrow{f^* \zeta_1} f^* \mathscr{O}_{\mathcal{Y}}$ determines an invertible element $\overline{r}$ of the commutative ring

$$\mathrm{Hom}_{\mathcal{X}}(X_{A[a^{-1}]}, f^* \mathscr{O}_{\mathcal{Y}}) \simeq \mathrm{Hom}_{\mathcal{Y}}(h^{A[a^{-1}]}, f_* f^* \mathscr{O}_{\mathcal{Y}}) \simeq (f_* f^* \mathscr{O}_{\mathcal{Y}})(A[a^{-1}]).$$

This is clear, since $\overline{r}$ is the image of r under the composite map

$$A \to A[a^{-1}] = \mathscr{O}_{\mathcal{Y}}(A[a^{-1}]) \to (f_* f^* \mathscr{O}_{\mathcal{Y}})(A[a^{-1}]).$$

□

1.2.4 Deligne-Mumford Stacks as Ringed Topoi

By definition, a scheme is a ringed space $(X, \mathcal{O}_X)$ which is locally isomorphic to the Zariski spectrum $\operatorname{Spec} R$ of a commutative ring R. We now consider an analogous definition, replacing the Zariski spectrum $\operatorname{Spec} R$ by the étale spectrum $\operatorname{Sp\acute{e}t} R$ of Definition 1.2.3.3.

Definition 1.2.4.1. Let $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ be a ringed topos. We will say that $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ is a *Deligne-Mumford stack* if there exists a collection of objects $U_\alpha \in \mathcal{X}$ satisfying the following conditions:

(1) The objects U_α cover $\mathcal{X}$. That is, the natural map $\amalg_\alpha U_\alpha \to \mathbf{1}$ is an epimorphism in $\mathcal{X}$, where $\mathbf{1}$ denotes the final object of $\mathcal{X}$.

(2) For each index α, the ringed topos $(\mathcal{X}_{/U_\alpha}, \mathcal{O}_\mathcal{X}|_{U_\alpha})$ is equivalent (in the 2-category $1\mathcal{T}\mathrm{op}_{\mathrm{CAlg}^\heartsuit}$) to a ringed topos of the form $\operatorname{Sp\acute{e}t} R_\alpha$, where R_α is a commutative ring.

Note that conditions (1) and (2) imply that $\mathcal{O}_\mathcal{X}$ is strictly Henselian. We let DM denote the full subcategory of $1\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}^\heartsuit}$ spanned by those ringed topoi $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ which are Deligne-Mumford stacks.

Definition 1.2.4.2. Let $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ be a Deligne-Mumford stack. We will say that $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ is *affine* if it is equivalent to $\operatorname{Sp\acute{e}t} R$ for some commutative ring R. We will say that an object $U \in \mathcal{X}$ is *affine* if the ringed topos $(\mathcal{X}_{/U}, \mathcal{O}_\mathcal{X}|_U)$ is affine.

Remark 1.2.4.3. Let $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ be a Deligne-Mumford stack. Then $\mathcal{X}$ is generated by affine objects. That is, for every object $X \in \mathcal{X}$, there exists an effective epimorphism $\amalg U_\alpha \to X$, where each U_α is affine. This assertion can be tested locally on $\mathcal{X}$: we may therefore assume without loss of generality that $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ is affine, in which case the desired result follows from Remark 1.2.3.7.

Remark 1.2.4.4. Let $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ be a ringed topos. Then $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ is a Deligne-Mumford stack if and only if, for each object $X \in \mathcal{X}$, there exists an effective epimorphism $\amalg U_\alpha \to X$ where each of the ringed topoi $(\mathcal{X}_{/U_\alpha}, \mathcal{O}_\mathcal{X}|_{U_\alpha})$ is an affine Deligne-Mumford stack. The "only if" direction follows immediately from the definition, and the "if" direction follows from Remark 1.2.4.3.

Remark 1.2.4.5. Let $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ be a ringed topos. The condition that $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ be a Deligne-Mumford stack can be tested locally on $\mathcal{X}$. More precisely:

(*i*) If $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ is a Deligne-Mumford stack, then any ringed topos of the form $(\mathcal{X}_{/U}, \mathcal{O}_\mathcal{X}|_U)$ is a Deligne-Mumford stack.

(*ii*) If the topos $\mathcal{X}$ admits a covering by objects U_α such that each of the ringed topoi $(\mathcal{X}_{/U_\alpha}, \mathcal{O}_\mathcal{X}|_{U_\alpha})$ is a Deligne-Mumford stack, then $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ is a Deligne-Mumford stack.

Both of these assertions follow immediately from the characterization of Deligne-Mumford stacks supplied by Remark 1.2.4.4.

Proposition 1.2.4.6. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a Deligne-Mumford stack. Then the collection of affine objects of $\mathcal{X}$ is closed under fiber products.*

Proof. For each object $U \in \mathcal{X}$, let X_U denote the Deligne-Mumford stack $(\mathcal{X}_{/U}, \mathscr{O}_{\mathcal{X}}|_U)$. The functor $R \mapsto \operatorname{Spét} R$ determines a fully faithful embedding $(\mathrm{CAlg}^{\heartsuit})^{\mathrm{op}} \to \mathrm{DM}$ which preserves small limits (since it is a right adjoint), so that its essential image is closed under small limits. The desired result now follows from the observation that the construction $U \mapsto \mathsf{X}_U$ determines a functor from $\mathcal{X}$ to DM which preserves fiber products. □

Proposition 1.2.4.7. *Let $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ and $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ be ringed topoi. If $\mathscr{O}_{\mathcal{X}}$ is strictly Henselian and $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ is a Deligne-Mumford stack, then the category $\mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}^{\heartsuit}}}((\mathcal{X}, \mathscr{O}_{\mathcal{X}}), (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}))$ is a groupoid.*

Proof. Let (f_*, α) and (f'_*, α') be maps from $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ to $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ in $1\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}^{\heartsuit}}$, and let γ be a morphism from (f_*, α) to (f'_*, α'). Let us identify γ with a natural transformation from f^* to f'^*. We wish to prove that γ is an isomorphism. Fix a covering of $\mathcal{Y}$ by objects $\{U_\beta\}_{\beta \in I}$ such that each $(\mathcal{Y}_{/U_\beta}, \mathscr{O}_{\mathcal{Y}}|_{U_\beta})$ is equivalent to $\operatorname{Spét} R_\beta$ for some commutative ring R_β. Then the objects $f'^* U_\beta$ cover the topos $\mathcal{X}$. The assertion that γ is an isomorphism can be tested locally on $\mathcal{X}$; we may therefore replace $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ by ringed topoi of the form $(\mathcal{X}_{/f^* U_\beta}, \mathscr{O}_{\mathcal{X}}|_{f^* U_\beta})$ and thereby reduce to the case where there exists a map $u : \mathbf{1}_{\mathcal{X}} \to f^* U_\beta$ in the topos $\mathcal{X}$, for some index β. In this case, the map u (and the induced map $u' : \mathbf{1}_{\mathcal{X}} \to f'^* U_\beta$) determine factorizations of f and f' through the ringed topos $(\mathcal{Y}_{/U_\beta}, \mathscr{O}_{\mathcal{Y}}|_{U_\beta})$. We may therefore reduce to the case where $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}) \simeq \operatorname{Spét} R_\beta$ is affine, in which case the desired result follows from Proposition 1.2.3.4. □

Corollary 1.2.4.8. *The 2-category* DM *of Deligne-Mumford stacks is a $(2,1)$-category. In other words, every 2-morphism in* DM *is invertible.*

Remark 1.2.4.9. Let $\mathcal{C}$ denote the simplicial category whose objects are Deligne-Mumford stacks $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$, with morphism spaces given by

$$\mathrm{Map}_{\mathcal{C}}((\mathcal{X}, \mathscr{O}_{\mathcal{X}}), (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})) = \mathrm{N}(\mathrm{Map}_{\mathrm{DM}}((\mathcal{X}, \mathscr{O}_{\mathcal{X}}), (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}))).$$

It follows from Corollary 1.2.4.8 that $\mathcal{C}$ is a fibrant simplicial category, so that its homotopy coherent nerve $\mathrm{N}(\mathcal{C})$ is an ∞-category. We will denote this ∞-category by N(DM), and refer to it as the *∞-category of Deligne-Mumford stacks.*

1.2.5 Deligne-Mumford Stacks as Functors

We now compare Definition 1.2.4.1 with the more traditional "functor-of-points" approach to the theory of Deligne-Mumford stacks.

Notation 1.2.5.1. Let $\tau_{\leqslant 1}\mathcal{S}$ denote the ∞-category of 1-truncated spaces (in other words, the ∞-category of groupoids). Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a Deligne-Mumford stack. We define a functor $h_{\mathsf{X}} : \mathrm{CAlg}^{\heartsuit} \to \tau_{\leqslant 1}\mathcal{S}$ by the formula $h_{\mathsf{X}}(R) = \mathrm{Map}_{1\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}^{\heartsuit}}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{X})$. We will refer to h_{X} as the *functor of points* of X.

Proposition 1.2.5.2. *The construction* $\mathsf{X} \mapsto h_{\mathsf{X}}$ *determines a fully faithful embedding of* ∞*-categories* $\mathrm{N}(\mathrm{DM}) \to \mathrm{Fun}(\mathrm{CAlg}^{\heartsuit}, \tau_{\leqslant 1}\mathcal{S})$.

Proof of Proposition 1.2.5.2. Let X and Y be Deligne-Mumford stacks. Write $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$. For each object $U \in \mathcal{X}$, set $\mathsf{X}_U = (\mathcal{X}_{/U}, \mathscr{O}_{\mathcal{X}}|_U)$ and consider the canonical map

$$\theta_U : \mathrm{Map}_{\mathrm{N}(\mathrm{DM})}(\mathsf{X}_U, \mathsf{Y}) \to \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\heartsuit}, \tau_{\leqslant 1}\mathcal{S})}(h_{\mathsf{X}_U}, h_{\mathsf{Y}}).$$

Let us say that an object $U \in \mathcal{X}$ is *good* if θ_U is a homotopy equivalence. We wish to show that the final object of $\mathcal{X}$ is good. In fact, we will show that every object of $\mathcal{X}$ is good. The proof proceeds in several steps:

(*i*) The construction $U \mapsto \theta_U$ carries coproducts in $\mathcal{X}$ to products. Consequently, the collection of good objects of $\mathcal{X}$ is closed under small coproducts.

(*ii*) Suppose that $f : U_0 \to X$ is an effective epimorphism of $\mathcal{X}$, and let $U_\bullet$ denote its Čech nerve. Then θ_X can be identified with the totalization of the cosimplicial object $\theta_{U_\bullet}$ in $\mathrm{Fun}(\Delta^1, \mathcal{S})$. Consequently, if each of the objects U_m is good, then X is good.

(*iii*) Every affine object of $\mathcal{X}$ is good (this follows from Yoneda's lemma).

(*iv*) Let $f : X \to Y$ be a monomorphism in $\mathcal{X}$. If Y is affine, then X is good. To prove this, choose an effective epimorphism $g : U_0 \to X$, where U_0 is a coproduct of affine objects U_α (see Remark 1.2.4.3). Let $U_\bullet$ be the Čech nerve of g. By virtue of (*ii*), it will suffice to show that each U_m is good. Using (*i*), we are reduced to showing that each fiber product $U_{\alpha_0} \times_X \cdots \times_X U_{\alpha_m}$ is good. Since f is a monomorphism, we have an equivalence

$$U_{\alpha_0} \times_X \cdots \times_X U_{\alpha_m} \simeq U_{\alpha_0} \times_Y \cdots \times_Y U_{\alpha_m}.$$

It follows from Proposition 1.2.4.6 that this object is affine, so that the desired result follows from (*iii*).

(*v*) Let $f : X \to Y$ be an arbitrary morphism in $\mathcal{X}$. If Y is affine, then X is good. To prove this, choose an effective epimorphism $g : U_0 \to X$, where U_0 is a coproduct of affine objects U_α (see Remark 1.2.4.3). Let $U_\bullet$ be the Čech nerve of g. By virtue of (*ii*), it will suffice to show that each U_m is good. Using (*i*), we are reduced to showing that each fiber product $U_{\alpha_0} \times_X \cdots \times_X U_{\alpha_m}$ is good. This follows from (*iv*), since there exists a monomorphism

$$U_{\alpha_0} \times_X \cdots \times_X U_{\alpha_m} \hookrightarrow U_{\alpha_0} \times_Y \cdots \times_Y U_{\alpha_m}$$

whose codomain is affine by virtue of Proposition 1.2.4.6.

(*vi*) Every object $X \in \mathcal{X}$ is good. To prove this, choose an effective epimorphism $g : U_0 \to X$, where U_0 is a coproduct of affine objects U_α (see Remark 1.2.4.3). Let $U_\bullet$ be the Čech nerve of g. By virtue of (*ii*), it will suffice to show that each U_m is good. Using (*i*), we are reduced to showing that each fiber product $U_{\alpha_0} \times_X \cdots \times_X U_{\alpha_m}$ is good. This follows from (*v*), since the projection map $U_{\alpha_0} \times_X \cdots \times_X U_{\alpha_m} \to U_{\alpha_0}$ has affine codomain.

□

For the remainder of this section, we will abuse notation by not distinguishing between a Deligne-Mumford stack and its image under the fully faithful embedding of Proposition 1.2.5.2 (in other words, we will identify a Deligne-Mumford stack $\mathsf{X} = (\mathcal{X}, \mathcal{O}_\mathcal{X})$ with the functor h_X).

Definition 1.2.5.3. Let R be a commutative ring and write $\operatorname{Spét} R = (\mathcal{X}, \mathcal{O}_\mathcal{X})$. For each object $U \in \mathcal{X} = \mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}_R^{\text{ét}})$, we let $\operatorname{Spét}_U R$ denote the ringed topos $(\mathcal{X}_{/U}, \mathcal{O}_\mathcal{X}|_U)$. Then $\operatorname{Spét}_U R$ is a Deligne-Mumford stack equipped with a canonical map $\operatorname{Spét}_U R \to \operatorname{Spét} R$.

If $f : X \to Y$ is an arbitrary morphism in $\mathrm{Fun}(\mathrm{CAlg}^\heartsuit, \tau_{\leqslant 1} \mathcal{S})$, we will say that f is *representable and étale* if, for every commutative ring R and every point $\eta \in Y(R)$, the fiber product $\operatorname{Spét} R \times_Y X$ is equivalent to $\operatorname{Spét}_U(R)$, for some object $U \in \mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}_R^{\text{ét}})$.

Remark 1.2.5.4. In the situation of Definition 1.2.5.3, a map $f : X \to Y$ is representable and étale if and only if, for each point $\eta \in Y(R)$, the fiber product $\operatorname{Spét} R \times_Y X$ is representable by an algebraic space which is étale over $\operatorname{Spét} R$. The veracity of this assertion requires that we adopt a slightly more general definition of algebraic space than the one given in [117].

Suppose that $X = \operatorname{Spét}_U(R)$ for some sheaf $U \in \mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}_R^{\text{ét}})$. Choosing a set of sections $\eta_\alpha \in U(R_\alpha)$ which generate U, we obtain an effective epimorphism $\amalg \operatorname{Spét} R_\alpha \to X$ in the category of étale sheaves on (the opposite of) the category $\mathrm{CAlg}_R^{\text{ét}}$. However, the maps $v_\alpha : \operatorname{Spét} R_\alpha \to X$ need not be relatively representable by schemes. Nevertheless, the maps v_α are relatively representable in the special case where there exists a monomorphism

$X \hookrightarrow \operatorname{Sp\acute{e}t} A$, for some étale R-algebra A. In this case, each fiber product $\operatorname{Sp\acute{e}t} B \times_X \operatorname{Sp\acute{e}t} R_\alpha$ can be identified with the functor corepresented by $B \otimes_A R_\alpha$.

In the general case, each fiber product $X_{\alpha,\beta} = \operatorname{Sp\acute{e}t} R_\alpha \times_X \operatorname{Sp\acute{e}t} R_\beta$ is again étale over $\operatorname{Sp\acute{e}t} R$ (in the sense of Definition 1.2.5.3), and admits a monomorphism

$$X_{\alpha,\beta} \hookrightarrow \operatorname{Sp\acute{e}t} R_\alpha \times_{\operatorname{Sp\acute{e}t} R} \operatorname{Sp\acute{e}t} R_\beta \simeq \operatorname{Sp\acute{e}t}(R_\alpha \otimes_R R_\beta).$$

It follows that each $X_{\alpha,\beta}$ is a representable by an algebraic space in the sense of [117], so that the maps $v_\alpha : \operatorname{Sp\acute{e}t} R_\alpha \to X$ are relatively representable by algebraic spaces.

Remark 1.2.5.5. Let $Y = (\mathcal{Y}, \mathcal{O}_\mathcal{Y})$ be a Deligne-Mumford stack, and suppose we are given a morphism $f : X \to Y$ in $\operatorname{Fun}(\mathrm{CAlg}^\heartsuit, \tau_{\leqslant 1} \mathcal{S})$. Assume further that X is a sheaf for the étale topology. Then the following conditions are equivalent:

(1) The functor X is equivalent (as an object of the ∞-category $\operatorname{Fun}(\mathrm{CAlg}^\heartsuit, \tau_{\leqslant 1} \mathcal{S})_{/Y}$) to a Deligne-Mumford stack of the form $(\mathcal{Y}_{/U}, \mathcal{O}_\mathcal{Y}|_U)$ for some object $U \in \mathcal{Y}$.

(2) The map f is representable and étale (in the sense of Definition 1.2.5.3).

The implication (1) $\Rightarrow$ (2) follows immediately from the definitions. The converse follows by using (2) to construct the object $U \in \mathcal{Y}$ locally, and then invoking the assumption that $\mathcal{X}$ is an étale sheaf.

Remark 1.2.5.6. Let $f : X \to Y$ be a morphism in $\operatorname{Fun}(\mathrm{CAlg}^\heartsuit, \tau_{\leqslant 1} \mathcal{S})$, and suppose that both X and Y are sheaves for the étale topology. Then f is étale and representable if and only if, for every Deligne-Mumford stack $Z = (\mathcal{Z}, \mathcal{O}_\mathcal{Z})$ equipped with a map $Z \to Y$, the fiber product $Z \times_Y X$ is equivalent to to $(\mathcal{Z}_{/U}, \mathcal{O}_\mathcal{Z}|_U)$ for some object $U \in \mathcal{Z}$. The "if" direction is obvious, and the converse follows from Remark 1.2.5.5. It follows from this characterization that the collection of representable étale morphisms (between étale sheaves) is closed under composition.

Proposition 1.2.5.7. *Let $\phi : A \to B$ be a homomorphism of commutative rings. The following conditions are equivalent:*

(1) *The ring homomorphism ϕ is étale (see §B.1).*

(2) *The induced map of Deligne-Mumford stacks* $\operatorname{Sp\acute{e}t} B \to \operatorname{Sp\acute{e}t} A$ *is representable and étale (here we abuse terminology by identifying* $\operatorname{Sp\acute{e}t} A$ *and* $\operatorname{Sp\acute{e}t} B$ *with the functors they represent).*

In other words, if A is a commutative ring, then an object $U \in \mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}^{\acute{e}t}_A)$ is affine if and only if U is corepresentable by an étale A-algebra B.

Proof. The implication (1) $\Rightarrow$ (2) follows immediately from the construction of $\operatorname{Sp\acute{e}t} B$. Conversely, suppose that (2) is satisfied. Write $\operatorname{Sp\acute{e}t} A = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$, so that $\operatorname{Sp\acute{e}t} B \simeq (\mathcal{X}_{/U}, \mathcal{O}_{\mathcal{X}}|_U)$ for some object $U \in \mathcal{X}$. For each étale A-algebra A', let $h^{A'} \in \mathcal{X}$ denote the functor corepresented by A'. The objects $h^{A'}$ generate the topos $\mathcal{X}$ under colimits. We may therefore choose a collection of étale A-algebras $\{A_\alpha\}_{\alpha \in I}$ and an effective epimorphism $\coprod_{\alpha \in I} h^{A_\alpha} \to U$ in $\mathcal{X}$. Under the identification of $\mathcal{X}_{/U}$ with $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}_B^{\acute{e}t})$, we can identify each h^{A_α} with an object $V_\alpha \in \mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}_B^{\acute{e}t})$. These objects cover the topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}_B^{\acute{e}t})$. We may therefore choose a finite collection of indices $\alpha_1, \alpha_2, \ldots, \alpha_n$ and a faithfully flat étale map $B \to \prod_{1 \leqslant i \leqslant n} B_i$ such that each $V_{\alpha_i}(B_i)$ is nonempty. Set $A' = \prod_{1 \leqslant i \leqslant n} A_{\alpha_i}$ and $B' = \prod B_i$, so that we morphisms of Deligne-Mumford stacks

$$\operatorname{Sp\acute{e}t} B' \to \operatorname{Sp\acute{e}t} A' \to \operatorname{Sp\acute{e}t} B \to \operatorname{Sp\acute{e}t} A,$$

induced by a sequence of ring homomorphisms $A \xrightarrow{\phi} B \to A' \to B'$. It follows that B' is a retract of $A' \otimes_B B'$ in the category of A-algebras. Since B' is étale over B and A' is étale over A, $A' \otimes_B B'$ is étale over A, so that B' is étale over A. Since the map $B \to B'$ is étale and faithfully flat, we conclude that B is also étale over A (see Proposition B.1.4.1). $\square$

Definition 1.2.5.8. Let $f_\alpha : X_\alpha \to Y$ be a collection of representable étale morphisms in the ∞-category $\mathrm{Fun}(\mathrm{CAlg}^{\heartsuit}, \tau_{\leqslant 1} \mathcal{S})$. We will say that the set $\{f_\alpha\}$ is *jointly surjective* if, for every commutative ring R and every point $\eta \in Y(R)$, if we write $\operatorname{Sp\acute{e}t} R \times_Y X_\alpha$ as $\operatorname{Sp\acute{e}t}_{U_\alpha} R$ for some $U_\alpha \in \mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}_R^{\acute{e}t})$, then the objects U_α comprise a covering of the topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}_R^{\acute{e}t})$.

We will say that a single representable étale morphism $f : X \to Y$ is *surjective* if the set $\{f\}$ is jointly surjective.

Remark 1.2.5.5 admits the following converse:

Theorem 1.2.5.9. *Let $X : \mathrm{CAlg}^{\heartsuit} \to \mathcal{S}_{\leqslant 1}$ be a functor. The following conditions are equivalent:*

(1) *The functor X is (representable by) a Deligne-Mumford stack.*

(2) *The functor X is a sheaf for the étale topology, and there exists a jointly surjective collection of representable étale morphisms $f_\alpha : U_\alpha \to X$, where each U_α is (representable by) an affine Deligne-Mumford stack* $\operatorname{Sp\acute{e}t} R_\alpha$.

(3) *The functor X is a sheaf for the étale topology, and there exists a jointly surjective collection of representable étale morphisms $f_\alpha : U_\alpha \to X$, where each U_α is (representable by) a Deligne-Mumford stack.*

(4) *The functor X is a sheaf for the étale topology, and there exists a representable étale surjection $f : U_0 \to X$, where U_0 is (representable by) a Deligne-Mumford stack.*

Example 1.2.5.10. Let $X : \mathrm{CAlg}^{\heartsuit} \to \mathcal{S}\mathrm{et}$ be a functor which is representable by a scheme. Then X satisfies condition (2) of Theorem 1.2.5.9 (in fact, we can take the maps $u_\alpha : \operatorname{Spec} R_\alpha \to X$ to be any open covering of X by affine schemes). Theorem 1.2.5.9 implies that the essential image of the functor $\mathrm{N}(\mathrm{DM}) \hookrightarrow \mathrm{Fun}(\mathrm{CAlg}^{\heartsuit}, \tau_{\leqslant 1}\mathcal{S})$ includes all functors which are representable by schemes. We therefore obtain a fully faithful embedding from the category Sch of schemes to the 2-category DM of Deligne-Mumford stacks, given on affine schemes by $\operatorname{Spec} R \mapsto \operatorname{Sp\acute{e}t} R$. Note that this embedding is *not* given by the formula $(X, \mathscr{O}_X) \mapsto (\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(X), \mathscr{O}_X)$, because the structure sheaf of a scheme is usually not strictly Henselian. Instead, the Deligne-Mumford stack associated to a scheme $(X, \mathscr{O}_X)$ can be viewed as the classifying topos for strict Henselizations of $\mathscr{O}_X$: see §1.6 for more details).

Proof of Theorem 1.2.5.9. Let $X : \mathrm{CAlg}^{\heartsuit} \to \tau_{\leqslant 1}\mathcal{S}$ be the functor represented by a Deligne-Mumford stack $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$. Fix a commutative ring A and write $\operatorname{Sp\acute{e}t} A = (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$. For every étale A-algebra A', let $h^{A'} \in \mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}_A^{\mathrm{\acute{e}t}})$ denote the functor corepresented by A'. Then the restriction of X to $\mathrm{CAlg}_A^{\mathrm{\acute{e}t}}$ is given by the formula

$$X(A') = \mathrm{Map}_{\mathrm{DM}}((\mathcal{Y}_{/h^{A'}}, \mathscr{O}_{\mathcal{Y}}|_{h^{A'}}), (\mathcal{X}, \mathscr{O}_{\mathcal{X}}),$$

from which it follows easily that the restriction of X to $\mathrm{CAlg}_A^{\mathrm{\acute{e}t}}$ is an étale sheaf. It follows that X is a sheaf for the étale topology, so that the implication (1) ⇒ (2) follows immediately from the definition of Deligne-Mumford stack.

The implication (2) ⇒ (3) is trivial, and the implication (3) ⇒ (4) follows by taking U_0 to be the coproduct of the U_α (in the 2-category of Deligne-Mumford stacks). We will complete the proof by showing that (4) ⇒ (1). Let U_0 be a functor which is representable by a Deligne-Mumford stack $(\mathcal{U}_0, \mathscr{O}_{\mathcal{U}_0})$, let $f : U_0 \to X$ be a representable étale surjection, and let $U_\bullet$ be the Čech nerve of f (formed in the ∞-category $\mathrm{Fun}(\mathrm{CAlg}^{\heartsuit}, \tau_{\leqslant 1}\mathcal{S})$). Since f is an effective epimorphism of étale sheaves, we can identify X with the geometric realization of $U_\bullet$ in the ∞-category of $\tau_{\leqslant 1}\mathcal{S}$-valued étale sheaves on $\mathrm{CAlg}^{\heartsuit}$. Each U_m admits a representable étale map to U_0, and is therefore representable by a Deligne-Mumford stack $(\mathcal{U}_m, \mathscr{O}_{\mathcal{U}_m})$. We can view $\mathcal{U}_\bullet$ as a simplicial object in the 2-category of Grothendieck topoi; let $\mathcal{X}$ denote its geometric realization (so that the objects of $\mathcal{X}$ can be identified with sequences $\{X_m \in \mathcal{U}_m\}_{m \geqslant 0}$ which are compatible with one another under pullback). Since each of the maps $U_m \to U_n$ is étale, the collection of structure sheaves $\{\mathscr{O}_{\mathcal{U}_m}\}_{m \geqslant 0}$ can be identified with a commutative ring object $\mathscr{O}_{\mathcal{X}} \in \mathcal{X}$.

For each integer m, the inclusion $[m] \hookrightarrow [m+1]$ determines a representable étale surjection map $U_{m+1} \to U_m$. We may therefore choose an object $V_m \in \mathcal{U}_m$ and an equivalence

$$(\mathcal{U}_{m+1}, \mathscr{O}_{\mathcal{U}_{m+1}}) \simeq (\mathcal{U}_{m/V_m}, \mathscr{O}_{\mathcal{U}_m}|_{V_m}).$$

The objects V_m are compatible under pullback, and therefore determine an object V of the topos $\mathcal{X}$. Since each V_m covers the final object of $\mathcal{U}_m$, the object V covers the final object of

$\mathcal{X}$. Moreover, we can identify $(\mathcal{X}_{/V}, \mathscr{O}_{\mathcal{X}}|_V)$ with the geometric realization of the simplicial ringed topos

$$(\mathcal{U}_{\bullet/V_\bullet}, \mathscr{O}_{\mathcal{U}_\bullet}|_{V_\bullet}) \simeq (\mathcal{U}_{\bullet+1}, \mathscr{O}_{\mathcal{U}_{\bullet+1}}),$$

which is equivalent to $(\mathcal{U}_0, \mathscr{O}_{\mathcal{U}_0})$. It follows from Remark 1.2.4.4 that $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is a Deligne-Mumford stack. Let $X' : \mathrm{CAlg}^{\heartsuit} \to \tau_{\leqslant 1}\mathcal{S}$ denote the functor represented by $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$. Let $f' : U_0 \to X'$ be the canonical map. The natural isomorphism $f^*V \simeq V_0$ shows that $U_\bullet$ is the Čech nerve of the map f', so that f' factors as a composition

$$U_0 \xrightarrow{f} |U_\bullet| \simeq X \xrightarrow{g} X',$$

where g is a monomorphism. To complete the proof, it will suffice to show that f' is an epimorphism of étale sheaves. This follows from the observation that V covers the final object of the topos $\mathcal{X}$. □

1.2.6 Quasi-Coherent Sheaves on a Deligne-Mumford Stack

We close this section with a brief discussion of quasi-coherent sheaves on a Deligne-Mumford stack, which will play a role in §1.4:

Definition 1.2.6.1. Let $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a Deligne-Mumford stack, and let $\mathscr{F}$ be a $\mathscr{O}_{\mathcal{X}}$-module object of $\mathcal{X}$. For each object $U \in \mathcal{X}$, we let $\mathscr{O}_{\mathcal{X}}(U)$ denote the commutative ring $\mathrm{Hom}_{\mathcal{X}}(U, \mathscr{O}_{\mathcal{X}})$, and $\mathscr{F}(U)$ the module $\mathrm{Hom}_{\mathcal{X}}(U, \mathscr{F})$. We will say that $\mathscr{F}$ is *quasi-coherent* if the following condition is satisfied:

(∗) For every morphism $U \to V$ between affine object of $\mathcal{X}$, the induced map

$$\mathscr{O}_{\mathcal{X}}(U) \otimes_{\mathscr{O}_{\mathcal{X}}(V)} \mathscr{F}(V) \to \mathscr{F}(U)$$

is an isomorphism of modules over the commutative ring $\mathscr{O}_{\mathcal{X}}(U)$.

Example 1.2.6.2. Let A be a commutative ring and let write $\mathrm{Spét}\, A = (\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}_A^{\text{ét}}), \mathscr{O})$. Proposition 1.2.5.7 implies that a $\mathscr{O}$-module $\mathscr{F}$ in $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}_A^{\text{ét}})$ is quasi-coherent if and only if, for every morphism $B \to C$ of étale A-algebras, the induced map $C \otimes_B \mathscr{F}(B) \to \mathscr{F}(C)$ is an equivalence. In other words, $\mathscr{F}$ is quasi-coherent if and only if there exists a (discrete) A-module M for which $\mathscr{F}$ is given by the formula $\mathscr{F}(B) = B \otimes_A M$. Conversely, for any discrete A-module M, the theory of faithfully flat descent implies that the construction $B \mapsto B \otimes_A M$ determines a sheaf for the étale topology on $\mathrm{CAlg}_A^{\text{ét}}$. We summarize the situation as follows: the category of quasi-coherent sheaves on $\mathrm{Spét}\, A$ is equivalent to the category of (discrete) A-modules.

Proposition 1.2.6.3. *Let $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a Deligne-Mumford stack, and let $\mathscr{F}$ be a $\mathscr{O}_{\mathcal{X}}$-module object of $\mathcal{X}$. The condition that $\mathscr{F}$ be quasi-coherent can be tested locally on $\mathcal{X}$. More precisely, if there exists a covering of $\mathcal{X}$ by objects U_α such that each restriction $\mathscr{F}|_{U_\alpha}$ is a quasi-coherent sheaf on $(\mathcal{X}_{/U_\alpha}, \mathscr{O}_{\mathcal{X}}|_{U_\alpha})$, then $\mathscr{F}$ is quasi-coherent.*

Proof. Let $f : V \to W$ be a morphism between affine objects of $\mathcal{X}$; we wish to show that the induced map $\mathscr{O}_{\mathcal{X}}(V) \otimes_{\mathscr{O}_{\mathcal{X}}(W)} \mathscr{F}(W) \to \mathscr{F}(V)$ is an isomorphism. Replacing $\mathcal{X}$ by $(\mathcal{X}_{/W}, \mathscr{O}_{\mathcal{X}}|_W)$, we may assume that $(\mathcal{X}, \mathscr{O}_{\mathcal{X}}) = \operatorname{Sp\acute{e}t} A$ for some commutative ring A. Let us identify $\mathcal{X}$ with $\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}_A^{\acute{e}t})$, so that we can view $\mathscr{F}$ as a functor from $\mathrm{CAlg}_A^{\acute{e}t}$ to the category of sets. To prove that $\mathscr{F}$ is quasi-coherent, it will suffice to show that for every étale A-algebra B, the natural map $B \otimes_A \mathscr{F}(A) \to \mathscr{F}(B)$ is an isomorphism (see Example 1.2.6.2).

We may assume without loss of generality that each U_α is affine and therefore associated to some étale A-algebra A_α. Since the objects U_α cover $\mathcal{X}$, we may choose a finite set of indices $\alpha_1, \ldots, \alpha_n$ for which the product $\prod_{1 \leqslant i \leqslant n} A_{\alpha_i}$ is faithfully flat over A. Our assumption on $\mathscr{F}$ guarantees that for any morphism of étale A-algebras $C \to C'$, if C admits the structure of an A_α-algebra for some index α, then the induced map $C' \otimes_C \mathscr{F}(C) \to \mathscr{F}(C')$ is an isomorphism.

For any étale A-algebra B, the hypothesis that $\mathscr{F}$ is an étale sheaf (and the flatness of B as an A-module) supplies a commutative diagram of short exact sequences

$$\begin{array}{ccccccc}
0 \longrightarrow & B \otimes_A \mathscr{F}(A) & \longrightarrow & \prod_{1 \leqslant i \leqslant n} B \otimes_A \mathscr{F}(A_{\alpha_i}) & \longrightarrow & \prod_{1 \leqslant i,j \leqslant n} B \otimes_A \mathscr{F}(A_{\alpha_i} \otimes_A A_{\alpha_j}) \\
& \downarrow \theta & & \downarrow \theta' & & \downarrow \theta'' \\
0 \longrightarrow & \mathscr{F}(B) & \longrightarrow & \prod_{1 \leqslant i \leqslant n} \mathscr{F}(B \otimes_A A_{\alpha_i}) & \longrightarrow & \prod_{1 \leqslant i,j \leqslant n} \mathscr{F}(B \otimes_A A_{\alpha_i} \otimes_A A_{\alpha_j}).
\end{array}$$

Since θ' and θ'' are isomorphisms, we conclude that θ is also an isomorphism. □

1.3 Sheaves of Spectra

In §1.1, we introduced the notion of a *spectrally ringed space*: that is, a pair $(X, \mathscr{O}_X)$ where X is a topological space and $\mathscr{O}_X$ is a sheaf of $\mathbb{E}_\infty$-rings on X. The language of spectrally ringed spaces is adequate for describing many of the algebro-geometric objects which we are interested in studying (such as the *spectral schemes* of Definition 1.1.2.8). However, to accommodate more exotic objects (such as the *spectral Deligne-Mumford stacks* of §1.4), it will be useful to work with a more general notion of CAlg-valued sheaf. In this section, we will study pairs $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ where $\mathcal{X}$ is an ∞-topos and $\mathscr{O}_{\mathcal{X}}$ is a sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$.

1.3.1 Sheaves on ∞-Topoi

Let $\mathcal{C}$ be an ∞-category. In §1.1, we introduced the notion of a $\mathcal{C}$-valued sheaf on a topological space X (Definition 1.1.2.1). This definition can be generalized to an arbitrary Grothendieck site:

Definition 1.3.1.1. Let $\mathcal{T}$ be an essentially small ∞-category. Recall that a *Grothendieck topology* on $\mathcal{T}$ is a Grothendieck topology on the homotopy category $\mathrm{h}\mathcal{T}$, in the sense of classical category theory (see §HTT.6.2.2 for a detailed discussion). Let $\mathcal{C}$ be an arbitrary ∞-category. We will say that a functor $\mathscr{O} : \mathcal{T}^{\mathrm{op}} \to \mathcal{C}$ is a *$\mathcal{C}$-valued sheaf on $\mathcal{T}$* if the following condition is satisfied: for every object $U \in \mathcal{T}$ and every covering sieve $\mathcal{T}^0_{/U} \subseteq \mathcal{T}_{/U}$, the composite map

$$(\mathcal{T}^0_{/U})^{\lhd} \subseteq (\mathcal{T}_{/U})^{\lhd} \to \mathcal{T} \xrightarrow{\mathscr{O}^{\mathrm{op}}} \mathcal{C}^{\mathrm{op}}$$

is a colimit diagram in $\mathcal{C}^{\mathrm{op}}$. We let $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{T})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{T}^{\mathrm{op}}, \mathcal{C})$ spanned by the $\mathcal{C}$-valued sheaves on $\mathcal{T}$.

More informally, a functor $\mathscr{O} : \mathcal{T}^{\mathrm{op}} \to \mathcal{C}$ is a $\mathcal{C}$-valued sheaf if, for every object $U \in \mathcal{T}$ and every covering sieve $\mathcal{T}^0_{/U}$ of U, the canonical map

$$\mathscr{O}(U) \to \varprojlim_{V \in \mathcal{T}^0_{/U}} \mathscr{O}(V)$$

is an equivalence in $\mathcal{C}$.

Example 1.3.1.2. Let X be a topological space, let $\mathcal{C}$ be an ∞-category, and let $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(X)$ be the ∞-category of $\mathcal{C}$-valued sheaves on X (Definition 1.1.2.1). Then $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(X) = \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{U}(X))$, where $\mathcal{U}(X)$ is the partially ordered set of all open subsets of X, which is endowed with the usual Grothendieck topology (so that a collection of inclusions $\{U_\alpha \subseteq U\}$ generates a covering sieve on U if and only if $U = \bigcup U_\alpha$).

Example 1.3.1.3. Let $\mathcal{T}$ be a small ∞-category equipped with a Grothendieck topology and let $\mathcal{S}$ denote the ∞-category of spaces. Then we will denote the ∞-category $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{T})$ simply by $\mathcal{S}\mathrm{hv}(\mathcal{T})$ and refer to it as the *∞-category of sheaves on $\mathcal{T}$*. The ∞-category $\mathcal{S}\mathrm{hv}(\mathcal{T})$ is an accessible left-exact localization of the presheaf ∞-category $\mathrm{Fun}(\mathcal{T}^{\mathrm{op}}, \mathcal{S})$, and is therefore an ∞-topos (see §HTT.6.2).

In the situation of Definition 1.3.1.1, the ∞-category $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{T})$ does not depend on the exact details of the Grothendieck site $\mathcal{T}$: it depends only on the associated ∞-topos $\mathcal{S}\mathrm{hv}(\mathcal{T})$. To see this, it will be convenient to introduce a site-independent version of Definition 1.3.1.1 (which also makes sense for ∞-topoi which do not arise as sheaves on a Grothendieck site).

Definition 1.3.1.4. Let $\mathcal{X}$ be an ∞-topos and let $\mathcal{C}$ be an arbitrary ∞-category. A *$\mathcal{C}$-valued sheaf on $\mathcal{X}$* is a functor $\mathcal{X}^{\mathrm{op}} \to \mathcal{C}$ which preserves small limits. We let $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C})$ spanned by the $\mathcal{C}$-valued sheaves on $\mathcal{X}$.

Warning 1.3.1.5. Let $\mathcal{X}$ be an ∞-topos, and let $\mathcal{C}$ be an arbitrary ∞-category. Then the ∞-category $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$ introduced in Definition 1.3.1.4 generally does *not* coincide with the ∞-category $\mathcal{C}$-valued sheaves with respect to a Grothendieck topology on $\mathcal{X}$ (for example, the canonical topology on $\mathcal{X}$). Consequently, the conventions of Definition 1.3.1.4 and 1.3.1.1 conflict with one another. However, there should be little danger of confusion: for example, an ∞-topos $\mathcal{X}$ is never essentially small as an ∞-category, unless $\mathcal{X}$ is a contractible Kan complex.

Remark 1.3.1.6. Let $\mathcal{C}$ be a presentable ∞-category and $\mathcal{X}$ an ∞-topos. Then the ∞-category $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$ can be identified with the tensor product $\mathcal{C} \otimes \mathcal{X}$ introduced in §HA.4.8.1. In particular, $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$ is a presentable ∞-category.

We now show that Definitions 1.3.1.1 and 1.3.1.4 are compatible with one another, at least when the ∞-category $\mathcal{C}$ admits small limits. For any ∞-category $\mathcal{T}$, we let $\mathcal{P}(\mathcal{T})$ denote the ∞-category $\mathrm{Fun}(\mathcal{T}^{\mathrm{op}}, \mathcal{S})$ of $\mathcal{S}$-valued presheaves on $\mathcal{T}$, and $j : \mathcal{T} \to \mathcal{P}(\mathcal{T})$ the Yoneda embedding.

Proposition 1.3.1.7. *Let $\mathcal{T}$ be a small ∞-category equipped with a Grothendieck topology. Let $j : \mathcal{T} \to \mathcal{P}(\mathcal{T})$ denote the Yoneda embedding and $L : \mathcal{P}(\mathcal{T}) \to \mathcal{S}\mathrm{hv}(\mathcal{T})$ a left adjoint to the inclusion. Let $\mathcal{C}$ be an arbitrary ∞-category which admits small limits. Then composition with $L \circ j$ induces an equivalence of ∞-categories $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{S}\mathrm{hv}(\mathcal{T})) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{T})$.*

Corollary 1.3.1.8. *Let X be a topological space and let $\mathcal{C}$ be an ∞-category which admits small limits. Then there is a canonical equivalence of ∞-categories $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(X) \simeq \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{S}\mathrm{hv}(X))$, where the left hand side is given by Definition 1.1.2.1 and the right hand side by Definition 1.3.1.4.*

Proof of Proposition 1.3.1.7. According to Theorem HTT.5.1.5.6, composition with j induces an equivalence of ∞-categories $\mathrm{Fun}_0(\mathcal{P}(\mathcal{T})^{\mathrm{op}}, \mathcal{C}) \to \mathrm{Fun}(\mathcal{T}^{\mathrm{op}}, \mathcal{C})$, where $\mathrm{Fun}_0(\mathcal{P}(\mathcal{T})^{\mathrm{op}}, \mathcal{C})$ denotes the full subcategory of $\mathrm{Fun}(\mathcal{P}(\mathcal{T})^{\mathrm{op}}, \mathcal{C})$ spanned by those functors which preserve small limits. According to Proposition HTT.5.5.4.20, composition with L induces a fully faithful embedding $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{S}\mathrm{hv}(\mathcal{T})) \to \mathrm{Fun}_0(\mathcal{P}(\mathcal{T})^{\mathrm{op}}, \mathcal{C})$. The essential image of this embedding consists of those limit-preserving functors $F : \mathcal{P}(\mathcal{T})^{\mathrm{op}} \to \mathcal{C}$ such that, for every $X \in \mathcal{T}$ and every covering sieve $\mathcal{T}^0_{/X} \subseteq \mathcal{T}_{/X}$, the induced map $F(jX) \to F(Y)$ is an equivalence in $\mathcal{C}$, where Y is the subobject of jX corresponding to the sieve $\mathcal{T}^0_{/X}$. Unwinding the definitions, this translates into the condition that the composition

$$(\mathcal{T}^0_{/X})^{\triangleright} \subseteq (\mathcal{T}_{/X})^{\triangleright} \to \mathcal{T} \xrightarrow{j} \mathcal{P}(\mathcal{T}) \xrightarrow{F} \mathcal{C}^{\mathrm{op}}$$

is a colimit diagram. It follows that the composition

$$\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{S}\mathrm{hv}(\mathcal{T})) \to \mathrm{Fun}_0(\mathcal{P}(\mathcal{T})^{\mathrm{op}}, \mathcal{C}) \to \mathrm{Fun}(\mathcal{T}^{\mathrm{op}}, \mathcal{C})$$

is fully faithful, and its essential image is the full subcategory $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{T})$. □

1.3.2 Sheaves of Spectra

In this book, are primarily interested in $\mathcal{C}$-valued sheaves when $\mathcal{C} = \mathrm{Sp}$ is the ∞-category of spectra.

Definition 1.3.2.1. Let $\mathcal{X}$ be an ∞-topos. A *sheaf of spectra* on $\mathcal{X}$ is a sheaf on $\mathcal{X}$ with values in the ∞-category Sp of spectra. We let $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathrm{Sp})$ spanned by the sheaves of spectra on $\mathcal{X}$.

Remark 1.3.2.2. Let $\mathcal{X}$ be an ∞-topos and let $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{S})$ spanned by those functors which preserve small limits. Recall that the ∞-category Sp of spectra can be defined as the full subcategory of $\mathrm{Fun}(\mathcal{S}_*^{\mathrm{fin}}, \mathcal{S})$ spanned by those functors $E : \mathcal{S}_*^{\mathrm{fin}} \to \mathcal{S}$ which are reduced and excisive; here $\mathcal{S}_*^{\mathrm{fin}}$ denotes the ∞-category of pointed finite spaces (Definition HA.1.4.3.1). We therefore obtain an isomorphism of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ with the full subcategory of $\mathrm{Fun}(\mathcal{S}_*^{\mathrm{fin}}, \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}))$ spanned by those functors which are reduced and excisive. Since the Yoneda embedding induces an equivalence of ∞-categories $\mathcal{X} \to \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X})$ (Proposition HTT.5.5.2.2), we obtain an equivalence of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ with the ∞-category $\mathrm{Sp}(\mathcal{X})$ of spectrum objects of $\mathcal{X}$ (see Definition HA.1.4.2.8). In particular, $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ is a presentable stable ∞-category. Moreover, we have a forgetful functor $\Omega^\infty : \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}) \to \mathcal{X}$, which is obtained by pointwise composition with the forgetful functor $\Omega^\infty : \mathrm{Sp} \to \mathcal{S}$ (together with the identification $\mathcal{X} \simeq \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X})$).

Notation 1.3.2.3. Let $\mathcal{X}$ be an ∞-topos and let $\mathcal{X}^{\heartsuit} = \tau_{\leqslant 0}\mathcal{X}$ denote its underlying topos. Composing the forgetful functor functor $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}) \simeq \mathcal{X}$ with the truncation functor $\tau_{\leqslant 0} : \mathcal{X} \to \mathcal{X}^{\heartsuit}$, we obtain a functor $\pi_0 : \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}) \to \mathcal{X}^{\heartsuit}$. More generally, for any integer n, we let $\pi_n : \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}) \to \tau_{\leqslant 0}\mathcal{X}$ denote the composition of the functor π_0 with the shift functor $\Omega^n : \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$. Note that π_n can also be described as the composition

$$\mathrm{Mod}_{\mathrm{Sp}}(\mathcal{X}) \xrightarrow{\Omega^{n-2}} \mathrm{Mod}_{\mathrm{Sp}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathcal{S}_*}(\mathcal{X}) \simeq \mathcal{X}_* \xrightarrow{\pi_2} \tau_{\leqslant 0}\mathcal{X}.$$

It follows that π_n can be regarded as a functor from $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ to the category of abelian groups objects of $\mathcal{X}^{\heartsuit}$.

Example 1.3.2.4. In the situation of Notation 1.3.2.3, suppose that $\mathcal{X} = \mathcal{S}\mathrm{hv}(X)$ for some topological space X, and let $\mathscr{F}$ be an object of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{S}\mathrm{hv}(X)) \simeq \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(X)$. For each integer n, we can identify $\pi_n \mathscr{F}$ with the sheaf of abelian groups on X given by sheafifying the presheaf $U \mapsto \pi_n(\mathscr{F}(U))$.

Definition 1.3.2.5. For every integer n, the functor $\Omega^{\infty-n} : \mathrm{Sp} \to \mathcal{S}$ induces a functor $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}) \simeq \mathcal{X}$, which we will also denote by $\Omega^{\infty-n}$. We will say that an object $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ is *n-truncated* if $\Omega^{\infty+n}\mathscr{F}$ is a discrete object of $\mathcal{X}$. We will say that a sheaf of spectra $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ is *n-connective* if the homotopy groups $\pi_m \mathscr{F}$ vanish for $m < n$.

We will say that M is *connective* if it is 0-connective (equivalently, M is connective if the object $\Omega^{\infty-m}\mathscr{F} \in \mathcal{X}$ is m-connective for every integer m). We let $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\geqslant n}$ denote the the full subcategory of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ spanned by the n-connective objects, and $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant n}$ the full subcategory of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ spanned by the n-truncated objects. In the special case $n = 0$, we will denote $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\geqslant 0}$ by $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})^{\mathrm{cn}}$.

Remark 1.3.2.6. Let $\mathcal{X}$ be an ∞-topos and let $\mathscr{F}$ be a sheaf of spectra on $\mathcal{X}$. Then $\mathscr{F}$ is n-truncated if and only if, for every object $U \in \mathcal{X}$, the spectrum $\mathscr{F}(U)$ is n-truncated.

The classes of 0-truncated and 0-connective spectrum-valued sheaves determine a t-structure:

Proposition 1.3.2.7. *Let $\mathcal{X}$ be an ∞-topos.*

(1) *The full subcategories $(\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\geqslant 0}, \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant 0})$ determine a t-structure on $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$.*

(2) *The t-structure on $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ is compatible with filtered colimits (that is, the full subcategory $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant 0} \subseteq \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ is closed under filtered colimits).*

(3) *The t-structure on $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ is right complete.*

(4) *The functor π_0 of Notation 1.3.2.3 determines an equivalence of categories from the heart of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ to the category of abelian group objects of $\mathcal{X}^{\heartsuit}$.*

Proof. It follows from Proposition HA.1.4.3.4 that $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ admits a t-structure given by the pair $(\mathcal{C}, \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant 0})$, where $\mathcal{C}$ is the collection of objects $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ for which the mapping space $\mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})}(\mathscr{F}, \Omega(\mathscr{G}))$ is contractible for every coconnective object $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant 0}$. Fix $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$; using Remark 1.3.2.2 we can identify $\mathscr{F}$ with a sequence of pointed objects $\mathscr{F}(n) \in \mathcal{X}_*$ and equivalences $\gamma_n : \mathscr{F}(n) \simeq \Omega\mathscr{F}(n+1)$. Set $\mathscr{F}'(n) = \tau_{\leqslant n-1}\mathscr{F}(n)$; the equivalences γ_n induce equivalences $\gamma'_n : \mathscr{F}'(n) \simeq \Omega\mathscr{F}'(n+1)$, so we can regard $\{\mathscr{F}'(n)\}$ as an object $\mathscr{F}' \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$. We have a canonical map $\mathscr{F} \to \mathscr{F}'$. If $\mathscr{G}$ is a coconnective object of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant 0}$, then we have

$$\begin{aligned} \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})}(\mathscr{F}, \Omega\mathscr{G}) &\simeq \varprojlim \mathrm{Map}_{\mathcal{X}_*}(\mathscr{F}(n), \Omega^{\infty+1-n}\mathscr{G}) \\ &\simeq \varprojlim \mathrm{Map}_{\mathcal{X}_*}(\mathscr{F}'(n), \Omega^{\infty+1-n}\mathscr{G}) \\ &\simeq \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})}(\mathscr{F}', \mathscr{G}). \end{aligned}$$

On the other hand, $\Omega^{-1}M'$ is a 0-truncated object of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$. It follows that $\mathscr{F} \in \mathcal{C}$ if and only if $\mathscr{F}' \simeq 0$. This is equivalent to the requirement that each $\mathscr{F}'(n) \simeq \tau_{\leqslant n-1}\mathscr{F}(n)$ is a final object of $\mathcal{X}_*$: that is, the requirement that each $\mathscr{F}'(n)$ is n-connective. This proves that $\mathcal{C} = \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\geqslant 0}$ so that assertion (1) holds.

We observe that the loop functor $\Omega : \mathcal{X}_* \to \mathcal{X}_*$ preserves filtered colimits (Example HTT.7.3.4.7), so that $\Omega^{\infty+1} : \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}) \to \mathcal{X}_*$ preserves filtered colimits for each n. It follows that the homotopy fiber of $\Omega^{\infty+1}$ (over the zero object $* \in \mathcal{X}_*$) is closed under filtered colimits, so that (2) is satisfied. It follows easily that $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant 0}$ is stable under countable coproducts. Any object $\mathscr{F} \in \bigcap_n \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant -n}$ has the property that $\Omega^{\infty-n}\mathscr{F} \in \mathcal{X}_*$ is final for each n, so that M is a zero object of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$. Assertion (3) now follows from Proposition HA.1.2.1.19 .

Let us identify $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ with the homotopy inverse limit of the tower of ∞-categories

$$\cdots \to \mathcal{X}_* \xrightarrow{\Omega_*} \mathcal{X}_* \xrightarrow{\Omega_*} \mathcal{X}_* .$$

Under this identification, the heart $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})^{\heartsuit} \subseteq \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ corresponds to the homotopy inverse limit of the tower

$$\cdots \to \mathcal{EM}_2(\mathcal{X}) \xrightarrow{\Omega} \mathcal{EM}_1(\mathcal{X}) \xrightarrow{\Omega} \mathcal{EM}_0(\mathcal{X}) = \mathcal{X}^{\heartsuit},$$

where $\mathcal{EM}_n(\mathcal{X}) \subseteq \mathcal{X}_*$ denotes the full subcategory spanned by the Eilenberg-MacLane objects (that is, objects which are both n-truncated and n-connective; see Definition HTT.7.2.2.1). Assertion (4) follows from the observation that $\mathcal{EM}_n(\mathcal{X})$ is equivalent to the category of abelian group objects of the underlying topos of $\mathcal{X}$ for $n \geqslant 2$ (Proposition HTT.7.2.2.12). □

Remark 1.3.2.8. Let $g^* : \mathcal{X} \to \mathcal{Y}$ be a geometric morphism of ∞-topoi (that is, a functor which preserves small colimits and finite limits). Then g^* is left exact, and therefore induces a functor $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}) \simeq \mathrm{Sp}(\mathcal{X}) \to \mathrm{Sp}(\mathcal{Y}) \simeq \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{Y})$. We will abuse notation by denoting this functor also by g^*. It is a left adjoint to the pushforward functor $g_* : \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{Y}) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$, given by pointwise composition with $g^* : \mathcal{X} \to \mathcal{Y}$.

Since the functor $g^* : \mathcal{X} \to \mathcal{Y}$ preserves n-truncated objects and n-connective objects for every integer n, we conclude that the functor $g^* : \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{Y})$ is t-exact: that is, it carries $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\geqslant n}$ into $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{Y})_{\geqslant n}$ and $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant n}$ into $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{Y})_{\leqslant n}$. It follows that g_* is left t-exact: that is, $g_* \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{Y})_{\leqslant n} \subseteq \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant n}$. The functor g_* is usually not right t-exact.

1.3.3 ∞-Connective Sheaves of Spectra

The t-structure on $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ is not left complete in general. For example, there may exist nonzero objects $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ whose homotopy groups $\pi_n \mathscr{F}$ vanish for all integers n.

Definition 1.3.3.1. Let $\mathcal{X}$ be an ∞-topos and let $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ be a sheaf of spectra on $\mathcal{X}$. We will say that $\mathscr{F}$ is *∞-connective* if it is n-connective for every integer n. In other words, $\mathscr{F}$ is ∞-connective if $\pi_n \mathscr{F} \simeq 0$ for every integer n.

Remark 1.3.3.2. Let $\mathcal{X}$ be an ∞-topos and let $\mathcal{X}^{\mathrm{hyp}} \subseteq \mathcal{X}$ be the full subcategory spanned by the hypercomplete objects. Then the inclusion map $f_* : \mathcal{X}^{\mathrm{hyp}} \to \mathcal{X}$ is a geometric morphism of ∞-topoi, which admits a left exact left adjoint $f^* : \mathcal{X} \to \mathcal{X}^{\mathrm{hyp}}$. Applying Remark 1.3.2.8, we obtain a pair of adjoint functors

$$\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}) \underset{f_*}{\overset{f^*}{\rightleftarrows}} \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}^{\mathrm{hyp}}).$$

Note that an object $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ is ∞-connective if and only if $f^* \mathscr{F} \simeq 0$. Since the inclusion $\mathcal{X}^{\mathrm{hyp}} \hookrightarrow \mathcal{X}$ is fully faithful, the functor $f_* : \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}^{\mathrm{hyp}}) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ is also fully faithful.

Proposition 1.3.3.3. *Let $\mathcal{X}$ be an ∞-topos and let $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$. The following conditions are equivalent:*

(1) *The object $\Omega^\infty \mathscr{F} \in \mathcal{X}$ is hypercomplete.*

(2) *The sheaf of spectra $\mathscr{F}$ belongs to the essential image of the fully faithful embedding $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}^{\mathrm{hyp}}) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$.*

(3) *For every ∞-connective object $\mathscr{G} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$, the mapping space $\mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})}(\mathscr{G}, \mathscr{F})$ is contractible.*

(4) *For every ∞-connective object $\mathscr{G} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$, every map $u : \mathscr{G} \to \mathscr{F}$ is nullhomotopic.*

Proof. We first show that (1) and (2) are equivalent. The implication (2) ⇒ (1) is immediate. Conversely, suppose that $\mathscr{F}$ satisfies condition (1). To show that $\mathscr{F}$ belongs to the essential image of the fully faithful embedding, it will suffice to show that $\Omega^{\infty-n} \mathscr{F} \in \mathcal{X}$ is hypercomplete for each $n \geqslant 0$. Proceeding by induction on n, we are reduced to proving that $\Omega^{\infty-1} \mathscr{F}$ is hypercomplete. We have a fiber sequence

$$\Omega^{\infty-1} \mathscr{F} \to \pi_{-1} \mathscr{F} \to \Omega^\infty(\Sigma^2(\tau_{\geqslant 0} \mathscr{F})).$$

Since $\pi_{-1} \mathscr{F}$ is a discrete object of $\mathcal{X}$ (and therefore hypercomplete), we are reduced to proving that the object $U = \Omega^\infty(\Sigma^2(\tau_{\geqslant 0} \mathscr{F})) \in \mathcal{X}$ is hypercomplete. Let U' denote its hypercomplete; we wish to show that the map $U \to U'$ is an equivalence in $\mathcal{X}$. Since U and U' are 2-connective pointed objects of $\mathcal{X}$, it will suffice to show that the induced map $\Omega^2 U \to \Omega^2 U'$ is an equivalence. Since the formation of hypercompletions is left exact, we can identify $\Omega^2 U'$ with the hypercompletion of $\Omega^2 U$. We are therefore reduced to proving that $\Omega^2 U \simeq \Omega^\infty \mathscr{F}$ is hypercomplete, which follows from assumption (1).

The implication (2) ⇒ (3) follows from Remark 1.3.3.2, and the implication (3) ⇒ (4) is immediate. We will complete the proof by showing that (4) ⇒ (2). Suppose that $\mathscr{F}$ satisfies condition (4), and consider the adjoint functors

$$\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}) \underset{f_*}{\overset{f^*}{\rightleftarrows}} \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}^{\mathrm{hyp}}).$$

appearing in Remark 1.3.3.2. To prove (2), it will suffice to show that the unit map $u : \mathscr{F} \to f_* f^* \mathscr{F}$ is an equivalence. Since the functor f_* is fully faithful, the pullback $f^* u$ is an equivalence. Since f^* is an exact functor, we conclude that $f^* \operatorname{fib}(u) \simeq 0$: that is, the fiber $\operatorname{fib}(u)$ is ∞-connective. Using (4), we deduce that the canonical map $\operatorname{fib}(u) \to \mathscr{F}$ is nullhomotopic. It follows that $\operatorname{cofib}(u)$ is a retract of $f_* f^* \mathscr{F}$ in the ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$. In particular, $\Omega^{\infty - n}(\operatorname{cofib}(u))$ is a retract of the hypercomplete object $\Omega^{\infty-n}(f_* f^* \mathscr{F})$ for every integer n, and is therefore hypercomplete. Since the homotopy groups of $\Omega^{\infty-n}(\operatorname{cofib}(u))$ vanish, we conclude that $\Omega^{\infty-n}(\operatorname{cofib}(u))$ is a final object of $\mathcal{X}$. It follows that $\operatorname{cofib}(u) \simeq 0$, so that u is an equivalence as desired. □

Definition 1.3.3.4. Let $\mathcal{X}$ be an ∞-topos. We will say that an object $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ is *hypercomplete* if it satisfies the equivalent conditions of Proposition 1.3.3.3.

Remark 1.3.3.5. Let $\mathcal{X}$ be an ∞-topos. Then the full subcategories of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ spanned by the ∞-connective and hypercomplete objects determine a t-structure on $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ (with trivial heart). In particular, every object $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ fits into an essentially unique fiber sequence $\mathscr{F}' \to \mathscr{F} \to \mathscr{F}''$ where $\mathscr{F}'$ is ∞-connective and $\mathscr{F}''$ is hypercomplete.

The condition of hypercompleteness can be tested locally:

Proposition 1.3.3.6. *Let $\mathcal{X}$ be an ∞-topos. The property that an object $X \in \mathcal{X}$ is hypercomplete can be tested locally on $\mathcal{X}$. In other words, if there exists a collection of objects $\{U_\alpha \in \mathcal{X}\}$ such that $\amalg_\alpha U_\alpha$ is 0-connective and each product $X \times U_\alpha$ is a hypercomplete object of the ∞-topos $\mathcal{X}_{/U_\alpha}$, then X is hypercomplete.*

Proof. Let $U = \amalg U_\alpha$, so that $X \times U$ is a hypercomplete object of the ∞-topos $\mathcal{X}_{/U} \simeq \prod_\alpha \mathcal{X}_{/U_\alpha}$. Let $U_\bullet$ be the simplicial object of $\mathcal{X}$ given by the Čech nerve of the effective epimorphism $U \to \mathbf{1}$, where $\mathbf{1}$ denotes a final object of $\mathcal{X}$.

Let $f : Y \to Z$ be an ∞-connected morphism in $\mathcal{X}$; we wish to prove that the induced map $\alpha : \mathrm{Map}_{\mathcal{X}}(Z, X) \to \mathrm{Map}_{\mathcal{X}}(Y, X)$ is a homotopy equivalence. We can obtain α as the totalization of a map of cosimplicial spaces

$$\alpha^\bullet : \mathrm{Map}_{\mathcal{X}}(Z \times U_\bullet, X) \to \mathrm{Map}_{\mathcal{X}}(Y \times U_\bullet, X).$$

It will therefore suffice to show that each α^n is an equivalence. Replacing Y by $Y \times U_n$ and Z by $Z \times U_n$, we can reduce to the case where $\alpha = 0$. In this case, α_0 can be identified with the map $\mathrm{Map}_{\mathcal{X}_{/U}}(Z \times U, X \times U) \to \mathrm{Map}_{\mathcal{X}_{/U}}(Y \times U, X \times U)$. This map is an equivalence because $X \times U$ is a hypercomplete object of $\mathcal{X}_{/U}$, and the map $Z \times U \to Y \times U$ is ∞-connected. □

Corollary 1.3.3.7. *Let $\mathcal{X}$ be an ∞-topos, and let $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$. If there exists a 0-connective object $\amalg U_\alpha$ in $\mathcal{X}$ such that each pullback $u_\alpha^* \mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}_{/U_\alpha})$ is hypercomplete (where $u_\alpha : \mathcal{X}_{/U_\alpha} \to \mathcal{X}$ denotes the étale geometric morphism determined by U_α), then $\mathscr{F}$ is hypercomplete.*

Corollary 1.3.3.8. *Let X be a topological space and let $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(X)$. If there exists an open covering U_α of X such that each restriction $\mathscr{F}|_{U_\alpha}$ is hypercomplete, then $\mathscr{F}$ is hypercomplete.*

Under some mild hypotheses on $\mathcal{X}$, one can show that the t-structure on $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ is left complete.

Definition 1.3.3.9. Let $\mathcal{X}$ be an ∞-topos, and let $n \geqslant 0$ be an integer. We will say that $\mathcal{X}$ is *locally of cohomological dimension* $\leqslant n$ if there exists a collection of objects $\{U_\alpha\}$ of $\mathcal{X}$ which generate $\mathcal{X}$ under small colimits, such that each of the ∞-topoi $\mathcal{X}_{/U_\alpha}$ has cohomological dimension $\leqslant n$ (see Definition HTT.7.2.2.18).

Proposition 1.3.3.10. *Let $\mathcal{X}$ be an ∞-topos and let $n \geqslant 2$ be an integer. The following conditions are equivalent:*

(1) *The ∞-topos $\mathcal{X}$ is locally of homotopy dimension $\leqslant n$ (see Definition HTT.7.2.1.8).*

(2) *The ∞-topos $\mathcal{X}$ is hypercomplete and locally of cohomological dimension $\leqslant n$.*

If these conditions are satisfied and U is an object of $\mathcal{X}$, then $\mathcal{X}_{/U}$ is of homotopy dimension $\leqslant n$ if and only if it is of cohomological dimension $\leqslant n$.

Proof. Let U be an object of $\mathcal{X}$. If $\mathcal{X}_{/U}$ is of homotopy dimension $\leqslant n$, then $\mathcal{X}_{/U}$ is of cohomological dimension $\leqslant n$ (Corollary HTT.7.2.2.30). It follows that if $\mathcal{X}$ is locally of homotopy dimension $\leqslant n$, then $\mathcal{X}$ is locally of cohomological dimension $\leqslant n$. The implication (1) $\Rightarrow$ (2) now follows from Corollary HTT.7.2.1.12 . For the converse, suppose that (2) is satisfied. We will complete the proof by showing that for each object $U \in \mathcal{X}$, if $\mathcal{X}_{/U}$ has cohomological dimension $\leqslant n$, then $\mathcal{X}_{/U}$ is of homotopy dimension $\leqslant n$. Replacing $\mathcal{X}$ by $\mathcal{X}_{/U}$, we are reduced to the problem of showing that $\mathcal{X}$ has homotopy dimension $\leqslant n$.

Let $\mathbf{1}$ denote the final object of $\mathcal{X}$, and let $\mathscr{F} \in \mathcal{X}$ be n-connective. We wish to prove that the mapping space $\mathrm{Map}_{\mathcal{X}}(\mathbf{1}, \mathscr{F})$ is nonempty. We begin by constructing a compatible sequence of maps $\phi_m : \mathbf{1} \to \tau_{\leqslant m} \mathscr{F}$. The construction proceeds by induction on m, the case $m < n$ being trivial. If $m \geqslant n$ and ϕ_{m-1} has already been constructed then the fiber product $\mathbf{1} \times_{\tau_{\leqslant m-1} \mathscr{F}} \tau_{\leqslant m} \mathscr{F}$ is an m-gerbe in $\mathcal{X}$. Our assumption that $\mathcal{X}$ has cohomological dimension $\leqslant n \leqslant m$ guarantees that this gerbe is automatically trivial, so that ϕ_{m-1} lifts to a map ϕ_m. Together, the maps $\{\phi_m\}_{m \geqslant 0}$ determine a map $\phi : \mathbf{1} \to \widehat{\mathscr{F}}$, where $\widehat{\mathscr{F}}$ denotes the limit $\varprojlim_m \tau_{\leqslant m} \mathscr{F}$. To complete the proof, it will suffice to show that the canonical map $\theta : \mathscr{F} \to \widehat{\mathscr{F}}$ is an equivalence. Because $\mathcal{X}$ is hypercomplete, this is equivalent to the assertion that θ induces an equivalence $\theta_m : \tau_{\leqslant m} \mathscr{F} \to \tau_{\leqslant m} \widehat{\mathscr{F}}$ for each $m \geqslant 0$. Note that θ_m is a right homotopy inverse to the canonical map

$$\gamma : \tau_{\leqslant m} \widehat{\mathscr{F}} \to \tau_{\leqslant m}(\tau_{\leqslant m} \mathscr{F}) \simeq \tau_{\leqslant m} \mathscr{F} .$$

It will therefore suffice to prove that γ is an equivalence: that is, the projection $\overline{\gamma} : \widehat{\mathscr{F}} \to \tau_{\leqslant m} \mathscr{F}$ exhibits $\tau_{\leqslant m} \mathscr{F}$ as an m-truncation of $\widehat{\mathscr{F}}$. In fact, we claim that the map $\overline{\gamma}$ is $(m+1)$-connective.

The map γ factors as a composition $\widehat{\mathscr{F}} \xrightarrow{\overline{\gamma}'} \tau_{\leqslant m+n} \mathscr{F} \xrightarrow{\overline{\gamma}''} \tau_{\leqslant m} \mathscr{F}$. Because $\overline{\gamma}''$ is $(m+1)$-connective, we are reduced to showing that $\overline{\gamma}'$ is $(m+1)$-connective. To prove this, it will suffice to show that $\mathcal{X}$ is generated under small colimits by objects V for which the map

$$\mathrm{Map}_{\mathcal{X}}(V, \widehat{\mathscr{F}}) \to \mathrm{Map}_{\mathcal{X}}(V, \tau_{\leqslant m+n} \mathscr{F})$$

is $(m+1)$-connective. In fact, we claim that this condition holds whenever $\mathcal{X}_{/V}$ has cohomological dimension $\leqslant n$. To prove this, it suffices to show that each of the maps $\psi : \mathrm{Map}_{\mathcal{X}}(V, \tau_{\leqslant t+1+n} \mathscr{F}) \to \mathrm{Map}_{\mathcal{X}}(V, \tau_{\leqslant t+n} \mathscr{F})$ is $(t+1)$-connective. Choose a point $\eta \in \mathrm{Map}_{\mathcal{X}}(V, \tau_{\leqslant t+n} \mathscr{F})$ and let $\overline{V} = V \times_{\tau_{\leqslant t+n} \mathscr{F}} \tau_{\leqslant t+1+n} \mathscr{F}$, so that the homotopy fiber of ψ over the point η can be identified with $\mathrm{Map}_{\mathcal{X}_{/V}}(V, \overline{V})$. By construction, $\overline{V}$ is an $(t+1+n)$-gerbe in $\mathcal{X}_{/V}$ banded by some abelian group object $\mathscr{A}$ of $\mathcal{X}_{/V}$. Since $\mathcal{X}_{/V}$ has cohomological dimension $\leqslant n$, the cohomology group $\mathrm{H}^{t+2+n}(\mathcal{X}_{/V}; \mathscr{F})$ vanishes, so that $\overline{V}$ is a trivial gerbe. We therefore obtain isomorphisms

$$\pi_j \mathrm{Map}_{\mathcal{X}_{/V}}(V, \overline{V}) \simeq \mathrm{H}^{t+1+n-j}(\mathcal{X}_{/V}; \mathscr{A}).$$

Since $\mathcal{X}_{/V}$ has cohomological dimension $\leqslant n$, this group vanishes for $j \leqslant t$, so that $\mathrm{Map}_{\mathcal{X}_{/V}}(V, \overline{V})$ is $(t+1)$-connective as desired. □

Corollary 1.3.3.11. *Let $\mathcal{X}$ be an ∞-topos. Assume that $\mathcal{X}$ is hypercomplete and locally of cohomological dimension $\leqslant n$, for some integer n. Then the t-structure on $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ is left complete.*

Proof. Without loss of generality, we may assume that $n \geqslant 2$. According to Proposition 1.3.3.10, $\mathcal{X}$ is locally of homotopy dimension $\leqslant 2$. It follows from Proposition HTT.7.2.1.10 that $\mathcal{X}$ is Postnikov complete (in the sense of Definition A.7.2.1). From this we immediately deduce that $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\geqslant 0}$ is Postnikov complete, so that $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ is left complete. □

1.3.4 Sheafification and Tensor Products

Our next objective is to describe a symmetric monoidal structure on the ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$. Roughly speaking, this symmetric monoidal structure is given by levelwise smash product, followed by sheafification. We begin by discussing the latter procedure.

Remark 1.3.4.1. Let $\mathcal{D}$ and $\mathcal{C}$ be small ∞-categories, and assume that $\mathcal{D}$ admits finite colimits. Composition with the Yoneda embeddings $\mathcal{D}^{\mathrm{op}} \to \mathcal{P}(\mathcal{D}^{\mathrm{op}})$ and $\mathcal{C} \to \mathrm{Ind}(\mathcal{C})$ yields functors

$$\mathrm{Fun}^*(\mathcal{P}(\mathcal{D}^{\mathrm{op}}), \mathcal{P}(\mathcal{C}^{\mathrm{op}})) \to \mathrm{Fun}^{\mathrm{lex}}(\mathcal{D}^{\mathrm{op}}, \mathcal{P}(\mathcal{C}^{\mathrm{op}})) \simeq \mathrm{Fun}(\mathcal{C}, \mathrm{Ind}(\mathcal{D})) \leftarrow \mathrm{Fun}'(\mathrm{Ind}(\mathcal{C}), \mathrm{Ind}(\mathcal{D})).$$

Here $\mathrm{Fun}^*(\mathcal{P}(\mathcal{D}^{\mathrm{op}}), \mathcal{P}(\mathcal{C}^{\mathrm{op}}))$ denotes the full subcategory of $\mathrm{Fun}(\mathcal{P}(\mathcal{D}^{\mathrm{op}}), \mathcal{P}(\mathcal{C}^{\mathrm{op}}))$ spanned by those functors which preserve small colimits and finite limits, $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{D}^{\mathrm{op}}, \mathcal{P}(\mathcal{C}^{\mathrm{op}}))$ the full subcategory of $\mathrm{Fun}(\mathcal{D}^{\mathrm{op}}, \mathcal{P}(\mathcal{C}^{\mathrm{op}}))$ spanned by those functors which preserve finite limits, and $\mathrm{Fun}'(\mathrm{Ind}(\mathcal{C}), \mathrm{Ind}(\mathcal{D}))$ the full subcategory of $\mathrm{Fun}(\mathrm{Ind}(\mathcal{C}), \mathrm{Ind}(\mathcal{D}))$ spanned by those functors which preserve filtered colimits. Each of these functors is an equivalence of ∞-categories (see Propositions HTT.6.1.5.2 and HTT.5.3.5.10; the middle equivalence is an isomorphism of simplicial sets obtained by identifying both sides with a full subcategory of $\mathrm{Fun}(\mathcal{D}^{\mathrm{op}} \times \mathcal{C}, \mathcal{S})$).

Assume that both $\mathcal{C}$ and $\mathcal{D}$ admit finite colimits, so that $\mathrm{Ind}(\mathcal{C})$ and $\mathrm{Ind}(\mathcal{D})$ are compactly generated presentable ∞-categories. The presheaf ∞-categories $\mathcal{P}(\mathcal{C}^{\mathrm{op}})$ and $\mathcal{P}(\mathcal{D}^{\mathrm{op}})$ are classifying ∞-topoi for $\mathrm{Ind}(\mathcal{C})$-valued and $\mathrm{Ind}(\mathcal{D})$-valued sheaves, respectively. The above argument shows that every geometric morphism between classifying ∞-topoi arises from a functor $\mathrm{Ind}(\mathcal{C}) \to \mathrm{Ind}(\mathcal{D})$ which preserves filtered colimits. Put more informally, every natural operation which takes $\mathrm{Ind}(\mathcal{C})$-valued sheaves and produces $\mathrm{Ind}(\mathcal{D})$-valued sheaves is determined by a functor $\mathrm{Ind}(\mathcal{C}) \to \mathrm{Ind}(\mathcal{D})$ which preserves filtered colimits.

Suppose now that we are given ∞-categories $\mathcal{C}$ and $\mathcal{D}$ which admit finite colimits, and let $f : \mathrm{Ind}(\mathcal{C}) \to \mathrm{Ind}(\mathcal{D})$ be a functor which preserves filtered colimits. Remark 1.3.4.1 guarantees the existence of an induced functor $\theta : \mathcal{S}\mathrm{hv}_{\mathrm{Ind}(\mathcal{C})}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathrm{Ind}(\mathcal{D})}(\mathcal{X})$ for an arbitrary ∞-topos $\mathcal{X}$, which depends functorially on $\mathcal{X}$. In the special case where $\mathcal{X} = \mathcal{P}(\mathcal{U})$ is an ∞-category of presheaves on some small ∞-category $\mathcal{U}$, we can write down the functor θ very explicitly: it fits into a homotopy commutative diagram

$$\begin{array}{ccc}
\mathcal{S}\mathrm{hv}_{\mathrm{Ind}(\mathcal{C})}(\mathcal{X}) & \longrightarrow & \mathcal{S}\mathrm{hv}_{\mathrm{Ind}(\mathcal{C})}(\mathcal{X}) \\
\downarrow & & \downarrow \\
\mathrm{Fun}(\mathcal{U}^{\mathrm{op}}, \mathrm{Ind}(\mathcal{C})) & \xrightarrow{\circ f} & \mathrm{Fun}(\mathcal{U}^{\mathrm{op}}, \mathrm{Ind}(\mathcal{D})),
\end{array}$$

where the vertical maps are equivalences of ∞-categories given by composition with the Yoneda embedding $\mathcal{U} \to \mathcal{P}(\mathcal{U})$. More generally, if we assume only that we are given a geometric morphism $\mathcal{P}(\mathcal{U}) \to \mathcal{X}$, then we obtain a larger (homotopy commutative) diagram

$$\begin{array}{ccc} \mathcal{S}\mathrm{hv}_{\mathrm{Ind}(\mathcal{C})}(\mathcal{X}) & \longrightarrow & \mathcal{S}\mathrm{hv}_{\mathrm{Ind}(\mathcal{D})}(\mathcal{X}) \\ \uparrow & & \uparrow \\ \mathcal{S}\mathrm{hv}_{\mathrm{Ind}(\mathcal{C})}(\mathcal{P}(\mathcal{U})) & \longrightarrow & \mathcal{S}\mathrm{hv}_{\mathrm{Ind}(\mathcal{D})}(\mathcal{P}(\mathcal{U})) \\ \downarrow & & \downarrow \\ \mathrm{Fun}(\mathcal{U}^{\mathrm{op}}, \mathrm{Ind}(\mathcal{C})) & \xrightarrow{\circ f} & \mathrm{Fun}(\mathcal{U}^{\mathrm{op}}, \mathrm{Ind}(\mathcal{D})). \end{array}$$

The existence of this diagram immediately implies the following result:

Lemma 1.3.4.2. *Let $\mathcal{U}$ be a small ∞-category and suppose we are given a geometric morphism of ∞-topoi $g^* : \mathcal{P}(\mathcal{U}) \to \mathcal{X}$. Let $\mathcal{C}$ be a small ∞-category which admits finite colimits, and let $T_{\mathcal{C}}$ denote the functor* $\mathrm{Fun}(\mathcal{U}^{\mathrm{op}}, \mathrm{Ind}(\mathcal{C})) \simeq \mathcal{S}\mathrm{hv}_{\mathrm{Ind}(\mathcal{C})}(\mathcal{P}(\mathcal{U})) \to \mathcal{S}\mathrm{hv}_{\mathrm{Ind}(\mathcal{C})}(\mathcal{X})$ *induced by g^*. Let $\mathcal{D}$ be another small ∞-category which admits finite colimits, and define $T_{\mathcal{D}}$ similarly. Suppose that $f : \mathrm{Ind}(\mathcal{C}) \to \mathrm{Ind}(\mathcal{D})$ is a functor which preserves small filtered colimits. Then if $\alpha : \mathscr{F} \to \mathscr{G}$ is a morphism in* $\mathrm{Fun}(\mathcal{U}^{\mathrm{op}}, \mathrm{Ind}(\mathcal{C}))$ *such that $T_{\mathcal{C}}(\alpha)$ is an equivalence, then the induced map $\alpha' : (f \circ \mathscr{F}) \to (f \circ \mathscr{G})$ also has the property that $T_{\mathcal{D}}(\alpha')$ is an equivalence.*

Lemma 1.3.4.3. *Let $\mathcal{X}$ be an ∞-topos and $\mathcal{C}$ a presentable ∞-category. Then the inclusion $i : \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \subseteq \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C})$ admits a left adjoint L.*

Proof. The proof does not really require that $\mathcal{X}$ is an ∞-topos, only that $\mathcal{X}$ is a presentable ∞-category. Under this assumption, we may suppose without loss of generality that $\mathcal{X} = \mathrm{Ind}_{\kappa}(\mathcal{X}_0)$, where κ is a regular cardinal and $\mathcal{X}_0$ is a small ∞-category which admits κ-small colimits. Then i is equivalent to the composition

$$\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \xrightarrow{G_{\mathcal{C}}} \mathrm{Fun}'(\mathcal{X}_0^{\mathrm{op}}, \mathcal{C}) \overset{i'}{\subseteq} \mathrm{Fun}(\mathcal{X}_0^{\mathrm{op}}, \mathcal{C}) \xrightarrow{G'_{\mathcal{C}}} \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C}),$$

where $\mathrm{Fun}'(\mathcal{X}_0^{\mathrm{op}}, \mathcal{C})$ is the full subcategory of $\mathrm{Fun}(\mathcal{X}_0^{\mathrm{op}}, \mathcal{C})$ spanned by those functors which preserve κ-small limits, $G_{\mathcal{C}}$ is the functor given by restriction along the Yoneda embedding $j : \mathcal{X}_0 \to \mathcal{X}$, and $G'_{\mathcal{C}}$ is given by right Kan extension along j. The functor $G_{\mathcal{C}}$ is an equivalence of ∞-categories (Proposition HTT.5.5.1.9), and the functor $G'_{\mathcal{C}}$ admits a left adjoint (given by composition with j). Consequently, it suffices to show that the inclusion i' admits a left adjoint. This follows immediately from Lemmas HTT.5.5.4.17 , HTT.5.5.4.18 , and HTT.5.5.4.19 . □

Lemma 1.3.4.4. *Let $\mathcal{X}$ be an ∞-topos, and let $f : \mathcal{C} \to \mathcal{D}$ be a functor between compactly generated presentable ∞-categories. Assume that f preserves small filtered colimits. Let $L_{\mathcal{C}}$:* $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C}) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$ *and $L_{\mathcal{D}} : \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{D}) \to \mathcal{S}\mathrm{hv}_{\mathcal{D}}(\mathcal{X})$ be left adjoints to the inclusion* *functors. Then composition with f determines a functor $F : \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C}) \to \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{D})$ which carries $L_{\mathcal{C}}$-equivalences to $L_{\mathcal{D}}$-equivalences.*

Remark 1.3.4.5. In the situation of Lemma 1.3.4.4, the functor F descends to a functor $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathcal{D}}(\mathcal{X})$, given by the composition $L_{\mathcal{D}} \circ F$. This is simply another description of the construction arising from Remark 1.3.4.1.

Proof. We use notation as in the proof of Lemma 1.3.4.3. For κ sufficiently large, the full subcategory $\mathcal{X}_0 \subseteq \mathcal{X}$ is stable under limits, so that (by Proposition HTT.6.1.5.2) we have a geometric morphism $g^* : \mathcal{P}(\mathcal{X}_0) \to \mathcal{X}$. Then the functor $L_{\mathcal{C}}$ can be realized as the composition of the restriction functor $r_{\mathcal{C}} : \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C}) \to \mathrm{Fun}(\mathcal{X}_0^{\mathrm{op}}, \mathcal{C})$ with the functor $T_{\mathcal{C}} : \mathrm{Fun}(\mathcal{X}_0^{\mathrm{op}}, \mathcal{C}) \simeq \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{P}(\mathcal{X}_0)) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$ induced by g^*, and we can similarly write $L_{\mathcal{D}} = T_{\mathcal{D}} \circ r_{\mathcal{D}}$. If α is a morphism in the ∞-category $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C})$ such that $L_{\mathcal{C}}(\alpha) = T_{\mathcal{C}}(r_{\mathcal{C}}(\alpha))$ is an equivalence, then Lemma 1.3.4.2 shows that $L_{\mathcal{D}}(F(\alpha)) = T_{\mathcal{D}}(r_{\mathcal{D}}(F\alpha))$ is an equivalence, as required. □

We will regard the ∞-category Sp of spectra as endowed with the smash product monoidal structure defined in §HA.4.8.2. This symmetric monoidal structure induces a symmetric monoidal structure on the ∞-category $\mathrm{Fun}(K, \mathrm{Sp})$, for any simplicial set K (Remark HA.2.1.3.4); we will refer to this symmetric monoidal structure as the *pointwise smash product monoidal structure.*

Proposition 1.3.4.6. *Let $\mathcal{X}$ be an ∞-topos, and let $L : \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathrm{Sp}) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ be a left adjoint to the inclusion. Then L is compatible with the pointwise smash product monoidal structure, in the sense of Definition HA.2.2.1.6: that is, if $f : \mathscr{F} \to \mathscr{F}'$ is an L-equivalence in $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathrm{Sp})$ and $\mathscr{G} \in \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathrm{Sp})$, then the induced map $\mathscr{F} \otimes \mathscr{G} \to \mathscr{F}' \otimes \mathscr{G}$ is also an L-equivalence in $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathrm{Sp})$. Consequently, the ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ inherits the structure of a symmetric monoidal ∞-category, with respect to which L is a symmetric monoidal functor (Proposition HA.2.2.1.9).*

Proof. Apply Lemma 1.3.4.4 to the tensor product functor $\otimes : \mathrm{Sp} \times \mathrm{Sp} \to \mathrm{Sp}$. □

We will henceforth regard the ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ as endowed with the symmetric monoidal structure of Proposition 1.3.4.6, for any ∞-topos $\mathcal{X}$. We will abuse terminology by referring to this symmetric monoidal structure as the *smash product* symmetric monoidal structure.

Proposition 1.3.4.7. *Let $\mathcal{X}$ be an ∞-topos, and let $L : \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathrm{Sp}) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ be a left adjoint to the inclusion. Regard $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathrm{Sp})$ as endowed with the t-structure induced by the natural t-structure on Sp. Then:*

(1) *The functor L is t-exact: that is, L carries $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathrm{Sp}_{\geqslant 0})$ into $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\geqslant 0}$ and $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathrm{Sp}_{\leqslant 0})$ into $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant 0}$.*

(2) *The smash product symmetric monoidal structure on* $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ *is compatible with the t-structure on* $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$. *In other words, the full subcategory* $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})^{\mathrm{cn}} \subseteq \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ *contains the unit object and is stable under tensor products.*

Proof. The construction of Lemma 1.3.4.3 shows that (for sufficiently large κ) we can factor L as the composition of a restriction functor $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathrm{Sp}) \to \mathrm{Fun}(\mathcal{X}_0^{\mathrm{op}}, \mathrm{Sp})$ with the functor $\mathrm{Fun}(\mathcal{X}_0^{\mathrm{op}}, \mathrm{Sp}) \simeq \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{P}(\mathcal{X}_0)) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ induced by a geometric morphism $g^* : \mathcal{P}(\mathcal{X}_0) \to \mathcal{X}$. Assertion (1) now follows from Remark 1.3.2.8. To prove (2), we show that if we are given a finite collection of connective objects $\{\mathscr{F}_i\}_{1 \leqslant i \leqslant n}$ of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$, then the tensor product $\mathscr{F}_1 \otimes \cdots \otimes \mathscr{F}_n$ is connective. Choose fiber sequences $\mathscr{F}'_i \to \mathscr{F}_i \to \mathscr{F}''_i$ in $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathrm{Sp})$, where $\mathscr{F}'_i \in \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathrm{Sp}_{\geqslant 0})$ and $\mathscr{F}''_i \in \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathrm{Sp}_{\leqslant -1})$. It follows from (1) that $L\mathscr{F}'_i \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\geqslant 0}$ and $L\mathscr{F}''_i \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant -1}$. We have fiber sequences

$$L\mathscr{F}'_i \to L\mathscr{F}_i \to L\mathscr{F}''_i$$

in $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$. Since $L\mathscr{F}_i \simeq \mathscr{F}_i$ is connective, we deduce that the map $L\mathscr{F}'_i \to L\mathscr{F}_i \simeq \mathscr{F}_i$ is an equivalence for every index i. Using Proposition 1.3.4.6, we deduce that the tensor product $\mathscr{F}_1 \otimes \cdots \otimes \mathscr{F}_n$ in the ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ can be written as $L(\mathscr{F}'_1 \otimes \cdots \otimes \mathscr{F}'_n)$. By virtue of (1), it will suffice to show that $\mathscr{F}'_1 \otimes \cdots \otimes \mathscr{F}'_n$ is a connective object of $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathrm{Sp})$, which follows because the smash product monoidal structure on Sp is compatible with its t-structure (Lemma HA.7.1.1.7). □

1.3.5 Sheaves of $\mathbb{E}_\infty$-Rings

We now study sheaves with values in the ∞-category CAlg of $\mathbb{E}_\infty$-rings.

Remark 1.3.5.1. The forgetful functor $\mathrm{CAlg} = \mathrm{CAlg}(\mathrm{Sp}) \to \mathrm{Sp}$ is conservative and preserves small limits (see Lemma HA.3.2.2.6 and Corollary HA.3.2.2.5). It follows that for any ∞-topos $\mathcal{X}$, we have a canonical equivalence of ∞-categories (even an isomorphism of simplicial sets) $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X}) \simeq \mathrm{CAlg}(\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}))$.

Remark 1.3.5.2. Let $\mathcal{X}$ be an ∞-topos and $\mathscr{O} : \mathcal{X}^{\mathrm{op}} \to \mathrm{CAlg}$ a sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$. Composing with the forgetful functor $\mathrm{CAlg} \to \mathrm{Sp}$, we obtain a sheaf of spectra on $\mathcal{X}$; we will generally abuse notation by denoting this sheaf of spectra also by $\mathscr{O}$. In particular, we can define homotopy groups $\pi_n \mathscr{O}$ as in Notation 1.3.2.3. These homotopy groups have a bit more structure in this case: $\pi_0 \mathscr{O}$ is a commutative ring object in the underlying topos of $\mathcal{X}$, while each $\pi_n \mathscr{O}$ has the structure of a $\pi_0 \mathscr{O}$-module.

Definition 1.3.5.3. Let $\mathcal{X}$ be an ∞-topos. We will say that a sheaf $\mathscr{O}$ of $\mathbb{E}_\infty$-rings on $\mathcal{X}$ is *connective* if it is connective when regarded as a sheaf of spectra on $\mathcal{X}$: that is, if the homotopy groups $\pi_n \mathscr{O}$ vanish for $n < 0$. We let $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})^{\mathrm{cn}}$ denote the full subcategory of $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$ spanned by the connective sheaves of $\mathbb{E}_\infty$-rings on $\mathcal{X}$.

Remark 1.3.5.4. Let $\mathcal{X}$ be an ∞-topos. Combining Proposition 1.3.4.7 with Remark HA.2.2.1.5 , we deduce that the inclusion $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})^{\mathrm{cn}} \hookrightarrow \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$ admits a right adjoint. In other words, if $\mathscr{O}$ is an arbitrary sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$, then we can find a connective sheaf of $\mathbb{E}_\infty$-rings $\mathscr{O}'$ equipped with a map $\alpha : \mathscr{O}' \to \mathscr{O}$ having the following universal property: for every object $\mathscr{A} \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})^{\mathrm{cn}}$, composition with α induces a homotopy equivalence

$$\mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})}(\mathscr{A}, \mathscr{O}') \to \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})}(\mathscr{A}, \mathscr{O}).$$

In this case, we will say that *$\mathscr{O}'$ is a connective cover of $\mathscr{O}$*, or that α *exhibits $\mathscr{O}'$ as a connective cover of $\mathscr{O}$*. Moreover, the map α exhibits $\mathscr{O}'$ as a connective cover of $\mathscr{O}$ in the ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$; in particular, it induces isomorphisms

$$\pi_m \mathscr{O}' \simeq \begin{cases} \pi_m \mathscr{O} & \text{if } m \geqslant 0 \\ 0 & \text{if } m < 0. \end{cases}$$

We will generally denote the connective cover of $\mathscr{O}$ by $\tau_{\geqslant 0} \mathscr{O}$.

Definition 1.3.5.5. Let $\mathcal{X}$ be an ∞-topos, let $\mathscr{O}$ be a connective sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$, and let $n \geqslant 0$ be an integer. We will say that $\mathscr{O}$ is *n-truncated* if the underlying spectrum-valued sheaf of $\mathscr{O}$ is n-truncated. We will say that $\mathscr{O}$ is *discrete* if it is 0-truncated. We let $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})^{\mathrm{cn}}_{\leqslant n}$ denote the full subcategory of $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})^{\mathrm{cn}}$ spanned by the n-truncated objects of $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})^{\mathrm{cn}}$.

Remark 1.3.5.6. Let $\mathcal{X}$ be an ∞-topos and let $n \geqslant 0$ be an integer. Then we can identify $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})^{\mathrm{cn}}_{\leqslant n}$ with the ∞-category of commutative algebra objects of the symmetric monoidal ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})^{\mathrm{cn}}_{\leqslant n}$. In particular, when $n = 0$, we can identify $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})^{\mathrm{cn}}_{\leqslant n}$ with the ordinary category of commutative ring objects of the underlying topos of $\mathcal{X}$ (see Proposition 1.3.2.7).

Combining Proposition 1.3.4.7 with Proposition HA.2.2.1.9 , we deduce that the inclusion functor

$$\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})^{\mathrm{cn}}_{\leqslant n} \hookrightarrow \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})^{\mathrm{cn}}_{\leqslant n}$$

admits a left adjoint. In other words, if $\mathscr{O}$ is an arbitrary connective sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$, then we can find an n-truncated connective sheaf of $\mathbb{E}_\infty$-rings $\mathscr{O}'$ equipped with a map $\alpha : \mathscr{O} \to \mathscr{O}'$ having the following universal property: for every object $\mathscr{A} \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})^{\mathrm{cn}}_{\leqslant n}$, composition with α induces a homotopy equivalence

$$\mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})}(\mathscr{O}', \mathscr{A}) \to \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})}(\mathscr{O}, \mathscr{A}).$$

In this case, we will say that *$\mathscr{O}'$ is an n-truncation of $\mathscr{O}$*, or that α *exhibits $\mathscr{O}'$ as an n-truncation of $\mathscr{O}$*. Moreover, the map α exhibits $\mathscr{O}'$ as an n-truncation of $\mathscr{O}$ in the ∞-category

$\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$; in particular, it induces isomorphisms

$$\pi_m \mathscr{O}' \simeq \begin{cases} \pi_m \mathscr{O} & \text{if } m \leqslant n \\ 0 & \text{if } m > n. \end{cases}$$

We will generally denote the n-truncation of $\mathscr{O}$ by $\tau_{\leqslant n} \mathscr{O}$.

Let $\mathcal{X}$ be an ∞-topos and let $\mathscr{F}$ be a spectrum-valued sheaf on $\mathcal{X}$. The condition that $\mathscr{F}$ be connective *does not* guarantee that $\mathscr{F}(U)$ is connective for each object $U \in \mathcal{X}$. Nevertheless, there is a close relationship between connective Sp-valued sheaves on $\mathcal{X}$ and $\mathrm{Sp}^{\mathrm{cn}}$-valued sheaves on $\mathcal{X}$:

Proposition 1.3.5.7. *Let $\mathcal{X}$ be an ∞-topos. Then composition with the truncation functor $\tau_{\geqslant 0} : \mathrm{Sp} \to \mathrm{Sp}^{\mathrm{cn}}$ induces an equivalence of ∞-categories $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})^{\mathrm{cn}} \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}^{\mathrm{cn}}}(\mathcal{X})$.*

We will deduce Proposition 1.3.5.7 from the following more general principle:

Proposition 1.3.5.8. *Let $\mathcal{C}$ be a compactly generated presentable ∞-category. Let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a full subcategory which is closed under the formation of colimits and which is generated under small colimits by compact objects of $\mathcal{C}$. Let $\mathcal{X}$ be an ∞-topos. Then:*

(1) *The ∞-category $\mathcal{C}_0$ is presentable and compactly generated.*

(2) *The inclusion $\mathcal{C}_0 \subseteq \mathcal{C}$ admits a right adjoint g which commutes with filtered colimits.*

(3) *Composition with g determines a functor $G : \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}_0}(\mathcal{X})$.*

(4) *The functor G admits a fully faithful left adjoint F.*

Remark 1.3.5.9. In the situation of Proposition 1.3.5.8, an object $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$ belongs to the essential image of the full faithful embedding $\mathcal{S}\mathrm{hv}_{\mathcal{C}_0}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$ if and only if the canonical map $G(\mathscr{F}) \to \mathscr{F}$ is an L-equivalence in $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C})$, where L denotes a left adjoint to the inclusion $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \hookrightarrow \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C})$.

Proof of Proposition 1.3.5.7. Let $\mathrm{Sp}^{\mathrm{cn}}$ denote the full subcategory of Sp spanned by the connective spectra. Then $\mathrm{Sp}^{\mathrm{cn}}$ is stable under small colimits in Sp, and is generated under small colimits by the sphere spectrum $S \in \mathrm{Sp}^{\mathrm{cn}}$ (which is a compact object of the ∞-category Sp). Consequently, Proposition 1.3.5.8 supplies a fully faithful embedding $F : \mathcal{S}\mathrm{hv}_{\mathrm{Sp}^{\mathrm{cn}}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ for every ∞-topos $\mathcal{X}$, which is right homotopy inverse to the functor $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}^{\mathrm{cn}}}(\mathcal{X})$ given by composition with $\tau_{\geqslant 0} : \mathrm{Sp} \to \mathrm{Sp}^{\mathrm{cn}}$. To complete the proof, it will suffice to show that $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})^{\mathrm{cn}}$ is the essential image of the functor F.

Let $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$, so that we have a fiber sequence $\tau_{\geqslant 0} \mathscr{F} \xrightarrow{\phi} \mathscr{F} \to \tau_{\leqslant -1} \mathscr{F}$ in the ∞-category $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathrm{Sp})$. Let $L : \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathrm{Sp}) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ be a left adjoint to the inclusion.

According to Remark 1.3.5.9, the object $\mathscr{F}$ belongs to the essential image of F if and only if $L(\phi)$ is an equivalence. Since the functor L is t-exact, this is equivalent to the requirement that $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})^{\mathrm{cn}}$. □

Many variations on Proposition 1.3.5.7 are possible:

Proposition 1.3.5.10. *Let $\mathcal{X}$ be an ∞-topos. Then composition with the functor $\tau_{\geqslant 0}$: $\mathrm{CAlg} \to \mathrm{CAlg}^{\mathrm{cn}}$ induces an equivalence of ∞-categories $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})^{\mathrm{cn}} \to \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}^{\mathrm{cn}}}(\mathcal{X})$.*

It is possible to deduce Proposition 1.3.5.10 from the fact the the equivalence of Proposition 1.3.5.7 respects the symmetric monoidal structures on $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})^{\mathrm{cn}}$ and $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}^{\mathrm{cn}}}(\mathcal{X})$. However, we will give an alternate argument which appeals to Proposition 1.3.5.8.

Proof of Proposition 1.3.5.10. The ∞-category $\mathrm{CAlg}^{\mathrm{cn}}$ is a colocalization of CAlg, which is generated under small colimits by the compact object $\mathrm{Sym}^*(S)$, where S denotes the sphere spectrum and $\mathrm{Sym}^* : \mathrm{Sp} \to \mathrm{CAlg}$ denotes a left adjoint to the forgetful functor. Proposition 1.3.5.8 gives a fully faithful embedding $F : \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}^{\mathrm{cn}}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$ for every ∞-topos $\mathcal{X}$, which is right homotopy inverse to the functor $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}^{\mathrm{cn}}}(\mathcal{X})$ given by composition with the functor $\tau_{\geqslant 0}\, \mathrm{CAlg} \to \mathrm{CAlg}$. To complete the proof, it will suffice to show that the essential image of F coincides with $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})^{\mathrm{cn}}$.

Let $\mathscr{O} \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$ be a sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$, and let $\tau_{\geqslant 0}\,\mathscr{O} \in \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathrm{CAlg})$ be the presheaf of $\mathbb{E}_\infty$-rings obtained by pointwise passage to the connective cover. Let $\mathscr{O}' \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$ be a sheafification of the presheaf $\tau_{\geqslant 0}\,\mathscr{O}$, so that the evident map $\tau_{\geqslant 0}\,\mathscr{O} \to \mathscr{O}$ induces a map of sheaves $\alpha : \mathscr{O}' \to \mathscr{O}$. According to Remark 1.3.5.9, the sheaf $\mathscr{O}$ belongs to the essential image of F if and only if α is an equivalence. Let $u : \mathrm{CAlg} \to \mathrm{Sp}$ denote the forgetful functor. Since u preserves small limits, composition with u induces a forgetful functor $U : \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$. Since u is conservative, the functor U is also conservative, so that α is an equivalence if and only if $U(\alpha)$ is an equivalence. Since u preserves filtered colimits, Lemma 1.3.4.4 implies that $U(\mathscr{O}')$ can be identified with a sheafification of $u \circ \tau_{\geqslant 0}\,\mathscr{O} \simeq \tau_{\geqslant 0}(u \circ \mathscr{O})$. The proof of Proposition 1.3.5.7 guarantees that $U(\alpha)$ is an equivalence if and only if $U(\mathscr{O})$ is connective as a sheaf of spectra: that is, if and only if $\mathscr{O}$ belongs to $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})^{\mathrm{cn}}$. □

Proof of Proposition 1.3.5.8. Since $\mathcal{C}_0$ is stable under small colimits in $\mathcal{C}$, the inclusion $i : \mathcal{C}_0 \subseteq \mathcal{C}$ preserves small colimits so that i admits a right adjoint $g : \mathcal{C} \to \mathcal{C}_0$ by Corollary HTT.5.5.2.9 . Let $\mathcal{D} \subseteq \mathcal{C}_0$ be the full subcategory spanned by those objects of $\mathcal{C}_0$ which are compact in $\mathcal{C}$. Any such object is automatically compact in $\mathcal{C}_0$, so we have a fully faithful embedding $q : \mathrm{Ind}(\mathcal{D}) \to \mathcal{C}_0$ (Proposition HTT.5.3.5.11). Since $\mathcal{C}_0$ is generated under small colimits by objects of $\mathcal{D}$, we deduce that q is an equivalence of ∞-categories; this proves (1). Moreover, it shows that the collection of compact objects in $\mathcal{C}_0$ is an idempotent completion of $\mathcal{D}$; since $\mathcal{D}$ is already idempotent complete, we deduce that every compact object of $\mathcal{C}_0$ is also compact in $\mathcal{C}$. Assertion (2) now follows from Proposition HTT.5.5.7.2 . Assertion (3) is obvious (since g preserves small limits; see Proposition HTT.5.2.3.5).

Let $L : \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C}) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$ be a left adjoint to the inclusion, and define L_0 similarly. We observe that G is equivalent to the composition

$$\mathcal{S}\mathrm{hv}(\mathcal{C}) \subseteq \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C}) \xrightarrow{G'} \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C}_0) \xrightarrow{L_0} \mathcal{S}\mathrm{hv}_{\mathcal{C}_0}(\mathcal{X}),$$

where G' is given by composition with g. It follows that G admits a left adjoint F, which can be described as the composition

$$\mathcal{S}\mathrm{hv}(\mathcal{C}) \xleftarrow{L} \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C}) \supseteq \mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C}_0) \supseteq \mathcal{S}\mathrm{hv}_{\mathcal{C}_0}(\mathcal{X}).$$

To complete the proof, it suffices to show that F is fully faithful. In other words, we wish to show that for every object $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathcal{C}_0}(\mathcal{X})$, the unit map $\mathscr{F} \to (G \circ F)(\mathscr{F})$ is an equivalence. In other words, we wish to show that the map $\alpha : \mathscr{F} \to L\mathscr{F}$ becomes an equivalence after applying the functor G'. Since $G'(\mathscr{F}) \simeq \mathscr{F}$ and $G'(L\mathscr{F})$ belong to $\mathcal{S}\mathrm{hv}_{\mathcal{C}_0}(\mathcal{X})$, this is equivalent to the requirement that $G'(\alpha)$ is an L_0-equivalence in the ∞-category $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C}_0)$. This follows from (3) and Lemma 1.3.4.4, since α is an L-equivalence in $\mathrm{Fun}(\mathcal{X}^{\mathrm{op}}, \mathcal{C})$. □

1.4 Spectral Deligne-Mumford Stacks

In §1.1 and §1.2 we introduced two different generalizations of the notion of scheme: the notion of spectral scheme (Definition 1.1.2.8) and the notion of Deligne-Mumford stack (Definition 1.2.4.1). These two generalizations serve rather different purposes:

- The ∞-category SpSch of spectral schemes can viewed roughly as a "left-derived" version of the category of schemes. More precisely, though the category Sch and the ∞-category SpSch both admit fiber products, the inclusion Sch $\hookrightarrow$ SpSch does *not* preserve fiber products. If $f : X \to Y$ and $f' : X' \to Y$ are morphisms of schemes, then we can form a fiber product $(Z, \mathscr{O}_Z)$ of X and X' over Y in the ∞-category SpSch, whose underlying ordinary scheme $(Z, \pi_0 \mathscr{O}_Z)$ is the fiber product $X \times_Y X'$ in the category of schemes. However, the structure sheaf $\mathscr{O}_Z$ need not be 0-truncated, so that $(Z, \mathscr{O}_Z)$ need not be an ordinary scheme. This is not a bug, but a feature: the sheaves $\pi_n \mathscr{O}_Z$ carry useful geometric information which can detect (and help correct for) the failure of the maps f and f' to be transversal with respect to one another.

- The collection of Deligne-Mumford stacks is organized into a 2-category DM which can be regarded as a "right-derived" enlargement of the category of schemes. More precisely, there is a fully faithful embedding Sch $\hookrightarrow \mathcal{C}$ which is not compatible with certain very basic colimit constructions, such as passage to quotients under the action of a finite group. If X is a scheme equipped with an action of a finite group G, then one can consider either the quotient X/G in the category of schemes (which exists under mild hypotheses on X), or the stack-theoretic quotient $X//G$ in the 2-category $\mathcal{C}$. The usual quotient X/G can be recovered as the "coarse moduli space" of the Deligne-Mumford stack $X//G$, but they are generally not the same unless G acts freely on X. Once again, this should be regarded as a feature rather than a bug: the stack-theoretic quotient $X//G$ carries useful geometric information about the subgroups of G which stabilize points of X; this information is forgotten when passing to the usual quotient X/G.

For some purposes, it is useful to enlarge the category of schemes simultaneously in both of these directions. To accomplish this, we will introduce the notion of a *spectral Deligne-Mumford stack* (Definition 1.4.4.2). Roughly speaking, the definition of a spectral Deligne-Mumford stacks is obtained by modifying the definition of a scheme $(X, \mathscr{O}_X)$ in three different ways:

(*i*) For every topological space X, the ∞-category $\mathcal{S}\mathrm{hv}(X)$ of sheaves of spaces on X is an ∞-topos. Moreover, if the topological space X is *sober* (that is, if every irreducible closed subset of X has a unique generic point), then we can recover X from $\mathcal{S}\mathrm{hv}(X)$: the points $x \in X$ can be identified with isomorphism classes of geometric morphisms $x^* : \mathcal{S}\mathrm{hv}(X) \to \mathcal{S}$, and open subsets of X can be identified with subobjects of the unit object $1 \in \mathcal{S}\mathrm{hv}(X)$. In other words, the space X and the ∞-topos $\mathcal{S}\mathrm{hv}(X)$ are interchangable: either one canonically determines the other. The situation described above can be summarized by saying that we can regard the theory of ∞-topoi as a *generalization* of the classical theory of topological spaces (more precisely, of the theory of sober topological spaces). For this reason, we opt to dispense with topological spaces altogether and work instead with a general ∞-topos $\mathcal{X}$.

(*ii*) In place of the sheaf $\mathscr{O}_X$ of commutative rings on X, we consider an arbitrary sheaf $\mathscr{O}_{\mathcal{X}}$ of $\mathbb{E}_\infty$-rings on $\mathcal{X}$.

(*iii*) In place of the requirement that $(X, \mathscr{O}_X)$ be locally isomorphic to the spectrum of a commutative ring, we require that $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be locally equivalent to $\mathrm{Sp\acute{e}t}\, A$, where A is an $\mathbb{E}_\infty$-ring and $\mathrm{Sp\acute{e}t}\, A$ denotes its spectrum with respect to the étale topology (see Proposition 1.4.2.4).

1.4.1 Spectrally Ringed ∞-Topoi

We begin with a discussion of CAlg-valued rings on ∞-topoi.

Definition 1.4.1.1. A *spectrally ringed ∞-topos* is a pair $(\mathcal{X}, \mathscr{O})$, where $\mathcal{X}$ is an ∞-topos and $\mathscr{O} \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$ is a sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$.

Remark 1.4.1.2. Let $\mathsf{X} = (\mathcal{X}, \mathcal{O})$ be a spectrally ringed ∞-topos. We will often refer to $\mathcal{O}$ as the *structure sheaf* of X. We will often denote the structure sheaf $\mathcal{O}$ by $\mathcal{O}_{\mathcal{X}}$ or $\mathcal{O}_{\mathsf{X}}$ (the latter notation is convenient when we wish to distinguish between spectrally ringed ∞-topoi having the same underlying ∞-topos).

Construction 1.4.1.3. Precomposition with a geometric morphism of ∞-topoi $f^* : \mathcal{X} \to \mathcal{Y}$ induces a pushforward functor $f_* : \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{Y})$. We may therefore view the construction $\mathcal{X} \mapsto \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})^{\mathrm{op}}$ as determining a functor $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}} : \infty\mathcal{T}\mathrm{op} \to \widehat{\mathcal{C}\mathrm{at}}_{\infty}$, where $\infty\mathcal{T}\mathrm{op}$ denotes the ∞-category of ∞-topoi. This functor classifies a coCartesian fibration $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}} \to \infty\mathcal{T}\mathrm{op}$. More informally, the objects of $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ are spectrally ringed ∞-topoi $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$, and a morphism from $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ to $(\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ in $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ is given by a pair (f^*, ϕ), where $f_* : \mathcal{X} \to \mathcal{Y}$ is a geometric morphism of ∞-topoi and $\phi : \mathcal{O}_{\mathcal{Y}} \to f_* \mathcal{O}_{\mathcal{X}}$ is a morphism of sheaves of $\mathbb{E}_{\infty}$-rings on $\mathcal{Y}$. We will refer to $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ as the *∞-category of spectrally ringed ∞-topoi.*

Remark 1.4.1.4. Let $\mathcal{X}$ be an ∞-topos and let $\mathcal{X}^{\heartsuit}$ denote the underlying topos of $\mathcal{X}$. For any sheaf of $\mathbb{E}_{\infty}$-rings $\mathcal{O}_{\mathcal{X}}$ on $\mathcal{X}$, we can regard $\pi_0 \mathcal{O}_{\mathcal{X}}$ as a commutative ring object of $\mathcal{X}^{\heartsuit}$. We will refer to $(\mathcal{X}^{\heartsuit}, \pi_0 \mathcal{O}_{\mathcal{X}})$ as the *underlying ringed topos* of $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$. The construction

$$(\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \mapsto (\mathcal{X}^{\heartsuit}, \pi_0 \mathcal{O}_{\mathcal{X}})$$

determines a functor from the homotopy 2-category of $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ to the 2-category $1\mathcal{T}\mathrm{op}_{\mathrm{CAlg}^{\heartsuit}}$ of ringed topoi.

Remark 1.4.1.5. Let $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a ringed topos, and let $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X})$ denote the 1-localic ∞-topos associated to $\mathcal{X}$ (see §HTT.6.4.5). Remark 1.3.5.6 supplies an equivalence from the category of commutative ring objects of $\mathcal{X}$ to the ∞-category of connective 0-truncated sheaves of $\mathbb{E}_{\infty}$-rings on $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X})$. We let $\mathcal{O}$ denote the image of $\mathcal{O}_{\mathcal{X}}$ under this equivalence. Then $(\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}), \mathcal{O})$ is a spectrally ringed ∞-topos. Moreover, the construction $(\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \mapsto (\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}), \mathcal{O})$ determines a fully faithful embedding from the ∞-category of ringed topoi (obtained from the 2-category $1\mathcal{T}\mathrm{op}_{\mathrm{CAlg}^{\heartsuit}}$ by discarding noninvertible 2-morphisms) to the ∞-category $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ of spectrally ringed ∞-topoi. The essential image of this fully faithful embedding consists of those spectrally ringed ∞-topoi $(\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ where $\mathcal{Y}$ is 1-localic and the structure sheaf $\mathcal{O}_{\mathcal{Y}}$ is connective and 0-truncated.

Remark 1.4.1.6. For every topological space X, Example 1.3.1.2 supplies an equivalence of ∞-categories $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{S}\mathrm{hv}_{\mathcal{S}}(X)) \to \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(X)$, which depends functorially on X. It follows that there is a commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathcal{T}\mathrm{op}_{\mathrm{CAlg}} & \xrightarrow{\overline{\phi}} & \infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}} \\ \downarrow & & \downarrow \\ \mathcal{T}\mathrm{op} & \xrightarrow{\phi} & \infty\mathcal{T}\mathrm{op}, \end{array}$$

where $\phi : \mathcal{T}\mathrm{op} \to \infty\mathcal{T}\mathrm{op}$ is the functor which carries a topological space X to its associated ∞-topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(X)$.

1.4.2 The Étale Spectrum of an $\mathbb{E}_\infty$-Ring

In §1.2, we constructed the *étale spectrum* $\mathrm{Sp\acute{e}t}\, R$ of a commutative ring R (Definition 1.2.2.5). We now introduce an analogous construction in the setting of $\mathbb{E}_\infty$-rings.

Definition 1.4.2.1. Let $\mathcal{X}$ be an ∞-topos and let $\mathcal{O}_{\mathcal{X}}$ be a sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$. We will say that $\mathcal{O}_{\mathcal{X}}$ is *local* if $\pi_0 \mathcal{O}_{\mathcal{X}}$ is local, when regarded as a commutative ring object of the topos $\mathcal{X}^{\heartsuit}$ (see Definition 1.2.1.4). We will say that $\mathcal{O}_{\mathcal{X}}$ is *strictly Henselian* if $\pi_0 \mathcal{O}_{\mathcal{X}}$ is strictly Henselian, in the sense of Definition 1.2.2.5.

If $f : \mathcal{O} \to \mathcal{O}'$ is a morphism of CAlg-valued sheaves on $\mathcal{X}$, we will say that f is *local* if it induces a local morphism $\pi_0 \mathcal{O} \to \pi_0 \mathcal{O}'$ of commutative ring objects of the topos $\mathcal{X}^{\heartsuit}$, in the sense of Definition 1.2.1.4.

We let $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ denote the subcategory of $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ whose objects are spectrally ringed ∞-topoi $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ for which $\mathcal{O}_{\mathcal{X}}$ is local, and whose morphisms are maps $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ for which the associated map $f^* \mathcal{O}_{\mathcal{Y}} \to \mathcal{O}_{\mathcal{X}}$ is a local morphism of CAlg-valued sheaves on $\mathcal{X}$. We let $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$ denote the full subcategory of $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ spanned by those pairs $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ where $\mathcal{O}_{\mathcal{X}}$ is strictly Henselian. We will say that a spectrally ringed ∞-topos $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is *local* if it belongs to $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$, and *strictly Henselian* if it belongs to $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$.

Remark 1.4.2.2. Let $(X, \mathcal{O}_X)$ be a spectrally ringed space. If $\mathcal{O}_X$ is strictly Henselian (when regarded as a CAlg-valued sheaf on the ∞-topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(X)$), then $\mathcal{O}_X$ is local (in the sense of Definition 1.1.5.3).

The equivalence of ∞-categories $\mathrm{CAlg}^{\mathrm{op}} \simeq \infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}} \times_{\infty\mathcal{T}\mathrm{op}} \{\mathcal{S}\}$ determines a fully faithful embedding $\mathrm{CAlg}^{\mathrm{op}} \hookrightarrow \infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$, which carries each $\mathbb{E}_\infty$-ring A to the spectrally ringed ∞-topos $(\mathcal{S}, \mathcal{O}_A)$ where $\mathcal{O}_A \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{S})$ is characterized by existence of an equivalence $\mathcal{O}_A(*) \simeq A$. This embedding admits a left adjoint, which carries a pair $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ to the $\mathbb{E}_\infty$-ring $\mathcal{O}_{\mathcal{X}}(\mathbf{1})$, where $\mathbf{1}$ is a final object of $\mathcal{X}$. We will denote this left adjoint by $(\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \mapsto \Gamma(\mathcal{X}; \mathcal{O}_{\mathcal{X}})$, and refer to it as the *global sections functor*.

We will need the following analogue of Remark 1.1.5.6:

Proposition 1.4.2.3. *The global sections functor*

$$\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}} \to \mathrm{CAlg}^{\mathrm{op}}$$

$$(\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \mapsto \Gamma(\mathcal{X}; \mathcal{O}_{\mathcal{X}})$$

admits a right adjoint $\mathrm{Sp\acute{e}t} : \mathrm{CAlg}^{\mathrm{op}} \to \infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$.

Proposition 1.4.2.3 asserts that for every $\mathbb{E}_\infty$-ring R, there exists a strictly Henselian spectrally ringed ∞-topos $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ and a map $\theta : R \to \Gamma(\mathcal{X}; \mathcal{O}_\mathcal{X})$ with the following universal property: for every strictly Henselian spectrally ringed ∞-topos $(\mathcal{Y}, \mathcal{O}_\mathcal{Y})$, composition with θ induces a homotopy equivalence

$$\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}((\mathcal{Y}, \mathcal{O}_\mathcal{Y}), (\mathcal{X}, \mathcal{O}_\mathcal{X})) \to \mathrm{Map}_{\mathrm{CAlg}}(R, \Gamma(\mathcal{Y}; \mathcal{O}_\mathcal{Y})).$$

The spectrally ringed ∞-topos $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ is uniquely determined up to equivalence and depends functorially on R. A more explicit description of $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ is given by the following:

Proposition 1.4.2.4. *Let R be an $\mathbb{E}_\infty$-ring, and let $\mathcal{O} : \mathrm{CAlg}^{\acute{e}t}_R \to \mathrm{CAlg}$ denote the forgetful functor. Then:*

(1) *The functor $\mathcal{O}$ is a sheaf with respect to the étale topology of Notation* **??**.

(2) *When regarded as a sheaf of $\mathbb{E}_\infty$-rings on the ∞-topos $\mathcal{S}\mathrm{hv}^{\acute{e}t}_R$ (see Proposition 1.3.1.7), the sheaf $\mathcal{O}$ is strictly Henselian.*

By construction, we have a canonical equivalence

$$\alpha : \Gamma(\mathcal{S}\mathrm{hv}^{\acute{e}t}_R; \mathcal{O}) \simeq \mathcal{O}(R) = R.$$

(3) *Let $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ be an arbitrary object of $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$. Then composition with α induces a homotopy equivalence*

$$\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}((\mathcal{X}, \mathcal{O}_\mathcal{X}), (\mathcal{S}\mathrm{hv}^{\acute{e}t}_R, \mathcal{O})) \to \mathrm{Map}_{\mathrm{CAlg}}(R, \Gamma(\mathcal{X}; \mathcal{O}_\mathcal{X})).$$

We postpone the proof for the moment.

Definition 1.4.2.5. Let R be an $\mathbb{E}_\infty$-ring. We let $\mathrm{Sp\acute{e}t}\, R$ denote the spectrally ringed ∞-topos $(\mathcal{S}\mathrm{hv}^{\text{ét}}_R, \mathcal{O})$ appearing in Proposition 1.4.2.4. We will refer to $\mathrm{Sp\acute{e}t}\, R$ as the *étale spectrum of R*.

Warning 1.4.2.6. Let R be a commutative ring. We now have two definitions for the étale spectrum of R:

(a) We can regard R as an ordinary commutative ring, and consider the ringed topos $(\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}^{\text{ét}}_R), \mathcal{O}_0)$ introduced in Definition 1.2.3.3.

(b) We can regard R as a discrete $\mathbb{E}_\infty$-ring, and consider the spectrally ringed ∞-topos $(\mathcal{S}\mathrm{hv}^{\text{ét}}_R, \mathcal{O})$ of Definition 1.4.2.5.

However, there should be little risk of confusion: these two mathematical objects are essentially identical with one another. More precisely, the spectrally ringed ∞-topos $(\mathcal{S}\mathrm{hv}^{\text{ét}}_R, \mathcal{O})$ is the image of $(\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}^{\text{ét}}_R), \mathcal{O}_0)$ under the fully faithful embedding described in Remark **??**.

Remark 1.4.2.7. It follows from the third assertion of Proposition 1.4.2.4 that the construction $R \mapsto \operatorname{Spét} R$ can be regarded as a right adjoint to the global sections functor $\Gamma : \infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}} \to \mathrm{CAlg}^{\mathrm{op}}$; in particular, the étale spectrum $\operatorname{Spét} R$ depends functorially on R.

1.4.3 Solution Sheaves

We now introduce some terminology which will be useful for the proof of Proposition 1.4.2.4.

Notation 1.4.3.1. Let $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a spectrally ringed ∞-topos. For each $\mathbb{E}_\infty$-ring R, the construction $(U \in \mathcal{X}) \mapsto \mathrm{Map}_{\mathrm{CAlg}}(R, \mathcal{O}_{\mathcal{X}}(U))$ determines a $\mathcal{S}$-valued sheaf on $\mathcal{X}$. We let $\mathcal{S}\mathrm{ol}_R(\mathcal{O}_{\mathcal{X}})$ denote an object of $\mathcal{X}$ which represents this functor.

Example 1.4.3.2. Let $R = \mathrm{Sym}^*(S^n)$ denote the free $\mathbb{E}_\infty$-ring on a single generator in degree n. If $\mathcal{O}_{\mathcal{X}}$ is a sheaf of $\mathbb{E}_\infty$-rings on an ∞-topos $\mathcal{X}$, then there is a canonical equivalence $\mathcal{S}\mathrm{ol}_R(\mathcal{O}_{\mathcal{X}}) \simeq \Omega^{\infty+n}\,\mathcal{O}_{\mathcal{X}}$ in the ∞-topos $\mathcal{X}$.

Remark 1.4.3.3 (Functoriality in R)**.** Let $\mathcal{X}$ be an ∞-topos and let $\mathcal{O}_{\mathcal{X}}$ be a sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$. Then the construction $R \mapsto \mathcal{S}\mathrm{ol}_R(\mathcal{O}_{\mathcal{X}})$ is contravariantly functorial in R. Moreover, it carries colimits (in the ∞-category CAlg of $\mathbb{E}_\infty$-rings) to limits (in the ∞-topos $\mathcal{X}$).

Remark 1.4.3.4 (Functoriality in $\mathcal{O}_{\mathcal{X}}$)**.** Let $\mathcal{X}$ be an ∞-topos and let R be an $\mathbb{E}_\infty$-ring. Then the construction $\mathcal{O}_{\mathcal{X}} \mapsto \mathcal{S}\mathrm{ol}_R(\mathcal{O}_{\mathcal{X}})$ determines a functor $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}(\mathcal{X})$ which preserves small limits.

Remark 1.4.3.5 (Functoriality in $\mathcal{X}$)**.** Let $f_* : \mathcal{X} \to \mathcal{Y}$ be a geometric morphism of ∞-topoi and let R be an $\mathbb{E}_\infty$-ring. Then the diagram

$$\begin{array}{ccc} \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X}) & \xrightarrow{\mathcal{S}\mathrm{ol}_R} & \mathcal{X} \\ \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} \\ \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{Y}) & \xrightarrow{\mathcal{S}\mathrm{ol}_R} & \mathcal{Y} \end{array}$$

commutes (up to canonical equivalence).

Remark 1.4.3.6. In the situation of Notation 1.4.3.1, suppose that R is connective. Then for any object $\mathcal{O}_{\mathcal{X}} \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$, the canonical map $\mathcal{S}\mathrm{ol}_R(\tau_{\geq 0}\,\mathcal{O}_{\mathcal{X}}) \to \mathcal{S}\mathrm{ol}_R(\mathcal{O}_{\mathcal{X}})$ is an equivalence in $\mathcal{X}$.

It follows from Remark 1.4.3.5 that for any geometric morphism of ∞-topoi $f_* : \mathcal{X} \to \mathcal{Y}$ and any $\mathbb{E}_\infty$-ring R, there is a canonical natural transformation of functors $f^*\,\mathcal{S}\mathrm{ol}_R \to \mathcal{S}\mathrm{ol}_R\,f^*$ from $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{Y})$ to $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$.

Lemma 1.4.3.7. *Let R be a compact object of* CAlg*. Then, for any geometric morphism of ∞-topoi $f_* : \mathcal{X} \to \mathcal{Y}$ and any sheaf $\mathscr{O}_{\mathcal{Y}}$ of $\mathbb{E}_\infty$-rings on $\mathcal{Y}$, the canonical map $f^* \mathcal{S}\mathrm{ol}_R(\mathscr{O}_{\mathcal{Y}}) \to \mathcal{S}\mathrm{ol}_R(f^* \mathscr{O}_{\mathcal{Y}})$ is an equivalence in $\mathcal{X}$.*

Proof. Let $\mathcal{C} \subseteq \mathrm{CAlg}_R$ be the full subcategory spanned by those objects R for which the natural map $f^* \mathcal{S}\mathrm{ol}_R \to \mathcal{S}\mathrm{ol}_R f^*$ is an equivalence of functors from $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{Y})$ to $\mathcal{X}$. Then $\mathcal{C}$ is closed under retracts, and it follows from Remark 1.4.3.3 (together with the left exactness of f^*) that $\mathcal{C}$ is closed under finite colimits in CAlg_R. To prove that $\mathcal{C}$ contains all compact objects of CAlg_R, it will suffice to show that it contains all free algebras of the form $\mathrm{Sym}^*(S^n)$, which follows from Example 1.4.3.2. □

Lemma 1.4.3.8. *Let $f : A \to B$ be an étale morphism between connective $\mathbb{E}_\infty$-rings, and let $\mathscr{O}_{\mathcal{X}}$ be a connective sheaf of $\mathbb{E}_\infty$-rings on an ∞-topos $\mathcal{X}$. Then the diagram*

$$\begin{array}{ccc} \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{X}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_B(\pi_0 \mathscr{O}_{\mathcal{X}}) \\ \downarrow & & \downarrow \\ \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{X}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_A(\pi_0 \mathscr{O}_{\mathcal{X}}) \end{array}$$

is a pullback square in $\mathcal{X}$.

Proof. Using Proposition B.1.1.3, we can choose a pushout diagram

$$\begin{array}{ccc} A_0 & \longrightarrow & A \\ \downarrow{\scriptstyle f_0} & & \downarrow{\scriptstyle f} \\ B_0 & \longrightarrow & B \end{array}$$

in CAlg, where f_0 is étale and the $\mathbb{E}_\infty$-rings A_0 and B_0 are compact and connective. Using Remark 1.4.3.3, we can replace f by f_0 and thereby reduce to the case where A and B are compact. Because $\mathcal{X}$ is an ∞-topos, we can choose a small ∞-category $\mathcal{C}$ and a geometric morphism $\phi_* : \mathcal{X} \to \mathcal{P}(\mathcal{C})$ which exhibits $\mathcal{X}$ as a left exact localization of $\mathcal{P}(\mathcal{C})$. We then have equivalences

$$\mathscr{O}_{\mathcal{X}} \simeq \phi^*(\tau_{\geqslant 0}\phi_* \mathscr{O}_{\mathcal{X}}) \qquad \pi_0 \mathscr{O}_{\mathcal{X}} \simeq \phi^*(\pi_0 \phi_* \mathscr{O}_{\mathcal{X}}).$$

Using Lemma 1.4.3.7, we can replace $\mathscr{O}_{\mathcal{X}}$ by $\tau_{\geqslant 0}(\phi_* \mathscr{O}_{\mathcal{X}})$ and thereby reduce to the case where $\mathcal{X} = \mathcal{P}(\mathcal{C})$ is an ∞-category of presheaves. In this case, we are reduced to proving that for every object $C \in \mathcal{C}$, the diagram of mapping spaces

$$\begin{array}{ccc} \mathrm{Map}_{\mathrm{CAlg}}(B, \mathscr{O}_{\mathcal{X}}(C)) & \longrightarrow & \mathrm{Map}_{\mathrm{CAlg}}(B, \pi_0 \mathscr{O}_{\mathcal{X}}(C)) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathrm{CAlg}}(A, \mathscr{O}_{\mathcal{X}}(C)) & \longrightarrow & \mathrm{Map}_{\mathrm{CAlg}}(A, \pi_0 \mathscr{O}_{\mathcal{X}}(C)) \end{array}$$

is a pullback square, which follows from Theorem HA.7.5.4.2 . □

Lemma 1.4.3.9. *(a) Let $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ be a spectrally ringed ∞-topos. Then $\mathcal{O}_\mathcal{X}$ is strictly Henselian if and only if, for every $\mathbb{E}_\infty$-ring A and every faithfully flat étale morphism $A \to \prod_{1 \leqslant i \leqslant n} A_i$, the induced map*

$$\coprod_{1 \leqslant i \leqslant n} \mathcal{S}\mathrm{ol}_{A_i}(\mathcal{O}_\mathcal{X}) \to \mathcal{S}\mathrm{ol}_A(\mathcal{O}_\mathcal{X})$$

is an effective epimorphism in $\mathcal{X}$.

(b) Let $f : (\mathcal{X}, \mathcal{O}_\mathcal{X}) \to (\mathcal{Y}, \mathcal{O}_\mathcal{Y})$ be a morphism of spectrally ringed ∞-topoi, where $\mathcal{O}_\mathcal{X}$ and $\mathcal{O}_\mathcal{Y}$ are strictly Henselian. Then f is a morphism in $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$ if and only if, for every étale morphism of $\mathbb{E}_\infty$-rings $A \to B$, the associated diagram

$$\begin{array}{ccc} f^* \mathcal{S}\mathrm{ol}_B(\mathcal{O}_\mathcal{Y}) & \longrightarrow & \mathcal{S}\mathrm{ol}_B(\mathcal{O}_\mathcal{X}) \\ \downarrow & & \downarrow \\ f^* \mathcal{S}\mathrm{ol}_A(\mathcal{O}_\mathcal{Y}) & \longrightarrow & \mathcal{S}\mathrm{ol}_A(\mathcal{O}_\mathcal{X}). \end{array}$$

Proof. We first prove the "only if" direction of (a). Assume that $\mathcal{O}_\mathcal{X}$ is strictly Henselian and that we are given a collection of étale morphisms $\{A \to A_i\}_{1 \leqslant i \leqslant n}$ for which the induced map $A \to \prod_{1 \leqslant i \leqslant n} A_i$ is faithfully flat. We wish to prove that the induced map

$$\coprod_{1 \leqslant i \leqslant n} \mathcal{S}\mathrm{ol}_{A_i}(\mathcal{O}_\mathcal{X}) \to \mathcal{S}\mathrm{ol}_A(\mathcal{O}_\mathcal{X})$$

is an effective epimorphism. Note that each of the maps $A \to A_i$ is flat, and therefore fits into a pushout square of $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc} \tau_{\geqslant 0} A & \longrightarrow & \tau_{\geqslant 0} A_i \\ \downarrow & & \downarrow \\ A & \longrightarrow & A_i. \end{array}$$

Using Remark 1.4.3.3, we obtain a pullback diagram

$$\begin{array}{ccc} \coprod_{1 \leqslant i \leqslant n} \mathcal{S}\mathrm{ol}_{A_i}(\mathcal{O}_\mathcal{X}) & \longrightarrow & \mathcal{S}\mathrm{ol}_A(\mathcal{O}_\mathcal{X}) \\ \downarrow & & \downarrow \\ \coprod_{1 \leqslant i \leqslant n} \mathcal{S}\mathrm{ol}_{\tau_{\geqslant 0} A_i}(\mathcal{O}_\mathcal{X}) & \longrightarrow & \mathcal{S}\mathrm{ol}_{\tau_{\geqslant 0} A}(\mathcal{O}_\mathcal{X}). \end{array}$$

Consequently, to prove the the upper horizontal map in this diagram is an effective epimorphism, it will suffice to show that the lower horizontal map is an effective epimorphism. We may therefore replace A by $\tau_{\geqslant 0} A$ (and each A_i with $\tau_{\geqslant 0} A_i$) and thereby reduce to the case where A is connective. In this case, there is no loss of generality in assuming that $\mathscr{O}_{\mathcal{X}}$ is connective (Remark 1.4.3.6). Lemma 1.4.3.8 now supplies a pullback diagram

$$\begin{array}{ccc} \coprod_{1 \leqslant i \leqslant n} \mathcal{S}\mathrm{ol}_{A_i}(\mathscr{O}_{\mathcal{X}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{X}}) \\ \downarrow & & \downarrow \\ \coprod_{1 \leqslant i \leqslant n} \mathcal{S}\mathrm{ol}_{A_i}(\pi_0 \mathscr{O}_{\mathcal{X}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_A(\pi_0 \mathscr{O}_{\mathcal{X}}), \end{array}$$

where the bottom horizontal map is an effective epimorphism (between discrete objects of $\mathcal{X}$) by virtue of our assumption that $\pi_0 \mathscr{O}_{\mathcal{X}}$ is strictly Henselian.

We now prove the "if" direction of (a). Assume that $\mathscr{O}_{\mathcal{X}}$ has the property described by (a); we wish to show that for every commutative ring R and every finite collection of étale morphisms $\{R \to R_i\}_{1 \leqslant i \leqslant n}$ for which the induced map $R \to \prod R_i$ is faithfully flat, the induced map $\amalg \mathcal{S}\mathrm{ol}_{R_i}(\pi_0 \mathscr{O}_{\mathcal{X}}) \to \mathcal{S}\mathrm{ol}_R(\pi_0 \mathscr{O}_{\mathcal{X}})$ is an effective epimorphism (between discrete objects of $\mathcal{X}$). Writing R as a direct limit of its finitely generated subrings, we may assume without loss of generality that R is finitely generated: that is, there exists a surjection of commutative rings $P \to R$, where P is a polynomial ring over $\mathbf{Z}$. Using the structure theory of étale morphisms of commutative rings (see Proposition B.1.1.3), we can lift each R_i to an étale P-algebra P_i. Let $U \subseteq \operatorname{Spec} P$ be the union of the images of the maps $\operatorname{Spec} P_i \to \operatorname{Spec} P$. Since étale morphisms have open images, the set U is open with respect to the Zariski topology. It is clearly quasi-compact, so we can choose a collection of elements $t_1, \ldots, t_k \in P$ for which U is covered by the open subsets $\operatorname{Spec} P[t_j^{-1}] \subseteq \operatorname{Spec} P$. Because the map $R \to \prod R_i$ is faithfully flat, the map $\operatorname{Spec} R \to \operatorname{Spec} P$ factors through U. We may therefore choose coefficients $\overline{c}_j \in R$ for which the sum $\overline{c}_1 t_1 + \cdots + \overline{c}_k t_k = 1$ in R; here we abuse notation by identifying each t_j with its image in R. Using the surjectivity of the map $P \to R$, we can lift each $\overline{c}_j$ to an element $c_j \in P$. Let $u = c_1 t_1 + \cdots + c_k t_k$. Then the map $P[u^{-1}] \to \prod P_i[u^{-1}]$ is faithfully flat and the map $P \to R$ factors through $P[u^{-1}]$. We may therefore replace R by $P[u^{-1}]$ and thereby reduce to the case where the commutative ring R has the form $\mathbf{Z}[x_1, \ldots, x_m][u^{-1}]$ for some $u \in \mathbf{Z}[x_1, \ldots, x_m]$.

Let $\overline{R}$ denote the $\mathbb{E}_\infty$-ring given by $S\{x_1, \ldots, x_m\}[u^{-1}]$, so that $R = \pi_0 \overline{R}$. Since the composite map

$$\coprod_{1 \leqslant i \leqslant n} \mathcal{S}\mathrm{ol}_{\overline{R}_i}(\mathscr{O}_{\mathcal{X}}) \xrightarrow{\rho} \mathcal{S}\mathrm{ol}_{\overline{R}}(\mathscr{O}_{\mathcal{X}}) \xrightarrow{\rho'} \mathcal{S}\mathrm{ol}_{\overline{R}}(\pi_0 \mathscr{O}_{\mathcal{X}}) \simeq \mathcal{S}\mathrm{ol}_R(\pi_0 \mathscr{O}_{\mathcal{X}})$$

factors through $\amalg_{1 \leqslant i \leqslant n} \mathcal{S}\mathrm{ol}_{R_i}(\pi_0 \mathscr{O}_{\mathcal{X}})$, it will suffice to show that ρ and ρ' are effective epimorphisms. The map ρ is an effective epimorphism by virtue of our assumption that $\mathscr{O}_{\mathcal{X}}$ satisfies the condition described in (a). The map ρ' is an effective epimorphism because it is a pullback of the mth power of the effective epimorphism $\Omega^\infty \mathscr{O}_{\mathcal{X}} \to \pi_0 \mathscr{O}_{\mathcal{X}}$. This completes the proof of (a).

We now prove (*b*). Suppose first that f is a morphism in $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$; we wish to show that if $\phi : A \to B$ is an étale morphism of $\mathbb{E}_\infty$-rings, then the diagram

$$\begin{array}{ccc} f^* \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{Y}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{X}}) \\ \downarrow & & \downarrow \\ f^* \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{Y}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{X}}) \end{array}$$

is a pullback square in $\mathcal{X}$. As in the first part of the proof, it will suffice to prove this in the special case where A and B are connective. Remark 1.4.3.6 then allows us to replace $\mathscr{O}_{\mathcal{X}}$ and $\mathscr{O}_{\mathcal{Y}}$ by their connective covers, and thereby reduce to the case where they are connective as well. In this case, we have a commutative diagram

$$\begin{array}{ccccc} f^* \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{Y}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{X}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_B(\pi_0 \mathscr{O}_{\mathcal{X}}) \\ \downarrow & & \downarrow & & \downarrow \\ f^* \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{Y}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{X}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_A(\pi_0 \mathscr{O}_{\mathcal{X}}) \end{array}$$

where the right square is a pullback by Lemma 1.4.3.8. It will therefore suffice to show that the outer rectangle is a pullback. This rectangle also appears in the commutative diagram

$$\begin{array}{ccccc} f^* \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{Y}}) & \longrightarrow & f^* \mathcal{S}\mathrm{ol}_B(\pi_0 \mathscr{O}_{\mathcal{Y}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_B(\pi_0 \mathscr{O}_{\mathcal{X}}) \\ \downarrow & & \downarrow & & \downarrow \\ f^* \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{Y}}) & \longrightarrow & f^* \mathcal{S}\mathrm{ol}_A(\pi_0 \mathscr{O}_{\mathcal{Y}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_A(\pi_0 \mathscr{O}_{\mathcal{X}}) \end{array}$$

where the left square is a pullback (Lemma 1.4.3.8). We are then reduced to showing that the right square is a pullback diagram (of discrete objects of $\mathcal{X}$), which follows from Proposition 1.2.2.12.

For the converse, suppose that f satisfies the condition described in (*b*); we claim that induced map $f^* \mathscr{O}_{\mathcal{Y}} \to \mathscr{O}_{\mathcal{X}}$ is local. Fix an object $X \in \mathcal{X}$ and a map $e : X \to \pi_0 f^* \mathscr{O}_{\mathcal{Y}}$, and let $\overline{e}$ denote the composite map $X \xrightarrow{e} \pi_0 f^* \mathscr{O}_{\mathcal{Y}} \to \pi_0 \mathscr{O}_{\mathcal{X}}$. We must show that if $\overline{e}$ is invertible when regarded as an element of the commutative ring $\pi_0 \mathrm{Map}_{\mathcal{X}}(X, \pi_0 \mathscr{O}_{\mathcal{X}})$, then e is invertible when regarded as an element of the commutative ring $\pi_0 \mathrm{Map}_{\mathcal{X}}(X, \pi_0 f^* \mathscr{O}_{\mathcal{Y}})$. This assertion is local X: we may therefore assume without loss of generality that e factors through a map $X \to f^* \mathscr{O}_{\mathcal{Y}}$. In this case, the desired result follows by inspecting the diagram

$$\begin{array}{ccccc} f^* \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{Y}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_B(\mathscr{O}_{\mathcal{X}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_B(\pi_0 \mathscr{O}_{\mathcal{X}}) \\ \downarrow & & \downarrow & & \downarrow \\ f^* \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{Y}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{X}}) & \longrightarrow & \mathcal{S}\mathrm{ol}_A(\pi_0 \mathscr{O}_{\mathcal{X}}) \end{array}$$

in the special case $A = S\{x\}$ and $B = S\{x\}[x^{-1}]$; here the left square is a pullback by virtue of our hypothesis on f and the right square is a pullback by virtue of Lemma 1.4.3.8. □

Proof of Proposition 1.4.2.4. Let R be an $\mathbb{E}_\infty$-ring and let $\mathscr{O} : \mathrm{CAlg}_R^{\text{ét}} \to \mathrm{CAlg}$ be the forgetful functor. It follows from Theorem D.6.3.5 that $\mathscr{O}$ is a CAlg-valued sheaf (with respect to the étale topology on $\mathrm{CAlg}_R^{\text{ét}}$). Note that $\pi_0 \mathscr{O}$ can be identified with the sheafification of the presheaf of commutative rings given by the composite map $\mathrm{CAlg}_R^{\text{ét}} \xrightarrow{\pi_0} \mathrm{CAlg}^{\heartsuit}$, which is the structure sheaf of the Deligne-Mumford stack $\mathrm{Spét}\, R$. It follows from Proposition 1.2.3.2 that $\pi_0 \mathscr{O}$ is strictly Henselian, so that the sheaf $\mathscr{O}$ is strictly Henselian.

Let $\mathcal{X}$ be an arbitrary ∞-topos and let $\mathscr{O}_{\mathcal{X}}$ be a strictly Henselian CAlg-valued sheaf on $\mathcal{X}$. The construction $A \mapsto \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{X}})$ determines a functor $\mathcal{S}\mathrm{ol}_\bullet(\mathscr{O}_{\mathcal{X}}) : \mathrm{CAlg}_R^{\text{ét}} \to \mathcal{X}^{\mathrm{op}}$. Applying Proposition HTT.6.1.5.2 , we can identify the mapping space $\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{X}, \mathcal{S}\mathrm{hv}_R^{\text{ét}})$ with the full subcategory of $\mathrm{Fun}(\mathrm{CAlg}_A^{\text{ét}}, \mathcal{X})^{\simeq}$ spanned by those functors $\chi : (\mathrm{CAlg}_R^{\text{ét}})^{\mathrm{op}} \to \mathcal{X}$ which satisfy the following conditions:

(i) The functor χ preserves finite limits.

(ii) For every faithfully flat étale morphism $A \to \prod_{1 \leqslant i \leqslant n} A_i$ in $\mathrm{CAlg}_R^{\text{ét}}$, the induced map $\amalg \chi(A_i) \to \chi(A)$ is an effective epimorphism in the ∞-topos $\mathcal{X}$.

If χ is a functor satisfying these conditions and $f_* : \mathcal{X} \to \mathcal{S}\mathrm{hv}_R^{\text{ét}}$ is the associated geometric morphism, then we can identify the direct image $f_* \mathscr{O}_{\mathcal{X}}$ with the CAlg-valued sheaf on $\mathrm{CAlg}_R^{\text{ét}}$ given by $\mathrm{CAlg}_R^{\text{ét}} \xrightarrow{\chi} \mathcal{X}^{\mathrm{op}} \xrightarrow{\mathscr{O}_{\mathcal{X}}} \mathrm{CAlg}$. We may therefore identify the mapping space $\mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{S}\mathrm{hv}_R^{\text{ét}})}(\mathscr{O}, f_* \mathscr{O}_{\mathcal{X}})$ with the mapping space $\mathrm{Map}_{\mathrm{Fun}((\mathrm{CAlg}_R^{\text{ét}})^{\mathrm{op}}, \mathcal{X})}(\chi, \mathcal{S}\mathrm{ol}_\bullet(\mathscr{O}_{\mathcal{X}}))$.

Let $\mathbf{1}_{\mathcal{X}}$ denote a final object of $\mathcal{X}$. Fix a morphism of $\mathbb{E}_\infty$-rings $\phi : R \to \Gamma(\mathcal{X}; \mathscr{O}_{\mathcal{X}})$, which we can identify with a map $\mathbf{1}_{\mathcal{X}} \to \mathcal{S}\mathrm{ol}_{\mathbf{R}}(\mathscr{O}_{\mathcal{X}})$. For each object $A \in \mathrm{CAlg}_R^{\text{ét}}$, let $\mathcal{S}\mathrm{ol}_A^0(\mathscr{O}_{\mathcal{X}})$ denote the fiber product $\mathbf{1}_{\mathcal{X}} \times_{\mathcal{S}\mathrm{ol}_{\mathbf{R}}(\mathscr{O}_{\mathcal{X}})} \mathcal{S}\mathrm{ol}_{\mathbf{A}}(\mathscr{O}_{\mathcal{X}})$, and regard the construction $A \mapsto \mathcal{S}\mathrm{ol}_A^0(\mathscr{O}_{\mathcal{X}})$ as a functor $\mathcal{S}\mathrm{ol}_\bullet^0 : (\mathrm{CAlg}_R^{\text{ét}})^{\mathrm{op}} \to \mathcal{X}$. The above analysis shows that the homotopy fiber of the canonical map

$$\theta : \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}}((\mathcal{X}, \mathscr{O}_{\mathcal{X}}), \mathrm{Spét}\, R) \to \mathrm{Fun}((\mathrm{CAlg}_A^{\text{ét}})^{\mathrm{op}}, \mathcal{X})^{\simeq} \times \mathrm{Map}_{\mathrm{CAlg}}(R, \Gamma(\mathcal{X}, \mathscr{O}_{\mathcal{X}}))$$

over the pair (χ, ϕ) can be identified with the mapping space $\mathrm{Map}_{\mathrm{Fun}((\mathrm{CAlg}_R^{\text{ét}})^{\mathrm{op}}, \mathcal{X})}(\chi, \mathcal{S}\mathrm{ol}_\bullet^0(\mathscr{O}_{\mathcal{X}}))$. It follows from Lemma 1.4.3.9 that this identification carries the homotopy fiber of the restriction

$$\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}^{\mathrm{sHen}}}((\mathcal{X}, \mathscr{O}_{\mathcal{X}}), \mathrm{Spét}\, R) \to \mathrm{Fun}((\mathrm{CAlg}_R^{\text{ét}})^{\mathrm{op}}, \mathcal{X})^{\simeq} \times \mathrm{Map}_{\mathrm{CAlg}}(R, \Gamma(\mathcal{X}, \mathscr{O}_{\mathcal{X}}))$$

to the subspace of $\mathrm{Map}_{\mathrm{Fun}((\mathrm{CAlg}_A^{\text{ét}})^{\mathrm{op}}, \mathcal{X})}(\chi, \mathcal{S}\mathrm{ol}_\bullet^0(\mathscr{O}_{\mathcal{X}}))$ spanned by the equivalences. It follows that the fiber product

$$\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}^{\mathrm{sHen}}}((\mathcal{X}, \mathscr{O}_{\mathcal{X}}), \mathrm{Spét}\, R) \times_{\mathrm{Map}_{\mathrm{CAlg}}(R, \Gamma(\mathcal{X}, \mathscr{O}_{\mathcal{X}}))} \{\phi\}$$

is either empty or contractible. We will complete the proof by explicitly constructing a point of this fiber product, given by a morphism of ringed ∞-topoi $(\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to \mathrm{Spét}\, R$. Let

$\chi : (\mathrm{CAlg}_R^{\text{ét}})^{\mathrm{op}} \to \mathcal{X}$ be the functor $A \mapsto \mathcal{S}\mathrm{ol}_A^0(\mathscr{O}_{\mathcal{X}})$. The construction $A \mapsto \mathcal{S}\mathrm{ol}_A(\mathscr{O}_{\mathcal{X}})$ carries colimits in CAlg to limits in $\mathcal{X}$. It follows that the functor $\mathcal{S}\mathrm{ol}_{\bullet}(\mathscr{O}_{\mathcal{X}})$ preserves pullbacks, so that $\mathcal{S}\mathrm{ol}_{\bullet}^0(\mathscr{O}_{\mathcal{X}})$ also preserves pullbacks. By construction, the functor $\mathcal{S}\mathrm{ol}_{\bullet}^0(\mathscr{O}_{\mathcal{X}})$ carries R to a final object of $\mathcal{X}$, so that $\mathcal{S}\mathrm{ol}_{\bullet}^0(\mathscr{O}_{\mathcal{X}})$ preserves finite limits. Since $\mathscr{O}_{\mathcal{X}}$ is strictly Henselian, Lemma 1.4.3.9 implies that the functor $\chi = \mathcal{S}\mathrm{ol}_{\bullet}^0(\mathscr{O}_{\mathcal{X}})$ satisfies condition (ii) above, and therefore determines a geometric morphism of ∞-topoi $f_* : \mathcal{X} \to \mathcal{S}\mathrm{hv}_R^{\text{ét}}$. The preceding analysis shows that the projection map $\mathcal{S}\mathrm{ol}_{\bullet}^0(\mathscr{O}_{\mathcal{X}}) \to \mathcal{S}\mathrm{ol}_{\bullet}(\mathscr{O}_{\mathcal{X}})$ determines a morphism of CAlg-valued sheaves $\alpha : \mathscr{O} \to f_* \mathscr{O}_{\mathcal{X}}$, so that we can regard $f = (f_*, \alpha)$ as a morphism of spectrally ringed topoi from $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ into $\mathrm{Sp\acute{e}t}\, A$. We will complete the proof by showing that f is a morphism in the ∞-category $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}^{\mathrm{sHen}}$. To this end, fix an object $U \in \mathcal{X}$ and an element $x \in \pi_0 \mathrm{Map}_{\mathcal{X}}(U, f^*(\pi_0 \mathscr{O}))$ whose image in $\pi_0 \mathrm{Map}_{\mathcal{X}}(U, \pi_0 \mathscr{O}_{\mathcal{X}})$ is invertible; we wish to show that x is invertible. For each object $A \in \mathrm{CAlg}_R^{\text{ét}}$, let $h^A \in \mathcal{S}\mathrm{hv}_R^{\text{ét}}$ denote the sheaf corepresented by B. Since the objects h^A generate $\mathcal{S}\mathrm{hv}_R^{\text{ét}}$ under small colimits, we can therefore choose an effective epimorphism $\amalg h^{A_\alpha} \to \pi_0 \mathscr{O}$, which induces an effective epimorphism $\coprod f^* h^{A_\alpha} \to f^* \pi_0 \mathscr{O}$. Working locally on U, we may assume that the map $x : U \to f^* \pi_0 \mathscr{O}$ factors as a composition $U \xrightarrow{\psi} f^* h^A \xrightarrow{f^* y} f^* \pi_0 \mathscr{O}$, where $\psi : U \to f^* h^A \simeq \mathcal{S}\mathrm{ol}_A^0(\mathscr{O}_{\mathcal{X}})$ classifies an R-algebra morphism $\overline{\phi} : A \to \mathscr{O}_{\mathcal{X}}(U)$, and $y : h^A \to \pi_0 \mathscr{O}$ is a map of discrete objects of $\mathcal{S}\mathrm{hv}_R^{\text{ét}}$ which we can identify with an element of the commutative ring $\pi_0 \mathscr{O}(A) = \pi_0 A$. Applying $\overline{\phi}$ to y, we obtain an element $\overline{\phi}(y) \in \pi_0(\mathscr{O}_{\mathcal{X}}(U))$ whose image in $\mathrm{Map}_{\mathcal{X}}(U, \pi_0 \mathscr{O}_{\mathcal{X}})$ is an equivalence. It follows that multiplication by $\overline{\phi}(y)$ induces an equivalence from $\mathscr{O}_{\mathcal{X}}|_U$ to itself, so that $\overline{\phi}(y)$ is invertible in $\mathscr{O}_{\mathcal{X}}|_U$. Consequently, the map ψ admits an (essentially unique) lift to a map $\overline{\psi} : U \to \mathcal{S}\mathrm{ol}_{A[y^{-1}]}^0(\mathscr{O}_{\mathcal{X}}) \simeq f^* h^{A[y^{-1}]}$, so that x factors as a composition $U \xrightarrow{\overline{\psi}} f^* h^{A[y^{-1}]} \xrightarrow{f^* y} f^* \pi_0 \mathscr{O}$, and is therefore invertible, as desired. □

1.4.4 Spectral Deligne-Mumford Stacks

We are now ready to introduce the main objects of study in this book.

Notation 1.4.4.1. Let $\mathcal{X}$ be an ∞-topos, let $\mathcal{C}$ be an arbitrary ∞-category, and let $\mathscr{O}_{\mathcal{X}}$ be a $\mathcal{C}$-valued sheaf on $\mathcal{X}$. For each object $U \in \mathcal{X}$, we let $\mathscr{O}_{\mathcal{X}}|_U$ denote the composite functor

$$(\mathcal{X}_{/U})^{\mathrm{op}} \to \mathcal{X}^{\mathrm{op}} \xrightarrow{\mathscr{O}_{\mathcal{X}}} \mathcal{C},$$

so that $\mathscr{O}_{\mathcal{X}}|_U$ is a $\mathcal{C}$-valued sheaf on the ∞-topos $\mathcal{X}_{/U}$. We will refer to $\mathscr{O}_{\mathcal{X}}|_U$ as the *restriction of $\mathscr{O}_{\mathcal{X}}$ to U*.

Definition 1.4.4.2. A *nonconnective spectral Deligne-Mumford stack* is a spectrally ringed ∞-topos $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ for which there exists a collection of objects $U_\alpha \in \mathcal{X}$ satisfying the following conditions:

(*i*) The objects U_α cover $\mathcal{X}$. That is, the coproduct $\amalg_\alpha U_\alpha$ is 0-connective.

(*ii*) For each index α, there exists an $\mathbb{E}_\infty$-ring A_α and an equivalence of spectrally ringed ∞-topoi $(\mathcal{X}_{/U_\alpha}, \mathscr{O}_\mathcal{X}|_{U_\alpha}) \simeq \operatorname{Sp\acute{e}t} A_\alpha$.

We let $\mathrm{SpDM}^{\mathrm{nc}}$ denote the full subcategory of $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$ spanned by the nonconnective spectral Deligne-Mumford stacks.

A *spectral Deligne-Mumford stack* is a nonconnective spectral Deligne-Mumford stack $(\mathcal{X}, \mathscr{O}_\mathcal{X})$ for which the structure sheaf $\mathscr{O}_\mathcal{X}$ is connective. We let SpDM denote the full subcategory of $\mathrm{SpDM}^{\mathrm{nc}}$ spanned by the spectral Deligne-Mumford stacks.

Remark 1.4.4.3. Let A be an $\mathbb{E}_\infty$-ring, and let $\mathscr{O}$ be the sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{S}\mathrm{hv}^{\acute{e}t}_A$ given in Proposition 1.4.2.4. If A is connective, then any étale A-algebra is also connective. It follows that $\mathscr{O}$ is a connective sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{S}\mathrm{hv}^{\acute{e}t}_A$, so that $\operatorname{Sp\acute{e}t} A$ is a spectral Deligne-Mumford stack.

Remark 1.4.4.4. Let $f : \mathsf{X} \to \mathsf{Y}$ be an étale morphism of spectrally ringed ∞-topoi. If Y is a (nonconnective) spectral Deligne-Mumford stack, then so is X. The converse holds if f is an étale surjection.

1.4.5 Connective Covers

Our next goal is to compare the theory of spectral Deligne-Mumford stacks with the more general theory of nonconnective spectral Deligne-Mumford stacks. To this end, we start by establishing an analogue of Proposition 1.1.7.5:

Proposition 1.4.5.1. *Let $(\mathcal{X}, \mathscr{O}_\mathcal{X})$ be a nonconnective spectral Deligne-Mumford stack. Then $(\mathcal{X}, \tau_{\geqslant 0}\mathscr{O}_\mathcal{X})$ is a spectral Deligne-Mumford stack. Moreover, it has the following universal property: for every object $(\mathcal{Y}, \mathscr{O}_\mathcal{Y}) \in \infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$, if $\mathscr{O}_\mathcal{Y}$ is connective, then the canonical map*

$$\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}((\mathcal{X}, \tau_{\geqslant 0}\mathscr{O}_\mathcal{X}), (\mathcal{Y}, \mathscr{O}_\mathcal{Y})) \to \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}((\mathcal{X}, \mathscr{O}_\mathcal{X}), (\mathcal{Y}, \mathscr{O}_\mathcal{Y}))$$

is a homotopy equivalence.

Corollary 1.4.5.2. *The inclusion functor* $\mathrm{SpDM} \hookrightarrow \mathrm{SpDM}^{\mathrm{nc}}$ *admits a left adjoint, given on objects by $(\mathcal{X}, \mathscr{O}_\mathcal{X}) \mapsto (\mathcal{X}, \tau_{\geqslant 0}\mathscr{O}_\mathcal{X})$.*

Proof of Proposition 1.4.5.1. Let $(\mathcal{Y}, \mathscr{O}_\mathcal{Y})$ be an arbitrary spectrally ringed ∞-topos for which $\mathscr{O}_\mathcal{Y}$ is connective. For every geometric morphism $f_* : \mathcal{X} \to \mathcal{Y}$, the pullback $f^*\mathscr{O}_\mathcal{Y}$ is also connective so that the natural map

$$\mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})}(f^*\mathscr{O}_\mathcal{Y}, \tau_{\geqslant 0}\mathscr{O}_\mathcal{X}) \to \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})}(f^*\mathscr{O}_\mathcal{Y}, \mathscr{O}_\mathcal{X})$$

is a homotopy equivalence. It follows that the homotopy fibers of the vertical maps in the diagram

$$\begin{array}{ccc} \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}}((\mathcal{X}, \tau_{\geqslant 0}\,\mathscr{O}_{\mathcal{X}}), (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})) & \xrightarrow{\theta} & \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}}((\mathcal{X}, \mathscr{O}_{\mathcal{X}}), (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})) \\ & \searrow \quad \swarrow & \\ & \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{X}, \mathcal{Y}) & \end{array}$$

are homotopy equivalent to one another, so that θ is a homotopy equivalence. If $\mathscr{O}_{\mathcal{Y}}$ is strictly Henselian, then θ restricts to a homotopy equivalence

$$\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}((\mathcal{X}, \tau_{\geqslant 0}\,\mathscr{O}_{\mathcal{X}}), (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})) \to \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}((\mathcal{X}, \mathscr{O}_{\mathcal{X}}), (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}))$$

(since $\pi_0(\tau_{\geqslant 0}\,\mathscr{O}_{\mathcal{X}})$ is isomorphic to $\pi_0\,\mathscr{O}_{\mathcal{X}}$).

To complete the proof, it will suffice to show that if $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is a nonconnective spectral Deligne-Mumford stack, then $(\mathcal{X}, \tau_{\geqslant 0}\,\mathscr{O}_{\mathcal{X}})$ is a spectral Deligne-Mumford stack. The assertion is local on $\mathcal{X}$. We may therefore assume without loss of generality that $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ has the form $\mathrm{Spét}\,A$ for some $\mathbb{E}_\infty$-ring A. Let $B = \tau_{\geqslant 0}A$. Then $\mathrm{Spét}\,B$ is a spectral Deligne-Mumford stack (Remark 1.4.4.3), so the canonical map $(\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to \mathrm{Spét}\,B$ factors as a composition

$$(\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \xrightarrow{\phi} (\mathcal{X}, \tau_{\geqslant 0}\,\mathscr{O}_{\mathcal{X}}) \xrightarrow{\psi} \mathrm{Spét}\,B.$$

To complete the proof, it will suffice to show that ψ is an equivalence. Using the explicit description of the functor Spét supplied by Proposition 1.4.2.4, we can identify both $\mathcal{X}$ and the underlying ∞-topos of $\mathrm{Spét}\,B$ with $\mathcal{S}\mathrm{hv}^{\mathrm{ét}}_A$. The structure sheaf $\mathscr{O}$ of $\mathrm{Spét}\,B$ is given by $\mathscr{O}(A') = \tau_{\geqslant 0}A'$, from which it immediately follows that $\mathscr{O}$ is a connective cover of $\mathscr{O}_{\mathcal{X}}$ (so that ψ is an equivalence). □

Corollary 1.4.5.3. *Let A be an $\mathbb{E}_\infty$-ring. If* Spét A *is a spectral Deligne-Mumford stack, then A is connective.*

Proof. Write $\mathrm{Spét}\,A = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$. The proof of Proposition 1.4.5.1 shows that $(\mathcal{X}, \tau_{\geqslant 0}\,\mathscr{O}_{\mathcal{X}}) \simeq \mathrm{Spét}(\tau_{\geqslant 0}A)$. Passing to global sections, we deduce that the canonical map $\tau_{\geqslant 0}A \simeq \Gamma(\mathcal{X}; \tau_{\geqslant 0}\,\mathscr{O}_{\mathcal{X}}) \to \Gamma(\mathcal{X}; \mathscr{O}_{\mathcal{X}}) \simeq A$ is an equivalence, so that A is connective. □

1.4.6 Truncated Spectral Deligne-Mumford Stacks

We now study the formation of Postnikov towers in the setting of spectral Deligne-Mumford stacks.

Definition 1.4.6.1. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack, and let $n \geqslant 0$ be an integer. We will say that X is *n-truncated* if $\mathscr{O}_{\mathcal{X}}$ is n-truncated when regarded as a sheaf of spectra on $\mathcal{X}$. We let $\mathrm{SpDM}^{\leqslant n}$ denote the full subcategory of SpDM spanned by the n-truncated spectral Deligne-Mumford stacks.

Example 1.4.6.2. Let A be an $\mathbb{E}_\infty$-ring. Then A can be recovered as the $\mathbb{E}_\infty$-ring of global sections of the structure sheaf of $\operatorname{Sp\acute{e}t} A$. Consequently, if $\operatorname{Sp\acute{e}t} A$ is an n-truncated spectral Deligne-Mumford stack, then A is connective (see Corollary 1.4.5.3) and n-truncated. Conversely, if A is connective and n-truncated, then the explicit description of $\operatorname{Sp\acute{e}t} A$ given by Proposition 1.4.2.4 shows that $\operatorname{Sp\acute{e}t} A$ is an n-truncated spectral Deligne-Mumford stack.

Proposition 1.4.6.3. *Let $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ be a spectral Deligne-Mumford stack. For each $n \geqslant 0$, the truncation $(\mathcal{X}, \tau_{\leqslant n} \mathcal{O}_\mathcal{X}$ is also a spectral Deligne-Mumford stack. Moreover, it has the following universal property: for every object $(\mathcal{Y}, \mathcal{O}_\mathcal{Y}) \in \infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$, if $\mathcal{O}_\mathcal{Y}$ is connective and n-truncated, then the canonical map*

$$\operatorname{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}((\mathcal{Y}, \mathcal{O}_\mathcal{Y}), (\mathcal{X}, \tau_{\leqslant n} \mathcal{O}_\mathcal{X})) \to \operatorname{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}((\mathcal{Y}, \mathcal{O}_\mathcal{Y}), (\mathcal{X}, \mathcal{O}_\mathcal{X}))$$

is a homotopy equivalence.

Corollary 1.4.6.4. *For each integer $n \geqslant 0$, the inclusion $\mathrm{SpDM}^{\leqslant n} \hookrightarrow \mathrm{SpDM}$ admits a right adjoint, given on objects by $(\mathcal{X}, \mathcal{O}_\mathcal{X}) \mapsto (\mathcal{X}, \tau_{\leqslant n} \mathcal{O}_\mathcal{X})$.*

Notation 1.4.6.5. If $\mathsf{X} = (\mathcal{X}, \mathcal{O}_\mathcal{X})$ is a spectral Deligne-Mumford stack and $n \geqslant 0$ is an integer, we let $\tau_{\leqslant n} \mathsf{X}$ denote the spectral Deligne-Mumford stack given by $(\mathcal{X}, \tau_{\leqslant n} \mathcal{O}_\mathcal{X})$. We will refer to $\tau_{\leqslant n} \mathsf{X}$ as the *n-truncation* of X

Proof of Proposition 1.4.6.3. Let $(\mathcal{Y}, \mathcal{O}_\mathcal{Y})$ be an arbitrary spectrally ringed ∞-topos for which $\mathcal{O}_\mathcal{Y}$ is n-truncated. For every geometric morphism $f_* : \mathcal{Y} \to \mathcal{X}$, the pushforward $f_* \mathcal{O}_\mathcal{Y}$ is also n-truncated. We therefore have a commutative diagram

$$\begin{array}{ccc} \operatorname{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})}(\tau_{\leqslant n} \mathcal{O}_\mathcal{X}, \tau_{\geqslant 0} f_* \mathcal{O}_\mathcal{Y}) & \longrightarrow & \operatorname{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})}(\mathcal{O}_\mathcal{X}, \tau_{\geqslant 0} f_* \mathcal{O}_\mathcal{Y}) \\ \downarrow & & \downarrow \\ \operatorname{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})}(\tau_{\leqslant n} \mathcal{O}_\mathcal{X}, f_* \mathcal{O}_\mathcal{Y}) & \longrightarrow & \operatorname{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})}(\mathcal{O}_\mathcal{X}, f_* \mathcal{O}_\mathcal{Y}) \end{array}$$

where the vertical maps are homotopy equivalences (since $\mathcal{O}_\mathcal{X}$ is connective) and the upper horizontal map is a homotopy equivalence (since $\tau_{\geqslant 0} f_* \mathcal{O}_\mathcal{Y}$ is connective and n-truncated). It follows that the lower horizontal map is also an equivalence. Allowing f to vary, we deduce that the homotopy fibers of the vertical maps in the diagram

$$\begin{array}{ccc} \operatorname{Map}_{\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}}((\mathcal{Y}, \mathcal{O}_\mathcal{Y}), (\mathcal{X}, \tau_{\leqslant n} \mathcal{O}_\mathcal{X})) & \xrightarrow{\theta} & \operatorname{Map}_{\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}}((\mathcal{Y}, \mathcal{O}_\mathcal{Y}), (\mathcal{X}, \mathcal{O}_\mathcal{X})) \\ & \searrow \quad \swarrow & \\ & \operatorname{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{Y}, \mathcal{X}) & \end{array}$$

are homotopy equivalent to one another, so that θ is a homotopy equivalence. If $\mathcal{O}_\mathcal{Y}$ is strictly Henselian, then θ restricts to a homotopy equivalence

$$\operatorname{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}((\mathcal{Y}, \mathcal{O}_\mathcal{Y}), (\mathcal{X}, \tau_{\leqslant n} \mathcal{O}_\mathcal{X})) \to \operatorname{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}((\mathcal{Y}, \mathcal{O}_\mathcal{Y}), (\mathcal{X}, \mathcal{O}_\mathcal{X}))$$

(since $\pi_0(\tau_{\leqslant n}\mathscr{O}_{\mathcal{X}})$ is isomorphic to $\pi_0\mathscr{O}_{\mathcal{X}}$).

To complete the proof, it will suffice to show that if $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is a spectral Deligne-Mumford stack, then $(\mathcal{X}, \tau_{\leqslant n}\mathscr{O}_{\mathcal{X}})$ is also a spectral Deligne-Mumford stack. The assertion is local on $\mathcal{X}$. We may therefore assume without loss of generality that $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ has the form $\operatorname{Sp\acute{e}t} A$ for some $\mathbb{E}_\infty$-ring A. It follows from Corollary 1.4.5.3 that A is connective. Let $B = \tau_{\leqslant n}A$. Then $\operatorname{Sp\acute{e}t} B$ is an n-truncated spectral Deligne-Mumford stack (Example 1.4.6.2), so the canonical map $\operatorname{Sp\acute{e}t} B \to \operatorname{Sp\acute{e}t} A \simeq (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ factors as a composition

$$\operatorname{Sp\acute{e}t} B \xrightarrow{\phi} (\mathcal{X}, \tau_{\leqslant n}\mathscr{O}_{\mathcal{X}}) \to (\mathcal{X}, \mathscr{O}_{\mathcal{X}}).$$

To complete the proof, it will suffice to show that ϕ is an equivalence. Using the explicit description of the functor Spét supplied by Proposition 1.4.2.4 and Theorem HA.7.5.0.6 , we can identify both $\mathcal{X}$ and the underlying ∞-topos of $\operatorname{Sp\acute{e}t} B$ with $\mathcal{S}\mathrm{hv}_A^{\acute{e}t}$. Under this identification structure sheaf $\mathscr{O}$ of $\operatorname{Sp\acute{e}t} B$ corresponds to the functor $\mathrm{CAlg}_A^{\acute{e}t}$ given by $\mathscr{O}(A') = \tau_{\leqslant n}A'$, from which we immediately deduce that ϕ is an equivalence. □

1.4.7 Affine Spectral Deligne-Mumford Stacks

Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a nonconnective spectral Deligne-Mumford stack. We will say that X is *affine* it is equivalent to $\operatorname{Sp\acute{e}t} A$, for some $\mathbb{E}_\infty$-ring A.

Remark 1.4.7.1. Arguing as in Remark 1.1.5.7, we see that the construction $A \mapsto \operatorname{Sp\acute{e}t} A$ determines a fully faithful embedding $\operatorname{Sp\acute{e}t} : \mathrm{CAlg}^{\mathrm{op}} \to \mathrm{SpDM}^{\mathrm{nc}}$, whose essential image is the full subcategory of $\mathrm{SpDM}^{\mathrm{nc}}$ spanned by the affine nonconnective spectral Deligne-Mumford stacks.

Our main goal is to establish the following characterization of affine spectral Deligne-Mumford stacks:

Proposition 1.4.7.2. *Let $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a spectrally ringed ∞-topos which satisfies the following conditions:*

(a) *Let $\mathcal{X}^{\heartsuit}$ denote the underlying topos of $\mathcal{X}$. Then the ringed topos $(\mathcal{X}^{\heartsuit}, \pi_0\mathscr{O}_{\mathcal{X}})$ is equivalent to* $\operatorname{Sp\acute{e}t} R$ *for some commutative ring R.*

(b) *The ∞-topos $\mathcal{X}$ is* 1*-localic (that is, the natural geometric morphism $\mathcal{X} \to \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}^{\heartsuit}) \simeq \mathcal{S}\mathrm{hv}_R^{\acute{e}t}$ is an equivalence).*

(c) *For each integer n, the $(\pi_0\mathscr{O}_{\mathcal{X}})$-module $\pi_n\mathscr{O}_{\mathcal{X}}$ is quasi-coherent (in the sense of Definition 1.2.6.1).*

(d) *The sheaf $\mathscr{O}_{\mathcal{X}}$ is hypercomplete.*

Then $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ *is equivalent to* $\operatorname{Sp\acute{e}t} A$*, for some* $\mathbb{E}_\infty$*-ring* A*.*

Corollary 1.4.7.3. *Let* $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ *be a nonconnective spectral Deligne-Mumford stack. Then* $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ *is affine if and only if the* 0*-truncated spectral Deligne-Mumford stack* $(\mathcal{X}, \pi_0 \mathcal{O}_{\mathcal{X}})$ *is affine.*

Corollary 1.4.7.4. *Suppose we are given a commutative diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X} & \xrightarrow{f} & \mathsf{Y} \\ & \searrow \quad \swarrow & \\ & \mathsf{Z}, & \end{array}$$

and suppose that the underlying map $\mathsf{X} \times_{\mathsf{Z}} \tau_{\leqslant 0} \mathsf{Z} \to \mathsf{Y} \times_{\mathsf{Z}} \tau_{\leqslant 0} \mathsf{Z}$ *is an equivalence. Then* f *is an equivalence.*

Proof. The assertion is local on Y; we may therefore assume without loss of generality that $\mathsf{Y} = \operatorname{Sp\acute{e}t} A$ and $\mathsf{Z} \simeq \operatorname{Sp\acute{e}t} R$ are affine. Our assumption guarantees that f induces an equivalence of 0-truncations, so that $\tau_{\leqslant 0} \mathsf{X}$ is affine. Applying Corollary 1.4.7.3, we deduce that $\mathsf{X} \simeq \operatorname{Sp\acute{e}t} B$ is affine. Let K denote the cofiber of the map $A \to B$ (formed in the ∞-category Mod_R). We wish to prove that $K \simeq 0$. Assume otherwise. Since K is connective, there exists a smallest integer n such that $\pi_n K$ is nontrivial. In this case, we have

$$\pi_n K \simeq \operatorname{Tor}_0^{\pi_0 R}(\pi_0 R, \pi_n K) \simeq \pi_n(\pi_0 R \otimes_R K) \simeq \pi_n \operatorname{cofib}(\pi_0 R \otimes_R A \to \pi_0 R \otimes_R B) \simeq 0,$$

and obtain a contradiction. □

The proof of Proposition 1.4.7.2 will require some preliminaries.

Lemma 1.4.7.5. *Let* $\mathcal{X}$ *be an* ∞*-topos and let* $n \geqslant -1$ *be an integer. Suppose we are given a collection of morphisms* $f_\alpha : U_\alpha \to X$ *in* $\mathcal{X}$ *with the following properties:*

(*i*) *Each of the morphisms* f_α *is* $(n-1)$*-truncated.*

(*ii*) *Each of the objects* U_α *is* n*-truncated.*

(*iii*) *The induced map* $f : \amalg_\alpha U_\alpha \to X$ *is an effective epimorphism in* $\mathcal{X}$*.*

Then X *is* n*-truncated.*

Proof. Without loss of generality, we may assume that $\mathcal{X}$ is given as a left exact localization of $\mathcal{P}(\mathcal{C}) = \operatorname{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$, for some small ∞-category $\mathcal{C}$. Let $L : \mathcal{P}(\mathcal{C}) \to \mathcal{X}$ be a left adjoint to the inclusion. For each object $C \in \mathcal{C}$, let $X'(C) \subseteq X(C)$ denote the union of those connected components which meet the image of one of the maps $U_\alpha(C) \to X(C)$, so that we have an effective epimorphism $f' : \amalg_\alpha U_\alpha \to X'$ in the ∞-topos $\mathcal{P}(\mathcal{C})$. It follows from (iii) that the functor L carries X' to X. Since L is left exact, it will suffice to prove that X' is n-truncated. We may therefore replace X by X', and thereby reduce to the case where $\mathcal{X} = \mathcal{P}(\mathcal{C})$ is an ∞-category of presheaves. Working objectwise, we may reduce to the case where $\mathcal{C} \simeq \Delta^0$, so that $\mathcal{X}$ is the ∞-category $\mathcal{S}$ of spaces.

If $n = -1$, then either X is empty or one of the maps h_α is an equivalence; in either case, we immediately conclude that X is (-1)-truncated. Suppose that $n \geqslant 0$. We wish to prove that $\pi_m(X, x) \simeq)$ for each integer $m > n$ and each base point $x \in X$. Using (iii), we may assume that $x = f_\alpha(\overline{x})$ for some point $\overline{x} \in U_\alpha$. In this case, condition (i) implies that the map $\pi_m(U_\alpha, \overline{x}) \to \pi_m(X, x)$ is an isomorphism, and condition (ii) implies that $\pi_m(U_\alpha, \overline{x}) \simeq 0$. □

Remark 1.4.7.6. In the situation of Lemma 1.4.7.5, we can replace (ii) by the following apparently weaker condition:

(ii') The map f_α factors as a composition $U_\alpha \to V_\alpha \to X$, where V_α is n-truncated.

Indeed, if this condition is satisfied, then U_α can be realized as a retract of $U_\alpha \times_X V_\alpha$. If f_α satisfies condition (i), then the projection map $U_\alpha \times_X V_\alpha \to V_\alpha$ is $(n-1)$-truncated. Since V_α is n-truncated, we conclude that $U_\alpha \times_X V_\alpha$ is n-truncated, and therefore U_α is n-truncated.

Lemma 1.4.7.7. *Let $\mathcal{X}$ be an ∞-topos containing an object X and let $n \geqslant 0$ be an integer. Then:*

(1) *If the ∞-topos $\mathcal{X}$ is $(n+1)$-localic and $\mathcal{X}_{/X}$ is n-localic, then the object X is n-truncated.*

(2) *If the ∞-topos $\mathcal{X}$ is n-localic and X is n-truncated, then the ∞-topos $\mathcal{X}_{/X}$ is n-localic.*

(3) *If the ∞-topos $\mathcal{X}_{/X}$ is $(n+1)$-localic and the object X is both n-truncated and 0-connective, then $\mathcal{X}$ is $(n+1)$-localic.*

Proof. We first prove (1). If $\mathcal{X}$ is $(n+1)$-localic, then we can choose an effective epimorphism $\amalg V_\alpha \to X$ where each V_α is an n-truncated object of $\mathcal{X}$. If $\mathcal{X}_{/X}$ is n-localic, then we can choose effective epimorphisms $\amalg U_{\alpha,\beta} \to V_\alpha$, where each $U_{\alpha,\beta}$ is an $(n-1)$-truncated object of $\mathcal{X}_{/X}$. Applying Remark 1.4.7.6, we conclude that X is n-truncated.

We now prove (2). If $\mathcal{X}$ is n-localic, then we can write $\mathcal{X}$ as a topological localization of $\mathcal{P}(\mathcal{C})$, for some small n-category $\mathcal{C}$ (see the proof of Proposition HTT.6.4.5.7). Let us identify $\mathcal{X}$ with the corresponding subcategory of $\mathcal{P}(\mathcal{C})$. Then $\mathcal{X}_{/X}$ is a topological localization of $\mathcal{P}(\mathcal{C})_{/X}$. According to Proposition HTT.6.4.5.9 , it will suffice to show that the ∞-topos $\mathcal{P}(\mathcal{C})_{/X}$ is n-localic. The presheaf $X : \mathcal{C}^{\mathrm{op}} \to \mathcal{S}$ classifies a right fibration of ∞-categories $\theta : \widetilde{\mathcal{C}} \to \mathcal{C}$. Since X is n-truncated, the fibers of θ are n-truncated Kan complexes, so that $\widetilde{\mathcal{C}}$ is also an n-category. We complete the proof by observing that there is a canonical equivalence of ∞-categories $\mathcal{P}(\mathcal{C})_{/X} \simeq \mathcal{P}(\widetilde{\mathcal{C}})$.

We now prove (3). Suppose that X is n-truncated and 0-connective and that $\mathcal{X}_{/X}$ is $(n+1)$-localic. Let $f_* : \mathcal{X} \to \mathcal{Y}$ be a geometric morphism which exhibits $\mathcal{Y}$ as an $(n+1)$-localic reflection of $\mathcal{X}$. Then the associated pullback functor f^* restricts to an equivalence $\tau_{\leqslant n} \mathcal{Y} \to \tau_{\leqslant n} \mathcal{X}$. In particular, we can assume without loss of generality that $X = f^* Y$ for some n-truncated object $Y \in \mathcal{Y}$. By construction, the pullback functor f^* induces an equivalence of ∞-categories $(\tau_{\leqslant n} \mathcal{Y})_{/Y} \to (\tau_{\leqslant n} \mathcal{X})_{/X}$. Restricting to n-truncated objects on both sides, we see that f^* induces an equivalence of ∞-categories $\tau_{\leqslant n}(\mathcal{Y}_{/Y}) \to \tau_{\leqslant n}(\mathcal{X}_{/X})$. It follows from (2) that $\mathcal{Y}_{/Y}$ is $(n+1)$-localic and the ∞-topos $\mathcal{X}_{/X}$ is $(n+1)$-localic by assumption, so that f^* induces an equivalence $\mathcal{Y}_{/Y} \to \mathcal{X}_{/X}$.

We will show that the counit map $v : f^* f_* \to \mathrm{id}_{\mathcal{X}}$ is an equivalence (that the unit map $u : \mathrm{id}_{\mathcal{Y}} \to f_* f^*$ is an equivalence can be proven by the same argument). Let X' be an object of $\mathcal{X}$; we wish to show that the natural map $v_{X'} : f^* f_* X' \to X'$ is an equivalence. Since X is 0-connective, it will suffice to show that

$$v_{X'} \times \mathrm{id}_X : (f^* f_* X') \times X \to X' \times X$$

is an equivalence. Unwinding the definitions, we see that this map factors as a composition

$$\begin{aligned} (f^* f_* X') \times X &\simeq f^*(f_* X' \times Y) \\ &\simeq f^* f_*(X' \times X) \\ &\to X' \times X, \end{aligned}$$

where the last map is an equivalence by virtue of our assumption that f^* and f_* induce mutually inverse equivalences between $\mathcal{Y}_{/Y}$ and $\mathcal{X}_{/X}$. □

Proof of Proposition 1.4.7.2. We proceed as in the proof of Proposition 1.1.3.4. For each integer n, we have a fiber sequence of spectrum-valued sheaves

$$\Sigma^n(\pi_n \mathscr{O}_{\mathcal{X}}) \to \tau_{\leqslant n} \mathscr{O}_{\mathcal{X}} \to \tau_{\leqslant n-1} \mathscr{O}_{\mathcal{X}},$$

where we abuse notation by identifying the sheaf of abelian groups $\pi_n \mathscr{O}_{\mathcal{X}}$ with the corresponding object in the heart of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$. Passing to global sections and extracting homotopy groups, we obtain a long exact sequence

$$\mathrm{H}^{n-m}(\mathcal{X}_{/U}; (\pi_n \mathscr{O}_{\mathcal{X}})|_U) \to \pi_m(\tau_{\leqslant n} \mathscr{O}_{\mathcal{X}})(U) \to \pi_m(\tau_{\leqslant n-1} \mathscr{O}_{\mathcal{X}}(U)) \to \mathrm{H}^{n-m+1}(\mathcal{X}_{/U}; (\pi_n \mathscr{O}_{\mathcal{X}})|_U)$$

for each object $U \in \mathcal{X}$. Using assumptions (a), (b), and (c), we see that the groups $\mathrm{H}^i(\mathcal{X}_{/U}; (\pi_n \mathscr{O}_{\mathcal{X}})|_U)$ vanish if $U \in \mathcal{X}^{\heartsuit}$ is affine and $i > 0$ (see §HTT.7.2.2 for a discussion of the cohomology of an ∞-topos, Remark HTT.7.2.2.17 for a comparison with the usual theory of sheaf cohomology, and §D.3 for a closely related discussion). Since $(\tau_{\leqslant n}\mathscr{O}_{\mathcal{X}})(U)$ and $(\tau_{\leqslant n-1}\mathscr{O}_{\mathcal{X}})(U)$ are n-truncated and $(n-1)$-truncated, respectively, we conclude that our long exact sequence degenerates to give isomorphisms

$$\pi_m(\tau_{\leqslant n}\mathscr{O}_{\mathcal{X}})(U) \simeq \begin{cases} 0 & \text{if } m > n \\ (\pi_n \mathscr{O}_{\mathcal{X}})(U) & \text{if } m = n \\ (\tau_{\leqslant n-1}\mathscr{O}_{\mathcal{X}})(U) & \text{if } m < n. \end{cases}$$

when $U \in \mathcal{X}^{\heartsuit}$ is affine.

Set $\mathscr{O}'_{\mathcal{X}} = \varprojlim_n \tau_{\leqslant n}\mathscr{O}_{\mathcal{X}} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$. We have an evident map $u : \mathscr{O}_{\mathcal{X}} \to \mathscr{O}'_{\mathcal{X}}$, and the above calculation shows that this map induces an equivalence $(\pi_n \mathscr{O}_{\mathcal{X}})(U) \to \pi_n(\mathscr{O}'_{\mathcal{X}}(U))$ for every affine object $U \in \mathcal{X}^{\heartsuit}$. In particular, u induces an isomorphism of sheaves $\pi_n \mathscr{O}_{\mathcal{X}} \to \pi_n \mathscr{O}'_{\mathcal{X}}$ for every integer n. Since $\mathscr{O}'_{\mathcal{X}}$ is hypercomplete by construction, condition (d) implies that u is an equivalence. It follows that the canonical map $\pi_n(\mathscr{O}_{\mathcal{X}}(U)) \to (\pi_n \mathscr{O}_{\mathcal{X}})(U)$ is an isomorphism for each affine object $U \in \mathcal{X}^{\heartsuit}$.

Set $A = \Gamma(\mathcal{X}; \mathscr{O}_{\mathcal{X}})$. Then Proposition 1.4.2.4 supplies a map of spectrally ringed ∞-topoi $f : (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to \mathrm{Spét}\, A$. Condition (a) implies that the final object of $\mathcal{X}$ is affine, so that the canonical map $\pi_n A \to \Gamma(\mathcal{X}^{\heartsuit}; \pi_n \mathscr{O}_{\mathcal{X}})$ is an isomorphism for every integer n. In particular, $\pi_0 A$ can be identified with the ring of global sections of $\pi_0 \mathscr{O}_{\mathcal{X}}$, so that (a) supplies an equivalence $\mathcal{X}^{\heartsuit} \simeq \mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}^{\text{ét}}_{\pi_0 A})$. Combining this observation with (b), we deduce that f induces an equivalence of the underlying ∞-topoi. Then f supplies a morphism of structure sheaves $\alpha : \mathscr{O} \to f_* \mathscr{O}_{\mathcal{X}}$; we wish to show that this map is an equivalence. Since $\mathcal{S}\mathrm{hv}^{\text{ét}}_A$ is generated under small colimits by corepresentable functors h^B, we are reduced to proving that α induces an equivalence

$$B \simeq \mathscr{O}(h^B) \to \mathscr{O}_{\mathcal{X}}(f^* h^B)$$

for each object $B \in \mathrm{CAlg}^{\text{ét}}_A$. We will prove that for each integer n, the map $\pi_n B \to \pi_n \mathscr{O}_{\mathcal{X}}(f^* h^B)$ is an isomorphism of abelian groups. Since $f^* h^B$ is an affine object of $\mathcal{X}^{\heartsuit}$, we can identify $\pi_n \mathscr{O}_{\mathcal{X}}(f^* h^B)$ with the abelian group $\mathrm{Hom}_{\mathcal{X}^{\heartsuit}}(f^* h^B, \pi_n \mathscr{O}_{\mathcal{X}})$. Assumption (b) implies that $\pi_n \mathscr{O}_{\mathcal{X}}$ is a quasi-coherent sheaf on the affine Deligne-Mumford stack $(\mathcal{X}^{\heartsuit}, \pi_0 \mathscr{O}_{\mathcal{X}})$, so that we can identify $\mathrm{Hom}_{\mathcal{X}^{\heartsuit}}(f^* h^B, \pi_n \mathscr{O}_{\mathcal{X}})$ with

$$\pi_0 B \otimes_{\pi_0 A} \Gamma(\mathcal{X}^{\heartsuit}, \pi_n \mathscr{O}_{\mathcal{X}}) \simeq \pi_0 B \otimes_{\pi_0 A} \pi_n A \simeq \pi_n B.$$

□

We close this section with a remark about affine "opens" in an arbitrary spectral Deligne-Mumford stack.

Definition 1.4.7.8. Let $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a nonconnective spectral Deligne-Mumford stack. We will say that an object $U \in \mathcal{X}$ is *affine* if the nonconnective spectral Deligne-Mumford stack $(\mathcal{X}_{/U}, \mathcal{O}_{\mathcal{X}}|_U)$ is affine.

Proposition 1.4.7.9. *Let $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be an nonconnective spectral Deligne-Mumford stack, and let $\mathcal{X}_0$ be the full subcategory of $\mathcal{X}$ spanned by the affine objects. Then $\mathcal{X}$ is generated by $\mathcal{X}_0$ under small colimits (in other words, $\mathcal{X}$ is the smallest full subcategory of itself which contains $\mathcal{X}_0$ and is closed under small colimits).*

Proof. Let $\mathcal{X}' \subseteq \mathcal{X}$ be a full subcategory containing $\mathcal{X}_0$ and closed under small colimits. We wish to prove that $\mathcal{X}'$ contains every object $X \in \mathcal{X}$. We first prove this under the additional assumption that there exists a morphism $X \to Y$, where $Y \in \mathcal{X}$ is affine. In this case, we can replace $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ by $(\mathcal{X}_{/Y}, \mathcal{O}_{\mathcal{X}}|_Y)$, and thereby reduce to the case where $(\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \simeq \operatorname{Spét} R$ is affine. In this case, we can identify $\mathcal{X}$ with $\mathcal{S}\mathrm{hv}_R^{\text{ét}}$. It follows that $\mathcal{X}$ is generated under small colimits by corepresentable functors h^A (where A ranges over étale R-algebras), each of which is affine.

We now treat the general case. Let $\mathbf{1}$ denote the final object of $\mathcal{X}$. Choose an effective epimorphism $U = \amalg_\alpha U_\alpha \to \mathbf{1}$, where each U_α is affine. Let $U_\bullet$ be the Čech nerve of the map $U \to \mathbf{1}$, so that $|U_\bullet| \simeq \mathbf{1}$. Then X is the geometric realization of the simplicial object $|X \times U_\bullet|$. It will therefore suffice to show that each of the objects $X \times U_n$ belongs to $\mathcal{X}'$. Note that there exists a map $U_n \to U$, so that we can write $X \times U_n$ as a coproduct of objects of the form $X \times U_n \times_U U_\alpha$. We conclude by observing that each of these objects admits a morphism to the affine object $U_\alpha \in \mathcal{X}$, and therefore belongs to $\mathcal{X}'$ by the first part of the proof. □

1.4.8 A Recognition Criterion for Spectral Deligne-Mumford Stacks

We now give a concrete characterization of the class of spectral Deligne-Mumford stacks which is more in the spirit of Definition 1.1.2.8.

Theorem 1.4.8.1. *Let $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a spectrally ringed ∞-topos, and let $\mathcal{X}^\heartsuit$ denote underlying topos of $\mathcal{X}$. Then $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is a nonconnective spectral Deligne-Mumford stack if and only if the following conditions are satisfied:*

(1) *The ringed topos $(\mathcal{X}^\heartsuit, \pi_0 \mathcal{O}_{\mathcal{X}})$ is a Deligne-Mumford stack, in the sense of Definition 1.2.4.1.*

(2) *The canonical geometric morphism $\phi_* : \mathcal{X} \to \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}^\heartsuit)$ (which exhibits $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}^\heartsuit)$ as a 1-localic reflection of $\mathcal{X}$) is étale.*

(3) *For each integer n, the homotopy group $\pi_n \mathcal{O}_{\mathcal{X}}$ is a quasi-coherent sheaf on $(\mathcal{X}^\heartsuit, \pi_0 \mathcal{O}_{\mathcal{X}})$, in the sense of Definition 1.2.6.1.*

(4) *The structure sheaf $\mathscr{O}_{\mathcal{X}}$ is hypercomplete (see Definition 1.3.3.4).*

Remark 1.4.8.2. Let $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a nonconnective spectral Deligne-Mumford stack. Then Theorem **??** implies that the ringed topos $(\mathcal{X}^{\heartsuit}, \pi_0 \mathscr{O}_{\mathcal{X}})$ is a Deligne-Mumford stack. We will refer to $(\mathcal{X}^{\heartsuit}, \pi_0 \mathscr{O}_{\mathcal{X}})$ as the *underlying Deligne-Mumford stack* of $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$.

Remark 1.4.8.3. Let $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a ringed topos, and let $(\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}), \mathscr{O})$ be the associated spectrally ringed ∞-topos (see Remark 1.4.1.5). Then the ∞-topos $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X})$ is 1-localic, the groups $\pi_n \mathscr{O}$ vanish for $n \neq 0$, and $\mathscr{O}$ is hypercomplete (since it is 0-truncated). Consequently, the spectrally ringed ∞-topos $(\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}), \mathscr{O})$ automatically satisfies conditions (2), (3), and (4) of Theorem 1.4.8.1. It follows that $(\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}), \mathscr{O})$ is a spectral Deligne-Mumford stack if and only if $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is a Deligne-Mumford stack. In particular, the construction

$$(\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \mapsto (\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}), \mathscr{O})$$

determines a fully faithful embedding $\mathrm{DM} \to \mathrm{SpDM}$, whose essential image consists of those spectral Deligne-Mumford stacks $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ for which the ∞-topos $\mathcal{X}$ is 1-localic and the structure sheaf $\mathscr{O}_{\mathcal{X}}$ is 0-truncated.

Remark 1.4.8.4. Let $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be an arbitrary spectral Deligne-Mumford stack, let $(\mathcal{X}^{\heartsuit}, \pi_0 \mathscr{O}_{\mathcal{X}})$ be its underlying Deligne-Mumford stack, and let $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ be the spectral Deligne-Mumford stack associated to $(\mathcal{X}^{\heartsuit}, \pi_0 \mathscr{O}_{\mathcal{X}})$ (Remark 1.4.8.3). Then we have a canonical diagram of spectral Deligne-Mumford stacks

$$(\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \xleftarrow{g} (\mathcal{X}, \pi_0 \mathscr{O}_{\mathcal{X}}) \xrightarrow{f} (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}).$$

Here the map f is étale (by Theorem 1.4.8.1), and the map g exhibits $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ as an "infinitesimal thickening" of $(\mathcal{X}, \pi_0 \mathscr{O}_{\mathcal{X}})$.

Remark 1.4.8.5. If $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is a 0-truncated spectral Deligne-Mumford stack, then Remark 1.4.8.4 supplies an étale map $(\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$, where $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ is a 0-truncated, 1-localic spectral Deligne-Mumford stack.

Proof of Theorem 1.4.8.1. Suppose first that $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is a nonconnective spectral Deligne-Mumford stack. Assertion (2) follows from Theorem **??**. Choose a covering of $\mathcal{X}$ by objects U_α for which each of the spectrally ringed ∞-topoi $(\mathcal{X}_{/U_\alpha}, \mathscr{O}_{\mathcal{X}}|_{U_\alpha})$ has the form $\mathrm{Sp\acute{e}t}\, R_\alpha$ for some $\mathbb{E}_\infty$-ring R_α. Using (2), we see that each of the geometric morphisms $\phi_{\alpha *} : \mathcal{X}_{/U_\alpha} \to \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}^{\heartsuit})$ is étale, so that we can choose equivalences $\mathcal{X}_{/U_\alpha} \simeq \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}^{\heartsuit})_{/V_\alpha}$ for some objects $V_\alpha \in \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}^{\heartsuit})_{/V_\alpha}$. The underlying ∞-topos of $\mathrm{Sp\acute{e}t}\, R_\alpha$ is 1-localic by construction, so that each V_α is 1-truncated by virtue of Lemma 1.4.7.7. Since $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}^{\heartsuit})$ is 1-localic, it is generated (under small colimits) by discrete objects. In particular, we can choose effective epimorphisms $u_\alpha : V'_\alpha \to V_\alpha$, where each V'_α is a discrete object of $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}^{\heartsuit})$.

Since V_α is 1-truncated, we see that each of the maps $u_\alpha : V'_\alpha \to V_\alpha$ is 0-truncated. We therefore have an equivalence

$$\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}^\heartsuit)_{/V'_\alpha} \simeq (\mathcal{S}\mathrm{hv}^{\text{ét}}_{R_\alpha})_{/W_\alpha}$$

for some discrete objects W_α in $\mathcal{S}\mathrm{hv}^{\text{ét}}_{R_\alpha}$. Let $\mathscr{O}$ denote the structure sheaf of $\operatorname{Spét} R_\alpha$, so that we obtain equivalences of ringed topoi

$$(\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}^{\text{ét}}_R)_{/W_\alpha}, (\pi_0 \mathscr{O})|_{W_\alpha}) \simeq (\mathcal{X}_{0/V'_\alpha}, (\pi_0 \mathscr{O}_{\mathcal{X}})_{/V'_\alpha}).$$

Since $(\mathcal{S}\mathrm{hv}_{\mathcal{S}\mathrm{et}}(\mathrm{CAlg}^{\text{ét}}_R), \pi_0 \mathscr{O}) \simeq \operatorname{Spét}(\pi_0 R)$ is a Deligne-Mumford stack, it follows from Remark 1.2.4.5 that $(\mathcal{X}^\heartsuit, \pi_0 \mathscr{O}_{\mathcal{X}})$ is also a Deligne-Mumford stack. This completes the proof of (1). Moreover, the above argument shows that we have a canonical isomorphism of sheaves $(\pi_n \mathscr{O}_{\mathcal{X}})|_{V'_\alpha} \simeq \mathscr{F}|_{W_\alpha}$, where $\mathscr{F}$ denotes the quasi-coherent sheaf on $\operatorname{Spét}(\pi_0 R)$ associated to the $\pi_0 R$-module $\pi_n R$ (see Example 1.2.6.2). Assertion (3) now follows from Proposition 1.2.6.3. To prove (4), we may work locally on $\mathcal{X}$ (by virtue of Proposition 1.3.3.6) and thereby reduce to the case where $(\mathcal{X}, \mathscr{O}_{\mathcal{X}}) = \operatorname{Spét} A$ for some $\mathbb{E}_\infty$-ring A. We may further assume that A is connective. In this case, $\mathscr{O}_{\mathcal{X}}$ can be written as the inverse limit of the structure sheaves of the spectral Deligne-Mumford stacks $\operatorname{Spét}(\tau_{\leqslant n} A)$, each of which is truncated and therefore hypercomplete.

Now suppose that conditions (1) through (4) are satisfied; we wish to prove that $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is a nonconnective spectral Deligne-Mumford stack. Using (2), we can write $\mathcal{X} = \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}^\heartsuit)_{/X}$ for some object $X \in \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}^\heartsuit)$. Using (1), we can choose an effective epimorphism $\amalg U_\alpha \to X$ in $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}^\heartsuit)$, where each U_α is an affine object of $\mathcal{X}^\heartsuit$. Then each U_α can be identified with an object $V_\alpha \in \mathcal{X}$. To complete the proof, it will suffice to show that each $(\mathcal{X}_{/V_\alpha}, \mathscr{O}_{\mathcal{X}}|_{V_\alpha})$ has the form $\operatorname{Spét} A$, for some $\mathbb{E}_\infty$-ring A. This follows from Proposition 1.4.7.2. □

1.4.9 Postnikov Towers of Spectral Deligne-Mumford Stacks

Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack. In §1.4.6, we saw that each truncation $\tau_{\leqslant n} \mathsf{X} = (\mathcal{X}, \tau_{\leqslant n} \mathscr{O}_{\mathcal{X}})$ is also a spectral Deligne-Mumford stack. We now show that X is determined by the collection of truncations $\{\tau_{\leqslant n} \mathsf{X}\}_{n \geqslant 0}$.

Proposition 1.4.9.1. *The ∞-category* SpDM *is a homotopy limit of the tower*

$$\cdots \to \mathrm{SpDM}^{\leqslant 3} \xrightarrow{\tau_{\leqslant 2}} \mathrm{SpDM}^{\leqslant 2} \xrightarrow{\tau_{\leqslant 1}} \mathrm{SpDM}^{\leqslant 1} \xrightarrow{\tau_{\leqslant 0}} \mathrm{SpDM}^{\leqslant 0}.$$

Proof. Let G denote the evident functor $\mathrm{SpDM} \to \varprojlim \mathrm{SpDM}^{\leqslant n}$. We first claim that G is fully faithful. Unwinding the definitions, we must show that if $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ and $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ are spectral Deligne-Mumford stacks, then the canonical map

$$\theta : \mathrm{Map}_{\mathrm{SpDM}}(\mathsf{X}, \mathsf{Y}) \to \varprojlim \mathrm{Map}_{\mathrm{SpDM}}((\mathcal{X}, \tau_{\leqslant n} \mathscr{O}_{\mathcal{X}}), \mathsf{Y})$$

is a homotopy equivalence. Let $K = \mathrm{Fun}^*(\mathcal{Y}, \mathcal{X})^{\simeq}$ denote the space of geometric morphisms from the underlying ∞-topos of X to the underlying ∞-topos of Y. We will show that θ induces a homotopy equivalence after passing to the homotopy fiber over any point of K, corresponding to a geometric morphism $f^* : \mathcal{Y} \to \mathcal{X}$. In this case, we wish to show that the canonical map

$$\phi : \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})}(f^* \mathscr{O}_{\mathcal{Y}}, \mathscr{O}_{\mathcal{X}}) \to \varprojlim \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})}(f^* \mathscr{O}_{\mathcal{Y}}, \tau_{\leqslant n} \mathscr{O}_{\mathcal{X}})$$

induces a homotopy equivalence on the summands corresponding to *local* maps between strictly Henselian sheaves of $\mathbb{E}_\infty$-rings on $\mathcal{X}$. This follows from the following pair of assertions:

(a) The map ϕ is a homotopy equivalence. In fact, the canonical map $\mathscr{O}_{\mathcal{X}} \to \varprojlim \tau_{\leqslant n} \mathscr{O}_{\mathcal{X}}$ is an equivalence of sheaves of $\mathbb{E}_\infty$-rings on $\mathcal{X}$: this follows from the proof of Theorem 1.4.8.1.

(b) A map $f^* \mathscr{O}_{\mathcal{Y}} \to \mathscr{O}_{\mathcal{X}}$ is local if and only if each of the induced maps $f^* \mathscr{O}_{\mathcal{Y}} \to \tau_{\leqslant n} \mathscr{O}_{\mathcal{X}}$ is local. Both conditions are equivalent to the assertion that the underlying map

$$\pi_0 f^* \mathscr{O}_{\mathcal{Y}} \to \pi_0 \mathscr{O}_{\mathcal{X}}$$

is local (Definition 1.4.2.1).

It remains to prove that G is essentially surjective. Suppose we are given an object of $\varprojlim_n \mathrm{SpDM}^{\leqslant n}$, given by a sequence of spectral Deligne-Mumford stacks

$$(\mathcal{X}_0, \mathscr{O}_0) \to (\mathcal{X}_1, \mathscr{O}_1) \to (\mathcal{X}_2, \mathscr{O}_2) \to \cdots$$

with the following property: each of the maps $(\mathcal{X}_i, \mathscr{O}_i) \to (\mathcal{X}_{i+1}, \mathscr{O}_{i+1})$ induces an equivalence $(\mathcal{X}_i, \mathscr{O}_i) \simeq \tau_{\leqslant i}(\mathcal{X}_{i+1}, \mathscr{O}_{i+1})$. It follows that the sequence of ∞-topoi $\mathcal{X}_0 \to \mathcal{X}_1 \to \cdots$ is equivalent to the constant sequence taking the value $\mathcal{X} = \mathcal{X}_0$. To complete the proof, it will suffice to verify the following:

(c) The spectrally ringed ∞-topos $\mathsf{X} = (\mathcal{X}, \varprojlim \mathscr{O}_n)$ is a spectral Deligne-Mumford stack.

(d) For every integer n, the canonical map $(\mathcal{X}, \mathscr{O}_n) \to \mathsf{X}$ induces an equivalence $(\mathcal{X}, \mathscr{O}_n) \to \tau_{\leqslant n} \mathsf{X}$.

Both of these assertions are local on X. We may therefore assume without loss of generality that $(\mathcal{X}, \mathscr{O}_0)$ is affine. It follows that each pair $(\mathsf{X}, \mathscr{O}_n)$ is affine (Corollary 1.4.7.3), so that the sequence of spectral Deligne-Mumford stacks above is determined by a tower of connective $\mathbb{E}_\infty$-rings

$$\cdots A_2 \to A_1 \to A_0$$

which induces equivalences $\tau_{\leqslant n} A_{n+1} \to A_n$ for each $n \geqslant 0$. Since the ∞-category $\mathrm{CAlg}^{\mathrm{cn}}$ is Postnikov complete (see Definition A.7.2.1 and Proposition HA.7.1.3.19), we can the limit $A = \varprojlim_n A_n$ is a connective $\mathbb{E}_\infty$-ring with $A_n \simeq \tau_{\leqslant n} A$ for every integer n. A simple calculation now shows that $\mathsf{X} \simeq \mathrm{Sp\acute{e}t}\, A$, from which assertions (c) and (d) follow easily. □

1.4.10 Étale Morphisms of Spectral Deligne-Mumford Stacks

In the setting of spectral Deligne-Mumford stacks, there are two *a priori* different notions of étale morphism $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ that one could consider: one could require that f is étale as a morphism of spectrally ringed ∞-topoi (see Definition 1.4.10.1 below), or one could require that f is obtained locally by applying the spectrum functor Spét to an étale morphism of $\mathbb{E}_\infty$-rings. Our next goal is to show that these definitions are equivalent (Corollary 1.4.10.3).

Definition 1.4.10.1. Let $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ be a morphism of spectrally ringed ∞-topoi. We will say that f is *étale* if the following conditions are satisfied:

- (a) The underlying geometric morphism $f_* : \mathcal{X} \to \mathcal{Y}$ is étale: that is, it induces an equivalence $\mathcal{X} \simeq \mathcal{Y}_{/U}$ for some object $U \in \mathcal{Y}$ (see §HTT.6.3.5).
- (b) The induced map $f^* \mathcal{O}_{\mathcal{Y}} \to \mathcal{O}_{\mathcal{X}}$ is an equivalence of sheaves of $\mathbb{E}_\infty$-rings on $\mathcal{X}$.

We will say that f is an *étale surjection* if, in addition, the object $U \in \mathcal{Y}$ appearing in (a) is 0-connective.

Theorem 1.4.10.2. *Let $\phi : A \to B$ be a map of $\mathbb{E}_\infty$-rings. Then ϕ is étale if and only if the induced map* $\operatorname{Spét} B \to \operatorname{Spét} A$ *is an étale morphism of nonconnective spectral Deligne-Mumford stacks.*

Corollary 1.4.10.3. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a map between nonconnective spectral Deligne-Mumford stacks. The following conditions are equivalent:*

- (i) *The map f is étale.*
- (ii) *For every commutative diagram*

$$\begin{array}{ccc} \operatorname{Spét} B & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow f \\ \operatorname{Spét} A & \longrightarrow & \mathsf{Y} \end{array}$$

  in which the horizontal maps are étale, the underlying map of $\mathbb{E}_\infty$-rings $A \to B$ is étale.

Proof of Theorem 1.4.10.2. We proceed as in the proof of Proposition 1.2.5.7. The implication (1) $\Rightarrow$ (2) follows immediately from the construction of $\operatorname{Spét} B$ (see Definition 1.2.3.3). Conversely, suppose that (2) is satisfied. Write $\operatorname{Spét} A = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$, so that $\operatorname{Spét} B \simeq (\mathcal{X}_{/U}, \mathcal{O}_{\mathcal{X}}|_U)$ for some object $U \in \mathcal{X}$. Choose an effective epimorphism $\amalg_{i \in I} V_i \to U$, where each $V_i \in \mathcal{X}$ is the functor corepresented by an étale A-algebra A_i. We can identify each V_i with an object of the ∞-topos $\mathcal{X}_{/U} \simeq \mathcal{S}\mathrm{hv}_B^{\text{ét}}$. We may therefore choose an effective epimorphism $\amalg_{j \in J} W_j \to U$, where each W_j is corepresented by an étale B-algebra B_j, and each of the maps $W_j \to U$ factors through $V_{\alpha(i)}$ for some map $\alpha : J \to I$. Without loss of generality, we may assume that the set J is finite. Replacing I by J and α by the identity map, we can assume that I is finite as well. Set $V = \amalg_{i \in I} V_i$ and $W = \amalg_{j \in J} W_j$, so that V is corepresented by an étale A-algebra A' (when regarded as an object of $\mathcal{S}\mathrm{hv}_A^{\text{ét}}$), and W is corepresented by an étale B-algebra B' (when regarded as an object of $\mathcal{S}\mathrm{hv}_B^{\text{ét}}$. We therefore have maps of spectral Deligne-Mumford stacks

$$\mathrm{Spét}\, B' \to \mathrm{Spét}\, A' \to \mathrm{Spét}\, B \to \mathrm{Spét}\, A.$$

Applying Remark 1.4.7.1, we obtain maps of $\mathbb{E}_\infty$-rings

$$A \to B \to A' \to B'.$$

It follows that B' is a retract of $A' \otimes_B B'$ in the ∞-category category of A-algebras. Since B' is étale over B and A' is étale over A, the algebra $A' \otimes_B B'$ is étale over A, so that B' is étale over A (Remark **??**). Since the map $B \to B'$ is étale and faithfully flat, we conclude that B is also étale over A (Proposition B.1.4.1). □

1.4.11 Limits of Spectral Deligne-Mumford Stacks

We close this section with a few remarks about the formation of limits in the ∞-category SpDM of spectral Deligne-Mumford stacks.

Proposition 1.4.11.1. (1) *The ∞-category* $\mathrm{SpDM}^{\mathrm{nc}}$ *of nonconnective spectral Deligne-Mumford stacks admits finite limits, and the inclusion functor* $\mathrm{SpDM}^{\mathrm{nc}} \hookrightarrow \infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$ *preserves finite limits.*

(2) *Suppose we are given a pullback diagram of nonconnective spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle \phi'} & & \downarrow{\scriptstyle \phi} \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y}. \end{array}$$

If ϕ is étale, so is ϕ'.

(3) *The functor* $\mathrm{Spét} : \mathrm{CAlg}^{\mathrm{op}} \to \mathrm{SpDM}^{\mathrm{nc}}$ *preserves finite products. That is, if R is an $\mathbb{E}_\infty$-ring and $A, B \in \mathrm{CAlg}_R$, then the canonical map*

$$\mathrm{Spét}(A \otimes_R B) \to (\mathrm{Spét}\, A) \times_{\mathrm{Spét}\, R} (\mathrm{Spét}\, B)$$

is an equivalence.

(4) *Suppose we are given a pullback diagram of nonconnective spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle \phi'} & & \downarrow{\scriptstyle \phi} \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y}. \end{array}$$

If X, Y, *and* Y' *are spectral Deligne-Mumford stacks, then* X' *is a spectral Deligne-Mumford stack.*

Proof. Assertion (1) is a special case of Proposition **??** (see Remark **??**), which we will prove in Part VI. Assertion (2) follows from Remark 21.4.6.7. Assertion (3) follows because the functor Spét is right adjoint to the global sections functor. To prove (4), we can use (2) to reduce to the case where X, Y, and Y' are affine. In this case, the desired result follows from (3). □

Corollary 1.4.11.2. *The* ∞*-category* $\mathrm{SpDM}^{\mathrm{nc}}$ *of nonconnective spectral Deligne-Mumford stacks is idempotent complete.*

Proof. The ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$ admits filtered limits (this is a special case of Proposition 21.4.3.2, but is also easy to verify directly) and is therefore idempotent complete. Consequently, it will suffice to show that the ∞-category $\mathrm{SpDM}^{\mathrm{nc}}$ is closed under retracts in $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$. Suppose we are given a commutative diagram

$$\begin{array}{ccccc} & & (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}) & & \\ & \overset{i}{\nearrow} & & \overset{r}{\searrow} & \\ (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) & & \xrightarrow{\mathrm{id}} & & (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \end{array}$$

in $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$, where $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ is a nonconnective spectral Deligne-Mumford stack; we wish to show that $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is also a nonconnective spectral Deligne-Mumford stack. We will show that $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ satisfies the criteria of Theorem 1.4.8.1:

(1) Let $\mathcal{X}^{\heartsuit}$ and $\mathcal{Y}^{\heartsuit}$ denote the topoi of discrete objects of $\mathcal{X}$ and $\mathcal{Y}$, respectively. Then the ringed topos $(\mathcal{X}^{\heartsuit}, \pi_0 \mathscr{O}_{\mathcal{X}})$ is a retract of $(\mathcal{Y}^{\heartsuit}, \pi_0 \mathscr{O}_{\mathcal{Y}})$ in the 2-category $1\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}^{\heartsuit}}$. Theorem 1.4.8.1 implies that $(\mathcal{Y}^{\heartsuit}, \pi_0 \mathscr{O}_{\mathcal{Y}})$ is a Deligne-Mumford stack. Since the 2-category of Deligne-Mumford stacks admits finite limits, it is idempotent complete; it follows that $(\mathcal{X}^{\heartsuit}, \pi_0 \mathscr{O}_{\mathcal{X}})$ is also a Deligne-Mumford stack.

(2) We have a commutative diagram of ∞-topoi

$$\begin{array}{ccccc} \mathcal{X} & \longrightarrow & \mathcal{Y} & \longrightarrow & \mathcal{X} \\ \downarrow & & \downarrow & & \downarrow \\ \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}^{\heartsuit}) & \longrightarrow & \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{Y}^{\heartsuit}) & \longrightarrow & \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}^{\heartsuit}). \end{array}$$

It follows from Theorem 1.4.8.1 that the middle vertical map is étale. Consequently, the fiber product $\mathcal{Z} = \mathcal{Y} \times_{\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{Y}^{\heartsuit})} \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}^{\heartsuit})$ (formed in the ∞-category $\infty\mathcal{T}\mathrm{op}$ of ∞-topoi) is étale over $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}^{\heartsuit})$. Since $\mathcal{X}$ is a retract of $\mathcal{Z}$ in $\infty\mathcal{T}\mathrm{op}_{/\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}^{\heartsuit})}$, it follows that the geometric morphism $\mathcal{X} \to \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}^{\heartsuit})$ is also étale.

(3) Let $j : (\mathcal{X}^{\heartsuit}, \pi_0 \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}^{\heartsuit}, \pi_0 \mathscr{O}_{\mathcal{Y}})$ be the map of Deligne-Mumford stacks determined by i, and let j^* denote the associated pullback functor on quasi-coherent sheaves. Theorem 1.4.8.1 implies that $\pi_n \mathscr{O}_{\mathcal{Y}}$ is quasi-coherent (when regarded as an object of the abelian category of $\pi_0 \mathscr{O}_{\mathcal{Y}}$-modules in $\mathcal{Y}^{\heartsuit}$), so that $j^* \pi_n \mathscr{O}_{\mathcal{Y}}$ is a quasi-coherent sheaf on $(\mathcal{X}^{\heartsuit}, \pi_0 \mathscr{O}_{\mathcal{X}})$. The homotopy group $\pi_n \mathscr{O}_{\mathcal{X}}$ is a retract and therefore a direct summand of $j^* \pi_n \mathscr{O}_{\mathcal{Y}}$, and therefore also quasi-coherent.

(4) Theorem 1.4.8.1 implies that $\mathscr{O}_{\mathcal{Y}}$ is hypercomplete (when regarded as a sheaf of spectra on $\mathcal{Y}$), so that $r_* \mathscr{O}_{\mathcal{Y}}$ is hypercomplete (when regarded as a sheaf of spectra on $\mathcal{X}$). Since $\mathscr{O}_{\mathcal{X}}$ is a retract (and therefore a direct summand, when regarded as a sheaf of spectra) of the direct image $r_* \mathscr{O}_{\mathcal{Y}}$, it is also hypercomplete.

□

1.5 Digression: Topological Spaces and ∞-Topoi

To every topological space X, one can associate an ∞-topos $\mathcal{S}\mathrm{hv}(X) = \mathcal{S}\mathrm{hv}_{\mathcal{S}}(X)$ of $\mathcal{S}$-valued sheaves on X. In this section, we will review a closely related construction, which assigns to each ∞-topos $\mathcal{X}$ an underlying topological space $|\mathcal{X}|$. These ideas will play an important role when we discuss the relationship between spectral schemes and spectral Deligne-Mumford stacks in §1.6.

1.5.1 Locales

We begin with a brief review of "pointless" topology. For a more detailed discussion, we refer the reader to [105].

Definition 1.5.1.1. Let Λ be a partially ordered set. We say that Λ is a *locale* if it satisfies the following pair of conditions:

(1) Every subset $S \subseteq \Lambda$ has a least upper bound $\bigvee S \in \Lambda$.

Note that condition (1) implies that every subset $S \subseteq \Lambda$ also has a greatest lower bound $\bigwedge S \in \Lambda$ (namely, the least upper bound of the set $T = \{U \in \Lambda : (\forall V \in S) U \leqslant V\}$). In particular, every pair of elements $U, V \in \Lambda$ have a greatest lower bound $U \wedge V$.

(2) For every subset $\{U_\alpha\} \subseteq \Lambda$ and every element $V \in \Lambda$, we have $(\bigvee U_\alpha) \wedge V = \bigvee (U_\alpha \wedge V)$.

Remark 1.5.1.2. In the situation of Definition 1.5.1.1, we can replace (2) by the following apparently weaker condition:

(2′) For every subset $\{U_\alpha\} \subseteq \Lambda$ and every element $V \in \Lambda$, we have

$$(\bigvee U_\alpha) \wedge V \leqslant \bigvee (U_\alpha \wedge V).$$

The reverse inequality is automatic.

Remark 1.5.1.3. Let Λ be a locale. Then Λ is a distributive lattice (see Proposition A.1.4.4): that is, it satisfies a distributive law

$$(\bigwedge_{U \in S} U) \vee V = \bigwedge_{U \in S} (U \vee V)$$

whenever S is a *finite* subset of Λ.

Example 1.5.1.4. Let X be a topological space, and let $\mathcal{U}(X)$ denote the collection of all open subsets of X. Then $\mathcal{U}(X)$ is a locale (when regarded as partially ordered by inclusion).

Definition 1.5.1.5. Let Λ and Λ' be locales. A *morphism of locales* from Λ to Λ' is a functor $f^* : \Lambda' \to \Lambda$ satisfying the following conditions:

(1) The function f^* preserves joins. That is, for every subset $S \subseteq \Lambda'$, we have $f^*(\bigvee S) = \bigvee(f^* S)$.

(2) The function f^* preserves finite meets. That is, for every finite subset $S \subseteq \Lambda'$, we have $f^*(\bigwedge S) = \bigwedge(f^* S)$.

The collection of locale morphisms is closed under composition. We may therefore organize the collection of locales into a category, which we will denote by Loc.

Example 1.5.1.6. Let $f : X \to Y$ be a continuous map of topological spaces. Then f induces a morphism of locales $\mathcal{U}(X) \to \mathcal{U}(Y)$, which carries an open subset $U \subseteq Y$ to its inverse image $f^{-1}U \subseteq X$. We may therefore regard the construction $X \mapsto \mathcal{U}(X)$ as a functor from the category $\mathcal{T}\mathrm{op}$ of topological spaces to the category Loc of locales.

1.5.2 Points of a Locale

The functor described in Example 1.5.1.6 admits a left adjoint. To describe it, we need to introduce a bit more terminology.

Definition 1.5.2.1. Let Λ be a locale. We will say that an object $U \in \Lambda$ is *indecomposable* if, whenever $U = \bigwedge S$ for some finite subset $S \subseteq \Lambda$, we have $U \in S$.

We let $|\Lambda|$ denote the set of all indecomposable elements of Λ. For each element $U \in \Lambda$, we let $|\Lambda|_U$ denote the subset $\{V \in |\Lambda| : U \nleqslant V\}$.

Proposition 1.5.2.2. *Let Λ be a locale. Then the set $|\Lambda|$ of indecomposable elements of Λ has the structure of a topological space, whose open sets are those of the form $|\Lambda|_U$. Moreover, the construction $U \mapsto |\Lambda|_U$ determines a morphism of locales $v^* : \mathcal{U}(|\Lambda|) \to \Lambda$.*

Proof. We claim the following:

(1) For every subset $S \subseteq \Lambda$, we have

$$|\Lambda|_{\bigvee S} = \bigcup_{U \in S} |\Lambda|_U.$$

(2) For every finite subset $S \subseteq \Lambda$, we have

$$|\Lambda|_{\bigwedge S} = \bigcap_{U \in S} |\Lambda|_U.$$

It follows from (1) that the collection of subsets of $|\Lambda|$ which have the form $|\Lambda|_U$ is closed under unions, and from (2) that the same collection is closed under finite intersections. Moreover, (1) and (2) immediately imply that v^* is a morphism of locales.

Assertion (1) is an immediate consequence of the definitions: we have $\bigvee S \nleq V$ if and only if $U \nleq V$ for some $U \in S$. To prove (2), we must show that if $S \subseteq \Lambda$ is finite and V is indecomposable, then $\bigwedge S \nleq V$ if and only if $U \nleq V$ for all U in S. The "only if" direction is clear (and does not require the assumption that V is indecomposable). Conversely, suppose that $U \nleq V$ for all U in S. Then $V \neq U \vee V$ for all $U \in S$. Since V is indecomposable, we conclude that $\bigwedge_{U \in S}(U \vee V) \neq V$. Applying Remark 1.5.1.3, we can rewrite the left hand side as $(\bigwedge S) \vee V$, so that $\bigwedge S \nleq V$. □

Proposition 1.5.2.3. *Let Λ be a locale and let X be a topological space. Then composition with the locale morphism $v^* : \mathcal{U}(|\Lambda|) \to \Lambda$ of Proposition 1.5.2.2 induces a bijection*

$$\theta : \mathrm{Hom}_{\mathcal{T}\mathrm{op}}(X, |\Lambda|) \to \mathrm{Hom}_{\mathrm{Loc}}(\mathcal{U}(X), \Lambda).$$

Proof. We first show that θ is injective. Suppose that $f, g : X \to |\Lambda|$ are continuous maps of topological spaces with $f \neq g$. Then there exists a point $x \in X$ such that $f(x) \neq g(x)$. Let us regard $f(x)$ and $g(x)$ as indecomposable elements of Λ. Without loss of generality we may assume that $f(x) \nleq g(x)$. We then ahve

$$f(x) \in |\Lambda|_{f(x)} \qquad g(x) \notin |\Lambda|_{f(x)}.$$

It follows that $f^{-1}|\Lambda|_{f(x)} \neq g^{-1}|\Lambda|_{f(x)}$, so that $\theta(f) \neq \theta(g)$.

We now prove that θ is surjective. Suppose we are given a morphism of locales from $\mathcal{U}(X)$ to Λ, given by a map $f^* : \Lambda \to \mathcal{U}(X)$. For each point $x \in X$, let $S_x = \{U \in \Lambda : x \notin f^*U\}$. Since f^* preserves infinite joins, S_x contains a largest element $U_x = \bigvee S_x$. We claim that

U_x is indecomposable. For suppose that $U_x = \bigwedge T$, where $T \subseteq \Lambda$ is finite. We then have $f^*(U_x) = \bigcap_{V \in T} f^*(V)$. Since $x \notin f^*(U_x)$, it follows that $x \notin f^*(V)$ for some $V \in T$. Then $V \in S_x$, so that $V = U_x$.

Let $f : X \to |\Lambda|$ be the map given by $f(x) = U_x$. For each point $x \in X$ and each element $V \in \Lambda$, we have

$$\begin{aligned} x \in f^{-1}|\Lambda|_V & \Leftrightarrow U_x \in |\Lambda|_V \\ & \Leftrightarrow V \nleq U_x \\ & \Leftrightarrow V \notin S_x \\ & \Leftrightarrow x \in f^*(V). \end{aligned}$$

It follows that for $V \in \Lambda$, the inverse image $f^{-1}|\Lambda|_V$ coincides with the open set $f^*(V) \subseteq X$, so that f is a continuous map. Moreover, our calculation immediately implies that $\theta(f) = f^*$. □

Corollary 1.5.2.4. *The functor $X \mapsto \mathcal{U}(X)$ admits a left adjoint, given on objects by the formula $\Lambda \mapsto |\Lambda|$. In particular, the topological space $|\Lambda|$ depends functorially on the locale Λ.*

Definition 1.5.2.5. Let Λ be a locale. We will say that Λ is *spatial* if the counit map $v^* : \mathcal{U}(|\Lambda|) \to \Lambda$ is an isomorphism of locales.

Remark 1.5.2.6. Let Λ be a locale. By definition, every open subset of $|\Lambda|$ has the form $|\Lambda|_U$, for some element $U \in \Lambda$. Consequently, the counit map $v^* : \mathcal{U}(|\Lambda|) \to \Lambda$ is automatically surjective (when regarded as a map of sets from Λ to $\mathcal{U}(|\Lambda|)$). The condition that Λ is spatial is equivalent to the condition that v^* is surjective: that is, that $|\Lambda|_U \neq |\Lambda|_V$ for $U \neq V$.

Corollary 1.5.2.7. *The construction $\Lambda \mapsto |\Lambda|$ determines a fully faithful embedding $\mathrm{Loc}^{\mathrm{spa}} \to \mathcal{T}\mathrm{op}$, where $\mathrm{Loc}^{\mathrm{spa}}$ denotes the full subcategory of Loc spanned by the spatial locales.*

Remark 1.5.2.8. Let X be a topological space. Then the locale $\mathcal{U}(X)$ is automatically spatial: an open subset $U \in \mathcal{U}(X)$ can be recovered as the inverse image of $|\mathcal{U}(X)|_U$ under the unit map $X \to |\mathcal{U}(X)|$. Consequently, if $|\mathcal{U}(X)|_U = |\mathcal{U}(X)|_V$, then $U = V$.

It follows that the construction $\Lambda \mapsto \mathcal{U}(|\Lambda|)$ determines a right adjoint to the inclusion functor $\mathrm{Loc}^{\mathrm{spa}} \hookrightarrow \mathrm{Loc}$. In particular, the category of spatial locales is a colocalization of the category of locales.

1.5.3 Sober Topological Spaces

Our next goal is to describe the essential image of the embedding $\mathrm{Loc}^{\mathrm{spa}} \hookrightarrow \mathcal{T}\mathrm{op}$.

Definition 1.5.3.1. Let X be a topological space. A closed subset $K \subseteq X$ is said to be *irreducible* if it is nonempty and cannot be written as a union $K_- \cup K_+$ of proper closed subsets $K_-, K_+ \subsetneq K$. A point $x \in K$ is said to be a *generic point* of K if K is the closure of $\{x\}$. The space X is said to be *sober* if every irreducible closed subset of X has a unique generic point.

Remark 1.5.3.2. Let X be a topological space. For every point $x \in X$, the closure of the set $\{x\}$ is irreducible.

Example 1.5.3.3. Every Hausdorff topological space X is sober (the only irreducible closed subsets of X are singletons).

Proposition 1.5.3.4. *Let Λ be a locale. Then the topological space $|\Lambda|$ is sober.*

Proof. Let U be an indecomposable element of Λ. For each $V \in \Lambda$, we have $U \notin |\Lambda|_V$ if and only if $V \leqslant U$. In particular, $|\Lambda|_U$ is the largest open subset of $|\Lambda|$ which does not contain U, and is therefore the complement of the closure $\{U\}$. If U' is another indecomposable element of Λ having the same closure in $|\Lambda|$, then for each $V \in \Lambda$ we have

$$U \notin |\Lambda|_V \Leftrightarrow U' \notin |\Lambda|_V,$$

so that $V \leqslant U \Leftrightarrow V \leqslant U'$ and therefore $U = U'$.

Let K be an irreducible closed subset of $|\Lambda|$. The above argument shows that K has at most one generic point. We will complete the proof by showing that there exists a generic point of K. Set $S = \{U \in \Lambda : K = |\Lambda| - |\Lambda|_U\}$. Since K is closed, the set S is nonempty. It follows that S contains a largest element U. We will complete the proof by showing that U is indecomposable, so that $K = |\Lambda| - |\Lambda|_U$ is the closure of U.

Suppose that T is a finite subset of Λ satisfying $U = \bigwedge_{V \in T} V$. We wish to show that $U \in T$. Suppose otherwise: then, by the maximality of U, each of the open sets $|\Lambda|_V$ has nontrivial intersection with K. Since K is irreducible, it follows that the intersection $\bigcap_{V \in T} |\Lambda|_V$ has nontrivial intersection with K, contradicting our assumption that $|\Lambda|_U \cap K = \varnothing$. □

Proposition 1.5.3.5. *Let X be a topological space. The following conditions are equivalent:*

(1) *The topological space X is sober.*

(2) *The unit map $u : X \to |\mathcal{U}(X)|$ is a homeomorphism.*

Proof of Proposition 1.5.3.5. The implication (2) ⇒ (1) follows immediately from Proposition 1.5.3.4. For the converse, suppose that (1) is satisfied. Note that an open set $U \in \mathcal{U}(X)$ is indecomposable if and only if the complement $X - U$ is irreducible. Consequently, we can identify $|\mathcal{U}(X)|$ with the collection of irreducible closed subsets of X. Under this identification, the map u carries a point $x \in X$ to the closure of $\{x\}$. The assumption that X is sober implies that the map u is bijective. To complete the proof that u is a homeomorphism, it will suffice to note that every open subset $U \subseteq X$ is the inverse image (under the map u) of the open subset $|\mathcal{U}(X)|_U \subseteq \mathcal{U}(X)$. □

Remark 1.5.3.6. Combining Propositions 1.5.3.4 and 1.5.3.5, we conclude that the category $\mathcal{T}\mathrm{op}^{\mathrm{sob}}$ of sober topological spaces is a localization of the category $\mathcal{T}\mathrm{op}$ of all topological spaces. The inclusion $\mathcal{T}\mathrm{op}^{\mathrm{sob}} \hookrightarrow \mathcal{T}\mathrm{op}$ admits a left adjoint, given by $X \mapsto |\mathcal{U}(X)|$. We refer to the topological space $|\mathcal{U}(X)|$ as the *soberification* of X. The points of $|\mathcal{U}(X)|$ can be identified with irreducible closed subsets of X.

The above arguments show that the adjoint functors

$$\mathcal{T}\mathrm{op} \underset{||}{\overset{\mathcal{U}}{\rightleftarrows}} \mathrm{Loc}$$

restrict to an equivalence between the category $\mathcal{T}\mathrm{op}^{\mathrm{sob}}$ of sober topological spaces and the category $\mathrm{Loc}^{\mathrm{spa}}$ of spatial locales. $\mathcal{T}\mathrm{op}^{\mathrm{sob}} \simeq \mathrm{Loc}^{\mathrm{spa}}$

Algebraic geometry furnishes plenty of examples of sober topological spaces.

Proposition 1.5.3.7. *Let X be a topological space. Then:*

(a) *If X is sober, then any open subset $U \subseteq X$ is sober.*

(b) *If X can be written as a union of sober open subsets U_α, then X is sober.*

Proof. We first prove (a). Let $K \subseteq U$ be an irreducible closed subset of U, and let $\overline{K}$ be its closure in X. We first claim that $\overline{K}$ is irreducible. Suppose otherwise: then we can write $\overline{K} = \overline{K}_- \cup \overline{K}_+$ for some proper closed subsets $\overline{K}_-, \overline{K}_+ \subseteq \overline{K}$. In this case, we also have $K = (U \cap \overline{K}_-) \cup (U \cap \overline{K}_+)$. The irreducibility of K then implies that $K = U \cap \overline{K}_-$ or $K = U \cap \overline{K}_+$. Since K is dense in $\overline{K}$, this contradicts our assumption that either $\overline{K}_-$ and $\overline{K}_+$ are proper subsets of $\overline{K}$.

If X is irreducible, we conclude that $\overline{K}$ has a unique generic point $x \in X$. Then x belongs to the nonempty open subset $U \cap \overline{K} = K$ of $\overline{K}$, and therefore belongs to U. It follows that x is a generic point of K in U. We claim that this generic point is unique. To see this, suppose that y is any other generic point of K in U. Then $y \in K \subseteq \overline{K}$, so that the closure of $\{y\}$ in X is contained in $\overline{K}$. However, the closure of $\{y\}$ in X contains K and therefore contains $\overline{K}$. It follows that y is a generic point of $\overline{K}$ in X, so that $y = x$ by virtue of our assumption that X is sober. This completes the proof of (a).

We now prove (b). Suppose that X admits a covering by sober open subsets $\{U_\alpha\}_{\alpha \in A}$. Let $K \subseteq X$ be an irreducible closed subset. Then K is nonempty, so that the intersection $K_\alpha = U_\alpha \cap K$ is nonempty for some $\alpha \in A$. Then we can write $K = \overline{K}_\alpha \cup (K \cap (X - U_\alpha))$. Using the irreducibility of K, we deduce that $K = \overline{K}_\alpha$: that is, K_α is dense in K. We now claim that K_α is an irreducible closed subset of U_α. To see this, suppose that $K_\alpha = K_- \cup K_+$ for some closed subsets $K_-, K_+ \subset K_\alpha$. Then $K = \overline{K}_- \cup \overline{K}_+$, so that the irreducibility of K implies that $K = \overline{K}_-$ or $\overline{K}_+$. Since K_- and K_+ are closed in U_α, we conclude that $K_\alpha = U_\alpha \cap K$ is equal to either K_- or K_+.

Since U_α is irreducible, the set K_α has a unique generic point $x \in U_\alpha$. Then the closure of $\{x\}$ in X is given by $\overline{K}_\alpha = K$, so that x is a generic point of K. Let y be any other generic point of K. Then y is contained in the nonempty open subset $K_\alpha \subseteq K$, so that $y \in U_\alpha$. It follows that y is a generic point of K_α in U_α, so that $y = x$ by virtue of our assumption that U_α is sober. This completes the proof of (b). □

Corollary 1.5.3.8. *Let $(X, \mathscr{O}_X)$ be a nonconnective spectral scheme. Then the topological space X is sober.*

Proof. Using Proposition 1.5.3.7 and Corollary 1.1.6.2, we can reduce to the case where $(X, \mathscr{O}_X) \simeq \operatorname{Spec} A$ for some connective $\mathbb{E}_\infty$-ring A, so that X is homeomorphic to $|\operatorname{Spec} R|$ for $R = \pi_0 A$. In this case, every closed set $K \subseteq X$ can be realized as the vanishing locus of a radical ideal $I \subseteq R$. Moreover, K is irreducible if and only if I is a prime ideal, in which case I is the unique generic point of K (when regarded as an element of $|\operatorname{Spec} R|$). □

1.5.4 Locales Associated to ∞-Topoi

We now discuss another class of examples of locales:

Definition 1.5.4.1. Let $\mathcal{X}$ be an ∞-topos. We let $\operatorname{Sub}(\mathcal{X})$ denote the collection of equivalence classes of (-1)-truncated objects of $\mathcal{X}$. For each (-1)-truncated object $U \in \mathcal{X}$, we let $[U] \in \operatorname{Sub}(\mathcal{X})$ denote the equivalence class of U. We regard $\operatorname{Sub}(\mathcal{X})$ as a partially ordered set, with $[U] \leqslant [V]$ if there exists a morphism from U to V in the ∞-topos $\mathcal{X}$. Then $\operatorname{Sub}(\mathcal{X})$ is a locale, which we refer to as the *underlying locale* of X (see §HTT.6.4.2).

Remark 1.5.4.2. The construction $\mathcal{X} \mapsto \operatorname{Sub}(\mathcal{X})$ determines a functor $\operatorname{Sub} : \infty\mathcal{T}\mathrm{op} \to \mathrm{Loc}$. This is a localization functor: that is, it admits a fully faithful right adjoint $\iota : \mathrm{Loc} \hookrightarrow \infty\mathcal{T}\mathrm{op}$, whose essential image is spanned by the 0-localic ∞-topoi (see §HTT.6.4.5 .

Definition 1.5.4.3. Let $\mathcal{X}$ be an ∞-topos. We let $|\mathcal{X}|$ denote the underlying topological space $|\operatorname{Sub}(\mathcal{X})|$ of the locale $\operatorname{Sub}(\mathcal{X})$. We will say that $\mathcal{X}$ is *spatial* if the locale $\operatorname{Sub}(\mathcal{X})$ is spatial.

Example 1.5.4.4. Let X be a topological space, and let $\mathcal{S}\mathrm{hv}(X)$ denote the ∞-topos of $\mathcal{S}$-valued sheaves on X. Then we can identify $\operatorname{Sub}(\mathcal{S}\mathrm{hv}(X))$ with the locale $\mathcal{U}(X)$ of open subsets of X. It follows that the topological space $|\mathcal{S}\mathrm{hv}(X)|$ can be identified with the soberification of X. In particular, there is a canonical map $X \to |\mathcal{S}\mathrm{hv}(X)|$, which is a homeomorphism if and only if X is sober.

Example 1.5.4.5. Let $\mathcal{X}$ be an ∞-topos. Every geometric morphism $f_* : \mathcal{S} \to \mathcal{X}$ induces a continuous map $|\,\mathcal{S}\,| \to |\,\mathcal{X}\,|$, which we can identify with a point η_f of the topological space $|\,\mathcal{X}\,|$. Let U be a (-1)-truncated object of $\mathcal{X}$. Then for each point $f_* : \mathcal{S} \to \mathcal{X}$, the space f^*U is either empty or contractible, depending on whether or not η_f belongs to $|\,\mathcal{X}\,|_U$. If V is another (-1)-truncated object of $\mathcal{X}$ satisfying $|\,\mathcal{X}\,|_V$, it follows that the canonical maps

$$f^*U \leftarrow f^*(U \times V) \to f^*(V)$$

are homotopy equivalences. If the ∞-topos $\mathcal{X}$ has enough points (see §A.4), we conclude that the projection maps $U \leftarrow U \times V \to V$ are equivalences, so that $[U] = [V] \in \mathrm{Sub}(\mathcal{X})$. It follows that every ∞-topos with enough points is spatial.

Proposition 1.5.4.6. *Let R be an $\mathbb{E}_\infty$-ring. Then the ∞-topos $\mathcal{S}\mathrm{hv}_R^{\acute{e}t}$ is spatial. Moreover, there is a canonical homeomorphism $|\,\mathcal{S}\mathrm{hv}_R^{\acute{e}t}\,| \simeq |\operatorname{Spec} R|$.*

Proof. Let $X = |\operatorname{Spec} R|$, and let $\mathcal{U}(X)$ be the collection of all open subsets of X. Let $\mathcal{C} = (\mathrm{CAlg}_R^{\acute{e}t})^{\mathrm{op}}$ denote the opposite of the ∞-category of étale R-algebras, so that $\mathcal{S}\mathrm{hv}_R^{\acute{e}t}$ is the full subcategory of $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ spanned by the étale sheaves. It follows that $\mathrm{Sub}(\mathcal{S}\mathrm{hv}_R^{\acute{e}t})$ can be identified with the partially ordered set P of sieves $\mathcal{C}^{(0)} \subseteq \mathcal{C}$ which are *saturated* in the following sense: if A is an étale R-algebra, and there exists an étale covering $\{A \to A_i\}$ for which each A_i belongs to $\mathcal{C}^{(0)}$, then A belongs to $\mathcal{C}^{(0)}$.

For each open set $U \subseteq X$, let $\lambda(U)$ denote the full subcategory of $\mathcal{C}$ spanned by those objects A for which the map $|\operatorname{Spec} A| \to |\operatorname{Spec} R|$ factors through U. We will complete the proof by showing that the construction $U \mapsto \lambda(U)$ determines an isomorphism of partially ordered sets $\lambda : \mathcal{U}(X) \to P$.

For each element $a \in \pi_0 R$, let $U_a = \{\mathfrak{p} \in |\operatorname{Spec} R| : a \notin \mathfrak{p}\}$. We first claim that if U and V are open subsets of X such that $\lambda(U) \subseteq \lambda(V)$, then $U \subseteq V$. Since U is the union of basic open sets of the form U_a, we may assume that $U = U_a$ for some $a \in \pi_0 R$. Then $R[a^{-1}] \in \lambda(U) \subseteq \lambda(V)$, so that V contains the image of the map $|\operatorname{Spec} R[a^{-1}]| \to |\operatorname{Spec} R| = X$ (which coincides with U).

