To prove $(*)$, it suffices to show that for every integer $j \geqslant 0$, the map $\pi_j M^{\wedge}_I \to \pi_j U(M)$ is an isomorphism of abelian groups. Both $M^{\wedge}_I$ and $U(M)$ are right t-exact functors of M. We may therefore replace M by $\tau_{\leqslant j} M$ and thereby reduce to proving $(*)$ under the additional assumption that M is p-truncated for some integer p. We now proceed by induction on p. If $p < 0$, then $M \simeq 0$ and there is nothing to prove. Otherwise, we have a map of fiber sequences

$$\begin{array}{ccccc} \Sigma^p(\pi_p M)^{\wedge}_I & \longrightarrow & M^{\wedge}_I & \longrightarrow & (\tau_{\leqslant p-1} M)^{\wedge}_I \\ \downarrow & & \downarrow & & \downarrow \\ \Sigma^p U(\pi_p M) & \longrightarrow & U(M) & \longrightarrow & U(\tau_{\leqslant p-1} M) \end{array}$$

where the right vertical map is an equivalence by our inductive hypothesis. We may therefore replace M by $\pi_p M$ and thereby reduce to the case where M is discrete. In this case, M has the structure of a module over the discrete A-algebra $R = (\pi_0 A)/I^k$.

For $n \geqslant 1$, set $R_n = A_n \otimes_A R$. Since I generates a nilpotent ideal in R, the tower of R-algebras $\{R_n\}_{n \geqslant 1}$ is equivalent (as a Pro-object of $\mathrm{CAlg}^{\mathrm{cn}}_R$) to the constant diagram taking the value R. It follows that we can identify β_M with the canonical map

$$M \simeq M_I^\wedge \to U(M) \simeq \varprojlim \{A_n \otimes_A M\} \simeq \varprojlim \{R_n \otimes_R M\} \simeq R \otimes_R M,$$

which is evidently an equivalence. □

Proof of Proposition 8.1.2.1. Let A be an adic $\mathbb{E}_\infty$-ring. We will show that the functor $\mathrm{Spét} : (\mathrm{CAlg}^{\mathrm{cn}})^{\mathrm{op}} \to \infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$ admits a left Kan extension to $(\mathrm{CAlg}^{\mathrm{cn}}_{\mathrm{ad}})^{\mathrm{op}}$ at A, whose value at A can be identified with $\mathrm{Spf}\, A$. Let $\{A_n\}_{n>0}$ be a tower of A-algebras which satisfies the requirements of Lemma 8.1.2.2, so that the construction $n \mapsto A_n$ determines a right cofinal map

$$\mathrm{N}(\mathbf{Z}^{\mathrm{op}}_{>0}) \to \mathrm{CAlg}^{\mathrm{cn}} \times_{\mathrm{CAlg}^{\mathrm{cn}}_{\mathrm{ad}}} (\mathrm{CAlg}^{\mathrm{cn}}_{\mathrm{ad}})_{A/}.$$

It will therefore suffice to show that we can identify $\mathrm{Spf}\, A$ with a colimit of the diagram $\{\mathrm{Spét}\, A_n\}_{n>0}$ in the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$.

Since each of the transition maps $A_{n+1} \to A_n$ induces a surjective ring homomorphism $\pi_0 A_{n+1} \to \pi_0 A_n$ with nilpotent kernel, the spectrally ringed ∞-topoi $\{\mathrm{Spét}\, A_n\}_{n>0}$ all have the same underlying ∞-topos, which we can identify with $\mathcal{S}\mathrm{hv}^{\mathrm{ad}}_A$ (see Remark 8.1.1.9). Let us use this identification to view each structure sheaf $\mathscr{O}_{\mathrm{Spét}\, A_n}$ as a CAlg-valued sheaf on $\mathcal{S}\mathrm{hv}^{\mathrm{ad}}_A$, given by the functor

$$\mathrm{CAlg}^{\text{ét}}_A \to \mathrm{CAlg} \qquad B \mapsto (A_n \otimes_A B).$$

Applying Lemma 8.1.2.3, we see that $\mathscr{O}_{\mathrm{Spf}\, A}$ can be identified with the limit of the tower $\{\mathscr{O}_{\mathrm{Spét}\, A_n}\}$ in the ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{S}\mathrm{hv}^{\mathrm{ad}}_A)$. It follows that we can identify $\mathrm{Spf}\, A$ with the colimit $\varinjlim \mathrm{Spét}\, A_n$ in the ∞-category $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ of *all* spectrally ringed ∞-topoi. To show that it is also a colimit of the diagram $\{\mathrm{Spét}\, A_n\}_{n>0}$ in the subcategory $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$, we must verify the following:

(∗) Let $\mathsf{X} = (\mathcal{X}, \mathscr{O})$ be an object of $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$. Then a morphism of spectrally ringed ∞-topoi $f : \mathrm{Spf}\, A \to \mathsf{X}$ is local if and only if each of the composite maps $\mathrm{Spét}\, A_n \to \mathrm{Spf}\, A \xrightarrow{f} \mathsf{X}$ is local.

To prove this, it suffices to show that each of the maps $\mathscr{O}_{\mathrm{Spf}\, A} \to \mathscr{O}_{\mathrm{Spét}\, A_n}$ is local (see Remark 1.2.1.7), which follows immediately from Lemma 8.1.1.14. □

Remark 8.1.2.4. Let A be an adic $\mathbb{E}_\infty$-ring with a finitely generated ideal of definition $I \subseteq \pi_0 A$, and let $\widehat{A}$ denote the I-completion $A^\wedge_I$. Choose a tower $\{A_n\}_{n>0}$ satisfying the requirements of Lemma 8.1.2.2 for A. The fiber of the unit map $u : A \to \widehat{A}$ is I-local and each A_n is I-nilpotent, so the tensor product $\mathrm{fib}(u) \otimes_A A_n$ vanishes. It follows that u induces equivalences $A_n \to \widehat{A} \otimes_A A_n$, from which we deduce that the tower $\{A_n\}_{n>0}$ also satisfies the requirements of Lemma 8.1.2.2 for $\widehat{A}$ (which we regard as an adic $\mathbb{E}_\infty$-ring by equipping $\pi_0 \widehat{A}$ with the $\widehat{I}$-adic topology for $\widehat{I} = I(\pi_0 \widehat{A})$).

It follows from Proposition 8.1.2.1 that u induces an equivalence of formal spectra $\mathrm{Spf}(u) : \mathrm{Spf}\,\widehat{A} \to \mathrm{Spf}\,A$ (both the domain and codomain of $\mathrm{Spf}(u)$ can be identified with the colimit of the diagram $\{\mathrm{Sp\acute{e}t}\,A_n\}_{n>0}$ in the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$).

8.1.3 Formal Spectral Deligne-Mumford Stacks

We are now ready to introduce our main objects of interest.

Definition 8.1.3.1. Let $\mathfrak{X} = (\mathcal{X}, \mathcal{O}_{\mathfrak{X}})$ be a spectrally ringed ∞-topos. We will say that $\mathfrak{X}$ is an *affine formal spectral Deligne-Mumford stack* if there exists an equivalence $\mathfrak{X} \simeq \mathrm{Spf}\,A$, where A is an adic $\mathbb{E}_\infty$-ring.

More generally, we will say that $\mathfrak{X}$ is a *formal spectral Deligne-Mumford stack* if there exists a covering of $\mathcal{X}$ by objects $\{U_\alpha \in \mathcal{X}\}$ such that each $(\mathcal{X}_{/U_\alpha}, \mathcal{O}_{\mathfrak{X}}|_{U_\alpha})$ is an affine formal spectral Deligne-Mumford stack. We let fSpDM denote the full subcategory of $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ spanned the formal spectral Deligne-Mumford stacks.

Any spectral Deligne-Mumford stack X is a formal spectral Deligne-Mumford stack: this follows from Example 8.1.1.11. Moreover, X is affine as a formal spectral Deligne-Mumford stack if and only if it is affine as a spectral Deligne-Mumford stack. This is an immediate consequence of the following:

Proposition 8.1.3.2. *Let A be an adic $\mathbb{E}_\infty$-ring with finitely generated ideal of definition $I \subseteq \pi_0 A$. The following conditions are equivalent:*

(1) *The ideal I is nilpotent.*

(2) *The canonical map* $\mathrm{Spf}\,A \to \mathrm{Sp\acute{e}t}\,A$ *is an equivalence of spectrally ringed ∞-topoi.*

(3) *The formal spectrum* $\mathrm{Spf}\,A$ *is a spectral Deligne-Mumford stack.*

Proof. The implications (1) ⇒ (2) ⇒ (3) are immediate. We will complete the proof by showing that (3) ⇒ (1). Note that $\mathrm{Spf}\,A$ is a quasi-compact, quasi-separated spectral algebraic space (the quasi-compactness and quasi-separatedness follow from the fact that the underlying ∞-topos of $\mathrm{Spf}\,A$ is $\mathcal{S}\mathrm{hv}^{\mathrm{ad}}_A$, and the fact that $\mathrm{Spf}\,A$ is a spectral algebraic space follows from Proposition 8.1.5.2). It follows that the global sections functor $\Gamma : \mathrm{QCoh}(\mathrm{Spf}\,A) \to \mathrm{Mod}_A$ commutes with filtered colimits. Every element $x \in I$ determines a global section of $\mathcal{O}_{\mathrm{Spf}\,A}$ which is nowhere invertible. It follows that $\mathcal{O}_{\mathrm{Spf}\,A}[x^{-1}] \simeq 0$, so that the unit element $1 \in \pi_0 A$ has vanishing image in $\Gamma(\mathrm{Spf}\,A; \mathcal{O}_{\mathrm{Spf}\,A}[x^{-1}]) \simeq \Gamma(\mathrm{Spf}\,A; \mathcal{O}_{\mathrm{Spf}\,A})[x^{-1}] = A[x^{-1}]$. It follows that x is nilpotent. Allowing x to vary (and invoking our assumption that I is finitely generated), we conclude that I is nilpotent. □

The condition of being a formal spectral Deligne-Mumford stack is local:

Proposition 8.1.3.3. *Let $\mathfrak{X} = (\mathcal{X}, \mathcal{O}_{\mathfrak{X}})$ be a spectrally ringed ∞-topos. Then:*

(*a*) *If $\mathfrak{X}$ is a formal spectral Deligne-Mumford stack, then $\mathfrak{X}_U = (\mathcal{X}_{/U}, \mathcal{O}_{\mathfrak{X}}|_U)$ is also a formal spectral Deligne-Mumford stack for any object $U \in \mathcal{X}$.*

(*b*) *If there exists a covering $\{U_\alpha\}$ of $\mathcal{X}$ such that each $\mathfrak{X}_{U_\alpha}$ is a formal spectral Deligne-Mumford stack, then $\mathfrak{X}$ is a formal spectral Deligne-Mumford stack.*

Proof. Assertion (b) follows immediately from the definitions. To prove (a), let us assume that $\mathfrak{X}$ is a formal spectral Deligne-Mumford stack and choose any object $U \in \mathcal{X}$; we wish to show that $\mathfrak{X}_U$ is also a formal spectral Deligne-Mumford stack. By virtue of (b), this can be tested locally on $\mathfrak{X}$. We may therefore assume that $\mathfrak{X}$ is affine: that is, there exists an equivalence $\mathfrak{X} \simeq \operatorname{Spf} A$ for some adic $\mathbb{E}_\infty$-ring A with a finitely generated ideal of definition $I \subseteq \pi_0 A$. Let us identify $\mathcal{X}$ with the ∞-topos $\mathcal{S}\mathrm{hv}^{\mathrm{ad}}_A$. Then $\mathcal{X}$ is generated under small colimits by objects which are affine (in the sense of Remark 8.1.1.12). We may therefore assume without loss of generality that U is affine: that is, it is the sheafification of the functor corepresented by some étale A-algebra $B \in \mathrm{CAlg}^{\text{ét}}_A$. In this case, we have an equivalence $\mathfrak{X}_U \simeq \operatorname{Spf} B$ (where we regard B as an adic $\mathbb{E}_\infty$-ring by taking $I(\pi_0 B)$ as an ideal of definition). $\square$

Definition 8.1.3.4. Let $\mathfrak{X} = (\mathcal{X}, \mathcal{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack. We will say that an object $U \in \mathcal{X}$ is *affine* if $(\mathcal{X}_{/U}, \mathcal{O}_{\mathfrak{X}}|_U)$ is an affine formal spectral Deligne-Mumford stack.

Example 8.1.3.5. Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathsf{X}})$ be a spectral Deligne-Mumford stack. Then an object $U \in \mathcal{X}$ is affine in the sense of Definition 8.1.3.4 if and only if it is affine in the sense of Definition 1.4.7.8: this follows from Proposition 8.1.3.2.

Proposition 8.1.3.6. *Let A be an adic $\mathbb{E}_\infty$-ring and consider the formal spectrum* $\operatorname{Spf} A = (\mathcal{S}\mathrm{hv}^{\mathrm{ad}}_A, \mathcal{O}_{\operatorname{Spf} A})$*. Then an object $U \in \mathcal{S}\mathrm{hv}^{\mathrm{ad}}_A$ is affine in the sense of Definition 8.1.3.4 if and only if it is affine in the sense of Remark 8.1.1.12: that is, if and only if it the pullback of an affine object of $\mathcal{S}\mathrm{hv}^{\text{ét}}_A$.*

Proof. The "if" direction follows immediately from the definitions. To prove the converse, suppose that $\mathfrak{X} = ((\mathcal{S}\mathrm{hv}^{\mathrm{ad}}_A)_{/U}, \mathcal{O}_{\operatorname{Spf} A}|_U)$ is equivalent to $\operatorname{Spf} B$ for some adic $\mathbb{E}_\infty$-ring B. Without loss of generality, we may assume that B is complete (Remark 8.1.2.4) so that the projection map $\mathfrak{X} \to \operatorname{Spf} A$ is determined by a morphism of adic $\mathbb{E}_\infty$-rings $f : A \to B$. Let $I \subseteq \pi_0 A$ and $J \subseteq \pi_0 B$ be ideals of definition, and set $A_0 = (\pi_0 A)/I$. Let U' denote the image of U under the equivalence of ∞-topoi $\mathcal{S}\mathrm{hv}^{\mathrm{ad}}_A \simeq \mathcal{S}\mathrm{hv}^{\text{ét}}_{A_0}$ of Example 8.1.1.9; we wish to show that U' is affine. Set $\mathsf{U} = ((\mathcal{S}\mathrm{hv}^{\text{ét}}_{A_0})_{/U'}, \mathcal{O}_{\operatorname{Spét} A_0}|_{U'})$, so that U is a spectral

Deligne-Mumford stack which fits into a pullback diagram

$$\begin{array}{ccc} \mathsf{U} & \longrightarrow & \operatorname{Spf} B \\ \downarrow & & \downarrow \\ \operatorname{Sp\acute{e}t} A_0 & \longrightarrow & \operatorname{Spf} A \end{array}$$

in the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$. Set $B_0 = A_0 \otimes_A B$, and regard B_0 as an adic $\mathbb{E}_\infty$-ring by equipping $\pi_0 B_0$ with the J-adic topology. It follows from Proposition 8.1.5.2 that U and $\operatorname{Spf} B_0$ represent the same functor $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, and are therefore equivalent as spectrally ringed ∞-topoi (Theorem 8.1.5.1). Invoking Example 8.1.3.5, we deduce that $U' \in (\mathcal{S}\mathrm{hv}^{\acute{e}t}_{A_0})$ is affine, as desired. □

We have the following analogue of Proposition 1.4.7.9:

Proposition 8.1.3.7. *Let $(\mathcal{X}, \mathcal{O})$ be an formal spectral Deligne-Mumford stack, and let $\mathcal{X}_0$ be the full subcategory of $\mathcal{X}$ spanned by the affine objects. Then $\mathcal{X}$ is generated by $\mathcal{X}_0$ under small colimits (in other words, $\mathcal{X}$ is the smallest full subcategory of itself which contains $\mathcal{X}_0$ and is closed under small colimits).*

Proof. Let $\mathcal{X}_1$ be the smallest full subcategory of $\mathcal{X}$ which contains $\mathcal{X}_0$ and is closed under small colimits. Fix an object $X \in \mathcal{X}$; we wish to show that $X \in \mathcal{X}_1$. Our assumption that $(\mathcal{X}, \mathcal{O})$ is a formal spectral Deligne-Mumford stack guarantees that we can choose an effective epimorphism $u : U \to X$, where each U is a coproduct of objects belonging to $\mathcal{X}_0$. Let $U_\bullet$ be the Čech nerve of u. Since $X \simeq |U_\bullet|$, it will suffice to show that each U_n belongs to $\mathcal{X}_1$. Choose a projection map $v : U_n \to U$. Since U is a coproduct of objects belonging to $\mathcal{X}_0$, we can write U_n as a coproduct of objects V which admit a map $V \to W$, for $W \in \mathcal{X}_0$. We may therefore replace $\mathcal{X}$ by $\mathcal{X}_{/W}$ and thereby reduce to the case where $(\mathcal{X}, \mathcal{O})$ is affine, in which case the desired result is obvious (Proposition 8.1.3.6). □

8.1.4 The Reduction of a Formal Spectral Deligne-Mumford Stack

Let $(X, \mathcal{O}_X)$ be a scheme. Then we can associate to X a reduced scheme X^{red} having the same underlying topological space, whose structure sheaf is given by $\mathcal{O}^{\mathrm{red}}_X = \mathcal{O}_X / \mathcal{I}$, where $\mathcal{I} \subseteq \mathcal{O}_X$ is the subsheaf of (locally) nilpotent sections of $\mathcal{O}_X$. The scheme X^{red} is then universal among reduced schemes equipped with a map to X. We now generalize this construction to the setting of formal spectral Deligne-Mumford stacks:

Definition 8.1.4.1. Let $f : \mathsf{X}_0 \to \mathfrak{X}$ be a morphism of formal spectral Deligne-Mumford stacks. We will say that f *exhibits* X_0 *as a reduction of* $\mathfrak{X}$ if the following pair of conditions is satisfied:

(a) The formal spectral Deligne-Mumford stack X_0 is a reduced spectral Deligne-Mumford stack.

(b) For every reduced spectral Deligne-Mumford stack Y, composition with f induces a homotopy equivalence

$$\mathrm{Map}_{\mathrm{SpDM}}(\mathsf{Y}, \mathsf{X}_0) \to \mathrm{Map}_{\mathrm{fSpDM}}(\mathsf{Y}, \mathfrak{X}).$$

Remark 8.1.4.2. It follows immediately from the definitions that if a formal spectral Deligne-Mumford stack $\mathfrak{X}$ admits a reduction X_0, then X_0 is uniquely determined (up to equivalence) and depends functorially on $\mathfrak{X}$. We will indicate this dependence by denoting X_0 by $\mathfrak{X}^{\mathrm{red}}$.

Remark 8.1.4.3. In the situation of Definition 8.1.4.1, it suffices to verify condition (b) in the special case where Y is affine.

We now show that every formal spectral Deligne-Mumford stack $\mathfrak{X}$ admit a reduction:

Proposition 8.1.4.4. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then there exists a morphism $f : \mathfrak{X}^{\mathrm{red}} \to \mathfrak{X}$ which exhibit $\mathfrak{X}^{\mathrm{red}}$ as a reduction of $\mathfrak{X}$. Moreover, the morphism f is an equivalence of the underlying ∞-topoi.*

Example 8.1.4.5. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ be a spectral Deligne-Mumford stack. Then $\mathsf{X}^{\mathrm{red}}$ is given by $(\mathcal{X}, \mathscr{O}_{\mathsf{X}}^{\mathrm{red}})$, where $\mathscr{O}_{\mathsf{X}}^{\mathrm{red}}$ denotes the quotient of $\pi_0 \mathscr{O}_{\mathsf{X}}$ by the subsheaf $\mathcal{I} \subseteq \pi_0 \mathscr{O}_{\mathsf{X}}$ of (locally) nilpotent sections of $\pi_0 \mathscr{O}_{\mathsf{X}}$.

We begin by treating the affine case:

Lemma 8.1.4.6. *Let A be an adic $\mathbb{E}_\infty$-ring with finitely generated ideal of definition $I \subseteq \pi_0(A)$, and set $R = (\pi_0 A)/I$. Then the canonical map $f : \mathrm{Sp\acute{e}t}(R^{\mathrm{red}}) \to \mathrm{Spf}(A)$ exhibits $\mathrm{Sp\acute{e}t}(R^{\mathrm{red}})$ as a reduction of the affine formal spectral Deligne-Mumford stack $\mathrm{Spf}(A)$.*

Proof. Since $\mathrm{Sp\acute{e}t}(R^{\mathrm{red}})$ is reduced, it will suffice to show that f satisfies condition (b) of Definition 8.1.4.1: that is, that the canonical map

$$\theta : \mathrm{Map}_{\mathrm{SpDM}}(\mathsf{Y}, \mathrm{Sp\acute{e}t}(R^{\mathrm{red}})) \to \mathrm{Map}_{\mathrm{fSpDM}}(\mathsf{Y}, \mathrm{Spf}(A))$$

is a homotopy equivalence for every reduced spectral Deligne-Mumford stack Y. Using Remark 8.1.4.3, we can reduce to the case $\mathsf{Y} = \mathrm{Sp\acute{e}t}(B)$, where B is a reduced commutative ring. In this case, we can identify θ with the composition

$$\mathrm{Map}_{\mathrm{CAlg}}(R^{\mathrm{red}}, B) \xrightarrow{\theta'} \mathrm{Map}_{\mathrm{CAlg}}(R, B) \xrightarrow{\theta''} \mathrm{Map}_{\mathrm{CAlg}_{\mathrm{ad}}^{\heartsuit}}(\pi_0 A, B) \xrightarrow{\theta'''} \mathrm{Map}_{\mathrm{CAlg}_{\mathrm{ad}}^{\mathrm{cn}}}(A, B).$$

The map θ' is a homotopy equivalence since B is reduced and the map θ''' is a homotopy equivalence since B is discrete. To prove that θ'' is a homotopy equivalence, we must show that a ring homomorphism $\rho : \pi_0 A \to B$ which satisfies $\rho(I^n) = 0$ for $n \gg 0$ must annihilate the ideal I itself. This is clear: each element $x \in I$ satisfies $\rho(x)^n = \rho(x^n) \in \rho(I^n) = \{0\}$, so that $\rho(x) = 0$ by virtue of our assumption that B is reduced. □

Lemma 8.1.4.7. *Suppose we are given a pullback diagram of formal spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}_0 & \longrightarrow & \mathsf{Y}_0 \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle g} \\ \mathfrak{X} & \xrightarrow{h} & \mathfrak{Y}, \end{array}$$

where h is étale. If g exhibits Y_0 as a reduction of $\mathfrak{Y}$, then f exhibits X_0 as a reduction of $\mathfrak{X}$.

Proof. Since h is étale, the morphism $\mathsf{X}_0 \to \mathsf{Y}_0$ is also étale. Using the assumption that Y_0 is a reduced spectral Deligne-Mumford stack, we deduce that X_0 is also a reduced spectral Deligne-Mumford stack. If Z is any reduced spectral Deligne-Mumford stack, we have a pullback diagram

$$\begin{array}{ccc} \mathrm{Map}_{\mathrm{SpDM}}(\mathsf{Z}, \mathsf{X}_0) & \longrightarrow & \mathrm{Map}_{\mathrm{SpDM}}(\mathsf{Z}, \mathsf{Y}_0) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathrm{SpDM}}(\mathsf{Z}, \mathfrak{X}) & \longrightarrow & \mathrm{Map}_{\mathrm{SpDM}}(\mathsf{Z}, \mathfrak{Y}). \end{array}$$

Our hypothesis guarantees that the right vertical map is a homotopy equivalence, so the left vertical map is a homotopy equivalence as well. □

Proof of Proposition 8.1.4.4. Let $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack. For each object $U \in \mathcal{X}$, let $\mathfrak{X}_U = (\mathcal{X}_{/U}, \mathscr{O}_{\mathfrak{X}}|_U)$. Let us say that U is *good* if the formal spectral Deligne-Mumford stack $\mathfrak{X}_U$ admits a reduction $\mathfrak{X}_U^{\mathrm{red}}$. It follows from Lemma 8.1.4.6 that every affine object of $\mathcal{X}$ is good. We claim that every object of $\mathcal{X}$ is good. By virtue of Proposition 8.1.3.7, it will suffice to show that the collection of good objects of $\mathcal{X}$ is closed under colimits. To prove this, suppose we are given a diagram $\{U_\alpha\}$ in $\mathcal{X}$, having colimit U. We then have a diagram of reduced spectral Deligne-Mumford stacks $\{\mathfrak{X}_{U_\alpha}^{\mathrm{red}}\}$, where the transition maps are étale (Lemma 8.1.4.7). This diagram therefore has a colimit $\mathfrak{X}_U^{\mathrm{red}}$ in the ∞-category of spectral Deligne-Mumford stacks. The universal property of the colimit yields a map $f : \mathfrak{X}_U^{\mathrm{red}} \to \mathfrak{X}_U$. We claim that f exhibits $\mathfrak{X}_U^{\mathrm{red}}$ as a reduction of $\mathfrak{X}_U$. It is immediate from the construction that $\mathfrak{X}_U^{\mathrm{red}}$ is reduced. It will therefore suffice to show that f satisfies condition (b) of Definition 8.1.4.1: that is, for every reduced spectral Deligne-Mumford stack Y and every morphism $g : \mathsf{Y} \to \mathfrak{X}_U$, the homotopy fiber $F = \mathrm{Map}_{\mathrm{SpDM}}(\mathsf{Y}, \mathfrak{X}_U^{\mathrm{red}} \times_{\mathrm{Map}_{\mathrm{fSpDM}}(\mathsf{Y}, \mathfrak{X}_U)} \{g\}$ is contractible. This assertion can be tested locally on Y; we may therefore assume without loss of generality that the map g factors through some $g_\alpha : \mathsf{Y} \to \mathfrak{X}_{U_\alpha}$. Note that the diagram of formal spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathfrak{X}^{\mathrm{red}}_{U_\alpha} & \longrightarrow & \mathfrak{X}^{\mathrm{red}}_{U} \\ \downarrow & & \downarrow \\ \mathfrak{X}_{U_\alpha} & \longrightarrow & \mathfrak{X}_U \end{array}$$

is a pullback square, so we can identify F with the homotopy fiber $\mathrm{Map}_{\mathrm{SpDM}}(\mathsf{Y}, \mathfrak{X}^{\mathrm{red}}_{U_\alpha} \times_{\mathrm{Map}_{\mathrm{fSpDM}}(\mathsf{Y}, \mathfrak{X}_{U_\alpha})} \{g_\alpha\}$. The contractibility of F now follows from our assumption that $\mathfrak{X}^{\mathrm{red}}_{U_\alpha}$ is a reduction of $\mathfrak{X}_{U_\alpha}$. This completes the proof that every object of $\mathcal{X}$ is good. In particular, the final object of $\mathcal{X}$ is good, so that $\mathfrak{X}$ admits a reduction $\mathfrak{X}^{\mathrm{red}}$. To complete the proof, we must show that the natural map $\mathfrak{X}^{\mathrm{red}} \to \mathfrak{X}$ induces an equivalence at the level of underlying ∞-topoi. By virtue of Lemma 8.1.4.7, this assertion can be tested locally on $\mathfrak{X}$. We may therefore assume without loss of generality that $\mathfrak{X} = \mathrm{Spf}(A)$ for some adic $\mathbb{E}_\infty$-ring A. Let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition, and set $R = (\pi_0 A)/I$. Then we can identify the underlying ∞-topos of $\mathfrak{X}$ with the closed subtopos $\mathcal{S}\mathrm{hv}^{\mathrm{ad}}_A \subseteq \mathcal{S}\mathrm{hv}^{\text{ét}}_A$ given by the vanishing locus of I, and Lemma 8.1.4.6 allows us to identify the underlying ∞-topos of $\mathfrak{X}^{\mathrm{red}}$ with $\mathcal{S}\mathrm{hv}^{\text{ét}}_{R^{\mathrm{red}}}$. The equivalence of these ∞-topoi follows from Proposition 3.1.4.1 (and its proof). □

8.1.5 The Functor of Points

Recall that if $\mathfrak{X}$ is a locally spectrally ringed ∞-topos, then $\mathfrak{X}$ represents a functor $h_{\mathfrak{X}} : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, given by the formula $h_{\mathfrak{X}}(R) = \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathrm{Sp\acute{e}t}\, R, \mathfrak{X})$ (Definition 1.6.4.1). Our next goal is to prove the following:

Theorem 8.1.5.1. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then, for every connective $\mathbb{E}_\infty$-ring R, the space $h_{\mathfrak{X}}(R) = \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathrm{Sp\acute{e}t}\, R, \mathfrak{X})$ is essentially small. Moreover, the construction $\mathfrak{X} \mapsto h_{\mathfrak{X}}$ determines a fully faithful embedding* $\mathrm{fSpDM} \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$.

We will give the proof of Theorem 8.1.5.1 at the end of this section. Our first step is to analyze the case of an affine formal spectral Deligne-Mumford stack.

Proposition 8.1.5.2. *Let A be an adic $\mathbb{E}_\infty$-ring with a finitely generated ideal of definition $I \subseteq \pi_0 A$, let R be an arbitrary $\mathbb{E}_\infty$-ring, and let*

$$\theta : \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathrm{Sp\acute{e}t}\, R, \mathrm{Spf}\, A) \to \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathrm{Sp\acute{e}t}\, R, \mathrm{Sp\acute{e}t}\, A) \simeq \mathrm{Map}_{\mathrm{CAlg}}(A, R)$$

by given by composition with the evident map $\iota : \mathrm{Spf}\, A \to \mathrm{Sp\acute{e}t}\, A$. Then θ induces a homotopy equivalence from $\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathrm{Sp\acute{e}t}\, R, \mathrm{Spf}\, A)$ to the summand of $\mathrm{Map}_{\mathrm{CAlg}}(A, R)$ spanned by those morphisms $\phi : A \to R$ which annihilate some power of the ideal I.

Proof. Fix a morphism of $\mathbb{E}_\infty$-rings $\phi : A \to R$ and let X_ϕ denote the homotopy fiber of θ over the point ϕ. Note that if ϕ does not annihilate a power of I, then the induced map of topological spaces $|\operatorname{Spec} R| \to |\operatorname{Spec} A|$ does not factor through the vanishing locus of I, so that X_ϕ is empty. We will complete the proof by showing that if ϕ *does* annihilate a power of I, then the space X_ϕ is contractible. Let $f : \operatorname{Spét} R \to \operatorname{Spét} A$ be the morphism of spectral Deligne-Mumford stacks determined by ϕ. Our assumption that ϕ annihilates some power of I guarantees that the underlying geometric morphism $f_* : \mathcal{S}\mathrm{hv}^{\text{ét}}_R \to \mathcal{S}\mathrm{hv}^{\text{ét}}_A$ factors through the closed subtopos $\mathcal{S}\mathrm{hv}^{\mathrm{ad}}_A \subseteq \mathcal{S}\mathrm{hv}^{\text{ét}}_A$. Note that any lift of f to a map of spectrally ringed ∞-topoi $\overline{f} : \operatorname{Spét} R \to \operatorname{Spf} A$ is automatically local (Lemma 8.1.1.14). It follows that we can identify X_ϕ with the mapping space $\operatorname{Map}_{\operatorname{Fun}(\mathrm{CAlg}^{\text{ét}}_A, \mathrm{CAlg}_A)_{\mathscr{O}_{\operatorname{Spét} A}/}}(\mathscr{O}_{\operatorname{Spf} A}, f_* \mathscr{O}_{\operatorname{Spét} R})$. To show that this space is contractible, it will suffice to show that the direct image $f_* \mathscr{O}_{\operatorname{Spét} R}$ takes values in I-complete A-modules: that is, that the tensor product $R \otimes_A B$ is I-complete for any étale R-algebra B. This is clear, since I generates a nilpotent ideal in $\pi_0 R$. □

Definition 8.1.5.3. Let A be an adic $\mathbb{E}_\infty$-ring. We will say that A is *complete* if it is I-complete, where $I \subseteq \pi_0 A$ is an ideal of definition.

Corollary 8.1.5.4. *Let A and B be adic $\mathbb{E}_\infty$-rings. If B is complete, then the canonical map* $\operatorname{Map}_{\mathrm{CAlg}^{\mathrm{cn}}_{\mathrm{ad}}}(A, B) \to \operatorname{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\operatorname{Spf} B, \operatorname{Spf} A)$ *is a homotopy equivalence.*

Proof. Let $\{B_n\}_{n>0}$ be a tower of $\mathbb{E}_\infty$-algebras over B satisfying the requirements of Lemma 8.1.2.2. We then have a commutative diagram

$$\begin{array}{ccc} \operatorname{Map}_{\mathrm{CAlg}^{\mathrm{cn}}_{\mathrm{ad}}}(A, B) & \longrightarrow & \operatorname{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\operatorname{Spf} B, \operatorname{Spf} A) \\ \downarrow & & \downarrow \\ \varprojlim \operatorname{Map}_{\mathrm{CAlg}^{\mathrm{cn}}_{\mathrm{ad}}}(A, B_n) & \longrightarrow & \varprojlim \operatorname{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\operatorname{Spét} B_n, \operatorname{Spf} A). \end{array}$$

The left vertical map is a homotopy equivalence by virtue of our assumption that B is complete (see Lemma 8.1.2.3), the right vertical map is a homotopy equivalence by virtue of Proposition 8.1.2.1, and the bottom horizontal map is a homotopy equivalence by virtue of Proposition 8.1.5.2. □

Proof of Theorem 8.1.5.1. Let $\widehat{\mathcal{S}\mathrm{hv}}$ denote the full subcategory of $\operatorname{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ spanned by those functors which are sheaves with respect to the étale topology, and let $\mathcal{S}\mathrm{hv}$ denote the full subcategory spanned by those sheaves $\mathscr{F}$ such that $\mathscr{F}(R)$ is essentially small for each $R \in \mathrm{CAlg}^{\mathrm{cn}}$. Let $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack. For each $U \in \mathcal{X}$, set $\mathfrak{X}_U = (\mathcal{X}_{/U}, \mathscr{O}_{\mathfrak{X}}|_U)$. Then $\mathfrak{X}_U$ is also a formal spectral Deligne-Mumford stack (Proposition 8.1.3.3), so the structure sheaf $\mathscr{O}_{\mathfrak{X}|_U}$ is strictly Henselian (Proposition 8.1.1.13). It follows that the construction $U \mapsto h_{\mathfrak{X}_U}$ determines a functor $\mathcal{X} \to \widehat{\mathcal{S}\mathrm{hv}}$ which commutes with small colimits. Note that if $\mathfrak{X}_U$ is affine, then $h_{\mathfrak{X}_U}$ belongs to the subcategory $\mathcal{S}\mathrm{hv} \subseteq \widehat{\mathcal{S}\mathrm{hv}}$. Since $\mathcal{S}\mathrm{hv}$ is closed under small colimits in $\widehat{\mathcal{S}\mathrm{hv}}$, it follows from Proposition 8.1.3.7 that $h_{\mathfrak{X}} \in \mathcal{S}\mathrm{hv}$.

Now suppose that we are given another formal spectral Deligne-Mumford stack $\mathfrak{Y}$. We wish to show that the canonical map $\theta : \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}(\mathfrak{X}, \mathfrak{Y}) \to \mathrm{Map}_{\mathcal{S}\mathrm{hv}}(h_{\mathfrak{X}}, h_{\mathfrak{Y}})$ is a homotopy equivalence. In fact, we will show more generally that the canonical map $\theta_U : \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}(\mathfrak{X}_U, \mathfrak{Y}) \to \mathrm{Map}_{\mathcal{S}\mathrm{hv}}(h_{\mathfrak{X}_U}, h_{\mathfrak{Y}})$ is an equivalence for each $U \in \mathcal{X}$. Note that the collection of objects $U \in \mathcal{X}$ for which θ_U is a homotopy equivalence is closed under small colimits. Using Proposition 8.1.3.7, we can reduce to the case where $\mathfrak{X} = \mathrm{Spf}\, A$ is affine. Let $\{A_n\}_{n>0}$ be a tower of $\mathbb{E}_\infty$-algebras over A which satisfies the hypotheses of Lemma 8.1.2.2. We then have a commutative diagram

$$\begin{array}{ccc}
\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}(\mathrm{Spf}\, A, \mathfrak{Y}) & \xrightarrow{\theta} & \mathrm{Map}_{\mathcal{S}\mathrm{hv}}(h_{\mathfrak{X}}, h_{\mathfrak{Y}}) \\
\downarrow & & \downarrow \\
\varprojlim \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}(\mathrm{Sp\acute{e}t}\, A_n, \mathfrak{Y}) & \longrightarrow & \varprojlim \mathrm{Map}_{\mathcal{S}\mathrm{hv}}(h_{\mathrm{Sp\acute{e}t}\, A_n}, h_{\mathfrak{Y}}).
\end{array}$$

The vertical maps are homotopy equivalences by virtue of Propositions 8.1.5.2 and 8.1.2.1. We are therefore reduced to showing that the lower horizontal map is an equivalence, which follows from Yoneda's lemma. □

8.1.6 Example: Formal Completions

Motivated by Proposition 8.1.5.2, let us introduce the following definition:

Definition 8.1.6.1. Let X be a spectral Deligne-Mumford stack and let $K \subseteq |\mathsf{X}|$ be a cocompact closed subset. We will say that a morphism of formal spectral Deligne-Mumford stacks $i : \mathfrak{X} \to \mathsf{X}$ *exhibits* $\mathfrak{X}$ *as a formal completion of* X *along* K if the following universal property is satisfied: for every connective $\mathbb{E}_\infty$-ring R, composition with i induces a homotopy equivalence from $h_{\mathfrak{X}}(R)$ to the summand of $h_{\mathsf{X}}(R)$ spanned by those maps $f : \mathrm{Sp\acute{e}t}\, R \to |\mathsf{X}|$ for which the underlying map of topological spaces $|\mathrm{Spec}\, R| \to |\mathsf{X}|$ factors through K.

Remark 8.1.6.2. In the situation of Definition 8.1.6.1, the formal spectral Deligne-Mumford stack $\mathfrak{X}$ depends only on X and the closed subset $K \subseteq |\mathsf{X}|$. We will indicate this dependence by writing $\mathfrak{X} = \mathsf{X}^{\wedge}_K$.

Remark 8.1.6.3. Let X be a spectral Deligne-Mumford stack, let $K \subseteq |\mathsf{X}|$ be a cocompact closed subset, and let $\mathsf{X}^{\wedge}_K$ be the formal completion of X along K. Then, for every spectral Deligne-Mumford stack Y, the canonical map $\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}(\mathsf{Y}, \mathsf{X}^{\wedge}_K) \to \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}(\mathsf{Y}, \mathsf{X})$ induces a homotopy equivalence from $\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}(\mathsf{Y}, \mathsf{X}^{\wedge}_K)$ to the summand of $\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}}(\mathsf{Y}, \mathsf{X})$ spanned by those maps $f : \mathsf{Y} \to \mathsf{X}$ for which the underlying map of topological spaces $|\mathsf{Y}| \to |\mathsf{X}|$ factors through K.

Example 8.1.6.4. Let A be a connective $\mathbb{E}_\infty$-ring and let $K \subseteq |\operatorname{Spec} A|$ be a cocompact closed subset. Then we can regard A as an adic $\mathbb{E}_\infty$-ring (by equipping $\pi_0 A$ with the I-adic topology, for some finitely generated ideal I with vanishing locus K). Using Proposition 8.1.5.2, we can identify the formal spectrum $\operatorname{Spf} A$ with the formal completion of $\operatorname{Spét} A$ along K.

Example 8.1.6.5. Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_\mathsf{X})$ be a spectral Deligne-Mumford stack and let $f : \mathfrak{X} = (\mathcal{X}', \mathcal{O}_\mathfrak{X}) \to \mathsf{X}$ be a morphism of formal spectral Deligne-Mumford stacks which exhibits $\mathfrak{X}$ as a formal completion of X along a cocompact closed subset $K \subseteq |\mathsf{X}|$. For every object $U \in \mathcal{X}$, the induced map $f_U : \mathfrak{X}_U = (\mathcal{X}'_{/f^*U}, \mathcal{O}_\mathfrak{X}|_{f^*U}) \to (\mathcal{X}_{/U}, \mathcal{O}_\mathsf{X}|_U) = \mathsf{X}_U$ exhibits $\mathfrak{X}_U$ as a formal completion of X_U along the inverse image of K.

Proposition 8.1.6.6. *Let X be a spectral Deligne-Mumford stack and $K \subseteq |\mathsf{X}|$ be a cocompact closed subset. Then there exists a map of formal Deligne-Mumford stacks $i : \mathfrak{X} \to \mathsf{X}$ which exhibits $\mathfrak{X}$ as a formal completion of X along K.*

Proof. Write $\mathsf{X} = (\mathcal{X}, \mathcal{O}_\mathsf{X})$. For each object $U \in \mathcal{X}$, set $\mathsf{X}_U = (\mathcal{X}_{/U}, \mathcal{O}_\mathsf{X}|_U)$ and let $K_U \subseteq |\mathsf{X}_U|$ be the inverse image of K. Let us say that U is *good* if there exists a formal completion of X_U along K_U. Let $\mathcal{X}_0 \subseteq \mathcal{X}$ be the full subcategory of $\mathcal{X}$ spanned by the good objects. Note that every affine object of $\mathcal{X}$ is good (Example 8.1.6.4). To complete the proof, it will suffice to show that $\mathcal{X}_0$ is closed under small colimits in $\mathcal{X}$ (Proposition 8.1.3.7). Let $\{U_\alpha\}_{\alpha \in I}$ be a small diagram in $\mathcal{X}_0$ having colimit $U \in \mathcal{X}$. The construction $(\alpha \in I) \mapsto (\mathsf{X}_{U_\alpha})^\wedge_{K_\alpha}$ determines a diagram of formal spectral Deligne-Mumford stacks in which the transition maps are étale (as morphisms of spectrally ringed ∞-topoi; see Example 8.1.6.5). Let $\mathfrak{X}_U$ denote the colimit of this diagram in $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$, so that we have an étale surjection $\amalg_\alpha (\mathsf{X}_{U_\alpha})^\wedge_{K_\alpha} \to \mathfrak{X}_U$ (see Proposition 21.4.6.4). It follows that $\mathfrak{X}_U$ is also a formal spectral Deligne-Mumford stack (Proposition 8.1.3.3). Moreover, the functor $h_{\mathfrak{X}_U}$ represented by $\mathfrak{X}_U$ can be identified with the colimit $\varinjlim h_{(\mathsf{X}_{U_\alpha})^\wedge_{K_\alpha}}$ in the ∞-category $\mathcal{S}\mathrm{hv} \subseteq \operatorname{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ of functors which are sheaves with respect to the étale topology, from which it is easy to see that $\mathfrak{X}_U$ is a formal completion of X_U along K_U. □

Remark 8.1.6.7. Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_\mathsf{X})$ be a spectral Deligne-Mumford stack, let $K \subseteq |\mathsf{X}|$ be a cocompact closed subset, and let $\mathsf{X}^\wedge_K$ be a formal completion of X along K. Then the underlying ∞-topos of X can be identified with the closed subtopos of $\mathcal{X}$ corresponding to K. To prove this, we can use Example 8.1.6.5 to reduce to the case where $\mathsf{X} = \operatorname{Spét} A$ is affine, in which case the desired result follows from Example 8.1.6.4 (and the construction of $\operatorname{Spf} A$).

8.1.7 Fiber Products

We close this section by establishing an analogue of Proposition 1.4.11.1:

Proposition 8.1.7.1. *The ∞-category* fSpDM *of formal spectral Deligne-Mumford stacks admits finite limits.*

Warning 8.1.7.2. The inclusion functor $\mathrm{fSpDM} \hookrightarrow \infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$ does not preserve finite limits: the formation of fiber products in the setting of formal spectral Deligne-Mumford stacks requires the formation of "completed" tensor products at the level of $\mathbb{E}_\infty$-rings.

We begin by establishing a simple special case of Proposition 8.1.7.1. First, we observe that the ∞-category $\mathrm{CAlg}^{\mathrm{cn}}_{\mathrm{ad}}$ of adic $\mathbb{E}_\infty$-rings admits pushouts: given a diagram of adic $\mathbb{E}_\infty$-rings $A \leftarrow R \rightarrow B$ (with finitely generated ideals of definition $I \subseteq \pi_0 A$ and $J \subseteq \pi_0 B$), the tensor product $A \otimes_R B$ inherits the structure of an adic $\mathbb{E}_\infty$-ring (where we equip $\pi_0(A \otimes_R B)$ with the K-adic topology, where $K \subseteq \pi_0(A \otimes_R B)$ is the ideal generated by the images of I and J).

Lemma 8.1.7.3. *The construction $A \mapsto \mathrm{Spf}\, A$ carries pushouts diagrams of adic $\mathbb{E}_\infty$-rings to pullback diagrams of formal spectral Deligne-Mumford stacks.*

Proof. Suppose we are given a pushout diagram of adic $\mathbb{E}_\infty$-rings σ :

$$\begin{array}{ccc} R & \longrightarrow & A \\ \downarrow & & \downarrow \\ B & \longrightarrow & A \otimes_R B. \end{array}$$

We wish to show that the associated diagram of formal spectra τ :

$$\begin{array}{ccc} \mathrm{Spf}\, R & \longleftarrow & \mathrm{Spf}\, A \\ \uparrow & & \uparrow \\ \mathrm{Spf}\, B & \longleftarrow & \mathrm{Spf}\, A \otimes_R B \end{array}$$

is a pullback square. By virtue of Theorem 8.1.5.1, it will suffice to show that τ is a pullback square in the larger ∞-category of functors $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. Using Proposition 8.1.5.2, we are reduced to showing that for any connective $\mathbb{E}_\infty$-ring C (which we regard as an adic $\mathbb{E}_\infty$-ring by equipping $\pi_0 C$ with the discrete topology), the diagram of spaces

$$\begin{array}{ccc} \mathrm{Map}_{\mathrm{CAlg}^{\mathrm{cn}}_{\mathrm{ad}}}(R, C) & \longleftarrow & \mathrm{Map}_{\mathrm{CAlg}^{\mathrm{cn}}_{\mathrm{ad}}}(A, C) \\ \uparrow & & \uparrow \\ \mathrm{Map}_{\mathrm{CAlg}^{\mathrm{cn}}_{\mathrm{ad}}}(B, C) & \longleftarrow & \mathrm{Map}_{\mathrm{CAlg}^{\mathrm{cn}}_{\mathrm{ad}}}(A \otimes_R B, C) \end{array}$$

is a pullback square, which follows immediately from our assumption that σ is a pullback square. □

Proof of Proposition 8.1.7.1. It is clear that the ∞-category fSpDM admits a final object (given by Spét S, where S is the sphere spectrum). We will complete the proof by showing that every diagram of formal spectral Deligne-Mumford stacks $\mathfrak{X} \xrightarrow{f} \mathfrak{Y} \xleftarrow{g} \mathfrak{Z}$ admits a pullback in fSpDM. Write $\mathfrak{Y} = (\mathcal{Y}, \mathscr{O}_{\mathfrak{Y}})$. For each object $U \in \mathcal{Y}$, set $\mathfrak{Y}_U = (\mathcal{Y}_{/U}, \mathscr{O}_{\mathfrak{Y}}|_U)$, $\mathfrak{X}_U = (\mathcal{X}_{/f^*U}, \mathscr{O}_{\mathfrak{X}}|_{f^*U})$, and $\mathfrak{Z}_U = (\mathcal{Z}_{/g^*U}, \mathscr{O}_{\mathfrak{Z}}|_{g^*U})$. Let us say that $U \in \mathcal{Y}$ is *good* if the fiber product $\mathfrak{X}_U \times_{\mathfrak{Y}_U} \mathfrak{Z}_U$ is representable by a formal spectral Deligne-Mumford stack $\mathfrak{W}_U$. Note that if $\{U_\alpha\}$ is a small diagram of good objects of $\mathcal{Y}$ having colimit U, then $\{\mathfrak{W}_{U_\alpha}\}$ is a diagram of formal spectral Deligne-Mumford stacks with étale transition maps. This diagram has some colimit $\mathfrak{W}_U \in \infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{CAlg}}$ (Proposition 21.4.6.4). The evident map $\amalg_\alpha \mathfrak{W}_{U_\alpha} \to \mathfrak{W}_U$ is an étale surjection, so Proposition 8.1.3.3 guarantees that $\mathfrak{W}_U$ is also a formal spectral Deligne-Mumford stack. If we let $\mathcal{S}\mathrm{hv} \subseteq \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ denote the ∞-category of functors which are sheaves with respect to the étale topology, then $h_{\mathfrak{W}_U}$ is the colimit of the diagram $\{h_{\mathfrak{W}_{U_\alpha}}\}$ in the ∞-category $\mathcal{S}\mathrm{hv}$. Applying the same argument to $h_{\mathfrak{X}_U}$, $h_{\mathfrak{Y}_U}$, and $h_{\mathfrak{Z}_U}$ (and using the fact that colimits are universal in the ∞-category $\mathcal{S}\mathrm{hv}$) we conclude that the diagram of functors

$$\begin{array}{ccc} h_{\mathfrak{W}_U} & \longrightarrow & h_{\mathfrak{X}_U} \\ \downarrow & & \downarrow \\ h_{\mathfrak{Z}_U} & \longrightarrow & h_{\mathfrak{Y}_U} \end{array}$$

is a pullback square. Theorem 8.1.5.1 implies we can identify $\mathfrak{W}_U$ with a fiber product $\mathfrak{X}_U \times_{\mathfrak{Y}_U} \mathfrak{Z}_U$ in the ∞-category fSpDM, so that U is good.

The preceding argument shows that the collection of good objects of $\mathcal{Y}$ is closed under small colimits. By virtue of Proposition 8.1.3.7, to show that all objects of $\mathcal{Y}$ are good, it will suffice to show that all affine objects of $\mathcal{Y}$ are good. We are therefore reduced to proving Proposition 8.1.7.1 in the special case where $\mathfrak{Y} \simeq \mathrm{Spf}\, R$ is affine. Using a simliar argument, we may assume that $\mathfrak{X} \simeq \mathrm{Spf}\, A$ and $\mathfrak{Z} \simeq \mathrm{Spf}\, B$ are affine. Without loss of generality, we may also assume that A and B are complete (Remark 8.1.2.4), so that f and g are obtained from morphisms of adic $\mathbb{E}_\infty$-rings $A \leftarrow R \rightarrow B$ (Corollary 8.1.5.4). In this case, the desired result follows from Lemma 8.1.7.3. □

8.2 Quasi-Coherent Sheaves on Formal Stacks

Let A be an adic $\mathbb{E}_\infty$-ring and let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition. In Chapter 7, we saw that the stable ∞-category Mod_A admits a pair of semi-orthogonal decompositions

$$(\mathrm{Mod}_A^{\mathrm{Nil}(I)}, \mathrm{Mod}_A^{\mathrm{Loc}(I)}) \qquad (\mathrm{Mod}_A^{\mathrm{Loc}(I)}, \mathrm{Mod}_A^{\mathrm{Cpl}(I)}),$$

where $\mathrm{Mod}_A^{\mathrm{Nil}(I)}, \mathrm{Mod}_A^{\mathrm{Loc}(I)}, \mathrm{Mod}_A^{\mathrm{Cpl}(I)} \subseteq \mathrm{Mod}_A$ denote the full subcategories spanned by the I-nilpotent, I-local, and I-complete A-modules, respectively. In this section, we will develop an analogous picture in the setting of sheaves on a formal spectral Deligne-Mumford stack $\mathfrak{X}$. Our principal results can be summarized as follows:

- In §8.2.3, we introduce the notion of a *weakly quasi-coherent sheaf* on a formal spectral Deligne-Mumford stack $\mathfrak{X}$ (Definition 8.2.3.1). The weakly quasi-coherent sheaves span a full subcategory $\mathrm{WCoh}(\mathfrak{X}) \subseteq \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ with good closure properties (for example, stability under small colimits and tensor products).

- The stable ∞-category $\mathrm{WCoh}(\mathfrak{X})$ admits a pair of semi-orthogonal decompositions $(\mathrm{NilCoh}(\mathfrak{X}), \mathrm{WCoh}^{\circ}(\mathfrak{X}))$ and $(\mathrm{WCoh}^{\circ}(\mathfrak{X}), \mathrm{QCoh}(\mathfrak{X}))$ (Corollaries 8.2.3.7 and 8.2.4.10). We refer to $\mathrm{NilCoh}(\mathfrak{X})$ and $\mathrm{QCoh}(\mathfrak{X})$ as the ∞-categories of *nilcoherent* and *quasi-coherent* sheaves on $\mathfrak{X}$, respectively. Moreover, the ∞-categories $\mathrm{NilCoh}(\mathfrak{X})$ and $\mathrm{QCoh}(\mathfrak{X})$ are canonically equivalent to one another (Corollary 8.2.4.12), though they are usually distinct as subcategories of $\mathrm{WCoh}(\mathfrak{X}) \subseteq \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$.

- In the special case where $\mathfrak{X} = \operatorname{Spf} A$ for some adic $\mathbb{E}_{\infty}$-ring A with finitely generated ideal of definition $I \subseteq \pi_0 A$, passage to global sections induces equivalences of ∞-categories

$$\Gamma(\mathfrak{X}; \bullet) : \mathrm{NilCoh}(\mathfrak{X}) \to \mathrm{Mod}_A^{\mathrm{Nil}(I)} \qquad \Gamma(\mathfrak{X}; \bullet) : \mathrm{QCoh}(\mathfrak{X}) \to \mathrm{Mod}_A^{\mathrm{Cpl}(I)}$$

  (see Proposition 8.2.1.3 and Corollary 8.2.4.15).

- In the special case where $\mathfrak{X}$ is an ordinary spectral Deligne-Mumford stack, we have $\mathrm{NilCoh}(\mathfrak{X}) = \mathrm{WCoh}(\mathfrak{X}) = \mathrm{QCoh}(\mathfrak{X})$ (and all three coincide with the full subcategory $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ spanned by those sheaves which are quasi-coherent in the sense of Definition 2.2.2.1.

Warning 8.2.0.4. In the special case where $\mathfrak{X} = \operatorname{Spf} A$ is affine, the ∞-categories $\mathrm{WCoh}(\mathfrak{X})$ and $\mathrm{WCoh}^{\circ}(\mathfrak{X})$ are typically much larger than Mod_A and $\mathrm{Mod}_A^{\mathrm{Loc}(I)}$, respectively: see Proposition 8.3.2.2.

8.2.1 Nilcoherent Sheaves

We begin by globalizing the notion of I-nilpotent module over an adic $\mathbb{E}_{\infty}$-ring A.

Definition 8.2.1.1. Let $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack and let $\mathscr{F} \in \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$. We will say that $\mathscr{F}$ is *nilcoherent* if it satisfies the following pair of conditions:

(*a*) For each affine object $U \in \mathcal{X}$, the spectrum $\mathscr{F}(U)$ is I-nilpotent when regarded as a module over $\mathscr{O}_{\mathfrak{X}}(U)$, where I is an ideal of definition of $\mathscr{O}_{\mathfrak{X}}(U)$.

(*b*) For every morphism $U \to V$ between affine objects of $\mathcal{X}$, the induced map $\mathscr{O}_{\mathfrak{X}}(U) \otimes_{\mathscr{O}_{\mathfrak{X}}(V)} \mathscr{F}(V) \to \mathscr{F}(U)$ is an equivalence.

We let $\mathrm{NilCoh}(\mathfrak{X})$ denote the full subcategory of $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ spanned by the nilcoherent objects.

Example 8.2.1.2. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ be a spectral Deligne-Mumford stack. Then every object $\mathscr{F} \in \mathrm{Mod}_{\mathscr{O}_{\mathsf{X}}}$ satisfies condition (a) of Definition 8.2.1.1 (see Example 8.1.3.5), and condition (b) is equivalent to the requirement that $\mathscr{F}$ is quasi-coherent (Proposition 2.2.4.3). We therefore have $\mathrm{NilCoh}(\mathsf{X}) = \mathrm{QCoh}(\mathsf{X})$.

We begin by analyzing Definition 8.2.1.1 in the affine case.

Proposition 8.2.1.3. *Let A be an adic $\mathbb{E}_\infty$-ring with a finitely generated ideal of definition $I \subseteq \pi_0 A$. Then the global sections functor $\Gamma(\mathrm{Spf}\, A; \bullet)$ induces an equivalence of ∞-categories $\Gamma : \mathrm{NilCoh}(\mathrm{Spf}\, A) \to \mathrm{Mod}_A^{I-nil}$.*

Proof. We begin by explicitly constructing a homotopy inverse to the functor Γ. Let us identify $\mathscr{O}_{\mathrm{Spf}\, A}$ with the commutative algebra object of $\mathrm{Fun}(\mathrm{CAlg}_A^{\text{ét}}, \mathrm{Sp})$ given by $B \mapsto B_I^\wedge$. For every A-module M, we let $\widetilde{M}$ denote the $\mathscr{O}_{\mathrm{Spf}\, A}$-module object of $\mathrm{Fun}(\mathrm{CAlg}_A^{\text{ét}}, \mathrm{Sp})$ given by $B \mapsto B_I^\wedge \otimes_A M$.

Note that if M is I-nilpotent, then we can identify $\widetilde{M}$ with the functor $B \mapsto B \otimes_A M$: that is, with the quasi-coherent sheaf on $\mathrm{Spét}\, A$ given by the construction of §2.2.1. In this case, $\widetilde{M}$ is a sheaf for the étale topology on $\mathrm{CAlg}_A^{\text{ét}}$, which vanishes when I generates the unit ideal of $\pi_0 B$ (by virtue of our assumption that M is I-nilpotent). We can therefore regard $\widetilde{M}$ as a $\mathscr{O}_{\mathrm{Spf}\, A}$-module object of the ∞-category $\mathrm{Sp}(\mathcal{S}\mathrm{hv}_A^{\mathrm{ad}})$. Using the description of affine objects of $\mathcal{S}\mathrm{hv}_A^{\mathrm{ad}}$ supplied by Proposition 8.1.3.6, we immediately deduce that $\widetilde{M}$ is nilcoherent. Consequently, we can regard the construction $M \mapsto \widetilde{M}$ as a functor $F : \mathrm{Mod}_A^{I-nil} \to \mathrm{NilCoh}(\mathrm{Spf}\, A)$. It follows immediately from the definitions that F is left adjoint to the global sections functor Γ, and that the unit map $M \to \Gamma(\mathrm{Spf}\, A; F(M))$ is equivalence for $M \in \mathrm{Mod}_A^{I-nil}$. To complete the proof, it suffices to observe that the functor Γ is conservative, which is an immediate consequence of condition (b) of Definition 8.2.1.1. □

Remark 8.2.1.4. In the situation of Proposition 8.2.1.3, the functor F is t-exact when viewed as a functor from Mod_A^{I-nil} to $\mathrm{Mod}_{\mathscr{O}_{\mathrm{Spf}\, A}}$. It follows that the subcategory $\mathrm{NilCoh}(\mathrm{Spf}\, A) \subseteq \mathrm{Mod}_{\mathscr{O}_{\mathrm{Spf}\, A}}$ is closed under the formation of truncations. In particular, the stable ∞-category $\mathrm{NilCoh}(\mathrm{Spf}\, A)$ inherits a t-structure from $\mathrm{Mod}_{\mathscr{O}_{\mathrm{Spf}\, A}}$, and the equivalence $\mathrm{NilCoh}(\mathrm{Spf}\, A) \simeq \mathrm{Mod}_A^{I-nil}$ is t-exact.

The condition of nilcoherence can be tested locally:

Proposition 8.2.1.5. *Let $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack and let $\mathscr{F} \in \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$. For each object $U \in \mathcal{X}$, set $\mathfrak{X}_U = (\mathcal{X}_{/U}, \mathscr{O}_{\mathfrak{X}}|_U)$. Then:*

- (a) *The sheaf $\mathscr{F}$ is nilcoherent if and only if $\mathscr{F}|_U \, \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}|_U}$ is nilcoherent for each affine object $U \in \mathcal{X}$.*

(b) *If $\mathscr{F}$ is nilcoherent, then $\mathscr{F}|_U \in \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}|_U}$ is nilcoherent for every object $U \in \mathcal{X}$.*

(c) *If there exists a covering of $\mathcal{X}$ by objects $\{U_\alpha\}$ for which each restriction $\mathscr{F}|_{U_\alpha} \in \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}|_{U_\alpha}}$ is nilcoherent, then $\mathscr{F}$ is nilcoherent.*

Proof. Assertion (a) follows immediately from the definitions, and (b) is an immediate consequence of (a). To prove (c), we can use (a) to reduce to the case where $\mathfrak{X}$ has the form $\mathrm{Spf}\, A$, for some adic $\mathbb{E}_\infty$-ring A. Let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition and let $\{U_\alpha\}$ be a covering of $\mathcal{X}$ for which each restriction $\mathscr{F}|_{U_\alpha}$ is nilcoherent. Without loss of generality, we may assume that each U_α is affine, corresponding to some étale A-algebra B_α. Let $i : \mathrm{Spf}\, A \to \mathrm{Spét}\, A$ be the canonical map and let $i_* \mathscr{F} \in \mathrm{Mod}_{\mathscr{O}_{\mathrm{Spét}\, A}}$ be the direct image of $\mathscr{F}$. Using Proposition 8.2.1.3, we deduce that $(i_* \mathscr{F})|_{\mathrm{Spét}\, B_\alpha}$ is quasi-coherent and supported on the vanishing locus of $I(\pi_0 B)$. Moreover, it follows immediately from the definition that $(i_* \mathscr{F})|_{\mathsf{V}}$ vanishes, where V is the open substack of $\mathrm{Spét}\, A$ complementary to the vanishing locus of I. Since $\mathrm{Spét}\, A$ is covered by $\{\mathrm{Spét}\, B_\alpha\}$ and V, it follows that $i_* \mathscr{F}$ is quasi-coherent and supported on the vanishing locus of I: that is, it is the quasi-coherent sheaf associated to some I-nilpotent A-module M. It follows that $\mathscr{F} \simeq \widetilde{M} \in \mathrm{NilCoh}(\mathrm{Spf}\, A)$, where $\widetilde{M}$ is defined as in the proof of Proposition 8.2.1.3. □

Corollary 8.2.1.6. *Let X be a spectral Deligne-Mumford stack, let $K \subseteq |\mathsf{X}|$ be a cocompact closed subset, and let $i : \mathfrak{X} \to \mathsf{X}$ be a morphism of formal spectral Deligne-Mumford stacks which exhibits $\mathfrak{X}$ as a formal completion of X along K. Then the direct image functor i_* induces an equivalence of ∞-categories $\mathrm{NilCoh}(\mathfrak{X}) \to \mathrm{QCoh}_K(\mathsf{X})$, where $\mathrm{QCoh}_K(\mathsf{X})$ is the ∞-category of quasi-coherent sheaves on X which are supported on K.*

Proof. By virtue of Proposition 8.2.1.5, we can work locally on X and thereby reduce to the case where X is affine. In this case, the desired result is a reformulation of Proposition 8.2.1.3. □

Proposition 8.2.1.7. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack and let $\mathscr{F}, \mathscr{G} \in \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$. If $\mathscr{F}$ and $\mathscr{G}$ are nilcoherent, then the tensor product $\mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{G}$ is nilcoherent.*

Proof. Using Proposition 8.2.1.5, we can reduce to the case where $\mathfrak{X}$ is affine. Write $\mathfrak{X} \simeq \mathrm{Spf}\, A$ for some adic $\mathbb{E}_\infty$-ring A with finitely generated ideal of definition $I \subseteq \pi_0 A$. The construction $M \mapsto \widetilde{M}$ appearing in the proof of Proposition 8.2.1.3 determines a nonunital symmetric monoidal functor $\mathrm{Mod}_A^{\mathrm{Nil}(I)} \to \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$. Since this functor is fully faithful, its essential image is closed under tensor products. □

We now establish a generalization of Proposition 2.2.4.1:

Proposition 8.2.1.8. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then:*

(1) *The ∞-category $\mathrm{NilCoh}(\mathfrak{X})$ is closed under small colimits in $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$.*

(2) *The* ∞*-category* $\mathrm{NilCoh}(\mathfrak{X})$ *is stable.*

(3) *The* ∞*-category* $\mathrm{NilCoh}(\mathfrak{X})$ *is presentable.*

Proof. To prove (1), we can use Proposition 8.2.1.5 to reduce to the case where $\mathfrak{X} = \operatorname{Spf} A$ is affine. In this case, the proof of Proposition 8.2.1.3 shows that $\mathrm{NilCoh}(\mathfrak{X})$ can be identified with the essential image of a fully faithful functor $F : \mathrm{Mod}_A^{\mathrm{Nil}(I)} \to \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ which preserves small colimits, and is therefore closed under small colimits.

Write $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$. For each object $U \in \mathcal{X}$, set $\mathfrak{X}_U = (\mathcal{X}_{/U}, \mathscr{O}_{\mathfrak{X}}|_U)$. Using Proposition 8.2.1.5, we see that the construction $U \mapsto \mathrm{NilCoh}(\mathsf{X}_U)$ determines a functor $\mathcal{X}^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ which carries colimits in $\mathcal{X}$ to limits in $\widehat{\mathcal{C}\mathrm{at}}_\infty$. Using (1), we see that each of the ∞-categories $\mathrm{NilCoh}(\mathsf{X}_U)$ admits small colimits and that each of the transition maps $\mathrm{NilCoh}(\mathfrak{X}_U) \to \mathrm{NilCoh}(\mathfrak{X}_V)$ preserves small colimits. Using Proposition HTT.5.5.3.13 and Theorem HA.**??**, we see that the collection of those objects $U \in \mathcal{X}$ for which $\mathrm{NilCoh}(\mathfrak{X}_U)$ is stable and presentable is closed under small colimits in $\mathcal{X}$. We may therefore use Proposition 8.1.3.7 to reduce the proofs of (2) and (3) to the case where $\mathfrak{X}$ is affine, in which case the desired result follows from Proposition 8.2.1.3. □

8.2.2 Approximate Units for $\mathrm{NilCoh}(\mathfrak{X})$

Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. The structure sheaf $\mathscr{O}_{\mathfrak{X}}$ is not necessarily nilcoherent: in fact, it is nilcoherent if and only if $\mathfrak{X}$ is a spectral Deligne-Mumford stack. However, it can be closely approximated by nilcoherent sheaves.

Definition 8.2.2.1. Let $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack. A *approximate unit* for $\mathrm{NilCoh}(\mathfrak{X})$ is a pair $(\mathscr{O}_{\mathfrak{X}}^{\approx}, \alpha)$ where $\mathscr{O}_{\mathfrak{X}}^{\approx}$ is a nilcoherent sheaf on $\mathfrak{X}$ and $\alpha : \mathscr{O}_{\mathfrak{X}}^{\approx} \to \mathscr{O}_{\mathfrak{X}}$ is a morphism with the following property:

($*$) For every object $\mathscr{F} \in \mathrm{NilCoh}(\mathfrak{X})$, the map α induces an equivalence

$$\mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{\mathfrak{X}}^{\approx} \xrightarrow{\mathrm{id} \otimes \alpha} \mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{\mathfrak{X}} \simeq \mathscr{F}.$$

Remark 8.2.2.2. In the situation of Definition 8.2.2.1, we will often abuse terminology by simply referring to the object $\mathscr{O}_{\mathfrak{X}}^{\approx}$ as an *approximate unit* for $\mathrm{NilCoh}(\mathfrak{X})$, or say that α *exhibits* $\mathscr{O}_{\mathfrak{X}}^{\approx}$ *as an approximate unit for* $\mathrm{NilCoh}(\mathfrak{X})$.

Example 8.2.2.3. Let A be an adic $\mathbb{E}_\infty$-ring and let $I \subseteq \pi_0 A$ be an ideal of definition. Then we can choose a fiber sequence of A-modules $\Gamma_I(A) \xrightarrow{u} A \to L_I(A)$ where $\Gamma_I(A)$ is I-nilpotent and $L_I(A)$ is I-local. For each A-module M, let $\widetilde{M} \in \mathrm{Mod}_{\mathscr{O}_{\operatorname{Spf} A}}$ be as in the proof of Proposition 8.2.1.3, and set $\mathscr{O}_{\operatorname{Spf} A}^{\approx} = \widetilde{\Gamma_I(A)}$. Then u induces a map

$$\alpha : \mathscr{O}_{\operatorname{Spf} A}^{\approx} = \widetilde{\Gamma_I(A)} \to \widetilde{A} = \mathscr{O}_{\operatorname{Spf} A}.$$

For any A-module M, we have a canonical fiber sequence $\Gamma_I(A) \otimes_A M \xrightarrow{u_M} A \otimes_A M \to L_I(A) \otimes_A M$. If M is I-nilpotent, then the third term vanishes, so that u_M induces an equivalence $\Gamma_I(A) \otimes_A M \to M$. It follows that α induces an equivalence $\mathscr{O}^{\approx}_{\operatorname{Spf} A} \otimes_{\mathscr{O}_{\operatorname{Spf} A}} \widetilde{M} \to \widetilde{M}$, so that $(\mathscr{O}^{\approx}_{\operatorname{Spf} A}, \alpha)$ is an approximate unit for $\operatorname{NilCoh}(\operatorname{Spf} A)$.

Example 8.2.2.4. Let X be a spectral Deligne-Mumford stack. Then a morphism $\alpha : \mathscr{O}^{\approx}_{\mathsf{X}} \to \mathscr{O}_{\mathsf{X}}$ is an approximate unit for $\operatorname{NilCoh}(\mathsf{X}) = \operatorname{QCoh}(\mathsf{X})$ if and only if α is an equivalence.

We now prove show that approximate units always exist and are essentially unique:

Proposition 8.2.2.5. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack and let $\mathcal{C}$ denote the full subcategory of $\operatorname{NilCoh}(\mathfrak{X}) \times_{\operatorname{Mod}_{\mathscr{O}_{\mathfrak{X}}}} (\operatorname{Mod}_{\mathscr{O}_{\mathfrak{X}}})_{/\mathscr{O}_{\mathfrak{X}}}$ spanned by those objects which are approximate units for $\operatorname{NilCoh}(\mathfrak{X})$. Then $\mathcal{C}$ is a contractible Kan complex. In particular, there exists an approximate unit for $\operatorname{NilCoh}(\mathfrak{X})$.*

Proof. Assume first that $\mathcal{C}$ is nonempty: that is, there exists an approximate unit $\alpha_0 : \mathscr{O}^{\approx}_{\mathfrak{X}} \to \mathscr{O}_{\mathfrak{X}}$. For every object $\mathscr{F} \in \mathcal{C}$, we have a commutative diagram $\sigma_{\mathscr{F}}$:

$$\begin{array}{ccc} \mathscr{O}^{\approx}_{\mathfrak{X}} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{F} & \longrightarrow & \mathscr{O}_{\mathfrak{X}} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{F} \\ \downarrow & & \downarrow \\ \mathscr{O}^{\approx}_{\mathfrak{X}} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{\mathfrak{X}} & \longrightarrow & \mathscr{O}_{\mathfrak{X}} \otimes_{\mathscr{O}_{\mathsf{X}}} \mathscr{O}_{\mathfrak{X}}, \end{array}$$

where the left vertical map and upper horizontal map are equivalences. The diagram $\sigma_{\mathscr{F}}$ then determines an equivalence of $\mathscr{O}^{\approx}_{\mathfrak{X}}$ with $\mathscr{F}$ in the ∞-category $(\operatorname{Mod}_{\mathscr{O}_{\mathfrak{X}/}})_{/\mathscr{O}_{\mathfrak{X}}}$. This equivalence depends functorially on $\mathscr{F}$: that is, the construction $\sigma_{\mathscr{F}}$ determines an equivalence from the identity functor $\operatorname{id}_{\mathcal{C}}$ to the constant functor with the value $\mathscr{O}^{\approx}_{\mathfrak{X}}$, so that $\mathcal{C}$ is a contractible Kan complex as desired.

We now treat the general case. Let $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack. For each object $U \in \mathcal{X}$, set $\mathfrak{X}_U = (\mathcal{X}_{/U}, \mathscr{O}_{\mathfrak{X}}|_U)$. Let us say that a morphism $\alpha : \mathscr{O}^{\approx} \to \mathscr{O}_{\mathfrak{X}}|_U$ in $\operatorname{Mod}_{\mathscr{O}_{\mathfrak{X}}|_U}$ is a *universal approximate unit* if, for every map $V \to U$ in $\mathcal{X}$, the induced map $\mathscr{O}^{\approx}|_V \to \mathscr{O}_{\mathfrak{X}}|_V$ is an approximate unit for $\operatorname{NilCoh}(\mathfrak{X}_V)$. Let $\mathcal{C}_U$ denote the full subcategory of $(\operatorname{Mod}_{\mathscr{O}_{\mathfrak{X}}|_U})_{/\mathscr{O}_{\mathfrak{X}}|_U}$ spanned by the universal approximate units. Then the construction $U \mapsto \mathcal{C}_U$ carries colimits in $\mathcal{X}$ to limits in $\widehat{\mathcal{C}\mathrm{at}}_{\infty}$, and Lemma **??** guarantees that $\mathcal{C}_U$ is either empty or a contractible Kan complex for each $U \in \mathcal{X}$. It follows that the collection of objects $U \in \mathcal{X}$ for which $\mathcal{C}_U$ is nonempty is closed under small colimits. By virtue of Proposition 8.1.3.7, it will suffice to show that $\mathcal{C}_U$ is nonempty in the special case where U is affine. This follows from Example 8.2.2.3 (note that if A is an adic $\mathbb{E}_{\infty}$-ring with finitely generated ideal of definition I, then the approximate unit $\Gamma_I(A)$ of Example 8.2.2.3 is a universal approximate unit, since $\Gamma_I(A) \otimes_A B \simeq \Gamma_{I\pi_0 B}(B)$ for any $\mathbb{E}_{\infty}$-algebra B over A). □

Remark 8.2.2.6. It follows from the proof of Proposition 8.2.2.5 that every approximate unit for $\mathfrak{X}$ is a universal approximate unit: that is, it remains an approximate unit after pullback along any étale morphism.

8.2.3 Weakly Quasi-Coherent Sheaves

We now introduce an enlargement of the ∞-category of nilcoherent sheaves.

Definition 8.2.3.1. Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. We will say that a sheaf $\mathscr{F} \in \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ is *weakly quasi-coherent* if $\mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{\mathfrak{X}}^{\approx}$ is nilcoherent. Here $\mathscr{O}_{\mathfrak{X}}^{\approx}$ denotes an approximate unit for $\mathrm{NilCoh}(\mathfrak{X})$. We let $\mathrm{WCoh}(\mathfrak{X})$ denote the full subcategory of $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ spanned by the weakly quasi-coherent sheaves.

Example 8.2.3.2. Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. If $\mathscr{F} \in \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ is nilcoherent, then it is weakly quasi-coherent (in this case, the tensor product $\mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{\mathfrak{X}}^{\approx}$ is equivalent to $\mathscr{F}$).

Example 8.2.3.3. Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then the structure sheaf $\mathscr{O}_{\mathfrak{X}}$ is weakly quasi-coherent (the nilcoherence of the tensor product $\mathscr{O}_{\mathfrak{X}} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{\mathfrak{X}}^{\approx} \simeq \mathscr{O}_{\mathfrak{X}^{\approx}}$ is part of the definition of approximate unit).

Example 8.2.3.4. Let X be a spectral Deligne-Mumford stack. Then a sheaf $\mathscr{F} \in \mathrm{Mod}_{\mathscr{O}_{\mathsf{X}}}$ is weakly quasi-coherent if and only if it is quasi-coherent (combine Examples 8.2.1.2 and 8.2.2.4).

Remark 8.2.3.5. Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then the ∞-category $\mathrm{WCoh}(\mathfrak{X})$ is closed under small colimits and desuspensions in $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$. In particular, it is a stable ∞-category. It is also a presentable ∞-category: this follows from Propositions 8.2.1.8 and HTT.5.5.3.13 .

Proposition 8.2.3.6. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then the inclusion* $\mathrm{NilCoh}(\mathfrak{X}) \hookrightarrow \mathrm{WCoh}(\mathfrak{X})$ *admits a right adjoint, given by the construction* $\mathscr{F} \mapsto \mathscr{O}_{\mathfrak{X}}^{\approx} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{F}$.

Proof. Let $\alpha : \mathscr{O}_{\mathfrak{X}}^{\approx} \to \mathscr{O}_{\mathfrak{X}}$ exhibit $\mathscr{O}_{\mathfrak{X}}^{\approx}$ as an approximate unit for $\mathscr{O}_{\mathfrak{X}}$ and let $L : \mathrm{WCoh}(\mathfrak{X}) \to \mathrm{NilCoh}(\mathfrak{X}) \subseteq \mathrm{WCoh}(\mathfrak{X})$ be the functor given by tensor product with $\mathscr{O}_{\mathfrak{X}}^{\approx}$. Then α induces a natural transformation of functors $u : L \to \mathrm{id}$. Note that the essential image of L coincides with $\mathrm{NilCoh}(\mathfrak{X})$ (since L is equivalent to the identity when restricted to $\mathrm{NilCoh}(\mathfrak{X})$). By virtue of Proposition HTT.5.2.7.4 , it will suffice to prove the following:

(a) For each object $\mathscr{F} \in \mathrm{WCoh}(\mathfrak{X})$, the map $u(L\mathscr{F}) : L(L\mathscr{F}) \to L\mathscr{F}$ is an equivalence.

(b) For each object $\mathscr{F} \in \mathrm{WCoh}(\mathfrak{X})$, the map $L(u(\mathscr{F})) : L(L\mathscr{F}) \to L\mathscr{F}$ is an equivalence.

Assertion (a) follows from the definition of an approximate unit (since $L\mathscr{F} \in \mathrm{NilCoh}(\mathfrak{X})$). Assertion (b) follows from (a) together with the observation that $L(u\mathscr{F}))$ is equivalent to the composition of $u(L\mathscr{F})$ with the automorphism of

$$L(L\mathscr{F}) \simeq \mathscr{O}_{\mathfrak{X}}^{\approx} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{\mathfrak{X}}^{\approx} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{F}$$

given by permuting the two factors of $\mathscr{O}_{\mathfrak{X}}^{\approx}$. □

Corollary 8.2.3.7. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then the ∞-category* $\mathrm{WCoh}(\mathfrak{X})$ *admits a semi-orthogonal decomposition* $(\mathrm{NilCoh}(\mathfrak{X}), \mathrm{WCoh}^{\circ}(\mathfrak{X}))$*, where* $\mathrm{WCoh}^{\circ}(\mathfrak{X})$ *is the full subcategory of* $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ *spanned by those objects $\mathscr{F}$ such that $\mathscr{O}_{\mathfrak{X}}^{\approx} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{F}$ vanishes.*

Proof. Combine Propositions 8.2.3.6 and 7.2.1.4. □

Remark 8.2.3.8. Corollary 8.2.3.7 implies in particular that each weakly quasi-coherent sheaf $\mathscr{F} \in \mathrm{WCoh}(\mathfrak{X})$ fits into an essentially unique fiber sequence $\mathscr{F}' \xrightarrow{u} \mathscr{F} \rightarrow \mathscr{F}''$, where $\mathscr{F}' \in \mathrm{NilCoh}(\mathfrak{X})$ and $\mathscr{F}'' \in \mathrm{WCoh}^{\circ}(\mathfrak{X})$. Here $\mathscr{F}'$ can be identified with the tensor product $\mathscr{O}_{\mathfrak{X}}^{\approx} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{F}$, and u is obtained by tensoring the canonical map $\mathscr{O}_{\mathfrak{X}}^{\approx} \rightarrow \mathscr{O}_{\mathfrak{X}}$ with the identity on $\mathscr{F}$.

The condition of weak quasi-coherence can be tested locally:

Proposition 8.2.3.9. *Let $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack and let $\mathscr{F} \in \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$. For each object $U \in \mathcal{X}$, set $\mathfrak{X}_U = (\mathcal{X}_{/U}, \mathscr{O}_{\mathfrak{X}}|_U)$. Then:*

(1) *If $\mathscr{F}$ is weakly quasi-coherent, then $\mathscr{F}|_U \in \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}|_U}$ is weakly quasi-coherent for every object $U \in \mathcal{X}$.*

(2) *If there exists a covering of $\mathcal{X}$ by objects $\{U_\alpha\}$ for which each restriction $\mathscr{F}|_{U_\alpha} \in \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}|_{U_\alpha}}$ is weakly quasi-coherent, then $\mathscr{F}$ is weakly quasi-coherent.*

Proof. Combine Proposition 8.2.1.5 with Remark 8.2.2.6. □

Proposition 8.2.3.10. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then* $\mathrm{WCoh}(\mathfrak{X})$ *is a symmetric monoidal subcategory of* $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$*: that is, it contains the unit object and is closed under tensor products. In particular, there is an essentially unique symmetric monoidal structure on* $\mathrm{WCoh}(\mathfrak{X})$ *for which the inclusion functor* $\mathrm{WCoh}(\mathfrak{X}) \hookrightarrow \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ *is symmetric monoidal.*

Proof. The first assertion follows from Example 8.2.3.3. To complete the proof, we must show that if $\mathscr{F}, \mathscr{G} \in \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ are weakly quasi-coherent, then the tensor product $\mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{G}$ is weakly quasi-coherent. Let $\mathscr{O}_{\mathfrak{X}}^{\approx}$ be an approximate unit for $\mathrm{NilCoh}(\mathfrak{X})$. We then have

$$\begin{aligned}
\mathscr{O}_{\mathfrak{X}}^{\approx} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{G} &\simeq (\mathscr{O}_{\mathfrak{X}}^{\approx} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{\mathfrak{X}}^{\approx}) \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{G} \\
&\simeq (\mathscr{O}_{\mathfrak{X}}^{\approx} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{F}) \otimes_{\mathscr{O}_{\mathfrak{X}}} (\mathscr{O}_{\mathfrak{X}}^{\approx} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{G}).
\end{aligned}$$

Our assumption that $\mathscr{F}$ and $\mathscr{G}$ are weakly quasi-coherent implies that the tensor products $\mathscr{O}_{\mathfrak{X}}^{\approx} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{F}$ and $\mathscr{O}_{\mathfrak{X}}^{\approx} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{G}$ are nilcoherent. Applying Proposition 8.2.1.7, we conclude that $\mathscr{O}_{\mathfrak{X}}^{\approx} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{G}$ is also nilcoherent, so that $\mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{G}$ is weakly quasi-coherent. □

Remark 8.2.3.11. Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then the full subcategory $\mathrm{NilCoh}(\mathfrak{X}) \subseteq \mathrm{WCoh}(\mathfrak{X})$ is closed under tensor products (but usually does not contain the unit object). It follows that $\mathrm{NilCoh}(\mathfrak{X})$ inherits the structure of a *nonunital* symmetric monoidal functor, which is determined uniquely by the requirement that the inclusion $\iota : \mathrm{NilCoh}(\mathfrak{X}) \hookrightarrow \mathrm{WCoh}(\mathfrak{X})$ be a nonunital symmetric monoidal functor. This nonunital symmetric monoidal structure on $\mathrm{NilCoh}(\mathfrak{X})$ can be promoted (in an essentially unique way) to a symmetric monoidal structure, with unit object given by $\mathscr{O}_{\mathfrak{X}}^{\approx}$ (see Corollary HA.5.4.4.7). However, the inclusion ι is usually not a symmetric monoidal functor.

We have the following criterion for weak quasi-coherence:

Proposition 8.2.3.12. *Let $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack and let $\mathscr{F} \in \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$. Then $\mathscr{F}$ is weakly quasi-coherent if and only if it satisfies the following condition:*

- $(*)$ *For every morphism $U \to V$ between affine objects of $\mathcal{X}$, the induced map $\mathscr{O}_{\mathfrak{X}}(U) \otimes_{\mathscr{O}_{\mathfrak{X}}(V)} \mathscr{F}(V) \to \mathscr{F}(U)$ has I_U-local fiber, where $I_U \subseteq \pi_0 \mathscr{O}_{\mathfrak{X}}(U)$ is a finitely generated ideal of definition.*

Remark 8.2.3.13. In the situation of Proposition 8.2.3.12, if $\mathscr{F}$ satisfies condition (a) of Definition 8.2.1.1, then $(*)$ is equivalent to condition (b) of Definition 8.2.1.1. From this point of view, the ∞-category $\mathrm{WCoh}(\mathfrak{X})$ appears as a natural enlargement of $\mathrm{NilCoh}(\mathfrak{X})$ (where we relax the nilpotence requirements on the local sections of $\mathscr{F}$ which are imposed by Definition 8.2.1.1).

Proof of Proposition 8.2.3.12. Using Proposition 8.2.3.9, we can reduce to the case where $\mathfrak{X}$ is affine. Write $\mathfrak{X} = \mathrm{Spf}\, A$, where A is a complete adic $\mathbb{E}_\infty$-ring. Let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition. Let us identify $\mathscr{O}_{\mathfrak{X}}$ with the functor

$$\mathrm{CAlg}_A^{\text{ét}} \to \mathrm{CAlg}_A \qquad B \mapsto B_I^{\wedge},$$

and view $\mathscr{F}$ as a $\mathscr{O}_{\mathfrak{X}}$-module object of the presheaf ∞-category $\mathrm{Fun}(\mathrm{CAlg}_A^{\text{ét}}, \mathrm{Sp})$. Set $M = \Gamma(\mathfrak{X}; \mathscr{F}) \in \mathrm{Mod}_A$. Then we can rephrase condition $(*)$ as follows:

- $(*')$ For every étale A-algebra B, the canonical map $B_I^{\wedge} \otimes_A M \to \mathscr{F}(B)$ has a fiber which is I-local.

Suppose first that $(*')$ is satisfied; we will show that $\mathscr{F}$ is weakly quasi-coherent. Note that we can identify the approximate unit $\mathscr{O}_{\mathfrak{X}}^{\approx}$ with the $\mathscr{O}_{\mathfrak{X}}$-module object of $\mathrm{Fun}(\mathrm{CAlg}_A^{\text{ét}}, \mathrm{Sp})$

given by the construction $B \mapsto \Gamma_I(B^{\wedge}_I) \simeq \Gamma_I(B)$ (see Example 8.2.2.3). It follows that the tensor product $\mathscr{O}^{\approx}_{\mathfrak{X}} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{F}$ is obtained by sheafifying the functor $\mathscr{F}^{\circ} : \mathrm{CAlg}^{\text{ét}}_B \to \mathrm{Sp}$ given by $\mathscr{F}^{\circ}(B) = \Gamma_I(B^{\wedge}_I) \otimes_{B^{\wedge}_I} \mathscr{F}(B)$. It follows from $(*')$ that the functor $\mathscr{F}^{\circ}$ is also given the formula

$$\mathscr{F}^{\circ}(B) = \Gamma_I(B^{\wedge}_I) \otimes_{B^{\wedge}_I} (B^{\wedge}_I \otimes_A M) \simeq \Gamma_I(B^{\wedge}_I) \otimes_A M \simeq B^{\wedge}_I \otimes_A \Gamma_I(M).$$

This functor is already a sheaf, which is the image of $\Gamma_I(M)$ under the equivalence $\mathrm{Mod}^{\mathrm{Nil}(I)}_A \simeq \mathrm{NilCoh}(\mathfrak{X})$ supplied by Proposition 8.2.1.3.

We now prove the converse. Suppose that $\mathscr{F}$ is weakly quasi-coherent; we wish to show that condition $(*')$ is satisfied. Choose a collection of elements $x_1, \ldots, x_n \in \pi_0 A$ which generate the ideal I. For $1 \leqslant i \leqslant n$, we note that $\mathscr{F}$ satisfies condition $(*')$ if and only if the cofiber of the map $x_i : \mathscr{F} \to \mathscr{F}$ also satisfies condition $(*')$. We may therefore replace $\mathscr{F}$ by $\mathrm{cofib}(x_i : \mathscr{F} \to \mathscr{F})$, and thereby reduce to the case where $\mathscr{F}(B)$ is (x_i)-nilpotent for each $B \in \mathrm{CAlg}^{\text{ét}}_A$. Applying this argument for $1 \leqslant i \leqslant n$, we can reduce to the case where $\mathscr{F}(B)$ is I-nilpotent for each $B \in \mathrm{CAlg}^{\text{ét}}_A$. In this case, the canonical map $\mathscr{F}^{\circ} \to \mathscr{F}$ is an equivalence of $\mathscr{O}_{\mathfrak{X}}$-module objects of $\mathrm{Fun}(\mathrm{CAlg}^{\text{ét}}_A, \mathrm{Sp})$. It follows that $\mathscr{F} \simeq \mathscr{O}^{\approx}_{\mathfrak{X}} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{F}$, so our assumption that $\mathscr{F}$ is weakly quasi-coherent guarantees that it is nilcoherent. In this case, the desired result follows immediately from the definitions. □

8.2.4 Quasi-Coherent Sheaves

We are now almost ready to introduce the main objects of interest in this section.

Construction 8.2.4.1 (Completions of Weakly Quasi-Coherent Sheaves)**.** Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack and let $\alpha : \mathscr{O}^{\approx}_{\mathfrak{X}} \to \mathscr{O}_{\mathfrak{X}}$ be an approximate unit for $\mathfrak{X}$ (Proposition 8.2.2.5). For every weakly quasi-coherent sheaf $\mathscr{F} \in \mathrm{NilCoh}(\mathfrak{X})$, we let $\mathscr{F}^{\wedge}$ denote the sheaf $\underline{\mathrm{Map}}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{O}^{\approx}_{\mathfrak{X}}, \mathscr{F}) \in \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ (see §6.5.3). We will refer to $\mathscr{F}^{\wedge}$ as the *completion* of $\mathscr{F}$. Note that α induces a canonical map $\alpha_{\mathscr{F}} : \mathscr{F} \to \mathscr{F}^{\wedge}$.

Remark 8.2.4.2. Construction 8.2.4.1 is compatible with localization: if $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$, then for each $U \in \mathcal{X}$ and $\mathscr{F} \in \mathrm{NilCoh}(\mathfrak{X})$ we a canonical equivalence $\mathscr{F}^{\wedge}|_U \simeq (\mathscr{F}|_U)^{\wedge}$ (see Remark 6.5.3.1). In particular, there is a canonical homotopy equivalence

$$\Omega^{\infty} \mathscr{F}^{\wedge}(U) \simeq \mathrm{Map}_{\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}|_U}}(\mathscr{O}^{\approx}_{\mathfrak{X}}|_U, \mathscr{F}|_U).$$

Remark 8.2.4.3. Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack and let $\mathscr{F} \in \mathrm{WCoh}(\mathfrak{X})$. Using Remark 8.2.4.2, we see that the canonical map $\mathscr{O}^{\approx}_{\mathfrak{X}} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{F} \to \mathscr{F}$ induces an equivalence of completions $(\mathscr{O}^{\approx}_{\mathfrak{X}} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{F})^{\wedge} \to \mathscr{F}^{\wedge}$.

Example 8.2.4.4. Let X be a spectral Deligne-Mumford stack. Then the structure sheaf $\mathscr{O}_{\mathsf{X}}$ is an approximate unit for $\mathrm{NilCoh}(\mathsf{X})$, so the completion functor $\mathscr{F} \mapsto \mathscr{F}^{\wedge}$ is equivalent to the identity.

We begin by analyzing the completion functor in the affine case.

Proposition 8.2.4.5. *Let A be an adic $\mathbb{E}_\infty$-ring, let $\mathscr{F} \in \mathrm{NilCoh}(\operatorname{Spf} A)$, and let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition. Then the canonical map $\mathscr{F} \to \mathscr{F}^\wedge$ exhibits $\mathscr{F}^\wedge$ as an I-completion of $\mathscr{F}$ (in the A-linear stable ∞-category $\mathrm{Mod}_{\mathscr{O}_{\operatorname{Spf} A}}$). In other words, for every object $U \in \mathcal{S}\mathrm{hv}_A^{\mathrm{ad}}$, the canonical map $u : \mathscr{F}(U) \to \mathscr{F}^\wedge(U)$ exhibits $\mathscr{F}^\wedge(U)$ as an I-completion of $\mathscr{F}(U)$.*

Proof. The assertion is local on U (since the formation of I-completions commutes with small limits). We may therefore assume without loss of generality that U is affine. Using Remark 8.2.4.2, we can further reduce to the case where U is the final object of $\mathcal{S}\mathrm{hv}_A^{\mathrm{ad}}$. In this case, we have canonical equivalences

$$\begin{aligned} \mathscr{F}^\wedge(U) &\simeq \Gamma(\operatorname{Spf} A; \underline{\mathrm{Map}}_{\mathscr{O}_{\operatorname{Spf} A}}(\mathscr{O}^{\approx}_{\operatorname{Spf} A}, \mathscr{F})) \\ &\simeq \underline{\mathrm{Map}}_A(\Gamma(\operatorname{Spf} A; \mathscr{O}^{\approx}_{\operatorname{Spf} A}), \Gamma(\operatorname{Spf} A; \mathscr{F})) \\ &\simeq \underline{\mathrm{Map}}_A(\Gamma_I(A), M). \end{aligned}$$

If $N \in \mathrm{Mod}_A$ is I-local, we obtain $\mathrm{Map}_{\mathrm{Mod}_A}(N, \mathscr{F}^\wedge(U)) \simeq \mathrm{Map}_{\mathrm{Mod}_A}(N \otimes_A \Gamma_I(A), M) \simeq 0$, since $N \otimes_A \Gamma_I(A) \simeq \Gamma_I(N) \simeq 0$. It follows that $\mathscr{F}^\wedge(U)$ is I-complete. To complete the proof, it will suffice to show that the fiber $\mathrm{fib}(u) \simeq \underline{\mathrm{Map}}_A(L_I(A), M)$ is I-local. This is clear: if N' is I-nilpotent, then the mapping space

$$\mathrm{Map}_{\mathrm{Mod}_A}(N', \underline{\mathrm{Map}}_A(L_I(A), M)) \simeq \mathrm{Map}_{\mathrm{Mod}_A}(N' \otimes_A L_I(A), M) \simeq \mathrm{Map}_{\mathrm{Mod}_A}(L_I(N'), M)$$

is contractible (since $L_I(N') \simeq 0$). □

Corollary 8.2.4.6. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack and let $\mathscr{F} \in \mathrm{WCoh}(\mathfrak{X})$ be a weakly quasi-coherent sheaf. Then the completion $\mathscr{F}^\wedge$ is also weakly quasi-coherent. Moreover, the canonical map $\mathscr{F} \to \mathscr{F}^\wedge$ induces an equivalence $\mathscr{O}^{\approx}_{\mathfrak{X}} \otimes_{\mathscr{O}_\mathfrak{X}} \mathscr{F} \to \mathscr{O}^{\approx}_{\mathfrak{X}} \otimes_{\mathscr{O}_\mathfrak{X}} \mathscr{F}^\wedge$.*

Proof. By virtue of Remark 8.2.4.3, we can assume without loss of generality that $\mathscr{F}$ is nilcoherent. Using Remark 8.2.4.2 and Proposition 8.2.3.9, we can further assume that $\mathfrak{X}$ is affine. In this case, the desired result follows from Proposition 8.2.4.5. □

Definition 8.2.4.7. Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. We will say that a sheaf $\mathscr{F} \in \mathrm{Mod}_{\mathscr{O}_\mathfrak{X}}$ is *quasi-coherent* if it belongs to the essential image of the completion functor $\mathrm{WCoh}(\mathfrak{X}) \to \mathrm{WCoh}(\mathfrak{X})$. We let $\mathrm{QCoh}(\mathfrak{X})$ denote the full subcategory of $\mathrm{Mod}_{\mathscr{O}_\mathfrak{X}}$ spanned by the quasi-coherent sheaves.

Example 8.2.4.8. Let X be a spectral Deligne-Mumford stack. Then a sheaf $\mathscr{F} \in \mathrm{Mod}_{\mathscr{O}_\mathsf{X}}$ is quasi-coherent in the sense of Definition 8.2.4.7 if and only if it is quasi-coherent in the sense of Definition 2.2.2.1 (see Examples 8.2.3.4 and 8.2.4.4).

Proposition 8.2.4.9. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then the construction $\mathscr{F} \mapsto \mathscr{F}^{\wedge}$ is left adjoint to the inclusion* $\mathrm{QCoh}(\mathfrak{X}) \hookrightarrow \mathrm{WCoh}(\mathfrak{X})$.

Proof. Let $\mathscr{F}$ be an object of $\mathrm{WCoh}(\mathfrak{X})$; we claim that the canonical map $\alpha : \mathscr{F} \to \mathscr{F}^{\wedge}$ exhibits $\mathscr{F}^{\wedge}$ as a $\mathrm{QCoh}(\mathfrak{X})$-localization of $\mathscr{F}$. Since $\mathscr{F}^{\wedge}$ is quasi-coherent, it will suffice to show that for each object $\mathscr{G} \in \mathrm{QCoh}(\mathfrak{X})$, composition with α induces a homotopy equivalence $\rho : \mathrm{Map}_{\mathrm{WCoh}(\mathfrak{X})}(\mathscr{F}^{\wedge}, \mathscr{G}) \to \mathrm{Map}_{\mathrm{WCoh}(\mathfrak{X})}(\mathscr{F}, \mathscr{G})$. Writing $\mathscr{G} = \mathscr{G}_0^{\wedge}$ for some $\mathscr{G}_0 \in \mathrm{WCoh}(\mathfrak{X})$, we can identify ρ with the natural map

$$\mathrm{Map}_{\mathrm{WCoh}(\mathfrak{X})}(\mathscr{O}_{\mathfrak{X}}^{\approx} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{F}^{\wedge}, \mathscr{G}_0) \to \mathrm{Map}_{\mathrm{WCoh}(\mathfrak{X})}(\mathscr{O}_{\mathfrak{X}}^{\approx} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{F}, \mathscr{G}_0),$$

which is a homotopy equivalence by virtue of Corollary 8.2.4.6. □

Corollary 8.2.4.10. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then the ∞-category* $\mathrm{WCoh}(\mathfrak{X})$ *admits a semi-orthogonal decomposition* $(\mathrm{WCoh}^{\circ}(\mathfrak{X}), \mathrm{QCoh}(\mathfrak{X}))$*, where* $\mathrm{WCoh}^{\circ}(\mathfrak{X})$ *is defined as in Corollary 8.2.3.7.*

Remark 8.2.4.11. Corollary 8.2.4.10 asserts that every weakly quasi-coherent sheaf $\mathscr{F}$ fits into an essentially unique fiber sequence $\mathscr{F}' \to \mathscr{F} \to \mathscr{F}''$, where $\mathscr{F}' \in \mathrm{WCoh}^{\circ}(\mathfrak{X})$ and $\mathscr{F}''$ is quasi-coherent. Here we can identify $\mathscr{F}''$ with the completion of $\mathscr{F}$ (in the sense of Construction 8.2.4.1).

Proof of Corollary 8.2.4.10. By virtue of Propositions 8.2.4.9 and 7.2.1.4, it will suffice to show that a weakly quasi-coherent sheaf $\mathscr{F}$ belongs to $\mathrm{WCoh}^{\circ}(\mathfrak{X})$ if and only if the completion $\mathscr{F}^{\wedge}$ vanishes. The "if" direction follows from Corollary 8.2.4.6, and the "only if" direction from Remark 8.2.4.3. □

Corollary 8.2.4.12. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then the construction $\mathscr{F} \mapsto \mathscr{F}^{\wedge}$ induces an equivalence of ∞-categories* $\mathrm{NilCoh}(\mathfrak{X}) \to \mathrm{QCoh}(\mathfrak{X})$. *The inverse equivalence is given by the construction $\mathscr{F} \mapsto \mathscr{O}_{\mathfrak{X}}^{\approx} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{F}$.*

Proof. Combine Corollary 8.2.4.10 with Proposition 7.2.1.10. □

Corollary 8.2.4.13. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then the ∞-category* $\mathrm{QCoh}(\mathfrak{X})$ *of quasi-coherent sheaves on $\mathfrak{X}$ is stable and presentable.*

Proof. Combine Corollary 8.2.4.12 with Proposition 8.2.1.8. □

Warning 8.2.4.14. In the situation of Corollary 8.2.4.13, the ∞-category $\mathrm{QCoh}(\mathfrak{X})$ need not be closed under colimits in $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$. However, it is closed under *limits* in the ∞-category $\mathrm{WCoh}(\mathfrak{X})$ (which is in turn closed under colimits in $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$).

Corollary 8.2.4.15. *Let A be an adic $\mathbb{E}_\infty$-ring and let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition. Then the global sections functor $\Gamma(\operatorname{Spf} A; \bullet) : \operatorname{Mod}_{\mathscr{O}_{\operatorname{Spf} A}} \to \operatorname{Mod}_A$ induces an equivalence of ∞-categories $\operatorname{QCoh}(\operatorname{Spf} A) \to \operatorname{Mod}_A^{\operatorname{Cpl}(I)}$.*

Proof. It follows from Lemma 8.2.4.5 that we have a commutative diagram of ∞-categories

$$\begin{array}{ccc} \operatorname{NilCoh}(\operatorname{Spf} A) & \longrightarrow & \operatorname{QCoh}(\operatorname{Spf} A) \\ \downarrow \Gamma & & \downarrow \Gamma \\ \operatorname{Mod}_A^{\operatorname{Nil}(I)} & \longrightarrow & \operatorname{Mod}_A^{\operatorname{Cpl}(I)} \end{array}$$

where the horizontal maps are given by I-adic completion and the vertical maps are given by passage to global sections. The upper horizontal map is an equivalence by Corollary 8.2.4.12, the left vertical map is an equivalence by Proposition 8.2.1.3, and the bottom horizontal map is an equivalence by Proposition 7.3.1.7. It follows that the right vertical map is also an equivalence of ∞-categories. □

Remark 8.2.4.16. Let A be as in Corollary 8.2.4.15, let $\mathscr{F} \in \operatorname{QCoh}(\operatorname{Spf} A)$, and let $M = \Gamma(\operatorname{Spf} A; \mathscr{F})$ be the corresponding I-complete A-module. It follows from Corollary 8.2.4.15 that $\mathscr{F}$ is determined by M, up to canonical equivalence. Moreover, the proof of Corollary 8.2.4.15 gives an explicit recipe for reconstructing $\mathscr{F}$: as a functor from $\operatorname{CAlg}_A^{\text{ét}}$ to the ∞-category Mod_A, the sheaf $\mathscr{F}$ is given by the formula

$$\mathscr{F}(B) = (B \otimes_A \Gamma_I(M))^\wedge_I \simeq (B \otimes_A M)^\wedge_I .$$

The condition of quasi-coherence can be tested locally:

Proposition 8.2.4.17. *Let $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack and let $\mathscr{F} \in \operatorname{Mod}_{\mathscr{O}_{\mathfrak{X}}}$. For each object $U \in \mathcal{X}$, set $\mathfrak{X}_U = (\mathcal{X}_{/U}, \mathscr{O}_{\mathfrak{X}}|_U)$. Then:*

(1) *If $\mathscr{F}$ is quasi-coherent, then $\mathscr{F}|_U \in \operatorname{Mod}_{\mathscr{O}_{\mathfrak{X}}|_U}$ is quasi-coherent for every object $U \in \mathcal{X}$.*

(2) *If there exists a covering of $\mathcal{X}$ by objects $\{U_\alpha\}$ for which each restriction $\mathscr{F}|_{U_\alpha} \in \operatorname{Mod}_{\mathscr{O}_{\mathfrak{X}}|_{U_\alpha}}$ is quasi-coherent, then $\mathscr{F}$ is quasi-coherent.*

Proof. Combine Proposition 8.2.3.9 with Remark 8.2.4.2. □

The class of quasi-coherent sheaves admits the following concrete characterization (compare with Definition 8.2.1.1):

Proposition 8.2.4.18. *Let $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack and let $\mathscr{F} \in \operatorname{Mod}_{\mathscr{O}_{\mathfrak{X}}}$. Then $\mathscr{F}$ is quasi-coherent if and only if the following conditions are satisfied:*

(*a*) *For every affine object* $U \in \mathcal{X}$*, the* $\mathscr{O}_{\mathfrak{X}}(U)$*-module* $\mathscr{F}(U)$ *is* I*-complete, where* I *is an ideal of definition of* $\mathscr{O}_{\mathfrak{X}}(U)$*.*

(*b*) *For every morphism* $U \to V$ *between affine objects of* $\mathcal{X}$*, the induced map* $\mathscr{O}_{\mathfrak{X}}(U) \otimes_{\mathscr{O}_{\mathfrak{X}}(V)} \mathscr{F}(V) \to \mathscr{F}(U)$ *exhibits* $\mathscr{F}(U)$ *as an* I*-completion of* $\mathscr{O}_{\mathfrak{X}}(U) \otimes_{\mathscr{O}_{\mathfrak{X}}(V)} \mathscr{F}(V)$*, where* I *is an ideal of definition of* $\mathscr{O}_{\mathfrak{X}}(U)$*.*

Proof. By virtue of Proposition 8.2.4.17, we can assume without loss of generality that $\mathfrak{X} = \operatorname{Spf} A$ is affine. If $\mathscr{F}$ is quasi-coherent, then assertions (*a*) and (*b*) follow immediately from the description given in Remark 8.2.4.16. Conversely, suppose that conditions (*a*) and (*b*) are satisfied and set $M = \Gamma(\operatorname{Spf} A; \mathscr{F})$. Then M is I-complete (where $I \subseteq \pi_0 A$ is a finitely generated ideal of definition). It follows from (*b*) that, when regarded as a sheaf on the ∞-category $\mathrm{CAlg}^{\text{ét}}_A$, the functor $\mathscr{F}$ is given by the formula $\mathscr{F}(B) = (B^{\wedge}_I \otimes_{A^{\wedge}_I} M)^{\wedge}_I \simeq (B \otimes_A \Gamma_I(M))^{\wedge}_I$, so that $\mathscr{F}$ is quasi-coherent by virtue of Proposition 8.2.4.5. □

Remark 8.2.4.19. In the situation of Proposition 8.2.4.18, if $\mathscr{F}$ satisfies condition (*a*), then condition (*b*) can restated as follows:

(b') The sheaf $\mathscr{F}$ is weakly quasi-coherent.

This follows from the criterion for weak quasi-coherence supplied by Proposition 8.2.3.12.

Corollary 8.2.4.20. *Let* $\mathfrak{X}$ *be a formal spectral Deligne-Mumford stack. Then the structure sheaf* $\mathscr{O}_{\mathfrak{X}}$ *is quasi-coherent.*

We close this section with a few remarks about tensor products of quasi-coherent sheaves.

Proposition 8.2.4.21. *Let* $\mathfrak{X}$ *be a formal spectral Deligne-Mumford stack. Then the completion functor*

$$\mathrm{WCoh}(\mathfrak{X}) \to \mathrm{QCoh}(\mathfrak{X}) \qquad \mathscr{F} \mapsto \mathscr{F}^{\wedge}$$

of Construction 8.2.4.1 is compatible (in the sense of Definition HA.2.2.1.6) with the symmetric monoidal structure on the ∞*-category* $\mathrm{WCoh}(\mathfrak{X})$ *described in Proposition 8.2.3.10.*

Proof. Using Corollary 8.2.4.10, we are reduced to showing that if $\mathscr{F} \in \mathrm{WCoh}^{\circ}(\mathfrak{X})$ and $\mathscr{G} \in \mathrm{WCoh}(\mathfrak{X})$, then the tensor product $\mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{G}$ belongs to $\mathrm{WCoh}^{\circ}(\mathfrak{X})$. This follows immediately from the definition of the ∞-category $\mathrm{WCoh}^{\circ}(\mathfrak{X})$ (see Corollary 8.2.3.7). □

Corollary 8.2.4.22. *Let* $\mathfrak{X}$ *be a formal spectral Deligne-Mumford stack. Then there exists an essentially unique symmetric monoidal structure on the* ∞*-category* $\mathrm{QCoh}(\mathfrak{X})$ *for which the completion functor* $\mathrm{WCoh}(\mathfrak{X}) \to \mathrm{QCoh}(\mathfrak{X})$ *is symmetric monoidal.*

Proof. Combine Propositions 8.2.4.21 and HA.2.2.1.9. □

Notation 8.2.4.23. Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. We will generally regard the ∞-category $\mathrm{QCoh}(\mathfrak{X})$ as equipped with the symmetric monoidal structure described in Corollary 8.2.4.22. We denote the tensor product on $\mathrm{QCoh}(\mathfrak{X})$ by $\widehat{\otimes} : \mathrm{QCoh}(\mathfrak{X}) \times \mathrm{QCoh}(\mathfrak{X}) \to \mathrm{QCoh}(\mathfrak{X})$ to distinguish it from the tensor product on the larger ∞-categories $\mathrm{WCoh}(\mathfrak{X}) \subseteq \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$. Concretely, it is given by the formula $\mathscr{F} \widehat{\otimes} \mathscr{G} = (\mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{G})^{\wedge}$. Moreover, the unit object of $\mathrm{QCoh}(\mathfrak{X})$ is the structure sheaf $\mathscr{O}_{\mathfrak{X}}$ (see Corollary 8.2.4.20).

Remark 8.2.4.24. Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then the equivalence $\mathrm{NilCoh}(\mathfrak{X}) \simeq \mathrm{QCoh}(\mathfrak{X})$ of Corollary 8.2.4.12 can be promoted to an equivalence of symmetric monoidal ∞-categories, where $\mathrm{QCoh}(\mathfrak{X})$ is equipped with the symmetric monoidal structure of Corollary 8.2.4.22 and $\mathrm{NilCoh}(\mathfrak{X})$ is equipped with the symmetric monoidal structure of Remark 8.2.3.11.

8.2.5 Connectivity Conditions

We now study the behavior of sheaves on formal spectral Deligne-Mumford stacks with respect to truncation. We begin with the nilcoherent case.

Proposition 8.2.5.1. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then:*

(a) *If $\mathscr{F} \in \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ is nilcoherent, then the truncations $\tau_{\geqslant n} \mathscr{F}$ and $\tau_{\leqslant n} \mathscr{F}$ are nilcoherent for all $n \in \mathbf{Z}$.*

(b) *Define full subcategories $\mathrm{NilCoh}(\mathfrak{X})_{\geqslant 0}, \mathrm{NilCoh}(\mathfrak{X})_{\leqslant 0} \subseteq \mathrm{NilCoh}(\mathfrak{X})$ by the formulae*

$$\mathrm{NilCoh}(\mathfrak{X})_{\geqslant 0} = \mathrm{NilCoh}(\mathfrak{X}) \cap (\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}})_{\geqslant 0} \qquad \mathrm{NilCoh}(\mathfrak{X})_{\leqslant 0} = \mathrm{NilCoh}(\mathfrak{X}) \cap (\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}})_{\leqslant 0}.$$

Then the pair $(\mathrm{NilCoh}(\mathfrak{X})_{\geqslant 0}, \mathrm{NilCoh}(\mathfrak{X})_{\leqslant 0})$ determines a t-structure on $\mathrm{NilCoh}(\mathfrak{X})$.

(c) *The t-structure of (b) is left and right complete and compatible with filtered colimits.*

Proof. To prove (a), we can use Proposition 8.2.1.5 to reduce to the case where $\mathfrak{X}$ is affine, in which case the desired result follows from Remark 8.2.1.4. Assertion (b) follows formally from (a). To prove (c), we can again reduce to the case where $\mathfrak{X} \simeq \mathrm{Spf}\, A$ is affine. In this case, Proposition **??** supplies a t-exact equivalence $\mathrm{NilCoh}(\mathfrak{X}) \simeq \mathrm{Mod}_A^{\mathrm{Nil}(I)}$ where $I \subseteq \pi_0 A$ is a finitely generated ideal of definition (see Remark 7.1.1.17). □

Remark 8.2.5.2. Let X be a spectral Deligne-Mumford stack, let $K \subseteq |\mathsf{X}|$ be a cocompact closed subset, and let $i_* : \mathrm{NilCoh}(\mathsf{X}^{\wedge}_K) \to \mathrm{QCoh}_K(\mathsf{X})$ be the equivalence of Corollary 8.2.1.6. Then i_* is t-exact (where we regard $\mathrm{NilCoh}(\mathsf{X}^{\wedge}_K)$ as equipped with the t-structure of Proposition 8.2.5.1 and $\mathrm{QCoh}_K(\mathsf{X})$ with the t-structure of Remark 7.1.5.2).

Proposition 8.2.5.3. *Let $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack, let $\mathscr{F} \in \mathrm{WCoh}(\mathfrak{X})$ be weakly quasi-coherent, and let $\mathscr{F}^{\wedge} \in \mathrm{QCoh}(\mathfrak{X})$ be its completion. Suppose that $\mathscr{F}$ is connective (when regarded as a sheaf of spectra on $\mathfrak{X}$). Then, for each affine object $U \in \mathcal{X}$, the spectrum $\mathscr{F}^{\wedge}(U)$ is connective.*

Proof. Without loss of generality, we may assume that U is the final object of $\mathcal{X}$, so that $\mathfrak{X} \simeq \operatorname{Spf} A$ for some adic $\mathbb{E}_\infty$-ring A. Let us regard $\mathrm{WCoh}(\mathfrak{X})$ as a stable A-linear ∞-category. Let $I \subseteq \pi_0 A$ be an ideal of definition which is generated by finitely many elements $x_1, \ldots, x_n \in \pi_0 A$. Set $M = \Gamma(\operatorname{Spf} A; \mathscr{F}^{\wedge})$; we wish to show that M is connective.

Fix $1 \leqslant i \leqslant n$. For $m \geqslant 0$, let M_m denote the cofiber of the map $x_i^m : M \to M$. Since M is I-complete, we have an equivalence $M \simeq \varprojlim M_m$. Consequently, to prove that M is connective, it will suffice to show that each M_m is connective and that each of the transition maps $\pi_0 M_{m+1} \to \pi_0 M_m$ is surjective. Using the fiber sequence $M_1 \xrightarrow{x_i^m} M_{m+1} \to M_m$, we are reduced to showing that M_1 is connective. We may therefore replace $\mathscr{F}$ by the cofiber of the map $x_i : \mathscr{F} \to \mathscr{F}$ and thereby reduce to the case where $\mathscr{F}$ is (x_i)-nilpotent. Applying this argument for $1 \leqslant i \leqslant n$, we can assume that $\mathscr{F}$ is I-nilpotent, hence nilcoherent (Corollary 8.3.2.3). Using Remark 8.2.1.4, we deduce that $\Gamma(\mathfrak{X}; \mathscr{F})$ is connective, so that the completion $M \simeq \Gamma(\mathfrak{X}; \mathscr{F})^{\wedge}_I$ is also connective (Proposition 7.3.4.4). □

Corollary 8.2.5.4. *Let A be an adic $\mathbb{E}_\infty$-ring and let $\mathscr{F} \in \mathrm{QCoh}(\operatorname{Spf} A)$. The following conditions are equivalent:*

(1) *The A-module $\Gamma(\operatorname{Spf} A; \mathscr{F})$ is connective.*

(2) *Write $\operatorname{Spf} A = (\mathcal{X}, \mathscr{O}_{\operatorname{Spf} A})$. For each affine object $U \in \mathcal{X}$, the spectrum $\mathscr{F}(U)$ is connective.*

(3) *The sheaf $\mathscr{F}$ is connective (when viewed as a sheaf of spectra on $\mathcal{X}$).*

Proof. Let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition and set $M = \Gamma(\operatorname{Spf} A; \mathscr{F})$. Using Example 8.1.3.5 and Remark 8.2.4.16, we see that for every affine object $U \in \mathcal{X}$, we can write $\mathscr{F}(U) = (B \otimes_A M)^{\wedge}_I$ for some étale A-algebra B. Since the I-completion functor is right t-exact (Proposition 7.3.4.4), it follows that (1) ⇒ (2). The implication (2) ⇒ (3) follows immediately from the definitions (since $\pi_n \mathscr{F}$ is the sheafification of the functor $U \mapsto \pi_n(\mathscr{F}(U))$), and the implication (3) ⇒ (1) follows from Proposition 8.2.5.3. □

Corollary 8.2.5.5. *Let $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack and let $\mathscr{F} \in \mathrm{QCoh}(\mathfrak{X})$ be a quasi-coherent sheaf. The following conditions are equivalent:*

(1) *The sheaf $\mathscr{F}$ is connective when viewed as a* Sp*-valued sheaf on $\mathcal{X}$: that is, the homotopy sheaves $\pi_n \mathscr{F}$ vanish for $n < 0$.*

(2) *For each affine object $U \in \mathcal{X}$, the spectrum $\mathscr{F}(U)$ is connective.*

Definition 8.2.5.6. Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. We will say that a quasi-coherent sheaf $\mathscr{F} \in \mathrm{QCoh}(\mathfrak{X})$ is *connective* if it satisfies the equivalent conditions of Corollary 8.2.5.5. We let $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{cn}}$ denote the full subcategory of $\mathrm{QCoh}(\mathfrak{X})$ spanned by the connective objects.

Variant 8.2.5.7. Let $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack. We say that a quasi-coherent sheaf $\mathscr{F} \in \mathrm{QCoh}(\mathfrak{X})$ is *almost connective* if, for every affine object $U \in \mathcal{X}$, the spectrum $\mathscr{F}(U)$ is almost connective (that is, it is $(-n)$-connective for $n \gg 0$). We let $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{acn}}$ denote the full subcategory of $\mathrm{QCoh}(\mathfrak{X})$ spanned by the almost connective objects.

Remark 8.2.5.8. Let $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack and let $\mathscr{F} \in \mathrm{QCoh}(\mathfrak{X})$. If $\Sigma^n \mathscr{F}$ is connective for some $n \gg 0$, then $\mathscr{F}$ is almost connective. The converse holds if $\mathcal{X}$ is quasi-compact.

Remark 8.2.5.9. Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack and let $\mathrm{WCoh}(\mathfrak{X})^{\mathrm{cn}}$ denote the full subcategory of $\mathrm{WCoh}(\mathfrak{X})$ spanned by those objects which are connective when viewed as Sp-valued sheaves. It follows from Proposition 8.2.5.3 that the completion functor $\mathrm{WCoh}(\mathfrak{X}) \to \mathrm{QCoh}(\mathfrak{X})$ of Construction 8.2.4.1 carries connective objects of $\mathrm{WCoh}(\mathfrak{X})$ to connective objects of $\mathrm{QCoh}(\mathfrak{X})$.

Proposition 8.2.5.10. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then:*

(1) *The ∞-category $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{cn}}$ contains the unit object of $\mathrm{QCoh}(\mathfrak{X})$ and is closed under the completed tensor product functor $\widehat{\otimes} : \mathrm{QCoh}(\mathfrak{X}) \times \mathrm{QCoh}(\mathfrak{X}) \to \mathrm{QCoh}(\mathfrak{X})$.*

(2) *The ∞-category $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{cn}}$ is closed under colimits and extensions in $\mathrm{QCoh}(\mathfrak{X})$.*

(3) *The ∞-category $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{cn}}$ is presentable.*

Proof. Note that the ∞-category $\mathrm{WCoh}(\mathfrak{X})^{\mathrm{cn}}$ is closed under small colimits and tensor products (since the analogous assertions hold in the larger ∞-category $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$). Assertions (1) and (2) now follow from Remark 8.2.5.9. To prove (3), it will suffice to show that the ∞-category $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{cn}}$ is accessible, which follows by applying Proposition HTT.5.4.6.6 to the pullback diagram

$$\begin{array}{ccc} \mathrm{QCoh}(\mathfrak{X})^{\mathrm{cn}} & \longrightarrow & \mathrm{QCoh}(\mathfrak{X}) \\ \downarrow & & \downarrow \\ \mathrm{Mod}^{\mathrm{cn}}_{\mathscr{O}_{\mathfrak{X}}} & \longrightarrow & \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}} . \end{array}$$

□

Corollary 8.2.5.11. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then the ∞-category $\mathrm{QCoh}(\mathfrak{X})$ admits an accessible t-structure $(\mathrm{QCoh}(\mathfrak{X})^{\mathrm{cn}}, \mathrm{QCoh}'(\mathfrak{X}))$.*

Proof. Combine Propositions 8.2.5.10 and HA.1.4.4.11. □

Warning 8.2.5.12. The t-structure $(\mathrm{QCoh}(\mathfrak{X})^{\mathrm{cn}}, \mathrm{QCoh}'(\mathfrak{X}))$ of Corollary 8.2.5.11 is generally not well-behaved: for example, it is not compatible with filtered colimits. Moreover, the inclusion functor $\mathrm{QCoh}(\mathfrak{X}) \hookrightarrow \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ is not t-exact (though it is right t-exact). These difficulties can often be circumvented by restricting attention to almost perfect sheaves in the locally Noetherian setting: see §8.4 for further discussion.

Warning 8.2.5.13. Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then the equivalence $\mathrm{NilCoh}(\mathfrak{X}) \to \mathrm{QCoh}(\mathfrak{X})$ of Corollary 8.2.4.12 is not t-exact, where we endow $\mathrm{NilCoh}(\mathfrak{X})$ with the t-structure of Proposition 8.2.5.1 and $\mathrm{QCoh}(\mathfrak{X})$ with the t-structure of Corollary 8.2.5.11. However, it is right t-exact (by virtue of Remark 8.2.5.9).

8.3 Direct and Inverse Images

In §8.2, we introduced the ∞-category $\mathrm{QCoh}(\mathfrak{X})$ of quasi-coherent sheaves on a formal spectral Deligne-Mumford stack $\mathfrak{X}$. In this section, we study the behavior of quasi-coherent sheaves as $\mathfrak{X}$ varies. If $f : \mathfrak{X} \to \mathfrak{Y}$ is a morphism of formal spectral Deligne-Mumford stacks, then the pullback functor $f^* : \mathrm{Mod}_{\mathscr{O}_{\mathfrak{Y}}} \to \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ does not necessarily preserve quasi-coherence. However, in §8.3.2 we show that f^* does preserve *weak* quasi-coherence (Proposition 8.3.2.1). Using this observation, we define a *completed* pullback functor $f^{\star} : \mathrm{QCoh}(\mathfrak{Y}) \to \mathrm{QCoh}(\mathfrak{X})$ (Remark 8.3.2.10). Under mild hypotheses, we show that the direct image functor f_* preserves quasi-coherence, and therefore restricts to a functor $f_* : \mathrm{QCoh}(\mathfrak{X}) \to \mathrm{QCoh}(\mathfrak{Y})$ which is right adjoint to $f^{\star}$ (Proposition 8.3.3.1).

Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack and let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be the functor represented by $\mathfrak{X}$. In §8.3.4, we use the completed pullback functors to define a canonical map $\mathrm{QCoh}(\mathfrak{X}) \to \mathrm{QCoh}(X)$, where $\mathrm{QCoh}(X)$ is the ∞-category of quasi-coherent sheaves on X introduced in Definition 6.2.2.1. Our main result asserts that this functor is an equivalence when restricted to connective (or almost connective) quasi-coherent sheaves (Theorem 8.3.4.4 and Corollary 8.3.4.6). In §**??**, we exploit this equivalence to study various finiteness conditions on quasi-coherent sheaves, which will play an important role in §8.5.

8.3.1 Digression: Representable Morphisms

In §6.3.2, we introduced the notion of a representable morphism between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. We now specialize to the setting where X and Y are (representable by) formal spectral Deligne-Mumford stacks.

Definition 8.3.1.1. Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a morphism of formal spectral Deligne-Mumford stacks. We will say that f is *representable* (or *representable by spectral Deligne-Mumford* *stacks*) if, for every pullback diagram of formal spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathsf{X}_0 & \longrightarrow & \mathfrak{X} \\ \downarrow & & \downarrow{\scriptstyle f} \\ \mathsf{Y}_0 & \longrightarrow & \mathfrak{Y} \end{array}$$

where Y_0 is a spectral Deligne-Mumford stack, X_0 is also a spectral Deligne-Mumford stack.

Remark 8.3.1.2. In the situation of Definition 8.3.1.1, the condition that X_0 is a spectral Deligne-Mumford stack can be tested locally on X_0 (with respect to the étale topology). Consequently, to show that a morphism $f : \mathfrak{X} \to \mathfrak{Y}$ is representable, it suffices to verify the following *a priori* weaker condition:

($*$) For every map $\operatorname{Sp\acute{e}t} R \to \mathfrak{Y}$, the fiber product $\mathfrak{X} \times_{\mathfrak{Y}} \operatorname{Sp\acute{e}t} R$ is a spectral Deligne-Mumford stack.

Remark 8.3.1.3. Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a morphism of formal spectral Deligne-Mumford stacks. Then f is representable (in the sense of Definition 8.3.1.1) if and only if the map of functors $h_{\mathfrak{X}} \to h_{\mathfrak{Y}}$ is representable (in the sense of Definition 6.3.2.1): this follows immediately from Remark 8.3.1.2.

Remark 8.3.1.4. Let $f : \mathfrak{X} \to \mathfrak{Y}$ and $g : \mathfrak{Y} \to \mathfrak{Z}$ be morphisms of formal spectral Deligne-Mumford stacks. If f and g are representable, then $(g \circ f) : \mathfrak{X} \to \mathfrak{Z}$ is representable.

Remark 8.3.1.5. Suppose we are given a pullback diagram of formal spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathfrak{X}' & \longrightarrow & \mathfrak{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathfrak{Y}' & \xrightarrow{g} & \mathfrak{Y}. \end{array}$$

If f is representable, then so is f'. The converse holds if g is an étale surjection.

Remark 8.3.1.6. Let $f : \mathfrak{X} \to \mathfrak{Y}$ be an étale morphism of formal spectral Deligne-Mumford stacks. Then f is representable.

We now specialize to the case of *affine* formal spectral Deligne-Mumford stacks.

Proposition 8.3.1.7. *Let $f : A \to B$ be a morphism of adic $\mathbb{E}_\infty$-rings and let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition. The following conditions are equivalent:*

(*a*) *The ideal $I(\pi_0 B) \subseteq \pi_0 B$ is an ideal of definition for B.*

(*b*) *The map $\operatorname{Spf} f : \operatorname{Spf} B \to \operatorname{Spf} A$ is representable (Definition 8.3.1.1).*

Remark 8.3.1.8. It follows from Proposition 8.3.1.7 that condition (a) is independent of the choice of ideal of definition $I \subseteq \pi_0 A$.