The above argument shows that λ is an isomorphism of $\mathcal{U}(X)$ onto a partially ordered subset of P. To complete the proof, it will suffice to show that λ is surjective. To this end, choose a saturated sieve $\mathcal{C}^{(0)} \subseteq \mathcal{C}$; we wish to show that $\mathcal{C}^{(0)}$ lies in the image of λ. For every étale R-algebra A, let U_A denote the image of the map $|\operatorname{Spec} A| \to |\operatorname{Spec} R|$; this is an open subset of X (Corollary B.2.2.5). Let U be the smallest open subset of X which contains U_A for each $A \in \mathcal{C}^{(0)}$. By construction, we have $\mathcal{C}^{(0)} \subseteq \lambda(U)$. To complete the proof, it suffices to show that this inclusion is an equality. That is, we must show that if A is an étale R-algebra such that the image of the map $\theta : |\operatorname{Spec} A| \to |\operatorname{Spec} R| = X$ is contained in U, then $A \in \mathcal{C}^{(0)}$. Since the image of θ is quasi-compact, it is contained in a finite union of $\bigcup_{1 \leqslant i \leqslant n} U_{B_i}$, where each $B_i \in \mathcal{C}^{(0)}$. It follows that the map $A \to \prod_{1 \leqslant i \leqslant n} (B_i \otimes_R A)$ is étale and faithfully flat. Since $\mathcal{C}^{(0)}$ is a saturated sieve containing each B_i, it must also contain A. □

Remark 1.5.4.7. Let $\phi : \mathcal{T}\mathrm{op} \to \infty\mathcal{T}\mathrm{op}$ be the functor of Remark 1.4.1.6, which carries a topological space X to the ∞-topos $\mathcal{S}\mathrm{hv}(X)$. Then ϕ factors as a composition

$$\mathcal{T}\mathrm{op} \xrightarrow{\mathcal{U}} \mathrm{Loc} \xrightarrow{\iota} \infty\mathcal{T}\mathrm{op},$$

where ι is the fully faithful embedding of Remark 1.5.4.2, and $\mathcal{U}$ is the functor of Example 1.5.1.6. It follows that ϕ is fully faithful when restricted to sober topological spaces (Remark 1.5.3.6). Consequently, the functor $\overline{\phi} : \mathcal{T}\mathrm{op}_{\mathrm{CAlg}} \to \infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ of Remark 1.4.1.6 is fully faithful when restricted to spectrally ringed spaces $(X, \mathscr{O}_X)$ for which X is sober. In particular, $\overline{\phi}$ is fully faithful when restricted to nonconnective spectral schemes (Corollary 1.5.3.8).

1.6 The Functor of Points

In classical algebraic geometry, we can often describe algebraic varieties (or schemes) as solutions to *moduli problems*. For example, the n-dimensional projective space $\mathbf{P}^n$ can be characterized as follows: it is universal among schemes over which there is a line bundle $\mathcal{L}$ generated by $(n+1)$ global sections. In particular, for any commutative ring A, the set $\mathrm{Hom}(\mathrm{Spec}\, A, \mathbf{P}^n)$ can be identified with the set of isomorphism classes of pairs $(L, \eta : A^{n+1} \to L)$ where L is an invertible A-module and η is a surjective A-module homomorphism (such a pair is determined up to unique isomorphism by the submodule $\ker(\eta) \subseteq A^{n+1}$).

More generally, *any* scheme X determines a covariant functor h_X from commutative rings to sets, given by the formula $h_X(A) = \mathrm{Hom}(\mathrm{Spec}\, A, X)$. We refer to $h_X(A)$ as the *set of A-valued points of* X, and to h_X as the *functor of points* of X. This functor determines X up to canonical isomorphism. More precisely, the construction $X \mapsto h_X$ determines a fully faithful embedding from the category of schemes to the presheaf category $\mathrm{Fun}(\mathrm{CAlg}^{\heartsuit}, \mathcal{S}\mathrm{et})$. Consequently, it is possible to think of schemes as objects of $\mathrm{Fun}(\mathrm{CAlg}^{\heartsuit}, \mathcal{S}\mathrm{et})$, rather than the category of locally ringed spaces. This point of view is often valuable: it is sometimes easier to describe the functor represented by a scheme X than it is to provide an explicit construction of X as a locally ringed space. Moreover, the "functor of points" perspective becomes essential when we wish to study more general algebro-geometric objects such as algebraic stacks.

1.6.1 The Case of a Spectrally Ringed Space

We begin by associating a functor to each spectrally ringed space.

Definition 1.6.1.1. Let $(X, \mathscr{O}_X)$ be a locally spectrally ringed space. We define a functor $h_X^{\mathrm{nc}} : \mathrm{CAlg} \to \mathcal{S}$ by the formula

$$h_X^{\mathrm{nc}}(R) = \mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathrm{Spec}\, R, (X, \mathscr{O}_X)),$$

where $\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ denotes the ∞-category of locally spectrally ringed spaces (see Definition 1.1.5.3). We let h_X denote the restriction of h_X^{nc} to the full subcategory $\mathrm{CAlg}^{\mathrm{cn}} \subseteq \mathrm{CAlg}$ spanned by the connective $\mathbb{E}_\infty$-rings. We will refer to both h_X and h_X^{nc} as the *functor of points* of $(X, \mathscr{O}_X)$.

Warning 1.6.1.2. The notation of Definition 1.6.1.1 is abusive: if $(X, \mathscr{O}_X)$ is a locally spectrally ringed ∞-topos, then the functors h_X^{nc} and h_X depend on the structure sheaf $\mathscr{O}_X$, and not only on the underlying topological space X.

1.6.2 Flat Descent

Our first main result in this section can be stated as follows:

Theorem 1.6.2.1. *Let $(X, \mathscr{O}_X)$ be a locally spectrally ringed space. Then the functor $h_X^{\mathrm{nc}} : \mathrm{CAlg} \to \mathcal{S}$ is a hypercomplete sheaf with respect to the fpqc topology of Proposition B.6.1.3.*

Since the construction $\mathrm{Spec} : \mathrm{CAlg}^{\mathrm{op}} \to \mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ is fully faithful (Remark 1.1.5.7), the functor $A \mapsto h^{\mathrm{nc}}_{\mathrm{Spec}\, A}$ coincides with the Yoneda embedding $\mathrm{CAlg}^{\mathrm{op}} \to \mathrm{Fun}(\mathrm{CAlg}, \mathcal{S})$. We may therefore view Theorem D.6.3.5 (which asserts that the fpqc topology on $\mathrm{CAlg}^{\mathrm{op}}$ is subcanonical) as a special case of Theorem 1.6.2.1. This observation does not supply a new proof of Theorem D.6.3.5, because Theorem D.6.3.5 is one of the main ingredients in our proof of Theorem 1.6.2.1. The other main ingredient is the compatibility of the Zariski topology with flat descent, which can be formulated more precisely as follows:

Proposition 1.6.2.2. *For every $\mathbb{E}_\infty$-ring A, let $\mathcal{U}(A)$ be the collection set of open subsets of the topological space $|\mathrm{Spec}\, A|$. Then $A \mapsto \mathcal{U}(A)$ determines a functor $\mathcal{U} : \mathrm{CAlg} \to \mathcal{S}\mathrm{et}$. This functor is a sheaf (of sets) with respect to the fpqc topology on $\mathrm{CAlg}^{\mathrm{op}}$.*

Remark 1.6.2.3. The sheaf $\mathcal{U} : \mathrm{CAlg} \to \mathcal{S}\mathrm{et}$ of Proposition 1.6.2.2 can be regarded as a discrete object in the ∞-category of $\mathcal{S}$-valued sheaves on $\mathrm{CAlg}^{\mathrm{op}}$. Consequently, it is automatically hypercomplete.

Proof of Proposition 1.6.2.2. We will show that the functor $\mathcal{U} : \mathrm{CAlg} \to \mathcal{S}\mathrm{et}$ satisfies conditions (1) and (2) of Proposition A.3.3.1. To verify (1), we must show that for every finite collection of $\mathbb{E}_\infty$-rings $\{A_i\}_{1 \leqslant i \leqslant n}$, the map $\mathcal{U}(\prod A_i) \to \prod \mathcal{U}(A_i)$ is bijective. This follows from the observation that there is a canonical homeomorphism $|\mathrm{Spec}(\prod_i A_i)| \simeq \amalg_i |\mathrm{Spec}\, A_i|$.

We now prove (2). Let $f : A \to B$ be a faithfully flat morphism of $\mathbb{E}_\infty$-rings; we wish to prove that

$$\mathcal{U}(A) \longrightarrow \mathcal{U}(B) \rightrightarrows \mathcal{U}(B \otimes_A B)$$

is an equalizer diagram in the category of sets. We can divide this assertion into two parts:

(a) The map $\mathcal{U}(A) \to \mathcal{U}(B)$ is injective. To prove this, we must show that an open subset $U \subseteq |\operatorname{Spec} A|$ is determined by its inverse image in $|\operatorname{Spec} B|$. This is clear, since the assumption that $A \to B$ is faithfully flat guarantees the induced map $|\operatorname{Spec} B| \to |\operatorname{Spec} A|$ is surjective.

(b) Let $\phi_0, \phi_1 : |\operatorname{Spec} B \otimes_A B| \to |\operatorname{Spec} B|$ be the two projection maps. We claim that if $Z \subseteq |\operatorname{Spec} B|$ is a closed subset with $\phi_0^{-1} Z = \phi_1^{-1} Z$, then $Z = \phi^{-1} V$ for some closed subset $V \subseteq |\operatorname{Spec} B|$. Choose an ideal $I \subseteq \pi_0 B$ such that $Z = \{\mathfrak{p} \subseteq \pi_0 B : I \subseteq \mathfrak{p}\}$, and let $J = f^{-1} I \subseteq \pi_0 A$. Set $V = \{\mathfrak{q} \subseteq \pi_0 A : J \subseteq \mathfrak{q}\}$. Then $\phi^{-1} V = \{\mathfrak{p} \subseteq \pi_0 B : f(J)\pi_0 B \subseteq \mathfrak{p}\}$. To prove that $\phi^{-1} V = Z$, it suffices to show that $f(J)\pi_0 B$ and I have the same nilradical. Let R denote the commutative ring $\pi_0 A / J$ and R' the commutative ring $\pi_0 B / J \pi_0 B$, and let I' denote the image of I in R'. Then $R \to R'$ is faithfully flat and the composite map $R \to R' \to R'/I'$ is injective; we wish to prove that every element $x \in I'$ is nilpotent. Since $\phi_0^{-1} Z = \phi_1^{-1} Z$, we deduce that the ideals $I' \otimes_R R'$ and $R' \otimes_R I'$ have the same radical in $R' \otimes_R R'$. Consequently, since $x \otimes 1$ belongs to $I' \otimes_R R'$, some power $x^n \otimes 1$ belongs to $R' \otimes_R I'$. It follows that the image of x^n vanishes in $R' \otimes_R R'/I'$. Since R' is flat over R, the injection $R \to R'/I'$ induces an injection $R' \to R' \otimes_R R'/I'$. It follows that $x^n = 0$ in R', as desired.

□

Proposition 1.6.2.4. (1) *The functor* $\operatorname{Spec} : \mathrm{CAlg}^{\mathrm{op}} \to \mathcal{T}\mathrm{op}_{\mathrm{CAlg}}^{\mathrm{loc}}$ *preserves finite coproducts.*

(2) *Let R be an $\mathbb{E}_\infty$-ring, and let $R^\bullet$ be a cosemisimplicial $\mathbb{E}_\infty$-ring which is a hypercovering of R with respect to the fpqc topology (see Definition A.5.7.1). Then* $\operatorname{Spec} R$ *is a colimit of the diagram* $\{\operatorname{Spec} R^\bullet\}$ *in* $\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}^{\mathrm{loc}}$.

Proof. Let $\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ denote the ∞-category of spectrally ringed spaces (Definition 1.1.2.5) and let $\mathcal{T}\mathrm{op}$ denote the ordinary category of topological spaces and continuous maps, so that we have forgetful functors

$$\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}^{\mathrm{loc}} \xrightarrow{j} \mathcal{T}\mathrm{op}_{\mathrm{CAlg}} \xrightarrow{q} \mathcal{T}\mathrm{op}.$$

We will deduce assertion (1) from the following three claims:

(1′) The functor $q \circ j \circ \operatorname{Spec} : \mathrm{CAlg}^{\mathrm{op}} \to \mathcal{T}\mathrm{op}$ preserves finite coproducts.

(1″) The functor $j \circ \mathrm{Spec} : \mathrm{CAlg}^{\mathrm{op}} \to \mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ carries finite coproducts to q-coproducts.

(1‴) The functor $\mathrm{Spec} : \mathrm{CAlg}^{\mathrm{op}} \to \mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ carries finite coproducts to j-coproducts.

To prove these claims, let $\{R_i\}_{1 \leqslant i \leqslant n}$ be a finite collection of $\mathbb{E}_\infty$-rings having product R. Let $X_i = |\operatorname{Spec} R_i|$ and let $X = |\operatorname{Spec} R|$, so that we can write $\operatorname{Spec} R_i = (X_i, \mathscr{O}_{X_i})$ and $\operatorname{Spec} R = (X, \mathscr{O}_X)$. For each index i, let $\phi_i : X_i \to X$ denote the map induced by the projection $R \to R_i$. Assertion (1′) was established as part of Proposition 1.6.2.2. By virtue of Proposition HTT.4.3.1.9 , assertion (1″) is equivalent to the requirement that the canonical map $\mathscr{O}_X \to \prod_i (\phi_i)_* \mathscr{O}_{X_i}$ is an equivalence of CAlg-valued X. Note that X has a basis of open sets of the form $U_f = \{\mathfrak{p} \subset \pi_0 R : f \notin \mathfrak{p}\}$, where $f = (f_1, \ldots, f_n)$ ranges over the elements of $\pi_0 R \simeq \pi_0 R_1 \times \cdots \times \pi_0 R_n$. Since this basis is stable under finite intersections, it suffices to observe that the canonical map

$$R[f^{-1}] \simeq \mathscr{O}_X(U_f) \to (\prod (\phi_i)_* \mathscr{O}_{X_i})(U_f) \simeq \prod \mathscr{O}_{X_i}(U_f \times_X X_i) \simeq \prod R_i[f_i^{-1}]$$

is an equivalence of $\mathbb{E}_\infty$-rings.

Unwinding the definitions, we can formulate assertion (1‴) as follows: a morphism $g : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ in $\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ belongs to $\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ if and only if, for $1 \leqslant i \leqslant n$, the induced map $g_i : (X_i, \mathscr{O}_{X_i}) \to (Y, \mathscr{O}_Y)$ belongs to $\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$. This follows immediately from the definitions, since $\mathscr{O}_{X_i}$ can be identified with the restriction $\mathscr{O}_X|_{X_i}$.

We now prove (2). Let $R^\bullet : \mathbf{\Delta}_{s,+} \to \mathrm{CAlg}_R$ be an fpqc hypercovering of $R = R^{-1}$ in the ∞-category $\mathrm{CAlg}^{\mathrm{op}}$. Reasoning as above, we are reduced to proving the following three assertions:

(2′) The composition $q \circ j \circ \operatorname{Spec} \circ R^\bullet$ is a colimit diagram in the ∞-category $\mathcal{T}\mathrm{op}$.

(2″) The composition $j \circ \operatorname{Spec} \circ R^\bullet$ is a q-colimit diagram in the ∞-category $\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$.

(2‴) The composition $\operatorname{Spec} \circ R^\bullet$ is a j-colimit diagram in the ∞-category $\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$.

By virtue of (1′) and Proposition A.5.7.2, assertion (2′) is equivalent to the requirement that the functor

$$q \circ j \circ \mathrm{Spec} : \mathrm{CAlg} \to \mathcal{T}\mathrm{op}^{\mathrm{op}}$$

is a hypercomplete sheaf with respect to the fpqc topology. Because $\mathcal{T}\mathrm{op}$ is an ordinary category, it will suffice to show that $q \circ j \circ \mathrm{Spec}$ is a sheaf with respect to the fpqc topology, which follows from Proposition 1.6.2.2. We now prove (2″). Let $X = |\operatorname{Spec} R|$, so that we can write $\operatorname{Spec} R = (X, \mathscr{O}_X)$. For every nonnegative integer n let $X_n = |\operatorname{Spec} R^n|$ and write $\operatorname{Spec} R^n = (X_n, \mathscr{O}_{X_n})$. Let $\mathscr{F}^n$ denote the pushforward of $\mathscr{O}_{X_n}$ along the canonical map $X_n \to X$. Then $\mathscr{F}^\bullet$ is a cosemisimplicial object in the ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(X)$. By virtue of Proposition HTT.4.3.1.9 , condition 23″) is equivalent to the requirement that the canonical map $\alpha : \mathscr{O}_X \to \varprojlim \mathscr{F}^\bullet$ is an equivalence. We note that X has a basis of open sets of the form $U_f = \{\mathfrak{p} \subset \pi_0 R^{-1} : f \notin \mathfrak{p}\}$. Since this collection is stable under finite intersection, to prove that α is an equivalence it suffices to show that α induces an equivalence of $\mathbb{E}_\infty$-rings $\mathscr{O}_X(U_f) \to \varprojlim \mathscr{F}^\bullet(U_f)$, for each $f \in \pi_0 R$. Replacing $R^\bullet$ by $R^\bullet[f^{-1}]$, we can reduce to the case where $U_f = X$. In this case, we need to show that the map

$$R \simeq \mathscr{O}(X) \to \varprojlim \mathscr{F}^\bullet(X) \simeq \varprojlim \mathscr{O}_{X_\bullet}(X_\bullet) \simeq \varprojlim R^\bullet$$

is an equivalence of $\mathbb{E}_\infty$-rings, which follows from Theorem D.6.3.5.

It remains to prove $(2''')$. Unwinding the definitions, we must show that if $(Y, \mathscr{O}_Y)$ is an object of $\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$, then a map $\phi : \operatorname{Spec} R \to (Y, \mathscr{O}_Y)$ in $\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ belongs to $\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ if and only if the induced map $\phi^0 : (Y, \mathscr{O}_Y) \to \operatorname{Spec} R^0$ belongs to $\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$. Let $f : X \to Y$ be the map of topological spaces underlying ϕ, and set $\mathscr{O}' = f^* \mathscr{O}_Y \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(X)$. Let $g : X_0 \to X$ denote the projection map. We are then reduced to proving the following: a morphism of sheaves of rings $\alpha : \pi_0 \mathscr{O}_X \to \pi_0 \mathscr{O}'$ is local if and only if the composite map $g^*\pi_0 \mathscr{O}' \xrightarrow{\alpha} g^*\pi_0 \mathscr{O}_X \to \pi_0 \mathscr{O}_{X_0}$ is a local map (between sheaves of local rings on X_0). This follows immediately from the observation that the map $g : X_0 \to X$ is surjective (since the underlying map of commutative rings $\pi_0 R \to \pi_0 R^0$ is assumed to be faithfully flat). □

Proof of Theorem 1.6.2.1. Combine Proposition 1.6.2.4 with Proposition A.5.7.2. □

1.6.3 The Functor of Points of a Spectral Scheme

We now use Theorem 1.6.2.1 to investigate the functor of points of a (possibly nonconnective) spectral scheme.

Proposition 1.6.3.1. *Let $\mathcal{S}\mathrm{hv}_{\mathrm{fpqc}} \subseteq \operatorname{Fun}(\mathrm{CAlg}, \mathcal{S})$ and $\mathcal{S}\mathrm{hv}^{\mathrm{cn}}_{\mathrm{fpqc}} \subseteq \operatorname{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ denote the full subcategories spanned by those functors which are sheaves for the fpqc topology. Let $(X, \mathscr{O}_X)$ be a spectrally ringed space. For each open set $U \subseteq X$, let us regard $(U, \mathscr{O}_X|_U)$ as a spectrally ringed space which represents functors $h^{\mathrm{nc}}_U \in \mathcal{S}\mathrm{hv}_{\mathrm{fpqc}}$ and $h_U \in \mathcal{S}\mathrm{hv}^{\mathrm{cn}}_{\mathrm{fpqc}}$. Then:*

(1) *The construction $U \mapsto h^{\mathrm{nc}}_U$ determines a $\mathcal{S}\mathrm{hv}^{\mathrm{op}}_{\mathrm{fpqc}}$-valued sheaf on X.*

(2) *The construction $U \mapsto h_U$ determines a $(\mathcal{S}\mathrm{hv}^{\mathrm{cn}}_{\mathrm{fpqc}})^{\mathrm{op}}$-valued sheaf on X.*

Proof. We will prove (1); the proof of (2) is similar. Let $\{U_\alpha\}$ be a collection of open subsets of X, let $U = \bigcup U_\alpha$, and let $\mathcal{U}$ be the collection of open subsets of X which are contained in some U_α. We wish to prove that h^{nc}_U is a colimit of the diagram $\{h^{\mathrm{nc}}_V\}_{V \in \mathcal{U}}$ in the ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{fpqc}}$. Let $\mathcal{Y} \subseteq \operatorname{Fun}(\mathrm{CAlg}, \widehat{\mathcal{S}})$ denote the full subcategory spanned by those functors which are sheaves with respect to the fpqc topology. Then $\mathcal{Y}$ is an ∞-topos (in a larger universe), and $\mathcal{S}\mathrm{hv}_{\mathrm{fpqc}}$ is a full subcategory of $\mathcal{Y}$. It will therefore suffice to show that h^{nc}_U is a colimit of the diagram $\{h^{\mathrm{nc}}_V\}_{V \in \mathcal{U}}$ in the ∞-category $\mathcal{Y}$.

Let $j : \mathrm{CAlg}^{\mathrm{op}} \to \mathrm{Fun}(\mathrm{CAlg}, \widehat{\mathcal{S}})$ denote the Yoneda embedding. Then j factors through $\mathcal{Y}$ (Theorem D.6.3.5), and sheaves of the form $j(R)$ generate $\mathcal{Y}$ under colimits. It will therefore suffice to show that for every map $\phi : j(R) \to h_U^{\mathrm{nc}}$, the canonical map

$$\varinjlim_{V \in \mathcal{U}} (j(R) \times_{h_U^{\mathrm{nc}}} h_V^{\mathrm{nc}}) \to j(R)$$

is an equivalence in $\mathcal{Y}$. Note that ϕ determines a continuous map of topological spaces $f : |\operatorname{Spec} R| \to U$, and that $j(R) \times_{h_U^{\mathrm{nc}}} h_V^{\mathrm{nc}}$ can be identified with the subfunctor $j_V(R) \subseteq j(R)$ which carries an $\mathbb{E}_\infty$-ring A to the summand of $\mathrm{Map}_{\mathrm{CAlg}}(R, A)$ spanned by those maps $R \to A$ for which the induced map of topological spaces $|\operatorname{Spec} A| \to |\operatorname{Spec} R|$ factors through $f^{-1}(V)$.

Let $\mathcal{C}^{(0)} \subseteq \mathcal{Y}_{/j(R)}$ denote the sieve generated by the collection of morphisms $\{j_V(R) \hookrightarrow j(R)\}_{V \in \mathcal{U}}$. Then the construction $V \mapsto j_V(R)$ determines a left cofinal map from $\mathcal{U}$ into $\mathcal{C}^{(0)}$. Consequently, to prove that $j(R) \simeq \varinjlim_{V \in \mathcal{U}} j_V(R)$, it will suffice to show that $\mathcal{C}^{(0)}$ is a covering sieve with respect to the canonical topology on $\mathcal{Y}$ (see §HTT.6.2.4). Because the open sets U_α cover U, we can choose elements $\{a_i \in \pi_0 R\}_{1 \leqslant i \leqslant n}$ which generate the unit ideal, such that each of the maps $|\operatorname{Spec} R[a_i^{-1}]| \to |\operatorname{Spec} R|$ factors through some $f^{-1} U_{\alpha_i}$. Then the sieve $\mathcal{C}^{(0)}$ contains the maps $j(R[a_i^{-1}]) \to j(R)$, and is therefore a covering sieve since the map $R \to \prod R[a_i^{-1}]$ is faithfully flat. □

Remark 1.6.3.2. In the statement and proof of Proposition 1.6.3.1, we can replace the fpqc topology with the Zariski topology.

Corollary 1.6.3.3. (1) *The construction* $(X, \mathscr{O}_X) \mapsto h_X^{\mathrm{nc}}$ *determines a fully faithful embedding* $\mathrm{SpSch}^{\mathrm{nc}} \to \mathrm{Fun}(\mathrm{CAlg}, \mathcal{S})$.

(2) *The construction* $(X, \mathscr{O}_X) \mapsto h_X$ *determines a fully faithful embedding* $\mathrm{SpSch} \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$.

Proof. We will prove (1); the proof of (2) is similar. Let $(X, \mathscr{O}_X)$ and $(Y, \mathscr{O}_Y)$ be nonconnective spectral schemes. For each open set $U \subseteq X$, let us regard $(U, \mathscr{O}_X|_U)$ as a nonconnective spectral scheme, which represents a functor $h_U^{\mathrm{nc}} : \mathrm{CAlg} \to \mathcal{S}$. Let us say that an open subset $U \subseteq X$ is *good* if the canonical map

$$\theta_U : \mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}((U, \mathscr{O}_X|_U), (Y, \mathscr{O}_Y)) \to \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}, \mathcal{S})}(h_U^{\mathrm{nc}}, h_Y^{\mathrm{nc}})$$

is an equivalence. We will complete the proof by showing that every open subset of X is good. The main step is the following:

(∗) Let U be an open subset of X which is given as a union $\bigcup_{\alpha \in A} U_\alpha$, and suppose that each finite intersection $U_{\alpha_1} \cap \cdots \cap U_{\alpha_n}$ is good. Then U is good.

Assertion $(*)$ follows immediately from Theorem 1.6.2.1 and Proposition 1.6.3.1, which implies that θ_U can be obtained as a limit of maps of the form θ_V where V has the form $U_{\alpha_1} \cap \cdots \cap U_{\alpha_n}$.

We now complete the argument as follows:

(a) Every affine open subset $U \subseteq X$ is good (this follows immediately from the definitions).

(b) Let $U \subseteq X$ be an open set which is contained in an affine open set V. Then we can write U as a union of affine open sets $\{U_\alpha\}$. Since the collection of affine open subsets of V is closed under finite intersections, it follows from (a) that every finite intersection $U_{\alpha_1} \cap \cdots \cap U_{\alpha_n}$ is good. Invoking $(*)$, we conclude that U is good.

(c) Let $U \subseteq X$ be an arbitrary open set, and write U as a union of affine open subsets U_α. Then each intersection $U_{\alpha_1} \cap \cdots U_{\alpha_n}$ is contained in U_{α_1}, and therefore good (by virtue of (b)). Applying $(*)$, we deduce that U is good.

□

1.6.4 The Functor of Points of a Spectrally Ringed ∞-Topos

We now introduce a variant of Definition 1.6.1.1, which is designed to accommodate spectral Deligne-Mumford stacks as well as spectral schemes.

Definition 1.6.4.1. Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_\mathcal{X})$ be a locally spectrally ringed ∞-topos. For every $\mathbb{E}_\infty$-ring R, we let $h^{\mathrm{nc}}_{\mathsf{X}}(R)$ denote the mapping space $\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{X})$. Then the construction $R \mapsto h^{\mathrm{nc}}_{\mathsf{X}}(R)$ determines a functor $h^{\mathrm{nc}}_{\mathsf{X}} : \mathrm{CAlg} \to \widehat{\mathcal{S}}$. We let h_{X} denote the restriction of $h^{\mathrm{nc}}_{\mathsf{X}}$ to the full subcategory $\mathrm{CAlg}^{\mathrm{cn}} \subseteq \mathrm{CAlg}$ spanned by the connective $\mathbb{E}_\infty$-rings. We refer to both $h^{\mathrm{nc}}_{\mathsf{X}}$ and h_{X} as the *functor of points* of the spectrally ringed ∞-topos X.

We have the following analogue of Corollary 1.6.3.3:

Proposition 1.6.4.2. (1) *Let X be a nonconnective spectral Deligne-Mumford stack. Then, for every $\mathbb{E}_\infty$-ring R, the space $h^{\mathrm{nc}}_{\mathsf{X}}(R) = \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{X})$ is essentially small.*

(2) *The construction $\mathsf{X} \mapsto h^{\mathrm{nc}}_{\mathsf{X}}$ determines a fully faithful embedding $\mathrm{SpDM}^{\mathrm{nc}} \to \mathrm{Fun}(\mathrm{CAlg}, \mathcal{S})$.*

(3) *The construction $\mathsf{X} \mapsto h_{\mathsf{X}}$ determines a fully faithful embedding $\mathrm{SpDM} \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$.*

Proof. This is a special case of Theorem **??**, which we will prove in Part VI. See Remarks **??** and **??**. (See also Theorem 8.1.5.1 for a generalization of (1) and (3)). □

1.6.5 The Spatial Case

We have now given introduced a "functor of points" in two different contexts: locally spectrally ringed spaces (Definition ??), and locally spectrally ringed ∞-topoi (Definition 1.6.4.1). These two definitions are not identical, but we will show that they are closely related to one another (Remark 1.6.5.13).

Construction 1.6.5.1. Let $\mathcal{X}$ be a spatial ∞-topos. Then the construction $U \mapsto |\mathcal{X}|_U$ determines an equivalence from the full subcategory $\tau_{\leqslant -1}\mathcal{X}$ of (-1)-truncated objects of $\mathcal{X}$ to the partially ordered set $\mathcal{U}(|\mathcal{X}|)$ of open subsets of $|\mathcal{X}|$.

Let $\mathcal{C}$ be an ∞-category, and let $\mathscr{O} \in \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$ be a $\mathcal{C}$-valued sheaf on $\mathcal{X}$. We let $\mathscr{O}^{\mathrm{spa}}$ denote the composite functor

$$\mathcal{U}(|\mathcal{X}|)^{\mathrm{op}} \simeq (\tau_{\leqslant -1}\mathcal{X})^{\mathrm{op}} \hookrightarrow \mathcal{X}^{\mathrm{op}} \xrightarrow{\mathscr{O}} \mathcal{C}.$$

Proposition 1.6.5.2. *Let $\mathcal{X}$ be a spatial ∞-topos, let $\mathcal{C}$ be an ∞-category, and let $\mathscr{O} : \mathcal{X}^{\mathrm{op}} \to \mathcal{C}$ be a $\mathcal{C}$-valued sheaf on $\mathcal{X}$. Then $\mathscr{O}^{\mathrm{spa}} : \mathcal{U}(|\mathcal{X}|)^{\mathrm{op}} \to \mathcal{C}$ is a $\mathcal{C}$-valued sheaf on the topological space $|\mathcal{X}|$.*

Proof. Let $\{U_\alpha\}$ be a collection of open subsets of $|\mathcal{X}|$ with union U, and let $\mathcal{U}$ be the collection of open subsets of $|\mathcal{X}|$ which are contained in some U_α. We wish to show that the functor $\mathscr{O}^{\mathrm{spa}}$ exhibits $\mathscr{O}^{\mathrm{spa}}(U)$ as a limit of the diagram $\{\mathscr{O}^{\mathrm{spa}}(V)\}_{V \in \mathcal{U}}$.

Let us abuse notation by identifying open subsets of $|\mathcal{X}|$ with (-1)-truncated objects of $\mathcal{X}$, so that we are required to prove that $\mathscr{O}$ exhibits $\mathscr{O}(U)$ as a limit of the diagram $\{\mathscr{O}(V)\}_{V \in \mathcal{U}}$. Since $\mathscr{O}$ is a sheaf, it will suffice to show that the canonical map $\varinjlim_{V \in \mathcal{U}} V \to U$ is an equivalence in the ∞-topos $\mathcal{X}$. Since the U_α cover U, this is equivalent to the assertion that each of the induced maps $U_\alpha \times_U (\varinjlim_{V \in \mathcal{U}} V) \to U_\alpha$ is an equivalence in $\mathcal{X}$. Since colimits are universal in $\mathcal{X}$, we can rewrite the domain of this map as a colimit $\varinjlim_{V \in \mathcal{U}}(U_\alpha \times_U V)$. Let $\mathcal{U}_\alpha$ denote the subset of $\mathcal{U}$ consisting of those open sets which are contained in U_α. Since the functor $V \mapsto U_\alpha \times_U V$ is a left Kan extension of its restriction to $\mathcal{U}_\alpha$, we are reduced to proving that the canonical map $\theta : \varinjlim_{V \in \mathcal{U}_\alpha}(U_\alpha \times_U V) \to U_\alpha$ is an equivalence. Because $\mathcal{U}_\alpha$ contains U_α as a final object, we can identify θ with the projection map $U_\alpha \times_U U_\alpha \to U_\alpha$, which is an equivalence because the map $U_\alpha \to U$ is (-1)-truncated. □

Remark 1.6.5.3. Let $\mathcal{X}$ be an ∞-topos. If $\mathcal{X}$ is spatial, then we can identify $\mathcal{S}\mathrm{hv}(|\mathcal{X}|)$ with the 0-localic reflection of $\mathcal{X}$, so that we have an evident geometric morphism of ∞-topoi $f_* : \mathcal{X} \to \mathcal{S}\mathrm{hv}(|\mathcal{X}|)$. If $\mathcal{C}$ is an ∞-category which admits small limits and $\mathscr{O} \in \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X})$, then $\mathscr{O}^{\mathrm{spa}}$ can be identified with the pushforward $f_* \mathscr{O}$ under the equivalence of ∞-categories $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{S}\mathrm{hv}(|\mathcal{X}|)) \simeq \mathcal{S}\mathrm{hv}_{\mathcal{X}}(|\mathcal{X}|)$ of Proposition 1.3.1.7.

Remark 1.6.5.4. Let $\mathcal{X}$ be an ∞-topos. There is an evident map from the locale of open subsets of $|\mathcal{X}|$ to the locale $\mathrm{Sub}(\mathcal{X})$, which is an equivalence if and only if $\mathcal{X}$ is spatial.

Passing to the associated ∞-topoi, we obtain a commutative diagram of geometric morphisms

$$\mathcal{X} \xrightarrow{f_*} \mathcal{X}_0 \xleftarrow{g_*} \mathcal{S}\mathrm{hv}(|\mathcal{X}|),$$

where f_* exhibits $\mathcal{X}_0$ as a 0-localic reflection of $\mathcal{X}$, and g_* is an equivalence if and only if $\mathcal{X}$ is spatial. In good cases, we can associate to each sheaf $\mathcal{O}$ on the ∞-topos $\mathcal{X}$ another sheaf $\mathcal{O}^{\mathrm{spa}}$ on $|\mathcal{X}|$, given by $g^* f_* \mathcal{O}$. However, unless $\mathcal{X}$ is spatial, there is no obvious description of the sections of $\mathcal{O}^{\mathrm{spa}}$ over an open subset $U \subseteq |\mathcal{X}|$.

Remark 1.6.5.5. Let X be a topological space and let $\mathcal{C}$ be an ∞-category. Then the canonical map $\epsilon : X \to |\mathcal{S}\mathrm{hv}(X)|$ induces an isomorphism from the lattice of open subsets of $|\mathcal{S}\mathrm{hv}(X)|$ to the lattice of open subsets of X, so that the pushforward functor $\epsilon_* : \mathcal{S}\mathrm{hv}_{\mathcal{C}}(X) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(|\mathcal{S}\mathrm{hv}(X)|)$ is an isomorphism of simplicial sets. Suppose that $\mathcal{C}$ admits small limits. Then the pushforward functor ϵ_* can be identified with the composition of the equivalence $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(X) \simeq \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{S}\mathrm{hv}(X))$ of Proposition 1.3.1.7 and the functor $\mathcal{O} \mapsto \mathcal{O}^{\mathrm{spa}}$ of Construction 1.6.5.1. In particular, we see that the construction $\mathcal{O} \mapsto \mathcal{O}^{\mathrm{spa}}$ induces an equivalence of ∞-categories $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{S}\mathrm{hv}(X)) \to \mathcal{S}\mathrm{hv}_{\mathcal{C}}(|\mathcal{S}\mathrm{hv}(X)|)$.

Definition 1.6.5.6. Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a spectrally ringed ∞-topos. We will say that X is *spatial* if the ∞-topos $\mathcal{X}$ is spatial (Definition 1.5.4.3). In this case, we let $\mathsf{X}^{\mathrm{spa}}$ denote the spectrally ringed space $(|\mathcal{X}|, \mathcal{O}_{\mathcal{X}}^{\mathrm{spa}})$.

Example 1.6.5.7. Let R be an $\mathbb{E}_\infty$-ring. Then $\mathrm{Sp\acute{e}t}\, R$ is spatial, and Proposition 1.5.4.6 supplies a canonical homeomorphism $|\mathcal{S}\mathrm{hv}_R^{\acute{e}t}| \simeq |\mathrm{Spec}\, R|$. Under this equivalence, an open set $U_a = \{\mathfrak{p} \in |\mathrm{Spec}\, R| : a \notin \mathfrak{p}\}$ corresponds to the sheaf $h^{R[a^{-1}]} \in \mathcal{S}\mathrm{hv}_R^{\acute{e}t}$ corepresented by $R[a^{-1}]$. Let $\mathcal{O}$ denote the structure sheaf of $\mathrm{Sp\acute{e}t}\, R$, so that $\mathcal{O}^{\mathrm{spa}}$ is given on basic open sets by the formula $\mathcal{O}^{\mathrm{spa}}(U_a) = R[a^{-1}]$, and therefore coincides with the structure sheaf of $\mathrm{Spec}\, R$ (see the proof of Proposition 1.1.4.3). Consequently, we obtain an equivalence of spectrally ringed spaces $(\mathrm{Sp\acute{e}t}\, R)^{\mathrm{spa}} \simeq \mathrm{Spec}\, R$, which depends functorially on R.

Proposition 1.6.5.8. *Let $\mathcal{X}$ be a spatial ∞-topos and let $X = |\mathcal{X}|$ denote its underlying topological space. If $\mathcal{O} \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$ is local (in the sense of Definition 1.4.2.1), then $(X, \mathcal{O}^{\mathrm{spa}})$ is a locally spectrally ringed space. The converse holds if $\mathcal{X}$ is* 0*-localic.*

Proof. Suppose that $\mathcal{O} \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$ is local; we wish to prove that $\mathcal{O}^{\mathrm{spa}}$ is local. To prove this, fix an open set $U \subseteq X$ and a collection of elements $\{f_i \in (\pi_0\, \mathcal{O}^{\mathrm{spa}})(U)\}_{1 \leqslant i \leqslant n}$ satisfying $\sum_{1 \leqslant i \leqslant n} f_i = 1$. We wish to prove that we can write U as a union of open sets $\{U_i\}_{1 \leqslant i \leqslant n}$, such that the image of f_i is invertible in $(\pi_0\, \mathcal{O}^{\mathrm{spa}})(U_i)$. The assertion is local on U; we may therefore assume without loss of generality that each f_i can be lifted to a section $\overline{f}_i \in \pi_0(\mathcal{O}^{\mathrm{spa}}(U))$, and that these sections satisfy $\sum_{1 \leqslant i \leqslant n} \overline{f}_i = 1 \in \pi_0(\mathcal{O}^{\mathrm{spa}}(U))$. Let us identify U with a (-1)-truncated object of $\mathcal{X}$, so that each $\overline{f}_i$ determines a morphism $U \to \pi_0 \mathscr{O}$ in the topos of discrete objects of $\mathcal{X}$. Form pullback diagrams

$$\begin{array}{ccc} U_i & \longrightarrow & U \\ \downarrow & & \downarrow \\ (\pi_0 \mathscr{O})^\times & \longrightarrow & \pi_0 \mathscr{O}. \end{array}$$

Then each of the maps $U_i \to U$ is (-1)-truncated, so that we can identify each U_i with an open subset of X. The assumption that $\pi_0 \mathscr{O}$ is local guarantees that the U_i form a covering of X. Replacing $\mathcal{X}$ by one of the $\mathcal{X}_{/U_i}$, we may assume that $X = U_i$ for some i. In this case, the image of $\overline{f}_i$ in $(\pi_0 \mathscr{O})(X)$ is invertible. Refining our covering if necessary, we may suppose that $\overline{f}_i$ is invertible in $\pi_0(\mathscr{O}(X)) \simeq \pi_0(\mathscr{O}^{\mathrm{spa}}(X))$, so that f_i is invertible in $(\pi_0 \mathscr{O}^{\mathrm{spa}})(X)$.

Now suppose that $\mathcal{X}$ is 0-localic and that $(X, \mathscr{O}^{\mathrm{spa}})$ is locally ringed; we will show that $\mathscr{O}$ is local. For this, it will suffice to show that for any discrete object $Y \in \mathcal{X}$ and any finite collection of sections $\{g_i \in (\pi_0 \mathscr{O})(Y)\}$ satisfying $\sum g_i = 1 \in (\pi_0 \mathscr{O})(Y)$, we can choose an effective epimorphism $\amalg Y_i \to Y$ such that each g_i is invertible when restricted to Y_i. The assertion is local on Y. Using the assumption that $\mathcal{X}$ is 0-localic, we can assume that Y is (-1)-truncated and that each g_i can be lifted to a section $\overline{g}_i \in \pi_0(\mathscr{O}(Y))$ satisfying $\sum \overline{g}_i = 1 \in \pi_0(\mathscr{O}(Y))$. In this case, we can identify Y with an open subset of X, and each $\overline{g}_i$ determines an element of $(\pi_0 \mathscr{O}^{\mathrm{spa}})(Y)$. Using the assumption that $\mathscr{O}^{\mathrm{spa}}$ is local, we conclude that Y can be written as a union of open subsets U_i, such that each $\overline{g}_i$ has invertible image in $(\pi_0 \mathscr{O}^{\mathrm{spa}})(U_i)$. Working locally on Y, we may assume that Y is equal to some U_i, and that $\overline{g}_i$ has invertible image in $\pi_0(\mathscr{O}^{\mathrm{spa}}(U_i)) = \pi_0(\mathscr{O}(U_i))$. It then follows that g_i is invertible. □

We will also need a variant of Proposition 1.6.5.8 for morphisms of spectrally ringed ∞-topoi:

Proposition 1.6.5.9. *Let $\phi : (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ be a morphism of spectrally ringed ∞-topoi. Assume that $\mathcal{X}$ and $\mathcal{Y}$ are spatial, and that $\mathscr{O}_{\mathcal{X}}$ and $\mathscr{O}_{\mathcal{Y}}$ are local. If f is local, then the induced map $(|\mathcal{X}|, \mathscr{O}^{\mathrm{spa}}_{\mathcal{X}}) \to (|\mathcal{Y}|, \mathscr{O}^{\mathrm{spa}}_{\mathcal{Y}})$ is a morphism of locally spectrally ringed spaces. The converse holds if $\mathcal{Y}$ is 0-localic.*

Proof. Let $X = |\mathcal{X}|$ and $Y = |\mathcal{Y}|$, so that ϕ induces a continuous map of topological spaces $f : X \to Y$. Suppose first that the underlying map $\alpha : \phi^* \mathscr{O}_{\mathcal{Y}} \to \mathscr{O}_{\mathcal{X}}$ is local. We wish to show that for each point $x \in X$, the induced map $(\pi_0 \mathscr{O}^{\mathrm{spa}}_{\mathcal{Y}})_{f(x)} \to (\pi_0 \mathscr{O}^{\mathrm{spa}}_{\mathcal{X}})_x$ is a local homomorphism of local commutative rings. Fix an element $u \in (\pi_0 \mathscr{O}^{\mathrm{spa}}_{\mathcal{Y}})_{f(x)}$ whose image in $(\pi_0 \mathscr{O}^{\mathrm{spa}}_{\mathcal{X}})_x$ is invertible. Choose an open subset $V \subseteq Y$ containing $f(x)$ and an element $\overline{u} \in \pi_0(\mathscr{O}^{\mathrm{spa}}_{\mathcal{Y}}(V)) \simeq \pi_0(\mathscr{O}_{\mathcal{Y}}(V))$ lifting u. Then there exists an open set $U \subseteq f^{-1}(V)$ containing x such that the image of $\overline{u}$ in $\pi_0(\mathscr{O}^{\mathrm{spa}}_{\mathcal{X}}(U)) \simeq \pi_0(\mathscr{O}_{\mathcal{X}}(U))$ is invertible. Since α is local, we conclude that there exists a subset $V' \subseteq V$ containing $f(x)$ such that the image of $\overline{u}$ in $\pi_0(\mathscr{O}^{\mathrm{spa}}_{\mathcal{Y}}(V')) \simeq \pi_0(\mathscr{O}_{\mathcal{Y}}(V'))$ is invertible, which immediately implies that u is invertible.

For the converse, assume that $\mathcal{X}$ is 0-localic and that that ϕ induces a morphism $\phi^{\mathrm{spa}} : (X, \mathscr{O}^{\mathrm{spa}}_{\mathcal{X}}) \to (Y, \mathscr{O}^{\mathrm{spa}}_{\mathcal{Y}})$ of locally spectrally ringed spaces; we wish to prove that α is local. Equivalently, we wish to show that the diagram

$$\begin{array}{ccc} \phi^*(\pi_0\,\mathscr{O}_{\mathcal{Y}})^\times & \longrightarrow & (\pi_0\,\mathscr{O}_{\mathcal{X}})^\times \\ \downarrow & & \downarrow \\ \phi^*\pi_0\,\mathscr{O}_{\mathcal{Y}} & \longrightarrow & \pi_0\,\mathscr{O}_{\mathcal{X}} \end{array}$$

is a pullback square of discrete objects of $\mathcal{X}$. We prove more generally that for every object $V \in \mathcal{Y}$ equipped with a map $u : V \to \pi_0\,\mathscr{O}_{\mathcal{Y}}$, if we let $V^\times$ denote the fiber product $V \times_{\pi_0\,\mathscr{O}_{\mathcal{Y}}} (\pi_0\,\mathscr{O}_{\mathcal{Y}})^\times$, then the diagram

$$\begin{array}{ccc} \phi^* V^\times & \longrightarrow & (\pi_0\,\mathscr{O}_{\mathcal{X}})^\times \\ \downarrow & & \downarrow \\ \phi^* V & \longrightarrow & \pi_0\,\mathscr{O}_{\mathcal{X}} \end{array}$$

is a pullback square in $\mathcal{X}$. This assertion can be tested locally on V. Using our assumption that $\mathcal{Y}$ is 0-localic, we may reduce to the case where V is (-1)-truncated (so that $V^\times$ is also (-1)-truncated) and where u lifts to an element $\overline{u} \in \pi_0(\mathscr{O}_{\mathcal{Y}}(V))$. Let U denote the fiber product $\phi^* V \times_{\pi_0\,\mathscr{O}_{\mathcal{X}}} (\pi_0\,\mathscr{O}_{\mathcal{X}})^\times$, so that U is a (-1)-truncated object of $\mathcal{X}$ (which we can identify with an open subset of X). We have an inclusion $f^{-1}(V^\times) \subseteq U$, and we wish to show that this inclusion is an equality. For this, it suffices to show that every point $x \in U \subseteq X$ is contained in $f^{-1}V^\times$. Note that if $x \in U$, then the image of $\overline{u}$ is invertible in the commutative ring $(\pi_0\,\mathscr{O}^{\mathrm{spa}}_{\mathcal{X}})_x$. Since ϕ^{spa} is local, we conclude that the image of $\overline{u}$ in $(\pi_0\,\mathscr{O}^{\mathrm{spa}}_{\mathcal{Y}})_{f(x)}$ is invertible, so that $f(x) \in V^\times$ as desired. □

Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a spatial locally spectrally ringed ∞-topos, and write $\mathsf{X}^{\mathrm{spa}} = (|\mathcal{X}|, \mathscr{O}^{\mathrm{spa}}_{\mathcal{X}})$. By functoriality (and Example 1.6.5.7), we obtain a canonical map

$$\begin{aligned} h^{\mathrm{nc}}_{\mathsf{X}}(R) &= \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathrm{Sp\acute{e}t}\,R, \mathsf{X}) \\ &\to \mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}((\mathrm{Sp\acute{e}t}\,R)^{\mathrm{spa}}, \mathsf{X}^{\mathrm{spa}}) \\ &\simeq \mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathrm{Spec}\,R, \mathsf{X}^{\mathrm{spa}}) \\ &= h^{\mathrm{nc}}_{|\mathcal{X}|}(R), \end{aligned}$$

depending functorially on R. Here the domain is given by Definition 1.6.4.1, and the codomain by Definition **??**.

Theorem 1.6.5.10. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a spatial locally spectrally ringed ∞-topos. If $\mathcal{X}$ is 0-localic, then the above construction induces an equivalence of functors $h^{\mathrm{nc}}_{\mathsf{X}} \to h^{\mathrm{nc}}_{|\mathcal{X}|}$ from* CAlg *to* $\widehat{\mathcal{S}}$.

Theorem 1.6.5.10 is an immediate consequence of the following more general assertion:

Proposition 1.6.5.11. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ and $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ be locally spectrally ringed ∞-topoi. Suppose that $\mathcal{X}$ and $\mathcal{Y}$ are spatial and that $\mathcal{Y}$ is 0-localic. Then the canonical map*

$$\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathsf{X}, \mathsf{Y}) \to \mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathsf{X}^{\mathrm{spa}}, \mathsf{Y}^{\mathrm{spa}})$$

is a homotopy equivalence.

Corollary 1.6.5.12. *Let $\infty\mathcal{T}\mathrm{op}^{\circ}_{\mathrm{CAlg}}$ denote the full subcategory of $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ spanned by those spectrally ringed ∞-topoi $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ where $\mathcal{X}$ is spatial and 0-localic. Then the construction $\mathsf{X} \mapsto \mathsf{X}^{\mathrm{spa}}$ induces a fully faithful embedding $\infty\mathcal{T}\mathrm{op}^{\circ}_{\mathrm{CAlg}} \to \mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$, whose essential image consists of those spectrally ringed spaces $(X, \mathscr{O}_X)$ for which X is sober.*

Proof. The full faithfulness follows from Proposition 1.6.5.11. For the essential surjectivity, we note that if X is sober, then we have $X \simeq |\mathcal{S}\mathrm{hv}(X)|$ (Example 1.5.4.4), in which case the desired result follows from Remark 1.6.5.5 and Proposition 1.6.5.8. □

Remark 1.6.5.13. Let $(X, \mathscr{O}_X)$ be a locally spectrally ringed space. If X is sober, then Corollary 1.6.5.12 implies that we can write $(X, \mathscr{O}_X) = \mathsf{X}^{\mathrm{spa}}$, where X is a locally spectrally ringed ∞-topos which is spatial and 0-localic (moreover, X is unique up to a contractible space of choices). It follows from Theorem 1.6.5.10 that the functor of points h^{nc}_X of $(X, \mathscr{O}_X)$ is equivalent to the functor of points $h^{\mathrm{nc}}_{\mathsf{X}}$ of X. Restricting to the full subcategory $\mathrm{CAlg}^{\mathrm{cn}} \subseteq \mathrm{CAlg}$, we obtain also an equivalence $h_X \simeq h_{\mathsf{X}}$. It follows that we can regard Definition 1.6.1.1 as a special case of Definition 1.6.4.1 (at least if we restrict our attention to locally spectrally ringed spaces $(X, \mathscr{O}_X)$ for which X is sober).

Proof of Proposition 1.6.5.11. We have a commutative diagram of spaces

$$\begin{array}{ccc} \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathsf{X}, \mathsf{Y}) & \xrightarrow{\theta} & \mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathsf{X}^{\mathrm{spa}}, \mathsf{Y}^{\mathrm{spa}}) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{X}, \mathcal{Y}) & \xrightarrow{\theta_0} & \mathrm{Hom}_{\mathcal{T}\mathrm{op}}(|\mathcal{X}|, |\mathcal{Y}|). \end{array}$$

To prove that θ is a homotopy equivalence, it will suffice to show that θ_0 is a homotopy equivalence, and that θ induces a homotopy equivalence after passing to vertical homotopy fibers over any chosen point $\phi_* \in \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{X}, \mathcal{Y})$. To prove the latter claim, we first note that since $\mathcal{Y}$ is 0-localic, Remark 1.6.5.5 supplies a homotopy equivalence

$$\begin{aligned} \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{Y})}(\mathscr{O}_{\mathcal{Y}}, \phi_* \mathscr{O}_{\mathcal{X}}) &\simeq \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(|\mathcal{Y}|)}(\mathscr{O}_{\mathcal{Y}}^{\mathrm{spa}}, (\phi_* \mathscr{O}_{\mathcal{X}})^{\mathrm{spa}}) \\ &\simeq \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(|\mathcal{Y}|)}(\mathscr{O}_{\mathcal{Y}}^{\mathrm{spa}}, f_* \mathscr{O}_{\mathcal{X}}^{\mathrm{spa}}), \end{aligned}$$

where $f : |\mathcal{X}| \to |\mathcal{Y}|$ denotes the continuous map of topological spaces determined by the geometric morphism ϕ_*. It now suffices to observe that a map of spectrally ringed ∞-topoi $(\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ is local if and only if the induced map of spectrally ringed spaces is local, by virtue of Proposition 1.6.5.9.

To complete the proof, it suffices to show that θ_0 is an equivalence. Note that θ_0 factors as a composition

$$\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}}(\mathcal{X}, \mathcal{Y}) \xrightarrow{\theta_0'} \mathrm{Hom}(\mathrm{Sub}(\mathcal{X}), \mathrm{Sub}(\mathcal{Y})) \xrightarrow{\theta_0''} \mathrm{Hom}_{\mathcal{T}\mathrm{op}}(|\mathcal{X}|, |\mathcal{Y}|),$$

where the middle term is the set of maps from $\mathrm{Sub}(\mathcal{X})$ to $\mathrm{Sub}(\mathcal{Y})$ in the category of 0-topoi (see §HTT.6.4.2). Our assumption that $\mathcal{Y}$ is 0-localic guarantees that θ_0' is a homotopy equivalence, and our assumption that $\mathcal{X}$ and $\mathcal{Y}$ are spatial guarantees that θ_0'' is bijective (see Remark 1.5.3.6). □

1.6.6 Comparison of Zariski and Étale Topologies

Our next goal is to show that there is a fully faithful embedding from the ∞-category $\mathrm{SpSch}^{\mathrm{nc}}$ of nonconnective spectral schemes to the ∞-category $\mathrm{SpDM}^{\mathrm{nc}}$ of nonconnective spectral Deligne-Mumford stacks. In terms of the functor of points, this embedding is the identity: we will show that for any (nonconnective) spectral scheme X, the functor h_X represented by X is *also* representable by a spectral Deligne-Mumford stack (Corollary 1.6.6.3).

Remark 1.6.6.1. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a nonconnective spectral Deligne-Mumford stack. Then the ∞-topos $\mathcal{X}$ is spatial, so that the spectrally ringed space $\mathsf{X}^{\mathrm{spa}} = (|\mathcal{X}|, \mathscr{O}_{\mathcal{X}}^{\mathrm{spa}})$ is well-defined. To prove this, it suffices to show that the hypercompletion $\mathcal{X}^{\mathrm{hyp}}$ is spatial, which follows from Corollary **??** and Example 1.5.4.5.

Theorem 1.6.6.2. *Let $(X, \mathscr{O}_X)$ be a nonconnective spectral scheme. Then there exists a nonconnective spectral Deligne-Mumford stack X and an equivalence of spectrally ringed spaces $\alpha : \mathsf{X}^{\mathrm{spa}} \simeq (X, \mathscr{O}_X)$ with the following universal property: for every spectrally ringed ∞-topos $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ for which $\mathcal{Y}$ is spatial and $\mathscr{O}_{\mathcal{Y}}$ is strictly Henselian, composition with α induces a homotopy equivalence*

$$\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}(\mathsf{Y}, \mathsf{X}) \to \mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathsf{Y}^{\mathrm{spa}}, (X, \mathscr{O}_X)).$$

Corollary 1.6.6.3. *Let* $\mathrm{SpSch}'^{\mathrm{nc}} \subseteq \mathrm{Fun}(\mathrm{CAlg}, \mathcal{S})$ *be the essential image of the fully faithful embedding* $h^{\mathrm{nc}} : \mathrm{SpSch}^{\mathrm{nc}} \hookrightarrow \mathrm{Fun}(\mathrm{CAlg}, \mathcal{S})$ *introduced in Definition 1.6.4.1, and let* $\mathrm{SpDM}'^{\mathrm{nc}} \subseteq \mathrm{Fun}(\mathrm{CAlg}, \mathcal{S})$ *be the essential image of the fully faithful embedding* $h^{\mathrm{nc}} : \mathrm{SpSch}^{\mathrm{nc}} \hookrightarrow \mathrm{Fun}(\mathrm{CAlg}, \mathcal{S})$ *of Definition 1.6.4.1. Then* $\mathrm{SpSch}'^{\mathrm{nc}} \subseteq \mathrm{SpDM}'^{\mathrm{nc}}$*.*

Proof. Let $(X, \mathcal{O}_X)$ be a nonconnective spectral scheme representing a functor $h_X^{\mathrm{nc}} : \mathrm{CAlg} \to \mathcal{S}$, and let $\mathsf{X} \in \mathrm{SpDM}^{\mathrm{nc}}$ be as in Theorem 1.6.6.2, so that X represents a functor $h_{\mathsf{X}}^{\mathrm{nc}} : \mathrm{CAlg} \to \mathcal{S}$. Taking $\mathsf{Y} = \mathrm{Sp\acute{e}t}\, R$ in the statement of Theorem 1.6.6.2, we conclude that the canonical map $h_{\mathsf{X}}^{\mathrm{nc}}(R) \to h_X^{\mathrm{nc}}(R)$ is a homotopy equivalence. It follows that the functor h_X^{nc} is representable by X, and therefore belongs to $\mathrm{SpDM}'^{\mathrm{nc}}$. $\square$

We now turn to the proof of Theorem 1.6.6.2. The main ingredient is the following general fact, which we will establish in Part VI (see Theorem **??**):

Proposition 1.6.6.4. *The inclusion functor* $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}} \hookrightarrow \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ *admits a right adjoint* $\mathrm{Spec}^{\acute{e}t}_{\mathrm{Zar}} : \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}} \to \infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$*.*

Proof of Theorem 1.6.6.2. Let $(X, \mathcal{O}_X)$ be a nonconnective spectral scheme. Then X is sober (Corollary 1.5.3.8), so Corollary 1.6.5.12 allows us to write $(X, \mathcal{O}_X) \simeq \mathsf{Y}^{\mathrm{spa}}$ where $\mathsf{X}' = (\mathcal{S}\mathrm{hv}(X), \mathcal{O})$ is a locally spectrally ringed ∞-topos. Let $\mathsf{X} = \mathrm{Spec}^{\mathrm{\acute{e}t}}_{\mathrm{Zar}}\, \mathsf{X}'$, so that $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is a spectrally ringed ∞-topos for which $\mathcal{O}_{\mathcal{X}}$ is locally ringed. We have evident map $\rho : \mathsf{X} \to \mathsf{X}'$ in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$. We will complete the proof by verifying the following:

(1) The spectrally ringed ∞-topos X is a nonconnective spectral Deligne-Mumford stack. In particular, X is spatial.

(2) The canonical map $\mathsf{X} \to \mathsf{Y}$ induces an equivalence of spectrally ringed spaces $\alpha : \mathsf{X}^{\mathrm{spa}} \simeq \mathsf{X}'^{\mathrm{spa}} \simeq (X, \mathcal{O}_X)$.

(3) For every spectrally ringed ∞-topos $\mathsf{Y} = (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ for which $\mathcal{Y}$ is spatial and $\mathcal{O}_{\mathcal{Y}}$ is strictly Henselian, composition with α induces a homotopy equivalence

$$\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}(\mathsf{Y}, \mathsf{X}) \to \mathrm{Map}_{\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathsf{Y}^{\mathrm{spa}}, (X, \mathcal{O}_X)).$$

Note that, by virtue of Proposition **??**, assertion (3) is equivalent to the requirement that the canonical map $\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}(\mathsf{Y}, \mathsf{X}) \to \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathsf{Y}, \mathsf{X}')$ is a homotopy equivalence, which follows immediately from the construction of X.

Let $f_* : \mathcal{X} \to \mathcal{S}\mathrm{hv}(X)$ be the geometric morphism underlying ρ. For each open subset $U \subseteq X$, we let f^*U denote the corresponding (-1)-truncated object of $\mathcal{X}$. It follows immediately from the definitions that we can identify $\mathsf{X}_{f^*U} = (\mathcal{X}_{/f^*U}, \mathcal{O}_{\mathcal{X}}|_{f^*U})$ with the relative spectrum $\mathrm{Spec}^{\mathrm{\acute{e}t}}_{\mathrm{Zar}}(\mathcal{S}\mathrm{hv}(U), \mathcal{O}|_U)$. Consequently, to prove assertions (1) and (2), we can work locally on X and thereby reduce to the case where $(X, \mathcal{O}_X) = \mathrm{Spec}\, R$ is affine.

In this case, the universal properties of $\operatorname{Spec} R$ and $\operatorname{Spét} R$ (see Propositions 1.1.5.5 and 1.4.2.4) supply an equivalence $\operatorname{Spec}^{\text{ét}}_{\text{Zar}} \mathsf{X}' \simeq \operatorname{Spét} R$. It follows that X is an affine spectral Deligne-Mumford stack, which proves (1). Assertion (2) follows from Example 1.6.5.7. □

Remark 1.6.6.5. The proof of Theorem 1.6.6.2 shows that the fully faithful embedding $\iota : \mathrm{SpSch}^{\mathrm{nc}} \to \mathrm{SpDM}^{\mathrm{nc}}$ carries SpSch into SpDM. Moreover, if $(X, \mathscr{O}_X)$ is an n-truncated spectral scheme, then $\iota(X, \mathscr{O}_X)$ is an n-truncated spectral Deligne-Mumford stack. In particular, we obtain a fully faithful embedding from the ∞-category of 0-truncated spectral schemes into the ∞-category of 0-truncated Deligne-Mumford stacks. This can be identified with the usual embedding of the category of schemes into the 2-category of Deligne-Mumford stacks, using the fully faithful embeddings of Proposition 1.1.8.4 and Remark 1.4.8.3.

1.6.7 Schematic Spectral Deligne-Mumford Stacks

It follows from Corollary 1.6.6.3 that there is a fully faithful embedding of ∞-categories $\iota : \mathrm{SpSch}^{\mathrm{nc}} \to \mathrm{SpDM}^{\mathrm{nc}}$, which carries each nonconnective spectral scheme $(X, \mathscr{O}_X)$ to a nonconnective spectral Deligne-Mumford stack X satisfying $h^{\mathrm{nc}}_{\mathsf{X}} \simeq h^{\mathrm{nc}}_X$. We will say that a nonconnective spectral Deligne-Mumford stack X is *schematic* if it belongs to the essential image of this fully faithful embedding.

Remark 1.6.7.1. It is often convenient to abuse notation and identify $\mathrm{SpSch}^{\mathrm{nc}}$ with its essential image under the functor ι: in other words, to not distinguish between a nonconnective spectral scheme and the associated schematic nonconnective spectral Deligne-Mumford stack.

We next give a characterization of the class of schematic spectral Deligne-Mumford stacks. For this, we need to introduce a bit of terminology.

Definition 1.6.7.2. Suppose that $j : \mathsf{U} \to \mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is a map of nonconnective spectral Deligne-Mumford stacks. We will say that j is an *open immersion* if it factors as a composition

$$\mathsf{U} \xrightarrow{j'} (\mathcal{X}_{/U}, \mathscr{O}_{\mathcal{X}}|_U) \xrightarrow{j''} (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$$

where j' is an equivalence and j'' is the étale morphism associated to a (-1)-truncated object $U \in \mathcal{X}$. In this case, we will also say that U is an *open substack* of X.

Proposition 1.6.7.3. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a nonconnective spectral Deligne-Mumford stack. The following conditions are equivalent:*

(1) *There exists a collection of open immersions $\{j_\alpha : \mathsf{U}_\alpha \to \mathsf{X}\}$ which are mutually surjective (that is, each U_α has the form $(\mathcal{X}_{/U_\alpha}, \mathscr{O}_{\mathcal{X}}|_{U_\alpha})$, and the coproduct $\amalg U_\alpha$ is a 0-connective object of $\mathcal{X}$), where each U_α is affine.*

(2) *The spectrally ringed space* $(X, \mathscr{O}_X) \simeq \mathsf{X}^{\mathrm{spa}}$ *is a nonconnective spectral scheme, and the identity map* $\mathrm{id} : \mathsf{X}^{\mathrm{spa}} \simeq (X, \mathscr{O}_X)$ *satisfies the requirements of Theorem 1.6.6.2.*

(3) *The nonconnective spectral Deligne-Mumford stack* X *is schematic.*

Proof. The equivalence of (2) and (3) is a tautology. Let us abuse notation by identifying (-1)-truncated objects of $\mathcal{X}$ with open subsets of the topological space X. If (2) is satisfied, then $\mathcal{X}$ admits a covering by (-1)-truncated objects U_α such that each $(U_\alpha, \mathscr{O}_X|_{U_\alpha})$ is an affine nonconnective spectral scheme $\operatorname{Spec} R_\alpha$. Arguing as in the proof of Theorem 1.6.6.2, we conclude that $(\mathcal{X}_{/U_\alpha}, \mathscr{O}_{\mathcal{X}}|_{U_\alpha})$ is equivalent to the affine nonconnective spectral Deligne-Mumford stack $\operatorname{Spét} R$, so that (1) is satisfied.

We complete the proof by showing that (1) $\Rightarrow$ (2). Note that assertion (2) can be tested locally on the topological space X. We are therefore free to replace X by an open substack and thereby to reduce to the case where $\mathsf{X} = \operatorname{Spét} R$ is affine, in which case the desired result follows from Example 1.6.5.7. □

Corollary 1.6.7.4. *Let* $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ *be a nonconnective spectral Deligne-Mumford stack. Then* X *is schematic if and only if the* 0*-truncated spectral Deligne-Mumford stack* $(\mathcal{X}, \pi_0 \mathscr{O}_{\mathcal{X}})$ *is schematic.*

Proof. This follows from Proposition 1.6.7.3, since a nonconnective spectral Deligne-Mumford stack $(\mathcal{U}, \mathscr{O}_{\mathcal{U}})$ is affine if and only if $(\mathcal{U}, \pi_0 \mathscr{O}_{\mathcal{U}})$ is affine (see Corollary 1.4.7.3). □

According to Proposition 1.4.11.1, the ∞-category $\mathrm{SpDM}^{\mathrm{nc}}$ of nonconnective spectal Deligne-Mumford stacks admits finite limits. One can use the same reasoning to prove that the ∞-category $\mathrm{SpSch}^{\mathrm{nc}}$ of nonconnective spectral schemes admits finite limits. However, the details are somewhat tedious; instead, we can deduce the statement about schemes from Proposition 1.4.11.1, using the characterization of schematic spectral Deligne-Mumford stacks supplied by Proposition 1.6.7.3.

Corollary 1.6.7.5. *Let* $\mathcal{C}$ *denote the full subcategory of* $\mathrm{SpDM}^{\mathrm{nc}}$ *spanned by the schematic nonconnective spectral Deligne-Mumford stacks. Then* $\mathcal{C}$ *is closed under finite limits in* $\mathrm{SpDM}^{\mathrm{nc}}$ *(which exist by virtue of Proposition 1.4.11.1).*

Proof. The final object $\operatorname{Spét} S \in \mathrm{SpDM}^{\mathrm{nc}}$ is affine, and therefore schematic. To complete the proof, it will suffice to show that for every pullback diagram

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y} \end{array}$$

in $\mathrm{SpDM}^{\mathrm{nc}}$, if X, Y, and Y' are schematic, then X' is also schematic. Write $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$, write $\mathsf{X}' = (\mathcal{X}', \mathscr{O}_{\mathcal{X}'})$, and let $f^* : \mathcal{Y} \to \mathcal{X}'$ be the underlying geometric morphism of ∞-topoi.

Using Proposition 1.6.7.3, we see that $\mathcal{Y}$ admits a covering by affine (-1)-truncated objects U_α. Note that each pullback $f^* U_\alpha$ is a (-1)-truncated object of $\mathcal{X}'$. Using the criterion of Proposition 1.6.7.3, we see that to prove that X' is schematic, it will suffice to show that each $(\mathcal{X}'_{/f^* U_\alpha}, \mathscr{O}_{\mathcal{X}'}|_{f^* U_\alpha})$ is schematic. We may therefore replace Y by $(\mathcal{Y}_{/U_\alpha}, \mathscr{O}_{\mathcal{Y}}|_{U_\alpha})$, and thereby reduce to the case where $\mathsf{Y} \simeq \operatorname{Sp\acute{e}t} A$ is affine. Using a similar argument, we can reduce to the case where $\mathsf{X} \simeq \operatorname{Sp\acute{e}t} B$ and $\mathsf{Y}' \simeq \operatorname{Sp\acute{e}t} A'$ are affine. In this case, we conclude that $\mathsf{X}' \simeq (\operatorname{Sp\acute{e}t} A') \times_{\operatorname{Sp\acute{e}t} A} \operatorname{Sp\acute{e}t} B \simeq \operatorname{Sp\acute{e}t}(A' \otimes_A B)$ is affine, and therefore schematic. □

Corollary 1.6.7.6. *The ∞-category $\mathrm{SpSch}^{\mathrm{nc}}$ of nonconnective spectral schemes admits finite limits.*

1.6.8 Spectral Deligne-Mumford n-Stacks

Recall that a spectral Deligne-Mumford stack $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is said to be *n-localic* if the underlying ∞-topos $\mathcal{X}$ is n-localic (Definition **??**). We now show that for $n > 0$, this condition can be formulated directly in terms of the functor h_{X} represented by X.

Definition 1.6.8.1. Let $n \geqslant 0$. A *spectral Deligne-Mumford n-stack* is a spectral Deligne-Mumford stack X with the following property: for every commutative ring R, the mapping space $\mathrm{Map}_{\mathrm{SpDM}}(\operatorname{Sp\acute{e}t} R, \mathsf{X})$ is n-truncated. A *spectral algebraic space* is a spectral Deligne-Mumford 0-stack.

Example 1.6.8.2. For every connective $\mathbb{E}_\infty$-ring A, the étale spectrum $\operatorname{Sp\acute{e}t} A$ is a spectral algebraic space.

Remark 1.6.8.3. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack. The condition that X be a spectral Deligne-Mumford n-stack depends only on the underlying 0-truncated spectral Deligne-Mumford stack $(\mathcal{X}, \pi_0 \mathscr{O}_{\mathcal{X}})$.

Remark 1.6.8.4. Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y}. \end{array}$$

Assume that X and Y' are spectral Deligne-Mumford n-stacks for some $n \geqslant 0$, and that Y is a spectral Deligne-Mumford $(n+1)$-stack. Then X' is a spectral Deligne-Mumford n-stack. In particular, if Y' and Y are affine and X is a spectral Deligne-Mumford n-stack, then X' is a spectral Deligne-Mumford n-stack.

Proposition 1.6.8.5. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack, and let $n \geqslant 1$ be an integer. Then X is n-localic if and only if it is a spectral Deligne-Mumford n-stack.*

Proposition 1.6.8.5 does not hold when $n = 0$. For example, if $\mathsf{X} = \mathrm{Sp\acute{e}t}\, A$ is affine, then X is a spectral algebraic space (Example 1.6.8.2), but is usually not 0-localic. However, we do have the following:

Corollary 1.6.8.6. *Let X be a spectral algebraic space. Then X is 1-localic.*

The proof of Proposition 1.6.8.5 depends on a few general observations about n-localic ∞-topoi.

Lemma 1.6.8.7. *Let $\mathcal{X}$ and $\mathcal{Y}$ be ∞-topoi, and suppose that $\mathcal{X}$ is n-localic for some $n \geqslant 0$. Let $\mathrm{Fun}^*(\mathcal{X}, \mathcal{Y})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{X}, \mathcal{Y})$ spanned by the geometric morphisms $f^* : \mathcal{X} \to \mathcal{Y}$. Then $\mathrm{Fun}^*(\mathcal{X}, \mathcal{Y})$ is equivalent to an n-category.*

Proof. Let $\tau_{\leqslant n-1}\,\mathcal{X}$ and $\tau_{\leqslant n-1}\,\mathcal{Y}$ denote the underlying n-topoi of $\mathcal{X}$ and $\mathcal{Y}$. Since $\mathcal{X}$ is n-localic, we can identify $\mathrm{Fun}^*(\mathcal{X}, \mathcal{Y})$ with the full subcategory of $\mathrm{Fun}(\tau_{\leqslant n-1}\,\mathcal{X}, \tau_{\leqslant n-1}\,\mathcal{Y})$ spanned by those functors which preserve small colimits and finite limits. The desired result now follows from the observation that $\tau_{\leqslant n-1}\,\mathcal{Y}$ is equivalent to an n-category. □

Lemma 1.6.8.8. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ and $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ be spectral Deligne-Mumford stacks. Assume that $\mathscr{O}_{\mathcal{Y}}$ is n-truncated, and that $\mathcal{X}$ is n-localic. Then the mapping space $\mathrm{Map}_{\mathrm{SpDM}}(\mathsf{Y}, \mathsf{X})$ is n-truncated.*

Proof. There is an evident forgetful functor $\theta : \mathrm{Map}_{\mathrm{SpDM}}(\mathsf{Y}, \mathsf{X}) \to \mathrm{Fun}^*(\mathsf{X}, \mathsf{Y})^{\simeq}$, where the codomain of θ is n-truncated by Lemma 1.6.8.7. It will therefore suffice to show that the homotopy fiber of θ over every geometric morphism $f^* : \mathcal{X} \to \mathcal{Y}$ is n-truncated. Unwinding the definitions, we see that this fiber can be identified with a summand of the mapping space $\mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{Y})}(f^*\,\mathscr{O}_{\mathcal{X}}, \mathscr{O}_{\mathcal{Y}})$, which is n-truncated by virtue of our assumption that $\mathscr{O}_{\mathcal{Y}}$ is n-truncated. □

Remark 1.6.8.9. Using exactly same argument, we can deduce an analogous result for spectral schemes. In particular, every spectral scheme represents a functor which carries discrete $\mathbb{E}_\infty$-rings to discrete spaces, so that every schematic spectral Deligne-Mumford stack is a spectral algebraic space.

Proof of Proposition 1.6.8.5. The implication (1) $\Rightarrow$ (2) follows from Lemma 1.6.8.8. Assume now that (2) is satisfied. Replacing $\mathscr{O}_{\mathcal{X}}$ by $\pi_0\,\mathscr{O}_{\mathcal{X}}$, we may assume that $\mathscr{O}_{\mathcal{X}}$ is discrete. It follows from Theorem 1.4.8.1 that there exists a 1-localic spectral Deligne-Mumford stack $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ and a 2-connective object $U \in \mathcal{Y}$ such that $\mathsf{X} \simeq (\mathcal{Y}_{/U}, \mathscr{O}_{\mathcal{Y}}|_U)$. To prove that X is n-localic, it will suffice to show that the object U is n-truncated (Lemma 1.4.7.7). Let $\mathcal{Y}_0$ be the full subcategory of $\mathcal{Y}$ spanned by those objects $Y \in \mathcal{Y}$ such that $\mathrm{Map}_{\mathcal{Y}}(Y, U)$ is n-truncated. We wish to show that $\mathcal{Y}_0 = \mathcal{Y}$. Since $\mathcal{Y}_0$ is closed under small colimits in $\mathcal{Y}$, it will suffice to show that $\mathcal{Y}_0$ contains every object Y for which

$(\mathcal{Y}_{/Y}, \mathscr{O}_{\mathcal{Y}}|_Y) \simeq \operatorname{Sp\acute{e}t} R$ is affine (note that in this case, R is automatically discrete). We now observe that $\operatorname{Map}_{\mathcal{Y}}(Y, U)$ can be identified with the homotopy fiber of the forgetful map $\operatorname{Map}_{\operatorname{SpDM}}(\operatorname{Sp\acute{e}t} R, \mathsf{X}) \to \operatorname{Map}_{\operatorname{SpDM}}(\operatorname{Sp\acute{e}t} R, \mathsf{Y})$. Here $\operatorname{Map}_{\operatorname{SpDM}}(\operatorname{Sp\acute{e}t} R, \mathsf{X})$ is n-truncated by assumption (2), and $\operatorname{Map}_{\operatorname{SpDM}}(\operatorname{Sp\acute{e}t} R, \mathsf{Y})$ is 1-truncated by Lemma 1.6.8.8, so that the homotopy fiber is also n-truncated. □

Chapter 2

Quasi-Coherent Sheaves

To every spectral Deligne-Mumford stack $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$, one can associate a theory of *quasi-coherent sheaves* on X. The collection of quasi-coherent sheaves on X can be organized into a stable ∞-category which we will denote by $\mathrm{QCoh}(\mathsf{X})$. The ∞-category $\mathrm{QCoh}(\mathsf{X})$ is our principal object of study in this section.

We begin in a more general setting. Let $(\mathcal{X}, \mathscr{O})$ be an arbitrary spectrally ringed ∞-topos. In §2.1, we will introduce a stable ∞-category $\mathrm{Mod}_{\mathscr{O}}$, whose objects are $\mathscr{O}$-module objects in the ∞-category $\mathrm{Sp}(\mathcal{X}) \simeq \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ of sheaves of spectra on $\mathcal{X}$. Our main result (Corollary 2.1.2.4) implies that if $\mathscr{O}$ is discrete and $\mathcal{X}$ is 1-localic (for example, if $(\mathcal{X}, \mathscr{O})$ is an ordinary Deligne-Mumford stack: see Proposition **??**), then $\mathrm{Mod}_{\mathscr{O}}$ contains the (bounded below) derived ∞-category $\mathcal{D}(\mathcal{A})_{<\infty}$ as a full subcategory, where $\mathcal{A}$ is the abelian category of discrete sheaves of $\mathscr{O}$-modules on $\mathcal{X}$.

Suppose now that $\mathsf{X} = (\mathcal{X}, \mathscr{O})$ is a spectral Deligne-Mumford stack. In §2.2, we will introduce a full subcategory $\mathrm{QCoh}(\mathsf{X}) \subseteq \mathrm{Mod}_{\mathscr{O}}$, which we call the *$\infty$-category of quasi-coherent sheaves on* X. It is uniquely characterized by the following properties:

- (a) Let $\mathscr{F} \in \mathrm{Mod}_{\mathscr{O}}$ be a sheaf of $\mathscr{O}$-modules on $\mathcal{X}$. Then the condition that $\mathscr{F}$ be quasi-coherent is of a local nature on $\mathcal{X}$. In particular, $\mathscr{F}$ is quasi-coherent if and only if, for every affine $U \in \mathsf{X}$, the restriction $\mathscr{F}|_U$ is a quasi-coherent sheaf on the spectral Deligne-Mumford stack $(\mathcal{X}_{/U}, \mathscr{O}|_U)$ (Remark 2.2.2.3).

- (b) Suppose that $\mathsf{X} = \mathrm{Spét}\, A$ is affine. Then the global sections functor $\Gamma : \mathrm{Mod}_{\mathscr{O}} \to \mathrm{Mod}_A$ admits a fully faithful left adjoint, whose essential image is the full subcategory $\mathrm{QCoh}(\mathsf{X}) \subseteq \mathrm{Mod}_{\mathscr{O}}$ (Proposition 2.2.3.3).

We will see that the collection of quasi-coherent sheaves admits several other characterizations (see Definition 2.2.2.1, Proposition 2.2.4.3, and Proposition 2.2.6.1).

In many situations, we will need to understand the global sections functor $(\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})) \mapsto \Gamma(\mathsf{X}; \mathscr{F})$ in the case where X is not affine. To ensure that this construction has reasonable behavior, one generally needs to make some assumptions about X. In §2.3, we discuss a hierarchy of "compactness" conditions on X (analogous to quasi-compactness and quasi-separatedness in the setting of classical algebraic geometry) which are relevant for this purpose.

If $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is an affine spectral Deligne-Mumford stack, then the global sections functor $\mathscr{F} \mapsto \Gamma(\mathsf{X}; \mathscr{F})$ induces an equivalence from the ∞-category $\mathrm{QCoh}(\mathsf{X})$ to the ∞-category $\mathrm{Mod}_{\Gamma(\mathsf{X}; \mathcal{O}_{\mathcal{X}})}$ of modules over the $\mathbb{E}_\infty$-ring $\Gamma(\mathsf{X}; \mathcal{O}_{\mathcal{X}})$. In §2.4, we will show that this is true more generally under the assumption that X is *quasi-affine*: that is, if X is quasi-compact and admits an open immersion into an affine spectral Deligne-Mumford stack (Proposition 2.4.1.4). In other words, if we work at the level of stable ∞-categories and $\mathbb{E}_\infty$-rings (rather than abelian categories and ordinary commutative rings), then quasi-affine spectral Deligne-Mumford stacks behave to a large extent as if they are affine. As another illustration of this philosophy, we show that if $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is quasi-affine, then its functor of points h_{X} is corepresented by the (possibly nonconnective) $\mathbb{E}_\infty$-ring $\Gamma(\mathcal{X}; \mathcal{O}_{\mathcal{X}})$ (Corollary 2.4.2.2). In particular, the construction $\mathsf{X} \mapsto \Gamma(\mathcal{X}; \mathcal{O}_{\mathcal{X}})$ determines a fully faithful embedding from (the opposite of) the ∞-category of quasi-affine spectral Deligne-Mumford stacks to the ∞-category of $\mathbb{E}_\infty$-rings. In §2.6, we give a description of the image of this fully faithful embedding, following work of Bhatt and Halpern-Leistner ([27]).

Let $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ be a map of spectrally ringed ∞-topoi. Then f determines a pair of adjoint functors

$$\mathrm{Mod}_{\mathcal{O}_{\mathcal{Y}}} \underset{f_*}{\overset{f^*}{\rightleftarrows}} \mathrm{Mod}_{\mathcal{O}_{\mathcal{X}}}.$$

If $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ and $\mathsf{Y} = (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ are spectral Deligne-Mumford stacks, then the pullback functor f^* carries quasi-coherent sheaves on Y to quasi-coherent sheaves on X. In §2.5, we will study conditions on f which guarantee that the pushforward f_* also preserves quasi-coherence. In particular, we will show that f_* preserves coherence when the morphism f is quasi-affine (Corollary 2.5.4.6). We will deduce this from a more general statement (Proposition 2.5.4.3) which we will apply in Chapter 3 to prove analogous results in the setting of quasi-compact, quasi-separated spectral algebraic spaces.

The theory of quasi-coherent sheaves on spectral Deligne-Mumford stacks can be regarded as a global analogue of the theory of modules over $\mathbb{E}_\infty$-rings. In particular, if P is any property of modules which can be tested locally with respect to the étale topology (see Definition 2.8.4.1), then it makes sense to ask if a quasi-coherent sheaf has the property P. In §2.8, we will study a number of properties which can be defined in this way. Many of these properties involve finiteness conditions on modules over $\mathbb{E}_\infty$-rings, which we study in detail in §2.7. A particularly important example is the property of invertibility: a quasi-coherent sheaf $\mathscr{F}$ on a spectral Deligne-Mumford stack $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is said to be *invertible* if there exists another quasi-coherent sheaf $\mathscr{F}^{-1}$ such that $\mathscr{F} \otimes \mathscr{F}^{-1} \simeq \mathcal{O}_{\mathcal{X}}$. The collection of (equivalence classes of) invertible quasi-coherent sheaves can be organized into an abelian group $\mathrm{Pic}^{\dagger}(\mathsf{X})$, the *extended Picard group* of X, which we will study in §2.9.

Contents

2.1 Sheaves on a Spectrally Ringed ∞-Topos

Let X be a topological space and let $\mathscr{O}$ be a sheaf of commutative rings on X. A *sheaf of $\mathscr{O}$-modules* is a sheaf of abelian groups $\mathscr{F}$ on X such that $\mathscr{F}(U)$ is equipped with the structure of a module over the commutative ring $\mathscr{O}(U)$ for every open subset $U \subseteq X$, depending functorially on U. Our goal in this section is to introduce an ∞-categorical analogue of the theory of sheaves of modules. We will replace the topological space X with an arbitrary ∞-topos $\mathcal{X}$, and $\mathscr{O}$ by an arbitrary sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$.

Definition 2.1.0.1. Let $\mathcal{X}$ be an ∞-topos and let $\mathscr{O} \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$ be a sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$. Recall that $\mathscr{O}$ can be identified with a commutative algebra object of the symmetric monoidal ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ of sheaves of spectra on $\mathcal{X}$ (see §**??**). We let $\mathrm{Mod}_{\mathscr{O}}$ denote the ∞-category $\mathrm{Mod}_{\mathscr{O}}(\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}))$ of $\mathscr{O}$-module objects of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$. Then $\mathrm{Mod}_{\mathscr{O}}$ can be regarded as a symmetric monoidal ∞-category with respect to the relative tensor product $\otimes_{\mathscr{O}}$ (see §HA.3.4.4). We will refer to the objects of $\mathrm{Mod}_{\mathscr{O}}$ as *sheaves of $\mathscr{O}$-modules on $\mathcal{X}$*, or sometimes just as *$\mathscr{O}$-modules.*

Warning 2.1.0.2. Let X be a topological space and let $\mathscr{O}$ be a sheaf of commutative rings on X. Then we can identify $\mathscr{O}$ with a sheaf of $\mathbb{E}_\infty$-rings on the ∞-topos $\mathcal{S}\mathrm{hv}(X)$. In this case, Definition 2.1.0.1 does not recover the classical theory of sheaves of $\mathscr{O}$-modules on X, because we allow ourselves to consider sheaves of spectra rather than sheaves of abelian groups. However, we will prove below that the ∞-category $\mathrm{Mod}_{\mathscr{O}}$ is stable and equipped with a natural t-structure (Proposition 2.1.1.1). The classical theory of sheaves of $\mathscr{O}$-modules can be recovered by taking the heart $\mathrm{Mod}_{\mathscr{O}}^{\heartsuit}$ of the ∞-category $\mathrm{Mod}_{\mathscr{O}}$. Moreover, the ∞-category $\mathrm{Mod}_{\mathscr{O}}$ is closely related to the derived ∞-category of its heart (see Corollary 2.1.2.3).

The next proposition summarizes some of the basic formal properties of Definition **??**:

Proposition 2.1.0.3. *Let $\mathcal{X}$ be an ∞-topos and $\mathscr{O}$ a sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$. Then:*

(1) *The ∞-category $\mathrm{Mod}_{\mathscr{O}}$ is stable.*

(2) *The ∞-category $\mathrm{Mod}_{\mathscr{O}}$ is presentable and the tensor product $\otimes_{\mathscr{O}} : \mathrm{Mod}_{\mathscr{O}} \times \mathrm{Mod}_{\mathscr{O}} \to \mathrm{Mod}_{\mathscr{O}}$ preserves small colimits separately in each variable.*

(3) *The forgetful functor $\theta : \mathrm{Mod}_{\mathscr{O}} \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ is conservative and preserves small limits and colimits.*

Proof. Assertion (1) follows from Proposition HA.7.1.1.4 , assertion (2) follows from Theorem HA.3.4.4.2 , and assertion (3) follows from Corollaries HA.3.4.3.2 and HA.3.4.4.6 . □

Notation 2.1.0.4. Let $(\mathcal{X}, \mathscr{O})$ be a spectrally ringed ∞-topos, and suppose we are given objects $\mathscr{F}, \mathscr{F}' \in \mathrm{Mod}_{\mathscr{O}}$. For every integer n, we let $\mathrm{Ext}^n_{\mathscr{O}}(\mathscr{F}, \mathscr{F}')$ denote the abelian group $\mathrm{Ext}^n_{\mathrm{Mod}_{\mathscr{O}}}(\mathscr{F}, \mathscr{F}')$ of homotopy classes of maps from $\mathscr{F}$ to $\Sigma^n \mathscr{F}'$ in $\mathrm{Mod}_{\mathscr{O}}$.

Remark 2.1.0.5. Let $(\mathcal{X}, \mathscr{O})$ be a spectrally ringed ∞-topos. Then the construction $(U \in \mathcal{X}) \mapsto \mathrm{Mod}_{\mathscr{O}|_U}$ determines a functor from $\mathcal{X}^{\mathrm{op}}$ into the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty$ of (not necessarily small) ∞-categories. Moreover, this functor preserves small limits.

To see this, consider the coCartesian fibration $p : \mathrm{Fun}(\Delta^1, \mathcal{X}) \to \mathrm{Fun}(\{1\}, \mathcal{X}) \simeq \mathcal{X}$ given by evaluation at $\{1\} \subseteq \Delta^1$. This coCartesian fibration is classified by a functor $\chi : \mathcal{X} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$, which assigns to each object $U \in \mathcal{X}$ the ∞-topos $\mathcal{X}^{/U}$. We claim that this functor preserves small colimits. To prove this, it suffices to show that the opposite functor $\chi : \mathcal{X}^{\mathrm{op}} \to \mathcal{P}\mathrm{r}^{\mathrm{L}\,\mathrm{op}} \simeq \mathcal{P}\mathrm{r}^{\mathrm{R}}$ preserves small limits; this functor classifies p as a *Cartesian* fibration, and is a limit diagram by virtue of Theorems HTT.6.1.3.9 and HTT.5.5.3.18 together Proposition HTT.5.5.3.13 . For any presentable ∞-category $\mathcal{C}$, we obtain a new functor given by the composition

$$\mathcal{X} \xrightarrow{\chi} \mathcal{P}\mathrm{r}^{\mathrm{L}} \xrightarrow{\otimes \mathcal{C}} \mathcal{P}\mathrm{r}^{\mathrm{L}},$$

which assigns to each object $U \in \mathcal{X}$ the ∞-category $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}^{/U})$ (see Remark 1.3.1.6). The same reasoning yields a limit-preserving functor $\mathcal{X}^{\mathrm{op}} \to \mathcal{P}\mathrm{r}^{\mathrm{L}\,\mathrm{op}} \simeq \mathcal{P}\mathrm{r}^{\mathrm{R}}$ which, by virtue of Theorem HTT.5.5.3.18, gives a limit-preserving functor $\chi[\mathcal{C}] : \mathcal{X}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_{\infty}$.

The evident forgetful functor Mod → CAlg determines a natural transformation of functors $\chi[\mathrm{Mod}] \to \chi[\mathrm{CAlg}]$ from $\mathcal{X}^{\mathrm{op}}$ to $\widehat{\mathcal{C}\mathrm{at}}_{\infty}$. Every sheaf $\mathscr{O}$ of $\mathbb{E}_{\infty}$-rings on $\mathcal{X}$ determines a natural transformation $* \to \chi[\mathrm{CAlg}]$, where $*$ denotes the constant functor $\mathcal{X}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_{\infty}$ taking the value Δ^0. Forming a pullback diagram

$$\begin{array}{ccc} \phi & \longrightarrow & \chi[\mathrm{Mod}] \\ \downarrow & & \downarrow \\ * & \longrightarrow & \chi[\mathrm{CAlg}], \end{array}$$

we obtain a new limit-preserving functor $\phi : \mathcal{X}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_{\infty}$. Unwinding the definitions, we see that ϕ assigns to each object $U \in \mathcal{X}$ the ∞-category $\mathrm{Mod}_{\mathscr{O}|_U}$, and to every morphism $f : U \to V$ in $\mathcal{X}$ the associated pullback functor $f^* : \mathrm{Mod}_{\mathscr{O}|_V} \to \mathrm{Mod}_{\mathscr{O}|_U}$. Since $\chi[\mathrm{CAlg}]$ and $\chi[\mathrm{Mod}]$ preserve small limits, so does ϕ.

2.1.1 The t-Structure on $\mathrm{Mod}_{\mathscr{O}}$

Let $\mathcal{X}$ be an ∞-topos and let $\mathscr{O}$ be a sheaf of $\mathbb{E}_{\infty}$-rings on $\mathcal{X}$. We will say that a $\mathscr{O}$-module $\mathscr{F}$ is *connective* if it is connective when viewed as a sheaf of spectra on $\mathcal{X}$: that is, if the homotopy sheaves $\pi_n \mathscr{F}$ vanish for $n < 0$. We let $\mathrm{Mod}_{\mathscr{O}}^{\mathrm{cn}}$ denote the full subcategory of $\mathrm{Mod}_{\mathscr{O}}$ spanned by the connective $\mathscr{O}$-modules. This notion is primarily useful in the case where the sheaf $\mathscr{O}$ is itself connective.

Proposition 2.1.1.1. *Let $\mathcal{X}$ be an ∞-topos and let $\mathscr{O}$ be a connective sheaf of $\mathbb{E}_{\infty}$-rings on $\mathcal{X}$. Then:*

(a) *The ∞-category $\mathrm{Mod}_{\mathscr{O}}$ admits a t-structure $(\mathrm{Mod}_{\mathscr{O}}^{\mathrm{cn}}, (\mathrm{Mod}_{\mathscr{O}})_{\leqslant 0})$, where $(\mathrm{Mod}_{\mathscr{O}})_{\leqslant 0}$ is the inverse image of $\mathcal{S}\mathrm{hv}(\mathrm{Sp})_{\leqslant 0}$ under the forgetful functor $\theta : \mathrm{Mod}_{\mathscr{O}} \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$.*

(b) *The t-structure on $(\mathrm{Mod}_{\mathscr{O}}^{\mathrm{cn}}, (\mathrm{Mod}_{\mathscr{O}})_{\leqslant 0})$ is compatible with the symmetric monoidal structure on $\mathrm{Mod}_{\mathscr{O}}$. In other words, the full subcategory $(\mathrm{Mod}_{\mathscr{O}}^{\mathrm{cn}} \subseteq \mathrm{Mod}_{\mathscr{O}}$ contains the unit object of $\mathrm{Mod}_{\mathscr{O}}$ and is closed under the relative tensor product $\otimes_{\mathscr{O}}$.*

(c) *The t-structure $(\mathrm{Mod}_{\mathscr{O}}^{\mathrm{cn}}, (\mathrm{Mod}_{\mathscr{O}})_{\leqslant 0})$ is right complete and compatible with filtered colimits (in other words, the full subcategory $(\mathrm{Mod}_{\mathscr{O}})_{\leqslant 0}$ is stable under filtered colimits in $\mathrm{Mod}_{\mathscr{O}}$).*

Proof. We first prove (a). It follows immediately from the definitions that the full subcategory $\mathrm{Mod}_{\mathscr{O}}^{\mathrm{cn}} \subseteq \mathrm{Mod}_{\mathscr{O}}$ is closed under small colimits and extensions. Using Proposition HA.1.4.4.11, we deduce the existence of an accessible t-structure $((\mathrm{Mod}_{\mathscr{O}}^{\mathrm{cn}}, \mathrm{Mod}'_{\mathscr{O}})$ on $\mathrm{Mod}_{\mathscr{O}}$. To complete the proof, it will suffice to show that $\mathrm{Mod}'_{\mathscr{O}} = (\mathrm{Mod}_{\mathscr{O}})_{\leqslant 0}$. Suppose first that $\mathscr{F} \in \mathrm{Mod}'_{\mathscr{O}}$. Then the mapping space $\mathrm{Map}_{\mathrm{Mod}_{\mathscr{O}}}(\mathscr{G}, \mathscr{F})$ is discrete for every object $\mathscr{G} \in (\mathrm{Mod}_{\mathscr{O}})_{\geqslant 0}$. In particular, for every connective sheaf of spectra $\mathcal{M} \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\geqslant 0}$, the mapping space $\mathrm{Map}_{\mathrm{Mod}_{\mathscr{O}}}(\mathcal{M} \otimes \mathscr{O}, \mathscr{F}) \simeq \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})}(\mathcal{M}, \theta(\mathscr{F}))$ is discrete, so that $\theta(\mathscr{F}) \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant 0}$ and therefore $\mathscr{F} \in (\mathrm{Mod}_{\mathscr{O}})_{\leqslant 0}$.

Conversely, suppose that $\mathscr{F} \in (\mathrm{Mod}_{\mathscr{O}})_{\leqslant 0}$. We wish to prove that $\mathscr{F} \in \mathrm{Mod}'_{\mathscr{O}}$. Let $\mathcal{C}$ denote the full subcategory of $\mathrm{Mod}_{\mathscr{O}}$ spanned by those objects $\mathscr{G} \in \mathrm{Mod}_{\mathscr{O}}$ for which the mapping space $\mathrm{Map}_{\mathrm{Mod}_{\mathscr{O}}}(\mathscr{G}, \mathscr{F})$ is discrete. We wish to prove that $\mathcal{C}$ contains $\mathrm{Mod}_{\mathscr{O}}^{\mathrm{cn}}$. Condition (3) shows that θ induces a functor $\mathrm{Mod}_{\mathscr{O}}^{\mathrm{cn}} \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\geqslant 0}$ which is conservative and preserves small colimits; moreover, this functor has a left adjoint F, given informally by the formula $F(\mathcal{M}) \simeq \mathscr{O} \otimes \mathcal{M}$. Using Proposition HA.4.7.3.14 , we conclude that $\mathrm{Mod}_{\mathscr{O}}^{\mathrm{cn}}$ is generated under geometric realizations by the essential image of F. Since $\mathcal{C}$ is stable under colimits, it will suffice to show that $\mathcal{C}$ contains the essential image of F. Unwinding the definitions, we are reduced to proving that the mapping space

$$\mathrm{Map}_{\mathrm{Mod}_{\mathscr{O}}}(F(\mathcal{M}), \mathscr{F}) \simeq \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})}(\mathcal{M}, \theta(\mathscr{F}))$$

is discrete for every connective sheaf of spectra $\mathcal{M}$ on $\mathcal{X}$, which is equivalent to our assumption that $\theta(\mathscr{F}) \in \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant 0}$. This completes the proof of (a).

We now prove (b). The unit object of $\mathrm{Mod}_{\mathscr{O}}$ is the sheaf $\mathscr{O}$ (regarded as a module over itself), which is connective by assumption. We claim that for every pair of objects $\mathscr{F}, \mathscr{G} \in \mathrm{Mod}_{\mathscr{O}}^{\mathrm{cn}}$, the relative tensor product $\mathscr{F} \otimes_{\mathscr{O}} \mathscr{G}$ is also connective. Note that, as a sheaf of spectra, the relative tensor prouct $\mathscr{F} \otimes_{\mathscr{O}} \mathscr{G}$ can be identified with the geometric realization of a simplicial object whose entires are iterated tensor products $\mathscr{F} \otimes \mathscr{O} \otimes \cdots \otimes \mathscr{O} \otimes \mathscr{G}$. Since $\mathscr{F}$, $\mathscr{G}$, and $\mathscr{O}$ are connective, the above tensor product is connective (Proposition 1.3.4.7); because $\mathrm{Mod}_{\mathrm{Sp}}(\mathcal{X})_{\geqslant 0}$ is closed under colimits we conclude that $\mathscr{F} \otimes_{\mathscr{O}} \mathscr{G}$ is connective.

We now prove (c). Since the forgetful functor $\theta : \mathrm{Mod}_{\mathscr{O}} \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ preserves filtered colimits (Proposition 2.1.0.3) and the full subcategory $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant 0} \subseteq \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ is closed under filtered colimits (Proposition 1.3.2.7), it follows that the full subcategory $(\mathrm{Mod}_{\mathscr{O}})_{\leqslant 0} \subseteq \mathrm{Mod}_{\mathscr{O}}$ is closed under filtered colimits. By virtue of Proposition HA.1.2.1.19 , to show that the t-structure $(\mathrm{Mod}_{\mathscr{O}}^{\mathrm{cn}}, (\mathrm{Mod}_{\mathscr{O}})_{\leqslant 0})$ is right-complete, it is sufficient to show that it is right-separated: that is, that the intersection

$$\bigcap (\mathrm{Mod}_{\mathscr{O}})_{\leqslant -n} \simeq \theta^{-1}(\bigcap \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant -n})$$

contains only zero objects of $\mathrm{Mod}_{\mathscr{O}}$. This follows from the conservativity of the functor θ, since the intersection $\bigcap \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant -n}$ contains only zero objects of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ (Proposition 1.3.2.7). □

Warning 2.1.1.2. The t-structure of Proposition 2.1.1.1 is generally not left complete or even left separated. However, it is left complete (left separated) whenever the t-structure $(\mathrm{Mod}_{\mathrm{Sp}}(\mathcal{X})_{\geqslant 0}, \mathrm{Mod}_{\mathrm{Sp}}(\mathcal{X})_{\leqslant 0})$ is left complete (left separated). For example, if $\mathcal{X}$ is hypercomplete, then $\mathrm{Mod}_{\mathscr{O}}$ is left separated; if Postnikov towers in $\mathcal{X}$ are convergent, then $\mathrm{Mod}_{\mathscr{O}}$ is left complete.

2.1.2 The Derived ∞-Category of $\mathrm{Mod}_{\mathscr{O}}^{\heartsuit}$

Let $\mathcal{X}$ be an ∞-topos and let $\mathscr{O}$ be a connective sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$. We let $\mathrm{Mod}_{\mathscr{O}}^{\heartsuit} \subseteq \mathrm{Mod}_{\mathscr{O}}$ denote the heart of the t-structure described in Proposition 2.1.1.1 (that is, the intersection $\mathrm{Mod}_{\mathscr{O}}^{\mathrm{cn}} \cap (\mathrm{Mod}_{\mathscr{O}})_{\leqslant 0}$).

Remark 2.1.2.1. Unwinding the definitions, we can identify $\pi_0 \mathscr{O}$ as a commutative ring object in the underlying topos $\mathcal{X}^{\heartsuit}$, and $\mathrm{Mod}_{\mathscr{O}}^{\heartsuit}$ with the abelian category of $(\pi_0 \mathscr{O})$-module objects of $\mathcal{X}^{\heartsuit}$.

According to Remark HA.1.3.5.23 , the inclusion $\iota : \mathrm{Mod}_{\mathscr{O}}^{\heartsuit} \hookrightarrow \mathrm{Mod}_{\mathscr{O}}$ admits an essentially unique extension to a t-exact functor $\mathcal{D}(\mathrm{Mod}_{\mathscr{O}}^{\heartsuit})_{<\infty} \to \mathrm{Mod}_{\mathscr{O}}$, where $\mathcal{D}(\mathrm{Mod}_{\mathscr{O}}^{\heartsuit})_{<\infty}$ denotes the derived ∞-category of $\mathrm{Mod}_{\mathscr{O}}^{\heartsuit}$ (see §HA.1.3.2). If the ∞-topos $\mathcal{X}$ is hypercomplete, then the t-structure on $\mathrm{Mod}_{\mathscr{O}}$ is left separated (Warning 2.1.1.2), so Theorem C.5.4.9 implies that ι admits an essentially unique extension to a colimit-preserving t-exact functor $\rho : \mathcal{D}(\mathrm{Mod}_{\mathscr{O}}^{\heartsuit}) \to \mathrm{Mod}_{\mathscr{O}}$.

Theorem 2.1.2.2. *Let $(\mathcal{X}, \mathscr{O})$ be a spectrally ringed ∞-topos satisfying the following conditions:*

(a) *The structure sheaf $\mathscr{O}$ is discrete.*

(b) *For each object $X \in \mathcal{X}$, there exists an effective epimorphism $U \to X$ where U is a discrete object of $\mathcal{X}$.*

(c) *The ∞-topos $\mathcal{X}$ is hypercomplete.*

Then the functor $\rho : \mathcal{D}(\mathrm{Mod}_{\mathscr{O}}^{\heartsuit}) \to \mathrm{Mod}_{\mathscr{O}}$ supplied by Theorem C.5.4.9 is an equivalence of ∞-categories.

Before giving the proof of Theorem 2.1.2.2, let us note some of its consequences.

Corollary 2.1.2.3. *Let $(\mathcal{X}, \mathscr{O})$ be a spectrally ringed ∞-topos satisfying the following conditions:*

(a) *The structure sheaf $\mathscr{O}$ is discrete.*

(b) *For each object $X \in \mathcal{X}$, there exists an effective epimorphism $U \to X$ where U is a discrete object of $\mathcal{X}$.*

Then the inclusion $\mathrm{Mod}_{\mathscr{O}}^{\heartsuit} \hookrightarrow \mathrm{Mod}_{\mathscr{O}}$ *extends to a fully faithful embedding* $\iota : \mathcal{D}(\mathrm{Mod}_{\mathscr{O}}^{\heartsuit}) \hookrightarrow \mathrm{Mod}_{\mathscr{O}}$*, whose essential image is the full subcategory of hypercomplete* $\mathscr{O}$*-module objects of* $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$*.*

Proof. Let $f^* : \mathcal{X} \to \mathcal{X}^{\mathrm{hyp}}$ be a left adjoint to the inclusion. Then the spectrally ringed ∞-topos $(\mathcal{X}^{\mathrm{hyp}}, f^* \mathscr{O})$ satisfies the hypotheses of Theorem 2.1.2.2, so that we have an equivalence of ∞-categories

$$\mathcal{D}(\mathrm{Mod}_{\mathscr{O}}^{\heartsuit}) \simeq \mathcal{D}(\mathrm{Mod}_{f^* \mathscr{O}}^{\heartsuit}) \simeq \mathrm{Mod}_{f^* \mathscr{O}}(\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}^{\mathrm{hyp}})).$$

We now define ι to be the composition of this equivalence with the pushforward functor

$$f_* : \mathrm{Mod}_{f^* \mathscr{O}}(\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}^{\mathrm{hyp}})) \to \mathrm{Mod}_{\mathscr{O}}(\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})) = \mathrm{Mod}_{\mathscr{O}}$$

(which is a fully faithful embedding whose essential image is spanned by the hypercomplete $\mathscr{O}$-module objects of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$). □

Corollary 2.1.2.4. *Let* $(\mathcal{X}, \mathscr{O})$ *be a spectrally ringed* ∞*-topos satisfying the following conditions:*

- (a) *The structure sheaf* $\mathscr{O}$ *is discrete.*
- (b) *For each object* $X \in \mathcal{X}$*, there exists an effective epimorphism* $U \to X$ *where* U *is a discrete object of* $\mathcal{X}$*.*

Then the functor $\iota : \mathcal{D}(\mathrm{Mod}_{\mathscr{O}}^{\heartsuit})_{<\infty} \to \mathrm{Mod}_{\mathscr{O}}$ *supplied by Remark HA.1.3.5.23 is a fully faithful embedding, whose essential image is the union* $\bigcup_{n \geqslant 0} (\mathrm{Mod}_{\mathscr{O}})_{\leqslant n}$*.*

We begin by proving Theorem 2.1.2.2 in the special case where $\mathcal{X}$ is a presheaf ∞-topos.

Proposition 2.1.2.5. *Let* $\mathcal{C}$ *be a category, let* $\mathscr{O} \in \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathrm{CAlg}^{\heartsuit})$ *be a presheaf of commutative rings on* $\mathcal{C}$*, and let* $\mathrm{Mod}_{\mathscr{O}} = \mathrm{Mod}_{\mathscr{O}}(\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathrm{Sp}))$ *be the* ∞*-category of* $\mathscr{O}$*-modules on the hypercomplete* ∞*-topos* $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$*. Then the canonical map* $\rho : \mathcal{D}(\mathrm{Mod}_{\mathscr{O}}^{\heartsuit}) \to \mathrm{Mod}_{\mathscr{O}}$ *(supplied by Corollary* **??***) is an equivalence of* ∞*-categories.*

Proof. For each object $C \in \mathcal{C}$, let $h_C : \mathcal{C}^{\mathrm{op}} \to \mathcal{S}\mathrm{et} \subset \mathcal{S}$ be the functor represented by C (given on objects by the formula $h_C(D) = \mathrm{Hom}_{\mathcal{C}}(D, C)$) and let $\mathscr{F}_C \in \mathrm{Mod}_{\mathscr{O}}$ be the tensor product $\mathscr{O} \otimes \Sigma^{\infty}_{+}(h_C)$, given on objects by the formula $\mathscr{F}_C(D) \simeq \bigoplus_{\eta: D \to C} \mathscr{O}(D)$. Note that $\mathscr{F}_C$ belongs to the heart of $\mathrm{Mod}_{\mathscr{O}}$.

For any object $\mathscr{G} \in \mathrm{Mod}_{\mathscr{O}}$, we have a canonical homotopy equivalence

$$\begin{aligned} \mathrm{Map}_{\mathrm{Mod}_{\mathscr{O}}}(\mathscr{F}_C, \mathscr{G}) &\simeq \mathrm{Map}_{\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathrm{Sp})}(\Sigma^{\infty}_{+} h_C, \mathscr{G}) \\ &\simeq \mathrm{Map}_{\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})}(h_C, \Omega^{\infty} \mathscr{G}) \\ &\simeq \Omega^{\infty} \mathscr{G}(C). \end{aligned}$$

Note that if $\mathscr{G} \in (\mathrm{Mod}_{\mathscr{O}})_{\geqslant 1}$, then we have $\pi_0 \mathrm{Map}_{\mathrm{Mod}_{\mathscr{O}}}(\mathscr{F}_C, \mathscr{G}) \simeq 0$: that is, $\mathscr{F}_C$ is a projective object of the ∞-category $\mathrm{Mod}_{\mathscr{O}}^{\mathrm{cn}}$, and in particular is a projective object of the abelian category $\mathrm{Mod}_{\mathscr{O}}^{\heartsuit}$. For an arbitrary object $\mathscr{G} \in \mathrm{Mod}_{\mathscr{O}}$, the induced map $\bigoplus_{\eta \in \pi_0 \mathscr{G}(C)} \mathscr{F}_C \to \mathscr{G}$ is an epimorphism on π_0. It follows that the abelian category $\mathrm{Mod}_{\mathscr{O}}^{\heartsuit}$ has enough projective objects, so that the derived ∞-category $\mathcal{D}(\mathrm{Mod}_{\mathscr{O}}^{\heartsuit})$ is left complete (see Proposition HA.1.3.5.24). The presheaf ∞-topos $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ is Postnikov complete (in the sense of Definition A.7.2.1), the t-structure on $\mathrm{Mod}_{\mathscr{O}}$ is also left complete (Warning 2.1.1.2). Consequently, to show that the functor ρ is an equivalence of ∞-categories, it will suffice to show that the underlying map

$$\rho_{<\infty} : \mathcal{D}(\mathrm{Mod}_{\mathscr{O}}^{\heartsuit})_{<\infty} \to (\mathrm{Mod}_{\mathscr{O}})_{<\infty}$$

is an equivalence of ∞-categories. Using the dual of Proposition HA.1.3.3.7 , we are reduced to proving the following:

(∗) For every pair of objects $\mathscr{G}, \mathscr{G}' \in \mathrm{Mod}_{\mathscr{O}}^{\heartsuit}$, there exists an epimorphism $\theta : \mathscr{F} \to \mathscr{G}$ in $\mathrm{Mod}_{\mathscr{O}}^{\heartsuit}$ for which the groups $\mathrm{Ext}^n_{\mathscr{O}}(\mathscr{F}, \mathscr{G}')$ vanish for $n > 0$.

This is clear: we can take θ to be the epimorphism $\bigoplus_{\eta \in \pi_0 \mathscr{G}(C)} \mathscr{F}(C) \to \mathscr{G}$ described above. □

The proof of Theorem 2.1.2.2 will require a brief digression. Let $\mathcal{X}$ be an ∞-topos and $\mathscr{O}$ a connective sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$. Then for every object $X \in \mathcal{X}$, we let $\mathscr{O}|_X$ denote the composition of $\mathscr{O}$ with the forgetful functor $\pi : \mathcal{X}_{/X} \to \mathcal{X}$, so that $\mathscr{O}|_X$ is a sheaf of $\mathbb{E}_\infty$-rings on the ∞-topos $\mathcal{X}_{/X}$. Composition with π determines a pullback functor $\mathrm{Mod}_{\mathscr{O}} \to \mathrm{Mod}_{\mathscr{O}|_X}$, which we will denote by π^*. The functor π^* preserves small limits and colimits, and therefore admits a left adjoint $\pi_! : \mathrm{Mod}_{\mathscr{O}|_X} \to \mathrm{Mod}_{\mathscr{O}}$ (Corollary HTT.5.5.2.9).

Lemma 2.1.2.6. *Let $\mathcal{X}$ be an ∞-topos, $\mathscr{O}$ a connective sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$, and X a discrete object of $\mathcal{X}$. Then the functor $\pi_! : \mathrm{Mod}_{\mathscr{O}|_X} \to \mathrm{Mod}_{\mathscr{O}}$ is t-exact (with respect to the t-structures introduced in Proposition 2.1.1.1).*

Proof. The functor $\pi_!$ is obviously right t-exact (since it is the left adjoint of the t-exact pullback functor $\pi^* : \mathrm{Mod}_{\mathscr{O}} \to \mathrm{Mod}_{\mathscr{O}|_X}$). It will therefore suffice to show that $\pi_!$ is left t-exact: that is, that $\pi_!$ carries $(\mathrm{Mod}_{\mathscr{O}|_X})_{\leqslant 0}$ to $(\mathrm{Mod}_{\mathscr{O}})_{\leqslant 0}$.

Without loss of generality, we may assume that $\mathcal{X}$ is an accessible left-exact localization of a presheaf ∞-category $\mathcal{P}(\mathcal{C}) = \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ for some small ∞-category $\mathcal{C}$; we will identify X with the corresponding discrete object of $\mathcal{P}(\mathcal{C})$. Then $\mathscr{O}$ can be obtained as the pullback of a connective sheaf of $\mathbb{E}_\infty$-rings $\mathscr{O}' \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{P}(\mathcal{C})) \simeq \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathrm{CAlg})$. We have a commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{Mod}_{\mathscr{O}'|_X} & \xrightarrow{\pi'_!} & \mathrm{Mod}_{\mathscr{O}'} \\ \downarrow{g^*} & & \downarrow{f^*} \\ \mathrm{Mod}_{\mathscr{O}|_X} & \xrightarrow{\pi_!} & \mathrm{Mod}_{\mathscr{O}}, \end{array}$$

where the vertical maps are given by pullback along the geometric morphisms

$$f_* : \mathcal{X} \hookrightarrow \mathcal{P}(\mathcal{C}) \qquad g_* : \mathcal{X}_{/X} \hookrightarrow \mathcal{P}(\mathcal{C})_{/X}$$

(and are therefore t-exact). For any object $\mathscr{F} \in (\mathrm{Mod}_{\mathscr{O}|_X})_{\leqslant 0}$, there exists an object $\mathscr{F}' \in (\mathrm{Mod}_{\mathscr{O}'|_X})_{\leqslant 0}$ such that $\mathscr{F} \simeq g^* \mathscr{F}'$: for example, we can take $\mathscr{F}'$ to be the pushforward $g_* \mathscr{F}$. Since the functor f^* is t-exact, to prove that $\pi_! \mathscr{F} \in (\mathrm{Mod}_{\mathscr{O}})_{\leqslant 0}$, it will suffice to show that $\pi'_! \mathscr{F}' \in (\mathrm{Mod}_{\mathscr{O}'})_{\leqslant 0}$. In other words, we wish to show that for every object $C \in \mathcal{C}$, the $\mathscr{O}'(C)$-module spectrum $(\pi'_! \mathscr{F}')(C)$ belongs to $\mathrm{Sp}_{\leqslant 0}$. Since X is discrete, we may assume without loss of generality that X is a $\mathcal{S}$et-valued functor on $\mathcal{C}^{\mathrm{op}}$. Note that $(\pi'_! \mathscr{F}')(C)$ can be written as a coproduct $\amalg_{\eta \in X(C)} \mathscr{F}'(C_\eta)$ where $C_\eta \in \mathcal{P}(\mathcal{C})_{/X}$ denotes map $j(C) \to X$ representing $\eta \in X(C)$, where $j : \mathcal{C} \to \mathcal{P}(\mathcal{C})$ is the Yoneda embedding. Since $\mathscr{F}' \in (\mathrm{Mod}_{\mathscr{O}'|_X})_{\leqslant 0}$, each of the spectra $\mathscr{F}'(C_\eta) \in (\mathrm{Sp})_{\leqslant 0}$, so that $(\pi_! \mathscr{F}')(C) \in \mathrm{Sp}_{\leqslant 0}$ as desired. □

Proposition 2.1.2.7. *Let $(\mathcal{X}, \mathscr{O})$ be a spectrally ringed ∞-topos and let $n \geqslant 0$ be an integer. Suppose that the following conditions are satisfied:*

- (a) *For every object $X \in \mathcal{X}$, there exists an effective epimorphism $U \to X$ where U is a discrete object of $\mathcal{X}$.*
- (b) *The structure sheaf $\mathscr{O}$ is connective and n-truncated.*

Then the ∞-category $\mathrm{Mod}^{\mathrm{cn}}_{\mathscr{O}}$ is n-complicial (see Definition C.5.3.1).

Proof. Using (a) and the presentability of $\mathcal{X}$, we can choose a collection of discrete objects $\{U_\alpha\}$ of $\mathcal{X}$ with the following property: for every object $X \in \mathcal{X}$, there exists an effective epimorphism $\overline{X} \to X$, where $\overline{X}$ can be written as a coproduct of objects belonging to $\{U_\alpha\}$. For each index α, let $\pi_{\alpha!} : \mathrm{Mod}_{\mathscr{O}|_{U_\alpha}} \to \mathrm{Mod}_{\mathscr{O}}$ denote the functor of Lemma 2.1.2.6 and set $\mathscr{O}_\alpha = \pi_{\alpha!}(\mathscr{O}|_{U_\alpha})$. Since each U_α is discrete, Lemma 2.1.2.6 (and assumption (b)) imply that each $\mathscr{O}_\alpha$ is an n-truncated object of $\mathrm{Mod}^{\mathrm{cn}}_{\mathscr{O}}$.

Let $\mathscr{F}$ be an object of $\mathrm{Mod}_{\mathscr{O}}$. Unwinding the definitions, we see that each element $\eta \in \pi_0 \mathscr{F}(U_\alpha)$ determines a homotopy class of maps $f_\eta : \mathscr{O}_\alpha \to \mathscr{F}$ in the ∞-category $\mathrm{Mod}_{\mathscr{O}}$. Amalgamating these maps as α and η vary, we obtain a map $f : \bigoplus_{\eta \in \pi_0 \mathscr{F}(U_\alpha)} \mathscr{O}_\alpha \to \mathscr{F}$. By construction, the morphism f induces an epimorphism on π_0 and the domain of f is n-truncated. Allowing $\mathscr{F}$ to vary, we conclude that $\mathrm{Mod}^{\mathrm{cn}}_{\mathscr{O}}$ is n-complicial. □

Proof of Theorem 2.1.2.2. Let $(\mathcal{X}, \mathcal{O})$ be a spectrally ringed ∞-topos. It follows from Theorem C.5.4.9 that the inclusion $\mathrm{Mod}_{\mathcal{O}}^{\heartsuit} \hookrightarrow \mathrm{Mod}_{\mathcal{O}}^{\mathrm{cn}}$ admits an essentially unique extension to a functor $\lambda : \mathcal{D}(\mathrm{Mod}_{\mathcal{O}}^{\heartsuit})_{\geqslant 0} \to \mathrm{Mod}_{\mathcal{O}}^{\mathrm{cn}}$ which preserves small colimits and finite limits. Suppose that $\mathcal{O}$ is discrete and that for every object $X \in \mathcal{X}$, there exists an effective epimorphism $U \to X$ where U is discrete. Applying Proposition 2.1.2.7, we deduce that the ∞-category $\mathrm{Mod}_{\mathcal{O}}^{\mathrm{cn}}$ is 0-complicial (in the sense of Definition C.5.3.1). If the ∞-topos $\mathcal{X}$ is hypercomplete, then $\mathrm{Mod}_{\mathcal{O}}^{\mathrm{cn}}$ is also separated (in the sense of Definition C.1.2.12). Since $\mathcal{D}(\mathrm{Mod}_{\mathcal{O}}^{\heartsuit})_{\geqslant 0}$ is also 0-complicial (Proposition C.5.3.2) and separated, Proposition C.5.4.5 implies that λ is an equivalence of ∞-categories. Passing to stabilizations, we obtain a t-exact equivalence

$$\mathcal{D}(\mathcal{A}) \simeq \mathrm{Sp}(\mathcal{D}(\mathcal{A})_{\geqslant 0}) \xrightarrow{\sim} \mathrm{Sp}(\mathrm{Mod}_{\mathcal{O}}^{\mathrm{cn}}) \simeq \mathrm{Mod}_{\mathcal{O}}.$$

$\square$

We close this section by proving a variant of Theorem 2.1.2.2 for morphisms between spectrally ringed ∞-topoi.

Theorem 2.1.2.8. *Let $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ be a morphism of spectrally ringed ∞-topoi which satisfy conditions (a) and (b) of Corollary 2.1.2.4 and let $f_*^{\heartsuit} : \mathrm{Mod}_{\mathcal{O}_{\mathcal{X}}}^{\heartsuit} \to \mathrm{Mod}_{\mathcal{O}_{\mathcal{Y}}}^{\heartsuit}$ be the functor of abelian categories given at the level of objects by the formula $f_*^{\heartsuit}\mathscr{F} = \pi_0(f_*\mathscr{F})$. Then the pushforward functor*

$$\mathcal{D}(\mathrm{Mod}_{\mathcal{O}_{\mathcal{X}}}^{\heartsuit})_{<\infty} \simeq \bigcup_n (\mathrm{Mod}_{\mathcal{O}_{\mathcal{X}}})_{\leqslant n} \xrightarrow{f_*} \bigcup_n (\mathrm{Mod}_{\mathcal{O}_{\mathcal{Y}}})_{\leqslant n} \simeq \mathcal{D}(\mathrm{Mod}_{\mathcal{O}_{\mathcal{Y}}}^{\heartsuit})_{<\infty}$$

is a right derived functor of $f_*^{\heartsuit}$ (see Example HA.1.3.3.4).

Proof. Let $\mathscr{F}$ be an injective object of the abelian category $\mathrm{Mod}_{\mathcal{O}_{\mathcal{X}}}^{\heartsuit}$. We wish to show that the pushforward $f_*\mathscr{F}$ belongs to the heart of $\mathrm{Mod}_{\mathcal{O}_{\mathcal{Y}}}$. Fix an object $Y \in \mathcal{Y}$ and an element $x \in \pi_n((f_*\mathscr{F})(Y))$; we wish to prove that if $n \neq 0$, then we can choose an effective epimorphism $Y' \to Y$ such that the image of x vanishes in $\pi_n((f_*\mathscr{F})(Y'))$. In fact, we will prove something stronger: the group $\pi_n((f_*\mathscr{F})(Y'))$ vanishes whenever Y' is a discrete object of $\mathcal{Y}$ (note that there exists an effective epimorphism $Y' \to Y$ with Y' discrete by virtue of our assumption that $\mathcal{Y}$ satisfies condition (b) of Corollary 2.1.2.4). Set $X = f^*Y'$; we wish to prove that $\pi_n\mathscr{F}(X) \in \mathcal{X}$ vanishes. Let $\pi_! : \mathrm{Mod}_{\mathcal{O}_{\mathcal{X}}|_X} \to \mathrm{Mod}_{\mathcal{O}_{\mathcal{X}}}$ be as Lemma 2.1.2.6. Since $X = f^*Y'$ is discrete, the functor $\pi_!$ is t-exact. It follows that $\pi_!(\mathcal{O}_{\mathcal{X}}|_X)$ belongs to $\mathrm{Mod}_{\mathcal{O}_{\mathcal{X}}}^{\heartsuit}$. Using Corollary 2.1.2.4 and the injectivity of $\mathscr{F}$, we obtain

$$\pi_n\mathscr{F}(X) \simeq \mathrm{Ext}^{-n}_{\mathrm{Mod}_{\mathcal{O}_{\mathcal{X}}|_X}}(\mathcal{O}_{\mathcal{X}}|_X, \mathscr{F}|_X) \simeq \mathrm{Ext}^{-n}_{\mathrm{Mod}_{\mathcal{O}_{\mathcal{X}}}}(\pi_!\mathcal{O}_{\mathcal{X}}|_X, \mathscr{F}) \simeq 0.$$

$\square$

2.2 Quasi-Coherent Sheaves on Spectral Deligne-Mumford Stacks

Let $(X, \mathscr{O}_X)$ be a scheme. Recall that a (discrete) sheaf $\mathscr{F}$ of $\mathscr{O}_X$-modules on X is said to be *quasi-coherent* if it satisfies the following condition:

$(*)$ For every pair of affine open subsets $U \subseteq V \subseteq X$, the canonical map

$$\mathscr{O}_X(U) \otimes_{\mathscr{O}_X(V)} \mathscr{F}(V) \to \mathscr{F}(U)$$

is an isomorphism.

The theory of quasi-coherent sheaves plays an essential role in classical algebraic geometry. Our goal in this section is to introduce an analogous theory in the setting of spectral algebraic geometry.

Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_\mathcal{X})$ be a spectrally ringed ∞-topos. In §2.1, we defined a stable ∞-category $\mathrm{Mod}_{\mathscr{O}_\mathcal{X}}$ whose objects are sheaves of $\mathscr{O}_\mathcal{X}$-module spectra on $\mathcal{X}$. In the special case where X is a nonconnective spectral Deligne-Mumford stack, we will define a full subcategory $\mathrm{QCoh}(\mathsf{X}) \subseteq \mathrm{Mod}_{\mathscr{O}_\mathcal{X}}$, which we will refer to as the ∞-category of *quasi-coherent* sheaves on X. The condition that a sheaf $\mathscr{F} \in \mathrm{Mod}_{\mathscr{O}_\mathcal{X}}$ is quasi-coherent can be expressed in several different ways:

(a) The triple $(\mathcal{X}, \mathscr{O}_\mathcal{X}, \mathscr{F})$ is locally equivalent to the spectrum (in the sense of Corollary 2.2.1.5 below) of a pair (A, M), where A is an $\mathbb{E}_\infty$-ring and M is an A-module spectrum.

(b) The sheaf $\mathscr{F}$ satisfies the analogue of condition $(*)$ above: for any morphism $U \to V$ between affine objects of $\mathcal{X}$, the induced map $\mathscr{O}_X(U) \otimes_{\mathscr{O}_X(V)} \mathscr{F}(V) \to \mathscr{F}(U)$ is an equivalence.

(c) Each homotopy group $\pi_n \mathscr{F}$ is a quasi-coherent sheaf over the underlying ordinary Deligne-Mumford stack $(\mathcal{X}^\heartsuit, \pi_0 \mathscr{O}_\mathcal{X})$, and the sheaf $\mathscr{F}$ is hypercomplete.

We will adopt characterization (a) as our definition of quasi-coherent sheaf, and prove its equivalence with (b) and (c) later in this section (Propositions 2.2.4.3 and 2.2.6.1, respectively).

2.2.1 The Étale Spectrum of a Module

Let $(\mathcal{X}, \mathscr{O})$ be a spectrally ringed ∞-topos and let $\mathscr{F} \in \mathrm{Mod}_\mathscr{O}$ be a $\mathscr{O}$-module object of $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$. Then we can view the pair $(\mathscr{O}, \mathscr{F})$ as a single sheaf on $\mathcal{X}$:

Notation 2.2.1.1. Let $\mathrm{Mod} = \mathrm{Mod}(\mathrm{Sp})$ denote the ∞-category of pairs (A, M), where A is an $\mathbb{E}_\infty$-ring and M is an A-module spectrum. We let $\infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}}$ denote the ∞-category whose objects are ∞-topoi $\mathcal{X}$ together with a Mod-valued sheaf on $\mathcal{X}$. More precisely, we let $\infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}}$ denote an ∞-category equipped with a coCartesian fibration $\infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}} \to \infty\mathcal{T}\mathrm{op}$, which is classified by the functor

$$\infty\mathcal{T}\mathrm{op} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$$

$$\mathcal{X} \mapsto \mathcal{S}\mathrm{hv}_{\mathrm{Mod}}(\mathcal{X})^{\mathrm{op}}.$$

We can describe the ∞-category $\infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}}$ more informally as follows:

- The objects of $\infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}}$ are triples $(\mathcal{X}, \mathcal{O}, \mathcal{F})$, where $\mathcal{X}$ is an ∞-topos, $\mathcal{O}$ is a sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$, and $\mathcal{F}$ is a sheaf of $\mathcal{O}$-module spectra on $\mathcal{X}$.

- A morphism from $(\mathcal{X}, \mathcal{O}, \mathcal{F})$ to $(\mathcal{X}', \mathcal{O}', \mathcal{F}')$ in $\infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}}$ consists of a triple (ϕ_*, α, β), where $\phi_* : \mathcal{X} \to \mathcal{X}'$ is a geometric morphism of ∞-topoi, $\alpha : \mathcal{O}' \to \phi_* \mathcal{O}$ is a morphism of CAlg-valued sheaves, and $\beta : \mathcal{F}' \to \phi_* \mathcal{F}$ is a morphism of $\mathcal{O}'$-modules.

Notation 2.2.1.2. We can identify the fiber product $\infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}} \times_{\mathcal{T}\mathrm{op}_\infty} \{\mathcal{S}\}$ with the ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{Mod}}(\mathcal{S})^{\mathrm{op}} \simeq \mathrm{Mod}^{\mathrm{op}}$. The induced functor $\mathrm{Mod}^{\mathrm{op}} \to \infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}}$ admits a left adjoint, given on objects by $(\mathcal{X}, \mathcal{O}, \mathcal{F}) \mapsto (\Gamma(\mathcal{X}; \mathcal{O}), \Gamma(\mathcal{X}; \mathcal{F}))$. We will refer to this left adjoint as the *global sections functor*, and denote it by $\Gamma : \infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}} \to \mathrm{Mod}^{\mathrm{op}}$.

Notation 2.2.1.3. There is an evident forgetful functor $\infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}} \to \infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$, given on objects by $(\mathcal{X}, \mathcal{O}, \mathcal{F}) \mapsto (\mathcal{X}, \mathcal{O})$. We let $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{Mod}}$ denote the fiber product

$$\infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}} \times_{\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}} \infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}},$$

so that $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{Mod}}$ is a subcategory of $\infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}}$ whose objects are triples $(\mathcal{X}, \mathcal{O}, \mathcal{F})$ for which the sheaf $\mathcal{O}$ is strictly Henselian.

Proposition 2.2.1.4. *Let A be an $\mathbb{E}_\infty$-ring and let M be an A-module. Let*

$$\rho : \mathrm{CAlg}^{\acute{e}t}_A \to \mathrm{Mod}$$

denote the functor given on objects by $B \mapsto (B, B \otimes_A M)$. Then:

(1) *The functor ρ is a sheaf with respect to the étale topology on $\mathrm{CAlg}^{\acute{e}t}_A$, and can therefore be identified with a* Mod*-valued sheaf $(\mathcal{O}, \mathcal{F})$ on the ∞-topos $\mathcal{S}\mathrm{hv}^{\acute{e}t}_A$ (see Proposition 1.3.1.7).*

(2) *The sheaf of $\mathbb{E}_\infty$-rings $\mathcal{O}$ is strictly Henselian, so that we can view $(\mathcal{S}\mathrm{hv}^{\acute{e}t}_A, \mathcal{O}, \mathcal{F})$ as an object of $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{Mod}}$.*

(3) *Let* $\Gamma : \infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}} \to \mathrm{Mod}^{\mathrm{op}}$ *be the global sections functor, so that* $\Gamma(\mathcal{S}\mathrm{hv}_A^{\acute{e}t}, \mathscr{O}, \mathscr{F}) \simeq (A, M)$*. For every object* $\mathsf{X} \in \infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}}^{\mathrm{sHen}}$*, the canonical map*

$$\theta : \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}}^{\mathrm{sHen}}}(\mathsf{X}, (\mathcal{S}\mathrm{hv}_A^{\acute{e}t}, \mathscr{O}, \mathscr{F})) \to \mathrm{Map}_{\mathrm{Mod}}((A, M), \Gamma(\mathsf{X}))$$

is a homotopy equivalence.

Proof of Proposition 2.2.1.4. Assertion (1) follows from Theorems D.6.3.5 and **??**. Assertion (2) from Proposition **??**. To prove (3), write $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}}, \mathscr{F}_{\mathcal{X}})$ and observe that we have a commutative diagram

$$\begin{array}{ccc} \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}}^{\mathrm{sHen}}}(\mathsf{X}, (\mathcal{S}\mathrm{hv}_A^{\acute{e}t}, \mathscr{O}, \mathscr{F})) & \xrightarrow{\theta} & \mathrm{Map}_{\mathrm{Mod}}((A, M), \Gamma(\mathsf{X})) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}^{\mathrm{sHen}}}((\mathcal{X}, \mathscr{O}_{\mathcal{X}}), (\mathcal{S}\mathrm{hv}_A^{\acute{e}t}, \mathscr{O})) & \xrightarrow{\theta_0} & \mathrm{Map}_{\mathrm{CAlg}}(A, \Gamma(\mathcal{X}; \mathscr{O})) \end{array}$$

where the map θ_0 is a homotopy equivalence by virtue of Proposition 1.4.2.4. Consequently, in order to prove that θ is a homotopy equivalence, it will suffice to show that it induces a homotopy equivalence after taking the homotopy fibers of the vertical maps over a point corresponding to a map of spectrally ringed ∞-topoi $\eta : (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to (\mathcal{S}\mathrm{hv}_A^{\acute{e}t}, \mathscr{O})$. Unwinding the definitions, we are reduced to proving that the formation of global sections induces a homotopy equivalence

$$\phi_M : \mathrm{Map}_{\mathrm{Mod}_{\mathscr{O}}}(\mathscr{F}, \eta_* \mathscr{F}_{\mathcal{X}}) \to \mathrm{Map}_{\mathrm{Mod}_A}(M, \Gamma(\mathcal{X}; \mathscr{F}_{\mathcal{X}})).$$

Let us say that an A-module M is *good* if the map ϕ_M is a homotopy equivalence for every choice of sheaf $\mathscr{F}_{\mathcal{X}} \in \mathrm{Mod}_{\mathscr{O}_{\mathcal{X}}}$. We wish to show that every A-module M is good. The collection of good A-modules span a stable subcategory of Mod_A which is closed under colimits. Consequently, we can reduce to the case $M = A$, in which case $\mathscr{F}$ is equivalent to the structure sheaf of Spét A and the desired result is obvious. □

Corollary 2.2.1.5. *Let* $\Gamma^{\mathrm{sHen}} : \infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}}^{\mathrm{sHen}} \to \mathrm{Mod}^{\mathrm{op}}$ *denote the restriction of the global sections functor* $\Gamma : \infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}} \to \mathrm{Mod}^{\mathrm{op}}$ *to the subcategory* $\infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}}^{\mathrm{sHen}} \subseteq \infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}}$*. Then* Γ^{sHen} *admits a right adjoint*

$$\mathrm{Sp\acute{e}t}_{\mathrm{Mod}} : \mathrm{Mod}^{\mathrm{op}} \to \infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}}^{\mathrm{sHen}}.$$

Remark 2.2.1.6. Given an $\mathbb{E}_\infty$-ring A and an A-module M, the object $\mathrm{Sp\acute{e}t}_{\mathrm{Mod}}(A, M)$ can be described explicitly using the construction of Proposition 2.2.1.4. In particular, we see that the underlying spectrally ringed ∞-topos of $\mathrm{Sp\acute{e}t}_{\mathrm{Mod}}(A, M)$ can be identified with the étale spectrum Spét A. It follows that the diagram of ∞-categories

$$\begin{array}{ccc} \infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{Mod}} & \longrightarrow & \mathrm{Mod}^{\mathrm{op}} \\ \downarrow & & \downarrow \\ \infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}} & \longrightarrow & \mathrm{CAlg}^{\mathrm{op}} \end{array}$$

is right adjointable, so that the diagram

$$\begin{array}{ccc} \mathrm{Mod}^{\mathrm{op}} & \xrightarrow{\mathrm{Sp\acute{e}t}_{\mathrm{Mod}}} & \infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{Mod}} \\ \downarrow & & \downarrow \\ \mathrm{CAlg}^{\mathrm{op}} & \xrightarrow{\mathrm{Sp\acute{e}t}} & \infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}} \end{array}$$

commutes up to canonical homotopy.

2.2.2 Quasi-Coherence

We are now ready to introduce our main objects of interest.

Definition 2.2.2.1. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O})$ be a nonconnective spectral Deligne-Mumford stack and let $\mathscr{F}$ be a sheaf of $\mathscr{O}$-modules on $\mathcal{X}$. We will say that $\mathscr{F}$ is *quasi-coherent* if there exists a collection of objects $U_\alpha \in \mathcal{X}$ which cover $\mathcal{X}$ (that is, the map $\amalg_\alpha U_\alpha \to \mathbf{1}$ is an effective epimorphism) satisfying the following condition:

($*$) For each α, there exists an $\mathbb{E}_\infty$-ring A_α, an A_α-module M_α, and an equivalence

$$(\mathcal{X}_{/U_\alpha}, \mathscr{O}|_{U_\alpha}, \mathscr{F}|_{U_\alpha}) \simeq \mathrm{Sp\acute{e}t}_{\mathrm{Mod}}(A_\alpha, M_\alpha)$$

in the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{Mod}}$.

We let $\mathrm{QCoh}(\mathsf{X})$ denote the full subcategory of $\mathrm{Mod}_{\mathscr{O}}$ spanned by the quasi-coherent sheaves of $\mathscr{O}$-modules on $\mathcal{X}$.

Remark 2.2.2.2. The existence of a covering $\{U_\alpha\}$ satisfying condition ($*$) guarantees that $(\mathcal{X}, \mathscr{O})$ is a nonconnective spectral Deligne-Mumford stack.

Remark 2.2.2.3. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O})$ be a nonconnective spectral Deligne-Mumford stack, and let $\mathscr{F}$ be a sheaf of $\mathscr{O}$-modules on $\mathcal{X}$. The condition that $\mathscr{F}$ be quasi-coherent is local on $\mathcal{X}$. In other words:

- For every morphism $U \to V$ in $\mathcal{X}$, if $\mathscr{F}|_V$ is a quasi-coherent sheaf on $(\mathcal{X}_{/V}, \mathscr{O}|_V)$, then $\mathscr{F}|_U$ is a quasi-coherent sheaf on $(\mathcal{X}_{/U}, \mathscr{O}|_U)$.
- Conversely, if we are given an effective epimorphism $\amalg_\alpha U_\alpha \to V$ and each restriction $\mathscr{F}|_{U_\alpha}$ is a quasi-coherent sheaf on $(\mathcal{X}_{/U_\alpha}, \mathscr{O}|_{U_\alpha})$, then $\mathscr{F}|_V$ is a quasi-coherent sheaf on $(\mathcal{X}_{/V}, \mathscr{O}|_V)$.

2.2.3 The Affine Case

Our next goal is to describe quasi-coherent sheaves over affine spectral Deligne-Mumford stacks. We begin with a few general remarks.

Lemma 2.2.3.1. *Let A be an $\mathbb{E}_\infty$-ring, let M be an A-module, and set $(\mathcal{X}, \mathcal{O}, \mathcal{F}) = \mathrm{Sp\acute{e}t}_{\mathrm{Mod}}(A, M)$. Let $U \in \mathcal{X}$ be affine. Then the canonical map $\mathcal{O}(U) \otimes_A M \to \mathcal{F}(U)$ is an equivalence.*

Proof. Since U is affine, Theorem 1.4.10.2 implies that $U \in \mathcal{X} \simeq \mathcal{S}\mathrm{hv}_A^{\acute{e}t}$ can be identified with the functor corepresented by an étale A-algebra B. In this case, the desired result follows immediately from the construction of $(\mathcal{X}, \mathcal{O}, \mathcal{F})$ supplied by Proposition 2.2.1.4. □

Lemma 2.2.3.2. *Let $(\mathcal{X}, \mathcal{O}) \simeq \mathrm{Sp\acute{e}t}\, A$ be an affine nonconnective spectral Deligne-Mumford stack. Let $\mathcal{F}$ be a quasi-coherent $\mathcal{O}$-module and let $M = \Gamma(\mathcal{X}; \mathcal{F})$ be the global sections of $\mathcal{F}$, regarded as an $A \simeq \Gamma(\mathcal{X}; \mathcal{O})$-module. Then the canonical map $(\mathcal{X}, \mathcal{O}, \mathcal{F}) \to \mathrm{Sp\acute{e}t}_{\mathrm{Mod}}(A, M)$ is an equivalence (in the ∞-category $\infty\mathcal{T}\mathrm{op}_{\mathrm{Mod}}^{\mathrm{sHen}}$).*

Proof. Using Proposition 1.4.2.4, we can identify $\mathcal{X}$ with the ∞-category $\mathcal{S}\mathrm{hv}_A^{\acute{e}t}$. Since $\mathcal{F}$ is quasi-coherent, there exists a collection of objects $U_\alpha \in \mathcal{X}$ covering $\mathcal{X}$ for which each $(\mathcal{X}_{/U_\alpha}, \mathcal{O}|_{U_\alpha}, \mathcal{F}|_{U_\alpha})$ has the form $\mathrm{Sp\acute{e}t}_{\mathrm{Mod}}(A_\alpha, M_\alpha)$ for some object $(A_\alpha, M_\alpha) \in \mathrm{Mod}$. In particular, $(\mathcal{X}_{/U_\alpha}, \mathcal{O}|_{U_\alpha}) \simeq \mathrm{Sp\acute{e}t}(A_\alpha)$ is an affine nonconnective spectral Deligne-Mumford stack, so that A_α is an étale A-algebra by Theorem 1.4.10.2. Without loss of generality, we may assume that the set of indices α is finite. Let $B = \prod B_\alpha$ so that $\mathrm{Sp\acute{e}t}\, B \simeq (\mathcal{X}_{/U}, \mathcal{O}|_U)$ for $U = \amalg_\alpha U_\alpha$. We now observe that $(\mathcal{X}_{/U}, \mathcal{O}|_U, \mathcal{F}|_U) \simeq \mathrm{Sp\acute{e}t}_{\mathrm{Mod}}(B, N)$ where $B = \prod A_\alpha$ and $N = \prod M_\alpha$.

Let us abuse notation by identifying the pair $(\mathcal{O}, \mathcal{F})$ with the underlying functor $\mathrm{CAlg}_A^{\acute{e}t} \to \mathrm{Mod}$. Using Lemma 2.2.3.1, we deduce that the canonical map $\mathcal{F}(R) \otimes_R R' \to \mathcal{F}(R')$ is an equivalence whenever $R \to R'$ is a morphism in $\mathrm{CAlg}_A^{\acute{e}t}$ for which the étale map $A \to R$ factors through B. Let $B^\bullet$ be the Čech nerve of the faithfully flat morphism $A \to B$. Since $\mathcal{F}$ is a sheaf, we have $M = \mathcal{F}(A) = \varprojlim \mathcal{F}(B^\bullet)$. The proof of Theorem D.6.3.1 shows that the canonical map $M \otimes_A B \to \mathcal{F}(B)$ is an equivalence, so that $M \otimes_A R \to \mathcal{F}(R)$ is an equivalence for any étale map $A \to R$ which factors through B. Let $\mathrm{Sp\acute{e}t}_{\mathrm{Mod}}(A, M) \simeq (\mathcal{X}, \mathcal{O}, \mathcal{F}')$, so that the map $M \to \mathcal{F}(A)$ induces a morphism of sheaves of $\mathcal{O}$-modules $\mathcal{F}' \to \mathcal{F}$. Using Lemma 2.2.3.1, we deduce that α induces an equivalence $\mathcal{F}'(R) \to \mathcal{F}(R)$ whenever $A \to R$ is an étale map which factors through B. Since $\mathcal{F}'$ and $\mathcal{F}$ are sheaves, they are determined by their restriction to the sieve generated by B, so that α is an equivalence as desired. □

Proposition 2.2.3.3. *Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}) \simeq \mathrm{Sp\acute{e}t}\, A$ be an affine nonconnective spectral Deligne-Mumford stack. Then the global sections functor $\Gamma(\mathcal{X}; \bullet) : \mathrm{Mod}_{\mathcal{O}} \to \mathrm{Mod}_A$ admits a fully faithful left adjoint, whose essential image is the full subcategory $\mathrm{QCoh}(\mathsf{X}) \subseteq \mathrm{Mod}_{\mathcal{O}}$.*

Proof. Let $F : \mathrm{Mod}_A \to \mathrm{Mod}_{\mathcal{O}}$ denote the functor given on objects by by the formula $\mathrm{Sp\acute{e}t}_{\mathrm{Mod}}(A, M) \simeq (\mathcal{X}, \mathcal{O}, F(M))$. Unwinding the definitions, we deduce immediately that F is a left adjoint to $\Gamma(\mathcal{X}; \bullet)$. It is clear that F carries A-modules to quasi-coherent $\mathcal{O}$-modules. Conversely, Lemma 2.2.3.2 implies that every quasi-coherent $\mathcal{O}$-module belongs to the essential image of F. To prove that F is fully faithful, it suffices to show that for every A-module M, the unit map $M \to \Gamma(\mathcal{X}; F(M))$ is an equivalence, which is a special case of Lemma 2.2.3.1. □

2.2.4 The General Case

We now use Proposition 2.2.3.3 together with the fact that quasi-coherence can be tested locally to establish some pleasant features of quasi-coherent sheaves on *arbitrary* nonconnective spectral Deligne-Mumford stacks.

Proposition 2.2.4.1. *Let $\mathsf{X} = (\mathcal{X}, \mathcal{O})$ be a nonconnective spectral Deligne-Mumford stack. Then:*

(1) *The ∞-category $\mathrm{QCoh}(\mathsf{X})$ is closed under small colimits in $\mathrm{Mod}_{\mathcal{O}}$.*

(2) *The ∞-category $\mathrm{QCoh}(\mathsf{X})$ is stable.*

(3) *The ∞-category $\mathrm{QCoh}(\mathsf{X})$ is presentable.*

Proof. We first prove (1). Suppose we are given a small diagram $\{\mathscr{F}_\alpha\}$ of quasi-coherent $\mathcal{O}$-modules, having a colimit $\mathscr{F} \in \mathrm{Mod}_{\mathcal{O}}$. We wish to prove that $\mathscr{F}$ is quasi-coherent. The assertion is local on $\mathcal{X}$: it therefore suffices to show that $\mathscr{F}|_U \simeq \varinjlim \mathscr{F}_\alpha|_U$ is a quasi-coherent sheaf on $\mathcal{X}_{/U}$ whenever $(\mathcal{X}_{/U}, \mathcal{O}|_U)$ is affine. Replacing $\mathcal{X}$ by $\mathcal{X}_{/U}$, we may assume that $(\mathcal{X}, \mathcal{O})$ is affine. In this case, the desired result follows from Proposition 2.2.3.3. Using exactly the same argument, we deduce that $\mathrm{QCoh}(\mathsf{X})$ is closed under shifts in the stable ∞-category $\mathrm{Mod}_{\mathcal{O}}$. Assertion (2) now follows from Lemma HA.1.1.3.3 .

To prove (3), we let $\mathcal{X}_0 \subseteq \mathcal{X}$ denote the full subcategory spanned by those objects U for which the ∞-category $\mathrm{QCoh}(\mathsf{X}_U)$ is presentable. We wish to prove that $\mathcal{X}_0 = \mathcal{X}$. According to Remark 2.1.0.5, the construction $U \mapsto \mathrm{Mod}_{\mathcal{O}|_U}$ defines a limit-preserving functor $\chi_{\mathcal{O}} : \mathcal{X}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$. This functor is classified by a Cartesian fibration $p : \widetilde{\mathcal{X}} \to \mathcal{X}$. Let $\widetilde{\mathcal{X}}'$ denote the full subcategory of $\widetilde{\mathcal{X}}$ spanned by those objects X which correspond to quasi-coherent sheaves on $\mathcal{X}_{/p(X)}$. Remark 2.2.2.3 guarantees that $p|\widetilde{\mathcal{X}}'$ is also a Cartesian fibration, which is classified by another functor $\chi'_{\mathcal{O}} : \mathcal{X}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ (given informally by $U \mapsto \mathrm{QCoh}(\mathsf{X}_U)$). Since the condition of quasi-coherence is local (Remark 2.2.2.3), Proposition HTT.3.3.3.1 shows that $\chi'_{\mathcal{O}}$ is again a limit diagram. The functor $\chi'_{\mathcal{O}}$ evidently factors through the subcategory $\widehat{\mathcal{C}\mathrm{at}}'_\infty \subseteq \widehat{\mathcal{C}\mathrm{at}}_\infty$ spanned by those ∞-categories which admit small colimits and those functors which preserve small colimits. The ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable ∞-categories can be identified with a full subcategory of $\widehat{\mathcal{C}\mathrm{at}}'_\infty$, so that $\mathcal{X}_0^{\mathrm{op}} = (\chi'_{\mathcal{O}})^{-1}\mathcal{P}\mathrm{r}^{\mathrm{L}}$. Since $\chi'_{\mathcal{O}}$ preserves small limits, it follows from Proposition HTT.5.5.3.13 that $\mathcal{X}_0$ is stable under small colimits in $\mathcal{X}$. It will therefore suffice to show that $\mathcal{X}_0$ contains every object $U \in \mathcal{X}$ such that $(\mathcal{X}_{/U}, \mathcal{O}|_U)$ is affine, which follows immediately from Proposition 2.2.3.3. □

Proposition 2.2.4.2. *Let* $\mathsf{X} = (\mathcal{X}, \mathcal{O})$ *be a nonconnective spectral Deligne-Mumford stack. Then the full subcategory* $\mathrm{QCoh}(\mathsf{X}) \subseteq \mathrm{Mod}_{\mathcal{O}}$ *contains the unit object* $\mathcal{O}$ *and is stable under tensor products, and therefore inherits a symmetric monoidal structure from the symmetric monoidal structure on* $\mathrm{Mod}_{\mathcal{O}}$ *(see Proposition HA.2.2.1.1).*

Proof. The assertion is local, so we may assume that $\mathsf{X} = \mathrm{Spét}\, A$ is an affine nonconnective spectral Deligne-Mumford stack. Let $F : \mathrm{Mod}_A \to \mathrm{Mod}_{\mathcal{O}}$ be the functor described in Proposition 2.2.3.3, so that the essential image of F is the full subcategory $\mathrm{QCoh}(\mathsf{X}) \subseteq \mathrm{Mod}_{\mathcal{O}}$. Then $F(A) \simeq \mathcal{O}$, so that $\mathcal{O}$ is quasi-coherent. To show that $\mathrm{QCoh}(\mathsf{X})$ is stable under tensor products, it suffices to show that $F(M) \otimes_{\mathcal{O}} F(N)$ is quasi-coherent, for every pair of A-modules $M, N \in \mathrm{Mod}_A$.

Let us identify the ∞-topos $\mathcal{X}$ with $\mathcal{S}\mathrm{hv}_A^{\text{ét}} \subseteq \mathrm{Fun}(\mathrm{CAlg}_A^{\text{ét}}, \mathcal{S})$. For any sheaf of $\mathcal{O}$-modules $\mathcal{F}$, we can identify the pair $(\mathcal{O}, \mathcal{F})$ with a Mod-valued sheaf $\mathrm{CAlg}_A^{\text{ét}} \to \mathrm{Mod}$. Using the construction supplied by Proposition 2.2.1.4, we see that $F(M)$ and $F(N)$ are given by the formulas

$$F(M)(B) = M \otimes_A B \qquad F(N)(B) = N \otimes_A B.$$

It follows that $F(M) \otimes_{\mathcal{O}} F(N)$ is the sheafification of the presheaf

$$B \mapsto F(M)(B) \otimes_{\mathcal{O}(B)} F(N)(B) \simeq (M \otimes_A B) \otimes_B (N \otimes_A B) \simeq (M \otimes_A N) \otimes_A B.$$

According to Proposition 2.2.1.4, this presheaf is already a sheaf which we will denote by $\mathcal{F}$. We have $\mathcal{F}(A) \simeq M \otimes_A N$ so the above formula shows that the canonical map $\mathcal{F}(A) \otimes_A B \to \mathcal{F}(B)$ is an equivalence for every étale A-algebra B; in other words, the counit map $F(\Gamma(\mathcal{X}; \mathcal{F})) \to \mathcal{F}$ is an equivalence, so that $\mathcal{F}$ belongs to the essential image $\mathrm{QCoh}(\mathsf{X}) \subseteq \mathrm{Mod}_{\mathcal{O}}$ of the functor F. □

Our next result can be regarded as a non-affine analogue of Proposition 2.2.3.3:

Proposition 2.2.4.3. *Let* $(\mathcal{X}, \mathcal{O})$ *be a nonconnective spectral Deligne-Mumford stack and let* $\mathcal{F}$ *be a sheaf of* $\mathcal{O}$*-modules on* $\mathcal{X}$*. The following conditions are equivalent:*

(1) *The sheaf* $\mathcal{F}$ *is quasi-coherent.*

(2) *Let* $f : U \to V$ *be a morphism in* $\mathcal{X}$ *such that* $(\mathcal{X}_{/U}, \mathcal{O}|_U)$ *and* $(\mathcal{X}_{/V}, \mathcal{O}|_V)$ *are affine. Then the canonical map* $\mathcal{F}(V) \otimes_{\mathcal{O}(V)} \mathcal{O}(U) \to \mathcal{F}(U)$ *is an equivalence.*

Proof. Assume first that (1) is satisfied. To prove (2), we are free to replace $\mathcal{X}$ by $\mathcal{X}_{/V}$ and thereby reduce to the case where $(\mathcal{X}, \mathscr{O})$ is affine. It follows that $(\mathcal{X}, \mathscr{O}, \mathscr{F}) \simeq \mathrm{Sp\acute{e}t}_{\mathrm{Mod}}(A, M)$ for some $(A, M) \in \mathrm{Mod}$ (Lemma 2.2.3.2), so that assertion (2) follows from Lemma 2.2.3.1.

Now suppose that (2) is satisfied; we wish to prove that $\mathscr{F}$ is quasi-coherent. The assertion is local on $\mathcal{X}$: we may therefore assume without loss of generality that $(\mathcal{X}, \mathscr{O})$ is an affine nonconnective spectral Deligne-Mumford stack $\mathrm{Sp\acute{e}t}\, A$. Let $M = \Gamma(\mathcal{X}; \mathscr{F})$, regarded as an $A \simeq \Gamma(\mathcal{X}; \mathscr{O})$-module. Then the identity map $M \to \Gamma(\mathcal{X}; \mathscr{F})$ induces a morphism $(\mathcal{X}, \mathscr{O}, \mathscr{F}) \to \mathrm{Sp\acute{e}t}_{\mathrm{Mod}}(A, M) \simeq (\mathcal{X}, \mathscr{O}, \mathscr{F}')$ in the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{Mod}}$. To complete the proof, it will suffice to show that this map induces an equivalence of spectrum-valued sheaves $\mathscr{F}' \to \mathscr{F}$. Since $\mathcal{X}$ is generated under small colimits by the full subcategory $\mathcal{X}_0 \subseteq \mathcal{X}$ spanned by those objects $U \in \mathcal{X}$ for which $(\mathcal{X}_{/U}, \mathscr{O}|_U)$ is affine (Lemma **??**), it will suffice to show that $\mathscr{F}'(U) \to \mathscr{F}(U)$ is an equivalence when U is affine. This follows from the observation that we have a commutative diagram

$$\begin{array}{ccc} & M \otimes_A \mathscr{O}(U) & \\ {}^{\psi}\swarrow & & \searrow^{\phi} \\ \mathscr{F}'(U) & \longrightarrow & \mathscr{F}(U) \end{array}$$

where ϕ is an equivalence by Lemma 2.2.3.1 and ψ is an equivalence by assumption (2). □

2.2.5 Truncations of Quasi-Coherent Sheaves

We now restrict our attention to the case of spectral Deligne-Mumford stacks $\mathsf{X} = (\mathcal{X}, \mathscr{O})$: that is, we assume that the structure sheaf $\mathscr{O}$ is connective. In this case, the ∞-category $\mathrm{QCoh}(\mathsf{X})$ inherits a t-structure.

Lemma 2.2.5.1. *Let A be a connective $\mathbb{E}_\infty$-ring, let $\mathrm{Sp\acute{e}t}\, A = (\mathcal{X}, \mathscr{O})$, and let $F : \mathrm{Mod}_A \to \mathrm{Mod}_{\mathscr{O}}$ be the fully faithful embedding of Proposition 2.2.3.3. Then F is t-exact.*

Proof. The functor F is left adjoint to the global sections functor $\mathscr{F} \mapsto \Gamma(\mathcal{X}; \mathscr{F})$, which is obviously left t-exact. It follows formally that F is right t-exact. To complete the proof, we will show that F is left t-exact: that is, if $M \in (\mathrm{Mod}_A)_{\leqslant 0}$, then $F(M) \in (\mathrm{Mod}_{\mathscr{O}})_{\leqslant 0}$. Let $\mathcal{X}_0$ be the full subcategory of $\mathcal{X}$ spanned by those objects $U \in \mathcal{X}$ such that $F(M)(U) \in \mathrm{Sp}_{\leqslant 0}$. We wish to prove that $\mathcal{X}_0 = \mathcal{X}$. Since $\mathscr{F}$ is a sheaf and the full subcategory $\mathrm{Sp}_{\leqslant 0} \subseteq \mathrm{Sp}$ is stable under limits, we deduce that $\mathcal{X}_0$ is stable under colimits in $\mathcal{X}$. It will therefore suffice to show that $\mathcal{X}_0$ contains all objects $U \in \mathcal{X}$ such that $(\mathcal{X}_{/U}, \mathscr{O}|U)$ is an affine spectral Deligne-Mumford stack $\mathrm{Sp\acute{e}t}\, B$ (Lemma **??**). We have a canonical equivalence $F(M)(U) \simeq M \otimes_A B$. The desired result now follows from Theorem HA.7.2.2.15 , since Theorem 1.4.10.2 guarantees that B is étale (and in particular flat) over A. □

Proposition 2.2.5.2. *Let $\mathsf{X} = (\mathcal{X}, \mathcal{O})$ be a spectral Deligne-Mumford stack. Then the full subcategory $\mathrm{QCoh}(\mathsf{X}) \subseteq \mathrm{Mod}_{\mathcal{O}}$ is compatible with the t-structure of Proposition 2.1.1.1. More precisely, if $\mathscr{F} \in \mathrm{Mod}_{\mathcal{O}}$ is quasi-coherent, then the truncations $\tau_{\geqslant n} \mathscr{F}$ and $\tau_{\leqslant n} \mathscr{F}$ are quasi-coherent, for every integer n. Consequently, the full subcategories $\mathrm{QCoh}(\mathsf{X})_{\geqslant 0} = \mathrm{QCoh}(\mathsf{X}) \cap (\mathrm{Mod}_{\mathcal{O}})_{\geqslant 0}$ and $\mathrm{QCoh}(\mathsf{X})_{\leqslant 0} = \mathrm{QCoh}(\mathsf{X}) \cap (\mathrm{Mod}_{\mathcal{O}})_{\leqslant 0}$ determine a t-structure on the ∞-category $\mathrm{QCoh}(\mathsf{X})$.*

Proof. Replacing $\mathscr{F}$ by its translates if necessary, it will suffice to show that if $\mathscr{F}$ is quasi-coherent, then $\tau_{\geqslant 0} \mathscr{F}$ and $\tau_{\leqslant -1} \mathscr{F}$ are quasi-coherent. This assertion is local on $\mathcal{X}$; we may therefore assume that $(\mathcal{X}, \mathcal{O}) \simeq \mathrm{Sp\acute{e}t}\, A$ is an affine spectral Deligne-Mumford stack (where A is a connective $\mathbb{E}_\infty$-ring). Let $F : \mathrm{Mod}_A \to \mathrm{Mod}_{\mathcal{O}}$ be the functor described in Proposition 2.2.3.3. Since $\mathscr{F}$ is quasi-coherent, we may assume without loss of generality that $\mathscr{F} = F(M)$ for some A-module M. Since A is connective, there is a fiber sequence

$$M' \to M \to M''$$

where M' is a connective A-module and $M'' \in (\mathrm{Mod}_A)_{\leqslant -1}$. Applying the exact functor F, we obtain a fiber sequence

$$F(M') \to \mathscr{F} \to F(M'')$$

in $\mathrm{Mod}_{\mathcal{O}}$. Lemma 2.2.5.1 guarantees that $F(M') \in (\mathrm{Mod}_{\mathcal{O}})_{\geqslant 0}$ and $F(M'') \in (\mathrm{Mod}_{\mathcal{O}})_{\leqslant -1}$. We therefore obtain identifications $F(M') \simeq \tau_{\geqslant 0} \mathscr{F}$ and $F(M'') \simeq \tau_{\leqslant -1} \mathscr{F}$ which proves that $\tau_{\geqslant 0} \mathscr{F}$ and $\tau_{\leqslant -1} \mathscr{F}$ are quasi-coherent. □

Notation 2.2.5.3. If $\mathsf{X} = (\mathcal{X}, \mathcal{O})$ is a spectral Deligne-Mumford stack, we let $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ denote the full subcategory $\mathrm{QCoh}(\mathsf{X})_{\geqslant 0} \subseteq \mathrm{QCoh}(\mathsf{X})$ defined in Proposition 2.2.5.2. We will say that a quasi-coherent sheaf $\mathscr{F}$ is *connective* if it belongs to $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$.

The basic properties of the t-structure on $\mathrm{QCoh}(\mathsf{X})$ can be summarized as follows:

Proposition 2.2.5.4. *Let $\mathsf{X} = (\mathcal{X}, \mathcal{O})$ be a spectral Deligne-Mumford stack. Then:*

(1) *The t-structure on $\mathrm{QCoh}(\mathsf{X})$ is accessible (see Definition HA.1.4.4.12).*

(2) *The t-structure on $\mathrm{QCoh}(\mathsf{X})$ is compatible with filtered colimits: that is, the full subcategory $\mathrm{QCoh}(\mathsf{X})_{\leqslant 0}$ is closed under filtered colimits.*

(3) *The t-structure on $\mathrm{QCoh}(\mathsf{X})$ is both right and left complete.*

Proof. Assertion (1) is equivalent to the statement that $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ is presentable (Proposition HA.1.4.4.13). This follows from Proposition HTT.5.5.3.12 , since $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ can be identified with the fiber product $\mathrm{QCoh}(\mathsf{X}) \times_{\mathrm{Mod}_{\mathcal{O}}} \mathrm{Mod}_{\mathcal{O}}^{\mathrm{cn}}$. Assertion (2) follows from Proposition 2.2.4.1 together with the corresponding result for $\mathrm{Mod}_{\mathcal{O}}$ (Proposition 2.1.1.1).

We now prove (3). Since $\mathrm{Mod}_{\mathcal{O}}$ is right-complete (Proposition 2.1.1.1), we deduce that $\bigcap_n \mathrm{QCoh}(\mathsf{X})_{\leqslant -n} \subseteq \bigcap_n (\mathrm{Mod}_{\mathcal{O}})_{\leqslant -n}$ contains only zero objects. Combining this observation with (2), we deduce that $\mathrm{QCoh}(\mathsf{X})$ is right-complete (see Proposition HA.1.2.1.19).

The proof that $\mathrm{QCoh}(\mathsf{X})$ is left-complete requires a bit more effort (note that $\mathrm{Mod}_{\mathcal{O}}$ need not be left complete). Consider the full subcategory $\mathcal{X}_0 \subseteq \mathcal{X}$ spanned by those objects $U \in \mathcal{X}$ for which the t-structure on $\mathrm{QCoh}(\mathcal{X}_{/U})$ is left-complete. To complete the proof, it will suffice to show that $\mathcal{X}_0 = \mathcal{X}$. Using Proposition 2.2.3.3, Lemma 2.2.5.1, and Proposition HA.7.1.1.13 , we deduce that $\mathcal{X}_0$ contains every affine object $U \in \mathcal{X}$. It will therefore suffice to show that $\mathcal{X}_0$ is closed under small colimits in $\mathcal{X}$ (Lemma **??**). Since the conditions of being quasi-coherent and n-truncated are local, the proof of Proposition 2.2.4.1 shows that the constructions

$$U \mapsto \mathrm{QCoh}(\mathsf{X}_U) \qquad U \mapsto \mathrm{QCoh}(\mathsf{X}_U)_{\leqslant n}$$

determine limit-preserving functors $\mathcal{X}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$. If $\{U_\alpha\}$ is a diagram in $\mathcal{X}$ having a colimit $U \in \mathcal{X}$, we have a commutative diagram

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{X}_U) & \longrightarrow & \varprojlim_\alpha \mathrm{QCoh}(\mathsf{X}_{U_\alpha}) \\ \downarrow & & \downarrow \theta \\ \varprojlim_n \mathrm{QCoh}(\mathsf{X}_U)_{\leqslant n} & \longrightarrow & \varprojlim_{n,\alpha} \mathrm{QCoh}(\mathsf{X}_{U_\alpha})_{\leqslant n}. \end{array}$$

where the vertical maps are equivalences. If each U_α belongs to $\mathcal{X}_0$, then the right vertical map is also an equivalence, so the left vertical map is an equivalence as well and $U \in \mathcal{X}_0$ as desired. □

2.2.6 Discrete Quasi-Coherent Sheaves

Let $\mathsf{X} = (\mathcal{X}, \mathcal{O})$ be a spectral Deligne-Mumford stack. The truncation map $\mathcal{O} \to \pi_0 \mathcal{O}$ induces an equivalence of abelian categories $\mathrm{Mod}^{\heartsuit}_{\pi_0 \mathcal{O}} \to \mathrm{Mod}^{\heartsuit}_{\mathcal{O}}$. Using the criterion for quasi-coherence supplied by Proposition 2.2.4.3, we see that this equivalence respects the property of quasi-coherence: that is, we have an equivalence of abelian categories

$$\mathrm{QCoh}(\mathcal{X}, \pi_0 \mathcal{O})^{\heartsuit} \simeq \mathrm{QCoh}(\mathsf{X})^{\heartsuit}.$$

(for a more general assertion of this nature, see Corollary 2.5.9.2).

Let $\mathcal{X}^{\heartsuit}$ be the underlying topos of $\mathcal{X}$, so that we can identify $\pi_0 \mathcal{O}$ with a commutative ring object of $\mathcal{X}^{\heartsuit}$. Then we can identify $\mathrm{Mod}^{\heartsuit}_{\mathcal{O}}$ with the abelian category of $\pi_0 \mathcal{O}$-module objects of $\mathcal{X}^{\heartsuit}$. Under this identification, the full subcategory $\mathrm{QCoh}(\mathsf{X})^{\heartsuit} \simeq \mathrm{QCoh}(\mathcal{X}, \pi_0 \mathcal{O})^{\heartsuit} \subseteq \mathrm{Mod}^{\heartsuit}_{\pi_0 \mathcal{O}}$ corresponds to the abelian category of quasi-coherent sheaves on the ordinary Deligne-Mumford stack $(\mathcal{X}^{\heartsuit}, \pi_0 \mathcal{O})$, in the sense of Definition 1.2.6.1 (this follows immediately from the characterization of Proposition 2.2.4.3).

In the non-discrete case, there is a similar characterization of quasi-coherence:

Proposition 2.2.6.1. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O})$ be a nonconnective spectral Deligne-Mumford stack and let $\mathscr{F}$ be a sheaf of $\mathscr{O}$-modules on $\mathcal{X}$. Then $\mathscr{F}$ is quasi-coherent if and only if it satisfies the following conditions:*

(1) *For every integer n, the homotopy sheaf $\pi_n \mathscr{F}$ is quasi-coherent (in the sense of Definition 1.2.6.1) when viewed as a $\pi_0 \mathscr{O}$-module object of the underlying topos $\mathcal{X}^{\heartsuit}$.*

(2) *The object $\Omega^\infty \mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}) \simeq \mathcal{X}$ is hypercomplete.*

Corollary 2.2.6.2. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O})$ be a spectral Deligne-Mumford stack. Assume that $\mathcal{X}$ is 1-localic and that the structure sheaf $\mathscr{O}$ is discrete. Then there is a canonical equivalence of ∞-categories $\mathrm{QCoh}(\mathsf{X}) \simeq \mathcal{D}(\mathrm{Mod}^{\heartsuit}_{\mathscr{O}})_{\mathrm{qc}}$, where $\mathcal{D}(\mathrm{Mod}^{\heartsuit}_{\mathscr{O}})_{\mathrm{qc}}$ denotes the full subcategory of the derived ∞-category $\mathcal{D}(\mathrm{Mod}^{\heartsuit}_{\mathscr{O}})$ spanned by those chain complexes of $\mathscr{O}$-module objects of $\mathcal{X}^{\heartsuit}$ whose homologies are quasi-coherent (in the sense of Definition 1.2.6.1).*

Proof. Combine Proposition 2.2.6.1 with Corollary 2.1.2.3. □

Remark 2.2.6.3. Under some slightly stronger hypotheses, one can show that the ∞-category $\mathrm{QCoh}(\mathsf{X})$ is equivalent to the derived ∞-category of its heart: see Corollary 10.3.4.13.

Proof of Proposition 2.2.6.1. Replacing $\mathscr{O}$ by its connective cover if necessary, we may assume that $\mathscr{O}$ is connective. If $\mathscr{F}$ is quasi-coherent, then Proposition 2.2.5.2 implies that each homotopy group $\pi_n \mathscr{F}$ is quasi-coherent as a $\mathscr{O}$-module. To prove that (2) is satisfied, it suffices to work locally on $\mathcal{X}$; we may therefore assume that $(\mathcal{X}, \mathscr{O}) \simeq \mathrm{Sp\acute{e}t}\, A$ for some connective $\mathbb{E}_\infty$-ring A. Let F be the functor of Proposition 2.2.3.3, so that $\mathscr{F} \simeq F(M)$ for some A-module M. Let us identify the pair $(\mathscr{O}, \mathscr{F})$ with the sheaf $\mathrm{CAlg}^{\text{ét}}_A \to \mathrm{Mod}$ given by $B \mapsto (B, B \otimes_A M)$. We note that for each $B \in \mathrm{CAlg}^{\text{ét}}_A$, we have

$$F(M)(B) \simeq B \otimes_A M \simeq \varprojlim \tau_{\leqslant n}(B \otimes_A M) \simeq \varprojlim B \otimes_A (\tau_{\leqslant n} M) \simeq \varprojlim F(\tau_{\leqslant n} M)(B).$$

It follows that $\mathscr{F} \simeq F(M) \simeq \varprojlim F(\tau_{\leqslant n} M)$ is a limit of truncated objects of $\mathrm{Mod}_{\mathscr{O}}$ (Lemma 2.2.5.1), so that $\Omega^\infty \mathscr{F}$ is a limit of truncated objects of $\mathcal{X}$ and therefore hypercomplete.

Now suppose that $\mathscr{F} \in \mathrm{Mod}_{\mathscr{O}}$ satisfies conditions (1) and (2). We wish to prove that $\mathscr{F}$ is quasi-coherent. Note that $\mathscr{F} \simeq \varinjlim \tau_{\geqslant -n} \mathscr{F}$ by Proposition 2.2.5.4. Since the collection of quasi-coherent sheaves is closed under colimits in $\mathrm{Mod}_{\mathscr{O}}$, it suffices to prove that each $\tau_{\geqslant -n} \mathscr{F}$ is quasi-coherent. Replacing $\mathscr{F}$ by $\Sigma^n(\tau_{\geqslant -n} \mathscr{F})$, we may assume that $\mathscr{F}$ is connective. Since the condition of being quasi-coherent is local on $\mathcal{X}$, we may suppose that $(\mathcal{X}, \mathscr{O}) \simeq \mathrm{Sp\acute{e}t}\, A$ is an affine spectral Deligne-Mumford stack, where A is a connective $\mathbb{E}_\infty$-ring; let $\mathcal{C}$ and $F : \mathrm{Mod}_A \to \mathrm{Mod}_{\mathscr{O}}$ be defined as above.

We now argue by induction on m that each truncation $\tau_{\leqslant m} \mathscr{F}$ is quasi-coherent. For $m < 0$, this is obvious. If $m \geqslant 0$, it follows from the existence of a fiber sequence

$$\tau_{\leqslant m-1} \mathscr{F} \to \tau_{\leqslant m} \mathscr{F} \to \Sigma^m(\pi_m \mathscr{F}).$$

Using Proposition 2.2.3.3, we may suppose that the tower $\{\tau_{\leqslant m} \mathscr{F}\}$ is obtained from a tower of A-modules $\{M_m\}_{m \geqslant 0}$. Using Lemma 2.2.5.1, we deduce that for $m \leqslant m'$, the map $M_{m'} \to M_m$ exhibits M_m as an m-truncation $\tau_{\leqslant m} M_{m'}$. Since Mod_A is left complete (Proposition HA.7.1.1.13), the A-module $M \simeq \varprojlim M_m$ has the property that $\tau_{\leqslant m} M \simeq M_m$ for every integer m. For every flat A-algebra B, we also obtain an equivalence $\tau_{\leqslant m}(M \otimes_A B) \simeq M_m \otimes_A B$, so that $M \otimes_A B \simeq \varprojlim (M_m \otimes_A B)$. It follows that $F(M) \simeq \varprojlim_m F(M_m) \simeq \varprojlim \tau_{\leqslant m} \mathscr{F}$ in the ∞-category $\mathrm{Mod}_{\mathscr{O}}$. In particular, we obtain a map $\alpha : \mathscr{F} \to F(M)$. To prove that $\mathscr{F}$ is quasi-coherent, it will suffice to show that α is an equivalence. Since $\mathscr{F}$ and $F(M)$ are both connective, this is equivalent to the requirement that α induces an equivalence $\Omega^\infty \mathscr{F} \to \Omega^\infty F(M)$ in $\mathcal{S}\mathrm{hv}_{\mathcal{S}}(\mathcal{X}) \simeq \mathcal{X}$. Since $\Omega^\infty \mathscr{F}$ is hypercomplete (by (2)) and $\Omega^\infty F(M) \simeq \varprojlim \Omega^\infty F(M_m)$ is hypercomplete (since it is an inverse limit of truncated objects of $\mathcal{X}$), it will suffice to show that the map $\Omega^\infty(\alpha) : \Omega^\infty \mathscr{F} \to \Omega^\infty F(M)$ is ∞-connective. This is clear, since for every integer $m \geqslant 0$, the truncation $\tau_{\leqslant m} \Omega^\infty(\alpha)$ is homotopic to the composition of equivalences

$$\tau_{\leqslant m} \Omega^\infty \mathscr{F} \simeq \Omega^\infty(\tau_{\leqslant m} \mathscr{F}) \simeq \Omega^\infty F(M_m) \simeq \Omega^\infty F(\tau_{\leqslant m} M) \simeq \Omega^\infty \tau_{\leqslant m} F(M) \simeq \tau_{\leqslant m} \Omega^\infty F(M).$$

□

2.3 Compactness Hypotheses on Spectral Deligne-Mumford Stacks

Let $(X, \mathscr{O}_X)$ be a scheme. Recall that X is said to be *quasi-compact* if every open covering of X has a finite subcovering, and *quasi-separated* if the collection of quasi-compact open subsets of X is closed under pairwise intersections. In this section, we will study analogous conditions in the setting of spectral Deligne-Mumford stacks.

2.3.1 Quasi-Compactness (Absolute Case)

Throughout this section, we will assume that the reader is familiar with the theory of coherent ∞-topoi developed in §A.2 (see Definition A.2.0.12).

Definition 2.3.1.1. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a nonconnective spectral Deligne-Mumford stack and let $n \geqslant 0$ be an integer. We will say that X is *n-quasi-compact* if the ∞-topos $\mathcal{X}$ is n-coherent (see §A.2). We will say that X is *quasi-compact* if it is 0-quasi-compact. We will say that X is *∞-quasi-compact* if it is n-quasi-compact for every integer n.

Proposition 2.3.1.2. *Let A be an $\mathbb{E}_\infty$-ring. Then the nonconnective spectral Deligne-Mumford stack* Spét A *is ∞-quasi-compact.*

Proof. Combine Propositions A.3.1.3 and 1.4.2.4. □

Corollary 2.3.1.3. *Let $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a nonconnective spectral Deligne-Mumford stack. Then the ∞-topos $\mathcal{X}$ is locally coherent (see Definition A.2.1.6).*

Corollary 2.3.1.4. *Let $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a nonconnective spectral Deligne-Mumford stack. Then the hypercompletion $\mathcal{X}^{\mathrm{hyp}}$ has enough points.*

Proof. Combine Corollary 2.3.1.3 with Theorem A.4.0.5. □

2.3.2 Quasi-Compactness (Relative Case)

Recall that if $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is a nonconnective spectral Deligne-Mumford stack, then we say an object $U \in \mathcal{X}$ is *affine* if the nonconnective spectral Deligne-Mumford stack $(\mathcal{X}_{/U}, \mathcal{O}_{\mathcal{X}}|_U)$ is affine.

Proposition 2.3.2.1. *Let $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ be a morphism of nonconnective spectral Deligne-Mumford stacks. Let $n \geqslant 0$ be an integer. The following conditions are equivalent:*

(1) *For every n-coherent object $U \in \mathcal{Y}$, the pullback f^*U is n-coherent.*

(2) *For every affine object $U \in \mathcal{Y}$, the pullback f^*U is an n-coherent object of $\mathcal{X}$.*

(3) *There exists a full subcategory $\mathcal{Y}_0 \subseteq \mathcal{Y}$ with the following properties:*

   (a) *Each object $U \in \mathcal{Y}_0$ is n-coherent.*

   (b) *For each $U \in \mathcal{Y}_0$, the pullback $f^*(U)$ is n-coherent.*

   (c) *For each object $Y \in \mathcal{Y}$, there exists an effective epimorphism $\amalg Y_i \to Y$, where each $Y_i \in \mathcal{Y}_0$.*

Moreover, if $n > 0$, then these conditions imply:

(4) *For every relatively $(n-1)$-coherent morphism $u : U \to Y$ in $\mathcal{Y}$, the pullback $f^*(u)$ is a relatively $(n-1)$-coherent morphism in $\mathcal{X}$.*

Definition 2.3.2.2. Let $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ be a morphism of nonconnective spectral Deligne-Mumford stacks. We will say that f is *n-quasi-compact* if it satisfies the equivalent conditions of Proposition 2.3.2.1. We will say that f is *quasi-compact* if it is 0-quasi-compact, and *∞-quasi-compact* if it is n-quasi-compact for every integer $n \geqslant 0$.

Proof of Proposition 2.3.2.1. We proceed by induction on n. The implication $(1) \Rightarrow (2)$ is immediately from Proposition 2.3.1.2. To see that $(2) \Rightarrow (3)$, we take $\mathcal{Y}_0$ to be the collection of all objects $U \in \mathcal{Y}$ such that $(\mathcal{Y}_{/U}, \mathcal{O}_{\mathcal{Y}}|_U)$ is affine. We next show that $(3) \Rightarrow (4)$ if $n > 0$. Let $u : U \to Y$ be an $(n-1)$-coherent morphism in $\mathcal{Y}$; we wish to show that $f^*(u)$ is a relatively $(n-1)$-coherent morphism in $\mathcal{X}$. Choose an effective epimorphism $\amalg_{i \in I} Y_i \to Y$, where each $Y_i \in \mathcal{Y}$. Using Corollary A.2.1.5, we are reduced to proving that the induced map $f^*(U \times_Y \amalg_{i \in I} Y_i) \to f^*(\amalg_{i \in I} Y_i)$ is relatively $(n-1)$-coherent. We may therefore replace Y by some Y_i and thereby reduce to the case where Y is n-coherent. Then U is $(n-1)$-coherent. Using (2) together with the inductive hypothesis, we deduce that f^*Y is n-coherent and that f^*U is $(n-1)$-coherent, so that $f^*(u)$ is relatively $(n-1)$-coherent as desired.

We now prove that (3) implies (1). Fix an n-coherent object $U \in \mathcal{Y}$; we wish to prove that $f^*(U)$ is an n-coherent object of $\mathcal{X}$. Choose an effective epimorphism $\amalg_{i \in I} U_i \to U$ where each $U_i \in \mathcal{Y}_0$. Since U is quasi-compact, we may assume without loss of generality that I is finite. Using (2) and Remark A.2.0.16, we conclude that $\amalg f^*(U_i)$ is an n-coherent object of $\mathcal{X}$. Moreover, the map $\amalg f^*(U_i) \to f^*(U)$ is an effective epimorphism which is $(n-1)$-coherent if $n > 0$ (by virtue of (4)). Using Proposition A.2.1.3 we conclude that f^*U is n-coherent as desired. □

Remark 2.3.2.3. Let $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ be a morphism of nonconnective spectral Deligne-Mumford stacks and let $n \geqslant 0$ be an integer. Suppose that f is n-quasi-compact. Then:

- (a) The pullback functor f^* carries compact objects of $\tau_{\leqslant n-1}\,\mathcal{Y}$ to compact objects of $\tau_{\leqslant n-1}\,\mathcal{X}$.
- (b) The pushforward functor $f_* : \tau_{\leqslant n-1}\,\mathcal{X} \to \tau_{\leqslant n-1}\,\mathcal{Y}$ commutes with filtered colimits.

Assertion (a) follows from Proposition 2.3.2.1 and Remark A.2.3.3, and assertion (b) follows from (a) and Proposition HTT.5.5.7.2 .

Example 2.3.2.4. Let $f : \mathsf{X} \to \mathsf{Y}$ be a map between affine nonconnective spectral Deligne-Mumford stacks. Then f is ∞-quasi-compact; this follows immediately from Proposition 2.3.1.2.

Remark 2.3.2.5. Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of nonconnective spectral Deligne-Mumford stacks and let $0 \leqslant n \leqslant \infty$. The following conditions are equivalent:

1. The map f is n-coherent.
2. For every étale morphism $\operatorname{Spét} A \to \mathsf{Y}$, the fiber product $\operatorname{Spét} A \times_{\mathsf{Y}} \mathsf{X}$ is n-coherent.

Proposition 2.3.2.6. *Let* X *be a quasi-compact nonconnective spectral Deligne-Mumford stack, and let* $n > 0$. *The following conditions on* X *are equivalent:*

1. *For every pair of maps* $\operatorname{Spét} A \to \mathsf{X} \leftarrow \operatorname{Spét} B$, *the fiber product* $\operatorname{Spec} A \times_{\mathsf{X}} \operatorname{Spét} B$ *is* $(n-1)$*-coherent.*
2. *Every map* $f : \operatorname{Spét} A \to \mathsf{X}$ *is* $(n-1)$*-coherent.*

(3) *For every pair of maps* $\operatorname{Spét} A \to \mathsf{X} \xleftarrow{u} \operatorname{Spét} B$ *where* u *is étale, the fiber product* $\operatorname{Spét} A \times_{\mathsf{X}} \operatorname{Spét} B$ *is* $(n-1)$*-coherent.*

(4) *Every étale map* $f : \operatorname{Spét} A \to \mathsf{X}$ *is* $(n-1)$*-coherent.*

(5) *For every pair of étale maps* $\operatorname{Spét} A \to \mathsf{X} \leftarrow \operatorname{Spét} B$*, the fiber product* $\operatorname{Spét} A \times_{\mathsf{X}} \operatorname{Spét} B$ *is* $(n-1)$*-coherent.*

(6) *The nonconnective spectral Deligne-Mumford stack* X *is* n*-coherent.*

Proof. The equivalences (1) ⇔ (2) and (3) ⇔ (4) are obvious. The equivalences (2) ⇔ (3) and (4) ⇔ (5) follow from Remark 2.3.2.5, and the equivalence (5) ⇔ (6) follows from Corollary A.2.1.4. □

Proposition 2.3.2.7. *Let* X *be a spectral Deligne-Mumford* n*-stack. If* X *is* $(n+1)$*-quasi-compact, then* X *is* ∞*-quasi-compact.*

Proof. It will suffice to show that if X is $(n+1)$-quasi-compact, then it is also $(n+2)$-quasi-compact. We proceed by induction on n. The case $n = 0$ will be established in §3.4 (Proposition 3.4.1.2). Assume that $n > 0$. To prove that X is $(n+2)$-quasi-compact, it will suffice to show that for every pullback diagram

$$\begin{array}{ccc} \mathsf{Y} & \longrightarrow & \operatorname{Spét} A \\ \downarrow & & \downarrow \\ \operatorname{Spét} B & \longrightarrow & \mathsf{X}, \end{array}$$

the spectral Deligne-Mumford stack Y is $(n+1)$-quasi-compact (Proposition 2.3.2.6). This follows from the inductive hypothesis, since Y is a spectral Deligne-Mumford $(n-1)$-stack (Remark 1.6.8.4). □

2.3.3 Pullbacks of Quasi-Compact Morphisms

Our next result describes the behavior of n-quasi-compact morphisms with respect to base change:

Proposition 2.3.3.1. *Suppose we are given a pullback diagram of nonconnective spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \xrightarrow{g'} & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \xrightarrow{g} & \mathsf{Y}, \end{array}$$

and let $0 \leqslant n \leqslant \infty$*. If* f *is* n*-quasi-compact, then* f' *is* n*-quasi-compact. The converse holds if* g *is quasi-compact and surjective (see Definition 3.5.5.5).*

We begin by establishing the first half of Proposition 2.3.3.1.

Lemma 2.3.3.2. *Suppose we are given a pullback diagram σ :*

$$\begin{array}{ccc} (\mathcal{X}', \mathcal{O}_{\mathcal{X}'}) & \xrightarrow{f'} & (\mathcal{Y}', \mathcal{O}_{\mathcal{Y}'}) \\ \downarrow{g'} & & \downarrow{g} \\ (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) & \xrightarrow{f} & (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) \end{array}$$

of nonconnective spectral Deligne-Mumford stacks. If f is n-quasi-compact, then f' is n-quasi-compact.

Proof. Let $\mathcal{Y}'_0$ be the full subcategory of $\mathcal{Y}'$ spanned by those objects $Y' \in \mathcal{Y}'$ with the following properties:

(*i*) The pair $(\mathcal{Y}'_{/Y'}, \mathcal{O}_{\mathcal{Y}'}|_{Y'})$ is affine.

(*ii*) There exists an object $Y \in \mathcal{Y}$ and a map $Y' \to g^*Y$, where $(\mathcal{Y}_{/Y}, \mathcal{O}_{\mathcal{Y}}|_Y)$ is affine.

This subcategory satisfies requirements (a), (b), and (c) of Proposition 2.3.2.1; it will therefore suffice to show that f'^*Y is an n-coherent object of $\mathcal{X}'$.

Replacing σ by the diagram

$$\begin{array}{ccc} (\mathcal{X}'_{/f'^*Y'}, \mathcal{O}_{\mathcal{X}'}|_{f'^*Y'}) & \xrightarrow{f'} & (\mathcal{Y}'_{/Y'}, \mathcal{O}_{\mathcal{Y}'}|_{Y'}) \\ \downarrow & & \downarrow{g} \\ (\mathcal{X}_{/f^*Y}, \mathcal{O}_{\mathcal{X}}|_{f^*Y}) & \xrightarrow{f} & (\mathcal{Y}_{/Y}, \mathcal{O}_{\mathcal{Y}}|_Y), \end{array}$$

we can reduce to the case where $(\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ and $(\mathcal{Y}', \mathcal{O}_{\mathcal{Y}'})$ are affine. Since f is n-quasi-compact, the ∞-topos $\mathcal{X}$ is n-coherent; we wish to prove that $\mathcal{X}'$ is n-coherent. To prove this, it suffices to show that the map g' is n-quasi-compact. This assertion is local on $\mathcal{X}$; we may therefore assume that $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is affine. Since σ is a pullback diagram, we conclude that $(\mathcal{X}', \mathcal{O}_{\mathcal{X}'})$ is affine and the desired result follows from Example 2.3.2.4. □

Corollary 2.3.3.3. *Let $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ be a map of nonconnective spectral Deligne-Mumford stacks. Assume that $(\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ is affine. Then f is n-quasi-compact if and only if $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is n-quasi-compact.*

Proof. The "only if" direction is obvious (and requires only that $(\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ be n-quasi-compact). Conversely, suppose that $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is affine. Let $U \in \mathcal{Y}$ be such that $(\mathcal{Y}_{/U}, \mathcal{O}_{\mathcal{Y}}|_U)$ is affine. We wish to prove that f^*U is an n-coherent object of $\mathcal{X}$. We have a pullback diagram

$$\begin{array}{ccc} (\mathcal{X}_{/f^*U}, \mathcal{O}_{\mathcal{X}}|_{f^*U}) & \longrightarrow & (\mathcal{Y}_{/U}, \mathcal{O}_{\mathcal{Y}}|_U) \\ \downarrow{g} & & \downarrow{g'} \\ (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) & \longrightarrow & (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}). \end{array}$$

The map g' is n-quasi-compact by Example 2.3.2.4, so that Lemma 2.3.3.2 guarantees that g is n-quasi-compact. Since the final object $\mathbf{1} \in \mathcal{X}$ is n-coherent, we conclude that $g^* \mathbf{1} \in \mathcal{X}_{/f^* U}$ is n-coherent: that is, $f^* U$ is an n-coherent object of $\mathcal{X}$. □

Proof of Proposition 2.3.3.1. The first assertion follows from Proposition 2.3.3.2. To prove the second, we may assume without loss of generality that $\mathsf{Y} = \operatorname{Sp\acute{e}t} A$ is affine. If the map $g : \mathsf{Y}' \to \mathsf{Y}$ is quasi-compact, then it follows that Y' is also quasi-compact. We may therefore choose an étale surjection $\operatorname{Sp\acute{e}t} B \to \mathsf{Y}'$. Replacing Y' by $\operatorname{Sp\acute{e}t} B$, we may assume that Y' is also affine.

Write $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ and $\mathsf{X}' = (\mathcal{X}', \mathcal{O}_{\mathcal{X}'})$. Our assumption that f' is n-quasi-compact is equivalent to the assumption that $\mathcal{X}'$ is n-coherent, and we wish to prove that $\mathcal{X}$ is also n-coherent (Corollary 2.3.3.3). We claim more generally that if $X \in \mathcal{X}$ is an object such that $g'^* X \in \mathcal{X}'$ is m-coherent, then X is m-coherent. The proof proceeds by induction on m. We begin with the case $m = 0$. Suppose that we are given an effective epimorphism $\coprod_{i \in I} U_i \to X$ in the ∞-topos $\mathcal{X}$. Then the induced map $\coprod_{i \in I} g'^* U_i \to g'^* X$ is an effective epimorphism in $\mathcal{X}'$. If $g'^* X$ is quasi-compact, then we can choose a finite subset $I_0 \subseteq I$ such that the induced map $\coprod_{i \in I_0} g'^* U_i \to g'^* X$ is an effective epimorphism. Since the map g' is surjective, it follows that the map $\coprod_{i \in I_0} U_i \to X$ is also an effective epimorphism.

We now treat the case $m > 0$. According to Corollary A.2.1.4, it will suffice to show that if we are given affine objects $U, V \in \mathcal{X}_{/X}$, then the fiber product $U \times_X V$ is $(m-1)$-coherent. By the inductive hypothesis, it suffices to show that $g'^*(U \times_X V) \simeq g'^* U \times_{g'^* X} g'^* V$ is $(m-1)$-coherent. This follows from the m-coherence of $g'^* X$, since $f^* U$ and $f^* V$ are affine. □

2.3.4 The Schematic Case

We now discuss the relationship of Definition 2.3.1.1 with classical scheme theory.

Lemma 2.3.4.1. *Let X be a topological space. The following conditions are equivalent:*

(1) *The ∞-topos $\mathcal{S}\mathrm{hv}(X)$ is coherent.*

(2) *The ∞-topos $\mathcal{S}\mathrm{hv}(X)$ is 1-coherent.*

(3) *The collection of quasi-compact open subsets of X is closed under finite intersections and forms a basis for the topology of X.*

Proof. The implication (1) ⇒ (2) is obvious. We prove that (2) ⇒ (3). For each $U \subseteq X$, let $\chi_U \in \mathcal{S}\mathrm{hv}(X)$ be the sheaf given by the formula

$$\chi_U(V) = \begin{cases} \Delta^0 & \text{if } V \subseteq U \\ \emptyset & \text{otherwise.} \end{cases}$$

We note that χ_U is a quasi-compact object of $\mathcal{X}$ if and only if U is quasi-compact as a topological space. If $\mathcal{S}\mathrm{hv}(X)$ is 1-coherent, then the collection of quasi-compact objects of $\mathcal{S}\mathrm{hv}(X)$ are closed under products. Since the construction $U \mapsto \chi_U$ carries finite intersections to finite products, we conclude that the collection of quasi-compact open subsets of X is closed under finite intersections. We claim that the quasi-compact open subsets form a basis for the topology of X. To prove this, choose an arbitrary open subset $U \subseteq X$. Since $\mathcal{S}\mathrm{hv}(X)$ is 1-coherent, there exists an effective epimorphism $\theta : \amalg \mathscr{F}_i \to \chi_U$, where each $\mathscr{F}_i$ is a quasi-compact object of $\mathcal{S}\mathrm{hv}(X)$. For each index i, we have $\tau_{\leqslant -1} \mathscr{F}_i \simeq \chi_{U_i}$ for some open set $U_i \subseteq X$. It follows that θ induces an effective epimorphism $\amalg_i \chi_{U_i} \to \chi_U$, so that $U = \bigcup U_i$. We claim that each U_i is quasi-compact: equivalently, each of the sheaves χ_{U_i} is a quasi-compact object of $\mathcal{S}\mathrm{hv}(X)$. This follows from the observation that we have effective epimorphisms $\mathscr{F}_i \to \chi_{U_i}$.

We now complete the proof by showing that (3) implies (1). Assume that X is a coherent topological space. Let $\mathcal{C} \subseteq \mathcal{S}\mathrm{hv}(X)$ be the full subcategory spanned by objects of the form χ_U, where U is a quasi-compact open subset of X. Since the quasi-compact open subsets of X form a basis for the topology of X, the ∞-category $\mathcal{C}$ generates $\mathcal{S}\mathrm{hv}(X)$ under small colimits. It will therefore suffice to show that $\mathcal{C}$ consists of coherent objects of $\mathcal{S}\mathrm{hv}(X)$. We prove by induction on n that the objects of $\mathcal{C}$ are n-coherent. The case $n = 0$ is clear. Assume that the objects of $\mathcal{C}$ are known to be n-coherent for $n \geqslant 0$. We wish to prove that if $U \subseteq X$ is a quasi-compact open subset, then χ_U is $(n+1)$-coherent. According to Corollary A.2.1.4, it will suffice to show that for every pair of objects $\chi_V, \chi_{V'} \in \mathcal{C}$, every fiber product $\chi_V \times_{\chi_U} \chi_{V'}$ is n-coherent. Unwinding the definitions, this is equivalent to the statement that $V \cap V'$ is quasi-compact, which follows from our assumption that the quasi-compact open subsets of X are closed under finite intersections. □

Proposition 2.3.4.2. *Let $(X, \mathscr{O}_X)$ be a spectral scheme and let $(\mathcal{X}, \mathscr{O}_{\mathcal{X}}) = \mathrm{Spec}^{\acute{e}t}_{\mathrm{Zar}}(X, \mathscr{O}_X)$ be the associated schematic spectral Deligne-Mumford stack. Then:*

(1) *The spectral Deligne-Mumford stack $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is quasi-compact if and only if the topological space X is quasi-compact.*

(2) *For $1 \leqslant n \leqslant \infty$, the spectral Deligne-Mumford stack $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is n-quasi-compact if and only if X is quasi-compact and quasi-separated.*

Proof. Assertion (1) and the "only if" direction of (2) follow immediately from Lemma **??**. To prove the converse, we prove by induction on $n > 0$ that if X is quasi-compact and quasi-separated, then $\mathcal{X}$ is n-coherent. To carry out the inductive step, it will suffice to show that for every pullback diagram

$$\begin{array}{ccc} (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}) & \longrightarrow & \operatorname{Sp\acute{e}t} A \\ \downarrow & & \downarrow u \\ \operatorname{Sp\acute{e}t} B & \xrightarrow{v} & (\mathcal{X}, \mathscr{O}_{\mathcal{Y}}), \end{array}$$

the spectral Deligne-Mumford stack $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ is $(n-1)$-quasi-compact (Proposition 2.3.2.6). By virtue of Corollary **??**, the maps u and v are induced by maps of spectral schemes $u_0 : \operatorname{Spec} A \to (X, \mathscr{O}_X)$ and $v_0 : \operatorname{Spec} B \to (X, \mathscr{O}_X)$. It follows that we can write $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}) \simeq \operatorname{Spec}^{\text{ét}}_{\text{Zar}}(Y, \mathscr{O}_Y)$, where $(Y, \mathscr{O}_Y)$ denotes the fiber product $\operatorname{Spec} A \times_{(X, \mathscr{O}_X)} \operatorname{Spec} B$ in the ∞-category of spectral schemes. We then have a pullback diagram of ordinary schemes

$$\begin{array}{ccc} (Y, \pi_0 \mathscr{O}_Y) & \longrightarrow & \operatorname{Spec} \pi_0 A \\ \downarrow & & \downarrow \\ \operatorname{Spec} \pi_0 B & \longrightarrow & (X, \pi_0 \mathscr{O}_X). \end{array}$$

Since X is quasi-compact and quasi-separated, Y is also quasi-compact and quasi-separated. Applying the inductive hypothesis (or part (1), if $n = 1$), we conclude that $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ is $(n-1)$-quasi-compact as desired. □

2.3.5 Transitivity Properties of Quasi-Compactness

We now discuss the closure of n-quasi-compact morphisms under composition.

Proposition 2.3.5.1. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of nonconnective spectral Deligne-Mumford stacks and let $0 \leqslant n \leqslant \infty$. Then:*

(1) *If Y is n-quasi-compact and f is n-quasi-compact, then X is n-quasi-compact.*

(2) *If X is n-quasi-compact and Y is $(n+1)$-quasi-compact, then f is n-quasi-compact.*

Proof. We proceed by induction on n. We begin with assertion (1). Assume that f and Y are n-quasi-compact; we wish to prove that X is n-quasi-compact. Choose an étale surjection $\operatorname{Sp\acute{e}t} R \to \mathsf{Y}$. Then the fiber product $\mathsf{X}' = \operatorname{Sp\acute{e}t} R \times_{\mathsf{Y}} \mathsf{X}$ is n-coherent. We have an étale surjection $\mathsf{X}' \to \mathsf{X}$, so that X is quasi-compact. This completes the proof when $n = 0$. Assume now that $n > 0$. By virtue of Proposition 2.3.2.6, it will suffice to show that every map $\operatorname{Sp\acute{e}t} A \to \mathsf{X}$ is $(n-1)$-quasi-compact. Using Proposition 2.3.3.1, we are reduced to showing that the induced map

$$u : \operatorname{Sp\acute{e}t} R \times_{\mathsf{Y}} \operatorname{Sp\acute{e}t} A \to \mathsf{X}'$$

is $(n-1)$-quasi-compact. Since X' is n-quasi-compact and $\mathrm{Sp\acute{e}t}\, R \times_{\mathsf{Y}} \mathrm{Sp\acute{e}t}\, A$ is $(n-1)$-quasi-compact (using Proposition 2.3.2.6 and the n-quasi-compact of Y), the $(n-1)$-quasi-compactness of u follows from the inductive hypothesis.

We now prove (2). Assume that X is n-quasi-compact and that Y is $(n+1)$-quasi-compact. We wish to show that for every map $\mathrm{Sp\acute{e}t}\, R \to \mathsf{Y}$, the fiber product $\mathsf{X}' = \mathrm{Sp\acute{e}t}\, R \times_{\mathsf{Y}} \mathsf{X}$ is n-quasi-compact. By (1), it will suffice to show that the projection map $\mathsf{X}' \to \mathsf{X}$ is n-quasi-compact. This follows from Proposition 2.3.3.1, since the map $\mathrm{Sp\acute{e}t}\, R \to \mathsf{Y}$ is n-quasi-compact by Corollary 2.3.2.4. □

Corollary 2.3.5.2. *Suppose we are given maps $f : \mathsf{X} \to \mathsf{Y}$ and $g : \mathsf{Y} \to \mathsf{Z}$ of nonconnective spectral Deligne-Mumford stacks. Then:*

(i) If f and g are n-quasi-compact, then $g \circ f$ is n-quasi-compact.

(ii) If g is $(n+1)$-quasi-compact and $g \circ f$ is n-quasi-compact, then f is n-quasi-compact.

Corollary 2.3.5.3. *Let Z be a quasi-compact nonconnective spectral Deligne-Mumford stack and let $n \geqslant 0$. Then Z is $(n+1)$-quasi-compact if and only if the following condition is satisfied: for every pair of maps $\mathsf{X} \to \mathsf{Z} \leftarrow \mathsf{Y}$ where X and Y are n-quasi-compact, the fiber product $\mathsf{X} \times_{\mathsf{Z}} \mathsf{Y}$ is n-quasi-compact.*

Proof. The "if" direction follows immediately from Proposition 2.3.2.6 (take X and Y to be affine). Conversely, suppose that Z is $(n+1)$-quasi-compact. If X is n-quasi-compact, then the map $\mathsf{X} \to \mathsf{Z}$ is n-quasi-compact. It follows from Proposition 2.3.3.1 that the projection map $\mathsf{X} \times_{\mathsf{Z}} \mathsf{Y} \to \mathsf{Y}$ is n-quasi-compact. Since Y is also n-quasi-compact, Proposition 2.3.5.1 implies that $\mathsf{X} \times_{\mathsf{Z}} \mathsf{Y}$ is n-quasi-compact. □

Corollary 2.3.5.4. *The collection of ∞-quasi-compact nonconnective spectral Deligne-Mumford stacks is closed under the formation of fiber products.*

2.4 Quasi-Affine Spectral Deligne-Mumford Stacks

Recall that a scheme X is said to be *quasi-affine* if it is quasi-compact and there exists an open immersion $j : X \hookrightarrow Y$, where Y is an affine scheme. In this section, we will study the analogous condition in the setting of spectral Deligne-Mumford stacks. Our main results are that quasi-affine spectral Deligne-Mumford stacks behave, in many respects, as if they were affine:

(a) If $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is a quasi-affine spectral Deligne-Mumford stack, then X can be functorially recovered from the $\mathbb{E}_\infty$-ring $\Gamma(\mathcal{X}; \mathcal{O}_{\mathcal{X}})$ of global sections of its structure sheaf (Corollary 2.4.2.2).

(b) If $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is a quasi-affine spectral Deligne-Mumford stack and $\mathscr{F}$ is a quasi-coherent sheaf on $\mathcal{X}$, then $\mathscr{F}$ can be functorially recovered from its spectrum of global sections $\Gamma(\mathcal{X}; \mathscr{F})$, regarded as a module over the $\mathbb{E}_\infty$-ring $\Gamma(\mathcal{X}; \mathcal{O}_{\mathcal{X}})$ (Proposition 2.4.1.4).

2.4.1 The Nonconnective Case

We with a study of quasi-affine objects in the setting of nonconnective spectral Deligne-Mumford stacks.

Definition 2.4.1.1. Let X be a nonconnective spectral Deligne-Mumford stack. We say that X is *quasi-affine* if X is quasi-compact and there exists an open immersion $j : \mathsf{X} \hookrightarrow \operatorname{Sp\acute{e}t} R$ for some $\mathbb{E}_\infty$-ring R (see Definition 1.6.7.2).

Remark 2.4.1.2. Let X be a nonconnective spectral Deligne-Mumford stack. If X is quasi-affine, then it is schematic.

Suppose that X is a quasi-affine nonconnective spectral Deligne-Mumford stack. Then there exists an open immersion $j : \mathsf{X} \to \mathsf{X}'$, where X' is affine. The following pair of results asserts that there is a canonical choice of X', for which the ∞-categories $\operatorname{QCoh}(\mathsf{X})$ and $\operatorname{QCoh}(\mathsf{X}')$ are equivalent.

Proposition 2.4.1.3. *Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a quasi-compact nonconnective spectral Deligne-Mumford stack. The following conditions are equivalent:*

(1) *The nonconnective spectral Deligne-Mumford stack X is quasi-affine.*

(2) *The canonical map $\mathsf{X} \to \operatorname{Sp\acute{e}t} \Gamma(\mathcal{X}; \mathcal{O}_{\mathcal{X}})$ is an open immersion.*

Proposition 2.4.1.4. *Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a quasi-affine nonconnective spectral Deligne-Mumford stack. The global sections functor $\mathscr{F} \mapsto \Gamma(\mathcal{X}; \mathscr{F})$ induces an equivalence of ∞-categories $e : \operatorname{QCoh}(\mathsf{X}) \to \operatorname{Mod}_{\Gamma(\mathcal{X}; \mathcal{O}_{\mathcal{X}})}$.*

The proofs of Propositions 2.4.1.3 and 2.4.1.4 depend on the following technical result:

Proposition 2.4.1.5. *Let X be a quasi-compact nonconnective spectral Deligne-Mumford stack and let $j : \mathsf{X} \to \operatorname{Sp\acute{e}t} R$ be an open immersion. Then:*

(1) *The global sections functor $\Gamma : \operatorname{QCoh}(\mathsf{X}) \to \operatorname{Mod}_R$ commutes with small colimits.*

(2) *Suppose that R is connective. Then there exists an integer n such that $\Gamma(\operatorname{QCoh}(\mathsf{X})_{\geqslant 0}) \subseteq (\operatorname{Mod}_R)_{\geqslant -n}$.*

(3) *Suppose we are given a pullback diagram of nonconnective spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \xrightarrow{j'} & \operatorname{Sp\acute{e}t} R' \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{X} & \xrightarrow{j} & \operatorname{Sp\acute{e}t} R. \end{array}$$

Then the associated diagram of ∞-categories

$$\begin{array}{ccc} \operatorname{Mod}_R & \xrightarrow{j^*} & \operatorname{QCoh}(\mathsf{X}) \\ \downarrow & & \downarrow \\ \operatorname{Mod}_{R'} & \xrightarrow{j'^*} & \operatorname{QCoh}(\mathsf{X}') \end{array}$$

is right adjointable.

Corollary 2.4.1.6. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a quasi-compact nonconnective spectral Deligne-Mumford stack and let $j : \mathsf{X} \to \operatorname{Spét} R$ be an open immersion. Then the global sections functor $\Gamma : \operatorname{QCoh}(\mathsf{X}) \to \operatorname{Mod}_R$ is fully faithful.*

Proof. Let $j^* : \operatorname{Mod}_R \to \operatorname{QCoh}(\mathsf{X})$ denote a left adjoint to Γ and let $\mathscr{F} \in \operatorname{QCoh}(\mathsf{X})$; we will show that the counit map $j^*\Gamma(\mathcal{X}; \mathscr{F}) \to \mathscr{F}$ is an equivalence. The open immersion j is determined by an open subset $U \subseteq |\operatorname{Spec} R|$. Write U as a union $\bigcup_{1 \leqslant i \leqslant n} U_i$, where each U_i is the open subset given by $|\operatorname{Spec} R[x_i^{-1}]|$ for some $x_i \in \pi_0 R$. For $1 \leqslant i \leqslant n$, let $g_i : \mathsf{U}_i \to \mathsf{X}$ be the open immersion determined by the inclusion $U_i \subseteq U$. It will therefore suffice to show that each of the induced maps $\theta_i : (j \circ g_i)^* \Gamma(\mathcal{X}; \mathscr{F}) \to g_i^* \Gamma(\mathcal{X}; \mathscr{F})$ is an equivalence. This follows immediately from Proposition 2.4.1.5, since the projection map $\mathsf{U}_i \times_{\operatorname{Spét} R} \mathsf{X} \to \mathsf{U}_i$ is an equivalence. □

Proof of Proposition 2.4.1.3. The implication (2) ⇒ (1) is obvious. We will show that (1) ⇒ (2). Assume therefore that there exists an open immersion $j : \mathsf{X} \to \operatorname{Spét} R$. Set $A = \Gamma(\mathcal{X}; \mathscr{O}_{\mathcal{X}})$, so that j determines a map of $\mathbb{E}_\infty$-rings $\phi : R \to A$. Then $\mathsf{X} \times_{\operatorname{Spét} R} \operatorname{Spét} A$ is an open substack of $\operatorname{Spét} A$. We will complete the proof by showing that the projection map $p : \mathsf{X} \times_{\operatorname{Spét} R} \operatorname{Spét} A \to \mathsf{X}$ is an equivalence. The map j determines an open subset U of the Zariski spectrum $|\operatorname{Spec} R|$. Since X is quasi-compact, this open subset can be written as a union $\bigcup_{1 \leqslant i \leqslant n} |\operatorname{Spec} R[x_i^{-1}]|$ for some elements $x_i \in \pi_0 R$. To show that p is an equivalence, it will suffice to show that each of the induced projection maps

$$p_i : \operatorname{Spét} R[x_i^{-1}] \times_{\operatorname{Spét} R} \operatorname{Spét} A \to \operatorname{Spét} R[x_i^{-1}]$$

is an equivalence.

Let $x = x_i$. We wish to prove that the map $\theta : R[x^{-1}] \to R[x^{-1}] \otimes_R A$ is an equivalence of $\mathbb{E}_\infty$-rings. Let $\mathcal{O}'$ denote the structure sheaf of $\operatorname{Spét} R$. For every open subset $V \subseteq |\operatorname{Spec} R|$, let V_0 denote the intersection of V with the open set $|\operatorname{Spec} R[x^{-1}]|$, and let f_V denote the canonical map $R[x^{-1}] \otimes_R \mathcal{O}'(V) \to \mathcal{O}'(V_0)$. We note that f_U is left inverse to θ. It will therefore suffice to show that f_U is an equivalence, which is a special case of Proposition 2.4.1.5. $\square$

Proof of Proposition 2.4.1.4. Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_\mathcal{X})$ be a quasi-affine nonconnective spectral Deligne-Mumford stack. Proposition 2.4.1.3 implies that the map $j : \mathsf{X} \to \operatorname{Spét} \Gamma(\mathcal{X}; \mathcal{O}_\mathcal{X})$ is an open immersion, so that the global sections functor $\Gamma : \operatorname{QCoh}(\mathsf{X}) \to \operatorname{Mod}_{\Gamma(\mathcal{X};\mathcal{O}_\mathcal{X})}$ is fully faithful by Corollary 2.4.1.6. Consequently, to prove that Γ is an equivalence of ∞-categories, it will suffice to show that the unit map $u_M : M \to \Gamma(\mathcal{X}; j^* M)$ is an equivalence for every A-module M. Since Γ commutes with small colimits (Proposition 2.4.1.5), the collection of those A-modules M for which u_M is an equivalence is closed under small colimits. It will therefore suffice to show that u_M is an equivalence in the case where M has the form $\Sigma^n \Gamma(\mathcal{X}; \mathcal{O}_\mathcal{X})$, for some integer n. We may easily reduce to the case $n = 0$, in which case the desired result is a tautology. $\square$

Proof of Proposition 2.4.1.5. The open immersion j is determined by an open subset $U \subseteq |\operatorname{Spec} R|$. For every open subset $V \subseteq U$, let $\Gamma_V : \operatorname{QCoh}(\mathsf{X}) \to \operatorname{Mod}_R$ be the functor given by evaluation at V (which we can identify with a (-1)-truncated object of the underlying ∞-topos $\mathcal{X}$ of X). Given a pair of open sets $V', V'' \subseteq U$, we obtain a pullback diagram of functors σ:

$$\begin{array}{ccc} \Gamma_{V' \cup V''} & \longrightarrow & \Gamma_{V''} \\ \downarrow & & \downarrow \\ \Gamma_{V'} & \longrightarrow & \Gamma_{V' \cap V''}. \end{array}$$

To prove (1), it will suffice to show that for every quasi-compact open subset $V \subseteq U$, the functor Γ_V commutes with filtered colimits. Since V is quasi-compact, we can write V as a union $\bigcup_{1 \leqslant i \leqslant n} V_i$ where each $V_i \subseteq |\operatorname{Spec} R|$ is given by $|\operatorname{Spec} R[x_i^{-1}]|$ for some $x_i \in \pi_0 R$. We proceed by induction on n. If $n = 0$, then V is empty and the result is obvious. If $n > 0$, we let $V' = V_1$ and $V'' = \bigcup_{1 < i \leqslant n} V_i$ so that $V = V' \cup V''$. The inductive hypothesis implies that $\Gamma_{V''}$ and $\Gamma_{V' \cap V''}$ commute with filtered colimits. Using the pullback diagram σ, we are reduced to proving that $\Gamma_{V'}$ commutes with filtered colimits. This is clear, since $\Gamma_{V'}$ is given by the composition

$$\operatorname{QCoh}(\mathsf{X}) \to \operatorname{QCoh}(\operatorname{Spét} R[x_1^{-1}]) \simeq \operatorname{Mod}_{R[x_1^{-1}]} \to \operatorname{Mod}_R .$$

We now prove (2). Assume that R is connective. We will show that if $V \subseteq U$ is an open subset which can be written as a union $\bigcup_{1 \leqslant i \leqslant n} V_i$, where each V_i is of the form $|\operatorname{Spec} R[x_i^{-1}]|$, then Γ_V carries $\mathrm{QCoh}(\mathsf{X})_{\geqslant 0}$ to $(\mathrm{Mod}_R)_{\geqslant 1-n}$. We proceed by induction on n. In the case $n = 0$, $V = \varnothing$ and there is nothing to prove. Assume therefore that $n > 0$ and define subsets $V', V'' \subseteq V$ as above. If $M \in \mathrm{QCoh}(\mathsf{X})_{\geqslant 0}$, then the pullback diagram σ gives a fiber sequence

$$\Gamma_V(M) \to \Gamma_{V'}(M) \oplus \Gamma_{V''}(M) \to \Gamma_{V' \cap V''}(M)$$

and therefore an exact sequence of abelian groups

$$\pi_{m+1}\Gamma_{V' \cap V''}(M) \to \pi_m \Gamma_V(M) \to \pi_m \Gamma_{V'}(M) \oplus \pi_m \Gamma_{V''}(M).$$

The functor $\Gamma_{V'}$ is given by the composition

$$\mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R[x_1^{-1}]) \simeq \mathrm{Mod}_{R[x_1^{-1}]} \to \mathrm{Mod}_R\,.$$

and is therefore t-exact. Using the inductive hypothesis, we deduce that if $m \leqslant -n$, then

$$\pi_{m+1}\Gamma_{V' \cap V''}(M) \simeq \pi_m \Gamma_{V''}(M) \simeq 0,$$

from which it follows that $\pi_m \Gamma_V(M) \simeq 0$.

We now prove (3). Let $\pi : |\operatorname{Spec} R'| \to |\operatorname{Spec} R|$ be the continuous map of topological spaces induced by the map of $\mathbb{E}_\infty$-rings $R \to R'$. For every open set $V \subseteq U$, let $\Gamma_{\pi^{-1}V} : \mathrm{QCoh}(\mathsf{X}') \to \mathrm{Mod}_{R'}$ be defined as above. Let us say that an open subset $V \subseteq U$ is *good* if the canonical map $R' \otimes_R \Gamma_V \to \Gamma_{\pi^{-1}V}$ is an equivalence of functors from $\mathrm{QCoh}(\mathsf{X})$ to $\mathrm{Mod}_{R'}$. Note that if $V', V'' \subseteq U$, then the canonical map

$$\Gamma_{\pi^{-1}(V' \cup V'')} \to \Gamma_{\pi^{-1}(V')} \times_{\Gamma_{\pi^{-1}(V' \cap V'')}} \Gamma_{\pi^{-1}(V'')}$$

is an equivalence. It follows that if V', V'', and $V' \cap V''$ are good, then $V' \cup V''$ is good. We will prove that every quasi-compact open subset $V \subseteq U$ is good. Write $V = \bigcup_{1 \leqslant i \leqslant n} V_i$ as above; we proceed by induction on n. When $n = 0$, $V = \varnothing$ and there is nothing to prove. If $n > 0$, we define $V', V'' \subseteq V$ as above, so that V'' and $V' \cap V''$ are good by the inductive hypothesis. We may therefore replace V by V' and thereby reduce to the case $\mathsf{X}_V = \mathrm{Sp\acute{e}t}\, R[x_1^{-1}]$, in which case the desired result follows from Lemma D.3.5.6. □

2.4.2 The Connective Case

Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a quasi-affine spectral Deligne-Mumford stack and let $A = \Gamma(\mathcal{X}; \mathscr{O}_{\mathcal{X}})$. Then the canonical map $j : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, A$ is an open immersion (Proposition 2.4.1.3). However, A is usually not connective:

Proposition 2.4.2.1. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a quasi-affine spectral Deligne-Mumford stack. If $A = \Gamma(\mathcal{X}; \mathscr{O}_{\mathcal{X}})$ is connective, then X is affine.*

Proof. The open immersion $j : \mathsf{X} \hookrightarrow \operatorname{Spét} A$ of Proposition 2.4.1.3 determines a quasi-compact open subset $U \subseteq |\operatorname{Spec} A|$, consisting of those prime ideals which fail to contain some finitely generated ideal $I = (x_1, \ldots, x_n) \subseteq \pi_0 A$. Let $M = (\pi_0 A)/I$, which we regard as a discrete A-module. Then $M[x_i^{-1}] \simeq 0$ for $1 \leqslant i \leqslant n$, so that M is annihilated by the pullback functor $\operatorname{Mod}_A \simeq \operatorname{QCoh}(\operatorname{Spét} A) \xrightarrow{j^*} \operatorname{QCoh}(\mathsf{X})$. Proposition 2.4.1.4 implies that the pullback functor j^* is an equivalence of ∞-categories, so that $M \simeq 0$. It follows that I is the unit ideal in $\pi_0 A$, so that j is an equivalence. □

Corollary 2.4.2.2. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a quasi-affine nonconnective spectral Deligne-Mumford stack, let $A = \Gamma(\mathcal{X}; \mathscr{O}_{\mathcal{X}})$, and let $j : \mathsf{X} \to \operatorname{Spét} A$ be the open immersion of Proposition 2.4.1.3. For every spectral Deligne-Mumford stack Y, composition with j induces a homotopy equivalence*

$$\theta : \operatorname{Map}_{\operatorname{SpDM}^{\mathrm{nc}}}(\mathsf{Y}, \mathsf{X}) \to \operatorname{Map}_{\operatorname{SpDM}^{\mathrm{nc}}}(\mathsf{Y}, \operatorname{Spét} A).$$

Proof. The assertion is local on Y; we may therefore assume that Y is affine, so that $\mathsf{Y} \simeq \operatorname{Spét} R$ for some connective $\mathbb{E}_\infty$-ring R. Since j is an open immersion, the map θ exhibits $\operatorname{Map}_{\operatorname{SpDM}}(\mathsf{Y}, \mathsf{X})$ as a summand of $\operatorname{Map}_{\operatorname{SpDM}}(\mathsf{Y}, \operatorname{Spét} A)$. It will therefore suffice to show that every map $f : \operatorname{Spét} R \to \operatorname{Spét} A$ factors through j. Form a pullback diagram

$$\begin{array}{ccc} (\mathcal{X}', \mathscr{O}_{\mathcal{X}'}) & \xrightarrow{j'} & \operatorname{Spét} R \\ \downarrow & & \downarrow \\ \mathsf{X} & \longrightarrow & \operatorname{Spét} A \end{array}$$

so that j' is an open immersion. Since $A \simeq \Gamma(\mathcal{X}; \mathscr{O}_{\mathcal{X}})$, Proposition 2.4.1.5 implies that the induced map $R \to \Gamma(\mathcal{X}'; \mathscr{O}_{\mathcal{X}'})$ is an equivalence. Since R is connective, it follows from Proposition 2.4.2.1 that j' is an equivalence. □

In spite of Proposition 2.4.2.1, every quasi-affine spectral Deligne-Mumford stack admits an open immersion into the spectrum of a *connective* $\mathbb{E}_\infty$-ring:

Proposition 2.4.2.3. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack. The following conditions are equivalent:*

(1) *There exists a connective $\mathbb{E}_\infty$-ring R and an open immersion $j : \mathsf{X} \to \operatorname{Spét} R$.*

(2) *The spectral Deligne-Mumford stack X is quasi-affine.*

(3) *The discrete spectral Deligne-Mumford stack $(\mathcal{X}, \pi_0 \mathscr{O}_{\mathcal{X}})$ is quasi-affine.*

Proof. The implication (1) ⇒ (2) is obvious. To prove (2) ⇒ (3), we note that if $j : \mathsf{X} \to \operatorname{Spét} R$ is an open immersion, then j induces an open immersion $(\mathcal{X}, \pi_0 \mathscr{O}_{\mathcal{X}}) \to \operatorname{Spét}(\pi_0 R)$.

It remains to prove that (3) ⇒ (1). For each $i \geqslant 0$, we let R_i denote the $\mathbb{E}_\infty$-ring $\Gamma(\mathcal{X}; \tau_{\leqslant i} \mathscr{O}_{\mathcal{X}})$, and let $R = \Gamma(\mathcal{X}; \mathscr{O}_{\mathcal{X}}) \simeq \varprojlim_i R_i$. Applying Proposition 2.4.1.5 to the quasi-affine spectral Deligne-Mumford stack $(\mathcal{X}, \pi_0 \mathscr{O}_{\mathcal{X}})$, we deduce that there exists an integer n such that $\Gamma(\mathcal{X}; \mathscr{F}) \in \mathrm{Sp}_{\geqslant -n}$ whenever $\mathscr{F}$ belongs to the heart of $\operatorname{QCoh}(\mathsf{X})$. The fiber sequence

$$\Sigma^m(\pi_m \mathscr{O}_{\mathcal{X}}) \to \tau_{\leqslant m} \mathscr{O}_{\mathcal{X}} \to \tau_{\leqslant m-1} \mathscr{O}_{\mathcal{X}}$$

yields a fiber sequence of spectra

$$\Sigma^m \Gamma(\mathcal{X}; \pi_m \mathscr{O}_{\mathcal{X}}) \to R_m \to R_{m-1}$$

so that the map $\pi_i R_m \to \pi_i R_{m-1}$ is an isomorphism for $m > n + i$. It follows that each of the maps $\pi_i R \to \pi_i R_{n+i}$ is an isomorphism.

Since condition (3) is satisfied, Proposition 2.4.1.3 implies that the canonical map $j_0 : (\mathcal{X}, \pi_0 \mathscr{O}_{\mathcal{X}}) \to \operatorname{Spét} R_0$ is an open immersion, corresponding to some quasi-compact open subset $U \subseteq |\operatorname{Spec} R_0|$. For each $x \in \pi_0 R_0$, let $U_x = \{\mathfrak{p} \in |\operatorname{Spec} R_0| : x \notin \mathfrak{p}\}$. We next prove the following:

(∗) Let x be an element of $\pi_0 R_0$ such that $U_x \subseteq U$. Then there exists an integer $m > 0$ such that x^m can be lifted to an element of $\pi_0 R$.

For every pair of integers $i \leqslant i'$, let $\phi_{i',i} : \pi_0 R_{i'} \to \pi_0 R_i$ be the canonical map. To prove (∗), we show that for each $i \geqslant 0$, some positive power x^m of x lies in the image of the map $\phi_{i,0} : \pi_0 R_i \to \pi_0 R_0$. Since $\pi_0 R \simeq \pi_0 R_n$, (∗) will follow if we prove this in the case $i = n$. We proceed by induction on i, the case $i = 0$ being trivial. Assume therefore that there exists an integer $m > 0$ such that $x^m = \phi_{i,0}(y)$ for some $y \in \pi_0 R_i$. We will prove that some positive power of y lies in the image of the map $\phi_{i+1,i}$. Using Theorem HA.7.4.1.26 , we deduce that $\tau_{\leqslant i+1} \mathscr{O}_{\mathcal{X}}$ is a square-zero extension of $\tau_{\leqslant i} \mathscr{O}_{\mathcal{X}}$ by the module $\Sigma^{i+1}(\pi_{i+1} \mathscr{O}_{\mathcal{X}})$. It follows that R_{i+1} is a square-zero extension of R_i by the module $\Gamma(\mathcal{X}; \Sigma^{i+1} \pi_{i+1} \mathscr{O}_{\mathcal{X}})$. In particular, the image of the map $\phi_{i+1,i}$ is the kernel of a derivation $d : \pi_0 R_i \to \pi_{-i-2} \Gamma(\mathcal{X}; \pi_{i+1} \mathscr{O}_{\mathcal{X}})$. We wish to prove that $d(y^{m'}) = 0$ for some $m' > 0$. Since d is a derivation, we have $d(y^{m'}) = m' y^{m'-1} dy$. It will therefore suffice to show that $dy \in \pi_{-i-2} \Gamma(\mathcal{X}; \pi_{i+1} \mathscr{O}_{\mathcal{X}})$ is annihilated by some power of y. Note that $\Gamma(\mathcal{X}; \pi_{i+1} \mathscr{O}_{\mathcal{X}})$ has the structure of a module over R_0. Moreover, Corollary 2.4.1.6 implies that $j_0^* \Gamma(\mathcal{X}; \pi_{i+1} \mathscr{O}_{\mathcal{X}})$ is equivalent to $\pi_{i+1} \mathscr{O}_{\mathcal{X}}$, which a discrete sheaf of spectra on $\mathcal{X}$. Since $U_x \subseteq U$, we deduce that $\Gamma(\mathcal{X}; \pi_{i+1} \mathscr{O}_{\mathcal{X}})[x^{-1}]$ is discrete. Since $i + 2 \neq 0$, it follows that every element of $\pi_{-i-2} \Gamma(\mathcal{X}; \pi_{i+1} \mathscr{O}_{\mathcal{X}})$ is annihilated by a power of x, and therefore by a power of y. This completes the proof of (∗).

Write U as a union of open sets $\bigcup_{1 \leqslant i \leqslant n} U_{x_i}$ for some elements $x_i \in \pi_0 R_0$. Using (∗), we may assume without loss of generality that each x_i is the image of some element $y_i \in \pi_0 R$.

For $1 \leqslant i \leqslant n$, let V_i denote the open subset $\{\mathfrak{p} \in |\operatorname{Spec} R| : y_i \notin \mathfrak{p}\}$, and let $V = \bigcup_{1 \leqslant i \leqslant n} V_i$. Let V denote the open substack of $\operatorname{Spét} R$ corresponding to V, and for $1 \leqslant i \leqslant n$ let V_i denote the open substack of V corresponding to V_i. Since V is the inverse image of U in $|\operatorname{Spec} R|$, the canonical map $j : \mathsf{X} \to \operatorname{Spét} R$ factors through V. We claim that j induces an equivalence $\mathsf{X} \to \mathsf{V}$. To prove this, it suffices to show that each of the induced maps $\mathsf{X} \times_{\mathsf{V}} \mathsf{V}_i \to \mathsf{V}_i$ is an equivalence. By virtue of Proposition 2.4.1.5, this is equivalent to the assertion that $\mathsf{X} \times$ is affine. This follows from Remark ??, since the 0-truncation of $\mathsf{X} \times_{\mathsf{V}} \mathsf{V}_i$ is given by $\operatorname{Spét} R_0[x_i^{-1}]$. □

2.4.3 Descent

Let X be a quasi-affine spectral Deligne-Mumford stack. Combining Corollary 2.4.2.2 with Theorem D.6.3.5, we deduce that the functor $R \mapsto \operatorname{Map}_{\operatorname{SpDM}}(\operatorname{Spét} R, \mathsf{X})$ is a hypercomplete sheaf with respect to the flat topology on $\operatorname{CAlg}^{\operatorname{cn}}$. In fact, we have the following stronger assertion:

Proposition 2.4.3.1. *Let X be quasi-affine nonconnective spectral Deligne-Mumford stack, and let $h_{\mathsf{X}} = h_{\mathsf{X}}^{\mathrm{nc},\acute{e}t}$ denote the functor of points of X (see Definition ??). Then h_{X} is a hypercomplete sheaf with respect to the flat topology on* CAlg*.*

Proof. Choose an open immersion $j : \mathsf{X} \hookrightarrow \operatorname{Spét} A$, for some $\mathbb{E}_\infty$-ring A. It follows from Theorem D.6.3.5 that the functor

$$R \mapsto \operatorname{Map}_{\operatorname{SpDM}^{\mathrm{nc}}}(\operatorname{Spét} R, \operatorname{Spét} A) \simeq \operatorname{Map}_{\operatorname{CAlg}}(A, R)$$

is a hypercomplete sheaf with respect to the flat topology on CAlg. According to Lemma D.4.3.2, it will suffice to show that for every map $\eta : \operatorname{Spét} R \to \operatorname{Spét} A$, the fiber product $\mathsf{X}' = \mathsf{X} \times_{\operatorname{Spét} A} \operatorname{Spét} R$ represents a hypercomplete sheaf with respect to the flat topology on CAlg_R. We can identify X' with an open substack of $\operatorname{Spét} R$, classified by an open set $U \subseteq |\operatorname{Spec} R|$. Unwinding the definitions, we are reduced to showing that if $\phi : B \to B'$ is a faithfully flat morphism in CAlg_R such that the map $|\operatorname{Spec} B'| \to |\operatorname{Spec} R|$ factors through U, then $|\operatorname{Spec} B| \to |\operatorname{Spec} R|$ also factors through U. This is clear, since the map $|\operatorname{Spec} B'| \to |\operatorname{Spec} B|$ is a surjection. □

In fact, we can prove an even stronger version of Proposition 2.4.3.1. For every $\mathbb{E}_\infty$-ring R, let $\operatorname{SpDM}^{\mathrm{nc}}_R$ denote the ∞-category $\operatorname{SpDM}^{\mathrm{nc}}_{/\operatorname{Spét} R}$ of nonconnective spectral Deligne-Mumford stacks X equipped with a map $f : \mathsf{X} \to \operatorname{Spét} R$. Let $\operatorname{QAff}^{\mathrm{nc}}_R$ denote the full subcategory of $\operatorname{SpDM}^{\mathrm{nc}}_R$ spanned by those maps $f : \mathsf{X} \to \operatorname{Spét} R$ where X is quasi-affine. If R is connective, we let QAff_R denote the full subcategory of $\operatorname{QAff}^{\mathrm{nc}}_R$ spanned by those morphisms where X is a spectral Deligne-Mumford stack.

Proposition 2.4.3.2 (Effective Descent for Quasi-Affine Morphisms)**.** *The functor $R \mapsto \mathrm{QAff}^{\mathrm{nc}}_R$, is a hypercomplete sheaf (with values in $\widehat{\mathcal{C}\mathrm{at}}_\infty$) with respect to the flat topology on* CAlg*. The functor $R \mapsto \mathrm{QAff}_R$ is a hypercomplete sheaf with respect to the flat topology on* $\mathrm{CAlg}^{\mathrm{cn}}$.

Proof. For every $\mathbb{E}_\infty$-ring R, let $\mathrm{Aff}^{\mathrm{nc}}_R$ denote the full subcategory of $\mathrm{SpDM}^{\mathrm{nc}}_R$ spanned by those morphisms $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ where X is an affine nonconnective spectral Deligne-Mumford stack. We have an equivalence of ∞-categories $(\mathrm{Aff}^{\mathrm{nc}}_R)^{\mathrm{op}} \simeq \mathrm{CAlg}^{\mathrm{op}}_R$. Using Corollary D.6.3.3, we deduce that the functor $R \mapsto \mathrm{Aff}^{\mathrm{nc}}_R$ is a hypercomplete sheaf with respect to the flat topology.

For every $\mathbb{E}_\infty$-ring R, let $Y(R)$ denote the full subcategory of $\mathrm{Fun}(\Delta^1, \mathrm{SpDM}^{\mathrm{nc}}_R)$ spanned by those morphisms $f : \mathsf{U} \to \mathsf{X}$, where U is affine and f is an open immersion. Let us regard Y as a functor $\mathrm{CAlg} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$. We claim that Y is a hypercomplete sheaf with respect to the flat topology. Evaluation at $\{1\} \subseteq \Delta^1$ determines a map $Y(R) \to \mathrm{Aff}^{\mathrm{nc}}_R$, depending functorially on R. Using Lemma D.4.3.2, we are reduced to verifying the following assertion:

- $(*)$ Let R be an $\mathbb{E}_\infty$-ring, let $f : \mathrm{Sp\acute{e}t}\, A \to \mathrm{Sp\acute{e}t}\, R$ be a map of affine spectral Deligne-Mumford stacks, and let $F : \mathrm{CAlg}_R \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ be the functor which assigns to each R-algebra R' the ∞-category of open substacks of $\mathrm{Sp\acute{e}t}\, R' \times_{\mathrm{Sp\acute{e}t}\, R} \mathrm{Sp\acute{e}t}\, A$. Then F is a hypercomplete sheaf with respect to the flat topology.

This follows easily from Proposition 1.6.2.2.

For every $\mathbb{E}_\infty$-ring R, let $Y'(R)$ denote the full subcategory of $Y(R)$ spanned by those morphisms $f : \mathsf{U} \to \mathsf{X}$ where U is quasi-compact. Let us regard Y' as a functor $\mathrm{CAlg} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$. We claim that Y' is a hypercomplete sheaf with respect to the flat topology. Since Y is a sheaf with respect to the flat topology, we may use Lemma D.4.3.2 to reduce to proving the following concrete assertion:

- $(*')$ Let $f : A \to A'$ be a faithfully flat map of $\mathbb{E}_\infty$-rings, and let $U \subseteq |\mathrm{Spec}\, A|$ be an open subset. If the inverse image of U in $|\mathrm{Spec}\, A'|$ is quasi-compact, then U is quasi-compact.

This is clear, since the map $|\mathrm{Spec}\, A'| \to |\mathrm{Spec}\, A|$ is surjective.

For every $\mathbb{E}_\infty$-ring R, let $Y''(R)$ denote the full subcategory of $Y'(R)$ spanned by those morphisms $f : (\mathcal{U}, \mathcal{O}_{\mathcal{U}}) \to \mathrm{Sp\acute{e}t}\, A$ which induce an equivalence of $\mathbb{E}_\infty$-rings $A \to \Gamma(\mathcal{U}; \mathcal{O}_{\mathcal{U}})$. Let us regard Y'' as a functor $\mathrm{CAlg} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$. We claim that Y'' is a hypercomplete sheaf with respect to the flat topology. This follows easily from Lemma D.4.3.2 and Corollary 2.5.4.6.

Evaluation at $\{0\} \subseteq \Delta^1$ induces a functor $\phi_R : Y''(R) \to \mathrm{QAff}^{\mathrm{nc}}_R$, depending functorially on R. Proposition 2.4.1.3 implies that each of these functors is an equivalence of ∞-categories. It follows that $R \mapsto \mathrm{QAff}^{\mathrm{nc}}_R$ is a hypercomplete sheaf with respect to the flat topology on

CAlg. To prove that the functor $R \mapsto \mathrm{QAff}_R$ is a hypercomplete sheaf with respect to the flat topology on $\mathrm{CAlg}^{\mathrm{cn}}$, we invoke Lemma D.4.3.2 to reduce to the following assertion:

$(*'')$ Suppose we are given a map of nonconnective spectral Deligne-Mumford stacks $\mathsf{U} \to \mathrm{Sp\acute{e}t}\, R$. Assume that R is connective and that there exists a faithfully flat morphism $R \to R'$ such that the fiber product $\mathsf{U} \times_{\mathrm{Sp\acute{e}t}\, R} \mathrm{Sp\acute{e}t}\, R'$ is a spectral Deligne-Mumford stack. Then U is a spectral Deligne-Mumford stack (that is, its structure sheaf is connective).

This follows immediately from Example 2.8.3.8. □

2.4.4 Affine and Quasi-Affine Morphisms

We conclude this section by introducing a relative version of the notion of a quasi-affine spectral Deligne-Mumford stack.

Definition 2.4.4.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of nonconnective spectral Deligne-Mumford stacks. We will say that f is *affine* if, for every map $\mathrm{Sp\acute{e}t}\, R \to \mathsf{Y}$, the fiber product $\mathsf{X} \times_{\mathsf{Y}} \mathrm{Sp\acute{e}t}\, R$ is affine. We will say that f is *quasi-affine* if, for every map $\mathrm{Sp\acute{e}t}\, R \to \mathsf{Y}$, the fiber product $\mathsf{X} \times_{\mathsf{Y}} \mathrm{Sp\acute{e}t}\, R$ is quasi-affine.

Remark 2.4.4.2. Let $f : (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ be a morphism of spectral Deligne-Mumford stacks. Then f is affine (quasi-affine) if and only if the underlying map of 0-truncated spectral Deligne-Mumford stacks $(\mathcal{X}, \pi_0 \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}, \pi_0 \mathscr{O}_{\mathcal{Y}})$ is affine (quasi-affine); see Corollary 1.4.7.3 (Proposition 2.4.2.3).

The following assertions regarding affine and quasi-affine morphisms follow immediately from the definition:

Proposition 2.4.4.3. (1) *Any equivalence of nonconnective spectral Deligne-Mumford stacks is affine. Any affine morphism is quasi-affine.*

(2) *Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of nonconnective spectral Deligne-Mumford stacks, and suppose that Y is affine. Then f is affine (quasi-affine) if and only if X is affine (quasi-affine).*

(3) *Suppose we are given a pullback diagram of nonconnective spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y}. \end{array}$$

If f is affine (quasi-affine), then f' is affine (quasi-affine).

2.5 Pullbacks and Pushforwards of Quasi-Coherent Sheaves

Let $f : (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}) \to (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a map of spectrally ringed ∞-topoi. Combining the pushforward functor $f_* : \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{Y}) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ with restriction of scalars along the underlying map $\mathscr{O}_{\mathcal{X}} \to f_* \mathscr{O}_{\mathcal{Y}}$ of CAlg-valued sheaves on $\mathcal{X}$, we obtain a pushforward functor $f_* : \mathrm{Mod}_{\mathscr{O}_{\mathcal{Y}}} \to \mathrm{Mod}_{\mathscr{O}_{\mathcal{X}}}$. This functor admits a left adjoint $\mathrm{Mod}_{\mathscr{O}_{\mathcal{X}}} \to \mathrm{Mod}_{\mathscr{O}_{\mathcal{Y}}}$ which we will generally denote by f^*.

Warning 2.5.0.1. Any geometric morphism of ∞-topoi $f_* : \mathcal{Y} \to \mathcal{X}$ induces a pullback functor $f^*_{\mathrm{Sp}} : \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ on spectrum-valued sheaves. If f_* is promoted to a morphism of spectrally ringed ∞-topoi $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}) \to (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$, then the pullback functor $f^* : \mathrm{Mod}_{\mathscr{O}_{\mathcal{X}}} \to \mathrm{Mod}_{\mathscr{O}_{\mathcal{Y}}}$ is usually not compatible with f^*_{Sp}. That is, the diagram of ∞-categories σ :

$$\begin{array}{ccc} \mathrm{Mod}_{\mathscr{O}_{\mathcal{X}}} & \xrightarrow{f^*} & \mathrm{Mod}_{\mathscr{O}_{\mathcal{Y}}} \\ \downarrow & & \downarrow \\ \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}) & \xrightarrow{f^*_{\mathrm{Sp}}} & \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{Y}) \end{array}$$

generally does not commute. Instead we have a commutative diagram

$$\begin{array}{ccc} \mathrm{Mod}_{\mathscr{O}_{\mathcal{Y}}} & \xrightarrow{f_*} & \mathrm{Mod}_{\mathscr{O}_{\mathcal{X}}} \\ \downarrow & & \downarrow \\ \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{Y}) & \xrightarrow{f_*} & \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}), \end{array}$$

which is left adjointable if and only if the morphism f exhibits $\mathscr{O}_{\mathcal{Y}}$ as the pullback of $\mathscr{O}_{\mathcal{X}}$.

Proposition 2.5.0.2. *Let $f : (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}) \to (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a morphism of nonconnective spectral Deligne-Mumford stacks. Then the pullback functor $f^* : \mathrm{Mod}_{\mathscr{O}_{\mathcal{X}}} \to \mathrm{Mod}_{\mathscr{O}_{\mathcal{Y}}}$ carries quasi-coherent sheaves on $\mathcal{X}$ to quasi-coherent sheaves on $\mathcal{Y}$.*

Proof. The assertion is local on $\mathcal{X}$ and $\mathcal{Y}$. We may therefore assume that both $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ and $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ are affine, in which case the desired result follows immediately from the characterization of quasi-coherent sheaves given by Proposition 2.2.3.3. □

Our goal in this section is to study conditions which guarantee that a pushforward functor f_* preserves quasi-coherence.