Proof of Proposition 8.3.1.7. Suppose first that (a) is satisfied; we will show that the map $\operatorname{Spf} B \to \operatorname{Spf} A$ satisfies condition $(*)$ of Remark 8.3.1.2. Choose a connective $\mathbb{E}_\infty$-ring R and a map $g : \operatorname{Sp\acute{e}t} R \to \operatorname{Spf} A$, which we can identify with a morphism of $\mathbb{E}_\infty$-rings $A \to R$ which annihilates some power of I (Proposition 8.1.5.2). Using Lemma 8.1.7.3 and assumption (a), we can identify the fiber product $(\operatorname{Sp\acute{e}t} R) \times_{\operatorname{Spf} A} \operatorname{Spf} B$ with $\operatorname{Spf}(B \otimes_A R)$, where we endow $\pi_0(B \otimes_A R)$ with the I-adic topology. Since I generates a nilpotent ideal in R, this topology coincides with the discrete topology, so that $\operatorname{Spf}(B \otimes_A R) \simeq \operatorname{Sp\acute{e}t}(B \otimes_A R)$ is an (affine) spectral Deligne-Mumford stack.

Now suppose that (b) is satisfied. Set $R = (\pi_0 A)/I$. Assumption (b) guarantees that the fiber product $(\operatorname{Sp\acute{e}t} R) \times_{\operatorname{Spf} A} \operatorname{Spf} B \simeq \operatorname{Spf}(B \otimes_A R)$ is a spectral Deligne-Mumford stack. Let $J \subseteq \pi_0 B$ be a finitely generated ideal of definition. Then the J-adic topology on $\pi_0(B \otimes_A R) \simeq (\pi_0 B)/I(\pi_0 B)$ coincides with the discrete topology. It follows that $J^n \subseteq I(\pi_0 B)$ for $n \gg 0$, so that $I(\pi_0 B)$ is also an ideal of definition for $\pi_0 B$. □

Corollary 8.3.1.9. *Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a morphism of formal spectral Deligne-Mumford stacks. The following conditions are equivalent:*

(1) *The morphism f is representable.*

(2) *For every commutative diagram*

$$\begin{array}{ccc} \operatorname{Spf} B & \longrightarrow & \mathfrak{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \operatorname{Spf} A & \longrightarrow & \mathfrak{Y} \end{array}$$

where the horizontal maps are étale and f' is induced by a morphism of adic $\mathbb{E}_\infty$-rings $A \to B$, if $I \subseteq \pi_0 A$ is a finitely generated ideal of definition, then $I(\pi_0 B)$ is an ideal of definition for B.

Proof. Suppose first that (1) is satisfied and consider a diagram

$$\begin{array}{ccc} \operatorname{Spf} B & \longrightarrow & \mathfrak{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \operatorname{Spf} A & \longrightarrow & \mathfrak{Y} \end{array}$$

as in (2). Then f' can be written as a composition $\operatorname{Spf} B \to (\mathsf{X} \times_{\mathsf{Y}} \operatorname{Spf} A) \to \operatorname{Spf} A$, where the first map is étale (and therefore representable by Remark 8.3.1.6) and the second map is representable by Remark 8.3.1.5. Applying Remark 8.3.1.4, we see that f' is representable, so that $I(\pi_0 B)$ is an ideal of definition for $\pi_0 B$ by virtue of Proposition 8.3.1.7.

Now suppose that (2) is satisfied; we wish to show that f is representable. Using Remark 8.3.1.5, we can reduce to the case where $\mathfrak{Y} = \operatorname{Spf} A$ is affine. We wish to show that for any morphism $g : \mathsf{Y}_0 \to \mathfrak{Y}$, where Y_0 is a spectral Deligne-Mumford stack, the fiber product $\mathfrak{X} \times_{\mathfrak{Y}} \mathsf{Y}_0$ is also a spectral Deligne-Mumford stack. Choose an étale surjection $\amalg \operatorname{Spf} B_\alpha \to \mathfrak{X}$. Then we have an étale surjection $\amalg \operatorname{Spf} B_\alpha \times_{\operatorname{Spf} A} \mathsf{Y}_0 \to \mathfrak{X} \times_{\mathfrak{Y}} \mathsf{Y}_0$. It will therefore suffice to show that each fiber product $\operatorname{Spf} B_\alpha \times_{\operatorname{Spf} A} \mathsf{Y}_0$ is a spectral Deligne-Mumford stack. Without loss of generality, we may assume that each B_α is complete (Remark 8.1.2.4), so that the map $\operatorname{Spf} B_\alpha \to \operatorname{Spf} A$ is induced by a morphism of adic $\mathbb{E}_\infty$-rings $A \to B_\alpha$ (Corollary **??**). The desired result now follows from assumption (2) together with Proposition 8.3.1.7. □

Corollary 8.3.1.10. *Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a morphism of formal spectral Deligne-Mumford stacks. If $\mathfrak{X}$ is a spectral Deligne-Mumford stack, then f is representable.*

Proof. Choose a commutative diagram

$$\begin{array}{ccc} \operatorname{Spf} B & \longrightarrow & \mathfrak{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \operatorname{Spf} A & \longrightarrow & \mathfrak{Y} \end{array}$$

as in Corollary 8.3.1.9. Let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition. Our assumption that $\mathfrak{X}$ is a spectral Deligne-Mumford stack guarantees that the topology on $\pi_0 B$ is discrete, so the map $A \to B$ annihilates some power of I. It follows that $I(\pi_0 B)$ is a nilpotent ideal (and therefore an ideal of definition for $\pi_0 B$). □

Corollary 8.3.1.11. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then the diagonal map $\mathfrak{X} \to \mathfrak{X} \times \mathfrak{X}$ is representable.*

Proof. Let $g : \mathsf{X} \to \mathfrak{X} \times \mathfrak{X}$ be a morphism of formal spectral Deligne-Mumford stacks, where X is a spectral Deligne-Mumford stack. Let Y denote the fiber product $\mathsf{X} \times_{\mathfrak{X} \times \mathfrak{X}} \mathfrak{X}$. We wish to show that Y is a spectral Deligne-Mumford stack. Identifying g with a pair of maps $g_0, g_1 : \mathsf{X} \to \mathfrak{X}$, we have a pullback diagram

$$\begin{array}{ccc} \mathsf{Y} & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow{\scriptstyle g_0} \\ \mathsf{X} & \xrightarrow{g_1} & \mathfrak{X}. \end{array}$$

The desired result now follows from the fact that g_0 is representable (Corollary 8.3.1.10). □

Proposition 8.3.1.12. *Let $f : X \to Y$ be a representable morphism in the ∞-category* $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. *If Y is representable by a formal spectral Deligne-Mumford stack, then X is representable by a formal spectral Deligne-Mumford stack.*

Proof. Let $\mathfrak{Y} = (\mathcal{Y}, \mathcal{O}_{\mathfrak{Y}})$ be a formal spectral Deligne-Mumford stack which represents the functor Y. For each object $V \in \mathcal{Y}$, let $\mathfrak{Y}_V = (\mathcal{Y}_{/V}, \mathcal{O}_{\mathfrak{Y}}|_V)$ and let Y_V be the functor represented by $\mathfrak{Y}_U$. Let us say that $V \in \mathcal{Y}$ is *good* if the fiber product $X \times_Y Y_V$ is representable by a formal spectral Deligne-Mumford stack. The collection of good objects of $\mathcal{Y}$ is closed under colimits. Consequently, it will suffice to show that every affine object $U \in \mathcal{Y}$ is good (Proposition 8.1.3.7). We may therefore reduce to the case where $\mathfrak{Y}$ is affine.

Choose an equivalence $\mathfrak{Y} \simeq \mathrm{Spf}\, A$, where A is an adic $\mathbb{E}_\infty$-ring with finitely generated ideal of definition $I \subseteq \pi_0 A$. Let $\{A_n\}_{n>0}$ be a tower of A-algebras satisfying the requirements of Lemma 8.1.2.2. Using our assumption that f is representable, we deduce that each fiber product $X_n = X \times_Y \mathrm{Spec}\, A_n$ is representable by a spectral Deligne-Mumford stack $\mathsf{X}_n = (\mathcal{X}_n, \mathcal{O}_n)$. These spectral Deligne-Mumford stacks fit into pullback diagrams

$$\begin{array}{ccc} \mathsf{X}_{n+1} & \longrightarrow & \mathsf{X}_n \\ \downarrow & & \downarrow \\ \mathrm{Sp\acute{e}t}\, A_{n+1} & \longrightarrow & \mathrm{Sp\acute{e}t}\, A_n. \end{array}$$

Since each of the maps $\pi_0 A_{n+1} \to \pi_0 A_n$ is a surjection with nilpotent kernel, the underlying geometric morphism $\mathcal{X}_{n+1} \to \mathcal{X}_n$ is an equivalence of ∞-topoi. We may therefore identify each $\mathcal{X}_n$ with a single ∞-topos $\mathcal{X}$. Set $\mathcal{O}_{\mathfrak{X}} = \varprojlim \mathcal{O}_n \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$ and define $\mathfrak{X} = (\mathcal{X}, \widehat{\mathcal{O}})$. To complete the proof, it will suffice to show verify the following:

(a) The spectrally ringed ∞-topos $\mathfrak{X} = (\mathcal{X}, \mathcal{O}_{\mathfrak{X}})$ is a formal spectral Deligne-Mumford stack.

(b) The functor X is represented by $\mathfrak{X}$.

We begin by proving (a). Fix an object $U \in \mathcal{X}$ such that $(\mathcal{X}_{/U}, \mathcal{O}_1|_U)$ is affine. Then $(\mathcal{X}_{/U}, \mathcal{O}_n|_U)$ is affine for all $n > 0$ (see Lemma 8.3.3.2). Write $(\mathcal{X}_{/U}, \mathcal{O}_n|_U) \simeq \mathrm{Sp\acute{e}t}\, B_n$ for some A_n-algebra B_n. Let B be the image of the tower $\{B_n\}_{n>0}$ under the (symmetric monoidal) equivalence of ∞-categories $\varprojlim \mathrm{Mod}^{\mathrm{cn}}_{A_n} \simeq (\mathrm{Mod}^{\mathrm{Cpl}(I)}_A)^{\mathrm{cn}}$ supplied by Theorem 8.3.4.4, so that we have equivalences $B_n \simeq A_n \otimes_A B$. Let us regard B as an adic $\mathbb{E}_\infty$-ring with ideal of definition $I(\pi_0 B)$. Note that the tower $\{B_n\}$ satisfies the requirements of Lemma 8.1.2.2 for B, so the proof of Proposition 8.1.2.1 yields an equivalence $(\mathcal{X}_{/U}, \mathcal{O}_{\mathfrak{X}}|_U) \simeq \mathrm{Spf}\, B$. Allowing U to vary, we deduce that $\mathfrak{X}$ is a formal spectral Deligne-Mumford stack.

To prove (b), let $X' : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be the functor represented by $\mathfrak{X}$. For each $n > 0$, the projection map $\mathcal{O}_{\mathfrak{X}} \to \mathcal{O}_n$ determines a natural transformation of functors $X_n \to X'$.

These maps are compatible as n varies, and give rise to a map $\alpha : X = \varinjlim_n X_n \to X'$. For each object $U \in \mathcal{X}$, let X'_U denote the functor represented by $(\mathcal{X}_{/U}, \mathscr{O}_{\mathfrak{X}}|_U)$ and set $X_U = X'_U \times_{X'} X$. Using Proposition 8.1.5.2, we deduce that the projection map $X_U \to X'_U$ is an equivalence whenever U is affine. Since the functors X and X' are both sheaves with respect to the étale topology and the map $\amalg_U X'_U \to X'$ is an effective epimorphism with respect to the étale topology (where the coproduct is taken over all affine objects $U \in \mathcal{X}$), it follows that α is an equivalence, so that X is representable by $\mathfrak{X}$. □

8.3.2 Inverse Images of Quasi-Coherent Sheaves

We now discuss the functorial dependence of the ∞-categories $\mathrm{NilCoh}(\mathfrak{X})$, $\mathrm{WCoh}(\mathfrak{X})$, and $\mathrm{QCoh}(\mathfrak{X})$ on the formal spectral Deligne-Mumford stack $\mathfrak{X}$. Recall that any morphism of spectrally ringed ∞-topoi $f : \mathfrak{X} \to \mathfrak{Y}$ determines a pair of adjoint functors

$$\mathrm{Mod}_{\mathscr{O}_{\mathfrak{Y}}} \underset{f_*}{\overset{f^*}{\rightleftarrows}} \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}} .$$

Proposition 8.3.2.1. *Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a morphism of formal spectral Deligne-Mumford stacks. Then the functor $f^* : \mathrm{Mod}_{\mathscr{O}_{\mathfrak{Y}}} \to \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ carries $\mathrm{WCoh}(\mathfrak{Y})$ to $\mathrm{WCoh}(\mathfrak{X})$.*

The proof of Proposition 8.3.2.1 will require some preliminaries.

Proposition 8.3.2.2. *Let A be an adic $\mathbb{E}_\infty$-ring with finitely generated ideal of definition $I \subseteq \pi_0 A$, and regard $\mathrm{Mod}_{\mathscr{O}_{\mathrm{Spf}\, A}}$ as a stable A-linear ∞-category. Let $\mathscr{F}$ be a $\mathscr{O}_{\mathrm{Spf}\, A}$-module. Then $\mathscr{F}$ is I-local if and only if it belongs to the full subcategory $\mathrm{WCoh}^\circ(\mathrm{Spf}\, A) \subseteq \mathrm{Mod}_{\mathscr{O}_{\mathrm{Spf}\, A}}$ appearing in Corollary 8.2.3.7.*

Proof. Without loss of generality, we may assume that A is complete. Let us identify $\mathscr{O}_{\mathfrak{X}}$ with the functor

$$\mathrm{CAlg}_A^{\text{ét}} \to \mathrm{CAlg}_A \qquad B \mapsto B_I^\wedge,$$

and view $\mathscr{F}$ as a $\mathscr{O}_{\mathfrak{X}}$-module object of the presheaf ∞-category $\mathrm{Fun}(\mathrm{CAlg}_A^{\text{ét}}, \mathrm{Sp})$. Define $\mathscr{F}^\circ : \mathrm{CAlg}_A^{\text{ét}} \to \mathrm{Sp}$ as in the proof of Proposition 8.2.3.12, so that $\mathscr{F}^\circ(B) \simeq \Gamma_I(B_I^\wedge) \otimes_{B_I^\wedge} \mathscr{F}(B)$. Then $\mathscr{O}^{\approx}_{\mathrm{Spf}\, A} \otimes_{\mathscr{O}_{\mathrm{Spf}\, A}} \mathscr{F}$ can be identified with the sheafification of $\mathscr{F}^\circ$. If $\mathscr{F}$ is I-local, then $\mathscr{F}^\circ \simeq 0$, so that $\mathscr{O}^{\approx}_{\mathrm{Spf}\, A} \otimes_{\mathscr{O}_{\mathrm{Spf}\, A}} \mathscr{F} \simeq 0$ and $\mathscr{F} \in \mathrm{WCoh}^\circ(\mathrm{Spf}\, A)$, as desired. Conversely, suppose that $\mathscr{F} \in \mathrm{WCoh}^\circ(\mathrm{Spf}\, A)$. Then $\mathscr{F}$ is weakly coherent. The proof of Proposition 8.2.3.12 shows that $\mathscr{F}^\circ$ is already a sheaf, so we have $\mathscr{F}^\circ \simeq \mathscr{O}^{\approx}_{\mathrm{Spf}\, A} \otimes_{\mathscr{O}_{\mathrm{Spf}\, A}} \mathscr{F} \simeq 0$. It follows that $\mathscr{F}^\circ(B) \simeq 0$ for all $B \in \mathrm{CAlg}_A^{\text{ét}}$, which implies that $\mathscr{F}(B)$ is I-local. Allowing B to vary, we conclude that $\mathscr{F}$ is I-local. □

Corollary 8.3.2.3. *Let A be an adic $\mathbb{E}_\infty$-ring with finitely generated ideal of definition $I \subseteq \pi_0 A$, and regard $\mathrm{WCoh}(\mathrm{Spf}\, A)$ as a stable A-linear ∞-category. Then:*

(*a*) *An object* $\mathscr{F} \in \mathrm{WCoh}(\mathrm{Spf}\, A)$ *is nilcoherent if and only if it is* I*-nilpotent.*

(*b*) *An object* $\mathscr{F} \in \mathrm{WCoh}(\mathrm{Spf}\, A)$ *is quasi-coherent if and only if it is* I*-complete.*

Proof. Combine Proposition 8.3.2.2 with Corollaries 8.2.3.7 and 8.2.4.10. □

Corollary 8.3.2.4. *Let* $f : \mathfrak{X} \to \mathfrak{Y}$ *be a morphism of formal spectral Deligne-Mumford stacks. Then the functor* $f^* : \mathrm{Mod}_{\mathscr{O}_{\mathfrak{Y}}} \to \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ *carries* $\mathrm{WCoh}^{\circ}(\mathfrak{Y})$ *to* $\mathrm{WCoh}^{\circ}(\mathfrak{X})$*.*

Proof. Without loss of generality, we can assume that $\mathfrak{X} \simeq \mathrm{Spf}\, B$ and $\mathfrak{Y} \simeq \mathrm{Spf}\, A$ are affine, and that f is induced by a morphism of adic $\mathbb{E}_\infty$-rings. In this case, we can regard the pullback $f^* : \mathrm{Mod}_{\mathscr{O}_{\mathfrak{Y}}} \to \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ as an A-linear functor. Let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition. Then f^* carries I-local objects of $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{Y}}}$ to I-local objects of $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$, which are then also J-local for any finitely generated ideal of definition $J \subseteq \pi_0 B$. The desired result now follows from the criterion of Proposition 8.3.2.2. □

Proof of Proposition 8.3.2.1. Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a morphism of formal spectral Deligne-Mumford stacks and let $\mathscr{F} \in \mathrm{WCoh}(\mathfrak{Y})$; we wish to show that $f^* \mathscr{F}$ is weakly quasi-coherent. Using Corollary 8.2.3.7, we obtain a fiber sequence $\mathscr{F}' \to \mathscr{F} \to \mathscr{F}''$ where $\mathscr{F}'$ is nilcoherent and $\mathscr{F}'' \in \mathrm{WCoh}^{\circ}(\mathfrak{Y})$. It follows from Proposition 8.3.2.2 that $f^* \mathscr{F}''$ is weakly quasi-coherent. It will therefore suffice to show that $f^* \mathscr{F}'$ is weakly quasi-coherent. We may therefore replace $\mathscr{F}$ by $\mathscr{F}'$ and thereby reduce to the case where $\mathscr{F}$ is nilcoherent.

Working locally on $\mathfrak{Y}$, we may further assume that $\mathfrak{Y} \simeq \mathrm{Spf}\, A$ for some adic $\mathbb{E}_\infty$-ring A. Let us regard $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{Y}}}$ and $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ as A-linear stable ∞-categories and f^* as an A-linear functor. Set $M = \Gamma(\mathfrak{Y}; \mathscr{F})$. Our assumption that $\mathscr{F}$ is nilcoherent guarantees that the canonical map $M \otimes_A \mathscr{O}_{\mathfrak{Y}} \to \mathscr{F}$ is an equivalence (see the proof of Proposition 8.2.1.3). We therefore obtain equivalences

$$f^* \mathscr{F} \simeq M \otimes_A f^* \mathscr{O}_{\mathfrak{Y}} \simeq M \otimes_A \mathscr{O}_{\mathfrak{X}}.$$

The full subcategory $\mathrm{WCoh}(\mathfrak{X}) \subseteq \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ is closed under small colimits and desuspensions (Remark 8.2.3.5), and is therefore an A-linear subcategory of $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$. The desired result now follows from the weak quasi-coherence of the structure sheaf $\mathscr{O}_{\mathfrak{X}}$ (Example 8.2.3.3). □

In the case of a representable morphism, Proposition 8.3.2.1 admits the following refinement:

Proposition 8.3.2.5. *Let* $f : \mathfrak{X} \to \mathfrak{Y}$ *be a representable morphism of formal spectral Deligne-Mumford stacks. Then the pullback functor* $f^* : \mathrm{Mod}_{\mathscr{O}_{\mathfrak{Y}}} \to \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ *carries nilcoherent sheaves on* $\mathfrak{Y}$ *to nilcoherent sheaves on* $\mathfrak{X}$*.*

Proof. Working locally on $\mathfrak{X}$ and $\mathfrak{Y}$, we can assume that $\mathfrak{Y} = \operatorname{Spf} A$ and $\mathfrak{X} = \operatorname{Spf} B$ are affine. Moreover, we may assume without loss of generality that B is complete (Remark 8.1.2.4), so that f is induced by a morphism of adic $\mathbb{E}_\infty$-rings $A \to B$. Let us regard $\operatorname{Mod}_{\mathscr{O}_\mathfrak{Y}}$ and $\operatorname{Mod}_{\mathscr{O}_\mathfrak{X}}$ as stable A-linear ∞-categories (so that the pullback functor f^* is A-linear). Let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition. Let $\mathscr{F} \in \operatorname{NilCoh}(\mathfrak{Y})$ and set $M = \Gamma(\mathfrak{Y}; \mathscr{F})$, so that M is an I-nilpotent A-module and $\mathscr{F} \simeq M \otimes_A \mathscr{O}_\mathfrak{Y}$.

$$f^* \mathscr{F} \simeq M \otimes_A (f^* \mathscr{O}_\mathfrak{Y}) \simeq M_B \otimes_B (f^* \mathscr{O}_\mathfrak{X}),$$

where $M_B = M \otimes_A B$. Note that $M \otimes_A B$ is $I(\pi_0 B)$-nilpotent. Our representability assumption guarantees that $I(\pi_0 B)$ is an ideal of definition for $\pi_0 B$ (Proposition 8.3.1.7), so that $f^* \mathscr{F}$ is also nilcoherent. □

In the case where $f : \mathfrak{X} \to \mathfrak{Y}$ is not representable, the conclusion of Proposition 8.3.2.5 generally does not hold without some additional assumptions. For example, we have the following:

Proposition 8.3.2.6. *Let* X *be a spectral Deligne-Mumford stack, let* $K \subseteq |\mathsf{X}|$ *be a cocompact closed subset, and let* $i : \mathsf{X}^\wedge_K \to \mathsf{X}$ *exhibit* $\mathsf{X}^\wedge_K$ *as a formal completion of* X *along* K*. If* $\mathscr{F} \in \operatorname{QCoh}(\mathsf{X})$ *is supported on* K*, then* $i^* \mathscr{F}$ *is nilcoherent.*

Proof. The assertion is local, so we may assume without loss of generality that $\mathsf{X} \simeq \operatorname{Spét} A$ is affine and that K is the vanishing locus of some finitely generated ideal $I \subseteq \pi_0 A$. In this case, our assumption that $\mathscr{F}$ is supported on K guarantees that $M = \Gamma(\mathsf{X}; \mathscr{F})$ is an I-nilpotent A-module. We then have $\mathscr{F} \simeq M \otimes_A \mathscr{O}_\mathsf{X}$, so that $f^* \mathscr{F} = M \otimes_A \mathscr{O}_{\mathsf{X}^\wedge_K}$ is nilcoherent as desired (see the proof of Proposition 8.2.1.3). □

Remark 8.3.2.7. In the situation of Proposition 8.3.2.6, the pullback functor $i^* : \operatorname{QCoh}_K(\mathsf{X}) \to \operatorname{NilCoh}(\mathfrak{X}^\wedge_K)$ is homotopy inverse to the equivalence $i_* : \operatorname{NilCoh}(\mathfrak{X}^\wedge_K) \to \operatorname{QCoh}_K(\mathsf{X})$ of Corollary 8.2.1.6.

We now consider the behavior of quasi-coherent sheaves with respect to pullback. Here, the situation is a bit more subtle: if $f : \mathfrak{X} \to \mathfrak{Y}$ is a morphism of formal spectral Deligne-Mumford stacks, then the pullback functor $f^* : \operatorname{WCoh}(\mathfrak{Y}) \to \operatorname{WCoh}(\mathfrak{X})$ need not carry quasi-coherent sheaves to quasi-coherent sheaves. Nevertheless, there is a well-defined *completed* pullback functor $f^\star : \operatorname{QCoh}(\mathfrak{Y}) \to \operatorname{QCoh}(\mathfrak{X})$.

Notation 8.3.2.8. Let $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{Mod}}$ be the ∞-category of Notation 2.2.1.3, whose objects are triples $(\mathcal{X}, \mathscr{O}, \mathscr{F})$ where $\mathcal{X}$ is an ∞-topos, $\mathscr{O}$ is a strictly Henselian sheaf of $\mathbb{E}_\infty$-rings on $\mathcal{X}$, and $\mathscr{F}$ is a $\mathscr{O}$-module. We let $\mathrm{fSpDM}_{\mathrm{WCoh}}$ denote the full subcategory of $\infty\mathcal{T}\mathrm{op}^{\mathrm{sHen}}_{\mathrm{Mod}}$ spanned by those triples $(\mathcal{X}, \mathscr{O}, \mathscr{F})$ where $(\mathcal{X}, \mathscr{O})$ is a formal spectral Deligne-Mumford stack and $\mathscr{F}$ is weakly quasi-coherent. It follows from Proposition 8.3.2.1 that the forgetful functor $(\mathcal{X}, \mathcal{O}, \mathscr{F}) \mapsto (\mathcal{X}, \mathcal{O})$ determines a Cartesian fibration $\mathrm{fSpDM}_{\mathrm{WCoh}} \to \mathrm{fSpDM}$, whose fiber over a formal spectral Deligne-Mumford stack $\mathfrak{X}$ can be identified with the ∞-category $\mathrm{WCoh}(\mathfrak{X})^{\mathrm{op}}$. We let $\mathrm{fSpDM}_{\mathrm{QCoh}}$ denote the full subcategory of $\mathrm{fSpDM}_{\mathrm{WCoh}}$ spanned by those triples $(\mathcal{X}, \mathcal{O}, \mathscr{F})$ where $\mathscr{F}$ is quasi-coherent.

Proposition 8.3.2.9. *The forgetful functor* $q : \mathrm{fSpDM}_{\mathrm{QCoh}} \to \mathrm{fSpDM}$ *is a Cartesian fibration.*

Remark 8.3.2.10. We can summarize the contents of Proposition 8.3.2.9 more informally as follows: the construction $\mathfrak{X} \mapsto \mathrm{QCoh}(\mathfrak{X})$ can be regarded as a functor $(\mathrm{fSpDM})^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_{\infty}$, which assigns to each morphism $f : \mathfrak{X} \to \mathfrak{Y}$ a functor $f^{\star} : \mathrm{QCoh}(\mathfrak{Y}) \to \mathrm{QCoh}(\mathfrak{X})$. We will see below that the functor $f^{\star}$ is given on objects by the formula $f^{\star} \mathscr{F} = (f^* \mathscr{F})^{\wedge}$. We will refer to $f^{\star}$ as the *completed pullback functor* associated to f.

Proof of Proposition 8.3.2.9. Let $f : \mathfrak{Y} = (\mathcal{Y}, \mathcal{O}_{\mathfrak{Y}}) \to (\mathcal{Z}, \mathcal{O}_{\mathfrak{Z}}) = \mathfrak{Z}$ be a morphism of formal spectral Deligne-Mumford stacks and let $\mathscr{F} \in \mathrm{QCoh}(\mathfrak{Z})$. Then $f^* \mathscr{F}$ is weakly quasi-coherent, so its completion $\mathscr{F}' = (f^* \mathscr{F})^{\wedge}$ can be regarded as an object of $\mathrm{QCoh}(\mathfrak{Y})$. The composite map $u : \mathscr{F} \to f_* f^* \mathscr{F} \to f_* \mathscr{F}'$ determines a lift of f to a morphism $\overline{f} : (\mathcal{Y}, \mathcal{O}_{\mathfrak{Y}}, \mathscr{F}') \to (\mathcal{Z}, \mathcal{O}_{\mathfrak{Z}}, \mathscr{F})$ in the ∞-category $\mathrm{fSpDM}_{\mathrm{QCoh}}$. We claim that $\overline{f}$ is q-Cartesian. To prove this, we must show that for every morphism of formal spectral Deligne-Mumford stacks $g : \mathfrak{X} \to \mathfrak{Y}$ and every object $\mathscr{G} \in \mathrm{QCoh}(\mathfrak{X})$, composition with u induces a homotopy equivalence

$$\rho : \mathrm{Map}_{\mathrm{QCoh}(\mathfrak{Y})}(\mathscr{F}', g_* \mathscr{G}) \to \mathrm{Map}_{\mathrm{QCoh}(\mathfrak{Z})}(\mathscr{F}, (f \circ g)_* \mathscr{G}).$$

Unwinding the definitions, we can identify ρ with the first map appearing in the fiber sequence

$$\mathrm{Map}_{\mathrm{WCoh}(\mathfrak{X})}(g^* \mathscr{F}', \mathscr{G}) \to \mathrm{Map}_{\mathrm{WCoh}(\mathfrak{X})}((f \circ g)^* \mathscr{F}, \mathscr{G}) \to \mathrm{Map}_{\mathrm{WCoh}(\mathfrak{X})}(g^* \mathrm{fib}(f^* \mathscr{F} \to \mathscr{F}'), \mathscr{G}).$$

To prove that ρ is a homotopy equivalence, it will suffice to show that the mapping space $\mathrm{Map}_{\mathrm{WCoh}(\mathfrak{X})}(g^* \mathrm{fib}(f^* \mathscr{F} \to \mathscr{F}'), \mathscr{G})$ is contractible. By virtue of our assumption that $\mathscr{G}$ is quasi-coherent, we are reduced to showing that $g^* \mathrm{fib}(f^* \mathscr{F} \to \mathscr{F}')$ belongs to $\mathrm{WCoh}^{\circ}(\mathfrak{X})$ (Corollary 8.2.4.10). This follows from Proposition 8.3.2.2, since $\mathrm{fib}(f^* \mathscr{F} \to \mathscr{F}')$ belongs to $\mathrm{WCoh}^{\circ}(\mathfrak{Y})$ (again by virtue of Corollary 8.2.4.10). □

Remark 8.3.2.11. The inclusion functor $\mathrm{fSpDM}_{\mathrm{QCoh}} \hookrightarrow \mathrm{fSpDM}_{\mathrm{WCoh}}$ admits a right adjoint relative to fSpDM. In particular, for every morphism $f : \mathfrak{X} \to \mathfrak{Y}$ of formal spectral Deligne-Mumford stacks, the diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{WCoh}(\mathfrak{Y}) & \xrightarrow{f^*} & \mathrm{WCoh}(\mathfrak{X}) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathfrak{Y}) & \xrightarrow{f^{\star}} & \mathrm{QCoh}(\mathfrak{X}) \end{array}$$

commutes up to canonical equivalence, where the vertical maps are given by the completion functors of Construction 8.2.4.1. It follows that we can regard $f^\star : \mathrm{QCoh}(\mathfrak{Y}) \to \mathrm{QCoh}(\mathfrak{X})$ as a symmetric monoidal functor, where $\mathrm{QCoh}(\mathfrak{X})$ and $\mathrm{QCoh}(\mathfrak{Y})$ are equipped with the symmetric monoidal structure described in Corollary 8.2.4.22.

Remark 8.3.2.12. Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a morphism of formal spectral Deligne-Mumford stacks. If $\mathfrak{X}$ is a spectral Deligne-Mumford stack, then the completion functor $\mathrm{WCoh}(\mathfrak{X}) \to \mathrm{QCoh}(\mathfrak{X})$ is equivalent to the identity. Consequently, the completed pullback functor $f^\star$ of Remark 8.3.2.10 coincides with the usual pullback functor f^* (restricted to the ∞-category $\mathrm{QCoh}(\mathfrak{Y})$).

Remark 8.3.2.13. Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a morphism of formal spectral Deligne-Mumford stacks. Then the completed pullback functor $f^\star : \mathrm{QCoh}(\mathfrak{Y}) \to \mathrm{QCoh}(\mathfrak{X})$ is right t-exact: that is, it carries $\mathrm{QCoh}(\mathfrak{Y})^{\mathrm{cn}}$ into $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{cn}}$. This follows from Remark 8.2.5.9, since the pullback functor $f^* : \mathrm{WCoh}(\mathfrak{Y}) \to \mathrm{WCoh}(\mathfrak{X})$ carries $\mathrm{WCoh}(\mathfrak{Y})^{\mathrm{cn}}$ into $\mathrm{WCoh}(\mathfrak{X})^{\mathrm{cn}}$.

8.3.3 Direct Images of Quasi-Coherent Sheaves

Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a morphism of formal spectral Deligne-Mumford stacks. Then f determines a direct image functor $f_* : \mathrm{Mod}_{\mathscr{O}_\mathfrak{X}} \to \mathrm{Mod}_{\mathscr{O}_\mathfrak{Y}}$. In good cases, this functor preserves quasi-coherence:

Proposition 8.3.3.1. *Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a morphism of formal spectral Deligne-Mumford stacks. Assume that f is representable by quasi-compact, quasi-separated spectral algebraic spaces: that is, for every map $\mathrm{Sp\acute{e}t}\, R \to \mathfrak{Y}$, the fiber product $\mathrm{Sp\acute{e}t}\, R \times_\mathfrak{Y} \mathfrak{X}$ is a quasi-compact, quasi-separated spectral algebraic space. Then the direct image functor $f_* : \mathrm{Mod}_{\mathscr{O}_\mathfrak{X}} \to \mathrm{Mod}_{\mathscr{O}_\mathfrak{Y}}$ carries $\mathrm{QCoh}(\mathfrak{X})$ into $\mathrm{QCoh}(\mathfrak{Y})$.*

The proof depends on the following:

Lemma 8.3.3.2. *Let A be an adic $\mathbb{E}_\infty$-ring with a finitely generated ideal of definition $I \subseteq \pi_0 A$, and let $f : \mathfrak{X} \to \mathrm{Spf}\, A$ be a representable morphism of formal spectral Deligne-Mumford stacks. The following conditions are equivalent:*

- (a) *The formal spectral Deligne-Mumford stack $\mathfrak{X}$ is affine.*
- (b) *The spectral Deligne-Mumford stack $\mathfrak{X} \times_{\mathrm{Spf}\, A} \mathrm{Sp\acute{e}t}(\pi_0 A/I)$ is affine.*

Proof. The implication $(a) \Rightarrow (b)$ is clear. Suppose that (b) is satisfied. Applying Lemma 17.1.3.7 repeatedly, we deduce the following stronger version of (b):

- (b') Let $J \subseteq \pi_0 A$ be an ideal containing I^n for some $n \gg 0$. Then the spectral Deligne-Mumford stack $\mathfrak{X} \times_{\mathrm{Spf}\, A} \mathrm{Sp\acute{e}t}(\pi_0 A/J)$ is affine.

Let $\{A_n\}_{n>0}$ be a tower of A-algebras satisfying the requirements of Lemma 8.1.2.2. Combining (b') with Corollary **??**, we deduce that $\mathfrak{X} \times_{\operatorname{Spf} A} \operatorname{Spét} A_n$ is affine for $n > 0$. Write $\mathfrak{X} \times_{\operatorname{Spf} A} \operatorname{Spét} A_n \simeq \operatorname{Spét} B_n$ for some $B_n \in \mathrm{CAlg}^{\mathrm{cn}}_{A_n}$. Then we can regard $\{B_n\}_{n>0}$ as a commutative algebra object of $\varprojlim \mathrm{Mod}^{\mathrm{cn}}_{A_n}$. Let $B \in \mathrm{CAlg}^{\mathrm{cn}}_A$ denote the image of the tower $\{B_n\}_{n>0}$ under the (symmetric monoidal) equivalence $\varprojlim \mathrm{Mod}^{\mathrm{cn}}_{A_n} \simeq (\mathrm{Mod}^{\mathrm{Cpl}(I)}_A)^{\mathrm{cn}}$ supplied by Proposition 8.3.4.4. Let us regard B as an adic $\mathbb{E}_\infty$-ring with ideal of definition $I(\pi_0 B)$. Using Proposition 8.1.5.2, we deduce that $\mathfrak{X}$ and $\operatorname{Spf} B$ represent the same functor $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, and are therefore equivalent (Theorem 8.1.5.1). □

Lemma 8.3.3.3. *Let $\phi : A \to B$ be a morphism of adic $\mathbb{E}_\infty$-rings and let $f : \operatorname{Spf} B \to \operatorname{Spf} A$ be the induced map of formal spectra. Assume that f is representable. Then the direct image functor $f_* : \mathrm{Mod}_{\mathscr{O}_{\operatorname{Spf} B}} \to \mathrm{Mod}_{\mathscr{O}_{\operatorname{Spf} A}}$ carries $\mathrm{QCoh}(\operatorname{Spf} B)$ to $\mathrm{QCoh}(\operatorname{Spf} A)$.*

Proof. Let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition, so that $I(\pi_0 B)$ is an ideal of definition for B. Let $\mathscr{F} \in \mathrm{QCoh}(\operatorname{Spf} B)$ and set $M = \Gamma(\operatorname{Spf} B; \mathscr{F}) \in \mathrm{Mod}_B$. As a spectrum-valued functor on $\mathcal{S}\mathrm{hv}^{\mathrm{ad}}_B$, we can identify $\mathscr{F}$ with the functor given by $B' \mapsto (M \otimes_B B')^\wedge_I$ (see Remark 8.2.4.16). It follows that $f_* \mathscr{F}$ can be identified with the functor $\mathrm{CAlg}^{\text{ét}}_A \to \mathrm{Sp}$ given by $A' \mapsto (M \otimes_B (B \otimes_A A')^\wedge_I \simeq (M \otimes_A A')^\wedge_I$, and is therefore quasi-coherent (Remark 8.2.4.16). □

Proof of Proposition 8.3.3.1. Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a morphism of formal spectral Deligne-Mumford stacks which is representable by quasi-compact, quasi-separated spectral algebraic spaces and let $\mathscr{F} \in \mathrm{QCoh}(\mathfrak{X})$; we wish to show that $f_* \mathscr{F}$ is quasi-coherent. This can be tested locally on $\mathfrak{Y}$ (Proposition 8.2.4.17), so we may assume without loss of generality that $\mathfrak{Y} = \operatorname{Spf} A$ is affine. Let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition and set $R = (\pi_0 A)/I$. Let $\mathcal{X}$ be the underlying ∞-topos of $\mathfrak{X}$, and for each object $U \in \mathcal{X}$ set $\mathfrak{X}_U = (\mathcal{X}_{/U}, \mathscr{O}_{\mathfrak{X}}|_U)$ and let $f_U : \mathfrak{X}_U \to \mathfrak{Y}$ be the canonical map. Let us say that U is *good* if $f_{U*}(\mathscr{F}|_U) \in \mathrm{Mod}_{\mathscr{O}_{\mathfrak{Y}}}$ is quasi-coherent. The collection of good objects of $\mathcal{X}$ contains all affine objects (Lemma 8.3.3.3) and is closed under finite colimits. Write $\operatorname{Spét} R \times_{\mathfrak{Y}} \mathfrak{X} \simeq (\mathcal{X}, \mathscr{O}_0)$. Note that an object $U \in \mathcal{X}$ is affine if and only if the spectral Deligne-Mumford stack $(\mathcal{X}_{/U}, \mathscr{O}_0|_U)$ is affine. Since $(\mathcal{X}, \mathscr{O}_0)$ is a quasi-compact, quasi-separated spectral algebraic space, Combining Proposition 2.5.3.5 with Theorem 3.4.2.1, we deduce that the final object of $\mathcal{X}$ is good, so that $f_* \mathscr{F}$ is quasi-coherent. □

Remark 8.3.3.4. In the situation of Proposition 8.3.3.1, the direct image functor $f_* : \mathrm{QCoh}(\mathfrak{X}) \to \mathrm{QCoh}(\mathfrak{Y})$ can be regarded as a right adjoint to the completed pullback functor $f^\star : \mathrm{QCoh}(\mathfrak{Y}) \to \mathrm{QCoh}(\mathfrak{X})$ of Remark 8.3.2.10.

Remark 8.3.3.5. In the situation of Proposition 8.3.3.1, if $\mathscr{F} \in \mathrm{QCoh}(\mathfrak{X})$ is almost connective, then $f_* \mathscr{F} \in \mathrm{QCoh}(\mathfrak{Y})$ is almost connective.

Proposition 8.3.3.6. *Suppose we are given a pullback diagram of formal spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathfrak{X}' & \xrightarrow{g'} & \mathfrak{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathfrak{Y}' & \xrightarrow{g} & \mathfrak{Y}. \end{array}$$

Assume that f is representable by quasi-compact, quasi-separated spectral algebraic spaces (so that f' has the same property). Then the diagram of completed pullback functors

$$\begin{array}{ccc} \mathrm{QCoh}(\mathfrak{Y}) & \xrightarrow{f^\star} & \mathrm{QCoh}(\mathfrak{X}) \\ \downarrow{\scriptstyle g^\star} & & \downarrow{\scriptstyle g'^\star} \\ \mathrm{QCoh}(\mathfrak{Y}') & \xrightarrow{g'^\star} & \mathrm{QCoh}(\mathfrak{X}') \end{array}$$

is right adjointable. In other words, for every quasi-coherent sheaf $\mathscr{F} \in \mathrm{QCoh}(\mathfrak{X})$, the Beck-Chevalley map $\rho : g^\star f_* \mathscr{F} \to f'_* g'^\star \mathscr{F}$ is an equivalence.

Proof. The assertion is local on both $\mathfrak{Y}$ and $\mathfrak{Y}'$, so we can assume that $\mathfrak{Y} \simeq \mathrm{Spf}\, A$ and $\mathfrak{Y}' \simeq \mathrm{Spf}\, A'$ are affine. Write $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$. For each object $U \in \mathcal{X}$, set $\mathfrak{X}_U = (\mathcal{X}_{/U}, \mathscr{O}_{\mathfrak{X}}|_U)$ and $\mathfrak{X}'_U = \mathfrak{X}' \times_{\mathfrak{X}} \mathfrak{X}_U$, so that we have a pullback diagram

$$\begin{array}{ccc} \mathfrak{X}'_U & \xrightarrow{g'_U} & \mathfrak{X}_U \\ \downarrow{\scriptstyle f'_U} & & \downarrow{\scriptstyle f_U} \\ \mathfrak{Y}' & \xrightarrow{g} & \mathfrak{Y}. \end{array}$$

Let us say that U is *good* if the induced map $g^\star f_{U*} \mathscr{F}|_U \to f'_{U*} g'^\star_U \mathscr{F}|_U$ is an equivalence. To complete the proof, it will suffice to show that the final object of $\mathcal{X}$ is good. Note that the collection of good objects of $\mathcal{X}$ is closed under pushouts. Arguing as in the proof of Proposition 8.3.3.1, we are reduced to showing that every affine object of $\mathcal{X}$ is good. We are therefore reduced to proving Proposition 8.3.3.6 in the special case where $\mathfrak{X} \simeq \mathrm{Spf}\, B$ is also affine. Let $I' \subseteq \pi_0 A'$ be a finitely generated ideal of definition, so that $\mathfrak{X}' \simeq \mathrm{Spf}\, B'$, where $B' = A' \otimes_A B$ is regarded as an adic $\mathbb{E}_\infty$-ring with ideal of definition $I'(\pi_0 B')$. It now suffices to observe that the domain and codomain of ρ can be identified with the quasi-coherent sheaf on $\mathrm{Spf}\, A'$ associated to the I'-completion of $A' \otimes_A \Gamma(\mathrm{Spf}\, B; \mathscr{F}) \simeq B' \otimes_B \Gamma(\mathrm{Spf}\, B; \mathscr{F})$. □

8.3.4 Quasi-Coherent Sheaves on Functors

In §6.2, we introduced the ∞-category $\mathrm{QCoh}(X)$ of quasi-coherent sheaves on an arbitrary functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ (Definition 6.2.2.1). In the special case where X is representable by a spectral Deligne-Mumford stack X, we have a canonical equivalence of ∞-categories $\mathrm{QCoh}(X) \simeq \mathrm{QCoh}(\mathsf{X})$ (Proposition 6.2.4.1). We now prove a similar (but slightly weaker) result in the setting of formal spectral Deligne-Mumford stacks.

Construction 8.3.4.1. Let fSpDM denote the ∞-category of formal spectral Deligne-Mumford stacks. It follows from Proposition 8.3.2.9 that we can regard the construction $\mathfrak{X} \to \mathrm{QCoh}(\mathfrak{X})$ as a functor $\mathrm{QCoh} : (\mathrm{fSpDM})^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$. Moreover, the composite functor

$$\mathrm{CAlg}^{\mathrm{cn}} \xrightarrow{\mathrm{Sp\acute{e}t}} (\mathrm{fSpDM})^{\mathrm{op}} \xrightarrow{\mathrm{NilCoh}} \widehat{\mathcal{C}\mathrm{at}}_\infty$$

can be identified with the functor $A \mapsto \mathrm{Mod}_A$ (see Example 8.2.4.8) Note that this composite functor admits a right Kan extension along the fully faithful embedding $\mathrm{Sp\acute{e}t} : \mathrm{CAlg}^{\mathrm{cn}} \to (\mathrm{fSpDM})^{\mathrm{op}}$, given by the construction $\mathfrak{X} \mapsto \mathrm{QCoh}(h_{\mathfrak{X}})$ of Definition 6.2.2.1; here $h_{\mathfrak{X}}$ denotes the functor represented by $\mathfrak{X}$. We therefore obtain a canonical map $\Theta_{\mathfrak{X}} : \mathrm{QCoh}(\mathfrak{X}) \to \mathrm{QCoh}(h_{\mathfrak{X}})$, which depends functorially on $\mathfrak{X}$ and is an equivalence when $\mathfrak{X} = \mathrm{Sp\acute{e}t}\, A$ for some connective $\mathbb{E}_\infty$-ring A.

Remark 8.3.4.2. Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then the ∞-category $\mathrm{QCoh}(h_{\mathfrak{X}})$ can be described informally as follows: an object of $\mathrm{QCoh}(h_{\mathfrak{X}})$ is rule which assigns to each map $\eta : \mathrm{Sp\acute{e}t}\, R \to \mathfrak{X}$ an R-module M_η, which is functorial in the sense that if $\eta' : \mathrm{Sp\acute{e}t}\, R' \to \mathfrak{X}$ is given by a composition $\mathrm{Sp\acute{e}t}\, R' \to \mathrm{Sp\acute{e}t}\, R \xrightarrow{\eta} \mathfrak{X}$, then we have a canonical equivalence $M_{\eta'} \times R' \otimes_R M_\eta$. We can describe the functor $\Theta_{\mathfrak{X}}$ of Construction 8.3.4.1 as follows: if $\mathscr{F} \in \mathrm{QCoh}(\mathfrak{X})$ is a quasi-coherent sheaf on $\mathfrak{X}$, then $\Theta_{\mathfrak{X}}(\mathscr{F})$ is the quasi-coherent sheaf on $h_{\mathfrak{X}}$ given by $\Theta_{\mathfrak{X}}(\mathscr{F})_\eta = \Gamma(\mathrm{Sp\acute{e}t}\, R; \eta^* \mathscr{F})$.

Remark 8.3.4.3. In the special case where X is a spectral Deligne-Mumford stack, the functor Θ_{X} coincides with the equivalence $\mathrm{QCoh}(\mathsf{X}) \simeq \mathrm{QCoh}(h_{\mathsf{X}})$ of Proposition 6.2.4.1.

We can now formulate our main result:

Theorem 8.3.4.4. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then the functor $\Theta_{\mathfrak{X}} : \mathrm{QCoh}(\mathfrak{X}) \to \mathrm{QCoh}(h_{\mathfrak{X}})$ induces an equivalence of ∞-categories $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{cn}} \to \mathrm{QCoh}(h_{\mathfrak{X}})^{\mathrm{cn}}$.*

Remark 8.3.4.5. We do not know if the connectivity hypotheses appearing in Theorem 8.3.4.4 can be dropped: that is, we do not know if the map $\Theta_{\mathfrak{X}}$ is itself an equivalence of ∞-categories. However, the analogous assertion holds in the setting of (formal) derived algebraic geometry. In particular, one can show that the map $\Theta_{\mathfrak{X}}$ is an equivalence if there exists a map $\mathfrak{X} \to \mathrm{Sp\acute{e}t}\, \mathbf{Q}$.

Proof of Theorem 8.3.4.4. Without loss of generality, we may assume that $\mathfrak{X}$ is affine. Choose an equivalence $\mathfrak{X} \simeq \mathrm{Spf}\, A$, where A is an adic $\mathbb{E}_\infty$-ring. Let $I \subseteq \pi_0 A$ be a finitely generated idea l of definition and let $\{A_n\}_{n>0}$ be a tower of $\mathbb{E}_\infty$-algebras over A which satisfies the requirements of Lemma 8.1.2.2. We then have an equivalence of functors $h_{\mathfrak{X}} \simeq \varinjlim \operatorname{Spec} A_n$, hence an equivalence of ∞-categories $\operatorname{QCoh}(h_{\mathfrak{X}}) \simeq \varprojlim \operatorname{Mod}_{A_n}$. Corollary 8.2.4.15 supplies an equivalence of ∞-categories $\operatorname{QCoh}(\mathfrak{X}) \simeq \operatorname{Mod}_A^{\operatorname{Cpl}(I)}$. Under these equivalences, we can identify $\Theta_{\mathfrak{X}}$ with the functor $F : \operatorname{Mod}_A^{\operatorname{Cpl}(I)} \to \varprojlim \operatorname{Mod}_{A_n}$ given on objects by $M \mapsto \{A_n \otimes_A M\}_{n>0}$. This functor admits a right adjoint G, which carries a compatible system $\{M_n \in \operatorname{Mod}_{A_n}\}_{n \geqslant 0}$ to the limit $G(\{M_n\}) = \varprojlim_n M_n \in \operatorname{Mod}_A$. By assumption each of the maps $A_{n+1} \to A_n$ is surjective on π_0. It follows that if each M_k is connective, then each of the maps $M_{n+1} \to A_n \otimes_{A_{n+1}} M_{n+1} \to M_n$ is surjective on π_0. In particular, $G(\{M_n\})$ is a connective A-module and each of the maps $G(\{M_n\}) \to M_n$ is surjective on π_0. Consequently, the restrictions of F and G yield a pair of adjoint functors

$$\operatorname{Mod}_A^{\operatorname{Cpl}(I)} \cap \operatorname{Mod}_A^{\operatorname{cn}} \underset{G^{\operatorname{cn}}}{\overset{F^{\operatorname{cn}}}{\rightleftarrows}} \varprojlim \operatorname{Mod}_{A_n}^{\operatorname{cn}}.$$

We wish to show that F^{cn} and G^{cn} are mutually inverse equivalences.

It follows from Lemma 8.1.2.3 that the unit map $\operatorname{id} \to G^{\operatorname{cn}} \circ F^{\operatorname{cn}}$ is an equivalence: that is, the functor F^{cn} induces a fully faithful embedding $\operatorname{Mod}_A^{\operatorname{Cpl}(I)} \cap \operatorname{Mod}_A^{\operatorname{cn}} \to \varprojlim \operatorname{Mod}_{A_n}^{\operatorname{cn}}$. To complete the proof, it will therefore suffice to show that the functor G^{cn} is conservative. Since G is an exact functor between stable ∞-categories, it will suffice to show that if $\{M_n\}$ is an object of $\varprojlim \operatorname{Mod}_{A_n}^{\operatorname{cn}}$ satisfying $G(\{M_n\}) \simeq 0$, then each $M_n \in \operatorname{Mod}_{A_n}$ vanishes. We prove by induction k that $\pi_i M_n \simeq 0$ for $i \leqslant k$. When $k = 0$, this follows from our observation that each of the maps $\pi_0 G(\{M_n\}) \to \pi_0 M_n$ is surjective. If $k > 0$, the inductive hypothesis implies that $\{M_n\}$ is the k-fold suspension of an object $\{N_n\} \in \varprojlim \operatorname{Mod}_{A_n}^{\operatorname{cn}}$. Then $G(\{N_n\}) \simeq 0$ and we can apply the inductive hypothesis to deduce that $\pi_k M_n \simeq \pi_0 N_n \simeq 0$. □

Corollary 8.3.4.6. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then the functor $\Theta_{\mathfrak{X}} : \operatorname{QCoh}(\mathfrak{X}) \to \operatorname{QCoh}(h_{\mathfrak{X}})$ induces an equivalence of ∞-categories $F : \operatorname{QCoh}(\mathfrak{X})^{\operatorname{acn}} \to \operatorname{QCoh}(h_{\mathfrak{X}})^{\operatorname{acn}}$.*

Proof. The assertion is local on $\mathfrak{X}$, so we may assume without loss of generality that $\mathfrak{X}$ is affine. In this case, we can write F as a filtered colimit of functors $F_{\geqslant -n} : \Sigma^{-n} \operatorname{QCoh}(\mathfrak{X})^{\operatorname{cn}} \to \Sigma^{-n} \operatorname{QCoh}(h_{\mathfrak{X}})^{\operatorname{cn}}$, each of which is an equivalence by virtue of Theorem 8.3.4.4. □

Under mild hypotheses, the equivalence of Theorem 8.3.4.4 is compatible with the formation of direct images:

Proposition 8.3.4.7. *Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a morphism of formal spectral Deligne-Mumford stacks. Assume that f is representable by quasi-compact, quasi-separated spectral algebraic spaces (see Proposition 8.3.3.1). Let $X, Y : \operatorname{CAlg}^{\operatorname{cn}} \to \mathcal{S}$ denote the functors represented by $\mathfrak{X}$ and $\mathfrak{Y}$, respectively, so that f determines a natural transformation $F : X \to Y$. Then the* *commutative diagram of ∞-categories*

$$\begin{array}{ccc} \mathrm{QCoh}(\mathfrak{Y}) & \xrightarrow{f^*} & \mathrm{QCoh}(\mathfrak{X}) \\ \downarrow{\scriptstyle \Theta_{\mathfrak{Y}}} & & \downarrow{\scriptstyle \Theta_{\mathfrak{X}}} \\ \mathrm{QCoh}(Y) & \xrightarrow{F^*} & \mathrm{QCoh}(X) \end{array}$$

is right adjointable. In other words, for every quasi-coherent sheaf $\mathscr{F} \in \mathrm{QCoh}(\mathfrak{X})$, the canonical map $\Theta_{\mathfrak{Y}}(f_* \mathscr{F}) \to F_*(\Theta_{\mathfrak{X}} \mathscr{F})$ is an equivalence in $\mathrm{QCoh}(X)$.

Proof. Apply Proposition 8.3.3.6. □

8.3.5 Finiteness Conditions on Quasi-Coherent Sheaves

We close this section by showing that the equivalence of Corollary 8.3.4.4 is compatible with several natural finiteness conditions on quasi-coherent sheaves.

Definition 8.3.5.1. Let $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack and let $\mathscr{F} \in \mathrm{QCoh}(\mathfrak{X})^{\mathrm{cn}}$. Then:

- We say that $\mathscr{F}$ is *perfect to order n* if, for every affine object $U \in \mathcal{X}$, the spectrum $\mathscr{F}(U)$ is perfect to order n when regarded as a module over $\mathscr{O}_{\mathfrak{X}}(U)$.
- We say that $\mathscr{F}$ is *almost perfect* if, for every affine object $U \in \mathcal{X}$, the spectrum $\mathscr{F}(U)$ is almost perfect when regarded as a module over $\mathscr{O}_{\mathfrak{X}}(U)$.
- We say that $\mathscr{F}$ is *perfect* if, for every affine object $U \in \mathcal{X}$, the spectrum $\mathscr{F}(U)$ is perfect when regarded as a module over $\mathscr{O}_{\mathfrak{X}}(U)$.
- We say that $\mathscr{F}$ is *locally free of finite rank* if, for every affine object $U \in \mathcal{X}$, the spectrum $\mathscr{F}(U)$ is locally free of finite rank when regarded as a module over $\mathscr{O}_{\mathfrak{X}}(U)$.

Our main result can be formulated as follows:

Theorem 8.3.5.2. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack and let $\mathscr{F} \in \mathrm{QCoh}(\mathfrak{X})$ be a quasi-coherent sheaf on $\mathfrak{X}$. Assume that $\mathscr{F}$ is almost connective. Then the following conditions are equivalent:*

(1) *The sheaf $\mathscr{F}$ is perfect to order n (almost perfect, perfect, locally free of finite rank), in the sense of Definition 8.3.5.1.*

(2) *For every morphism $f : \mathsf{X} \to \mathfrak{X}$, where X is a spectral Deligne-Mumford stack, the pullback $f^* \mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is perfect to order n (almost perfect, perfect, locally free of finite rank), in the sense of Definition 2.8.4.4.*

(3) *The image of* $\mathscr{F}$ *under the equivalence* $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{acn}} \to \mathrm{QCoh}(h_{\mathfrak{X}})^{\mathrm{acn}}$ *of Corollary 8.3.4.6 is perfect to order* n *(almost perfect, perfect, locally free of finite rank), in the sense of Definition 6.2.5.3).*

Corollary 8.3.5.3. *Let* $\mathfrak{X} = (\mathcal{X}, \mathcal{O}_{\mathfrak{X}})$ *be a formal spectral Deligne-Mumford stack and let* $\mathscr{F} \in \mathrm{QCoh}(\mathfrak{X})$. *Then:*

(a) *If* $\mathscr{F}$ *is perfect to order* n *(almost perfect, perfect, locally free of finite rank), then* $\mathscr{F}|_U \in \mathrm{QCoh}((\mathcal{X}_{/U}, \mathcal{O}_{\mathfrak{X}}|_U))$ *is also perfect to order* n *(almost perfect, perfect, locally free of finite rank).*

(b) *If* $\mathcal{X}$ *admits a covering by objects* $\{U_\alpha\}$ *such that each restriction* $\mathscr{F}|_{U_\alpha} \in \mathrm{QCoh}((\mathcal{X}_{/U_\alpha}, \mathcal{O}_{\mathfrak{X}}|_{U_\alpha}))$ *is perfect to order* n *(almost perfect, perfect, locally free of finite rank), then* $\mathscr{F}$ *is also perfect to order* n *(almost perfect, perfect, locally free of finite rank).*

Proof. Assertion (a) follows immediately from the definitions. To prove (b), we can use Theorem 8.3.5.2 to reduce to the case where $\mathfrak{X}$ is a spectral Deligne-Mumford stack, in which case the desired result follows from Propositions 2.8.4.7 and 2.9.1.4. □

The proof of Theorem 8.3.5.2 will require some preliminaries. We begin with a somewhat technical assertion.

Lemma 8.3.5.4. *Suppose we are given a tower of connective* $\mathbb{E}_\infty$*-rings*

$$\cdots \to A_3 \to A_2 \to A_1$$

having limit A, *where each of the maps* $\pi_0 A_{i+1} \to \pi_0 A_i$ *is surjection whose kernel is a nilpotent ideal of* $\pi_0 A_{i+1}$. *For every integer* $i > 0$, *suppose we are given a connective* A_i*-module* M_i, *and for* $i > 1$ *a map of* A_{i-1}*-modules* $\phi_i : A_{i-1} \otimes_{A_i} M_i \to M_{i-1}$. *Let* $n \geqslant 0$ *be an integer. Suppose that each of the spectra* $\mathrm{fib}(\phi_i)$ *is* n*-connective, and that* M_1 *is perfect to order* $(n-1)$ *if* $n > 0$. *Then:*

(1) *If* $n > 0$, *then* $M = \varprojlim M_i$ *is perfect to order* $(n-1)$, *when regarded as an* A*-module.*

(2) *For every integer* i, *let* $\psi_i : A_i \otimes_A M \to M_i$ *be the canonical map. Then* $\mathrm{fib}(\psi_i)$ *is* n*-connective.*

Proof. Since each M_i is connective and each of the maps $\pi_0 M_{i+1} \to \pi_0 M_i$ is surjective, we deduce that M is connective and that each of the maps $\pi_0 M \to \pi_0 M_i$ is surjective. This proves (2) in the case $n = 0$ (and condition (1) is automatic). We handle the general case using induction on n. Assume that $n > 0$. Then $\pi_0 M_1$ is finitely generated as a module over $\pi_0 A_1$. We may therefore choose finitely many elements $x_1, \ldots, x_k \in \pi_0 M$ whose images generate $\pi_0 M_1$. The elements x_i determine a map of A-modules $A^k \to M$, which in turn determines a compatible family of A_i-module maps $\theta_i : A_i^k \to M_i$. We claim that each of the maps θ_i is surjective on connected components. This holds by hypothesis when $i = 0$. If $i > 0$, then the image of θ_i generates $\pi_0 M_i / J \pi_0 M_i \simeq \pi_0 M_{i-1}$, where J denotes the kernel of $\pi_0 A_i \to \pi_0 A_{i-1}$, and therefore generates $\pi_0 M_i$ by Nakayama's lemma (since J is a nilpotent ideal).

For $i \geqslant 0$, form a fiber sequence $N_i \to A_i^k \to M_i$, so that each N_i is connective. Note that if $n \geqslant 2$, then N_1 is perfect to order $n-2$ as an A_1-module. Moreover, we have maps $\phi'_i : A_{i-1} \otimes_{A_i} N_i \to N_{i-1}$ such that $\mathrm{fib}(\phi'_i) \simeq \Sigma^{-1} \mathrm{fib}(\phi_i)$ is $(n-1)$-connective for each i. Let $N = \varprojlim N_i$. Applying our inductive hypothesis, we deduce that each of the maps $\psi'_i : A_i \otimes_A N \to N_i$ is $(n-1)$-connective. This proves (2), since $\mathrm{fib}(\psi_i) \simeq \Sigma \mathrm{fib}(\psi'_i)$. Note that N is connective, and is perfect to order $n-2$ if $n \geqslant 2$. Using the fiber sequence $N \to A^k \to M$, we deduce that M is perfect to order $n-1$, which proves (1). □

Proposition 8.3.5.5. *Let A be a connective $\mathbb{E}_\infty$-ring which is complete with respect to a finitely generated ideal $I \subseteq \pi_0 A$, let M be an A-module which is I-complete and almost connective, and let n be an integer. The following conditions are equivalent:*

(1) *The A-module M is perfect to order n.*

(2) *Set $R = (\pi_0 A)/I$. Then the R-module $R \otimes_A M$ is perfect to order n.*

(3) *For every morphism of connective $\mathbb{E}_\infty$-rings $f : A \to B$ which annihilates some power of I, the B-module $B \otimes_A M$ is perfect to order n.*

Proof. The implication (1) ⇒ (2) follows from Proposition 2.7.3.1 and the implication (2) ⇒ (3) from Proposition 2.7.3.2. We will complete the proof by showing that (3) implies (1). Replacing M by $\Sigma^k M$ (and n by $n+k$) for $k \gg 0$ and thereby reduce to the case where M is connective and $n \geqslant 0$. Choose a tower of A-algebras $\cdots \to A_3 \to A_2 \to A_1$ satisfying the requirements of Lemma 8.1.2.2. Since A and M are connective and I-complete, Lemma 8.1.2.3 supplies equivalences

$$A \simeq \varprojlim A_i \qquad M \simeq \varprojlim A_i \otimes_A M$$

(see Lemma 8.1.2.3). By virtue of Lemma 8.3.5.4, to show that M is perfect to order n, it will suffice to show that $A_1 \otimes_R A$ is perfect to order n, which follows immediately from assumption (3). □

Corollary 8.3.5.6. *Let A be a connective $\mathbb{E}_\infty$-ring which is complete with respect to a finitely generated ideal $I \subseteq \pi_0 A$ and let M be an A-module which is almost connective. The following conditions are equivalent:*

(1) *The A-module M is almost perfect.*

(2) *Set $R = (\pi_0 A)/I$. Then M is I-complete and the R-module $R \otimes_A M$ is almost perfect.*

(3) *The A-module M is I-complete, and for every morphism of connective $\mathbb{E}_\infty$-rings $f : A \to B$ which annihilates some power of I, the B-module $B \otimes_A M$ is almost perfect.*

Proof. Combine Propositions 7.3.5.7 and 8.3.5.5. □

Proposition 8.3.5.7. *Let A be a connective $\mathbb{E}_\infty$-ring which is complete with respect to a finitely generated ideal $I \subseteq \pi_0 A$ and let $M \in \mathrm{Mod}_A$ be almost connective. The following conditions are equivalent:*

(1) *The A-module M is locally free of finite rank.*

(2) *The A-module M is I-complete and the tensor product $R \otimes_A M$ is locally free of finite rank, where $R = (\pi_0 A)/I$.*

(3) *The A-module M is I-complete and, for every morphism of connective $\mathbb{E}_\infty$-rings $f : A \to B$ which annihilates some power of I, the B-module $B \otimes_A M$ is locally free of finite rank.*

Proof. The implication (1) $\Rightarrow$ (2) is follows from Proposition 7.3.5.7. If (2) is satisfied, then the tensor product $R \otimes_A M$ is connective, almost perfect, and of Tor-amplitude $\leqslant 0$. If $f : A \to B$ is as in (3), then $B \otimes_A M$ is likewise connective, almost perfect (Corollary 8.3.5.6), and of Tor-amplitude $\leqslant 0$ (Proposition 2.7.3.2). It follows that $B \otimes_A M$ is locally free of finite rank (Corollary 2.9.1.3), which proves (3).

We now complete the proof by showing that (3) implies (1). Assume that (3) is satisfied. Using Theorem 8.3.4.4 and Corollary 8.3.4.6, we deduce that M is connective. Corollary 8.3.5.6 shows that M is almost perfect, so the homotopy group $\pi_0 M$ is finitely presented as a module over $\pi_0 A$. We may therefore choose a map $u : A^n \to M$ which induces a surjection $\pi_0 A^n \to \pi_0 M$. To prove (1), it will suffice to show that u admits a section. For this, it suffices to show that the map

$$\phi : \mathrm{Map}_{\mathrm{Mod}_A}(M, A^n) \to \mathrm{Map}_{\mathrm{Mod}_A}(M, M)$$

is surjective on π_0. Letting K denote the cofiber of u, we are reduced to proving that the mapping space $\mathrm{Map}_{\mathrm{Mod}_A}(M, K)$ is connected. Choose a tower of $\mathbb{E}_\infty$-algebras

$$\cdots \to A_3 \to A_2 \to A_1$$

satisfying the requirements of Lemma 8.1.2.2. By virtue of Lemma 8.1.2.3, we can recover $K \simeq K^\wedge_I$ as the limit of the tower $\{A_i \otimes_A K\}$. Then $\mathrm{Map}_{\mathrm{Mod}_A}(M, K)$ is the limit of the tower $\mathrm{Map}_{\mathrm{Mod}_A}(M, A_i \times_A K)$. It will therefore suffice to prove the following:

(a) Each of the mapping spaces $\mathrm{Map}_{\mathrm{Mod}_A}(M, A_i \otimes_A K)$ is connected.

(b) Each of the maps $\psi_i : \mathrm{Map}_{\mathrm{Mod}_A}(M, A_i \otimes_A K) \to \mathrm{Map}_{\mathrm{Mod}_A}(M, A_{i-1} \otimes_R K)$ induces a surjection of fundamental groups.

Note that K is 1-connective, so that $A_i \otimes_A K$ is a 1-connective module over A_i. We have a homotopy equivalence $\mathrm{Map}_{\mathrm{Mod}_A}(M, A_i \otimes_A K) \simeq \mathrm{Map}_{\mathrm{Mod}_{A_i}}(A_i \otimes_A M, A_i \otimes_A K)$. Consequently, assertion (a) follows immediately from assumption (2). To prove (b), we note that the homotopy fiber of ψ_i (over the base point) can be identified with $\mathrm{Map}_{\mathrm{Mod}_{A_i}}(A_i \otimes_A M, J \otimes_A K)$, where $J = \mathrm{fib}(A_i \to A_{i-1})$. Since J is connective, $J \otimes_A K$ is 1-connective, and the desired result follows from the projectivity of $A_i \otimes_A M$. □

Corollary 8.3.5.8. *Let A be a connective $\mathbb{E}_\infty$-ring which is complete with respect to a finitely generated ideal $I \subseteq \pi_0 A$, let $M \in \mathrm{Mod}_A$ be almost perfect, and let n be an integer. The following conditions are equivalent:*

(1) *As an A-module, M has* Tor-*amplitude $\leqslant n$.*

(2) *The tensor product $R \otimes_A M$ has* Tor-*amplitude $\leqslant n$ over R, where $R = (\pi_0 A)/I$.*

(3) *For every morphism of connective $\mathbb{E}_\infty$-rings $f : A \to B$ which annihilates some power of I, the B-module $B \otimes_A M$ has* Tor-*amplitude $\leqslant n$.*

Proof. Choose k such that $M \in (\mathrm{Mod}_R)_{\geqslant -k}$. Replacing M by $\Sigma^k M$ and n by $n + k$, we may reduce to the case where M is connective. The implication (1) ⇒ (2) is obvious, and the implication (2) ⇒ (3) follows from Proposition 2.7.3.2. We will prove the implication (3) ⇒ (1) using induction on n. When $n = 0$, the desired result follows from Propositions 8.3.5.7 and HA.7.2.4.20 . If $n > 0$, we can choose a fiber sequence

$$N \to R^m \to M,$$

where N is connective. Then $f^* N$ has Tor-amplitude $\leqslant n - 1$, so the inductive hypothesis implies that N has Tor-amplitude $\leqslant n$. Using Proposition HA.7.2.4.23 , we deduce that M has Tor-amplitude $\leqslant n$. □

Corollary 8.3.5.9. *Let A be a connective $\mathbb{E}_\infty$-ring which is complete with respect to a finitely generated ideal $I \subseteq \pi_0 A$ and let $M \in \mathrm{Mod}_A$ be almost connective. The following conditions are equivalent:*

(1) *The A-module M is perfect.*

(2) *Set $R = (\pi_0 A)/I$. Then M is I-complete and the R-module $R \otimes_A M$ is perfect.*

(3) *The A-module M is I-complete, and for every morphism of connective $\mathbb{E}_\infty$-rings $f : A \to B$ which annihilates some power of I, the B-module $B \otimes_A M$ is perfect.*

Proof. Combine Corollaries 8.3.5.8 and 8.3.5.6 with the criterion of Proposition HA.7.2.4.23. □

Proof of Theorem 8.3.5.2. Let $\mathfrak{X} = (\mathcal{X}, \mathcal{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack and let $\mathscr{F} \in \mathrm{QCoh}(\mathfrak{X})^{\mathrm{acn}}$. We first show that (1) ⇒ (2). Assume that $\mathscr{F}$ is perfect to order n (almost perfect, perfect, locally free of finite rank) and let $f : \mathsf{X} \to \mathfrak{X}$ be a morphism where X is a spectral Deligne-Mumford stack; we wish to show that $f^* \mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is also perfect to order n (almost perfect, perfect, locally free of finite rank). By virtue of Proposition 2.8.4.7, this can be tested locally on X. We may therefore assume without loss of generality that $\mathsf{X} = \mathrm{Sp\acute{e}t}\, B$ is affine and that f factors as a composition $\mathrm{Sp\acute{e}t}\, B \xrightarrow{f'} \mathrm{Spf}\, A \to \mathfrak{X}$, where $A = \mathcal{O}_{\mathfrak{X}}(U)$ for some affine object $U \in \mathcal{X}$. In this case, the image of $f^* \mathscr{F}$ under the equivalence $\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, B) \simeq \mathrm{Mod}_B$ can be identified with the tensor product $B \otimes_A \mathscr{F}(U)$. Assumption (1) guarantees that $\mathscr{F}(U)$ is perfect to order n (almost perfect, perfect, locally free of finite rank) as an A-module, so that $B \otimes_A \mathscr{F}(U)$ is perfect to order n (almost perfect, perfect, locally free of finite rank) as a B-module.

The implication (2) ⇒ (3) follows immediately from the definitions. We will complete the proof by showing that (3) implies (1). Assume that the image of $\mathscr{F}$ under the equivalence $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{acn}} \simeq \mathrm{QCoh}(h_{\mathfrak{X}})^{\mathrm{acn}}$ is perfect to order n (almost perfect, perfect, locally free of finite rank), and let $U \in \mathcal{X}$ be affine. Set $A = \mathcal{O}_{\mathfrak{X}}(U)$, let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition, and set $R = (\pi_0 A)/I$. We have an evident map $f : \mathrm{Sp\acute{e}t}\, R \to \mathrm{Spf}\, A \to \mathfrak{X}$, and assumption (3) guarantees that $f^* \mathscr{F} \in \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R) \simeq \mathrm{Mod}_R$ is perfect to order n (almost perfect, perfect, locally free of finite rank). It follows that $R \otimes_A \mathscr{F}(U)$ is perfect to order n (almost perfect, perfect, locally free of finite rank). Applying Proposition 8.3.5.5 (Corollary 8.3.5.6, Corollary 8.3.5.9, Proposition 8.3.5.7), we deduce that $\mathscr{F}(U)$ is perfect to order n (almost perfect, perfect, locally free of finite rank) as an A-module. Allowing U to vary, we conclude that $\mathscr{F}$ satisfies condition (1). □

Corollary 8.3.5.10. *Let A be a complete adic $\mathbb{E}_\infty$-ring and let $\mathscr{F} \in \mathrm{QCoh}(\mathrm{Spf}\, A)$. The following conditions are equivalent:*

(1) *The quasi-coherent sheaf $\mathscr{F}$ is perfect to order n (almost perfect, perfect, locally free of finite rank).*

(2) *The A-module $\Gamma(\mathrm{Spf}\, A; \mathscr{F})$ is perfect to order n (almost perfect, perfect, locally free of finite rank).*

Proof. The implication (1) ⇒ (2) follows immediately from the definitions (note that $A \simeq \Gamma(\mathrm{Spf}\, A : \mathcal{O}_{\mathrm{Spf}\, A})$ by virtue of our assumption that A is complete). To prove the converse, we note that (2) implies that $\mathscr{F}$ is almost connective (Corollary 8.2.5.4). Using (2) together with Proposition 8.3.5.5 (Corollary 8.3.5.6, Corollary 8.3.5.9, Proposition 8.3.5.7), we deduce that the image of $\mathscr{F}$ under the equivalence $\mathrm{QCoh}(\mathrm{Spf}\, A)^{\mathrm{acn}} \simeq \mathrm{QCoh}(h_{\mathrm{Spf}\, A})^{\mathrm{acn}}$

is perfect to order n (almost perfect, perfect, locally free of finite rank). Assertion (1) now follows from Theorem 8.3.5.2. □

Warning 8.3.5.11. In the statement of Corollary 8.3.5.10, the assumption that A is complete is essential (note that replacing A by its completion does not change the formal spectrum $\mathrm{Spf}\, A$, but can drastically alter the finiteness properties enjoyed by the A-module $M = \Gamma(\mathrm{Spf}\, A; \mathscr{F})$).

8.4 The Noetherian Case

In §8.2, we introduced the stable ∞-category of quasi-coherent sheaves $\mathrm{QCoh}(\mathfrak{X})$ on a formal spectral Deligne-Mumford stack $\mathfrak{X}$ (Definition 8.2.4.7). In the special case where $\mathfrak{X} = \mathrm{Spf}\, A$ for some adic $\mathbb{E}_\infty$-ring A, there is a canonical equivalence of ∞-categories

$$\Gamma(\mathrm{Spf}\, A; \bullet) : \mathrm{QCoh}(\mathfrak{X}) \simeq \mathrm{Mod}_A^{\mathrm{Cpl}(I)},$$

where $I \subseteq \pi_0 A$ is a finitely generated ideal of definition. Note that the full subcategory $\mathrm{Mod}_A^{\mathrm{Cpl}(I)} \subseteq \mathrm{Mod}_A$ of I-complete A-modules is stable under truncation (Corollary 7.3.4.3), and therefore inherits a t-structure from Mod_A. A similar assertion holds in the non-affine setting: for any formal spectral Deligne-Mumford stack $\mathfrak{X}$, the ∞-category $\mathrm{QCoh}(\mathfrak{X})$ comes equipped with a t-structure $(\mathrm{QCoh}(\mathfrak{X})^{\mathrm{cn}}, \mathrm{QCoh}'(\mathfrak{X})$ (see Corollary 8.2.5.11), where $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{cn}}$ denotes the full subcategory of $\mathrm{QCoh}(\mathfrak{X})$ spanned by the *connective* quasi-coherent sheaves on $\mathfrak{X}$ (Definition 8.2.5.6). However, this observation is generally not very useful: we do not know a concrete description of the subcategory $\mathrm{QCoh}'(\mathfrak{X}) \subseteq \mathrm{QCoh}(\mathfrak{X})$ when $\mathfrak{X}$ is not affine (beware that the requirement that a quasi-coherent sheaf $\mathscr{F}$ belongs to $\mathrm{QCoh}'(\mathfrak{X})$ is not local for the étale topology). In this section, we will show that the situation improves considerably if we are willing to impose appropriate finiteness conditions on $\mathfrak{X}$ (by demanding that $\mathfrak{X}$ is *locally Noetherian*; see Definition **??**) and on the quasi-coherent sheaves that we consider (by restricting our attention to the full subcategory $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$ of quasi-coherent sheaves which are *almost perfect*, in the sense of Definition 8.3.5.1). Our main results can be summarized as follows:

- If $\mathfrak{X}$ is a locally Noetherian formal spectral Deligne-Mumford stack, then the ∞-category $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$ admits a t-structure $(\mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}_{\geqslant 0}, \mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}_{\leqslant 0})$, where $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}_{\geqslant 0} = \mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}} \cap \mathrm{QCoh}(\mathfrak{X})^{\mathrm{cn}}$ denotes the ∞-category of quasi-coherent sheaves on $\mathfrak{X}$ which are connective and almost perfect (Corollary 8.4.2.4). Moreover, this t-structure is compatible with étale localization.

- If $\mathfrak{X}$ is a locally Noetherian formal spectral Deligne-Mumford stack, then the heart $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}\,\heartsuit} \subseteq \mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$ admits a concrete description: it is equivalent to the abelian category of finitely 0-presented sheaves on the functor $h_{\mathfrak{X}}$ represented by $\mathfrak{X}$ (see Proposition 8.4.3.5).

8.4.1 Almost Perfect Sheaves

We begin with some general remarks which do not require any Noetherian hypotheses.

Notation 8.4.1.1. Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. We let $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$ denote the full subcategory of $\mathrm{QCoh}(\mathfrak{X})$ spanned by those quasi-coherent sheaves which are almost perfect, in the sense of Definition 8.3.5.1.

If $\mathfrak{X} = \operatorname{Spf} A$ is affine and A is complete, then Corollaries 8.3.5.10 and 8.2.4.15 supply an equivalence of ∞-categories $\Gamma(\mathfrak{X}; \bullet) : \mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}} \simeq \mathrm{Mod}_A^{\mathrm{aperf}}$. This functor admits an explicit homotopy inverse:

Proposition 8.4.1.2. *Let A be a complete adic $\mathbb{E}_\infty$-ring, set $\mathfrak{X} = \operatorname{Spf} A$, and regard $\mathrm{Mod}_{\mathscr{O}_{\operatorname{Spf} A}}$ as a stable A-linear ∞-category. Then the construction $M \mapsto M \otimes_A \mathscr{O}_{\mathfrak{X}}$ induces an equivalence of ∞-categories $\mathrm{Mod}_A^{\mathrm{aperf}} \to \mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}} \subseteq \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$, which is homotopy inverse to the equivalence $\Gamma(\mathfrak{X}; \bullet) : \mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}} \to \mathrm{Mod}_A^{\mathrm{aperf}}$.*

Proof. Let $I \subseteq \pi_0 A$ be a finitely generated ideal of definition. Let us regard $\mathscr{O}_{\mathfrak{X}}$ as a commutative algebra object of the stable presheaf ∞-category $\mathrm{Fun}(\mathrm{CAlg}_A^{\text{ét}}, \mathrm{Sp})$, given by the formula $\mathscr{O}_{\mathfrak{X}}(B) = B_I^{\wedge}$. We can then identify $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ with a full subcategory of the ∞-category of $\mathscr{O}_{\mathfrak{X}}$-module objects of $\mathrm{Fun}(\mathrm{CAlg}_A^{\text{ét}}, \mathrm{Sp})$. The equivalence $\Gamma(\mathfrak{X}; \bullet) : \mathrm{QCoh}(\mathfrak{X}) \to \mathrm{Mod}_A^{\mathrm{Cpl}(I)}$ of Corollary 8.2.4.15 admits a homotopy inverse ρ, which carries an A-module M to the sheaf given by $B \mapsto (M \otimes_A B)_I^{\wedge} \simeq (M \otimes_A B_I^{\wedge})_I^{\wedge}$ (see Remark 8.2.4.16). If M is almost perfect as an A-module, then $M \otimes_A B_I^{\wedge}$ is almost perfect as a $B_I^{\wedge}$-module and is therefore I-complete (Proposition 7.3.5.7). It follows that we can identify $\rho(M)$ with the tensor product $M \otimes_A \mathscr{O}_{\mathfrak{X}}$ (in the ∞-category $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}(\mathrm{Fun}(\mathrm{CAlg}_A^{\text{ét}}, \mathrm{Sp}))$, and therefore also in its localization $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$). The desired result now follows from Corollary 8.2.4.15. □

Corollary 8.4.1.3. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack and let $\mathscr{F}, \mathscr{G} \in \mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$. Then the tensor product $\mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{G}$ (formed in the ∞-category $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$) also belongs to $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$.*

Proof. The assertion is local on $\mathfrak{X}$, so we may assume without loss of generality that $\mathfrak{X} = \operatorname{Spf} A$ for some complete adic $\mathbb{E}_\infty$-ring A. Let us regard $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ as a stable A-linear ∞-category. Proposition 8.4.1.2 supplies equivalences

$$\mathscr{F} \simeq M \otimes_A \mathscr{O}_{\mathfrak{X}} \qquad \mathscr{G} \simeq N \otimes_A \mathscr{O}_{\mathfrak{X}}$$

for $M, N \in \mathrm{Mod}_A^{\mathrm{aperf}}$. We then have

$$\begin{aligned} \mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{G} &\simeq (M \otimes_A \mathscr{O}_{\mathfrak{X}}) \otimes_{\mathscr{O}_{\mathfrak{X}}} (N \otimes_A \mathscr{O}_{\mathfrak{X}}) \\ &\simeq (M \otimes_A N) \otimes_A \mathscr{O}_{\mathfrak{X}}. \end{aligned}$$

The desired result now follows from Proposition 8.4.1.2, since the tensor product $M \otimes_A N$ is an almost perfect A-module. □

It follows from Corollary 8.4.1.3 that the completed tensor product of Notation 8.2.4.23 coincides with the usual tensor product:

Corollary 8.4.1.4. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack, and let $\mathscr{F}, \mathscr{G} \in \mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$. Then the canonical map $\mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{G} \to \mathscr{F} \widehat{\otimes} \mathscr{G}$ is an equivalence in $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$.*

Corollary 8.4.1.5. *Let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack. Then $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$ is a symmetric monoidal subcategory of $\mathrm{QCoh}(\mathfrak{X})$ (that is, it contains the unit object and is closed under the completed tensor product functor $\widehat{\otimes}$). Moreover, the lax symmetric monoidal inclusion functor $\mathrm{QCoh}(\mathfrak{X}) \hookrightarrow \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ is symmetric monoidal when restricted to $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$.*

We can similar reasoning to the pullback functor associated to a map $f : \mathfrak{X} \to \mathfrak{Y}$ of formal spectral Deligne-Mumford stacks.

Corollary 8.4.1.6. *Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a morphism of formal spectral Deligne-Mumford stacks. If $\mathscr{F} \in \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ is quasi-coherent and almost perfect, then the pullback $f^* \mathscr{F} \in \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ is quasi-coherent and almost perfect.*

Proof. The desired conclusion can be tested locally on $\mathfrak{X}$. We may therefore assume without loss of generality that $\mathfrak{X}$ and $\mathfrak{Y}$ are affine. Write $\mathfrak{Y} = \mathrm{Spf}\, A$ and $\mathfrak{X} = \mathrm{Spf}\, B$, where A and B are complete adic $\mathbb{E}_\infty$-rings. Then f is induced by a morphism of adic $\mathbb{E}_\infty$-rings $\phi : A \to B$. Let us regard $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{Y}}}$ and $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$ as stable A-linear and B-linear ∞-categories, respectively. Using Proposition 8.4.1.2, we can write $\mathscr{F} = M \otimes_A \mathscr{O}_{\mathfrak{Y}}$. We then have an equivalence

$$\begin{aligned} f^* \mathscr{F} &\simeq f^*(M \otimes_A \mathscr{O}_{\mathfrak{Y}}) \\ &\simeq M \otimes_A f^* \mathscr{O}_{\mathfrak{Y}} \\ &\simeq M \otimes_A \mathscr{O}_{\mathfrak{X}} \\ &\simeq (M \otimes_A B) \otimes_B \mathscr{O}_{\mathfrak{X}}. \end{aligned}$$

Since $M \otimes_A B$ is an almost perfect B-module (Proposition 2.7.3.1), it follows from Proposition 8.4.1.2 that $f^* \mathscr{F}$ is quasi-coherent and almost perfect. □

Corollary 8.4.1.7. *Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a morphism of formal spectral Deligne-Mumford stacks. If $\mathscr{F} \in \mathrm{QCoh}(\mathfrak{Y})$ is almost perfect, then the completed pullback $f^{\star}\mathscr{F} \in \mathrm{QCoh}(\mathfrak{X})$ is also almost perfect. Moreover, the canonical map $f^{*}\mathscr{F} \to f^{\star}\mathscr{F}$ is an equivalence in $\mathrm{WCoh}(\mathfrak{X})$.*

Corollary 8.4.1.8. *Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a representable morphism of formal spectral Deligne-Mumford stacks. If $\mathscr{F} \in \mathrm{QCoh}(\mathfrak{Y})$ is nilcoherent and almost perfect, then $f^{\star}\mathscr{F} \in \mathrm{QCoh}(\mathfrak{X})$ is nilcoherent and almost perfect.*

Proof. Combine Corollary 8.4.1.7 with Proposition 8.3.2.5. □

Proposition 8.4.1.9. *Let $f : \mathfrak{X} \to \mathfrak{Y}$ be a morphism of formal spectral Deligne-Mumford stacks. Suppose that f is representable, proper, and locally almost of finite presentation (that is, for every map $\mathrm{Sp\acute{e}t}\, R \to \mathfrak{Y}$), the fiber product $\mathrm{Sp\acute{e}t}\, R \times_{\mathfrak{Y}} \mathfrak{X}$ is a spectral algebraic space which is proper and locally almost of finite presentation over R). If $\mathscr{F} \in \mathrm{QCoh}(\mathfrak{X})$ is almost perfect, then $f_{*}\mathscr{F} \in \mathrm{QCoh}(\mathfrak{Y})$ is almost perfect.*

Proof. Remark 8.3.3.5 implies that $f_{*}\mathscr{F}$ is almost connective. Using Proposition 8.3.3.6 and Theorem 8.3.5.2, we can reduce to the case where $\mathfrak{X}$ and $\mathfrak{Y}$ are spectral Deligne-Mumford stacks, in which case the desired result follows from Theorem 5.6.0.2. □

8.4.2 Locally Noetherian Formal Spectral Deligne-Mumford Stacks

We now generalize Definition 2.8.1.4 to the setting of formal spectral Deligne-Mumford stacks.

Definition 8.4.2.1. Let $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack. We will say that $\mathfrak{X}$ is *locally Noetherian* if, for every affine object $U \in \mathcal{X}$, the $\mathbb{E}_{\infty}$-ring $\mathscr{O}_{\mathfrak{X}}(U)$ is Noetherian.

Proposition 8.4.2.2. *Let A be a complete adic $\mathbb{E}_{\infty}$-ring. Then the formal spectrum $\mathrm{Spf}\, A$ is locally Noetherian if and only if A is Noetherian.*

Proof. It follows immediately from the definitions that if $\mathrm{Spf}\, A$ is locally Noetherian, then $A \simeq \Gamma(\mathrm{Spf}\, A; \mathscr{O}_{\mathrm{Spf}\, A})$ is locally Noetherian. For the converse, suppose that A is Noetherian, and let $U \in \mathcal{S}\mathrm{hv}_{A}^{\mathrm{ad}}$ be affine. It follows from Proposition 8.1.3.6 that we have an equivalence $\mathscr{O}_{\mathrm{Spf}\, A}(U) \simeq B_{I}^{\wedge}$, where B is an étale A-algebra and $I \subseteq \pi_0 A$ is a finitely generated ideal of definition. Theorem HA.7.2.4.31 implies that B is Noetherian, so that $B_{I}^{\wedge}$ is also Noetherian by virtue of Corollary 7.3.8.3. □

Proposition 8.4.2.3. *Let $\mathfrak{X}$ be a locally Noetherian formal spectral Deligne-Mumford stack and let $\mathscr{F} \in \mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$. Suppose that $\mathscr{F}$ is quasi-coherent and almost perfect. Then the truncations $\tau_{\geq n}\mathscr{F}$ and $\tau_{\leq n}\mathscr{F}$ are also quasi-coherent and almost perfect.*

Proof. The assertion is local on $\mathfrak{X}$. We may therefore assume without loss of generality that $\mathfrak{X} = \operatorname{Spf} A$ for some complete adic $\mathbb{E}_\infty$-ring A. Our assumption that $\mathfrak{X}$ is locally Noetherian guarantees that A is Noetherian. It follows that the subcategory $\operatorname{Mod}_A^{\mathrm{aperf}} \subseteq \operatorname{Mod}_A$ of almost perfect A-modules is closed under truncation, and therefore inherits a t-structure from Mod_A. Proposition 8.4.1.2 implies that the construction $M \mapsto M \otimes_A \mathscr{O}_{\mathfrak{X}}$ determines a fully faithful embedding $F : \operatorname{Mod}_A^{\mathrm{aperf}} \to \operatorname{Mod}_{\mathscr{O}_{\mathfrak{X}}}$, whose essential image is the full subcategory $\operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$. Consequently, to show that $\operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$ is closed under truncations in $\operatorname{Mod}_{\mathscr{O}_{\mathfrak{X}}}$, it will suffice to show that the functor F is t-exact. It follows immediately from the definitions that F is right t-exact. To verify left t-exactness, we must show that if $M \in (\operatorname{Mod}_A^{\mathrm{aperf}})_{\leqslant 0}$, then the sheaf $\mathscr{F} = M \otimes_A \mathscr{O}_{\mathfrak{X}}$ is 0-truncated. In fact, we claim that $\mathscr{F}(U)$ is 0-truncated for every affine object $U \in \mathcal{S}\mathrm{hv}_A^{\mathrm{ad}}$. To prove this, it suffices to show that $M \otimes_A B_I^\wedge$ is 0-truncated for every étale A-algebra B, where $I \subseteq \pi_0 A$ is a finitely generated ideal of definition. This is clear: our assumption that A is Noetherian guarantees that B is Noetherian (Theorem HA.7.2.4.31), so that $B_I^\wedge$ is flat over B (Corollary 7.3.6.9) and therefore also flat over A. □

Corollary 8.4.2.4. *Let $\mathfrak{X}$ be a locally Noetherian formal spectral Deligne-Mumford stack. Then the ∞-category $\operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$ is equipped with a t-structure $(\operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}}_{\geqslant 0}, \operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}}_{\leqslant 0})$, where $\operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}}_{\geqslant 0} = \operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}} \cap (\operatorname{Mod}_{\mathscr{O}_{\mathfrak{X}}})_{\geqslant 0}$ and $\operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}}_{\leqslant 0} = \operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}} \cap (\operatorname{Mod}_{\mathscr{O}_{\mathfrak{X}}})_{\leqslant 0}$.*

Remark 8.4.2.5. Let $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$ be a locally Noetherian formal spectral Deligne-Mumford stack. For each affine object $U \in \mathcal{X}$, the construction $\mathscr{F} \mapsto \mathscr{F}(U)$ determines a t-exact functor $\operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}} \to \operatorname{Mod}^{\mathrm{aperf}}_{\mathscr{O}_{\mathfrak{X}}(U)}$ (left t-exactness is clear from the definition, and right t-exactness follows from the proof of Proposition 8.4.2.3). We can therefore describe the t-structure of Corollary 8.4.2.4 as follows:

- A sheaf $\mathscr{F} \in \operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$ belongs to $\operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}}_{\geqslant 0}$ if and only if $\mathscr{F}(U)$ is connective, for each affine object $U \in \mathcal{X}$
- A sheaf $\mathscr{F} \in \operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$ belongs to $\operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}}_{\leqslant 0}$ if and only if $\mathscr{F}(U)$ is 0-truncated, for each affine object $U \in \mathcal{X}$.

Remark 8.4.2.6. Let $\mathfrak{X}$ be a locally Noetherian formal spectral Deligne-Mumford stack. Then the t-structure of Corollary 8.4.2.4 is left complete. To prove this, we can work locally on $\mathfrak{X}$ and thereby reduce to the case where $\mathfrak{X} \simeq \operatorname{Spf} A$, for some complete adic $\mathbb{E}_\infty$-ring A. In this case, Proposition 8.4.1.2 supplies a t-exact equivalence $\operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}} \simeq \operatorname{Mod}_A^{\mathrm{aperf}}$, and the t-structure on $\operatorname{Mod}_A^{\mathrm{aperf}}$ is evidently left complete (see Proposition HA.7.2.4.17).

Beware that the t-structure on $\operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$ is never right complete (except in trivial cases). However, it is right bounded (see §HA.1.2.1) when $\mathfrak{X}$ is quasi-compact.

Proposition 8.4.2.7. *Let $\mathfrak{X} = (\mathcal{X}, \mathscr{O}_{\mathfrak{X}})$ be a formal spectral Deligne-Mumford stack. Then:*

(1) *If $\mathfrak{X}$ is locally Noetherian, then $\mathfrak{X}_U = (\mathcal{X}_{/U}, \mathscr{O}_{\mathfrak{X}}|_U)$ is locally Noetherian for each object $U \in \mathcal{X}$.*

(2) *If there exists a collection of objects $\{U_\alpha\}$ which cover $\mathcal{X}$ such that each $\mathfrak{X}_{U_\alpha}$ is locally Noetherian, then $\mathfrak{X}$ is locally Noetherian.*

Proof. Assertion (1) follows immediately from the definitions. To prove (2), suppose that there exists a covering $\{U_\alpha\}$ such that each $\mathfrak{X}_{U_\alpha}$ is locally Noetherian. Using Proposition 8.4.2.3, we deduce the following:

($*$) Let $\mathscr{F} \in \mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$. Then, for any integer n, the truncations $\tau_{\geqslant n} \mathscr{F}$ and $\tau_{\leqslant n} \mathscr{F}$ also belong to $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$.

Let $V \in \mathcal{X}$ be any affine object. We wish to show that $\mathscr{O}_{\mathfrak{X}}(V)$ is Noetherian.

Replacing $\mathfrak{X}$ by $\mathfrak{X}_V$, we can reduce to the case where $\mathfrak{X} \simeq \operatorname{Spf} A$ for some complete adic $\mathbb{E}_\infty$-ring A. It follows from Proposition 8.4.1.2 that the construction $M \mapsto M \otimes_A \mathscr{O}_{\mathfrak{X}}$ determines an equivalence $F : \mathrm{Mod}_A^{\mathrm{aperf}} \to \mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$. Combining this observation with ($*$), we deduce that the ∞-category $\mathrm{Mod}_A^{\mathrm{aperf}}$ admits a t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ for which the functor F is t-exact. Note that an object $M \in \mathrm{Mod}_A^{\mathrm{aperf}}$ belongs to $\mathcal{C}_{\geqslant 0}$ if and only if M is connective (Corollary 8.2.5.4). In particular, every object $M \in \mathrm{Mod}_A^{\mathrm{aperf}}$ fits into a fiber sequence $M' \to M \to M''$ where M' is n-connective and $M'' \in \mathcal{C}_{\leqslant n-1}$. Then $F(M'')$ is a $(n-1)$-truncated object of $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}$, so that $M'' \simeq \Gamma(\mathfrak{X}; F(M''))$ is also $(n-1)$-truncated. We therefore have $M' \simeq \tau_{\geqslant n} M$ and $M'' \simeq \tau_{\leqslant n-1} M$. Allowing M to vary, we deduce that $\mathrm{Mod}_A^{\mathrm{aperf}}$ is closed under truncations (when regarded as a subcategory of the ∞-category Mod_A), so that the $\mathbb{E}_\infty$-ring A is coherent (Proposition HA.7.2.4.18).

To complete the proof, it will suffice to show that the commutative ring $\pi_0 A$ is Noetherian. Let $J \subseteq \pi_0 A$ be an ideal. Write J as a union of finitely generated ideals $J_\beta \subseteq J$. Since A is coherent, each J_α is almost perfect when regarded as an A-module (Proposition HA.7.2.4.17). It follows that $\{F(J_\beta)\}$ can be regarded as a filtered diagram of subobjects of $\pi_0 \mathscr{O}_{\mathfrak{X}}$ in the abelian category $\mathrm{Mod}_{\mathscr{O}_{\mathfrak{X}}}^{\heartsuit}$. Choose a covering of $\mathcal{X}$ by affine objects $\{U_i\}_{1 \leqslant i \leqslant n}$ such that each $\mathscr{O}_{\mathfrak{X}}(U_i)$ is Noetherian. For $1 \leqslant i \leqslant n$, we can regard $\{F(J_\beta)(U_i)\}$ as a filtered diagram of ideals in the Noetherian commutative ring $(\pi_0 \mathscr{O}_{\mathfrak{X}})(U_i) \simeq \pi_0 \mathscr{O}_{\mathfrak{X}}(U_i)$. Each of these diagrams must stabilize, so the diagram $\{F(J_\beta)\}$ must also stablize. Since F is an equivalence of ∞-categories, we conclude that the diagram of ideals $\{J_\beta\}$ stabilizes: that is, the ideal J is itself finitely generated. Allowing J to vary, we deduce that the commutative ring $\pi_0 A$ is Noetherian as desired. □

Corollary 8.4.2.8. *Let X be a locally Noetherian spectral Deligne-Mumford stack and let $K \subseteq |\mathsf{X}|$ be a closed subset. Then the formal completion $\mathsf{X}^{\wedge}_K$ is a locally Noetherian formal spectral Deligne-Mumford stack.*

Proof. The assertion is local on X, so we may assume without loss of generality that $\mathsf{X} = \operatorname{Spét} A$ for some Noetherian $\mathbb{E}_\infty$-ring A. Then K can be identified with the vanishing locus of a (finitely generated) ideal $I \subseteq \pi_0 A$. Example 8.1.6.4 and Remark 8.1.2.4 then supply equivalences $\mathsf{X}^\wedge_K \simeq \operatorname{Spf} A \simeq \operatorname{Spf} A^\wedge_I$. By virtue of Proposition 8.4.2.2, it will suffice to show that $A^\wedge_I$ is Noetherian, which follows from Corollary 7.3.8.3. □

Example 8.4.2.9. Let X be a spectral Deligne-Mumford stack. Then X is locally Noetherian in the sense of Definition 8.4.2.1 if and only if it is locally Noetherian in the sense of Definition 2.8.1.4.

Proposition 8.4.2.10. *Let X be a locally Noetherian spectral Deligne-Mumford stack, let $K \subseteq |\mathsf{X}|$ be a closed subset, and let $i : \mathsf{X}^\wedge_K \to \mathsf{X}$ be a morphism of formal spectral Deligne-Mumford stacks which exhibits $\mathsf{X}^\wedge_K$ as a formal completion of X along K. Then the pullback functor $i^* : \operatorname{QCoh}(\mathsf{X})^{\mathrm{aperf}} \to \operatorname{QCoh}(\mathsf{X}^\wedge_K)^{\mathrm{aperf}}$ is t-exact.*

Proof. Without loss of generality, we may assume that $\mathsf{X} = \operatorname{Spét} A$ is affine and that K is the vanishing locus of a finitely generated ideal $I \subseteq \pi_0 A$. Using Proposition 8.4.1.2, we can identify i^* with the functor $\operatorname{Mod}_A^{\mathrm{aperf}} \to \operatorname{Mod}_{A^\wedge_I}^{\mathrm{aperf}}$ given by extension of scalars along the canonical map $\phi : A \to A^\wedge_I$. It now suffices to observe that ϕ is flat (Corollary 7.3.6.9). □

8.4.3 The Heart of $\operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$

Let $\mathfrak{X}$ be a locally Noetherian formal spectral Deligne-Mumford stack, and regard $\operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$ as equipped with the t-structure described in Corollary 8.4.2.4. Our next goal is to describe the heart of $\operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}}$. More generally, we will describe the intersection $\operatorname{QCoh}(\mathfrak{X})^{\mathrm{cn}} \cap \operatorname{QCoh}(\mathfrak{X})^{\mathrm{aperf}}_{\leqslant n}$, for every integer $n \geqslant 0$. First, we need to introduce a variant of Definition 6.2.2.1.

Notation 8.4.3.1. Fix an integer $n \geqslant 0$. For every connective $\mathbb{E}_\infty$-ring A, let $\operatorname{Mod}_A^{n-fp}$ denote the full subcategory of Mod_A spanned by those A-modules which are connective and finitely n-presented (see Definition 2.7.1.1): in other words, the ∞-category of compact objects of $\tau_{\leqslant n} \operatorname{Mod}_A^{\mathrm{cn}}$.

Let $\operatorname{Mod} = \operatorname{Mod}(\mathrm{Sp})$ denote the ∞-category of pairs (A, M), where A is an $\mathbb{E}_\infty$-ring and M is an A-module spectrum, and let $\operatorname{Mod}^{n-fp}$ denote the full subcategory of Mod spanned by those pairs (A, M) where A is connective and $M \in \operatorname{Mod}_A^{n-fp}$. The construction $(A, M) \mapsto A$ determines a coCartesian fibration $q : \operatorname{Mod}^{n-fp} \to \operatorname{CAlg}^{\mathrm{cn}}$ which is classified by a functor $\operatorname{CAlg}^{\mathrm{cn}} \to \mathcal{C}\mathrm{at}_\infty$ given by $A \mapsto \operatorname{Mod}_A^{n-fp}$. If $f : A \to B$ is a map of connective $\mathbb{E}_\infty$-rings, then the induced functor $\operatorname{Mod}_A^{n-fp} \to \operatorname{Mod}_B^{n-fp}$ is given by the construction $M \mapsto \tau_{\leqslant n}(B \otimes_A M)$.

Let $\operatorname{QCoh}^{n-fp} : \operatorname{Fun}(\operatorname{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ denote the functor $\Phi'(q)$ obtained by applying Remark 6.2.1.11 to the coCartesian fibration q; here $\widehat{\mathcal{S}}$ denotes the ∞-category of spaces which are not necessarily small, and $\widehat{\mathcal{C}\mathrm{at}}_\infty$ is defined similarly.

Example 8.4.3.2. By virtue of Proposition 6.2.1.9, we can regard the construction $X \mapsto \mathrm{QCoh}^{n-fp}(X)$ as a right Kan extension of the construction $A \mapsto \mathrm{Mod}_A^{n-fp}$ along the Yoneda embedding $\mathrm{Spec} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})^{\mathrm{op}}$. In particular, for every connective $\mathbb{E}_\infty$-ring A, we have a canonical equivalence $\mathrm{QCoh}^{n-fp}(\mathrm{Spec}\, A) \simeq \mathrm{Mod}_A^{n-fp}$.

Example 8.4.3.3. Let X be a spectral Deligne-Mumford stack representing a functor $h_{\mathsf{X}} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Arguing as in the proof of Proposition 6.2.4.1, we see that there is a canonical equivalence $\mathrm{QCoh}^{n-fp}(\mathsf{X}) \simeq \mathrm{QCoh}^{n-fp}(h_{\mathsf{X}})$, where the left hand side is defined by Construction 4.5.2.2 and the right hand side is defined in Notation 8.4.3.1.

Remark 8.4.3.4. Let $X \in \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor classifying a left fibration $\mathcal{C} \to \mathrm{CAlg}^{\mathrm{cn}}$. We then have a canonical equivalence of ∞-categories $\mathrm{QCoh}^{n-fp}(X) \simeq \mathrm{Fun}^{\mathrm{ccart}}_{\mathrm{CAlg}^{\mathrm{cn}}}(\mathcal{C}, \mathrm{Mod}^{n-fp})$. More informally, we can view an object $\mathscr{F} \in \mathrm{QCoh}(X)$ as a rule which assigns to each point $\eta \in X(A)$ an A-module $\mathscr{F}(\eta) \in \mathrm{Mod}_A^{n-fp}$, which depends functorially on A in the following sense: for every morphism of connective $\mathbb{E}_\infty$-rings $\phi : A \to A'$ carrying η to a point $\eta' \in X(A')$, there is a canonical equivalence of A'-modules $\tau_{\leqslant n}(A' \otimes_A \mathscr{F}(\eta)) \xrightarrow{\sim} \mathscr{F}(\eta')$.

For any functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, we have an evident functor $\tau_{\leqslant n} : \mathrm{QCoh}(X)^{\mathrm{cn,aperf}} \to \mathrm{QCoh}(X)^{n-fp}$, which is given pointwise by the construction $(\tau_{\leqslant n}\mathscr{F})(\eta) \simeq \tau_{\leqslant n}(\mathscr{F}(\eta)) \in \mathrm{Mod}_A^{n-fp}$ for $\eta \in X(A)$. Our main result is the following:

Proposition 8.4.3.5. *Let $\mathfrak{X}$ be a locally Noetherian formal spectral Deligne-Mumford stack representing a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. For every integer $n \geqslant 0$, the composite functor*

$$\mathrm{QCoh}(\mathfrak{X})^{\mathrm{cn}} \cap \mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}_{\leqslant n} \hookrightarrow \mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}_{\geqslant 0} \simeq \mathrm{QCoh}(X)^{\mathrm{aperf}} \xrightarrow{\tau_{\leqslant n}} \mathrm{QCoh}^{n-fp}(X)$$

is an equivalence of ∞-categories.

Example 8.4.3.6. Let $\mathfrak{X}$ be a locally Noetherian formal spectral Deligne-Mumford stack. Applying Proposition 8.4.3.5 in the case $n = 0$, we obtain an equivalence of categories $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}\heartsuit} \xrightarrow{\sim} \mathrm{QCoh}^{0-fp}(X)$. Unwinding the definitions, we see that an object $\mathscr{F} \in \mathrm{QCoh}^{0-fp}(X)$ can be identified with a rule which does the following:

- (a) To each morphism $\eta_A : \mathrm{Sp\acute{e}t}\, A \to \mathfrak{X}$, $\mathscr{F}$ assigns a finitely presented (discrete) $(\pi_0 A)$-module $\mathscr{F}(\eta_A)$.
- (b) To every commutative diagram

$$\begin{array}{ccc} \mathrm{Sp\acute{e}t}\, B & \xrightarrow{\alpha} & \mathrm{Sp\acute{e}t}\, A \\ & {\scriptstyle \eta_B} \searrow \quad \swarrow {\scriptstyle \eta_A} & \\ & \mathfrak{X}, & \end{array}$$

  the object $\mathscr{F}$ assigns a homomorphism of discrete A-modules $u_\alpha : \mathscr{F}(\eta_A) \to \mathscr{F}(\eta_B)$, which induces an isomorphism $\pi_0(B \otimes_A \mathscr{F}(\eta_A)) \simeq \eta_B$ (and depends only on the homotopy class of α).

(c) The homomorphisms u_α appearing in (b) have the transitivity property $u_{\alpha\circ\beta} = u_\beta \circ u_\alpha$. In particular, when $B = A$ and $\eta_B = \eta_A$, we have $u_{\mathrm{id}_{\operatorname{Sp\acute{e}t} A}} = \mathrm{id}_{\mathscr{F}(\eta_A)}$.

Moreover, it suffices to specify the data of (a) and (b) (and to verify the condition (c)) for maps $\eta_A : \operatorname{Sp\acute{e}t} A \to \mathsf{X}$ where A is a commutative ring (since the abelian category of discrete modules over an arbitrary connective $\mathbb{E}_\infty$-ring A is equivalent to the abelian category of discrete modules over the commutative ring $\pi_0 A$).

Warning 8.4.3.7. In the situation of Example **??**, the existence of an equivalence of categories $\mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}\,\heartsuit} \xrightarrow{\sim} \mathrm{QCoh}^{0-fp}(X)$ implies that the category $\mathrm{QCoh}^{0-fp}(X)$ is abelian. This is not obvious from the definition: for a general functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, the category $\mathrm{QCoh}^{0-fp}(X)$ is additive, but need not be abelian. For example, if $X = \operatorname{Spec} R$ for some commutative ring R, then $\mathrm{QCoh}^{0-fp}(X)$ can be identified with the category of finitely presented R-modules (Example 8.4.3.2), which is abelian if and only if R is coherent.

8.4.4 The Proof of Proposition 8.4.3.5

The proof of Proposition 8.4.3.5 will require some preliminaries.

Lemma 8.4.4.1. *Let R be a Noetherian $\mathbb{E}_\infty$-ring, and let M be a connective R-module. If M is perfect to order n, then $\tau_{\leqslant n} M$ is almost perfect.*

Proof. According to Remark HA.7.2.4.19 , it will suffice to prove that $\pi_i M$ is a finitely generated module over $\pi_0 R$ for $0 \leqslant i \leqslant n$. We proceed by induction on n. When $n = 0$, the result is obvious. Assume therefore that $n > 0$. Then there exists a fiber sequence $N \to R^k \to M$ where N is connective and perfect to order $(n-1)$. For $i \leqslant n$, we have an exact sequence $(\pi_i R)^k \to \pi_i M \to \pi_{i-1} N$ of modules over $\pi_0 R$. Since $\pi_{i-1} N$ is finitely generated by the inductive hypothesis and $(\pi_i R)^k$ is finitely generated (by virtue of our assumption that R is Noetherian), we conclude that $\pi_i M$ is finitely generated, as desired. □

Lemma 8.4.4.2. *Let R be a Noetherian commutative ring, let $I \subseteq R$ be an ideal, and let M and N be discrete R-modules. Assume that N is I-nilpotent and that M is finitely generated. Then every class $\eta \in \mathrm{Ext}^p_R(M, N)$ vanishes when restricted to $\mathrm{Ext}^p_R(I^m M, N)$ for $m \gg 0$.*

Proof. We proceed by induction on p. If $p = 0$, the result is obvious. Otherwise, choose an injective map $u : N \to Q$, where Q is an injective R-module. Let $Q_0 \subseteq Q$ be the submodule consisting of elements which are annihilated by I^k for $k \gg 0$. Using Remark 7.1.3.5, we deduce that Q_0 is also an injective R-module. Since N is I-nilpotent, the map u factors through Q_0, so we have an exact sequence of I-nilpotent R-modules

$$0 \to N \to Q_0 \to N' \to 0.$$

Since $p > 0$, we have $\mathrm{Ext}^p_R(M, Q_0) \simeq 0$, so the boundary map $\partial : \mathrm{Ext}^{p-1}_R(M, N') \to \mathrm{Ext}^p_R(M, N)$ is surjective. Write $\eta = \partial(\overline{\eta})$ for some class $\overline{\eta} \in \mathrm{Ext}^{p-1}_R(M, N')$. Applying the inductive hypothesis, we deduce that $\overline{\eta}$ has trivial image in $\mathrm{Ext}^{p-1}_R(I^m M, N')$ for $m \gg 0$. It follows that the image of η in $\mathrm{Ext}^p_R(M, N)$ vanishes as well.

□

Lemma 8.4.4.3. *Let R be a Noetherian commutative ring and let M be a finitely generated discrete R-module. Let $I \subseteq R$ be an ideal, and choose a tower*

$$\cdots \to A_4 \to A_3 \to A_2 \to A_1$$

of $\mathbb{E}_\infty$-algebras over R satisfying the requirements of Lemma 8.1.2.2. For every integer $n \geqslant 0$, the canonical map

$$\theta : \{\tau_{\leqslant n} A_i \otimes_R M\}_{i>0} \to \{\pi_0(A_i \otimes_R M)\}_{i>0} \simeq \{M/I^j M\}_{j \geqslant 0}$$

is an equivalence of Pro-*objects of the ∞-category* Mod_R.

Proof. Let $\mathcal{C}$ be denote the full subcategory of Mod_R spanned by those objects which are connective, almost perfect, n-truncated, and I-nilpotent. Then the domain and codomain of θ can be identified with Pro-objects of $\mathcal{C}$. It will therefore suffice to show that θ induces a homotopy equivalence

$$\alpha_N : \varinjlim_{j>0} \mathrm{Map}_{\mathrm{Mod}_R}(M/I^j M, N) \to \varinjlim_{i>0} \mathrm{Map}_{\mathrm{Mod}_R}(\tau_{\leqslant n}(A_i \otimes_R M), N)$$

for every object $N \in \mathcal{C}$. Since N is n-truncated, we can identify the codomain of α with $\varinjlim_{i>0} \mathrm{Map}_{\mathrm{Mod}_R}(A_i \otimes_R M, N)$. The collection of those objects $N \in \mathcal{C}$ for which α_N is a homotopy equivalence is closed under extensions; we may therefore suppose that $N = \Sigma^m N_0$, where N_0 is a finitely generated discrete R-module and $0 \leqslant m \leqslant n$. Since N is I-nilpotent, N_0 is a module over the quotient ring R/I^k for $k \gg 0$. It follows that the codomain of α_N can be rewritten as $\varinjlim \mathrm{Map}_{\mathrm{Mod}_{R/I^k}}((R/I^k \otimes_R A_i) \otimes_R M, N)$. The projection map $\mathrm{Spf}\, R \times_{\mathrm{Sp\acute{e}t}\, R} \mathrm{Sp\acute{e}t}\, R/I^k \to \mathrm{Sp\acute{e}t}\, R/I^k$ is an equivalence, so the tower $\{R/I^k \otimes_R A_i\}$ is equivalent to R/I^k in the ∞-category $\mathrm{Pro}(\mathrm{CAlg})$. We can therefore identify the codomain of α_N with $\mathrm{Map}_{\mathrm{Mod}_{R/I^k}}(R/I^k \otimes_R M, N) \simeq \mathrm{Map}_{\mathrm{Mod}_R}(M, N)$. To prove that α_N is a homotopy equivalence, it will suffice to show that the direct limit $\varinjlim_{j \geqslant 0} \mathrm{Map}_{\mathrm{Mod}_R}(I^j M, N)$ vanishes. For this, it suffices to show for every integer p, the abelian group $\varinjlim_{j \geqslant 0} \mathrm{Ext}^p_R(I^j M, N_0)$ vanishes. This follows immediately from Lemma 8.4.4.2. □

Remark 8.4.4.4. Let Ab denote the category of abelian groups, and Pro(Ab) the category of Pro-objects of Ab. Let R be a commutative ring and $I \subseteq R$ an ideal. To any discrete

R-module M, we can associate an object of Pro(Ab), represented by the inverse system $\{M/I^n M\}_{n \geqslant 0}$. Given an exact sequence of discrete R-modules

$$0 \to M' \xrightarrow{\phi} M \to M'' \to 0,$$

we obtain an exact sequence of Pro-objects

$$0 \to \{M'/\phi^{-1}(I^n M)\}_{n \geqslant 0} \to \{M/I^n M\}_{n \geqslant 0} \to \{M''/I^n M''\}_{n \geqslant 0} \to 0.$$

If R is Noetherian and M is a finitely generated R-module, then the Artin-Rees lemma allows us to identify the term on the left side with the Pro-abelian group $\{M'/I^n M'\}_{n \geqslant 0}$. It follows that we have an exact sequence

$$0 \to \{M'/I^n M'\}_{n \geqslant 0} \to \{M/I^n M\}_{n \geqslant 0} \to \{M''/I^n M''\}_{n \geqslant 0} \to 0$$

in the abelian category Pro(Ab). We can summarize the above discussion as follows: if R is a Noetherian commutative ring and $I \subseteq R$ is an ideal, then the construction $M \mapsto \{M/I^n M\}_{n \geqslant 0}$ determines an exact functor from the category of finitely generated R-modules to the category Pro(Ab).

Lemma 8.4.4.5. *Let R be a Noetherian $\mathbb{E}_\infty$-ring, let $I \subseteq \pi_0 R$ be a finitely generated ideal, and choose a tower of R-algebras*

$$\cdots \to A_3 \to A_2 \to A_1$$

satisfying the requirements of Lemma 8.1.2.2. Let M be an almost perfect R-module. For every integer n, the canonical map

$$\theta_n^M : \{\pi_n(A_i \otimes_R M)\}_{i>0} \to \{\mathrm{Tor}_0^{\pi_0 R}(\pi_0 A_i, \pi_n M)\}_{i>0} \simeq \{(\pi_n M)/I^j(\pi_n M)\}_{j>0}$$

is an isomorphism in the category Pro(Ab) *of* Pro-*abelian groups.*

Proof. Let us say that an R-module M is *n-good* if the map θ_n^M is an isomorphism, and that M is *good* if it is n-good for every integer n. Note that M is n-good if and only if the truncation $\tau_{\leqslant n} M$ is n-good. Consequently, to prove that every almost perfect R-module M is good, it will suffice to treat the case where M is truncated.

Suppose we are given a fiber sequence of R-modules $M' \to M \to M''$. We then obtain a commutative diagram

$$\begin{array}{ccc}
\{\pi_{n+1}(A_i \otimes_R M'')\}_{i>0} & \xrightarrow{\theta^{M''}_{n+1}} & \{(\pi_{n+1}M'')/I^j(\pi_{n+1}M'')\}_{j>0} \\
\downarrow & & \downarrow \\
\{\pi_n(A_i \otimes_R M')\}_{i>0} & \xrightarrow{\theta^{M'}_{n}} & \{(\pi_n M')/I^j(\pi_n M')\}_{j>0} \\
\downarrow & & \downarrow \\
\{\pi_n(A_i \otimes_R M)\}_{i>0} & \xrightarrow{\theta^{M}_{n}} & \{(\pi_n M)/I^j(\pi_n M)\}_{j>0} \\
\downarrow & & \downarrow \\
\{\pi_n(A_i \otimes_R M'')\}_{i>0} & \xrightarrow{\theta^{M''}_{n}} & \{(\pi_n M'')/I^j(\pi_n M'')\}_{j>0} \\
\downarrow & & \downarrow \\
\{\pi_{n-1}(A_i \otimes_R M')\}_{i>0} & \xrightarrow{\theta^{M'}_{n-1}} & \{(\pi_{n-1}M')/I^j(\pi_{n-1}M')\}_{j>0}
\end{array}$$

in the category Pro(Ab). The left column is obviously exact. If M, M', and M'' are almost perfect, then Remark 8.4.4.4 shows that the right column is also exact. Applying the five lemma, we deduce that if M' and M'' are good, then M is also good. Consequently, the collection of almost perfect good R-modules is closed under extensions. To prove that every truncated almost perfect R-module M is good, it will suffice to treat the case where M is discrete. In this case, we can regard M as a module over the discrete commutative ring $\pi_0 R$. Replacing R by $\pi_0 R$ (and the tower $\{A_i\}_{i>0}$ with $\{\pi_0 R \otimes_R A_i\}_{i>0}$), we can assume that R is also discrete. In this case, the desired result follows immediately from Lemma 8.4.4.3. □

Lemma 8.4.4.6. *Let R be a Noetherian $\mathbb{E}_\infty$-ring which is complete with respect to a ideal $I \subseteq \pi_0 R$ and let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be the functor represented by the formal spectra* $\mathrm{Spf}\, R$ *(given by $X(B) = \mathrm{Map}_{\mathrm{CAlg}^{\mathrm{cn}}_{\mathrm{ad}}}(R, B)$). For every integer $n \geqslant 0$, the canonical map $f : \mathrm{Mod}_R^{n-fp} \to \mathrm{QCoh}^{n-fp}(X)$ is an equivalence of ∞-categories.*

Proof. Choose a tower of R-algebras

$$\cdots \to A_3 \to A_2 \to A_1$$

satisfying the requirements of Lemma 8.1.2.2, so that $R \simeq \varprojlim A_i$ and $\mathrm{Spf}\, R \simeq \varinjlim \mathrm{Sp\acute{e}t}\, A_i$. Then the ∞-category $\mathrm{QCoh}^{n-fp}(X)$ can be identified with the limit of the tower of ∞-categories $\{\mathrm{Mod}_{A_i}^{n-fp}\}_{i>0}$. The functor f is given by the restriction of a functor $F : (\mathrm{Mod}_R)_{\leqslant n} \to \varprojlim (\mathrm{Mod}_{A_i})_{\leqslant n}$. The functor F admits a right adjoint G, which carries a compatible family of n-truncated A_i-modules $\{M_i\}$ to the limit $\varprojlim M_i$. If each M_i is connective, then the maps

$$\pi_0 M_i \to \mathrm{Tor}_0^{\pi_0 A_i}(\pi_0 A_{i-1}, \pi_0 M_i) \simeq \pi_0 M_{i-1}$$

are surjective, so that $G\{M_i\} = \varprojlim M_i$ is also connective. If, in addition, each M_i is almost perfect, then Lemma 8.3.5.4 implies that $G\{M_i\}$ is perfect to order n. Since $G\{M_i\}$ is n-truncated, we conclude that $G\{M_i\}$ is almost perfect (Lemma 8.4.4.1). It follows that the functor G restricts to a functor $g : \varprojlim \mathrm{Mod}_{A_i}^{n-fp} \to \mathrm{Mod}_R^{n-fp}$, so we have an adjunction

$$\mathrm{Mod}_R^{n-fp} \underset{g}{\overset{f}{\rightleftarrows}} \varprojlim \mathrm{Mod}_{A_i}^{n-fp}.$$

It follows immediately from Lemma 8.3.5.4 that the counit map $f \circ g \to \mathrm{id}$ is an equivalence. We wish to prove that the unit map $\mathrm{id} \to g \circ f$ is also an equivalence. In other words, we wish to show that if $M \in \mathrm{Mod}_R^{n-fp}$, then the map $u_M : M \to \varprojlim \tau_{\leqslant n}(A_i \otimes_R M)$ is an equivalence. Let K denote the fiber of u and note that K is n-truncated. The proof of Theorem 8.3.4.4 shows that $M \simeq \varprojlim (A_i \otimes_R M)$, so that $K \simeq \varprojlim \tau_{\geqslant n+1}(A_i \otimes_R M)$. It follows that K is n-connective and that $\pi_n K \simeq \varprojlim^1 \pi_{n+1}(A_i \otimes_R M)$. It will therefore suffice to show that the abelian group $\varprojlim^1 \pi_{n+1}(A_i \otimes_R M)$ vanishes. This follows from the observation that the inverse system $\{\pi_{n+1}(A_i \otimes_R M)\}_{i \geqslant 0}$ is trivial as an object of $\mathrm{Pro}(\mathrm{Ab})$, because $\pi_{n+1} M \simeq 0$ (Lemma 8.4.4.5). □

Proof of Proposition 8.4.3.5. Let $\mathfrak{X}$ be a locally Noetherian formal spectral Deligne-Mumford stack, let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be the functor represented by $\mathfrak{X}$, and let $n \geqslant 0$ be an integer; we wish to show that the composite functor

$$\mathrm{QCoh}(\mathfrak{X})^{\mathrm{cn}} \cap \mathrm{QCoh}(\mathfrak{X})^{\mathrm{aperf}}_{\leqslant n} \hookrightarrow \mathrm{QCoh}(\mathsf{X}^{\wedge}_K)^{\mathrm{aperf}}_{\geqslant 0} \xrightarrow{\tau_{\leqslant n}} \mathrm{QCoh}^{n-fp}(X)$$

is an equivalence of ∞-categories. The assertion is local on $\mathfrak{X}$. We may therefore reduce to the case where $\mathfrak{X} = \mathrm{Spf}\, A$ for some complete adic $\mathbb{E}_\infty$-ring A, in which case the desired result follows from Lemma 8.4.4.6. □

8.5 The Grothendieck Existence Theorem

Let R be a commutative ring, let X be an R-scheme, and let $I \subseteq R$ be an ideal. For each $n \geqslant 0$, let X_n denote the fiber product $\mathrm{Spec}\, R/I^n \times_{\mathrm{Spec}\, R} X$ (formed in the category of schemes). Each X_n can be regarded as a closed subscheme of X, so we restriction functors

$$\mathrm{QCoh}(X)^{\heartsuit} \to \mathrm{QCoh}(X_n)^{\heartsuit} \qquad \mathscr{F} \mapsto \mathscr{F}|_{X_n}.$$

These restriction functors are compatible as n varies, and therefore define a restriction functor $\mathrm{QCoh}(X)^{\heartsuit} \to \varprojlim_{n \geqslant 0} \mathrm{QCoh}(X_n)^{\heartsuit}$. A fundamental theorem of Grothendieck (see Theorem 5.1.4 and Corollary 5.1.6 of [89]) asserts that, if we impose appropriate finiteness conditions, then this restriction functor becomes an equivalence of categories:

Theorem 8.5.0.1 (Grothendieck Existence Theorem)**.** *Let R be a Noetherian ring which is complete with respect to an ideal I, let X be a proper R-scheme, and for $m \geqslant 0$ define $X_m = X \times_{\operatorname{Spec} R} \operatorname{Spec}(R/I^m)$ as above. Let $\operatorname{Coh}(X)$ and $\operatorname{Coh}(X_m)$ denote the abelian categories of coherent sheaves on X and X_m, respectively. Then the canonical map $\operatorname{Coh}(X) \to \varprojlim\{\operatorname{Coh}(X_m)\}$ is an equivalence of categories.*

Remark 8.5.0.2. In the language of formal schemes, Theorem 8.5.0.1 asserts that the category of coherent sheaves on X is equivalent to the category of coherent sheaves on the formal scheme $X^\wedge$ obtained by completing X along the inverse image of the closed subset $|\operatorname{Spec} R/I| \subseteq |\operatorname{Spec} R|$.

Our goal in this section is to prove an analogue of Theorem 8.5.0.1 in the setting of spectral algebraic geometry. Our result can be stated as follows:

Theorem 8.5.0.3. *[Derived Grothendieck Existence Theorem] Let R be an $\mathbb{E}_\infty$-ring which is I-complete for some finitely generated ideal $I \subseteq \pi_0 R$, let X be a spectral algebraic space which is proper and locally almost of finite presentation over R, and let $\mathsf{X}^\wedge = \operatorname{Spf} R \times_{\operatorname{Spec} R} \mathsf{X}$ denote the formal completion of X along the vanishing locus of I. Then the restriction functor $\operatorname{QCoh}(\mathsf{X})^{\mathrm{aperf}} \to \operatorname{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}}$ is an equivalence of ∞-categories.*

The classical Grothendieck existence theorem is an immediate consequence of Theorem 8.5.0.3:

Proof of Theorem 8.5.0.1. Let R be a Noetherian ring which is complete with respect to an ideal I and let X be a proper R-scheme (or, more generally, a proper algebraic space over R). Let us identify X with a 0-truncated spectral algebraic space X over R (which is automatically locally almost of finite presentation over R in the sense of spectral algebraic geometry: see Remark 4.2.0.4). Choose a tower of $\mathbb{E}_\infty$-algebras $\cdots \to A_3 \to A_2 \to A_1$ satisfying the requirements of Lemma 8.1.2.2, so that each of the commutative rings $\pi_0 A_n$ can be identified with the quotient R/J_n for some ideal $J_n \subseteq R$. Let $\mathsf{X}^\wedge$ denote the formal completion $\mathsf{X} \times_{\operatorname{Sp\acute{e}t} R} \operatorname{Spf} R$. Theorem 8.5.0.3 implies that the restriction functor $\operatorname{QCoh}(\mathsf{X})^{\mathrm{aperf}} \to \operatorname{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}}$ is an equivalence of ∞-categories. Proposition 8.4.2.10 implies that this restriction functor is t-exact, where we regard $\operatorname{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}}$ as endowed with the t-structure of Corollary 8.4.2.4. We therefore obtain an equivalence of hearts $\operatorname{QCoh}(\mathsf{X})^{\mathrm{aperf}\heartsuit} \to \operatorname{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}\heartsuit}$. Using the description of these hearts supplied by Proposition 8.4.3.5, we obtain an equivalence of categories

$$\operatorname{QCoh}^{0-fp}(\mathsf{X}) \to \operatorname{QCoh}^{0-fp}(\mathsf{X}^\wedge) \simeq \varprojlim \operatorname{QCoh}^{0-fp}(\mathsf{X} \times_{\operatorname{Sp\acute{e}t} R} \operatorname{Sp\acute{e}t} A_n).$$

We now observe that the left hand side of this equivalence can be identified with the abelian category $\operatorname{Coh}(X)$ of coherent sheaves on X, while the right hand side can be identified with the limit $\varprojlim \{\mathrm{Coh}(X_n)\}_{n>0}$, where X_n denotes the fiber product $X \times_{\operatorname{Spec} R} \operatorname{Spec}(R/J_n)$ formed in the category of schemes (which is the underlying scheme of the spectral algebraic space $\mathsf{X} \times_{\operatorname{Sp\acute{e}t} R} \operatorname{Sp\acute{e}t} A_n$). Theorem 8.5.0.1 now follows by observing that the sequences of ideals $\{J_n\}_{n>0}$ and $\{I^m\}_{m \geqslant 0}$ are mutually cofinal. □

Remark 8.5.0.4. One feature which distinguishes Theorem 8.5.0.3 from its classical analogue is that it does need any Noetherian hypotheses on the $\mathbb{E}_\infty$-ring R. However, this generality comes at a price: Theorem 8.5.0.3 asserts the existence of an equivalence of ∞-categories, but does not *a priori* tell us anything at the level of abelian categories: in general the ∞-category $\mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}}$ is not closed under truncation, and therefore does not inherit a t-structure from $\mathrm{QCoh}(\mathsf{X})$.

Remark 8.5.0.5. In the situation of Theorem 8.5.0.3, an object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}}$ is perfect if and only if the restriction $\mathscr{F}|_{\mathsf{X}^\wedge} \in \mathrm{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}}$ is perfect. The "only if" direction is obvious. Conversely, if $\mathscr{F}|_{\mathsf{X}^\wedge}$ is perfect, then it is dualizable as an object of $\mathrm{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}}$, so that (by virtue of Theorem 8.5.0.3) the sheaf $\mathscr{F}$ is dualizable as an object of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}}$. It then follows that $\mathscr{F}$ is dualizable as an object of $\mathrm{QCoh}(\mathsf{X})$, and is therefore perfect by virtue of Proposition 6.2.6.2.

8.5.1 Full Faithfulness

As a first step towards the proof of Theorem 8.5.0.3, we show that the restriction functor $\mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}} \to \mathrm{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}}$ is fully faithful (Proposition 8.5.1.2). As we will see in a moment, this is essentially a formal consequence of the direct image theorem for proper morphisms (Theorem 5.6.0.2).

Lemma 8.5.1.1 (Derived Theorem on Formal Functions)**.** *Let R be a connective $\mathbb{E}_\infty$-ring which is I-complete for some finitely generated ideal $I \subseteq \pi_0 R$. Let X be a spectral algebraic space which is proper and locally almost of finite presentation over $\operatorname{Sp\acute{e}t} R$, let $\mathsf{X}^\wedge = \operatorname{Spf} R \times_{\operatorname{Sp\acute{e}t} R} \mathsf{X}$ be the formal completion of X along the vanishing locus of I, and let $f : \mathsf{X}^\wedge \hookrightarrow \mathsf{X}$ denote the canonical map. If $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ is almost perfect, then the restriction map $\theta : \Gamma(\mathsf{X}; \mathscr{F}) \to \Gamma(\mathsf{X}^\wedge; f^* \mathscr{F})$ is an equivalence of spectra.*

Proof. Using Proposition 8.3.3.6, we can replace $\mathscr{F}$ by $f_* \mathscr{F}$ and thereby reduce to the case where $\mathsf{X} = \operatorname{Sp\acute{e}t} R$ (note that $f_* \mathscr{F} \in \mathrm{QCoh}(\operatorname{Sp\acute{e}t} R)$ is almost perfect by virtue of Theorem 5.6.0.2). In this case, Lemma 8.1.2.3 implies that the map θ exhibits $\Gamma(\mathsf{X}^\wedge; f^* \mathscr{F})$ as an I-completion of $\Gamma(\mathsf{X}; \mathscr{F})$. We conclude by observing that $\Gamma(\mathsf{X}; \mathscr{F})$ is already I-complete: this follows from Proposition 7.3.5.7, since the $\mathbb{E}_\infty$-ring R is assumed to be I-complete. □

Proposition 8.5.1.2. *Let R be a connective $\mathbb{E}_\infty$-ring which is I-complete for some finitely generated ideal $I \subseteq \pi_0 R$. Let X be a spectral algebraic space which is proper and locally almost* *of finite presentation over* Spét R*, and let* $\mathsf{X}^\wedge = \operatorname{Spf} R \times_{\operatorname{Sp\acute{e}t} R} \mathsf{X}$ *denote the formal completion of* X *along the closed substack determined by* I*, and let* $f : \mathsf{X}^\wedge \to \mathsf{X}$ *be the canonical map. Let* $\mathscr{F}, \mathscr{G} \in \operatorname{QCoh}(\mathsf{X})$*, and assume that* $\mathscr{G}$ *is almost perfect. Then the canonical map*

$$\operatorname{Map}_{\operatorname{QCoh}(\mathsf{X})}(\mathscr{F}, \mathscr{G}) \to \operatorname{Map}_{\operatorname{QCoh}(\mathsf{X}^\wedge)}(f^\star \mathscr{F}, f^\star \mathscr{G})$$

is a homotopy equivalence.

Corollary 8.5.1.3. *In the situation of Proposition 8.5.1.2, the complted pullback functor* $f^\star : \operatorname{QCoh}(\mathsf{X}) \to \operatorname{QCoh}(\mathsf{X}^\wedge)$ *is fully faithful when restricted to the full subcategory* $\operatorname{QCoh}(\mathsf{X})^{\mathrm{aperf}} \subseteq \operatorname{QCoh}(\mathsf{X})$ *spanned by the almost perfect objects.*

Proof of Proposition 8.5.1.2. Let us first regard $\mathscr{G}$ as fixed, and regard the morphism

$$\theta_{\mathscr{F}} : \operatorname{Map}_{\operatorname{QCoh}(\mathsf{X})}(\mathscr{F}, \mathscr{G}) \to \operatorname{Map}_{\operatorname{QCoh}(\mathsf{X}^\wedge)}(f^\star \mathscr{F}, f^\star \mathscr{G})$$

as a functor of $\mathscr{F}$. This functor carries colimits in $\operatorname{QCoh}(\mathsf{X})$ to limits in $\operatorname{Fun}(\Delta^1, \mathcal{S})$. Consequently, the collection of those objects $\mathscr{F} \in \operatorname{QCoh}(\mathsf{X})$ for which $\theta_{\mathscr{F}}$ is a homotopy equivalence is closed under colimits. Using Theorem **??**, we are reduced to proving that $\theta_{\mathscr{F}}$ is an equivalence in the special case where $\mathscr{F}$ is perfect. In this case, $\mathscr{F}$ is a dualizable object of $\operatorname{QCoh}(\mathsf{X})$; let us denote its dual by $\mathscr{F}^\vee$. Replacing $\mathscr{G}$ by $\mathscr{F}^\vee \otimes \mathscr{G}$, we can reduce to the case where $\mathscr{F} = \mathscr{O}_{\mathsf{X}}$. In this case, we can identify $\theta_{\mathscr{F}}$ with the restriction map $\Gamma(\mathsf{X}; \mathscr{G}) \to \Gamma(\mathsf{X}^\wedge; f^\star \mathscr{G})$, which is an equivalence by virtue of Lemma 8.5.1.1. □

If the $\mathbb{E}_\infty$-ring R appearing in Proposition 8.5.1.2 is not Noetherian, then we generally do not have good t-structures on the ∞-categories $\operatorname{QCoh}(\mathsf{X})^{\mathrm{aperf}}$ and $\operatorname{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}}$. However, we nevertheless have the following exactness property (compare with Proposition 8.4.2.10):

Proposition 8.5.1.4. *Let* R *be a connective* $\mathbb{E}_\infty$*-ring which is* I*-complete for some finitely generated ideal* $I \subseteq \pi_0 R$*. Let* X *be a spectral algebraic space which is proper and locally almost of finite presentation over* Spét R*, let* $\mathscr{F} \in \operatorname{QCoh}(\mathsf{X})^{\mathrm{aperf}}$*, and let* $\mathsf{X}^\wedge$ *denote the formal completion* $\operatorname{Spf} R \times_{\operatorname{Sp\acute{e}t} R} \mathsf{X}$*. Then* $\mathscr{F}$ *is connective if and only if* $\mathscr{F}|_{\mathsf{X}^\wedge}$ *is connective.*

Proof. The "only if" direction is trivial. To prove the converse, let us suppose that $\mathscr{F}$ is not connective. Since X is quasi-compact, there exists some smallest integer $n < 0$ such that $\pi_n \mathscr{F}$ does not vanish. Let $K \subseteq |\mathsf{X}|$ be the support of X. Then $K \neq \emptyset$. Since f is proper, the image $f(K)$ is a nonempty closed subset of $|\operatorname{Spec} R|$. Let y be a closed point of $|\operatorname{Spec} R|$ which is contained in $f(K)$, and let $x \in |\mathsf{X}|$ be a point lying over y. Then we can choose an étale map $u : \operatorname{Sp\acute{e}t} A \to \mathsf{X}$ such that x lifts to a point $\overline{x} \in |\operatorname{Spec} A|$. Let κ denote the residue field of $\pi_0 A$ at the point $\overline{x}$. Since $\mathscr{F}$ is n-connective and almost perfect, $\pi_n u^* \mathscr{F}$ is a finitely generated module over $\pi_0 A$. Using Nakayama's lemma and our assumption $x \in \operatorname{Supp}(\mathscr{F})$, we deduce that $\pi_n(\kappa \otimes_A u^* \mathscr{F}) \neq 0$. Note that Remark 7.3.4.10 implies that the composite map $\operatorname{Sp\acute{e}t} \kappa \to \operatorname{Sp\acute{e}t} A \xrightarrow{u} \mathsf{X}$ factors through $\mathsf{X}^\wedge$, so that $\mathscr{F}|_{\mathsf{X}^\wedge}$ is not connective. □

8.5.2 The Grothendieck Existence Theorem

Our goal in this section is to give the proof of Theorem 8.5.0.3. We begin by treating the projective case. First, we note the following slight variant of Theorem 7.2.2.1:

Lemma 8.5.2.1. *Let R be a connective $\mathbb{E}_\infty$-ring, let $n \geqslant 0$, and let $q : \mathbf{P}^n_R \to \operatorname{Spét} R$ be the projection map. Suppose that $\mathscr{F} \in \operatorname{QCoh}(\mathbf{P}^n_R)$ is a quasi-coherent sheaf having the property that the direct images $q_*(\mathscr{F} \otimes \mathscr{O}(i))$ vanish for $0 \leqslant i \leqslant n$. Then $\mathscr{F} \simeq 0$.*

Proof. We will show that $\pi_m \mathscr{F} \simeq 0$ for every integer m. Replacing $\mathscr{F}$ by $\Sigma^{-m}\mathscr{F}$, we may assume that $m = 0$. Using Lemma 5.6.2.2, we can choose a map $\gamma : \bigoplus_\alpha \mathscr{O}(d_\alpha) \to \mathscr{F}$ which induces an epimorphism on π_0. It will therefore suffice to show that γ is nullhomotopic. In fact, we claim that the mapping space $\operatorname{Map}_{\operatorname{QCoh}(\mathbf{P}^n_R)}(\mathscr{O}(d), \mathscr{F}) \simeq \operatorname{Map}_{\operatorname{Mod}_R}(R, q_*(\mathscr{F} \otimes \mathscr{O}(-d)))$ is contractible for every integer d. To prove this, let S be the collection of integers i for which $q_*(\mathscr{F} \otimes \mathscr{O}(-d))$ vanishes. By hypothesis, S contains the set $\{0, -1, \ldots, -n\}$. Lemma 7.2.2.2 implies that whenever S contains the set $\{k, k-1, \ldots, k-n\}$, it also contains $k+1$ and $k-n-1$. An easy induction now shows that S contains all integers. □

Proposition 8.5.2.2. *Let R be an $\mathbb{E}_\infty$-ring which is I-complete for some finitely generated ideal $I \subseteq \pi_0 R$, let X be a spectral algebraic space which is equipped with a map $f : \mathsf{X} \to \mathbf{P}^n_R$ which is finite and locally almost of finite presentation, and let $\mathsf{X}^\wedge = \operatorname{Spf} R \times_{\operatorname{Spét} R} \mathsf{X}$ denote the formal completion of X along the vanishing locus of I. Then the restriction functor $\theta : \operatorname{QCoh}(\mathsf{X})^{\mathrm{aperf}} \to \operatorname{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}}$ is an equivalence of ∞-categories.*

Proof. Let $\mathscr{A}$ denote the direct image $f_* \mathscr{O}_{\mathsf{X}}$, which we regard as a commutative algebra object of $\operatorname{QCoh}(\mathbf{P}^n_R)$. Our assumption that f is finite and locally almost of finite presentation guarantees that $\mathscr{A} \in \operatorname{QCoh}(\mathbf{P}^n_R)$ is almost perfect (Corollary 5.2.2.2). Let us abuse notation by identifying $\mathscr{A}$ with its image under the restriction functor $\operatorname{QCoh}(\mathbf{P}^n_R)^{\mathrm{aperf}} \to \operatorname{QCoh}(\mathbf{P}^n_R \times_{\operatorname{Spét} R} \operatorname{Spf} R)^{\mathrm{aperf}}$. Since f is affine, it follows from Propositions 2.5.6.1, 5.6.1.1, and Corollary 8.3.4.6 that we have a commutative diagram of ∞-categories

$$\begin{array}{ccc} \operatorname{QCoh}(\mathsf{X})^{\mathrm{aperf}} & \xrightarrow{\theta} & \operatorname{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}} \\ \downarrow & & \downarrow \\ \operatorname{Mod}_{\mathscr{A}}(\operatorname{QCoh}(\mathbf{P}^n_R)^{\mathrm{aperf}}) & \longrightarrow & \operatorname{Mod}_{\mathscr{A}}(\operatorname{QCoh}(\mathbf{P}^n_R \times_{\operatorname{Spec} R} \operatorname{Spf} R)^{\mathrm{aperf}}) \end{array}$$

where the vertical maps are equivalences. We may therefore replace X by $\mathbf{P}^n_R$ and thereby reduce to the case where X is a projective space over R.

Let $q : \mathsf{X} \to \operatorname{Spét} R$ denote the projection map and let $\widehat{q} : \mathsf{X}^\wedge \to \operatorname{Spf} R$ denote its restriction to $\mathsf{X}^\wedge$. Consider the following assertion for $m \geqslant -1$:

$(*_m)$ If $\mathscr{F} \in \operatorname{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}}$ has the property that $\widehat{q}_*(\mathscr{F} \otimes \theta(\mathscr{O}(i)) \in \operatorname{QCoh}(\operatorname{Spf} R)^{\mathrm{aperf}}$ vanishes for $0 \leqslant i \leqslant m$, then $\mathscr{F}$ belongs to the essential image of θ.

Note that assertion $(*_{-1})$ is equivalent to Proposition 8.5.2.2 (since the restriction functor θ is already known to be fully faithful by virtue of Corollary 8.5.1.3). We will prove assertion that $(*_m)$ holds for all $m \leqslant n$ using descending induction on m. The case $m = n$ follows from Lemma 8.5.2.1. To carry out the inductive step, let us assume that $(*_m)$ is satisfied, and let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}}$ satisfy the hypotheses of $(*_{m-1})$. Set $\mathscr{G} = \widehat{q}_*(\mathscr{F} \otimes \mathscr{O}(m)) \in \mathrm{QCoh}(\operatorname{Spf} R)^{\mathrm{aperf}}$ and form a cofiber sequence $\widehat{q}^\star \mathscr{G} \otimes \mathscr{O}(-m) \xrightarrow{\alpha} \mathscr{F} \to \mathscr{F}'$. It follows from Theorem 5.4.2.6 (and the vanishing of $\widehat{q}_*(\mathscr{F} \otimes \mathscr{O}(i))$ for $0 \leqslant i < m$) that α induces an equivalence $\widehat{q}_*(\widehat{q}^\star \mathscr{G} \otimes \mathscr{O}(i-m)) \to \widehat{q}_*(\mathscr{F} \otimes \mathscr{O}(i))$ for $0 \leqslant i \leqslant m$. Applying our inductive hypothesis to $\mathscr{F}'$, we deduce that $\mathscr{F}'$ belongs to the essential image of θ. It will therefore suffice to show that $\mathscr{G}$ belongs to the essential image of θ, which follows from the commutativity of the diagram

$$\begin{array}{ccc} \mathrm{QCoh}(\operatorname{Sp\acute{e}t} R)^{\mathrm{aperf}} & \longrightarrow & \mathrm{QCoh}(\operatorname{Spf} R)^{\mathrm{aperf}} \\ \downarrow{\scriptstyle q^*} & & \downarrow{\scriptstyle \widehat{q}^\star} \\ \mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}} & \xrightarrow{\theta} & \mathrm{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}} \end{array}$$

(note that the upper horizontal map is an equivalence of ∞-categories by virtue of Corollary **??**). □

We now prove the general form of the Grothendieck existence theorem.

Proof of Theorem 8.5.0.3. Let R be a connective $\mathbb{E}_\infty$-ring which is complete with respect to a finitely generated ideal $I \subseteq \pi_0 R$, let $q : \mathsf{X} \to \operatorname{Sp\acute{e}t} R$ be a morphism of spectral algebraic spaces which is proper and locally almost of finite presentation, and let $\mathsf{X}^\wedge = \operatorname{Spf} R \times_{\operatorname{Sp\acute{e}t} R} \mathsf{X}$ denote the formal completion of X along the vanishing locus of I. We wish to show that the restriction functor $\theta : \mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}} \to \mathrm{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}}$ is an equivalence of ∞-categories. Note that we have already seen that θ is fully faithful (Corollary 8.5.1.3).

Applying Chow's Lemma (Theorem **??** and Remarks 5.5.0.3 and 5.5.0.4), we can choose a finite sequence of closed immersions

$$\varnothing = \mathsf{Y}_0 \to \mathsf{Y}_1 \to \mathsf{Y}_2 \to \cdots \to \mathsf{Y}_n \to \mathsf{X}$$

and closed immersions $h_i : \widetilde{\mathsf{Y}}_i \to \mathsf{Y}_i \times_{\operatorname{Sp\acute{e}t} R} \mathbf{P}^{d_i}_R$ which are almost of finite presentation satisfying the following conditions:

(i) The closed immersion $\mathsf{Y}_n \to \mathsf{X}$ induces a homeomorphism $|\mathsf{Y}_n| \to |\mathsf{X}|$.

(ii) The projection maps $\widetilde{\mathsf{Y}}_i \to \mathbf{P}^{d_i}_R$ are finite (and locally almost of finite presentation).

(iii) The projection maps $h'_i : \widetilde{\mathsf{Y}}_i \to \mathsf{Y}_i$ induce equivalences $\widetilde{\mathsf{Y}}_i \times_{\mathsf{Y}_i} \mathsf{U}_i \to \mathsf{U}_i$, where U_i is the open substack of Y_i complementary to Y_{i-1}.

For $0 \leqslant i \leqslant n$, let $Y_i \subseteq |\mathsf{X}|$ denote the image of $|\mathsf{Y}_i|$. We will prove the following:

$(*_i)$ Let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}}$ and let $\mathscr{G} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}}$ be supported on Y_i. Then the tensor product $\mathscr{F} \otimes \theta(\mathscr{G})$ belongs to the essential image of θ.

Note that $(*_n)$ implies Theorem 8.5.0.3 (since (i) implies we can take $\mathscr{G} = \mathscr{O}_{\mathsf{X}}$) and that $(*_0)$ is trivial. To complete the proof, it will suffice to show that if $1 \leqslant i \leqslant n$ and $(*_{i-1})$ is satisfied, then $(*_i)$ is also satisfied.

Let v denote the closed immersion $\mathsf{Y}_i \to \mathsf{X}$. We first establish the following special case of $(*_i)$:

$(*')$ For every object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}}$, the tensor product $\mathscr{F} \otimes \theta(v_* \mathscr{O}_{\mathsf{Y}_i})$ belongs to the essential image of θ.

To prove $(*')$, let $\mathscr{G}$ denote the fiber of the unit map $\mathscr{O}_{\mathsf{Y}_i} \to h'_{i*} \mathscr{O}_{\tilde{\mathsf{Y}}_i}$, so that we have a fiber sequence

$$\mathscr{F} \otimes \theta(v_* \mathscr{G}) \to \mathscr{F} \otimes \theta(v_* \mathscr{O}_{\mathsf{Y}_i}) \to \mathscr{F} \times \theta((v \circ h'_i)_* \mathscr{O}_{\tilde{\mathsf{Y}}_i}).$$

Assumption (iii) guarantees that $v_* \mathscr{G}$ is supported on Y_{i-1}, so that $\mathscr{F} \otimes \theta(v_* \mathscr{G})$ belongs to the essential image of θ by virtue of our inductive hypothesis $(*_{i-1})$. Let $\widetilde{\mathsf{Y}}_i^\wedge$ denote the formal completion $\widetilde{\mathsf{Y}}_i \times_{\mathrm{Sp\acute{e}t}\, R} \mathrm{Spf}\, R$, so that $(v \circ h'_i)$ induces a map $\widehat{u} : \widetilde{\mathsf{Y}}_i^\wedge \to \mathsf{X}^\wedge$. The projection formula (Corollary 6.3.4.3) then supplies an equivalence $\mathscr{F} \times \theta((v \circ h'_i)_* \mathscr{O}_{\tilde{\mathsf{Y}}_i}) \simeq \widehat{u}_* \widehat{u}^\star \mathscr{F}$. Using the commutativity of the diagram

$$\begin{array}{ccc} \mathrm{QCoh}(\widetilde{\mathsf{Y}}_i)^{\mathrm{aperf}} & \longrightarrow & \mathrm{QCoh}(\widetilde{\mathsf{Y}}_i^\wedge)^{\mathrm{aperf}} \\ \downarrow {\scriptstyle (v \circ h'_i)_*} & & \downarrow {\scriptstyle \widehat{u}_*} \\ \mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}} & \xrightarrow{\theta} & \mathrm{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}} \end{array}$$

and the observation that the upper horizontal map is an equivalence (by virtue of (ii) and Proposition 8.5.2.2), we see that $\widehat{u}_* \widehat{u}^\star \mathscr{F}$ belongs to the essential image of θ. Since the essential image of θ is closed under extensions, we deduce that $\mathscr{F} \otimes \theta(v_* \mathscr{O}_{\mathsf{Y}_i})$ is contained in the essential image of θ. This competes the proof of $(*')$.

We now return to the proof of $(*_i)$. Let us henceforth regard $\mathscr{F}$ as a fixed object of $\mathrm{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}}$, which we assume to be connective. Let $\mathcal{I}$ denote the fiber of the unit map $\mathscr{O}_{\mathsf{X}} \to v_* \mathscr{O}_{\mathsf{Y}_i}$. Fix an integer $m \geqslant 0$. It follows from $(*')$ that the cofiber of each of the natural maps

$$\mathscr{F} \otimes \theta(\mathcal{I}^{\otimes m}) \to \mathscr{F} \otimes \theta(\mathcal{I}^{\otimes m-1}) \to \cdots \to \mathscr{F} \otimes \theta(\mathcal{I}) \to \mathscr{F}$$

belongs to the essential image of θ. Since the essential image of θ is closed under extensions, we can choose a cofiber sequence $\mathscr{F} \otimes \theta(\mathcal{I}^{\otimes m}) \to \mathscr{F} \to \theta(\mathscr{F}_m)$ for some objects $\mathscr{F}_m \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}}$ (which are then automatically connective, by virtue of Proposition 8.5.1.4). To complete the proof, it will suffice to verify the following:

(a) For every connective object $\mathscr{G} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}}$ which is supported on Y_i, the towers $\{\mathscr{F}_m \otimes \mathscr{G}\}_{m \geqslant 0}$ and $\{\theta(\mathscr{F}_m \otimes \mathscr{G})\}_{m \geqslant 0}$ admit limits in the ∞-categories $\mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}} \cap \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ and $\mathrm{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}} \cap \mathrm{QCoh}(\mathsf{X}^\wedge)^{\mathrm{cn}}$, respectively.

(b) Let $\mathscr{G}$ be as in (a). Then the canonical maps

$$\mathscr{F} \otimes \theta(\mathscr{G}) \rightarrow \varprojlim_m \theta(\mathscr{F}_m \otimes \mathscr{G}) \leftarrow \theta(\varprojlim_m (\mathscr{F}_m \otimes \mathscr{G}))$$

are equivalences in the ∞-category $\mathrm{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}}$.

Note that we have a commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}} \cap \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} & \longrightarrow & \mathrm{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}} \cap \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \\ \downarrow & & \downarrow \\ \varprojlim_k \mathrm{QCoh}^{k-fp}(\mathsf{X}) & \longrightarrow & \varprojlim_k \mathrm{QCoh}^{k-fp}(\mathsf{X}^\wedge), \end{array}$$

where the vertical maps are equivalences of ∞-categories (see Notation 8.4.3.1). Consequently, in order to prove (a) and (b), it will suffice to verify the following analogous assertions, for each $k \geqslant 0$:

(a_k) For every connective object $\mathscr{G} \in \mathrm{QCoh}_{Y_i}(\mathsf{X})^{\mathrm{aperf}}$, the diagrams $\{\tau_{\leqslant k}(\mathscr{F}_m \otimes \mathscr{G})\}_{m \geqslant 0}$ and $\{\theta_k(\tau_{\leqslant k}(\mathscr{F}_m \otimes \mathscr{G}))\}_{m \geqslant 0}$ both admit limits in the ∞-categories $\mathrm{QCoh}^{k-fp}(\mathsf{X})$ and $\mathrm{QCoh}^{k-fp}(\mathsf{X}^\wedge)$, respectively. Here $\theta_k : \mathrm{QCoh}^{k-fp}(\mathsf{X}) \rightarrow \mathrm{QCoh}^{k-fp}(\mathsf{X}^\wedge)$ denotes the restriction map.

(b_k) Let $\mathscr{G}$ be as in (a_k). Then the canonical maps

$$\tau_{\leqslant k}(\mathscr{F} \otimes \theta(\mathscr{G})) \xrightarrow{\alpha} \varprojlim_m \theta_k(\tau_{\leqslant k}(\mathscr{F}_m \otimes \mathscr{G})) \leftarrow \theta_k(\varprojlim_m \tau_{\leqslant k}(\mathscr{F}_m \otimes \mathscr{G}))$$

are equivalences in the ∞-category $\mathrm{QCoh}^{k-fp}(\mathsf{X}^\wedge)$.

Since $\mathscr{G}$ is almost perfect and is supported on Y_i, it follows from Proposition **??** that there exists an integer $t \gg 0$ for which the composite map $\mathcal{I}^{\otimes t} \otimes \mathscr{G} \xrightarrow{e} \mathscr{G} \rightarrow \tau_{\leqslant k} \mathscr{G}$ is nullhomotopic. It follows that $\tau_{\leqslant k} \mathscr{G}$ is retract of $\tau_{\leqslant k}(\mathrm{cofib}(e))$. We may therefore replace $\mathscr{G}$ by $\mathrm{cofib}(e)$ and thereby reduce to the case where $\mathscr{G}$ can be written as a finite extension of objects belonging to the essential image of the functor $v_* : \mathrm{QCoh}(\mathsf{Y}_i)^{\mathrm{aperf}} \rightarrow \mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}}$. Consequently, it will suffice to prove the following:

(a') For every connective object $\mathscr{G} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}}$ which can be written as a finite extension of objects belonging to the essential image of v_*, the towers the towers $\{\mathscr{F}_m \otimes \mathscr{G}\}_{m \geqslant 0}$ and $\{\theta(\mathscr{F}_m \otimes \mathscr{G}))\}_{m \geqslant 0}$ are constant when regarded as Pro-objects of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}}$ and $\mathrm{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}}$, respectively.

(b') Let $\mathscr{G}$ be as in (a'). Then the canonical maps

$$\mathscr{F} \otimes \theta(\mathscr{G}) \xrightarrow{\alpha} \varprojlim_m \theta(\mathscr{F}_m \otimes \mathscr{G}) \xleftarrow{\beta} \theta(\varprojlim_m (\mathscr{F}_m \otimes \mathscr{G}))$$

are equivalences in the ∞-category $\mathrm{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}}$ (note that both limits are well-defined by virtue of (a')).

Note that the collection of those objects $\mathscr{G} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}}$ for which the conclusions of (a') and (b') are satisfied is closed under extensions. We may therefore assume that $\mathscr{G} = v_* \mathscr{G}_0$ for some object $\mathscr{G}_0 \in \mathrm{QCoh}(\mathsf{Y}_i)^{\mathrm{aperf}}$. We then have a fiber sequence of towers in $\mathrm{QCoh}(\mathsf{X}^\wedge)^{\mathrm{aperf}}$

$$\{\mathscr{F} \otimes \theta(\mathcal{I}^{\otimes m} \otimes v_* \mathscr{G}_0)\}_{m \geqslant 0} \to \{\mathscr{F} \otimes \theta(v_* \mathscr{G}_0)\}_{m \geqslant 0} \to \{\theta(\mathscr{F}_m \otimes v_* \mathscr{G}_0)\}_{m \geqslant 0}.$$

Here the tower on the left is trivial as a Pro-object (since it has vanishing transition maps) and the tower in the middle is constant already as a diagram, so the tower on the right as constant as Pro-object. This shows that α is an equivalence and, since the functor θ is fully faithful (Corollary 8.5.1.3), that the tower the tower $\{\mathscr{F}_m \otimes v_* \mathscr{G}_0\}_{m \geqslant 0}$ is constant as a Pro-object of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{aperf}}$. It follows formally that the tower $\{\theta(\mathscr{F}_m \otimes v_* \mathscr{G}_0)\}_{m \geqslant 0}$ is also a constant Pro-object and that the comparison map β is an equivalence. □

8.5.3 The Formal GAGA Theorem

Let R be a Noetherian commutative ring which is complete with respect to an ideal $I \subseteq R$. One of the most useful consequences of the classical Grothendieck existence theorem is that a proper R-scheme X is determined by its completion along the vanishing locus of I: that is, by the direct system of closed subschemes $\{\operatorname{Spec} R/I^n \times_{\operatorname{Spec} R} X\}_{n \geqslant 0}$. In the setting of spectral algebraic geometry, we have the following parallel result:

Theorem 8.5.3.1. *Let R be an $\mathbb{E}_\infty$-ring which is complete with respect to a finitely generated ideal $I \subseteq \pi_0 R$, let X be a spectral algebraic space which is proper and locally almost of finite presentation over R, and let $\mathsf{X}^\wedge = \operatorname{Spf} R \times_{\operatorname{Sp\acute{e}t} R} \mathsf{X}$ denote the formal completion of X along the vanishing locus of I. Let Y be a spectral algebraic space which is quasi-separated. Then the restriction map $\mathrm{Map}_{\mathrm{SpDM}}(\mathsf{X}, \mathsf{Y}) \to \mathrm{Map}_{\mathrm{fSpDM}}(\mathsf{X}^\wedge, \mathsf{Y})$ is a homotopy equivalence.*

Proof. Writing Y as a union of quasi-compact open substacks (and using the quasi-compactness of X and $\mathsf{X}^\wedge$), we can reduce to the case where Y is quasi-compact. We have a commutative diagram

$$\begin{array}{ccc} \mathrm{Map}_{\mathrm{SpDM}}(\mathsf{X}, \mathsf{Y}) & \longrightarrow & \mathrm{Map}_{\mathrm{fSpDM}}(\mathsf{X}^\wedge, \mathsf{Y}) \\ \downarrow & & \downarrow \\ \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(\mathsf{Y})^{\mathrm{perf}}, \mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}) & \longrightarrow & \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(\mathsf{Y})^{\mathrm{perf}}, \mathrm{QCoh}(\mathsf{X}^\wedge)^{\mathrm{perf}}). \end{array}$$

It follows from Corollary 9.6.4.2 and Theorem 8.1.5.1 that the vertical maps are fully faithful embeddings, and that their essential images are the full subcategories of $\mathrm{Fun}^{\otimes}(\mathrm{QCoh}(\mathsf{Y})^{\mathrm{perf}}, \mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}})$ and $\mathrm{Fun}^{\otimes}(\mathrm{QCoh}(\mathsf{Y})^{\mathrm{perf}}, \mathrm{QCoh}(\mathsf{X}^{\wedge})^{\mathrm{perf}})$ spanned by those symmetric monoidal functors which are exact. To complete the proof, it suffices to observe that the restriction map $\mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}} \to \mathrm{QCoh}(\mathsf{X}^{\wedge})^{\mathrm{perf}}$ is an equivalence of ∞-categories (by virtue of Theorem 8.5.0.3 and Remark 8.5.0.5). □

Remark 8.5.3.2. The conclusion of Theorem 8.5.3.1 is valid for many algebro-geometric objects Y other than quasi-separated algebraic spaces; see, for example, Corollary 9.5.5.3.

Corollary 8.5.3.3. *Let R be an $\mathbb{E}_\infty$-ring which is complete with respect to a finitely generated ideal ideal $I \subseteq \pi_0 R$. Let X and Y be spectral algebraic spaces over R, and let $\mathsf{X}^{\wedge}$ and $\mathsf{Y}^{\wedge}$ denote their formal completions along the vanishing locus of I. Assume that X is proper and locally almost of finite presentation over R and that Y is quasi-separated. Then the restriction map*

$$\mathrm{Map}_{\mathrm{SpDM}_{/\operatorname{Sp\acute{e}t} R}}(\mathsf{X}, \mathsf{Y}) \to \mathrm{Map}_{\mathrm{fSpDM}_{/\operatorname{Spf} R}}(\mathsf{X}^{\wedge}, \mathsf{Y}^{\wedge})$$

is a homotopy equivalence.

Corollary 8.5.3.4 (Formal GAGA Theorem)**.** *Let R be an $\mathbb{E}_\infty$-ring which is complete with respect to a finitely generated ideal $I \subseteq \pi_0 R$, and let $\mathcal{C}$ be the full subcategory of $\mathrm{SpDM}_{/\operatorname{Sp\acute{e}t} R}$ spanned by those spectral Deligne-Mumford stacks which are proper and locally almost of finite presentation over R. Then the construction $\mathsf{X} \mapsto \operatorname{Spf} R \times_{\operatorname{Sp\acute{e}t} R} \mathsf{X}$ determines a fully faithful embedding $\mathcal{C} \to \mathrm{fSpDM}_{/\operatorname{Spf} R}$.*

Remark 8.5.3.5. In the setting of spectral algebraic geometry, Theorem 8.5.3.1 (and Corollaries 8.5.3.3 and 8.5.3.4) do not require any Noetherian hypotheses on R. However, if R is not Noetherian, then the formation of I-completions generally does not have good exactness properties. Consequently, even if R is an ordinary commutative ring and X is an ordinary algebraic space over R, the formal completion $\mathsf{X}^{\wedge}$ which appears in Theorem 8.5.3.1 might differ from its classical analogue (which is simply the direct limit of the closed subspaces $\operatorname{Spec} R/I^n \times_{\operatorname{Spec} R} \mathsf{X} \subseteq \mathsf{X}$).

Remark 8.5.3.6. Let R be an adic $\mathbb{E}_\infty$-ring and let $\mathfrak{X}$ be a formal spectral Deligne-Mumford stack equipped with a map $f : \mathfrak{X} \to \operatorname{Spf} R$. We will say that $\mathfrak{X}$ is *algebraizable* if there exists a pullback square

$$\begin{array}{ccc} \mathfrak{X} & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow \\ \operatorname{Spf} R & \longrightarrow & \operatorname{Sp\acute{e}t} R, \end{array}$$

where X is a spectral algebraic space which is proper and locally almost of finite presentation over R. It follows from Corollary 8.5.3.4 that if such a diagram exists, then it is uniquely determined (up to a contractible space of choices).

8.6 Digression: Geometrically Reduced Morphisms

Let $f : X \to Y$ be a morphism of schemes. Recall that f is said to be *geometrically reduced* if f is flat and the geometric fibers of f are reduced. This definition extends to the setting of spectral algebraic geometry without essential change:

Definition 8.6.0.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. We will say that f is *geometrically reduced* if f is flat and, for every pullback diagram

$$\begin{array}{ccc} \mathsf{X}_\kappa & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow f \\ \operatorname{Sp\acute{e}t} \kappa & \longrightarrow & \mathsf{Y} \end{array}$$

where κ is a field, the fiber X_κ is reduced (Definition 3.1.6.1).

Our goal in this section is to establish some elementary properties of geometrically reduced morphisms in spectral algebraic geometry (most of which are immediate consequences of the analogous facts in classical algebraic geometry).

8.6.1 Geometrically Reduced Algebras over a Field

We begin by reviewing the classical theory of geometrically reduced algebras over a field.

Definition 8.6.1.1. Let κ be a field and let $A \in \mathrm{CAlg}_\kappa^\heartsuit$ be a commutative algebra over κ. We will say that A is *geometrically reduced over* κ if, for every extension field κ' of κ, the tensor product $A \otimes_\kappa \kappa'$ is reduced.

Remark 8.6.1.2. Let κ be a field and let $A \in \mathrm{CAlg}_\kappa^\heartsuit$ be geometrically reduced over κ. Then every localization of A is geometrically reduced over κ.

Remark 8.6.1.3. Let κ be a field and let $A \in \mathrm{CAlg}_\kappa^\heartsuit$. If A is geometrically reduced over κ, then every κ-subalgebra of A is geometrically reduced over κ. Conversely, if every finitely generated κ-subalgebra of A is geometrically reduced over κ, then A is geometrically reduced over κ.

Lemma 8.6.1.4. *Let κ' be a finitely generated extension of a field κ, and suppose that the module of Kähler differentials $\Omega_{\kappa'/\kappa}$ vanishes. Then κ' is a finite separable extension of κ.*

Proof. Suppose first that κ' is generated, as a field extension of κ, by a single element $x \in \kappa'$. If x is trancendental over κ, then κ' is the fraction field of $\kappa[x]$, so that dx is a nonzero element of $\Omega_{\kappa'/\kappa}$. We may therefore assume that x is algebraic over κ, so that we can write $\kappa' = \kappa[x]/(f(x))$ for some nonzero polynomial $f(x)$. Then $\Omega_{\kappa'/\kappa}$ can be identified with the cokernel of the map $\kappa' \xrightarrow{f'(x)} \kappa'$, where f' denotes the derivative of f with respect to x. The vanishing of $\Omega_{\kappa'/\kappa}$ then implies that $f'(x) \neq 0$, so that κ' is a separable extension of κ.

We now handle the general case. Suppose that κ' is generated, as a field extension of κ, by a sequence of elements $x_1, \ldots, x_n \in \kappa'$. We proceed by induction on n, the case $n = 0$ being trivial. To handle the inductive step, let $\kappa'_0 \subseteq \kappa'$ be the subfield generated by κ together with the elements $x_1, \ldots, x_{n-1}$. Since $\Omega_{\kappa'/\kappa'_0}$ is a quotient of $\Omega_{\kappa'/\kappa}$, we deduce that $\Omega_{\kappa'/\kappa'_0}$ vanishes. The first part of the proof shows that κ' is a finite separable extension of κ'_0. It follows that the canonical map $\kappa' \otimes_{\kappa'_0} \Omega_{\kappa'_0/\kappa} \to \Omega_{\kappa'/\kappa}$ is an isomorphism. Our vanishing assumption then gives $\Omega_{\kappa'_0/\kappa} \simeq 0$, so that κ'_0 is a finite separable extension of κ by our inductive hypothesis. By transitivity, we conclude that κ' is a finite separable extension of κ. □

Proposition 8.6.1.5. *Let κ' be an extension of a field κ. The following conditions are equivalent:*

- (a) *The field κ' is geometrically reduced over κ.*
- (b) *Either κ has characteristic zero, or κ has characteristic $p > 0$ and the tensor product $\kappa^{\frac{1}{p^n}} \otimes_\kappa \kappa'$ is reduced for all $n > 0$ (here $\kappa^{\frac{1}{p^n}}$ denotes a copy of the field κ, regarded as a κ-algebra by the nth power of the Frobenius map).*

Moreover, if κ' is a finitely generated field extension of κ, then both these conditions are equivalent to the following:

- (c) *The field κ' is a finite separable extension of a free extension $\kappa(x_1, \ldots, x_m)$ for some $m \geqslant 0$.*

Proof. Writing κ' as a union of finitely generated subextensions (and using Remark 8.6.1.3), we can assume that κ' is finitely generated as an extension field of κ. The implication $(a) \Rightarrow (b)$ is obvious. If (c) is satisfied, then κ' is étale over $\kappa(x_1, \ldots, x_m)$ for some $m \geqslant 0$. Writing $\kappa(x_1, \ldots, x_m)$ as a direct limit of localizations of $\kappa[x_1, \ldots, x_n]$ and using the structure theory of étale morphisms (Proposition B.1.1.3), we can choose an étale $\kappa[x_1, \ldots, x_n]$-algebra A and an isomorphism $\kappa' \simeq A \otimes_{\kappa[x_1,\ldots,x_n]} \kappa(x_1, \ldots, x_n)$. By virtue of Remark 8.6.1.2, it will suffice to show that A is geometrically reduced over κ. Note that for every field extension κ'' of κ, the tensor product $A \otimes_\kappa \kappa''$ is étale over the polynomial ring $\kappa''[x_1, \ldots, x_m]$, and is therefore reduced. This shows that $(c) \Rightarrow (a)$.

We now complete the proof by showing that (b) implies (c). Assume that (b) is satisfied and let $\Omega_{\kappa'/\kappa}$ denote the module of Kähler differentials of κ' over κ. Since κ' is a finitely generated field extension of κ, $\Omega_{\kappa'/\kappa}$ is finite-dimensional as a vector space over κ. We can therefore choose elements $x_1, \ldots, x_m \in \kappa'$ such that $\{dx_i \in \Omega_{\kappa'/\kappa}\}_{1 \leqslant i \leqslant m}$ forms a basis for $\Omega_{\kappa'/\kappa}$. Let $\overline{\kappa}$ denote the subfield of κ' generated by κ and the elements $\{x_i\}_{1 \leqslant i \leqslant m}$. Since the elements dx_i generate $\Omega_{\kappa'/\kappa}$, it follows that $\Omega_{\kappa'/\overline{\kappa}} \simeq 0$. Applying Lemma 8.6.1.4, we deduce that κ' is a finite separable extension of $\overline{\kappa}$. To complete the proof, it will suffice to show that $\overline{\kappa} \simeq \kappa(x_1, \ldots, x_m)$: that is, that the elements $x_1, \ldots, x_m$ are algebraically independent over κ. Assume otherwise: then there exists a nonzero polynomial $f(t_1, \ldots, t_m) \in \kappa[t_1, \ldots, t_m]$ satisfying $f(x_1, \ldots, x_m) = 0$. Let us assume that the we have chosen f so that its degree is minimal. Note that we have

$$0 = df(x_1, \ldots, x_m) = \sum \frac{\partial f}{\partial t_i}(x_1, \ldots, x_m) dx_i \in \Omega_{\kappa'/\kappa},$$

so that each of the polynomials $\frac{\partial f}{\partial t_i}$ vanishes on $(x_1, \ldots, x_m)$. It follows from the minimality of f that the polynomials $\frac{\partial f}{\partial t_i}$ vanish identically. Consequently, the field κ must have characteristic $p > 0$ and we can write $f(t_1, \ldots, t_m) = g(t_1^{p^n}, \ldots, t_m^{p^n})$ for some $n > 0$. Choose n as large as possible, so that g has at least one nonvanishing partial derivative. Let $h \in \kappa^{\frac{1}{p^n}}[t_1, \ldots, t_m]$ be the polynomial obtained from g by taking the p^nth root of each coefficient. We then have $0 = f(x_1, \ldots, x_m) = h(x_1, \ldots, x_m)^{p^n}$ in the tensor product $R = \kappa^{\frac{1}{p^n}} \otimes_\kappa \kappa'$. Since R is reduced, it follows that $h(x_1, \ldots, x_m) = 0$. As above, we compute

$$0 = dh(x_1, \ldots, x_m) = \sum \frac{\partial h}{\partial t_i}(x_1, \ldots, x_m) dx_i \in \Omega_{R/\kappa^{\frac{1}{p^n}}}.$$

Since the elements dx_i form a basis for $\Omega_{\kappa'/\kappa}$ as a κ'-module, they also form a basis for $\Omega_{R/\kappa^{\frac{1}{p^n}}}$ as an R-module. It follows that $\frac{\partial h}{\partial t_i}(x_1, \ldots, x_m)$ vanishes in R for each i. By assumption, there exists an index i such that $h_i = \frac{\partial h}{\partial t_i}$ is not identically zero. Then the polynomial $h_i(t_1, \ldots, t_n)^{p^n}$ has coefficients in κ and vanishes when evaluated on $x_1, \ldots, x_n$, contradicting the minimality of the degree of f. □

Remark 8.6.1.6. Let κ be a field and let A be a κ-algebra. Then:

(a) If κ has characteristic zero and A is reduced, then it is geometrically reduced over κ.

(b) If κ has characteristic $p > 0$ and $\kappa' \otimes_\kappa A$ is reduced for every finite purely inseparable extension κ' of κ, then A is geometrically reduced over κ.

To see this, we can use Remark 8.6.1.3 to reduce to the case where A is finitely generated over κ. Then A is a reduced Noetherian ring, so we have an injective map $A \to \prod_{1 \leqslant i \leqslant n} A_{\mathfrak{p}_i}$ where $\{\mathfrak{p}_1, \ldots, \mathfrak{p}_n\}$ are the minimal prime ideals of A. Using Remark 8.6.1.3 again, it will suffice to show that (a) and (b) hold for each of the localizations $A_{\mathfrak{p}_i}$, which is a finitely generated extension field of κ. In this case, the desired result follows from Proposition 8.6.1.5.

Corollary 8.6.1.7. *Let κ be a field, let A be a finitely generated algebra over κ, and let $\mathfrak{p}$ be a prime ideal in A. The following conditions are equivalent:*

(a) *The localization $A_{\mathfrak{p}}$ is geometrically reduced over κ.*

(b) *There exists elements $a, b \in A$ such that $a \notin \mathfrak{p}$, b is not a zero-divisor in $A[a^{-1}]$, and the localization $A[b^{-1}]$ factors as a product $\prod_{1 \leqslant i \leqslant n} A_i$, where each A_i admits an étale morphism $\kappa[x_1, \ldots, x_m] \to A_i$ (for some $m \geqslant 0$).*

Proof. Suppose that condition (b) is satisfied, and let κ' be an extension field of κ. Then $\kappa' \otimes_{\kappa} A[b^{-1}]$ can be identified with a subring of the product $\prod_{1 \leqslant i \leqslant n} \kappa' \otimes_{\kappa} A_i$, each factor of which is an étale algebra over some polynomial ring $\kappa'[x_1, \ldots, x_m]$. It follows that $\kappa' \otimes_{\kappa} A[(ab)^{-1}]$ is a localization of a subring of a reduced ring and therefore reduced. Since b is not a zero-divisor in $A[a^{-1}]$, we conclude that $\kappa' \otimes_{\kappa} A[a^{-1}]$ is also reduced. Consequently, $A[a^{-1}]$ is geometrically reduced over κ, so the further localization $A_{\mathfrak{p}}$ is geometrically reduced over κ by Remark 8.6.1.2. This shows that (b) implies (a).

We now show that (a) implies (b). Assume that $A_{\mathfrak{p}}$ is geometrically reduced over κ. Let $\{\mathfrak{q}_1, \ldots, \mathfrak{q}_n\}$ be the minimal prime ideals of A which are contained in $\mathfrak{p}$. Then each localization $A_{\mathfrak{q}_i}$ is a field K_i which is geometrically reduced over κ. Using Proposition 8.6.1.5, we can assume that each K_i is a finite separable extension of $\kappa(x_{i,1}, \ldots, x_{i,m_i})$ for some elements $x_{i,1}, \ldots, x_{i,m_i} \in K_i$ which are algebraically independent over κ. Choose an element $b \in A - \bigcup \mathfrak{q}_i$ such that each $x_{i,j}$ belongs to the image A_i of the natural map $A[b^{-1}] \to K_i$. We then have $K_i \simeq A_i \otimes_{\kappa[x_{i,1}, \ldots, x_{i,m_i}]} \kappa(x_{i,1}, \ldots, x_{i,m_i})$. Since K_i is étale over $\kappa(x_{i,1}, \ldots, x_{i,m_i})$, we can assume (after changing b if necessary) that each A_i is étale over $\kappa[x_{i,1}, \ldots, x_{i,m_i}]$ and that the natural map $A[b^{-1}] \to \prod A_i$ is an isomorphism. Let $I = \{x \in A : bx = 0\}$. Since $A_{\mathfrak{p}}$ is reduced and b does not belong to any $\mathfrak{q}_i$, the image of b in $A_{\mathfrak{p}}$ is not a zero-divisor. It follows that $I_{\mathfrak{p}} \simeq 0$. Since A is Noetherian, the ideal I is finitely generated. We can therefore choose $a \in A - \mathfrak{p}$ such that $I[a^{-1}] \simeq 0$, so that the image of b in $A[a^{-1}]$ is not a zero-divisor. □

8.6.2 Geometrically Reduced Morphisms of Spectral Deligne-Mumford Stacks

We now summarize some of the formal properties of Definition 8.6.0.1.

Proposition 8.6.2.1. *Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \xrightarrow{g} & \mathsf{Y}. \end{array}$$

If f is geometrically reduced, then f' is geometrically reduced. The converse holds if g is a flat covering (Definition 2.8.3.1).

Proof. The first assertion is immediate from the definitions. To prove the second, let us assume that g is a flat covering and quasi-compact and that f' is geometrically reduced. Then f' is flat, so f is flat. Suppose we are given a pullback diagram

$$\begin{array}{ccc} \mathsf{X}_\kappa & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow f \\ \mathrm{Sp\acute{e}t}\,\kappa & \xrightarrow{\eta} & \mathsf{Y}, \end{array}$$

where κ is a field. We wish to show that X_κ is reduced. Choose an étale map $\mathrm{Sp\acute{e}t}\,A \to \mathsf{X}_\kappa$; we will show that the $\mathbb{E}_\infty$-ring A is reduced. Since g is surjective, there exists an extension field κ' of κ such that η factors through g. In this case, we can obtain an étale map

$$\mathrm{Sp\acute{e}t}(\kappa' \otimes_\kappa A) \to \mathrm{Sp\acute{e}t}\,\kappa' \times_{\mathsf{Y}'} \mathsf{X}',$$

so our assumption that f' is geometrically reduced guarantees that the $\mathbb{E}_\infty$-ring $\kappa' \otimes_\kappa A$ is reduced. In particular, the homotopy groups $\pi_n(\kappa' \otimes_\kappa A) \simeq \kappa' \otimes_\kappa \pi_n A$ vanish for $n > 0$, so that A is discrete. Since the map $A \to \kappa' \otimes_\kappa A$ is injective, it follows that A is reduced. □

Proposition 8.6.2.2. *Let $\mathsf{X} \xrightarrow{f} \mathsf{Y} \xrightarrow{g} \mathsf{Z}$ be morphisms of spectral Deligne-Mumford stacks. If f is étale and g is geometrically reduced, then $g \circ f$ is geometrically reduced. If f is an étale surjection and $g \circ f$ is geometrically reduced, then g is geometrically reduced.*

Proof. Suppose first that f is étale and g is geometrically reduced. Then g is flat, so $g \circ f$ is flat. Moreover, for any field κ and any map $\mathrm{Sp\acute{e}t}\,\kappa \to \mathsf{Z}$, we have an étale map

$$\mathsf{X} \times_{\mathsf{Z}} \mathrm{Sp\acute{e}t}\,\kappa \to \mathsf{Y} \times_{\mathsf{Z}} \mathrm{Sp\acute{e}t}\,\kappa.$$

Since the codomain of this map is reduced, so is the domain.

Now suppose that f is an étale surjection and that $g \circ f$ is geometrically reduced. Then $g \circ f$ is flat (Proposition 2.8.2.4) and for every map $\mathrm{Sp\acute{e}t}\,\kappa \to \mathsf{Z}$ as above, we obtain an étale surjection $\mathsf{X} \times_{\mathsf{Z}} \mathrm{Sp\acute{e}t}\,\kappa \to \mathsf{Y} \times_{\mathsf{Z}} \mathrm{Sp\acute{e}t}\,\kappa$ whose domain is reduced. Since the property of being reduced is local for the étale topology (Remark 3.1.6.2) we deduce that the codomain is also reduced. □

Corollary 8.6.2.3. *Any étale morphism of spectral Deligne-Mumford stacks is geometrically reduced.*

Definition 8.6.2.4. Let $\phi : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings. We will say that ϕ is *geometrically reduced* if the map of spectral Deligne-Mumford stacks $\mathrm{Sp\acute{e}t}\,B \to \mathrm{Sp\acute{e}t}\,A$ is geometrically reduced. In other words, ϕ is geometrically reduced if it is flat and, for every morphism of $\mathbb{E}_\infty$-rings $A \to \kappa$ where κ is a field, the commutative ring $B_\kappa = B \otimes_A \kappa$ is reduced.

Remark 8.6.2.5. Let $\phi : A \to B$ be a flat morphism of connective $\mathbb{E}_\infty$-rings. Then ϕ is geometrically reduced if and only if, for every morphism of commutative rings $\pi_0 A \to \kappa$, the tensor product $B_\kappa = B \otimes_A \kappa$ is reduced.

Remark 8.6.2.6. In the case where A is a field, Definition 8.6.2.4 specializes to Definition 8.6.1.1.

Warning 8.6.2.7. To verify that a morphism $\phi : A \to B$ is geometrically reduced, it is not enough to show that the tensor product $B_\kappa = B \otimes_A \kappa$ is reduced for every residue field κ of A. However, it *is* sufficient to restrict attention to those fields κ which occur as finite purely inseparable extension fields of residue fields of A: this follows from Remark 8.6.1.6.

We now study the closure of geometrically reduced morphisms under composition.

Proposition 8.6.2.8. *Let A be a reduced Noetherian ring and let $\phi : A \to B$ be a geometrically reduced morphism. Then B is a reduced commutative ring.*

Proof. Since ϕ is flat, the $\mathbb{E}_\infty$-ring B is discrete. Let $\{\mathfrak{p}_1, \ldots, \mathfrak{p}_n\}$ be the minimal prime ideals of A. The assumption that A is reduced implies that each of the localizations $A_{\mathfrak{p}_i}$ is a field and that the localization map $A \to \prod_{1 \leqslant i \leqslant n} A_{\mathfrak{p}_i}$ is injective. Since B is flat over A, the induced map $B \to \prod_{1 \leqslant i \leqslant n} (A_{\mathfrak{p}_i} \otimes_A B)$ is injective. Our assumption that ϕ is geometrically reduced implies that each tensor product $A_{\mathfrak{p}_i} \otimes_A B$ is a reduced ring, so that B is also a reduced ring. □

Proposition 8.6.2.9. *Let $\mathsf{X} \xrightarrow{f} \mathsf{Y} \xrightarrow{g} \mathsf{Z}$ be morphisms of spectral Deligne-Mumford stacks. If f and g are geometrically reduced and g is locally of finite type, then the composition $(g \circ f)$ is geometrically reduced.*

Proof. Since f and g are flat, the composition $g \circ f$ is flat. Fix a field κ and a map $\operatorname{Spét} \kappa \to \mathsf{Z}$, so that f induces a map $f_\kappa : \mathsf{X} \times_{\mathsf{Z}} \operatorname{Spét} \kappa \to \mathsf{Y} \times_{\mathsf{Z}} \operatorname{Spét} \kappa$. We wish to show that the domain of f_κ is reduced. Choose an étale map $\operatorname{Spét} B \xrightarrow{\eta} \mathsf{X} \times_{\mathsf{Z}} \operatorname{Spét} \kappa$; we wish to show that the $\mathbb{E}_\infty$-ring B is reduced. This property is local with respect to the étale topology on B; we may therefore assume without loss of generality that the composite map $f_\kappa \circ \eta$ factors through an étale morphism $\operatorname{Spét} A \to \mathsf{Y} \times_{\mathsf{Z}} \operatorname{Spét} \kappa$. Since g is geometrically reduced and of finite type, the $\mathbb{E}_\infty$-ring A is reduced and finitely generated as a κ-algebra. In particular, A is Noetherian. Our assumption that f is geometrically reduced implies that the map $A \to B$ is geometrically reduced, so that B is reduced by virtue of Proposition 8.6.2.8. □

8.6.3 The Geometrically Reduced Locus

Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Since the property of being geometrically reduces is local on the domain with respect to the étale topology

(Proposition 8.6.2.2), there exists a largest open substack $\mathsf{U} \subseteq \mathsf{X}$ for which the restriction $f|_{\mathsf{U}} : \mathsf{U} \to \mathsf{Y}$ is geometrically reduced. Let us refer to U as the *geometrically reduced locus* of f. Note that if we are given a pullback diagram of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y}, \end{array}$$

then we can identify $\mathsf{U} \times_{\mathsf{X}} \mathsf{X}'$ with an open substack of X', and the restriction of f' to $\mathsf{U} \times_{\mathsf{X}} \mathsf{X}'$ is geometrically reduced (Proposition 8.6.2.1). Consequently, the fiber product $\mathsf{U} \times_{\mathsf{X}} \mathsf{X}'$ is contained in the geometrically reduced locus for the map f'. Under some mild assumptions, we can say more:

Proposition 8.6.3.1 (Universality of the Geometrically Reduced Locus)**.** *Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y} \end{array}$$

where f and f' are flat and locally almost of finite presentation. If $\mathsf{U} \subseteq \mathsf{X}$ is the geometrically reduced locus of f, then $\mathsf{U} \times_{\mathsf{X}} \mathsf{X}'$ is the geometrically reduced locus of f'.

Proof. Using Proposition 8.6.2.1, we can reduce to the case where $\mathsf{Y} \simeq \operatorname{Sp\acute{e}t} A$ and $\mathsf{Y}' \simeq \operatorname{Sp\acute{e}t} A'$ are affine. Using Proposition 8.6.2.2, we can further assume that $\mathsf{X} \simeq \operatorname{Sp\acute{e}t} B$ is affine, so that $\mathsf{X}' \simeq \operatorname{Sp\acute{e}t} B'$ for $B' = A' \otimes_A B$. Using Remark 8.6.2.5 we can replace A and A' by the commutative rings $\pi_0 A$ and $\pi_0 A'$ and thereby reduce to the case where A and A' are discrete. Then B is discrete and is finitely presented as a commutative algebra over A. We can therefore choose a finitely generated subalgebra $A_0 \subseteq A$ and a finitely presented A_0-algebra B_0 such that $B \simeq \tau_{\leqslant 0}(A \otimes_{A_0} B_0)$. Enlarging A_0 if necessary, we may assume that B_0 is flat over A_0 (Proposition 6.1.6.1). For each point $x \in |\operatorname{Spec} B_0|$, let $f_0(x) \in |\operatorname{Spec} A_0|$ denote its image and let $\kappa(f_0(x))$ denote the residue field of A_0 at the point $f_0(x)$. Set

$$V = \{\mathfrak{p} \in |\operatorname{Spec} B_0| : \kappa(f(x)) \otimes_{A_0} B_{0\mathfrak{p}} \text{ is geometrically reduced over } \kappa(f_0(x)) \}.$$

Unwinding the definitions, we see that U can be defined (as a subset of $|\operatorname{Spec} B|$) as the largest open set which is contained in $V \times_{|\operatorname{Spec} B_0|} |\operatorname{Spec} B|$, and the geometrically reduced locus of f' can be identified (as a subset of $|\operatorname{Spec} B'|$) with the largest open set which is contained in $V \times_{|\operatorname{Spec} B_0|} |\operatorname{Spec} B'|$. Consequently, to complete the proof, it will suffice to show that V is open in $|\operatorname{Spec} B_0|$. We will prove this by verifying the hypotheses of Lemma 6.1.5.3:

(a) The set V is stable under generalization. Suppose that x and x' are points of $|\operatorname{Spec} B_0|$ such that $x \in V$ and x belongs to the closure of $\{x'\}$; we wish to show that x' belongs to V. Using Proposition 5.3.2.2, we can choose a discrete valuation ring R and a map $\rho : \operatorname{Spét} R \to \operatorname{Spét} B_0$ which carries the closed point of $|\operatorname{Spec} R|$ to x and the generic point of $|\operatorname{Spec} R|$ to x'. Let t be a uniformizer of R and set $\overline{R} = R \otimes_{A_0} B_0$. Then ρ determines an R-algebra homomorphism $\epsilon : \overline{R} \to R$ such that $\mathfrak{p} = \ker(\epsilon)$ is a prime ideal of $\overline{R}$ lying over x' and $\mathfrak{q} = \epsilon^{-1}(t)$ is a prime ideal of $\overline{R}$ lying over x. To show that x' belongs to V, we must show that the localization $\overline{R}_{\mathfrak{p}}$ is geometrically reduced as an algebra over the fraction field K of R. Equivalently, we must show that $\overline{R}_{\mathfrak{p}} \otimes_K K'$ is reduced, for every finite purely inseparable extension K' of K (see Remark 8.6.1.6). Replacing R by a localization of the integral closure of R in K' (which is a Dedekind ring, by virtue of the Krull-Akizuki theorem; see Theorem 5.3.2.1), we can are reduced to showing that $\overline{R}_{\mathfrak{p}}$ is reduced. In fact, we claim that the localization $\overline{R}_{\mathfrak{q}}$ is reduced. To prove this, let I denote the nilradical of $\overline{R}_{\mathfrak{q}}$. Choose any element $a \in I$, so that $a^n = 0$ for $n \gg 0$. Our assumption that x belongs to V guarantees that the quotient $\overline{R}_{\mathfrak{q}}/t\overline{R}_{\mathfrak{q}}$ is reduced, so a belongs to the kernel of the reduction map $\overline{R}_{\mathfrak{q}} \to \overline{R}_{\mathfrak{q}}/t\overline{R}_{\mathfrak{q}}$. We can therefore write $a = tb$ for some $b \in \overline{R}_{\mathfrak{q}}$. We then have $t^n b^n = a^n = 0$. Since $\overline{R}$ is flat over R, it follows that $b^n = 0$. We therefore have $b \in I$, so that $a \in tI$. Since a was chosen arbitrarily, we conclude that $I \subseteq tI$. Iterating this observation, we obtain inclusions $I \subseteq tI \subseteq t^2 I \subseteq t^3 I \subseteq \cdots$, so that $I \subseteq \bigcap_{m \geqslant 0} (t^m)$. Since $\overline{R}_{\mathfrak{q}}$ is a Noetherian local ring, it follows from the Krull intersection theorem (Corollary 7.3.6.10) that $I = 0$, so that $\overline{R}_{\mathfrak{q}}$ is reduced.

(b) For every point $x \in V$, there exists an open subset of the closure $\overline{\{x\}}$ which is contained in V. Let us identify x with a prime ideal $\mathfrak{p} \subseteq B_0$, and let $\mathfrak{q} \subseteq A_0$ be the inverse image of $\mathfrak{p}$. Replacing A_0 by $A_0/\mathfrak{q}$, we can assume that A_0 is an integral domain and that $\mathfrak{q} = 0$. Let K be the fraction field of A_0. Our assumption that $x \in V$ implies that the localization $B_{0\mathfrak{p}}$ is geometrically reduced over K. Set $B_K = K \otimes_{A_0} B_0$. Applying Corollary 8.6.1.7, we may assume (after replacing B_0 by a localization if necessary) that there exists an element $b \in B_K$ which is not a zero-divisor such that $B_K[b^{-1}]$ factors as a product $\prod_{1 \leqslant i \leqslant n} B_{Ki}$, where each B_{Ki} is étale over a polynomial ring $K[x_1, \ldots, x_{m_i}]$. Replacing A_0 by a suitable localization, we may assume that b lies in B_0 (which we identify with a subring of B_K) and that $B_0[b^{-1}] \simeq \prod_{1 \leqslant i \leqslant n} B_{0i}$, where each B_{0i} is étale over a polynomial ring $A_0[x_1, \ldots, x_{m_i}]$. Let M denote the quotient B_0/bB_0. Using Lemma 6.1.5.4, we may assume (after passing to a suitable localization of A_0) that M is free as an A_0-module. It follows that, for every residue field κ of A_0, the exact sequence $0 \to B_0 \xrightarrow{b} B_0 \to M$ remains exact after tensoring with κ: that is, that the image of b not a zero-divisor in $\kappa \otimes_{A_0} B_0$. Applying the criterion of Corollary 8.6.1.7, we deduce that $\kappa \otimes_{A_0} B_0$ is geometrically reduced over κ, so that

$V = |\operatorname{Spec} B_0|$.

□

8.6.4 Geometric Connectivity

We now restrict our attention to *proper* geometrically reduced morphisms. In this case, we have the following:

Proposition 8.6.4.1. *Let $f : \mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}}) = \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is proper, locally almost of finite presentation, and geometrically reduced. The following conditions are equivalent:*

(1) *The morphism f is geometrically connected: that is, for every pullback square*

$$\begin{array}{ccc} \mathsf{X}_\kappa & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow f \\ \operatorname{Sp\acute{e}t} \kappa & \longrightarrow & \mathsf{Y} \end{array}$$

where κ is an algebraically closed field, the topological space $|\mathsf{X}_\kappa|$ is connected.

(2) *Let $u : \mathcal{O}_{\mathcal{Y}} \to f_* \mathcal{O}_{\mathcal{X}}$ be the unit map. Then $\operatorname{cofib}(u) \in \operatorname{QCoh}(\mathsf{Y})$ has Tor-amplitude $\leqslant -1$.*

The proof of Proposition 8.6.4.1 will require some algebraic preliminaries.

Lemma 8.6.4.2. *Let R be a commutative ring and let M be an R-module which is perfect to order 1. Let $\mathfrak{p} \subseteq R$ be a prime ideal and let κ denote the residue field at $\mathfrak{p}$. Then the following conditions are equivalent:*

(a) *There exists an element $a \in R$ which does not belong to $\mathfrak{p}$ for which the localization $M[a^{-1}] \in \operatorname{Mod}_{R[a^{-1}]}$ is 1-split (see Definition* **??***).*

(b) *The vector space $\pi_1(\kappa \otimes_R M)$ vanishes.*

Proof. The implication $(a) \Rightarrow (b)$ is obvious. Conversely, suppose that (b) is satisfied. Since M is perfect to order 1, it is k-connective for every sufficiently small integer k. We proceed by descending induction on k, beginning with the case $k = 1$. If M is 1-connective, then we have $\pi_1(\kappa \otimes_R M) \simeq \operatorname{Tor}_0^R(\kappa, \pi_1 M)$. Our assumption that M is perfect to order 1 guarantees that $\pi_1 M$ is a finitely generated R-module. Consequently, if condition (ii) is satisfied then Nakayama's lemma guarantees that $\pi_1 M[a^{-1}] \simeq 0$ for some $a \notin \mathfrak{p}$, so that $M[a^{-1}]$ is 2-connective and condition (a) follows.

To carry out the inductive step, assume that $k \leqslant 0$ and that M is k-connective. Then our assumption that M is perfect to order 1 guarantees that $\pi_k M$ is a finitely presented R-module, and the k-connectivity of M supplies an isomorphism $\pi_k(\kappa \otimes_R M) \simeq \mathrm{Tor}_0^R(\kappa, \pi_k M)$. Choose a collection of elements $x_1, \ldots, x_m \in \pi_k M$ whose images form a basis for $\mathrm{Tor}_0^R(\kappa, \pi_k M)$ as a vector space over κ. It follows from Nakayama's lemma that, after localizing at some element $a \in R - \mathfrak{p}$, we may assume that $x_1, \ldots, x_m$ generate $\pi_k M$ as an R-module, and therefore determine a map $u : \Sigma^k R^m \to M$ whose cofiber is $(k+1)$-connective. We have a short exact sequence

$$\pi_1(\kappa \otimes_R M) \to \pi_1(\kappa \otimes_R \mathrm{cofib}(u)) \to \pi_0(\kappa \otimes_R \Sigma^k R^m) \xrightarrow{\rho} \pi_0(\kappa \otimes_R M)$$

where the third term vanishes for $k < 0$ and ρ is injective when $k = 0$. Consequently, the cofiber $\mathrm{cofib}(u)$ also satisfies condition (ii). Applying the inductive hypothesis, we deduce that $\mathrm{cofib}(u)$ satisfies condition (i). Localizing if necessary, we may assume that $\mathrm{cofib}(u)$ splits as a direct sum $M' \oplus M''$, where M' is 2-connective and M'' is perfect of Tor-amplitude $\leqslant 1$. Then M can be described as the fiber of a map $\theta : M' \oplus M'' \to \Sigma^{k+1} R^m$. Since the codomain of θ is 1-truncated, the restriction $\theta|_{M'}$ is nullhomotopic, so that $M \simeq M' \oplus \mathrm{fib}(\theta|_{M''})$ is 1-split as desired. □

Corollary 8.6.4.3. *Let R be a connective $\mathbb{E}_\infty$-ring and let M be an almost perfect R-module. The following conditions are equivalent:*

- (a) *The module M is perfect of* Tor-*amplitude* $\leqslant 0$.
- (b) *For every maximal ideal $\mathfrak{m}$ of $\pi_0 R$ with residue field $\kappa = (\pi_0 R)/\mathfrak{m}$, the homotopy groups $\pi_n(\kappa \otimes_R M)$ vanish for $n > 0$.*

Proof. The implication $(a) \Rightarrow (b)$ is trivial. We will show that $(b) \Rightarrow (a)$. Using Proposition 2.7.3.2, we can reduce to the case where R is discrete. Since the condition of being perfect of Tor-amplitude $\leqslant 0$ can be tested locally with respect to the étale topology (Proposition 2.8.4.2), we can use condition (b) and Lemma 8.6.4.2 to reduce to the case where M splits as a direct sum $M' \oplus M''$, where M' is perfect of Tor-amplitude $\leqslant 0$ and M'' is 2-connective. We will complete the proof by showing that $M'' \simeq 0$. Assume otherwise: then there exists some smallest integer $n \geqslant 2$ such that $\pi_n M'' \neq 0$. Since M'' is a direct summand of M, it is almost perfect as an R-module. Consequently, the first nonvanishing homotopy group $\pi_n M''$ is a finitely generated R-module. For each maximal ideal $\mathfrak{m} \subseteq R$, the quotient $(\pi_n M'')/\mathfrak{m}(\pi_n M'')$ appears as a direct summand of $\pi_n(\kappa \otimes_R M)$ and therefore vanishes. Invoking Nakayama's lemma, we deduce that $\pi_n M'' \simeq 0$ and obtain a contradiction. □

Proof of Proposition 8.6.4.1. Let $f : \mathsf{X} = (\mathcal{X}, \mathcal{O}_\mathcal{X}) \to (\mathcal{Y}, \mathcal{O}_\mathcal{Y}) = \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is proper, locally almost of finite presentation, and geometrically reduced, and let $u : \mathscr{O}_{\mathcal{Y}} \to f_* \mathscr{O}_{\mathcal{X}}$ be the unit map. We wish to show that f has connected geometric fibers if and only if the cofiber $\mathrm{cofib}(u)$ has Tor-amplitude $\leqslant -1$. Both assertions are local on Y, so we may assume without loss of generality that $\mathsf{Y} \simeq \mathrm{Spét}\, R$ is affine. It follows from Theorem 5.6.0.2 that the cofiber $\mathrm{cofib}(u)$ is almost perfect. Using Corollary 8.6.4.3, we can reformulate (2) as follows:

($2'$) For every map $R \to \kappa$, where κ is an algebraically closed field, the homotopy groups $\pi_n(\kappa \otimes_R \mathrm{cofib}(u))$ vanish for $n \geqslant 0$.

Consequently, to prove the equivalence of (1) and ($2'$), there is no loss of generality in assuming that $R = \kappa$ is an algebraically closed field. In this case, X is a reduced spectral algebraic space, so that $\pi_n f_* \mathscr{O}_{\mathcal{X}}$ vanishes for $n > 0$. Consequently, assertion ($2'$) is equivalent to the statement that the unit map $e : \kappa \to \pi_0 f_* \mathscr{O}_{\mathcal{X}} = \mathrm{H}^0(\mathcal{X}; \mathscr{O}_{\mathcal{X}})$ is an isomorphism. If this condition is satisfied, the $\mathrm{H}^0(\mathcal{X}; \mathscr{O}_{\mathcal{X}})$ contains exactly two idempotent elements and therefore the topological space $|\mathsf{X}|$ is connected. For the converse, we observe that $\mathrm{H}^0(\mathcal{X}; \mathscr{O}_{\mathcal{X}})$ is finite-dimensional as a vector space over κ. The connectedness of $|\mathsf{X}|$ implies that $\mathrm{H}^0(\mathcal{X}; \mathscr{O}_{\mathcal{X}})$ is a local Artinian ring. Since f is geometrically reduced, this Artinian ring is reduced and is therefore a finite extension of κ. Since κ is algebraically closed, it follows that e is an isomorphism. □

8.7 Application: Stein Factorizations

Let $f : X \to Z$ be a morphism of Noetherian schemes. Then f admits an essentially unique factorization $X \xrightarrow{g} Y \xrightarrow{h} Z$, where g induces an isomorphism $\mathscr{O}_Y \to g_* \mathscr{O}_X$ (where g_* denotes the pushforward in the *abelian* category of quasi-coherent sheaves) and h is affine: the scheme Y can be described as the spectrum of the quasi-coherent sheaf of algebras $f_* \mathscr{O}_X$ on Z. If the morphism f is proper, then one can say more:

(*i*) The direct image $f_* \mathscr{O}_X$ is a *coherent* sheaf of algebras on Z.

(*ii*) The morphism h is finite.

(*iii*) The scheme Y is Noetherian.

(*iv*) The morphism g has connected fibers.

Assertion (*i*) is a special case of Theorem 5.6.0.1, the implications (*i*) ⇒ (*ii*) ⇒ (*iii*) are obvious, and assertion (*iv*) is Zariski's connectedness theorem. In this case, we refer to the pair (g, h) as the *Stein factorization* of the morphism f.

Stein factorizations are a very useful tool in algebraic geometry. However, one must take care that the formation of Stein factorizations is not compatible with base change: given a pullback diagram of Noetherian schemes

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Z' & \xrightarrow{u} & Z, \end{array}$$

the associated comparison map $\alpha : u^* f_* \mathscr{O}_X \to f'_* \mathscr{O}_{X'}$ need not be an isomorphism in general (Warning 8.7.1.8). However, the situation is somewhat better if we make the additional assumption that f is geometrically reduced (Definition ??): in this case, the scheme Y appearing in the Stein factorization of f is étale over Z and is compatible with arbitrary base change (Remark 8.7.3.4).

Our goal in this section is to discuss Stein factorizations in the setting of spectral algebraic geometry. Here the situation is a bit more complicated. There are (at least) two generalizations of the Stein factorization:

(a) If $f : \mathsf{X} \to \mathsf{Z}$ is a quasi-compact, quasi-separated morphism of spectral algebraic spaces, then f admits an essentially unique factorization

$$\mathsf{X} \xrightarrow{g} \mathsf{Y} \xrightarrow{h} \mathsf{Z}$$

where h is affine and g exhibits the structure sheaf of Y as the connective cover of the (derived) direct image $f_* \mathscr{O}_{\mathsf{X}}$ (Theorem 8.7.1.5). If X and Z are locally Noetherian and f is proper, then we can use Theorem 5.6.0.2 to see that Y is locally Noetherian and the morphism h is finite, and we can use Theorem 8.5.0.3 to show that the geometric fibers of g are connected, just as in classical algebraic geometry.

(b) If $f : \mathsf{X} \to \mathsf{Z}$ is a morphism of spectral algebraic spaces which is proper, locally almost of finite presentation, and geometrically reduced (Definition 8.6.0.1), then f admits an essentially unique factorization $\mathsf{X} \xrightarrow{g'} \mathsf{Y}' \xrightarrow{h'} \mathsf{Z}$, where h' is finite étale and the geometric fibers of g' are connected (Theorem 8.7.3.1).

However, in the setting of spectral algebraic geometry, these factorizations are generally distinct from one another. To distinguish them, we will refer to (a) as the *Stein factorization of f* (Definition 8.7.1.4) and to (b) as the *reduced Stein factorization of f* (Definition 8.7.3.2).

8.7.1 Stein Factorizations

We begin with some general observations.

Proposition 8.7.1.1. *Suppose we are given a commutative diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X} & \longrightarrow & \mathsf{Z}' \\ \downarrow{\scriptstyle g} & \nearrow & \downarrow{\scriptstyle h} \\ \mathsf{Y} & \longrightarrow & \mathsf{Z} \end{array}$$

satisfying the following conditions:

(*a*) *The morphism h is affine.*

(*b*) *The unit map $\mathscr{O}_{\mathcal{Y}} \to f_* \mathscr{O}_{\mathcal{X}}$ exhibits $\mathscr{O}_{\mathcal{Y}}$ as a connective cover of $g_* \mathscr{O}_{\mathcal{X}}$.*

Then the mapping space $\mathrm{Map}_{\mathrm{SpDM}_{\mathsf{X}//\mathsf{Z}}}(\mathsf{Y}, \mathsf{Z}')$ *(which parametrizes dotted arrows as indicated in the diagram above) is contractible.*

Proof. The assertion can be tested locally with respect to the étale topology of Z. We may therefore assume without loss of generality that $\mathsf{Z} \simeq \mathrm{Spét}\, A$ is affine. Since h is affine, it follows that $\mathsf{Z}' \simeq \mathrm{Spét}\, B$ is affine. Using the universal properties of $\mathrm{Spét}\, A$ and $\mathrm{Spét}\, B$, we obtain a fiber sequence

$$\mathrm{Map}_{\mathrm{SpDM}_{\mathsf{X}//\mathsf{Z}}}(\mathsf{Y}, \mathsf{Z}') \to \mathrm{Map}_{\mathrm{CAlg}_A}(B, \Gamma(\mathcal{Y}; \mathscr{O}_{\mathcal{Y}})) \xrightarrow{\rho} \mathrm{Map}_{\mathrm{CAlg}_A}(B; \Gamma(\mathcal{X}, \mathscr{O}_{\mathcal{X}})).$$

It will therefore suffice to show that ρ is a homotopy equivalence. Since B is connective, this follows immediately from (b) (which guarantees that the unit map $\Gamma(\mathcal{Y}; \mathscr{O}_{\mathcal{Y}}) \to \Gamma(\mathcal{X}; \mathscr{O}_{\mathcal{X}})$ induces an equivalence of connective covers). □

Proposition 8.7.1.2. *Let $f : \mathsf{X} \to \mathsf{Z}$ be a morphism of spectral Deligne-Mumford stacks. Assume that f is a quasi-compact, quasi-separated relative algebraic space. Then f factors as a composition $\mathsf{X} \xrightarrow{g} \mathsf{Y} \xrightarrow{h} \mathsf{Z}$, where h is affine and g satisfies condition* (b) *of Proposition 8.7.1.1.*

Proof. Let $\mathscr{O}_{\mathsf{X}}$ denote the structure sheaf of X. It follows from Corollary 3.4.2.2 that the direct image $f_* \mathscr{O}_{\mathcal{X}} \in \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{Z}))$ is quasi-coherent. Then $\mathscr{A} = \tau_{\geq 0} f_* \mathscr{O}_{\mathcal{X}}$ is a connective quasi-coherent commutative algebra object of $\mathrm{QCoh}(\mathsf{Z})$. Let Y denote the spectrum of $\mathscr{A}$ relative to Z (see Notation **??**). Then Y is equipped with affine map $h : \mathsf{Y} \to \mathsf{Z}$ (and is therefore a spectral Deligne-Mumford stack), and the canonical map $f^* \mathscr{A} \to f^* f_* \mathscr{O}_{\mathcal{X}} \to \mathscr{O}_{\mathcal{X}}$ in $\mathrm{CAlg}(\mathrm{QCoh}(\mathsf{X}))$ classifies a morphism $g : \mathsf{X} \to \mathsf{Y}$ in $\mathrm{SpDM}_{/\mathsf{Z}}$. Let $\mathscr{O}_{\mathsf{Y}}$ denote the structure sheaf of Y; we wish to show that the unit map $u : \mathscr{O}_{\mathsf{Y}} \to g_* \mathscr{O}_{\mathsf{X}}$ exhibits $\mathscr{O}_{\mathsf{Y}}$ as a connective cover of $g_* \mathscr{O}_{\mathsf{X}}$. Since h is affine, the direct image functor $h_* : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{Z})$ is conservative and t-exact. It will therefore suffice to show that the map $h_*(u) : h_* \mathscr{O}_{\mathsf{Y}} \to h_* g_* \mathscr{O}_{\mathsf{X}} \simeq f_* \mathscr{O}_{\mathsf{X}}$ exhibits $h_* \mathscr{O}_{\mathsf{Y}}$ as the connective cover of $f_* \mathscr{O}_{\mathsf{X}}$, which follows immediately from the definition of Y. □

Remark 8.7.1.3. In the situation of Proposition 8.7.1.2, the morphism $g : \mathsf{X} \to \mathsf{Y}$ is also a quasi-compact, quasi-separated relative algebraic space.

Definition 8.7.1.4. Let $f : \mathsf{X} \to \mathsf{Z}$ be a morphism of spectral Deligne-Mumford stacks which is a quasi-compact, quasi-separated relative algebraic space. We will say that a commutative diagram

$$\begin{array}{ccc} \mathsf{X} & \xrightarrow{f} & \mathsf{Z} \\ & {\scriptstyle g}\searrow \quad \nearrow{\scriptstyle h} & \\ & \mathsf{Y} & \end{array}$$

is a *Stein factorization of* f if g and h satisfy the requirements of Proposition 8.7.1.2.

Theorem 8.7.1.5. *Let* SpDM° *denote the subcategory of* SpDM *whose objects are spectral Deligne-Mumford stacks and whose morphisms are quasi-compact, quasi-separated relative algebraic spaces. Let* S^L *denote the collection of morphisms* $f : (\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ *in* SpDM° *which exhibit* $\mathcal{O}_{\mathcal{Y}}$ *as a connective cover of* $f_* \mathcal{O}_{\mathsf{X}}$*, and let* S^R *denote the collection of affine morphisms in* SpDM°*. Then the pair* (S^L, S^R) *is a factorization system on the* ∞*-category* SpDM° *(see Definition HTT.5.2.8.8).*

Proof. Combine Propositions 8.7.1.1 and 8.7.1.2 (and Remark 8.7.1.3). □

Remark 8.7.1.6. It follows from Theorem 8.7.1.5 that every quasi-compact, quasi-separated relative algebraic space $f : \mathsf{X} \to \mathsf{Z}$ admits a Stein factorization $\mathsf{X} \xrightarrow{g} \mathsf{Y} \xrightarrow{h} \mathsf{Z}$, which is uniquely determined up to a contractible space of choices (see Proposition HTT.5.2.8.17).

Proposition 8.7.1.7. *Suppose we are given a diagram of spectal Deligne-Mumford stacks* σ :

$$\begin{array}{ccccc} \mathsf{X}' & \xrightarrow{g'} & \mathsf{Y}' & \xrightarrow{h'} & \mathsf{Z}' \\ \downarrow & & \downarrow{\scriptstyle r} & & \downarrow{\scriptstyle q} \\ \mathsf{X} & \xrightarrow{g} & \mathsf{Y} & \xrightarrow{h} & \mathsf{Z}, \end{array}$$

where all morphisms are quasi-compact, quasi-separated relative algebraic spaces, both squares are pullbacks, and the pair (g, h) *is a Stein factorization of* $f = h \circ g$*. If* q *is flat, then the paif* (g', h') *is a Stein factorization of* $f' = h' \circ g'$*.*

Warning 8.7.1.8. Proposition 8.7.1.7 is usually not true if we do not assume that q is flat. In other words, the formation of Stein factorizations is compatible with flat base change, but not with arbitrary base change.

Proof of Proposition 8.7.1.7. It is clear that h' is affine. It will therefore suffice to show that the unit map $e' : \mathcal{O}_{\mathsf{Y}'} \to g'_* \mathcal{O}_{\mathsf{X}'}$ exhibits $\mathcal{O}_{\mathsf{Y}'}$ as a connective cover of $g'_* \mathcal{O}_{\mathsf{X}'}$. Since the structure sheaf $\mathcal{O}_{\mathsf{Y}'}$ is connective, this is equivalent to the requirement that $\mathrm{cofib}(e')$ belongs to $\mathrm{QCoh}(\mathsf{Y}')_{\leqslant -1}$. Because both squares in the diagram σ are pullbacks, we can identify $\mathrm{cofib}(e')$ with $r^* \mathrm{cofib}(e)$, where $e : \mathscr{O}_{\mathsf{Y}} \to g_* \mathscr{O}_{\mathsf{X}}$ is the unit map determined by g. Since (g, h) is a Stein factorization of $f = h \circ g$, the cofiber $\mathrm{cofib}(e)$ belongs to $\mathrm{QCoh}(\mathsf{Y})_{\leqslant -1}$. The desired result now follows from the observation that the pullback functor $r^* : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{Y}')$ is t-exact (by virtue of our assumption that q is flat). □

8.7.2 The Noetherian Case

Let $f : \mathsf{X} \to \mathsf{Z}$ be a morphism of quasi-compact, quasi-separated spectral algebraic spaces. It follows from Proposition 8.7.1.2 that f admits a Stein factorization $\mathsf{X} \xrightarrow{g} \mathsf{Y} \xrightarrow{h} \mathsf{Z}$. However, the spectral algebraic space Y which appears in this factorization is generally a somewhat wild object, which one should not expect to have any good finiteness properties. The situation is better if we assume that f is a proper morphism whose domain and codomain are locally Noetherian:

Theorem 8.7.2.1. *Let $f : \mathsf{X} \to \mathsf{Z}$ be a proper morphism between locally Noetherian spectral Deligne-Mumford stacks, and let $\mathsf{X} \xrightarrow{g} \mathsf{Y} \xrightarrow{h} \mathsf{Z}$ be a Stein factorization of X. Then:*

- (a) *The morphism h is finite.*
- (b) *The spectral Deligne-Mumford stack Y is locally Noetherian.*
- (c) *The morphism g is proper.*

Proof. Since X and Z are locally Noetherian, it follows from Remark 4.2.0.4 that f is locally almost of finite presentation. Applying Theorem 5.6.0.2, we deduce that the direct image $f_* \mathscr{O}_{\mathsf{X}}$ is almost perfect. Since Z is locally Noetherian, it follows that the truncation $\tau_{\geqslant 0} f_* \mathscr{O}_{\mathsf{X}} \simeq h_* \mathscr{O}_{\mathsf{Y}}$ is almost perfect. Applying Corollary 5.2.2.2, we deduce that h is finite and locally almost of finite presentation. This proves (a), and (b) follows from Remark 4.2.0.4. Assertion (c) now follows from Proposition 5.1.4.1. □

In the situation of Theorem 8.7.2.1, the factorization $\mathsf{X} \xrightarrow{\mathsf{Y}} \xrightarrow{\mathsf{Z}}$ enjoys several pleasant features:

Theorem 8.7.2.2 (Zariski Connectedness Theorem)**.** *Let $f : \mathsf{X} \to \mathsf{Z}$ be a proper morphism between locally Noetherian spectral Deligne-Mumford stacks, and let $\mathsf{X} \xrightarrow{g} \mathsf{Y} \xrightarrow{h} \mathsf{Z}$ be a Stein factorization of f. Then the morphism g is geometrically connected. That is, for every field κ and every map $\eta : \mathrm{Sp\acute{e}t}\, \kappa \to \mathsf{Y}$, the fiber product $\mathsf{X} \times_{\mathsf{Y}} \mathrm{Sp\acute{e}t}\, \kappa$ is connected.*

Proof. Without loss of generality, we may replace Z by Y and thereby reduce to the case where (f, id) is the Stein factorization of f: that is, f exhibits $\mathscr{O}_{\mathsf{Z}}$ as the connective cover of $f_* \mathscr{O}_{\mathsf{X}}$. In this case, we wish to deduce that for every field κ and every map $\eta : \mathrm{Sp\acute{e}t}\, \kappa \to \mathsf{Z}$, the fiber $\mathrm{Sp\acute{e}t}\,\kappa \times_{\mathsf{Z}} \mathsf{X}$ is connected. Replacing κ by an extension field if necessary, we may assume that η factors through an étale map $q : \mathrm{Sp\acute{e}t}\, A \to \mathsf{Z}$. Using Proposition 8.7.1.7, we can replace Z by $\mathrm{Sp\acute{e}t}\, A$ and thereby reduce to the case where $\mathsf{Z} = \mathrm{Sp\acute{e}t}\, A$ is affine. The map η is then classified by a homomorphism of commutative rings $\phi : \pi_0 A \to \kappa$. Write κ as a filtered colimit $\varinjlim \kappa_\alpha$, where each κ_α is the fraction field of a finitely generated $\pi_0 A$-algebra. Using Proposition 4.3.5.5, we see that in order to prove that $\mathsf{X} \times_{\mathsf{Z}} \mathrm{Sp\acute{e}t}\,\kappa$ is connected, it will suffice to show that each fiber product $\mathsf{X} \times_{\mathsf{Z}} \mathrm{Sp\acute{e}t}\,\kappa_\alpha$ is connected. We may therefore replace κ by κ_α and reduce to the case where κ is the fraction field of the subring $R \subseteq \kappa$ generated by the elements $\{x_i\}$ and the image of $\pi_0 A$.

Let $A[\mathbf{Z}^n_{\geqslant 0}]$ denote the monoid algebra over A on the commutative monoid $\mathbf{Z}^n_{\geqslant 0}$ (see Notation 5.4.1.1), so we can write $\pi_0 A[Z^n_{\geqslant 0}] \simeq (\pi_0 A)[X_1, \ldots, X_n]$. It follows that ϕ admits a unique extension to a ring homomorphism $\overline{\phi} : \pi_0 A[\mathbf{Z}^n_{\geqslant 0}] \to \kappa$ satisfying $\overline{\phi}(X_i) = x_i$. The ring homomorphism $\overline{\phi}$ classifies a map $\overline{\eta} : \mathrm{Sp\acute{e}t}\,\kappa \to \mathrm{Sp\acute{e}t}\, A[\mathbf{Z}^n_{\geqslant 0}]$. Since $A[\mathbf{Z}^n_{\geqslant 0}]$ is flat over A, we can use Proposition 8.7.1.7 to replace A by $A[\mathbf{Z}^n_{\geqslant 0}]$ and η by $\overline{\eta}$ and thereby reduce to the case where κ is the fraction field of the image of the map ϕ: in other words, ϕ exhibits κ as the residue field of $\pi_0 A$ as some prime ideal $\mathfrak{p} \subseteq \pi_0 A$. Let $A^\wedge$ denote the $\mathfrak{q}$-completion of the localization $A_{\mathfrak{q}}$. Since $A_{\mathfrak{q}}$ is Noetherian, $A^\wedge$ is flat over A (Corollary 7.3.6.9). Using Proposition 8.7.1.7 again, we can replace A by $A^\wedge$ and thereby reduce to the case where $\pi_0 A$ is a complete local Noetherian ring with residue field $\mathfrak{q}$.

Set $\mathsf{X}_0 = \mathsf{X} \times_{\mathsf{Z}} \mathrm{Sp\acute{e}t}\,\kappa$. Then X_0 is a proper algebraic space over κ, so the topological space $|\,\mathsf{X}_0\,|$ is Noetherian (Remark 3.6.3.5). It follows that we can write X_0 as a disjoint union of finitely many connected components $\{\mathsf{K}_i\}_{1 \leqslant i \leqslant m}$. Let $\mathsf{X}^\wedge$ denote the formal completion of X along the vanishing locus of $\mathfrak{q}$, so that the decomposition $\mathsf{X}_0 \simeq \amalg \mathsf{K}_i$ induces a decomposition of $\mathsf{X}^\wedge$ as a disjoint union $\amalg \mathsf{K}_i^\wedge$. Lemma 8.5.1.1 implies that we can identify A with the connective cover of $\Gamma(\mathsf{X}^\wedge; \mathscr{O}_{\mathsf{X}^\wedge})$. Consequently, the decomposition $\mathsf{X}^\wedge \simeq \amalg \mathsf{K}_i^\wedge$ determines a direct product decomposition $A \simeq \prod_{1 \leqslant i \leqslant m} A_i$. Since A is local and each factor A_i is nonzero, we must have $m = 1$: that is, X_0 is connected. □

Theorem 8.7.2.3. *Let $f : \mathsf{X} \to \mathsf{Z}$ be a proper morphism between locally Noetherian, quasi-compact, quasi-separated spectral algebraic spaces, let $\mathsf{X} \xrightarrow{g} \mathsf{Y} \xrightarrow{h} \mathsf{Z}$ be a Stein factorization of f, and let $x \in |\,\mathsf{X}\,|$ be a point. The following conditions are equivalent:*

- *(a) The point x is isolated in the fiber $|\,\mathsf{X}\,| \times_{|\,\mathsf{Z}\,|} \{x\}$.*
- *(b) There exists an open substack $\mathsf{U} \subseteq \mathsf{Y}$ which contains the image of x, for which the projection map $\mathsf{X} \times_{\mathsf{Y}} \mathsf{U} \to \mathsf{U}$ is an equivalence.*

Proof. Since the morphism h is finite, the topological space $|\,\mathsf{Y}\,| \times_{|\,\mathsf{Z}\,|} \{x\}$ is discrete (and consists of finitely many points). Consequently, x is isolated in the fiber $|\,\mathsf{X}\,| \times_{|\,\mathsf{Z}\,|} \{x\}$ if and only if it is isolated in the fiber $|\,\mathsf{X}\,| \times_{|\,\mathsf{Y}\,|} \{x\}$. We may therefore replace Z by Y and thereby reduce to the case where h is an equivalence: that if, the morphism f exhibits $\mathscr{O}_{\mathsf{Z}}$ as a connective cover of $f_* \mathscr{O}_{\mathsf{X}}$. Take U to be the largest open substack of Y for which the projection map $\mathsf{X} \times_{\mathsf{Z}} \mathsf{U} \to \mathsf{U}$ is an equivalence. We wish to show that $|\mathsf{U}|$ contains the image of x. This assertion is local on Z: we may therefore assume without loss of generality that $\mathsf{Z} \simeq \operatorname{Sp\acute{e}t} R$ is affine, so we can identify the image of x in $|\mathsf{Z}| \simeq |\operatorname{Spec} A|$ with a prime ideal $\mathfrak{p} \subseteq \pi_0 R$. To show that this point is contained in $|\mathsf{U}|$, we must show that the projection map $f_a : \mathsf{X} \times_{\operatorname{Sp\acute{e}t} R} \operatorname{Sp\acute{e}t} R[a^{-1}] \to \operatorname{Sp\acute{e}t} R[a^{-1}]$ is an equivalence for some $a \notin \mathfrak{p}$. Note that this is equivalent to the requirement that f_a is affine (since f_a satisfies condition (b) of Proposition 8.7.1.1). Using Proposition 4.6.1.1 and Remark 2.4.4.2, we are reduced to showing that the map $\mathsf{X} \times_{\operatorname{Sp\acute{e}t} R} \operatorname{Sp\acute{e}t} R_{\mathfrak{p}} \to \operatorname{Sp\acute{e}t} R_{\mathfrak{p}}$ is affine. Consequently, we may replace R by $R_{\mathfrak{p}}$ and thereby reduce to the case where R is a local $\mathbb{E}_\infty$-ring with maximal ideal $\mathfrak{p}$; in this case, we will show that f is an equivalence. Let $R^\wedge$ denote the completion of R with respect to $\mathfrak{p}$. Since R is Noetherian, $R^\wedge$ is faithfully flat over R (Corollary 7.3.6.9). Using Corollary 2.8.3.4 and Proposition 8.7.1.7, we can replace R by $R^\wedge$ and thereby reduce to the case where R is $\mathfrak{p}$-complete.

Let κ denote the residue field of R, let $\mathsf{X}_0 = \operatorname{Sp\acute{e}t} \kappa \times_{\operatorname{Sp\acute{e}t} R} \mathsf{X}$, and let $\mathsf{X}^\wedge$ denote the formal spectral Deligne-Mumford stack given by $\operatorname{Spf} R^\wedge \times_{\operatorname{Spec} R} \mathsf{X}$. Since x is isolated, the topological space $|\mathsf{X}_0|$ has a single point, so that X_0 is affine. Using Lemma 8.3.3.2, we deduce that $\mathsf{X}^\wedge$ is affine. Write $\mathsf{X}^\wedge = \operatorname{Spf} A$ for some adic $\mathbb{E}_\infty$-ring A. Using Lemma 8.5.1.1, we deduce that $\Gamma(\mathsf{X}; \mathscr{O}_{\mathsf{X}}) \simeq \Gamma(\mathsf{X}^\wedge; \mathscr{O}_{\mathsf{X}^\wedge}) \simeq A$ is connective. It follows that the unit map $R \to A$ is an equivalence, so that the projection $\mathsf{X}^\wedge \to \operatorname{Spf} R$ is an equivalence. Applying Corollary 8.5.3.4, we deduce that the projection map $\mathsf{X} \to \operatorname{Sp\acute{e}t} R$ is also an equivalence, as desired.

□

8.7.3 Reduced Stein Factorizations

We now show that all every proper geometrically reduced morphism which is locally almost of finite presentation can be obtained by combining Corollary 8.6.2.3 with Proposition 8.6.4.1. More precisely, we have the following result:

Theorem 8.7.3.1. *Let $\mathcal{C}$ denote the subcategory of* SpDM *spanned by all objects and those morphisms $f : \mathsf{X} \to \mathsf{Z}$ which are proper, geometrically reduced, and locally almost of finite presentation. Then $\mathcal{C}$ admits a factorization system (S^L, S^R), where S^L consists of those morphisms f which are geometrically connected (see Proposition 8.6.4.1) and S^R consists of those morphisms which are finite étale. In other words:*

(*a*) *For every commutative diagram*

$$\begin{array}{ccc} \mathsf{X} & \longrightarrow & \mathsf{Y} \\ {\scriptstyle f}\downarrow & \nearrow & \downarrow{\scriptstyle g} \\ \mathsf{Z} & \longrightarrow & \mathsf{Z}' \end{array}$$

in $\mathcal{C}$ *where* f *is geometrically connected and* g *is finite étale, the space* $\mathrm{Map}_{\mathcal{C}_{\mathsf{X}//\mathsf{Z}'}}(\mathsf{Z},\mathsf{Y})$ *(parametrizing dotted arrows which render the preceding diagram commutative) is contractible.*

(*b*) *Every morphism* $f : \mathsf{X} \to \mathsf{Z}$ *in* $\mathcal{C}$ *admits a factorization* $\mathsf{X} \xrightarrow{f'} \mathsf{Y} \xrightarrow{f''} \mathsf{Z}$*, where* f' *is geometrically connected and* f'' *is finite étale.*

Definition 8.7.3.2. Let $f : \mathsf{X} \to \mathsf{Z}$ be a morphism of spectral Deligne-Mumford stacks which is proper, geometrically reduced, and locally almost of finite presentation. We will refer to the factorization $\mathsf{X} \xrightarrow{f'} \mathsf{Y} \xrightarrow{f''} \mathsf{Z}$ whose existence is asserted by part (*b*) of Theorem 8.7.3.1 as the *reduced Stein factorization* of f. It follows from part (*a*) of Theorem 8.7.3.1 (and Proposition HTT.5.2.8.17) that the reduced Stein factorization is well-defined up to a contractible space of choices.

Warning 8.7.3.3. Let $f : \mathsf{X} \to \mathsf{Z}$ be a morphism of spectral Deligne-Mumford stacks which is proper, geometrically reduced, and locally almost of finite presentation, and let $\mathsf{X} \xrightarrow{f'} \mathsf{Y} \xrightarrow{f''} \mathsf{Z}$ be the Stein factorization of f (Definition 8.7.1.4). If $\mathscr{O}_{\mathsf{Z}}$ is 0-truncated, then we will prove in a moment that (f', f'') is also a reduced Stein factorization of f (Proposition 8.7.4.2). However, if $\mathscr{O}_{\mathsf{Z}}$ is not 0-truncated, then (f', f'') is usually *not* a reduced Stein factorization of f. Roughly speaking, the problem is that direct image of the homotopy sheaves $\pi_n \mathscr{O}_{\mathsf{X}}$ make "contributions" to the algebra $\tau_{\geqslant 0} f_* \mathscr{O}_{\mathsf{X}}$ in all degrees $\leqslant n$, but to obtain a spectral Deligne-Mumford stack which is étale over Z we will need to discard the "contributions" in degrees $< n$.

Remark 8.7.3.4 (Functoriality of Reduced Stein Factorizations)**.** Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks σ :

$$\begin{array}{ccc} \mathsf{X}' & \xrightarrow{f'} & \mathsf{Z}' \\ \downarrow & & \downarrow \\ \mathsf{X} & \xrightarrow{f} & \mathsf{Z}, \end{array}$$

where the horizontal maps are proper, geometrically reduced, and locally almost of finite presentation. Then f admits a reduced Stein factorization $\mathsf{X} \xrightarrow{g} \mathsf{Y} \xrightarrow{h} \mathsf{Z}$. Define $\mathsf{Y}' = \mathsf{Y} \times_{\mathsf{Z}} \mathsf{Z}'$, so that we can extend σ to a diagram

$$\begin{array}{ccccc} \mathsf{X}' & \xrightarrow{g'} & \mathsf{Y}' & \xrightarrow{h'} & \mathsf{Z}' \\ \downarrow & & \downarrow & & \downarrow \\ \mathsf{X} & \xrightarrow{g} & \mathsf{Y} & \xrightarrow{h} & \mathsf{Z}. \end{array}$$

The map h' is defined as a pullback to h, and is therefore finite étale. Since the right square and the outer rectangle are pullbacks, it follows that the left square is a pullback as well. In particular, g' is a pullback of g and is therefore proper, geometrically reduced, geometrically connected, and locally almost of finite presentation. It follows that (g', h') is the reduced Stein factorization of f'.

8.7.4 The Proof of Theorem 8.7.3.1

We begin by proving part (a) of Theorem 8.7.3.1. Note that by replacing Y by the fiber product $\mathsf{Y} \times_{\mathsf{Z}'} \mathsf{Z}$, we may reduce to the case where $\mathsf{Z}' = \mathsf{Z}$. In this case, the desired result is a consequence of the following more general assertion:

Proposition 8.7.4.1. *Let $f : \mathsf{X} \to \mathsf{Z}$ and $g : \mathsf{Y} \to \mathsf{Z}$ be morphisms of spectral Deligne-Mumford stacks. Assume that f is proper and geometrically connected (that is, it satisfies condition* (1) *of Proposition 8.6.4.1) and that g is finite étale. Then composition with f induces a homotopy equivalence*

$$\theta : \mathrm{Map}_{\mathrm{SpDM}_{/\mathsf{Z}}}(\mathsf{Z}, \mathsf{Y}) \to \mathrm{Map}_{\mathrm{SpDM}_{/\mathsf{Z}}}(\mathsf{X}, \mathsf{Y}).$$

Proof. The assertion is local on Z. We may therefore assume without loss of generality that Z is affine and that g exhibits Y as a disjoint union of n copies of Z (see Lemma B.7.6.3). In this case, we can identify the domain of θ with the set of all decompositions of the topological space $|\mathsf{Z}|$ into n open sets, and the codomain of θ with the set of all decompositions of the topological space $|\mathsf{X}|$ into n open sets. To prove that θ is bijective, it will suffice to show that the construction $U \mapsto f^{-1}U$ induces a bijection from the set of closed and open subsets of $|\mathsf{Z}|$ to the set of closed and open subsets of $|\mathsf{X}|$. Since f is geometrically connected, the underlying map of topological spaces $|\mathsf{X}| \to |\mathsf{Z}|$ is surjective: consequently, an open set $U \subseteq |\mathsf{Z}|$ is determined by its inverse image $f^{-1}U$. To complete the proof, we must show that if $V \subseteq |\mathsf{X}|$ is a closed and open subset, then V has the form $f^{-1}U$ where $U \subseteq |\mathsf{Z}|$ is a closed an open subset. Since f is proper, the images $f(V)$ and $f(|\mathsf{X}| - V)$ are closed subsets of $|\mathsf{Z}|$. The surjectivity of f implies that these subsets cover $|\mathsf{Z}|$. If $f(V) \cap f(|\mathsf{X}| - V)$ were nonempty, then we could choose a geometric point $\mathrm{Sp\acute{e}t}\,\kappa \to \mathsf{Z}$ of the intersection, in which case V and $|\mathsf{X}| - V$ supply a nontrivial decomposition of the topological space $|\mathsf{X} \times_{\mathsf{Z}} \mathrm{Sp\acute{e}t}\,\kappa|$, contradicting our assumption that f is geometrically reduced. It follows that $U = f(V)$ is closed and open in $|\mathsf{Z}|$. We have $V \subseteq f^{-1}U$ by definition, and the reverse inclusion follows from

$$|\mathsf{X}| - V \subseteq f^{-1}f(|\mathsf{X}| - V))f^{-1}(|\mathsf{Z}| - U) = \mathsf{X} - f^{-1}U.$$

□

Proposition 8.7.4.2. *Let $f : \mathsf{X} \to \mathsf{Z}$ be a morphism of 0-truncated spectral Deligne-Mumford stacks which is proper, geometrically reduced, and locally almost of finite presentation, and let $\mathsf{X} \xrightarrow{f'} \mathsf{Y} \xrightarrow{f''} \mathsf{Z}$ be a reduced Stein factorization of f (Definition 8.7.1.4). Then (f', f'') is also a reduced Stein factorization of f: that is, the morphism f'' is finite étale and the morphism f' satisfies the equivalent conditions of Proposition 8.6.4.1.*

Proof. Using Proposition 8.7.1.7, we see that the desired conclusions can be tested locally with respect to the étale topology on X. We may therefore assume without loss of generality that $\mathsf{Z} \simeq \operatorname{Spét} R$ for some commutative ring R. Using Theorem 4.4.2.2, Proposition 5.5.4.1, and Proposition 6.1.6.1, we can choose a finitely generated subring $R_0 \subseteq R$ and a pullback square

$$\begin{array}{ccc} \mathsf{X} & \longrightarrow & \mathsf{X}_0 \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f_0} \\ \operatorname{Spét} R & \longrightarrow & \operatorname{Spét} R_0 \end{array}$$

where f_0 is proper, flat, and locally almost of finite presentation. Let $K \subseteq |\mathsf{X}_0|$ be the complement of the geometrically reduced locus of f_0. Since f_0 is proper, the image $f_0(K)$ is a closed subset of $|\operatorname{Spec} R_0|$ and is therefore defined by a finitely generated ideal $I \subseteq R_0$. Since the map f is geometrically reduced, Proposition 8.6.3.1 guarantees that $f^{-1}K \subseteq |\mathsf{X}|$ is empty. Consequently, IR is the unit ideal in R, so we have an equation $1 = x_1 y_1 + \cdots + x_k y_k$ in the ring R where each x_i belongs to I. Enlarging R_0 if necessary, we may assume that each y_i belong to I, so that $I = R_0$ and the map f_0 is geometrically reduced. Regard the pushforward $f_{0*} \mathscr{O}_{\mathsf{X}_0}$ as an object of Mod_{R_0}, so that we have a canonical equivalence $f_* \mathscr{O}_{\mathsf{X}} \simeq R \otimes_{R_0} f_{0*} \mathscr{O}_{\mathsf{X}_0}$. We therefore have a fiber sequence

$$R \otimes_{R_0} (\tau_{\geqslant 0} f_{0*} \mathscr{O}_{\mathsf{X}_0}) \to f_* \mathscr{O}_{\mathcal{X}} \to R \otimes_{R_0} (\tau_{\leqslant -1} f_{0*} \mathscr{O}_{\mathsf{X}_0}).$$

Note that the first term of this sequence is connective. Consequently, if $\tau_{\leqslant -1} f_{0*}(\mathscr{O}_{\mathsf{X}_0})$ has Tor-amplitude $\leqslant -1$, then then the third term of this fiber sequence belongs to $(\operatorname{Mod}_R)_{\leqslant -1}$, so that we obtain equivalences

$$R \otimes_{R_0} (\tau_{\geqslant 0} f_{0*} \mathscr{O}_{\mathsf{X}_0}) \simeq \tau_{\geqslant 0} f_* \mathscr{O}_{\mathsf{X}} \qquad R \otimes_{R_0} (\tau_{\leqslant -1} f_{0*} \mathscr{O}_{\mathsf{X}_0}) \simeq \tau_{\leqslant -1} f_* \mathscr{O}_{\mathsf{X}}.$$

Consequently, to show that $\tau_{\geqslant 0} f_* \mathscr{O}_{\mathsf{X}}$ is finite étale over R and that $\tau_{\leqslant -1} f_* \mathscr{O}_{\mathsf{X}}$ has Tor-amplitude $\leqslant -1$, it will suffice to show that $\tau_{\geqslant 0} f_{0*} \mathscr{O}_{\mathsf{X}_0}$ is finite étale over R_0 and that

$\tau_{\leqslant -1} f_{0*} \mathscr{O}_{\mathsf{X}_0}$ has Tor-amplitude $\leqslant -1$ over R_0. We may therefore replace f by f_0 and thereby reduce to the case where the commutative ring R is Noetherian.

Applying Theorem 8.7.2.1, we deduce that $A = \pi_0 f_* \mathscr{O}_{\mathsf{X}}$ is finitely generated as an R-module, and therefore also as an R-algebra. Consequently, to show that A is finite étale over R, it will suffice to show that the relative cotangent complex $L_{A/R}$ vanishes (Lemma B.1.3.3). Since A is locally almost of finite presentation over R (Theorem HA.7.2.4.31), the relative cotangent complex $L_{A/R}$ is almost perfect as an A-module, and therefore also as an R-module (since A is finite over R). Note that Theorem 8.7.2.1 also guarantees that the truncation $\tau_{\leqslant -1} f_* \mathscr{O}_{\mathsf{X}}$ is almost perfect. Using Corollary 2.7.4.4 and Corollary 8.6.4.3, we see that it will suffice to prove verify the following conditions for every ring homomorphism $\rho : R \to \kappa$, where κ is a field:

(i) The tensor product $\kappa \otimes_R L_{A/R}$ vanishes.

(ii) The homotopy groups $\pi_n(\kappa \otimes_R \tau_{\leqslant -1} f_* \mathscr{O}_{\mathsf{X}})$ vanish for $n \geqslant 0$.

In fact, it suffices to verify (i) and (ii) in the special case where κ is a finite extension of some residue field of R (or even in the special case where κ itself is a residue field of R). Set $A_0 = \pi_0(\kappa \otimes_R f_* \mathscr{O}_{\mathcal{X}})$, so that A_0 is the ring of functions on fiber $\mathsf{X}_0 = \mathsf{X} \times_{\operatorname{Sp\acute{e}t} R} \operatorname{Sp\acute{e}t} \kappa$. Then A_0 is a finite κ-algebra. Since f is geometrically reduced, A_0 is a product of finite separable extensions of κ. Replacing κ by a finite extension if necessary, we may assume that there exists an isomorphism $\alpha_0 : \kappa^m \simeq A_0$ for some integer m, so that the fiber X_0 decomposes as a disjoint union of connected components $\amalg_{1 \leqslant i \leqslant m} \mathsf{X}_{0,i}$.

Note that to verify (i) and (ii), we are free to extend scalars along any *flat* map $v : R \to R'$ for which ρ factors through v. In particular, we may replace R by a polynomial ring $R[x_1, \ldots, x_k]$ to ensure that κ is a residue field of R (rather than a finite extension therefof). Set $\mathfrak{m} = \ker(\rho)$. Replacing R by the completion of the local ring $R_{\mathfrak{m}}$, we may assume that R is a complete local ring with maximal ideal $\mathfrak{m}$ and residue field κ. Let $\mathsf{X}^{\wedge}$ denote the formal completion of X along the vanishing locus of $\mathfrak{m}$. Using Theorem 8.5.0.3, we can identify $A = \pi_0 f_* \mathscr{O}_{\mathsf{X}}$ with the endomorphism ring $\operatorname{Ext}^0_{\operatorname{QCoh}(\mathsf{X}^{\wedge}_{\mathfrak{m}})}(\mathscr{O}_{\mathsf{X}^{\wedge}}, \mathscr{O}_{\mathsf{X}^{\wedge}})$. The decomposition $\mathsf{X}_0 \simeq \amalg_{1 \leqslant i \leqslant m} \mathsf{X}_{0,i}$ lifts to a decomposition of formal spectral Deligne-Mumford stacks $\mathsf{X}^{\wedge} \simeq \amalg_{1 \leqslant i \leqslant m} \mathsf{X}^{\wedge}_i$, so that the endomorphism ring A admits a corresponding decomposition $A \simeq \prod_{1 \leqslant i \leqslant m} A_i$. Each A_i is an R-algebra, so that α_0 lifts to a map of R-algebras $\alpha : R^m \to A$. Composing α with the natural map $A \to f_* \mathscr{O}_{\mathsf{X}}$, we obtain a fiber sequence of R-modules

$$R^m \xrightarrow{\alpha} f_* \mathscr{O}_{\mathsf{X}} \to M$$

for some perfect R-module M. By construction, $\kappa \otimes_R M$ is the cofiber of the map $\kappa^m \simeq A_0 \to \kappa \otimes_R f_* \mathscr{O}_{\mathsf{X}})$ and therefore belongs to $(\operatorname{Mod}_\kappa)_{\leqslant -1}$. Applying Corollary 8.6.4.3, we deduce that M has Tor-amplitude $\leqslant -1$. In particular, since R is discrete, we have $M \in (\operatorname{Mod}_R)_{\leqslant -1}$, so that α exhibits R^m as the connective cover of $f_* \mathscr{O}_{\mathsf{X}}$ and M as the truncation $\tau_{\leqslant -1} f_* \mathscr{O}_{\mathsf{X}}$. Assertions (i) and (ii) now follow immediately. □

Proof of Theorem 8.7.3.1. Part (a) follows immediately from Proposition 8.7.4.1. We will prove (b). Let $f : \mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}}) \to (\mathcal{Z}, \mathscr{O}_{\mathsf{Z}}) = \mathsf{Z}$ be a morphism of spectral Deligne-Mumford stacks which is proper, geometrically reduced, and locally almost of finite presentation. We wish to show that f admits a reduced Stein factorization. Consider the induced map of 0-truncated spectral Deligne-Mumford stacks

$$f_0 : \mathsf{X}_0 = (\mathcal{X}, \pi_0 \mathscr{O}_{\mathsf{X}}) \to (\mathcal{Z}, \pi_0 \mathscr{O}_{\mathsf{Z}}) = \mathsf{Z}.$$

Using Proposition 8.7.4.2, we deduce that f_0 admits a reduced Stein factorization $\mathsf{X}_0 \xrightarrow{f_0'} \mathsf{Y}_0 \xrightarrow{f_0''} \mathsf{Z}_0$. Then f_0'' is étale, so we can write $\mathsf{Y}_0 = (\mathcal{Z}_{/U}, (\pi_0 \mathscr{O}_{\mathsf{Z}})|_U)$ for some object $U \in \mathcal{Z}$. The map f_0' determines a point $\eta \in \Gamma(\mathsf{X}; f^* U)$, which in turn determines a map $f' : \mathsf{X} \to (\mathcal{Z}_{/U}, \mathscr{O}_{\mathsf{Z}}|_U)$. The map f' fits into a commutative diagram

$$\begin{array}{ccccc} \mathsf{X}_0 & \xrightarrow{f_0'} & (\mathcal{Z}_{/U}, \pi_0 \mathscr{O}_{\mathsf{Z}}|_U) & \xrightarrow{f_0''} & \mathsf{Z}_0 \\ \downarrow & & \downarrow & & \downarrow \\ \mathsf{X} & \xrightarrow{f'} & (\mathcal{Z}_{/U}, \mathscr{O}_{\mathsf{Z}}|_U) & \xrightarrow{f''} & \mathsf{Z} \end{array}$$

where the outer rectangle is a pullback (by virtue of our assumption that f is flat) and the right square is a pullback by inspection. It follows that the left square is a pullback as well. Since f_0' is geometrically reduced, it follows from Remark 8.6.2.5 that the map f' is geometrically reduced. The map f'' is finite étale by construction, so that f' is proper by Proposition 5.1.4.1 and locally almost of finite presentation by Proposition 4.2.3.3. Consequently, the pair (f', f'') is a reduced Stein factorization of f. □

Part III

Tannaka Reconstruction and Quasi-Coherent Stacks

Let X be a scheme and let $\Gamma(X; \mathscr{O}_X)$ denote the ring of regular functions on X. We can then ask to what extent the scheme X is determined by the commutative ring $\Gamma(X; \mathscr{O}_X)$. More precisely, we ask the following:

Question 8.7.0.1. Let A be a commutative ring. Every morphism of schemes $f : \operatorname{Spec} A \to X$ determines a ring homomorphism $f^* : \Gamma(X; \mathscr{O}_X) \to A$, given by pullback along f. The construction $f \mapsto f^*$ determines a map ρ_A from the set $X(A)$ of A-valued points of X to the set of ring homomorphisms $\operatorname{Hom}(\Gamma(X; \mathscr{O}_X), A)$. When is the function ρ_A a bijection?

Question 8.7.0.2. The construction $\mathscr{F} \mapsto \Gamma(X; \mathscr{F})$ determines a functor $\Gamma(X; \bullet)$ from the abelian category of quasi-coherent sheaves on X to the abelian category of $\Gamma(X; \mathscr{O}_X)$-modules. When is the functor $\Gamma(X; \bullet)$ an equivalence of categories?

Roughly speaking, the answers each of these questions is "only if X is affine." More precisely, we have the following:

- (i) A scheme X is affine if and only if the map ρ_A of Question 8.7.0.1 is a bijection for every commutative ring A (this is an immediate consequence of the universal property characterizing the affine scheme $\operatorname{Spec} \Gamma(X; \mathscr{O}_X)$).
- (ii) If X is affine, then the functor $\Gamma(X; \bullet)$ of Question 8.7.0.2 is an equivalence of categories. The converse holds if X is quasi-compact and separated (this is one formulation Serre's affineness criterion; see Proposition 11.4.3.1 for a related statement).

Our goal in Part III is to study *categorified* versions of Questions 8.7.0.1 and 8.7.0.2, informed by the following heuristic dictionary:

Remark 8.7.0.3.

Classical Notion	Categorified Notion
Regular Function on X	Quasi-Coherent Sheaf on X
Commutative Ring	Symmetric monoidal ∞-category
Ring homomorphism	Symmetric monoidal functor
$\Gamma(X; \mathscr{O}_X)$	$\operatorname{QCoh}(X)$
Quasi-coherent sheaf on X	Quasi-coherent stack on X
$\Gamma(X; \mathscr{O}_X)$-Modules	∞-Category Tensored over $\operatorname{QCoh}(X)$

The central theme of Part III is that the categorified analogues of Questions 8.7.0.1 and 8.7.0.2 have affirmative answers for a much larger class of geometric objects X: roughly speaking, we do not need to assume that X is affine, only that the diagonal map $\delta : X \to X \times X$ is affine (or, in some cases, quasi-affine).

Let us begin considering the analogue of Question 8.7.0.1. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor (for example, the functor represented by a scheme or some other algebro-geometric object). Let $\mathrm{QCoh}(X)$ denote the ∞-category of quasi-coherent sheaves on X (Definition 6.2.2.1). Given a connective $\mathbb{E}_\infty$-ring A and a point $\eta \in X(A)$, we can regard the pullback functor $\eta^* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(\operatorname{Spec} A) \simeq \mathrm{Mod}_A$ as an object of the ∞-category $\mathrm{LFun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{Mod}_A)$ of symmetric monoidal functors from $\mathrm{QCoh}(X)$ to Mod_A which preserve small colimits. The construction $\eta \mapsto \eta^*$ determines a functor $\theta : X(A) \to \mathrm{LFun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{Mod}_A)$, which we can regard as a categorified analogue of the map ρ_A appearing in Question 8.7.0.1. In Chapter 9, we will show that the functor θ is often very close to being an equivalence:

- If X is a quasi-compact, quasi-separated spectral algebraic space, then the functor θ is always an equivalence (Theorem 9.6.0.1).
- If X is a quasi-geometric stack (see Definition 9.1.0.1; roughly speaking, this means that X has quasi-affine diagonal), then the functor θ is always fully faithful (Theorem 9.2.0.2).
- For quasi-geometric stacks satisfying various auxiliary conditions, we can explicitly describe the essential image of θ (see Theorems 9.3.0.3, 9.3.5.1, 9.3.7.1, 9.4.1.4, 9.4.4.7, 9.5.4.1, 9.5.4.2, and 9.7.2.1).
- If we restrict our attention to the case where X is a classical algebro-geometric object, then there is analogous way to recover X from the *abelian* category $\mathrm{QCoh}(X)^{\heartsuit}$ of quasi-coherent sheaves on X (Theorem **??**). In the special case where $X = BG$ is the classifying stack of an affine group scheme G, this recovers the classical theory of Tannaka duality for the group G (see Theorem 9.0.0.1).

The bulk of Chapter 10 is devoted studying the categorified analogue of Question 8.7.0.2. Our first step is to introduce the notion of a *quasi-coherent stack* on a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ (see Construction 10.1.1.1). Roughly speaking, a *stable quasi-coherent stack* $\mathcal{C}$ on X is a rule which assigns to each point $\eta \in X(R)$ an R-linear stable ∞-category $\mathcal{C}_\eta$, in the sense of Appendix D. The collection of stable quasi-coherent stacks on X form an ∞-category $\mathrm{QStk}^{\mathrm{St}}(X)$, which we can regard as a categorified analogue of the ∞-category $\mathrm{QCoh}(X)$ of quasi-coherent sheaves on X. To each object $\mathcal{C} \in \mathrm{QStk}^{\mathrm{St}}(X)$ a stable ∞-category $\mathrm{QCoh}(X; \mathcal{C})$ of *quasi-coherent sheaves on X with values in $\mathcal{C}$*, which is endowed with an action of the symmetric monoidal ∞-category $\mathrm{QCoh}(X)$. Under mild assumptions on X, the construction

$\mathcal{C} \mapsto \mathrm{QCoh}(X;\mathcal{C})$ detemrines a functor $\mathrm{QCoh}(X;\bullet) : \mathrm{QStk}^{\mathrm{St}}(X) \to \mathrm{Mod}_{\mathrm{QCoh}(X)}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$, which we regard as an analogue of the functor $\Gamma(X;\bullet)$ appearing in Question 8.7.0.2. One of our main results asserts that if X is a quasi-compact, quasi-separated algebraic space, then the functor $\mathrm{QCoh}(X;\bullet)$ is an equivalence of ∞-categories. In fact, we establish a more general result for *prestable* quasi-coherent stacks (Theorem 10.2.0.2), and slightly weaker results for more general functors X (see Theorems 10.2.0.1, 10.4.2.3, and 10.6.2.1).

The results of Chapters 9 and 10 suggest in particular that any spectral algebraic space X which is quasi-compact and quasi-separated can be viewed as the "spectrum" of the ∞-category $\mathrm{QCoh}(\mathsf{X})$, which can regard as a commutative algebra object in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ of presentable stable ∞-categories. In Chapter 11, we consider what happens if we neglect the algebra structure on $\mathrm{QCoh}(\mathsf{X})$. More precisely, we ask the following:

Question 8.7.0.4. Let R be a connective $\mathbb{E}_\infty$-ring and let $q : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ be a morphism of spectral algebraic spaces. To what extent is X controlled by the stable R-linear ∞-category $\mathrm{QCoh}(\mathsf{X})$ (without its symmetric monoidal structure)?

Question 8.7.0.4 leads naturally to the subject of (derived) *non-commutative geometry*. Although one generally needs the symmetric monoidal structure on $\mathrm{QCoh}(\mathsf{X})$ in order to recover X itself, some of the most important geometric conditions on X can be formulated directly in terms of $\mathrm{QCoh}(\mathsf{X})$ (while neglecting its tensor structure). Following ideas of Kontsevich, we introduce the notions of *smooth* and *proper* stable R-linear ∞-categories, and show that the smoothness and properness of $\mathrm{QCoh}(\mathsf{X})$ are closely related to the corresponding geometric properties of the morphism $q : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ (see Theorems 11.1.4.1, 11.3.6.1, and 11.4.0.3).