2.5.1 The Affine Case

We begin by proving Proposition 2.5.0.2 in the case where the morphism $f : \mathsf{Y} \to \mathsf{X}$ is affine, in the sense of Definition 2.4.4.1.

Proposition 2.5.1.1. *Let $f : \mathsf{Y} \to \mathsf{X}$ be an affine morphism of nonconnective spectral Deligne-Mumford stacks. Then:*

(1) *The direct image functor $f_* : \mathrm{Mod}_{\mathscr{O}_\mathsf{Y}} \to \mathrm{Mod}_{\mathscr{O}_\mathsf{X}}$ carries quasi-coherent sheaves on Y to quasi-coherent sheaves on X.*

(2) *The functor $f_* : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ preserves small colimits.*

(3) *If Y and X are spectral Deligne-Mumford stacks, then the functor f_* is t-exact.*

Proof. The assertion is local on X, so we may assume without loss of generality that $\mathsf{X} = \mathrm{Spét}\, A$ is affine. In this case, the affineness of f guarantees that $\mathsf{Y} = \mathrm{Spét}\, B$ is also affine. Let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})$ be the quasi-coherent sheaf associated to some B-module M, and let $\mathscr{F}' \in \mathrm{QCoh}(\mathsf{X})$ denote the quasi-coherent sheaf associated to the image of M under the forgetful functor $\mathrm{Mod}_B \to \mathrm{Mod}_A$. The counit map $B \otimes_A M \to M$ determines a map $f^* \mathscr{F}' \to \mathscr{F}$, which is adjoint to a map of $\mathscr{O}_\mathsf{Y}$-modules $\mathscr{F}' \to f_* \mathscr{F}$. We claim that this map is an equivalence. For this, we must show that $u : \mathscr{F}'(U) \to (f_* \mathscr{F})(U) \simeq \mathscr{F}(f^* U)$ is an equivalence of spectra for each object $U \in \mathcal{X}$; here $\mathcal{X}$ denotes the underlying ∞-topos of X. The collection of those objects U which satisfy this condition is stable under colimits. We may therefore assume that U is representable by an étale A-algebra A'. In this case, u can be identified with the canonical equivalence $M \otimes_A A' \simeq M \otimes_B (B \otimes_A A')$. This proves (1), and shows that the induced map $f_* : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ can be identified with the forgetful functor $\mathrm{Mod}_B \to \mathrm{Mod}_A$. Assertions (2) and (3) follow immediately from this identification. □

We can use Proposition 2.5.1.1 to classify affine morphisms of spectral Deligne-Mumford stacks. Let X be a spectral Deligne-Mumford stack and let Aff_X denote the full subcategory of $\mathrm{SpDM}_{/\mathsf{X}}$ spanned by the affine morphisms $f : \mathsf{Y} \to \mathsf{X}$. It follows from Proposition **??** that the construction

$$(f : \mathsf{Y} \to \mathsf{X}) \mapsto (f_* \mathscr{O}_\mathsf{Y} \in \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}))$$

determines a functor $\lambda : \mathrm{Aff}_\mathsf{X}^{\mathrm{op}} \to \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}})$.

Proposition 2.5.1.2. *Let X be a spectral Deligne-Mumford stack. Then the functor $\lambda : \mathrm{Aff}_\mathsf{X}^{\mathrm{op}} \to \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}})$ described above is an equivalence of ∞-categories.*

Proof. The assertion is local on X. We may therefore reduce to the case where $\mathsf{X} = \mathrm{Spét}\, A$ is affine, in which case λ is a homotopy inverse to the evident equivalence

$$\begin{aligned} \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}) &\simeq \mathrm{CAlg}(\mathrm{Mod}_A^{\mathrm{cn}}) \\ &\simeq \mathrm{CAlg}_A^{\mathrm{cn}} \\ &\xrightarrow{\mathrm{Spét}} \mathrm{Aff}_{\mathrm{Spét}\, A}\,. \end{aligned}$$

□

Construction 2.5.1.3. [The Relative Spectrum] Let X be a spectral Deligne-Mumford stack. We let

$$\mathrm{Sp\acute{e}t}_{\mathsf{X}} : \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}) \to \mathrm{Aff}_{\mathsf{X}}^{\mathrm{op}} \subseteq \mathrm{SpDM}_{/\mathsf{X}}^{\mathrm{op}}$$

denote a homotopy inverse to the equivalence λ of Proposition 2.5.1.2. Given an object $\mathscr{A} \in \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}})$, we will refer to $\mathrm{Sp\acute{e}t}_{\mathsf{X}}(\mathscr{A})$ as the *spectrum of* $\mathscr{A}$ *relative to* X.

Example 2.5.1.4. For any spectral Deligne-Mumford stack X, we have a canonical equivalence $\mathrm{Sp\acute{e}t}_{\mathsf{X}}\, \mathscr{O}_{\mathsf{X}} \simeq \mathsf{X}$.

Example 2.5.1.5. Let $\mathsf{X} = \mathrm{Sp\acute{e}t}\, A$ be an affine spectral Deligne-Mumford stack. Then the relative spectrum functor $\mathrm{Sp\acute{e}t}_{\mathsf{X}}$ can be identified with the functor

$$\mathrm{CAlg}(\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}) \simeq \mathrm{CAlg}_A^{\mathrm{cn}} \xrightarrow{\mathrm{Sp\acute{e}t}} \mathrm{SpDM}_{/\mathrm{Sp\acute{e}t}\, A}^{\mathrm{op}}$$

appearing in the proof of Proposition 2.5.1.2.

2.5.2 Excision Squares

Let $\mathcal{X}$ be an ∞-topos, and let $U \in \mathcal{X}$ be a (-1)-truncated object. We let $\mathcal{X}/U$ denote the full subcategory of $\mathcal{X}$ spanned by those objects $X \in \mathcal{X}$ for which the projection map $X \times U \to U$ is an equivalence. Then $\mathcal{X}/U$ is itself an ∞-topos, and the inclusion functor $i_* : \mathcal{X}/U \to \mathcal{X}$ is a geometric morphism of ∞-topoi. Recall that a geometric morphism $f_* : \mathcal{Y} \to \mathcal{X}$ is a *closed immersion* if it factors as a composition

$$\mathcal{Y} \xrightarrow{g_*} \mathcal{X}/U \xrightarrow{i_*} \mathcal{X},$$

where U is a (-1)-truncated object of $\mathcal{X}$ and g_* is an equivalence. For a more thorough discussion, we refer the reader to §HTT.7.3.2 .

Proposition 2.5.2.1. *Let $\mathcal{X}$ be an ∞-topos and suppose we are given a diagram σ :*

$$\begin{array}{ccc} U & \xrightarrow{f} & U' \\ \downarrow & & \downarrow \\ V & \xrightarrow{f'} & V', \end{array}$$

in $\mathcal{X}$. The following conditions are equivalent:

(1) *The diagram σ is both a pushout square and a pullback square, and the map f' is (-1)-truncated.*

(2) *The diagram σ is a pushout square and the map f is (-1)-truncated.*

(3) *The diagram σ is a pullback square, f' is (-1)-truncated, and if we let $i^* : \mathcal{X}_{/V'} \to \mathcal{X}_{/V'}/V$ denote the corresponding closed immersion, then $i^* U'$ is a final object of $\mathcal{X}_{/V'}/V$.*

Proof. The equivalence of (1) and (3) is a matter of unwinding definitions, and the implication (1) $\Rightarrow$ (2) is obvious. We will show that (2) $\Rightarrow$ (1). Since $\mathcal{X}$ is an ∞-topos, there exists a fully faithful geometric morphism $i_* : \mathcal{X} \to \mathcal{P}(\mathcal{C})$, for some small ∞-category $\mathcal{C}$. Form a pushout diagram τ :

$$\begin{array}{ccc} i_* U & \longrightarrow & i_* U' \\ \downarrow & & \downarrow \\ i_* V & \xrightarrow{g'} & W \end{array}$$

in $\mathcal{P}(\mathcal{C})$. Then $\sigma \simeq i^*(\tau)$. It will therefore suffice to show that τ is a pullback diagram and that g' is (-1)-truncated. In other words, we may replace $\mathcal{X}$ by $\mathcal{P}(\mathcal{C})$ and thereby reduce to the case where $\mathcal{X}$ is an ∞-category of presheaves. Working pointwise, we can reduce to the case $\mathcal{X} = \mathcal{S}$. In this case, the condition that f is (-1)-truncated guarantees that $U' \simeq U \amalg X$ for some space X, in which case $V' \simeq V \amalg X$ and the result is obvious. $\square$

Definition 2.5.2.2. We will say that a diagram

$$\begin{array}{ccc} U & \longrightarrow & U' \\ \downarrow & & \downarrow \\ V & \longrightarrow & V' \end{array}$$

in an ∞-topos $\mathcal{X}$ is an *excision square* if it satisfies the equivalent conditions of Proposition 2.5.2.1.

Variant 2.5.2.3. Suppose we are given a commutative diagram σ :

$$\begin{array}{ccc} \mathsf{U} & \longrightarrow & \mathsf{U}' \\ \downarrow & & \downarrow \\ \mathsf{V} & \longrightarrow & \mathsf{V}' \end{array}$$

of spectrally ringed ∞-topoi. We will say that σ is an *excision square* if it is equivalent to a diagram of the form

$$\begin{array}{ccc} (\mathcal{X}_{/U}, \mathcal{O}_{\mathcal{X}}|_U) & \longrightarrow & (\mathcal{X}_{/U'}, \mathcal{O}_{\mathcal{X}}|_{U'}) \\ \downarrow & & \downarrow \\ (\mathcal{X}_{/V}, \mathcal{O}_{\mathcal{X}}|_V) & \longrightarrow & (\mathcal{X}_{/V'}, \mathcal{O}_{\mathcal{X}}|_{V'}) \end{array}$$

for some spectrally ringed ∞-topos $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ and some excision square

$$\begin{array}{ccc} U & \longrightarrow & U' \\ \downarrow & & \downarrow \\ V & \longrightarrow & V' \end{array}$$

in $\mathcal{X}$. In this case, we may assume without loss of generality that V' is a final object of $\mathcal{X}$ (otherwise, we can replace $\mathcal{X}$ by $\mathcal{X}_{/V'}$).

2.5.3 Scallop Decompositions

Let X be a quasi-compact quasi-separated scheme. Then we can choose a finite collection of affine open subsets $U_1, \ldots, U_n \subseteq X$ which cover X. Many basic results in the theory of schemes can be proven by considering the filtration of X by open subschemes

$$\emptyset \subseteq U_1 \subseteq U_1 \cup U_2 \subseteq U_1 \cup U_2 \cup U_3 \subseteq \cdots \subseteq U_1 \cup \cdots \cup U_n = X.$$

We now introduce an analogous device for analyzing (spectral) algebraic spaces which are not schematic.

Definition 2.5.3.1. Let $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a nonconnective spectral Deligne-Mumford stack. A *scallop decomposition* of $\mathcal{X}$ consists of a sequence of (-1)-truncated morphisms

$$U_0 \to U_1 \to \cdots \to U_n$$

in $\mathcal{X}$ satisfying the following conditions:

(a) The object $U_0 \in \mathcal{X}$ is initial and the object $U_n \in \mathcal{X}$ is final.

(b) For $1 \leqslant i \leqslant n$, there exists an excision square

$$\begin{array}{ccc} V & \longrightarrow & X \\ \downarrow & & \downarrow \\ U_{i-1} & \longrightarrow & U_i \end{array}$$

where X is affine and V is quasi-compact.

In this case, we will refer to n as the *length* of the scallop decomposition.

Remark 2.5.3.2. In the situation of Definition 2.5.3.1, each of the objects U_i in $\mathcal{X}$ determines an open substack $\mathsf{U}_i = (\mathcal{X}_{/U_i}, \mathcal{O}_{\mathcal{X}}|_{U_i})$ of X. In this case, we will also refer to the sequence of open immersions

$$\emptyset \simeq \mathsf{U}_0 \hookrightarrow \cdots \hookrightarrow \mathsf{U}_n \simeq \mathsf{X}$$

as a *scallop decomposition* of X.

Example 2.5.3.3. Let X be a quasi-affine nonconnective spectral Deligne-Mumford stack. Then X admits a scallop decomposition.

Remark 2.5.3.4. We will show later that a spectral Deligne-Mumford stack admits a scallop decomposition if and only if it is a quasi-compact, quasi-separated spectral algebraic space (Theorem 3.4.2.1).

Before stating our next result, we need to introduce a bit of terminology. Let $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a nonconnective spectral Deligne-Mumford stack. We say that an object $U \in \mathcal{X}$ is *semiaffine* if it is quasi-compact and there exists a (-1)-truncated map $U \to X$ in $\mathcal{X}$, where X is affine. We will say that a morphism $f : U \to V$ in $\mathcal{X}$ is *semiaffine* if the fiber product $U \times_V X$ is semiaffine, whenever $X \in \mathcal{X}$ is affine.

Proposition 2.5.3.5. *Let $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a nonconnective spectral Deligne-Mumford stack which admits a scallop decomposition. Suppose that $\mathcal{C} \subseteq \mathcal{X}$ is a full subcategory satisfying the following conditions:*

(0) *The ∞-category $\mathcal{C}$ is closed under equivalence in $\mathcal{X}$.*

(1) *Initial objects of $\mathcal{X}$ belong to $\mathcal{C}$.*

(2) *If we are given an excision square*

$$\begin{array}{ccc} U & \longrightarrow & U' \\ \downarrow & & \downarrow \\ V & \longrightarrow & V' \end{array}$$

of semiaffine morphisms in $\mathcal{X}$ where U' is affine and $U, V \in \mathcal{C}$, then $V' \in \mathcal{C}$.

Then $\mathcal{C}$ contains the final objects of $\mathcal{X}$.

Corollary 2.5.3.6. *Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a nonconnective spectral Deligne-Mumford stack which admits a scallop decomposition. Suppose that $\mathcal{C} \subseteq \mathcal{X}$ is a full subcategory which contains all affine objects of $\mathcal{X}$ and is closed under pushouts. Then $\mathcal{C}$ contains the final object of $\mathcal{X}$.*

Proof of Proposition 2.5.3.5. It follows immediately from (1) and (2) that every affine object of $\mathcal{X}$ belongs to $\mathcal{C}$. We next show that if $U \in \mathcal{X}$ is semiaffine, then $U \in \mathcal{C}$. Choose a (-1)-truncated map $j : U \to X$ where X is affine, so that $(\mathcal{X}_{/X}, \mathcal{O}_{\mathcal{X}} | X) \simeq \operatorname{Spét} R$. Then we can identify U with an open subset of the topological space $|\operatorname{Spec} R|$. Since U is quasi-compact, we can write U as a finite union $\bigcup_{1 \leqslant i \leqslant n} |\operatorname{Spec} R[x_i^{-1}]|$ for some elements $x_i \in \pi_0 R$. Choose n as small as possible. We proceed by induction on n. If $n = 0$, then U is an initial object of $\mathcal{X}$ and therefore $U \in \mathcal{C}$ by virtue of (1). Assume therefore that $n > 0$. Let

$U_0 = \bigcup_{1 \leqslant i < n} |\operatorname{Spec} R[x_i^{-1}]|$, let $U_1 = |\operatorname{Spec} R[x_n^{-1}]|$, and let $U_{01} = U_0 \cap U_1$. We identify U_0, U_1, and U_{01} with (-1)-truncated objects of $\mathcal{X}$, so that we have an excision square

$$\begin{array}{ccc} U_{01} & \longrightarrow & U_1 \\ \downarrow & & \downarrow \\ U_0 & \longrightarrow & U. \end{array}$$

Since $U_{01}, U_0 \in \mathcal{C}$ be the inductive hypothesis and U_1 is affine, we deduce that $U \in \mathcal{C}$ by (2).

Choose a scallop decomposition

$$U_0 \to U_1 \to \cdots \to U_n$$

for $\mathcal{X}$. We prove by induction on i that each U_i belongs to $\mathcal{C}$. When $i = 0$, this follows from (1). Taking $i = n$ we will obtain the result. To carry out the inductive step, suppose that $U_i \in \mathcal{C}$. Choose an excision square

$$\begin{array}{ccc} V & \longrightarrow & X \\ \downarrow & & \downarrow \\ U_i & \longrightarrow & U_{i+1} \end{array}$$

where X is affine and V is quasi-compact. The map $V \to X$ is (-1)-truncated, so that V is semiaffine and therefore $V \in \mathcal{C}$. It follows from (2) that $U_{i+1} \in \mathcal{C}$, as desired. □

2.5.4 Pushforwards of Quasi-Coherent Sheaves

We next introduce a hypothesis on morphisms $f : \mathsf{X} \to \mathsf{Y}$ which will guarantee that the pushforward f_* preserves quasi-coherence (Proposition 2.5.4.3).

Definition 2.5.4.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of nonconnective spectral Deligne-Mumford stacks. We will say that f is *relatively scalloped* if, for every map $\operatorname{Spét} R \to \mathsf{Y}$, the fiber product $\mathsf{X} \times_{\mathsf{Y}} \operatorname{Spét} R$ admits a scallop decomposition.

Example 2.5.4.2. Every quasi-affine morphism is relatively scalloped (see Example 2.5.3.3).

Proposition 2.5.4.3. *Let $f : \mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) = \mathsf{Y}$ be a relatively scalloped map of nonconnective spectral Deligne-Mumford stacks. Then the pushforward functor $f_* : \operatorname{Mod}_{\mathcal{O}_{\mathcal{X}}} \to \operatorname{Mod}_{\mathcal{O}_{\mathcal{Y}}}$ carries quasi-coherent sheaves to quasi-coherent sheaves. Moreover, the induced functor $f_* : \operatorname{QCoh}(\mathsf{X}) \to \operatorname{QCoh}(\mathsf{Y})$ commutes with small colimits.*

Proof. The assertion is local on $\mathcal{Y}$; we may therefore assume without loss of generality that $\mathsf{Y} = \operatorname{Spét} R$ is affine. For each object $U \in \mathcal{X}$, let $\Gamma_U : \operatorname{Mod}_{\mathcal{O}_{\mathcal{X}}} \to \operatorname{Mod}_{\mathcal{O}_{\mathcal{Y}}}$ denote the composite functor

$$\operatorname{Mod}_{\mathcal{O}_{\mathcal{X}}} \to \operatorname{Mod}_{\mathcal{O}_{\mathcal{X}}|U}(\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}_{/U})) \to \operatorname{Mod}_{\mathcal{O}_{\mathcal{Y}}}.$$

Let us say that U is *good* if Γ_U restricts to a colimit-preserving functor from $\mathrm{QCoh}(\mathsf{X})$ into $\mathrm{QCoh}(\mathsf{Y})$. The construction $U \mapsto \Gamma_U$ carries pushout square to pullback squares. It follows that the collection of good objects of $\mathcal{X}$ is stable under finite colimits. Since every affine object of $\mathcal{X}$ is good (Proposition 2.5.1.1) and X admits a scallop decomposition, Corollary 2.5.3.6 implies that the final object of $\mathcal{X}$ is good. □

In the situation of Proposition 2.5.4.3, we can also bound the cohomological amplitude of the pushforward functor f_*:

Proposition 2.5.4.4. *Let $f : \mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) = \mathsf{Y}$ be a relatively scalloped map of spectral Deligne-Mumford stacks. Assume that Y is quasi-compact. Then there exists an integer n such that the pushforward functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ carries $\mathrm{QCoh}(\mathsf{X})_{\geqslant 0}$ into $\mathrm{QCoh}(\mathsf{Y})_{\geqslant -n}$.*

Proof. Since Y is quasi-compact, we can choose an étale surjection $\mathrm{Sp\acute{e}t}\, R \to \mathsf{Y}$ for some connective $\mathbb{E}_\infty$-ring R. Replacing Y by $\mathrm{Sp\acute{e}t}\, R$, we may assume that Y is affine so that X admits a scallop decomposition. We define the class of *good* objects $U \in \mathcal{X}$ as in the proof of Proposition 2.5.4.3. For every good object $U \in \mathcal{X}$, let $\Gamma_U : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ be defined as in the proof of Proposition 2.5.4.3. Let us say that U is *n-good* if $\Gamma_U(\mathrm{QCoh}(\mathsf{X})_{\geqslant 0}) \subseteq \mathrm{QCoh}(\mathsf{Y})_{\geqslant -n}$. Note that if we are given a pushout diagram

$$\begin{array}{ccc} U & \longrightarrow & U' \\ \downarrow & & \downarrow \\ V & \longrightarrow & V' \end{array}$$

in $\mathcal{X}$, then we have a fiber sequence of functors

$$\Gamma_{U'} \oplus \Gamma_V \to \Gamma_{V'} \to \Sigma \Gamma_U.$$

It follows that if U' and V are n-good and U is $(n-1)$-good, then V' is also n-good. Let us say that a good object $U \in \mathcal{X}$ is *very good* if it n-good for some integer $n \geqslant 0$. It follows that the collection of very good objects of $\mathcal{X}$ is closed under pushouts. Any affine object of $\mathcal{X}$ is 0-good, and therefore very good. Using Corollary 2.5.3.6, we deduce that the final object of $\mathcal{X}$ is very good, which implies the desired result. □

The formation of pushforwards along a relatively scalloped morphism is compatible with base change:

Proposition 2.5.4.5. *Suppose we are given a pullback diagram of nonconnective spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \xrightarrow{g'} & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \xrightarrow{g} & \mathsf{Y} \end{array}$$

where f (and therefore f') is relatively scalloped. Then the diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{Y}) & \xrightarrow{f^*} & \mathrm{QCoh}(\mathsf{X}) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{Y}') & \xrightarrow{f'^*} & \mathrm{QCoh}(\mathsf{X}') \end{array}$$

is right adjointable. In other words, for every object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$, the canonical map $\lambda : g^* f_* \mathscr{F} \to f'_* g'^* \mathscr{F}$ is an equivalence in $\mathrm{QCoh}(\mathsf{Y}')$.

Proof. The assertion is local on $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ and $\mathsf{Y}' = (\mathcal{Y}', \mathscr{O}_{\mathcal{Y}'})$; we may therefore assume that $\mathsf{Y} = \mathrm{Spét}\, R$ and $\mathsf{Y}' = \mathrm{Spét}\, R'$ are affine. Write $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ and $\mathsf{X}' = (\mathcal{X}', \mathscr{O}_{\mathcal{X}'})$. Let $U \in \mathcal{X}$ be an object and $U' = g'^* U$ its pullback to X'. Define functors $\Gamma_U : \mathrm{Mod}_{\mathscr{O}_{\mathcal{X}}} \to \mathrm{Mod}_{\mathscr{O}_{\mathcal{Y}}}$ and $\Gamma_{U'} : \mathrm{Mod}_{\mathscr{O}_{\mathcal{X}'}} \to \mathrm{Mod}_{\mathscr{O}_{\mathcal{Y}'}}$ as in the proof of Proposition 2.5.4.3. Let us say that $U \in \mathcal{X}$ is *good* if the canonical map $\lambda_U : g^* \Gamma_U(\mathscr{F}) \to \Gamma_{U'}(f'^* \mathscr{F})$ is an equivalence of $\mathscr{O}_{\mathcal{Y}'}$-modules. Since the construction $U \mapsto \lambda_U$ carries finite colimits to finite limits, the collection of good objects of $\mathcal{X}$ is closed under finite colimits. We wish to prove that the final object of $\mathcal{X}$ is good. Since $\mathcal{X}$ admits a scallop decomposition, it will suffice to show that every affine object of $\mathcal{X}$ is good (Corollary 2.5.3.6). We may therefore reduce to the case where $\mathcal{X}$ (and therefore also $\mathcal{X}'$) are affine, in which case the desired assertion is a special case of Lemma D.3.5.6. □

Corollary 2.5.4.6. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a quasi-affine map of nonconnective spectral Deligne-Mumford stacks. Then the pushforward functor f_* restricts to a colimit-preserving functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$. Moreover, for every pullback diagram*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y}, \end{array}$$

the induced diagram

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{Y}) & \xrightarrow{f^*} & \mathrm{QCoh}(\mathsf{X}) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{Y}') & \xrightarrow{f'^*} & \mathrm{QCoh}(\mathsf{X}') \end{array}$$

is right adjointable.

Proof. Combine Proposition 2.5.4.3, Proposition 2.5.4.5, and Example 2.5.4.2. □

2.5.5 Categorical Digression

If $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ is an arbitrary morphism of spectrally ringed ∞-topoi, then the direct image functor $f_* : \mathrm{Mod}_{\mathcal{O}_{\mathcal{X}}} \to \mathrm{Mod}_{\mathcal{O}_{\mathcal{Y}}}$ is lax symmetric monoidal. This is a consequence of the following general categorical observation:

Proposition 2.5.5.1. *Let $F : \mathcal{C}^{\otimes} \to \mathcal{D}^{\otimes}$ be a symmetric monoidal functor between symmetric monoidal ∞-categories, and suppose that the underlying functor $f : \mathcal{C} \to \mathcal{D}$ admits a right adjoint g. Then g is lax symmetric monoidal: that is, it extends naturally to a map of ∞-operads $G : \mathcal{D}^{\otimes} \to \mathcal{C}^{\otimes}$.*

Proof. Consider the diagram

$$\begin{array}{ccc} \mathcal{C}^{\otimes} & \xrightarrow{F} & \mathcal{D}^{\otimes} \\ & {\scriptstyle p}\searrow \quad \swarrow & \\ & \mathcal{F}\mathrm{in}_* . & \end{array}$$

For every object $\langle n \rangle \in \mathcal{F}\mathrm{in}_*$, the induced map $\mathcal{C}^{\otimes}_{\langle n \rangle} \to \mathcal{D}^{\otimes}_{\langle n \rangle}$ can be identified with $f^n : \mathcal{C}^n \to \mathcal{D}^n$, and therefore admits a right adjoint $g^n : \mathcal{D}^n \to \mathcal{C}^n$. Since F carries p-coCartesian morphisms to q-coCartesian morphisms, Proposition HA.7.3.2.6 guarantees the existence of a functor $G : \mathcal{D}^{\otimes} \to \mathcal{C}^{\otimes}$ which is a right adjoint of F relative to $\mathcal{F}\mathrm{in}_*$. In particular, $G|_{\mathcal{D}}$ is a right adjoint to f and we may therefore assume that $G|_{\mathcal{D}} = g$. To see that G is a map of ∞-operads, it suffices to observe that for every injection $\langle m \rangle^{\circ} \hookrightarrow \langle n \rangle^{\circ}$, the diagram

$$\begin{array}{ccc} \mathcal{C}^n & \longrightarrow & \mathcal{D}^n \\ \downarrow & & \downarrow \\ \mathcal{C}^m & \longrightarrow & \mathcal{D}^m \end{array}$$

is right adjointable. □

Remark 2.5.5.2. In the situation of Proposition 2.5.5.1, F and G determine adjoint functors

$$\mathrm{CAlg}(\mathcal{C}) \rightleftarrows \mathrm{CAlg}(\mathcal{D}).$$

Corollary 2.5.5.3. *Let $F : \mathcal{C}^{\otimes} \to \mathcal{D}^{\otimes}$ be a symmetric monoidal functor between symmetric monoidal ∞-categories, and suppose that the underlying functor $f : \mathcal{C} \to \mathcal{D}$ admits a right adjoint g; let $G : \mathcal{D}^{\otimes} \to \mathcal{C}^{\otimes}$ be the resulting map of ∞-operads. Then:*

(1) *If $\mathbf{1}$ denotes the unit object of $\mathcal{D}$, then $A = g(\mathbf{1})$ has the structure of a commutative algebra object of $\mathcal{C}$.*

(2) *The functor G factors as a composition*

$$\mathcal{D}^{\otimes} \simeq \mathrm{Mod}_{\mathbf{1}}(\mathcal{D})^{\otimes} \to \mathrm{Mod}_A(\mathcal{C})^{\otimes} \to \mathcal{C}^{\otimes} .$$

Example 2.5.5.4. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectrally ringed ∞-topoi. Then the direct image functor $f_* : \mathrm{Mod}_{\mathscr{O}_\mathsf{X}} \to \mathrm{Mod}_{\mathscr{O}_\mathsf{Y}}$ is lax symmetric monoidal, and therefore factors as a composition

$$\mathrm{Mod}_{\mathscr{O}_\mathsf{X}} \to \mathrm{Mod}_{f_* \mathscr{O}_\mathsf{X}} \to \mathrm{Mod}_{\mathscr{O}_\mathsf{Y}}.$$

If X and Y are spectral Deligne-Mumford stacks and f is relatively scalloped, then the induced map $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ is lax symmetric monoidal, and canonically factors as a composition $\mathrm{QCoh}(\mathsf{X}) \to \mathrm{Mod}_{f_* \mathscr{O}_\mathsf{X}}(\mathrm{QCoh}(\mathsf{Y})) \to \mathrm{QCoh}(\mathsf{Y})$.

2.5.6 The Quasi-Affine Case

We now describe some consequences of Proposition 2.5.4.5 in the case where $f : \mathsf{X} \to \mathsf{Y}$ is a quasi-affine morphism of spectral Deligne-Mumford stacks.

Proposition 2.5.6.1. *Let $f : \mathsf{X} = (\mathcal{X}, \mathscr{O}_\mathcal{X}) \to \mathsf{Y}$ be a quasi-affine map of spectral Deligne-Mumford stacks. Then the induced functor $\mathrm{QCoh}(\mathsf{X}) \to \mathrm{Mod}_{f_* \mathscr{O}_\mathcal{X}}(\mathrm{QCoh}(\mathsf{Y}))$ is an equivalence of ∞-categories.*

Proof. The assertion is local on Y. We may therefore assume that $\mathsf{Y} = \mathrm{Spét}\, R$ is affine, so that X is quasi-affine and the desired result follows from Proposition 2.4.1.4. □

Proposition 2.5.6.2. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a quasi-affine morphism between spectral Deligne-Mumford stacks, and let $\mathscr{F}$ be a quasi-coherent sheaf on X. Then $\mathscr{F}$ belongs to $\mathrm{QCoh}(\mathsf{X})_{\leqslant 0}$ if and only if the direct image $f_* \mathscr{F}$ belongs to $\mathrm{QCoh}(\mathsf{Y})_{\leqslant 0}$.*

Proof. Since the pullback functor f^* is right t-exact, the right adjoint f_* is left t-exact. Consequently, the "only if" direction is tautological (and does not require the assumption that f is quasi-affine). Conversely, suppose that $f_* \mathscr{F}$ belongs to $\mathrm{QCoh}(\mathsf{Y})_{\leqslant 0}$; we wish to show that $\mathscr{F}$ belongs to $\mathrm{QCoh}(\mathsf{X})_{\leqslant 0}$. By virtue of Proposition 2.5.4.5, we can work locally on Y and thereby reduce to the case where $\mathsf{Y} = \mathrm{Spét}\, A$ for some connective $\mathbb{E}_\infty$-ring A. Since f is quasi-affine, we can factor f as a composition

$$\mathsf{X} \xrightarrow{f'} \mathrm{Spét}\, B \xrightarrow{f''} \mathrm{Spét}\, A$$

for some connective $\mathbb{E}_\infty$-ring B, where f' is a quasi-compact open immersion. Since the functor f''_* is t-exact and conservative, it follows that $f'_* \mathscr{F}$ belongs to $\mathrm{QCoh}(\mathrm{Spét}\, B)_{\leqslant 0}$. Because f' is an open immersion, the diagram

$$\begin{array}{ccc} \mathsf{X} & \xrightarrow{\mathrm{id}} & \mathsf{X} \\ \downarrow{\scriptstyle \mathrm{id}} & & \downarrow{\scriptstyle f'} \\ \mathsf{X} & \xrightarrow{f'} & \mathrm{Spét}\, B \end{array}$$

is a pullback square. Applying Proposition 2.5.4.5, we deduce that $\mathscr{F}$ can be identified with the pullback $f'^* f'_* \mathscr{F}$, and therefore belongs to $f'^* \operatorname{QCoh}(\operatorname{Spét} B)_{\leqslant 0} \subseteq \operatorname{QCoh}(\mathsf{X})_{\leqslant 0}$ as desired. □

Corollary 2.5.6.3. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a quasi-affine morphism between spectral Deligne-Mumford stacks. Then $\operatorname{QCoh}(\mathsf{X})^{\mathrm{cn}}$ is the smallest full subcategory of $\operatorname{QCoh}(\mathsf{X})$ which is closed under colimits and extensions and contains the pullback $f^* \mathscr{F}$ for each $\mathscr{F} \in \operatorname{QCoh}(\mathsf{Y})^{\mathrm{cn}}$.*

Proof. By virtue of Proposition HA.1.4.4.11 , the ∞-category $\operatorname{QCoh}(\mathsf{X})$ admits a t-structure $(\operatorname{QCoh}'(\mathsf{X}), \operatorname{QCoh}''(\mathsf{X}))$, where $\operatorname{QCoh}'(\mathsf{X})$ is the smallest full subcategory of $\operatorname{QCoh}(\mathsf{X})$ which is closed under colimits and extensions and contains $f^* \operatorname{QCoh}(\mathsf{Y})^{\mathrm{cn}}$, and $\operatorname{QCoh}''(\mathsf{X})$ is the full subcategory of $\operatorname{QCoh}(\mathsf{X})$ spanned by those sheaves $\mathscr{G}$ having the property that the groups $\operatorname{Ext}^n_{\operatorname{QCoh}(\mathsf{X})}(f^* \mathscr{F}, \mathscr{G})$ vanish for $n < 0$ and every connective object $\mathscr{F} \in \operatorname{QCoh}(\mathsf{Y})$. Using the identification $\operatorname{Ext}^n_{\operatorname{QCoh}(\mathsf{X})}(f^* \mathscr{F}, \mathscr{G}) \simeq \operatorname{Ext}^n_{\operatorname{QCoh}(\mathsf{Y})}(\mathscr{F}, f_* \mathscr{G})$, we deduce that $\mathscr{G}$ belongs to $\operatorname{QCoh}''(\mathsf{X})$ if and only if $f_* \mathscr{G} \in \operatorname{QCoh}(\mathsf{Y})_{\leqslant 0}$. Applying Proposition 2.5.6.2, we deduce that $\operatorname{QCoh}''(\mathsf{X}) = \operatorname{QCoh}(\mathsf{X})_{\leqslant 0}$, so that the t-structure $(\operatorname{QCoh}'(\mathsf{X}), \operatorname{QCoh}''(\mathsf{X}))$ coincides with the t-structure of Proposition 2.2.5.2 and therefore $\operatorname{QCoh}'(\mathsf{X}) = \operatorname{QCoh}(\mathsf{X})^{\mathrm{cn}}$. □

Corollary 2.5.6.4. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a quasi-affine spectral Deligne-Mumford stack. Then $\operatorname{QCoh}(\mathsf{X})^{\mathrm{cn}}$ is the smallest full subcategory of $\operatorname{QCoh}(\mathsf{X})$ which contains the unit object $\mathscr{O}_{\mathcal{X}}$ and is closed under colimits and extensions.*

Proof. Apply Corollary 2.5.6.3 in the special case where $Y = \operatorname{Spét} S$, where S denotes the sphere spectrum. □

2.5.7 Compositions of Quasi-Affine Morphisms

We now show that the collection of quasi-affine morphisms is closed under composition.

Lemma 2.5.7.1. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a quasi-affine morphism of spectral Deligne-Mumford stacks, and set $\mathscr{A} = \tau_{\geqslant 0} f_* \mathscr{O}_{\mathsf{X}}$. Then the canonical map $\mathsf{X} \to \operatorname{Spec}^{\acute{e}t}_{\mathsf{Y}} \mathscr{A}$ (see Construction 2.5.1.3) is a quasi-compact open immersion.*

Proof. The assertion is local on Y. We may therefore assume that Y is affine, in which case the desired result follows from Proposition 2.4.1.3 (and the proof of Proposition 2.4.2.3). □

Lemma 2.5.7.2. *Let $f : \mathsf{X} \to \mathsf{Y}$ be an affine morphism of spectral Deligne-Mumford stacks. If Y is quasi-affine, then X is quasi-affine.*

Proof. Set $A = \Gamma(\mathsf{Y}; \mathscr{O}_{\mathsf{Y}})$ and $B = \Gamma(\mathsf{X}; \mathscr{O}_{\mathsf{X}})$, so that we have a commutative diagram of nonconnective spectral Deligne-Mumford stacks σ :

$$\begin{array}{ccc} \mathsf{X} & \xrightarrow{g} & \operatorname{Sp\acute{e}t} B \\ \downarrow^{f} & & \downarrow \\ \mathsf{Y} & \xrightarrow{g_0} & \operatorname{Sp\acute{e}t} A. \end{array}$$

Note that B can be identified with the image of $f_* \mathscr{O}_{\mathsf{X}}$ under the equivalence $\mathrm{QCoh}(\mathsf{Y}) \simeq \mathrm{Mod}_A$ of Proposition 2.5.6.1. Write $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathsf{Y}})$. For every affine object $U \in \mathcal{Y}$, we obtain an equivalence

$$\mathscr{O}_{\mathsf{X}}(f^* U) \simeq (f_* \mathscr{O}_{\mathsf{X}})(U) \simeq \mathscr{O}_{\mathsf{Y}}(U) \otimes_A B,$$

so that the outer rectangle in the associated diagram

$$\begin{array}{ccccc} \mathsf{X} \times_{\mathsf{Y}} \mathsf{Y}_U & \longrightarrow & \mathsf{X} & \xrightarrow{g} & \operatorname{Sp\acute{e}t} B \\ \downarrow & & \downarrow^{f} & & \downarrow \\ \mathsf{Y}_U & \longrightarrow & \mathsf{Y} & \xrightarrow{g_0} & \operatorname{Sp\acute{e}t} A \end{array}$$

is a pullback square, where $\mathsf{Y}_U = (\mathcal{Y}_{/U}, \mathscr{O}_{\mathsf{Y}} |_U)$. Allowing U to vary, we deduce that σ is a pullback square. Since the map g_0 is a quasi-compact open immersion (Proposition 2.4.1.3), it follows that g is a quasi-compact open immersio, so that X is quasi-affine as desired. □

Proposition 2.5.7.3. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Suppose that Y is quasi-affine and that f is quasi-affine. Then X is quasi-affine.*

Proof. Set $\mathscr{A} = \tau_{\geqslant 0} f_* \mathscr{O}_{\mathsf{X}}$. Regard $\mathscr{A}$ as a a commutative algebra object of $\mathrm{QCoh}(\mathsf{Y})^{\mathrm{cn}}$, and set $\mathsf{X}' = \operatorname{Sp\acute{e}t}_{\mathsf{Y}} \mathscr{A}$ (see Construction 2.5.1.3). Lemma 2.5.7.1 implies that the canonical map $\mathsf{X} \to \mathsf{X}'$ is a quasi-compact open immersion. It will therefore suffice to show that X' is quasi-affine, which follows from Lemma 2.5.7.2. □

Proposition 2.5.7.4. *Suppose we are given a commutative diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccccc} & & \mathsf{Y} & & \\ & \nearrow^{f} & & \searrow^{g} & \\ \mathsf{X} & & \xrightarrow{h} & & \mathsf{Z}, \end{array}$$

where g is quasi-affine. Then f is quasi-affine if and only if h is quasi-affine.

Proof. Suppose first that f is quasi-affine; we wish to show that h is quasi-affine. Equivalently, we wish to show that for every map $\operatorname{Sp\acute{e}t} R \to \mathsf{Z}$, the fiber product $\operatorname{Sp\acute{e}t} R \times_{\mathsf{Z}} \mathsf{X}$ is quasi-affine. Our hypothesis on g guarantees that $\operatorname{Sp\acute{e}t} R \times_{\mathsf{Z}} \mathsf{Y}$ is quasi-affine. The projection map $\operatorname{Sp\acute{e}t} R \times_{\mathsf{Z}} \mathsf{X} \to \operatorname{Sp\acute{e}t} R \times_{\mathsf{Z}} \mathsf{Y}$ is a pullback of f and is therefore quasi-affine, so that $\operatorname{Sp\acute{e}t} R \times_{\mathsf{Z}} \mathsf{X}$ is quasi-affine by virtue of Proposition 2.5.7.3.

Now suppose that h is quasi-affine; we wish to show that f has the same property. Choose a map $\eta : \operatorname{Sp\acute{e}t} R \to \mathsf{Y}$; we wish to show that the fiber product $\operatorname{Sp\acute{e}t} R \times_{\mathsf{Y}} \mathsf{X}$ is quasi-affine. Our hypotheses on g and h imply that the fiber products $\mathsf{X}_R = \operatorname{Sp\acute{e}t} R \times_{\mathsf{Z}} \mathsf{X}$ and $\mathsf{Y}_R = \operatorname{Sp\acute{e}t} R \times_{\mathsf{Z}} \mathsf{Y}$ are quasi-affine, and we have a pullback diagram

$$\begin{array}{ccc} \operatorname{Sp\acute{e}t} R \times_{\mathsf{Y}} \mathsf{X} & \longrightarrow & \operatorname{Sp\acute{e}t} R \\ \downarrow & & \downarrow \\ \mathsf{X}_R & \longrightarrow & \mathsf{Y}_R . \end{array}$$

Since Y_R is quasi-affine, the right vertical map is affine. It follows that the left vertical map is also affine, so that $\operatorname{Sp\acute{e}t} R \times_{\mathsf{Y}} \mathsf{X}$ is quasi-affine by virtue of Lemma 2.5.7.2. □

2.5.8 Pushforwards of Truncated Quasi-Coherent Sheaves

If we are willing to restrict our attention to truncated quasi-coherent sheaves on spectral Deligne-Mumford stacks, then we can verify the quasi-coherence of direct images under conditions much weaker than those of Proposition 2.5.4.3:

Theorem 2.5.8.1. *Let $f : (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a map of spectral Deligne-Mumford stacks which is ∞-quasi-compact. Then the induced functor $f_* : \operatorname{Mod}_{\mathcal{O}_{\mathcal{Y}}} \to \operatorname{Mod}_{\mathcal{O}_{\mathcal{X}}}$ carries $\operatorname{QCoh}(\mathcal{Y})_{\leqslant 0}$ into $\operatorname{QCoh}(\mathcal{X})_{\leqslant 0}$.*

The proof of Theorem 2.5.8.1 will require the following somewhat technical definition:

Definition 2.5.8.2. Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack. We let $\operatorname{Mod}^{\heartsuit}_{\mathcal{O}_{\mathcal{X}}}$ denote the heart of the ∞-category $\operatorname{Mod}_{\mathcal{O}_{\mathcal{X}}}$: it can be identified with (the nerve of) the abelian category of sheaves of discrete modules over $\pi_0 \mathcal{O}_{\mathcal{X}}$. We will say that an object of $\operatorname{Mod}^{\heartsuit}_{\mathcal{O}_{\mathcal{X}}}$ is *quasi-coherent* if it belongs to $\operatorname{QCoh}(\mathsf{X})^{\heartsuit} = \operatorname{QCoh}(\mathsf{X}) \cap \operatorname{Mod}^{\heartsuit}_{\mathcal{O}_{\mathcal{X}}}$. We will say that an object $\mathscr{F} \in \operatorname{Mod}^{\heartsuit}_{\mathcal{O}_{\mathcal{X}}}$ is *semicoherent* if, for every affine object $U \in \mathcal{X}$, there exists a composition series

$$0 = \mathscr{F}_0 \hookrightarrow \mathscr{F}_1 \hookrightarrow \cdots \hookrightarrow \mathscr{F}_n = \mathscr{F}|_U$$

such that each quotient $\mathscr{F}_i / \mathscr{F}_{i-1}$ is a subobject of some quasi-coherent object $\mathscr{G}_i \in \operatorname{QCoh}(\mathsf{U})^{\heartsuit}$, where $\mathsf{U} = (\mathcal{X}_{/U}, \mathcal{O}_{\mathcal{X}}|_U)$.

Theorem 2.5.8.1 admits the following refinement:

Theorem 2.5.8.3. *Let $f : (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be an n-quasi-compact morphism between spectral Deligne-Mumford stacks. Let $\mathscr{F} \in (\operatorname{Mod}_{\mathcal{O}_{\mathcal{Y}}})_{\leqslant 0}$ be sheaf of $\mathcal{O}_{\mathcal{Y}}$-modules satisfying the following conditions:*

(*a*) *For* $0 \leqslant i < n$, $\pi_{-i}\mathscr{F}$ *is quasi-coherent.*

(*b*) *The sheaf* $\pi_{-n}\mathscr{F}$ *is semicoherent.*

Then the direct image $f_*\mathscr{F}$ *also satisfies conditions* (*a*) *and* (*b*).

Proof of Theorem 2.5.8.1. Combine Theorem 2.5.8.3 with the quasi-coherence criterion of Proposition 2.2.6.1. □

The proof of Theorem 2.5.8.3 will require a few preliminaries. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack. Since the t-structure on $\mathrm{Mod}_{\mathscr{O}_{\mathcal{X}}}$ restricts to a t-structure on the full subcategory $\mathrm{QCoh}(\mathsf{X})$, we can identify $\mathrm{QCoh}(\mathsf{X})^{\heartsuit}$ with a full subcategory of the abelian category $\mathrm{Mod}_{\mathscr{O}_{\mathcal{X}}}^{\heartsuit}$ which is closed under the formation of kernels, cokernels, and extensions. Our first goal is to extend these observations to semicoherent sheaves.

Lemma 2.5.8.4. *Let* $\mathsf{X} = (\mathcal{X}, \mathscr{O})$ *be a spectral Deligne-Mumford stack, and suppose we are given a morphism* $\alpha : \mathscr{F} \to \mathscr{G}$ *in the abelian category* $\mathrm{Mod}_{\mathscr{O}}^{\heartsuit}$. *If* $\mathscr{F}$ *is quasi-coherent and* $\mathscr{G}$ *is semicoherent, then the kernel* $\ker(\alpha)$ *and the image* $\mathrm{im}(\alpha)$ *(formed in the abelian category* $\mathrm{Mod}_{\mathscr{O}}^{\heartsuit}$*) are quasi-coherent.*

Proof. The assertion is local on $\mathcal{X}$; we may therefore assume that X is affine so that there exists a finite filtration

$$0 = \mathscr{G}_0 \hookrightarrow \mathscr{G}_1 \hookrightarrow \cdots \hookrightarrow \mathscr{G}_n = \mathscr{G}$$

such that each quotient $\mathscr{G}_i / \mathscr{G}_{i-1}$ is a subobject of a quasi-coherent object $\mathscr{H}_i \in \mathrm{QCoh}(\mathsf{X})^{\heartsuit}$. Let $\mathcal{K}_i$ denote the kernel of the composite map

$$\mathscr{F} \xrightarrow{\alpha} \mathscr{G} \to \mathscr{G} / \mathscr{G}_i .$$

For each index i, α induces a monomorphism

$$\mathcal{K}_i / \mathcal{K}_{i-1} \hookrightarrow \mathscr{G}_i / \mathscr{G}_{i-1} \to \mathscr{H}_i .$$

Thus $\mathcal{K}_{i-1}$ can be identified with the kernel of a map $\mathcal{K}_i \to \mathscr{H}_i$. Note that $\mathcal{K}_n \simeq \mathscr{F}$ is quasi-coherent. It follows by descending induction on i that each $\mathcal{K}_i$ is quasi-coherent. In particular, $\mathcal{K}_0 = \ker(\alpha)$ is quasi-coherent. Using the exact sequence

$$0 \to \ker(\alpha) \to \mathscr{F} \to \mathrm{im}(\alpha) \to 0,$$

we see that $\mathrm{im}(\alpha)$ is quasi-coherent as well. □

Lemma 2.5.8.5. *Let* $\mathsf{X} = (\mathcal{X}, \mathscr{O})$ *be a spectral Deligne-Mumford stack, and suppose we are given an exact sequence*

$$0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0$$

in the abelian category $\mathrm{Mod}_{\mathscr{O}}^{\heartsuit}$.

(a) *If* $\mathscr{F}'$ *and* $\mathscr{F}''$ *are psuedo-coherent, then* $\mathscr{F}$ *is semicoherent.*

(b) *If* $\mathscr{F}$ *is semicoherent, then* $\mathscr{F}'$ *is semicoherent.*

(c) *If* $\mathscr{F}'$ *is quasi-coherent and* $\mathscr{F}$ *is semicoherent, then* $\mathscr{F}''$ *is semicoherent.*

Proof. Assertion (a) follows immediately from the definitions. We next prove (b). Without loss of generality, we may assume that X is affine. Then $\mathscr{F}$ admits a finite filtration

$$0 = \mathscr{F}_0 \hookrightarrow \cdots \hookrightarrow \mathscr{F}_n = \mathscr{F}$$

and a collection of monomorphisms $\mathscr{F}_i / \mathscr{F}_{i-1} \hookrightarrow \mathscr{G}_i$, where $\mathscr{G}_i \in \mathrm{QCoh}(\mathsf{X})^{\heartsuit}$. Let us regard $\mathscr{F}_i$ and $\mathscr{F}'$ as subobjects of $\mathscr{F}$, and set $\mathscr{F}'_i = \mathscr{F}_i \cap \mathscr{F}'$. Then we have a filtration

$$0 = \mathscr{F}'_0 \hookrightarrow \cdots \hookrightarrow \mathscr{F}'_n = \mathscr{F}'$$

where each quotient $\mathscr{F}'_i / \mathscr{F}'_{i-1}$ is equivalent to a subobject of $\mathscr{F}_i / \mathscr{F}_{i-1}$, and therefore to a subobject of $\mathscr{G}_i$. This proves that $\mathscr{F}'$ is semicoherent.

It remains to prove (c). Again we may assume without loss of generality that X is affine, so that $\mathscr{F}$ and $\mathscr{F}'$ admit composition series as indicated above. We first prove by descending induction on i that each $\mathscr{F}'_i$ is quasi-coherent. The result is obvious for $i = n$, since $\mathscr{F}'_n \simeq \mathscr{F}'$. For the inductive step, we note that $\mathscr{F}'_i$ can be described as the kernel of a map $\mathscr{F}'_{i+1} \to \mathscr{F}_{i+1} / \mathscr{F}_i \hookrightarrow \mathscr{G}_i$, and is therefore quasi-coherent. It follows that each of the quotients $\mathscr{F}'_i / \mathscr{F}'_{i-1}$ is quasi-coherent. Form a short exact sequence

$$0 \to \mathscr{F}'_i / \mathscr{F}'_{i-1} \to \mathscr{G}_i \to \mathscr{H}_i \to 0,$$

so that each $\mathscr{H}_i$ is quasi-coherent. Let $\mathscr{F}''_i$ denote the image of $\mathscr{F}_i$ in $\mathscr{F}''$. Then we have a finite filtration

$$0 = \mathscr{F}''_0 \hookrightarrow \cdots \hookrightarrow \mathscr{F}''_n = \mathscr{F}''.$$

For each index i, the monomorphism $\mathscr{F}_i / \mathscr{F}_{i-1} \hookrightarrow \mathscr{G}_i$ induces a monomorphism $\mathscr{F}''_i / \mathscr{F}''_{i-1} \to \mathscr{H}_i$. It follows that $\mathscr{F}''$ is semicoherent, as desired. □

Lemma 2.5.8.6. *Let* $f : (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}) \to (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ *be an affine morphism between spectral Deligne-Mumford stacks. Let* $\mathscr{F} \in (\mathrm{Mod}_{\mathscr{O}_{\mathcal{Y}}})_{\leqslant 0}$ *be such that* $\pi_0 \mathscr{F}$ *is semicoherent. Then* $(f_* \mathscr{F}) \in (\mathrm{Mod}_{\mathscr{O}_{\mathcal{X}}})_{\leqslant 0}$, *and* $\pi_0(f_* \mathscr{F})$ *is semicoherent.*

Proof. We first note that the pushforward functor f_* is left t-exact. Let $\mathscr{F} \in (\mathrm{Mod}_{\mathscr{O}_{\mathcal{Y}}})_{\leqslant 0}$ be such that $\pi_0 \mathscr{F}$ is semicoherent; we wish to prove that $\pi_0(f_* \mathscr{F})$ is semicoherent. Since f_* is left t-exact, the map $f_*(\tau_{\geqslant 0} \mathscr{F}) \to f_* \mathscr{F}$ induces an equivalence $\pi_0 f_*(\tau_{\geqslant 0} \mathscr{F}) \to \pi_0(f_* \mathscr{F})$. We may therefore replace $\mathscr{F}$ by $\tau_{\geqslant 0} \mathscr{F}$ and thereby reduce to the case $\mathscr{F} \in \mathrm{Mod}^{\heartsuit}_{\mathscr{O}_{\mathcal{Y}}}$. We may assume without loss of generality that $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is affine. Since f is affine, we deduce that

$(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ is affine, so that $\mathscr{F} \simeq \pi_0 \mathscr{F}$ admits a composition series $\mathscr{F} \simeq \pi_0 \mathscr{F}$ is semicoherent, we can choose a composition series

$$0 = \mathscr{F}_0 \hookrightarrow \cdots \hookrightarrow \mathscr{F}_n \simeq \mathscr{F}$$

where each quotient admits a monomorphism $\mathscr{F}_i / \mathscr{F}_{i-1} \hookrightarrow \mathscr{G}_i$ foe some quasi-coherent object $\mathscr{G}_i \in \mathrm{Mod}^{\heartsuit}_{\mathscr{O}_{\mathcal{Y}}}$. Since f_* is left t-exact, we get an induced filtration

$$0 = \pi_0 f_* \mathscr{F}_0 \hookrightarrow \cdots \hookrightarrow \pi_0 f_* \mathscr{F}_n = \pi_0 f_* \mathscr{F}$$

where each successive quotient $(\pi_0 f_* \mathscr{F}_i)/(\pi_0 f_* \mathscr{F}_{i-1})$ admits a monomorphism

$$(\pi_0 f_* \mathscr{F}_i)/(\pi_0 f_* \mathscr{F}_{i-1}) \hookrightarrow \pi_0 f_*(\mathscr{F}_i / \mathscr{F}_{i-1}) \hookrightarrow \pi_0 f_* \mathscr{G}_i .$$

It now suffices to observe that $\pi_0 f_* \mathscr{G}_i$ is a quasi-coherent $\mathscr{O}_{\mathcal{X}}$-module (Corollary 2.5.4.6). □

Proof of Theorem 2.5.8.3. Without loss of generality, we may assume that $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is affine. We proceed by induction on n. Then the ∞-topos $\mathcal{Y}$ is n-coherent, and in particular quasi-compact. We may therefore choose an effective epimorphism $u : U_0 \to \mathbf{1}$ in $\mathcal{Y}$, where $\mathbf{1}$ denotes the final object and $(\mathcal{Y}_{/U_0}, \mathscr{O}_{\mathcal{Y}} |U_0)$ is affine. Let $U_\bullet$ denote the Čech nerve of u. For each $k \geqslant 0$, let $f^k : (\mathcal{Y}_{/U_k}, \mathscr{O}_{\mathcal{Y}} |U_k) \to (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be the map induced by f, and let $\mathscr{G}^k = f^k_*(\mathscr{F} |U_k) \in (\mathrm{Mod}_{\mathscr{O}_{\mathcal{X}}})_{\leqslant 0}$. We obtain a cosimplicial object $\mathscr{G}^\bullet$ of $(\mathrm{Mod}_{\mathscr{O}_{\mathcal{X}}})_{\leqslant 0}$ whose totalization is equivalent to $f_* \mathscr{F}$. Applying Proposition HA.1.2.4.5 and Variant HA.1.2.4.9 , we deduce the existence of a spectral sequence $\{E_r^{p,q}, d_r\}_{r \geqslant 1}$ in the abelian category $\mathrm{Mod}^{\heartsuit}_{\mathscr{O}_{\mathcal{X}}}$ with the following properties:

- (i) We have $E_1^{p,q} \simeq \pi_{-q} \mathscr{G}^p$ for $p, q \geqslant 0$, and $E_1^{p,q} \simeq 0$ otherwise.
- (ii) The differentials d_r have bidegree $(r, 1-r)$: that is, they carry $E_r^{p,q}$ into $E_r^{p+r,q-r+1}$.
- (iii) The spectral sequence $\{E_r^{p,q}, d_r\}_{r \geqslant 1}$ converges to $\pi_{-p-q} f_* \mathscr{F}$ in the following sense: for every integer $k \geqslant 0$, there exists a finite filtration

$$0 = F^{-1}\pi_{-k}(f_* \mathscr{F}) \hookrightarrow F^0 \pi_{-k}(f_* \mathscr{F}) \hookrightarrow \cdots \hookrightarrow F^k \pi_{-k}(f_* \mathscr{F}) = \pi_{-k}(f_* \mathscr{F})$$

  in the abelian category $\mathrm{Mod}^{\heartsuit}_{\mathscr{O}_{\mathcal{X}}}$ such that each successive quotient $F^q \pi_0(f_* \mathscr{F})/F^{q-1}\pi_0(f_* \mathscr{F})$ is isomorphic to $E_r^{k-q,q}$ for $r \gg 0$.

Since $\mathcal{Y}$ is n-coherent, each of the objects $U_q \in \mathcal{Y}$ is $(n-1)$-coherent. Using the inductive hypothesis and (i), we deduce:

- (iv) The objects $E_1^{p,q}$ are quasi-coherent for $q < n-1$ and semicoherent for $q = n-1$.

When $p = 0$ we can do a bit better: since $(\mathcal{Y}_{/U_0}, \mathscr{O}_{\mathcal{Y}} |U_0)$ is affine, Lemma 2.5.8.6 gives:

(*v*) The objects $E_1^{0,q}$ are quasi-coherent for $q < n$ and semicoherent for $q = n$.

We now prove the following statement by induction on r:

(∗) The object $E_r^{p,q}$ is psuedo-coherent if $p+q = n$, and quasi-coherent if $p+q < n$.

In the case $r = 1$, assertion (∗) follows from (*iv*), (*v*), and (*i*). In the general case, we can describe $E_r^{p,q}$ as the cohomology of a cochain complex

$$E_{r-1}^{p-r,q+r-1} \xrightarrow{\alpha} E_{r-1}^{p,q} \xrightarrow{\beta} E_{r-1}^{p+r,q-r+1}.$$

so that we have an exact sequence

$$0 \to \mathrm{im}(\alpha) \to \ker(\beta) \to E_r^{p,q} \to 0.$$

If $p+q < n$, then $E_{r-1}^{p,q}$ and $E_{r-1}^{p-r,q+r-1}$ are quasi-coherent and $E_{r-1}^{p+r,q-r+1}$ is semicoherent (by the inductive hypothesis). It follows that $\mathrm{im}(\alpha)$ and $\ker(\beta)$ are quasi-coherent (Lemma 2.5.8.5), so that $E_r^{p,q}$ is quasi-coherent. If $p+q = n$, then the inductive hypothesis guarantees instead that $E_{r-1}^{p-r,q+r-1}$ is quasi-coherent and $E_r^{p,q}$ is semicoherent. Lemma 2.5.8.4 then guarantees that $\mathrm{im}(\alpha)$ is quasi-coherent and Lemma 2.5.8.5 guarantees that $\ker(\beta)$ is semicoherent, so that $E_r^{p,q}$ is semicoherent by Lemma 2.5.8.5.

Using (∗) and (3), we deduce that $\pi_{-k} f_* \mathscr{F}$ admits a finite filtration by objects of $\mathrm{Mod}_{\mathscr{O}_{\mathcal{X}}}^{\heartsuit}$ which are quasi-coherent if $k < n$ and semicoherent if $k = n$. Since the classes of quasi-coherent and semicoherent objects of $\mathrm{Mod}_{\mathscr{O}_{\mathcal{X}}}^{\heartsuit}$ are stable under extensions (Lemma 2.5.8.5), we conclude that $\pi_{-k} f_* \mathscr{F}$ is quasi-coherent for $k < n$ and semicoherent for $k = n$, as desired. □

2.5.9 Connectivity Hypotheses

We conclude this section with a few remarks about the behavior of the pushforward functor f_* in the case where $f : \mathsf{X} \to \mathsf{Y}$ is a "highly connected" affine morphism.

Proposition 2.5.9.1. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ and $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ be spectral Deligne-Mumford stacks. Let $f : \mathsf{X} \to \mathsf{Y}$ be an affine morphism, let $n \geqslant 0$ be an integer, and suppose that the fiber of the map $\mathscr{O}_{\mathcal{Y}} \to f_* \mathscr{O}_{\mathcal{X}}$ is n-connective. Then:*

(1) *The pushforward functor $f_* : \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}_{\leqslant n} \to \mathrm{QCoh}(\mathsf{Y})^{\mathrm{cn}}_{\leqslant n}$ is fully faithful.*

(2) *The pushforward functor $f_* : \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}_{\leqslant n-1} \to \mathrm{QCoh}(\mathsf{Y})^{\mathrm{cn}}_{\leqslant n-1}$ is an equivalence of ∞-categories.*

Proof. The assertion is local on Y, so we may assume without loss of generality that Y is affine. Write $\mathsf{Y} = \mathrm{Sp\acute{e}t}\, A$ for some connective $\mathbb{E}_\infty$-ring A. Since f is affine, we can assume

$\mathsf{X} = \operatorname{Sp\acute{e}t} B$ for some connective A-algebra B. Let $u : A \to B$ denote the underlying map of $\mathbb{E}_\infty$-rings, so that $\mathrm{fib}(u)$ is an n-connective spectrum. To prove (1), we must show that the forgetful functor $\phi_n : (\mathrm{Mod}_B^{\mathrm{cn}})_{\leqslant n} \to (\mathrm{Mod}_A^{\mathrm{cn}})_{\leqslant n}$ is fully faithful. We observe that ϕ_n has a left adjoint ψ_n, given by $M \mapsto \tau_{\leqslant n}(B \otimes_A M)$. We wish to show that the counit map $\psi_n \circ \phi_n \to \mathrm{id}$ is an equivalence. Unwinding the definitions, we must show that if $M \in (\mathrm{Mod}_B^{\mathrm{cn}})_{\leqslant n}$, then the canonical map $\theta : B \otimes_A M \to M$ exhibits M as an n-truncation of $B \otimes_A M$. Since M is n-truncated, this is equivalent to the requirement that $\mathrm{fib}(\theta)$ is $(n+1)$-connective. Let θ_0 be the multiplication map $B \otimes_A B \to B$, so that $\mathrm{fib}(\theta) \simeq \mathrm{fib}(\theta_0) \otimes_B M$. Since M is connective, it will suffice to show that $\mathrm{fib}(\theta_0)$ is $(n+1)$-connective. Note that θ_0 admits a section s, so we can identify $\mathrm{fib}(\theta_0)$ with the $\mathrm{cofib}(s) = B \otimes_A \mathrm{cofib}(u)$. We complete the proof of (1) by observing that $\mathrm{cofib}(u) = \Sigma \, \mathrm{fib}(u)$ is $(n+1)$-connective.

We now prove (2). Let ϕ_{n-1} and ψ_{n-1} be defined as above; we wish to show that the unit map $\mathrm{id} \to \phi_{n-1} \circ \psi_{n-1}$ is an equivalence. In other words, we wish to show that if $N \in (\mathrm{Mod}_A^{\mathrm{cn}})_{\leqslant n-1}$, then the canonical map $N \to B \otimes_A N$ induces an isomorphism $\pi_i N \to \pi_i(B \otimes_A N)$ for $i < n$. We have a long exact sequence

$$\pi_i(\mathrm{fib}(u) \otimes_A N) \to \pi_i N \to \pi_i(B \otimes_A N) \to \pi_{i-1}(\mathrm{fib}(u) \otimes_A N).$$

It therefore suffices to show that the homotopy groups $\pi_i(\mathrm{fib}(u) \otimes_A N)$ vanish for $i < n$. This is clear, since $\mathrm{fib}(u)$ is n-connective and N is connective. □

Corollary 2.5.9.2. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ and $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ be spectral Deligne-Mumford stacks. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism which induces an equivalence of ∞-topoi $\mathsf{X} \simeq \mathsf{Y}$ and an equivalence of n-truncations $\tau_{\leqslant n} \mathscr{O}_{\mathcal{Y}} \simeq \tau_{\leqslant n} f_* \mathscr{O}_{\mathcal{X}}$. Then the pushforward functor f_* induces an equivalence of ∞-categories $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}_{\leqslant n} \simeq \mathrm{QCoh}(\mathsf{Y})^{\mathrm{cn}}_{\leqslant n}$.*

Proof. Let $\tau_{\leqslant n} \mathsf{X} = (\mathcal{X}, \tau_{\leqslant n} \mathscr{O}_{\mathcal{X}})$ and define $\tau_{\leqslant n} \mathsf{Y}$ similarly, so that we have a commutative diagram

$$\begin{array}{ccc} \tau_{\leqslant n} \mathsf{X} & \longrightarrow & \tau_{\leqslant n} \mathsf{Y} \\ \downarrow{\scriptstyle \phi} & & \downarrow{\scriptstyle \psi} \\ \mathsf{X} & \longrightarrow & \mathsf{Y} \end{array}$$

where the upper horizontal map is an equivalence. It will therefore suffice to show that the vertical maps induce equivalences of ∞-categories

$$\phi_* : \mathrm{QCoh}(\tau_{\leqslant n} \mathsf{X})^{\mathrm{cn}}_{\leqslant n} \to \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}_{\leqslant n} \qquad \psi_* : \mathrm{QCoh}(\tau_{\leqslant n} \mathsf{Y})^{\mathrm{cn}}_{\leqslant n} \to \mathrm{QCoh}(\mathsf{Y})^{\mathrm{cn}}_{\leqslant n}.$$

Both of these assertions follow immediately from Proposition 2.5.9.1. □

Corollary 2.5.9.3. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ be a spectral Deligne-Mumford stack. For each $n \geqslant 0$, set $\mathsf{X}_n = (\mathcal{X}, \tau_{\leqslant n} \mathscr{O}_{\mathsf{X}})$. Then the canonical maps $i_n : \mathsf{X}_n \to \mathsf{X}$ induce an equivalence $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \to \varprojlim \mathrm{QCoh}(\mathsf{X}_n)^{\mathrm{cn}}$.*

Proof. Combine Corollary 2.5.9.2 with Proposition 2.2.5.4. □

2.6 Classification of Quasi-Affine Spectral Deligne-Mumford Stacks

It follows from Corollary 2.4.2.2 that a quasi-affine spectral Deligne-Mumford stack $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ can be recovered from the $\mathbb{E}_\infty$-ring $\Gamma(\mathcal{X}; \mathcal{O}_{\mathcal{X}})$ of global sections of its structure sheaf. Our goal in this section is to prove a more precise result of Bhatt and Halpern-Leistner (see [27]). First, we recall a bit of terminology.

Definition 2.6.0.1. Let R be an $\mathbb{E}_\infty$-ring. We will say that an object $A \in \mathrm{CAlg}_R$ is *idempotent* if the multiplication map $m : A \otimes_R A \to A$ is an equivalence.

Theorem 2.6.0.2. *Let* QAff *denote the full subcategory of* SpDM *spanned by the quasi-affine spectral Deligne-Mumford stacks. Then the construction* $(\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \mapsto \Gamma(\mathcal{X}; \mathcal{O}_{\mathcal{X}})$ *determines fully faithful functor* $\rho : \mathrm{QAff}^{\mathrm{op}} \to \mathrm{CAlg}$*. Moreover, the following conditions on an object* $A \in \mathrm{CAlg}$ *are equivalent:*

(1) *The* $\mathbb{E}_\infty$*-ring* A *belongs to the essential image of the functor* ρ.

(2) *The* $\mathbb{E}_\infty$*-ring* A *is* $(-n)$*-connective for* $n \gg 0$ *and* A *is a compact idempotent object of* $\mathrm{CAlg}_{\tau_{\geqslant 0} A}$.

(3) *The* $\mathbb{E}_\infty$*-ring* A *is* $(-n)$*-connective for* $n \gg 0$ *and there exists a connective* $\mathbb{E}_\infty$*-ring* R *and a morphism* $R \to A$ *which exhibits* A *as a compact idempotent object of* CAlg_R.

We will deduce Theorem 2.6.0.2 from the following more precise result, which we will prove at the end of this section.

Proposition 2.6.0.3. *Let* R *be a connective* $\mathbb{E}_\infty$*-ring and let* $\operatorname{Spec} R = (|\operatorname{Spec} R|, \mathcal{O})$ *be its Zariski spectrum (Example 1.1.1.2). Then the construction* $U \mapsto \mathcal{O}(U)$ *determines a fully faithful embedding from the set of quasi-compact open subsets of* $|\operatorname{Spec} A|$ *(ordered by reverse inclusion) to the full subcategory of* CAlg_R *spanned by those object which are compact, idempotent, and* $(-n)$*-connective for some* $n \gg 0$.

Proof of Theorem 2.6.0.2 from Proposition 2.6.0.3. If $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ and $\mathsf{Y} = (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ are spectral Deligne-Mumford stacks for which $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is quasi-affine, then the canonical map

$$\mathrm{Map}_{\mathrm{SpDM}}(\mathsf{Y}, \mathsf{X}) \to \mathrm{Map}_{\mathrm{SpDM}^{\mathrm{nc}}}(\mathsf{Y}, \operatorname{Sp\acute{e}t} \Gamma(\mathcal{X}; \mathcal{O}_{\mathcal{X}})) \simeq \mathrm{Map}_{\mathrm{CAlg}}(\Gamma(\mathcal{X}; \mathcal{O}_{\mathcal{X}}), \Gamma(\mathcal{Y}; \mathcal{O}_{\mathcal{Y}})$$

is a homotopy equivalence by virtue of Corollary 2.4.2.2. This proves that the global sections functor $\rho : \mathrm{QAff}^{\mathrm{op}} \to \mathrm{CAlg}$ is fully faithful.

According to Proposition 2.4.2.3, a spectral Deligne-Mumford stack $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is quasi-affine if and only if there exists a quasi-compact open immersion $\mathsf{X} \hookrightarrow \operatorname{Sp\acute{e}t} R$, for some connective $\mathbb{E}_\infty$-ring R. Consequently, the equivalence of conditions (1) and (3) follows from Proposition 2.6.0.3. The implication (2) ⇒ (3) is obvious, and the implication (1) ⇒ (2) follows from Proposition 2.6.0.3 together with the observation that if X is quasi-affine, then the canonical map the canonical map $\mathsf{X} \to \mathrm{Sp\acute{e}t}\, \tau_{\geqslant 0}\Gamma(\mathcal{X}; \mathscr{O}_{\mathcal{X}})$ is an open immersion (see Proposition 2.4.1.3). □

2.6.1 The Case of a Noetherian Commutative Ring

We begin by discussing the classification of idempotent R-algebras in the case where R is a Noetherian commutative ring, following Hopkins and Neeman (see [98], [160], and [197]).

Notation 2.6.1.1. Let R be a connective $\mathbb{E}_\infty$-ring. For each point $x \in |\operatorname{Spec} R|$, we let $\kappa(x)$ denote the residue field of the commutative ring $\pi_0 R$ at the point x. If $A \in \mathrm{CAlg}_R$ is idempotent, we let $\mathrm{Supp}(A)$ denote the set $\{x \in |\operatorname{Spec} R| : A \otimes_R \kappa(x) \neq 0\}$. We will refer to $\mathrm{Supp}(A)$ as the *support* of A.

Theorem 2.6.1.2. *Let R be a commutative Noetherian ring. Then the construction $A \mapsto \mathrm{Supp}(A)$ induces an equivalence from the full subcategory $\mathrm{CAlg}_R^{\mathrm{Idem}} \subseteq \mathrm{CAlg}_R$ spanned by the idempotent objects to the collection of $U \subseteq |\operatorname{Spec} R|$ which are closed under generalization (meaning that $x \in \overline{\{y\}} \cap U$ implies $y \in U$), ordered by reverse inclusion.*

The proof of Theorem 2.6.1.2 will require some preliminaries.

Lemma 2.6.1.3. *Let R be a Noetherian commutative ring and let $M \in \mathrm{Mod}_R$. Assume that, for every residue field κ of R, the tensor product $\kappa \otimes_R M$ vanishes. Then $M \simeq 0$.*

Proof. We will prove that for every ideal $I \subseteq R$, the tensor product $R/I \otimes_R M$ vanishes. Since R is Noetherian, we may proceed by induction: to prove that $R/I \otimes_R M \simeq 0$, we may assume that $R/J \otimes_R M \simeq 0$ for every ideal $I' \subseteq R$ containing I. Replacing R by R/I and M by $R/I \otimes_R M$, we may assume that $R/I' \otimes_R M \simeq 0$ for every nonzero ideal $I' \subseteq R$, and we wish to prove that $M \simeq 0$.

Let $J \subseteq R$ be maximal among those ideals for which the tensor product $J \otimes_R M$ vanishes. We wish to prove that $J = R$. Assume otherwise. Then R/J has an associated prime $\mathfrak{p}$ of R, so that $\mathfrak{p}$ occurs as the annihilator of an element element $x \in R/J$. Let $J' \subseteq R$ denote the inverse image of the cyclic module $Rx \subseteq R/I$, so that J' is an ideal of R which properly contains J. We have a short exact sequence of discrete R-modules

$$0 \to J \to J' \to R/\mathfrak{p} \to 0,$$

hence a fiber sequence

$$J \otimes_R M \to J' \otimes_R M \to R/\mathfrak{p} \otimes_R M.$$

To obtain a contradiction, it will suffice to show that $J' \otimes_R M$ vanishes. Since $J \otimes_R M \simeq 0$, we are reduced to proving that $R/\mathfrak{p} \otimes_R M \simeq 0$. We may therefore replace R by $R/\mathfrak{p}$ and thereby reduce to the case where R is an integral domain.

Since R is an integral domain, we have a short exact sequence of discrete R-modules

$$0 \to R \xrightarrow{y} R \to R/Ry \to 0.$$

It follows that $R/Ry \otimes_R M$ is the cofiber of the map $\phi_y : M \to M$ given by multiplication by y. Since Ry is a nonzero ideal of R, the tensor product $R/Ry \otimes_R M$ vanishes. It follows that ϕ_y is invertible.

Let K denote the fraction field of R. Then K is flat as an R-module, so the canonical map $K \otimes_R \pi_* M \to \pi_*(K \otimes_R M)$ is an isomorphism. Since every nonzero element of R acts invertibly on $\pi_* R$, it follows that the map $\pi_* M \to \pi_*(K \otimes_R M)$ is an isomorphism. Then $M \simeq K \otimes_R M \simeq 0$, since K is a residue field of R. □

Corollary 2.6.1.4. *Let R be a Noetherian $\mathbb{E}_\infty$-ring and let M be an almost connective R-module. Suppose that for every residue field κ of $\pi_0 R$, the tensor product $\kappa \otimes_R M$ vanishes. Then $M \simeq 0$.*

Proof. Assume that $M \neq 0$. There exists some smallest integer n such that $\pi_n M$ is nonzero. Then $\pi_n(\pi_0 R \otimes_R M) \simeq \pi_n M$ is also nonzero. Invoking Lemma 2.6.1.3, we deduce that there exists a residue field κ of $\pi_0 R$ such that

$$\kappa \otimes_{\pi_0 R} (\pi_0 R \otimes_R M) \simeq \kappa \otimes_R M$$

is nonzero. □

Warning 2.6.1.5. In the situation of Corollary 2.6.1.4, the hypothesis that M is almost connective cannot be removed. For example, let K denote the complex K-theory spectrum and let K/p denote the cofiber of the map $K \to K$ given by multiplication by a prime number p. Then K/p can be regarded as a module over the sphere spectrum S, and this module has the property that $\kappa \otimes_S K/p = \kappa \otimes K/p \simeq 0$ for every field κ (in other words, spectrum K/p has vanishing homology with coefficients in any field).

Lemma 2.6.1.6. *Let κ be a field and let $A \in \mathrm{CAlg}_\kappa$ be an idempotent object. Then either $A \simeq 0$ or the unit map $e : \kappa \to A$ is an equivalence.*

Proof. Since A is idempotent, the canonical map $A \simeq A \otimes_\kappa \kappa \to A \otimes_\kappa A$ is an equivalence. Passing to cofibers, we deduce that $A \otimes_\kappa \mathrm{cofib}(e) \simeq 0$. If A is nonzero, then it contains κ as a direct summand (in the ∞-category Mod_κ) so that $\kappa \otimes_\kappa \mathrm{cofib}(e) \simeq \mathrm{cofib}(e)$ vanishes and therefore e is an equivalence. □

Lemma 2.6.1.7. *Let R be a Noetherian commutative ring and let $\phi : A \to B$ be a morphism in CAlg_R. If A and B are idempotent and $\mathrm{Supp}(A) = \mathrm{Supp}(B)$, then ϕ is an equivalence.*

Proof. By virtue of Lemma 2.6.1.3, it will suffice to show that ϕ induces an equivalence $A \otimes_R \kappa \to B \otimes_R \kappa$ for every residue field κ of R. This follows from Lemma 2.6.1.6 and our assumption that $\mathrm{Supp}(A) = \mathrm{Supp}(B)$. □

Proof of Theorem 2.6.1.2. We first note that if $A, B \in \mathrm{CAlg}_R$ and A is idempotent, then the mapping space $\mathrm{Map}_{\mathrm{CAlg}_R}(A, B)$ is either empty or contractible: this follows from the observation that the diagonal map

$$\mathrm{Map}_{\mathrm{CAlg}_R}(A, B) \to \mathrm{Map}_{\mathrm{CAlg}_R}(A, B) \times \mathrm{Map}_{\mathrm{CAlg}_R}(A, B)) \simeq \mathrm{Map}_{\mathrm{CAlg}_R}(A \otimes_R A, B)$$

is a homotopy equivalence. It will therefore suffice to verify the following:

(a) For $A, B \in \mathrm{CAlg}_R^{\mathrm{Idem}}$, the mapping space $\mathrm{Map}_{\mathrm{CAlg}_R}(A, B)$ is nonempty if and only if $\mathrm{Supp}(A) \supseteq \mathrm{Supp}(B)$.

(b) A subset $U \subseteq |\operatorname{Spec} R|$ has the form $\mathrm{Supp}(A)$ for some $A \in \mathrm{CAlg}_R^{\mathrm{Idem}}$ if and only if U is closed under generalization.

We first prove (a). Let A and B be idempotent $\mathbb{E}_\infty$-algebras over R. If there exists a morphism $\phi : A \to B$, then for every residue field κ of $\pi_0 A$ there is an induced map $A \otimes_R \kappa \to B \otimes_R \kappa$. Consequently, if $A \otimes_R \kappa \simeq 0$, then we also have $B \otimes_R \kappa$. This proves that $\mathrm{Supp}(A) \supseteq \mathrm{Supp}(B)$.

For the converse, suppose that $\mathrm{Supp}(A) \supseteq \mathrm{Supp}(B)$. Then $\mathrm{Supp}(A \otimes_R B) = \mathrm{Supp}(A) \cap \mathrm{Supp}(B) = \mathrm{Supp}(B)$. It follows from Lemma 2.6.1.7 that the natural map $B \to A \otimes_R B$ is an equivalence, so that there exists a morphism $A \to A \otimes_R B \simeq B$. This completes the proof of (a).

We now prove (b). Suppose first that $A \in \mathrm{CAlg}_R^{\mathrm{Idem}}$: we will show that the support $\mathrm{Supp}(A)$ is closed under generalization. Choose points $x, y \in |\operatorname{Spec} R|$ such that $x \in \overline{\{y\}} \cap \mathrm{Supp}(A)$; we wish to show that $y \in \mathrm{Supp}(A)$. Using Lemma **??**, we can choose a ring homomorphism $R \to R'$, where R' is a discrete valuation ring and the induced map $|\operatorname{Spec} R'| \to |\operatorname{Spec} R|$ carries the closed point of $|\operatorname{Spec} R'|$ to x and the generic point of $|\operatorname{Spec} R'|$ to y. Replacing A by $A \otimes_R R' \in \mathrm{CAlg}_{R'}$, we can reduce to the case where $R = R'$ is a discrete valuation ring. Let π be a uniformizer of R. If $\mathrm{Supp}(A)$ does not contain the generic point of $|\operatorname{Spec} R|$, then $A[\pi^{-1}] \simeq 0$ and therefore multiplication by π is locally nilpotent on $\pi_0 A$. Since $A \neq 0$, it follows that $\pi_0 A$ contains a nonzero element which is annihilated by π. Using the exactness of the sequence

$$\pi_1(A \otimes_R (R/\pi)) \to \pi_0 A \xrightarrow{\pi} \pi_0 A,$$

we conclude that $\pi_1(A \otimes_R (R/\pi)) \neq 0$. This contradicts Lemma 2.6.1.6, since $A \otimes_R (R/\pi)$ is an idempotent $\mathbb{E}_\infty$-algebra over the residue field R/π.

Now suppose that $U \subseteq |\operatorname{Spec} R|$ is stable under generalization; we wish to prove that $U = \operatorname{Supp}(A_U)$ for some $A_U \in \mathrm{CAlg}_R^{\mathrm{Idem}}$. We first consider the case where U is an open subset of $|\operatorname{Spec} R|$. Since R is Noetherian, the open set U is automatically quasi-compact and therefore determines a quasi-affine open substack $\mathsf{U} \subseteq \operatorname{Sp\acute{e}t} R$. Let A_U denote the $\mathbb{E}_\infty$-algebra of global sections of the structure sheaf of U. Note that the diagonal map $\mathsf{U} \to \mathsf{U} \times_{\operatorname{Sp\acute{e}t} R} \mathsf{U}$ is an equivalence. Using Proposition 2.5.4.5 (and Example 2.5.3.3), we deduce that A_U is an idempotent object of CAlg_R satisfying $\operatorname{Supp}(A_U) = U$.

We now treat the general case. Let U be a subset of $|\operatorname{Spec} R|$ which is stable under generalization. For every open set $V \subseteq |\operatorname{Spec} R|$ containing U, let $A_V \in \mathrm{CAlg}_R^{\mathrm{Idem}}$ be defined as above. Then the construction $V \mapsto A_V$ is functorial (this follows from assertion (a); alternatively, we can observe that A_V is the value of the structure sheaf of $\operatorname{Sp\acute{e}t} R$ on V). Then $A = \varinjlim_{U \subseteq V} A_V$ is a filtered colimit of idempotent objects of CAlg_R, hence idempotent. Unwinding the definitions, we deduce that $\operatorname{Supp}(A) = \bigcap_{U \subseteq V} \operatorname{Supp}(A_V) = \bigcap_{U \subseteq V} V$, where the intersection is taken over all open neighborhoods of U in $|\operatorname{Spec} R|$. Since U is closed under generalization, this intersection is equal to U. □

Warning 2.6.1.8. If R is a non-Noetherian commutative ring, then the support of an idempotent object $A \in \mathrm{CAlg}_R$ need not be stable under generalization. For example, if R is a valuation ring with value group $\mathbf{Q}$, then the residue field of R is an idempotent R-algebra which is supported at the closed point of $|\operatorname{Spec} R|$.

2.6.2 The Case of a Commutative Ring

If R is a non-Noetherian commutative ring, then it is not so easy to describe the idempotent objects of CAlg_R. However, there is still a simple classification of *compact* idempotent objects:

Proposition 2.6.2.1. *Let R be a connective $\mathbb{E}_\infty$-ring and let $\mathscr{O} \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(|\operatorname{Spec} R|)$ denote the structure sheaf of* $\operatorname{Spec} R$ *(regarded as a spectral scheme). Then the construction $U \mapsto \mathscr{O}(U)$ induces a fully faithful embedding from the category of quasi-compact open subsets of $|\operatorname{Spec} R|$ (ordered by reverse inclusion) to the full subcategory of* CAlg_R *spanned by the compact idempotent objects. If R is discrete, then this functor is an equivalence.*

Proof. Unwinding the definitions, we must verify the following:

- (a) For every quasi-compact open subset $U \subseteq |\operatorname{Spec} R|$, the algebra $\mathscr{O}(U) \in \mathrm{CAlg}_R$ is compact and idempotent.
- (b) For every pair of quasi-compact open subsets $U, V \subseteq |\operatorname{Spec} R|$, the mapping space $\mathrm{Map}_{\mathrm{CAlg}_R}(\mathscr{O}(U), \mathscr{O}(V))$ is contractible if $V \subseteq U$ and empty otherwise.

(c) If R is discrete, then every compact idempotent object $A \in \mathrm{CAlg}_R$ has the form $\mathscr{O}(U)$ for some quasi-compact open subset $U \subseteq |\operatorname{Spec} R|$.

We begin by verifying (a). Note that each open subset $U \subseteq |\operatorname{Spec} R|$ determines an open substack U of $\operatorname{Spét} R$, and we can identify $\mathscr{O}(U)$ with the $\mathbb{E}_\infty$-ring of global sections of the structure sheaf of U. If U is quasi-compact, then U is quasi-affine. Applying Proposition 2.5.4.5 and Example 2.5.3.3, we can identify $\mathscr{O}(U) \otimes_R \mathscr{O}(U)$ with the $\mathbb{E}_\infty$-ring of global sections of the structure sheaf of $\mathsf{U} \times_{\operatorname{Spét} R} \mathsf{U}$. Since the diagonal map $\mathsf{U} \to \mathsf{U} \times_{\operatorname{Spét} R} \mathsf{U}$ is an equivalence, it follows that $\mathscr{O}(U) \in \mathrm{CAlg}_R$ is idempotent.

We next show that $\mathscr{O}(U)$ is a compact object of CAlg_R. Since U is quasi-compact, it can be identified with the complement of the vanishing locus of a finitely generated ideal $I = (x_1, \ldots, x_n) \subseteq \pi_0 R$. For $1 \leqslant i \leqslant n$, let $\operatorname{cofib}(x_i) \in \mathrm{Mod}_R$ denote the cofiber of the map $x_i : R \to R$, and let K denote the tensor product $\operatorname{cofib}(x_1) \otimes_R \cdots \otimes_R \operatorname{cofib}(x_n)$. We will prove the following:

($*$) For any object $A \in \mathrm{CAlg}_R$, we have

$$\operatorname{Map}_{\mathrm{CAlg}_R}(\mathscr{O}(U), A) \simeq \begin{cases} \emptyset & \text{if } A \otimes_R K \neq 0 \\ * & \text{if } A \otimes_R K \simeq 0. \end{cases}$$

It follows from this description (and the fact that $K \in \mathrm{Mod}_R$ is perfect) that the functor $A \mapsto \operatorname{Map}_{\mathrm{CAlg}_R}(\mathscr{O}(U), A)$ commutes with filtered colimits.

We now prove ($*$). By construction, the image of K under the equivalence $\mathrm{Mod}_R \simeq \operatorname{QCoh}(\operatorname{Spét} R)$ is a quasi-coherent sheaf which vanishes on U, so the tensor product $\mathscr{O}(U) \otimes_R K$ vanishes. It follows that if $A \otimes_R K \neq 0$, then there do not exist any R-algebra maps $\mathscr{O}(U) \to A$. We wish prove the converse: if $A \otimes_R K = 0$, then the mapping space $\operatorname{Map}_{\mathrm{CAlg}_R}(\mathscr{O}(U), A)$ is nonempty (it is then automatically contractible, since $\mathscr{O}(U)$ is an idempotent object of CAlg_R). Note that we have canonical maps $\mathscr{O}(U) \to A \otimes_R \mathscr{O}(U) \xleftarrow{v} A$. Consequently, to show that there exists an R-algebra morphism from $\mathscr{O}(U)$ to A, it will suffice to show that v is an equivalence, or equivalently that $A \otimes_R \operatorname{cofib}(R \to \mathscr{O}(U)) \simeq 0$. This is a consequence of the following more general assertion:

($*'_m$) Let M be an R-module satisfying $M[x_i^{-1}] \simeq 0$ for $1 \leqslant i \leqslant m$. Then $A \otimes_R \operatorname{cofib}(x_{m+1}) \otimes_R \cdots \otimes_R \operatorname{cofib}(x_n) \otimes_R M \simeq 0$.

We prove ($*'_m$) using induction on m. The case $m = 0$ follows from our assumption that $A \otimes_R K \simeq 0$. To carry out the inductive step, suppose that $m > 0$ and that M satisfies $M[x_i^{-1}]$ for $1 \leqslant i \leqslant m$, and set $N = A \otimes_R \operatorname{cofib}(x_{m+1}) \otimes_R \cdots \otimes_R \operatorname{cofib}(x_n) \otimes_R M \simeq 0$. Our inductive hypothesis implies that $N \otimes_R \operatorname{cofib}(x_m) \simeq 0$: that is, the multiplication map $x_m : N \to N$ is an equivalence. It follows that the unit map $N \to N[x_m^{-1}]$ is an equivalence.

Since $M[x_m^{-1}]$ vanishes, we conclude that $N[x_m^{-1}] \simeq 0$, so that $N \simeq 0$ as desired. This completes the proof of (a).

We now prove (b). Because $\mathscr{O}$ is a functor, it is immediate that the mapping space $\mathrm{Map}_{\mathrm{CAlg}_R}(\mathscr{O}(U), \mathscr{O}(V))$ is nonempty whenever $V \subseteq U$ (in which case it is automatically contractible, since $\mathscr{O}(U)$ is idempotent). It will therefore suffice to show that if V is not contained in U, then the mapping space $\mathrm{Map}_{\mathrm{CAlg}_R}(\mathscr{O}(U), \mathscr{O}(V))$ is empty. Choose a point $x \in V$ which does not belong to U, and let $\kappa(x)$ denote the residue field of the commutative ring $\pi_0 R$ at x. Since the mapping space $\mathrm{Map}_{\mathrm{CAlg}_R}(\mathscr{O}(V), \kappa(x))$ is nonempty, it will suffice to show that $\mathrm{Map}_{\mathrm{CAlg}_R}(\mathscr{O}(U), \kappa(x))$ is empty. This follows immediately from $(*)$, since

$$\pi_0(\kappa(x) \otimes_R K) \simeq \kappa(x)/(x_1, \ldots, x_n) \simeq \kappa(x) \neq 0$$

by virtue of our assumption that $x \notin U$.

We now prove (c). Assume that R is discrete and let $A \in \mathrm{CAlg}_R$ be a compact object. Writing R as a direct limit of its finitely generated subrings, we can apply Theorem **??** to write $A = R \otimes_{R_0} A_0$, where $R_0 \subseteq R$ is a finitely generated subalgebra and A_0 is a compact object of CAlg_{R_0}. Let $m_0 : A_0 \otimes_{R_0} A_0 \to A_0$ be the multiplication map. If A is idempotent, then the morphism m_0 becomes an equivalence after applying the extension-of-scalars functor $\mathrm{CAlg}_{R_0} \to \mathrm{CAlg}_R$. Applying Theorem **??** again, we deduce that there is a finitely generated subring $R_1 \subseteq R$ containing R_0 such that the multiplication $A_1 \otimes_{R_1} A_1 \to A_1$ is an equivalence, where $A_1 = R_1 \otimes_{R_0} A_0$. Then A_1 is a compact idempotent object of CAlg_{R_1}. We may therefore replace the object $A \in \mathrm{CAlg}_R$ by $A_1 \in \mathrm{CAlg}_{R_1}$ and thereby reduce to the case where the commutative ring R is Noetherian. Let $U = \mathrm{Supp}(A)$. The proof of Theorem 2.6.1.2 shows that we can write $A = \varinjlim \mathscr{O}(V)$ where the colimit is taken over all open subsets $V \subseteq |\operatorname{Spec} R|$ which contain U. Since $A \in \mathrm{CAlg}_R$ is compact, it follows that A is a retract of some $\mathscr{O}(V)$ and is therefore equivalent to $\mathscr{O}(V)$ (since every morphism from $\mathscr{O}_V$ to itself is homotopic to the identity, every retract of $\mathscr{O}(V)$ is equivalent to $\mathscr{O}(V)$ itself). □

2.6.3 The General Case

It follows from Proposition 2.6.2.1 that if R is a commutative ring, then every compact idempotent object $A \in \mathrm{CAlg}_R$ arises from a quasi-compact open subset $U \subseteq |\operatorname{Spec} R|$. For more general (connective) $\mathbb{E}_\infty$-rings, this need not be true:

Example 2.6.3.1. Let $R = \mathrm{Sym}^*_{\mathbf{Q}}(\Sigma^2 \mathbf{Q})$ be the free $\mathbb{E}_\infty$-algebra over $\mathbf{Q}$ on a single generator of degree 2, so that we have a canonical isomorphism $\pi_* R \simeq \mathbf{Q}[t]$ where $t \in \pi_2 R$. Then $|\operatorname{Spec} R|$ consists of a single point. However, the localization $R[t^{-1}]$ is a compact idempotent object of CAlg_R which is not equivalent to 0 or R.

Example 2.6.3.2. Let $R = S_{(p)}$ be the p-local sphere spectrum. Then $|\operatorname{Spec} R| \simeq |\operatorname{Spec} \mathbf{Z}_{(p)}|$ has exactly three open subsets, which determine compact idempotent objects

$0, \mathbf{Q}, S_{(p)} \in \mathrm{CAlg}_R$. However, there are many other compact idempotent objects of CAlg_R, given by *telescopic localizations* of the sphere spectrum (see, for example, [171]).

We can rule out the sort of "wild" idempotents appearing in Examples 2.6.3.1 and 2.6.3.2 by imposing connectivity hypotheses.

Proof of Proposition 2.6.0.3. Let R be a connective $\mathbb{E}_\infty$-ring and let A be a compact idempotent object of CAlg_R. By virtue of Proposition 2.6.2.1, it will suffice to prove that the following conditions on A are equivalent:

- (i) The $\mathbb{E}_\infty$-ring A is $(-n)$-connective for $n \gg 0$.
- (ii) There exists a quasi-compact open subset $U \subseteq |\operatorname{Spec} R|$ and an equivalence $A \simeq \mathscr{O}(U)$, where $\mathscr{O}$ denotes the structure sheaf of the spectral scheme $\operatorname{Spec} R$.

The implication $(ii) \Rightarrow (i)$ follows immediately from Proposition 2.5.4.4. We now prove the converse. Let A be a compact idempotent object of CAlg_R and set $A_0 = (\pi_0 R) \otimes_R A$, so that A_0 is a compact idempotent object of $\mathrm{CAlg}_{\pi_0 R}$. Let $\mathscr{O}_0$ denote the structure sheaf of the spectral scheme $\operatorname{Spec} \pi_0 R$. Applying Proposition 2.6.2.1, we deduce that $A_0 = \mathscr{O}_0(U)$ for some quasi-compact open subset $U \subseteq |\operatorname{Spec} \pi_0 R| \simeq |\operatorname{Spec} R|$. Set $A' = \mathscr{O}(U)$. We will complete the proof by showing that if A satisfies (i), then A and A' are equivalent objects of CAlg_R. More precisely, we will show that the canonical maps

$$A \xrightarrow{u} A \otimes_R A' \xleftarrow{v} A'$$

are both equivalences in CAlg_R. Using the implication $(ii) \Rightarrow (i)$, we see that A' also satisfies condition (i), so that the tensor product $A \otimes_R A'$ satisfies (i) as well. It follows that $\mathrm{cofib}(u)$ and $\mathrm{cofib}(v)$ are $(-n)$-connective for $n \gg 0$. Consequently, to show that $\mathrm{cofib}(u)$ and $\mathrm{cofib}(v)$ vanish, it will suffice to show that the tensor products $\mathrm{cofib}(u) \otimes_R (\pi_0 R)$ and $\mathrm{cofib}(v) \otimes_R (\pi_0 R)$ vanish. In other words, it suffices to show that u and v are equivalences after extension of scalars along the map $R \to \pi_0 R$, which is immediate from our construction. □

2.7 Finiteness Properties of Modules

Let A be an $\mathbb{E}_\infty$-ring and let M be an A-module. Recall that M is said to be *perfect* if it is a compact object of Mod_A (see §HA.7.2.4). If A is discrete, then we can identify Mod_A with the derived ∞-category of the abelian category $\mathrm{Mod}_A^\heartsuit$ of discrete A-modules (Remark HA.7.1.1.16). In this case, an object $K \in \mathrm{Mod}_A \simeq \mathcal{D}(\mathrm{Mod}_A^\heartsuit)$ is perfect if and only if it can be represented by a bounded chain complex of finitely generated projective A-modules. In this section, we will study some weaker finiteness conditions on A-modules, which correspond (in the case where A is discrete) to chain complexes which are required to be finitely generated and projective only in a certain range of degrees.

Definition 2.7.0.1. Let A be a connective $\mathbb{E}_1$-ring and let M be a left A-module. We will say that M is *perfect to order n* if, for every filtered diagram $\{N_\alpha\}$ in $(\mathrm{LMod}_A)_{\leqslant 0}$, the canonical map $\varinjlim_\alpha \mathrm{Ext}^i_A(M, N_\alpha) \to \mathrm{Ext}^i_A(M, \varinjlim N_\alpha)$ injective for $i = n$ and bijective for $i < n$.

Remark 2.7.0.2. If A is a connective $\mathbb{E}_1$-ring, then a left A-module M is almost perfect (see Definition HA.7.2.4.10) if and only if it is perfect to order n for every integer n.

Example 2.7.0.3. Let A be a connective $\mathbb{E}_1$-ring. If $M \in \mathrm{LMod}_A$ is $(n+1)$-connective, then it is perfect to order n.

The following reformulation of Definition 2.7.0.1 is often convenient:

Proposition 2.7.0.4. *Let A be a connective $\mathbb{E}_1$-ring, let M be a left A-module, and let n be an integer. The following conditions are equivalent:*

(1) *The left A-module M is perfect to order n, in the sense of Definition 2.7.0.1.*

(2) *For every filtered diagram $\{N_\alpha\}$ in LMod_A where each N_α is 0-truncated and each transition map $\pi_0 N_\alpha \to \pi_0 N_\beta$ is a monomorphism, the canonical map $\varinjlim_\alpha \mathrm{Map}_{\mathrm{LMod}_A}(M, \Sigma^n N_\alpha) \to \mathrm{Map}_{\mathrm{LMod}_A}(M, \varinjlim \Sigma^n N_\alpha)$ is a homotopy equivalence.*

(3) *The module M is almost connective. Moreover, if $\{N_\alpha\}$ is a filtered diagram in $\mathrm{LMod}_A^\heartsuit$ having the property that each transition map $N_\alpha \to N_\beta$ is a monomorphism, then the canonical map $\varinjlim_\alpha \mathrm{Map}_{\mathrm{LMod}_A}(M, \Sigma^n N_\alpha) \to \mathrm{Map}_{\mathrm{LMod}_A}(M, \varinjlim \Sigma^n N_\alpha)$ is a homotopy equivalence.*

Proof. Without loss of generality we may assume $n = 0$. We first show that (1) implies (2). Suppose first that M is perfect to order n, and let $\{N_\alpha\}$ be as in (2). Since each of the transition maps $\pi_0 N_\alpha \to \pi_0 N_\beta$ is an monomorphism, it follows that each of the maps $\pi_0 N_\alpha \to \pi_0 N$ is a monomorphism. For each index α, form a cofiber sequence $N_\alpha \to N \to K_\alpha$, so that K_α is 0-truncated. Applying our hypothesis that M is perfect to order 0 to the filtered diagram $\{K_\alpha\}$, we conclude that the canonical map

$$\varinjlim \mathrm{Ext}^i_A(M, K_\alpha) \to \mathrm{Ext}^i_A(M, \varinjlim K_\alpha) \simeq \mathrm{Ext}^i_A(M, 0) \simeq 0$$

is injective for $i = 0$ and bijective for $i < 0$: that is, the abelian groups $\varinjlim \mathrm{Ext}^i_A(M, K_\alpha)$ vanish for $i \leqslant 0$. It follows that the space $\varinjlim_\alpha \mathrm{Map}_{\mathrm{LMod}_A}(M, K_\alpha)$ is contractible. Using the evident fiber sequence

$$\varinjlim_\alpha \mathrm{Map}_{\mathrm{LMod}_A}(M, N_\alpha) \xrightarrow{\rho} \mathrm{Map}_{\mathrm{LMod}_A}(M, N) \to \varinjlim_\alpha \mathrm{Map}_{\mathrm{LMod}_A}(M, K_\alpha),$$

we deduce that ρ is a homotopy equivalence.

Note that if M satisfies condition (2), then the canonical map $\varinjlim_k \mathrm{Map}_{\mathrm{LMod}_A}(M, \tau_{\geqslant -k}(\tau_{\leqslant 0} M)) \to \mathrm{Map}_{\mathrm{LMod}_A}(M, \tau_{\leqslant 0} M)$ is a homotopy equivalence. In particular, the canonical map $M \to \tau_{\leqslant 0} M$ factors through some truncation $\tau_{\geqslant -k} \tau_{\leqslant 0} M$, which implies that M is $(-k)$-connective. This shows that (2) ⇒ (3).

We now complete the proof by showing that (3) ⇒ (1). Assume that M satisfies condition (3), and let $\{N_\alpha\}$ be a filtered diagram of 0-truncated A-modules having some colimit N. We wish to show that the canonical map $\varinjlim \mathrm{Ext}^i_A(M, N_\alpha) \to \mathrm{Ext}^i_A(M, N)$ is bijective for $i < 0$ and injective for $i = 0$. Equivalently, we wish to show that the canonical map $\theta : \varinjlim_\alpha \mathrm{Map}_{\mathrm{LMod}_A}(M, N_\alpha) \to \mathrm{Map}_{\mathrm{LMod}_A}(M, N)$ has (-1)-truncated homotopy fibers. Choose an integer $k \gg 0$ for which M is $(-k)$-connective. We can then replace $\{N_\alpha\}$ by $\{\tau_{\geqslant -k} N_\alpha\}$, and thereby reduce to the case where each N_α is $(-m)$-connective for some fixed $m \geqslant 0$. We now proceed by induction on m. Assume that $m > 0$. Set $N'_\alpha = \tau_{\geqslant 1-m} N_\alpha$ and $N''_\alpha = \tau_{\leqslant -m} N_\alpha$, so that we have a commutative diagram of fiber sequences

$$\begin{array}{ccc}
\varinjlim_\alpha \mathrm{Map}_{\mathrm{LMod}_A}(M, N'_\alpha) & \xrightarrow{\theta'} & \mathrm{Map}_{\mathrm{LMod}_A}(M, N') \\
\downarrow & & \downarrow \\
\varinjlim_\alpha \mathrm{Map}_{\mathrm{LMod}_A}(M, N_\alpha) & \xrightarrow{\theta} & \mathrm{Map}_{\mathrm{LMod}_A}(M, N) \\
\downarrow & & \downarrow \\
\varinjlim_\alpha \mathrm{Map}_{\mathrm{LMod}_A}(M, N''_\alpha) & \xrightarrow{\theta''} & \mathrm{Map}_{\mathrm{LMod}_A}(M, N'')
\end{array}$$

where $N' = \varinjlim N'_\alpha$ and $N'' = \varinjlim N''_\alpha$. Since the map θ' has (-1)-truncated homotopy fibers by our inductive hypothesis, we are reduced to proving that the map θ'' has (-1)-truncated homotopy fibers. The map θ'' is obtained by applying the functor Ω^m to the canonical map $\varinjlim_\alpha \mathrm{Map}_{\mathrm{LMod}_A}(M, \pi_{-m} N_\alpha) \to \mathrm{Map}_{\mathrm{LMod}_A}(M, \pi_{-m} N)$. Replacing $\{N_\alpha\}$ by $\{\pi_{-m} N_\alpha\}$, we may reduce to the case $m = 0$.

Let us regard each N_α as a discrete left module over the associative ring $\pi_0 A$. Without loss of generality, we may assume that the diagram $\{N_\alpha\}$ is indexed by a filtered partially ordered set I. For $\alpha \leqslant \beta$ in I, let $K_{\alpha,\beta}$ denote the kernel of the transition map $N_\alpha \to N_\beta$. For fixed α, we can regard $\{K_{\alpha,\beta}\}_{\beta \geqslant \alpha}$ as a filtered diagram of discrete A-modules whose transition maps are monomorphisms, whose colimit $K_\alpha = \varinjlim_{\beta \geqslant \alpha} K_{\alpha,\beta}$ can be identified with the kernel of the map $N_\alpha \to N$. Applying assumption (3), we deduce that the canonical map $\varinjlim_{\beta \geqslant \alpha} \mathrm{Map}_{\mathrm{LMod}_A}(M, K_{\alpha,\beta}) \to \mathrm{Map}_{\mathrm{LMod}_A}(M, K_\alpha)$ is a homotopy equivalence. Set $N'_\alpha = N_\alpha / K_\alpha \simeq \mathrm{im}(N_\alpha \to N)$, so that we have a fiber sequence of spaces

$$\varinjlim_{\beta \geqslant \alpha} \mathrm{Map}_{\mathrm{LMod}_A}(M, K_{\alpha,\beta}) \to \mathrm{Map}_{\mathrm{LMod}_A}(M, N_\alpha) \to \mathrm{Map}_{\mathrm{LMod}_A}(M, N'_\alpha).$$

Applying assumption (3) to the diagram $\{N'_\alpha\}_{\alpha \in I}$, we deduce that the canonical map $\varinjlim_\alpha \mathrm{Map}_{\mathrm{LMod}_A}(M, N'_\alpha) \to \mathrm{Map}_{\mathrm{LMod}_A}(M, N)$ is a homotopy equivalence. It follows that the map θ fits into a fiber sequence

$$\varinjlim_{\alpha \in I} \varinjlim_{\beta \geqslant \alpha} \mathrm{Map}_{\mathrm{LMod}_A}(M, K_{\alpha,\beta}) \to \varinjlim_{\alpha} \mathrm{Map}_{\mathrm{LMod}_A}(M, N_\alpha) \xrightarrow{\theta} \mathrm{Map}_{\mathrm{LMod}_A}(M, N).$$

The first term is contractible, since the transition map $K_{\alpha,\beta} \to K_{\alpha',\beta'}$ vanishes for $\alpha' \geqslant \beta$. It follows that θ is (-1)-truncated, as desired. □

Remark 2.7.0.5. Let A be a connective $\mathbb{E}_1$-ring, let M be a left A-module, and let n be an integer. Then:

(a) If $\tau_{\leqslant n} M$ is a compact object of $\tau_{\leqslant n} \mathrm{LMod}_A$, then M is perfect to order n.

(b) If M is perfect to order n, then $\tau_{\leqslant n-1} M$ is a compact object of $\tau_{\leqslant n-1} \mathrm{LMod}_A$.

Remark 2.7.0.6. Let A be a connective $\mathbb{E}_1$-ring, and let M be a left A-module which is perfect to order n for some integer n. Then $M \in (\mathrm{LMod}_A)_{\geqslant -m}$ for some m. This follows immediately from Remark 2.7.0.5.

Remark 2.7.0.7. Let A be a connective $\mathbb{E}_1$-ring and suppose we are given a fiber sequence of left A-modules $M' \to M \to M''$. If M' is perfect to order n, then M is perfect to order n if and only if M'' is perfect to order n. This follows immediately from an inspection of the associated long exact sequence of Ext-groups.

Remark 2.7.0.8. Suppose we are given a finite collection of connective $\mathbb{E}_1$-rings $\{A_i\}_{1 \leqslant i \leqslant n}$ having product A. Let M be a left A-module, so that $M \simeq \prod M_i$ where each M_i is a left module over A_i. Then M is perfect to order n if and only if each M_i is perfect to order n.

2.7.1 Finitely n-Presented Modules

We now consider a slight variant of Definition 2.7.0.1.

Definition 2.7.1.1. Let A be a connective $\mathbb{E}_1$-ring, let M be a left A-module, and let n be an integer. We will say that M is *finitely n-presented* if M is n-truncated and perfect to order $(n+1)$.

Remark 2.7.1.2. Let A be a connective $\mathbb{E}_1$-ring, and suppose we are given a map of left A-modules $f : M \to M'$ such that the induced map $\pi_i M \to \pi_i M'$ is surjective when $i = n$ and bijective for $i < n$. Let $N \in (\mathrm{LMod}_A)_{\leqslant 0}$. Then the induced map $\mathrm{Ext}^i_A(M', N) \to \mathrm{Ext}^i_A(M, N)$ is injective for $i = n$ and bijective for $i < n$. It follows that if M is perfect to order n, so is M'.

Remark 2.7.1.3. Let A be a connective $\mathbb{E}_1$-ring. If M is a left A-module which is perfect to order $n+1$, then $\tau_{\leqslant n} M$ is also perfect to order $n+1$ (this is a special case of Remark 2.7.1.2), and is therefore finitely n-presented.

Remark 2.7.1.4. Let A be a connective $\mathbb{E}_1$-ring and let M be a compact object of $(\mathrm{LMod}_A)_{\leqslant n}$. Since LMod_A is compactly generated, we deduce that M is a retract of $\tau_{\leqslant n} M'$ for some compact object $M' \in \mathrm{LMod}_A$. It follows from Remark 2.7.1.3 that M is finitely n-presented. Conversely, if M is finitely n-presented, then it is a compact object of $(\mathrm{LMod}_A)_{\leqslant n}$ by virtue of Remark 2.7.0.5.

Proposition 2.7.1.5. *Let A be discrete $\mathbb{E}_1$-ring and let M be a left A-module. The following conditions are equivalent:*

(1) *The left A-module M is finitely 0-presented and, for every discrete right A-module N, the abelian group $\pi_1(N \otimes_A M)$ vanishes.*

(2) *The left A-module M is perfect and of* Tor*-amplitude $\leqslant 0$.*

Proof. We will show that (1) implies (2); the reverse implication is obvious. It follows from Remark **??** that the module M is $(-n)$-connective for $n \gg 0$. We proceed by induction on n. If $n = 0$, then M is a discrete A-module. Condition (1) then implies that the group $\mathrm{Tor}_1^A(N, M) \simeq 0$ for every discrete A-module N, so that M is flat over A. Since it is also finitely presented as a left A-module, it is a projective module of finite rank, hence perfect and of Tor-amplitude $\leqslant 0$.

We now carry out the inductive step. Suppose that M is $(-n)$-connective for $n > 0$. It follows from Remark 2.7.0.5 that $\pi_{-n} M$ is a finitely generated module over $\pi_0 A$. We can therefore choose a map $\alpha : \Sigma^{-n} A^k \to M$ which is surjective on π_{-n}, so that $\mathrm{cofib}(\alpha)$ is $(1-n)$-connective. Remark 2.7.0.7 implies that $\mathrm{cofib}(\alpha)$ is perfect to order 1, and for $m > 0$ the exact sequence $\pi_m M \to \pi_m \mathrm{cofib}(\alpha) \to \pi_{m-1} \Sigma^{-n} A^k$ shows that $\mathrm{cofib}(\alpha)$ is 0-truncated. If N is a discrete right A-module, the existence of a short exact sequence

$$\pi_1(N \otimes_A M) \to \pi_1(N \otimes_A \mathrm{cofib}(\alpha)) \to \pi_0(N \otimes_A \Sigma^{-n} A)$$

implies that $\pi_1(N \otimes_A \mathrm{cofib}(\alpha)) \simeq 0$. Applying our inductive hypothesis, we deduce that $\mathrm{cofib}(\alpha)$ is perfect of Tor-amplitude $\leqslant 0$. Using the fiber sequence $\Sigma^{-n} A^k \to M \to \mathrm{cofib}(\alpha)$, we deduce that M is also perfect of Tor-amplitude $\leqslant 0$. □

2.7.2 Alternate Characterizations

Our next result gives a formulation of Definition 2.7.0.1 which is well-adapted to making inductive arguments:

Proposition 2.7.2.1. *Let A be a connective $\mathbb{E}_1$-ring and let M be a connective left A-module. Then:*

(1) *The module M is perfect to order 0 if and only if $\pi_0 M$ is finitely generated as a module over $\pi_0 A$.*

(2) *Let $n > 0$ and suppose we are given a map of A-modules $\phi : A^k \to M$ which induces a surjection $\pi_0 A^k \to \pi_0 M$. Then M is perfect to order n if and only if* $\mathrm{fib}(\phi)$ *is perfect to order $(n-1)$.*

Proof. We first prove (1). For each $N \in (\mathrm{LMod}_A)_{\leqslant 0}$, we have $\mathrm{Ext}^i_A(M, N) \simeq 0$ for $i < 0$, and $\mathrm{Ext}^0_A(M, N)$ is the abelian group of $\pi_0 A$-module homomorphisms from $\pi_0 M$ into $\pi_0 N$. Consequently, M is perfect to order 0 if and only if, for every filtered diagram of discrete $\pi_0 A$-modules N_α having colimit N, the canonical map

$$\varinjlim_{\alpha} \mathrm{Ext}^0_{\pi_0 A}(\pi_0 M, N_\alpha) \to \mathrm{Ext}^0_{\pi_0 A}(\pi_0 M, N)$$

is injective. If $\pi_0 M$ is finitely generated as a $\pi_0 A$-module, then we can choose a surjection $(\pi_0 A)^k \to \pi_0 M$, in which case the domain and codomain of θ can be identified with subgroups of the abelian group N^k; this proves the "if" direction of (1). For the converse, suppose that M is perfect to order 0. Let $\{N_\alpha\}$ be the (filtered) diagram of all quotients of the form $(\pi_0 M)/S$, where S is a finitely generated submodule of $\pi_0 M$. Then $\varinjlim N_\alpha \simeq 0$. It follows that $\varinjlim_\alpha \mathrm{Ext}^0_{\pi_0 A}(\pi_0 M, N_\alpha) \simeq 0$, so that the canonical epimorphism $\pi_0 M \to N_\alpha$ is the zero map for some index α. This implies that $\pi_0 M$ is finitely generated.

We now prove (2). Choose a fiber sequence of connective A-modules

$$M' \to A^k \to M,$$

and suppose we are given a filtered diagram $\{N_\alpha\}$ in $(\mathrm{LMod}_A)_{\leqslant 0}$ having a colimit N. For every pair of object $X, Y \in \mathrm{LMod}_A$, let $\mathrm{Mor}(X, Y)$ denote the spectrum of maps from X to Y in LMod_A, so that $\mathrm{Ext}^i_A(X, Y) = \pi_{-i} \mathrm{Mor}(X, Y)$. Let $F(X)$ denote the fiber of the canonical map $\varinjlim_\alpha \mathrm{Mor}(X, N_\alpha) \to \mathrm{Mor}(X, N)$. Note that $F(A) \simeq 0$. We have a fiber sequence of spectra

$$F(M') \to F(A^k) \to F(M),$$

so that $F(M)$ can be identified with the suspension of $F(M')$. In particular, $\pi_i F(M) \simeq 0$ for $i \geqslant n$ if and only if $\pi_i F(M') \simeq 0$ for $i \geqslant n-1$, from which (2) follows. □

Corollary 2.7.2.2. *Let A be a connective $\mathbb{E}_1$-ring and let M be a left A-module. The following conditions are equivalent:*

(1) *The left module M is perfect to order n.*

(2) *There exists a perfect left A-module P of* Tor*-amplitude $\leqslant n$ and a morphism $P \to M$ whose fiber is n-connective.*

(3) *There exists a perfect left A-module P and a morphism $P \to M$ whose fiber is n-connective.*

Proof. The implication (2) ⇒ (3) is obvious. We next show that (3) ⇒ (1). Let $\alpha : P \to M$ be a morphism of left A-modules, where P is perfect and $\mathrm{fib}(\alpha)$ is n-connective. Then $\mathrm{cofib}(\alpha) \simeq \Sigma\,\mathrm{fib}(\alpha)$ is perfect to order n (Example 2.7.0.3). Applying Remark 2.7.0.7 to the fiber sequence $P \to M \to \mathrm{cofib}(\alpha)$, we deduce that M is perfect to order n.

Note that if (1) is satisfied Remark D.7.7.4 implies that M is k-connective for some $k \ll 0$. To prove that (1) ⇒ (2), we may (after replacing M by $\Sigma^{-k}M$ and n by $n-k$) reduce to the case where M is connective. We now proceed by induction on n. If $n < 0$, there is nothing to prove (by Example 2.7.0.3). Let us therefore suppose that $n \geqslant 0$. Using Proposition 2.7.2.1, we can choose a finitely generated free A-module F and a fiber sequence

$$M' \xrightarrow{\alpha} F \to M$$

where M' is connective. Applying Remark 2.7.0.7 to the shifted sequence

$$F \to M \to \Sigma M',$$

we deduce that $\Sigma M'$ is perfect to order n, so that M' is perfect to order $(n-1)$. By virtue of the inductive hypothesis, there exists a perfect A-module P of Tor-amplitude $\leqslant n-1$ and a map $\beta : P \to M$ with $(n-1)$-connective fiber. Set $Q = \mathrm{cofib}(\beta \circ \alpha)$. Then Q is a perfect left A-module of Tor-amplitude $\leqslant n$ equipped with a map $\gamma : Q \to M$. We have a commutative diagram of fiber sequences

$$\begin{array}{ccccc} \mathrm{fib}(\beta) & \longrightarrow & P & \longrightarrow & M \\ \downarrow & & \downarrow & & \downarrow \\ 0 & \longrightarrow & F & \longrightarrow & F \\ \downarrow & & \downarrow & & \downarrow \\ \mathrm{fib}(\gamma) & \longrightarrow & Q & \longrightarrow & M \end{array}$$

which supplies an equivalence $\mathrm{fib}(\gamma) \simeq \Sigma\,\mathrm{fib}(\beta)$, so that $\mathrm{fib}(\gamma)$ is n-connective. □

Corollary 2.7.2.3. *Let A be a connective $\mathbb{E}_1$-ring and let M be a left A-module. Assume that A is left Noetherian (that is, each homotopy group $\pi_n A$ is Noetherian when viewed as a left module over $\pi_0 A$). Then M is perfect to order n if and only if it satisfies the following conditions:*

(1) *The homotopy groups $\pi_i M$ vanish for $i \ll 0$.*

(2) *For each $m \leqslant n$, the homotopy group $\pi_m M$ is finitely generated as a module over $\pi_0 A$.*

Proof. The necessity of condition (1) follows from Remark **??**. We may therefore assume without loss of generality that (1) is satisfied. Replacing M by $\Sigma^p M$ and n by $n+p$ and thereby reduce to the case where M is connective. We now proceed by induction on n. If $n < 0$ there is nothing to prove and if $n = 0$ the desired result follows from Proposition 2.7.2.1. Let us therefore assume that $n > 0$. Note that if M is perfect to order n, then it is perfect to order 0 and therefore $\pi_0 M$ is finitely generated as a module over $\pi_0 A$. We may therefore assume without loss of generality that there exists a fiber sequence

$$M' \to A^m \to M$$

of connective left A-modules. For each $i \geqslant 0$, we have a short exact sequence

$$(\pi_{i+1} A)^m \to \pi_{i+1} M \to \pi_i M' \to (\pi_i A)^m.$$

Since $\pi_0 A$ is a left Noetherian ring and the modules $\pi_i A$ and $\pi_{i+1} A$ are finitely generated, it follows that $\pi_{i+1} A$ is finitely generated over $\pi_0 A$ if and only if $\pi_i M'$ is finitely generated over $\pi_0 A$. Allowing i to vary, we deduce that M satisfies condition (2) if and only if the homotopy groups $\pi_i M'$ are finitely generated for $i < n$. By virtue of the inductive hypothesis, this is equivalent to the requirement that M' is perfect to order $(n-1)$. The desired result now follows from Proposition 2.7.2.1. □

Corollary 2.7.2.4. *Let A be a connective $\mathbb{E}_1$-ring, let M be a connective left module over A, and let $n \geqslant 0$ be an integer. The following conditions are equivalent:*

- (a) *The module M is perfect to order n.*
- (b) *There exists a simplicial object $M_\bullet$ of the ∞-category $\mathrm{LMod}_A^{\mathrm{cn}}$ such that $|M_\bullet| \simeq M$ and each of the modules M_k is finitely generated and free for $k \leqslant n$.*
- (c) *There exists a simplicial object $M_\bullet$ of the ∞-category $\mathrm{LMod}_A^{\mathrm{cn}}$ such that $|M_\bullet| \simeq M$ and, for each $0 \leqslant k \leqslant n$, the module M_k is perfect to order $n-k$.*

Proof. Suppose first that (a) is satisfied. Using Proposition 2.7.2.1, we can choose a free A-module of finite rank P_0 and a map $\phi_0 : P_0 \to M$ whose fiber is 0-connective. We will extend this to a diagram

$$P_0 \to P_1 \to P_2 \to \cdots$$

in $(\mathrm{Mod}_A)_{/M}$, where each P_m is perfect and each of the structure morphisms $\phi_m : P_m \to M$ has m-connective fiber. The construction proceeds by induction. Assume that $\phi_m : P_m \to M$ has been constructed for some $m \geqslant 0$. If $m < n$, then the cofiber $\mathrm{cofib}(\phi_m)$ is $(m+1)$-connective and perfect to order $(m+1)$, so we can choose a free left A-module F of finite rank and a morphism $\Sigma^{m+1} F \to \mathrm{cofib}(\phi_m)$ which is surjective on π_{m+1}. We then define P_{m+1} to be the fiber product $\Sigma^{m+1} F \times_{\mathrm{cofib}(\phi_m)} M$, so that we have a canonical fiber sequence

$$P_m \to P_{m+1} \to \Sigma^{m+1} F$$

which immediately shows that P_{m+1} is perfect. If $m \geqslant n$, we simply set $P_{m+1} = M$.

Applying Theorem HA.1.2.4.1 , we see that there exists a simplicial object $M_\bullet$ of LMod_A for which the diagram

$$P_0 \to P_1 \to P_2 \to \cdots \to P_n \to M \to M \to M \to \cdots$$

agrees with the skeletal filtration of $|M_\bullet|$. In particular, we have $|M_\bullet| \simeq M$, and each M_k can be identified with a direct sum of finitely many copies of modules of the form P_0 and $\Sigma^{-m}\,\mathrm{cofib}(P_{m-1} \to P_m)$ for $m \leqslant k$. It follows from the above construction that M_k is a free left A-module of finite rank for $k \leqslant n$, so that condition (b) is satisfied.

The implication $(b) \Rightarrow (c)$ is obvious. We will complete the proof by showing that (c) implies (a). Let $M_\bullet$ be a simplicial object of $\mathrm{LMod}_A^{\mathrm{cn}}$ satisfying the requirements of (c), and let

$$P_0 \to P_1 \to P_2 \to P_3 \to \cdots$$

be the associated filtered object of LMod_A (see Theorem HA.1.2.4.1). We then have a fiber sequence

$$P_n \to M \to K$$

where K is $(n+1)$-connective. It follows from Example 2.7.0.3 that K is perfect to order n. Consequently, to prove that M is perfect to order n, it will suffice to show that P_n is perfect to order n (Remark 2.7.0.7). We will prove more generally that P_m is perfect to order n for each $m \leqslant n$. The proof proceeds by induction on m. In the case $m = 0$, we simply note that $P_0 \simeq M_0$ is perfect to order n by assumption. To carry out the inductive step, we note that if $m > 0$ then we have a fiber sequence

$$P_{m-1} \to P_m \to \Sigma^m N$$

where N denotes the mth term in the normalized chain complex associated to the simplicial object $M_\bullet$ of the homotopy category hLMod_A. If $m \leqslant n$, then N is perfect to order $(n-m)$ (since it is a direct summand of M_n) and therefore the suspension $\Sigma^m N$ is perfect to order n. Since P_{m-1} is also perfect to order n by our inductive hypothesis, it follows from Remark 2.7.0.7 that P_m is also perfect to order n. □

2.7.3 Extension of Scalars

We now study the behavior of finiteness conditions on modules with respect to base change.

Proposition 2.7.3.1. *Let $f : A \to B$ be a map of connective $\mathbb{E}_1$-rings and let M be a left A-module. If M is perfect to order n as an A-module, then $B \otimes_A M$ is perfect to order n as a B-module. The converse holds if B is faithfully flat (as a right module) over A.*

Proof. Assume first that M is perfect to order n as an A-module. We wish to show that $B \otimes_A M$ is perfect to order n as a B-module. Remark **??** implies that $M \in (\mathrm{LMod}_A)_{\geqslant -m}$ for some $m \gg 0$. Replacing M by $\Sigma^m M$ (and n by $n+m$) we may assume that M is connective and that $n \geqslant 0$. We proceed by induction on n. If $n = 0$, then we are reduced to proving that $\pi_0(B \otimes_A M) \simeq \mathrm{Tor}_0^{\pi_0 A}(\pi_0 B, \pi_0 M)$ is finitely generated as a module over $\pi_0 B$, which follows because $\pi_0 M$ is finitely generated over $\pi_0 A$. If $n > 0$, then we can choose a fiber sequence of connective left A-modules

$$M' \to A^k \to M.$$

Tensoring with B, we obtain a fiber sequence of connective left B-modules

$$B \otimes_A M' \to B^k \to B \otimes_A M$$

Using Proposition 2.7.2.1, we deduce that M' is perfect to order $(n-1)$ as an A-module. The inductive hypothesis implies that $B \otimes_A M'$ is perfect to order $(n-1)$ as a B-module. Using Proposition 2.7.2.1 again, we deduce that $B \otimes_A M$ is perfect to order n as a B-module.

We now prove the converse. Assume that f is faithfully flat and that $B \otimes_A M$ is perfect to order n as a B-module. Then there exists an integer m such that $\pi_i(B \otimes_A M) \simeq \mathrm{Tor}_i^{\pi_0 A}(\pi_0 B, \pi_i M)$ vanishes for $i < -m$. Since $\pi_0 B$ is faithfully flat over $\pi_0 A$, we deduce that $\pi_i M \simeq 0$ for $i < -m$. Replacing M by $\Sigma^m(M)$ and n by $n+m$, we may assume that M is connective and that $n \geqslant 0$. We prove that M is perfect to order n using induction on n. We first treat the case $n = 0$. We must show that $\pi_0 M$ is finitely generated as a module over $\pi_0 A$. Our assumption that $B \otimes_A M$ is perfect to order 0 guarantees that $\mathrm{Tor}_0^{\pi_0 A}(\pi_0 B, \pi_0 M)$ is finitely generated as a module over $\pi_0 B$. We may therefore choose a finitely generated submodule $M_0 \subseteq \pi_0 M$ such that the induced map $\mathrm{Tor}_0^{\pi_0 A}(\pi_0 B, M_0) \to \mathrm{Tor}_0^{\pi_0 A}(\pi_0 B, \pi_0 M)$ is surjective, so that $\mathrm{Tor}_0^{\pi_0 A}(\pi_0 B, (\pi_0 M)/M_0)) \simeq 0$. Since $\pi_0 B$ is faithfully flat over $\pi_0 A$, we deduce that $(\pi_0 M)/M_0 \simeq 0$. It follows that $\pi_0 M \simeq M_0$ is finitely generated.

Now suppose that $n > 0$. The argument above shows that $\pi_0 M$ is finitely generated, so we can choose a fiber sequence of connective left A-modules

$$M' \to A^k \to M.$$

Tensoring with B, we obtain a fiber sequence of connective left B-modules

$$B \otimes_A M' \to B^k \to B \otimes_A M.$$

Since $B \otimes_A M$ is perfect to order n, Proposition 2.7.2.1 implies that $B \otimes_A M'$ is perfect to order $n-1$. It follows from the inductive hypothesis that M' is perfect to order $n-1$, so that M is perfect to order n by Proposition 2.7.2.1. □

Proposition 2.7.3.1 admits the following converse:

Proposition 2.7.3.2. *Let $f : A \to A'$ be a map of connective $\mathbb{E}_1$-rings. Assume that the underlying map of associative rings $\pi_0 A \to \pi_0 A'$ is a surjection whose kernel is a nilpotent ideal $I \subseteq \pi_0 A$. Let M be a connective left A-module, and set $M' = A' \otimes_A M$. Then:*

- (a) *The A-module M is perfect to order n over A if and only if the A'-module M' is perfect to order n.*
- (b) *The A-module M is almost perfect if and only if the A'-module M' is almost perfect.*
- (c) *The A-module M has* Tor*-amplitude $\leqslant k$ if and only if the A'-module M' has* Tor*-amplitude $\leqslant k$.*
- (d) *The A-module M is perfect if and only if the A'-module M' is perfect.*
- (e) *The A-module M is n-connective if and only if the A'-module M' is n-connective.*

Proof. The "only if" directions of assertions (a) through $(de$ are clear. To complete the proof of (a), suppose that M' is perfect to order n as a left A'-module. We will prove that M is perfect to order n as an A-module. The proof proceeds by induction on n. If $n < 0$, there is nothing to prove (since M is assumed to be connective). If $n = 0$, we must show that $\pi_0 M$ is finitely generated as a module over $\pi_0 A$. Our assumption that M' is perfect to order 0 guarantees that $\pi_0 M' \simeq (\pi_0 M)/I(\pi_0 M)$ is finitely generated as a module over $\pi_0 A' \simeq (\pi_0 A)/I$. The desired result now follows from our assumption that I is nilpotent.

Assume now that $n > 0$ and that M' is perfect to order n over A. The argument above shows that $\pi_0 M$ is finitely generated as a module over $\pi_0 A$, so we can choose a fiber sequence

$$N \to A^k \to M$$

where N is connective. Applying Proposition 2.7.2.1, we deduce that $A' \otimes_A N$ is perfect to order $(n-1)$ over A'. The inductive hypothesis now shows that N is perfect to order $(n-1)$ over A, so that M is perfect to order n over A (by Proposition 2.7.2.1 again). This completes the proof of (a).

Assertion (b) follows immediately from (a). We now prove (c). Suppose that M' has Tor-amplitude $\leqslant k$ over A', and let N be a discrete right A-module. Then N can be written as a finite extension of (discrete) modules over the form $I^k N / I^{k+1} N$, each of which can be regarded as a module over A'. Our assumption that M' has Tor-amplitude $\leqslant k$ guarantees that each tensor product $(I^k N/I^{k+1} N) \otimes_A M \simeq (I^k N/I^{+1} N) \otimes_{A'} M'$ is k-truncated. Since the collection of k-truncated spectra is closed under extensions, we conclude that $N \otimes_A M$ is k-truncated. Allowing N to vary, we conclude that M has Tor-amplitude $\leqslant k$ over A.

Assertion (d) follows from (b) and (c), by virtue of Proposition HA.7.2.4.23 . To prove (e), we proceed by induction on n. The case $n \leqslant 0$ is trivial (since M is assumed to be connective). To carry out the inductive step, assume that M' is $(n+1)$-connective for some

$n \geqslant 0$; we will prove that M is also $(n+1)$-connective. Our inductive hypothesis guarantees that M is n-connective. It follows that we have an isomorphism $\pi_n M' \simeq (\pi_n M)/I(\pi_n M)$. The $(n+1)$-connectivity of M' then guarantees that $\pi_n M = I(\pi_n M)$. Since I is a nilpotent ideal, it follows that $\pi_n M \simeq 0$, so that M is $(n+1)$-connective as desired. □

Proposition 2.7.3.3. *Let $f : A \to B$ be a morphism of connective $\mathbb{E}_1$-rings and let $n \geqslant 0$ be an integer. The following conditions are equivalent:*

(1) *The morphism f exhibits B as a left A-module which is perfect to order n.*

(2) *Let M be a connective left B-module. If M is perfect to order n as a left B-module, then it is also perfect to order n as a left A-module.*

Proof. The implication (2) ⇒ (1) is immediate (take $M = B$). For the converse, we proceed by induction on n. Assume that (1) is satisfied and let M be a connective left B-module which is perfect to order n over B. If $n = 0$, then $\pi_0 B$ is finitely generated as a left module over $\pi_0 B$, and therefore also as a left module over $\pi_0 A$. Consequently, M is perfect to order 0 over A (Proposition 2.7.2.1). Let us therefore assume that $n > 0$. Choose a map $\alpha : B^r \to M$ which is surjective on π_0. Then $\operatorname{fib}(\alpha)$ is connective and perfect to order $(n-1)$ over B, so our inductive hypothesis guarantees that $\operatorname{fib}(\alpha)$ is perfect to order $(n-1)$ over A. We then have a fiber sequence $B^r \to M \to \Sigma \operatorname{fib}(\alpha)$ where both B^r and $\Sigma \operatorname{fib}(\alpha)$ are perfect to order n over A, so that M is also perfect to order n over A. □

2.7.4 Fiberwise Connectivity Criterion

Let A be a commutative ring and let M be a finitely generated (discrete) A-module. It follows from Nakayama's lemma that if the fiber of M vanishes at some point of $x \in |\operatorname{Spec} A|$, then the module M itself vanishes in some neighborhood of x. We now formulate a "derived" analogue of this observation:

Proposition 2.7.4.1. *Let A be a connective $\mathbb{E}_\infty$-ring, let M be an A-module which is perfect to order n for some integer $n \geqslant 0$, and let κ be the residue field of A at some prime ideal $\mathfrak{p} \subseteq A$. The following conditions are equivalent:*

(a) *There exists an element $a \in \pi_0 A$ which is not contained in $\mathfrak{p}$ for which the localization $M[a^{-1}]$ is $(n+1)$-connective.*

(b) *The tensor product $\kappa \otimes_A M$ is $(n+1)$-connective.*

Proof. The implication (a) ⇒ (b) is trivial. Suppose that (b) is satisfied. For each $k \leqslant n$, we will prove that there exists an element $a \in (\pi_0 A) - \mathfrak{p}$ such that the localization $M[a^{-1}]$ is $(k+1)$-connective. Note that this condition is automatically satisfied for $k \ll 0$ by virtue of Remark **??**. To carry out the inductive step, let us assume that $k \leqslant n$ and that there exists $b \in (\pi_0 A) - \mathfrak{p}$ such that $M[b^{-1}]$ is k-connective. Replacing A by $A[b^{-1}]$ and M by $M[b^{-1}]$, we may assume that M itself is k-connective. It follows from Proposition 2.7.2.1 that $\pi_k M$ is a finitely generated module over $\pi_0 A$. Assumption (b) guarantees that

$$\mathrm{Tor}_0^{\pi_0 A}(\kappa, \pi_k M) \simeq \pi_k(\kappa \otimes_A M) \simeq 0.$$

Applying Nakayama's lemma, we deduce that $\pi_k M$ is annihilated by some element $a \in (\pi_0 A) - \mathfrak{p}$, so that $M[a^{-1}]$ is $(k+1)$-connective. □

Corollary 2.7.4.2. *Let A be a connective $\mathbb{E}_\infty$-ring and let M be an A-module which is perfect to order n for some integer $n \geqslant 0$. The following conditions are equivalent:*

- (a) *The module M is $(n+1)$-connective.*
- (b) *For every residue field κ of A, the tensor product $\kappa \otimes_A M$ is $(n+1)$-connective.*

Corollary 2.7.4.3. *Let A be a connective $\mathbb{E}_\infty$-ring, let M be an A-module which is almost perfect, and let n be an integer. Then M is n-connective if and only if, for every residue field κ of A, the tensor product $\kappa \otimes_A M$ is n-connective.*

Corollary 2.7.4.4. *Let A be a connective $\mathbb{E}_\infty$-ring and let M be an A-module which is almost perfect. Then $M \simeq 0$ if and only if, for every residue field κ of A, the tensor product $\kappa \otimes_A M$ vanishes.*

2.8 Local Properties of Quasi-Coherent Sheaves

Let X be a spectral Deligne-Mumford stack. In §2.2, we introduced the ∞-category $\mathrm{QCoh}(\mathsf{X})$ of *quasi-coherent* sheaves on X. In this section, we will study some examples properties of quasi-coherent sheaves on X which can be tested *locally* on X.

2.8.1 Étale-Local Properties of Spectral Deligne-Mumford Stacks

We begin with some general remarks about local conditions on spectral Deligne-Mumford stacks.

Definition 2.8.1.1. Let Y be a nonconnective spectral Deligne-Mumford stack. We will say that a collection of morphisms $\{f_\alpha : \mathsf{X}_\alpha \to \mathsf{Y}\}$ is *jointly surjective* if the induced map $\amalg_\alpha \mathsf{X}_\alpha \to \mathsf{Y}$ is surjective (see Definition 3.5.5.5).

Definition 2.8.1.2. Let P be a property of nonconnective spectral Deligne-Mumford stacks. We will say that P is *local for the étale topology* if the following conditions hold:

- (i) For every étale morphism of nonconnective spectral Deligne-Mumford stacks $f : \mathsf{X} \to \mathsf{Y}$, if Y has the property P, then X also has the property P.

(*ii*) Given a jointly surjective collection of étale morphisms $\{\mathsf{X}_\alpha \to \mathsf{Y}\}$, if each X_α has the property P, then Y has the property P.

Remark 2.8.1.3. Let P be a property of nonconnective spectral Deligne-Mumford stacks which is local for the étale topology. A nonconnective spectral Deligne-Mumford stack $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ has the property P if and only if, for every affine $U \in \mathcal{X}$, the affine nonconnective spectral Deligne-Mumford stack $(\mathcal{X}_{/U}, \mathcal{O}_\mathcal{X}|_U)$ has the property P. Consequently, P is determined by the full subcategory $\mathrm{CAlg}(P) \subseteq \mathrm{CAlg}$ spanned by those $\mathbb{E}_\infty$-rings A such that $\mathrm{Sp\acute{e}t}\, A$ has the property P. Moreover, the full subcategory $\mathrm{CAlg}(P)$ has the following properties:

(*i*) If $f : A \to A'$ is an étale morphism of $\mathbb{E}_\infty$-rings and $A \in \mathrm{CAlg}(P)$, then $A' \in \mathrm{CAlg}(P)$.

(*ii*) Given a finite collection of étale maps $\{A \to A_\alpha\}$ such that $A \to \prod_\alpha A_\alpha$ is faithfully flat, if each $A_\alpha \in \mathrm{CAlg}(P)$, then $A \in \mathrm{CAlg}(P)$.

Conversely, given a full subcategory $\mathrm{CAlg}(P) \subseteq \mathrm{CAlg}$, we obtain a property P of nonconnective spectral Deligne-Mumford stacks as follows: a pair $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ has the property P if and only if, whenever we have an equivalence $(\mathcal{X}_{/U}, \mathcal{O}_\mathcal{X}|_U) \simeq \mathrm{Sp\acute{e}t}\, A$, the $\mathbb{E}_\infty$-ring A belongs to $\mathrm{CAlg}(P)$. If $\mathrm{CAlg}(P)$ satisfies conditions (*i*) and (*ii*), then the property P is local for the étale topology.

Recall that an $\mathbb{E}_\infty$-ring A is said to be *Noetherian* if A is connective, $\pi_0 A$ is a Noetherian commutative ring, and $\pi_n A$ is a finitely generated module over $\pi_0 A$ for every integer n.

Definition 2.8.1.4. Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_\mathcal{X})$ be a spectral Deligne-Mumford stack. We will say that X is *locally Noetherian* if, whenever $U \in \mathcal{X}$ is affine so that $(\mathcal{X}_{/U}, \mathcal{O}_\mathcal{X}|_U) \simeq \mathrm{Sp\acute{e}t}\, A$, the $\mathbb{E}_\infty$-ring A is Noetherian.

Proposition 2.8.1.5. *The property of being a locally Noetherian spectral Deligne-Mumford stack is local for the étale topology.*

Lemma 2.8.1.6. *Let $f : A \to B$ be a faithfully flat map of $\mathbb{E}_\infty$-rings. If B is Noetherian, then A is Noetherian.*

Proof. We first show that $\pi_0 A$ is a Noetherian commutative ring. We claim that the collection of ideals in $\pi_0 A$ satisfies the ascending chain condition. To prove this, it will suffice to show that the construction $I \mapsto I(\pi_0 B)$ determines an injection from the partially ordered set of ideals of $\pi_0 A$ to the partially ordered set of ideals of $\pi_0 B$. Since $\pi_0 B$ is flat over $\pi_0 A$, the map $I \otimes_{\pi_0 A} \pi_0 B$ is an injection with image $I(\pi_0 B)$. Given a pair of ideals $I, J \subseteq \pi_0 A$ we have an exact sequence of $\pi_0 A$-modules

$$0 \to I \cap J \to I \oplus J \to I + J \to 0.$$

This sequence remains exact after tensoring with $\pi_0 B$, so that $(I \cap J)(\pi_0 B) = I(\pi_0 B) \cap J(\pi_0 B)$. It follows that if $I(\pi_0 B) = J(\pi_0 B)$, then the inclusion $(I \cap J)(\pi_0 B) \hookrightarrow I(\pi_0 B)$ is bijective, so that $I/(I \cap J) \otimes_{\pi_0 A} \pi_0 B \simeq 0$. Since $\pi_0 B$ is faithfully flat over $\pi_0 A$, this implies that $I/(I \cap J) = 0$, so that $I \subseteq J$. A similar argument shows that $J \subseteq I$, so that $I = J$. This completes the proof that $\pi_0 A$ is a Noetherian commutative ring.

Since f is faithfully flat, we have $\pi_n B \simeq \pi_n A \otimes_{\pi_0 A} \pi_0 B$. Since $\pi_n B \simeq 0$ for $n < 0$, the faithful flatness of $\pi_0 B$ over $\pi_0 A$ implies that $\pi_n A \simeq 0$. This proves that A is connective. To complete the proof, we must show that each $\pi_n A$ is finitely generated as a module over $\pi_0 A$. Since $\pi_n B$ is finitely generated as a $\pi_0 B$-module, we can choose a finitely generated submodule $M \subseteq \pi_n A$ such that the map

$$M \otimes_{\pi_0 A} \pi_0 B \to \pi_n A \otimes_{\pi_0 A} \pi_0 B \simeq \pi_n B$$

is surjective. The cokernel of this map is given by $(\pi_n A)/M \otimes_{\pi_0 A} \pi_n B$. Since $\pi_0 B$ is faithfully flat over $\pi_0 A$, we deduce that $(\pi_n A)/M \simeq 0$, so that $\pi_n A \simeq M$ is finitely generated as a module over $\pi_0 A$. □

Proof of Proposition 2.8.1.5. By virtue of Remark 2.8.1.3, it will suffice to prove the following assertions:

- (i) If $f : A \to A'$ is an étale morphism of $\mathbb{E}_\infty$-rings and A is Noetherian, then A' is also Noetherian.
- (ii) Given a finite collection of étale maps $\{A \to A_\alpha\}$ such that $A \to \prod_\alpha A_\alpha$ is faithfully flat, if each A_α is Noetherian, then A is Noetherian.

Assertion (i) is obvious, and assertion (ii) follows immediately from Lemma 2.8.1.6. □

We now turn our attention to properties of morphisms of spectral Deligne-Mumford stacks.

Definition 2.8.1.7. Let P be a property of morphisms between nonconnective spectral Deligne-Mumford stacks. We will say that P is *local on the source with respect to the étale topology.* if the following conditions hold:

- (i) For every composable pair of morphisms $\mathsf{X} \xrightarrow{f} \mathsf{Y} \xrightarrow{g} \mathsf{Z}$. if f is étale and g has the property P, then $g \circ f$ has the property P.
- (ii) Given a jointly surjective collection of étale maps $\{f_\alpha : \mathsf{X}_\alpha \to \mathsf{Y}\}$ and a morphism $g : \mathsf{Y} \to \mathsf{Z}$, if each of the composite maps $g \circ f_\alpha$ has the property P, then g has the property P.

Example 2.8.1.8. Let P be the property of being an étale morphism between nonconnective spectral Deligne-Mumford stacks. Then P is local on the source with respect to the étale topology.

2.8.2 Flat Morphisms

Let $f : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ is a morphism of schemes. Recall that f is said to be *flat* if the underlying map of local commutative rings $\mathscr{O}_{Y,f(x)} \to \mathscr{O}_{X,x}$ is flat for each $x \in X$. We now study an analogous condition in the setting of spectral algebraic geometry.

Definition 2.8.2.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of nonconnective spectral Deligne-Mumford stacks. We will say that f is *flat* if the following condition is satisfied:

(∗) For every commutative diagram

$$\begin{array}{ccc} \operatorname{Spét} B & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow f \\ \operatorname{Spét} A & \longrightarrow & \mathsf{Y} \end{array}$$

in which the horizontal maps are étale, the underlying map of $\mathbb{E}_\infty$-rings $A \to B$ is flat.

Lemma 2.8.2.2. *Let $\phi : A \to B$ be an étale morphism of $\mathbb{E}_\infty$-rings, and let M be a B-module spectrum. If M is flat over A, then it is flat over B.*

Proof. If M is flat over A, then the tensor product $B \otimes_A M \simeq (B \otimes_A B) \otimes_B M$ is flat over B. Since ϕ is étale, B is a retract of $B \otimes_A B$, so that $M \simeq B \otimes_B M$ is a retract of $(B \otimes_A B) \otimes_B M$ and therefore also flat over B. □

Proposition 2.8.2.3. *Let $\phi : A \to B$ be a map of $\mathbb{E}_\infty$-rings. The following conditions are equivalent:*

(1) *The map ϕ is flat.*

(2) *The map ϕ induces a flat morphism $\operatorname{Spét} B \to \operatorname{Spét} A$ of nonconnective spectral Deligne-Mumford stacks.*

Proof. The implication (2) ⇒ (1) is obvious. Conversely, suppose that (1) is satisfied. Suppose we are given a commutative diagram

$$\begin{array}{ccc} \operatorname{Spét} B' & \longrightarrow & \operatorname{Spét} B \\ \downarrow & & \downarrow \\ \operatorname{Spét} A' & \longrightarrow & \operatorname{Spét} A \end{array}$$

where the horizontal maps are étale; we wish to prove that B' is flat over A'. Using Theorem 1.4.10.2, we deduce that the map of $\mathbb{E}_\infty$-rings $B \to B'$ is étale. It follows that B' is flat over A. Since A' is étale over A (Theorem 1.4.10.2), the desired result follows from Lemma 2.8.2.2. □

Proposition 2.8.2.4. *The property of being a flat morphism (between nonconnective spectral Deligne-Mumford stacks) is local on the source with respect to the étale topology.*

Proof of Proposition 2.8.2.4. Condition (i) of Definition 2.8.1.7 follows immediately from the definition. To prove (ii), suppose we are given a morphism $g : \mathsf{Y} \to \mathsf{Z}$ and a jointly surjective collection of étale maps $f_\alpha : \mathsf{X}_\alpha \to \mathsf{Z}$ such that each composition $g \circ f_\alpha$ is flat. We wish to show that g is flat. Choose a commutative diagram

$$\begin{array}{ccc} \operatorname{Spét} B & \longrightarrow & \mathsf{Y} \\ \downarrow & & \downarrow g \\ \operatorname{Spét} A & \longrightarrow & \mathsf{Z} \end{array}$$

where the horizontal maps are étale. We wish to show that B is flat over A. Since the maps f_α are jointly surjective, we can choose a finite collection of étale maps $\{B \to B_\beta\}$ such that $B \to \prod_\beta B_\beta$ is faithfully flat, and each of the induced maps $\operatorname{Spét} B_\beta \to \operatorname{Spét} B \to \mathsf{Y}$ factors through some X_α. Since $g \circ f_\alpha$ is assumed to be flat, we deduce that B_β is flat as an A-module. It follows that $\prod_\beta B_\beta$ is flat as an A-module. Using Lemma B.1.4.2, we deduce that B is flat over A. $\square$

Remark 2.8.2.5. Let k be a commutative ring, regarded as a discrete $\mathbb{E}_\infty$-ring. Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_\mathcal{X})$ be a nonconnective spectral Deligne-Mumford stack equipped with a morphism $\phi : \mathsf{X} \to \operatorname{Spét} k$. We will say that X is *flat over* k if the morphism ϕ is flat, in the sense of Definition 2.8.2.1. In this case, the structure sheaf $\mathcal{O}_\mathcal{X}$ is automatically discrete. Suppose that $\mathcal{X}$ is 1-localic and $\mathcal{O}_\mathcal{X}$ is discrete, so we may identify $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ with an ordinary Deligne-Mumford stack X. Then X is flat over k if and only if X is flat over k (in the sense of classical algebraic geometry). Consequently, Proposition **??** furnishes an equivalence between the ∞-category of spectral Deligne-Mumford 1-stacks which are flat over k with the ∞-category of ordinary Deligne-Mumford stacks which are flat over k.

Remark 2.8.2.6. Suppose we are given a pullback diagram

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow f' & & \downarrow f \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y} \end{array}$$

of nonconnective spectral Deligne-Mumford stacks. If f is flat, then f' is flat.

Remark 2.8.2.7. Suppose we are given morphisms of nonconnective spectral Deligne-Mumford stacks $\mathsf{X} \xrightarrow{f} \mathsf{Y} \xrightarrow{g} \mathsf{Z}$. If f and g are flat, then the composition $g \circ f$ is flat. To prove this, suppose we are given a commutative diagram

$$\begin{array}{ccc} \operatorname{Sp\acute{e}t} C & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow \\ \operatorname{Sp\acute{e}t} A & \longrightarrow & \mathsf{Z} \end{array}$$

where the horizontal maps are étale; we wish to show that C is flat over A. This assertion is local on $\operatorname{Sp\acute{e}t} C$ with respect to the étale topology (Proposition 2.8.2.4), so we may assume that the map $\operatorname{Sp\acute{e}t} C \to \operatorname{Sp\acute{e}t} A \times_{\mathsf{Z}} \mathsf{Y}$ factors as a composition $\operatorname{Sp\acute{e}t} C \to \operatorname{Sp\acute{e}t} B \xrightarrow{u} \operatorname{Sp\acute{e}t} A \times_{\mathsf{Z}} \mathsf{Y}$ where u is étale. Since f is flat, C is flat over B. Because g is flat, B is flat over A. It follows from Lemma B.1.4.2 that C is flat over A.

Remark 2.8.2.8. Let k' be an $\mathbb{E}_\infty$-ring and let $k = \tau_{\geqslant 0} k'$ be its connective cover. The proof of Proposition **??** shows that if A is an $\mathbb{E}_\infty$-algebra over k' with $\operatorname{Sp\acute{e}t} A = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$, then $(\mathcal{X}, \tau_{\geqslant 0} \mathscr{O}_{\mathcal{X}})$ is a spectral Deligne-Mumford stack which can be identified with the spectrum of $\tau_{\geqslant 0 A}$. In particular, if $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is flat over k', then $(\mathcal{X}, \tau_{\geqslant 0} \mathscr{O}_{\mathcal{X}})$ is flat over k. By reduction to the affine case, we obtain the more general global assertion: if $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is a flat over k', then $(\mathcal{X}, \tau_{\geqslant 0} \mathscr{O}_{\mathcal{X}})$ is flat over k.

Definition 2.8.2.9. Let A be an $\mathbb{E}_\infty$-ring. A *(nonconnective) spectral Deligne-Mumford stack over* A is a (nonconnective) spectral Deligne-Mumford stack X equipped with a map $\phi : \mathsf{X} \to \operatorname{Sp\acute{e}t} A$. We let $\mathrm{SpDM}^{\mathrm{nc}}_A$ denote the ∞-category $\mathrm{SpDM}^{\mathrm{nc}}_{/\operatorname{Sp\acute{e}t} A}$ of nonconnective spectral Deligne-Mumford stacks over A. Let $\mathrm{SpDM}^{\flat}_A$ denote the full subcategory of $\mathrm{SpDM}^{\mathrm{nc}}_A$ spanned by those objects for which the map ϕ is flat.

Proposition 2.8.2.10. *Let $f : A \to B$ be a morphism of $\mathbb{E}_\infty$-rings, and suppose that f induces an isomorphism $\pi_n(A) \to \pi_n(B)$ for $n \geqslant 0$. Then the pullback functor*

$$\mathsf{X} \mapsto \mathsf{X} \times_{\operatorname{Sp\acute{e}t} A} \operatorname{Sp\acute{e}t} B$$

induces an equivalence of ∞-categories $f^* : \mathrm{SpDM}^{\flat}_B \to \mathrm{SpDM}^{\flat}_A$.

Proof. It follows from Remark 2.8.2.6 that if X is flat over A, then $f^* \mathsf{X}$ is flat over B. Let $\overline{A}$ denote a connective cover of A (which is also a connective cover of B, since $\pi_n A \simeq \pi_n B$ for $n \geqslant 0$). We have a commutative diagram of pullback functors

$$\begin{array}{ccc} \mathrm{SpDM}^{\flat}_B & \longrightarrow & \mathrm{SpDM}^{\flat}_A \\ & \searrow \quad \swarrow & \\ & \mathrm{SpDM}^{\flat}_{\overline{A}}. & \end{array}$$

It will therefore suffice to prove that the vertical functors are equivalences of ∞-categories. We may therefore reduce to the case where f exhibits A as a connective cover of B. In this case, the functor f^* has a right adjoint G, given informally by the formula $G(\mathcal{X}, \mathscr{O}_{\mathcal{X}}) = (\mathcal{X}, \tau_{\geqslant 0}\, \mathscr{O}_{\mathcal{X}})$ (this functor preserves flatness by Remark 2.8.2.8). Consequently, it suffices to show that the unit and counit transformations

$$FG(\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \qquad (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}) \to GF(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$$

are equivalences whenever $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is a nonconnective spectral Deligne-Mumford stack which is flat over B or $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ is a spectral Deligne-Mumford stack which is flat over A. These assertions are local on $\mathcal{X}$ and $\mathcal{Y}$; we may therefore reduce to the affine case, where the desired result follows from Proposition HA.7.2.2.24 . □

2.8.3 Fpqc-Local Properties of Spectral Deligne-Mumford Stacks

We now study an analogue of Definition 2.8.1.2 for the flat topology.

Definition 2.8.3.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks. We will say that f is a *flat covering* if the following conditions are satisfied:

(1) The map f is flat.

(2) For every quasi-compact open substack $\mathsf{V} \hookrightarrow \mathsf{Y}$, there exists a quasi-compact open substack $\mathsf{U} \hookrightarrow \mathsf{X}$ such that f induces a surjection $\mathsf{U} \to \mathsf{V}$.

Example 2.8.3.2. Let $f : \mathsf{X} \to \mathsf{Y}$ be an étale surjection. Then f is a flat covering. Condition (1) of Definition 2.8.3.1 is obvious. To prove (2), we first replace Y by V and thereby reduce to the case where Y is quasi-compact. Choose an étale surjection $\operatorname{Spét} A \to \mathsf{Y}$. Write $\operatorname{Spét} A \times_{\mathsf{Y}} \mathsf{X}$ as $(\mathcal{X}, \mathscr{O}_{\mathcal{X}})$. For every affine object $X \in \mathcal{X}$, we can write $(\mathcal{X}_{/X}, \mathscr{O}_{\mathcal{X}}|_X) \simeq \operatorname{Spét} B$ for some étale A-algebra B, so that the map $|\operatorname{Spec} B| \to |\operatorname{Spec} A|$ has image given by some open subset $U_X \subseteq |\operatorname{Spec} A|$ (Proposition **??**). Since f is surjective, the open sets U_X cover $|\operatorname{Spec} A|$. Since $|\operatorname{Spec} A|$ is quasi-compact, this open cover has a finite subcover. Taking the disjoint union of the corresponding objects of $\mathcal{X}$, we obtain an affine object $X \in \mathcal{X}$ such that the induced map $(\mathcal{X}_{/X}, \mathscr{O}_{\mathcal{X}}|_X) \to \operatorname{Spét} A$ is surjective. Since X is quasi-compact, the image of $(\mathcal{X}_{/X}, \mathscr{O}_{\mathcal{X}}|_X)$ in X is a quasi-compact open substack $\mathsf{U} \subseteq \mathsf{X}$ having the desired properties.

Proposition 2.8.3.3. *Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{Y}' \\ \downarrow{\scriptstyle g'} & & \downarrow{\scriptstyle g} \\ \mathsf{X} & \xrightarrow{f} & \mathsf{Y}, \end{array}$$

where g' is étale and f is a flat covering. Then g is étale.

Proof. Without loss of generality we may assume that $\mathsf{Y} = \operatorname{Sp\acute{e}t} A$ and $\mathsf{Y}' = \operatorname{Sp\acute{e}t} A'$ are affine. Replacing X by a quasi-compact open substack, we can assume that there exists an étale surjection $\operatorname{Sp\acute{e}t} B \to \mathsf{X}$, so that B is faithfully flat over A. Our hypothesis that g' is étale guarantees that $B' = B \otimes_A A'$ is étale over B. In particular, B' is locally of finite presentation over B, so that A' is locally of finite presentation over A (see Proposition 4.2.1.5). We have $B \otimes_A L_{A'/A} \simeq L_{B'/B} \simeq 0$, so that $L_{A'/A} \simeq 0$ by virtue of our assumption that B is faithfully flat over A. It follows from Lemma B.1.3.3 that A' is étale over A, as desired. □

Corollary 2.8.3.4. *Suppose we are given a pullback diagram*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{Y}' \\ \downarrow{\scriptstyle g'} & & \downarrow{\scriptstyle g} \\ \mathsf{X} & \xrightarrow{f} & \mathsf{Y}, \end{array}$$

where g' is an equivalence and f is a flat covering. Then the following conditions are equivalent:

- (i) *The morphism g is an equivalence.*
- (ii) *There exists an integer $n \gg 0$ such that g is a relative spectral Deligne-Mumford n-stack (that is, $\mathsf{Y}' \times_{\mathsf{Y}} \operatorname{Sp\acute{e}t} R$ is a spectral Deligne-Mumford n-stack for every map $\operatorname{Sp\acute{e}t} R \to \mathsf{Y}$).*

Proof. The implication $(i) \Rightarrow (ii)$ is obvious. Assume that (ii) is satisfied. It follows from Proposition 2.8.3.3 that g is étale. Set $\mathsf{Y} = (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$, so that we can write Y' as $(\mathcal{Y}_{/U}, \mathcal{O}_{\mathcal{Y}}|_U)$ for some object $U \in \mathcal{Y}$. Assumption (ii) implies that U is n-truncated for some integer $n \gg 0$. We proceed by induction on n. Applying our inductive hypothesis to the diagonal map $\mathsf{Y}' \to \mathsf{Y}' \times_{\mathsf{Y}} \mathsf{Y}'$, we deduce that the diagonal map $U \to U \times U$ is an equivalence: that is, U is a (-1)-truncated object of Y, so that g is an open immersion. The map f is surjective and factors up to homotopy through g, so that g is a surjective open immersion and therefore an equivalence. □

Warning 2.8.3.5. In the situation of Corollary 2.8.3.4, condition (ii) is not automatic. For example, let κ be a field and write $\operatorname{Sp\acute{e}t} \kappa = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$. If $U \in \mathcal{X}$ is an ∞-connective object, then the projection map $g : (\mathcal{X}_{/U}, \mathcal{O}_{\mathcal{X}}|_U) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) = \operatorname{Sp\acute{e}t} \kappa$ becomes an equivalence after pulling back along the faithfully flat $\operatorname{Sp\acute{e}t} \overline{\kappa} \to \operatorname{Sp\acute{e}t} \kappa$, where $\operatorname{Sp\acute{e}t} \overline{\kappa}$ is an algebraic closure of κ. However, g is not an equivalence unless U is a final object of $\mathcal{X}$ (which need not be the case: see Warning HTT.7.2.2.31).

Definition 2.8.3.6. Let P be a property of nonconnective spectral Deligne-Mumford stacks. We will say that P is *local for the flat topology* if the following conditions hold:

(*i*) For every flat morphism of nonconnective spectral Deligne-Mumford stacks $f : \mathsf{X} \to \mathsf{Y}$, if Y has the property P, then X also has the property P.

(*ii*) Given a collection of flat morphisms $\{\mathsf{X}_\alpha \to \mathsf{Y}\}$, if each X_α has the property P and the induced map $\amalg \mathsf{X}_\alpha \to \mathsf{Y}$ is a flat covering, then Y has the property P.

Proposition 2.8.3.7. *Let P be a property of nonconnective spectral Deligne-Mumford stacks. Then P is local for the flat topology if and only if the following conditions are satisfied:*

(1) *The property P is local for the étale topology (Definition 2.8.3.6).*

(2) *If $f : A \to B$ is a flat morphism of $\mathbb{E}_\infty$-rings such that* $\operatorname{Sp\acute{e}t} A$ *has the property P, then* $\operatorname{Sp\acute{e}t} B$ *has the property P. The converse holds provided that f is faithfully flat.*

Proof. If P is local for the flat topology, then condition (2) is obvious and condition (1) follows from Example 2.8.3.2. Conversely, suppose that conditions (1) and (2) are satisfied. We first verify condition (*i*) of Definition 2.8.3.6. Let $f : \mathsf{X} \to \mathsf{Y}$ be a flat morphism of spectral Deligne-Mumford stacks, and assume that Y has the property P. We wish to show that X has the property P. By virtue of assumption (1), this condition is local with respect to the étale topology on X. We may therefore assume that $\mathsf{X} \simeq \operatorname{Sp\acute{e}t} B$ and that the map f factors as a composition $\mathsf{X} \to \operatorname{Sp\acute{e}t} A \xrightarrow{f''} \mathsf{Y}$ where f'' is étale. Then $\operatorname{Sp\acute{e}t} A$ has the property P. Since f is flat, B is flat over A. It then follows from (2) that $\mathsf{X} \simeq \operatorname{Sp\acute{e}t} B$ has the property P, as desired.

We now verify condition (*ii*). Let $f : \mathsf{X} \to \mathsf{Y}$ be a flat covering and suppose that X has the property P; we wish to show that Y has the property P. The assertion is local with respect to the étale topology on Y, so we may suppose that $\mathsf{Y} \simeq \operatorname{Sp\acute{e}t} A$ is affine. In particular, Y is quasi-compact. Replacing X by an open substack if necessary (and using (1)), we can reduce to the case where X is quasi-compact. We can then choose an étale surjection $\operatorname{Sp\acute{e}t} B \to \mathsf{X}$. Then $\operatorname{Sp\acute{e}t} B$ has the property P (by (1)) and B is faithfully flat over A, so that $\operatorname{Sp\acute{e}t} A$ has the property P by (2). □

Example 2.8.3.8. Let P be the property of being a spectral Deligne-Mumford stack, so that a nonconnective spectral Deligne-Mumford stack $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ has the property P if and only if the structure sheaf $\mathcal{O}_\mathcal{X}$ is connective. Then P is local with respect to the flat topology.

Example 2.8.3.9. Let P be the property of being an n-truncated spectral Deligne-Mumford stack, so that $(\mathcal{X}, \mathcal{O}_\mathcal{X})$ has the property P if and only if the structure sheaf $\mathcal{O}_\mathcal{X}$ is connective and n-truncated. Then P is local with respect to the flat topology.

We now consider a relative version of Definition 2.8.3.6.

Definition 2.8.3.10. Let P be a property of morphisms between nonconnective spectral Deligne-Mumford stacks. We will say that P is *local on the source with respect to the flat topology* if the following conditions hold:

(*i*) For every composable pair of morphisms $\mathsf{X} \xrightarrow{f} \mathsf{Y} \xrightarrow{g} \mathsf{Z}$, if f is flat and g has the property P, then $g \circ f$ has the property P.

(*ii*) Given a collection of flat morphisms $\{f_\alpha : \mathsf{X}_\alpha \to \mathsf{Y}\}$ which determine a flat covering $\amalg_\alpha \mathsf{X}_\alpha \to \mathsf{Y}$ and a morphism $g : \mathsf{Y} \to \mathsf{Z}$, if each of the composite maps $g \circ f_\alpha$ has the property P, then g has the property P.

Proposition 2.8.3.7 has the following analogue for properties of morphisms between nonconnective spectral Deligne-Mumford stacks, which is proven in the same way:

Proposition 2.8.3.11. *Let P be a property of morphisms between nonconnective spectral Deligne-Mumford stacks. Then P is local on the source for the flat topology if and only if the following conditions are satisfied:*

(1) *The property P is local on the source for the étale topology (Definition 2.8.3.6).*

(2) *Suppose we are given a pair of maps $\mathrm{Spét}\, B \xrightarrow{f} \mathrm{Spét}\, A \xrightarrow{g} \mathsf{Z}$ such that B is flat over A. If g has the property P, then $g \circ f$ has the property P. The converse holds if B is faithfully flat over A.*

Example 2.8.3.12. The property of being a flat morphism is local on the source with respect to the flat topology. By virtue of Proposition 2.8.2.4, it will suffice to show that the property of flatness satisfies condition (2) of Proposition 2.8.3.11. The first assertion is obvious (since the collection of flat morphisms is closed under composition, by Remark 2.8.2.7). Conversely, suppose that B is faithfully flat over A and that we are given a map $g : \mathrm{Spét}\, A \to \mathsf{Z}$ such that the composite map $\mathrm{Spét}\, B \to \mathrm{Spét}\, A \to \mathsf{Z}$ is flat. We wish to show that g is flat. This follows immediately from the definitions, together with Lemma B.1.4.2.

2.8.4 Fpqc-Local Properties of Modules

We now consider properties of quasi-coherent sheaves which can be tested locally with respect to the flat topology.

Definition 2.8.4.1. Let P be a property of pairs (A, M), where A is a connective $\mathbb{E}_\infty$-ring and M is an A-module. We will say that P is *local for the flat topology* if the following conditions are satisfied:

(1) Let $f : A \to B$ be a flat morphism of connective $\mathbb{E}_\infty$-rings, let M be an A-module. If (A, M) has the property P, then $(B, B \otimes_A M)$ has the property P. The converse holds if f is faithfully flat.

(2) Suppose we are given a finite collection of pairs $(A_i, M_i) \in \mathrm{CAlg}^{\mathrm{cn}} \times_{\mathrm{CAlg}} \mathrm{Mod}$, each of which has the property P. Then the product $(\prod A_i, \prod M_i) \in \mathcal{C}$ has the property P.

We now illustrate Definition 2.8.4.1 with some examples:

Proposition 2.8.4.2. *The following conditions on a pair* $(A, M) \in \mathrm{Mod} \times_{\mathrm{CAlg}} \mathrm{CAlg}^{\mathrm{cn}}$ *are local for the flat topology:*

(1) *The condition that* M *is* n*-connective (when regarded as a spectrum), where* n *is a fixed integer.*

(2) *The condition that* M *is almost connective: that is, that* M *is* $(-n)$*-connective for* $n \gg 0$.

(3) *The condition that* M *is* n*-truncated (that is, that* $\pi_i M \simeq 0$ *for* $i > n$*), where* n *is a fixed integer.*

(4) *The condition that* M *is truncated (that is, that* $\pi_i M \simeq 0$ *for* $i \gg 0$*).*

(5) *The condition that* M *is has* Tor*-amplitude* $\leqslant n$*, where* n *is a fixed integer.*

(6) *The condition that* M *is flat.*

(7) *The condition that* M *is perfect to order* n *over* A*, where* n *is a fixed integer.*

(8) *The condition that* M *is finitely* n*-presented over* A*, where* $n \geqslant 0$ *is a fixed integer.*

(9) *The condition that* M *is almost perfect over* A*.*

(10) *The condition that* M *is perfect over* A*.*

Lemma 2.8.4.3. *Let* $f : A \to B$ *be a faithfully flat morphism of connective* $\mathbb{E}_\infty$*-rings and let* M *be a left* A*-module. If* $B \otimes_A M$ *has* Tor*-amplitude* $\leqslant n$ *over* B*, then* M *has* Tor*-amplitude* $\leqslant n$ *over* A *(see Definition HA.7.2.4.21).*

Proof. Let N be a discrete A-module; we wish to show that $M \otimes_A N$ is n-truncated. Since B is faithfully flat over A, it suffices to show that

$$B \otimes_A (M \otimes_A N) \simeq (B \otimes_A M) \otimes_B (B \otimes_A N)$$

is n-truncated. This follows from our assumption that $B \otimes_A M$ has Tor-amplitude $\leqslant n$, since $B \otimes_A N$ is a discrete B-module. □

Proof of Proposition 2.8.4.2. Assertions (1) and (3) follow from Proposition HA.7.2.2.13, and assertions (2) and (4) follow immediately from (1) and (3). Assertion (5) follows from Lemma 2.8.4.3. Assertion (6) follows from (5) and (1). Assertion (7) follows from Proposition 2.7.3.1 and Remark 2.7.0.8. Assertion (8) follows from (1), (3), and (7). Assertion (9) follows from (7). Assertion (10) follows (5), (9), and Proposition HA.7.2.4.23. □

Definition 2.8.4.4. Let P be a property of pairs (A, M), where A is a connective $\mathbb{E}_\infty$-ring and M is an A-module, and assume that P is local for the flat topology. Let X be a spectral Deligne-Mumford stack and let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$. We will say that $\mathscr{F}$ *has the property* P if, for every étale morphism $f : \mathrm{Spét}\, A \to \mathscr{F}$, the pullback $f^* \mathscr{F} \in \mathrm{QCoh}(\mathrm{Spét}\, A) \simeq \mathrm{Mod}_A$ corresponds to an A-module M for which the pair (A, M) has the property P.

Let us spell out the contents of Definition 2.8.4.4 in the examples provided by Proposition 2.8.4.2. Let $\mathscr{F}$ be a quasi-coherent sheaf on a spectral Deligne-Mumford stack X. We say that $\mathscr{F}$ is:

(1) *n-connective* if, for every étale morphism $f : \mathrm{Spét}\, A \to \mathsf{X}$, the pullback $f^* \mathscr{F} \in \mathrm{Mod}_A$ is n-connective. This is equivalent to the requirement that $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})_{\geqslant n}$.

(2) *almost connective* if, for every étale morphism $f : \mathrm{Spét}\, A \to \mathsf{X}$, the pullback $f^* \mathscr{F} \in \mathrm{Mod}_A$ is almost connective. If X is quasi-compact, then this condition is equivalent to the requirement that $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})_{\geqslant -n}$ for some integer n.

(3) *n-truncated* if, for every étale morphism $f : \mathrm{Spét}\, A \to \mathsf{X}$, the pullback $f^* \mathscr{F} \in \mathrm{Mod}_A$ is n-truncated. This is equivalent to the requirement that $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})_{\leqslant n}$.

(4) *locally truncated* if, for every étale morphism $f : \mathrm{Spét}\, A \to \mathsf{X}$, the pullback $f^* \mathscr{F} \in \mathrm{Mod}_A$ is n-truncated for some integer n. If X is quasi-compact, this is equivalent to the requirement that $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})_{\leqslant n}$ for some integer n.

(5) *of* Tor-*amplitude* $\leqslant n$ if, for every étale morphism $f : \mathrm{Spét}\, A \to \mathsf{X}$, the pullback $f^* \mathscr{F} \in \mathrm{Mod}_A$ is of Tor-amplitude $\leqslant n$.

(6) *flat* if, for every étale morphism $f : \mathrm{Spét}\, A \to \mathsf{X}$, the pullback $f^* \mathscr{F} \in \mathrm{Mod}_A$ is flat.

(7) *perfect to order n* if, for every étale morphism $f : \mathrm{Spét}\, A \to \mathsf{X}$, the pullback $f^* \mathscr{F} \in \mathrm{Mod}_A$ is perfect to order n.

(8) *finitely n-presented* if, for every étale morphism $f : \mathrm{Spét}\, A \to \mathsf{X}$, the pullback $f^* \mathscr{F} \in \mathrm{Mod}_A$ is finitely n-presented.

(9) *almost perfect* if, for every étale morphism $f : \mathrm{Spét}\, A \to \mathsf{X}$, the pullback $f^* \mathscr{F} \in \mathrm{Mod}_A$ is almost perfect.

(10) *perfect* if, for every étale morphism $f : \mathrm{Spét}\, A \to \mathsf{X}$, the pullback $f^* \in \mathrm{Mod}_A$ is perfect.

Remark 2.8.4.5. In case (4), our terminology does not quite conform to the general convention of Definition 2.8.4.4. We use the term "locally truncated" rather than "truncated" to emphasize the possibility that if $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is a quasi-coherent sheaf whose pullback $f^* \mathscr{F}$ is truncated for every étale map $f : \mathrm{Spét}\, A \to \mathsf{X}$, then $\mathscr{F}$ need not belong to $\bigcup \mathrm{QCoh}(\mathsf{X})_{\leqslant n}$ unless we assume that X is quasi-compact.

Remark 2.8.4.6. In the setting of classical scheme theory, the notions of *perfect to order* n and *almost perfect* were introduced by Illusie in [101], who refers to an object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ as *n-pseudo-coherent* if it is perfect to order n (in our terminology), and as *pseudo-coherent* it is almost perfect (in our terminology).

We have the following analogue of Proposition 2.8.1.7, which can be proven by exactly the same argument:

Proposition 2.8.4.7. *Let P be a property of pairs (A, M), where A is a connective $\mathbb{E}_\infty$-ring and M is an A-module, and assume that P is local for the flat topology. Let X be a spectral Deligne-Mumford stack and let $\mathscr{F}$ be a quasi-coherent sheaf on X. Then:*

(1) *If $f : \mathsf{Y} \to \mathsf{X}$ is a flat morphism and $\mathscr{F}$ has the property P, then $f^* \mathscr{F}$ has the property P. In particular, if $\mathscr{F}$ is n-connective (almost connective, n-truncated, locally truncated, of* Tor*-amplitude $\leqslant n$, flat, perfect to order n, finitely n-presented, almost perfect, perfect), then $f^* \mathscr{F}$ has the same property.*

(2) *If we are given a collection of flat maps $\{f_\alpha : \mathsf{Y}_\alpha \to \mathsf{X}\}$ which induces a flat covering $\amalg \mathsf{Y}_\alpha \to \mathsf{X}$, and each pullback $f_\alpha^* \mathscr{F}$ has the property P, then $\mathscr{F}$ has the property P. In particular, if each $f_\alpha^* \mathscr{F}$ is n-connective (almost connective, n-truncated, locally truncated, of* Tor*-amplitude $\leqslant n$, flat, perfect to order n, finitely n-presented, almost perfect, perfect), then $\mathscr{F}$ has the same property.*

2.9 Vector Bundles and Invertible Sheaves

Let X be a scheme. One of the most important invariants of X is its *Picard group* $\mathrm{Pic}(X)$: the group of isomorphism classes of invertible sheaves on X. Our goal in this section is to extend the theory of the Picard group to the setting of spectral algebraic geometry.

2.9.1 Locally Free Modules

We begin with a more general discussion of locally free sheaves.

Definition 2.9.1.1. Let A be a connective $\mathbb{E}_\infty$-ring and let M be an A-module. We will say that M is *locally free of finite rank* if there exists an integer n such that M is a direct summand of A^n.

Remark 2.9.1.2. Let A be a connective $\mathbb{E}_\infty$-ring. Using Proposition HA.7.2.4.20 , we conclude that an A-module M is locally free of finite rank if and only if M is flat and almost perfect.

Corollary 2.9.1.3. *Let A be a connective $\mathbb{E}_1$-ring and let M be a left A-module of* Tor*-amplitude $\leqslant 0$. If M is perfect to order 1, then it is perfect. If, in addition, M is connective, then it is locally free of finite rank.*

Proof. Using Proposition 2.7.3.2, we can reduce to the case where A is discrete. In this case, the first assertion follows from Proposition 2.7.1.5, and the second from Remark 2.9.1.2. □

Combining Proposition 2.8.4.2, Proposition 6.2.5.2, and Remark 2.9.1.2, we obtain the following:

Proposition 2.9.1.4. *The property of being a locally free module of finite rank is stable under base change and local with respect to the flat topology.*

Our next result gives another characterization of the class of locally free modules:

Proposition 2.9.1.5. *Let R be a connective $\mathbb{E}_\infty$-ring and let M be a connective R-module. The following conditions are equivalent:*

(1) *The module M is locally free of finite rank.*

(2) *The module M is a dualizable object of the symmetric monoidal ∞-category $\mathrm{Mod}_R^{\mathrm{cn}}$.*

Proof. The collection of dualizable objects of $\mathrm{Mod}_R^{\mathrm{cn}}$ is evidently closed under the formation of retracts and direct sums. Since the unit object $R \in \mathrm{Mod}_R^{\mathrm{cn}}$ is dualizable, we conclude that (1) $\Rightarrow$ (2). Conversely, suppose that M is a dualizable object of $\mathrm{Mod}_R^{\mathrm{cn}}$. Then M is a dualizable object of Mod_R, and therefore a perfect R-module (Proposition 6.2.6.2). Let $M^\vee$ denote the dual of M. For any discrete R-module N, we have isomorphisms $\pi_i(M \otimes_R N) \simeq \pi_i \mathrm{Map}_{\mathrm{Mod}_R}(M^\vee, N)$ for $i \geqslant 0$. Since $M^\vee$ is connective, we deduce that $\pi_i(M \otimes_R N)$ vanishes for $i > 0$. It follows that M is flat, so that M is locally free of finite rank by Proposition HA.7.2.4.20. □

2.9.2 The Rank of a Locally Free Module

We now restrict our attention to modules which are locally free of a particular rank $n \in \mathbf{Z}_{\geqslant 0}$.

Definition 2.9.2.1. Let R be a connective $\mathbb{E}_\infty$-ring, let M be an R-module, and let $n \geqslant 0$ be an integer. We will say that M is *locally free of rank n* if the following conditions are satisfied:

(a) The module M is locally free of finite rank (equivalently, M is flat and almost perfect as an R-module: see Proposition HA.7.2.4.20).

(b) For every field κ and every map of $\mathbb{E}_\infty$-rings $R \to \kappa$, the vector space $\pi_0(\kappa \otimes_R M)$ has dimension n over κ.

Remark 2.9.2.2. To verify condition (b) of Definition 2.9.2.1, we are free to pass to any field extension of κ. We may therefore assume without loss of generality that κ is algebraically closed.

The terminology of Definitions 2.9.1.1 and 2.9.2.1 is motivated by the following observation:

Proposition 2.9.2.3. *Let R be a connective $\mathbb{E}_\infty$-ring and let M be an R-module which is locally free of finite rank. Then there exists a sequence of elements $x_1, \ldots, x_m \in \pi_0 R$ which generate the unit ideal, such that each of the modules $M[x_i^{-1}] = R[x_i^{-1}] \otimes_R M$ is free of rank n_i over $R[x_i^{-1}]$. If M is locally free of rank n, then we can assume that $n_i = n$ for every integer i.*

Proof. Let us say that an element $x \in \pi_0 R$ is *good* if $M[x^{-1}]$ is a free module of finite rank over $R[x^{-1}]$ (which is of rank n in the case where M is locally free of rank n). To complete the proof, it will suffice to show that the collection of good elements of $\pi_0 R$ generate the unit ideal in $\pi_0 R$. Assume otherwise; then there exists a maximal ideal $\mathfrak{m}$ of $\pi_0 R$ which contains every good element of R. Let $\kappa = (\pi_0 R)/\mathfrak{m}$ denote the residue field of $\pi_0 R$ at $\mathfrak{m}$. Then $\pi_0(\kappa \otimes_R M)$ is a finite dimensional vector space over k (which is of dimension n in the case M is locally free of rank n). Let n' be the dimension of this vector space, and choose elements $y_1, \ldots, y_{n'} \in \pi_0 M$ whose images form a basis for $\pi_0(\kappa \otimes_R M)$. Since $\pi_0 M$ is finitely generated as a module over $\pi_0 R$, Nakayama's lemma implies that the images of the elements y_i generate the localization $(\pi_0 M)_{\mathfrak{m}}$. We may therefore choose an element $x \in (\pi_0 R) - \mathfrak{m}$ such that the elements y_i generate the module $(\pi_0 M)[x^{-1}]$. It follows that there is a map a map $\phi : R[x^{-1}]^{n'} \to M$ which induces a surjection $(\pi_0 R[x^{-1}])^{n'} \to \pi_0 M[x^{-1}]$. Since M is projective, the map ϕ admits a right homotopy inverse $\psi : M[x^{-1}] \to R[x^{-1}]^{n'}$. The composite map $\psi \circ \phi : R[x^{-1}]^{n'} \to R[x^{-1}]^{n'}$ determines an n'-by-n' matrix A_{ij} with values in the commutative ring $\pi_0 R[x^{-1}]$. Let D denote the determinant of this matrix, and choose an element $x' \in \pi_0 R$ with $x^a D = x'$. Since ϕ induces an isomorphism of vector spaces $k^{n'} \simeq \pi_0(\kappa \otimes_R M)$, the element x' does not belong to $\mathfrak{m}$. We note that the image of D in $\pi_0 R[x^{-1}, x'^{-1}]$ is invertible, so that ϕ induces an equivalence $R[x^{-1}, x'^{-1}]^{n'} \to M[x^{-1}, x'^{-1}]$. It follows that $xx' \in \pi_0 R$ is good. Since the product xx' does not belong to $\mathfrak{m}$, we obtain a contradiction. □

Proposition 2.9.2.4. *The condition that an R-module M be locally free of rank n is stable under base change and local with respect to the flat topology (see Definitions 2.8.4.1 and 6.2.5.1).*

Proof. According to Proposition 2.9.1.4, the condition of being locally free of finite rank is stable under base change and local with respect to the flat topology. It will therefore suffice to prove the following:

(∗) Let R be a connective $\mathbb{E}_\infty$-ring, M a locally free R-module of finite rank, and $R \to \prod_{1 \leqslant i \leqslant m} R_i$ a faithfully flat map of $\mathbb{E}_\infty$-rings. If each tensor product $R_i \otimes_R M$ satisfies condition (b) of Definition 2.9.2.1, then so does M.

To prove (∗), let us suppose we are given a field κ and a map $R \to \kappa$; we wish to prove that $\pi_0(\kappa \otimes_R M)$ is a κ-vector space of dimension n. Since $R \to \prod_{1 \leqslant i \leqslant m} R_i$ is faithfully flat, there exists an index i such that $\kappa \otimes_R R_i \neq 0$. Let κ' be a residue field of the commutative ring $\kappa \otimes_R R_i$. Then κ' is a field extension of κ, so it will suffice to show that $\pi_0(\kappa' \otimes_R M)$ has dimension n over κ' (Remark 2.9.2.2). This follows from the existence of an isomorphism

$$\pi_0(\kappa' \otimes_R M) \simeq \pi_0(\kappa' \otimes_{R_i} (R_i \otimes_R M)),$$

since $R_i \otimes_R M$ is locally free of rank n over R_i. □

2.9.3 Locally Free Sheaves

Using Proposition 2.9.2.4, we can introduce a global version of Definition 2.9.2.1.

Notation 2.9.3.1. Let X be a spectral Deligne-Mumford stack. We say that a quasi-coherent sheaf $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is *locally free of rank n* if, for every étale morphism $f : \mathrm{Spét}\, A \to \mathsf{X}$, the pullback $f^* \mathscr{F} \in \mathrm{QCoh}(\mathrm{Spét}\, A) \simeq \mathrm{Mod}_A$ is locally free of rank n when regarded as an A-module. Note that if this condition is satsified, then $g^* \mathscr{F} \in \mathrm{Mod}_B$ is locally free of rank n for every map $g : \mathrm{Spét}\, B \to \mathsf{X}$.

For perfect quasi-coherent sheaves, local freeness is an open condition:

Proposition 2.9.3.2. *Let X be a spectral Deligne-Mumford stack and let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ be perfect. Then:*

(1) *For every integer n, there exists a largest open substack $i_n : \mathsf{X}_n \hookrightarrow \mathsf{X}$ such that $i_n^* \mathscr{F}$ is locally free of rank n.*

(2) *The sheaf $\mathscr{F}$ is locally free of finite rank if and only if the canonical map $\theta : \amalg_n \mathsf{X}_n \to \mathsf{X}$ is an equivalence of spectral Deligne-Mumford stacks.*

(3) *Let $f : \mathsf{Y} \to \mathsf{X}$ be a map of spectral Deligne-Mumford stacks. Then f factors through X_n if and only if $f^* \mathscr{F}$ is locally free of rank n.*

In particular, if $\mathscr{F}$ is locally free of finite rank, then each of the maps i_n is a clopen immersion (see Definition 3.1.7.2).

Lemma 2.9.3.3. *Let X be a spectral Deligne-Mumford stack, and let $\mathscr{F}$ be an almost perfect quasi-coherent sheaf on X. For every integer n, there exists quasi-compact open immersion $i : \mathsf{U} \to \mathsf{X}$ with the following property: a morphism of spectral Deligne-Mumford stacks $f : \mathsf{X}' \to \mathsf{X}$ factors through U if and only if $f^* \mathscr{F}$ is n-connective.*

Proof. The assertion is local on X. We may therefore assume without loss of generality that X is quasi-compact, so that $\mathscr{F}$ is m-connective for some integer m. We proceed by induction on the difference $n - m$. If $n - m \leqslant 0$, then we can take $\mathsf{U} = \mathsf{X}$. Assume that $m < n$. Using the inductive hypothesis, we can choose a quasi-compact open immersion $j : \mathsf{V} \to \mathsf{X}$ such that a map $\mathsf{X}' \to \mathsf{X}$ factors through j if and only if $f^* \mathscr{F}$ is $(n-1)$-connective. Replacing X by V, we may assume that $\mathscr{F}$ is $(n-1)$-connective. Since the assertion is local on X, we may assume without loss of generality that $\mathsf{X} = \operatorname{Spét} R$ is affine, so that $\mathscr{F}$ corresponds to an $(n-1)$-connective R-module M. Since $\mathscr{F}$ is almost perfect, $\pi_{n-1} M$ is finitely presented over $\pi_0 R$. We may therefore choose a presentation

$$(\pi_0 R)^{m'} \xrightarrow{T} (\pi_0 R)^m \to \pi_{n-1} M \simeq 0.$$

Let $I \subseteq \pi_0 R$ be the ideal generated by all m-by-m minors of the matrix representing the map T. Let $U = \{\mathfrak{p} \in |\operatorname{Spec} R| : I \nsubseteq \mathfrak{p}\} \subseteq |\operatorname{Spec} R|$ and let U be the corresponding open substack of X. We claim that U has the desired properties. To prove this, it suffices to observe that a map $\operatorname{Spét} R' \to \mathsf{X}$ factors through U if and only if the abelian group $\operatorname{Tor}_0^{\pi_0 R}(\pi_0 R', \pi_{n-1} M) \simeq \pi_{n-1}(R' \otimes_R M)$ vanishes. □

Lemma 2.9.3.4. *Let X be a spectral Deligne-Mumford stack, and let $\mathscr{F}$ be a perfect quasi-coherent sheaf on $\mathscr{F}$. Then there exists a quasi-compact open immersion $i : \mathsf{U} \to \mathsf{X}$ with the following property: a morphism of spectral Deligne-Mumford stacks $f : \mathsf{X}' \to \mathsf{X}$ factors through U if and only if $f^* \mathscr{F}$ is locally free of finite rank.*

Proof. Since $\mathscr{F}$ is perfect, it is a dualizable object of $\operatorname{QCoh}(\mathsf{X})$ (Proposition 6.2.6.2); let us denote its dual by $\mathscr{F}^\vee$. Note that $\mathscr{F}$ is locally free of finite rank if and only if both $\mathscr{F}$ and $\mathscr{F}^\vee$ are connective (Proposition HA.7.2.4.20). The desired result now follows from Lemma 2.9.3.3. □

Proof of Proposition 2.9.3.2. Assertion (1) follows immediately from Proposition 2.9.2.4, and the "if" direction of (2) is immediate. Conversely, suppose that $\mathscr{F}$ is locally free of finite rank; we wish to show that the map θ is an equivalence. The map θ is evidently étale, and is surjective by virtue of Proposition 2.9.2.3. To prove that θ is an equivalence, it will suffice to show that the diagonal map

$$\amalg_n \mathsf{X}_n \to (\amalg_n \mathsf{X}_n) \times_{\mathsf{X}} (\amalg_n \mathsf{X}_n) \simeq \amalg_{m,n} (\mathsf{X}_m \times_{\mathsf{X}} \mathsf{X}_n)$$

is an equivalence. Since each i_n is an open immersion, each of the maps $\mathsf{X}_n \to \mathsf{X}_n \times_{\mathsf{X}} \mathsf{X}_n$ is an equivalence. It will therefore suffice to show that $\mathsf{X}_m \times_{\mathsf{X}} \mathsf{X}_n$ is trivial for $m \neq n$. Equivalently, we must show that if R is a connective $\mathbb{E}_\infty$-ring and M is a locally free R-module of rank m which is also of rank $n \neq m$, then $R \simeq 0$. Assume otherwise, and let κ be a residue field of $\pi_0 R$. We obtain an immediate contradiction, since $\pi_0(\kappa \otimes_R M)$ is a vector space over k which is dimension m and also of dimension $n \neq m$.

It remains to prove (3). Using Lemma 2.9.3.4, we may reduce to the case where $\mathscr{F}$ is locally free of finite rank, so that the above argument shows that θ is an equivalence. Let $f : \mathsf{Y} \to \mathsf{X}$ be such that $f^* \mathscr{F}$ is locally free of rank n. Then we can write f as a coproduct of maps $f_m : \mathsf{Y}_m \to \mathsf{X}_m$. Then $(i_m \circ f_m)^* \mathscr{F}$ is locally free of rank m and locally free of rank n. It follows that Y_m is empty for $m \neq n$, so that $\mathsf{Y}_n \simeq \mathsf{Y}$ and f factors through i_n as desired. □

2.9.4 Line Bundles

We now consider quasi-coherent sheaves which are locally free of rank 1.

Definition 2.9.4.1. Let X be a spectral Deligne-Mumford stack. We will say that a quasi-coherent sheaf $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is a *line bundle* if it is locally free of rank 1. We let $\mathscr{P}\mathrm{ic}(\mathsf{X})$ denote the full subcategory of $\mathrm{QCoh}(\mathsf{X})^{\simeq}$ spanned by the line bundles on X, and we let $\mathrm{Pic}(\mathsf{X}) = \pi_0 \mathscr{P}\mathrm{ic}(\mathsf{X})$ collection of homotopy equivalences classes of line bundles on X. We will refer to $\mathrm{Pic}(\mathsf{X})$ as the *Picard group* of X.

Proposition 2.9.4.2. *Let X be a spectral Deligne-Mumford stack and let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$. The following conditions are equivalent:*

(1) *The quasi-coherent sheaf $\mathscr{F}$ is a line bundle on X.*

(2) *The quasi-coherent sheaf $\mathscr{F}$ is an invertible object of the symmetric monoidal ∞-category $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$.*

Proof. Suppose first that (1) is satisfied. Then $\mathscr{F}$ is locally free of finite rank, and therefore a dualizable object of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ (see Proposition 2.9.1.5). Let us denote its dual by $\mathscr{F}^{\vee}$, and let $e : \mathscr{F} \otimes \mathscr{F}^{\vee} \to \mathscr{O}$ be the evaluation map (where $\mathscr{O}$ denotes the structure sheaf of X). We claim that e is an equivalence. To prove this, it suffices to show that e induces an equivalence of R-modules $\eta^*(\mathscr{F} \otimes \mathscr{F}^{\vee}) \to R$ for every map $\eta : \mathrm{Sp\acute{e}t}\, R \to \mathsf{X}$. The assertion is local on $|\operatorname{Spec} R|$, so we can apply Proposition 2.9.2.3 to reduce further to the case where $\eta^* \mathscr{F} \simeq R$, in which case the result is obvious.

We now prove (2). Assume that $\mathscr{F}$ is an invertible object in $\mathrm{QCoh}(X)^{\mathrm{cn}}$. We wish to show that for every point $\eta \in X(R)$, the pullback $M = \eta^* \mathscr{F} \in \mathrm{QCoh}(\operatorname{Spec} R) \simeq \mathrm{Mod}_R$ is locally free of rank 1. Note that M is a dualizable object of $\mathrm{Mod}_R^{\mathrm{cn}}$ and therefore locally free of finite rank (Proposition 2.9.1.5). In particular, for every map from R to a field κ, the tensor product $\kappa \otimes_R M$ can be identified with a finite dimensional vector space over κ, which is invertible as an object of $\mathrm{Mod}_\kappa^{\mathrm{cn}}$. It follows easily that $\kappa \otimes_R M$ has dimension 1 over κ, so that M is locally free of rank 1. □

2.9.5 Invertible Sheaves

For some purposes, it is convenient to consider a slight enlargement of the Picard group $\mathrm{Pic}(\mathsf{X})$.

Definition 2.9.5.1. Let X be a spectral Deligne-Mumford stack, and let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$. We will say that $\mathscr{F}$ is *invertible* if it is invertible as an object of the symmetric monoidal ∞-category $\mathrm{QCoh}(\mathsf{X})$: that is, if there exists another object $\mathscr{F}' \in \mathrm{QCoh}(\mathsf{X})$ such that $\mathscr{F} \otimes \mathscr{F}'$ is equivalent to the unit object of $\mathrm{QCoh}(\mathsf{X})$. We let $\mathscr{P}\mathrm{ic}^{\dagger}(\mathsf{X})$ denote the full subcategory of $\mathrm{QCoh}(\mathsf{X})^{\simeq}$ spanned by the invertible objects, and we let $\mathrm{Pic}^{\dagger}(\mathsf{X})$ denote the set of connected components $\pi_0 \mathscr{P}\mathrm{ic}^{\dagger}(\mathsf{X})$. We will refer to $\mathrm{Pic}^{\dagger}(\mathsf{X})$ as the *extended Picard group* of X.

Remark 2.9.5.2. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack. Then $\mathscr{P}\mathrm{ic}^{\dagger}(\mathsf{X}) \subseteq \mathrm{QCoh}(\mathsf{X})$ is essentially small. To prove this, choose a regular cardinal κ for which the global sections functor $\mathscr{F} \mapsto \Gamma(\mathsf{X}; \mathscr{F})$ commutes with κ-filtered colimits. If $\mathcal{L}$ is an invertible object of $\mathrm{QCoh}(\mathsf{X})$, then the canonical equivalence $\mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathcal{L}, \mathscr{F}) \simeq \Gamma(\mathsf{X}; \mathcal{L}^{-1} \otimes \mathscr{F})$ shows that $\mathcal{L}$ is a κ-compact object of $\mathrm{QCoh}(\mathsf{X})$. Since the full subcategory of $\mathrm{QCoh}(\mathsf{X})$ spanned by the κ-compact objects is essentially small, it follows that $\mathscr{P}\mathrm{ic}^{\dagger}(\mathsf{X})$ is essentially small.

Remark 2.9.5.3. Let X be a spectral Deligne-Mumford stack. It follows from Proposition 2.9.4.2 that every line bundle on X is an invertible object of $\mathrm{QCoh}(\mathsf{X})$, so that we have inclusions

$$\mathscr{P}\mathrm{ic}(\mathsf{X}) \subseteq \mathscr{P}\mathrm{ic}^{\dagger}(\mathsf{X}) \qquad \mathrm{Pic}(\mathsf{X}) \subseteq \mathrm{Pic}^{\dagger}(\mathsf{X}).$$

It follows from Remark 2.9.5.2 that $\mathscr{P}\mathrm{ic}(\mathsf{X})$ is essentially small, and that the sets $\mathrm{Pic}(\mathsf{X})$ and $\mathrm{Pic}^{\dagger}(\mathsf{X})$ are small.

Remark 2.9.5.4. Let $\mathcal{C}$ be a symmetric monoidal ∞-category, and let $\mathcal{E}$ denote the full subcategory of $\mathcal{C}^{\simeq}$ spanned by the invertible objects of $\mathcal{C}$. Then $\mathcal{E}$ inherits the structure of a symmetric monoidal ∞-category. It can therefore be viewed as grouplike commutative monoid object of the ∞-category $\mathcal{S}$ of spaces. It follows from Remark HA.5.2.6.26 that $\mathcal{E}$ is an infinite loop space; in particular, the symmetric monoidal structure on $\mathcal{C}$ determines an abelian group structure on $\pi_0 \mathcal{E}$. Applying this observation to the symmetric monoidal ∞-categories $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ and $\mathrm{QCoh}(\mathsf{X})$ (where X is a spectral Deligne-Mumford stack), we conclude that $\mathscr{P}\mathrm{ic}(\mathsf{X})$ and $\mathscr{P}\mathrm{ic}^{\dagger}(\mathsf{X})$ are infinite loop spaces, and that the sets $\mathrm{Pic}(\mathsf{X})$ and $\mathrm{Pic}^{\dagger}(\mathsf{X})$ can be regarded as abelian groups.

Remark 2.9.5.5. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack, and let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$. Then $\mathscr{F}$ is invertible if and only if $\mathscr{F}$ is dualizable, and the evaluation map $\mathscr{F} \otimes \mathscr{F}^{\vee} \to \mathscr{O}_{\mathcal{X}}$ is an equivalence. It follows that the condition that $\mathscr{F}$ be invertible is local with respect to the flat topology on X.

We next describe the relationship between line bundles and invertible sheaves.

Proposition 2.9.5.6. *Let X be a spectral Deligne-Mumford stack, and let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ be perfect. For each integer $n \in \mathbf{Z}$, let X_n denote the largest open substack of X for which the restriction of $\Sigma^n \mathscr{F}$ to X_n is a line bundle (see Proposition 2.9.3.2). Then:*

(1) *The canonical map $j : \amalg_{n \in \mathbf{Z}} \mathsf{X}_n \to \mathsf{X}$ is an open immersion.*

(2) *Let $g : \mathsf{Y} \to \mathsf{X}$ be a map of spectral Deligne-Mumford stacks. Then g factors through j if and only if $g^* \mathscr{F}$ is invertible.*

Corollary 2.9.5.7. *Let X be a spectral Deligne-Mumford stack and let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$. The following conditions are equivalent:*

(1) *There exists an equivalence $\mathsf{X} \simeq \amalg_{n \in \mathbf{Z}} \mathsf{X}_n$ such that, for each $n \in \mathbf{Z}$, the restriction of $\Sigma^n \mathscr{F}$ to X_n is a line bundle.*

(2) *There exists a mutually surjective collection of étale maps $f_\alpha : \mathsf{U}_\alpha \to \mathsf{X}$, integers n_α, and line bundles $\mathcal{L}_\alpha \in \mathscr{P}\mathrm{ic}(\mathsf{U}_\alpha)$ such that $f_\alpha^* \mathscr{F} \simeq \Sigma^{n_\alpha} \mathcal{L}_\alpha$.*

(3) *There exists a mutually surjective collection of étale maps $f_\alpha : \mathsf{U}_\alpha \to \mathsf{X}$, such that each $f_\alpha^* \mathscr{F}$ is invertible.*

(4) *The object $\mathscr{F}$ is invertible.*

Proof. The implications (1) ⇒ (2) ⇒ (3) are immediate, and (3) ⇒ (4) follows from Remark 2.9.5.5. Suppose that (4) is satisfied. Then $\mathscr{F}$ is perfect, so that condition (1) follows from Proposition 2.9.5.6. □

Remark 2.9.5.8. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack. Using Corollary 2.9.5.7, we obtain an isomorphism of abelian groups

$$\mathrm{Pic}^{\dagger}(\mathsf{X}) \simeq \mathrm{Pic}(\mathsf{X}) \times \Gamma(\mathcal{X}; \underline{\mathbf{Z}}),$$

where $\underline{\mathbf{Z}}$ denotes the constant sheaf on $\mathcal{X}$ taking the value $\mathbf{Z}$. In other words, $\mathrm{Pic}^{\dagger}(\mathsf{X})$ is the product of $\mathrm{Pic}(\mathsf{X})$ with the abelian group of locally constant $\mathbf{Z}$-valued functions on X. In particular, if X is connected, we obtain an isomorphism $\mathrm{Pic}^{\dagger}(\mathsf{X}) \simeq \mathrm{Pic}(\mathsf{X}) \times \mathbf{Z}$: that is, every invertible object of $\mathrm{QCoh}(\mathsf{X})$ can be written uniquely in the form $\Sigma^n \mathcal{L}$, where n is an integer and $\mathcal{L}$ is a line bundle on X.

Proof of Proposition 2.9.5.6. We first claim that j is an open immersion. Arguing as in the proof of Proposition 2.9.3.2, we are reduced to proving that the fiber product $\mathsf{X}_m \times_{\mathsf{X}} \mathsf{X}_n$ is empty for $m \neq n$. Suppose otherwise; then there exists a field κ and a map $\eta : \mathrm{Sp\acute{e}t}\, \kappa \to \mathsf{X}$ which factors through both X_m and X_n. Then $\pi_0 \eta^* \Sigma^m \mathscr{F}$ is a 1-dimensional vector space over κ (since η factors through X_m) and also a 0-dimensional vector space over κ (since η factors through X_n), so we obtain a contradiction. This proves (1).

The "only if" direction of (2) is obvious. For the converse, suppose we are given a map $g : \mathsf{Y} \to \mathsf{X}$ such that $g^* \mathscr{F}$ is invertible; we wish to show that g factors through j. Without loss of generality, we may suppose that $\mathsf{Y} = \operatorname{Spét} R$ is affine. Let us identify $g^* \mathscr{F}$ with an invertible R-module M. To prove that g factors through j, it will suffice to show that for every maximal ideal $\mathfrak{m} \subseteq \pi_0 R$, there exists an element $a \in \pi_0 R$ which does not belong to $\mathfrak{m}$ and an integer n such that $\Sigma^{-n} M[a^{-1}]$ is locally free of rank 1.

Let $\kappa = (\pi_0 R)/\mathfrak{m}$. Then $\kappa \otimes_R M$ is an invertible κ-module, so that $\pi_*(\kappa \otimes_R M)$ is an invertible object in the symmetric monoidal category of graded vector spaces over κ. It follows that there exists an integer n such that

$$\pi_i(\kappa \otimes_R M) \simeq \begin{cases} \kappa & \text{if } i = n \\ 0 & \text{otherwise.} \end{cases}$$

Since M is an invertible R-module, it is nonzero and perfect. It follows that there exists a smallest integer m such that $\pi_m M \neq 0$. If $m < n$, then $(\pi_m M)/\mathfrak{m}(\pi_m M) \simeq \pi_m(\kappa \otimes_R M) \simeq 0$. Since $\pi_m M$ is finitely generated as a module over $\pi_0 R$, it follows from Nakayama's lemma that there exists an element $a \in (\pi_0 R) - \mathfrak{m}$ such that $\pi_m M[a^{-1}] = 0$. Replacing R by the localization $R[a^{-1}]$, we may reduce to the case where $\pi_m M = 0$. Iterating this procedure, we may reduce to the case where $\pi_m M \simeq 0$ for $m < n$. Applying a similar argument to the dual $M^\vee$ of M, we may suppose that $\pi_m M^\vee \simeq 0$ for $m < -n$: that is, M has Tor-amplitude $\geqslant n$. It then follows from Remark 2.9.1.2 that $\Sigma^{-n} M$ is locally free of finite rank. Using Proposition 2.9.3.2 we may suppose (after further localization) that $\Sigma^{-n} M$ is locally free of rank 1, as desired. □

2.9.6 The Affine Case

Let X be a spectral Deligne-Mumford stack and let X_0 be its underlying ordinary Deligne-Mumford stack. Every line bundle on X determines a line bundle on X_0, so there is a natural map from the Picard group of X (in the sense of Definition 2.9.4.1) to the Picard group of X_0 (in the sense of classical algebraic geometry). In general, this map need not be an isomorphism. However, it is an isomorphism whenever X is affine (Proposition 2.9.6.2).

Notation 2.9.6.1. Let R be a connective $\mathbb{E}_\infty$-ring. We define

$$\mathscr{P}\mathrm{ic}(R) = \mathscr{P}\mathrm{ic}(\operatorname{Spét} R) \qquad \mathscr{P}\mathrm{ic}^\dagger(R) = \mathscr{P}\mathrm{ic}^\dagger(\operatorname{Spét} R)$$

$$\operatorname{Pic}(R) = \operatorname{Pic}(\operatorname{Spét} R) \qquad \operatorname{Pic}^\dagger(R) = \operatorname{Pic}^\dagger(\operatorname{Spét} R).$$

We will refer to $\operatorname{Pic}(R)$ and $\operatorname{Pic}^\dagger(R)$ as the *Picard group of* R and the *extended Picard group of* R, respectively.

Proposition 2.9.6.2. *Let R be a connective $\mathbb{E}_\infty$-ring. Then the canonical maps*

$$\alpha : \mathrm{Pic}(R) \to \mathrm{Pic}(\pi_0 R) \qquad \beta : \mathrm{Pic}^\dagger(R) \to \mathrm{Pic}^\dagger(\pi_0 R)$$

are isomorphisms.

Proof. By virtue of Remark 2.9.5.8, it will suffice to prove that α is an isomorphism, which follows from Corollary HA.7.2.2.19 . □

Corollary 2.9.6.3. *Let R be a connective $\mathbb{E}_\infty$-ring. Then the canonical maps*

$$\mathscr{P}\mathrm{ic}(R) \to \varprojlim \mathscr{P}\mathrm{ic}(\tau_{\leqslant n} R) \qquad \mathscr{P}\mathrm{ic}^\dagger(R) \to \varprojlim \mathscr{P}\mathrm{ic}(\tau_{\leqslant n} R)$$

are homotopy equivalences.

Proof. Using Proposition 2.9.6.2, we see that the maps

$$\pi_m \mathscr{P}\mathrm{ic}(R) \to \pi_m \mathscr{P}\mathrm{ic}(\tau_{\leqslant n} R) \qquad \pi_m \mathscr{P}\mathrm{ic}^\dagger(R) \to \pi_m \mathscr{P}\mathrm{ic}^\dagger(\tau_{\leqslant n} R)$$

are isomorphisms as soon as $n \geqslant m - 1$. □

Chapter 3

Spectral Algebraic Spaces

Recall that a spectral Deligne-Mumford stack X is a *spectral algebraic space* if the mapping space $\mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{X})$ is discrete for every commutative ring R (Definition 1.6.8.1). In this section, we will develop some foundations for the theory of spectral algebraic spaces. Our main technical result (Theorem 3.4.2.1) asserts that every quasi-compact, quasi-separated spectral algebraic space admits a scallop decomposition, in the sense of Definition 2.5.3.1. This has a number of pleasant consequences: for example, it implies that if $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ is a morphism of quasi-compact, quasi-separated spectral algebraic spaces, then the pushforward functor $f_* : \mathrm{Mod}_{\mathcal{O}_{\mathcal{X}}} \to \mathrm{Mod}_{\mathcal{O}_{\mathcal{Y}}}$ preserves quasi-coherence (Corollary 3.4.2.2).

Our proof of Theorem 3.4.2.1 will require a long detour through some of the fundamentals of spectral algebraic geometry. We begin in §3.1 by introducing the notion of a *closed immersion* between spectral Deligne-Mumford stacks (Definition 3.1.0.1). We will say that a spectral algebraic space X is *separated* if the diagonal map $\mathsf{X} \to \mathsf{X} \times \mathsf{X}$ is a closed immersion. In §3.2, we prove a slightly weaker version of Theorem 3.4.2.1: every quasi-compact, separated spectral algebraic space admits a scallop decomposition (Proposition 3.2.3.1). As a consequence, we will see that for any morphism between quasi-compact, separated spectral algebraic spaces $f : \mathsf{X} \to \mathsf{Y}$, there is a well-behaved pushforward operation f_* on quasi-coherent sheaves (Corollary 3.2.3.3). We will apply this result in §3.3 to develop a theory of quasi-finite morphisms between spectral Deligne-Mumford stacks. In particular, we will prove the following version of Zariski's Main Theorem: if $f : \mathsf{X} \to \mathsf{Y}$ is quasi-compact, separated, and locally quasi-finite, then f is quasi-affine (Theorem 3.3.0.2). We will apply this result in §3.4 to prove the existence of scallop decompositions for arbitrary quasi-compact, quasi-separated spectral algebraic spaces, and describe some applicatoins.

In §3.6, we study the underlying topological space $|\mathsf{X}|$ of a spectral Deligne-Mumford stack $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$. We define $|\mathsf{X}|$ to be the space of points of the locale underlying the ∞-topos $\mathcal{X}$. More or less by definition, we can identify open subsets of $|\mathsf{X}|$ with open substacks of X. However, it is not immediately clear how to describe the *points* of X. In the special case where X is a quasi-separated spectral algebraic space, we will use Theorem 3.4.2.1 to show that there is a bijection between points of $|\mathsf{X}|$ and (equivalence classes of) *geometric points* of X: that is, maps $\iota : \text{Spét}\, \kappa \to \mathsf{X}$, where κ is a separably closed field. The latter are closely related to points of the underlying ∞-topos $\mathcal{X}$, which we study in §3.5.

The topology on the space $|\mathsf{X}|$ can be regarded as an analogue of the Zariski topology in the setting of spectral algebraic spaces. There is a version of the Nisnevich topology as well, which we will discuss in §3.7. In particular, we prove that the class of Nisnevich sheaves can be characterized by an excision property, just as with ordinary schemes (Theorem 3.7.5.1).

Contents

3.1 Closed Immersions

Let $f : X \to Y$ be a morphism of schemes. Recall that f is said to be a *closed immersion* if it induces a homeomorphism from the underlying topological space of X to a closed subset of the underlying topological space of Y, and an epimorphism of structure sheaves $f^{-1}\mathscr{O}_Y \to \mathscr{O}_X$. In this section, we will develop an analogous theory of closed immersions in the setting of spectral algebraic geometry.

Definition 3.1.0.1. Let $f : (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ be a morphism of spectrally ringed ∞-topoi. We will say that f is a *closed immersion* if the following conditions are satisfied:

(*a*) The underlying geometric morphism $f_* : \mathcal{X} \to \mathcal{Y}$ is a closed immersion of ∞-topoi. That is, f_* induces an equivalence $\mathcal{X} \to \mathcal{Y}/U$, for some (-1)-truncated object $U \in \mathcal{Y}$ (see Notation **??**).

(*b*) The structure sheaves $\mathscr{O}_{\mathcal{X}}$ and $\mathscr{O}_{\mathcal{Y}}$ are connective.

(*c*) Let $f^{-1} : \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{Y}) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$ denote the left adjoint of the pushforward functor f_*. Then the underlying map $f^{-1}\mathscr{O}_{\mathcal{Y}} \to \mathscr{O}_{\mathcal{X}}$ has a connective fiber. In other words, the induced map $f^{-1}\pi_0\mathscr{O}_{\mathcal{Y}} \to \pi_0\mathscr{O}_{\mathcal{X}}$ is an epimorphism (in the abelian category of abelian group objects of $\mathcal{X}^{\heartsuit}$).

3.1.1 Classification of Closed Immersions

In the setting of *locally* spectrally ringed ∞-topoi, closed immersions having a fixed codomain admit a reasonably simple description.

Proposition 3.1.1.1. *Let $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a locally spectrally ringed ∞-topos. Assume that the structure sheaf $\mathcal{O}_{\mathcal{X}}$ is connective and let $\alpha : \mathcal{O}_{\mathcal{X}} \to \mathcal{O}'$ be a morphism of connective sheaves of $\mathbb{E}_\infty$-rings on $\mathcal{X}$ which induces an epimorphism $\pi_0 \mathcal{O}_{\mathcal{X}} \to \pi_0 \mathcal{O}'$. Then there exists a closed immersion $f : (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ and an equivalence $\beta : \mathcal{O}' \simeq f_* \mathcal{O}_{\mathcal{Y}}$ in $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})_{\mathcal{O}_{\mathcal{X}}/}$ with the following universal property: for every morphism of locally spectrally ringed ∞-topos $h : (\mathcal{Z}, \mathcal{O}_{\mathcal{Z}}) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$, composition with β induces a homotopy equivalence*

$$\begin{aligned}\mathrm{Map}_{(\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}})_{/(\mathcal{X},\mathcal{O}_{\mathcal{X}})}}((\mathcal{Z}, \mathcal{O}_{\mathcal{Z}}), (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})) &\to \mathrm{Map}_{(\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}})_{/(\mathcal{X},\mathcal{O}_{\mathcal{X}})}}((\mathcal{Z}, \mathcal{O}_{\mathcal{Z}}), (\mathcal{X}, \mathcal{O}'))\\ &\simeq \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})_{\mathcal{O}_{\mathcal{X}}/}}(\mathcal{O}', h_* \mathcal{O}_{\mathcal{Z}}).\end{aligned}$$

Proof. Let U denote the (-1)-truncated object of $\mathcal{X}$ given by $\mathbf{1} \times_{\pi_0 \mathcal{O}'} (\pi_0 \mathcal{O}')^\times$ (see Remark 1.2.1.6), let $f_* : \mathcal{Y} \to \mathcal{X}$ be the closed immersion of ∞-topoi complementary to U (so that $\mathcal{Y}$ can be identified with the full subcategory $\mathcal{X}/U \subseteq \mathcal{X}$ spanned by those objects X for which $U \times X$ is initial in $\mathcal{X}$), and let $\mathcal{O}_{\mathcal{Y}} = f^* \mathcal{O}'$. Since the restriction $\mathcal{O}'|_U$ vanishes, the unit map $\beta : \mathcal{O}' \to f_* \mathcal{O}_{\mathcal{Y}}$ is an equivalence. It follows from Proposition 1.2.1.8 that the spectrally ringed ∞-topos $(\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ is local.

Note that if $h : (\mathcal{Z}, \mathcal{O}_{\mathcal{Z}}) \to (\mathcal{X}, \mathcal{O}')$ is any morphism of spectrally ringed ∞-topoi, the pullback h^*U admits a morphism to the fiber product $V = \mathbf{1} \times_{\pi_0 \mathcal{O}_{\mathcal{Z}}} (\pi_0 \mathcal{O}_{\mathcal{Z}})^\times$ in the ∞-topos $\mathcal{Z}$. If $\mathcal{O}_{\mathcal{Z}}$ is local, then V is initial in $\mathcal{Z}$, so that U is also initial in $\mathcal{Z}$ so that the underlying map of ∞-topoi $h_* : \mathcal{Z} \to \mathcal{X}$ must factor as a composition $\mathcal{Z} \xrightarrow{g_*} \mathcal{Y} \xrightarrow{f_*} \mathcal{X}$. In this case, we can promote g_* to a morphism of spectrally ringed ∞-topoi $g : (\mathcal{Z}, \mathcal{O}_{\mathcal{Z}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$. To complete the proof, it will suffice to show that g is local if and only if h is local, which is an immediate consequence of Remark 1.2.1.7. □

Remark 3.1.1.2. Let $h : (\mathcal{Y}, \mathcal{O}_{\mathcal{Z}}) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be an arbitrary closed immersion in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$. Then the induced map $\mathcal{O}_{\mathcal{X}} \to h_* \mathcal{O}_{\mathcal{Z}}$ induces an epimorphism $\alpha : \pi_0 \mathcal{O}_{\mathcal{X}} \to \pi_0 h_* \mathcal{O}_{\mathcal{Z}}$. Let $f : (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be the closed immersion obtained by applying Proposition 3.1.1.1 to α. The universal property of f guarantees that h factors as a composition $(\mathcal{Z}, \mathcal{O}_{\mathcal{Z}}) \xrightarrow{g} (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) \xrightarrow{f} (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$. A simple calculation shows that g is an equivalence. It follows that every closed immersion $h : (\mathcal{Y}, \mathcal{O}_{\mathcal{Z}}) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ can be obtained using the construction of Proposition 3.1.1.1.

Corollary 3.1.1.3. *Let $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a locally spectrally ringed ∞-topos where $\mathcal{O}_{\mathcal{X}}$ is connective. Let $\mathcal{C} \subseteq (\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}})_{/(\mathcal{X},\mathcal{O}_{\mathcal{X}})}$ denote the subcategory spanned by those maps f :*

$(\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ which are closed immersions. Then the construction

$$(f : (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}})) \mapsto f_* \mathcal{O}_{\mathcal{Y}}$$

determines a fully faithful embedding $\theta : \mathcal{C}^{\mathrm{op}} \to \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})_{\mathcal{O}_{\mathcal{X}}/}$. Moreover, the essential image of θ is the full subcategory $\mathcal{C}' \subseteq \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})_{\mathcal{O}_{\mathcal{X}}/}$ spanned by those maps $\alpha : \mathcal{O}_{\mathcal{X}} \to \mathcal{O}'$ where $\mathcal{O}'$ is connective and $\mathrm{fib}(\alpha)$ *is connective.*

Proof. It follows from Proposition 3.1.1.1 that the functor $\theta : \mathcal{C}^{\mathrm{op}} \to \mathcal{C}'$ is essentially surjective. To prove that it is fully faithful, suppose we are given closed immersions

$$f : (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \qquad g : (\mathcal{Z}, \mathcal{O}_{\mathcal{Z}}) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$$

in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$; we wish to show that θ induces a homotopy equivalence

$$\rho : \mathrm{Map}_{(\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}})_{/(\mathcal{X}, \mathcal{O}_{\mathcal{X}})}}((\mathcal{Z}, \mathcal{O}_{\mathcal{Z}}), (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})) \to \mathrm{Map}_{\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})_{\mathcal{O}_{\mathcal{X}}/}}(f_* \mathcal{O}_{\mathcal{Y}}, g_* \mathcal{O}_{\mathcal{Z}}).$$

To prove this, it suffices to show that the closed immersion f enjoys the universal property described in Proposition 3.1.1.1, which follows from Remark 3.1.1.2. □

Remark 3.1.1.4. Let $f : (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) \to (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a closed immersion in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$. If $\mathcal{O}_{\mathcal{X}}$ is strictly Henselian, then $\mathcal{O}_{\mathcal{Y}}$ is strictly Henselian (this follows immediately from Proposition 1.2.2.14).

3.1.2 Closed Immersions of Spectral Deligne-Mumford Stacks

Let R be a commutative ring. Then the construction $I \mapsto \mathrm{Spec}\, R/I$ induces a bijective correspondence between ideals $I \subseteq R$ and closed subschemes of the affine scheme $\mathrm{Spec}\, R$. Our main goal in this section is to establish an analogous correspondence in the setting of spectral algebraic geometry:

Theorem 3.1.2.1. *Let A be a connective $\mathbb{E}_\infty$-ring and let $f : (\mathcal{X}, \mathcal{O}) \to \mathrm{Sp\acute{e}t}\, A$ be a map of spectral Deligne-Mumford stacks. The following conditions are equivalent:*

(1) *The map f is a closed immersion.*

(2) *The spectral Deligne-Mumford stack $(\mathcal{X}, \mathcal{O})$ is affine and the canonical map $A \to \Gamma(\mathcal{X}; \mathcal{O})$ induces a surjection of commutative rings $\pi_0 A \to \pi_0 \Gamma(\mathcal{X}; \mathcal{O})$.*

Remark 3.1.2.2. The condition that a morphism $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks be a closed immersion is local on the target with respect to the étale topology (see Definition 6.3.1.1). Together with Theorem 3.1.2.1, this observation completely determines the class of closed immersions between spectral Deligne-Mumford stacks.

Before giving the proof of Theorem 3.1.2.1, let us describe some of its consequences.

Corollary 3.1.2.3. *Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y}. \end{array}$$

If f is a closed immersion, so is f'.

Proof. The assertion is local on Y and Y'. We may therefore assume without loss of generality that $\mathsf{Y} \simeq \operatorname{Spét} A$ is affine, so that Theorem 3.1.2.1 implies that X has the form $\operatorname{Spét} B$ for some connective $\mathbb{E}_\infty$-ring A' for which the map $\phi : A \to B$ is 0-connective. Similarly, we may assume that $\mathsf{Y}' \simeq \operatorname{Spét} A'$ for some connective $\mathbb{E}_\infty$-ring A'. According to Theorem 3.1.2.1, it will suffice to show that the map $\phi' : A' \to B \otimes_A A'$ is connective. This is clear, since $\operatorname{fib}(\phi') \simeq \operatorname{fib}(\phi) \otimes_A A'$. □

Corollary 3.1.2.4. *Suppose we are given a commutative diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccccc} \mathsf{X} & & \xrightarrow{f} & & \mathsf{Y} \\ & {\scriptstyle h}\searrow & & \swarrow{\scriptstyle g} & \\ & & \mathsf{Z}. & & \end{array}$$

If g is a closed immersion, then f is a closed immersion if and only if h is a closed immersion.

Proof. The assertion is local on Z. We may therefore assume without loss of generality that $\mathsf{Z} \simeq \operatorname{Spét} C$ for some connective $\mathbb{E}_\infty$-ring C. It follows from Theorem 3.1.2.1 that $\mathsf{Y} \simeq \operatorname{Spét} B$ is affine, and that the map $\pi_0 C \to \pi_0 B$ is surjective. Theorem 3.1.2.1 also implies that if either f or h is a closed immersion, then X has the form $\operatorname{Spét} A$, for some connective $\mathbb{E}_\infty$-ring A. The desired result now follows from the observation that a map $\pi_0 B \to \pi_0 A$ is surjective if and only if the composite map $\pi_0 C \to \pi_0 B \to \pi_0 A$ is surjective. □

Remark 3.1.2.5. Corollaries 3.1.2.3 and 3.1.2.4 are true in the more general setting of spectrally ringed ∞-topoi. See Corollary **??** and Remark **??**.

Warning 3.1.2.6. In the setting of classical algebraic geometry, every closed immersion is a monomorphism. The analogous statement is not true in spectral algebraic geometry. If $f : \mathsf{Y} \to \mathsf{X}$ is a closed immersion of spectral Deligne-Mumford stacks and R is a connective $\mathbb{E}_\infty$-ring, then it is generally not true that the induced map

$$\theta : \operatorname{Map}_{\mathrm{SpDM}}(\operatorname{Spét} R, \mathsf{Y}) \to \operatorname{Map}_{\mathrm{SpDM}}(\operatorname{Spét} R, \mathsf{X})$$

is the inclusion of a summand. However, this *is* true in the special case where R is discrete. To prove this, fix a map $\eta : \mathrm{Sp\acute{e}t}\, R \to \mathsf{X}$ and apply Theorem 3.1.2.1 to write the fiber product $\mathrm{Sp\acute{e}t}\, R \times_{\mathsf{X}} \mathsf{Y}$ can be written as $\mathrm{Sp\acute{e}t}\, A$, where A is an $\mathbb{E}_\infty$-algebra over R for which the map $\phi : R \to \pi_0 A$ is surjective. It follows that the fiber product

$$\mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{Y}) \times_{\mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, X, \mathsf{X})} \{\eta\}$$

is either empty (if $\ker(\phi) \neq 0$) or contractible (if $\ker(\phi) \simeq 0$).

Remark 3.1.2.7. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack, and suppose we are given a closed immersion $f : (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}) \to (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ in the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ of locally spectrally ringed ∞-topoi. The following conditions are equivalent:

(1) The spectrally ringed ∞-topos $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ is a spectral Deligne-Mumford stack.

(2) The direct image $f_* \mathscr{O}_{\mathcal{Y}}$ is quasi-coherent as an $\mathscr{O}_{\mathcal{X}}$-module.

To prove this, we may assume that $\mathsf{X} = \mathrm{Sp\acute{e}t}\, A$ is affine. If condition (1) is satisfied, then Theorem 3.1.2.1 guarantees that $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}) \simeq \mathrm{Sp\acute{e}t}\, B$ for some connective $\mathbb{E}_\infty$-algebra A over B, in which case the direct image $f_* \mathscr{O}_{\mathcal{Y}}$ can be identified with the quasi-coherent sheaf associated to the A-module B. Conversely, suppose that (2) is satisfied. Then $f_* \mathscr{O}_{\mathcal{Y}}$ can be regarded as a commutative algebra object of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \simeq \mathrm{Mod}_A^{\mathrm{cn}}$ which we can identify with a connective A-algebra B for which the map $\pi_0 A \to \pi_0 B$ is surjective. It then follows from Corollary 3.1.1.3 that $(\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ is equivalent to the affine spectral Deligne-Mumford stack $\mathrm{Sp\acute{e}t}\, B$.

3.1.3 Closed Immersion of ∞-Topoi

The proof of Theorem 3.1.2.1 will require a number of preliminaries. We begin by with general remarks about the topological properties of closed immersions.

Lemma 3.1.3.1. *Let $\mathcal{X}$ be an ∞-topos and let $f_* : \mathcal{Y} \to \mathcal{X}$ be a closed immersion of ∞-topoi. If $\mathcal{X}$ is n-coherent (for some $n \geqslant 0$), then $\mathcal{Y}$ is n-coherent.*

Proof. The proof proceeds by induction on n. In the case $n = 0$, we must show that if $\mathcal{X}$ is quasi-compact then $\mathcal{Y}$ is also quasi-compact. Assume that $\mathcal{X}$ is quasi-compact and choose an effective epimorphism $\theta : \coprod_{i \in I} Y_i \to \mathbf{1}$ in $\mathcal{Y}$, where $\mathbf{1}$ denotes the final object of $\mathcal{Y}$. We wish to show that there exists a finite subset $I_0 \subseteq I$ such that the induced map $\coprod_{i \in I_0} Y_i \to \mathbf{1}$ is an effective epimorphism. If I is empty, we can take $I_0 = I$. Otherwise, we can use Lemma 3.1.3.2 (since f_* is a closed immersion) to see that the induced map $\coprod_{i \in I} f_*(Y_i) \to f_* \mathbf{1}$ is effective epimorphism in $\mathcal{X}$. Since $\mathcal{X}$ is quasi-compact, there exists a finite subset $I_0 \subseteq I$ such that the map $\coprod_{i \in I_0} f_*(Y_i) \to f_* \mathbf{1}$ is an effective epimorphism, so that $\coprod_{i \in I_0} Y_i \to \mathbf{1}$ is an effective epimorphism in $\mathcal{Y}$.

Now suppose that $n > 0$. The inductive hypothesis guarantees that the pullback functor f^* carries $(n-1)$-coherent objects of $\mathcal{X}$ to $(n-1)$-coherent objects of $\mathcal{Y}$. Assume that $\mathcal{X}$ is $(n-1)$-coherent. Let $\mathcal{Y}_0 \subseteq \mathcal{Y}$ be the collection of all objects of the form f^*X, where $X \in \mathcal{X}$ is $(n-1)$-coherent. Then $\mathcal{Y}_0$ is stable under products in $\mathcal{Y}$ and every object $Y \in \mathcal{Y}$ admits an effective epimorphism $\amalg Y_i \to Y$, where each $Y_i \in \mathcal{Y}_0$. Applying Corollary A.2.1.4, we deduce that $\mathcal{Y}$ is n-coherent. □

Lemma 3.1.3.2. *Let $\mathcal{X}$ be an ∞-topos containing a (-1)-truncated object U, and let $i^* : \mathcal{X} \to \mathcal{X}/U$ and $j^* : \mathcal{X} \to \mathcal{X}_{/U}$ be the associated geometric morphisms. Suppose we are given a family of morphisms $\{\alpha_i : X_i \to X\}$ in $\mathcal{X}$. Then the composite map $\amalg X_i \to X$ is an effective epimorphism if and only if the corresponding maps*

$$\amalg i^* X_i \to f^* X \qquad \amalg\, j^* X_i \to g^* X$$

are effective epimorphisms in $\mathcal{X}/U$ and $\mathcal{X}_{/U}$, respectively.

Proof. Since i^* and j^* commute with coproducts, we can replace the family $\{X_i \to X\}$ by the single map $\alpha : X_0 \to X$, where $X_0 = \amalg_i X_i$. Let $X_\bullet$ be the Čech nerve of α and let X' be its geometric realization. Then α is an effective epimorphism if and only if it induces an equivalence $\beta : X' \to X$. Similarly, $f^*(\alpha)$ and $g^*(\alpha)$ are effective epimorphisms if and only if $i^*(\beta)$ and $j^*(\beta)$ are equivalences. The desired result now follows from Lemma HA.A.5.11 . □

Lemma 3.1.3.3. *Let $f_* : \mathcal{Y} \to \mathcal{X}$ be a closed immersion of ∞-topoi. Then:*

(1) *The functor f_* carries n-connective objects of $\mathcal{Y}$ to n-connective objects of $\mathcal{X}$.*

(2) *The functor f_* carries n-connective morphisms of $\mathcal{Y}$ to n-connective morphisms of $\mathcal{X}$.*

(3) *The functor f_* induces a left t-exact pushforward functor $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{Y}) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X})$.*

Proof. Since f_* carries final objects of $\mathcal{Y}$ to final objects of $\mathcal{X}$, assertion (1) follows from (2). Assertion (3) is an immediate consequence of (1). It will therefore suffice to prove (2). We proceed by induction on n: when $n = 0$, the desired result follows from Lemma 3.1.3.2. Assume that $n > 0$, and let $u : X \to Y$ be an n-connective morphism in $\mathcal{Y}$. We wish to show that $f_*(u)$ is n-connective. We have already seen that $f_*(u)$ is an effective epimorphism; it will therefore suffice to show that the diagonal map $f_*(X) \to f_*(X) \times_{f_*(Y)} f_*(X)$ is $(n-1)$-connective. This follows from the inductive hypothesis, since the diagonal map $X \to X \times_Y X$ is $(n-1)$-connective. □

Lemma 3.1.3.4. *Suppose we are given a commutative diagram*

$$\begin{array}{ccc} \mathcal{X} & \xrightarrow{f_*} & \mathcal{Y} \\ & {\scriptstyle h_*}\searrow \quad \swarrow{\scriptstyle g_*} & \\ & \mathcal{Z} & \end{array}$$

in $\mathcal{T}\mathrm{op}_\infty$*, where* g_* *and* h_* *are closed immersions of* ∞*-topoi. Then* f_* *is a closed immersion of* ∞*-topoi.*

Proof. Without loss of generality, we may assume that $\mathcal{X} = \mathcal{Z}_{/U}$ and $\mathcal{Y} = \mathcal{Z}_{/V}$ for some (-1)-truncated objects $U, V \in \mathcal{Z}$. The commutativity of the diagram implies $\mathcal{Z}_{/U} \subseteq \mathcal{Z}_{/V}$. An object $Z \in \mathcal{Z}$ belongs to $\mathcal{Z}_{/U}$ if and only if the projection map $p : Z \times U \to U$ is an equivalence. Using Lemma HA.A.5.11 , we see that this is equivalent to the assertion that $Z \in \mathcal{Y}_{/V}$ and that $g^*(p)$ is an equivalence. Thus f_* induces an equivalence from $\mathcal{X}$ to $\mathcal{Y}_{/g^*U}$ and is therefore a closed immersion. □

Lemma 3.1.3.5. *Let* $\mathcal{X}$ *be an* n*-localic* ∞*-topos. Then any closed subtopos of* $\mathcal{X}$ *is also* n*-localic.*

Proof. Any closed subtopos of $\mathcal{X}$ is a topological localization of $\mathcal{X}$ (Proposition HTT.7.3.2.3) and therefore n-localic by virtue of Proposition HTT.6.4.5.9 . □

3.1.4 The Proof of Theorem 3.1.2.1

We will deduce Theorem 3.1.2.1 from the following slightly weaker assertion:

Proposition 3.1.4.1. *Let* $\phi : A \to B$ *be a map of connective* $\mathbb{E}_\infty$*-rings which induces a surjection* $\pi_0 A \to \pi_0 B$*. Then the corresponding map* $f : \mathrm{Sp\acute{e}t}\, B \to \mathrm{Sp\acute{e}t}\, A$ *induces a closed immersion of the underlying* ∞*-topoi.*

Remark 3.1.4.2. Proposition 3.1.4.1 is essentially a theorem of commutative algebra: it follows from (and implies) the statement that a surjection of commutative rings induces a closed immersion of their étale topoi.

Proof of Proposition 3.1.4.1. Using Proposition 1.4.2.4, we can identify the underlying ∞-topoi of $\mathrm{Sp\acute{e}t}\, A$ and $\mathrm{Spec}^{\acute{e}t B}$ with $\mathcal{S}\mathrm{hv}^{\acute{e}t}_A \subseteq \mathrm{Fun}(\mathrm{CAlg}^{\acute{e}t}_A, \mathcal{S})$ and $\mathcal{S}\mathrm{hv}^{\acute{e}t}_B \subseteq \mathrm{Fun}(\mathrm{CAlg}^{\acute{e}t}_B, \mathcal{S})$, respectively. Under these identifications, the functor f_* is given by composition with the extension-of-scalars functor

$$\mathrm{CAlg}^{\acute{e}t}_A \to \mathrm{CAlg}^{\acute{e}t}_B \qquad A' \mapsto A' \otimes_A B.$$

Let $U \in \mathrm{CAlg}_A^{\text{ét}} \to \mathcal{S}$ be the functor described by the formula

$$U(A') = \begin{cases} \Delta^0 & \text{if } A' \otimes_A B \simeq 0 \\ \varnothing & \text{otherwise.} \end{cases}$$

Then U is a (-1)-truncated object of $\mathcal{S}\mathrm{hv}_A^{\text{ét}}$, and the pushforward functor f_* carries the ∞-category $\mathcal{S}\mathrm{hv}_B^{\text{ét}}$ into the full subcategory $\mathcal{S}\mathrm{hv}_A^{\text{ét}}/U \subseteq \mathcal{S}\mathrm{hv}_A^{\text{ét}}$. We will complete the proof by showing that the adjoint functors

$$\mathcal{S}\mathrm{hv}_A^{\text{ét}}/U \underset{f_*}{\overset{f^*}{\rightleftarrows}} \mathcal{S}\mathrm{hv}_B^{\text{ét}}$$

are mutually inverse equivalences of ∞-categories. Note that $\mathrm{CAlg}_A^{\text{ét}}$ and $\mathrm{CAlg}_B^{\text{ét}}$ are equivalent to the nerves of ordinary categories, by Theorem HA.7.5.0.6 . It follows that $\mathcal{S}\mathrm{hv}_A^{\text{ét}}$ and $\mathcal{S}\mathrm{hv}_B^{\text{ét}}$ are 1-localic ∞-topoi. Using Lemma 3.1.3.5, we conclude that $\mathcal{S}\mathrm{hv}_A^{\text{ét}}/U$ is also a 1-localic ∞-topos. Consequently, it will suffice to show that the adjoint functors (f^*, f_*) induce mutually inverse equivalences when restricted to discrete objects of $\mathcal{S}\mathrm{hv}_A^{\text{ét}}/U$ and $\mathcal{S}\mathrm{hv}_B^{\text{ét}}$.

We begin by showing that the functor f_* is conservative. Let $\alpha : \mathscr{F} \to \mathscr{F}'$ be a morphism in $\mathcal{S}\mathrm{hv}_B^{\text{ét}}$ such that $f_*(\alpha)$ is an equivalence. We will show that α induces an equivalence $\mathscr{F}(B') \to \mathscr{F}'(B')$ for every étale B-algebra B'. Using Proposition B.1.1.3, we deduce the existence of a pushout diagram

$$\begin{array}{ccc} A\{x_1, \ldots, x_m\} & \xrightarrow{g} & B \\ \downarrow & & \downarrow \\ A\{y_1, \ldots, y_m\}[\Delta^{-1}] & \longrightarrow & B', \end{array}$$

where the left vertical map carries each x_i to some polynomial $f_i(y_1, \ldots, y_m) \in \pi_0 A\{y_1, \ldots, y_m\}$ and $\Delta \in \pi_0 A\{y_1, \ldots, y_m\}$ denotes the determinant of the Jacobian matrix $[\frac{\partial f_i}{\partial y_j}]_{1 \leqslant i,j \leqslant m}$. Since the map $A \to B$ is surjective on π_0, the map g factors through A. Set $A' = A \otimes_{A\{x_1,\ldots,x_m\}} A\{y_1, \ldots, y_m\}[\Delta^{-1}]$. Then A' is an étale A-algebra. Since $f_*(\alpha)$ is an equivalence, we deduce that the natural map

$$\mathscr{F}(B') \simeq (f_* \mathscr{F})(A') \to (f_* \mathscr{F}')(A') \simeq \mathscr{F}'(B')$$

is an equivalence, as desired.

To complete the proof, it will suffice to show that if $\mathscr{F}$ is a discrete object of $\mathcal{S}\mathrm{hv}_A^{\text{ét}})/U$, then the unit map $u : \mathscr{F} \to f_* f^* \mathscr{F}$ is an equivalence. Since both $\mathscr{F}$ and $f_* f^* \mathscr{F}$ are discrete objects of $\mathcal{S}\mathrm{hv}_A^{\text{ét}}$, they are hypercomplete: it will therefore suffice to show that the map u is ∞-connective. According to Theorem A.4.0.5, the ∞-topos $(\mathcal{S}\mathrm{hv}_A^{\text{ét}})^{\mathrm{hyp}}$ has enough points. It will therefore suffice to show that for every geometric morphism $\eta^* : \mathcal{S}\mathrm{hv}_A^{\text{ét}} \to \mathcal{S}$, the map $\eta^*(u)$ is a homotopy equivalence.

According to Corollary 3.5.2.2, the geometric morphism η^* corresponds to a strictly Henselian A-algebra A' which can be written as a filtered colimit $\varinjlim A'_\alpha$, where each A'_α is étale over A. More precisely, the functor η^* is given by the formula $\eta^* \mathscr{G} \simeq \varinjlim \mathscr{G}(A'_\alpha)$. There are two cases to consider:

(1) Suppose that $A' \otimes_A B \simeq 0$. Then $1 = 0$ in $\pi_0(A' \otimes_A B) \simeq \varinjlim \pi_0(A'_\alpha \otimes_A B)$, so that $A'_\alpha \otimes_A B \simeq 0$ for some α. Reindexing our diagram, we may suppose that $A'_\alpha \otimes_A B \simeq 0$ for all α. Thus $\eta^* \mathscr{G} \simeq \varinjlim \mathscr{G}(A'_\alpha)$ is contractible whenever $\mathscr{G} \in \mathcal{S}\mathrm{hv}^{\text{ét}}_A /U$. In particular, $\eta^*(u)$ is a map between contractible spaces and therefore a homotopy equivalence.

(2) The tensor product $A' \otimes_A B \neq 0$. Note that $A' \otimes_A B \simeq \varinjlim A'_\alpha \otimes_A B$ is a filtered colimit of étale B-algebras. The map $A' \to A' \otimes_A B$ induces a surjection $\pi_0 A' \to \pi_0(A' \otimes_A B)$. It follows from Corollary B.3.3.2 that $A' \otimes_A B$ is strictly Henselian, and therefore determines a map $\eta'^* : \mathcal{S}\mathrm{hv}^{\text{ét}}_B \to \mathcal{S}$. Moreover, the composite map $(\mathcal{S}\mathrm{hv}(*), A' \otimes_A B) \to (\mathcal{S}\mathrm{hv}(*), A') \to \mathrm{Spét}\, A$ determines the same point of the ∞-topos $\mathcal{S}\mathrm{hv}^{\text{ét}}_A$; it follows that $\eta^* \simeq \eta'^* \circ f^*$. We therefore have a chain of equivalences

$$\begin{aligned} \eta^*(f_* f^* \mathscr{F}) &\simeq \varinjlim (f_* f^* \mathscr{F})(A'_\alpha) \\ &\simeq \varinjlim (f^* \mathscr{F})(A'_\alpha \otimes_A B) \\ &\simeq \eta'^* f^* \mathscr{F} \\ &\simeq \eta^* \mathscr{F} \end{aligned}$$

whose composition is a homotopy inverse to $\eta^*(u)$.

□

Lemma 3.1.4.3. *Let $f : (\mathcal{X}, \mathcal{O}_\mathcal{X}) \to (\mathcal{Y}, \mathcal{O}_\mathcal{Y})$ be a map of spectral Deligne-Mumford stacks, and assume that the underlying geometric morphism $\mathcal{X} \to \mathcal{Y}$ is a closed immersion in $\mathcal{T}\mathrm{op}_\infty$. Then the pushforward functor $f_* : \mathrm{Mod}_{\mathcal{O}_\mathcal{X}} \to \mathrm{Mod}_{\mathcal{O}_\mathcal{Y}}$ carries quasi-coherent sheaves to quasi-coherent sheaves.*

Proof. Note that f_* is left t-exact and commutes with small limits. It follows that if $\mathscr{F} \in \mathrm{Mod}_{\mathcal{O}_\mathcal{X}}$ is quasi-coherent, then

$$f_* \mathscr{F} \simeq f_* \varprojlim (\tau_{\leqslant n} \mathscr{F}) \simeq \varprojlim f_* \tau_{\leqslant n} \mathscr{F}$$

is the limit of a tower of truncated objects of $\mathrm{Mod}_{\mathcal{O}_\mathcal{X}}$, and therefore hypercomplete. According to Proposition 2.2.6.1, it will suffice to show that each homotopy group $\pi_n f_* \mathscr{F}$ is quasi-coherent. Since f_* is right t-exact (Lemma 3.1.3.3), we can replace $\mathscr{F}$ by $\tau_{\leqslant n} \mathscr{F}$. The desired result now follows from Corollary **??**, since Lemma 3.1.3.1 implies that f is k-quasi-separated for every integer $k \geqslant 0$. □

Proof of Theorem 3.1.2.1. We must prove two things:

(1) If $\phi : A \to B$ is a morphism of connective $\mathbb{E}_\infty$-rings which induces a surjective ring homomorphism $\pi_0 A \to \pi_0 B$, then the induced map $\operatorname{Sp\acute{e}t} B \to \operatorname{Sp\acute{e}t} A$ is a closed immersion of spectral Deligne-Mumford stacks.