Chapter 9

Tannaka Duality

Let G be an affine algebraic group over a field κ. For every commutative κ-algebra A, let $G(A)$ denote the group of A-valued points of G. Let $\mathrm{Rep}(G)$ denote the abelian category of finite-dimensional representations of G. By definition, for each $V \in \mathrm{Rep}(G)$, we can equip the tensor product $A \otimes_{\kappa} V$ with an action of the group $G(A)$. This action depends functorially on V: consequently, we can view the group $G(A)$ as acting on the forgetful functor $e : \mathrm{Rep}(G) \to \mathrm{Mod}_A^{\mathrm{lf}}$ given by $e(V) = A \otimes_{\kappa} V$; here $\mathrm{Mod}_A^{\mathrm{lf}}$ denotes the category of projective A-modules of finite rank. The theory of Tannaka duality (in its algebro-geometric incarnation) asserts that this action can be used to recover the group $G(A)$:

Theorem 9.0.0.1 (Tannaka Duality)**.** *Let G be an affine algebraic group over a field κ, let A be a commutative κ-algebra, and let $e : \mathrm{Rep}(G) \to \mathrm{Mod}_A^{\heartsuit}$ be the functor given by $e(V) = A \otimes_{\kappa} V$. Then the the above construction induces an isomorphism $G(A) \to \mathrm{Aut}^{\otimes}(e)$; here $\mathrm{Aut}^{\otimes}(e)$ denotes the automorphism group of e in the category of (symmetric) monoidal functors from $\mathrm{Rep}(G)$ to $\mathrm{Mod}_A^{\mathrm{lf}}$.*

For a proof, we refer the reader to [48] (see also Corollaries 9.2.2.2 and 9.3.7.5).

It is often convenient to interpret Theorem 9.0.0.1 as a statement about the classifying stack of the algebraic group G. For every commutative κ-algebra A, let $\mathrm{Nil}()G(A)$ denote the category of G-torsors on the affine scheme $\mathrm{Spec}\, A$ (which we require to be locally trivial with respect to the fpqc topology). The construction $A \mapsto \mathrm{Nil}()G(A)$ determines a stack (with respect to the fpqc topology) on the category of commutative κ-algebras, which we denote by BG and refer to as the *classifying stack* of G. We can then identify $\mathrm{Rep}(G)$ with the category of quasi-coherent sheaves on BG which are locally free of finite rank.

If A is a commutative ring, then the datum of a map $\epsilon : \mathrm{Spec}\, A \to BG$ is equivalent to the data of a pair $(\phi, \mathcal{P})$, where $\phi : \kappa \to A$ is a ring homomorphism and $\mathcal{P}$ is a G-torsor on $\mathrm{Spec}\, A$. For every commutative κ-algebra A, the trivial G-torsor on $\mathrm{Spec}\, A$ is classified by a map $\epsilon_0 : \mathrm{Spec}\, A \to BG$. The fiber functor e appearing in Theorem 9.0.0.1 is given by pullback along ϵ_0, and we can identify $G(A)$ with the automorphism group of ϵ_0 (equivalently, the automorphism group of the trivial G-torsor on $\operatorname{Spec} A$). Theorem 9.0.0.1 can then be regarded as a special case of the following assertion:

Theorem 9.0.0.2. *Let G be an affine algebraic group over a field κ and let A be a commutative ring Then the construction*

$$(\epsilon : \operatorname{Spec} A \to BG) \mapsto (\epsilon^* : \operatorname{Rep}(G) \to \operatorname{Mod}_A^{\heartsuit})$$

determines a fully faithful embedding from the category of A-valued points of BG to the category of symmetric monoidal functors from $\operatorname{Rep}(G)$ to $\operatorname{Mod}_A^{\heartsuit}$.

Our goal in this chapter is to discuss two questions which are inspired by Theorem 9.0.0.2:

Question 9.0.0.3. For which algebro-geometric objects X can one expect some analogue of Theorem 9.0.0.2, asserting that a map $f : \operatorname{Spec} A \to X$ can be recovered from the pullback functor $f^* : \operatorname{QCoh}(X) \to \operatorname{Mod}_A$ on quasi-coherent sheaves (or some variant thereof)?

Question 9.0.0.4. How can one characterize those symmetric monoidal functors $F : \operatorname{QCoh}(X) \to \operatorname{Mod}_A$ which are of the form f^*, for some map $f : \operatorname{Spec} A \to X$?

Let us now outline the contents of this chapter. We begin in §9.1 by introducing the notion of a *quasi-geometric stack*. Roughly speaking, a quasi-geometric stack is an object which arises as the quotient of an affine spectral algebraic space $\operatorname{Spec} A$ by the action of a groupoid which is flat and quasi-affine (see Definition 9.1.0.1 and Remark 9.1.1.6). The class of quasi-geometric stacks includes all quasi-compact, quasi-separated spectral algebraic spaces (Corollary 9.1.4.6), and also the classifying stack of any affine group scheme over a field (see Example 9.1.1.7). Our motivation for introducing the notion of quasi-geometric stack is that this notion provides an answer to Question 9.0.0.3. In §9.2, we will show that if X is a quasi-geometric stack and A is a connective $\mathbb{E}_\infty$-ring, then the construction $(f : \operatorname{Spec} A \to X) \mapsto (f^* : \operatorname{QCoh}(X) \to \operatorname{Mod}_A)$ determines a fully faithful embedding Θ from the space $X(A)$ of A-valued points of X to the ∞-category $\operatorname{Fun}^{\otimes}(\operatorname{QCoh}(X), \operatorname{Mod}_A)$ of symmetric monoidal functors from $\operatorname{QCoh}(X)$ to Mod_A (Proposition 9.2.2.1). Moreover, we also address Question 9.0.0.4 by characterizing the essential image of Θ: according to Theorem 9.2.0.2, it consists of those symmetric monoidal functors F which are right t-exact and participate in an adjunction $\operatorname{QCoh}(X) \underset{G}{\overset{F}{\rightleftarrows}} \operatorname{Mod}_A$ of colimit-preserving functors which satisfies a projection formula.

Theorem 9.2.0.2 can be regarded as an ∞-categorical avatar of the classical theory of Tannaka duality, and is the basic prototype of the sort of result we are interested in. The remainder of this chapter is devoted to studying special classes of quasi-geometric stacks for which stronger results are available:

- In §9.3, we study the class of *geometric stacks*: quasi-geometric stacks X for which the diagonal map $\delta : X \to X \times X$ is affine. For geometric stacks, we give a different characterization of the essential image of Θ: it consists of those symmetric monoidal functors $F : \mathrm{QCoh}(X) \to \mathrm{Mod}_A$ which preserve small colimits, connective objects, and flat objects (Theorem 9.3.0.3).

- In §9.4, we study the class of *perfect stacks*: quasi-geometric stacks X for which the ∞-category $\mathrm{QCoh}(X)$ has "enough" perfect objects (see also [23]). For perfect stacks, the essential image of Θ admits an even simpler characterization: it consists of those symmetric monoidal functors $F : \mathrm{QCoh}(X) \to \mathrm{Mod}_A$ which preserve small colimits and connective objects (this was proven by Bhatt and Halpern-Leistner in [27]; we include a proof here as Corollary 9.4.4.7);

- In §9.5, we study *locally Noetherian* stacks: quasi-geometric stacks X for which there exists a faithfully flat map $\mathrm{Spec}\, A \to X$, where A is Noetherian. For locally Noetherian geometric stacks, the essential image of Θ again admits a simple description: it again consists of those symmetric monoidal functors $F : \mathrm{QCoh}(X) \to \mathrm{Mod}_A$ which preserve small colimits and connective objects (Theorem 9.5.4.1; moreover, we prove a slightly weaker statement in the quasi-geometric case as Theorem 9.5.4.2).

- In §9.6, we consider the case where X is a quasi-compact, quasi-separated algebraic space. In this case, we have a further simplification: the essential image of Θ consists of all symmetric monoidal functors $F : \mathrm{QCoh}(X) \to \mathrm{Mod}_A$ which preserve small colimits (Theorem 9.6.0.1).

- In §9.7, we describe the relationship between the ∞-categorical version of Tannaka duality studied in this section (which is formulated in terms of ∞-categories of quasi-coherent sheaves) and its incarnation in classical algebraic geometry (which is formulated in terms of abelian categories of quasi-coherent sheaves). We say that a quasi-geometric stack X is 0-*truncated* if there exists a faithfully flat map $\mathrm{Spec}\, R \to X$, where R is a commutative ring (Definition 9.1.6.2). Any 0-truncated quasi-geometric stack X can be regarded as a *classical* algebro-geometric object, in the sense that it can be recovered from knowledge of its A-valued points where A ranges over ordinary commutative rings (Proposition 9.1.6.9). In §9.7, we show that a 0-truncated geometric stack X can also be recovered from its abelian category of quasi-coherent sheaves $\mathrm{QCoh}(X)^{\heartsuit}$ (Theorem 9.7.3.2). In fact, one can even recover X from the full subcategory $\mathrm{QCoh}(X)^{\flat} \subseteq \mathrm{QCoh}(X)^{\heartsuit}$ spanned by the flat quasi-coherent sheaves on X (Theorem 9.7.2.1).

Remark 9.0.0.5. Many variations on the theme of this chapter have been explored in the literature. For further discussion, we refer the reader to Bhatt ([26]), Bhatt-Halpern-Leistner

([27]). Brandenburg-Chirvasitu ([33]), Fukuyama-Iwanari ([70]), Hall-Rydh ([92]), Iwanari ([102]), Lurie ([137]), Schäppi ([178], [180], [181], [182]), and Wallbridge ([221]).

9.1 Quasi-Geometric Stacks

Our goal in this section is to set the stage for our discussion of Tannaka duality by introducing the class of algebro-geometric objects that we are interested in:

Definition 9.1.0.1. A *quasi-geometric stack* is a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ which satisfies the following conditions:

(a) The functor X satisfies descent with respect to the fpqc topology.

(b) The diagonal map $\delta : X \to X \times X$ is quasi-affine (in the sense of Example 6.3.3.6).

(c) There exists a connective $\mathbb{E}_\infty$-ring A and a faithfully flat morphism $f : \operatorname{Spec} A \to X$ (see Definition 6.3.3.7).

More informally, a quasi-geometric stack is an object which can be obtained as the quotient (with respect to the fpqc topology) of an affine spectral scheme $\operatorname{Spec} A$ by the action of a groupoid $G \underset{q}{\overset{p}{\rightrightarrows}} \operatorname{Sp\acute{e}t} A$ which is flat and quasi-affine (see Remark 9.1.1.6). As we will see in §9.2, the hypotheses of Definition 9.1.0.1 guarantee that the functor X can be functorially recovered from the ∞-category $\mathrm{QCoh}(X)$ of quasi-coherent sheaves on X (Theorem 9.2.0.2). Moreover, these hypotheses are not terribly restrictive: the class of quasi-geometric stacks includes most algebro-geometric objects which arise in practice:

(a) Any quasi-compact, quasi-separated spectral algebraic space is a quasi-geometric stack (when identified with its functor of points): see Corollary 9.1.4.6.

(b) If G is an affine group scheme over a field κ, then the classifying stack BG can be regarded as a quasi-geometric stack; this recovers the classical setting for Tannaka duality (see Corollary 9.2.2.2).

(c) More generally, any quasi-compact Artin stack with quasi-affine diagonal (in the sense of classical algebraic geometry) can be regarded as a quasi-geometric stack.

(d) The class of quasi-geometric stacks includes some "infinite-dimensional" algebraic stacks which arise naturally in the study of chromatic homotopy theory, such as the moduli stack of 1-dimensional formal groups and its homotopy-theoretic analogue (see Examples **??** and 9.3.1.8).

Remark 9.1.0.2. In Definition 9.1.0.1, we allow the functor X to take values in the ∞-category $\widehat{\mathcal{S}}$ of spaces which are not necessarily small. This is motivated by a set-theoretic technicality: the class of functors $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ is not closed under sheafification with respect to the fpqc topology. However, we will see later that if X is a quasi-geometric stack, then the space $X(R)$ is essentially small for every connective $\mathbb{E}_\infty$-ring R (Proposition 9.2.4.2). Consequently, every quasi-geometric stack X can be regarded as a functor from $\mathrm{CAlg}^{\mathrm{cn}}$ to the ∞-category $\mathcal{S}$ of (small) spaces, so we can replace the ∞-category $\widehat{\mathcal{S}}$ by $\mathcal{S}$ in Definition 9.1.0.1 with no essential change.

9.1.1 Examples of Quasi-Geometric Stacks

Our first goal is to show that quasi-geometric stacks exist in great abundance. We begin with some general remarks about the axiomatics of Definition 9.1.0.1:

Proposition 9.1.1.1. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor. The following conditions are equivalent:*

(b) *The diagonal map $X \to X \times X$ is quasi-affine.*

(b′) *For every pair of connective $\mathbb{E}_\infty$-rings A and B equipped with maps $\operatorname{Spec} A \to X \leftarrow \operatorname{Spec} B$, the fiber product $\operatorname{Spec} A \times_X \operatorname{Spec} B$ is quasi-affine (that is, it is representable by a quasi-affine spectral Deligne-Mumford stack).*

(b″) *For every connective $\mathbb{E}_\infty$-ring A and every morphism $f : \operatorname{Spec} A \to X$, the morphism f is quasi-affine.*

Proof. The equivalence $(b') \Leftrightarrow (b'')$ is clear. To show that $(b') \Rightarrow (b)$, choose any morphism $\operatorname{Spec} A \to X \times X$, corresponding to a pair of maps $f, g : \operatorname{Spec} A \to X$. We have a pullback

diagram

$$\begin{array}{ccc} \operatorname{Spec} A \times_{X \times X} X & \longrightarrow & \operatorname{Spec} A \times_X \operatorname{Spec} A \\ \downarrow & & \downarrow \\ \operatorname{Spec} A & \longrightarrow & \operatorname{Spec} A \times \operatorname{Spec} A \end{array}$$

where the bottom horizontal map is affine, so the upper horizontal map is affine as well. Condition (b') implies that the codomain of the upper horizontal map is quasi-affine, so that the domain is quasi-affine by virtue of Lemma 2.5.7.2. The implication $(b) \Rightarrow (b')$ follows from the observation that for any pair of morphisms $\operatorname{Spec} A \to X \leftarrow \operatorname{Spec} B$, we have an equivalence

$$\operatorname{Spec} A \times_X \operatorname{Spec} B \simeq \operatorname{Spec}(A \otimes B) \times_{X \times X} X.$$

□

It follows from Proposition 9.1.1.1 that if $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ is a functor with quasi-affine diagonal, then *any* morphism $\operatorname{Spec} A \to X$ is quasi-affine. We will need the following converse:

Proposition 9.1.1.2. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor which is a sheaf for the fpqc topology and suppose that there exists a morphism $f : \operatorname{Spec} A \to X$ which is representable and faithfully flat. If f is quasi-affine, then the diagonal map $\delta : X \to X \times X$ is quasi-affine.*

Lemma 9.1.1.3. *Suppose we are given a pullback diagram*

$$\begin{array}{ccc} X' & \xrightarrow{f'} & Y' \\ \downarrow & & \downarrow g \\ X & \xrightarrow{f} & Y \end{array}$$

in the ∞-category $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}} \subseteq \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ of fpqc sheaves. If f' is quasi-affine and g is an effective epimorphism of fpqc sheaves, then f is quasi-affine.

Proof. Choose any map $\eta : \operatorname{Spec} R \to Y$; we wish to show that the fiber product $Z = \operatorname{Spec} R \times_Y X$ is quasi-affine. Since g is an fpqc surjection, we can choose a faithfully flat map $R \to R^0$ such that $\eta|_{\operatorname{Spec} R^0}$ factors through Y'. Let $R^\bullet$ denote the Čech nerve of the faithfully flat map $R \to R^0$ (formed in the ∞-category $\mathrm{CAlg}^{\mathrm{op}}$) and set $Z_\bullet = \operatorname{Spec} R^\bullet \times_Y X$. By construction, each of the maps $\operatorname{Spec} R^m \to Y$ factors through Y', so that each Z_m is quasi-affine by virtue of our assumption on f'. Using Proposition 2.4.3.2, we can write $Z_\bullet = \operatorname{Spec} R^\bullet \times_{\operatorname{Spec} R} Z'$ for some quasi-affine map $Z' \to \operatorname{Spec} R$. Then both Z and Z' can be identified with the geometric realization $|Z_\bullet|$ (formed in the ∞-category $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$), so that Z is quasi-affine as desired. □

Proof of Proposition 9.1.1.2. By virtue of Proposition 9.1.1.1, it will suffice to show that every morphism $g : \operatorname{Spec} B \to X$ is quasi-affine. Using Lemma 9.1.1.3, we are reduced to showing that the projection map $\operatorname{Spec} A \times_X \operatorname{Spec} B \to \operatorname{Spec} A$ is quasi-affine. This is equivalent to the quasi-affineness of the fiber product $\operatorname{Spec} A \times_X \operatorname{Spec} B$, which follows from our assumption that $f : \operatorname{Spec} A \to X$ is quasi-affine. □

Proposition 9.1.1.4. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor which satisfies descent for the fpqc topology, and suppose there exists a morphism $f : X_0 \to X$ satisfying the following conditions:*

(a) *The functor $X_0 : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ is a quasi-geometric stack.*

(b) *The morphism f is representable, quasi-affine, and faithfully flat.*

Then X is a quasi-geometric stack.

Proof. Since X_0 is a quasi-geometric stack, we can choose a connective $\mathbb{E}_\infty$-ring A and a faithfully flat morphism $g : \operatorname{Spec} A \to X_0$ (which is automatically representable and quasi-affine, by virtue of Remark 9.1.1.1). Replacing f by $f \circ g$, we can assume that $X_0 = \operatorname{Spec} A$ is a corepresentable functor. Then the diagonal $\delta : X \to X \times X$ is quasi-affine by virtue of Proposition 9.1.1.2, so that X is a quasi-geometric stack. □

Corollary 9.1.1.5. *Let $X_\bullet$ be a simplicial object of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ satisfying the following conditions:*

(a) *The functor $X_0 : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ is a quasi-geometric stack.*

(b) *The functor $X_\bullet$ is a groupoid object of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$.*

(c) *The face map $d_0 : X_1 \to X_0$ is representable, quasi-affine, and faithfully flat.*

Then the geometric realization $X = |X_\bullet|$ (formed in the ∞-category $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$ of fpqc sheaves) is a quasi-geometric stack.

Proof. We have a pullback diagram

$$\begin{array}{ccc} X_1 & \xrightarrow{d_0} & X_0 \\ \downarrow{\scriptstyle d_1} & & \downarrow \\ X_0 & \longrightarrow & X \end{array}$$

where the vertical maps are effective epimorphisms in $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$. It follows from (c) and Lemma 9.1.1.3 that the map $X_0 \to X$ is quasi-affine and faithfully flat, so that X is a quasi-geometric stack by virtue of Proposition 9.1.1.4. □

Remark 9.1.1.6 (Existence of Atlases)**.** Every quasi-geometric stack X can be written as a geometric realization $|X_\bullet|$, where $X_\bullet$ satisfies the hypotheses of Corollary 9.1.1.5 and X_0 is affine: to see this, we can take $X_\bullet$ to be the Čech nerve of any faithfully flat map $\operatorname{Spec} A \to X$.

Example 9.1.1.7 (The Classifying Stack of a Group Scheme)**.** Let R be a commutative ring and let G be a flat quasi-affine group scheme over R. For each $n \geqslant 0$, let $X_n : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ denote the functor represented by the R-scheme $G \times_{\operatorname{Spec} R} G \times_{\operatorname{Spec} R} \cdots \times_{\operatorname{Spec} R} G$ (where the factor G appears n times). Using the group structure on G, we can regard the construction $[n] \mapsto X_n$ as a simplicial object $X_\bullet$ of the ∞-category $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$. We let BG denote the geometric realization $|X_\bullet|$ in the ∞-category $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$. It follows from Corollary 9.1.1.5 that BG is a quasi-geometric stack, which we will refer to as the *classifying stack* of G.

Remark 9.1.1.8. Let R be a commutative ring and let G be a flat quasi-affine group scheme over R. For every commutative ring A, we can identify $BG(A)$ with the classifying space for the groupoid of pairs $(\phi, \mathcal{P})$, where $\phi : R \to A$ is a ring homomorphism and $\mathcal{P}$ is a G-torsor on the affine scheme $\operatorname{Spec} A$ (which is locally trivial with respect to the fpqc topology).

9.1.2 Quasi-Geometric Morphisms

Definitions 9.1.0.1 and 9.3.0.1 can be relativized:

Definition 9.1.2.1. Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. We will say that f is *quasi-geometric* if, for every connective $\mathbb{E}_\infty$-ring A and every morphism $\operatorname{Spec} A \to Y$, the fiber product $\operatorname{Spec} A \times_Y X$ is a quasi-geometric stack (geometric stack).

Proposition 9.1.2.2. *Suppose we are given a pullback square*

$$\begin{array}{ccc} X' & \xrightarrow{f'} & Y' \\ \downarrow & & \downarrow g \\ X & \xrightarrow{f} & Y \end{array}$$

in the ∞-category $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$. If f is quasi-geometric, then f' is also quasi-geometric. The converse holds if g is an effective epimorphism in $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$.

Proof. The first assertion is immediate. To prove the second, suppose we are given a map $\operatorname{Spec} R \to Y$ and set $Z = \operatorname{Spec} R \times_Y X$; we wish to show that Z is a quasi-geometric stack. Since g is an effective epimorphism, we can choose a faithfully flat map $R \to R'$ for which the composite map $\operatorname{Spec} R' \to \operatorname{Spec} R \to Y$ factors through Y'. If f' is quasi-geometric, then the fiber product $Z' = \operatorname{Spec} R' \times_{\operatorname{Spec} R} Z \simeq \operatorname{Spec} R' \times_{Y'} X'$ is a quasi-geometric stack. Since the projection map $Z' \to Z$ is affine and faithfully flat, it follows from Proposition 9.1.1.4 that Z is also a quasi-geometric stack. □

Proposition 9.1.2.3. *Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. If Y is a quasi-geometric stack and f is quasi-geometric, then X is a quasi-geometric stack.*

Proof. Choose a connective $\mathbb{E}_\infty$-ring A and a faithfully flat morphism $u : \operatorname{Spec} A \to Y$. Set $X_0 = \operatorname{Spec} A \times_Y X$. Since Y is quasi-geometric, the morphism u is quasi-affine. It follows that the projection map $u' : X_0 \to X$ is quasi-affine and faithfully flat. Our assumption that f is quasi-geometric guarantees that X_0 is a quasi-geometric stack, so that X is also a quasi-geometric stack by virtue of Proposition 9.1.1.4. □

Corollary 9.1.2.4. *Let $f : X \to Y$ and $g : Y \to Z$ be quasi-geometric morphisms in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$. Then $g \circ f : X \to Z$ is also quasi-geometric.*

Corollary 9.1.2.5. *Let Y be a quasi-geometric stack and let $f : X \to Y$ be a natural transformation in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$. If X is a quasi-geometric stack, then the morphism f is quasi-geometric.*

Proof. Suppose we are given a map $u : \operatorname{Spec} A \to Y$; we wish to show that the fiber product $\operatorname{Spec} A \times_Y X$ is a quasi-geometric stack. Since Y is quasi-geometric, the morphism u is quasi-affine, so the projection map $\operatorname{Spec} A \times_Y X \to X$ is quasi-affine (and therefore also quasi-geometric). Since X is a quasi-geometric stack, Proposition 9.1.2.3 implies that $\operatorname{Spec} A \times_Y X$ is a quasi-geometric stack. □

Corollary 9.1.2.6. *Suppose we are given a pullback diagram*

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \longrightarrow & Y \end{array}$$

in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$. *Assume that Y is a quasi-geometric stack. If X and Y' are quasi-geometric stacks, then X' is also a quasi-geometric stack.*

Proof. It follows from Corollary 9.1.2.5 that the morphism f is quasi-geometric, so that f' is also quasi-geometric. Since Y' is a quasi-geometric stack (geometric stack), Proposition 9.1.2.3 implies that X' is also a quasi-geometric stack. □

9.1.3 Quasi-Coherent Sheaves on a Quasi-Geometric Stack

We begin by showing that if $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ is a quasi-geometric stack, then the ∞-category of quasi-coherent sheaves $\mathrm{QCoh}(X)$ is well-behaved. Our main result can be expressed most efficiently using the formalism of prestable ∞-categories developed in §C:

Proposition 9.1.3.1. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a quasi-geometric stack. Then $\mathrm{QCoh}(X)^{\mathrm{cn}}$ is a complete Grothendieck prestable ∞-category. Moreover, the inclusion $\mathrm{QCoh}(X)^{\mathrm{cn}} \hookrightarrow \mathrm{QCoh}(X)$ exhibits $\mathrm{QCoh}(X)$ as a stabilization of $\mathrm{QCoh}(X)^{\mathrm{cn}}$.*

Proof. Choose a faithfully flat map $f : X_0 \to X$, where $X_0 = \operatorname{Spec} A$ for some connective $\mathbb{E}_\infty$-ring A. Let $X_\bullet$ denote the Čech nerve of f. Since f is faithfully flat, we can identify X with the geometric realization of $X_\bullet$ in the ∞-category of fpqc sheaves. Using Proposition 6.2.3.1 (and the right cofinality of the inclusion map $\mathbf{\Delta}_s \hookrightarrow \mathbf{\Delta}$), we obtain equivalences

$$\mathrm{QCoh}(X) \simeq \varprojlim_{[n] \in \mathbf{\Delta}_s} \mathrm{QCoh}(X_n) \qquad \mathrm{QCoh}(X)^{\mathrm{cn}} \simeq \varprojlim_{[n] \in \mathbf{\Delta}_s} \mathrm{QCoh}(X_n)^{\mathrm{cn}}.$$

Since the diagonal of X is quasi-affine, each X_n is (representable by) a quasi-affine spectral Deligne-Mumford stack. It follows that each $\mathrm{QCoh}(X_n)^{\mathrm{cn}}$ is a complete Grothendieck prestable ∞-category and that each of the inclusion maps $\mathrm{QCoh}(X_n)^{\mathrm{cn}} \hookrightarrow \mathrm{QCoh}(X_n)$ exhibits $\mathrm{QCoh}(X_n)$ as a stabilization of $\mathrm{QCoh}(X_n)^{\mathrm{cn}}$ (Proposition 2.2.5.4). Moreover, for every *injective* map $[m] \to [n]$ of finite linearly ordered sets, the associated transition map $X_n \to X_m$ is flat (since it is a composition of pullbacks of the flat morphism f), so that the associated pullback functor $\mathrm{QCoh}(X_m)^{\mathrm{cn}} \to \mathrm{QCoh}(X_n)^{\mathrm{cn}}$ is left exact. Applying Proposition C.3.2.4 to the semisimplicial ∞-category of $\mathrm{QCoh}(X_\bullet)^{\mathrm{cn}}$, we deduce that $\mathrm{QCoh}(X)^{\mathrm{cn}}$ is a Grothendieck prestable ∞-category, which is automatically complete (see Proposition C.3.6.3). The final assertion now follows from Corollary C.3.2.5. □

Using Proposition C.1.4.1, we can reformulate Proposition 9.1.3.1 as follows:

Corollary 9.1.3.2. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a quasi-geometric stack. Then:*

(1) *The stable ∞-category $\mathrm{QCoh}(X)$ is presentable.*

(2) *There exists a t-structure $(\mathrm{QCoh}(X)_{\geqslant 0}, \mathrm{QCoh}(X)_{\leqslant 0})$ on $\mathrm{QCoh}(X)$, where $\mathrm{QCoh}(X)_{\geqslant 0} = \mathrm{QCoh}(X)^{\mathrm{cn}}$ is the full subcategory of $\mathrm{QCoh}(X)$ spanned by the connective objects.*

(3) *The t-structure on $\mathrm{QCoh}(X)$ is compatible with filtered colimits: that is, $\mathrm{QCoh}(X)_{\leqslant 0}$ is closed under filtered colimits in $\mathrm{QCoh}(X)$.*

(4) *The t-structure on $\mathrm{QCoh}(X)$ is both right and left complete.*

Remark 9.1.3.3. To prove Proposition 9.1.3.1 (or the equivalent Corollary 9.1.3.2), one does not need the full strength of the assertion that X is a quasi-geometric stack: it is enough to assume that there exists a morphism $u : X_0 \to X$, where u is representable and faithfully flat and X_0 is (representable by) a spectral Deligne-Mumford stack. However, for the moment we are primarily interested in the case of quasi-geometric stacks (we will study some other variants in Part VIII).

Remark 9.1.3.4. Let X be a quasi-geometric stack and let $f : \operatorname{Spec} A \to X$ be a faithfully flat map. The proof of Proposition 9.1.3.1 shows that the pullback functor $f^* : \mathrm{QCoh}(X)^{\mathrm{cn}} \to \mathrm{QCoh}(\operatorname{Spec} A)^{\mathrm{cn}} \simeq \mathrm{Mod}_A^{\mathrm{cn}}$ is left exact and conservative. Equivalently, the pullback functor $f^* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(\operatorname{Spec} A) \simeq \mathrm{Mod}_A$ is t-exact and conservative. In particular, a quasi-coherent sheaf $\mathscr{F} \in \mathrm{QCoh}(X)$ belongs to $\mathrm{QCoh}(X)_{\leqslant 0}$ if and only if $f^* \mathscr{F} \in \mathrm{Mod}_A$ belongs to $(\mathrm{Mod}_A)_{\leqslant 0}$.

We now consider a slight variant of Remark 9.1.3.4:

Proposition 9.1.3.5. *Let P be a property of pairs $(A, M) \in \mathrm{CAlg}^{\mathrm{cn}} \times_{\mathrm{CAlg}} \mathrm{Mod}(\mathrm{Sp})$ which is stable under base change and local with respect to the flat topology. Let X be a quasi-geometric stack, and choose a faithfully flat morphism $f : \operatorname{Spec} A \to X$. Let $\mathscr{F} \in \mathrm{QCoh}(X)$ and set $M = f^* \mathscr{F} \in \mathrm{QCoh}(\operatorname{Spec} A) \simeq \mathrm{Mod}_A$. Then $\mathscr{F}$ has the property P (in the sense of Definition 6.2.5.3) if and only if the pair (A, M) has the property P.*

Proof. The "only if" assertion is obvious. Conversely, suppose that the pair (A, M) has the property P. Let B be a connective $\mathbb{E}_\infty$-ring, $g : \operatorname{Spec} B \to X$ be an arbitrary morphism, and $N = g^* \mathscr{F} \in \mathrm{QCoh}(\operatorname{Spec} B) \simeq \mathrm{Mod}_B$. We wish to show that the pair (B, N) has the property P. Choose a flat surjection $\operatorname{Spec} C \to \operatorname{Spec} A \times_X \operatorname{Spec} B$. Since f is faithfully flat, it follows that C is faithfully flat over B. Since P is local with respect to the flat topology, we may B by C and thereby reduce to the case where the map g factors through f, in which case the desired result follows from our assumption that P is stable under base change. □

9.1.4 Quasi-Geometric Deligne-Mumford Stacks

We now consider a variant of Definition 9.1.2.1 in the setting of spectral Deligne-Mumford stacks.

Definition 9.1.4.1. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. We will say that f is *quasi-geometric* if it is quasi-compact and the diagonal map $\delta : \mathsf{X} \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ is quasi-affine.

We will say that a spectral Deligne-Mumford stack X is *quasi-geometric* if the map $\mathsf{X} \to \operatorname{Spét} S$ is quasi-geometric; here S denotes the sphere spectrum.

Remark 9.1.4.2. The condition that a morphism $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks be quasi-geometric is local on the target with respect to the étale topology and stable under base change. This follows immediately from the corresponding assertions for quasi-affine morphisms (see Example 6.3.3.6).

Let X be a spectral Deligne-Mumford stack and let $h_{\mathsf{X}} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ denote the functor represented by X. It follows immediately from the definitions that if the functor h_{X} is quasi-geometric (in the sense of Definition 9.1.0.1), then the spectral Deligne-Mumford stack X is quasi-geometric (in the sense of Definition 9.1.4.1). It is not immediately obvious that the converse holds: in general, the functor h_{X} represented by a spectral Deligne-Mumford stack X need not be a sheaf with respect to the fpqc topology. However, this problem does not arise if X is quasi-geometric:

Proposition 9.1.4.3. *Let X be a quasi-geometric spectral Deligne-Mumford stack, and let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be the functor represented by X. Then X is a hypercomplete sheaf with respect to the fpqc topology on $\mathrm{CAlg}^{\mathrm{cn}}$.*

Proof. Let $\widehat{\mathcal{S}\mathrm{hv}}^{\mathrm{hyp}}_{\mathrm{fpqc}}$ denote the full subcategory of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ spanned by those functors which are hypercomplete sheaves with respect to the flat topology. The inclusion $\widehat{\mathcal{S}\mathrm{hv}}^{\mathrm{hyp}}_{\mathrm{fpqc}} \hookrightarrow \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ admits a left exact left adjoint, which we will denote by L. Let $Y = LX \in \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$. We would like to show that the unit map $X \to Y$ is an equivalence. We first claim that for every connective $\mathbb{E}_\infty$-ring R, the map $X(R) \to Y(R)$ is (-1)-truncated: that is, it exhibits $X(R)$ as a summand of $Y(R)$. To prove this, it will suffice to show that for any pair of points $x, x' \in X(R)$, the induced map $\theta : \{x\} \times_{X(R)} \{x'\} \to \{x\} \times_{Y(R)} \{x'\}$ is a homotopy equivalence. We note that x and x' determine a pair of maps from $\mathrm{Sp\acute{e}t}\, R$ to X. Let X' denote the fiber product $\mathrm{Sp\acute{e}t}\, R \times_{\mathsf{X}} \mathrm{Sp\acute{e}t}\, R$ and let X' be the functor represented by X'. To prove that θ is a homotopy equivalence, it will suffice to show that the canonical map $\beta : X' \to \mathrm{Spec}\, R \times_Y \mathrm{Spec}\, R$ is an equivalence. Since the functor L is left exact, β induces an equivalence $LX' \simeq \mathrm{Spec}\, R \times_Y \mathrm{Spec}\, R$. It will therefore suffice to show that X' is a hypercomplete sheaf with respect to the flat topology. This follows from Proposition 2.4.3.1, since our hypothesis that X is quasi-geometric guarantees that X' is quasi-affine.

Note that X and Y are both sheaves with respect to the étale topology on $\mathrm{CAlg}^{\mathrm{cn}}$. To complete the proof that the unit map $X \to Y$ is an equivalence, it will suffice to show that it is an effective epimorphism with respect to the étale topology. Choose a point $\eta \in Y(A)$ for some connective $\mathbb{E}_\infty$-ring A. For every morphism of connective $\mathbb{E}_\infty$-rings $A \to B$, let η_B denote the image of η in $Y(B)$. We wish to prove that there exists a faithfully flat étale map $A \to B$ such that η_B belongs to the essential image of the map $X(B) \to Y(B)$.

Since $Y = LX$, there exists finite collection of flat maps $A \to B_\alpha$ such that the induced map $A \to \prod_\alpha B_\alpha$ is faithfully flat and each η_{B_α} belongs to the essential image of the map $X(B_\alpha) \to Y(B_\alpha)$. Let $B^0 = \prod_\alpha B_\alpha$, and let $B^\bullet$ be the cosimplicial object of $\mathrm{CAlg}^{\mathrm{cn}}$ given by the Čech nerve of the map $A \to B^0$. For every integer n, the point η_{B^n} belongs to the essential image of the fully faithful embedding $X(B^n) \to Y(B^n)$, and therefore classifies a morphism of spectral Deligne-Mumford stacks $\phi_n : \mathrm{Sp\acute{e}t}\, B^n \to \mathsf{X}$.

Choose an étale surjection $\mathsf{U} \to \mathsf{X}$, where U is affine. For each $n \geqslant 0$, let $\mathsf{V}_n = \mathsf{U} \times_{\mathsf{X}} \mathrm{Sp\acute{e}t}\, B^n$. Since X is quasi-geometric, each V_n is a quasi-affine spectral Deligne-Mumford stack over B^n. Using Proposition 2.4.3.2, we deduce that there exists a quasi-affine spectral Deligne-Mumford stack V and a map $\mathsf{V} \to \mathrm{Sp\acute{e}t}\, A$ such that $\mathsf{V} \times_{\mathrm{Sp\acute{e}t}\, A} \mathrm{Sp\acute{e}t}\, B^\bullet \simeq \mathsf{V}_\bullet$. Since $\mathsf{U} \to \mathsf{X}$ is surjective, the map $\mathsf{V}_0 \to \mathrm{Sp\acute{e}t}\, B^0$ is surjective. Because B^0 is faithfully flat over A, the composite map $\mathsf{V}_0 \to \mathrm{Sp\acute{e}t}\, B^0 \to \mathrm{Sp\acute{e}t}\, A$ is surjective. It follows that $\mathsf{V} \to \mathrm{Sp\acute{e}t}\, A$ is surjective. Using Proposition 2.8.3.3, we deduce that $\mathsf{V} \to \mathrm{Sp\acute{e}t}\, A$ is étale. Choose an étale surjection $\mathrm{Sp\acute{e}t}\, A' \to \mathsf{V}$, so that A' is a faithfully flat étale A-algebra. By construction, the point $\eta_{A'} \in Y(A')$ lifts to $X(A')$. □

Corollary 9.1.4.4. *Let X be a spectral Deligne-Mumford stack and let $h_{\mathsf{X}} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be the functor represented by X. Then X is quasi-geometric (in the sense of Definition 9.1.4.1) if and only if the functor h_{X} is quasi-geometric (in the sense of Definition 9.1.0.1).*

Corollary 9.1.4.5. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Then f is quasi-geometric if and only if the induced map $h_{\mathsf{X}} \to h_{\mathsf{Y}}$ is quasi-geometric.*

Corollary 9.1.4.6. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor which is represented by a quasi-compact, quasi-separated spectral algebraic space. Then X is a quasi-geometric stack.*

Proof. Combine Corollary 9.1.4.4 with Proposition 3.4.1.3. □

9.1.5 Compact Objects of $\mathrm{QCoh}(X)$

Let X be a quasi-geometric stack and let $\mathscr{F} \in \mathrm{QCoh}(X)$ be a quasi-coherent sheaf on X. We now study the relationship between two natural finiteness conditions on $\mathscr{F}$: the condition that $\mathscr{F}$ is perfect (which can be tested locally on X), and the condition that $\mathscr{F}$ is a compact object of $\mathrm{QCoh}(X)$ (which is an *a priori* global condition).

Proposition 9.1.5.1. *Let X be a quasi-geometric stack and let $\mathscr{F} \in \mathrm{QCoh}(X)$. The following conditions are equivalent:*

- (a) *The sheaf $\mathscr{F} \in \mathrm{QCoh}(X)$ is almost perfect.*
- (b) *For every integer n, the functor $\mathscr{G} \mapsto \mathrm{Map}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G})$ commutes with filtered colimits when restricted to $\mathrm{QCoh}(X)_{\leqslant n}$.*

Proof. We first show that $(a) \Rightarrow (b)$. Assume that $\mathscr{F}$ is almost perfect. Replacing $\mathscr{F}$ by a suspension if necessary, we may assume that $\mathscr{F}$ is connective. Fix an integer $n \geqslant 0$ and let $\lambda : \mathrm{QCoh}(X)_{\leqslant n} \to \mathcal{S}_{\leqslant n}$ be the functor given by $\lambda(\mathscr{G}) = \mathrm{Map}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G})$; we wish to show that λ commutes with filtered colimits. Choose a faithfully flat Choose a faithfully flat map $u : X_0 \to X$, where $X_0 \simeq \operatorname{Spec} A$ is affine. Let $X_\bullet$ denote the Čech nerve of u and for each $k \geqslant 0$ let $u_k : X_k \to X$ denote the projection map. Then the construction $\mathscr{G} \mapsto \operatorname{Map}_{\operatorname{QCoh}(X_k)}(u_k^* \mathscr{F}, u_k^* \mathscr{G})$ determines a functor $\lambda^k : \operatorname{QCoh}(X)_{\leqslant n} \to \mathcal{S}_{\leqslant n}$, and we can identify λ with the totalization of the cosimplicial functor $\lambda^\bullet$. Since $\mathcal{S}_{\leqslant n}$ is equivalent to an $(n+1)$-category, the totalization $\lambda \simeq \operatorname{Tot}(\lambda^\bullet)$ can be identified with the partial totalization $\operatorname{Tot}^{n+1}(\lambda^\bullet)$, which is a finite limit of the functors λ^k. It will therefore suffice to show that each λ^k commutes with filtered colimits. We may therefore replace X by X_k and thereby reduce to the case where X_k is quasi-affine. In particular, we may assume that X has affine diagonal. Repeating the above argument, we can reduce to the case where $X \simeq \operatorname{Spec} B$ is affine, so that the equivalence $\operatorname{QCoh}(X) \simeq \operatorname{Mod}_B$ carries $\mathscr{F}$ to an almost perfect B-module M. In this case, the desired result follows immediately from the definitions.

We now show that $(b) \Rightarrow (a)$. Assume that $\mathscr{F}$ satisfies condition (b); we wish to show that $\mathscr{F}$ is almost perfect. This is equivalent to the assertion that $u^* \mathscr{F} \in \operatorname{QCoh}(X_0) \simeq \operatorname{Mod}_A$ is almost perfect: that is, that for every integer n, the functor

$$(\operatorname{Mod}_A)_{\leqslant n} \simeq \operatorname{QCoh}(X_0)_{\leqslant n} \xrightarrow{\operatorname{Map}_{\operatorname{QCoh}(X_0)}(u^* \mathscr{F}, \bullet)} \mathcal{S}$$

commutes with filtered colimits. Unwinding the definnitions, we see that this functor can be rewritten as a composition

$$(\operatorname{Mod}_A)_{\leqslant n} \simeq \operatorname{QCoh}(X_0)_{\leqslant n} \xrightarrow{u_*} \operatorname{QCoh}(X)_{\leqslant n} \xrightarrow{\operatorname{Map}_{\operatorname{QCoh}(X)}(\mathscr{F}, \bullet)} \mathcal{S}.$$

The desired result now follows from (b) and the fact that u_* commutes with filtered colimits (see Corollary 6.3.4.3). □

The analogue of Proposition 9.1.5.1 for perfect objects is more subtle.

Proposition 9.1.5.2. *Let X be a quasi-geometric stack and let $\mathscr{F}$ be a compact object of* $\operatorname{QCoh}(X)$*. Then $\mathscr{F}$ is perfect.*

Proof. Choose a map $f : \operatorname{Spec} R \to X$; we wish to show that $f^* \mathscr{F} \in \operatorname{QCoh}(\operatorname{Spec} R) \simeq \operatorname{Mod}_R$ is perfect. Since X is quasi-geometric, the morphism f is quasi-affine. It follows from Proposition 6.3.4.1 and Corollary 6.3.4.3 that the pullback functor $f^* : \operatorname{QCoh}(X) \to \operatorname{QCoh}(U)$ admits a right adjoint that preserves small colimits. It follows that the functor f^* carries compact objects of $\operatorname{QCoh}(X)$ to compact objects of $\operatorname{QCoh}(\operatorname{Spec} R)$ (Proposition HTT.5.5.7.2), so that $f^* \mathscr{F}$ is perfect as desired. □

The converse of Proposition 9.1.5.2 is false in general.

Proposition 9.1.5.3. *Let X be a quasi-geometric stack. The following conditions are equivalent:*

(1) *The quasi-geometric stack X has finite cohomological dimension. That is, there exists an integer $n \gg 0$ for which the global sections functor $\mathscr{F} \mapsto \Gamma(X; \mathscr{F})$ carries* $\mathrm{QCoh}(X)_{\geqslant 0}$ *into* $\mathrm{Sp}_{\geqslant -n}$.

(2) *The structure sheaf $\mathscr{O}_X \in \mathrm{QCoh}(X)$ is compact.*

(3) *The global sections functor $\Gamma(X; \bullet) : \mathrm{QCoh}(X) \to \mathrm{Sp}$ commutes with small colimits.*

(4) *Every perfect object $\mathscr{F} \in \mathrm{QCoh}(X)$ is compact.*

(5) *An object $\mathscr{F} \in \mathrm{QCoh}(X)$ is compact if and only if it is perfect.*

Remark 9.1.5.4. Let κ be a field and let X be an Artin stack of finite type over κ, in the sense of classical algebraic geometry (see [129]). If the diagonal map $X \to X \times_{\operatorname{Spec} \kappa} X$ is quasi-affine, then we can identify X with a quasi-geometric stack (by Kan extending along the inclusion $\mathrm{CAlg}^{\heartsuit} \hookrightarrow \mathrm{CAlg}^{\mathrm{cn}}$ and then sheafifying with respect to the fpqc topology). In this case, we see a sharp dichotomy:

- If the field κ has characteristic zero, then X always satisfies the equivalent conditions of Proposition 9.1.5.3 (this is proven by Drinfeld and Gaitsgory; see [51]).
- If the field κ has characteristic $p > 0$, then it is very rare for X to satisfy the conditions of Proposition 9.1.5.3 (at least when X exhibits "stacky" behavior) . For example, if X is the classifying stack of the finite group $\mathbf{Z}/p\,\mathbf{Z}$, then $\mathscr{O}_X$ is not a compact object of $\mathrm{QCoh}(X)$. If $X = B\mathbf{G}_a$ is the classifying stack of the additive group, then the ∞-category $\mathrm{QCoh}(X)$ does not contain any nonzero compact objects at all (see [93]).

Proof of Proposition 9.1.5.3. We first show that (1) $\Rightarrow$ (2). Assume that there exists an integer $n \gg 0$ for which the functor $\mathscr{F} \mapsto \Gamma(X; \mathscr{F})$ carries $\mathrm{QCoh}(X)_{\geqslant 0}$ into $\mathrm{Sp}_{\geqslant -n}$. We wish to show that the functor $\mathscr{F} \mapsto \mathrm{Map}_{\mathrm{QCoh}(X)}(\mathscr{O}_X, \mathscr{F})$ commutes with filtered colimits. Equivalently, we wish to show that for every integer $k \geqslant 0$, the construction

$$\mathscr{F} \mapsto \pi_k \mathrm{Map}_{\mathrm{QCoh}(X)}(\mathscr{O}_X, \mathscr{F}) = \pi_k \Gamma(X; \mathscr{F})$$

commutes with filtered colimits. Using the exactness of the sequence

$$\pi_k \Gamma(X; \tau_{\geqslant n+k+1} \mathscr{F}) \to \pi_k \Gamma(X; \mathscr{F}) \to \pi_k \Gamma(X; \tau_{\leqslant n+k} \mathscr{F}) \to \pi_{k-1} \Gamma(X; \tau_{\geqslant n+k+1} \mathscr{F})$$

(where the outer terms vanish by virtue of assumption (1)), we are reduced to showing that the construction

$$\mathscr{F} \mapsto \pi_k \Gamma(X; \tau_{\leqslant n+k} \mathscr{F}) \simeq \pi_k \mathrm{Map}_{\mathrm{QCoh}(X)}(\mathscr{O}_X, \tau_{\leqslant n+k} \mathscr{F})$$

commutes with filtered colimits, which follows from Proposition 9.1.5.1 (since $\mathscr{O}_X \in \mathrm{QCoh}(X)$ is almost perfect).

We now show that (2) ⇒ (3). The global sections functor $\Gamma : \mathrm{QCoh}(X) \to \mathrm{Sp}$ is an exact functor of stable ∞-categories, and therefore commutes with small colimits if and only if it commutes with small filtered colimits: that is, if and only if for each integer n the composite functor

$$\mathrm{QCoh}(X) \xrightarrow{\Gamma} \mathrm{Sp} \xrightarrow{\Omega^{\infty-n}} \mathcal{S}$$

preserves small filtered colimits. Unwinding the definitions, we see that this functor is given by $\mathscr{F} \mapsto \mathrm{Map}_{\mathrm{QCoh}(X)}(\mathscr{O}_X, \Sigma^n \mathscr{F})$, which commutes with filtered colimits if $\mathscr{O}_X$ is compact.

We next show that (3) implies (4). If $\mathscr{F} \in \mathrm{QCoh}(X)$ is perfect, then it is a dualizable object of $\mathrm{QCoh}(X)$ (Proposition 6.2.6.2). It follows that for each $\mathscr{G} \in \mathrm{QCoh}(X)$, we have a canonical homotopy equivalence

$$\mathrm{Map}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G}) \simeq \Omega^{\infty}\Gamma(X; \mathscr{F}^{\vee} \otimes \mathscr{G}).$$

Consequently, if the global sections functor Γ commutes with small colimits, then $\mathscr{F}$ is compact.

The implication (4) ⇒ (5) follows from Proposition 9.1.5.2. We now complete the proof by showing that (5) ⇒ (1). Assume, for a contradiction, that X does not have finite cohomological dimension. It follows that for every integer $n \geqslant 0$, we can choose an n-connective object $\mathscr{F}_n \in \mathrm{QCoh}(X)_{\geqslant n}$ and a map $\eta_n : \mathscr{O}_X \to \mathscr{F}_n$ which is not nullhomotopy. Since the t-structure on $\mathrm{QCoh}(X)$ is left complete (Corollary 9.1.3.2), it follows that the canonical map $\bigoplus_{n \geqslant 0} \mathscr{F}_n \to \prod_{n \geqslant 0} \mathscr{F}_n$ is an equivalence. Consequently, the maps $\{\eta_n\}_{n \geqslant 0}$ determine a map $\eta : \mathscr{O}_X \to \bigoplus_{n \geqslant 0} \mathscr{F}_n$. If (5) is satisfied, then $\mathscr{O}_X$ is compact, so that η factors through some finite sum $\bigoplus_{0 \leqslant n \leqslant N} \mathscr{F}_n$. This guarantees that η_n is nullhomotopic for $n > N$, contrary to our assumption. □

Corollary 9.1.5.5. *Let* X *be a quasi-compact, quasi-separated spectral algebraic space. Then an object* $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ *is compact if and only if it is perfect.*

Proof. Combine Corollary 3.4.2.2 with Proposition 9.1.5.3. □

Proposition 9.1.5.6. *Suppose we are given a morphism* $f : X \to Y$ *in* $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$, *where* X *is a quasi-geometric stack and* $Y \simeq \mathrm{Spec}\, R$ *is affine. Assume that the structure sheaf* $\mathscr{O}_X$ *is a compact object of* $\mathrm{QCoh}(X)$. *Then:*

(a) *The pullback functor* $f^* : \mathrm{QCoh}(Y) \to \mathrm{QCoh}(X)$ *admits a right adjoint* f_*.

(b) *The functor* f_* *commutes with small colimits.*

(c) *For every pair of sheaves* $\mathscr{F} \in \mathrm{QCoh}(Y)$ *and* $\mathscr{G} \in \mathrm{QCoh}(\mathrm{Spec}\, X)$, *the canonical map*

$$\theta_{\mathscr{F},\mathscr{G}} : \mathscr{F} \otimes f_* \mathscr{G} \to f_*(f^* \mathscr{F} \otimes \mathscr{G})$$

is an equivalence in $\mathrm{QCoh}(Y)$.

Proof. Since the ∞-categories $\mathrm{QCoh}(X)$ and $\mathrm{QCoh}(Y)$ are presentable (Corollary 9.1.3.2) and the pullback functor f^* preserves small colimits, assertion (a) follows from the adjoint functor theorem (Corollary HTT.5.5.2.9). To prove (b), we note that the composite functor

$$\mathrm{QCoh}(X) \xrightarrow{f_*} \mathrm{QCoh}(Y) \xrightarrow{\Gamma(Y;\bullet)} \mathrm{Sp}$$

can be identified with the global sections functor $\Gamma(X;\bullet)$, and therefore commutes with filtered colimits by virtue of Proposition 9.1.5.3 (and our assumption that $\mathscr{O}_X$ is compact). Since Y is affine the functor $\Gamma(Y;\bullet)$ is conservative and preserves small colimits, so the functor f_* must preserve small colimits as well. This proves (b). To prove (c), we note that if $\mathscr{G}$ is fixed, then the collection of those objects $\mathscr{F} \in \mathrm{QCoh}(Y)$ for which $\theta_{\mathscr{F},\mathscr{G}}$ is an equivalence is a stable subcategory of $\mathrm{QCoh}(Y)$ which is closed under small colimits (by virtue of (b)). To show that this subcategory coincides with $\mathrm{QCoh}(Y)$, it will suffice (because of our assumption that Y is affine) to show that it contains the structure sheaf $\mathscr{O}_Y$. This is clear, since $\theta_{\mathscr{O}_Y,\mathscr{G}}$ is equivalent to the identity map from $f_*\mathscr{G}$ to itself. □

We now consider a variant of Proposition 9.1.5.6 where Y is not assumed to be affine.

Proposition 9.1.5.7. *Let $f : X \to Y$ be a morphism in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ which satisfies the following condition:*

- $(*)$ *For every connective $\mathbb{E}_\infty$-ring R and every point $\eta \in Y(R)$, the fiber product $X_\eta = \mathrm{Spec}\, R \times_Y X$ is a quasi-geometric stack and the structure sheaf $\mathscr{O}_{X_\eta}$ is a compact object of $\mathrm{QCoh}(X_\eta)$.*

Then:

1. *The pullback functor $f^* : \mathrm{QCoh}(Y) \to \mathrm{QCoh}(X)$ admits a right adjoint $f_* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$.*

2. *The functor f_* commutes with small colimits.*

3. *For every pullback diagram*

$$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow{g} & Y \end{array}$$

in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$, the associated diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(Y) & \xrightarrow{f^*} & \mathrm{QCoh}(X) \\ \downarrow{\scriptstyle g^*} & & \downarrow{\scriptstyle g'^*} \\ \mathrm{QCoh}(Y') & \xrightarrow{f'^*} & \mathrm{QCoh}(X') \end{array}$$

is right adjointable: in other words, the Beck-Chevalley transformation $g^* f_* \to f'_* g'^*$ *is an equivalence of functors from* $\mathrm{QCoh}(X)$ *to* $\mathrm{QCoh}(Y')$.

(4) *For every pair of sheaves* $\mathscr{F} \in \mathrm{QCoh}(Y)$ *and* $\mathscr{G} \in \mathrm{QCoh}(\mathrm{Spec}\, X)$*, the canonical map*

$$\theta_{\mathscr{F},\mathscr{G}} : \mathscr{F} \otimes f_* \mathscr{G} \to f_*(f^* \mathscr{F} \otimes \mathscr{G})$$

is an equivalence in $\mathrm{QCoh}(Y)$.

Proof. We proceed as in the proof of Proposition 6.3.4.1. Write Y as the colimit of a diagram $q : S \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$, where each $Y_s = q(s)$ is affine. Hypothesis $(*)$ guarantees that each of the fiber products $X_s = X \times_Y Y_s$ is a quasi-geometric stack for which $\mathscr{O}_{X_s}$ is a compact object of $\mathrm{QCoh}(X_s)$. Every edge $s \to s'$ in S determines a pullback diagram

$$\begin{array}{ccc} X_s & \longrightarrow & X_{s'} \\ \downarrow & & \downarrow \\ Y_s & \longrightarrow & Y_{s'}. \end{array}$$

Using part (c) of Proposition 9.1.5.6, we deduce that the associated diagram of pullback functors

$$\begin{array}{ccc} \mathrm{QCoh}(Y_{s'}) & \longrightarrow & \mathrm{QCoh}(X_{s'}) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(Y_s) & \longrightarrow & \mathrm{QCoh}(X_s) \end{array}$$

is right adjointable. Using the equivalences $\mathrm{QCoh}(X) \simeq \varprojlim \mathrm{QCoh}(X_s)$ and $\mathrm{QCoh}(Y) \simeq \varprojlim \mathrm{QCoh}(Y_s)$, Corollary HA.4.7.4.18 implies the following:

(i) The functor $f^* : \mathrm{QCoh}(Y) \to \mathrm{QCoh}(X)$ admits a right adjoint.

(ii) For each $s \in S$, the diagram

$$\begin{array}{ccc} \mathrm{QCoh}(Y) & \xrightarrow{f^*} & \mathrm{QCoh}(X) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(Y_s) & \xrightarrow{f_s^*} & \mathrm{QCoh}(X_s) \end{array}$$

is right adjointable.

This proves (1). Moreover, we can assume that every morphism $\mathrm{Spec}\, A \to Y$ appears as a map $Y_s \to Y$ for some $s \in S$, so that (ii) implies that (3) is satisfied whenever Y' is affine. To prove (3) in general, consider a pullback square σ :

$$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow{g} & Y \end{array}$$

and let $\mathscr{F} \in \mathrm{QCoh}(X)$; we wish to show that the Beck-Chevalley map $\theta : g^* f_* \mathscr{F} \to f'_* g'^* \mathscr{F}$ is an equivalence. To prove this, it will suffice to show that for every map $h : \operatorname{Spec} A \to Y'$, the pullback $h^*(\theta)$ is an equivalence in $\mathrm{QCoh}(\operatorname{Spec} A)$. Extending σ to a rectangular diagram

$$\begin{array}{ccccc} X'' & \xrightarrow{h'} & X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f''} & & \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \operatorname{Spec} A & \xrightarrow{h} & Y' & \xrightarrow{g} & Y \end{array}$$

where both squares are pullbacks, we see that $h^*(\theta)$ fits into a commutative diagram

$$\begin{array}{ccc} & h^* f'_* g'^* \mathscr{F} & \\ {\scriptstyle h^*(\theta)} \nearrow & & \searrow {\scriptstyle \theta'} \\ h^* g^* f_* \mathscr{F} & \xrightarrow{\theta''} & f''_* h'^* g'^* \mathscr{F}, \end{array}$$

where θ' and θ'' are equivalences by virtue of the fact that (2) holds in the special case where Y' is affine. This completes the proof of (3).

To prove (2) and (4), we can use (3) to reduce to the special case where Y is affine. In this case, the desired result follows from Proposition 9.1.5.6. □

Proposition 9.1.5.8. *Let $f : X \to Y$ be a morphism of quasi-geometric stacks. If $\mathscr{O}_X$ is a compact object of $\mathrm{QCoh}(X)$, then f satisfies condition $(*)$ of Proposition 9.1.5.7.*

Proof. Let R be a connective $\mathbb{E}_\infty$-ring, let $\eta \in Y(R)$, and let $X_R = X \times_Y \operatorname{Spec} R$. We then have a pullback diagram

$$\begin{array}{ccc} X_R & \xrightarrow{g'} & X \\ \downarrow & & \downarrow \\ \operatorname{Spec} R & \xrightarrow{g} & Y. \end{array}$$

Since Y is quasi-geometric, the map g is quasi-affine. It follows that g' is also quasi-affine, so the pullback functor g'^* admits a right adjoint $g'_* : \mathrm{QCoh}(X_R) \to \mathrm{QCoh}(X)$ which preserves small colimits (Corollary 6.3.4.3). The global sections functor $\Gamma(X_R; \bullet)$ factors as a composition

$$\mathrm{QCoh}(X_R) \xrightarrow{g'_*} \mathrm{QCoh}(X) \xrightarrow{\Gamma(X;\bullet)} \mathrm{Sp},$$

and therefore also preserves small colimits. Applying Proposition 9.1.5.3, we deduce that $\mathscr{O}_{X_R}$ is a compact object of $\mathrm{QCoh}(X_R)$. □

9.1.6 Truncations of Quasi-Geometric Stacks

Let R be a commutative ring and let G be a quasi-affine group scheme over R. By our definition, the classifying stack BG of Example 9.1.1.7 is a functor from the ∞-category $\mathrm{CAlg}^{\mathrm{cn}}$ of connective $\mathbb{E}_\infty$-rings to the ∞-category $\widehat{\mathcal{S}}$ of spaces. However, the classifying stack BG is really a *classical* algebro-geometric object. Our goal in this section is to make this idea more precise, and to show that no information is lost by restricting the domain of BG to the full subcategory $\mathrm{CAlg}^{\heartsuit} \subseteq \mathrm{CAlg}^{\mathrm{cn}}$ spanned by the ordinary commutative rings (which is described in Remark 9.1.1.8).

Proposition 9.1.6.1. *Let X be a quasi-geometric stack and let $n \geqslant 0$ be an integer. The following conditions are equivalent:*

(a) *For every flat morphism $f : \operatorname{Spec} A \to X$, the $\mathbb{E}_\infty$-ring A is n-truncated.*

(b) *There exists a faithfully flat morphism $\operatorname{Spec} A \to X$, where the $\mathbb{E}_\infty$-ring A is n-truncated.*

Proof. The implication $(a) \Rightarrow (b)$ is immediate. Conversely, suppose that (b) is satisfied, so that there exists a faithfully flat map $f : \operatorname{Spec} A \to X$ where A is n-truncated. Let $g : \operatorname{Spec} B \to X$ be any flat map, and form a pullback diagram

$$\begin{array}{ccc} Y & \xrightarrow{f'} & \operatorname{Spec} B \\ \downarrow{\scriptstyle g'} & & \downarrow{\scriptstyle g} \\ \operatorname{Spec} A & \xrightarrow{f} & X. \end{array}$$

Since X is a quasi-geometric stack, the functor Y is (representable by) a quasi-affine spectral Deligne-Mumford stack. Since g is flat, the morphism g' is flat and therefore Y is n-truncated (by virtue of our assumption that A is n-truncated). Since f' is faithfully flat, it follows that $\operatorname{Spec} B$ is n-truncated: that is, the $\mathbb{E}_\infty$-ring B is n-truncated. This shows that $(b) \Rightarrow (a)$. $\square$

Definition 9.1.6.2. Let X be a quasi-geometric stack and let n be a nonnegative integer. We will say that X is *n-truncated* if it satisfies the equivalent conditions of Proposition 9.1.6.1.

Example 9.1.6.3. Let R be a commutative ring, let G be a flat quasi-affine group scheme over R, and let BG denote the classifying stack of G (Example 9.1.1.7). Then BG is a 0-truncated quasi-geometric stack.

Example 9.1.6.4. Let X be a quasi-geometric Deligne-Mumford stack and let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be the functor represented by X. Then X is n-truncated (in the sense of Definition 1.4.6.1) if and only if X is n-truncated (in the sense of Definition **??**).

Definition 9.1.6.5. Let $f : X \to Y$ be a morphism of quasi-geometric stacks and let $n \geqslant 0$ be an integer. We will say that the morphism f *exhibits X as an n-truncation of Y* if the following conditions are satisfied:

(a) The quasi-geometric stack X is n-truncated.

(b) For every n-truncated quasi-geometric stack X', composition with f induces a homotopy equivalence $\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}},\widehat{\mathcal{S}})}(X', X) \to \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}},\widehat{\mathcal{S}})}(X', Y)$.

Let Y be a quasi-geometric stack. It follows immediately from Definition 9.1.6.5 that if there exists a morphism $f : X \to Y$ which exhibits X as the n-truncation of Y, then the quasi-geometric stack X (and the morphism f) are uniquely determined up to equivalence. For existence, we have the following result:

Proposition 9.1.6.6. *Let $f : X \to Y$ be a morphism of quasi-geometric stacks. Suppose that f is affine and the unit map $\mathscr{O}_Y \to f_* \mathscr{O}_X$ exhibits $f_* \mathscr{O}_X$ as an n-truncation of $\mathscr{O}_Y$ in the ∞-category* $\mathrm{QCoh}(Y)$*. Then f exhibits X as an n-truncation of Y, in the sense of Definition 9.1.6.5.*

Proof. Choose a faithfully flat map $g : Y_0 \to Y$, where $Y_0 \simeq \operatorname{Spec} A$ is affine. Form a pullback diagram of quasi-geometric stacks

$$\begin{array}{ccc} X_0 & \xrightarrow{f_0} & Y_0 \\ \downarrow{\scriptstyle g'} & & \downarrow{\scriptstyle g} \\ X & \xrightarrow{f} & Y. \end{array}$$

Since f is affine, the map f_0 is affine, so that $X_0 \simeq \operatorname{Spec} B$ is affine. Since f exhibits $f_* \mathscr{O}_X$ as an n-truncation of $\mathscr{O}_Y$ and the map g is flat, it follows that f_0 exhibits $f_{0*} \mathscr{O}_{X_0}$ as an n-truncation of $\mathscr{O}_{Y_0}$ in $\mathrm{QCoh}(Y_0)$: in other words, we can identify B with the truncation $\tau_{\leqslant n} A$. The map g' is a pullback of g and therefore faithfully flat. Since B is n-truncated, it follows that the quasi-geometric stack X is n-truncated (Proposition 9.1.6.1).

Let X' be an n-truncated quasi-geometric stack; we wish to show that composition with f induces a homotopy equivalence $\theta : \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}},\mathcal{S})}(X', X) \to \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}},\mathcal{S})}(X', Y)$. Since the morphism f is affine, we can identify the homotopy fiber of θ over a point $h \in \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}},\mathcal{S})}(X', Y)$ with the mapping space $\mathrm{Map}_{\mathrm{CAlg}(\mathrm{QCoh}(X')}(h^* f_* \mathscr{O}_X, \mathscr{O}_{X'})$. Note that the unit map $u : \mathscr{O}_{X'} \simeq h^* \mathscr{O}_Y \to h^* f_* \mathscr{O}_X$ induces an equivalence of n-truncations. Since $\mathscr{O}_{X'}$ is n-truncated, it follows that composition with u induces a homotopy equivalence

$$\mathrm{Map}_{\mathrm{CAlg}(\mathrm{QCoh}(X'))}(h^* f_* \mathscr{O}_X, \mathscr{O}_{X'}) \simeq \mathrm{Map}_{\mathrm{CAlg}(\mathrm{QCoh}(X'))}(\mathscr{O}_{X'}, \mathscr{O}_{X'}),$$

so that the mapping space $\mathrm{Map}_{\mathrm{CAlg}(\mathrm{QCoh}(X'))}(h^* f_* \mathscr{O}_X, \mathscr{O}_{X'})$ is contractible as desired. $\square$

Corollary 9.1.6.7. *Let Y be a quasi-geometric stack and let $n \geqslant 0$ be an integer. Then there exists a morphism $f : X \to Y$ of quasi-geometric stacks which exhibits X as an n-truncation of Y. Moreover, f is affine.*

Proof. Combine Propositions 9.1.6.6 and 6.3.4.5. □

Corollary 9.1.6.8. *Let $\mathcal{C} \subseteq \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ denote the full subcategory spanned by the quasi-geometric stacks, let $n \geqslant 0$ be an integer, and let $\mathcal{C}_n \subseteq \mathcal{C}$ denote the full subcategory spanned by the n-truncated quasi-geometric stacks. Then the inclusion $\mathcal{C}_n \hookrightarrow \mathcal{C}$ admits a right adjoint (which assigns to each quasi-geometric stack its n-truncation).*

We now observe that an n-truncated quasi-geometric stack X is determined by its values on n-truncated connective $\mathbb{E}_\infty$-rings.

Proposition 9.1.6.9. *Let X be a quasi-geometric stack which is n-truncated for some $n \geqslant 0$, and let $X' : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a left Kan extension of $X|_{\tau_{\leqslant n} \mathrm{CAlg}^{\mathrm{cn}}}$. Then the canonical map $X' \to X$ exhibits X as a sheafification of X' with respect to the fpqc topology.*

Proof. Choose a faithfully flat map $f : X_0 \to X$, where X_0 is affine. Let $X_\bullet$ denote the Čech nerve of f. For each $k \geqslant 0$, let X'_k denote a left Kan extension of $X|_{\tau_{\leqslant n} \mathrm{CAlg}^{\mathrm{cn}}}$. We then have a commutative diagram

$$\begin{array}{ccc} |X'_\bullet| & \longrightarrow & |X_\bullet| \\ \downarrow & & \downarrow \\ X' & \longrightarrow & X, \end{array}$$

where the geometric realizations are formed in the ∞-category $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$. We wish to show that the lower horizontal map induces an equivalence after sheafification with respect to the fpqc topology. Since the vertical maps induce equivalences after sheafification for the fpqc topology, it will suffice to prove that the upper horizontal map induces an equivalence after fpqc sheafification. In other words, it will suffice to show that the conclusion of Proposition 9.1.6.9 after replacing X by X_k, for each $k \geqslant 0$. We may therefore assume without loss of generality that X is (representable by) a quasi-affine spectral algebraic space. In this case, the diagonal of X is affine. Repeating the above argument, we can reduce to the case where $X \simeq \operatorname{Spec} R$ for some connective $\mathbb{E}_\infty$-ring R. In this case, our assumption that X is n-truncated guarantees that R is n-truncated, so that the map $X' \to X$ is an equivalence. □

Corollary 9.1.6.10. *Let $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be functors, let $n \geqslant 0$ be an integer, and let $X_0, Y_0 : \tau_{\leqslant n} \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ denote the restrictions of X and Y. If X is an n-truncated* *quasi-geometric stack and Y is a sheaf with respect to the fpqc topology, then the restriction map*

$$\phi : \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(X, Y) \to \mathrm{Map}_{\mathrm{Fun}(\tau_{\leqslant n} \mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(X_0, Y_0).$$

Proof. Let X' be as in Proposition 9.1.6.9. We then have a commutative diagram

$$\begin{array}{ccccc} & & \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(X, Y) & & \\ & \nearrow^{\psi} & & \searrow^{\phi} & \\ \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(X', Y) & & \xrightarrow{\phi \circ \psi} & & \mathrm{Map}_{\mathrm{Fun}(\tau_{\leqslant n} \mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(X_0, Y_0). \end{array}$$

The map ψ is a homotopy equivalence by virtue of our assumption that Y is a sheaf for the fpqc topology, and the composite map $\phi \circ \psi$ is a homotopy equivalence because X' is defined as a left Kan extension of X_0. It follows that the map ϕ is a homotopy equivalence as well. □

Corollary 9.1.6.11. *Let $n \geqslant 0$ and let $\mathcal{C}_n \subseteq \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ denote the full subcategory spanned by the n-truncated quasi-geometric stacks. Then the restriction functor $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}}) \to \mathrm{Fun}(\tau_{\leqslant n} \mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ is fully faithful when restricted to $\mathcal{C}_n$.*

9.2 Tannaka Duality for Quasi-Geometric Stacks

Our goal in this section is to address the following general question:

Question 9.2.0.1. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor. To what extent can X be recovered from the ∞-category $\mathrm{QCoh}(Y)$ of quasi-coherent sheaves on Y?

Our main result addresses Question 9.2.0.1 in the special case where X is a quasi-geometric stack (see Definition 9.1.0.1):

Theorem 9.2.0.2 (Tannaka Duality for Quasi-Geometric Stacks)**.** *Let $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be functors. Assume that X is a quasi-geometric stack and that Y is (representable by) a quasi-compact, quasi-separated spectral algebraic space. Let $\mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y))$ denote the ∞-category of symmetric monoidal functors from $\mathrm{QCoh}(X)$ to $\mathrm{QCoh}(Y)$. Then the construction $(f : Y \to X) \mapsto (f^* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y))$ determines a fully faithful embedding*

$$\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(Y, X) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y))$$

whose essential image is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ which satisfy the following additional conditions:

- (a) *The functor F admits a right adjoint G (equivalently, the functor F preserves small colimits: see Corollary HTT.5.5.2.9).*

(b) *The functor F carries connective objects of* $\mathrm{QCoh}(X)$ *to connective objects of* $\mathrm{QCoh}(Y)$ *(equivalently, the functor* $G : \mathrm{QCoh}(Y) \to \mathrm{QCoh}(X)$ *is left t-exact).*

(c) *The functor G preserves small colimits.*

(d) *For every pair of objects* $\mathscr{F} \in \mathrm{QCoh}(X)$ *and* $\mathscr{G} \in \mathrm{QCoh}(Y)$*, the canonical map*

$$\mathscr{F} \otimes G(\mathscr{G}) \to G(F(\mathscr{F}) \otimes \mathscr{G})$$

is an equivalence in $\mathrm{QCoh}(X)$ *(in other words, the adjoint functors* $\mathrm{QCoh}(X) \underset{G}{\overset{F}{\rightleftarrows}} \mathrm{QCoh}(Y)$ *satisfy a projection formula).*

9.2.1 Digression on Quasi-Affine Morphisms

Let $\widehat{\mathcal{C}\mathrm{at}}_\infty$ denote the ∞-category of (not necessarily small) ∞-categories. We let $\widehat{\mathcal{C}\mathrm{at}}_\infty^L$ denote the subcategory of $\widehat{\mathcal{C}\mathrm{at}}_\infty$ whose objects are ∞-categories which admit small colimits and whose morphisms are functors which preserve small colimits. We will regard $\widehat{\mathcal{C}\mathrm{at}}_\infty^L$ as equipped with the symmetric monoidal described in §HA.4.8.1 : given a pair of objects $\mathcal{C}$ and $\mathcal{D}$ in $\widehat{\mathcal{C}\mathrm{at}}_\infty^L$, the tensor product $\mathcal{C} \otimes \mathcal{D}$ is universal among objects $\mathcal{E} \in \widehat{\mathcal{C}\mathrm{at}}_\infty^L$ for which there exists a functor $\mathcal{C} \times \mathcal{D} \to \mathcal{E}$ which preserves small colimits separately in each variable. Note that we can identify commutative algebra objects of $\widehat{\mathcal{C}\mathrm{at}}_\infty^L$ with symmetric monoidal ∞-categories $\mathcal{C}$ for which $\mathcal{C}$ admits small colimits and the tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves small colimits separately in each variable.

For every functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, let QAff_X be the full subcategory of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})_{/X}$ spanned by the quasi-affine morphisms $Y \to X$. Our proof of Theorem 9.2.0.2 will make use of the following:

Proposition 9.2.1.1. *Let* $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ *be a functor. Then the construction* $(f : Y \to X) \mapsto \mathrm{QCoh}(Y)$ *determines a fully faithful embedding* $\mathrm{QAff}_X \to \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty^L)_{\mathrm{QCoh}(X)/}$.

Lemma 9.2.1.2. *Suppose we are given morphisms* $f : Y \to X$, $g : Z \to X$ *in* $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$. *Assume that f is quasi-affine, and let* $\mathscr{A} = f_* \mathscr{O}_Y \in \mathrm{CAlg}(\mathrm{QCoh}(X))$. *Then the canonical map*

$$\theta : \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})_{/X}}(Z, Y) \to \mathrm{Map}_{\mathrm{CAlg}(\mathrm{QCoh}(Z))}(g^* \mathscr{A}, \mathscr{O}_Z)$$

is a homotopy equivalence.

Proof. When regarded as functors of Z, both the domain and codomain of θ carry colimits of functors to limits of spaces. Writing Z as a colimit of corepresentable functors, we may reduce to the case where Z is corepresentable by a connective $\mathbb{E}_\infty$-ring R. Replacing X by Z and Y by the fiber product $Y \times_X Z$, we may reduce to the case where Y is representable by a quasi-affine spectral Deligne-Mumford stack Y equipped with a map $\mathsf{Y} \to \mathrm{Sp\acute{e}t}\, R$. In this case, the desired result is a consequence of Proposition ??. □

Proof of Proposition 9.2.1.1. For every quasi-affine morphism $f : Y \to X$, let $\mathscr{A}_Y = f_* \mathscr{O}_X \in \mathrm{CAlg}(\mathrm{QCoh}(X))$. Proposition 6.3.4.6 supplies an equivalence of ∞-categories $\mathrm{QCoh}(Y) \simeq \mathrm{Mod}_{\mathscr{A}_Y}(\mathrm{QCoh}(X))$. If we are given another quasi-affine morphism $g : Z \to X$, then Corollary HA.4.8.5.21 supplies a homotopy equivalence

$$\begin{aligned} \mathrm{Map}_{\mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}^L_\infty)_{\mathrm{QCoh}(X)/}}(\mathrm{QCoh}(Y), \mathrm{QCoh}(Z)) &\simeq \mathrm{Map}_{\mathrm{CAlg}(\mathrm{QCoh}(X))}(\mathscr{A}_Y, \mathscr{A}_Z) \\ &\simeq \mathrm{Map}_{\mathrm{CAlg}(\mathrm{QCoh}(Z))}(g^* \mathscr{A}_Y, \mathscr{O}_Z). \end{aligned}$$

The desired result now follows from Lemma 9.2.1.2. □

Remark 9.2.1.3. Suppose we are given quasi-affine morphisms $f : Y \to X$ and $g : Z \to X$ in the ∞-category $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$. Proposition 9.2.1.1 implies that if $F : \mathrm{QCoh}(Z) \to \mathrm{QCoh}(Y)$ is a $\mathrm{QCoh}(X)$-linear symmetric monoidal functor which preserves small colimits, then F is given by pullback along some map $h : Y \to Z$ such that $h \circ f \simeq g$. Moreover, if we are given two such maps $h, h' : Y \to Z$, then any $\mathrm{QCoh}(X)$-linear symmetric monoidal equivalence α between h^* and h'^* can be lifted to a homotopy between h and h'. In fact, the assumption that α is an equivalence is superfluous: any $\mathrm{QCoh}(X)$-linear symmetric monoidal functor from h^* to h'^* is automatically an equivalence (Remark HA.4.8.5.9).

9.2.2 Weak Tannaka Duality

We are now ready to prove a preliminary version of Theorem 9.2.0.2.

Proposition 9.2.2.1. *Let $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be functors, and suppose that the diagonal map $\delta : X \to X \times X$ is quasi-affine. Then the canonical map*

$$\theta : \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(Y, X) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y))$$

is fully faithful. Here $\mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y))$ denotes the ∞-category of symmetric monoidal functors from $\mathrm{QCoh}(X)$ to $\mathrm{QCoh}(Y)$. In particular, for any pair of maps $f, f' : Y \to X$, then any $\mathrm{QCoh}(X)$-linear symmetric monoidal natural transformation $\alpha : f^* \to f'^*$ is an equivalence.

Before giving the proof of Proposition 9.2.2.1, let us explain its relationship to the classical theory of Tannaka duality.

Let κ be a field, let G be an affine group scheme over κ, and let BG denote the classifying stack of G (Example 9.1.1.7). In the situation of Notation **??**, the classifying stack BG is equipped with a canonical base point $\epsilon : \mathrm{Spec}\, \kappa \to BG$. For every commutative κ-algebra A, let ϵ_A denote the composite map $\mathrm{Spec}\, A \to \mathrm{Spec}\, R \xrightarrow{\epsilon} BG$. Since the classifying space BG has quasi-affine diagonal, Proposition 9.2.2.1 guarantees that the natural map

$$\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(\mathrm{Spec}\, A, BG) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(BG), \mathrm{Mod}_A)$$

is fully faithful. In particular, we obtain a homotopy equivalence

$$\{\epsilon_A\} \times_{\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(\operatorname{Spec} A, BG)} \{\epsilon_A\} \to \mathrm{Map}_{\mathrm{Fun}^{\otimes}(\mathrm{QCoh}(BG), \mathrm{Mod}_A)}(\epsilon_A^*, \epsilon_A^*).$$

Unwinding the definitions, we see that the domain of this homotopy equivalence can be identified with the set $G(A)$ of A-valued points of G. We therefore obtain the following:

Corollary 9.2.2.2 (Classical Tannaka Duality, Derived Version)**.** *Let G be an affine group scheme over a field κ and let A be a commutative κ-algebra. Then the canonical map $G(A) \to \mathrm{Map}_{\mathrm{Fun}^{\otimes}(\mathrm{QCoh}(BG), \mathrm{Mod}_A)}(\epsilon_A^*, \epsilon_A^*)$ is a homotopy equivalence. More informally, we can identify $G(A)$ with the group of symmetric monoidal automorphisms of the functor $\epsilon_A^* : \mathrm{QCoh}(BG) \to \mathrm{Mod}_A$ (moreover, every symmetric monoidal endomorphism of ϵ_A^* is also an isomorphism).*

Remark 9.2.2.3. Corollary 9.2.2.2 is very similar Theorem 9.0.0.1. Unwinding the definitions, we can identify the category $\mathrm{Rep}(G)$ of finite-dimensional representations of G with the full subcategory of $\mathrm{QCoh}(BG)$ spanned by those quasi-coherent sheaves which are locally free of finite rank. For any commutative κ-algebra A, the functor ϵ_A^* restricts to a functor $e : \mathrm{Rep}(G) \to \mathrm{Mod}_A^{\mathrm{lf}}$, where $\mathrm{Mod}_A^{\mathrm{lf}}$ denotes the category of projective A-modules of finite rank. Let $\mathrm{Aut}^{\otimes}(\epsilon_A^*)$ denote the space of equivalences from ϵ_A^* with itself as a symmetric monoidal functor of ∞-categories, and let $\mathrm{Aut}^{\otimes}(e)$ denote the set of isomorphisms of e with itself as a symmetric monoidal functor of ordinary categories. We then have a commutative diagram

$$\begin{array}{ccccc} & & \mathrm{Aut}^{\otimes}(\epsilon_A^*) & & \\ & \nearrow & & \searrow & \\ G(A) & & \longrightarrow & & \mathrm{Aut}^{\otimes}(e). \end{array}$$

The classical version of Tannaka duality asserts that the bottom horizontal map is an isomorphism (Theorem 9.0.0.1), while our derived version of Tannaka duality asserts that the diagonal map on the left is a homotopy equivalence. To see that these assertions are equivalent, it would suffice to show that the diagonal map on the right is also a homotopy equivalence: that is, that the datum of a symmetric monoidal automorphism of $\epsilon_A^* : \mathrm{QCoh}(BG) \to \mathrm{Mod}_A$ is equivalent to the datum of a symmetric monoidal automorphism of $\epsilon_A^*|_{\mathrm{Rep}(G)}$. We will discuss this comparison in §9.7; see Corollary 9.3.7.5.

Remark 9.2.2.4. It follows from Proposition 9.2.2.1 that many of the hypotheses of Corollary 9.2.2.2 are superfluous:

(*a*) We do not need to assume that the map $\epsilon_A : \operatorname{Spec} A \to BG$ factors through the base point $\epsilon : \operatorname{Spec} \kappa \to BG$. The proof of Corollary 9.2.2.2 shows more generally that for any pair of maps $u, v : \operatorname{Spec} A \to BG$, we obtain a homotopy equivalence

$$\{u\} \times_{BG(A)} \{v\} \simeq \mathrm{Map}_{\mathrm{Fun}^{\otimes}(\mathrm{QCoh}(BG), \mathrm{Mod}_A)}(u^*, v^*).$$

Here u and v classify G-torsors $\mathcal{P}_u$ and $\mathcal{P}_v$ over $\operatorname{Spec} A$, and we can identify the fiber product $\{u\} \times_{BG(A)} \{v\}$ with the space of isomorphisms between $\mathcal{P}_u$ and $\mathcal{P}_v$.

(*b*) We do not need to assume that A is a commutative ring: Corollary 9.2.2.2 is valid more generally if A is a connective $\mathbb{E}_\infty$-algebra over κ.

(*c*) We do not need to assume that κ is a field: Corollary 9.2.2.2 remains valid if κ is an arbitrary connective $\mathbb{E}_\infty$-ring, provided that G is flat over κ.

(*d*) We do not need to assume that G is affine: Corollary 9.2.2.2 is valid more generally if G is quasi-affine.

Note however that for the additional generality described in (*b*), (*c*), and (*d*), it is necessary to work in the derived setting (rather than at the level of abelian categories, as in the statement of Theorem 9.0.0.1).

Remark 9.2.2.5. We will be primarily interested in the special case of Proposition 9.2.2.1 where X is a quasi-geometric stack (in which case we can describe the essential image of the embedding $\operatorname{Map}_{\operatorname{Fun}(\operatorname{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(Y, X) \hookrightarrow \operatorname{Fun}^{\otimes}(\operatorname{QCoh}(X), \operatorname{QCoh}(Y))$ using Theorem 9.2.0.2). However, there are algebro-geometric objects X of interest which are not quasi-geometric but nonetheless satisfy the hypotheses of Proposition 9.2.2.1: for example, quasi-separated spectral algebraic spaces which are not quasi-compact (see Warning **??**).

Proof of Proposition 9.2.2.1. Fix a functor $X : \operatorname{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ for which the diagonal $\delta : X \to X \times X$ is quasi-affine. The constructions

$$Y \mapsto \operatorname{Map}_{\operatorname{Fun}(\operatorname{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(Y, X) \qquad Y \mapsto \operatorname{Fun}^{\otimes}(\operatorname{QCoh}(X), \operatorname{QCoh}(Y))$$

both carry colimits in $\operatorname{Fun}(\operatorname{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ to limits of ∞-categories. Writing Y as a colimit of corepresentable functors, we may reduce to the case where $Y = \operatorname{Spec} R$ for some connective $\mathbb{E}_\infty$-ring R. Since δ is quasi-affine, any morphism $Y \to X$ is automatically quasi-affine (Proposition 9.1.1.1). Choose a pair of maps $f, g : Y \to X$, which we will identify with objects $Y_f, Y_g \in \operatorname{Fun}(\operatorname{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})_{/X}$. Remark 9.2.1.3 implies that every symmetric monoidal transformation from f^* to g^* is an equivalence. We have a commutative diagram

$$\begin{array}{ccc} \operatorname{Map}_{\operatorname{Fun}(\operatorname{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})_{/X}}(Y_f, Y_g) & \longrightarrow & \operatorname{Map}_{\operatorname{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty^L)_{\operatorname{QCoh}(X)/}}(\operatorname{QCoh}(Y), \operatorname{QCoh}(Y)) \\ \downarrow & & \downarrow \\ \operatorname{Map}_{\operatorname{Fun}(\operatorname{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(Y, Y) & \longrightarrow & \operatorname{Map}_{\operatorname{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty^L)_{\mathrm{Sp}/}}(\operatorname{QCoh}(Y), \operatorname{QCoh}(Y)). \end{array}$$

We wish to show that this diagram induces a homotopy equivalence between the homotopy fibers of the vertical maps (taken over the points id_Y and $\mathrm{id}_{\operatorname{QCoh}(Y)}$). To prove this, it suffices to show that the horizontal maps are equivalences. This follows from Proposition 9.2.1.1, since the maps $f, g : Y \to X$ and the projection $Y \to *$ are all quasi-affine (here $*$ denotes the final object of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$). □

9.2.3 The Proof of Theorem 9.2.0.2

We now turn to the proof of Theorem 9.2.0.2. Suppose that we are given functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, where X is a quasi-geometric stack and Y is (representable by) a quasi-compact, quasi-separated spectral algebraic space. Suppose we are given a morphism $f : Y \to X$. Note that any morphism $\mathrm{Spec}\, R \to X$ is quasi-affine (Proposition 9.1.1.1), so the fiber product $\mathrm{Spec}\, R \times_X Y$ is quasi-affine over Y and is therefore also (representable by) a quasi-compact, quasi-separated spectral algebraic space. It follows that the pullback functor f^* admits a right adjoint $f_* : \mathrm{QCoh}(Y) \to \mathrm{QCoh}(X)$ (Proposition 6.3.4.1) which preserves small colimits and satisfies the projection formula (Corollary 6.3.4.3); moreover, the functor f_* will be left t-exact (since f^* preserves connective objects). Using Proposition 9.2.2.1, we deduce that the canonical map

$$\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(Y, X) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y))$$

is a fully faithful embedding whose image consists of functors $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ which satisfy the hypotheses of Theorem 9.2.0.2. To complete the proof, we must verify the converse:

Proposition 9.2.3.1. *Let X be a quasi-geometric stack, let Y be a quasi-compact, quasi-separated spectral algebraic space, and let $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ be a symmetric monoidal functor satisfying the following conditions:*

(a) *The functor F admits a right adjoint G.*

(b) *The functor F is right t-exact (so that G is left t-exact).*

(c) *The functor G preserves small colimits.*

(d) *For every pair of objects $\mathscr{F} \in \mathrm{QCoh}(X)$ and $\mathscr{G} \in \mathrm{QCoh}(Y)$, the canonical map*

$$\mathscr{F} \otimes G(\mathscr{G}) \to G(F(\mathscr{F}) \otimes \mathscr{G})$$

is an equivalence in $\mathrm{QCoh}(X)$.

Then there exists a map $f : Y \to X$ and a symmetric monoidal equivalence $F \simeq f^*$.

Proof. For every morphism $g : Y' \to Y$ of quasi-compact, quasi-separated spectral algebraic spaces, let F_g denote the composite functor $\mathrm{QCoh}(X) \xrightarrow{F} \mathrm{QCoh}(Y) \xrightarrow{g^*} \mathrm{QCoh}(Y')$. Note that if F satisfies conditions (a) through (d), then so does F_g (the functor F_g admits a right adjoint given by the composition $G \circ g_*$, which will preserve small colimits and satisfy the projection formula by virtue of Corollary 3.4.2.2 and Remark 3.4.2.6). In this case, let $\chi(Y')$ denote the homotopy fiber of the map $\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(Y', X) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y'))$ over the point F_g. It follows from Proposition 9.2.2.1 that the space $\chi(Y')$ is either empty or contractible. We wish to show that $\chi(Y)$ is nonempty. Since X is a sheaf with respect to the fpqc topology, the construction $Y' \mapsto \chi(Y')$ satisfies fpqc descent. Consequently, it will suffice to show that there exists a faithfully flat morphism $g : Y' \to Y$ such that $\chi(Y')$ is nonempty. In particular, we may assume without loss of generality that $Y = \mathrm{Spec}\, R$ is affine.

Since X is quasi-geometric, we can choose a faithfully flat morphism $u : U \to X$, where U is affine. Set $\mathscr{A} = u_* \mathscr{O}_U \in \mathrm{CAlg}(\mathrm{QCoh}(X))$. The key point is to prove the following:

$(*)$ There exists a faithfully flat, quasi-affine morphism $v : Y' \to Y$ and an equivalence $F(\mathscr{A}) \simeq v_* \mathscr{O}_{Y'}$ in $\mathrm{CAlg}(\mathrm{QCoh}(Y))$.

Assume for the moment that $(*)$ is satisfied. Then Proposition 6.3.4.6 supplies (symmetric monoidal) equivalences

$$\mathrm{QCoh}(U) \simeq \mathrm{Mod}_{\mathcal{A}}(\mathrm{QCoh}(X))$$

$$\mathrm{QCoh}(Y') \simeq \mathrm{Mod}_{v_* \mathscr{O}_{Y'}}(\mathrm{QCoh}(Y)) \simeq \mathrm{Mod}_{F(\mathscr{A})}(\mathrm{QCoh}(Y)).$$

Consequently, F induces a symmetric monoidal functor $F' : \mathrm{QCoh}(U) \to \mathrm{QCoh}(Y')$ which fits into a commutative diagram

$$\begin{array}{ccc} \mathrm{QCoh}(X) & \xrightarrow{F} & \mathrm{QCoh}(Y) \\ \downarrow{u^*} & & \downarrow{v^*} \\ \mathrm{QCoh}(U) & \xrightarrow{F'} & \mathrm{QCoh}(Y'). \end{array}$$

Since U is affine and Y' is quasi-affine, Proposition 9.2.1.1 implies the existence of a symmetric monoidal equivalence $F' \simeq f'^*$ for some map $f' : Y' \to U$. It follows that there is a symmetric monoidal equivalence $F_v \simeq (u \circ f')^*$, so that $\chi(Y') \neq \emptyset$ and therefore $\chi(Y) \neq \emptyset$ (since Y' is faithfully flat over Y).

We now prove $(*)$. Write $Y = \mathrm{Spec}\, R$ for some connective $\mathbb{E}_\infty$-ring R, so that we can identify $F(\mathscr{A})$ with an $\mathbb{E}_\infty$-algebra $A \in \mathrm{CAlg}_R$. Set $B = F(\tau_{\geq 0} \mathscr{A}) \in \mathrm{CAlg}_R$, so that assumption (b) guarantees that B is connective. We first claim that there is an equivalence $F(\mathscr{A}) \simeq v_* \mathscr{O}_{Y'}$ for some quasi-affine morphism $v : Y' \to Y$. By virtue of Theorem 2.6.0.2, it will suffice to verify the following:

(i) There exists an integer $n \gg 0$ such that A is $(-n)$-connective.

(ii) The $\mathbb{E}_\infty$-ring A is a compact idempotent object of CAlg_B.

Note first that $U \times_X U$ is quasi-affine, so that the spectrum

$$\Gamma(U \times_X U; \mathscr{O}_{U \times_X U}) \simeq \Gamma(U; u^* u_* \mathscr{O}_U)$$

is $(-n)$-connective for $n \gg 0$. Since U is affine, it follows that $u^* u_* \mathscr{O}_U$ is $(-n)$-connective as an object of $\mathrm{QCoh}(U)$. Since the map u is faithfully flat, it follows from Proposition 9.1.3.5 that $\mathscr{A} = u_* \mathscr{O}_U$ is a $(-n)$-connective object of $\mathrm{QCoh}(X)$ for $n \gg 0$, so that assertion (i) follows from our assumption (b).

We now prove (ii). Note that the projection map $q : U \times_X U \to U$ (onto either factor) is quasi-affine, so that $u^* \mathscr{A} \simeq q_* \mathscr{O}_{U \times_X U}$ satisfies the equivalent conditions of Theorem 2.6.0.2. In particular, $u^* \mathscr{A}$ is an idempotent algebra over its connective cover $\tau_{\geqslant 0} u^* \mathscr{A}$. That is, the multiplication map

$$u^* \mathscr{A} \otimes_{\tau_{\geqslant 0} u^* \mathscr{A}} u^* \mathscr{A} \to u^* \mathscr{A}$$

is an equivalence. Since u is faithfully flat, it follows that the multiplication map $\mathscr{A} \otimes_{\tau_{\geqslant 0} \mathscr{A}} \mathscr{A} \to \mathscr{A}$ is an equivalence in $\mathrm{QCoh}(X)$. Applying the functor F, we deduce that the multiplication $A \otimes_B A \to A$ is an equivalence, so that A is an idempotent object of CAlg_B.

We now complete the proof of (2) by showing that A is a compact object of CAlg_B. Suppose we are given a filtered diagram $\{B_\alpha\}$ in CAlg_B; we wish to show that the canonical map

$$\varinjlim \mathrm{Map}_{\mathrm{CAlg}_B}(A, B_\alpha) \to \mathrm{Map}_{\mathrm{CAlg}_B}(A, \varinjlim B_\alpha)$$

is a homotopy equivalence. Set $\mathcal{C} = \mathrm{CAlg}_{\tau_{\geqslant 0} \mathscr{A}}(\mathrm{QCoh}(X))$. Unwinding the definitions, we wish to show that the composite map

$$\varinjlim \mathrm{Map}_{\mathcal{C}}(\mathscr{A}, G(B_\alpha)) \to \mathrm{Map}_{\mathcal{C}}(\mathscr{A}, \varinjlim G(B_\alpha)) \to \mathrm{Map}_{\mathcal{C}}(\mathscr{A}, G(\varinjlim B_\alpha))$$

is a homotopy equivalence. The map on the right is a homotopy equivalence by virtue of our assumption (c). It will therefore suffice to show that $\mathscr{A}$ is a compact object of $\mathcal{C}$. Note that for any object $\mathscr{A}' \in \mathcal{C}$, the mapping space $\mathrm{Map}_{\mathcal{C}}(\mathscr{A}, \mathscr{A}')$ is either empty (if the unit map $e : \mathscr{A}' \to \mathscr{A} \otimes_{\tau_{\geqslant 0} \mathscr{A}} \mathscr{A}'$ is not an equivalence) or contractible. Note that since u is faithfully flat, the map e is an equivalence if and only if $u^*(e)$ is an equivalence. Consequently, to show that $\mathscr{A}$ is a compact object of $\mathcal{C}$, it will suffice to show that $u^* \mathscr{A}$ is a compact object of $\mathrm{CAlg}_{\tau_{\geqslant 0} u^* \mathscr{A}}(\mathrm{QCoh}(U))$, which is a consequence of Theorem 2.6.0.2. This completes our verification of (i) and (ii), which establishes the existence of a quasi-affine morphism $v : Y' \to Y$ and an equivalence $v_* \mathscr{O}_{Y'} \simeq F(\mathscr{A})$.

We now show that v is flat. Since Y is affine, it will suffice to show that for each $\mathscr{F} \in \mathrm{QCoh}(Y)^{\heartsuit}$, the pullback $v^* \mathscr{F}$ belongs to $\mathrm{QCoh}(Y')_{\leqslant 0}$. Since Y' is quasi-affine, this is equivalent to the statement that the spectrum $\Gamma(Y'; v^* \mathscr{F})$ is 0-truncated. We have equivalences

$$\begin{aligned}\Gamma(Y'; v^* \mathscr{F}) &\simeq \Gamma(Y; v_* v^* \mathscr{F}) \\ &\simeq \Gamma(Y; v_* \mathscr{O}_{Y'} \otimes \mathscr{F}) \\ &\simeq \Gamma(Y; F(\mathscr{A}) \otimes \mathscr{F}) \\ &\simeq \Gamma(X; G(F(\mathscr{A}) \otimes \mathscr{F})) \\ &\xleftarrow{\gamma} \Gamma(X; \mathscr{A} \otimes G(\mathscr{F})) \\ &\simeq \Gamma(X; u_* \mathscr{O}_U \otimes G(\mathscr{F})) \\ &\simeq \Gamma(X; u_* u^* G(\mathscr{F})) \\ &\simeq \Gamma(U; u^* G(\mathscr{F}));\end{aligned}$$

here the map γ is an equivalence by virtue of assumption (d). The spectrum $\Gamma(U; u^* G(\mathscr{F}))$ is 0-truncated because $\mathscr{F}$ is 0-truncated, the functor G is left t-exact (by virtue of (b)), and the functor u^* is t-exact. This completes the proof that v is flat.

It remains to show that v is faithfully flat. For this, it will suffice to show that for $\mathscr{F} \in \mathrm{QCoh}(Y)^{\heartsuit}$ as above, the canonical map $\rho : \Gamma(Y; \mathscr{F}) \to \Gamma(Y'; v^* \mathscr{F})$ induces an injection on π_0 (in this case, the vanishing of $v^* \mathscr{F}$ guarantees the vanishing of $\pi_0 \Gamma(Y; \mathscr{F})$, hence also the vanishing of $\mathscr{F}$ since Y is affine and $\mathscr{F}$ is discrete). Using the preceding calculation, we can identify ρ with the canonical map $\Gamma(X; G(\mathscr{F})) \to \Gamma(U; u^* G(\mathscr{F}))$, which is injective on π_0 since $G(\mathscr{F}) \in \mathrm{QCoh}(X)$ is 0-truncated and the map u is faithfully flat. □

9.2.4 Some Consequences of Tannaka Duality

We now collect a few easy consequences of Theorem 9.2.0.2.

Proposition 9.2.4.1. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a quasi-geometric stack. Then X is a hypercomplete sheaf with respect to the fpqc topology on $\mathrm{CAlg}^{\mathrm{cn}}$.*

Proof. Our assumption that X is quasi-geometric guarantees that X is a sheaf with respect to the fpqc topology. To show that X is hypercomplete, it will suffice (by virtue of Proposition D.6.7.4) to show that for every connective $\mathbb{E}_\infty$-ring R and every pair of points $\eta, \eta' \in X(R)$, the functor $Y : \mathrm{CAlg}^{\mathrm{cn}}_R \to \mathcal{S}$ given by $Y(A) = \{\eta\} \times_{X(A)} \{\eta'\}$ is a hypercomplete sheaf with respect to the fpqc topology. For each $A \in \mathrm{CAlg}^{\mathrm{cn}}_R$, let $\eta_A, \eta'_A : \operatorname{Spec} A \to X$ denote the maps determined by η and η'. By virtue of Proposition 9.2.2.1, the functor Y is given by the formula $Y(A) = \mathrm{Map}_{\mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{Mod}_A)}(\eta_A^*, \eta_A'^*)$. Since the construction $A \mapsto \mathrm{Mod}_A$ determines a hypercomplete sheaf (with values in the ∞-category $\mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty)$ of symmetric monoidal ∞-categories) by virtue of Corollary D.6.3.3, it follows that Y is hypercomplete.

□

Proposition 9.2.4.2. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a quasi-geometric stack. Then, for every connective $\mathbb{E}_\infty$-ring A, the space $X(A)$ is essentially small.*

Proof. Proposition 9.1.3.1 guarantees that $\mathrm{QCoh}(X)$ is a presentable ∞-category. Consequently, if τ is a sufficiently large regular cardinal, then there is an equivalence $\mathrm{QCoh}(X) \simeq \mathrm{Ind}_\tau(\mathrm{QCoh}(X)^\tau)$, where $\mathrm{QCoh}(X)^\tau$ denotes the full subcategory of $\mathrm{QCoh}(X)$ spanned by the τ-compact objects. Enlarging τ if necessary, we may assume that the full subcategory $\mathrm{QCoh}(X)^\tau$ contains the unit object $\mathscr{O}_X$ and is closed under tensor products. It follows that $\mathrm{QCoh}(X)^\tau$ inherits the structure of a symmetric monoidal ∞-category. Let Mod^τ_A denote the full subcategory of Mod_A spanned by the τ-compact objects, which we also regard as a symmetric monoidal ∞-category. Proposition HA.4.8.1.10 guarantees that $\mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)_\tau, \mathrm{Mod}^\tau_A)$ can be identified with the full subcategory of $\mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{Mod}_A)$ spanned by those symmetric monoidal functors which preserve τ-filtered colimits and τ-compact objects. Note that these conditions are automatically satisfied for any functor $F : \mathrm{QCoh}(X) \to \mathrm{Mod}_A$ which admits a right adjoint that preserves small colimits (see Proposition HTT.5.5.7.2). Consequently, Theorem 9.2.0.2 supplies a fully faithful embedding

$$X(A) \simeq \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(\mathrm{Spec}\, A, X) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^\tau, \mathrm{Mod}^\tau_A).$$

Since the codomain of this embedding is essentially small, it follows that $X(A)$ is essentially small. □

Proposition 9.2.4.3. *Let $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be quasi-geometric stacks and let $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ be a t-exact symmetric monoidal equivalence of ∞-categories. Then we have $F \simeq f^*$ for some equivalence $f : Y \xrightarrow{\sim} X$ (uniquely determined up to equivalence, by virtue of Proposition 9.2.2.1).*

Proof. We claim that for every functor $Z : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ and every natural transformation $g : Z \to Y$, the composite functor $\mathrm{QCoh}(X) \xrightarrow{F} \mathrm{QCoh}(Y) \xrightarrow{g^*} \mathrm{QCoh}(Z)$ is equivalent to f^*_Z, for some map $f_Z : Z \to X$. Applying this result in the case $Z = Y$, we deduce that $F \simeq f^*$ for some map $f : Y \to X$, in which case Theorem 9.2.0.2 shows that f induces a homotopy equivalence $Y(R) \to X(R)$ for every connective $\mathbb{E}_\infty$-ring R, and is therefore an equivalence. To prove the existence of f_Z, we can assume (by virtue of the uniqueness provided by Proposition 9.2.2.1) write Z as a colimit of corepresentable functors and thereby reduce to the case where Z is corepresentable. In this case, it will suffice to show that the functor $g^* \circ F$ satisfies criteria (a) through (d) of Theorem 9.2.0.2. This is clear, since F is a t-exact equivalence of ∞-categories and g^* satisfies conditions (a) through (d) of Theorem 9.2.0.2. □

Proposition 9.2.4.4. *Let $f : A \to B$ be a flat morphism of connective $\mathbb{E}_\infty$-rings and let $I \subseteq \pi_0 A$ be a finitely generated ideal. Let $U \subseteq \mathrm{Spec}\, A$ be the open subfunctor complementary* *to the vanishing locus of I (so that $U(R) \subseteq \mathrm{Map}_{\mathrm{CAlg}}(A, R)$ is the subspace consisting of those maps $A \to R$ which exhibit R as an I-local A-module, for each $R \in \mathrm{CAlg}^{\mathrm{cn}}$), and define $V = U \times_{\mathrm{Spec}\, A} \mathrm{Spec}\, B \subseteq \mathrm{Spec}\, B$ similarly. Suppose that f an equivalence of I-completions $A^{\wedge}_{I} \to B^{\wedge}_{I}$. Then, for every quasi-geometric stack X, the diagram σ :*

$$\begin{array}{ccc} X(A) & \longrightarrow & \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(U, X) \\ \downarrow & & \downarrow \\ X(B) & \longrightarrow & \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(V, X) \end{array}$$

is a pullback square.

Remark 9.2.4.5. Let A be a Noetherian $\mathbb{E}_\infty$-ring and let $I \subseteq \pi_0 A$ be an ideal. Then the canonical map $A \to A^{\wedge}_{I}$ satisfies the hypotheses of Proposition 9.2.4.4 (see Corollary 7.3.6.9).

Proof of Proposition 9.2.4.4. It follows from Theorem 7.4.0.1 that the diagram of pullback functors σ :

$$\begin{array}{ccc} \mathrm{QCoh}(\mathrm{Spec}\, A) & \longrightarrow & \mathrm{QCoh}(U) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathrm{Spec}\, B) & \longrightarrow & \mathrm{QCoh}(V) \end{array}$$

is a pullback square of (symmetric monoidal) ∞-categories. We therefore obtain a pullback diagram

$$\begin{array}{ccc} \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(\mathrm{Spec}\, A)) & \longrightarrow & \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(U)) \\ \downarrow & & \downarrow \\ \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(\mathrm{Spec}\, B)) & \longrightarrow & \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(V)). \end{array}$$

Combining this observation with Proposition 9.2.2.1, we immediately deduce that the natural map

$$X(A) \to X(B) \times_{\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(V, X)} \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(U, X)$$

is fully faithful. To verify essential surjectivity, it will suffice to show that if $F_A : \mathrm{QCoh}(X) \to \mathrm{QCoh}(\mathrm{Spec}\, A)$ is a symmetric monoidal functor having the property that the induced maps

$$F_B : \mathrm{QCoh}(X) \to \mathrm{QCoh}(\mathrm{Spec}\, B)$$

$$F_U : \mathrm{QCoh}(X) \to \mathrm{QCoh}(U)$$

$$F_V : \mathrm{QCoh}(X) \to \mathrm{QCoh}(V)$$

satisfy conditions (a) through (d) of Theorem 9.2.0.2, then F_A also satisfies conditions (a) through (d) of Theorem 9.2.0.2. We consider each of these conditions in turn:

(a) Suppose that the functors F_B, F_U, and F_V admit right adjoints

$$G_B : \mathrm{QCoh}(\operatorname{Spec} B) \to \mathrm{QCoh}(X)$$

$$G_U : \mathrm{QCoh}(\operatorname{Spec} B) \to \mathrm{QCoh}(X)$$

$$G_V : \mathrm{QCoh}(V) \to \mathrm{QCoh}(X).$$

Then F_B, F_U, and F_V preserve small colimits. Since σ is a pullback square, it follows that F_A preserves small colimits, and therefore admits a right adjoint G_A : $\mathrm{QCoh}(\operatorname{Spec} A) \to \mathrm{QCoh}(X)$ by virtue of the adjoint functor theorem (Corollary HTT.5.5.2.9). However, we do not need to appeal to the adjoint functor theorem: the right adjoint G_A can be given directly by the formula

$$G_A(\mathscr{F}) \simeq G_B(\mathscr{F}|_{\operatorname{Spec} B}) \times_{G_V(\mathscr{F}|_V)} G_U(\mathscr{F}|_U).$$

(b) Because f is flat, the maps $\operatorname{Spec} B \to \operatorname{Spec} A \leftarrow U$ comprise a flat covering. Consequently, an object $\mathscr{F} \in \mathrm{QCoh}(\operatorname{Spec} A)$ is connective if and only if $\mathscr{F}|_{\operatorname{Spec} B}$ and $\mathscr{F}|_U$ are connective. Since F_B and F_U are right t-exact, it follows that F_A is also right t-exact.

(c) The functors G_B, G_V, and G_U preserve small colimits. Using the canonical identification $G_A(\mathscr{F}) \simeq G_B(\mathscr{F}|_{\operatorname{Spec} B}) \times_{G_V(\mathscr{F}|_V} G_U(\mathscr{F}|_U)$, we deduce that the functor G_A also preserves small colimits.

(d) Suppose we are given a pair of objects $\mathscr{F} \in \mathrm{QCoh}(X)$ and $\mathscr{G} \in \mathrm{QCoh}(\operatorname{Spec} A)$. We wish to show that the canonical map

$$\theta_A : \mathscr{F} \otimes G_A(\mathscr{G}) \to G_A(F_A(\mathscr{F}) \otimes \mathscr{G})$$

is an equivalence in $\mathrm{QCoh}(X)$. Unwinding the definitions, we see that there is a pullback diagram

$$\begin{array}{ccc} \theta_A & \longrightarrow & \theta_U \\ \downarrow & & \downarrow \\ \theta_B & \longrightarrow & \theta_V \end{array}$$

in the ∞-category $\mathrm{Fun}(\Delta^1, \mathrm{QCoh}(X))$, where

$$\theta_B : \mathscr{F} \otimes G_B(\mathscr{G}|_{\operatorname{Spec} B}) \to G_B(F_B(\mathscr{F}) \otimes \mathscr{G}|_{\operatorname{Spec} B})$$

$$\theta_V : \mathscr{F} \otimes G_V(\mathscr{G}|_V) \to G_V(F_V(\mathscr{F}) \otimes \mathscr{G}|_V)$$

$$\theta_U : \mathscr{F} \otimes G_U(\mathscr{G}|_U) \to G_U(F_U(\mathscr{F}) \otimes \mathscr{G}|_U)$$

are the equivalences appearing in the projection formula for F_B, F_V, and F_U, respectively. It follows that θ_A is an equivalence, as desired.

□

Example 9.2.4.6. Let $f : A \to B$ be a morphism of Noetherian $\mathbb{E}_\infty$-rings and let $x \in \pi_0 A$ be an element for which f induces an equivalence $A^{\wedge}_{(x)} \to B^{\wedge}_{(x)}$. Then, for every quasi-geometric stack $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, the diagram

$$\begin{array}{ccc} X(A) & \longrightarrow & X(B) \\ \downarrow & & \downarrow \\ X(A[x^{-1}]) & \longrightarrow & X(B[x^{-1}]) \end{array}$$

is a pullback square.

9.3 Geometric Stacks

In §9.1, we introduced the notion of a *quasi-geometric stack* $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. The main result of §9.2 implies that a quasi-geometric stack X can be functorially recovered from the ∞-category $\mathrm{QCoh}(X)$. More precisely, Theorem 9.2.0.2 asserts that if Y is a quasi-compact, quasi-separated algebraic space, then the datum of a map $Y \to X$ is equivalent to the datum of a symmetric monoidal, right t-exact functor $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ which admits a right adjoint G that preserves colimits and satisfies a projection formula. However, for many applications, this characterization is inconvenient: one would prefer to have a more direct description involving only properties of the functor F (which can be tested locally on Y), rather than its right adjoint G (which depends on the global structure of Y). In this section, we will study a special class of quasi-geometric stacks for which such a description is possible:

Definition 9.3.0.1. A *geometric stack* is a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ which satisfies the following conditions:

(a) The functor X satisfies descent with respect to the fpqc topology.

(b) The diagonal map $\delta : X \to X \times X$ is affine.

(c) There exists a connective $\mathbb{E}_\infty$-ring A and a faithfully flat morphism $f : \operatorname{Spec} A \to X$.

Remark 9.3.0.2. A geometric stack X can be defined as a quasi-geometric stack (in the sense of Definition 9.1.0.1) for which the diagonal map $\delta : X \to X \times X$ is affine (see Remark 9.1.0.2). It follows from Proposition 9.2.4.1 that a geometric stack X is automatically a hypercomplete sheaf with respect to the fpqc topology).

The main result of this section is the following variant of Theorem 9.2.0.2:

Theorem 9.3.0.3. *[Tannaka Duality for Geometric Stacks] Let* $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ *be functors, and suppose that* X *is a geometric stack. Then the construction* $(f : Y \to X) \mapsto (f^* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y))$ *determines a fully faithful embedding*

$$\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(Y, X) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y)),$$

whose essential image is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ *which satisfy the following conditions:*

(a) *The functor* F *preserves small colimits.*

(b) *The functor* F *carries connective objects of* $\mathrm{QCoh}(X)$ *to connective objects of* $\mathrm{QCoh}(Y)$.

(c) *The functor* F *carries flat objects of* $\mathrm{QCoh}(X)$ *to flat objects of* $\mathrm{QCoh}(Y)$.

9.3.1 Examples of Geometric Stacks

We begin with some general remarks concerning Definition **??**. First, we need an analogue of Lemma 9.1.1.3:

Lemma 9.3.1.1. *Suppose we are given a pullback diagram*

$$\begin{array}{ccc} X' & \xrightarrow{f'} & Y' \\ \downarrow & & \downarrow g \\ X & \xrightarrow{f} & Y \end{array}$$

in the ∞*-category* $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}} \subseteq \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ *of fpqc sheaves. If* f' *is affine and* g *is an effective epimorphism of fpqc sheaves, then* f *is affine.*

Proof. Choose any map $\eta : \operatorname{Spec} R \to Y$; we wish to show that the fiber product $Z = \operatorname{Spec} R \times_Y X$ is affine. Since g is an fpqc surjection, we can choose a faithfully flat map $R \to R^0$ such that $\eta|_{\operatorname{Spec} R^0}$ factors through Y'. Let $R^\bullet$ denote the Čech nerve of the faithfully flat map $R \to R^0$ (formed in the ∞-category $\mathrm{CAlg}^{\mathrm{op}}$) and set $Z_\bullet = \operatorname{Spec} R^\bullet \times_Y X$. By construction, each of the maps $\operatorname{Spec} R^m \to Y$ factors through Y', so we can write $Z_m \simeq \operatorname{Spec} A^\bullet$ for some cosimplicial object $A^\bullet$ of $\mathrm{CAlg}^{\mathrm{cn}}$. Using Theorem D.6.3.5, we deduce that $A^\bullet \simeq A \otimes_R R^\bullet$ for some connective $\mathbb{E}_\infty$-algebra A over R. Then

$$Z \simeq |Z_\bullet| \simeq |\operatorname{Spec} A^\bullet| \simeq \operatorname{Spec} A \times_{\operatorname{Spec} R} |\operatorname{Spec} R^\bullet| \simeq \operatorname{Spec} A$$

is affine, as desired. □

Proposition 9.3.1.2. *Let* $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ *be a quasi-geometric stack. The following conditions are equivalent:*

(1) *The diagonal map* $\delta : X \to X \times X$ *is affine (that is,* X *is a geometric stack).*

(2) *For every pair of morphisms* $\operatorname{Spec} A \to X \leftarrow \operatorname{Spec} B$*, the fiber product* $\operatorname{Spec} A \times_X \operatorname{Spec} B$ *is affine.*

(3) *Every morphism* $\operatorname{Spec} A \to X$ *is affine.*

(4) *There exists a faithfully flat affine morphism* $f : \operatorname{Spec} A \to X$*.*

Proof. The implication (1) ⇒ (2) follows from the existence of a pullback diagram

$$\begin{array}{ccc} \operatorname{Spec} A \times_X \operatorname{Spec} B & \longrightarrow & \operatorname{Spec}(A \otimes B) \\ \downarrow & & \downarrow \\ X & \longrightarrow & X \times X, \end{array}$$

and the equivalence (2) ⇔ (3) is tautological. The implication (2) ⇒ (1) follows from the observation that every map $\operatorname{Spec} A \to X \times X$ determines a pullback square

$$\begin{array}{ccc} \operatorname{Spec} A \times_{X \times X} X & \longrightarrow & \operatorname{Spec} A \times_X \operatorname{Spec} A \\ \downarrow & & \downarrow \\ \operatorname{Spec} A & \longrightarrow & \operatorname{Spec} A \times \operatorname{Spec} A. \end{array}$$

The implication (3) ⇒ (4) follows from our assumption that X is quasi-geometric (which guarantees the existence of a faithfully flat quasi-affine morphism $\operatorname{Spec} A \to X$). We will complete the proof by showing that (4) ⇒ (3). Let $f : \operatorname{Spec} A \to X$ be a faithfully flat affine morphism and let $g : \operatorname{Spec} B \to X$ be arbitrary; we claim that g is affine. Form a pullback square

$$\begin{array}{ccc} Y & \longrightarrow & \operatorname{Spec} A \\ \downarrow{\scriptstyle g'} & & \downarrow{\scriptstyle f} \\ \operatorname{Spec} B & \xrightarrow{g} & X. \end{array}$$

By virtue of Lemma 9.3.1.1, it will suffice to show that g' is affine. This is clear, since our assumption that f is affine guarantees that Y is affine. □

Proposition 9.3.1.3. *Let* $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ *be a functor which satisfies descent for the fpqc topology, and suppose there exists a morphism* $f : X_0 \to X$ *satisfying the following conditions:*

(*a*) *The functor* $X_0 : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ *is a geometric stack.*

(*b*) *The morphism* f *is representable, affine, and faithfully flat.*

Then X is a geometric stack.

Proof. The functor X is a quasi-geometric stack by virtue of Proposition 9.1.1.4. Choose a faithfully flat map $g : \operatorname{Spec} A \to X_0$. Condition (a) implies that g is affine (Proposition 9.3.1.2). It follows from (b) that the composition $g \circ f$ is affine, so that X is a geometric stack by virtue of Proposition 9.3.1.2. □

Corollary 9.3.1.4. *Let $X_\bullet$ be a simplicial object of $\operatorname{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ satisfying the following conditions:*

(a) *The functor $X_0 : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ is a geometric stack.*

(b) *The functor $X_\bullet$ is a groupoid object of $\operatorname{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$.*

(c) *The face map $d_0 : X_1 \to X_0$ is representable, affine, and faithfully flat.*

Then the geometric realization $X = |X_\bullet|$ (formed in the ∞-category $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$ of fpqc sheaves) is a geometric stack.

Proof. We have a pullback diagram

$$\begin{array}{ccc} X_1 & \xrightarrow{d_0} & X_0 \\ \downarrow{\scriptstyle d_1} & & \downarrow \\ X_0 & \longrightarrow & X \end{array}$$

where the vertical maps are effective epimorphisms in $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$. It follows from (c) and Lemma 9.3.1.1 that the map $X_0 \to X$ is affine and faithfully flat, so that X is a geometric stack by virtue of Proposition 9.3.1.3. □

Remark 9.3.1.5 (Existence of Atlases)**.** Every geometric stack X can be written as a geometric realization $|X_\bullet|$, where $X_\bullet$ satisfies the hypotheses of Corollary 9.3.1.4 and X_0 is affine: to see this, we can take $X_\bullet$ to be the Čech nerve of any faithfully flat map $\operatorname{Spec} A \to X$.

Example 9.3.1.6 (Classifying Stacks)**.** Let R be a commutative ring and let G be a flat affine group scheme over R. Then the classifying stack BG (see Example 9.1.1.7) is a geometric stack.

Example 9.3.1.7 (The Moduli Stack of Formal Groups)**.** Let R be a commutative ring. We define the category $\mathcal{FGL}(R)$ of *formal group laws over R* as follows:

- An object of $\mathcal{FGL}(R)$ is a (commutative, 1-dimensional) formal group law over R: that is, a power series $f(x, y) \in R[[x, y]]$ satisfying the identities

$$f(x,y) = f(y,x) \qquad f(x,0) = x \qquad f(x, f(y,z)) = f(f(x,y), z).$$

- If f and f' are formal group laws over R, then a morphism from f to f' in $\mathcal{FGL}(R)$ is an invertible formal power series $g(x) \in R[[x]]$ satisfying $f(g(x), g(y)) = g(f'(x,y))$.

For each $n \geqslant 0$, let $\mathrm{N}(\mathcal{FGL}(R))_n$ denote the set of n-simplices of the nerve of the category $\mathcal{FGL}(R)$: that is, the collection of $(n+1)$-tuples of formal group laws $f_0, \ldots, f_n \in R[[x,y]]$ together with invertible power series $g_1, \ldots, g_n \in R[[x]]$ satisfying $f_i(g_i(x), g_i(y)) = g_i(f_{i+1}(x,y))$. The construction $R \mapsto \mathrm{N}(\mathcal{FGL}(R))_n$ determines a functor from the category of commutative rings to the category of sets. It is not difficult to show that this functor is corepresentable: that is, there exists a commutative ring L^n and a bijection $\mathrm{N}(\mathcal{FGL}(R))_n \simeq \mathrm{Hom}_{\mathrm{CAlg}^\heartsuit}(L^n, R)$. Let $\operatorname{Spec} L^n$ denote the functor corepresented by L^n on the ∞-category of connective $\mathbb{E}_\infty$-rings, so that we can regard $\operatorname{Spec} L^\bullet$ as a simplicial object of $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$. It is not difficult to show that $\operatorname{Spec} L^\bullet$ satisfies the hypotheses of Corollary 9.3.1.4, so that the geometric realization $|\operatorname{Spec} L^\bullet|$ (formed in the ∞-category $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$) is a geometric stack. We will denote this geometric stack by $\mathcal{FG}$ and refer to it as the *moduli stack of formal groups*. We will refer to the commutative ring L^0 as the *Lazard ring*: by a theorem of Lazard, it is isomorphic to a polynomial ring $\mathbf{Z}[v_1, v_2, \ldots]$ on infinitely many variables. Concretely, the geometric stack $\mathcal{FG}$ can be described as the quotient of the affine scheme $\operatorname{Spec} L^0$ by the action of the affine group scheme $\operatorname{Spec} \mathbf{Z}[a_1^{\pm 1}, a_2, a_3, \ldots]$ parametrizing invertible formal power series $g(x) = \sum_{n>0} a_n x^n$. For every commutative ring R, one can identify $\mathcal{FG}(R)$ with (the nerve of) the groupoid of (commutative, 1-dimensional) formal groups $\mathbf{G}$ over R. This category can be regarded as a slight enlargement of the category $\mathcal{FGL}(R)$ (more precisely, there is a fully faithful embedding $\mathcal{FGL}(R) \hookrightarrow \mathcal{FG}(R)$ whose essential image consists of those formal groups $\mathbf{G}$ over R whose Lie algebra is isomorphic to R).

Example 9.3.1.8 (The Derived Moduli Stack of Formal Groups)**.** Let MP denote the $\mathbb{E}_\infty$-ring of *periodic complex bordism*: that is, the Thom spectrum of the tautological virtual complex vector bundle on the classifying space $\mathbf{Z} \times \mathrm{BU}$ for complex K-theory. We let $\mathrm{MP}^\bullet$ denote the cosimplicial $\mathbb{E}_\infty$-ring given by the Čech nerve (in the ∞-category $\mathrm{CAlg}^{\mathrm{op}}$) of the unit map $S \to \mathrm{MP}$, so that MP^n can be identified with the $(n+1)$-fold smash power of MP. A celebrated theorem of Quillen supplies an isomorphism $L^0 \xrightarrow{\sim} \pi_0 \mathrm{MP}$, where L^0 is the Lazard ring of Example 9.3.1.7 (see [169]). A slight elaboration of Quillen's theorem establishes an isomorphism of cosimplicial commutative rings $L^\bullet \xrightarrow{\sim} \pi_0 \mathrm{MP}^\bullet$.

The cosimplicial $\mathbb{E}_\infty$-ring $\mathrm{MP}^\bullet$ does not quite fit into the framework of this section, because the $\mathbb{E}_\infty$-rings MP^n are not connective (in fact, each MP^n even periodic: that is, we have noncanonical isomorphisms $\pi_* \mathrm{MP}^n \simeq (\pi_0 \mathrm{MP}^n)[u^{\pm 1}]$ for some $u \in \pi_2 \mathrm{MP}^n$). We can correct this by passing to connective covers: one can show that the spectrum $\operatorname{Spec} \tau_{\geqslant 0} \mathrm{MP}^\bullet$ is a simplicial object of $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$ which satisfies the hypotheses of Corollary 9.3.1.4, so that the geometric realization $|\operatorname{Spec} \tau_{\geqslant 0} \mathrm{MP}^\bullet|$ (formed in the ∞-category $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$) is a geometric stack, which we will denote by $\mathcal{FG}^{\mathrm{der}}$. The geometric stack $\mathcal{FG}^{\mathrm{der}}$ can be regarded as a "derived version" of the moduli stack of formal groups $\mathcal{FG}$ defined in Example 9.3.1.7: the isomorphisms $L^{\bullet} \simeq \pi_0 \, \mathrm{MP}^{\bullet}$ induce a morphism of geometric stacks $\mathcal{FG} \to \mathcal{FG}^{\mathrm{der}}$ which exhibit $\mathcal{FG}$ as the 0-truncation of $\mathcal{FG}^{\mathrm{der}}$, in the sense of Definition **??**.

Remark 9.3.1.9 (The Adams-Novikov Spectral Sequence)**.** Let E be a spectrum, and let $\mathrm{MP}^{\bullet}$ be the cosimplicial $\mathbb{E}_{\infty}$-ring appearing in Example 9.3.1.8. The construction $[n] \mapsto E \otimes \mathrm{MP}^n$ determines an object $\mathscr{F}_E \in \mathrm{Tot}(\mathrm{Mod}_{\tau_{\geqslant 0} \mathrm{MP}^{\bullet}}) \simeq \mathrm{QCoh}(\mathcal{FG}^{\mathrm{der}})$. Moreover, we have a canonical map $E \to \mathrm{Tot}(E \otimes \mathrm{MP}^{\bullet}) \simeq \Gamma(\mathcal{FG}^{\mathrm{der}}; \mathscr{F}_E)$, which is an equivalence in many cases (for example, it is an equivalence whenever E is connective). For every integer n, we can regard $\pi_n \mathscr{F}_E$ as an object of the abelian category $\mathrm{QCoh}(\mathcal{FG}^{\mathrm{der}})^{\heartsuit} \simeq \mathrm{QCoh}(\mathcal{FG})^{\heartsuit}$. We will denote the homotopy groups $\pi_* \Gamma(\mathcal{FG}; \pi_n \mathscr{F}_E)$ by $\mathrm{H}^{-*}(\mathcal{FG}; \pi_n \mathscr{F}_E)$, and refer to them as the *cohomology groups of $\mathcal{FG}$ with coefficients in $\mathscr{F}_E$*. The cosimplicial spectrum $E \otimes \mathrm{MP}^{\bullet}$ determines a Bousfield-Kan spectral sequence $\{E_r^{s,t}, d_r\}_{r \geqslant 2}$, whose second page is given by $E_2^{s,t} = \mathrm{H}^{-t}(\mathcal{FG}; \pi_s \mathscr{F}_E)$ which, in good cases, converges to $\pi_{s+t} E$. This spectral sequence is known as the *Adams-Novikov spectral sequence*.