(2) Every closed immersion $(\mathcal{X}, \mathcal{O}) \to \operatorname{Sp\acute{e}t} A$ arises in this way.

We first prove (1). For every connective $\mathbb{E}_\infty$-ring R, let $\operatorname{Sp\acute{e}t} R = (\mathcal{X}_R, \mathcal{O}_R)$. It follows from Proposition 3.1.4.1 that if $\phi : A \to B$ induces a surjection $\pi_0 A \to \pi_0 B$, then the corresponding map $f : (\mathcal{X}_B, \mathcal{O}_B) \to (\mathcal{X}_A, \mathcal{O}_A)$ induces a closed immersion of ∞-topoi $\mathcal{X}_B \to \mathcal{X}_A$. It remains to show that the map $f^{-1} \mathcal{O}_A \to \mathcal{O}_B$ has a connective fiber. Since f_* is a closed immersion, it suffices to show that the adjoint map $\mathcal{O}_A \simeq f_* f^{-1} \mathcal{O}_A \to f_* \mathcal{O}_B$ has a connective fiber. It follows from Lemma 3.1.4.3 that $f_* \mathcal{O}_B$ is a quasi-coherent sheaf on $(\mathcal{X}_A, \mathcal{O}_A)$. Since the equivalence $\operatorname{QCoh}(\mathcal{X}_A) \simeq \operatorname{Mod}_A$ is t-exact, it suffices to show that the map

$$A \simeq \Gamma(\mathcal{X}_A; \mathcal{O}_A) \to \Gamma(\mathcal{X}_A; f_* \mathcal{O}_B) \simeq \Gamma(\mathcal{X}_B; \mathcal{O}_B) \simeq B$$

has a connective fiber, which follows from our assumption on ϕ.

We now prove (2). Suppose we are given a closed immersion of spectral Deligne-Mumford stacks $f : (\mathcal{X}, \mathcal{O}) \to (\mathcal{X}_A, \mathcal{O}_A)$. Let $B = \Gamma(\mathcal{X}; \mathcal{O}) \simeq \Gamma(\mathcal{X}_A; f_* \mathcal{O})$. Using Lemmas 3.1.3.3 and 3.1.4.3, we deduce that $f_* \mathcal{O}$ is a connective quasi-coherent sheaf on $(\mathcal{X}_A, \mathcal{O}_A)$, so that B is a connective A-algebra. Moreover, since f is a closed immersion, the map $f^* \mathcal{O}_A \to \mathcal{O}$ is an epimorphism on π_0. Since f is a closed immersion, the adjoint map $\mathcal{O}_A \simeq f_* f^* \mathcal{O}_A \to f_* \mathcal{O}$ is a map of quasi-coherent sheaves with connective fiber. Since the equivalence $\operatorname{Mod}_A \simeq \operatorname{QCoh}(\mathcal{X}_A)$ is t-exact, we conclude that the map $A \to B$ is surjective on π_0. The universal property of $\operatorname{Sp\acute{e}t} B$ gives a commutative diagram

$$\begin{array}{ccc} (\mathcal{X}, \mathcal{O}) & \xrightarrow{f'} & \operatorname{Sp\acute{e}t} B \\ & {\scriptstyle f} \searrow \quad \swarrow {\scriptstyle f''} & \\ & \operatorname{Sp\acute{e}t} A. & \end{array}$$

Part (1) shows that f'' is a closed immersion of spectral Deligne-Mumford stacks. Using Lemma 3.1.3.4, we see that f' induces a closed immersion of ∞-topoi $\mathcal{X} \to \mathcal{X}_B$. Moreover, f' induces a map of quasi-coherent sheaves $\mathcal{O}_B \to f'_* \mathcal{O}$ which induces an equivalence on global sections; it follows that $\mathcal{O}_B \simeq f'_* \mathcal{O}$. We will complete the proof by showing that f' induces an equivalence of ∞-topoi $\mathcal{X} \simeq \mathcal{X}_B$. We have an equivalence $\mathcal{X} \simeq \mathcal{X}_B / U$ for some (-1)-truncated object $U \in \mathcal{X}_B$; we wish to show that U is an initial object of $\mathcal{X}_B$. The proof of Proposition 1.4.2.4 shows that we can identify $\mathcal{X}_B$ with the ∞-topos $\mathcal{S}\mathrm{hv}_B^{\acute{e}t}$. If U is not an initial object, then $U(B')$ is nonempty for some nonzero étale B-algebra B'. The equivalences $B' \simeq \mathcal{O}_B(B') \simeq (f'_* \mathcal{O})(B') \simeq 0$ now yield a contradiction. $\square$

3.1.5 Example: Schematic Images

Let $f : X \to Y$ be a quasi-compact morphism of schemes. Then there is a smallest closed subscheme $Y_0 \subseteq Y$ such that f factors through Y_0. The closed subscheme $Y_0 \subseteq Y$ is called the *schematic image* (or *scheme-theoretic image*) of the morphism f. We now describe a slight generalization of this construction.

Construction 3.1.5.1 (Schematic Images)**.** Let $f : \mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}) = \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Assume that the map f is ∞-quasi-compact and that the structure sheaf $\mathscr{O}_{\mathcal{X}}$ is discrete. Then the direct image $f_* \mathscr{O}_{\mathcal{X}} \in \mathrm{Mod}_{\mathscr{O}_{\mathcal{Y}}}$ is quasi-coherent (Theorem 2.5.8.1) and 0-truncated. It follows that the unit map $\mathscr{O}_{\mathcal{Y}} \to f_* \mathscr{O}_{\mathcal{X}}$ factors as a composition

$$\mathscr{O}_{\mathcal{Y}} \to \pi_0 \mathscr{O}_{\mathcal{Y}} \xrightarrow{\alpha} \pi_0 \mathscr{O}_{\mathcal{X}} \to \mathscr{O}_{\mathcal{X}} .$$

Let $\mathscr{A}$ denote the image of α: then $\mathscr{A}$ is a connective commutative algebra object of $\mathrm{QCoh}(\mathsf{Y})$ for which the unit map $\mathscr{O}_{\mathcal{Y}} \to \mathscr{A}$ is an epimorphism. Using Corollary 3.1.1.3 and Remark 3.1.2.7, we see that there exists an essentially unique closed immersion $\iota : \mathsf{Y}_0 \hookrightarrow (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ for which $\mathscr{A}$ is the direct image of the structure sheaf of Y_0. Note that Y_0 is 0-truncated, and Proposition 3.1.1.1 shows that f admits an essentially unique factorization $\mathsf{X} \xrightarrow{f'} \mathsf{Y}_0 \xrightarrow{\iota} \mathsf{Y}$. We will refer to Y_0 as the *schematic image of* f.

Warning 3.1.5.2. The term "schematic image" is potentially misleading: in general, the spectral Deligne-Mumford stack Y_0 which appears in Construction 3.1.5.1 will not be schematic. However, it is schematic if Y is schematic (since it is affine over Y).

Remark 3.1.5.3. In the situation of Construction 3.1.5.1, it is not necessary to assume that f is ∞-quasi-compact: we really only need the quasi-coherence of the ideal sheaf $\ker(\alpha)$, which requires only that f is quasi-compact.

Remark 3.1.5.4. In the situation of Construction 3.1.5.1, we do not need to require that Y is 0-truncated. However, there is no harm in doing so: if X is 0-truncated, then any map $f : \mathsf{X} \to \mathsf{Y}$ automatically factors through the 0-truncation $\tau_{\leqslant 0} \mathsf{Y}$, and the schematic image of f is equivalent to the schematic image of the induced map $\mathsf{X} \to \tau_{\leqslant 0} \mathsf{Y}$. In other words, Construction 3.1.5.1 really belongs to the setting of classical algebraic geometry.

Remark 3.1.5.5. Let X be a 0-truncated spectral Deligne-Mumford stack. Then the schematic image of an ∞-quasi-compact morphism $f : \mathsf{X} \to \mathsf{Y}$ is initial among 0-truncated closed substacks Y_0 of Y such that f factors through Y_0.

Remark 3.1.5.6. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Assume that X is 0-truncated and that f is ∞-quasi-compact, and let Y_0 denote the schematic image of f. Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathsf{X}' & \xrightarrow{f'} & \mathsf{Y}' \\ \downarrow & & \downarrow g \\ \mathsf{X} & \xrightarrow{f} & \mathsf{Y}. \end{array}$$

If g is flat, then X' is also 0-truncated, and we can identify the fiber product $\mathsf{Y}'_0 = \mathsf{Y}' \times_{\mathsf{Y}} \mathsf{Y}_0$ with the schematic image of f'. Beware that this is generally not true if g is not flat.

3.1.6 Reduced Closed Substacks

If X is a topological space, then there is a bijection from the set of closed subsets of X to the set of open subsets of X, given by $Y \mapsto X - Y$. In algebraic geometry, the situation is more subtle. Every closed subscheme Y of a scheme X has an open complement $U = X - Y$. However, this construction is not bijective: a closed subset of X generally admits many different scheme structures. Nevertheless, we can recover a bijective correspondence by restricting our attention to *reduced* closed subschemes of X. There is an entirely analogous picture in the setting of spectral algebraic geometry.

Definition 3.1.6.1. Let X be a spectral Deligne-Mumford stack. We will say that X is *reduced* if, for every étale map $\operatorname{Spét} R \to \mathsf{X}$, the $\mathbb{E}_\infty$-ring R is discrete and the underlying commutative ring.

Remark 3.1.6.2. The condition that a spectral Deligne-Mumford stack X be reduced is local with respect to the étale topology.

Proposition 3.1.6.3. *Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack. Let $\mathcal{C}$ denote the full subcategory of $\mathrm{SpDM}_{/\mathsf{X}}$ spanned by the closed immersions $i : \mathsf{X}_0 \to \mathsf{X}$, where X_0 is reduced. For every object $(i : \mathsf{X}_0 \to \mathsf{X})$ of $\mathrm{SpDM}_{/\mathsf{X}}$, let X_0^c denote the pushforward $i_*(\emptyset)$, where $\emptyset$ denotes an initial object in the underlying ∞-topos of X_0. Then the construction $(i : \mathsf{X}_0 \to \mathsf{X}) \mapsto \mathsf{X}_0^c$ determines an equivalence of ∞-categories $\mathcal{C} \simeq (\tau_{\leqslant -1} \mathcal{X})^{\mathrm{op}}$.*

Remark 3.1.6.4. We can state Proposition 3.1.6.3 more informally as follows: there is an order-reversing bijection between equivalence classes of reduced closed substacks of X and open substacks of X.

3.1.7 Clopen Immersions

In some cases, closed immersions are also open immersions:

Proposition 3.1.7.1. *Let $\mathcal{X}$ be an ∞-topos containing a (-1)-truncated object U, and let $i_* : \mathcal{X}_{/U} \to \mathcal{X}$ be the corresponding closed immersion of ∞-topoi. The following conditions are equivalent:*

(1) *The geometric morphism i_* is étale.*

(2) *The (-1)-truncated object U is complemented: that is, there exists an object $U' \in \mathcal{X}$ such that the coproduct $U \amalg U'$ is a final object of $\mathcal{X}$.*

Proof. The implication (2) ⇒ (1) is clear: if $U \amalg U'$ is a final object of $\mathcal{X}$, then the construction $X \mapsto U \amalg X$ determines an equivalence of ∞-categories $\mathcal{X}_{/U'} \to \mathcal{X}/U$. Conversely, suppose that (2) is satisfied. Then the pullback functor $i^* : \mathcal{X} \to \mathcal{X}/U$ admits a left adjoint $i_!$. Let $\mathbf{1}$ denote a final object of $\mathcal{X}$ and let $V = i_! i^* \mathbf{1}$. Then

$$U \times V \simeq U \times i_! i^* \mathbf{1} \simeq i_!(i^* U \times i^* \mathbf{1}) \simeq i_! i^*(U).$$

Since $i^*(U)$ is an initial object of $\mathcal{X}/U$, the object $U \times V \simeq i_! i^* U$ is an initial object of $\mathcal{X}$. Let $U' = \tau_{\leqslant -1} V$, so that $U \times U'$ is an initial object of $\mathcal{X}$. It follows that $U \amalg U'$ is also a (-1)-truncated object of $\mathcal{X}$. The identity map $\mathrm{id} : i_! i^* \mathbf{1} \to V$ induces a map $i^* \mathbf{1} \to i^* V$ in $\mathcal{X}/U$, which determines a map

$$\mathbf{1} \simeq i_* i^* \mathbf{1} \to i_* i^* V \simeq U \amalg_{U \times V} V \simeq U \amalg V.$$

Composing with the projection map $V \to \tau_{\leqslant -1} V$, we obtain a map $\mathbf{1} \to U \amalg U'$, so that $U \amalg U'$ is a (-1)-truncated, 0-connective object of $\mathcal{X}$ and therefore a final object of $\mathcal{X}$. □

Definition 3.1.7.2. Let $f_* : \mathcal{X} \to \mathcal{Y}$ be a geometric morphism of ∞-topoi. We will say that f_* is a *clopen immersion* if it satisfies the equivalent conditions of Proposition 3.1.7.1: that is, if it is both étale and a closed immersion. We will say that a map of nonconnective spectral Deligne-Mumford stacks $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ is a *clopen immersion* if it is étale and the underlying geometric morphism $f_* : \mathcal{X} \to \mathcal{Y}$ is a clopen immersion of ∞-topoi.

Remark 3.1.7.3. Every clopen immersion of spectral Deligne-Mumford stacks is also a closed immersion; in particular, it is an affine map. Let R be a connective $\mathbb{E}_\infty$-ring. A map of spectral Deligne-Mumford stacks $\mathsf{X} \to \mathrm{Spét}\, R$ is a clopen immersion if and only if X has the form $\mathrm{Spét}\, R[e^{-1}]$, where e is an idempotent element in the commutative ring $\pi_0 R$.

Proof. The assertion is local on X. We may therefore assume without loss of generality that $\mathsf{X} = \mathrm{Spét}\, R$ is affine. Using Theorem 3.1.2.1, we see that every closed immersion $i : \mathsf{X}_0 \to \mathsf{X}$ is induced by a map of connective $\mathbb{E}_\infty$-rings $R \to R'$ which induces a surjection $\pi_0 R \to \pi_0 R'$. Moreover, X_0 is reduced if and only if R' is a discrete commutative ring of the form $(\pi_0 R)/I$ for some radical ideal $I \subseteq \pi_0 R$. It follows that $\mathrm{Sub}^{\mathrm{red}}(\mathsf{X})$ is equivalent to the the nerve of the partially ordered set of closed subsets of the Zariski spectrum $|\mathrm{Spec}\, R|$. The desired equivalence now follows from Lemma **??**. □

3.2 Separated Morphisms

Recall that a scheme X is said to be *separated* if the diagonal map $X \to X \times X$ is a closed immersion. In this section, we will study the analogous condition in the setting of spectral algebraic geometry.

Definition 3.2.0.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. We will say that f is *separated* if the diagonal morphism $\mathsf{X} \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ is a closed immersion. We will say that a spectral Deligne-Mumford stack X is *separated* if it the morphism $\mathsf{X} \to \operatorname{Sp\acute{e}t} S$ is separated; here S denotes the sphere spectrum. In other words, X is separated if the absolute diagonal $\mathsf{X} \to \mathsf{X} \times \mathsf{X}$ is a closed immersion.

Warning 3.2.0.2. Our Definition 3.2.0.1 is somewhat nonstandard. In the theory of algebraic stacks, it is traditional to say that a map $\mathsf{X} \to \mathsf{Y}$ is separated if the diagonal map $\mathsf{X} \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ is proper, rather than a closed immersion. Our Definition 3.2.0.1 corresponds to the usual notion of a *separated representable* morphism of stacks: that is, a separated morphism whose fibers are algebraic spaces.

3.2.1 Properties of Separated Morphisms

We begin with some general observations about Definition 3.2.0.1.

Remark 3.2.1.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a separated morphism of spectral Deligne-Mumford stacks. It follows from Warning 3.1.2.6 that for every discrete commutative ring R, the map $\operatorname{Map}_{\mathrm{SpDM}}(\operatorname{Sp\acute{e}t} R, \mathsf{X}) \to \operatorname{Map}_{\mathrm{SpDM}}(\operatorname{Sp\acute{e}t} R, \mathsf{Y})$ is 0-truncated. In particular, if Y is a spectral algebraic space, then X is also a spectral algebraic space. In particular, every separated spectral Deligne-Mumford stack is a spectral algebraic space.

Remark 3.2.1.2. Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks, and let $\delta : \mathsf{X} \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ be the diagonal map. Write $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ and $\mathsf{X} \times_{\mathsf{Y}} \mathsf{X} = (\mathcal{Z}, \mathscr{O}_{\mathcal{Z}})$. The map $\delta^{-1} \mathscr{O}_{\mathcal{Z}} \to \mathscr{O}_{\mathcal{X}}$ admits a right inverse, and therefore induces an epimorphism $\pi_0 \delta^{-1} \mathscr{O}_{\mathcal{Z}} \to \pi_0 \mathscr{O}_{\mathcal{X}}$. It follows f is separated if and only if the underlying geometric morphism of ∞-topoi $\delta_* : \mathcal{X} \to \mathcal{Z}$ is a closed immersion.

Remark 3.2.1.3. If $j : \mathsf{U} \to \mathsf{X}$ is an open immersion of spectral Deligne-Mumford stacks, then the diagonal map $\mathsf{U} \to \mathsf{U} \times_{\mathsf{X}} \mathsf{U}$ is an equivalence. It follows that every open immersion between spectral Deligne-Mumford stacks is separated. In particular, if X is a separated spectral algebraic space, then U is also a separated spectral algebraic space.

Remark 3.2.1.4. Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathsf{X}' & \xrightarrow{f'} & \mathsf{X} \\ \downarrow & & \downarrow f \\ \mathsf{Y}' & \xrightarrow{g} & \mathsf{Y}. \end{array}$$

If f is separated, then so is f'; this follows immediately from Corollary 3.1.2.3. The converse holds if g is an étale surjection (see Remark 3.1.2.2).

Remark 3.2.1.5. Suppose we are given a commutative diagram

$$\begin{array}{ccc} & \mathsf{X} & \\ {}^{f}\swarrow & & \searrow^{h} \\ \mathsf{Y} & \xrightarrow{g} & \mathsf{Z} \end{array}$$

of spectral Deligne-Mumford stacks. If g is separated, then f is separated if and only if h is separated. In particular, the collection of separated morphisms is closed under composition. To see this, consider the diagram

$$\begin{array}{ccccc} \mathsf{X} & \xrightarrow{\delta} & \mathsf{X} \times_{\mathsf{Y}} \mathsf{X} & \xrightarrow{\delta'} & \mathsf{X} \times_{\mathsf{Z}} \mathsf{X} \\ & & \downarrow & & \downarrow \\ & & \mathsf{Y} & \xrightarrow{\delta''} & \mathsf{Y} \times_{\mathsf{Z}} \mathsf{Y}. \end{array}$$

Since g is separated, δ'' is a closed immersion. It follows from Corollary 3.1.2.3 that δ' is a closed immersion, so that δ is a closed immersion if and only if $\delta' \circ \delta$ is a closed immersion (Corollary 3.1.2.4).

Remark 3.2.1.6. Suppose we are given morphisms of spectral Deligne-Mumford stacks $\mathsf{X} \xrightarrow{f} \mathsf{Y} \xleftarrow{g} \mathsf{Z}$. If f and g are separated, then the induced map $\mathsf{X} \times_{\mathsf{Y}} \mathsf{Z} \to \mathsf{Y}$ is also separated. This follows immediately from Remarks 3.2.1.5 and 3.2.1.4.

Remark 3.2.1.7. Let $f : (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ be a morphism of spectral Deligne-Mumford stacks. The condition that f be separated depends only the underlying morphism of 0-truncated spectral Deligne-Mumford stacks $(\mathcal{X}, \pi_0 \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}, \pi_0 \mathscr{O}_{\mathcal{Y}})$.

Example 3.2.1.8. Let R be a connective $\mathbb{E}_\infty$-ring. Then the multiplication map $R \otimes R \to R$ induces a surjection $\pi_0(R \otimes R) \to \pi_0 R$. It follows from Theorem 3.1.2.1 that the diagonal map $\operatorname{Spét} R \to \operatorname{Spét} R \times \operatorname{Spét} R$ is a closed immersion, so that $\operatorname{Spét} R$ is separated.

Example 3.2.1.9. Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks. Suppose that, for every commutative ring R, the induced map $\mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{X}) \to \mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{Y})$ is (-1)-truncated. It follows that the diagonal map

$$\mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{X}) \to \mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{X} \times_{\mathsf{Y}} \mathsf{X})$$

is a homotopy equivalence for every discrete commutative ring R. The map $\mathsf{X} \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ induces an equivalence between the underlying 0-truncated spectral Deligne-Mumford stacks, and is therefore a closed immersion (Remark 3.2.1.7). It follows that f is separated.

Remark 3.2.1.10. Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks. Assume that Y is separated. Then X is separated if and only if f is separated: this follows immediately from Remark 3.2.1.5. In particular, if we are given a map $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ for some connective $\mathbb{E}_\infty$-ring R, then X is separated if and only if f is separated: that is, if and only if the diagonal map $\mathsf{X} \to \mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X}$ is a closed immersion.

Example 3.2.1.11. Let $f : \mathsf{X} \to \mathsf{Y}$ be a quasi-affine morphism between spectral Deligne-Mumford stacks. Then f is separated. To prove this, we may work locally on Y to reduce to the case where Y is affine, in which case the result follows from Remark 3.2.1.10 and Examples 3.2.1.8 and 3.2.1.9.

3.2.2 Configuration Spaces

Let X be a separated spectral Deligne-Mumford stack. Then the diagonal map $\delta : \mathsf{X} \to \mathsf{X} \times \mathsf{X}$ is a closed immersion, which is complementary to an open substack $\mathrm{Conf}^2(\mathsf{X}) \subseteq \mathsf{X} \times \mathsf{X}$. Informally, we can regard $\mathrm{Conf}^2(\mathsf{X})$ as a "parameter space" for pairs of distinct points of X. We now consider a variant of this construction where we work relative to a base Y, and contemplate n-tuples of points in place of pairs of points:

Construction 3.2.2.1. Suppose we are given a separated morphism $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks. Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ and $\mathsf{X} \times_{\mathsf{Y}} \mathsf{X} = (\mathcal{Z}, \mathcal{O}_{\mathcal{Z}})$, so that the diagonal map induces a closed immersion of ∞-topoi $\delta_* : \mathcal{X} \to \mathcal{Z}$. Let $\emptyset$ denote an initial object of $\mathcal{X}$ and let $U = \delta_*(\emptyset)$, so that U is a (-1)-truncated object of $\mathcal{Z}$ and δ_* induces an equivalence of ∞-topoi $\mathcal{X} \to \mathcal{Z}_{/U}$.

For every finite set I, let $\overline{\mathrm{Conf}}^I_{\mathsf{Y}}(\mathsf{X})$ denote the I-fold product of X with itself in the ∞-category $\mathrm{SpDM}_{/\mathsf{Y}}$. For every pair of distinct elements $i, j \in I$, we obtain an evaluation map

$$p_{i,j} : \overline{\mathrm{Conf}}^I_{\mathsf{Y}}(\mathsf{X}) \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}.$$

Let V denote the product $\prod_{i \neq j} p^*_{i,j}(U)$ in the underlying ∞-topos of $\overline{\mathrm{Conf}}^I_{\mathsf{Y}}(\mathsf{X})$. We let $\mathrm{Conf}^I_{\mathsf{Y}}(\mathsf{X})$ denote the open substack of $\overline{\mathrm{Conf}}^I_{\mathsf{Y}}(\mathsf{X})$ corresponding to the (-1)-truncated object

V. We will refer to $\mathrm{Conf}^I_{\mathsf{Y}}(\mathsf{X})$ as the *spectral Deligne-Mumford stack of I-configurations in* X (relative to Y).

Note that $\mathrm{Conf}^I_{\mathsf{Y}}(\mathsf{X})$ depends functorially on I. In particular, it is acted on by the group of all permutations of I, and (up to equivalence) depends only on the cardinality of the set I. When $I = \{1, 2, \ldots, n\}$, we will denote $\mathrm{Conf}^I_{\mathsf{Y}}(\mathsf{X})$ by $\mathrm{Conf}^n_{\mathsf{Y}}(\mathsf{X})$, so that $\mathrm{Conf}^n_{\mathsf{Y}}(\mathsf{X})$ carries an action of the symmetric group Σ_n.

Remark 3.2.2.2. In the situation of Construction 3.2.2.1, the projection map $\overline{\mathrm{Conf}}^I_{\mathsf{Y}}(\mathsf{X}) \to \mathsf{Y}$ is separated by Remark 3.2.1.6. The open immersion $\mathrm{Conf}^I_{\mathsf{Y}}(\mathsf{X}) \to \overline{\mathrm{Conf}}^I_{\mathsf{Y}}(\mathsf{X})$ is separated (Remark 3.2.1.3), so the projection $\mathrm{Conf}^I_{\mathsf{Y}}(\mathsf{X}) \to \mathsf{Y}$ is also separated (Remark 3.2.1.5).

Notation 3.2.2.3. Let X be a spectral Deligne-Mumford stack. If G is a discrete group, an *action* of G on X is a diagram $\chi : BG \to \mathrm{SpDM}$ carrying the base point of BG to X. Since every morphism in BG is an equivalence, χ is automatically a diagram consisting of étale morphisms in SpDM, so there exists a colimit $\varinjlim(\chi)$ of the diagram χ (Proposition **??**). We will denote this colimit by X/G, and refer to it as the *quotient of* X *by the action of* G. There is an evident étale surjection $\mathsf{X} \to \mathsf{X}/G$. Moreover, there is a canonical equivalence

$$\mathsf{X} \times_{\mathsf{X}/G} \mathsf{X} \simeq \amalg_{g \in G} \mathsf{X}.$$

The main property of Construction 3.2.2.1 we will need is the following:

Proposition 3.2.2.4. *Let Y be a separated spectral algebraic space and let $f : \mathsf{X} \to \mathsf{Y}$ be an étale map, where X is affine. For every $n > 0$, the quotient $\mathrm{Conf}^n_{\mathsf{Y}}(\mathsf{X})/\Sigma_n$ is affine.*

We will deduce Proposition 3.2.2.4 from the following general observation:

Proposition 3.2.2.5. *Let R be an $\mathbb{E}_\infty$-ring equipped with an action of a finite group G, and let R^G denote the $\mathbb{E}_\infty$-ring of invariants. Suppose that the action of G on the commutative ring $\pi_0 R$ is free (see Definition B.7.1.2). Then the canonical map $(\mathrm{Sp\acute{e}t}\, R)/G \to \mathrm{Sp\acute{e}t}\, R^G$ is an equivalence of spectral Deligne-Mumford stacks. In particular, the quotient $(\mathrm{Sp\acute{e}t}\, R)/G$ is affine.*

Proof. Let $\mathsf{X}_\bullet$ be the Čech nerve of the map $\mathrm{Sp\acute{e}t}\, R \to (\mathrm{Sp\acute{e}t}\, R)/G$, and let $\mathsf{Y}_\bullet$ be the Čech nerve of the map $\mathrm{Sp\acute{e}t}\, R \to \mathrm{Sp\acute{e}t}\, R^G$. It follows from Corollary **??** that the map $R^G \to R$ is faithfully flat and étale, so that the vertical maps in the diagram

$$\begin{array}{ccc} |\mathsf{X}_\bullet| & \longrightarrow & |\mathsf{Y}_\bullet| \\ \downarrow & & \downarrow \\ (\mathrm{Sp\acute{e}t}\, R)/G & \longrightarrow & \mathrm{Sp\acute{e}t}\, R^G \end{array}$$

are equivalences. It will therefore suffice to show that the canonical map $\mathsf{X}_n \to \mathsf{Y}_n$ is an equivalence for every integer n. Since $\mathsf{X}_\bullet$ and $\mathsf{Y}_\bullet$ are groupoid objects of SpDM, we only need to consider the cases $n = 0$ and $n = 1$. When $n = 0$, the result is obvious. When $n = 1$, we must show that the canonical map

$$\amalg_{g \in G} \mathsf{X} \rightarrow \operatorname{Spec}(R \otimes_{R^G} R)$$

is an equivalence. Equivalently, we must show that the canonical map

$$R \otimes_{R^G} R \rightarrow \prod_{g \in G} R$$

is an equivalence of $\mathbb{E}_\infty$-rings, which follows from Corollary **??**. □

Lemma 3.2.2.6. *Let $f : \mathsf{X} \rightarrow \mathsf{Y}$ be a map of spectral algebraic spaces. If f is separated, then the mapping space $\operatorname{Map}_{\mathrm{SpDM}}(\operatorname{Spét} R, \operatorname{Conf}^n_{\mathsf{Y}}(\mathsf{X}))$ is discrete for every commutative ring R and every integer $n \geqslant 0$. If R is nonzero, then the symmetric group Σ_n acts freely on the set $\pi_0 \operatorname{Map}_{\mathrm{SpDM}}(\operatorname{Spét} R, \operatorname{Conf}^n_{\mathsf{Y}}(\mathsf{X}))$.*

Proof. For any commutative ring R, the map $\theta : \operatorname{Map}_{\mathrm{SpDM}}(\operatorname{Spét} R, \mathsf{X}) \rightarrow \operatorname{Map}_{\mathrm{SpDM}}(\operatorname{Spét} R, \mathsf{Y})$ has discrete homotopy fibers (Remark 3.2.1.1). Since the codomain of θ is discrete, we conclude that the domain of θ is also discrete. Let $S = \pi_0 \operatorname{Map}_{\mathrm{SpDM}}(\operatorname{Spét} R, \mathsf{X})$ and $T = \pi_0 \operatorname{Map}_{\mathrm{SpDM}}(\operatorname{Spét} R, \mathsf{Y})$. There is an evident injection from $\pi_0 \operatorname{Map}_{\mathrm{SpDM}}(\operatorname{Spét} A, \operatorname{Conf}^n_{\mathsf{Y}}(\mathsf{X}))$ to the set $K = S \times_T \cdots \times_T S$ given by the n-fold fiber power of S over T. If $\sigma \in \Sigma_n$ is a nontrivial permutation which fixes an element $(s_1, \ldots, s_n)$ of K, then we must have $s_i = s_j$ for some $i \neq j$, in which case the corresponding map $\operatorname{Spét} R \rightarrow \overline{\operatorname{Conf}}^n_{\mathsf{Y}}(\mathsf{X}) \rightarrow \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ factors through the diagonal. By construction, the fiber product $\mathsf{X} \times_{\mathsf{X} \times_{\mathsf{Y}} \mathsf{X}} \operatorname{Conf}^n_{\mathsf{Y}}(\mathsf{X})$ is empty, which is impossible unless $R \simeq 0$. □

Remark 3.2.2.7. Let $f : \mathsf{X} \rightarrow \mathsf{Y}$ be a separated étale morphism of spectral Deligne-Mumford stacks. Then the diagonal map $\mathsf{X} \rightarrow \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ is a clopen immersion (see Definition 3.1.7.2). If we write $\mathsf{X} \times_{\mathsf{Y}} \mathsf{X} = (\mathcal{Z}, \mathcal{O}_{\mathcal{Z}})$ and define $U \in \mathcal{Z}$ as in Construction 3.2.2.1, then it follows that U has a complement (in the underlying locale of $\mathcal{Z}$). It follows that for any finite set I, the object $V = \prod_{i \neq j} p^*_{i,j}(U)$ appearing in Construction 3.2.2.1 has a complement in the underlying locale of $\overline{\operatorname{Conf}}^I_{\mathsf{Y}}(\mathsf{X})$, so that the open immersion $\operatorname{Conf}^I_{\mathsf{Y}}(\mathsf{X}) \rightarrow \overline{\operatorname{Conf}}^I_{\mathsf{Y}}(\mathsf{X})$ is also a clopen immersion.

Proposition 3.2.2.8. *Let Y be a separated spectral algebraic space. Suppose we are given an étale map $\mathsf{X} \rightarrow \mathsf{Y}$. If X is affine, then $\operatorname{Conf}^n_{\mathsf{Y}}(\mathsf{X})$ is affine for every $n > 0$.*

Proof. Since the diagonal of Y is affine, the fiber product

$$\overline{\operatorname{Conf}}^n_{\mathsf{Y}}(\mathsf{X}) \simeq \mathsf{X} \times_{\mathsf{Y}} \cdots \times_{\mathsf{Y}} \mathsf{X}$$

is affine. The desired result now follows from Remarks 3.2.2.7 and 3.1.7.3. □

Proof of Proposition 3.2.2.4. Let $f : \mathsf{X} \to \mathsf{Y}$ be an étale morphism of separated spectral algebraic spaces, where X is affine. Proposition 3.2.2.8 implies that $\mathrm{Conf}^n_{\mathsf{Y}}(\mathsf{X})$ is affine, hence of the form $\mathrm{Spét}\, R$ for some connective $\mathbb{E}_\infty$-ring R. According to Proposition 3.2.2.5, it will suffice to show that the action of the symmetric group Σ_n on R is free, which follows from Lemma 3.2.2.6. □

3.2.3 Existence of Scallop Decompositions (Separated Case)

We can now state the main result of this section:

Proposition 3.2.3.1. *Let Y be a quasi-compact separated spectral algebraic space. Then Y admits a scallop decomposition (see Definition 2.5.3.1).*

Remark 3.2.3.2. In §3.4, we will prove that the hypothesis of separatedness can be replaced by quasi-separatedness; see Theorem 3.4.2.1.

Corollary 3.2.3.3. *Let $f : \mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to \mathsf{Y} = (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ be a quasi-compact separated morphism of spectral Deligne-Mumford stacks. Then:*

(1) *The pushforward functor $f_* : \mathrm{Mod}_{\mathcal{O}_{\mathcal{X}}} \to \mathrm{Mod}_{\mathcal{O}_{\mathcal{Y}}}$ carries quasi-coherent sheaves to quasi-coherent sheaves.*

(2) *The induced functor $\mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ commutes with small colimits.*

(3) *For every pullback diagram*

$$\begin{array}{ccc} \mathsf{X}' & \xrightarrow{g'} & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \xrightarrow{g} & \mathsf{Y}, \end{array}$$

the associated diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{Y}) & \xrightarrow{f^*} & \mathrm{QCoh}(\mathsf{X}) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{Y}') & \xrightarrow{f'^*} & \mathrm{QCoh}(\mathsf{X}') \end{array}$$

is right adjointable. In other words, for every object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$, the canonical map $\lambda : g^* f_* \mathscr{F} \to f'_* g'^* \mathscr{F}$ is an equivalence in $\mathrm{QCoh}(\mathsf{Y}')$.

Proof. Combine Propositions 2.5.4.3, 2.5.4.5, and 3.2.3.1. □

We now turn to the proof of Proposition 3.2.3.1. We will need a bit of commutative algebra.

Lemma 3.2.3.4. *Let $f : R \to R'$ be an étale morphism of commutative rings. For every prime ideal $\mathfrak{p} \subseteq R$, let $\kappa(\mathfrak{p})$ denote the residue field of R at the prime ideal $\mathfrak{p}$, and let $r(\mathfrak{p})$ denote the dimension of the $\kappa(\mathfrak{p})$-vector space $R' \otimes_R \kappa(\mathfrak{p})$. Then:*

(1) *For every integer n, the set $\{\mathfrak{p} \in |\operatorname{Spec} R| : r(\mathfrak{p}) > n\}$ is quasi-compact and open in $|\operatorname{Spec} R|$.*

(2) *The function r is constant with value $n \in \mathbf{Z}$ if and only if f exhibits R' as a locally free R-module of degree n.*

(3) *The function r is bounded above.*

Proof. We will prove (1) and (2) using induction on n. We begin with the case $n = 0$. In this case, assertion (2) is obvious, and assertion (1) follows from the fact that the map $|\operatorname{Spec} R'| \to |\operatorname{Spec} R|$ has quasi-compact open image.

Now suppose $n > 0$. We first prove (1). Let $U = \{\mathfrak{p} \in |\operatorname{Spec} R| : r(\mathfrak{p}) > 0\}$. and let $V = \{\mathfrak{p} \in |\operatorname{Spec} R| : r(\mathfrak{p}) > n\}$. The inductive hypothesis implies that U is open, so it will suffice to show that V is a quasi-compact open subset of U. Using Proposition 1.6.2.2, we deduce that the map $\phi : |\operatorname{Spec} R'| \to U$ is a quotient map; it will therefore suffice to show that $\phi^{-1}U$ is a quasi-compact open subset of $|\operatorname{Spec} R'|$. Since f is étale, the tensor product $R' \otimes_R R'$ factors as a product $R' \times R''$. Then the set

$$\phi^{-1}U = \{\mathfrak{q} \in |\operatorname{Spec} R'| : \dim_{\kappa(\mathfrak{q})}(R'' \otimes_{R'} \kappa(\mathfrak{q})) > n-1\}$$

is open by the inductive hypothesis.

It remains to prove (2). The "only if" direction is obvious. For the converse, assume that r is a constant function with value $n > 0$. Then $U = |\operatorname{Spec} R|$, so f is faithfully flat. It therefore suffices to show that $R' \otimes_R R'$ is a locally free R'-module of rank n. This is equivalent to the requirement that R'' be a locally free R'-module of rank $(n-1)$, which follows from the inductive hypothesis.

We now prove (3). Using (1), we see that each of the sets $\{\mathfrak{p} \in |\operatorname{Spec} R| : r(\mathfrak{p}) > n\}$ is closed with respect to the constructible topology on $|\operatorname{Spec} R|$ (see §4.3). Since

$$\bigcap_n \{\mathfrak{p} \in |\operatorname{Spec} R| : r(\mathfrak{p}) > n\} = \varnothing$$

and $|\operatorname{Spec} R|$ is compact with respect to the constructible topology, we conclude that there exists an integer n such that $\{\mathfrak{p} \in |\operatorname{Spec} R| : r(\mathfrak{p}) > n\} = \varnothing$. □

Proof of Proposition 3.2.3.1. Since Y is quasi-compact, we can choose an étale surjection $u : \mathsf{X} \to \mathsf{Y}$, where X is affine. For every map $\eta : \operatorname{Spét} A \to \mathsf{Y}$, the pullback $\mathsf{X} \times_{\mathsf{Y}} \operatorname{Spét} A$ has the form $\operatorname{Spét} A'$, for some étale A-algebra A'. Let $r_\eta : |\operatorname{Spec} A| \to \mathbf{Z}_{\geqslant 0}$ be defined by the formula

$$r_\eta(\mathfrak{p}) = \dim_{\kappa(\mathfrak{p})}(A' \otimes_A \kappa(\mathfrak{p})).$$

Using Lemma 3.2.3.4, we can define open immersions $\mathsf{V}_i \hookrightarrow \mathsf{Y}$ so that the following universal property is satisfied: a map $\eta : \operatorname{Spét} A \to \mathsf{Y}$ factors through V_i if and only if $r_\eta(\mathfrak{p}) \geqslant i$ for every prime ideal $\mathfrak{p} \subseteq \pi_0 A$. Lemma 3.2.3.4 implies that the fiber product $\operatorname{Spét} A \times_{\mathsf{Y}} \mathsf{V}_i$ is empty for $i \gg 0$. Using the quasi-compactness of Y, we conclude that there exists an integer n such that V_{n+1} is empty. The surjectivity of u guarantees that $\mathsf{V}_1 \simeq \mathsf{Y}$. For $0 \leqslant i \leqslant n$, let $U_i \in \mathcal{Y}$ be the (-1)-truncated object corresponding to the open substack V_{n+1-i}. We claim that the sequence of morphisms

$$U_0 \to U_1 \to \cdots \to U_n$$

gives a scallop decomposition of Y.

Note that each $0 \leqslant i < n$, the étale map $\operatorname{Conf}^{n-i}_{\mathsf{Y}}(\mathsf{X})/\Sigma_{n-i} \to \mathsf{Y}$ determines an object $X_i \in \mathcal{Y}$. It follows from Proposition 3.2.2.4 that X_i is affine. Choose an equivalence $\operatorname{Conf}^{n-i}_{\mathsf{Y}}(\mathsf{X})/\Sigma_{n-i} \simeq \operatorname{Spét} R_i$, so that we have an étale map $v_i : \operatorname{Spét} R_i \to \mathsf{Y}$. For every map $\eta : \operatorname{Spét} A \to \mathsf{Y}$, choose an equivalence $\operatorname{Spét} A \times_{\mathsf{Y}} (\operatorname{Conf}^{n-i}_{\mathsf{Y}}(\mathsf{X})/\Sigma_i) \simeq \operatorname{Spét} A^{(i)}$, and define a function $r^{(i)}_\eta : |\operatorname{Spec} A| \to \mathbf{Z}_{\geqslant 0}$ by the formula

$$r^{(i)}_\eta(\mathfrak{p}) = \dim_{\kappa(\mathfrak{p})}(A^{(i)} \otimes_A \kappa(\mathfrak{p})).$$

An easy calculation shows that $r^{(i)}_\eta(\mathfrak{p})$ is equal to the binomial coefficient $\binom{r_\eta(\mathfrak{p})}{n-i}$. In particular, $r^{(i)}_\eta(\mathfrak{p})$ takes positive values if and only if $r^{(1)}_\eta(\mathfrak{p}) \geqslant n-i$ for every $\mathfrak{p} \in |\operatorname{Spec} A|$. It follows that the map v_i factors through V_i. Form a pullback diagram σ_i:

$$\begin{array}{ccc} X_i \times_{U_{i+1}} U_i & \longrightarrow & X_i \\ \downarrow & & \downarrow \\ U_i & \longrightarrow & U_{i+1}. \end{array}$$

Note that there is an effective epimorphism

$$\amalg_{0 \leqslant j < i} X_i \times X_j \to X_i \times_{U_{i+1}} U_i.$$

Since Y is separated, each product $X_i \times X_j$ is affine and therefore quasi-compact, so that $X_i \times_{U_{i+1}} U_i$ is quasi-compact.

To complete the proof, it will suffice to show that each σ_i is an excision square. For this, we may replace Y by the reduced closed substack K_i of U_{i+1} which is complementary to U_i, and thereby reduce to the case where the function r_η takes the constant value i, for every $\eta : \operatorname{Spét} A \to \mathsf{Y}$. In this case, the function $r^{(i)}_\eta$ is constant with value 1, so that the map $A \to A^{(i)}$ is finite étale of degree 1 and therefore an equivalence (Lemma 3.2.3.4). It follows that the map $\operatorname{Spét} R_i \to \mathsf{Y}$ is also an equivalence, as desired. $\square$

3.3 Quasi-Finite Morphisms

Recall that a morphism $\phi : A \to B$ of commutative rings is said to be *quasi-finite* if the following conditions are satisfied:

(i) The commutative ring B is finitely generated as an A-algebra.

(ii) For each residue field κ of A, the fiber $\mathrm{Tor}_0^A(B, \kappa)$ is a finite-dimensional vector space over κ.

Remark 3.3.0.1. Assuming (i), condition (ii) is equivalent to the requirement that the induced map of topological spaces $|\operatorname{Spec} B| \to |\operatorname{Spec} A|$ has finite fibers.

A morphism of schemes $f : X \to Y$ is said to be *locally quasi-finite* if, for every point $x \in X$, there exist affine open neighborhoods $\operatorname{Spec} B \simeq U \subseteq X$ of x and $\operatorname{Spec} A \simeq V \subseteq Y$ such that $f(U) \subseteq V$ and the induced ring homomorphism $A \to B$ is quasi-finite. Our goal in this section is generalize the notion of locally quasi-finite morphism to the setting of spectral algebraic geometry. Our main result is the following version of Zariski's Main Theorem:

Theorem 3.3.0.2. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Assume that f is quasi-compact, separated, and locally quasi-finite. Then f is quasi-affine.*

3.3.1 Relative Dimension

We will assume that the reader is familiar with the theory of relative dimension for homomorphisms of commutative rings (see §B.2 for an overview). We now describe a "globalized" version of the relative dimension:

Definition 3.3.1.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks and let $d \geqslant 0$ be an integer. We will say that f is *of relative dimension* $\leqslant d$ if the following condition is satisfied: for every commutative diagram

$$\begin{array}{ccc} \operatorname{Sp\acute{e}t} B & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow f \\ \operatorname{Sp\acute{e}t} A & \longrightarrow & \mathsf{Y} \end{array}$$

in which the horizontal maps are étale, the induced map of commutative rings $\pi_0 A \to \pi_0 B$ is of relative dimension $\leqslant d$ (Definition B.2.3.1). We will say that f is *locally quasi-finite* if it is locally of relative dimension $\leqslant 0$.

Example 3.3.1.2. Every étale morphism of spectral Deligne-Mumford stacks is locally quasi-finite.

Example 3.3.1.3. Every closed immersion of spectral Deligne-Mumford stacks is locally quasi-finite.

Proposition 3.3.1.4. *For every nonnegative integer $d \geqslant 0$, the condition that a map of spectral Deligne-Mumford stacks $f : \mathsf{X} \to \mathsf{Y}$ be of relative dimension $\leqslant d$ is local on the source with respect to the étale topology (see Definition 2.8.1.7). In particular, the condition that f is locally quasi-finite is local on the source with respect to the étale topology.*

Proof. It is clear that if $f : \mathsf{X} \to \mathsf{Y}$ is of relative dimension $\leqslant d$ and $g : \mathsf{U} \to \mathsf{X}$ is étale, then the composite map $f \circ g$ is of relative dimension $\leqslant d$. To complete the proof, let us suppose that $f : \mathsf{X} \to \mathsf{Y}$ is arbitrary and that we are given a jointly surjective collection of étale morphisms $\{g_\alpha : \mathsf{U}_\alpha \to \mathsf{X}\}$ such that each composition $f \circ g_\alpha$ is locally of relative dimension $\leqslant d$. We wish to show that f has the same property. Choose a commutative diagram

$$\begin{array}{ccc} \operatorname{Spét} B & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow f \\ \operatorname{Spét} A & \longrightarrow & \mathsf{Y} \end{array}$$

where the horizontal maps are étale. We wish to show that $\pi_0 B$ is of relative dimension d over $\pi_0 A$. It follows from Proposition 4.2.1.1 that $\pi_0 B$ is finitely generated as an algebra over $\pi_0 A$. Fix a prime ideal $\mathfrak{p} \subseteq \pi_0 B$ and let $\mathfrak{q}$ be its inverse image in $\pi_0 A$. We wish to show that the local ring $R = (\pi_0 B)_{\mathfrak{p}}/\mathfrak{q}(\pi_0 B)_{\mathfrak{p}}$ has dimension $\leqslant d$ (see Corollary B.2.3.10). Since the maps g_α are jointly surjective, we can choose an étale map $B \to B'$ and a prime ideal $\mathfrak{p}' \subseteq \pi_0 B'$ lying over $\mathfrak{p}$ for which the composite map $\operatorname{Spét} B' \to \operatorname{Spét} B \to \mathsf{X}$ factors through some U_α. Invoking our assumption that $f \circ g_\alpha$ is of relative dimension $\leqslant d$, we conclude that the local ring $R' = (\pi_0 B')_{\mathfrak{p}'}/\mathfrak{q}(\pi_0 A)_{\mathfrak{p}'}$ has dimension $\leqslant d$. Since R' is étale and faithfully flat over R, it follows that R also has dimension $\leqslant d$ (Variant B.2.2.4). □

Corollary 3.3.1.5. *Suppose we are given a morphisms of spectral Deligne-Mumford stacks*

$$\mathsf{X} \xrightarrow{f} \mathsf{Y} \xrightarrow{g} \mathsf{Z}.$$

If f is of relative dimension $\leqslant d$ and g is of relative dimension $\leqslant d'$, then the composition $g \circ f$ is of relative dimension $\leqslant (d + d')$. In particular, if f and g are locally quasi-finite, then so is $g \circ f$.

Proof. Suppose we are given a commutative diagram

$$\begin{array}{ccc} \operatorname{Spét} C & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow \\ \operatorname{Spét} A & \longrightarrow & \mathsf{Z} \end{array}$$

where the horizontal maps are étale. We wish to show that $\pi_0 C$ is of relative dimension $\leqslant (d+d')$ over $\pi_0 A$. The proof of Proposition 3.3.1.4 shows that this condition is étale local on C; we may therefore assume that the map $\mathrm{Sp\acute{e}t}\, C \to \mathrm{Sp\acute{e}t}\, A \times_{\mathsf{Z}} \mathsf{Y}$ factors through some étale map $\mathrm{Sp\acute{e}t}\, B \to \mathrm{Sp\acute{e}t}\, A \times_{\mathsf{Z}} \mathsf{Y}$. Since f and g are of relative dimension $\leqslant d$ and $\leqslant d'$, the ring homomorphisms $\pi_0 B \to \pi_0 C$ and $\pi_0 A \to \pi_0 B$ have relative dimensions $\leqslant d$ and $\leqslant d'$, respectively. The desired result now follows from Proposition B.2.3.7. □

Proposition 3.3.1.6. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks and let $d \geqslant 0$ be an integer. Then:*

(1) *The map f is of relative dimension $\leqslant d$ if and only if, for every étale map $\mathrm{Sp\acute{e}t}\, A \to \mathsf{Y}$, the induced map $\mathrm{Sp\acute{e}t}\, A \times_{\mathsf{Y}} \mathsf{X} \to \mathrm{Sp\acute{e}t}\, A$ is of relative dimension $\leqslant d$.*

(2) *Assume that $\mathsf{Y} \simeq \mathrm{Sp\acute{e}t}\, A$ is affine. Then f is of relative dimension $\leqslant d$ if and only if, for every étale map $\mathrm{Sp\acute{e}t}\, B \to \mathsf{X}$, the induced map of commutative rings $\pi_0 A \to \pi_0 B$ is of relative dimension $\leqslant d$.*

(3) *Assume that $\mathsf{Y} \simeq \mathrm{Sp\acute{e}t}\, A$ and $\mathsf{X} \simeq \mathrm{Sp\acute{e}t}\, B$ are both affine. Then f is of relative dimension $\leqslant d$ if and only if the underlying map of commutative rings $\pi_0 A \to \pi_0 B$ is of relative dimension $\leqslant d$.*

Proof. Assertion (1) follows immediately from the definition, and the "only if" directions of (2) and (3) are obvious. To complete the proof of (2), assume that $\mathsf{Y} \simeq \mathrm{Sp\acute{e}t}\, A$ and consider an arbitrary commutative diagram

$$\begin{array}{ccc} \mathrm{Sp\acute{e}t}\, B & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow{\scriptstyle f} \\ \mathrm{Sp\acute{e}t}\, A' & \longrightarrow & \mathrm{Sp\acute{e}t}\, A \end{array}$$

where the horizontal maps are étale. If $\pi_0 B$ is of relative dimension $\leqslant d$ over $\pi_0 A$, then it is also of relative dimension $\leqslant d$ over $\pi_0 A'$ (Remark B.2.3.4). The proof of (3) is similar. □

Proposition 3.3.1.7. *The condition that a map of spectral Deligne-Mumford stacks $f : \mathsf{X} \to \mathsf{Y}$ be of relative dimension $\leqslant d$ (locally quasi-finite) is local on the target with respect to the étale topology. That is, if we are given a jointly surjective collection of étale maps $\mathsf{U}_\alpha \to \mathsf{Y}$ for which each of the projections $\mathsf{X} \times_{\mathsf{Y}} \mathsf{U}_\alpha \to \mathsf{U}_\alpha$ is of relative dimension $\leqslant d$ (locally quasi-finite), then f is of relative dimension $\leqslant d$ (locally quasi-finite).*

Proof. Using Example 3.3.1.2 and Corollary 3.3.1.5, we see that each of the induced maps $\mathsf{U}_\alpha \times_{\mathsf{Y}} \mathsf{X} \to \mathsf{Y}$ is of relative dimension $\leqslant d$. Applying Proposition 3.3.1.4, we deduce that f is of relative dimension $\leqslant d$. □

Proposition 3.3.1.8. *Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \xrightarrow{g} & \mathsf{Y}. \end{array}$$

If f is of relative dimension $\leqslant d$ (locally quasi-finite), then so is f'. The converse holds if g is faithfully flat and quasi-compact.

Proof. Assume first that f is of relative dimension $\leqslant d$; we wish to show that f' has the same property. Using Proposition 3.3.1.7 we can reduce to the case where $\mathsf{Y} = \operatorname{Sp\acute{e}t} A$ is affine, and the map g factors as a composition

$$\mathsf{Y}' \to \operatorname{Sp\acute{e}t} A_0 \xrightarrow{g'} \mathsf{Y},$$

where g' is étale. Replacing Y by $\operatorname{Sp\acute{e}t} A_0$, we may assume that Y is affine. Using Proposition 3.3.1.4, we may further suppose that $\mathsf{X} = \operatorname{Sp\acute{e}t} B_0$ is affine, so that $\mathsf{X}' \simeq \operatorname{Sp\acute{e}t}(A \otimes_{A_0} B_0)$ is also affine. In this case, the desired result follows from Proposition B.2.3.5.

Now suppose that g is faithfully flat and quasi-compact and that f' is locally quasi-finite; we wish to show that f is locally quasi-finite. Using Propositions 3.3.1.4 and 3.3.1.7, we may assume that $\mathsf{Y} = \operatorname{Sp\acute{e}t} A_0$ and $\mathsf{X} = \operatorname{Sp\acute{e}t} B_0$ are affine. Replacing Y' by an étale cover if necessary, we may suppose that $\mathsf{Y}' = \operatorname{Sp\acute{e}t} A$ for some flat A_0-algebra A. In this case, the desired result again follows from Proposition B.2.3.5. □

We have the following converse to Corollary 3.3.1.5:

Proposition 3.3.1.9. *Suppose we are given morphisms of spectral Deligne-Mumford stacks*

$$\mathsf{X} \xrightarrow{f} \mathsf{Y} \xrightarrow{g} \mathsf{Z}.$$

If $g \circ f$ is of relative dimension $\leqslant d$ (locally quasi-finite), then so is f.

Proof. Using Propositions 3.3.1.4 and 3.3.1.7, we can reduce to the case where $\mathsf{X} = \operatorname{Sp\acute{e}t} C$, $\mathsf{Y} = \operatorname{Sp\acute{e}t} B$, and $\mathsf{Z} = \operatorname{Sp\acute{e}t} A$ are affine, in which case the desired result follows from Remark B.2.3.4. □

3.3.2 Zariski's Main Theorem

The essential step in the proof of Theorem 3.3.0.2 is the following:

Proposition 3.3.2.1. *Let $f : \mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}) = \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Suppose that:*

(a) *The map f is quasi-compact, separated and locally quasi-finite.*

(b) *The unit map $\mathscr{O}_{\mathcal{Y}} \to f_* \mathscr{O}_{\mathcal{X}}$ exhibits $\mathscr{O}_{\mathcal{Y}}$ as a connective cover of $f_* \mathscr{O}_{\mathcal{X}}$.*

Then f is an open immersion.

Remark 3.3.2.2. It follows from Corollary 3.2.3.3 that condition (b) of Proposition 3.3.2.1 is stable under flat base change.

The proof will require a few preliminaries.

Definition 3.3.2.3. Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks. We will say that f is *finite étale of degree n* if, for every morphism $\operatorname{Spét} R \to \mathsf{Y}$, the fiber product $\mathsf{X} \times_{\mathsf{Y}} \operatorname{Spét} R$ has the form $\operatorname{Spét} R'$, where R' is a étale R-algebra which is locally free of degree n.

Example 3.3.2.4. Let $f : \mathsf{X} \to \mathsf{Y}$ be a finite étale map of spectral Deligne-Mumford stacks of degree n. Then f is separated, so the configuration stack $\operatorname{Conf}^n_{\mathsf{Y}}(\mathsf{X})$ is defined and carries an action of the symmetric group Σ_n. We claim that the canonical map $\operatorname{Conf}^n_{\mathsf{Y}}(\mathsf{X})/\Sigma_n \to \mathsf{Y}$ is an equivalence. To prove this, we may work locally on Y and thereby reduce to the case where $\mathsf{Y} = \operatorname{Spét} R$ and $\mathsf{X} = \operatorname{Spét} R^n$. In this case, the result follows from a simple calculation (note that $\operatorname{Conf}^n_{\mathsf{Y}}(\mathsf{X}) \simeq \amalg_{\sigma \in \Sigma_n} \operatorname{Spét} R$).

Proposition 3.3.2.5. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a finite étale morphism of degree $n > 0$ between spectral Deligne-Mumford stacks. Assume that Y is a spectral algebraic space and that X is affine. Then Y is affine.*

Proof. Example 3.3.2.4 implies that Y can be described as the quotient $\operatorname{Conf}^n_{\mathsf{Y}}(\mathsf{X})$ by the action of the symmetric group Σ_n. Note that $\operatorname{Conf}^n_{\mathsf{Y}}(\mathsf{X})$ admits a clopen immersion (Definition 3.1.7.2) into the iterated fiber product $\mathsf{X} \times_{\mathsf{Y}} \mathsf{X} \times \cdots \times_{\mathsf{Y}} \mathsf{X}$. Since $n > 0$, we have a finite étale projection map $\mathsf{X} \times_{\mathsf{Y}} \cdots \times_{\mathsf{Y}} \mathsf{X} \to \mathsf{X}$. Since X is affine, it follows that $\mathsf{X} \times_{\mathsf{Y}} \cdots \times_{\mathsf{Y}} \mathsf{X}$ is affine and therefore $\operatorname{Conf}^n_{\mathsf{Y}}(\mathsf{X}) \simeq \operatorname{Spét} A$ is affine. To complete the proof, it will suffice to show that the action of Σ_n on $\operatorname{Spét} A$ is free, which follows from Lemma 3.2.2.6. □

Remark 3.3.2.6. Let $f : \mathsf{X} \to \mathsf{Y}$ be a finite étale map of spectral Deligne-Mumford stacks. Then f determines a decomposition $\mathsf{Y} \simeq \amalg_{n \geqslant 0} \mathsf{Y}_n$, where each of the induced maps $\mathsf{X} \times_{\mathsf{Y}} \mathsf{Y}_n \to \mathsf{Y}_n$ is finite étale of degree n.

Proof of Proposition 3.3.2.1. The assertion is local on Y; we may therefore reduce to the case where $\mathsf{Y} = \operatorname{Spét} R$ is affine (so that X is a separated spectral algebraic space). Then X is quasi-compact, so we can choose an étale surjection $u : \operatorname{Spét} A \to \mathsf{X}$. Let $\mathfrak{p} \in |\operatorname{Spec} A|$ and let $\mathfrak{q}$ be its image in $|\operatorname{Spec} R|$. We will show that there exists an open set $U_{\mathfrak{q}} \subseteq |\operatorname{Spec} R|$ such that, if $\mathsf{U}_{\mathfrak{q}}$ denotes the corresponding open substack of Y, then the projection map

$\mathsf{X} \times_{\mathsf{Y}} \mathsf{U}_{\mathfrak{q}} \to \mathsf{U}_{\mathfrak{q}}$ is an equivalence. Let $U = \bigcup_{\mathfrak{p} \in |\operatorname{Spec} A|} U_{\mathfrak{q}}$ and let U be the corresponding open substack of Y. Then the projection $\mathsf{X} \times_{\mathsf{Y}} \mathsf{U} \to \mathsf{U}$ is an equivalence. Moreover, the open substack $\mathsf{U} \times_{\mathsf{Y}} \operatorname{Spét} A$ is equivalent to $\operatorname{Spét} A$. Since u is surjective, it follows that $\mathsf{X} \times_{\mathsf{Y}} \mathsf{U} \simeq \mathsf{X}$, so that we can identify f with the open immersion $\mathsf{U} \hookrightarrow \mathsf{Y}$.

It remains to construct the open set $U_{\mathfrak{q}}$. Let κ denote the residue field of $\pi_0 R$ at the prime ideal $\mathfrak{q}$. Since f is locally quasi-finite and u is étale, the map of commutative rings $\pi_0 R \to \pi_0 A$ is quasi-finite. It follows from Corollary B.3.4.5 that the map $\pi_0 R \to \kappa$ factors as a composition $\pi_0 R \to R'_0 \to \kappa$, where R'_0 is an étale $(\pi_0 R)$-algebra and $(\pi_0 A) \otimes_{\pi_0 R} R'_0$ decomposes as a product $B'_0 \times B''_0$, where B' is a finite R'_0-module and $\operatorname{Tor}_0^{R'_0}(B'', \kappa) \simeq 0$. Using Theorem HA.7.5.0.6 , we can choose an étale R-algebra R' with $\pi_0 R' \simeq R'_0$, so that $A \otimes_R R'$ decomposes as a product $B' \times B''$ with $\pi_0 B' \simeq B'_0$ and $\pi_0 B'' \simeq B''_0$. Since the map $|\operatorname{Spec} R'| \to |\operatorname{Spec} R|$ is open and its image contains $\mathfrak{q}$, we can replace R by R' and thereby assume that $A \simeq B' \times B''$, where $\pi_0 B'$ is a finitely generated module over $\pi_0 R$ and $B'' \otimes_R \kappa \simeq 0$. Since $A \otimes_R \kappa \neq 0$, it follows that $B' \otimes_R \kappa \neq 0$. The composite map

$$u' : \operatorname{Spét} B' \to \operatorname{Spét} A \to \mathsf{X}$$

is étale. Since X is separated, the map u' is affine. Since $\pi_0 B'$ is finitely generated as a $\pi_0 R$-module, we deduce that u' is finite étale. Using Remark 3.3.2.6, we deduce that X admits a decomposition $\mathsf{X} \simeq \amalg_{n \geqslant 0} \mathsf{X}_n$, where each of the induced maps $\operatorname{Spét} B' \times_{\mathsf{X}} \mathsf{X}_n \to \mathsf{X}_n$ is finite étale of degree n. Each fiber product $\operatorname{Spét} B' \times_{\mathsf{X}} \mathsf{X}_n$ is a summand of $\operatorname{Spét} B'$, and therefore affine. It follows from Proposition 3.3.2.5 that X_n is also affine for $n > 0$. Since X is quasi-compact, the stacks X_n are empty for $n \gg 0$. It follows that $\mathsf{X}' = \amalg_{n > 0} \mathsf{X}_n$ is an affine open substack of X. Note that since $\operatorname{Spét} \kappa \times_{\operatorname{Spét} R} \operatorname{Spét} B'$ is nonempty, the fiber product $\operatorname{Spét} \kappa \times_{\operatorname{Spét} R} \mathsf{X}'$ is also nonempty.

Using (b), we can choose an idempotent element $e \in \pi_0 R$ which vanishes on X_0 but not on X'. Since $\operatorname{Spét} \kappa \times_{\operatorname{Spét} R} \mathsf{X}' \neq \emptyset$, we must have $e \notin \mathfrak{q}$. We may therefore replace R by $R[e^{-1}]$ and thereby reduce to the case where X_0 is empty. In this case, $\mathsf{X} \simeq \mathsf{X}'$ is affine. Using (b) again, we deduce that f is an equivalence. □

Proof of Theorem 3.3.0.2. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is separated, quasi-compact, and locally quasi-finite; we wish to show that f is quasi-affine. The assertion is local on Y; we may therefore assume that $\mathsf{Y} \simeq \operatorname{Spét} R$ is affine. Let $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$, and let A be the connective cover $f_* \mathcal{O}_{\mathcal{X}} \in \operatorname{CAlg}_R$. Then f factors as a composition $\mathsf{X} \xrightarrow{f'} \operatorname{Spét} A \xrightarrow{f''} \operatorname{Spét} R$. Since f is locally quasi-finite, the morphism f' is also locally quasi-finite (Proposition 3.3.1.9). Using Proposition 3.3.2.1, we deduce that f' is an open immersion, so that X can be identified with a quasi-compact open substack of $\operatorname{Spét} A$ and is therefore quasi-affine. □

3.4 Quasi-Separated Morphisms

Recall that a scheme X is said to be *quasi-separated* if the diagonal map $X \to X \times X$ is quasi-compact. In this section, we will investigate the analogous condition in the setting of spectral Deligne-Mumford stacks (Definition 3.4.0.1). Our main result (Theorem 3.4.2.1) asserts that a spectral Deligne-Mumford stack X admits a scallop decomposition (see Definition 2.5.3.1) if and only it is is a quasi-compact, quasi-separated spectral algebraic space. From this we will deduce a number of consequences concerning the global sections functor $\Gamma(\mathsf{X}; \bullet)$ on the ∞-category $\mathrm{QCoh}(\mathsf{X})$ of quasi-coherent sheaves on X.

Definition 3.4.0.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of nonconnective spectral Deligne-Mumford stacks. We will say that f is *quasi-separated* if the diagonal map $\mathsf{X} \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ is quasi-compact. We say that a nonconnective spectral Deligne-Mumford stack X is *quasi-separated* if the map $\mathsf{X} \to \mathrm{Sp\acute{e}t}\, S$ is quasi-separated, where S denotes the sphere spectrum. In other words, X is quasi-separated if the absolute diagonal $\mathsf{X} \to \mathsf{X} \times \mathsf{X}$ is quasi-compact.

Example 3.4.0.2. If $f : \mathsf{X} \to \mathsf{Y}$ is a separated morphism of spectral Deligne-Mumford stacks. Then the diagonal map $\delta : \mathsf{X} \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ is a closed immersion, hence affine, and in particular quasi-compact. It follows that f is quasi-separated.

3.4.1 Quasi-Separatedness

We begin by summarizing some easy formal properties of Definition 3.4.0.1.

Proposition 3.4.1.1. *Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a nonconnective spectral Deligne-Mumford stack. The following conditions are equivalent:*

(1) *The nonconnective spectral Deligne-Mumford stack X is quasi-separated.*

(2) *For every $\mathbb{E}_\infty$-ring R and every pair of maps $f, g : \mathrm{Sp\acute{e}t}\, R \to \mathsf{X}$, the fiber product $\mathrm{Sp\acute{e}t}\, R \times_{\mathsf{X}} \mathrm{Sp\acute{e}t}\, R$ is quasi-compact.*

(3) *For every pair of maps $f : \mathrm{Sp\acute{e}t}\, R \to \mathsf{X}$, $g : \mathrm{Sp\acute{e}t}\, R' \to \mathsf{X}$, the fiber product $\mathrm{Sp\acute{e}t}\, R \times_{\mathsf{X}} \mathrm{Sp\acute{e}t}\, R'$ is quasi-compact.*

(4) *For every pair of étale maps maps $f : \mathrm{Sp\acute{e}t}\, R \to \mathsf{X}$, $g : \mathrm{Sp\acute{e}t}\, R' \to \mathsf{X}$, the fiber product $\mathrm{Sp\acute{e}t}\, R \times_{\mathsf{X}} \mathrm{Sp\acute{e}t}\, R'$ is quasi-compact.*

(5) *For every pair of affine objects $U, V \in \mathcal{X}$, the product $U \times V \in \mathcal{X}$ is quasi-compact.*

(6) *For every pair of quasi-compact objects $U, V \in \mathcal{X}$, the product $U \times V \in \mathcal{X}$ is quasi-compact.*

Proof. The implications (1) ⇔ (2) ⇐ (3) ⇒ (4) ⇔ (5) ⇐ (6) are obvious. We next prove that (2) ⇒ (3). Suppose we are given a pair of maps $f : \mathrm{Spét}\, R \to \mathsf{X}$, $g : \mathrm{Spét}\, R' \to \mathsf{X}$. Let $A = R \otimes R'$, so that f and g define maps $f', g' : \mathrm{Spét}\, A \to \mathsf{X}$. Note that

$$\mathrm{Spét}\, R \times_{\mathsf{X}} \mathrm{Spét}\, R' \simeq (\mathrm{Spét}\, A \times_{\mathsf{X}} \mathrm{Spét}\, A) \times_{\mathrm{Spét}(A \otimes A)} \mathrm{Spét}\, A.$$

If (2) is satisfied, then there exists an étale surjectiion $\mathrm{Spét}\, B \to \mathrm{Spét}\, A \times_{\mathsf{X}} \mathrm{Spét}\, A$. It follows that there is an étale surjection

$$\mathrm{Spét}(B \otimes_{A \otimes A} A) \to \mathrm{Spét}\, R \times_{\mathsf{X}} \mathrm{Spét}\, R',$$

so that $\mathrm{Spét}\, R \times_{\mathsf{X}} \mathrm{Spét}\, R'$ is quasi-compact.

We next show that (4) ⇒ (3). Assume we are given arbitrary maps $f : \mathrm{Spét}\, R \to \mathsf{X}$ and $g : \mathrm{Spét}\, R' \to \mathsf{X}$. Choose a faithfully flat étale map $R \to A$ such that the composite map $\mathrm{Spét}\, A \to \mathrm{Spét}\, R \xrightarrow{f} \mathsf{X}$ factors through some étale map $\mathrm{Spét}\, B \to \mathsf{X}$, and a faithfully flat étale map $R' \to A'$ such that the composite map $\mathrm{Spét}\, A' \to \mathrm{Spét}\, R' \xrightarrow{g} \mathsf{X}$ factors through an étale map $\mathrm{Spét}\, B' \to \mathsf{X}$. Condition (4) implies that $\mathrm{Spét}\, B \times_{\mathsf{X}} \mathrm{Spét}\, B'$ is quasi-compact, so there is an étale surjection $\mathrm{Spét}\, T \to \mathrm{Spét}\, B \times_{\mathsf{X}} \mathrm{Spét}\, B'$. It follows that the composite map

$$\mathrm{Spét}(T \otimes_{B \otimes B'} (A \otimes A'')) \to \mathrm{Spét}\, A \times_{\mathsf{X}} \mathrm{Spét}\, A' \to \mathrm{Spét}\, R \times_{\mathsf{X}} \mathrm{Spét}\, R'$$

is an étale surjection, so that $\mathrm{Spét}\, R \times_{\mathsf{X}} \mathrm{Spét}\, R'$ is also quasi-compact.

We complete the proof by showing that (5) ⇒ (6). Assume $U, V \in \mathcal{X}$ are quasi-compact. Then there exist effective epimorphisms $U' \to U$ and $V' \to V$, where U' and V' are affine. Condition (5) implies that $U' \times V'$ is quasi-compact. Since we have an effective epimorphism $U' \times V' \to U \times V$, it follows that $U \times V$ is quasi-compact. □

Proposition 3.4.1.2. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a quasi-compact, quasi-separated spectral algebraic space. Then the ∞-topos $\mathcal{X}$ is coherent.*

Proof. We first suppose that X is separated. Using Corollary A.2.1.4, it suffices to show that if we are given affine objects $U, V \in \mathcal{X}$, then the product $U \times V \in \mathcal{X}$ is coherent. Let U and V be the spectral Deligne-Mumford stacks determined by U and V. We claim that $U \times V$ is affine. This follows from Theorem 3.1.2.1, since $\mathsf{Y} \simeq \mathsf{U} \times_{\mathsf{X}} \mathsf{V}$ admits a closed immersion into the affine spectral Deligne-Mumford stack $\mathsf{U} \times \mathsf{V}$.

We now treat the general case. Once again, it suffices to show that if $U, V \in \mathcal{X}$ are affine, then $U \times V$ is coherent. By the first part of the proof, we are reduced to proving that $\mathsf{U} \times_{\mathsf{X}} \mathsf{V}$ is separated. For this, it suffices to show that the map $\mathsf{U} \times_{\mathsf{X}} \mathsf{V} \to \mathsf{U} \times \mathsf{V}$ is separated, which follows from Example 3.2.1.9 (since X is a spectral algebraic space). □

Proposition 3.4.1.3. *Let X be a quasi-separated spectral algebraic space. Suppose we are given étale maps $\mathrm{Spét}\, R \to \mathsf{X} \leftarrow \mathrm{Spét}\, R'$. Then the fiber product $\mathsf{Y} \simeq \mathrm{Spét}\, R \times_{\mathsf{X}} \mathrm{Spét}\, R'$ is quasi-affine.*

Proof. Since X is quasi-separated, the spectral Deligne-Mumford stack Y is quasi-compact. Because X is a spectral algebraic space, the canonical map

$$\mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, A, \mathsf{Y}) \to \mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, A, \mathrm{Sp\acute{e}t}(R \otimes R'))$$

is (-1)-truncated for any commutative ring A. In particular, $\mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, A, \mathsf{Y})$ is discrete, so that Y is a spectral algebraic space. It follows from Example 3.2.1.9 that the map Y is separated. The projection map $\mathsf{Y} \to \mathrm{Sp\acute{e}t}\, R$ is étale and therefore locally quasi-finite. It follows from Theorem 3.3.0.2 that Y is quasi-affine. □

Remark 3.4.1.4. In the situation of Proposition 3.4.1.3, Remark 2.4.1.2 implies that the fiber product $\mathrm{Sp\acute{e}t}\, R \times_{\mathsf{X}} \mathrm{Sp\acute{e}t}\, R'$ is schematic. It follows that the full subcategory of SpDM spanned by the quasi-separated, 0-truncated spectral algebraic spaces is equivalent to the category of algebraic spaces introduced in [117].

3.4.2 Existence of Scallop Decompositions (Quasi-Separated Case)

We can now state the main result of this section.

Theorem 3.4.2.1. *Let $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ be a spectral Deligne-Mumford stack. Then Y admits a scallop decomposition if and only if it is a quasi-compact, quasi-separated spectral algebraic space.*

We defer the proof of Theorem 3.4.2.1 until later in this section. First, let us summarize some of its consequences.

Corollary 3.4.2.2. *Let $f : \mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to \mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ be a morphism of spectral Deligne-Mumford stacks. Assume that f is a relative spectral algebraic space which is quasi-compact and quasi-separated. Then:*

(1) *The pushforward functor $f_* : \mathrm{Mod}_{\mathscr{O}_{\mathcal{X}}} \to \mathrm{Mod}_{\mathscr{O}_{\mathcal{Y}}}$ carries quasi-coherent sheaves to quasi-coherent sheaves.*

(2) *The induced functor $\mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ commutes with small colimits.*

(3) *For every pullback diagram*

$$\begin{array}{ccc} \mathsf{X}' & \xrightarrow{g'} & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \xrightarrow{g} & \mathsf{Y}, \end{array}$$

the associated diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{Y}) & \xrightarrow{f^*} & \mathrm{QCoh}(\mathsf{X}) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{Y}') & \xrightarrow{f'^*} & \mathrm{QCoh}(\mathsf{X}') \end{array}$$

is right adjointable. In other words, for every object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$, the canonical map $\lambda : g^* f_* \mathscr{F} \to f'_* g'^* \mathscr{F}$ is an equivalence in $\mathrm{QCoh}(\mathsf{Y}')$.

Proof. Combine Theorem 3.2.3.1 with Propositions 2.5.4.3 and 2.5.4.5. □

Corollary 3.4.2.3. *Let X be a quasi-compact, quasi-separated spectral algebraic space. Then there exists an integer n such that the global sections functor $\Gamma : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{Sp}$ carries $\mathrm{QCoh}(\mathsf{X})_{\geqslant 0}$ into $\mathrm{Sp}_{\geqslant -n}$.*

Proof. Combine Proposition 2.5.4.4 with Theorem 3.4.2.1. □

Corollary 3.4.2.4. *Let X be a quasi-separated spectral algebraic space. If X is nonempty, then there exists an open immersion $j : \mathrm{Sp\acute{e}t}\, R \to \mathsf{X}$ for some nonzero connective $\mathbb{E}_\infty$-ring R.*

Proof. Replacing X by an open substack if necessary, we may suppose that X is quasi-compact. Choose a scallop decomposition $\mathsf{U}_0 \to \mathsf{U}_1 \to \cdots \to \mathsf{U}_n$ of X. Let i be the smallest integer such that U_i is nonempty. Then U_i is an affine open substack of X. □

Another consequence of Theorem 3.4.2.1 is that it is possible to choose a "Nisnevich neighborhood" around any point of quasi-separated spectral algebraic space.

Corollary 3.4.2.5. *Let Y be a quasi-separated spectral algebraic space. Let κ be a field, and suppose we are given a map $\eta : \mathrm{Sp\acute{e}t}\, \kappa \to \mathsf{Y}$. Then η admits a factorization*

$$\mathrm{Sp\acute{e}t}\, \kappa \xrightarrow{\eta'} \mathrm{Sp\acute{e}t}\, R \xrightarrow{\eta''} \mathsf{Y},$$

where η' is étale.

Remark 3.4.2.6 (Projection Formula)**.** Let $f : \mathsf{X} \to \mathsf{Y}$ be a quasi-compact, quasi-separated morphism of spectral Deligne-Mumford stacks, and assume that $\mathrm{Sp\acute{e}t}\, R \times_{\mathsf{Y}} \mathsf{X}$ is a spectral algebraic space for every map $\mathrm{Sp\acute{e}t}\, R \to \mathsf{Y}$. Suppose we are given quasi-coherent sheaves $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ and $\mathscr{G} \in \mathrm{QCoh}(\mathsf{Y})$. The counit map $f^* f_* \mathscr{F} \to \mathscr{F}$ induces a morphism $f^*(f_* \mathscr{F} \otimes \mathscr{G}) \simeq f^* f_* \mathscr{F} \otimes f^* \mathscr{G} \to \mathscr{F} \otimes f^* \mathscr{G}$, which is adjoint to a map $\theta : f_* \mathscr{F} \otimes \mathscr{G} \to f_*(\mathscr{F} \otimes f^* \mathscr{G})$. We claim that θ is an equivalence. To prove this, we may work locally on Y and thereby reduce to the case where $\mathsf{Y} = \mathrm{Sp\acute{e}t}\, R$ is affine. The collection of those objects $\mathscr{G} \in \mathrm{QCoh}(\mathsf{Y}) \simeq \mathrm{Mod}_R$ for which θ is an equivalence is stable under shifts and colimits in $\mathrm{QCoh}(\mathsf{Y})$. It will therefore suffice to show that θ is an equivalence in the special case where $\mathscr{G}$ corresponds to the unit object $R \in \mathrm{Mod}_R \simeq \mathrm{QCoh}(\mathsf{Y})$, which is obvious.

3.4.3 The Proof of Theorem 3.4.2.1

Our proof of Theorem 3.4.2.1 will require a number of preliminaries.

Lemma 3.4.3.1. *Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a quasi-affine spectral Deligne-Mumford stack acted on by a finite group G. Assume that the action of G is free in the following sense: for every nonzero commutative ring R, G acts freely on the set $\pi_0 \operatorname{Map}_{\mathrm{SpDM}}(\operatorname{Sp\acute{e}t} R, \mathsf{X})$. Then there exist a finite collection of G-equivariant (-1)-truncated objects $\{U_i \in \mathcal{X}\}_{1 \leqslant i \leqslant n}$ with the following properties:*

(1) *For $1 \leqslant i \leqslant n$, let U_i denote the open substack $(\mathcal{X}_{/U_i}, \mathcal{O}_{\mathcal{X}} |U_i)$ of X. Then each of the quotients U_i / G is affine.*

(2) *The objects U_i cover $\mathcal{X}$. That is, if $\mathbf{1}$ denotes a final object of $\mathcal{X}$, then the canonical map $\amalg_{1 \leqslant i \leqslant n} U_i \to \mathbf{1}$ is an effective epimorphism.*

Proof. Let R denote the connective cover of the $\mathbb{E}_\infty$-ring $\Gamma(\mathcal{X}; \mathcal{O}_{\mathcal{X}}) \simeq \mathcal{O}_{\mathcal{X}}(\mathbf{1})$. Since X is quasi-affine, the canonical map $j : \mathsf{X} \to \operatorname{Sp\acute{e}t} R$ is an open immersion (Proposition 2.4.1.3), classified by some quasi-compact open subset $U \subseteq |\operatorname{Spec} R|$. Then $U = \{\mathfrak{p} \in |\operatorname{Spec} R| : I \nsubseteq \mathfrak{p}\}$ for some radical ideal $I \subseteq \pi_0 R$. Note that the finite group G acts on the commutative ring $\pi_0 R$ and the ideal I is G-invariant. For every point $\mathfrak{p} \in U$, none of the prime ideals $\{\sigma(\mathfrak{p})\}_{\sigma \in G}$ contains I. Consequently, there exists an element $x \in I$ such that $\sigma(x) \notin \mathfrak{p}$ for each $\sigma \in G$. Replacing x by $\prod_{\sigma \in G} \sigma(x)$ if necessary, we may suppose that x is G-invariant. Let $U_{\mathfrak{p}} = \{\mathfrak{q} \in |\operatorname{Spec} R| : x \notin \mathfrak{q}\}$. Then $U_{\mathfrak{p}}$ is an open subset of U containing the point $\mathfrak{p}$. The collection of open sets $\{U_{\mathfrak{p}}\}_{\mathfrak{p} \in U}$ is an open covering of U. Since U is quasi-compact, there exists a finite subcovering by open sets $U_{\mathfrak{p}_1}, \ldots, U_{\mathfrak{p}_n}$, which we can identify with (-1)-truncated objects $U_1, \ldots, U_n \in \mathcal{X}$. It is clear that these objects satisfy condition (2). To verify (1), we note that each of the open substacks $\mathsf{U}_i = (\mathcal{X}_{/U_i}, \mathcal{O}_{\mathcal{X}} |U_i)$ of X has the form $|\operatorname{Spec} R[x^{-1}]|$ for some G-invariant element $x \in \pi_0 R$. Since G acts freely on X, it also acts freely on the open substack U_i, so that U_i / G is affine by virtue of Lemma 3.4.3.1. □

Lemma 3.4.3.2. *Let $u : \mathsf{X} \to \mathsf{Y}$ be a map of spectral algebraic spaces. If X is separated, then u is separated.*

Proof. The map u factors as a composition $\mathsf{X} \xrightarrow{u'} \mathsf{X} \times \mathsf{Y} \xrightarrow{u''} \mathsf{Y}$. Since X is separated, the morphism u'' is separated. The morphism u' is a pullback of the diagonal map $\delta : \mathsf{Y} \to \mathsf{Y} \times \mathsf{Y}$. Since Y is a spectral algebraic space, Example 3.2.1.9 implies that δ is separated. It follows that u' is separated, so that $u = u'' \circ u'$ is also separated. □

Lemma 3.4.3.3. *Let $j : \mathsf{U} \to \mathsf{X}$ be a map of spectral Deligne-Mumford stacks. Assume that j is separated, quasi-compact, and that for every map $\operatorname{Sp\acute{e}t} \kappa \to \mathsf{X}$ where κ is a field, the fiber product $\mathsf{U} \times_{\mathsf{X}} \operatorname{Sp\acute{e}t} \kappa$ is either empty or equivalent to $\operatorname{Sp\acute{e}t} \kappa$. Then j is an open immersion.*

Proof. The assertion is local on X, so we may assume that X is affine. In this case, Theorem 3.3.0.2 implies that U is quasi-affine. Choose a covering of U by affine open substacks U_i, and for each index i let V_i be the open substack of X given by the image of U_i. Then each V_i is quasi-affine and therefore a separated spectral algebraic space. Since U_i is affine, the maps $u_i : \mathsf{U}_i \to \mathsf{V}_i$ are affine and étale. Our condition on the fibers of j guarantee that each u_i is finite étale of degree 1 and therefore an equivalence. It follows that j induces an equivalence from U to the open substack of X given by the union of the open substacks V_i. □

We will say that a diagram of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \widetilde{\mathsf{U}} & \xrightarrow{j} & \widetilde{\mathsf{Y}} \\ \downarrow g & & \downarrow \\ \mathsf{U} & \longrightarrow & \mathsf{Y} \end{array}$$

is an *excision square* if it is a pushout square, where j is an open immersion and g is étale (see Definition 2.5.2.2).

Lemma 3.4.3.4. *Let Y be a spectral Deligne-Mumford stack. Suppose that there exists an excision square of spectral Deligne-Mumford stacks σ :*

$$\begin{array}{ccc} \widetilde{\mathsf{U}} & \longrightarrow & \widetilde{\mathsf{Y}} \\ \downarrow & & \downarrow \\ \mathsf{U} & \longrightarrow & \mathsf{Y} \end{array}$$

where U is a quasi-compact quasi-separated spectral algebraic space, $\widetilde{\mathsf{Y}}$ is affine, and $\widetilde{\mathsf{U}}$ is quasi-compact. Then Y is a quasi-compact quasi-separated spectral algebraic space.

Proof. The map $\mathsf{U} \amalg \widetilde{\mathsf{Y}} \to \mathsf{Y}$ is an étale surjection. Since $\widetilde{\mathsf{Y}}$ and U are quasi-compact, it follows immediately that Y is quasi-compact. We next prove that Y is quasi-separated. Choose maps $\mathsf{V}_0, \mathsf{V}_1 \to \mathsf{Y}$, where V_0 and V_1 are affine. We wish to prove that the fiber product $\mathsf{V}_0 \times_{\mathsf{Y}} \mathsf{V}_1$ is quasi-compact. Passing to an étale covering of V_0 and V_1 if necessary we may suppose that the maps $\mathsf{V}_i \to \mathsf{Y}$ factor through either U or $\widetilde{\mathsf{Y}}$. There are three cases to consider:

(*a*) Suppose that both of the maps $\mathsf{V}_i \to \mathsf{Y}$ factor through U. Then $\mathsf{V}_0 \times_{\mathsf{Y}} \mathsf{V}_1 \simeq \mathsf{V}_0 \times_{\mathsf{U}} \mathsf{V}_1$ is quasi-compact by virtue of our assumption that U is quasi-separated.

(*b*) Suppose that the map $\mathsf{V}_0 \to \mathsf{Y}$ factors through U and the map $\mathsf{V}_1 \to \mathsf{Y}$ factors through $\widetilde{\mathsf{Y}}$.

$$\mathsf{V}_0 \times_{\mathsf{Y}} \mathsf{V}_1 \simeq \mathsf{V}_0 \times_{\mathsf{U}} (\mathsf{U} \times_{\mathsf{Y}} \mathsf{V}_1) \simeq \mathsf{V}_0 \times_{\mathsf{U}} (\widetilde{\mathsf{U}} \times_{\widetilde{\mathsf{Y}}} \mathsf{V}_1).$$

Since $\widetilde{\mathsf{U}}$ is quasi-compact and $\widetilde{\mathsf{Y}}$ is quasi-separated, the fiber product $\widetilde{\mathsf{U}} \times_{\widetilde{\mathsf{Y}}} \mathsf{V}_1$ is quasi-compact. Using the quasi-separateness of U we deduce that $\mathsf{V}_0 \times_{\mathsf{Y}} \mathsf{V}_1$ is quasi-compact.

(c) Suppose that both of the maps $\mathsf{V}_i \to \mathsf{Y}$ factor through $\widetilde{\mathsf{Y}}$. Since σ is an excision square, the map

$$\widetilde{\mathsf{Y}} \amalg (\widetilde{\mathsf{U}} \times_{\mathsf{Y}} \widetilde{\mathsf{U}}) \to \widetilde{\mathsf{Y}} \times_{\mathsf{Y}} \widetilde{\mathsf{Y}}$$

is an étale surjection. We therefore obtain an étale surjection

$$(\mathsf{V}_0 \times_{\widetilde{\mathsf{Y}}} \mathsf{V}_1) \amalg ((\mathsf{V}_0 \times_{\widetilde{\mathsf{Y}}} \widetilde{\mathsf{U}}) \times_{\mathsf{U}} (\mathsf{V}_1 \times_{\widetilde{\mathsf{Y}}} \widetilde{\mathsf{U}})) \to \mathsf{V}_0 \times_{\mathsf{Y}} \mathsf{V}_1 .$$

The fiber product $\mathsf{V}_0 \times_{\widetilde{\mathsf{Y}}} \mathsf{V}_1$ is affine and therefore quasi-compact. Since $\widetilde{\mathsf{U}}$ is quasi-compact, the fiber products $\mathsf{V}_i \times_{\widetilde{\mathsf{Y}}} \widetilde{\mathsf{U}}$ are quasi-compact. Using the quasi-separateness of U, we deduce that the fiber product $(\mathsf{V}_0 \times_{\widetilde{\mathsf{Y}}} \widetilde{\mathsf{U}}) \times_{\mathsf{U}} (\mathsf{V}_1 \times_{\widetilde{\mathsf{Y}}} \widetilde{\mathsf{U}})$ is quasi-compact, so that $\mathsf{V}_0 \times_{\mathsf{Y}} \mathsf{V}_1$ is also quasi-compact.

It remains to prove that Y is a spectral algebraic space. We wish to show that the mapping space $\mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{Y})$ is discrete for every commutative ring R. For every map $f : \mathrm{Sp\acute{e}t}\, R \to \mathsf{Y}$, the fiber product $\mathsf{U} \times_{\mathsf{Y}} \mathrm{Sp\acute{e}t}\, R$ is an open substack of $\mathrm{Sp\acute{e}t}\, R$ corresponding to an open subset $V_f \subseteq |\operatorname{Spec} R|$. Fix an open set $V \subseteq |\operatorname{Spec} R|$, and let $\mathrm{Map}^V_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{Y})$ denote the summand of $\mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{Y})$ spanned by those maps f with $V_f = V$. Then $\mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{Y}) \simeq \amalg_V \mathrm{Map}^V_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{Y})$, so it will suffice to show that each $\mathrm{Map}^V_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{Y})$ is discrete.

Let V denote the open substack of $\mathrm{Sp\acute{e}t}\, R$ corresponding to V. Write $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ and $\mathrm{Sp\acute{e}t}\, R = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$, so we can identify V with a (-1)-truncated object of $\mathcal{X}$. The étale map $\widetilde{\mathsf{Y}} \to \mathsf{Y}$ determines an object $\widetilde{Y} \in \mathcal{Y}$. Every map $f : \mathrm{Sp\acute{e}t}\, R \to \mathsf{Y}$ determines an object $f^* \widetilde{Y} \in \mathcal{X}$. This construction determines a functor θ fitting into a commutative diagram

$$\begin{array}{ccc} \mathrm{Map}^V_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{Y}) & \longrightarrow & \mathrm{Map}_{\mathrm{SpDM}}(\mathsf{V}, \mathsf{U}) \\ \downarrow \theta & & \downarrow \theta_0 \\ \mathcal{X} & \longrightarrow & \mathcal{X}_{/V} . \end{array}$$

Since $\widetilde{\mathsf{U}} \to \mathsf{U}$ is a map between spectral algebraic spaces, the homotopy fibers of the induced map

$$\mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R', \widetilde{\mathsf{U}}) \to \mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R', \mathsf{U})$$

are discrete for every étale R-algebra R'. It follows that θ_0 factors through the full subcategory $\tau_{\leqslant 0}\, \mathcal{X}_{/V} \subseteq \mathcal{X}_{/V}$ spanned by the discrete objects. Let $\mathcal{X}_0$ denote the full subcategory of $\mathcal{X}$ spanned by those objects X such that the image of X in $\mathcal{X}/V$ is a final object, so that θ factors through $\mathcal{X}_0$. Using Proposition HA.A.8.15 , we deduce that the homotopy fiber of the forgetful functor $\mathcal{X}_0 \to \mathcal{X}_{/V}$ over an object $\widetilde{V} \in \mathcal{X}_{/V}$ can be identified with the space $\mathrm{Map}_{\mathcal{X}_{/V}}(V, \widetilde{V})$; in particular, it is discrete if $\widetilde{V}$ is discrete. It follows that the map

$$\mathrm{Map}_{\mathrm{SpDM}}(\mathsf{V}, \mathsf{U}) \times_{\mathcal{X}_{/V}} \mathcal{X} \to \mathrm{Map}_{\mathrm{SpDM}}(\mathsf{V}, \mathsf{U})$$

has discrete homotopy fibers. Since the structure sheaf of V is discrete and U is a spectral algebraic space, the mapping space $\mathrm{Map}_{\mathrm{SpDM}}(\mathsf{V},\mathsf{U})$ is discrete. We conclude that the Kan complex $\mathrm{Map}_{\mathrm{SpDM}}(\mathsf{V},\mathsf{U}) \times_{\mathcal{X}_{/V}} \mathcal{X}$ is discrete. To complete the proof, it will suffice to show that the canonical map

$$\phi : \mathrm{Map}^V_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{Y}) \to \mathrm{Map}_{\mathrm{SpDM}}(\mathsf{V},\mathsf{U}) \times_{\mathcal{X}_{/V}} \mathcal{X}$$

has discrete homotopy fibers. To this end, we fix an object $\widetilde{X} \in \mathcal{X}$ having image $\widetilde{V} \in \mathcal{X}_{/V}$; we will show that the map

$$\phi_{\widetilde{X}} : \mathrm{Map}^V_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{Y}) \times_{\mathcal{X}} \{\widetilde{X}\} \to \mathrm{Map}_{\mathrm{SpDM}}(\mathsf{V},\mathsf{U}) \times_{\mathcal{X}_{/V}} \{\widetilde{V}\}$$

has discrete homotopy fibers. To prove this, we observe that $\phi_{\widetilde{X}}$ is a pullback of the map

$$\mathrm{Map}^V_{\mathrm{SpDM}}(\widetilde{\mathsf{X}},\widetilde{\mathsf{Y}}) \to \mathrm{Map}_{\mathrm{SpDM}}(\widetilde{\mathsf{V}},\widetilde{\mathsf{U}}),$$

where $\mathrm{Map}^V_{\mathrm{SpDM}}(\widetilde{\mathsf{X}},\widetilde{\mathsf{Y}})$ is the summand of $\mathrm{Map}_{\mathrm{SpDM}}(\widetilde{\mathsf{X}},\widetilde{\mathsf{Y}})$ corresponding to those maps satisfying $\widetilde{\mathsf{V}} \simeq \widetilde{\mathsf{U}} \times_{\widetilde{\mathsf{Y}}} \widetilde{\mathsf{X}}$. It now suffices to observe that $\mathrm{Map}^V_{\mathrm{SpDM}}(\widetilde{\mathsf{X}},\widetilde{\mathsf{Y}})$ and $\mathrm{Map}_{\mathrm{SpDM}}(\widetilde{\mathsf{V}},\widetilde{\mathsf{U}})$ are both discrete, since both $\widetilde{\mathsf{X}}$ and $\widetilde{\mathsf{V}}$ have discrete structure sheaves and both $\widetilde{\mathsf{Y}}$ and $\widetilde{\mathsf{U}}$ are spectral algebraic spaces. □

Proof of Theorem 3.4.2.1. If Y is a spectral Deligne-Mumford stack which admits a scallop decomposition, then Lemma 3.4.3.2 immediately implies that Y is a quasi-compact, quasi-separated spectral algebraic space (using induction on the length of the scallop decomposition). We will prove the converse using a slightly more complicated version of the proof of Proposition 3.2.3.1. Assume that Y is a quasi-compact, quasi-separated spectral algebraic space. Since Y is quasi-compact, we can choose an étale surjection $u : \mathsf{X} \to \mathsf{Y}$ where X is affine. Lemma 3.4.3.2 implies that u is separated. For $i \geqslant 1$, each of the evaluation maps $\mathrm{Conf}^i_{\mathsf{Y}}(\mathsf{X}) \to \mathsf{X}$ is étale, separated, and quasi-compact (since Y is assumed to be quasi-separated). Since X is affine, we conclude that $\mathrm{Conf}^i_{\mathsf{Y}}(\mathsf{X})$ is quasi-affine (Theorem 3.3.0.2). Using the quasi-compactness of Y, we deduce the existence of an integer n such that $\mathrm{Conf}^{n+1}_{\mathsf{Y}}(\mathsf{X})$ is empty. For $0 \leqslant i < n$, we can use Lemma 3.4.3.1 to obtain a finite covering of $\mathrm{Conf}^{n-i}_{\mathsf{Y}}(\mathsf{X})$ by Σ_i-invariant open substacks $\{\mathsf{U}_{i,j}\}_{1 \leqslant j \leqslant m_i}$ such that each quotient $\mathsf{U}_{i,j}/\Sigma_{n-i}$ is affine. Let $m = \sum_{0 \leqslant i < n} m_i$. If $1 \leqslant k \leqslant m$, then we can write $k = m_0 + \cdots + m_{i-1} + j$ where $1 \leqslant j \leqslant m_i$, and we let U_k denote the spectral Deligne-Mumford stack $\mathsf{U}_{i,j}$. For $0 \leqslant k \leqslant m$, we let V_k denote the open substack of Y given by the image of the étale map $\amalg_{1 \leqslant k' \leqslant k} \mathsf{U}_{k'} \to \mathsf{Y}$. We claim that the sequence of open immersions

$$\mathsf{V}_0 \to \mathsf{V}_1 \to \cdots \to \mathsf{V}_m$$

is a scallop decomposition of Y. Since u is surjective, it is clear that $\mathsf{V}_m \simeq \mathsf{Y}$, and V_0 is empty by construction. Let $0 < k \leqslant m$, and write $k = m_0 + \cdots + m_{i-1} + j$ for $1 \leqslant j \leqslant m_i$.

Form a pullback square

$$\begin{array}{ccc} \mathsf{W} & \longrightarrow & \mathsf{U}_{i,j}/\Sigma_{n-i} \\ \downarrow & & \downarrow q \\ \mathsf{V}_{k-1} & \longrightarrow & \mathsf{V}_k . \end{array}$$

We claim that this diagram is an excision square. To prove this, can replace Y by the reduced closed substack complementary to V_{k-1}, and thereby reduce to the case where $\mathrm{Conf}^{n-i+1}_{\mathsf{Y}}(\mathsf{X})$ is empty. In this case, we wish to show that q is an equivalence. Since q is an étale surjection by construction, it suffices to show that the map $\mathsf{U}_{i,j}/\Sigma_{n-i} \to \mathsf{Y}$ is an open immersion. In fact, we claim that the map $j : \mathrm{Conf}^{n-i}_{\mathsf{Y}}(\mathsf{X})/\Sigma_{n-i} \to \mathsf{Y}$ is an open immersion: this follows from Lemma 3.4.3.3 (since $\mathrm{Conf}^{n-i+1}_{\mathsf{Y}}(\mathsf{X})$ is empty). □

3.5 Geometric Points

Let $\mathcal{X}$ be an ∞-topos. Recall that a *point* of $\mathcal{X}$ is a geometric morphism $x^* : \mathcal{X} \to \mathcal{S}$, where $\mathcal{S}$ denotes the ∞-category of spaces. Our goal in this section is to give an explicit description of the points of $\mathcal{X}$ in the special case where $\mathcal{X}$ is the underlying ∞-topos of a spectral Deligne-Mumford stack $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$.

3.5.1 Strictly Henselian $\mathbb{E}_\infty$-Rings

We begin by introducing some terminology.

Definition 3.5.1.1. Let A be an $\mathbb{E}_\infty$-ring. We will say that A is *strictly Henselian* if the commutative ring $\pi_0 A$ is strictly Henselian, in the sense of Definition B.3.5.1.

Remark 3.5.1.2. An $\mathbb{E}_\infty$-ring A is strictly Henselian if and only if it is strictly Henselian when regarded as a sheaf of $\mathbb{E}_\infty$-rings on the ∞-topos $\mathcal{S}$, in the sense of Definition 1.4.2.1.

Remark 3.5.1.3. Let A be an $\mathbb{E}_\infty$-ring. Then A is strictly Henselian if and only if it satisfies the following condition: for every collection of étale morphisms $\{\phi_\alpha : A \to A_\alpha\}$ which generate a covering sieve on A with respect to the étale topology, one of the maps ϕ_α admits a left homotopy inverse. To prove this, we can use Theorem HA.7.5.0.6 to reduce to the case where A is discrete, in which case it follows from Proposition B.3.5.3.

Proposition 3.5.1.4. *Let $f : A \to A'$ be a map of $\mathbb{E}_\infty$-rings which induces a surjective ring homomorphism $\pi_0 A \to \pi_0 A'$. If A is strictly Henselian and $A' \neq 0$, then A' is strictly Henselian.*

Proof. This follows from Corollary B.3.3.2, since the local rings $\pi_0 A$ and $\pi_0 A'$ have the same residue field. □

3.5.2 Points of Affine Spectral Deligne-Mumford Stacks

Fix an $\mathbb{E}_\infty$-ring A. Let $\mathrm{CAlg}_A^{\text{ét}}$ denote the full subcategory of CAlg_A spanned by the $\mathbb{E}_\infty$-algebras which are étale over A, and $\mathcal{S}\mathrm{hv}_A^{\text{ét}}$ the full subcategory of $\mathrm{Fun}(\mathrm{CAlg}_A^{\text{ét}}, \mathcal{S})$ spanned by those functors which are sheaves with respect to the étale topology. By definition, a *point* of the ∞-topos $\mathcal{S}\mathrm{hv}_A^{\text{ét}}$ is a geometric morphism $f^* : \mathcal{S}\mathrm{hv}_A^{\text{ét}} \to \mathcal{S}$. Composition with the Yoneda embedding $(\mathrm{CAlg}_A^{\text{ét}})^{\mathrm{op}} \hookrightarrow \mathrm{Fun}(\mathrm{CAlg}_A^{\text{ét}}, \mathcal{S})$ induces an equivalence between the ∞-category of points of the presheaf ∞-topos $\mathrm{Fun}(\mathrm{CAlg}_A^{\text{ét}}, \mathcal{S})$ with the full subcategory $\mathrm{Ind}(\mathrm{CAlg}_A^{\text{ét}}) \subseteq \mathrm{Fun}(\mathrm{CAlg}_A^{\text{ét}})^{\mathrm{op}}, \mathcal{S})$ (Proposition HTT.6.1.5.2). We will say that an A-algebra B is Ind-*étale* if it is a filtered colimit of étale A-algebras. Since every étale A-algebra is a compact object of CAlg_A (Corollary HA.7.5.4.4), we can identify $\mathrm{Ind}(\mathrm{CAlg}_A^{\text{ét}})$ with a full subcategory $\mathrm{CAlg}_A^{\mathrm{Ind}-\text{ét}} \subseteq \mathrm{CAlg}_A$ spanned by the Ind-étale A-algebras.

Proposition 3.5.2.1. *Let A be an $\mathbb{E}_\infty$-ring, let B be an* Ind-*étale A-algebra, and let $\eta_* : \mathcal{S} \to \mathrm{Fun}(\mathrm{CAlg}_A^{ét}, \mathcal{S})$ be the geometric morphism determined by B. The following conditions are equivalent:*

(1) *The geometric morphism η_* factors through the full subcategory $\mathcal{S}\mathrm{hv}_A^{\text{ét}} \subseteq \mathrm{Fun}(\mathrm{CAlg}_A^{ét}, \mathcal{S})$.*

(2) *The $\mathbb{E}_\infty$-ring B is strictly Henselian.*

Proof. Using Proposition HTT.6.2.3.20 , we see that (1) is equivalent to the following condition:

$(*)$ Let A' be an étale$A$-algebra, and suppose we are given a finite collection of étale maps $\{A' \to A'_\alpha\}$ such that $A \to \prod_\alpha A_\alpha$ is faithfully flat (see Definition B.6.1.1). Then any A-algebra map $A' \to B$ factors (up to homotopy) through A'_α for some index α.

The implication (2) $\Rightarrow$ $(*)$ follows immediately by applying Remark 3.5.1.3 to the family of morphisms $\{B \to B \otimes_{A'} A'_\alpha\}$ (which generate a covering sieve on B with respect to the étale topology). Conversely, suppose that $(*)$ is satisfied. We will prove that B is strictly Henselian by verifying the criterion of Remark 3.5.1.3. Suppose we are given a finite collection of étale morphisms $\{B \to B_\alpha\}$ which induce a faithfully flat map $\theta : B \to \prod_\alpha B_\alpha$; we wish to show that there is an index α and a map of B-algebras $B_\alpha \to B$.

Write B as a filtered colimit of étale A-algebras $B(\beta)$. Using the structure theorem for étale morphisms (Proposition B.1.1.3), we can choose an index β and étale morphisms $\{B(\beta) \to B(\beta)_\alpha\}$ such that $B_\alpha \simeq B \otimes_{B(\beta)} B(\beta)_\alpha$. The image of the induced map

$$\amalg_\alpha |\operatorname{Spec} B(\beta)_\alpha| \to |\operatorname{Spec} B(\beta)|$$

is a quasi-compact open subset $U \subseteq |\operatorname{Spec} B(\beta)|$ (Proposition **??**) corresponding to a radical ideal $I \subseteq \pi_0 B(\beta)$. Since θ is faithfully flat, the image of I generates the unit ideal in

$\pi_0 B$. Changing our index β, we may suppose that I is the unit ideal, so that the map $B(\beta) \to \prod_\alpha B(\beta)_\alpha$ is faithfully flat. It follows from $(*)$ that there exists an index α and a map of $B(\beta)$-algebras $B(\beta)_\alpha \to B$, which determines a map of B-algebras $B_\alpha \to B$. $\square$

Proposition 3.5.2.1 yields the following description for points of an *affine* spectral Deligne-Mumford stacks:

Corollary 3.5.2.2. *Let A be an $\mathbb{E}_\infty$-ring, and let $\mathcal{C}$ be the full subcategory of $\mathrm{Fun}(\mathcal{S}\mathrm{hv}_A^{\acute{e}t}, \mathcal{S})$ spanned by those functors which are left exact and preserve small colimits. Then composition with the Yoneda embedding $(\mathrm{CAlg}_A^{\acute{e}t})^{\mathrm{op}} \hookrightarrow \mathcal{S}\mathrm{hv}_A^{\acute{e}t}$ induces an equivalence of $\mathcal{C}$ with the full subcategory of $\mathrm{Ind}(\mathrm{CAlg}_A^{\acute{e}t}) \simeq \mathrm{CAlg}_A^{\mathrm{Ind}-\acute{e}t} \subseteq \mathrm{CAlg}_A$ spanned by those A-algebras which are strictly Henselian and* Ind-*étale over A.*

Remark 3.5.2.3. Let A be an $\mathbb{E}_\infty$-ring and let $(\mathcal{X}, \mathcal{O}) = \mathrm{Sp\acute{e}t}(A)$ be the corresponding spectral Deligne-Mumford stack. Let $f^* : \mathcal{X} \to \mathcal{S}\mathrm{hv}(*) = \mathcal{S}$ be a point of $\mathcal{X}$, which corresponds under the equivalence of Corollary 3.5.2.2 to a strictly Henselian A-algebra $A' \simeq \varinjlim A'_\alpha$, where each A'_α is an étale A-algebra. Let $\mathcal{C}$ be an arbitrary compactly generated ∞-category, and let $\mathscr{F} \in \mathcal{S}\mathrm{hv}_{\mathcal{C}}(\mathcal{X}) \simeq \mathcal{S}\mathrm{hv}_{\mathcal{C}}((\mathrm{CAlg}_A^{\acute{e}t})^{\mathrm{op}})$. Unwinding the definitions, we obtain a canonical equivalence $f^* \mathscr{F} \simeq \varinjlim \mathscr{F}(A'_\alpha)$ in the ∞-category $\mathcal{S}\mathrm{hv}_{\mathcal{C}}(*) \simeq \mathcal{C}$. In particular, A' can be identified with the stalk of the structure sheaf $f^* \mathcal{O} \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{S}) \simeq \mathrm{CAlg}$.

Remark 3.5.2.4. Let A be an $\mathbb{E}_\infty$-ring and let $(\mathcal{X}, \mathcal{O}) = \mathrm{Sp\acute{e}t}(A)$. Let B be a strictly Henselian $\mathbb{E}_\infty$-ring; let us identify B with the corresponding object of $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{S})$, so that $(\mathcal{S}, B)$ is an object of $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}^{\acute{e}t}$. We then have a canonical homotopy equivalence

$$\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}^{\acute{e}t}}((\mathcal{S}, B), (\mathcal{X}, \mathcal{O})) \to \mathrm{Map}_{\mathrm{CAlg}}(A, B).$$

Under the equivalence of Corollary 3.5.2.2, this assertion translates as follows: every map of $\mathbb{E}_\infty$-rings $f : A \to B$ factors uniquely as a composition

$$A \xrightarrow{f'} A' \xrightarrow{f''} B,$$

where A' is strictly Henselian, f' is Ind-étale, and f'' is local. We will refer to A' as the *strict Henselization of A along f*.

3.5.3 Minimal Geometric Points

It is often convenient to describe points of spectral Deligne-Mumford stacks by Henselizing the spectra of separably closed fields.

Definition 3.5.3.1. Let X be a spectral Deligne-Mumford stack. A *geometric point* of X is a morphism of spectral Deligne-Mumford stacks $\eta : \mathrm{Sp\acute{e}t}\, \kappa \to \mathsf{X}$, where κ is a separably closed field. We will say that a geometric point $\eta : \operatorname{Sp\acute{e}t} \kappa \to \mathsf{X}$ is *minimal* if it factors as a composition

$$\operatorname{Sp\acute{e}t} \kappa \xrightarrow{\eta'} \operatorname{Sp\acute{e}t} A \xrightarrow{\eta''} \mathsf{X}$$

where η'' is étale and η' induces a map of commutative rings $\phi : \pi_0 A \to \kappa$ which exhibits κ as a separable algebraic extension of some residue field of $\pi_0 A$.

For each object $\mathsf{X} \in \mathrm{SpDM}$, we let $\mathrm{Pt}_{\mathrm{g}}(\mathsf{X})$ denote the full subcategory of $\mathrm{SpDM}_{/\mathsf{X}}$ spanned by the minimal geometric points $\eta : \mathsf{X}_0 \to \mathsf{X}$.

Remark 3.5.3.2. Let X be a spectral Deligne-Mumford stack and let $\eta : \operatorname{Sp\acute{e}t} \kappa \to \mathsf{X}$ be a minimal geometric point of X. For *every* factorization

$$\operatorname{Sp\acute{e}t} \kappa \xrightarrow{\eta'} \operatorname{Sp\acute{e}t} A \xrightarrow{\eta''} \mathsf{X}$$

of η where η'' is étale, the map η' exhibits κ as a separable closure of the residue field $\kappa(\mathfrak{p})$ for prime ideal $\mathfrak{p} \subseteq \pi_0 A$.

Remark 3.5.3.3. Let $\phi : \mathsf{U} \to \mathsf{X}$ be an étale map of spectral Deligne-Mumford stacks, and suppose we are given a geometric point $\eta : \operatorname{Sp\acute{e}t} \kappa \to \mathsf{U}$. Then η is a minimal geometric point of U if and only if $\phi \circ \eta$ is a minimal geometric point of X.

Remark 3.5.3.4. Suppose we are given a commutative diagram of fields

$$\begin{array}{ccccc} & & \kappa & & \\ & \swarrow^{\phi} & & \searrow^{\psi} & \\ \kappa & & \xrightarrow{\theta} & & \kappa''. \end{array}$$

If ϕ and ψ exhibit κ' and κ'' as separable closures of κ, then θ is an isomorphism. It follows that if X is a spectral Deligne-Mumford stack, then every morphism between minimal geometric points of X is an equivalence: that is, the ∞-category $\mathrm{Pt}_{\mathrm{g}}(\mathsf{X})$ is a Kan complex.

3.5.4 Comparison of Points with Geometric Points

Let $\eta : \mathsf{X}_0 \to \mathsf{X}$ be a geometric point of a connective spectral Deligne-Mumford stack $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$. Then X_0 is the spectrum of a separably closed field, so that underlying ∞-topos of X_0 is canonically equivalent to $\mathcal{S}$. Consequently, the pullback functor η^* can be viewed as a geometric morphism $\mathcal{X} \to \mathcal{S}$.

Remark 3.5.4.1. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a spectral Deligne stack. Let $U \in \mathcal{X}$ be an object of let $\mathsf{U} = (\mathcal{X}_{/U}, \mathscr{O}_{\mathcal{X}}|_U)$. The étale map of spectral Deligne-Mumford stacks $\phi : \mathsf{U} \to \mathsf{X}$ induces a map of Kan complexes $\theta : \mathrm{Pt}_{\mathrm{g}}(\mathsf{U}) \to \mathrm{Pt}_{\mathrm{g}}(\mathsf{X})$. Using Remark 3.5.3.3, we deduce that the homotopy fiber of θ over a point $\eta \in \mathrm{Pt}_{\mathrm{g}}(\mathsf{X})$ can be identified with the space $\eta^*(U) \in \mathcal{S}$.

Proposition 3.5.4.2. *Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack. The construction*

$$(\eta : \mathsf{X}_0 \to \mathsf{X}) \mapsto (\eta^* \in \mathrm{Fun}(\mathcal{X}, \mathcal{S}))$$

determines an equivalence from the ∞-category $\mathrm{Pt}_{\mathrm{g}}(\mathsf{X})$ of minimal geometric points of X to the subcategory $\mathrm{Fun}^*(\mathcal{X}, \mathcal{S})^{\simeq} \subseteq \mathrm{Fun}(\mathcal{X}, \mathcal{S})$ whose objects are functors which preserve small colimits and finite limits and whose morphisms are equivalences.

Proof. For each object $U \in \mathcal{X}$, let X_U denote the spectral Deligne-Mumford stack $(\mathcal{X}_{/U}, \mathcal{O}_{\mathcal{X}}|_U)$. We let $\mathrm{Fun}^*(\mathcal{X}_{/U}, \mathcal{S})^{\simeq}$ denote the subcategory of $\mathrm{Fun}(\mathcal{X}_{/U}, \mathcal{S})$ whose objects are functors which preserve small colimits and finite limits and whose morphisms are equivalences. For each $U \in \mathcal{X}$, we have a canonical map of Kan complexes $\mathrm{Pt}_{\mathrm{g}}(\mathsf{X}_U) \to \mathrm{Fun}(\mathcal{X}_{/U}, \mathcal{S})^{\simeq}$. Let us say that U is *good* if θ_U is a homotopy equivalence. For any morphism $U \to V$ in $\mathcal{X}$, Remark 3.5.4.1 implies that the diagram

$$\begin{array}{ccc} \mathrm{Pt}_{\mathrm{g}}(\mathsf{X}_U) & \xrightarrow{\theta_U} & \mathrm{Fun}(\mathcal{X}_{/U}, \mathcal{S})^{\simeq} \\ \downarrow & & \downarrow \\ \mathrm{Pt}_{\mathrm{g}}(\mathsf{X}_V) & \xrightarrow{\theta_V} & \mathrm{Fun}(\mathcal{X}_{/V}, \mathcal{S})^{\simeq} \end{array}$$

is a pullback square. Since colimits in $\mathcal{S}$ are universal, we conclude that for every diagram $\{U_\alpha\}$ in $\mathcal{X}$ having colimit U, the induced diagram

$$\begin{array}{ccc} \varinjlim \mathrm{Pt}_{\mathrm{g}}(\mathsf{X}_{U_\alpha}) & \longrightarrow & \varinjlim \mathrm{Fun}(\mathcal{X}_{/U_\alpha}, \mathcal{S})^{\simeq} \\ \downarrow & & \downarrow \\ \mathrm{Pt}_{\mathrm{g}}(U) & \xrightarrow{\theta_U} & \mathrm{Fun}(\mathcal{X}_{/U}, \mathcal{S})^{\simeq} \end{array}$$

is a pullback square. It follows from Proposition HTT.6.3.5.5 that the right vertical map in this diagram is a homotopy equivalence, so that the left vertical map is a homotopy equivalence as well. Consequently, if each U_α is good, then U is good. We wish to prove that every object $U \in \mathcal{X}$ is good. By virtue of Proposition 1.4.7.9, it will suffice to treat the case where U is affine. Replacing X by X_U, we may assume that $\mathsf{X} = \mathrm{Sp\acute{e}t}\, A$ for some connective $\mathbb{E}_\infty$-ring A.

Let $\mathsf{X}_0 = \mathrm{Sp\acute{e}t}(\pi_0 A)$. The underlying ∞-topoi of X and X_0 are the same, and the canonical map

$$\mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, \kappa, \mathsf{X}_0) \to \mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, \kappa, \mathsf{X})$$

is a homotopy equivalence for every discrete $\mathbb{E}_\infty$-ring κ. We may therefore replace A by $\pi_0 A$ and thereby reduce to the case where A is a discrete $\mathbb{E}_\infty$-ring.

Let $\mathrm{Fun}^*(\mathcal{X}, \mathcal{S})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{X}, \mathcal{S})$ spanned by those functors which preserve small colimits and finite limits. Using Corollary 3.5.2.2, we can identify

$\mathrm{Fun}^*(\mathcal{X}, \mathcal{S})$ with the full subcategory of $\mathcal{C} \subseteq \mathrm{CAlg}_A$ whose objects are A-algebras B which are strictly Henselian and can be written as a filtered colimit of étale A-algebras. We can identify $\mathrm{Pt_g}(\mathsf{X})$ with the groupoid consisting of those A-algebras κ which are separable closures of some residue field of A. We will denote the functor $\theta : \mathrm{Pt_g}(\mathsf{X}) \to \mathcal{C}$ by $\kappa \mapsto A_\kappa$. This construction can be characterized by the following universal property: for every object $\kappa \in \mathrm{Pt_g}(\mathsf{X})$ and every étale A-algebra B, we have a canonical bijection

$$\mathrm{Hom}_A(B, A_\kappa) \simeq \mathrm{Hom}_k(B \otimes_A \kappa, \kappa) \simeq \mathrm{Hom}_A(B, \kappa).$$

Here $\mathrm{Hom}_R(R', R'')$ denotes the set of R-algebra maps from R' to R''. Note that this bijection extends naturally to the case where B is a filtered colimit of étale A-algebras.

For every object $B \in \mathcal{C}$, let $\mathfrak{p}_B$ denote the inverse image in A of the maximal ideal of B. Any morphism $B \to B'$ in $\mathcal{C}$ determines an inclusion of prime ideals $\mathfrak{p}_{B'} \subseteq \mathfrak{p}_B$. We let $\mathcal{C}_0$ denote the subcategory of $\mathcal{C}$ consisting of those morphisms $B \to B'$ for which $\mathfrak{p}_B = \mathfrak{p}_{B'}$. Since $\mathcal{C}_0$ contains all equivalences in $\mathcal{C}$, the map θ factors through $\mathcal{C}_0$. We will show that θ induces an equivalence $\mathrm{Pt_g}(\mathsf{X}) \to \mathcal{C}_0$. From this, it will follow that $\mathcal{C}_0$ is a Kan complex, hence that $\mathcal{C}_0$ is the largest Kan complex contained in $\mathcal{C}$ and therefore that θ exhibits $\mathrm{Pt_g}(\mathsf{X})$ as equivalent to the largest Kan complex contained in $\mathcal{C}$.

Let $\kappa \in \mathrm{Pt_g}(\mathsf{X})$, and let $\mathfrak{p} = \mathfrak{p}_{A_k}$. Note that $\mathrm{Hom}_A(A[u^{-1}], A_\kappa)$ is empty if and only if $u \in \mathfrak{p}$. It follows that $\mathfrak{p}$ is the kernel of the map $A \to \kappa$, so that κ is a separable closure of the residue field $\kappa(\mathfrak{p})$ of A. Since A_κ is a filtered colimit of étale A-algebras, the quotient $(A_\kappa/\mathfrak{p}A_\kappa) \simeq A_\kappa \otimes_A \kappa(\mathfrak{p})$ is a filtered colimit of finite étale algebras over $\kappa(\mathfrak{p})$. Since A_κ is strictly Henselian, the quotient $A_\kappa/\mathfrak{p}A_\kappa$ is also strictly Henselian and therefore a separable closure of the residue field $\kappa(\mathfrak{p})$. Let κ' be another separable closure of $\kappa(\mathfrak{p})$. The canonical map

$$v : \mathrm{Hom}_A(\kappa, \kappa') \simeq \mathrm{Map}_{\mathrm{Pt_g}(\mathsf{X})}(\kappa, \kappa') \to \mathrm{Map}_{\mathcal{C}}(A_\kappa, A_{\kappa'}) \simeq \mathrm{Hom}_A(A_\kappa, A_{\kappa'}) \simeq \mathrm{Hom}_A(A_\kappa, \kappa')$$

is given by composition with a map $v_0 : A_\kappa/\mathfrak{p}A_\kappa \to \kappa$. Here v_0 is a $\kappa(\mathfrak{p})$-algebra map between separable closures of $\kappa(\mathfrak{p})$, and therefore an isomorphism. It follows that v is bijective, which proves that $\theta : \mathrm{Pt_g}(\mathsf{X}) \to \mathcal{C}_0$ is fully faithful.

It remains to prove that θ is essentially surjective. Let $B \in \mathcal{C}$ and let $\mathfrak{p} = \mathfrak{p}_B$. Then $\kappa = B/\mathfrak{p}B \simeq B \otimes_A \kappa(\mathfrak{p})$ is a filtered colimit of étale $\kappa(\mathfrak{p})$-algebras. Since κ is strictly Henselian, we deduce that κ is a separable closure of $\kappa(\mathfrak{p})$. In particular, $\mathfrak{p}B$ is the maximal ideal of B, and we can identify κ with an object of $\mathrm{Pt_g}(\mathsf{X})$. For every étale A-algebra B', we have a canonical map

$$\mathrm{Hom}_A(B', B) \to \mathrm{Hom}_A(B', B/\mathfrak{p}B) = \mathrm{Hom}_A(B', \kappa) \simeq \mathrm{Hom}_A(B', A_\kappa).$$

Since B is Henselian, this map is bijective. Since B and A_κ can both be obtained as a filtered colimit of étale A-algebras, we conclude that $B \simeq A_\kappa$. □

Remark 3.5.4.3. Let X be a spectral Deligne-Mumford stack, and suppose we are given a morphism $\eta : \text{Spét}\, \kappa \to \mathsf{X}$, where κ is a separably closed field. Then η factors as a composition $\text{Spét}\, \kappa \xrightarrow{\eta'} \mathsf{U} \xrightarrow{\eta''} \mathsf{X}$, where U is affine and η'' is étale. Write $\mathsf{U} = \text{Spét}\, A$, so that η' determines a map of $\mathbb{E}_\infty$-rings $A \to \kappa$. The image of the map of commutative rings $\pi_0 A \to \kappa$ generates a subfield of $\kappa' \subseteq \kappa$. Let $\kappa_0 \subseteq \kappa$ denote the separable closure of κ' in κ. Then η factors as a composition $\text{Spét}\, \kappa \to \text{Spét}\, \kappa_0 \xrightarrow{\eta_0} \mathsf{X}$, where η_0 is a minimal geometric point of X and the inclusion $\kappa_0 \subseteq \kappa$ is an extension of separably closed fields.

3.5.5 Existence of Geometric Points

Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack. We will say that X is *empty* if $\mathcal{X}$ is a contractible Kan complex (that is, if $\mathcal{X}$ is equivalent to the ∞-category of sheaves on the empty topological space). Otherwise, we will say that X is *nonempty*.

Remark 3.5.5.1. A spectral Deligne-Mumford stack X is empty if and only if it is an initial object of the ∞-category SpDM of spectral Deligne-Mumford stacks.

Lemma 3.5.5.2. *Let X be a spectral Deligne-Mumford stack. The following conditions are equivalent:*

(1) *The spectral Deligne-Mumford stack X is not empty.*

(2) *There exists a nonzero connective $\mathbb{E}_\infty$-ring A and an étale map $\text{Spét}\, A \to \mathsf{X}$.*

(3) *There exists a minimal geometric point $\text{Spét}\, \kappa \to \mathsf{X}$.*

Proof. The implications (2) ⇒ (3) and (3) ⇒ (1) are obvious. We prove that (1) ⇒ (2). Assume that (1) is satisfied. Write $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$, so that there exists an object of $\mathcal{X}$ which is not initial. It follows that there exists an affine object $U \in \mathcal{X}$ which is not initial. Then $(\mathcal{X}_{/U}, \mathcal{O}_{\mathcal{X}}|_U)$ is equivalent to $\text{Spét}\, A$ for some connective $\mathbb{E}_\infty$-ring A. We therefore have an étale map $\text{Spét}\, A \to \mathsf{X}$. Since U is not an initial object of $\mathcal{X}$, A is nonzero; this proves (2). □

Remark 3.5.5.3. The implication (1) ⇒ (3) of Lemma 3.5.5.2 can also be deduced from Proposition 3.5.4.2 and Theorem A.4.0.5.

Proposition 3.5.5.4. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. The following conditions are equivalent:*

(1) *Let $\mathcal{X}$ and $\mathcal{Y}$ denote the underlying ∞-topoi of X and Y, respectively. Then every geometric morphism of ∞-topoi $\eta_* : \mathcal{S} \to \mathcal{Y}$ factors through the geometric morphism $f_* : \mathcal{X} \to \mathcal{Y}$.*

(2) *For every field* κ *and every map* $\eta : \mathrm{Sp\acute{e}t}\,\kappa \to \mathsf{Y}$*, there exists a field extension* κ' *of* κ *such that the composite map* $\mathrm{Sp\acute{e}t}\,\kappa' \to \mathrm{Sp\acute{e}t}\,\kappa \to \mathsf{Y}$ *factors through* f*.*

(3) *For every field* κ *and every map* $\eta : \mathrm{Sp\acute{e}t}\,\kappa \to \mathsf{Y}$*, the fiber product* $\mathrm{Sp\acute{e}t}\,\kappa \times_{\mathsf{Y}} \mathsf{X}$ *is nonempty.*

Definition 3.5.5.5. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. We will say that f is *surjective* if it satisfies the equivalent conditions of Proposition 3.5.5.4.

Remark 3.5.5.6. Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y}. \end{array}$$

If f is surjective, then f' is surjective.

Remark 3.5.5.7. Suppose we are given maps of spectral Deligne-Mumford stacks

$$\mathsf{X} \xrightarrow{f} \mathsf{Y} \xrightarrow{g} \mathsf{Z},$$

where f is surjective. Then g is surjective if and only if $g \circ f$ is surjective.

Example 3.5.5.8. Let $f : \mathsf{X} \to \mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ be an étale morphism of spectral Deligne-Mumford stacks, so that $\mathsf{X} \simeq (\mathcal{Y}_{/U}, \mathscr{O}_{\mathcal{Y}}|_U)$ for some object $U \in \mathsf{Y}$. The following conditions are equivalent:

(i) The object $U \in \mathcal{Y}$ is 0-connective.

(ii) The morphism f is surjective.

Proof of Proposition 3.5.5.4. The implication (2) ⇒ (3) is obvious, and the implication (3) ⇒ (1) follows from Lemma 3.5.5.2. We will show that (1) ⇒ (2). Let $\eta : \mathrm{Sp\acute{e}t}\,\kappa \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. We wish to show that, after enlarging κ if necessary, the map η factors through X. Without loss of generality, we may assume that κ is separably closed. Note that η determines a geometric morphism of ∞-topoi $\eta_* : \mathcal{S} \to \mathcal{Y}$. Using condition (1), we deduce that η_* factors as a composition $\mathcal{S} \xrightarrow{\eta'_*} \mathcal{X} \xrightarrow{f_*} \mathcal{Y}$. According to Proposition 3.5.4.2, the geometric morphism η'_* is determined by a minimal geometric point $\eta' : \mathrm{Sp\acute{e}t}\,k' \to \mathsf{X}$. Using Remark 3.5.4.3, we see that η and $f \circ \eta'$ admit factorizations

$$\mathrm{Sp\acute{e}t}\,\kappa \to \mathrm{Sp\acute{e}t}\,\kappa_0 \xrightarrow{\eta_0} \mathsf{Y} \qquad \mathrm{Sp\acute{e}t}\,\kappa' \to \mathrm{Sp\acute{e}t}\,\kappa'_0 \xrightarrow{\eta'_0} \mathsf{Y},$$

where κ_0 and κ'_0 are separably closed subfields of κ and κ', respectively, and η_0 and η'_0 are minimal geometric points of Y. By construction, the pushforward functors $(\eta_0)_*, (\eta'_0)_* : \mathcal{S} \to$

$\mathcal{Y}$ are homotopic. It follows from Proposition 3.5.4.2 that there is an isomorphism of fields $\kappa_0 \simeq \kappa_0'$ such that the diagram

$$\begin{array}{ccc} \operatorname{Sp\acute{e}t} \kappa_0 & \longrightarrow & \operatorname{Sp\acute{e}t} \kappa_0' \\ & {\scriptstyle \eta_0} \searrow \quad \swarrow {\scriptstyle \eta_0'} & \\ & \mathsf{Y} & \end{array}$$

commutes up to homotopy. Let κ'' be any residue field of the tensor product $\kappa \otimes_{\kappa_0} \kappa'$. Then the composite map $\operatorname{Sp\acute{e}t} \kappa'' \to \operatorname{Sp\acute{e}t} \kappa \xrightarrow{\eta} \mathsf{Y}$ factors through $f \circ \eta$, and therefore lifts to a map $\operatorname{Sp\acute{e}t} \kappa'' \to \mathsf{X}$. □

3.6 Points of Spectral Algebraic Spaces

Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack. In §3.5, we studied the Kan complex $\operatorname{Fun}^*(\mathcal{X}, \mathcal{S})^{\simeq}$ of *points* of the ∞-topos X, and proved that it was equivalent to the ∞-category $\operatorname{Pt}_{\mathrm{g}}(\mathsf{X})$ of minimal geometric points of X (Proposition 3.5.4.2). In this section, we will study an *a priori* different notion of point, given by points of the locale $\tau_{\leqslant -1} \mathcal{X}$ of (-1)-truncated points of X. In good cases, one can show that $|\mathsf{X}|$ can be identified with the set of isomorphism classes of minimal geometric points of X (Corollary 3.6.4.4).

3.6.1 The Underlying Topological Space

In §1.5, we associated to each ∞-topos $\mathcal{X}$ a topological space $|\mathcal{X}|$ (see Definition 1.5.4.3). In this section, we will be interested in the case where $\mathcal{X}$ is the underlying ∞-topos of a spectral Deligne-Mumford stack.

Definition 3.6.1.1. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack. We $|\mathsf{X}|$ denote the underlying topological $|\mathcal{X}|$ of the ∞-topos $\mathcal{X}$. We will refer to $|\mathsf{X}|$ as the *underlying topological space* of X.

More concretely, an element $x \in |\mathsf{X}|$ can be identified with an equivalence class of open substacks $\mathsf{U}_x \hookrightarrow \mathsf{X}$ having the following property:

$(*)$ Given a finite collection $\{\mathsf{V}_i \subseteq \mathsf{X}\}_{1 \leqslant i \leqslant n}$ of open substacks of X having intersection U_x, we have $\mathsf{U}_x = \mathsf{V}_i$ for some i.

Here we should think of U_x as the open substack of X given by the complement of the closure of the point x. We will regard $|\mathsf{X}|$ as a topological space, having open sets of the form $\{x \in |\mathsf{X}| : \mathsf{U} \nsubseteq \mathsf{U}_x\}$ where U ranges over open substacks of X.

Remark 3.6.1.2. In this section, we are primarily interested in studying the topological space $|\mathsf{X}|$ in the case where X is a quasi-separated spectral algebraic space. All of our results can be deduced immediately from their counterparts in the classical theory of algebraic spaces (see, for example, [117]). We include proofs here for the sake of completeness.

Remark 3.6.1.3. Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack. The ∞-topos $\mathcal{X}$ is locally coherent, so that the hypercompletion $\mathcal{X}^{\mathrm{hyp}}$ has enough points (Theorem A.4.0.5). It follows immediately that the locale of open substacks of X has enough points: that is, there is a one-to-one correspondence between open subsets of the topological space $|\mathsf{X}|$ and equivalence classes of open substacks of X.

Example 3.6.1.4. Let R be an $\mathbb{E}_\infty$-ring. Then there is a bijective correspondence between equivalence classes of open substacks of $\operatorname{Sp\acute{e}t} R$ and open subsets of the topological space $|\operatorname{Spec} R|$ (see Lemma **??**). Since every irreducible closed subset of $|\operatorname{Spec} R|$ has a unique generic point, we obtain a canonical homeomorphism $|\operatorname{Sp\acute{e}t} R| \simeq |\operatorname{Spec} R|$. In particular, if R is a field, then the topological space $|\operatorname{Sp\acute{e}t} R|$ consists of a single point.

Example 3.6.1.5. Let X be a schematic spectral algebraic space, and let $(X, \mathcal{O}_X)$ be the associated spectral scheme (see Definition **??**). Then $|\mathsf{X}|$ is homeomorphic to X (see Remark 1.1.2.10).

Proposition 3.6.1.6. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of quasi-separated spectral algebraic spaces. Assume that X is 0-truncated and quasi-compact, and let Y_0 be the schematic image of f (see Construction 3.1.5.1). Then the image of the closed immersion $|\mathsf{Y}_0| \hookrightarrow |\mathsf{Y}|$ is the closure of the image of the map $|f| : |\mathsf{X}| \to |\mathsf{Y}|$.*

Proof. Replacing Y by Y_0, we can reduce to the case where Y is 0-truncated and the unit map $u : \mathcal{O}_{\mathcal{Y}} \to \pi_0 f_* \mathcal{O}_{\mathcal{X}}$ is a monomorphism (here $\mathcal{O}_{\mathcal{X}}$ and $\mathcal{O}_{\mathcal{Y}}$ denote the structure sheaves of X and Y, respectively). In this case, we wish to show that the map $|\mathsf{X}| \to |\mathsf{Y}|$ has dense image. Assume otherwise: then there exists a nonempty open subset $U \subseteq |\mathsf{Y}|$ which does not intersect the image of f. Let U denote the open substack of Y corresponding to U. Using Remark 3.1.5.6, we can replace Y by U and thereby reduce to the case where X is empty. In this case, the assertion that u is a monomorphism guarantees that $\mathcal{O}_{\mathcal{Y}} \simeq 0$, contradicting our assumption that $U \neq \emptyset$. □

3.6.2 Points

Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a spectral Deligne-Mumford stack. Every point of the ∞-topos $\mathcal{X}$ determines a point of the topological space $|\mathsf{X}|$. This observation determines a map of sets $\theta : \pi_0 \operatorname{Pt_g}(\mathsf{X}) \to |\mathsf{X}|$, where $\operatorname{Pt_g}(\mathsf{X})$ denotes the space of geometric points of X (Proposition 3.5.4.2). In good cases, one can show that the map θ is bijective. One of our goals in this section is prove this in the case where X is a quasi-separated spectral algebraic space. To do so, it will be convenient to describe the elements of $|\mathsf{X}|$ in a different way.

Definition 3.6.2.1. Let X be a spectral algebraic space. A *point* of X is a morphism $\eta : \mathsf{X}_0 \to \mathsf{X}$ with the following properties:

(1) The object $\mathsf{X}_0 \in \mathrm{SpDM}$ is equivalent to the spectrum of a field κ.

(2) For every commutative ring R, the map

$$\mathrm{Hom}_{\mathrm{CAlg}^{\heartsuit}}(\kappa, R) \simeq \pi_0 \mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{X}_0) \to \pi_0 \mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, X)$$

is injective.

Example 3.6.2.2. Let R be a connective $\mathbb{E}_\infty$-ring. A map $\eta : \mathrm{Sp\acute{e}t}\, \kappa \to \mathrm{Sp\acute{e}t}\, R$ is a point of R if and only if κ is a field and the underlying map $R \to \kappa$ exhibits κ as the residue field of the commutative ring $\pi_0 R$ at some prime ideal $\mathfrak{p} \subseteq \pi_0 R$.

Remark 3.6.2.3. Let X be a quasi-separated spectral algebraic space, and suppose we are given a point $\eta : \mathrm{Sp\acute{e}t}\, \kappa \to \mathsf{X}$. Choose any étale map $u : \mathrm{Sp\acute{e}t}\, R \to \mathsf{X}$, and let Y denote the fiber product $\mathrm{Sp\acute{e}t}\, \kappa \times_{\mathsf{X}} \mathrm{Sp\acute{e}t}\, R$. Since the diagonal of X is quasi-affine, Y has the form $\mathrm{Sp\acute{e}t}\, \kappa'$ for some étale κ-algebra κ'. We may therefore write κ' as a finite product $\prod_\alpha \kappa'_\alpha$, where each κ'_α is a finite separable extension of the field κ. Each of the induced maps $\mathrm{Sp\acute{e}t}\, \kappa'_\alpha \to \mathrm{Sp\acute{e}t}\, \kappa' \to \mathrm{Sp\acute{e}t}\, R$ is a point of $\mathrm{Sp\acute{e}t}\, R$, so that each κ'_α can be identified with a residue field of the commutative ring $\pi_0 R$ (Example 3.6.2.2) at some prime ideal $\mathfrak{p}_\alpha$. Moreover, the prime ideals $\mathfrak{p}_\alpha$ are distinct from one another.

Remark 3.6.2.4. Let X be a quasi-separated spectral algebraic space, and suppose we are given a commutative diagram

$$\begin{array}{ccc} \mathrm{Sp\acute{e}t}\, \kappa & \xrightarrow{\theta} & \mathrm{Sp\acute{e}t}\, \kappa' \\ & {\scriptstyle \eta} \searrow \quad \swarrow {\scriptstyle \eta'} & \\ & \mathsf{X} & \end{array}$$

where η is a point of X and κ' is a field. Choose an étale map $u : \mathrm{Sp\acute{e}t}\, R \to \mathsf{X}$ such that $\mathsf{Y} = \mathrm{Sp\acute{e}t}\, \kappa' \times_{\mathsf{X}} \mathrm{Sp\acute{e}t}\, R$ is nonempty, so that Y has the form $\mathrm{Sp\acute{e}t}\, \kappa''$ for some nonzero étale κ'-algebra κ''. Then $\mathrm{Sp\acute{e}t}\, \kappa \times_{\mathsf{X}} \mathrm{Sp\acute{e}t}\, R$ is the spectrum of the commutative ring $\kappa \otimes_{\kappa'} \kappa''$. It follows from Remark 3.6.2.3 that the composite map $\pi_0 R \to \kappa'' \to \kappa \otimes_{\kappa'} \kappa''$ is surjective. In particular, the map $\kappa'' \to \kappa \otimes_{\kappa'} \kappa''$ is surjective, so we must have $\kappa' \simeq \kappa$: that is, the map θ is an equivalence.

Notation 3.6.2.5. Let X be a quasi-separated spectral algebraic space, and let $\mathrm{Pt}(\mathsf{X})$ be the full subcategory of $\mathrm{SpDM}_{/\mathsf{X}}$ spanned by the points of X. Remark 3.6.2.4 implies that $\mathrm{Pt}(\mathsf{X})$ is a Kan complex, and it follows immediately from the definition that all mapping spaces in $\mathrm{Pt}(\mathsf{X})$ are either empty or contractible. It follows that $\mathrm{Pt}(\mathsf{X})$ is homotopy equivalent to the discrete space $\pi_0 \mathrm{Pt}(\mathsf{X})$. We will generally abuse notation by identifying $\mathrm{Pt}(\mathsf{X})$ with $\pi_0 \mathrm{Pt}(\mathsf{X})$. If $\eta \in \mathrm{Pt}(\mathsf{X})$ corresponds to a morphism $\mathrm{Sp\acute{e}t}\, \kappa \to \mathsf{X}$, we will refer to κ as the *residue field* of X at the point η, and denote it by $\kappa(\eta)$.

Remark 3.6.2.6. Let $i : \mathsf{X}_0 \to \mathsf{X}$ be a closed immersion of quasi-separated spectral algebraic spaces, and let $j : \mathsf{U} \to \mathsf{X}$ be the complementary open immersion. Then the induced maps $\pi_0 \mathrm{Pt}(\mathsf{X}_0) \to \pi_0 \mathrm{Pt}(\mathsf{X}) \leftarrow \pi_0 \mathrm{Pt}(\mathsf{U})$ determine a bijection $\pi_0 \mathrm{Pt}(\mathsf{X}_0) \amalg \pi_0 \mathrm{Pt}(\mathsf{U}) \to \pi_0 \mathrm{Pt}(\mathsf{X})$.

3.6.3 Comparison of $\mathrm{Pt}(\mathsf{X})$ with $|\mathsf{X}|$

Let X be a spectral algebraic space. For every point $\eta : \mathrm{Sp\acute{e}t}\, \kappa \to \mathsf{X}$, the induced map of topological spaces $|\mathrm{Sp\acute{e}t}\, \kappa| \to |\mathsf{X}|$ determines an element of $|\mathsf{X}|$ (see Example 3.6.1.4). This construction determines a map of sets $\pi_0 \mathrm{Pt}(\mathsf{X}) \to |\mathsf{X}|$. Under mild hypotheses, this map is bijective:

Proposition 3.6.3.1. *Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a quasi-separated spectral algebraic space. Then construction above determines a bijection of sets $\theta : \pi_0 \mathrm{Pt}(\mathsf{X}) \to |\mathsf{X}|$.*

Proof. The topological space $|\mathsf{X}|$ is sober: that is, every irreducible closed subset of $|\mathsf{X}|$ has a unique generic point. It will therefore suffice to show that for every irreducible closed subset $K \subseteq |\mathsf{X}|$, there is a unique equivalence class of points $\eta : \mathrm{Sp\acute{e}t}\, \kappa \to \mathsf{X}$ which determine a generic point of K. Using Proposition 3.1.6.3, we can assume that K is the image of $|\mathsf{X}_0|$ for some closed immersion $\mathsf{X}_0 \to \mathsf{X}$. Replacing X by X_0, we may suppose X is reduced and that $|\mathsf{X}|$ is itself irreducible. In particular, X is nonempty; we may therefore choose an open immersion $j : \mathrm{Sp\acute{e}t}\, R \to \mathsf{X}$ for some nonzero $\mathbb{E}_\infty$-ring R (Corollary 3.4.2.4). Since X is reduced, R is an ordinary commutative ring. Then the Zariski spectrum $|\mathrm{Spec}\, R|$ is homeomorphic to nonempty open subset of $|\mathsf{X}|$ and is therefore irreducible. It follows that R is an integral domain. Let $\eta \in |\mathsf{X}|$ be the image of the zero ideal $(0) \in |\mathrm{Spec}\, R|$, so that η corresponds to the point given by the composition

$$\mathrm{Sp\acute{e}t}\, \kappa \to \mathrm{Sp\acute{e}t}\, R \to \mathsf{X}$$

where κ is the fraction field of R. We claim that η is a generic point of $|\mathsf{X}|$: that is, that η belongs to every nonempty open subset $V \subseteq |\mathsf{X}|$. To see this, we note that because $|\mathsf{X}|$ is irreducible, the inverse image of V in $|\mathrm{Spec}\, R|$ is nonempty and therefore contains the ideal (0). This proves the surjectivity of θ. To prove injectivity, let us suppose we are given any other point $\eta' : \mathrm{Sp\acute{e}t}\, \kappa' \to \mathsf{X}$ which determines a generic point of $|\mathsf{X}'|$. Since η' determines a generic point of $|\mathsf{X}|$, it must factor through the nonempty open substack $\operatorname{Sp\acute{e}t} R$ of X. We may therefore identify κ' with the residue field of R at some prime ideal $\mathfrak{p} \subseteq R$. which belongs to every nonempty open subset of $|\operatorname{Spec} R|$. It follows that for every nonzero element $x \in R$, $\mathfrak{p} \in |\operatorname{Spec} R[x^{-1}]|$ and therefore $x \notin \mathfrak{p}$. This proves that $\mathfrak{p}$ coincides with the zero ideal (0), so that $\eta' \simeq \eta$. □

We now describe some consequences of Proposition 3.6.3.1.

Corollary 3.6.3.2. *Suppose we are given a pullback diagram*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y} \end{array}$$

of quasi-separated spectral algebraic spaces. Then the induced map $|\mathsf{X}'| \to |\mathsf{X}| \times_{|\mathsf{Y}|} |\mathsf{Y}'|$ is a surjection of topological spaces.

Proof. Every point $\eta : |\mathsf{X}| \times_{|\mathsf{Y}|} |\mathsf{Y}'|$ can be lifted to a commutative diagram

$$\begin{array}{ccccc} \operatorname{Sp\acute{e}t} \kappa & \longrightarrow & \operatorname{Sp\acute{e}t} \kappa' & \longleftarrow & \operatorname{Sp\acute{e}t} \kappa'' \\ \downarrow & & \downarrow & & \downarrow \\ \mathsf{X} & \longrightarrow & \mathsf{Y} & \longleftarrow & \mathsf{Y}' \end{array}$$

where κ, κ', and κ'' are fields. To prove that η can be lifted to a point of $|\mathsf{X}|$, it suffices to observe that $|\operatorname{Sp\acute{e}t} \kappa \times_{\operatorname{Sp\acute{e}t} \kappa'} \operatorname{Sp\acute{e}t} \kappa''|$ is nonempty: that is, that commutative ring $\kappa \otimes_{\kappa'} \kappa''$ is nonzero. □

Proposition 3.6.3.3. *Let X be a quasi-separated spectral algebraic space. Then:*

(1) *The topological space $|\mathsf{X}|$ is sober, and is quasi-compact if X is quasi-compact.*

(2) *The topological space $|\mathsf{X}|$ has a basis consisting of quasi-compact open sets.*

(3) *The topological space $|\mathsf{X}|$ is quasi-separated (that is, if U and V are quasi-compact open subsets of $|\mathsf{X}|$, then the intersection $U \cap V$ is also quasi-compact).*

Moreover, if $f : \mathsf{X} \to \mathsf{Y}$ is a quasi-compact morphism of quasi-separated spectral algebraic spaces, and $U \subseteq |\mathsf{Y}|$ is quasi-compact, then $f^{-1}U \subseteq |\mathsf{X}|$ is quasi-compact.

Corollary 3.6.3.4. *Let X be a quasi-compact, quasi-separated spectral algebraic space. Then the topological space $|\mathsf{X}|$ is coherent. Consequently, $|\mathsf{X}|$ is homeomorphic to the spectrum $\operatorname{Sp}(\mathcal{U}(\mathsf{X}))$, where $\mathcal{U}(\mathsf{X})$ denotes the collection of all quasi-compact open subsets of $|\mathsf{X}|$ (see Proposition A.1.5.10).*

Remark 3.6.3.5. Let X be a spectral Deligne-Mumford stack. Assume that X is locally Noetherian and quasi-compact. Then the topological space $|\mathsf{X}|$ is Noetherian: that is, every open subset of $|\mathsf{X}|$ is quasi-compact. To prove this, choose an $\mathbb{E}_\infty$-ring R and an étale surjection $\operatorname{Spét} R \to \mathsf{X}$. Since the lattice of open subsets of $|\mathsf{X}|$ injects into the lattice of open subsets of $|\operatorname{Spét} R| \simeq |\operatorname{Spec} R|$, we are reduced to proving that the topological space $|\operatorname{Spec} R|$ is locally Noetherian. This follows immediately from our assumption that $\pi_0 R$ is Noetherian.

Proof of Proposition 3.6.3.3. Assertion (1) follows immediately from the definitions. Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_\mathcal{X})$, and identify the collection of open sets in $|\mathsf{X}|$ with the collection of (equivalence classes of) (-1)-truncated objects of $\mathcal{X}$. For every object $U \in \mathcal{X}$, if we write $\mathsf{X}_U = (\mathcal{X}_{/U}, \mathcal{O}_\mathcal{X}|_U)$, then the open subset of $|\mathsf{X}|$ corresponding to $\tau_{\leqslant -1} U$ can be described as the image of the map $|\mathsf{X}_U| \to |\mathsf{X}|$. Since $\mathcal{X}$ is generated under small colimits by affine objects, we see that $|\mathsf{X}|$ has a basis of open sets given by the images of maps $|\mathsf{U}| \to |\mathsf{X}|$, where U is an affine spectral algebraic space which is étale over X. In this case, $|\mathsf{U}|$ is quasi-compact by (1), so that $|\mathsf{X}|$ has a basis of quasi-compact open sets.

We now prove that $|\mathsf{X}|$ is quasi-separated. Suppose we are given quasi-compact open sets $U, V \subseteq |\mathsf{X}|$; we wish to show that $U \cap V$ is quasi-compact. Without loss of generality, we may assume that U and V are the images of maps $|\mathsf{U}| \to |\mathsf{X}|$ and $|\mathsf{V}| \to |\mathsf{X}|$, where U and V are affine spectral algebraic spaces which are étale over X. Using Corollary 3.6.3.2, we see that $U \cap V$ is the image of the map $\theta : |\mathsf{U} \times_\mathsf{X} \mathsf{V}| \to |\mathsf{X}|$. Since X is quasi-separated, the fiber product $\mathsf{U} \times_\mathsf{X} \mathsf{V}$ is quasi-compact, so that the underlying topological space $|\mathsf{U} \times_\mathsf{X} \mathsf{V}|$ is also quasi-compact by (1). It follows that the image of θ is quasi-compact, as desired.

Now suppose that $f : \mathsf{X} \to \mathsf{Y}$ is a quasi-compact morphism between quasi-separated spectral algebraic spaces and let $U \subseteq |\mathsf{Y}|$ be a quasi-compact open set; we wish to show that its inverse image is a quasi-compact open subset of $|\mathsf{X}|$. Without loss of generality, we may suppose that U is the image of a map $|\mathsf{U}| \to |\mathsf{Y}|$, where U is affine and étale over Y. Using Corollary 3.6.3.2 we see that the inverse image of U is the image of the map $\theta : |\mathsf{U} \times_\mathsf{Y} \mathsf{X}| \to |\mathsf{X}|$. Since f is quasi-compact, $\mathsf{U} \times_\mathsf{Y} \mathsf{X}$ is quasi-compact. It follows from (1) that the topological space $|\mathsf{U} \times_\mathsf{Y} \mathsf{X}|$ is quasi-compact, from which it follows that the image of θ is quasi-compact. □

Proposition 3.6.3.6. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a faithfully flat, quasi-compact morphism between quasi-separated spectral algebraic spaces. Then the induced map $|\mathsf{X}| \to |\mathsf{Y}|$ is a quotient map of topological spaces.*

Proof. Writing Y as a union of its quasi-compact open substacks, we can reduce to the case where Y (and therefore also X) is quasi-compact. Choose an étale surjection $\operatorname{Spét} R \to \mathsf{Y}$ and an étale surjection $\operatorname{Spét} R' \to \operatorname{Spét} R \times_\mathsf{Y} \mathsf{X}$. Then R' is faithfully flat over R, so that $|\operatorname{Spec} R'| \to |\operatorname{Spec} R|$ is a quotient map (Proposition 1.6.2.2). It will therefore suffice to show that the vertical maps appearing in the diagram

$$\begin{array}{ccc} |\operatorname{Spec} R'| & \longrightarrow & |\operatorname{Spec} R| \\ \downarrow{\scriptstyle \phi'} & & \downarrow{\scriptstyle \phi} \\ |\mathsf{X}| & \longrightarrow & |\mathsf{Y}| \end{array}$$

are quotient maps. We will prove that ϕ is a quotient map; the proof for ϕ' is similar. Fix a subset $U \subseteq \mathsf{Y}$, and suppose that $\phi^{-1}U$ is an open subset of $|\operatorname{Spec} R|$. Then the inverse images of $\phi^{-1}U$ under the two projection maps $|\operatorname{Sp\acute{e}t} R \times_{\mathsf{Y}} \operatorname{Sp\acute{e}t} R| \to |\operatorname{Sp\acute{e}t} R|$ coincide, so that $\phi^{-1}U = \phi^{-1}V$ for some open set $V \subseteq |\mathsf{Y}|$. Since ϕ is surjective, we obtain

$$U = \phi(\phi^{-1}U) = \phi(\phi^{-1}V) = V,$$

so that U is open. □

3.6.4 Comparison of $\mathrm{Pt}(\mathsf{X})$ with $\mathrm{Pt}_{\mathrm{g}}(\mathsf{X})$

We close this section with a discussion of the relationship between points of a spectral algebraic space X and geometric points of X.

Notation 3.6.4.1. Let X be a quasi-separated spectral algebraic space. Recall that $\mathrm{Pt}_{\mathrm{g}}(\mathsf{X})$ denotes the full subcategory of $\mathrm{SpDM}_{/\mathsf{X}}$ spanned by the minimal geometric points of X (see Definition 3.5.3.1). We let $\mathrm{Pt}_{\mathrm{g}}{}'(\mathsf{X})$ denote the full subcategory of $\mathrm{Fun}(\Delta^1, \mathrm{SpDM}_{/\mathsf{X}})$ whose objects are equivalent to commutative diagrams

$$\begin{array}{ccc} \operatorname{Sp\acute{e}t} \overline{\kappa} & \longrightarrow & \operatorname{Sp\acute{e}t} \kappa \\ & {\scriptstyle \eta'} \searrow \quad \swarrow {\scriptstyle \eta} & \\ & \mathsf{X} & \end{array}$$

where η is a point of X and η' is a minimal geometric point of X.

Proposition 3.6.4.2. *Let X be a quasi-separated spectral algebraic space. Then the forgetful functor $\mathrm{Pt}_{\mathrm{g}}{}'(\mathsf{X}) \to \mathrm{Pt}_{\mathrm{g}}(\mathsf{X})$ is an equivalence of ∞-categories.*

More informally, Proposition 3.6.4.2 asserts that every geometric point of a quasi-separated spectral algebraic space X determines a point of X.

Proof. It is clear that the forgetful functor $\theta : \mathrm{Pt}_{\mathrm{g}}{}'(\mathsf{X}) \to \mathrm{Pt}_{\mathrm{g}}(\mathsf{X})$ is fully faithful. We must prove that θ is essentially surjective. Fix a geometric point $\eta : \operatorname{Sp\acute{e}t} \overline{\kappa} \to \mathsf{X}$. Replacing X by an open substack if necessary, we may suppose that X is quasi-compact. Using Theorem 3.4.2.1, we can choose a scallop decomposition

$$\emptyset = \mathsf{U}_0 \to \mathsf{U}_1 \to \cdots \to \mathsf{U}_n \simeq \mathsf{X}.$$

Let i be the smallest integer such that η factors through U_i. Let K be the reduced closed substack of U_i complementary to U_{i-1}. Since $\overline{\kappa}$ is a field and η does not factor through U_{i-1}, it must factor through K. Note that $\mathsf{K} \simeq \operatorname{Spét} R$ is affine. It follows that η factors as a composition

$$\operatorname{Spét} \overline{\kappa} \to \operatorname{Spét} \kappa \to \operatorname{Spét} R \to \mathsf{U}_i \to \mathsf{X}$$

where κ is the residue field of $\pi_0 R$ at some prime ideal $\mathfrak{p} \subseteq \pi_0 R$. We now observe that the map $\operatorname{Spét} \kappa \to \mathsf{X}$ is a point of X. □

Proposition 3.6.4.3. *Let X be a quasi-separated spectral algebraic space, let $\eta : \operatorname{Spét} \kappa \to \mathsf{X}$ be a point of X, and let $\overline{\kappa}$ be a field extension of κ. The following conditions are equivalent:*

(1) *The field $\overline{\kappa}$ is a separable closure of κ.*

(2) *The composite map $\eta' : \operatorname{Spét} \overline{\kappa} \to \operatorname{Spét} \kappa \to \mathsf{X}$ is a minimal geometric point of X.*

Proof. We may assume without loss of generality that $\overline{\kappa}$ is separably closed (since this follows from both (1) and (2)). Choose an étale map $u : \operatorname{Spét} R \to \mathsf{X}$ such that the fiber product $\operatorname{Spét} R \times_{\mathsf{X}} \operatorname{Spét} \kappa$ is nonempty. Using Remark 3.6.2.3, we deduce that there is a commutative diagram

$$\begin{array}{ccc} \operatorname{Spét} \kappa' & \xrightarrow{u'} & \operatorname{Spét} R \\ \downarrow & & \downarrow \\ \operatorname{Spét} \kappa & \longrightarrow & \mathsf{X} \end{array}$$

where κ' is a finite separable extension of κ, and u' exhibits κ' as a residue field of the commutative ring $\pi_0 R$. Since $\overline{\kappa}$ is separably closed, we can choose a map of κ-algebras $\kappa' \to \overline{\kappa}$, so that η' factors as a composition

$$\operatorname{Spét} \overline{\kappa} \xrightarrow{v} \operatorname{Spét} R \xrightarrow{v'} \mathsf{X}.$$

Then η' is a geometric point of X if and only if v exhibits $\overline{\kappa}$ as a separable closure of the residue field of $\pi_0 R$: that is, if and only if $\overline{\kappa}$ is a separable closure of κ'. Since κ' is a separably algebraic extension of κ, this is equivalent to the requirement that $\overline{\kappa}$ be a separable closure of κ. □

Combining Proposition 3.6.4.3, Proposition 3.6.4.2, and the discussion of Notation 3.6.2.5, we deduce:

Corollary 3.6.4.4. *Let X be a quasi-separated spectral algebraic space. Then the ∞-category $\operatorname{Pt}_{\mathrm{g}}(\mathsf{X})$ is canonically equivalent to the groupoid whose objects are pairs $(\eta, \overline{\kappa})$, where $\eta \in \pi_0 \operatorname{Pt}(\mathsf{X})$ is a point of X and $\overline{\kappa}$ is a separable closure of the residue field $\kappa(\eta)$.*

Corollary 3.6.4.5. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a surjective map between quasi-separated spectral algebraic spaces. Then the induced map $|\,\mathsf{X}\,| \to |\,\mathsf{Y}\,|$ is surjective.*

3.7 The Nisnevich Topology of a Spectral Algebraic Space

Let X be a quasi-projective algebraic variety of dimension d over a field κ. Then, for any (discrete) quasi-coherent sheaf $\mathscr{F}$ on X, the cohomology groups $\mathrm{H}^n(X; \mathscr{F})$ vanish for $n > d$. This is a special case of a much more general assertion:

Theorem 3.7.0.1 (Grothendieck)**.** *Let X be a Noetherian topological space of Krull dimension $\leqslant d$. Then the cohomology groups $\mathrm{H}^n(X; \mathscr{F})$ vanish for every integer $n > d$ and every sheaf $\mathscr{F}$ of abelian groups on X.*

Unfortunately, Theorem 3.7.0.1 does not apply directly in the case where X is an algebraic space, rather than a scheme. Nevertheless, we do have the following result:

Theorem 3.7.0.2. *Let X be a quasi-compact locally Noetherian spectral algebraic space and let $\mathscr{F}$ be a connective quasi-coherent sheaf on X. If the underlying topological space $|\mathsf{X}|$ has Krull dimension $\leqslant d$, then the homotopy groups $\pi_{-n}\Gamma(\mathsf{X}; \mathscr{F})$ vanish for $n > d$.*

Our goal in this section is to give a proof of Theorem 3.7.0.2 by deducing it from a variant of Theorem 3.7.0.1. Write $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$, so that we have a geometric morphism of ∞-topoi $\pi_* : \mathcal{X} \to \mathcal{S}\mathrm{hv}(|\mathsf{X}|)$ which induces a pushforward functor on spectrum-valued sheaves $\pi_* : \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(\mathcal{X}) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(|\mathsf{X}|)$. Note that if $U \subseteq |\mathsf{X}|$ is an open set which determines an *affine* substack of X, then our assumption that $\mathscr{F}$ is connective and quasi-coherent guarantees that the spectrum $(\pi_* \mathscr{F})(U)$ is connective. Consequently, when X is schematic, the pushforward $\pi_* \mathscr{F}$ is connective when viewed as a sheaf of spectra on $|\mathsf{X}|$, so the desired result follows (modulo issues of convergence) from Theorem 3.7.0.1. If X is not schematic, then the pushforward $\pi_* \mathscr{F}$ is not necessarily connective and this argument does not apply. We will prove Theorem 3.7.0.2 in the general case by instead comparing $\mathcal{X}$ with the ∞-topos $\mathcal{S}\mathrm{hv}_{\mathrm{Nis}}(\mathsf{X})$ of *Nisnevich sheaves* on X. This ∞-topos shares the good features of the Zariski site in the schematic case:

- Every quasi-compact, quasi-separated spectral algebraic space X admits a finite Nisnevich covering by affine spectral algebraic spaces (Example 3.7.1.5), so that connective quasi-coherent sheaves on X remain quasi-coherent when viewed as a sheaves for the Nisnevich topology (Example **??**).

- If X is quasi-compact, locally Noetherian, and $|\mathsf{X}|$ has Krull dimension $\leqslant d$, then the ∞-topos $\mathcal{S}\mathrm{hv}_{\mathrm{Nis}}(\mathsf{X})$ has homotopy dimension $\leqslant d$ (Theorem 3.7.7.1).

3.7.1 Nisnevich Coverings

We begin by defining the Nisnevich site of a spectral algebraic space $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$. Note that there is no loss of generality in restricting to the case of an ordinary algebraic space: replacing X by its 0-truncation $(\mathcal{X}, \pi_0 \mathscr{O}_{\mathcal{X}})$ has no effect on the theory of Nisnevich sheaves.

Definition 3.7.1.1. Let X be a quasi-compact, quasi-separated spectral algebraic space, and suppose that we are given a collection of étale morphisms $\{u_\alpha : \mathsf{X}_\alpha \to \mathsf{X}\}$. We will say that the morphisms u_α generate a *Nisnevich covering* of X if there exists a sequence of open immersions

$$\varnothing \simeq \mathsf{U}_0 \hookrightarrow \cdots \hookrightarrow \mathsf{U}_n \simeq \mathsf{X}$$

with the following property:

(∗) For $1 \leqslant i \leqslant n$, let K_i denote the reduced closed substack of U_i complementary to U_{i-1}. Then the composite map $\mathsf{K}_i \to \mathsf{U}_i \to \mathsf{X}$ factors through some u_α.

Notation 3.7.1.2. Let X be a quasi-compact, quasi-separated spectral algebraic space. We let $\mathcal{T}_{\mathsf{X}}$ denote the full subcategory of $\mathrm{SpDM}_{/\mathsf{X}}$ spanned by those maps $u : \mathsf{U} \to \mathsf{X}$ where u is étale and U is a quasi-compact, quasi-separated spectral algebraic space.

Remark 3.7.1.3. Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ be a quasi-compact, quasi-separated spectral algebraic space. Then the construction $U \mapsto (\mathcal{X}_{/U}, \mathcal{O}_{\mathcal{X}}|_U)$ determines a fully faithful embedding $\mathcal{X} \to \mathrm{SpDM}_{/\mathsf{X}}$, whose essential image is spanned by the étale maps $\mathsf{U} \to \mathsf{X}$. Under this equivalence of ∞-categories, $\mathcal{T}_{\mathsf{X}}$ corresponds to the full subcategory of $\mathcal{X}$ spanned by those objects which are coherent and discrete. In particular, $\mathcal{T}_{\mathsf{X}}$ is essentially small.

Remark 3.7.1.4 (Functoriality)**.** Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism between quasi-compact, quasi-separated spectral algebraic spaces. If $\{\mathsf{Y}_\alpha \in \mathcal{T}_{\mathsf{Y}}\}$ is a Nisnevich covering of Y, then the collection of fiber products $\{\mathsf{Y}_\alpha \times_{\mathsf{Y}} \mathsf{X} \in \mathcal{T}_{\mathsf{X}}\}$ is a Nisnevich covering of X.

Example 3.7.1.5. Let X be a quasi-compact, quasi-separated spectral algebraic space. Choose a scallop decomposition $\varnothing \simeq \mathsf{U}_0 \hookrightarrow \mathsf{U}_1 \hookrightarrow \cdots \hookrightarrow \mathsf{U}_n \simeq \mathsf{X}$, so that each of the open immersions $\mathsf{U}_{i-1} \hookrightarrow \mathsf{U}_i$ fits into an excision square

$$\begin{array}{ccc} \mathsf{V}_i & \longrightarrow & \operatorname{Sp\acute{e}t} R_i \\ \downarrow & & \downarrow \\ \mathsf{U}_{i-1} & \longrightarrow & \mathsf{U}_i \end{array}$$

(such a decomposition of X can always be found, by virtue of Theorem 3.4.2.1). Then the collection of maps $\operatorname{Sp\acute{e}t} R_i \to \mathsf{X}$ generate a Nisnevich covering of X. In particular, X admits a Nisnevich covering by finitely many affine spectral algebraic spaces.

3.7.2 The Affine Case

Definition 3.7.1.1 is closely related to the theory of Nisnevich coverings of $\mathbb{E}_\infty$-rings which was introduced in §B.4:

Proposition 3.7.2.1. *Suppose we are given a collection of étale morphisms $\{u_\alpha : \mathsf{X}_\alpha \to \mathsf{X}\}$ between quasi-compact, quasi-separated spectral algebraic spaces. The following conditions are equivalent:*

(1) *The morphisms u_α generate a Nisnevich covering of X, in the sense of Definition 3.7.1.1.*

(2) *For every map $\mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$, where A is a connective $\mathbb{E}_\infty$-ring, there exists a collection of étale maps $\{A \to A_\beta\}$ such that each of the composite maps $\mathrm{Sp\acute{e}t}\, A_\beta \to \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$ factors through some u_α, and the underlying ring homomorphisms $\{\pi_0 A \to \pi_0 A_\beta\}$ are a Nisnevich covering in the sense of Definition B.4.1.1.*

(3) *For every étale map $\mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$, where A is a connective $\mathbb{E}_\infty$-ring, there exists a collection of étale maps $\{A \to A_\beta\}$ such that each of the composite maps $\mathrm{Sp\acute{e}t}\, A_\beta \to \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$ factors through some u_α, and the underlying ring homomorphisms $\{\pi_0 A \to \pi_0 A_\beta\}$ are a Nisnevich covering in the sense of Definition B.4.1.1.*

Proof. We first prove that (1) $\Rightarrow$ (2). Assume that the morphisms u_α generate a Nisnevich covering of X. Then we can choose a sequence of open immersions

$$\emptyset \simeq \mathsf{U}_0 \hookrightarrow \cdots \hookrightarrow \mathsf{U}_n \simeq \mathsf{X}$$

having the property that for $1 \leqslant i \leqslant n$, if we let $\mathcal{K}_i$ denote the reduced closed substack of U_i complementary to U_{i-1}, then each of the maps $\mathcal{K}_i \to \mathsf{X}$ factors through some u_{α_i}.

Fix a map $f : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$, where A is connective $\mathbb{E}_\infty$-ring. For $1 \leqslant i \leqslant n$, the fiber product $\mathsf{U}_i \times_{\mathsf{X}} \mathrm{Sp\acute{e}t}\, A$ can be identified with an open substack of $\mathrm{Sp\acute{e}t}\, A$, corresponding to a quasi-compact open set $U_i \subseteq |\operatorname{Spec} A|$. Choose a scallop decomposition

$$\emptyset \simeq \mathsf{V}_{i,0} \hookrightarrow \cdots \hookrightarrow \mathsf{V}_{i,m_i} \simeq \mathsf{X}_{\alpha_i} \times_{\mathsf{X}} \mathrm{Sp\acute{e}t}\, A,$$

so that we have excision squares

$$\begin{array}{ccc} \mathsf{W}_{i,j} & \longrightarrow & \mathrm{Sp\acute{e}t}\, A_{i,j} \\ \downarrow & & \downarrow \\ \mathsf{V}_{i,j-1} & \longrightarrow & \mathsf{V}_{i,j}\,. \end{array}$$

We can identify each $\mathsf{V}_{i,j}$ with an open substack of $\mathrm{Sp\acute{e}t}\, A$, which corresponds to a quasi-compact open subset $V_{i,j} \subseteq |\operatorname{Spec} A|$. Write each union $V'_{i,j} = U_{i-1} \cup V_{i,j}$ as the complement of the vanishing locus of a finitely generated ideal $I_{i,j} \subseteq \pi_0 A$. Without loss of generality, we may assume that there are inclusions

$$(0) = I_{1,0} \subseteq I_{1,1} \subseteq \cdots \subseteq I_{1,m_1} = I_{2,0} \subseteq \cdots \subseteq I_{n,m_n} = \pi_0 A.$$

We may therefore choose a finite set of elements $a_1, \ldots, a_\ell \in \pi_0 A$, such that each of the ideals $I_{i,j}$ is generated by the elements $\{a_k\}_{1 \leqslant k \leqslant k_0}$ for some integer k_0 (which depends on i and j). For $1 \leqslant k \leqslant \ell$, set $B_k = (\pi_0 A)/(a_1, \ldots, a_{k-1})[a_k^{-1}]$. By construction, each of the maps $\operatorname{Spét} B_k \rightarrow \operatorname{Spét} A \xrightarrow{f} \mathsf{X}$ factors through $\operatorname{Spét} R_{i,j}$ for some pair of integers i and j. It follows that the the maps $\{\pi_0 A \rightarrow \pi_0 A_{i,j}\}$ form a Nisnevich covering in the sense of Definition B.4.1.1, so that (2) is satisfied.

The implication (2) $\Rightarrow$ (3) is obvious. We will complete the proof by showing that (3) $\Rightarrow$ (1). Using Theorem 3.4.2.1, we can choose a scallop decomposition

$$\varnothing \simeq \mathsf{U}_0 \hookrightarrow \cdots \hookrightarrow \mathsf{U}_n \simeq \mathsf{X},$$

so that each of the maps $\mathsf{U}_{i-1} \hookrightarrow \mathsf{U}_i$ fits into an excision square

$$\begin{array}{ccc} \mathsf{U}'_{i-1} & \longrightarrow & \operatorname{Spét} B_i \\ \downarrow & & \downarrow \\ \mathsf{U}_{i-1} & \longrightarrow & \mathsf{U}_i . \end{array}$$

If condition (3) is satisfied, then for each of the $\mathbb{E}_\infty$-rings B_i we can choose a finite collection of étale maps $B_i \rightarrow B_{i,j}$ for which the underlying ring homomorphisms $\{\pi_0 B_i \rightarrow \pi_0 B_{i,j}\}$ are a Nisnevich covering (in the sense of Definition B.4.1.1) and each of the composite maps

$$\operatorname{Spét} B_{i,j} \rightarrow \operatorname{Spét} B_i \rightarrow \mathsf{U}_i \rightarrow \mathsf{X}$$

factors through some u_α. We can therefore assume that for each $1 \leqslant i \leqslant n$, we can choose a sequence of elements $b_{i,1}, \ldots, b_{i,m_i} \in \pi_0 B_i$ which generate the unit ideal, such that each of the induced maps

$$\operatorname{Spét}(\pi_0 B_i)/(b_{i,1}, \ldots, b_{i,j-1})[b_{i,j}^{-1}] \rightarrow \operatorname{Spét} B_i \rightarrow \mathsf{U}_i \rightarrow \mathsf{X}$$

factors through some U_α. Passing to refinement of our original scallop decomposition, we may assume that for $1 \leqslant i \leqslant n$, the composite map $\mathsf{K}_i \rightarrow \mathsf{U}_i \rightarrow \mathsf{X}$ factors through some u_α, where K_i denotes the reduced closed substack of U_i complementary to U_{i-1}. This completes the proof of (1). □

3.7.3 The Noetherian Case

We will primarily be interested in studying Nisnevich coverings in the setting where X is locally Noetherian. In this case, Definition 3.7.1.1 can be simplified:

Proposition 3.7.3.1. *Let $\{u_\alpha : \mathsf{X}_\alpha \rightarrow \mathsf{X}\}$ be a collection of étale morphisms between quasi-compact, quasi-separated spectral algebraic spaces. If X is locally Noetherian, then the following conditions are equivalent:*

(1) *For each point* $x \in |\mathsf{X}|$*, there exists an index* α *and a point* $x_\alpha \in |\mathsf{X}_\alpha|$ *such that* $u_\alpha(x_\alpha) = x$*, and* u_α *induces an isomorphism of residue fields* $\kappa(x) \to \kappa(x_\alpha)$*.*

(2) *The collection of morphisms* u_α *determine a Nisnevich covering of* X*.*

Proof. Suppose that (2) is satisfied. Then the collection of morphisms $\operatorname{Sp\acute{e}t} \kappa(x) \times_{\mathsf{X}} \mathsf{X}_\alpha$ is a Nisnevich covering of $\operatorname{Sp\acute{e}t} \kappa(x)$ (Remark 3.7.1.4). It follows immediately from the definitions that one of the projection maps $\operatorname{Sp\acute{e}t} \kappa(x) \times_{\mathsf{X}} \mathsf{X}_\alpha \to \operatorname{Sp\acute{e}t} \kappa(x)$ admits a section, which determines a point $x_\alpha \in |\mathsf{X}_\alpha|$ having the desired properties. This proves that (2) $\Rightarrow$ (1) (note that this argument does not require the assumption that X is locally Noetherian).

We now prove that (1) $\Rightarrow$ (2). Assume that (1) is satisfied. We will prove that the collection of morphisms u_α form a Nisnevich covering of X by verifying the third condition of Proposition 3.7.2.1. Let $f : \operatorname{Sp\acute{e}t} A \to \mathsf{X}$ be an étale map. Since X is locally Noetherian, the $\mathbb{E}_\infty$-ring A is Noetherian. It will therefore suffice to show that for every point $y \in |\operatorname{Spec} A|$, there exists an étale A-algebra A' and a point $y' \in |\operatorname{Spec} A'|$ lying over y such that $\kappa(y') \simeq \kappa(y)$, and the induced map $\operatorname{Sp\acute{e}t} A' \to \operatorname{Sp\acute{e}t} A \to \mathsf{X}$ factors through some X_α (Proposition B.4.3.1). Let $x \in |\mathsf{X}|$ denote the image of y. Using assumption (1), we can factor the composite map $\operatorname{Sp\acute{e}t} \kappa(y) \to \operatorname{Sp\acute{e}t} \kappa(x) \to \mathsf{X}$ through u_α for some α, so that we obtain a map $\operatorname{Sp\acute{e}t} \kappa(y) \to \operatorname{Sp\acute{e}t} A \times_{\mathsf{X}} \mathsf{X}_\alpha$. The desired result now follows from Corollary 3.4.2.5. □

3.7.4 Nisnevich Sheaves

Using Definition 3.7.1.1, we can associate a Grothendieck site to every quasi-compact, quasi-separated spectral algebraic space.

Proposition 3.7.4.1. *Let* X *be a quasi-compact, quasi-separated spectral algebraic space. Then there is a Grothendieck topology on the* ∞*-category* $\mathcal{T}_{\mathsf{X}}$ *which can be characterized as follows: for each object* $\mathsf{X}' \in \mathcal{T}_{\mathsf{X}}$*, a sieve* $\mathcal{C}^{(0)} \subseteq \mathcal{T}_{\mathsf{X}'} \simeq (\mathcal{T}_{\mathsf{X}})_{/\mathsf{X}'}$ *is covering if and only if it is is a Nisnevich covering of* X'*, in the sense of Definition 3.7.1.1.*

We will refer to the Grothendieck topology of Proposition 3.7.4.1 as the *Nisnevich topology* on $\mathcal{T}_{\mathsf{X}}$.

Remark 3.7.4.2. Let X be a quasi-compact, quasi-separated spectral algebraic space. Then the Nisnevich topology on $\mathcal{T}_{\mathsf{X}}$ is finitary, in the sense of Definition A.3.1.1.

Proof of Proposition 3.7.4.1. It follows immediately from the definitions that each $\mathcal{T}_{\mathsf{X}'}$ is a covering sieve of itself, and Remark 3.7.1.4 implies that the collection of covering sieves is closed under pullbacks. To verify transitivity, it will suffice to establish the following:

(∗) Suppose we are given a Nisnevich covering $\{\mathsf{Y}_\alpha \to \mathsf{Y}\}_{\alpha \in S}$ and, for each index $\alpha \in S$, another Nisnevich covering $\{\mathsf{Y}_{\alpha,\beta} \to \mathsf{Y}_\alpha\}$. Then the collection of composite maps $\mathsf{Y}_{\alpha,\beta} \to \mathsf{Y}_\alpha \to \mathsf{Y}$ is a Nisnevich covering of Y.

We will prove (∗) by verifying that the collection of maps $\{\mathsf{Y}_{\alpha,\beta} \to \mathsf{Y}\}$ satisfies condition (3) of Proposition 3.7.2.1. Fix a map $f : \operatorname{Spét} A \to \mathsf{Y}$. Applying Proposition 3.7.2.1, we conclude that A admits a Nisnevich covering $\{A \to A_i\}$ such that each of the composite maps $\operatorname{Spét} A_i \to \operatorname{Spét} A \to \mathsf{Y}$ factors through some Y_{α_i}. Applying Proposition 3.7.2.1 again, we conclude that each A_i admits a Nisnevich covering $\{A_i \to A_{i,j}\}$ for which each of the composite maps $\operatorname{Spét} A_{i,j} \to \operatorname{Spét} A_i \to \mathsf{Y}_{\alpha_i}$ factors through some $\mathsf{Y}_{\alpha_i,\beta}$. We now conclude by observing that the collection of maps $\{A \to A_{i,j}\}$ is a Nisnevich covering (Proposition B.4.2.3). □

Definition 3.7.4.3. Let X be a quasi-compact, quasi-separated spectral algebraic space and let $\mathscr{F} : \mathcal{T}_{\mathsf{X}}^{\mathrm{op}} \to \mathcal{C}$ be a functor from $\mathcal{T}_{\mathsf{X}}^{\mathrm{op}}$ to another ∞-category $\mathcal{C}$. We will say that $\mathscr{F}$ is a *Nisnevich sheaf* if it is a sheaf with respect to the Nisnevich topology of Proposition 3.7.4.1. We let $\mathcal{S}\mathrm{hv}_{\mathrm{Nis}}(\mathsf{X})$ denote the full subcategory of $\operatorname{Fun}(\mathcal{T}_{\mathsf{X}}^{\mathrm{op}}, \mathcal{S})$ spanned by the Nisnevich sheaves; we will refer to $\mathcal{S}\mathrm{hv}_{\mathrm{Nis}}(\mathsf{X})$ as the *Nisnevich ∞-topos of* X.

Example 3.7.4.4. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a quasi-compact, quasi-separated spectral algebraic space and let us identify $\mathcal{T}_{\mathsf{X}}$ with the full subcategory of $\mathcal{X}$ spanned by the coherent 0-truncated objects (Remark 3.7.1.3). Then the ∞-topos $\mathcal{X}$ is 1-localic (Corollary 1.6.8.6) and the underlying topos $\mathcal{X}^{\heartsuit}$ is coherent. It follows that the restricted Yoneda embedding

$$(X \in \mathcal{X}) \mapsto (h_X \in \operatorname{Fun}(\mathcal{T}_{\mathsf{X}}^{\mathrm{op}}, \mathcal{S})) \qquad h_X(U) = \operatorname{Map}_{\mathcal{X}}(U, X)$$

is fully faithful. The essential image of the construction $X \mapsto h_X$ consists of those functors $\mathcal{T}_{\mathsf{X}}^{\mathrm{op}} \to \mathcal{S}$ which are sheaves with respect to the étale topology. Since every covering for the Nisnevich topology is also a covering for the étale topology, we obtain a fully faithful geometric morphism $\rho_* : \mathcal{X} \to \mathcal{S}\mathrm{hv}_{\mathrm{Nis}}(\mathsf{X})$.

In the special case where X is affine, Definition 3.7.4.3 recovers the theory studied in §B.4:

Proposition 3.7.4.5. *Let A be a connective $\mathbb{E}_\infty$-ring, let $\mathsf{X} = \operatorname{Spét} A$, and let $\mathscr{F} : \mathcal{T}_{\mathsf{X}}^{\mathrm{op}} \to \mathcal{S}$ be a functor. Then $\mathscr{F}$ is a sheaf with respect to the Nisnevich topology of Proposition 3.7.4.1 if and only if it satisfies the following conditions:*

(1) *Let $\theta : \mathrm{CAlg}_A^{\text{ét}} \to \mathcal{T}_{\mathsf{X}}^{\mathrm{op}}$ denote the functor given by $B \mapsto \operatorname{Spét} B$. Then $\mathscr{F} \circ \theta \in \operatorname{Fun}(\mathrm{CAlg}_A^{\text{ét}}, \mathcal{S})$ is a sheaf with respect to the Nisnevich topology of Definition B.4.2.2.*

(2) *The functor $\mathscr{F}$ is a right Kan extension of its restriction to the essential image of θ.*

Corollary 3.7.4.6. *Let A be a connective $\mathbb{E}_\infty$-ring and let $\mathsf{X} = \operatorname{Sp\acute{e}t} A$. Then we have a canonical equivalence of ∞-categories $\mathcal{S}\mathrm{hv}_{\mathrm{Nis}}(\mathsf{X}) \simeq \mathcal{S}\mathrm{hv}_A^{\mathrm{Nis}}$.*

Proof. Combine Propositions 3.7.4.5 and HTT.4.3.2.15 . □

Proof of Proposition 3.7.4.5. Suppose first that $\mathscr{F}$ satisfies conditions (1) and (2); we will show that $\mathscr{F}$ is a sheaf with respect to the Nisnevich topology. Let $\mathsf{Y} \in \mathcal{T}_{\mathsf{X}}$ and let $\mathcal{C} \subseteq \mathcal{T}_{\mathsf{Y}}$ be a covering sieve for the Nisnevich topology; we must show that the canonical map $\mathscr{F}(\mathsf{Y}) \to \varprojlim_{\mathsf{Z} \in \mathcal{C}} \mathscr{F}(\mathsf{Z})$ is an equivalence. Let $\mathcal{D}$ be the the full subcategory of $\mathcal{T}_{\mathsf{Y}}$ spanned by those maps $\mathsf{Z} \to \mathsf{Y}$ where Z is affine. Using condition (2), we deduce that $\mathscr{F}|_{\mathcal{C}^{\mathrm{op}}}$ is a right Kan extension of $\mathscr{F}|_{(\mathcal{C} \cap \mathcal{D})^{\mathrm{op}}}$. It will therefore suffice to show that $\mathscr{F}(\mathsf{Y})$ is a limit of the diagram $\mathscr{F}|_{(\mathcal{C} \cap \mathcal{D})^{\mathrm{op}}}$ (Lemma HTT.4.3.2.7). Using condition (1) and Proposition 3.7.2.1, we see that $\mathscr{F}|_{\mathcal{D}^{\mathrm{op}}}$ is a right Kan extension of $\mathscr{F}|_{(\mathcal{C} \cap \mathcal{D})^{\mathrm{op}}}$. Using Lemma HTT.4.3.2.7 again, we are reduced to proving that the map $\mathscr{F}(\mathsf{Y}) \to \varprojlim \mathscr{F}|_{\mathcal{D}^{\mathrm{op}}}$ is an equivalence, which follows from (2).

Now suppose that $\mathscr{F}$ is a sheaf with respect to the Nisnevich topology. We first claim that $\mathscr{F}$ satisfies (1). Let B be an étale A-algebra, and let $\mathcal{C} \subseteq (\mathrm{CAlg}_B^{\acute{e}t})^{\mathrm{op}}$ be a covering sieve with respect to the Nisnevich topology; we wish to show that the canonical map

$$\mathscr{F}(\operatorname{Sp\acute{e}t} B) \to \varprojlim_{C \in \mathcal{C}} \mathscr{F}(\operatorname{Sp\acute{e}t} C)$$

is a homotopy equivalence. To this end, we let $\mathcal{D} \subseteq \mathcal{T}_{\operatorname{Sp\acute{e}t} B}$ denote the sieve generated by the objects $\{\operatorname{Sp\acute{e}t} C\}_{C \in \mathcal{C}}$. Then the construction $C \mapsto \operatorname{Sp\acute{e}t} C$ determines a left cofinal functor $\mathcal{C}^{\mathrm{op}} \to \mathcal{D}$, so it will suffice to show that $\mathscr{F}(\operatorname{Sp\acute{e}t} B)$ is a limit of the diagram $\mathscr{F}|_{\mathcal{D}^{\mathrm{op}}}$. This follows from our assumption that $\mathscr{F}$ is a Nisnevich sheaf, since $\mathcal{D}$ is a covering sieve for the Nisnevich topology (by virtue of Proposition 3.7.2.1).

We now prove that $\mathscr{F}$ satisfies (2). Let $\mathscr{F}' : \mathcal{T}_{\mathsf{X}}^{\mathrm{op}} \to \mathcal{S}$ be a right Kan extension of $\mathscr{F} \circ \theta$ along the functor θ, so that we have a canonical map $\alpha : \mathscr{F} \to \mathscr{F}'$ which is an equivalence on affine objects of $\mathcal{T}_{\mathsf{X}}$. Since $\mathscr{F}$ satisfies condition (1), the functor $\mathscr{F}'$ satisfies conditions (1) and (2), and is therefore a Nisnevich sheaf by the first part of the proof. Invoking Propositions 3.7.5.3 and 3.7.5.2, we conclude that α is an equivalence, so that $\mathscr{F}$ is a right Kan extension of $\mathscr{F} \circ \theta$ along θ. □

3.7.5 Nisnevich Excision

We next prove a global analogue of Theorem B.5.0.3.

Theorem 3.7.5.1. *[Morel-Voevodsky] Let X be a quasi-compact, quasi-separated spectral algebraic space and let $\mathscr{F} : \mathcal{T}_{\mathsf{X}}^{\mathrm{op}} \to \mathcal{S}$ be a functor. The following conditions are equivalent:*

(1) *The functor $\mathscr{F}$ is a sheaf with respect to the Nisnevich topology of Proposition 3.7.4.1.*

(2) *The space* $\mathscr{F}(\emptyset)$ *is contractible and for every excision square*

$$\begin{array}{ccc} \mathsf{U}' & \longrightarrow & \mathsf{Y}' \\ \downarrow & & \downarrow \\ \mathsf{U} & \longrightarrow & \mathsf{Y} \end{array}$$

in $\mathcal{T}_{\mathsf{X}}$, *the diagram of spaces*

$$\begin{array}{ccc} \mathscr{F}(\mathsf{U}') & \longleftarrow & \mathscr{F}(\mathsf{Y}') \\ \uparrow & & \uparrow \\ \mathscr{F}(\mathsf{U}) & \longleftarrow & \mathscr{F}(\mathsf{Y}) \end{array}$$

is a pullback square.

The proof of Theorem 3.7.5.1 will require some preliminaries. We first show that (1) ⇒ (2):

Proposition 3.7.5.2. *Let* X *be a quasi-compact, quasi-separated spectral algebraic space, and let* $\mathscr{F} : \mathcal{T}_{\mathsf{X}}^{\mathrm{op}} \to \mathcal{S}$ *be a sheaf for the Nisnevich topology. Then for every excision square*

$$\begin{array}{ccc} \mathsf{U}' & \longrightarrow & \mathsf{Y}' \\ \downarrow & & \downarrow \\ \mathsf{U} & \longrightarrow & \mathsf{Y} \end{array}$$

in $\mathcal{T}_{\mathsf{X}}$, *the diagram of spaces*

$$\begin{array}{ccc} \mathscr{F}(\mathsf{U}') & \longleftarrow & \mathscr{F}(\mathsf{Y}') \\ \uparrow & & \uparrow \\ \mathscr{F}(\mathsf{U}) & \longleftarrow & \mathscr{F}(\mathsf{Y}) \end{array}$$

is a pullback square.

Proof. For each object $\mathsf{Y} \in \mathcal{T}_{\mathsf{X}}$, let $h_{\mathsf{Y}} : \mathcal{T}_{\mathsf{X}}^{\mathrm{op}} \to \mathcal{S}$ denote the functor represented by Y. To prove Proposition 3.7.5.2, it will suffice to show that the construction $\mathsf{Y} \mapsto h_{\mathsf{Y}}$ carries excision square in $\mathcal{T}_{\mathsf{X}}$ to pushout diagrams in $\mathcal{S}\mathrm{hv}(\mathcal{T}_{\mathsf{X}})$. This follows immediately from Proposition 2.5.2.1. □

Proposition 3.7.5.3. *Let* X *be a quasi-compact, quasi-separated spectral algebraic space, and let* $\alpha : \mathscr{F} \to \mathscr{F}'$ *be a natural transformation between functors* $\mathscr{F}, \mathscr{F}' : \mathcal{T}_{\mathsf{X}}^{\mathrm{op}} \to \mathcal{S}$. *Assume that* $\mathscr{F}$ *and* $\mathscr{F}'$ *satisfy condition* (2) *of Theorem 3.7.5.1. If* α *induces a homotopy equivalence* $\mathscr{F}(\mathsf{Y}) \to \mathscr{F}'(\mathsf{Y})$ *whenever* $\mathsf{Y} \in \mathcal{T}_{\mathsf{X}}$ *is affine, then* α *is an equivalence.*

Proof. Let Y be an arbitrary object of $\mathcal{T}_{\mathsf{X}}$; we wish to show that α induces a homotopy equivalence $\alpha_{\mathsf{Y}} : \mathscr{F}(\mathsf{Y}) \to \mathscr{F}'(\mathsf{Y})$. We first treat the case where Y is quasi-affine. In this case, Y admits an open covering by finitely many affine open substacks $\{\mathsf{U}_i\}_{1 \leqslant i \leqslant n}$. We proceed by induction on n, the case $n \leqslant 1$ being trivial. To carry out the inductive step, we let Y' denote the open substack of Y given by the union of the open substacks $\{\mathsf{U}_i\}_{1 \leqslant i < n}$, so that we have an excision square

$$\begin{array}{ccc} \mathsf{U}_n \times_{\mathsf{Y}} \mathsf{Y}' & \longrightarrow & \mathsf{U}_n \\ \downarrow & & \downarrow \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y}. \end{array}$$

It follows from the inductive hypothesis that $\alpha_{\mathsf{Y}'}$, α_{U_n}, and $\alpha_{\mathsf{U}_n \times_{\mathsf{Y}} \mathsf{Y}'}$ are homotopy equivalences. Since $\mathscr{F}$ and $\mathscr{F}'$ satisfy condition (2) of Theorem 3.7.5.1, we conclude that α_{Y} is a homotopy equivalence.

We now treat the general case. Using Theorem 3.4.2.1, we can choose a scallop decomposition $\varnothing = \mathsf{V}_0 \hookrightarrow \cdots \hookrightarrow \mathsf{V}_m \simeq \mathsf{Y}$ where each V_i fits into an excision square

$$\begin{array}{ccc} \mathsf{W}_i & \longrightarrow & \operatorname{Sp\acute{e}t} R_i \\ \downarrow & & \downarrow \\ \mathsf{V}_{i-1} & \longrightarrow & \mathsf{V}_i. \end{array}$$

The argument given above shows that the maps α_{W_i} and $\alpha_{\operatorname{Sp\acute{e}t} R_i}$ are homotopy equivalences. Using our assumption on $\mathscr{F}$ and $\mathscr{F}'$ together with induction on i, we conclude that each of the maps α_{V_i} is a homotopy equivalence. Taking $i = m$, we deduce that α_{Y} is a homotopy equivalence, as desired. □

Proof of Theorem 3.7.5.1. The implication (1) ⇒ (2) follows immediately from Proposition 3.7.5.2. Conversely, suppose that $\mathscr{F}$ satisfies (2). We begin by treating the case where $\mathsf{X} = \operatorname{Sp\acute{e}t} A$ is affine. Let $\mathscr{F}_0 : \mathrm{CAlg}_A^{\acute{e}t} \to \mathcal{S}$ be the functor given by $\mathscr{F}_0(B) = \mathscr{F}(\operatorname{Sp\acute{e}t} B)$. If $\mathscr{F}$ satisfies condition (2), then $\mathscr{F}_0$ satisfies Nisnevich excision (Definition B.5.0.1) and is therefore a sheaf with respect to the Nisnevich topology on $\mathrm{CAlg}_A^{\acute{e}t}$ (Theorem B.5.0.3). Let $\mathscr{F}' : \mathcal{T}_{\mathsf{X}}^{op} \to \mathcal{S}$ be a right Kan extension of $\mathscr{F}_0$ along the fully faithful embedding $\operatorname{Sp\acute{e}t} : \mathrm{CAlg}_A^{\acute{e}t} \hookrightarrow \mathcal{T}_{\mathsf{X}}^{op}$. Then $\mathscr{F}'$ is a Nisnevich sheaf (Proposition 3.7.4.5) and the canonical map $\alpha : \mathscr{F} \to \mathscr{F}'$ is an equivalence on all affine objects $\mathsf{U} \in \mathcal{T}_{\mathsf{X}}$. It follows from Proposition 3.7.5.3 that α is an equivalence, so that $\mathscr{F}$ is also a Nisnevich sheaf.

We now treat the general case. Let $\alpha : \mathscr{F} \to \mathscr{F}'$ be a natural transformation of functors which exhibits $\mathscr{F}'$ as a sheafification of $\mathscr{F}$ with respect to the Nisnevich topology. The first part of the proof shows that for every affine object $\mathsf{Y} \in \mathcal{T}_{\mathsf{X}}$, the restriction of $\mathscr{F}$ to $\mathcal{T}_{\mathsf{Y}}^{op}$ is already a Nisnevich sheaf. It follows that α induces an equivalence $\mathscr{F}(\mathsf{Y}) \to \mathscr{F}'(\mathsf{Y})$. Invoking Proposition 3.7.5.3, we conclude that α is an equivalence, so that $\mathscr{F}$ is a Nisnevich sheaf. □

3.7.6 Height and Krull Dimension

We now study the dimension theory of spectral algebraic spaces.

Definition 3.7.6.1. Let X be a quasi-separated spectral algebraic space. We will say that a point $x \in |\mathsf{X}|$ has *height* $\leqslant n$ if the following condition is satisfied:

($*$) For every sequence of points $x = x_0, x_1, \ldots, x_m \in |\mathsf{X}|$ having the property that $x_i \in \overline{\{x_{i+1}\}} - \{x_{i+1}\}$ for $0 \leqslant i < m$, we have $m \leqslant n$.

We say that x is of *finite height* if it has height $\leqslant n$ for some integer $n \geqslant 0$. In this case, we define the *height* of x to be the smallest nonnegative integer $n \geqslant 0$ such that x has height $\leqslant n$. We let $\mathrm{ht}(x)$ denote the height of x.

Proposition 3.7.6.2. *Let X be a quasi-separated spectral algebraic space, let A be a Noetherian $\mathbb{E}_\infty$-ring, and let $f : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$ be an étale map. Let $\mathfrak{p} \subseteq \pi_0 A$ be a prime ideal, and let x denote the image of $\mathfrak{p}$ under the continuous map $|\operatorname{Spec} A| \to |\mathsf{X}|$ determined by f. Then the height of x is equal to the Krull dimension of the local commutative ring $\pi_0 A_{\mathfrak{p}}$.*

Corollary 3.7.6.3. *Let X be a locally Noetherian spectral algebraic space. Then every point $x \in |\mathsf{X}|$ has finite height.*

Corollary 3.7.6.4. *Let $f : \mathsf{X} \to \mathsf{Y}$ be an étale morphism between locally Noetherian spectral algebraic spaces. Then for every point $x \in |\mathsf{X}|$, we have $\mathrm{ht}(x) = \mathrm{ht}(f(x))$.*

Proof. Combine Proposition 3.7.6.2 with Variant B.2.2.4. □

Proof of Proposition 3.7.6.2. Replacing X by an open substack if necessary, we may assume without loss of generality that X is quasi-compact. Let n denote the Krull dimension of the local ring $\pi_0 A_{\mathfrak{p}}$. Suppose we are given a chain of distinct points $x = x_0, x_1, \ldots, x_m \in |\mathsf{X}|$, where each x_i is contained in the closure of x_{i+1}. Applying Corollary 4.3.4.4 repeatedly, we can choose a descending chain of ideals

$$\mathfrak{p} = \mathfrak{p}_0 \supsetneq \mathfrak{p}_1 \supsetneq \cdots \supsetneq \mathfrak{p}_m$$

in $\pi_0 A$, so that $m \leqslant n$. It follows that x has height $\leqslant n$. To prove that equality holds, we note that $\pi_0 A$ contains a descending chain of ideals

$$\mathfrak{p} = \mathfrak{p}_0 \supsetneq \mathfrak{p}_1 \supsetneq \cdots \supsetneq \mathfrak{p}_n,$$

whose image in $|\mathsf{X}|$ is a chain of points $x = x_0, x_1, \ldots, x_n$ for which each x_i is contained in the closure of x_{i+1}. To complete the proof, it suffices to show that the points x_i are distinct from one another. Suppose that $x_i = x_j$. Then the pair $(\mathfrak{p}_i, \mathfrak{p}_j)$ can be lifted to a point of $|\mathrm{Sp\acute{e}t}\, A \times_{\mathsf{X}} \mathrm{Sp\acute{e}t}\, A|$ (Corollary 3.6.3.2). We can therefore choose an étale map

$u : \mathrm{Spét}\, B \to \mathrm{Spét}\, A \times_{\mathsf{X}} \mathrm{Spét}\, A$ and a prime ideal $\mathfrak{q} \subseteq \pi_0 B$ lying over $(\mathfrak{p}_i, \mathfrak{p}_j)$. Since the map $f : \mathrm{Spét}\, A \to \mathsf{X}$ is étale, the map u determines a pair of étale morphisms $A \to B$. Using Variant B.2.2.4 we obtain

$$n - i = \dim \pi_0 A_{\mathfrak{p}_i} = \dim \pi_0 B_{\mathfrak{q}} = \dim \pi_0 A_{\mathfrak{p}_j} = n - j,$$

so that $i = j$ as desired. □

Definition 3.7.6.5. Let X be a locally Noetherian spectral algebraic space. We will say that X has *Krull dimension* $\leqslant n$ if every point $x \in |\mathsf{X}|$ has height $\leqslant n$.

Remark 3.7.6.6. Let X be a spectral algebraic space which is quasi-compact and locally Noetherian. Then $|\mathsf{X}|$ is a Noetherian topological space (Remark 3.6.3.5). The spectral algebraic space X has Krull dimension $\leqslant n$ if and only if every chain of irreducible closed subsets

$$K_0 \subsetneq K_1 \subsetneq K_2 \subsetneq \cdots \subsetneq K_m \subseteq |\mathsf{X}|$$

has length $m \leqslant n$. In other words, the Krull dimension of X is the same as the Krull dimension of the topological space $|\mathsf{X}|$; see §HTT.7.2.4 .

Remark 3.7.6.7. Let X be a locally Noetherian spectral algebraic space. The condition that X be of Krull dimension $\leqslant n$ is local with respect to the étale topology (Corollary 3.7.6.4).

3.7.7 A Vanishing Theorem for Nisnevich Sheaves

Let X be a spectral algebraic space which is quasi-compact, locally Noetherian, and of Krull dimension $\leqslant n$. Combining Remark 3.7.6.6 with Corollary HTT.7.2.4.17 , we see that the ∞-topos $\mathcal{S}\mathrm{hv}(|\mathsf{X}|)$ has homotopy dimensional $\leqslant n$. At the end of this section, we will prove the following analogue for Nisnevich sheaves:

Theorem 3.7.7.1. *Let X be a spectral algebraic space which is quasi-compact, locally Noetherian, and of Krull dimension $\leqslant n$. Then the ∞-topos $\mathcal{S}\mathrm{hv}_{\mathrm{Nis}}(\mathsf{X})$ has homotopy dimension $\leqslant n$.*

In the situation of Theorem 3.7.7.1, the ∞-topos $\mathcal{S}\mathrm{hv}_{\mathrm{Nis}}(\mathsf{X})$ is generated under colimits by objects U for which $\mathcal{S}\mathrm{hv}_{\mathrm{Nis}}(\mathsf{X})_{/U} \simeq \mathcal{S}\mathrm{hv}_{\mathrm{Nis}}(\mathsf{U})$, where U is étale over X and therefore also of Krull dimension $\leqslant n$. We therefore obtain the following variant:

Corollary 3.7.7.2. *Let X be a spectral algebraic space which is quasi-compact, locally Noetherian, and of Krull dimension $\leqslant n$. Then the ∞-topos $\mathcal{S}\mathrm{hv}_{\mathrm{Nis}}(\mathsf{X})$ is locally of homotopy dimension $\leqslant n$.*

Corollary 3.7.7.3. *Let* X *be a spectral algebraic space which is quasi-compact, locally Noetherian, and of finite Krull dimension. Then the* ∞*-topos* $\mathcal{S}\mathrm{hv}_{\mathrm{Nis}}(\mathsf{X})$ *is Postnikov complete (Definition A.7.2.1). In particular, the* ∞*-topos* $\mathcal{S}\mathrm{hv}_{\mathrm{Nis}}(\mathsf{X})$ *is hypercomplete.*

Proof. Combine Theorem 3.7.7.1, Proposition HTT.7.2.1.10 , and Proposition **??**. □

Proof of Theorem 3.7.0.2. Let X be a quasi-compact locally Noetherian spectral algebraic space of Krull dimension $\leqslant d$ and let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$. We wish to show that the homotopy groups $\pi_{-n}(\mathsf{X}; \mathscr{F})$ vanish for $n > d$. The quasi-coherent sheaf $\mathscr{F}$ determines a Nisnevich sheaf

$$\mathscr{G} : \mathcal{T}_{\mathsf{X}}^{\mathrm{op}} \to \mathcal{S} \qquad \mathscr{G}(\mathsf{Y}) = \Omega^{\infty-n}\Gamma(\mathsf{Y}; \mathscr{F}|_{\mathsf{Y}}).$$

Since $\mathscr{F}$ is connective and quasi-coherent, the space $\mathscr{G}(\mathsf{Y})$ is n-connective whenever Y is affine. Since every object of $\mathcal{T}_{\mathsf{X}}$ admits a Nisnevich covering by affine objects of $\mathcal{T}_{\mathsf{X}}$ (Example 3.7.1.5), the sheaf $\mathscr{G}$ is n-connective when viewed as an object of the ∞-topos $\mathcal{S}\mathrm{hv}_{\mathrm{Nis}}(\mathsf{X})$. Theorem 3.7.7.1 asserts that $\mathcal{S}\mathrm{hv}_{\mathrm{Nis}}(\mathsf{X})$ has homotopy dimension $\leqslant d$, so that the space $\mathscr{G}(\mathsf{X})$ is $(n-d)$-connective. In particular, we have $\pi_{-n}\Gamma(\mathsf{X}; \mathscr{F}) \simeq \pi_0 \mathscr{G}(\mathsf{X}) \simeq 0$. □

3.7.8 Proof of the Vanishing Theorem

We now give the proof of Theorem 3.7.7.1. It involves some variants of the ideas used in §B.5 which might be of independent interest (from the proof, one can extract stronger versions of Theorem 3.7.0.2).

Definition 3.7.8.1. Let X be a spectral algebraic space which is quasi-compact and locally Noetherian. Given a morphism $\alpha : \mathscr{F} \to \mathscr{F}'$ in $\mathcal{S}\mathrm{hv}(\mathcal{T}_{\mathsf{X}})$ and a point $u \in \mathscr{F}'(\mathsf{U})$, we let $\mathscr{F}_u \in \mathcal{S}\mathrm{hv}(\mathcal{T}_{\mathsf{U}})$ denote the sheaf given by $\mathscr{F}_u(\mathsf{V}) = \mathscr{F}(\mathsf{V}) \times_{\mathscr{F}'(\mathsf{V})} \{u\}$. We will say that α is *weakly* n*-connective* if the following condition is satisfied:

- (∗) For each point $u \in \mathscr{F}'(\mathsf{U})$, each $x \in |\,\mathsf{U}\,|$, and each map of spaces $S^k \to \mathscr{F}_u(\mathsf{U})$ where $-1 \leqslant k < n - \mathrm{ht}(x)$, there exists a map $g : \mathsf{U}' \to \mathsf{U}$, a point $x' \in |\,\mathsf{U}'\,|$ with $g(x') = x$ and $\kappa(x) \simeq \kappa(x')$ for which the composite map $S^k \to \mathscr{F}_u(\mathsf{U}) \to \mathscr{F}_u(\mathsf{U}')$ is nullhomotopic (when $k = -1$, this means that $\mathscr{F}_u(\mathsf{U}')$ is nonempty).

Remark 3.7.8.2. In the situation of Definition 3.7.8.1, the collection of weakly n-connective morphisms in $\mathcal{S}\mathrm{hv}(\mathcal{T}_{\mathsf{X}})$ is closed under pullbacks.

Lemma 3.7.8.3. *Let* X *be a spectral algebraic space which is quasi-compact and locally Noetherian, and let* $n \geqslant 0$*. Then a morphism* $\theta : \mathscr{F} \to \mathscr{F}'$ *in* $\mathcal{S}\mathrm{hv}(\mathcal{T}_{\mathsf{X}})$ *is weakly* n*-connective if and only if the following conditions are satisfied:*

(1) *For every point $u \in \mathscr{F}'(\mathsf{U})$, and every point $x \in |\,\mathsf{U}\,|$ of height $\leqslant n$, there exists a map there exists a map $g : \mathsf{U}' \to \mathsf{U}$, a point $x' \in |\,\mathsf{U}'\,|$ with $g(x') = x$ and $\kappa(x) \simeq \kappa(x')$ for whcih $\mathscr{F}_u(\mathsf{U}')$ is nonempty.*

(2) *If $n > 0$, then the diagonal map $\mathscr{F} \to \mathscr{F} \times_{\mathscr{F}'} \mathscr{F}$ is weakly $(n-1)$-connective.*

The proof is a simple matter of unravelling definitions (see the proof of Lemma B.5.2.5).

Remark 3.7.8.4. Let X be a quasi-compact, locally Noetherian spectral algebraic space. Then every n-connective morphism in $\mathcal{S}\mathrm{hv}(\mathcal{T}_{\mathsf{X}})$ is weakly n-connective. This follows immediately by induction on n, using the criteria of Lemma 3.7.8.3.

Lemma 3.7.8.5. *Let X be a spectral algebraic space which is quasi-compact and locally Noetherian. For each object $\mathsf{U} \in \mathcal{T}_{\mathsf{X}}$, let $h_{\mathsf{U}} \in \mathcal{S}\mathrm{hv}(\mathcal{T}_{\mathsf{X}}) \subseteq \mathrm{Fun}(\mathcal{T}_{\mathsf{X}}^{\mathrm{op}}, \mathcal{S})$ denote the functor represented by U. If $\theta : \mathscr{F} \to h_{\mathsf{X}}$ is a weakly n-connective morphism in $\mathcal{S}\mathrm{hv}(\mathcal{T}_{\mathsf{X}})$, then there exists a finite collection of points $\{x_1, \ldots, x_m\} \subseteq |\,\mathsf{X}\,|$ of height $> n$ and a commutative diagram σ :*

$$\begin{array}{ccc} & \mathscr{F} & \\ \nearrow & & \searrow^{\theta} \\ h_{\mathsf{U}} & \longrightarrow & h_{\mathsf{X}} \end{array}$$

where U denote the open substack of X corresponding to the open subset $U = |\,\mathsf{X}\,| - \bigcup_{1 \leqslant i \leqslant m} \overline{\{x_i\}}$.

Proof. We proceed as in the proof of Lemma 3.7.8.5, using induction on n. When $n = -1$, we take $x_1, \ldots, x_m$ to be the set of generic points of X, so that $U = \emptyset$ and the existence of the diagram σ is automatic. Assume now that $n \geqslant 0$ and that the result is known for the integer $n-1$, so that we can choose a commutative diagram

$$\begin{array}{ccc} & \mathscr{F} & \\ {}^{\phi}\nearrow & & \searrow^{\theta} \\ h_{\mathsf{V}} & \longrightarrow & h_{\mathsf{X}}. \end{array}$$

Here V denotes the open substack of X corresponding to an open set $V = |\,\mathsf{X}\,| - \bigcup_{1 \leqslant i \leqslant m} \overline{\{x_i\}}$ where the points x_i have height $\geqslant n$. Reordering the points x_i if necessary, we may assume that $x_1, x_2, \ldots, x_k$ have height n while $x_{k+1}, \ldots, x_m$ have height $> n$. We assume that this data has been chosen so that k is as small as possible. We will complete the induction by showing that $k = 0$. Otherwise, the point x_1 has height n. Since θ is weakly n-connective, there exists a map $f : \mathsf{X}' \to \mathsf{X}$ and a point $x' \in |\,\mathsf{X}'\,|$ such that $f(x') = x_1$, $\kappa(x) \simeq \kappa(x')$, and

$\mathscr{F}(|\mathsf{X}'|)$ is nonempty. We may therefore choose a commutative diagram

$$\begin{array}{ccc} & \mathscr{F} & \\ {\scriptstyle\psi}\nearrow & & \searrow{\scriptstyle\theta} \\ h_{\mathsf{X}'} & \xrightarrow{f} & h_{\mathsf{X}} \end{array}$$

Let V' denote the open substack of X corresponding to the open set $|\mathsf{X}| - \bigcup_{2 \leqslant i \leqslant m} \overline{\{x_i\}}$. Replacing X' by an open substack if necessary, we may suppose that there is an excision square

$$\begin{array}{ccc} \mathsf{V} \times_{\mathsf{X}} \mathsf{X}' & \longrightarrow & \mathsf{X}' \\ \downarrow & & \downarrow \\ \mathsf{V} & \longrightarrow & \mathsf{V}'. \end{array}$$

It follows from Lemma 3.7.8.3 that the canonical map

$$h_{\mathsf{V}} \times_{\mathscr{F}} h_{\mathsf{X}'} \to h_{\mathsf{V} \times_{\mathsf{X}} \mathsf{X}'}$$

is weakly $(n-1)$-connective. Applying the inductive hypothesis, we deduce that there is a finite collection of points $y_1, \ldots, y_{m'} \in |\mathsf{V} \times_{\mathsf{X}} \mathsf{X}'|$ of height $\geqslant n$ and a commutative diagram

$$\begin{array}{ccc} & h_{\mathsf{V}} \times_{\mathscr{F}} h_{\mathsf{X}'} & \\ \nearrow & & \searrow \\ h_{\mathsf{W}} & \longrightarrow & h_{\mathsf{V} \times_{\mathsf{X}} \mathsf{X}'}, \end{array}$$

where W is the open substack of $\mathsf{V} \times_{\mathsf{X}} \mathsf{X}'$ corresponding to the open subset $|\mathsf{V} \times_{\mathsf{X}} \mathsf{X}'| - \bigcup \overline{\{y_j\}}$. Replacing X' by the open substack complementary to the closures of the points y_j (which contains x', since x' is a point of height n and therefore cannot lie in the closure of any other point of height n), we may assume that $\mathsf{W} = \mathsf{V} \times_{\mathsf{X}} \mathsf{X}'$, so that the maps ϕ and ψ are homotopic when restricted to $\mathsf{V} \times_{\mathsf{X}} \mathsf{X}'$. It follows that ϕ and ψ can be amalgamated to a map $h_{\mathsf{V}'} \to \mathscr{F}$, contradicting the minimality of k. □

Proof of Theorem 3.7.7.1. Let $\mathscr{F}$ be an n-connective object of $\mathcal{S}\mathrm{hv}(\mathcal{T}_{\mathsf{X}})$; we wish to prove that the canonical map $\alpha : \mathscr{F} \to h_{\mathsf{X}}$ admits a section. Remark 3.7.8.4 shows that α is weakly n-connective. The desired result now follows from Lemma 3.7.8.5, combined with the observation that $|\mathsf{X}|$ does not contain any points of height $> n$ (by virtue of our assumption that X has Krull dimension $\leqslant n$). □

Part II

Proper Morphisms

Recall that a continuous map $f : X \to Y$ of Hausdorff topological spaces is said to be *proper* if it is closed (that is, for every closed subset $K \subseteq X$, the image $f(K) \subseteq Y$ is also closed) and, for every point $y \in Y$, the fiber $X_y = f^{-1}\{y\}$ is compact. In the setting of schemes, Grothendieck introduced the following analogous notion:

Definition 3.7.0.1. Let $f : X \to Y$ be a morphism of schemes. We say that f is *proper* if it satisfies the following conditions:

(1) The morphism f is *quasi-compact*: that is, for every quasi-compact open subset $V \subseteq Y$, the inverse image $f^{-1}V \subseteq X$ is also quasi-compact.

(2) The morphism f is *separated*: that is, the diagonal map $\delta : X \to X \times_Y X$ is a closed immersion.

(3) The morphism f is *locally of finite type*: that is, for every affine open subscheme $\operatorname{Spec} B \simeq U \subseteq X$ for which $f|_U$ factors through an affine open subscheme $\operatorname{Spec} A \simeq V \subseteq Y$, the commutative ring B is finitely generated as an A-algebra.

(4) The morphism f is *universally closed*: that is, for every pullback diagram of schemes

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \longrightarrow & Y, \end{array}$$

the underlying map of topological spaces $X' \to Y'$ is closed.

Definition 3.7.0.1 plays a central role in the theory of schemes, thanks in part to the following foundational results of Grothendieck:

Theorem 3.7.0.2 (Direct Image Theorem)**.** *Let $f : X \to Y$ be a proper morphism between Noetherian schemes, and let $\mathscr{F}$ be a coherent sheaf on X. Then, for every integer $n \geqslant 0$, the higher direct image $R^n f_* \mathscr{F}$ is a coherent sheaf on Y.*

Theorem 3.7.0.3 (Grothendieck Existence Theorem)**.** *Let R be a Noetherian ring which is complete with respect to an ideal I, let $f : X \to \operatorname{Spec} R$ be a proper morphism of schemes, and for $m \geqslant 0$ set $X_m = \operatorname{Spec}(R/I^m) \times_{\operatorname{Spec} R} X$. Let $\operatorname{Coh}(X)$ and $\operatorname{Coh}(X_m)$ denote the abelian categories of coherent sheaves on X and X_m, respectively. Then the canonical map $\operatorname{Coh}(X) \to \varprojlim \{\operatorname{Coh}(X_m)\}$ is an equivalence of categories.*

Our primary goal in Part II is to adapt Definition 3.7.0.1 to the setting of spectral algebraic geometry and to prove analogues of Theorems 3.7.0.2 and 3.7.0.3 in the spectral setting. Some of the groundwork has already been laid in Part I, where we discussed the notions of *quasi-compact* and *separated* morphisms of spectral algebraic spaces (see Definitions 2.3.2.2 and 3.2.0.1). The next thing we need is an analogue of condition (3) of Definition 3.7.0.1. Here, we take our cue from classical algebraic geometry: we say that a morphism of spectral Deligne-Mumford stacks $f : \mathsf{X} \to \mathsf{Y}$ is *locally of finite type* if the underlying map of ordinary algebraic spaces locally of finite type. However, this definition comes with an important caveat. In classical algebraic geometry, if $f : X \to Y$ is locally of finite type and Y is locally Noetherian, then X is also locally Noetherian. The analogous statement in spectral algebraic geometry is false: if $f : \mathsf{X} \to \mathsf{Y}$ is a morphism of spectral algebraic spaces, then the hypothesis that f is locally of finite type imposes a finiteness condition only on $\pi_0 \mathscr{O}_{\mathsf{X}}$, and not on the higher homotopy sheaves on $\mathscr{O}_{\mathsf{X}}$. To ensure that finiteness properties of the structure sheaf $\mathscr{O}_{\mathsf{Y}}$ are inherited by $\mathscr{O}_{\mathsf{X}}$, one needs to impose the stronger condition that f is *locally almost of finite presentation* (see Definition 4.2.0.1). There is a significant difference between demanding that f be locally of finite type and demanding that it be locally almost of finite presentation: in fact, there is an entire hierarchy of finiteness conditions intermediate between the two, which we will study in detail in Chapter 4.

In Chapter 5, we define the notion of proper morphism of spectral algebraic spaces by direct analogy with Definition 3.7.0.1: a morphism $f : \mathsf{X} \to \mathsf{Y}$ is said to be *proper* if it is quasi-compact, separated, locally of finite type, and universally closed (equivalently, f is proper if the underlying map of ordinary algebraic spaces is proper; see Definition 5.1.2.1). To provide examples, we give a construction of projective spaces over an arbitrary connective $\mathbb{E}_\infty$-ring R (Construction 5.4.1.3). We then prove an analogue of Chow's lemma, which shows that arbitrary proper morphism of spectral algebraic spaces can be approximated by projective morphisms (Theorem 5.5.0.1). Using this result, we prove a spectral analogue of Theorem 3.7.0.2: if $f : \mathsf{X} \to \mathsf{Y}$ is proper and locally almost of finite presentation, then the direct image functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ carries almost perfect objects of $\mathrm{QCoh}(\mathsf{X})$ to almost perfect objects of $\mathrm{QCoh}(\mathsf{Y})$ (Theorem 5.6.0.2).

In practice, the assertion that the direct image functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ preserves almost perfect objects is often not good enough: for many applications, one wants to know that f_* carries perfect objects of $\mathrm{QCoh}(\mathsf{X})$ to perfect objects of $\mathrm{QCoh}(\mathsf{Y})$. This is generally not true if we assume only that f is proper (even if X and Y are Noetherian). In Chapter 6, we introduce the notion of a *morphism of finite* Tor-*amplitude* (Definition 6.1.1.1) and show that the direct image functor f_* preserves perfect objects whenever f is proper, locally almost of finite presentation, and of finite Tor-amplitude (Theorem 6.1.3.2; see also Theorem 11.1.4.1 for a converse). Under the same assumptions, we develop a version of Grothendieck duality: there is a quasi-coherent sheaf $\omega_{\mathsf{X}/\mathsf{Y}} \in \mathrm{QCoh}(\mathsf{X})$, which we call the *dualizing sheaf of* f, which satisfies $(f_* \mathscr{F})^\vee \simeq f_*(\mathscr{F}^\vee \otimes \omega_{\mathsf{X}/\mathsf{Y}})$ for each $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}$.

The remainder Part **??** is devoted to establishing a spectral analogue of Theorem 3.7.0.3. Let X be a spectral algebraic space (or, more generally, a spectral Deligne-Mumford stack). In Chapter 8, we will associate to each (cocompact) closed subset $K \subseteq |\mathsf{X}|$ another algebro-geometric object $\mathsf{X}^\wedge_K$, which we call the *formal completion of* X *along* K (Definition **??**). To this object, we can associate an ∞-category of quasi-coherent sheaves $\mathrm{QCoh}(\mathsf{X}^\wedge_K)$ and a restriction functor $\rho : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{X}^\wedge_K)$. Our main result asserts that if $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ is proper and locally almost of finite presentation, the closed set $K \subseteq |\mathsf{X}|$ is defined by the vanishing locus of a finitely generated ideal $I \subseteq \pi_0 R$, and the $\mathbb{E}_\infty$-ring R is I-complete (see Definition 7.3.0.5), then ρ restricts to an equivalence of ∞-categories $\mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}} \to \mathrm{QCoh}(\mathsf{X}^\wedge_K)^{\mathrm{aperf}}$, where $\mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}}$ denote the full subcategory of $\mathrm{QCoh}(\mathsf{X})$ spanned by the almost perfect objects and $\mathrm{QCoh}(\mathsf{X}^\wedge_K)^{\mathrm{aperf}}$ is defined similarly (Theorem 8.5.0.3). The proof will require a detailed study of completions in the setting of $\mathbb{E}_\infty$-rings and their modules, which we carry out in Chapter 7 (in somewhat greater generality).

Remark 3.7.0.4. If $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ is a proper morphism between locally Noetherian spectral algebraic spaces, then f is automatically locally almost of finite presentation (Remark 4.2.0.4). In this case, it is not difficult to deduce Theorems 5.6.0.2 and 8.5.0.3 from Theorems 3.7.0.2 and 3.7.0.3 (or, more precisely, from the analogous statements for algebraic spaces), applied to the underlying map of ordinary algebraic spaces $\tau_{\leqslant 0} \mathsf{X} \to \mathrm{Spec}(\pi_0 R)$. However, one pleasant feature of the spectral setting is that Theorems 5.6.0.2 and 8.5.0.3 do not require any Noetherian hypotheses, provided that F is locally almost of finite presentation. In the setting of classical algebraic geometry, the resulting generalization of Theorem 3.7.0.2 is due to Illusie (in the projective case) and Kiehl (in general); see [101] and [116].

Chapter 4

Morphisms of Finite Presentation

Let A be a commutative ring and let X be an A-scheme. Recall that X is said to be *locally of finite type* over A if, for every affine open subscheme $\operatorname{Spec} B \subseteq X$, the commutative ring B is finitely generated as an A-algebra. The scheme X is said to be *locally of finite presentation* over A if, for every open affine subscheme $\operatorname{Spec} B \subseteq X$, the commutative ring B is finitely presented as an A-algebra. Our goal in this section is to study some analogous finiteness conditions in the setting of spectral algebraic geometry.

We begin by considering finiteness conditions which can be imposed on a morphism $\phi : A \to B$ of connective $\mathbb{E}_\infty$-rings. Here the situation is more subtle than in classical commutative algebra. If A is a commutative ring, then one can specify a commutative A-algebra B by writing down generators and relations: that is, by writing B as the cofiber of a map of polynomial algebras $A[\vec{y}] \to A[\vec{x}]$. In the setting of $\mathbb{E}_\infty$-rings, the naive analogue of this statement is false: not every $\mathbb{E}_\infty$-algebra B over A can be obtained as the cofiber of a map of free A-algebras $A\{\vec{y}\} \to A\{\vec{x}\}$. In general, one needs to specify not only generators and relations, but relations among the relations, relations among those, and so forth. As a consequence, there is an entire hierarchy of natural finiteness conditions which can be thought of as intermediate between "finite type" and "finite presentation." We will study these conditions (and their interrelatinoships) in §4.2.

In §4.2, we apply the ideas of §4.1 to introduce several conditions on a morphism $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks (see Definition 4.2.0.1):

(a) The condition that f is locally of finite presentation.

(b) The condition that f is locally almost of finite presentation.

(c) The condition that f is locally of finite generation to order n, for some integer $n \geqslant 0$.

Condition (b) will be the most useful to us in this book: the role of "almost finite presentation" in spectral algebraic geometry can be regarded as analogous to the role of "finite presentation" in classical scheme theory (condition (a) is a bit too strong to play this role: for example, if $f : X \to Y$ is a morphism of finite presentation of Noetherian schemes, then f need not satisfy condition (a) when regarded as a morphism of spectral Deligne-Mumford stacks, but will always satisfy condition (b)). The role of condition (c) is more technical: it is equivalent to (b) if both X and Y are locally Noetherian, but otherwise provides a sequence of weaker finiteness conditions which "converge" to (b) (a morphism f is locally almost of finite presentation if and only if it is locally of finite generation to order n for *every* $n \geqslant 0$).

One of the useful features of finite presentation in classical algebraic geometry is that it enables arguments by *Noetherian approximation*. If A is a commutative ring and X is an A-scheme of finite presentation, then one can always find a finitely generated subring $A_0 \subseteq A$ and an isomorphism $X \simeq \operatorname{Spec} A \times_{\operatorname{Spec} A_0} X_0$, where X_0 is an A_0-scheme of finite presentation. This observation can be used to reduce many questions about arbitrary schemes to questions about Noetherian schemes, where they can be addressed using tools that are specific to the Noetherian case (such as dimension theory). In §4.4, we will adapt the technique of Noetherian approximation to the setting of spectral algebraic geometry. Here we encounter a new complication: the structure sheaf of a spectral Deligne-Mumford stack $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ has infinitely many homotopy sheaves $\{\pi_m \mathcal{O}_{\mathcal{X}}\}_{m \geqslant 0}$, and it is hard to approximate all of them simultaneously. We will therefore restrict our attention to Noetherian approximation in the setting of n-truncated spectral Deligne-Mumford stacks, where $n \geqslant 0$ is a fixed integer. For this purpose, the refined finiteness conditions studied in §4.2 will play an essential role.

Let $A_0 \subseteq A$ and $X \simeq \operatorname{Spec} A \times_{\operatorname{Spec} A_0} X_0$ be as above. To employ Noetherian approximation effectively, we often want to arrange that X_0 reflects whatever features of X we are interested in. This leads to questions of the following sort:

Question 4.0.0.1. Let $\mathscr{F}$ be a quasi-coherent sheaf on X. Under what conditions can we arrange that $\mathscr{F}$ is the pullback of a quasi-coherent sheaf $\mathscr{F}_0$ on X_0?

Question 4.0.0.2. Suppose that the scheme X has some property P. Under what conditions can we arrange that the scheme X_0 also has the property P?

We will discuss the analogues of Questions 4.0.0.1 and 4.0.0.2 in spectral algebraic geometry in §4.5 and §4.6, respectively. In the latter case, we will need some elementary facts about constructible subsets of (spectral) algebraic spaces, which we review in §4.3.

Contents

4.1 Finiteness Conditions on $\mathbb{E}_\infty$-Algebras

In the setting of classical commutative algebra, there are two natural finiteness conditions one can impose on a ring homomorphism $\phi : A \to B$:

(i) One can demand that ϕ is *of finite type*: that is, that it exhibits B as a finitely generated A-algebra (so that B is isomorphic, as an A-algebra, to a quotient $A[x_1, \ldots, x_n]/I$ for some $n \gg 0$ and some ideal $I \subseteq A[x_1, \ldots, x_n]$).

(ii) One can demand that ϕ is *of finite presentation*: that is, it exhibits B as a finitely presented A-algebra (so that B is isomorphic, as an A-algebra, to a quotient $A[x_1, \ldots, x_n]/I$ for some $n \gg 0$ and some finitely generated ideal $I \subseteq A[x_1, \ldots, x_n]$).

There are analogous demands that one can make on a morphism $\phi : A \to B$ of connective $\mathbb{E}_\infty$-rings:

(i') We will say that ϕ is *of finite type* if the underlying ring homomorphism $\pi_0 A \to \pi_0 B$ is of finite type. Equivalently, ϕ is of finite type if there exists a morphism of $A\{x_1, \ldots, x_n\} \to B$ of $\mathbb{E}_\infty$-algebras over A which is surjective on π_0.

(ii') We say that ϕ is *of finite presentation* if B can be built (as an object of the ∞-category CAlg_A) from the free algebra $A\{x\}$ using finite colimits (see Definition HA.7.2.4.26).

However, the passage from ordinary commutative algebra to the theory of (connective) $\mathbb{E}_\infty$-rings introduces a number of subtleties which will require us to study finiteness conditions that are intermediate between conditions (i') and (ii'):

- Let $\phi : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings. The condition that ϕ is of finite presentation is not local (either on A or on B) with respect to the Zariski topology. It is often more convenient to require that $\phi : A \to B$ is *locally of finite presentation*: that is, that the functor $C \mapsto \mathrm{Map}_{\mathrm{CAlg}_A}(B, C)$ commutes with filtered colimits (Definition HA.7.2.4.26). This condition is local with respect to the étale topology on A and B (see Remark 4.1.4.2), and is closely related to the condition that ϕ is of finite presentation (the morphism ϕ is locally of finite presentation if and only if it becomes of finite presentation after passing to some Zariski covering of B).

- If $\phi : A \to B$ is a homomorphism of commutative Noetherian rings, then conditions (i) and (ii) are equivalent (the Hilbert basis theorem guarantees that every ideal $I \subseteq A[x_1, \ldots, x_n]$). However, these conditions do not guarantee that ϕ is of finite presentation (or even locally of finite presentation) when regarded as a morphism of $\mathbb{E}_\infty$-rings. Nevertheless, they *do* guarantee that ϕ is *almost of finite presentation* (see Definition HA.7.2.4.26): that is, that the construction $C \mapsto \mathrm{Map}_{\mathrm{CAlg}_A}(B, C)$ preserves filtered colimits when restricted to n-truncated connective A-algebras, for each $n \gg 0$.

- If $\phi : A \to B$ is a homomorphism of commutative rings, then we can think of B as built from A by generators and relations: condition (i) asserts that we need only finitely many generators, and condition (ii) asserts that we need finitely many generators *and* finitely many relations. In the setting of connective $\mathbb{E}_\infty$-rings, one should instead imagine that B is built from A by successively attaching n-cells for different values of $n \geqslant 0$: these can be thought as generators in the case $n = 0$ and relations in the case $n = 1$, but we generally need higher-dimensional cells as well. We can use the language of cell attachments to give informal descriptions of the finiteness conditions introduced above:

– The morphism ϕ is of finite type if B can be built using only finitely many 0-cells (but possibly infinitely many cells of each positive dimension).

– The morphism ϕ is almost of finite presentation if B can be built using only finitely many cells of each dimension.

– The morphism ϕ is of finite presentation if B can be built using only finitely many cells in total.

For many applications (for example, in our study of Noetherian approximation in §4.4) it will be useful to consider a hierarchy of finiteness conditions which interpolate between (i') and (ii'). For each $n \geqslant 0$, we will define a class of morphisms which we call *morphisms of finite generation to order* n (Definition 4.1.1.1). Roughly speaking, a morphism $\phi : A \to B$ is of finite generation to order n if the $\mathbb{E}_\infty$-ring B can be built from A using only finitely many cells of dimension $\leqslant n$ (but possibly infinitely many cells of higher dimension). When $n = 0$, this reduces to the condition that ϕ is of finite type. On the other hand, the morphism ϕ is almost of finite presentation if and only if it is of finite generation to order n for all $n \geqslant 0$ (Remark 4.1.1.5).

The relationship between the various finiteness conditions on a morphism $\phi : A \to B$ are summarized in the following diagram:

$$\begin{array}{ccc}
\phi \text{ of finite generation to order } 0 & \Longleftrightarrow & \pi_0\phi \text{ of finite type} \\
\Uparrow & & \Uparrow \\
\phi \text{ of finite generation to order } 1 & \Longrightarrow & \pi_0\phi \text{ of finite presentation} \\
\Uparrow & \overset{(*)}{\swarrow} & \\
\cdots & & \\
\Uparrow & & \\
\phi \text{ almost of finite presentation} & & \\
\Uparrow & & \\
\phi \text{ locally of finite presentation} & & \\
\Uparrow & & \\
\phi \text{ of finite presentation} & &
\end{array}$$

where the conditions on the right hand side are formulated in classical commutative algebra, and the implication $(*)$ holds under the assumption that both A and B are Noetherian.

4.1.1 Morphisms of Finite Generation

We now give a precise formulation of the finiteness conditions to be studied in this section.

Definition 4.1.1.1. Let $\phi : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings and let $n \geqslant 0$. We will say that ϕ is *of finite generation to order* n if the following condition is satisfied:

$(*)$ Let $\{C_\alpha\}$ be a filtered diagram of connective $\mathbb{E}_\infty$-rings over A having colimit C. Assume that each C_α is n-truncated and that each of the transition maps $\pi_n C_\alpha \to \pi_n C_\beta$ is a monomorphism. Then the canonical map

$$\varinjlim_\alpha \mathrm{Map}_{\mathrm{CAlg}_A}(B, C_\alpha) \to \mathrm{Map}_{\mathrm{CAlg}_A}(B, C)$$

is a homotopy equivalence.

In this case, we will also say that B is *of finite generation to order n over A*.

We will say that ϕ is *of finite type* if it is of finite generation to order 0. In this case, we will also say that B *is of finite type over A*.

Remark 4.1.1.2. Let $\phi : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings. It is possible formulate the condition that ϕ is of finite generation to order n using the language of cell attachments. However, it will be more convenient to adopt Definition 4.1.1.1, which does not require us to make auxiliary choices (such as presentation of B as an object of $\mathrm{CAlg}_A^{\mathrm{cn}}$).

In the case $n = 0$, Definition 4.1.1.1 can be made very concrete:

Proposition 4.1.1.3. *Let $\phi : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings. The following conditions are equivalent:*

(a) *The morphism ϕ is of finite type (in the sense of Definition* **??***).*

(b) *The commutative ring $\pi_0 B$ is finitely generated as an algebra over $\pi_0 A$.*

Proof. Write $\pi_0 B$ as a (filtered) direct limit of subalgebras $\{C_\alpha\}$ which are finitely generated as algebras over $\pi_0 A$. If condition (a) is satisfied, then the canonical map $\varinjlim_\alpha \mathrm{Map}_{\mathrm{CAlg}_A}(B, C_\alpha) \to \mathrm{Map}_{\mathrm{CAlg}_A}(B, \pi_0 B)$ is a homotopy equivalence. In particular, the canonical map $B \to \pi_0 B$ factors through some C_α. It follows that $C_\alpha = \pi_0 B$, so that $\pi_0 B$ is finitely generated as an algebra over $\pi_0 A$.

Conversely, suppose that (b) is satisfied. Let $\{C_\alpha\}$ be *any* filtered diagram in CAlg_A, where each C_α is discrete and each of the transition maps $C_\alpha \to C_\beta$ is a monomorphism. Set $C = \varinjlim C_\alpha$. By abuse of notation, we can identify each C_α with its image in C. Since C is discrete, we have a commutative diagram

$$\begin{array}{ccc} \varinjlim \mathrm{Hom}_{\mathrm{CAlg}^\heartsuit_{\pi_0 A}}(\pi_0 B, C_\alpha) & \xrightarrow{\overline{\rho}} & \mathrm{Hom}_{\mathrm{CAlg}^\heartsuit_{\pi_0 A}}(\pi_0 B, C) \\ \downarrow & & \downarrow \\ \varinjlim \mathrm{Map}_{\mathrm{CAlg}_A}(B, C_\alpha) & \xrightarrow{\rho} & \mathrm{Map}_{\mathrm{CAlg}_A}(B, C) \end{array}$$

where the vertical maps are homotopy equivalences. Consequently, to show that ρ is a homotopy equivalence, it will suffice to show that $\overline{\rho}$ is bijective. In other words, we must show that every morphism $\phi : \pi_0 B \to C$ of $(\pi_0 A)$-algebras factors through some C_α. This is clear: condition (b) implies that there exists a finite collection of elements $b_1, \ldots, b_k \in \pi_0 B$ which generate $\pi_0 B$ as an algebra over $\pi_0 A$, so it suffices to consider any C_α which contains the elements $\{\phi(b_i)\}_{1 \leqslant i \leqslant k}$. □

Remark 4.1.1.4. Let $\phi : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings and let $n \geqslant 0$. Then:

(1) If $\tau_{\leqslant n} B$ is a compact object of $\tau_{\leqslant n} \mathrm{CAlg}_A$, then ϕ is of finite generation to order n.

(2) If ϕ is of finite generation to order $(n+1)$, then $\tau_{\leqslant n} B$ is a compact object of $\tau_{\leqslant n} \mathrm{CAlg}_A$.

In particular, if ϕ is of finite generation to order n for any $n > 0$, then $\pi_0 B$ is finitely presented as a commutative algebra over $\pi_0 A$ in the sense of classical commutative algebra.

Remark 4.1.1.5. Using Remark 4.1.1.4, we see that a morphism $\phi : A \to B$ of connective $\mathbb{E}_\infty$-rings is almost of finite presentation (see Definition HA.7.2.4.26) if and only if it is of finite generation to order n, for each $n \geqslant 0$.

Remark 4.1.1.6. Suppose we are given a finite collection $\{f_\alpha : A_\alpha \to B_\alpha\}$ of morphisms between connective $\mathbb{E}_\infty$-rings. Let $f : \prod_\alpha A_\alpha \to \prod_\alpha B_\alpha$ be the induced map. Then f is of finite generation to order n (almost of finite presentation, locally of finite presentation) if and only if each of the morphisms f_α is of finite generation to order n (almost of finite presentation, locally of finite presentation).

Remark 4.1.1.7. Suppose we are given a commutative diagram of connective $\mathbb{E}_\infty$-rings

$$\begin{array}{ccccc} & & B & & \\ & \overset{\phi}{\nearrow} & & \overset{\psi}{\searrow} & \\ A & & \xrightarrow{\phi'} & & B'. \end{array}$$

Let $n \geqslant 0$, and assume that the map ψ induces a surjection $\pi_n B \to \pi_n B'$ and a bijection $\pi_i B \to \pi_i B'$ for $i < n$. If ϕ is of finite generation to order n, then so is ϕ'. To prove this, consider any filtered diagram $\{C_\alpha\}$ of n-truncated objects of CAlg_A having colimit C, and suppose that each of the transition maps $\pi_n C_\alpha \to \pi_n C_\beta$ is a monomorphism. Then each of the maps $\pi_n C_\alpha \to \pi_n C$ is a monomorphism. It follows from our assumption on ψ that the diagram

$$\begin{array}{ccc} \varinjlim \mathrm{Map}_{\mathrm{CAlg}_A}(B', C_\alpha) & \longrightarrow & \mathrm{Map}_{\mathrm{CAlg}_A}(B', C) \\ \downarrow & & \downarrow \\ \varinjlim \mathrm{Map}_{\mathrm{CAlg}_A}(B, C_\alpha) & \longrightarrow & \mathrm{Map}_{\mathrm{CAlg}_A}(B, C) \end{array}$$

is a pullback square. If ϕ is of finite generation to order n, then the bottom horizontal map is a homotopy equivalence, so the upper horizontal map is a homotopy equivalence as well.

Remark 4.1.1.8. Let $f : A \to B$ be a map of connective $\mathbb{E}_\infty$-rings which is of finite generation to order $n > 0$. Then the induced map $A \to \tau_{\leqslant n-1} B$ is also of finite generation to order n (this is a special case of Remark 4.1.1.7).

Remark 4.1.1.9. Let $f : A \to B$ be a map of connective $\mathbb{E}_\infty$-rings which exhibits B as a compact object of $\tau_{\leqslant n-1}\operatorname{CAlg}_A^{\mathrm{cn}}$ (for some $n > 0$). Then B is a retract of $\tau_{\leqslant n-1} B'$ for some compact object $B' \in \operatorname{CAlg}_A^{\mathrm{cn}}$. Since the map $A \to B'$ is of finite generation to order n, so is the map $A \to B$ (by Remark 4.1.1.8). It follows that an object $B \in \tau_{\leqslant n-1}\operatorname{CAlg}_A^{\mathrm{cn}}$ is compact if and only if the map $A \to B$ is of finite generation to order n.

4.1.2 Differential Characterization

Let $\phi : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings. According to Theorem HA.7.4.3.18 , the morphism ϕ is almost of finite presentation if and only if it exhibits $\pi_0 B$ as a finitely presented algebra over $\pi_0 A$ and the relative cotangent complex $L_{B/A}$ is almost perfect. We will need the following more refined statement:

Proposition 4.1.2.1. *Let $f : A \to B$ be a map of connective $\mathbb{E}_\infty$-rings and let $n > 0$. Then f is of finite generation to order n if and only if the following conditions are satisfied:*

(1) *The commutative ring $\pi_0 B$ is finitely presented over $\pi_0 A$.*

(2) *The relative cotangent complex $L_{B/A}$ is perfect to order n as an B-module (see Definition 2.7.0.1).*

Proof. First suppose that f is of finite generation to order n. Since $n > 0$, condition (1) follows from Remark 4.1.1.4. To prove (2), we will show that the relative cotangent complex $L_{B/A}$ satisfies the third criterion of Proposition 2.7.0.4. Choose a filtered diagram $\{N_\alpha\}$ in $\operatorname{Mod}_B^\heartsuit$, where each of the transition maps $N_\alpha \to N_\beta$ is a monomorphism. We wish to show that the canonical map

$$\rho : \varinjlim_{\alpha} \operatorname{Map}_{\operatorname{Mod}_B}(L_{B/A}, \Sigma^n N_\alpha) \to \operatorname{Map}_{\operatorname{Mod}_B}(L_{B/A}, \Sigma^n \varinjlim N_\alpha)$$

is a homotopy equivalence. This follows from the observation that ρ fits into a pullback square

$$\begin{array}{ccc} \varinjlim \operatorname{Map}_{\operatorname{Mod}_B}(L_{B/A}, \Sigma^n N_\alpha) & \xrightarrow{\rho} & \operatorname{Map}_{\operatorname{Mod}_B}(L_{B/A}, \Sigma^n \varinjlim N_\alpha) \\ \downarrow & & \\ \varinjlim \operatorname{Map}_{\operatorname{CAlg}_A}(B, (\tau_{\leqslant n} B) \oplus \Sigma^n N_\alpha) & \longrightarrow & \operatorname{Map}_{\operatorname{CAlg}_A}(B, (\tau_{\leqslant n} B) \oplus \Sigma^n \varinjlim N_\alpha), \end{array}$$

where the lower horizontal map is a homotopy equivalence by virtue of our assumption that f is of finite generation to order n.

Now suppose that conditions (1) and (2) are satisfied and choose a filtered diagram $\{C_\alpha\}$ in $\mathrm{CAlg}_A^{\mathrm{cn}}$ having colimit C. Assume that each C_α is n-truncated and that the transition maps $\pi_n C_\alpha \to \pi_n C_\beta$ are monomorphisms. For $0 \leqslant i \leqslant n$, let θ_i denote the canonical map

$$\varinjlim_\alpha \mathrm{Map}_{\mathrm{CAlg}_A}(B, \tau_{\leqslant i} C_\alpha) \to \mathrm{Map}_{\mathrm{CAlg}_A}(B, \tau_{\leqslant i} C).$$

We will prove that θ_i is a homotopy equivalence for $0 \leqslant i \leqslant n$ using induction on i. When $i = 0$, the desired result follows from (1). Assume that $0 < i \leqslant n$ and that θ_{i-1} is a homotopy equivalence. Using the results of §HA.7.4.1 , we obtain a map of fiber sequences

$$\begin{array}{ccc} \varinjlim_\alpha \mathrm{Map}_{\mathrm{CAlg}_A}(B, \tau_{\leqslant i} C_\alpha) & \xrightarrow{\theta_i} & \mathrm{Map}_{\mathrm{CAlg}_A}(B, \tau_{\leqslant i} C) \\ \downarrow & & \downarrow \\ \varinjlim_\alpha \mathrm{Map}_{\mathrm{CAlg}_A}(B, \tau_{\leqslant i-1} C_\alpha) & \xrightarrow{\theta_{i-1}} & \mathrm{Map}_{\mathrm{CAlg}_A}(B, \tau_{\leqslant i-1} C) \\ \downarrow & & \downarrow \\ \varinjlim_\alpha \mathrm{Map}_{\mathrm{Mod}_B}(L_{B/A}, \Sigma^{i+1} \pi_i C_\alpha)) & \xrightarrow{\phi} & \mathrm{Map}_{\mathrm{Mod}_B}(L_{B/A}, \Sigma^{i+1} \pi_i C)). \end{array}$$

Set $D_\alpha = \mathrm{fib}(\Sigma^{i+1} \pi_i C_\alpha \to \Sigma^{i+1} \pi_i C)$, so that each D_α is n-truncated and $\varinjlim D_\alpha \simeq 0$. Assumption (2) implies that the canonical map $\varinjlim \mathrm{Ext}^i_B(L_{B/A}, D_\alpha) \to \mathrm{Ext}^i_B(L_{B/A} \varinjlim D_\alpha)$ is bijective for $i < 0$ and injective when $i = 0$: that is, the groups $\varinjlim \mathrm{Ext}^i_B(L_{B/A}, D_\alpha)$ vanish, so that the direct limit $Z = \varinjlim \mathrm{Map}_{\mathrm{Mod}_B}(L_{B/A}, D_\alpha)$ is contractible. Each nonempty homotopy fiber of ϕ is homotopy equivalent to Z, so the morphism ϕ is (-1)-truncated. Our hypothesis that θ_{i-1} is a homotopy equivalence now implies that θ_i is also a homotopy equivalence, as desired. □

4.1.3 Persistence of Finite Generation

We now use Proposition 4.1.2.1 to establish some elementary formal properties of Definition 4.1.1.1.

Proposition 4.1.3.1. *Suppose we are given maps $f : A \to B$ and $g : B \to C$ of connective $\mathbb{E}_\infty$-rings. Assume that f is of finite generation to order n. Then g is of finite generation to order n if and only if $g \circ f$ is of finite generation to order n.*

Proof. If $n = 0$, then the desired result follows immediately from Proposition 4.1.1.3. Let us therefore assume that $n > 0$. Then $\pi_0 B$ is finitely presented as an algebra over $\pi_0 A$. It follows that $\pi_0 C$ is finitely presented over $\pi_0 B$ if and only if it is finitely presented over $\pi_0 A$. Using Proposition 4.1.2.1, we are reduced to proving that $L_{C/A}$ is perfect to order n if and only if $L_{C/B}$ is perfect to order n. This follows by applying Remark 2.7.0.7 to the fiber sequence $C \otimes_B L_{B/A} \to L_{C/A} \to L_{C/B}$, since $C \otimes_B L_{B/A}$ is perfect to order n by Proposition 4.1.2.1 and Proposition 2.7.3.1. □

Proposition 4.1.3.2. *Suppose we are given a pushout diagram of connective $\mathbb{E}_\infty$-rings σ :*

$$\begin{array}{ccc} A & \xrightarrow{f} & B \\ \downarrow & & \downarrow \\ A' & \xrightarrow{f'} & B'. \end{array}$$

If f is of finite generation to order n, then f' is of finite generation to order n.

Proof. Using Proposition HA.7.2.2.13 , we obtain an isomorphism of commutative rings $\pi_0 B' \simeq \mathrm{Tor}_0^{\pi_0 A}(\pi_0 B, \pi_0 A')$. It follows that if $\pi_0 B$ is finitely generated (finitely presented) as a commutative ring over $\pi_0 A$, then $\pi_0 B'$ is finitely generated (finitely presented) as a commutative ring over $\pi_0 A'$. This completes the proof when $n = 0$ (Proposition 4.1.1.3). If $n > 0$, we must also show that $L_{B'/A'} \simeq B' \otimes_B L_{B/A}$ is perfect to order n as a B'-module (Proposition 4.1.2.1), which follows from Proposition 2.7.3.1 (since $L_{B/A}$ is perfect to order n as a B-module, by Proposition 4.1.2.1). □

Corollary 4.1.3.3. *Let R be a connective $\mathbb{E}_\infty$-ring, and suppose we are given a pushout diagram of connective $\mathbb{E}_\infty$-algebras over R:*

$$\begin{array}{ccc} A & \xrightarrow{f} & B \\ \downarrow & & \downarrow \\ A' & \xrightarrow{f'} & B'. \end{array}$$

If A, B, and A' are of finite generation to order n over R, then B' is of finite generation to order n over R.

Proof. Since A' is of finite generation to order n over R, it will suffice to show that f' is of finite generation to order n (Proposition 4.1.3.1). Using Proposition 4.1.3.2, we are reduced to proving that f is of finite generation to order n. This follows from Proposition 4.1.3.1, since A and B are both of finite generation to order n over R. □

Proposition 4.1.3.4. *Let $f : A \to B$ be a map of connective $\mathbb{E}_\infty$-rings, let $B_0 = \pi_0 A \otimes_A B$, and let $n \geqslant 0$. Then f is of finite generation to order n if and only if the induced map $f_0 : \pi_0 A \to B_0$ is of finite generation to order n.*

Proof. We have $\pi_0 B_0 = \pi_0(\pi_0 A \otimes_A B) \simeq \pi_0 B$, so that $\pi_0 B_0$ is finitely generated (finitely presented) over $\pi_0 A$ if and only if $\pi_0 B$ is finite generated (finitely presented) over $\pi_0 A$. This completes the proof when $n = 0$ (see Proposition 4.1.1.3). If $n > 0$, then the assertion that either f or f_0 is of finite generation to order n guarantees that $\pi_0 B$ is finitely presented over $\pi_0 A$. Using Proposition 4.1.2.1, we are reduced to proving that $L_{B/A}$ is perfect to order n over B if and only if $L_{B_0/\pi_0 A} \simeq B_0 \otimes_B L_{B/A}$ is perfect to order n is perfect to order n

over B_0. According to Proposition 2.9.4.2, both of these conditions are equivalent to the requirement that $\pi_0 B \otimes_B L_{B/A}$ is perfect to order n as a module over $\pi_0 B$. □

Corollary 4.1.3.5. *Let $f : A \to B$ be a map of connective $\mathbb{E}_\infty$-rings, let $B_0 = \pi_0 A \otimes_A B$, and let $n \geqslant 0$. Then f is almost of finite presentation if and only if the induced map $f_0 : \pi_0 A \to B_0$ is almost of finite presentation.*

4.1.4 Local Nature of Finite Generation

For applications in spectral algebraic geometry, we need to understand how the finiteness conditions introduced in Definition 4.1.1.1 behave with respect to the étale topology. Note that if $f : A \to B$ is a morphism of connective $\mathbb{E}_\infty$-rings which exhibits B as a compact object of CAlg_A, then f is of finite generation to order n. In particular, any étale morphism of of finite generation to order n (Corollary HA.7.5.4.4).

Proposition 4.1.4.1. *Let $f : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings. Then:*

(1) *For every étale morphism $B \to B'$, if f is of finite generation to order n, then so is the composite map $A \to B \to B'$.*

(2) *Suppose we are given a finite collection of étale maps $B \to B_\alpha$ such that the composition $B \to \prod_\alpha B_\alpha$ is faithfully flat. If each of the composite maps $A \to B \to B_\alpha$ is of finite generation to order n, then f is of finite generation to order n.*

Proof. Assertion (1) is immediate from Proposition 4.1.3.1, since étale morphisms are of finite generation to order n. Let us prove (2). We first treat the case $n = 0$. Let $B' = \prod_\alpha B_\alpha$. Since each $\pi_0 B_\alpha$ is finitely generated as an algebra over $\pi_0 A$, we deduce that $\pi_0 B'$ is finitely generated over $\pi_0 A$. The map of commutative rings $\pi_0 B \to \pi_0 B'$ is étale. Using the structure theory of étale morphisms (see Proposition B.1.1.3), we can choose a subalgebra $R \subseteq \pi_0 B$ which is finitely generated over $\pi_0 A$ and a faithfully flat étale R-algebra R' fitting into a pushout diagram

$$\begin{array}{ccc} \pi_0 B & \longrightarrow & \pi_0 B' \\ \downarrow & & \downarrow \\ R & \longrightarrow & R'. \end{array}$$

Since $\pi_0 B'$ is finitely generated, we may assume (after enlarging R if necessary) that the map $R' \to \pi_0 B'$ is surjective. Then $R' \otimes_R (\pi_0 B/R) \simeq 0$, so (by faithful flatness) we deduce that $\pi_0 B = R$ is finitely generated as a $\pi_0 A$-algebra.

Assume now that $n > 0$. We will show that the map $A \to B$ satisfies conditions (1) and (2) of Proposition 4.1.2.1. We first show that $\pi_0 B$ is finitely presented as a $\pi_0 A$-algebra. We have already seen that $\pi_0 B$ is finitely generated as a $\pi_0 A$-algebra, so we can choose an isomorphism $\pi_0 B \simeq R/I$ where R is a polynomial algebra over $\pi_0 A$. Write I as a filtered colimit of finitely generated ideals $I_\alpha \subseteq I$. Using the structure theory of étale morphisms, we can choose a finitely generated ideal $J \subseteq I$ and a faithfully flat étale map $R/J \to S$ such that $\pi_0 B' \simeq S \otimes_{R/J} R/I$. Then $\pi_0 B'$ is the quotient of S by the ideal IS. Since $\pi_0 B'$ is finitely presented as an $\pi_0 A$-algebra, we deduce that $\pi_0 B' \simeq S/I_0 S$ for some finitely generated ideal $I_0 \subseteq I$ containing J. Since S is faithfully flat over R/J, the map $I/I_0 \to IS/I_0 S \simeq 0$ is injective. Thus $I = I_0$ is a finitely generated ideal and $\pi_0 B$ is finitely presented over $\pi_0 A$ as desired.

It remains to verify condition (2) of Proposition 4.1.2.1. We have a fiber sequence of B'-modules $B' \otimes_B L_{B/A} \to L_{B'/A} \to L_{B'/B}$. Since B' is étale over B, the relative cotangent complex $L_{B'/B}$ vanishes. It follows that $L_{B'/A} \simeq B' \otimes_B L_{B/A}$. Proposition 4.1.2.1 implies that $L_{B'/A}$ is perfect to order n as a B'-module, so that $L_{B/A}$ is perfect to order n as a B-module by Proposition 2.7.3.1. □

Remark 4.1.4.2. In the situation of part (2) of Proposition 4.1.4.1, suppose that each B_α is locally of finite presentation over A (see Definition HA.7.2.4.26). Then B is locally of finite presentation over A. To prove this, we note that it follows from Proposition 4.1.4.1 that B is almost of finite presentation over A. It will therefore suffice to show that $L_{B/A}$ is perfect as a module over B. Using Proposition 2.8.4.2, we are reduced to proving that each $B_\alpha \otimes_B L_{B/A}$ is perfect as a module over B_α. This is clear, since the vanishing of $L_{B_\alpha/B}$ implies that the canonical map $B_\alpha \otimes_B L_{B/A} \to L_{B_\alpha/A}$ is an equivalence.

Proposition 4.1.4.3. *Let $f : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings. Suppose that there exists a finite collection of flat morphisms $A \to A_\alpha$ with the following properties:*

(1) *The map $A \to \prod_\alpha A_\alpha$ is faithfully flat.*

(2) *Each of the maps $f_\alpha : A_\alpha \to A_\alpha \otimes_A B$ is of finite generation to order n (almost of finite presentation, locally of finite presentation).*

Then f is of finite generation to order n (almost of finite presentation, locally of finite presentation).

Proof. Let $A' = \prod_\alpha A_\alpha$, let $B' = A' \otimes_A B$, and let $f' : A' \to B'$ be the induced map. Let us first suppose that each f_α is of finite type. Then f' is of finite type (Remark 4.1.1.6), so that $\pi_0 B' = \pi_0 A' \otimes_{\pi_0 A} \pi_0 B$ is finitely generated as a commutative algebra over $\pi_0 A'$. We may therefore choose a finite collection of elements $x_1, \ldots, x_n \in \pi_0 B$ which generate $\pi_0 B'$ as an algebra over $\pi_0 A'$. Let R denote the polynomial ring $(\pi_0 A)[x_1, \ldots, x_n]$, so we have a map of commutative rings $\phi : R \to \pi_0 B$ which induces a surjection $\pi_0 A' \otimes_{\pi_0 A} R \to \pi_0 A' \otimes_{\pi_0 A} \pi_0 B$. Since $\pi_0 A'$ is faithfully flat over $\pi_0 A$, we deduce that ϕ is surjective, so that $\pi_0 B$ is finitely generated as a commutative ring over $\pi_0 A$ and therefore f is of finite type.

Now suppose that each f_α is of finite generation to order 1. Using Remark 4.1.1.6 and Proposition 4.1.2.1, we deduce that $\pi_0 B'$ is finitely presented as an algebra over $\pi_0 A'$. Define $\phi : R \to \pi_0 B$ be the surjection defined above. Let $I = \ker(\phi)$. Since A' is flat over A, we can identify $I \otimes_{\pi_0 A} \pi_0 A'$ with the kernel of the surjection $\pi_0 A' \otimes_{\pi_0 A} R \to \pi_0 B'$. The assumption that $\pi_0 B'$ is of finite presentation over $\pi_0 A'$ implies that this kernel is finitely generated. We may therefore choose a finitely generated submodule $J \subseteq I$ such that the induced map $J \otimes_{\pi_0 A} \pi_0 A' \to I \otimes_{\pi_0 A} \pi_0 A'$ is surjective. Since A' is faithfully flat over A, we deduce that $I = J$ is finitely generated, so that $\pi_0 B \simeq R/I$ is finitely presented as a commutative ring over $\pi_0 A$. Suppose that we wish to prove that f is of finite generation to order $n \geqslant 1$ (almost of finite presentation, locally of finite presentation). Using Proposition 4.1.2.1 and Theorem HA.7.4.3.18 , we are reduced to proving that the relative cotangent complex $L_{B/A}$ is perfect to order n (almost perfect, perfect) as a module over B. Using Remark 4.1.1.6 we deduce that $B' \otimes_B L_{B/A} \simeq L_{B'/A'}$ is perfect to order n (almost perfect, perfect) as a module over B'. Since B' is faithfully flat over B, the desired result follows from Proposition 2.8.4.2. □

4.2 Finiteness Conditions on Spectral Deligne-Mumford Stacks

Our goal in this section is to translate the ideas of §4.1 into the language of spectral Deligne-Mumford stacks.

Definition 4.2.0.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. We will say that f is *locally of finite generation to order n* (*locally almost of finite presentation*, *locally of finite presentation*) if the following condition is satisfied: for every commutative diagram

$$\begin{array}{ccc} \operatorname{Sp\acute{e}t} B & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow f \\ \operatorname{Sp\acute{e}t} A & \longrightarrow & \mathsf{Y} \end{array}$$

where the horizontal maps are étale, the $\mathbb{E}_\infty$-ring B is of finite generation to order n (almost of finite presentation, locally of finite presentation) over A. We will say that f is *locally of finite type* if it is locally of finite generation to order 0.

Example 4.2.0.2. A map of spectral Deligne-Mumford stacks $f : \mathsf{X} \to \mathsf{Y}$ is locally of finite type if and only if the underlying map of ordinary Deligne-Mumford stacks is locally of finite type (in the sense of classical algebraic geometry).

Example 4.2.0.3. If $f : \mathsf{X} \to \mathsf{Y}$ is a morphism of spectral Deligne-Mumford stacks which is of finite generation to order 1, then the underlying map of ordinary Deligne-Mumford stacks is locally of finite presentation (in the sense of classical algebraic geometry). The converse holds if the structure sheaf of X is 0-truncated.

Remark 4.2.0.4. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks, and suppose that Y is locally Noetherian. Then the following conditions are equivalent:

(a) The morphism f is locally of finite type and X is locally Noetherian.

(b) The morphism f is locally almost of finite presentation.

To prove this, we can reduce to the case where X and Y are affine, in which case the desired result follows from Theorem HA.7.2.4.31 .

Warning 4.2.0.5. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of Deligne-Mumford stacks which is locally of finite presentation in the sense of classical algebraic geometry. If Y is not locally Noetherian, then f need not be locally almost of finite presentation when regarded as a morphism of 0-truncated spectral Deligne-Mumford stacks. The latter condition corresponds, in the terminology of [101], to the condition that f is *pseudo-coherent*: see Corollary 5.2.2.3 and Remark 5.2.2.4.

4.2.1 Morphisms Locally of Finite Generation

We begin by establishing some formal properties of Definition 4.2.0.1.

Proposition 4.2.1.1. *The condition that a morphism $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks be locally of finite generation to order n (locally almost of finite presentation, locally of finite presentation) is local on the source and target with respect to the étale topology (see Definition 2.8.1.7).*

Proof. It is clear that if f is locally of finite generation to order n (locally almost of finite presentation, locally of finite presentatiion) and $g : \mathsf{U} \to \mathsf{X}$ is étale, $f \circ g$ is locally of finite generation to order n (locally almost of finite presentation, locally of finite presentation). To complete the proof, let us suppose that $g : \mathsf{Y} \to \mathsf{Z}$ is arbitrary and that we are given a jointly surjective collection of étale maps $\{f_\alpha : \mathsf{X}_\alpha \to \mathsf{Y}\}$ such that each composition $g \circ f_\alpha$ is locally of finite generation to order n (locally almost of finite presentation, locally of finite presentation). We wish to show that g has the same property. Choose a commutative diagram

$$\begin{array}{ccc} \operatorname{Sp\acute{e}t} B & \longrightarrow & \mathsf{Y} \\ \downarrow & & \downarrow \\ \operatorname{Sp\acute{e}t} A & \longrightarrow & \mathsf{Z} \end{array}$$

where the horizontal maps are étale. We wish to show that B is of finite generation to order n (almost of finite presentation, locally of finite presentation) over A. Since the maps f_α are jointly surjective, we can choose an étale covering $\{B \to B_i\}$ such that each of the composite maps $\mathrm{Sp\acute{e}t}\, B_i \to \mathrm{Sp\acute{e}t}\, B \to \mathsf{Y}$ factors through some X_α. Using our assumption on $g \circ f_\alpha$, we deduce that each B_i is of finite generation to order n (almost of finite presentation, locally of finite presentation) over A. The desired result now follows from Proposition 4.1.4.1 and Remark 4.1.4.2. □

Remark 4.2.1.2. Let $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ be a map of spectral Deligne-Mumford stacks. Then f is locally of finite generation to order n (locally almost of finite presentation, locally of finite presentation) if and only if the following condition is satisfied:

(∗) For every étale map $\mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$, the $\mathbb{E}_\infty$-ring A is of finite generation to order n (almost of finite presentation, locally of finite presentation) over R.

The "only if" direction is obvious. Conversely, suppose that (∗) is satisfied and we are given a commutative diagram

$$\begin{array}{ccc} \mathrm{Sp\acute{e}t}\, A & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow \\ \mathrm{Sp\acute{e}t}\, R' & \longrightarrow & \mathrm{Sp\acute{e}t}\, R \end{array}$$

where the horizontal maps are étale. Using condition (∗), we deduce that A is of finite generation to order n (almost of finite presentation, locally of finite presentation) over R. It follows from Theorem 1.4.10.2 that R' is étale over R, and therefore locally of finite presentation over R. The desired result now follows from Proposition 4.1.3.1 and Remark HA.7.2.4.29 .

Remark 4.2.1.3. Let $f : \mathrm{Sp\acute{e}t}\, A \to \mathrm{Sp\acute{e}t}\, R$ be a map of affine spectral Deligne-Mumford stacks. Then f is locally of finite generation to order n (locally almost of finite presentation, locally of finite presentation) if and only if A is of finite generation to order n (almost of finite presentation, locally of finite presentation) over R. The "only if" direction follows immediately from the definitions. To prove the converse, it suffices to observe that if A is of finite generation to order n (almost of finite presentation, locally of finite presentation) over R and A' is an étale A-algebra, then A' is of finite generation to order n (almost of finite presentation, locally of finite presentation) over R.

Remark 4.2.1.4. Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks. Then f is locally of finite generation to order n (locally almost of finite presentation, locally of finite presentation) if and only if, for every étale map $\mathrm{Sp\acute{e}t}\, R \to \mathsf{Y}$, the induced map $\mathsf{X} \times_{\mathsf{Y}} \mathrm{Sp\acute{e}t}\, R \to \mathrm{Sp\acute{e}t}\, R$ is locally of finite generation to order n (locally almost of finite presentation, locally of finite presentation).

Proposition 4.2.1.5. *The condition that a morphism $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks be locally of finite generation to order n (locally almost of finite presentation,* *locally of finite presentation) is local on the target with respect to the flat topology. That is, if there exists a flat covering* $\{\mathsf{Y}_\alpha \to \mathsf{Y}\}$ *such that each of the induced maps* $f_\alpha : \mathsf{Y}_\alpha \times_{\mathsf{Y}} \mathsf{X} \to \mathsf{Y}_\alpha$ *is locally of finite generation to order* n *(locally almost of finite presentation, locally of finite presentation), then* f *has the same property.*

Proof. Choose a commutative diagram

$$\begin{array}{ccc} \operatorname{Spét} B & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow f \\ \operatorname{Spét} A & \longrightarrow & \mathsf{Y} \end{array}$$

where the horizontal maps are étale; we wish to show that A is of finite generation to order n (almost of finite presentation, locally of finite presentation) over A. Since the map $\amalg \mathsf{Y}_\alpha \to \mathsf{Y}$ is a flat covering, there exists a faithfully flat map $A \to \prod_{1 \leqslant i \leqslant n} A_i$ such that each of the maps $\operatorname{Spét} A_i \to \operatorname{Spét} A \to \mathsf{Y}$ factors through an étale map $\operatorname{Spét} A_i \to \mathsf{Y}_\alpha$. Using our hypothesis on Y_α, we deduce that $A_i \otimes_R B$ is of finite generation to order n (almost of finite presentation, locally of finite presentation) over A_i. We now conclude by invoking Proposition 4.1.4.3. □

Proposition 4.2.1.6. *Suppose we are given a pullback diagram*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow f' & & \downarrow f \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y} \end{array}$$

of spectral Deligne-Mumford stacks. If f *is locally of finite generation to order* n *(locally almost of finite presentation, locally of finite presentation), then so is* f'*.*

Proof. Proposition 4.2.1.5 implies that the assertion is local on Y'; we may therefore assume without loss of generality that $\mathsf{Y}' = \operatorname{Spét} R'$ is affine and that the map $\mathsf{Y}' \to \mathsf{Y}$ factors as a composition $\operatorname{Spét} R' \to \operatorname{Spét} R \xrightarrow{u} \mathsf{Y}$, where u is étale. Replacing Y by $\operatorname{Spét} R$, we may assume that Y is also affine. Proposition 4.2.1.1 implies that the assertion is local on X' and therefore local on X; we may therefore suppose that $\mathsf{X} = \operatorname{Spét} A$ is affine. Then $\mathsf{X}' = \operatorname{Spét} A'$, where $A' = R' \otimes_R A$. Using Remark 4.2.1.3, we are reduced to proving that A' is of finite generation to order n (almost of finite presentation, locally of finite presentation) over R'. This follows from Proposition 4.1.3.2, since A is of finite generation to order n (almost of finite presentation, locally of finite presentation) over R. □

Proposition 4.2.1.7. *Let* $f : \mathsf{X} \to \mathsf{Y}$ *be a morphism of spectral Deligne-Mumford stacks which satisfies the following conditions:*

(1) *The spectral Deligne-Mumford stack* Y *is locally Noetherian.*

(2) *The map* f *is quasi-compact, separated, and locally of finite type.*

(3) *For every field* κ *and every morphism* $\mathrm{Sp\acute{e}t}\,\kappa \to \mathsf{Y}$*, the projection map* $\mathsf{X} \times_{\mathsf{Y}} \mathrm{Sp\acute{e}t}\,\kappa \to \mathrm{Sp\acute{e}t}\,\kappa$ *is an equivalence.*

Then f *is an equivalence.*

Proof. The assertion is local on Y. We may therefore assume without loss of generality that $\mathsf{Y} = \mathrm{Sp\acute{e}t}\,R$ for some Noetherian $\mathbb{E}_\infty$-ring R. For every étale map $\mathrm{Sp\acute{e}t}\,A \to \mathsf{X}$ and every residue field κ of $\pi_0 R$, condition (3) implies that $A \otimes_R \kappa$ is étale over κ. Using this together with (2), we deduce that f is locally quasi-finite. Invoking Theorem 3.3.0.2, we deduce that X is quasi-affine. Let R' be the $\mathbb{E}_\infty$-ring of global sections of the structure sheaf of X. Corollary 3.4.2.3 now guarantees that R' is almost connective. Using condition (3) and Proposition 2.5.4.5, we deduce that the canonical map $\theta : R \to R'$ induces an equivalence $\kappa \to R' \otimes_R \kappa$ for every residue field κ of $\pi_0 R$. Corollary 2.6.1.4 implies that θ is an equivalence, so that f is an equivalence by Proposition **??**. □

4.2.2 Digression: Bounds on the Relative Dimension

Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks and let $d \geqslant 0$ be a nonnegative integer. The condition that f has relative dimension $\leqslant d$ is local with respect to the étale topology on X (see Proposition 3.3.1.4). Consequently, there exists a largest open substack $\mathsf{U} \subseteq \mathsf{X}$ such that $f|_{\mathsf{U}} : \mathsf{U} \to \mathsf{X}$ is of relative dimension $\leqslant d$. We will refer to U as the *relative dimension* $\leqslant d$ *locus of the morphism* f. Note that if we are given any pullback diagram

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y}, \end{array}$$

then we can identify $\mathsf{U} \times_{\mathsf{X}} \mathsf{X}'$ with an open substack of X', and the restriction of f' to this open substack is also of relative dimension d (Corollary 3.3.1.5). It follows that $\mathsf{U} \times_{\mathsf{X}} \mathsf{X}'$ is contained in the relative dimension $\leqslant d$ locus of f'. Under mild hypotheses, we have equality:

Proposition 4.2.2.1 (Universality of the Relative Dimension $\leqslant d$ Locus)**.** *Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \xrightarrow{g} & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y} \end{array}$$

where f and f' are locally of finite type. If $\mathsf{U} \subseteq \mathsf{X}$ is the relative dimension $\leqslant d$ locus of f, then $\mathsf{U} \times_{\mathsf{X}} \mathsf{X}'$ is the relative dimension $\leqslant d$ locus of f'.

Proof. Without loss of generality, we may assume that $\mathsf{Y} \simeq \operatorname{Spét} A$ and $\mathsf{Y}' \simeq \operatorname{Spét} A'$ are affine. Similarly, we may assume that $\mathsf{X} \simeq \operatorname{Spét} B$ is affine, so that $\mathsf{X}' \simeq \operatorname{Spét} B'$ for $B' = A' \otimes_A B$. Let $x' \in |\operatorname{Spec} B'|$ be a point which belongs to the relative dimension $\leqslant d$ locus of f'; we wish to show that $x = g(x') \in |\operatorname{Spec} B|$ belongs to the relative dimension $\leqslant d$ locus of f. Let $\kappa(x')$ denote the residue field of B' at x' and let $\kappa(x)$ denote the residue field of B at x. Set $R = \pi_0(\kappa(x) \otimes_A B)$. Our assumption that f is locally of finite type guarantees that R is finitely generated as an algebra over $\kappa(x)$. Moreover, the canonical map $B \to \kappa(x)$ determines an augmentation $\epsilon : R \to \kappa(x)$ whose kernel is a maximal ideal $\mathfrak{m} \subseteq R$. Set $R' = \kappa(x') \otimes_{\kappa(x)} R$, so that ϵ determines an augmentation $\epsilon' : R' \to \kappa(x')$ whose kernel is a maximal ideal $\mathfrak{m}' \subseteq R'$. Let h and h' denote the Krull dimensions of the local rings $R_{\mathfrak{m}}$ and $R'_{\mathfrak{m}'}$. It follows from Theorem B.2.1.2 that $h = h'$ (note that $R_{\mathfrak{m}}$ and $R'_{\mathfrak{m}'}$ have the same Hilbert-Samuel polynomials). Our assumption that x' belongs to the relative dimension $\leqslant d$ locus of f' guarantees that $h' \leqslant d$. It follows that $h \leqslant d$. Applying Corollary B.2.4.8, we deduce that there exists an element $b \in \pi_0 B$ which does not vanish at x such that $B[b^{-1}]$ has relative dimension $\leqslant d$ over A, so that x belongs to the relative dimension $\leqslant d$ locus of f as desired. □

4.2.3 Morphisms Locally of Finite Presentation

Roughly speaking, the condition that a morphism of spectral Deligne-Mumford stacks $(\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ be locally of finite generation to order $(n+1)$ can be viewed as a finiteness condition on the homotopy groups $\pi_i \mathcal{O}_{\mathcal{X}}$ for $i \leqslant n$. In practice, it is often useful to use this notion in conjunction with another hypothesis which controls the homotopy groups $\pi_i \mathcal{O}_{\mathcal{X}}$ for $i > n$.

Definition 4.2.3.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks. We will say that $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is *locally finitely n-presented* over Y if the following conditions are satisfied:

(i) The structure sheaf $\mathcal{O}_{\mathcal{X}}$ is n-truncated.

(ii) The map f is locally of finite generation to order $n+1$.

In this case, we will also say that the morphism f is locally finitely n-presented.

Example 4.2.3.2. Let $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ be a morphism of spectral Deligne-Mumford stacks. Then f is locally finitely 0-presented if and only if the following conditions are satisfied:

(i) The structure sheaf $\mathcal{O}_{\mathcal{X}}$ is discrete.

(ii) The induced map of ordinary Deligne-Mumford stacks $(\mathcal{X}^{\heartsuit}, \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}^{\heartsuit}, \pi_0 \mathscr{O}_{\mathcal{Y}})$, when is locally of finite presentation, in the sense of classical algebraic geometry.

We now summarize some of the formal properties of Definition 4.2.3.1.

Proposition 4.2.3.3. *Fix an integer $n \geqslant 0$.*

(1) *The condition that a map $f : \mathsf{X} \to \mathsf{Y}$ be locally finitely n-presented is local on the source with respect to the étale topology.*

(2) *The condition that a map $f : \mathsf{X} \to \mathsf{Y}$ be locally finitely n-presented is local on the target with respect to the flat topology.*

(3) *Suppose given a pair of maps $f : \mathsf{X} \to \mathsf{Y}$ and $g : \mathsf{Y} \to \mathsf{Z}$. Assume that g is locally finitely n-presented. Then f is locally finitely n-presented if and only if $g \circ f$ is locally finitely n-presented.*

Proof. Assertion (1) follows from Proposition 4.2.1.1 and Example 2.8.3.9, assertion (2) follows from Proposition 4.2.1.5 and Example 2.8.3.9, and assertion (3) follows from Proposition 4.1.3.1. □

We conclude with the following observation:

Proposition 4.2.3.4. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Then f is étale if and only if the following three conditions are satisfied:*

(1) *The morphism f is flat.*

(2) *The diagonal map $\delta : \mathsf{X} \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ is flat.*

(3) *The morphism f is locally almost of finite presentation.*

Proof. The necessity of conditions (1), (2), and (3) is clear. Conversely, suppose that (1), (2) and (3) are satisfied; we wish to show that f is étale. Choose étale maps $\operatorname{Spét} A \to \mathsf{Y}$ and $\operatorname{Spét} B \to \operatorname{Spét} A \times_{\mathsf{Y}} \mathsf{X}$; we wish to show that B is étale over A. Then the induced map $\operatorname{Spét} B \to \operatorname{Spét}(B \otimes_A B) \times_{\mathsf{X} \times_{\mathsf{Y}} \mathsf{X}} \mathsf{X}$ is étale, so condition (2) guarantees that B is flat over $B \otimes_A B$. Set $R = \pi_0(B \otimes_A B)$ and let I deote the kernel of the underlying ring homomorphism $R \to \pi_0 B$. Condition (3) guarantees that $\pi_0 B$ is finitely generated as an algebra over $\pi_0 A$, so the ideal I is finitely generated. It follows that $\pi_0 B$ is finitely presented and flat as a module R. Using Lazard's theorem, we deduce that $\pi_0 B$ is a projective module over R. It follows that the canonical map $R \to \pi_0 B$ splits, so we can write $I = (e)$ for some idempotent element $e \in R$. It now follows from (1) and (3) that B is étale over A, as desired (see Definition HA.7.5.0.4). □

4.2.4 The Locally Noetherian Case

In the setting of locally Noetherian spectral Deligne-Mumford stacks, Definition 4.2.3.1 can be dramatically simplified:

Proposition 4.2.4.1. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks. Assume that Y is locally Noetherian. Then f is locally finitely n-presented if and only if the following conditions are satisfied:*

(1) *The morphism f is locally of finite type.*

(2) *The spectral Deligne-Mumford stack $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is locally Noetherian.*

(3) *The structure sheaf $\mathcal{O}_{\mathcal{X}}$ is n-truncated.*

Warning 4.2.4.2. Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks which is locally finitely n-presented. If Y is not locally Noetherian, then f need not be locally finitely m-presented for $m > n$.

We will deduce Proposition 4.2.4.1 from the following general categorical fact:

Lemma 4.2.4.3. *Let $\mathcal{C}$ be a projectively generated ∞-category containing an object X and let $n \geqslant 0$ be an integer. The following conditions are equivalent:*

(*i*) *The truncation $\tau_{\leqslant n} X$ is compact when viewed as an object of $\tau_{\leqslant n} \mathcal{C}$.*

(*ii*) *There exists a compact object $Y \in \mathcal{C}$ and a morphism $Y \to X$ which induces an equivalence $\tau_{\leqslant n} Y \to \tau_{\leqslant n} X$.*

In particular, every compact object of $\tau_{\leqslant n} \mathcal{C}$ has the form $\tau_{\leqslant n} Y$ for some compact object $Y \in \mathcal{C}$.

Proof of Proposition 4.2.4.1. We may assume without loss of generality that $\mathsf{Y} \simeq \operatorname{Spét} A$ and $\mathsf{X} \simeq \operatorname{Spét} B$ are affine. Assume first that f is locally finitely n-presented. Conditions (1) and (3) are obvious. To prove (2), we note that B is a compact object of $\tau_{\leqslant n} \mathrm{CAlg}_A$ (Remark 4.1.1.9), so that $B \simeq \tau_{\leqslant n} B'$ for some A-algebra B' which is of finite presentation over A (Lemma 4.2.4.3). It follows from Proposition HA.7.2.4.31 that B' is Noetherian, so that B is also Noetherian.

Now suppose that (1), (2), and (3) are satisfied. Using (1), (2), and Proposition HA.7.2.4.31 , we deduce that the map $A \to B$ is locally almost of finite presentation, and in particular of finite generation to order $(n+1)$ over A. Combining this with (3), we deduce that f is finitely n-presented as desired. □

Remark 4.2.4.4. Let $\mathcal{C}$ be a projectively generated ∞-category. Recall that a morphism $X \to Y$ in $\mathcal{C}$ exhibits Y as an n-truncation of X if and only if, for every compact projective object $P \in \mathcal{C}$, the induced map $\mathrm{Map}_{\mathcal{C}}(P, X) \to \mathrm{Map}_{\mathcal{C}}(P, Y)$ exhibits the space $\mathrm{Map}_{\mathcal{C}}(P, Y)$ as an n-truncation of $\mathrm{Map}_{\mathcal{C}}(P, X)$. Consequently, if we are given a pullback diagram

$$\begin{array}{ccc} X_0 & \longrightarrow & X_1 \\ \downarrow{\scriptstyle \alpha} & & \downarrow{\scriptstyle \beta} \\ Y_0 & \longrightarrow & Y_1 \end{array}$$

in $\mathcal{C}$ where Y_0 is n-truncated and β exhibits Y_1 as an n-truncation of X_1, then α exhibits Y_0 as an n-truncation of X_0 (to prove this, it suffices to verify the analogous assertion in the ∞-category of spaces, which follows from the observation that the homotopy fibers of α are $(n+1)$-connective provided that the homotopy fibers of β are $(n+1)$-connective).

Proof of Lemma 4.2.4.3. The implication $(ii) \Rightarrow (i)$ is clear. To prove the converse, let $\mathcal{E} \subseteq \tau_{\leqslant n}\mathcal{C}$ denote the full subcategory spanned by those objects $\overline{X}$ with the following property:

- $(*)$ For every object $X \in \mathcal{C}$ equipped with an equivalence $\tau_{\leqslant n} X \simeq \overline{X}$, there exists a compact object $Y \in \mathcal{C}$ and a morphism $Y \to X$ which induces an equivalence $\tau_{\leqslant n} Y \to \tau_{\leqslant n} X \simeq \overline{X}$.

It is clear that every object of $\mathcal{E}$ is compact in $\tau_{\leqslant n}\mathcal{C}$. To complete the proof, it will suffice to show that every compact object of $\tau_{\leqslant n}\mathcal{C}$ belongs to $\mathcal{E}$. The main step will be to show that $\mathcal{E}$ is closed under finite colimits in $\tau_{\leqslant n}\mathcal{C}$. Assuming this for the moment, let $\overline{\mathcal{E}}$ denote the full subcategory of $\mathcal{C}$ spanned by those compact objects X for which $\tau \leqslant nX$ belongs to $\mathcal{E}$. Note that $\mathcal{E}$ contains the truncation $\tau_{\leqslant n} P$ for every compact projective object $P \in \mathcal{C}$ (for any object X equipped with an equivalence $\alpha : \tau_{\leqslant n} X \simeq \tau_{\leqslant n} P$, the projectivity of P guarantees that the map $P \to \tau_{\leqslant n} P \xrightarrow{\alpha^{-1}} \tau_{\leqslant n} X$ can be lifted to a map $P \to X$). Since $\mathcal{C}$ is generated under small colimits by its compact projective objects, the ∞-category $\tau_{\leqslant n}\mathcal{C}$ is generated by $\mathcal{E}$ under filtered colimits so that every compact object of $\tau_{\leqslant n}\mathcal{C}$ is a retract of an object of $\mathcal{E}$. But $\mathcal{E}$ is equivalent to an $(n+1)$-category, so the existence of finite limits in $\mathcal{E}$ guarantees that it is idempotent complete.

It remains to prove that $\mathcal{E}$ is closed under finite colimits. We have already observed that it contains the initial object of $\tau_{\leqslant n}\mathcal{C}$ (since the initial object can be computed as the n-truncation of the initial object of $\mathcal{C}$, which is compact and projective). It will therefore suffice to show that $\mathcal{E}$ is closed under pushouts. Suppose we are given a pushout diagram

$$\begin{array}{ccc} \overline{X}_{01} & \longrightarrow & \overline{X}_0 \\ \downarrow & & \downarrow \\ \overline{X}_1 & \longrightarrow & \overline{X} \end{array}$$

where $\overline{X}_{01}$, $\overline{X}_0$, and $\overline{X}_1$ belong to $\mathcal{E}$. We wish to show that $\overline{X}$ belongs to $\mathcal{E}$. Choose an object X equipped with a map $X \to \overline{X}$ which exhibits $\overline{X}$ as an n-truncation of X. Set $X_0 = X \times_{\overline{X}} \overline{X}_0$ and $X_1 = X \times_{\overline{X}} \overline{X}_1$. It follows from Remark 4.2.4.4 that the maps $X_0 \to \overline{X}_0$ and $X_1 \to \overline{X}_1$ exhibit $\overline{X}_0$ and $\overline{X}_1$ as n-truncations of X_0 and X_1, respectively. Our assumption that $\overline{X}_0$ and $\overline{X}_1$ satisfy condition $(*)$ guarantees that we can choose compact objects $Y_0, Y_1 \in \mathcal{C}$ equipped with maps $Y_0 \to X_0$ and $Y_1 \to X_1$ which induce equivalences $\tau_{\leqslant n} Y_0 \to \tau_{\leqslant n} X_0$ and $\tau_{\leqslant n} Y_1 \to \tau_{\leqslant n} X_1$. Set

$$X_{01} = Y_0 \times_{\overline{X}_0} \overline{X}_{01} \times_{\overline{X}_1} Y_1.$$

It follows from two applications of Remark 4.2.4.4 that the projection map $X_{01} \to \overline{X}_{01}$ exhibits $\overline{X}_{01}$ as an n-truncation of X_{01}. Because $\overline{X}_{01}$ satisfies condition $(*)$, we can choose a compact object $Y_{01} \in \mathcal{C}$ and a map $Y_{01} \to X_{01}$ which induces an equivalence $\tau_{\leqslant n} Y_{01} \simeq \tau_{\leqslant n} X_{01}$. Let Y denote the pushout $Y_0 \amalg_{Y_{01}} Y_1$. Then Y is a compact object of $\mathcal{C}$ equipped with a map $Y \to X$ which induces an equivalence $\tau_{\leqslant n} Y \simeq \tau_{\leqslant n} X$. □

4.2.5 Morphisms of Finite Presentation

We now combine the local finiteness condition of Definition 4.2.3.1 with some global considerations.

Definition 4.2.5.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks and let $n \geqslant 0$ be an integer. We will say that f is *finitely n-presented* if the following conditions are satisfied:

(1) The map f is locally finitely n-presented (see Definition 4.2.3.1).

(2) For every map Spét $A \to \mathsf{Y}$, the fiber product Spét $A \times_{\mathsf{Y}} \mathsf{X}$ is a spectral Deligne-Mumford m-stack for some integer $m \geqslant 0$.

(3) The morphism f is ∞-quasi-compact (see Definition 2.3.2.2).

Remark 4.2.5.2. In the situation of Definition 4.2.5.1, assume that Y is quasi-compact. Then condition (2) is equivalent to the following:

(2′) The map $f : \mathsf{X} \to \mathsf{Y}$ is a relative spectral Deligne-Mumford m-stack for some $m \geqslant 0$.

In this case, Proposition 2.3.2.7 implies that condition (3) is equivalent to the following *a priori* weaker condition:

(3′) The morphism f is $(m + 1)$-quasi-compact.

If $m = 0$ (in other words, if $f : \mathsf{X} \to \mathsf{Y}$ is a relative spectral algebraic space), then (3′) is equivalent to the following:

(3″) The morphism f is quasi-compact and quasi-separated.

Remark 4.2.5.3. Suppose we are given maps of spectral Deligne-Mumford stacks

$$\mathsf{X} \xrightarrow{f} \mathsf{Y} \xrightarrow{g} \mathsf{Z}.$$

Assume that g is finitely n-presented. Then f is finitely n-presented if and only if g is finitely n-presented (combine Proposition 4.2.3.3 with Corollary 2.3.5.2).

The property of being finitely n-presented is not stable under arbitrary base change. Given a pullback diagram

$$\begin{array}{ccc} \mathsf{Y}' & \longrightarrow & \mathsf{Y} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{X}' & \xrightarrow{g} & \mathsf{X} \end{array}$$

where f is finitely n-presented, the morphism f' need not be finitely n-presented without some flatness assumption on the morphism g. We can correct this difficulty by truncating the structure sheaf of the spectral Deligne-Mumford stack Y'.

Proposition 4.2.5.4. *Suppose we are given a pullback diagram*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y} \end{array}$$

of spectral Deligne-Mumford stacks. If $\tau_{\leqslant n}\mathsf{X}$ *is finitely* n*-presented over* Y*, then* $\tau_{\leqslant n}\mathsf{X}'$ *is finitely* n*-presented over* Y'*.*

Proof. We may assume without loss of generality that $\mathsf{Y} \simeq \operatorname{Sp\acute{e}t} A$ and $\mathsf{Y}' \simeq \operatorname{Sp\acute{e}t} A'$ are affine. Then X is an ∞-quasi-compact spectral Deligne-Mumford m-stack for some $m \geqslant 0$. It follows that X' is also an ∞-quasi-compact spectral Deligne-Mumford m-stack (see Remark 1.6.8.4 and Corollary 2.3.5.4). To complete the proof, it will suffice to show that f' is locally finitely n-presented. Replacing X by $\tau_{\leqslant n}\mathsf{X}$, we may assume that $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is locally of finite generation to order $(n+1)$ over A. It follows that $\mathsf{X}' = (\mathcal{X}', \mathscr{O}_{\mathcal{X}'})$ is locally of finite generation to order $(n+1)$ over $\operatorname{Sp\acute{e}t} A'$. Using Remark 4.1.1.8, we deduce that $(\mathcal{X}', \tau_{\leqslant n}\mathscr{O}_{\mathcal{X}'})$ is also locally of finite generation to order $(n+1)$ over $\operatorname{Sp\acute{e}t} A'$, hence locally finitely n-presented over $\operatorname{Sp\acute{e}t} A'$. □

Corollary 4.2.5.5. *Suppose we are given a commutative diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccccc} \mathsf{X}_0 & \longrightarrow & \mathsf{X} & \longleftarrow & \mathsf{X}_1 \\ & \searrow & \downarrow & \swarrow & \\ & & \mathsf{Y} & & \end{array}$$

where X_0*,* X_1*, and* X *are finitely* n*-presented over* Y*. Then* $\tau_{\leqslant n}(\mathsf{X}_0 \times_{\mathsf{X}} \mathsf{X}_1)$ *is finitely* n*-presented over* Y*.*

Proof. Using Remark 4.2.5.3, we see that X_0 is finitely n-presented over X. It follows from Proposition 4.2.5.4 that $\tau_{\leqslant n}(\mathsf{X}_0 \times_{\mathsf{X}} \mathsf{X}_1)$ is finitely n-presnented over X_1, and hence also finitely n-presented over X (Remark 4.2.5.3). □

4.3 Constructible Sets

Let $(X, \mathscr{O}_X)$ be a quasi-compact, quasi-separated scheme. A subset $K \subseteq X$ is said to be *constructible* if it can be written as a finite union of sets of the form $U - V$, where U and $V \subseteq U$ are quasi-compact open subsets of X. Constructible sets are ubiquitous in algebraic geometry: for many important properties P of points of X, one can show that the locus of points $x \in X$ satisfying P is constructible. For example, if $f : Y \to X$ is a morphism of schemes which is of finite presentation, then Chevalley's *constructibility theorem* asserts that the image of f is a constructible subset of X (see Theorem 4.3.3.1 and Corollary 4.3.4.2).

Our goal in this section is to review the theory of constructible sets. We will work in the setting of spectral algebraic spaces, though this represents no real gain in generality (the underlying topological space $|\mathsf{X}|$ of a spectral algebraic space X depends only on the ordinary algebraic space $\tau_{\leqslant 0}\mathsf{X}$).

4.3.1 The Constructible Topology

We begin with some general remarks. We will assume that the reader is familiar with the theory of distributive lattices and Boolean algebras; for a brief review, see §A.1.

Proposition 4.3.1.1. *Let* Lat *denote the category of distributive lattices (see Definition A.1.5.3) and let* BAlg $\subseteq$ Lat *denote the full subcategory spanned by the Boolean algebras (Definition A.1.6.4). Then* BAlg *is a localization of* Lat*: that is, the inclusion functor* BAlg $\hookrightarrow$ Lat *admits a left adjoint.*

Proof. Note that the categories Lat and BAlg are presentable. By virtue of the adjoint functor theorem (Corollary HTT.5.5.2.9), it will suffice to show that the inclusion functor BAlg $\hookrightarrow$ Lat preserves small limits and filtered colimits. The first of these assertions follows immediately from the definitions. To prove the second, it will suffice to show that if $\{\Lambda_\alpha\}$ is a filtered diagram of Boolean algebras having colimit $\Lambda = \varinjlim \Lambda_\alpha$ in the category Lat, then Λ is also a Boolean algebra. Note that every element $x \in \Lambda$ is the image of an element x_α of some Λ_α. Since x_α complemented, x is complemented (Remark A.1.6.3). □

Combining Theorem A.1.6.11 and Proposition A.1.5.10, we obtain the following consequence of Proposition 4.3.1.1:

Corollary 4.3.1.2. *Let $\mathcal{T}\mathrm{op}_{\mathrm{coh}}$ denote the category whose objects are coherent topological spaces and whose morphisms are quasi-compact continuous maps (Definition A.1.5.9) and let $\mathcal{T}\mathrm{op}_{\mathrm{St}} \subseteq \mathcal{T}\mathrm{op}_{\mathrm{coh}}$ denote the full subcategory spanned by the Stone spaces (Definition A.1.6.8). Then the inclusion functor $\mathcal{T}\mathrm{op}_{\mathrm{St}} \hookrightarrow \mathcal{T}\mathrm{op}_{\mathrm{coh}}$ admits a right adjoint.*

Notation 4.3.1.3. We will denote the right adjoint to the inclusion functor $\mathcal{T}\mathrm{op}_{\mathrm{St}} \hookrightarrow \mathcal{T}\mathrm{op}_{\mathrm{coh}}$ by $X \mapsto X_{\mathrm{c}}$. If X is a coherent topological space, then X_{c} is another topological space equipped with a continuous map $\phi : X_{\mathrm{c}} \to X$, which is characterized up to homeomorphism by the following pair of conditions:

(a) The topological space X_{c} is a Stone space and the map ϕ is quasi-compact.

(b) For every Stone space Y, composition with ϕ induces a bijection from the set of continuous maps $\mathrm{Hom}_{\mathcal{T}\mathrm{op}}(Y, X_{\mathrm{c}})$ to the set of quasi-compact continuous maps $\mathrm{Hom}_{\mathcal{T}\mathrm{op}_{\mathrm{coh}}}(Y, X)$.

Proposition 4.3.1.4. *Let X be a coherent topological space. Then the canonical map $\phi : X_{\mathrm{c}} \to X$ is a bijection.*

Proof. Let $*$ denote the topological space consisting of a single point, so that $* \in \mathcal{T}\mathrm{op}_{\mathrm{St}}$. As a map of sets, ϕ is given by the composition of bijections

$$X_{\mathrm{c}} \simeq \mathrm{Hom}_{\mathcal{T}\mathrm{op}_{\mathrm{St}}}(*, X_{\mathrm{c}}) \simeq \mathrm{Hom}_{\mathcal{T}\mathrm{op}_{\mathrm{coh}}}(*, X) \simeq X.$$

□

Remark 4.3.1.5. Let X be a coherent topological space. We will use Proposition 4.3.1.4 to identify the underlying sets of the topological spaces X and X_{c}. We may therefore view X_{c} as the space X endowed with a new topology, which we refer to as the *constructible topology*. We say that a subset $K \subseteq X$ is *constructible* if it is compact and open when regarded as a subset of X_{c}.

4.3.2 Constructible Open Sets

Let X be a coherent topological space. Then we can describe the class of constructible sets as the smallest Boolean algebra of subsets of X which contains every quasi-compact open subset of X. In particular, every quasi-compact open subset of X is constructible. The following converse is often useful:

Proposition 4.3.2.1. *Let X be a coherent topological space and let U be a subset of X. Then U is quasi-compact and open if and only if it satisfies the following conditions:*

(a) *The set U is constructible.*

(b) *The set U is stable under generalization. That is, if $x \in U$ and x belongs to the closure of a point $y \in X$, then $y \in U$.*

Corollary 4.3.2.2. *Let X be a coherent topological space, and let U be an open subset of X. Then U is constructible if and only if it is quasi-compact.*

Proof of Proposition 4.3.2.1. It is clear that conditions (a) and (b) necessary. We will show that they are sufficient using the following:

(∗) For every constructible subset $V \subseteq X$, we have $\overline{V} = \bigcup_{x \in V} \overline{\{x\}}$.

Assertion (∗) implies that for any constructible subset $U \subseteq X$, the interior of U is given by $X - \bigcup_{x \notin U} \overline{\{x\}}$, so that U is open if U satisfies (b).

The collection of constructible sets K satisfying condition (∗) is closed under finite unions. Consequently, to prove (∗) in general, it will suffice to prove (∗) in the special case where $K = V' \cap (X - W)$, where V' and W are quasi-compact open subsets of X. Replacing X by $X - W$, we may assume that V is a quasi-compact open subset of X.

Fix a point $y \in \overline{V}$. Let $\{V_\alpha\}$ denote the collection of all open subsets of V of the form $U \cap V$, where U is an open subset of X which contains y. Then each V_α is quasi-compact and nonempty (by virtue of our assumption that $y \in \overline{V}$). Moreover, the collection of open sets $\{V_\alpha\}$ is closed under finite intersections. Applying Remark A.1.5.11, we conclude that there exists a point $x \in \bigcap V_\alpha$. Then x is a point of V which belongs to every quasi-compact open subset of X which contains y, so that $y \in \overline{\{x\}}$. □

4.3.3 Chevalley's Constructibility Theorem

We will need the following classical theorem of Chevalley:

Theorem 4.3.3.1. *Let $f : A \to B$ be a homomorphism of commutative rings such that B is finitely presented as an A-algebra. Then the induced map $\phi : |\operatorname{Spec} B| \to |\operatorname{Spec} A|$ carries constructible subsets of $|\operatorname{Spec} B|$ to constructible subsets of $|\operatorname{Spec} A|$.*

Proof. Let Y be a constructible subset of $|\operatorname{Spec} B|$; we wish to show that $\phi(Y)$ is a constructible subset of $|\operatorname{Spec} A|$. Since B is finitely presented over A, we can choose a finitely generated subring $A_0 \subseteq A$ and a pushout diagram of commutative rings

$$\begin{array}{ccc} A_0 & \longrightarrow & A \\ \downarrow{\scriptstyle f_0} & & \downarrow{\scriptstyle f} \\ B_0 & \longrightarrow & B, \end{array}$$

where B_0 is a finitely presented A_0-algebra. Enlarging A_0 if necessary, we may assume that Y is the inverse image of a constructible subset $Y_0 \subseteq |\operatorname{Spec} B_0|$ (Corollary 4.3.5.2). Let

$\phi_0 : |\operatorname{Spec} B_0| \to |\operatorname{Spec} A_0|$ be the map determined by f_0, so that $\phi(Y)$ is the inverse image of $\phi_0(Y_0)$. It will then suffice to show that $\phi_0(Y_0)$ is a constructible subset of $|\operatorname{Spec} A_0|$. Replacing f by f_0, we are reduced to proving Theorem 4.3.3.1 in the special case where the ring A is finitely generated. In particular, we may assume that A is Noetherian.

Write f as a composition of maps

$$A = A_0 \to A_1 \to \cdots \to A_n = B,$$

where each A_i is generated as an A_{i-1}-algebra by a single element. It will then suffice to show that each of the maps $|\operatorname{Spec} A_i| \to |\operatorname{Spec} A_{i-1}|$ carries constructible sets to constructible sets. We may therefore assume without loss of generality that $B = A[x]/I$ for some ideal $I \subseteq A[x]$. Since A is Noetherian, the ideal I is finitely generated. It follows that the closed immersion $|\operatorname{Spec} B| \to |\operatorname{Spec} A[x]|$ carries constructible sets to constructible sets. We may therefore reduce to the case where $B = A[x]$.

Let $Y \subseteq |\operatorname{Spec} A[x]|$ be a constructible set; we wish to show that $\phi(Y) \subseteq |\operatorname{Spec} A|$ is constructible. Writing Y as a finite union of locally closed subsets of $|\operatorname{Spec} A[x]|$, we can reduce to the case where Y is locally closed. We now proceed by Noetherian induction on A. Let us say that an ideal $I \subseteq A$ is *good* if the inverse image of $\phi(Y)$ in $|\operatorname{Spec} A/I|$ is constructible. We claim that every ideal $I \subseteq |\operatorname{Spec} A|$ is good. Assume otherwise. Since A is Noetherian, we can choose an ideal $I \subseteq A$ which is maximal among those ideals which are not good. Replacing A by A/I, we may reduce to the case where every nonzero ideal in A is good. It follows immediately that the ring A is reduced. If $A \simeq 0$, there is nothing to prove. Otherwise, we can choose a minimal prime ideal $\mathfrak{p} \subseteq A$, so that the localization $A_{\mathfrak{p}}$ is a field K.

Since Y is locally closed, we can write $Y = Z - Z'$, where Z is the vanishing locus of a radical ideal $J \subseteq A[x]$ and Z' is the vanishing locus of a radical ideal $J' \subseteq A[x]$ which contains J. Then the localizations $J_{\mathfrak{p}}$ and $J'_{\mathfrak{p}}$ are ideals in the polynomial ring $K[x]$. We distinguish three cases:

(*a*) The ideals $J_{\mathfrak{p}}$ and $J'_{\mathfrak{p}}$ are equal to one another. In this case, we can choose an element $a \in A - \mathfrak{p}$ such that $J[a^{-1}] = J'[a^{-1}]$. Let $U \subseteq |\operatorname{Spec} A|$ denote the open subset given by $|\operatorname{Spec} A[a^{-1}]|$, so that $U \times_{|\operatorname{Spec} A|} Z = U \times_{|\operatorname{Spec} A|} Z'$ and therefore $\phi(Y) \cap U = \varnothing$. The inductive hypothesis implies that $\phi(Y)$ is a constructible when regarded as a subset of $|\operatorname{Spec} A/(a)|$, and therefore constructible when regarded as a subset of $|\operatorname{Spec} A|$.

(*b*) The ideal $J_{\mathfrak{p}}$ is zero, and $J'_{\mathfrak{p}}$ is not zero. Since $K[x]$ is a principal ideal domain, the ideal $J'_{\mathfrak{p}}$ is generated by some (square-free) monic polynomial $f(x) \in K[x]$. Let us lift $f(x)$ to a monic polynomial $\overline{f}(x)$ with coefficients in the ring $A[a^{-1}]$, for some $a \in A - \mathfrak{p}$. Modifying the choice of a if necessary, we may assume that $J[a^{-1}] = 0$ and $J'[a^{-1}]$ is the ideal generated by $\overline{f}(x)$. In this case, $\phi(Y)$ contains the open set $U = |\operatorname{Spec} A[a^{-1}]|$. Since $\phi(Y) \cap |\operatorname{Spec} A/(a)|$ is constructible by our inductive hypothesis, it follows that $\phi(Y) = U \cup (\phi(Y) \cap |\operatorname{Spec} A/(a)|)$ is also constructible.

(c) The ideal $J'_{\mathfrak{p}}$ is generated by some (square-free) monic polynomial $f(x)$, the ideal $J_{\mathfrak{p}}$ is generated by a product $f(x)g(x)$, where $g(x)$ is a square-free monic polynomial which is relatively prime to $f(x)$ having degree > 0. In this case, the polynomials $f(x)$ and $g(x)$ generate the unit ideal in $K[x]$. Let us lift $f(x)$ and $g(x)$ to monic polynomial $\overline{f}(x)$ and $\overline{g}(x)$ with coefficients in the ring $A[a^{-1}]$, for some $a \in A - \mathfrak{p}$. Modifying a if necessary, we may assume that $J[a^{-1}]$ and $J'[a^{-1}]$ are generated by $\overline{f}(x)\overline{g}(x)$ and $\overline{f}(x)$, respectively, and that the polynomials $\overline{f}(x)$ and $\overline{g}(x)$ generate the unit ideal in $A[a^{-1}][x]$. Let $U = |\operatorname{Spec} A[a^{-1}]|$. Then we can identify $Y \times_{|\operatorname{Spec} A|} U$ with the vanishing locus of the polynomial $\overline{g}(x)$. Since $\overline{g}$ is a monic polynomial of positive degree, it follows that the projection map $Y \times_{|\operatorname{Spec} A|} U \to U$ is surjective. Since $\phi(Y) \cap |\operatorname{Spec} A/(a)|$ is constructible by our inductive hypothesis, it follows that $\phi(Y) = U \cup (\phi(Y) \cap |\operatorname{Spec} A/(a)|)$ is also constructible.

□

4.3.4 Constructibility in Algebraic Geometry

Let X be a quasi-compact, quasi-separated spectral algebraic space. Then the topological space $|\mathsf{X}|$ is coherent (Proposition 3.6.3.3). It therefore makes sense to consider constructible subsets of $|\mathsf{X}|$. It follows from Chevalley's constructibility theorem that this condition can be tested locally in a very strong sense:

Proposition 4.3.4.1. *Let X be a spectral algebraic space which is quasi-compact and quasi-separated, and let K be a subset of $|\mathsf{X}|$. The following conditions are equivalent:*

(1) *The set K is constructible.*

(2) *For every quasi-compact, quasi-separated spectral algebraic space Y and every map $f : \mathsf{Y} \to \mathsf{X}$, the inverse image $f^{-1}K \subseteq |\mathsf{Y}|$ is constructible.*

(3) *There exists an étale surjection $f : \operatorname{Spét} R \to \mathsf{X}$ for which the inverse image $f^{-1}K \subseteq |\operatorname{Spét} R| \simeq |\operatorname{Spec} R|$ is constructible.*

(4) *There exists a quasi-compact, quasi-separated algebraic space Y and a surjection $f : \mathsf{Y} \to \mathsf{X}$ such that $\tau_{\leqslant 0}\mathsf{Y}$ is locally finitely 0-presented over X (see Definition 4.2.3.1), and $f^{-1}K$ is a constructible subset of $|\mathsf{Y}|$.*

Proof. The implication (1) ⇒ (2) follows from Proposition 3.6.3.3, and the implications (2) ⇒ (3) and (3) ⇒ (4) are obvious. We will complete the proof by showing that (4) ⇒ (1).

Suppose that $f : \mathsf{Y} \to \mathsf{X}$ is a surjective morphism of quasi-compact, quasi-separated spectral algebraic spaces for which $\tau_{\leqslant 0}\,\mathsf{Y}$ is finitely 0-presented over X, and that $K \subseteq |\,\mathsf{X}\,|$ is a subset for which $f^{-1}K \subseteq |\,\mathsf{Y}\,|$ is constructible. We wish to prove that K is constructible. Applying Theorem 3.4.2.1, we can choose a scallop decomposition

$$\varnothing = \mathsf{U}_0 \hookrightarrow \mathsf{U}_1 \hookrightarrow \cdots \hookrightarrow \mathsf{U}_n = \mathsf{X}$$

of the spectral algebraic space $|\,\mathsf{X}\,|$. Then each $|\,\mathsf{U}_i\,|$ determines a quasi-compact open subset $U_i \subseteq |\,\mathsf{X}\,|$. We will prove that the intersection $K \cap U_i$ is a constructible subset of $|\,\mathsf{X}\,|$, using induction on i. The case $i = 0$ is trivial. To carry out the inductive step, assume that $i > 0$ and that $K \cap U_{i-1}$ is a constructible subset of $|\,\mathsf{X}\,|$. Choose an excision square

$$\begin{array}{ccc} \mathsf{V} & \xrightarrow{j} & \operatorname{Sp\acute{e}t} A \\ \downarrow & & \downarrow{\scriptstyle v} \\ \mathsf{U}_{i-1} & \longrightarrow & \mathsf{U}_i \end{array}$$

for some connective $\mathbb{E}_\infty$-ring A. Let $V = |\,\mathsf{V}\,|$, so that the open immersion j allows us to identify V with a quasi-compact open subset of $|\operatorname{Spec} A|$. Then v induces a continuous map $\phi : |\operatorname{Spec} A| \to U_i$, which restricts to a homeomorphism from $|\operatorname{Spec} A| - V$ to $U_i - U_{i-1}$. It follows that

$$K \cap U_i = (K \cap U_{i-1}) \cup \phi(\phi^{-1}(K \cap U_i) - V)$$

is constructible if and only if $\phi^{-1}(K \cap U_i) - V$ is a constructible subset of $|\operatorname{Spec} A|$. To prove this, it suffices to show that $\phi^{-1}K \subseteq |\operatorname{Spec} A|$ is constructible. Replacing X by $\operatorname{Sp\acute{e}t} A$, Y by $\operatorname{Sp\acute{e}t} A \times_{\mathsf{X}} \mathsf{Y}$, and K by $\phi^{-1}K$, we may reduce to the case where $\mathsf{X} = \operatorname{Sp\acute{e}t} A$ is affine.

Since Y is quasi-compact, we can choose an étale surjection $g : \operatorname{Sp\acute{e}t} B \to \mathsf{Y}$. Since $f^{-1}K$ is a constructible subset of $|\,\mathsf{Y}\,|$, Proposition 3.6.3.3 implies that $L = g^{-1}(f^{-1}K)$ is a constructible subset of $|\operatorname{Spec} B|$. Since f and g are surjective, we can identify K with the image of L under the continuous map $|\operatorname{Spec} B| \to |\operatorname{Spec} A|$. Our assumption that $\tau_{\leqslant 0}\,\mathsf{Y}$ is locally finitely 0-presented over X guarantees that $\pi_0 B$ is finitely presented as a commutative algebra over $\pi_0 A$, so that the constructibility of K follows from Theorem 4.3.3.1. □

Using Proposition 4.3.4.1, we immediately deduce the following "global" version of Theorem 4.3.3.1:

Corollary 4.3.4.2. *Let $f : \mathsf{Y} \to \mathsf{X}$ be a map of quasi-compact, quasi-separated algebraic spaces which is locally of finite generation to order* 1*. Then the induced map $\phi : |\,\mathsf{Y}\,| \to |\,\mathsf{X}\,|$ carries constructible subsets of $|\,\mathsf{Y}\,|$ to constructible subsets of $|\,\mathsf{X}\,|$.*

Proof. Let $K \subseteq |\,\mathsf{Y}\,|$ be constructible; we wish to show that $\phi(K)$ is a constructible subset of $|\,\mathsf{X}\,|$. Since X is quasi-compact and quasi-separated, we can choose étale surjections

$$\operatorname{Sp\acute{e}t} A \to \mathsf{X} \qquad \operatorname{Sp\acute{e}t} B \to \operatorname{Sp\acute{e}t} A \times_{\mathsf{X}} \mathsf{Y},$$

which determine a commutative diagram of topological spaces

$$\begin{array}{ccc} |\operatorname{Spec} B| & \xrightarrow{\phi'} & |\operatorname{Spec} A| \\ \downarrow{\scriptstyle \psi'} & & \downarrow{\scriptstyle \psi} \\ |\mathsf{Y}| & \xrightarrow{\phi} & |\mathsf{X}|. \end{array}$$

Our assumption on f implies that $\pi_0 B$ is finitely presented as a commutative algebra over $\pi_0 A$, so that Theorem 4.3.3.1 guarantees that $\psi'(\psi'^{-1}K)$ is a constructible subset of $|\operatorname{Spec} A|$. Corollary 3.6.3.2 supplies an equality $\psi^{-1}\phi(K) = \phi'(\psi'^{-1}K)$, so that $\psi^{-1}\phi(K)$ is constructible. It follows from Proposition 4.3.4.1 that $\phi(K) \subseteq |\mathsf{X}|$ is constructible. □

Corollary 4.3.4.3. *Let $f : \mathsf{Y} \to \mathsf{X}$ be a morphism of quasi-compact, quasi-separated spectral algebraic spaces. Suppose that f is flat and exhibits $\tau_{\leqslant 0}\mathsf{Y}$ as locally finitely 0-presented over X. Then the induced map of topological spaces $\phi : |\mathsf{Y}| \to |\mathsf{X}|$ is open.*

Proof. Let $U \subseteq |\mathsf{Y}|$ be an open subset of $|\mathsf{Y}|$; we wish to prove that $\phi(U) \subseteq |\mathsf{X}|$ is open. Writing U as a union of quasi-compact open subsets of $|\mathsf{Y}|$, we may assume that U is quasi-compact. Then U determines a quasi-compact open substack $\mathsf{U} \hookrightarrow \mathsf{Y}$. Replacing Y by U, we are reduced to proving that the map ϕ has open image.

Choose an étale surjection $\operatorname{Spét} A \to \mathsf{X}$, which induces a continuous map $\psi : |\operatorname{Spec} A| \to |\mathsf{X}|$. It follows from Proposition 3.6.3.6 that ψ is a quotient map. It will therefore suffice to show that $\psi^{-1}\phi(|\mathsf{Y}|)$ is an open subset of $|\operatorname{Spec} A|$. Using Corollary 3.6.3.2, we can replace X by $\operatorname{Spét} A$ and Y by $\operatorname{Spét} A \times_{\mathsf{X}} \mathsf{Y}$, and thereby reduce to the case where X is affine. Choosing an étale surjection $\operatorname{Spét} B \to \mathsf{Y}$, we are reduced to proving that the map $\nu : |\operatorname{Spec} B| \to |\operatorname{Spec} A|$ has open image. Since $\pi_0 B$ is finitely presented as an algebra over $\pi_0 A$, the image of ν is a constructible subset of $|\operatorname{Spec} A|$ (Theorem 4.3.3.1). It will therefore suffice to show that the image of ν is stable under generalization (Proposition 4.3.2.1). This follows from Theorem B.2.2.1, since $\pi_0 B$ is flat over $\pi_0 A$. □

Corollary 4.3.4.4. *Let $f : \mathsf{Y} \to \mathsf{X}$ be an étale morphism between quasi-compact, quasi-separated spectral algebraic spaces. Then f has the going down property: that is, if $y \in |\mathsf{Y}|$ is a point for which $f(y) \in |\mathsf{X}|$ lies in the closure of of some point $x \in |\mathsf{X}|$, then we can write $x = f(\overline{x})$ for some point $\overline{x} \in |\mathsf{Y}|$ for which x lies in the closure of $\{\overline{x}\}$.*

Proof. Let K be the closure of $\{x\}$ in $|\mathsf{X}|$. Then $f^{-1}K \subseteq |\mathsf{Y}|$ is a closed set containing $f^{-1}\{x\}$. Since f is an open map (Corollary 4.3.4.3), any open subset $U \subseteq |\mathsf{Y}|$ which intersects $f^{-1}K$ has the property that K intersects $f(U)$, so that $x \in f(U)$ and therefore $f^{-1}\{x\}$ intersects U. It follows that $f^{-1}K$ is the closure of the set $f^{-1}\{x\}$. Since f is étale and quasi-compact, the set $f^{-1}\{x\}$ is finite. Consequently, $y \in K$ belongs to the closure of some point $\overline{x} \in f^{-1}\{x\}$, as desired. □

4.3.5 Constructible Subsets of Inverse Limits

We conclude this section with a few observations about the behavior of the constructible topology with respect to direct limits.

Proposition 4.3.5.1. *For every commutative ring R, let $\mathcal{U}(R)$ denote the distributive lattice of quasi-compact open subsets of the Zariski spectrum $|\operatorname{Spec} R|$. Then the functor $R \mapsto \mathcal{U}(R)$ commutes with filtered colimits.*

Proof. The partially ordered set of *all* open subsets of $|\operatorname{Spec} R|$ is isomorphic to the partially ordered set of radical ideals $I \subseteq R$. Under this isomorphism, $\mathcal{U}(R)$ corresponds to the collection of radical ideals I such that $I = \sqrt{J}$ for some finitely generated ideal $J \subseteq R$.

Let $\{R_\alpha\}_{\alpha \in A}$ be a diagram of commutative rings indexed by a filtered partially ordered set A, and let R be a colimit of this diagram. We wish to show that the canonical map $\phi : \varinjlim \mathcal{U}(R_\alpha) \to \mathcal{U}(R)$ is surjective. The surjectivity of ϕ follows from the observation that every finitely generated ideal $J \subseteq R$ has the form $J_\alpha R$, where J_α is a finitely generated ideal in R_α for some $\alpha \in A$. To prove the injectivity, we must show that if $J, J' \subseteq R_\alpha$ are two finitely generated ideals such that JR and $J'R$ have the same radical, then JR_β and $J'R_\beta$ have the same radical for some $\beta \geqslant \alpha$. Choose generators $x_1, \ldots, x_n \in R_\alpha$ for the ideal J, and generators $y_1, \ldots, y_m \in R_\alpha$ for the ideal J'. Let $\psi : R_\alpha \to R$ be the canonical map. The equality $\sqrt{JR} = \sqrt{J'R}$ implies that there are equations of the form

$$\psi(x_i)^{c_i} = \sum_j \lambda_{i,j} \psi(y_j) \qquad \psi(y_j)^{d_j} = \sum_i \mu_{i,j} \psi(x_i)$$

in the commutative ring R, where c_i and d_j are positive integers. Choose $\beta \geqslant \alpha$ such that the coefficients $\lambda_{i,j}$ and $\mu_{i,j}$ can be lifted to elements $\overline{\lambda}_{i,j}, \overline{\mu}_{i,j} \in R_\beta$. Let $\psi_\beta : R_\alpha \to R_\beta$ be the canonical map. Enlarging β if necessary, we may assume that the equations

$$\psi_\beta(x_i)^{c_i} = \sum_j \overline{\lambda}_{i,j} \psi_\beta(y_j) \qquad \psi_\beta(y_j)^{d_j} = \sum_i \overline{\mu}_{i,j} \psi_\beta(x_i)$$

hold in the commutative ring R_β, so that $\sqrt{JR_\beta} = \sqrt{J'R_\beta}$ as desired. □

Corollary 4.3.5.2. *For every commutative ring R, let $\mathcal{B}(R)$ denote the Boolean algebra consisting of constructible subsets of $|\operatorname{Spec} R|$. Then the functor $R \mapsto \mathcal{B}(R)$ commutes with filtered colimits.*

Proof. Let $R \mapsto \mathcal{U}(R)$ be the functor of Proposition 4.3.5.1. Using Proposition 4.3.1.4, we see that $\mathcal{B}$ is given by the composition $\mathrm{CAlg}^{\heartsuit} \xrightarrow{\mathcal{U}} \mathrm{Lat} \xrightarrow{U} \mathrm{BAlg}$, where U is as in Proposition 4.3.1.1. The functor U commutes with all colimits (since it is a left adjoint), and the functor $\mathcal{U}$ commutes with filtered colimits by Proposition 4.3.5.1. □

Corollary 4.3.5.3. *Let $\{R_\alpha\}_{\alpha \in A}$ be a diagram of commutative rings having colimit R, indexed by a filtered partially ordered set A Let $\alpha \in A$ and let $K \subseteq |\operatorname{Spec} R_\alpha|$ be a constructible subset. Suppose that the inverse image of K in $|\operatorname{Spec} R|$ is empty. Then there exists $\beta \geqslant \alpha$ in A such that the inverse image of K in $|\operatorname{Spec} R_\beta|$ is empty.*

Corollary 4.3.5.4. *Let A_0 be a commutative ring, and let $\{A_\alpha\}$ be a filtered diagram of commutative A_0-algebras having colimit A. Suppose that B_0 is an A_0-algebra of finite presentation, set $B = \pi_0(B_0 \otimes_{A_0} A)$, and assume that the map $|\operatorname{Spec} B| \to |\operatorname{Spec} A|$ is surjective. Then there exists an index α such that the map $|\operatorname{Spec} B_\alpha| \to |\operatorname{Spec} A_\alpha|$ is surjective, where $B_\alpha = \pi_0(B_0 \otimes_{A_0} A_\alpha)$.*

Proof. Combine Theorem 4.3.3.1 with Corollary 4.3.5.3. □

Proposition 4.3.5.5. *Let R be a connective $\mathbb{E}_\infty$-ring and let X be a quasi-compact quasi-separated spectral algebraic space over R. For every map of connective $\mathbb{E}_\infty$-rings $R \to R'$, let $\mathsf{X}_{R'} = \operatorname{Spét} R' \times_{\operatorname{Spét} R} \mathsf{X}$, and let $\mathcal{U}_{\mathsf{X}}(R')$ denote the distributive lattice of quasi-compact open subsets of $|\mathsf{X}_{R'}|$. Then:*

(1) *The functor $R' \mapsto \mathcal{U}_{\mathsf{X}}(R')$ commutes with filtered colimits.*

(2) *The functor $R' \mapsto |\mathsf{X}_{R'}|$ carries filtered colimits of R-algebras to filtered limits of topological spaces.*

Proof. By virtue of Remark A.1.5.12 and Corollary 3.6.3.4, assertion (2) follows from (1). We now prove (1). Since X is quasi-compact, we can choose an étale surjection $\operatorname{Spét} A^0 \to \mathsf{X}$. Since X is quasi-separated, we can choose an étale surjection $\operatorname{Spét} A^1 \to \operatorname{Spét} A^0 \times_{\mathsf{X}} \operatorname{Spét} A^0$. For every commutative ring B, let $\mathcal{U}(B)$ be defined as in Proposition 4.3.5.1. Then for $R' \in \mathrm{CAlg}_R^{\mathrm{cn}}$, we have an equalizer diagram of sets

$$\mathcal{U}_{\mathsf{X}}(R') \longrightarrow \mathcal{U}(\pi_0(R' \otimes_R A^0)) \rightrightarrows \mathcal{U}(\pi_0(R' \otimes_R A^1)).$$

Since $\mathcal{U}$ commutes with filtered colimits, we conclude that $\mathcal{U}_{\mathsf{X}}$ commutes with filtered colimits. □

4.4 Noetherian Approximation

Let X be a scheme of finite presentation over a commutative ring R. Then there exists a finitely generated subring $R_0 \subseteq R$, an R_0-scheme X_0 of finite presentation, and an isomorphism of schemes $X \simeq \operatorname{Spec} R \times_{\operatorname{Spec} R_0} X_0$. This observation is the basis of a technique called *Noetherian approximation*: one can often reduce questions about the scheme X to questions about the scheme X_0, which may be easier to answer because X_0 is Noetherian.

Our goal in this section is to adapt the technique of Noetherian approximation to the setting of spectral algebraic geometry. More specifically, we would like to address questions like the following:

Question 4.4.0.1. Let X be a spectral Deligne-Mumford stack over a connective $\mathbb{E}_\infty$-ring R, and suppose that R is given as a filtered colimit $\varinjlim R_\alpha$ of connective $\mathbb{E}_\infty$-rings. Can we find an index α, a spectral Deligne-Mumford stack X_α over R_α, and an equivalence of spectral Deligne-Mumford stacks $\mathsf{X} \simeq \operatorname{Spét} R \times_{\operatorname{Spét} R_\alpha} \mathsf{X}_\alpha$?

To have a chance at an affirmative answer, we need to make some finiteness assumptions on X. However, even with finiteness assumptions in place, Question 4.4.0.1 is more subtle than its classical analogue. The main issue is that the data of a spectral Deligne-Mumford stack $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ is infinitary in nature, because the structure sheaf $\mathcal{O}_{\mathcal{X}}$ may have an infinite number of nonzero homotopy sheaves $\pi_m \mathcal{O}_{\mathcal{X}}$. When looking for "approximations" to X, we can generally only control finitely many of these homotopy groups at one time. We can attempt to avoid the issue by studying *truncations* of X. Recall that for each $n \geqslant 0$, $\tau_{\leqslant n} \mathsf{X}$ denotes the spectral Deligne-Mumford stack $(\mathcal{X}, \tau_{\leqslant n} \mathcal{O}_{\mathcal{X}})$. A more reasonable version of Question 4.4.0.1 is the following:

Question 4.4.0.2. Let X be a spectral Deligne-Mumford stack over a connective $\mathbb{E}_\infty$-ring R. Suppose that R is given as a filtered colimit $\varinjlim R_\alpha$, and let $n \geqslant 0$ be an integer. Can we find an index α, a spectral Deligne-Mumford stack X_α over R_α, and an equivalence of spectral Deligne-Mumford stacks $\tau_{\leqslant n} \mathsf{X} \simeq \tau_{\leqslant n}(\operatorname{Spét} R \times_{\operatorname{Spét} R_\alpha} \mathsf{X}_\alpha)$?

Our main result (Theorem 4.4.2.2) supplies an affirmative answer in the case where X is finitely n-presented over R, in the sense of Definition 4.2.5.1. Moreover, in this case, we can assume that X_α is finitely n-presented over R_α, in which case X_α is essentially unique (more precisely, any two choices for X_α become equivalent after extending scalars along some transition map $R_\alpha \to R_\beta$ of our filtered diagram).

4.4.1 Approximation in the Affine Case

We begin by discussing the special case of Questions 4.4.0.1 and 4.4.0.2 in which X is assumed to be affine. In this case, we can formulate the following slight variant of Question 4.4.0.1:

Question 4.4.1.1. Let $\phi : R \to A$ be a morphism of connective $\mathbb{E}_\infty$-rings, and suppose that R is given as the colimit of a filtered diagram of connective $\mathbb{E}_\infty$-rings $\{R_\alpha\}$. Can we find an index α, an object $A_\alpha \in \operatorname{CAlg}^{\mathrm{cn}}_{R_\alpha}$, and an equivalence $A \simeq R \otimes_{R_\alpha} A_\alpha$?

We will address Question 4.4.1.1 using the following general categorical principle:

Proposition 4.4.1.2. *Let $\mathcal{C}$ be a compactly generated ∞-category. Then:*

(1) *For each object $C \in \mathcal{C}$, the ∞-category $\mathcal{C}_{C/}$ is compactly generated.*

(2) *Let $f : C \to D$ be a morphism in $\mathcal{C}$. Then f is compact when viewed as an object of $\mathcal{C}_{C/}$ if and only if there exists a pushout diagram*

$$\begin{array}{ccc} C_0 & \longrightarrow & D_0 \\ \downarrow & & \downarrow \\ C & \longrightarrow & D, \end{array}$$

where C_0 and D_0 are compact objects of $\mathcal{C}$.

(3) *Let $\mathcal{D}$ denote the full subcategory of $\mathrm{Fun}(\Delta^1, \mathcal{C})$ spanned by those morphisms $f : C \to D$ which are compact when viewed as objects of $\mathcal{C}_{C/}$. Then evaluation at $\{0\} \subseteq \Delta^1$ induces a coCartesian fibration $\mathcal{D} \to \mathcal{C}$. Moreover, this coCartesian fibration is classified by a functor $\chi : \mathcal{C} \to \mathcal{C}\mathrm{at}_\infty$ which commutes with filtered colimits.*

Before giving the proof of Proposition 4.4.1.2, let us describe some consequences.

Corollary 4.4.1.3. *For every connective $\mathbb{E}_\infty$-ring R, let $\mathrm{CAlg}^{\mathrm{fp}}_R$ denote the full subcategory of $\mathrm{CAlg}^{\mathrm{cn}}_R$ spanned by those $\mathbb{E}_\infty$-algebras which are locally of finite presentation over R. Then the construction $R \mapsto \mathrm{CAlg}^{\mathrm{fp}}_R$ commutes with filtered colimits.*

Corollary 4.4.1.4. *For every connective $\mathbb{E}_\infty$-ring R, let CAlg^{n-fp}_R denote the full subcategory of CAlg_R spanned by those connective $\mathbb{E}_\infty$-algebras over R which are n-truncated and of finite generation to order $(n+1)$. Then the construction $R \mapsto \mathrm{CAlg}^{n-fp}_R$ determines a functor $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{C}\mathrm{at}_\infty$ which commutes with filtered colimits.*

Proof. Using Remark 4.1.1.9, we can identify CAlg^{n-fp}_R with the full subcategory of $\tau_{\leqslant n} \mathrm{CAlg}^{\mathrm{cn}}_R \simeq \tau_{\leqslant n} \mathrm{CAlg}^{\mathrm{cn}}_{\tau_{\leqslant n} R}$ spanned by the compact objects. The desired result now follows by applying Proposition 4.4.1.2 to the ∞-category $\tau_{\leqslant n} \mathrm{CAlg}^{\mathrm{cn}}$ of n-truncated connective $\mathbb{E}_\infty$-rings (together with the observation that the truncation functor $\tau_{\leqslant n} : \mathrm{CAlg}^{\mathrm{cn}} \to \tau_{\leqslant n} \mathrm{CAlg}^{\mathrm{cn}}$ commutes with filtered colimits). □

We will deduce Proposition 4.4.1.2 from the following:

Proposition 4.4.1.5. *Let $\mathcal{C}$ be a presentable ∞-category, and let $\chi : \mathcal{C} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ classify the coCartesian fibration $\mathrm{Fun}(\Delta^1, \mathcal{C}) \to \mathrm{Fun}(\{0\}, \mathcal{C}) \simeq \mathcal{C}$ (so that $\chi(C) \simeq \mathcal{C}_{C/}$). Then χ preserves K-indexed colimits, for every small weakly contractible simplicial set K.*

Proof. The forgetful functor $q : \mathrm{Fun}(\Delta^1, \mathcal{C}) \to \mathrm{Fun}(\{0\}, \mathcal{C}) \simeq \mathcal{C}$ as a Cartesian fibration which is classified by a map $\chi' : \mathcal{C}^{\mathrm{op}} \to \mathcal{P}\mathrm{r}^{\mathrm{R}}$. Let K be a small simplicial set which is weakly contractible. To show that χ preserves K-indexed colimits, it will suffice to show that χ' preserves K^{op}-indexed limits (Corollary HTT.5.5.3.4). For this purpose, it does not matter whether we regard χ' as a functor taking values in $\mathcal{P}\mathrm{r}^{\mathrm{R}}$ or in the larger ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty$ (Theorem HTT.5.5.3.18). Without loss of generality, we may suppose that K is an ∞-category. Choose a colimit diagram $p : K^{\triangleright} \to \mathcal{C}$. We will show that the induced map

$$\mathrm{Fun}(\Delta^1, \mathcal{C}) \times_{\mathcal{C}} K^{\triangleright} \to K^{\triangleright}$$

satisfies the dual version of the hypotheses of Proposition HA.5.2.2.36:

(*a*) Let v denote the cone point of $K^{\triangleright}$. We must show that the collection of forgetful functors $\mathcal{C}_{q(v)/} \to \mathcal{C}_{q(k)/}$ is jointly conservative (here k varies over the collection of all vertices of k). This is clear, since K is nonempty and each of these functors is individually conservative.

(*b*) Let $\overline{p}_0 : K \to \mathrm{Fun}(\Delta^1, \mathcal{C})$ be a functor which carries each edge of K to a q-Cartesian morphism in $\mathrm{Fun}(\Delta^1, \mathcal{C})$ and satisfies $q \circ \overline{p}_0 = p|_K$. Since q is a presentable fibration, we can extend $\overline{p}_0$ to a q-colimit diagram $\overline{p}$ with $q \circ \overline{p} = p$. We claim that $\overline{p}$ carries every morphism in $K^{\triangleleft}$ to a q-Cartesian morphism in $\mathrm{Fun}(\Delta^1, \mathcal{C})$. To prove this, let us identify $\overline{p}$ with a map $P : K^{\triangleright} \times \Delta^1 \to \mathcal{C}$, so that $p = P|_{K^{\triangleright} \times \{0\}}$. Let L denote the full subcategory of $K^{\triangleright} \times \Delta^1$ obtained by removing the final vertex. Since p is a colimit diagram, $P|_L$ is a left Kan extension of $P|_{K \times \Delta^1}$. Because $\overline{p}$ is a q-colimit diagram, P is a colimit diagram. Using Lemma HTT.4.3.2.7, we conclude that P exhibits $P(v, 1)$ as a colimit of $P|_{K \times \Delta^1}$. Because the inclusion $K \times \{1\} \hookrightarrow K \times \Delta^1$ is left cofinal, this implies that $P|_{K^{\triangleright} \times \{1\}}$ is a colimit diagram. Since $\overline{p}$ carries each morphism in K to a q-Cartesian morphism in $\mathrm{Fun}(\Delta^1, \mathcal{C})$, P carries each morphism in $K \times \{1\}$ to an equivalence in $\mathcal{C}$. Applying Corollary HTT.4.4.4.10 (and the weak contractibility of K), we conclude that P carries each morphism in $K^{\triangleright} \times \{1\}$ to an equivalence in $\mathcal{C}$, so that $\overline{p}$ carries each morphism in $K^{\triangleleft}$ to a q-Cartesian morphism in $\mathcal{C}$.

□

Proof of Proposition 4.4.1.2. First note that if $f_0 : C_0 \to D_0$ is a morphism between compact objects of $\mathcal{C}$, then f_0 is compact when viewed as an object of $\mathcal{C}_{C_0/}$, since the functor corepresented by f is given by

$$E \mapsto \mathrm{fib}(\mathrm{Map}_{\mathcal{C}}(D_0, E) \to \mathrm{Map}_{\mathcal{C}}(C_0, E)).$$

If $g : C_0 \to C$ is any map between objects of $\mathcal{C}$, then composition with g determines a functor $\mathcal{C}_{C/} \to \mathcal{C}_{C_0/}$ which preserves filtered colimits (Proposition HTT.4.4.2.9), so that the construction $D_0 \mapsto C \amalg_{C_0} D_0$ preserves compact objects (Proposition HTT.5.5.7.2). This proves the "if" direction of (2).

We now prove (1). Fix an object $C \in \mathcal{C}$, and let $\mathcal{E} \subseteq \mathcal{C}_{C/}$ denote the full subcategory spanned by the compact objects. Then the inclusion $\mathcal{E} \hookrightarrow \mathcal{C}_{C/}$ extends to a fully faithful embedding $F : \mathrm{Ind}(\mathcal{E}) \hookrightarrow \mathcal{C}_{C/}$ which preserves small colimits (Proposition HTT.5.5.1.9). To prove (1), it will suffice to show that F is an equivalence of ∞-categories. By virtue of Corollary HTT.5.5.2.9 , the functor F admits a right adjoint G. We are therefore reduced to proving that G is conservative. Let $u : D \to E$ be a morphism in $\mathcal{C}_{C/}$ such that $G(u)$ is an equivalence. Then u inducs a homotopy equivalence

$$\mathrm{Map}_{\mathcal{C}_{C/}}(X, D) \to \mathrm{Map}_{\mathcal{C}_{C/}}(X, E)$$

for every compact object $X \in \mathcal{C}_{C/}$. In particular, if X_0 is a compact object of $\mathcal{C}$, then we can take X to be the coproduct $C \amalg X_0$ to deduce that u induces a homotopy equivalence $\mathrm{Map}_{\mathcal{C}}(X_0, D) \to \mathrm{Map}_{\mathcal{C}}(X_0, E)$. Since $\mathcal{C}$ is compactly generated, this proves that u is an equivalence.

Assertion (3) follows from (1), Proposition 4.4.1.5, and Lemma HA.7.3.5.11 . We complete the proof by verifying the "only if" direction of (2). Let $f : C \to D$ be a morphism in $\mathcal{C}$ which is compact as an object of $\mathcal{C}_{C/}$; we wish to prove the existence of a pushout diagram

$$\begin{array}{ccc} C_0 & \xrightarrow{f_0} & D_0 \\ \downarrow & & \downarrow \\ C & \xrightarrow{f} & D \end{array}$$

where C_0 and D_0 are compact. Since $\mathcal{C}$ is compactly generated, we can write C as the colimit of a filtered diagram $\{C_\alpha\}$ of compact objects of $\mathcal{C}$. Using (3), we see that there exists an index α and a pushout diagram

$$\begin{array}{ccc} C_\alpha & \xrightarrow{f_\alpha} & D_\alpha \\ \downarrow & & \downarrow \\ C & \xrightarrow{f} & D \end{array}$$

where f_α is compact when viewed as an object of $\mathcal{C}_{C_\alpha/}$. We will complete the proof by showing that D_α is a compact object of $\mathcal{C}$. To prove this, suppose we are given a filtered diagram $\{E_\beta\}$ in $\mathcal{C}$, having colimit E. We wish to show that the upper horizontal map in the diagram

$$\begin{array}{ccc} \varinjlim \mathrm{Map}_{\mathcal{C}}(D_\alpha, E_\beta) & \longrightarrow & \mathrm{Map}_{\mathcal{C}}(D_\alpha, E) \\ \downarrow & & \downarrow \\ \varinjlim_{\mathcal{C}}(C_\alpha, E_\beta) & \longrightarrow & \mathrm{Map}_{\mathcal{C}}(C_\alpha, E) \end{array}$$

is a homotopy equivalence. Since C_α is a compact object of $\mathcal{C}$, the lower horizontal map is a homotopy equivalence. We are therefore reduced to proving that the upper horizontal map induces a homotopy equivalence after passing to the homotopy fiber over any point of the direct limit $\varinjlim_{\mathcal{C}}(C_\alpha, E_\beta)$, which follows from our assumption that f_α is compact as an object of $\mathcal{C}_{C_\alpha/}$. $\square$

4.4.2 Approximation in the General Case

We now formulate an answer to Question 4.4.0.2 in the case where X is not assumed to be affine.

Construction 4.4.2.1. Let R be a connective $\mathbb{E}_\infty$-ring. We let $\mathrm{DM}_n^{\mathrm{fp}}(R)$ denote the full subcategory of $\mathrm{SpDM}_{/\mathrm{Sp\acute{e}t}\, R}$ spanned by those maps $\mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ which exhibit X as finitely n-presented over R. We will regard the construction $R \mapsto \mathrm{DM}_n^{\mathrm{fp}}(R)$ as a functor from $\mathrm{CAlg}^{\mathrm{cn}}$ to the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty$. More precisely, we let $\mathrm{DM}_n^{\mathrm{fp}}$ be a functor which classifies the Cartesian fibration $p : \mathcal{C} \to (\mathrm{CAlg}^{\mathrm{cn}})^{\mathrm{op}}$, where $\mathcal{C}$ denotes the full subcategory of

$$\mathrm{Fun}(\Delta^1, \mathrm{SpDM}) \times_{\mathrm{Fun}(\{1\}, \mathrm{SpDM})} (\mathrm{CAlg}^{\mathrm{cn}})^{\mathrm{op}}$$

spanned by those morphisms $\mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ where R is a connective $\mathbb{E}_\infty$-ring and X is a spectral Deligne-Mumford stack which is finitely n-presented over $\mathrm{Sp\acute{e}t}\, R$ (it follows from Proposition 4.2.5.4 that p is indeed a Cartesian fibration). To every morphism $f : A \to B$ of connective $\mathbb{E}_\infty$-rings, the functor $\mathrm{DM}_n^{\mathrm{fp}}$ associates the map $\mathrm{DM}_n^{\mathrm{fp}}(A) \to \mathrm{DM}_n^{\mathrm{fp}}(B)$ given on objects by the formula $\mathsf{X} \mapsto \tau_{\leqslant n}(\mathrm{Sp\acute{e}t}\, B \times_{\mathrm{Sp\acute{e}t}\, A} \mathsf{X})$.

Our main result can be stated as follows:

Theorem 4.4.2.2. *Let $n \geqslant 0$ be an integer, and let $\mathrm{DM}_n^{\mathrm{fp}} : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ be as in Construction 4.4.2.1. Then:*

(1) *For every connective $\mathbb{E}_\infty$-ring R, the ∞-category $\mathrm{DM}_n^{\mathrm{fp}}(R)$ is essentially small.*

(2) *The functor $\mathrm{DM}_n^{\mathrm{fp}}$ commutes with small filtered colimits.*

Before embarking on the proof of Theorem 4.4.2.2, let us describe one of its consequences. Fix a connective $\mathbb{E}_\infty$-ring R and finitely n-presented morphism $\mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$. For any n-truncated R-algebra A, we have a canonical homotopy equivalence

$$\begin{aligned} \mathrm{Map}_{\mathrm{DM}_n^{\mathrm{fp}}(A)}(\mathrm{Sp\acute{e}t}\, A, \tau_{\leqslant n}(\mathrm{Sp\acute{e}t}\, A \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X})) &\simeq \mathrm{Map}_{\mathrm{SpDM}_{/\mathrm{Sp\acute{e}t}\, A}}(\mathrm{Sp\acute{e}t}\, A, \mathrm{Sp\acute{e}t}\, A \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X}) \\ &\simeq \mathrm{Map}_{\mathrm{SpDM}_{/\mathrm{Sp\acute{e}t}\, R}}(\mathrm{Sp\acute{e}t}\, A, \mathsf{X}). \end{aligned}$$

The domain and codomain of this equivalence depend functorially on A, and Theorem 4.4.2.2 implies that the domain commutes with filtered colimits (as a functor of A). We therefore deduce the following consequence:

Proposition 4.4.2.3. *Let R be a connective $\mathbb{E}_\infty$-ring, let $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ be a finitely n-presented morphism of spectral Deligne-Mumford stacks, and let $h_{\mathsf{X}} : \tau_{\leqslant n} \mathrm{CAlg}_R^{\mathrm{cn}} \to \mathcal{S}$ be the functor represented by X, given by the formula $h_{\mathsf{X}}(A) = \mathrm{Map}_{\mathrm{SpDM}_{/\mathrm{Sp\acute{e}t}\, R}}(\mathrm{Sp\acute{e}t}\, A, \mathsf{X})$. Then the functor h_{X} commutes with filtered colimits.*

In what follows, we will show that the converse is true: that is, Theorem 4.4.2.2 can be deduced from Proposition 4.4.2.3. We will give an independent proof of Proposition 4.4.2.3 in §17.4. In fact, we will prove a stronger statement: the conclusion of Proposition 4.4.2.3 is valid provided that f is locally of finite generation to order $(n+1)$ and X is a Deligne-Mumford m-stack for $m \gg 0$ (in other words, we need not assume that X is n-truncated or ∞-quasi-compact); see Proposition 17.4.3.1.

Remark 4.4.2.4. In the special case where X is affine, Proposition 4.4.2.3 follows immediately from Remarks 4.1.1.9 and 4.2.1.3.

4.4.3 Deduction of Theorem 4.4.2.2 from Proposition 4.4.2.3

Let us say that a map $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford is a *quasi-monomorphism* if, for every commutative ring A, the induced map

$$\mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, A, \mathsf{X}) \to \mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, A, \mathsf{Y})$$

is (-1)-truncated. For $m \geqslant 0$ and any connective $\mathbb{E}_\infty$-ring R, let $\mathrm{DM}^{\mathrm{fp}}_{n,m}(R)$ denote the full subcategory of $\mathrm{DM}^{\mathrm{fp}}_n(R)$ spanned by those maps $f : \mathsf{X} \to \mathrm{Spec}\, R$ which are finitely n-presented, where X is a spectral Deligne-Mumford m-stack. Let $\mathrm{DM}^{\mathrm{fp}}_{n,-1}(R) \subseteq \mathrm{DM}^{\mathrm{fp}}_n(R)$ be the full subcategory spanned by those maps $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ which fit into a commutative diagram of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathsf{X} & \xrightarrow{u} & \mathrm{Sp\acute{e}t}\, A \\ & {\scriptstyle f}\searrow \quad \swarrow & \\ & \mathrm{Sp\acute{e}t}\, R & \end{array}$$

where u is a quasi-monomorphism and A is finitely n-presented over R. Let $\mathrm{DM}^{\mathrm{fp}}_{n,-2}(R) \subseteq \mathrm{DM}^{\mathrm{fp}}_n(R)$ denote the full subcategory spanned by those maps $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ where X is affine. Note that if $R \to R'$ is a map of connective $\mathbb{E}_\infty$-rings, then the associated base-change functor $\mathrm{DM}^{\mathrm{fp}}_n(R) \to \mathrm{DM}^{\mathrm{fp}}_n(R')$ carries $\mathrm{DM}^{\mathrm{fp}}_{n,m}(R)$ into $\mathrm{DM}^{\mathrm{fp}}_{n,m}(R')$, for each $m \geqslant -2$. Consequently, we have functors $\mathrm{DM}^{\mathrm{fp}}_{n,m} : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ for each $m \geqslant -2$, and $\mathrm{DM}^{\mathrm{fp}}_n \simeq \varinjlim_m \mathrm{DM}^{\mathrm{fp}}_{n,m}$. Theorem 4.4.2.2 is therefore an immediate consequence of the following:

Proposition 4.4.3.1. *Let $n \geqslant 0$ and $m \geqslant -2$ be integers. Then:*

(1) *For every connective $\mathbb{E}_\infty$-ring R, the ∞-category $\mathrm{DM}^{\mathrm{fp}}_{n,m}(R)$ is essentially small.*

(2) *The functor $R \mapsto \mathrm{DM}^{\mathrm{fp}}_{n,m}(R)$ commutes with filtered colimits.*

Proof. We proceed by induction on m. In the case $m = -2$, the desired result follows from Corollary 4.4.1.4. Suppose therefore that $m > -2$, and let $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ be an object of

$\mathrm{DM}^{\mathrm{fp}}_{n,m}(R)$ for some connective $\mathbb{E}_\infty$-ring R. Then X is quasi-compact, so we can choose an étale surjection $u : \mathsf{X}_0 \to \mathsf{X}$ where X_0 is affine. Let $\mathsf{X}_\bullet$ denote the Čech nerve of u in the ∞-category of n-truncated spectral Deligne-Mumford stacks. We claim that each X_i belongs to $\mathrm{DM}^{\mathrm{fp}}_{n,m-1}(R)$. For $m > 0$ this is clear. When $m = 0$, we let Y denote n-truncation of the i-fold fiber power of X_0 over $\mathrm{Spét}\, R$. Then Y is affine, and the canonical map $\mathsf{X}_i \to \mathsf{Y}$ is a quasi-monomorphism. If $m = -1$, we can choose a commutative diagram

$$\begin{array}{ccc} \mathsf{X} & \xrightarrow{v} & \mathrm{Spét}\, A \\ & {\scriptstyle f}\searrow \quad \swarrow & \\ & \mathrm{Spét}\, R & \end{array}$$

where v is a quasi-monomorphism and A is finitely n-presented over R. Let $\mathsf{X}'_\bullet$ be the Čech nerve of the composite map $(v \circ u) : \mathsf{X}_0 \to \mathrm{Spét}\, A$. Since v is a quasi-monomorphism, the induced map $\mathsf{X}_\bullet \to \mathsf{X}'_\bullet$ induces an equivalence of 0-truncations. Since each X'_i is affine, each X_i is affine by Theorem 1.4.8.1.

We now prove (1). Fix a connective $\mathbb{E}_\infty$-ring R. Since $\mathrm{DM}^{\mathrm{fp}}_{n,m-1}(R)$ is essentially small by the inductive hypothesis, the ∞-category of simplicial objects of $\mathrm{DM}^{\mathrm{fp}}_{n,m-1}(R)$ is also essentially small. The above argument shows that every object of $\mathrm{DM}^{\mathrm{fp}}_{n,m}(R)$ can be obtained as the geometric realization (in $\mathrm{SpDM}_{/\,\mathrm{Spét}\, R}$) of a simplicial object $\mathsf{X}_\bullet$ of $\mathrm{DM}^{\mathrm{fp}}_{n,m-1}(R)$, so that $\mathrm{DM}^{\mathrm{fp}}_{n,m}(R)$ is essentially small.

We now prove (2). Choose a filtered diagram of connective $\mathbb{E}_\infty$-rings $\{R_\alpha\}$ having colimit R, and consider the functor $\theta : \varinjlim_\alpha \mathrm{DM}^{\mathrm{fp}}_{n,m}(R_\alpha) \to \mathrm{DM}^{\mathrm{fp}}_{n,m}(R)$. We first show that θ is fully faithful. We may assume without loss of generality that the diagram $\{R_\alpha\}$ is indexed by the nerve of a filtered partially ordered set P (Proposition HTT.5.3.1.18). Fix objects $\mathsf{X}_\alpha, \mathsf{Y}_\alpha \in \mathrm{DM}^{\mathrm{fp}}_{n,m}(R_\alpha)$. For $\beta \geqslant \alpha$, let X_β and Y_β denote the images of X_α and Y_α in $\mathrm{DM}^{\mathrm{fp}}_{n,m}(R_\beta)$, and let X and Y denote the images of X_α and Y_α in $\mathrm{DM}^{\mathrm{fp}}_{n,m}(R)$. We wish to show that the canonical map

$$\rho : \varinjlim_{\beta \geqslant \alpha} \mathrm{Map}_{\mathrm{SpDM}_{/\,\mathrm{Spét}\, R_\beta}}(\mathsf{X}_\beta, \mathsf{Y}_\beta) \to \mathrm{Map}_{\mathrm{SpDM}_{/\,\mathrm{Spét}\, R}}(\mathsf{X}, \mathsf{Y})$$

is a homotopy equivalence. Unwinding the definitions, we see that ρ can be identified with the canonical map

$$\varinjlim_{\beta \geqslant \alpha} \mathrm{Map}_{\mathrm{SpDM}_{/\,\mathrm{Spét}\, R_\alpha}}(\mathsf{X}_\beta, \mathsf{Y}_\alpha) \to \mathrm{Map}_{\mathrm{SpDM}_{/\,\mathrm{Spét}\, R_\alpha}}(\mathsf{X}, \mathsf{Y}_\alpha)$$

In what follows, let us regard the object Y_α as fixed; we wish to prove the following:

$(*)$ For every object $\mathsf{X}_\alpha \in \mathrm{DM}^{\mathrm{fp}}_{n,m'}(R_\alpha)$, the canonical map

$$\varinjlim_{\beta \geqslant \alpha} \mathrm{Map}_{\mathrm{SpDM}_{/\,\mathrm{Spét}\, R_\alpha}}(\mathsf{X}_\beta, \mathsf{Y}_\alpha) \to \mathrm{Map}_{\mathrm{SpDM}_{/\,\mathrm{Spét}\, R_\alpha}}(\mathsf{X}, \mathsf{Y}_\alpha)$$

is a homotopy equivalence.

The proof of $(*)$ proceeds by induction on m'. Suppose first that $m' = -2$, so that $\mathsf{X}_\alpha \simeq \operatorname{Sp\acute{e}t} A_\alpha$ for some connective $\mathbb{E}_\infty$-algebra A_α over R_α. Unwinding the definitions, we see that $\mathsf{X}_\beta \simeq \tau_{\leqslant n}(A_\alpha \otimes_{R_\alpha} R_\beta)$ and that $\mathsf{X} \simeq \tau_{\leqslant n}(A_\alpha \otimes_{R_\alpha} R)$. Since $R \simeq \varinjlim R_\beta$, we conclude that the canonical map

$$\varinjlim_{\beta \geqslant \alpha} \tau_{\leqslant n}(A_\alpha \otimes_{R_\alpha} R_\beta) \to \tau_{\leqslant n}(A_\alpha \otimes_{R_\alpha} R)$$

is an equivalence. Assertion $(*)$ now follows from Proposition 4.4.2.3.

Now suppose that $m' > -2$. Choose an étale surjection $u : \mathsf{X}_{\alpha,0} \to \mathsf{X}_\alpha$ where $\mathsf{X}_{\alpha,0}$ is affine, and let $\mathsf{X}_{\alpha,\bullet}$ be the Čech nerve of u. Define $\mathsf{X}_{\beta,\bullet}$ and $\mathsf{X}_\bullet$ as above. We wish to show that the canonical map

$$\phi : \varinjlim_{\beta \geqslant \alpha} \varprojlim_{[p] \in \mathbf{\Delta}} \operatorname{Map}_{\mathrm{SpDM}_{/ \operatorname{Sp\acute{e}t} R_\alpha}}(\mathsf{X}_{\beta,p}, \mathsf{Y}_\alpha) \to \varprojlim_{[p] \in \mathbf{\Delta}} \operatorname{Map}_{\mathrm{SpDM}_{/ \operatorname{Sp\acute{e}t} R}}(\mathsf{X}_p, \mathsf{Y}_\alpha)$$

is a homotopy equivalence. Choose an integer $k \geqslant m, n$, so all of the mapping spaces above are k-truncated (Lemma 1.6.8.8). Arguing as in the proof of Lemma HA.1.3.3.10 , we can identify ϕ with the map

$$\varinjlim_{\beta \geqslant \alpha} \varprojlim_{[p] \in \mathbf{\Delta}_{s, \leqslant k+1}} \operatorname{Map}_{\mathrm{SpDM}_{/ \operatorname{Sp\acute{e}t} R}}(\mathsf{X}_{\beta,p}, \mathsf{Y}) \to \varprojlim_{[p] \in \mathbf{\Delta}_{s, \leqslant k+1}} \operatorname{Map}_{\mathrm{SpDM}_{/ \operatorname{Sp\acute{e}t} R}}(\mathsf{X}_p, \mathsf{Y}).$$

Since filtered colimits in $\mathcal{S}$ commute with finite limits, ϕ is a finite limit of morphisms

$$\phi_p : \varinjlim_{\beta \geqslant \alpha} \operatorname{Map}_{\mathrm{SpDM}_{/ \operatorname{Sp\acute{e}t} R}}(\mathsf{X}_{\beta,p}, \mathsf{Y}) \to \operatorname{Map}_{\mathrm{SpDM}_{/ \operatorname{Sp\acute{e}t} R}}(\mathsf{X}_p, \mathsf{Y}).$$

Since $\mathsf{X}_{\alpha,p} \in \mathrm{DM}^{\mathrm{fp}}_{n,m-1}(R_\alpha)$, the map ϕ_p is an equivalence by the inductive hypothesis. This completes the proof that θ is fully faithful.

It remains to prove that θ is essentially surjective. Fix an object $\mathsf{X} \in \mathrm{DM}^{\mathrm{fp}}_{n,m}(R)$ and choose an étale surjection $u : \mathsf{X}_0 \to \mathsf{X}$, where X_0 is affine. Let $\mathsf{X}_\bullet$ be the Čech nerve of u. Choose $k \geqslant m, n$, so that the ∞-category $\mathrm{DM}^{\mathrm{fp}}_{n,m-1}(R)$ is equivalent to a $(k+1)$-category (Lemma 1.6.8.8). It follows that $\mathsf{X}_\bullet$ is a right Kan extension of $\mathsf{X}^t_\bullet = \mathsf{X}_\bullet |_{\mathbf{\Delta}^{\mathrm{op}}_{\leqslant k+3}}$ (Proposition A.8.2.6), which is an $(k+2)$-skeletal category object of $\mathrm{DM}^{\mathrm{fp}}_{n,m-1}(R)$ (see Definition A.8.2.2). Since $\mathrm{DM}^{\mathrm{fp}}_{n,m-1}(R) \simeq \varinjlim_\alpha \mathrm{DM}^{\mathrm{fp}}_{n,m-1}(R_\alpha)$ by the inductive hypothesis and the simplicial set $\mathrm{N}(\mathbf{\Delta}^{\mathrm{op}}_{\leqslant k+3})$ has a finite $(k+2)$-skeleton, $\mathsf{X}^t_\bullet$ is the image of a $(k+3)$-skeletal simplicial object $\overline{\mathsf{X}}^t_\bullet$ of $\mathrm{DM}^{\mathrm{fp}}_{n,m-1}(R_\alpha)$ for some index α. Enlarging α if necessary, we may assume that $\overline{\mathsf{X}}^t_\bullet$ is a $(k+3)$-skeletal category object of $\mathrm{DM}^{\mathrm{fp}}_{n,m-1}(R_\alpha)$. Let $\overline{\mathsf{X}}_\bullet : \mathbf{\Delta}^{\mathrm{op}} \to \mathrm{DM}^{\mathrm{fp}}_{n,m-1}$ be a right Kan extension of $\overline{\mathsf{X}}^t_\bullet$. Using Propositions 4.4.2.3 and A.8.2.7, we deduce that $\overline{\mathsf{X}}_\bullet$ is a category object of $\mathrm{DM}^{\mathrm{fp}}_{n,m-1}$. Enlarging α if necessary, we may assume that $\overline{\mathsf{X}}_\bullet$ is a groupoid object of $\mathrm{DM}^{\mathrm{fp}}_{n,m-1}(R_\alpha)$, and that the projection maps $\overline{\mathsf{X}}_1 \to \overline{\mathsf{X}}_0$ are étale. Then $\overline{\mathsf{X}}_\bullet$ has a geometric realization $\overline{\mathsf{X}}$ in $\mathrm{SpDM}_{/\operatorname{Sp\acute{e}t} R_\alpha}$. We will prove that, after enlarging α if necessary, we have $\overline{\mathsf{X}} \in \mathrm{DM}^{\mathrm{fp}}_{n,m}(R_\alpha)$. It will then follow that $\overline{\mathsf{X}}$ is a preimage of $\mathsf{X} \in \mathrm{DM}^{\mathrm{fp}}_{n,m}(R)$ and the proof will be complete.

Since we have an étale surjection $\overline{\mathsf{X}}_0 \to \overline{\mathsf{X}}$, it is clear that $\overline{\mathsf{X}}$ is locally finitely n-presented over R_α. We next prove that the underlying ∞-topos $\mathcal{X}$ of $\overline{\mathsf{X}}$ is coherent. The étale map $\overline{\mathsf{X}}_0 \to \overline{\mathsf{X}}$ corresponds to an object $U \in \mathcal{X}$. Since $\overline{\mathsf{X}}_0$ and $\overline{\mathsf{X}}_1$ belong to $\mathrm{DM}^{\mathrm{fp}}_n(R_\alpha)$, U and $U \times U$ are coherent objects of $\mathcal{X}$. Example A.2.1.2 shows that the projection map $U \times U \to U$ is relatively i-coherent for every integer i. Let $\mathbf{1}$ denote the final object of $\mathcal{X}$. Since $p : U \to \mathbf{1}$ is an effective epimorphism, we deduce that p is relatively i-coherent for every integer i (Corollary A.2.1.5). Using the i-coherence of U, we deduce that $\mathcal{X}$ is i-coherent. Allowing i to vary, we deduce that $\mathcal{X}$ is coherent.

Let us now treat the case $m = -1$. Choose a commutative diagram

$$\begin{array}{ccc} \mathsf{X} & \xrightarrow{u} & \operatorname{Sp\acute{e}t} A \\ & {\scriptstyle f}\searrow \quad \swarrow & \\ & \operatorname{Sp\acute{e}t} R & \end{array}$$

where u is a quasi-monomorphism and A is finitely n-presented over R. Applying Corollary 4.4.1.4, we may assume that $A = \tau_{\leqslant n}(\overline{A} \otimes_{R_\alpha} R)$ for some n-truncated $\overline{A}$ which is finitely n-presented over R_α. It follows from $(*)$ that we may assume (after enlarging α if necessary) that u is the image of a map $\overline{u} : \overline{\mathsf{X}} \to \operatorname{Sp\acute{e}t} \overline{A}$ in $\mathrm{SpDM}_{/\operatorname{Sp\acute{e}t} R_\alpha}$. To complete the proof, it will suffice to show that $\overline{u}$ is a quasi-monomorphism. That is, we must show that the diagonal map $\overline{\mathsf{X}} \to \overline{\mathsf{X}} \times_{\operatorname{Sp\acute{e}t} \overline{A}} \overline{\mathsf{X}}$ induces an equivalence of 0-truncations. This assertion is local on $\overline{\mathsf{X}}$: it therefore suffices to show that the map $\phi : \overline{\mathsf{X}}_1 \simeq \overline{\mathsf{X}}_0 \times_{\overline{\mathsf{X}}} \overline{\mathsf{X}}_0 \to \overline{\mathsf{X}}_0 \times_{\operatorname{Spec} \overline{A}} \overline{\mathsf{X}}_0$. Note that the domain and codomain of ϕ are affine and that the image of ϕ under the natural map $\mathrm{DM}^{\mathrm{fp}}_{0,-2}(R_\alpha) \to \mathrm{DM}^{\mathrm{fp}}_{0,-2}(R)$ is an equivalence (by virtue of our assumption that u is a quasi-monomorphism). Applying Corollary 4.4.1.4 again, we deduce that there exists $\beta \geqslant \alpha$ such that the image of ϕ in $\mathrm{DM}^{\mathrm{fp}}_{0,-2}(R_\beta)$ is an equivalence. Replacing α by β, we deduce that $\overline{u}$ is a quasi-monomorphism as desired.

Assume now that $m \geqslant 0$. To complete the proof that $\overline{\mathsf{X}} \in \mathrm{DM}^{\mathrm{fp}}_{n,m}$, we must show that for every discrete commutative ring A, the mapping space $\mathrm{Map}_{\mathrm{SpDM}}(\operatorname{Sp\acute{e}t} A, \overline{\mathsf{X}})$ is m-truncated. For every étale map $A \to A'$, set

$$\mathscr{F}(A') = \mathrm{Map}_{\mathrm{SpDM}}(\operatorname{Sp\acute{e}t} A', \overline{\mathsf{X}}) \qquad \mathscr{F}_\bullet(A') = \mathrm{Map}_{\mathrm{SpDM}}(\operatorname{Sp\acute{e}t} A', \overline{\mathsf{X}}_\bullet).$$

Then $\mathscr{F}$ is a sheaf for the étale topology; we will prove that it is m-truncated. The projection $\overline{\mathsf{X}}_0 \to \overline{\mathsf{X}}$ induces an effective epimorphism of étale sheaves $\mathscr{F}_0 \to \mathscr{F}$. Since X_0 is affine, we may assume (enlarging α if necessary) that $\overline{\mathsf{X}}_0$ is affine, so that $\mathscr{F}_0$ is 0-truncated. If $m > 0$, it suffices to prove that $\mathscr{F}_1 = \mathscr{F}_0 \times_{\mathscr{F}} \mathscr{F}_0$ is $(m-1)$-truncated, which follows because $\overline{\mathsf{X}}_1 \in \mathrm{DM}^{\mathrm{fp}}_{n,m-1}$. If $m = 0$, we must work a bit harder: to show that $\mathscr{F}$ is discrete, we must show that $\mathscr{F}_1$ is an equivalence relation on $\mathscr{F}_0$ (note that each $\mathscr{F}_i$ is a *discrete* étale sheaf on A when $m \leqslant 1$). For this, it suffices to show that the diagonal map $v : \mathscr{F}_1 \to \mathscr{F}_1 \times_{\mathscr{F}_0 \times \mathscr{F}_0} \mathscr{F}_1$ is an equivalence. Consider the diagonal map $\overline{\delta} : \overline{\mathsf{X}}_1 \to \overline{\mathsf{X}}_1 \times_{\overline{\mathsf{X}}_0 \times \overline{\mathsf{X}}_0} \overline{\mathsf{X}}_1$. Since X is a spectral algebraic space, the map $\delta : \mathsf{X}_1 \to \mathsf{X}_1 \times_{\mathsf{X}_0 \times \mathsf{X}_0} \mathsf{X}_1$ induces an equivalence of 0-truncations. Our earlier argument shows that $\mathrm{DM}^{\mathrm{fp}}_{0,-1}(R) \simeq \varinjlim_{\beta \geqslant \alpha} \mathrm{DM}^{\mathrm{fp}}_{0,-1}(R_\beta)$, so we may assume (after enlarging α if necessary) that $\overline{\delta}$ also induces an equivalence of 0-truncations. It follows that v is an equivalence, as desired. □

4.4.4 Approximation without Truncation

We conclude this section by describing a useful variant of Theorem 4.4.2.2.

Proposition 4.4.4.1. *Let R be a connective $\mathbb{E}_\infty$-ring, let $f : \mathsf{X} \to \operatorname{Sp\acute{e}t} R$ be a morphism of spectral algebraic spaces, and let $n \geqslant 0$ be an integer. The following conditions are equivalent:*

(a) *The truncation $\tau_{\leqslant n} \mathsf{X}$ is finitely n-presented over R.*

(b) *There exists a commutative diagram of spectral algebraic spaces σ :*

$$\begin{array}{ccc} \mathsf{X} & \longrightarrow & \mathsf{X}_0 \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f_0} \\ \operatorname{Sp\acute{e}t} R & \longrightarrow & \operatorname{Sp\acute{e}t} R_0 \end{array}$$

where R_0 is finitely presented over the sphere spectrum S, the morphism f_0 is almost of finite presentation, and σ induces an equivalence $\tau_{\leqslant n} \mathsf{X} \to \tau_{\leqslant n}(\mathsf{X}_0 \times_{\operatorname{Sp\acute{e}t} R_0} \operatorname{Sp\acute{e}t} R)$.

Proof. The implication $(b) \Rightarrow (a)$ is obvious. For the converse, assume that (a) is satisfied. Write R as a filtered colimit $\varinjlim R_\alpha$, where each R_α is a connective $\mathbb{E}_\infty$-ring which is of finite presentation over the sphere spectrum S. Using Theorem 4.4.2.2, we deduce that there exists an index α and a diagram σ':

$$\begin{array}{ccc} \tau_{\leqslant n} \mathsf{X} & \xrightarrow{g} & \mathsf{X}_\alpha \\ \downarrow & & \downarrow{\scriptstyle f_\alpha} \\ \operatorname{Sp\acute{e}t} R & \longrightarrow & \operatorname{Sp\acute{e}t} R_\alpha \end{array}$$

with the following properties:

(a) The morphism f_α exhibits X_α as finitely n-presented over $\operatorname{Sp\acute{e}t} R_\alpha$.

(b) The diagram σ' induces an equivalence $\tau_{\leqslant n} \mathsf{X} \to \tau_{\leqslant n}(\mathsf{X}_\alpha \times_{\operatorname{Sp\acute{e}t} R_0} \operatorname{Sp\acute{e}t} R)$.

It follows from (b) and Remark 2.4.4.2 that the morphism g is affine. Set $R_0 = R_\alpha$. Since R_0 is finitely presented over the sphere spectrum S, it is Noetherian. Consequently, the morphism f_α is almost of finite presentation and X_α is locally Noetherian (see Proposition 4.2.4.1). Applying Proposition 17.1.6.1, we can extend σ' to a commutative diagram $\overline{\sigma}'$:

$$\begin{array}{ccc} \tau_{\leqslant n} \mathsf{X} & \longrightarrow & \mathsf{X}_\alpha \\ \downarrow & & \downarrow f'_\alpha \\ \mathsf{X} & \longrightarrow & \mathsf{X}_0 \\ \downarrow f & & \downarrow f''_\alpha \\ \operatorname{Sp\acute{e}t} R & \longrightarrow & \operatorname{Sp\acute{e}t} R_0 \end{array}$$

where X_0 is locally Noetherian and the morphism f'_α induces an equivalence $\tau_{\leqslant n} \mathsf{X}_\alpha \simeq \tau_{\leqslant n} \mathsf{X}_0$. Since f_α is of finite type, it follows that f''_α is of finite type. Using Remark 4.2.0.4, we deduce that f''_α is almost of finite presentation, so that the lower half of the diagram $\overline{\sigma}'$ witnesses assertion (b). □

4.5 Approximation of Quasi-Coherent Sheaves

Let X be spectral Deligne-Mumford stack which is finitely n-presented over a connective $\mathbb{E}_\infty$-ring R, and suppose that R is given as a filtered colimit of connective $\mathbb{E}_\infty$-rings $\{R_\alpha\}$. Theorem 4.4.2.2 implies that we can write X as a truncated fiber product $\tau_{\leqslant n}(\operatorname{Sp\acute{e}t} R \times_{\operatorname{Sp\acute{e}t} R_\alpha} \mathsf{X}_\alpha)$ for some index α and some spectral Deligne-Mumford stack X_α which is finitely n-presented over R_α. In this section, we will prove a linear analogue of Theorem 4.4.2.2, which relates quasi-coherent sheaves on X (satisfying suitable finiteness hypotheses) to quasi-coherent sheaves on X_α.

4.5.1 Approximation of Modules

We begin by studying the quasi-coherent sheaves on affine spectral Deligne-Mumford stacks. In this case, we wish to answer the following:

Question 4.5.1.1. Let $\{R_\alpha\}$ be a filtered diagram of connective $\mathbb{E}_\infty$-rings having colimit $R = \varinjlim R_\alpha$. What is the relationship between the ∞-category Mod_R and the diagram of ∞-categories $\{\operatorname{Mod}_{R_\alpha}\}$?

To answer Question 4.5.1.1, it is convenient to begin by studying the analogous question for $\mathbb{E}_1$-rings. Note that if M is a spectrum and R is an $\mathbb{E}_1$-ring, then giving a left action of R on M is equivalent to giving a morphism of $\mathbb{E}_1$-rings $\phi : R \to \operatorname{End}(M)$. If R is given as the colimit of a diagram $\{R_\alpha\}$ in the ∞-category Alg of $\mathbb{E}_1$-rings, then we can think of a morphism $\phi : R \to \mathrm{End}(M)$ as equivalent to supplying a compatible family of maps $\phi_\alpha : R_\alpha \to \mathrm{End}(M)$: that is, to equipping M with a compatible family of left R_α-module structures. We can formulate this idea more precisely as follows:

Proposition 4.5.1.2. *Let $\{R_\alpha\}$ be a diagram of $\mathbb{E}_1$-rings indexed by a contractible simplicial set K, having colimit R. Then the forgetful functor $\mathrm{LMod}_R \to \varprojlim\{\mathrm{LMod}_{R_\alpha}\}$ is an equivalence of ∞-categories.*

Proof. Combine Lemma HA.7.3.5.12 , Corollary HTT.5.5.3.4 , and Proposition HTT.5.5.3.18 . □

In the situation of Proposition 4.5.1.2, suppose that each R_α is connective, so that R is likewise connective. It follows that the forgetful functor $\mathrm{LMod}_R^{\mathrm{cn}} \to \varprojlim\{\mathrm{LMod}_{R_\alpha}^{\mathrm{cn}}\}$ is an equivalence of ∞-categories, and that for each $n \geqslant 0$ the forgetful functor $(\mathrm{LMod}_R)_{\leqslant n} \to \varprojlim\{(\mathrm{LMod}_{R_\alpha})_{\leqslant n}\}$ is an equivalence of ∞-categories. This immediately implies the following:

Corollary 4.5.1.3. *The construction $R \mapsto \mathrm{LMod}_R^{\mathrm{cn}}$ determines a functor $\mathrm{Alg}^{\mathrm{cn}} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ which preserves colimits indexed by small weakly contractible simplicial sets.*

Corollary 4.5.1.4. *For each integer n, the construction $R \mapsto (\mathrm{LMod}_R^{\mathrm{cn}})_{\leqslant n}$ determines a functor $\mathrm{Alg}^{\mathrm{cn}} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ which preserves colimits indexed by small weakly contractible simplicial sets.*

Since the forgetful functor CAlg → Alg commutes with filtered colimits, we immediately obtain the following variants:

Corollary 4.5.1.5. *The construction $R \mapsto \mathrm{Mod}_R$ determines a functor $\mathrm{CAlg} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ which commutes with filtered colimits.*

Corollary 4.5.1.6. *The construction $R \mapsto \mathrm{Mod}_R^{\mathrm{cn}}$ determines a functor $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ which preserves small filtered colimits.*

Corollary 4.5.1.7. *For each integer n, the construction $R \mapsto (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant n}$ determines a functor $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ which preserves small filtered colimits.*

Combining these results with Lemma HA.7.3.5.11 , we obtain the following:

Corollary 4.5.1.8. *The construction $R \mapsto \mathrm{Mod}_R^{\mathrm{perf}}$ determines a functor $\mathrm{CAlg} \to \mathcal{C}\mathrm{at}_\infty$ which commutes with filtered colimits.*

Corollary 4.5.1.9. *The construction $R \mapsto \mathrm{Mod}_R^{\mathrm{cn}} \cap \mathrm{Mod}_R^{\mathrm{perf}}$ determines a functor $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{C}\mathrm{at}_\infty$ which commutes with filtered colimits.*

Corollary 4.5.1.10. *Let $n \geqslant 0$ be an integer. For every connective $\mathbb{E}_\infty$-ring R, let Mod_R^{n-fp} denote the full subcategory of Mod_R spanned by those R-modules which are connective, n-truncated, and perfect to order $(n+1)$ (that is, the full subcategory spanned by the compact objects of $\tau_{\leqslant n} \mathrm{Mod}_R^{\mathrm{cn}}$). Then the construction $R \mapsto \mathrm{Mod}_R^{n-fp}$ determines a functor $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{C}\mathrm{at}_\infty$ which commutes with filtered colimits.*

4.5.2 The Non-Affine Case

Let R be a connective $\mathbb{E}_\infty$-ring and $n \geqslant 0$ an integer. Recall that a connective R-module M is said to be *finitely n-presented* if it is a compact object of the ∞-category $(\mathrm{Mod}_R)_{\leqslant n}$: equivalently, M is finitely n-presented if it is n-truncated and perfect to order $(n+1)$ (Definition 2.7.1.1). If X is a spectral Deligne-Mumford stack and $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$, we see that $\mathscr{F}$ is *finitely n-presented* if, for every étale map $\eta : \mathrm{Spét}\, R \to \mathsf{X}$, the pullback $\eta^* \mathscr{F}$ is finitely n-presented when regarded as an object of $\mathrm{Mod}_R \simeq \mathrm{QCoh}(\mathrm{Spét}\, R)$ (see Definition 2.8.4.4).

Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks, and let $\mathscr{F}$ be a quasi-coherent sheaf on Y which is finitely n-presented. If f is flat, then $f^* \mathscr{F}$ is a finitely n-presented quasi-coherent sheaf on X. In the non-flat case, this need not be true. However, we do have the following analogue of Proposition 4.2.5.4:

Proposition 4.5.2.1. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks, and let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})$ be finitely n-presented. Then $\tau_{\leqslant n} f^* \mathscr{F}$ is finitely n-presented.*

Proof. Since $\mathscr{F}$ is perfect to order $(n+1)$, we deduce that $f^* \mathscr{F}$ is perfect to order $(n+1)$. It follows that $\tau_{\leqslant n} f^* \mathscr{F}$ is also perfect to order $(n+1)$ (see Remark 2.7.1.3). Since $\tau_{\leqslant n} f^* \mathscr{F}$ is obviously n-truncated, it is finitely n-presented. □

Construction 4.5.2.2. The functor $\mathsf{X} \mapsto \mathrm{QCoh}(\mathsf{X})$ classifies a Cartesian fibration $\theta : \mathcal{C} \to \mathrm{SpDM}$. We can identify objects of $\mathcal{C}$ with pairs $(\mathsf{X}, \mathscr{F})$, where X is a spectral Deligne-Mumford stack and $\mathscr{F}$ is a quasi-coherent sheaf on X. Let $n \geqslant 0$ be an integer, and let $\mathcal{C}^{n-fp}$ denote the full subcategory of $\mathcal{C}$ spanned by those pairs $(\mathsf{X}, \mathscr{F})$, where $\mathscr{F}$ is connective and finitely n-presented. It follows from Proposition 4.5.2.1 that θ restricts to a Cartesian fibration $\mathcal{C}^{n-fp} \to \mathrm{SpDM}$. This Cartesian fibration is classified by a functor $\mathrm{QCoh}^{n-fp} : \mathrm{SpDM}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$. We can describe this functor concretely as follows:

(a) To every spectral Deligne-Mumford stack X, $\mathrm{QCoh}^{n-fp}(\mathsf{X})$ can be identified with the full subcategory of $\mathrm{QCoh}(\mathsf{X})$ spanned by those quasi-coherent sheaves $\mathscr{F}$ which are connective and finitely n-presented.

(b) To every map $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks, the functor

$$\mathrm{QCoh}^{n-fp}(f) : \mathrm{QCoh}^{n-fp}(\mathsf{Y}) \to \mathrm{QCoh}^{n-fp}(\mathsf{X})$$

is given on objects by the construction $\mathscr{F} \mapsto \tau_{\leqslant n} f^* \mathscr{F}$.

The remainder of this section is devoted to the proof of the following result:

Theorem 4.5.2.3. *Let R be a connective $\mathbb{E}_\infty$-ring and let X be a spectral Deligne-Mumford m-stack over R, for some integer $m < \infty$. Assume that X is ∞-quasi-compact and let $n \geqslant 0$ be an integer. Then:*

(1) *The ∞-category $\mathrm{QCoh}^{n-fp}(\mathsf{X})$ is essentially small.*

(2) *Suppose we are given a filtered diagram $\{R_\alpha\}$ of connective $\mathbb{E}_\infty$-algebras over R having colimit R'. Let $\mathsf{X}_\alpha = \mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathrm{Sp\acute{e}t}\, R_\alpha$, and let $\mathsf{X}' = \mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathrm{Sp\acute{e}t}\, R'$. Then the canonical map*
$$\theta : \varinjlim_{\alpha} \mathrm{QCoh}^{n-fp}(\mathsf{X}_\alpha) \to \mathrm{QCoh}^{n-fp}(\mathsf{X}')$$
is an equivalence of ∞-categories.

4.5.3 The Proof of Theorem 4.5.2.3

The proof of Theorem 4.5.2.3 will require the following general observation.

Lemma 4.5.3.1. *Filtered colimits are left exact in the ∞-category $\mathcal{C}\mathrm{at}_\infty$ of small ∞-categories.*

Proof. Let $G : \mathcal{C}\mathrm{at}_\infty \to \mathrm{Fun}(\mathbf{\Delta}^{\mathrm{op}}, \mathcal{S})$ be the fully faithful embedding of Proposition HA.A.7.10 , given by $G(\mathcal{C})([n]) = \mathrm{Map}_{\mathcal{C}\mathrm{at}_\infty}(\Delta^n, \mathcal{C})$. Since filtered colimits in $\mathrm{Fun}(\mathbf{\Delta}^{\mathrm{op}}, \mathcal{S})$ are left exact (Example HTT.7.3.4.7), it will suffice to show that G preserves finite limits and filtered colimits. The first assertion is obvious, and the second follows from the observation that each Δ^n is a compact object of $\mathcal{C}\mathrm{at}_\infty$. □

Proof of Theorem 4.5.2.3. Let X be a spectral Deligne-Mumford stack over a connective $\mathbb{E}_\infty$-ring R. Consider the following hypothesis for $m \geqslant -2$:

($*_m$) If $m \geqslant 0$, then X is a spectral Deligne-Mumford m-stack. If $m = -1$, then there exists a quasi-monomorphism $\mathsf{X} \to \mathrm{Sp\acute{e}t}\, A$ for some connective $\mathbb{E}_\infty$-algebra A over R (see the proof of Theorem 4.4.2.2). If $m = -2$, then X is affine.

The hypothesis of Theorem 4.5.2.3 is that X satisfies ($*_m$) for m sufficiently large. We proceed by induction on m, beginning with the case $m = -2$. In this case, we can write $\mathsf{X} = \mathrm{Sp\acute{e}t}\, A$ for some connective $\mathbb{E}_\infty$-ring A. Using Remark 2.7.1.4, we deduce that $\mathrm{QCoh}^{n-fp}(\mathsf{X})$ is equivalent to the ∞-category of compact objects of the presentable ∞-category $(\mathrm{Mod}_A^{\mathrm{cn}})_{\leqslant n}$, which proves (1). Assertion (2) follows from Corollary 4.5.1.10.

Now suppose that $m \geqslant -1$. Since X is quasi-compact, we can choose an étale surjection $u : \mathsf{X}_0 \to \mathsf{X}$, where X_0 is affine. Let $\mathsf{X}_\bullet$ be the Čech nerve of u. Then each X_p satisfies ($*_{m-1}$). Using the equivalence of ∞-categories $\mathrm{QCoh}^{n-fp}(\mathsf{X}) \simeq \varprojlim \mathrm{QCoh}^{n-fp}(\mathsf{X}_\bullet)$ and the inductive hypothesis, we deduce that $\mathrm{QCoh}^{n-fp}(\mathsf{X})$ is essentially small; this proves (1). To prove (2), we let $\mathsf{X}_{\bullet,\alpha}$ denote the simplicial spectral Deligne-Mumford stack given by $\mathsf{X}_\bullet \times_{\mathrm{Sp\acute{e}t}\, R} \mathrm{Sp\acute{e}t}\, R_\alpha$, and $\mathsf{X}'_\bullet$ the simplicial spectral Deligne-Mumford stack given by $\mathsf{X}_\bullet \times_{\mathrm{Sp\acute{e}t}\, R} \mathrm{Sp\acute{e}t}\, R'$. We have a commutative diagram

$$\begin{array}{ccc}
\varinjlim_\alpha \mathrm{QCoh}^{n-fp}(\mathsf{X}_\alpha) & \xrightarrow{\theta} & \mathrm{QCoh}^{n-fp}(\mathsf{X}') \\
\downarrow & & \downarrow \\
\varinjlim_\alpha \varprojlim_{[k]\in\mathbf{\Delta}} \mathrm{QCoh}^{n-fp}(\mathsf{X}_{k,\alpha}) & \longrightarrow & \varprojlim_{[k]\in\mathbf{\Delta}} \mathrm{QCoh}^{n-fp}(\mathsf{X}'_k) \\
\downarrow & & \downarrow \\
\varinjlim_\alpha \varprojlim_{[k]\in\mathbf{\Delta}_{s,\leqslant n+2}} \mathrm{QCoh}^{n-fp}(\mathsf{X}_{k,\alpha}) & \xrightarrow{\phi} & \varprojlim_{[k]\in\mathbf{\Delta}_{s,\leqslant n+2}} \mathrm{QCoh}^{n-fp}(\mathsf{X}'_k).
\end{array}$$

Here the vertical maps are equivalences by virtue of the observation that the functor QCoh^{n-fp} takes values in the full subcategory of $\widehat{\mathcal{C}\mathrm{at}}_\infty$ spanned by those ∞-categories which are equivalent to $(n+1)$-categories (since $\mathrm{QCoh}(\mathsf{Y})^{\mathrm{cn}}_{\leqslant n}$ is equivalent to an $(n+1)$-category, for every spectral Deligne-Mumford stack Y), and that this subcategory of $\widehat{\mathcal{C}\mathrm{at}}_\infty$ is itself equivalent to an $(n+2)$-category. Consequently, to prove that θ is an equivalence of ∞-categories, it will suffice to show that ϕ is an equivalence of ∞-categories. The functor ϕ fits into a commutative diagram

$$\begin{array}{ccc}
\varinjlim_\alpha \varprojlim_{[k]\in\mathbf{\Delta}_{s,\leqslant n+2}} \mathrm{QCoh}^{n-fp}(\mathsf{X}_{k,\alpha}) & & \\
 & \searrow^{\phi'} & \\
\downarrow \phi & & \varprojlim_{[k]\in\mathbf{\Delta}_{s,\leqslant n+2}} \varinjlim_\alpha \mathrm{QCoh}^{n-fp}(\mathsf{X}_{k,\alpha}). \\
 & \swarrow_{\phi''} & \\
\varprojlim_{[k]\in\mathbf{\Delta}_{s,\leqslant n+2}} \mathrm{QCoh}^{n-fp}(\mathsf{X}'_k) & &
\end{array}$$

Here ϕ' is an equivalence of ∞-categories by Lemma 4.5.3.1, and ϕ'' is an equivalence of ∞-categories by the inductive hypothesis. □

4.6 Descent of Properties along Filtered Colimits

Let $f : \mathsf{X} \to \mathsf{Y}$ be a a map of spectral Deligne-Mumford stack which are finitely n-presented over a connective $\mathbb{E}_\infty$-ring A, and suppose that A is given as the colimit of a filtered diagram of connective $\mathbb{E}_\infty$-rings $\{A_\alpha\}$. Using Theorem 4.4.2.2, we deduce the existence of an index α and a map $f_\alpha : \mathsf{X}_\alpha \to \mathsf{Y}_\alpha$ of spectral Deligne-Mumford stacks which are finitely n-presented over A_α, such that f is equivalent to the induced map

$$\tau_{\leqslant n}(\operatorname{Sp\acute{e}t} A \times_{\operatorname{Sp\acute{e}t} A_\alpha} \mathsf{X}_\alpha) \to \tau_{\leqslant n}(\operatorname{Sp\acute{e}t} A \times_{\operatorname{Sp\acute{e}t} A_\alpha} \mathsf{Y}_\alpha).$$

Our goal in this section is to prove a variety of results which assert that if f has some property P, then we can arrange that f_α also has the property P. Our results can be summarized as follows:

(a) If f is affine, then f_α can be chosen to be affine (Proposition 4.6.1.1).

(b) If f is surjective, then f_α can be chosen to be surjective (Proposition 4.6.1.2).

(c) If f is a closed immersion, then f_α can be chosen to be a closed immersion (Proposition 4.6.1.3).

(d) If f is separated, then f_α can be chosen to be separated (Corollary 4.6.1.4).

(e) If f is étale, then f_α can be chosen to be étale (Proposition 4.6.2.1).

(f) If f is an open immersion, then f_α can be chosen to be an open immersion (Corollary 4.6.2.2).

4.6.1 Examples of Descent

We begin by handling the easy cases.

Proposition 4.6.1.1. *Let A_0 be a connective $\mathbb{E}_\infty$-ring. Suppose we are given a filtered diagram of connective A_0-algebras $\{A_\alpha\}$ having colimit A. Let $n \geqslant 0$ be an integer, let $f_0 : \mathsf{X}_0 \to \mathsf{Y}_0$ be a morphism in $\mathrm{DM}_n^{\mathrm{fp}}(A_0)$. Let $f : \mathsf{X} \to \mathsf{Y}$ be the image of f_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A)$. Suppose that f is affine. Then there exists an index α such that the image of f_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A_\alpha)$ is affine.*

Proof. Since Y_0 is quasi-compact, we can choose an étale surjection $\mathsf{Y}'_0 \to \mathsf{Y}_0$, where $\mathsf{Y}'_0 \simeq \operatorname{Sp\acute{e}t} B_0$ is affine. Replacing Y_0 by Y'_0, we can reduce to the case where Y_0 is affine, so that X is also affine. Corollary 4.4.1.4 shows that there exists an index α and an affine spectral Deligne-Mumford stack $\mathsf{Z} \in \mathrm{DM}_n^{\mathrm{fp}}(A_\alpha)$ having image X in $\mathrm{DM}_n^{\mathrm{fp}}(A)$. Let X_α denote the image of X_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A_\alpha)$. Then X_α and Z have equivalent images in $\mathrm{DM}_n^{\mathrm{fp}}(A)$. Altering our choice of α, we may assume with X_α is equivalent to Z (Theorem 4.4.2.2), so that X_α is affine and therefore the image of f_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A_\alpha)$ is affine. □

Proposition 4.6.1.2. *Let A_0 be a connective $\mathbb{E}_\infty$-ring. Suppose we are given a filtered diagram of connective A_0-algebras $\{A_\alpha\}$ having colimit A. Let $n \geqslant 0$ be an integer, let $f_0 : \mathsf{X}_0 \to \mathsf{Y}_0$ be a morphism in $\mathrm{DM}_n^{\mathrm{fp}}(A_0)$. Let $f : \mathsf{X} \to \mathsf{Y}$ be the image of f_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A)$. Suppose that f is surjective. Then there exists an index α such that the image of f_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A_\alpha)$ is surjective.*

Proof. We may assume without loss of generality that the diagram $\{A_\alpha\}$ is indexed by a filtered partially ordered set. Since Y_0 is quasi-compact, we can choose an étale surjection $\mathsf{Y}'_0 \to \mathsf{Y}_0$, where Y'_0 is quasi-compact. Replacing Y_0 by Y'_0, we can reduce to the case where $\mathsf{Y}_0 \simeq \operatorname{Spét} B_0$ is affine. Similarly, we can assume that $\mathsf{X}_0 \simeq \operatorname{Spét} C_0$ is affine. Our assumption implies that the map of topological spaces

$$|\operatorname{Spec} \operatorname{Tor}_0^{\pi_0 A_0}(\pi_0 C_0, \pi_0 A)| \to |\operatorname{Spec} \operatorname{Tor}_0^{\pi_0 A_0}(\pi_0 B_0, \pi_0 A)|$$

is surjective. Using Corollary 4.3.5.4, we deduce the existence of an index α such that the map

$$|\operatorname{Spec} \operatorname{Tor}_0^{\pi_0 A_0}(\pi_0 C_0, \pi_0 A_\alpha)| \to |\operatorname{Spec} \operatorname{Tor}_0^{\pi_0 A_0}(\pi_0 B_0, \pi_0 A_\alpha)|$$

is surjective. It follows that the image of f_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A_\alpha)$ is a surjective map of spectral Deligne-Mumford stacks. □

Proposition 4.6.1.3. *Let A_0 be a connective $\mathbb{E}_\infty$-ring. Suppose we are given a filtered diagram of connective A_0-algebras $\{A_\alpha\}$ having colimit A. Let $n \geqslant 0$ be an integer, let $f_0 : \mathsf{X}_0 \to \mathsf{Y}_0$ be a morphism in $\mathrm{DM}_n^{\mathrm{fp}}(A_0)$. Let $f : \mathsf{X} \to \mathsf{Y}$ be the image of f_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A)$. Suppose that f is a closed immersion. Then there exists an index α such that the image of f_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A_\alpha)$ is a closed immersion.*

Proof. Since Y_0 is quasi-compact, we can choose an étale surjection $\mathsf{Y}'_0 \to \mathsf{Y}_0$, where $\mathsf{Y}'_0 \simeq \operatorname{Spét} B_0$ is affine. Replacing Y_0 by Y'_0, we can reduce to the case where Y_0 is affine. Using Proposition 4.6.1.1, we may assume that $\mathsf{X}_0 \simeq \operatorname{Spét} C_0$ is also affine. The condition that f is a closed immersion guarantees that the map

$$\varinjlim \operatorname{Tor}_0^{\pi_0 A_0}(\pi_0 A_\alpha, \pi_0 B_0) \to \varinjlim \operatorname{Tor}_0^{\pi_0 A_0}(\pi_0 A_\alpha, \pi_0 C_0)$$

is surjective. Since $\pi_0 C_0$ is a finitely presented algebra over $\pi_0 B_0$, we deduce that there is an index α such that the image of the map

$$\operatorname{Tor}_0^{\pi_0 A_0}(\pi_0 A_\alpha, \pi_0 B_0) \to \operatorname{Tor}_0^{\pi_0 A_0}(\pi_0 A_\alpha, \pi_0 C_0)$$

contains the image of $\pi_0 C_0$, and is therefore surjective. It follows that the image of f_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A_\alpha)$ is a closed immersion. □

Corollary 4.6.1.4. *Let A_0 be a connective $\mathbb{E}_\infty$-ring. Suppose we are given a filtered diagram of connective A_0-algebras $\{A_\alpha\}$ having colimit A. Let $n \geqslant 0$ be an integer, let $f_0 : \mathsf{X}_0 \to \mathsf{Y}_0$ be a morphism in $\mathrm{DM}_n^{\mathrm{fp}}(A_0)$. Let $f : \mathsf{X} \to \mathsf{Y}$ be the image of f_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A)$. Suppose that f is separated. Then there exists an index α such that the image of f_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A_\alpha)$ is separated.*

Proof. Apply Proposition 4.6.1.3 to the diagonal map $\mathsf{X}_0 \to \mathsf{X}_0 \times_{\mathsf{Y}_0} \mathsf{X}_0$. □

4.6.2 Descending Étale Morphisms

The final result of this section is somewhat more difficult.

Proposition 4.6.2.1. *Let A_0 be a connective $\mathbb{E}_\infty$-ring. Suppose we are given a filtered diagram of connective A_0-algebras $\{A_\alpha\}$ having colimit A. Let $n \geqslant 0$ be an integer, let $f_0 : \mathsf{X}_0 \to \mathsf{Y}_0$ be a morphism in $\mathrm{DM}_n^{\mathrm{fp}}(A_0)$. Let $f : \mathsf{X} \to \mathsf{Y}$ be the image of f_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A)$. Suppose that f is étale. Then there exists an index α such that the image of f_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A_\alpha)$ is étale.*

Corollary 4.6.2.2. *Let A_0 be a connective $\mathbb{E}_\infty$-ring. Suppose we are given a filtered diagram of connective A_0-algebras $\{A_\alpha\}$ having colimit A. Let $n \geqslant 0$ be an integer, let $f_0 : \mathsf{X}_0 \to \mathsf{Y}_0$ be a morphism in $\mathrm{DM}_n^{\mathrm{fp}}(A_0)$. Let $f : \mathsf{X} \to \mathsf{Y}$ be the image of f_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A)$. Suppose that f is an open immersion. Then there exists an index α such that the image of f_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A_\alpha)$ is an open immersion.*

Proof. Using Proposition 4.6.2.1, we can reduce to the case where f_0 is étale. Let δ_0 denote the diagonal map $\mathsf{X}_0 \to \mathsf{X}_0 \times_{\mathsf{Y}_0} \mathsf{X}_0$. Then the image of δ_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A)$ is an equivalence. Theorem 4.4.2.2 implies that there exists an index α such that the image of δ_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A_\alpha)$ is an equivalence. It follows that the image of f_0 in $\mathrm{DM}_n^{\mathrm{fp}}(A_\alpha)$ is an open immersion. □

The proof of Proposition 4.6.2.1 will require some preliminaries.

Remark 4.6.2.3. Let B be a connective $\mathbb{E}_\infty$-ring and let $n \geqslant 0$ be an integer. The truncation map $B \to \tau_{\leqslant n} B$ is $(n+1)$-connective. Consequently, Theorem HA.7.4.3.1 supplies an $(2n+3)$-connective map $(\tau_{\leqslant n} B \otimes_B \tau_{\geqslant n+1} B) \to \Sigma^{-1} L_{\tau_{\leqslant n} B/B}$. The map $\tau_{\geqslant n+1} B \to (\tau_{\leqslant n} B \otimes_B \tau_{\geqslant n+1} B)$ is $(2n+2)$-connective, so that the induced map $\tau_{\geqslant n+1} B \to \Sigma^{-1} L_{\tau_{\leqslant n} B/B}$ determines isomorphisms $\theta_m : \pi_m B \to \pi_{m+1} L_{\tau_{\leqslant n} B/B}$ for $n < m < 2n+2$ and a surjection when $m = 2n+2$.

Let $f : A \to B$ be a map of connective $\mathbb{E}_\infty$-rings, and let $\partial : \Sigma^{-1} L_{\tau_{\leqslant n} B/B} \to L_{B/A}$ be the associated boundary map. Unwinding the definitions, we see that for $m > n$, the composition

$$\pi_m B \xrightarrow{\theta_m} \pi_{m+1} L_{\tau_{\leqslant n} B/B} \xrightarrow{\partial} \pi_m L_{B/A}$$

is induced by the universal A-linear derivation $d : B \to L_{B/A}$. In particular (taking $n = 0$), we conclude that the induced maps $\pi_m B \to \pi_m L_{B/A}$ is $\pi_0 B$-linear for $m > 0$.

Lemma 4.6.2.4. *Let $f : A \to B$ be a map of connective $\mathbb{E}_\infty$-rings, and let $n \geqslant 0$. The induced map $\tau_{\leqslant n} A \to \tau_{\leqslant n} B$ is étale if and only if the following conditions are satisfied:*

(1) *The commutative ring $\pi_0 B$ is finitely presented over $\pi_0 A$.*

(2) *The relative cotangent complex $L_{B/A}$ is $(n+1)$-connective.*

(3) *Let $d : B \to L_{B/A}$ be the universal derivation (so that d is a map of A-module spectra). Then d induces a surjection $\pi_{n+1}B \to \pi_{n+1}L_{B/A}$.*

Proof. Suppose first that $\tau_{\leqslant n}B$ is étale over $\tau_{\leqslant n}A$. Then $\pi_0 B$ is étale over $\pi_0 A$, which immediately implies (1). Using Theorem HA.7.5.0.6 , we can choose an étale A-algebra A' and an isomorphism $\alpha : \pi_0 A' \simeq \pi_0 B$. Theorem HA.7.5.4.2 implies that α can be lifted to a map of A-algebras $\overline{\alpha} : A' \to B$. Since $L_{A'/A} \simeq 0$, we conclude that the canonical map $L_{B/A} \to L_{B/A'}$ is an equivalence. Note that $\overline{\alpha}$ induces an equivalence $\tau_{\leqslant n}A' \to \tau_{\leqslant n}B$, and is therefore n-connective. Using Corollary HA.7.4.3.2 , we deduce that $L_{B/A} \simeq L_{B/A'}$ is $(n+1)$-connective, thereby proving (2). To prove (3), we note that the composite map $A' \to B \to \tau_{\leqslant n}B$ is $(n+1)$-connective, so that $L_{\tau_{\leqslant n}B/A} \simeq L_{\tau_{\leqslant n}B/A'}$ is $(n+2)$-connective. We have a fiber sequence

$$(\tau_{\leqslant n}B) \otimes_B L_{B/A} \to L_{\tau_{\leqslant n}B/A} \to L_{\tau_{\leqslant n}B/B}.$$

The vanishing of $\pi_{n+1}L_{\tau_{\leqslant n}B/A}$ implies that the boundary map

$$\theta : \pi_{n+2}L_{\tau_{\leqslant n}B/B} \to \pi_{n+1}(\tau_{\leqslant n}B \otimes_B L_{B/A}) \simeq \pi_{n+1}L_{B/A}$$

is surjective. Using Remark 4.6.2.3, we deduce that the universal derivation $d : B \to L_{B/A}$ induces a surjection $\pi_{n+1}B \to \pi_{n+1}L_{B/A}$, so that (3) is satisfied.

Now suppose that conditions (1), (2), and (3) hold. We wish to prove that $\tau_{\leqslant n}B$ is étale over $\tau_{\leqslant n}A$. Consider the fiber sequence

$$(\tau_{\leqslant n}B) \otimes_B L_{B/A} \to L_{\tau_{\leqslant n}B/A} \to L_{\tau_{\leqslant n}B/B}.$$

It follows from condition (2) that $(\tau_{\leqslant n}B) \otimes_B L_{B/A}$ is $(n+1)$-connective, and we have a canonical isomorphism $\pi_{n+1}(\tau_{\leqslant n}B \otimes_B L_{B/A}) \simeq \pi_{n+1}L_{B/A}$. Using Remark 4.6.2.3, we deduce that $L_{\tau_{\leqslant n}B/B}$ is $(n+2)$-connective and obtain a canonical isomorphism $\pi_{n+2}L_{\tau_{\leqslant n}B/B} \simeq \pi_{n+1}B$. It follows that $L_{\tau_{\leqslant n}B/A}$ is $(n+1)$-connective, and we have a short exact sequence of abelian groups

$$\pi_{n+1}B \to \pi_{n+1}L_{B/A} \to \pi_{n+1}L_{\tau_{\leqslant n}B/A} \to 0.$$

Using condition (3), we conclude that $L_{\tau_{\leqslant n}B/A}$ is $(n+2)$-connective. Invoking Lemma B.1.3.2, we see that f factors as a composition $A \xrightarrow{f'} A' \xrightarrow{f''} B$ where f' is étale and f'' is $(n+1)$-connective. It follows that $\tau_{\leqslant n}B \simeq \tau_{\leqslant n}A'$ is étale over $\tau_{\leqslant n}A$, as desired. □

We now prove Proposition 4.6.2.1 in the affine case.

Lemma 4.6.2.5. *Let A_0 be a connective $\mathbb{E}_\infty$-ring. Suppose we are given a filtered diagram of connective A_0-algebras $\{A_\alpha\}$ having colimit A. Let $f : A_0 \to B_0$ be a map of connective $\mathbb{E}_\infty$-rings which is of finite generation to order $n+1$ for some $n \geqslant 0$. Let $B_\alpha = A_\alpha \otimes_{A_0} B_0$ and let $B = \varinjlim B_\alpha \simeq A \otimes_{A_0} B_0$. Suppose that $\tau_{\leqslant n}B$ is étale over $\tau_{\leqslant n}A$. Then there exists an index α such that $\tau_{\leqslant n}B_\alpha$ is étale over $\tau_{\leqslant n}A_\alpha$.*

Proof. Using Lemma 4.6.2.4, we see that $L_{B/A} \simeq B \otimes_{B_0} L_{B_0/A_0}$ is $(n+1)$-connective. Using Theorem 4.5.2.3, we deduce that there exists an index α such that $B_\alpha \otimes_{B_0} L_{B_0/A_0}$ is $(n+1)$-connective. Since B_0 is of finite generation to order $(n+1)$ over A_0, the relative cotangent complex L_{B_0/A_0} is perfect to order $(n+1)$ so that $\pi_{n+1} L_{B_0/A_0}$ is finitely generated as a module over $\pi_0 B_0$. Choose a finite collection of generators $x_1, \ldots, x_k$ for $\pi_{n+1} L_{B_0/A_0}$, and let $x'_1, \ldots, x'_k$ denote their images in $\pi_{n+1} L_{B/A}$. Lemma 4.6.2.4 implies that the universal derivation $B \to L_{B/A}$ induces a surjection

$$\phi : \varinjlim \pi_{n+1} B_\alpha \simeq \pi_{n+1} B \to \pi_{n+1} L_{B/A}.$$

It follows that there exists an index α and elements $y_1, \ldots, y_k \in \pi_{n+1} B_\alpha$ such that $\phi(y_i) = x'_i$ for $1 \leqslant i \leqslant k$. Let x''_i denote the image of x_i in $\pi_{n+1} L_{B_\alpha/A_\alpha}$. Enlarging α if necessary, we may assume that the universal derivation $d_\alpha : B_\alpha \to L_{B_\alpha/A_\alpha}$ carries each y_i to x''_i. Note that $\pi_{n+1} L_{B_\alpha/A_\alpha} \simeq \mathrm{Tor}_0^{\pi_0 B_0}(\pi_0 B, \pi_{n+1} L_{B_0/A_0})$, so that the elements x''_i generate $\pi_{n+1} L_{B_\alpha/A_\alpha}$ as a module over $\pi_0 B_\alpha$. Since the universal derivation induces a $\pi_0 B_\alpha$-linear map $\pi_{n+1} B_\alpha \to \pi_{n+1} L_{B_\alpha/A_\alpha}$ (see Remark 4.6.2.3), we deduce that this map is surjective. Applying Lemma 4.6.2.4, we conclude that $\tau_{\leqslant n} B_\alpha$ is étale over $\tau_{\leqslant n} A_\alpha$, as desired. □

Proof of Proposition 4.6.2.1. Since Y_0 is quasi-compact, we can choose an étale surjection $\mathsf{Y}'_0 \to \mathsf{Y}_0$, where Y'_0 is affine. Replacing Y_0 by Y'_0 and X_0 by the fiber product $\mathsf{X}_0 \times_{\mathsf{Y}_0} \mathsf{Y}'_0$, we can assume that Y_0 is affine. Since X_0 is quasi-compact, we can choose an étale surjection $\mathsf{X}'_0 \to \mathsf{X}_0$, where X'_0 is affine. We may therefore replace X_0 by X'_0 and thereby reduce to the case where X_0 is also affine. The desired result now follows immediately from Theorem 1.4.10.2 and Lemma 4.6.2.5. □

Chapter 5

Proper Morphisms in Spectral Algebraic Geometry

Let $f : X \to Y$ be a morphism of schemes. Recall that f is said to be *proper* if it is separated, of finite type, and universally closed (Definition 3.7.0.1). Our goal in this section is to study the same hypothesis in the setting of spectral algebraic geometry. We begin in §5.1 by introducing the notion of a *proper morphism* between spectral Deligne-Mumford stacks $f : \mathsf{X} \to \mathsf{Y}$ (Definition 5.1.2.1).

In the setting of classical algebraic geometry, there are two important sources of examples of proper morphisms:

(*a*) Every closed immersion of schemes is proper. More generally, any finite morphism of schemes $f : X \to Y$ is proper (recall that $f : X \to Y$ is said to be *finite* if, for every affine open subscheme $\operatorname{Spét} A \simeq U \subseteq Y$, the inverse image $f^{-1}(U) \subseteq X$ is an affine scheme of the form $\operatorname{Spec} B$, where B is finitely generated as an A-module).

(*b*) For any commutative ring R, the projection map $\mathbf{P}^n_R \to \operatorname{Spec} R$ is proper, where $\mathbf{P}^n_R$ denotes projective space of dimension n over R.

In §5.2, we will see that the theory of finite morphisms can be generalized to the setting of spectral algebraic geometry in a straightforward way. The case of projective space is more subtle. In §5.4, we will associate to each connective $\mathbb{E}_\infty$-ring R a spectral algebraic space $\mathbf{P}^n_R$, which we call *projective space of dimension n over R* (Construction 5.4.1.3). These projective spaces share many of the pleasant features of their classical counterparts: for example, Serre's calculation of the cohomology of line bundles on projective space extends to the spectral setting without essential change (Theorem 5.4.2.6). However, there are a few surprises: for example, the projective spaces of Construction 5.4.1.3 are somewhat rigid objects (unlike projective spaces in classical algebraic geometry, which are homogeneous spaces).

Most (but not all) examples of proper morphisms of schemes can be obtained by combining (a) and (b). Recall that a complex algebraic variety X is said to be *proper* if the projection map $X \to \operatorname{Spec} \mathbf{C}$ is proper, and is said to be *projective* if there exists a closed immersion $X \hookrightarrow \mathbf{P}^n_{\mathbf{C}}$ for some $n \geqslant 0$ (or, equivalently, if there exists a finite morphism $X \to \mathbf{P}^n_{\mathbf{C}}$ for some $n \geqslant 0$). Every projective algebraic variety is proper, but not every proper algebraic variety is projective. However, a general proper algebraic variety X is not far from being projective: according to Chow's lemma, one can always choose a projective birational map $\pi : \overline{X} \to X$, where the variety $\overline{X}$ is projective. In §5.5, we establish a version of Chow's lemma in the setting of spectral algebraic geometry (Theorem 5.5.0.1).

Recall that scheme X is determined (up to canonical isomorphism) by its functor of points $h_X : \mathrm{CAlg}^{\heartsuit} \to \mathcal{S}\mathrm{et}$. In particular, the condition that a morphism of schemes $f : X \to Y$ is proper depends only the induced natural transformation $h_X \to h_Y$. If we assume that f is of finite type, then we can be more explicit: according to Grothendieck's *valuative criterion of properness*, f is proper if and only if, for every valuation ring V with fraction field K, the induced map $h_X(V) \to h_X(K) \times_{h_Y(K)} h_Y(V)$ is a bijection. In §5.3, we discuss an analogous valuative criterion in the setting of spectral algebraic spaces (see Theorem 5.3.0.1 and Corollary 5.3.1.2).

Remark 5.0.0.1. The material described in §5.1 through §5.3 really has nothing to do with spectral algebraic geometry. If $f : \mathsf{X} \to \mathsf{Y}$ is a morphism of spectral algebraic spaces and $f_0 : \mathsf{X}_0 \to \mathsf{Y}_0$ is the underlying map of classical algebraic spaces, then:

- The morphism f is proper if and only if f_0 is proper (Remark 5.1.2.2).
- The morphism f is finite if and only if f_0 is finite (Remark 5.2.0.2).
- The morphism f satisfies the valuative criterion of properness (or separatedness) if and only if the morphism f_0 satisfies the valuative criterion of properness (or separatedness).

Let X be a topological space and let $\mathcal{O}$ be a sheaf of commutative rings on X. Recall that a sheaf $\mathscr{F}$ of (discrete) $\mathcal{O}$-modules is said to be *coherent* if $\mathscr{F}$ is locally finitely generated and, for any open subset $U \subseteq X$ and any map $\alpha : \mathcal{O}^n |_U \to \mathscr{F} |_U$, the kernel of α is also locally finitely generated. In §**??**, we extend the definition of coherence to sheaves of module spectra on a spectrally ringed ∞-topos $\mathsf{X} = (\mathcal{X}, \mathcal{O})$ (Definition **??**). In the case where X is a locally Noetherian spectral Deligne-Mumford stack, we show that an object $\mathscr{F} \in \mathrm{Mod}_{\mathcal{O}}$ is coherent and hypercomplete if and only if it is quasi-coherent and almost perfect (Proposition **??**). Consequently, we can view the theory of almost perfect sheaves as providing an extension of the theory of coherent sheaves to non-Noetherian settings. Alternatively, we can view the theory of coherent sheaves as an extension of the theory of almost perfect sheaves to settings outside of algebraic geometry (such as the setting of derived complex analytic geometry, which we study in §**??**).

If $f : X \to Y$ is a proper morphism between Noetherian schemes, then Grothendieck's direct image theorem asserts that the derived direct image functors $R^i f_*$ carry coherent sheaves on X to coherent sheaves on Y. This theorem was generalized to the setting of algebraic spaces by Knutson ([117]). In the language of spectral algebraic geometry, Knutson's result asserts that if $f : \mathsf{X} \to \mathsf{Y}$ is a proper morphism between 0-truncated spectral algebraic spaces, then the direct image functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ carries coherent objects to coherent objects, or equivalently (by virtue of Proposition **??**) that f_* carries almost perfect objects of $\mathrm{QCoh}(\mathsf{X})$ to almost perfect objects of $\mathrm{QCoh}(\mathsf{Y})$. In §5.6, we will prove a more general assertion: for any morphism of spectral Deligne-Mumford stacks $f : \mathsf{X} \to \mathsf{Y}$ which is proper and locally almost of finite presentation, the direct image functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ carries almost perfect objects to almost perfect objects (Theorem 5.6.0.2). When X and Y are locally Noetherian, this is an elementary consequence of the direct image theorem of classical algebraic geometry (in the setting of algebraic spaces). We will prove Theorem 5.6.0.2 in general by reduction to the Noetherian case, using the approximation techniques of Chapter 4.

Remark 5.0.0.2. In the setting of classical algebraic geometry, Theorem 5.6.0.2 was proven by Illusie in the case where $f : \mathsf{X} \to \mathsf{Y}$ is projective, and by Kiehl in general. See [101] and [116].

Warning 5.0.0.3. The notion of proper morphism that we consider in this section is more restrictive than the standard notion in the stack-theoretic literature: for a morphism $f : \mathsf{X} \to \mathsf{Y}$ to be proper, we require that the relative diagonal $\delta : \mathsf{X} \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ be a closed immersion. This excludes many examples of geometric interest (such as moduli stacks of stable curves).

Contents

5.1 Properness

5.1.1 Universally Closed Morphisms

Let $f : \mathsf{X} \to \mathsf{Y}$ be a separated morphism of spectral algebraic spaces. Then, for every pullback diagram

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y} \end{array}$$

the map f' is also separated. It follows that if Y' is a quasi-separated spectral algebraic space, then X' is also a quasi-separated spectral algebraic space. In this case, f' induces a map of topological spaces $|\mathsf{X}'| \to |\mathsf{Y}'|$.

Proposition 5.1.1.1. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a separated morphism of spectral algebraic spaces. The following conditions are equivalent:*

(*a*) *For every pullback diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow{\scriptstyle f} \\ \operatorname{Sp\acute{e}t} R & \longrightarrow & \mathsf{Y}, \end{array}$$

the induced map of topological spaces $|\,\mathsf{X}'\,| \to |\operatorname{Sp\acute{e}t} R| \simeq |\operatorname{Spec} R|$ *is closed.*

(*b*) *For every pullback diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y} \end{array}$$

where Y' *is a quasi-separated spectral algebraic space, the induced map of topological spaces* $|\,\mathsf{X}'\,| \to |\,\mathsf{Y}'\,|$ *is closed.*

Definition 5.1.1.2. Let $f : \mathsf{X} \to \mathsf{Y}$ be a separated morphism of spectral Deligne-Mumford stacks. We will say that f is *universally closed* if it satisfies the equivalent conditions of Proposition 5.1.1.1.

Proof of Proposition 5.1.1.1. The implication $(b) \Rightarrow (a)$ is obvious. Conversely, suppose that (a) is satisfied and that we are given a pullback square

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y}, \end{array}$$

where Y' is a quasi-separated spectral algebraic space. We wish to show that the natural map $|\,\mathsf{X}'\,| \to |\,\mathsf{Y}'\,|$ is closed. Writing Y' as a union of its quasi-compact open substacks, we can reduce to the case where Y' is quasi-compact. Choose an étale surjection $\operatorname{Sp\acute{e}t} R \to \mathsf{Y}'$, and form a pullback diagram

$$\begin{array}{ccc} \mathsf{X}'' & \longrightarrow & \mathsf{X}' \\ \downarrow & & \downarrow \\ \operatorname{Sp\acute{e}t} R & \longrightarrow & \mathsf{Y}'. \end{array}$$

We then obtain a diagram of topological spaces

$$\begin{array}{ccc} |\,\mathsf{X}''\,| & \xrightarrow{\psi} & |\,\mathsf{X}'\,| \\ \downarrow{\scriptstyle \phi'} & & \downarrow{\scriptstyle \phi} \\ |\operatorname{Spec} R| & \xrightarrow{\psi'} & |\,\mathsf{Y}'\,|. \end{array}$$

Let $K \subseteq |\mathsf{X}'|$ be closed; we wish to show that $\phi(K)$ is closed. Since $\psi^{-1}K$ is a closed subset of $|\mathsf{X}'|$, condition (a) implies that $\phi'(\psi^{-1}K)$ is a closed subset of $|\operatorname{Spec} R|$. Corollary 3.6.3.2 gives $\psi'^{-1}(\phi(K)) = \phi'(\psi^{-1}K)$, so that $\psi'^{-1}(\phi(K))$ is a closed subset of $|\operatorname{Spec} R|$. Since ψ' is a quotient map (Proposition 3.6.3.6), we conclude that $\phi(K)$ is a closed subset of $|\mathsf{Y}'|$. □

Remark 5.1.1.3. Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y}, \end{array}$$

where the vertical maps are separated. If f is universally closed, then so is f'.

Remark 5.1.1.4. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of quasi-compact, quasi-separated algebraic spaces, and let $\phi : |\mathsf{X}| \to |\mathsf{Y}|$ be the underlying map of topological spaces. Then the fibers of ϕ are quasi-compact. It follows that for any filtered collection of closed subsets $\{K_\alpha \subseteq |\mathsf{X}|\}$, we have $\phi(\bigcap K_\alpha) = \bigcap \phi(K_\alpha)$. Since $|\mathsf{X}|$ has a basis of quasi-compact open subsets, every closed set $K \subseteq |\mathsf{X}|$ can be obtained as a (filtered) intersection of closed subsets with quasi-compact complements. Consequently, to prove that ϕ is closed, it will suffice to show that $\phi(K) \subseteq |\mathsf{Y}|$ is closed whenever $K \subseteq |\mathsf{X}|$ is the complement of a quasi-compact open subset of $|\mathsf{X}|$.

Remark 5.1.1.5. Let $f : \mathsf{X} \to \operatorname{Spét} R$ be a morphism of quasi-compact, quasi-separated spectral algebraic spaces. Suppose we wish to verify that f is universally closed. Let $R \to R'$ be an arbitrary map of connective $\mathbb{E}_\infty$-rings and set $\mathsf{X}' = \mathsf{X} \times_{\operatorname{Spét} R} \operatorname{Spét} R'$; we wish to prove that the map $\phi : |\mathsf{X}'| \to |\operatorname{Spec} R'|$ is closed. According to Remark 5.1.1.4, it suffices to show that $\phi(K) \subseteq |\operatorname{Spec} R'|$ is closed whenever $K \subseteq |\mathsf{X}'|$ is the complement of a quasi-compact open subset of $|\mathsf{X}'|$. Write $R' = \varinjlim R_\alpha$ in $\mathrm{CAlg}^{\mathrm{cn}}_R$, where each R_α is of finite presentation over R, and set $\mathsf{X}_\alpha = \mathsf{X} \times_{\operatorname{Spét} R} \operatorname{Spét} R_\alpha$. According to Proposition 4.3.5.5, every quasi-compact open subset of $|\mathsf{X}'|$ is the inverse image of a quasi-compact open subset of some $|\mathsf{X}_\alpha|$. It will therefore suffice to show that the map $\phi_\alpha : |\mathsf{X}_\alpha| \to |\operatorname{Spec} R_\alpha|$ is closed. In other words, to verify condition (a) of Proposition 5.1.1.1, it suffices to treat the case where R' is finitely presented over R. In particular, if R is Noetherian, we may assume that R' is also Noetherian (Proposition HA.7.2.4.31).

5.1.2 Proper Morphisms

We can now introduce the main definition of interest to us in this section:

Definition 5.1.2.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. We will say that f is *proper* if it is quasi-compact (Definition 2.3.2.2, separated (Definition 3.2.0.1), locally of finite type (Definition 4.2.0.1), and universally closed (Definition 5.1.1.2).

Remark 5.1.2.2. The condition that a morphism of spectral Deligne-Mumford stacks $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ be proper depends only on the induced map of 0-truncated spectral Deligne-Mumford stacks $(\mathcal{X}, \pi_0 \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \pi_0 \mathcal{O}_{\mathcal{Y}})$. If $(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$ and $(\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ are spectral algebraic spaces, then f is proper if and only if the induced map $(\mathcal{X}, \pi_0 \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \pi_0 \mathcal{O}_{\mathcal{Y}})$ is proper when regarded as a map of algebraic spaces, in the sense of [117].

Warning 5.1.2.3. When restricted to 0-truncated, 1-localic spectral Deligne-Mumford stacks, Definition 5.1.2.1 does not recover the usual notion of proper morphism between ordinary Deligne-Mumford stacks (because Definition 5.1.2.1 requires that the diagonal of a proper morphism $\mathsf{X} \to \mathsf{Y}$ is a closed immersion). It is possible to introduce a less restrictive version of Definition 5.1.2.1, which agrees with the usual notion of proper morphism in the classical case. However, this more general concept of properness will not be needed in this book.

Example 5.1.2.4. Let $f : \mathsf{X} \to \mathsf{Y}$ be a closed immersion of spectral Deligne-Mumford stacks. Then f is proper.

5.1.3 Pullbacks of Proper Morphisms

We now study the behavior of proper morphisms under base change.

Proposition 5.1.3.1. *Suppose we are given a pullback diagram*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \xrightarrow{g} & \mathsf{Y} \end{array}$$

of spectral Deligne-Mumford stacks. Then:

(*a*) *If f is proper, then f' is also proper.*

(*b*) *If f' is proper, f is separated, and g is a flat covering (Definition 2.8.3.1), then f is proper.*

Proof. Assertion (*a*) follows from the fact that the collections of separated, locally finite type, quasi-compact, and universally closed morphisms are stable under pullbacks (Remark 3.2.1.4, Proposition 4.2.1.6, Proposition 2.3.3.1, and Remark 5.1.1.3). Let us prove (*b*). Assume that f' is proper, f is separated, and that g is a flat covering. We wish to prove that f is proper. It follows from Proposition 4.2.1.5 that f is locally of finite type. We wish to show that f is quasi-compact and universally closed. In other words, we wish to show that for any map $\mathsf{Y}_0 \to \mathsf{Y}$ where Y_0 is affine, the fiber product $\mathsf{X}_0 = \mathsf{Y}_0 \times_{\mathsf{Y}} \mathsf{X}$ is quasi-compact and the projection map $|\mathsf{X}_0| \to |\mathsf{Y}_0|$ is closed. Since g is a flat covering, we can choose an étale map $\mathsf{Y}'_0 \to \mathsf{Y}' \times_{\mathsf{Y}} \mathsf{Y}_0$ where Y'_0 is affine and the map $\mathsf{Y}'_0 \to \mathsf{Y}_0$ is flat and surjective. Set $\mathsf{X}'_0 = \mathsf{Y}'_0 \times_{\mathsf{Y}} \mathsf{X}$. Since f' is quasi-compact, we conclude that X'_0 is quasi-compact, so that X_0 is quasi-compact by virtue of Proposition 2.3.3.1. We have a commutative diagram of topological spaces

$$\begin{array}{ccc} |\mathsf{X}'_0| & \xrightarrow{\psi} & |\mathsf{X}_0| \\ \downarrow{\scriptstyle \phi'} & & \downarrow{\scriptstyle \phi} \\ |\mathsf{Y}'_0| & \xrightarrow{\psi'} & |\mathsf{Y}_0|. \end{array}$$

Let $K \subseteq |\mathsf{X}_0|$ be closed; we wish to show that $\phi(K) \subseteq |\mathsf{Y}_0|$ is closed. Since $\psi^{-1}K$ is a closed subset of $|\mathsf{X}'_0|$, our hypothesis that f' is proper guarantees that $\phi'(\psi^{-1}K)$ is a closed subset of $|\operatorname{Spec} R|$. Corollary 3.6.3.2 gives $\psi'^{-1}(\phi(K)) = \phi'(\psi^{-1}K)$, so that $\psi'^{-1}(\phi(K))$ is a closed subset of $|\mathsf{Y}'_0|$. Since ψ' is a quotient map (Proposition 3.6.3.6), we conclude that $\phi(K)$ is a closed subset of $|\mathsf{Y}_0|$ as desired. □

Corollary 5.1.3.2. *The condition that a morphism $f : \mathsf{X} \to \mathsf{Y}$ be proper is local on the target with respect to the étale topology. That is, if we are given an étale surjection for which the projection map $\mathsf{X} \times_{\mathsf{Y}} \mathsf{Y}' \to \mathsf{Y}'$ is proper, then f is proper.*

Proof. Combine Remark 3.2.1.4 with Proposition 5.1.3.1. □

Remark 5.1.3.3. Suppose we are given a collection of proper morphisms $\{f_\alpha : \mathsf{X}_\alpha \to \mathsf{Y}_\alpha\}$. Then the induced map $\amalg \mathsf{X}_\alpha \to \amalg \mathsf{Y}_\alpha$ is proper.

5.1.4 Composition of Proper Morphisms

We conclude this section by studying the behavior of proper morphisms under composition.

Proposition 5.1.4.1. *Suppose we are given a commutative diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X} & \xrightarrow{f} & \mathsf{Y} \\ & \searrow \quad \swarrow{\scriptstyle g} & \\ & \mathsf{Z}. & \end{array}$$

Then:

(1) *If f and g are proper, then $g \circ f$ is proper.*

(2) *If $g \circ f$ is proper and g is separated, then f is proper.*

(3) *If $g \circ f$ is proper, g is separated and locally of finite type, and f is surjective, then g is proper.*

Proof. We first prove (1). Assume that f and g are proper. Using Remark 3.2.1.6, Proposition 2.3.5.1, and Proposition 4.1.3.1, we see that $g \circ f$ is separated, quasi-compact, and locally of finite type. It will therefore suffice to show that $g \circ f$ is universally closed. Choose a morphism $\mathsf{Z}_0 \to \mathsf{Z}$, where Z_0 is quasi-separated spectral algebraic space; we wish to show that the composite map

$$|\,\mathsf{Z}_0 \times_{\mathsf{Z}} \mathsf{X}\,| \xrightarrow{\phi} |\,\mathsf{Z}_0 \times_{\mathsf{Z}} \mathsf{Y}\,| \xrightarrow{\psi} |\,\mathsf{Z}_0\,|$$

is closed. This is clear: our assumption that f is universally closed guarantees that ϕ is closed, and our assumption that g is universally closed guarantees that ψ is closed.

We now prove (2). Assume that g is separated and that $g \circ f$ is proper. The map f factors as a composition

$$\mathsf{X} \xrightarrow{f'} \mathsf{X} \times_{\mathsf{Z}} \mathsf{Y} \xrightarrow{f''} \mathsf{Y}.$$

The map f'' is a pullback of $g \circ f$ and therefore proper (Proposition 5.1.3.1). The map f' is a pullback of the diagonal map $\mathsf{Y} \to \mathsf{Y} \times_{\mathsf{Z}} \mathsf{Y}$, and is therefore a closed immersion by virtue of our assumption that g is separated. It follows that f' is proper (Example 5.1.2.4), so that $f = f'' \circ f'$ is proper by assertion (1).

We now prove (3). The assertion is local on Z, so we may assume without loss of generality that $\mathsf{Z} = \operatorname{Spét} R$ is affine. Then X is quasi-compact. Since f is surjective, we deduce that Y is quasi-compact (Proposition 2.3.3.1), so that the morphism g is quasi-compact. We will complete the proof by showing that g is universally closed. Let R' be a connective R-algebra; we wish to show that the map $|\operatorname{Spét} R' \times_{\operatorname{Spét} R} \mathsf{Y}\,| \to |\operatorname{Spec} R'|$ is closed. Replacing Z by $\operatorname{Spét} R'$, we are reduced to proving that the map $|\,\mathsf{Y}\,| \to |\,\mathsf{Z}\,|$ is closed. Let $K \subseteq |\,\mathsf{Y}\,|$ be a closed subset. Since f is surjective, and $g \circ f$ is proper, we deduce that $g(K) = (g \circ f)(f^{-1}K)$ is a closed subset of $|\,\mathsf{Z}\,|$, as desired. □

5.2 Finite Morphisms

Let $f : X \to Y$ be a morphism of schemes. Recall that f is said to be *finite* if, for every map $\operatorname{Spec} A \to Y$, the fiber product $X \times_Y \operatorname{Spec} A$ is isomorphic to an affine scheme $\operatorname{Spec} B$, where B is finitely generated as an A-module. This notion admits a straightforward extension to the setting of spectral algebraic geometry:

Definition 5.2.0.1. Let $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ be a morphism of spectral Deligne-Mumford stacks. We will say that f is *finite* if it satisfies the following pair of conditions:

(1) The morphism f is affine.

(2) The pushforward $f_* \mathcal{O}_{\mathcal{X}}$ is perfect to order 0 (as a quasi-coherent sheaf on $(\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$).

Remark 5.2.0.2. Let $f : (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ be a morphism of spectral Deligne-Mumford stacks. Then f is finite if and only if the induced map $f_0 : (\mathcal{X}, \pi_0 \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}, \pi_0 \mathscr{O}_{\mathcal{Y}})$ is finite (see Remark 2.4.4.2). In particular, a morphism of spectral algebraic spaces is finite if and only if it induces a finite morphism between the underlying ordinary algebraic spaces, in the sense of classical algebraic geometry.

5.2.1 Finite Morphisms and Proper Morphisms

Definitions 5.2.0.1 and 5.1.2.1 are closely related:

Proposition 5.2.1.1. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. The following conditions are equivalent:*

(1) *The morphism f is finite.*

(2) *The morphism f is proper and locally quasi-finite.*

(3) *The morphism f is proper and quasi-affine.*

(4) *The morphism f is proper and affine.*

The proof of Proposition 5.2.1.1 depends on the following bit of commutative algebra:

Proposition 5.2.1.2 ("Lying Over")**.** *Let $f : R \to R'$ be a homomorphism of commutative rings. Suppose that f is injective and integral (that is, every element of R' is integral over R). Then the induced map $|\operatorname{Spec} R'| \to |\operatorname{Spec} R|$ is surjective.*

Proof. Let $\mathfrak{p}$ be a prime ideal of R; we wish to show that $\mathfrak{p}$ lies in the image of the map $|\operatorname{Spec} R'| \to |\operatorname{Spec} R|$. Replacing R by the localization $R_{\mathfrak{p}}$ (and R' by the ring $R_{\mathfrak{p}} \otimes_R R'$), we may assume that R is a local ring and that $\mathfrak{p}$ is its maximal ideal. We wish to show that there is a prime ideal of R' which lies over $\mathfrak{p}$: in other words, that the quotient $R'/\mathfrak{p}R'$ is not zero. Assume otherwise: then $\mathfrak{p}R' = R'$. We can therefore choose a finitely generated R'-subalgebra $R'' \subseteq R'$ such that $\mathfrak{p}R'' = R''$. Since every element of R' is integral over R, the ring R'' is finitely generated as an R-module. Applying Nakayama's lemma, we deduce that $R'' \simeq 0$. Since the composite map $R \to R'' \to R'$ is injective, we conclude that $R \simeq 0$, contradicting our assumption that R is local. □

Corollary 5.2.1.3. *Let $f : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings. The following conditions are equivalent:*

(*a*) *Every element of the commutative ring $\pi_0 B$ is integral over $\pi_0 A$.*

(*b*) *The induced map $\operatorname{Spét} B \to \operatorname{Spét} A$ is universally closed. In other words, for every connective A-algebra A', the induced map of topological spaces $|\operatorname{Spec} A' \otimes_A B| \to |\operatorname{Spec} A'|$ is closed.*

Proof. We first show that $(a) \Rightarrow (b)$. Replacing A and B by A' and B', it will suffice to show that condition (a) implies that the map $\phi : |\operatorname{Spec} B| \rightarrow |\operatorname{Spec} A|$ is closed. Let K be a closed subset of $|\operatorname{Spec} B|$; we wish to show that $\phi(K) \subseteq |\operatorname{Spec} A|$ is closed. Write K as the image of $|\operatorname{Spec} B/I|$ for some ideal $I \subseteq B$. Set $J = f^{-1}(I) \subseteq A$. We wish to show that the composite map $K \simeq |\operatorname{Spec} B/I| \xrightarrow{\phi_0} |\operatorname{Spec} A/J| \xrightarrow{\psi} |\operatorname{Spec} A|$ has closed image. This is clear, since ψ has closed image and the map ϕ_0 is surjective by virtue of Proposition 5.2.1.2.

We now show that (b) implies (a). Assume that f satisfies condition (b) and let x be an element of $\pi_0 B$; we wish to show that x is integral over $\pi_0 A$. Since f is universally closed, the map

$$|\operatorname{Spec}(\pi_0 B)[y]| \simeq |\operatorname{Spec}(\pi_0 A)[y] \otimes_A B| \rightarrow |\operatorname{Spec}(\pi_0 A)[y]|$$

is closed. Set $R = (\pi_0 B)[x^{-1}]$, so that we can identify R with the quotient of $(\pi_0 B)[y]$ by the ideal generated by the element $1 - xy$. It follows that the map $|\operatorname{Spec} R| \rightarrow |\operatorname{Spec}(\pi_0 A)[y]|$ has closed image, which can be described as the vanishing locus of some ideal $J \subseteq (\pi_0 A)[y]$. Note that K does not intersect the vanishing locus of the principal ideal $(y) \subseteq (\pi_0 A)(y)$ (since the image of y in R is invertible), so that J and (y) generate the unit ideal in $(\pi_0 A)[y]$. It follows that J contains some polynomial of the form $1 + a_1 y + \cdots + a_n y^n$, where the coefficients a_i belong to $\pi_0 A$. Raising this polynomial to a suitable power, we may assume that its image in R vanishes: that is, we have $1 + a_1 x^{-1} + \cdots + a_n x^{-n} = 0$ in $R = (\pi_0 B)[x^{-1}]$. It follows that It follows that $x^{m+n} + a_1 x^{m+n-1} + \cdots + a_n x^m$ vanishes in $\pi_0 B$ for $m \gg 0$, so that x is integral over $\pi_0 A$ as desired. □

Proof of Proposition 5.2.1.1. Let $f : \mathsf{X} \rightarrow \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Note that each of the conditions appearing in the statement of Proposition 5.2.1.1 can be tested locally on Y; we may therefore assume without loss of generality that $\mathsf{Y} \simeq \operatorname{Spét} A$ is affine.

We first show that $(1) \Rightarrow (2)$. Assume that f is finite, so that $\mathsf{X} \simeq \operatorname{Spét} B$ for some connective $\mathbb{E}_\infty$-ring B for which $\pi_0 B$ is finitely generated as a module over $\pi_0 A$. We claim that f is proper. It is clear that f is quasi-compact, separated, and locally of finite type. We claim that it is universally closed: that is, for every connective A-algebra A', the induced map of topological spaces $|\operatorname{Spec}(A' \otimes_A B)| \rightarrow |\operatorname{Spec} A'|$ is closed. This is an immediate consequence of Corollary 5.2.1.3 (since every element of $\pi_0(A' \otimes_A B) \simeq \operatorname{Tor}_0^{\pi_0 A}(\pi_0 A', \pi_0 B)$ is integral over $\pi_0 A'$). To complete the proof of the implication $(1) \Rightarrow (2)$, it suffices to observe that every finite morphism of commutative rings is quasi-finite (Example B.2.4.4).

The implication $(2) \Rightarrow (3)$ follows from Theorem 3.3.0.2. We next show that $(3) \Rightarrow (4)$. Assume that f is proper and quasi-affine, so there exists a quasi-compact open immersion $j : \mathsf{X} \rightarrow \operatorname{Spét} B$ for some connective $\mathbb{E}_\infty$-algebra B over A. The projection map $\operatorname{Spét} A \rightarrow \operatorname{Spét} R$ is separated, so that j induces a closed immersion $\gamma : \mathsf{X} \rightarrow \mathsf{X} \times_{\operatorname{Spét} A} \operatorname{Spét} B$. Since f is proper, the canonical map $|\mathsf{X} \times_{\operatorname{Spét} A} \operatorname{Spét} B| \rightarrow |\operatorname{Spét} B|$ is closed. It follows that j has closed image in the topological space $|\operatorname{Sp\acute{e}t} B| \simeq |\operatorname{Spec} B|$, so that j is a clopen immersion and therefore X is affine.

We now complete the proof by showing that (4) ⇒ (1). Assume that f is proper and affine, so that we can write $\mathsf{X} = \operatorname{Sp\acute{e}t} B$ for some connective $\mathbb{E}_\infty$-ring B. Since f is locally of finite type, the commutative ring $\pi_0 B$ is finitely generated as an algebra over $\pi_0 A$. Corollary 5.2.1.3 shows that every element of $\pi_0 B$ is integral over $\pi_0 A$, so that $\pi_0 B$ is also finitely generated as a $\pi_0 A$-module. □

5.2.2 Stronger Finiteness Conditions

Let $f : A \to B$ be a homomorphism of commutative rings which exhibits B as a finitely generated A-module. Then B is finitely presented as an A-module if and only if it is finitely presented as an A-algebra. This observation generalizes to the setting of spectral algebraic geometry:

Proposition 5.2.2.1. *Let $f : \mathsf{X} = (\mathcal{X}, \mathcal{O}_\mathcal{X}) \to \mathsf{Y}$ be a finite morphism of spectral Deligne-Mumford stacks and let $n \geqslant 0$. The following conditions are equivalent:*

(1) *The morphism f is locally finitely n-presented (Definition 4.2.3.1)*

(2) *The direct image $f_* \mathcal{O}_\mathcal{X}$ is finitely n-presented as an object of* $\operatorname{QCoh}(\mathsf{Y})$ *(Definition 2.8.4.4).*

Corollary 5.2.2.2. *Let $f : \mathsf{X} = (\mathcal{X}, \mathcal{O}_\mathcal{X}) \to \mathsf{Y}$ be a finite morphism of spectral Deligne-Mumford stacks. The following conditions are equivalent:*

(1) *The morphism f is locally almost of finite presentation.*

(2) *The direct image $f_* \mathcal{O}_\mathcal{X}$ is almost perfect as an object of* $\operatorname{QCoh}(\mathsf{Y})$.

Corollary 5.2.2.3. *Let $\phi : A \to B$ be a morphism of commutative rings. Then the following conditions are equivalent:*

(a) *The morphism ϕ is almost of finite presentation when regarded as a morphism of $\mathbb{E}_\infty$-rings.*

(b) *The morphism ϕ factors as a composition $A \to A[x_1, \ldots, x_n] \xrightarrow{\phi'} B$, where ϕ exhibits B as an almost perfect module over $A[x_1, \ldots, x_n]$.*

Proof. Suppose first that (b) is satisfied. Corollary 5.2.2.2 implies that the map $\phi' : A[x_1, \ldots, x_n] \to B$ is almost of finite presentation, so we are reduced to showing that the map $A \to A[x_1, \ldots, x_n]$ is almost of finite presentation. Since the condition of being almost of finite presentation is stable under base change, we may assume without loss of generality that $A = \mathbf{Z}$, in which case the desired result follows from Theorem HA.7.2.4.31 .

Now suppose that (a) is satisfied. Then B is of finite type over A, so there exists a surjection of A-algebras $\phi' : A[x_1, \ldots, x_n] \to B$. Since B and $A[x_1, \ldots, x_n]$ are both almost of finite presentation over A, the morphism ϕ' is almost of finite presentation (Corollary HA.7.4.3.19). It follows from Corollary 5.2.2.2 that ϕ' exhibits B as an almost perfect $A[x_1, \ldots, x_n]$-module, so that condition (b) is satisfied. □

Remark 5.2.2.4. In the language of [101], Corollary 5.2.2.3 asserts that ϕ is almost of finite presentation if and only if the induced map of affine schemes $\operatorname{Spec} B \to \operatorname{Spec} A$ is *pseudo-coherent*.

Corollary 5.2.2.5. *Let $f : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings which exhibits A as a square-zero extension of B by a connective B-module M. If M is almost perfect as a B-module, then f is almost of finite presentation.*

Proof. By virtue of Corollary 5.2.2.2, it will suffice to show that B is almost perfect as an A-module. We argue that, for every integer $n \geqslant 0$, B is perfect to order n as an A-module. The proof proceeds by induction on n. The case $n = 0$ is trivial (since the map $\pi_0 A \to \pi_0 B$ is surjective). To carry out the inductive step, let us assume $n > 0$ and that B is perfect to order $(n-1)$ as an A-module. It follows from Proposition 2.7.3.3 that M is also perfect to order $(n-1)$ as an A-module. The cofiber sequence of A-modules $A \to B \to \Sigma(M)$ then shows that B is perfect to order n as an A-module, as desired. □

The proof of Proposition 5.2.2.1 will require the following category-theoretic fact:

Lemma 5.2.2.6. *Let $\mathcal{C}$ be a symmetric monoidal ∞-category which admits filtered colimits, and suppose that the tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves filtered colimits. Let $A \in \mathrm{CAlg}(\mathcal{C})$. Assume that $\mathcal{C}$ is equivalent to an n-category for some integer $n \geqslant 1$, and that each tensor power $A^{\otimes m}$ is a compact object of $\mathcal{C}$. Then A is a compact object of $\mathrm{CAlg}(\mathcal{C})$.*

Proof. Let P be a filtered partially ordered set, let $P^{\rhd}$ be the partially ordered set obtained from P by adjoining a new largest element which we will denote by ω, and suppose we are given a diagram $B : \mathrm{N}(P^{\rhd}) \to \mathrm{CAlg}(\mathcal{C})$. We wish to prove that the canonical map

$$\varinjlim_{\alpha \in P} \mathrm{Map}_{\mathrm{CAlg}(\mathcal{C})}(A, B(\alpha)) \to \mathrm{Map}_{\mathrm{CAlg}(\mathcal{C})}(A, B(\omega))$$

is a homotopy equivalence.

For each element $\alpha \in P^{\rhd}$, we let $P^{\rhd}_{\geqslant \alpha}$ denote the subset of $P^{\rhd}$ consisting of elements which are $\geqslant \alpha$, and let $B^{\geqslant \alpha}$ be the restriction of B to $\mathrm{N}(P^{\rhd}_{\geqslant \alpha})$. Let $\mathrm{Comm}^{\otimes}$ denote the commutative ∞-operad, and let $q : \mathcal{C}^{\otimes} \to \mathrm{Comm}^{\otimes}$ exhibit $\mathcal{C}^{\otimes}$ as a symmetric monoidal ∞-category. Since $\mathcal{C}$ is equivalent to an n-category, we may assume without loss of generality that the simplicial set $\mathcal{C}^{\otimes}$ is $(n+2)$-coskeletal.

For each index $\alpha \in P^{\rhd}$, let $\mathcal{C}(\alpha)^{\otimes}$ denote the ∞-operad $\mathcal{C}^{\otimes}_{/B^{\geqslant\alpha}_{\mathrm{Comm}^{\otimes}}}$ described in Theorem HA.2.2.2.4 , so that we have canonical equivalences

$$\mathrm{CAlg}(\mathcal{C}(\alpha)) \simeq \mathrm{CAlg}(\mathcal{C})_{/B^{\geqslant\alpha}} \simeq \mathrm{CAlg}(\mathcal{C})_{/B(\alpha)}$$

for each $\alpha \in P^{\rhd}$. We are therefore reduced to proving that the canonical map

$$\varinjlim_{\alpha\in P} \mathrm{CAlg}(\mathcal{C}(\alpha)) \times_{\mathrm{CAlg}(\mathcal{C})} \{A\} \to \mathrm{CAlg}(\mathcal{C}(\omega)) \times_{\mathrm{CAlg}(\mathcal{C})} \{A\}$$

is a homotopy equivalence.

For each α in $P^{\rhd}$, let $\mathcal{B}(\alpha)^{\otimes}$ denote the fiber product $\mathrm{Comm}^{\otimes} \times_{\mathcal{C}^{\otimes}} \mathcal{C}(\alpha)^{\otimes}$. We wish to prove that the canonical map $\varinjlim_{\alpha\in P} \mathrm{CAlg}(\mathcal{B}(\alpha)) \to \mathrm{CAlg}(\mathcal{B}(\omega))$ is a homotopy equivalence. Since the $(n+2)$-skeleton of $\mathrm{Comm}^{\otimes}$ is a finite simplicial set, the construction $\mathcal{D}^{\otimes} \mapsto \mathrm{CAlg}(\mathcal{D})$ commutes with filtered colimits when restricted to ∞-operads which are $(n+2)$-coskeletal. We are therefore reduced to proving that the map $\theta : \varinjlim_{\alpha\in P} \mathcal{B}(\alpha)^{\otimes} \to \mathcal{B}(\omega)^{\otimes}$ is an equivalence of ∞-operads. This follows easily from our assumption that each tensor power $A^{\otimes m}$ is compact when regarded as an object of $\mathcal{C}$. □

Proof of Proposition 5.2.2.1. Let $f : \mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to \mathsf{Y}$ be a finite morphism of spectral Deligne-Mumford stacks; we wish to show that f is locally finitely n-presented if and only if the direct image $f_* \mathscr{O}_{\mathcal{X}} \in \mathrm{QCoh}(\mathsf{Y})$ is finitely n-presented. Both assertions can be tested locally on Y, so we may assume without loss of generality that $\mathsf{Y} \simeq \mathrm{Sp\acute{e}t}\, A$ is affine. Since f is finite, we can write $\mathsf{X} \simeq \mathrm{Sp\acute{e}t}\, B$ for some connective $\mathbb{E}_{\infty}$-algebra B over A. Suppose first that f is locally almost of finite presentation; we wish to show that B is finitely n-presented as an A-module. Write A as a filtered colimit $\varinjlim A_{\alpha}$, where each A_{α} is a compact object of $\mathrm{CAlg}^{\mathrm{cn}}$ and therefore Noetherian. Using Corollary **??**, we can choose an index α and an equivalence $B \simeq \tau_{\leqslant n}(A \otimes_{A_{\alpha}} B_{\alpha})$, where B_{α} is finitely n-presented over A_{α}. Let $x_1, \ldots, x_n \in \pi_0 B_{\alpha}$ be a collection of elements which generate $\pi_0 B_{\alpha}$ as an algebra over $\pi_0 A_{\alpha}$. Let $\overline{x}_i$ denote the image of x_i in $\pi_0 B$. Since $\pi_0 B$ is a finitely generated module over $\pi_0 A$, each $\overline{x}_i$ is integral over $\pi_0 A$ and therefore is therefore the solution to some polynomial equation $\overline{f}_i(\overline{x}_i) = 0$ where the coefficients of $\overline{f}_i$ lie in $\pi_0 A$. Enlarging α if necessary, we can assume that each $\overline{f}_i$ can be lifted to a polynomial f_i having coefficients in $\pi_0 A_{\alpha}$ and that $f_i(x_i) = 0$. It follows that each x_i is integral over $\pi_0 A_{\alpha}$, so that $\pi_0 B_{\alpha}$ is finitely generated as a module over $\pi_0 A_{\alpha}$. We may therefore replace A by A_{α} and B by B_{α}, thereby reducing to the case where A is Noetherian. In this case, B is also Noetherian. It follows that each homotopy group $\pi_i B$ is finitely generated as a module over $\pi_0 B$, and therefore also as a module over $\pi_0 A$ (since $\pi_0 B$ is a finitely generated $\pi_0 A$-module). It follows from Corollary 2.7.2.3 that B is finitely n-presented over A, as desired.

Now suppose that B is finitely n-presented as an A-module; we wish to show that f is locally finitely n-presented. Let $\mathcal{C}$ denote the full subcategory of Mod_A spanned by those

A-modules which are connective and n-truncated. Note that $\mathcal{C}$ inherits a symmetric monoidal structure, whose tensor product is given by the construction $(M, N) \mapsto \tau_{\leqslant n}(M \otimes_A N)$. Then B is compact when viewed as an object of $\mathcal{C}$, and we wish to show that B is compact when viewed as an object of $\mathrm{CAlg}(\mathcal{C})$. This follows from Lemma 5.2.2.6, since $\mathcal{C}$ is equivalent to an $(n+1)$-category and the collection of compact objects of $\mathcal{C}$ is stable under the tensor product on $\mathcal{C}$. □

5.2.3 Finite Flat Morphisms

We close this section by introducing the class of finite flat morphisms between spectral Deligne-Mumford stacks.

Definition 5.2.3.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. We will say that f is *finite flat* if f is finite and the direct image $f_* \mathscr{O}_{\mathsf{X}} \in \mathrm{QCoh}(\mathsf{Y})$ is locally free of finite rank (see Notation 2.9.3.1). We will say that f is *finite flat of degree d* if it is finite flat and the direct image $f_* \mathscr{O}_{\mathsf{X}}$ is locally free of rank d.

Example 5.2.3.2. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. If f is finite étale of degree d (Definition 3.3.2.3), then it is finite flat of degree d.

Proposition 5.2.3.3. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Then f is finite flat (in the sense of Definition 5.2.3.1) if and only if f is proper, flat, locally quasi-finite, and locally almost of finite presentation over Y.*

Proof. Suppose first that f is finite flat. Then f is finite, hence proper and locally quasi-finite (Proposition 5.2.1.1). Since f is affine and the direct image $f_* \mathscr{O}_{\mathsf{X}}$ is flat, we conclude that f is flat. Finally, f is locally almost of finite presentation because $f_* \mathscr{O}_{\mathsf{X}} \in \mathrm{QCoh}(\mathsf{Y})$ is almost perfect (Corollary 5.2.2.2).

For the converse, suppose that f is proper, flat, locally quasi-finite, and locally almost of finite presentation over Y. Then f is finite (Proposition 5.2.1.1), and in particular affine. The flatness of f then guarantees that $\mathscr{A} = f_* \mathscr{O}_{\mathsf{X}}$ is flat. Moreover, our assumption that f is locally almost of finite presentation guarantees that $f_* \mathscr{O}_{\mathsf{X}}$ is almost perfect. Applying Proposition HA.7.2.4.20 , we deduce that $\mathscr{A}$ is locally free of finite rank.

□

Warning 5.2.3.4. The hypothesis that f be locally almost of finite presentation is necessary in Proposition 5.2.3.3. A morphism $f : \mathsf{X} \to \mathsf{Y}$ which is both finite and flat need not be finite flat. For example, if X is a totally disconnected compact Hausdorff space, R is the commutative ring of locally constant $\mathbf{C}$-valued functions on X, and $\epsilon : R \to \mathbf{C}$ is the map given by evaluation at some point $x \in X$, then the induced map $\mathrm{Sp\acute{e}t}\, \mathbf{C} \to \mathrm{Sp\acute{e}t}\, R$ is both finite and flat, but exhibits $\mathbf{C}$ as a projective R-module only when x is an isolated point of X (otherwise, the field $\mathbf{C}$ is not finitely presented over R).

Remark 5.2.3.5. Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y}. \end{array}$$

If f is finite flat (of degree d), then f' is finite flat (of degree d). The converse holds if g is a flat covering.

Remark 5.2.3.6. Let $f : \mathsf{X} \to \mathsf{Y}$ and $g : \mathsf{Y} \to \mathsf{Z}$ be morphisms of spectral Deligne-Mumford stacks. If f is finite flat (of degree d) and g is finite flat (of degree d'), then the composition $g \circ f$ is also finite flat (of degree dd'). To prove this, we can assume without loss of generality that $\mathsf{Z} \simeq \operatorname{Spét} A$ is affine, so that $\mathsf{Y} \simeq \operatorname{Spét} B$ for some $\mathbb{E}_\infty$-algebra which is locally free of rank d' as an A-module, and $\mathsf{X} \simeq \operatorname{Spét} C$ for some $\mathbb{E}_\infty$-algebra C which is locally free rank d as a B-module; it then follows that C is locally free of rank dd' as an A-module.

5.3 Valuative Criteria

Let $f : X \to Y$ be a morphism of schemes which is separated and of finite type. According to the *valuative criterion of properness*, the morphism f is proper if and only if it satisfies the following condition:

$(*)$ For every valuation ring V with fraction field K and every commutative diagram

$$\begin{array}{ccc} \operatorname{Spec} K & \longrightarrow & X \\ \downarrow & \nearrow & \downarrow{\scriptstyle f} \\ \operatorname{Spec} V & \longrightarrow & Y, \end{array}$$

there exists a dotted arrow as indicated, rendering the diagram commutative (since f is separated, the dotted arrow is essentially unique).

Our goal in this section is to prove the following analogue in the setting of spectral Deligne-Mumford stacks:

Theorem 5.3.0.1 (Valuative Criterion for Properness)**.** *Let $f : \mathsf{X} \to \mathsf{Y}$ be a quasi-compact, separated map of spectral Deligne-Mumford stacks which is locally of finite type. Then f is proper if and only if the following condition is satisfied:*

$(*)$ *For every valuation ring V with fraction field K and every commutative diagram*

$$\begin{array}{ccc} \operatorname{Spét} K & \longrightarrow & \mathsf{X} \\ \downarrow & \nearrow & \downarrow \\ \operatorname{Spét} V & \longrightarrow & \mathsf{Y}, \end{array}$$

there exists a dotted arrow as indicated, rendering the diagram commutative.

Moreover, if Y *is locally Noetherian, then it suffices to verify condition* $(*)$ *in the special case where* V *is a discrete valuation ring.*

Remark 5.3.0.2. In the statement of Theorem 5.3.0.1, there is no loss of generality in assuming that Y is a spectral algebraic space (or even that Y is affine), in which case X is also a spectral algebraic space. In this case, the condition that $f : \mathsf{X} \to \mathsf{Y}$ is proper depends only on the underlying map $f_0 : \tau_{\leqslant 0} \mathsf{X} \to \tau_{\leqslant 0} \mathsf{Y}$ of ordinary algebraic spaces. Consequently, Theorem 5.3.0.1 follows immediately from the analogous statement for ordinary algebraic spaces (see [129] for a more general statement, which does not require that the diagonal of f is a closed immersion).

5.3.1 The Valuative Criterion for Separatedness

Before giving the proof of Theorem 5.3.0.1, let us describe some easy consequences:

Proposition 5.3.1.1 (Valuative Criterion for Separatedness)**.** *Let* $f : \mathsf{X} \to \mathsf{Y}$ *be a quasi-separated map of spectral Deligne-Mumford stacks which represent functors* $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$*. Assume that* f *is a relative spectral algebraic space (that is, that the induced map* $X(R) \to Y(R)$ *has discrete homotopy fibers, for every commutative ring* R*). The following conditions are equivalent:*

(1) *The map* f *is separated.*

(2) *The diagonal map* $\delta : \mathsf{X} \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ *is proper.*

(3) *For every valuation ring* V *with fraction field* K*, the canonical map* $X(V) \to X(K) \times_{Y(K)} Y(V)$ *is* (-1)*-truncated (that is, it is the inclusion of a summand).*

Moreover, if f *is locally of finite type and* Y *is locally Noetherian, then it suffices to verify condition* (3) *in the special case where* V *is a discrete valuation ring.*

Proof. The implication (1) $\Rightarrow$ (2) is immediate (since any closed immersion is proper). Let $\mathsf{Z} = \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$, and let $\delta' : \mathsf{X} \to \mathsf{X} \times_{\mathsf{Z}} \mathsf{X}$ be the diagonal of the map δ. Since f is a relative spectral algebraic space, the map δ' induces an equivalence between the underlying 0-truncated spectral Deligne-Mumford stacks, and is therefore a closed immersion. It follows that δ is separated. Since X is quasi-separated, the map δ is quasi-compact. Since δ admits a left homotopy inverse, it is locally of finite type. Using Theorem 5.3.0.1, we see that δ is proper if and only if the following condition is satisfied:

($2'$) Let $Z : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be the functor represented by Z. Then, for every valuation ring V with fraction field K, the canonical map $X(V) \to X(K) \times_{Z(K)} Z(V)$ is surjective on connected components.

The equivalence $(2') \Leftrightarrow (3)$ now follows by inspection.

Write $\mathsf{Z} = (\mathcal{Z}, \mathcal{O}_{\mathcal{Z}})$ and $\mathsf{Z}_0 = (\mathcal{Z}, \pi_0 \mathcal{O}_{\mathcal{Z}})$. Note that δ is proper if and only if the induced map $\mathsf{X} \times_{\mathsf{Z}} \mathsf{Z}_0 \to \mathsf{Z}_0$ is proper. If f is locally of finite type and Y is locally Noetherian, then Z_0 is locally Noetherian. Using Theorem 5.3.0.1, we deduce that δ is proper if and only if condition $(2')$ is satisfied whenever V is a discrete valuation ring (which is equivalent to the requirement that (3) is satisfied whenever V is a discrete valuation ring).

To complete the proof, it will suffice to show that $(2) \Rightarrow (1)$. Assume that δ is proper. Since δ is locally quasi-finite, we conclude that δ is finite (Proposition 5.2.1.1). Choose a map $\operatorname{Sp\acute{e}t} R \to \mathsf{Z}$, so that $\mathsf{X} \times_{\mathsf{Z}} \operatorname{Sp\acute{e}t} R \simeq \operatorname{Sp\acute{e}t} R'$ for some R-algebra R'. We wish to prove that the underlying map of commutative rings $\pi_0 R \to \pi_0 R'$ is surjective. Replacing R by $\pi_0 R$, we may assume that R is a commutative ring. Since a map of discrete R-modules $M \to N$ is surjective if and only if it surjective after localization at any prime ideal $\mathfrak{p}$ of R, we may replace R by $R_{\mathfrak{p}}$ and thereby reduce to the case where R is local. Since $\pi_0 R'$ is finitely generated as a module over R, we may use Nakayama's lemma to replace R by its residue field and thereby reduce to the case where R is a field κ. Then $\pi_0 R'$ is a finite dimensional algebra over κ. We will complete the proof by showing that the dimension of $\pi_0 R'$ is $\leqslant 1$. For this, it suffices to show that the inclusion of the first factor induces an isomorphism

$$\pi_0 R' \to (\pi_0 R') \otimes_{\kappa} (\pi_0 R') \simeq \pi_0 (R' \otimes_{\kappa} R').$$

This follows immediately from our observation that δ' induces an equivalence on the underlying 0-truncated spectral Deligne-Mumford stacks. □

Corollary 5.3.1.2. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of quasi-compact, quasi-separated morphism of spectral Deligne-Mumford stacks which is locally of finite type. Let $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ denote the functors represented by X and Y, and suppose that f is a relative spectral algebraic space. Then f is proper if and only if, for every valuation ring V with fraction field K, the induced map $X(V) \to X(K) \times_{Y(K)} Y(V)$ is a homotopy equivalence. Moreover, if Y is locally Noetherian, then it suffices to verify this condition in the special case where V is a discrete valuation ring.*

Proof. Combine Theorem 5.3.0.1 with Proposition 5.3.1.1. □

5.3.2 Interlude

We now review some commutative algebra which will be needed in the proof of Theorem 5.3.0.1.

Theorem 5.3.2.1 (Krull-Akizuki)**.** *Let R be a Noetherian integral domain of Krull dimension $\leqslant 1$, let K denote the fraction field of R, and let R' be the integral closure of R in K. Then R' is a Dedekind ring.*

Proof. We first show that R' is Noetherian. Let $I \subseteq R'$ be an ideal; we wish to show that I is finitely generated. If $I = (0)$, there is nothing to prove. Otherwise, we can choose some nonzero element $x \in I \subseteq R'$. The element x is integral over R, so we have $x^n + a_1 x^{n-1} + \cdots + a_n = 0$ for some elements $\{a_i\}_{1 \leqslant i \leqslant n}$ in R. Choose n as small as possible, so that $a_n \neq 0$. Then $t = r_n$ is a nonzero element of $I \cap R$.

Since R has Krull dimension $\leqslant 1$, the quotient R/tR is an R-module of finite length. For every R-module M of finite length, let $\ell(M)$ denote the length of M. Note that if $A \subseteq R'$ is a finitely generated R-subalgebra, then A is finitely generated as an R-module (since every element of R' is integral over R), so that $A/t^m A$ is a finitely generated module over $R/t^m R$ and is therefore an R-module of finite length for each $m \geqslant 0$. We have an exact sequence of R-modules $R/t^m R \to A/t^m A \to A/(R + t^m A) \to 0$, which gives inequalities

$$m\ell(A/tA) = \ell(A/t^m A) \leqslant \ell(R/t^m R) + \ell(A/(R + t^m A)) \leqslant m\ell(R/tR) + \ell(A/R).$$

Since R-module A/R has finite length (it is finitely generated and vanishes after extending scalars to K), it follows that $\ell(A/tA) \leqslant \ell(R/tR)$. In particular, the image of the map $A \to R'/tR'$ is a module of finite length which is bounded above by an integer $\ell(R/tR)$ which does not depend on A. Writing R' as a union of its finitely generated R-subalgebras, we deduce that R'/tR' is an R-module of finite length (bounded above by $\ell(R/tR)$. It follows that the quotient I/tR' is finitely generated as an R-module (and therefore also as an R'-module), so that the ideal I is finitely generated as desired.

To complete the proof, we must show that the Noetherian ring R' is a Dedekind ring. Since R' is integrally closed by construction, it will suffice to show that R' has Krull dimension $\leqslant 1$. To prove this, it will suffice to show that if $I \subseteq R'$ is a *prime* ideal and $t \in R$ is chosen as above, then I is minimal among prime ideals of R' containing (t). In fact, the quotient R'/tR' is an Artinian ring, since it of finite length as an R-module (and therefore also as an (R'/tR')-module). □

Proposition 5.3.2.2. *Let R be a commutative ring, let K be a field, and let $\phi : R \to K$ be a ring homomorphism. Let $\mathfrak{p} \subseteq R$ be a prime ideal containing* $\ker(\phi)$. *Then there exists a valuation subring $V \subseteq K$ (with fraction field K) such that $\phi(R) \subseteq V$ and $\mathfrak{p} = \phi^{-1}\mathfrak{m}$, where $\mathfrak{m}$ denotes the maximal ideal of V. Moreover, if R is Noetherian, $\mathfrak{p} \neq \ker(\phi)$, and K is a localization of a finitely generated R-algebra, then we can arrange that V is a discrete valuation ring.*

Proof. We first treat the general case (where R is not assumed to be Noetherian). Replacing R by the localization $R_{\mathfrak{p}}$, we may assume that R is a local ring with maximal ideal $\mathfrak{p}$. Let P denote the partially ordered consisting of subrings $A \subseteq K$ which contain $\phi(R)$ and satisfy $\mathfrak{p}A \neq A$. Using Zorn's lemma, we deduce that P has a maximal element, which we will denote by V. We will show that V has the desired properties.

We first claim that V is a local ring. Choose elements $x, y \in V$ with $x + y = 1$; we must show that either x or y is invertible in V. Since $V/\mathfrak{p}V \neq 0$, one of the localizations $(V/\mathfrak{p}V)[x^{-1}]$ and $(V/\mathfrak{q}V)[y^{-1}]$ must be nonzero. Without loss of generality, we may assume that $(V/\mathfrak{q}V)[x^{-1}] \neq 0$, so that $V[x^{-1}] \neq \mathfrak{q}V[x^{-1}]$. The maximality of V then implies that $V = V[x^{-1}]$, so that x is invertible in V.

Let $\mathfrak{m}$ denote the maximal ideal of V. Since $\mathfrak{p}V$ is a proper ideal of V, we have $\mathfrak{p}V \subseteq \mathfrak{m}$ and therefore $\mathfrak{p} \subseteq \phi^{-1}\mathfrak{m}$. Since $\mathfrak{p}$ is a maximal ideal of R, we conclude that $\mathfrak{p} = \phi^{-1}\mathfrak{m}$.

We now complete the proof by showing that V is a valuation ring with fraction field K. Let x be a nonzero element of K; we wish to show that either x or x^{-1} belongs to V. If x^{-1} does not belong to V, then the subring $V' \subseteq K$ generated by V and x^{-1} is strictly larger than V and therefore satisfies $V' = \mathfrak{p}V'$. In particular, we can write $1 = \sum_{0 \leqslant i \leqslant n} c_i x^{-i}$ for some coefficients $c_i \in \mathfrak{p}V \subseteq \mathfrak{m}$. Then $x^n = \sum_{1 \leqslant i \leqslant n} \frac{c_i}{1-c_0} x^{n-i}$ so that x is integral over V. If x does not belong to V, then the subring $V'' \subseteq K$ generated by V and x properly contains V and is finitely generated as an V-module. The maximality of V implies that $V'' = \mathfrak{p}V''$. Using Nakayama's lemma, we deduce that $V'' = 0$ and obtain a contradiction. This completes the proof of the first assertion.

Now suppose that R is Noetherian, $\mathfrak{p} \neq \ker(\phi)$, and that K is finitely generated over R. Replacing R by its image in K, we may suppose that R is a subring of K. Let $x_1, \ldots, x_n \in K$ be a transcendence basis for K over the fraction field of R. Replacing R by $R[x_1, \ldots, x_n]$ and $\mathfrak{p}$ by $\mathfrak{p}[x_1, \ldots, x_n]$, we may reduce to the case where K is a finite algebraic extension of the fraction field of R. Replacing R by the localization $R_{\mathfrak{p}}$, we may assume that R is a local ring with maximal ideal $\mathfrak{p}$. Since R is Noetherian, we can choose a finite set of generators $y_1, \ldots, y_m \in \mathfrak{p}$ for the ideal $\mathfrak{p}$. For $1 \leqslant i \leqslant m$, let R_i denote the subring of K generated by R together with the elements $\frac{y_j}{y_i}$. We now claim:

$(*)$ There exists $1 \leqslant i \leqslant m$ such that y_i is not invertible in R_i.

Suppose that $(*)$ is not satisfied: that is, $y_i^{-1} \in R_i$ for every index i. Then each y_i^{-1} can be written as a polynomial (with coefficients in R) in the variables $\frac{y_j}{y_i}$. Clearing denominators, we deduce that there exists an integer a such that $y_i^a \in \mathfrak{p}^{a+1}$ for every index i. It follows that $\mathfrak{p}^b \subseteq \mathfrak{p}^{b+1}$ for $b > a(m-1)$. Since R is Noetherian with maximal ideal $\mathfrak{p}$, the Krull intersection theorem (Corollary 7.3.6.10) implies that $\bigcap_{b \geqslant 0} \mathfrak{p}^b = 0$, so that $\mathfrak{p}^b = 0$ for $b > a(m-1)$. In particular, $\mathfrak{p}$ consists of nilpotent elements of R. Since $R \subseteq K$ is an integral domain, we deduce that $\mathfrak{p} = 0$, contradicting our assumption that $\mathfrak{p} \neq \ker(\phi)$. This completes the proof of $(*)$.

Using $(*)$, let us choose an index i such that y_i is not invertible in R_i. Let $\mathfrak{q}$ be minimal among prime ideals of R_i which contain y_i. Then $\mathfrak{q}$ contains each y_j, so that $\mathfrak{q} \cap R$ contains $\mathfrak{p}$. Since $\mathfrak{p}$ is a maximal ideal of R, we deduce that $\mathfrak{q} \cap R = \mathfrak{p}$. We may therefore replace R by $(R_i)_{\mathfrak{q}}$ (which is Noetherian, since it is finitely generated over R) and thereby reduce to the case where the prime ideal $\mathfrak{p}$ of R is minimal among prime ideals containing some element $x \in R$. It follows that R is a local Noetherian ring of dimension $\leqslant 1$ (Theorem B.2.1.2). Let R' denote the integral closure of R in K, so that R' is a Dedekind domain (Theorem 5.3.2.1). Since R' is integral over R, the maximal ideal $\mathfrak{p}$ of R can be lifted to a maximal ideal $\mathfrak{p}'$ of R' (Proposition 5.2.1.2). Then $V = R'_{\mathfrak{p}'}$ is a discrete valuation ring having the desired properties. □

Lemma 5.3.2.3. *Let V and $\{W_i\}_{1 \leqslant i \leqslant n}$ be valuation rings having the same fraction field K. If $W_i \nsubseteq V$ for $1 \leqslant i \leqslant n$, then $\bigcap W_i \nsubseteq V$.*

Proof. Set $R = V \cap \bigcap_{1 \leqslant i \leqslant n} W_i$. Let $\mathfrak{p} \subseteq R$ denote the inverse image of the maximal ideal of V, and for $1 \leqslant i \leqslant n$ let $\mathfrak{q}_i \subseteq R$ denote the inverse image of the maximal ideal of W_i. We will show that $\mathfrak{p} \nsubseteq \mathfrak{q}_i$ for $1 \leqslant i \leqslant n$. It then follows from prime avoidance that there exists an element $x \in \mathfrak{p}$ which does not belong to any $\mathfrak{q}_i$. Then $\frac{1}{x} \in K$ belongs to each W_i but does not belong to V.

It remains to show that $\mathfrak{p} \nsubseteq \mathfrak{q}_i$. To prove this, choose an element $y \in W_i$ which does not belong to V. We claim that there exists an integer d such that $\frac{y-1}{y^d-1}$ belongs to $\mathfrak{q}_i$ but does not belong to $\mathfrak{p}$ (note that $y \notin V$ guarantees that y is not a root of unity in K, so that $\frac{y-1}{y^d-1}$ is well-defined). To guarantee this, it will suffice to ensure the following:

(*a*) The element $\frac{y-1}{y^d-1}$ belongs to V and to each W_i (and is therefore an element of A).

(*b*) The product $y\frac{y-1}{y^d-1}$ belongs to V.

Note that $\frac{y-1}{y^d-1}$ has a multiplicative inverse $y^{d-1} + \cdots + 1 \in W_i$, and therefore cannot belong to the prime ideal $\mathfrak{q}_i$. On the other hand, if (*a*) and (*b*) are satisfied, then $\frac{y-1}{y^d-1}$ does belong to $\mathfrak{p}$: otherwise, it would be an invertible element of the valuation ring V, so that (*b*) would imply $y \in V$. We now complete the proof by observing that conditions (*a*) and (*b*) are satisfied for any $d \geqslant 2$ for which y does not represent a dth root of unity in the residue field of any of the valuation rings V, $\{W_i\}_{1 \leqslant i \leqslant n}$ to which it belongs. □

Proposition 5.3.2.4. *Let V be a valuation ring with maximal ideal $\mathfrak{m}$ and fraction field K, let K' be a finite product of finite algebraic extension fields of K, and let R be a subring of K' containing V. Then there are at most finitely many prime ideals $\mathfrak{q} \subseteq R$ such that $\mathfrak{q} \cap V = \mathfrak{m}$.*

Proof. Write $K' = \prod_{1 \leqslant i \leqslant m} K_i$, where each K_i is finite algebraic extension field of K. For $1 \leqslant i \leqslant n$, let $\mathfrak{p}_i \subseteq R$ denote the kernel of the composite map $R \hookrightarrow K' \to K_i$. Note that every prime ideal $\mathfrak{q} \subseteq R$ contains one of the prime ideals $\mathfrak{p}_i$ (otherwise, we could choose elements $x_i \in \mathfrak{p}_i - \mathfrak{q}$ for $1 \leqslant i \leqslant m$, in which case we have $0 = \prod_{1 \leqslant i \leqslant m} x_i \notin \mathfrak{q}$). It will therefore suffice to show that for $1 \leqslant i \leqslant m$, there are only finitely many prime ideals $\mathfrak{q} \subseteq R$

such that $\mathfrak{p}_i \subseteq \mathfrak{q}$ and $\mathfrak{q} \cap V = \mathfrak{m}$. To prove this, we can replace K' by K_i and R by its image in K_i, and thereby reduce to the case where K' is a finite algebraic extension of K.

If K is a field of characteristic p, let K^{perf} denote the perfect closure of K, given as the direct limit of the sequence $K \xrightarrow{x \mapsto x^p} K \xrightarrow{x \mapsto x^p} K \to \cdots$, and define ${K'}^{\mathrm{perf}}$, V^{perf} and R^{perf} similarly. Then we have a commutative diagram

$$\begin{array}{ccc} |\operatorname{Spec} R^{\mathrm{perf}}| & \longrightarrow & |\operatorname{Spec} R| \\ \downarrow & & \downarrow \\ |\operatorname{Spec} V^{\mathrm{perf}}| & \longrightarrow & |\operatorname{Spec} V| \end{array}$$

where the horizontal maps are bijective. We may therefore replace K by K^{perf} in the statement of Corollary 5.3.2.4, and thereby reduce to the case where K is perfect. Then K' is a separable extension of K. Enlarging K' if necessary, we may assume that K' is a Galois extension of K with Galois group G.

For every prime ideal $\mathfrak{q} \subseteq R$, there exists a valuation ring $V' \subseteq K'$ with fraction field K' and maximal ideal $\mathfrak{m}'$ such that $R \subseteq V'$ and $\mathfrak{q} = R \cap \mathfrak{m}'$ (Proposition 5.3.2.2). In particular, it follows that $\mathfrak{m} = \mathfrak{m}' \cap V$, so we can recover V as $V' \cap K$. We will complete the proof by showing that there are only finitely many such valuation rings $V' \subseteq K'$. More precisely, we claim that if W_0 and W_1 are valuation rings in K' satisfying $W_0 \cap K = W_1 \cap K$, then W_0 and W_1 are conjugate by the action of the Galois group G. To prove this, we first note that if $g(W_0) \nsubseteq W_1$ for all $g \in G$, then Lemma 5.3.2.3 supplies an element $x \in \bigcap_{g \in G} g(W_0)$ which does not belong to W_1. This is a contradiction, since the product $\prod_{g \in G} g(x)$ belongs to $W_0 \cap K$ but not to $W_1 \cap K$. We therefore have $g(W_0) \subseteq W_1$ for some $g \in G$, and similarly $h(W_1) \subseteq W_0$ for some $h \in G$. This yields a chain of inclusions

$$W_0 \supseteq h(W_1) \supseteq hg(W_0) \supseteq hgh(W_1) \supseteq \cdots \supseteq (hg)^n(W_0) = W_0,$$

where n denotes the order of the element $hg \in G$. It follows that equality holds throughout, so that W_1 and W_0 are conjugate by the action of G. □

5.3.3 The Proof of Theorem 5.3.0.1

Fix a morphism $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks which is separated, quasi-compact, and locally of finite type. We wish to show that f is proper if and only if it satisfies the valuative criterion:

$(*)$ For every valuation ring V with fraction field K and every commutative diagram

$$\begin{array}{ccc} \operatorname{Sp\acute{e}t} K & \longrightarrow & \mathsf{X} \\ \downarrow & \nearrow & \downarrow \\ \operatorname{Sp\acute{e}t} V & \longrightarrow & \mathsf{Y}, \end{array}$$

there exists a dotted arrow as indicated, rendering the diagram commutative.

We first prove that condition $(*)$ is satisfied when f is proper. Without loss of generality, we may replace Y by $\operatorname{Spét} V$. Let K denote the fraction field of V; we wish to show that if $f : \mathsf{X} \to \operatorname{Spét} V$ is proper, then every map $\phi : \operatorname{Spét} K \to \mathsf{X}$ (of spectral algebraic spaces over V) can be extended to a map $\operatorname{Spét} V \to \mathsf{X}$. The map ϕ determines a point $\eta \in |\mathsf{X}|$. Let Z denote the smallest closed subset of $|\mathsf{X}|$ containing the point η. Let Z denote the reduced closed substack of X corresponding to the subset Z.

Lemma 5.3.3.1. *In the situation above, the composite map* $\mathsf{Z} \hookrightarrow \mathsf{X} \xrightarrow{f} \operatorname{Spét} V$ *is locally quasi-finite.*

Proof. This assertion is local on X. Let us therefore choose an étale map $g : \operatorname{Spét} A \to \mathsf{X}$, and set

$$\operatorname{Spét} K \times_{\mathsf{X}} \operatorname{Spét} A \simeq \operatorname{Spét} K' \qquad \mathsf{Z} \times_{\mathsf{X}} \operatorname{Spét} A \simeq \operatorname{Spét} B.$$

Since g is étale, K' is a product $\prod_{1 \leqslant i \leqslant n} K_i$ of separable algebraic extension fields of K. Similarly, $\operatorname{Spét} B \to \mathsf{Z}$ is étale, so that B is a reduced commutative ring. By construction, the map $\operatorname{Spét} K \to \mathsf{Z}$ induces an injective map of commutative rings $B \hookrightarrow K'$. Since f is locally of finite type, B is finitely generated as a commutative ring over V. To show that $\mathsf{Z} \to \operatorname{Spét} V$ is locally quasi-finite, we wish to that for every prime ideal $\mathfrak{p} \subseteq V$, there are only finitely many prime ideals of B lying over $\mathfrak{p}$. Replacing V by $V_{\mathfrak{p}}$, we may reduce to the case where $\mathfrak{p}$ is the maximal ideal of V. In this case, the desired result follows from Proposition 5.3.2.4. □

Returning the proof of Theorem 5.3.0.1, we note that the map $f|_{\mathsf{Z}} : \mathsf{Z} \to \operatorname{Spét} V$ is both proper and locally quasi-finite. It follows that it is *finite*: that is, we can write $\mathsf{Y} \simeq \operatorname{Spét} R$ for some commutative ring R which is finitely generated as a V-module (see Proposition 5.2.1.1). Moreover, the map $\operatorname{Spét} K \to \mathsf{Y}$ induces an injection $R \to K$. We may therefore identify R with a subalgebra of K which is finitely generated as a module over V. Since V is a valuation ring of K, it is integrally closed in K. It follows that $R \simeq V$, so that the inclusion $\mathsf{Z} \hookrightarrow \mathsf{X}$ gives the desired extension of ϕ.

Suppose now that $(*)$ is satisfied and that we are given a pullback diagram

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow \\ \operatorname{Spét} R & \longrightarrow & \mathsf{Y}; \end{array}$$

we wish to prove that the induced map of topological spaces $|\mathsf{X}'| \to |\operatorname{Spec} R|$ is closed. Let Z be a closed subset of $|\mathsf{X}'|$ and let Z be the corresponding reduced closed substack of X'. Choose an étale surjection $\operatorname{Spét} B \to \mathsf{Z}$ (so that B is a reduced commutative ring) and let I

denote the kernel of the induced map of commutative rings $\pi_0 R \to B$. We will prove that $\psi(Z) \subseteq |\operatorname{Spec} R|$ agrees with the image of the closed embedding $|\operatorname{Spec}(\pi_0 R)/I| \hookrightarrow |\operatorname{Spec} R|$. To this end, let $\mathfrak{q}$ be a prime ideal of $\pi_0 R$ containing the ideal I; we wish to show that $\mathfrak{q}$ belongs to $\psi(Z)$. Using Zorn's lemma, we see that there is a prime ideal $\mathfrak{p} \subseteq \mathfrak{q}$ of $\pi_0 R$ which is minimal among prime ideals which contain I. The injection of commutative rings $(\pi_0 R)/I \hookrightarrow B$ induces an injection $((\pi_0 R)/I)_{\mathfrak{p}} \to B_{\mathfrak{p}}$, so that the localization $B_{\mathfrak{p}}$ is nonzero. It follows that $B_{\mathfrak{p}}$ contains a prime ideal, which is the localization of a prime ideal $\mathfrak{p}' \subseteq B$. Note that the image of $\mathfrak{p}'$ in $|\operatorname{Spec} R|$ belongs to the image of the inclusion $|\operatorname{Spec}((\pi_0 R)/I)_{\mathfrak{p}}| \hookrightarrow |\operatorname{Spec} R|$. By construction, the ring $((\pi_0 R)/I)_{\mathfrak{p}}$ contains a unique prime ideal, whose image in $|\operatorname{Spec} R|$ coincides with $\mathfrak{p}$. It follows that the map $|\operatorname{Spec} B| \to |\operatorname{Spec} R|$ carries $\mathfrak{p}'$ to $\mathfrak{p}$.

Let K denote the fraction field of $B/\mathfrak{p}'$ and let $\psi : \pi_0 R \to K$ be the induced map. Using Proposition 5.3.2.2, we can choose a valuation ring $V \subseteq K$ with fraction field K and maximal ideal $\mathfrak{m}$, such that $\psi^{-1}\mathfrak{m} = \mathfrak{q}$. This determines a commutative diagram

$$\begin{array}{ccc} \operatorname{Sp\acute{e}t} K & \longrightarrow & \mathsf{X}' \\ \downarrow & \overset{i}{\nearrow} & \downarrow \\ \operatorname{Sp\acute{e}t} V & \longrightarrow & \operatorname{Sp\acute{e}t} R. \end{array}$$

Applying condition $(*)$, we deduce the existence of a dotted arrow as indicated in the diagram. Since the map $\operatorname{Sp\acute{e}t} K \to \mathsf{X}'$ factors through the closed immersion $\mathsf{Z} \hookrightarrow \mathsf{X}'$, the map i also factors through Z. It follows that $\psi(Y)$ contains the image of the map $|\operatorname{Spec} V| \to |\operatorname{Spec} R|$, which includes the point $\mathfrak{q} \in |\operatorname{Spec} R|$. This completes the proof that f is proper.

Now let us assume that Y is locally Noetherian, and that condition $(*)$ is satisfied whenever V is a discrete valuation ring. We wish to show that f is proper. The assertion is local on Y; we may therefore assume that $\mathsf{Y} = \operatorname{Sp\acute{e}t} R$ for some Noetherian $\mathbb{E}_\infty$-ring R. We wish to show that for every pullback diagram

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow \\ \operatorname{Sp\acute{e}t} R' & \longrightarrow & \operatorname{Sp\acute{e}t} R, \end{array}$$

the induced map of topological spaces $|\mathsf{X}'| \to |\operatorname{Spec} R'|$ is closed. Using Remark 5.1.1.5, we assume without loss of generality that R' is Noetherian. Replacing R by R', we are reduced to proving that the map $|\mathsf{X}| \to |\operatorname{Spec} R|$ is closed. The proof now proceeds as in the previous case, using the second part of Proposition 5.3.2.2 to arrange that the valuation ring V is actually discrete.

5.4 Projective Spaces

For each $n \geqslant 0$, the complex projective space $\mathbf{CP}^n$ can be defined as the set of 1-dimensional subspaces of the vector space $\mathbf{C}^{n+1}$. The set $\mathbf{CP}^n$ can be regarded as an algebraic variety: more precisely, it can be identified with the set of $\mathbf{C}$-valued points of a smooth $\mathbf{C}$-scheme $\mathbf{P}^n_{\mathbf{C}}$, which (by slight abuse of terminology) we also refer to as complex projective space. In fact, this scheme can be defined over $\mathbf{Z}$: that is, there exists a smooth $\mathbf{Z}$-scheme $\mathbf{P}^n_{\mathbf{Z}}$ and an isomorphism $\mathbf{P}^n_{\mathbf{C}} \simeq \operatorname{Spec} \mathbf{C} \times_{\operatorname{Spec} \mathbf{Z}} \mathbf{P}^n_{\mathbf{Z}}$. In the setting of spectral algebraic geometry, one can ask for more:

Question 5.4.0.1. Can projective spaces be defined over the sphere spectrum? In other words, can we write $\mathbf{P}^n_{\mathbf{Z}} = \operatorname{Spec} \mathbf{Z} \times_{\operatorname{Spec} S} \mathbf{P}^n_S$ for some spectral scheme $\mathbf{P}^n_S$ defined over S?

Our first goal in this section is to supply an affirmative answer to Question 5.4.0.1 by means of an explicit construction (Construction 5.4.1.3). However, this answer comes with some caveats:

(a) The projective spaces $\mathbf{P}^n_S$ of Construction 5.4.1.3 are not as nicely behaved as their classical counterparts. For example, projective spaces in classical algebraic geometry are homogeneous: if k is a field, then for any two k-valued points x and y of $\mathbf{P}^n_{\mathbf{Z}}$, there exists an automorphism of $\mathbf{P}^n_k = \operatorname{Spec} k \times_{\operatorname{Spec} \mathbf{Z}} \mathbf{P}^n_{\mathbf{Z}}$ which carries x to y. However, the spectral schemes $\mathbf{P}^n_S$ are much more rigid: for example, one can define S-valued points $\{0, 1, \infty\}$ of $\mathbf{P}^1_S$, but there is no automorphism of $\mathbf{P}^1_S$ which exchanges 0 and 1.

(b) The projective space $\mathbf{P}^n_{\mathbf{Z}}$ can be characterized by a universal property: it represents a functor $F : \mathrm{CAlg}^{\heartsuit} \rightarrow \mathcal{S}\mathrm{et}$ which assigns to each commutative ring R the collection of all direct summands of R^{n+1} which are locally free of rank 1. The functor F admits a canonical extension $\overline{F} : \mathrm{CAlg}^{\mathrm{cn}} \rightarrow \mathcal{S}$. However, the functor $\overline{F}$ is *not* represented by the spectral scheme $\mathbf{P}^n_S$ of Construction 5.4.1.3 (the functor $\overline{F}$ *is* representable by a spectral scheme $\mathbf{P}^n_{\mathrm{sm}}$, but $\mathbf{P}^n_{\mathrm{sm}}$ is not flat over S: it follows that we cannot recover the classical projective space $\mathbf{P}^n_{\mathbf{Z}}$ as the fiber product $\operatorname{Spec} \mathbf{Z} \times_{\operatorname{Spec} S} \mathbf{P}^n_{\mathrm{sm}}$).

Remark 5.4.0.2. In §19.2.6, we will describe a different notion of projective space in the setting of spectral algebraic geometry which does not share problems (a) and (b) (but suffers from its own defects; see Remark 19.2.6.7.

5.4.1 Projective Spaces in Spectral Algebraic Geometry

We begin by introducing some definitions.

Notation 5.4.1.1. Let R be an $\mathbb{E}_\infty$-ring. For every space X, we let $R[X]$ denote the R-module given by $R \otimes \Sigma^\infty_+ X$. The construction $X \mapsto R[X]$ determines a symmetric monoidal functor $\mathcal{S} \to \mathrm{Mod}_R$. Consequently, it induces a functor $\mathrm{CAlg}(\mathcal{S}) \to \mathrm{CAlg}(\mathrm{Mod}_R) \simeq \mathrm{CAlg}_R$, which we will also denote by $X \mapsto R[X]$. In particular, if X is a commutative monoid (regarded as a commutative algebra object of $\mathcal{S}$ by endowing X with the discrete topology), then we can regard $R[X]$ as an $\mathbb{E}_\infty$-algebra over R. We will refer to $R[X]$ as the *monoid algebra of X over R*.

Remark 5.4.1.2. Let R be an $\mathbb{E}_\infty$-ring and let X be a set (regarded a space equipped with the discrete topology). Then we can identify $R[X]$ with the coproduct $\bigoplus_{x \in X} R$. If X has the structure of a commutative monoid, then $R[X]$ is a flat R-algebra, whose underlying commutative ring $\pi_0 R[X]$ can be identified with the monoid algebra $(\pi_0 R)[X]$ (in the sense of classical commutative algebra).