Example 9.3.1.10 (Closure Under Pullbacks)**.** Suppose we are given a pullback diagram

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \longrightarrow & Y \end{array}$$

in $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$, where X and Y' are geometric stacks and Y is a quasi-geometric stack. Then X' is a geometric stack. To prove this, we first note that X' is a quasi-geometric stack (Corollary 9.1.2.6). It will therefore suffice to show that the diagonal map $\delta_{X'} : X' \to X' \times X'$ is affine. The map $\delta_{X'}$ factors as a composition $X' \xrightarrow{u} X' \times_X X' \xrightarrow{v} X' \times X'$, where u is a pullback of the relative diagonal map $u_0 : Y' \to Y' \times_Y Y'$ and v is a pullback of the diagonal map $\delta_X : X \to X \times X$. The diagonal δ_X is affine by virtue of our assumption that X is geometric, so it will suffice to show that u_0 is affine. For this, we note that u_0 factors as a composition

$$Y' \xrightarrow{u_0'} (Y' \times_Y Y') \times_{Y' \times Y'} Y' \xrightarrow{u_0''} (Y' \times_Y Y')$$

where u_0'' is a pullback of the diagonal $\delta_{Y'} : Y \to Y \times Y$ and is therefore affine (since Y is geometric). We are therefore reduced to showing that u_0' is affine, which follows from the observation that u_0' is a pullback of the relative diagonal $Y \to Y \times_{Y \times Y} Y$ of the diagonal map $\delta_Y : Y \to Y \times Y$. Since Y is quasi-geometric, the map δ_Y is quasi-affine, so its relative diagonal is affine as desired.

9.3.2 Tannaka Duality for Geometric Stacks

Let $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be functors, and suppose that X is a geometric stack. Using Proposition 9.2.2.1, we deduce that the construction

$$(f : Y \to X) \mapsto (f^* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y))$$

determines a fully faithful embedding $\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}},\mathcal{S})}(Y, X) \to \mathrm{Fun}^{\otimes}(X, Y)$. To prove Theorem 9.3.0.3, we must show that the essential image of this fully faithful embedding is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ which preserve small colimits, connective objects, and flat objects. Writing Y as a colimit of corepresentable functors, we can assume without loss of generality that $Y \simeq \mathrm{Spec}\, A$ for some connective $\mathbb{E}_\infty$-ring A. We are therefore reduced to proving the following:

Proposition 9.3.2.1. *Let X be a geometric stack, let A be a connective $\mathbb{E}_\infty$-ring, and let $F : \mathrm{QCoh}(X) \to \mathrm{Mod}_A$ be a symmetric monoidal functor which preserves small colimits and connective objects. The following conditions are equivalent:*

(1) *There exists a point $\eta \in X(A)$ and a symmetric monoidal equivalence $F \simeq \eta^*$.*

(2) *The functor F carries flat objects of $\mathrm{QCoh}(X)$ to flat objects of Mod_A.*

(3) *For every faithfully flat morphism $g : X_0 \to X$ where X_0 is affine, the A-algebra $F(g_* \mathscr{O}_{X_0})$ is faithfully flat.*

(4) *There exists a faithfully flat morphism $g : X_0 \to X$ where X_0 is affine and the A-algebra $F(g_* \mathscr{O}_{X_0})$ is faithfully flat.*

Proof. The implication (1) $\Rightarrow$ (2) is obvious. We next show that (2) implies (3). Let $g : X_0 \to X$ be a faithfully flat morphism, where X_0 is affine. Set $\mathscr{B} = g_* \mathscr{O}_{X_0} \in \mathrm{CAlg}(\mathrm{QCoh}(X))$. Since X is geometric, the morphism g is affine, so that $\mathscr{B}$ is a faithfully flat commutative algebra object of $\mathrm{QCoh}(X)$. Using Lemma D.4.4.3, we see that the cofiber of the unit map $e : \mathscr{O}_X \to \mathscr{B}$ is flat. Assumption (2) then implies that $F(\mathrm{cofib}(e)) \in \mathrm{Mod}_A$ is flat, so that $F(\mathscr{B})$ is faithfully flat over A (by virtue of Lemma D.4.4.3).

The implication (3) $\Rightarrow$ (4) follows immediately from the existence of a faithfully flat morphism $g : X_0 \to X$, where X_0 is affine (which follows from our assumption that X is geometric). We will complete the proof by showing that (4) implies (1). Let $g : X_0 \to X$ be a faithfully flat where X_0 is affine, and set $\mathscr{B} = g_* \mathscr{O}_{X_0}$ as above. Since F preserves small colimits, it follows from the adjoint functor theorem (Corollary HTT.5.5.2.9) that F admits a right adjoint G. By virtue of Theorem 9.2.0.2, it will suffice to prove the following:

(a) The functor G preserves small colimits.

(b) For every quasi-coherent sheaf $\mathscr{F} \in \mathrm{QCoh}(X)$ and every object $M \in \mathrm{Mod}_A$, the canonical map $G(M) \otimes \mathscr{F} \to G(M \otimes_A F(\mathscr{F}))$ is an equivalence in $\mathrm{QCoh}(X)$.

Set $A^0 = F(\mathscr{B})$. Since F is exact and preserves flatness, it follows that the cofiber of the unit map $A \to A^0$ is a flat A-module: that is, A^0 is faithfully flat over A (Lemma D.4.4.3). Let $\mathscr{B}^\bullet$ denote the Čech nerve of the unit map $\mathscr{O}_X \to \mathscr{B}$ (computed the ∞-category $\mathrm{CAlg}(\mathrm{QCoh}(X))^{\mathrm{op}}$) and set $A^\bullet = F(\mathscr{B}^\bullet)$. Let $X_\bullet$ be the Čech nerve of g, so that we have an equivalence of cosimplicial ∞-categories $\mathrm{QCoh}(X_\bullet) \simeq \mathrm{Mod}_{\mathscr{B}^\bullet}(\mathrm{QCoh}(X))$. Since X is geometric, the map each of the functors Xk is corepresentable: that is, we can write $X_\bullet \simeq \operatorname{Spec} B^\bullet$ for some cosimplicial connective $\mathbb{E}_\infty$-ring $B^\bullet$.

The functor F determines a natural transformation of cosimplicial ∞-categories

$$F^\bullet \, \mathrm{Mod}_{B^\bullet} \simeq \mathrm{QCoh}(X_\bullet) \simeq \mathrm{Mod}_{\mathscr{B}^\bullet}(\mathrm{QCoh}(X)) \to \mathrm{Mod}_{A^\bullet}(\mathrm{Mod}_A) \simeq \mathrm{Mod}_{A^\bullet}.$$

Using Lemma D.3.5.6, we deduce that for every map $[m] \to [n]$ in $\mathbf{\Delta}$, the diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(X_m) & \xrightarrow{F^m} & \mathrm{Mod}_{A^m} \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(X_n) & \xrightarrow{F^n} & \mathrm{Mod}_{A^n} \end{array}$$

is right adjointable; moreover, the right adjoint to $F^n : \mathrm{QCoh}(X_n) \to \mathrm{Mod}_{A^n}$ can be identified with the forgetful functor $G_n : \mathrm{Mod}_{A^n} \to \mathrm{Mod}_{B^n}$ induced by a map of $\mathbb{E}_\infty$-rings $B^n \to A^n$. In particular, G_n commutes with small colimits.

Since $X \simeq |X_\bullet|$ in $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$, we get a canonical equivalence $\mathrm{QCoh}(X) \simeq \varprojlim \mathrm{QCoh}(X_\bullet)$. Corollary D.6.3.3 guarantees that $\mathrm{Mod}_A \simeq \varprojlim \mathrm{Mod}_{A^\bullet}$, so that the functor F can be identified with the limit of the functors F^n. It follows from Corollary HA.4.7.4.18 that each of the diagrams

$$\begin{array}{ccc} \mathrm{QCoh}(X) & \xrightarrow{F} & \mathrm{Mod}_{A} \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(X_n) & \xrightarrow{F^n} & \mathrm{Mod}_{A^n} \end{array}$$

is right adjointable.

To prove that $G : \mathrm{Mod}_A \to \mathrm{QCoh}(X) \simeq \varprojlim \mathrm{QCoh}(X_\bullet)$ preserves small colimits, it suffices to show that each of the composite functors $\mathrm{Mod}_A \to \mathrm{QCoh}(X) \to \mathrm{QCoh}(X_n)$ preserves small colimits. By the above, this is equivalent to the assertion that the composite functor

$$\mathrm{Mod}_A \to \mathrm{Mod}_{A^n} \xrightarrow{G_n} \mathrm{QCoh}(X_n) \simeq \mathrm{Mod}_{B^n} \qquad (M \mapsto G_n(A^n \otimes_A M))$$

preserves small colimits, which is clear (since G_n preserves small colimits). This completes the proof of (a).

It remains to verify that the functor $G : \mathrm{Mod}_A \to \mathrm{QCoh}(X)$ satisfies (b). Fix an A-module M and a quasi-coherent sheaf $\mathscr{F}$ on X; we wish to show that the canonical map $\alpha : G(M) \otimes \mathscr{F} \to G(M \otimes_A F(\mathscr{F}))$ is an equivalence in $\mathrm{QCoh}(X)$. Since the pullback functor $g^* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(X_0) \simeq \mathrm{Mod}_B$ is conservative, it will suffice to show that the induced map

$$g^*(\alpha) : g^* G(M) \otimes g^* \mathscr{F} \to g^* G(M \otimes_A F(\mathscr{F}))$$

is an equivalence of B-modules. This map fits into a commutative diagram

$$\begin{array}{ccc} g^*G(M) \otimes g^* \mathscr{F} & \xrightarrow{g^*(\alpha)} & g^*G(M \otimes_A F(\mathscr{F})) \\ \downarrow & & \downarrow \\ G_0(A^0 \otimes_A M) \otimes g^* \mathscr{F} & \longrightarrow & G_0(A^0 \otimes_A M \otimes F(\mathscr{F})) \end{array}$$

where the vertical maps are equivalences. We are therefore reduced to showing that the bottom horizontal map is an equivalence, which follows from the projection formula for the adjunction $\mathrm{Mod}_B \underset{G^0}{\overset{F^0}{\rightleftarrows}} \mathrm{Mod}_{A^0}$. □

9.3.3 The Resolution Property

Let X be a geometric stack, and let $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be some other functor According to Theorem 9.3.0.3, we can identify maps $f : Y \to X$ with symmetric monoidal functors $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ which preserve small colimits, connective objects, and flat objects. There are some cases in which the last condition follows from the first two. For example, if $\mathscr{F} \in \mathrm{QCoh}(X)$ is locally free of finite rank, then $\mathscr{F}$ is dualizable as an object of $\mathrm{QCoh}(X)^{\mathrm{cn}}$ (Proposition 6.2.6.3). If F is symmetric monoidal and preserves connective objects, it follows that $F(\mathscr{F})$ is dualizable as an object of $\mathrm{QCoh}(Y)^{\mathrm{cn}}$, hence locally free of finite rank (and in particular flat). To fully exploit this observation, it will be useful to restrict our attention to geometric stacks which have "enough" sheaves which are locally free of finite rank.

Notation 9.3.3.1. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be an arbitrary functor. We let $\mathrm{Vect}(X)$ denote the full subcategory of $\mathrm{QCoh}(X)$ spanned by those quasi-coherent sheaves $\mathscr{F}$ which are locally free of finite rank (equivalently, $\mathrm{Vect}(X)$ is the full subcategory of $\mathrm{QCoh}(X)^{\mathrm{cn}}$ spanned by the dualizable objects: see Proposition 6.2.6.3).

Definition 9.3.3.2. Let X be a geometric stack. We will say that X *has the resolution property* if, for every truncated object $\mathscr{F} \in \mathrm{QCoh}(X)$, the following condition is satisfied:

($*$) There exists a collection of objects $\{\mathscr{E}_\alpha\}_{\alpha \in I}$ of $\mathrm{Vect}(X)$ and a collection of maps $\rho_\alpha : \mathscr{E}_\alpha \to \mathscr{F}$ for which the induced map $\bigoplus_{\alpha \in I} \pi_0 \mathscr{E}_\alpha \to \pi_0 \mathscr{F}$ is an epimorphism in the abelian category $\mathrm{QCoh}(X)^\heartsuit$.

Remark 9.3.3.3. In the situation of Definition 9.3.3.2, it suffices to verify condition ($*$) when $\mathscr{F}$ is connective.

Remark 9.3.3.4. Let X be a 0-truncated geometric stack. In this case, we can identify the $\mathrm{QCoh}(X)$ with the completed derived ∞-category of the abelian category $\mathrm{QCoh}(X)^\heartsuit$

(Proposition **??**). Using this identification, we can represented each truncated object $\mathscr{F} \in \mathrm{QCoh}(X)$ by a chain complex

$$\cdots \to \mathcal{I}_2 \xrightarrow{d_2} \mathcal{I}_1 \xrightarrow{d_1} \mathcal{I}_0 \xrightarrow{d_0} \mathcal{I}_{-1} \xrightarrow{d_{-1}} \mathcal{I}_{-2} \to \cdots$$

of injective objects of $\mathrm{QCoh}(X)^{\heartsuit}$, where $\mathcal{I}_n \simeq 0$ for $n \gg 0$. It follows that there exists a map $\ker(d_0) \to \mathscr{F}$ which is an epimorphism on π_0, where $\ker(d_0) \in \mathrm{QCoh}(X)^{\heartsuit}$. Consequently, in the situation of Definition 9.3.3.2, it suffices to verify condition $(*)$ in the special case where $\mathscr{F} \in \mathrm{QCoh}(X)^{\heartsuit}$.

Remark 9.3.3.5. Let X be a geometric stack and suppose that X is locally Noetherian (see Definition 9.5.1.1). Using Proposition 9.5.2.3 and Corollary **??**, we see that every object $\mathscr{F} \in \mathrm{QCoh}(X)_{\leqslant n}$ can be written as the colimit of a filtered diagram $\{\mathscr{F}_\beta\}$, where each $\mathscr{F}_\beta \in \mathrm{QCoh}(X)_{\leqslant n}$ is almost perfect. Consequently, to verify assertion $(*)$ of Definition 9.3.3.2 for X, it suffices to verify $(*)$ for each $\mathscr{F}_\beta$. Note that since $\mathscr{F}_\beta$ is almost perfect, a map $\bigoplus_{\alpha \in I} \mathscr{E}_\alpha \to \mathscr{F}_\beta$ induces an epimorphism on π_0 if and only if there exists a finite subset $I_0 \subseteq I$ for which the composite map

$$\bigoplus_{\alpha \in I_0} \mathscr{E}_\alpha \to \bigoplus_{\alpha \in I} \mathscr{E}_\alpha \to \mathscr{F}_\beta$$

is an epimorphism on π_0. It follows that X has the resolution property if and only if every truncated object $\mathscr{F} \in \mathrm{QCoh}(X)^{\mathrm{aperf}}$ satisfies the following condition:

$(*')$ There exists a map $\rho : \mathscr{E} \to \mathscr{F}$, where $\mathscr{E} \in \mathrm{Vect}(X)$ and the induced map $\pi_0 \mathscr{E} \to \pi_0 \mathscr{F}$ is an epimorphism in the abelian category $\mathrm{QCoh}(X)^{\heartsuit}$.

Remark 9.3.3.6. Let X be a geometric stack which is 0-truncated and locally Noetherian. Combining Remarks 9.3.3.3, 9.3.3.4, and 9.3.3.5, we see that X has the resolution property if and only if, for every object $\mathscr{F} \in \mathrm{Coh}(X)^{\heartsuit}$ (Notation 9.5.2.1), there exists an epimorphism $\mathscr{E} \to \mathscr{F}$ with $\mathscr{E} \in \mathrm{Vect}(X)$. In the setting of Artin stacks, this condition has been studied by many authors; see for example [217].

Proposition 9.3.3.7. *Let X be a geometric stack, and suppose that the structure sheaf $\mathscr{O}_X$ is a compact object of $\mathrm{QCoh}(X)$. The following conditions are equivalent:*

(1) *The geometric stack X has the resolution property (Definition 9.3.3.2).*

(2) *The full subcategory $\mathrm{Vect}(X) \subseteq \mathrm{QCoh}(X)^{\mathrm{cn}}$ is a generating subcategory for $\mathrm{QCoh}(X)^{\mathrm{cn}}$, in the sense of Definition C.2.1.1. In other words, for every object $\mathscr{F} \in \mathrm{QCoh}(X)^{\mathrm{cn}}$, there exists a collection of objects $\{\mathscr{E}_\alpha\}_{\alpha \in I}$ of $\mathrm{Vect}(X)$ and a map $\bigoplus_{\alpha \in I} \mathscr{E}_\alpha \to \mathscr{F}$ which is an epimorphism on π_0.*

Proof. The implication (2) $\Rightarrow$ (1) is immediate (and does not require the assumption that $\mathscr{O}_X$ is compact). To prove the converse, we note that the assumption that $\mathscr{O}_X$ is compact guarantees that there exists an integer $n \gg 0$ such that the functor $\mathscr{G} \mapsto \Gamma(X; \mathscr{G})$ carries $\mathrm{QCoh}(X)_{\geqslant 0}$ into $\mathrm{Sp}_{\geqslant -n}$ (Proposition 9.1.5.3). Let $\mathscr{F}$ be an arbitrary object of $\mathrm{QCoh}(X)$. Using assumption (1), we deduce the existence of objects $\mathscr{E}_\alpha \in \mathrm{Vect}(X)$ and maps $\rho_\alpha : \mathscr{E}_\alpha \to \tau_{\leqslant n} \mathscr{F}$ which induce an epimorphism $\bigoplus \pi_0 \mathscr{E}_\alpha \to \pi_0 \mathscr{F}$. Using the exactness of the sequences

$$\pi_0 \Gamma(X; \mathscr{E}_\alpha^\vee \otimes \mathscr{F}) \to \pi_0 \Gamma(X; \mathscr{E}_\alpha^\vee \otimes \tau_{\leqslant n} \mathscr{F}) \to \pi_{-1} \Gamma(X; \mathscr{E}_\alpha^\vee \otimes \tau_{\geqslant n+1} \mathscr{F})$$

(whose third terms vanishes, by virtue of our assumption on n), we see that each ρ_α can be lifted to a map $\overline{\rho}_\alpha : \mathscr{E}_\alpha \to \mathscr{F}$. We conclude by observing that the induced map $\bigoplus_{\alpha \in I} \mathscr{E}_\alpha \to \mathscr{F}$ is also surjective on π_0. □

Proposition 9.3.3.8. *Let $f : X \to Y$ be a morphism of geometric stacks. If f is quasi-affine and Y has the resolution property, then X has the resolution property.*

Proof. Let $\mathscr{F}$ be a truncated object of $\mathrm{QCoh}(X)$. Then $f_* \mathscr{F}$ is a truncated object of $\mathrm{QCoh}(Y)$. Since Y has the resolution property, we can choose objects $\mathscr{E}_\alpha \in \mathrm{Vect}(Y)$ and a map $\rho : \bigoplus_\alpha \mathscr{E}_\alpha \to f_* \mathscr{F}$ which induces an epimorphism on π_0. We can then identify ρ with a map $\rho' : \bigoplus_\alpha f^* \mathscr{E}_\alpha \to \mathscr{F}$ in $\mathrm{QCoh}(X)$. Since f is quasi-affine, it follows that ρ' is also an epimorphism on π_0. □

Corollary 9.3.3.9. *Let X be a geometric stack. If X has the resolution property, then the n-truncation of X also has the resolution property, for any $n \geqslant 0$.*

9.3.4 The Adams Condition

Let X be a geometric stack. It is somewhat difficult to verify that X has the resolution property by proceeding directly from the definition: *a priori*, it would require us to "resolve" every truncated quasi-coherent sheaf $\mathscr{F}$ on X by vector bundles. In this section, we will show that (under mild hypotheses) the condition that X has the resolution property admits an alternative formulation which is often much easier to verify.

Remark 9.3.4.1. For 0-truncated geometric stacks, the results of this section are due to Schäppi. We will follow the presentation of [178] with some minor modifications.

Definition 9.3.4.2. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a geometric stack. We will say that X *satisfies the Adams condition* if there exists a faithfully flat map $f : U \to X$ where U is affine and the direct image $f_* \mathscr{O}_U$ can be written as the colimit of a filtered diagram $\{\mathscr{F}_\alpha\}$, where each $\mathscr{F}_\alpha \in \mathrm{QCoh}(X)$ is locally free of finite rank.

Remark 9.3.4.3. Definition 9.3.4.2 can be regarded as a "derived" version of the notion of Adams stack introduced in [80]; it specializes to the definition given in [80] in the case when X is 0-truncated (that is, when there exists a faithfully flat morphism $\operatorname{Spec} A \to X$, where A is a commutative ring).

Remark 9.3.4.4. Let $f : X \to Y$ be a morphism of geometric stacks. If f is affine and Y satisfies the Adams condition, then X satisfies the Adams condition. To see this, suppose that $g : U \to Y$ is a faithfully flat morphism, where $g_* \mathscr{O}_U$ can be written as the colimit of a filtered diagram $\{\mathscr{F}_\alpha\}$ in $\operatorname{QCoh}(Y)$ with each $\mathscr{F}_\alpha$ locally free of finite rank. Form a pullback diagram

$$\begin{array}{ccc} V & \longrightarrow & U \\ \downarrow{\scriptstyle g'} & & \downarrow{\scriptstyle g} \\ X & \xrightarrow{f} & Y. \end{array}$$

Our assumption that f is affine guarantees that V is affine, and the projection formula allows us to identify $g'_* \mathscr{O}_V$ with the colimit of the diagram $\{f^* \mathscr{F}_\alpha\}$ in $\operatorname{QCoh}(X)$. Since g' is faithfully flat and each $f^* \mathscr{F}_\alpha$ is locally free of finite rank, it follows that X satisfies the Adams condition.

Remark 9.3.4.5. Let X be a geometric stack and let $n \geqslant 0$ be an integer. If X satisfies the Adams condition, then the n-truncation X' of X satisfies the Adams condition: this follows from Remark 9.3.4.4, since the canonical map $X' \to X$ is affine (see Remark **??**).

The terminology of Definition 9.3.4.2 is motivated by the following example, which based on an observation of Adams:

Example 9.3.4.6 (The Derived Moduli Stack of Formal Groups)**.** Let $\mathcal{FG}^{\mathrm{der}}$ denote the derived moduli stack of formal groups (Example 9.3.1.8). Then $\mathcal{FG}^{\mathrm{der}}$ satisfies the Adams condition. To see this, let MP denote the periodic complex bordism spectrum, given as the Thom spectrum of the (universal) virtual complex vector bundle ξ over the space $\mathbf{Z} \times \mathrm{BU}$. By construction, there exists a faithfully flat map $f : U \to \mathcal{FG}^{\mathrm{der}}$, where $U = \operatorname{Spec} \tau_{\geqslant 0} \mathrm{MP}$ is affine. One can show that the direct image $f_* \mathscr{O}_U \in \operatorname{QCoh}(\mathcal{FG}^{\mathrm{der}})$ is the truncation $\tau_{\geqslant 0} \mathscr{F}_{\mathrm{MP}}$, where $\mathscr{F}_{\mathrm{MP}} \in \operatorname{QCoh}(\mathcal{FG}^{\mathrm{der}})$ is the quasi-coherent sheaf appearing in Remark 9.3.1.9. The space $\mathbf{Z} \times \mathrm{BU}$ can be written as a filtered homotopy colimit $\varinjlim F_\alpha$, where each F_α is a disjoint union of Grassmann manifolds $\mathrm{Gr}_{p,q} = \{V \subseteq \mathbf{C}^{p+q} : \dim(V) = p\}$. For each index α, let E_α denote the Thom spectrum of $\xi|_{F_\alpha}$, so that we have equivalences

$$\varinjlim E_\alpha \simeq \mathrm{MP} \qquad \varinjlim \mathscr{F}_{E_\alpha} \simeq \mathscr{F}_{\mathrm{MP}} .$$

To prove the desired result, it suffices to observe that each $\tau_{\geqslant 0} \mathscr{F}_{E_\alpha} \in \operatorname{QCoh}(\mathcal{FG}^{\mathrm{der}})$ is locally free of finite rank. This is a consequence of the fact that each $\mathrm{Gr}_{p,q}$ admits a cell decomposition which uses only cells of even dimension (for example, the Bruhat decomposition of $\mathrm{Gr}_{p,q}$) together with the fact that the homotopy groups of MP are concentrated in even degrees.

Example 9.3.4.7 (The Moduli Stack of Formal Groups)**.** Let $\mathcal{FG}$ denote the moduli stack of formal groups (Example 9.3.1.7). Then $\mathcal{FG}$ satisfies the Adams condition. This follows from Example 9.3.4.6 and Remark 9.3.4.5, since $\mathcal{FG}$ can be identified with the 0-truncation of $\mathcal{FG}^{\mathrm{der}}$. For a more direct proof (which does not appeal to Quillen's work on the relationship between formal group laws and complex bordism) we refer the reader to [80].

The Adams condition of Definition 9.3.4.2 is linked to the resolution property of Definition 9.3.3.2 by the following result:

Theorem 9.3.4.8. *Let X be a geometric stack. Assume either that $\mathscr{O}_X$ is a compact object of $\mathrm{QCoh}(X)$ or that X is n-truncated for some $n \geqslant 0$. Then X has the resolution property if and only if X satisfies the Adams condition.*

Remark 9.3.4.9. When X is 0-truncated, Theorem 9.3.4.8 appears in [178].

Theorem 9.3.4.8 is a consequence of the following more precise assertions:

Proposition 9.3.4.10. *Let X be a geometric stack. If X satisfies the Adams condition, then X has the resolution property.*

Proposition 9.3.4.11. *Let X be a geometric stack. Assume either that $\mathscr{O}_X$ is a compact object of $\mathrm{QCoh}(X)$ or that X is n-truncated for some $n \geqslant 0$. Then, for any flat map $f : U \to X$ where U is affine, the direct image $f_* \mathscr{O}_U$ can be written as the colimit of a filtered diagram in $\mathrm{Vect}(X)$. In particular, X satisfies the Adams condition.*

Remark 9.3.4.12. It follows from Propositions 9.3.4.10 and 9.3.4.11 that, if $\mathscr{O}_X$ is compact or X is n-truncated, then the statement of the Adams condition appearing in Definition 9.3.4.2 does not depend on the choice of the faithfully flat map $f : U \to X$ (so long as U is affine).

Proof of Proposition 9.3.4.10. Let X be a geometric stack. If X satisfies the Adams condition, then we can choose a there exists a faithfully flat morphism $f : U \to X$ with U affine and an equivalence of $f_* \mathscr{O}_U$ with the colimit of a filtered diagram $\{\mathscr{E}_\alpha\}$, where each $\mathscr{E}_\alpha$ belongs to $\mathrm{Vect}(X)$. We wish to prove that X has the resolution property. Let $\mathscr{F}$ be a truncated object of $\mathrm{QCoh}(X)$. Since U is affine, we can choose a map $\bigoplus_{\beta \in I} \mathscr{O}_U \xrightarrow{u} f^* \mathscr{F}$ which induces an epimorphism on π_0. For each $\beta \in I$, we can identify the restriction of u to the corresponding summand of $\bigoplus_{\beta \in I} \mathscr{O}_U$ with a map $u_\beta : \mathscr{O}_X \to f_* f^* \mathscr{F} \simeq \mathscr{F} \otimes f_* \mathscr{O}_U \simeq \varinjlim \mathscr{F} \otimes \mathscr{E}_\alpha$. Using Proposition 9.1.5.1 (and our assumption that $\mathscr{F}$ is truncated), we deduce that u_β factors as a composition $\mathscr{O}_X \xrightarrow{u'_\beta} \mathscr{F} \otimes \mathscr{E}_\alpha \to \mathscr{F} \otimes f_* \mathscr{O}_U$ for some index α (which might depend on β). Then u'_β classifies a map $v_\beta : \mathscr{E}_\alpha^\vee \to \mathscr{F}$. Amalgamating these, we obtain a map $v : \bigoplus \mathscr{E}_\alpha^\vee \to \mathscr{F}$. By construction, the map u factors through $f^*(v)$. Since u induces an epimorphism on π_0, it follows that $f^*(v)$ also induces an epimorphism on π_0. The map f is faithfully flat, so that v must also induce an epimorphism on π_0. Allowing $\mathscr{F}$ to vary, we deduce that X has the resolution property. □

The proof of Proposition 9.3.4.11 is more involved. We first establish the following:

Lemma 9.3.4.13. *Let X be a geometric stack. Assume that X has the resolution property and satisfies one of the following additional conditions:*

- (i) *The structure sheaf $\mathscr{O}_X$ is a compact object of* $\mathrm{QCoh}(X)$.
- (ii) *There exists an integer $n \geqslant 0$ such that X is n-truncated.*

Let $f : U \to X$ be a flat morphism, where U is affine. Then the ∞-category $\mathrm{Vect}(X) \times_{\mathrm{QCoh}(X)} \mathrm{QCoh}(X)_{/f_* \mathscr{O}_U}$ *is filtered.*

Proof. Suppose we are given a finite simplicial set K and a diagram $q : K \to \mathrm{Vect}(X) \times_{\mathrm{QCoh}(X)} \mathrm{QCoh}(X)_{/f_* \mathscr{O}_U}$; we wish to show that q can be extended to a map $\overline{q} : K^{\rhd} \to \mathrm{Vect}(X) \times_{\mathrm{QCoh}(X)} \mathrm{QCoh}(X)_{/f_* \mathscr{O}_U}$. For each vertex $\alpha \in K$, let us view $q(\alpha)$ as an object $\mathscr{E}_\alpha \in \mathrm{Vect}(X)$ equipped with a map $u_\alpha : \mathscr{E}_\alpha \to f_* \mathscr{O}_U$, which we will identify with a map $u'_\alpha : f^* \mathscr{E}_\alpha \to \mathscr{O}_U$. Amalgamating the maps u'_α, we obtain a map $u' : \varinjlim_\alpha f^* \mathscr{E}_\alpha \to \mathscr{O}_U$, which we can identify with a map $u'^\vee : \mathscr{O}_U \to \varprojlim_\alpha f^* \mathscr{E}_\alpha^\vee \simeq f^* \varprojlim_\alpha \mathscr{E}_\alpha^\vee$. We claim that there exists a collection of objects $\{\mathscr{G}_\beta\}_{\beta \in I}$ in $\mathrm{Vect}(X)$ and a map $v : \bigoplus \mathscr{G}_\beta \to \varprojlim \mathscr{E}_\alpha^\vee$ in $\mathrm{QCoh}(X)$ which induces an epimorphism on π_0. If condition (ii) is satisfied, then there exists an integer $n \geqslant 0$ such that X is n-truncated, so that each $\mathscr{E}_\alpha^\vee \in \mathrm{Vect}(X)$ is also n-truncated and therefore $\varprojlim_\alpha \mathscr{E}_\alpha^\vee$ is an n-truncated object of $\mathrm{QCoh}(X)$. In this case, the existence of v follows from our assumption that X has the resolution property. If condition (i) is satisfied, the existence of v follows from Proposition 9.3.3.7.

Since U is affine, the structure sheaf $\mathscr{O}_U$ is a compact projective object of $\mathrm{QCoh}(U)^{\mathrm{cn}}$. It follows that we can choose a finite subset $I_0 \subseteq I$ for which the map $u'^\vee$ factors as a composition $\mathscr{O}_U \xrightarrow{w} \bigoplus_{\beta \in I_0} f^* \mathscr{G}_\beta \xrightarrow{f^* v} f^* \varprojlim_\alpha \mathscr{F}_\alpha^\vee$. Set $\mathscr{G} = \bigoplus_{\beta \in I_0} \mathscr{G}_\beta$, so that $\mathscr{G} \in \mathrm{QCoh}(X)$ is locally free of finite rank. Then $v_0 = v|_{\mathscr{G}}$ determines a morphism $v_0^\vee : \varinjlim_\alpha \mathscr{E}_\alpha \to \mathscr{G}^\vee$ in the ∞-category $\mathrm{QCoh}(X)$ for which the map u' factors as a composition

$$f^* \varinjlim_\alpha \mathscr{E}_\alpha \xrightarrow{f^* v_0^\vee} f^* \mathscr{G}^\vee \xrightarrow{w^\vee} \mathscr{O}_U;$$

a choice of such factorization can be identified with the desired extension $\overline{q}$. □

Proof of Proposition 9.3.4.11. Let X be a geometric stack satisfying the hypotheses of Lemma 9.3.4.13 and let $f : U \to X$ be a flat morphism, where U is affine. We wish to show that $f_* \mathscr{O}_U$ can be written as as the colimit of a filtered diagram in $\mathrm{Vect}(X)$. Let $\mathcal{C} = \mathrm{Fun}^\pi(\mathrm{Vect}(X)^{\mathrm{op}}, \mathcal{S})$ denote the full subcategory of $\mathrm{Fun}(\mathrm{Vect}(X)^{\mathrm{op}}, \mathcal{S})$ spanned by those functors which preserve finite products. The construction $(\mathscr{F} \in \mathrm{QCoh}(X)^{\mathrm{cn}}) \mapsto$

$\mathrm{Map}_{\mathrm{QCoh}(X)}(\bullet, \mathscr{F})$ determines a left exact functor of Grothendieck prestable ∞-categories $G : \mathrm{QCoh}(X)^{\mathrm{cn}} \to \mathcal{C}$. The functor G admits a left adjoint $F : \mathcal{C} \to \mathrm{QCoh}(X)^{\mathrm{cn}}$ (which can be characterized abstractly as the essentially unique extension of the inclusion $\mathrm{Vect}(X) \hookrightarrow \mathrm{QCoh}(X)^{\mathrm{cn}}$ which commutes with sifted colimits). Unwinding the definitions, we see that for each object $\mathscr{F} \in \mathrm{QCoh}(X)^{\mathrm{cn}}$, the counit map $v_{\mathscr{F}} : (F \circ G)(\mathscr{F}) \to \mathscr{F}$ can be identified with the natural map

$$\varinjlim_{\mathscr{E} \in \mathrm{Vect}(X) \times_{\mathrm{QCoh}(X)} \mathrm{QCoh}(X)_{/\mathscr{F}}} \mathscr{E} \to \mathscr{F}.$$

If $\mathscr{F} = f_* \mathscr{O}_U$, then Lemma 9.3.4.13 implies that the domain of $v_{\mathscr{F}}$ is the colimit of a filtered diagram taking values in $\mathrm{Vect}(X)$. It will therefore suffice to show that $v_{\mathscr{F}}$ is an equivalence. We consider two cases:

- (i) Suppose that $\mathscr{O}_X$ is compact. In this case, our assumption that X has the resolution property guarantees that $\mathrm{Vect}(X)$ is a generating subcategory of $\mathrm{QCoh}(X)^{\mathrm{cn}}$, in the sense of Definition C.2.1.1 (see Proposition 9.3.3.7). Since $\mathrm{QCoh}(X)^{\mathrm{cn}}$ is separated, the ∞-categorical Gabriel-Popescu theorem (Theorem C.2.1.6) implies that G is fully faithful, so that $v_{\mathscr{F}}$ is an equivalence for *every* object of $\mathscr{F} \in \mathrm{QCoh}(X)^{\mathrm{cn}}$.

- (ii) Suppose that X is n-truncated. Then every object $\mathscr{E} \in \mathrm{Vect}(X)$ is n-truncated. Combining our assumption that X has the resolution property with Propositions C.2.5.2 and C.2.5.3, we deduce that F is left exact and that G is fully faithful when restricted to n-truncated objects. In particular, for every n-truncated object $\mathscr{F} \in \mathrm{QCoh}(X)^{\mathrm{cn}}$, the counit map $v_{\mathscr{F}} : (F \circ G)(\mathscr{F}) \to \mathscr{F}$ is an equivalence. We now conclude by observing that our assumption that X is n-truncated guarantees that $f_* \mathscr{O}_U \in \mathrm{QCoh}(X)^{\mathrm{cn}}$ is n-truncated.

□

9.3.5 Consequences for Tannaka Duality

In the presence of the resolution property, Tannaka duality takes a particularly simple form.

Theorem 9.3.5.1 (Tannaka Duality for Adams Stacks)**.** *Let X be a geometric stack, and suppose that the* 0*-truncation of X has the resolution property. Then the construction* $(f : Y \to X) \mapsto (f^* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y))$ *determines a fully faithful embedding*

$$\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(Y, X) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y)),$$

whose essential image is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ *which preserve small colimits and connective objects.*

Remark 9.3.5.2. In the situation of Theorem **??**, the hypothesis that the 0-truncation of X has the resolution property is satisfied whenever X itself has the resolution property (Corollary 9.3.3.9).

Remark 9.3.5.3. Theorem 9.3.5.1 is a "derived" analogue of a result of Schäppi (see [178]), which we will discuss in §9.7; see Theorem **??**.

Proof of Theorem 9.3.5.1. Choose a faithfully flat map $f : U \to X$, where U is affine. By virtue of Theorem 9.3.0.3, it will suffice to show that if $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ is a symmetric monoidal functor which preserves small colimits and connective objects, then $F(\mathscr{O}_U) \in \mathrm{CAlg}(\mathrm{QCoh}(Y))$ is faithfully flat. To verify this condition, we may assume without loss of generality that $Y \simeq \operatorname{Spec} A$ is affine. Let us abuse notation by identifying F with a symmetric monoidal functor $\mathrm{QCoh}(X) \to \mathrm{Mod}_A$. Set $B = F(\pi_0 \mathscr{O}_X)$. Since F is right t-exact, the canonical map $A \simeq F(\mathscr{O}_X) \to F(\pi_0 \mathscr{O}_X) = B$ has 1-connective fiber. In particular, it induces an isomorphism of commutative rings $\pi_0 A \to \pi_0 B$. It follows that an A-algebra A' is faithfully flat if and only if the tensor product $B \otimes_A A'$ is faithfully flat over B. Note that F induces a functor $F' : \mathrm{Mod}_{\pi_0 \mathscr{O}_X}(\mathrm{QCoh}(X)) \to \mathrm{Mod}_B$ which fits into a commutative diagram

$$\begin{array}{ccc} \mathrm{QCoh}(X) & \xrightarrow{F} & \mathrm{Mod}_A \\ \downarrow & & \downarrow{\scriptstyle B\otimes_A} \\ \mathrm{Mod}_{\pi_0 \mathscr{O}_X}(\mathrm{QCoh}(X)) & \xrightarrow{F'} & \mathrm{Mod}_B . \end{array}$$

Here we can identify $\mathrm{Mod}_{\pi_0 \mathscr{O}_X}(\mathrm{QCoh}(X))$ with the ∞-category of quasi-coherent sheaves on the 0-truncation X_0 of X. Replacing X by X_0 and F by F', we are reduced to proving Theorem 9.3.5.1 in the special case where X is 0-truncated. In this case, Proposition 9.3.4.11 implies that we can write $f_* \mathscr{O}_U$ can be written as the colimit of a diagram $\{\mathscr{E}_\alpha\}_{\alpha \in I}$ indexed by a filtered partially ordered set I, where each $\mathscr{E}_\alpha$ belongs to $\mathrm{Vect}(X)$. Our assumption that X is 0-truncated implies that each $\mathscr{E}_\alpha$ belongs to the heart of $\mathrm{QCoh}(X)$. Since $\mathscr{O}_X$ is a compact object of $\mathrm{QCoh}(X)^\heartsuit$ (Proposition 9.1.5.1), we may assume that the unit map $e : \mathscr{O}_X \to f_* \mathscr{O}_U$ factors as a composition $\mathscr{O}_X \xrightarrow{e_\alpha} \mathscr{E}_\alpha \to f_* \mathscr{O}_X$ for some $\alpha \in I$. For $\beta \geqslant \alpha$, let e_β denote the composition of e_α with the transition map $\mathscr{E}_\alpha \to \mathscr{E}_\beta$, so that we have an equivalence $\mathrm{cofib}(e) \simeq \varinjlim_{\beta \geqslant \alpha} \mathrm{cofib}(e_\beta)$. By virtue of Lemma D.4.4.3, to prove that $F(f_* \mathscr{O}_U)$ is faithfully flat, it will suffice to show that $\mathrm{cofib}\, F(e) \simeq \varinjlim_{\beta \geqslant \alpha} F(\mathrm{cofib}(e_\beta)) \in \mathrm{Mod}_A$ is flat. Since the collection of flat objects of Mod_A is closed under filtered colimits, it will suffice to show that each $F(\mathrm{cofib}(e_\beta) \in \mathrm{Mod}_A$ is flat. In fact, we will prove that each $F(\mathrm{cofib}(e_\beta))$ is locally free of finite rank: that is, that it is a dualizable object of $\mathrm{Mod}_A^{\mathrm{cn}}$ (see Proposition 6.2.6.3). By assumption, the functor F is symmetric monoidal and preserves connective objects; it will therefore suffice to show that each $\mathrm{cofib}(e_\beta)$ is a dualizable object of $\mathrm{QCoh}(X)^{\mathrm{cn}}$.

Note that the composite map $f^* \mathscr{O}_X \xrightarrow{f^* e_\beta} f^* \mathscr{E}_\alpha \to f^* f_* \mathscr{O}_U \to \mathscr{O}_U$ is an equivalence, so that $f^* e_\alpha$ admits a left homotopy inverse. It follows that $\mathrm{cofib}(f^* e_\alpha) \simeq f^* \mathrm{cofib}(e_\beta)$ is a direct summand of $f^* \mathscr{E}_\alpha$, and is therefore locally free of finite rank. Since the map f is faithfully flat, it follows that $\mathrm{cofib}(e_\beta)$ is locally free of finite rank, and therefore dualizable as an object of $\mathrm{QCoh}(X)^{\mathrm{cn}}$ by virtue of Proposition 6.2.6.3. □

9.3.6 Example: Classifying Stacks over Dedekind Rings

The following observation furnishes many examples of geometric stacks with the resolution property:

Proposition 9.3.6.1. *Let X be a geometric stack. Suppose that there exists a faithfully flat morphism $q : \operatorname{Spec} R \to X$, where R is a Dedekind ring. Then the inclusion $\mathrm{Vect}(X) \hookrightarrow \mathrm{QCoh}(X)$ induces an equivalence of ∞-categories $\mathrm{Ind}(\mathrm{Vect}(X)) \simeq \mathrm{QCoh}(X)^\flat$; here $\mathrm{QCoh}(X)^\flat$ denotes the full subcategory of $\mathrm{QCoh}(X)$ spanned by the flat objects.*

Corollary 9.3.6.2. *Let X be a geometric stack. If there exists a faithfully flat morphism $\operatorname{Spec} R \to X$, where R is a Dedekind ring, then X has the resolution property.*

Proof. Combine Propositions 9.3.6.1 and 9.3.4.10. □

Example 9.3.6.3. Let R be a Dedekind ring and let G be a flat affine group scheme over R. Then the classifying stack BG (see Example 9.1.1.7) has the resolution property.

Proof of Proposition 9.3.6.1. Let $U : \mathrm{QCoh}(X)^\heartsuit \to \mathrm{QCoh}(X)^\heartsuit$ denote the functor given by $q_* q^*$. For any object $\mathscr{G} \in \mathrm{QCoh}(X)^\heartsuit$, we can identify $\mathscr{G}$ with the totalization of the cosimplicial object $U^{\bullet+1}\mathscr{G}$. For each $\mathscr{F} \in \mathrm{QCoh}(X)^\heartsuit$, we have a canonical bijection

$$\begin{aligned}
\mathrm{Hom}_{\mathrm{QCoh}(X)^\heartsuit}(\mathscr{F}, \mathscr{G}) &\simeq \mathrm{Tot}(\mathrm{Hom}_{\mathrm{QCoh}(X)^\heartsuit}(\mathscr{F}, U^{\bullet+1}\mathscr{G}) \\
&\simeq \ker(\mathrm{Hom}_{\mathrm{QCoh}(X)^\heartsuit}(\mathscr{F}, U\mathscr{G}) \to \mathrm{Hom}_{\mathrm{QCoh}(X)^\heartsuit}(\mathscr{F}, U^2\mathscr{G})) \\
&\simeq \ker(\mathrm{Hom}_{\mathrm{Mod}_R^\heartsuit}(q^*\mathscr{F}, q^*\mathscr{G}) \to \mathrm{Hom}_{\mathrm{Mod}_R^\heartsuit}(q^*\mathscr{F}, q^* q_* q^*\mathscr{G})).
\end{aligned}$$

If $\mathscr{F}$ is locally free of finite rank, then $q^*\mathscr{F}$ is compact as an object of $\mathrm{Mod}_R^\heartsuit$, so that the constructions

$$\mathscr{G} \mapsto \mathrm{Hom}_{\mathrm{Mod}_R^\heartsuit}(q^*\mathscr{F}, q^*\mathscr{G}) \qquad \mathscr{G} \mapsto \mathrm{Hom}_{\mathrm{Mod}_R^\heartsuit}(q^*\mathscr{F}, q^* q_* q^*\mathscr{G})$$

commute with filtered colimits. It follows that the construction $\mathscr{G} \mapsto \mathrm{Hom}_{\mathrm{QCoh}(X)^\heartsuit}(\mathscr{F}, \mathscr{G})$ also commutes with filtered colimits: that is, $\mathscr{F}$ is a compact object of the abelian category $\mathrm{QCoh}(X)^\heartsuit$, and therefore also as an object of $\mathrm{QCoh}(X)^\flat$. It follows that the construction $\theta : \mathrm{Ind}(\mathrm{Vect}(X)) \to \mathrm{QCoh}(X)^\flat$ is fully faithful.

We now prove that θ is essentially surjective. Let $\mathscr{F} \in \mathrm{QCoh}(X)^{\flat}$, so that $M = q^* \mathscr{F}$ is a flat R-module. Write M as a union $\bigcup M_\alpha$, where each M_α is a finitely generated submodule of M. For each index α, set $\mathscr{F}_\alpha = \mathscr{F} \times_{q_* M} q_* M_\alpha$, where the fiber product is formed in the abelian category $\mathrm{QCoh}(X)^{\heartsuit}$. Since $\mathrm{QCoh}(X)^{\heartsuit}$ is a Grothendieck abelian category, the formation of filtered colimits in $\mathrm{QCoh}(X)^{\heartsuit}$ commutes with finite limits. We therefore have an equivalence $\mathscr{F} \simeq \varinjlim \mathscr{F}_\alpha$. To complete the proof, it will suffice to show that each $\mathscr{F}_\alpha$ is locally free of finite rank. In other words, we wish to show that $q^* \mathscr{F}_\alpha$ is locally free of finite rank when regarded as an R-module. Note that the projection map $\mathscr{F}_\alpha \to \mathscr{F}$ induces a monomorphism $q^* \mathscr{F}_\alpha \to q^* \mathscr{F} \simeq M$ which factors through M_α, so that $q^* \mathscr{F}_\alpha$ is a submodule of M_α. Since M_α is finitely generated and R is Noetherian, it follows that $q^* \mathscr{F}_\alpha$ is also finitely generated as an R-module. The flatness $\mathscr{F}$ guarantees that $M = q^* \mathscr{F}$ is a torsion free R-module, so that the submodule $q^* \mathscr{F}_\alpha$ is also torsion-free and therefore a locally free R-module (by virtue of our assumption that R is a Dedekind ring). □

9.3.7 Restriction to Vector Bundles

Let X be a geometric stack. It follows from Proposition 9.2.2.1 that an A-valued point $\eta \in X(A)$ is determined (up to contractible ambiguity) by the symmetric monoidal pullback functor $\eta^* : \mathrm{QCoh}(X) \to \mathrm{Mod}_A$. In fact, we can often make do with less: if X has "enough" vector bundles, then η is determined by the functor $\eta^*|_{\mathrm{Vect}(X)}$.

Theorem 9.3.7.1 (Tannaka Duality, Vector Bundle Version)**.** *Let X be a geometric stack which has the resolution property. Assume either that X is n-truncated for some integer $n \geqslant 0$ or that $\mathscr{O}_X$ is a compact object of* $\mathrm{QCoh}(X)$*. Then, for any functor $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, the construction $(f : Y \to X) \mapsto (f^* : \mathrm{Vect}(X) \to \mathrm{Vect}(Y))$ determines a fully faithful embedding*

$$\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(Y, X) \to \mathrm{Fun}^{\otimes}(\mathrm{Vect}(X), \mathrm{Vect}(Y))$$

whose essential image is spanned by those symmetric monoidal functors $f : \mathrm{Vect}(X) \to \mathrm{Vect}(Y)$ which satisfy the following condition:

(∗) *The functor f preserves zero objects and, for every diagram σ :*

$$\begin{array}{ccc} \mathscr{E}' & \longrightarrow & \mathscr{E} \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & \mathscr{E}'' \end{array}$$

in $\mathrm{Vect}(X)$ *which is a cofiber sequence* $\mathrm{QCoh}(X)^{\mathrm{cn}}$*, the image $f(\sigma)$ is a cofiber sequence in* $\mathrm{QCoh}(Y)^{\mathrm{cn}}$*.*

Remark 9.3.7.2. In the special case where X is 0-truncated, Theorem **??** was proven by Schäppi in [178].

Before giving the proof of Theorem 9.3.7.1, let us describe some of its consequences.

Corollary 9.3.7.3. *Let R be a Dedekind ring, let G be a flat affine group scheme over R, and let $\mathrm{Rep}(G)$ denote the category of algebraic representations of G which are projective R-modules of finite rank (which we identify with the full subcategory $\mathrm{Vect}(BG) \subseteq \mathrm{QCoh}(BG)$). Let $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be an arbitrary functor. Then the canonical map*

$$\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(Y, BG) \to \mathrm{Fun}^{\otimes}(\mathrm{Rep}(G), \mathrm{Vect}(Y))$$

is a fully faithful embedding, whose essential image is the full subcategory spanned by those symmetric monoidal functors $F : \mathrm{Rep}(G) \to \mathrm{Vect}(Y)$ which carry exact sequences

$$0 \to V' \to V \to V'' \to 0$$

in $\mathrm{Rep}(G)$ to fiber sequences in $\mathrm{QCoh}(Y)$.

Proof. Combine Theorem 9.3.7.1 with Proposition 9.3.6.1. □

Warning 9.3.7.4. In the situation of Corollary 9.3.7.3, the exactness condition on the functor $F : \mathrm{Rep}(G) \to \mathrm{Vect}(Y)$ is not automatic. For example, suppose that $Y = \mathrm{Spec}\, \mathbf{C}[x, y]$ is an affine space of dimension 2, and that $U \subseteq Y$ is the open subset obtained from Y by deleting the origin. Then the restriction map $\mathrm{Vect}(Y) \to \mathrm{Vect}(U)$ is an equivalence of symmetric monoidal categories. However, there can exist G-torsors $\mathcal{P}$ on U which do not extend to G-torsors on Y. For example, if $G = \mathbf{G}_a$ denotes the additive group (regarded as a group scheme over $\mathbf{C}$, say), then every G-torsor on Y is trivial (since Y is affine), while G-torsors on U are classified up to isomorphism by the cohomology group $\mathrm{H}^1(U; \mathscr{O}_U)$ (which is an infinite-dimensional vector space over $\mathbf{C}$). Nontrivial elements of $\mathrm{H}^1(U; \mathscr{O}_U)$ are classified by symmetric monoidal functors $\mathrm{Rep}(G) \to \mathrm{Vect}(U) \simeq \mathrm{Vect}(Y)$ which carry exact sequences in $\mathrm{Rep}(G)$ to diagrams $0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0$ in $\mathrm{Vect}(Y)$ which are not necessarily exact (but are exact when restricted to U).

From Corollary **??**, we immediately deduce a slightly stronger version of Theorem 9.0.0.1:

Corollary 9.3.7.5. *Let R be a Dedekind ring, let G be a flat affine group scheme over R, let A be a commutative R-algebra, and let $e : \mathrm{Rep}(G) \to \mathrm{Mod}_A^{\mathrm{lf}}$ be the symmetric monoidal functor given by $V \mapsto A \otimes_R V$. Then the canonical map $G(A) \to \mathrm{Aut}^{\otimes}(e)$ is an isomorphism, where $\mathrm{Aut}^{\otimes}(e)$ denotes the automorphism group of e in the category $\mathrm{Fun}^{\otimes}(\mathrm{Rep}(G), \mathrm{Mod}_A^{\mathrm{lf}})$ of symmetric monoidal functors from $\mathrm{Rep}(G)$ to $\mathrm{Mod}_A^{\mathrm{lf}}$.*

Corollary 9.3.7.6. *Let X be a geometric stack which has the resolution property. Assume either that X is n-truncated for some integer $n \geqslant 0$ or that $\mathscr{O}_X$ is a compact object of $\mathrm{QCoh}(X)$. Let R be a connective $\mathbb{E}_\infty$-ring which is complete with respect to a finitely* *generated ideal I, let Y be a spectral algebraic spaces which is proper and almost of finite presentation over R, and let $\mathsf{Y}^\wedge = \mathsf{Y} \times_{\operatorname{Spec} R} \operatorname{Spf} R$ be the formal completion of Y along the vanishing locus of I. Let us abuse notation by regarding Y and $\mathsf{Y}^\wedge$ with the functors $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ that they represent. Then the canonical map*

$$\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(\mathsf{Y}, X) \to \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(\mathsf{Y}^\wedge, X)$$

is a homotopy equivalence.

Proof. By virtue of Theorem 9.3.7.1, it will suffice to show that the restriction map $\mathrm{Vect}(\mathsf{Y}) \to \mathrm{Vect}(\mathsf{Y}^\wedge)$ is an equivalence of ∞-categories. Note that $\mathrm{Vect}(\mathsf{Y})$ and $\mathrm{Vect}(\mathsf{Y}^\wedge)$ can be identified with the full subcategories of $\mathrm{QCoh}(\mathsf{Y})^{\mathrm{aperf},\mathrm{cn}}$ and $\mathrm{QCoh}(\mathsf{Y}^\wedge)^{\mathrm{aperf},\mathrm{cn}}$ spanned by the dualizable objects. We conclude by observing that Theorem 8.5.0.3 (together with Theorems 8.3.4.4 and 8.3.5.2) and Proposition 8.5.1.4 imply that the restriction functor $\mathrm{QCoh}(\mathsf{Y})^{\mathrm{aperf},\mathrm{cn}} \to \mathrm{QCoh}(\mathsf{Y}^\wedge)^{\mathrm{aperf},\mathrm{cn}}$ is an equivalence of ∞-categories. □

The proof of Theorem 9.3.7.1 is based on the following:

Proposition 9.3.7.7. *Let X be a geometric stack which has the resolution property. Assume either that X is n-truncated for some integer $n \geqslant 0$ or that $\mathscr{O}_X$ is a compact object of $\mathrm{QCoh}(X)$. Let $G : \mathrm{QCoh}(X)^{\mathrm{cn}} \to \mathrm{Fun}^{\pi}(\mathrm{Vect}(X)^{\mathrm{op}}, \mathcal{S})$ be the functor given by $G(\mathscr{F})(\mathscr{E}) = \mathrm{Map}_{\mathrm{QCoh}(X)}(\mathscr{E}, \mathscr{F})$. Then, for every integer $m \geqslant 0$, the functor G restricts to a fully faithful embedding*

$$\mathrm{QCoh}(X)^{\mathrm{cn}}_{\leqslant m} \hookrightarrow \mathrm{Fun}^{\pi}(\mathrm{Vect}(X)^{\mathrm{op}}, \tau_{\leqslant m} \mathcal{S})$$

whose essential image is spanned by those functors $\lambda : \mathrm{Vect}(X)^{\mathrm{op}} \to \tau_{\leqslant m} \mathcal{S}$ which satisfy the following additional condition:

($\star$) *The space $\lambda(0)$ is contractible and, for every diagram σ :*

$$\begin{array}{ccc} \mathscr{E}' & \longrightarrow & \mathscr{E} \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & \mathscr{E}'' \end{array}$$

in $\mathrm{Vect}(X)$ which is a cofiber sequence $\mathrm{QCoh}(X)^{\mathrm{cn}}$, the diagram $\lambda(\sigma)$ is a pullback square in $\mathcal{S}$.

Proof. Set $\mathcal{C} = \mathrm{Fun}^{\pi}(\mathrm{Vect}(X)^{\mathrm{op}}, \mathcal{S})$, and let $F : \mathcal{C} \to \mathrm{QCoh}(X)^{\mathrm{cn}}$ be left adjoint to G. Using our assumption that X has the resolution property (together with Proposition 9.3.3.7), we see that $\mathrm{Vect}(X) \hookrightarrow \mathrm{QCoh}(X)^{\mathrm{cn}}$ satisfies the hypothesis $(*_k)$ of Propositions C.2.5.2 and C.2.5.3, where we take $k = \infty$ if $\mathscr{O}_X$ is a compact object of $\mathrm{QCoh}(X)$, or any finite $k \geqslant n$ if X is n-truncated. We therefore obtain the following:

(i) The functor $F : \mathcal{C} \to \mathrm{QCoh}(X)^{\mathrm{cn}}$ is left exact.

(ii) The functor G is fully faithful when restricted to $\mathrm{QCoh}(X)^{\mathrm{cn}}_{\leqslant m}$, for any $m \geqslant 0$. (moreover, if $\mathscr{O}_X$ is compact, then the functor G itself is fully faithful).

Let $\mathcal{C}_0 \subseteq \mathcal{C}$ denote the full subcategory spanned by the m-truncated objects functors which satisfy condition $(\star)$, and let $\mathcal{C}_1$ be the essential image of $G|_{\mathrm{QCoh}(X)^{\mathrm{cn}}_{\leqslant m}}$. We wish to show that $\mathcal{C}_0 = \mathcal{C}_1$. The inclusion $\mathcal{C}_1 \subseteq \mathcal{C}_0$ follows immediately from the definition. To prove the reverse inclusion, we observe that for every object $C \in \mathcal{C}_0$, the unit map $u : C \to (G \circ F)(C)$ is m-truncated (since the domain and codomain of u are m-truncated), the codomain of u belongs to $\mathcal{C}_1$, and $F(u)$ is an equivalence (since the functor G is fully faithful). It will therefore suffice to prove the following:

(a_k) Let $f : C \to D$ be a k-truncated morphism between objects of $\mathcal{C}_0$. If $F(f)$ is an equivalence, then f is an equivalence.

Our proof of (a_k) proceeds by induction on k. If $k = -2$, then the assumption that f is k-truncated guarantees that f is an equivalence, so there is nothing to prove. Let us therefore assume that $k \geqslant -1$. Our assumption that f is k-truncated implies that the diagonal map $\delta : C \to C \times_D C$ is $(k-1)$-truncated. Using (i), we deduce that $F(\delta)$ is an equivalence, so that our inductive hypothesis guarantees that δ is an equivalence. It follows that the morphism $f : C \to D$ is (-1)-truncated: that is, it induces a homotopy equivalence $C(\mathscr{E}) \to D(\mathscr{E})$ for each object $\mathscr{E} \in \mathrm{Vect}(X)$. To complete the proof that f is an equivalence, it will suffice to show that each point $\eta \in D(\mathscr{E})$ can be lifted to a point of $C(\mathscr{E})$. To prove this, we can replace D by $\mathscr{E}$ and C by the fiber product $C \times_D \mathscr{E}$ and thereby reduce to the case where η classifies an equivalence $\mathscr{E} \to D$ in the ∞-category $\mathcal{C}$.

Choose a collection of objects $\{\mathscr{E}_i\}_{i \in I}$ in $\mathrm{Vect}(X)$ and morphisms $\phi_i : \mathscr{E}_i \to C$ which induce an epimorphism $\pi_0(\bigoplus \mathscr{E}_i) \to \pi_0 C$ in the abelian category $\mathcal{C}^{\heartsuit}$. Since $F(f)$ is an equivalence, it follows that the composite map

$$\psi : \bigoplus_{i \in I} \mathscr{E}_i \xrightarrow{F(\phi_i)} F(C) \xrightarrow{F(f)} F(D) = \mathscr{E}$$

induces an epimorphism on π_0 in the abelian category $\mathrm{QCoh}(X)^{\heartsuit}$. We may therefore choose a finite subset $I_0 \subseteq I$ for which $\psi|_{\bigoplus_{i \in I_0} \mathscr{E}_i}$ induces an epimorphism on π_0. Set $\overline{\mathscr{E}} = \bigoplus_{i \in I_0} \mathscr{E}_i$. Amalgamating the maps $\{\phi_i\}_{i \in I_0}$, we obtain a morphism $\phi : \overline{\mathscr{E}} \to \mathscr{E}$ in $\mathrm{Vect}(X)$ which induces an epimorphism on π_0, so that the fiber $\mathrm{fib}(\phi)$ belongs to $\mathrm{Vect}(X)$. Since $C, D \in \mathcal{C}_0$, we have a commutative diagram of fiber sequences

$$\begin{array}{ccccc} C(\mathscr{E}) & \longrightarrow & C(\overline{\mathscr{E}}) & \longrightarrow & C(\mathrm{fib}(\phi)) \\ \downarrow & & \downarrow & & \downarrow \\ D(\mathscr{E}) & \longrightarrow & D(\overline{\mathscr{E}}) & \longrightarrow & D(\mathrm{fib}(\phi)) \end{array}$$

where the vertical maps are induced by f and therefore have (-1)-truncated homotopy fibers. By construction, the image of η in $D(\overline{\mathscr{E}})$ can be lifted to a point of $C(\overline{\mathscr{E}})$, so that η can be lifted to a point of $C(\mathscr{E})$ as desired. □

Proof of Theorem 9.3.7.1. Let X be a geometric stack with the resolution property. If $\mathcal{D}$ is an ∞-category which admits small colimits, we let $\mathrm{Fun}^{\otimes}_{\mathrm{ex}}(\mathrm{Vect}(X), \mathcal{D})$ denote the full subcategory of $\mathrm{Fun}^{\otimes}(\mathrm{Vect}(X), \mathcal{D})$ spanned by those symmetric monoidal functors f which satisfy the following additional condition:

$(*_{\mathcal{D}})$ The functor f preserves initial objects and, for every diagram σ :

$$\begin{array}{ccc} \mathscr{E}' & \longrightarrow & \mathscr{E} \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & \mathscr{E}'' \end{array}$$

in $\mathrm{Vect}(X)$ which is a cofiber sequence $\mathrm{QCoh}(X)^{\mathrm{cn}}$, the image $f(\sigma)$ is a cofiber sequence in $\mathrm{QCoh}(Y)^{\mathrm{cn}}$.

Note that when $\mathcal{D} = \mathrm{QCoh}(Y)^{\mathrm{cn}}$, then any symmetric monoidal functor $f : \mathrm{Vect}(X) \to \mathcal{D}$ automatically factors through the full subcategory $\mathrm{Vect}(Y) \subseteq \mathrm{QCoh}(Y)^{\mathrm{cn}}$.

Assume now that either X is n-truncated for some integer n, or that the structure sheaf $\mathscr{O}_X$ is a compact object of $\mathrm{QCoh}(X)$. We wish to show that the canonical map

$$\rho : \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(Y, X) \to \mathrm{Fun}^{\otimes}_{\mathrm{ex}}(\mathrm{Vect}(X), \mathrm{QCoh}(Y)^{\mathrm{cn}})$$

is an equivalence of ∞-categories. Without loss of generality, we may assume that $Y = \operatorname{Spec} R$ is affine. Using Theorem 9.3.5.1, we can identify the domain of ρ with the ∞-category $\mathrm{LFun}^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{cn}}, \mathrm{QCoh}(Y)^{\mathrm{cn}})$ of colimit-preserving symmetric monoidal functors from $\mathrm{QCoh}(X)^{\mathrm{cn}}$ to $\mathrm{QCoh}(Y)^{\mathrm{cn}}$. In this case, we can identify ρ with the limit of a tower of forgetful functors

$$\rho_m : \mathrm{LFun}^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{cn}}, \mathrm{QCoh}(Y)^{\mathrm{cn}}_{\leqslant m}) \to \mathrm{Fun}^{\otimes}_{\mathrm{ex}}(\mathrm{Vect}(X), \mathrm{QCoh}(Y)^{\mathrm{cn}}_{\leqslant m}).$$

It will therefore suffice to show that each ρ_m is an equivalence of ∞-categories.

Let $\mathcal{C} = \mathcal{P}_{\Sigma}(\mathrm{Vect}(X))$ be the full subcategory $\mathrm{Fun}^{\pi}(\mathrm{Vect}(X)^{\mathrm{op}}, \mathcal{S}) \subseteq \mathrm{Fun}(\mathrm{Vect}(X)^{\mathrm{op}}, \mathcal{S})$ spanned by those functors which preserve finite products. Let us abuse notation by identifying $\mathrm{Vect}(X)$ with its essential image under the Yoneda embedding $\mathrm{Vect}(X) \to \mathcal{C}$. Using the results of §**??**, we see that if $\mathcal{D}$ is any presentable symmetric monoidal ∞-category (whose tensor product preserves small colimits separately in each variable), then the restriction functor $\theta : \mathrm{LFun}^{\otimes}(\mathcal{C}, \mathcal{D}) \to \mathrm{Fun}^{\otimes}(\mathrm{Vect}(X), \mathcal{D})$ is fully faithful, and its essential image is spanned by those symmetric monoidal functors $\mathrm{Vect}(X) \to \mathcal{D}$ which preserve finite coproducts. In particular, the inclusion $\mathrm{Vect}(X) \hookrightarrow \mathrm{QCoh}(X)^{\mathrm{cn}}$ determines an object $F : \mathrm{LFun}^{\otimes}(\mathcal{C}, \mathrm{QCoh}(X)^{\mathrm{cn}})$. Let $\mathrm{LFun}^{\otimes}_0(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\mathrm{LFun}^{\otimes}(\mathcal{C}, \mathcal{D})$ spanned by those functors which satisfy condition $(*_{\mathcal{D}})$, so that θ restricts to an equivalence of ∞-categories $\mathrm{LFun}^{\otimes}_0(\mathcal{C}, \mathcal{D}) \to \mathrm{Fun}^{\otimes}_{\mathrm{ex}}(\mathrm{Vect}(X), \mathcal{D})$. Under this equivalence, we see can identify ρ_m with the functor

$$\mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{cn}}, \mathrm{QCoh}(Y)^{\mathrm{cn}}_{\leqslant m}) \to \mathrm{Fun}^{\otimes}_0(\mathcal{C}, \mathrm{QCoh}(Y)^{\mathrm{cn}}_{\leqslant m})$$

given by composition with F. It follows from Proposition 9.3.7.7 that this functor is an equivalence of ∞-categories. □

9.4 Perfect Stacks

Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a quasi-geometric stack. For every connective $\mathbb{E}_\infty$-ring R, Theorem 9.2.0.2 supplies a fully faithful embedding $X(R) \hookrightarrow \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{Mod}_R)$, whose essential image is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X) \to \mathrm{Mod}_R$ which satisfy the following conditions:

(1) The functor F preserves small colimits and is right t-exact.

(2) The functor F admits a right adjoint G which preserves small colimits and satisfies a projection formula.

In this section, we will show that for a large class of quasi-geometric stacks X, condition (2) is a formal consequence of (1). To get a sense of the ideas involved, note that if the stable ∞-category $\mathrm{QCoh}(X)$ is compactly generated, then a colimit-preserving functor $F : \mathrm{QCoh}(X) \to \mathrm{Mod}_R$ preserves compact objects if and only if it has a right adjoint G which preserves filtered colimits (hence all colimits, since G is an exact functor between stable ∞-categories). Consequently, to simplify the hypotheses of Theorem 9.2.0.2, it is convenient to assume that the ∞-category $\mathrm{QCoh}(X)$ is compactly generated. Following [23], we will say that a quasi-geometric stack X is *perfect* if the canonical map $\mathrm{Ind}(\mathrm{QCoh}(X)^{\mathrm{perf}}) \to \mathrm{QCoh}(X)$ is an equivalence of ∞-categories (see Definition 9.4.4.1). A result of Bhatt and Halpern-Leistner asserts that if X is perfect, then a symmetric monoidal functor $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ is given by pullback along a map $f : Y \to X$ if and only if F preserves small colimits and connective objects (Corollary 9.4.4.7). In this section, we will introduce several *a priori* weaker conditions on X which guarantee the same result, which are related as follows:

$$\begin{array}{c} X \text{ is perfect} \\ \Downarrow \\ X \text{ is weakly perfect} \\ \Downarrow \\ \mathrm{QCoh}(X) \text{ is dualizable} \\ \Downarrow \\ X \text{ has the diagonal approximation property.} \end{array}$$

Remark 9.4.0.1. We do not know which (if any) of the above implications are reversible.

9.4.1 The Diagonal Approximation Property

Let $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ denote the subcategory of $\widehat{\mathcal{C}\mathrm{at}}_\infty$ whose objects are presentable stable ∞-categories and whose morphisms are functors which preserve small colimits. We will regard $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ as equipped with the symmetric monoidal structure described in §HA.4.8.2 : if $\mathcal{C}$ and $\mathcal{D}$ are presentable stable ∞-categories, then the tensor product $\mathcal{C} \otimes \mathcal{D}$ is universal among presentable stable ∞-categories $\mathcal{E}$ for which there exists a map $\mathcal{C} \times \mathcal{D} \to \mathcal{E}$ which preserves small colimits separately in each variable.

Construction 9.4.1.1. Let $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be quasi-geometric stacks, and consider the projection maps $X \xleftarrow{p} X \times Y \xrightarrow{q} Y$. For every pair of quasi-coherent sheaves $\mathscr{F} \in \mathrm{QCoh}(X)$ and $\mathscr{G} \in \mathrm{QCoh}(Y)$, we let $\mathscr{F} \boxtimes \mathscr{G}$ denote the tensor product $p^* \mathscr{F} \otimes q^* \mathscr{G} \in \mathrm{QCoh}(X \times Y)$. We will refer to $\mathscr{F} \boxtimes \mathscr{G}$ as the *external tensor product of* $\mathscr{F}$ *and* $\mathscr{G}$. The construction $(\mathscr{F}, \mathscr{G}) \mapsto \mathscr{F} \boxtimes \mathscr{G}$ determines a functor $\boxtimes : \mathrm{QCoh}(X) \times \mathrm{QCoh}(Y) \to \mathrm{QCoh}(X \times Y)$ which preserves colimits separately in each variable, and is therefore classified by a colimit-preserving functor $e_{X,Y} : \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(Y) \to \mathrm{QCoh}(X \times Y)$.

Definition 9.4.1.2. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a quasi-geometric stack. We will say that X has the *diagonal approximation property* if the functor $e_{X,X} : \mathrm{QCoh}(X) \times \mathrm{QCoh}(X) \to \mathrm{QCoh}(X \times X)$ of Construction 9.4.1.1 is an equivalence of ∞-categories.

Remark 9.4.1.3. Let X be a quasi-geometric stack and let $\delta : X \to X \times X$ denote the diagonal map. The terminology of Definition 9.4.1.2 is motivated by the observation that if X has the diagonal approximation property, then $\delta_* \mathscr{O}_X$ belongs to the essential image of the functor $e_{X,X} : \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(X) \to \mathrm{QCoh}(X \times X)$ (in other words, the structure sheaf of the diagonal of X can be "built from" quasi-coherent sheaves which are arise as pullbacks along the projection maps $X \leftarrow X \times X \to X$). We will see later that under a mild additional hypothesis, the converse holds: that is, if $\delta_* \mathscr{O}_X$ belongs to the essential image of $e_{X,X}$, then $e_{X,X}$ is an equivalence of ∞-categories (Corollary 9.4.3.2).

Our main interest in Definition 9.4.1.2 is due to the following:

Theorem 9.4.1.4 (Tannaka Duality, Diagonal Approximation Version)**.** *Let $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be functors. Assume that X is a quasi-geometric stack with the diagonal approximation property. Then the construction $(f : Y \to X) \mapsto (f^* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y))$ determines a fully faithful embedding*

$$\theta : \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(Y, X) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y))$$

whose essential image is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ which preserve small colimits and connective objects.

Proof. Writing Y as a (not necessarily small) colimit of corepresentable functors, we can reduce to the case where $Y = \mathrm{Spec}\, R$ for some connective $\mathbb{E}_\infty$-ring R. In this case, Theorem 9.2.0.2 implies that the functor θ is a fully faithful embedding whose essential image is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ which preserve small colimits, connective objects, and admit a right adjoint G which preserves small colimits and satisfies the projection formula. To prove Theorem 9.4.1.4, it will suffice to verify the following:

($*$) Let $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ be a symmetric monoidal functor which preserves small colimits. Then F admits a right adjoint $G : \mathrm{QCoh}(Y) \to \mathrm{QCoh}(X)$ which also preserves small colimits. Moreover, the functor G is automatically $\mathrm{QCoh}(X)$-linear (that is, G satisfies the projection formula).

To prove ($*$), we note that the functor F factors as a composition

$$\mathrm{QCoh}(X) \xrightarrow{F'} \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(Y) \xrightarrow{F''} \mathrm{QCoh}(Y),$$

where F' is obtained by tensoring the identity functor $\mathrm{id}_{\mathrm{QCoh}(X)}$ with the unit map $e : \mathrm{Sp} \to \mathrm{QCoh}(Y)$ classifying the structure sheaf $\mathscr{O}_Y$, while F'' classifies the functor $\mathrm{QCoh}(X) \times \mathrm{QCoh}(Y) \to \mathrm{QCoh}(Y)$ given by $(\mathscr{F}, \mathscr{G}) \mapsto F(\mathscr{F}) \otimes \mathscr{G}$. Let us regard $\mathrm{QCoh}(X) \otimes \mathrm{QCoh}(Y)$ as a $\mathrm{QCoh}(X)$-module object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ by allowing $\mathrm{QCoh}(X)$ to act on the first factor (so that $\mathrm{QCoh}(X) \otimes \mathrm{QCoh}(Y)$ is the free $\mathrm{QCoh}(X)$-module generated by $\mathrm{QCoh}(Y)$). To prove ($*$), it will suffice to verify the following:

($*'$) The functor $F' : \mathrm{QCoh}(X) \to \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(Y)$ admits a right adjoint $G' : \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(Y) \to \mathrm{QCoh}(X)$ which preserves small colimits and is $\mathrm{QCoh}(X)$-linear.

$(*'')$ The functor $F'' : \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(Y) \to \mathrm{QCoh}(Y)$ admits a right adjoint $G'' : \mathrm{QCoh}(Y) \to \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(Y)$ which preserves small colimits and is $\mathrm{QCoh}(X)$-linear.

To prove $(*')$, we note that the unit map $e : \mathrm{Sp} \to \mathrm{QCoh}(Y)$ admits a right adjoint $\Gamma : \mathrm{QCoh}(Y) \to \mathrm{Sp}$. Since Y is affine, the global sections functor Γ preserves small colimits, and can therefore be identified with a morphism in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$. Tensoring Γ with the identity functor $\mathrm{id}_{\mathrm{QCoh}(X)}$, we obtain a $\mathrm{QCoh}(X)$-linear functor $G' : \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(Y) \to \mathrm{QCoh}(X)$, which is easily seen to be a left adjoint to F'.

The proof of $(*'')$ is similar. Let $\mathcal{C}$ denote the tensor product $\mathrm{QCoh}(X) \otimes \mathrm{QCoh}(X)$ and let $m : \mathcal{C} \to \mathrm{QCoh}(X)$ classify the tensor product functor $\otimes : \mathrm{QCoh}(X) \times \mathrm{QCoh}(X) \to \mathrm{QCoh}(X)$. Note that the functor m factors as a composition

$$\mathcal{C} = \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(X) \xrightarrow{e_{X,X}} \mathrm{QCoh}(X \times X) \xrightarrow{\delta^*} \mathrm{QCoh}(X),$$

where $e_{X,X}$ is the functor given in Construction 9.4.1.1 and $\delta : X \to X \times X$ is the diagonal. Since X is quasi-geometric, the map δ is quasi-affine. It follows functor δ^* has a right adjoint given by the direct image functor $\delta_* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(X \times X)$ (Proposition 6.3.4.1), which is colimit-preserving and $\mathrm{QCoh}(X \times X)$-linear by virtue of Corollary 6.3.4.3. Because X has the diagonal approximation property, the functor $e_{X,X}$ is an equivalence of ∞-categories. It follows that the functor $m : \mathcal{C} \to \mathrm{QCoh}(X)$ admits a right adjoint $m' : \mathrm{QCoh}(X) \to \mathcal{C}$ which preserves small colimits and is $\mathcal{C}$-linear. Then m' induces a colimit-preserving, $\mathcal{C}$-linear functor

$$\begin{aligned} \mathrm{QCoh}(Y) &\simeq \mathrm{QCoh}(X) \otimes_{\mathcal{C}} (\mathrm{QCoh}(X) \otimes \mathrm{QCoh}(Y)) \\ &\xrightarrow{m' \otimes \mathrm{id}} \mathcal{C} \otimes_{\mathcal{C}} (\mathrm{QCoh}(X) \otimes \mathrm{QCoh}(Y)) \\ &\simeq \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(Y), \end{aligned}$$

which is easily seen to be right adjoint to F''. □

9.4.2 Dualizability

We now record some observations relating the diagonal approximation property of Definition 9.4.1.2 to the duality theory of presentable stable ∞-categories.

Proposition 9.4.2.1. *Let X be a quasi-geometric stack with the diagonal approximation property. Then the ∞-category $\mathrm{QCoh}(X)$ is smooth when regarded as an algebra object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ (in the sense of Definition HA.4.6.4.13). That is, $\mathrm{QCoh}(X)$ is dualizable when viewed as a module over $\mathrm{QCoh}(X) \otimes \mathrm{QCoh}(X)$.*

Proof. Let $\delta : X \to X \times X$ be the diagonal map, and let $\mathscr{A} = \delta_* \mathscr{O}_X$. Since δ is quasi-affine, it induces an equivalence $\mathrm{QCoh}(X) \simeq \mathrm{Mod}_{\mathscr{A}}(\mathrm{QCoh}(X \times X))$ (Proposition 6.3.4.6).

Consequently, $\mathrm{QCoh}(X)$ is dualizable (in fact, it is self-dual) when viewed as a module over $\mathrm{QCoh}(X \times X)$ (see Remark HA.4.8.4.8). If X has the diagonal approximation property, it follows that $\mathrm{QCoh}(X)$ is also dualizable when viewed as a module over $\mathrm{QCoh}(X) \otimes \mathrm{QCoh}(X)$. □

Corollary 9.4.2.2. *Let X be a quasi-coherent stack and let $\mathcal{C} \in \mathrm{Mod}_{\mathrm{QCoh}(X)}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$ be a presentable stable ∞-category equipped with an action of $\mathrm{QCoh}(X)$. If X has the diagonal approximation property and $\mathcal{C}$ is dualizable as an object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$, then it is also dualizable as an object of $\mathrm{Mod}_{\mathrm{QCoh}(X)}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$.*

Corollary 9.4.2.3. *Suppose we are given a pullback diagram of quasi-geometric stacks*

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \longrightarrow & Y. \end{array}$$

If Y has the diagonal approximation property and $\mathrm{QCoh}(Y')$ is a dualizable object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$, then the diagram

$$\begin{array}{ccc} \mathrm{QCoh}(X') & \longleftarrow & \mathrm{QCoh}(X) \\ \uparrow & & \uparrow \\ \mathrm{QCoh}(Y') & \longleftarrow & \mathrm{QCoh}(Y) \end{array}$$

is a pushout square in $\mathrm{CAlg}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$: that is, the canonical map $\theta : \mathrm{QCoh}(Y') \otimes_{\mathrm{QCoh}(Y)} \mathrm{QCoh}(X) \to \mathrm{QCoh}(X')$ is an equivalence of ∞-categories.

Proof. Choose a faithfully flat map $f : U_0 \to X$, where U_0 is affine. Let $U_\bullet$ be the Čech nerve of f. Then X can be identified with the geometric realization $|U_\bullet|$ in the ∞-category $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$, and X' can be identified with the geometric realization $|Y' \times_Y U_\bullet|$ in the ∞-category $\widehat{\mathcal{S}\mathrm{hv}}_{\mathrm{fpqc}}$. In particular, we have equivalences

$$\mathrm{QCoh}(X') \simeq \mathrm{Tot}\,\mathrm{QCoh}(Y' \times_Y U_\bullet) \qquad \mathrm{QCoh}(X) \simeq \mathrm{Tot}\,\mathrm{QCoh}(U_\bullet).$$

Using these equivalences, we can identify θ with the composition

$$\begin{aligned} \mathrm{QCoh}(Y') \otimes_{\mathrm{QCoh}(Y)} \mathrm{Tot}(\mathrm{QCoh}(U_\bullet)) &\xrightarrow{\theta'} \mathrm{Tot}(\mathrm{QCoh}(Y') \otimes_{\mathrm{QCoh}(Y)} \mathrm{QCoh}(U_\bullet)) \\ &\xrightarrow{\theta''} \mathrm{Tot}(\mathrm{QCoh}(Y' \times_Y U_\bullet)). \end{aligned}$$

Since $\mathrm{QCoh}(Y)$ is dualizable as an object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$, it is also dualizable as a module over $\mathrm{QCoh}(Y)$ (Corollary 9.4.2.2). Consequently, the construction $\mathcal{C} \mapsto \mathrm{QCoh}(Y) \otimes_{\mathrm{QCoh}(Y')} \mathcal{C}$ commutes with limits, so that θ' is an equivalence of ∞-categories. To show that θ'' is an equivalence of ∞-categories, it will suffice to show that the natural map $\mathrm{QCoh}(Y') \otimes_{\mathrm{QCoh}(Y)}$

$\mathrm{QCoh}(U_k) \to \mathrm{QCoh}(Y' \otimes_Y U_k)$ is an equivalence for each $k \geqslant 0$. In other words, to prove Corollary 9.4.2.3 we are free to replace X by U_k, and thereby reduce to the case where X is quasi-affine. In this case, our assumption that Y is quasi-geometric guarantees that the morphism f is quasi-affine. Set $\mathscr{A} = f_* \mathscr{O}_X$, so that Proposition 6.3.4.6 supplies an equivalence $\mathrm{QCoh}(X) \to \mathrm{Mod}_{\mathscr{A}}(\mathrm{QCoh}(Y))$. Similarly, using Proposition 6.3.4.6 and Corollary 6.3.4.3 we obtain a compatible equivalence $\mathrm{QCoh}(X') \simeq \mathrm{Mod}_{\mathscr{A}}(\mathrm{QCoh}(Y'))$. Using these equivalences, we can identify the functor θ with the natural map

$$\mathrm{QCoh}(Y') \otimes_{\mathrm{QCoh}(Y)} \mathrm{Mod}_{\mathscr{A}}(\mathrm{QCoh}(Y)) \to \mathrm{Mod}_{\mathscr{A}}(\mathrm{QCoh}(Y')),$$

which is an equivalence of ∞-categories by virtue of Theorem HA.4.8.4.6. □

Applying Corollary 9.4.2.3 in the special case where $Y = \operatorname{Spec} S$, we obtain the following:

Corollary 9.4.2.4. *Let X and Y be quasi-geometric stacks. If $\mathrm{QCoh}(X)$ is a dualizable object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$, then the map $e_{X,Y} : \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(Y) \to \mathrm{QCoh}(X \times Y)$ of Construction 9.4.1.1 is an equivalence of ∞-categories.*

Corollary 9.4.2.5. *Let X and Y be quasi-geometric stacks. If $\mathrm{QCoh}(X)$ and $\mathrm{QCoh}(Y)$ are dualizable objects of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$, then $\mathrm{QCoh}(X \times Y)$ is a dualizable object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$.*

Corollary 9.4.2.6. *Let X be a quasi-geometric stack. If $\mathrm{QCoh}(X)$ is a dualizable object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$, then X has the diagonal approximation property.*

Corollary 9.4.2.7. *Let $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be functors. Assume that X is a quasi-geometric stack and that $\mathrm{QCoh}(X)$ is a dualizable object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$. Then the construction $(f : Y \to X) \mapsto (f^* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y))$ determines a fully faithful embedding*

$$\theta : \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(Y, X) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y))$$

whose essential image is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ which preserve small colimits and connective objects.

Proof. Combine Corollary 9.4.2.6 with Theorem 9.4.1.4. □

9.4.3 Weakly Perfect Stacks

One can ask if Proposition 9.4.2.4 has a converse: if X is a quasi-geometric stack with the diagonal approximation property, then is the ∞-category $\mathrm{QCoh}(X)$ dualizable as an object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$? We next show that, under a mild additional hypothesis, the diagonal approximation property ensures not only that $\mathrm{QCoh}(X)$ is dualizable, but that it is (canonically) self-dual (Proposition 9.4.3.1).

Proposition 9.4.3.1. *Let X be a quasi-geometric stack which satisfies the following conditions:*

(1) *The structure sheaf $\mathscr{O}_X$ is a compact object of* $\mathrm{QCoh}(X)$*.*

(2) *Let $\delta : X \to X \times X$ denote the diagonal map. Then $\delta_* \mathscr{O}_X$ belongs to the essential image of the functor $e_{X,X} : \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(X) \to \mathrm{QCoh}(X)$ of Construction 9.4.1.1.*

Let $m : \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(X) \to \mathrm{QCoh}(X)$ classify the tensor product on $\mathrm{QCoh}(X)$. Then the composite functor

$$e : \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(X) \xrightarrow{m} \mathrm{QCoh}(X) \xrightarrow{\Gamma(X;\bullet)} \mathrm{Sp}$$

is a duality datum in the symmetric monoidal ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$. In particular, $\mathrm{QCoh}(X)$ is a dualizable object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$.

Corollary 9.4.3.2. *Let X be a quasi-geometric stack and suppose that $\mathscr{O}_X$ is a compact object of $\mathrm{QCoh}(X)$. Then the following conditions are equivalent:*

(a) *The ∞-category $\mathrm{QCoh}(X)$ is a dualizable object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$.*

(b) *The quasi-geometric stack X has the diagonal approximation property.*

(c) *The object $\delta_* \mathscr{O}_X$ belongs to the essential image of the functor $e_{X,X} : \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(X) \to \mathrm{QCoh}(X \times X)$.*

Proof. The implication $(a) \to (b)$ follows from Proposition 9.4.2.4, the implication $(b) \Rightarrow (c)$ is tautological, and the implication $(c) \Rightarrow (a)$ follows from Proposition 9.4.3.1. □

Definition 9.4.3.3. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor. We will say that X is a *weakly perfect stack* if it satisfies the equivalent conditions of Corollary 9.4.3.2: that is, if X is a quasi-geometric stack with the diagonal approximation property and the structure sheaf $\mathscr{O}_X$ is a compact object of $\mathrm{QCoh}(X)$.

Proof of Proposition 9.4.3.1. Let X be a quasi-geometric stack and let $C \in \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(X)$ satisfy $e_{X,X}(C) \simeq \delta_* \mathscr{O}_X$. The object C classifies a colimit-preserving functor $c : \mathrm{Sp} \to \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(X)$. We will show that c is a coevaluation map compatible with the functor $\Gamma(X; \bullet) \circ m$: in other words, that the composition

$$\begin{aligned} \mathrm{QCoh}(X) &\xrightarrow{c \otimes \mathrm{id}} \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(X) \\ &\xrightarrow{\mathrm{id} \otimes m} \mathrm{QCoh}(X) \otimes \mathrm{QCoh}(X) \\ &\xrightarrow{\mathrm{id} \otimes \Gamma} \mathrm{QCoh}(X). \end{aligned}$$

determines a functor $\lambda : \mathrm{QCoh}(X) \to \mathrm{QCoh}(X)$ which is homotopic to the identity map.

Let S denote the sphere spectrum and let $p : X \to \operatorname{Spec} S$ denote the projection map, so that we have a pullback diagram of quasi-geometric stacks σ :

$$\begin{array}{ccc} X \times X & \xrightarrow{\pi_1} & X \\ \downarrow{\scriptstyle \pi_2} & & \downarrow{\scriptstyle p} \\ X & \xrightarrow{p} & \operatorname{Spec} S. \end{array}$$

The construction $(\mathscr{F}, \mathscr{G}) \mapsto \mathscr{F} \otimes \pi_2^* \mathscr{G}$ determines a functor $\operatorname{QCoh}(X \times X) \times \operatorname{QCoh}(X) \to \operatorname{QCoh}(X \times X)$ which preserves small colimits separately in each variable, and is therefore classified by a functor $M : \operatorname{QCoh}(X \times X) \otimes \operatorname{QCoh}(X) \to \operatorname{QCoh}(X \times X)$. Consider the diagram of ∞-categories

$$\begin{array}{ccc} \operatorname{QCoh}(X) & \xrightarrow{\delta_* \mathscr{O}_X \otimes \operatorname{id}} & \\ \downarrow & & \searrow \\ \operatorname{QCoh}(X) \times \operatorname{QCoh}(X) \otimes \operatorname{QCoh}(X) & \xrightarrow{e_{X,X} \otimes \operatorname{id}} & \operatorname{QCoh}(X \times X) \otimes \operatorname{QCoh}(X) \\ \downarrow{\scriptstyle \operatorname{id} \otimes m} & & \downarrow{\scriptstyle M} \\ \operatorname{QCoh}(X) \otimes \operatorname{QCoh}(X) & \xrightarrow{e_{X,X}} & \operatorname{QCoh}(X \times X) \\ \downarrow{\scriptstyle \operatorname{id} \otimes \Gamma(X; \bullet)} & \swarrow{\scriptstyle \pi_{1*}} & \\ \operatorname{QCoh}(X). & & \end{array}$$

We claim that it commutes up to canonical homotopy:

- The upper triangle commutes by the definition of c.
- The middle square commutes, since the composition in either direction classifies the functor $\operatorname{QCoh}(X) \times \operatorname{QCoh}(X) \times \operatorname{QCoh}(X) \to \operatorname{QCoh}(X \times X)$ given on objects by $(\mathscr{F}, \mathscr{G}, \mathscr{H}) \mapsto \pi_1^* \mathscr{F} \otimes \pi_2^* \mathscr{G} \otimes \pi_2^* \mathscr{H}$.
- The commutativity of the lower triangle follows from the calculation

$$\begin{aligned} \mathscr{F} \otimes p^* p_* \mathscr{G} &\simeq \mathscr{F} \otimes \pi_{1*} \pi_2^* \mathscr{G} \\ &\simeq \pi_{1*}(\pi_1^* \mathscr{F} \otimes \pi_2^* \mathscr{G}) \end{aligned}$$

for $\mathscr{F}, \mathscr{G} \in \operatorname{QCoh}(X)$, where the equivalences are obtained by applying Proposition 9.1.5.7 to the pullback square σ.

It follows that the functor $\lambda : \mathrm{QCoh}(X) \to \mathrm{QCoh}(X)$ is given by the construction

$$\begin{aligned}\lambda(\mathscr{F}) &= \pi_{1*}(\delta_* \mathscr{O}_X \otimes \pi_2^* \mathscr{F}) \\ &\simeq \pi_{1*}(\delta_*(\mathscr{O}_X \otimes \delta^* \pi_2^* \mathscr{F}) \\ &\simeq \pi_{1*}(\delta_*(\mathscr{O}_X \otimes \mathscr{F}) \\ &\simeq \pi_{1*}\delta_*(\mathscr{F}) \\ &\simeq \mathscr{F},\end{aligned}$$

where the calculation uses the fact that $\pi_1 \circ \delta$ and $\pi_2 \circ \delta$ are both homotopic to the identity map id_X, together with the projection formula for the quasi-affine map δ (Corollary 6.3.4.3). □

Corollary 9.4.3.4. *Let X be a weakly perfect stack. Then the global sections functor $\Gamma : \mathrm{QCoh}(X) \to \mathrm{Sp}$ exhibits $\mathrm{QCoh}(X)$ as a Frobenius algebra object of the symmetric monoidal ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ (see Definition HA.4.6.5.1).*

Corollary 9.4.3.5. *Let X be a weakly perfect stack and suppose we are given a duality datum $e : \mathcal{C} \otimes_{\mathrm{QCoh}(X)} \mathcal{D} \to \mathrm{QCoh}(X)$ in the symmetric monoidal ∞-category $\mathrm{Mod}_{\mathrm{QCoh}(X)}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$. Then the composite functor*

$$\mathcal{C} \otimes \mathcal{D} \to \mathcal{C} \otimes_{\mathrm{QCoh}(X)} \mathcal{D} \xrightarrow{e} \mathrm{QCoh}(X) \xrightarrow{\Gamma(X;\bullet)} \mathrm{Sp}$$

is a duality datum in $\mathcal{P}\mathrm{r}^{\mathrm{St}}$.

Proof. Combine Corollary 9.4.3.4 with Corollary HA.4.6.5.14. □

In the situation of Corollary 9.4.3.5, the ∞-category $\mathrm{QCoh}(X)$ is also a smooth algebra object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ (Proposition 9.4.2.1). We therefore have the following converse to Corollary 9.4.3.5 (which is a more precise version of Corollary 9.4.2.2); see Remark HA.4.6.5.15:

Corollary 9.4.3.6. *Let X be a weakly perfect stack and let $\mathcal{C} \in \mathrm{Mod}_{\mathrm{QCoh}(X)}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$. Suppose that $e : \mathcal{C} \otimes \mathcal{D} \to \mathrm{Sp}$ is a duality datum in $\mathcal{P}\mathrm{r}^{\mathrm{St}}$. Then $\mathcal{D}$ can be equipped with an action of $\mathrm{QCoh}(X)$ for which the functor e factors as a composition*

$$\mathcal{C} \otimes \mathcal{D} \to \mathcal{C} \otimes_{\mathrm{QCoh}(X)} \mathcal{D} \xrightarrow{\overline{e}} \mathrm{QCoh}(X) \xrightarrow{\Gamma(X;\bullet)} \mathrm{Sp},$$

where $\overline{e}$ is a duality datum in $\mathrm{Mod}_{\mathrm{QCoh}(X)}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$.

Remark 9.4.3.7. We can summarize Corollaries **??** and 9.4.3.6 more informally as follows: if $\mathrm{QCoh}(X)$ is a weakly perfect stack, then the forgetful functor $\mathrm{Mod}_{\mathrm{QCoh}(X)}(\mathcal{P}\mathrm{r}^{\mathrm{St}}) \to \mathcal{P}\mathrm{r}^{\mathrm{St}}$ is compatible with duality.

Corollary 9.4.3.8. *Suppose we are given a pullback diagram*

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \longrightarrow & Y \end{array}$$

of quasi-geometric stacks, where Y is weakly perfect. Then:

(*a*) *If either* $\mathrm{QCoh}(X)$ *or* $\mathrm{QCoh}(Y')$ *is dualizable as an object of* $\mathcal{P}\mathrm{r}^{\mathrm{St}}$, *then the canonical map* $\mathrm{QCoh}(Y') \otimes_{\mathrm{QCoh}(Y)} \mathrm{QCoh}(X) \to \mathrm{QCoh}(X')$ *is an equivalence of ∞-categories.*

(*b*) *If both* $\mathrm{QCoh}(X)$ *and* $\mathrm{QCoh}(Y')$ *are dualizable as objects of* $\mathcal{P}\mathrm{r}^{\mathrm{St}}$, *then* $\mathrm{QCoh}(X')$ *is also dualizable as an object of* $\mathcal{P}\mathrm{r}^{\mathrm{St}}$.

(*c*) *If X and Y' are weakly perfect, then X' is weakly perfect.*

Proof. Assertion (*a*) is a special case of Corollary 9.4.2.3. To prove (*b*), we first note that if $\mathrm{QCoh}(X)$ and $\mathrm{QCoh}(Y')$ are dualizable as objects of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$, then they are also dualizable as modules over $\mathrm{QCoh}(Y)$ (Corollary 9.4.2.2). It follows from (*a*) that $\mathrm{QCoh}(X') \simeq \mathrm{QCoh}(Y') \otimes_{\mathrm{QCoh}(Y)} \mathrm{QCoh}(X)$ is also dualizable as a module over $\mathrm{QCoh}(Y)$. Using Corollary 9.4.3.5, we deduce that $\mathrm{QCoh}(X')$ is dualizable as an object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$.

We now prove (*c*). Assume that X and Y' are weakly perfect. Since $\mathscr{O}_X$ is a compact object of $\mathrm{QCoh}(X)$ and Y is quasi-geometric, Proposition 9.1.5.8 implies that f satisfies condition $(*)$ of Proposition 9.1.5.7. It follows that f' satisfies the same condition, so that the pullback functor f'^* admits a right adjoint $f_* : \mathrm{QCoh}(X') \to \mathrm{QCoh}(Y')$ which preserves small colimits. The global sections functor $\Gamma(X'; \bullet)$ factors as a composition

$$\mathrm{QCoh}(X') \xrightarrow{f_*} \mathrm{QCoh}(Y') \xrightarrow{\Gamma(Y'; \bullet)} \mathrm{Sp},$$

so our assumption that $\mathscr{O}_Y$ is compact guarantees that $\Gamma(X'; \bullet)$ commutes with small colimits. Combining this with assertion (*b*), we deduce that X' is weakly perfect. □

9.4.4 Perfect Stacks

We now specialize to the study of quasi-geometric stacks X for which $\mathrm{QCoh}(X)$ has "enough" compact objects.

Definition 9.4.4.1. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor. We will say that X is a *perfect stack* if it satisfies the following conditions:

(*a*) The functor X is a quasi-geometric stack (Definition 9.1.0.1).

(*b*) The structure sheaf $\mathscr{O}_X$ is a compact object of $\mathrm{QCoh}(X)$.

(c) Every quasi-coherent sheaf $\mathscr{F} \in \mathrm{QCoh}(X)$ can be obtained as the colimit of a filtered diagram $\{\mathscr{F}_\alpha\}$, where each $\mathscr{F}_\alpha$ is a perfect object of $\mathrm{QCoh}(X)$.

Remark 9.4.4.2. Definition 9.4.4.1 is a slight variant of the notion of perfect stack introduced in [23]. There are three differences:

- For a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ to be a perfect stack in the sense of Definition 9.4.4.1, we require the existence of a faithfully flat map $\operatorname{Spec} A \to X$ for some connective $\mathbb{E}_\infty$-ring A; in [23] this requirement does not appear.
- The definition of a perfect stack X given in [23] requires that the diagonal map $\delta : X \to X \times X$ is affine, while Definition 9.4.4.1 requires only that it is quasi-affine.
- Definition 9.4.4.1 requires a perfect stack to satisfy descent with respect to the fpqc topology, while [23] requires descent only for the étale topology (though the difference is immaterial if we are interested only in properties of the ∞-category $\mathrm{QCoh}(X)$; see Proposition 6.2.3.1).

Example 9.4.4.3. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be (the functor represented by) a quasi-compact, quasi-separated algebraic space. In §9.6, we will show that X is a perfect stack (Proposition 9.6.1.1).

Example 9.4.4.4. Let G be an affine algebraic group defined over a field κ of characteristic zero. Then the classifying stack BG is perfect. More generally, if X is quasi-projective κ-scheme equipped with an action of G, then the (stack-theoretic) quotient X/G is a perfect stack (see [23]).

We now consider some equivalent formulations of Definition 9.4.4.1:

Proposition 9.4.4.5. *Let X be a quasi-geometric stack. The following conditions are equivalent:*

(1) *The quasi-geometric stack X is perfect.*

(2) *The ∞-category $\mathrm{QCoh}(X)$ is compactly generated and the structure sheaf $\mathscr{O}_X$ is a compact object of $\mathrm{QCoh}(X)$.*

(3) *The inclusion $\mathrm{QCoh}(X)^{\mathrm{perf}} \hookrightarrow \mathrm{QCoh}(X)$ extends to an equivalence of ∞-categories $\mathrm{Ind}(\mathrm{QCoh}(X)^{\mathrm{perf}}) \to \mathrm{QCoh}(X)$.*

Proof. Note that conditions (1), (2), and (3) all guarantee that $\mathscr{O}_X$ is a compact object of $\mathrm{QCoh}(X)$. It then follows that an object $\mathscr{F} \in \mathrm{QCoh}(X)$ is compact if and only if it is perfect (Proposition 9.1.5.3), from which the equivalences (1) $\Leftrightarrow$ (2) $\Leftrightarrow$ (3) follow immediately. □

Corollary 9.4.4.6. *Let X be a perfect stack. Then X is weakly perfect. In particular, X has the diagonal approximation property.*

Proof. Since X is perfect, the ∞-category $\mathrm{QCoh}(X)$ is compactly generated (Proposition 9.4.4.5) and is therefore dualizable as an object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ (Proposition D.7.2.3). The desired result now follows from Corollary 9.4.3.2. □

Combining Corollary 9.4.4.6 with Theorem 9.4.1.4, we obtain the following result of Bhatt and Halpern-Leistner (see [27]):

Corollary 9.4.4.7 (Tannaka Duality, Perfect Stack Version)**.** *Let $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be functors. If X is perfect, then the construction $(f : Y \to X) \mapsto (f^* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y))$ determines a fully faithful embedding*

$$\theta : \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(Y, X) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y))$$

whose essential image is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ which preserve small colimits and connective objects.

Remark 9.4.4.8. In the situation of Corollary 9.4.4.7, let $\mathrm{LFun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y))$ denote the full subcategory of $\mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y))$ spanned by those symmetric monoidal functors which preserve small colimits and let $\mathrm{Fun}^{\otimes}_{\mathrm{ex}}(\mathrm{QCoh}(X)^{\mathrm{perf}}, \mathrm{QCoh}(Y)^{\mathrm{perf}})$ denotes the full subcategory of $\mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{perf}}, \mathrm{QCoh}(Y)^{\mathrm{perf}})$ spanned by the symmetric monoidal functors which are exact. Since X is a perfect stack, composition with the inclusion $\mathrm{QCoh}(X)^{\mathrm{perf}} \hookrightarrow \mathrm{QCoh}(X)$ induces an equivalence of ∞-categories $\mathrm{LFun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y)) \to \mathrm{Fun}^{\otimes}_{\mathrm{ex}}(\mathrm{QCoh}(X)^{\mathrm{perf}}, \mathrm{QCoh}(Y)^{\mathrm{perf}})$. However, it is not obvious how to describe the essential image of $\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(Y, X)$ under this equivalence, since the full subcategory $\mathrm{QCoh}(X)^{\mathrm{perf}} \subseteq \mathrm{QCoh}(X)$ need not be closed under truncations.

We conclude by observing a pleasant stability property of the class of perfect stacks:

Proposition 9.4.4.9. *Suppose we are given a pullback diagram*

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \longrightarrow & Y \end{array}$$

in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. If X and Y' are perfect stacks and Y is weakly perfect, then X' is perfect.

Proof. It follows from Corollary 9.4.3.8 that X' is weakly perfect and that the induced map

$$\mathrm{QCoh}(Y') \otimes_{\mathrm{QCoh}(Y)} \mathrm{QCoh}(X) \to \mathrm{QCoh}(X')$$

is an equivalence of ∞-categories. Combining this with the assumption that X and Y' are perfect, we deduce that $\mathrm{QCoh}(X)$ is generated under colimits by the essential image of the composite functor

$$\mathrm{QCoh}(Y')^{\mathrm{perf}} \times \mathrm{QCoh}(X)^{\mathrm{perf}} \to \mathrm{QCoh}(Y') \otimes_{\mathrm{QCoh}(Y)} \mathrm{QCoh}(X) \to \mathrm{QCoh}(X').$$

Since this composite functor factors through $\mathrm{QCoh}(X')^{\mathrm{perf}}$, it follows that X' is perfect. □

9.5 Locally Noetherian Stacks

Let X be a geometric stack and let R be an $\mathbb{E}_\infty$-ring. According to Theorem 9.3.0.3, we can identify R-valued points of X with symmetric monoidal functors $F : \mathrm{QCoh}(X) \to \mathrm{Mod}_R$ which preserve small colimits, connective objects, and flat objects. In §9.4, we proved that if X is perfect, then the third condition is superfluous: any symmetric monoidal functor $F : \mathrm{QCoh}(X) \to \mathrm{Mod}_R$ which preserves small colimits and connective objects automatically preserves flat objects (Corollary 9.4.4.7). The assumption X is perfect is a kind of finiteness hypothesis: it guarantees that the ∞-category $\mathrm{QCoh}(X)$ has "enough" perfect objects. In this section, we will study a different finiteness hypothesis: the condition that X is *locally Noetherian* (Definition 9.5.1.1). Our main result asserts that if X is locally Noetherian geometric stack, then Tannaka duality again takes a particularly simple form: every symmetric monoidal functor $F : \mathrm{QCoh}(X) \to \mathrm{Mod}_R$ which preserves small colimits and connective objects automatically preserves flat objects, and therefore arises from an essentially unique R-valued point of X (Theorem 9.5.4.1). We also prove a slightly weaker result in the case where X is quasi-geometric (Theorem 9.5.4.2).

9.5.1 Noetherian and Locally Noetherian Quasi-Geometric Stacks

We now introduce some finiteness conditions on quasi-geometric stacks.

Definition 9.5.1.1. Let X be a quasi-geometric stack. We will say that X is *locally Noetherian* if there exists a faithfully flat map $\operatorname{Spec} R \to X$, where R is a Noetherian $\mathbb{E}_\infty$-ring.

Let X be a quasi-geometric stack. The condition that X is locally Noetherian guarantees that there *exists* a faithfully flat map $\operatorname{Spec} R \to X$, where R is Noetherian. However, it does not follow that for *every* faithfully flat map $f : \operatorname{Spec} R \to X$, the $\mathbb{E}_\infty$-ring R is Noetherian (this condition is essentially never satisfied). However, we can do better if we assume some finiteness conditions on f:

Proposition 9.5.1.2. *Let X be a locally Noetherian quasi-geometric stack, and let $f : \operatorname{Spec} R \to X$ be a morphism which locally almost of finite presentation. Then R is Noetherian.*

Proof. Since X is locally Noetherian, we can choose a faithfully flat map $g : \operatorname{Spec} A \to X$, where A is Noetherian. Form a pullback diagram

$$\begin{array}{ccc} Y & \xrightarrow{g'} & \operatorname{Spec} R \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \operatorname{Spec} A & \xrightarrow{g} & X. \end{array}$$

Then Y is (representable by) a quasi-affine spectral algebraic space. Choose an étale surjection $\operatorname{Spec} B \to Y$. Since f is locally almost of finite presentation, the $\mathbb{E}_\infty$-ring B is almost of finite presentation over A and is therefore Noetherian (Proposition HA.7.2.4.31). The map g is faithfully flat, so B is faithfully flat over R. Applying Lemma 2.8.1.6, we deduce that R is Noetherian. □

Corollary 9.5.1.3. *Let X be a quasi-geometric stack and suppose that there exists a morphism $f : \operatorname{Spec} A \to X$ which is faithfully flat and locally almost of finite presentation. Then the following conditions are equivalent:*

- (a) *For every morphism $\operatorname{Spec} B \to X$ which is locally almost of finite presentation, the $\mathbb{E}_\infty$-ring B is Noetherian.*
- (b) *The $\mathbb{E}_\infty$-ring A is Noetherian.*
- (c) *The quasi-geometric stack X is locally Noetherian.*

Proof. The implications $(a) \Rightarrow (b) \Rightarrow (c)$ are tautological, and the implication $(c) \Rightarrow (a)$ follows from Proposition 9.5.1.2. □

Definition 9.5.1.4. We will say that a quasi-geometric stack X is *Noetherian* if it satisfies the equivalent conditions of Corollary 9.5.1.3 (that is, if there exists a morphism $f : \operatorname{Spec} A \to X$ which is faithfully flat and locally almost of finite presentation, where A is Noetherian).

Example 9.5.1.5. Let R be a Noetherian commutative ring and let G be a flat quasi-affine group scheme over R. Then the classifying stack BG (see Example 9.1.1.7) is locally Noetherian. If G is of finite presentation over R, then BG is Noetherian.

Example 9.5.1.6. Let $\mathcal{FG}$ be the moduli stack of formal groups (see Example 9.3.1.7). Then $\mathcal{FG}$ is not locally Noetherian. For every prime number p and every integer $n \geqslant 1$, the open substack $\mathcal{FG}_{\leqslant n} \subseteq \mathcal{FG} \times_{\operatorname{Spec} \mathbf{Z}} \operatorname{Spec} \mathbf{Z}_{(p)}$ classifying formal groups of height $\leqslant n$ (over p-local rings) is locally Noetherian but not Noetherian.

9.5.2 Noetherian Hypotheses and Quasi-Coherent Sheaves

We now show that if X is a locally Noetherian quasi-geometric stack, then the Grothendieck prestable ∞-category $\mathrm{QCoh}(X)^{\mathrm{cn}}$ is locally Noetherian (in the sense of Definition C.6.9.1). We begin by isolating an appropriate finiteness condition on objects of the abelian category $\mathrm{QCoh}(X)^{\heartsuit}$.

Notation 9.5.2.1. Let X be a locally Noetherian quasi-geometric stack. We let $\mathrm{Coh}(X)^{\heartsuit}$ denote the full subcategory of $\mathrm{QCoh}(X)^{\heartsuit}$ spanned by those object $\mathscr{F} \in \mathrm{QCoh}(X)^{\heartsuit}$ which are almost perfect.

Remark 9.5.2.2. Let X be a locally Noetherian quasi-geometric stack and let $f : \operatorname{Spec} A \to X$ be a faithfully flat surjection, where A is a Noetherian $\mathbb{E}_\infty$-ring. Then the pullback functor f^* determines an exact functor of abelian categories $\mathrm{QCoh}(X)^{\heartsuit} \to \mathrm{QCoh}(\operatorname{Spec} A)^{\heartsuit} \simeq \mathrm{Mod}_A^{\heartsuit}$, and an object $\mathscr{F} \in \mathrm{QCoh}(X)^{\heartsuit}$ belongs to $\mathrm{Coh}(X)^{\heartsuit}$ if and only if $f^* \mathscr{F}$ is finitely generated when regarded as an A-module (Propositions 9.1.3.5 and HA.7.2.4.17). It follows that $\mathrm{Coh}(X)^{\heartsuit}$ is an abelian subcategory of $\mathrm{QCoh}(X)^{\heartsuit}$ which is closed under extensions, subobjects, and quotient objects.

Proposition 9.5.2.3. *Let X be a locally Noetherian quasi-geometric stack. Then the prestable ∞-category $\mathrm{QCoh}(X)^{\mathrm{cn}}$ is locally Noetherian (see Definition C.6.9.1). Moreover, an object $\mathscr{F} \in \mathrm{QCoh}(X)^{\heartsuit}$ is Noetherian if and only if it belongs to $\mathrm{Coh}(X)^{\heartsuit}$.*

Proof. Choose a faithfully flat map $f : \operatorname{Spec} A \to X$, where A is a Noetherian $\mathbb{E}_\infty$-ring. We first claim that each object $\mathscr{F} \in \mathrm{Coh}(X)^{\heartsuit}$ is a Noetherian object of $\mathrm{QCoh}(X)^{\heartsuit}$. To prove this, it will suffice to show that every ascending sequence of subobjects

$$\mathscr{F}_0 \subseteq \mathscr{F}_1 \subseteq \mathscr{F}_2 \subseteq \cdots$$

of $\mathscr{F}$ (in the abelian category $\mathrm{QCoh}(X)^{\heartsuit}$) is eventually constant. Since the pullback functor $f^* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(\operatorname{Spec} A) \simeq \mathrm{Mod}_A$ is t-exact, we can identify $\{f^* \mathscr{F}_n\}_{n \geqslant 0}$ as an ascending sequence of subobjects of $f^* \mathscr{F} \in \mathrm{Mod}_A^{\heartsuit}$. Our assumption that $\mathscr{F} \in \mathrm{Coh}(X)^{\heartsuit}$ guarantees that $f^* \mathscr{F}$ is finitely generated as a module over $\pi_0 A$. Since $\pi_0 A$ is a Noetherian ring, the chain of submodules $\{f^* \mathscr{F}_n\}_{n \geqslant 0}$ is eventually constant. Since the functor f^* is conservative, it follows that the ascending chain $\{\mathscr{F}_n\}_{n \geqslant 0}$ is also eventually constant.

We now prove that every object $\mathscr{F} \in \mathrm{QCoh}(X)^{\heartsuit}$ can be obtained as a filtered colimit of Noetherian subobjects of $\mathscr{F}$, using an argument of Deligne. Let us identify $\mathscr{G} = f^* \mathscr{F}$ with a (discrete) module over the ring $\pi_0 A$. Write $\mathscr{G}$ as a filtered colimit $\varinjlim \mathscr{G}_\beta$, where each $\mathscr{G}_\beta$ is subobject of $\mathscr{G}$ which corresponds to a finitely generated module over $\pi_0 A$. Since the direct image functor f_* is left t-exact, we can identify each truncation $\tau_{\geqslant 0} f_* \mathscr{G}_\beta$ with a subobject of $\tau_{\geqslant 0} f_* \mathscr{G}$. For each index β, let $\mathscr{F}_\beta$ denote the subobject of $\mathscr{F}$ given by the fiber product $\mathscr{F} \times_{\tau_{\geqslant 0} f_* \mathscr{G}} \tau_{\geqslant 0} f_* \mathscr{G}_\beta$. Since the functor f_* preserves small colimits, we have $f_* \mathscr{G} \simeq \varinjlim f_* \mathscr{G}_\beta$. The t-structure on $\mathrm{QCoh}(X)$ is compatible with filtered colimits (Corollary 9.1.3.2), so we have $\tau_{\geqslant 0} f_* \mathscr{G} \simeq \varinjlim \tau_{\geqslant 0} f_* \mathscr{G}_\beta$ and we can therefore identify $\mathscr{F}$ with the colimit of the diagram $\{\mathscr{F}_\beta\}$. It will therefore suffice to show that each $\mathscr{F}_\beta$ belongs to $\mathrm{Coh}(X)^\heartsuit$. Equivalently, we must show that the pullback $f^* \mathscr{F}_\beta$ is finitely generated when regarded as a (discrete) module over the commutative ring $\pi_0 A$. By construction, we have a commutative diagram

$$\begin{array}{ccc} f^* \mathscr{F}_\beta & \longrightarrow & f^* \mathscr{F} \\ \downarrow & & \downarrow \\ f^* \tau_{\geqslant 0} f_* \mathscr{G}_\beta & \longrightarrow & f^* \tau_{\geqslant 0} f_* \mathscr{G} \\ \downarrow & & \downarrow \\ \mathscr{G}_\beta & \longrightarrow & \mathscr{G} \end{array}$$

in the abelian category $\mathrm{QCoh}(\operatorname{Spec} A)^\heartsuit$. The upper horizontal map in this diagram is a monomorphism and the right vertical composition is an isomorphism. It follows by a diagram chase that the left vertical composition is a monomorphism, so that we can regard $f^* \mathscr{F}_\beta$ as a subobject of $\mathscr{G}_\beta$. By construction, $\mathscr{G}_\beta$ corresponds to a finitely generated module over $\pi_0 A$. Since the commutative ring $\pi_0 A$ is Noetherian, it follows that $f^* \mathscr{F}_\beta$ also corresponds to a finitely generated module over $\pi_0 A$, so that $\mathscr{F}_\beta$ belongs to $\mathrm{Coh}(X)^\heartsuit$ as desired (Remark 9.5.2.2).

Note that if $\mathscr{F} \in \mathrm{QCoh}(X)^\heartsuit$ is Noetherian, then writing $\mathscr{F} \simeq \varinjlim \mathscr{F}_\beta$ as above we must have $\mathscr{F} \simeq \mathscr{F}_\beta$ for some index β, so that $\mathscr{F} \in \mathrm{Coh}(X)^\heartsuit$. Combining this with the first part of the argument, we see that an object $\mathscr{F} \in \mathrm{QCoh}(X)^\heartsuit$ is Noetherian if and only if it belongs to $\mathrm{Coh}(X)^\heartsuit$. Consequently, the above argument shows that each object $\mathscr{F} \in \mathrm{QCoh}(X)^\heartsuit$ is a filtered colimit of Noetherian subobjects of $\mathscr{F}$, so that the abelian category $\mathrm{QCoh}(X)^\heartsuit$ is locally Noetherian. To complete the proof that $\mathrm{QCoh}(X)^{\mathrm{cn}}$ is locally Noetherian, it will suffice to show that every object $\mathscr{F} \in \mathrm{Coh}(X)^\heartsuit$ is a compact object of $\mathrm{QCoh}(X)^{\mathrm{cn}}_{\leqslant n}$ for each $n \geqslant 0$. In other words, we wish to show that the construction $\mathscr{G} \mapsto \mathrm{Map}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G})$ determines a functor $U : \mathrm{QCoh}(X) \to \mathcal{S}$ which commutes with filtered colimits when restricted to $\mathrm{QCoh}(X)^{\mathrm{cn}}_{\leqslant n}$.

Let $X_\bullet$ denote the Čech nerve of f, so that each X_m is (representable by) a quasi-affine spectral Deligne-Mumford stack. For each $m \geqslant 0$, let $f_m : X_m \to X$ denote the projection map, and let $U^m : \mathrm{QCoh}(X) \to \mathcal{S}$ denote the functor given by $\mathscr{G} \mapsto \mathrm{Map}_{\mathrm{QCoh}(X_m)}(f_m^* \mathscr{F}, f_m^* \mathscr{G})$. Since f is faithfully flat, we have $\mathrm{QCoh}(X) \simeq \mathrm{Tot}(\mathrm{QCoh}(X_\bullet))$, so we can identify U with the functor $\mathrm{Tot}(U^\bullet) = \varprojlim_{[m] \in \mathbf{\Delta}} U^m \simeq \varprojlim_{[m] \in \mathbf{\Delta}_+} U^m$. Note that, when restricted to $\mathrm{QCoh}(X)^{\mathrm{cn}}_{\leqslant n}$, each of the functors U^m takes values in $\tau_{\leqslant n} \mathcal{S}$. It follows that the restriction map $\mathrm{Tot}(U^\bullet) \to \varprojlim_{[m] \in \mathbf{\Delta}_{+, \leqslant n+1}} U^m$ is an equivalence when restricted to $\mathrm{QCoh}(X)^{\mathrm{cn}}_{\leqslant n}$. We may therefore identify $U|_{\mathrm{QCoh}(X)^{\mathrm{cn}}_{\leqslant n}}$ with the finite limit

$\varprojlim_{[m]\in\mathbf{\Delta}_{+,\leqslant n+1}} U^m|_{\mathrm{QCoh}(X)^{\mathrm{cn}}_{\leqslant n}}$. It will therefore suffice to show that each of the functors U^m commutes with filtered colimits when restricted to $\mathrm{QCoh}(X)^{\mathrm{cn}}_{\leqslant n}$. This is clear, since X_m is (representable by) a quasi-affine spectral Deligne-Mumford stack and $f_m^* \mathscr{F} \in \mathrm{QCoh}(X_m)$ is almost perfect. □

9.5.3 Digression: Internal Hom-Sheaves

Let X be a quasi-geometric stack. Then the ∞-category $\mathrm{QCoh}(X)$ is presentable (Corollary 9.1.3.2) and the tensor product $\otimes : \mathrm{QCoh}(X) \times \mathrm{QCoh}(X) \to \mathrm{QCoh}(X)$ preserves small colimits separately in each variable. It follows that the symmetric monoidal structure on $\mathrm{QCoh}(X)$ is *closed*: that is, for every pair of quasi-coherent sheaves $\mathscr{F}, \mathscr{G} \in \mathrm{QCoh}(X)$, we can define a new object $\underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G}) \in \mathrm{QCoh}(X)$ with the following universal property: there is an evaluation map $e : \mathscr{F} \otimes \underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G}) \to \mathscr{G}$ such that, for every object $\mathscr{H} \in \mathrm{QCoh}(X)$, the composite map

$$\begin{aligned} \mathrm{Map}_{\mathrm{QCoh}(X)}(\mathscr{H}, \underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G})) &\to \mathrm{Map}_{\mathrm{QCoh}(X)}(\mathscr{F} \otimes \mathscr{H}, \mathscr{F} \otimes \underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G})) \\ &\xrightarrow{e} \mathrm{Map}_{\mathrm{QCoh}(X)}(\mathscr{F} \otimes \mathscr{H}, \mathscr{G}) \end{aligned}$$

is a homotopy equivalence.

Remark 9.5.3.1. Let X be a quasi-geometric stack and suppose we are given quasi-coherent sheaves $\mathscr{F} \in \mathrm{QCoh}(X)_{\geqslant 0}$ and $\mathscr{G} \in \mathrm{QCoh}(X)_{\leqslant 0}$. Then $\underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G}) \in \mathrm{QCoh}(X)_{\leqslant 0}$. To prove this, it suffices to observe that for $\mathscr{H} \in \mathrm{QCoh}(X)_{\geqslant 1}$, the mapping space

$$\mathrm{Map}_{\mathrm{QCoh}(X)}(\mathscr{H}, \underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G})) \simeq \mathrm{Map}_{\mathrm{QCoh}(X)}(\mathscr{F} \otimes \mathscr{H}, \mathscr{G})$$

is contractible.

Remark 9.5.3.2. In the special case where $X = \operatorname{Spec} A$ is affine, we can identify $\mathscr{F}$ and $\mathscr{G}$ with A-modules M and N. In this case, we can identify the mapping object $\underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G})$ with an A-module which we will denote by $\underline{\mathrm{Map}}_A(M, N)$.

Suppose we are given a morphism $f : Y \to X$ of quasi-geometric stacks, and quasi-coherent sheaves $\mathscr{F}, \mathscr{G} \in \mathrm{QCoh}(X)$. Applying the pullback functor f^* to the evaluation map e, we obtain a map

$$f^*(e) : f^* \mathscr{F} \otimes f^* \underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G}) \to f^* \mathscr{G},$$

which is classified by a morphism $\rho : f^* \underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G}) \to \underline{\mathrm{Map}}_{\mathrm{QCoh}(Y)}(f^* \mathscr{F}, f^* \mathscr{G})$. In general, the morphism ρ need not be an equivalence (in other words, the construction $(\mathscr{F}, \mathscr{G}) \mapsto \underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G})$ is not "local" on X). However, we have the following:

Proposition 9.5.3.3. *Let $f : Y \to X$ be a morphism of quasi-geometric stacks which is quasi-affine and flat, let $\mathscr{F} \in \mathrm{QCoh}(X)$ be almost perfect, and let $\mathscr{G} \in \mathrm{QCoh}(X)_{\leqslant 0}$. Then the canonical map*

$$\rho : f^* \underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G}) \to \underline{\mathrm{Map}}_{\mathrm{QCoh}(Y)}(f^* \mathscr{F}, f^* \mathscr{G})$$

is an equivalence.

Remark 9.5.3.4. In the statement of Proposition 9.5.3.3, the hypothesis that f is quasi-affine is not really needed. However, it will be satisfied in our case of interest, and will slightly simplify the proof.

Remark 9.5.3.5. For a closely related result in a different context, see §6.5.3.

Proof of Proposition 9.5.3.3. Replacing $\mathscr{F}$ by a suspension if necessary, we may assume that $\mathscr{F}$ is connective. Choose a faithfully flat map $u : X_0 \to X$, where X_0 is affine. Let $X_\bullet$ denote the Čech nerve of u_0 and for $n \geqslant 0$ let $u_n : X_n \to X$ denote the evident map. Set $\mathscr{G}^n = u_{n*} u_n^* \mathscr{G}$, so that $\mathscr{G}^\bullet$ is a cosimplicial object of $\mathrm{QCoh}(X)_{\leqslant 0}$ and we have a canonical equivalence $\mathscr{G} \simeq \mathrm{Tot}(\mathscr{G}^\bullet)$. We can therefore identify $\underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G})$ with the totalization $\mathrm{Tot}(\underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G}^\bullet))$. Since the map f is flat, the pullback functor f^* preserves totalizations of cosimplicial objects of $\mathrm{QCoh}(X)_{\leqslant 0}$. Using Remark 9.5.3.1, we obtain equivalences

$$f^* \mathscr{G} \simeq \mathrm{Tot}(f^* \mathscr{G}^\bullet) \qquad f^* \mathrm{Tot}(\underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G}^\bullet)) \simeq \mathrm{Tot}(f^* \underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G}^\bullet)).$$

Using these equivalences, we can identify ρ with the totalization of a cosimplicial map

$$\rho^\bullet : f^* \underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G}^\bullet) \to \underline{\mathrm{Map}}_{\mathrm{QCoh}(Y)}(f^* \mathscr{F}, f^* \mathscr{G}^\bullet).$$

We may therefore replace $\mathscr{G}$ by $\mathscr{G}^n$ and thereby reduce to the case where $\mathscr{G} \simeq u_* \mathscr{G}'$ for some $\mathscr{G}' \in \mathrm{QCoh}(X_0)_{\leqslant 0}$. Form a pullback diagram

$$\begin{array}{ccc} Y_0 & \xrightarrow{f_0} & X_0 \\ \downarrow{\scriptstyle v} & & \downarrow{\scriptstyle u} \\ Y & \xrightarrow{f} & X \end{array}$$

so that we have equivalences

$$\underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G}) \simeq u_* \underline{\mathrm{Map}}_{\mathrm{QCoh}(X_0)}(u^* \mathscr{F}, \mathscr{G}')$$

$$\underline{\mathrm{Map}}_{\mathrm{QCoh}(Y)}(f^* \mathscr{F}, f^* \mathscr{G}) \simeq v_* \underline{\mathrm{Map}}_{\mathrm{QCoh}(Y_0)}(f_0^* u^* \mathscr{F}, f_0^* \mathscr{G}).$$

Combining these equivalences with the projection formula of Corollary 6.3.4.3, we can identify ρ with the direct image under v of the map

$$\rho_0 : f_0^* \underline{\mathrm{Map}}_{\mathrm{QCoh}(X_0)}(u^* \mathscr{F}, \mathscr{G}') \to \underline{\mathrm{Map}}_{\mathrm{QCoh}(Y_0)}(f_0^* u^* \mathscr{F}, f_0^* \mathscr{G}').$$

Replacing $f : Y \to X$ by $f_0 : Y_0 \to X_0$, we may thereby reduce to the special case where $X = \operatorname{Spec} A$ is affine.