Construction 5.4.1.3 (Projective Space)**.** Let $[n]$ denote the set $\{0 < 1 < \ldots < n\}$, let $P([n])$ denote the collection of all subsets of $[n]$, and let $P^\circ([n]) \subseteq P([n])$ denote the collection of all nonempty subsets of $[n]$. For every subset $I \subseteq [n]$, set M_I denote the subset of $\mathbf{Z}^{n+1}$ consisting of those tuples $(k_0, \ldots, k_n)$ satisfying $k_0 + \cdots + k_n = 0$ and $k_i \geqslant 0$ for $i \notin I$. Then M_I is a commutative monoid which depends functorially on I. If R is a connective $\mathbb{E}_\infty$-ring, we let $R[M_I]$ denote the associated monoid algebra (Notation 5.4.1.1). Note that the construction $I \mapsto R[M_I]$ determines a functor from $P([n])$ to the ∞-category $\mathrm{CAlg}_R^{\mathrm{cn}}$ of connective $\mathbb{E}_\infty$-algebras over R, so the construction $I \mapsto \mathrm{Sp\acute{e}t}\, R[M_I]$ determines a functor $P([n])^{\mathrm{op}} \to \mathrm{SpDM}$. Note that if $\varnothing \neq I \subseteq J \subseteq [n]$, then the map $R[M_I] \to R[M_J]$ exhibits $R[M_J]$ as a localization of $R[M_I]$, so the induced map $\mathrm{Sp\acute{e}t}\, R[M_J] \to \mathrm{Sp\acute{e}t}\, R[M_I]$ is étale (in fact, an open immersion). We let $\mathbf{P}^n_R$ denote the colimit $\varinjlim_{I \in P^\circ([n])^{\mathrm{op}}} \mathrm{Sp\acute{e}t}\, R[M_I]$, formed in the ∞-category SpDM of spectral Deligne-Mumford stacks. We will refer to $\mathbf{P}^n_R$ as *projective space of dimension n over R*.

Remark 5.4.1.4. Let R be a connective $\mathbb{E}_\infty$-ring. Then the commutative ring $\pi_0 R[\mathbf{Z}^{n+1}]$ can be identified with the ring of Laurent polynomials $(\pi_0 R)[x_0^{\pm 1}, x_1^{\pm 1}, \ldots, x_n^{\pm 1}]$. For every subset $I \subseteq [n]$, the inclusion $M_I \hookrightarrow \mathbf{Z}^{n+1}$ induces a monomorphism $\pi_0 R[M_I] \to (\pi_0 R)[x_0^{\pm 1}, \ldots, x_n^{\pm 1}]$ whose image is the $(\pi_0 R)$-subalgebra generated by $\frac{x_j}{x_i}$ where $i \in I$. In what follows, we will generally abuse notation by identifying $\frac{x_j}{x_i}$ with an element of $\pi_0 R[M_I]$.

If we are given subsets $I \subseteq J \subseteq [n]$ and an element $i \in I$, then we can identify $R[M_J]$ with the localization of $R[M_I]$ obtained by inverting the elements $\frac{x_j}{x_i}$, where $j \in J$. If follows that for any pair of subsets $I, J \subseteq [n]$ having nonempty intersection, the diagram

$$\begin{array}{ccc} R[M_{I \cap J}] & \longrightarrow & R[M_I] \\ \downarrow & & \downarrow \\ R[M_J] & \longrightarrow & R[M_{I \cup J}] \end{array}$$

is a pushout diagram of $\mathbb{E}_\infty$-rings.

Remark 5.4.1.5. When the set $I \subseteq [n]$ is empty, the monoid M_I is trivial and we have $R[M_I] \simeq R$. Consequently, the diagram

$$P([n])^{\mathrm{op}} \to \mathrm{SpDM} \qquad I \mapsto \mathrm{Sp\acute{e}t}\, R[M_I]$$

determines a tautological map $q : \mathbf{P}^n_R = \varinjlim_{I \neq \varnothing} \mathrm{Sp\acute{e}t}\, R[M_i] \to \mathrm{Sp\acute{e}t}\, R[M_\varnothing] \simeq \mathrm{Sp\acute{e}t}\, R$. It follows from Remark 5.4.1.4 that for each $I \subseteq [n]$, the $\mathbb{E}_\infty$-algebra $R[M_I]$ is flat over R; consequently, the spectral Deligne-Mumford stack $\mathbf{P}^n_R$ is flat over R.

Remark 5.4.1.6. Construction 5.4.1.3 is compatible with base change in R: for any morphism $R \to R'$ of connective $\mathbb{E}_\infty$-rings, we have a canonical pullback diagram

$$\begin{array}{ccc} \mathbf{P}^n_{R'} & \longrightarrow & \mathbf{P}^n_R \\ \downarrow{\scriptstyle q'} & & \downarrow{\scriptstyle q} \\ \mathrm{Sp\acute{e}t}\, R' & \longrightarrow & \mathrm{Sp\acute{e}t}\, R, \end{array}$$

where q is defined as in Remark 5.4.1.5 and q' is defined similarly.

Proposition 5.4.1.7. *Let R be a connective $\mathbb{E}_\infty$-ring and let $\mathbf{P}^n_R$ be projective space of dimension n over R. For each nonempty subset $I \subseteq [n]$, let $R[M_I]$ be as in Construction 5.4.1.3, so that we have a tautological map $\phi_I : \mathrm{Sp\acute{e}t}\, R[M_I] \to \mathbf{P}^n_R$.*

- (a) *For $0 \leqslant i \leqslant n$, the map $\phi_{\{i\}} : \mathrm{Sp\acute{e}t}\, R[M_{\{i\}}] \to \mathbf{P}^n_R$ is an open immersion.*
- (b) *For each nonempty subset $I \subseteq [n]$, the map $\phi_I : \mathrm{Sp\acute{e}t}\, R[M_I] \to \mathbf{P}^n_R$ is an open immersion, whose image is the intersection of the images of the maps $\{\phi_{\{i\}}\}_{i \in I}$.*
- (c) *The spectral Deligne-Mumford stack $\mathbf{P}^n_R$ is schematic. In particular, it is a spectral algebraic space.*

Proof. We first prove (a). Fix an element $i \in [n]$, let $P^\circ([n] - \{i\})$ be the collection of all nonempty subsets of $[n] - \{i\}$, and let X denote the colimit $\varinjlim_{I \in P^\circ([n]-\{i\})^{\mathrm{op}}} \mathrm{Sp\acute{e}t}\, R[M_I]$. For each $I \in P^\circ([n] - \{i\})$, Remark 5.4.1.4 implies that $\mathrm{Sp\acute{e}t}\, R[M_{I \cup \{i\}}]$ can be identified with an open substack of $\mathrm{Sp\acute{e}t}\, R[M_I]$, and that for $I \subseteq J$ the induced diagram

$$\begin{array}{ccc} \mathrm{Sp\acute{e}t}\, R[M_{J \cup \{i\}}] & \longrightarrow & \mathrm{Sp\acute{e}t}\, R[M_{I \cup \{i\}}] \\ \downarrow & & \downarrow \\ \mathrm{Sp\acute{e}t}\, R[M_J] & \longrightarrow & \mathrm{Sp\acute{e}t}\, R[M_I] \end{array}$$

is a pullback square. It follows that the colimit $\varinjlim_{I \in P^\circ([n]-\{i\})^{\mathrm{op}}} \mathrm{Sp\acute{e}t}\, R[M_{I \cup \{i\}}]$. can be identified with an open substack $\mathsf{U} \subseteq \mathsf{X}$, and that for each $I \in P^\circ([n] - \{i\})$ the diagram

$$\begin{array}{ccc} \mathrm{Sp\acute{e}t}\, R[M_{I \cup \{i\}}] & \longrightarrow & \mathrm{Sp\acute{e}t}\, R[M_I] \\ \downarrow & & \downarrow \\ \mathsf{U} & \xrightarrow{\ j\ } & \mathsf{X} \end{array}$$

is a pullback square. Unwinding the definitions, we see the projective space $\mathbf{P}^n_R$ fits into a pushout diagram of spectral Deligne-Mumford stacks σ :

$$\begin{array}{ccc} \mathsf{U} & \xrightarrow{j} & \mathsf{X} \\ \downarrow & & \downarrow \\ \operatorname{Sp\acute{e}t} R[M_{\{i\}}] & \xrightarrow{\phi_{\{i\}}} & \mathbf{P}^n_R \end{array}$$

in which all morphisms are étale. Since j is an open immersion, it follows that σ is an excision square: in particular, it is a pullback square and the map $\phi_{\{i\}}$ is an open immersion (see Proposition 2.5.2.1). This proves (a), and shows that for every nonempty subset $I \subseteq [n]-\{i\}$, the diagram

$$\begin{array}{ccc} \operatorname{Sp\acute{e}t} R[M_{I\cup\{i\}}] & \longrightarrow & \operatorname{Sp\acute{e}t} R[M_I] \\ \downarrow & & \downarrow \\ \operatorname{Sp\acute{e}t} R[M_{\{i\}}] & \longrightarrow & \mathbf{P}^n_R \end{array}$$

is a pullback square. Assertion (b) now follows by induction on the size of I, and assertion (c) follows from (a) together with Proposition 1.6.7.3 (since the open immersions $\phi_{\{i\}}$ are mutually surjective). $\square$

Example 5.4.1.8. Let R be a commutative ring. Then $\mathbf{P}^n_R$ is schematic (Proposition 5.4.1.7) and 0-truncated (since it is flat over R by virtue of Remark 5.4.1.5), and can therefore be identified with an ordinary scheme. Proposition 5.4.1.7 shows that this scheme can be covered by affine open subschemes $U_0, \ldots, U_n \subseteq \mathbf{P}^n_R$, where $U_i \simeq \operatorname{Spec} R[M_{\{i\}}] \simeq R[\frac{x_0}{x_i}, \frac{x_1}{x_i}, \ldots, \frac{x_{i-1}}{x_i}, \frac{x_{i+1}}{x_i}, \ldots, \frac{x_n}{x_i}]$ is an n-dimensional affine space over R, which are "glued together" along the intersections $U_i \cap U_j \simeq \operatorname{Spec} R[M_{\{i,j\}}]$. From this description, we see that Construction 5.4.1.3 recovers the usual definition of projective space of dimension n over R.

Remark 5.4.1.9. Using a more elaborate version of Construction 5.4.1.3, one can develop a theory of toric varieties over any connective $\mathbb{E}_\infty$-ring R, generalizing the classical theory of toric varieties over commutative rings (as described, for example, in [72]).

5.4.2 Line Bundles on Projective Space

Let $n \geqslant 0$ be an integer. By definition, there is a bijective correspondence between points $x \in \mathbf{CP}^n$ and 1-dimensional subspaces $L_x \subseteq \mathbf{C}^{n+1}$. The construction $x \mapsto L_x$ determines a complex analytic vector bundle of rank 1 over $\mathbf{CP}^n$. This vector bundle is algebraic: that is, it arises from line bundle $\mathscr{O}(-1)$ on the scheme $\mathbf{P}^n_{\mathbf{C}}$. For every integer m, we let $\mathscr{O}(m)$ denote the tensor power $\mathscr{O}(-1)^{\otimes -m}$. Our next goal is to show that the line bundles

$\mathscr{O}(m)$ are "defined over the sphere": that is, they are the pullbacks of line bundles on the spectral algebraic space $\mathbf{P}^n_S$. To produce these line bundles, we will need a slight variant of Construction 5.4.1.3.

Construction 5.4.2.1. Let $n \geqslant 0$ be an integer and let R be a connective $\mathbb{E}_\infty$-ring. For each subset $I \subseteq [n]$ and each integer m, we let $M_I(m)$ denote the subset of $\mathbf{Z}^{n+1}$ consisting of those tuples $(k_0, \ldots, k_n)$ satisfying $k_0 + \cdots + k_n = m$ and $k_i \geqslant 0$ for $i \notin I$. We regard $M_I(m)$ as a set equipped with an action of the monoid $M_I = M_I(0)$ appearing in Construction 5.4.1.3.

Note that if $I \neq \varnothing$, then $M_I(m)$ is free module over M_I on a single generator. More precisely, it is freely generated by any tuple $(k_0, \ldots, k_n) \in M_I(m)$ which satisfies $k_i = 0$ for $i \notin I$. From this description, we see that if $(k_0, \ldots, k_n)$ freely generates $M_I(m)$ as a module over M_I, then it freely generates $M_J(m)$ as a module over M_J for any $J \supseteq I$. It follows that the inclusion $M_I(m) \hookrightarrow M_J(m)$ induces an equivalence of $R[M_J] \otimes_{R[M_I]} R[M_I(m)] \to R[M_J(m)]$ in the ∞-category of $R[M_J]$-modules. We may therefore regard the diagram $I \mapsto R[M_I(m)]$ as an object of the ∞-category

$$\varprojlim_{I \in P^\circ([n])} \mathrm{Mod}_{R[M_i]} \simeq \varprojlim_{I \in P^\circ([n])} \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R[M_i]) \simeq \mathrm{QCoh}(\mathbf{P}^n_R).$$

We will denote this object by $\mathscr{O}(m)$.

Remark 5.4.2.2. In the situation of Construction 5.4.2.1, the module $R[M_I(m)]$ is free of rank 1 over $R[M_I]$ for every nonempty subset $I \subseteq [n]$. It follows that $\mathscr{O}(m) \in \mathrm{QCoh}(\mathbf{P}^n_R)$ is a line bundle on $\mathbf{P}^n_R$.

Remark 5.4.2.3. Construction 5.4.2.1 does not really depend on the choice of $\mathbb{E}_\infty$-ring R: if $f : R \to R'$ is a morphism of $\mathbb{E}_\infty$-rings and we let

$$\mathscr{O}(m)_R \in \mathrm{QCoh}(\mathbf{P}^n_R) \qquad \mathscr{O}(m)_{R'} \in \mathrm{QCoh}(\mathbf{P}^n_{R'})$$

denote the line bundles obtained by applying Construction 5.4.2.1 to R and R', respectively, then we have a canonical equivalence $\mathscr{O}(m)_{R'} \simeq F^* \mathscr{O}(m)_R$, where $F : \mathbf{P}^n_{R'} \to \mathbf{P}^n_R$ denotes the map induced by f.

Example 5.4.2.4. In Construction 5.4.2.1, we have $M_\varnothing(m) = \{(k_0, k_1, \ldots, k_n) \in \mathbf{Z}^{n+1}_{\geqslant 0} : k_0 + \cdots + k_n = m\}$. It follows that $M_\varnothing(m)$ is a finite set of cardinality $\binom{m+n}{n}$ if $m \geqslant 0$, and is empty for $m < 0$.

In the situation of Construction 5.4.2.1, we let $\Gamma(\mathbf{P}^n_R; \mathscr{O}(m))$ denote the spectrum of global section of the line bundle $\mathscr{O}(m)$ on $\mathbf{P}^n_R$. In the case where R is an ordinary commutative ring, we can regard $\mathscr{O}(m)$ as a sheaf of abelian groups on $\mathbf{P}^n_R$, and the homotopy groups of $\Gamma(\mathbf{P}^n_R; \mathscr{O}(m))$ are given by

$$\pi_* \Gamma(\mathbf{P}^n_R; \mathscr{O}(m)) = \mathrm{H}^{-*}(\mathbf{P}^n_R; \mathscr{O}(m)).$$

The cohomology groups on the right hand side were computed by Serre in [187] (with two slight caveats: [187] considers cohomology with respect to the Zariski topology rather than the étale topology, and restricts attention to the case where R is an algebraically closed field).

Our next goal is to reproduce Serre's calculation over an arbitrary connective $\mathbb{E}_\infty$-ring R. We begin by constructing some global sections of the line bundles $\mathscr{O}(m)$.

Construction 5.4.2.5. Let $n \geqslant 0$ be an integer and let R be a connective $\mathbb{E}_\infty$-ring. Let $\vec{k} = (k_0, \ldots, k_n) \in \mathbf{Z}^{n+1}_{\geqslant 0}$, and set $m = k_0 + \cdots + k_n$. Then $\vec{k}$ can be regarded as an element of $M_I(m)$ for every subset $I \subseteq [n]$, and therefore determines a map

$$R \simeq \varprojlim_{I \in P^\circ([n])} R[\{\vec{k}\}] \rightarrow \varprojlim_{I \in P^\circ([n])} R[M_I(m)] \simeq \Gamma(\mathbf{P}^n_R; \mathscr{O}(m)).$$

We will denote this map by $x^{\vec{k}} : R \rightarrow \Gamma(\mathbf{P}^n_R; \mathscr{O}(m))$.

We can now formulate Serre's result as follows:

Theorem 5.4.2.6 (Serre)**.** *Let R be a connective $\mathbb{E}_\infty$-ring, let $n \geqslant 0$ be an integer, and let $\mathscr{O}(m)$ be the line bundle on $\mathbf{P}^n_R$ given by Construction 5.4.2.1. Then:*

1. *If $m \geqslant 0$, then the maps $x^{\vec{k}} : R \rightarrow \Gamma(\mathbf{P}^n_R; \mathscr{O}(m))$ induce an equivalence $\bigoplus_{\vec{k} \in M_\varnothing(m)} R \simeq \Gamma(\mathbf{P}^n_R; \mathscr{O}(m))$. In particular, $\Gamma(\mathbf{P}^n_R; \mathscr{O}(m))$ is a free R-module of rank $\binom{m+n}{n}$ (see Example 5.4.2.4).*

2. *If $m < 0$, then $\Gamma(\mathbf{P}^n_R; \mathscr{O}(m))$ is equivalent to a direct sum of $\binom{-m-1}{n}$ copies of $\Sigma^{-n} R$. In particular, $\Gamma(\mathbf{P}^n_R; \mathscr{O}(m))$ vanishes for $-n \leqslant m \leqslant -1$.*

Proof. For each element $\vec{k} = (k_0, \ldots, k_n) \in \mathbf{Z}^{n+1}$ and each $I \subseteq [n]$, set $M_I(\vec{k}) = M_I \cap \{\vec{k}\}$. Then $M_I(\vec{k})$ is either empty (if $k_i < 0$ for some $i \notin I$) or consists of the single element $\{\vec{k}\}$. Let $Q \subseteq P^\circ([n])$ be the partially ordered subset consisting of those nonempty sets $I \subseteq [n]$ such that $M_I(\vec{k})$ is empty.

Let us regard the construction $I \mapsto R[M_I(\vec{k})]$ as a functor $\lambda_{\vec{k}} : P^\circ([n]) \rightarrow \mathrm{Mod}_R$. Let $\underline{R} : P^\circ([n]) \rightarrow \mathrm{Mod}_R$ denote the constant functor with the value R. We have a canonical map $u : \lambda_{\vec{k}} \rightarrow \underline{R}$. Note that the canonical map $\underline{R} \rightarrow \mathrm{cofib}(u)$ is an equivalence when restricted to Q, and that $\mathrm{cofib}(u)$ is a right Kan extension of its restriction to Q. Consequently, we have $\varprojlim_{I \in P^\circ([n])} \mathrm{cofib}(u)(I) \simeq \varprojlim_{I \in Q} R \simeq R^{\mathrm{N}(Q)}$, where $R^{\mathrm{N}(Q)}$ denotes the function spectrum of maps $\mathrm{N}(Q) \rightarrow R$. It follows that $\varprojlim \lambda_{\vec{k}}$ can be identified with the fiber of the diagonal map $R \rightarrow R^{\mathrm{N}(Q)}$. We now distinguish three cases:

(a) All of the integers k_i are nonnegative. In this case, $Q = \varnothing$, and we have $\varprojlim \lambda_{\vec{k}} \simeq R$.

(b) Some of the integers k_i are negative and some are not. In this case, we claim that the simplicial set $\mathrm{N}(Q)$ is weakly contractible, so that $\varprojlim \lambda_{\vec{k}} \simeq 0$. To prove this, fix $i \in [n]$ such that $k_i \geqslant 0$, and let $Q' \subseteq Q$ consist of those elements $I \in Q$ which contain i. Then the inclusion $Q' \hookrightarrow Q$ admits a left adjoint (given by $I \hookrightarrow I \cup \{i\}$) and therefore induces a weak homotopy equivalence $\mathrm{N}(Q') \hookrightarrow \mathrm{N}(Q)$. We are therefore reduced to proving that $\mathrm{N}(Q')$ is weakly contractible. This is clear, since the singleton $\{i\}$ is a least element of Q'.

(c) All of the integers k_i are negative. In this case, Q is the collection of all nonempty, proper subsets of $[n]$. It follows that the simplicial set $\mathrm{N}(Q)$ can be identified with the subdivision of $\partial \Delta^n$, so we obtain an equivalence $\varprojlim \lambda_{\vec{k}} \simeq \mathrm{fib}(R \to R^{\mathrm{N}(Q)} \simeq R^{\partial \Delta^n}) \simeq \Sigma^{-n} R$.

Unwinding the definitions, we have

$$\begin{aligned}
\Gamma(\mathbf{P}^n_R; \mathscr{O}(m)) &\simeq \varprojlim_{I \in P^{\circ}([n])} R[M_I(m)] \\
&\simeq \varprojlim_{I \in P^{\circ}([n])} \bigoplus_{\vec{k} \in M_{[n]}(m)} R[M_I(\vec{k})] \\
&\simeq \bigoplus_{\vec{k} \in M_{[n]}(m)} \varprojlim_{I \in P^{\circ}([n])} R[M_I(\vec{k})] \\
&\simeq \bigoplus_{\vec{k} \in M_{[n]}(m)} \varprojlim \lambda_{\vec{k}}.
\end{aligned}$$

We now distinguish two cases:

(1) If $m \geqslant 0$, then no element $\vec{k} \in M_{[n]}(m)$ can satisfy (c), and for those which satisfy (b) the corresponding summand $\varprojlim \lambda_{\vec{k}}$ vanishes. The remaining summands are indexed by the finite set $M_{\varnothing}(m)$, and each summand is equivalent to R. We therefore obtain a decomposition $\Gamma(\mathbf{P}^n_R; \mathscr{O}(m)) \simeq \bigoplus_{\vec{k} \in M_{\varnothing}(m)}$, given by the maps $x^{\vec{k}} : R \to \Gamma(\mathbf{P}^n_R; \mathscr{O}(m))$ of Construction 5.4.2.5.

(2) If $m < 0$, then no element $\vec{k} \in M_{[n]}(m)$ can satisfy (a), and for thiose which satisfy (b) the corresponding summand $\varprojlim \lambda_{\vec{k}}$ vanishes. The remaining summands are indexed by the finite set $T = \{(k_0, \ldots, k_n) \in \mathbf{Z}^{n+1}_{<0} : k_0 + \cdots + k_n = m\}$ of size $\binom{-m-1}{n}$, and each summand is equivalent to $\Sigma^{-n} R$. We therefore obtain an equivalence $\Gamma(\mathbf{P}^n_R; \mathscr{O}(m)) \simeq \bigoplus_{\vec{k} \in T} \Sigma^{-n} R$.

□

5.4.3 The Universal Property of Projective Space

Let $\mathbf{P}^n_R$ be projective space of dimension n over a connective $\mathbb{E}_\infty$-ring R. We will refer to the line bundle $\mathscr{O}(-1) \in \mathrm{QCoh}(\mathbf{P}^n_R)$ as the *tautological line bundle* over $\mathbf{P}^n_R$. Construction 5.4.2.5 produces a finite collection of elements

$$x_0, \ldots, x_n \in \pi_0 \Gamma(\mathbf{P}^n_R; \mathscr{O}(1)) = \pi_0 \operatorname{Map}_{\mathrm{QCoh}(\mathbf{P}^n_R)}(\mathscr{O}(-1), \mathscr{O}),$$

which we can identify with a single map $e : \mathscr{O}(-1) \to \mathscr{O}^{n+1}$ (here $\mathscr{O} = \mathscr{O}(0)$ denote the structure sheaf of $\mathbf{P}^n_R$). It is not hard to see that the cofiber $\mathrm{cofib}(e)$ is a vector bundle of rank n on $\mathbf{P}^n_R$. In the setting of classical algebraic geometry, the projective space $\mathbf{P}^n_R$ is universal with respect to these features:

Theorem 5.4.3.1. *Let A be a commutative ring and let $X(A)$ denote the set of submodules $L \subseteq A^{n+1}$ for which the quotient A^{n+1}/L is a locally free A-module of rank n (from which it follows that L is locally free of rank 1). Then the construction*

$$(f : \operatorname{Spét} A \to \mathbf{P}^n_S) \mapsto (\operatorname{im}(f^*(e) \subseteq A^{n+1})$$

induces a homotopy equivalence (of discrete spaces) $\operatorname{Map}_{\mathrm{SpDM}}(\operatorname{Spét} A, \mathbf{P}^n_S) \simeq X(A)$; here S denotes the sphere spectrum and $e : \mathscr{O}(-1) \to \mathscr{O}^{n+1}$ is defined as above.

Remark 5.4.3.2. In the statement of Theorem 5.4.3.1, we can replace the sphere spectrum S with the ring $\mathbf{Z}$ of integers (or any connective $\mathbb{E}_\infty$-ring R satisfying $\pi_0 R \simeq \mathbf{Z}$).

Warning 5.4.3.3. Theorem 5.4.3.1 does not extend (at least in a naive way) to the case where A is a connective $\mathbb{E}_\infty$-ring. A slight refinement of Construction 5.4.2.1 shows that we can regard the construction $m \mapsto \mathscr{O}(m)$ as a symmetric monoidal functor from the set $\mathbf{Z}$ of integers (regarded as a category with no non-identity morphisms) to the ∞-category $\mathscr{P}\mathrm{ic}(\mathbf{P}^n_S)$ of line bundles on the projective space $\mathbf{P}^n_S$ (see Definition 2.9.4.1). Consequently, for any map $f : \operatorname{Spét} A \to \mathbf{P}^n_S$, the construction $m \mapsto f^* \mathscr{O}(m)$ determines a symmetric monoidal functor $\mathbf{Z} \to \mathscr{P}\mathrm{ic}(A)$. This symmetric monoidal functor equips the invertible A-module $L = f^* \mathscr{O}(-1)$ with some additional structures: for example, it supplies a nullhomotopy of the automorphism of $L \otimes_A L$ given by "swapping" the factors of L. In the setting of spectral algebraic geometry, this structure is not automatic.

In §19.2, we will show that there is a variant of the projective space $\mathbf{P}^n_S$ (which is not given by Construction 5.4.1.3) for which Theorem 5.4.3.1 does extend to the setting of $\mathbb{E}_\infty$-rings (see Definition 19.2.6.3).

Proof of Theorem 5.4.3.1. For every commutative ring A, set $Y(A) = \operatorname{Map}_{\mathrm{SpDM}}(\operatorname{Spét} A, \mathbf{P}^n_S)$, which we will regard as a set (since A is discrete and $\mathbf{P}^n_S$ is a spectral algebraic space), so that the construction $f \mapsto \operatorname{im}(f^*(e))$ determines a map $\gamma(A) : Y(A) \to X(A)$; we wish to show that $\gamma(A)$ is a bijection.

For every nonempty $I \subseteq [n]$, let $X_I(A)$ denote the subset of $X(A)$ consisting of those submodules $L \subseteq A^{n+1}$ for which the composite map $L \hookrightarrow A^{n+1} \xrightarrow{p_i} A$ is an isomorphism for each $i \in I$; here $p_i : A^{n+1} \to A$ denotes the projection onto the ith factor. Let $Y_I(A)$ denote the subset of $Y(A)$ consisting of those maps $\operatorname{Spét} A \to \mathbf{P}^n_S$ which factor through the open immersion $\phi_I : \operatorname{Spét} S[M_I] \hookrightarrow \mathbf{P}^n_S$ of Proposition 5.4.1.7. Note that the map $\gamma(A) : Y(A) \to X(A)$ restricts to give maps $\gamma_I(A) : Y_I(A) \to X_I(A)$ for every nonempty $I \subseteq [n]$. Given an element $L \in X_I(A)$, the construction

Given an element $(L, \alpha_0, \ldots, \alpha_n)$ in $X_I(A)$, the construction $(k_0, \ldots, k_n) \mapsto (\bigotimes_{0 \leqslant i \leqslant n} (p_i|_L)^{\otimes k_i})$ determines a monoid homomorphism

$$M_I \to \operatorname{Hom}_A(L^{\otimes k_0 + \cdots + k_n}, A^{\otimes k_0 + \cdots + k_n}) \simeq \operatorname{Hom}_A(A, A) \simeq A$$

(where we regard A as monoid with respect to multiplication multiplication). This construction determines a map

$$X_I(A) \to \operatorname{Map}_{\operatorname{CAlg}^\heartsuit}(\mathbf{Z}[M_I], A) \simeq \operatorname{Map}_{\operatorname{CAlg}}(S[M_I], A) \simeq Y_I(A)$$

which is easily seen to be inverse to $\gamma_I(A)$. It follows that each of the maps $\gamma_I(A)$ is a bijection.

We now prove that the map $\gamma(A)$ is injective. Suppose we are given elements $f, g \in Y(A)$ satisfying $\gamma(A)(f) = \gamma(A)(g)$; we wish to show that $f = g$. To prove this, we can work locally with respect to the Zariski topology on $\operatorname{Spec} A$ and thereby reduce to the case where $f \in Y_{\{i\}}(A)$ and $g \in Y_{\{j\}}(A)$ for some $i, j \in [n]$. Then $\gamma(A)(f) = \gamma(A)(g)$ belongs to $X_{\{i\}}(A) \cap X_{\{j\}}(A) = X_{\{i,j\}}(A)$. It follows from the above arguments that we can write $\gamma(A)(f) = \gamma(A)(h) = \gamma(A)(g)$ for some $h \in Y_{\{i,j\}}(A)$. The injectivity of $\gamma_{\{i\}}(A)$ then shows that $f = h$, and the injectivity of $\gamma_{\{j\}}(A)$ shows that $h = g$. It follows by transitivity that $f = g$, as desired.

Note that the constructions $A \mapsto X(A)$ and $A \mapsto Y(A)$ are both sheaves with respect to the Zariski topology, and the construction $A \mapsto \gamma(A)$ determines a morphism of sheaves. Consequently, to complete the proof, it will suffice to show that the natural transformation $\gamma : X \to Y$ is an effective epimorphism of Zariski sheaves. For each $i \in [n]$, the constructions $A \mapsto X_{\{i\}}(A)$ and $A \mapsto Y_{\{i\}}(A)$ determine Zariski sheaves $X_{\{i\}}$ and $Y_{\{i\}}$, and the maps $\gamma_{\{i\}}(A)$ induce an isomorphism $X_{\{i\}} \simeq Y_{\{i\}}$. It follows that the natural map $\rho : \amalg_{0 \leqslant i \leqslant n} Y_{\{i\}} \to Y$ factors through γ. Since the map ρ is an effective epimorphism of Zariski sheaves, it follows that γ is also an effective epimorphism of Zariski sheaves. $\square$

Corollary 5.4.3.4. *Let R be a connective $\mathbb{E}_\infty$-ring. Then the projection map $\mathbf{P}^n_R \to \operatorname{Spét} R$ is proper and locally almost of finite presentation.*

Warning 5.4.3.5. If the $\mathbb{E}_\infty$-ring R is not a $\mathbf{Q}$-algebra, then the morphism $\mathbf{P}^n_R \to \operatorname{Spét} R$ is not locally of finite presentation.

Proof of Corollary 5.4.3.4. Using Remark 5.4.1.6, we can reduce to the case where $R = S$ is there sphere spectrum. For $0 \leqslant i \leqslant n$, the monoid $M_{\{i\}}$ of Construction 5.4.1.3 is isomorphic to $\mathbf{Z}^n_{\geqslant 0}$, so that $\pi_* S[M_{\{i\}}]$ is isomorphic to a polynomial ring $(\pi_* S)[y_1 \ldots, y_n]$. It follows that $S[M_{\{i\}}]$ is Noetherian and of finite type over S. Since $\mathbf{P}^n_S$ can be covered by open substacks of the form $\operatorname{Spét} S[M_{\{i\}}]$, it is locally Noetherian and locally of finite type over S. Applying Remark 4.2.0.4, we deduce that $\mathbf{P}^n_S$ is locally almost of finite presentation over S.

It follows from Proposition 5.4.1.7 that $\mathbf{P}^n_S$ is a spectral algebraic space. Moreover, it is covered by finitely many open immersions $\phi_{\{i\}} : \operatorname{Spét} S[M_{\{i\}}] \to \mathbf{P}^n_S$ for which the fiber products

$$\operatorname{Spét} S[M_{\{i\}}] \times_{\mathbf{P}^n_S} \operatorname{Spét} S[M_{\{j\}}] \simeq \operatorname{Spét} S[M_{\{i,j\}}]$$

are affine. It follows that $\mathbf{P}^n_S$ is quasi-compact and that the diagonal of $\mathbf{P}^n_S$ is affine. In particular, $\mathbf{P}^n_S$ is quasi-separated.

To complete the proof of Corollary 5.4.3.4, it will suffice to show that the projection map $\mathbf{P}^n_S \to S$ satisfies the valuative criterion of properness (see Corollary 5.3.1.2). That is, we must show that if V is a valuation ring with fraction field K, then the induced map $\operatorname{Map}_{\mathrm{SpDM}}(\operatorname{Spét} V, \mathbf{P}^n_S) \to \operatorname{Map}_{\mathrm{SpDM}}(\operatorname{Spét} K, \mathbf{P}^n_S)$ is a homotopy equivalence. Equivalently, we must show that the restriction map $X(V) \to X(K)$ is bijective, where X is defined as in the statement of Theorem 5.4.3.1. We must show that if L is a 1-dimensional subspace of K^{n+1}, then there is a unique V-submodule $L_0 \subseteq L \cap V^{n+1}$ such that V^{n+1}/L_0 is locally free of rank n. Choose a nonzero vector $x \in L \subseteq K^{n+1}$, and write $x = (x_0, \ldots, x_n)$. Since V is a valuation ring, the fractional ideal generated by the elements $\{x_i\}_{0 \leqslant i \leqslant n}$ is principal: that is, we can choose $i \in [n]$ such that $x_j = \lambda_j x_i$ for some coefficients $\lambda_j \in V$. A simple calculation shows that the unique candidate for L_0 is the free V-submodule of V^{n+1} generated by the vector $(\lambda_0, \lambda_1, \ldots, \lambda_n)$. □

5.5 Chow's Lemma

In the setting of classical algebraic geometry (even over the field $\mathbf{C}$ of complex numbers), there are many examples of algebraic varieties which are not quasi-projective. However, *Chow's lemma* asserts that for every complex algebraic variety X, there exists a projective birational map $\pi : \widetilde{X} \to X$, where $\widetilde{X}$ is quasi-projective. Our goal in this section is to establish the following variant of Chow's lemma in the setting of spectral algebraic geometry:

Theorem 5.5.0.1 (Chow's Lemma for Spectral Algebraic Spaces)**.** *Let R be a connective $\mathbb{E}_\infty$-ring, let X be a quasi-compact separated algebraic space over R, and suppose that the underlying ordinary algebraic space $\tau_{\leqslant 0} \mathsf{X}$ is finitely* 0*-presented over R. Then there exists a finite sequence of closed immersions*

$$\varnothing = \mathsf{Y}_0 \to \mathsf{Y}_1 \to \mathsf{Y}_2 \to \cdots \to \mathsf{Y}_n \to \mathsf{X}$$

with the following properties:

(a) *Each of the closed immersions* $\mathsf{Y}_i \to \mathsf{X}$ *is locally almost of finite presentation.*

(b) *The closed immersion* $\mathsf{Y}_n \to \mathsf{X}$ *induces an equivalence of the underlying ordinary algebraic spaces* $\tau_{\leqslant 0}\mathsf{Y}_n \to \tau_{\leqslant 0}\mathsf{X}$.

(c) *For* $1 \leqslant i \leqslant n$, *there exists an integer* $d_i \geqslant 0$ *and a closed immersion* $h_i : \widetilde{\mathsf{Y}}_i \to \mathsf{Y}_i \times_{\operatorname{Sp\acute{e}t} R} \mathbf{P}^{d_i}_R$ *such that* h_i *is locally almost of finite presentation, the composite map* $\widetilde{\mathsf{Y}}_i \xrightarrow{h_i} \mathsf{Y}_i \times_{\operatorname{Sp\acute{e}t} R} \mathbf{P}^{d_i}_R \to \mathbf{P}^{d_i}_R$ *is locally quasi-finite, and the projection map* $\widetilde{\mathsf{Y}}_i \times_{\mathsf{Y}_i} \mathsf{U}_i \to \mathsf{U}_i$ *is an equivalence, where* U_i *denotes the open substack of* Y_i *complementary to the closed immersion* $\mathsf{Y}_{i-1} \to \mathsf{Y}_i$.

Remark 5.5.0.2. Many refinements of Theorem 5.5.0.1 are possible. For example, we can arrange that each of the maps $\widetilde{\mathsf{Y}}_i \xrightarrow{h_i} \mathsf{Y}_i \times_{\operatorname{Sp\acute{e}t} R} \mathbf{P}^{d_i}_R \to \mathbf{P}^{d_i}_R$ is an immersion (meaning that it factors as as a closed immersion followed by an open immersion), and the hypothesis that the base $\operatorname{Sp\acute{e}t} R$ be affine can be considerably weakened. However, Theorem 5.5.0.1 will be sufficient for our needs in this book.

Remark 5.5.0.3. In the situation of Theorem 5.5.0.1, each of the natural maps $\widetilde{\mathsf{Y}}_i \to \mathsf{X}$ factors as a composition

$$\widetilde{\mathsf{Y}_i} \xrightarrow{h_i} \mathsf{Y}_i \times_{\operatorname{Sp\acute{e}t} R} \mathbf{P}^{d_i}_R \to \mathsf{X} \times_{\operatorname{Sp\acute{e}t} R} \mathbf{P}^{d_i}_R \xrightarrow{q} \mathsf{X},$$

where the first two maps are closed immersions which are locally almost of finite presentation and q is a pullback of the projection map $\mathbf{P}^{d_i}_R \to \operatorname{Sp\acute{e}t} R$, which is proper and locally almost of finite presentation by virtue of Corollary 5.4.3.4. It follows that each map $\widetilde{\mathsf{Y}}_i \to \mathsf{X}$ is proper and locally almost of finite presentation.

Remark 5.5.0.4. In the situation of Theorem 5.5.0.1, each of the natural maps $\rho_i : \widetilde{\mathsf{Y}}_i \to \mathbf{P}^{d_i}_R$ factors as a composition

$$\widetilde{\mathsf{Y}_i} \xrightarrow{h_i} \mathsf{Y}_i \times_{\operatorname{Sp\acute{e}t} R} \mathbf{P}^{d_i}_R \to \mathsf{X} \times_{\operatorname{Sp\acute{e}t} R} \mathbf{P}^{d_i}_R \xrightarrow{q'} \mathbf{P}^{d_i}_R,$$

where the first two maps are closed immersions which are locally almost of finite presentation and q' is given by projection onto the second factor. Consequently:

(i) If X is proper over R, then the map $\rho_i : \widetilde{\mathsf{Y}}_i \to \mathbf{P}^{d_i}_R$ is proper. Since ρ_i is also locally quasi-finite, it follows that ρ_i is finite.

(ii) If X is locally almost of finite presentation over R, then the map ρ_i is locally almost of finite presentation.

The remainder of this section is devoted to the proof of Theorem 5.5.0.1. Our strategy is to use the Noetherian approximation techniques of Chapter 4 to reduce to the case where R is Noetherian and X is locally Noetherian. In this case, the canonical map $\tau_{\leqslant 0}\mathsf{X} \to \mathsf{X}$ is locally almost of finite presentation. We can therefore replace X by $\tau_{\leqslant 0}\mathsf{X}$ and thereby reduce to proving Theorem 5.5.0.1 for ordinary algebraic spaces. Here we follow the strategy of Knutson in [117] (where a variant of Theorem 5.5.0.1 appears as Theorem IV.3.1).

5.5.1 Digression on Projective Space

We begin by reviewing some auxiliary constructions which will be useful for proving the analogue of Theorem 5.5.0.1 in the setting of classical algebraic geometry.

Notation 5.5.1.1. Let $n \geqslant 0$ be an integer. For every commutative ring R, let $R[x]_{\leqslant n}$ denote the subset of $R[x]$ consisting of polynomials of degree $\leqslant n$. We let $\mathbf{P}^n(R)$ denote the collection of R-submodules $L \subseteq R[x]_{\leqslant n}$ which have the following properties:

- (a) As an R-module, L is projective of rank 1.
- (b) The R-module L is a direct summand of $R[x]_{\leqslant n}$ (in other words, the quotient $R[x]_{\leqslant n}/L$ is also projective).

We will regard the construction $R \mapsto \mathbf{P}^n(R)$ as a functor from the category of commutative rings to the category of sets.

Remark 5.5.1.2. Since $R[x]_{\leqslant n}$ is isomorphic (as an R-module) to R^{n+1}, Theorem 5.4.3.1 shows that the functor $\mathbf{P}^n : \mathrm{CAlg}^{\heartsuit} \to \mathcal{S}\mathrm{et}$ of Notation 5.5.1.1 is represented by the algebraic space $\mathbf{P}^n_{\mathbf{Z}}$.

Remark 5.5.1.3. Let R be a commutative ring and let $f(x) \in R[x]$ be a polynomial of degree $\leqslant n$. Then the cyclic submodule $Rf(x) \subseteq R[x]_{\leqslant n}$ is an element of $\mathbf{P}^n(R)$ if and only if the coefficients of $f(x)$ generate the unit ideal in R (in other words, if and only if $f(x)$ has nonzero image in $\kappa[x]$, for each residue field κ of R.

Construction 5.5.1.4. Let R be a commutative ring. For every pair of integers $m, n \geqslant 0$, multiplication of polynomials determines a map $R[x]_{\leqslant m} \otimes_R R[x]_{\leqslant n} \to R[x]_{\leqslant m+n}$. If $L \subseteq R[x]_{\leqslant m}$ and $L' \subseteq R[x]_{\leqslant n}$ are submodules satisfying conditions (a) and (b) of Notation 5.5.1.1, then the image of the composite map

$$L \otimes L' \to R[x]_{\leqslant m} \otimes_R R[x]_{\leqslant n} \to R[x]_{\leqslant m+n}$$

is a submodule which also satisfies conditions (a) and (b) of Notation 5.5.1.1. We will denote this image by LL'. The construction $(L, L') \mapsto LL'$ determines a map $\mathbf{P}^m(R) \times \mathbf{P}^n(R) \to \mathbf{P}^{m+n}(R)$. Iterating this construction, we obtain maps

$$\mathbf{P}^{k_1}(R) \times \mathbf{P}^{k_2}(R) \times \cdots \times \mathbf{P}^{k_n}(R) \to \mathbf{P}^{k_1+\cdots+k_n}(R).$$

We will be particularly interested in the case $k_1 = k_2 = \cdots = k_n = k$ for some integer k, in which case we obtain a map $\gamma(R) : \mathbf{P}^k(R)^n \to \mathbf{P}^{kn}(R)$. The maps $\gamma(R)$ determine a natural transformation of functors $\gamma : (\mathbf{P}^1)^n \to \mathbf{P}^n$, which (by virtue of Remark 5.5.1.2) we can view as a morphism of algebraic spaces $\mathbf{P}^k_{\mathbf{Z}} \times_{\mathrm{Spét}\,\mathbf{Z}} \cdots \times_{\mathrm{Spét}\,\mathbf{Z}} \mathbf{P}^k_{\mathbf{Z}} \to \mathbf{P}^{kn}_{\mathbf{Z}}$.

Proposition 5.5.1.5. *For each $k, n \geqslant 0$, the morphism of algebraic spaces $\gamma : \mathbf{P}^k_{\mathbf{Z}} \times_{\mathrm{Spec}\,\mathbf{Z}} \cdots \times_{\mathrm{Spec}\,\mathbf{Z}} \mathbf{P}^k_{\mathbf{Z}} \to \mathbf{P}^{kn}_{\mathbf{Z}}$ of Construction 5.5.1.4 is finite.*

Proof. Since the domain and codomain of γ are proper over $\mathbf{Z}$ (Corollary 5.4.3.4), the morphism γ is automatically proper. It will therefore suffice to show that the fibers of γ are finite. This can be checked at the level of κ-valued points, where κ is an algebraically closed field. The desired result now follows from the observation that, if $f(x) \in \kappa[x]$ is a nonzero polynomial of degree $\leqslant kn$, then up to rescaling there are only finitely many factorizations $f(x) = f_1(x) \cdots f_n(x)$ into polynomials of degree $\leqslant k$ (since $\kappa[x]$ is a unique factorization domain). □

Notation 5.5.1.6. Let $\phi : A \to B$ be a homomorphism of commutative rings which is finite flat of rank n. Then the induced map of polynomial rings $A[x] \to B[x]$ is also finite flat of rank n. We therefore have a well-defined norm map $Nm_{B[x]/A[x]} : B[x] \to A[x]$. Unwinding the definitions, we see that the norm map $Nm_{B[x]/A[x]}$ carries $B[x]_{\leqslant k}$ into $A[x]_{\leqslant kn}$.

Lemma 5.5.1.7. *Let $\phi : A \to B$ be as in Remark 5.5.1.6, and let $L \subseteq B[x]_{\leqslant k}$ be an element of $\mathbf{P}^k(B)$, and let $Nm_{B/A}(L)$ denote the A-submodule of $A[x]_{\leqslant nk}$ generated by elements of the form $Nm_{B[x]/A[x]}(f)$ where $f \in L$. Then $Nm_{B/A}(L) \in \mathbf{P}^{nk}(A)$.*

Proof. The assertion is local with respect to the Zariski topology on A. We may therefore assume without loss of generality that L is free of rank 1, generated by a polynomial $f(x) \in B[x]$ of degree $\leqslant k$. Since $Nm_{B[x]/A[x]}(\lambda f(x)) = Nm_{B/A}(\lambda) Nm_{B[x]/A[x]}(f(x))$ for $\lambda \in B$, we can identify $Nm_{B/A}(L)$ with the A-submodule of $A[x]_{\leqslant kn}$ generated by $Nm_{B[x]/A[x]}(f(x))$. We wish to show that this submodule is an element of $\mathbf{P}^{nk}(A)$. Using Remark 5.5.1.3, we can reduce to the case where $A = \kappa$ is a field, in which case we wish to show that $Nm_{B[x]/A[x]}(f(x))$ has invertible image in the fraction field $\kappa(x)$ of the polynomial ring $\kappa[x]$. To prove this, it will suffice to show that $f(x)$ has invertible image in the tensor product $B[x] \otimes_{\kappa[x]} \kappa(x)$, which follows from the criterion of Remark 5.5.1.3. □

Construction 5.5.1.8. Let $u : \mathsf{U} \to \mathsf{X}$ be a morphism of algebraic spaces which is finite flat of degree n, and suppose we are given a morphism $f : \mathsf{U} \to \mathbf{P}^k_{\mathbf{Z}}$. For every A-valued point η of X, our assumption that q is finite flat of degree n implies that we can write $\mathsf{U} \times_{\mathsf{X}} \mathrm{Spét}\,A = \mathrm{Spét}\,B$ for some B which is finite flat of degree n over A. The composite map $\mathrm{Spét}\,B \to \mathsf{U} \xrightarrow{f} \mathbf{P}^k_{\mathbf{Z}}$ then determines an element $L_\eta \in \mathbf{P}^k(B)$, so that Lemma 5.5.1.7 produces an element $Nm_{B/A}(L_\eta) \in \mathbf{P}^{kn}(A)$. The construction $\eta \mapsto Nm_{B/A}(L_\eta)$ depends functorially on A and is therefore classified by a map of algebraic spaces $Nm_q(f) : \mathsf{X} \to \mathbf{P}^{kn}_{\mathbf{Z}}$.

We will need the following compatibility between Constructions 5.5.1.4 and 5.5.1.8:

Proposition 5.5.1.9. *Let $q : \mathsf{U} \to \mathsf{X}$ be a morphism of algebraic spaces which is finite étale of rank n, let $f : \mathsf{U} \to \mathbf{P}^k_{\mathbf{Z}}$ be a morphism of algebraic spaces, and let $\mathrm{Conf}^n_{\mathsf{X}}(\mathsf{U})$ be as in Construction 3.2.2.1. Then the diagram*

$$\begin{array}{ccccc} \mathrm{Conf}^n_{\mathsf{X}}(\mathsf{U}) & \longrightarrow & \mathsf{U} \times_{\mathsf{X}} \cdots \times_{\mathsf{X}} \mathsf{U} & \xrightarrow{f} & \mathbf{P}^k_{\mathbf{Z}} \times_{\mathrm{Spét}\,\mathbf{Z}} \cdots \times_{\mathrm{Spét}\,\mathbf{Z}} \mathbf{P}^k\,\mathbf{Z} \\ \downarrow & & & & \downarrow \gamma \\ \mathsf{X} & & \xrightarrow{Nm_q(f)} & & \mathbf{P}^{kn}_{\mathbf{Z}} \end{array}$$

commutes, where $Nm_q(f)$ is the map defined in Construction 5.5.1.8 and γ is the map defined in Construction 5.5.1.4.

Proof. The assertion is local with respect to the étale topology on X. We may therefore assume without loss of generality that $\mathsf{X} = \mathrm{Spét}\,A$ is affine, that $\mathsf{U} = \mathrm{Spét}\,A^n$, and that the map $f : \mathsf{U} \to \mathbf{P}^k_{\mathbf{Z}}$ is given by an element $L \in \mathbf{P}^k(A^n)$ which is free as an A^n-module: that is, it is given by an n-tuple of elements $f_1(x), \ldots, f_n(x) \in A[x]_{\leqslant k}$. The result now follows from the observation that for every permutation σ of the set $\{1, \ldots, n\}$, the norm $Nm_{A^n[x]/A[x]}(f_1(x), \ldots, f_n(x))$ coincides with the product $\prod_{1 \leqslant i \leqslant n} f_{\sigma(i)}(x)$. □

Warning 5.5.1.10. The constructions of this section (specifically, Constructions 5.5.1.4 and 5.5.1.8) have no obvious analogue in the setting of spectral algebraic geometry: they use special features of commutative rings that do not hold for $\mathbb{E}_\infty$-rings.

5.5.2 Chow's Lemma in Classical Algebraic Geometry

Our next goal is to prove the following version of Chow's lemma in classical algebraic geometry:

Proposition 5.5.2.1. *Let R be a commutative ring and let X be an algebraic space which is nonempty, quasi-compact, separated, and locally of finite type over R. Then there exists a commutative diagram of algebraic spaces σ :*

$$\begin{array}{ccc} \widetilde{\mathsf{X}} & \xrightarrow{\phi} & \mathbf{P}^n_R \\ \downarrow \psi & & \downarrow \\ \mathsf{X} & \longrightarrow & \mathrm{Spét}\,R \end{array}$$

with the following properties:

(*a*) *The diagram σ induces a closed immersion $\widetilde{\mathsf{X}} \hookrightarrow \mathsf{X} \times_{\mathrm{Spét}\,R} \mathbf{P}^n_R$.*

(*b*) *There exists a nonempty open substack* $\mathsf{U} \subseteq \mathsf{X}$ *for which the projection map* $\psi_{\mathsf{U}} : \widetilde{\mathsf{X}} \times_{\mathsf{X}} \mathsf{U} \to \mathsf{U}$ *is an equivalence.*

(*c*) *The map* ϕ *is locally quasi-finite.*

Proof. Let us regard the commutative ring R as fixed. For each $k \geqslant 0$, we let $\mathbf{P}^k$ denote the projective space $\mathbf{P}^k_R$ of dimension k over R, and $\mathbf{A}^k$ the affine space $\operatorname{Spét} R[t_1, \ldots, t_k]$ of dimension k over R. All products are formed in the (ordinary) category of algebraic spaces over R (so that we write $\mathsf{X} \times \mathsf{Y}$ in place of $\tau_{\leqslant 0}(\mathsf{X} \times_{\operatorname{Spét} R} \mathsf{Y})$, if X and Y are 0-truncated spectral algebraic spaces over R).

We now follow the proof of Chow's lemma given in [117]. Since X is quasi-compact, we can choose a surjective étale map $u : \mathsf{U} \to \mathsf{X}$, where U is affine. Since X is separated, the morphism u is affine. For each point $x \in |\mathsf{X}|$, let $\kappa(x)$ denote the residue field of X at x (see Notation 3.6.2.5). Then the fiber $u^{-1}(x) = \operatorname{Spét} \kappa(x) \times_{\mathsf{X}} \mathsf{U}$ has the form $\operatorname{Spét} T_x$, where T_x is an étale $\kappa(x)$-algebra (that is, a finite product of finite separable field extensions of $\kappa(x)$). Let $r(x)$ denote the dimension of T_x as a $\kappa(x)$-algebra. It follows from Lemma 3.2.3.4 that the function $r : |\mathsf{X}| \to \mathbf{Z}_{\geqslant 0}$ is lower semicontinuous and bounded above. Set $n = \sup\{r(x) : x \in |\mathsf{X}|\}$, and note that $n > 0$ (since U is nonempty). Let $\mathsf{X}_0 \subseteq \mathsf{X}$ be the open substack corresponding to the open subset Choose a nonempty open subset $\{x \in |\mathsf{X}| : r(x) = n\} \subseteq |\mathsf{X}|$. Note that X_0 is quasi-compact (Lemma 3.2.3.4). Let $\mathsf{U}_0 \subseteq \mathsf{U}$ denote the inverse image of X_0 in U. Then u restricts to a map $u_0 : \mathsf{U}_0 \to \mathsf{X}_0$, and Lemma 3.2.3.4 implies that u_0 is finite étale of rank n (in particular, it is finite flat of rank n).

Since U is affine and locally of finite type over R, we can choose a closed immersion $e : \mathsf{U} \to \mathbf{A}^k$ for some $k \gg 0$. Let $\overline{e}$ denote the composite map $\mathsf{X} \xrightarrow{e} \mathbf{A}^k \hookrightarrow \mathbf{P}^k$, and let $\rho : \mathsf{X}_0 \to \mathbf{P}^{kn}$ denote the norm $Nm_{u_0}(\overline{e}|_{\mathsf{U}_0})$ (see Construction 5.5.1.8). Let $v : \mathsf{X}_0 \hookrightarrow \mathsf{X}$ denote the inclusion map. We define $\widetilde{\mathsf{X}}$ to be the schematic image (see Construction 3.1.5.1) of the map $(v, \rho) : \mathsf{X}_0 \to \mathsf{X} \times \mathbf{P}^{kn}$. By construction, we have an evident commutative diagram

$$\begin{array}{ccc} \widetilde{\mathsf{X}} & \xrightarrow{\phi} & \mathbf{P}^{kn} \\ \downarrow{\scriptstyle \psi} & & \downarrow \\ \mathsf{X} & \longrightarrow & \operatorname{Spét} R. \end{array}$$

We claim that this diagram satisfies the requirements of Theorem 5.5.2.1. Condition (*a*) is obvious (since $\widetilde{\mathsf{X}}$ is defined as a closed substack of $\mathsf{X} \times \mathbf{P}^{kn}$). To verify (*b*), it will suffice to show that the projection map $\psi_0 : \mathsf{X}_0 \times_{\mathsf{X}} \widetilde{\mathsf{X}} \to \mathsf{X}_0$ is an isomorphism. Using Remark 3.1.5.6, we see that the fiber product $\mathsf{X}_0 \times_{\mathsf{X}} \widetilde{\mathsf{X}}$ can be identified with the schematic image of the map $(\mathrm{id}, \rho) : \mathsf{X}_0 \to \mathsf{X}_0 \times \mathbf{P}^{kn}$. This map is already a closed immersion (since $\mathbf{P}^{kn}$ is separated), so its schematic image is equivalent to X_0.

It remains to prove that the map $\phi : \mathsf{X} \to \mathbf{P}^{kn}$ is locally quasi-finite. Let $\mathsf{Y}_0 = \mathrm{Conf}^n_{\mathsf{X}_0}(\mathsf{U}_0)$ (see Construction 3.2.2.1). Proposition 5.5.1.9 supplies a commutative diagram

$$\begin{array}{ccc} \mathsf{Y}_0 & \xrightarrow{\overline{\rho}} & (\mathbf{P}^k)^n \\ \downarrow{\scriptstyle \pi} & & \downarrow{\scriptstyle \gamma} \\ \mathsf{X}_0 & \xrightarrow{\rho} & \mathbf{P}^n \end{array}$$

where $\gamma : (\mathbf{P}^k)^n \to \mathbf{P}^{kn}$ is defined in Construction 5.5.1.4. Let Y denote the schematic image of the map $(v \circ \pi, \overline{\rho}) : \mathsf{Y}_0 \to \mathsf{X} \times (\mathbf{P}^k)^n$. We then have a commutative diagram

$$\begin{array}{ccccccc} \mathsf{Y}_0 & \longrightarrow & \mathsf{Y} & \xrightarrow{\overline{i}} & \mathsf{X} \times (\mathbf{P}^k)^n & \longrightarrow & (\mathbf{P}^k)^n \\ \downarrow{\scriptstyle \pi} & & \downarrow{\scriptstyle \overline{\pi}} & & \downarrow & & \downarrow{\scriptstyle \gamma} \\ \mathsf{X}_0 & \longrightarrow & \widetilde{\mathsf{X}} & \xrightarrow{i} & \mathsf{X} \times \mathbf{P}^{kn} & \longrightarrow & \mathbf{P}^{kn}. \end{array}$$

The map γ is finite (Proposition 5.5.1.5) and therefore induces a closed map of topological spaces $|\mathsf{X} \times (\mathbf{P}^k)^n| \to |\mathsf{X} \times \mathbf{P}^{kn}|$ (Proposition 5.2.1.1). It follows that $|\mathsf{Y}|$ has closed image in $|\mathsf{X} \times \mathbf{P}^{kn}|$. Since π is surjective, it follows from Proposition 3.6.1.6 that the image of $|\mathsf{Y}|$ contains $|\mathsf{X}|$: that is, the map $\overline{\pi} : \mathsf{Y} \to \mathsf{X}$ is surjective. Consequently, to show that to show that ϕ is locally quasi-finite, it will suffice to show that $\phi \circ \overline{\pi}$ is quasi-finite. Let $\overline{\phi}$ denote the composite map $\mathsf{Y} \xrightarrow{\overline{i}} \mathsf{X} \times (\mathbf{P}^k)^n \to (\mathbf{P}^k)^n$. Then $\phi \circ \overline{\pi} = \gamma \circ \overline{\phi}$. Since γ is finite, it will suffice to show that $\overline{\phi}$ is locally quasi-finite.

For $1 \leqslant j \leqslant n$, let $\mathsf{V}_j \subseteq (\mathbf{P}^k)^n$ denote the inverse image of $\mathbf{A}^k$ under the jth projection $(\mathbf{P}^k)^n = \mathbf{P}^k$, and let Y_j denote the open substack of Y given by $\mathsf{Y}_j \times_{(\mathbf{P}^k)^n} \mathsf{V}_j$. To complete the proof of Theorem 5.5.2.1, it will suffice to verify the following:

(a) For $1 \leqslant j \leqslant n$, the restriction $\overline{\phi}|_{\mathsf{Y}_j} : \mathsf{Y}_j \to \mathsf{V}_j$ is locally quasi-finite.

(b) The open substacks $\{\mathsf{Y}_j\}_{1 \leqslant j \leqslant n}$ cover Y.

We begin with the proof of (a). Using Remark 3.1.5.6, we can identify Y_j with the schematic image of the map $(v \circ \pi, \overline{\rho}) : \mathsf{Y}_0 \to \mathsf{X} \times \mathsf{V}_j$. Unwinding the definitions (and identifying V_j with the product $\mathbf{A}^k \times (\mathbf{P}^k)^{n-1}$, we see that this map factors as a composition

$$\mathsf{Y}_0 \to \mathsf{U} \times (\mathbf{P}^k)^{n-1} \xrightarrow{h_j} \mathsf{X} \times \mathbf{A}^k \times (\mathbf{P}^k)^{n-1},$$

where h_j is the product of the map $(u, e) : \mathsf{U} \to \mathsf{X} \times \mathbf{A}^k$ with the identity map on $(\mathbf{P}^k)^{n-1}$. The map (u, e) is a closed immersion (since e is a closed immersion and X is separated), so h_j is a closed immersion. We can therefore identify Y_j with a closed substack of the product

$\mathsf{U} \times (\mathbf{P}^k)^{n-1}$. Consequently, to show that $\overline{\phi}|_{\mathsf{Y}_j}$ is locally quasi-finite, it will suffice to show that the composition

$$\mathsf{U} \times (\mathbf{P}^k)^{n-1} \xrightarrow{h_j} \mathsf{X} \times \mathbf{A}^k \times (\mathbf{P}^k)^{n-1} \to \mathbf{A}^k \times (\mathbf{P}^k)^{n-1}$$

is locally quasi-finite. In fact, this composition is a closed immersion (since it is a pullback of the closed immersion $e : \mathsf{U} \hookrightarrow \mathbf{A}^k$).

We now prove (b). Since the map $u : \mathsf{U} \to \mathsf{X}$ is surjective, it will suffice to show that $\mathsf{U} \times_{\mathsf{X}} \mathsf{Y}$ is covered by the open substacks $\{\mathsf{U} \times_{\mathsf{X}} \mathsf{Y}_j\}_{1 \leqslant j \leqslant n}$. Using Remark 3.1.5.6, we see that $\mathsf{U} \times_{\mathsf{X}} \mathsf{Y}_0 \simeq \mathsf{U}_0 \times_{\mathsf{X}_0} \mathsf{Y}_0$ is dense in $\mathsf{U} \times_{\mathsf{X}} \mathsf{Y}$. Since the map $u_0 : \mathsf{U}_0 \to \mathsf{X}_0$ is finite étale of rank n, it is split after base change along the map $\mathsf{Y}_0 = \mathrm{Conf}^n_{\mathsf{X}_0}(\mathsf{U}_0)$: that is, we can identify the fiber product $\mathsf{U}_0 \times_{\mathsf{X}_0} \mathsf{Y}_0$ with a disjoint union $\amalg_{1 \leqslant j \leqslant n} \mathsf{Y}_0$. For $1 \leqslant j \leqslant n$, let $Z_j \subseteq |\, \mathsf{U}_0 \times_{\mathsf{X}_0} \mathsf{Y}_0 \,|$ denote the jth summand, and let $\overline{Z}_j$ denote the closure of Z_j in $|\, \mathsf{U} \times_{\mathsf{X}} \mathsf{Y} \,|$. Using Proposition 3.6.1.6, we see that the closed sets $\overline{Z}_j$ cover $|\, \mathsf{U} \times_{\mathsf{X}} \mathsf{Y} \,|$. Consequently, it will suffice to show that each $\overline{Z}_j$ is contained in $|\, \mathsf{U} \times_{\mathsf{X}} \mathsf{Y}_j \,|$. To prove this, we observe that $|\, \mathsf{U} \times_{\mathsf{X} \times \mathbf{P}^k} \mathsf{Y} \,|$ is a closed subspace of $|\, \mathsf{U} \times_{\mathsf{X}} \mathsf{Y} \,|$ which is contained in $|\, \mathsf{U} \times_{\mathsf{X}} \mathsf{Y}_j \,|$ and contains Z_j. □

5.5.3 Chow's Lemma in Spectral Algebraic Geometry

We now turn to the proof of Theorem 5.5.0.1. We begin by considering the case of ordinary algebraic spaces over a Noetherian commutative ring. In this case, we will use Proposition 5.5.2.1 to establish the following special case of Theorem 5.5.0.1.

Proposition 5.5.3.1. *Let R be a Noetherian commutative ring and let X be an algebraic space which is quasi-compact, separated, and locally of finite type over R. In the category of algebraic spaces over R, there exist closed immersions*

$$\varnothing = \mathsf{Y}_0 \hookrightarrow \mathsf{Y}_1 \hookrightarrow \mathsf{Y}_2 \hookrightarrow \cdots \hookrightarrow \mathsf{Y}_n = \mathsf{X}$$

and $h_i : \widetilde{\mathsf{Y}}_i \hookrightarrow \mathsf{Y}_i \times_{\mathrm{Sp\acute{e}t}\, R} \mathbf{P}^{d_i}_R$ such that each composite map $\widetilde{\mathsf{Y}}_i \xrightarrow{h_i} \mathsf{Y}_i \times_{\mathrm{Sp\acute{e}t}\, R} \mathbf{P}^{d_i}_R \to \mathbf{P}^{d_i}_R$ is locally quasi-finite and each projection map $\widetilde{\mathsf{Y}}_i \times_{\mathsf{Y}_i} \mathsf{U}_i \to \mathsf{U}_i$ is an equivalence, where U_i denotes the open substack of Y_i complementary to the closed immersion $\mathsf{Y}_{i-1} \hookrightarrow \mathsf{Y}_i$.

Proof. Proceeding by Noetherian induction, we may suppose that the conclusion of Proposition 5.5.3.1 is satisfied for every closed subspace $\mathsf{X}' \subsetneq \mathsf{X}$. If X is empty, then there is nothing to prove. Otherwise, let σ :

$$\begin{array}{ccc} \widetilde{\mathsf{X}} & \xrightarrow{\phi} & \mathbf{P}^k_R \\ \downarrow{\scriptstyle \psi} & & \downarrow \\ \mathsf{X} & \longrightarrow & \mathrm{Sp\acute{e}t}\, R \end{array}$$

and $\mathsf{U} \subseteq \mathsf{X}$ satisfy the requirements of Proposition 5.5.2.1 and let X' be the reduced closed substack of X complementary to U. Applying our inductive hypothesis to X', we deduce the existence of closed immersions

$$\varnothing = \mathsf{Y}_0 \hookrightarrow \mathsf{Y}_1 \hookrightarrow \mathsf{Y}_2 \hookrightarrow \cdots \hookrightarrow \mathsf{Y}_n = \mathsf{X}'$$

and $h_i : \widetilde{\mathsf{Y}}_i \hookrightarrow \mathsf{Y}_i \times_{\operatorname{Sp\acute{e}t} R} \mathbf{P}^{d_i}_R$ satisfying the requirements of Proposition 5.5.3.1 for X'. We then obtain a proof of Proposition 5.5.3.1 by setting $\mathsf{Y}_{n+1} = \mathsf{X}$ and taking $h_{n+1} : \widetilde{\mathsf{X}} \to \mathsf{Y}_{n+1} \times_{\operatorname{Sp\acute{e}t} R} \mathbf{P}^k_R$ to be the map classifying σ. □

Proof of Theorem 5.5.0.1. Let $f : \mathsf{X} \to \operatorname{Sp\acute{e}t} R$ be a quasi-compact, separated morphism of spectral algebraic spaces which exhibits $\tau_{\leqslant 0} \mathsf{X}$ as finitely 0-presented over R. Applying Proposition 4.4.4.1, we can choose a diagram σ :

$$\begin{array}{ccc} \mathsf{X} & \longrightarrow & \mathsf{X}_0 \\ \downarrow f & & \downarrow f_0 \\ \operatorname{Sp\acute{e}t} R & \longrightarrow & \operatorname{Sp\acute{e}t} R_0 \end{array}$$

where R_0 is finitely presented over the sphere spectrum S, the morphism f_0 is almost of finite presentation, and σ induces an equivalence $\tau_{\leqslant 0} \mathsf{X} \to \tau_{\leqslant 0}(\mathsf{X}_0 \times_{\operatorname{Sp\acute{e}t} R_0} \operatorname{Sp\acute{e}t} R)$. Using Corollary 4.6.1.4, we may further assume (after replacing R_0 by an extension if necessary) that X_0 is a separated spectral algebraic space. Applying Proposition 5.5.3.1 to the map of ordinary algebraic spaces $\tau_{\leqslant 0} \mathsf{X}_0 \to \operatorname{Sp\acute{e}t} \pi_0 R$, we deduce the existence of a sequence of closed immersions

$$\varnothing = \mathsf{Y}'_0 \hookrightarrow \mathsf{Y}'_1 \hookrightarrow \mathsf{Y}'_2 \hookrightarrow \cdots \hookrightarrow \mathsf{Y}'_n = \tau_{\leqslant 0} \mathsf{X}_0 .$$

and

$$h'_i : \widetilde{\mathsf{Y}}'_i \hookrightarrow \mathsf{Y}'_i \times_{\operatorname{Sp\acute{e}t} \pi_0 R_0} \mathbf{P}^{d_i}_{\pi_0 R_0} \simeq \mathsf{Y}' \times_{\operatorname{Sp\acute{e}t} R_0} \mathbf{P}^{d_i}_{R_0}$$

of 0-truncated algebraic spaces over R_0 for which the induced maps $e_i : \widetilde{\mathsf{Y}}'_i \to \mathbf{P}^{d_i}_{\pi_0 R_0}$ are locally quasi-finite and the projection maps $\widetilde{\mathsf{Y}}'_i \times_{\mathsf{Y}'_i} \mathsf{U}'_i \to \mathsf{U}'_i$ are equivalences, where U'_i denotes the open substack of Y'_i complementary to Y'_{i-1}. We now set $\mathsf{Y}_i = \mathsf{X} \times_{\mathsf{X}_0} \mathsf{Y}'_i$ and $\widetilde{\mathsf{Y}}'_i = \mathsf{X} \times_{\mathsf{X}_0} \widetilde{\mathsf{Y}}'_i$. By construction, we have closed immersions of spectral algebraic spaces

$$\varnothing = \mathsf{Y}_0 \to \mathsf{Y}_1 \to \cdots \to \mathsf{Y}_n = \mathsf{X} \times_{\mathsf{X}_0} \tau_{\leqslant 0} \mathsf{X}_0 \xrightarrow{g} \mathsf{X},$$

where g induces an equivalence of the underlying ordinary algebraic spaces. Each of the closed immersions $\mathsf{Y}_i \to \mathsf{X}$ is a pullback of the closed immersion $\mathsf{Y}'_i \to \mathsf{X}_0$, which is automatically almost of finite presentation because Y'_i and X_0 are locally Noetherian (Remark 4.2.0.4).

Finally, each of the maps h'_i fits into a commutative diagram

$$\begin{array}{ccc} \widetilde{\mathsf{Y}}_i & \xrightarrow{h_i} & \mathsf{Y}_i \times_{\mathrm{Sp\acute{e}t}\, R} \mathbf{P}^{d_i}_R \\ \downarrow & & \downarrow \\ \widetilde{\mathsf{Y}}'_i & \xrightarrow{h'_i} & \mathsf{Y}'_i \times_{\mathrm{Sp\acute{e}t}\, R_0} \mathbf{P}^{d_i}_{R_0}. \end{array}$$

Since h'_i is a closed immersion of locally Noetherian algebraic spaces, it is automatically locally almost of finite presentation when regarded as a morphism of spectral algebraic spaces (Remark refontinet), so that h_i is also a closed immersion which is locally almost of finite presentation. Since the projection maps $\widetilde{\mathsf{Y}}'_i \times_{\mathsf{Y}'_i} \mathsf{U}'_i \to \mathsf{U}'_i$ are equivalences, it follows that the maps h_i induce equivalences $\widetilde{\mathsf{Y}}_i \times_{\mathsf{Y}_i} \mathsf{U}_i \simeq \mathsf{U}_i$, where $\mathsf{U}_i \simeq \mathsf{U}'_i \times_{\mathsf{Y}'_i} \mathsf{Y}_i$ is the open substack of Y_i complementary to the image of Y_{i-1}. We conclude by observing that each of the composite maps $\widetilde{\mathsf{Y}}_i \xrightarrow{h_i} \mathsf{Y}_i \times_{\mathrm{Sp\acute{e}t}\, R} \mathbf{P}^{d_i}_R$ is locally quasi-finite, since it is a pullback of the composition $\widetilde{\mathsf{Y}}'_i \xrightarrow{e_i} \mathbf{P}^{d_i}_{\pi_0 R_0} \xrightarrow{u} \mathbf{P}^{d_i}_R$ where e_i is locally quasi-finite by construction and the map u is locally quasi-finite since it induces an equivalence of 0-truncations. □

5.5.4 Application: Noetherian Approximation for Properness

We close this section by describing typical application of Chow's lemma.

Proposition 5.5.4.1. *Let A_0 be a connective $\mathbb{E}_\infty$-ring. Suppose we are given a filtered diagram of connective A_0-algebras $\{A_\alpha\}$ having colimit A. Let $n \geqslant 0$ be an integer, let $\mathsf{X}_0 \in \mathrm{DM}^{\mathrm{fp}}_n(A_0)$. For each index α, let X_α denote the image of X_0 in $\mathrm{DM}^{\mathrm{fp}}_n(A_\alpha)$, and let X denote the image of X_0 in $\mathrm{DM}^{\mathrm{fp}}_n(A)$. If X is proper over $\mathrm{Sp\acute{e}t}\, A$, then there exists an index α such that X_α is proper over $\mathrm{Sp\acute{e}t}\, A_\alpha$.*

We begin with an easier version of Proposition 5.5.4.1.

Lemma 5.5.4.2. *Let A_0 be a connective $\mathbb{E}_\infty$-ring. Suppose we are given a filtered diagram of connective A_0-algebras $\{A_\alpha\}$ having colimit A. Let $n \geqslant 0$ be an integer, let $\mathsf{X}_0 \in \mathrm{DM}^{\mathrm{fp}}_n(A_0)$. For each index α, let X_α denote the image of X_0 in $\mathrm{DM}^{\mathrm{fp}}_n(A_\alpha)$, and let X denote the image of X_0 in $\mathrm{DM}^{\mathrm{fp}}_n(A)$. If X is finite over $\mathrm{Sp\acute{e}t}\, A$, then there exists an index α such that X_α is finite over $\mathrm{Sp\acute{e}t}\, A_\alpha$.*

Remark 5.5.4.3. By virtue of Proposition 5.2.1.1, Lemma 5.5.4.2 is an immediate consequence of Propositions 5.5.4.1 and 4.6.1.1. However, we will use Lemma 5.5.4.2 in our proof of Proposition 5.5.4.1.

Proof of Lemma 5.5.4.2. Using Proposition 4.6.1.1, we see that there exists an index α such that X_α is affine: that is, we can write $\mathsf{X}_\alpha = \mathrm{Sp\acute{e}t}\, B_\alpha$ for some B_α which is finitely n-presented over A. Choose a finite collection of elements $x_1, \ldots, x_n \in \pi_0 B_\alpha$ which generate $\pi_0 B_\alpha$ as an algebra over $\pi_0 A_\alpha$. Since X is finite over A, the commutative ring $\pi_0(A \otimes_{A_\alpha} B_\alpha)$ is finitely generated as a module over $\pi_0 A$. It follows that the image of each x_i in $\pi_0(A \otimes_{A_\alpha} B_\alpha)$ is integral over $\pi_0 A$. Modifying α if necessary, we may assume that each x_i is integral over $\pi_0 A_\alpha$. It then follows that $\pi_0 B_\alpha$ is finitely generated as a module over $\pi_0 A_\alpha$, so that X_α is finite over A_α. □

Proof of Proposition 5.5.4.1. Using Remark 5.1.2.2, we may reduce to the case where $n = 0$. Using Corollary 4.6.1.4, we may assume without loss of generality that X_0 is a separated spectral algebraic space of finite type over A_0. Choose closed immersions

$$\emptyset = \mathsf{Y}'_0 \to \cdots \to \mathsf{Y}'_n \to \mathsf{X}_0$$

and $h'_i : \widetilde{\mathsf{Y}}'_i \to \mathsf{Y}'_i \times_{\mathrm{Sp\acute{e}t}\, A_0} \mathbf{P}^{d_i}_{A_0}$. satisfying the requirements of Theorem 5.5.0.1. Set $\mathsf{Y}_i = \mathsf{Y}'_i \times_{\mathsf{X}_0} \mathsf{X}$ and $\widetilde{\mathsf{Y}}_i = \widetilde{\mathsf{Y}}'_i \times_{\mathsf{X}_0} \mathsf{X}$, so that the maps h'_i induce closed immersions $h_i : \widetilde{\mathsf{Y}}_i \to \mathsf{Y}_i \times_{\mathrm{Sp\acute{e}t}\, A} \mathbf{P}^{d_i}_A$. Since X is proper over A, it follows from Remark 5.5.0.4 that each of the induced maps $\widetilde{\mathsf{Y}}_i \to \mathbf{P}^{d_i}_A$ is finite. Using Lemma 5.5.4.2, we can assume (after replacing A_0 by some A_α) that each of the maps $\widetilde{\mathsf{Y}}'_i \to \mathbf{P}^{d_i}_{A_0}$ is finite. Combining Proposition 5.2.1.1 with Corollary 5.4.3.4, we deduce that each $\widetilde{\mathsf{Y}}'_i$ is proper over $\mathrm{Sp\acute{e}t}\, A_0$. Since the map $\amalg \widetilde{\mathsf{Y}}'_i \to \mathsf{X}_0$ is surjective, it follows from Proposition 5.1.4.1 that X_0 is also proper over $\mathrm{Sp\acute{e}t}\, A_0$. □

5.6 The Direct Image Theorem

Recall the direct image theorem for proper morphisms of Noetherian algebraic spaces (see [117]):

Theorem 5.6.0.1. *Let $f : X \to Y$ be a proper morphism between Noetherian algebraic spaces and let $\mathscr{F}$ be an object in the abelian category of coherent sheaves on X. Then, for each $i \geqslant 0$, the higher direct image $R^i f_* \mathscr{F}$ is a coherent sheaf on Y.*

If we regard X and Y as spectral algebraic spaces, then the higher direct images $R^i f_* \mathscr{F}$ are just the homotopy sheaves of the (derived) direct image $f_* \mathscr{F}$. By virtue of Corollary 2.7.2.3, the requirement that these homotopy sheaves are coherent (in the sense of classical algebraic geometry) is equivalent to the requirement that $f_* \mathscr{F}$ is almost perfect (in the sense of Definition 2.8.4.4). Consequently, Theorem 5.6.0.1 can be regarded as a special case of the following more general assertion:

Theorem 5.6.0.2. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is proper and locally almost of finite presentation. Then the pushforward functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ carries almost perfect objects of $\mathrm{QCoh}(\mathsf{X})$ to almost perfect objects of $\mathrm{QCoh}(\mathsf{Y})$.*

Our goal in this section is to give a proof of Theorem 5.6.0.2. We will employ the same basic strategy used by Knutson to prove Theorem 5.6.0.1 in [117] (and earlier by Grothendieck to establish the special case of Theorem 5.6.0.1 where X and Y are schemes): namely, we use Chow's lemma to reduce to the case where X is a projective space over Y, in which case the desired result can be deduced from Serre's calculation of the cohomology of line bundles on projective space (Theorem 5.4.2.6). However, the proof of Theorem 5.6.0.2 is a bit more subtle, because we do not make any Noetherian assumptions on X and Y.

Remark 5.6.0.3. In the setting of classical algebraic geometry, Theorem 5.6.0.2 was proven by Illusie in the special case where f is projective (see [101]), and by Kiehl for a general proper morphism (see [116]).

5.6.1 The Case of a Finite Morphism

We begin with an easy special case of Theorem 5.6.0.2.

Proposition 5.6.1.1. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is finite and locally almost of finite presentation. Then an object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is almost perfect if and only if the direct image $f_* \mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})$ is almost perfect.*

We will deduce Proposition 5.6.1.1 from the following:

Lemma 5.6.1.2. *Let $f : A \to B$ be a morphism of connective $\mathbb{E}_1$-rings, and let M be a left B-module. Suppose that B is almost perfect when regarded as a left A-module. Then, for every integer n, the module M is perfect to order n over B if and only if it is perfect to order n over A. In particular, M is almost perfect when regarded as a left B-module if and only if it is almost perfect when regarded as a left A-module.*

Proof. Note that if M is perfect to order n as a left module over either A or B, then M is $(-m)$-connective for $m \gg 0$. Replacing M by $\Sigma^m M$ (and n by $n+m$), we may assume that M is connective. We now proceed by induction on n. If $n < 0$, there is nothing to prove. Let us therefore assume that $n \geqslant 0$. Note that since B is almost perfect as a left A-module, the homotopy group $\pi_0 B$ is finitely generated as a left A-module. It follows that $\pi_0 M$ is finitely generated as a left module over $\pi_0 A$ if and only if it is finitely generated as a module over $\pi_0 B$. If neither of these conditions is satisfied, then M is not perfect to order n as either a left A-module or as a left B-module, and the proof is complete. Otherwise, we can choose a fiber sequence of left B-modules $M' \to B^n \to M$, where M' is connective. Note that B^n is almost perfect both as a left A-module and as a left B-module. It follows that M is perfect to order n (as a left module over either A or B) if and only if M' is perfect to order $(n-1)$ (as a left module over either A or B); see Remark 2.7.0.7. The desired result now follows by applying our inductive hypothesis to M'. □

Proof of Proposition 5.6.1.1. Let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$; we wish to show that $\mathscr{F}$ is almost perfect if and only if $f_* \mathscr{F}$ is almost perfect. Both conditions are local on Y, so we may assume without loss of generality that $\mathsf{Y} = \operatorname{Sp\acute{e}t} A$ is affine. In this case, our assumption that f is finite guarantees that $\mathsf{X} \simeq \operatorname{Sp\acute{e}t} B$ is also affine. Since f is locally almost of finite presentation, the $\mathbb{E}_\infty$-ring B is almost perfect when regarded as an A-module (Proposition 5.2.2.2). The desired result now follows from Lemma **??**. □

5.6.2 The Case of Projective Space

We begin by establishing the following special case of Theorem 5.6.0.2:

Proposition 5.6.2.1. *Let R be a connective $\mathbb{E}_\infty$-ring, let $n \geqslant 0$ be an integer, and let $q : \mathbf{P}^n_R \to \operatorname{Sp\acute{e}t} R$ denote the projection map. Then the direct image functor carries almost perfect objects of $\mathrm{QCoh}(\mathbf{P}^n_R)$ to almost perfect objects of $\mathrm{QCoh}(\operatorname{Sp\acute{e}t} R) \simeq \mathrm{Mod}_R$.*

We will deduce Proposition 5.6.2.1 from Theorem 5.4.2.6 and the following:

Lemma 5.6.2.2. *Let R be a connective $\mathbb{E}_\infty$-ring and let $\mathscr{F} \in \mathrm{QCoh}(\mathbf{P}^n_R)^{\mathrm{cn}}$. Then there exists a fiber sequence $\mathscr{F}' \to \mathscr{G} \to \mathscr{F}$ in $\mathrm{QCoh}(\mathbf{P}^n_R)$, where $\mathscr{G} \simeq \bigoplus_\alpha \mathscr{O}(d_\alpha)$ is a coproduct of copies of the line bundles $\mathscr{O}(d)$ described in Construction 5.4.2.1, and $\mathscr{F}'$ is connective.*

Proof. Let us denote the monoid algebra $R[\mathbf{Z}^{n+1}_{\geqslant 0}]$ by $R[x_0, \ldots, x_n]$. Set $\mathsf{X} = \operatorname{Sp\acute{e}t} R[x_0, \ldots, x_n]$. Let $\mathsf{U} \subseteq \mathsf{X}$ denote the open substack complementary to the vanishing locus of the ideal $(x_0, \ldots, x_n) \subseteq \pi_0 R[x_0, \ldots, x_n]$. For $0 \leqslant i \leqslant n$, let $\mathsf{U}_i \subseteq \mathsf{U} \subseteq \mathsf{X}$ denote the open substack complementary to the vanishing locus of (x_i), and for each $I \subseteq [n]$ let U_I denote the intersection $\bigcap_{i \in I} \mathsf{U}_i$. Since the open stack U is covered by $\{\mathsf{U}_i\}_{0 \leqslant i \leqslant n}$, we can write U as the colimit $\varinjlim_{\varnothing \neq I \subseteq [n]} \mathsf{U}_I$ (formed in the ∞-category of spectral Deligne-Mumford stacks).

For each subset $I \subseteq [n]$, set $M_I^+ = \{(k_0, \ldots, k_n) \in \mathbf{Z}^{n+1} : (k_i < 0) \Rightarrow (i \in I)\}$, so we have a canonical equivalence $\mathsf{U}_I \simeq \operatorname{Sp\acute{e}t} R[M_I^+]$. Let $M_I \subseteq M_I^+$ denote the subset consisting of those tuples $(k_0, \ldots, k_n)$ satisfying $k_0 + \cdots + k_n = 0$. The inclusion $M_I \hookrightarrow M_I^+$ induces a morphism of $\mathbb{E}_\infty$-algebras $R[M_I] \to R[M_I^+]$. These morphisms depend functorially on I and therefore induce a map

$$q : \mathsf{U} \simeq \varinjlim_{\varnothing \neq I \subseteq [n]} \mathsf{U}_I = \varinjlim_{\varnothing \neq I \subseteq [n]} \operatorname{Sp\acute{e}t} R[M_I^+] \to \varinjlim_{\varnothing \neq I \subseteq [n]} \operatorname{Sp\acute{e}t} R[M_I] \simeq \mathbf{P}^n_R.$$

Write $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ and $\mathsf{U} = (\mathcal{U}, \mathscr{O}_{\mathcal{U}})$, and let $j : \mathsf{U} \hookrightarrow \mathsf{X}$ denote the inclusion map. Since X is affine, there exists a set A and a morphism $\rho_{\mathsf{X}} : \bigoplus_{\alpha \in A} \mathscr{O}_{\mathcal{X}} \to j_* q^* \mathscr{F}$ which induces an epimorphism $\pi_0(\bigoplus \mathscr{O}_{\mathcal{X}}) \to \pi_0(j_* q^* \mathscr{F})$ in the abelian category $\mathrm{QCoh}(\mathsf{X})^{\heartsuit}$. Restricting to U, we obtain a map $\rho_{\mathsf{U}} : \bigoplus_{\alpha \in A} \mathscr{O}_{\mathcal{U}} \to q^* \mathscr{F}$ in $\mathrm{QCoh}(\mathsf{U})$ which induces an epimorphism on π_0. Let us identify ρ_{U} with a map

$$\bigoplus_{\alpha \in A} \mathscr{O}(0) \to q_* q^* \mathscr{F} \simeq \mathscr{F} \otimes q_* \mathscr{O}_{\mathcal{U}},$$

which classifies a family of maps $\{\rho_\alpha : \mathscr{O}(0) \to \mathscr{F} \otimes q_* \mathscr{O}_{\mathcal{U}}\}_{\alpha \in A}$. Unwinding the definitions, we see that $q_* \mathscr{O}_{\mathcal{U}}$ can be identified with the direct sum $\bigoplus_{m \in \mathbf{Z}} \mathscr{O}(m)$. Since $\mathbf{P}^n_R$ is a quasi-compact and quasi-separated spectral algebraic space, the global section functor on $\mathbf{P}^n_R$ commutes with filtered colimits. It follows that for each $\alpha \in A$, there exists a constant $c_\alpha \geqslant 0$ such that ρ_α factors as a composition

$$\mathscr{O}(0) \xrightarrow{\rho'_\alpha} \bigoplus_{|m| \leqslant c_\alpha} \mathscr{F} \otimes \mathscr{O}(m) \to \bigoplus_{m \in \mathbf{Z}} \mathscr{F} \otimes \mathscr{O}(m) \simeq \mathscr{F} \otimes q_* \mathscr{O}_{\mathcal{U}}.$$

Each of the maps ρ'_α can in turn be identified with a finite collection of maps $\{\rho'_{\alpha,m} : \mathscr{O}(-m) \to \mathscr{F}\}_{|m| \leqslant c_\alpha}$ in the ∞-category $\mathrm{QCoh}(\mathbf{P}^n_R)$. Set $\mathscr{G} = \bigoplus_{\alpha \in A, |m| \leqslant c_\alpha} \mathscr{O}(-m)$, and let $\mu : \mathscr{G} \to \mathscr{F}$ be the amalgam of the maps $\rho'_{\alpha,m}$. We claim that the fiber of μ is connective. Since the map $q : \mathsf{U} \to \mathbf{P}^n_R$ is faithfully flat, it will suffice to show that the pullback $q^* \mu$ has connective fiber: that is, that $q^* \mu$ induces an epimorphism $\pi_0 q^* \mathscr{G} \to \pi_0 q^* \mathscr{F}$. This is clear, since the map ρ_{U} factors through $q^* \mu$. □

Remark 5.6.2.3. In the situation of Lemma 5.6.2.2, suppose that the quasi-coherent sheaf $\mathscr{F}$ is perfect to order 0. Using the quasi-compactness of $\mathbf{P}^n_R$, we can choose a finite set of indices $\{\alpha_1, \ldots, \alpha_k\}$ such that the composite map $\bigoplus_{1 \leqslant i \leqslant k} \mathscr{O}(d_{\alpha_i}) \to \mathscr{G} \to \mathscr{F}$ has connective fiber. In other words, we can assume that $\mathscr{G}$ is a coproduct of *finitely many* line bundles of the form $\mathscr{O}(n)$. In this case, the existence of a fiber sequence $\mathscr{F}' \to \mathscr{G} \to \mathscr{F}$ implies that if $\mathscr{F}$ is perfect to order $m+1$ for $m \geqslant 0$, then $\mathscr{F}'$ is perfect to order m (see Proposition 2.7.2.1). In particular, if $\mathscr{F}$ is almost perfect, then $\mathscr{F}'$ is almost perfect.

Proof of Proposition 5.6.2.1. Let $\mathscr{F} \in \mathrm{QCoh}(\mathbf{P}^n_R)$ be almost perfect and let $q : \mathbf{P}^n_R \to \mathrm{Sp\acute{e}t}\, R$ be the projection map. We wish to show that the direct image $q_* \mathscr{F} \in \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R) \simeq \mathrm{Mod}_R$ is almost perfect. Replacing $\mathscr{F}$ by a suspension if necessary, we may assume without loss of generality that $\mathscr{F}$ is connective. In this case, the desired result follows from the following family of assertions.

$(*_m)$ Let $\mathscr{F} \in \mathrm{QCoh}(\mathbf{P}^n_R)$ be connective and almost perfect. Then $q_* \mathscr{F} \in \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R) \simeq \mathrm{Mod}_R$ is perfect to order m.

Corollary 3.4.2.3 implies that there exists an integer $k \ll 0$ such that for every connective object $\mathscr{F} \in \mathrm{QCoh}(\mathbf{P}^n_R)$, the direct image $q_* \mathscr{F}$ is k-connective (in fact, we can take $k = -n$, since $\mathbf{P}^n_R$ is a separated spectral algebraic space which admits an open cover by $(n+1)$ affine open substacks). Consequently, assertion $(*_m)$ is automatic for $m < k$. We prove $(*_m)$ in general using induction on m. Suppose that $\mathscr{F} \in \mathrm{QCoh}(\mathbf{P}^n_R)$ is connective and almost perfect. Using Remark 5.6.2.3, we can choose a fiber sequence $\mathscr{F}' \to \mathscr{G} \to \mathscr{F}$, where $\mathscr{G}$ is a direct sum of finitely many line bundles of the form $\mathscr{O}(a)$ and $\mathscr{F}'$ is also connective and almost perfect. We then have a fiber sequence of R-modules $q_* \mathscr{F}' \to q_* \mathscr{G} \to q_* \mathscr{F}$.

Theorem 5.4.2.6 shows that $q_* \mathscr{G}$ is a perfect R-module and our inductive hypothesis implies that $q_* \mathscr{F}'$ is perfect to order $(m-1)$, so that $q_* \mathscr{F}$ is perfect to order m as desired. $\square$

Remark 5.6.2.4. The proof of Proposition 5.6.2.1 yields the following slightly stronger assertion:

$(*)$ Let $\mathscr{F} \in \mathrm{QCoh}(\mathbf{P}^n_R)$ be connective and perfect to order m for $m \geqslant 0$, and let $q : \mathbf{P}^n_R \to \mathrm{Sp\acute{e}t}\, R$ denote the projection map. Then $q_* \mathscr{F} \in \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R) \simeq \mathrm{Mod}_R$ is perfect to order $m-n$.

5.6.3 Sheaves Supported on a Closed Subset

Let $f : X \to Y$ be a morphism of complex algebraic varieties, and let $\mathscr{F}$ be a coherent sheaf on X. To guarantee the coherence of the higher direct images $R^i f_* \mathscr{F}$, it is not necessary to assume that f is proper: it is enough to know that the restriction of $f|_K$ is proper, where $K \subseteq X$ is the support of $\mathscr{F}$. To prove an analogous generalization of Theorem 5.6.0.2, we will need the following:

Proposition 5.6.3.1. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ be a quasi-compact, quasi-separated spectral algebraic space, let $i : (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}}) \to \mathsf{X}$ be a closed immersion which is locally almost of finite presentation, let $j : \mathsf{U} \hookrightarrow \mathsf{X}$ be the complementary open immersion, and let $\mathcal{I}$ denote the fiber of the unit map $\mathscr{O}_{\mathcal{X}} \to i_* \mathscr{O}_{\mathcal{Y}}$. Suppose we are given quasi-coherent sheaves $\mathscr{F}, \mathscr{G} \in \mathrm{QCoh}(\mathsf{X})$ such that $\mathscr{F}$ is almost perfect, $\mathscr{G}$ is truncated, and $j^* \mathscr{G} \simeq 0$. Then the direct limit $\varinjlim \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathcal{I}^{\otimes n} \otimes \mathscr{F}, \mathscr{G})$ vanishes.*

Proof. For each object $U \in \mathcal{X}$, set $\mathsf{X}_U = (\mathcal{X}_{/U}, \mathscr{O}_{\mathcal{X}}|_U)$ and let $T_{\mathscr{G}}(U)$ denote the direct limit $\varinjlim \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X}|_U)}(\mathcal{I}^{\otimes n}|_U \otimes \mathscr{F}|_U, \mathscr{G}|_U)$. Since filtered colimits in $\mathcal{S}$ are left exact, the construction $U \mapsto T_{\mathscr{G}}(U)$ carries finite colimits in $\mathcal{X}$ to finite limits in $\mathcal{S}$. It follows that the collection of those objects $U \in \mathcal{X}$ for which $T_{\mathscr{G}}(U)$ is contractible is closed under finite colimits. We wish to show that $T_{\mathscr{G}}(\mathbf{1})$ is contractible, where $\mathbf{1}$ denotes a final object of $\mathcal{X}$. By virtue of Proposition 2.5.3.5 (and Theorem 3.4.2.1), it will suffice to show that $T_{\mathscr{G}}(U)$ is contractible when $U \in \mathcal{X}$ is affine. Replacing X by X_U, we may assume that X is affine. Let us now denote $T_{\mathscr{G}}(\mathbf{1})$ simply by $T_{\mathscr{G}}$.

Our assumption that i is locally almost of finite presentation guarantees that the sheaf $\mathcal{I}$ is almost perfect (Corollary 5.2.2.2). Consequently, each of the sheaves $\mathcal{I}^{\otimes n} \otimes \mathscr{F}$ is almost perfect. It follows that the the construction $\mathscr{G} \mapsto T_{\mathscr{G}}$ commutes with filtered colimits when restricted to n-truncated objects of $\mathrm{QCoh}(\mathsf{X})$, for any integer n. It will therefore suffice to show that the space $T_{\tau_{\geqslant m} \mathscr{G}}$ is contractible for every integer m. This is automatic for $m \gg 0$ (since $\mathscr{G}$ is truncated). We handle the general case by descending induction on m. To carry out the inductive step, we note that the fiber sequence $\tau_{\geqslant m+1} \mathscr{G} \to \tau_{\geqslant m} \mathscr{G} \to \Sigma^m \pi_m \mathscr{G}$

induces a fiber sequence of spaces

$$T_{\tau_{\geqslant m+1}\mathscr{G}} \to T_{\tau_{\geqslant m}\mathscr{G}} \to T_{\Sigma^m \pi_m \mathscr{G}}.$$

We are therefore reduced to showing that $T_{\Sigma^m \pi_m \mathscr{G}}$ is contractible. Replacing $\mathscr{F}$ by $\Sigma^{-m}\mathscr{F}$ and $\mathscr{G}$ by $\pi_m \mathscr{G}$, we are reduced to proving that $T_{\mathscr{G}}$ is contractible in the special case where $\mathscr{G} \in \mathrm{QCoh}(\mathsf{X})^{\heartsuit}$.

Write $\mathsf{X} = \mathrm{Spét}\, A$, so that $\mathscr{F}$ corresponds to an almost perfect A-module M and $\mathscr{G}$ to a discrete A-module N. Writing N as a colimit of its finitely generated submodules, we can reduce to the case where N is finitely generated. Let $I \subseteq \pi_0 A$ be the ideal given by the kernel of the map $\pi_0 A \to \pi_0 \Gamma(\mathcal{Y}; \mathscr{O}_{\mathcal{Y}})$. Since $\mathcal{I}$ is almost perfect, the ideal I is finitely generated. Our assumption that $j^* \mathscr{G} \simeq 0$ guarantees that every element $x \in I$ has a locally nilpotent action on N. Since I and N are finitely generated, it follows that $I^k N = 0$ for some $k \gg 0$. Then the multiplication map $\mathcal{I}^{\otimes k} \otimes \mathscr{G} \to \mathscr{G}$ is nullhomotopic, so the transition map $\mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathcal{I}^{\otimes n} \otimes \mathscr{F}, \mathscr{G}) \to \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathcal{I}^{\otimes n+k} \otimes \mathscr{F}, \mathscr{G})$ is nullhomotopic. Passing to the direct limit, we deduce that $T_{\mathscr{G}} \simeq \varinjlim \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathcal{I}^{\otimes n} \otimes \mathscr{F}, \mathscr{G})$ is contractible, as desired. □

Example 5.6.3.2. In the situation of Proposition 5.6.3.1, suppose that $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is almost perfect and $j^* \mathscr{F} \simeq 0$. Then, for every integer n, there exists $k \gg 0$ such that the composite map $\mathcal{I}^{\otimes k} \otimes \mathscr{F} \to \mathscr{F} \to \tau_{\leqslant n} \mathscr{F}$ is nullhomotopic.

Proposition 5.6.3.3. *Let $i : \mathsf{Y} \to \mathsf{X}$ and $f : \mathsf{X} \to \mathsf{Z}$ be morphisms of quasi-compact, quasi-separated spectral algebraic spaces. Suppose that i is a closed immersion which is locally almost of finite presentation, let $j : \mathsf{U} \hookrightarrow \mathsf{X}$ be the complementary open immersion, and let $K \subseteq |\mathsf{X}|$ denote the image of $|\mathsf{Y}|$. Assume that the direct image functor $(f \circ i)_* : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{Z})$ carries almost perfect objects of $\mathrm{QCoh}(\mathsf{Y})$ to almost perfect objects of $\mathrm{QCoh}(\mathsf{Z})$. Suppose that $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is almost perfect and that $j^* \mathscr{F} \simeq 0$. Then $f_* \mathscr{F} \in \mathrm{QCoh}(\mathsf{Z})$ is almost perfect.*

Proof. Fix an integer n; we will show that $\tau_{\leqslant n} f_* \mathscr{F} \in \mathrm{QCoh}(\mathsf{Z})$ is finitely n-presented. Enlarging n if necessary, we may assume that $n \geqslant 0$ and that the functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Z})$ carries $\mathrm{QCoh}(\mathsf{X})_{\geqslant 0}$ into $\mathrm{QCoh}(\mathsf{Z})_{\geqslant -n}$. Let $\mathcal{I}$ be as in the statement of Proposition 5.6.3.1. Using Example 5.6.3.2, we deduce that there exists an integer $k \gg 0$ such that the multiplication map $\mathcal{I}^{\otimes k} \otimes \mathscr{F} \xrightarrow{v} \mathscr{F} \to \tau_{\leqslant 2n} \mathscr{F}$ is nullhomotopic. It follows that the truncation map $u : \mathscr{F} \to \tau_{\leqslant 2n} \mathscr{F}$ factors through $\mathrm{cofib}(v)$. We have a fiber sequence $f_*(\tau_{\geqslant 2n+1} \mathscr{F}) \to f_* \mathscr{F} \xrightarrow{f_* u} f_*(\tau_{\leqslant 2n} \mathscr{F})$ whose first term belongs to $\mathrm{QCoh}(\mathsf{Z})_{\geqslant n+1}$, so that $f_*(u)$ induces an equivalence $\tau_{\leqslant n} f_* \mathscr{F} \simeq \tau_{\leqslant n} f_*(\tau_{\leqslant 2n} \mathscr{F})$. It follows that $\tau_{\leqslant n} f_* \mathscr{F}$ is a retract of $\tau_{\leqslant n} f_* \, \mathrm{cofib}(v)$. It will therefore suffice to show that $\tau_{\leqslant n} f_*(\mathrm{cofib}(v))$ is finitely n-presented. In fact, we claim that $f_*(\mathrm{cofib}(v))$ is almost perfect. This a special case of the following assertion:

(∗) For every $\mathscr{G} \in \mathrm{QCoh}(\mathsf{X})$ almost perfect and each $k \geqslant 0$, the functor f_* carries $\mathrm{cofib}(\mathcal{I}^{\otimes k} \otimes \mathscr{G} \to \mathscr{G})$ to an almost perfect object of $\mathrm{QCoh}(\mathsf{Z})$.

The proof of (∗) proceeds by induction on k, the case $k = 0$ being trivial. To carry out the inductive step, we observe that the multiplication map $v : \mathcal{I}^{\otimes k} \otimes \mathscr{G} \to \mathscr{G}$ factors as a composition

$$\mathcal{I}^{\otimes k} \otimes \mathscr{G} \xrightarrow{v'} \mathcal{I} \otimes \mathscr{G} \xrightarrow{v''} \mathscr{G},$$

so we have a fiber sequence $\mathrm{cofib}(v') \to \mathrm{cofib}(v) \to \mathrm{cofib}(v'')$. Since the direct image $f_* \mathrm{cofib}(v')$ is almost perfect by our inductive hypothesis, we are reduced to showing that the direct image $f_* \mathrm{cofib}(v'')$. This is clear, since we have an equivalence $f_* \mathrm{cofib}(v) \simeq (f \circ i)_* i^* \mathscr{G}$, and the functors $(f \circ i)_*$ and i^* both preserve almost perfect objects. □

5.6.4 The Proof of Theorem 5.6.0.2

We are now ready to give the proof of Theorem 5.6.0.2. Suppose that $f : \mathsf{X} \to \mathsf{Z}$ is a morphism of spectral Deligne-Mumford stacks which is proper and locally almost of finite presentation. We wish to show that the direct image functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Z})$ carries almost perfect objects of $\mathrm{QCoh}(\mathsf{X})$ to almost perfect objects of $\mathrm{QCoh}(\mathsf{Z})$. To prove this, we can assume without loss of generality that $\mathsf{Z} = \mathrm{Sp\acute{e}t}\, R$ is affine. Applying Theorem 5.5.0.1, we deduce the existence of a sequence of closed immersions

$$\varnothing = \mathsf{Y}_0 \to \mathsf{Y}_1 \to \mathsf{Y}_2 \to \cdots \to \mathsf{Y}_n \to \mathsf{X}$$

and $h_i : \widetilde{\mathsf{Y}}_i \to \mathsf{Y}_i \times_{\mathrm{Sp\acute{e}t}\, R} \mathbf{P}^{d_i}_R$ which are locally almost of finite presentation, where the map $\mathsf{Y}_n \to \mathsf{X}$ induces a homeomorphism $|\mathsf{Y}_n| \simeq |\mathsf{X}|$, where each of the induced maps $\rho_i : \widetilde{\mathsf{Y}}_i \to \mathbf{P}^{d_i}_R$ is finite and locally almost of finite presentation (Remark 5.5.0.4), and each of the projection maps $\widetilde{\mathsf{Y}}_i \times_{\mathsf{Y}_i} \mathsf{U}_i \to \mathsf{U}_i$ is an equivalence, where U_i denotes the open substack of Y_i complementary to Y_{i-1}. For $0 \leqslant i \leqslant n$, let $v_i : \mathsf{Y}_i \to \mathsf{X}$ be the corresponding closed immersion. By virtue of Proposition 5.6.3.3, to prove that the functor f_* carries almost perfect objects to almost perfect objects, it will suffice to show that the functor $(v_n \circ f)_* : \mathrm{QCoh}(\mathsf{Y}_n) \to \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R)$ carries almost perfect objects to almost perfect objects. This is a special case of the following:

($*_i$) The functor $(f \circ v_i)_* : \mathrm{QCoh}(\mathsf{Y}_i) \to \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R)$ carries almost perfect objects to almost perfect objects.

The proof of ($*_i$) proceeds by induction on i, the case $i = 0$ being trivial. To carry out the inductive step, let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})$ be almost perfect. Let $u : \widetilde{\mathsf{Y}}_i \to \mathsf{Y}_i$ denote the composition

$$\widetilde{\mathsf{Y}}_i \xrightarrow{h_i} \mathsf{Y}_i \times_{\mathrm{Sp\acute{e}t}\, R} \mathbf{P}^{d_i}_R \to \mathsf{Y}_i\,.$$

It follows from Propositions 5.6.1.1 and 5.6.2.1 that the functor $u_* : \mathrm{QCoh}(\widetilde{\mathsf{Y}}_i) \to \mathrm{QCoh}(\mathsf{Y}_i)$ carries almost perfect objects to almost perfect objects. Form a fiber sequence $\mathscr{F}' \to \mathscr{F} \to u_* u^* \mathscr{F}$. Note that $(f \circ v_i)_* u_* u^* \mathscr{F}$ can be identified with the direct image of $u^* \mathscr{F}$ under the composite map $\widetilde{\mathsf{Y}}_i \xrightarrow{\rho_i} \mathbf{P}^{d_i}_R \to \mathrm{Sp\acute{e}t}\, R$, and is therefore almost perfect by virtue of Propositions 5.6.1.1 and 5.6.2.1. Consequently, to show that $(f \circ v_i)_* \mathscr{F}$ is almost perfect, it will suffice to show that $(f \circ v_i)_* \mathscr{F}'$ is almost perfect. This follows from $(*_{i-1})$ and Proposition 5.6.3.3, since the restriction $\mathscr{F}'|_{\mathsf{U}_i}$ vanishes (by virtue our assumption that the projection map $\widetilde{\mathsf{Y}}_i \times_{\mathsf{Y}_i} \mathsf{U}_i \to \mathsf{U}_i$ is an equivalence). This completes the proof of Theorem 5.6.0.2.

5.6.5 The Direct Image Theorem for Sheaves with Proper Support

We close this section with a slight generalization of Theorem 5.6.0.2.

Definition 5.6.5.1. Let X be a spectral Deligne-Mumford stack, let $K \subseteq |\mathsf{X}|$ be a closed subset, and let $j : \mathsf{U} \to \mathsf{X}$ be the complementary open immersion. We will say that K is *cocompact* if the map j is quasi-compact. Note that this is equivalent to the assertion that, for every map $\phi : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$, the inverse image of K in $|\mathrm{Spec}\, A|$ can be written as the vanishing locus of a finitely generated ideal $I \subseteq \pi_0 A$.

Proposition 5.6.5.2. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is locally almost of finite presentation, let $K \subseteq |\mathsf{X}|$ be a cocompact closed subset, let K be the reduced closed substack of X corresponding to K, and suppose that the composite map $\mathsf{K} \to \mathsf{X} \xrightarrow{f} \mathsf{Y}$ is proper. If $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is almost perfect and supported on K (meaning that $j^* \mathscr{F} \simeq 0$, where $j : \mathsf{U} \hookrightarrow \mathsf{X}$ is an open immersion complementary to K), then the direct image $f_* \mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})$ is almost perfect.*

Proof. The assertion is local on Y, so we may assume without loss of generality that $\mathsf{Y} = \mathrm{Sp\acute{e}t}\, R$ is affine. Using Proposition 4.4.4.1, we can choose a commutative diagram

$$\begin{array}{ccc} \mathsf{X} & \longrightarrow & \mathsf{X}_0 \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f_0} \\ \mathrm{Sp\acute{e}t}\, R & \longrightarrow & \mathrm{Sp\acute{e}t}\, R_0 \end{array}$$

where R_0 is Noetherian, f_0 is locally almost of finite presentation, and the map $\mathsf{X} \to \mathrm{Sp\acute{e}t}\, R \times_{\mathrm{Sp\acute{e}t}\, R_0} \mathsf{X}_0$ induces an equivalence of 0-truncations. Using Proposition 4.3.5.5 we can assume (after modifying R_0 if necessary) that K is the inverse image of a closed subset $K_0 \subseteq |\mathsf{X}_0|$ (automatically cocompact, since X_0 is locally Noetherian). Let K_0 denote the reduced closed substack of X_0 corresponding to K_0. Since X_0 is locally Noetherian, the closed immersion $\mathsf{K}_0 \to \mathsf{X}_0$ is locally almost of finite presentation. Set $\mathsf{K}' = \mathsf{K}_0 \times_{\mathsf{X}_0} \mathsf{X}$, so we have a closed immersion $i : \mathsf{K}' \to \mathsf{X}$ which locally almost of finite presentation. Note that we can identify K with the underlying reduced substack of K', so our assumption that

K is proper over R guarantees that K' is also proper over R. Applying Theorem 5.6.0.2, we deduce that the functor $(f \circ i)_* : \mathrm{QCoh}(\mathsf{K}') \to \mathrm{QCoh}(\mathsf{Y})$ carries almost perfect objects to almost perfect objects. It now follows from Proposition 5.6.3.3 that if $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is almost perfect and supported on K, then $f_* \mathscr{F}$ is almost perfect. □

5.6.6 Application: Proper Descent for Quasi-Coherent Sheaves

Let $f : X \to Y$ be a morphism of schemes which is faithfully flat and quasi-compact. Using Grothendieck's theory of faithfully flat descent, one can identify the abelian category $\mathrm{QCoh}(Y)^{\heartsuit}$ of quasi-coherent sheaves on Y with the abelian category of quasi-coherent sheaves on X which are equipped with descent data: in other words, $\mathrm{QCoh}(Y)^{\heartsuit}$ is equivalent to the totalization of the cosimplicial abelian category

$$\mathrm{QCoh}(X)^{\heartsuit} \rightrightarrows \mathrm{QCoh}(X \times_Y X)^{\heartsuit} \rightrightarrows \mathrm{QCoh}(X \times_Y X \times_Y X) \rightrightarrows \cdots$$

It follows from Corollary D.6.3.3 that a similar statement holds at the "derived" level: that is, we can identify the stable ∞-category $\mathrm{QCoh}(\mathsf{Y})$ with the totalization of the cosimplicial ∞-category $\mathrm{QCoh}(\mathsf{X}_\bullet)$; here X and Y denote the spectral algebraic spaces associated to X and Y, and $\mathsf{X}_\bullet$ denotes the Čech nerve of the map $f : \mathsf{X} \to \mathsf{Y}$.

Let us now consider the analogous descent questions in the case where $f : X \to Y$ is a proper surjection of schemes. Here, the failure of f to be flat creates two (related) difficulties:

(a) The pullback functor $f^* : \mathrm{QCoh}(Y)^{\heartsuit} \to \mathrm{QCoh}(X)^{\heartsuit}$ need not be an exact functor, and therefore need not coincide with the "derived" pullback functor $f^* : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$.

(b) The fiber product $X \times_Y X$, formed in the category of schemes, need not agree with the fiber product $\mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ formed in the ∞-category of spectral algebraic spaces.

Because of (a) and (b), it is difficult to formulate a theory of proper descent purely in the language of classical algebraic geometry. However, in the setting of spectral algebraic geometry, we have the following:

Theorem 5.6.6.1 (Proper Descent For Quasi-Coherent Sheaves)**.** *Let $f : \mathsf{X} \to \mathsf{Y}$ be a surjective proper morphism of spectral Deligne-Mumford stacks, and let $\mathsf{X}_\bullet$ denote the Čech nerve of f. Assume that Y is locally Noetherian and that the structure sheaf $\mathscr{O}_{\mathsf{Y}}$ is truncated. Then the pullback functor $\mathrm{QCoh}(\mathsf{Y}) \to \mathrm{Tot}\,\mathrm{QCoh}(\mathsf{X}_\bullet)$ is an equivalence of ∞-categories.*

Warning 5.6.6.2. In the statement of Theorem 5.6.6.1, the structure sheaves of the iterated fiber products $\mathsf{X} \times_{\mathsf{Y}} \cdots \times_{\mathsf{Y}} \mathsf{X}$ need not be truncated, even if the structure sheaves $\mathscr{O}_{\mathsf{X}}$ and $\mathscr{O}_{\mathsf{Y}}$ are truncated.

The proof of Theorem 5.6.6.1 is based on the following:

Proposition 5.6.6.3. *Let R be a truncated Noetherian $\mathbb{E}_\infty$-ring, let $f : \mathsf{X} \to \operatorname{Spét} R$ be a proper surjection of spectral algebraic spaces, and let $\mathcal{C}$ denote the smallest stable subcategory of Mod_R which contains $\Gamma(\mathsf{X}; \mathscr{F})$ for each $\mathscr{F} \in \operatorname{QCoh}(\mathsf{X})$ and is closed under retracts. Then $\mathcal{C} = \operatorname{Mod}_R$.*

Proof. Since R is truncated, every R-module M admits a finite filtration whose successive quotients are of the form $(\pi_n R) \otimes_R M$. Because $\mathcal{C}$ is closed under extensions, it will suffice to show that $\mathcal{C}$ contains the essential image of the forgetful functor $\operatorname{Mod}_{\pi_0 R} \to \operatorname{Mod}_R$. We may therefore replace R by $\pi_0 R$ and thereby reduce to the case where R is discrete.

Let us say that an ideal $I \subseteq R$ is *good* if $\mathcal{C}$ contains the essential image of the forgetful functor $\operatorname{Mod}_{R/I} \to \operatorname{Mod}_R$. To complete the proof, it will suffice to show that the zero ideal $(0) \subseteq R$ is good. Assume otherwise: then, since R is Noetherian, we can choose an ideal $I \subseteq R$ which is maximal among those ideals which are not good. Replacing R by R/I, we can reduce to the case where every nonzero ideal of R is good.

Since R is Noetherian, every finitely generated discrete R-module N admits a finite filtration whose successive quotients have the form $R/\mathfrak{p}$, for some prime ideal $\mathfrak{p} \subseteq R$. Applying this observation in the case $R = N$, we deduce that each object $M \in \operatorname{Mod}_R$ admits a finite filtration whose successive quotients have the form $(R/\mathfrak{p}) \otimes_R M$. Consequently, to show that $M \in \mathcal{C}$, it will suffice to show that each tensor product $(R/\mathfrak{p}) \otimes_R M$ belongs to $\mathcal{C}$. By virtue of our assumption on R, this is automatic unless $\mathfrak{p} = (0)$. We may therefore assume without loss of generality that R is an integral domain.

Let K be the fraction field of R. Our assumption that f is surjective guarantees that we can choose a closed point x of the generic fiber $|\mathsf{X} \times_{\operatorname{Spét} R} \operatorname{Spét} K|$. Let X' be the schematic closure of x in X, and let us abuse notation by identifying the structure sheaf $\mathscr{O}_{\mathsf{X}'}$ with a (discrete) quasi-coherent sheaf on X. Set $N = \Gamma(\mathsf{X}'; \mathscr{O}_{\mathsf{X}'})$. It follows from Theorem 5.6.0.2 (or from Theorem 5.6.0.1) that N is an almost perfect R-module. Moreover, $K \otimes_R N \simeq \kappa(x)$ is a finite extension field of K; in particular, it is a free K-module of finite rank. We can therefore choose elements $x_1, \ldots, x_d \in \pi_0 N$ whose images form a basis for $K \otimes_R N$ as a vector space over K. These elements determine a map $\rho : R^d \to N$ whose fiber $\operatorname{fib}(\rho)$ satisfies $K \otimes_R \operatorname{fib}(\rho) \simeq 0$. Note that the R-module $\operatorname{fib}(\rho)$ is 0-truncated and almost perfect, so that the homotopy groups $\pi_i \operatorname{fib}(\rho)$ are finitely generated R-modules which vanish for all but finitely many integers i. It follows that $\operatorname{fib}(\rho)$ admits a finite filtration whose successive quotients have the form $\Sigma^i (R/\mathfrak{p})$, where $\mathfrak{p}$ is a nonzero prime ideal in R. Our hypothesis on R then guarantees that for any R-module M, the tensor product $\operatorname{fib}(\rho) \otimes_R M$ belongs to $\mathcal{C}$. Note that the projection formula for f gives an equivalence $N \otimes_R M \simeq f_*(\mathscr{O}_{\mathsf{X}'} \otimes f^* M)$, so that $N \otimes_R M$ also belongs to $\mathcal{C}$. Using the evident fiber sequence $\operatorname{fib}(\rho) \otimes_R M \to R^d \otimes_R M \to N \otimes_R M$, we conclude that $R^d \otimes_R M \simeq M^d$ belongs to $\mathcal{C}$. Since $\mathcal{C}$ is closed under retracts, we conclude that $M \in \mathcal{C}$. $\square$

Proposition 5.6.6.4. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a proper surjection of spectral Deligne-Mumford stacks. Assume that Y is locally Noetherian and that the structure sheaf $\mathscr{O}_{\mathsf{Y}}$ is truncated. Then the adjunction* $\mathrm{QCoh}(\mathsf{Y}) \underset{f_*}{\overset{f^*}{\rightleftarrows}} \mathrm{QCoh}(\mathsf{X})$ *is comonadic: that is, it induces an equivalence of* $\mathrm{QCoh}(\mathsf{Y})$ *with the ∞-category of comodules for the comonad $f^* f_*$ on* $\mathrm{QCoh}(\mathsf{X})$ *(see Definition HA.4.7.3.4).*

Proof. By virtue of the Barr-Beck theorem (Theorem HA.4.7.3.5), it will suffice to verify the following:

(i) The pullback functor $f^* : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ is conservative.

(ii) The pullback functor $f^* : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ preserves totalizations of f^*-split cosimplicial objects.

Both of these assertions are local on Y, so we may assume without loss of generality that $\mathsf{Y} \simeq \mathrm{Sp\acute{e}t}\, R$ is affine.

We first prove (i). Suppose we are given an R-module $N \in \mathrm{Mod}_R \simeq \mathrm{QCoh}(\mathsf{Y})$ such that $f^*N \simeq 0$. Let $\mathcal{C} \subseteq \mathrm{Mod}_R$ be the full subcategory spanned by those R-modules M such that $M \otimes_R N \simeq 0$. For each $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$, we have $\Gamma(\mathsf{X}; \mathscr{F}) \otimes_R N \simeq \Gamma(\mathsf{X}; \mathscr{F} \otimes f^*N) \simeq 0$, so that $\Gamma(\mathsf{X}; \mathscr{F})$ belongs to $\mathcal{C}$. Since $\mathcal{C}$ is evidently a stable subcategory of Mod_R which is closed under retracts, Proposition 5.6.6.3 guarantees that $R \in \mathcal{C}$, so that $N \simeq R \otimes_R N \simeq 0$.

The proof of (ii) is similar. Suppose that $N^\bullet$ is an f^*-split cosimplicial object of $\mathrm{Mod}_R \simeq \mathrm{QCoh}(\mathsf{Y})$. Let $\mathcal{D} \subseteq \mathrm{Mod}_R$ be the full subcategory spanned by those R-modules M for which the tautological map $f^*(\mathrm{Tot}(M \otimes_R N^\bullet)) \to \mathrm{Tot}(f^*(M \otimes_R N^\bullet))$ is an equivalence. Note that for each $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$, the cosimplicial R-module $\Gamma(\mathsf{X}; \mathscr{F}) \otimes_R N^\bullet \simeq \Gamma(\mathsf{X}; \mathscr{F} \otimes f^* N^\bullet)$ is split, so that $\Gamma(\mathsf{X}; \mathscr{F})$ belongs to $\mathcal{D}$. Because $\mathcal{D}$ is a stable subcategory of Mod_R which is closed under retracts, Proposition 5.6.6.3 guarantees that $R \in \mathcal{D}$, so that the canonical map $f^*(\mathrm{Tot}(N^\bullet)) \to \mathrm{Tot}(f^* N^\bullet)$ is an equivalence. □

Proof of Theorem 5.6.6.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a proper morphism of spectral Deligne-Mumford stacks, where Y is locally Noetherian and $\mathscr{O}_{\mathsf{Y}}$ is truncated. Let $\mathsf{X}_\bullet$ denote the Čech nerve of f, which we regard as an augmented simplicial object of SpDM (so that $\mathsf{X}_0 \simeq \mathsf{X}$ and $\mathsf{X}_{-1} \simeq \mathsf{Y}$). We wish to show that the augmented cosimplicial ∞-category $\mathrm{QCoh}(\mathsf{X}_\bullet)$ determines a limit diagram $\mathbf{\Delta}_+ \to \widehat{\mathcal{C}\mathrm{at}}_\infty$. Using (the dual of) Corollary HA.4.7.5.3 , it will suffice to verify the following:

(a) The adjunction $\mathrm{QCoh}(\mathsf{Y}) \underset{f_*}{\overset{f^*}{\rightleftarrows}} \mathrm{QCoh}(\mathsf{X})$ is comonadic.

(b) The augmented cosimplicial ∞-category $\mathrm{QCoh}(\mathsf{X}_\bullet)$ satisfies the Beck-Chevalley condition. More precisely, for every morphism $\alpha : [m] \to [n]$ in $\mathbf{\Delta}_+$, the diagram of pullback functors

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{X}_m) & \longrightarrow & \mathrm{QCoh}(\mathsf{X}_{m+1}) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{X}_n) & \longrightarrow & \mathrm{QCoh}(\mathsf{X}_{n+1}) \end{array}$$

is right adjointable.

Assertion (a) follows from Proposition 5.6.6.4, and assertion (b) is a special case of Corollary 3.4.2.2. □

In the statement of Theorem 5.6.6.1, the truncatedness hypothesis on $\mathscr{O}_{\mathsf{Y}}$ is necessary. For example, let $R = \mathrm{Sym}^*_{\mathbf{Q}}(\Sigma^2 \mathbf{Q})$ be the free $\mathbb{E}_\infty$-algebra over $\mathbf{Q}$ on a single generator $t \in \pi_2 R$. Then the truncation map $R \to \pi_0 R \simeq \mathbf{Q}$ induces a proper morphism $f : \mathrm{Sp\acute{e}t}\, \mathbf{Q} \to \mathrm{Sp\acute{e}t}\, R$. However, the pullback functor $f^* : \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R) \to \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, \mathbf{Q})$ is not conservative: for example, it annihilates the localization $R[t^{-1}]$. If we restrict our attention to *connective* quasi-coherent sheaves, this difficulty does not arise:

Corollary 5.6.6.5. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a proper morphism of spectral Deligne-Mumford stacks and let $\mathsf{X}_\bullet$ denote the Čech nerve of f. If Y is locally Noetherian, then the induced map $\mathrm{QCoh}(\mathsf{Y})^{\mathrm{cn}} \to \mathrm{Tot}(\mathrm{QCoh}(\mathsf{X}_\bullet)^{\mathrm{cn}})$ is fully faithful.*

Warning 5.6.6.6. In the setting of Corollary 5.6.6.5, the pulback functor $\mathrm{QCoh}(\mathsf{Y})^{\mathrm{cn}} \to \mathrm{Tot}\, \mathrm{QCoh}(\mathsf{X}_\bullet)^{\mathrm{cn}}$ need not be an equivalence of ∞-categories, even when the structure sheaves of $\mathscr{O}_{\mathsf{X}}$ and $\mathscr{O}_{\mathsf{Y}}$ are both discrete. In other words, given an object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})$ whose pullback $f^* \mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is connective, we cannot conclude that $\mathscr{F}$ is connective (for a counterexample, take $\mathsf{Y} = \mathrm{Sp\acute{e}t}\, \mathbf{C}[x, y]$ to be an affine space of dimension 2, X to be the $\mathbf{C}$-scheme obtained from Y by a blow-up at the origin, and $\mathscr{F}$ to be the (derived) pushforward $j_* \mathscr{O}_{\mathsf{U}}$, where $j : \mathsf{U} \hookrightarrow \mathsf{Y}$ is the open immersion complementary to the origin).

Proof of Corollary 5.6.6.5. Write $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ and $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathsf{Y}})$. For each $n \geqslant 0$, set $\mathsf{X}(n) = (\mathcal{X}, \tau_{\leqslant n} \mathscr{O}_{\mathsf{X}})$ and $\mathsf{Y}(n) = (\mathcal{Y}, \tau_{\leqslant n} \mathscr{O}_{\mathsf{Y}})$. Then f induces a proper morphism $f(n) : \mathsf{X}(n) \to \mathsf{Y}(n)$ having a Čech nerve $\mathsf{X}(n)_\bullet$. We then have a commutative diagram of pullback functors

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{Y})^{\mathrm{cn}} & \longrightarrow & \mathrm{Tot}\, \mathrm{QCoh}(\mathsf{X}_\bullet)^{\mathrm{cn}} \\ \downarrow & & \downarrow \\ \varprojlim_n \mathrm{QCoh}(\mathsf{Y}(n))^{\mathrm{cn}} & \longrightarrow & \varprojlim_n \mathrm{Tot}\, \mathrm{QCoh}(\mathsf{X}(n)_\bullet). \end{array}$$

It follows from Corollary 2.5.9.3 that the vertical maps are equivalences of ∞-categories. Since each $\mathsf{Y}(n)$ has a truncated structure sheaf, the bottom horizontal map is fully faithful by virtue of Theorem 5.6.6.1. □

Remark 5.6.6.7. In the statements of Theorem 5.6.6.1 and Corollary 5.6.6.5, we do not need the full strength of the assumption that Y is locally Noetherian: it is sufficient to assume that the 0-truncation of Y is locally Noetherian.

Chapter 6

Grothendieck Duality

Let X be a smooth projective variety of dimension n over a field κ, and let Ω^n_X denote the *canonical bundle* of X: that is, the top exterior power of the cotangent bundle of X. The celebrated *Serre duality theorem* asserts the following:

(a) There is a canonical trace map $\mathrm{tr} : \mathrm{H}^n(X; \Omega^n_X) \to \kappa$, which is an isomorphism if X is connected.

(b) If $\mathscr{E}$ is any vector bundle on X, then the bilinear map

$$\mathrm{H}^i(X; \mathscr{E}) \times \mathrm{H}^{n-i}(X; \Omega^n_X \otimes \mathscr{E}^\vee) \to \mathrm{H}^n(X; \Omega^n_X) \xrightarrow{\mathrm{tr}} \kappa$$

is a perfect pairing for every integer i: that is, we have canonical isomorphisms $\mathrm{H}^i(X; \mathscr{E})^\vee \simeq \mathrm{H}^{n-i}(X; \Omega^n_X \otimes \mathscr{E}^\vee)$.

Serre duality was generalized by Grothendieck to the setting where X is not assumed to be smooth. In general, one needs to replace the line bundle Ω^n_X by the *dualizing complex* ω_X, which is an object of the derived category $D(X)$ (when X is smooth of dimension n, we take $\omega_X = \Omega^n_X[n]$). In this case, assertion (b) generalizes as follows:

(b') For every quasi-coherent sheaf $\mathscr{F}$ on X, there is a canonical isomorphism $\mathrm{H}^i(X; \mathscr{F})^\vee \simeq \mathrm{Hom}_{D(X)}(\mathscr{F}[i], \omega_X)$.

Moreover, Grothendieck's work placed the duality theory of coherent sheaves in a more general context: rather than restricting attention to projective algebraic varieties over a field, he developed a *relative* theory of duality for any proper morphism $f : X \to S$ of separated Noetherian schemes. In this case, one should replace the dualizing complex ω_X by the *relative dualizing complex* $\omega_{X/Y}$ of the morphism f, in which case (b') admits the following further generalization:

(b'') For every object $\mathscr{F}$ of the derived category $D(X)$, there is a canonical isomorphism $\mathrm{Hom}_{D(X)}(\mathscr{F}, \omega_{X/Y}) \simeq \mathrm{Hom}_{D(Y)} Rf_* \mathscr{F}, \mathscr{O}_Y)$.

The relative dualizing sheaf $\omega_{X/Y} \in D(X)$ is characterized up to isomorphism by the property described in (b'): more precisely, it can be described as the image of $\mathscr{O}_Y$ under a functor $f^! : D(Y) \to D(X)$ which is right adjoint to the (derived) direct image functor $Rf_* : D(X) \to D(Y)$. We refer the reader to [**?**] for a detailed exposition.

Our goal in this chapter is to describe an generalization of Grothendieck duality to the setting of spectral algebraic geometry. Let $f : \mathsf{X} \to \mathsf{Y}$ be any morphism of quasi-compact, quasi-separated spectral algebraic spaces. Then the direct image functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ preserves small colimits (Corollary 3.4.2.2). It follows from the adjoint functor theorem (Corollary HTT.5.5.2.9) that f_* admits a right adjoint. In general, this right adjoint is a somewhat pathological construction (for example, it cannot be computed locally, even on Y). Roughly speaking, one would expect the functor f_* to have a *well-behaved* right adjoint only in cases where we can guarantee that the construction $\mathscr{F} \mapsto f_* \mathscr{F}$ preserves finiteness conditions (see, for example, Proposition HTT.5.5.7.2). One such case was studied in Chapter 5: if the morphism $f : \mathsf{X} \to \mathsf{Y}$ is proper and locally almost of finite presentation, then the direct image functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ carries almost perfect objects of $\mathrm{QCoh}(\mathsf{X})$ to almost perfect objects of $\mathrm{QCoh}(\mathsf{Y})$ (Theorem 5.6.0.2). In this case, we will denote the right adjoint to f_* by $f^!$ and refer to it as the *exceptional inverse image functor associated to* f. In §6.4 we will use Theorem 5.6.0.2 to show that the functor $f^!$ is well-behaved, at least when restricted to truncated objects of $\mathrm{QCoh}(\mathsf{Y})$ (see Proposition 6.4.1.4 and Corollary 6.4.1.9).

To obtain a robust duality theory for *unbounded* quasi-coherent sheaves, it is necessary to impose stronger finiteness assumptions on the direct image functor f_*. If we assume that $f : \mathsf{X} \to \mathsf{Y}$ is proper and locally almost of finite presentation and that $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is perfect, then Theorem 5.6.0.2 guarantees that the direct image $f_* \mathscr{F}$ is *almost* perfect. However, it need not be perfect (this fails, for example, when f is the closed immersion $\mathrm{Sp\acute{e}t}\, \mathbf{Z}/2\mathbf{Z} \hookrightarrow \mathrm{Sp\acute{e}t}\, \mathbf{Z}/4\mathbf{Z}$). To address this issue, we introduce in §6.1 the notion of a *morphism of finite* Tor-*amplitude*. Our main goal is to show that if f is proper, locally almost of finite presentation, and of finite Tor-amplitude, then the direct image functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ carries perfect objects to perfect objects (Theorem 6.1.3.2; for a converse, see Theorem 11.1.4.1). In §6.4.1, we will show that under the same assumptions, the exceptional inverse image functor $f^!$ is given by the formula $f^! \mathscr{F} \simeq \omega_{\mathsf{X}/\mathsf{Y}} \otimes f^* \mathscr{F}$, (Corollary 6.4.2.7), where $\omega_{\mathsf{X}/\mathsf{Y}} \in \mathrm{QCoh}(\mathsf{X})$ is the *relative dualizing sheaf of* f (Definition 6.4.2.4).

The second half of this chapter is devoted to studying the notion of an *absolute* dualizing sheaf in the setting of Noetherian spectral algebraic spaces. Roughly speaking, an object $\omega_{\mathsf{X}} \in \mathrm{QCoh}(\mathsf{X})$ is a *dualizing sheaf for* X if the construction $\mathscr{F} \mapsto \underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\mathscr{F}, \omega_{\mathsf{X}})$ is involutive when restricted to *coherent* sheaves (see Definition 6.6.1.1 and Theorem 6.6.1.8). In §6.6, we show that such objects often exist (see Theorems 6.6.4.1 and 6.6.4.3) and are unique up to invertible twists (Proposition 6.6.2.1). Our exposition will rely on a few facts about injective dimension of quasi-coherent sheaves in the setting of spectral algebraic geometry, which we discuss in §6.5.

Warning 6.0.0.1. In this book, we define the exceptional inverse image functor $f^!$: $\mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ only in the case where $f : \mathsf{X} \to \mathsf{Y}$ is proper (and locally almost of finite presentation). It is possible to develop a more elaborate theory of Grothendieck duality for non-proper morphisms, (which is essential if one wishes to carry out a local study of relative dualizing sheaves $\omega_{\mathsf{X}/\mathsf{Y}}$), but the construction requires some rather elaborate categorical constructions which we do not wish to undertake here. For more details (in a different but closely related context), we refer the reader to the work of Gaitsgory and Rozenblyum ([77]).

Contents

6.1 Morphisms of Finite Tor-Amplitude

Let $f : \mathsf{X} \to \mathsf{Y}$ be a proper map of spectral Deligne-Mumford stacks which is locally almost of finite presentation. According to Theorem 5.6.0.2, the pushforward functor f_* carries almost perfect objects of $\mathrm{QCoh}(\mathsf{X})$ to almost perfect objects of $\mathrm{QCoh}(\mathsf{Y})$. It is natural for additional conditions which guarantee that the pushforward functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ also preserves perfect objects. In this section, we will show that it is sufficient to assume that the morphism f has finite Tor-amplitude (Theorem 6.1.3.2). In §11.1, we will see that this condition is also necessary, at least if Y is affine (see Theorem 11.1.4.1).

6.1.1 Tor-Amplitude

Let $\phi : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings. Recall that ϕ is said to be *flat* if it exhibits B as a flat A-module. More generally, if $n \geqslant 0$ is an integer, we will say that ϕ has Tor-*amplitude* $\leqslant n$ if B has Tor-amplitude $\leqslant n$ as an A-module: in other words, if the extension of scalars functor

$$\mathrm{Mod}_A \to \mathrm{Mod}_B \qquad M \mapsto B \otimes_A M$$

carries $\mathrm{Mod}_A^\heartsuit$ into $(\mathrm{Mod}_B)_{\leqslant n}$. This condition can be globalized as follows:

Definition 6.1.1.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks and let $n \geqslant 0$ be an integer. We will say that f has Tor-*amplitude* $\leqslant n$ if, for every commutative diagram

$$\begin{array}{ccc} \operatorname{Sp\acute{e}t} B & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow f \\ \operatorname{Sp\acute{e}t} A & \longrightarrow & \mathsf{Y} \end{array}$$

where the horizontal maps are étale, the $\mathbb{E}_\infty$-ring B has Tor-amplitude $\leqslant n$ as an A-module (see Definition HA.7.2.4.21). We say that f has *finite* Tor-*amplitude* if it has Tor-amplitude $\leqslant n$ for some integer n.

Example 6.1.1.2. Let κ be a field, and let $f : \mathsf{X} \to \operatorname{Sp\acute{e}t} \kappa$ be a morphism of spectral Deligne-Mumford stacks. Then f has Tor-amplitude $\leqslant n$ if and only if X is n-truncated.

Example 6.1.1.3. A morphism of spectral Deligne-Mumford stacks $f : \mathsf{X} \to \mathsf{Y}$ has Tor-amplitude $\leqslant 0$ if and only if f is flat.

When restricted to affine spectral Deligne-Mumford stacks, Definition 6.1.1.1 recovers the algebraic notion of Tor-amplitude:

Proposition 6.1.1.4. *Let $f : \operatorname{Sp\acute{e}t} B \to \operatorname{Sp\acute{e}t} A$ be a morphism between affine spectral Deligne-Mumford stacks and let $n \geqslant 0$. Then f has* Tor-*amplitude $\leqslant n$ if and only if B has* Tor-*amplitude $\leqslant n$ as an A-module.*

Lemma 6.1.1.5. *Let $f : \mathsf{X} \to \operatorname{Sp\acute{e}t} A$ be a morphism of spectral Deligne-Mumford stacks, and let $n \geqslant 0$. The following conditions are equivalent:*

(1) *The morphism f has* Tor-*amplitude $\leqslant n$.*

(2) *For every étale morphism* $\operatorname{Sp\acute{e}t} B \to \mathsf{X}$*, B has* Tor-*amplitude $\leqslant n$ as an A-module.*

Proof. It is clear that (1) $\Rightarrow$ (2). Conversely, suppose that (2) is satisfied, and suppose we are given an étale map $g : \operatorname{Sp\acute{e}t} B \to \mathsf{X}$ such that $f \circ g$ factors as a composition $\operatorname{Sp\acute{e}t} B \to \operatorname{Sp\acute{e}t} A' \to \operatorname{Sp\acute{e}t} A$, for some A' which is étale over A. We wish to show that B has Tor-amplitude $\leqslant n$ as an A'-module. Since A' is étale over A, B is a retract (as an A'-module) of $A' \otimes_A B$, which is of Tor-amplitude $\leqslant n$ over A' by virtue of (2). □

Lemma 6.1.1.6. *Let $f : A \to B$ be a morphism of connective $\mathbb{E}_1$-rings, and let M be a left B-module. Suppose that B has* Tor-*amplitude $\leqslant m$ as a left A-module, and the M has* Tor-*amplitude $\leqslant n$ as a left B-module. Then M has* Tor-*amplitude $\leqslant m + n$ as a left A-module.*

Proof. Let $N \in (\mathrm{LMod}_A)_{\leqslant p}$; we wish to show that $N \otimes_R M$ is $(p+m+n)$-truncated. We have $N \otimes_A M \simeq (N \otimes_A B) \otimes_B M$. The desired result now follows from the observation that $N \otimes_A B$ is $(p+m)$-truncated. □

Proof of Proposition 6.1.1.4. It follows immediately from the definitions that if $f : \operatorname{Spét} B \to \operatorname{Spét} A$ is a morphism of Tor-amplitude $\leqslant n$, then B has Tor-amplitude $\leqslant n$ as an A-module. Conversely, suppose that B has Tor-amplitude $\leqslant n$ as an A-module; we wish to show that f has Tor-amplitude $\leqslant n$. By virtue of Lemma 6.1.1.5, it will suffice to show that every étale B-algebra B' has Tor-amplitude $\leqslant n$ as an A-module. This is an immediate consequence of Lemma 6.1.1.6, since B' is flat (and therefore of Tor-amplitude $\leqslant 0$) over B. □

6.1.2 Pullback and Composition of Morphisms of Finite Tor-Amplitude

We now summarize some of the formal properties enjoyed by the class of morphisms of finite Tor-amplitude.

Proposition 6.1.2.1. *For each $n \geqslant 0$, the condition that a morphism of spectral Deligne-Mumford stacks $f : \mathsf{X} \to \mathsf{Y}$ be of* Tor*-amplitude $\leqslant n$ is local on the source with respect to the flat topology (see Definition 2.8.3.10).*

Proof. First suppose that f has Tor-amplitude $\leqslant n$, and that we are given a flat map $g : \mathsf{X}' \to \mathsf{X}$. We wish to show that $g \circ f$ has Tor-amplitude $\leqslant n$. Consider a commutative diagram

$$\begin{array}{ccc} \operatorname{Spét} C & \longrightarrow & \mathsf{X}' \\ \downarrow & & \downarrow \\ \operatorname{Spét} A & \longrightarrow & \mathsf{Y}; \end{array}$$

we wish to show that C has Tor-amplitude $\leqslant n$ as an A-module. In other words, we wish to show that if M is a discrete A-module, then $C \otimes_A M$ is n-truncated. This assertion is local on C with respect to the étale topology. We may therefore suppose that the map $\operatorname{Spét} C \to \operatorname{Spét} A \times_{\mathsf{Y}} \mathsf{X}$ factors as a composition

$$\operatorname{Spét} C \to \operatorname{Spét} B \xrightarrow{u} \operatorname{Spét} A \times_{\mathsf{Y}} \mathsf{X},$$

where u is étale. Since f has Tor-amplitude $\leqslant n$, we see that $B \otimes_A M$ is n-truncated. Then $C \otimes_A M \simeq C \otimes_B (B \otimes_A M)$ is n-truncated because C is flat over B.

Now suppose that we are given a flat covering $\{g_\alpha : \mathsf{X}_\alpha \to \mathsf{X}\}$ such that each $g_\alpha \circ f$ has Tor-amplitude $\leqslant n$; we wish to show that f has Tor-amplitude $\leqslant n$. We may assume without loss of generality that $\mathsf{Y} = \operatorname{Spét} A$ is affine. Choose an étale map $\operatorname{Spét} B \to \mathsf{X}$; we wish to show that B has Tor-amplitude $\leqslant n$ over A (see Lemma 6.1.1.5). Since the g_α form a flat covering, we can find finitely many étale maps $\operatorname{Spét} C_\alpha \to \mathsf{X}_\alpha \times_{\mathsf{X}} \operatorname{Spét} B$ such that $C = \prod C_\alpha$

is faithfully flat over B. If M is a discrete A-module, then $C \otimes_A M \simeq C \otimes_B (B \otimes_A M)$ is n-truncated; it follows that $B \otimes_A M$ is n-truncated so that B has Tor-amplitude $\leqslant n$ over A. □

Proposition 6.1.2.2. *Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \xrightarrow{g} & \mathsf{Y}. \end{array}$$

If f has Tor*-amplitude $\leqslant n$, so does f'. The converse holds if g is a flat covering.*

Proof. Suppose first that f has Tor-amplitude $\leqslant n$. To prove that f' has Tor-amplitude $\leqslant n$, we may assume without loss of generality that $\mathsf{Y}' = \operatorname{Sp\acute{e}t} A'$ is affine. Choose a faithfully flat étale morphism $A' \to A''$ such that the composite map

$$\operatorname{Sp\acute{e}t} A'' \to \operatorname{Sp\acute{e}t} A' \to \mathsf{Y}$$

factors through an étale map $\operatorname{Sp\acute{e}t} A \to \mathsf{Y}$. Using Proposition 6.1.2.1, we are reduced to proving that for every étale map $\operatorname{Sp\acute{e}t} B' \to \mathsf{X}_{\operatorname{Sp\acute{e}t} A'} \operatorname{Sp\acute{e}t} A''$, B' has Tor-amplitude $\leqslant n$ over A'. Using Proposition 6.1.2.1 we may further reduce to the case where the map

$$\operatorname{Sp\acute{e}t} B' \to \operatorname{Sp\acute{e}t} A \times_{\mathsf{Y}} \mathsf{X}$$

factors through some étale map $\operatorname{Sp\acute{e}t} B \to \operatorname{Sp\acute{e}t} A \times_{\mathsf{Y}} \mathsf{X}$. The map $A' \to B'$ factors as a composition $A' \to A'' \to A'' \otimes_A B \to B'$, where the first and third map are étale, and the middle map has Tor-amplitude $\leqslant n$. It follows that B' has Tor-amplitude $\leqslant n$ over A', as desired.

Now suppose that g is a flat covering and that f' has Tor-amplitude $\leqslant n$; we wish to show that f has the same property. We may assume without loss of generality that $\mathsf{Y} = \operatorname{Sp\acute{e}t} A$ is affine. Using Proposition 6.1.2.1 we can further reduce to the case where $\mathsf{X} = \operatorname{Sp\acute{e}t} B$ is affine. Since g is a flat covering, we can choose an étale map $\operatorname{Sp\acute{e}t} A' \to \mathsf{Y}'$ such that A' is faithfully flat over B. Because f' has Tor-amplitude $\leqslant n$, we deduce that $A' \otimes_A B$ has Tor-amplitude $\leqslant n$ over A'. It then follows from Lemma 2.8.4.3 that B has Tor-amplitude $\leqslant n$ over A. □

In the locally Noetherian case, Proposition 6.1.2.2 admits a converse:

Proposition 6.1.2.3. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism spectral Deligne-Mumford stacks and let $n \geqslant 0$ be an integer. Assume that Y is locally Noetherian. The following conditions are equivalent:*

(*a*) *The morphism* f *has* Tor-*amplitude* $\leqslant n$.

(*b*) *For every field* κ *and every pullback diagram*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \operatorname{Sp\acute{e}t}(\kappa) & \longrightarrow & \mathsf{Y}, \end{array}$$

the morphism f' *has* Tor-*amplitude* $\leqslant n$.

(*c*) *For every field* κ *and every morphism* $\operatorname{Sp\acute{e}t}(\kappa) \to \mathsf{Y}$, *the fiber product* $\operatorname{Sp\acute{e}t}(\kappa) \times_{\mathsf{Y}} \mathsf{X}$ *is* n*-truncated.*

The equivalence $(b) \Leftrightarrow (c)$ follows from Proposition 6.1.1.2, and the implication $(a) \Rightarrow (b)$ from Proposition 6.1.2.2. The nontrivial implication $(b) \Rightarrow (a)$ reduces immediately to the affine case, which follows from the following more general assertion:

Lemma 6.1.2.4. *Let* A *be a Noetherian* $\mathbb{E}_\infty$*-ring and let* M *be an* A*-module. The following conditions are equivalent:*

(*i*) *The module* M *has* Tor-*amplitude* $\leqslant n$.

(*ii*) *For each residue field* κ *of* A, *the tensor product* $\kappa \otimes_A M$ *is* n*-truncated.*

Proof. The implication $(i) \Rightarrow (ii)$ is immediate. For the converse, assume that (ii) is satisfied. We wish to show that, for every discrete A-module N, the tensor product $N \otimes_A M$ is n-truncated. Writing N as a filtered colimit of finite generated submodules, we may assume that N is finitely generated as a module over $\pi_0(A)$. Let $Y \subseteq |\operatorname{Spec}(A)|$ be the support of N. Proceeding by Noetherian induction, we may assume that $N' \otimes_A M$ is n-truncated for every discrete A-module N' whose support is strictly contained in Y. Writing N as a finite extension of modules of the form $\pi_0(A)/\mathfrak{p}_i$, where $\mathfrak{p}_i \subseteq \pi_0(A)$ is prime, we can reduce to the case where $N = \pi_0(A)/\mathfrak{p}$ for some prime ideal $\mathfrak{p} \subseteq \pi_0(A)$. Replacing A by $\pi_0(A)/\mathfrak{p}$ (and M by $(\pi_0(A)/\mathfrak{p}) \otimes_A M$), we can reduce to the case where A is an integral domain (regarded as a discrete $\mathbb{E}_\infty$-ring) and $N = A$; in this case, we wish to show that M itself is n-truncated. Let K denote the fraction field of A. Then K/A can be written as a filtered colimit of finitely generated submodules having support smaller than Y. It follows from our inductive hypothesis that the tensor product $(K/A) \otimes_A M$ is n-truncated. Assumption (2) guarantees that $K \otimes_A M$ is also n-truncated, so that $M \simeq \operatorname{fib}(K \otimes_A M \to (K/A) \otimes_A M)$ is n-truncated as desired. □

Proposition 6.1.2.5. *Let* $f : \mathsf{X} \to \mathsf{Y}$ *and* $g : \mathsf{Y} \to \mathsf{Z}$ *be maps of spectral Deligne-Mumford stacks. If* f *has* Tor-*amplitude* $\leqslant m$ *and* g *has* Tor-*amplitude* $\leqslant n$, *then* $g \circ f$ *has* Tor-*amplitude* $\leqslant m + n$.

Proof. Using Propositions 6.1.2.1 and 6.1.2.2, we can reduce to the case where X, Y, and Z are affine. In this case, the desired result follows from Lemma 6.1.1.6 and Proposition 6.1.1.4. □

Remark 6.1.2.6. Let $f : \mathsf{X} \to \operatorname{Spét} R$ be a map of spectral Deligne-Mumford stacks, and form a pullback square

$$\begin{array}{ccc} \mathsf{X}_0 & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f_0} & & \downarrow{\scriptstyle f} \\ \operatorname{Spét} \pi_0 R & \longrightarrow & \operatorname{Spét} R. \end{array}$$

Then f has Tor-amplitude $\leqslant n$ if and only if f_0 has Tor-amplitude $\leqslant n$.

6.1.3 Direct Images of Perfect Quasi-Coherent Sheaves

Our main result is a simple consequence of Theorem 5.6.0.2 together with the following:

Proposition 6.1.3.1. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks which is of* Tor*-amplitude $\leqslant n$. Assume that f is quasi-compact, quasi-separated, and exhibits X are a relative spectral algebraic space over Y. Let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ be a quasi-coherent sheaf which is locally of* Tor*-amplitude $\leqslant k$. Then the pushforward $f_* \mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})$ has* Tor*-amplitude $\leqslant n + k$.*

Proof. The assertion is local on Y; we may therefore suppose that $\mathsf{Y} \simeq \operatorname{Spét} R$ is affine. Write $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$. Let us say that an object $U \in \mathcal{X}$ is *good* if $\mathscr{F}(U)$ is of Tor-amplitude $\leqslant n + k$ over R. It follows from Lemma 6.1.1.6 that every affine object of $\mathcal{X}$ is good, and Proposition HA.7.2.4.23 implies that the collection of good objects of $\mathcal{X}$ is closed under pushouts. Using Theorem 3.4.2.1 and Corollary 2.5.3.6, we conclude that the final object of $\mathcal{X}$ is good, so that $f_* \mathscr{F}$ has Tor-amplitude $\leqslant n + k$. □

Theorem 6.1.3.2. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks which is proper, locally almost of finite presentation, and of finite* Tor*-amplitude. Then the pushforward functor f_* carries perfect objects of $\mathrm{QCoh}(\mathsf{X})$ to perfect objects of $\mathrm{QCoh}(\mathsf{Y})$.*

Proof. Let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ be perfect; we wish to show that $f_* \mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})$ is perfect. This assertion is local on Y, so we may assume without loss of generality that Y is affine. Since the morphism f is proper, X is quasi-compact. It follows that $\mathscr{F}$ has Tor-amplitude $\leqslant n$ for some n, so that $f_* \mathscr{F}$ has finite Tor-amplitude by virtue of Proposition 6.1.3.1. Since $f_* \mathscr{F}$ is almost perfect (by virtue of Theorem 5.6.0.2), it follows from Proposition HA.7.2.4.23 that $f_* \mathscr{F}$ is perfect. □

Remark 6.1.3.3. In the setting of classical algebraic geometry, Theorem 6.1.3.2 appears in [134].

6.1.4 Tor Amplitude at a Point

Let $f : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ be a morphism of schemes, let $x \in X$ be a point, and let $y = f(x) \in Y$. Recall that f is said to be *flat at x* if the induced map of local rings $\mathscr{O}_{Y,y} \to \mathscr{O}_{X,x}$ is flat. We then have the following:

(i) The morphism f is flat if and only if it is flat at x, for each point $x \in X$.

(ii) If f is locally of finite presentation, then the collection of points $x \in X$ at which f is flat is an open subset of X.

We now describe generalizations of (i) and (ii), where flatness is replaced by a bound on Tor-amplitude. For simplicity, we will restrict our attention to the affine case.

Notation 6.1.4.1. If A is an $\mathbb{E}_\infty$-ring and $\mathfrak{p} \subseteq \pi_0 A$ is a prime ideal, we let $A_\mathfrak{p}$ denote the localization $A[S^{-1}]$, where $S = \pi_0 A - \mathfrak{p}$. For any A-module M, we let $A_\mathfrak{p}$ denote the tensor product $A_\mathfrak{p} \otimes_A M$.

Definition 6.1.4.2. Let $\phi : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings and let M be a B-module. For each integer n and each prime ideal $\mathfrak{p} \subseteq \pi_0 B$, we say that M *has* Tor-*amplitude* $\leqslant n$ *over A at* $\mathfrak{p}$ if the localization $M_\mathfrak{p}$ has Tor-amplitude $\leqslant n$ as an A-module. If M is connective, then we M *is flat over A at* $\mathfrak{p}$ if the localization $M_\mathfrak{p}$ is a flat A-module.

Remark 6.1.4.3. In the situation of Definition 6.1.4.2, we can regard $M_\mathfrak{p}$ as a module over the localization $A_\mathfrak{q}$, where $\mathfrak{q} \subseteq \pi_0 A$ is the inverse image of $\mathfrak{p}$. Then M has Tor-amplitude $\leqslant n$ over A at $\mathfrak{p}$ if and only if the localization $M_\mathfrak{p}$ has Tor-amplitude $\leqslant n$ as a module over $A_\mathfrak{q}$.

Proposition 6.1.4.4. *Let $\phi : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings, let M be an B-module, and let n be an integer. Then the following conditions are equivalent:*

(a) *The A-module M has* Tor-*amplitude* $\leqslant n$.

(b) *The module M has* Tor-*amplitude* $\leqslant n$ *over A at $\mathfrak{p}$ for each prime ideal $\mathfrak{p} \subseteq \pi_0 B$.*

Proof. Suppose that (a) is satisfied, and let $\mathfrak{p} \subseteq \pi_0 B$ be a prime ideal. Since $M_\mathfrak{p}$ can be obtained as a filtered colimit of copies of M, it follows that $M_\mathfrak{p}$ also has Tor-amplitude $\leqslant n$ as an A-module. Conversely, suppose that (b) is satisfied. Let N be a discrete A-module; we wish to prove that $\pi_m(M \otimes_A N) \simeq 0$ for $m > n$. Let us regard $M \otimes_A N$ as a module over B. It will therefore suffice to show that $\pi_m(M \otimes_R N)_\mathfrak{p}$ for each prime ideal $\mathfrak{p} \subseteq \pi_0 B$. This follows from ($b$), since we have a canonical isomorphism $\pi_m(M \otimes_A N)_\mathfrak{p} \simeq \pi_m(M_\mathfrak{p} \otimes_A N)$. □

We have the following generalization of (ii):

Proposition 6.1.4.5. *Let $m \geqslant n \geqslant 0$ be integers, let A be a commutative ring, let B be an $\mathbb{E}_\infty$-algebra over A which is of finite generation to order $n+1$, and let M be a connective B-module which is finitely m-presented. Let $\mathfrak{p} \subseteq \pi_0 B$ be a prime ideal, and let $\mathfrak{q} \subseteq A$ denote its inverse image, and let κ denote the residue field of A at $\mathfrak{q}$. Then the following conditions are equivalent:*

(a) *The module M has* Tor*-amplitude $\leqslant n$ over A at $\mathfrak{p}$.*

(b) *The homotopy groups $\pi_i(M \otimes_A \kappa)_{\mathfrak{p}}$ vanish for $n < i \leqslant m+1$.*

Moreover, the collection of prime ideals $\mathfrak{p} \subseteq \pi_0 B$ which satisfy these conditions is an open subset of $|\operatorname{Spec} B|$.

Before giving the proof of Proposition 6.1.4.5, let us describe some of its consequences. Taking $B = A$ in Proposition 6.1.4.5, we obtain the following:

Corollary 6.1.4.6. *Let $m \geqslant n \geqslant 0$ be integers, let A be a commutative ring, and let M be a connective A-module which is finitely m-presented. For each prime ideal $\mathfrak{p} \subseteq A$, the following conditions are equivalent:*

(a) *The localization $M_{\mathfrak{p}}$ has* Tor*-amplitude $\leqslant n$ over A.*

(b) *The homotopy groups $\pi_i(M \otimes_A \kappa)_{\mathfrak{p}}$ vanish for $n < i \leqslant m+1$, where κ denotes the residue field of A at $\mathfrak{p}$.*

Moreover, the collection of those prime ideals $\mathfrak{p} \subseteq A$ which satisfy these conditions is an open subset of $|\operatorname{Spec} A|$.

Corollary 6.1.4.7. *Let $n \geqslant 0$ be an integer, let A be a connective $\mathbb{E}_\infty$-ring, and let M be an almost perfect A-module. Then M has* Tor*-amplitude $\leqslant n$ if and only if, for every maximal ideal $\mathfrak{m} \subseteq \pi_0 A$ with residue field $\kappa = (\pi_0 A)/\mathfrak{m}$, the homotopy groups $\pi_i(M \otimes_A \kappa)$ vanish for $i > n$.*

Proof. The "only if" direction is obvious. For the converse, we can use Remark 6.1.2.6 to reduce to the case where A is discrete. Fix $m \geqslant n$. For every maximal ideal $\mathfrak{m} \subseteq \pi_0 A$ with residue field $\kappa = (\pi_0 A)/\mathfrak{m}$, the natural map $\pi_i(M \otimes_A \kappa) \to \pi_i(\tau_{\leqslant m} M \otimes_A \kappa)$ is surjective for $i = m+1$ and bijective for $i \leqslant m$. It follows that $\pi_i(\tau_{\leqslant m} M \otimes_A \kappa) \simeq 0$ for $n < i \leqslant m+1$. Applying Corollary 6.1.4.6 and Proposition 6.1.4.4, we deduce that $\tau_{\leqslant m} M$ has Tor-amplitude $\leqslant n$ over A. Since A is discrete, this implies that $\tau_{\leqslant m} M$ is n-truncated. Allowing m to vary, we deduce that M is n-truncated, so that $M \simeq \tau_{\leqslant n} M$ has Tor-amplitude $\leqslant n$ over A. □

Corollary 6.1.4.8. *Let $n \geqslant 0$ and let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism between spectral Deligne-Mumford stacks which is locally almost of finite presentation. The following conditions are equivalent:*

(1) *The morphism f is of* Tor*-amplitude* $\leqslant n$.

(2) *For every field κ and every map* $\operatorname{Sp\acute{e}t} \kappa \to \mathsf{Y}$*, the fiber* $\operatorname{Sp\acute{e}t} \kappa \times_{\mathsf{Y}} \mathsf{X}$ *is n-truncated.*

Proof. The implication (1) ⇒ (2) follows from Proposition 6.1.2.2 and Example 6.1.1.2. To prove the converse, we can work locally and thereby reduce to the case where $\mathsf{Y} = \operatorname{Sp\acute{e}t} A$ and $\mathsf{X} = \operatorname{Sp\acute{e}t} B$ are affine. Assume that (2) is satisfied; we wish to prove that B has Tor-amplitude $\leqslant n$ over A. Using Remark 6.1.2.6, we can replace A by $\pi_0 A$ and B by $\pi_0 A \otimes_A B$, and thereby reduce to the case where A is discrete. It follows from Propositions 6.1.4.5 and 6.1.4.4 that for each $m \geqslant n$, the truncation $\tau_{\leqslant m} B$ has Tor-amplitude $\leqslant n$ over A. In particular, we deduce that $\pi_i B \simeq 0$ for $n < i \leqslant m$. Since m is arbitrary, we conclude that A is n-truncated. It follows that $A \simeq \tau_{\leqslant n} A$ has Tor-amplitude $\leqslant n$ over R. □

Corollary 6.1.4.8 immediately implies the following classical result:

Corollary 6.1.4.9 (Fiberwise Flatness Criterion)**.** *Suppose given a commutative diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X} & \xrightarrow{f} & \mathsf{Y} \\ & \searrow \quad \swarrow & \\ & \mathsf{Z}, & \end{array}$$

where f is locally almost of finite presentation. The following conditions are equivalent:

(1) *The morphism f is flat.*

(2) *For every field κ and every map* $\operatorname{Sp\acute{e}t} \kappa \to \mathsf{Z}$*, the induced map* $f_\kappa : \operatorname{Sp\acute{e}t} \kappa \times_{\mathsf{Z}} \mathsf{X} \to \operatorname{Sp\acute{e}t} \kappa \times_{\mathsf{Z}} \mathsf{Y}$ *is flat.*

Corollary 6.1.4.10. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is proper and locally almost of finite presentation. The following conditions are equivalent:*

(1) *The morphism f is finite flat.*

(2) *For every field κ and every morphism* $\operatorname{Sp\acute{e}t} \kappa \to \mathsf{Y}$*, the projection map* $\operatorname{Sp\acute{e}t} \kappa \times_{\mathsf{Y}} \mathsf{X} \to \operatorname{Sp\acute{e}t} \kappa$ *is finite flat.*

Proof. Combine Corollary 6.1.4.9 with Proposition 5.2.3.3. □

Corollary 6.1.4.11. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism between spectral Deligne-Mumford stacks. Then f is étale if and only if it satisfies the following conditions:*

(1) *The morphism f is locally almost of finite presentation.*

(2) *For every field κ and every map* $\mathrm{Sp\acute{e}t}\,\kappa \to \mathsf{Y}$*, the projection map* $\mathrm{Sp\acute{e}t}\,\kappa \times_{\mathsf{Y}} \mathsf{X} \to \mathrm{Sp\acute{e}t}\,\kappa$ *is étale.*

Proof. Combine Corollary 6.1.4.8 with Proposition 4.2.3.4. □

Corollary 6.1.4.12. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism between spectral Deligne-Mumford stacks. Then f is an equivalence if and only if it satisfies the following conditions:*

(1) *The morphism f is locally almost of finite presentation.*

(2) *For every field κ and every map* $\mathrm{Sp\acute{e}t}\,\kappa \to \mathsf{Y}$*, the projection map* $\mathrm{Sp\acute{e}t}\,\kappa \times_{\mathsf{Y}} \mathsf{X} \to \mathrm{Sp\acute{e}t}\,\kappa$ *is an equivalence.*

(3) *The morphism f is a relative n-stack for some $n \gg 0$ (see Definition 6.3.1.11).*

Proof. The necessity of conditions (1) through (3) is obvious. To prove the converse, suppose that conditions (1) through (3) are satisfied; we wish to show that f is an equivalence. Using (1) and (2), we deduce that f is étale. Write $\mathsf{Y} = (\mathcal{Y}, \mathcal{O}_{\mathsf{Y}})$, so that we have $\mathsf{X} \simeq (\mathcal{Y}_{/U}, \mathcal{O}_{\mathsf{Y}}|_U)$ for some object $U \in \mathcal{Y}$. Using (2) and Proposition 3.5.4.2, we deduce that $\eta^* U$ is contractible for every point $\eta^* \in \mathrm{Fun}^*(\mathcal{Y}, \mathcal{S})$. Since the hypercompletion of $\mathcal{Y}$ has enough points (Theorem A.4.0.5), it folows that U is ∞-connective (see Proposition A.4.2.1). Condition (3) guarantees that U is n-truncated for $n \gg 0$, so that U is a final object of $\mathcal{Y}$ and f is an equivalence as desired. □

6.1.5 The Proof of Proposition 6.1.4.5

The proof of Proposition 6.1.4.5 is fairly technical. We begin by discussing the case where A is Noetherian, in which case the desired result is a minor modification of Theorem 11.1.1 of [90].

Lemma 6.1.5.1. *Let R be a commutative ring, let M be a connective R-module spectrum, and suppose that M is $(n+1)$-truncated for some integer $n \geqslant 0$. The following conditions are equivalent:*

(a) *The R-module spectrum M has* Tor*-amplitude $\leqslant n$ over R.*

(b) *For every discrete R-module N, the homotopy group $\pi_{n+1}(M \otimes_R N)$ vanishes.*

Proof. The implication $(a) \Rightarrow (b)$ is immediate. We will prove the converse using induction on n. Suppose first that $n = 0$. Applying (b) in the case $N = R$, we deduce that M is a discrete R-module. Condition (b) then asserts that that $\mathrm{Tor}_1^R(M, N) \simeq 0$ for every discrete R-module N (see Corollary HA.7.2.1.22), so that the functor $N \mapsto \mathrm{Tor}_0^R(M, N)$ is exact and therefore M is flat over R. Assume now that $n > 0$. Choose a free R-module P and a map $\phi : P \to M$ which induces a surjection $\pi_0 P \to \pi_0 M$. Then ϕ fits into a fiber sequence $M' \to P \to M$. Consequently, to prove that M has Tor-amplitude $\leqslant n$, it will suffice to show that M' has Tor-amplitude $\leqslant n-1$. Using the exact sequence $\pi_{m+1} M \to \pi_m M' \to \pi_m P$, we deduce that M' is $(n-1)$-truncated. By virtue of the inductive hypothesis, we are reduced to proving that $\pi_n(M' \otimes_R N) \simeq 0$ for any discrete R-module N. We have a short exact sequence $\pi_{n+1}(M \otimes_R N) \to \pi_n(M' \otimes_R N) \to \pi_n(P \otimes_R N)$. Since P is a free R-module and N is discrete, $\pi_n(P \otimes_R N)$. Consequently, if condition (b) is satisfied, then $\pi_n(M' \otimes_R N) \simeq 0$ as desired. □

Lemma 6.1.5.2. *Let $m > n \geqslant 0$ be integers, let A be a Noetherian commutative ring, let B be a connective $\mathbb{E}_\infty$-algebra which is almost of finite presentation over A, and let M be a B-module which is of finite presentation to order m. Let $\mathfrak{p} \subseteq \pi_0 B$ be a prime ideal, let $\mathfrak{q}$ denote its inverse image in A, and let $\kappa = \kappa(\mathfrak{q})$ denote the residue field of A at $\mathfrak{q}$. Then the following conditions are equivalent:*

- (a) *The module M has* Tor*-amplitude $\leqslant n$ over A at $\mathfrak{p}$.*
- (b) *The homotopy groups $\pi_i(M \otimes_A \kappa)_{\mathfrak{p}}$ vanish for $n < i \leqslant m$.*

Proof. The implication $(a) \Rightarrow (b)$ is immediate. Conversely, suppose that (b) is satisfied; we will show that $M_{\mathfrak{p}}$ has Tor-amplitude $\leqslant n$ over A. Proceeding by descending induction on n, we can reduced to the case $m = n + 1$. According to Lemma 6.1.5.1 (and Remark 6.1.4.3), it will suffice to show that $\pi_{n+1}(M_{\mathfrak{p}} \otimes_{A_{\mathfrak{q}}} N) \simeq 0$ for every discrete $A_{\mathfrak{q}}$-module N. Writing N as a filtered colimit of finitely generated submodules, we may reduce to the case where N is finitely generated. The collection of those $A_{\mathfrak{q}}$-modules N for which $\pi_{n+1}(M_{\mathfrak{p}} \otimes_{R_{\mathfrak{q}}} N) \simeq 0$ is closed under extensions. We may therefore reduce to the case $N = A_{\mathfrak{q}}/I$, where I is a prime ideal in $A_{\mathfrak{q}}$. Proceeding by Noetherian induction, we may assume that $\pi_{n+1}(M_{\mathfrak{p}} \otimes_{A_{\mathfrak{q}}} A_{\mathfrak{q}}/J) \simeq 0$ whenever J is a prime ideal of $R_{\mathfrak{q}}$ properly containing I.

Let $A' = A_{\mathfrak{q}}/I$. If A' is a field, then I is the maximal ideal of $A_{\mathfrak{q}}$ and the desired result follows from (b). Otherwise, we can choose a nonzero element x belonging to the maximal ideal of A'. Note that $A'/(x)$ can be written as a finite extension of $A_{\mathfrak{q}}$-modules of the form $A_{\mathfrak{q}}/J$, where J is a prime ideal of $A_{\mathfrak{q}}$ properly containing I. It follows that $\pi_{n+1}(M_{\mathfrak{p}} \otimes_{A_{\mathfrak{q}}} A'/(x)) \simeq 0$, so that multiplication by x induces a surjection from $\pi_{n+1}(M_{\mathfrak{p}} \otimes_{A_{\mathfrak{q}}} A')$ to itself. Note that $M_{\mathfrak{p}} \otimes_{A_{\mathfrak{q}}} A'$ is almost perfect as a module over $B_{\mathfrak{p}}$. Proposition HA.7.2.4.31 implies that B is Noetherian, so that $B_{\mathfrak{p}}$ is Noetherian and therefore $\pi_{n+1}(M_{\mathfrak{p}} \otimes_{A_{\mathfrak{q}}} A')$ is finitely generated as a discrete module over the local ring $\pi_0 B_{\mathfrak{p}}$. The image of x in $\pi_0 B_{\mathfrak{p}}$ belongs to the maximal ideal. Applying Nakayama's lemma, we deduce that $\pi_{n+1}(M_{\mathfrak{p}} \otimes_{A_{\mathfrak{q}}} A') \simeq 0$, as desired. □

We now wish to study the loci of prime ideals $\mathfrak{p} \subseteq \pi_0 B$ which satisfy the conditions appearing in Lemma 6.1.5.2.

Lemma 6.1.5.3. *Let X be a sober Noetherian topological space and let $U \subseteq X$ be a subset. Then U is open if and only if it satisfies the following conditions:*

(a) *The set U is stable under generalization: that is, if points $x, y \in X$ satisfy $x \in \overline{\{y\}}$ and x belongs to U, then y also belongs to U.*

(b) *For every point $x \in U$, the intersection $U \cap \overline{\{x\}}$ contains an nonempty open subset of $\overline{\{x\}}$.*

Proof. The necessity of conditions (a) and (b) are obvious. Conversely, suppose that (a) and (b) are satisfied; we wish to show that U is open. Let U° denote the interior of U. Replacing X by $X - U^{\circ}$ and U by $U - U^{\circ}$, we can reduce to the case where $U^{\circ} = \varnothing$. Writing X as a union of its irreducible components, we may assume that X is irreducible. If U is empty, there is nothing to prove; otherwise, there exists a point $x \in U$. Using (a), we deduce that the generic point of X belongs to U. It then follows from (b) that the interior of U is nonempty, contrary to our assumptions. □

Lemma 6.1.5.4 (Generic Freeness)**.** *Let A be a Noetherian integral domain, let B be a finitely generated (discrete) A-algebra, and let M be a finitely generated B-module. Then there exists a nonzero element $a \in A$ such that $M[a^{-1}]$ is a free $A[a^{-1}]$-module.*

Proof. Choose a finite collection of elements $b_1, \ldots, b_n \in B$ which generate B as an A-algebra. We proceed by induction on n. In the case $n = 0$, M is a finitely generated A-module. Let K denote the fraction field of A, so that $K \otimes_A M$ is a finitely generated vector space over K. We can then choose finitely many elements $x_1, \ldots, x_k \in M$ whose images form a basis for $K \otimes_A M$. The elements $\{x_i\}_{1 \leqslant i \leqslant k}$ determine a map $\phi : A^k \to M$ such that $K \otimes_A \ker(\phi) \simeq 0 \simeq K \otimes_A \operatorname{coker}(\phi)$. Since A is Noetherian, the kernel and cokernel of ϕ are finitely generated. We can therefore choose an element $a \in A$ which annihilates $\ker(\phi)$ and $\operatorname{coker}(\phi)$, so that ϕ induces an isomorphism $A[a^{-1}]^k \simeq M[a^{-1}]$.

We now treat the case $n > 0$. Let B_0 denote the A-subalgebra of B generated by $b_1, \ldots, b_{n-1}$. Let $M_0 \subseteq M$ be a finitely generated B_0-submodule which generates M as a B-module. For $i \geqslant 0$, set $M_i = M_0 + b_n M_0 + \cdots + b_m^i M_0 \subseteq M$, so that we have $M = \bigcup M_i$. For each $i \geqslant 0$, multiplication by b_n^{i+1} induces a surjection $M_0 \to M_{i+1}/M_i$ whose kernel is a submodule $N_i \subseteq M_0$. The ring B_0 is Noetherian (by virtue of the Hilbert basis theorem) and M_0 is a finitely generated module over B_0. It follows that the ascending chain of submodules $N_0 \subseteq N_1 \subseteq \cdots$ eventually stabilizes. In other words, there exists an integer $i \geqslant 0$ for which the maps $b_n^j : M_{i+1}/M_i \to M_{i+j+1}/M_{i+j}$ are isomorphisms for each $j \geqslant 0$. Using our inductive hypothesis repeatedly, we can choose a nonzero element $a \in A$ for which each of the localizations $M_0[a^{-1}], (M_1/M_0)[a^{-1}], (M_2/M_1)[a^{-1}], \ldots, (M_{i+1}/M_i)[a^{-1}]$ is a free module over $A[a^{-1}]$, so that $(M_{j+1}/M_j)[a^{-1}]$ is a free $A[a^{-1}]$-module for all i. It follows that each of the exact sequences $0 \to M_j[a^{-1}] \to M_{j+1}[a^{-1} \to (M_{j+1}/M_j)[a^{-1}] \to 0$ splits, so that $M[a^{-1}] \simeq M_0[a^{-1}] \oplus \bigoplus_{j \geqslant 0}(M_{j+1}/M_j)[a^{-1}]$ is also a free module over $A[a^{-1}]$, as desired. □

Lemma 6.1.5.5. *Let $m > n \geqslant 0$ be integers, let A be a Noetherian commutative ring, let B be a connective $\mathbb{E}_\infty$-algebra which is almost of finite presentation over A, and let M be a B-module which is of finite presentation to order m. Let $U \subseteq |\operatorname{Spec} B|$ denote the set consisting of those prime ideals $\mathfrak{p} \subseteq \pi_0 B$ such that M has* Tor*-amplitude $\leqslant n$ over A at $\mathfrak{p}$. Then U is open.*

Proof. Since A is Noetherian, the $\mathbb{E}_\infty$-ring B is also Noetherian (Theorem HA.7.2.4.31) so that the topological space $|\operatorname{Spec} B|$ is Noetherian. It will therefore suffice to show that the set U satisfies conditions (a) and (b) of Lemma 6.1.5.3. Condition (a) is obvious: if we are given prime ideals $\mathfrak{p} \subseteq \mathfrak{p}' \subseteq \pi_0 B$, then the localization $M_{\mathfrak{p}}$ can be obtained as a filtered colimit of copies of $M_{\mathfrak{p}'}$, so that if $M_{\mathfrak{p}'}$ has Tor-amplitude $\leqslant n$ as an A-module then $M_{\mathfrak{p}}$ also has Tor-amplitude $\leqslant n$ as an A-module.

We now verify condition (b). Choose $\mathfrak{p} \in U$, and let $\mathfrak{q} \subseteq A$ be the inverse image of $\mathfrak{p}$. Set $A' = A/\mathfrak{q}$, $B' = A' \otimes_A B$, and $M' = B' \otimes_B M$. Our assumption that $\mathfrak{p}$ belongs to U guarantees that the homotopy groups $\pi_i M'_{\mathfrak{q}}$ vanish for $n < i \leqslant m$. Since each of these homotopy groups is a finitely generated module over $\pi_0 B$, we can choose an element $b \in (\pi_0 B) - \mathfrak{q}$ such that $\pi_i M'[b^{-1}]$ vanishes for $n < i \leqslant m$. Using Lemma 6.1.5.4, we can choose a nonzero element $\overline{a} \in A'$ such that $\pi_i M'[b^{-1}][\overline{a}^{-1}]$ is a free $A'[\overline{a}^{-1}]$-module for $0 \leqslant i \leqslant n$. Choose an element $a \in A$ lifting $\overline{a} \in A'$, and let us abuse notation by identifying a with its image in $\pi_0 B$. We will complete the proof by showing that U contains every prime ideal $\mathfrak{p}' \subseteq (\pi_0 B)$ such that $\mathfrak{p} \subseteq \mathfrak{p}'$ and $a, b \notin \mathfrak{p}'$ (note that the collection of such prime ideals forms an open subset of the closure of $\mathfrak{p}$ in $|\operatorname{Spec} B|$). To prove this, let $\mathfrak{q}' \subseteq A$ be the inverse image of $\mathfrak{p}'$, and let κ be the residue field of A at $\mathfrak{q}'$. Using the criterion of Lemma 6.1.5.2, we are reduced to showing that the homotopy groups $\pi_i(M \otimes_A \kappa)_{\mathfrak{q}'} \simeq \pi_i(M' \otimes_{A'} \kappa)_{\mathfrak{q}'}$ vanishes for $n < i \leqslant m$. Note that these homotopy groups are localizations of $\pi_i(M'[b^{-1}\overline{a}^{-1}] \otimes_{A'[\overline{a}^{-1}]} \kappa)$. Proposition HA.7.2.1.19 supplies a spectral sequence $\{E_r^{s,t}, d_r\}_{r \geqslant 2}$ with second page $E_2^{s,t} = \operatorname{Tor}_s^{A'[\overline{a}^{-1}]}(\pi_t M'[b^{-1}\overline{a}^{-1}], \kappa)$ converging to $\pi_{s+t}(M'[b^{-1}\overline{a}^{-1}] \otimes_{A'[\overline{a}^{-1}]} \kappa$ It now suffices to observe that $E_2^{s,t}$ vanishes for $n < s+t \leqslant m$ (since the modules $\pi_t M'[b^{-1}\overline{a}^{-1}]$ are free for $0 \leqslant t \leqslant n$ and vanish for $n < t \leqslant m$). □

Lemma 6.1.5.6. *Let $m \geqslant n \geqslant 0$ be integers, let A_0 be a Noetherian commutative ring, let B_0 be an $\mathbb{E}_\infty$-algebra over A_0 which is finitely m-presented, and let M_0 be a connective B_0-module which is finitely m-presented. Suppose we are given a diagram $\{A_\alpha\}_{\alpha \in I}$ of discrete Noetherian A_0-algebras indexed by a filtered partially ordered set I, and set $A = \varinjlim A_\alpha$ (so that A need not be Noetherian). For each $\alpha \in I$, set $B_\alpha = \tau_{\leqslant m}(A_\alpha \otimes_{A_0} B_0)$ and $M_\alpha = \tau_{\leqslant m}(B_\alpha \otimes_{B_0} M_0)$, and set $B = \tau_{\leqslant m}(A \otimes_{A_0} B_0)) \simeq \varinjlim B_\alpha$ and $M = \tau_{\leqslant m}(B \otimes_{B_0} M_0) \simeq \varinjlim M_\alpha$. Let $\mathfrak{p} \subseteq \pi_0 BA$ be a prime ideal having inverse images $\mathfrak{q} \subseteq A$, $\mathfrak{p}_\alpha \subseteq \pi_0 B_\alpha$, and $\mathfrak{q}_\alpha \subseteq A_\alpha$. Let κ denote the* *residue field of R at $\mathfrak{q}$, and for each $\alpha \in I$ let κ_α denote the residue field of A_α at $\mathfrak{q}_\alpha$. Then the following conditions are equivalent:*

- (a) *The module M has* Tor*-amplitude $\leqslant n$ over A at $\mathfrak{p}$.*
- (a') *There exists an index $\alpha \in I$ such that M_α has* Tor*-amplitude $\leqslant n$ over A_α at $\mathfrak{p}_\alpha$.*
- (b) *The homotopy groups $\pi_i(M \otimes_A \kappa)_{\mathfrak{p}}$ vanish for $n < i \leqslant m+1$.*
- (b') *There exists an index $\alpha \in I$ such that the homotopy groups $\pi_i(M_\alpha \otimes_{A_\alpha} \kappa_\alpha)_{\mathfrak{p}_\alpha}$ vanish for $n < i \leqslant m+1$.*

Proof. We will show that $(a) \Rightarrow (b) \Rightarrow (b') \Rightarrow (a') \Rightarrow (a)$. The implication $(a) \Rightarrow (b)$ is immediate from the definitions.

We now show that $(b') \Leftrightarrow (a')$. For each $\alpha \in I$, the commutative ring A_α is Noetherian and B_α is finitely m-presented over A_α; it follows from Proposition 4.2.4.1 that B_α is almost of finite presentation over A_α. In particular, B_α is Noetherian. Consequently, the assumption that M_α is finitely m-presented over B_α guarantees that it is also finitely $(m+1)$-presented over B_α. The desired result now follows from Lemma 6.1.5.2 (applied to the pair of integers $m+1 > n$).

Note that for each $\alpha \in I$, we have an equivalence $M \simeq \tau_{\leqslant m}(A \otimes_{A_\alpha} M_\alpha)$, and therefore an equivalence $M_{\mathfrak{p}} \simeq \tau_{\leqslant m}(A \otimes_{A_\alpha} M_\alpha \mathfrak{p}_\alpha)_{\mathfrak{p}}$. If M_α has Tor-amplitude $\leqslant n$ over A_α at $\mathfrak{p}_\alpha$, then the tensor product $A \otimes_{A_\alpha} M_{\alpha \mathfrak{p}_\alpha}$ is n-truncated, and therefore also m-truncated. It then follows that $M_{\mathfrak{p}}$ is a localization of $A \otimes_{A_\alpha} M_{\alpha \mathfrak{p}_\alpha}$, and is therefore of Tor-amplitude $\leqslant n$ over A. This proves that $(a') \Rightarrow (a)$.

We now complete the proof by showing that (b) implies (b'). Let $\mathfrak{p}_0$ and $\mathfrak{q}_0$ denote the inverse images of $\mathfrak{p}$ in the commutative rings $\pi_0 B_0$ and A_0, respectively. Let κ_0 denote the residue field of A_0 at $\mathfrak{p}$ and define

$$K_0 = \kappa_0 \otimes_{A_0} M_0 \qquad K_\alpha = \kappa_\alpha \otimes_{A_\alpha} M_\alpha \qquad K = \kappa \otimes_A M.$$

By construction, we have $(m+1)$-connective maps $A_\alpha \otimes_{A_0} M_0 \to M_\alpha$ and $A \otimes_{A_0} M_0 \to M$, so that the induced maps

$$\rho_i : \kappa \otimes_{\kappa_0} (\pi_i K_0) \to \pi_i K \qquad \rho_{i,\alpha} : \kappa \otimes_{\kappa_0} (\pi_i K_0) \to \kappa \otimes_{\kappa_\alpha} (\pi_i K_\alpha)$$

are isomorphisms for $i \leqslant m$ and surjections for $i = m+1$. For $n < i \leqslant m+1$, condition (b) implies that $(\pi_i K)_{\mathfrak{p}} \simeq 0$. It follows that the map ρ_i vanishes after localization at $\mathfrak{p}$. Since $\pi_i K_0$ is a finitely generated module over $\pi_0(\kappa_0 \otimes_{A_0} B_0)$, we conclude that the image of ρ_i is annihilated by some element $b \in (\pi_0 B) - \mathfrak{p}$. Without loss of generality, we may assume that there exists an element $\alpha_i \in I$ such that b is the image of some element $\overline{b} \in \pi_0 B_{\alpha_i}$. Enlarging α_i if necessary, we may assume that multiplication by $\overline{b}$ annihilates the image of the map ρ_{i,α_i}. Consequently, condition (b') is satisfied for any $\alpha \in I$ which is an upper bound for $\{\alpha_{n+1}, \alpha_{n+2}, \ldots, \alpha_{m+1}\}$. □

Proof of Proposition 6.1.4.5. Let $m \geqslant n \geqslant 0$ be integers, let A be a commutative ring, let B be a connective $\mathbb{E}_\infty$-algebra over A which is of finite generation to order $(m+1)$, and let M be a connective B-module which is finitely m-presented. Let $\mathfrak{p} \subseteq \pi_0 B$ be a prime ideal, let $\mathfrak{q} \subseteq A$ be its inverse image, and let κ denote the residue field of A at $\mathfrak{q}$. We wish to show that M has Tor-amplitude $\leqslant n$ over A at $\mathfrak{p}$ if and only if the homotopy groups $\pi_i(\kappa \otimes_A M_{\mathfrak{p}})$ vanish for $n < i \leqslant m+1$. To prove this, we are free to replace B by $\tau_{\leqslant m} B$ and thereby reduce to the case where B is finitely m-presented over A.

Write A as a union of its finitely generated subalgebras $\{A_\alpha\}_{\alpha \in I}$. Using Corollary 4.4.1.4, we see that there exists an index $\alpha \in I$, an $\mathbb{E}_\infty$-algebra B_α which is finitely m-presented over A_α, and an equivalence $B \simeq \tau_{\leqslant m}(A \otimes_{A_\alpha} B_\alpha)$. Using Corollary 4.5.1.10, we can (after enlarging α if necessary) assume that there exists a B_α-module M_α which is connective and finitely m-presented and an equivalence $M \simeq \tau_{\leqslant m}(B \otimes_{B_\alpha} M_\alpha)$. The desired equivalence now follows from Lemma 6.1.5.6

For each $\beta \geqslant \alpha$, set $B_\beta = \tau_{\leqslant m}(A_\beta \otimes_{A_\alpha} B_\alpha)$ and $M_\beta = \tau_{\leqslant m}(B_\beta \otimes_{B_\alpha} M_\alpha)$. Let U denote the subset of $|\operatorname{Spec} B|$ consisting of those prime ideals $\mathfrak{p}$ such that M has Tor-amplitude $\leqslant n$ over A at $\mathfrak{p}$, and let U_β denote the subset of $|\operatorname{Spec} B_\beta|$ consisting of those prime ideals $\mathfrak{p}$ such that M_β has Tor-amplitude $\leqslant n$ over A_β at $\mathfrak{p}$. It follows from Lemma 6.1.5.5 that each U_β is an open subset of $|\operatorname{Spec} B_\beta|$. Lemma 6.1.5.6 implies that U is the union of the inverse images of the sets U_β, so that U is an open subset of $|\operatorname{Spec} B|$. □

6.1.6 Tor-Amplitude and Filtered Colimits

We close this section by mentioning a few consequences of Proposition 6.1.4.5.

Proposition 6.1.6.1. *Let $m \geqslant n \geqslant 0$ be integers, let A_0 be a commutative ring and let B_0 be an $\mathbb{E}_\infty$-algebra over A_0 which is finitely m-presented. Suppose we are given a diagram $\{A_\alpha\}_{\alpha \in I}$ of discrete A_0-algebras indexed by a filtered partially ordered set I, and set $A = \varinjlim A_\alpha$. Set $B_\alpha = \tau_{\leqslant m}(A_\alpha \otimes_{A_0} B_0)$ and $B = \tau_{\leqslant m}(A \otimes_{A_0} B_0) \simeq \varinjlim B_\alpha$. If B has* Tor-*amplitude $\leqslant n$ over A, then there exists an index α such that B_α has* Tor-*amplitude $\leqslant n$ over A.*

Warning 6.1.6.2. In the statement of Proposition 6.1.6.1, the hypothesis that the diagram $\{A_\alpha\}$ consists of commutative rings (rather than connective $\mathbb{E}_\infty$-rings) cannot be eliminated.

Proof of Proposition 6.1.6.1. Write A as a union of finitely generated subalgebras $\{R_\beta\}_{\beta \in J}$. Using Corollary 4.4.1.4, we conclude that there exists an index $\beta \in J$, an $\mathbb{E}_\infty$-algebra S_β which is is finitely m-presented over R_β, and an equivalence $B \simeq \tau_{\leqslant m}(A \otimes_{R_\beta} S_\beta)$. For each $\beta' \geqslant \beta$, set $S_{\beta'} = \tau_{\leqslant m}(R_{\beta'} \otimes_{R_\beta} S_\beta)$, and let $U_{\beta'} \subseteq |\operatorname{Spec} S_{\beta'}|$ be the set consisting of those prime ideals $\mathfrak{p}$ such that $S_{\beta'}$ has Tor-amplitude $\leqslant n$ over $R_{\beta'}$ at $\mathfrak{p}$. Then each $U_{\beta'}$ is an open subset of $|\operatorname{Spec} S_{\beta'}|$ (Lemma 6.1.5.5). It follows from Lemma 6.1.5.6 (and our assumption that B has Tor-amplitude $\leqslant n$ over A) that $|\operatorname{Spec} B|$ is covered by the the inverse images of the open sets $U_{\beta'}$. Since $|\operatorname{Spec} B|$ is quasi-compact, it follows that there exists $\beta' \geqslant \beta$ for which the map $|\operatorname{Spec} B| \to |\operatorname{Spec} S_{\beta'}|$ factors through $U_{\beta'}$. Using Proposition 4.3.5.1, we deduce that there exists $\beta'' \geqslant \beta'$ such that the map $|\operatorname{Spec} S_{\beta''}| \to |\operatorname{Spec} S_{\beta'}|$ factors through $U_{\beta'}$. It then follows that $U_{\beta''} = |\operatorname{Spec} S_{\beta''}|$, so that $S_{\beta''}$ has Tor-amplitude $\leqslant n$ over $R_{\beta''}$ (Proposition 6.1.4.4).

Since $R_{\beta''}$ is finitely presented as a commutative ring, the inclusion $R_{\beta'} \to A$ must factor through A_α for some $\alpha \in I$. Set $B'_\alpha = A_\alpha \otimes_{R_{\beta''}} S_{\beta''}$, so that B'_α has Tor-amplitude $\leqslant n$ over A_α. Note that B_α and B'_α are $\mathbb{E}_\infty$-algebras which are finitely m-presented over A_α and we have a canonical equivalence $\tau_{\leqslant m}(A \otimes_{A_\alpha} B_\alpha) \simeq B \simeq \tau_{\leqslant m}(A \otimes_{A_\alpha} B'_\alpha)$. Using Corollary 4.4.1.4, we can assume (after enlarging α if necessary) that B_α and B'_α are equivalent as $\mathbb{E}_\infty$-algebras over A_α, so that B_α has Tor-amplitude $\leqslant n$ over A_α. □

Corollary 6.1.6.3. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Suppose that there exists an integer n such that f is locally of finite generation to order $(n+1)$ and of* Tor*-amplitude $\leqslant n$. Then f is locally almost of finite presentation.*

Proof. The assertion is local on X and Y, so we may assume without loss of generality that $\mathsf{Y} = \operatorname{Spét} A$ and $\mathsf{X} = \operatorname{Spét} B$ are affine. We wish to show that B is almost of finite presentation over A. By virtue of Proposition 4.1.3.4, we can replace A by $\pi_0 A$ and B by the tensor product $B \otimes_A \pi_0 A$, and thereby reduce to the case where A is discrete. Since B is of Tor-amplitude $\leqslant n$ over A, it is n-truncated. It is therefore finitely n-presented over A.

Write A as a filtered colimit its finitely generated subrings and applying Corollary 4.4.1.4, we deduce that there exists a finitely generated subring $A_0 \subseteq A$ and an equivalence $B \simeq \tau_{\leqslant n}(A \otimes_{A_0} B_0)$, where B_0 is finitely n-presented over A_0. By virtue of Proposition 6.1.6.1, we may assume (after enlarging A_0 if necessary) that B_0 has Tor-amplitude $\leqslant n$ over A_0. It follows that the tensor product $A \otimes_{A_0} B_0$ is n-truncated, and is therefore equivalent to B. Replacing A by A_0 and B by B_0, we can reduce to the case where A is Noetherian. In this case, Proposition 4.2.4.1 implies that B is Noetherian and of finite type over A, so that B is almost of finite presentation over A by virtue of Remark 4.2.0.4. □

Corollary 6.1.6.4. *Let $f : \mathsf{X} \to \mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathsf{Y}})$ be a morphism of spectral Deligne-Mumford stacks. The following conditions are equivalent:*

(1) *The map f is flat and locally almost of finite presentation.*

(2) *Let $\mathsf{Y}_0 = (\mathcal{Y}, \pi_0 \mathscr{O}_{\mathsf{Y}})$, and let $\mathsf{X}_0 = \mathsf{X} \times_{\mathsf{Y}} \mathsf{Y}_0$. Then the projection map $\mathsf{X}_0 \to \mathsf{Y}_0$ is flat and locally finitely* 0*-presented.*

Proof. The implication (1) ⇒ (2) is clear. For the converse, we may assume without loss of generality that $\mathsf{X} \simeq \operatorname{Spét} B$ and $\mathsf{Y} \simeq \operatorname{Spét} A$ are affine. Condition (2) then guarantees that $B_0 = B \otimes_A (\pi_0 A)$ is flat and finitely 0-presented over $\pi_0 A$. It follows immediately that B is flat over A. We will complete the proof by showing that B is almost of finite presentation over A. Using assumption (2) and Proposition 4.1.2.1, we deduce that the cotangent complex $L_{B_0/\pi_0 A} \simeq B_0 \otimes_B L_{B/A}$ is perfect to order 1 as a B_0-module (Proposition 4.1.2.1). Using Proposition 2.7.3.2, we see that $L_{B/A}$ is perfect to order 1 as a module over B. Since $\pi_0 B$ is finitely presented as an algebra over $\pi_0 A$, Proposition 4.1.2.1 implies that B is of finite generation to order 1 over A. Using the flatness of B over A and Corollary 6.1.6.3, we deduce that B is almost of finite presentation over A, as desired. □

Corollary 6.1.6.5. *Let $f : R \to A$ be a morphism of connective $\mathbb{E}_\infty$-rings. Suppose that there exists a faithful flat morphism $g : A \to B$ such that g and $g \circ f$ are almost of finite presentation. Then f is almost of finite presentation.*

Proof. We first show that $\pi_0 A$ is finitely generated as an algebra over $\pi_0 R$. Write $\pi_0 A$ as a filtered colimit of commutative rings $\{A_\alpha\}$ which are finitely presented over $\pi_0 R$. Since $\pi_0 B \simeq \pi_0 A \otimes_A B$ is almost of finite presentation over $\pi_0 A$, we can write $\pi_0 B \simeq \tau_{\leqslant 0}(\pi_0 A \otimes_{A_\alpha} B_\alpha)$ for some B_α which is finitely 0-presented over A_α. Using Proposition 6.1.6.1 and Proposition 4.6.1.2, we may assume without loss of generality that B_α is faithfully flat over A_α; in particular, B_α is discrete. Choose a finite collection of elements $x_1, \ldots, x_n$ which generate $\pi_0 B$ as an algebra over $\pi_0 R$. Changing α if necessary, we may suppose that each x_i can be lifted to an element $\overline{x}_i$ in B_α. Then the map $\psi : B_\alpha \to \pi_0 B$ is surjective. Since B_α is faithfully flat over A_α, we conclude that the map $A_\alpha \to \pi_0 A$ is surjective, so that $\pi_0 A$ is finitely generated over $\pi_0 R$.

Let I denote the kernel of the map $A_\alpha \to \pi_0 A$. Then $I B_\alpha$ is the kernel of ψ. Since ψ is a surjection between finitely presented $\pi_0 R$-algebras, $\ker(\psi)$ is finitely generated. Since B_α is faithfully flat over A_α, we conclude that I is finitely generated, so that $\pi_0 A \simeq A_\alpha / I$ is finitely presented as a commutative ring over $\pi_0 R$.

To complete the proof that A is almost of finite presention over R, it will suffice to show that $L_{A/R}$ is almost perfect as an A-module (Proposition 4.1.2.1). Since B is faithfully flat over A, it will suffice to prove that $B \otimes_A L_{A/R}$ is almost perfect as a B-module (Proposition 2.8.4.2). This follows from the existence of a fiber sequence $B \otimes_A L_{A/R} \to L_{B/R} \to L_{B/A}$, since $L_{B/A}$ and $L_{B/R}$ are almost perfect by virtue of Proposition 4.1.2.1. □

6.2 Digression: Quasi-Coherent Sheaves on a Functor

In §2.2, we introduced the notion of a *quasi-coherent sheaf* on a spectral Deligne-Mumford stack X. Every spectral Deligne-Mumford stack X determines a "functor of points" $h_{\mathsf{X}} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, given on objects by the formula $h_{\mathsf{X}}(R) = \mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Spét}\, R, \mathsf{X})$. According to Proposition **??**, the spectral Deligne-Mumford stack X is determined (up to canonical equivalence) from the functor h_{X}. In particular, the ∞-category $\mathrm{QCoh}(\mathsf{X})$ is depends only on the functor h_{X}. Our goal in this section is to make the passage from h_{X} to $\mathrm{QCoh}(\mathsf{X})$ explicit. To accomplish this, we will associate to any functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ an ∞-category $\mathrm{QCoh}(X)$, which we call the *∞-category of quasi-coherent sheaves on the functor X*. Roughly speaking, an object $\mathscr{F} \in \mathrm{QCoh}(X)$ can be viewed as a rule which assigns to each point $\eta \in X(R)$ an R-module $\mathscr{F}(\eta)$, which depends functorially on R in the following sense: if $\phi : R \to R'$ is a map of connective $\mathbb{E}_\infty$-rings and η' denotes the image of η in $X(R')$, then we have a canonical equivalence $R' \otimes_R \mathscr{F}(\eta) \simeq \mathscr{F}(\eta')$. Moreover, we require that this equivalence is compatible with composition of morphisms in $\mathrm{CAlg}^{\mathrm{cn}}$, up to coherent homotopy. The first part of this section is devoted to converting the above discussion into a precise definition (Definition 6.2.2.1). We then show that, in the special case where X is the functor represented by a spectral Deligne-Mumford stack X, there is a canonical equivalence of ∞-categories $\mathrm{QCoh}(X) \simeq \mathrm{QCoh}(\mathsf{X})$ (Proposition 6.2.4.1).

6.2.1 Categorical Digression

Our first goal is to make turn the heuristic description of $\mathrm{QCoh}(X)$ sketched above into a precise definition. For this, we will need to develop a bit of categorical machinery. In what follows, we will assume that the reader is familiar with the theory of Cartesian fibrations developed in §HTT.2.4 .

Definition 6.2.1.1. Let $q : \mathcal{D} \to \mathcal{E}$ be a Cartesian fibration of simplicial sets. Given another map of simplicial sets $e : \mathcal{C} \to \mathcal{E}$, we let $\mathrm{Fun}_{\mathcal{E}}(\mathcal{C}, \mathcal{D})$ denote the ∞-category $\mathrm{Fun}(\mathcal{C}, \mathcal{D}) \times_{\mathrm{Fun}(\mathcal{C},\mathcal{E})} \{e\}$ whose objects are maps $F : \mathcal{C} \to \mathcal{D}$ which fit into a commutative diagram

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{F} & \mathcal{D} \\ & {}_{e}\searrow \quad \swarrow_{q} & \\ & \mathcal{E}. & \end{array}$$

We will say that such an object F is *q-Cartesian* if it carries every edge of $\mathcal{C}$ to a q-Cartesian edge of $\mathcal{D}$. $\mathrm{Fun}^{\mathrm{cart}}_{\mathcal{E}}(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\mathrm{Fun}_{\mathcal{E}}(\mathcal{C}, \mathcal{D})$ spanned by the Cartesian maps.

Remark 6.2.1.2. As our notation suggests, we will be primarily interested in the special case of Definition 6.2.1.1 where $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{E}$ are ∞-categories. However, Definition 6.2.1.1 makes sense in greater generality: the assumption that q is a Cartesian fibration guarantees that $\mathrm{Fun}_{\mathcal{E}}(\mathcal{C}, \mathcal{D})$ and $\mathrm{Fun}^{\mathrm{cart}}_{\mathcal{E}}(\mathcal{C}, \mathcal{D})$ are ∞-categories, regardless of whether or not $\mathcal{C}$, $\mathcal{D}$, or $\mathcal{E}$ are ∞-categories.

Remark 6.2.1.3. In the situation of Definition 6.2.1.1, suppose that $q : \mathcal{D} \to \mathcal{E}$ is a right fibration. Then every edge of $\mathcal{D}$ is q-Cartesian, so we have $\mathrm{Fun}^{\mathrm{cart}}_{\mathcal{E}}(\mathcal{C}, \mathcal{D}) = \mathrm{Fun}_{\mathcal{E}}(\mathcal{C}, \mathcal{D})$.

In the situation of Definition 6.2.1.1, the assumption that $q : \mathcal{D} \to \mathcal{E}$ is a Cartesian fibration means that we can regard the construction $(E \in \mathcal{E}) \mapsto \mathcal{D}_E = \mathcal{D} \times_{\mathcal{E}} \{E\}$ as a contravariant functor from $\mathcal{D}$ to the ∞-category $\mathcal{C}\mathrm{at}_\infty$ of small ∞-categories. Using Proposition HTT.3.3.3.1 , we can identify the ∞-category $\mathrm{Fun}^{\mathrm{cart}}_{\mathcal{E}}(\mathcal{C}, \mathcal{D})$ with a limit of the composite functor $\mathcal{C}^{\mathrm{op}} \to \mathcal{D}^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty$. We now study the naturality of this identification, focusing on the special case where the map $e : \mathcal{C} \to \mathcal{E}$ is a right fibration.

Notation 6.2.1.4. Let $\mathcal{S}\mathrm{et}_\Delta$ denote the category of simplicial sets. Given a simplicial set $\mathcal{E}$, we let $(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}}$ denote the full subcategory of $(\mathcal{S}\mathrm{et}_\Delta)_{/\mathcal{E}}$ whose objects are right fibrations $e : \mathcal{C} \to \mathcal{E}$. We will regard $(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}}$ as a simplicial category, with mapping spaces given by

$$\mathrm{Map}_{(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}}}(\mathcal{C}, \mathcal{D}) = \mathrm{Fun}_{\mathcal{E}}(\mathcal{C}, \mathcal{D}) = \mathrm{Fun}^{\mathrm{cart}}_{\mathcal{E}}(\mathcal{C}, \mathcal{D})$$

(see Remark 6.2.1.3). Note that the simplicial category $(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}}$ is fibrant: that is, for every pair of objects $\mathcal{C}, \mathcal{D} \in (\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}}$, the mapping space $\mathrm{Fun}_{\mathcal{E}}(\mathcal{C}, \mathcal{D})$ is a Kan complex. Let $\mathrm{N}(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}}$ denote the homotopy coherent nerve of the simplicial category $(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}}$. It follows from Proposition HTT.1.1.5.10 that $\mathrm{N}(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}}$ is an ∞-category. We will refer to $\mathrm{N}(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}}$ as *the ∞-category of right fibrations over $\mathcal{E}$*.

Remark 6.2.1.5. Let $\mathcal{E}$ be a simplicial set. Then we can regard $(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}}$ as the full subcategory of $(\mathcal{S}\mathrm{et}_\Delta)_{/\mathcal{E}}$ spanned by those objects which are fibrant with respect to the *contravariant model structure* described in §HTT.2.1.4 (note that such objects are also cofibrant: every object $(\mathcal{S}\mathrm{et}_\Delta)_{/\mathcal{E}}$ is cofibrant with respect to the contravariant model structure). Consequently, we can regard $\mathrm{N}(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}}$ is the underlying ∞-category of the simplicial model category $(\mathcal{S}\mathrm{et}_\Delta)_{/\mathcal{E}}$.

Remark 6.2.1.6. Let $\mathcal{E}$ be a simplicial set. Then Proposition HTT.5.1.1.1 supplies canonical equivalences of ∞-categories $\mathrm{Fun}(\mathcal{E}^{\mathrm{op}}, \mathcal{S}) \xleftarrow{\sim} \mathcal{P}''(\mathcal{E}) \xrightarrow{\sim} \mathrm{N}(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}}$, where $\mathcal{P}''(\mathcal{E})$ denotes the ∞-category underlying the model category of simplicial presheaves on the simplicial category $\mathfrak{C}[\mathcal{E}]$ (see §HTT.1.1.5)

Construction 6.2.1.7. Recall that the ∞-category $\mathcal{C}\mathrm{at}_\infty$ of small ∞-categories is defined as the homotopy coherent nerve of the simplicial category $\mathcal{C}\mathrm{at}^\Delta_\infty$, where the objects of $\mathcal{C}\mathrm{at}^\Delta_\infty$ are (small) ∞-categories and the mapping spaces are given by $\mathrm{Map}_{\mathcal{C}\mathrm{at}^\Delta_\infty}(\mathcal{C}, \mathcal{D}) = \mathrm{Fun}(\mathcal{C}, \mathcal{D})^\simeq$

Let $q : \mathcal{D} \to \mathcal{E}$ be a Cartesian fibration of simplicial sets. Then the construction $\mathcal{C} \mapsto \mathrm{Fun}^{\mathrm{cart}}_{\mathcal{E}}(\mathcal{C}, \mathcal{D})$ determines a contravariant simplicial functor $(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}} \to (\mathcal{C}\mathrm{at}^\Delta_\infty)$. Passing to homotopy coherent nerves, we obtain a functor of ∞-categories $\Phi_0 : (\mathrm{N}(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}})^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty$. Composing this functor with the equivalence $\mathrm{Fun}(\mathcal{E}^{\mathrm{op}}, \mathcal{S}) \simeq \mathrm{N}(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}}$ of Remark 6.2.1.6, we obtain a functor $\Phi(q) : \mathrm{Fun}(\mathcal{E}^{\mathrm{op}}, \mathcal{S})^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty$, which is well-defined up to (canonical) homotopy.

Remark 6.2.1.8. Let $q : \mathcal{D} \to \mathcal{E}$ be a Cartesian fibration of simplicial sets and let $X : \mathcal{E}^{\mathrm{op}} \to \mathcal{S}$ be a functor. Then the functor $\Phi(q)$ of Construction 6.2.1.7 carries X to the ∞-category $\mathrm{Fun}^{\mathrm{cart}}_{\mathcal{E}}(\mathcal{C}, \mathcal{D})$, where $e : \mathcal{C} \to \mathcal{E}$ is a right fibration classified by X. More informally, the ∞-category $\Phi(q)(X)$ can be described as the limit $\varprojlim_{E \in \mathcal{E}, \eta \in X(E)} \mathcal{D}_E$: in other words, an object of $\Phi(q)(X)$ is a rule $\mathscr{F}$ which assigns to each object $E \in \mathcal{E}$ and each point $\eta \in X(E)$ an object $\mathscr{F}(\eta) \in \mathcal{D}_E$, which depends functorially on E and η.

The functor $\Phi(q)$ of Construction 6.2.1.7 can be characterized by a universal mapping property:

Proposition 6.2.1.9. *Let $q : \mathcal{D} \to \mathcal{E}$ be a Cartesian fibration of simplicial sets which is classified by a functor $\chi : \mathcal{E}^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty$, let $j : \mathcal{E}^{\mathrm{op}} \to \mathrm{Fun}(\mathcal{E}^{\mathrm{op}}, \mathcal{S})^{\mathrm{op}}$ be the Yoneda embedding, and let let $\Phi(q) : \mathrm{Fun}(\mathcal{E}^{\mathrm{op}}, \mathcal{S})^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty$ be as in Construction 6.2.1.7. Then $\Phi(q)$ is a right Kan extension of χ along j.*

Remark 6.2.1.10. There are evident dual versions of the constructions described above. If $q : \mathcal{D} \to \mathcal{E}$ is a coCartesian fibration of simplicial sets and we are given a map $e : \mathcal{C} \to \mathcal{E}$, then we will say that a functor $\mathscr{F} \in \mathrm{Fun}_{\mathcal{E}}(\mathcal{C}, \mathcal{D})$ is *q-coCartesian* if it carries every edge of $\mathcal{C}$ to a q-coCartesian edge of $\mathcal{D}$. We let $\mathrm{Fun}^{\mathrm{ccart}}_{\mathcal{E}}(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\mathrm{Fun}_{\mathcal{E}}(\mathcal{C}, \mathcal{D})$ spanned by the q-coCartesian maps. Using a dual version of Construction 6.2.1.7, we see that the construction $\mathcal{C} \mapsto \mathrm{Fun}^{\mathrm{ccart}}_{\mathcal{E}}(\mathcal{C}, \mathcal{E})$ determines a functor $\Phi'(q) : \mathrm{Fun}(\mathcal{E}, \mathcal{S})^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty$. If $\chi : \mathcal{E} \to \mathcal{C}\mathrm{at}_\infty$ is a functor classifying the coCartesian fibration q, then Proposition 6.2.1.9 implies that $\Phi'(q)$ is a right Kan extension of χ along the Yoneda embedding $j : \mathcal{E} \to \mathrm{Fun}(\mathcal{E}, \mathcal{S})^{\mathrm{op}}$.

Remark 6.2.1.11. Remark 6.2.1.10 has an evident analogue in the setting of simplicial sets and ∞-categories that are not necessarily small. If $q : \mathcal{D} \to \mathcal{E}$ is a coCartesian fibration between simplicial sets which are not necessarily small, then q is classified by a functor $\chi : S \to \widehat{\mathcal{C}\mathrm{at}}_\infty$. Performing Construction 6.2.1.7 in a larger universe, we obtain a functor $\Phi'(q) : \mathrm{Fun}(\mathcal{E}, \widehat{\mathcal{S}})^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$, which we can identify with a right Kan extension of χ along the Yoneda embedding $\mathcal{E} \to \mathrm{Fun}(\mathcal{E}, \widehat{\mathcal{S}})^{\mathrm{op}}$.

We now turn to the proof of Proposition 6.2.1.9. By virtue of Lemma HTT.5.1.5.5 , it will suffice to verify the following pair of assertions:

Lemma 6.2.1.12. *Let $q : \mathcal{D} \to \mathcal{E}$ be a Cartesian fibration of simplicial sets. Then the functor $\Phi(q) : \mathrm{Fun}(\mathcal{E}^{\mathrm{op}}, \mathcal{S})^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty$ of Construction 6.2.1.7 commutes with small limits.*

Lemma 6.2.1.13. *Let $q : \mathcal{D} \to \mathcal{E}$ be a Cartesian fibration of simplicial sets, let $\Phi(q) : \mathrm{Fun}(\mathcal{E}^{\mathrm{op}}, \mathcal{S})^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty$ be as in Construction 6.2.1.7, and let $j : \mathcal{E} \to \mathrm{Fun}(\mathcal{E}^{\mathrm{op}}, \mathcal{S})$ denote the Yoneda embedding. Then the composition $(\Phi(q) \circ j^{\mathrm{op}}) : \mathcal{E}^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty$ classifies the Cartesian fibration q.*

Note that the statement of Lemma 6.2.1.13 involves the functor $\Phi(q)$ of Construction 6.2.1.7, which is in turn defined using the equivalence $\mathrm{Fun}(\mathcal{E}^{\mathrm{op}}, \mathcal{S}) \simeq \mathrm{N}(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}}$ of Remark 6.2.1.6. Consequently, any proof of Lemma 6.2.1.13 will require us to analyze this equivalence, which was established using the straightening and unstraightening construction of §HTT.3.2 . In the proof that follows, we will assume that the reader is familiar with these constructions (a reader who does not wish to be burdened with these technical matters can regard Proposition 6.2.1.9 as providing alternative definition of the functor $\Phi(q)$ and proceed directly to Definition 6.2.2.1, where we will return to the study of algebraic geometry).

Proof of Lemma 6.2.1.13. We begin by recalling the definition of the Yoneda embedding j. Choose a weak equivalence of simplicial categories $\phi : \mathfrak{C}[\mathcal{E}] \to \mathcal{C}^{\mathrm{op}}$, where $\mathcal{C}$ is fibrant (that is, the mapping space $\mathrm{Map}_{\mathcal{C}}(X, Y)$ is a Kan complex for every pair of objects $X, Y \in \mathcal{C}$). The construction $X \mapsto \mathrm{Map}_{\mathcal{C}}(X, \bullet)$ determines a simplicial functor $F : \mathcal{C}^{\mathrm{op}} \to (\mathcal{S}\mathrm{et}_\Delta^{\mathcal{C}})^\circ$, which (after composing with ϕ) yields a map of simplicial sets $f : \mathcal{E} \to \mathrm{N}(\mathcal{S}\mathrm{et}_\Delta^{\mathcal{C}})^\circ$; here we regard $\mathcal{S}\mathrm{et}_\Delta^{\mathcal{C}}$ as endowed with the projective model structure and we let $(\mathcal{S}\mathrm{et})_\Delta^{\mathcal{C}})^\circ$ denote the full of $\mathcal{S}\mathrm{et}_\Delta^{\mathcal{C}}$ spanned by the fibrant-cofibrant objects. The Yoneda embedding j is obtained by composing f with the equivalences $\theta : \mathrm{N}(\mathcal{S}\mathrm{et}_\Delta^{\mathcal{C}})^\circ \to \mathrm{N}(\mathcal{S}\mathrm{et}_\Delta^{\mathfrak{C}[\mathcal{E}^{\mathrm{op}}]})^\circ$ and $\theta' : \mathrm{N}(\mathcal{S}\mathrm{et}_\Delta^{\mathfrak{C}[\mathcal{E}^{\mathrm{op}}]})^\circ \to \mathrm{Fun}(\mathcal{E}^{\mathrm{op}}, \mathcal{S})$ The functor $\Phi(q)$ is obtained by composing a homotopy inverse to θ', the equivalence $U : \mathrm{N}(\mathcal{S}\mathrm{et}_\Delta^{\mathfrak{C}[\mathcal{E}^{\mathrm{op}}]})^\circ \to \mathrm{N}(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}}$ induced by the unstraightening functor $\mathrm{Un}_{\mathcal{E}}$ of §HTT.3.2.1 , and the functor Φ_0 of Construction 6.2.1.7. It therefore suffices to show that the composition $\Phi(q) \circ j \simeq \Phi_0 \circ U \circ \theta \circ f = \Phi_0 \circ \mathrm{Un}_\phi \circ f$ classifies the Cartesian fibration q.

Without loss of generality, we may suppose that $\mathcal{D} \simeq \mathrm{Un}_\phi^+ \chi$, where χ is a fibrant-cofibrant object of $(\mathcal{S}\mathrm{et}_\Delta^+)^{\mathcal{C}}$ (Theorem HTT.3.2.0.1). Then the composition $\Phi_0 \circ \mathrm{Un}_\phi : \mathrm{N}(\mathcal{S}\mathrm{et}_\Delta^{\mathcal{C}})^\circ \to \mathcal{C}\mathrm{at}_\infty$ is given by the homotopy coherent nerve of the simplicial functor $F \mapsto \mathrm{Map}_{(\mathcal{S}\mathrm{et}_\Delta^+)_{/S}}(\mathrm{Un}_\phi^+ F^\sharp, \mathrm{Un}_\phi^+ \chi)$, which is equivalent to the functor $F \mapsto \mathrm{Map}_{(\mathcal{S}\mathrm{et}_\Delta^+)^{\mathcal{C}}}(F^\sharp, \chi)$; here $F^\sharp : \mathcal{C} \to \mathcal{S}\mathrm{et}_\Delta^+$ denotes the functor given by $F^\sharp(C) = F(C)^\sharp$. In particular, if F is representable by an object $C \in \mathcal{C}$, the classical (simplicially enriched) version of Yoneda's lemma gives a canonical isomorphism $\mathrm{Map}_{(\mathcal{S}\mathrm{et}_\Delta^+)^{\mathcal{C}}}(F^\sharp, \chi) \simeq \chi(C)$. We conclude that $\Phi(q) \circ j \simeq \Phi_0 \circ \mathrm{Un}_\phi \circ f$ is adjoint to the simplicial functor $\mathfrak{C}[\mathcal{E}^{\mathrm{op}}] \to \mathcal{C} \xrightarrow{\chi} \mathcal{C}\mathrm{at}_\infty^\Delta$, so that $\Phi(q) \circ j$ classifies the Cartesian fibration q as desired. □

We now turn to Lemma 6.2.1.12. In comparison with Lemma 6.2.1.13, the proof is relatively formal.

Lemma 6.2.1.14. *Let S be a simplicial set. Let $(\mathcal{S}\mathrm{et}_\Delta^+)_{/S}$ denote the category of marked simplicial sets equipped with a map to S, which we regard as endowed with the Cartesian model structure (see §HTT.3.1). Let $F : (\mathcal{S}\mathrm{et}_\Delta)_{/S} \to (\mathcal{S}\mathrm{et}_\Delta^+)_{/S}$ be the functor given by*

$X \mapsto X^\sharp$, and regard $(\mathcal{S}\mathrm{et}_\Delta)_{/S}$ as endowed with the contravariant model structure (see §HTT.2.1.4). Then:

(1) *The functor F carries fibrant objects of $(\mathcal{S}\mathrm{et}_\Delta)_{/S}$ (with respect to the contravariant model structure) to fibrant objects of $(\mathcal{S}\mathrm{et}^+_\Delta)_{/S}$, and therefore induces a functor of ∞-categories $f : \mathrm{N}(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/S} \to \mathrm{N}(\mathcal{S}\mathrm{et}^+_\Delta)^\circ_{/S}$. Here $(\mathcal{S}\mathrm{et}^+_\Delta)^\circ_{/S}$ denotes the simplicial category of fibrant objects of $(\mathcal{S}\mathrm{et}^+_\Delta)_{/S}$, and $\mathrm{N}(\mathcal{S}\mathrm{et}^+_\Delta)^\circ_{/S}$ denotes its homotopy coherent nerve.*

(2) *The functor f preserves small limits and colimits.*

Proof. Assertion (1) follows immediately from Proposition HTT.2.4.2.4 . To prove (2), we observe that f fits into a homotopy commutative diagram

$$\begin{array}{ccc} \mathrm{N}((\mathcal{S}\mathrm{et}_\Delta)^{\mathfrak{C}[S]^{\mathrm{op}}})^\circ & \xrightarrow{f'} & \mathrm{N}((\mathcal{S}\mathrm{et}^+_\Delta)^{\mathfrak{C}[S]^{\mathrm{op}}})^\circ \\ \downarrow & & \downarrow \\ \mathrm{N}(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/S} & \xrightarrow{f} & \mathrm{N}(\mathcal{S}\mathrm{et}^+_\Delta)^\circ_{/S} \end{array}$$

where the vertical maps are given by the unstraightening functors of §HTT.2.2.1 and §HTT.3.2.1 , and therefore equivalences of ∞-categories. It therefore suffices to prove that the map f' preserves small limits. Using Proposition HTT.4.2.4.4 , we can identify f'' with the map $\mathrm{Fun}(S^{\mathrm{op}}, \mathcal{S}) \to \mathrm{Fun}(S^{\mathrm{op}}, \mathcal{C}\mathrm{at}_\infty)$ induced by the inclusion $i : \mathcal{S} \to \mathcal{C}\mathrm{at}_\infty$. It therefore suffices to show that i preserves small and colimits, which follows from the observation that i admits left and right adjoints. □

Proof of Lemma 6.2.1.12. Let $q : \mathcal{D} \to \mathcal{E}$ be a Cartesian fibration of simplicial sets. To show that the functor $\Phi(q) : \mathrm{Fun}(\mathcal{E}^{\mathrm{op}}, \mathcal{S})^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty$ commutes with small limits, it will suffice to show that the functor $\Phi_0 : \mathrm{N}(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}} \to \mathcal{C}\mathrm{at}_\infty$ appearing in Construction 6.2.1.7 has the same property (since $\Phi(q)$ is obtained from Φ_q by precomposition with an equiavalence of ∞-categories). By definition, the functor Φ_0 can be obtained by composing the functor $f : \mathrm{N}(\mathcal{S}\mathrm{et}_\Delta)^\circ_{/\mathcal{E}} \to \mathrm{N}(\mathcal{S}\mathrm{et}^+_\Delta)^\circ_{/\mathcal{E}}$ of Lemma 6.2.1.14 with the functor $G_0 : \mathrm{N}(\mathcal{S}\mathrm{et}^+_\Delta)^\circ_{/S} \to (\mathcal{S}\mathrm{et}^+_\Delta)^\circ$ induced by the right adjoint to the left Quillen functor $K \mapsto K \times S^\sharp$ from $\mathcal{S}\mathrm{et}^+_\Delta$ to $(\mathcal{S}\mathrm{et}^+_\Delta)_{/S}$. Since the functor G_0 preserves small limits, it follows from Lemma 6.2.1.14 that the functor Φ_0 also preserves small limits. □

6.2.2 Application: Quasi-Coherent Sheaves

We now consider Construction 6.2.1.7 (or, rather, of the variant of Remark 6.2.1.11) in a concrete example.

Definition 6.2.2.1. Let $\mathrm{CAlg}^{\mathrm{cn}} \times_{\mathrm{CAlg}} \mathrm{Mod}$ denote the ∞-category whose objects are pairs (A, M), where A is a connective $\mathbb{E}_\infty$-ring and M is an A-module spectrum. Let q :

$\mathrm{CAlg}^{\mathrm{cn}} \times_{\mathrm{CAlg}} \mathrm{Mod} \to \mathrm{CAlg}^{\mathrm{cn}}$ denote the projection onto the first factor, so that q is a coCartesian fibration. We let $\mathrm{QCoh} : \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ denote the functor $\Phi'(q)$ obtained by applying Remark 6.2.1.11 to q; here $\widehat{\mathcal{S}}$ denotes the ∞-category of spaces which are not necessarily small, and $\widehat{\mathcal{C}\mathrm{at}}_\infty$ is defined similarly.

If $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ is any functor, we will refer to $\mathrm{QCoh}(X) \in \widehat{\mathcal{C}\mathrm{at}}_\infty$ as the *∞-category of quasi-coherent sheaves on X*.

Remark 6.2.2.2. There is no real need to restrict to connective $\mathbb{E}_\infty$-rings in Definition 6.2.2.1. Using exactly the same procedure, we can associate to any functor $X : \mathrm{CAlg} \to \widehat{\mathcal{S}}$ an ∞-category $\mathrm{QCoh}'(X)$ of quasi-coherent sheaves on X. In some sense, this definition is strictly more general than that of Definition 6.2.2.1: if $X_0 : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ is any functor, then there is a canonical equivalence of ∞-categories $\mathrm{QCoh}(X_0) \simeq \mathrm{QCoh}'(X)$, where $X : \mathrm{CAlg} \to \widehat{\mathcal{S}}$ is a left Kan extension of X_0. However, for most of our applications it will be convenient to consider functors which are defined only on the full subcategory $\mathrm{CAlg}^{\mathrm{cn}} \subseteq \mathrm{CAlg}$ spanned by the connective $\mathbb{E}_\infty$-rings.

Notation 6.2.2.3. Let R be a connective $\mathbb{E}_\infty$-ring. We let $\operatorname{Spec} R : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S} \subseteq \widehat{\mathcal{S}}$ denote the functor corepresented by R, given by the formula $(\operatorname{Spec} R)(A) = \mathrm{Map}_{\mathrm{CAlg}}(R, A)$. We will sometimes refer to $\operatorname{Spec} R$ as the *spectrum of R*.

Remark 6.2.2.4. If R is a connective $\mathbb{E}_\infty$-ring, then we can identify $\operatorname{Spec} R$ with the functor represented by the affine spectral Deligne-Mumford stack $\operatorname{Sp\acute{e}t} R$. In other words, the fully faithful embedding $h : \mathrm{SpDM} \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ carries $\operatorname{Sp\acute{e}t} R$ to $\operatorname{Spec} R$.

Remark 6.2.2.5. Lemma 6.2.1.13 implies that the composition of the Yoneda embedding $\mathrm{CAlg}^{\mathrm{cn}} \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})^{\mathrm{op}}$ with the functor $\mathrm{QCoh} : \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ classifies the coCartesian fibration $\mathrm{CAlg}^{\mathrm{cn}} \times_{\mathrm{CAlg}} \mathrm{Mod} \to \mathrm{CAlg}^{\mathrm{cn}}$. In other words, for every $\mathbb{E}_\infty$-ring R we have an equivalence of ∞-categories $\mathrm{QCoh}(\operatorname{Spec} R) \simeq \mathrm{Mod}_R$, which depends functorially on R.

Notation 6.2.2.6. If $f : X \to X'$ is a natural transformation between functors $X, X' : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, then f determines a functor $\mathrm{QCoh}(X') \to \mathrm{QCoh}(X)$. We will denote this functor by f^*, and refer to it as the functor given by *pullback along f*.

Remark 6.2.2.7. By construction, if $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ is a functor classifying a left fibration $\mathcal{C} \to \mathrm{CAlg}$, then the ∞-category $\mathrm{QCoh}(X)$ of quasi-coherent sheaves on F can be identified with the ∞-category $\mathrm{Fun}^{\mathrm{ccart}}_{\mathrm{CAlg}}(\mathcal{C}, \mathrm{Mod})$ of Construction 6.2.1.7. More informally, we can think of an object $\mathscr{F} \in \mathrm{QCoh}(X)$ as a functor which assigns to every connective $\mathbb{E}_\infty$-ring R and every point $\eta \in X(R)$ (encoded by an object $\widetilde{R} \in \mathcal{C}$ lifting R) an R-module $\mathscr{F}(\eta) \in \mathrm{Mod}_R$. These modules are required to depend functorially on R in the following strong sense: if $\phi : R \to R'$ is a map of connective $\mathbb{E}_\infty$-rings and $\eta' \in X(R')$ is the image of

η under ϕ (so that we have a morphism $\widetilde{f} : \widetilde{R} \to \widetilde{R}'$ in $\mathcal{C}$), then we obtain a q-coCartesian morphism $\mathscr{F}(\eta) \to \mathscr{F}(\eta')$ in Mod, which we can view as an equivalence of R'-modules $R' \otimes_R \mathscr{F}(\eta) \xrightarrow{\sim} \mathscr{F}(\eta')$.

Note that we can identify with a choice of point $\eta \in X(R)$ with a natural transformation of functors $\operatorname{Spec} R \to X$. Then $\mathscr{F}(\eta)$ can be identified with the the image of $\mathscr{F}$ under the composition $\operatorname{QCoh}(X) \xrightarrow{\eta^*} \operatorname{QCoh}(\operatorname{Spec} R) \simeq \operatorname{Mod}_R$, where the equivalence $\operatorname{QCoh}(\operatorname{Spec} R) \simeq \operatorname{Mod}_R$ is supplied by Remark 6.2.2.5. Motivated by this observation, we will sometimes denote the R-module $\mathscr{F}(\eta)$ by $\eta^* \mathscr{F}$.

6.2.3 Formal Properties of $\operatorname{QCoh}(X)$

Let $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$ denote the full subcategory of $\operatorname{Fun}(\operatorname{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ spanned by those functors which are sheaves with respect to the fpqc topology of Variant B.6.1.7.

Proposition 6.2.3.1. *Let* $L : \operatorname{Fun}(\operatorname{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}}) \to \widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$ *denote a left adjoint to the inclusion functor. Then:*

(a) *The canonical map* $\operatorname{QCoh} \circ L \to \operatorname{QCoh}$ *is an equivalence of functors from* $\operatorname{Fun}(\operatorname{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})^{\mathrm{op}}$ *to* $\widehat{\mathcal{C}\mathrm{at}}_\infty$.

(b) *The restriction* $\operatorname{QCoh}|_{(\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}})^{\mathrm{op}}} : \widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ *preserves small limits.*

Proof. Since the functor QCoh preserves limits (Lemma 6.2.1.12), Proposition 1.3.1.7 implies that the functor QCoh factors through L if and only if the composition of QCoh with the Yoneda embedding $\operatorname{CAlg}^{\mathrm{cn}} \xrightarrow{j} \operatorname{Fun}(\operatorname{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})^{\mathrm{op}}$ is a $\widehat{\mathcal{C}\mathrm{at}}_\infty$-valued sheaf on $\operatorname{CAlg}^{\mathrm{cn}}$. Assertion ($a$) now follows from Corollary D.6.3.3, and (b) is an immediate consequence of (a). □

Remark 6.2.3.2. We can restate Proposition 6.2.3.1 as follows: if $X : \operatorname{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ is any functor and X' is the sheafification of F with respect to the fpqc topology, then the pullback map $\operatorname{QCoh}(X') \to \operatorname{QCoh}(X)$ is an equivalence of ∞-categories.

Remark 6.2.3.3. We can strengthen Proposition 6.2.3.1 slightly: the ∞-category $\operatorname{QCoh}(X)$ of quasi-coherent sheaves on a functor $X : \operatorname{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ depends only on the *hypercompletion* of the sheaf $L(X) \in \widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$.

We now summarize some formal properties enjoyed by ∞-categories of the form $\operatorname{QCoh}(X)$:

Proposition 6.2.3.4. (1) *For every functor* $X : \operatorname{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, *the* ∞*-category* $\operatorname{QCoh}(X)$ *is stable and admits small colimits.*

(2) *For every natural transformation morphism* $\alpha : X \to X'$ *in* $\operatorname{Fun}(\operatorname{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$, *the pullback functor* $\alpha^* : \operatorname{QCoh}(X') \to \operatorname{QCoh}(X)$ *preserves small colimits. In particular, it is exact.*

(3) *Suppose that* $X \in \widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$ *belongs to the smallest full subcategory of* $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$ *which is closed under small colimits and contains the essential image of the Yoneda embedding. Then the* ∞*-category* $\mathrm{QCoh}(X)$ *is presentable.*

Proof. Let $\mathcal{C}$ denote the subcategory of $\widehat{\mathcal{C}\mathrm{at}}_\infty$ spanned by those ∞-categories which are stable and admit small colimits, and those functors which preserve small colimits. Then $\mathcal{C}$ admits limits, and the inclusion $\mathcal{C} \hookrightarrow \widehat{\mathcal{C}\mathrm{at}}_\infty$ preserves limits. Since the coCartesian fibration $\mathrm{CAlg}^{\mathrm{cn}} \times_{\mathrm{CAlg}} \mathrm{Mod} \to \mathrm{CAlg}^{\mathrm{cn}}$ is classified by a functor $\chi : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{C}$, it follows from Proposition 6.2.1.9 that QCoh factors through $\mathcal{C}$. This proves (1) and (2). To prove (3), we let $\mathcal{C}_0$ denote the full subcategory of $\mathcal{C}$ spanned by the presentable ∞-categories. Using Proposition HTT.5.5.3.13 , we deduce that $\mathcal{C}_0$ is stable under small limits in $\mathcal{C}$, so that $\mathrm{QCoh}^{-1}\mathcal{C}_0$ is stable under small colimits in $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$. It therefore suffices to observe that $\mathrm{QCoh}(X)$ is presentable whenever X is corepresented by a connective $\mathbb{E}_\infty$-ring R: this follows from the equivalence $\mathrm{QCoh}(X) \simeq \mathrm{Mod}_R$ of Remark 6.2.2.5. □

6.2.4 Comparison with the Geometric Definition

We now show that when we restrict our attention to functors which are (representable by) spectral Deligne-Mumford stacks, Definition 6.2.2.1 recovers the theory of quasi-coherent sheaves developed in Chapter 2.

Proposition 6.2.4.1. *Let* X *be a spectral Deligne-Mumford stack and let* $h_{\mathsf{X}} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ *denote the functor represented by* X *(given by the formula* $h_{\mathsf{X}}(A) = \mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, A, \mathsf{X})$*). Then there is a canonical equivalence of* ∞*-categories* $\mathrm{QCoh}(\mathsf{X}) \simeq \mathrm{QCoh}(h_{\mathsf{X}})$*, where* $\mathrm{QCoh}(\mathsf{X})$ *is given by Definition 2.2.2.1 and* $\mathrm{QCoh}(h_{\mathsf{X}})$ *by Definition 6.2.2.1.*

Proof. To avoid confusion, let us temporarily denote the ∞-category of quasi-coherent sheaves on a spectral Deligne-Mumford stack X by $\mathrm{QCoh}'(\mathsf{X})$, so that the construction $\mathsf{X} \mapsto \mathrm{QCoh}'(\mathsf{X})$ determines a functor $\mathrm{QCoh}' : \mathrm{SpDM}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$. Let $h : \mathrm{SpDM} \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ be the fully faithful embedding of Proposition 1.6.4.2. Lemma 6.2.1.13 shows that the functors QCoh' and $\mathrm{QCoh} \circ h$ are equivalent when restricted to the full subcategory $\mathrm{Aff} \subseteq \mathrm{SpDM}$ spanned by the affine spectral Deligne-Mumford stacks. Since the functor h is fully faithful, Proposition 6.2.1.9 implies that $\mathrm{QCoh} \circ h$ is a right Kan extension of its restriction to Aff, so we obtain a natural transformation of functors $\alpha : \mathrm{QCoh}' \to \mathrm{QCoh} \circ h$ (which is an equivalence when restricted to affine spectral Deligne-Mumford stacks). We will complete the proof by showing that α is an equivalence: that is, for every spectral Deligne-Mumford stack $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$, the induced map $\alpha(\mathsf{X}) : \mathrm{QCoh}'(\mathsf{X}) \to \mathrm{QCoh}(h_{\mathsf{X}})$ is an equivalence.

For each object $U \in \mathcal{X}$, let X_U denote the spectral Deligne-Mumford stack given by $(\mathcal{X}_{/U}, \mathcal{O}_{\mathcal{X}}|_U)$, so that α determines a functor $\alpha(\mathsf{X}_U) : \mathrm{QCoh}'(\mathsf{X}_U) \to \mathrm{QCoh}(h_{\mathsf{X}_U})$. Let $\mathcal{X}_0$ denote the full subcategory of $\mathcal{X}$ spanned by those objects U for which $\alpha(\mathsf{X}_U)$ is an equivalence. We will complete the proof by showing that $\mathcal{X}_0 = \mathcal{X}$. By construction, $\mathcal{X}_0$

contains every affine object $U \in \mathcal{X}$. By virtue of Proposition 1.4.7.9, it will suffice to show that $\mathcal{X}_0$ is closed under small colimits in $\mathcal{X}$. To prove this, suppose we are given a small diagram $\{U_\alpha\}$ in the ∞-category $\mathcal{X}_0$ having a colimit $U \in \mathcal{X}$. We then have a commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}'(\mathsf{X}_U) & \xrightarrow{\alpha(\mathsf{X}_U)} & \mathrm{QCoh}(h_{\mathsf{X}_U}) \\ \downarrow & & \downarrow \phi \\ \varprojlim \mathrm{QCoh}'(\mathsf{X}_{U_\alpha}) & \longrightarrow & \varprojlim \mathrm{QCoh}(h_{\mathsf{X}_{U_\alpha}}). \end{array}$$

The lower horizontal map is an equivalence by virtue of our assumption that each U_α belongs to $\mathcal{X}_0$, and the left vertical map is an equivalence by the proof of Proposition 2.2.4.1. It will therefore suffice to show that the functor ϕ is an equivalence. Using Lemma **??**, we see that X_U can be identified with the colimit of the diagram $\{\mathsf{X}_{U_\alpha}\}$ in the ∞-category $\widehat{\mathcal{S}\mathrm{hv}}_{\text{ét}}$ of étale sheaves. It follows that $L\,\mathsf{X}_U$ can be identified with the colimit of the diagram $\{L\,\mathsf{X}_{U_\alpha}\}$ in the ∞-category $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$, where $L : \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}}) \to \widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$ is a left adjoint to the inclusion. The desired result now follows from Proposition 6.2.3.1. □

6.2.5 Local Properties of Quasi-Coherent Sheaves

Many of the local properties of quasi-coherent sheaves discussed in §2.8 make sense in the context of quasi-coherent sheaves on an arbitrary functor.

Definition 6.2.5.1. Let P be a condition on pairs (A, M), where A is a connective $\mathbb{E}_\infty$-ring and M is an A-module. We will say that P is *stable under base change* if, whenever a pair (A, M) has the property P and $f : A \to B$ is a map of connective $\mathbb{E}_\infty$-rings, the pair $(B, B \otimes_A M)$ also has the property P.

Proposition 6.2.5.2. *The following conditions on a pair* $(A, M) \in \mathrm{CAlg}^{\mathrm{cn}} \times_{\mathrm{CAlg}} \mathrm{Mod}$ *are stable under base change:*

(1) *The condition that M is n-connective (when regarded as a spectrum), where n is a fixed integer.*

(2) *The condition that M is almost connective: that is, M is $(-n)$-connective for $n \gg 0$.*

(3) *The condition that M is has* Tor*-amplitude $\leqslant n$, where n is a fixed integer.*

(4) *The condition that M is flat.*

(5) *The condition that M is perfect to order n over A, where n is a fixed integer.*

(6) *The condition that M is almost perfect over A.*

(7) *The condition that M is perfect over A.*

(8) *The condition that M is locally free of finite rank over A.*

Proof. Assertions (1), (2), and (7) are obvious. Assertion (3) follows from Lemma 2.8.4.3 and assertion (5) from Proposition 2.7.3.1. Assertions (4) and (6) are immediate consequences of (1), (3), and (5), and assertion (8) follows from (4) and (7). □

Definition 6.2.5.3. Let P be a condition on objects $(A, M) \in \mathrm{CAlg}^{\mathrm{cn}} \times_{\mathrm{CAlg}} \mathrm{Mod}$ which is stable under base change and let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor. We will say that an object $\mathscr{F} \in \mathrm{QCoh}(X)$ *has the property* P if, for every connective $\mathbb{E}_\infty$-ring R and every point $\eta \in X(R)$, the pair $(R, \mathscr{F}(\eta))$ has the property P, where $\mathscr{F}(\eta) \in \mathrm{Mod}_R$ is the R-module of Remark 6.2.2.7.

Remark 6.2.5.4. Let P be a condition on pairs $(A, M) \in \mathrm{CAlg}^{\mathrm{cn}} \times_{\mathrm{CAlg}} \mathrm{Mod}$ which is stable under base change and let $\alpha : X \to X'$ be a natural transformation between functors $X, X' : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. If $\mathscr{F} \in \mathrm{QCoh}(X')$ has the property P, then $\alpha^* \mathscr{F} \in \mathrm{QCoh}(X)$ has the property P.

Example 6.2.5.5. Let R be a connective $\mathbb{E}_\infty$-ring and let $\operatorname{Spec} R : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be the functor corepresented by R, so that Remark 6.2.2.5 gives an equivalence of ∞-categories $\theta : \mathrm{QCoh}(\operatorname{Spec} R) \simeq \mathrm{Mod}_R$. If P is a property of objects of $\mathrm{CAlg}^{\mathrm{cn}} \times_{\mathrm{CAlg}} \mathrm{Mod}$ which is stable under base change, then an object $\mathscr{F} \in \mathrm{QCoh}(\operatorname{Spec} R)$ has the property P if and only if the pair $(R, \theta(\mathscr{F}))$ has the property P.

Remark 6.2.5.6. Let $\alpha : X \to X'$ be a natural transformation between functors $X, X' : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, and suppose that α induces an equivalence after sheafification with respect to the flat topology. Proposition 6.2.3.1 implies that the pullback functor $\alpha^* : \mathrm{QCoh}(X') \to \mathrm{QCoh}(X)$ is an equivalence of ∞-categories. If P is a property of objects of $\mathrm{CAlg}^{\mathrm{cn}} \times_{\mathrm{CAlg}} \mathrm{Mod}$ which is stable under base change and $\mathscr{F} \in \mathrm{QCoh}(X')$ has the property P, then the pullback $\alpha^* \mathscr{F} \in \mathrm{QCoh}(X)$ has the property P (Remark 6.2.5.4). The converse holds provided that P is local with respect to the flat topology, in the sense of Definition 2.8.4.1.

Example 6.2.5.7. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor and let $\mathscr{F} \in \mathrm{QCoh}(X)$. We say that $\mathscr{F}$ is *connective* if, for every point $\eta \in X(R)$, the R-module $\mathscr{F}(\eta)$ is connective. We let $\mathrm{QCoh}(X)^{\mathrm{cn}}$ denote the full subcategory of $\mathrm{QCoh}(X)$ spanned by the connective quasi-coherent sheaves on X. It is clear that $\mathrm{QCoh}(X)^{\mathrm{cn}}$ is closed under small colimits and extensions in $\mathrm{QCoh}(X)$, and is therefore a prestable ∞-category in the sense of Definition C.1.2.1.

Remark 6.2.5.8. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor which satisfies condition (3) of Proposition 6.2.3.4. Arguing as in the proof of Proposition 6.2.3.4, we deduce that the ∞-category $\mathrm{QCoh}(X)^{\mathrm{cn}}$ is presentable. It follows from Proposition HA.1.4.4.11 that the pair of subcategories $(\mathrm{QCoh}(X)^{\mathrm{cn}}, \mathrm{QCoh}(X)_{\leqslant 0})$ determines an accessible t-structure on $\mathrm{QCoh}(X)$, where $\mathrm{QCoh}(X)_{\leqslant 0}$ denotes the full subcategory of $\mathrm{QCoh}(X)$ spanned by those objects $\mathscr{G}$ for which the mapping space $\mathrm{Map}_{\mathrm{QCoh}(X)}(\Sigma \mathscr{F}, \mathscr{G})$ is contractible for all $\mathscr{F} \in \mathrm{QCoh}(X)^{\mathrm{cn}}$.

Warning 6.2.5.9. In the situation of Remark 6.2.5.8, there is no obvious way to test that whether an object $\mathscr{F} \in \mathrm{QCoh}(X)$ belongs to $\mathrm{QCoh}(X)_{\leqslant 0}$. For example, the inclusion $\mathscr{F} \in \mathrm{QCoh}(X)$ does *not* imply that $\mathscr{F}(\eta) \in (\mathrm{Mod}_R)_{\leqslant 0}$ when $\eta \in X(R)$, since the property of being 0-truncated is not stable under base change. In general, the t-structure of Remark 6.2.5.8 is generally not compatible with filtered colimits, and the prestable ∞-category $\mathrm{QCoh}(X)^{\mathrm{cn}}$ is not a Grothendieck prestable ∞-category (see Definition C.1.4.2). To guarantee that the t-structure of Remark 6.2.5.8 is well-behaved, we typically need to impose some additional assumptions on X (like the assumption that X is representable by a spectral Deligne-Mumford stack, or admits a flat covering by a spectral Deligne-Mumford stack).

Proposition 6.2.5.10. *Let X be a spectral Deligne-Mumford stack, let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ denote the functor represented by X, and let $\theta : \mathrm{QCoh}(\mathsf{X}) \simeq \mathrm{QCoh}(X)$ be the equivalence supplied by the proof of Proposition 6.2.4.1. Let P be a property of objects of $\mathrm{CAlg}^{\mathrm{cn}} \times_{\mathrm{CAlg}} \mathrm{Mod}$ which is stable under base change and local for the flat topology. An object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ has the property P if and only if $\theta(\mathscr{F}) \in \mathrm{QCoh}(F)$ has the property P.*

Proof. The "only if" direction is obvious. For the converse, let us suppose that $\mathscr{F}$ has the property P. Let A be a connective $\mathbb{E}_\infty$-ring and let $f : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$ be a map of spectral Deligne-Mumford stacks; we wish to show that the pair $(A, f^* \mathscr{F})$ has the property P. In verifying this, we are free to replace X by any open substack through which f factors; we may therefore assume without loss of generality that X is quasi-compact. Choose an étale surjection $u : \mathsf{U} \to \mathsf{X}$, where $\mathsf{U} \simeq \mathrm{Sp\acute{e}t}\, R$ is affine. We can then choose a faithfully flat étale map $A \to A'$ such that the composite map $\mathrm{Sp\acute{e}t}\, A' \to \mathrm{Sp\acute{e}t}\, A \xrightarrow{f} \mathsf{X}$ factors through U. Since P is local for the flat topology, we may replace A by A' and thereby reduce to the case where f factors through U. Then $f^* \mathscr{F} \simeq A \otimes_R u^* \mathscr{F}$. Since P is stable under base change, we are reduced to proving that the pair $(R, u^* \mathscr{F})$ has the property P, which follows from our assumption that $\mathscr{F}$ has the property P. □

6.2.6 Tensor Products of Quasi-Coherent Sheaves

Let $\mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty)$ denote the ∞-category of (not necessarily small) symmetric monoidal ∞-categories. We have an evident forgetful functor $\theta : \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty) \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ which preserves limits. The functor $R \mapsto \mathrm{Mod}_R$ factors as a composition

$$\mathrm{CAlg}^{\mathrm{cn}} \xrightarrow{U} \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty) \xrightarrow{\theta} \widehat{\mathcal{C}\mathrm{at}}_\infty,$$

where U assigns to each connective $\mathbb{E}_\infty$-ring the symmetric monoidal ∞-category $\mathrm{Mod}_R^{\otimes}$ (see §HA.4.5.3). Let $\mathrm{QCoh}^{\otimes} : \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})^{\mathrm{op}} \to \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty)$ be a right Kan extension of U

along the Yoneda embedding $(\mathrm{CAlg}^{\mathrm{cn}})^{\mathrm{op}} \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})^{\mathrm{op}}$. Then the functor $\mathrm{QCoh}^{\otimes}$ assigns to each functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ a symmetric monoidal ∞-category $\mathrm{QCoh}(X)^{\otimes}$, whose underyling ∞-category can be identified with $\mathrm{QCoh}(X)$. We can describe the situation more informally by saying that for every functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, the ∞-category $\mathrm{QCoh}(X)$ admits a symmetric monoidal structure. Unwinding the definitions, we see that the tensor product on $\mathrm{QCoh}(X)$ is given pointwise: that is, it is described by the formula

$$(\mathscr{F} \otimes \mathscr{F}')(\eta) \simeq \mathscr{F}(\eta) \otimes_R \mathscr{F}'(\eta)$$

for $\eta \in X(R)$. It follows that the tensor product on $\mathrm{QCoh}(X)$ preserves small colimits separately in each variable.

Notation 6.2.6.1. For any functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, we let $\mathscr{O}_X$ denote the unit object of $\mathrm{QCoh}(X)$ (with respect to the symmetric monoidal structure defined above). More informally, $\mathscr{O}_X$ assigns to each point $\eta \in X(R)$ the spectrum R, regarded as a module over itself. We will refer to $\mathscr{O}_X$ as the *structure sheaf* of the functor X.

Proposition 6.2.6.2. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor, and let $\mathscr{F} \in \mathrm{QCoh}(X)$. The following conditions are equivalent:*

(1) *The quasi-coherent sheaf $\mathscr{F}$ is perfect.*

(2) *The quasi-coherent sheaf is a dualizable object of the symmetric monoidal ∞-category $\mathrm{QCoh}(X)$.*

Proof. Using Proposition HA.4.6.1.11 , we can reduce to the case where X is corepresentable by a connective $\mathbb{E}_\infty$-ring R. In this case, we can identify $\mathscr{F}$ with an R-module M. We wish to show that M is a dualizable object of Mod_R if and only if M is perfect. The collection of dualizable objects of Mod_R forms a stable subcategory which is closed under retracts. Since $R \in \mathrm{Mod}_R$ is dualizable, it follows that every perfect object of Mod_R is dualizable. Conversely, suppose that M admits a dual $M^\vee$. Then the functor $N \mapsto \mathrm{Map}_{\mathrm{Mod}_R}(M, N)$ is given by $N \mapsto \Omega^\infty(M^\vee \otimes_R N)$, and therefore commutes with filtered colimits. It follows that M is a compact object of Mod_R, and therefore perfect (Proposition HA.7.2.4.2). □

Note that for any functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, the full subcategory $\mathrm{QCoh}(X)^{\mathrm{cn}} \subseteq \mathrm{QCoh}(X)$ contains $\mathscr{O}_X$ and is closed under tensor products, and therefore inherits the structure of a symmetric monoidal ∞-category.

Proposition 6.2.6.3. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor and let $\mathscr{F} \in \mathrm{QCoh}(X)^{\mathrm{cn}}$. Then $\mathscr{F}$ is a dualizable object of $\mathrm{QCoh}(X)^{\mathrm{cn}}$ if and only if $\mathscr{F}$ is locally free of finite rank.*

Proof. Combine Propositions HA.4.6.1.11 and 2.9.1.5. □

6.3 Relative Representability

Let X and Y be functors $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. In this section, we will study natural transformations $f : X \to Y$ which are *relatively representable*, meaning that the fiber of f over any representable functor $\operatorname{Spec} R$ is representable by a spectral Deligne-Mumford stack (Definition 6.3.2.1).

6.3.1 Étale-Local Properties of Morphisms

We begin by introducing some terminology.

Definition 6.3.1.1. Let P be a property of morphisms $f : \mathsf{X} \to \mathsf{Y}$ between spectral Deligne-Mumford stacks. We will say that f is *local on the target with respect to the étale topology* if the following conditions are satisfied:

(1) Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \xrightarrow{g} & \mathsf{Y} \end{array}$$

where g is étale. If f has the property P, then f' also has the property P.

(2) Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks, and suppose we are given a surjective étale morphism $\amalg_\alpha \mathsf{Y}_\alpha \to \mathsf{Y}$. If each of the induced maps $\mathsf{Y}_\alpha \times_{\mathsf{Y}} \mathsf{X} \to \mathsf{Y}_\alpha$ has the property P, then f has the property P.

Remark 6.3.1.2. Let P be a property of morphisms between spectral Deligne-Mumford stacks which is local on the target with respect to the étale topology. Then a morphism $f : \mathsf{X} \to \mathsf{Y}$ has the property P if and only if, for every étale map $u : \operatorname{Spét} R \to \mathsf{Y}$, the pullback $\operatorname{Spét} R \times_{\mathsf{Y}} \mathsf{X} \to \operatorname{Spét} R$ has the property P.

Remark 6.3.1.3. Suppose we are given a property P_0 of morphisms of spectral Deligne-Mumford stacks having the form $\mathsf{Z} \to \operatorname{Spét} R$. Let $f : \mathsf{X} \to \mathsf{Y}$ be an arbitrary morphism of spectral Deligne-Mumford stacks. We will say that f *locally has the property* P_0 if, for every étale map $\operatorname{Spét} R \to \mathsf{Y}$, the induced map $\operatorname{Spét} R \times_{\mathsf{Y}} \mathsf{X} \to \operatorname{Spét} R$ has the property P_0. Suppose that P_0 satisfies the following conditions:

(i) Let $f : \mathsf{Z} \to \operatorname{Spét} R$ be a map of spectral Deligne-Mumford stacks and $u : R \to R'$ an étale morphism of $\mathbb{E}_\infty$-rings. If f has the property P_0, then the induced map $\operatorname{Spét} R' \times_{\operatorname{Spét} R} \mathsf{Z} \to \operatorname{Spét} R$ has the property P_0. The converse holds if u is faithfully flat.

(*ii*) If we are given a finite collection of morphisms $\{\mathsf{Z}_i \to \mathrm{Sp\acute{e}t}\, R_i\}$ having the property P_0, then the induced map $\amalg \mathsf{Z}_i \to \mathrm{Sp\acute{e}t}(\prod R_i)$ has the property P_0.

Then the condition that a morphism f locally has the property P_0 is local on the target with respect to the étale topology, in the sense of Definition 6.3.1.1. Moreover, a morphism $f : \mathsf{Z} \to \mathrm{Sp\acute{e}t}\, R$ satisfies this condition if and only if f has the property P_0 (this follows immediately from (*i*)). Combining this observation with Remark 6.3.1.2, we obtain a bijective correspondence between the following:

(*a*) Properties P of arbitrary morphisms $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks, which are local on the target with respect to the étale topology.

(*b*) Properties P_0 of morphisms of the form $f : \mathsf{Z} \to \mathrm{Sp\acute{e}t}\, R$ which satisfy conditions (*i*) and (*ii*).

Example 6.3.1.4. The condition that a morphism $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks is étale is local on the target with respect to the étale topology.

Example 6.3.1.5. The condition that a morphism $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks is an equivalence is local on the target with respect to the étale topology.

Example 6.3.1.6. The condition that a morphism $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks is an open immersion is local on the target with respect to the étale topology. This follows from Examples 6.3.1.4 and 6.3.1.5, since f is an open immersion if and only if f is étale and the diagonal map $\mathsf{X} \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ is an equivalence.

Example 6.3.1.7. The condition that a morphism $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks is surjective is local on the target with respect to the étale topology (see Proposition 3.5.5.4).

Example 6.3.1.8. The condition that a morphism $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks is flat is local on the target with respect to the étale topology.

Example 6.3.1.9. For $0 \leqslant n \leqslant \infty$, the condition that a morphism $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks is n-quasi-compact is local on the target with respect to the étale topology (Proposition 2.3.3.1).

Example 6.3.1.10. For every integer $n \geqslant 0$, the condition that a map of spectral Deligne-Mumford stacks $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ induce an equivalence $(\mathcal{X}, \tau_{\leqslant n} \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \tau_{\leqslant n} \mathcal{O}_{\mathcal{Y}})$ is local on the target with respect to the étale topology.

Definition 6.3.1.11. Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks and let $n \geqslant -2$ be an integer. We will say that f is a *relative n-stack* if, for every discrete commutative ring R, the induced map

$$\mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{X}) \to \mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{Y})$$

has n-truncated homotopy fibers. We will say that f is a *relative spectral algebraic space* if it is a relative 0-stack.

Example 6.3.1.12. When $n = -2$, a map of spectral Deligne-Mumford stacks $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ is a relative Deligne-Mumford n-stack if and only if, for every discrete commutative ring R, the map

$$\mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, (\mathcal{X}, \mathcal{O}_{\mathcal{X}})) \to \mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}))$$

is a homotopy equivalence. This is equivalent to the requirement that f induces an equivalence $(\mathcal{X}, \pi_0 \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \pi_0 \mathcal{O}_{\mathcal{Y}})$.

Remark 6.3.1.13. The condition that a map $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ be a relative Deligne-Mumford n-stack depends only on the underlying map of 0-truncated spectral Deligne-Mumford stacks $(\mathcal{X}, \pi_0 \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \pi_0 \mathcal{O}_{\mathcal{Y}})$.

Remark 6.3.1.14. If $n \geqslant 0$, then a morphism $f : \mathsf{X} \to \mathsf{Y}$ is a relative Deligne-Mumford n-stack if and only if, for every discrete commutative ring R and every map $u : \mathrm{Sp\acute{e}t}\, R \to \mathsf{Y}$, the pullback $\mathrm{Sp\acute{e}t}\, R \times_{\mathsf{Y}} \mathsf{X}$ is a spectral Deligne-Mumford n-stack (Definition 1.6.8.1). Using Remark 6.3.1.13, we see that this is equivalent to assertion that for every connective $\mathbb{E}_\infty$-ring R and every map $u : \mathrm{Sp\acute{e}t}\, R \to \mathsf{Y}$, the pullback $\mathrm{Sp\acute{e}t}\, R \times_{\mathsf{Y}} \mathsf{X}$ is a spectral Deligne-Mumford n-stack.

Proposition 6.3.1.15. *Let $n \geqslant -2$ be an integer. The condition that a map $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks be a relative spectral Deligne-Mumford n-stack is local on the target with respect to the étale topology.*

Proof. The proof proceeds by induction on n. When $n = -2$, the desired result follows from Examples 6.2.2.7 and 6.3.1.9. If $n > -2$, we observe that $f : \mathsf{X} \to \mathsf{Y}$ is a relative spectral Deligne-Mumford n-stack if and only if the diagonal map $\mathsf{X} \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ is a relative Deligne-Mumford $(n-1)$-stack. □

Proposition 6.3.1.16. *The condition that a map $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks be affine is local on the target with respect to the étale topology.*

Proof. Using Remark 6.3.1.3, we are reduced to verifying the following assertion:

(∗) Let $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ be a map of spectral Deligne-Mumford stacks, and suppose there exists a faithfully flat étale morphism $R \to R^0$ such that the fiber product $\mathsf{X}_0 = \mathrm{Sp\acute{e}t}\, R^0 \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X}$ is affine. Then X is affine.

To prove (∗), let $R^\bullet$ be the Čech nerve of the map $R \to R^0$ (in the ∞-category $\mathrm{CAlg}^{\mathrm{op}}$). For each $n \geqslant 0$, the fiber product $\mathrm{Sp\acute{e}t}\, R^n \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X}$ is an affine spectral Deligne-Mumford stack, of the form Spét A^n for some $\mathbb{E}_\infty$-ring A^n. Let A denote the totalization of the cosimplicial $\mathbb{E}_\infty$-ring $A^\bullet$. It follows from Theorem D.6.3.1 that $A^\bullet$ is the Čech nerve of the morphism $A \to A^0 \simeq R^0 \otimes_R A$. Write $\mathsf{X} = (\mathcal{X}, \mathcal{O}_\mathcal{X})$, so that the simplicial spectral Deligne-Mumford stack $\mathsf{X}_\bullet$ corresponds to a simplicial object $U_\bullet$ in $\mathcal{X}$, whose geometric realization is a final object $\mathbf{1} \in \mathcal{X}$. Then we have a chain of equivalences

$$\mathcal{O}_\mathcal{X}(\mathbf{1}) = \mathcal{O}_\mathcal{X}(|U_\bullet|) \simeq \varprojlim \mathcal{O}_\mathcal{X}(U_\bullet) \simeq \varprojlim A^\bullet \simeq A.$$

The composite equivalence determines a map $\theta : \mathsf{X} \to \text{Spét}\, A$. The map θ is an equivalence, since it can be obtained as the geometric realization of an equivalence of simplicial spectral Deligne-Mumford stacks $\mathsf{X}_\bullet \simeq \text{Spét}\, A^\bullet$. This proves that X is affine, as desired. □

Proposition 6.3.1.17. *The condition that a morphism of spectral Deligne-Mumford stacks $f : \mathsf{X} \to \mathsf{Y}$ be quasi-affine is local on the target with respect to the étale topology.*

Proof. Using Remark 6.3.1.3, we are reduced to proving the following:

(∗) Let $f : \mathsf{X} \to \text{Spét}\, R$ be a map of spectral Deligne-Mumford stacks, and suppose there exists a faithfully flat étale morphism $R \to R^0$ such that the fiber product $\mathsf{X}_0 = \text{Spét}\, R^0 \times_{\text{Spét}\, R} \mathsf{X}$ is quasi-affine. Then X is quasi-affine.

Write $\mathsf{X} = (\mathcal{X}, \mathcal{O}_\mathcal{X})$. We first claim that the pushforward $f_* \mathcal{O}_\mathcal{X}$ is a quasi-coherent sheaf on Spét R. This assertion can be tested locally with respect to the étale topology on Spét R, and therefore follows from Corollary 2.5.4.6. We can identify $f_* \mathcal{O}_\mathcal{X}$ with an $\mathbb{E}_\infty$-algebra over R. Let A denote the connective cover of this $\mathbb{E}_\infty$-algebra. The map $A \to f_* \mathcal{O}_\mathcal{X}$ classifies a map of spectral Deligne-Mumford stacks $g : \mathsf{X} \to \text{Spét}\, A$. We claim that g is a quasi-compact open immersion. Since this assertion is local on the target with respect to the étale topology (Examples 6.3.1.6 and 6.3.1.9), we may replace R by R' and thereby reduce to the case where X is quasi-affine. In this case, the desired result follows from Proposition 2.4.1.3 (see the proof of Proposition 2.4.2.3). □

6.3.2 Representable Morphisms of Functors

Recall that the ∞-category SpDM of spectral Deligne-Mumford stacks can be identified with a full subcategory of $\text{Fun}(\text{CAlg}^{\text{cn}}, \mathcal{S})$ (the identification is given by carrying a spectral Deligne-Mumford stack X to the functor given informally by the formula $R \mapsto \text{Map}_{\text{SpDM}}(\text{Spét}\, R, \mathsf{X})$). Many of the properties of morphisms considered above can be generalized to the setting of natural transformations between functors $X, Y : \text{CAlg}^{\text{cn}} \to \mathcal{S}$.

Definition 6.3.2.1. Let $f : X \to Y$ be a natural transformation between functors $X, Y : \text{CAlg}^{\text{cn}} \to \widehat{\mathcal{S}}$. We will say that f is *representable* if, for every connective $\mathbb{E}_\infty$-ring R and every natural transformation $\text{Spec}\, R \to Y$ (corresponding to a choice of point $\eta \in Y(R)$), the fiber product $X \times_Y \operatorname{Spec} R$ is representable by a spectral Deligne-Mumford stack (here $\operatorname{Spec} R$ denotes the functor corepresented by R).

Proposition 6.3.2.2. *Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. Assume that Y is representable by a spectral Deligne-Mumford stack Y. Then f is representable (in the sense of Definition 6.3.2.1) if and only if X is representable by a spectral Deligne-Mumford stack.*

The proof of Proposition 6.3.2.2 will require the following general observation about sheaves.

Proof of Proposition 6.3.2.2. Let $\widehat{\mathcal{S}\mathrm{hv}}_{\text{ét}}$ be the full subcategory of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ spanned by those functors which are sheaves with respect to the étale topology. Since the ∞-category of spectral Deligne-Mumford stacks admits fiber products, it is clear that if X is representable by a spectral Deligne-Mumford stack, then f is representable. To prove the converse, write $\mathsf{Y} = (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$. For every object $U \in \mathcal{Y}$, let Y_U denote the functor represented by the spectral Deligne-Mumford stack $\mathsf{Y}_U = (\mathcal{Y}_{/U}, \mathcal{O}_{\mathcal{Y}}|_U)$, and let $X_U = X \times_Y Y_U$. Let us say that U is *good* if X_U is representable by a spectral Deligne-Mumford stack X_U. Assuming that f is representable by spectral Deligne-Mumford stacks, we will show that every object $U \in \mathcal{Y}$. Our assumption immediately implies that every affine object $U \in \mathcal{Y}$ is good. It will therefore suffice to show that the collection of good objects of $\mathcal{Y}$ is closed under small colimits (Lemma **??**). To this end, suppose we are given a diagram of object $\{U_\alpha\}$ in $\mathcal{Y}$ having a colimit U, and that each X_{U_α} is representable by a spectral Deligne-Mumford stack X_{U_α}. Note that for every morphism $U_\alpha \to U_\beta$ in our diagram, the induced map $\mathsf{X}_{U_\alpha} \to \mathsf{X}_{U_\beta}$ is étale(since it is a pullback of the étale morphism $\mathsf{Y}_{U_\alpha} \to \mathsf{Y}_{U_\beta}$). It follows from Proposition **??** that the diagram $\{\mathsf{X}_{U_\alpha}\}$ has a colimit X_U in the ∞-category SpDM. Moreover, X_U represents a functor $F : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ which is the colimit of the diagram $\{X_{U_\alpha}\}$ in the ∞-category $\widehat{\mathcal{S}\mathrm{hv}}_{\text{ét}}$ spanned by the étale sheaves (Lemma **??**). To prove that U is good, it will suffice to show that $F \simeq X_U$: that is, that X_U is the colimit of the diagram $\{X_{U_\alpha}\}$ in $\widehat{\mathcal{S}\mathrm{hv}}_{\text{ét}}$. Since colimits in $\widehat{\mathcal{S}\mathrm{hv}}_{\text{ét}}$ are universal, we are reduced to proving the following pair of assertions:

(a) The functor X is a sheaf with respect to the étale topology.

(b) The functor Y_U is a colimit of the diagram $\{Y_{U_\alpha}\}$ in $\widehat{\mathcal{S}\mathrm{hv}}_{\text{ét}}$.

Assertion (a) follows from Lemma D.4.3.2, and assertion (b) follows from Lemma **??**. □

Corollary 6.3.2.3. *Suppose we are given natural transformations $X \xrightarrow{f} Y \xrightarrow{g} Z$ of functors $X, Y, Z : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, and assume that g is representable. Then f is representable if and only if $g \circ f$ is representable.*

Proof. Without loss of generality, we may assume that Z is corepresentable by a connective $\mathbb{E}_\infty$-ring R. Then Y is representable by a spectral Deligne-Mumford stack Y. The desired equivalence now follows immediately from Proposition 6.3.2.2. □

6.3.3 Properties Stable Under Base Change

We now consider properties of morphisms $f : X \to Y$ in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ which can be tested "fiberwise": that is, after base change along an arbitrary map $\mathrm{Spec}\, R \to Y$.

Definition 6.3.3.1. Let P be a property of morphisms of spectral Deligne-Mumford stacks. We will say that P is *stable under base change* if, for every pullback diagram of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y} \end{array}$$

such that f has the property P, the morphism f' also has the property P.

Remark 6.3.3.2. Let P be a property of morphisms of spectral Deligne-Mumford stacks which is local on the target with respect to the étale topology. Then P is stable under base change if and only if, for every pullback diagram

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathrm{Sp\acute{e}t}\, R' & \longrightarrow & \mathrm{Sp\acute{e}t}\, R \end{array}$$

such that f has the property P, the morphism f' also has the property P.

Definition 6.3.3.3. Let P be a property of morphisms of spectral Deligne-Mumford stacks which is local on the target with respect to the étale topology and stable under base change. Let $f : X \to Y$ be a representable morphism between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. We will say that f *has the property* P if, for every connective $\mathbb{E}_\infty$-ring R and every natural transformation $\mathrm{Spec}\, R \to Y$ (determined by a point $\eta \in Y(R)$), the fiber product $\mathrm{Spec}\, R \times_Y X$ is representable by a spectral Deligne-Mumford stack X_η such that the induced map $\mathsf{X}_\eta \to \mathrm{Sp\acute{e}t}\, R$ has the property P.

Remark 6.3.3.4. In the situation of Definition 6.3.3.3, the natural transformation $f : X \to Y$ has the property P if and only if the following apparently stronger condition holds: for every pullback diagram of functors

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow & & \downarrow \\ Y' & \longrightarrow & Y, \end{array}$$

if Y' is representable by a spectral Deligne-Mumford stack Y (so that X' is representable by a spectral Deligne-Mumford stack X, by virtue of Proposition 6.3.2.2), the induced map $\mathsf{X} \to \mathsf{Y}$ has the property P.

Remark 6.3.3.5. Let P a property of morphisms of spectral Deligne-Mumford stacks which is local on the target with respect to the étale topology and stable under base change. Let $\phi : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks, let $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be the functors represented by X and Y, and let $f : X \to Y$ be the natural transformation determined by ϕ. Then f has the property P if and only if ϕ has the property P.

Example 6.3.3.6. The following conditions on a morphism of spectral Deligne-Mumford stacks $f : \mathsf{X} \to \mathsf{Y}$ are local for the étale topology and stable under base change:

(1) The condition that f is étale.

(2) The condition that f is an equivalence.

(3) The condition that f is an open immersion.

(4) The condition that f is flat.

(5) The condition that f is a relative Deligne-Mumford n-stack, where $n \geqslant -2$ is some fixed integer (see Definition 6.3.1.11).

(6) The condition that $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ induces an equivalence $(\mathcal{X}, \tau_{\leqslant n} \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \tau_{\leqslant n} \mathcal{O}_{\mathcal{Y}})$, where $n \geqslant 0$ is some fixed integer.

(7) The condition that f is a relative spectral algebraic space.

(8) The condition that f is surjective.

(9) The condition that f is affine.

(10) The condition that f is quasi-affine.

(11) The condition that f is quasi-compact.

(12) The condition that f is quasi-separated.

(13) The condition that f is locally almost of finite presentation.

(14) The condition that f is proper.

Consequently, we make make sense of each of these conditions for an arbitrary representable morphism $f : X \to Y$ between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$.

Definition 6.3.3.7. Let $f : X \to Y$ be a representable morphism of functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. We will say that f is *faithfully flat* if it is flat and surjective (in the sense of Example 6.3.3.6).

Remark 6.3.3.8. Let $f : X \to Y$ be a representable natural transformation of functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. Assume that Y is a sheaf with respect to the fpqc topology. Then X is also a sheaf with respect to the fpqc topology (see Proposition **??**). Moreover, if f is faithfully flat and quasi-compact, then it is an effective epimorphism of fpqc sheaves.

Remark 6.3.3.9. Let P be a property of morphisms of spectral Deligne-Mumford stacks which is local on the target with respect to the étale topology and stable under base change. Let $f : X \to Y$ be a natural transformation of functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, and suppose that Y is given as the colimit of a diagram $\{Y_\alpha\}$ in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$. Then f is representable and has the property P if and only if each of the induced maps $X \times_Y Y_\alpha \to Y_\alpha$ satisfies the same conditions. The "only if" direction is obvious, and the converse follows from the observation that every map map $\mathrm{Sp\acute{e}t}\, A \to Y$ factors through some Y_α.

6.3.4 Direct Image Functors

Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. In §6.2, we introduced ∞-categories $\mathrm{QCoh}(X)$ and $\mathrm{QCoh}(Y)$ of quasi-coherent sheaves on X and Y and the pullback functor $f^* : \mathrm{QCoh}(Y) \to \mathrm{QCoh}(X)$. Under mild hypotheses, the functor f^* admits a right adjoint.

Proposition 6.3.4.1. *Let $f : X \to Y$ be a morphism in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ which is quasi-compact, quasi-separated relative spectral algebraic space. Then:*

(a) *The functor $f^* : \mathrm{QCoh}(Y) \to \mathrm{QCoh}(X)$ admits a right adjoint $f_* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$.*

(b) *For every pullback diagram*

$$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow{g} & Y \end{array}$$

in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$, the associated diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(Y) & \xrightarrow{f^*} & \mathrm{QCoh}(X) \\ \downarrow{\scriptstyle g^*} & & \downarrow{\scriptstyle g'^*} \\ \mathrm{QCoh}(Y') & \xrightarrow{f'^*} & \mathrm{QCoh}(X') \end{array}$$

is right adjointable: that is, the Beck-Chevalley transformation $g^* f_* \to f'_* g'^*$ is an equivalence of functors from $\mathrm{QCoh}(X)$ *to* $\mathrm{QCoh}(Y')$*.*

Proof. Write Y as the colimit of a diagram $q : S \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$, where each $q(s) \simeq \operatorname{Spec} A_s$ is affine. Our hypothesis on f guarantees that each of the fiber products $X \times_Y \operatorname{Spec} A_s$ is representable by a spectral algebraic space X_s which is quasi-compact and quasi-separated. Every edge $s \to s'$ in S determines a pullback diagram

$$\begin{array}{ccc} \mathsf{X}_s & \longrightarrow & \mathsf{X}_{s'} \\ \downarrow & & \downarrow \\ \operatorname{Sp\acute{e}t} A_s & \longrightarrow & \operatorname{Sp\acute{e}t} A_{s'}. \end{array}$$

Using Corollary **??**, we deduce that the associated diagram of pullback functors

$$\begin{array}{ccc} \mathrm{QCoh}(\operatorname{Spec} A_{s'}) & \longrightarrow & \mathrm{QCoh}(\mathsf{X}_{s'}) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\operatorname{Spec} A_s) & \longrightarrow & \mathrm{QCoh}(\mathsf{X}_s) \end{array}$$

is right adjointable. Since $\mathrm{QCoh}(X) \simeq \varprojlim \mathrm{QCoh}(\mathsf{X}_s)$ and $\mathrm{QCoh}(Y) \simeq \varprojlim \mathrm{QCoh}(\operatorname{Spec} A_s)$, Corollary HA.4.7.4.18 implies the following:

(i) The functor $f^* : \mathrm{QCoh}(Y) \to \mathrm{QCoh}(X)$ admits a right adjoint.

(ii) For each $s \in S$, the diagram

$$\begin{array}{ccc} \mathrm{QCoh}(Y) & \xrightarrow{f^*} & \mathrm{QCoh}(X) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\operatorname{Sp\acute{e}t} A_s) & \xrightarrow{f_s^*} & \mathrm{QCoh}(\mathsf{X}_s) \end{array}$$

is right adjointable.

This proves (a). Moreover, we can assume that every morphism $\operatorname{Spec} A \to Y$ appears as a map $q(s) \to Y$ for some $s \in S$, so that (ii) implies that (b) is satisfied whenever Y' is affine. To prove (b) in general, consider a pullback square σ :

$$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow{g} & Y \end{array}$$

and let $\mathscr{F} \in \mathrm{QCoh}(X)$; we wish to show that the Beck-Chevalley map $\theta : g^* f_* \mathscr{F} \to f'_* g'^* \mathscr{F}$ is an equivalence. To prove this, it will suffice to show that for every map $h : \operatorname{Spec} A \to Y'$, the pullback $h^*(\theta)$ is an equivalence in $\mathrm{QCoh}(\operatorname{Spec} A)$. Extending σ to a rectangular diagram

$$\begin{array}{ccccc} X'' & \xrightarrow{h'} & X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f''} & & \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \operatorname{Spec} A & \xrightarrow{h} & Y' & \xrightarrow{g} & Y \end{array}$$

where both squares are pullbacks, we see that $h^*(\theta)$ fits into a commutative diagram

$$\begin{array}{ccc} & h^* f'_* g'^* \mathscr{F} & \\ {\scriptstyle h^*(\theta)} \nearrow & & \searrow {\scriptstyle \theta'} \\ h^* g^* f_* \mathscr{F} & \xrightarrow{\theta''} & f''_* h'^* g'^* \mathscr{F}, \end{array}$$

where θ' and θ'' are equivalences by virtue of the fact that (b) holds in the special case where Y' is corepresentable. □

Warning 6.3.4.2. The existence of the right adjoint f_* follows from Corollary HTT.5.5.2.9 if $\mathrm{QCoh}(X)$ and $\mathrm{QCoh}(Y)$ are presentable. However, it is generally a poorly behaved construction (and is not compatible with base change) without additional hypotheses on f (such as those which appear in the statement of Proposition 6.3.4.1).

Corollary 6.3.4.3 (Projection Formula)**.** *Let $f : X \to Y$ be a morphism in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ which is quasi-compact, quasi-separated relative spectral algebraic space. Then:*

(1) *The direct image functor $f_* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ preserves small colimits.*

(2) *For every pair of objects $\mathscr{F} \in \mathrm{QCoh}(X)$ and $\mathscr{G} \in \mathrm{QCoh}(Y)$, the canonical map $\mathscr{F} \otimes f_* \mathscr{G} \to f_*(f^* \mathscr{F} \otimes \mathscr{G})$ is an equivalence.*

Proof. Using assertion (b) of Proposition 6.3.4.1, we can reduce to the case where $Y = \operatorname{Spec} R$ is affine. In this case, assertion (1) follows from Corollary 3.4.2.2 and assertion (2) from Remark 3.4.2.6. □

Corollary 6.3.4.4. *Let $f : X \to Y$ be a morphism in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ which is representable, proper, and locally almost of finite presentation. Then the functor $f_* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ of Proposition 6.3.4.1 carries almost perfect objects of $\mathrm{QCoh}(X)$ to almost perfect objects of $\mathrm{QCoh}(Y)$.*

Proof. Combine Proposition 6.3.4.1 with Theorem 5.6.0.2. □

Proposition 6.3.4.5. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor and let $\mathrm{Aff}_{/X}$ denote the full subcategory of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ spanned by those morphisms $f : Y \to X$ which are affine (in the sense of Example 6.3.3.6). Then the construction $Y \mapsto f_* \mathscr{O}_Y$ induces an equivalence of ∞-categories $\mathrm{Aff}_{/X} \to \mathrm{CAlg}(\mathrm{QCoh}(X)^{\mathrm{cn}})$.*

Proof. Writing X as a colimit of representable functors, we can reduce to the case where $X = \operatorname{Spec} A$ is corepresentable, in which case the desired result follows from Proposition 2.5.1.2. □

In the situation of Proposition 6.3.4.1, the direct image functor $f_* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ is lax symmetric monoidal (Proposition 2.5.5.1) and therefore admits a canonical factorization $\mathrm{QCoh}(X) \to \mathrm{Mod}_{f_* \mathscr{O}_X}(\mathrm{QCoh}(Y)) \to \mathrm{QCoh}(Y)$ (Corollary 2.5.5.3).

Proposition 6.3.4.6. *Let $f : X \to Y$ be a morphism in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ which is representable and quasi-affine. Then the induced map $\mathrm{QCoh}(X) \to \mathrm{Mod}_{f_* \mathcal{O}_X}(\mathrm{QCoh}(Y))$ is an equivalence of ∞-categories.*

Proof. When Y is a corepresentable functor, the desired result follows from Corollaries 2.5.4.6 and **??**. In general, we can write Y as the colimit of a diagram $q : S \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$, where each $q(s) \simeq \operatorname{Sp\acute{e}t} A_s$ is affine. Since f is representable and quasi-affine, each of the fiber products $X \times_Y q(s)$ is representable by a quasi-affine spectral algebraic space X_s. Using Proposition 6.3.4.1, we deduce that $f_* \mathcal{O}_X$ is a quasi-coherent sheaf on Y whose restriction to each $\operatorname{Spec} A_s$ is given by $B_s = (f_s)_* \mathscr{O}_s$, where $\mathscr{O}_s$ denotes the structure sheaf of X_s. It follows that the functor $\mathrm{QCoh}(X) \to \mathrm{Mod}_{f_* \mathscr{O}_X}(\mathrm{QCoh}(Y))$ is given by a limit of equivalences $\mathrm{QCoh}(\mathsf{X}_s) \to \mathrm{Mod}_{B_s}(\mathrm{QCoh}(\operatorname{Sp\acute{e}t} A_s))$, and is therefore an equivalence. □

Corollary 6.3.4.7. *Suppose we are given a pullback diagram*

$$\begin{array}{ccc} X & \xleftarrow{f} & Y \\ \updownarrow{\scriptstyle g} & & \uparrow{\scriptstyle g'} \\ X' & \xleftarrow{f'} & Y' \end{array}$$

in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$, where f is representable and quasi-affine. Assume that $\mathrm{QCoh}(X)$ and $\mathrm{QCoh}(X')$ are presentable. Then the diagram of symmetric monoidal ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(X) & \longrightarrow & \mathrm{QCoh}(Y) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(X') & \longrightarrow & \mathrm{QCoh}(Y') \end{array}$$

is a pushout square in $\mathrm{CAlg}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$.

6.4 Grothendieck Duality

Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks and suppose that, for every map $\operatorname{Sp\acute{e}t} R \to \mathsf{Y}$, the fiber $\mathsf{X}_R = \operatorname{Sp\acute{e}t} R \times_{\mathsf{Y}} \mathsf{X}$ is a quasi-compact, quasi-separated spectral algebraic space. It follows from Corollary 3.4.2.2 that the direct image functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ preserves small colimits. Using the adjoint functor theorem (Corollary HTT.5.5.2.9), we deduce that the functor f_* admits a right adjoint. We will be interested in the following special case:

Definition 6.4.0.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is proper and locally almost of finite presentation. We let $f^! : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ denote a right adjoint to the direct image functor f_*. We refer to $f^!$ as the *exceptional inverse image functor* associated to f.

Warning 6.4.0.2. To guarantee that the direct image functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ admits a right adjoint, we need much weaker assumptions than those of Definition 6.4.0.1. However, we will denote the right adjoint of f_* by $f^!$ only when f is proper and locally almost of finite presentation (see Remark **??**).

Example 6.4.0.3. Let $\phi : A \to B$ be a finite morphism of $\mathbb{E}_\infty$-rings. Then ϕ induces a morphism $f : \operatorname{Sp\acute{e}t} B \to \operatorname{Sp\acute{e}t} A$ which is proper (Proposition 5.2.1.1) and locally almost of finite presentation (Corollary 5.2.2.2). The functor $f^! : \mathrm{Mod}_A \simeq \mathrm{QCoh}(\operatorname{Sp\acute{e}t} A) \to \mathrm{QCoh}(\operatorname{Sp\acute{e}t} B) \simeq \mathrm{Mod}_B$ is right adjoint to the restriction of scalars functor $\mathrm{Mod}_B \to \mathrm{Mod}_A$. At the level of spectra, it is given by the construction $M \mapsto \underline{\mathrm{Map}}_A(B, M)$.

Example 6.4.0.4. Let A be a commutative ring and let $a \in A$ be a regular element, so that the sequence of A-modules $0 \to A \xrightarrow{a} A \to A/(a) \to 0$ is exact. Let $f : \operatorname{Sp\acute{e}t} A/(a) \to \operatorname{Sp\acute{e}t} A$ be the associated closed immersion. Then the functor $f^! : \mathrm{Mod}_A \to \mathrm{Mod}_{A/(a)}$ is given by

$$M \mapsto \underline{\mathrm{Map}}_A(A/(a), M) \simeq \mathrm{fib}(M \xrightarrow{a} M) \simeq \Omega((A/(a)) \otimes_A M).$$

In particular, there is an equivalence of functors $f^! \simeq \Omega f^*$. Beware that this equivalence depends on the choice of a (and not only on the closed immersion f).

Remark 6.4.0.5. The definition exceptional inverse image functor $f^! : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ admits a natural generalization to non-proper morphisms $f : \mathsf{X} \to \mathsf{Y}$ (which are still assumed to be locally almost of finite presentation). However, the definition requires some care (in the case where f is not proper, the functor $f^!$ is not right adjoint to the direct image functor f_*), so we will confine our attention in this book to the case where f is proper.

The goal of this section is to study the functor $f^!$ of Definition 6.4.0.1 and to establish some of its basic formal properties. Our principal results can be summarized as follows:

(*a*) Let $f : \mathsf{X} \to \mathsf{Y}$ be any morphism of spectral Deligne-Mumford stacks which is proper and locally almost of finite presentation. When restricted to *truncated* quasi-coherent sheaves, the exceptional inverse image functor $f^!$ is compatible with base change along morphisms $g : \mathsf{Y}' \to \mathsf{Y}$ which are of finite Tor-amplitude (Proposition 6.4.1.4). In particular, it is compatible with étale base change: that is, it is "local" on Y.

(*b*) If X and Y are locally Noetherian, then the functor $f^! : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ carries truncated coherent sheaves on Y to truncated coherent sheaves on X (Proposition 6.4.3.4).

(*c*) Suppose that $f : \mathsf{X} \to \mathsf{Y}$ is proper, locally almost of finite presentation, and locally of finite Tor-amplitude. Then there is a canonical equivalence $f^! \mathscr{F} \simeq f^* \mathscr{F} \otimes \omega_{\mathsf{X}/\mathsf{Y}}$ for $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})$ (Corollary 6.4.2.7), where $\omega_{\mathsf{X}/\mathsf{Y}}$ is the *relative dualizing sheaf* of $\mathscr{F}$ (Definition 6.4.2.4).

(*d*) Under the hypotheses of (*c*), the relative dualizing sheaf $\omega_{\mathsf{X}/\mathsf{Y}}$ is almost perfect and of finite Tor-amplitude over X (Proposition 6.4.4.1). Moreover, the construction $\mathscr{F} \mapsto f_*(\mathscr{F} \otimes \omega_{\mathsf{X}/\mathsf{Y}})$ determines a *left* adjoint to the pullback functor $f^* : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ (Proposition 6.4.5.3).

6.4.1 The Exceptional Inverse Image Functor

Our first goal is to show that the exceptional inverse image functor of Definition 6.4.0.1 behaves well with respect to base change, under some mild additional assumptions.

Notation 6.4.1.1. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ be a spectral Deligne-Mumford stack. Recall that a quasi-coherent sheaf $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is *locally truncated* if, for every affine $U \in \mathcal{X}$, the object $\mathscr{F}(U) \in \mathrm{Mod}_{\mathscr{O}_{\mathsf{X}}(U)}$ is truncated (if X is quasi-compact, this is equivalent to the requirement that $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})_{\leqslant n}$ for some $n \gg 0$). We let $\mathrm{QCoh}(\mathsf{X})_{\mathrm{ltr}}$ denote the full subcategory of $\mathrm{QCoh}(\mathsf{X})$ spanned by those objects which are locally truncated.

Remark 6.4.1.2. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. If f is locally of finite Tor-amplitude, then the pullback functor $f^* : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ carries $\mathrm{QCoh}(\mathsf{Y})_{\mathrm{ltr}}$ into $\mathrm{QCoh}(\mathsf{X})_{\mathrm{ltr}}$).

Remark 6.4.1.3. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is proper and locally almost of finite presentation. If Y is affine, then Corollary 3.4.2.3 guarantees that there exists an integer n for which the direct image functor f_* carries $\mathrm{QCoh}(\mathsf{X})_{\geqslant 0}$ into $\mathrm{QCoh}(\mathsf{Y})_{\geqslant -n}$. It follows that the exceptional inverse image functor $f^!$ carries $\mathrm{QCoh}(\mathsf{Y})_{\leqslant 0}$ into $\mathrm{QCoh}(\mathsf{X})_{\leqslant n}$. In particular, $f^!$ carries $\mathrm{QCoh}(\mathsf{Y})_{\mathrm{ltr}}$ into $\mathrm{QCoh}(\mathsf{X})_{\mathrm{ltr}}$.

Proposition 6.4.1.4. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is proper and locally almost of finite presentation. Then:*

(1) *The exceptional inverse image functor* $f^! : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ *carries* $\mathrm{QCoh}(\mathsf{Y})_{\mathrm{ltr}}$ *into* $\mathrm{QCoh}(\mathsf{X})_{\mathrm{ltr}}$.

(2) *Suppose we are given a pullback diagram*

$$\begin{array}{ccc} \mathsf{X}' & \xrightarrow{g'} & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \xrightarrow{g} & \mathsf{Y}, \end{array}$$

where g *is locally of finite* Tor*-amplitude. Then the commutative diagram of* ∞*-categories*

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{X})_{\mathrm{ltr}} & \xrightarrow{f_*} & \mathrm{QCoh}(\mathsf{Y})_{\mathrm{ltr}} \\ \downarrow{\scriptstyle g'^*} & & \downarrow{\scriptstyle g^*} \\ \mathrm{QCoh}(\mathsf{X}')_{\mathrm{ltr}} & \xrightarrow{f'_*} & \mathrm{QCoh}(\mathsf{Y}')_{\mathrm{ltr}} \end{array}$$

is right adjointable. In other words, for every truncated quasi-coherent sheaf $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})_{\mathrm{ltr}}$*, the canonical map* $g'^* f^! \mathscr{F} \to f'^! g^* \mathscr{F}$ *is an equivalence in* $\mathrm{QCoh}(\mathsf{X}')$.

The proof of Proposition 6.4.1.4 will require some preliminaries. We begin by analyzing the case where Y is affine.

Lemma 6.4.1.5. *Let* $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, A$ *be a morphism of spectral algebraic spaces which is proper and locally almost of finite presentation. Then the exceptional inverse image functor* $f^! : \mathrm{Mod}_A \simeq \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A) \to \mathrm{QCoh}(\mathsf{X})$ *commutes with filtered colimits when restricted to* $(\mathrm{Mod}_A)_{\leqslant 0}$.

Proof. According to Proposition 9.6.1.1, the ∞-category $\mathrm{QCoh}(\mathsf{X})$ is compactly generated and an object of $\mathrm{QCoh}(\mathsf{X})$ is compact if and only if it is perfect. It will therefore suffice to show that for every perfect object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$, the construction

$$(M \in (\mathrm{Mod}_A)_{\leqslant 0}) \mapsto \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, f^! M) \to \mathrm{Map}_{\mathrm{Mod}_A}(\Gamma(\mathsf{X}; \mathscr{F}); M)$$

commutes with filtered colimits. To prove this, it suffices to observe that $\Gamma(\mathsf{X}; \mathscr{F})$ is almost perfect when regarded as an A-module, by virtue of Theorem 5.6.0.2. □

Remark 6.4.1.6. Lemma 6.4.1.5 is essentially a reformulation of Theorem 5.6.0.2.

Construction 6.4.1.7. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is proper and locally almost of finite presentation. Suppose we are given quasi-coherent sheaves $\mathscr{F}, \mathscr{G} \in \mathrm{QCoh}(\mathsf{Y})$. Then the projection formula of Remark 3.4.2.6 supplies an equivalence $\theta : (f_* f^! \mathscr{F}) \otimes \mathscr{G} \to f_*(f^! \mathscr{F} \otimes f^* \mathscr{G})$. The inverse equivalence θ^{-1} then determines a morphism $\theta' : f^! \mathscr{F} \otimes f^* \mathscr{G} \to f^!((f_* f^! \mathscr{F}) \otimes \mathscr{G})$. Composing with the counit map $f_* f^! \mathscr{F} \to \mathscr{F}$, we obtain a natural map $\rho_{\mathscr{F},\mathscr{G}} : f^! \mathscr{F} \otimes f^* \mathscr{G} \to f^!(\mathscr{F} \otimes \mathscr{G})$, depending naturally on $\mathscr{F}$ and $\mathscr{G}$.

Lemma 6.4.1.8. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is proper and locally almost of finite presentation. Suppose that Y is affine. Let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})$ be truncated and let $\mathscr{G} \in \mathrm{QCoh}(\mathsf{Y})$ be of finite* Tor*-amplitude. Then the map $\rho_{\mathscr{F},\mathscr{G}} : f^! \mathscr{F} \otimes f^* \mathscr{G} \to f^!(\mathscr{F} \otimes \mathscr{G})$ of Construction 6.4.1.7 is an equivalence.*

Proof. Without loss of generality, we may assume that $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})_{\leqslant 0}$ and that $\mathscr{G}$ has Tor-amplitude $\leqslant 0$. Using Proposition 9.6.7.1, we can write $\mathscr{G}$ as the colimit of a filtered diagram $\{\mathscr{G}_\alpha\}$, where each $\mathscr{G}_\alpha \in \mathrm{QCoh}(\mathsf{Y})$ is perfect and of Tor-amplitude $\leqslant 0$. Then each tensor product $\mathscr{F} \otimes \mathscr{G}_\alpha$ is 0-truncated. Using Lemma 6.4.1.5, we can identify $\rho_{\mathscr{F},\mathscr{G}}$ with the colimit of the diagram $\{\rho_{\mathscr{F},\mathscr{G}_\alpha}\}$ in the ∞-category $\mathrm{Fun}(\Delta^1, \mathrm{QCoh}(\mathsf{X}))$. We may therefore replace $\mathscr{G}$ by $\mathscr{G}_\alpha$ and thereby reduce to the case where $\mathscr{G}$ is perfect.

Let us regard $\mathscr{F}$ as fixed. Let $\mathcal{C} \subseteq \mathrm{QCoh}(\mathsf{Y})$ be the full subcategory of $\mathrm{QCoh}(\mathsf{Y})$ spanned by those objects $\mathscr{G}$ for which the morphism $\rho_{\mathscr{F},\mathscr{G}}$ is an equivalence. We will complete the proof by showing that every perfect object of $\mathrm{QCoh}(\mathsf{Y})$ belongs to $\mathcal{C}$. Since the construction $\mathscr{G} \mapsto \rho_{\mathscr{F},\mathscr{G}}$ is exact, the ∞-category $\mathcal{C}$ is a stable subcategory of $\mathrm{QCoh}(\mathsf{Y})$ which is closed under retracts. By virtue of our assumption that Y is affine, it will suffice to show that $\mathcal{C}$ contains the structure sheaf $\mathscr{O}_{\mathsf{Y}}$, which follows immediately from the construction of $\rho_{\mathscr{F},\mathscr{G}}$. □

Proof of Proposition 6.4.1.4. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is proper and locally almost of finite presentation. Write $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathsf{Y}})$. For each $U \in \mathcal{Y}$, set $\mathsf{Y}_U = (\mathcal{Y}_{/U}, \mathscr{O}_{\mathsf{Y}}|_U)$ and $\mathsf{X}_U = \mathsf{X} \times_{\mathsf{Y}} \mathsf{Y}_U$, and let $f_U : \mathsf{X}_U \to \mathsf{Y}_U$ denote the projection onto the second factor. Let us say that $U \in \mathcal{Y}$ is *good* if it satisfies the following condition:

- $(*)$ For every morphism $h : \mathrm{Sp\acute{e}t}\, A \to \mathsf{Y}_U$ which is locally of finite Tor-amplitude, the diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{X}_U)_{\mathrm{ltr}} & \xrightarrow{f_{U*}} & \mathrm{QCoh}(\mathsf{Y}_U)_{\mathrm{ltr}} \\ \downarrow & & \downarrow h^* \\ \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A \times_{\mathsf{Y}_U} \mathsf{X}_U)_{\mathrm{ltr}} & \longrightarrow & \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A)_{\mathrm{ltr}} \end{array}$$

  is right adjointable.

Note that $(*)$ implies in particular that the direct image functor $f_{U*} : \mathrm{QCoh}(\mathsf{X}_U)_{\mathrm{ltr}} \to \mathrm{QCoh}(\mathsf{Y}_U)_{\mathrm{ltr}}$ admits a right adjoint, which we will denote by $f_U^{\dagger}$.

Our first step is to prove the following:

(*a*) If $V \to U$ is a morphism of good objects of $\mathcal{Y}$, then the diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{X}_U)_{\mathrm{ltr}} & \xrightarrow{f_{U*}} & \mathrm{QCoh}(\mathsf{Y}_U)_{\mathrm{ltr}} \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{X}_V)_{\mathrm{ltr}} & \xrightarrow{f_{V*}} & \mathrm{QCoh}(\mathsf{Y}_V)_{\mathrm{ltr}} \end{array}$$

is right adjointable.

Let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y}_U)$ be truncated; we wish to show that the canonical map $\xi : (f_U^\dagger \mathscr{F})|_{\mathsf{X}_V} \to f_V^\dagger(\mathscr{F}|_{\mathsf{Y}_V})$ is an equivalence. To prove this, it will suffice to show that for every map $W \to V$ where $W \in \mathcal{Y}$ is affine, the map ξ becomes an equivalence after restriction to X_W. This follows from our assumption that U and V are good (applying condition $(*)$ to the maps $\mathsf{Y}_W \to \mathsf{Y}_V$ and $\mathsf{Y}_W \to \mathsf{Y}_U$).

We next prove:

(*b*) The collection of good objects of $\mathcal{Y}$ is closed under small colimits.

To prove (*b*), suppose that $\{U_\alpha\}$ is a small diagram of good objects of $\mathcal{Y}$ having colimit $U \in \mathcal{Y}$. Combining (*a*) with Corollary HA.4.7.4.18 , we deduce that the functor $f_{U*} : \mathrm{QCoh}(\mathsf{X}_U)_{\mathrm{ltr}} \to \mathrm{QCoh}(\mathsf{Y}_U)_{\mathrm{ltr}}$ admits a right adjoint $f_U^\dagger$ and that the diagram

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{X}_U)_{\mathrm{ltr}} & \xrightarrow{f_{U*}} & \mathrm{QCoh}(\mathsf{Y}_U)_{\mathrm{ltr}} \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{X}_{U_\alpha})_{\mathrm{ltr}} & \xrightarrow{f_{V*}} & \mathrm{QCoh}(\mathsf{Y}_{U_\alpha})_{\mathrm{ltr}} \end{array}$$

is right adjointable for each index α. To complete the proof of (*b*), we must show that for each $u : \mathrm{Spét}\, A \to \mathsf{Y}_U$, the diagram appearing in condition $(*)$ is right adjointable. Using Lemma 6.4.1.8, we see that this assertion can be tested locally with respect to the étale topology on $\mathrm{Spét}\, A$, so we may assume that u factors through Y_{U_α} for some index α. In this case, the desired result follows from our assumption that U_α is good.

It follows from Lemma 6.4.1.8 that every affine object $U \in \mathcal{Y}$ is good. Combining (*b*) with Proposition 1.4.7.9, we deduce that every object of $\mathcal{Y}$ is good. In particular, the final object of $\mathcal{Y}$ is good. That is, we have the following:

$(*')$ For every morphism $h : \mathrm{Spét}\, A \to \mathsf{Y}$ which is locally of finite Tor-amplitude, the diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{X})_{\mathrm{ltr}} & \xrightarrow{f_*} & \mathrm{QCoh}(\mathsf{Y})_{\mathrm{ltr}} \\ \downarrow & & \downarrow h^* \\ \mathrm{QCoh}(\mathrm{Spét}\, A \times_{\mathsf{Y}} \mathsf{X})_{\mathrm{ltr}} & \longrightarrow & \mathrm{QCoh}(\mathrm{Spét}\, A)_{\mathrm{ltr}} \end{array}$$

is right adjointable.

In particular, the functor $f_* : \mathrm{QCoh}(\mathsf{X})_{\mathrm{ltr}} \to \mathrm{QCoh}(\mathsf{Y})_{\mathrm{ltr}}$ admits a right adjoint $f^\dagger : \mathrm{QCoh}(\mathsf{Y})_{\mathrm{ltr}} \to \mathrm{QCoh}(\mathsf{X})_{\mathrm{ltr}}$. We next prove:

(c) For each $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})_{\mathrm{ltr}}$, the counit map $v : f_* f^\dagger \mathscr{F} \to \mathscr{F}$ induces an equivalence $f^\dagger \mathscr{F} \to f^! \mathscr{F}$. In other words, $f^\dagger$ coincides with the restriction of $f^!$ to $\mathrm{QCoh}(\mathsf{Y})_{\mathrm{ltr}}$.

To prove (c), it will suffice to show that for each object $\mathscr{G} \in \mathrm{QCoh}(\mathsf{X})$ (not necessarily locally truncated), composition with v induces a homotopy equivalence $\rho : \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{G}, f^\dagger \mathscr{F}) \to \mathrm{Map}_{\mathrm{QCoh}(\mathsf{Y})}(f_* \mathscr{G}, \mathscr{F})$. More generally, for each $U \in \mathcal{Y}$, composition with v induces a map $\rho_U : \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X}_U)}(\mathscr{G}|_{\mathsf{X}_U}, (f^\dagger \mathscr{F})|_{\mathsf{X}_U}) \to \mathrm{Map}_{\mathrm{QCoh}(\mathsf{Y}_U)}((f_* \mathscr{G})_{\mathsf{Y}_U}, \mathscr{F}|_{\mathsf{Y}_U})$. Note that the collection of those objects $U \in \mathcal{Y}$ for which ρ_U is an equivalence is closed under small colimits. By virtue of Proposition 1.4.7.9, it will suffice to show that ρ_U is an equivalence when $U \in \mathcal{Y}$ is affine. Using (a), we can replace Y by Y_U and thereby reduce to the case where Y is affine. In this case, Remark 6.4.1.3 implies that $f^! \mathscr{F}$ is locally truncated, so that assertion (c) is clear.

Assertion (1) of Proposition 6.4.1.4 is an immediate consequence of (c). To prove (2), suppose we are given a pullback square

$$\begin{array}{ccc} \mathsf{X}' & \xrightarrow{g'} & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \xrightarrow{g} & \mathsf{Y}, \end{array}$$

where g is locally of finite Tor-amplitude. We wish to show that for each $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})_{\mathrm{ltr}}$, the canonical map $u : g'^* f^! \mathscr{F} \to f'^! g^* \mathscr{F}$ is an equivalence. Fix an étale morphism $h : \mathrm{Spét}\, A \to \mathsf{Y}'$; we will show that $h^*(u)$ is an equivalence. This follows from the commutativity of the diagram

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{X})_{\mathrm{ltr}} & \xrightarrow{f_*} & \mathrm{QCoh}(\mathsf{Y})_{\mathrm{ltr}} \\ \downarrow{\scriptstyle g'^*} & & \downarrow{\scriptstyle g^*} \\ \mathrm{QCoh}(\mathsf{X}')_{\mathrm{ltr}} & \xrightarrow{f'_*} & \mathrm{QCoh}(\mathsf{Y}')_{\mathrm{ltr}} \\ \downarrow & & \downarrow{\scriptstyle h^*} \\ \mathrm{QCoh}(\mathrm{Spét}\, A \times_{\mathsf{Y}'} \mathsf{X}')_{\mathrm{ltr}} & \longrightarrow & \mathrm{QCoh}(\mathrm{Spét}\, A)_{\mathrm{ltr}}, \end{array}$$

since the lower square and outer rectangle are right adjointable by virtue of $(*')$. $\square$

Using Proposition 6.4.1.4, we immediately deduce "global" analogues of Lemmas 6.4.1.5 and 6.4.1.8:

Corollary 6.4.1.9. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is proper and locally almost of finite presentation. Then:*

(1) *The exceptional inverse image functor* $f^! : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ *commutes with filtered colimits when restricted to* $\mathrm{QCoh}(\mathsf{Y})_{\leqslant 0}$.

(2) *If* $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})$ *is truncated and* $\mathscr{G} \in \mathrm{QCoh}(\mathsf{Y})$ *is of finite* Tor*-amplitude, then the map* $\rho_{\mathscr{F},\mathscr{G}} : f^! \mathscr{F} \otimes f^* \mathscr{G} \to f^!(\mathscr{F} \otimes \mathscr{G})$ *of Construction 6.4.1.7 is an equivalence.*

Proof. Using Proposition 6.4.1.4, we can reduce to the case where Y is affine, in which case the desired results follow from Lemmas 6.4.1.5 and 6.4.1.8. □

6.4.2 The Relative Dualizing Sheaf

When restricted to morphisms of finite Tor-amplitude, the exceptional inverse image functor of Definition 6.4.0.1 is particularly well-behaved. In particular, we will see that it is compatible with base change, and therefore makes sense more generally for morphisms of (not necessarily representable) functors.

Proposition 6.4.2.1. *Let* $f : X \to Y$ *be a natural transformation between functors* $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. *Assume that* f *is representable, proper, locally almost of finite presentation, and locally of finite* Tor*-amplitude. Then:*

(a) *The direct image functor* $f_* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ *admits a right adjoint* $f^! : \mathrm{QCoh}(Y) \to \mathrm{QCoh}(X)$.

(b) *For every pullback diagram of functors*

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow & & \downarrow \\ Y' & \longrightarrow & Y, \end{array}$$

the commutative diagram of ∞*-categories*

$$\begin{array}{ccc} \mathrm{QCoh}(X) & \xrightarrow{f_*} & \mathrm{QCoh}(Y) \\ \downarrow{\scriptstyle g'^*} & & \downarrow{\scriptstyle g^*} \\ \mathrm{QCoh}(X') & \xrightarrow{f'_*} & \mathrm{QCoh}(Y') \end{array}$$

(supplied by Proposition 6.3.4.1) is right adjointable. In other words, for every quasi-coherent sheaf $\mathscr{F} \in \mathrm{QCoh}(Y)$*, the canonical map* $g'^* f^! \mathscr{F} \to f'^! g^* \mathscr{F}$ *is an equivalence in* $\mathrm{QCoh}(X')$.

As in the proof of Proposition 6.4.1.4, we begin with an analysis of the affine case.

Lemma 6.4.2.2. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is proper, locally almost of finite presentation, and locally of finite* Tor*-amplitude. Assume that Y is affine. Then:*

(1) *The exceptional inverse image functor $f^! : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ commutes with small colimits.*

(2) *For every pair of objects $\mathscr{F}, \mathscr{G} \in \mathrm{QCoh}(\mathsf{Y})$, the map $\rho_{\mathscr{F},\mathscr{G}} : f^! \mathscr{F} \otimes f^* \mathscr{G} \to f^!(\mathscr{F} \otimes \mathscr{G})$ of Construction 6.4.1.7 is an equivalence in $\mathrm{QCoh}(\mathsf{X})$.*

Remark 6.4.2.3. In the statement of Lemma 6.4.2.2, the assumption that Y is affine is superfluous; see Corollary 6.4.2.7 below.

Proof of Lemma 6.4.2.2. Note that X is a quasi-compact, quasi-separated spectral algebraic space. It follows that $\mathrm{QCoh}(\mathsf{X})$ is compactly generated, and that an object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is compact if and only if it is perfect (Proposition 9.6.1.1). Using Theorem 6.1.3.2, we deduce that the direct image functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ carries compact objects to compact objects. Applying Proposition HTT.5.5.7.2 , we deduce that the exceptional inverse image functor $f^! : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ commutes with filtered colimits, and therefore with all small colimits (since it is an exact functor of stable ∞-categories); this completes the proof of (1).

To prove (2), let us regard $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})$ as fixed, and let $\mathcal{C} \subseteq \mathrm{QCoh}(\mathsf{Y})$ be the full subcategory spanned by those objects $\mathscr{G}$ for which the map $\rho_{\mathscr{F},\mathscr{G}}$ is an equivalence. Using (1), we see that $\mathcal{C}$ is a stable subcategory of $\mathrm{QCoh}(\mathsf{Y})$ which is closed under small colimits. Since Y is affine, to show that $\mathcal{C} = \mathrm{QCoh}(\mathsf{Y})$ it will suffice to show that $\mathcal{C}$ contains the structure sheaf $\mathscr{O}_{\mathsf{Y}}$, which follows immediately from the definition given in Construction 6.4.1.7. □

Proof of Proposition 6.4.2.1. We proceed as in the proof of Proposition 6.3.4.1. Let $f : X \to Y$ be a morphism of functors which is representable, proper, locally almost of finite presentation, and locally of finite Tor-amplitude. Write Y as the colimit of a diagram $q : S \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$, where each $q(s) \simeq \mathrm{Spec}\, A_s$ is affine. Our hypothesis on f guarantees that each of the fiber products $X \times_Y \mathrm{Spec}\, A_s$ is representable by a spectral algebraic space X_s which is proper, locally almost of finite presentation, and locally of finite Tor-amplitude over A_s. Every edge $s \to s'$ in S determines a pullback diagram

$$\begin{array}{ccc} \mathsf{X}_s & \longrightarrow & \mathsf{X}_{s'} \\ \downarrow{\scriptstyle f_s} & & \downarrow{\scriptstyle f_{s'}} \\ \mathrm{Sp\acute{e}t}\, A_s & \longrightarrow & \mathrm{Sp\acute{e}t}\, A_{s'}. \end{array}$$

Using Lemma 6.4.2.2, we deduce that the associated diagram of pullback functors

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{X}_{s'}) & \xrightarrow{f_{s*}} & \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A_{s'}) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{X}_{s}) & \xrightarrow{f_{s*}} & \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A_{s}) \end{array}$$

is right adjointable. Since $\mathrm{QCoh}(X) \simeq \varprojlim \mathrm{QCoh}(\mathsf{X}_s)$ and $\mathrm{QCoh}(Y) \simeq \varprojlim \mathrm{QCoh}(\mathrm{Spec}\, A_s)$, Corollary HA.4.7.4.18 implies the following:

(i) The direct image functor $f_* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ admits a right adjoint $f^!$.

(ii) For each $s \in S$, the diagram

$$\begin{array}{ccc} \mathrm{QCoh}(X) & \xrightarrow{f_{*}} & \mathrm{QCoh}(Y) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{X}_{s}) & \xrightarrow{f_{s*}} & \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A_{s}) \end{array}$$

is right adjointable.

This proves (a). Moreover, we can assume that every morphism $\mathrm{Spec}\, A \to Y$ appears as a map $q(s) \to Y$ for some $s \in S$, so that (ii) shows that (b) is satisfied whenever Y' is affine. To prove (b) in general, consider a pullback square σ :

$$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow{g} & Y \end{array}$$

and let $\mathscr{F} \in \mathrm{QCoh}(Y)$; we wish to show that the Beck-Chevalley map $\theta : g'^* f^! \mathscr{F} \to f'^! g^* \mathscr{F}$ is an equivalence in $\mathrm{QCoh}(X')$. To prove this, it will suffice to show that for every map $h : \mathrm{Spec}\, A \to Y'$, the image of θ in $\mathrm{QCoh}(X' \times_{Y'} \mathrm{Spec}\, A)$ is an equivalence. Extending σ to a rectangular diagram

$$\begin{array}{ccccc} X'' & \xrightarrow{h'} & X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f''} & & \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathrm{Spec}\, A & \xrightarrow{h} & Y' & \xrightarrow{g} & Y \end{array}$$

where both squares are pullbacks, we see that $h'^*(\theta)$ fits into a commutative diagram

$$\begin{array}{ccccc} & & h'^* f'^! g^* \mathscr{F} & & \\ & \nearrow^{h'^*(\theta)} & & \searrow^{\theta'} & \\ h'^* g'^* f^! \mathscr{F} & & \xrightarrow{\theta''} & & f''^! h^* g^* \mathscr{F}, \end{array}$$

where θ' and θ'' are equivalences by virtue of the fact that (b) holds in the special case where Y' is corepresentable. $\square$

Definition 6.4.2.4. Let $f : X \to Y$ be a morphism of functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ which is representable, proper, locally almost of finite presentation, and locally of finite Tor-amplitude. We let $\omega_{X/Y}$ denote the quasi-coherent sheaf $f^! \mathscr{O}_Y \in \mathrm{QCoh}(X)$. We will refer to $\omega_{X/Y}$ as the *relative dualizing sheaf* of the morphism f.

Variant 6.4.2.5. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is proper and locally almost of finite presentation. In this case, we let $\omega_{\mathsf{X}/\mathsf{Y}}$ denote the quasi-coherent sheaf $f^! \mathscr{O}_{\mathsf{Y}} \in \mathrm{QCoh}(\mathsf{X})$. We will refer to $\omega_{\mathsf{X}/\mathsf{Y}}$ as the *relative dualizing sheaf* of the morphism f. Note that if f is locally of finite Tor-amplitude, then this definition agrees with Definition 6.4.2.4 (where we abuse notation by identifying X and Y with the corresponding representable functors).

Remark 6.4.2.6. Suppose we are given a pullback diagram

$$\begin{array}{ccc} X' & \xrightarrow{g} & X \\ \downarrow & & \downarrow{\scriptstyle f} \\ Y' & \longrightarrow & Y \end{array}$$

in the ∞-category $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$, where f is representable, proper, locally almost of finite presentation, and locally of finite Tor-amplitude. In this case, Proposition 6.4.1.4 supplies a canonical equivalence $g^* \omega_{X/Y} \simeq \omega_{X'/Y'}$.

If we are given a pullback diagram of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathsf{X}' & \xrightarrow{g} & \mathsf{X} \\ \downarrow & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \xrightarrow{g'} & \mathsf{Y}. \end{array}$$

where f is proper and locally almost of finite presentation, then there is a canonical map $\rho : g^* \omega_{\mathsf{X}/\mathsf{Y}} \to \omega_{\mathsf{X}'/\mathsf{Y}'}$. This map need not be an equivalence. However, it is an equivalence if either f or g' has finite Tor-amplitude (Propositions 6.4.2.1 and 6.4.1.4).

Corollary 6.4.2.7. *Let $f : X \to Y$ be a morphism between functors $X, Y \in \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ which is representable, proper, locally almost of finite presentation, and locally of finite* Tor*-amplitude. Then, for any quasi-coherent sheaf $\mathscr{F} \in \mathrm{QCoh}(Y)$, we have a canonical equivalence $\omega_{X/Y} \otimes f^* \mathscr{F} \simeq f^! \mathscr{F}$ in the ∞-category* $\mathrm{QCoh}(X)$.

Proof. Arguing as in Construction 6.4.1.7, we have a canonical map

$$\rho : \omega_{X/Y} \otimes f^* \mathscr{F} \simeq (f^! \mathscr{O}_Y) \otimes (f^* \mathscr{F}) \to f^!(\mathscr{O}_Y \otimes \mathscr{F}) \simeq f^! \mathscr{F}.$$

We claim that this map is an equivalence. By virtue of Proposition 6.4.2.1, the assertion is local on Y. We may therefore assume that Y is affine, in which case the desired result is a special case of Lemma 6.4.2.2. □

Corollary 6.4.2.8. *[Transitivity] Let $f : X \to Y$ and $g : Y \to Z$ be morphisms between functors $X, Y, Z \in \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ which are representable, proper, locally almost of finite presentation, and locally of finite* Tor*-amplitude. Then there is a canonical equivalence $\omega_{X/Z} \simeq \omega_{X/Y} \otimes \omega_{Y/Z}$ in the ∞-category* $\mathrm{QCoh}(X)$.

Example 6.4.2.9. Let A be a commutative ring, let $\mathsf{Y} = \mathrm{Spét}\, A$, and let X denote the closed subspace of Y given by the vanishing locus of an ideal $I \subseteq A$. If I is generated by a regular sequence $a_1, a_2, \ldots, a_n \in A$, then Example 6.4.0.4 supplies an equivalence $\omega_{\mathsf{X}/\mathsf{Y}} \simeq \Sigma^{-n} \mathscr{O}_{\mathsf{X}}$ (which depends on the choice of regular sequence $a_1, \ldots, a_n$).

6.4.3 Preservation of Coherence

Our next goal is to establish a finiteness property enjoyed by the exceptional inverse image functor $f^!$ of Definition 6.4.0.1. First, we need to introduce a bit of terminology.

Definition 6.4.3.1. Let X be a locally Noetherian spectral Deligne-Mumford stack. We will say that an object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is *coherent* if, for every integer n, the truncation $\tau_{\geqslant n} \mathscr{F}$ is almost perfect. We let $\mathrm{Coh}(\mathsf{X})$ denote the full subcategory of $\mathrm{QCoh}(\mathsf{X})$ spanned by the coherent sheaves.

Example 6.4.3.2. Let $\mathsf{X} = \mathrm{Spét}\, A$ be an affine spectral algebraic space and let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ be the quasi-coherent sheaf corresponding to the A-module $M = \Gamma(\mathsf{X}; \mathscr{F})$. Then $\mathscr{F}$ is coherent if and only if each homotopy group $\pi_n M$ is finitely generated as a module over $\pi_0 A$.

Warning 6.4.3.3. In Definition 6.4.3.1, we impose no boundedness conditions on $\mathscr{F}$.

Proposition 6.4.3.4. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a proper morphism between locally Noetherian spectral Deligne-Mumford stacks and let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})$. If $\mathscr{F}$ is coherent and locally truncated, then $f^! \mathscr{F}$ is coherent and locally truncated.*

The proof of Proposition 6.4.3.4 will require some preliminaries.

Lemma 6.4.3.5. *Let A be a Noetherian $\mathbb{E}_\infty$-ring, let M be an almost perfect A-module, and let N be a truncated A-module whose homotopy groups are finitely generated over $\pi_0 A$. Then the groups $\mathrm{Ext}^i_A(M, N)$ are finitely generated modules over $\pi_0 A$.*

Proof. Replacing M and N by suitable suspensions, we can assume that N is 0-truncated and that $i = 0$. Choose an integer m such that M is m-connective. We proceed by descending induction on m. Note that if $m > 0$, then $\mathrm{Ext}^0_A(M, N) \simeq 0$ and there is nothing to prove. Otherwise, the assumption that M is almost perfect guarantees the existence of a fiber sequence $\Sigma^m A^k \to M \to M'$, where M' is $(m+1)$-connective. We have an exact sequence of $\pi_0 A$-modules $\mathrm{Ext}^0_A(M', N) \to \mathrm{Ext}^0_A(M, N) \to \mathrm{Ext}^0_A(\Sigma^m A^k, N)$. The inductive hypothesis implies that $\mathrm{Ext}^0_A(M', N)$ is finitely generated over $\pi_0 A$, and we have a canonical isomorphism $\mathrm{Ext}^0_A(\Sigma^m A^k, N) \simeq (\pi_m N)^k$. It follows that $\mathrm{Ext}^0_A(M, N)$ is finitely generated over $\pi_0 A$. □

Corollary 6.4.3.6. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a finite morphism of locally Noetherian spectral Deligne-Mumford stacks. Then the functor $f^! : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ carries locally truncated coherent objects of $\mathrm{QCoh}(\mathsf{Y})$ to locally truncated coherent objects of $\mathrm{QCoh}(\mathsf{X})$.*

Proof. By virtue of Proposition 6.4.1.4, the assertion is local on Y; we may therefore assume without loss of generality that $\mathsf{Y} = \mathrm{Sp\acute{e}t}\, A$ is affine. In this case, the desired result follows immediately from Lemma 6.4.3.5. □

Lemma 6.4.3.7. *Let $f : A \to B$ be a map of Noetherian $\mathbb{E}_\infty$-rings, Suppose that the induced map $\pi_0 A \to \pi_0 B$ is a surjection of commutative rings whose kernel $I \subseteq \pi_0 A$ is nilpotent. Let K be a truncated A-module, and suppose that the homotopy groups $\pi_i \underline{\mathrm{Map}}_A(B, K)$ are finitely generated modules over $\pi_0 B$. Then the homotopy groups $\pi_i K$ are finitely generated modules over $\pi_0 A$.*

Proof. We may assume without loss of generality that K is 0-truncated. We prove that the homotopy groups $\pi_{-n} K$ are finitely generated over $\pi_0 A$ using induction on n, the case $n < 0$ being trivial. For each integer $k \geqslant 1$, let $M(k)$ denote the submodule of $\pi_0 K$ consisting of elements which are annihilated by I^k. Since $\pi_0 A$ is Noetherian, there exists a finite set of generators $x_1, \ldots, x_n$ for the ideal I. Multiplication by the elements x_i determines a map $M(k) \to M(k-1)^n$, which fits into an exact sequence $0 \to M(1) \to M(k) \to M(k-1)^n$ Note that $M(1) \simeq \pi_0 \underline{\mathrm{Map}}_A(B, K)$ is finitely generated over $\pi_0 A$. It follows by induction on k that each $M(k)$ is finitely generated over $\pi_0 A$. Since the ideal I is nilpotent, we have $M(k) \simeq \pi_0 K$ for $k \gg 0$, so that $\pi_0 K$ is finitely generated over $\pi_0 A$. This completes the proof when $n = 0$. If $n > 0$, we apply Lemma 6.4.3.5 to deduce that the homotopy groups of $\underline{\mathrm{Map}}_A(B, \pi_0 K)$ are finitely generated over $\pi_0 A$, and therefore finitely generated over $\pi_0 B$. Let $K' = \Sigma(\tau_{\leqslant -1} K)$, so that we have a fiber sequence of A-modules $\pi_0 K \to K \to \Sigma^{-1} K'$. It follows that the homotopy groups of $\pi_0 \underline{\mathrm{Map}}_A(B, K')$ are finitely generated over $\pi_0 B$. Applying the inductive hypothesis, we deduce that $\pi_{-n} K \simeq \pi_{1-n} K'$ is finitely generated over $\pi_0 A$, as desired. □

Corollary 6.4.3.8. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ be a locally Noetherian spectral Deligne-Mumford stack, let $\mathsf{X}_0 = (\mathcal{X}, \pi_0 \mathscr{O}_{\mathsf{X}})$ be the 0-truncation of X, and let $i : \mathsf{X}_0 \to \mathsf{X}$ denote the associated* *closed immersion. If* $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ *is locally truncated and* $i^! \mathscr{F} \in \mathrm{QCoh}(\mathsf{X}_0)$ *is coherent, then* $\mathscr{F}$ *is coherent.*

Proof. Using Proposition 6.4.1.4, we can reduce to the case where X is affine, in which case the desired result follows from Lemma 6.4.3.7. □

Proof of Proposition 6.4.3.4. Let $f : \mathsf{X} \to \mathsf{Y}$ be a proper morphism of locally Noetherian spectral Deligne-Mumford stacks and let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})$ be truncated and coherent. Then $f^! \mathscr{F}$ is locally truncated by virtue of Proposition 6.4.1.4; we wish to show that it is also coherent. Let X_0 and Y_0 denote the 0-truncations of X and Y, respectively, so that we have a commutative diagram

$$\begin{array}{ccc} \mathsf{X}_0 & \xrightarrow{i} & \mathsf{X} \\ \downarrow{\scriptstyle f_0} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}_0 & \xrightarrow{i'} & \mathsf{Y} \end{array}$$

where the horizontal maps are closed immersions. To show that $f^! \mathscr{F}$ is locally truncated, it will suffice (by virtue of Corollary 6.4.3.8) to show that $i^! f^! \mathscr{F} \simeq f_0^! i'^! \mathscr{F}$ is coherent. It follows from Corollary 6.4.3.6 that $i'^! \mathscr{F} \in \mathrm{QCoh}(\mathsf{Y}_0)$ is truncated and coherent. We may therefore replace f by f_0 and thereby reduce to the case where X and Y are 0-truncated.

Using Proposition 6.4.1.4, we see that the assertion that $f^! \mathscr{F}$ is coherent can be tested locally with respect to the étale topology of Y. We may therefore assume without loss of generality that $\mathsf{Y} = \mathrm{Sp\acute{e}t}\, A$ for some Noetherian commutative ring A. Choose an étale surjection $u : \mathsf{U} \to \mathsf{X}$ where $\mathsf{U} \simeq \mathrm{Sp\acute{e}t}\, B$ is affine; we will show that $u^* f^! \mathscr{F}$ is coherent. Since the morphism f is of finite type, the commutative ring B is finitely generated as an A-algebra. We can therefore choose a surjection of A-algebras $\phi : A[x_1, \ldots, x_n] \to B$. Set $\mathsf{Y}' = \mathrm{Sp\acute{e}t}\, A[x_1, \ldots, x_n]$ and form a pullback square

$$\begin{array}{ccc} \mathsf{X}' & \xrightarrow{g'} & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \xrightarrow{g} & \mathsf{Y}. \end{array}$$

Amalgamating u and ϕ, we obtain a map $\overline{u} : \mathsf{U} \to \mathsf{X}'$. By construction, $f' \circ \overline{u}$ is a closed immersion. Since f' is separated, it follows that $\overline{u}$ is a closed immersion.

Locally on X', the morphism $\overline{u}$ exhibits U as the closed substack of X' given by the vanishing locus of a regular sequence (of length n). It follows that the morphism $\overline{u}$ has finite Tor-amplitude. Moreover, Example 6.4.2.9 (and Proposition 6.4.1.4) imply that relative dualizing sheaf $\omega_{\mathsf{U}/\mathsf{X}'}$ has the form $\Sigma^{-n} \mathscr{L}$, where $\mathscr{L}$ is a line bundle on U. Consequently, to show that $u^* f^! \mathscr{F}$ is coherent, it will suffice to show that the tensor product $\omega_{\mathsf{U}/\mathsf{X}'} \otimes u^* f^! \mathscr{F}$

is coherent Using Corollary 6.4.2.7 and Proposition 6.4.1.4, we obtain equivalences

$$\begin{aligned} \omega_{\mathsf{U}/\mathsf{X}'} \otimes u^* f^! \mathscr{F} &\simeq \omega_{\mathsf{U}/\mathsf{X}'} \otimes \overline{u}^* g'^* f^! \mathscr{F} \\ &\simeq \overline{u}^! g'^* f^! \mathscr{F} \\ &\simeq \overline{u}^! f'^! g^* \mathscr{F}. \end{aligned}$$

We may therefore replace Y by Y', $\mathscr{F}$ by $g^* \mathscr{F}$, and f by the map $(f' \circ \overline{u}) : \mathsf{U} \to \mathsf{Y}'$ determined by ϕ, and thereby reduce to proving Proposition 6.4.3.4 in the special case where f is a closed immersion. In this case, the desired result follows from Corollary 6.4.3.6. □

6.4.4 Finiteness Properties of $\omega_{X/Y}$

We now apply Proposition 6.4.3.4 to study the finiteness properties of relative dualizing sheaves. Our goal is to prove the following:

Proposition 6.4.4.1. *Let $f : X \to Y$ be a morphism of functors which is representable, proper, locally almost of finite presentation, and locally of finite* Tor*-amplitude. Then the relative dualizing sheaf $\omega_{X/Y} \in \mathrm{QCoh}(X)$ is almost perfect.*

The proof of Proposition 6.4.4.1 will require some preliminaries.

Lemma 6.4.4.2. *Let X be a spectral algebraic space which is quasi-compact and separated, let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$, and let n be an integer. Suppose that, for every perfect object $\mathscr{G} \in \mathrm{QCoh}(\mathsf{X})$ having* Tor*-amplitude $\leqslant 0$, the groups $\mathrm{Ext}^i_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{G}, \mathscr{F})$ vanish for $i > n$. Then $\mathscr{F}$ is $(-n)$-connective.*

Proof. Let $f : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$ be an étale morphism; we wish to show that $\Gamma(\mathrm{Sp\acute{e}t}\, A; f^* \mathscr{F}) \in \mathrm{Mod}_A$ is $(-n)$-connective. Note that we have canonical equivalences $\Gamma(\mathrm{Sp\acute{e}t}\, A; f^* \mathscr{F}) \simeq \Gamma(\mathsf{X}; f_* f^* \mathscr{F}) \simeq \Gamma(\mathsf{X}; (f_* \mathscr{O}_{\mathrm{Sp\acute{e}t}\, A}) \otimes \mathscr{F})$. Since f is affine, the direct image $f_* \mathscr{O}_{\mathrm{Sp\acute{e}t}\, A} \in \mathrm{QCoh}(\mathsf{X})$ is connective. Using Proposition 9.6.1.2, we can write $f_* \mathscr{O}_{\mathrm{Sp\acute{e}t}\, A}$ as the colimit of a filtered diagram $\{\mathscr{G}_\alpha\}$, where each $\mathscr{G}_\alpha \in \mathrm{QCoh}(\mathsf{X})$ is connective and almost perfect. Since the global sections functor $\Gamma(\mathsf{X}; \bullet)$ commutes with filtered colimits, we are reduced to showing that each of the spectra $\Gamma(\mathsf{X}; \mathscr{G}_\alpha \otimes \mathscr{F})$ is $(-n)$-connective: in other words, that the homotopy groups

$$\pi_{-i} \Gamma(\mathsf{X}; \mathscr{G}_\alpha \otimes \mathscr{F}) \simeq \mathrm{Ext}^i_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{G}_\alpha^\vee, \mathscr{F})$$

vanish for $i > n$. This follows from our hypothesis on $\mathscr{F}$, since each $\mathscr{G}_\alpha^\vee$ has Tor-amplitude $\leqslant 0$. □

Lemma 6.4.4.3. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is proper, locally almost of finite presentation, and of* Tor*-amplitude $\leqslant n$. Then the relative dualizing sheaf $\omega_{\mathsf{X}/\mathsf{Y}}$ is $(-n)$-connective.*

Proof. By virtue of Proposition 6.4.2.1, the assertion is local on Y; we may therefore assume without loss of generality that $\mathsf{Y} \simeq \operatorname{Sp\acute{e}t} A$ is affine. Using Lemma 6.4.4.2, we are reduced to showing that if $\mathscr{G} \in \mathrm{QCoh}(\mathsf{X})$ is perfect of Tor-amplitude $\leqslant 0$, then the groups $\operatorname{Ext}^i_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{G}, \omega_{\mathsf{X}/\mathsf{Y}})$ vanish for $i > n$. Set $N = \Gamma(\mathsf{X}; \mathscr{G})$, so that N is a perfect A-module (Theorem 6.1.3.2) and we have a canonical isomorphism $\operatorname{Ext}^i_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{G}, \omega_{\mathsf{X}/\mathsf{Y}}) \simeq \operatorname{Ext}^i_A(N, A) \simeq \pi_{-i} N^\vee$. It will therefore suffice to show that $N^\vee$ is $(-n)$-connective, or equivalently that N has Tor-amplitude $\leqslant n$ as an A-module. Let $M \in \mathrm{Mod}^\heartsuit_A$, and let $\mathscr{F} = f^* M \in \mathrm{QCoh}(\mathsf{X})$ be the associated quasi-coherent sheaf on X. Then we have a canonical equivalence $M \otimes_A N \simeq \Gamma(\mathsf{X}; \mathscr{F} \otimes \mathscr{G})$. Since f has Tor-amplitude $\leqslant n$, the quasi-coherent sheaf $\mathscr{F}$ is n-truncated. Since $\mathscr{G}$ has Tor-amplitude $\leqslant 0$, the tensor product $\mathscr{F} \otimes \mathscr{G}$ is n-truncated, so that the A-module $M \otimes_A N \simeq \Gamma(\mathsf{X}; \mathscr{F} \otimes \mathscr{G}$ is also n-truncated. Allowing M to vary, we conclude that N has Tor-amplitude $\leqslant n$ as desired. □

Proof of Proposition 6.4.4.1. Assume that $f : X \to Y$ is representable proper, locally almost of finite presentation, and locally of finite Tor-amplitude; we wish to show that $\omega_{X/Y}$ is almost perfect. By virtue of Remark 6.4.2.6, the assertion is local on Y; we may therefore assume without loss of generality that $Y \simeq \operatorname{Spec} A$ is affine. Then X is representable by a spectral algebraic space X which is proper over A. In particular, X is quasi-compact, so there exists an integer n for which f has Tor-amplitude $\leqslant n$. Using Lemma 6.4.4.3, we deduce that $\omega_{X/Y}$ is $(-n)$-connective. Set $\mathsf{X}_0 = \mathsf{X} \times_{\operatorname{Sp\acute{e}t} A} \operatorname{Sp\acute{e}t}(\pi_0 A)$, and let $i : \mathsf{X}_0 \to \mathsf{X}$ be the evident closed immersion. To complete the proof that $\omega_{X/Y}$ is almost perfect, it will suffice to show that $i^* \omega_{X/Y}$ is almost perfect (Proposition 2.7.3.2). Using Proposition 6.4.2.1, we can replace f by the projection map $\mathsf{X}_0 \to \operatorname{Sp\acute{e}t}(\pi_0 A)$ and thereby reduce to the case where A is discrete.

Write A as the colimit of a filtered diagram $\{A_\alpha\}$, where each A_α is a finitely generated commutative ring. Using Theorem 4.4.2.2, we deduce that there exists an index α, a finitely n-presented morphism $f_\alpha : \mathsf{X}_\alpha \to \operatorname{Sp\acute{e}t} A_\alpha$, and an identification of X with the n-truncation of $\mathsf{X}_\alpha \times_{\operatorname{Sp\acute{e}t} A_\alpha} \operatorname{Sp\acute{e}t} A$. Enlarging α if necessary, we can assume that f_α is proper (Proposition 5.5.4.1) and of Tor-amplitude $\leqslant n$ (Proposition 6.1.6.1), so that f is a pullback of f_α. Applying Remark 6.4.2.6 again, we can replace f by f_α and thereby reduce to the case where A is Noetherian. In this case, Corollary 6.4.3.6 implies that $\omega_{X/Y} \in \mathrm{QCoh}(X)$ is coherent. In particular, the truncation $\tau_{\geqslant -n} \omega_{X/Y}$ is almost perfect. Since $\omega_{X/Y}$ is $(-n)$-connective (Lemma 6.4.4.2), we conclude that $\omega_{X/Y}$ is almost perfect. □

Warning 6.4.4.4. In the situation of Proposition 6.4.4.1, the relative dualizing sheaf $\omega_{X/Y}$ need not be perfect: in other words, it need not be of finite Tor-amplitude over X. However, it is always locally of finite Tor-amplitude over Y. In other words, for every commutative

diagram

$$\begin{array}{ccc} \operatorname{Spec} B & \xrightarrow{g} & X \\ \downarrow & & \downarrow f \\ \operatorname{Spec} A & \xrightarrow{g'} & Y \end{array}$$

for which the induced map $\operatorname{Spec} B \to \operatorname{Spec} A \times_Y X$ is étale, the pullback $g^* \omega_{X/Y} \in \operatorname{QCoh}(\operatorname{Spec} B) \simeq \operatorname{Mod}_B$ has finite Tor-amplitude when regarded as an A-module. To prove this, we may replace Y by $\operatorname{Spec} A$ and thereby reduce to the case where g' is an equivalence. Then there exists an integer n for which the exceptional inverse image functor $f^! : \operatorname{Mod}_A \simeq \operatorname{QCoh}(Y) \to \operatorname{QCoh}(X)$ carries $(\operatorname{Mod}_A)_{\leqslant 0}$ into $\operatorname{QCoh}(X)_{\leqslant n}$ (see Remark 6.4.1.3). Using Corollary 6.4.2.7, we deduce that $\omega_{X/Y} \otimes f^* M \simeq f^! M$ is n-truncated for every discrete A-module M, so that $\omega_{X/Y}$ has Tor-amplitude $\leqslant n$ over A.

6.4.5 The Functor f_+

Let $f : X \to Y$ be a morphism of functors $X, Y : \operatorname{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ which is representable, proper, locally almost of finite presentation, and locally of finite Tor-amplitude. Let $\omega_{X/Y}$ denote the relative dualizing sheaf of f. According to Corollary 6.4.2.7, the construction

$$(\mathscr{F} \in \operatorname{QCoh}(Y)) \mapsto (\omega_{\mathsf{X}/\mathsf{Y}} \otimes f^* \mathscr{F} \in \operatorname{QCoh}(X))$$

determines a right adjoint to the direct image functor f_*. In this section, we will discuss a closely related (but formally dual) feature of the sheaf $\omega_{X/Y}$: it can be used to construct a *left* adjoint to the pullback functor f^*.

Construction 6.4.5.1. Let $f : X \to Y$ be a morphism of functors $X, Y : \operatorname{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ which is representable, proper, locally almost of finite presentation, and locally of finite Tor-amplitude. We let $f_+ : \operatorname{QCoh}(X) \to \operatorname{QCoh}(Y)$ denote the functor given by the formula $f_+ \mathscr{F} = f_*(\omega_{X/Y} \otimes \mathscr{F})$. Let $v_0 : f_* \omega_{X/Y} = f_* f^! \mathscr{O}_Y \to \mathscr{O}_Y$ denote the counit for the adjunction between f_* and $f^!$. For each object $\mathscr{F} \in \operatorname{QCoh}(Y)$, v_0 induces a map

$$f_+ f^* \mathscr{F} = f_*(\omega_{X/Y} \otimes f^* \mathscr{F}) \simeq (f_* \omega_{X/Y}) \otimes \mathscr{F} \xrightarrow{\mathrm{id} \otimes v_0} \mathscr{F}.$$

This construction depends functorially on $\mathscr{F}$, and therefore determines a natural transformation of functors $f_+ f^* \to \mathrm{id}_{\operatorname{QCoh}(Y)}$.

Remark 6.4.5.2. Let $f : X \to Y$ be as in Construction 6.4.5.1. Then:

- (a) If $\mathscr{F} \in \operatorname{QCoh}(\mathsf{X})$ is locally of finite Tor-amplitude, then $f_+ \mathscr{F} \in \operatorname{QCoh}(Y)$ is locally of finite Tor-amplitude.

- (b) If $\mathscr{F} \in \operatorname{QCoh}(\mathsf{X})$ is almost perfect, then $f_+ \mathscr{F} \in \operatorname{QCoh}(Y)$ is almost perfect.

(c) If $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is perfect, then $f_+ \mathscr{F} \in \mathrm{QCoh}(Y)$ is perfect.

Assertion (a) follows from Proposition 6.4.4.1 and Theorem 5.6.0.2, assertion (b) follows from Warning 6.4.4.4, and assertion (c) is an immediate consequence of (a) and (b).

Proposition 6.4.5.3. *Let $f : X \to Y$ as in Construction 6.4.5.1. Then the natural transformation $v : f_+ f^* \to \mathrm{id}_{\mathrm{QCoh}(Y)}$ of Construction 6.4.5.1 exhibits the functor f_+ as a left adjoint of the functor f^*.*

Proof. Let $\mathscr{F} \in \mathrm{QCoh}(X)$ and $\mathscr{G} \in \mathrm{QCoh}(Y)$; we wish to show that the composite map

$$\rho_{\mathscr{F},\mathscr{G}} : \mathrm{Map}_{\mathrm{QCoh}(X)}(\mathscr{F}, f^* \mathscr{G}) \to \mathrm{Map}_{\mathrm{QCoh}(Y)}(f_+ \mathscr{F}, f_+ f^* \mathscr{G}) \xrightarrow{v} \mathrm{Map}_{\mathrm{QCoh}(Y)}(f_+ \mathscr{F}, \mathscr{G})$$

is a homotopy equivalence. Writing Y as a colimit of representable functors, we can reduce to the case where $Y = \mathrm{Spec}\, A$ is affine. In this case, X is representable by a spectral algebraic space X which is quasi-compact and quasi-separated. Applying Proposition 9.6.1.1, we can write $\mathscr{F}$ as the colimit of a filtered diagram $\{\mathscr{F}_\alpha\}$, where each $\mathscr{F}_\alpha \in \mathrm{QCoh}(\mathsf{X})$ is perfect (Proposition 9.6.1.1). It follows that $\rho_{\mathscr{F},\mathscr{G}}$ can be identified with the limit of the diagram $\{\rho_{\mathscr{F}_\alpha,\mathscr{G}}\}$. It will therefore suffice to show that each $\rho_{\mathscr{F}_\alpha,\mathscr{G}}$ is a homotopy equivalence. Replacing $\mathscr{F}$ by $\mathscr{F}_\alpha$, we may reduce to the case where $\mathscr{F}$ is perfect.

The assumption that $\mathscr{F}$ is perfect guarantees that $f_+ \mathscr{F}$ is also perfect (Remark 6.4.5.2). In this case, we can write $\rho_{\mathscr{F},\mathscr{G}} = \Omega^\infty \overline{\rho_{\mathscr{F},\mathscr{G}}}$, where $\overline{\rho}_{\mathscr{F},\mathscr{G}}$ denotes the map of spectra given by the composition

$$\Gamma(\mathsf{X}; \mathscr{F}^\vee \otimes f^* \mathscr{G}) \xrightarrow{\Gamma} (\mathsf{Y}; (f_+ \mathscr{F})^\vee \otimes (f_+ f^* \mathscr{G})) \xrightarrow{v} \Gamma(\mathrm{Sp\acute{e}t}\, A; (f_+ \mathscr{F})^\vee \otimes \mathscr{G}).$$

Let us regard $\mathscr{F}$ as fixed, and let $\mathcal{C}$ denote the full subcategory of $\mathrm{QCoh}(Y)$ spanned by those objects $\mathscr{G}$ for which the map $\overline{\rho}_{\mathscr{F},\mathscr{G}}$ is an equivalence. Then $\mathcal{C}$ is a stable subcategory of $\mathrm{QCoh}(Y)$. Our assumption that $\mathscr{F}$ is perfect guarantees that $f_+ \mathscr{F}$ is also perfect (Remark 6.4.5.2), so that the ∞-category $\mathcal{C}$ is closed under filtered colimits. Consequently, to show that $\mathcal{C} = \mathrm{QCoh}(Y)$, it will suffice to show that $\mathcal{C}$ contains the structure sheaf $\mathscr{O}_Y$ (by virtue of our assumption that Y is affine). We may therefore assume without loss of generality that $\mathscr{G} = \mathscr{O}_Y$. In this case, $\overline{\rho}_{\mathscr{F},\mathscr{G}}$ is a morphism of perfect A-modules, whose dual can be identified with a morphism $\psi : f_+ \mathscr{F} \to (f_* \mathscr{F}^\vee)^\vee$ in the ∞-category $\mathrm{QCoh}(Y)$. To complete the proof, it will suffice to show that for every object $\mathscr{H} \in \mathrm{QCoh}(Y)$, composition with ψ induces a homotopy equivalence $\psi_{\mathscr{H}} : \mathrm{Map}_{\mathrm{QCoh}(Y)}(\mathscr{H}, f_+ \mathscr{F}) \to \mathrm{Map}_{\mathrm{QCoh}(Y)}(\mathscr{H}, (f_* \mathscr{F}^\vee)^\vee)$. We now complete the proof by observing that $\psi_{\mathscr{H}}$ can be identified with the composition of homotopy equivalences

$$\begin{aligned}
\mathrm{Map}_{\mathrm{QCoh}(Y)}(\mathscr{H}, f_+ \mathscr{F}) &= \mathrm{Map}_{\mathrm{QCoh}(Y)}(\mathscr{H}, f_*(\omega_{X/Y} \otimes \mathscr{F})) \\
&\simeq \mathrm{Map}_{\mathrm{QCoh}(X)}(f^* \mathscr{H}, \omega_{X/Y} \otimes \mathscr{F}) \\
&\simeq \mathrm{Map}_{\mathrm{QCoh}(X)}((f^* \mathscr{H}) \otimes \mathscr{F}^\vee, \omega_{X/Y}) \\
&= \mathrm{Map}_{\mathrm{QCoh}(X)}((f^* \mathscr{H}) \otimes \mathscr{F}^\vee, f^! \mathscr{O}_Y) \\
&\simeq \mathrm{Map}_{\mathrm{QCoh}(Y)}(f_*(f^* \mathscr{H} \otimes \mathscr{F}^\vee), \mathscr{O}_Y) \\
&\simeq \mathrm{Map}_{\mathrm{QCoh}(Y)}(\mathscr{H} \otimes f_* \mathscr{F}^\vee, \mathscr{O}_Y) \\
&\simeq \mathrm{Map}_{\mathrm{QCoh}(Y)}(\mathscr{H}, (f_* \mathscr{F}^\vee)^\vee).
\end{aligned}$$

□

We now study the behavior of the functor f_+ with respect to base change. With an eye toward future applications, we work in a slightly different setting:

Proposition 6.4.5.4. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a map between quasi-compact, quasi-separated spectral algebraic spaces.*

(1) *Suppose that the pushforward functor f_* carries perfect objects of $\mathrm{QCoh}(\mathsf{X})$ to perfect objects of $\mathrm{QCoh}(\mathsf{Y})$. Then the pullback functor $f^* : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ admits a left adjoint $f_+ : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$, whose restriction to $\mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}$ is given by $f_+(\mathscr{F}) = (f_* \mathscr{F}^\vee)^\vee$.*

(2) *Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc}
\mathsf{X}' & \xrightarrow{g'} & \mathsf{X} \\
\downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\
\mathsf{Y}' & \xrightarrow{g} & \mathsf{Y},
\end{array}$$

where f and f' satisfy the assumptions of (1). Then the diagram of ∞-categories

$$\begin{array}{ccc}
\mathrm{QCoh}(\mathsf{Y}) & \xrightarrow{f^*} & \mathrm{QCoh}(\mathsf{X}) \\
\downarrow{\scriptstyle g^*} & & \downarrow{\scriptstyle g'^*} \\
\mathrm{QCoh}(\mathsf{Y}') & \xrightarrow{f'^*} & \mathrm{QCoh}(\mathsf{X}')
\end{array}$$

is left adjointable. In other words, the canonical natural transformation $f'_+ \circ g'^* \to g^* \circ f_+$ is an equivalence of functors from $\mathrm{QCoh}(\mathsf{X})$ to $\mathrm{QCoh}(\mathsf{Y}')$.

Remark 6.4.5.5. The hypotheses of Proposition 6.4.5.4 are satisfied when f is proper, locally almost of finite presentation, and locally of finite Tor-amplitude (Theorem 6.1.3.2); in this case, Proposition 6.4.5.3 guarantees that the functor f_+ appearing in Proposition 6.4.5.4 agrees with the functor appearing in Construction 6.4.5.1. We will later see that the converse holds under some mild additional hypotheses (see Theorem 11.1.4.1); our proof of this will make use of Proposition 6.4.5.4.

Proof of Proposition 6.4.5.4. We first prove (1). The collection of those objects $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ for which the functor $\mathscr{G} \mapsto \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, f^* \mathscr{G})$ is corepresentable by an object of $\mathrm{QCoh}(\mathsf{Y})$ is closed under small colimits in $\mathrm{QCoh}(\mathsf{X})$. Consequently, to verify the existence of f_+, it will suffice to show prove the corepresentability in the case where $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is perfect. In this case, we have canonical homotopy equivalences

$$\begin{aligned} \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, f^* \mathscr{G}) &\simeq \Omega^\infty \Gamma(\mathsf{X}; \mathscr{F}^\vee \otimes f^* \mathscr{G}) \\ &\simeq \Omega^\infty \Gamma(\mathsf{Y}; f_*(\mathscr{F}^\vee \otimes f^* \mathscr{G})) \\ &\simeq \Omega^\infty \Gamma(\mathsf{Y}; (f_* \mathscr{F}^\vee) \otimes \mathscr{G}) \\ &\simeq \mathrm{Map}_{\mathrm{QCoh}(\mathsf{Y})}((f_* \mathscr{F}^\vee)^\vee, \mathscr{G}). \end{aligned}$$

We now prove (2). Since the functors f_+, f'_+, g'^*, and g^* preserve filtered colimits, it suffices to show that the base change map $f'_+ g'^* \mathscr{F} \to g^* f_+ \mathscr{F}$ is an equivalence when $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is perfect, in which case the desired result follows immediately from the description of f_+ and f'_+ on compact objects. □

Remark 6.4.5.6. Let R be a connective $\mathbb{E}_\infty$-ring, let $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ exhibit X as a quasi-compact quasi-separated spectral algebraic space over R, and suppose that the pushforward functor f_* carries $\mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}$ into $\mathrm{Mod}_R^{\mathrm{perf}}$. Regard $\mathrm{QCoh}(\mathsf{X})$ as tensored over the ∞-category Mod_R. For every object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ and every R-module M, we have a canonical map

$$\gamma_M : f_+(M \otimes_R \mathscr{F}) \to f_+(M \otimes_R (f^* f_+ \mathscr{F})) \simeq f_+ f^*(M \otimes_R f_+ \mathscr{F}) \to M \otimes_R f_+ \mathscr{F}.$$

The map γ_M is clearly an equivalence when $M = R$. As functors of M, both sides are exact and preserve small colimits. It follows that γ_M is an equivalence for all $M \in \mathrm{Mod}_R$.

Remark 6.4.5.7. Suppose we are given a pullback diagram

$$\begin{array}{ccc} \mathsf{X}' & \xrightarrow{g'} & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathrm{Sp\acute{e}t}\, R' & \xrightarrow{g} & \mathrm{Sp\acute{e}t}\, R, \end{array}$$

where the pushforward functors preserve perfect objects. Proposition 6.4.5.4 supplies an equivalence $g^* f_+ \simeq f'_+ g'^*$, which is adjoint to a natural transformation $\alpha : f_+ g'_* \to g_* f'_+$. We claim that the natural transformation α is also an equivalence. To prove this, we first observe that the collection of objects $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X}')$ such that α induces an equivalence $\alpha_{\mathscr{F}} : f_+ g'_* \mathscr{F} \to g_* f'_+ \mathscr{F}$ is closed under small colimits in $\mathrm{QCoh}(\mathsf{X}')$. Since $\mathrm{QCoh}(\mathsf{X}') \simeq \mathrm{Mod}_{R'}(\mathrm{QCoh}(\mathsf{X}))$ is generated under small colimits by the essential image of the pullback functor g'^*, it will suffice to show that $\alpha_{\mathscr{F}}$ is an equivalence when $\mathscr{F} = g'^* \mathscr{G}$, for some $\mathscr{G} \in \mathsf{X}$. In this case, we can use Proposition 6.4.5.4 to identify $\alpha_{\mathscr{F}}$ with the canonical map

$$f_+(R' \otimes_R \mathscr{F}) \simeq f_+(g'_* g'^* \mathscr{F}) \to g_* g^* f_+ \mathscr{F} \simeq R' \otimes_R f_+ \mathscr{F},$$

appearing in Remark 6.4.5.6.

6.5 Digression: Injective Dimension of Quasi-Coherent Sheaves

Our goal in this section is to review some general facts about injective dimension of quasi-coherent sheaves on Noetherian spectral algebraic spaces which will be needed for our discussion of absolute dualizing sheaves in §6.6.

6.5.1 Injective Dimension

We begin by introducing some terminology.

Definition 6.5.1.1. Let $\mathcal{C}$ be a presentable stable ∞-category equipped with a t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ which is right complete and compatible with filtered colimits. Let n be an integer. We will say that an object $C \in \mathcal{C}$ has *injective dimension* $\leqslant n$ if, for every object $D \in \mathcal{C}^{\heartsuit}$, the abelian groups $\mathrm{Ext}^i_{\mathcal{C}}(D, C)$ vanish for $i > n$.

Example 6.5.1.2. Let $\mathcal{C}$ be as in Definition 6.5.1.1. Then an object $C \in \mathcal{C}$ is injective (in the sense of Definition C.5.7.2) if and only if it belongs to $\mathcal{C}_{\leqslant 0}$ and has injective dimension $\leqslant 0$.

Remark 6.5.1.3. Let $\mathcal{C}$ be as in Definition 6.5.1.1. Then an object $C \in \mathcal{C}$ has injective dimension $\leqslant n$ if and only if the suspension $\Sigma^k C$ has injective dimension $\leqslant n - k$.

Remark 6.5.1.4. Let $\mathcal{C}$ be as in Definition 6.5.1.1 and suppose we are given a fiber sequence $C' \to C \to C''$ in $\mathcal{C}$. Using the exactness of the sequence $\mathrm{Ext}^i_{\mathcal{C}}(\bullet, C') \to \mathrm{Ext}^i_{\mathcal{C}}(\bullet, C) \to \mathrm{Ext}^i_{\mathcal{C}}(\bullet, C'')$, we deduce the following:

- If C' and C'' have injective dimension $\leqslant n$, then C has injective dimension $\leqslant n$.

Combining this observation with Remark 6.5.1.3, we also have:

- If C has injective dimension $\leqslant n$ and C'' has injective dimension $\leqslant n-1$, then C' has injective dimension $\leqslant n$.
- If C has injective dimension $\leqslant n$ and C' has injective dimension $\leqslant n+1$, then C'' has injective dimension $\leqslant n$.

Remark 6.5.1.5. Let $\mathcal{C}$ be as in Definition 6.5.1.1 and let C be an object of $\mathcal{C}$. Then C has injective dimension $\leqslant n$ if and only if the following condition is satisfied:

$(*)$ For every object $D \in \mathcal{C}_{\leqslant m}$, the groups $\mathrm{Ext}^i_{\mathcal{C}}(D, C)$ vanish for $i > n + m$.

The "if" direction is obvious. To prove the converse, we may assume (replacing C by a suspension if necessary) that $i \leqslant 0$. Assume that C has injective dimension $\leqslant n$ and that $D \in \mathcal{C}_{\leqslant m}$; we will show that the mapping pace $\mathrm{Map}_{\mathcal{C}}(D, C)$ is $(-m-n)$-connective. Since the t-structure on $\mathcal{C}$ is right complete, we can identify $\mathrm{Map}_{\mathcal{C}}(D, C)$ with the limit of a tower of spaces $\{\mathrm{Map}_{\mathcal{C}}(\tau_{\geqslant k} D, C)\}_{k \in \mathbf{Z}}$. Note that when $k > m$, the truncation $\tau_{\geqslant k} D$ vanishes, so the space $\mathrm{Map}_{\mathcal{C}}(\tau_{\geqslant k} D, C)$ is contractible. It will therefore suffice to show that for $k \leqslant m$, the transition map $\rho : \mathrm{Map}_{\mathcal{C}}(\tau_{\geqslant k} D, C) \to \mathrm{Map}_{\mathcal{C}}(\tau_{\geqslant k+1} D, C)$ has $(-m-n)$-connective homotopy fibers. This is clear, since each nonempty homotopy fiber of ρ is equivalent to $\mathrm{Map}_{\mathcal{C}}(\Sigma^k(\pi_k D), C)$, whose sth homotopy group is given by $\mathrm{Ext}^{-s-k}_{\mathcal{C}}(\pi_{-k} D, C)$ and therefore vanishes for $s < -m-n \leqslant -k-n$ (by virtue of our assumption that C has injective dimension $\leqslant n$).

Example 6.5.1.6. Let $\mathcal{C}$ be as in Definition 6.5.1.1, let $C \in \mathcal{C}$ be an object, and suppose we are given a morphism $u : C \to Q$ where $Q \in \mathcal{C}$ is injective. Using Remark 6.5.1.4, we deduce that if $n > 0$, then C has injective dimension $\leqslant n$ if and only if $\mathrm{cofib}(u)$ has injective dimension $\leqslant n-1$.

6.5.2 The Case of $\mathrm{QCoh}(\mathsf{X})$

We will be primarily interested in studying the notion of injective dimension for truncated objects $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$, where X is a spectral algebraic space. To ensure that this notion is well-behaved, we will need some mild assumptions.

Definition 6.5.2.1. Let X be a spectral algebraic space. We will say that X is *Noetherian* if it is locally Noetherian (Definition 2.8.1.4), quasi-compact, and quasi-separated.

Proposition 6.5.2.2. *Let $f : \mathsf{X} \to \mathsf{Y}$ be an étale morphism between Noetherian spectral algebraic spaces and let $\mathscr{F}$ be a truncated object of* $\mathrm{QCoh}(\mathsf{Y})$*. Then:*

(a) If $\mathscr{F}$ has injective dimension $\leqslant n$, then $f^* \mathscr{F}$ has injective dimension $\leqslant n$.

(b) *If f is surjective and $f^* \mathscr{F}$ has injective dimension $\leqslant n$, then $\mathscr{F}$ has injective dimension $\leqslant n$.*

Proof. Replacing $\mathscr{F}$ by a suitable suspension $\Sigma^k(\mathscr{F})$ (and replacing n by $n-k$), we may assume that $\mathscr{F}$ belongs to $\mathrm{QCoh}(\mathsf{Y})_{\leqslant 0}$. Note that if $n < 0$, then $\mathscr{F}$ has injective dimension $\leqslant n$ if and only if $\mathscr{F} \simeq 0$ (and similarly for $f^* \mathscr{F}$), so that assertions (a) and (b) are obvious. The proof in general proceeds by induction on n. In the case $n = 0$, the desired result follows from Theorem 10.5.3.4, Remark 10.5.3.3, and Example 6.5.1.2. Suppose that $n > 0$, and choose a morphism $u : \mathscr{F} \to \mathscr{G}$ in $\mathrm{QCoh}(\mathsf{Y})$ which exhibits $\mathscr{G}$ as an injective hull of $\mathscr{F}$ (see Example C.5.7.9). Then $f^* \mathscr{G} \in \mathrm{QCoh}(\mathsf{X})$ is injective (by virtue of our inductive hypothesis). Our inductive hypothesis also implies that if $\mathrm{cofib}(u)$ has injective dimension $\leqslant n-1$, then $f^* \mathrm{cofib}(u)$ has injective dimension $\leqslant n-1$; moreover, the converse holds if f is surjective. The desired result now follows from Example 6.5.1.6. □

Remark 6.5.2.3. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is proper and locally almost of finite presentation and let $f^! : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ be the exceptional inverse image functor of Definition 6.4.0.1. If $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})$ has injective dimension $\leqslant n$, then $f^! \mathscr{F}$ in $\mathrm{QCoh}(\mathsf{X})$ has injective dimension $\leqslant n$: this follows immediately from the characterization of injective dimension supplied by Remark 6.5.1.5 (and the left t-exactness of the direct image functor f_*).

Using Proposition 6.5.2.2, we can often reduce questions about the injective dimension of sheaves $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ to the case where X is affine. In this case, the following observation is convenient:

Proposition 6.5.2.4. *Let A be a Noetherian $\mathbb{E}_\infty$-ring, let K be a truncated A-module, and let n be an integer. The following conditions are equivalent:*

(a) *The A-module K has injective dimension $\leqslant n$.*

(b) *For every prime ideal $\mathfrak{p} \subseteq \pi_0 A$, the groups $\mathrm{Ext}^i_A((\pi_0 A)/\mathfrak{p}, K)$ vanish for $i > n$.*

Proof. The implication (a) ⇒ (b) is immediate. To prove the converse, we may replace K by a suitable desuspension to reduce to the case where $K \in (\mathrm{Mod}_A)_{\leqslant 0}$. In this case, we proceed by induction on n. We first treat the case $n = 0$. Suppose that condition (b) is satisfied, and let $M \in \mathrm{Mod}_A^{\heartsuit}$ be finitely generated as a module over $\pi_0 A$. Then M admits a finite filtration by $(\pi_0 A)$-modules of the form $(\pi_0 A)/\mathfrak{p}$, so condition (b) implies that $\mathrm{Ext}^i_A(M, K) \simeq 0$ for $i > 0$. Applying Proposition C.6.10.1, we deduce that K is an injective object of Mod_A.

Now suppose that $n > 0$. Choose a map $\alpha : K \to Q$ which exhibits Q as an injective hull of K (Example C.5.7.9). For every prime ideal $\mathfrak{p} \subseteq \pi_0 A$, we have short exact sequences

$$\mathrm{Ext}^i_A((\pi_0 A)/\mathfrak{p}, Q) \to \mathrm{Ext}^i_A((\pi_0 A)/\mathfrak{p}, \mathrm{cofib}(\alpha)) \to \mathrm{Ext}^{i+1}_A((\pi_0 A)/\mathfrak{p}, M).$$

It follows from assumption (b) that the groups $\mathrm{Ext}^i_A((\pi_0 A)/\mathfrak{p}, \mathrm{cofib}(\alpha))$ vanish for $i \geqslant n$. Applying our inductive hypothesis, we deduce that $\mathrm{cofib}(\alpha)$ has injective dimension $\leqslant n-1$. Using the fiber sequence $K \to Q \to \mathrm{cofib}(\alpha)$, we conclude that K has injective dimension $\leqslant n$. □

Proposition 6.5.2.5. *Let X be a Noetherian spectral algebraic space and let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$. If $\mathscr{F}$ is truncated and of injective dimension $\leqslant m$ and $\mathscr{O}_{\mathsf{X}}$ is n-truncated, then $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})_{\geqslant -m-n}$.*

Proof. Replacing $\mathscr{F}$ by a suitable desuspension, we may assume that $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})_{\leqslant 0}$. We now proceed by induction on m. Suppose first that $m = 0$: that is, $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is injective; we wish to prove that $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})_{\geqslant -n}$. By virtue of Proposition 6.5.2.2, this assertion can be tested locally on X. We may therefore assume without loss of generality that $\mathsf{X} = \mathrm{Sp\acute{e}t}\, A$ for some n-truncated Noetherian $\mathbb{E}_\infty$-ring. In this case, the Grothendieck prestable ∞-category $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \simeq \mathrm{Mod}_A^{\mathrm{cn}}$ is n-complicial (Example C.5.3.5), so that $\mathscr{F}$ is $(-n)$-connective by virtue of Proposition C.5.7.11.

We now carry out the inductive step. Assume that $m > 0$ and that $\mathscr{F}$ has injective dimension $\leqslant m$. Let $\alpha : \mathscr{F} \to \mathscr{G}$ be a morphism in $\mathrm{QCoh}(\mathsf{X})_{\leqslant 0}$ which exhibits $\mathscr{G}$ as an injective hull of $\mathscr{F}$ (Example C.5.7.9). Then $\mathrm{cofib}(\alpha)$ has injective dimension $\leqslant m-1$. Applying our inductive hypothesis, we deduce that $\mathscr{G}$ and $\mathrm{cofib}(\alpha)$ belong to $\mathrm{QCoh}(\mathsf{X})_{\geqslant 1-m-n}$. The fiber sequence $\mathscr{F} \to \mathscr{G} \to \mathrm{cofib}(\alpha)$ then shows that $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})_{\geqslant -m-n}$, as desired. □

6.5.3 Internal Mapping Sheaves

Let $(\mathcal{X}, \mathscr{O})$ be a spectrally ringed ∞-topos. Then the symmetric monoidal ∞-category $\mathrm{Mod}_{\mathscr{O}}$ is closed: that is, for every pair of objects $\mathscr{F}, \mathscr{G} \in \mathrm{Mod}_{\mathscr{O}}$, there exists an object $\underline{\mathrm{Map}}_{\mathscr{O}}(\mathscr{F}, \mathscr{G}) \in \mathrm{Mod}_{\mathscr{O}}$ with the following universal property: for every object $\mathscr{E} \in \mathrm{Mod}_{\mathscr{O}}$, there is a canonical homotopy equivalence

$$\mathrm{Map}_{\mathrm{Mod}_{\mathscr{O}}}(\mathscr{E}, \underline{\mathrm{Map}}_{\mathscr{O}}(\mathscr{F}, \mathscr{G})) \simeq \mathrm{Map}_{\mathrm{Mod}_{\mathscr{O}}}(\mathscr{E} \otimes_{\mathscr{O}} \mathscr{F}, \mathscr{G}).$$

We now discuss some circumstances in which the construction $(\mathscr{F}, \mathscr{G}) \mapsto \underline{\mathrm{Map}}_{\mathscr{O}}(\mathscr{F}, \mathscr{G})$ preserves quasi-coherence, in the case where X is a spectral Deligne-Mumford stack. We begin with some general observations.

Remark 6.5.3.1. Let $(\mathcal{X}, \mathscr{O})$ be a spectrally ringed ∞-topos and let $\mathscr{F}, \mathscr{G} \in \mathrm{Mod}_{\mathscr{O}}$. For each $U \in \mathcal{X}$, we have a canonical homotopy equivalence $\Omega^\infty \underline{\mathrm{Map}}_{\mathscr{O}}(\mathscr{F}, \mathscr{G})(U) \simeq \mathrm{Map}_{\mathrm{Mod}_{\mathscr{O}|_U}}(\mathscr{F}|_U, \mathscr{G}|_U)$ (this follows immediately from the universal property of $\underline{\mathrm{Map}}_{\mathscr{O}}(\mathscr{F}, \mathscr{G})$, applied in the special case where $\mathscr{E}$ is the the image of $\mathscr{O}|_U$ under the left adjoint to the restriction functor $\mathrm{Mod}_{\mathscr{O}} \to \mathrm{Mod}_{\mathscr{O}|_U}$).

Variant 6.5.3.2. If A is an $\mathbb{E}_\infty$-ring, then the symmetric monoidal ∞-category Mod_A is closed. Given objects $M, N \in \mathrm{Mod}_A$ we let $\underline{\mathrm{Map}}_A(M,N) \in \mathrm{Mod}_A$ denote a classifying object for morphisms from M to N in the ∞-category Mod_A: that is, $\underline{\mathrm{Map}}_A(M,N)$ is an A-module with the following universal property: there exists a map $e : \underline{\mathrm{Map}}_A(M,N) \otimes_A M \to N$ such that, for every A-module M', composition with e induces a homotopy equivalence $\mathrm{Map}_{\mathrm{Mod}_A}(M', \underline{\mathrm{Map}}_A(M,N)) \to \mathrm{Map}_{\mathrm{Mod}_A}(M' \otimes_A M, N)$. Note that this is really a special case of the construction $(\mathscr{F}, \mathscr{G}) \mapsto \underline{\mathrm{Map}}_{\mathscr{O}}(\mathscr{F}, \mathscr{G})$, where we take the ∞-topos $\mathcal{X}$ to be the ∞-category $\mathcal{S}$ of spaces.

Example 6.5.3.3. Let $(\mathcal{X}, \mathscr{O})$ be a spectrally ringed ∞-topos and let $A = \Gamma(\mathcal{X}; \mathscr{O})$ be the $\mathbb{E}_\infty$-ring of global sections of $\mathscr{O}$. For every pair of objects $\mathscr{F}, \mathscr{G} \in \mathrm{Mod}_{\mathscr{O}}$, the global sections functor $\Gamma(\mathcal{X}; \bullet) : \mathrm{Mod}_{\mathscr{O}} \mapsto \mathrm{Mod}_A$ induces a map

$$\theta_{\mathscr{F},\mathscr{G}} : \Gamma(\mathcal{X}; \underline{\mathrm{Map}}_{\mathscr{O}}(\mathscr{F}, \mathscr{G})) \mapsto \underline{\mathrm{Map}}_A(\Gamma(\mathcal{X}; \mathscr{F}), \Gamma(\mathcal{X}; \mathscr{G})).$$

The map $\theta_{\mathscr{F},\mathscr{G}}$ is an equivalence in either of the following cases:

(a) The sheaf $\mathscr{F}$ coincides with $\mathscr{O}$.

(b) The pair $\mathsf{X} = (\mathcal{X}, \mathscr{O})$ is an affine spectral Deligne-Mumford stack and the sheaf $\mathscr{F}$ is quasi-coherent.

Assertion (a) follows easily from Remark 6.5.3.1. To prove (b), we observe that for fixed $\mathscr{G}$, the construction $\mathscr{F} \mapsto \theta_{\mathscr{F},\mathscr{G}}$ carries colimits in $\mathrm{Mod}_{\mathscr{O}}$ to limits in $\mathrm{Fun}(\Delta^1, \mathrm{Mod}_A)$. Consequently, the objects $\mathscr{F} \in \mathrm{Mod}_{\mathscr{O}}$ for which the morphism $\theta_{\mathscr{F},\mathscr{G}}$ is an equivalence span a stable subcategory of $\mathrm{Mod}_{\mathscr{O}}$ which is closed under colimits. This subcategory contains $\mathscr{O}$ by (a), and therefore contains all quasi-coherent sheaves on X.

Remark 6.5.3.4. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O})$ be a spectral Deligne-Mumford stack and let $\mathscr{F}, \mathscr{G} \in \mathrm{Mod}_{\mathscr{O}}$. Assume that $\mathscr{F}$ is quasi-coherent. Combining Proposition 2.2.4.3 with Example 6.5.3.3, we deduce that $\underline{\mathrm{Map}}_{\mathscr{O}}(\mathscr{F}, \mathscr{G})$ is quasi-coherent if and only if the following condition is satisfied:

($*$) For every morphism $U \to V$ in $\mathcal{X}$, where U and V are affine, the natural map

$$\mathscr{O}(U) \otimes_{\mathscr{O}(V)} \underline{\mathrm{Map}}_{\mathscr{O}(V)}(\mathscr{F}(V), \mathscr{G}(V)) \to \underline{\mathrm{Map}}_{\mathscr{O}(U)}(\mathscr{F}(U), \mathscr{G}(U))$$

is an equivalence of $\mathscr{O}(U)$-modules.

If $\mathscr{G}$ is also quasi-coherent, then we can rephrase ($*$) as follows:

($*'$) For every morphism $U \to V$ in $\mathcal{X}$, where U and V are affine, the natural map

$$\mathscr{O}(U) \otimes_{\mathscr{O}(U)} \underline{\mathrm{Map}}_{\mathscr{O}(V)}(\mathscr{F}(V), \mathscr{G}(V)) \to \underline{\mathrm{Map}}_{\mathscr{O}(V)}(\mathscr{F}(V), \mathscr{O}(U) \otimes_{\mathscr{O}(V)} \mathscr{G}(V))$$

is an equivalence of $\mathscr{O}(U)$-modules.

Proposition 6.5.3.5. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a proper morphism between Noetherian spectral Deligne-Mumford stacks. Then the direct image functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ carries $\mathrm{Coh}(\mathsf{X})$ into $\mathrm{Coh}(\mathsf{Y})$.*

Proof. We first note that f is locally almost of finite presentation (Remark 4.2.0.4). We wish to show that for every integer n, the truncation $\tau_{\geqslant n} f_* \mathscr{F}$ is almost perfect. Using Corollary 3.4.2.3, we can replace $\mathscr{F}$ by $\tau_{\geqslant -m} \mathscr{F}$ for some $m \gg 0$. In this case, $\mathscr{F}$ is almost perfect, so that $f_* \mathscr{F}$ is also almost perfect (Theorem 5.6.0.2). Since Y is locally Noetherian, it follows that the truncation $\tau_{\geqslant n} f_* \mathscr{F}$ is also almost perfect. □

Proposition 6.5.3.6. *Let $\mathsf{X} = (\mathcal{X}, \mathcal{O})$ be a spectral Deligne-Mumford stack and let $\mathscr{F}, \mathscr{G} \in \mathrm{QCoh}(\mathsf{X})$. Then $\underline{\mathrm{Map}}_{\mathscr{O}}(\mathscr{F}, \mathscr{G})$ is quasi-coherent under any of the following additional assumptions:*

(a) The quasi-coherent sheaf $\mathscr{F}$ is perfect.

(b) The quasi-coherent sheaf $\mathscr{F}$ is almost perfect and $\mathscr{G}$ is truncated.

(c) The spectral Deligne-Mumford stack X is a Noetherian spectral algebraic space, each truncation $\tau_{\geqslant -n} \mathscr{F}$ is almost perfect, and $\mathscr{G}$ is truncated and of finite injective dimension.

The proof of Proposition 6.5.3.6 rests on the following:

Lemma 6.5.3.7. *Let A be a connective $\mathbb{E}_\infty$-ring, and suppose we are given modules $M, N, P \in \mathrm{Mod}_A$. Assume that M is almost perfect, that N is truncated, and that P has finite* Tor*-amplitude. Then the canonical map*

$$\theta_M : P \otimes_A \underline{\mathrm{Map}}_A(M, N) \to \underline{\mathrm{Map}}_A(M, P \otimes_A N)$$

is an equivalence.

Proof. Replacing N and P by suitable suspensions, we may assume without loss of generality that that N is 0-truncated and that P has Tor-amplitude $\leqslant 0$. Fix an integer n. Since M is almost perfect, we can choose a fiber sequence $M' \to M \to M''$ where M' is perfect and M'' is n-connective (Corollary 2.7.2.2). We then have a fiber sequence of A-modules $\mathrm{fib}(\theta_{M''}) \xrightarrow{\alpha} \mathrm{fib}(\theta_M) \to \mathrm{fib}(\theta_{M'})$. Since M' is perfect, the map $\theta_{M'}$ is an equivalence. It follows that $\mathrm{fib}(\theta_{M'}) \simeq 0$ and therefore α is an equivalence. Since N is 0-truncated and P has Tor-amplitude $\leqslant 0$, the tensor product $P \otimes_A N$ is also 0-truncated. Applying Remark 9.5.3.1, we deduce that $\underline{\mathrm{Map}}_A(M'', N)$ and $\underline{\mathrm{Map}}_A(M'', P \otimes_A N)$ are $(-n)$-truncated. Using our assumption that P has Tor-amplitude $\leqslant 0$, we conclude that $P \otimes_A \underline{\mathrm{Map}}_A(M'', N)$ is $(-n)$-truncated. The map $\theta_{M''}$ has $(-n)$-truncated domain and codomain, so that $\mathrm{fib}(\theta_{M''})$ is also $(-n)$-truncated. Since α is an equivalence, it follows that $\mathrm{fib}(\theta_M)$ is $(-n)$-truncated. Since n is arbitrary, we conclude that $\mathrm{fib}(\theta_M) \simeq 0$, so that θ_M is an equivalence as desired. □

Proof of Proposition 6.5.3.6. Let $\mathsf{X} = (\mathcal{X}, \mathcal{O})$ be a spectral Deligne-Mumford stack and let $\mathscr{F}, \mathscr{G} \in \mathrm{QCoh}(\mathsf{X})$. We will show that if any of the conditions (a), (b), or (c) is satisfied, then the pair $(\mathscr{F}, \mathscr{G})$ satisfies hypothesis $(*')$ of Remark 6.5.3.4. Fix a morphism $U \to V$ between affine objects of $\mathcal{X}$, so that we have equivalences $(\mathcal{X}_{/V}, \mathcal{O}|_V) \simeq \operatorname{Sp\acute{e}t} A$ and $(\mathcal{X}_{/U}, \mathcal{O}|_U) \simeq \operatorname{Sp\acute{e}t} B$ for some $\mathbb{E}_\infty$-rings A and B. Set $M = \mathscr{F}(V)$ and $N = \mathscr{G}(V)$; we wish to show that the canonical map $\rho : B \otimes_A \underline{\mathrm{Map}}_A(M, N) \to \underline{\mathrm{Map}}_A(M, B \otimes_A N)$ is an equivalence. This is trivial in case (a), and follows from Proposition 6.5.3.6 in case (b). To handle case (c), we may assume without loss of generality that $\mathscr{G}$ has injective dimension $\leqslant 0$. Using Proposition 6.5.2.2, we deduce that N has injective dimension $\leqslant 0$ as an object of the ∞-category Mod_A and that $B \otimes_A N$ has injective dimension $\leqslant 0$ as an object of the ∞-category Mod_B (hence also as an object of the ∞-category Mod_A, since B is flat over A). For each integer n, we have a commutative diagram

$$\begin{array}{ccc} B \otimes_A \underline{\mathrm{Map}}_A(M, N) & \xrightarrow{\rho} & \underline{\mathrm{Map}}_A(M, B \otimes_A N) \\ & & \downarrow \\ B \otimes_A \underline{\mathrm{Map}}_A(\tau_{\geqslant -n} M, N) & \xrightarrow{\rho'} & \underline{\mathrm{Map}}_A(\tau_{\geqslant -n} M, B \otimes_A N). \end{array}$$

The map ρ' is an equivalence by virtue of (b), and the vertical maps induce isomorphisms on π_n. It follows that ρ induces an isomorphism $\pi_n(B \otimes_A \underline{\mathrm{Map}}_A(M, N)) \to \pi_n(\underline{\mathrm{Map}}_A(M, B \otimes_A N))$. Since n was arbitrary, the morphism ρ is an equivalence as desired. □

Remark 6.5.3.8. Let $\mathsf{X} = (\mathcal{X}, \mathcal{O})$ be a spectral Deligne-Mumford stack. Then $\mathrm{QCoh}(\mathsf{X})$ is a presentable ∞-category and the tensor product $\otimes : \mathrm{QCoh}(\mathsf{X}) \times \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{X})$ preserves small colimits separately in each variable. It follows that the symmetric monoidal structure on $\mathrm{QCoh}(\mathsf{X})$ is closed: that is, for every pair of objects $\mathscr{F}, \mathscr{G} \in \mathrm{QCoh}(\mathsf{X})$, there exists an object $\underline{\mathrm{Map}}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, \mathscr{G}) \in \mathrm{QCoh}(\mathsf{X})$ with the following universal property: for every *quasi-coherent* sheaf $\mathscr{E} \in \mathrm{QCoh}(\mathsf{X})$, there is a canonical homotopy equivalence $\mathrm{Map}_{\mathrm{Mod}_\mathcal{O}}(\mathscr{E}, \underline{\mathrm{Map}}_\mathcal{O}(\mathscr{F}, \mathscr{G})) \simeq \mathrm{Map}_{\mathrm{Mod}_\mathcal{O}}(\mathscr{E} \otimes_\mathcal{O} \mathscr{F}, \mathscr{G})$. It follows immediately from the definitions that there is a canonical map $\theta : \underline{\mathrm{Map}}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, \mathscr{G}) \to \underline{\mathrm{Map}}_\mathcal{O}(\mathscr{F}, \mathscr{G})$, which exhibits $\underline{\mathrm{Map}}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, \mathscr{G})$ as universal among quasi-coherent sheaves $\mathscr{E}$ equipped with a map $\mathscr{E} \to \underline{\mathrm{Map}}_\mathcal{O}(\mathscr{F}, \mathscr{G})$. In particular, the morphism θ is an equivalence if and only if $\underline{\mathrm{Map}}_\mathcal{O}(\mathscr{F}, \mathscr{G})$ is quasi-coherent. Beware that if θ is not an equivalence, then $\underline{\mathrm{Map}}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, \mathscr{G})$ is badly behaved in general: for example, it need not be compatible with étale base change.

6.5.4 !-Fibers and Injective Dimension

For later use, we record a facts about the relationship between the Krull dimension of Noetherian spectral algebraic space X and the injective dimension of coherent sheaves on X.

Notation 6.5.4.1. Let X be a Noetherian spectral algebraic space, let x be a point of the underlying topological space $|\mathsf{X}|$. Let $\kappa(x)$ denote the residue field of X at the point x and let $\mathsf{X}_0 \subseteq \mathsf{X}$ be the schematic image of the associated map $i : \operatorname{Sp\acute{e}t} \kappa(x) \to |\mathsf{X}|$ (that is, the reduced closed subspace of X corresponding to the closed subset $\overline{\{x\}} \subseteq |\mathsf{X}|$), so that the map i factors as a composition $\operatorname{Sp\acute{e}t} \kappa(x) \xrightarrow{i'} \mathsf{X}_0 \xrightarrow{i''} \mathsf{X}$. If $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})_{\mathrm{ltr}}$, we let $\mathscr{F}^!_x$ denote the image of $\mathscr{F}$ under the composite functor

$$\mathrm{QCoh}(\mathsf{X}) \xrightarrow{i''^!} \mathrm{QCoh}(\mathsf{X}_0) \xrightarrow{i'^*} \mathrm{QCoh}(\operatorname{Sp\acute{e}t} \kappa(x)) \simeq \mathrm{Mod}_{\kappa(x)} .$$

We will refer to $\mathscr{F}^!_x$ as the *!-fiber of $\mathscr{F}$ at the point x*. In the special case where $\mathscr{F} = \mathscr{O}_{\mathsf{X}}$, we will denote $\mathscr{F}^!_x$ by $\mathscr{O}^!_{X,x}$.

Our next result summarizes some of the formal properties of the formation of !-fibers:

Proposition 6.5.4.2. *Let X be a Noetherian spectral algebraic space, let $x \in |\mathsf{X}|$, and let $U : \mathrm{QCoh}(\mathsf{X})_{\mathrm{ltr}} \to \mathrm{Mod}_\kappa$ be the functor given by $\mathscr{F} \mapsto \mathscr{F}^!_x$. Then:*

(1) *The functor U commutes with filtered colimits when restricted to $\mathrm{QCoh}(\mathsf{X})_{\leqslant 0}$.*

(2) *The functor U is left t-exact.*

(3) *If $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})_{\mathrm{ltr}}$ is coherent, then $\mathscr{F}^!_x$ is coherent: that is, each homotopy group $\pi_i \mathscr{F}^!_x$ is finite-dimensional when regarded as a vector space over $\kappa(x)$.*

Proof. Assertion (1) follows from Proposition 6.4.1.4, assertion (2) follows from the observation that the map $i' : \operatorname{Sp\acute{e}t} \kappa(x) \to \mathsf{X}_0$ appearing in Notation 6.5.4.1 is flat, and assertion (3) follows from Proposition 6.4.3.4. □

Remark 6.5.4.3. Let X be a Noetherian spectral algebraic space, let $x \in |\mathsf{X}|$, and let $\mathscr{F}, \mathscr{G} \in \mathrm{QCoh}(\mathsf{X})$. If $\mathscr{F}$ is truncated and $\mathscr{G}$ has finite Tor-amplitude, then Corollary 6.4.1.9 supplies a canonical equivalence $\mathscr{F}^!_x \otimes_{\kappa(x)} \mathscr{G}_x \simeq (\mathscr{F} \otimes \mathscr{G})^!_x$, where $\mathscr{G}_x$ denotes the fiber of $\mathscr{G}$ at x (that is, the image of $\mathscr{G}$ under the pullback functor $\mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\operatorname{Sp\acute{e}t} \kappa(x)) \simeq \mathrm{Mod}_{\kappa(x)}$).

Remark 6.5.4.4. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism between Noetherian spectral algebraic spaces which is locally of finite Tor-amplitude. Let x be a point of $|\mathsf{X}|$, let $y = f(x)$ be the image of x in $|\mathsf{Y}|$, and let X_y denote the fiber product $\mathsf{X} \times_{\mathsf{Y}} \operatorname{Sp\acute{e}t} \kappa(y)$. Then, for every object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})_{\mathrm{ltr}}$, we have a canonical equivalence $(f^* \mathscr{F})^!_x \simeq \mathscr{F}^!_y \otimes_{\kappa(y)} \mathscr{O}^!_{\mathsf{X}_y, x}$ in $\mathrm{Mod}_{\kappa(x)}$. This follows by applying Proposition 6.4.1.4 to the upper square and bottom right square of the commutative diagram

$$\begin{array}{ccccc}
\operatorname{Sp\acute{e}t}\kappa(x) & \longrightarrow & \mathsf{X}_0 \times_{\mathsf{Y}_0} \operatorname{Sp\acute{e}t}\kappa(y) & \longrightarrow & \mathsf{X}_0 \\
 & & \downarrow & & \downarrow \\
 & & \mathsf{X}_y & \longrightarrow & \mathsf{X} \times_{\mathsf{Y}} \mathsf{Y}_0 & \longrightarrow & \mathsf{X} \\
 & & \downarrow & & \downarrow & & \downarrow \\
 & & \operatorname{Sp\acute{e}t}\kappa(y) & \longrightarrow & \mathsf{Y}_0 & \longrightarrow & \mathsf{Y};
\end{array}$$

here X_0 and Y_0 denote the schematic images of $\operatorname{Sp\acute{e}t}\kappa(x)$ and $\operatorname{Sp\acute{e}t}\kappa(y)$ in X and Y, respectively.

Example 6.5.4.5. Let $f : \mathsf{X} \to \mathsf{Y}$ be a flat morphism of Noetherian spectral algebraic spaces, let $x \in |\mathsf{X}|$ be a point having image $y = f(x) \in |\mathsf{Y}|$, and suppose that the diagram

$$\begin{array}{ccc}
\operatorname{Sp\acute{e}t}\kappa(x) & \longrightarrow & \mathsf{X} \\
\downarrow & & \downarrow \\
\operatorname{Sp\acute{e}t}\kappa(y) & \longrightarrow & \mathsf{Y}
\end{array}$$

is a pullback square. Then, for every object $\mathscr{F} \in \operatorname{QCoh}(\mathsf{Y})_{\mathrm{ltr}}$, Remark 6.5.4.4 supplies an equivalence $(f^* \mathscr{F})^!_x \simeq \mathscr{F}^!_y \otimes_{\kappa(y)} \kappa(x)$.

Example 6.5.4.6. Let $\mathsf{X} = \operatorname{Sp\acute{e}t} A$, where A is a Noetherian commutative ring, and let $x \in |\mathsf{X}| = |\operatorname{Spec} A|$ be a point corresponding to a prime ideal $\mathfrak{p} \subseteq A$ for which $A_{\mathfrak{p}}$ is a regular Noetherian ring of Krull dimension d. Then $\mathscr{O}^!_{\mathsf{X},x} \simeq \Sigma^{-d}\kappa(x)$.

Lemma 6.5.4.7. *Let X be Noetherian spectral algebraic space, let $x \in |\mathsf{X}|$, and let $\mathscr{F} \in \operatorname{Coh}(\mathsf{X})$. Suppose that $\mathscr{F}$ is n-truncated and that the coherent sheaf $\pi_n \mathscr{F}$ does not vanish at x. Then $\pi_m \mathscr{F}^!_x \neq 0$ for some $m \geqslant n - \operatorname{ht}(x)$, where $\operatorname{ht}(x)$ denotes the height of x (see Definition 3.7.6.1).*

Proof. Using Example 6.5.4.5, we can reduce to the case where $\mathsf{X} = \operatorname{Sp\acute{e}t} A$ where A is a local Noetherian $\mathbb{E}_\infty$-ring and x is the closed point of $|\operatorname{Spec} A|$. Set $d = \operatorname{ht}(x)$, and let $a_1, \ldots, a_d \in \pi_0 A$ be a system of parameters for $\pi_0 A$. For $1 \leqslant i \leqslant d$, let $N(i) \in \operatorname{Mod}_A$ denote the cofiber of the multiplication map $a_i : A \to A$. Set $M = \Gamma(\mathsf{X}; \mathscr{F})$ and set $K = M \otimes_A N(1) \otimes_A \cdots \otimes_A N(d)$. Note that each $N(i)$ has Tor-amplitude $\leqslant 1$, so that K is $(n+d)$-truncated. Applying Nakayama's lemma repeatedly, we deduce that $\pi_n K \neq 0$. Let s be the largest integer for which $\pi_s K$ is nonzero. Then $\pi_s K$ is an Artinian module over $\pi_0 A$, so there exists a nonzero map $\rho : \kappa(x) \to \pi_s K$. Set

$$N_\kappa(i) = \kappa(x) \otimes_A N(i) \simeq \operatorname{cofib}(a_i : \kappa(x) \to \kappa(x)) \simeq \kappa(x) \oplus \Sigma\kappa(x)$$

Then we can identify ρ with a nonzero element of

$$\begin{aligned}\pi_s \underline{\mathrm{Map}}_A(\kappa(x), K) &\simeq \pi_s(\mathscr{F}^!_x \otimes_{\kappa(x)} N_\kappa(1) \otimes_{\kappa(x)} \cdots \otimes_{\kappa(x)} N_\kappa(d)) \\ &\simeq \pi_s \bigoplus_{J \subseteq \{1,\ldots,d\}} \Sigma^{|J|} \mathscr{F}^!_x \\ &\simeq \bigoplus_{J \subseteq \{1,\ldots,d\}} \pi_{s-|J|} \mathscr{F}^!_x .\end{aligned}$$

It follows that $\pi_m \mathscr{F}^!_x$ does not vanish for some $m \geqslant s - d \geqslant n - d = n - \mathrm{ht}(x)$. □

Proposition 6.5.4.8. *Let* X *be a Noetherian spectral algebraic space, let* $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ *be truncated and coherent, and let* $x \in |\mathsf{X}|$. *The following conditions are equivalent:*

- (a) *The stalk of the sheaf* $\mathscr{F}$ *vanishes at the point* x.
- (b) *The* !*-fiber* $\mathscr{F}^!_x$ *vanishes.*

Proof. The implication $(a) \Rightarrow (b)$ is obvious, and the converse follows from Lemma 6.5.4.7. □

Proposition 6.5.4.9. *Let* X *be a Noetherian spectral algebraic space, let* $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})_{\mathrm{ltr}}$, *and let* n *be an integer. The following conditions are equivalent:*

1. *The sheaf* $\mathscr{F}$ *has injective dimension* $\leqslant n$.
2. *For every point* $x \in |\mathsf{X}|$, *the homotopy groups* $\pi_i \mathscr{F}^!_x$ *vanish for* $i < -n$.

Proof. Suppose first that condition (1) is satisfied. Let $x \in |\mathsf{X}|$ and let X_0 be the schematic image of the map $\mathrm{Sp\acute{e}t}\, \kappa(x) \to \mathsf{X}$. Let $i : \mathsf{X}_0 \hookrightarrow \mathsf{X}$ be the tautological closed immersion. Since the direct image functor i_* is t-exact, the sheaf $i^! \mathscr{F} \in \mathrm{QCoh}(\mathsf{X}_0)$ has injective dimension $\leqslant n$. The structure sheaf of X_0 is 0-truncated, so Proposition 6.5.2.5 implies that $i^! \mathscr{F} \in \mathrm{QCoh}(\mathsf{X}_0)_{\geqslant -n}$. Restricting to the generic point of X_0, we deduce that $\mathscr{F}^!_x$ is $(-n)$-connective.

Now suppose that condition (2) is satisfied; we wish to show that $\mathscr{F}$ has injective dimension $\leqslant n$. Using Proposition 6.5.2.2 and Remark 6.5.4.4, we can work locally on X and thereby reduce to the case where $\mathsf{X} = \mathrm{Sp\acute{e}t}\, A$ is affine. In this case, we can identify $\mathscr{F}$ with the truncated A-module $M = \Gamma(\mathsf{X}; \mathscr{F})$. Let us say that an ideal $I \subseteq \pi_0 A$ is *good* if the module $\underline{\mathrm{Map}}_A((\pi_0 A)/I, M)$ is $(-n)$-connective. To prove (1), it will suffice to show that every prime ideal $\mathfrak{p} \subset \pi_0 A$ is good (Proposition 6.5.2.4). Suppose otherwise: then, by virtue of our assumption that A is Noetherian, there exists an ideal $I \subseteq \pi_0 A$ which is maximal among those ideals which are not good. Replacing A by $(\pi_0 A)/I$ and K by $\underline{\mathrm{Map}}_A((\pi_0 A)/I, M)$, we may assume that A is discrete and that $I = (0)$. If A is not an integral domain, then the maximality of I implies that every prime ideal of A is good, so that M has injective dimension $\geqslant -n$ by virtue of Proposition 6.5.2.4, which contradicts our assumption that $I = (0)$ is not good. We may therefore assume without loss of generality that A is an integral domain and that every nonzero ideal of A is good.

Since $I = (0)$ is not good, the module M is not $(-n)$-truncated. We may therefore choose a nonzero element $u \in \pi_m M$ for $m < -n$. Let K denote the fraction field of A. Applying assumption (2) (in the case where x is the generic point of X) we deduce that $K \otimes_A (\pi_m M) \simeq \pi_m \mathscr{F}^!_x \simeq 0$. It follows u is annihilated by some nonzero element $a \in A$. The exactness of the sequence $\pi_m \underline{\mathrm{Map}}_A(A/(a), M) \to \pi_m M \xrightarrow{a} \pi_m M$ then shows that $\pi_m \underline{\mathrm{Map}}_A(A/(a), M) \neq 0$, contradicting our assumption that the nonzero ideal (a) is good. □

Corollary 6.5.4.10 (Serre)**.** *Let A be a regular Noetherian ring of Krull dimension $\leqslant n$. Then A has injective dimension $\leqslant n$ (when regarded as an object of* Mod_A*).*

Proof. Combine Proposition 6.5.4.9 with Example 6.5.4.6. □

6.6 Absolute Dualizing Sheaves

In his work on the duality theory of coherent sheaves, Grothendieck introduced the notion of a *dualizing complex* on a Noetherian scheme X (see [94]). Our goal in this section is to adapt the theory of dualizing complexes to the setting of spectral algebraic geometry. If X is a Noetherian spectral algebraic space, we define the notion of a *dualizing sheaf* $\omega_{\mathsf{X}} \in \mathrm{QCoh}(\mathsf{X})$ (Definition 6.6.1.1). Specializing to the case where $\mathsf{X} = \mathrm{Sp\acute{e}t}\, A$ is affine and using the equivalence $\mathrm{QCoh}(\mathsf{X}) \simeq \mathrm{Mod}_A$, we obtain the notion of a *dualizing module* for A. Our principal results can be summarized as follows:

- Let X be a Noetherian spectral algebraic space and let $\mathrm{Coh}(\mathsf{X}) \subseteq \mathrm{QCoh}(\mathsf{X})$ denote the full subcategory spanned by those objects having coherent homotopy (Definition **??**). If X admits a dualizing sheaf ω_{X}, then the construction $\mathscr{F} \mapsto \underline{\mathrm{Map}}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, \omega_{\mathsf{X}})$ determines an equivalence of the ∞-category $\mathrm{Coh}(\mathsf{X})$ with its opposite (Theorem 6.6.1.8).

- If X is a Noetherian spectral algebraic space which admits a dualizing sheaf ω_{X}, then ω_{X} is unique up to tensor product with an invertible object of $\mathrm{QCoh}(\mathsf{X})$ (Proposition 6.6.2.1).

- Let $f : \mathsf{X} \to \mathsf{Y}$ be a proper morphism between Noetherian spectral algebraic spaces. Then the functor $f^! : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ of Definition 6.4.0.1 carries dualizing sheaves on Y to dualizing sheaves on X (Proposition 6.6.3.1). In particular, if Y admits a dualizing sheaf, then so does X.

- A Noetherian $\mathbb{E}_\infty$-ring A admits a dualizing module if and only if the commutative ring $\pi_0 A$ admits a dualizing module (Theorem 6.6.4.1).

- Let $\phi : A \to B$ be a morphism of Noetherian $\mathbb{E}_\infty$-rings which is almost of finite presentation. If A admits a dualizing module, then so does B (Theorem 6.6.4.3).

Warning 6.6.0.1. In the setting of classical algebraic geometry, the term *dualizing complex* is commonly used to refer to what we call a *dualizing sheaf* (or *dualizing module*). Our choice of terminology is consistent with our convention of using the term *quasi-coherent sheaf* to refer to any object of the stable ∞-category $\mathrm{QCoh}(\mathsf{X})$, as opposed to objects which belong to the heart $\mathrm{QCoh}(\mathsf{X})^\heartsuit$. Note also that the term "complex" is potentially misleading: if X is not 0-truncated, then the stable ∞-category $\mathrm{QCoh}(\mathsf{X})$ cannot be recovered as the derived ∞-category of its heart; consequently, it is unreasonable to expect a dualizing sheaf ω_{X} to admit an explicit representative as a chain complex.

6.6.1 Dualizing Sheaves

We begin by introducing the central definition of this section:

Definition 6.6.1.1. Let X be a Noetherian spectral algebraic space. We will say that an object $\omega_{\mathsf{X}} \in \mathrm{QCoh}(\mathsf{X})$ is a *dualizing sheaf* if it satisfies the following conditions:

(1) The sheaf ω_{X} is truncated (that is, the homotopy sheaves $\pi_n \omega_{\mathsf{X}}$ vanish for $n \gg 0$).

(2) The sheaf ω_{X} is coherent: that is, each truncation $\tau_{\geqslant -n}\omega_{\mathsf{X}}$ is almost perfect.

(3) The sheaf ω_{X} has finite injective dimension (Definition 6.5.1.1).

(4) The unit map $\mathscr{O}_{\mathsf{X}} \to \underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\omega_{\mathsf{X}}, \omega_{\mathsf{X}})$ is an equivalence.

If A is a Noetherian $\mathbb{E}_\infty$-ring, we will say that an object $K \in \mathrm{Mod}_A$ is a *dualizing module* if it is the image of a dualizing sheaf under the equivalence $\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A) \simeq \mathrm{Mod}_A$.

Remark 6.6.1.2. In the situation of Definition 6.6.1.1, conditions (1), (2) and (3) guarantee that the sheaf $\underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\omega_{\mathsf{X}}, \omega_{\mathsf{X}})$ is quasi-coherent (Proposition 6.5.3.6).

Remark 6.6.1.3. Let $f : \mathsf{X} \to \mathsf{Y}$ be an étale morphism between Noetherian spectral algebraic spaces and let $\omega_{\mathsf{Y}} \in \mathrm{QCoh}(\mathsf{Y})$. Then:

- If ω_{Y} is a dualizing sheaf for Y, then $f^*\omega_{\mathsf{Y}}$ is a dualizing sheaf for X.

- If f is surjective and $f^*\omega_{\mathsf{Y}}$ is a dualizing sheaf for Y, then ω_{Y} is a dualizing sheaf for Y.

In fact, the corresponding assertions hold for each of the properties (1) through (4) which appear in Definition 6.6.1.1. For properties (1), (2) and (4) this is obvious, and for (3) it follows from Proposition 6.5.2.2.

Remark 6.6.1.4. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ be a Noetherian spectral algebraic space. Using Remark 6.6.1.3, we see that an object $\omega_{\mathsf{X}} \in \mathrm{QCoh}(\mathsf{X})$ is a dualizing module if and only if $\omega_{\mathsf{X}}(U)$ is a dualizing module for $\mathscr{O}_{\mathsf{X}}(U)$ for every affine object $U \in \mathcal{X}$.

Remark 6.6.1.5. In the situation of Definition 6.6.1.1, condition (4) can be rephrased as follows:

(4′) For every object $\mathscr{F} \in \mathrm{Mod}_{\mathscr{O}_{\mathsf{X}}}$, the canonical map $\mathrm{Map}_{\mathrm{Mod}_{\mathscr{O}_{\mathsf{X}}}}(\mathscr{F}, \mathscr{O}_{\mathsf{X}}) \to \mathrm{Map}_{\mathrm{Mod}_{\mathscr{O}_{\mathsf{X}}}}(\mathscr{F} \otimes \omega_{\mathsf{X}}, \omega_{\mathsf{X}})$ is a homotopy equivalence.

(4″) For every object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$, the canonical map $\mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, \mathscr{O}_{\mathsf{X}}) \to \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F} \otimes \omega_{\mathsf{X}}, \omega_{\mathsf{X}})$ is a homotopy equivalence.

The implications $(4) \Leftrightarrow (4') \Rightarrow (4'')$ are tautological, and the implication $(4'') \Rightarrow (4')$ follows from the quasi-coherence of $\underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\omega_{\mathsf{X}}, \omega_{\mathsf{X}})$ (see Remarks 6.5.3.8 and 6.6.1.2).

Construction 6.6.1.6 (Grothendieck Duality)**.** Let X be a Noetherian spectral algebraic space and suppose that we have fixed a dualizing sheaf $\omega_{\mathsf{X}} \in \mathrm{QCoh}(\mathsf{X})$. For each $\mathscr{F} \in \mathrm{Coh}(\mathsf{X})$, we let $\mathbb{D}(\mathscr{F})$ denote the sheaf given by $\underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\mathscr{F}, \omega_{\mathsf{X}})$ (note that the quasi-coherence of $\mathbb{D}(\mathscr{F})$ follows from Proposition 6.5.3.6). We will refer to $\mathbb{D}(\mathscr{F})$ as the *Grothendieck dual* of $\mathscr{F}$.

Warning 6.6.1.7. The Grothendieck dual $\mathbb{D}(\mathscr{F})$ depends on a choice of dualizing sheaf $\omega_{\mathsf{X}} \in \mathrm{QCoh}(\mathsf{X})$.

The terminology of Definition 6.6.1.1 is motivated by the following observation:

Theorem 6.6.1.8. *Let X be a Noetherian spectral algebraic space and let ω_{X} be a dualizing sheaf on X. Then:*

(1) *The construction $\mathscr{F} \mapsto \mathbb{D}(\mathscr{F})$ induces a contravariant equivalence of* $\mathrm{Coh}(\mathsf{X})$ *with itself.*

(2) *For $\mathscr{F} \in \mathrm{Coh}(\mathsf{X})$, the canonical map $\mathscr{F} \to \mathbb{D}(\mathbb{D}(\mathscr{F}))$ is an equivalence.*

Proof. We first show that if $\mathscr{F} \in \mathrm{Coh}(\mathsf{X})$, then $\mathbb{D}(\mathscr{F}) \in \mathrm{Coh}(\mathsf{X})$. This assertion is local on X, so we may assume that $\mathsf{X} = \mathrm{Sp\acute{e}t}\, A$ is affine. Set $M = \Gamma(\mathsf{X}; \mathscr{F}) \in \mathrm{Mod}_A$ and $K = \Gamma(\mathsf{X}; \omega_{\mathsf{X}}) \in \mathrm{Mod}_A$. It follows from Proposition 6.5.3.6 that $\mathbb{D}(\mathscr{F})$ is quasi-coherent, and is therefore determined by the A-module $\Gamma(\mathsf{X}; \mathbb{D}(\mathscr{F})) \simeq \underline{\mathrm{Map}}_A(M, K)$. We wish to show that each homotopy group $\pi_i \underline{\mathrm{Map}}_A(M, K) = \mathrm{Ext}_A^{-i}(M, K)$ is finitely generated as a module over $\pi_0 A$. Replacing M by a suitable suspension, we can assume that $i = 0$.

Choose an integer n such that $K \in \mathrm{Mod}_A$ has injective dimension $\leqslant n$, and choose a fiber sequence $M' \to M \to M''$ where M' is $(-n)$-connective and M'' is $(-n-1)$-truncated. We have an exact sequence $\mathrm{Ext}_A^0(M'', K) \to \mathrm{Ext}_A^0(M, K) \to \mathrm{Ext}_A^0(M', K)$, where the first term vanishes by virtue of Remark Remark 6.5.1.5. Since the commutative ring $\pi_0 A$ is Noetherian, it will suffice to show that $\mathrm{Ext}_A^0(M', K)$ is finitely generated as a module over $\pi_0 A$. Replacing M by M', we may reduce to the case where there exists an integer k such that M is k-connective. We now proceed by descending induction on k. If $k \gg 0$, then $\mathrm{Ext}_A^0(M, K) \simeq 0$ (since K is truncated). To carry out the inductive step, choose a map $\alpha : \Sigma^k A^a \to M$ which induces a surjection $(\pi_0 A)^a \to \pi_k M$ and set $N = \mathrm{cofib}(\alpha)$. Then N is $(k+1)$-connective, so that $\mathrm{Ext}_A^0(N, K)$ is finitely generated by our inductive hypothesis. Using the exact sequence $\mathrm{Ext}_A^0(N, K) \to \mathrm{Ext}_A^0(M, K) \to (\pi_k K)^a$, we deduce that $\mathrm{Ext}_A^0(M, K)$ is also finitely generated as a module over $\pi_0 A$ as desired.

To complete the proof of (1), it will suffice to prove (2) (so that the duality functor $\mathscr{F} \mapsto \mathbb{D}(\mathscr{F})$ is homotopy inverse to itself). Let $\mathscr{F} \in \mathrm{Coh}(\mathsf{X})$; we wish to show that the biduality map $u_{\mathscr{F}} : \mathscr{F} \to \mathbb{D}(\mathbb{D}(\mathscr{F}))$ is an equivalence. Once again, the assertion is local, so that we may assume that $\mathsf{X} = \mathrm{Sp\acute{e}t}\, A$ is affine so that $\mathscr{F}$ is determined by the module $M = \Gamma(\mathsf{X}; \mathscr{F}) \in \mathrm{Mod}_A$. We wish to show that for every integer i, the map $u_{\mathscr{F}}$ induces an isomorphism $\pi_i M \to \pi_i \underline{\mathrm{Map}}_A(\underline{\mathrm{Map}}_A(M, K), K)$. Replacing M by a suspension if necessary, we may again suppose that $i = 0$.

Choose an integer m such that K is m-truncated. Then for every k-truncated A-module N, the dual $\underline{\mathrm{Map}}_A(N, K)$ is $(-n-k)$-connective (Remark 6.5.1.5), so that the double dual $\underline{\mathrm{Map}}_A(\underline{\mathrm{Map}}_A(M, K), K)$ is $(m+n+k)$-truncated. Choose k so that both k and $m+n+k$ are negative. Then the fiber sequence $\tau_{\geqslant k+1} M \xrightarrow{\rho} M \to \tau_{\leqslant k} M$ gives rise to a fiber sequence

$$\underline{\mathrm{Map}}_A(\underline{\mathrm{Map}}_A(\tau_{\geqslant k+1} M, K), K) \xrightarrow{\rho'} \underline{\mathrm{Map}}_A(\underline{\mathrm{Map}}_A(M, K), K) \to \underline{\mathrm{Map}}_A(\underline{\mathrm{Map}}_A(\tau_{\leqslant k} M, K), K),$$

where ρ and ρ' both induce isomorphisms on π_0. We may therefore replace M by $\tau_{\geqslant k+1} M$ and thereby reduce to showing that the map $u_{\mathscr{F}}$ is an equivalence whenever M is almost connective. Replacing M by a suitable suspension, we are reduced to proving the following:

$(*)$ Let $M \in \mathrm{Mod}_A$ be connective and almost perfect. Then the biduality map $\theta_M : M \to \underline{\mathrm{Map}}_A(\underline{\mathrm{Map}}_A(M, K), K)$ is an equivalence.

To prove $(*)$, we show that the morphism θ_M is p-connective for every integer p. Since M is connective, the dual $\underline{\mathrm{Map}}_A(M, K)$ is m-truncated, so that $\underline{\mathrm{Map}}_A(\underline{\mathrm{Map}}_A(M, K), K)$ is $(-n-m)$-connective. Our claim therefore follows automatically if $p < 0, -n-m$. We proceed in general using induction on p. Since $\pi_0 M$ is finitely generated as a $\pi_0 A$-module, we can choose a fiber sequence $N \to A^a \to M$ where $N \in \mathrm{Mod}_A$ is connective and almost perfect. We therefore have a fiber sequence $\mathrm{fib}(\theta_N) \to \mathrm{fib}(\theta_A)^a \to \mathrm{fib}(\theta_M)$. The definition of a dualizing complex guarantees that u_A is an equivalence, so we obtain an equivalence $\mathrm{fib}(\theta_M) \simeq \Sigma\,\mathrm{fib}(\theta_N)$. The inductive hypothesis implies that $\Sigma\,\mathrm{fib}(\theta_N)$ is $(p-1)$-connective, so that $\mathrm{fib}(\theta_M)$ is p-connective as desired. □

In the situation of Theorem 6.6.1.8, there is a close relationship between properties of a sheaf $\mathscr{F} \in \mathrm{Coh}(\mathsf{X})$ and properties of its Grothendieck dual $\mathbb{D}(\mathscr{F})$:

Proposition 6.6.1.9. *Let X be a Noetherian spectral algebraic space, let ω_{X} be a dualizing sheaf on X, and let $\mathscr{F} \in \mathrm{Coh}(\mathsf{X})$. Then:*

(a) *The sheaf $\mathscr{F}$ is almost perfect if and only if $\mathbb{D}(\mathscr{F})$ is truncated.*

(b) *If $\mathscr{F}$ has finite* Tor*-amplitude, then the dual $\mathbb{D}(\mathscr{F})$ has finite injective dimension.*

(c) *The sheaf $\mathscr{F}$ is perfect if and only if $\mathbb{D}(\mathscr{F})$ is truncated and of finite injective dimension.*

Lemma 6.6.1.10. *Let X be a Noetherian spectral algebraic space, let $\mathscr{F}, \mathscr{G} \in \mathrm{QCoh}(\mathsf{X})$, and assume that $\mathscr{F}$ is coherent.*

(1) *If $\mathscr{F}$ is m-connective and $\mathscr{G}$ is n-truncated, then $\underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\mathscr{F}, \mathscr{G})$ is $(n-m)$-truncated.*

(2) *If $\mathscr{F}$ has* Tor*-amplitude $\leqslant m$ and $\mathscr{G}$ has injective dimension $\leqslant n$, then $\underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\mathscr{F}, \mathscr{G})$ has injective dimension $\leqslant n+m$.*

Proof. For each object $\mathscr{H} \in \mathrm{QCoh}(\mathsf{X})$, we have canonical isomorphisms

$$\mathrm{Ext}^*_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{H}, \underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\mathscr{F}, \mathscr{G})) \simeq \mathrm{Ext}^*_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F} \otimes \mathscr{H}, \mathscr{G}).$$

If the hypothesis of (1) is satisfied and $\mathscr{H}$ is connective, then $\mathscr{F} \otimes \mathscr{H}$ is m-connective, so that our assumption that $\mathscr{G}$ is n-truncated guarantees that the groups $\mathrm{Ext}^*_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F} \otimes \mathscr{H}, \mathscr{G})$ vanish for $* < -n+m$, so that $\underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\mathscr{F}, \mathscr{G})$ is $(n-m)$-truncated. If the hypothesis of (2) is satisfied and $\mathscr{H}$ is 0-truncated, then the tensor product $\mathscr{F} \otimes \mathscr{H}$ is m-truncated. Our assumption that $\mathscr{G}$ has injective dimension $\leqslant n$ guarantees that the groups $\mathrm{Ext}^*_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F} \otimes \mathscr{H}, \mathscr{G})$ vanish for $* > n+m$, so that $\underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\mathscr{F}, \mathscr{G})$ has injective dimension $\leqslant n+m$. □

Proof of Proposition 6.6.1.9. Let X be a Noetherian spectral algebraic space which admits a dualizing sheaf ω_{X}. Replacing ω_{X} by a shift if necessary, we may assume that ω_{X} is 0-truncated and has injective dimension $\leqslant n$, for some integer n. If $\mathscr{F}$ is almost perfect, then it is $(-m)$-connective for some $m \gg 0$, so that $\mathbb{D}(\mathscr{F})$ is m-truncated by virtue of Lemma 6.6.1.10. Conversely, suppose that $\mathbb{D}(\mathscr{F})$ is k-truncated for some integer k. We claim that $\mathbb{D}(\mathbb{D}(\mathscr{F}))$ is $(-k-n)$-connective, so that $\mathscr{F}$ is $(-k-n)$-connective (by virtue of Theorem

6.6.1.8). To prove this, we can work locally (Proposition 6.5.3.6) and thereby reduce to the case where $\mathsf{X} \simeq \text{Spét}\, A$ is affine. In this case, it suffices to show that the homotopy groups

$$\pi_{-i}\Gamma(\mathsf{X}; \mathbb{D}(\mathbb{D}(\mathscr{F}))) \simeq \text{Ext}^i_{\text{QCoh}(\mathsf{X})}(\mathbb{D}(\mathscr{F}), \omega_{\mathsf{X}})$$

vanish for $i > k + n$, which follows from our assumption that $\mathbb{D}(\mathscr{F})$ is k-truncated and ω_{X} has injective dimension $\leqslant n$ (see Remark 6.5.1.5). This completes the proof of (a).

If $\mathscr{F}$ has Tor-amplitude $\leqslant k$, then Lemma 6.6.1.10 guarantees that $\mathbb{D}(\mathscr{F})$ has injective dimension $\leqslant k + n$, which proves (b).

If $\mathscr{F}$ is perfect, then it is both almost perfect and of finite Tor-amplitude, so that $\mathbb{D}(\mathscr{F})$ is truncated and of finite injective dimension by virtue of (a) and (b). We will complete the proof by establishing the converse. Assume that $\mathbb{D}(\mathscr{F})$ is truncated and of finite injective dimension; we wish to show that $\mathscr{F}$ is perfect. This assertion can be tested locally on X (see Propositions 6.5.2.2 and 6.5.3.6), so we may assume without loss of generality that $\mathsf{X} \simeq \text{Spét}\, A$ is affine.

Choose an integer k such that $\mathbb{D}(\mathscr{F})$ has injective dimension $\leqslant k$. Applying Corollary 2.7.2.2, we can choose a fiber sequence $\mathscr{F}' \to \mathscr{F} \xrightarrow{\alpha} \mathscr{F}''$ in $\text{QCoh}(\mathsf{X})$, where $\mathscr{F}'$ is perfect and $\mathscr{F}''$ is $(k+1)$-connective. Lemma 6.6.1.10 then implies that the Grothendieck dual $\mathbf{D}(\mathscr{F}'')$ is $(-k-1)$-truncated. Invoking our assumption that $\mathbb{D}(\mathscr{F})$ has injective dimension $\leqslant k$ (and Remark 6.5.1.5), we conclude that the map $\mathbb{D}(\alpha) : \mathbb{D}(\mathscr{F}'') \to \mathbb{D}(\mathscr{F})$ is nullhomotopic. Theorem 6.6.1.8 implies that α is nullhomotopic, so that $\mathscr{F}$ is equivalent to a direct summand of $\mathscr{F}'$ and is therefore perfect, as desired. □

Let X be a Noetherian spectral algebraic space with dualizing sheaf ω_{X}. If $\mathscr{F} \in \text{Coh}(\mathsf{X})$ is perfect, then the Grothendieck dual $\mathbb{D}(\mathscr{F})$ is given by the tensor product $\mathscr{F}^\vee \otimes \omega_{\mathsf{X}}$, where $\mathscr{F}^\vee$ is the $\mathscr{O}_{\mathsf{X}}$-linear dual of $\mathscr{F}$. Note that the construction $\mathscr{F} \mapsto \mathscr{F}^\vee$ induces an equivalence of the ∞-category $\text{QCoh}(\mathsf{X})^{\text{perf}}$ with its opposite. Combining this observation with Theorem 6.6.1.8 and Proposition 6.6.1.9, we obtain the following:

Corollary 6.6.1.11. *Let X be a Noetherian spectral algebraic space with dualizing sheaf ω_{X}. Then the construction $\mathscr{F} \mapsto \mathscr{F} \otimes \omega_{\mathsf{X}}$ determines a fully faithful embedding $\text{QCoh}(\mathsf{X})^{\text{perf}} \to \text{Coh}(\mathsf{X})$, whose essential image is spanned by those objects $\mathscr{G} \in \text{Coh}(\mathsf{X})$ which are truncated and of finite injective dimension.*

6.6.2 Uniqueness of Dualizing Sheaves

If X is a Noetherian spectral algebraic space which admits a dualizing sheaf ω_{X}, then ω_{X} is essentially unique.

Proposition 6.6.2.1. *Let X be a Noetherian spectral algebraic space and let ω_{X} be a dualizing sheaf for X. Then an arbitrary object $\omega'_{\mathsf{X}} \in \text{QCoh}(\mathsf{X})$ is a dualizing sheaf if and only if there exists an equivalence $\omega'_{\mathsf{X}} \simeq \omega_{\mathsf{X}} \otimes \mathscr{L}$, where $\mathscr{L}$ is an invertible object of $\text{QCoh}(\mathsf{X})$.*

Remark 6.6.2.2. In the situation of Proposition 6.6.2.1, the invertible sheaf $\mathscr{L} \in \mathrm{QCoh}(\mathsf{X})$ is uniquely determined up to equivalence: it can be recovered as $\underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\omega_{\mathsf{X}}, \omega'_{\mathsf{X}})$. In fact, we have the following more precise assertion: if X admits a dualizing sheaf ω_{X}, then the functor $\mathscr{L} \mapsto \omega_{\mathsf{X}} \otimes \mathscr{L}$ determines an equivalence from the full subcategory of $\mathrm{QCoh}(\mathsf{X})$ spanned by the invertible objects to the full subcategory of $\mathrm{QCoh}(\mathsf{X})$ spanned by the dualizing sheaves (this follows by combining Proposition 6.6.2.1 with Corollary 6.6.1.11).

Lemma 6.6.2.3. *Let A be a Noetherian $\mathbb{E}_\infty$-ring, let K be a dualizing module for A, and let Q be an R-module of finite injective dimension. For every almost perfect R-module M, the canonical map*

$$f_M : M \otimes_A \underline{\mathrm{Map}}_A(K, Q) \simeq \underline{\mathrm{Map}}_A(\underline{\mathrm{Map}}_A(M, K), K) \otimes_R \underline{\mathrm{Map}}_A(K, Q) \to \underline{\mathrm{Map}}_A(\underline{\mathrm{Map}}_A(M, K), Q)$$

is an equivalence.

Proof. Replacing M by a shift, we may assume without loss of generality that M is connective. Let K be m-truncated and let Q have injective dimension $\leqslant n$. Remark 6.5.1.5 implies that $\underline{\mathrm{Map}}_A(K, Q)$ is $(-n-m)$-connective, so that the tensor product $M \otimes_A \underline{\mathrm{Map}}_A(K, Q)$ is $(-n-m)$-connective. Similarly, the connectivity of M implies that $\underline{\mathrm{Map}}_A(M, K)$ is m-truncated, so that $\underline{\mathrm{Map}}_A(\underline{\mathrm{Map}}_A(M, K), Q)$ is also $(-n-m)$-connective. It follows that the morphism f_M is $(-n-m-1)$-connective. We prove that f_M is k-connective for every integer k, using induction on k. Since $\pi_0 M$ is a finitely generated module over $\pi_0 A$, we can choose a fiber sequence $M' \to A^a \to M$, where M' is connective. We therefore obtain a fiber sequence $\mathrm{fib}(f_{M'}) \to \mathrm{fib}(f_A)^a \to \mathrm{fib}(f_M)$. It follows immediately from the definitions that f_A is an equivalence, so that $\mathrm{fib}(f_M) \simeq \Sigma \, \mathrm{fib}(f_{M'})$. The inductive hypothesis implies that $\mathrm{fib}(f_{M'})$ is $(k-1)$-conncetive, so that $\mathrm{fib}(f_M)$ is k-connective as desired. □

Proof of Proposition 6.6.2.1. It follows immediately from the definitions that if ω_{X} is a dualizing sheaf on X and $\omega'_{\mathsf{X}} \simeq \omega_{\mathsf{X}} \otimes \mathscr{L}$ for some invertible object $\mathscr{L} \in \mathrm{QCoh}(\mathsf{X})$, then ω'_{X} is also a dualizing sheaf on X. To prove the converse, suppose that $\omega_{\mathsf{X}}, \omega'_{\mathsf{X}} \in \mathrm{QCoh}(\mathsf{X})$ are both dualizing sheaves. Set $\mathscr{L} = \underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\omega_{\mathsf{X}}, \omega'_{\mathsf{X}})$. It follows from Lemma 6.6.2.3 that if $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is almost perfect, then the canonical map

$$\mathscr{F} \otimes \mathscr{L} \to \underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\mathscr{F}, \omega_{\mathsf{X}}), \omega'_{\mathsf{X}})$$

is an equivalence. Taking $\mathscr{F} = \underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}'}}(\omega'_{\mathsf{X}}, \omega_{\mathsf{X}})$ (which is almost perfect by Proposition 6.6.1.9), we obtain an equivalence $\mathscr{F} \otimes \mathscr{L} \simeq \underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\omega'_{\mathsf{X}}, \omega'_{\mathsf{X}}) \simeq \mathscr{O}_{\mathsf{X}}$, so that $\mathscr{L}$ is an invertible object of $\mathrm{QCoh}(\mathsf{X})$. To complete the proof, it will suffice to show that the canonical map $\omega_{\mathsf{X}} \otimes \mathscr{L} \to \omega'_{\mathsf{X}}$ is an equivalence. This is a consequence of the following more general assertion (applied in the case $\mathscr{G} = \omega_{\mathsf{X}}$):

$(*)$ For every object $\mathscr{G} \in \mathrm{Coh}(\mathsf{X})$, the canonical map $u_{\mathscr{G}} : \mathscr{G} \otimes \mathscr{L} \to \underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\mathscr{G}, \omega_{\mathsf{X}}), \omega'_{\mathsf{X}})$ is an equivalence.

To prove $(*)$, it will suffice to show that $u_{\mathscr{G}}$ induces an isomorphism of homotopy sheaves

$$\pi_i(\mathscr{G} \otimes \mathscr{L}) \to \pi_i \underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\mathscr{G}, \omega_{\mathsf{X}}), \omega'_{\mathsf{X}})$$

for every integer i. Replacing $\mathscr{G}$ by a shift, we may suppose that $i = 0$. Let $\mathscr{F}$ be defined as above, so that we can identify the domain of $u_{\mathscr{G}}$ with $\underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\mathscr{F}, \mathscr{G})$. Choose an integer a such that $\mathscr{F}$ is a-connective. For every integer k, the spectrum $\underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\mathscr{F}, \tau_{\leqslant k}\mathscr{G})$ is $(a+k)$-truncated. Let ω_{X} have injective dimension $\leqslant n$, so that $\underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\tau_{\leqslant k}\mathscr{G}, \omega_{\mathsf{X}})$ is $(-n-k)$-connective (Remark 6.5.1.5). Choose m such that ω'_{X} is m-truncated, so that $\underline{\mathrm{Map}}_{\omega_{\mathsf{X}}}(\underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\tau_{\leqslant k}\mathscr{G}, \omega_{\mathsf{X}}), \omega'_{\mathsf{X}})$ is $(k+m+n)$-truncated. It follows that if $k < -a, -m-n$, then the maps

$$\pi_0((\tau_{\geqslant k}\mathscr{G}) \otimes \mathscr{L}) \to \pi_0(\mathscr{G} \otimes \mathscr{L})$$

$$\pi_0 \underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\tau_{\leqslant k}\mathscr{G}, \omega_{\mathsf{X}}), \omega'_{\mathsf{X}}) \to \pi_0 \underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\mathscr{G}, \omega_{\mathsf{X}}), \omega'_{\mathsf{X}})$$

are isomorphisms. We may therefore replace $\mathscr{G}$ with $\tau_{\geqslant k}\mathscr{G}$, in which case the desired result follows from Lemma 6.6.2.3. □

6.6.3 Base Change of Dualizing Sheaves

If $f : \mathsf{X} \to \mathsf{Y}$ is a proper morphism of Noetherian spectral algebraic spaces, then there is a close relationship between dualizing sheaves on X and dualizing sheaves on Y:

Proposition 6.6.3.1. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a proper morphism of Noetherian spectral algebraic spaces, and let $f^! : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ be the exceptional inverse image functor of Definition 6.4.0.1. If ω_{Y} is a dualizing sheaf on Y, then $f^!\omega_{\mathsf{Y}}$ is a dualizing sheaf on X. In particular, if Y admits a dualizing sheaf, then so does X.*

Proof. Set $\omega_{\mathsf{X}} = f^!\omega_{\mathsf{Y}}$. It follows from Proposition 6.4.3.4 that ω_{X} is truncated and coherent, and it follows from Remark 6.5.2.3 that ω_{X} has finite injective dimension. To complete the proof, it will suffice to show that the canonical map $\mathscr{O}_{\mathsf{X}} \to \underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\omega_{\mathsf{X}}, \omega_{\mathsf{X}})$ is an equivalence. Equivalently, we must show that for each object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$, tensor product with ω_{X} induces a homotopy equivalence

$$\theta : \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, \mathscr{O}_{\mathsf{X}}) \to \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F} \otimes \omega_{\mathsf{X}}, \omega_{\mathsf{X}}) \simeq \mathrm{Map}_{\mathrm{QCoh}(\mathsf{Y})}(f_*(\mathscr{F} \otimes \omega_{\mathsf{X}}), \omega_{\mathsf{Y}}).$$

Writing $\mathscr{F}$ as a filtered colimit of perfect objects of $\mathrm{QCoh}(\mathsf{X})$ (Proposition 9.6.1.1), we can assume that $\mathscr{F}$ is perfect. Let $\mathscr{F}^\vee = \underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\mathscr{F}, \mathscr{O}_{\mathsf{X}})$. We then have a canonical equivalence

$$\begin{aligned} f_*(\mathscr{F} \otimes \omega_{\mathsf{X}}) &\simeq f_* \underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\mathscr{F}^\vee, \omega_{\mathsf{X}}) \\ &\simeq f_* \underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\mathscr{F}^\vee, f^!\omega_{\mathsf{Y}}) \\ &\simeq \underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{Y}}}(f_* \mathscr{F}^\vee, \omega_{\mathsf{Y}}). \end{aligned}$$

Under this equivalence, the map θ is obtained from the biduality map $\theta' : f_* \mathscr{F}^\vee \to \underline{\mathrm{Map}}_{\mathscr{O}_\mathsf{Y}}(\underline{\mathrm{Map}}_{\mathscr{O}_\mathsf{Y}}(f_* \mathscr{F}^\vee, \omega_\mathsf{Y})\omega_\mathsf{Y})$ by passing to global sections. It follows from Theorem 5.6.0.2 that $f_* \mathscr{F}^\vee \in \mathrm{QCoh}(\mathsf{Y})$ is almost perfect, so that θ' is an equivalence by virtue of Theorem 6.6.1.8. □

Corollary 6.6.3.2. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of Noetherian spectral algebraic spaces which is proper and locally of finite* Tor*-amplitude. Suppose that Y admits a dualizing sheaf ω_Y. Then the tensor product $\omega_{\mathsf{X}/\mathsf{Y}} \otimes f^* \omega_\mathsf{Y}$ is a dualizing sheaf for X.*

Proof. Combine Proposition 6.6.3.1 with Corollary 6.4.2.7. □

In the special case where X and Y are affine, Proposition 6.6.3.1 specializes to the following:

Corollary 6.6.3.3. *Let A be a Noetherian $\mathbb{E}_\infty$-ring which admits a dualizing module K. Let $f : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings which exhibits B as an almost perfect A-module. Then $K' = \underline{\mathrm{Map}}_A(B, K)$ is a dualizing module for B.*

Corollary 6.6.3.4. *Let A be a Noetherian $\mathbb{E}_\infty$-ring. If A admits a dualizing module, then the commutative ring $\pi_0 A$ admits a dualizing module.*

Corollary 6.6.3.5. *Let X be a Noetherian spectral algebraic space and let $\omega \in \mathrm{QCoh}(\mathsf{X})$ be a dualizing sheaf. Then, for each $x \in |\mathsf{X}|$ with residue field $\kappa(x)$, the !-fiber $\omega_x^!$ is an invertible object of $\mathrm{Mod}_{\kappa(x)}$ (that is, it is equivalent to some suspension $\Sigma^d \kappa(x)$).*

Proof. Using Remark 6.6.1.3, we can reduce to the case where $\mathsf{X} = \mathrm{Spét}\, A$ is affine, so $M = \Gamma(\mathsf{X}; \omega)$ is a dualizing module for A and the point x corresponds to some prime ideal $\mathfrak{p} \subseteq A$. Using Corollary 6.6.3.3, we may replace A by $(\pi_0 A)/\mathfrak{p}$ and M by $\underline{\mathrm{Map}}_A((\pi_0 A)/\mathfrak{p}, M)$ and further reduce to the case where A is an integral domain and $\mathfrak{p} = (0)$. Let $K = \kappa(x)$ be the fraction field of A, so that we can identify $\omega_x^!$ with the tensor product $K \otimes_A M$. Our assumption that M is a dualizing module guarantee that the homotopy groups $\pi_n M$ are finitely generated modules over A which vanish for $n \gg 0$, and Proposition 6.5.2.5 guarantees that they also vanish for $n \ll 0$. Using Lemma **??**, we deduce that the canonical map

$$\theta : K \otimes_A \underline{\mathrm{Map}}_A(M, M) \to \underline{\mathrm{Map}}_A(M, K \otimes_A M) \simeq \underline{\mathrm{Map}}_K(K \otimes_A M, K \otimes_A M)$$

is an equivalence. Since M is a dualizing module for A, we can identify the domain of θ with K. It follows that $K \otimes_A M$ is an indecomposable K-module (that is, it is nonzero and cannot be nontrivially decomposed as a direct sum). Since K is a field, it follows that $\omega_x^! \simeq K \otimes_A M$ an invertible object of Mod_K. □

6.6.4 Reduction to Commutative Algebra

Our next goal is to establish a converse of Corollary 6.6.3.4:

Theorem 6.6.4.1. *Let A be a Noetherian $\mathbb{E}_\infty$-ring. If $\pi_0 A$ admits a dualizing module, then A admits a dualizing module.*

Example 6.6.4.2. Let S denote the sphere spectrum. Since $\pi_0 S \simeq \mathbf{Z}$ admits a dualizing module, S also admits a dualizing module. In fact, we can describe this dualizing module explicitly. Let $I \in \mathrm{Sp}$ be the Brown-Comenetz dual of the sphere spectrum (see Example HA.**??**). Then I is an injective object of Sp, which is characterized up to equivalence by the formula

$$\pi_n \underline{\mathrm{Map}}_S(M, I) \simeq \mathrm{Hom}(\pi_{-n} M, \mathbf{Q}/\mathbf{Z})$$

for every integer n and every spectrum M. In particular, we have

$$\pi_n I \simeq \begin{cases} 0 & \text{if } n > 0 \\ \mathbf{Q}/\mathbf{Z} & \text{if } n = 0 \\ \mathrm{Hom}(\pi_{-n} S, \mathbf{Q}/\mathbf{Z}) & \text{if } n < 0. \end{cases}$$

Let $\mathbf{Q}$ denote the field of rational numbers, which we regard as a discrete spectrum. The map of abelian groups $\mathbf{Q} \to \mathbf{Q}/\mathbf{Z}$ induces a map of spectra $\alpha : \mathbf{Q} \to I$. We let K denote the fiber of α. Then

$$\underline{\mathrm{Map}}_S(\mathbf{Z}, K) \simeq \mathrm{fib}(\underline{\mathrm{Map}}_S(\mathbf{Z}, \mathbf{Q}) \to \underline{\mathrm{Map}}_S(\mathbf{Z}, I)) \simeq \mathrm{fib}(\mathbf{Q} \to \mathbf{Q}/\mathbf{Z}) \simeq \mathbf{Z}$$

is a dualizing module for $\mathbf{Z}$. It follows from Proposition 6.6.4.6 that K is a dualizing module for S. The spectrum K is often called the *Anderson dual* of the sphere spectrum. Its homotopy groups are given by

$$\pi_n K \simeq \begin{cases} 0 & \text{if } n > 0 \\ \mathbf{Z} & \text{if } n = 0 \\ 0 & \text{if } n = -1 \\ \mathrm{Hom}(\pi_k S, \mathbf{Q}/\mathbf{Z}) & \text{if } n = -k-1, k > 0. \end{cases}$$

Before turning the proof of Theorem 6.6.4.1, let us note the following consequence:

Theorem 6.6.4.3. *Let A be a Noetherian $\mathbb{E}_\infty$-ring, and let $B \in \mathrm{CAlg}_A^{\mathrm{cn}}$ be almost of finite presentation over A. If A admits a dualizing module, then B admits a dualizing module.*

Remark 6.6.4.4. Since the sphere spectrum S admits a dualizing module (Example 6.6.4.2), it follows from Theorem 6.6.4.3 that every $\mathbb{E}_\infty$-ring B which is almost of finite presentation over S also admits a dualizing module. In particular, every connective $\mathbb{E}_\infty$-ring R can be written as a filtered colimit of Noetherian $\mathbb{E}_\infty$-rings which admit dualizing modules. This fact can be quite useful in combination with the Noetherian approximation techniques of Chapter **??**.

Proof of Theorem 6.6.4.3. It follows from Theorem HA.7.2.4.31 that B is Noetherian. We wish to show that B admits a dualizing module. Using Corollary 6.6.3.4 and Theorem 6.6.4.1, we can replace A and B by $\pi_0 A$ and $\pi_0 B$, and thereby reduce to the case where B is a commutative ring which is finitely presented as an algebra over the Noetherian commutative ring A. Choose a surjection $A[x_1, \ldots, x_n] \rightarrow B$. To prove that A admits a dualizing module, it will suffice to show that $A[x_1, \ldots, x_n]$ admits a dualizing module (Proposition 6.6.3.3), or equivalently that the affine space $\operatorname{Sp\acute{e}t} A[x_1, \ldots, x_n]$ admits a dualizing sheaf. Note that there exists an open immersion $j : \operatorname{Sp\acute{e}t} A[x_1, \ldots, x_n] \hookrightarrow \mathbf{P}^n_A$. By virtue of Remark 6.6.1.3, it will suffice to show that $\mathbf{P}^n_A$ admits a dualizing sheaf. This follows from Proposition 6.6.4.6, since the projection map $\mathbf{P}^n_A \rightarrow \operatorname{Sp\acute{e}t} A$ is proper (Corollary 5.4.3.4). □

Remark 6.6.4.5. In the proof of Theorem 6.6.4.3, we can be more precise: if A is a Noetherian commutative ring and K is a dualizing module for A, then $K[x_1, \ldots, x_n] = K \otimes_A A[x_1, \ldots, x_n]$ is a dualizing module for $A[x_1, \ldots, x_n]$.

Our proof of Theorem 6.6.4.1 is based on the following recognition criterion:

Proposition 6.6.4.6. *Let $f : A \rightarrow B$ be a map of Noetherian $\mathbb{E}_\infty$-rings. Suppose that the induced map $\pi_0 A \rightarrow \pi_0 B$ is a surjection of commutative rings whose kernel $I \subseteq \pi_0 A$ is nilpotent. Let K be a truncated A-module, and suppose that $\underline{\operatorname{Map}}_A(B, K)$ is a dualizing module for B. Then K is a dualizing module for A.*

Proof. Let $f : A \rightarrow B$ be a morphism of Noetherian $\mathbb{E}_\infty$-rings which exhibits $\pi_0 B$ as the quotient of $\pi_0 A$ by a nilpotent ideal $I \subseteq \pi_0 A$, and suppose that $K \in \operatorname{Mod}_A$ has the property that $f^\dagger K = \underline{\operatorname{Map}}_K(B, A)$ is a dualizing module for B. It follows from Lemma 6.4.3.7 that the homotopy groups of $\pi_i K$ are finitely generated over $\pi_0 A$. Choose $n \gg 0$ such that $\underline{\operatorname{Map}}_A(B, K)$ has injective dimension $\leqslant n$ as a B-module. We claim that K has injective dimension $\leqslant n$ as an A-module. Let M be a discrete A-module; we wish to prove that the groups $\operatorname{Ext}^i_A(M, K)$ vanish for $i > n$. Since I is nilpotent, the module M is annihilated by I^k for some integer $k \geqslant 1$. We proceed by induction on k. We have an exact sequence $0 \rightarrow IM \rightarrow M \rightarrow M/IM \rightarrow 0$ of discrete $\pi_0 A$-modules, giving rise to short exact sequences $\operatorname{Ext}^i_A(M/IM, K) \rightarrow \operatorname{Ext}^i_A(M, K) \rightarrow \operatorname{Ext}^i_A(IM, K)$. The groups $\operatorname{Ext}^i_A(IM, K)$ vanish for $i > n$ by the inductive hypothesis. The quotient M/IM has the structure of a module over $\pi_0 B$, so that $\operatorname{Ext}^i_A(IM, K) \simeq \operatorname{Ext}^i_B(IM, \underline{\operatorname{Map}}_A(B, K))$ vanishes since $\underline{\operatorname{Map}}_A(B, K)$ has injective dimension $\leqslant n$. It follows that $\operatorname{Ext}^i_A(M, K)$ vanishes, as desired.

To complete the proof, it will suffice to show that the biduality map $A \to \underline{\mathrm{Map}}_A(K, K)$ is an equivalence. We will prove more generally that for every almost perfect A-module M, the canonical map $u_M : M \to \underline{\mathrm{Map}}_A(\underline{\mathrm{Map}}_A(M, K), K)$ is an equivalence. For this, it suffices to show that u_M induces an isomorphism $\pi_i M \to \pi_i \underline{\mathrm{Map}}_A(\underline{\mathrm{Map}}_A(M, K), K)$ for every integer i. Replacing M by a shift, we can assume that $i = 0$. Choose an integer m such that K is m-truncated. For every integer k, the module $\underline{\mathrm{Map}}_A(\tau_{\geqslant k} M, K)$ is $(m-k)$-truncated, so that $\underline{\mathrm{Map}}_A(\underline{\mathrm{Map}}_A(\tau_{\geqslant k} M, K), K)$ is $(k-n-m)$-connective (Remark 6.5.1.5). If $k > n+m$, it follows that the canonical map

$$\pi_0 \underline{\mathrm{Map}}_A(\underline{\mathrm{Map}}_A(M, K), K) \to \pi_0 \underline{\mathrm{Map}}_A(\underline{\mathrm{Map}}_A(\tau_{\leqslant k-1} M, K), K)$$

is an isomorphism. Assuming also that k is positive (so that $\pi_0 M \simeq \pi_0 \tau_{\leqslant k-1} M$), we may replace M by $\tau_{\leqslant k-1} M$ and thereby reduce to the case where M is truncated. It will therefore suffice to show that u_M is an equivalence whenever M is truncated and almost perfect. In this case, M is a successive extension of A-modules which are concentrated in a single degree. It will therefore suffice to show that u_M is an equivalence when M is discrete A-module which is finitely generated over $\pi_0 A$. Since I is nilpotent, we can write M as a successive extension of discrete A-modules which are annihilated by I. We may therefore assume that M is annihilated by I, and therefore admits the structure of a B-module. In this case, we have

$$\underline{\mathrm{Map}}_A(\underline{\mathrm{Map}}_A(M, K), K) \simeq \underline{\mathrm{Map}}_A(\underline{\mathrm{Map}}_B(M, K'), K) \simeq \underline{\mathrm{Map}}_B(\underline{\mathrm{Map}}_B(M, K'), K'),$$

where $K' = \underline{\mathrm{Map}}_A(B, K)$. The assertion that u_M is an equivalence now follows from Theorem 6.6.1.8. □

Notation 6.6.4.7. For every connective $\mathbb{E}_\infty$-ring A, let $(\mathrm{Mod}_A)_{<\infty}$ denote the full subcategory of Mod_A spanned by the truncated A-modules (that is, $(\mathrm{Mod}_A)_{<\infty} = \bigcup_n (\mathrm{Mod}_A)_{\leqslant n}$).

If $f : A \to B$ be a morphism fo connective $\mathbb{E}_\infty$-rings, we let $f^\dagger : \mathrm{Mod}_A \to \mathrm{Mod}_B$ denote the right adjoint to the forgetful functor $\mathrm{Mod}_B \to \mathrm{Mod}_A$, given by $f^\dagger M = \underline{\mathrm{Map}}_A(B, M)$. Note that the functor $f^\dagger : \mathrm{Mod}_A \to \mathrm{Mod}_B$ carries $(\mathrm{Mod}_A)_{<\infty}$ into $(\mathrm{Mod}_B)_{<\infty}$.

Lemma 6.6.4.8. *Suppose we are given a pullback diagram of connective $\mathbb{E}_\infty$-rings τ :*

$$\begin{array}{ccc} A' & \xrightarrow{f'} & A \\ \downarrow{\scriptstyle g'} & & \downarrow{\scriptstyle g} \\ B' & \xrightarrow{f} & B, \end{array}$$

where f and g induce surjections $\pi_0 A \to \pi_0 B$, $\pi_0 B' \to \pi_0 B$. Then the induced diagram σ :

$$\begin{array}{ccc} (\mathrm{Mod}_{A'})_{<\infty} & \xrightarrow{f'^{\dagger}} & (\mathrm{Mod}_{A})_{<\infty} \\ \downarrow{\scriptstyle g'^{\dagger}} & & \downarrow{\scriptstyle g^{\dagger}} \\ (\mathrm{Mod}_{B'})_{<\infty} & \xrightarrow{f^{\dagger}} & (\mathrm{Mod}_{B})_{<\infty} \end{array}$$

is a pullback square of ∞-categories.

Proof. Let $\mathcal{C}$ denote the fiber product $(\mathrm{Mod}_A)_{<\infty} \times_{(\mathrm{Mod}_B)_{<\infty}} (\mathrm{Mod}_{B'})_{<\infty}$. Unwinding the definitions, we can identify the objects of $\mathcal{C}$ with triples (M, N, α), where M is a truncated A-module, N is a truncated B'-module, and $\alpha : \underline{\mathrm{Map}}_A(B, M) \to \underline{\mathrm{Map}}_{B'}(B, N)$ is an equivalence of B'-modules. The diagram σ determines a functor $G : (\mathrm{Mod}_{A'})_{<\infty} \to \mathcal{C}$; we wish to prove that G is an equivalence. We note that G has a left adjoint F, given on objects by the formula $F(M, N, \alpha) = M \amalg_{\underline{\mathrm{Map}}_A(B,M)} N$. We first prove that the counit map $v : F \circ G \to \mathrm{id}$ is an equivalence from $(\mathrm{Mod}_{A'})_{<\infty}$ to itself. Unwinding the definitions, we must show that if M is a truncated A'-module, then the diagram

$$\begin{array}{ccc} \underline{\mathrm{Map}}_{A'}(B, M) & \longrightarrow & \underline{\mathrm{Map}}_{A'}(A, M) \\ \downarrow & & \downarrow \\ \underline{\mathrm{Map}}_{A'}(B', M) & \longrightarrow & \underline{\mathrm{Map}}_{A'}(A', M) \end{array}$$

is a pushout square of A'-modules. This follows from our assumption that τ is a pullback square.

Since v is an equivalence, we deduce that the functor G is fully faithful. To complete the proof, it will suffice to show that F is conservative. Since F is an exact functor between stable ∞-categories, it will suffice to show that if (M, N, α) is an object of $\mathcal{C}$ which is annihilated by F, then M and N are both trivial. Suppose otherwise. Then there exists a smallest integer n such that $\pi_i M \simeq \pi_i N \simeq 0$ for $i > n$. Then $\pi_n M$ and $\pi_n N$ cannot both vanish; without loss of generality, we may assume that $\pi_n N \neq 0$. We have an exact sequence

$$0 \to \pi_n \underline{\mathrm{Map}}_A(B, M) \to \pi_n M \oplus \pi_n N \to \pi_n F(M, N, \alpha).$$

Since $\pi_n F(M, N, \alpha)$ vanishes, we deduce that the map $\pi_n \underline{\mathrm{Map}}_A(B, M) \to \pi_n M \oplus \pi_n N$ is an isomorphism. This contradicts the nontriviality of $\pi_n N$, since the map $\pi_n \underline{\mathrm{Map}}_A(B, M) \simeq \pi_n M$ is injective (because the homotopy groups $\pi_i M$ vanish for $i > n$). □

Lemma 6.6.4.9. *Let B be a Noetherian $\mathbb{E}_\infty$-ring, and let A be a square-zero extension of B by a connective, almost perfect B-module M. Suppose that B admits a dualizing module K. Then there exists a dualizing module K' for A and an equivalence $K \simeq \underline{\mathrm{Map}}_A(B, K')$.*

Proof. We will show that there exists a truncated A-module K' and an equivalence $K \simeq \underline{\mathrm{Map}}_A(B, K')$. Then K' is automatically a dualizing module for A, by Proposition 6.6.4.6. We have a pullback diagram of $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc} A & \longrightarrow & B \\ \downarrow & & \downarrow \eta \\ B & \xrightarrow{\eta_0} & B \oplus \Sigma M. \end{array}$$

By virtue of Lemma 6.6.4.8, it will suffice to show that $\eta^\dagger K$ and $\eta_0^\dagger K$ are equivalent as modules over $B \oplus \Sigma M$. Both $\eta^\dagger K$ and $\eta_0^\dagger K$ are dualizing modules for $B \oplus \Sigma M$ (Proposition 6.6.3.1). It follows that there exists an invertible module P for $B \oplus \Sigma M$ and an equivalence $\eta_0^\dagger K \simeq \eta^\dagger K \otimes_{B \oplus \Sigma M} P$. To complete the proof, it will suffice to show that P is trivial. Let $p : B \oplus \Sigma M \to B$ denote the projection map. Then

$$K \simeq p^\dagger \eta_0^\dagger K \simeq p^\dagger(\eta^\dagger K \otimes_{B \oplus \Sigma M} P) \simeq (p^\dagger \eta^\dagger K) \otimes_{B \oplus \Sigma M} P \simeq K \otimes_{B \oplus \Sigma M} P.$$

Invoking Remark 6.6.2.2, we deduce that $P \otimes_{B \oplus \Sigma M} B$ is equivalent to B (as an B-module). In particular, there exists an isomorphism

$$\pi_0 P \simeq \pi_0(P \otimes_{B \oplus \Sigma M} B) \simeq \pi_0 B.$$

Lifting the unit element of $\pi_0 B$ under such an isomorphism, we obtain an element $e \in \pi_0 P$, which determines a map $\gamma : B \oplus \Sigma M \to P$ of $(B \oplus \Sigma M)$-modules. Then $\mathrm{fib}(\gamma) \otimes_{B \oplus \Sigma M} B$ vanishes, so that $\mathrm{fib}(\gamma) \otimes_{B \oplus \Sigma M} N \simeq 0$ whenever N admits the structure of a B-module. SInce $B \oplus \Sigma M$ can be obtained as an extension of two $(B \oplus \Sigma M)$-modules which admit B-module structures, we deduce htat

$$\mathrm{fib}(\gamma) \simeq \mathrm{fib}(\gamma) \otimes_{B \oplus \Sigma M} (B \oplus \Sigma M)$$

vanishes, so that γ is an equivalence and $P \simeq B \oplus \Sigma M$ as desired. □

Proof of Theorem 6.6.4.1. Let A be a Noetherian $\mathbb{E}_\infty$-ring, and let $K(0)$ be a dualizing module for $\pi_0 A$. Without loss of generality, we may assume that $K(0)$ is 0-truncated. We will show that there exists a 0-truncated A-module K and an equivalence $K(0) \simeq \underline{\mathrm{Map}}_A(\pi_0 A, K)$. It will then follow from Proposition 6.6.4.6 that K is a dualizing module for A.

Since each truncation $\tau_{\leq n+1} A$ is a square-zero extension of $\tau_{\leq n} A$, Lemma 6.6.4.9 allows us to choose a sequence $K(n)$ of dualizing modules for $\tau_{\leq n} A$, together with equivalences

$$K(n) \simeq \underline{\mathrm{Map}}_{\tau_{\leq n+1} A}(\tau_{\leq n} A, K(n+1)).$$

It then follows by induction on n that each $K(n)$ is 0-truncated. Moreover, we have canonical fiber sequences

$$K(n-1) \xrightarrow{\beta_n} K(n) \to \underline{\mathrm{Map}}_{\tau_{\leq n+1} A}(\Sigma^n(\pi_n A), K(n)),$$

so that $\mathrm{cofib}(\beta_n)$ is $(-n)$-truncated for every integer n. Let $K = \varinjlim_n K(n)$, where the colimit is taken in the ∞-category Mod_A. Then K is a 0-truncated R-module, and we have a canonical map of $\pi_0 A$-modules $\alpha : K(0) \to K$. We will complete the proof by showing that α induces an equivalence $e : K(0) \to \underline{\mathrm{Map}}_A(\pi_0 A, K)$. Fix an integer $n \geqslant 0$, so that e is given by the composition

$$K(0) \simeq \underline{\mathrm{Map}}_{\tau_{\leqslant n} A}(\pi_0 A, K(n)) \xrightarrow{e'} \underline{\mathrm{Map}}_{\tau_{\leqslant n} A}(\pi_0 A, \underline{\mathrm{Map}}_A(\tau_{\leqslant n} A, K)) \simeq \underline{\mathrm{Map}}_A(\pi_0 A, K).$$

Here e' is induced by the map $f : K(n) \to \underline{\mathrm{Map}}_A(\tau_{\leqslant n} A, K)$. Let $f' : \underline{\mathrm{Map}}_A(\tau_{\leqslant n} A, K) \to K$ be the canonical map, so that $\mathrm{cofib}(f') \simeq \underline{\mathrm{Map}}_A(\tau_{\geqslant n+1} A, K)$ is $(-n-1)$-truncated. Since each of the maps β_m has $(-m)$-truncated cofiber, we deduce that $\mathrm{cofib}(f' \circ f)$ is $(-n-1)$-truncated. It follows that $\mathrm{cofib}(f)$ is $(-n-1)$-truncated, so that $\mathrm{cofib}(e') \simeq \mathrm{cofib}(e)$ is $(-n-1)$-truncated. Since we can choose n to be arbitrarily large, we conclude that e is an equivalence. □

6.6.5 Gorenstein Spectral Algebraic Spaces

Let X be a Noetherian spectral algebraic space. Then the structure sheaf $\mathscr{O}_{\mathsf{X}}$ automatically satisfies conditions (2) and (4) of Definition 6.6.1.1: that is, it is a coherent sheaf for which the unit map $\mathscr{O}_{\mathsf{X}} \to \underline{\mathrm{Map}}_{\mathscr{O}_{\mathsf{X}}}(\mathscr{O}_{\mathsf{X}}, \mathscr{O}_{\mathsf{X}}$ is an equivalence. This motivates the following:

Definition 6.6.5.1. Let X be a spectral algebraic space. We say that X is *Gorenstein* if X is Noetherian and the structure sheaf $\mathscr{O}_{\mathsf{X}}$ is a dualizing sheaf for X (see Definition 6.6.1.1). We say that a connective $\mathbb{E}_\infty$-ring A is *Gorenstein* if the spectral algebraic space $\mathrm{Spét}\, A$ is Gorenstein.

Remark 6.6.5.2. Gorenstein conditions in the setting of (not necessarily commutative) differential graded algebras have been investigated by a number of authors (see, for example, [63] and [66]). Gorenstein conditions on ring spectra are studied Dywer-Greenlees-Iyengar ([55]), though the context differs from the one we consider here (the reference [**?**] formulates a *local* version of Gorenstein duality, for ring spectra which need not be connective or commutative).

Remark 6.6.5.3. Unwinding the definitions, we see that a Noetherian spectral algebraic space X is Gorenstein if and only if the structure sheaf $\mathscr{O}_{\mathsf{X}}$ is truncated and of finite injective dimension.

Example 6.6.5.4. Let A be a regular Noetherian ring of finite Krull dimension. Then A is Gorenstein (Corollary 6.5.4.10).

Remark 6.6.5.5. Let X be a Noetherian spectral algebraic space. Using Proposition 6.5.4.9, we deduce that X is Gorenstein if and only if there exists integers $m, n \gg 0$ which satisfy the following conditions:

(a) The structure sheaf $\mathscr{O}_{\mathsf{X}}$ is m-truncated.

(b) For each point $x \in |\mathsf{X}|$ having residue field $\kappa(x)$, the !-fiber $\mathscr{O}^!_{\mathsf{X},x} \in \mathrm{Mod}_{\kappa(x)}$ is $(-n)$-connective.

If these conditions are satisfied, then Corollary 6.6.3.5 guarantees that for each $x \in |\mathsf{X}|$, there is an equivalence $\mathscr{O}^!_{\mathsf{X},x} \simeq \Sigma^{d(x)}\kappa(x)$ for some $-n \leqslant d(x) \leqslant m$. Note that Lemma 6.5.4.7 guarantees that $d(x) \geqslant -\mathrm{ht}(x)$, where $\mathrm{ht}(x)$ denotes the height of the point $x \in |\mathsf{X}|$.

Remark 6.6.5.6. Let X be a quasi-compact spectral algebraic space. The condition that X is Gorenstein can be tested locally (with respect to the étale topology) on X. More precisely, suppose that $f : \mathsf{U} \to \mathsf{X}$ is an étale morphism of spectral algebraic spaces, where U is quasi-compact (and therefore also Noetherian). If X is Gorenstein, then U is also Gorenstein; the converse holds if f is surjective (this is an immediate consequence of Remark 6.6.1.3).

Warning 6.6.5.7. In the setting of classical algebraic geometry, Definition 6.6.5.1 is not standard. Condition (a) of Remark 6.6.5.5 is automatic in classical algebraic geometry, but many authors replace (b) by the following *a priori* weaker condition:

(b') For each point $x \in |\mathsf{X}|$, the !-fiber $\mathscr{O}^!_{\mathsf{X},x}$ is an invertible object of $\mathrm{Mod}_{\kappa(x)}$.

Note that if Lemma 6.5.4.7 then guarantees that $\mathscr{O}^!_{\mathsf{X},x} \simeq \Sigma^d\kappa(x)$ for some $d \geqslant -\mathrm{ht}(x)$, where $\mathrm{ht}(x)$ denotes the height of the point $x \in |\mathsf{X}|$. It follows that if $|\mathsf{X}|$ has finite Krull dimension, then conditions (b) and (b') are equivalent.

The Gorenstein property is geometric, in the following sense:

Proposition 6.6.5.8. *Let κ be a field, let $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\,\kappa$ be a morphism between Noetherian spectral algebraic spaces which is of finite type, and let κ' be an extension field of κ. Then X is Gorenstein if and only if $\mathsf{X}' = \mathsf{X} \times_{\mathrm{Sp\acute{e}t}\,\kappa} \mathrm{Sp\acute{e}t}\,\kappa'$ is Gorenstein.*

Proof. Without loss of generality, we may assume that the structure sheaf $\mathscr{O}_{\mathsf{X}}$ is truncated (so that $\mathscr{O}_{\mathsf{X}'}$ is also truncated). Let $q : \mathsf{X}' \to \mathsf{X}$ be the projection map. Since the pullback functor q^* is t-exact, the direct image functor q_* carries objects of $\mathrm{QCoh}(\mathsf{X}')$ of injective dimension $\leqslant n$ to objects of $\mathrm{QCoh}(\mathsf{X})$ of injective dimension $\leqslant n$. Consequently, if X' is Gorenstein, then $q_* \mathscr{O}_{\mathsf{X}'}$ has finite injective dimension. It then follows that $\mathscr{O}_{\mathsf{X}}$ has finite injective dimension (since it is a direct summand of $q_* \mathscr{O}_{\mathsf{X}'}$), so that X is also Gorenstein.

For the converse, assume that X is Gorenstein; we wish to show that X' is also Gorenstein. Without loss of generality, we may assume that $\mathsf{X} = \mathrm{Sp\acute{e}t}\,A$ is affine (Remark 6.6.5.6), so that $\mathsf{X}' \simeq \mathrm{Sp\acute{e}t}\,A'$ for $A' = \kappa' \otimes_\kappa A$. Choose an integer d such that $\pi_0 A$ is generated as a κ-algebra by d elements. Our assumption that X is Gorenstein guarantees that there exists an integer $n \gg 0$ such that $\mathscr{O}^!_{\mathsf{X},x}$ is $(-n)$-connective for each point $x \in |\mathsf{X}|$ (Remark 6.6.5.5). For each point $x' \in |\mathsf{X}'|$ having image $x \in |\mathsf{X}|$, let $\mathsf{X}'_x = \mathrm{Sp\acute{e}t}\,\kappa(x) \times_{\mathsf{X}} \mathsf{X}'$. Note that $\kappa(x)$ is a finitely generated field extension of κ, and can therefore be identified with the fraction field of a reduced closed subvariety $\mathsf{Y} \subseteq \mathbf{P}^m_\kappa$ for some $m \gg 0$. Let $\omega = \omega_{\mathsf{Y}/\operatorname{Sp\acute{e}t}\kappa}$ denote the relative dualizing sheaf of the projection map $\mathsf{Y} \to \operatorname{Sp\acute{e}t}\kappa$, so that $\omega \in \operatorname{QCoh}(\mathsf{Y})$ is also an (absolute) dualizing sheaf (Proposition 6.6.3.1). Set $\mathsf{Y}' = \mathsf{Y} \times_{\mathbf{P}^m_\kappa} \mathbf{P}^m_{\kappa'}$ and let $g : \mathsf{Y}' \to \mathsf{Y}$ be the projection map, so that $g^*\omega \simeq \omega_{\mathsf{Y}'/\operatorname{Sp\acute{e}t}\kappa'}$ is a dualizing sheaf for Y' (Proposition 6.6.3.1 and Remark 6.4.2.6). It follows from Corollary 6.6.3.5 that the restriction of ω to the generic point $\operatorname{Sp\acute{e}t}\kappa(x)$ of Y is an invertible object of $\operatorname{QCoh}(\operatorname{Mod}_{\kappa(x)})$, so $(g^*\omega)|_{\mathsf{X}'_x}$ is an invertible object of $|\mathsf{X}'_x|$. Since $g^*\omega$ is a dualizing sheaf on Y', it has finite injective dimension; the criterion of Proposition 6.5.4.9 then shows that $(g^*\omega)|_{\mathsf{X}'_x} \in \operatorname{QCoh}(\mathsf{X}'_x)$ is also of finite injective dimension, so that X'_x is Gorenstein. Since X'_x has Krull dimension $\leqslant d$, the !-fiber $\mathscr{O}^!_{\mathsf{X}'_x, x'}$ for each point $x' \in |\mathsf{X}'|$ lying over x. Remark 6.5.4.4 then supplies an equivalence $\mathscr{O}^!_{\mathsf{X}',x'} \simeq \mathscr{O}^!_{\mathsf{X},x} \otimes_{\kappa(x)} \mathscr{O}^!_{\mathsf{X}'_x,x'}$, which shows that $\mathscr{O}^!_{\mathsf{X}',x'}$ is $(-n-d)$-connective. Using the criterion of Remark 6.6.5.5, we deduce that X' is Gorenstein. □

6.6.6 Gorenstein Morphisms

We now introduce a relative version of Definition **??**.

Definition 6.6.6.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. We will say that f is *Gorenstein* if the following conditions are satisfied:

(*a*) The morphism f is locally almost of finite presentation and locally of finite Tor-amplitude.

(*b*) For every field κ and every morphism $\eta : \operatorname{Sp\acute{e}t}\kappa \to \mathsf{Y}$, the fiber product $\mathsf{X}_\eta = \mathsf{X} \times_{\mathsf{Y}} \operatorname{Sp\acute{e}t}\kappa$ is locally Gorenstein: that is, for every étale morphism $\operatorname{Sp\acute{e}t} A \to \mathsf{X}_\eta$, the $\mathbb{E}_\infty$-ring A is Gorenstein (Definition 6.6.5.1).

Warning 6.6.6.2. In Definition 6.6.6.1, we do *not* require that the morphism $f : \mathsf{X} \to \mathsf{Y}$ is flat: an assumption of flatness would exclude many examples of interest (for example, quasi-smooth morphisms in the setting of derived algebraic geometry; see Example **??**).

Remark 6.6.6.3. In the situation of Definition 6.6.6.1, suppose that Y is a quasi-separated spectral algebraic space. Then it suffices to check the following *a priori* weaker version of condition (*b*):

(*b'*) For every point $y \in |\mathsf{Y}|$ with residue field $\kappa(y)$, the fiber product $\mathsf{X}_y = \operatorname{Sp\acute{e}t}\kappa(y) \times_{\mathsf{Y}} \mathsf{X}$ is Gorenstein.

This follows from Proposition 6.6.5.8.

Proposition 6.6.6.4. *Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \xrightarrow{g} & \mathsf{Y}. \end{array}$$

If f is Gorenstein, so is f'. The converse holds if g is a flat covering.

Proof. The first assertion follows immediately from Propositions 4.2.1.6 and 6.1.2.2. For the converse, assume that g is flat cover and that f' is Gorenstein. Using Propositions 4.2.1.5 and 6.1.2.2, we deduce that f is locally of finite Tor-amplitude and locally almost of finite presentation. To complete the proof that f is Gorenstein, it will suffice to show that for every field κ and every morphism $\eta : \operatorname{Sp\acute{e}t} \kappa \to \mathsf{Y}$, the fiber product $\mathsf{X}_\eta = \operatorname{Sp\acute{e}t} \kappa \times_{\mathsf{Y}} \mathsf{X}$ is locally Gorenstein. Using Proposition 6.6.5.8, we can enlarge the field κ and thereby reduce to the case where η factors through g, in which case the desired result follows from our assumption that f' is Gorenstein. □

Proposition 6.6.6.5. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of Noetherian spectral algebraic spaces. Assume that f is locally of finite type, that f is of finite* Tor*-amplitude, and that $\mathscr{O}_{\mathsf{Y}}$ is truncated. If Y is Gorenstein and the morphism f is Gorenstein, then X is Gorenstein. The converse holds if f is surjective.*

Proof. Suppose first that Y is Gorenstein and that f is Gorenstein; we wish to prove that X is Gorenstein. Without loss of generality, we may suppose that $\mathsf{Y} \simeq \operatorname{Sp\acute{e}t} A$ and $\mathsf{X} = \operatorname{Sp\acute{e}t} B$ are affine. Choose integers $a, b \geqslant 0$ such that A is a-truncated and f has Tor-amplitude $\leqslant b$, so that B is $(a+b)$-truncated. Since f is locally of finite type, we can choose a finite collection of elements $b_1, \ldots, b_d \in \pi_0 B$ which generate $\pi_0 B$ as an algebra over $\pi_0 A$. Since Y is Gorenstein, there exists an integer $n \gg 0$ such that $\mathscr{O}^!_{\mathsf{Y},y}$ is $(-n)$-connective for each $y \in |\mathsf{Y}|$. Let $x \in |\mathsf{X}|$, let $\kappa(x)$ denote the residue field of x. Set $y = f(x) \in |\mathsf{Y}|$ and $\mathsf{X}_y = \operatorname{Sp\acute{e}t} \kappa(x) \times_{\mathsf{Y}} \mathsf{X}$. Since $\mathsf{X}_y \simeq \operatorname{Sp\acute{e}t}(\kappa \otimes_A B)$ has Krull dimension $\leqslant d$, our assumption that f is Gorenstein guarantees that $\mathscr{O}^!_{\mathsf{Y}_y,x}$ is $(-d)$-connective (see Remark 6.6.5.5). It follows Using Remark 6.5.4.4, we obtain a canonical equivalence $\mathscr{O}^!_{\mathsf{X},x} \simeq \mathscr{O}^!_{\mathsf{Y},y} \otimes_{\kappa(y)} \mathscr{O}^!_{\mathsf{X}_y,x}$, so that $\mathscr{O}^!_{\mathsf{X},x}$ is $(-n-d)$-connective. Applying Remark 6.6.5.5, we deduce that X is Gorenstein.

Now suppose that f is surjective and that X is Gorenstein. Choose an integer m such that $\mathscr{O}^!_{\mathsf{X},x}$ is $(-m)$-connective for every point $x \in |\mathsf{X}|$. For each $y \in |\mathsf{Y}|$, we can choose some $x \in |\mathsf{X}|$ lying over y. Then $\mathscr{O}^!_{\mathsf{X}_y,x}$ is nonzero and b-truncated (Proposition 6.5.4.8). Using the equivalence $\mathscr{O}^!_{\mathsf{X},x} \simeq \mathscr{O}^!_{\mathsf{Y},y} \otimes_{\kappa(y)} \mathscr{O}^!_{\mathsf{X}_y,x}$ of Remark 6.5.4.4, we deduce that $\mathscr{O}^!_{\mathsf{Y},y}$ is $(-m-b)$-connective. Applying Remark 6.6.5.5, we conclude that Y is Gorenstein. Similarly, since $\mathscr{O}^!_{\mathsf{Y},y}$ is nonzero and a-truncated, we deduce that $\mathscr{O}^!_{\mathsf{Y}_y,x}$ is $(-m-a)$-connective for each $x \in |\mathsf{X}|$ lying over y, so that the fiber product $\mathsf{X} \times_{\mathsf{Y}} \operatorname{Sp\acute{e}t} \kappa(y)$ is Gorenstein (Remark 6.6.5.5). Using Remark 6.6.6.3, we conclude that f is Gorenstein. □

Corollary 6.6.6.6. *Let $f : \mathsf{X} \to \mathsf{Y}$ and $g : \mathsf{Y} \to \mathsf{Z}$ be morphisms of spectral Deligne-Mumford stacks. If f and g are Gorenstein, then the composition $g \circ f$ is Gorenstein.*

Proof. It follows from Proposition 4.2.3.3 that $(g \circ f)$ is locally almost of finite presentation and from Proposition 6.1.2.5 that $(g \circ f)$ is locally of finite Tor-amplitude. To complete the proof, it will suffice to show that for every field κ and every map $\eta : \operatorname{Spét} \kappa \to \mathsf{Z}$, the fiber product $\mathsf{X}_\eta = \operatorname{Spét} \kappa \times_{\mathsf{Z}} \mathsf{X}$ is Gorenstein. Set $\mathsf{Y}_\eta = \operatorname{Spét} \kappa \times_{\mathsf{Z}} \mathsf{Y}$. Since g is Gorenstein, the fiber Y_η is Gorenstein. The projection map $f_\eta : \mathsf{X}_\eta \to \mathsf{Y}_\eta$ is a pullback of f and is therefore Gorenstein by virtue of Proposition 6.6.6.4. Applying Proposition 6.6.6.4, we deduce that X_η is also Gorenstein. □

In the case of a proper morphism, Definition 6.6.6.1 admits a reformulation in terms of the relative dualizing complex:

Proposition 6.6.6.7. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is proper, locally almost of finite presentation, and locally of finite* Tor*-amplitude. The following conditions are equivalent:*

(a) The morphism f is Gorenstein, in the sense of Definition 6.6.6.1.

(b) The relative dualizing sheaf $\omega_{\mathsf{X}/\mathsf{Y}}$ is an invertible object of $\operatorname{QCoh}(\mathsf{X})$*.*

The proof of Proposition 6.6.6.7 will require the following:

Lemma 6.6.6.8. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks and let $\mathscr{F} \in \operatorname{QCoh}(\mathsf{X})$. Assume that:*

(i) The quasi-coherent sheaf $\mathscr{F}$ is almost perfect.

(ii) The morphism f has finite Tor*-amplitude and the quasi-coherent sheaf $\mathscr{F}$ has finite* Tor*-amplitude over Y (see Warning 6.4.4.4).*

(iii) For every field κ and every map $\eta : \operatorname{Spét} \kappa \to \mathsf{Y}$, the restriction of $\mathscr{F}$ to the fiber $\mathsf{X}_\eta = \operatorname{Spét} \kappa \times_{\mathsf{Y}} \mathsf{X}$ is an invertible object of $\operatorname{QCoh}(\mathsf{X}_\eta)$*.*

Then $\mathscr{F}$ is an invertible object of $\operatorname{QCoh}(\mathsf{X})$*.*

Proof. The assertion is local on X. We may therefore assume without loss of generality, we may assume that $\mathsf{Y} \simeq \operatorname{Spét} A$ and $\mathsf{X} \simeq \operatorname{Spét} B$ are affine. Set $M = \Gamma(\mathsf{X}; \mathscr{F})$; we wish to show that M is an invertible object of Mod_A. Fix a point $x \in |\mathsf{X}| \simeq |\operatorname{Spec} A|$ and let $\kappa(x)$ denote the residue field of A at x. It follows from (iii) that $\kappa(x) \times_B M$ is an invertible $\kappa(x)$-module. Replacing M by a suitable suspension, we may assume that $\kappa(x) \otimes_B M \simeq \kappa(x)$. Using our assumption that M is almost perfect, we can assume (after replacing X by an open neighborhood of x if necessary) that M is connective (Proposition 2.7.4.1). Choose an element $u \in \pi_0 M$ having nonzero image in $\pi_0(\kappa(x) \otimes_A M)$, so that u determines an A-module map $\alpha : B \to M$. We will show that, after replacing X by a smaller neighborhood of x if necessary, we can assume that α is an equivalence. To prove this, we are free to replace B by $\pi_0 B$, the $\mathbb{E}_\infty$-ring A by the tensor product $(\pi_0 B) \otimes_B A$, and the module M by the tensor product $(\pi_0 B) \otimes_B M$. In this case, assumption (ii) guarantees that $\mathrm{cofib}(\alpha)$ is n-truncated for some $n \gg 0$. Since $\kappa(x) \otimes_B \mathrm{cofib}(\alpha) \simeq 0$, we can arrange (after replacing X by a smaller neighborhood of x) that $\mathrm{cofib}(\alpha)$ is $(n+1)$-connective (Proposition 2.7.4.1), so that $\mathrm{cofib}(\alpha) \simeq 0$. It follows that α is an equivalence, so that M is an invertible object of Mod_A. □

Proof of Proposition 6.6.6.7. Suppose first that (a) is satisfied. It follows from Proposition 6.4.4.1 and Warning 6.4.4.4 that $\omega_{\mathsf{X}/\mathsf{Y}}$ is almost perfect and of finite Tor-amplitude over Y. For every map $\eta : \mathrm{Sp\acute{e}t}\,\kappa \to \mathsf{Y}$, set $\mathsf{X}_\eta = \mathrm{Sp\acute{e}t}\,\kappa \times_{\mathsf{Y}} \mathsf{X}$. Remark 6.4.2.6 supplies an equivalence $\omega_{\mathsf{X}_\eta/\mathrm{Sp\acute{e}t}\,\kappa} \simeq \omega_{\mathsf{X}/\mathsf{Y}}|_{\mathsf{X}_\eta}$. Proposition 6.6.3.1 guarantees that $\omega_{\mathsf{X}_\eta/\mathrm{Sp\acute{e}t}\,\kappa}$ is a dualizing sheaf for X_η, and is therefore invertible by virtue of assumption (a). Using Lemma 6.6.6.8, we deduce that $\omega_{\mathsf{X}/\mathsf{Y}}$ is invertible.

Now suppose that (b) is satisfied. We wish to show that for every field κ and every map $\eta : \mathrm{Sp\acute{e}t}\,\kappa \to \mathsf{Y}$ as above, the fiber $\mathsf{X}_\eta = \mathrm{Sp\acute{e}t}\,\kappa \times_{\mathsf{Y}} \mathsf{X}$ is Gorenstein. Assumption (b) guarantees that $\omega_{\mathsf{X}_\eta/\mathrm{Sp\acute{e}t}\,\kappa} \simeq \omega_{\mathsf{X}/\mathsf{Y}}|_{\mathsf{X}_\eta}$ is an invertible object of $\mathrm{QCoh}(\mathsf{X}_\eta)$. Since $\omega_{\mathsf{X}_\eta/\mathrm{Sp\acute{e}t}\,\kappa}$ is a dualizing object sheaf for X_η (Proposition 6.6.3.1), Proposition 6.6.2.1 guarantees that $\mathscr{O}_{\mathsf{X}_\eta}$ is also a dualizing sheaf for X_η, so that X_η is Gorenstein as desired. □

Chapter 7

Nilpotent, Local, and Complete Modules

Let X be a spectral Deligne-Mumford stack and let $j : \mathsf{U} \to \mathsf{X}$ be a quasi-compact open immersion, corresponding to an open subset $U \subseteq |\mathsf{X}|$. Then the pushforward functor $j_* : \mathrm{QCoh}(\mathsf{U}) \to \mathrm{QCoh}(\mathsf{X})$ is fully faithful. Roughly speaking, we can think of the ∞-category $\mathrm{QCoh}(\mathsf{X})$ as built from two parts: sheaves coming from the open set U (that is, those sheaves which lie in the essential image of j_*), and sheaves coming from the closed subset $K = |\mathsf{X}| - U$. In this section, we will develop some language which allows us to articulate this idea more precisely.

We begin in §7.1 by studying support conditions on quasi-coherent sheaves. We say that a sheaf $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is *supported* on the closed set $K \subseteq |\mathsf{X}|$ if the pullback $j^* \mathscr{F} \in \mathrm{QCoh}(\mathsf{U})$ vanishes. The quasi-coherent sheaves which are supported on K form a full subcategory $\mathrm{QCoh}_K(\mathsf{X}) \subseteq \mathrm{QCoh}(\mathsf{X})$. We will be particularly interested in the case where $\mathsf{X} = \mathrm{Sp\acute{e}t}\, R$ is affine. In this case, we can identify $K \subseteq |\mathsf{X}| \simeq |\mathrm{Spec}\, R|$ with the vanishing locus of an ideal $I \subseteq \pi_0 R$. A quasi-coherent sheaf $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is supported on K if and only if the R-module $M = \Gamma(\mathsf{X}; \mathscr{F})$ is *I-nilpotent*: that is, if and only the action of each element $x \in I$ is locally nilpotent on $\pi_* M$. We let $\mathrm{Mod}_R^{\mathrm{Nil}(I)}$ denote the full subcategory of Mod_R spanned by the I-nilpotent R-modules, so that the equivalence of ∞-category $\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R) \simeq \mathrm{Mod}_R$ restricts to an equivalence $\mathrm{QCoh}_K(\mathrm{Sp\acute{e}t}\, R) \simeq \mathrm{Mod}_R^{\mathrm{Nil}(I)}$.

We will say that an R-module M is *I-local* if, for every I-nilpotent R-module N, the mapping space $\mathrm{Map}_{\mathrm{Mod}_R}(N, M)$ is contractible. The collection of I-local R-modules span a full subcategory $\mathrm{Mod}_R^{\mathrm{Loc}(I)} \subseteq \mathrm{Mod}_R$. In §7.2, we will show that the pair of subcategories $(\mathrm{Mod}_R^{\mathrm{Nil}(I)}, \mathrm{Mod}_R^{\mathrm{Loc}(I)})$ determine a *semi-orthogonal decomposition* of the stable ∞-category Mod_R (Definition 7.2.0.1): in other words, every R-module M fits into an essentially unique fiber sequence $\Gamma_I M \to M \to L_I M$, where $\Gamma_I M$ is I-nilpotent and $L_I M$ is I-local. This is essentially a formal consequence of the observation that the collection of I-nilpotent objects of Mod_R is closed under colimits: modulo set-theoretic technicalities, one can construct $\Gamma_I M$ as the colimit $\varinjlim_{N \to M} N$, where N ranges over all I-nilpotent objects of $(\mathrm{Mod}_R)_{/M}$. Alternatively, when the ideal I is finitely generated, then the construction $M \mapsto L_I M$ can be identified with the localization functor $\mathscr{F} \mapsto j_* j^* \mathscr{F}$, where $j : \mathsf{U} \hookrightarrow \mathrm{Spét}\, R$ is the open immersion complementary to the vanishing locus of I.

We will say that an R-module M is *I-complete* if, for every I-local R-module N, the mapping space $\mathrm{Map}_{\mathrm{Mod}_R}(N, M)$ is contractible. If the ideal I is finitely generated, then the pair of subcategories $(\mathrm{Mod}_R^{\mathrm{Loc}(I)}, \mathrm{Mod}_R^{\mathrm{Cpl}(I)})$ determine another semi-orthogonal decomposition of the stable ∞-category Mod_R: in other words, every R-module M fits into an essentially unique fiber sequence $M' \to M \to M^{\wedge}_I$, where M' is I-local and $M^{\wedge}_I$ is I-complete. We will refer to the R-module $M^{\wedge}_I$ as the *I-completion* of M. In §7.3, we will make a detailed study of the construction $M \mapsto M^{\wedge}_I$ and its relationship with the classical I-adic completion functor $M \mapsto \varprojlim \{M/I^n M\}$ on the category $\mathrm{Mod}_R^{\heartsuit}$ of discrete R-modules.

Remark 7.0.0.1. By definition, and R-module M is I-nilpotent if and only if, for each $x \in M$, the colimit of the sequence

$$M \xrightarrow{x} M \xrightarrow{x} M \to \cdots$$

vanishes. Similarly, an R-module M is I-complete if and only if, for each $x \in I$, the inverse limit of the tower

$$\cdots \to M \xrightarrow{x} M \xrightarrow{x} M$$

vanishes. The conditions of I-nilpotence and I-completeness are two different ways of making precise the idea that an R-module M should be concentrated on the vanishing locus of the ideal I. In fact, the ∞-categories of I-nilpotent and I-complete R-modules are canonically equivalent (Proposition 7.3.1.7), though they do not coincide as subcategories of Mod_R.

The semi-orthogonal decompositions $(\mathrm{Mod}_R^{\mathrm{Nil}(I)}, \mathrm{Mod}_R^{\mathrm{Loc}(I)})$ and $(\mathrm{Mod}_R^{\mathrm{Loc}(I)}, \mathrm{Mod}_R^{\mathrm{Cpl}(I)})$ of Mod_R can be viewed as "linear" incarnations of a geometric idea: namely, that the affine spectral Deligne-Mumford stack $\mathsf{X} = \mathrm{Spét}\, R$ is obtained by "gluing" a formal neighborhood of the closed set $K \subseteq |\mathsf{X}|$ to the open substack $\mathsf{U} \subseteq \mathsf{X}$ complementary to K. In §7.4, we will make this idea more precise by establishing an ∞-categorical Beauville-Laszlo theorem (Theorem 7.4.0.1): if we take $\widehat{R} = R^{\wedge}_I$ to be the I-completion of R and $\widehat{\mathsf{U}}$ the inverse image of U in $\mathrm{Spét}\, \widehat{R}$, then the diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(\mathrm{Spét}\, R) & \longrightarrow & \mathrm{QCoh}(\mathsf{U}) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathrm{Spét}\, \widehat{R}) & \longrightarrow & \mathrm{QCoh}(\widehat{\mathsf{U}}) \end{array}$$

is a pullback square.

Though our main interest in this section is in studying R-modules, many of the notions we introduce in this section (such as I-nilpotence, I-locality, and I-completeness) make sense in greater generality. With an eye toward later applications, we frame most of our definitions in the context of R-linear ∞-categories, where R is an $\mathbb{E}_2$-ring. For a review of the relevant definitions, we refer the reader to Appendix D

Contents

7.1 Nilpotence and Support Conditions

Let X be a topological space, let $Y \subseteq X$ be a closed subset, and let $\mathscr{F}$ be a sheaf of abelian groups on X. We will say that $\mathscr{F}$ is *supported on* Y if the restriction $\mathscr{F}|_U \simeq 0$, where $U \subseteq X$ is the complement of Y. If $X = \operatorname{Spec} R$ is an affine scheme, Y is the vanishing locus of an ideal $I \subseteq R$, and $\mathscr{F}$ is the quasi-coherent sheaf associated to an R-module $M = \mathscr{F}(X)$, then $\mathscr{F}$ is supported on Y if and only if each element $x \in I$ determines a locally nilpotent map $M \xrightarrow{x} M$: that is, if and only if the localization $M[x^{-1}]$ vanishes for $x \in I$. Our goal in this section is to study an analogous condition in the setting of spectral algebraic geometry.

7.1.1 I-Nilpotent Objects

We begin with some general remarks. In what follows, we will assume that the reader is familiar with the language of R-linear prestable ∞-categories developed in Appendix D.

Definition 7.1.1.1. Let R be a connective $\mathbb{E}_2$-ring, let $x \in \pi_0 R$, and let $\mathcal{C}$ be a prestable R-linear ∞-category (see Definition D.1.2.1). For each object $C \in \mathcal{C}$, we let $C[x^{-1}]$ denote the relative tensor product $R[x^{-1}] \otimes_R C$ (which we will regard either as an object of $\mathcal{C}$ or of $R[x^{-1}] \otimes_R \mathcal{C} = \mathrm{LMod}_{R[x^{-1}]}(\mathcal{C})$, depending on the context). We will say that C is *x-nilpotent* if the localization $C[x^{-1}]$ vanishes.

Example 7.1.1.2. We will be primarily interested in the special case of Definition 7.1.1.1 where $\mathcal{C} = \mathrm{LMod}_R$ is the ∞-category of left R-modules. In this case, an object $M \in \mathcal{C}$ is x-nilpotent if and only if the action of x on $\pi_* M$ is locally nilpotent: that is, if and only if for each $y \in \pi_k M$, there exists an integer $n \gg 0$ such that $x^n y = 0$ (in the abelian group $\pi_k M$).

Remark 7.1.1.3. Let R be a connective $\mathbb{E}_2$-ring and let M be a left R-module. Then the canonical maps

$$R[x^{-1}] \otimes_R M \to R[x^{-1}] \otimes_R M \otimes_R R[x^{-1}] \leftarrow M \otimes_R R[x^{-1}]$$

are equivalences. Consequently, the localization $M[x^{-1}]$ can be obtained from M by tensoring with $R[x^{-1}]$ on either the left or the right.

Remark 7.1.1.4. Let R be a connective $\mathbb{E}_2$-ring, let $x \in \pi_0 R$, and let $\mathcal{C}$ be a prestable R-linear ∞-category. If $C \in \mathcal{C}$ is x-nilpotent, then the tensor product $M \otimes_R C$ vanishes for any left R-module M for which the map $M \xrightarrow{x} M$ is an equivalence. In this case, the unit map $M \to M[x^{-1}]$ is also an equivalence, so we have

$$M \otimes_R C \simeq M[x^{-1}] \otimes_R C \simeq M \otimes_R R[x^{-1}] \otimes_R C \simeq M \otimes_R C[x^{-1}] \simeq 0.$$

Proposition 7.1.1.5. *Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a prestable R-linear ∞-category, and let $C \in \mathcal{C}$ be an object. Then the set $I = \{x \in \pi_0 R : C \text{ is } x\text{-nilpotent } \}$ is a radical ideal in the commutative ring $\pi_0 R$.*

Proof. For $x, y \in \pi_0 R$, we have $C[(xy)^{-1}] \simeq (C[x^{-1}])[y^{-1}]$, so that $x \in I \Rightarrow xy \in I$. We next show that I is closed under addition. Choose elements $x, y \in \pi_0 R$, so that we have a cofiber sequence of connective R-modules

$$R[(x+y)^{-1}] \to R[(x+y)^{-1}, x^{-1}] \oplus R[(x+y)^{-1}, y^{-1}] \to R[(x+y)^{-1}, x^{-1}, y^{-1}],$$

hence a cofiber sequence

$$C[(x+y)^{-1}] \to C[x^{-1}][(x+y)^{-1}] \oplus C[y^{-1}][(x+y)^{-1}] \to C[x^{-1}][y^{-1}][(x+y)^{-1}].$$

If x and y belong to I, then the second terms in this fiber sequence vanish, so that the first does as well. This completes the proof that I is an ideal. We conclude by observing that for each $x \in \pi_0 R$, we have $C[x^{-1}] \simeq C[(x^n)^{-1}]$ for any $n > 0$, so that $x \in I$ if and only if $x^n \in I$. □

Definition 7.1.1.6. Let R be a connective $\mathbb{E}_\infty$-ring, let $\mathcal{C}$ be a prestable R-linear ∞-category, and let $I \subseteq \pi_0 R$ be an ideal. We say that an object $C \in \mathcal{C}$ is *I-nilpotent* if it is x-nilpotent for each $x \in I$ (in other words, if I is contained in the radical ideal of Proposition 7.1.1.5). We let $\mathcal{C}^{\mathrm{Nil}(I)}$ denote the full subcategory of $\mathcal{C}$ spanned by the I-nilpotent objects.

Example 7.1.1.7. Let R be a connective $\mathbb{E}_2$-ring and let $I \subseteq \pi_0 R$ be a finitely generated ideal. Then a left R-module M is I-nilpotent if and only if every element of $\pi_* M$ is annihilated by some power of I.

Remark 7.1.1.8. Let R be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a prestable R-linear ∞-category. The condition that an object $C \in \mathcal{C}$ is I-nilpotent depends only on the nilradical of I (Proposition 7.1.1.5). In other words, it depends only on the closed subset of $|\operatorname{Spec} \pi_0 R|$ given by the vanishing locus of I.

Remark 7.1.1.9. Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be an R-linear prestable ∞-category, and let $I \subseteq \pi_0 R$ be the sum of a collection of ideals $I_\alpha \subseteq \pi_0 R$. Then an object $C \in \mathcal{C}$ is I-nilpotent if and only if C is I_α-nilpotent for each α.

Remark 7.1.1.10. Let $\phi : R \to R'$ be a morphism of connective $\mathbb{E}_2$-rings, let $I \subseteq \pi_0 R$ be an ideal, and let I' denote the ideal of $\pi_0 R'$ generated by the image of I. Let $\mathcal{C}$ be a R'-linear prestable ∞-category, which we regard as an R-linear prestable ∞-category by restriction of scalars. Then an object $C \in \mathcal{C}$ is I'-nilpotent if and only if it is I-nilpotent.

Remark 7.1.1.11. If we restrict our attention to the case where $\mathcal{C}$ is stable, then Definition 7.1.1.6 makes sense without the assumption that R is connective (see Variant D.1.5.1). However, this does not really result in any additional generality: by virtue of Remark 7.1.1.10, the I-nilpotence of an object $C \in \mathcal{C}$ does not depend on whether we regard $\mathcal{C}$ as an R-linear ∞-category or as a $(\tau_{\geq 0} R)$-linear ∞-category.

Proposition 7.1.1.12. *Let R be a connective $\mathbb{E}_\infty$-ring, let $\mathcal{C}$ be a prestable R-linear ∞-category, and let $I \subseteq \pi_0 R$ be an ideal. Then:*

- (a) *The ∞-category $\mathcal{C}^{\mathrm{Nil}(I)}$ is presentable and is closed under colimits and extensions in $\mathcal{C}$, and is therefore a Grothendieck prestable ∞-category.*
- (b) *For every left R-module M, the construction $C \mapsto M \otimes_R C$ carries I-nilpotent objects of $\mathcal{C}$ to I-nilpotent objects of $\mathcal{C}$. Consequently, $\mathcal{C}^{\mathrm{Nil}(I)}$ inherits the structure of an R-linear prestable ∞-category.*
- (c) *If $\mathcal{C}$ is stable, then $\mathcal{C}^{\mathrm{Nil}(I)}$ is stable.*
- (d) *The full subcategory $\mathcal{C}^{\mathrm{Nil}(I)}$ is closed under finite limits. Consequently, the inclusion functor $\mathcal{C}^{\mathrm{Nil}(I)} \hookrightarrow \mathcal{C}$ is left exact.*
- (e) *If $\mathcal{C}$ is compactly generated and I is finitely generated, then $\mathcal{C}^{\mathrm{Nil}(I)}$ is also compactly generated. Moreover, the inclusion $\mathcal{C}^{\mathrm{Nil}(I)} \hookrightarrow \mathcal{C}$ preserves compact objects.*

Proof. Assertion (a) is obvious, and assertion (b) follows from the calculation

$$\begin{aligned}(M \otimes_R C)[x^{-1}] &\simeq R[x^{-1}] \otimes_R M \otimes_R C \\ &\simeq M[x^{-1}] \otimes_R C \\ &\simeq M \otimes_R R[x^{-1}] \otimes_R C \\ &\simeq M \otimes_R C[x^{-1}];\end{aligned}$$

see Remark 7.1.1.3. Assertion (c) is an immediate consequence of (a), since the collection of I-nilpotent objects of $\mathcal{C}$ is closed under desuspension. To prove (d), it suffices to show that for each $x \in \pi_0 R$, the collection of x-nilpotent objects of $\mathcal{C}$ is closed under finite limits. This follows from the fact that filtered colimits in $\mathcal{C}$ are left exact (so that the construction $C \mapsto C[x^{-1}] = \varinjlim(C \xrightarrow{x} C \xrightarrow{x} C \xrightarrow{x} \cdots)$ commutes with finite limits).