Let us identify $\mathrm{QCoh}(X)$ with the ∞-category Mod_A. Set $B = \Gamma(Y; \mathscr{O}_Y)$. Since f is quasi-affine, the global sections functor $\Gamma(Y; \bullet)$ induces an equivalence of ∞-categories $\mathrm{QCoh}(Y) \to \mathrm{Mod}_B$ (Proposition 2.4.1.4). Under this equivalence, the construction $\mathscr{H} \mapsto \Gamma(Y; f^* \mathscr{H})$ corresponds to the extension of scalars functor $M \mapsto B \otimes_A M$. Since f is flat, the construction $\mathscr{H} \mapsto \Gamma(Y; f^* \mathscr{H})$ is left t-exact, so that B has Tor-amplitude $\leqslant 0$ over A. Set $M = \Gamma(X; \mathscr{F})$ and $N = \Gamma(X; \mathscr{G})$. Unwinding the definitions, we are reduced to showing that the canonical map

$$B \otimes_A \underline{\mathrm{Map}}_A(M, N) \to \underline{\mathrm{Map}}_A(M, B \otimes_A N) \simeq \underline{\mathrm{Map}}_B(B \otimes_A M, B \otimes_A N)$$

is an equivalence of B-modules, which is a special case of Lemma 6.5.3.7. □

Corollary 9.5.3.6. *Let X be a quasi-geometric stack and let $\mathscr{F}, \mathscr{G}, \mathscr{H} \in \mathrm{QCoh}(X)$. Suppose that $\mathscr{F}$ is almost perfect, $\mathscr{G}$ is 0-truncated, and $\mathscr{H}$ has* Tor*-amplitude $\leqslant 0$. Then the canonical map*

$$\theta : \mathscr{H} \otimes \underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G}) \to \underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{H} \otimes \mathscr{G})$$

is an equivalence.

Proof. Using Proposition 9.5.3.3, we can reduce to the case where X is affine, in which case Corollary 9.5.3.6 is a reformulation of Lemma 6.5.3.7. □

9.5.4 Tannaka Duality in the Locally Noetherian Case

We consider Tannaka duality in the locally Noetherian context. Our main results can be stated as follows:

Theorem 9.5.4.1 (Tannaka Duality for Locally Noetherian Geometric Stacks)**.** *Let $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be functors and suppose that X is a locally Noetherian geometric stack. Then the construction $(f : Y \to X) \mapsto (f^* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y))$ determines a fully faithful embedding*

$$\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(Y, X) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y)),$$

whose essential image is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ which preserve small colimits and connective objects.

For quasi-geometric stacks, we have the following slightly weaker result:

Theorem 9.5.4.2 (Tannaka Duality for Locally Noetherian Quasi-Geometric Stacks)**.** *Let $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be functors and suppose that X is a locally Noetherian quasi-geometric stack. Then the construction $(f : Y \to X) \mapsto (f^* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y))$ determines a fully faithful embedding*

$$\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(Y, X) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y)),$$

whose essential image is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ which preserve small colimits, connective objects, and almost perfect objects.

Remark 9.5.4.3. In the case where X is assumed to be Noetherian, Theorem 9.5.4.2 was proven by by Bhatt and Halpern-Leistner in [27]; our proof will follow a similar strategy.

Remark 9.5.4.4. In the statements of Theorems 9.5.4.1 and 9.5.4.2, we can replace the assumption that X is locally Noetherian by the weaker assumption that the 0-truncation of X is locally Noetherian, or that there exists an affine map from the 0-truncation of X to a locally Noetherian quasi-geometric stack. The last condition is automatically satisfied for a large class of algebraic stacks (see [177]).

The main step in the proof of Theorems 9.5.4.1 and 9.5.4.2 is contained in the following:

Lemma 9.5.4.5. *Let X be a 0-truncated quasi-geometric stack, let R be a connective $\mathbb{E}_\infty$-ring, and let $F : \mathrm{QCoh}(X) \to \mathrm{Mod}_R$ be a functor which preserves small colimits and connective objects. Let $\alpha : \mathscr{F} \to \mathscr{F}'$ be a morphism in $\mathrm{QCoh}(X)$, where $\mathscr{F}$ is almost perfect and $\mathscr{F}'$ has* Tor*-amplitude $\leqslant 0$. Then, for every object $M \in (\mathrm{Mod}_R)_{\leqslant 0}$, the induced map $\alpha_M : M \otimes_R F(\mathscr{F}) \to M \otimes_R F(\mathscr{F}')$ factors through an object of $(\mathrm{Mod}_R)_{\leqslant 0}$.*

Proof. Set $\mathscr{F}^\vee = \underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{O}_X)$. Since $\mathscr{F}$ is almost perfect, $\mathscr{O}_X$ is 0-truncated, and $\mathscr{F}'$ has Tor-amplitude $\leqslant 0$, it follows from Corollary 9.5.3.6 that the canonical map

$$\rho : \mathscr{F}^\vee \otimes \mathscr{F}' \to \underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{F}')$$

is an equivalence. Let $\mathscr{G} = \tau_{\geqslant 0} \mathscr{F}^\vee$ denote the connective cover of $\mathscr{F}^\vee$. Since $\mathscr{F}'$ has Tor-amplitude $\leqslant 0$, the natural map $\mathscr{G} \otimes \mathscr{F}' \to \mathscr{F}^\vee \otimes \mathscr{F}'$ induces an equivalence on connective covers. It follows that we can choose a map $c : \mathscr{O}_X \to \mathscr{G} \otimes \mathscr{F}'$ which is determined (uniquely up to homotopy) by the requirement that the composition

$$\mathscr{O}_X \xrightarrow{c} \mathscr{G} \otimes \mathscr{F}' \to \mathscr{F}^\vee \otimes \mathscr{F}' \xrightarrow{\rho} \underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{F}')$$

classifies α. The tautological pairing $\mathscr{F} \otimes \mathscr{F}^\vee \to \mathscr{O}_X$ determines an "evaluation map" $e : \mathscr{F} \otimes \mathscr{G} \to \mathscr{O}_X$. Unwinding the definitions, we see that the composite map

$$\mathscr{F} \xrightarrow{\mathrm{id} \otimes c} \mathscr{F} \otimes \mathscr{G} \otimes \mathscr{F}' \xrightarrow{e \otimes \mathrm{id}} \mathscr{F}'$$

is homotopic to α.

Set $N = \underline{\mathrm{Map}}_R(F(\mathscr{G}), M)$. The evaluation morphism e determines a map $e_M : M \otimes_R F(\mathscr{F}) \otimes_R F(\mathscr{G}) \to M$, which is classified by a morphism of R-modules $\beta : M \otimes_R F(\mathscr{F}) \to N$. Let γ denote the composite map

$$N \xrightarrow{\mathrm{id} \otimes F(c)} N \otimes_R F(\mathscr{G}) \otimes_R F(\mathscr{F}') \to M \otimes_R F(\mathscr{F}').$$

Using the fact that $(e \otimes \mathrm{id}) \circ (\mathrm{id} \otimes c)$ is homotopic to α, we deduce that the composition $\gamma \circ \beta$ is homotopic to α_M. Because functor F preserves connective objects, so that R-module $F(\mathscr{G})$ is connective. Since $M \in (\mathrm{Mod}_R)_{\leqslant 0}$, it follows that $N \in (\mathrm{Mod}_R)_{\leqslant 0}$, so that (β, γ) provides the desired factorization of α. □

Proposition 9.5.4.6. *Let $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be functors and let $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ be a symmetric monoidal functor which preserves small colimits and connective objects. If X is a locally Noetherian quasi-geometric stack and $\mathscr{F} \in \mathrm{QCoh}(X)$ has* Tor*-amplitude $\leqslant 0$, then $F(\mathscr{F}) \in \mathrm{QCoh}(Y)$ has* Tor*-amplitude $\leqslant 0$.*

Proof. Without loss of generality we may assume that $Y = \operatorname{Spec} R$ is affine, in which case we can identify $\mathrm{QCoh}(Y)$ with the ∞-category Mod_R. Let M be a discrete R-module; we wish to show that $M \otimes_R F(\mathscr{F})$ belongs to $(\mathrm{Mod}_R)_{\leqslant 0}$. Set $R' = F(\pi_0 \mathscr{O}_X)$. Since the functor F preserves connective objects, the unit map $R = F(\mathscr{O}_X) \to F(\pi_0 \mathscr{O}_X) \to R'$ has 1-connective fiber and therefore induces an isomorphism on π_0. Since M is discrete, it can be regarded as an R'-module in an essentially unique way. Let $v : X' \to X$ exhibit X' as a 0-truncation of X. The functor F then induces a symmetric monoidal functor

$$F' : \mathrm{QCoh}(X') \simeq \mathrm{Mod}_{\pi_0 \mathscr{O}_X}(\mathrm{QCoh}(X)) \xrightarrow{F} \mathrm{Mod}_{R'}$$

which preserves small colimits and connective objects. We have a canonical equivalence $M \otimes_R F(\mathscr{F}) \simeq M \otimes_{R'} F'(v^* \mathscr{F})$. Replacing X by X', F by F', and $\mathscr{F}$ by $v^* \mathscr{F}$, we may reduce to the case where X is 0-truncated. In this case, the assumption that $\mathscr{F}$ has Tor-amplitude $\leqslant 0$ guarantees that it belongs to $\mathrm{QCoh}(X)_{\leqslant 0}$. Our assumption that X is locally Noetherian guarantees that the prestable ∞-category $\mathrm{QCoh}(X)^{\mathrm{cn}}$ is locally Noetherian (Proposition 9.5.2.3). Applying Corollary **??**, we deduce that $\mathscr{F}$ can be written as the colimit of a filtered diagram $\{\mathscr{F}_\alpha\}$ where each $\mathscr{F}_\alpha$ is almost perfect (and 0-truncated, but we will not need this). Since the functor F preserves colimits, we obtain an equivalence $M \otimes_R F(\mathscr{F}) \simeq \varinjlim (M \otimes_R F(\mathscr{F}_\alpha))$. In particular, any element of $\pi_n(M \otimes_R F(\mathscr{F}))$ lies in the image of the natural map $\pi_n(M \otimes_R F(\mathscr{F}_\alpha)) \to \pi_n(M \otimes_R F(\mathscr{F}))$ for some index α. These maps vanish for $n > 0$ by virtue of Lemma 9.5.4.5, so that $M \otimes_R F(\mathscr{F})$ belongs to $(\mathrm{Mod}_R)_{\leqslant 0}$ as desired. □

Corollary 9.5.4.7. *Let $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be functors and let $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ be a symmetric monoidal functor which preserves small colimits and connective objects. If X is a locally Noetherian quasi-geometric stack, then F carries flat objects to flat objects.*

Proof. If $\mathscr{F} \in \mathrm{QCoh}(X)$ is flat, then $\mathscr{F}$ is connective and of Tor-amplitude $\leqslant 0$. It follows from Proposition 9.5.4.6 (and our assumption that F preserves connective objects) that $F(\mathscr{F})$ is connective and of Tor-amplitude $\leqslant 0$, and is therefore flat. □

Proof of Theorem 9.5.4.1. Combine Theorem 9.3.0.3 with Corollary 9.5.4.7. □

Remark 9.5.4.8. The proof of Theorem 9.5.4.1 did not require full strength of the assumption that X is locally Noetherian: only that every discrete object of $\mathrm{QCoh}(X)$ can be written as a filtered colimit of almost perfect objects of $\mathrm{QCoh}(X)$. This condition is also satisfied when X is perfect, which gives an alternative proof of Corollary 9.4.4.7 (at least when X has affine diagonal).

Proof of Theorem 9.5.4.2. We begin as in the proof of Theorem 9.2.0.2. Let X be a locally Noetherian quasi-geometric stack and let $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be arbitrary. Note that the map $\theta_Y : \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(Y, X) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y))$ is automatically fully faithful (Proposition 9.2.2.1). It will therefore suffice to show that if $F : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$ is a symmetric monoidal functor which preserves small colimits, connective objects, and almost perfect objects, then there exists a symmetric monoidal equivalence $F \simeq f^*$ for some map $f : Y \to X$; the map f is then uniquely determined (up to a contractible space of choices). Writing Y as a colimit of corepresentable functors, we can assume that $Y = \operatorname{Spec} R$ for some connective $\mathbb{E}_\infty$-ring R.

Since X is quasi-geometric, we can choose a faithfully flat morphism $u : U \to X$, where U is affine (in fact, we can assume that U is corepresentable by a Noetherian $\mathbb{E}_\infty$-ring, but we will not need this). Set $\mathscr{A} = u_* \mathscr{O}_U \in \mathrm{CAlg}(\mathrm{QCoh}(X))$. As in the proof of Theorem 9.2.0.2, the main step is to establish the following:

$(*)$ There exists a faithfully flat, quasi-affine morphism $v : Y' \to Y$ and an equivalence $F(\mathscr{A}) \simeq v_* \mathscr{O}_{Y'}$ in $\mathrm{CAlg}(\mathrm{QCoh}(Y))$.

Assuming $(*)$, we can apply Proposition 6.3.4.6 to obtain symmetric monoidal equivalences

$$\mathrm{QCoh}(U) \simeq \mathrm{Mod}_{\mathcal{A}}(\mathrm{QCoh}(X))$$

$$\mathrm{QCoh}(Y') \simeq \mathrm{Mod}_{v_* \mathscr{O}_{Y'}}(\mathrm{QCoh}(Y)) \simeq \mathrm{Mod}_{F(\mathscr{A})}(\mathrm{QCoh}(Y)).$$

Consequently, F induces a symmetric monoidal functor $F' : \mathrm{QCoh}(U) \to \mathrm{QCoh}(Y')$ which fits into a commutative diagram

$$\begin{array}{ccc} \mathrm{QCoh}(X) & \xrightarrow{F} & \mathrm{QCoh}(Y) \\ \downarrow u^* & & \downarrow v^* \\ \mathrm{QCoh}(U) & \xrightarrow{F'} & \mathrm{QCoh}(Y'). \end{array}$$

Since U is affine and Y' is quasi-affine, Proposition 9.2.1.1 implies the existence of a symmetric monoidal equivalence $F' \simeq f'^*$ for some map $f' : Y' \to U$. It follows that $v^* \circ F$ belongs to the essential image of the fully faithful embedding $\theta_{Y'}$. Since v is faithfully flat, it will then follow that F belongs to the essential image of θ_Y, as desired.

We now prove $(*)$. Using Proposition 6.3.4.5, we can write $\tau_{\geqslant 0} \mathscr{A}$ as the direct image $\overline{u}_* \mathscr{O}_{\overline{U}}$ for some affine morphism of quasi-geometric stacks $\overline{u} : \overline{U} \to X$ (beware that $\overline{U}$ is not affine). The natural map $\tau_{\geqslant 0} \mathscr{A} \hookrightarrow \mathscr{A}$ then determines a map $j : U \to \overline{U}$. Since X is a quasi-geometric stack, the map u is quasi-affine, so that j is a quasi-compact open immersion. Let $\mathcal{I} \subseteq \pi_0 \mathscr{A}$ be the ideal sheaf whose vanishing locus is the reduced closed substack of $\overline{U}$ complementary to j. Since X is locally Noetherian, we can write $\mathcal{I}$ as the colimit of a filtered diagram $\{\mathscr{F}_\alpha\}$ in $\mathrm{Coh}(X)^\heartsuit$ (Proposition 9.5.2.3). For each index α, the we have a map $e_\alpha : \mathscr{F}_\alpha \to \mathcal{I}$ whose image generates an ideal sheaf $\mathcal{I}_\alpha \subseteq \mathcal{I}$, whose vanishing locus is complementary to an open subfunctor $U_\alpha \subseteq U$. Note that $U = \bigcup_\alpha U_\alpha$. Since j is quasi-compact, we can choose an index α such that $U_\alpha = U$. Set $\mathscr{F} = \mathscr{F}_\alpha$ and $e = e_\alpha$, so that we have a map $e : \mathscr{F} \to \mathcal{I}$ in $\mathrm{QCoh}(X)^\heartsuit$.

Set $A = F(\tau_{\geqslant 0} \mathscr{A}) \in \mathrm{CAlg}_R^{\mathrm{cn}}$ and set $\overline{Y}' = \operatorname{Spec} A$. Note that e determines a map

$$F(\mathscr{F}) \xrightarrow{F(e)} F(\mathcal{I}) \to F(\pi_0 \mathscr{A}).$$

Since F is right t-exact, the projection map $F(\tau_{\geqslant 0} \mathscr{A}) \to F(\pi_0 \mathscr{A})$ induces an isomorphism on π_0, so that $F(e)$ induces a map of discrete R-modules $\lambda : \pi_0 F(\mathscr{F}) \to \pi_0 A$. Let $J \subseteq \pi_0 A$ be the ideal generated by the image of λ. The object $\mathscr{F} \in \mathrm{QCoh}(X)$ is connective and almost perfect, so that the R-module $F(\mathscr{F})$ is connective and almost perfect. It follows that $\pi_0 F(\mathscr{F})$ is a finitely presented R-module, so that the ideal J is finitely generated. Let $Y' \subseteq \overline{Y}'$ denote the open substack complementary to the vanishing locus of J. The affine projection map $\overline{v} : \overline{Y}' \to Y = \operatorname{Spec} R$ then restricts to a quasi-affine map $v : Y' \to \operatorname{Spec} R$. We will deduce $(*)$ from the following:

$(*')$ There is a canonical equivalence $F(\mathscr{A}) \simeq v_* \mathscr{O}_{Y'}$ in the ∞-category $\mathrm{CAlg}(\mathrm{QCoh}(Y)) \simeq \mathrm{CAlg}_R$.

By construction, we can identify $v_* \mathscr{O}_{Y'}$ with the J-localization of the $\mathbb{E}_\infty$-ring $A = F(\tau_{\geqslant 0} \mathscr{A})$. Set $M = \mathrm{fib}(A \to F(\mathscr{A})) \simeq F(\Sigma(\tau_{\leqslant -1} \mathscr{A}))$, so that we have a canonical fiber sequence $M \to A \to F(\mathscr{A})$. To prove $(*')$, it will suffice to show that this fiber sequence exhibits $F(\mathscr{A})$ as a J-localization of A. This is equivalent to the following pair of assertions:

(i) The R-module M is J-nilpotent.

(ii) The R-module $F(\mathscr{A})$ is J-local.

We first prove (i). Note that we can write M as a successive extension of shifted copies of objects of the form $F(\pi_m \mathscr{A})$, where $m < 0$. It will therefore suffice to show that $F(\pi_m \mathscr{A}) \in \mathrm{Mod}_R$ is J-nilpotent for $m < 0$. Using Proposition 9.5.2.3, we can write $\pi_m \mathscr{A}$ as the colimit of a filtered diagram $\{\mathscr{G}_\beta\}$ in the abelian category $\mathrm{QCoh}(X)^\heartsuit$. For each index β, let $\mathscr{G}_\beta^+$ denote the $(\pi_0 \mathscr{A})$-submodule of $\pi_m \mathscr{A}$ generated by $\mathscr{G}_\beta$. Under the equivalence $\mathrm{QCoh}(\overline{U}) \simeq \mathrm{Mod}_{\tau_{\geqslant 0} \mathscr{A}}(\mathrm{QCoh}(X))$, we can identify $\mathscr{G}_\beta^+$ with an object of $\mathrm{QCoh}(\overline{U})^\heartsuit$ which is perfect to order 0 and whose image in $\mathrm{QCoh}(U)$ vanishes (since $m < 0$). It follows that there exists an integer $n \gg 0$ such that the composite map

$$\mathscr{F}^{\otimes n} \otimes \mathscr{G}_\beta^+ \xrightarrow{e^n \otimes \mathrm{id}} (\pi_0 \mathscr{A}) \otimes \mathscr{G}_\beta \to \mathscr{G}_\beta^+$$

is nullhomotopic. Applying the functor F, we deduce that the map $F(\mathscr{F}^{\otimes n}) \otimes F(\mathscr{G}_\beta^+) \to F(\mathscr{G}_\beta^+)$ is nullhomotopic, so that the graded $(\pi_0 R)$-module $\pi_* F(\mathscr{G}_\beta^+)$ is annihilated by the ideal J^n and therefore $F(\mathscr{G}_\beta^+)$ is J-nilpotent. Writing $F(\pi_m \mathscr{A}) \simeq \varinjlim_\beta F(\mathscr{G}_\beta^+)$, we deduce that $F(\pi_m \mathscr{A})$ is J-nilpotent for $m < 0$, which completes the proof of (i).

We now prove (ii). Let us identify the map $e : \mathscr{F} \to \pi_0 \mathscr{A} = \overline{u}_*(\pi_0 \mathscr{O}_{\overline{U}})$ with a map $e' : \overline{u}^* \mathscr{F} \to \pi_0 \mathscr{O}_{\overline{U}}$. By construction, the induced map $e'|_U : u^* \mathscr{F} \to \pi_0 \mathscr{O}_U$ induces an epimorphism on π_0. Since U is affine, it follows that we can choose a map $s : \mathscr{O}_U \to u^* \mathscr{F}$ whose composition with $e'|_U$ is the identity section of $\pi_0 \mathscr{O}_U$. The direct image of s along u can be identified with a morphism $\mathscr{A} \to \mathscr{A} \otimes \mathscr{F}$ of $\mathscr{A}$-module objects of $\mathrm{QCoh}(X)$, and therefore determines a morphism of R-modules $F(s) : F(\mathscr{A}) \to F(\mathscr{A}) \otimes_R F(\mathscr{F})$. By construction, the map $F(s)$ fits into a commutative diagram

$$\begin{array}{ccc} & F(\mathscr{A}) & \\ {}^{F(s)}\swarrow & & \searrow \\ F(\mathscr{A}) \otimes_R F(\mathscr{F}) & \longrightarrow & F(\mathscr{A}) \otimes_A \pi_0 A. \end{array}$$

It follows that the composite map $F(\mathscr{A}) \to F(\mathscr{A}) \otimes_A (\pi_0 A) \to F(\mathscr{A}) \otimes_A (\pi_0 A/J)$ is nullhomotopic. Since this map is a morphism of $\mathbb{E}_\infty$-algebras, we conclude that $F(\mathscr{A}) \otimes_A (\pi_0 A/J)$. Since $\mathscr{A}$ is almost connective (Proposition 9.1.3.5) and the functor F is right t-exact, the A-algebra $F(\mathscr{A})$ is almost connective. Applying Lemma **??**, we deduce that $F(\mathscr{A})$ is J-local, as desired. This completes the proof of (ii), and therefore also the proof of $(*')$.

To complete the proof of $(*)$, we must show that the map $v : Y' \to Y$ is faithfully flat. We first claim that v is flat. Since Y is affine, it will suffice to show that for each

$\mathscr{G} \in \mathrm{QCoh}(Y)^{\heartsuit}$, the pullback $v^* \mathscr{G}$ belongs to $\mathrm{QCoh}(Y')_{\leqslant 0}$. Since Y' is quasi-affine, this is equivalent to the statement that the spectrum $\Gamma(Y'; v^* \mathscr{G})$ is 0-truncated. We now compute

$$\begin{aligned} \Gamma(Y'; v^* \mathscr{G}) &\simeq \Gamma(Y; v_* v^* \mathscr{G}) \\ &\simeq \Gamma(Y; v_* \mathscr{O}_{Y'} \otimes \mathscr{G}) \\ &\simeq \Gamma(Y; F(\mathscr{A}) \otimes \mathscr{G}). \end{aligned}$$

It now suffices to observe that $F(\mathscr{A}) \otimes \mathscr{G}$ is 0-truncated, since $\mathscr{G}$ is 0-truncated by assumption that $F(\mathscr{A})$ has Tor-amplitude $\leqslant 0$ by virtue of Proposition 9.5.4.6.

It remains to show that v is faithfully flat. For this, it will suffice to show that for $\mathscr{G} \in \mathrm{QCoh}(Y)^{\heartsuit}$ as above, the canonical map $\rho : \Gamma(Y; \mathscr{G}) \to \Gamma(Y'; v^* \mathscr{G})$ induces an injection on π_0 (in this case, the vanishing of $v^* \mathscr{G}$ guarantees the vanishing of $\pi_0 \Gamma(Y; \mathscr{G})$, hence also the vanishing of $\mathscr{G}$ since Y is affine and $\mathscr{G}$ is discrete). Using the preceding calculation, we can identify ρ with the canonical map $\Gamma(Y; \mathscr{G}) \to \Gamma(Y; F(\mathscr{A}) \otimes \mathscr{G})$, whose cofiber is given by $\Gamma(Y; F(\mathrm{cofib}(\mathscr{O}_X \to \mathscr{A})) \otimes \mathscr{G})$. It will therefore suffice to show that the group $\pi_1 \Gamma(Y; F(\mathrm{cofib}(\mathscr{O}_X \to \mathscr{A})) \otimes \mathscr{G})$ vanishes. This is clear: the tensor product $F(\mathrm{cofib}(\mathscr{O}_X \to \mathscr{A})) \otimes \mathscr{G}$ is 0-truncated, since $\mathscr{G}$ is 0-truncated by assumption and $F(\mathrm{cofib}(\mathscr{O}_X \to \mathscr{A}))$ has Tor-amplitude $\leqslant 0$ by virtue of Proposition 9.5.4.6. □

9.5.5 Almost Perfect Sheaves

Let X be a locally Noetherian quasi-geometric stack. It follows from Proposition 9.5.2.3 that the ∞-category $\mathrm{QCoh}(X)$ contains many almost perfect objects. We now show that the Tannaka duality results of §9.5.4 can be reformulated in terms of almost perfect sheaves.

Theorem 9.5.5.1. *Let $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be functors and suppose that X is a locally Noetherian geometric stack. Then the construction $(f : Y \to X) \mapsto (f^* : \mathrm{QCoh}(X)^{\mathrm{aperf}} \to \mathrm{QCoh}(Y)^{\mathrm{aperf}})$ determines a fully faithful embedding*

$$\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})}(Y, X) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{aperf}}, \mathrm{QCoh}(Y)^{\mathrm{aperf}}),$$

whose essential image is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X)^{\mathrm{aperf}} \to \mathrm{QCoh}(Y)^{\mathrm{aperf}}$ which are exact and preserve connective objects.

Remark 9.5.5.2. Under the slightly stronger assumption that X is Noetherian, Theorem 9.5.5.1 was proven by Bhatt and Halpern-Leistner in [27].

Corollary 9.5.5.3. *Let R be a connective $\mathbb{E}_\infty$-ring which is complete with respect to a finitely generated ideal I, let Y be a spectral algebraic spaces which is proper and almost of finite presentation over R, and let $\mathsf{Y}^{\wedge} = \mathsf{Y} \times_{\mathrm{Spec}\, R} \mathrm{Spf}\, R$ be the formal completion of Y*

along the vanishing locus of I, which we regard as a functor $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Let X be a locally Noetherian quasi-geometric stack. Then the restriction map

$$\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}},\mathcal{S})}(\mathsf{Y}, X) \to \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}},\mathcal{S})}(\mathsf{Y}^{\wedge}, X)$$

is a homotopy equivalence.

Proof. It follows from Theorem 8.5.0.3 (together with Corollary 8.3.4.6 and Theorem 8.3.5.2) that the restriction functor $\mathrm{QCoh}(\mathsf{Y})^{\mathrm{aperf}} \to \mathrm{QCoh}(\mathsf{Y}^{\wedge})^{\mathrm{aperf}}$ is an equivalence of ∞-categories, and from Proposition 8.5.1.4 that an object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})^{\mathrm{aperf}}$ is connective if and only if $\mathscr{F}|_{\mathsf{Y}^{\wedge}}$ is connective. The desired result now follows from Theorem 9.5.5.1. □

Proof of Theorem 9.5.5.1. Without loss of generality, we may assume that $Y = \mathrm{Spec}\, R$ is affine. Using Theorem 9.5.4.2, we can identify $\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}},\mathcal{S})}(Y, X)$ with the full subcategory

$$\mathrm{Fun}_0^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y)) \subseteq \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y))$$

spanned by those symmetric monoidal functors which preserve small colimits, connective objects, and almost perfect objects. Let $\mathrm{Fun}_0^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{aperf}}, \mathrm{QCoh}(Y))$ denote the full subcategory of $\mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{aperf}}, \mathrm{QCoh}(Y))$ spanned by those symmetric monoidal functors which preserve finite colimits, connective objects, and almost perfect objects. We wish to show that the restriction map

$$\theta : \mathrm{Fun}_0^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y)) \to \mathrm{Fun}_0^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{aperf}}, \mathrm{QCoh}(Y))$$

is an equivalence of ∞-categories. To prove this, we may assume without loss of generality that $Y = \mathrm{Spec}\, R$ is affine.

Since X is locally Noetherian, the full subcategory $\mathrm{QCoh}(X)^{\mathrm{aperf}} \subseteq \mathrm{QCoh}(X)$ is stable under truncation, and therefore inherits a t-structure $(\mathrm{QCoh}(X)^{\mathrm{aperf}}_{\geqslant 0}, \mathrm{QCoh}(X)^{\mathrm{aperf}}_{\leqslant 0})$ where $\mathrm{QCoh}(X)^{\mathrm{aperf}}_{\geqslant 0} = \mathrm{QCoh}(X)^{\mathrm{aperf}} \cap \mathrm{QCoh}(X)_{\geqslant 0}$ and $\mathrm{QCoh}(X)^{\mathrm{aperf}}_{\leqslant 0} = \mathrm{QCoh}(X)^{\mathrm{aperf}} \cap \mathrm{QCoh}(X)_{\leqslant 0}$. Note that every almost perfect object of $\mathrm{QCoh}(X)$ is $(-n)$-truncated for $n \gg 0$, so that the t-structure $(\mathrm{QCoh}(X)^{\mathrm{aperf}}_{\geqslant 0}, \mathrm{QCoh}(X)^{\mathrm{aperf}}_{\leqslant 0})$ is right-bounded. Set $\mathcal{C} = \mathrm{Ind}(\mathrm{QCoh}(X)^{\mathrm{aperf}})$, so that $\mathcal{C}$ inherits a t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ with $\mathcal{C}_{\geqslant 0} \simeq \mathrm{Ind}(\mathrm{QCoh}(X)^{\mathrm{aperf}}_{\geqslant 0})$ and $\mathcal{C}_{\leqslant 0} \simeq \mathrm{Ind}(\mathrm{QCoh}(X)^{\mathrm{aperf}}_{\leqslant 0})$. Moreover, the t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ is right complete and compatible with filtered colimits (Lemma C.2.4.3).

Let $\mathcal{D}$ be any symmetric monoidal ∞-category which admits small colimits, for which the tensor product $\mathcal{D} \times \mathcal{D} \to \mathcal{D}$ preserves small colimits separately in each variable. Using Corollary HA.4.8.1.14 , we see that composition with the Yoneda embedding $\mathrm{QCoh}(X)^{\mathrm{aperf}} \hookrightarrow \mathcal{C}$ induces an equivalence of ∞-categories

$$\mathrm{LFun}^{\otimes}(\mathcal{C}, \mathcal{D}) \to \mathrm{Fun}^{\otimes}_{\mathrm{rex}}(\mathrm{QCoh}(X)^{\mathrm{aperf}}, \mathcal{D}),$$

where $\mathrm{LFun}^{\otimes}(\mathcal{C}, \mathcal{D})$ denotes the full subcategory of $\mathrm{Fun}^{\otimes}(\mathcal{C}, \mathcal{D})$ spanned by those symmetric monoidal functors which preserve small colimits, and $\mathrm{Fun}^{\otimes}_{\mathrm{rex}}(\mathrm{QCoh}(X)^{\mathrm{aperf}}, \mathcal{D})$ denotes the full subcategory of $\mathrm{Fun}^{\otimes}_{\mathrm{rex}}(\mathrm{QCoh}(X)^{\mathrm{aperf}}, \mathcal{D})$ spanned by those functors which preserve finite colimits. Applying this observation with $\mathcal{D} = \mathrm{QCoh}(X)$ (and using the fact that the t-structure on $\mathrm{QCoh}(X)$ is compatible with filtered colimits), we see that the inclusion $\mathrm{QCoh}(X)^{\mathrm{aperf}} \hookrightarrow \mathrm{QCoh}(X)$ admits an essentially unique extension $\lambda : \mathcal{C} \to \mathrm{QCoh}(X)$ which commutes with small colimits; moreover, λ is t-exact. Similarly, taking $\mathcal{D} = \mathrm{QCoh}(Y)$, we obtain an equivalence of ∞-categories $\mathrm{Fun}^{\otimes}_{0}(\mathrm{QCoh}(X)^{\mathrm{aperf}}, \mathrm{QCoh}(Y)) \simeq \mathrm{Fun}^{\otimes}_{0}(\mathcal{C}, \mathrm{QCoh}(Y))$, where $\mathrm{Fun}^{\otimes}_{0}(\mathcal{C}, \mathrm{QCoh}(Y))$ denotes the full subcategory of $\mathrm{Fun}^{\otimes}(\mathcal{C}, \mathrm{QCoh}(Y))$ spanned by those symmetric monoidal functors which are right t-exact and preserve small colimits. Under this equivalence, we can identify θ with the map $\mathrm{Fun}^{\otimes}_{0}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y)) \to \mathrm{Fun}^{\otimes}_{0}(\mathcal{C}, \mathrm{QCoh}(Y))$ given by precomposition with λ.

Let $\mathrm{Fun}^{\otimes}_{0}(\mathrm{QCoh}(X)^{\mathrm{cn}}, \mathrm{QCoh}(Y)^{\mathrm{cn}}) \subseteq \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{cn}}, \mathrm{QCoh}(Y)^{\mathrm{cn}})$ be the full subcategory spanned by those symmetric monoidal functors which preserve small colimits, and define $\mathrm{Fun}^{\otimes}_{0}(\mathcal{C}_{\geqslant 0}, \mathrm{QCoh}(Y)^{\mathrm{cn}})$ similarly. Using Proposition C.3.1.1 (together with the observation that the construction $\mathcal{E} \mapsto \mathrm{Sp}(\mathcal{E})$ determines a symmetric monoidal functor $\mathsf{Groth}_{\infty} \to \mathcal{P}\mathrm{r}^{\mathrm{St}}$), we obtain a commutative diagram

$$\begin{array}{ccc} \mathrm{Fun}^{\otimes}_{0}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y)) & \xrightarrow{\theta} & \mathrm{Fun}^{\otimes}_{0}(\mathcal{C}, \mathrm{QCoh}(Y)) \\ \downarrow & & \downarrow \\ \mathrm{Fun}^{\otimes}_{0}(\mathrm{QCoh}(X)^{\mathrm{cn}}, \mathrm{QCoh}(Y)^{\mathrm{cn}}) & \xrightarrow{\theta'} & \mathrm{Fun}^{\otimes}_{0}(\mathcal{C}_{\geqslant 0}, \mathrm{QCoh}(Y)^{\mathrm{cn}}) \end{array}$$

where the vertical maps are equivalences. We will complete the proof by showing that θ' is an equivalence of ∞-categories. Since the Grothendieck prestable ∞-category $\mathrm{QCoh}(Y)^{\mathrm{cn}} \simeq \mathrm{Mod}^{\mathrm{cn}}_{R}$ is complete, it will suffice to show that the functor $\lambda : \mathcal{C}_{\geqslant 0} \to \mathrm{QCoh}(X)^{\mathrm{cn}}$ exhibits $\mathrm{QCoh}(X)^{\mathrm{cn}}$ as the completion of $\mathcal{C}_{\geqslant 0}$, in the sense of Proposition C.3.6.3. In other words, it will suffice to show that for each $n \geqslant 0$, the functor λ induces an equivalence of ∞-categories $\tau_{\leqslant n} \mathcal{C}_{\geqslant 0} \to \tau_{\leqslant n} \mathrm{QCoh}(X)^{\mathrm{cn}}$. Note that the domain of this functor can be identified with $\mathrm{Ind}(\tau_{\leqslant n} \mathrm{QCoh}(X)^{\mathrm{aperf}}_{\geqslant 0})$. The desired result now follows from Corollary **??** (since the Grothendieck prestable ∞-category $\mathrm{QCoh}(X)^{\mathrm{cn}}$ is locally Noetherian by virtue of Proposition 9.5.2.3. □

9.6 Tannaka Duality for Spectral Algebraic Spaces

Let X be a spectral algebraic space which is quasi-compact and quasi-separated. Throughout this section, we will abuse notation by not distinguishing between X and the functor $h_{\mathsf{X}} : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ represented by X. With this abuse, we can regard X as a quasi-geometric stack (Corollary 9.1.4.6). It follows from Theorem 9.2.0.2 that X can be recovered from the symmetric monoidal ∞-category $\mathrm{QCoh}(\mathsf{X})$ of quasi-coherent sheaves on X, together with its t-structure. In this section, we will show that even the t-structure is unnecessary, thanks to the following refinement of Theorem 9.2.0.2:

Theorem 9.6.0.1 (Tannaka Duality for Spectral Algebraic Spaces)**.** *Let X and Y be spectral Deligne-Mumford stacks. Assume that X is a quasi-compact, quasi-separated spectral algebraic space. Then the construction $(f : \mathsf{Y} \to \mathsf{X}) \mapsto (f^* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y}))$ induces a fully faithful embedding $\mathrm{Map}_{\mathrm{SpDM}}(\mathsf{Y}, \mathsf{X}) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(\mathsf{X}), \mathrm{QCoh}(\mathsf{Y}))$, whose essential image is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ which preserve small colimits.*

Corollary 9.6.0.2. *Let $\mathcal{C} \subseteq \mathrm{SpDM}$ denote the full subcategory spanned by the quasi-compact, quasi-separated algebraic spaces. Then the construction $\mathsf{X} \mapsto \mathrm{QCoh}(\mathsf{X})$ determines a fully faithful embedding $\mathcal{C}^{\mathrm{op}} \to \mathrm{CAlg}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$.*

9.6.1 Compact Generation of $\mathrm{QCoh}(\mathsf{X})$

Our first step in the proof of Theorem 9.6.0.1 is to establish the following:

Proposition 9.6.1.1. *Let X be a quasi-compact, quasi-separated spectral algebraic space. Then the ∞-category $\mathrm{QCoh}(\mathsf{X})$ is compactly generated. Moreover, an object of $\mathrm{QCoh}(\mathsf{X})$ is compact if and only if it is perfect. In other words, X is a perfect stack (Definition 9.4.4.1).*

Combining Proposition 9.6.1.1 with Corollary 9.4.4.7, we immediately obtain the following weaker version of Theorem 9.6.0.1:

$(*)$ If X is a quasi-compact, quasi-separated spectral algebraic space and Y is an arbitrary spectral Deligne-Mumford stack, then the construction $(f : \mathsf{Y} \to \mathsf{X}) \mapsto (f^* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y}))$ determines an equivalence from $\mathrm{Map}_{\mathrm{SpDM}}(\mathsf{Y}, \mathsf{X})$ to the full subcategory of $\mathrm{Fun}^{\otimes}(\mathrm{QCoh}(\mathsf{X}), \mathrm{QCoh}(\mathsf{Y}))$ spanned by those symmetric monoidal functors which are right t-exact and preserve small colimits.

To deduce Theorem 9.6.0.1 from $(*)$, we will need to show that the hypothesis of right t-exactness is automatically satisfied. To prove this, we will need the following variant of Proposition 9.6.1.1:

Proposition 9.6.1.2. *Let X be a quasi-compact, quasi-separated spectral algebraic space, and let $\mathcal{C} \subseteq \mathrm{QCoh}(\mathsf{X})$ denote the full subcategory spanned by those quasi-coherent sheaves which are perfect and connective. Then the inclusion $\mathcal{C} \hookrightarrow \mathrm{QCoh}(\mathsf{X})$ extends to an equivalence of ∞-categories $\mathrm{Ind}(\mathcal{C}) \simeq \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$.*

Before giving the proof of Proposition 9.6.1.2, let us describe some of its consequences.

Corollary 9.6.1.3. *Let* X *be a quasi-compact, quasi-separated spectral algebraic space, and let* $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ *be connective and* n*-truncated. Then* $\mathscr{F}$ *can be written as a filtered colimit* $\varinjlim \mathscr{F}_\alpha$*, where each* $\mathscr{F}_\alpha$ *is connective and finitely* n*-presented.*

Proof. Using Proposition 9.6.1.2, we can write $\mathscr{F}$ as a filtered colimit $\varinjlim_\alpha \mathscr{G}_\alpha$, where each $\mathscr{G}_\alpha$ is connective and perfect. Since $\mathscr{F}$ is n-truncated, we obtain $\mathscr{F} \simeq \tau_{\leqslant n} \mathscr{F} \simeq \varinjlim_\alpha \tau_{\leqslant n} \mathscr{G}_\alpha$, where each $\tau_{\leqslant n} \mathscr{G}_\alpha$ is connective and finitely n-presented. □

Corollary 9.6.1.4. *Let* $f : \mathsf{X} \to \mathsf{Y}$ *be a morphism of spectral Deligne-Mumford stacks which is proper, locally almost of finite presentation, and of relative dimension* $\leqslant d$*. Then the pushforward functor* $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ *carries* $\mathrm{QCoh}(\mathsf{X})_{\geqslant 0}$ *into* $\mathrm{QCoh}(\mathsf{Y})_{\geqslant -d}$*.*

Proof. Let $\mathscr{F}$ be a connective quasi-coherent sheaf on X; we wish to show that $f_* \mathscr{F}$ is $(-d)$-connective. This assertion is local on Y; we may therefore assume without loss of generality that $\mathsf{Y} \simeq \mathrm{Sp\acute{e}t}\, A$ for some connective $\mathbb{E}_\infty$-ring A. Under this assumption, X is a quasi-compact quasi-separated spectral algebraic space. Using Proposition 9.6.1.2, we can write $\mathscr{F}$ as the colimit of a filtered diagram $\{\mathscr{F}_\alpha\}$ in $\mathrm{QCoh}(\mathsf{X})$, where each $\mathscr{F}_\alpha$ is perfect and connective. Since the functor f_* commutes with filtered colimits and the full subcategory $\mathrm{QCoh}(\mathsf{Y})_{\geqslant -d} \subseteq \mathrm{QCoh}(\mathsf{Y})$ is closed under filtered colimits, it will suffice to show that each pushforward $f_* \mathscr{F}_\alpha$ belongs to $\mathrm{QCoh}(\mathsf{Y})_{\geqslant -d}$. We may therefore replace $\mathscr{F}$ by $\mathscr{F}_\alpha$ and thereby reduce to the case where $\mathscr{F}$ is perfect. In this case, $f_* \mathscr{F} \in \mathrm{QCoh}(\mathsf{Y}) \simeq \mathrm{Mod}_A$ is almost perfect (Theorem 5.6.0.2). Consequently, to prove that $f_* \mathscr{F}$ is n-connective, it will suffice to show that for each residue field κ of A, the tensor product $\kappa \otimes_A f_* \mathscr{F}$ is n-connective (Corollary 2.7.4.3). We may therefore replace A by κ and thereby reduce to the case where $A = \kappa$ is a field. In this case, our assumption that f has relative dimension $\leqslant d$ guarantees that X is a locally Noetherian spectral algebraic space of Krull dimension $\leqslant d$ (Proposition 3.7.6.2), so that the $f_* \mathscr{F} \simeq \Gamma(\mathsf{X}; \mathscr{F})$ is $(-d)$-connective by virtue of Theorem 3.7.0.2. □

Warning 9.6.1.5. Corollary 9.6.1.4 is not true if f is not assumed to be proper. For example, every open immersion $j : \mathsf{U} \hookrightarrow \mathsf{X}$ has relative dimension $\leqslant 0$, but the pushforward functor j_* is generally not right t-exact unless j is affine.

Proof of Proposition 9.6.1.1 from Proposition 9.6.1.2. Let X be a spectral algebraic space which is quasi-compact and quasi-separated and let $\mathcal{C}$ denote the full subcategory of $\mathrm{QCoh}(\mathsf{X})$ spanned by the perfect objects. It follows from Corollary 9.1.5.5 that the inclusion $\mathcal{C} \hookrightarrow \mathrm{QCoh}(\mathsf{X})$ extends to a fully faithful embedding $\theta : \mathrm{Ind}(\mathcal{C}) \to \mathrm{QCoh}(\mathsf{X})$, whose essential image is closed under small colimits. Let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$; we wish to show that $\mathscr{F}$ belongs to the essential image of θ. Since the t-structure on $\mathrm{QCoh}(\mathsf{X})$ is right-complete, we can write $\mathscr{F}$ as a colimit of the sequence

$$\cdots \to \tau_{\geqslant 0} \mathscr{F} \to \tau_{\geqslant -1} \mathscr{F} \to \tau_{\geqslant -2} \mathscr{F} \to \cdots .$$

It therefore suffices to show that each truncation $\tau_{\geqslant -n}\mathscr{F}$ belongs to the essential image of θ, which follows immediately from Proposition 9.6.1.2. □

Corollary 9.6.1.6. *Let R be a connective $\mathbb{E}_\infty$-ring and let X be a quasi-compact, quasi-separated spectral algebraic space over R. For every map of connective $\mathbb{E}_\infty$-rings $R \to A$, let X_A denote the fiber product $\mathrm{Sp\acute{e}t}\, A \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X}$, and let $\mathrm{QCoh}(\mathsf{X}_A)^{\mathrm{perf}}$ denote the full subcategory of $\mathrm{QCoh}(\mathsf{X}_A)$ spanned by those quasi-coherent sheaves which are perfect. Then construction $A \mapsto \mathrm{QCoh}(\mathsf{X}_A)^{\mathrm{perf}}$ determines a functor $\mathrm{CAlg}_R^{\mathrm{cn}} \to \mathcal{C}\mathrm{at}_\infty$ which preserves small filtered colimits.*

Proof. Since X is perfect (Proposition 9.6.1.1), Corollary 9.4.2.3 supplies equivalences

$$\mathrm{QCoh}(\mathsf{X}_A) \simeq \mathrm{Mod}_A \otimes_{\mathrm{Mod}_R} \mathrm{QCoh}(\mathsf{X}).$$

Using Lemma HA.7.3.5.12 (and that the forgetful functor $\mathrm{CAlg}^{\mathrm{cn}} \to \mathrm{Alg}$ preserves filtered colimits), we deduce that the construction $A \mapsto \mathrm{QCoh}(\mathsf{X}_A)$ determines a functor $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ which preserves small filtered colimits. Using Corollary 9.1.5.5, we can identify $\mathrm{QCoh}(\mathsf{X}_A)^{\mathrm{perf}}$ with the full subcategory of $\mathrm{QCoh}(\mathsf{X}_A)$ spanned by the compact objects. The desired result now follows from Lemma HA.7.3.5.11 . □

9.6.2 The Proof of Proposition 9.6.1.2

If X is a spectral algebraic space, then $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ is a Grothendieck prestable ∞-category. We wish to show that if X is quasi-compact and quasi-separated, then the ∞-category $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ is compactly generated (note that an object of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ is compact if and only if it is perfect, by virtue of Corollary 9.1.5.5 and Lemma C.6.1.3). By virtue of Corollary C.6.3.3, Proposition 9.6.1.2 can be reformulated as follows:

Proposition 9.6.2.1. *Let X be a quasi-compact, quasi-separated spectral algebraic space and let $\mathscr{F}$ be a nonzero connective object of $\mathrm{QCoh}(\mathsf{X})$. Then there exists a connective perfect object $\mathscr{F}_0 \in \mathrm{QCoh}(\mathsf{X})$ and a morphism $\mathscr{F}_0 \to \mathscr{F}$ which is not nullhomotopic.*

The proof of Proposition 9.6.2.1 will require some preliminaries.

Lemma 9.6.2.2. *Let A be a connective $\mathbb{E}_\infty$-ring, let $I = (a_1, \ldots, a_d)$ be a finitely generated ideal in $\pi_0 A$, let M be an I-nilpotent A-module, and let $K \subseteq \pi_0 M$ be a finitely generated $(\pi_0 A)$-submodule. Then there exists a connective perfect I-nilpotent A-module P and a map $\beta : P \to M$ which induces a surjection from $\pi_0 P$ onto K. Moreover, if Q is an A-module of* Tor*-amplitude $\leqslant 0$ and we are given an element $\eta \in \pi_n(M \otimes_A Q)$ for $n \geqslant 0$, then we can arrange that η lifts to a class $\eta_P \in \pi_n(P \otimes_A Q)$.*

Proof. We will prove that for each $0 \leqslant i \leqslant d$, we can choose a connective perfect A-module P_i which is $(a_1, \ldots, a_i)$-nilpotent, and a map $\beta_i : P_i \to M$ which induces a surjection from $\pi_0 P_i$ on K, and for which η is the image of some class $\eta_i \in \pi_n(P_i \otimes_A Q)$.

We first treat the case $i = 0$. Write $\tau_{\geqslant 0} M$ as a colimit $\varinjlim N_\alpha$ indexed by a filtered partially ordered set, where each N_α is perfect and connective. Since K is finitely generated, we can choose α for which the image of the map $\pi_0 N_\alpha \to \pi_0 M$ contains K. The condition that Q has Tor-amplitude $\leqslant 0$ implies that the map $\pi_n(\tau_{\geqslant 0} M \otimes_A Q) \to \pi_n(M \otimes_A Q)$ is bijective. Enlarging α if necessary, we can arrange that η belongs to the image of the map $\pi_n(N_\alpha \otimes_A Q) \to \pi_n(M \otimes_A Q)$. We can therefore take $P_0 = N_\alpha$.

To carry out the inductive step, assume that $\beta_{i-1} : P_{i-1} \to M$ has been constructed. Since P_{i-1} is perfect, we can identify β_{i-1} with an element of $\pi_0(P_{i-1}^\vee \otimes_A M)$, where $P_{i-1}^\vee$ denotes the A-linear dual of P_{i-1}. Since M is I-nilpotent, the tensor product $\pi_0(P_{i-1}^\vee \otimes_A M)$ is I-nilpotent. It follows that β_{i-1} is annihilated by a_i^e for $e \gg 0$. Consequently, the map β_{i-1} factors as a composition $P_{i-1} \to P_i \xrightarrow{\beta_i} M$, where $P_i = \mathrm{cofib}(a_i^e : P_{i-1} \to P_{i-1}$. We can then take η_i to be the image of η_{i-1}. □

Lemma 9.6.2.3. *Let A be a connective $\mathbb{E}_\infty$-ring, let $I = (a_1, \ldots, a_d)$ be a finitely generated ideal in $\pi_0 A$, and let M be a perfect A-module for which each localization $M[a_i^{-1}]$ is connective. Then there exists a morphism of A-modules $\alpha : M' \to M$, where M' is perfect and connective and* $\mathrm{cofib}(\alpha)$ *is I-nilpotent.*

Moreover, if Q is an A-module of Tor*-amplitude $\leqslant 0$ and $\eta \in \pi_0(M \otimes_A Q)$, then we choose α so that η lifts to an element $\eta' \in \pi_0(M' \otimes_A Q)$.*

Proof. Since M is perfect, we can choose an integer n such that M is $(-n)$-connective. We proceed by induction on n. If $n \geqslant 0$, then M is connected and we can take $\alpha = \mathrm{id}_M$. Assume therefore that $n < 0$. Then $\pi_{-n} M$ is a finitely generated module over $\pi_0 A$, and each of the localizations $(\pi_{-n} M)[a_i^{-1}]$ vanishes. Replacing the a_i by suitable powers, we may assume without loss of generality that $\pi_{-n} M$ is annihilated by each a_i. Let N denote the tensor product of the A-modules $\mathrm{cofib}(a_i : A \to A)$, so that $\pi_1(N \otimes_A (\pi_{-n} M))$ is a direct sum of finitely many copies of $(\pi_{-n} M)$, and therefore a finitely generated module over $\pi_0 A$.

Let η_N denote the image of η in $\pi_0(N \otimes_A M \otimes_A Q)$. We have an exact sequence

$$\pi_{1-n}(N \otimes_A \tau_{\geqslant 1-n} M) \xrightarrow{\phi} \pi_{1-n}(N \otimes_A M) \to \pi_1(N \otimes_A (\pi_{-n} M)) \to 0.$$

We can therefore choose a finitely generated submodule $K \subseteq \pi_{1-n}(N \otimes_A M)$ such that $K + \mathrm{im}(\phi) = \pi_{1-n}(N \otimes_A M)$. Applying Lemma 9.6.2.2, we can choose a connective perfect A-module P which is I-nilpotent and a map $\beta : \Sigma^{1-n} P \to N \otimes_A M$ which induces a surjection $\pi_0 P \to K \subseteq \pi_{1-n}(N \otimes_A M)$, and for which η_N lifts to an element $\overline{\eta}_N \in \pi_0(\Sigma^{1-n} P \otimes_A Q)$.

Form a pullback diagram

$$\begin{array}{ccc} M'' & \longrightarrow & \Sigma^{1-n} P \\ \downarrow & & \downarrow \beta \\ M & \longrightarrow & N \otimes_A M. \end{array}$$

Using the exactness of the sequence

$$\pi_0(M'' \otimes_A Q) \to \pi_0(M \otimes_A Q) \oplus \pi_0(\Sigma^{1-n} P \otimes_A Q) \to \pi_0(N \otimes_A M \otimes_A Q),$$

we deduce that there exists an element $\eta'' \in \pi_0(M'' \otimes_A Q)$ lifting η.

It is clear from the construction that M'' is $(-n)$-connective, and we have an exact sequence

$$\pi_0 P \oplus \pi_{1-n} M \xrightarrow{u} \pi_{1-n}(N \otimes_A M) \to \pi_{-n} M'' \to \pi_{-n} M \xrightarrow{v} \pi_{-n}(N \otimes_A V).$$

By construction, u is surjective and v is bijective, so that $\pi_{-n} M'' \simeq 0$. Since $N \otimes_A M$ and P are I-nilpotent, the map $M'' \to M$ induces an equivalence $M''[a_i^{-1}] \simeq M[a_i^{-1}]$ for $1 \leqslant i \leqslant d$. Applying the inductive hypothesis, we conclude that there is a connective perfect A-module M' with a map $M' \to M''$ which induces equivalences $M'[a_i^{-1}] \simeq M''[a_i^{-1}]$ for $1 \leqslant i \leqslant d$, and for which $\eta'' \in (M'' \otimes_A Q)$ can be lifted to an element $\eta' \in (M' \otimes_A Q)$. The composite map $M' \to M'' \to M$ has the desired properties. □

Lemma 9.6.2.4. *Let A be a connective $\mathbb{E}_\infty$-ring, let $I = (a_1, \ldots, a_d)$ be a finitely generated ideal in $\pi_0 A$, and let M be a perfect A-module for which each localization $M[a_i^{-1}]$ is connective. Then there exists a morphism of A-modules $\alpha : M' \to M$, where M' is perfect and connective and* $\mathrm{cofib}(\alpha)$ *is I-nilpotent.*

Proof. Since M is perfect, we can choose an integer n such that M is $(-n)$-connective. We proceed by induction on n. If $n \geqslant 0$, then M is connected and we can take $\alpha = \mathrm{id}_M$. Assume therefore that $n < 0$. Then $\pi_{-n} M$ is a finitely generated module over $\pi_0 A$, and each of the localizations $(\pi_{-n} M)[a_i^{-1}]$ vanishes. Replacing the a_i by suitable powers, we may assume without loss of generality that $\pi_{-n} M$ is annihilated by each a_i. Let N denote the tensor product of the A-modules $\mathrm{cofib}(a_i : A \to A)$, so that $\pi_1(N \otimes_A (\pi_{-n} M))$ is a direct sum of finitely many copies of $(\pi_{-n} M)$, and therefore a finitely generated module over $\pi_0 A$. We have an exact sequence

$$\pi_{1-n}(N \otimes_A \tau_{\geqslant 1-n} M) \xrightarrow{\phi} \pi_{1-n}(N \otimes_A M) \to \pi_1(N \otimes_A (\pi_{-n} M)) \to 0.$$

We can therefore choose a finitely generated submodule $K \subseteq \pi_{1-n}(N \otimes_A M)$ such that $K + \mathrm{im}(\phi) = \pi_{1-n}(N \otimes_A M)$. Applying Lemma 9.6.2.2, we can choose a connective perfect

A-module P which is I-nilpotent and a map $\beta : \Sigma^{1-n} P \to N \otimes_A M$ which induces a surjection $\pi_0 P \to K \subseteq \pi_{1-n}(N \otimes_A M)$. Form a pullback diagram

$$\begin{array}{ccc} M'' & \longrightarrow & \Sigma^{1-n} P \\ \downarrow & & \downarrow \beta \\ M & \longrightarrow & N \otimes_A M. \end{array}$$

It is clear from the construction that M'' is $(-n)$-connective, and we have an exact sequence

$$\pi_0 P \oplus \pi_{1-n} M \xrightarrow{u} \pi_{1-n}(N \otimes_A M) \to \pi_{-n} M'' \to \pi_{-n} M \xrightarrow{v} \pi_{-n}(N \otimes_A V).$$

By construction, u is surjective and v is bijective, so that $\pi_{-n} M'' \simeq 0$. Since $N \otimes_A M$ and P are I-nilpotent, the map $M'' \to M$ induces an equivalence $M''[a_i^{-1}] \simeq M[a_i^{-1}]$ for $1 \leqslant i \leqslant d$. Applying the inductive hypothesis, we conclude that there is a connective perfect A-module M' with a map $M' \to M''$ which induces equivalences $M'[a_i^{-1}] \simeq M''[a_i^{-1}]$ for $1 \leqslant i \leqslant d$. The composite map $M' \to M'' \to M$ has the desired properties. □

Proof of Proposition 9.6.2.1. Let X be a quasi-compact, quasi-separated algebraic space and let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ be nonzero and connective. Using Theorem 3.4.2.1, we can choose a scallop decomposition

$$\varnothing \simeq \mathsf{U}_0 \hookrightarrow \cdots \hookrightarrow \mathsf{U}_m \simeq \mathsf{X}.$$

For $0 \leqslant i \leqslant m$, let $\mathscr{F}_i$ denote the restriction of $\mathscr{F}$ to U_i. Let i_0 be the smallest integer such that $\mathscr{F}_{i_0} \neq 0$. Then there exists an integer $n \geqslant 0$ for which $\pi_n \mathscr{F}_{i_0} \neq 0$. Replacing $\mathscr{F}$ by $\Omega^n \mathscr{F}$, we can assume that $\pi_0 \mathscr{F}_{i_0} \neq 0$, while $\mathscr{F}_i \simeq 0$ for $i < i_0$. We will complete the proof by showing the following:

- $(*)$ For $i_0 \leqslant i \leqslant m$, there exists a perfect connective object $\mathscr{G}_i \in \mathrm{QCoh}(\mathsf{U}_i)$ and a nonzero morphism $\beta_i : \mathscr{G}_i \to \mathscr{F}_i$.

The proof proceeds by induction on i. Choose an excision square

$$\begin{array}{ccc} \mathsf{V} & \xrightarrow{f} & \mathrm{Sp\acute{e}t}\, A \\ \downarrow g & & \downarrow \\ \mathsf{U}_{i-1} & \longrightarrow & \mathsf{U}_i, \end{array}$$

so that V is the quasi-compact open substack of $\mathrm{Sp\acute{e}t}\, A$ complementary to the vanishing locus of a finitely generated ideal $I = (a_1, \ldots, a_d) \subseteq \pi_0 A$. Let $M \in \mathrm{Mod}_A \simeq \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A)$ denote the connective A-module given by the pullback of $\mathscr{F}_i$.

We begin by treating the base case $i = i_0$. In this case, we have $\mathscr{F}_{i-1} \simeq 0$ so that the module M is I-nilpotent. By construction, we have $\pi_0 M \neq 0$. Then Lemma 9.6.2.2

guarantees the existence of a connective perfect I-nilpotent A-module P and a nonzero map $q : P \to M$. It follows from Nisnevich descent that we can identify the ∞-category of I-nilpotent A-modules with the full subcategory of $\mathrm{QCoh}(\mathsf{U}_i)$ consisting of objects which vanish in $\mathrm{QCoh}(\mathsf{U}_{i-1})$, so that q determines a map $\beta_i : \mathscr{G}_i \to \mathscr{F}_i$ having the desired properties.

We now carry out the inductive step. Assume that $i > i_0$ and that $\beta_{i-1} : \mathscr{G}_{i-1} \to \mathscr{F}_{i-1}$ has already been constructed. Replacing $\mathscr{G}_{i-1}$ by $\mathscr{G}_{i-1} \oplus \Sigma \mathscr{G}_{i-1}$ if necessary, we may assume that $g^* \mathscr{G}_{i-1} \simeq f^* N$ for some perfect object $N \in \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A)$ (Lemma **??**). In this case, we can identify $g^* \beta_{i-1}$ with a map $v_0 : f^* N \to f^* M$.

Let $u : M \to f_* f^* M$ denote the unit map. Then $\mathrm{fib}(u)$ is I-nilpotent, and can therefore be written as a filtered colimit of perfect I-nilpotent A-modules K_α. For each index α, let M_α denote the cofiber of the map $K_\alpha \to N$, so that $f_* f^* M \simeq \varinjlim M_\alpha$. The map v_0 can be identified with a map $N \to f_* f^* M \simeq \varinjlim M_\alpha$. Since N is perfect, this map factors as a composition $N \xrightarrow{p} M_\alpha \to f_* f^* M$. Form a pullback diagram

$$\begin{array}{ccc} N' & \longrightarrow & N \\ \downarrow & & \downarrow \\ M & \longrightarrow & M_\alpha, \end{array}$$

so that we have a fiber sequence $K_\alpha \to N' \to N$. Replacing N by N', we can reduce to the case where v_0 lifts to a map $v : N \to M$. Applying Lemma 9.6.2.4, we may further reduce to the case where N is connective. Using Nisnevich descent, we conclude that v and β_{i-1} can be amalgamated to a morphism $\beta_i : \mathscr{G}_i \to \mathscr{F}_i$ in $\mathrm{QCoh}(\mathsf{U}_i)$ having the desired properties. □

9.6.3 Generation of $\mathrm{QCoh}(\mathsf{X})$ by a Single Object

Let X be a quasi-compact, quasi-separated spectral algebraic space. Proposition 9.6.1.1 asserts that the ∞-category $\mathrm{QCoh}(\mathsf{X})$ is compactly generated. In fact, we can say a bit more: it can be generated (as a presentable stable ∞-category) by a single compact object. This is a consequence of the following:

Proposition 9.6.3.1. *Let X be a quasi-compact, quasi-separated spectral algebraic space. Then there exists an object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}$ with the following property:*

- $(*)$ *Let $\mathcal{C}$ be the smallest full subcategory of $\mathrm{QCoh}(\mathsf{X})$ which contains $\mathscr{F}$ and is closed under colimits and extensions. Then $\mathrm{QCoh}(\mathsf{X})_{\geq 0} \subseteq \mathcal{C}$.*

Corollary 9.6.3.2. *Let X be a quasi-compact, quasi-separated spectral algebraic space. Then the ∞-category $\mathrm{QCoh}(\mathsf{X})$ has a compact generator. More precisely, there exists an object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}$ such that, for every nonzero object $\mathscr{G} \in \mathrm{QCoh}(\mathsf{X})$, the graded abelian group $\mathrm{Ext}^*_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, \mathscr{G})$ is nonzero.*

Corollary 9.6.3.3. *Let* X *be a quasi-compact, quasi-separated spectral algebraic space. Then there exists an* $\mathbb{E}_1$*-ring* A *and an equivalence of* ∞*-categories* $\mathrm{QCoh}(\mathsf{X}) \simeq \mathrm{LMod}_A$.

Proof. Combine Corollary 9.6.3.2 with Theorem HA.7.1.2.1 . □

Proof of Proposition 9.6.3.1. Let X be a quasi-compact, quasi-separated spectral algebraic space. Using Theorem 3.4.2.1, we can choose a scallop decomposition

$$\varnothing = \mathsf{U}_0 \hookrightarrow \mathsf{U}_1 \hookrightarrow \cdots \hookrightarrow \mathsf{U}_n = \mathsf{X}.$$

For $0 \leqslant i \leqslant n$, let $K_i \subseteq |\mathsf{X}|$ denote the closed subset complementary to the image of the open immersion $\mathsf{U}_i \hookrightarrow \mathsf{X}$. We will prove, by descending induction on i, that there exists objects $\mathscr{F}_i \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}$ and integers c_i satisfying the following version of $(*)$:

- $(*_i)$ Let $\mathcal{C}_{i+1}$ be the smallest full subcategory of $\mathrm{QCoh}(\mathsf{X})$ which contains $\mathscr{F}_i$ and is closed under colimits and extensions. Then $\mathrm{QCoh}_{K_i}(\mathsf{X})_{\geqslant c_i} \subseteq \mathcal{C}$.

When $i = n$, this is evident (since $K_n = \varnothing$, we can take $\mathscr{F}_n = 0$), and when $i = 0$ it implies the desired result (take $\mathscr{F} = \Sigma^{-c_0}\mathscr{F}_0$). We now carry out the inductive step. Suppose that $i < n$, and that we are given a sheaf $\mathscr{F}_{i+1} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}$ and an integer c_{i+1} satisfying $(*_{i+1})$. Choose an excision square

$$\begin{array}{ccc} \mathsf{V} & \xrightarrow{j} & \mathrm{Sp\acute{e}t}\, A \\ \downarrow & & \downarrow g \\ \mathsf{U}_i & \longrightarrow & \mathsf{U}_{i+1} \end{array}$$

where j is a quasi-compact open immersion. In what follows, we will abuse notation by identifying quasi-coherent sheaves on $\mathrm{Sp\acute{e}t}\, A$ with their images under the equivalence of ∞-categories $\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A) \simeq \mathrm{Mod}_A$. Let $Y \subseteq |\operatorname{Spec} A|$ denote the complement of the image of j, so that Y is the vanishing locus of a finitely generated ideal $(x_1, \ldots, x_d) \subseteq \pi_0 A$. For $1 \leqslant k \leqslant d$, let M_k denote the fiber of the map $x_k : A \to A$, and set $M = \bigotimes_{1 \leqslant k \leqslant d} M_k$, so that M is a perfect A-module whose restriction to V vanishes. We will identify M with the corresponding quasi-coherent sheaf on $\mathrm{Sp\acute{e}t}\, A$, so that $g_* M$ is a perfect object of $\mathrm{QCoh}(\mathsf{U}_{i+1})$. The proof of Theorem **??** shows that the direct sum $g_* M \oplus \Sigma g_* M$ can be written as the restriction to U_{i+1} of some object $\mathscr{F}' \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}$.

Let g' denote the composition of g with the inclusion map $\mathsf{U}_{i+1} \hookrightarrow \mathsf{X}$. Proposition 2.5.4.4 implies that there exists an integer n such that the pushforward functor g'_* carries $\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A)_{\geqslant 0}$ into $\mathrm{QCoh}(\mathsf{X})_{\geqslant -n}$ (if X is separated, then g' is an affine morphism and we can take $n = 0$). Let $\mathscr{F}''$ denote the cofiber of the canonical map $\mathscr{F}' \to g'_* M \oplus \Sigma g'_* M$. Since $\mathscr{F}'$ is perfect and $g'_* \oplus \Sigma g'_* M \in \mathrm{QCoh}(\mathsf{X})_{\geqslant -n}$, the sheaf $\mathscr{F}''$ belongs to $\mathcal{S}\mathrm{hv}_{K_{i+1}}(\mathsf{X})_{\geqslant -m}$ for some integer m. Choose an integer $c_i \geqslant 0$ such that $c_i > c_{i+1} + n$ and $c_i \geqslant c_{i+1} + m$, and set $\mathscr{F}_i = \mathscr{F}_{i+1} \oplus \mathscr{F}$. We will prove that $(\mathscr{F}_i, c_i)$ satisfies $(*)$.

Fir an object $\mathscr{G} \in \mathrm{QCoh}_{K_i}(\mathsf{X})_{\geqslant c_i}$; we wish to show that $\mathscr{G} \in \mathcal{C}_i$. We have a canonical fiber sequence $\mathscr{G}' \to \mathscr{G} \to g'_* g'^* \mathscr{G}$. Our choice of n guarantees that $g'_* g'^* \mathscr{G} \in \mathrm{QCoh}(\mathsf{X})_{\geqslant c_i - n} \subseteq \mathrm{QCoh}(\mathsf{X})_{\geqslant c_{i+1}+1}$, so that $\mathscr{G}' \in \mathrm{QCoh}_{K_{i+1}}(\mathsf{X})_{\geqslant c_{i+1}} \subseteq \mathcal{C}_{i+1} \subseteq \mathcal{C}_i$. Since $\mathcal{C}_i$ is closed under extensions, we are reduced to proving that $g'_* g'^* \mathscr{G} \in \mathcal{C}_i$. This follows from the following more general claim:

$(*')$ For every object $N \in \mathrm{QCoh}_Y(\mathrm{Spét}\, A)_{\geqslant c_i}$, the direct image $g'_* N$ belongs to $\mathcal{C}_i$.

We will prove the following more general claim, using descending induction on $k \leqslant d$:

$(*'_k)$ For every objcet $N \in \mathrm{QCoh}_Y(\mathrm{Spét}\, A)_{\geqslant c_i}$, the direct image $g'_*(N \otimes_A M_1 \otimes_A \cdots \otimes_A M_k)$ belongs to $\mathcal{C}_i$.

Assume that $k < d$ and that $(*'_{k+1})$ has been verified. Since N is supported on Y, the action of x_{k+1} on $\pi_* N$ is locally nilpotent. It follows that we can write N as a filtered colimit of the A-modules $\mathrm{fib}(x^t_{k+1} : N \to N)$. Since $\mathcal{C}_i$ is closed under colimits, we are reduced to proving that $g'_* \Sigma^{-k}(\mathrm{fib}(x^t_{k+1} : N \to N) \otimes_A M_1 \otimes_A \cdots \otimes_A M_k) \in \mathcal{C}_i$ for each $t \geqslant 0$. Since $\mathcal{C}_i$ is closed under extensions, we can reduce to the case where $t = 1$, which follows from $(*'_{k+1})$.

It remains to prove $(*'_d)$. Here, we prove the following more general claim:

$(*'')$ For every object $N \in \mathrm{QCoh}(\mathrm{Spét}\, A)_{\geqslant c_i}$, the direct image $g'_*(N \otimes_A M_1 \otimes_A \cdots \otimes_A M_d)$ belongs to $\mathcal{C}_i$.

Since $\mathrm{QCoh}(\mathrm{Spét}\, A)_{\geqslant c_i}$ is generated under small colimits by the B-module $\Sigma^{c_i} A$, it suffices to prove $(*'')$ in the case $N = \Sigma^{c_i} A$. That is, we are reduced to proving that $\Sigma^{c_i} g'_* M \in \mathcal{C}_i$. Since $\mathcal{C}_i$ is closed under retracts, it will suffice to show that $\Sigma^{c_i} g'_* M \oplus \Sigma^{c_i+1} g'_* M$ belongs to $\mathcal{C}_i$. We have a fiber sequence

$$\Sigma^{c_i} \mathscr{F}' \to \Sigma^{c_i} g'_* M \oplus \Sigma^{c_i+1} g'_* M \to \Sigma^{c_i} \mathscr{F}''.$$

Here $\Sigma^{c_i} \mathscr{F}' \in \mathcal{C}_i$ since $c_i \geqslant 0$, and

$$\Sigma^{c_i} \mathscr{F}'' \in \mathrm{QCoh}_{K_{i+1}}(\mathsf{X})_{\geqslant c_i - m} \subseteq \mathrm{QCoh}_{K_{i+1}}(\mathsf{X})_{\geqslant c_{i+1}} \subseteq \mathcal{C}_{i+1} \subseteq \mathcal{C}_i .$$

Since $\mathcal{C}_i$ is closed under extensions, we conclude that $\Sigma^{c_i} g'_* M \oplus \Sigma^{c_i+1} g'_* M \in \mathcal{C}_i$ as desired. □

9.6.4 The Proof of Theorem 9.6.0.1

Let X and Y be spectral Deligne-Mumford stacks, where X is a quasi-compact, quasi-separated algebraic space. Let

$$\theta : \mathrm{Map}_{\mathrm{SpDM}}(\mathsf{Y}, \mathsf{X}) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(\mathsf{X}), \mathrm{QCoh}(\mathsf{Y}))$$

denote the functor given by $(f : \mathsf{Y} \to \mathsf{X}) \mapsto (f^* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y}))$. Using Proposition 9.6.1.1 and Corollary 9.4.4.7, we deduce that θ is a fully faithful embedding whose essential image consists of those symmetric monoidal functors $F : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ which satisfy the following conditions:

- (a) The functor F preserves small colimits.
- (b) The functor F carries connective objects of $\mathrm{QCoh}(\mathsf{X})$ to connective objects of $\mathrm{QCoh}(\mathsf{Y})$.

To prove Theorem 9.6.0.1, it will suffice to show that any symmetric monoidal functor $F : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ which satisfies (a) automatically satisfies (b) as well. Note that condition (b) can be tested locally on Y; we may therefore assume without loss of generality that $\mathsf{Y} \simeq \mathrm{Sp\acute{e}t}\, R$ is affine.

Since F is a symmetric monoidal functor, it carries dualizable objects of $\mathrm{QCoh}(\mathsf{X})$ to dualizable objects of $\mathrm{QCoh}(\mathsf{Y}) \simeq \mathrm{Mod}_R$. Consequently, for every perfect object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$, the R-module $F(\mathscr{F})$ is perfect.

Let $\mathscr{F}_0 \in \mathrm{QCoh}(\mathsf{X})$ be a perfect object which satisfies the requirements of Proposition 9.6.3.1. Then $F(\mathscr{F}_0) \in \mathrm{Mod}_R$ is perfect. It follows that there exists an integer n such that $F(\mathscr{F}_0)$ is $(-n)$-connective. Let $\mathcal{C} \subseteq \mathrm{QCoh}(\mathsf{X})$ denote the full subcategory spanned by those objects $\mathscr{F}$ such that $F(\mathscr{F})$ is $(-n)$-connective. Since F preserves small colimits, the full subcategory $\mathcal{C}$ is closed under colimits and extensions, and therefore contains $\mathrm{QCoh}(\mathsf{X})_{\geqslant 0}$. This proves the following weaker version of (b):

- (b') There exists an integer $n \gg 0$ such that the functor F carries $\mathrm{QCoh}(\mathsf{X})_{\geqslant 0}$ into $\mathrm{QCoh}(\mathsf{Y})_{\geqslant -n}$.

We now claim that F satisfies (b). Fix a connective object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$; we wish to show that $F(\mathscr{F})$ is connective. Using (a) and Proposition 9.6.1.2, we can assume that $\mathscr{F}$ is perfect. Then $F(\mathscr{F})$ is perfect. Suppose that $F(\mathscr{F})$ is not connective: then there exists some largest integer m such that $\pi_{-m}F(\mathscr{F}) \neq 0$. Since $\pi_{-m}F(\mathscr{F})$ is a finitely generated module over $\pi_0 R$, it follows from Nakayama's lemma that there exists some residue field κ of R for which $\pi_{-m}(\kappa \otimes_R F(\mathscr{F})) \neq 0$. Replacing $\mathscr{F}$ by $\mathscr{F}^{\otimes(n+1)}$, we can arrange that $m > n$, which contradicts (b'). This completes the proof of Theorem 9.6.0.1.

Corollary 9.6.4.1. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism between quasi-compact, quasi-separated spectral algebraic spaces. If the pullback functor $f^* : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ is an equivalence of ∞-categories, then f is an equivalence.*

Corollary 9.6.4.2. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor which is representable by a quasi-compact, quasi-separated spectral algebraic space. Then for every functor $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, the canonical map*

$$\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(Y, X) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{perf}}, \mathrm{QCoh}(Y)^{\mathrm{perf}})$$

is a fully faithful embedding, whose essential image is spanned by the exact symmetric monoidal functors from $\mathrm{QCoh}(X)^{\mathrm{perf}}$ *to* $\mathrm{QCoh}(Y)^{\mathrm{perf}}$*.*

Proof. The assertion is compatible with colimits in Y; we may therefore assume without loss of generality that Y is representable by an affine spectral Deligne-Mumford stack $\mathrm{Sp\acute{e}t}\, R$. Note that every symmetric monoidal functor $\mathrm{QCoh}(X)^{\mathrm{perf}} \to \mathrm{QCoh}(Y)$ preserves dualizable objects and therefore takes values in the full subcategory $\mathrm{QCoh}(Y)^{\mathrm{perf}} \subseteq \mathrm{QCoh}(X)$. It will therefore suffice to show that the canonical map

$$\theta : \mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(Y, X) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{perf}}, \mathrm{QCoh}(Y))$$

is a fully faithful embedding, whose essential image is spanned by the exact functors. Note that θ factors as a composition

$$\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})}(Y, X) \xrightarrow{\theta'} \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{QCoh}(Y)) \xrightarrow{\theta''} \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{perf}}, \mathrm{QCoh}(Y)).$$

Theorem 9.6.0.1 implies that θ' is a fully faithful embedding, whose essential image $\mathcal{C}$ is spanned by those symmetric monoidal functors from $\mathrm{QCoh}(X)$ to $\mathrm{QCoh}(Y)$ which preserve small colimits. It follows from Proposition 9.6.1.1 that the restriction $\theta''|_{\mathcal{C}}$ is fully faithful, and that its essential image is the full subcategory of $\mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{perf}}, \mathrm{QCoh}(Y))$ spanned by those symmetric monoidal functors which preserve finite colimits. □

9.6.5 Application: Serre's Criterion for Affineness

We now use Tannaka duality to establish the following converse to Proposition **??**:

Proposition 9.6.5.1 (Serre's Affineness Criterion)**.** *Let* X *be a quasi-compact, quasi-separated spectral algebraic space. Then* X *is affine if and only if the global sections functor* $\Gamma(\mathsf{X}; \bullet) : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{Sp}$ *is t-exact.*

Proof. If $\mathsf{X} \simeq \mathrm{Sp\acute{e}t}\, A$ is affine, then the global sections functor $\Gamma(\mathsf{X}; \bullet)$ can be identified with the forgetful functor $\mathrm{Mod}_A(\mathrm{Sp}) \to \mathrm{Sp}$ and is therefore t-exact. Conversely, suppose that $\Gamma(\mathsf{X}; \bullet)$ is t-exact and set $A = \Gamma(\mathsf{X}; \mathscr{O}_{\mathsf{X}})$, so that A is a connective $\mathbb{E}_\infty$-ring. The identity map $A \to \Gamma(\mathsf{X}; \mathscr{O}_{\mathsf{X}})$ determines a map $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, A$ which satisfies the following condition:

- $(*)$ The pushforward functor $f_* : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A) \simeq \mathrm{Mod}_A$ is t-exact and the unit map $A \to f_* \mathscr{O}_{\mathsf{X}}$ is an equivalence.

We wish to show that condition $(*)$ implies that f is an equivalence. By virtue of Corollary 9.6.4.1, this is equivalent to the requirement that the pullback functor $f^* : \mathrm{Mod}_A \simeq \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A) \to \mathrm{QCoh}(\mathsf{X})$ is an equivalence of ∞-categories. By construction, A is the endomorphism ring of the compact object $\mathscr{O}_{\mathsf{X}} \in \mathrm{QCoh}(\mathsf{X})$. Using Theorem HA.7.1.2.1 and Remark **??**, it will suffice to show that the structure sheaf $\mathscr{O}_{\mathsf{X}}$ generates the stable ∞-category $\mathrm{QCoh}(\mathsf{X})$: that is, that the global sections functor $\Gamma(\mathsf{X}; \bullet) : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{Sp}$ is conservative.

Our proof proceeds in several steps.

(a) Suppose first that A is a field κ. Then $\Gamma(\mathsf{X}; \mathscr{O}_{\mathsf{X}}) \neq 0$, so X is nonempty. Since X is a quasi-compact, quasi-separated spectral algebraic space, it admits a scallop decomposition (Theorem 3.4.2.1). In particular, there a quasi-compact open substack $\mathsf{U} \subsetneq \mathsf{X}$ which fits into an excision square

$$\begin{array}{ccc} \mathsf{V} & \xrightarrow{j} & \operatorname{Spét} B \\ \downarrow & & \downarrow \\ \mathsf{U} & \longrightarrow & \mathsf{X}. \end{array}$$

The image of j is a quasi-compact open subset of the Zariski spectrum $|\operatorname{Spec} B|$, whose complement $K \subseteq |\operatorname{Spec} B|$ can be identified with the vanishing locus of a finitely generated ideal $I \subseteq (\pi_0 B)$. Let us identify the quotient $(\pi_0 B)/I^2$ with a quasi-coherent sheaf on $\operatorname{Spét} B$ whose restriction to V vanishes. Since the diagram of ∞-categories

$$\begin{array}{ccc} \operatorname{QCoh}(\mathsf{X}) & \longrightarrow & \operatorname{QCoh}(\mathsf{U}) \\ \downarrow & & \downarrow \\ \operatorname{QCoh}(\operatorname{Spét} B) & \longrightarrow & \operatorname{QCoh}(\mathsf{V}) \end{array}$$

is a pullback square, the quotient $(\pi_0 B)/I^2$ admits an essentially unique lift to an object $\mathscr{F} \in \operatorname{QCoh}(\mathsf{X})^{\heartsuit}$ satisfying $\mathscr{F}|_{\mathsf{U}} \simeq 0$. Note that the unit map $\pi_0 \mathscr{O}_{\mathsf{X}} \to \mathscr{F}$ is an epimorphism in $\operatorname{QCoh}(\mathsf{X})^{\heartsuit}$. Since the global sections functor $\Gamma(\mathsf{X}; \bullet)$ is t-exact, the induced map

$$\kappa \simeq \pi_0 \Gamma(\mathsf{X}; \mathscr{O}_{\mathsf{X}}) \simeq \Gamma(\mathsf{X}; \pi_0 \mathscr{O}_{\mathsf{X}}) \to \Gamma(\mathsf{X}; \mathscr{F}) \simeq (\pi_0 B)/I^2$$

is surjective. The assumption $\mathsf{U} \neq \mathsf{X}$ guarantees that $(\pi_0 B)/I \neq 0$. Using the fact that κ is a field, we deduce that the surjections $\kappa \to (\pi_0 B)/I^2 \to (\pi_0 B)/I \neq 0$ are also injective: that is, we have $I^2 = I$. Since I is finitely generated, it follows that I is generated by an idempotent element $e \in \pi_0 B$. We therefore have $\operatorname{Spét} B \simeq (\operatorname{Spét} B[e^{-1}]) \amalg \mathsf{V}$ and therefore $\mathsf{X} \simeq \mathsf{U} \amalg \operatorname{Spét} B[e^{-1}]$. Because $\Gamma(\mathsf{X}; \mathscr{O}_{\mathsf{X}}) \simeq \kappa$ is a field, the spectral algebraic space X must be connected: we therefore have $\mathsf{U} \simeq \emptyset$ and $\mathsf{X} \simeq \operatorname{Spét} B[e^{-1}]$ is affine as desired.

(b) Suppose that A is a valuation ring and the map $f : \mathsf{X} \to \operatorname{Spét} A$ admits a section $s : \operatorname{Spét} A \to \mathsf{X}$. Note that for every residue field κ of A, the induced map

$$f_\kappa : \mathsf{X} \times_{\operatorname{Spét} A} \operatorname{Spét} \kappa \to \operatorname{Spét} \kappa$$

also satisfies condition $(*)$. It follows from (a) that f_κ is an equivalence. Consequently, the map f induces a bijection $|f| : |\mathsf{X}| \to |\operatorname{Spét} A|$ between the underlying topological spaces of X and $\operatorname{Spét} A$. Since f admits a section, the map $|f|$ is a homeomorphism.

Since X is a quasi-compact, quasi-separated spectral algebraic space, it admits a scallop decomposition

$$\emptyset \simeq \mathsf{U}_0 \hookrightarrow \mathsf{U}_1 \hookrightarrow \cdots \hookrightarrow \mathsf{U}_n = \mathsf{X}\,.$$

We will prove that f is an equivalence using induction on n, the case $n = 0$ being trivial. Assume that $n > 0$, so that U_{n-1} determines a quasi-compact open subset of the topological space $|\mathsf{X}|$. Since $|f|$ is a homeomorphism, it follows that U_{n-1} can be identified with the inverse image of a quasi-compact open substack $\mathsf{W} \subseteq \operatorname{Spét} A$. Since A is a valuation ring, we can write $\mathsf{W} \simeq \operatorname{Spét} A[t^{-1}]$ for some $t \in A$. Applying the inductive hypothesis to the map $f_0 : \mathsf{U}_{n-1} \to \mathsf{W}$, we deduce that f_0 is an equivalence. In particular, the pushforward functor $f_{0*} : \mathrm{QCoh}(\mathsf{U}_{n-1}) \to \mathsf{W}$ is conservative. Consequently, if $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ satisfies $f_* \mathscr{F} \simeq 0$, then the restriction $\mathscr{F}|_{\mathsf{U}} = 0$. Since the inclusion $j : \mathsf{U}_{n-1} \to \mathsf{X}$ fits into an excision square σ :

$$\begin{array}{ccc} \mathsf{V} & \longrightarrow & \operatorname{Spét} B \\ \downarrow & & \downarrow g \\ \mathsf{U}_{n-1} & \xrightarrow{j} & \mathsf{X}, \end{array}$$

it follows that we can write $\mathscr{F} = g_* \mathscr{G}$, where $\mathscr{G} \in \mathrm{QCoh}(\operatorname{Spét} B)$ is a quasi-coherent sheaf satisfying $\mathscr{G}|_{\mathsf{V}} \simeq 0$. Since $\operatorname{Spét} B$ is affine, the vanishing of $\Gamma(\mathsf{X}; \mathscr{F}) \simeq \Gamma(\operatorname{Spét} B; \mathscr{G})$ guarantees that $\mathscr{G} \simeq 0$, so that $\mathscr{F} \simeq g_* \mathscr{G} \simeq 0$.

(c) We next claim that any map of quasi-compact quasi-separated algebraic spaces $f : \mathsf{X} \to \operatorname{Spét} A$ satisfying condition $(*)$ is separated. To prove this, we will verify that f satisfies the valuative criterion for separatedness (Corollary **??**). Let $V \in \mathrm{CAlg}_A$ be a valuation ring with residue field K suppose we are given a pair of maps $g_0, g_1 : \operatorname{Spét} V \to \mathsf{X}$ of spectral Deligne-Mumford stacks over A. We claim that g_0 and g_1 are homotopic to one another. To prove this, we can replace A by V and X by the fiber product $\operatorname{Spét} V \times_{\operatorname{Spét} A} \mathsf{X}$ and thereby reduce to the case where $A = V$. In this case, the map f admits a section (given by either g_0 or g_1), so that f is an equivalence by virtue of (b).

(d) We now handle the general case. Let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ satisfy $\Gamma(\mathsf{X}; \mathscr{F}) \simeq 0$; we wish to prove that $\mathscr{F} \simeq 0$. Since $\Gamma(\mathsf{X}; \bullet)$ is t-exact, we have $\Gamma(\mathsf{X}; \pi_n \mathscr{F}) \simeq \pi_n \Gamma(\mathsf{X}; \mathscr{F}) \simeq 0$ for each integer n. We may therefore replace $\mathscr{F}$ by $\pi_n \mathscr{F}$ and thereby reduce to the case where $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})^{\heartsuit}$.

Fix a map $\eta : \operatorname{Spét} B \to \mathsf{X}$ and let $\mathcal{B} \in \mathrm{QCoh}(\mathsf{X})$ denote the direct image of the structure sheaf of $\operatorname{Spét} B$. Note that each element $b \in \pi_0 B$ determines a map $\phi_b : \mathscr{O}_{\mathsf{X}} \to \mathcal{B}$. We claim that the induced map $\bigoplus_{b \in \pi_0 B} \mathscr{O}_{\mathsf{X}} \to \mathcal{B}$ induces an epimorphism on π_0 (in the abelian category $\mathrm{QCoh}(\mathsf{X})^{\heartsuit}$). To prove this, it will suffice to show that for every map $\eta' : \operatorname{Spét} B' \to \mathsf{X}$, the induced map $\bigoplus_{b \in \pi_0 B} \pi_0 \eta'^* \mathscr{O}_{\mathsf{X}} \to \pi_0 \eta'^* \mathcal{B}$ is a surjection of

$(\pi_0 B')$-modules. Write $\operatorname{Sp\acute{e}t} B \times_{\mathsf{X}} \operatorname{Sp\acute{e}t} B' = \operatorname{Sp\acute{e}t} R$. Unwinding the definitions, we wish to show that $\pi_0 R$ is generated (as a module over $\pi_0 B'$) by the elements of B: that is, that the canonical map $\pi_0(B \otimes_A B') \to \pi_0 R$ is surjective. This is equivalent to the statement that the map

$$\operatorname{Sp\acute{e}t} B \times_{\mathsf{X}} \operatorname{Sp\acute{e}t} B' \to \operatorname{Sp\acute{e}t} B \times_{\operatorname{Sp\acute{e}t} A} \operatorname{Sp\acute{e}t} B'$$

is a closed immersion, which follows from the separatedness of X over $\operatorname{Sp\acute{e}t} A$.

It follows that the map ϕ_b induce an epimorphism

$$\bigoplus_{b \in \pi_0 B} \mathscr{F} \simeq \bigoplus_{b \in \pi_0 B} \pi_0(\mathscr{O}_{\mathsf{X}} \otimes \mathscr{F}) \to \pi_0(\mathcal{B} \otimes \mathscr{F}) \simeq \pi_0(\eta_* \eta^* \mathscr{F})$$

in the abelian category $\operatorname{QCoh}(\mathsf{X})^{\heartsuit}$. Using the t-exactness of the global sections functor $\Gamma(\mathsf{X}; \bullet)$, we obtain a surjection

$$0 \simeq \bigoplus_{b \in \pi_0 B} \Gamma(\mathsf{X}; \mathscr{F}) \to \Gamma(\mathsf{X}; \pi_0 \eta_* \eta^* \mathscr{F}) \simeq \pi_0 \Gamma(\operatorname{Sp\acute{e}t} B; \eta^* \mathscr{F}).$$

Since $\operatorname{Sp\acute{e}t} B$ is affine, this guarantees that $\pi_0 \eta^* \mathscr{F}$ vanishes. Since the map η was chosen arbitrarily, we conclude that $\pi_0 \mathscr{F} \simeq 0$ and therefore $\mathscr{F} \simeq 0$, as desired.

□

9.6.6 Application: A Criterion for Quasi-Affineness

We now discuss a variant of Proposition 9.6.5.1, which characterizes the class of quasi-affine spectral Deligne-Mumford stacks.

Proposition 9.6.6.1. *Let X be a quasi-compact, quasi-separated spectral algebraic space. The following conditions are equivalent:*

(1) *The spectral algebraic space X is quasi-affine.*

(2) *The structure sheaf $\mathscr{O}_{\mathsf{X}}$ generates the t-structure on $\operatorname{QCoh}(\mathsf{X})$, in the sense of Definition C.2.1.1. That is, for every quasi-coherent sheaf $\mathscr{F} \in \operatorname{QCoh}(\mathsf{X})$, there exists a map $\bigoplus \mathscr{O}_{\mathsf{X}} \to \mathscr{F}$ which is an epimorphism on π_0.*

Proof. Suppose first that (1) is satisfied, so there exists a quasi-compact open immersion $j : \mathsf{X} \hookrightarrow \operatorname{Sp\acute{e}t} A$ for some connective $\mathbb{E}_\infty$-ring A. Let $\mathscr{F}$ be a quasi-coherent sheaf on X. Choose a collection of elements $f_i \in \pi_0 \Gamma(\mathsf{X}; \mathscr{F})$ which generate $\pi_0 \Gamma(\mathsf{X}; \mathscr{F})$ as a module over A. The elements f_i classify a map $\bigoplus A \to \Gamma(\mathsf{X}; \mathscr{F})$ in the ∞-category Mod_A which is an epimorphism on π_0. Applying the functor $j^* : \operatorname{Mod}_A \simeq \operatorname{QCoh}(\operatorname{Sp\acute{e}t} A) \to \mathsf{X}$, we obtain a map $\bigoplus \mathscr{O}_{\mathsf{X}} \to j^* \Gamma(\mathsf{X}; \mathscr{F}) \simeq \mathscr{F}$ which is an epimorphism on π_0. Allowing $\mathscr{F}$ to range over all quasi-coherent sheaves on X, we deduce that condition (2) is satisfied.

Now suppose that (2) is satisfied. Choose a morphism of $\mathbb{E}_\infty$-rings $\rho : A \to \Gamma(\mathsf{X}; \mathscr{O}_{\mathsf{X}})$ which exhibits A as a connective cover of $\Gamma(\mathsf{X}; \mathscr{O}_{\mathsf{X}})$, so that ρ classifies a morphism of spectral Deligne-Mumford stacks $f : \mathsf{X} \to \operatorname{Spét} A$. It follows from assumption (2) and Theorem **??** that the pullback functor $f^* : \operatorname{Mod}_A \simeq \operatorname{QCoh}(\operatorname{Spét} A) \to \operatorname{QCoh}(\mathsf{X})$ is t-exact and that its right adjoint $f_* : \operatorname{QCoh}(\mathsf{X}) \to \operatorname{Mod}_A$ is fully faithful. It follows that $\operatorname{QCoh}(\mathsf{X})$ is idempotent as an A-linear ∞-category: that is, the multiplication map $\operatorname{QCoh}(\mathsf{X}) \otimes_A \operatorname{QCoh}(\mathsf{X}) \to \operatorname{QCoh}(\mathsf{X})$ is an equivalence of ∞-categories. Combining this observation with Corollaries 9.4.2.3 and 9.6.4.1, we deduce that the diagonal map $\delta : \mathsf{X} \to \mathsf{X} \times_{\operatorname{Spét} A} \mathsf{X}$ is an equivalence: in other words, the map f is a monomorphism (in the ∞-category of spectral algebraic spaces). It is also flat (since the pullback functor f^* is t-exact). We will complete the proof by establishing the following:

$(*)$ Let $f : \mathsf{X} \to \operatorname{Spét} A$ be a flat monomorphism between quasi-compact, quasi-separated spectral algebraic spaces which exhibits A as the connective cover of $\Gamma(\mathsf{X}; \mathscr{O}_{\mathsf{X}})$. Then f is an open immersion.

To prove $(*)$, we first apply Theorem 3.4.2.1 to choose a scallop decomposition

$$\emptyset \simeq \mathsf{U}_0 \hookrightarrow \cdots \hookrightarrow \mathsf{U}_n \simeq \mathsf{X}$$

of X. We will prove that each of the maps $f|_{\mathsf{U}_i}$ is an open immersion. The proof proceeds by induction on i, the case $i = 0$ being trivial. To carry out the inductive step, let us assume that $i < n$ and that we have established that $f|_{\mathsf{U}_i}$ is an open immersion; we wish to prove that $f|_{\mathsf{U}_{i+1}}$ is an open immersion. Let $\mathfrak{p}$ be a prime ideal of the commutative ring $\pi_0 A$ which belongs to the image of the map $|\mathsf{U}_{i+1}| \to |\operatorname{Spét} A| \simeq |\operatorname{Spec} A|$; we will show that there exists an open neighborhood of $\mathfrak{p}$ over which the map $f|_{\mathsf{U}_{i+1}}$ is an equivalence. Let $A_{\mathfrak{p}}$ denote the localization of A at $\mathfrak{p}$. The projection morphism $f_{\mathfrak{p}} : \operatorname{Spét} A_{\mathfrak{p}} \times_{\operatorname{Spét} A} \mathsf{X} \to \operatorname{Spét} A_{\mathfrak{p}}$ is a flat map whose image contains the closed point of $|\operatorname{Spec} A_{\mathfrak{p}}|$. It is therefore faithfully flat. Since f is a monomorphism, the pullback of $f_{\mathfrak{p}}$ along the faithfully flat map $f_{\mathfrak{p}}$ is an equivalence. Applying Proposition 2.8.3.3, we deduce that $f_{\mathfrak{p}}$ is an equivalence. In particular, the restriction of $f_{\mathfrak{p}}$ to the fiber product $\operatorname{Spét} A_{\mathfrak{p}} \times_{\operatorname{Spét} A} \mathsf{U}_{i+1}$ is an open immersion. Since the image of this open immersion contains the closed point of $|\operatorname{Spec} A_{\mathfrak{p}}|$, it is an equivalence: that is, the inclusion map

$$\operatorname{Spét} A_{\mathfrak{p}} \times_{\operatorname{Spét} A} \mathsf{U}_{i+1} \hookrightarrow \operatorname{Spét} A_{\mathfrak{p}} \times_{\operatorname{Spét} A} \mathsf{X}$$

is an equivalence.

Let Z be the (reduced) closed substack of X complementary to the open immersion $\mathsf{U}_{i+1} \hookrightarrow \mathsf{X}$, so that $\operatorname{Spét} A_{\mathfrak{p}} \times_{\operatorname{Spét} A} \mathsf{Z} \simeq \emptyset$. Since Z is quasi-compact, it follows that there exists an element $a \in \pi_0 A$ which does not belong to $\mathfrak{p}$ such that $\operatorname{Sp\acute{e}t} A[a^{-1}] \times_{\operatorname{Sp\acute{e}t} A} \mathsf{Z} \simeq \emptyset$. Replacing A by $A[a^{-1}]$, we may assume that $\mathsf{Z} = \emptyset$ and therefore $\mathsf{X} = \mathsf{U}_{i+1}$. It follows that there exists an excision square σ :

$$\begin{array}{ccc} \mathsf{V} & \longrightarrow & \operatorname{Sp\acute{e}t} B \\ \downarrow & & \downarrow \\ \mathsf{U}_i & \longrightarrow & \mathsf{X}. \end{array}$$

Let us regard B as an $\mathbb{E}_\infty$-algebra over A, and let $B_{\mathfrak{p}}$ denote the tensor product $A_{\mathfrak{p}} \otimes_A B$. Since $f_{\mathfrak{p}}$ is an equivalence, we see that σ determines another excision square

$$\begin{array}{ccc} \operatorname{Sp\acute{e}t} A_{\mathfrak{p}} \times_{\operatorname{Sp\acute{e}t} A} \mathsf{V} & \longrightarrow & \operatorname{Sp\acute{e}t} B_{\mathfrak{p}} \\ \downarrow & & \downarrow \\ \operatorname{Sp\acute{e}t} A_{\mathfrak{p}} \times_{\operatorname{Sp\acute{e}t} A} \mathsf{U}_i & \longrightarrow & \operatorname{Sp\acute{e}t} A_{\mathfrak{p}} \end{array}$$

In particular, the canonical map $A_{\mathfrak{p}} \to B_{\mathfrak{p}}$ is étale. Using the structure theory of étale morphisms (Proposition B.1.1.3), we can assume (replacing A by a localization $A[a^{-1}]$ if necessary) that there exists an étale A-algebra B' and a map $\phi : B' \to B$ which induces an equivalence after localization at $\mathfrak{p}$. We can therefore extend σ to a commutative diagram $\overline{\sigma}$:

$$\begin{array}{ccccc} \mathsf{V} & \longrightarrow & \operatorname{Sp\acute{e}t} B & \longrightarrow & \operatorname{Sp\acute{e}t} B' \\ \downarrow & & \downarrow & & \downarrow \\ \mathsf{U}_i & \longrightarrow & \mathsf{X} & \longrightarrow & \operatorname{Sp\acute{e}t} A. \end{array}$$

The outer rectangle in $\overline{\sigma}$ becomes an excision square after localization at $\mathfrak{p}$. We can therefore replace A by a localization $A[a^{-1}]$ for some $a \in (\pi_0 A) - \mathfrak{p}$ and thereby reduce to the case where the outer rectangle in $\overline{\sigma}$ is itself an excision square. Let $\mathscr{O}_{\mathcal{V}}$ denote the structure sheaf of V. Passing to global functors, we obtain a commutative diagram

$$\begin{array}{ccccc} \Gamma(\mathsf{V}; \mathscr{O}_{\mathcal{V}}) & \longleftarrow & B & \xleftarrow{\phi} & B' \\ \uparrow & & \uparrow & & \uparrow \\ \Gamma(\mathsf{U}_i; \mathscr{O}_{\mathcal{X}}|_{\mathsf{U}_i}) & \longleftarrow & \Gamma(\mathsf{X}; \mathscr{O}_{\mathsf{X}}) & \xleftarrow{\rho} & A \end{array}$$

where the left square and the outer rectangle are pullback squares. It follows that the right square is a pullback as well. Consequently, it induces a homotopy equivalence of spectra $\operatorname{cofib}(\rho) \simeq \operatorname{cofib}(\phi)$. Since ρ exhibits A as a connective cover of $\Gamma(\mathsf{X}; \mathscr{O}_{\mathsf{X}})$, the cofiber $\operatorname{cofib}(\rho)$ belongs to $\mathrm{Sp}_{\leqslant -1}$. But ϕ is a morphism of connective spectra, so $\operatorname{cofib}(\phi)$ is connective. It follows that $\operatorname{cofib}(\phi) \simeq 0$, so that ϕ is an equivalence. Since the right square in the diagram $\overline{\sigma}$ is a pushout, we conclude that the map $\mathsf{X} \to \operatorname{Sp\acute{e}t} A$ is also an equivalence, as desired. $\square$

9.6.7 Perfect Approximation for Sheaves of Tor-Amplitude $\leqslant 0$

We close this section by proving a dual version of Proposition 9.6.1.2:

Proposition 9.6.7.1. *Let* X *be a quasi-compact, quasi-separated spectral algebraic space. Let* $\mathcal{C} \subseteq \mathrm{QCoh}(\mathsf{X})$ *denote the full subcategory spanned by those quasi-coherent sheaves* $\mathscr{F}$ *for which* $\mathscr{F}$ *is perfect and of* Tor*-amplitude* $\leqslant 0$*. Then the inclusion* $\mathcal{C} \hookrightarrow \mathrm{QCoh}(\mathsf{X})$ *extends to a fully faithful embedding* $\mathrm{Ind}(\mathcal{C}) \to \mathrm{QCoh}(\mathsf{X})$*, whose essential image is spanned by those quasi-coherent sheaves which have* Tor*-amplitude* $\leqslant 0$*.*

Lemma 9.6.7.2. *Let* X *be a quasi-compact, quasi-separated spectral algebraic space, and let* $\alpha : \mathscr{F}_0 \to \mathscr{F}$ *be a morphism in* $\mathrm{QCoh}(\mathsf{X})$*, where* $\mathscr{F}_0$ *is perfect and* $\mathscr{F}$ *has* Tor*-amplitude* $\leqslant 0$*. Then* α *factors as a composition* $\mathscr{F}_0 \to \mathscr{F}'_0 \to \mathscr{F}$*, where* $\mathscr{F}'_0$ *is perfect and of* Tor*-amplitude* $\leqslant 0$*.*

Proof. Write $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$, and identify α with a point $\eta \in \pi_0 \Gamma(\mathsf{X}; \mathscr{F}_0^{\vee} \otimes \mathscr{F})$. For each object $U \in \mathcal{X}$, set $\mathsf{X}_U = (\mathcal{X}_{/U}, \mathscr{O}_{\mathcal{X}}|_U)$, and let η_U denote the image of η in $\pi_0 \Gamma(\mathsf{X}_U; (\mathscr{F}_0^{\vee} \otimes \mathscr{F})|_U)$. Using Theorem 3.4.2.1, we can choose a scallop decomposition

$$\varnothing \simeq U_0 \hookrightarrow U_1 \hookrightarrow \cdots \hookrightarrow U_m = \mathsf{X}.$$

We will prove the following:

$(*_i)$ There exists a connective perfect object $\mathscr{G}_i \in \mathrm{QCoh}(\mathsf{X}_{U_i})$ equipped with a map $\mathscr{G}_i \to \mathscr{F}_0^{\vee}|_{U_i}$ for which η_{U_i} can be lifted to an element of $\pi_0 \Gamma(\mathsf{X}_{U_i}; \mathscr{G}_i \otimes \mathscr{F}|_{U_i})$.

Assuming that $(*_m)$ is satisfied, we complete the proof by taking $\mathscr{F}'_0 = \mathscr{G}_m^{\vee}$. The proof of $(*_i)$ proceeds by induction on i, the case $i = 0$ being trivial. Assume that $i > 0$ and that $(*_{i-1})$ is satisfied. Choose an excision square

$$\begin{array}{ccc} W & \longrightarrow & V \\ \downarrow & & \downarrow \\ U_{i-1} & \longrightarrow & U_i, \end{array}$$

where V is affine and W is quasi-compact. Write $\mathsf{X}_V = \mathrm{Spét}\, A$, so that X_W is the quasi-compact open substack of $\mathrm{Spét}\, A$ complementary to the vanishing locus of a finitely generated ideal $I \subseteq \pi_0 A$. Let $\mathscr{G}_W$ denote the image of $\mathscr{G}_{i-1}$ in $\mathrm{QCoh}(\mathsf{X}_W)$. Replacing $\mathscr{G}_{i-1}$ by $\mathscr{G}_{i-1} \oplus \Sigma \mathscr{G}_{i-1}$, we can assume that $\mathscr{G}_W$ can be extended to a perfect object $M \in \mathrm{Mod}_A \simeq \mathrm{QCoh}(\mathsf{X}_V)$ (Lemma **??**).

Let N be the perfect A-module given by the restriction $\mathscr{F}_0^{\vee}|_V$, and let $N' \in \mathrm{Mod}_A$ denote the direct image of $\mathscr{F}_0^{\vee}|_W$. We have a canonical map $N \to N'$, whose cofiber is I-nilpotent. We may therefore write $\mathrm{cofib}(N \to N')$ as a filtered colimit $\varinjlim N''_{\gamma}$, where each

N''_γ is perfect and I-nilpotent. The map $\mathscr{G}_{i-1} \to \mathscr{F}_0^\vee|_{U_{i-1}}$ determines a map of A-modules $\beta : M \to N'$. Since M is perfect, the composite map $M \xrightarrow{\beta} N' \to \varinjlim N''_\gamma$ factors through some N''_γ. Replacing M by $\mathrm{fib}(M \to N''_\gamma)$, we may suppose that β factors through a map $\overline{\beta} : M \to N$.

Let M' denote the direct image of $\mathscr{G}_W$ in $\mathrm{QCoh}(\mathsf{X}_V)$, so that we have a canonical map $v : M \to N \times_{N'} M'$ such that $\mathrm{cofib}(v)$ is I-nilpotent. We may therefore write $\mathrm{cofib}(v) \simeq \varinjlim L_\beta$, where each L_β is perfect and I-nilpotent. Let $Q \in \mathrm{Mod}_A \simeq \mathrm{QCoh}(\mathsf{X}_V)$ denote the inverse image of $\mathscr{F}$. Together, the points η_{i-1} and η_V determine a point $\eta' \in \pi_0((N \times_{N'} M') \otimes_A Q)$. Let η'' denote the image of η' in $\pi_0(\mathrm{cofib}(v) \otimes_A Q)$. Then η'' can be lifted to a point of $\pi_0(L_\beta \otimes_A Q)$ for some index β. Replacing M by the fiber product $(N \times_{N'} M') \times_{\mathrm{cofib}(v)} L_\beta$, we can assume that η' lifts to an element $\overline{\eta}' \in \pi_0(M \otimes_A Q)$. Using Lemma 9.6.2.3, we can reduce further to the case where M is connective. In this case, M and $\mathscr{G}_{i-1}$ can be amalgamated to a connective perfect object $\mathscr{G}_i \in \mathrm{QCoh}(\mathsf{X}_{U_i})$, and $\overline{\eta}'$ and η_{i-1} can be amalgamated to an element $\eta_i \in \pi_0\Gamma(\mathsf{X}_{U_i}; \mathscr{G}_i \otimes \mathscr{F}|_{U_i})$. □

Proof of Proposition 9.6.7.1. Let X be a quasi-compact, quasi-separated spectral algebraic space and let $\mathcal{C} \subseteq \mathrm{QCoh}(\mathsf{X})$ be the full subcategory spanned by those objects which are perfect and of Tor-amplitude $\leqslant 0$. The inclusion $\mathcal{C} \hookrightarrow \mathrm{QCoh}(\mathsf{X})$ extends to a functor $\rho : \mathrm{Ind}(\mathcal{C}) \to \mathrm{QCoh}(\mathsf{X})$. Since every object of $\mathcal{C}$ is compact in $\mathrm{QCoh}(\mathsf{X})$ (Corollary 9.1.5.5), the functor ρ is fully faithful. Let us denote its essential image by $\mathcal{C}' \subseteq \mathrm{QCoh}(\mathsf{X})$. Since the collection of quasi-coherent sheaves of Tor-amplitude $\leqslant 0$ is closed under filtered colimits, we conclude that each object of $\mathcal{C}'$ has Tor-amplitude $\leqslant 0$. We wish to prove the converse.

For each object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$, let $\mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}_{/\mathscr{F}}$ denote the full subcategory of $\mathrm{QCoh}(\mathsf{X})_{/\mathscr{F}}$ spanned by those maps $\mathscr{F}_0 \to \mathscr{F}$ where $\mathscr{F}_0$ is perfect. Let $U(\mathscr{F})$ denote a colimit of the projection map $\mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}_{/\mathscr{F}} \to \mathrm{QCoh}(\mathsf{X})$, so that we have a canonical map $u_{\mathscr{F}} : U(\mathscr{F}) \to \mathscr{F}$. If $\mathscr{F}$ is perfect, then $\mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}_{/\mathscr{F}}$ has a final object, and the map $u_{\mathscr{F}}$ is an equivalence. More generally, the fact that each perfect object of $\mathrm{QCoh}(\mathsf{X})$ is compact (Corollary 9.1.5.5) implies that the functor $\mathscr{F} \mapsto U(\mathscr{F})$ preserves filtered colimits, so that the collection of those objects $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ for which $u_{\mathscr{F}}$ is an equivalence is closed under filtered colimits. Applying Proposition 9.6.1.1, we see that $u_{\mathscr{F}}$ is an equivalence for every object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$.

Suppose now that $\mathscr{F}$ has Tor-amplitude $\leqslant 0$. Let $\mathcal{E} \subseteq \mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}_{/\mathscr{F}}$ denote the full subcategory spanned by those morphisms $\mathscr{F}_0 \to \mathscr{F}$ where $\mathscr{F}_0$ is perfect and of Tor-amplitude $\leqslant 0$. If K is a finite simplicial set and we are given a diagram $q : K \to \mathcal{E}$, then K admits a colimit in the ∞-category $\mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}_{/\mathscr{F}}$, which we can identify with a morphism $\mathscr{F}_0 \to \mathscr{F}$ in $\mathrm{QCoh}(\mathsf{X})$. Applying Lemma 9.6.7.2, we can factor α as a composition $\mathscr{F}_0 \to \mathscr{F}'_0 \to \mathscr{F}$, where $\mathscr{F}'_0$ is perfect and of Tor-amplitude $\leqslant 0$, and therefore determines an object of $\mathcal{E}$. It follows that $\mathcal{E}_{q/}$ is nonempty. Allowing q to vary over all finite diagrams, we conclude that the ∞-category $\mathcal{E}$ is filtered. It follows that the colimit of the composite map $\mathcal{E} \xrightarrow{\iota} \mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}_{/\mathscr{F}} \to \mathrm{QCoh}(\mathsf{X})$ belongs to the ∞-category $\mathcal{C}'$. Consequently, to prove that $\mathscr{F}$ belongs to $\mathcal{C}'$, it will suffice to show that the inclusion ι is left cofinal.

Fix an object $\mathscr{F}_0 \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}_{/\mathscr{F}}$. We wish to prove that the ∞-category

$$\mathcal{E}_{\mathscr{F}_0/} = \mathcal{E} \times_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}_{/\mathscr{F}}} (\mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}_{/\mathscr{F}})_{\mathscr{F}_0/}$$

is weakly contractible. In fact, we claim that $\mathcal{E}_{\mathscr{F}_0/}$ is filtered. Let $q : K \to \mathcal{E}_{\mathscr{F}_0/}$ be a diagram indexed by a finite simplicial set. Arguing as above, we see that q admits a colimit in the ∞-category $\mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}_{/\mathscr{F}}$, which we can identify with a map $\beta : \mathscr{F}'_0 \to \mathscr{F}$. Applying Lemma 9.6.7.2, we deduce that β factors as a composition $\mathscr{F}'_0 \to \mathscr{F}''_0 \to \mathscr{F}$, where $\mathscr{F}''_0$ is perfect and of Tor-amplitude $\leqslant 0$. It follows that $(\mathcal{E}_{\mathscr{F}_0/})_{q/}$ is nonempty, as desired. □

9.7 Tannaka Duality for Abelian Categories

Let X be a quasi-geometric stack. It follows from Theorem 9.2.0.2 that X can be recovered, up to canonical equivalence, from the symmetric monoidal ∞-category $\mathrm{QCoh}(X)$ (together with its t-structure). In this section, we study an analogous problem in a more concrete setting: to what extent is X determined by the abelian category $\mathrm{QCoh}(X)^{\heartsuit}$? Note that the abelian category $\mathrm{QCoh}(X)^{\heartsuit}$ depends only the the 0-truncation of X (see Remark **??**), so at best we could only hope to recover the 0-truncation of X. In the positive direction, we have the following:

Theorem 9.7.0.1. *Let X be a 0-truncated geometric stack. For any commutative ring R, the construction*

$$(\eta \in X(R)) \mapsto (\tau_{\leqslant 0}\eta^* : \mathrm{QCoh}(X)^{\heartsuit} \to \mathrm{Mod}_R^{\heartsuit})$$

induces a fully faithful embedding $X(R) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\heartsuit}, \mathrm{Mod}_R^{\heartsuit})$ whose essential image is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X)^{\heartsuit} \to \mathrm{Mod}_R^{\heartsuit}$ with the following properties:

(1) *The functor F preserves small colimits. In other words, F is right exact and commutes with arbitrary direct sums.*

(2) *The functor F carries flat quasi-coherent sheaves on X to flat R-modules.*

(3) *For every exact sequence $0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0$ of flat quasi-coherent sheaves on X, the sequence of R-modules*

$$0 \to F(\mathscr{F}') \to F(\mathscr{F}) \to F(\mathscr{F}'') \to 0$$

is also exact.

It is possible to prove Theorem **??** by imitating the proof of Theorem 9.3.0.3 at the level of abelian categories (for a proof along these lines, we refer the reader to [137]). We will give a different proof in §9.7.3 (see Theorem 9.7.3.2 and Example 9.7.3.4), which proceeds by reducing Theorem **??** to Theorem 9.3.0.3. Though more circuitous than the direct approach, our method has the virtue of yielding several other results of independent interest (for example, we will show how to recover an arbitrary geometric stack X from the full subcateegory $\mathrm{QCoh}(X)^\flat$ of flat quasi-coherent sheaves on X; see Theorem 9.7.2.1).

9.7.1 Exact Functors on Flat Sheaves

For every geometric stack X, we let $\mathrm{QCoh}(X)^\flat$ denote the full subcategory of $\mathrm{QCoh}(X)$ spanned by the flat quasi-coherent sheaves on X. According to Theorem 9.3.0.3, an arbitrary map $f : Y \to X$ is determined by the symmetric monoidal functor $f^* : \mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$. In fact, we will show in a moment that f can be recovered from the restriction $f^*|_{\mathrm{QCoh}(X)^\flat} : \mathrm{QCoh}(X)^\flat \to \mathrm{QCoh}(Y)^\flat$. First, let us single out an important property enjoyed by functors of this form.

Proposition 9.7.1.1. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a geometric stack, let $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be an arbitrary functor, and let $F : \mathrm{QCoh}(X)^\flat \to \mathrm{QCoh}(Y)^\flat$ be a symmetric monoidal functor which preserves filtered colimits. Then the following conditions are equivalent:*

(1) *The functor F preserves finite direct sums and carries faithfully flat commutative algebra objects of $\mathrm{QCoh}(X)$ to faithfully flat commutative algebra objects of $\mathrm{QCoh}(Y)$.*

(2) *The functor F preserves zero objects, and for every fiber sequence σ:*

$$\begin{array}{ccc} \mathscr{F}' & \longrightarrow & \mathscr{F} \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & \mathscr{F}'' \end{array}$$

in $\mathrm{QCoh}(X)$ where $\mathscr{F}'$, $\mathscr{F}$, and $\mathscr{F}''$ are flat, the image $F(\sigma)$ is a fiber sequence in $\mathrm{QCoh}(Y)$.

(3) *The functor F preserves finite direct sums, and for every fiber sequence σ :*

$$\begin{array}{ccc} \mathscr{O}_X & \longrightarrow & \mathscr{F} \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & \mathscr{F}'' \end{array}$$

in $\mathrm{QCoh}(X)$ where $\mathscr{F}$ and $\mathscr{F}''$ are flat, the image $F(\sigma)$ is a fiber sequence in $\mathrm{QCoh}(Y)$.

Remark 9.7.1.2. Condition (2) of Proposition 9.7.1.1 is automatically satisfied if F extends to a right exact functor $\mathrm{QCoh}(X)^{\mathrm{cn}} \to \mathrm{QCoh}(Y)^{\mathrm{cn}}$ (or an exact functor $\mathrm{QCoh}(X) \to \mathrm{QCoh}(Y)$).

Motivated by Remark 9.7.1.2, we introduce the following terminology:

Definition 9.7.1.3. Let X be a geometric stack, let $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be an arbitrary functor, and let $F : \mathrm{QCoh}(X)^{\flat} \to \mathrm{QCoh}(Y)^{\flat}$ be a symmetric monoidal functor which preserves filtered colimits. We will say that F is *exact* if it satisfies the equivalent conditions of Proposition 9.7.1.1.

Proof of Proposition 9.7.1.1. Let us assume that the functor F preserves zero objects. Note that for every pair of objects $\mathscr{F}', \mathscr{F}'' \in \mathrm{QCoh}(X)^{\flat}$, we have a fiber sequence σ :

$$\begin{array}{ccc} \mathscr{F}' & \longrightarrow & \mathscr{F}' \oplus \mathscr{F}'' \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & \mathscr{F}'', \end{array}$$

and that $F(\sigma)$ is a fiber sequence in $\mathrm{QCoh}(Y)$ if and only if F carries $F(\mathscr{F}' \oplus \mathscr{F}'')$ to a direct sum of $F(\mathscr{F}')$ and $F(\mathscr{F}'')$. It follows immediately that $(2) \Rightarrow (3)$. The implication $(3) \Rightarrow (1)$ follows from Lemma D.4.4.3. We will complete the proof by showing that $(1) \Rightarrow (2)$. Suppose that condition (1) is satisfied, and that σ :

$$\begin{array}{ccc} \mathscr{F}' & \longrightarrow & \mathscr{F} \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & \mathscr{F}'' \end{array}$$

is a pullback diagram in $\mathrm{QCoh}(X)$ consisting of flat objects. We wish to show that $F(\sigma)$ is a pullback square in $\mathrm{QCoh}(Y)$. Since X is geometric, there exists a faithfully flat map $\pi : \mathrm{Spec}\, A \to X$ for some connective $\mathbb{E}_\infty$-ring A. Set $\mathscr{A} = f_* \mathscr{O}_{\mathrm{Spec}\, A} \in \mathrm{CAlg}(\mathrm{QCoh}(X))$, so that $\mathscr{A}$ is a faithfully flat commutative algebra object of $\mathrm{QCoh}(X)$. It follows from (1) that $F(\mathscr{A})$ is a faithfully flat object of $\mathrm{QCoh}(Y)$. It will therefore suffice to show that $F(\sigma)$ becomes a pullback square after tensoring with $F(\mathscr{A})$. Since F is a symmetric monoidal functor, we are reduce to proving that $F(\pi_* \pi^* \sigma)$ is a pullback square in $\mathrm{QCoh}(Y)$.

Let us abuse notation by identifying $\mathrm{QCoh}(\mathrm{Spec}\, A)$ with Mod_A, so that $\pi^* \sigma$ can be identified with a fiber sequence of flat A-modules $M' \to M \to M''$. Using Theorem HA.7.2.2.15 , we can write M'' as a filtered colimit $\varinjlim M''_\alpha$, where each M''_α is a free A-module. For each index α, set $M_\alpha = M \times_{M''} M''_\alpha$, so that we have a fiber sequence $\tau_\alpha : M' \to M_\alpha \to M''_\alpha$. Since M' is connective and M''_α is free, this sequence splits. It follows that $\pi_* \tau_\alpha$ is a split fiber sequence in $\mathrm{QCoh}(X)$. Since F preserves finite direct sums, we conclude that $F(\pi_* \tau_\alpha)$ is a (split) fiber sequence in $\mathrm{QCoh}(Y)$. Because F preserves filtered colimits, the diagram $F(\pi_* \pi^* \sigma) \simeq \varinjlim F(\pi_* \tau_\alpha)$ is also a fiber sequence in $\mathrm{QCoh}(Y)$. □

9.7.2 Recovering X from $\mathrm{QCoh}(X)^{\flat}$

We can now formulate our main result.

Theorem 9.7.2.1 (Tannaka Duality, Flat Sheaf Version)**.** *Let X be a geometric stack and let $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be an arbitrary functor. Then the construction $(f : Y \to X) \mapsto (f^* : \mathrm{QCoh}(X)^{\flat} \to \mathrm{QCoh}(Y)^{\flat})$ determines a fully faithful embedding*

$$\mathrm{Map}_{\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}},\mathcal{S})}(Y,X) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\flat}, \mathrm{QCoh}(Y)^{\flat}),$$

whose essential image is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X)^{\flat} \to \mathrm{QCoh}(Y)^{\flat}$ which preserve filtered colimits and are exact (in the sense of Definition 9.7.1.3).

We will deduce both Theorem 9.7.2.1 and Theorem **??** from the following result, whose proof we defer until §**??**:

Theorem 9.7.2.2. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a geometric stack, let $0 \leqslant d \leqslant \infty$, and let R be a connective $\mathbb{E}_{\infty}$-ring which is d-truncated. Let $\mathcal{C}$ denote the full subcategory of $\mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{cn}}, (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d})$ spanned by those symmetric monoidal functors which preserve small colimits and restrict to an exact functor $\mathrm{QCoh}(X)^{\flat} \to \mathrm{Mod}_R^{\flat}$ (in the sense of Definition 9.7.1.3). Then the restriction functor $\mathcal{C} \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\flat}, (\mathrm{Mod}_R^{\flat})_{\leqslant d})$ is a fully faithful embedding. Its essential image is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X)^{\flat} \to \mathrm{Mod}_R^{\flat}$ which are exact and preserve filtered colimits.*

Corollary 9.7.2.3. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a geometric stack, let R be a connective $\mathbb{E}_{\infty}$-ring, and let $\mathcal{E}$ denote the full subcategory of $\mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{Mod}_R)$ spanned by those symmetric monoidal functors which preserve small colimits, flat objects, and connective objects. Then the restriction functor $\mathcal{E} \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\flat}, \mathrm{Mod}_R^{\flat})$ is a fully faithful embedding. Its essential image is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X)^{\flat} \to \mathrm{Mod}_R^{\flat}$ which are exact and preserve filtered colimits.*

Proof. Let $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ denote the ∞-category of presentable ∞-categories. We regard $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ as equipped with the symmetric monoidal structure described in §HA.4.8.1 . Let $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ denote the full subcategory of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ spanned by the presentable stable ∞-categories, so that $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ inherits a symmetric monoidal structure. The inclusion $\mathcal{P}\mathrm{r}^{\mathrm{St}} \hookrightarrow \mathcal{P}\mathrm{r}^{\mathrm{L}}$ admits a symmetric monoidal left adjoint, given by $\mathcal{C} \mapsto \mathrm{Sp}(\mathcal{C})$. Consequently, if $\mathcal{C}$ and $\mathcal{C}'$ are presentable symmetric monoidal ∞-categories for which the tensor product functors

$$\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \qquad \otimes : \mathcal{C}' \times \mathcal{C}' \to \mathcal{C}'$$

preserve small colimits separately in each variable, and $\mathcal{C}'$ is stable, then we have a canonical homotopy equivalence $\mathrm{Map}_{\mathrm{CAlg}(\mathcal{P}\mathrm{r}^{\mathrm{L}})}(\mathcal{C}, \mathcal{C}') \simeq \mathrm{Map}_{\mathrm{CAlg}(\mathcal{P}\mathrm{r}^{\mathrm{St}})}(\mathrm{Sp}(\mathcal{C}), \mathcal{C}')$. Replacing $\mathcal{C}'$ by $\mathrm{Fun}(K, \mathcal{C}')$ and allowing K to vary, we obtain an equivalence

$$\mathrm{Fun}_0^{\otimes}(\mathcal{C}, \mathcal{C}') \simeq \mathrm{Fun}_0^{\otimes}(\mathrm{Sp}(\mathcal{C}), \mathcal{C}'),$$

where $\mathrm{Fun}_0^{\otimes}(\mathcal{C}, \mathcal{C}')$ denotes the full subcategory of $\mathrm{Fun}^{\otimes}(\mathcal{C}, \mathcal{C}')$ spanned by those symmetric monoidal functors which preserve small colimits, and $\mathrm{Fun}_0^{\otimes}(\mathrm{Sp}(\mathcal{C}), \mathcal{C}')$ is defined similarly. Taking $\mathcal{C} = \mathrm{QCoh}(X)^{\mathrm{cn}}$, we observe that $\mathrm{Sp}(\mathcal{C})$ can be identified with $\mathrm{QCoh}(X)$ (Proposition 9.1.3.1). It follows that the restriction functor

$$\mathrm{Fun}_0^{\otimes}(\mathrm{QCoh}(X), \mathrm{Mod}_R) \to \mathrm{Fun}_0^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{cn}}, \mathrm{Mod}_R)$$

is an equivalence of ∞-categories. Under this equivalence, $\mathcal{E}$ can be identified with the full subcategory of $\mathrm{Fun}_0^{\otimes}(\mathrm{QCoh}(X), \mathrm{Mod}_R)$ spanned by those functors which preserve connective and flat objects. The desired result now follows from Theorem 9.7.2.2 (applied in the case $d = \infty$). □

Proof of Theorem 9.7.2.1. Writing Y as a colimit of corepresentable functors, we can reduce to the case where $Y = \mathrm{Spec}\, R$ is affine. Let $\mathcal{E} \subseteq \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X), \mathrm{Mod}_R)$ be defined as in Corollary 9.7.2.3. $\theta : X(R) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\flat}, \mathrm{Mod}_R^{\flat})$ factors as a composition

$$X(R) \xrightarrow{\theta'} \mathcal{E} \xrightarrow{\theta''} \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\flat}, \mathrm{Mod}_R^{\flat}).$$

Corollary 9.7.2.3 implies that θ'' is a fully faithful embedding whose essential image is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X)^{\flat} \to \mathrm{Mod}_R^{\flat}$ which are exact and preserve filtered colimits. We are therefore reduced to showing that θ' is an equivalence of ∞-categories, which follows from Theorem 9.3.0.3. □

9.7.3 The Truncated Case

Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a geometric stack. For every connective $\mathbb{E}_\infty$-ring R, Theorem 9.3.0.3 allows us to recover the space $X(R)$ from the symmetric monoidal ∞-category $\mathrm{QCoh}(X)$. We now show that if R is n-truncated, we can recover $X(R)$ from the full subcategory $\mathrm{QCoh}(X)^{\mathrm{cn}}$ spanned by the n-truncated objects.

Remark 9.7.3.1. If X is a geometric stack, then the symmetric monoidal structure on $\mathrm{QCoh}(X)$ is compatible with its t-structure. It follows that for each $n \geqslant 0$, the ∞-category $\mathrm{QCoh}(X)^{\mathrm{cn}}_{\leqslant n}$ inherits the structure of a symmetric monoidal ∞-category, with tensor product given by $(\mathscr{F}, \mathscr{G}) \mapsto \tau_{\leqslant n}(\mathscr{F} \otimes \mathscr{G})$.

Theorem 9.7.3.2. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a geometric stack, let $n \geqslant 0$ be an integer, let R be a connective $\mathbb{E}_\infty$-ring which is n-truncated, and let $\theta : X(R) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{cn}}_{\leqslant n}, (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant n})$ be the map which carries a point $\eta \in X(R)$ to the functor $\mathscr{F} \mapsto \tau_{\leqslant n}\eta^* \mathscr{F}$. Then θ is a fully faithful embedding, whose essential image is spanned by those symmetric monoidal functors $F : (\mathrm{QCoh}(X)^{\mathrm{cn}})_{\leqslant n} \to (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant n}$ with the following properties:*

(a) *The functor F preserves small colimits.*

(b) *The construction* $\mathscr{F} \mapsto F(\tau_{\leqslant n}\mathscr{F})$ *determines a functor from* $\mathrm{QCoh}(X)^{\flat}$ *to* $\mathrm{Mod}_R^{\flat}$ *which is exact (in the sense of Definition 9.7.1.3).*

Remark 9.7.3.3. In the situation of Theorem 9.7.3.2, suppose that X is an n-truncated geometric stack. Then every object $\mathscr{F} \in \mathrm{QCoh}(X)^{\flat}$ is n-truncated. We can therefore rephrase condition (b) as follows:

(b') The construction $\mathscr{F} \mapsto F(\mathscr{F})$ determines a functor from $\mathrm{QCoh}(X)^{\flat}$ to $\mathrm{Mod}_R^{\flat}$ which is exact (in the sense of Definition 9.7.1.3).

Example 9.7.3.4. Let X be a 0-truncated geometric stack. Applying Theorem 9.7.3.2 (and Remark 9.7.3.3) in the case $n = 0$, we deduce that for every commutative ring, the natural map $X(R) \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\heartsuit}, \mathrm{Mod}_R^{\heartsuit})$ is a fully faithful embedding, whose essential image is spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X)^{\heartsuit} \to \mathrm{Mod}_R^{\heartsuit}$ which preserve small colimits, flat objects, and exact sequences of flat objects. We can therefore regard Theorem 9.7.3.2 as a generalization of Theorem **??**.

Proof of Theorem 9.7.3.2. Let $\mathcal{C} \subseteq \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{cn}}_{\leqslant n}, (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant n})$ be the full subcategory spanned by those functors which satisfy conditions (a) and (b). It is clear that θ factors through $\mathcal{C}$.

Let $\mathrm{Fun}_0^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{cn}}_{\leqslant n}, (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant n}) \subseteq \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{cn}}_{\leqslant n}, (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant n})$ be the full subcategory spanned by those functors which preserve small colimits, and define the ∞-category $\mathrm{Fun}_0^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{cn}}, (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant n})$ similarly. Since $(\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant n}$ is equivalent to an $(n+1)$-category, Remark HA.4.8.2.17 implies that composition with the truncation map $\tau_{\leqslant n} : \mathrm{QCoh}(X)^{\mathrm{cn}} \to (\mathrm{QCoh}(X)^{\mathrm{cn}})_{\leqslant n}$ induces an equivalence of ∞-categories

$$\mathrm{Fun}_0^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{cn}}_{\leqslant n}, (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant n}) \to \mathrm{Fun}_0^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{cn}}, (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant n}).$$

This induces an equivalence of $\mathcal{C}$ with the full subcategory $\mathcal{C}' \subseteq \mathrm{Fun}_0^{\otimes}(\mathrm{QCoh}(X)^{\mathrm{cn}}, (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant n})$ spanned by those functors which restrict to exact functors $\mathrm{QCoh}(X)^{\flat} \to \mathrm{Mod}_R^{\flat}$. Using Theorem 9.7.2.2 (and the theory of faithfully flat descent), we see that that the restriction map $\mathcal{C}' \to \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\flat}, \mathrm{Mod}_R^{\flat})$ is a fully faithful embedding, whose essential image is the full subcategory $\mathcal{C}'' \subseteq \mathrm{Fun}^{\otimes}(\mathrm{QCoh}(X)^{\flat}, \mathrm{Mod}_R^{\flat})$ spanned by those symmetric monoidal functors $F : \mathrm{QCoh}(X)^{\flat} \to \mathrm{Mod}_R^{\flat}$ which are exact and preserve filtered colimits. We have a commutative diagram

$$\begin{array}{ccccc} & & & & \mathcal{C} \\ & \overset{\theta}{\nearrow} & & \nearrow \sim & \\ X(R) & \longrightarrow & \mathcal{C}' & & \\ & \underset{\theta'}{\searrow} & & \searrow \sim & \\ & & & & \mathcal{C}''. \end{array}$$

It will therefore suffice to show that θ' is an equivalence of ∞-categories, which follows from Theorem 9.7.2.1. □

9.7.4 The Proof of Theorem 9.7.2.2

We now provide a proof of Theorem 9.7.2.2. Let X be a geometric stack, let $0 \leqslant d \leqslant \infty$, and let R be an $\mathbb{E}_\infty$-ring which is connective and d-truncated. Roughly speaking, Theorem 9.7.2.2 asserts that a well-behaved symmetric monoidal functor $F : \mathrm{QCoh}(X)^{\mathrm{cn}} \to (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d}$ can be reconstructed from the restriction $F^\flat = F|_{\mathrm{QCoh}(X)^\flat}$. Since the details of this reconstruction process are somewhat involved, let us first sketch the basic idea. Suppose that $\mathscr{F} \in \mathrm{QCoh}(X)^{\mathrm{cn}}$, and that we wish to describe $F(\mathscr{F})$ using only the functor $F^\flat$. If X is affine, then $\mathrm{QCoh}(X)^{\mathrm{cn}}$ is freely generated under sifted colimits by the full subcategory $\mathrm{Vect}(X) \subseteq \mathrm{QCoh}(X)^{\mathrm{cn}}$ spanned by the locally free sheaves of finite rank. It follows that any functor $F : \mathrm{QCoh}(X)^{\mathrm{cn}} \to (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d}$ which preserves small colimits (or even small sifted colimits) can be recovered from its restriction to $\mathrm{Vect}(X) \subseteq \mathrm{QCoh}(X)^\flat \subseteq \mathrm{QCoh}(X)^{\mathrm{cn}}$. To handle the general case, we will choose a faithfully flat map $\phi : U_0 \to X$, where U_0 is affine. Setting $\mathscr{A} = \phi_* \mathscr{O}_{U_0}$, we see that F determines a symmetric monoidal functor

$$F_0 : \mathrm{QCoh}(U_0)^{\mathrm{cn}} \simeq \mathrm{Mod}_{\mathscr{A}}(\mathrm{QCoh}(X)^{\mathrm{cn}}) \xrightarrow{F} (\mathrm{Mod}_{F(\mathscr{A})}^{\mathrm{cn}})_{\leqslant d}.$$

Since U_0 is affine, the functor F_0 is determined by its restriction $F_0^\flat = F_0|_{\mathrm{QCoh}(U_0)^\flat}$, and therefore by $F^\flat$. We can then recover the functor F from F_0 using faithfully flat descent (which involves making an analogous argument for the iterated fiber products $U_0 \times_X U_0 \times_X \cdots \times_X U_0$). Our implementation of this strategy will be complicated by the fact that we need to recover F from $F^\flat$ not only as a functor, but as a *symmetric monoidal* functor. In what follows, we will assume that the reader is familiar with the language of symmetric monoidal ∞-categories developed in [139].

Notation 9.7.4.1. For each $n \geqslant 0$, we let $\langle n \rangle$ denote the finite pointed set $\{1, 2, \ldots, n, *\}$ (with base point $*$). Let $\mathcal{F}\mathrm{in}_*$ denote the category whose objects are pointed sets of the form $\langle n \rangle$, and whose morphisms are maps $\alpha : \langle m \rangle \to \langle n \rangle$ satisfying $\alpha(*) = *$. Recall that if $\mathcal{E}$ is an ∞-category which admits finite products, then a *commutative monoid object* of $\mathcal{E}$ is a functor $G : \mathcal{F}\mathrm{in}_* \to \mathcal{E}$ which satisfies the "Segal condition" that the natural map $G(\langle n \rangle) \to G(\langle 1 \rangle)^n$ is an equivalence. In what follows, it will be convenient to identify symmetric monoidal ∞-categories with commutative monoid objects of the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty$ of (not necessarily small) ∞-categories.

Let X be a geometric stack, and choose a faithfully flat morphism $\phi : U_0 \to X$, where U_0 is affine. Let $U_\bullet$ denote the Čech nerve of ϕ. We will regard $U_\bullet$ as an augmented simplicial object of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$ with $U_{-1} = X$. For each $n \geqslant -1$, we will regard $\mathrm{QCoh}(U_n)^{\mathrm{cn}}$ as a symmetric monoidal ∞-category: that is, as an object of the ∞-category

$\mathrm{Mon}_{\mathrm{Comm}}(\widehat{\mathcal{C}\mathrm{at}}_\infty) \subseteq \mathrm{Fun}(\mathcal{F}\mathrm{in}_*, \widehat{\mathcal{C}\mathrm{at}}_\infty)$ spanned by the commutative monoid objects. The construction $[n] \mapsto \mathrm{QCoh}(U_n)^{\mathrm{cn}}$ determines a functor

$$\mathbf{\Delta}_+ \to \mathrm{Mon}_{\mathrm{Comm}}(\widehat{\mathcal{C}\mathrm{at}}_\infty) \subseteq \mathrm{Fun}(\mathcal{F}\mathrm{in}_*, \widehat{\mathcal{C}\mathrm{at}}_\infty),$$

which we can identify with a map $\mathbf{\Delta}_+ \times \mathcal{F}\mathrm{in}_* \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ classifying a coCartesian fibration of ∞-categories $p : \mathcal{M}_+ \to \mathbf{\Delta}_+ \times \mathcal{F}\mathrm{in}_*$. We can describe the ∞-category $\mathcal{M}_+$ more informally as follows:

- An object of $\mathcal{M}_+$ is a tuple $([m], \mathscr{F}_1, \ldots, \mathscr{F}_n)$, where $m \geqslant -1$ and each $\mathscr{F}_i$ is an object of $\mathrm{QCoh}(U_m)^{\mathrm{cn}}$.
- A morphism from $([m], \mathscr{F}_1, \ldots, \mathscr{F}_n)$ to $([m'], \mathscr{F}'_1, \ldots, \mathscr{F}'_{n'})$ in $\mathcal{M}_+$ consists of a nondecreasing map $\alpha : [m] \to [m']$, a map of pointed finite sets $\beta : \langle n \rangle \to \langle n' \rangle$, and a collection of maps $\{q^* \bigoplus_{\beta(i)=j} \mathscr{F}_i \to \mathscr{F}'_j\}_{1 \leqslant j \leqslant n'}$ in $\mathrm{QCoh}(U_{m'})$, where $q : U_{m'} \to U_m$ denotes the map determined by α.

Let $\mathcal{M}_+^\flat$ denote the full subcategory of $\mathcal{M}_+$ spanned by those objects $([m], \mathscr{F}_1, \ldots, \mathscr{F}_n)$ where each $\mathscr{F}_i$ is flat (as a quasi-coherent sheaf on U_m). The symmetric monoidal structure on $\mathrm{QCoh}(X)^{\mathrm{cn}}$ is encoded by a coCartesian fibration $p_{-1} : \mathrm{QCoh}(X)^{\mathrm{cn}\otimes} \to \mathcal{F}\mathrm{in}_*$, where we can identify $\mathrm{QCoh}(X)^{\mathrm{cn}\otimes}$ with the full subcategory of $\mathcal{M}_+$ spanned by objects of the form $([-1], \mathscr{F}_1, \ldots, \mathscr{F}_n)$ Similarly, the symmetric monoidal structure on $\mathrm{QCoh}(X)^\flat$ is encoded by a coCartesian fibration $\mathrm{QCoh}(X)^{\flat\otimes} \to \mathcal{F}\mathrm{in}_*$, where we can identify $\mathrm{QCoh}(X)^{\flat\otimes}$ with the full subcategory of $\mathcal{M}_+^\flat$ spanned by objects of the form $([-1], \mathscr{F}_1, \ldots, \mathscr{F}_n)$.

Notation 9.7.4.2. Let $0 \leqslant d \leqslant \infty$ and let R be a connective $\mathbb{E}_\infty$-ring which is d-truncated. We let $\mathcal{N}$ denote the ∞-category $(\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d}$. The symmetric monoidal structure on $\mathcal{N}$ is encoded by a coCartesian fibration of ∞-categories $r : \mathcal{N}^\otimes \to \mathcal{F}\mathrm{in}_*$. More concretely, the objects of $\mathcal{N}^\otimes$ can be identified with finite sequences $(M_1, \ldots, M_n)$, where each M_i is a connective d-truncated R-module; the functor r is given on objects by $r(M_1, \ldots, M_n) = \langle n \rangle$.

We will identify the ∞-category $\mathrm{Fun}^\otimes(\mathrm{QCoh}(X)^{\mathrm{cn}}, (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d})$ of symmetric monoidal functors from $\mathrm{QCoh}(X)^{\mathrm{cn}}$ to $(\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d}$ with the full subcategory of $\mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathrm{QCoh}(X)^{\mathrm{cn}\otimes}, \mathcal{N}^\otimes)$ spanned by those maps $F : \mathrm{QCoh}(X)^{\mathrm{cn}\otimes} \to \mathcal{N}^\otimes$ which carry p_{-1}-coCartesian morphisms of $\mathrm{QCoh}(X)^{\mathrm{cn}\otimes}$ to r-coCartesian morphisms of $\mathcal{N}^\otimes$. Similarly, let us identify the ∞-category $\mathrm{Fun}^\otimes(\mathrm{QCoh}(X)^\flat, \mathrm{Mod}_R^\flat)$ with a full subcategory of $\mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathrm{QCoh}(X)^{\flat\otimes}, \mathcal{N}^\otimes)$.

Let $\mathcal{C} \subseteq \mathrm{Fun}^\otimes(\mathrm{QCoh}(X)^{\mathrm{cn}}, (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d})$ be the full subcategory spanned by those symmetric monoidal functors which the underlying functor $\mathrm{QCoh}(X)^{\mathrm{cn}} \to (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d}$ preserves small colimits and carries $\mathrm{QCoh}(X)^\flat$ into $\mathrm{Mod}_R^\flat$. Let $\mathcal{C}^\flat$ denote the full subcategory of $\mathrm{Fun}^\otimes(\mathrm{QCoh}(X)^\flat, (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d})$ spanned by those objects for which the underlying functor $\mathrm{QCoh}(X)^\flat \to (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d}$ factors through $\mathrm{Mod}_R^\flat$, preserves small filtered colimits, and is exact in the sense of Definition 9.7.1.3. To prove Theorem 9.7.2.2, we must show that the evident restriction functor $\mathcal{C} \to \mathcal{C}^\flat$ is an equivalence of ∞-categories.

Notation 9.7.4.3. Let $\mathcal{M} = \mathcal{M}_+ \times_{\mathbf{\Delta}_+} \mathbf{\Delta}$, and let $\mathcal{M}^\flat = \mathcal{M}_+^\flat \cap \mathcal{M}$. Suppose we are given a map $F \in \mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}^\flat, \mathcal{N}^\otimes)$ whose restriction to $\{[m]\} \times_{\mathbf{\Delta}} \mathcal{M}^\flat$ is a lax symmetric monoidal functor, for each $m \geq 0$. For each $m \geq 0$, we can regard $\mathscr{O}_{U_m}$ as a commutative algebra object of $\mathrm{QCoh}(U_m)^\flat$, so that $F(\mathscr{O}_{U_m})$ can be regarded as a commutative algebra object $A_F^m \in \mathrm{CAlg}(\mathcal{N}) \simeq \tau_{\leq d}\,\mathrm{CAlg}_R^{\mathrm{cn}}$. The construction $[m] \mapsto A_F^m$ determines a functor $\mathbf{\Delta} \to \tau_{\leq d}\,\mathrm{CAlg}_R^{\mathrm{cn}}$, which we will denote by $A_F^\bullet$. If $\overline{F} \in \mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}, \mathcal{N}^\otimes)$ is a map whose restriction to $\{[m]\} \times_{\mathbf{\Delta}} \mathcal{M}$ is lax symmetric monoidal for each $m \geq 0$, then we let $A_{\overline{F}}^\bullet$ denote the cosimplicial object $A_F^\bullet$, where $F = \overline{F}|_{\mathcal{M}^\flat}$.

Notation 9.7.4.4. We let $\mathcal{D}$ denote the full subcategory of $\mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}, \mathcal{N}^\otimes)$ spanned by those functors $F : \mathcal{M} \to \mathcal{N}^\otimes$ which satisfy the following conditions:

- (a) For each $m \geq 0$, the restriction of F to $\{[m]\} \times_{\mathbf{\Delta}} \mathcal{M}$ is a lax symmetric monoidal functor (that is, F carries inert morphisms in $\{[m]\} \times_{\mathbf{\Delta}} \mathcal{M}$ to inert morphisms in $\mathcal{N}^\otimes$).
- (b) Let $q : \mathcal{M} \to \mathbf{\Delta}$ denote the projection map. Then F carries q-Cartesian morphisms in $\mathcal{M}$ to equivalences in $\mathcal{N}^\otimes$.
- (c) Let $m \geq 0$, and let $F(m) : \mathrm{QCoh}(U_m) \to (\mathrm{Mod}_R^{\mathrm{cn}})_{\leq d}$ denote the restriction of F to $\mathrm{QCoh}(U_m)^{\mathrm{cn}} \simeq \{([m], \langle 1 \rangle)\} \times_{\mathbf{\Delta} \times \mathcal{F}\mathrm{in}_*} \mathcal{M}$. Then $F(m)$ preserves small colimits.
- (d) The cosimplicial object $A_F^\bullet$ of $\mathrm{CAlg}_R^{\mathrm{cn}}$ is 0-coskeletal: that is, for each $m \geq 0$, the inclusions $\{i\} \hookrightarrow [m]$ induce an equivalence $\bigotimes_{0 \leq i \leq m} A_F^0 \to A_F^m$. Moreover, A_F^0 is faithfully flat over R.

Similarly, we let $\mathcal{D}^\flat$ denote the full subcategory of $\mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}^\flat, \mathcal{N}^\otimes)$ spanned by those functors $F : \mathcal{M}^\flat \to \mathcal{N}^\otimes$ which satisfy the following analogous conditions:

- (a') For each $m \geq 0$, the restriction of F to $\{[m]\} \times_{\mathbf{\Delta}} \mathcal{M}^\flat$ is a lax symmetric monoidal functor from $\mathrm{QCoh}(U_m)^\flat$ to $\mathrm{Mod}_R^\flat$.
- (b') Let $q^\flat : \mathcal{M}^\flat \to \mathbf{\Delta}$ denote the projection map. Then F carries $q^\flat$-Cartesian morphisms in $\mathcal{M}^\flat$ to equivalences in $\mathcal{N}^\otimes$.
- (c') Let $m \geq 0$, and let $F(m) : \mathrm{QCoh}(U_m)^\flat \to \mathrm{Mod}_R^\flat$ denote the restriction of F to $\mathrm{QCoh}(U_m)^\flat \simeq \{([m], \langle 1 \rangle)\} \times_{\mathbf{\Delta} \times \mathcal{F}\mathrm{in}_*} \mathcal{M}$. Then $F(m)$ preserves small filtered colimits and finite direct sums.
- (d') The cosimplicial object $A_F^\bullet$ of $\mathrm{CAlg}_R^{\mathrm{cn}}$ is 0-coskeletal: that is, for each $m \geq 0$, the inclusions $\{i\} \hookrightarrow [m]$ induce an equivalence $\bigotimes_{0 \leq i \leq m} A_F^0 \to A_F^m$. Moreover, A_F^0 is faithfully flat over R.

We will deduce Theorem 9.7.2.2 from the following assertions:

Lemma 9.7.4.5. *Let $F \in \mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}_+, \mathcal{N}^{\otimes})$. The following conditions are equivalent:*

- (i) *The restriction $F|_{\mathrm{QCoh}(X)^{\mathrm{cn}\otimes}}$ belongs to $\mathcal{C}$, and F is an r-left Kan extension of $F|_{\mathrm{QCoh}(X)^{\mathrm{cn}\otimes}}$.*
- (ii) *The restriction $F|_{\mathcal{M}}$ belongs to $\mathcal{D}$, and F is an r-right Kan extension of $F|_{\mathrm{QCoh}(X)^{\mathrm{cn}\otimes}}$.*

Moreover, every functor $F_0 \in \mathcal{C}$ admits an r-left Kan extension $F \in \mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}_+, \mathcal{N}^{\otimes})$, and every functor $F_1 \in \mathcal{D}$ admits an r-right Kan extension $F \in \mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}_+, \mathcal{N}^{\otimes})$.

Lemma 9.7.4.6. *Let $F \in \mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}^{\flat}_+, \mathcal{N}^{\otimes})$. The following conditions are equivalent:*

- (i') *The restriction $F|_{\mathrm{QCoh}(X)^{\flat\otimes}}$ belongs to $\mathcal{C}$, and F is an r-left Kan extension of $F|_{\mathrm{QCoh}(X)^{\flat\otimes}}$.*
- (ii') *The restriction $F|_{\mathcal{M}^{\flat}}$ belongs to $\mathcal{D}$, and F is an r-right Kan extension of $F|_{\mathrm{QCoh}(X)^{\flat\otimes}}$.*

Moreover, every functor $F_0 \in \mathcal{C}^{\flat}$ admits an r-left Kan extension $F \in \mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}^{\flat}_+, \mathcal{N}^{\otimes})$, and every functor $F_1 \in \mathcal{D}^{\flat}$ admits an r-right Kan extension $F \in \mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}^{\flat}_+, \mathcal{N}^{\otimes})$.

Lemma 9.7.4.7. *A functor $F \in \mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}, \mathcal{N}^{\otimes})$ belongs to $\mathcal{D}$ if and only if $F|_{\mathcal{M}^{\flat}}$ belongs to $\mathcal{D}^{\flat}$ and and F is an r-left Kan extension of $F|_{\mathcal{M}^{\flat}}$*

Lemma 9.7.4.8. *Every functor $F_0 \in \mathcal{D}^{\flat}$ admits an r-left Kan extension $F \in \mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}, \mathcal{N}^{\otimes})$.*

Proof of Theorem 9.7.2.2. Let $\mathcal{E}$ denote the full subcategory of $\mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}_+, \mathcal{N}^{\otimes})$ spanned by those functors which satisfy conditions (i) and (ii) of Lemma 9.7.4.5, and let $\mathcal{E}^{\flat}$ denote the full subcategory of $\mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}^{\flat}_+, \mathcal{N}^{\otimes})$ spanned by those functors which satisfy conditions (i') and (ii') of Lemma 9.7.4.6. We have a commutative diagram of ∞-categories and restriction maps

$$\begin{array}{ccccc} \mathcal{C} & \longleftarrow & \mathcal{E} & \longrightarrow & \mathcal{D} \\ \downarrow & & \downarrow & & \downarrow \\ \mathcal{C}^{\flat} & \longleftarrow & \mathcal{E}^{\flat} & \longrightarrow & \mathcal{D}^{\flat} . \end{array}$$

Using Lemmas 9.7.4.5 and 9.7.4.6 together with Proposition HTT.4.3.2.15 , we deduce that the horizontal maps in this diagram are equivalences. Consequently, to complete the proof, it will suffice to show that the restriction map $\mathcal{D} \to \mathcal{D}^{\flat}$ is an equivalence. This follows from Lemmas 9.7.4.7 and 9.7.4.8, together with Proposition HTT.4.3.2.15 . □

Proof of Lemma 9.7.4.8. Let $F_0 \in \mathcal{D}^{\flat}$; we wish to show that F admits an r-left Kan extension $F \in \mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}, \mathcal{N}^{\otimes})$. Let $M = ([m], \mathscr{F}_1, \ldots, \mathscr{F}_n)$ be an object of $\mathcal{M}$, and let $\mathcal{M}^{\flat}_{/M}$ denote the fiber product $\mathcal{M}^{\flat} \times_{\mathcal{M}} \mathcal{M}_{/M}$. According to Lemma HTT.4.3.2.13 , it will suffice to show that the lifting problem

$$\begin{array}{ccc} \mathcal{M}^{\flat}_{/M} & \xrightarrow{F_0|_{\mathcal{M}^{\flat}_{/M}}} & \mathcal{N}^{\otimes} \\ \downarrow & \nearrow & \downarrow \\ (\mathcal{M}^{\flat}_{/M})^{\triangleleft} & \longrightarrow & \mathcal{F}\mathrm{in}_* \end{array}$$

admits a solution, where the dotted arrow is an r-colimit diagram. Let $\mathcal{X}$ denote the fiber product

$$(\mathcal{M}^{\flat}_{/M}) \times_{\mathbf{\Delta}_{/[m]} \times \mathcal{F}\mathrm{in}_{*/\langle n \rangle}} \{(\mathrm{id}_{[m]}, \mathrm{id}_{\langle n \rangle})\}.$$

Note that the inclusion $\mathcal{X} \hookrightarrow \mathcal{M}^{\flat}_{/M}$ admits a left adjoint, and is therefore left cofinal. Let f denote the composite map $\mathcal{X} \to \mathcal{M}^{\flat}_{/M} \to \mathcal{M}^{\flat} \xrightarrow{F_0} \mathcal{N}^{\otimes}$. We are therefore reduced to proving that f can be extended to an r-colimit diagram $\mathcal{X}^{\triangleleft} \to \mathcal{N}^{\otimes}_{\langle n \rangle}$.

Unwinding the definitions, we can identify $\mathcal{X}$ with the product $\prod_{1 \leqslant i \leqslant n} \mathrm{QCoh}(U_m)^{\flat}_{/\mathscr{F}_i}$, where $\mathrm{QCoh}(U_m)^{\flat}_{/\mathscr{F}_i}$ denotes the full subcategory of $\mathrm{QCoh}(U_m)_{/\mathscr{F}_i}$ spanned by those maps $\mathscr{F}'_i \to \mathscr{F}_i$ where $\mathscr{F}'_i \in \mathrm{QCoh}(U_m)$ is flat. Let $\mathrm{Vect}(U_m)_{/\mathscr{F}_i}$ be the full subcategory of $\mathrm{QCoh}(U_m)_{/\mathscr{F}_i}$ spanned by those maps $\mathscr{F}'_i \to \mathscr{F}_i$ where $\mathscr{F}'_i$ is locally free of finite rank, so that we can identify the product $\prod_{1 \leqslant i \leqslant n} \mathrm{Vect}(U_m)_{/\mathscr{F}_i}$ with a full subcategory $\mathcal{X}_0 \subseteq \mathcal{X}$. We first claim that f is an r-left Kan extension of $f_0 = f|_{\mathcal{X}_0}$. To prove this, fix an object $M' \in \mathcal{X}$, corresponding to a collection of maps $\mathscr{F}'_i \to \mathscr{F}_i$ in $\mathrm{QCoh}(U_m)$ where each $\mathscr{F}'_i$ is flat, and let $\mathcal{Y} = \mathcal{X}_0 \times_{\mathcal{X}} \mathcal{X}_{/M'}$. Then f induces a map $g : \mathcal{Y}^{\triangleleft} \to \mathcal{N}^{\otimes}_{\langle n \rangle} \subseteq \mathcal{N}^{\otimes}$; we wish to prove that g is an r-colimit diagram. Note that $\mathcal{Y}$ can be identified with the product $\prod_{1 \leqslant i \leqslant n} \mathrm{Vect}(U_m)_{/\mathscr{F}'_i}$. In particular, the ∞-category $\mathcal{Y}$ admits finite coproducts, and is therefore sifted. Since the tensor product on $(\mathrm{Mod}^{\mathrm{cn}}_R)_{\leqslant d}$ preserves small colimits separately in each variable, every map of pointed finite sets $\langle a \rangle \to \langle b \rangle$ induces a functor $\mathcal{N}^{\otimes}_{\langle a \rangle} \to \mathcal{N}^{\otimes}_{\langle b \rangle}$ which preserves small sifted colimits. Using Proposition HTT.4.3.1.10 , we see that g is an r-colimit diagram in $\mathcal{N}^{\otimes}$ if and only if it is a colimit diagram in the ∞-category $\mathcal{N}^{\otimes}_{\langle n \rangle} \simeq (\mathrm{Mod}^{\mathrm{cn}}_R)^n_{\leqslant d}$. Since F_0 satisfies condition (a) of Notation 9.7.4.4, we are reduced to proving that for $1 \leqslant i \leqslant n$, the composite map

$$\mathcal{Y}^{\triangleleft} \to \mathrm{Vect}(U_m)^{\triangleleft}_{/\mathscr{F}'_i} \xrightarrow{g_i} (\mathrm{Mod}^{\mathrm{cn}}_R)_{\leqslant d}$$

is a colimit diagram, where g_i is induced by the map $F_0(m) : \mathrm{QCoh}(U_m) \to \mathrm{Mod}^{\flat}_R$ appearing in assertion (c'). Since $\mathrm{Vect}(U_m)_{/\mathscr{F}'_j}$ is weakly contractible for $j \neq i$, we are reduced to proving that each g_i is a colimit diagram. In fact, we claim that the functor $F_0(m)$ is a left Kan extension of its restriction to $\mathrm{Vect}(U_m)$. This follows from Lemma HTT.5.3.5.8 , since $\mathrm{QCoh}(U_m)^{\flat} \simeq \mathrm{Ind}(\mathrm{Vect}(U_m))$ by Proposition HA.7.2.2.15 and the functor $F_0(m)$ preserves small filtered colimits by virtue of our assumption that F_0 satisfies (c').

Since f is an r-left Kan extension of f_0, we are reduced to proving that f_0 can be extended to an r-colimit diagram $\mathcal{X}_0^{\triangleleft} \to \mathcal{N}^{\otimes}_{\langle n \rangle}$ (Proposition HTT.4.3.2.8). Using Proposition

HTT.4.3.1.10 , we are reduced to proving that f_0 admits a colimit in the ∞-category $\mathcal{N}^{\otimes}_{\langle n \rangle}$. This is clear, since $\mathcal{N}^{\otimes}_{\langle n \rangle} \simeq (\mathrm{Mod}_R^{\mathrm{cn}})^n_{\leqslant d}$ admits small colimits. □

Our proof of Lemma 9.7.4.8 immediately yields the following variant of Lemma 9.7.4.7:

Lemma 9.7.4.9. *Let $F \in \mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}, \mathcal{N}^{\otimes})$ be a functor such that $F|_{\mathcal{M}^\flat}$ belongs to $\mathcal{D}^\flat$. Then F is an r-left Kan extension of $F|_{\mathcal{M}^\flat}$ if and only if, for every object $([m], \mathscr{F}_1, \ldots, \mathscr{F}_n) \in \mathcal{M}$, the canonical map*

$$\varinjlim_{\mathscr{F}'_i \in \mathrm{Vect}(U_m)_{/\mathscr{F}_i}} F([m], \mathscr{F}'_1, \ldots, \mathscr{F}'_n) \to F([m], \mathscr{F}_1, \ldots, \mathscr{F}_n)$$

is an equivalence in $\mathcal{N}^{\otimes}_{\langle n \rangle} \simeq (\mathrm{Mod}_R^{\mathrm{cn}})^n_{\leqslant d}$.

Proof of Lemma 9.7.4.7. Let $F \in \mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}, \mathcal{N}^{\otimes})$ be a functor such that $F|_{\mathcal{M}^\flat}$ belongs to $\mathcal{D}^\flat$. We will show that $F \in \mathcal{D}$ if and only if F satisfies the criterion of Lemma 9.7.4.9. We first establish the "only if" direction. Assume that F satisfies conditions (a) through (d) of Notation 9.7.4.4, and let $([m], \mathscr{F}_1, \ldots, \mathscr{F}_n) \in \mathcal{M}$; we wish to show that the canonical map

$$\varinjlim_{\mathscr{F}'_i \in \mathrm{Vect}(U_m)_{/\mathscr{F}_i}} F([m], \mathscr{F}'_1, \ldots, \mathscr{F}'_n) \to F([m], \mathscr{F}_1, \ldots, \mathscr{F}_n)$$

is an equivalence in $(\mathrm{Mod}_R^{\mathrm{cn}})^n_{\leqslant d}$. Using (a) and the weak contractibility of the simplicial sets $\mathrm{Vect}(U_m)_{/\mathscr{F}_i}$, we may reduce to the case $n = 1$. In this case, we are reduced to proving that the functor $F(m) : \mathrm{QCoh}(U_m)^{\mathrm{cn}} \to (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d}$ appearing in (c) is a left Kan extension of its restriction to $\mathrm{Vect}(U_m)$. Since $\mathrm{Vect}(U_m)$ is a subcategory of compact projective generators for $\mathrm{QCoh}(U_m)^{\mathrm{cn}}$, it suffices to note that $F(m)$ preserves small sifted colimits (see Proposition HTT.5.5.8.15 and its proof), which follows from assumption (c).

We now establish the "if" direction. Let $F \in \mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}, \mathcal{N}^{\otimes})$ be such that $F_0 = F|_{\mathcal{M}^\flat}$ belongs to $\mathcal{D}^\flat$, and assume that F satisfies the criterion of Lemma 9.7.4.9. We wish to prove that $F \in \mathcal{D}$. For this, we must verify that F satisfies conditions (a) through (d) of Notation 9.7.4.4:

(a) Let $\alpha : \langle n \rangle \to \langle n' \rangle$ be an inert morphism in $\mathcal{F}\mathrm{in}_*$, let $m \geqslant 0$, and let $\overline{\alpha}$ be an inert morphism in $\{[m]\} \times_{\mathbf{\Delta}} \mathcal{M} \simeq \mathrm{QCoh}(U_m)^{\otimes}$ lying over α; we wish to show that $F(\overline{\alpha})$ is an inert morphism in $\mathcal{N}^{\otimes}$. Without loss of generality, $\overline{\alpha}$ is given by

$$([m], \mathscr{F}_1, \ldots, \mathscr{F}_n) \to ([m], \mathscr{F}_{\alpha^{-1}(1)}, \ldots, \mathscr{F}_{\alpha^{-1}(n')}).$$

Since F satisfies the criterion of $(2')$, we can identify $F(\alpha)$ with the canonical map

$$\varinjlim_{\mathscr{F}'_i \in \mathrm{Vect}(U_m)_{/\mathscr{F}_i}} F_0([m], \mathscr{F}'_1, \ldots, \mathscr{F}'_n) \to \varinjlim_{\mathscr{F}'_i \in \mathrm{Vect}(U_m)_{/\mathscr{F}_i}} F_0([m], \mathscr{F}'_{\alpha^{-1}(1)}, \ldots, \mathscr{F}'_{\alpha^{-1}(n')}),$$

which is an inert morphism by virtue of our assumption that F_0 satisfies condition (a').

(c) Let $m \geqslant 0$, and let $F(m) : \mathrm{QCoh}(U_m)^{\mathrm{cn}} \to (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d}$ be the map induced by F. We wish to show that $F(m)$ preserves small colimits. By assumption, $F(m)$ is a left Kan extension of its restriction to $\mathrm{Vect}(U_m)$. Using Proposition HTT.5.5.8.15 , we are reduced to proving that $F(m)|_{\mathrm{Vect}(U_m)}$ preserves finite coproducts, which follows from our assumption that F_0 satisfies (c').

(b) Let $\beta : [m] \to [m']$ be a morphism in $\mathbf{\Delta}$, and let $\psi : U_{m'} \to U_m$ be the induced map in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. We wish to show that, for every n-tuple of objects $\mathscr{F}_1, \ldots, \mathscr{F}_n \in \mathrm{QCoh}(U_{m'})^{\mathrm{cn}}$, the canonical map

$$F([m], \psi_* \mathscr{F}_1, \ldots, \psi_* \mathscr{F}_n) \to F([m'], \mathscr{F}_1, \ldots, \mathscr{F}_n)$$

is an equivalence of R-modules. Since F satisfies (a), we can reduce to the case where $n = 1$. That is, we must show that for $\mathscr{F} \in \mathrm{QCoh}(U'_m)^{\mathrm{cn}}$, the canonical map $\xi_{\mathscr{F}} : F([m], \psi_* \mathscr{F}) \to F([m'], \mathscr{F})$ is an equivalence of R-modules. Since F satisfies (b), the collection of those $\mathscr{F}$ for which $\xi_{\mathscr{F}}$ is an equivalence is closed under small colimits in $\mathrm{QCoh}(U_m)^{\mathrm{cn}}$. It will therefore suffice to show that $\xi_{\mathscr{F}}$ is an equivalence when $\mathscr{F} = \mathscr{O}_{U_m}$, which follows from our assumption that F_0 satisfies (b').

(d) By definition, we have $A^\bullet_F = A^\bullet_{F_0}$, so that F satisfies condition (d) if and only if F_0 satisfies condition (d').

□

Proofs of Lemmas 9.7.4.5 and 9.7.4.6. We will give the proof of Lemma 9.7.4.5. The proof of Lemma 9.7.4.6 is similar, requiring only minor changes of notation. We begin by observing that $\mathrm{QCoh}(X)^{\mathrm{cn}\otimes}$ is a colocalization of $\mathcal{M}_+$: that is, the inclusion $\mathrm{QCoh}(X)^{\mathrm{cn}\otimes} \hookrightarrow \mathcal{M}_+$ admits a left adjoint ν, given on objects by

$$([m], \mathscr{F}_1, \ldots, \mathscr{F}_n) \mapsto ([-1], \phi_{m*} \mathscr{F}_1, \ldots, \phi_{m*} \mathscr{F}_n),$$

where $\phi_m : U_m \to X$ denotes the projection map. Moreover, for every object $M \in \mathcal{M}_+$, the image in $\mathcal{F}\mathrm{in}_*$ of the canonical map $\nu(M) \to M$ is an equivalence in $\mathcal{F}\mathrm{in}_*$. We may therefore assume without loss of generality that ν is the identity on $\mathrm{QCoh}(X)^{\otimes}$, and that the image of each map $\nu(M) \to M$ is an identity morphism in $\mathcal{F}\mathrm{in}_*$. It follows that every functor $F_0 \in \mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathrm{QCoh}(X)^{\mathrm{cn}\otimes}, \mathcal{N}^{\otimes})$ admits an r-left Kan extension $F \in \mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}_+, \mathcal{N}^{\otimes})$, given by $F = F_0 \circ \nu$. To show that (i) implies (ii), we first show that if $F_0 \in \mathcal{C}$, then F satisfies conditions (a) through (d) of Notation 9.7.4.4:

(a) The assumption that $F_0 \in \mathcal{C}$ implies that F_0 can be identified with a symmetric monoidal functor from $\mathrm{QCoh}(X)^{\mathrm{cn}}$ to $(\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d}$. To prove that the restriction of F to $\{[m]\} \times_{\mathbf{\Delta}_+} \mathcal{M}_+$ is lax symmetric monoidal, it suffices to observe that the restriction of ν to $\{[m]\} \times_{\mathbf{\Delta}_+} \mathcal{M}_+$ is a lax symmetric monoidal functor (which is clear from the description of ν given above).

(*b*) Let α be a q-Cartesian morphism in $\mathcal{M}$. We wish to prove that $F(\alpha)$ is an equivalence in $\mathcal{N}^{\otimes}$. To prove this, it suffices to observe that $\mu(\alpha)$ is an equivalence in $\mathrm{QCoh}(X)^{\mathrm{cn},\otimes}$.

(*c*) Let $m \geqslant 0$ and let $F(m) : \mathrm{QCoh}(U_m)^{\mathrm{cn}} \to (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d}$ be the restriction of F. We wish to prove that $F(m)$ preserves small colimits. This follows from the observation that $F(m)$ is given by the composition of functors

$$\mathrm{QCoh}(U_m)^{\mathrm{cn}} \xrightarrow{\phi_{m*}} \mathrm{QCoh}(X)^{\mathrm{cn}} \xrightarrow{F_0} (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d},$$

each of which preserves small colimits.

(*d*) Let $\mathscr{A} = \phi_* \mathscr{O}_{U_0} \in \mathrm{CAlg}(\mathrm{QCoh}(X))$. Then $\phi_{m*} \mathscr{O}_{U_m} \simeq \mathscr{A}^{\otimes m+1}$ for each $m \geqslant 0$. Since F_0 is a symmetric monoidal functor, we obtain a canonical equivalence $A_F^m \simeq F_0(\mathscr{A})^{\otimes m+1}$. It follows immediately that $A_F^{\bullet}$ is 0-coskeletal. Moreover, since $\phi : U_0 \to X$ is faithfully flat, $\mathscr{A}$ is faithfully flat. Since F_0 restricts to an exact symmetric monoidal functor $\mathrm{QCoh}(X)^{\flat} \to \mathrm{Mod}_R^{\flat}$, it follows that A_F^0 is faithfully flat.

To complete the proof that (*i*) implies (*ii*), we show that if $F_0 \in \mathcal{C}$, then F is an r-right Kan extension of $F|_{\mathcal{M}}$. To prove this, it suffice to show that for each object $M = ([-1], \mathscr{F}_1, \ldots, \mathscr{F}_n) \in \mathrm{QCoh}(X)^{\mathrm{cn}\otimes} \subseteq \mathcal{M}_+$, the composite map

$$(\mathcal{M} \times_{\mathcal{M}_+} (\mathcal{M}_+)_{M/})^{\triangleleft} \to \mathcal{M}_+ \xrightarrow{F} \mathcal{N}^{\otimes}$$

is an r-limit diagram. Note that the construction $[m] \mapsto ([m], \phi_m^* \mathscr{F}_1, \ldots, \phi_m^* \mathscr{F}_n)$ determines a right cofinal map $\mathbf{\Delta} \to (\mathcal{M} \times_{\mathcal{M}_+} (\mathcal{M}_+)_{M/})$. We are therefore reduced to proving that $F(M)$ is an r-limit of the diagram $[m] \mapsto F([m], \phi_m^* \mathscr{F}_1, \ldots, \phi_m^* \mathscr{F}_n)$. Using Corollary HTT.4.3.1.15 , we see that this is equivalent to the requirement that $F(M)$ is a limit of the diagram $[m] \mapsto F([m], \phi_m^* \mathscr{F}_1, \ldots, \phi_m^* \mathscr{F}_n)$ in $\mathcal{N}^{\otimes}_{\langle n \rangle}$. Equivalently, we must show that for $1 \leqslant i \leqslant n$, the map F exhibits $F_0(\mathscr{F}_i)$ as a totalization of the simplicial object $[m] \mapsto F([m], \phi_m^* \mathscr{F}_i)$. Invoking the definition of F, we are reduced to proving that $F_0(\mathscr{F}_i)$ is a limit of the diagram $[m] \mapsto F_0(\phi_{m*}\phi_m^* \mathscr{F}_i)$ in the ∞-category $(\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d}$. In fact, we claim that $F_0(\mathscr{F}_i)$ is a limit of the diagram $[m] \mapsto F_0(\phi_{m*}\phi_m^* \mathscr{F}_i)$ in the larger ∞-category Mod_R. To prove this, let $\mathscr{A}^{\bullet}$ denote the cosimplicial object of $\mathrm{CAlg}(\mathrm{QCoh}(X)^{\mathrm{cn}})$ given by $\mathscr{A}^m = \phi_{m*} \mathscr{O}_{U_m}$, and let $R' = F_0(\mathscr{A}^0)$. Since $F_0 \in \mathcal{C}$, R' is a faithfully flat R-module, and we can identify $F_0(\mathscr{A}^m)$ with the $(m+1)$st tensor power of R' over R. We then have canonical equivalences

$$F_0(\phi_{m*}\phi_m^* \mathscr{F}_i) \simeq F_0(\mathscr{A}^m \otimes \mathscr{F}_i) \simeq R'^{\otimes(m+1)} \otimes_R F(\mathscr{F}_i).$$

The desired result now follows from Corollary D.6.3.4. This completes the proof that $(i) \Rightarrow (ii)$.

Now suppose that $G \in \mathcal{D} \subseteq \mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}, \mathcal{N}^{\otimes})$. For each $m \geqslant 0$, let $G_{[m]} : \mathrm{QCoh}(U_m)^{\otimes} \to \mathcal{N}^{\otimes}$ denote the restriction of G to $\{[m]\} \times_{\mathbf{\Delta}} \mathcal{M}$. Using the above arguments, we see that G admits an r-right Kan extension $\overline{G} \subseteq \mathrm{Fun}_{\mathcal{F}\mathrm{in}_*}(\mathcal{M}_+, \mathcal{N}^{\otimes})$, given on objects of $\mathrm{QCoh}(X)^{\mathrm{cn}\otimes} \subseteq \mathcal{M}_+$ by the formula

$$\overline{G}([-1], \mathscr{F}_1, \ldots, \mathscr{F}_n) = \varprojlim_{[m] \in \mathbf{\Delta}} G([m], \phi_m^* \mathscr{F}_1, \ldots, \phi_m^* \mathscr{F}_n).$$

To prove that (ii) implies (i), we first show that $\overline{G}$ is an r-left Kan extension of $\overline{G}|_{\mathrm{QCoh}(X)^{\mathrm{cn}\otimes}}$.

Note that each $G_{[m]}$ is a lax symmetric monoidal functor from $\mathrm{QCoh}(U_m)$ to $(\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d}$ carrying the unit object $\mathscr{O}_{U_m}$ to the commutative R-algebra $A_G^m \in \mathrm{CAlg}_R^{\mathrm{cn}}$, and therefore induces a lax symmetric monoidal functor $\widetilde{G}_{[m]} : \mathrm{QCoh}(U_m)^{\mathrm{cn}} \to (\mathrm{Mod}_{A_G^m}^{\mathrm{cn}})_{\leqslant d}$. We claim that $\widetilde{G}_{[m]}$ is actually a symmetric monoidal functor. It is clear that $\widetilde{G}_{[m]}$ preserves unit objects; it will therefore suffice to show that for every pair of objects $\mathscr{F}, \mathscr{F}' \in \mathrm{QCoh}(U_m)^{\mathrm{cn}}$, the canonical map $\widetilde{G}_{[m]}(\mathscr{F}) \otimes_{A_G^m} \widetilde{G}_{[m]}(\mathscr{F}') \to \widetilde{G}_{[m]}(\mathscr{F} \otimes \mathscr{F}')$ exhibits $\widetilde{G}_{[m]}(\mathscr{F} \otimes \mathscr{F}')$ as a d-truncation of $\widetilde{G}_{[m]}(\mathscr{F}) \otimes_R \widetilde{G}_{[m]}(\mathscr{F}')$. If we regard $\mathscr{F}$ as fixed, the collection of those objects $\mathscr{F}' \in \mathrm{QCoh}(U_m)^{\mathrm{cn}}$ which satisfy this condition is closed under small colimits. Since U_m is corepresented by a connective $\mathbb{E}_\infty$-ring, the ∞-category $\mathrm{QCoh}(U_m)^{\mathrm{cn}}$ is generated under small colimits by the unit object $\mathscr{O}_{U_m}$. We may therefore reduce to the case where $\mathscr{F}' = \mathscr{O}_{U_m}$. Similarly, we can reduce to the case where $\mathscr{F} = \mathscr{O}_{U_m}$, in which case the result is obvious.

Fix an object $M = ([m], \mathscr{F}_1, \ldots, \mathscr{F}_n) \in \mathcal{M}$, so that $\nu(M) = ([-1], \phi_{m*} \mathscr{F}_1, \ldots, \phi_{m*} \mathscr{F}_n)$. We wish to show that the map $\gamma : \overline{G}(\nu(M)) \to \overline{G}(M) = G(M)$ is an equivalence. Unwinding the definitions, we see that the left hand side is given by

$$\overline{G}(\nu(M)) \simeq \varprojlim_{[m'] \in \mathbf{\Delta}} G([m'], \phi_{m'}^* \phi_{m*} \mathscr{F}_1, \ldots, \phi_{m'}^* \phi_{m*} \mathscr{F}_n).$$

Using condition (a) of Notation 9.7.4.4, we can reduce to the case where $n = 1$. Set $\mathscr{F} = \mathscr{F}_1$. For each $m' \geqslant 0$, let $\psi_{m'}$ denote the projection map from $U_m \times_X U_{m'} \simeq U_{m+m'+1}$ onto U_m. Using condition (b), we can rewrite $\overline{G}(\nu(M))$ as the limit

$$\begin{aligned} \varprojlim_{[m'] \in \mathbf{\Delta}} G([m], \psi_{m'*} \psi_{m'}^* \mathscr{F}) &\simeq \varprojlim_{[m'] \in \mathbf{\Delta}} G([m], \mathscr{F} \otimes \psi_{m'*} \psi_{m'}^* \mathscr{O}_{U_m}) \\ &\simeq \varprojlim_{[m'] \in \mathbf{\Delta}} G([m], \mathscr{F} \otimes (\phi_m^* \mathscr{A})^{\otimes m'+1}) \\ &\simeq \varprojlim_{[m'] \in \mathbf{\Delta}} (G([m], \mathscr{F}) \otimes_{A_G^m} B^{\otimes m+1} \end{aligned}$$

where $B = G([m], \phi_m^* \mathscr{A})$, and the limit (and tensor power) are computed in the ∞-category $(\mathrm{Mod}_{A_G^m}^{\mathrm{cn}})_{\leqslant d}$. Since ϕ is faithfully flat, $\phi_m^* \mathscr{A}$ is a faithfully flat commutative algebra object of $\mathrm{QCoh}(U_m)$. It follows that the cofiber of the unit map $\mathscr{O}_{U_m} \to \phi_m^* \mathscr{A}$ is flat (Lemma D.4.4.3), and can therefore be written as a filtered colimit of finite direct sums of copies of $\mathscr{O}_{U_m}$ (Theorem HA.7.2.2.15). Since $G_{[m]}$ preserves filtered colimits and finite direct sums, we conclude that B is a flat A_G^m-module. We now observe that γ is a left homotopy inverse of the canonical map $\gamma' : G([m], \mathscr{F}) \to \varprojlim_{[m'] \in \mathbf{\Delta}} G([m], \mathscr{F}) \otimes_{A_G^m} B^{\otimes m+1}$. Corollary D.6.3.4 impies that γ' is an equivalence, so that γ is also an equivalence.

Let $g : \mathrm{QCoh}(X)^{\mathrm{cn}\otimes} \to \mathcal{N}^{\otimes}$ be the restriction of $\overline{G}$ to $\mathrm{QCoh}(X)^{\mathrm{cn}\otimes}$. We will complete the proof by showing that $g \in \mathcal{C}$. The description of g given above shows that it is a lax symmetric monoidal functor. Let g' denote the composition $\mathrm{QCoh}(X)^{\mathrm{cn}\otimes} \xrightarrow{\phi_0^*} \mathrm{QCoh}(U_0)^{\mathrm{cn}\otimes} \xrightarrow{G_{[0]}} \mathcal{N}^{\otimes}$, so that g' is also a lax symmetric monoidal functor, with $g'(\mathscr{O}_X) = A_G^0$. We have an evident (lax symmetric monoidal) natural transformation $g \to g'$. In particular, for each $\mathscr{F} \in \mathrm{QCoh}(X)^{\mathrm{cn}}$, we obtain a canonical map

$$\theta_{\mathscr{F}} : g(\mathscr{F}) \otimes_R A_G^0 \to g'(\mathscr{F}) \otimes_R g'(\mathscr{O}_X) \to g'(\mathscr{F} \times \mathscr{O}_X) \simeq g'(\mathscr{F}).$$

We will prove:

$(*)$ For each $\mathscr{F} \in \mathrm{QCoh}(X)^{\mathrm{cn}}$, the map $\theta_{\mathscr{F}}$ is an equivalence.

Assuming $(*)$ for the moment, we show that the functor g belongs to $\mathcal{C}$. First, we claim that g is actually a symmetric monoidal functor: that is, that the canonical map

$$g(\mathscr{F}_1) \otimes_R \cdots \otimes_R g(\mathscr{F}_n) \to g(\mathscr{F}_1 \otimes \cdots \otimes \mathscr{F}_n)$$

exhibits $g(\mathscr{F}_1 \otimes \cdots \otimes \mathscr{F}_n)$ as a d-truncation of $g(\mathscr{F}_1) \otimes_R \cdots \otimes_R g(\mathscr{F}_n)$ for every sequence of objects $\mathscr{F}_1, \ldots, \mathscr{F}_n \in \mathrm{QCoh}(X)^{\mathrm{cn}}$. Since A_G^0 is faithfully flat over R, it will suffice to prove that the induced map

$$g(\mathscr{F}_1) \otimes_R \cdots \otimes_R g(\mathscr{F}_n) \otimes_R A_G^0 \to g(\mathscr{F}_1 \otimes \cdots \otimes \mathscr{F}_n) \otimes_R A_G^0$$

exhibits $g(\mathscr{F}_1 \otimes \cdots \otimes \mathscr{F}_n) \otimes_R A_G^0$ as a d-truncation of $g(\mathscr{F}_1 \otimes_R \cdots \otimes_R g(\mathscr{F}_n) \otimes_R A_G^0$. Using $(*)$, we are reduced to proving that the map

$$g'(\mathscr{F}_1) \otimes_{A_G^0} \cdots \otimes g'(\mathscr{F}_n) \to g'(\mathscr{F}_1 \otimes \cdots \otimes \mathscr{F}_n)$$

exhibits $g'(\mathscr{F}_1 \otimes \cdots \otimes \mathscr{F}_n)$ as a d-truncation of $g'(\mathscr{F}_1) \otimes_{A_G^0} \cdots \otimes_{A_G^0} g'(\mathscr{F}_n)$. In other words, we are reduced to proving that g' induces a symmetric monoidal functor from $\mathrm{QCoh}(X)^{\mathrm{cn}}$ to $(\mathrm{Mod}_{A_G^0}^{\mathrm{cn}})_{\leqslant d}$ is a symmetric monoidal functor. This is clear, since the functors ϕ_0^* and $\widetilde{G}_{[0]}$ are symmetric monoidal.

We next claim that the functor $\mathrm{QCoh}(X)^{\mathrm{cn}} \to (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d}$ determined by g preserves small colimits. Since A_G^0 is faithfully flat over R, it suffices to show that the functor

$\mathscr{F} \mapsto g(\mathscr{F}) \otimes_R A_G^0$ preserves small colimits. Using $(*)$, we are reduced to proving that the functor $\mathscr{F} \mapsto g'(\mathscr{F})$ preserves small colimits. This is clear, since the pullback functor ϕ_0^* preserves small colimits, and $G_{[0]} : \mathrm{QCoh}(U_0)^{\mathrm{cn}} \to (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d}$ preserves small colimits by virtue of our assumption that G satisfies condition (c) of Notation 9.7.4.4.

Finally, we claim that the functor g carries flat objects of $\mathrm{QCoh}(X)^{\mathrm{cn}}$ to flat R-modules (the exactness of the restriction $g|_{\mathrm{QCoh}(X)^{\flat}}$ is then automatic, by virtue of Remark 9.7.1.2). Since A_G^0 is faithfully flat over R, it will suffice to show that $g(\mathscr{F}) \otimes_R A_G^0$ is flat for each $\mathscr{F} \in \mathrm{QCoh}(X)^{\flat}$ (Proposition 2.8.4.2). Since ϕ_0^* carries $\mathrm{QCoh}(X)^{\flat}$ into $\mathrm{QCoh}(U_0)^{\flat}$, it will suffice to show that the functor $G_{[0]}$ carries $\mathrm{QCoh}(U_0)^{\flat}$ into $\mathrm{Mod}_R^{\flat}$. Condition (c) implies that $G_{[0]} : \mathrm{QCoh}(U_0)^{\mathrm{cn}} \to (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d}$ preserves finite direct sums and filtered colimits. Since $\mathrm{QCoh}(U_0)^{\flat}$ is generated by $\mathscr{O}_{U_0}$ under finite direct sums and filtered colimits (Theorem HA.7.2.2.15), we are reduced to proving that $G_{[0]}(\mathscr{O}_{U_0}) = A_G^0$ is a flat R-module, which follows from our assumption that G satisfies condition (d).

It now remains only to prove $(*)$. Let us regard $A_G^\bullet$ as defining a map $\mathbf{\Delta} \to \mathrm{CAlg}(\mathcal{N})$, let $\mathcal{Z}$ denote the fiber product $\mathbf{\Delta} \times_{\mathrm{CAlg}(\mathcal{N})} \mathrm{Mod}(\mathcal{N})$. Let $\Gamma = \mathrm{Fun}_{\mathbf{\Delta}}(\mathbf{\Delta}, \mathcal{Z})$ denote the ∞-category of sections of the projection map $v : \mathcal{Z} \to \mathbf{\Delta}$. We have an evident functor $\iota : (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d} \to \Gamma$, which carries an object $M \in (\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d}$ to the section of v given by $[m] \mapsto M \otimes_R A_G^m$. It follows from Corollary D.6.3.4 that the functor ι is fully faithful, and that its essential image is the full subcategory $\Gamma_0 \subseteq \Gamma$ spanned by those sections which carry each morphism in $\mathbf{\Delta}$ to a v-coCartesian morphism in $\mathcal{Z}$. Note that the functor ι admits a right adjoint ξ, which carries a section $M^\bullet : \mathbf{\Delta} \to \mathcal{Z}$ to the limit of the underlying diagram in $(\mathrm{Mod}_R^{\mathrm{cn}})_{\leqslant d}$.

Every object $\mathscr{F} \in \mathrm{QCoh}(X)^{\mathrm{cn}}$ determines an object $M^\bullet \in \Gamma$, given by $M^m = \widetilde{G}_{[m]}(\phi_m^* \mathscr{F})$. Note that we have canonical equivalences $g(\mathscr{F}) \simeq \xi(M^\bullet)$ and $g'(\mathscr{F}) \simeq M^0$, which we can use to identify $\theta_{\mathscr{F}} : g(\mathscr{F}) \otimes_R A_G^0 \to g'(\mathscr{F})$ with the map induced by the counit $\iota(\xi(M^\bullet)) \to M^\bullet$. We will prove $(*)$ by showing that this counit map is an equivalence: that is, that $M^\bullet$ belongs to the full subcategory $\Gamma_0 \subseteq \Gamma$. For this, we must show that for every map $[m] \to [n]$ in $\mathbf{\Delta}$, the induced map $G_{[m]}(\phi_m^* \mathscr{F}) \otimes_{A_G^m} A_G^n \to G_{[n]}(\phi_n^* \mathscr{F})$ is an equivalence. This is a consequence of the following more general claim: for every object $\mathscr{F}' \in \mathrm{QCoh}(U_m)^{\mathrm{cn}})$, the canonical map $G_{[m]}(\mathscr{F}') \otimes_{A_G^m} A_G^n \to G_{[n]}(\gamma^* \mathscr{F}')$ is an equivalence, where $\gamma : U_n \to U_m$ denotes the projection map. Since the functors $G_{[m]}$ and $G_{[n]}$ preserve small colimits, the collection of those objects $\mathscr{F}' \in \mathrm{QCoh}(U_m)$ which satisfy this condition is closed under small colimits in $\mathrm{QCoh}(U_m)^{\mathrm{cn}}$. We may therefore reduce to the case where $\mathscr{F}' = \mathscr{O}_{U_m}$, in which case the result is obvious. $\square$

Chapter 10

Quasi-Coherent Stacks

Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ be a spectral Deligne-Mumford stack. According to Proposition 6.2.4.1, there are (at least) two different ways to define the notion of a quasi-coherent sheaf on X:

(*a*) A quasi-coherent sheaf $\mathscr{F}$ on X can be viewed as a spectrum object of $\mathcal{X}$ which is equipped with an action of the structure sheaf $\mathscr{O}_{\mathsf{X}}$ and satisfies certain local conditions.

(*b*) A quasi-coherent sheaf $\mathscr{F}$ on X can be viewed as a rule which assigns to each R-point $\eta : \operatorname{Spét} R \to \mathsf{X}$ an R-module $\mathscr{F}(\eta) \in \operatorname{Mod}_R$, depending functorially on the pair (R, η).

The equivalence of these two definitions relies on the fact that the construction $R \mapsto \operatorname{Mod}_R$ is a sheaf with respect to the étale topology. In Appendix D, we prove a categorified version of this result. For every connective $\mathbb{E}_\infty$-ring R, let $\operatorname{LinCat}_R^{\mathrm{PSt}}$ denote the ∞-category of R-linear prestable ∞-categories (Definition D.1.4.1). According to Theorem D.4.1.2, the construction $R \mapsto \operatorname{LinCat}_R^{\mathrm{PSt}}$ is also a sheaf for the étale topology. In §10.1, we will apply Theorem D.4.1.2 to develop a "global" version of the theory of prestable R-linear ∞-categories. To every spectral Deligne-Mumford stack X, we associate an ∞-category $\operatorname{QStk}^{\mathrm{PSt}}(\mathsf{X})$, which we call the ∞-category of (prestable) *quasi-coherent stacks* on X (Definition 10.1.2.1). The definition is suggested by (*b*): in essence, a quasi-coherent stack on X is a rule which assigns to each R-point $\eta : \operatorname{Spét} R \to \mathsf{X}$ an R-linear ∞-category $\mathcal{C}_\eta \in \operatorname{LinCat}_R$, depending functorially on the pair (R, η).

Let X be a spectral Deligne-Mumford stack and let $R = \Gamma(\mathsf{X}; \mathscr{O}_{\mathsf{X}})$ denote the $\mathbb{E}_\infty$-ring of global functions on X. Then the construction $\mathscr{F} \mapsto \Gamma(\mathsf{X}; \mathscr{F})$ determines a functor $\Gamma : \operatorname{QCoh}(\mathsf{X}) \to \operatorname{Mod}_R$. If X is affine, then this functor is an equivalence of ∞-categories. In §10.2, we will study the analogous construction for quasi-coherent stacks. To every prestable quasi-coherent stack $\mathcal{C}$ on X, we will associate a Grothendieck prestable ∞-category $\operatorname{QCoh}(\mathsf{X}; \mathcal{C})$, whose objects we refer to as *quasi-coherent sheaves on* X *with values in* $\mathcal{C}$ (Construction 10.1.7.1). The ∞-category $\operatorname{QCoh}(\mathsf{X}; \mathcal{C})$ is naturally tensored over the

∞-category $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ of connective quasi-coherent sheaves on X, and the construction $\mathcal{C} \mapsto \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ can be viewed as a "global sections functor"

$$\mathrm{QCoh}(\mathsf{X}; \bullet) : \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}) \to \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_{\infty}).$$

In the special case where $\mathsf{X} = \mathrm{Sp\acute{e}t}\, R$ is affine, it follows easily from the definitions that this functor is an equivalence of ∞-categories: both the domain and codomain can be identified with the ∞-category $\mathrm{LinCat}_R^{\mathrm{PSt}}$ of prestable R-linear ∞-categories studied in Appendix D. The main result of §10.2 asserts that this is a much more general phenomenon: the functor $\mathrm{QCoh}(\mathsf{X}; \bullet)$ is an equivalence of ∞-categories whenever X is a quasi-compact, quasi-separated spectral algebraic space (Theorem 10.2.0.2).

To develop the theory of quasi-coherent stacks on X, the assumption that X is a spectral Deligne-Mumford stack is not essential: the same definition makes sense for an arbitrary functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. For example, we could take X to be the classifying stack BG, where G is a flat group scheme over a commutative ring A (see Example 9.1.1.7). In this case, we would like to say that a prestable quasi-coherent stack on X can be viewed as a prestable A-linear ∞-category equipped with an "action" of the group scheme G. However, we encounter a technical obstacle: Theorem D.4.1.2 guarantees that the construction $R \mapsto \mathrm{LinCat}_R^{\mathrm{PSt}}$ satisfies descent for the étale topology, but we do not know if the analogous statement holds for the flat topology. To address this difficulty, it is convenient to restrict our attention to prestable quasi-coherent stacks $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(X)$ which are *complete* in the sense that the prestable R-linear ∞-category $\mathcal{C}_\eta$ is complete for each point $\eta \in X(R)$. The collection of complete prestable quasi-coherent stacks on X forms a full subcategory $\mathrm{QStk}^{\mathrm{comp}}(X) \subseteq \mathrm{QStk}^{\mathrm{PSt}}(X)$ which we will study in §10.4. Our main result is another local-to-global principle: if X is a geometric stack, then the global sections functor $\mathrm{QCoh}(X; \bullet) : \mathrm{QStk}^{\mathrm{comp}}(X) \to \mathrm{Mod}_{\mathrm{QCoh}(X)^{\mathrm{cn}}}(\mathsf{Groth}_{\infty})$ is a fully faithful embedding, whose essential image admits admits a simple description (Theorem 10.4.2.3).

The definition of a complete quasi-coherent stack illustrates a general paradigm: given any property P of Grothendieck prestable ∞-categories, we say that a prestable quasi-coherent stack $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(X)$ *has the property* P if, for every connective $\mathbb{E}_\infty$-ring R and every point $\eta \in X(R)$, the ∞-category $\mathcal{C}_\eta$ has the property P. In §10.3 and §10.5, we will illustrate this paradigm in several examples, choosing P from among the properties introduced in Appendix C. Our principal results again take the form of local-to-global principles, asserting that under certain conditions a quasi-coherent stack $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(X)$ has the property P if and only if the ∞-category $\mathrm{QCoh}(X; \mathcal{C})$ has the property P. For example, if X is a quasi-compact, quasi-separated spectral algebraic space, we show that $\mathcal{C}$ is compactly generated if and only if $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is compactly generated (see Theorem 10.3.2.1).

Remark 10.0.0.1. Compact generation is a rather mild finiteness condition in the setting of prestable ∞-categories. In Chapter 11, we will study more sophisticated finiteness conditions on quasi-coherent stacks, whose local-to-global principles are more intimately tied to the algebro-geometric properties of X.

Throughout this chapter, we will concentrate primarily on the study of *prestable* quasi-coherent stacks on a functor X, which associate to each point $\eta \in X(R)$ a prestable R-linear ∞-category. However, there is an entirely parallel story in a more familiar setting: we define an *abelian quasi-coherent stack* on X to be a rule which assigns to each point $\eta \in X(R)$ an R-linear Grothendieck abelian category $\mathcal{C}_\eta$, depending functorially on the pair (R, η). The collection of abelian quasi-coherent stacks can be organized into a 2-category which we denote by $\mathrm{QStk}^{\mathrm{Ab}}(X)$ (see Definition 10.1.2.1). In §10.6, we will establish a local-to-global principle for abelian quasi-coherent stacks (Theorem 10.6.2.1) and study the relationship between the abelian and prestable theories (the abelian theory is in some sense subsumed by the prestable theory: see Theorem 10.6.6.1).

Remark 10.0.0.2. The study of abelian quasi-coherent stacks really belongs to classical algebraic geometry, rather than spectral algebraic geometry: the notion of R-linear abelian category depends only on the commutative ring $\pi_0 R$ (see Example D.1.3.6), and similarly the notion of abelian quasi-coherent stack on a functor X depends only the restriction of X to the subcategory $\mathrm{CAlg}^{\heartsuit} \subseteq \mathrm{CAlg}^{\mathrm{cn}}$ (see Remark 10.1.2.6).

Contents

10.1 Sheaves of ∞-Categories

Let R be a connective $\mathbb{E}_\infty$-ring. We define an *additive R-linear ∞-category* to be a presentable ∞-category $\mathcal{C}$ which is tensored over $\mathrm{Mod}_R^{\mathrm{cn}}$ and for which the action $\otimes : \mathrm{Mod}_R^{\mathrm{cn}} \times \mathcal{C} \to \mathcal{C}$ preserves small colimits separately in each variable (see Definition D.1.2.1). The collection of all additive R-linear ∞-categories can be organized into an ∞-category $\mathrm{LinCat}_R^{\mathrm{Add}} = \mathrm{Mod}_{\mathrm{Mod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$. In Appendix D, we introduced full subcategories

$$\mathrm{LinCat}_R^{\mathrm{St}}, \mathrm{LinCat}_R^{\mathrm{PSt}}, \mathrm{LinCat}_R^{\mathrm{Ab}} \subseteq \mathrm{LinCat}_R^{\mathrm{Add}},$$

whose objects are the stable R-linear ∞-categories, prestable R-linear ∞-categories, and abelian R-linear ∞-categories, respectively (Definition D.1.4.1). Our goal in this section is to study global versions of these constructions, where the $\mathbb{E}_\infty$-ring R is replaced by an arbitrary functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. We will primarily be interested in the cases where X is (representable by) a spectral Deligne-Mumford stack, or where X is quasi-geometric (in the sense of Definition 9.1.0.1).

10.1.1 Quasi-Coherent Stacks on a Functor

Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor. The ∞-category $\mathrm{QCoh}(X)$ of quasi-coherent sheaves on X can be described informally as the inverse limit $\varprojlim_{\eta \in X(R)} \mathrm{Mod}_R$, taken over all R-valued points η of X (see Definition 6.2.2.1). We now consider a variant of this definition, where we replace R-modules by additive R-linear ∞-categories.

Construction 10.1.1.1. Let $\mathrm{LinCat}^{\mathrm{Add}}$ denote the ∞-category $\mathrm{CAlg}^{\mathrm{cn}} \times_{\mathrm{Alg}(\mathcal{P}\mathrm{r}^{\mathrm{L}})} \mathrm{Mod}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ whose objects are pairs $(R, \mathcal{C})$, where R is a connective $\mathbb{E}_\infty$-ring and $\mathcal{C}$ is an additive R-linear ∞-category (Definition D.1.2.1). We let

$$\mathrm{QStk}^{\mathrm{Add}} : \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$$

denote the functor obtained by applying Construction 6.2.1.7 to the projection map $q : \mathrm{LinCat}^{\mathrm{Add}} \to \mathrm{CAlg}^{\mathrm{cn}}$. Given a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, we will refer to the $\mathrm{QStk}^{\mathrm{Add}}(X)$ as the *∞-category of additive quasi-coherent stacks on X*.

Remark 10.1.1.2. According to Lemma 6.2.1.13, the functor $\mathrm{QStk}^{\mathrm{Add}} : \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ is characterized (up to equivalence) by the following properties:

(*i*) The composition of $\mathrm{QStk}^{\mathrm{Add}}$ with the Yoneda embedding $\mathrm{CAlg}^{\mathrm{cn}} \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})^{\mathrm{op}}$ classifies the coCartesian fibration $\mathrm{LinCat}^{\mathrm{Add}} \to \mathrm{CAlg}^{\mathrm{cn}}$. More informally, for every connective $\mathbb{E}_\infty$-ring R, we have a canonical equivalence $\mathrm{QStk}^{\mathrm{Add}}(\operatorname{Spec} R) \simeq \mathrm{LinCat}_R^{\mathrm{Add}}$.

(*ii*) The functor $\mathrm{QStk}^{\mathrm{Add}}$ preserves limits. Consequently, for every functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, the canonical map

$$\mathrm{QStk}^{\mathrm{Add}}(X) \to \varprojlim_{\eta \in X(R)} \mathrm{QStk}^{\mathrm{Add}}(\operatorname{Spec} R) \simeq \varprojlim_{\eta \in X(R)} \mathrm{LinCat}_R^{\mathrm{Add}}$$

is an equivalence of ∞-categories.

Remark 10.1.1.3. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor which classifies a left fibration $p : \mathrm{CAlg}_X^{\mathrm{cn}} \to \mathrm{CAlg}^{\mathrm{cn}}$ (so that an object of $\mathrm{CAlg}_X^{\mathrm{cn}}$ can be identified with a pair (R, η), where R is a connective $\mathbb{E}_\infty$-ring and $\eta \in X(R)$ is an R-valued point of X). Then the ∞-category $\mathrm{QStk}^{\mathrm{Add}}(X)$ of additive quasi-coherent stacks on X can be identified with the full subcategory of $\mathrm{Fun}_{\mathrm{CAlg}^{\mathrm{cn}}}(\mathrm{CAlg}_X^{\mathrm{cn}}, \mathrm{LinCat}^{\mathrm{Add}})$ spanned by those commutative diagrams

$$\begin{array}{ccc} \mathrm{CAlg}_X^{\mathrm{cn}} & \longrightarrow & \mathrm{LinCat}^{\mathrm{Add}} \\ & \searrow \quad \swarrow_q & \\ & \mathrm{CAlg}^{\mathrm{cn}} & \end{array}$$

where the horizontal map carries p-coCartesian morphisms of $\mathrm{CAlg}_X^{\mathrm{cn}}$ to q-coCartesian morphisms of $\mathrm{LinCat}^{\mathrm{Add}}$. More informally, we can think of an object $\mathcal{C} \in \mathrm{QStk}^{\mathrm{Add}}(X)$ as a rule which assigns to each point $\eta \in X(A)$ an additive A-linear ∞-category $\mathcal{C}_\eta$ which is functorial in the following sense: if $f : A \to B$ is a map of connective $\mathbb{E}_\infty$-rings and η has image $f_!(\eta) \in X(B)$, then there is a canonical equivalence

$$\mathcal{C}_{f_!(\eta)} \simeq B \otimes_A \mathcal{C}_\eta = \mathrm{LMod}_B(\mathcal{C}_\eta)$$

of additive B-linear ∞-categories.

10.1.2 Stable, Prestable, and Abelian Quasi-Coherent Stacks

The theory of additive R-linear ∞-categories is not particularly well-behaved from an algebro-geometric point of view: for example, the construction $R \mapsto \mathrm{LinCat}_R^{\mathrm{Add}}$ does not even satisfy descent with respect to the Zariski topology. Consequently, the functor $X \mapsto \mathrm{QStk}^{\mathrm{Add}}(X)$ of Construction 10.1.1.1 has poor formal properties. However, we can remedy this by restricting our attention to additive quasi-coherent stacks which satisfy some further conditions.

Definition 10.1.2.1. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor and let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{Add}}(X)$ be an additive quasi-coherent stack. For each point $\eta \in X(R)$, let $\mathcal{C}_\eta \in \mathrm{LinCat}_R^{\mathrm{Add}}$ be defined as in Remark 10.1.1.3. Then:

- We will say that $\mathcal{C}$ is a *stable quasi-coherent stack* if, for each connective $\mathbb{E}_\infty$-ring R and each point $\eta \in X(R)$, the ∞-category $\mathcal{C}_\eta$ is stable. We let $\mathrm{QStk}^{\mathrm{St}}(X)$ denote the full subcategory of $\mathrm{QStk}^{\mathrm{Add}}(X)$ spanned by the stable quasi-coherent stacks.

- We will say that $\mathcal{C}$ is a *prestable quasi-coherent stack* if, for each connective $\mathbb{E}_\infty$-ring R and each point $\eta \in X(R)$, the ∞-category $\mathcal{C}_\eta$ is a Grothendieck prestable ∞-category. Let $\mathrm{QStk}^{\mathrm{PSt}}(X)$ denote the full subcategory of $\mathrm{QStk}^{\mathrm{Add}}(X)$ spanned by the prestable quasi-coherent stacks.

- We will say that $\mathcal{C}$ is an *abelian quasi-coherent stack* if, for each connective $\mathbb{E}_\infty$-ring R and each point $\eta \in X(R)$, the ∞-category $\mathcal{C}_\eta$ is a Grothendieck abelian category. Let $\mathrm{QStk}^{\mathrm{Ab}}(X)$ denote the full subcategory of $\mathrm{QStk}^{\mathrm{Add}}(X)$ spanned by the abelian quasi-coherent stacks.

Remark 10.1.2.2. Every presentable stable ∞-category is a Grothendieck prestable ∞-category. Consequently, for any functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, we have inclusions $\mathrm{QStk}^{\mathrm{St}}(X) \subseteq \mathrm{QStk}^{\mathrm{PSt}}(X) \subseteq \mathrm{QStk}^{\mathrm{Add}}(X)$

Notation 10.1.2.3 (Pullback of Quasi-Coherent Stacks)**.** If $f : X \to Y$ is a morphism in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$, we let f^* denote the induced functor $\mathrm{QStk}^{\mathrm{Add}}(Y) \to \mathrm{QStk}^{\mathrm{Add}}(X)$, given concretely by the formula $(f^* \mathcal{C})_\eta = \mathcal{C}_{f(\eta)}$ for each point $\eta \in X(R)$. Note that f^* restricts to functors

$$\mathrm{QStk}^{\mathrm{St}}(Y) \to \mathrm{QStk}^{\mathrm{St}}(X) \qquad \mathrm{QStk}^{\mathrm{PSt}}(Y) \to \mathrm{QStk}^{\mathrm{PSt}}(X) \qquad \mathrm{QStk}^{\mathrm{Ab}}(Y) \to \mathrm{QStk}^{\mathrm{Ab}}(X),$$

which we will also denote by f^*.

Remark 10.1.2.4. The constructions $X \mapsto \mathrm{QStk}^{\mathrm{St}}(X), \mathrm{QStk}^{\mathrm{PSt}}(X), \mathrm{QStk}^{\mathrm{Ab}}(X)$ determine functors

$$\mathrm{QStk}^{\mathrm{St}}, \mathrm{QStk}^{\mathrm{PSt}}, \mathrm{QStk}^{\mathrm{Ab}} : \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty.$$

These functors are right Kan extensions of the constructions

$$R \mapsto \mathrm{LinCat}_R^{\mathrm{St}} \qquad R \mapsto \mathrm{LinCat}_R^{\mathrm{PSt}} \qquad R \mapsto \mathrm{LinCat}_R^{\mathrm{Ab}}$$

along the Yoneda embedding $j : \mathrm{CAlg}^{\mathrm{cn}} \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})^{\mathrm{op}}$.

Example 10.1.2.5 (The Affine Case)**.** Let R be connective $\mathbb{E}_\infty$-ring. Then we have canonical equivalences

$$\mathrm{QStk}^{\mathrm{Add}}(\operatorname{Spec} R) \simeq \mathrm{LinCat}_R^{\mathrm{Add}} \qquad \mathrm{QStk}^{\mathrm{St}}(\operatorname{Spec} R) \simeq \mathrm{LinCat}_R^{\mathrm{St}}$$

$$\mathrm{QStk}^{\mathrm{PSt}}(\operatorname{Spec} R) \simeq \mathrm{LinCat}_R^{\mathrm{PSt}} \qquad \mathrm{QStk}^{\mathrm{Ab}}(\operatorname{Spec} R) \simeq \mathrm{LinCat}_R^{\mathrm{Ab}}.$$

We will generally abuse terminology by using these equivalences to identify (additive, stable, prestable, abelian) quasi-coherent stacks on $\operatorname{Spec} R$ with the corresponding (additive, stable, prestable, abelian) R-linear ∞-categories.

Remark 10.1.2.6. For every connective $\mathbb{E}_\infty$-ring R, extension of scalars induces an equivalence of ∞-categories $\mathrm{LinCat}_R^{\mathrm{Ab}} \simeq \mathrm{LinCat}_{\pi_0 R}^{\mathrm{Ab}}$ (see Remark D.1.4.6). In other words, the functor $R \mapsto \mathrm{LinCat}_R^{\mathrm{Ab}}$ is a right Kan extension of its restriction to discrete $\mathbb{E}_\infty$-rings. It follows that for any functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, the ∞-category $\mathrm{QStk}^{\mathrm{Ab}}(X)$ of abelian quasi-coherent stacks on X depends only on the restriction of X to the full subcategory of $\mathrm{CAlg}^{\mathrm{cn}}$ spanned by the discrete $\mathbb{E}_\infty$-rings. In particular, if $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$ is a spectral Deligne-Mumford stack with 0-truncation $\mathsf{X}_0 = (\mathcal{X}, \pi_0 \mathscr{O}_{\mathcal{X}})$, then the pullback map $\mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X}) \to \mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X}_0)$ is an equivalence of ∞-categories.

Construction 10.1.2.7 (Stabilization of Quasi-Coherent Stacks)**.** For every connective $\mathbb{E}_\infty$-ring R, the construction $\mathcal{C} \mapsto \mathrm{Sp}(\mathcal{C})$ determines a stabilization functor $\mathrm{LinCat}_R^{\mathrm{PSt}} \to \mathrm{LinCat}_R^{\mathrm{St}}$. These functors depend functorially on R and can therefore be extended to a functor $\mathrm{QStk}^{\mathrm{PSt}}(X) \to \mathrm{QStk}^{\mathrm{St}}(X)$ for each $X \in \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$, which we will also denote by $\mathcal{C} \mapsto \mathrm{Sp}(\mathcal{C})$. More informally, this functor is given by the formula $\mathrm{Sp}(\mathcal{C})_\eta = \mathrm{Sp}(\mathcal{C}_\eta)$. It can is a left adjoint to the inclusion $\mathrm{QStk}^{\mathrm{St}}(X) \hookrightarrow \mathrm{QStk}^{\mathrm{PSt}}(X)$ of Remark 10.1.2.2.

Construction 10.1.2.8 (Hearts of Quasi-Coherent Stacks)**.** For every connective $\mathbb{E}_\infty$-ring R, the construction $\mathcal{C} \mapsto \mathcal{C}^\heartsuit$ determines a functor $\mathrm{LinCat}_R^{\mathrm{PSt}} \to \mathrm{LinCat}_R^{\mathrm{Ab}}$. These functors depend functorially on R and can therefore be extended to a functor $\mathrm{QStk}^{\mathrm{PSt}}(X) \to \mathrm{QStk}^{\mathrm{Ab}}(X)$ for each $X \in \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$, which we will also denote by $\mathcal{C} \mapsto \mathcal{C}^\heartsuit$. More informally, this functor is given by the formula $(\mathcal{C}^\heartsuit)_\eta = (\mathcal{C}_\eta)^\heartsuit$.

Remark 10.1.2.9 (Descent for Prestable Quasi-Coherent Stacks)**.** Let $f : X \to Y$ be a map in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ which induces an equivalence after sheafification with respect to the étale topology. Then the pullback functor $f^* : \mathrm{QStk}^{\mathrm{PSt}}(Y) \to \mathrm{QStk}^{\mathrm{PSt}}(X)$ is an equivalence of ∞-categories. This follows immediately from Theorem D.4.1.2 (together with the characterization of the functor $\mathrm{QStk}^{\mathrm{PSt}}$ supplied by Remark 10.1.2.4).

Remark 10.1.2.10 (Descent for Stable Quasi-Coherent Stacks)**.** Let $f : X \to Y$ be a map in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ which induces an equivalence after sheafification with respect to the étale topology. Then the pullback functor $f^* : \mathrm{QStk}^{\mathrm{St}}(Y) \to \mathrm{QStk}^{\mathrm{St}}(X)$ is an equivalence of ∞-categories. This follows from Remark 10.1.2.9, together with the fact that the stability of a prestable R-linear ∞-category can be tested locally with respect to the étale topology on R (Proposition D.5.1.1).

Remark 10.1.2.11 (Descent for Abelian Quasi-Coherent Stacks)**.** Let $f : X \to Y$ be a map in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ which induces an equivalence after sheafification with respect to the fpqc topology. Then the pullback functor $f^* : \mathrm{QStk}^{\mathrm{Ab}}(Y) \to \mathrm{QStk}^{\mathrm{Ab}}(X)$ is an equivalence of ∞-categories. This follows from Corollary D.6.8.4 (together with Remark 10.1.2.4).

10.1.3 Limits and Colimits of Prestable Quasi-Coherent Stacks

Let A be a connective $\mathbb{E}_\infty$-ring. Then the ∞-category $\mathrm{LinCat}_A^{\mathrm{Add}}$ of additive A-linear ∞-categories admits small limits and colimits. Moreover, for every morphism $f : A \to B$, the extension of scalars functor $\mathrm{LinCat}_A^{\mathrm{Add}} \to \mathrm{LinCat}_B^{\mathrm{Add}}$ preserves small limits and colimits. From this, it follows formally that for any functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, the ∞-category $\mathrm{QStk}^{\mathrm{Add}}(X)$ of additive quasi-coherent stacks on X admits small limits and colimits (which can be computed "levelwise"). However, if we restrict our attention to *prestable* quasi-coherent stacks, then the situation is more delicate. In this case, the existence of limits and colimits requires some additional hypotheses.

Definition 10.1.3.1. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor and let $F : \mathcal{C} \to \mathcal{D}$ be a morphism in $\mathrm{QStk}^{\mathrm{PSt}}(X)$. We will say that F is *left exact* if, for every connective $\mathbb{E}_\infty$-ring A and every point $\eta \in X(A)$, the underlying A-linear functor $F_\eta : \mathcal{C}_\eta \to \mathcal{D}_\eta$ is left exact (see Proposition C.3.2.1). We will say that F is *compact* if, for every connective $\mathbb{E}_\infty$-ring A and every point $\eta \in X(A)$, the underlying functor $F_\eta : \mathcal{C}_\eta \to \mathcal{D}_\eta$ is compact (that is, the right adjoint of F_η commutes with filtered colimits).

We let $\mathrm{QStk}^{\mathrm{lex}}(X)$ denote the subcategory of $\mathrm{QStk}^{\mathrm{PSt}}(X)$ whose morphisms are left exact morphisms in $\mathrm{QStk}^{\mathrm{PSt}}(X)$, and we let $\mathrm{QStk}^{c}(X)$ denote the subcategory of $\mathrm{QStk}^{\mathrm{PSt}}(X)$ whose morphisms are compact morphisms in $\mathrm{QStk}^{\mathrm{PSt}}(X)$.

Remark 10.1.3.2. Let $F : \mathcal{C} \to \mathcal{D}$ be a morphism between prestable quasi-coherent stacks on a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. If $\mathcal{C}$ is stable, then F is automatically left exact. Consequently, we can regard the ∞-category $\mathrm{QStk}^{\mathrm{St}}(X)$ as a full subcategory the ∞-category $\mathrm{QStk}^{\mathrm{lex}}(X)$.

Remark 10.1.3.3. Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, and let $F : \mathcal{C} \to \mathcal{D}$ be a morphism of quasi-coherent stacks on Y. If F is left exact (compact), then so is the induced map $f^*(F) : f^*\mathcal{C} \to f^*\mathcal{D}$. Conversely, if $f : X \to Y$ induces an effective epimorphism after sheafification with respect to the étale topology and $f^*\mathcal{C}$ is left exact (compact), then so is $\mathcal{C}$: this follows from Proposition D.5.2.1 (D.5.2.2).

Proposition 10.1.3.4 (Limits of Prestable Quasi-Coherent Stacks)**.** *Let $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor. Then:*

- (a) *The ∞-category $\mathrm{QStk}^{\mathrm{lex}}(Y)$ admits small limits.*
- (b) *The inclusion functor $\mathrm{QStk}^{\mathrm{lex}}(Y) \hookrightarrow \mathrm{QStk}^{\mathrm{Add}}(Y)$ preserves small limits.*
- (c) *For every map $f : X \to Y$, the pullback functor $f^* : \mathrm{QStk}^{\mathrm{lex}}(Y) \to \mathrm{QStk}^{\mathrm{lex}}(X)$ preserves small limits.*

In particular, for every point $\eta \in Y(R)$, the construction

$$(\mathcal{C} \in \mathrm{QStk}^{\mathrm{lex}}(Y)) \mapsto (\mathcal{C}_\eta \in \mathrm{LinCat}_R^{\mathrm{Add}})$$

preserves small limits.

Proof. In the case where $Y = \operatorname{Spec} A$ is affine, assertions (a) and (b) follow from Remark D.1.6.1. If, in addition, $X = \operatorname{Spec} B$ is affine, then assertion (c) follows from the observation that $\mathrm{Mod}_B^{\mathrm{cn}}$ is dualizable as an object of $\mathrm{LinCat}_A^{\mathrm{Add}}$ (so that the extension of scalars functor $\mathrm{LinCat}_A^{\mathrm{Add}} \to \mathrm{LinCat}_B^{\mathrm{Add}}$ preserves all limits which exist in $\mathrm{LinCat}_A^{\mathrm{Add}}$). The general case reduces to the affine case by formal arguments. $\square$

Variant 10.1.3.5 (Limits of Stable Quasi-Coherent Stacks)**.** Let $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor. Then the collection of stable quasi-coherent stacks on Y is closed under small limits in the ∞-category $\mathrm{QStk}^{\mathrm{lex}}(Y)$. Consequently, we have the following analogue of Proposition 10.1.3.4:

- (a) The ∞-category $\mathrm{QStk}^{\mathrm{St}}(Y)$ admits small limits.
- (b) The inclusion functor $\mathrm{QStk}^{\mathrm{St}}(Y) \hookrightarrow \mathrm{QStk}^{\mathrm{Add}}(Y)$ preserves small limits.

(c) For every map $f : X \to Y$, the pullback functor $f^* : \mathrm{QStk}^{\mathrm{St}}(Y) \to \mathrm{QStk}^{\mathrm{St}}(X)$ preserves small limits.

Variant 10.1.3.6 (Limits of Abelian Quasi-Coherent Stacks)**.** Let $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor and let $F : \mathcal{C} \to \mathcal{D}$ be a morphism in $\mathrm{QStk}^{\mathrm{Ab}}(Y)$. We will say that F is *left exact* if, for every connective $\mathbb{E}_\infty$-ring A and every point $\eta \in Y(A)$, the underlying A-linear functor $F_\eta : \mathcal{C}_\eta \to \mathcal{D}_\eta$ is a left exact (and therefore exact) functor of abelian categories. We let $\mathrm{QStk}^{\mathrm{Ab,lex}}(Y)$ denote the subcategory of $\mathrm{QStk}^{\mathrm{Ab}}(Y)$ whose morphisms are left exact functors. Arguing as in the proof of Proposition 10.1.3.4 (using Remark D.1.6.5 in place of Remark D.1.6.1), we deduce that the ∞-category $\mathrm{QStk}^{\mathrm{Ab,lex}}(Y)$ admits small limits which can be computed levelwise (and are therefore preserved by pullback along any map $f : X \to Y$). Moreover, the construction $\mathcal{C} \mapsto \mathcal{C}^{\heartsuit}$ of Construction 10.1.2.8 restricts to a functor $\mathrm{QStk}^{\mathrm{lex}}(X) \to \mathrm{QStk}^{\mathrm{Ab,lex}}(X)$ which preserves small limits (see Remark D.1.6.8).

Proposition 10.1.3.7 (Filtered Colimits of Prestable Quasi-Coherent Stacks)**.** *Let $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor. Then:*

(a) *The ∞-category $\mathrm{QStk}^{\mathrm{PSt}}(Y)$ admits small filtered colimits.*

(b) *The inclusion functor $\mathrm{QStk}^{\mathrm{PSt}}(Y) \hookrightarrow \mathrm{QStk}^{\mathrm{Add}}(Y)$ preserves small filtered colimits.*

(c) *For every map $f : X \to Y$, the pullback functor $f^* : \mathrm{QStk}^{\mathrm{PSt}}(Y) \to \mathrm{QStk}^{\mathrm{PSt}}(X)$ preserves small filtered colimits.*

In particular, for every point $\eta \in Y(R)$, the construction

$$(\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(Y)) \mapsto (\mathcal{C}_\eta \to \mathrm{LinCat}_R^{\mathrm{PSt}})$$

preserves small filtered colimits.

Proof. In the case where $Y = \operatorname{Spec} A$ is affine, assertions (a) and (b) follow from Remark D.1.6.2. If, in addition, $X = \operatorname{Spec} B$ is affine, then assertion (c) follows from the observation that the extension of scalars functor $\mathrm{LinCat}_A^{\mathrm{Add}} \to \mathrm{LinCat}_B^{\mathrm{Add}}$ preserves small colimits. The general case reduces to the affine case by formal arguments. □

Variant 10.1.3.8 (Colimits of Stable Quasi-Coherent Stacks)**.** For any $\mathbb{E}_\infty$-ring A, the ∞-category $\mathrm{LinCat}_A^{\mathrm{St}}$ of *stable* A-linear ∞-categories admits all small colimits, which are preserved by the extension of scalars functor $\mathrm{LinCat}_A^{\mathrm{St}} \to \mathrm{LinCat}_B^{\mathrm{St}}$ associated to any morphism of $\mathbb{E}_\infty$-rings $A \to B$, and by the inclusion functor $\mathrm{LinCat}_A^{\mathrm{St}} \hookrightarrow \mathrm{LinCat}_A^{\mathrm{Add}}$ whenever A is connective. We therefore have the following analogue of Proposition 10.1.3.7:

(a) For any functor $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, the ∞-category $\mathrm{QStk}^{\mathrm{St}}(Y)$ admits small colimits.

(*b*) For any functor $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, the inclusion functors $\mathrm{QStk}^{\mathrm{St}}(Y) \hookrightarrow \mathrm{QStk}^{\mathrm{Add}}(Y)$ preserves small colimits.

(*c*) For every natural transformation $f : X \to Y$ between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, the pullback functor $f^* : \mathrm{QStk}^{\mathrm{St}}(Y) \to \mathrm{QStk}^{\mathrm{St}}(X)$ preserves small colimits.

Variant 10.1.3.9 (Filtered Colimits of Abelian Quasi-Coherent Stacks)**.** Let $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor. Then:

(*a*) The ∞-category $\mathrm{QStk}^{\mathrm{Ab}}(Y)$ admits small filtered colimits.

(*b*) The inclusion functor $\mathrm{QStk}^{\mathrm{Ab}}(Y) \hookrightarrow \mathrm{QStk}^{\mathrm{Add}}(Y)$ preserves small filtered colimits.

(*c*) For every map $f : X \to Y$, the pullback functor $f^* : \mathrm{QStk}^{\mathrm{Ab}}(Y) \to \mathrm{QStk}^{\mathrm{Ab}}(X)$ preserves small filtered colimits.

This can be proven in the same way as Proposition 10.1.3.7, using Remark D.1.6.6 in place of Remark D.1.6.2.

Remark 10.1.3.10. Let $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor. Then the ∞-categories $\mathrm{QStk}^{\mathrm{PSt,lex}}(Y)$ and $\mathrm{QStk}^{\mathrm{Ab,lex}}(Y)$ admit small filtered colimits, which are preserved by the inclusion functors

$$\mathrm{QStk}^{\mathrm{PSt,lex}}(Y) \hookrightarrow \mathrm{QStk}^{\mathrm{PSt}}(Y) \qquad \mathrm{QStk}^{\mathrm{Ab,lex}}(Y) \hookrightarrow \mathrm{QStk}^{\mathrm{Ab}}(Y).$$

To prove this, we can immediately reduce to the case where Y is affine, in which case the desired result follows from Remarks D.1.6.2 and **??**.

Remark 10.1.3.11. Let $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor. Then the constructions

$$\mathrm{QStk}^{\mathrm{St}}(Y) \xleftarrow{\mathrm{Sp}} \mathrm{QStk}^{\mathrm{PSt}}(Y) \xrightarrow{\heartsuit} \mathrm{QStk}^{\mathrm{Ab}}(Y)$$

preserve small filtered colimits. To see this, we can reduce to the case where Y is affine, in which case the desired result follows from Remark D.1.6.7.

If we restrict our attention to diagrams involving compact transition maps, then we can obtain a stronger version of Proposition 10.1.3.7:

Proposition 10.1.3.12 (Colimits of Quasi-Coherent Stacks)**.** *Let* $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ *be a functor. Then:*

(*a*) *The* ∞*-category* $\mathrm{QStk}^{c}(Y)$ *admits small colimits.*

(*b*) *The inclusion functor* $\mathrm{QStk}^{c}(Y) \hookrightarrow \mathrm{QStk}^{\mathrm{PSt}}(Y)$ *preserves small colimits.*

(*c*) *For every map* $f : X \to Y$*, the pullback functor* $f^* : \mathrm{QStk}^{c}(Y) \to \mathrm{QStk}^{c}(X)$ *preserves small colimits.*

In particular, for every point $\eta \in Y(R)$, the construction

$$(\mathcal{C} \in \mathrm{QStk}^c(Y)) \mapsto (\mathcal{C}_\eta \to \mathrm{LinCat}_R^{\mathrm{PSt}})$$

preserves small colimits.

Proof. In the case where $Y = \operatorname{Spec} A$ is affine, assertions (a) and (b) follow from Remark D.1.6.3. If, in addition, $X = \operatorname{Spec} B$ is affine, then assertion (c) follows from the observation that $\mathrm{Mod}_B^{\mathrm{cn}}$ is dualizable as an object of $\mathrm{LinCat}_A^{\mathrm{PSt}}$ (so that the extension of scalars functor $\mathrm{LinCat}_A^{\mathrm{PSt}} \to \mathrm{LinCat}_B^{\mathrm{PSt}}$ preserves all colimits which exist in $\mathrm{LinCat}_A^{\mathrm{PSt}}$). The general case reduces to the affine case by formal arguments. □

Warning 10.1.3.13. In the situation of Proposition 10.1.3.12, the inclusion functor $\mathrm{QStk}^c(Y) \hookrightarrow \mathrm{QStk}^{\mathrm{Add}}(Y)$ usually does not preserve small colimits.

Warning 10.1.3.14. If $Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ is a functor, then the stabilization construction $\mathrm{QStk}^c(Y) \subseteq \mathrm{QStk}^{\mathrm{PSt}}(Y) \xrightarrow{\mathrm{Sp}} \mathrm{QStk}^{\mathrm{St}}(Y)$ generally does not preserve small colimits, even when Y is corepresentable (see Warning D.1.6.9).

10.1.4 Direct Images of Quasi-Coherent Stacks

Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. Given a quasi-coherent stack $\mathcal{C}$ on X, one can attempt to define a quasi-coherent stack $f_* \mathcal{C}$ on Y with the following universal property: for every quasi-coherent stack $\mathcal{D}$ on Y, giving a map of quasi-coherent stacks $\mathcal{D} \to f_* \mathcal{C}$ (on Y) is equivalent to giving a map of quasi-coherent stacks $f^* \mathcal{D} \to \mathcal{C}$ (on X). At least heuristically, this construction can be given explicitly by the formula $(f_* \mathcal{C})_\eta = \varprojlim_{\overline{\eta}} \mathcal{C}_{\overline{\eta}}$, where $\eta : \operatorname{Spec} A \to Y$ is an A-valued point of Y and the limit on the right hand side is taken over all commutative diagrams σ :

$$\begin{array}{ccc} \operatorname{Spec} B & \xrightarrow{\overline{\eta}} & X \\ \downarrow & & \downarrow f \\ \operatorname{Spec} A & \xrightarrow{\eta} & Y. \end{array}$$

Here we encounter a technical point: the ∞-category $\mathrm{LinCat}_A^{\mathrm{Add}}$ admits all *small* limits, but the collection of all commutative diagrams σ as above need not be small. To circumvent this difficulty, we will make the following additional assumptions:

(i) The morphism $f : X \to Y$ representable, in the sense of Definition 6.3.2.1. That is, for every map $\operatorname{Spec} A \to Y$, the fiber product $X_A = X \times_Y \operatorname{Spec} A$ is (representable by) a spectral Deligne-Mumford stack.

(*ii*) The quasi-coherent stack $\mathcal{C}$ is either prestable or abelian: that is, it belongs to a class of objects which satisfy descent for the étale topology (see Remarks 10.1.2.9 and 10.1.2.11).

We will see below that under these assumptions, we do not need to take the limit of *all* diagrams σ as above: it suffices to consider those diagrams which classify an étale morphism $\operatorname{Spec} B \to X_A$.

Proposition 10.1.4.1. (1) *Let $f : X \to Y$ be a representable morphism between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. Then the pullback functors*

$$f^* : \mathrm{QStk}^{\mathrm{PSt}}(Y) \to \mathrm{QStk}^{\mathrm{PSt}}(X) \qquad f^* : \mathrm{QStk}^{\mathrm{Ab}}(Y) \to \mathrm{QStk}^{\mathrm{Ab}}(X)$$

admit right adjoints, which we will denote by f_*.

(2) *Suppose we are given a pullback diagram*

$$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y & \xrightarrow{g} & Y \end{array}$$

in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$*, where f is representable. Then the associated diagram*

$$\begin{array}{ccc} \mathrm{QStk}^{\mathrm{PSt}}(Y) & \xrightarrow{f^*} & \mathrm{QStk}^{\mathrm{PSt}}(X) \\ \downarrow{\scriptstyle g^*} & & \downarrow{\scriptstyle g'^*} \\ \mathrm{QStk}^{\mathrm{PSt}}(Y') & \xrightarrow{f'^*} & \mathrm{QStk}^{\mathrm{PSt}}(X') \end{array}$$

is right adjointable: that is, the canonical natural transformation $g^* f_* \to f'_* g'^*$ is an equivalence.

(2′) *Suppose we are given a pullback diagram*

$$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y & \xrightarrow{g} & Y \end{array}$$

in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$*. Then the associated diagram*

$$\begin{array}{ccc} \mathrm{QStk}^{\mathrm{Ab}}(Y) & \xrightarrow{f^*} & \mathrm{QStk}^{\mathrm{Ab}}(X) \\ \downarrow{\scriptstyle g^*} & & \downarrow{\scriptstyle g'^*} \\ \mathrm{QStk}^{\mathrm{Ab}}(Y') & \xrightarrow{f'^*} & \mathrm{QStk}^{\mathrm{Ab}}(X') \end{array}$$

is right adjointable: that is, the canonical natural transformation $g^* f_* \to f'_* g'^*$ is an equivalence.

Proof of Proposition 10.1.4.1. We will prove the existence of the pushforward $f_* : \mathrm{QStk}^{\mathrm{PSt}}(X) \to \mathrm{QStk}^{\mathrm{PSt}}(Y)$ and verify part (2); the analogous assertions in the setting of abelian quasi-coherent stacks can be proven using the same argument (with some slight changes in notation). We begin by proving (1) in the special case where $Y = \operatorname{Spec} A$ is affine. Let us identify $\mathrm{QStk}^{\mathrm{PSt}}(Y)$ with the ∞-category $\mathrm{LinCat}_A^{\mathrm{PSt}}$ of prestable A-linear ∞-categories. Our assumption that f is representable guarantees that X is (representable by) a spectral Deligne-Mumford stack $(\mathcal{X}, \mathscr{O}_X)$.

Fix an object $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(X)$. For every object $U \in \mathcal{X}$, let X_U denote the functor represented by the spectral Deligne-Mumford stack $(\mathcal{X}_{/U}, \mathscr{O}_X|_U)$, let $f_U : X_U \to Y$ be the restriction of f, and let let $\mathcal{C}_U \in \mathrm{QStk}^{\mathrm{PSt}}(X_U)$ denote the restriction of $\mathcal{C}$. We define a functor $\chi_U : (\mathrm{LinCat}_A^{\mathrm{PSt}})^{\mathrm{op}} \to \widehat{\mathcal{S}}$ by the formula $\chi_U(\mathcal{D}) = \mathrm{Map}_{\mathrm{QStk}^{\mathrm{PSt}}(X_U)}(f_U^* \mathcal{D}, \mathcal{C}_U)$. Let us say that a point $\eta \in \chi_U(\mathcal{D})$ is *left exact* if, for every map $V \to U$ in $\mathcal{X}$ where $\mathsf{X}_V \simeq \operatorname{Spec} B$ is affine, the image of η in the mapping space

$$\chi_V(\mathcal{D}) = \mathrm{Map}_{\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}_V)}(f_V^* \mathcal{D}, \mathcal{C}_V) \simeq \mathrm{Map}_{\mathrm{LinCat}_A^{\mathrm{PSt}}}(\mathcal{D}, \mathcal{C}_V)$$

determines a left exact functor from $\mathcal{D}$ to $\mathcal{C}_V$ (here we abuse notation by identifying $\mathcal{C}_V$ with the associated prestable B-linear ∞-category, regarded as a prestable A-linear ∞-category by restriction of scalars). Let $\chi'_U(\mathcal{D})$ denote the summand of $\chi_U(\mathcal{D})$ consisting of the left exact points, so that we can regard the construction $\mathcal{D} \mapsto \chi'_U(\mathcal{D})$ as a functor $\chi'_U : (\mathrm{LinCat}_A^{\mathrm{lex}})^{\mathrm{op}} \to \widehat{\mathcal{S}}$.

Note that the construction $U \mapsto \chi_U$ carries colimits in $\mathcal{X}$ to limits in the ∞-category $\mathrm{Fun}((\mathrm{LinCat}_A^{\mathrm{PSt}})^{\mathrm{op}}, \widehat{\mathcal{S}})$. Using Proposition D.5.2.1, we see that the condition that a point $\eta \in \chi_U(\mathcal{D})$ is left exact can be tested locally on U, so that the functor $U \mapsto \chi'_U$ carries colimits in $\mathcal{X}$ to limits in the ∞-category $\mathrm{Fun}((\mathrm{LinCat}_A^{\mathrm{lex}})^{\mathrm{op}}, \widehat{\mathcal{S}})$ Let $\mathcal{X}_0 \subseteq \mathcal{X}$ be the full subcategory spanned by those objects U for which the functor χ'_U is representable by an object of $\mathrm{LinCat}_A^{\mathrm{lex}}$. Since the ∞-categoy $\mathrm{LinCat}_A^{\mathrm{lex}}$ admits small limits (Remark D.1.6.1), it follows that $\mathcal{X}_0$ is closed under small colimits in $\mathcal{X}$. Moreover, if $U \in \mathcal{X}$ is affine so that $\mathsf{X}_U \simeq \operatorname{Spec} B$ for some connective A-algebra B, then we can regard $\mathcal{C}_U$ as a prestable B-linear ∞-category. In this case, the underlying prestable A-linear ∞-category of $\mathcal{C}_U$ represents the functor χ'_U, so that $U \in \mathcal{X}_0$. Since $\mathcal{X}$ is generated under small colimits by its affine objects (see Lemma **??**), it follows that $\mathcal{X}_0 = \mathcal{X}$.

For each object $U \in \mathcal{X}$, let $\Gamma(U; \mathcal{C})$ be a prestable A-linear ∞-category which represents the functor χ'_U. Then we can regard the construction $U \mapsto \Gamma(U; \mathcal{C})$ as a functor from $\mathcal{X}^{\mathrm{op}}$ to the ∞-category $\mathrm{LinCat}_A^{\mathrm{lex}}$ which preserves small limits. By construction, each $\Gamma(U; \mathcal{C})$ is equipped with a map $v_U : f_U^* \Gamma(U; \mathcal{C}) \to \mathcal{C}_U$ having the following universal property: for every prestable A-linear ∞-category $\mathcal{D}$, composition with v_U induces a homotopy equivalence from

$\mathrm{Map}_{\mathrm{LinCat}_A^{\mathrm{lex}}}(\mathcal{D}, \Gamma(U;\mathcal{C}))$ to the summand of $\mathrm{Map}_{\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}_U)}(f_U^* \mathcal{D}, \mathcal{C}_U)$ consisting of the left exact points. Let $\mathcal{X}_1$ be the full subcategory of $\mathcal{X}$ spanned by those objects U having the property that, for every prestable A-linear ∞-category $\mathcal{D}$, composition with v_U also induces a homotopy equivalence

$$\mathrm{Map}_{\mathrm{LinCat}_A^{\mathrm{PSt}}}(\mathcal{D}, \Gamma(U;\mathcal{C})) \to \mathrm{Map}_{\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}_U)}(f_U^* \mathcal{D}, \mathcal{C}_U).$$

It follows immediately from the construction of $\Gamma(U;\mathcal{C})$ given above that every affine object of $\mathcal{X}$ is contained in $\mathcal{X}_1$. Because the forgetful functor $\mathrm{LinCat}_A^{\mathrm{lex}} \hookrightarrow \mathrm{LinCat}_A^{\mathrm{PSt}}$ preserves small limits (Remark D.1.6.1), the full subcategory $\mathcal{X}_1 \subseteq \mathcal{X}$ is closed under small colimits. Since $\mathcal{X}$ is generated under small colimits by its affine objects (Lemma **??**), we conclude that $\mathcal{X}_1 = \mathcal{X}$. In particular, the final object $\mathbf{1} \in \mathcal{X}$ is good. Setting $\Gamma(X;\mathcal{C}) = \Gamma(\mathbf{1};\mathcal{C})$, we deduce the existence of a map $v = v_{\mathbf{1}} : f^*\Gamma(X;\mathcal{C}) \to \mathcal{C}$ which induces a homotopy equivalence

$$\mathrm{Map}_{\mathrm{LinCat}_A^{\mathrm{PSt}}}(\mathcal{D}, \Gamma(\mathcal{X};\mathcal{C})) \to \mathrm{Map}_{\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})}(f^* \mathcal{D}, \mathcal{C})$$

for every prestable A-linear ∞-category $\mathcal{D}$. Allowing $\mathcal{C}$ to vary, we deduce that the pullback functor $f^* : \mathrm{LinCat}_A^{\mathrm{PSt}} \to \mathrm{QStk}^{\mathrm{PSt}}(X)$ admits a right adjoint, given on objects by the construction $\mathcal{C} \mapsto \Gamma(X;\mathcal{C})$.

We now prove (2) under the assumption that $Y = \mathrm{Spec}\, A$ and $Y' = \mathrm{Spec}\, A'$ are both affine. It follows that X and X' are representable by spectral Deligne-Mumford stacks $(\mathcal{X}, \mathscr{O}_X)$ and $(\mathcal{X}', \mathscr{O}_{X'})$. For each $U \in \mathcal{X}$, let U' denote its inverse image in $\mathcal{X}'$, and let $\Gamma(U';\bullet) : \mathrm{QStk}^{\mathrm{PSt}}(X') \to \mathrm{LinCat}_{A'}^{\mathrm{lex}}$ be defined as above. We will prove that for each $U \in \mathcal{X}$, the canonical map $\alpha_U : A' \otimes_A \Gamma(U;\mathcal{C}) \to \Gamma(U'; g'^* \mathcal{C})$. is an equivalence. When regarded as a functors of U, both the domain and codomain of α_U carry colimits in $\mathcal{X}$ to limits in $\mathrm{LinCat}_{A'}^{\mathrm{lex}}$. It will therefore suffice to prove that α_U is an equivalence when U is affine. We may therefore reduce to the case where $X \simeq \mathrm{Spec}\, B$, so that $X' = \mathrm{Spec}\, B'$ for $B' = A' \otimes_A B$. The desired result now follows from Lemma D.3.5.6, since the canonical map $\mathrm{Mod}_{A'}^{\mathrm{cn}} \otimes_{\mathrm{Mod}_A^{\mathrm{cn}}} \mathrm{Mod}_B^{\mathrm{cn}} \to \mathrm{Mod}_{B'}^{\mathrm{cn}}$ is an equivalence of ∞-categories.

We now treat the general case of (1). Write Y as the colimit of a (not necessarily small) diagram $q : S \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$, where each $Y_s = q(s)$ is affine. For each $s \in S$, set $X_s = X \times_Y Y_s$. Every edge $s \to s'$ in S determines a pullback diagram

$$\begin{array}{ccc} X_s & \longrightarrow & X_{s'} \\ \downarrow & & \downarrow \\ Y_s & \longrightarrow & Y_{s'}. \end{array}$$

Using assertion (2) in the affine case, we deduce that the associated diagram of pullback functors

$$\begin{array}{ccc} \mathrm{QStk}^{\mathrm{PSt}}(Y_{s'}) & \longrightarrow & \mathrm{QStk}^{\mathrm{PSt}}(X_{s'}) \\ \downarrow & & \downarrow \\ \mathrm{QStk}^{\mathrm{PSt}}(Y_s) & \longrightarrow & \mathrm{QStk}^{\mathrm{PSt}}(X_s) \end{array}$$

is right adjointable. Since the construction $Z \mapsto \mathrm{QStk}^{\mathrm{PSt}}(Z)$ carries colimits to limits, Corollary HA.4.7.4.18 implies the following:

(*i*) The functor $f^* : \mathrm{QStk}^{\mathrm{PSt}}(Y) \to \mathrm{QStk}^{\mathrm{PSt}}(X)$ admits a right adjoint f_*.

(*ii*) For each $s \in S$, the diagram

$$\begin{array}{ccc} \mathrm{QStk}^{\mathrm{PSt}}(Y) & \xrightarrow{f^*} & \mathrm{QStk}^{\mathrm{PSt}}(X) \\ \downarrow & & \downarrow \\ \mathrm{QStk}^{\mathrm{PSt}}(Y_s) & \longrightarrow & \mathrm{QStk}^{\mathrm{PSt}}(X_s) \end{array}$$

is right adjointable.

This proves (1). Moreover, we can assume without loss of generality that every morphism $\mathrm{Spec}\, A \to Y$ appears as a map $q(s) \to Y$ for some $s \in S$, so that (*ii*) implies that (2) is satisfied whenever Y' is affine. To prove (2) in general, consider a pullback square σ :

$$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow{g} & Y \end{array}$$

and let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(X)$; we wish to show that the Beck-Chevalley map $\theta : g^* f_* \mathcal{C} \to f'_* g'^* \mathcal{C}$ is an equivalence. Unwinding the definitions, this is equivalent to the assertion that for every map $h : \mathrm{Spec}\, A \to Y'$, the pullback $h^*(\theta)$ is an equivalence in $\mathrm{QStk}^{\mathrm{PSt}}(\mathrm{Spec}\, A)$. Extending σ to a rectangular diagram

$$\begin{array}{ccccc} X'' & \xrightarrow{h'} & X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f''} & & \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathrm{Spec}\, A & \xrightarrow{h} & Y' & \xrightarrow{g} & Y \end{array}$$

where both squares are pullbacks, we see that $h^*(\theta)$ fits into a commutative diagram

$$\begin{array}{ccccc} & & h^* f'_* g'^* \mathcal{C} & & \\ & \nearrow^{h^*(\theta)} & & \searrow^{\theta'} & \\ h^* g^* f_* \mathcal{C} & & \xrightarrow{\theta''} & & f''_* h'^* g'^* \mathcal{C}, \end{array}$$

where θ' and θ'' are equivalences by virtue of the fact that (2) holds in the special case treated above. □

10.1.5 Properties of the Direct Image

Proposition 10.1.4.1 establishes the existence of pushforwards in both the prestable and abelian settings. We now show that these are compatible:

Proposition 10.1.5.1. *Let $f : X \to Y$ be a representable morphism between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. Then the diagram*

$$\begin{array}{ccc} \mathrm{QStk}^{\mathrm{PSt}}(Y) & \xrightarrow{f^*} & \mathrm{QStk}^{\mathrm{PSt}}(X) \\ \downarrow \heartsuit & & \downarrow \heartsuit \\ \mathrm{QStk}^{\mathrm{Ab}}(Y) & \xrightarrow{f^*} & \mathrm{QStk}^{\mathrm{Ab}}(X) \end{array}$$

is right adjointable. In other words, for every object $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(X)$, the canonical map $(f_* \mathcal{C})^{\heartsuit} \to f_*(\mathcal{C}^{\heartsuit})$ is an equivalence of abelian quasi-coherent stacks on Y.

Proof. Using assertions (2) and (2′) of Proposition 10.1.4.1, we can reduce to the case where $Y = \operatorname{Spec} A$ is affine. Since f is representable, the functor X is representable by some spectral Deligne-Mumford stack $(\mathcal{X}, \mathscr{O}_X)$. For each $U \in \mathcal{X}$, define $\mathcal{C}_U$ and $\Gamma(U; \mathcal{C}_U)$ as in the proof of Proposition 10.1.4.1, and define $(\mathcal{C}^{\heartsuit})_U$ and $\Gamma(U; (\mathcal{C}^{\heartsuit})_U)$ similarly, so that we have an evident map $\theta_U : \Gamma(U; \mathcal{C}_U)^{\heartsuit} \to \Gamma(U; (\mathcal{C}^{\heartsuit})_U)$. It follows from the definition of $\mathcal{C}^{\heartsuit}$ that the map θ_U is an equivalence whenever U is affine. Since the construction $U \mapsto \theta_U$ carries colimits in $\mathcal{X}$ to limits in $\mathrm{LinCat}_A^{\mathrm{Ab,lex}}$ (see Remark D.1.6.8), it follows that θ_U is an equivalence when U is a final object of $\mathcal{X}$, which is an equivalent formulation of Proposition 10.1.5.1. □

We now specialize Proposition 10.1.4.1 to the stable setting.

Proposition 10.1.5.2. *Let $f : X \to Y$ be a representable morphism between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. Then the pushforward functor $f_* : \mathrm{QStk}^{\mathrm{PSt}}(X) \to \mathrm{QStk}^{\mathrm{PSt}}(Y)$ of Proposition 10.1.4.1 carries stable quasi-coherent stacks on X to stable quasi-coherent stacks on Y.*

Proof. Using Proposition 10.1.4.1, we can assume without loss of generality that $Y = \operatorname{Spec} A$ is affine. Since f is representable, the functor X is representable by some spectral Deligne-Mumford stack $(\mathcal{X}, \mathscr{O}_X)$. For each $U \in \mathcal{X}$, define $\mathcal{C}_U$ and $\Gamma(U; \mathcal{C}_U)$ as in the proof of Proposition 10.1.4.1. Let $\mathcal{X}_0$ be the full subcategory of $\mathcal{X}$ spanned by those objects U for which the prestable A-linear ∞-category $\Gamma(U; \mathcal{C}_U)$ is stable. The construction $U \mapsto \Gamma(U; \mathcal{C}_U)$ carries colimits in $\mathcal{X}$ to limits in $\mathrm{LinCat}_A^{\mathrm{PSt}}$, and the full subcategory $\mathrm{LinCat}_A^{\mathrm{St}} \subseteq \mathrm{LinCat}_A^{\mathrm{PSt}}$

is closed under limits (since the inclusion admits a left adjoint). It follows that $\mathcal{X}_0$ is closed under small colimits in $\mathcal{X}$. Our assumption that $\mathcal{C}$ is stable guarantees that $\mathcal{X}_0$ contains all affine objects of $\mathcal{X}$. Using Lemma **??**, we deduce that $\mathcal{X}_0 = \mathcal{X}$. In particular, $\mathcal{X}_0$ contains a final object of $\mathcal{X}$, so that $f_* \mathcal{C}$ is stable. □

Combining Propositions 10.1.4.1 and 10.1.5.2, we obtain the following:

Corollary 10.1.5.3. (1) *Let $f : X \to Y$ be a representable morphism between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. Then the pullback functors $f^* : \mathrm{QStk}^{\mathrm{St}}(Y) \to \mathrm{QStk}^{\mathrm{St}}(X)$ admits a right adjoint $f_* : \mathrm{QStk}^{\mathrm{St}}(X) \to \mathrm{QStk}^{\mathrm{St}}(Y)$.*

(2) *Suppose we are given a pullback diagram*

$$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y & \xrightarrow{g} & Y \end{array}$$

in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$, where f is representable. Then the associated diagram

$$\begin{array}{ccc} \mathrm{QStk}^{\mathrm{St}}(Y) & \xrightarrow{f^*} & \mathrm{QStk}^{\mathrm{St}}(X) \\ \downarrow{\scriptstyle g^*} & & \downarrow{\scriptstyle g'^*} \\ \mathrm{QStk}^{\mathrm{St}}(Y') & \xrightarrow{f'^*} & \mathrm{QStk}^{\mathrm{St}}(X') \end{array}$$

is right adjointable: that is, the canonical natural transformation $g^* f_* \to f'_* g'^*$ is an equivalence.

We also have the following analogue of Proposition 10.1.5.1:

Proposition 10.1.5.4. *Let $f : X \to Y$ be a representable morphism between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. Then the diagram*

$$\begin{array}{ccc} \mathrm{QStk}^{\mathrm{PSt}}(Y) & \xrightarrow{f^*} & \mathrm{QStk}^{\mathrm{PSt}}(X) \\ \downarrow{\scriptstyle \mathrm{Sp}} & & \downarrow{\scriptstyle \mathrm{Sp}} \\ \mathrm{QStk}^{\mathrm{St}}(Y) & \xrightarrow{f^*} & \mathrm{QStk}^{\mathrm{St}}(X) \end{array}$$

is right adjointable. In other words, for every object $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(X)$, the canonical map $\mathrm{Sp}(f_* \mathcal{C}) \to f_*(\mathrm{Sp}(\mathcal{C}))$ is an equivalence of stable quasi-coherent stacks on Y.

Proof. Using Proposition 10.1.4.1, we can reduce to the case where $Y = \operatorname{Spec} A$ is affine. Since f is representable, the functor X is representable by some spectral Deligne-Mumford stack $(\mathcal{X}, \mathscr{O}_X)$. For each $U \in \mathcal{X}$, let $\mathcal{C}_U$ and $\Gamma(U; \mathcal{C}_U)$ be as in the proof of Proposition 10.1.4.1, and define $\operatorname{Sp}(\mathcal{C})_U$ and $\Gamma(U; \operatorname{Sp}(\mathcal{C})_U)$ similarly. Let $\mathcal{X}_0$ denote the full subcategory of $\mathcal{X}$ for which the canonical map $\operatorname{Sp}(\Gamma(U; \mathcal{C}_U)) \to \Gamma(U; \operatorname{Sp}(\mathcal{C})_U)$ is an equivalence. It follows from Remark D.1.6.8 that the subcategory $\mathcal{X}_0$ is closed under colimits in $\mathcal{X}$, and it follows from the definition of $\operatorname{Sp}(\mathcal{C})$ that $\mathcal{X}_0$ contains every affine object of $\mathcal{X}$. Applying Lemma **??**, we deduce that $\mathcal{X}_0 = \mathcal{X}$. In particular, $\mathcal{X}_0$ contains a final object of $\mathcal{X}$, so that the canonical map $\operatorname{Sp}(f_* \mathcal{C}) \to f_*(\operatorname{Sp}(\mathcal{C}))$ is an equivalence. □

10.1.6 Tensor Products of Quasi-Coherent Stacks

Let A be a connective $\mathbb{E}_\infty$-ring. If $\mathcal{C}$ and $\mathcal{D}$ are additive A-linear ∞-categories, then the relative tensor product $\mathcal{C} \otimes_A \mathcal{D}$ of Construction D.2.1.1 inherits the structure of an additive A-linear ∞-category. By means of this construction, we obtain a symmetric monoidal structure on the ∞-category $\operatorname{LinCat}_A^{\mathrm{Add}} \simeq \operatorname{Mod}_{\operatorname{Mod}_A^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ of additive A-linear ∞-categories (see Remark D.2.3.1). This symmetric monoidal structure depends functorially on A: that is, we can regard the construction $A \mapsto \operatorname{LinCat}_A^{\mathrm{PSt}}$ as a functor from $\mathrm{CAlg}^{\mathrm{cn}}$ to the ∞-category $\mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty)$ of symmetric monoidal ∞-categories. Taking a right Kan extension along the Yoneda embedding $\mathrm{CAlg}^{\mathrm{cn}} \hookrightarrow \operatorname{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})^{\mathrm{op}}$, we obtain a functor

$$\mathrm{QStk}^{\mathrm{Add}} : \operatorname{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}}) \to \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty).$$

It follows from Remark 10.1.1.2 that the composition of $\mathrm{QStk}^{\mathrm{Add}}$ with the forgetful functor $\mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty) \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ agrees with Construction 10.1.1.1. We can summarize the situation more informally as follows:

(*a*) For every functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, the ∞-category $\mathrm{QStk}^{\mathrm{Add}}(X)$ of additive quasi-coherent stacks on X inherits the structure of a symmetric monoidal ∞-category.

(*b*) For every map $f : X \to Y$ in $\operatorname{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$, the pullback functor $f^* : \mathrm{QStk}^{\mathrm{Add}}(Y) \to \mathrm{QStk}^{\mathrm{Add}}(X)$ is symmetric monoidal.

(*c*) When $X = \operatorname{Spec} A$ is a corepresentable functor, the symmetric monoidal structure on $\mathrm{QStk}^{\mathrm{Add}}(X) \simeq \operatorname{LinCat}_A^{\mathrm{Add}}$ is given by the relative tensor product $(\mathcal{C}, \mathcal{D}) \mapsto \mathcal{C} \otimes_A \mathcal{D}$.

Remark 10.1.6.1. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor. It follows from (*a*), (*b*) and (*c*) above that the tensor product on $\mathrm{QStk}^{\mathrm{Add}}(X)$ is computed "pointwise" in the following sense: for every connective $\mathbb{E}_\infty$-ring A and every point $\eta \in X(A)$, we have a canonical equivalence of A-linear ∞-categories $(\mathcal{C} \otimes \mathcal{D})_\eta \simeq \mathcal{C}_\eta \otimes_A \mathcal{D}_\eta$.

Example 10.1.6.2. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor. We let $\mathcal{Q}_X^{\mathrm{cn}}$ denote the unit object of the symmetric monoidal ∞-category $\mathrm{QStk}^{\mathrm{Add}}(X)$. The quasi-coherent stack $\mathcal{Q}_X^{\mathrm{cn}}$ can be described more informally as follows: to every point $\eta \in X(A)$, it assigns the prestable A-linear ∞-category $\mathrm{Mod}_A^{\mathrm{cn}}$ (which is the unit object of the symmetric monoidal ∞-category $\mathrm{LinCat}_A^{\mathrm{Add}} = \mathrm{Mod}_{\mathrm{Mod}_A^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$).

We now restrict our attention to tensor products of prestable, stable, and abelian quasi-coherent stacks.