We now prove (e). Assume that $\mathcal{C}$ is compactly generated; we will prove that $\mathcal{C}^{\mathrm{Nil}(I)}$ is compactly generated by verifying the criterion of Corollary C.6.3.3. Let C be a nonzero I-nilpotent object of $\mathcal{C}$; we wish to show that there exists a nonzero map $C_0 \to C$, where C_0 is a compact object of $\mathcal{C}^{\mathrm{Nil}(I)}$. Applying the criterion of Corollary C.6.3.3 to the ∞-category $\mathcal{C}$, we deduce that there exists a nonzero map $\rho : C' \to C$, where C' is a compact object of $\mathcal{C}$. For each $x \in I$, the localization $C[x^{-1}]$ vanishes so that the composite map $C' \xrightarrow{\rho} C \to C[x^{-1}]$ is nullhomotopic. Realizing $C[x^{-1}]$ as the colimit of the sequence

$$C \xrightarrow{x} C \xrightarrow{x} C \xrightarrow{x} \cdots,$$

we deduce that the composite map $C' \xrightarrow{\rho} C \xrightarrow{x^k} C$ vanishes for $k \gg 0$. Using the commutativity of the diagram

$$\begin{array}{ccc} C' & \xrightarrow{\rho} & C \\ \downarrow{x^k} & & \downarrow{x^k} \\ C' & \xrightarrow{\rho} & C, \end{array}$$

we deduce that ρ factors through the cofiber $\mathrm{cofib}(x^k : C' \to C')$ We may therefore replace C' by $\mathrm{cofib}(x^k : C' \to C')$ and thereby reduce to the case where $C'[x^{-1}] \simeq 0$. Applying this procedure repeatedly, we can reduce to the case where $C'[x_i^{-1}] \simeq 0$ for some finite sequence $x_1, \ldots, x_n \in I$ which generates the ideal I. Then C' is I-nilpotent (Proposition 7.1.1.5), so that $\rho : C' \to C$ is a nonzero morphism in $\mathcal{C}^{\mathrm{Nil}(I)}$ whose domain is compact.

The preceding argument shows that every nonzero object $C \in \mathcal{C}^{\mathrm{Nil}(I)}$ admits a nonzero map where $C' \in \mathcal{D}$ is compact as an object of $\mathcal{C}$. The collection of such objects is closed under finite colimits and extensions, and therefore forms a set of compact generators for $\mathcal{C}^{\mathrm{Nil}(I)}$ (see Proposition C.6.3.1 and Corollary C.6.3.3). It follows immediately that $\mathcal{C}^{\mathrm{Nil}(I)}$ is compactly generated and that the inclusion $\mathcal{C}^{\mathrm{Nil}(I)} \hookrightarrow \mathcal{C}$ preserves compact objects, as desired. □

Variant 7.1.1.13. Let R be a connective $\mathbb{E}_\infty$-ring, let $\mathcal{C}$ be an abelian R-linear ∞-category (see Definition D.1.4.1), and let $I \subseteq \pi_0 R$ be an ideal. Then $\mathcal{C}^{\mathrm{Nil}(I)}$ is also an R-linear abelian category.

Example 7.1.1.14. Let R be a connective $\mathbb{E}_2$-ring and let $I \subseteq \pi_0 R$ be an ideal. Then the ∞-category $\mathrm{LMod}_R^{\mathrm{Nil}(I)}$ is bitensored over LMod_R. More precisely, if $M \in \mathrm{LMod}_R$ is I-nilpotent and $N \in \mathrm{LMod}_R$ is arbitrary, then $M \otimes_R N$ and $N \otimes_R M$ are I-nilpotent.

Remark 7.1.1.15. Let R be a connective $\mathbb{E}_2$-ring, and let $F : \mathcal{C} \to \mathcal{D}$ be an R-linear functor between prestable R-linear ∞-categories. For every ideal $I \subseteq \pi_0 R$, F restricts to an R-linear functor $F^{\mathrm{Nil}(I)} : \mathcal{C}^{\mathrm{Nil}(I)} \to \mathcal{D}^{\mathrm{Nil}(I)}$. It follows from assertion (d) of Proposition 7.1.1.12 that if F is left exact, then $F^{\mathrm{Nil}(I)}$ is left exact.

Remark 7.1.1.16. Let R be a connective $\mathbb{E}_2$-ring and let $\mathcal{C}$ be an R-linear prestable ∞-category. For each $x \in \pi_0 R$ and each $C \in \mathcal{C}$, we have canonical isomorphisms $\pi_n C[x^{-1}] \simeq (\pi_n C)[x^{-1}]$ in the abelian category $\mathcal{C}^{\heartsuit}$. Consequently, if $\mathcal{C}$ is separated and $I \subseteq \pi_0 R$ is an ideal, then an object $C \in \mathcal{C}$ is I-nilpotent if and only if $\pi_n C \in \mathcal{C}^{\heartsuit}$ is I-nilpotent for each $n \geqslant 0$. In this case, the prestable ∞-category $\mathcal{C}^{\mathrm{Nil}(I)}$ is also separated. If $\mathcal{C}$ is complete, the $\mathcal{C}^{\mathrm{Nil}(I)}$ is also complete.

Remark 7.1.1.17. Let R be a connective $\mathbb{E}_2$-ring and let $\mathcal{C}$ be an R-linear stable ∞-category equipped with a t-structure that is right complete and compatible with filtered colimits (so that $\mathcal{C}_{\geqslant 0}$ is a prestable R-linear ∞-category and $\mathcal{C} \simeq \mathrm{Sp}(\mathcal{C}_{\geqslant 0})$). For every ideal $I \subseteq \pi_0 R$, the following conditions on an object $C \in \mathcal{C}$ are equivalent:

- (a) The object $C \in \mathcal{C}$ is I-nilpotent.
- (b) For every integer n, the truncations $\tau_{\geqslant n} C$ and $\tau_{\leqslant n} C$ are I-nilpotent.
- (c) For every integer n, the truncation $\tau_{\geqslant n} C$ is I-nilpotent.

It follows that the pair $(\mathcal{C}^{\mathrm{Nil}(I)}_{\geqslant 0}, \mathcal{C}^{\mathrm{Nil}(I)}_{\leqslant 0}) = (\mathcal{C}^{\mathrm{Nil}(I)} \cap \mathcal{C}_{\geqslant 0}, \mathcal{C}^{\mathrm{Nil}(I)} \cap \mathcal{C}_{\leqslant 0})$ is a right compete t-structure on $\mathcal{C}^{\mathrm{Nil}(I)}$ which is compatible with filtered colimits. In particular, we have $\mathcal{C}^{\mathrm{Nil}(I)} \simeq \mathrm{Sp}(\mathcal{C}^{\mathrm{Nil}(I)}_{\geqslant 0})$.

If the t-structure on $\mathcal{C}$ is separated (meaning that $\bigcap \mathcal{C}_{\geqslant n}$ consists only of zero objects of $\mathcal{C}$), then conditions (a), (b), and (c) are equivalent to the following *a priori* weaker condition:

- (d) For each $n \in \mathbf{Z}$, the object $\pi_n C \in \mathcal{C}^{\heartsuit}$ is I-nilpotent.

Remark 7.1.1.18. Let R be connective $\mathbb{E}_2$-ring and let $I \subseteq \pi_0 R$ be an ideal. Let us say that a prestable R-linear ∞-category $\mathcal{C}$ is *I-nilpotent* if $\mathcal{C} = \mathcal{C}^{\mathrm{Nil}(I)}$: that is, if every object $C \in \mathcal{C}$ is I-nilpotent. Let $\mathrm{LinCat}^{\mathrm{PSt}}_R$ denote the ∞-category of prestable R-linear ∞-categories (Definition D.1.4.1), and let $\mathrm{LinCat}^{\mathrm{Nil}(I)}_R$ denote the full category of $\mathrm{LinCat}^{\mathrm{PSt}}_R$ spanned by the I-nilpotent prestable R-linear ∞-categories. It follows from Remark 7.1.1.15 that if $\mathcal{C}$ is I-nilpotent, then any R-linear functor $F : \mathcal{C} \to \mathcal{D}$ factors through the full subcategory $\mathcal{D}^{\mathrm{Nil}(I)}$. Consequently, we can view the construction $\mathcal{C} \mapsto \mathcal{C}^{\mathrm{Nil}(I)}$ as a right adjoint to the inclusion $\mathrm{LinCat}^{\mathrm{Nil}(I)}_R \hookrightarrow \mathrm{LinCat}^{\mathrm{PSt}}_R$.

7.1.2 Local Cohomology

Let R be a commutative ring containing an ideal $I \subseteq R$. Every (discrete) R-module M contains a largest I-nilpotent submodule $M_0 \subseteq M$, given by $M_0 = \{x \in M : (\forall y \in I)[y^n x = 0 \text{ for } n \gg 0\}$. We now discuss a generalization of this construction.

Definition 7.1.2.1. Let R be a connective $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be an ideal, and let $\mathcal{C}$ be a prestable R-linear ∞-category. We let $\Gamma_I : \mathcal{C} \to \mathcal{C}^{\mathrm{Nil}(I)}$ denote a right adjoint to the inclusion functor $\iota : \mathcal{C}^{\mathrm{Nil}(I)} \hookrightarrow \mathcal{C}$ (note that the existence of Γ_I is guaranteed by Corollary HTT.5.5.2.9 , since ι is a colimit preserving functor between presentable ∞-categories).

Warning 7.1.2.2. The notation of Definition 7.1.2.1 is potentially ambiguous: the functor Γ_I depends not only on the ideal I, but also on the prestable R-linear ∞-category $\mathcal{C}$. When the ∞-category $\mathcal{C}$ is not clear from the context, we will denote the functor Γ_I by $\Gamma^{\mathcal{C}}_I$.

Our next goal is to show that the operation Γ_I is reasonably well-behaved when the ideal I is finitely generated. We begin by treating the case where I is a principal ideal:

Proposition 7.1.2.3. *Let R be a connective $\mathbb{E}_2$-ring, let x be an element of $\pi_0 R$, and let $\mathcal{C}$ be a prestable R-linear ∞-category. For every object $C \in \mathcal{C}$, we have a fiber sequence (depending functorially on C) $\Gamma_{(x)} C \to C \to C[x^{-1}]$.*

Proof. Let $u : C \to C[x^{-1}]$ denote the canonical map (obtained from the localization map $R \to R[x^{-1}]$ by tensoring with C). Since filtered colimits in $\mathcal{C}$ are left exact, we have $\mathrm{fib}(u)[x^{-1}] = \mathrm{fib}(C[x^{-1}] \to (C[x^{-1}])[x^{-1}]) \simeq 0$: that is, the fiber $\mathrm{fib}(u)$ is (x)-nilpotent. For any (x)-nilpotent object $D \in \mathcal{C}$, the mapping space $\mathrm{Map}_{\mathcal{C}}(D, C[x^{-1}]) \simeq \mathrm{Map}_{\mathrm{LMod}_{R[x^{-1}]}(\mathcal{C})}(D[x^{-1}], C[x^{-1}])$ is contractible. It follows that the map $\mathrm{Map}_{\mathcal{C}}(D, \mathrm{fib}(u)) \to \mathrm{Map}_{\mathcal{C}}(D, C)$ is a homotopy equivalence, so that $\mathrm{fib}(u) \simeq \Gamma_{(x)} C$. □

Remark 7.1.2.4. Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a prestable R-linear ∞-category, and let $I, J \subseteq \pi_0 R$ be ideals. It follows from Remark 7.1.1.9 that we have $\mathcal{C}^{\mathrm{Nil}(I+J)} = (\mathcal{C}^{\mathrm{Nil}(I)})^{\mathrm{Nil}(J)}$. Consequently, the inclusion $\mathcal{C}^{\mathrm{Nil}(I+J)} \hookrightarrow \mathcal{C}$ factors as a composition $(\mathcal{C}^{\mathrm{Nil}(I)})^{\mathrm{Nil}(J)} \hookrightarrow \mathcal{C}^{\mathrm{Nil}(I)} \hookrightarrow \mathcal{C}$. It follows that the functor $\Gamma^{\mathcal{C}}_{I+J} : \mathcal{C} \to \mathcal{C}^{\mathrm{Nil}(I+J)}$ decomposes as compositions

$$\mathcal{C} \xrightarrow{\Gamma^{\mathcal{C}}_I} \mathcal{C}^{\mathrm{Nil}(I)} \xrightarrow{\Gamma^{\mathcal{C}^{\mathrm{Nil}(I)}}_J} (\mathcal{C}^{\mathrm{Nil}(I)})^{\mathrm{Nil}(J)} = \mathcal{C}^{\mathrm{Nil}(I+J)}.$$

Corollary 7.1.2.5. *Let R be a connective $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let $\mathcal{C}$ be a prestable R-linear ∞-category. Then the functor $\Gamma_I : \mathcal{C} \to \mathcal{C}^{\mathrm{Nil}(I)}$ commutes with filtered colimits.*

Proof. Using Remark 7.1.2.4, we can reduce to the case where I is generated by a single element, in which case the desired result follows from Proposition 7.1.2.3. □

Remark 7.1.2.6. In the situation of Corollary 7.1.2.5, suppose that the ∞-category $\mathcal{C}$ is stable. Then the full subcategory $\mathcal{C}^{\mathrm{Nil}(I)} \subseteq \mathcal{C}$ is also stable (Proposition 7.1.1.12). Consequently, the assumption that I is finitely generated implies that we can regard $\Gamma_I : \mathcal{C} \to \mathcal{C}^{\mathrm{Nil}(I)}$ as an R-linear functor (Remark D.1.5.3).

Corollary 7.1.2.7. *Let R be a connective $\mathbb{E}_2$-ring and let $I \subseteq \pi_0 R$ be a finitely generated ideal. Then there exists a left R-module V such that the functor $M \mapsto M \otimes_R V$ is right adjoint to the inclusion $\mathrm{LMod}_R^{\mathrm{Nil}(I)} \hookrightarrow \mathrm{LMod}_R$.*

Proof. Using Remark 7.1.2.6, we see that the functor $\Gamma_I : \mathrm{LMod}_R \to \mathrm{LMod}_R^{\mathrm{Nil}(I)}$ is given by $M \mapsto M \otimes_R \Gamma_I(R)$. □

Corollary 7.1.2.8. *Let R be a connective $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let $F : \mathcal{C} \to \mathcal{D}$ be an R-linear functor between prestable R-linear ∞-categories. If F is compact (Definition C.3.4.2), then the induced map $F^{\mathrm{Nil}(I)} : \mathcal{C}^{\mathrm{Nil}(I)} \to \mathcal{D}^{\mathrm{Nil}(I)}$ is also compact.*

Proof. The commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathcal{C}^{\mathrm{Nil}(I)} & \longrightarrow & \mathcal{C} \\ \downarrow{\scriptstyle F^{\mathrm{Nil}(I)}} & & \downarrow{\scriptstyle F} \\ \mathcal{D}^{\mathrm{Nil}(I)} & \longrightarrow & \mathcal{D} \end{array}$$

yields a commutative diagram of right adjoints

$$\begin{array}{ccc} \mathcal{C}^{\mathrm{Nil}(I)} & \xleftarrow{\Gamma_I^{\mathcal{C}}} & \mathcal{C} \\ \uparrow{\scriptstyle G'} & & \uparrow{\scriptstyle G} \\ \mathcal{D}^{\mathrm{Nil}(I)} & \xleftarrow{\Gamma_I^{\mathcal{D}}} & \mathcal{D} . \end{array}$$

Since F is compact, the functor G commutes with filtered colimits. Using Corollary 7.1.2.5, we deduce that the functor $(\Gamma_I^{\mathcal{C}} \circ G \simeq G' \circ \Gamma_I^{\mathcal{D}}) : \mathcal{D} \to \mathcal{C}^{\mathrm{Nil}(I)}$ commutes with filtered colimits. Restricting to the full subcategory $\mathcal{D}^{\mathrm{Nil}(I)} \subseteq \mathcal{D}$, we conclude that G' commutes with filtered colimits, so that $F^{\mathrm{Nil}(I)}$ is compact. □

Remark 7.1.2.9. In the special case where $\mathcal{C}$ is compactly generated, Corollaries 7.1.2.5 and 7.1.2.8 can also be deduced from part (e) of Proposition 7.1.1.12 (see Proposition HTT.5.5.7.2).

Corollary 7.1.2.10. *Let R be a connective $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let $F : \mathcal{C} \to \mathcal{D}$ be an R-linear functor between prestable R-linear ∞-categories. If F is left exact, then the diagram*

$$\begin{array}{ccc} \mathcal{C}^{\mathrm{Nil}(I)} & \longrightarrow & \mathcal{C} \\ \downarrow{\scriptstyle F^{\mathrm{Nil}(I)}} & & \downarrow{\scriptstyle F} \\ \mathcal{D}^{\mathrm{Nil}(I)} & \longrightarrow & \mathcal{D} \end{array}$$

is right adjointable. In particular, we have a canonical equivalence $F^{\mathrm{Nil}(I)} \circ \Gamma_I^{\mathcal{C}} \simeq \Gamma_I^{\mathcal{D}} \circ F$.

Proof. Using Remarks 7.1.2.4 and 7.1.1.15, we can reduce to the case where $I = (x)$ is generated by a single element. In this case, the desired result follows from the explicit description of the functors $\Gamma_I^{\mathcal{C}}$ and $\Gamma_I^{\mathcal{D}}$ given by Proposition 7.1.2.3. □

Corollary 7.1.2.11. *Let R be a connective $\mathbb{E}_2$-ring and let $I \subseteq \pi_0 R$ be a finitely generated ideal. For any prestable R-linear ∞-category $\mathcal{C}$, the canonical map*

$$\theta : (\mathrm{LMod}_R^{\mathrm{cn}})^{\mathrm{Nil}(I)} \otimes_R \mathcal{C} \to \mathrm{LMod}_R^{\mathrm{cn}} \otimes_R \mathcal{C} \simeq \mathcal{C}$$

is a fully faithful embedding, whose essential image is the full subcategory $\mathcal{C}^{\mathrm{Nil}(I)} \subseteq \mathcal{C}$.

Proof. Note that if $M \in \mathrm{LMod}_R^{\mathrm{cn}}$ is I-nilpotent, then the tensor product $M \otimes_R C$ is I-nilpotent for each $C \in \mathcal{C}$. It follows that the functor θ factors as a composition

$$(\mathrm{LMod}_R^{\mathrm{cn}})^{\mathrm{Nil}(I)} \otimes_R \mathcal{C} \xrightarrow{\theta_0} \mathcal{C}^{\mathrm{Nil}(I)} \hookrightarrow \mathcal{C}$$

Since the inclusion $(\mathrm{LMod}_R^{\mathrm{cn}})^{\mathrm{Nil}(I)} \hookrightarrow \mathrm{LMod}_R^{\mathrm{cn}}$ is left exact (Proposition 7.1.1.12), Proposition C.4.4.1 shows that the functor θ is left exact. Since $\mathcal{C}^{\mathrm{Nil}(I)}$ is closed under finite limits in $\mathcal{C}$ (Proposition 7.1.1.12) we conclude that θ_0 is left exact. It follows that the induced map of stabilizations

$$\mathrm{Sp}(\theta_0) : \mathrm{Sp}((\mathrm{LMod}_R^{\mathrm{cn}})^{\mathrm{Nil}(I)} \otimes_R \mathcal{C}) \to \mathrm{Sp}(\mathcal{C}^{\mathrm{Nil}(I)})$$

is t-exact. Consequently, to show that θ_0 is an equivalence of ∞-categories, it will suffice to show that $\mathrm{Sp}(\theta_0)$ is an equivalence of ∞-categories. For this, we can replace $\mathcal{C}$ by $\mathrm{Sp}(\mathcal{C})$ and thereby reduce to the case where $\mathcal{C}$ is stable, and we can identify $\mathrm{Sp}(\theta)$ with the canonical map

$$\mathrm{LMod}_R^{\mathrm{Nil}(I)} \otimes_R \mathcal{C} \to \mathrm{LMod}_R \otimes_R \mathcal{C} \simeq \mathcal{C}\,.$$

Let us regard the inclusion $\iota : \mathrm{LMod}_R^{\mathrm{Nil}(I)} \hookrightarrow \mathrm{LMod}_R$ and the functor $\Gamma_I : \mathrm{LMod}_R \to \mathrm{LMod}_R^{\mathrm{Nil}(I)}$ of Definition 7.1.2.1 as linear with respect to the *right* actions of LMod_R on LMod_R and $\mathrm{LMod}_R^{\mathrm{Nil}(I)}$ (Remark 7.1.2.6). It follows that Γ_I induces a functor

$$\phi : \mathrm{Sp}(\mathcal{C}) \simeq \mathrm{LMod}_R \otimes_R \mathrm{Sp}(\mathcal{C}) \to \mathrm{LMod}_R^{\mathrm{Nil}(I)} \otimes_R \mathrm{Sp}(\mathcal{C})$$

which we can regard as a right adjoint to $\mathrm{Sp}(\theta)$. Since the unit map $\mathrm{id}_{\mathrm{LMod}_R^{\mathrm{Nil}(I)}} \to \Gamma_I \circ \iota$ is an equivalence, it follows that the unit map $\mathrm{id} \to \phi \circ \mathrm{Sp}(\theta)$ is also an equivalence: that is, the functor $\mathrm{Sp}(\theta)$ is fully faithful. It will therefore suffice to show that the essential image of $\mathrm{Sp}(\theta)$ coincides with $\mathcal{C}^{\mathrm{Nil}(I)}$. Equivalently, we wish to show that an object $C \in \mathcal{C}$ is I-nilpotent if and only if it can be obtained as a colimit of objects of the form $M \otimes_R C'$, where $C' \in \mathcal{C}$ is arbitrary and $M \in \mathrm{LMod}_R$ is I-nilpotent. The "only if" direction is clear. To prove the converse, we first note that the construction $M \mapsto M \otimes_R C$ determines an R-linear functor $\mathrm{LMod}_R \to \mathcal{C}$. If C is I-nilpotent, then Corollary 7.1.2.10 supplies an equivalence

$$C \simeq \Gamma_I^{\mathcal{C}}(C) = \Gamma_I^{\mathcal{C}}(R \otimes_R C) \simeq \Gamma_I^{\mathrm{LMod}_R}(R) \otimes_R C,$$

where $\Gamma_I^{\mathrm{LMod}_R}(R)$ is I-nilpotent □

Remark 7.1.2.12. In the statements of Proposition 7.1.2.3 (and Corollaries 7.1.2.5, 7.1.2.7, 7.1.2.8, 7.1.2.10, and 7.1.2.11), the hypothesis that I is finitely generated can be weakened: it is sufficient to assume that there exists a finitely generated ideal $J \subseteq I$ having the same radical as I (see Remark 7.1.1.8).

7.1.3 The Locally Noetherian Case

We now specialize Definition 7.1.1.6 to the locally Noetherian case.

Proposition 7.1.3.1. *Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{A}$ be an abelian R-linear ∞-category, and let $I \subseteq \pi_0 R$ be an ideal. If $\mathcal{A}$ is locally Noetherian, then $\mathcal{A}^{\mathrm{Nil}(I)}$ is locally Noetherian.*

Proof. It follows from Variant 7.1.1.13 that $\mathcal{A}^{\mathrm{Nil}(I)}$ is an abelian R-linear ∞-category. If $\mathcal{A}$ is locally Noetherian, then every object $X \in \mathcal{A}^{\mathrm{Nil}(I)}$ can be written as a filtered colimit of Noetherian subobjects $X' \subseteq X$. Since X is I-nilpotent, any such subobject is also I-nilpotent, and is therefore a Noetherian object of $\mathcal{A}^{\mathrm{Nil}(I)}$. □

Corollary 7.1.3.2. *Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be an prestable R-linear ∞-category, and let $I \subseteq \pi_0 R$ be an ideal. If $\mathcal{C}$ is locally Noetherian (see Definition C.6.9.1), then $\mathcal{C}^{\mathrm{Nil}(I)}$ is locally Noetherian.*

Proof. Proposition 7.1.3.1 shows that the heart of $\mathcal{C}^{\mathrm{Nil}(I)}$ is locally Noetherian. Moreover, an object $X \in \mathcal{C}^{\mathrm{Nil}(I)\heartsuit}$ is Noetherian if and only if it is Noetherian when regarded as an object of $\mathcal{C}^{\heartsuit}$ (since the partially ordered set of isomorphism classes of subobjects of X does not depend on whether we view X as an object of $\mathcal{C}^{\heartsuit}$ or $\mathcal{C}^{\mathrm{Nil}(I)\heartsuit}$). In this case, our assumption that $\mathcal{C}$ is locally Noetherian guarantees that X is a compact object of $\tau_{\leqslant n}\mathcal{C}$ for each $n \geqslant 0$, and therefore also compact when viewed as an object of the ∞-category $\tau_{\leqslant n}\mathcal{C}^{\mathrm{Nil}(I)}$. □

Remark 7.1.3.3. Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a prestable R-linear ∞-category, and let $I \subseteq \pi_0 R$ be a finitely generated ideal. It follows immediately from the definitions that the functor $\Gamma_I : \mathrm{Sp}(\mathcal{C}) \to \mathrm{Sp}(\mathcal{C})^{\mathrm{Nil}(I)}$ carries injective objects of $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ to injective objects of $\mathrm{Sp}(\mathcal{C})^{\mathrm{Nil}(I)}_{\leqslant 0}$.

Proposition 7.1.3.4. *Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a prestable R-linear ∞-category, and let $I \subseteq \pi_0 R$ be an ideal. Suppose that I is finitely generated and that $\mathcal{C}$ is locally Noetherian. Then the inclusion map $\mathrm{Sp}(\mathcal{C}^{\mathrm{Nil}(I)}) \simeq \mathrm{Sp}(\mathcal{C})^{\mathrm{Nil}(I)} \hookrightarrow \mathrm{Sp}(\mathcal{C})$ carries injective objects of $\mathrm{Sp}(\mathcal{C}^{\mathrm{Nil}(I)})$ to injective objects of $\mathrm{Sp}(\mathcal{C})$ (see .Definition C.5.7.2).*

Proof. Proceeding by induction on the number of generators of I (and using Remark 7.1.2.4), we can reduce to the case where I is generated by a single element. Let Q be an injective object of $\mathrm{Sp}(\mathcal{C}^{\mathrm{Nil}(I)})_{\leqslant 0}$; we wish to show that Q is also injective when viewed as an object of $\mathrm{Sp}(\mathcal{C})$. By virtue of Proposition C.6.10.1, it will suffice to show that the group $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X, Q)$ vanishes for $n > 0$ when X is a Noetherian object of $\mathcal{C}^{\heartsuit}$. Let X' denote the kernel of the map $u : X \to X[x^{-1}]$, and let X'' be the image of u. We then have an exact sequence $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X'', Q) \to \mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X, Q) \to \mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X', Q)$, where the third term vanishes since

X' belongs to the heart of $\mathcal{C}^{\mathrm{Nil}(I)}$. We may therefore replace X by X'' and thereby reduce to the case where the multiplication map $x : X \to X$ is a monomorphism.

Since $\mathcal{C}$ is locally Noetherian, the object X is compact in $\tau_{\leqslant n}\mathcal{C}$, so the construction

$$Y \mapsto \mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X, Y) \simeq \pi_0 \mathrm{Map}_{\mathcal{C}}(X, \Omega^{\infty - n} Y)$$

commutes with filtered colimits when restricted to $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$. In particular, the vanishing of $Q[x^{-1}]$ guarantees that the action of x on $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X, Q)$ is locally nilpotent. It follows that every element of $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X, Q)$ lies in the image of the natural map $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(\mathrm{cofib}(x^k : X \to X), Q) \to \mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(X, Q)$ for $k \gg 0$. We conclude by observing that the abelian group $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(\mathrm{cofib}(x^k : X \to X), Q)$ vanishes, since $\mathrm{cofib}(x^k : X \to X)$ is I-nilpotent and Q is an injective object of $\mathrm{Sp}(\mathcal{C}^{\mathrm{Nil}(I)})_{\leqslant 0}$. □

Remark 7.1.3.5. Let R be a commutative ring, let $I \subseteq R$ be a finitely generated ideal, and let $\mathcal{A}$ be an abelian R-linear category which is locally Noetherian. Combining Proposition 7.1.3.4 with Theorem C.5.7.4, we deduce that the inclusion functor $\mathcal{A}^{\mathrm{Nil}(I)} \hookrightarrow \mathcal{A}$ carries injective objects to injective objects.

7.1.4 The Case of a Derived ∞-Category

Let $\mathcal{A}$ be a Grothendieck abelian category, and let $\mathcal{D}(\mathcal{A})$ be its derived ∞-category (see §HA.**??**). In what follows, we will abuse notation by identifying $\mathcal{A}$ with the full subcategory $\mathcal{D}(\mathcal{A})^{\heartsuit} \subseteq \mathcal{D}(\mathcal{A})$. If $\mathcal{A}$ is equipped with an action of a connective $\mathbb{E}_\infty$-ring R, then $\mathcal{D}(\mathcal{A})$ inherits an action of R (Example D.1.3.9). If $I \subseteq \pi_0 R$ is an ideal, we will say that an object $X \in \mathcal{A}$ is *I-nilpotent* if it is I-nilpotent when regarded as an object of $\mathcal{D}(\mathcal{A})$. Let $\mathcal{A}^{\mathrm{Nil}(I)}$ denote the full subcategory of $\mathcal{A}$ spanned by the I-nilpotent objects. Then $\mathcal{A}^{\mathrm{Nil}(I)} \simeq \mathcal{D}(\mathcal{A})^{\mathrm{Nil}(I)}_{\geqslant 0} \cap \mathcal{D}(\mathcal{A})^{\mathrm{Nil}(I)}_{\leqslant 0}$ is the heart of t-structure $(\mathcal{D}(\mathcal{A})^{\mathrm{Nil}(I)}_{\geqslant 0}, \mathcal{D}(\mathcal{A})^{\mathrm{Nil}(I)}_{\leqslant 0})$ of Remark 7.1.1.17. In particular, $\mathcal{A}^{\mathrm{Nil}(I)}$ is a Grothendieck abelian category which is stable under extensions in $\mathcal{A}$, and the inclusion $\mathcal{A}^{\mathrm{Nil}(I)} \hookrightarrow \mathcal{A}$ is an exact functor. Using Theorem C.5.4.9, we see that the inclusion $\mathcal{A}^{\mathrm{Nil}(I)} \hookrightarrow \mathcal{D}(\mathcal{A})^{\mathrm{Nil}(I)}$ extends to a t-exact functor $\mathcal{D}(\mathcal{A}^{\mathrm{Nil}(I)}) \to \mathcal{D}(\mathcal{A})^{\mathrm{Nil}(I)}$.

Theorem 7.1.4.1. *Let R be a commutative ring, let $I \subseteq R$ be an ideal, and let $\mathcal{A}$ be an abelian R-linear ∞-category. Suppose that $\mathcal{A}$ is locally Noetherian and that I is finitely generated. Then the map $\theta : \mathcal{D}(\mathcal{A}^{\mathrm{Nil}(I)}) \to \mathcal{D}(\mathcal{A})^{\mathrm{Nil}(I)}$ described above is an equivalence of ∞-categories.*

Remark 7.1.4.2. In the statement of Theorem 7.1.4.1, the assumption that R is discrete is irrelevant: the same conclusion is valid for any connective $\mathbb{E}_2$-ring R (see Example D.1.3.6).

We are primarily interested in the following special case of Theorem 7.1.4.1:

Corollary 7.1.4.3. *Let R be a Noetherian commutative ring, let $I \subseteq R$ be an ideal, and let $\mathrm{Mod}_R^{\heartsuit\,\mathrm{Nil}(I)}$ denote the abelian category of discrete, I-nilpotent R-modules. Then the inclusion $\mathrm{Mod}_R^{\heartsuit\,\mathrm{Nil}(I)} \hookrightarrow \mathrm{Mod}_R^{\mathrm{Nil}(I)}$ extends to a t-exact equivalence of ∞-categories $\mathcal{D}(\mathrm{Mod}_R^{\heartsuit\,\mathrm{Nil}(I)}) \to \mathrm{Mod}_R^{\mathrm{Nil}(I)}$.*

The proof of Theorem 7.1.4.1 will require some preliminaries.

Proposition 7.1.4.4. *Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a prestable R-linear ∞-category, let $n \geqslant 0$ be an integer, and let $I \subseteq \pi_0 R$ be a finitely generated ideal. Then:*

(a) If $\mathcal{C}$ is locally Noetherian and weakly n-complicial, then $\mathcal{C}^{\mathrm{Nil}(I)}$ is weakly n-complicial.

(b) If $\mathcal{C}$ is locally Noetherian and n-complicial, then $\mathcal{C}^{\mathrm{Nil}(I)}$ is n-complicial.

Proof. We first prove (a). Assume that $\mathcal{C}$ is locally Noetherian and weakly n-complicial; we wish to show that $\mathcal{C}^{\mathrm{Nil}(I)}$ is weakly n-complicial. By virtue of Proposition C.5.7.11, it will suffice to show that every injective object $Q \in \mathrm{Sp}(\mathcal{C}^{\mathrm{Nil}(I)})$ belongs to $\mathrm{Sp}(\mathcal{C}^{\mathrm{Nil}(I)})_{\geqslant -n}$. Our assumption that $\mathcal{C}$ is locally Noetherian guarantees that Q is also injective when viewed as an object of $\mathrm{Sp}(\mathcal{C})$ (Proposition 7.1.3.4). The desired result now follows from Proposition C.5.7.11, since $\mathcal{C}$ is assumed to be weakly n-complicial.

We now prove (b). Assume that $\mathcal{C}$ is locally Noetherian and n-complicial; we wish to show that $\mathcal{C}^{\mathrm{Nil}(I)}$ is also n-complicial. Proceeding by induction on the number of generators of I, we can reduce to the case where $I = (x)$ is a principal ideal. Fix an object $X \in \mathcal{C}^{\mathrm{Nil}(I)}$; we wish to prove that there exists a map $f : Y \to X$ which induces an epimorphism on π_0, where Y is an n-truncated object of $\mathcal{C}^{\mathrm{Nil}(I)}$. Writing X as a filtered colimit of objects of the form $\mathrm{fib}(x^n : X \to X)$, we can reduce to the case where the map $x^n : X \to X$ is nullhomotopic. Our assumption that $\mathcal{C}$ is n-complicial guarantees that we can find a map $g : Z \to X$ which induces an epimorphism on π_0, where Z is an n-truncated object of $\mathcal{C}$. Then g factors as a composition $Z \to Z' \xrightarrow{g'} X$, where $Z' = \mathrm{cofib}(x^n : Z \to Z)$. Since Z is n-truncated, the object Z' is $(n+1)$-truncated. We now apply (a) to deduce the existence of an n-truncated object $Y \in \mathcal{C}^{\mathrm{Nil}(I)}$ and a morphism $h : Y \to Z'$ which induces an epimorphism on π_0. We complete the proof by setting $f = g' \circ h$. □

Proof of Theorem 7.1.4.1. Combine Proposition 7.1.4.4 with Remark C.5.4.11.

□

Remark 7.1.4.5. In the situation of Theorem 7.1.4.1, it follows from Remark 7.1.3.3 that the functor $\Gamma_I|_{\mathcal{D}^+(\mathcal{A})} : \mathcal{D}^+(\mathcal{A}) \to \mathcal{D}^+(\mathcal{A}^{\mathrm{Nil}(I)})$ can be identified with the right derived functor of the left exact functor of abelian categories $\Gamma_I^{\heartsuit} : \mathcal{A} \to \mathcal{A}^{\mathrm{Nil}(I)}$, in the sense of Example HA.1.3.3.4 .

Example 7.1.4.6. Let R be a Noetherian commutative ring and let $I \subseteq R$ be an ideal. Applying Remark 7.1.4.5 to the abelian category $\mathcal{A} = \mathrm{Mod}_R^{\heartsuit}$, we see that the functor $\Gamma_I : \mathrm{Mod}_R \to \mathrm{Mod}_R^{\mathrm{Nil}(I)}$ can be identified with the right derived functor of $\Gamma_I^{\heartsuit} : \mathrm{Mod}_R^{\heartsuit} \to \mathrm{Mod}_R^{\heartsuit \, \mathrm{Nil}(I)}$ given by $\Gamma_I^{\heartsuit} M = \{x \in M : I^n x = 0 \text{ for } n \gg 0\} \subseteq M$. In other words, Definition 7.1.2.1 reproduces Grothendieck's theory of local cohomology (see, for example, [**?**]).

7.1.5 Supports of Quasi-Coherent Sheaves

Let R be a connective $\mathbb{E}_\infty$-ring, let $I \subseteq \pi_0 R$ be an ideal, and let M be an R-module. We now observe that the condition M is I-nilpotent (Definition 7.1.1.6) has a geometric interpretation: it is equivalent to the requirement that the quasi-coherent sheaf associated to M is supported on the vanishing locus of I (Proposition 7.1.5.3).

Definition 7.1.5.1. Let X be a spectral Deligne-Mumford stack, let $K \subseteq |\mathsf{X}|$ be a closed subset, and let $j : \mathsf{U} \to \mathsf{X}$ be the complementary open immersion. We will say that a quasi-coherent sheaf $\mathscr{F} \in \mathsf{X}$ is *supported on* K if $j^* \mathscr{F}$ is a zero object of $\mathrm{QCoh}(\mathsf{U})$. We let $\mathrm{QCoh}_K(\mathsf{X})$ denote the full subcategory of $\mathrm{QCoh}(\mathsf{X})$ spanned by those quasi-coherent sheaves which are supported on K.

Remark 7.1.5.2. Let X be a spectral Deligne-Mumford stack, let $K \subseteq |\mathsf{X}|$ be a closed subset, and let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$. Then $\mathscr{F}$ is supported on K if and only if each of the homotopy sheaves $\pi_i \mathscr{F}$ is supported on K. It follows that the full subcategories

$$\mathrm{QCoh}_K(\mathsf{X})_{\geqslant 0} = \mathrm{QCoh}_K(\mathsf{X}) \cap \mathrm{QCoh}(\mathsf{X})_{\geqslant 0} \qquad \mathrm{QCoh}_K(\mathsf{X})_{\leqslant 0} = \mathrm{QCoh}_K(\mathsf{X}) \cap \mathrm{QCoh}(\mathsf{X})_{\leqslant 0}$$

determine a t-structure on $\mathrm{QCoh}_K(\mathsf{X})$.

In the case where X is affine, Definition 7.1.5.1 reduces to Definition 7.1.1.6:

Proposition 7.1.5.3. *Let $\mathsf{X} = \mathrm{Sp\acute{e}t}\, A$ be an affine spectral Deligne-Mumford stack, let $I \subseteq \pi_0 A$ be an ideal, and let $K \subseteq |\mathsf{X}| \simeq |\mathrm{Spec}\, A|$ be the vanishing locus of I. Then the equivalence of ∞-categories $\mathrm{QCoh}(\mathsf{X}) \simeq \mathrm{Mod}_A$ restricts to an equivalence of ∞-categories $\mathrm{QCoh}_K(\mathsf{X}) \simeq \mathrm{Mod}_A^{\mathrm{Nil}(I)}$.*

Proof. Let U be the open substack of X complementary to K. Note that U can be written as a union of open substacks of the form $\mathrm{Sp\acute{e}t}\, A[x^{-1}]$, where $x \in I$. Let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ be a quasi-coherent sheaf with image $M \in \mathrm{Mod}_A$. Then $\mathscr{F} \in \mathrm{QCoh}_K(\mathsf{X})$ if and only if $A[x^{-1}] \otimes_A M \simeq 0$ for each $x \in I$: that is, if and only if the action of each $x \in I$ is locally nilpotent on $\pi_* M$. □

Definition 7.1.5.4. Let X be a spectral Deligne-Mumford stack and let $\mathscr{F}$ be a quasi-coherent sheaf on X. The collection of closed subsets $K \subseteq |\mathsf{X}|$ such that $\mathscr{F}$ is supported on

K is closed under intersections. It follows that there is a smallest closed subset $K \subseteq |\mathsf{X}|$ such that $\mathscr{F} \in \mathrm{QCoh}_K(\mathsf{X})$. We will refer to the set K as the *support of* $\mathscr{F}$ and denote it by $\mathrm{Supp}(\mathscr{F})$.

In general, the support $\mathrm{Supp}(\mathscr{F})$ of a quasi-coherent sheaf is not a very well-behaved invariant: for example, it is not stable under base change. However, the situation is better if we assume that $\mathscr{F}$ is perfect.

Proposition 7.1.5.5. *Let* X *be a spectral Deligne-Mumford stack, and let* $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ *be perfect. Then:*

- (a) *The support* $\mathrm{Supp}(\mathscr{F})$ *is cocompact. That is, if* U *denotes the open substack of* X *complementary to* $\mathrm{Supp}(\mathscr{F})$*, then the open immersion* $\mathsf{U} \hookrightarrow \mathsf{X}$ *is quasi-compact.*

- (b) *For every field* κ *and every map* $\eta : \mathrm{Sp\acute{e}t}\,\kappa \to \mathsf{X}$*, the resulting point of* $|\mathsf{X}|$ *belongs to* $\mathrm{Supp}(\mathscr{F})$ *if and only if* $\eta^* \mathscr{F} \neq 0$*.*

Corollary 7.1.5.6. *Let* X *be a spectral Deligne-Mumford stack, and let* $\mathscr{F}, \mathscr{G} \in \mathrm{QCoh}(\mathsf{X})$ *be perfect. Then* $\mathrm{Supp}(\mathscr{F} \otimes \mathscr{G}) = \mathrm{Supp}(\mathscr{F}) \cap \mathrm{Supp}(\mathscr{G})$*. In particular, if* $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ *is perfect and* $\mathrm{End}(\mathscr{F}) \simeq \mathscr{F} \otimes \mathscr{F}^\vee \in \mathrm{Alg}(\mathrm{QCoh}(\mathsf{X}))$ *classifies endomorphisms of* $\mathscr{F}$*, then* $\mathrm{Supp}(\mathrm{End}(\mathscr{F})) = \mathrm{Supp}(\mathscr{F})$*.*

Corollary 7.1.5.7. *Let* $f : \mathsf{X} \to \mathsf{Y}$ *be a morphism of spectral Deligne-Mumford stacks, and let* $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})$ *be perfect. Then* $\mathrm{Supp}(f^* \mathscr{F}) \subseteq |\mathsf{X}|$ *is the inverse image of* $\mathrm{Supp}(\mathscr{F}) \subseteq |\mathsf{Y}|$ *under the induced map* $|f| : |\mathsf{X}| \to |\mathsf{Y}|$*.*

Proof of Proposition 7.1.5.5. We first claim that there exists a unique closed subset $K \subseteq |\mathsf{X}|$ with the following property:

- (b') For every field κ and every map $\eta : \mathrm{Sp\acute{e}t}\,\kappa \to \mathsf{X}$, the resulting point of $|\mathsf{X}|$ belongs to K if and only if $\eta^* \mathscr{F} \neq 0$.

Moreover, we claim that K is cocompact.

To prove these assertions, we can work locally on X and thereby reduce to the case where $\mathsf{X} = \mathrm{Sp\acute{e}t}\,A$ for some connective $\mathbb{E}_\infty$-ring A, and that $\mathscr{F}$ corresponds to perfect A-module M under the equivalence $\mathrm{QCoh}(\mathsf{X}) \simeq \mathrm{Mod}_A$. Replacing A by $\pi_0 A$ and M by $(\pi_0 A) \otimes_A M$, we may assume that A is discrete. Write A as a union of finitely generated subrings A_α. Using Lemma HA.7.3.5.13 , we can write $M = A \otimes_{A_\alpha} M_\alpha$, for some index α and some perfect A_α-module M_α. We may therefore replace A by A_α, and thereby reduce to the case where A is a finitely generated discrete commutative ring. In particular, A is Noetherian.

Since M is an almost perfect A-module, each homotopy group $\pi_n M$ is a finitely generated as a discrete module over A (Proposition HA.7.2.4.17). Since A is discrete, every A-module of finite Tor-amplitude (and therefore every perfect A-module) is m-truncated for $m \gg 0$. It follows that $\pi_* M$ is a finitely generated A-module. Let $I \subseteq A$ be the annihilator of $\pi_* M$. Then I determines a closed subset $K \subseteq |\operatorname{Spec} A| \simeq |\mathsf{X}|$ (which is automatically cocompact, since A is Noetherian). We claim that K satisfies (b').

Suppose first that we are given a field κ and a ring homomorphism $\phi : A \to \kappa$ for which the induced map $|\operatorname{Sp\acute{e}t} \kappa| \to |\mathsf{X}|$ does not factor through K. Then I contains an element a such that $\phi(a) \neq 0$. Since $a \in I$, we have $M[a^{-1}] \simeq 0$. Then $\kappa \otimes_A M \simeq \kappa \otimes_{A[a^{-1}]} M[a^{-1}] \simeq 0$.

Conversely, suppose that $\phi : A \to \kappa$ is a ring homomorphism such that $\phi(I) = 0$. We wish to prove that $\kappa \otimes_A M \neq 0$. Let $\mathfrak{p} = \ker(\phi)$. Since $\phi(I) = 0$, the localization $(\pi_* M)_{\mathfrak{p}}$ does not vanish. Let n be the smallest integer such that $(\pi_n M)_{\mathfrak{p}}$ is nonzero. Then the direct sum $\bigoplus_{m<n} \pi_m M$ is a finitely generated A-module whose tensor product with $A_{\mathfrak{p}}$ vanishes. It follows that there exists an element $a \notin \mathfrak{p}$ such that $\pi_m M[a^{-1}] \simeq 0$ for $m < n$. Replacing A by $A[a^{-1}]$ and M by $M[a^{-1}]$, we may assume that $\pi_m M \simeq 0$ for $m < n$. In this case, Corollary HA.7.2.1.23 supplies a canonical isomorphism $\pi_n(\kappa \otimes_A M) \simeq \operatorname{Tor}_0^A(\kappa, \pi_n M)$. Since $(\pi_n M)_{\mathfrak{p}}$ is a nonzero and finitely generated over $A_{\mathfrak{p}}$, Nakayama's lemma implies that $\operatorname{Tor}_0^A(\kappa, \pi_n M) \neq 0$, so that $\kappa \otimes_A M \neq 0$. This completes the proof of (b').

To complete the proof of Proposition 7.1.5.5, it will suffice to show that $K = \operatorname{Supp}(\mathscr{F})$. The inclusion $K \subseteq \operatorname{Supp}(\mathscr{F})$ follows immediately from (b'). To prove the reverse inclusion, it will suffice to show that if U is the open substack of X complementary to K, then $\mathscr{F}|_{\mathsf{U}} \simeq 0$. Replacing X by U, we are reduced to proving that $K = \emptyset$ implies $\mathscr{F} \simeq 0$. The desired conclusion $\mathscr{F} \simeq 0$ can be tested locally on X, so we may assume as above that $\mathsf{X} \simeq \operatorname{Sp\acute{e}t} A$ is affine and that $\mathscr{F}$ corresponds to a perfect A-module M. Suppose that M is nonzero. Since M is perfect, there exists a smallest integer n such that $\pi_n M \neq 0$. For every prime ideal $\mathfrak{p} \subseteq \pi_0 A$, let $\kappa(\mathfrak{p})$ denote the residue field of $\pi_0 A$ at $\mathfrak{p}$. Since $\operatorname{Supp}(M) = \emptyset$, Corollary HA.7.2.1.23 supplies an isomorphism $\operatorname{Tor}_0^{\pi_0 A}(\kappa(\mathfrak{p}), \pi_n M) \simeq \pi_n(\kappa(\mathfrak{p}) \otimes_A M) \simeq 0$ for every prime ideal $\mathfrak{p} \subseteq \pi_0 A$. Since $\pi_n M$ is a finitely generated module over $\pi_0 A$, Nakayama's lemma implies that the localization $(\pi_n M)_{\mathfrak{p}}$ vanishes. Since $\mathfrak{p}$ is arbitrary, we deduce that $\pi_n M \simeq 0$, contrary to our assumption that $M \neq 0$. $\square$

7.2 Semi-Orthogonal Decompositions

Let X be a topological space, let $Y \subseteq X$ be a closed subset, and let $U = X - Y$ denote the complement of Y. Let $i : Y \hookrightarrow X$ and $j : U \hookrightarrow X$ be the corresponding closed and open immersions. Then the direct image functors

$$i_* : \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(Y) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(X) \qquad j_* : \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(U) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(X)$$

are fully faithful. Moreover, for every spectrum-valued sheaf $\mathscr{F}$ on X, we have a canonical fiber sequence $i_* i^! \mathscr{F} \to \mathscr{F} \to j_* j^* \mathscr{F}$, where $i^!$ denotes the right adjoint to i_*. The following definition allows us to describe the situation axiomatically:

Definition 7.2.0.1. Let $\mathcal{C}$ be a stable ∞-category. We will say that a pair $(\mathcal{C}_+, \mathcal{C}_-)$ of full subcategories $\mathcal{C}_+, \mathcal{C}_- \subseteq \mathcal{C}$ is a *semi-orthogonal decomposition* of $\mathcal{C}$ is the following axioms are satisfied:

(a) The full subcategories $\mathcal{C}_+$ and $\mathcal{C}_-$ are closed under finite limits and colimits (in particular, they are stable).

(b) For every object $C \in \mathcal{C}_+$ and every object $D \in \mathcal{C}_-$, the mapping space $\mathrm{Map}_{\mathcal{C}}(C, D)$ is contractible.

(c) Every object $C \in \mathcal{C}$, there exists a fiber sequence $C_+ \to C \to C_-$, where $C_+ \in \mathcal{C}_+$ and $C_- \in \mathcal{C}_-$.

Remark 7.2.0.2. Let $\mathcal{C}$ be a stable ∞-category. Unwinding the definitions, we see that a semi-orthogonal decomposition of $\mathcal{C}$ is a t-structure $(\mathcal{C}_+, \mathcal{C}_-)$ on $\mathcal{C}$ such that $\mathcal{C}_+$ and $\mathcal{C}_-$ are stable subcategories of $\mathcal{C}$ (see Definition HA.1.2.1.1). It follows that for each object $C \in \mathcal{C}$, the fiber sequence $C_+ \to C \to C_-$ whose existence is asserted by part (c) of Definition 7.2.0.1 is essentially unique, and depends functorially on C: the construction $C \mapsto C_+$ is right adjoint to the inclusion $\mathcal{C}_+ \hookrightarrow \mathcal{C}$, and the construction $C \mapsto C_-$ is left adjoint to the inclusion $\mathcal{C}_- \hookrightarrow \mathcal{C}$.

Example 7.2.0.3. Let X be a topological space, let $i : Y \hookrightarrow X$ be a closed immersion, and let $j : U \hookrightarrow X$ be the complementary open immersion. Then the ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(X)$ admits a semiorthogonal decomposition $(\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(X)_+, \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(X)_-)$, where $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(X)_+$ is the essential image of the fully faithful embedding $i_* : \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(Y) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(X)$ and $\mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(X)_-$ is the essential image of the fully faithful embedding $j_* : \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(U) \to \mathcal{S}\mathrm{hv}_{\mathrm{Sp}}(X)$.

Our goal in this section is to review the theory of semi-orthogonal decompositions and to describe some examples which arise naturally in algebraic geometry.

7.2.1 Semi-Orthogonal Decompositions of Stable ∞-Categories

We begin with a few general categorical remarks.

Definition 7.2.1.1. Let $\mathcal{C}$ be an ∞-category and let $\mathcal{D} \subseteq \mathcal{C}$ be a subcategory. We define full subcategories ${}^{\perp}\mathcal{D} \subseteq \mathcal{C} \supseteq \mathcal{D}^{\perp}$ as follows:

- An object $X \in \mathcal{C}$ belongs to ${}^{\perp}\mathcal{D}$ if and only if, for every object $Y \in \mathcal{D}$, the mapping space $\mathrm{Map}_{\mathcal{C}}(X, Y)$ is contractible.
- An object $Y \in \mathcal{C}$ belongs to $\mathcal{D}^{\perp}$ if and only if, for every object $X \in \mathcal{D}$, the mapping space $\mathrm{Map}_{\mathcal{C}}(X, Y)$ is contractible.

We will refer to ${}^{\perp}\mathcal{D}$ as the *left orthogonal* to the full subcategory $\mathcal{D} \subseteq \mathcal{C}$, and to $\mathcal{D}^{\perp}$ as the *right orthogonal* to $\mathcal{D} \subseteq \mathcal{C}$.

Example 7.2.1.2. Let $\mathcal{C}$ be a stable ∞-category equipped with a t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$. Then for every integer n, we have ${}^{\perp}\mathcal{C}_{\geqslant n} = \mathcal{C}_{\leqslant n-1}$ and $\mathcal{C}_{\leqslant n}^{\perp} = \mathcal{C}_{\geqslant n+1}$. In particular, if $(\mathcal{C}_{+}, \mathcal{C}_{-})$ is a semi-orthogonal decomposition of $\mathcal{C}$, then $\mathcal{C}_{-} = {}^{\perp}\mathcal{C}_{+}$ and $\mathcal{C}_{+} = \mathcal{C}_{-}^{\perp}$.

Remark 7.2.1.3. Let $\mathcal{C}$ be a stable ∞-category and let $\mathcal{D}$ be a stable subcategory of $\mathcal{C}$. Then the left and right orthogonals ${}^{\perp}\mathcal{D}$ and $\mathcal{D}^{\perp}$ are stable subcategories of $\mathcal{C}$, and we have evident inclusions ${}^{\perp}(\mathcal{D}^{\perp}) \supseteq \mathcal{D} \subseteq ({}^{\perp}\mathcal{D})^{\perp}$. Moreover, the subcategory $\mathcal{D}^{\perp}$ is closed under all limits which exist in $\mathcal{C}$, and the subcategory ${}^{\perp}\mathcal{D}$ is closed under all colimits which exist in $\mathcal{C}$.

Proposition 7.2.1.4. *Let $\mathcal{C}$ be a stable ∞-category and let $\mathcal{D} \subseteq \mathcal{C}$ be a stable subcategory which is closed under equivalence. Then the following conditions are equivalent:*

(1) *There exists a semi-orthogonal decomposition $(\mathcal{C}_{+}, \mathcal{C}_{-})$ of $\mathcal{C}$ with $\mathcal{C}_{+} = \mathcal{D}$.*

(2) *There exists a t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ on $\mathcal{C}$ with $\mathcal{C}_{\geqslant 0} = \mathcal{D}$.*

(3) *The inclusion functor $\iota : \mathcal{D} \to \mathcal{C}$ admits a right adjoint.*

Proof. The implications (1) ⇒ (2) ⇒ (3) are clear. Conversely, suppose that (3) is satisfied. Set $\mathcal{C}_{+} = \mathcal{D}$ and $\mathcal{C}_{-} = \mathcal{D}^{\perp}$; we claim that $(\mathcal{C}_{+}, \mathcal{C}_{-})$ is a semi-orthogonal decomposition of $\mathcal{C}$. Note that $\mathcal{C}_{+}$ is a stable subcategory of $\mathcal{C}$ by assumption and that $\mathcal{C}_{-}$ is a stable subcategory of $\mathcal{C}$ by virtue of Remark 7.2.1.3. The definition of $\mathcal{C}_{-}$ guarantees that $\operatorname{Map}_{\mathcal{C}}(C_{+}, C_{-})$ is contractible for all $C_{+} \in \mathcal{C}_{+}$, $C_{-} \in \mathcal{C}_{-}$. To complete the proof, it will suffice to show that for every object $C \in \mathcal{C}$, there exists a cofiber sequence $C_{+} \xrightarrow{\alpha} C \to C_{-}$ where $C_{+} \in \mathcal{C}_{+}$ and $C_{-} \in \mathcal{C}_{-}$. Assumption (3) guarantees that we can choose such a fiber sequence for which α exhibit C_{+} as a $\mathcal{D}$-colocalization of C: that is, such that α induces a homotopy equivalence $\operatorname{Map}_{\mathcal{C}}(D, C') \to \operatorname{Map}_{\mathcal{C}}(D, C)$ for each $D \in \mathcal{D}$. It follows that $\operatorname{fib}(\alpha) \in \mathcal{D}^{\perp} = \mathcal{C}_{-}$, so that $C_{-} = \Sigma \operatorname{fib}(\alpha)$ also belong to $\mathcal{C}_{-}$. □

Remark 7.2.1.5. In the situation of Proposition 7.2.1.4, the t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ is uniquely determined by the requirement $\mathcal{C}_{\geqslant 0} = \mathcal{D}$ (and is therefore automatically a semi-orthogonal decomposition).

Remark 7.2.1.6. Let $\mathcal{C}$ be a stable ∞-category equipped with a t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$. Using Proposition 7.2.1.4, we see that the following conditions are equivalent:

(i) The t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ is a semi-orthogonal decomposition of $\mathcal{C}$.

(ii) The full subcategory $\mathcal{C}_{\geqslant 0} \subseteq \mathcal{C}$ is closed under desuspension.

(iii) The full subcategory $\mathcal{C}_{\leqslant 0} \subseteq \mathcal{C}$ is closed under suspension.

Not that conditions (*ii*) and (*iii*) are both equivalent to the requirement that the heart $\mathcal{C}^{\heartsuit} = \mathcal{C}_{\geqslant 0} \cap \mathcal{C}_{\leqslant 0}$ contains only zero objects of $\mathcal{C}$.

Replacing $\mathcal{C}$ by its opposite ∞-category, we obtain the following dual version of Proposition 7.2.1.4:

Corollary 7.2.1.7. *Let $\mathcal{C}$ be a stable ∞-category, let $\mathcal{D} \subseteq \mathcal{C}$ be a stable subcategory which is closed under equivalence. Then the following conditions are equivalent:*

(1) *There exists a semi-orthogonal decomposition $(\mathcal{C}_+, \mathcal{C}_-)$ of $\mathcal{C}$ with $\mathcal{C}_- = \mathcal{D}$.*

(2) *There exists a t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ on $\mathcal{C}$ with $\mathcal{C}_{\leqslant 0} = \mathcal{D}$.*

(3) *The inclusion functor $\iota : \mathcal{D} \to \mathcal{C}$ admits a left adjoint.*

Corollary 7.2.1.8. *Let $\mathcal{C}$ be a stable ∞-category, let $\mathcal{D}$ be a stable subcategory of $\mathcal{C}$, and let $\iota : \mathcal{D} \to \mathcal{C}$ be the inclusion functor. If ι admits a right adjoint, then the inclusion $\mathcal{D} \subseteq {}^{\perp}(\mathcal{D}^{\perp})$ is an equivalence of ∞-categories. If ι admits a left adjoint, then the inclusion $\mathcal{D} \subseteq ({}^{\perp}\mathcal{D})^{\perp}$ is an equivalence of ∞-categories.*

Proof. Without loss of generality, we may assume that $\mathcal{D}$ coincides with the essential image of ι. By symmetry, it will suffice to prove the first assertion. Using Proposition 7.2.1.4, we see that there exists a semi-orthogonal decomposition $(\mathcal{C}_+, \mathcal{C}_-)$ of $\mathcal{C}$ with $\mathcal{C}_+ = \mathcal{D}$, so that $\mathcal{C}_- = \mathcal{D}^{\perp}$. It follows that the inclusion $\mathcal{D}^{\perp} \hookrightarrow \mathcal{C}$ admits a left adjoint. Applying Corollary 7.2.1.7, we deduce that there exists a semi-orthogonal decompositions $(\mathcal{C}'_+, \mathcal{C}'_-)$ of $\mathcal{C}$ with $\mathcal{C}'_- = \mathcal{D}^{\perp}$, so that $\mathcal{C}'_+ = {}^{\perp}(\mathcal{D}^{\perp})$. Since $\mathcal{C}'_- = \mathcal{C}_-$, we conclude that $\mathcal{D} = \mathcal{C}_+ = \mathcal{C}'_+ = {}^{\perp}(\mathcal{D}^{\perp})$. □

Example 7.2.1.9. Let $\mathcal{C}$ be a presentable stable ∞-category, let $\mathcal{D} \subseteq \mathcal{C}$ be a stable subcategory which is also presentable, and let $\iota : \mathcal{D} \hookrightarrow \mathcal{C}$ denote the inclusion map. Then:

(a) If $\mathcal{D}$ is closed under small colimits in $\mathcal{C}$, then Corollary HTT.5.5.2.9 implies that ι admits a left adjoint, so that $(\mathcal{D}, \mathcal{D}^{\perp})$ is a semi-orthogonal decomposition of $\mathcal{C}$ and $\mathcal{D} = {}^{\perp}(\mathcal{D}^{\perp})$.

(b) Suppose there exists a regular cardinal κ such that $\mathcal{D}$ is closed under small limits and under κ-filtered colimits in $\mathcal{C}$. Then Corollary HTT.5.5.2.9 implies that ι admits a right adjoint, so that $({}^{\perp}\mathcal{D}, \mathcal{D})$ is a semi-orthogonal decomposition of $\mathcal{C}$ and $\mathcal{D} = ({}^{\perp}\mathcal{D})^{\perp}$.

Proposition 7.2.1.10. *Let $\mathcal{C}$ be a stable ∞-category, let $\mathcal{D} \subseteq \mathcal{C}$ be a stable subcategory, and suppose that the inclusion map $\iota : \mathcal{D} \to \mathcal{C}$ admits both a left and a right adjoint. Let $F : \mathcal{C} \to \mathcal{D}^{\perp}$ be a left adjoint to the inclusion (which exhibits by virtue of Proposition 7.2.1.4). Then F induces an equivalence of ∞-categories ${}^{\perp}\mathcal{D} \to \mathcal{D}^{\perp}$.*

Proof. Let $F_0 : {}^{\perp}\mathcal{D} \to \mathcal{D}^{\perp}$ be the restriction of F. Corollary 7.2.1.7 implies that the inclusion ${}^{\perp}\mathcal{D} \hookrightarrow \mathcal{C}$ admits a right adjoint G. Let G_0 denote the restriction of G to $\mathcal{D}^{\perp}$. Then G_0 is given by the composition $\mathcal{D}^{\perp} \hookrightarrow \mathcal{C} \xrightarrow{G} {}^{\perp}\mathcal{D}$, and is therefore right adjoint to F_0. We claim that G_0 is homotopy inverse to F_0. To prove this, we will show that the unit map $u : \mathrm{id} \to G_0 \circ F_0$ is an equivalence of functors from ${}^{\perp}\mathcal{D}$ to itself; the proof that the counit map $v : F_0 \circ G_0 \to \mathrm{id}$ is an equivalence follows by the same argument. Fix an object $C \in {}^{\perp}\mathcal{D}$; we wish to show that the canonical map $\alpha : C \to G(F(C))$ is an equivalence. Unwinding the definitions, we see that α is obtained by composing a homotopy inverse to the equivalence $G(C) \to C$ with the canonical map $\alpha' : G(C) \to G(F(C))$. We are therefore reduced to proving that α' is an equivalence. By construction, we have a fiber sequence $D \to C \to F(C)$, where $D \in \mathcal{D}$. Since G is an exact functor, we are reduced to proving that $G(D) \simeq 0$, which follows immediately from the definitions. □

7.2.2 Example: Quasi-Coherent Sheaves on the Projective Line

Our next result describes an elementary example of a semi-orthogonal decomposition in algebraic geometry:

Theorem 7.2.2.1. *Let R be a connective $\mathbb{E}_\infty$-ring and let $q : \mathbf{P}^1_R \to \operatorname{Sp\acute{e}t} R$ be the projection map. Then:*

(1) *For every integer n, the construction $\mathscr{F} \mapsto \mathscr{O}(n) \otimes q^* \mathscr{F}$ induces a fully faithful embedding $\mathrm{QCoh}(\operatorname{Sp\acute{e}t} R) \to \mathrm{QCoh}(\mathbf{P}^1_R)$, whose essential image we will denote by $\mathcal{E}(n)$.*

(2) *For every integer n, the pair $(\mathcal{E}(n), \mathcal{E}(n-1))$ is a semi-orthogonal decomposition of the ∞-category $\mathrm{QCoh}(\mathbf{P}^1_R)$.*

The proof of Theorem 7.2.2.1 will require a brief digression. Fix a connective $\mathbb{E}_\infty$-ring R, and consider the projective space $\mathbf{P}^n_R$ of dimension n over R. Construction 5.4.2.5 provides canonical maps $x_0, x_1, \ldots, x_n : \mathscr{O}(0) \to \mathscr{O}(1)$ in $\mathrm{QCoh}(\mathbf{P}^n_R)$. Taking the tensor product of these maps, we obtain a cubical diagram

$$P([n]) \to \mathrm{QCoh}(\mathbf{P}^n_R) \qquad J \mapsto \bigotimes_{j \in J} \mathscr{O}(1) \simeq \mathscr{O}(|J|),$$

where $P([n])$ denotes the collection of all subsets of $[n]$.

Lemma 7.2.2.2. *For every connective $\mathbb{E}_\infty$-ring R and every $n \geqslant 0$, the functor $P([n]) \to \mathrm{QCoh}(\mathbf{P}^n_R)$ described above is a colimit diagram: that is, it classifies an equivalence $\rho : \varinjlim_{J \subsetneq [n]} \mathscr{O}(|J|) \to \mathscr{O}(n+1)$ in the ∞-category $\mathrm{QCoh}(\mathbf{P}^n_R)$.*

Proof. It will suffice to show that ρ is an equivalence after pulling back along each of the open immersions $\phi_I : \mathrm{Sp\acute{e}t}\, R[M_I] \to \mathbf{P}^n_R$ appearing in Proposition 5.4.1.7. This is clear, since the map $\phi_I^* \mathscr{O}(0) \xrightarrow{x_i} \phi_I^* \mathscr{O}(1)$ is an equivalence for any $i \in I$. □

Specializing Lemma 7.2.2.2 to the case $n = 1$, we deduce the existence of a pushout diagram

$$\begin{array}{ccc} \mathscr{O}(0) & \longrightarrow & \mathscr{O}(1) \\ \downarrow & & \downarrow \\ \mathscr{O}(1) & \longrightarrow & \mathscr{O}(2) \end{array}$$

in the ∞-category $\mathrm{QCoh}(\mathbf{P}^1_R)$. Tensoring with $\mathscr{O}(m)$, we obtain the following:

Lemma 7.2.2.3. *For every integer m, there exists a fiber sequence $\mathscr{O}(m) \to \mathscr{O}(m+1) \oplus \mathscr{O}(m+1) \to \mathscr{O}(m+2)$ in the ∞-category $\mathrm{QCoh}(\mathbf{P}^1_R)$.*

Proof of Theorem 7.2.2.1. To prove (1), we may assume without loss of generality that $n = 0$ (since the construction $\mathscr{G} \mapsto \mathcal{O}(n) \otimes \mathscr{G}$ induces an equivalence from $\mathrm{QCoh}(\mathbf{P}^1_R)$ to itself). In this case, we wish to show that the pullback functor $q^* : \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R) \to \mathrm{QCoh}(\mathbf{P}^1_R)$ is fully faithful: that is, that the unit map $u_{\mathscr{F}} : \mathscr{F} \to q_* q^* \mathscr{F}$ is an equivalence for each $\mathscr{F} \in \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R)$. Note that the collection of those objects $\mathscr{F} \in \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R) \simeq \mathrm{Mod}_R$ for which $u_{\mathscr{F}}$ is an equivalence is closed under colimits and desuspensions. It will therefore suffice to show that $u_{\mathscr{F}}$ is an equivalence when $\mathscr{F}$ is the structure sheaf of $\mathrm{Sp\acute{e}t}\, R$, which follows from Theorem 5.4.2.6.

We now prove (2). Once again, it will suffice to treat the case $n = 0$. We will show that the pair of subcategories $(\mathcal{E}(0), \mathcal{E}(-1))$ satisfies conditions (a), (b) and (c) of Definition 7.2.0.1:

- (a) Since the functors $\mathscr{F} \mapsto q^* \mathscr{F}$ and $\mathscr{F} \mapsto \mathscr{O}(-1) \otimes q^* \mathscr{F}$ are fully faithful and exact, their essential images $\mathcal{E}(0)$ and $\mathcal{E}(-1)$ are stable subcategories of $\mathrm{QCoh}(\mathbf{P}^1_R)$.

- (b) Let $\mathscr{F}$ and $\mathscr{G}$ be objects of $\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R)$; we wish to prove that the mapping space

$$\begin{aligned} \mathrm{Map}_{\mathrm{QCoh}(\mathbf{P}^1_R)}(q^* \mathscr{F}, \mathscr{O}(-1) \otimes q^* \mathscr{G}) &\simeq \mathrm{Map}_{\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R)}(\mathscr{F}, q_*(\mathscr{O}(-1) \otimes q^* \mathscr{G})) \\ &\simeq \mathrm{Map}_{\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R)}(\mathscr{F}, (q_* \mathscr{O}(-1)) \otimes \mathscr{G}) \end{aligned}$$

  is contractible. This follows from the vanishing of $q_* \mathscr{O}(-1)$ (Theorem 5.4.2.6).

- (c) Let $\mathscr{F}$ be an object of $\mathrm{QCoh}(\mathbf{P}^1_R)$, and form a cofiber sequence $q^* q_* \mathscr{F} \to \mathscr{F} \to \mathscr{G}$. We claim that $\mathscr{G}$ belongs to $\mathcal{E}(-1)$: that is, that the counit map $v : q^* q_*(\mathscr{O}(1) \otimes \mathscr{G}) \to \mathscr{O}(1) \otimes \mathscr{G}$ is an equivalence. Note that the domain of v belongs to $\mathcal{E}(0)$ and therefore to ${}^{\perp}\mathcal{E}(1)$ (by virtue of (b)), and that the codomain of v belongs to ${}^{\perp}\mathcal{E}(1)$ since $\mathscr{G} \in {}^{\perp}\mathcal{E}(0)$

by construction. It follows that $\mathrm{cofib}(v) \in {}^{\perp}\mathcal{E}(1)$, and we also have $\mathrm{cofib}(v) \in {}^{\perp}\mathcal{E}(0)$. In particular, we have

$$\mathrm{Ext}^*_{\mathrm{QCoh}(\mathbf{P}^1_R)}(\mathscr{O}(0), \mathrm{cofib}(v)) \simeq 0 \simeq \mathrm{Ext}^*_{\mathrm{QCoh}(\mathbf{P}^1_R)}(\mathscr{O}(1), \mathrm{cofib}(v)).$$

It follows from Lemma 7.2.2.3 the groups $\mathrm{Ext}^*_{\mathrm{QCoh}(\mathbf{P}^1_R)}(\mathscr{O}(n), \mathrm{cofib}(v))$ vanish for every integer n. It follows from Lemma 5.6.2.2 that there exists a morphism $\alpha : \mathscr{H} \to \mathrm{cofib}(v)$ which induces an epimorphism $\pi_* \mathscr{H} \to \pi_* \mathrm{cofib}(v)$, where $\mathscr{H}$ can be written as a direct sum of sheaves of the form $\Sigma^m \mathscr{O}(n)$. Then the map α is automatically nullhomotopic, so $\pi_* \mathrm{cofib}(v) \simeq 0$ and therefore v is an equivalence as desired.

□

Remark 7.2.2.4. In the situation of Theorem 7.2.2.1, each of the full subcategories $\mathcal{E}(n) \subseteq \mathrm{QCoh}(\mathbf{P}^1_R)$ is canonically equivalent to $\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R) \simeq \mathrm{Mod}_R$. Moreover, we have ${}^{\perp}\mathcal{E}(n) = \mathcal{E}(n+1)$ and $\mathcal{E}(n)^{\perp} = \mathcal{E}(n-1)$.

7.2.3 Example: Closed and Open Subspaces

We now consider an algebro-geometric version of Example 7.2.0.3.

Proposition 7.2.3.1. *Let $j : \mathsf{U} \to \mathsf{X}$ be a quasi-compact open immersion of spectral Deligne-Mumford stacks, and let $K \subseteq |\mathsf{X}|$ denote the complement of the image of j. Then:*

(1) *The pushforward functor $j_* : \mathrm{QCoh}(\mathsf{U}) \to \mathrm{QCoh}(\mathsf{X})$ is fully faithful. Let us denote its essential image by $\mathcal{E} \subseteq \mathrm{QCoh}(\mathsf{X})$.*

(2) *The left orthogonal ${}^{\perp}\mathcal{E}$ coincides with $\mathrm{QCoh}_K(\mathsf{X})$.*

(3) *The pair $(\mathrm{QCoh}_K(\mathsf{X}), \mathcal{E})$ is a semi-orthogonal decomposition of $\mathrm{QCoh}(\mathsf{X})$.*

(4) *The inclusion $\iota : \mathrm{QCoh}_K(\mathsf{X}) \hookrightarrow \mathrm{QCoh}(\mathsf{X})$ admits a left adjoint.*

(5) *The ∞-category $\mathcal{E}$ coincides with the right orthogonal $\mathrm{QCoh}_K(\mathsf{X})^{\perp}$.*

Proof. Since the morphism j is quasi-affine, it is is relatively scalloped (Example 2.5.3.3). Applying Proposition 2.5.4.5 to the pullback diagram

$$\begin{array}{ccc} \mathsf{U} & \longrightarrow & \mathsf{U} \\ \downarrow & & \downarrow j \\ \mathsf{U} & \xrightarrow{j} & \mathsf{X}, \end{array}$$

we deduce that the counit map $j^* j_* \to \mathrm{id}_{\mathrm{QCoh}(\mathsf{U})}$ is an equivalence, so that j_* is fully faithful. This proves (1). To prove (2), we note that a quasi-coherent sheaf $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ belongs to ${}^{\perp}\mathcal{E}$ if and only if the mapping space

$$\mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, j_* \mathscr{G}) \simeq \mathrm{Map}_{\mathrm{QCoh}(\mathsf{U})}(j^* \mathscr{F}, \mathscr{G})$$

is contractible for every object $\mathscr{G} \in \mathrm{QCoh}(\mathsf{U})$, which is equivalent to the vanishing of $j^* \mathscr{F}$. Assertion (3) now follows from Corollary 7.2.1.7, and (4) and (5) are formal consequences of (3) (see Corollary 7.2.1.8). □

7.2.4 Example: Nilpotent and Local Objects

In the special case where $\mathsf{X} = \mathrm{Spét}\, R$ is affine, then the full subcategory $\mathrm{QCoh}_K(\mathsf{X}) \subseteq \mathrm{QCoh}(\mathsf{X})$ appearing in Proposition 7.2.3.1 can be identified with the subcategory $\mathrm{Mod}_R^{\mathrm{Nil}(I)} \subseteq \mathrm{Mod}_R$, where $I \subseteq \pi_0 R$ is an ideal defining the closed subset $K \subseteq |\mathrm{Spec}\, R|$ (Proposition 7.1.5.3). We now consider a more general situation:

Definition 7.2.4.1. Let R be an $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be an ideal, and let $\mathcal{C}$ be a stable R-linear ∞-category. We will say that an object $C \in \mathcal{C}$ is *I-local* if, for every I-nilpotent object $D \in \mathcal{C}$, the mapping space $\mathrm{Map}_{\mathcal{C}}(D, C)$ is contractible. We let $\mathcal{C}^{\mathrm{Loc}(I)}$ denote the full subcategory of $\mathcal{C}$ spanned by the I-local objects.

Remark 7.2.4.2. In the situation of Definition 7.2.4.1, the ∞-category $\mathcal{C}^{\mathrm{Loc}(I)}$ is the right orthogonal of the full subcategory $\mathcal{C}^{\mathrm{Nil}(I)} \subseteq \mathcal{C}$ of Definition 7.1.1.6. In particular, $\mathcal{C}^{\mathrm{Loc}(I)}$ is a stable subcategory of $\mathcal{C}$ which is closed under small limits (Remark 7.2.1.3).

Example 7.2.4.3. Let R be a connective $\mathbb{E}_\infty$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let U be the open substack of $\mathrm{Spét}\, A$ complementary to the vanishing locus of I. Using Proposition 7.2.3.1, we deduce that the global sections functor $\Gamma : \mathrm{QCoh}(\mathsf{U}) \to \mathrm{Mod}_A$ is a fully faithful embedding, whose essential image is the full subcategory $\mathrm{Mod}_A^{\mathrm{Loc}(I)} \subseteq \mathrm{Mod}_A$.

Combining Proposition 7.1.1.12 with Example 7.2.1.9, we obtain the following:

Proposition 7.2.4.4. *Let R be an $\mathbb{E}_2$-ring and let $\mathcal{C}$ be a stable R-linear ∞-category. For every ideal $I \subseteq \pi_0 R$, the pair $(\mathcal{C}^{\mathrm{Nil}(I)}, \mathcal{C}^{\mathrm{Loc}(I)})$ is a semi-orthogonal decomposition of $\mathcal{C}$.*

Example 7.2.4.5. Let R be an $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a stable R-linear ∞-category, and let $I, J \subseteq \pi_0 R$ be ideals satisfying $I + J = \pi_0 R$. Then Remark 7.1.2.4 shows that $(\mathcal{C}^{\mathrm{Nil}(I)})^{\mathrm{Nil}(J)} = \mathcal{C}^{\mathrm{Nil}(I+J)}$ contains only zero objects of $\mathcal{C}$. It follows that $(\mathcal{C}^{\mathrm{Nil}(I)})^{\mathrm{Loc}(J)} = \mathcal{C}^{\mathrm{Nil}(I)}$. In other words, every I-nilpotent object of $\mathcal{C}$ is J-local.

Notation 7.2.4.6. In the situation of Proposition 7.2.4.4, the inclusion functor $\mathcal{C}^{\mathrm{Loc}(I)} \to \mathcal{C}$ admits a left adjoint, which we will denote by $L_I : \mathcal{C} \to \mathcal{C}^{\mathrm{Loc}(I)}$. If we regard L_I as a functor from $\mathcal{C}$ to itself, then it fits into a canonical fiber sequence $\Gamma_I \to \mathrm{id}_{\mathcal{C}} \to L_I$, where $\Gamma_I : \mathcal{C} \to \mathcal{C}^{\mathrm{Nil}(I)} \subseteq \mathcal{C}$ is as in Definition 7.1.2.1.

Remark 7.2.4.7. Let $\phi : R \to R'$ be a morphism of $\mathbb{E}_2$-rings, let $I \subseteq \pi_0 R$ be an ideal, and let $I' \subseteq \pi_0 R'$ be the ideal generated by the image of I. Suppose that $\mathcal{C}$ is a stable R'-linear ∞-category, which we can also regard as a stable R-linear ∞-category (by restriction of scalars). Then $\mathcal{C}^{\mathrm{Nil}(I)} = \mathcal{C}^{\mathrm{Nil}(I')}$ (Remark 7.1.1.10), so $\mathcal{C}^{\mathrm{Loc}(I)} = \mathcal{C}^{\mathrm{Loc}(I')}$. In particular, the notion of I-local object does not change if we replace an $\mathbb{E}_2$-ring R by its connective cover $\tau_{\geqslant 0} R$.

Remark 7.2.4.8. Let R be a commutative ring, let $I \subseteq R$ be a finitely generated ideal, and let $\mathcal{A}$ be a locally Noetherian abelian category equipped with an action of R. It follows from Remark 7.1.3.3 that the functor $\Gamma_I : \mathcal{D}(\mathcal{A}) \to \mathcal{D}(\mathcal{A})^{\mathrm{Nil}(I)} \subseteq \mathcal{D}(\mathcal{A})$ carries injective objects $\mathcal{A}$ to injective objects of $\mathcal{A}^{\mathrm{Nil}(I)}$. Consequently, if $Q \in \mathcal{A}$ is injective, then the canonical map $\Gamma_I^{\heartsuit} Q = \pi_0 \Gamma_I Q \to \Gamma_I Q$ is an equivalence, where $\Gamma_I^{\heartsuit} : \mathcal{A} \to \mathcal{A}^{\mathrm{Nil}(I)}$ denotes a right adjoint to the inclusion (so that we can identify $\Gamma_I^{\heartsuit} X$ with the largest I-nilpotent subobject of X, for any object $X \in \mathcal{A}$). It follows that the functor L_I also carries injective objects of $\mathcal{A}$ to the heart $\mathcal{D}(\mathcal{A})$: that is, $L_I : \mathcal{D}(\mathcal{A}) \to \mathcal{D}(\mathcal{A})$ is derived from the left exact functor of abelian categories $X \mapsto \pi_0 L_I(X)$.

We will be interested primarily in the case where the ideal I is finitely generated.

Proposition 7.2.4.9. *Let R be an $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let $\mathcal{C}$ be a stable R-linear ∞-category. Then:*

(1) *The functor L_I of Notation 7.2.4.6 preserves small colimits, when viewed as a functor from $\mathcal{C}$ to itself.*

(2) *The full subcategory $\mathcal{C}^{\mathrm{Loc}(I)} \subseteq \mathcal{C}$ is closed under small colimits.*

(3) *For every left R-module M and every I-local object $C \in \mathcal{C}$, the tensor product $M \otimes_R C$ is I-local. Consequently, $\mathcal{C}^{\mathrm{Loc}(I)}$ inherits the structure of a stable R-linear ∞-category (for which the inclusion $\mathcal{C}^{\mathrm{Loc}(I)} \hookrightarrow \mathcal{C}$ is R-linear).*

(4) *Let $F : \mathcal{C} \to \mathcal{D}$ be an R-linear functor between stable R-linear ∞-categories. Then F carries I-local objects of $\mathcal{C}$ to I-local objects of $\mathcal{D}$.*

Remark 7.2.4.10. In the situation of Proposition 7.2.4.9, we can regard $\mathcal{C}^{\mathrm{Loc}(I)}$ as an R-linear ∞-category even if the ideal I is not finitely generated. However, in general it is not true that the inclusion $\mathcal{C}^{\mathrm{Loc}(I)} \hookrightarrow \mathcal{C}$ is an R-linear functor (since it need not commute with filtered colimits). However, we can always regard $L_I : \mathcal{C} \to \mathcal{C}^{\mathrm{Loc}(I)}$ as an R-linear functor.

Proof of Proposition 7.2.4.9. Assertion (1) follows from Corollary 7.1.2.5 and the fiber sequence $\Gamma_I \to \mathrm{id}_{\mathcal{C}} \to L_I$ of Notation 7.2.4.6. Assertion (2) follows immediately from (1), and assertion (3) follows from (2): if $C \in \mathcal{C}$ is I-local, then the collection of those left R-modules M such that $M \otimes_R C$ is I-local contains R and is closed under colimits and desuspensions, and therefore contains all left R-modules. To prove (4), we note that an object $C \in \mathcal{C}$ is I-local if and only if $\Gamma_I C \simeq 0$. In this case, Corollary 7.1.2.10 implies that $\Gamma_I F(C) \simeq F(\Gamma_I C) \simeq 0$, so that $F(C)$ is an I-local object of $\mathcal{D}$. □

Remark 7.2.4.11. Let R be an $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let $\mathcal{C}$ be a stable R-linear ∞-category. Proposition 7.2.4.9 implies that the inclusion $\mathcal{C}^{\mathrm{Loc}(I)} \hookrightarrow \mathcal{C}$ commutes with filtered colimits. Applying Proposition HTT.5.5.7.2 , we deduce that the functor $L_I : \mathcal{C} \to \mathcal{C}^{\mathrm{Loc}(I)}$ carries compact objects of $\mathcal{C}$ to compact objects of $\mathcal{C}^{\mathrm{Loc}(I)}$. In particular, if $\mathcal{C}$ is compactly generated, then $\mathcal{C}^{\mathrm{Loc}(I)}$ is also compactly generated.

Corollary 7.2.4.12. *Let R be an $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let M and N be left R-modules. If either M or N is I-local, then the tensor product $M \otimes_R N$ is I-local.*

Proof. The case where N is I-nilpotent follows from Proposition 7.2.4.9, and the other case follows by symmetry. □

7.2.5 Spectral Decompositions of Injective Objects

Let R be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be an additive R-linear ∞-category. We can think of the action of R on $\mathcal{C}$ as providing a kind of spectral decomposition for the ∞-category $\mathcal{C}$, breaking $\mathcal{C}$ into pieces parametrized by the topological space $|\operatorname{Spec} R|$. We now make this heuristic a bit more precise.

Definition 7.2.5.1. Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a prestable R-linear ∞-category, and let C be an object of $\mathcal{C}$. We will say that C is *centered* if, for every element $x \in \pi_0 R$, one of the following conditions holds:

- (i) The object C is (x)-nilpotent: that is, the localization $C[x^{-1}]$ vanishes.
- (ii) The object C is (x)-local: that is, the canonical map $C \to C[x^{-1}]$ is an equivalence.

Warning 7.2.5.2. In the situation of Definition 7.2.5.1, the condition that an object $C \in \mathcal{C}$ be centered depends on the chosen action of R on $\mathcal{C}$.

Remark 7.2.5.3. In the situation of Definition 7.2.5.1, the zero object $0 \in \mathcal{C}$ is always centered: it satisfies *both* conditions (i) and (ii), for any element $x \in \pi_0 R$. This is a somewhat degenerate situation: note that a nonzero object $C \in \mathcal{C}$ cannot satisfy simultaneously satisfy conditions (i) and (ii).

Example 7.2.5.4. In the situation of Definition 7.2.5.1, suppose that R is a field. Then every object $C \in \mathcal{C}$ is centered: it is (x)-nilpotent for $x = 0$ and (x)-local for $x \neq 0$.

Remark 7.2.5.5. Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a prestable R-linear ∞-category and let C be a nonzero object of $\mathcal{C}$. Set $\mathfrak{p} = \{x \in \pi_0 R : C[x^{-1}] \simeq 0\}$. It follows from Proposition 7.1.1.5 that $\mathfrak{p}$ is an ideal of $\pi_0 R$. If C is centered, then the complement of $\mathfrak{p}$ is the set $\{x \in \pi_0 R : C \simeq C[x^{-1}]\}$, which is closed under multiplication. It follows that $\mathfrak{p}$ is a prime ideal of $\pi_0 R$.

Motivated by Remark 7.2.5.5, we introduce the following slight refinement of Definition 7.2.5.1:

Definition 7.2.5.6. Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a prestable R-linear ∞-category. Suppose we are given an object $C \in \mathcal{C}$ and a prime ideal $\mathfrak{p} \subseteq \pi_0 R$. We will say that C is *centered at* $\mathfrak{p}$ if C is (x)-nilpotent for $x \in \mathfrak{p}$ and (x)-local for $x \notin \mathfrak{p}$. We let $\mathcal{C}[\mathfrak{p}]$ denote the full subcategory of $\mathcal{C}$ spanned by those objects of $\mathcal{C}$ which are centered at $\mathfrak{p}$.

Remark 7.2.5.7. In the situation of Definition 7.2.5.6, suppose that $C \in \mathcal{C}$ is nonzero. Then C is centered (in the sense of Definition 7.2.5.1) if and only if it is centered at $\mathfrak{p}$, for some $\mathfrak{p} \in |\operatorname{Spec} R|$ (in the sense of Definition 7.2.5.6). Moreover, the prime ideal $\mathfrak{p}$ is uniquely determined (Remark 7.2.5.5).

The zero object $0 \in \mathcal{C}$ is centered at every point $\mathfrak{p} \in |\operatorname{Spec} R|$.

Remark 7.2.5.8. Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a prestable R-linear ∞-category, and let $\mathfrak{p} \in |\operatorname{Spec} R|$. Then the full subcategory $\mathcal{C}[\mathfrak{p}] \subseteq \mathcal{C}$ is closed under small colimits, finite limits, and extensions. Moreover, it follows from Proposition HTT.5.4.7.10 that $\mathcal{C}[\mathfrak{p}]$ is accessible. It follows that $\mathcal{C}[\mathfrak{p}]$ is also an R-linear Grothendieck prestable ∞-category.

Example 7.2.5.9. Let $R = \mathbf{C}[x]$ and let V be a discrete R-module, which we identify with a complex vector space equipped with a $\mathbf{C}$-linear endomorphism $x : V \to V$. Let $\mathfrak{p}$ be a closed point of $|\operatorname{Spec} R|$ corresponding to the prime ideal $(x - \lambda)$, for some complex number λ. Then V is centered at $\mathfrak{p}$ if and only if multiplication by $(x - \lambda)$ is locally nilpotent on V: in other words, if and only if every element $v \in V$ is a generalized eigenvector for x with eigenvalue λ.

If V is a finite-dimensional vector space over $\mathbf{C}$, then V admits an (essentially unique) decomposition $V \simeq \bigoplus V_\alpha$ into submodules which are centered at closed points of $|\operatorname{Spec} R|$. However, such a decomposition need not exist if V is not finite dimensional (for example, the module $V = R$ does not contain any nonzero submodules which are centered).

Remark 7.2.5.10. In the situation of Definition 7.2.5.6, suppose that we are given object $C \in \mathcal{C}[\mathfrak{p}]$ and $D \in \mathcal{C}[\mathfrak{q}]$. If $\mathfrak{p} \subsetneq \mathfrak{q}$, then we can choose an element $x \in \mathfrak{p} - \mathfrak{q}$ for which C is (x)-nilpotent and D is (x)-local. It follows that the mapping space $\operatorname{Map}_{\mathcal{C}}(C, D)$ is contractible.

Proposition 7.2.5.11. *Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a prestable R-linear ∞-category, and let Q be an indecomposable injective object of $\mathrm{Sp}(\mathcal{C})$. If $\mathcal{C}$ is locally Noetherian, then Q is centered.*

Proof. Fix an object $x \in \pi_0 R$, let $I \subseteq \pi_0 R$ denote the principal ideal generated by (x), and set $Q' = \Gamma_I(Q)$. Since the inclusion $\mathrm{Sp}(\mathcal{C}^{\mathrm{Nil}(I)}) \hookrightarrow \mathrm{Sp}(\mathcal{C})$ is t-exact, Q' is an injective object of $\mathrm{Sp}(\mathcal{C}^{\mathrm{Nil}(I)})$. Applying Proposition 7.1.3.4, we conclude that Q' is an injective object of $\mathrm{Sp}(\mathcal{C})$. Since $Q[x^{-1}] \in \mathrm{Sp}(\mathcal{C})_{\leqslant 0}$, we have $\mathrm{Ext}^1_{\mathrm{Sp}(\mathcal{C})}(Q[x^{-1}], Q') \simeq 0$. It follows that the fiber sequence $Q' \to Q \to Q[x^{-1}]$ splits: that is, Q' is a direct summand of Q. Since Q is indecomposable, it follows that either $Q' \simeq Q$ (in which case Q is (x)-nilpotent) or $Q' \simeq 0$ (in which case Q is (x)-local). □

Corollary 7.2.5.12. *Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a prestable R-linear ∞-category, and let Q be an injective object of $\mathrm{Sp}(\mathcal{C})$. If $\mathcal{C}$ is locally Noetherian, then there exists a decomposition*

$$Q \simeq \bigoplus_{\mathfrak{p} \in |\operatorname{Spec} R|} Q(\mathfrak{p}),$$

where each $Q(\mathfrak{p})$ is an injective object of $\mathrm{Sp}(\mathcal{C})$ which is centered at $\mathfrak{p}$.

Proof. Combine Propositions 7.2.5.11 and C.6.10.6. □

Corollary 7.2.5.13. *Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a prestable R-linear ∞-category, and let Q be an injective object of $\mathrm{Sp}(\mathcal{C})$. Let $I \subseteq \pi_0 R$ be a finitely generated ideal. If $\mathcal{C}$ is locally Noetherian, then the fiber sequence $\Gamma_I(Q) \to Q \to L_I Q$ splits. In particular, both $\Gamma_I(Q)$ and $L_I Q$ are injective objects of $\mathrm{Sp}(\mathcal{C})$.*

Proof. Using Corollary 7.2.5.12, we can assume that Q is centered at some point $\mathfrak{p} \in |\operatorname{Spec} R|$. In this case, we either have $\Gamma_I(Q) \simeq 0$ (if $I \subsetneq \mathfrak{p}$) or $L_I Q \simeq 0$ (if $I \subseteq \mathfrak{p}$). □

Corollary 7.2.5.14. *Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a prestable R-linear ∞-category, and let $f : X \to Q$ be a morphism in $\mathrm{Sp}(\mathcal{C})$ which exhibits Q as an injective hull of X (see Example C.5.7.9). If X is centered at a point $\mathfrak{p} \in |\operatorname{Spec} R|$, then Q is also centered at $\mathfrak{p}$.*

Proof. Fix an element $x \in \pi_0 R$ and let $I = (x)$ be the principal ideal generated by x. If $x \in \mathfrak{p}$, then X is (x)-nilpotent, so the map f factors as a composition $X \to \Gamma_I Q \xrightarrow{f'} Q$. It follows from Corollary 7.2.5.13 that the map f' exhibits $\Gamma_I Q$ as a direct summand of Q. Since $\pi_0 Q$ is an essential extension of $\pi_0 X$, the map f' must be an equivalence, so that Q is also (x)-nilpotent.

If $x \notin \mathfrak{p}$, then X is I-local. In this case, $\pi_0(\Gamma_I Q)$ is a subobject of $\pi_0 Q$ whose intersection with $\pi_0 X$ vanishes. Since $\pi_0 Q$ is an essential extension of $\pi_0 X$, it follows that $\pi_0(\Gamma_I Q) \simeq 0$. Using Theorem C.5.7.4, we conclude that $\Gamma_I Q \simeq 0$, so that Q is I-local. □

Example 7.2.5.15. Let R be a Noetherian $\mathbb{E}_\infty$-ring. For every prime ideal $\mathfrak{p} \subseteq \pi_0 R$, let $Q_\mathfrak{p} \in \mathrm{Mod}_R$ be an injective hull of the residue field $\kappa(\mathfrak{p})$. According to Example C.6.10.7, every indecomposable injective R-module Q has the form $Q_\mathfrak{p}$, for some $\mathfrak{p} \subseteq \pi_0 R$. It follows from Corollary 7.2.5.14 that $Q_\mathfrak{p}$ is centered at $\mathfrak{p}$.

Consequently, in the case $\mathcal{C} = \mathrm{Mod}_R^{\mathrm{cn}}$ we obtain a stronger version of Proposition 7.2.5.11: for every point $\mathfrak{p} \in |\operatorname{Spec} R|$ there is a *unique* indecomposable injective object of $\mathrm{Sp}(\mathcal{C})$ (up to equivalence) which is centered at $\mathfrak{p}$.

Lemma 7.2.5.16. *Let R be a connective $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be an ideal, let $\mathcal{C}$ be a prestable R-linear ∞-category, and let $C \in \mathcal{C}$ be an I-nilpotent object. Suppose we are given elements $x, y \in \pi_0 R$ such that $x \equiv y \operatorname{Mod} I$. Then C is (x)-local if and only if it is (y)-local.*

Proof. Consider the commutative diagram

$$\begin{array}{ccc} C & \xrightarrow{\alpha} & C[x^{-1}] \\ \downarrow{\scriptstyle\beta} & & \downarrow{\scriptstyle\beta'} \\ C[y^{-1}] & \xrightarrow{\alpha'} & C[(xy)^{-1}]. \end{array}$$

We wish to show that α is an equivalence if and only if β is an equivalence. To prove this, it will suffice to show that α' and β' are equivalences. We will show that α' is an equivalence (the proof that β' is an equivalence is similar). For this, we note that $C[y^{-1}]$ is an $I[y^{-1}]$-nilpotent object of $\mathrm{LMod}_{R[y^{-1}]}(\mathcal{C})$, so that multiplication by x is invertible on $C[y^{-1}]$ by virtue of Example 7.2.4.5. □

Proposition 7.2.5.17. *Let $\phi : R \to R'$ be an étale morphism of connective $\mathbb{E}_2$-rings let $\mathfrak{p}' \subseteq \pi_0 R'$ be a prime ideal, and let $\mathfrak{p} = \phi^{-1}\mathfrak{p}' \subseteq \pi_0 R$. Let $\mathcal{C}$ be a prestable R-linear ∞-category and set $\mathcal{C}' = R' \otimes_R \mathcal{C}$. If ϕ induces an isomorphism of residue fields $\kappa(\mathfrak{p}) \to \kappa(\mathfrak{p}')$, then restriction of scalars induces an equivalence of ∞-categories $\mathcal{C}'[\mathfrak{p}'] \to \mathcal{C}[\mathfrak{p}]$.*

Proof. Replacing R' by a localization $R'[b^{-1}]$ for suitably chosen $b \notin \mathfrak{p}'$, we can arrange that $\mathfrak{p}'$ is the only prime ideal of R' lying over $\mathfrak{p}$. In this case, the canonical map $\kappa(\mathfrak{p}) \to (\pi_0 R') \otimes_{\pi_0 R} \kappa(\mathfrak{p})$ is an isomorphism. Using a direct limit argument, we deduce that there exists a finitely generated ideal $I \subseteq \mathfrak{p}$ and an element $a \in (\pi_0 R) - \mathfrak{p}$ for which the induced map $\xi : (\pi_0 R)/I[a^{-1}] \to (\pi_0 R')/I[a^{-1}]$ is also an isomorphism. Replacing R by $R[a^{-1}]$ (and R' by $R'[a^{-1}]$), we can reduce to the case where we have an excision square of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathsf{U}' & \longrightarrow & \operatorname{Sp\acute{e}t} R' \\ \downarrow & & \downarrow \\ \mathsf{U} & \longrightarrow & \operatorname{Sp\acute{e}t} R, \end{array}$$

so that restriction of scalars induces an equivalence of ∞-categories $\rho : \mathcal{C}'^{\mathrm{Nil}(I)} \to \mathcal{C}^{\mathrm{Nil}(I)}$. To complete the proof, it will suffice to show that if C is an I-nilpotent object of $\mathcal{C}'$ and $\rho(C)$ is centered at $\mathfrak{p}$, then C is centered at $\mathfrak{p}'$. Note that since $\mathfrak{p}'$ is generated by the image of $\mathfrak{p}$, our assumption that $\rho(C)$ is $\mathfrak{p}$-nilpotent guarantees that C is $\mathfrak{p}'$-nilpotent. To complete the proof, it will suffice to show that C is (x)-local for each $x \in (\pi_0 R') - \mathfrak{p}'$. Since ξ is an isomorphism, we can find an element $y \in \pi_0 R$ such that $x \equiv \phi(y) \operatorname{Mod} \mathfrak{p}'$. In this case, our assumption that $\rho(C)$ is centered at $\mathfrak{p}$ guarantees that the object $\rho(C) \in \mathcal{C}$ is (y)-local, or equivalently that $C \in \mathcal{C}'$ is $(\phi(y))$-local. Applying Lemma 7.2.5.16, we deduce that C is also (x)-local, as desired. □

Remark 7.2.5.18. In the situation of Proposition 7.2.5.17, suppose that $Q \in \mathrm{Sp}(\mathcal{C})$ is an injective object centered at $\mathfrak{p}$. Let $\theta : \mathrm{Sp}(\mathcal{C}') \to \mathrm{Sp}(\mathcal{C})$ be the restriction of scalars functor, so that we can write $Q = \theta(Q')$ for some object $Q' \in \mathrm{Sp}(\mathcal{C}')$ centered at $\mathfrak{p}'$. We claim that Q' is an injective object of $\mathrm{Sp}(\mathcal{C}')$. To prove this, choose a morphism $f : Q' \to Q''$ in $\mathrm{Sp}(\mathcal{C}')$ which exhibits Q'' as an injective hull of Q'. Then Q'' is also centered at $\mathfrak{p}$ (Corollary **??**). It follows from Proposition **??** that the induced map $\theta(f) : Q \simeq \theta(Q') \to \theta(Q'')$ exhibits $\pi_0\theta(Q')$ as an essential extension of $\pi_0\theta(Q'')$. Moreover, the object $\theta(Q'') \in \mathrm{Sp}(\mathcal{C})$ is injective (since the functor θ is right adjoint to the t-exact functor $X \mapsto R' \otimes_R X$). It follows that $\theta(f)$ exhibits $\theta(Q'')$ as an injective hull of Q in the ∞-category $\mathrm{Sp}(\mathcal{C})$. Since Q is injective, the map $\theta(f)$ must be an equivalence (see Example C.5.7.9). Applying Proposition 7.2.5.17, we deduce that f is an equivalence, so that $Q' \in \mathrm{Sp}(\mathcal{C}')$ is injective as desired.

Corollary 7.2.5.19. *Let $\phi : A \to B$ be an étale morphism of connective $\mathbb{E}_\infty$-rings, let $\mathcal{C}$ be a prestable A-linear ∞-category, and let Q be an injective object of $\mathrm{Sp}(\mathcal{C})$. If $\mathcal{C}$ is locally Noetherian, then $B \otimes_A Q$ is an injective object of $\mathrm{Sp}(B \otimes_A \mathcal{C}) \simeq \mathrm{LMod}_B(\mathrm{Sp}(\mathcal{C}))$.*

Proof. Suppose first that $\phi : A \to B$ is a finite étale morphism. In this case, there exists a B-linear equivalence $B \simeq B^\vee$, where $B^\vee$ denotes the A-linear dual of B. It follows that the extension of scalars functor $F : \mathrm{Sp}(\mathcal{C}) \to \mathrm{LMod}_B(\mathrm{Sp}(\mathcal{C}))$ is *right* adjoint to the restriction of scalars functor $G : \mathrm{LMod}_B(\mathrm{Sp}(\mathcal{C})) \to \mathrm{Sp}(\mathcal{C})$. Since G is t-exact, it follows that functor F carries injective objects to injective objects.

We now treat the general case. Using Corollaries 7.2.5.12 and C.6.10.3, we can reduce to the case where Q is centered at some point $\mathfrak{p} \in |\operatorname{Spec} A|$. Using Corollary B.3.4.5, we can choose an étale morphism $A \to A'$ and a prime ideal $\mathfrak{p}' \in |\operatorname{Spec} A'|$ lying over $\mathfrak{p}$ such that $\kappa(\mathfrak{p}) \simeq \kappa(\mathfrak{p}')$ and the tensor product $B' = A' \otimes_A B$ factors as a Cartesian product $B'_0 \times B'_1$, where B'_0 is finite étale over A' and $B'_1 \otimes_{A'} \kappa(\mathfrak{p}') \simeq 0$. Using Proposition 7.2.5.17, we can lift Q to an object $Q' \in \mathrm{Sp}(A' \otimes_A \mathcal{C})$ which is centered at $\mathfrak{p}'$. Moreover, the object Q' is injective (Remark 7.2.5.18). Then $B \otimes_A Q$ is the image of $B' \otimes_{A'} Q'$ under the restriction of scalars functor $\theta : \mathrm{LMod}_{B'}(\mathrm{Sp}(\mathcal{C})) \to \mathrm{LMod}_B(\mathrm{Sp}(\mathcal{C}))$. Since B' is flat over B, the extension of scalars functor $\mathrm{LMod}_B(\mathrm{Sp}(\mathcal{C})) \to \mathrm{LMod}_{B'}(\mathrm{Sp}(\mathcal{C}))$ is t-exact, so the functor θ carries injective objects to injective objects. We will complete the proof by showing that $B' \otimes_{A'} Q' \in \mathrm{LMod}_{B'}(\mathrm{Sp}(\mathcal{C}))$ is injective. Equivalently, we will show that $B'_0 \otimes_{A'} Q'$ is an injective object of $\mathrm{LMod}_{B'_0}(\mathrm{Sp}(\mathcal{C}))$ and that $B'_1 \otimes_{A'} Q'$ is an injective object of $\mathrm{LMod}_{B'_1}(\mathrm{Sp}(\mathcal{C}))$. In the former case, this follows from the first part of the proof (since B'_0 is finite étale over A'); in the latter, it follows from our assumption that Q' is centered at $\mathfrak{p}'$ (so that $B'_1 \otimes_{A'} Q' \simeq 0$). □

We close by proving a converse to Corollary 7.2.5.19, which implies that injectivity can be tested locally with respect to the étale topology:

Proposition 7.2.5.20. *Let $\phi : A \to B$ be a faithfully flat étale morphism of connective $\mathbb{E}_\infty$-rings, let $\mathcal{C}$ be a prestable A-linear ∞-category, and let Q be an object of $\mathrm{Sp}(\mathcal{C})$. If $\mathcal{C}$ is locally Noetherian and $B \otimes_A Q$ is an injective object of $\mathrm{Sp}(B \otimes_A \mathcal{C}) \simeq \mathrm{LMod}_B(\mathrm{Sp}(\mathcal{C}))$, then Q is an injective object of $\mathrm{Sp}(\mathcal{C})$.*

Proof. Using Propositions B.1.1.3 and 4.6.1.2, we can reduce to the case where A and B are Noetherian. Let $I \subseteq \pi_0 A$ be an ideal which is maximal with respect to the property that $L_I Q \in \mathrm{Sp}(\mathcal{C})$ is injective. Since the collection of injective objects of $\mathrm{Sp}(\mathcal{C})$ is closed under extensions, to show that $Q \in \mathrm{Sp}(\mathcal{C})$ is injective, it will suffice to show that $\Gamma_I Q$ is injective. We may therefore replace Q by $\Gamma_I Q$ (note that this does not injure our hypothesis that $B \otimes_A Q \in \mathrm{LMod}_B(\mathrm{Sp}(\mathcal{C}))$ is injective, by virtue of Corollary 7.2.5.13) and thereby reduce to the case where Q is I-nilpotent. If $I = \pi_0 A$, then $Q \simeq 0$ and there is nothing to prove. Otherwise, choose $\mathfrak{p} \subseteq \pi_0 A$ which is minimal among prime ideals containing I. Using Corollary B.3.4.5, we can choose an étale morphism $A \to A'$ and a prime ideal $\mathfrak{p}' \in |\operatorname{Spec} A'|$ lying over $\mathfrak{p}$ such that $\kappa(\mathfrak{p}) \simeq \kappa(\mathfrak{p}')$ and the tensor product $B' = A' \otimes_A B$ factors as a Cartesian product $B'_0 \times B'_1$, where B'_0 is finite étale over A' and $B'_1 \otimes_{A'} \kappa(\mathfrak{p}') \simeq 0$. Replacing A' by a localization if necessary, we may assume that B'_0 is faithfully flat over A' and that the map of affine schemes $j : \operatorname{Spec}(\pi_0 A')/I(\pi_0 A') \to \operatorname{Spec} \pi_0 A/I(\pi_0 A)$ is an open immersion.

Combining our assumption that $B \otimes_A Q$ is an injective object of $\mathrm{LMod}_B(\mathrm{Sp}(\mathcal{C}))$ with Corollary 7.2.5.19, we deduce that $B'_0 \otimes_A Q$ is an injective object of $\mathrm{LMod}_{B'_0}(\mathrm{Sp}(\mathcal{C}))$. Since the forgetful functor $\mathrm{LMod}_{B'_0}(\mathrm{Sp}(\mathcal{C})) \to \mathrm{LMod}_{A'}(\mathrm{Sp}(\mathcal{C}))$ admits a t-exact left adjoint, it follows that $B'_0 \otimes_A Q$ is an injective object of $\mathrm{LMod}_{A'}(\mathrm{Sp}(\mathcal{C}))$. Since B'_0 is faithfully flat and finite étale over A', the unit map $A' \to B'_0$ admits a left homotopy inverse in the ∞-category $\mathrm{Mod}_{A'}$. It follows that $A' \otimes_A Q$ is a retract of $B' \otimes_A Q$ in the ∞-category $\mathrm{LMod}_{A'}(\mathrm{Sp}(\mathcal{C}))$, so that $A' \otimes_A Q$ is also an injective object of $\mathrm{LMod}_{A'}(\mathrm{Sp}(\mathcal{C}))$. The forgetful functor $\mathrm{LMod}_{A'}(\mathrm{Sp}(\mathcal{C})) \to \mathrm{Sp}(\mathcal{C})$ admits a t-exact left adjoint, and therefore carries injective objects to injective objects. It follows that $A' \otimes_A Q$ is an injective object of $\mathrm{Sp}(\mathcal{C})$. Since Q is I-nilpotent and the map j is an open immersion, we can identify $A' \otimes_A Q$ with the localization $L_{I'} Q$, where $I' \supseteq I$ is an ideal in $\pi_0 A$ whose vanishing locus is complementary to the image of j. The injectivity of $L_{I'}Q$ now contradicts our maximality assumption on I. □

7.3 Completions of Modules

Let R be a commutative ring, let $I \subseteq R$ be an ideal, and let M be a (discrete) R-module. We let $\mathrm{Cpl}(M; I)$ denote the inverse limit of the tower

$$\cdots \to M/I^4M \to M/I^3M \to M/I^2M \to M/IM,$$

formed in the abelian category $\mathrm{Mod}_R^{\heartsuit}$ of discrete R-modules. We will refer to $\mathrm{Cpl}(M; I)$ as the *I-adic completion of M*. We say that M is *I-adically complete* if the canonical map $M \to \mathrm{Cpl}(M; I)$ is an isomorphism.

If the ring R is Noetherian and we restrict our attention to finitely generated R-modules, then the I-adic completion $M \mapsto \mathrm{Cpl}(M; I)$ has excellent formal properties: for example, it is an exact functor of M. If we are given a short exact sequence of R-modules $0 \to M' \to M \to M'' \to 0$, then we obtain a short exact sequence

$$0 \to K \to \mathrm{Cpl}(M; I) \to \mathrm{Cpl}(M''; I) \to 0,$$

where K denotes the completion of M' with respect to topology given by the descending sequence of submodules $\{M' \cap I^n M\}_{n \geqslant 0}$. If R is Noetherian and M is finitely generated, then the Artin-Rees lemma allows us to identify K with the I-adic completion of M'. However, this fails in general: even when $R = \mathbf{Z}$ and $I = (p)$ for some prime number p, the theory of I-adic completions can exhibit some bad behavior:

Example 7.3.0.1. The p-adic completion functor on abelian groups is not left exact. For example, let $M = \mathbf{Q}_p / \mathbf{Z}_p$, and let M' be the submodule of M generated by $\frac{1}{p} \in \mathbf{Q}_p$ (so that M' is a cyclic group of order p). Then the p-adic completion of M vanishes (since $pM = M$), but the p-adic completion of M' is isomorphic to M'. Consequently, the inclusion $M' \hookrightarrow M$ does not induce an injection of p-adic completions.

Example 7.3.0.2. The p-adic completion functor on abelian groups is not right exact. To see this, consider the exact sequence

$$0 \to \bigoplus_{n \geqslant 0} p^n \mathbf{Z} \xrightarrow{\beta} \bigoplus_{n \geqslant 0} \mathbf{Z} \xrightarrow{\alpha} \bigoplus_{n \geqslant 0} \mathbf{Z} / p^n \mathbf{Z} \to 0.$$

Then:

- The p-adic completion of $\bigoplus_{n \geqslant 0} \mathbf{Z}$ can be identified with the submodule $N \subseteq \prod_{n \geqslant 0} \mathbf{Z}_p$ consisting of those sequences $\{\lambda_n \in \mathbf{Z}_p\}_{n \geqslant 0}$ which converge p-adically to zero.

- The p-adic completion of $\bigoplus_{n \geqslant 0} p^n \mathbf{Z}$ can be identified with the submodule $N' \subseteq \prod_{n \geqslant 0} \mathbf{Z}_p$ consisting of those sequences $\{\lambda_n \in \mathbf{Z}_p\}_{n \geqslant 0}$ for which each λ_n is divisible by p^n and the sequence $p^{-n}\lambda_n$ converges p-adically to zero.

- The p-adic completion of $\bigoplus_{n \geqslant 0} \mathbf{Z}/p^n \mathbf{Z}$ can be identified with the image N'' of N in the product $\prod_{n \geqslant 0} \mathbf{Z}/p^n \mathbf{Z}$.

- The p-adic completion of α is surjection whose kernel is given by the product $\prod_{n \geqslant 0} p^n \mathbf{Z}_p \subseteq N$.

Consequently, the sequence of I-adic completions $0 \to N' \xrightarrow{\widehat{\beta}} N \xrightarrow{\widehat{\alpha}} N'' \to 0$ is not exact in the middle: that is, we have $\operatorname{im}(\widehat{\beta}) \subsetneq \ker(\widehat{\alpha})$.

Example 7.3.0.3. The collection of p-adically complete abelian groups is not closed under the formation of cokernels. For example, if $\widehat{\beta} : N' \hookrightarrow N$ is as in Example 7.3.0.3, then the cokernel of $\widehat{\beta}$ is not p-adically complete (the p-adic completion of $\operatorname{coker}(\widehat{\beta})$ can be identified with N'').

Example 7.3.0.4. The collection of p-adically complete abelian groups is not closed under extensions. For example, in the situation of Example 7.3.0.1, we have a short exact sequence of abelian groups

$$0 \to \ker(\widehat{\alpha})/\operatorname{im}(\widehat{\beta}) \to \operatorname{coker}(\widehat{\beta}) \to N'' \to 0$$

where the outer terms are p-adically complete, but the middle term is not.

When working with modules which are not finitely generated or rings which are not Noetherian, it is often convenient to consider a different notion of completion.

Definition 7.3.0.5. Let R be a commutative ring, let M be a (discrete) R-module, and let $I \subseteq R$ be a finitely generated ideal. We will say that M is *I-complete* if, for every $x \in I$, we have $\operatorname{Ext}^0_R(R[x^{-1}], M) \simeq 0 \simeq \operatorname{Ext}^1_R(R[x^{-1}], M)$.

Remark 7.3.0.6. The vanishing conditions $\operatorname{Ext}^0_R(R[x^{-1}], M) \simeq 0 \simeq \operatorname{Ext}^1_R(R[x^{-1}], M)$ are equivalent to the requirement that every short exact sequence

$$0 \to M \to N \to R[x^{-1}] \to 0$$

admits a unique splitting. Note that the groups $\operatorname{Ext}^i_R(R[x^{-1}], M)$ automatically vanish for $i > 1$, since $R[x^{-1}]$ is an R-module of projective dimension $\leqslant 1$.

Remark 7.3.0.7. In the situation of Definition 7.3.0.5, if $I = (x_1, \ldots, x_n)$, then to verify that an R-module M is I-complete it suffices to have $\operatorname{Ext}^0_R(R[x_i^{-1}], M) \simeq 0 \simeq \operatorname{Ext}^1_R(R[x_i^{-1}], M)$ for $1 \leqslant i \leqslant n$ (see Remark 7.3.4.2).

We now summarize some of the pleasant features of Definition 7.3.0.5:

- Let R be a commutative ring, let $I \subseteq R$ be a finitely generated ideal, and let $\mathcal{A} \subseteq \mathrm{Mod}_R^{\heartsuit}$ be the full subcategory of spanned by the I-complete R-modules. Then $\mathcal{A}$ is closed under the formation of kernels, cokernels, and extensions in $\mathrm{Mod}_R^{\heartsuit}$. In particular, $\mathcal{A}$ is an abelian category, and the inclusion $\mathcal{A} \hookrightarrow \mathrm{Mod}_R^{\heartsuit}$ is an exact functor (Corollary 7.3.4.6).

- Every I-adically complete R-module M is I-complete. Conversely, if M is I-complete and I-adically separated (meaning that $\bigcap_{n \geqslant 0} I^n M = \{0\}$), then M is I-adically complete (Corollary 7.3.6.3). However, in general there can exist R-modules M which are I-complete but not I-adically separated (and therefore not I-adically complete): for example, the module $\mathrm{coker}(\widehat{\beta})$ appearing in Example 7.3.0.3.

- The inclusion $\mathcal{A} \hookrightarrow \mathrm{Mod}_R^{\heartsuit}$ admits a left adjoint $L : \mathrm{Mod}_R^{\heartsuit} \to \mathcal{A}$ (Remark 7.3.4.7). For any R-module M, there is a canonical epimorphism $LM \to \mathrm{Cpl}(M; I)$ (Corollary 7.3.6.2), which is an isomorphism in many cases (for example, if M is a Noetherian R-module; see Proposition 7.3.6.1).

Since the inclusion $\mathcal{A} \hookrightarrow \mathrm{Mod}_R^{\heartsuit}$ is an exact functor, it follows formally that that the functor $L : \mathrm{Mod}_R^{\heartsuit} \to \mathcal{A}$ is right exact (unlike the formation of I-adic completions; see Example 7.3.0.2). However, it is usually not left exact. To obtain a more complete picture, it is convenient to work at the derived level: that is, to replace the abelian category $\mathrm{Mod}_R^{\heartsuit}$ of discrete R-modules by the ∞-category Mod_R of all R-modules. In this section, we will introduce a full subcategory $\mathrm{Mod}_R^{\mathrm{Cpl}(I)} \subseteq \mathrm{Mod}_R$ whose objects we will refer to as *I-complete R-modules* (Definition 7.3.1.1), whose intersection with $\mathrm{Mod}_R^{\heartsuit}$ consists of those discrete R-modules which are I-complete in the sense of Definition 7.3.0.5 (Corollary 7.3.4.6). We will see inclusion functor $\mathrm{Mod}_R^{\mathrm{Cpl}(I)} \hookrightarrow \mathrm{Mod}_R$ admits a left adjoint, which we will refer to as *I-completion* and denote by $M \mapsto M_I^{\wedge}$ (Notation 7.3.1.5). The localization functor $L : \mathrm{Mod}_R^{\heartsuit} \to \mathcal{A}$ is then given by the construction $M \mapsto \pi_0 M_I^{\wedge}$ (Remark 7.3.4.7). When R is Noetherian, we can be more precise: the stable ∞-category $\mathrm{Mod}_R^{\mathrm{Cpl}(I)}$ agrees (up to right completion) with the derived ∞-category of the abelian category $\mathcal{A}$ (Proposition 7.3.7.3), and the I-completion functor $M \mapsto M_I^{\wedge}$ agrees with the left derived functor of $L : \mathrm{Mod}_R^{\heartsuit} \to \mathcal{A}$ (Corollary 7.3.7.5).

7.3.1 Completeness

We begin by discussing completions in a very general setting.

Definition 7.3.1.1. Let R be an $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a stable R-linear ∞-category, and let $I \subseteq \pi_0 R$ be an ideal. We will say that an object $C \in \mathcal{C}$ is *I-complete* if, for every I-local object $D \in \mathcal{C}$ (Definition 7.2.4.1), the mapping space $\mathrm{Map}_{\mathcal{C}}(D, C)$ is contractible. We let $\mathcal{C}^{\mathrm{Cpl}(I)}$ denote the full subcategory of $\mathcal{C}$ spanned by the I-complete objects.

Remark 7.3.1.2. In the situation of Definition 7.3.1.1, suppose that $I, J \subseteq \pi_0 R$ are two ideals having the same radical. Then an object $C \in \mathcal{C}$ is I-complete if and only if it is J-complete.

Remark 7.3.1.3. Let $\phi : R \to R'$ be a morphism of $\mathbb{E}_2$-rings, let $\mathcal{C}$ be a stable R'-linear ∞-category. Let $I \subseteq \pi_0 R$ be an ideal and let $I' \subseteq \pi_0 R'$ be the ideal generated by the image of I. Then an object $C \in \mathcal{C}$ is I'-complete if and only if it is I-complete (where we regard $\mathcal{C}$ as a stable R-linear ∞-category via restriction of scalars).

We will generally be interested in Definition 7.3.1.1 only in the special case where I is finitely generated (or at least contains a finitely generated ideal with the same radical). In this case, we have the following:

Proposition 7.3.1.4. *Let R be an $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a stable R-linear ∞-category, and let $I \subseteq \pi_0 R$ be a finitely generated ideal. Then the pair $(\mathcal{C}^{\mathrm{Loc}(I)}, \mathcal{C}^{\mathrm{Cpl}(I)})$ is a semi-orthogonal decomposition of $\mathcal{C}$. In particular, every object $C \in \mathcal{C}$ fits into an (essentially unique) fiber sequence $C' \to C \to C''$, where C' is I-local and C'' is I-complete.*

Proof. Our assumption that I is finitely generated implies that $\mathcal{C}^{\mathrm{Loc}(I)}$ is closed under small colimits in $\mathcal{C}$ (Proposition 7.2.4.9). The desired result now follows from Example 7.2.1.9. □

Notation 7.3.1.5. Let R be an $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let $\mathcal{C}$ be a stable R-linear ∞-category. It follows from Proposition 7.3.1.4 that the inclusion $\mathcal{C}^{\mathrm{Cpl}(I)} \hookrightarrow \mathcal{C}$ admits a left adjoint. We will refer to this left adjoint as the *I-completion functor*, and denote it by $C \mapsto C^{\wedge}_I$.

Remark 7.3.1.6. Let R be an $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let $\mathcal{C}$ be a stable R-linear ∞-category. For each object $C \in \mathcal{C}$, the diagram σ_C :

$$\begin{array}{ccc} C & \longrightarrow & C^{\wedge}_I \\ \downarrow & & \downarrow \\ L_I(C) & \longrightarrow & L_I(C^{\wedge}_I) \end{array}$$

is a pullback square. To see this, we observe that the fibers of the vertical maps are I-nilpotent, while the fibers of the horizontal maps are I-local. It follows that the total homotopy fiber of σ_C is both I-nilpotent and I-local, and therefore vanishes.

Proposition 7.3.1.7. *Let R be an $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a stable R-linear ∞-category, and let $I \subseteq \pi_0 R$ be a finitely generated ideal. Then the functors $C \mapsto C^{\wedge}_I$ and $C \mapsto \Gamma_I C$ induce mutually inverse equivalences $\mathcal{C}^{\mathrm{Nil}(I)} \underset{\Gamma_I}{\rightleftarrows} \mathcal{C}^{\mathrm{Cpl}(I)}$.*

Proof. Combine Propositions 7.2.1.10 and 7.3.1.4. □

Remark 7.3.1.8. In the situation of Proposition 7.3.1.7, we can regard $\mathcal{C}^{\mathrm{Nil}(I)}$ as a stable R-linear ∞-category (Proposition 7.1.1.12). Consequently, there is an essentially unique action of R on the ∞-category $\mathcal{C}^{\mathrm{Cpl}(I)}$ for which the equivalence of Proposition 7.3.1.7 is R-linear. Note that the composition of this equivalence with the I-completion functor $\mathcal{C} \to \mathcal{C}^{\mathrm{Cpl}(I)}$ can be identified with the functor $\Gamma_I : \mathcal{C} \to \mathcal{C}^{\mathrm{Nil}(I)}$, which is R-linear by virtue of Remark 7.1.2.6. It follows that we can regard the I-completion functor $\mathcal{C} \to \mathcal{C}^{\mathrm{Cpl}(I)}$ as an R-linear functor.

Warning 7.3.1.9. In the situation of Proposition 7.3.1.7, the inclusion $\mathcal{C}^{\mathrm{Cpl}(I)} \hookrightarrow \mathcal{C}$ is usually not an R-linear functor (where we regard $\mathcal{C}^{\mathrm{Cpl}(I)}$ as a stable R-linear ∞-category as in Remark 7.3.1.8), because it need not commute with filtered colimits.

Warning 7.3.1.10. Let R be an $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let $F : \mathcal{C} \to \mathcal{D}$ be an R-linear functor between stable R-linear ∞-categories. Then the functor F need not carry I-complete objects of $\mathcal{C}$ to I-complete objects of $\mathcal{D}$. However, the functor F admits a right adjoint G which carries I-complete objects of $\mathcal{D}$ to I-complete objects of $\mathcal{C}$ (since F carries I-local objects of $\mathcal{C}$ to I-local objects of $\mathcal{D}$; see Proposition 7.2.4.9).

7.3.2 The Case of a Principal Ideal

We now study the I-completion functor $C \mapsto C^{\wedge}_I$ in the situation where the ideal I is generated by a single element. In this case, we have the following dual version of Proposition 7.1.2.3.

Proposition 7.3.2.1. *Let R be an $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a stable R-linear ∞-category, and let $x \in \pi_0 R$ be an element. For any object $C \in \mathcal{C}$, let $T(C)$ denote the limit of the tower*

$$\cdots \xrightarrow{x} C \xrightarrow{x} C \xrightarrow{x} C \xrightarrow{x} C.$$

Then the (x)-completion of C can be identified with the cofiber of the canonical map $\theta : T(C) \to C$.

Proof. For any object $D \in \mathcal{C}$, we can identify the mapping space $\mathrm{Map}_{\mathcal{C}}(D, T(C))$ with the homotopy limit of the tower of spaces

$$\cdots \xrightarrow{x} \mathrm{Map}_{\mathcal{C}}(D, C) \xrightarrow{x} \mathrm{Map}_{\mathcal{C}}(D, C) \xrightarrow{x} \mathrm{Map}_{\mathcal{C}}(D, C) \xrightarrow{x} \mathrm{Map}_{\mathcal{C}}(D, C).$$

If D is (x)-local, then each of the transition maps in this diagram is a homotopy equivalence. It follows that composition with θ induces a homotopy equivalence $\mathrm{Map}_{\mathcal{C}}(D, T(C)) \to \mathrm{Map}_{\mathcal{C}}(D, C)$, so that $\mathrm{Map}_{\mathcal{C}}(D, \mathrm{fib}(\theta))$ is contractible. Allowing D to vary, we deduce that

$\mathrm{fib}(\theta)$ is (x)-complete, so that $\mathrm{cofib}(\theta) = \Sigma \mathrm{fib}(\theta)$ is also (x)-complete. For any (x)-complete object $E \in \mathcal{C}$, we have a canonical fiber sequence

$$\mathrm{Map}_{\mathcal{C}}(\mathrm{cofib}(\theta), E) \xrightarrow{\alpha} \mathrm{Map}_{\mathcal{C}}(C, E) \to \mathrm{Map}_{\mathcal{C}}(T(C), E).$$

It is not difficult to see that $T(C)$ is (x)-local, so the third term in this fiber sequence is contractible and therefore α is a homotopy equivalence. It follows that the natural map $C \to \mathrm{cofib}(\theta)$ exhibits $\mathrm{cofib}(\theta)$ as an (x)-completion of C. □

Corollary 7.3.2.2. *Let R be an $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a stable R-linear ∞-category, and let $x \in \pi_0 R$. The following conditions on an object $C \in \mathcal{C}$ are equivalent:*

(1) *The module C is (x)-complete.*

(2) *The limit of the tower*
$$\cdots \xrightarrow{x} C \xrightarrow{x} C \xrightarrow{x} C \xrightarrow{x} C.$$
vanishes.

Corollary 7.3.2.3. *Let R be an $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a stable R-linear ∞-category, let $I \subseteq \pi_0 R$ be an ideal, and let $x \in \pi_0 R$. Then the (x)-completion functor $C \mapsto C^{\wedge}_{(x)}$ carries I-complete objects of $\mathcal{C}$ to I-complete objects of $\mathcal{C}$.*

Proof. Combine the description of the functor $C \mapsto C^{\wedge}_{(x)}$ given by Proposition 7.3.2.1 with the observation that $\mathcal{C}^{\mathrm{Cpl}(I)}$ is closed under limits in $\mathcal{C}$. □

We now study the exactness properties of the (x)-completion functor in the case $\mathcal{C} = \mathrm{LMod}_R$.

Corollary 7.3.2.4. *Let R be an $\mathbb{E}_2$-ring, let $x \in \pi_0 R$, and let M be a left R-module.*

(1) *If M is connective, then $M^{\wedge}_{(x)}$ is connective.*

(2) *If $M \in (\mathrm{LMod}_R)_{\leqslant 0}$, then $M^{\wedge}_{(x)}$ belongs to $(\mathrm{LMod}_R)_{\leqslant 1}$.*

Proof. Let $T(M)$ be as in the statement of Proposition 7.3.2.1, so that we have an exact sequence $\pi_k M \to \pi_k M^{\wedge}_{(x)} \to \pi_{k-1} T(M)$. In case (1), the desired result follows from the observation that $\pi_{k-1} T(M) \simeq 0$ for $k < 0$. In case (2), we observe instead that $\pi_{k-1} T(M) \simeq 0$ for $k > 1$. □

7.3.3 The Case of a Finitely Generated Ideal

We now show that many of the preceding results can be generalized from principal ideals to finitely generated ideals. Our starting point is the following observation:

Lemma 7.3.3.1. *Let R be an $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a stable R-linear ∞-category, and suppose we are given a pair of ideals $I, J \subseteq \pi_0 R$. Assume that either I or J is finitely generated. Then the full subcategory $\mathcal{C}^{\mathrm{Loc}(I+J)}$ is generated under extensions by the full subcategories $\mathcal{C}^{\mathrm{Loc}(I)}, \mathcal{C}^{\mathrm{Loc}(J)} \subseteq \mathcal{C}^{\mathrm{Loc}(I+J)}$.*

Proof. Suppose that I is finitely generated and let C be an object of $\mathcal{C}^{\mathrm{Loc}(I+J)}$. Using Proposition 7.2.4.4, we can choose a fiber sequence $C' \to C \to C''$ where C' is J-nilpotent and C'' is J-local. Then C'' is also $(I+J)$-local, that C' is $(I+J)$-local. Consider the fiber sequence $\Gamma_I C' \xrightarrow{\alpha} C' \xrightarrow{L}_I C'$. Since I is finitely generated, the functor Γ_I is R-linear (Remark 7.1.2.6) and therefore carries J-nilpotent objects of $\mathcal{C}$ to J-nilpotent objects of $\mathcal{C}$ (Proposition 7.1.1.12). Consequently, $\Gamma_I C'$ is both I-nilpotent and J-nilpotent, and is therefore $(I+J)$-nilpotent (Remark 7.1.1.9). Since C' is $(I+J)$-local, the morphism α is nullhomotopic. It follows that C' is a direct summand of $L_I C'$ and is therefore I-local. It follows that C can be written as an extension of a J-local object of $\mathcal{C}$ by an I-local object of $\mathcal{C}$. □

Proposition 7.3.3.2. *Let R be an $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a stable R-linear ∞-category, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let $I' \subseteq \pi_0 R$ be the ideal generated by I together with an element $x \in \pi_0 R$. For each object $C \in \mathcal{C}$, the composite map*

$$C \xrightarrow{\alpha} M_I^{\wedge} \xrightarrow{\beta} (M_I^{\wedge})_{(x)}^{\wedge}$$

exhibits $(C_I^{\wedge})_{(x)}^{\wedge}$ as an I'-completion of M.

Proof. It is clear that $(C_I^{\wedge})_{(x)}^{\wedge}$ is (x)-complete, and Corollary 7.3.2.3 shows that it is also I-complete. Using Lemma 7.3.3.1 we deduce that $(C_I^{\wedge})_{(x)}^{\wedge}$ is I'-complete. It will therefore suffice to show that the fiber of $\beta \circ \alpha$ is I'-local. This follows because the fibers $\mathrm{fib}(\alpha)$ and $\mathrm{fib}(\beta)$ are both I'-local: in fact, $\mathrm{fib}(\alpha)$ is I-local and $\mathrm{fib}(\beta)$ is (x)-local. □

Corollary 7.3.3.3. *Let R be an $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a stable R-linear ∞-category, and let $I \subseteq \pi_0 R$ be a finitely generated ideal. The following conditions on an object $C \in \mathcal{C}$ are equivalent:*

(1) *The object C is I-complete.*

(2) *For each $x \in I$, the object C is (x)-complete.*

(3) *There exists a set of generators $x_1, \ldots, x_n$ for the ideal I such that C is (x_i)-complete for $1 \leqslant i \leqslant n$.*

Proof. The implications (1) $\Rightarrow$ (2) $\Rightarrow$ (3) are obvious. We prove that (3) $\Rightarrow$ (1). Assume that (3) is satisfied. For $0 \leqslant i \leqslant n$, let $I(i)$ be the ideal generated by $x_1, \ldots, x_i$. We prove that C is $I(i)$-complete by induction on i, the case $i = 0$ being trivial. Assume that $i < n$ and that M is $I(i)$-complete. Then the map $\alpha : M \to M^{\wedge}_{I(i)}$ is an equivalence. Since M is x_{i+1}-complete, the map $\beta : M \to M^{\wedge}_{(x_{i+1})}$ is also an equivalence. Using Proposition 7.3.3.2, we deduce that the map $M \to M^{\wedge}_{I(i+1)}$ is an equivalence, so that M is $I(i+1)$-complete. □

Corollary 7.3.3.4. *Let R be an $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let $F : \mathcal{C} \to \mathcal{D}$ be an R-linear functor between stable R-linear ∞-categories. Suppose that F commutes with sequential inverse limits. Then:*

(a) *The functor F carries I-complete objects of $\mathcal{C}$ to I-complete object of $\mathcal{D}$.*

(b) *The functor F commutes with I-completion: that is, for every object $C \in \mathcal{C}$, the canonical map $F(C) \to F(C^{\wedge}_I)$ exhibits $F(C^{\wedge}_I)$ as an I-completion of $F(C)$.*

Proof. To prove (a), we can use Corollary 7.3.3.3 to reduce to the case where I is generated by a single element, in which case the desired result follows from the criterion of Corollary 7.3.2.2. To prove (b), let $C \in \mathcal{C}$ be an object and let $\alpha : C \to C^{\wedge}_I$ be the canonical map. Then $\mathrm{fib}(\alpha)$ is an I-local object of $\mathcal{C}$, so that $F(\mathrm{fib}(\alpha)) \simeq \mathrm{fib}(F(\alpha))$ is an I-local object of $\mathcal{D}$ by virtue of Proposition 7.2.4.9. Since the codomain of $F(C^{\wedge}_I)$ is I-complete, it follows that $F(\alpha)$ exhibits $F(C^{\wedge}_I)$ as an I-completion of C. □

Corollary 7.3.3.5. *Let $\phi : R \to R'$ be a morphism of $\mathbb{E}_2$-rings, let $\mathcal{C}$ be a stable R-linear ∞-category, and let $\mathcal{C}' = R' \otimes_R \mathcal{C} = \mathrm{LMod}_{R'}(\mathcal{C})$ be the stable R'-linear ∞-category obtained from $\mathcal{C}$ by extension of scalars. Let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let $I' \subseteq \pi_0 R'$ be the ideal generated by the image of I. Then:*

(1) *An object $C \in \mathcal{C}'$ is I'-complete if and only if its image under the forgetful functor $\rho : \mathcal{C}' \to \mathcal{C}$ is I-complete.*

(2) *For each object $C \in \mathcal{C}'$, the canonical map $C \to C^{\wedge}_{I'}$ exhibits $\rho(C^{\wedge}_{I'})$ as an I-completion of $\rho(C)$.*

Proof. Assertion (2) follows from Corollary 7.3.3.4 and Remark 7.3.1.3. Assertion (1) is a consequence of (2), since the functor ρ is conservative. □

Corollary 7.3.3.6. *Let $\phi : R \to R'$ be a morphism of $\mathbb{E}_2$-rings, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let $I' \subseteq \pi_0 R'$ be the ideal generated by the image of I. Then:*

(1) *A left R'-module M is I'-complete if and only if it is I-complete (when regarded as an R-module).*

(2) *For every left R'-module M, the canonical map $M \to M^{\wedge}_{I'}$ exhibits $M^{\wedge}_{I'}$ as an I-completion of M (when regarded as a morphism of R-modules).*

Example 7.3.3.7. Let $\phi : R \to R'$ be a morphism of $\mathbb{E}_2$-rings and let M be a left R'-module. Then, when regarded as an R-module, M is complete with respect to any finitely generated ideal $I \subseteq \pi_0 R$ which is annihilated by ϕ.

7.3.4 Completeness and Homotopy Groups

We now show that the completeness of modules over an $\mathbb{E}_2$-ring can be tested at the level of homotopy groups:

Theorem 7.3.4.1. *Let R be an $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let M be a left R-module. The following conditions are equivalent:*

(a) *The left R-module M is I-complete, in the sense of Definition 7.3.1.1.*

(b) *For every integer k, the homotopy group $\pi_k M$ is I-complete when regarded as a discrete module over the commutative ring $A = \pi_0 R$, in the sense of Definition 7.3.0.5. That is, for each $x \in I$, we have $\mathrm{Ext}^0_A(A[x^{-1}], \pi_k M) \simeq 0 \simeq \mathrm{Ext}^1_A(A[x^{-1}], \pi_k M)$.*

Proof. Fix an element $x \in \pi_0 R$, and let $T(M)$ denote the limit of the tower

$$\cdots \xrightarrow{x} M \xrightarrow{x} M \xrightarrow{x} M \xrightarrow{x} M$$

as in Proposition 7.3.2.1. For each integer k, let D_k denote the tower of abelian groups

$$\cdots \xrightarrow{x} \pi_k M \xrightarrow{x} \pi_k M \xrightarrow{x} \pi_k M \xrightarrow{x} \pi_k M,$$

so that we have Milnor exact sequences

$$0 \to \varprojlim{}^1 D_{k+1} \to \pi_k T(M) \to \varprojlim{}^0 D_k \to 0.$$

Writing $A[x^{-1}]$ as the direct limit of the sequence $A \xrightarrow{x} A \xrightarrow{x} A \xrightarrow{x} \cdots$, we obtain canonical isomorphisms

$$\varprojlim{}^1 D_{k+1} \simeq \mathrm{Ext}^1_A(A[x^{-1}], \pi_{k+1} M) \qquad \varprojlim{}^0 D_k \simeq \mathrm{Ext}^0_A(A[x^{-1}], \pi_k M).$$

Consequently, the groups $\mathrm{Ext}^i_A(A[x^{-1}], \pi_k M)$ vanish for all $k \in \mathbf{Z}$ and $i \in \{0, 1\}$ if and only if $T(M) \simeq 0$: that is, if and only if M is (x)-complete (Corollary 7.3.2.2). The equivalence of (a) and (b) now follows from Corollary 7.3.3.3. □

Remark 7.3.4.2. In the situation of Theorem 7.3.4.1, if $x_1, \ldots, x_n \in I$ is a set of generators for I, then it suffices to verify condition (b) in the special case $x = x_i$ (Corollary 7.3.3.3).

Corollary 7.3.4.3. *Let R be a connective $\mathbb{E}_2$-ring and let $I \subseteq \pi_0 R$ be a finitely generated ideal. If $M \in \mathrm{LMod}_R$ is I-complete, then the truncations $\tau_{\geqslant n} M$ and $\tau_{\leqslant n} M$ are I-complete for every integer n.*

Proposition 7.3.4.4. *Let R be a connective $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and set*

$$(\mathrm{LMod}_R^{\mathrm{Cpl}(I)})_{\leqslant 0} = (\mathrm{LMod}_R)_{\leqslant 0} \cap \mathrm{LMod}_R^{\mathrm{Cpl}(I)} \quad (\mathrm{LMod}_R^{\mathrm{Cpl}(I)})_{\geqslant 0} = (\mathrm{LMod}_R)_{\geqslant 0} \cap \mathrm{LMod}_R^{\mathrm{Cpl}(I)}.$$

Then:

(1) *The pair $((\mathrm{LMod}_R^{\mathrm{Cpl}(I)})_{\geqslant 0}, (\mathrm{LMod}_R^{\mathrm{Cpl}(I)})_{\leqslant 0})$ determines a t-structure on the stable ∞-category $\mathrm{LMod}_R^{\mathrm{Cpl}(I)}$ which is both left and right complete.*

(2) *The inclusion functor $\mathrm{LMod}_R^{\mathrm{Cpl}(I)} \hookrightarrow \mathrm{LMod}_R$ is t-exact.*

(3) *The I-completion functor $\mathrm{LMod}_R \to \mathrm{LMod}_R^{\mathrm{Cpl}(I)}$ is right t-exact.*

(4) *If I is generated by n elements, then the I-completion functor $\mathrm{LMod}_R \to \mathrm{LMod}_R^{\mathrm{Cpl}(I)}$ carries $(\mathrm{LMod}_R)_{\leqslant 0}$ into $(\mathrm{LMod}_R^{\mathrm{Cpl}(I)})_{\leqslant n}$.*

Proof. Assertion (1) follows immediately from Corollary 7.3.4.3 (and the left and right completeness for the standard t-structure on LMod_R), assertion (2) immediate from the definition, and assertion (3) is a formal consequence of (2). To prove (4), choose a set of generators $x_1, \ldots, x_n$ for the ideal I. Proposition 7.3.3.2 implies that the I-completion functor can be obtained by composing the (x_i)-completion functors for $1 \leqslant i \leqslant n$. We can therefore reduce to the case where $I = (x)$ is generated by a single element, in which case the desired result follows from Corollary 7.3.2.4.

□

Warning 7.3.4.5. In the situation of Proposition 7.3.4.4, the t-structure on $\mathrm{LMod}_R^{\mathrm{Cpl}(I)}$ is usually not compatible with filtered colimits. For example, suppose that $R = \mathbf{Z}$ and set $I = (p)$ for some prime number p. The direct system of abelian groups

$$(p^{-1}\mathbf{Z})/\mathbf{Z} \hookrightarrow (p^{-2}\mathbf{Z})/\mathbf{Z} \hookrightarrow (p^{-3}\mathbf{Z})/\mathbf{Z} \hookrightarrow (p^{-4}\mathbf{Z})/\mathbf{Z} \hookrightarrow \cdots$$

can be regarded as a diagram in the heart of $\mathrm{Mod}_{\mathbf{Z}}^{\mathrm{Cpl}(I)}$. However, the colimit of this diagram in $\mathrm{Mod}_{\mathbf{Z}}^{\mathrm{Cpl}(I)}$ is given by the I-completion of $\mathbf{Z}[p^{-1}]/\mathbf{Z} \simeq \mathbf{Q}_p/\mathbf{Z}_p$, which is the suspension of $\mathbf{Z}_p \in \mathrm{Mod}_{\mathbf{Z}}^{\mathrm{Cpl}(p)}$.

Corollary 7.3.4.6. *Let R be a commutative ring, let $I \subseteq R$ be a finitely generated ideal, and let M be a discrete R-module. The following conditions are equivalent:*

(a) *The R-module M is I-complete in the sense of Definition 7.3.1.1: that is, the mapping space* $\mathrm{Map}_{\mathrm{Mod}_R}(N, M)$ *is contractible whenever* $N \in \mathrm{Mod}_R$ *is I-local.*

(b) *The R-module M is I-complete in the sense of Definition 7.3.0.5: that is, we have* $\mathrm{Ext}^0_R(R[x^{-1}], M) \simeq 0 \simeq \mathrm{Ext}^1_R(R[x^{-1}], M)$ *for every* $x \in I$.

Moreover, the collection of those R-modules M which satisfy these conditions span an abelian subcategory $\mathcal{A} \subseteq \mathrm{Mod}_R^{\heartsuit}$ *which is closed under kernels, cokernels, and extensions.*

Remark 7.3.4.7. In the situation of Corollary 7.3.4.6, the inclusion $\mathcal{A} \hookrightarrow \mathrm{Mod}_R^{\heartsuit}$ admits a left adjoint, given by the construction $M \mapsto \pi_0 M_I^{\wedge}$.

Proposition 7.3.4.8. *Let R be a connective $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let $x \in \pi_0 R$ be an element whose image in $(\pi_0 R)/I$ is invertible. If M is an I-complete left R-module, then multiplication by x induces an equivalence from M to itself.*

Proof. Using Proposition 7.3.1.7, we can write $M = N_I^{\wedge}$ for some I-nilpotent left R-module N. It will now that the map $x : N \to N$ induces an isomorphism on each homotopy group, which follows from Example 7.2.4.5. □

Corollary 7.3.4.9. *Let R be an $\mathbb{E}_2$-ring which is complete with respect to a finitely generated ideal $I \subseteq \pi_0 R$, and let $x \in \pi_0 R$ be an element whose image in $(\pi_0 R)/I$ is invertible. Then x is invertible in $\pi_0 R$.*

Remark 7.3.4.10. We can rephrase Corollary 7.3.4.9 as follows: if R is an $\mathbb{E}_2$-ring which is complete with respect to a finitely generated ideal $I \subseteq \pi_0 R$, then I is contained in the Jacobson radical of $\pi_0 R$.

7.3.5 Monoidal Structures

Let R be an $\mathbb{E}_2$-ring. We now show that if $I \subseteq \pi_0 R$ is a finitely generated ideal, then the ∞-category $\mathrm{LMod}_R^{\mathrm{Cpl}(I)}$ inherits the structure of a monoidal ∞-category.

Proposition 7.3.5.1. *Let R be an $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let $\alpha : M \to M'$ be a morphism of left R-modules which induces an equivalence $M_I^{\wedge} \simeq M_I'^{\wedge}$. Then, for any left R-module N, the induced maps*

$$(M \otimes_A N)_I^{\wedge} \to (M' \otimes_A N)_I^{\wedge} \qquad (N \otimes_A M)_I^{\wedge} \to (N \otimes_A M')_I^{\wedge}$$

are equivalences.

Proof. Note that α induces an equivalence of I-completions if and only if the fiber $\mathrm{fib}(\alpha)$ is I-local. Consequently, we can view Proposition 7.3.5.1 as a reformulation of Corollary 7.2.4.12. □

Combining Proposition 7.3.5.1 with Proposition HA.2.2.1.9 , we obtain the following:

Corollary 7.3.5.2. *Let R be an $\mathbb{E}_2$-ring and let $I \subseteq \pi_0 R$ be a finitely generated ideal. Then there is an essentially unique monoidal structure on the ∞-category $\mathrm{LMod}_R^{\mathrm{Cpl}(I)}$ for which the I-completion functor $M \mapsto M_I^\wedge$ is monoidal.*

Warning 7.3.5.3. In the situation of Corollary 7.3.5.2, the inclusion functor $\mathrm{LMod}_R^{\mathrm{Cpl}(I)} \hookrightarrow \mathrm{LMod}_R$ is generally not monoidal (however, it has the structure of a lax monoidal functor, since it is right adjoint to the monoidal completion functor $\mathrm{LMod}_R^{\mathrm{Cpl}(I)} \to \mathrm{LMod}_R$). To emphasize that the tensor product on $\mathrm{LMod}_R^{\mathrm{Cpl}(I)}$ differs from the tensor product on LMod_R, it is convenient to denote the former by $(M, N) \mapsto M \widehat{\otimes}_R N$. Concretely, it is given by the formula $M \widehat{\otimes}_R N = (M \otimes_R N)_I^\wedge$. Similarly, the unit object of $\mathrm{LMod}_R^{\mathrm{Cpl}(I)}$ is given by $R_I^\wedge$.

Remark 7.3.5.4. In the situation of Corollary 7.3.5.2, the monoidal I-completion functor $\mathrm{LMod}_R \to \mathrm{LMod}_R^{\mathrm{Cpl}(I)}$ determines an action of R on the stable ∞-category $\mathrm{LMod}_R^{\mathrm{Cpl}(I)}$. It is not difficult to see that this action of R agrees with the action given in Remark 7.3.1.8.

Remark 7.3.5.5. In the situation of Corollary 7.3.5.2, the I-completion functor $\mathrm{LMod}_R \to \mathrm{LMod}_R^{\mathrm{Cpl}(I)}$ can be regarded as morphism between associative algebra objects of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$. Consequently, it induces a functor

$$\mathrm{LMod}_{\mathrm{LMod}_R^{\mathrm{Cpl}(I)}}(\mathcal{P}\mathrm{r}^{\mathrm{St}}) \to \mathrm{LMod}_{\mathrm{LMod}_R}(\mathcal{P}\mathrm{r}^{\mathrm{St}}) \simeq \mathrm{LinCat}_R^{\mathrm{St}}.$$

It is not difficult to see that this functor is a fully faithful embedding, whose essential image is spanned by those stable R-linear ∞-categories $\mathcal{C}$ which are I-nilpotent in the sense of Remark 7.1.1.18. In particular, if $\mathcal{C}$ is a stable R-linear ∞-category which is I-nilpotent, then we can regard $\mathcal{C}$ as an ∞-category which is left-tensored over $\mathrm{LMod}_R^{\mathrm{Cpl}(I)}$.

Variant 7.3.5.6. Let R be an $\mathbb{E}_{k+1}$-ring for $1 \leqslant k \leqslant \infty$, so that the ∞-category LMod_R inherits the structure of an $\mathbb{E}_k$-monoidal ∞-category. Let $I \subseteq \pi_0 R$ be a finitely generated ideal. Using Proposition 7.3.5.1, we see that $\mathrm{LMod}_R^{\mathrm{Cpl}(I)}$ inherits the structure of an $\mathbb{E}_k$-monoidal ∞-category for which the I-completion functor $\mathrm{LMod}_R^{\mathrm{Cpl}(I)}$ is $\mathbb{E}_k$-monoidal. In particular, if R is an $\mathbb{E}_\infty$-ring, then we can regard $\mathrm{Mod}_R^{\mathrm{Cpl}(I)}$ as a symmetric monoidal ∞-category (with respect to the I-completed tensor product $\widehat{\otimes}_R$ of Warning 7.3.5.3) and the construction $M \mapsto M_I^\wedge$ as a symmetric monoidal functor $\mathrm{Mod}_R \to \mathrm{Mod}_R^{\mathrm{Cpl}(I)}$.

Let R be an $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ a finitely generated ideal, and let M be a left R-module. Using Proposition 7.3.5.1, we see that the canonical map $M \simeq R \otimes_R M \to R_I^\wedge \otimes_R M$ induces an equivalence of I-completions. We therefore obtain a canonical map $R_I^\wedge \otimes_R M \to M_I^\wedge$.

Proposition 7.3.5.7. *Let R be a connective $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let M be an almost perfect R-module. Then the canonical map $R_I^\wedge \otimes_R M \to M_I^\wedge$ is an equivalence. In particular, if R is I-complete, then M is I-complete.*

Proof. Fix an integer n; we will show that the map $\phi_M : R^{\wedge}_I \otimes_R M \to M^{\wedge}_I$ is n-connective. Since M is almost perfect, there exists a perfect R-module N and an n-connective map $N \to M$. We have a commutative diagram

$$\begin{array}{ccc} R^{\wedge}_I \otimes_R N & \xrightarrow{\phi_N} & N^{\wedge}_I \\ \downarrow & & \downarrow \\ R^{\wedge}_I \otimes_R M & \xrightarrow{\phi_M} & M^{\wedge}_I . \end{array}$$

Since the I-completion functor is right t-exact (Proposition 7.3.4.4), the vertical maps in this diagram are n-connective. It will therefore suffice to show that the map ϕ_N is n-connective. Let $\mathcal{C} \subseteq \mathrm{LMod}_R$ be the full subcategory spanned by those objects N for which ϕ_N is an equivalence. Then $\mathcal{C}$ is a stable subcategory which is closed under the formation of retracts. Consequently, to show that $\mathcal{C}$ contains all perfect R-modules, it suffices to show that $\mathcal{C}$ contains R, which is clear. □

7.3.6 Comparison with I-adic Completions

Let R be a commutative ring and let M be a discrete R-module. If $I \subseteq R$ is a finitely generated ideal, we let $\mathrm{Cpl}(M; I)$ denote the I-adic completion of M: that is, the limit of the tower

$$\cdots \to M/I^4M \to M/I^3M \to M/I^2M \to M/IM.$$

Here we can form the limit either in the abelian category $\mathrm{Mod}^{\heartsuit}_R$ of discrete R-modules or in the larger ∞-category Mod_R: the result is the same, since the group $\varprojlim^1\{M/I^nM\}$ vanishes by virtue of the surjectivity of the transition maps $M/I^{n+1}M \to M/I^nM$. Note that each quotient M/I^nM can be regarded as a module over the ring R/I^n and is therefore complete with respect to the ideal I^n (Example 7.3.3.7), hence also with respect to I. It follows that the I-adic completion $\mathrm{Cpl}(M; I)$ is I-complete (in the sense of Definition 7.3.1.1), so that the canonical map $M \to \mathrm{Cpl}(M; I)$ admits an essentially unique factorization $M \to M^{\wedge}_I \xrightarrow{\alpha} \mathrm{Cpl}(M; I)$. The map α is generally not an equivalence. However, it is an equivalence under some mild finiteness assumptions:

Proposition 7.3.6.1. *Let R be a connective $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let M be a discrete R-module. Assume that M is Noetherian: that is, that every submodule of M is finitely generated. For every set S, the canonical map $M'^{\wedge}_I \to \mathrm{Cpl}(M'; I)$ is an equivalence, where $M' = \bigoplus_{\beta \in S} M$. In particular, we have $M^{\wedge}_I \simeq \mathrm{Cpl}(M; I)$*

Proof. We proceed by induction on the minimal number of generators of I. If $I = (0)$ there is nothing to prove. Otherwise, we may assume that $I = J + (x)$ for some $x \in \pi_0 A$ and that $M'^{\wedge}_J = \mathrm{Cpl}(M'; J)$. Using Proposition 7.3.3.2, we deduce that $M'^{\wedge}_I \simeq (\mathrm{Cpl}(M'; J))^{\wedge}_{(x)}$.

For $m, n \geqslant 0$, we let $X_{m,n}$ denote the cofiber of the map $M'/J^m M' \to M'/J^m M'$ given by multiplication by x^n. Then $\pi_i X_{m,n}$ vanishes for $i \notin \{0,1\}$, and Proposition 7.3.2.1 implies that $M'^{\wedge}_I \simeq \varprojlim \{X_{m,n}\}$. It follows that there is a canonical isomorphism $\pi_1 M'^{\wedge}_I \simeq \varprojlim \{\pi_1 X_{m,n}\}$ and a short exact sequence

$$0 \to \varprojlim{}^1 \{\pi_1 X_{m,n}\} \to \pi_0 M'^{\wedge}_I \to \varprojlim \{\pi_0 X_{m,n}\} \to 0.$$

To complete the proof, it will suffice to show that $\varprojlim \{\pi_1 X_{m,n}\} \simeq \varprojlim{}^1 \{\pi_1 X_{m,n}\} \simeq 0$. In fact, we claim that $\{\pi_1 X_{m,n}\}_{m,n \geqslant 0}$ is trivial as a pro-object in the category of abelian groups. To prove this, it suffices to show that for each $m, n \geqslant 0$, there exists $n' \geqslant n$ such that the induced map $\pi_1 X_{m,n'} \to \pi_1 X_{m,n}$ is zero. For each $k \geqslant 0$, let $Y(k) = \{y \in M/I^m M : x^k y = 0\}$. Since M is Noetherian, the quotient $M/I^m M$ is also Noetherian, so the ascending chain of submodules

$$0 = Y(0) \subseteq Y(1) \subseteq Y(2) \subseteq \cdots$$

must eventually stabilize. It follows that there exists $k \geqslant 0$ such that if $y \in M/I^m M$ is annihilated by x^{k+1}, then it is annihilated by x^k. It follows that the map $\pi_1 X_{m,n+k} \to \pi_1 X_{m,n}$ is zero, as desired. □

Corollary 7.3.6.2. *Let R be a commutative ring, let $I \subseteq R$ be a finitely generated ideal, and let M be a discrete R-module. Then the canonical map $M^{\wedge}_I \to \mathrm{Cpl}(M; I)$ induces a surjection $\pi_0 M^{\wedge}_I \to \mathrm{Cpl}(M; I)$.*

Proof. Choose a finite set $(x_1, \ldots, x_n)$ of generators for I. Replacing R by the subring generated by the $\{x_i\}$, we can reduce to the case where R is Noetherian. Choose a surjection $\alpha : P \to M$, where P is a free R-module. We then have a commutative diagram

$$\begin{array}{ccc} \pi_0 P^{\wedge}_I & \longrightarrow & \pi_0 M^{\wedge}_I \\ \downarrow & & \downarrow \\ \mathrm{Cpl}(P; I) & \longrightarrow & \mathrm{Cpl}(M; I). \end{array}$$

The left vertical map is an isomorphism by virtue of Proposition 7.3.6.1 and the lower horizontal map is surjective because α is surjective. It follows from a diagram chase that the right vertical map is also surjective. □

Corollary 7.3.6.3. *Let R be a commutative ring, let $I \subseteq R$ be a finitely generated ideal, and let M be a discrete R-module. The following conditions are equivalent:*

- (*a*) *The module M is I-adically complete (that is, the canonical map $M \to \mathrm{Cpl}(M; I)$ is an isomorphism).*
- (*b*) *The module M is I-complete and I-adically separated (that is, the canonical map $M \to \mathrm{Cpl}(M; I)$ is injective).*

Proof. The implication $(a) \Rightarrow (b)$ is obvious. Conversely, suppose that (b) is satisfied. Then the canonical map $M \to \mathrm{Cpl}(M; I)$ is an injection by virtue of our assumption that M is I-adically separated, and a surjection by virtue of Corollary 7.3.6.2. □

Corollary 7.3.6.4. *Let R be a commutative ring and let $I \subseteq R$ be a finitely generated ideal. If R is I-complete, then the canonical map $\epsilon : R \to \mathrm{Cpl}(R; I) = \varprojlim R/I^n$ is a surjection and the kernel $\ker(\epsilon)$ is nilpotent.*

Proof. The surjectivity of ϵ follows from Corollary 7.3.6.2. Write $I = (x_1, \ldots, x_n)$. We will complete the proof by showing that every element $t \in \ker(\epsilon)$ satisfies $t^{n+1} = 0$. For $1 \leqslant i \leqslant n$ and $m \geqslant 0$, let $K_{i,m}$ denote the cofiber of the map $x_i^m : R \to R$, and set $K_m = \bigotimes_{1 \leqslant i \leqslant n} K_{i,m}$ (that is, K_m is the Koszul complex of the sequence $(x_1^m, \ldots, x_n^m)$). Note that each homotopy group of K_m is annihilated by some power of I, and is therefore annihilated by t. It follows that, for each $k \geqslant 0$, multiplication by t annihilates the Pro-object $\{\pi_k K_m\}_{m \geqslant 0}$, so that the map $\{\tau_{\geqslant k} K_m\}_{m \geqslant 0} \xrightarrow{t} \{\tau_{\geqslant k} K_m\}_{m \geqslant 0}$ factors through the tower $\{\tau_{\geqslant k+1} K_m\}_{m \geqslant 0}$. Invoking this observation repeatedly, we deduce that each of the maps $t^s : \{K_m\}_{m \geqslant 0} \to \{K_m\}_{m \geqslant 0}$ factors through the tower $\{\tau_{\geqslant s} K_m\}_{m \geqslant 0}$, which vanishes for $s > n$. It follows that multiplication by t^{n+1} annihilates the Pro-object $\{K_m\}_{m \geqslant 0}$ and therefore annihilates its inverse limit $\varprojlim K_m \simeq R$. □

Corollary 7.3.6.5. *Let R be a commutative ring which is I-complete for some finitely generated ideal $I \subseteq R$. Then the pair (R, I) is Henselian.*

Proof. Let $J = \bigcap_n I^n$ be the kernel of the map $R \to \varprojlim R/I^n$. Then J is a nilpotent ideal (Corollary 7.3.6.4), so the pair (R, J) is Henselian (Corollary B.3.1.5). We may therefore replace R by R/J (Corollary B.3.3.3) and thereby reduce to the case where $R \simeq \varprojlim R/I^n$ is I-adically complete in the classical sense, in which case the desired result follows from Hensel's lemma (Proposition B.3.1.4). □

Corollary 7.3.6.6. *Let R be an $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let $M \in \mathrm{LMod}_R$. Assume that each of the homotopy groups $\pi_n M$ is Noetherian when regarded as a (discrete) module over $\pi_0 R$. Then, for each integer n, there is a canonical isomorphism $\pi_n M_I^{\wedge} \simeq \mathrm{Cpl}(\pi_n M; I)$.*

Proof. Using Corollary 7.3.3.6, we can reduce to the case where R is connective. Then each homotopy group $\pi_n M$ can be regarded as a module over R. Using Corollary 7.3.3.6 and Proposition 7.3.6.1, we deduce that the completion $(\pi_n M)_I^{\wedge}$ can be identified with $\mathrm{Cpl}(\pi_n M; I)$. In particular, $(\pi_n M)_I^{\wedge}$ is a discrete R-module. We will complete the proof by producing isomorphisms $\pi_n(M_I^{\wedge}) \simeq (\pi_n M)_I^{\wedge}$. We have a fiber sequence of R-modules $\tau_{\geqslant n+1} M \to M \to \tau_{\leqslant n} M$, hence a fiber sequence of I-complete R-modules $(\tau_{\geqslant n+1} M)_I^{\wedge} \to M_I^{\wedge} \to (\tau_{\leqslant n} M)_I^{\wedge}$. Since the functor of I-completion is right t-exact, the associated long exact sequence of homotopy groups gives an isomorphism $\pi_n M^{\wedge}_I \simeq \pi_n(\tau_{\leqslant n} M)^{\wedge}_I$. We may therefore replace M by $\tau_{\leqslant n} M$ and thereby reduce to the case where M is n-truncated. Let $N = \tau_{\leqslant n-1} M$, so that we have a fiber sequence $\Sigma^n(\pi_n M) \to M \to N$, hence a fiber sequence of I-completions $\Sigma^n(\pi_n M)^{\wedge}_I \to M^{\wedge}_I \to N^{\wedge}_I$. Using the associated long exact sequence, we are reduced to proving that $N^{\wedge}_I$ is $(n-1)$-truncated. We first prove by descending induction on k that $(\tau_{\geqslant k} N)^{\wedge}_I$ is $(n-1)$-truncated. For $k \geqslant n$, there is nothing to prove. Assume therefore that $k < n$. $(\tau_{\geqslant k+1} N)^{\wedge}_I \to (\tau_{\geqslant k} N)^{\wedge}_I \to \Sigma^k(\pi_k N)^{\wedge}_I$. The inductive hypothesis implies that $(\tau_{\geqslant k+1} N)^{\wedge}_I$ is $(n-1)$-truncated, and Proposition 7.3.6.1 implies that $(\pi_k N)^{\wedge}_I$ is discrete. It follows that $(\tau_{\geqslant k} N)^{\wedge}_I$ is $(n-1)$-truncated. We have a fiber sequence $(\tau_{\geqslant k} N)^{\wedge}_I \to N^{\wedge}_I \to (\tau_{\leqslant k-1} N)^{\wedge}_I$. For $k \ll 0$, Proposition 7.3.4.4 implies that $(\tau_{\leqslant k-1} N)^{\wedge}_I$ is $(n-1)$-truncated, so that $N^{\wedge}_I$ is $(n-1)$-truncated as desired. □

Remark 7.3.6.7. Let R be a Noetherian $\mathbb{E}_\infty$-ring, let $I \subseteq \pi_0 R$ be an ideal, and suppose that $\pi_0 R$ is I-adically complete: that is, that the canonical map $\pi_0 R \to \varprojlim_n (\pi_0 R)/I^n$ is an isomorphism of commutative rings. Proposition 7.3.6.1 implies that $\pi_0 R$ is I-complete. Using Propositions HA.7.2.4.17 and 7.3.5.7, we deduce that every finitely generated discrete module over $\pi_0 R$ is I-complete. It then follows from Theorem 7.3.4.1 that R is I-complete.

Remark 7.3.6.8. Let R be a Noetherian $\mathbb{E}_\infty$-ring and suppose we are given a pair of ideals $I \subseteq J \subseteq \pi_0(R)$. If R is I-complete and $\pi_0(R)/I$ is (J/I)-complete, then R is J-complete. To prove this, it will suffice to show that every finitely generated $\pi_0(R)$-module M is J-complete. Our assumption that R is I-complete guarantees that M is I-complete (Proposition 7.3.6.1) and therefore I-adically complete (Corollary 7.3.6.6). Realizing M as the limit of the tower $M/I^k M$, we are reduced to showing that each $M/I^k M$ is J-complete. Proceeding by induction on k, we are reduced to showing that $I^{k-1}M/I^k M$ is J-complete. This follows from Proposition 7.3.6.1, since $\pi_0(R)/I$ is (J/I)-complete and $I^{k-1}M/I^k M$ is almost perfect as a module over $\pi_0(R)/I$.

Corollary 7.3.6.9. *Let R be a Noetherian $\mathbb{E}_\infty$-ring and let $I \subseteq \pi_0 R$ be an ideal. Then the completion $R^{\wedge}_I$ is flat over R.*

Proof. Let M be a discrete R-module; we wish to show that $R^{\wedge}_I \otimes_R M$ is discrete. Since the construction $M \mapsto R^{\wedge}_I \otimes_R M$ commutes with filtered colimits, we can assume that M is finitely presented (when regarded as a module over the commutative ring $\pi_0 R$). In this case, M is almost perfect as an R-module (Proposition HA.7.2.4.17), so that $R^{\wedge}_I \otimes_R M$ can be identified with the I-completion $M^{\wedge}_I$ (Proposition 7.3.5.7). The discreteness of $M^{\wedge}_I$ now follows from Proposition 7.3.6.1. □

Corollary 7.3.6.10 (Krull Intersection Theorem)**.** *Let R be a local Noetherian ring and let $I \subsetneq R$ be an ideal. Then R is I-adically separated: that is, the $\bigcap_{n \geqslant 0} I^n = \{0\}$.*

Proof. Let $\mathfrak{m}$ denote the maximal ideal of R, so that $I \subseteq \mathfrak{m}$. The canonical map $R \to R/\mathfrak{m}$ factors through R/I, and therefore also through $R^{\wedge}_I$. It follows that the flat map $\phi : R \to R^{\wedge}_I$ of Corollary 7.3.6.9 is faithfully flat, and is therefore injective. It follows from Proposition 7.3.6.1 that we can identify $R^{\wedge}_I$ with the I-adic completion $\varprojlim\{R/I^n\}$, so that $\bigcap_{n \geqslant 0} I^n = \ker(\phi) = (0)$. □

7.3.7 Complete Modules as a Derived Category

Let R be a connective $\mathbb{E}_2$-ring and let $I \subseteq \pi_0 R$ be a finitely generated ideal. We let $\mathrm{LMod}_R^{\heartsuit\,\mathrm{Cpl}(I)}$ denote the full subcategory of LMod_R spanned by those R-modules M which are both discrete and I-complete. Then $\mathrm{LMod}_R^{\heartsuit\,\mathrm{Cpl}(I)}$ is the heart of the t-structure on $\mathrm{LMod}_R^{\mathrm{Cpl}(I)}$ described in Proposition 7.3.4.4. In particular, it is an abelian category.

Remark 7.3.7.1. In the situation described above, the inclusion functor $\mathrm{LMod}_R^{\mathrm{Cpl}(I)} \hookrightarrow \mathrm{LMod}_R$ is t-exact and therefore restricts to an exact functor $\mathrm{LMod}_R^{\heartsuit\,\mathrm{Cpl}(I)} \hookrightarrow \mathrm{LMod}_R^{\heartsuit}$. In particular, if $\alpha : M \to N$ is a morphism of discrete I-complete R-modules, then α is a monomorphism (epimorphism) in the abelian category $\mathrm{LMod}_R^{\heartsuit\,\mathrm{Cpl}(I)}$ if and only if it is injective (surjective) when regarded as a homomorphism of abelian groups.

Proposition 7.3.7.2. *Let R be a connective $\mathbb{E}_2$-ring and let $I \subseteq \pi_0 R$ be a finitely generated ideal. Then the abelian category $\mathrm{LMod}_R^{\heartsuit\,\mathrm{Cpl}(I)}$ has enough projective objects.*

Proof. Let M be a left R-module which is discrete and I-complete. Choose a morphism $\alpha : P \to M$ in LMod_R which is surjective on π_0, where P is a direct sum of copies of R. Since M is I-complete, the morphism α factors as a composition $P \to P^{\wedge}_I \xrightarrow{\beta} M$. Since M is discrete, the morphism β factors as a composition $P^{\wedge}_I \to \pi_0 P^{\wedge}_I \xrightarrow{\gamma} M$. Note that $\pi_0 P^{\wedge}_I$ is discrete and I-complete (Corollary 7.3.4.3), so we can regard γ as an epimorphism in the abelian category $\mathrm{LMod}_R^{\heartsuit\,\mathrm{Cpl}(I)}$ (Remark 7.3.7.1). We will complete the proof by showing that $\pi_0 P^{\wedge}_I$ is a projective object of $\mathrm{LMod}_R^{\heartsuit\,\mathrm{Cpl}(I)}$. Let $u : N' \to N$ be an epimorphism in $\mathrm{LMod}_R^{\heartsuit\,\mathrm{Cpl}(I)}$; we wish to show that the left vertical map in the diagram

$$\begin{array}{ccc} \mathrm{Map}_{\mathrm{LMod}_R}(\pi_0 P^{\wedge}_I, N') & \longrightarrow & \mathrm{Map}_{\mathrm{LMod}_R}(P, N') \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathrm{LMod}_R}(\pi_0 P^{\wedge}_I, N) & \longrightarrow & \mathrm{Map}_{\mathrm{LMod}_R}(P, N) \end{array}$$

is surjective on connected components. Since N and N' are discrete and I-complete, the horizontal maps are homotopy equivalences. It will therefore suffice to show that the right vertical map is surjective on connected components. This is clear: the right vertical map can be identified with a direct product of copies of the underlying map $N' \to N$, which is a surjection of abelian groups (Remark 7.3.7.1). □

In the situation of Proposition 7.3.7.2, the existence of enough projective objects in the abelian category $\mathrm{LMod}_R^{\heartsuit\,\mathrm{Cpl}(I)}$ allows us to consider the derived ∞-category $\mathcal{D}^-(\mathrm{LMod}_R^{\heartsuit\,\mathrm{Cpl}(I)})$. Since the t-structure on $\mathrm{LMod}_R^{\mathrm{Cpl}(I)}$ is left complete, Theorem HA.1.3.3.2 and Remark HA.1.3.3.6 imply that the inclusion map $\mathrm{LMod}_R^{\heartsuit\,\mathrm{Cpl}(I)} \hookrightarrow \mathrm{LMod}_R^{\mathrm{Cpl}(I)}$ admits an essentially unique extension to a t-exact functor $F : \mathcal{D}^-(\mathrm{LMod}_R^{\heartsuit\,\mathrm{Cpl}(I)}) \to \mathrm{LMod}_R^{\mathrm{Cpl}(I)}$.

Proposition 7.3.7.3. *Let R be a Noetherian commutative ring and let $I \subseteq R$ be an ideal. Then the functor $F : \mathcal{D}^-(\mathrm{Mod}_R^{\heartsuit\,\mathrm{Cpl}(I)}) \to \mathrm{Mod}_R^{\mathrm{Cpl}(I)}$ is a fully faithful embedding whose essential image is the full subcategory $\bigcup_n (\mathrm{Mod}_R^{\mathrm{Cpl}(I)})_{\geqslant -n}$ consisting of right-bounded objects of $\mathrm{Mod}_R^{\mathrm{Cpl}(I)}$.*

Proof. By virtue of Proposition HA.1.3.3.7 , it will suffice to show that the abelian groups $\mathrm{Ext}^i_R(X, Y)$ vanish for $i > 0$ if X and Y are objects of $\mathrm{Mod}_R^{\heartsuit\,\mathrm{Cpl}(I)}$ with X projective. The proof of Proposition 7.3.7.2 shows that there exists an epimorphism $\pi_0 P^{\wedge}_I \to X$, where P is a direct sum of copies of R. Since X is projective, this epimorphism splits. Since R is Noetherian, Proposition 7.3.6.1 implies that $P^{\wedge}_I$ is discrete. It follows that X is a direct summand of $P^{\wedge}_I$. It will therefore suffice to show that the groups $\mathrm{Ext}^i_R(P^{\wedge}_I, Y) \simeq \mathrm{Ext}^i_R(P, Y)$ vanish for $i > 0$. This is clear, since Y is discrete and P is a direct sum of copies of R. □

Warning 7.3.7.4. In the situation of Proposition 7.3.7.3, the abelian category $\mathrm{Mod}_R^{\heartsuit\,\mathrm{Cpl}(I)}$ is usually not a Grothendieck abelian category.

Corollary 7.3.7.5. *Let R be a Noetherian commutative ring, let $I \subseteq R$ be an ideal, and let $\rho : \mathrm{Mod}_R^{\heartsuit} \to \mathrm{Mod}_R^{\heartsuit\,\mathrm{Cpl}(I)}$ be the functor of abelian categories given by $\rho(M) = \pi_0 M^{\wedge}_I$. Then:*

(1) *The functor ρ preserves small colimits. In particular, it is right exact.*

(2) *If M is a projective R-module, there is a canonical isomorphism $\rho(M) \simeq \mathrm{Cpl}(M; I)$.*

(3) *The diagram of ∞-categories*

$$\begin{array}{ccc} \mathcal{D}^-(\mathrm{Mod}_R^{\heartsuit}) & \xrightarrow{L\rho} & \mathcal{D}^-(\mathrm{Mod}_R^{\heartsuit\,\mathrm{Cpl}(I)}) \\ \downarrow & & \downarrow \\ \mathrm{Mod}_R & \longrightarrow & \mathrm{Mod}_R^{\mathrm{Cpl}(I)} \end{array}$$

*commutes up to canonical homotopy, where the vertical maps are the full faithful embeddings provided by Proposition 7.3.7.3, $L\rho$ denotes the left derived functor of ρ (see Example **??**), and the bottom horizontal map is given by I-completion.*

Remark 7.3.7.6. Let R be a Noetherian commutative ring, let M be a discrete R-module, and choose a projective resolution

$$\cdots \to P_3 \to P_2 \to P_1 \to P_0 \to M.$$

It follows from Corollary 7.3.7.5 that for any ideal $I \subseteq R$, the completion $M^{\wedge}_I$ is represented by the chain complex of R-modules

$$\cdots \to \mathrm{Cpl}(P_3; I) \to \mathrm{Cpl}(P_2; I) \to \mathrm{Cpl}(P_1; I) \to \mathrm{Cpl}(P_0; I).$$

Proof of Corollary 7.3.7.5. Assertion (1) follows from the right t-exactness of the functor $M \mapsto M^{\wedge}_I$ and assertion (2) follows from Proposition 7.3.6.1. Assertion (3) follows from (2) and Theorem HA.1.3.3.2 . □

7.3.8 Complete Noetherian Rings

We conclude this section by reviewing a few standard facts about the completion of Noetherian rings.

Proposition 7.3.8.1. *Let R be a commutative ring and let $I \subseteq R$ be a finitely generated ideal. Suppose that R is I-adically complete: that is, that the canonical map $R \to \varprojlim\{R/I^n\}$ is an isomorphism. If R/I is Noetherian, then R is Noetherian.*

Proof. For each $n \geqslant 0$, set $A_n = I^n/I^{n+1}$, and let A denote the graded ring $\bigoplus A_n$. Choose a finite set of generators $x_1, \ldots, x_k$ for the ideal I, and let $\overline{x}_1, \ldots, \overline{x}_k$ denote their images in $A_1 = I/I^2$. The elements $\overline{x}_i$ generate A as an algebra over $A_0 = R/I$. It follows from the Hilbert basis theorem that A is Noetherian.

Let $J \subseteq R$ be an arbitrary ideal; we wish to show that J is finitely generated. For each $n \geqslant 0$, set $J_n = (J \cap I^n)/(J \cap I^{n+1})$, which we regard as a submodule of A_n. The direct sum $\bigoplus_{n \geqslant 0} J_n$ is an ideal in the commutative ring A. Since A is Noetherian, this ideal is finitely generated. Choose a finite set of homogeneous generators $\overline{y}_1, \ldots, \overline{y}_m \in \bigoplus_{n \geqslant 0} J_n$, where $\overline{y}_i \in J_{d_i}$. For $1 \leqslant i \leqslant m$, let y_i denote a lift of $\overline{y}_i$ to $J \cap I^n$. We claim that the elements $y_1, \ldots, y_m \in J$ generate the ideal J.

Let $d = \max\{d_i\}$. We will prove the following:

- $(*)$ For each $z \in J \cap I^n$, we can find coefficients $c_i \in R$ such that $c_i \in I^{n-d}$ if $n > d$, and $z - \sum_{1 \leqslant i \leqslant m} c_i y_i$ belongs to I^{n+1}.

To prove $(*)$, we let $\overline{z}$ denote the image of z in J_n. Since the elements $\overline{y}_i$ generate $\bigoplus J_n$ as an A-module, we can write $\overline{z} = \sum \overline{c_i y_i}$ for some homogeneous elements $\overline{c}_i \in A$ of degree $n - d_i$. For $1 \leqslant i \leqslant m$, choose $c_i \in I^{n-d_i}$ to be any lift of $\overline{c_i}$; then the elements c_i have the desired property.

Now let $z \in J$ be an arbitrary element. We will define a sequence of elements $z_0, z_1, \ldots, \in J$ such that $z - z_q \in I^q$. Set $z_0 = 0$. Assuming that z_q has been defined, we apply $(*)$ to write

$$z - z_q \equiv \sum_{1 \leqslant i \leqslant m} c_{i,q} y_i \pmod{I^{q+1}}$$

where $c_{i,q} \in I^{q-d}$ for $q \geqslant d$. Now set $z_{q+1} = z - z_q - \sum_{1 \leqslant i \leqslant m} c_{i,q} y_i$. For each $1 \leqslant i \leqslant m$, the sum $\sum_{q \geqslant 0} c_{i,q}$ converges I-adically to a unique element $c_i \in R$. We now observe that $z = \sum c_i y_i$ belongs to the ideal generated by the elements y_i, as desired. □

Corollary 7.3.8.2. *Let R be a Noetherian ring, let $I \subseteq R$ be an ideal, and let $\mathrm{Cpl}(R; I) = \varprojlim \{R/I^n\}$ denote the I-adic completion of R. Then $\mathrm{Cpl}(R; I)$ is Noetherian.*

Proof. For each integer n, let J_n denote the ideal of $\mathrm{Cpl}(R; I)$ given by $\varprojlim I^n / I^{n+m}$, so that the canonical map $\phi : R \to \mathrm{Cpl}(R; I)$ induces isomorphisms $R/I^n \to \mathrm{Cpl}(R; I)/J_n$ for each $n \geqslant 0$. It follows that the canonical map $\mathrm{Cpl}(R; I) \to \varprojlim \mathrm{Cpl}(R; I)/J_n$ is an isomorphism. We will show that $J_n = I^n \mathrm{Cpl}(R; I)$ for each $n \geqslant 0$. Assuming this, we deduce that J_1 is finitely generated, that $\mathrm{Cpl}(R; I)$ is J_1-adically complete, and that $\mathrm{Cpl}(R; I)/J_1 \simeq R/I$ is Noetherian. It then follows from Proposition 7.3.8.1 that $\mathrm{Cpl}(R; I)$ is Noetherian.

Choose a finite set of generators $x_1, \ldots, x_k$ for the ideal I^n and an arbitrary $z \in J_n$, given by a compatible sequence of elements $\{\overline{z}_m \in I^n / I^{n+m}\}_{m \geqslant 0}$. Lift each $\overline{z_m}$ to an element $z_m \in I^n$. Then $z_{m+1} - z_m \in I^{n+m}$, so we can write

$$z_{m+1} = z_m + \sum_{1 \leqslant i \leqslant k} c_{m,i} x_i$$

for some $c_{m,i} \in I^m$. For $1 \leqslant i \leqslant k$, the residue classes of the partial sums $\{\sum_{j \leqslant m} c_{j,i}\}_{m \geqslant 0}$ determine an element $c_i \in \mathrm{Cpl}(R; I)$. Then $z = \phi(z_0) + \sum c_i \phi(x_i)$, so that z belongs to the ideal $I^n \mathrm{Cpl}(R; I)$. □

Corollary 7.3.8.3. *Let R be a Noetherian $\mathbb{E}_\infty$-ring and let $I \subseteq \pi_0 R$ be an ideal. Then the completion $R^\wedge_I$ is a Noetherian $\mathbb{E}_\infty$-ring.*

Proof. Corollary 7.3.6.6 implies that $\pi_0 R^\wedge_I$ is the I-adic completion of the Noetherian commutative ring $\pi_0 R$, and therefore a Noetherian commutative ring (Corollary 7.3.8.2). To complete the proof, it will suffice to show that each $\pi_k R^\wedge_I$ is a finitely generated module over $\pi_0 R^\wedge_I$. Since $A \to A^\wedge_I$ is flat (Corollary 7.3.6.9), we have a canonical isomorphism

$$\pi_k R^\wedge_I \simeq \mathrm{Tor}_0^{\pi_0 R}(\pi_0 R^\wedge_I, \pi_k R).$$

It will therefore suffice to show that $\pi_k R$ is a finitely generated module over $\pi_0 R$, which follows from our assumption that A is Noetherian. □

7.4 The Beauville-Laszlo Theorem

Let A be a commutative ring containing an element x and let $\widehat{A} = \varprojlim A/x^n A$ denote the (x)-adic completion of A. We then have a diagram of commutative rings

$$\begin{array}{ccc} A & \longrightarrow & \widehat{A} \\ \downarrow & & \downarrow \\ A[x^{-1}] & \longrightarrow & \widehat{A}[x^{-1}], \end{array}$$

which determines a diagram of categories σ :

$$\begin{array}{ccc} \mathrm{Mod}^{\mathrm{lf}}_A & \longrightarrow & \mathrm{Mod}^{\mathrm{lf}}_{\widehat{A}} \\ \downarrow & & \downarrow \\ \mathrm{Mod}^{\mathrm{lf}}_{A[x^{-1}]} & \longrightarrow & \mathrm{Mod}^{\mathrm{lf}}_{\widehat{A}[x^{-1}]}; \end{array}$$

here $\mathrm{Mod}^{\mathrm{lf}}_R$ denotes the category whose objects are projective R-modules of finite rank. The *Beauville-Laszlo theorem* asserts that if x is not a zero-divisor in A, then the diagram σ is a (homotopy) pullback diagram of categories (see [**?**]). In other words, the data of a projective A-module of finite rank is equivalent to the data of a triple (M_0, M_1, α), where M_0 and M_1 are projective modules of finite rank over $A[x^{-1}]$ and $\widehat{A}$, respectively, and $\alpha : \widehat{A}[x^{-1}] \otimes_{A[x^{-1}]} M_0 \simeq M_1[x^{-1}]$ is an isomorphism of $\widehat{A}[x^{-1}]$-modules. Heuristically, the Beauville-Laszlo theorem is one expression of the idea that the diagram of affine schemes

$$\begin{array}{ccc} \mathrm{Spec}\, A & \longleftarrow & \mathrm{Spec}\, \widehat{A} \\ \uparrow & & \uparrow \\ \mathrm{Spec}\, A[x^{-1}] & \longleftarrow & \mathrm{Spec}\, \widehat{A}[x^{-1}] \end{array}$$

exhibits $X = \mathrm{Spec}\, R$ as obtained from the open subscheme $U = \mathrm{Spec}\, R[x^{-1}]$ by "gluing in" a formal neighborhood of the divisor $D = X - U$.

Our goal in this section is to establish the following variant of the Beauville-Laszlo theorem:

Theorem 7.4.0.1. *Let $\phi : A \to B$ be a map of connective $\mathbb{E}_\infty$-rings, let $I \subseteq \pi_0 A$ be a finitely generated ideal, and let U denote the quasi-compact open substack of* $\mathrm{Sp\acute{e}t}\, A$ *which is complementary to the vanishing locus of I, and form a pullback diagram*

$$\begin{array}{ccc} \mathsf{V} & \longrightarrow & \mathsf{U} \\ \downarrow & & \downarrow \\ \mathrm{Sp\acute{e}t}\, B & \longrightarrow & \mathrm{Sp\acute{e}t}\, A. \end{array}$$

If ϕ induces an equivalence of I-completions $A^{\wedge}_{I} \to B^{\wedge}_{I}$, then the diagrams of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A) & \longrightarrow & \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, B) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{U}) & \longrightarrow & \mathrm{QCoh}(\mathsf{V}) \end{array}$$

is a pullback square.

Example 7.4.0.2. Let A be a connective $\mathbb{E}_{\infty}$-ring, let $I \subseteq \pi_0 A$ be a finitely generated ideal, let U be the open substack of $\mathrm{Sp\acute{e}t}\, A$ complementary to the vanishing locus of I, and form pullback diagrams

$$\begin{array}{ccc} \mathsf{V} & \longrightarrow & \mathsf{U} \\ \downarrow & & \downarrow \\ \mathrm{Sp\acute{e}t}\, A^{\wedge}_{I} & \longrightarrow & \mathrm{Sp\acute{e}t}\, A. \end{array}$$

Then Theorem 7.4.0.1 implies that the diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A) & \longrightarrow & \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A^{\wedge}_{I}) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{U}) & \longrightarrow & \mathrm{QCoh}(\mathsf{V}) \end{array}$$

is a pullback square.

7.4.1 Proof of the Beauville-Laszlo Theorem

Theorem 7.4.0.1 is an immediate consequence of the following more general result (together with the description of the ∞-category of quasi-coherent sheaves on a quasi-affine spectral Deligne-Mumford stack given by Proposition 2.4.1.4):

Proposition 7.4.1.1. *Let R be an $\mathbb{E}_2$-ring and let $I \subseteq \pi_0 R$ be a finitely generated ideal. Let $\phi : A \to B$ be a morphism of $\mathbb{E}_1$-algebras over R, and suppose that ϕ induces an equivalence of I-completions $A^{\wedge}_{I} \to B^{\wedge}_{I}$. Then, for every stable R-linear ∞-category $\mathcal{C}$, the diagram*

$$\begin{array}{ccc} \mathrm{LMod}_A(\mathcal{C}) & \longrightarrow & \mathrm{LMod}_B(\mathcal{C}) \\ \downarrow & & \downarrow \\ \mathrm{LMod}_{L_I(A)}(\mathcal{C}) & \longrightarrow & \mathrm{LMod}_{L_I(B)}(\mathcal{C}) \end{array}$$

is a pullback square of ∞-categories.

Lemma 7.4.1.2. *Let R be an $\mathbb{E}_2$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and let $\phi : A \to B$ be a morphism of $\mathbb{E}_1$-algebras over R which induces an equivalence $A^{\wedge}_I \to B^{\wedge}_I$. Let $\mathcal{C}$ be a stable R-linear ∞-category. Then, for every object $M \in \mathrm{LMod}_A(\mathcal{C})$, the diagram σ :*

$$\begin{array}{ccc} M & \longrightarrow & B \otimes_A M \\ \downarrow & & \downarrow \\ L_I M & \longrightarrow & L_I(B \otimes_A M) \end{array}$$

is a pullback square.

Proof. Let K denote the fiber of the map

$$M \to (B \otimes_A M) \times_{L_I(B \otimes_A M)} L_I(M).$$

Then $K^{\wedge}_I \simeq 0$ (since the horizontal maps in the diagram σ are equivalences after I-completion) and $L_I(K) \simeq 0$ (since the vertical maps in the diagram σ are equivalences after applying the functor L_I). It follows that $K \simeq 0$, so that σ is a pullback diagram as desired. □

Proof of Proposition 7.4.1.1. Form a pullback diagram of ∞-categories

$$\begin{array}{ccc} \mathcal{D} & \longrightarrow & \mathrm{LMod}_B(\mathcal{C}) \\ \downarrow & & \downarrow \\ \mathrm{LMod}_{L_I(A)}(\mathcal{C}) & \longrightarrow & \mathrm{LMod}_{L_I(B)}(\mathcal{C}), \end{array}$$

and let us identify objects of $\mathcal{D}$ with triples (P, Q, α), where P is a left B-module object of $\mathcal{C}$, Q is a left $L_I(A)$-module object of $\mathcal{C}$, and $\alpha : L_I(B) \otimes_B P \to L_I(B) \otimes_{L_I(A)} Q$ is an equivalence. Let F denote the canonical map from $\mathrm{LMod}_A(\mathcal{C})$ to $\mathcal{D}$, given on objects by

$$M \mapsto (B \otimes_A M, L_I(A) \otimes_A N, \mathrm{id}_{L_I(B) \otimes_A M}).$$

Then F admits a right adjoint G, given by $G(P, Q, \alpha) = P \times_{L_I B \otimes_{L_I A} Q} Q$. We first claim that F is fully faithful: that is, that the unit map $u_M : M \to (G \circ F)(M)$ is an equivalence for each $M \in \mathrm{LMod}_A(\mathcal{C})$. This follows immediately from Lemma 7.4.1.2. To complete the proof that F is an equivalence of ∞-categories, it will suffice to show that the functor G is conservative. Since G is an exact functor between stable ∞-categories, we are reduced to proving that if $G(P, Q, \alpha) \simeq 0$, then $P \simeq Q \simeq 0$. Note that for any M in LMod_R, we have a canonical equivalence $L_I M \simeq L_I R \otimes_R M$. In particular, the canonical map $B \to L_I B$ is an equivalence after tensoring with $L_I R$. It follows that for every object $P \in \mathrm{LMod}_B(\mathcal{C})$, the canonical map $P \to L_I(B) \otimes_B P$ becomes equivalence (in $\mathcal{C}$) after tensoring with $L_I R$. We conclude that the projection map $G(P, Q, \alpha) \to Q$ becomes an equivalence after tensoring with $L_I(R)$. We then have

$$\begin{aligned} Q &\simeq L_I(A) \otimes_{L_I(A)} Q \\ &\simeq (L_I R \otimes_R L_I(A)) \otimes_{L_I(A)} Q \\ &\simeq L_I R \otimes_R Q \\ &\simeq L_I R \otimes_R G(P, Q, \alpha) \\ &\simeq 0. \end{aligned}$$

It follows that the projection map $G(P, Q, \alpha) \to P$ is an equivalence, so that $P \simeq 0$ as well. □

Remark 7.4.1.3. In the situation of Proposition 7.4.1.1, suppose that the R-linear ∞-category $\mathcal{C}$ is compactly generated. For every object $R' \in \mathrm{Alg}_R$, let $\mathrm{LMod}_{R'}(\mathcal{C})^c$ denote the full subcategory of $\mathrm{LMod}_{R'}(\mathcal{C})$ spanned by the compact objects, so that we have a commutative diagram of ∞-categories τ :

$$\begin{array}{ccc} \mathrm{LMod}_A(\mathcal{C})^c & \longrightarrow & \mathrm{LMod}_B(\mathcal{C})^c \\ \downarrow & & \downarrow \\ \mathrm{LMod}_{L_I(A)}(\mathcal{C})^c & \longrightarrow & \mathrm{LMod}_{L_I(B)}(\mathcal{C})^c \end{array}$$

Then τ is a pullback square. That is, the functor F appearing in the proof of Proposition 7.4.1.1 restricts to an equivalence of ∞-categories

$$F^c : \mathrm{LMod}_A(\mathcal{C})^c \to \mathrm{LMod}_B(\mathcal{C})^c \times_{\mathrm{LMod}_{L_I(B)}(\mathcal{C})^c} \mathrm{LMod}_{L_I(A)}(\mathcal{C})^c.$$

It follows immediately from Proposition 7.4.1.1 that F^c is fully faithful. The essential surjectivity follows from the observation that every object of the fiber product

$$\mathrm{LMod}_B(\mathcal{C})^c \times_{\mathrm{LMod}_{L_I(B)}(\mathcal{C})^c} \mathrm{LMod}_{L_I(A)}(\mathcal{C})^c$$

is compact when viewed as an object of $\mathrm{LMod}_B(\mathcal{C}) \times_{\mathrm{LMod}_{L_I(B)}(\mathcal{C})} \mathrm{LMod}_{L_I(A)}(\mathcal{C})$.

7.4.2 The Case of Vector Bundles

To recover the classical Beauville-Laszlo theorem, we would like to know that the pullback diagram

$$\begin{array}{ccc} \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A) & \longrightarrow & \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, B) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{U}) & \longrightarrow & \mathrm{QCoh}(\mathsf{V}) \end{array}$$

remains a pullback square if we restrict our attention to the full subcategories spanned by the locally free sheaves. This is a consequence of the following:

Proposition 7.4.2.1. *Let P be one of the following properties of quasi-coherent sheaves:*

(a) *The property of being perfect.*

(b) *The property of being perfect with* Tor*-amplitude $\leqslant n$.*

(c) *The property of being perfect and n-connective.*

(d) *The property of being locally free of finite rank.*

For every spectral Deligne-Mumford stack X, let $\mathrm{QCoh}(\mathsf{X})^P$ denote the full subcategory of $\mathrm{QCoh}(\mathsf{X})$ spanned by those quasi-coherent sheaves having the property P. Let $\phi : A \to B$ be a map of connective $\mathbb{E}_\infty$-rings, let $I \subseteq \pi_0 A$ be a finitely generated ideal, and define

$$\begin{array}{ccc} \mathsf{V} & \longrightarrow & \mathsf{U} \\ \downarrow & & \downarrow u \\ \mathrm{Sp\acute{e}t}\, B & \xrightarrow{v} & \mathrm{Sp\acute{e}t}\, A. \end{array}$$

as in Theorem 7.4.0.1. If ϕ induces an equivalence $A^{\wedge}_I \to B^{\wedge}_I$, then the diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A)^P & \longrightarrow & \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, B)^P \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{U})^P & \longrightarrow & \mathrm{QCoh}(\mathsf{V})^P \end{array}$$

is a pullback square.

Remark 7.4.2.2. In the situation of Proposition 7.4.2.1, suppose that A is Noetherian and that $B = A^{\wedge}_I$. Then the map $\phi : A \to B$ is flat (Corollary 7.3.6.9), so that the induced map

$$\mathrm{Sp\acute{e}t}\, B \amalg \mathsf{U} \to \mathrm{Sp\acute{e}t}\, A$$

is a flat covering (see Definition 2.8.3.1). It follows that the conclusion of Proposition 7.4.2.1 is valid for any property P which is local with respect to the flat topology.

Proof of Proposition 7.4.2.1. By virtue of Theorem 7.4.0.1, it will suffice to show that if $\mathscr{F} \in \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A)$ is a quasi-coherent sheaf such that $u^* \mathscr{F}$ and $v^* \mathscr{F}$ have the property P, then $\mathscr{F}$ has the property P. We have four cases to consider.

(a) Suppose that $u^* \mathscr{F}$ and $v^* \mathscr{F}$ are perfect. Then $u^* \mathscr{F}$ and $v^* \mathscr{F}$ are compact objects of $\mathrm{QCoh}(\mathsf{U})$ and $\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, B)$ (Theorem **??**), so that $\mathscr{F}$ is a compact object of $\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A)$ (Remark 7.4.1.3) and is therefore perfect.

(*b*) Suppose that $u^* \mathscr{F}$ and $v^* \mathscr{F}$ are perfect with Tor-amplitude $\leqslant n$, for some integer n. It follows from (*a*) that $\mathscr{F}$ is perfect. We wish to show that $\mathscr{F}$ has Tor-amplitude $\leqslant n$, for some integer n. Replacing $\mathscr{F}$ by a shift if necessary, we may suppose that $\mathscr{F}$ is connective. Using Corollary 6.1.4.7, we are reduced to proving that $\eta^* \mathscr{F}$ is n-truncated, for any map $\eta : \mathrm{Sp\acute{e}t}\, \kappa \to \mathrm{Sp\acute{e}t}\, A$ where κ is a field. Then η determines a map of commutative rings $\pi_0 A \to \kappa$, whose kernel is a prime ideal $\mathfrak{p} \subseteq \pi_0 A$. If $I \subseteq \mathfrak{p}$, then η factors through v, and the desired result follows from our assumption that $v^* \mathscr{F}$ has Tor-amplitude $\leqslant n$. If $I \nsubseteq \mathfrak{p}$, then η factors through u, and the desired result follows from our assumption that $u^* \mathscr{F}$ has Tor-amplitude $\leqslant n$.

(*c*) Suppose that $u^* \mathscr{F}$ and $v^* \mathscr{F}$ are perfect and n-connective. It follows from (*a*) that $\mathscr{F}$ is perfect, and therefore a dualizable object of $\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A)$. Let $\mathscr{F}^\vee$ denote its dual. Then $u^* \mathscr{F}^\vee$ and $v^* \mathscr{F}^\vee$ have Tor-amplitude $\leqslant -n$, so that (*b*) implies that $\mathscr{F}^\vee$ has Tor-amplitude $\leqslant -n$, and therefore $\mathscr{F}$ is n-connective.

(*d*) Suppose that $u^* \mathscr{F}$ and $v^* \mathscr{F}$ are locally free of finite rank. It follows from (*b*) and (*c*) that $\mathscr{F}$ is flat and perfect, hence locally free of finite rank.

□

We conclude by recording a concrete consequence of Remark 7.4.2.2, which we will need in §**??**:

Corollary 7.4.2.3. *Let A be a Noetherian commutative ring containing an element a and let $\widehat{A}$ denote the completion of A with respect to the principal ideal (a). Suppose we are given a discrete $A[a^{-1}]$-module N and a discrete $\widehat{A}$-module $\widehat{M}$, together with a map $\alpha : N \simeq \widehat{M}[a^{-1}]$ which induces an isomorphism $\overline{\alpha} : \widehat{A}[a^{-1}] \otimes_{A[a^{-1}]} N \to \widehat{M}[a^{-1}]$. Then the canonical map $\mu : N \oplus \widehat{M} \to \widehat{M}[a^{-1}]$ is surjective. Moreover, if N and $\widehat{M}$ are finitely generated over $A[a^{-1}]$ and $\widehat{A}$, respectively, then* $\ker(\mu)$ *is a finitely generated A-module.*

Proof. Using Theorem 7.4.0.1, we deduce that there exists an A-module M equipped with equivalences $\widehat{M} \simeq \widehat{A} \otimes_A M$ and $N \simeq M[a^{-1}]$, compatible with the map α. Tensoring M with the fiber sequence $A \to \widehat{A} \oplus A[a^{-1}] \to \widehat{A}[a^{-1}]$, we obtain a fiber sequence $M \to \widehat{M} \oplus N \xrightarrow{\mu} \widehat{M}[a^{-1}]$. Since the property of being discrete is local with respect to the flat topology (Proposition 2.8.4.2), we deduce that M is discrete (Remark 7.4.2.2), so that μ is surjective and $M \simeq \ker(\mu)$. Now suppose that N and $\widehat{M}$ are finitely generated over $A[a^{-1}]$ and $\widehat{A}$, respectively. Since the property of being perfect to order 0 is local with respect to the flat topology (Proposition 2.8.4.2), we deduce that M is perfect to order 0 (Remark 7.4.2.2) and therefore finitely generated as a module over A. □

Chapter 8

Formal Spectral Algebraic Geometry

In Chapter 7, we studied the operation of completing a module M over an $\mathbb{E}_\infty$-ring R with respect to a finitely generated ideal $I \subseteq \pi_0 R$. In this chapter, we will study a geometric counterpart of this operation. Given a spectral Deligne-Mumford stack X and a (cocompact) closed subset $K \subseteq |\mathsf{X}|$, we will associate a new object $\mathsf{X}^\wedge_K$ which we call the *formal completion of* X *along* K (Definition 8.1.6.1). The formal completion $\mathsf{X}^\wedge_K$ can be considered from (at least) two different perspectives:

(*a*) If X is given as a spectrally ringed ∞-topos $(\mathcal{X}, \mathscr{O}_\mathsf{X})$, then we can identify $\mathsf{X}^\wedge_K$ with a spectrally ringed ringed ∞-topos $(\mathcal{X}_K, \mathscr{O}^\wedge_\mathsf{X})$, where $\mathcal{X}_K$ denotes the closed subtopos of $\mathcal{X}$ determined by K and $\mathscr{O}^\wedge_\mathsf{X}$ is obtained from $\mathscr{O}_\mathsf{X}$ by a suitable completion construction.

(*b*) If we identify X with its functor of points $h_\mathsf{X} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, then we can identify the formal completion $\mathsf{X}^\wedge_K$ with a subfunctor of h_X: namely, the functor which assigns to each connective $\mathbb{E}_\infty$-ring R the summand $\mathsf{X}^\wedge_K(R) \subseteq \mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{X})$ consisting of those maps $\phi : \mathrm{Sp\acute{e}t}\, R \to \mathsf{X}$ for which the underlying map of topological spaces $|\operatorname{Spec} R| \to |\mathsf{X}|$ factors through K.

The formal completion $\mathsf{X}^\wedge_K$ is generally not a spectral Deligne-Mumford stack. However, it is a prototypical example of a more general type of geometric object called a *formal spectral Deligne-Mumford stack*, which we introduce in §8.1 (Definition 8.1.3.1). Following the same outline as in Chapter 1, we begin from the "geometric" perspective (defining a formal spectral Deligne-Mumford to be a spectrally ringed ∞-topos $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_\mathfrak{X})$ satisfying certain local requiremets) and then establish the equivalence with the "functorial" perspective (by showing that a formal spectral Deligne-Mumford stack $\mathfrak{X}$ is determined by its functor of points $h_\mathfrak{X} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$: see Theorem 8.1.5.1).

In Chapter 6, we defined the ∞-category $\mathrm{QCoh}(X)$ of quasi-coherent sheaves on an arbitrary functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ (see Definition 6.2.2.1). In the special case where X is representable by a spectral Deligne-Mumford stack X, we established an equivalence of $\mathrm{QCoh}(X)$ with the ∞-category $\mathrm{QCoh}(\mathsf{X}) \subseteq \mathrm{Mod}_{\mathscr{O}_{\mathsf{X}}}$ of quasi-coherent $\mathscr{O}_{\mathsf{X}}$-modules (Proposition 6.2.4.1). Our main goal in this first half of this chapter is to prove a variant of this result for *formal* spectral Deligne-Mumford stacks. In §8.2, we associate to each formal spectral Deligne-Mumford stack $\mathfrak{X}$ a full subcategory $\mathrm{QCoh}(\mathfrak{X}) \subseteq \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ of *quasi-coherent* sheaves of $\mathscr{O}_{\mathfrak{X}}$-modules (Definition 8.2.4.7); this can be regarded as a globalization of the theory of complete modules developed in Chapter 7. In §8.3, we show that if $X = h_{\mathfrak{X}}$ is the functor represented by a formal spectral Deligne-Mumford stack $\mathfrak{X}$, then there is a canonical restriction map $\mathrm{QCoh}(\mathfrak{X}) \to \mathrm{QCoh}(X)$ which is an equivalence when restricted to connective quasi-coherent sheaves (Theorem 8.3.4.4).

The formal completion construction $\mathsf{X} \mapsto \mathsf{X}^{\wedge}_{K}$ is easiest to analyze in the case where $\mathsf{X} = \mathrm{Sp\acute{e}t}\, A$ is affine. The hypothesis that $K \subseteq |\mathsf{X}|$ is cocompact guarantees that it can be described as the vanishing locus of a finitely generated ideal $I \subseteq \pi_0 A$. In this case, we will denote the formal completion $\mathsf{X}^{\wedge}_{K}$ by $\mathrm{Spf}\, A$ and refer to it as the *formal spectrum of* A. In this case, the ∞-category $\mathrm{QCoh}(\mathrm{Spf}\, A)$ can be identified with the ∞-category $\mathrm{Mod}_A^{\mathrm{Cpl}(I)}$ of I-complete A-modules (Corollary 8.2.4.15). If A itself is I-complete, then this restricts to an equivalence $\mathrm{QCoh}(\mathrm{Spf}\, A)^{\mathrm{aperf}} \simeq \mathrm{Mod}_A^{\mathrm{aperf}}$ of almost perfect quasi-coherent sheaves on $\mathrm{Spf}\, A$ with almost perfect modules over A. In §8.5, we apply the results of Chapter 5 to prove a much stronger result: if A is I-complete and $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, A$ is a morphism which is proper and almost of finite presentation, then the restriction functor $\mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathrm{Spf}\, A \times_{\mathrm{Sp\acute{e}t}\, A} \mathsf{X})$ induces an equivalence on almost perfect objects (Theorem 8.5.0.3). This can be regarded as a derived version of the classical Grothendieck existence theorem, and has many useful consequences: for example, it implies that the formal completion construction $\mathsf{X} \mapsto \mathrm{Spf}\, A \times_{\mathrm{Sp\acute{e}t}\, A} \mathsf{X}$ is fully faithful when restricted to spectral algebraic spaces which are proper and locally almost of finite presentation over A (Corollary 8.5.3.4).

One pleasant feature of the present framework is that the Grothendieck existence theorem and its corollaries (such as the theorem on formal functions and the formal GAGA principle) do not require any Noetherian hypotheses on A. However, the price we pay for working with non-Noetherian rings is that we get statements only at the "derived" level (that is, at the level of ∞-categories), rather than at the level of abelian categories. For a general spectral Deligne-Mumford stack X, the ∞-category $\mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}}$ does not have a (useful) t-structure. However, the situation is better if X is locally Noetherian: in this case, the full subcategory $\mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}} \subseteq \mathrm{QCoh}(\mathsf{X})$ is closed under truncations, and therefore inherits a t-structure from $\mathrm{QCoh}(\mathsf{X})$. In §8.4, we show that an analogous situation holds in the setting of formal spectral algebraic geometry. More precisely, we introduce a notion of locally Noetherian formal spectral Deligne-Mumford stack (Definition 8.4.2.1) and show that, if $\mathfrak{X}$ is locally Noetherian, then the ∞-category $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$ of almost perfect quasi-coherent sheaves on $\mathfrak{X}$ is closed under truncations (in the larger ∞-category $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$) and therefore inherits a t-structure (Corollary 8.4.2.4). Moreover, the heart of $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$ can be identified with the abelian category of coherent sheaves on the underlying classical formal stack (for a precise statement, see 8.4.3.5 and Example 8.4.3.6). Specializing to the case where A is a Noetherian $\mathbb{E}_\infty$-ring which is I-complete for some $I \subseteq \pi_0 A$ and $\mathfrak{X} = \mathrm{Spf}\, A \times_{\mathrm{Sp\acute{e}t}\, A} \mathsf{X}$ for some X which is proper and almost of finite presentation over A, the equivalence $\mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}} \simeq \mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$ of Theorem 8.5.0.3 is t-exact (Proposition 8.4.2.10) and therefore induces equivalence of abelian categories, from which one can extract the classical Grothendieck existence theorem (Theorem 8.5.0.1).

Remark 8.0.0.1. In non-Noetherian situations, the failure of the Grothendieck existence theorem at the level of abelian categories is only to be expected, since the operation of I-completion $M \mapsto M^\wedge_I$ does not have good exactness properties.

In classical algebraic geometry, one very useful consequence of the Grothendieck existence theorem (or, more precisely, of Grothendieck's theorem on formal functions) is Zariski's connectedness theorem: if $f : X \to Z$ is a proper morphism of Noetherian schemes, then f admits a *Stein factorization* $X \xrightarrow{g} Y \xrightarrow{h} Z$ where h is a finite morphism and g has connected (geometric) fibers. In §8.7, we discuss Stein factorizations and show that an analogous assertion holds in spectral algebraic geometry (Theorem **??**). We also discuss a related construction which we call the *reduced Stein factorization* (Definition 8.7.3.2). The theory of reduced Stein factorizations will require some basic facts about geometrically reduced morphisms of spectral Deligne-Mumford stacks, which we discuss in §8.6.

Contents

8.1 Formal Spectral Deligne-Mumford Stacks

Let us begin with a brief review of the theory of the classical theory of (locally Noetherian) formal schemes.

Construction 8.1.0.1 (The Formal Spectrum)**.** Let A be a Noetherian commutative ring and let $I \subseteq A$ be an ideal. The *formal spectrum of* A (with respect to I) is the ringed space $(|\operatorname{Spf} A|, \mathscr{O}_{|\operatorname{Spf} A|})$ given as follows:

- The underlying topological space $|\operatorname{Spf} A|$ is the closed subset of the Zariski spectrum $|\operatorname{Spec} A|$ given by the vanishing locus of the ideal I: that is, the collection of those prime ideals $\mathfrak{p} \subseteq A$ which contain I. We endow $|\operatorname{Spf} A|$ with the subspace topology, so that it has a basis of open sets of the form $U_x = \{\mathfrak{p} \subseteq A : I \subseteq \mathfrak{p}, x \notin \mathfrak{p}\}$ for $x \in X$.

- The structure sheaf $\mathscr{O}_{|\operatorname{Spf} A|}$ is given on basic open sets by the formula $\mathscr{O}_{|\operatorname{Spf} A|}(U_x) = \varprojlim (A/I^n)[x^{-1}]$. In other words, $\mathscr{O}_{|\operatorname{Spf} A|}$ is the inverse limit of the structure sheaves of the affine schemes $\operatorname{Spec} A/I^n$, each of which has underlying topological space $|\operatorname{Spf} A|$.

Remark 8.1.0.2. In the setting of Construction 8.1.0.1, it is not necessary to assume that A is I-adically complete. However, it is harmless to add this assumption: replacing A by its I-adic completion $\varprojlim A/I^n$ does not change the ringed space $(|\operatorname{Spf} A|, \mathscr{O}_{|\operatorname{Spf} A|})$.

Definition 8.1.0.3. Let $(X, \mathscr{O}_X)$ be a ringed space. We say that $(X, \mathscr{O}_X)$ is a *locally Noetherian formal scheme* if there exists a covering of X by open subsets U_α such that each of the ringed spaces $(U_\alpha, \mathscr{O}_X|_{U_\alpha})$ has the form $(|\operatorname{Spf} A_\alpha|, \mathscr{O}_{|\operatorname{Spf} A_\alpha|})$, for some Noetherian ring A_α (and some ideal $I_\alpha \subseteq A_\alpha$).

Our goal in this section is to introduce a variant of Definition 8.1.0.3 to the setting of spectral algebraic geometry. We begin in §8.1.1 by introducing the *formal spectrum* $\operatorname{Spf} A$ of an $\mathbb{E}_\infty$-ring A with respect to an ideal $I \subseteq \pi_0 A$ (Construction 8.1.1.10). Our definition is loosely modeled on Construction 8.1.0.1, with a few important differences:

(a) In Construction 8.1.1.10, we allow A to be a connective $\mathbb{E}_\infty$-ring (rather than an ordinary commutative ring).

(b) In Construction 8.1.1.10, we do not require A to be Noetherian (however, we do require the ideal $I \subseteq \pi_0 A$ to be finitely generated).

(c) In place of the topological space $|\operatorname{Spf} A|$ (which is a closed subset of the Zariski spectrum $|\operatorname{Spec} A|$), we consider an ∞-topos $\mathcal{S}\mathrm{hv}^{\mathrm{ad}}_A$ (which is a closed subtopos of the ∞-topos $\mathcal{S}\mathrm{hv}^{\text{ét}}_A$). In other words, we work locally with respect to the étale topology, rather than the Zariski topology.

Warning 8.1.0.4. In Construction 8.1.0.1, the hypothesis that A is Noetherian is not necessary. However, when applied to non-Noetherian rings, Construction 8.1.0.1 yields a notion of formal spectrum which is not compatible with Construction 8.1.1.10. Roughly speaking, this is because Construction 8.1.0.1 involves the I-adic completion functor $A \mapsto \varprojlim A/I^n$, while Construction 8.1.1.10 involves the I-completion functor $A \mapsto A^\wedge_I$ of Notation 7.3.1.5. We refer the reader to §7.3 for a comparison of these two notions of completion (and some indication of why the latter might be preferable in non-Noetherian contexts).

In §8.1.3, we define a notion of *formal spectral Deligne-Mumford stack* (Definition 8.1.3.1). Here we take our cue from Definition 8.1.0.3: a formal spectral Deligne-Mumford stack is a spectrally ringed ∞-topos $\mathfrak{X}$ which is locally of the form $\operatorname{Spf} A$, for some connective $\mathbb{E}_\infty$-ring A (and some finitely generated ideal $I \subseteq \pi_0 A$).

The collection of formal spectral Deligne-Mumford stacks can be organized into an ∞-category fSpDM, which contains the ∞-category SpDM of spectral Deligne-Mumford stacks as a full subcategory. An underlying theme of this section is that an object $\mathfrak{X} \in \mathrm{fSpDM}$ can be "built from" the ordinary spectral Deligne-Mumford stacks which map to $\mathfrak{X}$. In §8.1.3, we will give a precise articulation of this idea in the case where $\mathfrak{X} = \operatorname{Spf} A$ is a formal spectrum: in this case, we can identify $\mathfrak{X}$ with the direct limit $\varinjlim \operatorname{Spét} B$, where B ranges over all connective A-algebras for which the ideal $I(\pi_0 B)$ is nilpotent; here the direct limit is formed in the ∞-category of locally spectrally ringed ∞-topoi (Proposition 8.1.2.1). In §8.1.5, we use this result to show that a formal spectral Deligne-Mumford stack $\mathfrak{X}$ is determined by its "functor of points" $R \mapsto \mathrm{Map}_{\mathrm{fSpDM}}(\operatorname{Spét} R, \mathfrak{X})$ (Theorem 8.1.5.1).

For our purposes, the theory of formal spectral Deligne-Mumford stacks is primarily of interest as a tool for proving results about ordinary spectral Deligne-Mumford stacks. In §8.1.6, we will define the *formal completion* $\mathsf{X}^\wedge_K$ of a spectral Deligne-Mumford stack X along a (cocompact) closed subset $K \subseteq |\mathsf{X}|$ (Definition 8.1.6.1). Roughly speaking, $\mathsf{X}^\wedge_K$ is a formal spectral Deligne-Mumford stack which encodes the behavior of X "infinitesimally close" to K. This language will play an essential role when we discuss the Grothendieck existence theorem in §8.5.

8.1.1 Adic $\mathbb{E}_\infty$-Rings and Formal Spectra

We start by reviewing some terminology from commutative algebra.

Definition 8.1.1.1. Let A be a commutative ring. Every ideal $I \subseteq A$ determines a topology on A, which has a basis of open sets of the form $x + I^n \subseteq A$ where $x \in A$ and $n \geqslant 0$. We will refer to this topology as the *I-adic topology*.

If A is a topological commutative ring, we say that an ideal $I \subseteq A$ is an *ideal of definition* if the topology on A coincides with the I-adic topology.

An *adic ring* is a commutative ring A equipped with a topology which admits a finitely generated ideal of definition. We let $\mathrm{CAlg}^\heartsuit_{\mathrm{ad}}$ denote the category whose objects are adic rings and whose morphisms are continuous ring homomorphisms.

Warning 8.1.1.2. Definition 8.1.1.1 is not standard: many authors allow topological commutative rings which admit an ideal of definition $I \subseteq A$, without imposing the requirement that I is finitely generated. Additionally, it is common to also require that A is I-adically complete (that is, that the canonical map $A \to \varprojlim A/I^n$ is an isomorphism), which we do not assume.

Remark 8.1.1.3. Let A and A' be adic rings having finitely generated ideals of definition $I \subseteq A$ and $I' \subseteq A'$. Then a ring homomorphism $\phi : A \to A'$ is continuous if and only if $\phi(I^n) \subseteq I'$ for some $n \gg 0$. Equivalently, ϕ is continuous if and only if the induced map $|\operatorname{Spec} A'| \to |\operatorname{Spec} A|$ carries the vanishing locus of I' to the vanishing locus of I.

Remark 8.1.1.4. Let A be a commutative ring. For any finitely generated ideal $I \subseteq A$, we can regard A as an adic ring by equipping it with the I-adic topology. Note that if $I, J \subseteq A$ are finitely generated ideals, then the I-adic topology and J-adic topology coincide if and only if $I^n \subseteq J$ and $J^n \subseteq I$ for $n \gg 0$. Equivalently, the I-adic topology and J-adic topology coincide if and only if I and J have the same vanishing locus in the Zariski spectrum $|\operatorname{Spec} A|$.

Definition 8.1.1.5. An *adic* $\mathbb{E}_\infty$*-ring* is a connective $\mathbb{E}_\infty$-ring together with a topology on the commutative ring $\pi_0 A$, which makes $\pi_0 A$ into an adic ring (in the sense of Definition 8.1.1.1). We let $\mathrm{CAlg}^{\mathrm{cn}}_{\mathrm{ad}}$ denote the fiber product $\mathrm{CAlg}^{\heartsuit}_{\mathrm{ad}} \times_{\mathrm{CAlg}^{\heartsuit}} \mathrm{CAlg}^{\mathrm{cn}}$. We will refer to $\mathrm{CAlg}^{\mathrm{cn}}_{\mathrm{ad}}$ as the ∞*-category of adic* $\mathbb{E}_\infty$*-rings*.

Remark 8.1.1.6. Put more informally: the objects of $\mathrm{CAlg}^{\mathrm{cn}}_{\mathrm{ad}}$ are adic $\mathbb{E}_\infty$-rings, and the morphisms in $\mathrm{CAlg}^{\mathrm{cn}}_{\mathrm{ad}}$ are morphisms $\phi : A \to A'$ of $\mathbb{E}_\infty$-rings for which the underlying ring homomorphism $\pi_0 A \to \pi_0 A'$ is continuous.

Remark 8.1.1.7. Let A be a connective $\mathbb{E}_\infty$-ring. Using Remark 8.1.1.4, we see that there is a canonical bijection between the following data:

- Topologies on $\pi_0 A$ which admit a finitely generated ideal of definition.
- Closed subsets $X \subseteq |\operatorname{Spec} A|$ with quasi-compact complement.

By means of this bijection, we can identify adic $\mathbb{E}_\infty$-rings with pairs (A, X), where A is a connective $\mathbb{E}_\infty$-ring and $X \subseteq |\operatorname{Spec} A|$ is a closed set with quasi-compact complement. Under this identification, a morphism of adic $\mathbb{E}_\infty$-rings from (A, X) to (A', X') is a morphism of $\mathbb{E}_\infty$-rings $\phi : A \to A'$ for which the induced map $|\operatorname{Spec} A'| \to |\operatorname{Spec} A|$ carries X' into X.

Notation 8.1.1.8. Let A be an adic $\mathbb{E}_\infty$-ring and let $\mathcal{S}\mathrm{hv}^{\mathrm{\acute{e}t}}_A$ denote the ∞-category of functors $\mathscr{F} : \mathrm{CAlg}^{\mathrm{\acute{e}t}}_A \to \mathcal{S}$ which are sheaves with respect to the étale topology. Let $X \subseteq |\operatorname{Spec} A|$ be the vanishing locus of an ideal of definition of $\pi_0 A$. We let $\mathcal{S}\mathrm{hv}^{\mathrm{ad}}_A$ denote the closed subtopos of $\mathcal{S}\mathrm{hv}^{\mathrm{\acute{e}t}}_A$ corresponding to the closed subset $X \subseteq |\operatorname{Spec} A|$. More precisely, we let $\mathcal{S}\mathrm{hv}^{\mathrm{ad}}_A$ denote the full subcategory of $\mathcal{S}\mathrm{hv}^{\mathrm{\acute{e}t}}_A$ spanned by those sheaves $\mathscr{F}$ having the property that $\mathscr{F}(B)$ is contractible whenever $X \times_{|\operatorname{Spec} A|} |\operatorname{Spec} B|$ is empty.

Remark 8.1.1.9. Let A be an adic $\mathbb{E}_\infty$-ring and let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition. Using Proposition 3.1.4.1, we obtain a canonical equivalence of ∞-categories $\mathcal{S}\mathrm{hv}^{\mathrm{ad}}_A \simeq \mathcal{S}\mathrm{hv}^{\mathrm{\acute{e}t}}_{(\pi_0 A)/I}$.

Construction 8.1.1.10. Let A be an adic $\mathbb{E}_\infty$-ring and let $\mathscr{O}_{\mathrm{Sp\acute{e}t}\, A}$ be the structure sheaf of the étale spectrum Spét A, which we identify with the inclusion functor $\mathrm{CAlg}_A^{\acute{e}t} \hookrightarrow \mathrm{CAlg}_A$. Let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition. We let $\mathscr{O}_{\mathrm{Spf}\, A} : \mathrm{CAlg}_A^{\acute{e}t} \to \mathrm{CAlg}_A$ denote the composition of $\mathscr{O}_{\mathrm{Sp\acute{e}t}\, A}$ with the I-completion functor, given by $B \mapsto B_I^\wedge$. Note that $\mathscr{O}_{\mathrm{Spf}\, A}$ is still a sheaf with respect to the étale topology (since the formation of I-completions preserves small limits). Moreover, $\mathscr{O}_{\mathrm{Spf}\, A}(B) = B_I^\wedge$ vanishes whenever I generates the unit ideal of $\pi_0 B$. It follows that we can regard $\mathscr{O}_{\mathrm{Spf}\, A}$ as a CAlg_A-valued sheaf on the closed subtopos $\mathcal{S}\mathrm{hv}_A^{\mathrm{ad}} \subseteq \mathcal{S}\mathrm{hv}_A^{\acute{e}t}$. We let Spf A denote the spectrally ringed ∞-topos $(\mathcal{S}\mathrm{hv}_A^{\mathrm{ad}}, \mathscr{O}_{\mathrm{Spf}\, A})$. We will refer to Spf A as the *formal spectrum of A*.

Example 8.1.1.11. In the situation of Construction 8.1.1.10, suppose that I is nilpotent: that is, the commutative ring $\pi_0 A$ is equipped with the discrete topology. Then the formal spectrum Spf A is equivalent to the étale spectrum Spét A.

Remark 8.1.1.12. Let A be an adic $\mathbb{E}_\infty$-ring. Then the inclusion functor $\mathcal{S}\mathrm{hv}_A^{\mathrm{ad}} \hookrightarrow \mathcal{S}\mathrm{hv}_A^{\acute{e}t}$ admits a (left exact) left adjoint $i^* : \mathcal{S}\mathrm{hv}_A^{\acute{e}t} \to \mathcal{S}\mathrm{hv}_A^{\mathrm{ad}}$. We will say that an object $U \in \mathcal{S}\mathrm{hv}_A^{\mathrm{ad}}$ is *affine* if it has the form $i^*\overline{U}$, where $\overline{U} \in \mathcal{S}\mathrm{hv}_A^{\acute{e}t}$ is affine (in other words, $\overline{U}$ is corepresentable by some object $B \in \mathrm{CAlg}_A^{\acute{e}t}$).

Note that $U \in \mathcal{S}\mathrm{hv}_A^{\mathrm{ad}}$ is affine if and only if its image under the equivalence $\mathcal{S}\mathrm{hv}_A^{\mathrm{ad}} \simeq \mathcal{S}\mathrm{hv}_{(\pi_0 A)/I}^{\acute{e}t}$ of Remark 8.1.1.9 is affine.

Proposition 8.1.1.13. *Let A be an adic $\mathbb{E}_\infty$-ring and let* Spf $A = (\mathcal{S}\mathrm{hv}_A^{\mathrm{ad}}, \mathscr{O}_{\mathrm{Spf}\, A})$ *be its formal spectrum (Construction 8.1.1.10). Then the structure sheaf $\mathscr{O}_{\mathrm{Spf}\, A}$ is connective and strictly Henselian.*

The proof of Proposition 8.1.1.13 will require an elementary observation about the formation of completions:

Lemma 8.1.1.14. *Let $R \to R'$ be an étale morphism of connective $\mathbb{E}_\infty$-rings and let S be a connective $\mathbb{E}_\infty$-algebra over R which is I-complete for some finitely generated ideal $I \subseteq \pi_0 S$. Then the canonical map $\rho : \mathrm{Map}_{\mathrm{CAlg}_R}(R', S) \to \mathrm{Map}_{\mathrm{CAlg}_R}(R', (\pi_0 S)/I)$ is a homotopy equivalence.*

Proof. Without loss of generality we may assume that S is discrete. Proceeding by induction on the number of generators of I, we can assume that $I = (x)$ is a principal ideal. For each $n \geqslant 1$, let S_n denote the tensor product $S \otimes_{\mathbf{Z}[x]} \mathbf{Z}[x]/(x^n)$. Then we have a canonical isomorphism $S/I \simeq \pi_0 S_1$, and the map ρ factors as a composition

$$\mathrm{Map}_{\mathrm{CAlg}_R}(R', S) \xrightarrow{\rho'} \varprojlim_{n \geqslant 1} \mathrm{Map}_{\mathrm{CAlg}_R}(R', S_n) \xrightarrow{\rho''} \mathrm{Map}_{\mathrm{CAlg}_R}(R', S_1) \xrightarrow{\rho'''} \mathrm{Map}_{\mathrm{CAlg}_R}(R', S/I).$$

The map ρ' is a homotopy equivalence by virtue of our assumption that S is I-complete, the map ρ'' is a homotopy equivalence since each S_{n+1} is a square-zero extension of S_n, and the map ρ''' is an equivalence since S_1 is a square-zero extension of S/I. $\square$

Proof of Proposition 8.1.1.13. Let A be an adic $\mathbb{E}_\infty$-ring. Note that if $U \in \mathcal{S}\mathrm{hv}_A^{\mathrm{ad}}$ is affine (in the sense of Remark 8.1.1.12), then $\mathscr{O}_{\mathrm{Spf}\, A}(U) \simeq B^\wedge_I$ for some étale A-algebra B and is therefore connective. Since $\mathcal{S}\mathrm{hv}_A^{\mathrm{ad}}$ is generated under small colimits by affine objects, it follows that $\mathscr{O}_{\mathrm{Spf}\, A}$ is connective. We now argue that $\mathscr{O}_{\mathrm{Spf}\, A}$ is strictly Henselian. Let R be a commutative ring, let $\{R \to R_\alpha\}$ be a finite collection of étale maps for which the map $R \to \prod R_\alpha$ is faithfully flat, and suppose we are given a map $\rho : R \to (\pi_0\, \mathscr{O}_{\mathrm{Spf}\, A})(U)$ for some object $U \in \mathcal{S}\mathrm{hv}_A^{\mathrm{ad}}$. We wish to show that there exists a covering $\{U_\alpha \to U\}$ of U such that each of the composite maps $R \to (\pi_0\, \mathscr{O}_{\mathrm{Spf}\, A})(U) \to (\pi_0\, \mathscr{O}_{\mathrm{Spf}\, A}(U_\alpha)$ factors through R_α. Without loss of generality, we may assume that R is a finitely generated commutative ring. The desired conclusion is local on U, so we may further and that ρ is given by a map $\overline{\rho} : R \to \pi_0(\mathscr{O}_{\mathrm{Spf}\, A}(U))$. Let $i^* : \mathcal{S}\mathrm{hv}_A^{\text{ét}} \to \mathcal{S}\mathrm{hv}_A^{\mathrm{ad}}$ be a left adjoint to the inclusion. Localizing further, we may assume that U is affine: that is, we have $U \simeq i^* h^B$, where h^B denotes the functor corepresented by some étale A-algebra B. In this case, we can regard $\overline{\rho}$ as a ring homomorphism $R \to \pi_0(B^\wedge_I)$. For each index α, set $C_\alpha = R_\alpha \otimes_R (\pi_0 B)/I(\pi_0 B)$. Using the classification of étale morphisms (Proposition B.1.1.3), we can write each C_α as a tensor product $B_\alpha \otimes_B (\pi_0 B)/I(\pi_0 B)$, where B_α is étale over B. Setting $U_\alpha = i^* B_\alpha$, we obtain a covering $\{U_\alpha \to U\}$ in the ∞-topos $\mathcal{S}\mathrm{hv}_A^{\mathrm{ad}}$. We will complete the proof by showing that each of the composite maps $R \xrightarrow{\overline{\rho}} \pi_0(\mathscr{O}_{\mathrm{Spf}\, A}(U)) \to \pi_0(\mathscr{O}_{\mathrm{Spf}\, A}(U_\alpha)) \simeq \pi_0(B_\alpha)^\wedge_I$ factors through R_α. Set $S = \pi_0(B_\alpha)^\wedge_I$. Then S is I-complete (Theorem 7.3.4.1), so Lemma 8.1.1.14 implies that the map $\mathrm{Hom}_R(R_\alpha, S) \to \mathrm{Hom}_R(R_\alpha, S/IS)$ is bijective. We conclude by observing that the codomain of this map is nonempty (since S/IS is isomorphic to C_α). □

8.1.2 Functoriality of the Formal Spectrum

Let A be an adic $\mathbb{E}_\infty$-ring and let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition I. Roughly speaking, we can think of the formal spectrum Spf A as the "formal completion" of Spét A along the vanishing locus $K \subseteq |\operatorname{Spec} A|$ of the ideal I. We now articulate this idea more precisely by showing that Spf A can be identified with the colimit $\varinjlim \text{Spét}\, B$, where B ranges over all connective A-algebras for which the underlying map $|\operatorname{Spec} B| \to |\operatorname{Spec} A|$ factors through K (we will revisit the same idea in §8.1.6).

Proposition 8.1.2.1. *Let $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ denote the ∞-category introduced in Definition 1.4.2.1, whose objects are spectrally ringed ∞-topoi $(\mathcal{X}, \mathscr{O})$, where $\mathscr{O}$ is strictly Henselian. The étale spectrum functor* Spét : $(\mathrm{CAlg}^{\mathrm{cn}})^{\mathrm{op}} \to \infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ *admits a left Kan extension along the inclusion* $(\mathrm{CAlg}^{\mathrm{cn}})^{\mathrm{op}} \hookrightarrow (\mathrm{CAlg}^{\mathrm{cn}}_{\mathrm{ad}})^{\mathrm{op}}$. *This left Kan extension is given on objects by the construction $A \mapsto$ Spf A.*

The proof of Proposition 8.1.2.1 will require some preliminaries.

Lemma 8.1.2.2. *Let A be an adic $\mathbb{E}_\infty$-ring having a finitely generated ideal of definition $I \subseteq \pi_0 A$. Then there exists a tower $\cdots \to A_4 \to A_3 \to A_2 \to A_1$ in the ∞-category CAlg_A with the following properties:*

(a) Each A_i is a connective $\mathbb{E}_\infty$-algebra over A, and each of the maps $A_{i+1} \to A_i$ induces a surjection $\pi_0 A_{i+1} \to \pi_0 A_i$ with nilpotent kernel.

(b) For every connective $\mathbb{E}_\infty$-ring B, the canonical map $\varinjlim_n \mathrm{Map}_{\mathrm{CAlg}}(A_n, B) \to \mathrm{Map}_{\mathrm{CAlg}}(A, B)$ induces a homotopy equivalence of $\varinjlim_n \mathrm{Map}_{\mathrm{CAlg}}(A_n, B)$ with the summand of $\mathrm{Map}_{\mathrm{CAlg}}(A, B)$ consisting of those maps $\phi : A \to B$ which annihilate some power of the ideal I.

(c) Each of the $\mathbb{E}_\infty$-rings A_n is almost perfect when regarded as an A-module.

Proof. Choose any element $x \in \pi_0 A$. We will construct a tower of $\mathbb{E}_\infty$-algebras over A

$$\cdots \to A(x)_3 \to A(x)_2 \to A(x)_1$$

having the following properties:

(a_x) Each $A(x)_i$ is a connective $\mathbb{E}_\infty$-ring, and each of the maps $A(x)_{i+1} \to A(x)_i$ determines a surjection $\pi_0 A(x)_{i+1} \to \pi_0 A(x)_i$ with nilpotent kernel.

(b_x) That is, for every connective $\mathbb{E}_\infty$-ring B, the canonical map $\varinjlim_n \mathrm{Map}_{\mathrm{CAlg}}(A(x)_n, B) \to \mathrm{Map}_{\mathrm{CAlg}}(A, B)$ induces a homotopy equivalence of $\varinjlim_n \mathrm{Map}_{\mathrm{CAlg}}(A(x)_n, B)$ with the summand of $\mathrm{Map}_{\mathrm{CAlg}}(A, B)$ consisting of those maps $\phi : A \to B$ which annihilate some power of x.

(c_x) Each of $\mathbb{E}_\infty$-rings $A(x)_n$ is almost perfect when regarded as an A-module.

Assuming that this can be done, choose a finite set of generators $x_1, \ldots, x_k$ for the ideal I. Setting $A_n = A(x_1)_n \otimes_A A(x_2)_n \otimes_A \cdots \otimes_A A(x_k)_n$, we obtain a tower of $\mathbb{E}_\infty$-algebras over A satisfying conditions (a), (b), and (c).

It remains to construct the tower $\{A(x)_n\}$. For each integer $n > 0$, let $A\{t_n\}$ denote a free $\mathbb{E}_\infty$-algebra over A on one generator t_n. We have A-algebra morphisms $\alpha_n : A\{t_n\} \to A$ and $\beta_n : A\{t_n\} \to A$, determined uniquely up to homotopy by the requirements that $t_n \mapsto x^n \in \pi_0 A$ and $t_n \mapsto 0 \in \pi_0 A$. Moreover, we have maps $\gamma_n : A\{t_n\} \to A\{t_{n-1}\}$ determined up to homotopy by the requirement that $t_n \mapsto x t_{n-1} \in \pi_0 A\{t_{n-1}\}$. For each $n \geqslant 0$, the diagram

$$\begin{array}{ccc} A & \xrightarrow{\mathrm{id}} & A \\ \uparrow{\scriptstyle \alpha_n} & & \uparrow{\scriptstyle \alpha_{n-1}} \\ A\{t_n\} & \xrightarrow{\gamma_n} & A\{t_{n-1}\} \\ \downarrow{\scriptstyle \beta_n} & & \downarrow{\scriptstyle \beta_{n-1}} \\ A & \xrightarrow{\mathrm{id}} & A \end{array}$$

commutes up to homotopy and can therefore be lifted to a commutative diagram in CAlg_A (since it is indexed by a partially ordered set whose nerve has dimension $\leqslant 2$).

$$\begin{array}{ccccccc}
\cdots & \longrightarrow & A & \xrightarrow{\mathrm{id}} & A & \xrightarrow{\mathrm{id}} & A \\
\uparrow & & \uparrow{\scriptstyle \alpha_3} & & \uparrow{\scriptstyle \alpha_2} & & \uparrow{\scriptstyle \alpha_1} \\
\cdots & \longrightarrow & A\{t_3\} & \xrightarrow{\gamma_3} & A\{t_2\} & \xrightarrow{\gamma_2} & A\{t_1\} \\
\downarrow & & \downarrow{\scriptstyle \beta_3} & & \downarrow{\scriptstyle \beta_2} & & {\scriptstyle \beta_1}\downarrow \\
\cdots & \longrightarrow & A & \xrightarrow{\mathrm{id}} & A & \xrightarrow{\mathrm{id}} & A.
\end{array}$$

For each $n > 0$, let $A(x)_n$ denote the colimit of the nth column of this diagram, so that we have a tower

$$\cdots \rightarrow A(x)_3 \rightarrow A(x)_2 \rightarrow A(x)_1$$

where $A(x)_n \simeq A \otimes_{A\{t_n\}} A$ is the A-algebra obtained by freely "coning off" the element $x^n \in \pi_0 A$. In particular, we have $\pi_0 A(x)_n \simeq (\pi_0 A)/(x^n)$, thereby verifying condition (a_x). To verify (c_x), it will suffice to show that A is almost perfect when regarded as an $A\{t_n\}$-module via β. For this, it suffices to show that the sphere spectrum is almost perfect when regarded as an $S\{t_n\}$-module via the map of $\mathbb{E}_\infty$-rings $S\{t_n\} \rightarrow S$ given by $t_n \mapsto 0 \in \pi_0 S$. Since $S\{t_n\}$ is Noetherian (Proposition HA.7.2.4.31), this is equivalent to the assertion that each homotopy group $\pi_k S$ is finitely generated as a module over the commutative ring $\pi_0(S\{t_n\}) \simeq \mathbf{Z}[t_n]$ (Proposition HA.7.2.4.17). This is clear, since the stable homotopy groups of spheres are finitely generated abelian groups.

To verify (b_x), we note that if $\phi : A \rightarrow B$ is a map of connective $\mathbb{E}_\infty$-rings, then the homotopy fiber of the map $\varinjlim_n \mathrm{Map}_{\mathrm{CAlg}}(A(x)_n, B) \rightarrow \mathrm{Map}_{\mathrm{CAlg}}(A, B)$ over the point ϕ is given by a sequential colimit $\varinjlim_n P_n$, where each P_n can be identified with a space of paths in $\Omega^\infty B$ joining the base point to a suitably chosen representative for the image of x^n in $\pi_0 B$. Let $y \in \pi_0 B$ be the image of x under ϕ. If y is not nilpotent, then each P_n is empty. Assume otherwise; we wish to show that $P_\infty = \varinjlim P_n$ is contractible. Note that if P_n contains some point p_n, the we have canonical isomorphisms $\pi_k(P_n, p_n) \simeq \pi_{k+1} B$. For $m \geqslant n$, let p_m denote the image of p_n in P_m, and let p_∞ denote the image of p_n in P_∞. Note that the induced map

$$\pi_{k+1} B \simeq \pi_k(P_n, p_n) \rightarrow \pi_k(P_m, p_m) \rightarrow \pi_{k+1} B$$

is given by multiplication by y^{m-n}. Since y is nilpotent, this map is trivial for $m \gg n$. It follows that $\pi_k(P_\infty, p_\infty) \simeq \varinjlim \pi_k(P_m, p_m)$ is trivial. Since p_n was chosen arbitrarily, we conclude that P_∞ is contractible as desired. □

Lemma 8.1.2.3. *Let A be an adic $\mathbb{E}_\infty$-ring, let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition, and let $\{A_n\}_{n \geqslant 1}$ be as in Lemma 8.1.2.2. For every connective A-module M, the canonical map $M \rightarrow \varprojlim(A_n \otimes_A M)$ exhibits $\varprojlim(A_n \otimes_A M)$ as an I-completion of M.*

Proof. For each R-module M, set $U(M) = \varprojlim(A_n \otimes_A M)$. Note that each $A_n \otimes_A M$ is I-complete (since I generates a nilpotent ideal in A_n), so that $U(M)$ is I-complete. Consequently, the canonical map $M \to U(M)$ factors as a composition $M \to M^{\wedge}_I \xrightarrow{\beta_M} U(M)$. We wish to show that β_M is an equivalence when M is connective.

Choose an element $x \in I$, and let $C(x^n)$ denote the cofiber of the map of A-modules $A \to A$ given by multiplication by x^n. Since $\mathrm{fib}(\beta_M)$ is I-complete, we have

$$\mathrm{fib}(\beta_M) \simeq \varprojlim \mathrm{fib}(\beta_M) \otimes_A C(x^n);$$

it will therefore suffice to show that each tensor product $\mathrm{fib}(\beta_M) \otimes_A C(x^n)$ vanishes. Since $C(x^n)$ can be obtained as a successive extension of n copies of $C(x)$, we may suppose that $n = 1$. Note that $\mathrm{fib}(\beta_M) \otimes_A C(x) \simeq \mathrm{fib}(\beta_{M \otimes_A C(x)})$. Consequently, to show that β_M is an equivalence, it suffices to show that $\beta_{M \otimes_A C(x)}$ is an equivalence.

Choose generators $x_1, \ldots, x_n \in I$ for the ideal I. Using the above argument repeatedly, we are reduced to proving that β_N is an equivalence when $N = M \otimes_A C(x_1) \otimes_A C(x_2) \otimes \cdots \otimes_A C(x_n)$. For $1 \leqslant i \leqslant n$, we observe that N can be obtained as a successive extension of 2^{n-1} (shifted) copies of $M \otimes_A C(x_i)$. Since the homotopy groups of $M \otimes_A C(x_i)$ are annihilated by multiplication by x_i^2, we conclude that each of the homotopy groups of N is annihilated by multiplication by $x_i^{2^n}$. We are therefore reduced to proving the following special case of Lemma 8.1.2.3:

$(*)$ Let M be a connective A-module, and suppose that there exists an integer k such that each homotopy group $\pi_i M$ is annihilated by the ideal $I^k \subseteq \pi_0 A$. Then $\beta_M : M^{\wedge}_I \to U(M)$ is an equivalence.