Proposition 10.1.6.3 (Tensor Products of Prestable Quasi-Coherent Stacks)**.** *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor. Then the full subcategory $\mathrm{QStk}^{\mathrm{PSt}}(X) \subseteq \mathrm{QStk}^{\mathrm{Add}}(X)$ of prestable quasi-coherent stacks on X contains the unit object $\mathcal{Q}_X^{\mathrm{cn}} \in \mathrm{QStk}^{\mathrm{Add}}(X)$ and is closed under tensor products. Consequently, $\mathrm{QStk}^{\mathrm{PSt}}(X)$ inherits the structure of a symmetric monoidal ∞-category (for which the inclusion $\mathrm{QStk}^{\mathrm{PSt}}(X) \hookrightarrow \mathrm{QStk}^{\mathrm{Add}}(X)$ is symmetric monoidal).*

Proof. Using Remark 10.1.6.1, we can reduce to the case where $X = \operatorname{Spec} A$ is affine, in which case the desired result follows from Proposition D.2.2.1. □

Proposition 10.1.6.4 (Tensor Products of Stable Quasi-Coherent Stacks)**.** *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor, and let $L : \mathrm{QStk}^{\mathrm{Add}}(X) \to \mathrm{QStk}^{\mathrm{St}}(X)$ be a left adjoint to the inclusion (given by $\mathcal{C} \mapsto \mathrm{Sp}(\mathcal{C})$). Then the localization functor L is compatible with the symmetric monoidal structure on $\mathrm{QStk}^{\mathrm{Add}}(X)$, in the sense of Definition HA.2.2.1.6. Consequently, the ∞-category $\mathrm{QStk}^{\mathrm{St}}(X)$ inherits a symmetric monoidal structure, which is determined (up to essentially unique equivalence) by the requirement that the functor L is symmetric monoidal.*

Proof. Unwinding the definitions, we must show that for every pair of objects $\mathcal{C}, \mathcal{D} \in \mathrm{QStk}^{\mathrm{Add}}(X)$, the canonical map

$$\mathrm{Sp}(\mathcal{C} \otimes \mathcal{D}) \to \mathrm{Sp}(\mathrm{Sp}(\mathcal{C}) \otimes \mathrm{Sp}(\mathcal{D}))$$

is an equivalence. Without loss of generality, we can assume that $X = \operatorname{Spec} A$ is affine, in which case the desired result follows from the observation that Mod_A is an idempotent object in the symmetric monoidal ∞-category $\mathrm{LinCat}_A^{\mathrm{Add}}$. □

Remark 10.1.6.5. Let $\mathcal{C}$ and $\mathcal{D}$ be additive quasi-coherent stacks on a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. If either $\mathcal{C}$ or $\mathcal{D}$ is stable, then the tensor product $\mathcal{C} \otimes \mathcal{D}$ is stable. It follows that the tensor product on $\mathrm{QStk}^{\mathrm{St}}(X)$ agrees with the tensor product on $\mathrm{QStk}^{\mathrm{Add}}(X)$: in other words, the diagram

$$\begin{array}{ccc} \mathrm{QStk}^{\mathrm{St}}(X) \times \mathrm{QStk}^{\mathrm{St}}(X) & \xrightarrow{\otimes} & \mathrm{QStk}^{\mathrm{St}}(X) \\ \downarrow & & \downarrow \\ \mathrm{QStk}^{\mathrm{Add}}(X) \times \mathrm{QStk}^{\mathrm{Add}}(X) & \xrightarrow{\otimes} & \mathrm{QStk}^{\mathrm{Add}}(X). \end{array}$$

However, the inclusion $\mathrm{QStk}^{\mathrm{St}}(X) \hookrightarrow \mathrm{QStk}^{\mathrm{Add}}(X)$ is not symmetric monoidal, because the unit objects are different: the unit object of $\mathrm{QStk}^{\mathrm{St}}(X)$ is the stable quasi-coherent stack $\mathcal{Q}_X = \mathrm{Sp}(\mathcal{Q}_X^{\mathrm{cn}})$, which can be described more informally as follows: to every point $\eta \in X(A)$, it assigns the stable A-linear ∞-category Mod_A (which is the unit object of the symmetric monoidal ∞-category $\mathrm{LinCat}_A^{\mathrm{St}} = \mathrm{Mod}_{\mathrm{Mod}_A}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$).

Remark 10.1.6.6. For each functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, the stabilization construction $\mathrm{QStk}^{\mathrm{PSt}}(X) \to \mathrm{QStk}^{\mathrm{St}}(X)$ is symmetric monoidal functor. Moreover, it is given by the construction $\mathcal{C} \mapsto \mathcal{Q}_X \otimes \mathcal{C}$.

Remark 10.1.6.7. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor. Then the ∞-category $\mathrm{QStk}^{\mathrm{St}}(X)$ admits small colimits (see Variant 10.1.3.8) and the tensor product functor $\otimes : \mathrm{QStk}^{\mathrm{St}}(X) \times \mathrm{QStk}^{\mathrm{St}}(X) \to \mathrm{QStk}^{\mathrm{St}}(X)$ preserves small colimits separately in each variable. However, the analogous statement for prestable quasi-coherent stacks is false, even if we restrict our attention to compact morphisms (see Warning **??**).

Variant 10.1.6.8 (Tensor Products of Abelian Quasi-Coherent Stacks)**.** For every connective $\mathbb{E}_\infty$-ring A, the ∞-category $\mathrm{LinCat}_A^{\mathrm{Ab}}$ of abelian A-linear ∞-categories is equipped with a symmetric monoidal structure given by the construction $(\mathcal{C}, \mathcal{D}) \mapsto \mathcal{C} \otimes_A \mathcal{D}$ (see Variant D.2.3.2). Arguing as above, we see that for every functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, we can regard the ∞-category $\mathrm{QStk}^{\mathrm{Ab}}(X)$ as equipped with a symmetric monoidal structure, which depends functorially on X and is given pointwise by the construction $(\mathcal{C} \otimes \mathcal{D})_\eta = \mathcal{C}_\eta \otimes_A \mathcal{D}_\eta)$. In particular, the tensor product on $\mathrm{QStk}^{\mathrm{Ab}}(X)$ agrees with the tensor product on the larger ∞-category $\mathrm{QStk}^{\mathrm{Add}}(X)$. However, the inclusion functor $\mathrm{QStk}^{\mathrm{Ab}}(X) \hookrightarrow \mathrm{QStk}^{\mathrm{Add}}(X)$ is not a symmetric monoidal functor, because it does not preserve unit objects. We will denote the unit object of $\mathrm{QStk}^{\mathrm{Ab}}(X)$ by $\mathcal{Q}_X^{\heartsuit}$: it is given informally by the formula $(\mathcal{Q}_X^{\heartsuit})_\eta = \mathrm{Mod}_A^{\heartsuit}$ for each point $\eta \in X(A)$.

Remark 10.1.6.9. For every functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, the functor

$$\mathrm{QStk}^{\mathrm{PSt}}(X) \to \mathrm{QStk}^{\mathrm{Ab}}(X) \qquad \mathcal{C} \mapsto \mathcal{C}^{\heartsuit}$$

of Construction 10.1.2.8 determines a symmetric monoidal functor $\mathrm{QStk}^{\mathrm{PSt}}(X)$ to $\mathrm{QStk}^{\mathrm{Ab}}(X)$, which depends functorially on X. We observe that this construction is given by the formula $\mathcal{C}^{\heartsuit} = \mathcal{Q}_X^{\heartsuit} \otimes \mathcal{C}$, where the tensor product is formed in the ∞-category $\mathrm{QStk}^{\mathrm{Add}}(X)$.

Remark 10.1.6.10. Let $f : X \to Y$ be a representable morphism in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. Then the pullback functors

$$f^* : \mathrm{QStk}^{\mathrm{PSt}}(Y) \to \mathrm{QStk}^{\mathrm{PSt}}(X) \qquad f^* : \mathrm{QStk}^{\mathrm{Ab}}(Y) \to \mathrm{QStk}^{\mathrm{Ab}}(X)$$

are symmetric monoidal. It follows that the direct image functors

$$f_* : \mathrm{QStk}^{\mathrm{PSt}}(X) \to \mathrm{QStk}^{\mathrm{PSt}}(Y) \qquad f_* : \mathrm{QStk}^{\mathrm{Ab}}(X) \to \mathrm{QStk}^{\mathrm{Ab}}(Y)$$

of Proposition 10.1.4.1 are lax symmetric monoidal. In particular, they carry commutative algebra objects of $\mathrm{QStk}^{\mathrm{PSt}}(X)$ and $\mathrm{QStk}^{\mathrm{Ab}}(X)$ to commutative algebra objects of $\mathrm{QStk}^{\mathrm{Ab}}(Y)$ and $\mathrm{QStk}^{\mathrm{Ab}}(Y)$, respectively.

10.1.7 Global Sections of Quasi-Coherent Stacks

Let X be a spectral Deligne-Mumford stack and let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be the functor represented by X (given by $X(R) = \mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, R, \mathsf{X})$). We define a *(additive, stable, prestable, abelian) quasi-coherent stack on* X to be a (additive, stable, prestable, abelian) quasi-coherent stack on the functor X, and we define

$$\mathrm{QStk}^{\mathrm{Add}}(\mathsf{X}) = \mathrm{QStk}^{\mathrm{Add}}(X) \qquad \mathrm{QStk}^{\mathrm{St}}(\mathsf{X}) = \mathrm{QStk}^{\mathrm{St}}(X)$$
$$\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}) = \mathrm{QStk}^{\mathrm{PSt}}(X) \qquad \mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X}) = \mathrm{QStk}^{\mathrm{PSt}}(X).$$

Construction 10.1.7.1 (Global Sections of Quasi-Coherent Stacks)**.** Let S denote the sphere spectrum, so that we have a canonical equivalences

$$\mathrm{QStk}^{\mathrm{PSt}}(\mathrm{Sp\acute{e}t}\, S) \simeq \mathrm{LinCat}_S^{\mathrm{PSt}} \simeq \mathsf{Groth}_\infty \qquad \mathrm{QStk}^{\mathrm{Ab}}(\mathrm{Sp\acute{e}t}\, S) \simeq \mathrm{LinCat}_S^{\mathrm{Ab}} \simeq \mathsf{Groth}_{\mathrm{ab}}\,.$$

For every spectral Deligne-Mumford stack X, there is an essentially unique morphism $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, S$ which determines a representable morphism in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})$. Applying Proposition 10.1.4.1, we obtain direct image functors

$$\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}) \xrightarrow{f_*} \mathrm{QStk}^{\mathrm{PSt}}(\mathrm{Sp\acute{e}t}\, S) \simeq \mathsf{Groth}_\infty \qquad \mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X}) \xrightarrow{f_*} \mathrm{QStk}^{\mathrm{Ab}}(\mathrm{Sp\acute{e}t}\, S) \simeq \mathsf{Groth}_{\mathrm{ab}}\,.$$

We will refer to either of these functors as the *global sections functor* and denote it by $\mathcal{C} \mapsto \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$.

As the notation suggests, one can view $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ as the ∞-category of quasi-coherent sheaves on X with coefficients in the quasi-coherent stack $\mathcal{C}$.

Example 10.1.7.2. Let X be a spectral Deligne-Mumford stack and let $\mathcal{Q}_{\mathsf{X}}^{\mathrm{cn}}$ be the unit object of $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ (see Example 10.1.6.2). Then there is a canonical equivalence of ∞-categories $\mathrm{QCoh}(\mathsf{X}; \mathcal{Q}_{\mathsf{X}}^{\mathrm{cn}}) \simeq \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$.

Variant 10.1.7.3. Let X be a spectral Deligne-Mumford stack and let K be a closed subset of $|\,\mathsf{X}\,|$. For every map $\phi : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$, the inverse image of K in $|\,\mathrm{Sp\acute{e}t}\, A| \simeq |\,\mathrm{Spec}\, A|$ is the vanishing locus of some ideal $I_\phi \subseteq \pi_0 A$. Using Remark **??**, we see that the construction

$$(\phi : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}) \mapsto (\mathrm{Mod}_A^{\mathrm{cn}})^{\mathrm{Nil}(I_\phi)}$$

determines a quasi-coherent stack on X. We will denote this quasi-coherent stack by $\mathcal{Q}_K^{\mathrm{cn}}$. By construction, we have a map of quasi-coherent stacks $\mathcal{Q}_K^{\mathrm{cn}} \to \mathcal{Q}_{\mathsf{X}}^{\mathrm{cn}}$, which induces an equivalence

$$\mathrm{QCoh}(\mathsf{X}; \mathcal{Q}_K^{\mathrm{cn}}) \simeq \mathrm{QCoh}_K(\mathsf{X})^{\mathrm{cn}} \subseteq \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} = \Gamma(\mathsf{X}; \mathcal{Q}_{\mathsf{X}}^{\mathrm{cn}}).$$

Remark 10.1.7.4. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks, and let $\mathcal{C}$ be a prestable or abelian quasi-coherent stack on X. Then we have a canonical equivalence of ∞-categories $\mathrm{QCoh}(\mathsf{X}; \mathcal{C}) \simeq \mathrm{QCoh}(\mathsf{Y}; f_* \mathcal{C})$.

Construction 10.1.7.5. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks and let $\mathcal{C}$ be a prestable or abelian quasi-coherent stack on Y. Then the unit map $u_{\mathcal{C}} : \mathcal{C} \to f_* f^* \mathcal{C}$ induces a functor

$$\mathrm{QCoh}(\mathsf{Y}; \mathcal{C}) \to \mathrm{QCoh}(\mathsf{Y}; f_* f^* \mathcal{C}) \simeq \mathrm{QCoh}(\mathsf{X}; f^* \mathcal{C}).$$

We will refer to this functor as *pullback along* f and denote it by $f^* : \mathrm{QCoh}(\mathsf{Y}; \mathcal{C}) \to \mathrm{QCoh}(\mathsf{X}; f^* \mathcal{C})$. It follows immediately from the definitions that the functor f^* preserves small colimits and therefore admits a right adjoint (see Corollary HTT.5.5.2.9), which we will denote by $f_* : \mathrm{QCoh}(\mathsf{X}; f^* \mathcal{C}) \to \mathrm{QCoh}(\mathsf{Y}; \mathcal{C})$.

We now study the functorial behavior of Construction 10.1.7.5. To simplify the exposition, we will restrict our attention to the setting of prestable quasi-coherent stacks. First, we need to introduce some terminology.

Definition 10.1.7.6. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor and let $u : \mathcal{C} \to \mathcal{D}$ be a morphism of prestable quasi-coherent stacks on X. Then:

(1) We will say that u is *left exact* if, for every connective $\mathbb{E}_\infty$-ring A and every point $\eta \in X(A)$, the induced A-linear functor $u_\eta : \mathcal{C}_\eta \to \mathcal{D}_\eta$ is left exact.

(2) We will say that u is *compact* if, for every connective $\mathbb{E}_\infty$-ring A and every point $\eta \in X(A)$, the induced A-linear functor $u_\eta ; \mathcal{C}_\eta \to \mathcal{D}_\eta$ is compact (that is, u_η admits a right adjoint which commutes with filtered colimits).

Remark 10.1.7.7. Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, and let $u : \mathcal{C} \to \mathcal{D}$ be a morphism in $\mathrm{QStk}^{\mathrm{PSt}}(Y)$. If u is left exact (compact), then $f^*(u)$ is left exact (compact). The converse holds if f induces an effective epimorphism after sheafification with respect to the étale topology (see Propositions D.5.2.1 and D.5.2.2).

Remark 10.1.7.8. Let A be a connective $\mathbb{E}_\infty$-ring and let $u : \mathcal{C} \to \mathcal{D}$ be an A-linear functor between prestable A-linear ∞-categories. Then u is left exact (compact) if and only if it is left exact (compact) when regarded as a morphism of prestable quasi-coherent stacks on $\operatorname{Spec} A$.

Proposition 10.1.7.9. *Let $f : X \to Y$ be a morphism in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ which is representable and flat. Then, for every prestable or abelian quasi-coherent stack $\mathcal{C}$ on Y, the unit map $\mathcal{C} \to f_* f^* \mathcal{C}$ is left exact.*

Proof. We will assume that $\mathcal{C}$ is prestable; the proof in the abelian case is the same. By virtue of Proposition 10.1.4.1, we can reduce to the case where $Y = \operatorname{Spec} A$ is affine. Then X is representable by a spectral Deligne-Mumford stack $(\mathcal{X}, \mathscr{O}_X)$ which is flat over A. For each object $U \in \mathcal{X}$, let $\Gamma(U; f^* \mathcal{C})$ be defined as in the proof of Proposition 10.1.4.1. Let us identify $\mathcal{C}$ and $f_* f^* \mathcal{C}$ with prestable A-linear ∞-categories, and let $\mathcal{X}_0 \subseteq \mathcal{X}$ be the full subcategory spanned by those objects U for which the composite map

$$\mathcal{C} \to f_* f^* \mathcal{C} \to \Gamma(U; f^* \mathcal{C})$$

is left exact. We wish to prove that $\mathcal{X}_0$ contains the final object of $\mathcal{X}$. Since the construction $U \mapsto \Gamma(U; f^* \mathcal{C})$ carries colimits in $\mathcal{X}$ to limits in $\mathrm{LinCat}_A^{\mathrm{lex}}$, the ∞-category $\mathcal{X}_0$ is closed under small colimits. It will therefore suffice to show that $\mathcal{X}_0$ contains all affine objects of $\mathcal{X}$. In other words, we are reduced to proving Lemma 10.1.7.9 in the special case where $X \simeq \operatorname{Spec} B$ is also affine. In this case, we wish to show that the extension of scalars functor $\mathcal{C} \to B \otimes_A \mathcal{C}$ is left exact. Equivalently, we wish to show that the construction $C \mapsto B \otimes_A C$ determines a left exact functor from $\mathcal{C}$ to itself. This is clear, since B is flat over A and can therefore be written as a filtered colimit of free A-modules of finite rank (Proposition HA.7.2.2.15). □

Corollary 10.1.7.10. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks and let $\mathcal{C}$ be a prestable or abelian quasi-coherent stack on Y. If f is flat, then the induced map $f^* : \mathrm{QCoh}(\mathsf{Y}; \mathcal{C}) \to \mathrm{QCoh}(\mathsf{X}; f^* \mathcal{C})$ is left exact.*

Proof. Combine Propositions 10.1.7.9 and 10.3.1.14. □

Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks and let $F : \mathcal{C} \to \mathcal{D}$ be a morphism of prestable quasi-coherent stacks on Y. Then we have a commutative diagram of unit maps

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{u_{\mathcal{C}}} & f_* f^* \mathcal{C} \\ \downarrow F & & \downarrow f_* f^* F \\ \mathcal{D} & \xrightarrow{u_{\mathcal{D}}} & f_* f^* \mathcal{D}. \end{array}$$

Passing to global sections, we obtain a commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{Y}; \mathcal{C}) & \xrightarrow{f^*} & \mathrm{QCoh}(\mathsf{X}; f^* \mathcal{C}) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{Y}; \mathcal{D}) & \xrightarrow{f^*} & \mathrm{QCoh}(\mathsf{Y}; \mathcal{D}). \end{array}$$

Proposition 10.1.7.11. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks and let $F : \mathcal{C} \to \mathcal{D}$ be a morphism of prestable quasi-coherent stacks on Y. If f is flat and that F is compact, then the diagram of ∞-categories*

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{Y}; \mathcal{C}) & \xrightarrow{F} & \mathrm{QCoh}(\mathsf{Y}; \mathcal{D}) \\ \downarrow{\scriptstyle f^*} & & \downarrow{\scriptstyle f^*} \\ \mathrm{QCoh}(\mathsf{X}; f^* \mathcal{C}) & \xrightarrow{F} & \mathrm{QCoh}(\mathsf{X}; f^* \mathcal{D}) \end{array}$$

is right adjointable.

We first verify Proposition 10.1.7.11 in the case where X and Y are affine.

Lemma 10.1.7.12. *Let $\phi : A \to B$ be a flat morphism between connective $\mathbb{E}_\infty$-rings, and let $F : \mathcal{C} \to \mathcal{D}$ be a compact A-linear functor between prestable A-linear ∞-categories. Then the diagram of ∞-categories*

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{F} & \mathcal{D} \\ \downarrow & & \downarrow \\ B \otimes_A \mathcal{C} & \xrightarrow{F} & B \otimes_A \mathcal{D} \end{array}$$

is right adjointable (here the vertical maps are given by extension of scalars).

Proof. Let $G : \mathcal{D} \to \mathcal{C}$ be right adjoint to F. Unwinding the definitions, we wish to show that for every object $D \in \mathcal{D}$, the canonical map $\rho : B \otimes_A G(D) \to G(B \otimes_A D)$ is an equivalence in $\mathcal{C}$. Our assumption that F is compact guarantees that the functor G commutes with filtered colimits. Since B flat over A, we can write B as the colimit of a filtered diagram $\{M_\alpha\}$ where each M_α is a free A-module of finite rank (Proposition HA.7.2.2.15). It follows that ρ can be written as a filtered colimit of maps $\rho_\alpha : M_\alpha \otimes_A G(D) \to G(M_\alpha \otimes_A D)$, each of which is an equivalence because the functor G commutes with finite products. □

Proof of Proposition 10.1.7.11. We first treat the case where the morphism f is étale. Write $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathsf{Y}})$. For each object $U \in \mathcal{Y}$, define $\Gamma(U; \mathcal{C})$ and $\Gamma(U; \mathcal{D})$ as in the proof of Proposition 10.1.4.1. Let us say that a morphism $u : U \to V$ in $\mathcal{Y}$ is *good* if the diagram

$$\begin{array}{ccc} \Gamma(V; \mathcal{C}) & \xrightarrow{F} & \Gamma(V; \mathcal{D}) \\ \downarrow{\scriptstyle u^*} & & \downarrow{\scriptstyle u^*} \\ \Gamma(U; \mathcal{C}) & \xrightarrow{F} & \Gamma(U; \mathcal{D}) \end{array}$$

is right adjointable. We now proceed in several steps:

(*a*) If $U, V \in \mathcal{Y}$ are affine, then any morphism $u : U \to V$ is good. This follows from Lemma 10.1.7.12.

(b) Suppose we are given a small diagram $\{U_\alpha\}$ in the ∞-category $\mathcal{Y}$ having a colimit U. For each index α, let $u_\alpha : U_\alpha \to U$ denote the tautological map. If each of the transition maps $U_\alpha \to U_\beta$ is good, then each u_α is good. This is a special case of Corollary HA.4.7.4.18 .

(c) Suppose we are given morphisms $\{u_\alpha : U_\alpha \to U\}$ and $v : U \to V$ in the ∞-category $\mathcal{Y}$, where the morphisms u_α are good and the induced map $\coprod U_\alpha \to U$ is an effective epimorphism. Then v is good if and only if each composition $v \circ u_\alpha$ is good.

Let us say that an object $V \in \mathcal{Y}$ is *good* if, for every affine object $U \in \mathcal{Y}$, every morphism $U \to V$ is good.

(d) Every affine object of $\mathcal{Y}$ is good: this is an immediate consequence of (a).

(e) Let $v : U \to V$ be a morphism in $\mathcal{Y}$. If U and V are good, then v is good. To prove this, choose a covering $\{u_\alpha : U_\alpha \to U\}$ where each U_α is affine. Our assumption that U is good now implies that each u_α is good. Our assumption that V is good guarantees that each composition $v \circ u_\alpha$ is good. Applying (c), we deduce that v is good.

(f) Let $\{V_\alpha\}$ be a small diagram in $\mathcal{Y}$ having a colimit V, and suppose that each V_α is good. Then V is good. To prove this, choose an arbitrary map $v : U \to V$ where U is affine; we wish to show that v is good. Choose a covering $\{u_\beta : U_\beta \to U\}$, where each U_β is affine and each composition $v \circ u_\beta$ factors as a composition $U_\beta \xrightarrow{v_\beta} V_\alpha \to V$ for some index α. Our assumption that V_α is good then guarantees that v_β is good. Using (b) and (e), we deduce that the tautological map $V_\alpha \to V$ is good, so that $v \circ u_\beta$ is good. It follows from (a) that each of the maps u_β is good. Applying (c), we deduce that v is good.

(g) Every object of $\mathcal{Y}$ is good: this follows from (d) and (f), together with Proposition 1.4.7.9.

(h) Every morphism in $\mathcal{Y}$ is good: this follows from (e) and (g).

We now prove Proposition 10.1.7.11 for a general flat morphism $f : \mathsf{X} \to \mathsf{Y}$. Choose a mutually surjective collection étale morphisms $u_\alpha : \mathsf{X}_\alpha \to \mathsf{X}$, where each X_α is affine and each of the composite maps $\mathsf{X}_\alpha \xrightarrow{u_\alpha} \mathsf{X} \xrightarrow{f} \mathsf{Y}$ factors through some étale morphism $v_\alpha : \mathsf{Y}_\alpha \to \mathsf{Y}$, where Y_α is affine. For each index α, we have a commutative diagram of ∞-categories

$$\begin{array}{ccc}
\mathrm{QCoh}(\mathsf{Y};\mathcal{C}) & \xrightarrow{F} & \mathrm{QCoh}(\mathsf{Y};\mathcal{D}) \\
\downarrow{\scriptstyle f^*} & & \downarrow{\scriptstyle f^*} \\
\mathrm{QCoh}(\mathsf{X}; f^*\mathcal{C}) & \xrightarrow{F} & \mathrm{QCoh}(\mathsf{X}; f^*\mathcal{D}) \\
\downarrow{\scriptstyle u_\alpha^*} & & \downarrow{\scriptstyle u_\alpha^*} \\
\mathrm{QCoh}(\mathsf{X}_\alpha; u_\alpha^* f^*\mathcal{C}) & \xrightarrow{F} & \mathrm{QCoh}(\mathsf{X}_\alpha; u_\alpha^* f^*\mathcal{D}).
\end{array}$$

Applying (h) to the spectral Deligne-Mumford stack X, we see that the lower square in this diagram is right adjointable. Since the morphisms u_α are mutually surjective, the pullback functors $u_\alpha^* : \mathrm{QCoh}(\mathsf{X}; f^*\mathcal{C}) \to \mathrm{QCoh}(\mathsf{X}; u_\alpha^* f^*\mathcal{C})$ are mutually conservative. Consequently, to show that the upper square is right adjointable, it will suffice to show that the outer rectangle is right adjointable. Equivalently, we are reduced to showing that the outer rectangle in the diagram

$$\begin{array}{ccc}
\mathrm{QCoh}(\mathsf{Y};\mathcal{C}) & \xrightarrow{F} & \mathrm{QCoh}(\mathsf{Y};\mathcal{D}) \\
\downarrow{\scriptstyle v_\alpha^*} & & \downarrow{\scriptstyle f^*} \\
\mathrm{QCoh}(\mathsf{Y}_\alpha; v_\alpha^*\mathcal{C}) & \xrightarrow{F} & \mathrm{QCoh}(\mathsf{Y}_\alpha; v_\alpha^*\mathcal{D}) \\
\downarrow & & \downarrow{\scriptstyle v_\alpha^*} \\
\mathrm{QCoh}(\mathsf{X}_\alpha; u_\alpha^* f^*\mathcal{C}) & \xrightarrow{F} & \mathrm{QCoh}(\mathsf{X}_\alpha; u_\alpha^* f^*\mathcal{D}).
\end{array}$$

Applying (h) again, we see that the upper square is right adjointable, and are therefore reduced to verifying the right adjointability of the lower square. In other words, we may replace X by X_α and Y by Y_α, and thereby reduce to the case where $\mathsf{Y} \simeq \operatorname{Spét} A$ and $\mathsf{X} \simeq \operatorname{Spét} B$ are affine. $\square$

Proposition 10.1.7.13. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks and let $F : \mathcal{C} \to \mathcal{D}$ be a morphism of prestable quasi-coherent stacks on Y. Suppose that F is left exact and that, for every morphism $\operatorname{Spét} R \to \mathsf{Y}$, the fiber product $\mathsf{X} \times_{\mathsf{Y}} \operatorname{Spét} R$ is a quasi-compact, quasi-separated spectral algebraic space. Then the diagram of ∞-categories*

$$\begin{array}{ccc}
\mathrm{QCoh}(\mathsf{Y};\mathcal{C}) & \xrightarrow{f^*} & \mathrm{QCoh}(\mathsf{X}; f^*\mathcal{C}) \\
\downarrow{\scriptstyle F} & & \downarrow{\scriptstyle F} \\
\mathrm{QCoh}(\mathsf{Y};\mathcal{D})) & \xrightarrow{f^*} & \mathrm{QCoh}(\mathsf{X}; f^*\mathcal{D})
\end{array}$$

is right adjointable.

We begin by proving Proposition 10.1.7.13 in the special case where Y is affine.

Lemma 10.1.7.14. *Let R be a connective $\mathbb{E}_\infty$-ring and let X be a quasi-compact, quasi-separated spectral algebraic space equipped with a map $f : \mathsf{X} \to \operatorname{Sp\acute{e}t} R$. Let $\mathcal{C}$ and $\mathcal{D}$ be prestable R-linear ∞-categories and let $f^* \mathcal{C}$ and $f^* \mathcal{D}$ denote the associate prestable quasi-coherent stacks on X. Suppose that $F : \mathcal{C} \to \mathcal{D}$ is a left exact R-linear functor. Then the diagram of ∞-categories*

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{f^*} & \operatorname{QCoh}(\mathsf{X}; f^* \mathcal{C}) \\ \downarrow F & & \downarrow F \\ \mathcal{D} & \xrightarrow{f^*} & \operatorname{QCoh}(\mathsf{X}; f^* \mathcal{D}) \end{array}$$

is right adjointable.

Proof. Write $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$. For each object $U \in \mathcal{X}$, set $\mathsf{X}_U = (\mathcal{X}_{/U}, \mathscr{O}_{\mathsf{X}}|_U)$, let $f_U : \mathsf{X}_U \to \operatorname{Sp\acute{e}t} R$ be the tautological map, and let

$$\Gamma_{\mathcal{C}}(U; \bullet) : \operatorname{QCoh}(\mathsf{X}_U; f_U^* \mathcal{C}) \to \mathcal{C} \qquad \Gamma_{\mathcal{D}}(U; \bullet) : \operatorname{QCoh}(\mathsf{X}_U; f_U^* \mathcal{D}) \to \mathcal{D}$$

denote the pushforward functors associated to the map f_U. Suppose we are given an object $C \in \operatorname{QCoh}(\mathsf{X}; f^* \mathcal{C})$. For each object $U \in \mathcal{X}$, let C_U denote the image of C in $\operatorname{QCoh}(\mathsf{X}_U; f_U^* \mathcal{C})$ and let $F(C_U) \in \operatorname{QCoh}(\mathsf{X}_U; f_U^* \mathcal{D})$ be the image of C_U under the functor determined by F. Then we have a tautological map $\rho_U : F\Gamma(U; C_U) \to \Gamma(U; F(C_U))$, which is an equivalence whenever $U \in \mathcal{X}$ is affine. Since F is left exact, the collection of those objects $U \in \mathcal{X}$ for which ρ_U is an equivalence is closed under finite colimits. Applying Proposition 2.5.3.5 and Theorem 3.4.2.1, we deduce that ρ_U is an equivalence when U is a final object of $\mathcal{X}$, which is equivalent to the statement of Lemma 10.1.7.14. □

Lemma 10.1.7.15. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks and let $\mathcal{C}$ be a prestable quasi-coherent stack on Y. Suppose that for every morphism $\operatorname{Sp\acute{e}t} R \to \mathsf{Y}$, the fiber product $\mathsf{X} \times_{\mathsf{Y}} \operatorname{Sp\acute{e}t} R$ is a quasi-compact, quasi-separated spectral algebraic space. Then the unit map $u : \mathcal{C} \to f_* f^* \mathcal{C}$ is a compact morphism of prestable quasi-coherent stacks on Y.*

Proof. The assertion is local on Y. We may therefore assume without loss of generality that $\mathsf{Y} = \operatorname{Sp\acute{e}t} R$ is affine, so that X is a quasi-compact, quasi-separated spectral algebraic space. Write $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$, and for each $U \in \mathcal{X}$ define $f_U : \mathsf{X}_U \to \operatorname{Sp\acute{e}t} R$ and $\Gamma(U; \bullet) : \operatorname{QCoh}(\mathsf{X}_U; f_U^* \mathcal{C}) \to \mathcal{C}$ as in the proof of Lemma 10.1.7.14. Let $\mathcal{X}_0 \subseteq \mathcal{X}$ be the full subcategory spanned by those objects U for which the functor $\Gamma(U; \bullet)$ commutes with small filtered colimits. Since $\mathcal{C}$ is a Grothendieck prestable ∞-category, the formation of filtered colimits in $\mathcal{C}$ commutes with finite colimits, so that $\mathcal{X}_0$ is closed under finite colimits in $\mathcal{X}$. Note that if $U \in \mathcal{X}$ is affine, then $\Gamma(U; \bullet)$ is equivalent to the forgetful functor $\operatorname{LMod}_A(\mathcal{C}) \to \mathcal{C}$ for some connective $\mathbb{E}_\infty$-algebra A over R, so that $\Gamma(U; \bullet)$ commutes with all small colimits; in particular, we have $U \in \mathcal{X}_0$. Applying Proposition 2.5.3.5 and Theorem 3.4.2.1, we deduce that $\mathcal{X}_0$ contains the final object of $\mathcal{X}$, so that the unit map $\mathcal{C} \to f_* f^* \mathcal{C}$ is compact as desired. □

Proof of Proposition 10.1.7.13. Set $\mathcal{C}' = f_* f^* \mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{Y})$ and $\mathcal{D}' = f_* f^* \mathcal{D} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{Y})$, so that we have a commutative diagram

$$\begin{array}{ccc} \mathcal{C} & \longrightarrow & \mathcal{C}' \\ \downarrow & & \downarrow \\ \mathcal{D} & \longrightarrow & \mathcal{D}' \end{array}$$

in $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{Y})$ where the horizontal morphisms are compact (Lemma 10.1.7.15). Choose a mutually surjective collection of étale morphisms $u_\alpha : \mathsf{Y}_\alpha \to \mathsf{Y}$, where each Y_α is affine, and consider the diagrams

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{Y}; \mathcal{C}) & \longrightarrow & \mathrm{QCoh}(\mathsf{Y}; \mathcal{C}') \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{Y}; \mathcal{D}) & \longrightarrow & \mathrm{QCoh}(\mathsf{Y}; \mathcal{D}') \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{Y}_\alpha; u_\alpha^* \mathcal{D}) & \longrightarrow & \mathrm{QCoh}(\mathsf{Y}_\alpha, u_\alpha^* \mathcal{D}'). \end{array}$$

We wish to show that the upper square is right adjointable. Note that each of the lower squares are right adjointable (Proposition 10.1.7.11). Since the pullback functors $u_\alpha^* : \mathrm{QCoh}(\mathsf{Y}; \mathcal{D}) \to \mathrm{QCoh}(\mathsf{Y}_\alpha; u_\alpha^* \mathcal{D})$ are mutually conservative, it will suffice to show that the outer rectangles are right adjointable. Equivalently, we are reduced to proving the right adjointability of the outer rectangle in the diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{Y}; \mathcal{C}) & \longrightarrow & \mathrm{QCoh}(\mathsf{Y}; \mathcal{C}') \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{Y}_\alpha; u_\alpha^*) & \longrightarrow & \mathrm{QCoh}(\mathsf{Y}_\alpha; u_\alpha^* \mathcal{C}') \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{Y}_\alpha; u_\alpha^* \mathcal{D}) & \longrightarrow & \mathrm{QCoh}(\mathsf{Y}_\alpha, u_\alpha^* \mathcal{D}'). \end{array}$$

Here the upper square is right adjointable by virtue of Proposition 10.1.7.11, so it will suffice to show that the lower square is also right adjointable. In other words, to prove Proposition 10.1.7.13, we can replace Y by Y_α and thereby reduce to the case where Y is affine, in which case the desired result follows from Lemma 10.1.7.14. □

We close this section by establishing a relative version of Theorem 5.6.6.1:

Proposition 10.1.7.16. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a surjective proper morphism of spectral Deligne-Mumford stacks and let $\mathsf{X}_\bullet$ be the Čech nerve of f. For each $n \geqslant 0$, let $f_n : \mathsf{X}_n \to \mathsf{Y}$ denote the associated projection map. Assume that Y is locally Noetherian and that the structure sheaf $\mathscr{O}_{\mathsf{Y}}$ is truncated. Then, for any stable quasi-coherent stack $\mathcal{C}$ on Y, the pullback functors f_n^* induces an equivalence of ∞-categories $\mathrm{QCoh}(\mathsf{Y}; \mathcal{C}) \to \mathrm{Tot}\,\mathrm{QCoh}(\mathsf{X}_n; f_n^* \mathcal{C})$.*

Proof. Let us regard $\mathsf{X}_\bullet$ as an *augmented* simplicial object of SpDM via the convention $\mathsf{X}_{-1} = \mathsf{Y}$. We wish to show that the augmented cosimplicial ∞-category $\mathrm{QCoh}(\mathsf{X}_\bullet; f_n^* \mathcal{C})$ determines a limit diagram $\mathbf{\Delta}_+ \to \widehat{\mathcal{C}\mathrm{at}}_\infty$. Using (the dual of) Corollary HA.4.7.5.3 , it will suffice to verify the following:

(*a*) The adjunction $\mathrm{QCoh}(\mathsf{Y}; \mathcal{C}) \underset{f_*}{\overset{f^*}{\rightleftarrows}} \mathrm{QCoh}(\mathsf{X}; f^* \mathcal{C})$ is comonadic.

(*b*) The augmented cosimplicial ∞-category $\mathrm{QCoh}(\mathsf{X}_\bullet; f_\bullet^* \mathcal{C})$ satisfies the Beck-Chevalley condition. More precisely, for every morphism $\alpha : [m] \to [n]$ in $\mathbf{\Delta}_+$, the diagram of pullback functors

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{X}_m; f_m^* \mathcal{C}) & \longrightarrow & \mathrm{QCoh}(\mathsf{X}_{m+1}; f_{m+1}^* \mathcal{C}) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{X}_n; f_n^* \mathcal{C}) & \longrightarrow & \mathrm{QCoh}(\mathsf{X}_{n+1}; f_{n+1}^* \mathcal{C}) \end{array}$$

is right adjointable.

Assertion (*b*) follows from Propositions 10.1.4.1 and 10.1.7.13. To prove (*a*), it will suffice (by virtue of Theorem HA.4.7.3.5) to show that the functor $f^* : \mathrm{QCoh}(\mathsf{Y}; \mathcal{C}) \to \mathrm{QCoh}(\mathsf{X}; f^* \mathcal{C})$ is conservative and preserves totalizations of f^*-split cosimplicial objects of $\mathrm{QCoh}(\mathsf{Y}; \mathcal{C})$. Both of these assertions can be tested locally on Y. We may assume without loss of generality that $\mathsf{Y} = \mathrm{Spét}\, R$ is affine. Let us abuse notation by identifying $\mathcal{C}$ with the corresponding R-linear ∞-category.

We proceed as in the proof of Proposition 5.6.6.4. We first show that the functor f^* is conservative. Fix an object $C \in \mathcal{C}$, and suppose that $f^* C \in \mathrm{QCoh}(\mathsf{X}; f^* \mathcal{C})$ vanishes. $\mathcal{E} \subseteq \mathrm{Mod}_R$ be the full subcategory spanned by those R-modules M such that $M \otimes_R C \simeq 0$. Let us regard $\mathrm{QCoh}(\mathsf{X}; f^* \mathcal{C})$ as tensored over the ∞-category $\mathrm{QCoh}(\mathsf{X})$ of quasi-coherent sheaves on X (see §10.2). For each $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$, we have $\Gamma(\mathsf{X}; \mathscr{F}) \otimes_R C \simeq f_*(\mathscr{F} \otimes f^* C) \simeq 0$, so that $\Gamma(\mathsf{X}; \mathscr{F})$ belongs to $\mathcal{E}$. Since $\mathcal{E}$ is evidently a stable subcategory of Mod_R which is closed under retracts, Proposition 5.6.6.3 guarantees that $R \in \mathcal{E}$, so that $C \simeq R \otimes_R C \simeq 0$.

Now suppose that $D^\bullet$ is an f^*-split cosimplicial object of $\mathcal{C}$. Let $\mathcal{E}' \subseteq \mathrm{Mod}_R$ be the full subcategory spanned by those R-modules M for which the tautological map $f^*(\mathrm{Tot}(M \otimes_R$

$C^\bullet)) \to \mathrm{Tot}(f^*(M \otimes_R C^\bullet))$ is an equivalence in $\mathrm{QCoh}(\mathsf{X}; f^*\mathcal{C})$. Note that for each $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$, the cosimplicial object $\Gamma(\mathsf{X}; \mathscr{F}) \otimes_R C^\bullet \simeq \Gamma(\mathsf{X}; \mathscr{F} \otimes f^* C^\bullet)$ is split, so that $\Gamma(\mathsf{X}; \mathscr{F})$ belongs to $\mathcal{E}'$. Because $\mathcal{E}'$ is a stable subcategory of Mod_R which is closed under retracts, Proposition 5.6.6.3 guarantees that $R \in \mathcal{E}'$, so that the canonical map $f^*(\mathrm{Tot}(C^\bullet)) \to \mathrm{Tot}(f^* C^\bullet)$ is an equivalence as desired. □

10.2 Quasi-Coherent Stacks on Spectral Algebraic Spaces

Let X be a spectral Deligne-Mumford stack and let $\mathrm{QCoh}(\mathsf{X}; \bullet) : \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}) \to \mathsf{Groth}_\infty$ be the global sections functor of Construction 10.1.7.1. It follows from Remark 10.1.6.10 that $\mathrm{QCoh}(\mathsf{X}; \bullet)$ is a lax symmetric monoidal functor. In particular, it carries the unit object $\mathcal{Q}^{\mathrm{cn}}_{\mathsf{X}}$ to a commutative algebra object $\mathrm{QCoh}(\mathsf{X}; \mathcal{Q}^{\mathrm{cn}}_{\mathsf{X}})$ of Groth_∞. Unwinding the definitions, we see that this commutative algebra object can be identified with the ∞-category $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ of connective quasi-coherent sheaves on X (equipped with its usual symmetric monoidal structure). Consequently, we can promote the global sections functor $\mathrm{QCoh}(\mathsf{X}; \bullet)$ to a functor

$$\begin{aligned} \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}) & \simeq \mathrm{Mod}_{\mathcal{Q}^{\mathrm{cn}}_{\mathsf{X}}}(\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})) \\ & \xrightarrow{\mathrm{QCoh}(\mathsf{X};\bullet)} \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X}; \mathcal{Q}^{\mathrm{cn}}_{\mathsf{X}})}(\mathsf{Groth}_\infty) \\ & \simeq \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty). \end{aligned}$$

We will abuse notation by denoting this functor also by $\mathcal{C} \mapsto \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$. We can describe the situation more informally as follows: for every quasi-coherent stack $\mathcal{C}$ on X, the ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ of global sections of $\mathcal{C}$ is a Grothendieck prestable ∞-category which is tensored over ∞-category $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ of connective quasi-coherent sheaves on X, and the action

$$\otimes : \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \times \mathrm{QCoh}(\mathsf{X}; \mathcal{C}) \to \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$$

preserves small colimits separately in each variable.

Our goal in this section is to show that, under some mild hypotheses on X, a prestable quasi-coherent stack $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ can be recovered from the ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ (as an ∞-category which is tensored over $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$). Our main results can be formulated as follows:

Theorem 10.2.0.1. *Let X be a spectral Deligne-Mumford stack, and suppose that X is quasi-geometric (that is, that X is quasi-compact and the diagonal map $\delta : \mathsf{X} \to \mathsf{X} \times \mathsf{X}$ is quasi-affine; see Definition 9.1.4.1). Then the global sections functor*

$$\mathrm{QCoh}(\mathsf{X}; \bullet) : \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}) \to \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)$$

is fully faithful.

Theorem 10.2.0.2. *Let X be a quasi-compact, quasi-separated spectral algebraic space. Then the global sections functor*

$$\mathrm{QCoh}(\mathsf{X}; \bullet) : \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}) \to \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)$$

is an equivalence of ∞-categories.

Corollary 10.2.0.3. *Let $f : X \to Y$ be a morphism in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ which is representable by quasi-compact, quasi-separated spectral algebraic spaces. Then the direct image functor f_* of Proposition 10.1.4.1 induces an equivalence of ∞-categories*

$$\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}) \to \mathrm{Mod}_{f_* \mathcal{Q}^{\mathrm{cn}}_{\mathsf{X}}}(\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{Y})).$$

Proof. Using Proposition 10.1.4.1, we can reduce to the case where Y is affine, in which case the desired result reduces to Theorem 10.2.0.2. □

10.2.1 Base Change Along Quasi-Affine Morphisms

In §C.4, we proved that the ∞-category Groth_∞ of Grothendieck prestable ∞-categories admits a symmetric monoidal structure. For every spectral Deligne-Mumford stack, we can regard the ∞-category $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ as a commutative algebra object of the ∞-category Groth_∞ and study the associated ∞-category of modules $\mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)$. However, since the ∞-category Groth_∞ generally does not admit colimits, the study of modules in Groth_∞ can be somewhat delicate. For example, it is not clear that the ∞-category $\mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)$ inherits a symmetric monoidal structure: the standard procedure for constructing a tensor product $\mathcal{M} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{N}$ involves forming the geometric realization of a two-sided bar construction $\mathrm{Bar}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathcal{M}, \mathcal{N})_\bullet$, which might fail to exist.

One way to address this concern is to embed the ∞-category Groth_∞ of Grothendieck prestable ∞-categories into some larger symmetric monoidal ∞-category $\mathcal{E}$ which does admit small colimits, and for which the tensor product $\otimes : \mathcal{E} \times \mathcal{E} \to \mathcal{E}$ preserves small colimits separately in each variable. In this case, the formation of relative tensor products

$$\mathcal{M} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{N} \simeq |\, \mathrm{Bar}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathcal{M}, \mathcal{N})_\bullet|$$

is a perfectly well-behaved operation *in the larger ∞-category $\mathcal{E}$*, and one can hope that in good cases the resulting object is actually again a Grothendieck prestable ∞-category.

There are (at least) two natural candidates for the ∞-category $\mathcal{E}$:

(*a*) We can take $\mathcal{E}$ to be the ∞-category the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{Add}} \simeq \mathrm{Mod}_{\mathrm{Sp}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ of additive presentable ∞-categories (see Corollary C.4.1.3), equipped with the symmetric monoidal structure of Corollary C.4.1.4.

(b) We can take $\mathcal{E}$ to be the ∞-category Groth_∞^+ of Remark **??**, whose objects are pairs $(\mathcal{C}, \mathcal{C}_{\geqslant 0})$ where $\mathcal{C}$ is a presentable stable ∞-category and $\mathcal{C}_{\geqslant 0} \subseteq \mathcal{C}$ is a full subcategory which is closed under small colimits and extensions. The ∞-category Groth_∞^+ can be regarded as an enlargement of Groth_∞ (Remark **??**) which admits small limits and colimits (Remark C.3.1.7) and inherits a tensor product (Remark C.4.2.3) which preserves small colimits separately in each variable (Proposition C.4.5.3).

In order to prove Theorems 10.2.0.1 and 10.2.0.2, we will need to study relative tensor products of the form $\mathrm{QCoh}^{\mathrm{cn}}(\mathsf{U}) \times_{\mathrm{QCoh}^{\mathrm{cn}}(\mathsf{X})} \mathcal{C}$, where $f : \mathsf{U} \to \mathsf{X}$ is a quasi-affine morphism of spectral Deligne-Mumford stacks. We now show that this construction is well-behaved *if* we adopt convention (b): that is, if we form the relative tensor product $\mathrm{QCoh}^{\mathrm{cn}}(\mathsf{U}) \times_{\mathrm{QCoh}^{\mathrm{cn}}(\mathsf{X})} \mathcal{N}$ in the ∞-category Groth_∞^+, then it belongs to the essential image of the fully faithful embedding $\mathsf{Groth}_\infty \hookrightarrow \mathsf{Groth}_\infty^+$ (Proposition 10.2.1.3). Beware that this is *a priori* different from the relative tensor product in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{Add}}$ of presentable additive ∞-categories: see Warnings 10.2.5.4 and 10.2.1.5. However, we will see later that there is no difference when X is a quasi-compact algebraic space with affine diagonal (Proposition 10.2.6.7).

Construction 10.2.1.1. Let $f : \mathsf{U} \to \mathsf{X}$ be a quasi-affine morphism of spectral Deligne-Mumford stacks and let $\mathcal{C}$ be a Grothendieck prestable ∞-category equipped with an action of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ (which we view as a commutative algebra object of the ∞-category Groth_∞). Then the stable ∞-category $\mathrm{Sp}(\mathcal{C})$ inherits an action of the ∞-category $\mathrm{QCoh}(\mathsf{X})$ (viewed as a commutative algebra object in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ of presentable stable ∞-categories).

Set $\mathscr{A} = f_* \mathscr{O}_{\mathsf{U}} \in \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{X}))$, let $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))$ denote the ∞-category of $\mathscr{A}$-module objects of $\mathrm{Sp}(\mathcal{C})$, and let $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$ be the smallest full subcategory of $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))$ which contains the essential image of the composite functor

$$\rho : \mathcal{C} \xrightarrow{\Sigma^\infty} \mathrm{Sp}(\mathcal{C}) \xrightarrow{\mathscr{A} \otimes} \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))$$

and is closed under small colimits and extensions. Using Proposition HA.1.4.4.11 , we deduce that the stable ∞-category $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))$ admits an accessible t-structure

$$(\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}, \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\leqslant 0}).$$

Note that an object $X \in \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))$ belongs to $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\leqslant 0}$ if and only if the abelian groups

$$\mathrm{Ext}^n_{\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))}(\rho(C), X) \quad \simeq \quad \mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(\Sigma^\infty C, X)$$

vanish for $n < 0$: that is, if and only if the image of X in $\mathrm{Sp}(\mathcal{C})$ belongs to $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$. Since the forgetful functor $\theta : \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C})) \to \mathrm{Sp}(\mathcal{C})$ commutes with filtered colimits and the t-structure on $\mathrm{Sp}(\mathcal{C})$ is compatible with filtered colimits, it follows that the t-structure $(\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}, \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\leqslant 0})$ is also compatible with filtered colimits. In particular, $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$ is a Grothendieck prestable ∞-category. Moreover, the intersection $\bigcap_{n \geqslant 0} \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\leqslant -n}$ is the inverse image under θ of the intersection $\bigcap_{n \geqslant 0} \mathrm{Sp}(\mathcal{C})_{\leqslant -n}$. Since the t-structure on $\mathrm{Sp}(\mathcal{C})$ is right complete and the functor θ is conservative, it follows that the intersection $\bigcap_{n \geqslant 0} \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\leqslant -n}$ consists only of zero object of $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))$. Applying Proposition HA.1.2.1.19 , we deduce that the t-structure $(\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}, \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\leqslant 0})$ is right complete: that is, we can identify $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))$ with the stabilization of the Grothendieck prestable ∞-category $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))$.

Warning 10.2.1.2. In the situation of Construction 10.2.1.1, the full subcategory

$$\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\leqslant 0} \subseteq \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))$$

is the inverse image of $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ under the forgetful functor $\theta : \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C})) \to \mathrm{Sp}(\mathcal{C})$. However, it is usually *not* true that we can identify $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$ with the inverse image of $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ under the functor θ. In general, this holds only when the algebra object $\mathscr{A} \in \mathrm{QCoh}(\mathsf{X})$ is connective: that is, when the morphism $f : \mathsf{U} \to \mathsf{X}$ is assumed to be affine.

Proposition 10.2.1.3. *Let $f : \mathsf{U} \to \mathsf{X}$ be a quasi-affine map and let $\mathcal{C}$ be a Grothendieck prestable ∞-category equipped with an action of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$. Then:*

(*a*) *The pair $(\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C})), \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0})$ appearing Construction 10.2.1.1 can be identified with the relative tensor product*

$$(\mathrm{QCoh}(\mathsf{U}), \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}}) \otimes_{(\mathrm{QCoh}(\mathsf{X}), \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}})} (\mathrm{Sp}(\mathcal{C}), \mathrm{Sp}(\mathcal{C})_{\geqslant 0})$$

in the ∞-category $\mathsf{Groth}_{\infty}^{+}$.

(*b*) *The Grothendieck prestable ∞-category $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$ appearing in Construction 10.2.1.1 can be identified with the geometric of the two-sided bar construction $\mathrm{Bar}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}}, \mathcal{C})$ in the ∞-category Groth_{∞}; moreover, this geometric realization is preserved by the fully faithful embedding $\mathsf{Groth}_{\infty} \hookrightarrow \mathsf{Groth}_{\infty}^{+}$ of Remark* **??**.

Remark 10.2.1.4 (Relative Tensor Products in $\mathsf{Groth}_{\infty}^{+}$)**.** Let $\mathsf{Groth}_{\infty}^{+}$ be the ∞-category introduced in Remark **??**, equipped with the symmetric monoidal structure described in Remark C.4.2.3. Suppose that $(\mathcal{C}, \mathcal{C}_{\geqslant 0})$ is an algebra object of $\mathsf{Groth}_{\infty}^{+}$, and let $(\mathcal{M}, \mathcal{M}_{\geqslant 0})$ and $(\mathcal{N}, \mathcal{N}_{\geqslant 0})$ be right and left modules over $(\mathcal{C}, \mathcal{C}_{\geqslant 0})$, respectively. More concretely, this means that we have the following data:

(*a*) A presentable stable ∞-category $\mathcal{C}$ equipped with a monoidal structure $m : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ which preserves small colimits separately in each variable.

(*b*) A presentable stable ∞-category $\mathcal{M}$ which is right-tensored over $\mathcal{C}$ for which the action $a : \mathcal{M} \times \mathcal{C} \to \mathcal{M}$ preserves small colimits separately in each variable.

(*c*) A presentable stable ∞-category $\mathcal{N}$ which is left-tensored over $\mathcal{C}$ for which the action map $a' : \mathcal{C} \times \mathcal{N} \to \mathcal{N}$ preserves small colimits separately in each variable.

(*d*) Full subcategories

$$\mathcal{M}_{\geqslant 0} \subseteq \mathcal{M} \qquad \mathcal{C}_{\geqslant 0} \subseteq \mathcal{C} \qquad \mathcal{N}_{\geqslant 0} \subseteq \mathcal{N}$$

which are closed under colimits and extensions and satisfy

$$\mathbf{1}_{\mathcal{C}} \in \mathcal{C}_{\geqslant 0} \qquad m(\mathcal{C}_{\geqslant 0} \times \mathcal{C}_{\geqslant 0}) \subseteq \mathcal{C}_{\geqslant 0}$$

$$a(\mathcal{M}_{\geqslant 0} \times \mathcal{C}_{\geqslant 0}) \subseteq \mathcal{M}_{\geqslant 0} \qquad a'(\mathcal{C}_{\geqslant 0} \times \mathcal{N}_{\geqslant 0}) \subseteq \mathcal{N}_{\geqslant 0}.$$

Since the ∞-category $\mathsf{Groth}_{\infty}^{+}$ admits small colimits and the tensor product on $\mathsf{Groth}_{\infty}^{+}$ preserves small colimits separately in each variable, the relative tensor product

$$(\mathcal{M}, \mathcal{M}_{\geqslant 0}) \otimes_{(\mathcal{C}, \mathcal{C}_{\geqslant 0})} (\mathcal{N}, \mathcal{N}_{\geqslant 0})$$

is well-defined, given by the geometric realization (as an object of the ∞-category $\mathsf{Groth}_{\infty}^{+}$) of the two-sided bar construction $\mathrm{Bar}_{(\mathcal{C}, \mathcal{C}_{\geqslant 0})}((\mathcal{M}, \mathcal{M}_{\geqslant 0}), (\mathcal{N}, \mathcal{N}_{\geqslant 0}))_{\bullet}$. Unwinding the definitions, we see that this relative tensor product is given by the pair $(\mathcal{M} \otimes_{\mathcal{C}} \mathcal{N}, \mathcal{E})$, where the relative tensor product $\mathcal{M} \otimes_{\mathcal{C}} \mathcal{N}$ is computed in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ of presentable stable ∞-categories and $\mathcal{E} \subseteq \mathcal{M} \otimes_{\mathcal{C}} \mathcal{N}$ is the smallest full subcategory which is closed under colimits and extensions and contains the essential image of the composite map

$$\mathcal{M}_{\geqslant 0} \times \mathcal{N}_{\geqslant 0} \to \mathcal{M} \times \mathcal{N} \to \mathcal{M} \otimes \mathcal{N} \to \mathcal{M} \otimes_{\mathcal{C}} \mathcal{N}.$$

Proof of Proposition 10.2.1.3. Because f is quasi-affine, the pushforward functor f_* induces an equivalence of ∞-categories $\mathrm{QCoh}(\mathsf{U}) \simeq \mathrm{Mod}_{\mathscr{A}}(\mathrm{QCoh}(\mathsf{X}))$ (Corollary **??**). Applying Theorem HA.4.8.4.6 , we can identify the ∞-category $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))$ with the tensor product

$$\mathrm{QCoh}(\mathsf{U}) \otimes_{\mathrm{QCoh}(\mathsf{X})} \mathrm{Sp}(\mathcal{C})$$

in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ of presentable stable ∞-categories. By virtue of Remark 10.2.1.4, it remains only to prove that $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$ is the smallest full subcategory of $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))$ which is closed under colimits and extensions and contains the essential image of the functor

$$\psi : \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \times \mathcal{C} \to \mathrm{QCoh}(\mathsf{U}) \otimes \mathrm{Sp}(\mathcal{C}) \to \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C})).$$

Here the only nontrivial point is to show that the functor ψ factors through $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$. Fix an object $C \in \mathcal{C}$, and let $\mathrm{QCoh}'(\mathsf{U})$ be the full subcategory of $\mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}}$ spanned by those sheaves $\mathscr{F}$ for which $\psi(\mathscr{F}, C)$ belongs to $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$. Then $\mathrm{QCoh}'(\mathsf{U})$ is closed under colimits and extensions and contains the essential image of the functor $f^*|_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}$. Since f is quasi-affine, Corollary 2.5.6.3 guarantees that $\mathrm{QCoh}'(\mathsf{U}) = \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}}$, as desired. $\square$

Warning 10.2.1.5. Proposition 10.2.1.3 does *not* assert that the ∞-category $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$ is a geometric realization of the bar construction $\mathrm{Bar}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}}, \mathcal{C})$ in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable stable ∞-categories.

Remark 10.2.1.6. In the situation of Proposition 10.2.1.3, the pullback map $f^* : \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \to \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}}$ induces a functor $F : \mathcal{C} \to \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C}$ which admits a right adjoint $G : \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C} \to \mathcal{C}$. We claim that G does not annihilate any nonzero objects of $\mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C}$. To prove this, we let $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))$ be as in Construction 10.2.1.1, so that we have a commutative diagram

$$\begin{array}{ccc} \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C})) & \longrightarrow & \mathrm{Sp}(\mathcal{C}) \\ \downarrow \tau_{\geqslant 0} & & \downarrow \Omega^{\infty} \\ \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C} & \xrightarrow{G} & \mathcal{C}. \end{array}$$

Any object X of the tensor product $\mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C}$ satisfying $GX \simeq 0$ can be identified with an object $\overline{X} \in \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$ which is annihilated by the composite functor $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C})) \to \mathrm{Sp}(\mathcal{C}) \xrightarrow{\Omega^{\infty}} \mathcal{C}$. It follows that we can identify $\overline{X}$ with a left $\mathscr{A}$-module object of the subcategory $\mathrm{Sp}(\mathcal{C})_{\leqslant -1} \subseteq \mathrm{Sp}(\mathcal{C})$, so that $\overline{X}$ belongs to the intersection $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0} \cap \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\leqslant -1}$ and is therefore a zero object.

Example 10.2.1.7 (Pullback Diagrams)**.** Suppose we are given a diagram of spectral Deligne-Mumford stacks σ :

$$\begin{array}{ccc} \mathsf{U}' & \longrightarrow & \mathsf{U} \\ \downarrow f' & & \downarrow f \\ \mathsf{X}' & \longrightarrow & \mathsf{X} \end{array}$$

where the morphism f is quasi-affine. Proposition 10.2.1.3 guarantees the existence of a relative tensor product $\mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathrm{QCoh}(\mathsf{X}')^{\mathrm{cn}}$ in the ∞-category Groth_{∞} of Grothendieck prestable ∞-categories, and the diagram σ determines a colimit-preserving functor

$$F : \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathrm{QCoh}(\mathsf{X}')^{\mathrm{cn}} \to \mathrm{QCoh}(\mathsf{U}')^{\mathrm{cn}}.$$

If σ is a pullback diagram, then F is an equivalence. To prove this, it suffices to verify conditions (a) and (b) of Remark C.3.1.8:

- (a) The induced functor of stable ∞-categories $\mathrm{QCoh}(\mathsf{U}) \otimes_{\mathrm{QCoh}(\mathsf{X})} \mathrm{QCoh}(\mathsf{X}') \to \mathrm{QCoh}(\mathsf{U}')$ is an equivalence; this is a special case of Corollary 6.3.4.7.

- (b) The right adjoint to F does not annihilate any nonzero objects of $\mathrm{QCoh}(\mathsf{U}')^{\mathrm{cn}}$. By virtue of Remark 10.2.1.6, this is equivalent to the assertion that the pullback functor $f'^* : \mathrm{QCoh}(\mathsf{X}')^{\mathrm{cn}} \to \mathrm{QCoh}(\mathsf{U}')^{\mathrm{cn}}$ admits a right adjoint which does not annihilate any nonzero objects of $\mathrm{QCoh}(\mathsf{U}')^{\mathrm{cn}}$. Note that the right adjoint to f'^* is given by the construction $\mathscr{F} \mapsto \tau_{\geqslant 0} f'_* \mathscr{F}$, which annihilates an object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{U}')^{\mathrm{cn}}$ if and only if the pushforward $f'_* \mathscr{F}$ belongs to $\mathrm{QCoh}(\mathsf{X}')_{\leqslant -1}$. Since f' is quasi-affine, this implies that $\mathscr{F}$ belongs to $\mathrm{QCoh}(\mathsf{U}')_{\leqslant -1}$ (Proposition 2.5.6.2), so that $\mathscr{F} \simeq 0$.

10.2.2 Compatibility with Inverse Limits

We next show that, under mild hypotheses, the relative tensor product of Proposition 10.2.1.3 is compatible with the formation of inverse limits.

Notation 10.2.2.1. Let X be a spectral Deligne-Mumford stack. We let $\mathrm{Mod}^{\mathrm{lex}}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)$ denote the fiber product $\mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty) \times_{\mathsf{Groth}_\infty} \mathsf{Groth}^{\mathrm{lex}}_\infty$. More concretely, the objects of the ∞-category $\mathrm{Mod}^{\mathrm{lex}}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)$ are Grothendieck prestable ∞-categories equipped with an action of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$, and the morphisms in $\mathrm{Mod}^{\mathrm{lex}}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)$ are $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$-linear functors which preserve small colimits and finite limits.

Remark 10.2.2.2. According to Proposition C.3.2.4, the ∞-category $\mathsf{Groth}^{\mathrm{lex}}_\infty$ admits small limits which are preserved by the inclusion functor $\mathsf{Groth}^{\mathrm{lex}}_\infty \hookrightarrow \mathsf{Groth}_\infty$. Combining this observation with Corollary HA.4.2.3.3 , we deduce that $\mathrm{Mod}^{\mathrm{lex}}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)$ admits small limits, which are preserved by the inclusion functor $\mathrm{Mod}^{\mathrm{lex}}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty) \hookrightarrow \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)$ and also by the forgetful functor $\mathrm{Mod}^{\mathrm{lex}}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty) \to \mathsf{Groth}^{\mathrm{lex}}_\infty \subseteq \mathsf{Groth}_\infty$.

Proposition 10.2.2.3. *Let $q : \mathsf{U} \to \mathsf{X}$ be a quasi-affine morphism between spectral Deligne-Mumford stacks. Then:*

(1) *The tensor product construction $\mathcal{C} \mapsto \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C}$ of Proposition 10.2.1.3 carries left exact morphisms in $\mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)$ to left exact morphisms in $\mathrm{Mod}_{\mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)$.*

(2) *The associated functor $\mathrm{Mod}^{\mathrm{lex}}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty) \to \mathrm{Mod}^{\mathrm{lex}}_{\mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)$ preserves small limits.*

Proof. We first prove (1). Let $f : \mathcal{C} \to \mathcal{D}$ be a left exact morphism between $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$-module objects of Groth_∞; we wish to show that the induced map

$$f_{\mathsf{U}} : \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C} \to \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{D}$$

is also left exact. Let $F : \mathrm{Sp}(\mathcal{C}) \to \mathrm{Sp}(\mathcal{D})$ be the map of stable ∞-categories determined by f, which we regard as a morphism of $\mathrm{QCoh}(\mathsf{X})$-module objects of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$. Let $\mathscr{A} \in \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{X}))$ denote the direct image of the structure sheaf of U. Proposition 10.2.1.3 shows that we can identify the induced map $F_{\mathsf{U}} : \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C})) \to \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{D}))$ with the stabilization of the functor f_{U}. To prove that f_{U} is left exact, it will suffice to show that the functor F_{U} is left t-exact (Proposition C.3.2.1). Invoking the definition of the t-structure on $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{D}))$ (see Construction 10.2.1.1), we wish to prove that the composite functor

$$\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\leqslant 0} \subseteq \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C})) \xrightarrow{F_{\mathsf{U}}} \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{D})) \rightarrow \mathrm{Sp}(\mathcal{D})$$

factors through the full subcategory $\mathrm{Sp}(\mathcal{D})_{\leqslant 0} \subseteq \mathrm{Sp}(\mathcal{D})$. This follows immediately from the left exactness of F and the commutativity of the diagram

$$\begin{array}{ccc} \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C})) & \xrightarrow{F_{\mathsf{U}}} & \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{D})) \\ \downarrow & & \downarrow \\ \mathrm{Sp}(\mathcal{C}) & \xrightarrow{F} & \mathrm{Sp}(\mathcal{D}). \end{array}$$

We now prove (2). Note that we have a commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{Mod}^{\mathrm{lex}}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_{\infty}) & \longrightarrow & \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})}(\mathcal{P}\mathrm{r}^{\mathrm{St}}) \\ \downarrow {\scriptstyle \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \bullet} & & \downarrow {\scriptstyle \mathrm{QCoh}(\mathsf{U}) \otimes_{\mathrm{QCoh}(\mathsf{X})} \bullet} \\ \mathsf{Groth}^{\mathrm{lex}}_{\infty} & \longrightarrow & \mathcal{P}\mathrm{r}^{\mathrm{St}} \end{array}$$

where the horizontal maps are given by stabilization. We wish to show that the left vertical map preserves small limits (this is equivalent to assertion (2), since the forgetful functor $\mathrm{Mod}^{\mathrm{lex}}_{\mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}}}(\mathsf{Groth}_{\infty}) \rightarrow \mathsf{Groth}^{\mathrm{lex}}_{\infty}$ is conservative and preserves small limits). Note that the horizontal maps preserve small limits (Corollary C.3.2.5). Moreover, the right vertical map preserves small limits: this follows from the fact that $\mathrm{QCoh}(\mathsf{U})$ can be identified with the module ∞-category $\mathrm{Mod}_{\mathscr{A}}(\mathrm{QCoh}(\mathsf{X}))$ (Corollary **??**) and is therefore dualizable (in fact, self-dual) when viewed as a $\mathrm{QCoh}(\mathsf{X})$-module object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$.

Let $\{\mathcal{C}_{\alpha}\}$ be a small diagram in $\mathrm{Mod}^{\mathrm{lex}}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_{\infty})$ having a limit $\mathcal{C}$; we wish to prove that the canonical map

$$\theta : \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C} \rightarrow \varprojlim_{\alpha} \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C}_{\alpha}$$

is an equivalence of Grothendieck prestable ∞-categories. It follows from the above arguments that θ induces an equivalence after passing to the stabilization of both sides: more concretely, the stabilization of both sides can be identified with the ∞-category $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))$. To complete the proof that θ is an equivalence, it suffices to show that the domain and codomain of θ determine the same t-structure on the stable ∞-category $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))$. This follows immediately from the construction: either t-structure can be characterized by the observation that an object C of $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))$ belongs to $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))_{\leqslant 0}$ if and only if, for each index α, the image of C under the composite functor $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C})) \rightarrow \mathrm{Sp}(\mathcal{C}) \rightarrow \mathrm{Sp}(\mathcal{C}_{\alpha})$ belongs to the subcategory $\mathrm{Sp}(\mathcal{C}_{\alpha})_{\leqslant 0} \subseteq \mathrm{Sp}(\mathcal{C}_{\alpha})$. □

10.2.3 Excision for $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$-Modules

Let X be a spectral Deligne-Mumford stack. It follows from Remark 10.1.2.9 that the theory of prestable quasi-coherent stacks on X satisfies descent for the étale topology, and therefore also with respect to the Nisnevich topology. In particular, it we are given an excision square

$$\begin{array}{ccc} \mathsf{U}' & \longrightarrow & \mathsf{X}' \\ \downarrow & & \downarrow \\ \mathsf{U} & \longrightarrow & \mathsf{X} \end{array}$$

(see Variant 2.5.2.3), then a prestable quasi-coherent stack on X can be recovered from by its restriction to X' and U, together with an identification of their restrictions to U'. The main step in our proof of Theorem 10.2.0.2 is to show that, under some mild assumptions, the theory of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$-module objects of Groth_∞ has the same property.

Proposition 10.2.3.1. *Let X be a quasi-compact, quasi-separated spectral algebraic space and suppose we are given an excision square*

$$\begin{array}{ccc} \mathsf{U}' & \longrightarrow & \mathsf{X}' \\ \downarrow & & \downarrow{\scriptstyle f} \\ \mathsf{U} & \xrightarrow{j} & \mathsf{X} \end{array}$$

where the morphism j is a quasi-compact open immersion and the morphism f is étale and quasi-affine. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category equipped with an action of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$. Then the associated diagram $\overline{\sigma}$:

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{U}')^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C} & \longleftarrow & \mathrm{QCoh}(\mathsf{X}')^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C} \\ \uparrow & & \uparrow \\ \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C} & \longleftarrow & \mathcal{C} \end{array}$$

is a pullback square in the ∞-category $\mathsf{Groth}_\infty^{\mathrm{lex}}$ (hence also in the ∞-category Groth_∞).

The proof of Proposition 10.2.3.1 will require some preliminaries.

Lemma 10.2.3.2. *Let X be a quasi-compact, quasi-separated spectral algebraic space and let $\mathcal{C}$ be a Grothendieck prestable ∞-category equipped with an action of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$, so that the presentable stable ∞-category $\mathrm{Sp}(\mathcal{C})$ inherits an action of $\mathrm{QCoh}(\mathsf{X})$. Let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ be a quasi-coherent sheaf having Tor-amplitude $\leqslant 0$. Then the functor*

$$(\mathscr{F} \otimes \bullet) : \mathrm{Sp}(\mathcal{C}) \to \mathrm{Sp}(\mathcal{C})$$

is left t-exact.

Proof. Let C be an object of $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$; we wish to show that $\mathscr{F} \otimes C$ also belongs to $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$. Using Proposition 9.6.7.1, we can write $\mathscr{F}$ as the colimit of a filtered diagram $\{\mathscr{F}_\alpha\}$, where each $\mathscr{F}_\alpha$ is *perfect* and of Tor-amplitude $\leqslant 0$. The assumption that the prestable ∞-category $\mathcal{C}$ is Grothendieck guarantees that $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$ is closed under filtered colimits in $\mathrm{Sp}(\mathcal{C})$; it will therefore suffice to show that each tensor product $\mathscr{F}_\alpha \otimes C$ belongs to $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$. This is equivalent to the assertion that the groups $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(D, \mathscr{F}_\alpha \otimes C)$ vanish for each $D \in \mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ and each $n < 0$. Since $\mathscr{F}_\alpha$ is perfect, it admits a dual $\mathscr{F}_\alpha^\vee$ in the symmetric monoidal ∞-category $\mathrm{QCoh}(\mathsf{X})$. We are therefore reduced to proving that the groups $\mathrm{Ext}^n_{\mathrm{Sp}(\mathcal{C})}(\mathscr{F}_\alpha^\vee \otimes D, C)$ vanish for $n < 0$. Because C is assumed to belong to $\mathrm{Sp}(\mathcal{C})_{\leqslant 0}$, we are reduced to proving that $\mathscr{F}_\alpha^\vee \otimes D$ belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. This follows from the commutativity of the diagram

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \times \mathcal{C} & \xrightarrow{\otimes} & \mathcal{C} \\ \downarrow{\scriptstyle \mathrm{id} \times \Sigma^\infty} & & \downarrow{\scriptstyle \Sigma^\infty} \\ \mathrm{QCoh}(\mathsf{X}) \times \mathrm{Sp}(\mathcal{C}) & \xrightarrow{\otimes} & \mathrm{Sp}(\mathcal{C}), \end{array}$$

since the assumption that $\mathscr{F}_\alpha$ has Tor-amplitude $\leqslant 0$ is equivalent to the statement that $\mathscr{F}_\alpha^\vee$ is connective. □

Lemma 10.2.3.3. *Let $f : \mathsf{U} \to \mathsf{X}$ be a flat quasi-affine morphism between quasi-compact, quasi-separated spectral algebraic spaces and let $\mathcal{C}$ be a Grothendieck prestable ∞-category equipped with an action of $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{cn}}$. Then the induced map $\mathcal{C} \to \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C}$ is left exact.*

Proof. Let $\mathscr{A} \in \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{X}))$ denote the direct image under f of the structure sheaf of U. Using the description of $\mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C}$ supplied by Proposition 10.2.1.3 and the criterion of Proposition C.3.2.1, we are reduced to showing that the functor

$$(\mathscr{A} \otimes \bullet) : \mathrm{Sp}(\mathcal{C}) \to \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))$$

is left t-exact. Here $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C}))$ is equipped with the t-structure appearing in the proof of Construction 10.2.1.1, so that the forgetful functor $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C})) \to \mathrm{Sp}(\mathcal{C})$ is conservative and left t-exact. It will therefore suffice to show that the formation of tensor product with $\mathscr{A}$ determines a left t-exact functor from $\mathrm{Sp}(\mathcal{C})$ to itself. By virtue of Lemma 10.2.3.2, we are reduced to proving that the quasi-coherent sheaf $\mathscr{A}$ has Tor-amplitude $\leqslant 0$. This assertion can be tested locally on X, so we may assume without loss of generality that $\mathsf{X} \simeq \mathrm{Spét}\, R$ is affine. In this case, we can identify $\mathscr{A}$ with a (nonconnective) $\mathbb{E}_\infty$-algebra A over R, and the assertion that A has Tor-amplitude $\leqslant 0$ is equivalent to the requirement that the construction $M \mapsto A \otimes_R M$ determines a left t-exact functor from the ∞-category Mod_R to itself. Under the identification $\mathrm{Mod}_R \simeq \mathrm{QCoh}(\mathsf{X})$, we can identify this functor which the composition $f_* f^*$. We conclude by observing that the functors f_* and f^* are both left t-exact: in the first case, this is automatic; in the second it follows from our assumption that f is flat. □

Proof of Proposition 10.2.3.1. It follows from Lemma 10.2.3.3 that each of the functors which appear in the diagram $\overline{\sigma}$:

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{U}')^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C} & \longleftarrow & \mathrm{QCoh}(\mathsf{X}')^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C} \\ \uparrow & & \uparrow \\ \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C} & \longleftarrow & \mathcal{C} \end{array}$$

are left exact.

Consequently, the diagram

$$\mathrm{QCoh}(\mathsf{X}')^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C} \to \mathrm{QCoh}(\mathsf{U}')^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C} \leftarrow \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C}$$

admits a limit $\mathcal{D}$ in the ∞-category $\mathsf{Groth}_{\infty}^{\mathrm{lex}}$, and the diagram $\overline{\sigma}$ determines a left exact, colimit-preserving functor $\mathcal{C} \to \mathcal{D}$ which we can identify (using Propositions C.3.1.1 and C.3.2.1) with a t-exact functor from $\mathrm{Sp}(\mathcal{C})$ to $\mathrm{Sp}(\mathcal{D})$. To complete the proof, it will suffice to show that this functor is an equivalence: that is, that the image of $\underline{\sigma}$ under the stabilization functor $\mathsf{Groth}_{\infty}^{\mathrm{lex}} \to \mathcal{P}\mathrm{r}^{\mathrm{St}}$ is a pullback diagram of *stable* ∞-categories.

Let $\mathscr{A} \in \mathrm{QCoh}(\mathsf{X})$ denote the direct image of the structure sheaf of X' and let $\mathscr{B} \in \mathrm{QCoh}(\mathsf{X})$ denote the direct image of the structure sheaf of U. Then $\mathscr{A}$ and $\mathscr{B}$ are commutative algebra objects of $\mathrm{QCoh}(\mathsf{X})$ whose tensor product $\mathscr{A} \otimes \mathscr{B}$ is the direct image of the structure sheaf of U'. The proof of Proposition **??** shows that we can identify the image of $\overline{\sigma}$ under the stabilization functor with the diagram of stable ∞-categories

$$\begin{array}{ccc} \mathrm{LMod}_{\mathscr{A} \otimes \mathscr{B}}(\mathrm{Sp}(\mathcal{C})) & \xleftarrow{\mathscr{B} \otimes} & \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C})) \\ \uparrow{\scriptstyle \mathscr{A} \otimes} & & \uparrow{\scriptstyle \mathscr{A} \otimes} \\ \mathrm{LMod}_{\mathscr{B}}(\mathrm{Sp}(\mathcal{C})) & \xleftarrow{\mathscr{B} \otimes} & \mathrm{Sp}(\mathcal{C}). \end{array}$$

To prove that this diagram is a pullback square, we wish to show that the canonical map

$$u : \mathrm{Sp}(\mathcal{C}) \to \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C})) \times_{\mathrm{LMod}_{\mathscr{A} \otimes \mathscr{B}}(\mathrm{Sp}(\mathcal{C}))} \mathrm{LMod}_{\mathscr{B}}(\mathrm{Sp}(\mathcal{C}))$$

is an equivalence of ∞-categories. Let us identify objects of the codomain of u with triples (M, N, β) where M is a left $\mathscr{A}$-module objects of $\mathrm{Sp}(\mathcal{C})$, N is a left $\mathscr{B}$-module object of $\mathrm{Sp}(\mathcal{C})$, and $\beta : \mathscr{B} \otimes M \simeq \mathscr{A} \otimes N$ is an equivalence of left $\mathscr{A} \otimes \mathscr{B}$-module objects of $\mathrm{Sp}(\mathcal{C})$. Then the functor u admits a right adjoint v, given on objects by the formula

$$v(M, N, \beta) = M \times_{\mathscr{B} \otimes M} N.$$

We first show that u is fully faithful by establishing that the unit map claim that the unit map $\mathrm{id}_{\mathrm{Sp}(\mathcal{C})} \to v \circ u$ is an equivalence of functors from $\mathrm{Sp}(\mathcal{C})$ to itself. For this, it suffices to show that for each object $C \in \mathrm{Sp}(\mathcal{C})$, the diagram

$$\begin{array}{ccc} C & \longrightarrow & \mathscr{A} \otimes C \\ \downarrow & & \downarrow \\ \mathscr{B} \otimes C & \longrightarrow & \mathscr{A} \otimes \mathscr{B} \otimes C \end{array}$$

is a pullback diagram in $\mathrm{Sp}(\mathcal{C})$. Since $\mathrm{Sp}(\mathcal{C})$ is stable, it suffices to show that this diagram is a pushout square. Since the action $\mathrm{QCoh}(\mathsf{X})$ on $\mathrm{Sp}(\mathcal{C})$ preserves colimits in each variable, we are reduced to proving that the diagram

$$\begin{array}{ccc} \mathscr{O}_{\mathsf{X}} & \longrightarrow & \mathscr{A} \\ \downarrow & & \downarrow \\ \mathscr{B} & \longrightarrow & \mathscr{A} \otimes \mathscr{B}, \end{array}$$

is a pushout square in the ∞-category $\mathrm{QCoh}(\mathsf{X})$. Using stability again, we are reduced to proving that this diagram is a pullback square. This follows from our assumption that σ is a pushout diagram (in the ∞-category of spectral Deligne-Mumford stacks which are étale over X).

To complete the proof that the functor u is an equivalence, it will suffice to show that the functor v is conservative. Suppose we are given an object

$$(M, N, \beta) \in \mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C})) \times_{\mathrm{LMod}_{\mathscr{A} \otimes \mathscr{B}}(\mathrm{Sp}(\mathcal{C}))} \mathrm{LMod}_{\mathscr{B}}(\mathrm{Sp}(\mathcal{C}))$$

satisfying $g(M, N, \beta) \simeq 0$. Since j is an open immersion, the commutative algebra object $\mathscr{B} \in \mathrm{QCoh}(\mathsf{X})$ is idempotent. It follows that the canonical map $M \to \mathscr{B} \otimes M$ becomes an equivalence after tensoring with $\mathscr{B}$, so that the projection map $g(M, N, \beta) \to N$ becomes an equivalence after tensoring with $\mathscr{B}$. Since N is a $\mathscr{B}$-module, we deduce that

$$N \simeq \mathscr{B} \otimes N \simeq \mathscr{B} \otimes g(M, N, \beta) \simeq \mathscr{B} \otimes 0 \simeq 0.$$

It follows that $\mathscr{B} \otimes M \simeq \mathscr{A} \otimes N \simeq 0$, so that the projection map $g(M, N, \beta) \to M$ is an equivalence. Since $g(M, N, \beta) \simeq 0$, we deduce that $M \simeq 0$, so that (M, N, β) is a zero object of the ∞-category $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathcal{C})) \times_{\mathrm{LMod}_{\mathscr{A} \otimes \mathscr{B}}(\mathrm{Sp}(\mathcal{C}))} \mathrm{LMod}_{\mathscr{B}}(\mathrm{Sp}(\mathcal{C}))$. □

10.2.4 Proofs of Theorems 10.2.0.1 and 10.2.0.2

Let X be a spectral Deligne-Mumford stack, and suppose that the diagonal $\delta : \mathsf{X} \to \mathsf{X} \times \mathsf{X}$ is quasi-affine. To prove Theorem 10.2.0.1, we must show that every prestable quasi-coherent stack $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathcal{C})$ can be recovered from the ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$: in other words, that the "global sections" of $\mathcal{C}$ determine its "local sections."

Construction 10.2.4.1. Let X be a spectral Deligne-Mumford stack and let $\mathcal{C}$ be a quasi-coherent stack on X. Then we can regard $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ as a module over $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ in the ∞-category Groth_∞. This construction depends functorially on X: if $f : \mathsf{U} \to \mathsf{X}$ is a morphism of spectral Deligne-Mumford stacks, then the unit map

$$\mathrm{QCoh}(\mathsf{X};\mathcal{C}) \to \mathrm{QCoh}(\mathsf{X}; f_* f^* \mathcal{C}) \simeq \mathrm{QCoh}(\mathsf{U}; f^* \mathcal{C})$$

can be regarded as morphism of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$-module objects of Groth_∞. In the special case where f is quasi-affine, Proposition 10.2.1.3 allows us to “extend scalars” to obtain a morphism

$$\theta : \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathrm{QCoh}(\mathsf{X};\mathcal{C}) \to \mathrm{QCoh}(\mathsf{U}; f^* \mathcal{C})$$

of $\mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}}$-module objects of Groth_∞.

Proposition 10.2.4.2. *Let $f : \mathsf{U} \to \mathsf{X}$ be a quasi-affine morphism of spectral Deligne-Mumford stacks and let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$. Then the map*

$$\theta_{\mathcal{C}} : \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathrm{QCoh}(\mathsf{X};\mathcal{C}) \to \mathrm{QCoh}(\mathsf{U}; f^* \mathcal{C})$$

of Construction 10.2.4.1 is an equivalence of Grothendieck prestable ∞-categories.

Proof. Write $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$. For each object $V \in \mathcal{X}$, set $\mathsf{X}_V = (\mathcal{X}_{/V}, \mathscr{O}_{\mathcal{X}}|_V)$, let $g_V : \mathsf{X}_V \to \mathsf{X}$ be the projection map, and let $\mathcal{C}_V \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ be the quasi-coherent stack given by $g_{V*} g_V^* \mathcal{C}$. Let us say that an object $V \in \mathcal{X}$ is *good* if the map $\theta_{\mathcal{C}_V}$ is an equivalence of Grothendieck prestable ∞-categories. To prove Proposition 10.2.4.2, it will suffice to show that the final object of $\mathcal{X}$ is good. In fact, we will prove something stronger: every object of $\mathcal{X}$ is good.

Note that the construction $V \mapsto \mathcal{C}_V$ determines a functor $\mathcal{X}^{\mathrm{op}} \to \mathrm{QStk}^{\mathrm{lex}}(\mathsf{X})$ which preserves small limits. Combining this observation with Propositions 10.2.2.3 and 10.1.3.4, we deduce that the constructions

$$V \mapsto \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathrm{QCoh}(\mathsf{X};\mathcal{C}_V) \qquad V \mapsto \mathrm{QCoh}(\mathsf{U}; f^* \mathcal{C}_V)$$

carry colimits in $\mathcal{X}$ to limits in $\mathsf{Groth}_\infty^{\mathrm{lex}}$. Consequently, the collection of those objects $V \in \mathcal{X}$ for which $\theta_{\mathcal{C}_V}$ is an equivalence is closed under small colimits. Since $\mathcal{X}$ is generated under small colimits by the collection of affine objects of $\mathcal{X}$ (Lemma **??**), we are reduced to proving that every affine object $V \in \mathcal{X}$ is good. Let U_V denote the fiber product $\mathsf{X}_V \times_{\mathsf{X}} \mathsf{U}$, and note that U_V is quasi-affine (since it admits a quasi-affine map to the affine spectral Deligne-Mumford stack X_V). Using Example 10.2.1.7, we can identify the domain of the functor $\theta_{\mathcal{C}_V}$ with the relative tensor product

$$\mathrm{QCoh}(\mathsf{U}_V)^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X}_V)^{\mathrm{cn}}} \mathrm{QCoh}(\mathsf{X};\mathcal{C}_V) \simeq \mathrm{QCoh}(\mathsf{U}_V)^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X}_V)^{\mathrm{cn}}} \mathrm{QCoh}(\mathsf{X}_V; g_V^* \mathcal{C}).$$

Using Proposition 10.1.4.1, we can identify the codomain of $\theta_{\mathcal{C}_V}$ with the ∞-category $\mathrm{QCoh}(\mathsf{U}_V; f_V^* g_V^* \mathcal{C})$, where $f_V : \mathsf{U}_V \to \mathsf{X}_V$ is the projection onto the first factor. We may therefore replace X by X_V, the morphism f by f_V, and the quasi-coherent stack $\mathcal{C}$ by its pullback $g_V^* \mathcal{C}$ and thereby reduce to the case where X is affine.

Since U is quasi-affine, we can cover U by finitely many affine open substacks $\mathsf{U}_1, \ldots, \mathsf{U}_n \subseteq \mathsf{U}$. We now proceed by induction on n. If $n = 1$, then U and X are both affine and the desired result follows immediately from the definitions. If $n > 1$, we let V be open substack of U given by the union of $\{\mathsf{U}_i\}_{2 \leqslant i \leqslant n}$. Applying Proposition 10.2.3.1 to the diagram

$$\begin{array}{ccc} \mathsf{V} \times_{\mathsf{U}} \mathsf{U}_1 & \longrightarrow & \mathsf{U}_1 \\ \downarrow & & \downarrow \\ \mathsf{V} & \longrightarrow & \mathsf{U}, \end{array}$$

we deduce that the morphism θ_{U} can be identified with the fiber product of θ_{V} with θ_{U_1} over $\theta_{\mathsf{V} \times_{\mathsf{U}} \mathsf{U}_1}$ (as objects of the ∞-category $\mathrm{Fun}(\Delta^1, \mathsf{Groth}_\infty)$). Our inductive hypothesis guarantees that the morphisms θ_{V}, θ_{U_1}, and $\theta_{\mathsf{V} \times_{\mathsf{U}} \mathsf{U}_1}$ are equivalences, so that θ_{U} is an equivalence as well. □

Construction 10.2.4.3. Let X be a spectral Deligne-Mumford stack and suppose that the diagonal $\delta : \mathsf{X} \to \mathsf{X} \times \mathsf{X}$ is quasi-affine. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category equipped with an action of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$. If A is a connective $\mathbb{E}_\infty$-ring, then any map $\eta : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$ is quasi-affine. Define $\mathcal{C}_\eta = \mathrm{Mod}_A^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C}$, where the relative tensor product is formed in the ∞-category Groth_∞ (the existence of this tensor product follows from Proposition **??**). It is not difficult to see that the construction $\eta \mapsto \mathcal{C}_\eta$ determines a quasi-coherent stack on X, which we will denote by $\Psi_{\mathsf{X}}(\mathcal{C})$. The construction $\mathcal{C} \mapsto \Psi_{\mathsf{X}}(\mathcal{C})$ determines a functor

$$\Psi_{\mathsf{X}} : \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty) \to \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}).$$

If $q : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, S$ is the projection map, then the functor Ψ_{X} can be described more informally by the formula $\Psi_{\mathsf{X}}(\mathcal{C}) = q^* \mathcal{C} \otimes_{q^* q_* \mathcal{Q}_{\mathsf{X}}^{\mathrm{cn}}} \mathcal{Q}_{\mathsf{X}}^{\mathrm{cn}}$. From this description, it is not hard to see that Ψ_{X} is a left adjoint to the global sections functor $\mathrm{QCoh}(\mathsf{X}; \bullet) : \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}) \to \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)$.

Proof of Theorem 10.2.0.1. Let X be a quasi-geometric spectral Deligne-Mumford stack and let $\mathcal{C}$ be a prestable quasi-coherent stack on X; we wish to show that the counit map $v : \Psi_{\mathsf{X}}\, \mathrm{QCoh}(\mathsf{X}; \mathcal{C}) \to \mathcal{C}$ is an equivalence in $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$. To prove this, it will suffice to show that for every map of spectral Deligne-Mumford stacks $\eta : \mathsf{U} \to \mathsf{X}$ where $\mathsf{U} \simeq \mathrm{Sp\acute{e}t}\, A$ is affine, the pullback

$$\eta^*(v) : \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathrm{QCoh}(\mathsf{X}; \mathcal{C}) \to \mathrm{QCoh}(\mathsf{U}; \eta^* \mathcal{C}) = \mathcal{C}_\eta$$

is an equivalence of prestable A-linear ∞-categories. This is a special case of Proposition 10.2.4.2, since our assumption that X is quasi-geometric guarantees that the map η is quasi-affine. □

Proof of Theorem 10.2.0.2. Let X be a quasi-compact, quasi-separated spectral algebraic space; we wish to show that the global sections functor

$$\mathrm{QCoh}(\mathsf{X}; \bullet) : \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}) \to \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_{\infty})$$

is an equivalence of ∞-categories. Since X is quasi-geometric, Theorem 10.2.0.1 guarantees that the functor $\mathrm{QCoh}(\mathsf{X}; \bullet)$ is fully faithful. To complete the proof, it will suffice to show that the left adjoint $\Psi_{\mathsf{X}} : \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_{\infty}) \to \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ is conservative.

Write $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$. For each object $U \in \mathcal{X}$, set $\mathsf{X}_U = (\mathcal{X}_{/U}, \mathscr{O}_{\mathsf{X}}|_U)$. Let us say that an object $U \in \mathcal{X}$ is *good* if it satisfies the following conditions:

(a) The spectral Deligne-Mumford stack X_U is a quasi-compact, quasi-separated spectral algebraic space.

(b) The functor $\Psi_{\mathsf{X}_U} : \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X}_U)^{\mathrm{cn}}}(\mathsf{Groth}_{\infty}) \to \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}_U)$ is conservative.

We wish to show that the final object of $\mathcal{X}$ is good. Since X admits a scallop decomposition (Theorem 3.4.2.1), it will suffice to show that the collection of good objects of $\mathcal{X}$ satisfies the hypotheses of Proposition 2.5.3.5. This follows immediately from Proposition 10.2.3.1. □

Remark 10.2.4.4. Let X be a spectral Deligne-Mumford stack which is weakly perfect (Definition 9.4.3.3). If $\mathcal{C}$ is a compactly generated stable ∞-category equipped with an action of $\mathrm{QCoh}(\mathsf{X})$, then $\mathcal{C}$ is dualizable as an object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ and therefore also as an object of $\mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$ (Corollary **??**). so that the construction $\mathcal{D} \mapsto \mathcal{D} \otimes_{\mathrm{QCoh}(\mathsf{X})} \mathcal{C}$ commutes with small limits. In particular, the unit

$$\begin{aligned}
\mathcal{C} &\simeq \mathrm{QCoh}(\mathsf{X}) \otimes_{\mathrm{QCoh}(\mathsf{X})} \mathcal{C} \\
&\simeq (\varprojlim_{\eta : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}} \mathrm{Mod}_A) \otimes_{\mathrm{QCoh}(\mathsf{X})} \mathcal{C} \\
&\to \varprojlim_{\eta : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}} (\mathrm{Mod}_A \otimes_{\mathrm{QCoh}(\mathsf{X})} \mathcal{C}) \\
&\simeq \varprojlim_{\eta : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}} (\mathrm{Mod}_A^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathcal{C}) \\
&\simeq \mathrm{QCoh}(\mathsf{X}; \Psi_{\mathsf{X}} \mathcal{C}).
\end{aligned}$$

is an equivalence, where $\Psi_{\mathsf{X}} : \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_{\infty}) \to \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ is as in Construction 10.2.4.3. It follows that $\mathcal{C}$ belongs to the essential image of the fully faithful embedding

$$\mathrm{QCoh}(\mathsf{X}; \bullet) : \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}) \to \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_{\infty})$$

of Theorem 10.2.0.1.

10.2.5 Digression: Relative Tensor Products in Groth_∞

Let X be a quasi-compact, quasi-separated spectral algebraic space. For applications, it will be useful to know that the equivalence $\mathrm{QCoh}(\mathsf{X};\bullet) : \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}) \to \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)$ of Theorem 10.2.0.2 is compatible with tensor products. This requires a bit of care: as we discussed in §10.2.1, it is not *a priori* clear that the tensor product of of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$-modules is well-defined. However, it is well-defined in the case of interest to us, by virtue of the following:

Proposition 10.2.5.1. *Let $\mathcal{C}$ be a monoidal ∞-category which satisfies the following conditions:*

- (a) *The underlying ∞-category $\mathcal{C}$ is a compactly generated Grothendieck prestable ∞-category.*
- (b) *The unit object $\mathbf{1} \in \mathcal{C}$ is compact.*
- (c) *The tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves small colimits separately in each variable, so that we can view $\mathcal{C}$ as an algebra object of the ∞-category Groth_∞.*
- (d) *For every compact object $C \in \mathcal{C}$, the image $\Sigma^\infty C \in \mathrm{Sp}(\mathcal{C})$ is dualizable.*

Then:

1. *The monoidal structure on $\mathcal{C}$ exhibits $\mathcal{C}$ as an algebra object of the subcategory $\mathsf{Groth}_\infty^{\mathrm{c}} \subseteq \mathsf{Groth}_\infty$ of Definition C.3.4.2. In other words, the multiplication and unit maps*
$$\mathcal{C} \otimes \mathcal{C} \to \mathcal{C} \qquad \mathrm{Sp}^{\mathrm{cn}} \to \mathcal{C}$$
admit right adjoints which commute with filtered colimits.

2. *Let $\mathcal{N}$ be a left $\mathcal{C}$-module object of Groth_∞. Then $\mathcal{N}$ is also a left $\mathcal{C}$-module object of $\mathsf{Groth}_\infty^{\mathrm{c}}$. In other words, the action map $a : \mathcal{C} \otimes \mathcal{N} \to \mathcal{N}$ admits a right adjoint which commutes with filtered colimits.*

3. *Let $\mathcal{M}$ and $\mathcal{N}$ be Grothendieck prestable ∞-categories equipped with right and left actions of the monoidal ∞-category $\mathcal{C}$, and suppose that the action maps*
$$\mathcal{M} \times \mathcal{C} \to \mathcal{M} \qquad \mathcal{C} \times \mathcal{N} \to \mathcal{N}$$
*preserve small colimits separately in each variable. Then there exists a relative tensor product $\mathcal{M} \otimes_{\mathcal{C}} \mathcal{N}$ in the ∞-category Groth_∞ of Grothendieck prestable ∞-categories. In other words, the two-sided bar construction $\mathrm{Bar}_{\mathcal{C}}(\mathcal{M},\mathcal{N})_\bullet$ of Construction HA.4.4.2.7 admits a geometric realization in the ∞-category Groth_∞. Moreover, this geometric realization is preserved by the (symmetric monoidal) embedding $\mathsf{Groth}_\infty \hookrightarrow \mathsf{Groth}_\infty^{+}$ of Remark **??**.*

Remark 10.2.5.2. Let $\mathcal{C}$ be a monoidal ∞-category satisfying conditions (a) through (d) of Proposition 10.2.5.1. Then an object $C \in \mathcal{C}$ is compact if and only if $\Sigma^\infty(C)$ is a dualizable object of $\mathrm{Sp}(\mathcal{C})$. The "only if" direction follows from (d). Conversely, if $\Sigma^\infty(C)$ is dualizable, then the construction

$$\begin{array}{rcl} D & \mapsto & \mathrm{Map}_{\mathcal{C}}(C, D) \\ & \simeq & \mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(\Sigma^\infty C, \Sigma^\infty D) \\ & \simeq & \mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(\Sigma^\infty \mathbf{1}, (\Sigma^\infty C)^\vee \otimes \Sigma^\infty D) \\ & \simeq & \mathrm{Map}_{\mathcal{C}}(\mathbf{1}, \Omega^\infty((\Sigma^\infty C)^\vee \otimes \Sigma^\infty D) \end{array}$$

commutes with filtered colimits, since the constructions

$$D \mapsto \Sigma^\infty D \qquad X \mapsto (\Sigma^\infty C)^\vee \otimes X$$

$$Y \mapsto \Omega^\infty Y \qquad Z \mapsto \mathrm{Map}_{\mathcal{C}}(\mathbf{1}, Z)$$

individually commute with filtered colimits; it follows that $C \in \mathcal{C}$ is compact.

Example 10.2.5.3. Let X be a quasi-compact, quasi-separated spectral algebraic space. It follows from Proposition 9.6.1.2 that the ∞-category $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ is compactly generated and that an object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ is compact if and only if it is perfect: that is, if and only if it is dualizable as an object in the larger ∞-category $\mathrm{QCoh}(\mathsf{X})$. Consequently, the symmetric monoidal ∞-category $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ satisfies conditions (a) through (d) of Proposition 10.2.5.1.

Warning 10.2.5.4. Proposition 10.2.5.1 is closely related to Proposition D.2.2.1. If R is a connective $\mathbb{E}_2$-ring, then the monoidal ∞-category $\mathrm{LMod}_R^{\mathrm{cn}}$ satisfies hypotheses (a) through (d) of Proposition 10.2.5.1. Consequently Proposition 10.2.5.1 asserts that if $\mathcal{M}$ and $\mathcal{N}$ are Grothendieck prestable ∞-categories equipped with right and left actions of $\mathrm{LMod}_R^{\mathrm{cn}}$ respectively, then there exists a relative tensor product $\mathcal{N} \otimes_{\mathrm{LMod}_R^{\mathrm{cn}}} \mathcal{M}$ in the ∞-category Groth_∞ of Grothendieck prestable ∞-categories. This special case of assertion (3) of Proposition 10.2.5.1 is a formal consequence of Proposition D.2.2.1 (moreover, the analogous special cases of assertions (1) and (2) appear in our proof of Proposition D.2.2.1). However, the assertion of Proposition D.2.2.1 is stronger: it guarantees not only the existence of the relative tensor product $\mathcal{M} \otimes_{\mathrm{LMod}_R^{\mathrm{cn}}} \mathcal{N}$ in the ∞-category Groth_∞, but that this tensor product *coincides* with the analogous construction in larger ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable ∞-categories. For example, this implies that the tensor product $\mathcal{M} \otimes_{\mathrm{LMod}_R^{\mathrm{cn}}} \mathcal{N}$ is generated under small colimits by the essential image of the multiplication map $\mathcal{M} \times \mathcal{N} \to \mathcal{M} \otimes_{\mathrm{LMod}_R^{\mathrm{cn}}} \mathcal{N}$.

In the situation of Proposition 10.2.5.1, we do not know if relative tensor product $\mathcal{M} \otimes_{\mathcal{C}} \mathcal{N}$ is generated under small colimits by the essential image of the multiplication map $m : \mathcal{M} \times \mathcal{N} \to \mathcal{M} \otimes_{\mathcal{C}} \mathcal{N}$. However assertion that the geometric realization of the bar construction $\mathrm{Bar}_{\mathcal{C}}(\mathcal{M}, \mathcal{N})_\bullet$ is preserved by the embedding $\mathsf{Groth}_\infty \hookrightarrow \mathsf{Groth}_\infty^+$ gives a slightly weaker statement: the ∞-category $\mathcal{M} \otimes_{\mathcal{C}} \mathcal{N}$ is generated under small colimits *and extensions* by the essential image of the functor m.

We will later see that this unpleasant phenomenon does not occur in the special case $\mathcal{C} = \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$, where X is a quasi-compact spectral algebraic space with *affine* diagonal; see Proposition 10.2.6.7.

Proof of Proposition 10.2.5.1. We first prove (2). Let $\mathcal{C}$ be a monoidal ∞-category satisfying conditions (a) through (d) and let $\mathcal{N}$ be a Grothendieck prestable ∞-category equipped with a left action of $\mathcal{C}$. Since $\mathcal{C}$ is compactly generated, we can identify $\mathcal{C}$ with $\mathrm{Ind}(\mathcal{C}_0)$, where $\mathcal{C}_0$ is the full subcategory of $\mathcal{C}$ spanned by the compact objects. Using Proposition HA.4.8.1.17 , we can identify the tensor product $\mathcal{C} \otimes \mathcal{N}$ (formed in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable ∞-categories) with the ∞-category $\mathrm{RFun}(\mathcal{C}^{\mathrm{op}}, \mathcal{N}) \simeq \mathrm{Fun}^{\mathrm{lex}}(\mathcal{C}_0^{\mathrm{op}}, \mathcal{N})$ of left exact functors from $\mathcal{C}_0^{\mathrm{op}}$ to $\mathcal{N}$. Since $\mathcal{N}$ is a Grothendieck prestable ∞-category, the ∞-category $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{C}_0^{\mathrm{op}}, \mathcal{N})$ is closed under filtered colimits in the ambient ∞-category $\mathrm{Fun}(\mathcal{C}_0^{\mathrm{op}}, \mathcal{N})$: in other words, filtered colimits in $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{C}_0^{\mathrm{op}}, \mathcal{N})$ can be computed pointwise. The right adjoint to the action map $\mathcal{C} \otimes \mathcal{N} \to \mathcal{N}$ determines a functor $\lambda : \mathcal{N} \to \mathrm{Fun}^{\mathrm{lex}}(\mathcal{C}_0^{\mathrm{op}}, \mathcal{N})$. For each compact object $C \in \mathcal{C}$, let $\lambda_C : \mathcal{N} \to \mathcal{N}$ denote the composition of λ with the functor $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{C}_0^{\mathrm{op}}, \mathcal{N}) \to \mathcal{N}$ given by evaluation at C. We wish to show that each of the functors λ_C commutes with filtered colimits. Unwinding the definitions, we see that λ_C can be identified with the right adjoint of the functor given by tensoring with the object C. Let us regard the stable ∞-category $\mathrm{Sp}(\mathcal{N})$ as equipped with a left action of $\mathrm{Sp}(\mathcal{C})$. By virtue of assumption (d), the object $\Sigma^\infty C \in \mathrm{Sp}(\mathcal{C})$ admits a dual $(\Sigma^\infty C)^\vee$. Using the prestability of $\mathcal{N}$, we compute

$$\begin{aligned}
\mathrm{Map}_{\mathcal{N}}(N, \lambda_C(N')) &\simeq \mathrm{Map}_{\mathcal{N}}(C \otimes N, N') \\
&\simeq \mathrm{Map}_{\mathrm{Sp}(\mathcal{N})}(\Sigma^\infty C \otimes \Sigma^\infty N, \Sigma^\infty N') \\
&\simeq \mathrm{Map}_{\mathrm{Sp}(\mathcal{N})}(\Sigma^\infty N, (\Sigma^\infty C)^\vee \otimes \Sigma^\infty N') \\
&\simeq \mathrm{Map}_{\mathcal{N}}(N, \Omega^\infty((\Sigma^\infty C)^\vee \otimes \Sigma^\infty N')).
\end{aligned}$$

It follows that we can identify λ_C with the composition of functors

$$\mathcal{N} \xrightarrow{\Sigma^\infty} \mathrm{Sp}(\mathcal{N}) \xrightarrow{(\Sigma^\infty C)^\vee \otimes} \mathrm{Sp}(\mathcal{N}) \xrightarrow{\Omega^\infty} \mathcal{N},$$

each of which commutes with filtered colimits, so that λ_C commutes with filtered colimits as desired. This completes the proof of (2).

We now prove (1). Applying assertion (2) to the left action of $\mathcal{C}$ on itself, we deduce that the multiplication map $\mathcal{C} \otimes \mathcal{C} \to \mathcal{C}$ admits a right adjoint which commutes with filtered colimits. It will therefore suffice to show that if $G : \mathcal{C} \to \mathrm{Sp}^{\mathrm{cn}}$ is the right adjoint to the unit map $\mathrm{Sp}^{\mathrm{cn}} \to \mathcal{C}$, then G commutes with filtered colimits. Since the functor $\Omega^\infty : \mathrm{Sp}^{\mathrm{cn}} \to \mathcal{S}$ is conservative and commutes with filtered colimits, it will suffice to show that the composition

$\mathcal{C} \xrightarrow{G} \mathrm{Sp}^{\mathrm{cn}} \xrightarrow{\Omega^\infty} \mathcal{S}$ commutes with filtered colimits. Unwinding the definitions, we see that this composite functor is corepresented by the unit object $\mathbf{1} \in \mathcal{C}$; the desired result now follows from our assumption that the object $\mathbf{1}$ is compact.

Now suppose that $\mathcal{M}$ and $\mathcal{N}$ are Grothendieck prestable ∞-categories equipped with right and left actions of $\mathcal{C}$. It follows from assertions (1) and (2) that we can regard $\mathcal{M}$ and $\mathcal{N}$ as right and left modules over $\mathcal{C}$ in the symmetric monoidal subcategory $\mathsf{Groth}_\infty^{\mathrm{c}} \subseteq \mathsf{Groth}_\infty$, so that the bar construction $\mathrm{Bar}_{\mathcal{C}}(\mathcal{M}, \mathcal{N})_\bullet$ can be viewed as a simplicial object of $\mathsf{Groth}_\infty^{\mathrm{c}}$. Since the ∞-category $\mathsf{Groth}_\infty^{\mathrm{c}}$ admits small colimits which are preserved by the functors $\mathsf{Groth}_\infty^{\mathrm{c}} \hookrightarrow \mathsf{Groth}_\infty \to \mathsf{Groth}_\infty^{+}$ (Propositions C.3.5.1, Remark C.3.5.2, and Proposition C.3.5.3), it follows that $\mathrm{Bar}_{\mathcal{C}}(\mathcal{M}, \mathcal{N})_\bullet$ admits a geometric realization in Groth_∞ which is preserved by the functor $\mathsf{Groth}_\infty \hookrightarrow \mathsf{Groth}_\infty^{+}$. □

10.2.6 The Projection Formula for Quasi-Coherent Stacks

We now extract some easy consequences of Proposition 10.2.5.1 and Theorem 10.2.0.2.

Proposition 10.2.6.1. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism between quasi-compact, quasi-separated spectral algebraic spaces. For any quasi-coherent stack $\mathcal{C}$ on Y, the canonical map*

$$\mathrm{QCoh}(\mathsf{Y}; \mathcal{C}) \to \mathrm{QCoh}(\mathsf{Y}; f_* f^* \mathcal{C}) \simeq \mathrm{QCoh}(\mathsf{X}; f^* \mathcal{C})$$

extends to an equivalence of ∞-categories

$$\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{Y})^{\mathrm{cn}}} \mathrm{QCoh}(\mathsf{Y}; \mathcal{C}) \to \mathrm{QCoh}(\mathsf{X}; f^* \mathcal{C});$$

here the left hand side is defined as in Proposition 10.2.5.1.

Proof. Unwinding the definitions, we wish to prove the left adjointability of the commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}) & \xrightarrow{f_*} & \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{Y}) \\ \downarrow{\scriptstyle \mathrm{QCoh}(\mathsf{X};\bullet)} & & \downarrow{\scriptstyle \mathrm{QCoh}(\mathsf{Y};\bullet)} \\ \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty) & \longrightarrow & \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{Y})^{\mathrm{cn}}}(\mathsf{Groth}_\infty). \end{array}$$

This is an immediate consequence of Theorem 10.2.0.2, which guarantees that the vertical maps are equivalences (under the assumption that X and Y are quasi-compact, quasi-separated spectral algebraic spaces). □

Example 10.2.6.2. In the situation of Proposition 10.2.6.1, suppose that the morphism f is affine and let $\mathscr{A} \in \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{Y}))$ denote the direct image direct image of the structure sheaf of X. Then we can identify $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ with the ∞-category $\mathrm{Mod}_{\mathscr{A}}(\mathrm{QCoh}(\mathsf{Y})^{\mathrm{cn}})$. Combining this observation with Theorem HA.4.8.4.6 and Proposition 10.2.6.1, we obtain an equivalence $\mathrm{QCoh}(\mathsf{X}; f^* \mathcal{C}) \simeq \mathrm{LMod}_{\mathscr{A}}(\mathrm{QCoh}(\mathsf{Y}; \mathcal{C}))$ for any quasi-coherent stack $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{Y})$. Under this identification, the "pullback" functor

$$\mathrm{QCoh}(\mathsf{Y}; \mathcal{C}) \to \mathrm{QCoh}(\mathsf{Y}; f_* f^* \mathcal{C}) \simeq \mathrm{QCoh}(\mathsf{X}; f^* \mathcal{C})$$

is given by forming the tensor product with $\mathscr{A}$, which is right adjoint to the forgetful functor $\mathrm{LMod}_{\mathscr{A}}(\mathrm{QCoh}(\mathsf{Y}; \mathcal{C})) \to \mathrm{QCoh}(\mathsf{Y}; \mathcal{C})$.

Corollary 10.2.6.3. *Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \xrightarrow{f'} & \mathsf{Y}' \\ \downarrow{\scriptstyle g'} & & \downarrow{\scriptstyle g} \\ \mathsf{X} & \xrightarrow{f} & \mathsf{Y}. \end{array}$$

If X *and* Y *are quasi-compact, quasi-separated spectral algebraic spaces, then the induced map*

$$\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{Y})^{\mathrm{cn}}} \mathrm{QCoh}(\mathsf{Y}')^{\mathrm{cn}} \to \mathrm{QCoh}(\mathsf{X}')^{\mathrm{cn}}$$

is an equivalence of Grothendieck prestable ∞*-categories.*

Remark 10.2.6.4. In the situation of Corollary 10.2.6.3, it follows that the induced map

$$\mathrm{QCoh}(\mathsf{X}) \otimes_{\mathrm{QCoh}(\mathsf{Y})} \mathrm{QCoh}(\mathsf{Y}') \to \mathrm{QCoh}(\mathsf{X}')$$

is an equivalence of presentable stable ∞-categories. This consequence is valid more generally for pullback diagrams of weakly perfect stacks; see Corollary 9.4.3.8.

Proof of Corollary 10.2.6.3. Using Propositions 10.2.6.1 and 10.1.4.1, we compute

$$\begin{aligned} \mathrm{QCoh}(\mathsf{X}')^{\mathrm{cn}} &\simeq \mathrm{QCoh}(\mathsf{X}; g'_* \mathscr{Q}^{\mathrm{cn}}_{\mathsf{X}'}) \\ &\simeq \mathrm{QCoh}(\mathsf{X}; g'_* f'^* \mathscr{Q}^{\mathrm{cn}}_{\mathsf{Y}'}) \\ &\xleftarrow{\sim} \mathrm{QCoh}(\mathsf{X}; f^* g_* \mathscr{Q}^{\mathrm{cn}}_{\mathsf{Y}'}) \\ &\xleftarrow{\sim} \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{Y})^{\mathrm{cn}}} \mathrm{QCoh}(\mathsf{Y}; g_* \mathscr{Q}^{\mathrm{cn}}_{\mathsf{Y}'}) \\ &\simeq \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{Y})^{\mathrm{cn}}} \mathrm{QCoh}(\mathsf{Y}')^{\mathrm{cn}}. \end{aligned}$$

□

Corollary 10.2.6.5. *Let* X *be a quasi-compact, quasi-separated spectral algebraic space. For every pair of quasi-coherent stacks* $\mathcal{C}, \mathcal{D} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$*, the canonical map*

$$\mathrm{QCoh}(\mathsf{X}; \mathcal{C}) \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathrm{QCoh}(\mathsf{X}; \mathcal{D}) \to \mathrm{QCoh}(\mathsf{X}; \mathcal{C} \otimes \mathcal{D})$$

is an equivalence of Grothendieck prestable ∞*-categories.*

Corollary 10.2.6.6 (Projection Formula)**.** *Let $f : X \to Y$ be a morphism in* $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})$ *which is representable by quasi-compact, quasi-separated spectral algebraic spaces. For every pair of prestable quasi-coherent stacks $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(Y)$, $\mathcal{D} \in \mathrm{QStk}^{\mathrm{PSt}}(X)$, the canonical map*

$$\theta : \mathcal{C} \otimes (f_* \mathcal{D}) \to f_* f^* (\mathcal{C} \otimes f_* \mathcal{D}) \simeq f_*((f^* \mathcal{C}) \otimes (f^* f_* \mathcal{D})) \to f_*((f^* \mathcal{C}) \otimes \mathcal{D})$$

is an equivalence of quasi-coherent stacks on Y.

Proof. Using Proposition 10.1.4.1, we can reduce to the case where $Y = \mathrm{Spec}\, A$ is affine, so that both X and Y are representable by quasi-compact, quasi-separated spectral algebraic spaces. By virtue of Theorem 10.2.0.2, it will suffice to show that θ induces an equivalence of Grothendieck prestable ∞-categories

$$\rho : \mathrm{QCoh}(Y; \mathcal{C} \otimes f_* \mathcal{D}) \to \mathrm{QCoh}(Y; f_*(f^* \mathcal{C} \otimes \mathcal{D})) \simeq \mathrm{QCoh}(X; f^* \mathcal{C} \otimes \mathcal{D}).$$

Using Corollary 10.2.6.5 and Proposition 10.2.6.1, we can identify ρ with the evident equivalence

$$\begin{array}{c} \mathrm{QCoh}(Y; \mathcal{C}) \otimes_{\mathrm{QCoh}(Y)^{\mathrm{cn}}} \mathrm{QCoh}(X; \mathcal{D}) \\ \big\downarrow \sim \\ (\mathrm{QCoh}(Y; \mathcal{C}) \otimes_{\mathrm{QCoh}(Y)^{\mathrm{cn}}} \mathrm{QCoh}(X)^{\mathrm{cn}}) \otimes_{\mathrm{QCoh}(X)^{\mathrm{cn}}} \mathrm{QCoh}(X; \mathcal{D}). \end{array}$$

□

We close this section by partially addressing the technical point raised in Warning 10.2.5.4. Suppose that X is a spectral Deligne-Mumford stack and that we are given a pair of Grothendieck prestable ∞-categories $\mathcal{M}$ and $\mathcal{N}$ equipped with actions of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$. If X is a quasi-compact, quasi-separated spectral algebraic space, then Proposition 10.2.5.1 guarantees that the two-sided bar construction $\mathrm{Bar}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathcal{M}, \mathcal{N})_\bullet$ admits a colimit in the ∞-category Groth_∞. It also admits an *a priori* different colimit in the larger ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of all presentable ∞-categories. However, these colimits agree whenever X has affine diagonal:

Proposition 10.2.6.7. *Let X be a quasi-compact spectral algebraic space and suppose that the diagonal map $\delta : \mathsf{X} \to \mathsf{X} \times \mathsf{X}$ is affine (this condition is satisfied, for example, if X is separated). Let $\mathcal{M}$ and $\mathcal{N}$ be Grothendieck prestable ∞-categories equipped with actions of* $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$*, and let* $\mathrm{Bar}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathcal{M}, \mathcal{N})_\bullet$ *be the simplicial object of* Groth_∞ *given by applying the two-sided bar construction of Construction HA.4.4.2.7. Then the inclusion functor* $\mathsf{Groth}_\infty \hookrightarrow \mathcal{P}\mathrm{r}^{\mathrm{L}}$ *preserves the geometric realization of* $\mathrm{Bar}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathcal{M}, \mathcal{N})_\bullet$*. In other words, the geometric realization* $|\mathrm{Bar}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathcal{M}, \mathcal{N})_\bullet|$ *in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ is again a Grothendieck prestable ∞-category.*

Proof. We proceed as in the proof of Proposition D.2.2.1. By virtue of Lemma HTT.6.5.3.7, we can identify the geometric realization of $\mathrm{Bar}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathcal{M},\mathcal{N})_\bullet$ with the colimit of the underlying semisimplicial object of Groth_∞. To show that this colimit (formed in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$) is again a Grothendieck prestable ∞-category, it will suffice to show that this semisimplicial object satisfies the hypotheses of Remark C.3.5.4: that is, for every injective map $\alpha : [m] \hookrightarrow [n]$, the associated functor $f_\alpha : \mathrm{Bar}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathcal{M},\mathcal{N})_n \to \mathrm{Bar}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathcal{M},\mathcal{N})_m$ admits a right adjoint which preserves small colimits. Factoring α as a composition, we may reduce to the case $m = n-1$, so that f_α is one of the face maps of the simplicial object $\mathrm{Bar}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathcal{M},\mathcal{N})_\bullet$. Unwinding the definitions, we see that f_α is obtained from one of the maps

$$m : \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \otimes \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \to \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$$

$$a : \mathcal{M} \otimes \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \to \mathcal{M} \qquad a' : \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \otimes \mathcal{N} \to \mathcal{N}$$

by tensoring with some auxiliary object of Groth_∞; here the functor a is given by the action of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ on $\mathcal{M}$, the functor m is given by the tensor product of quasi-coherent sheaves, and the functor a' is given by the action of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ on $\mathcal{N}$. By virtue of Remark C.4.4.5, it will suffice to show that the functors a, m, and a' admit right adjoints which preserve small colimits. We will prove this for the functor a; the other cases then follow by symmetry.

Since X is a quasi-compact, quasi-separated spectral algebraic space, Theorem 10.2.0.2 implies that we can write $\mathcal{M}$ as the ∞-category $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ for some quasi-coherent stack $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$. Let $p : \mathsf{X} \times \mathsf{X} \to \mathsf{X}$ denote the projection map onto the first factor. Using Proposition 10.2.6.1, we can identify the tensor product $\mathcal{M} \otimes \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ with the ∞-category $\mathrm{QCoh}(\mathsf{X} \times \mathsf{X}; p^* \mathcal{C})$. Under this identification, the map a corresponds to the functor

$$\mathrm{QCoh}(\mathsf{X} \times \mathsf{X}; p^* \mathcal{C}) \to \mathrm{QCoh}(\mathsf{X} \times \mathsf{X}; \delta_* \delta^* p^* \mathcal{C}) \simeq \mathrm{QCoh}(\mathsf{X} \times \mathsf{X}; \delta_* \mathcal{C}) \simeq \mathrm{QCoh}(\mathsf{X}; \mathcal{C}) \simeq \mathcal{M}$$

given informally by "pullback along δ." Since δ is an affine morphism, the desired result is a consequence of Example 10.2.6.2. □

10.3 Local Properties of Quasi-Coherent Stacks

We now study various local conditions which can be imposed on quasi-coherent stacks.

Definition 10.3.0.1. Let P be a condition on pairs $(A, \mathcal{C})$, where A is a connective $\mathbb{E}_\infty$-ring and $\mathcal{C}$ is a prestable A-linear ∞-category. We will say that P is *local for the étale topology* if the following conditions are satisfied:

(i) Whenever a pair $(A, \mathcal{C})$ satisfies the condition P and $\phi : A \to B$ is an étale morphism, the pair $(B, B \otimes_A \mathcal{C})$ also satisfies condition P.

(ii) Let A be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a prestable A-linear ∞-category. If there exists a finite collection of étale morphisms $\{A \to B_\alpha\}$ for which the induced map $A \to \prod B_\alpha$ is faithfully flat and each pair $(B_\alpha, B_\alpha \otimes_A \mathcal{C})$ satisfies the condition P, then $(A, \mathcal{C})$ satisfies the condition P.

Example 10.3.0.2. The following conditions on a pair $(A, \mathcal{C})$ are local for the étale topology:

(1) The condition that $\mathcal{C}$ is stable (Proposition D.5.1.1).

(2) The condition that $\mathcal{C}$ is separated (Proposition D.5.1.2).

(3) The condition that $\mathcal{C}$ is complete (Proposition D.5.1.3).

(4) The condition that $\mathcal{C}$ is compactly generated (Theorem D.5.3.1).

(5) The condition that $\mathcal{C}$ is anticomplete (Theorems D.5.4.1 and D.5.4.9).

(6) The condition that $\mathcal{C}$ is weakly coherent (Theorem D.5.5.1 and Corollary D.5.5.11).

(7) The condition that $\mathcal{C}$ is locally Noetherian (Propositions D.5.6.1 and D.5.6.4).

(8) The condition that $\mathcal{C}$ is weakly n-complicial (Proposition D.5.7.1).

(9) The condition that $\mathcal{C}$ is anticomplete and n-complicial (Corollary D.5.7.3).

(10) The condition that $\mathcal{C}$ is separated and n-complicial (Corollary D.5.7.3).

We have the following easy analogue of Proposition 2.8.1.7:

Proposition 10.3.0.3. *Let P be a condition on pairs $(A, \mathcal{C})$, where A is connective $\mathbb{E}_\infty$-ring and $\mathcal{C}$ is a prestable A-linear ∞-category. Let X be a spectral Deligne-Mumford stack and let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ be a prestable quasi-coherent stack on X. Suppose that P is local for the étale topology (in the sense of Definition 10.3.0.1). Then the following conditions are equivalent:*

(a) *For every étale morphism $\eta : \mathrm{Spét}\, A \to \mathsf{X}$, the pair $(A, \mathcal{C}_\eta)$ satisfies condition P.*

(b) *There exists mutually surjective collection of étale morphisms $\{\eta_\alpha : \mathrm{Spét}\, A_\alpha \to \mathsf{X}\}$ such that each of the pairs $(A_\alpha, \mathcal{C}_{\eta_\alpha})$ has the property P.*

In the situation of Proposition 10.3.0.3, we will generally say that a quasi-coherent stack $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ *has the property P* if the equivalent conditions of Proposition 10.3.0.3 are satisfied. Our goal in this section is to address the following:

Question 10.3.0.4. Let X be a spectral Deligne-Mumford stack, let $\mathcal{C}$ be a prestable quasi-coherent stack on X, and let P be as in Proposition 10.3.0.3. If $\mathcal{C}$ has the property P, then does the Grothendieck prestable ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ also have the property P? Conversely, if $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ has the property P, then can we conclude that $\mathcal{C}$ has the property P?

10.3.1 Properties Stable Under Base Change

We begin by considering instances of Question 10.3.0.4 which make sense in somewhat greater generality.

Definition 10.3.1.1. Let P be a condition on pairs $(A, \mathcal{C})$, where A is a connective $\mathbb{E}_\infty$-ring and $\mathcal{C}$ is a prestable A-linear ∞-category. We will say that P is *stable under base change* if, for every morphism $\phi : A \to B$ of connective $\mathbb{E}_\infty$-rings and every prestable A-linear ∞-category $\mathcal{C}$ such that $(A, \mathcal{C})$ satisfies the condition P, the pair $(B, B \otimes_A \mathcal{C})$ also satisfies the condition P.

Example 10.3.1.2. The following conditions on a pair $(A, \mathcal{C})$ are stable under base change (in the sense of Definition 10.3.1.1):

(1) The condition that $\mathcal{C}$ is stable (Proposition D.5.1.1).

(2) The condition that $\mathcal{C}$ is separated (Proposition D.5.1.2).

(3) The condition that $\mathcal{C}$ is complete (Proposition D.5.1.3).

(4) The condition that $\mathcal{C}$ is compactly generated (Lemma D.5.3.3).

Beware that the other conditions mentioned in Example 10.3.0.2 are *not* stable under base change.

Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be an arbitrary functor and let $\mathcal{C}$ be a prestable quasi-coherent stack on X. If P is as in Definition 10.3.1.1, we will generally say that $\mathcal{C}$ *satisfies the condition* P if, for every point $\eta \in X(A)$, the pair $(A, \mathcal{C}_\eta)$ satisfies the condition P, where $\mathcal{C}_\eta \in \mathrm{LinCat}_A^{\mathrm{PSt}}$ is as in Remark 10.1.1.3. Note that if P is local for the étale topology (in the sense of Defintiion 10.3.0.1) and X is representable by a spectral Deligne-Mumford stack, then this is equivalent to satisfying either of the conditions appearing in the statement of Proposition 10.3.0.3.

Specializing to the conditions appearing in Example 10.3.1.2, we obtain the following:

Definition 10.3.1.3. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor and let $\mathcal{C}$ be a prestable quasi-coherent stack on X.

(1) We will say that $\mathcal{C}$ is *stable* if, for every connective $\mathbb{E}_\infty$-ring A and every point $\eta \in X(A)$, the A-linear ∞-category $\mathcal{C}_\eta$ is stable (note that this agrees with Definition 10.1.2.1).

(2) We will say that $\mathcal{C}$ is *separated* if, for every connective $\mathbb{E}_\infty$-ring A and every point $\eta \in X(A)$, the A-linear ∞-category $\mathcal{C}_\eta$ is separated.

(3) We will say that $\mathcal{C}$ is *complete* if, for every connective $\mathbb{E}_\infty$-ring A and every point $\eta \in X(A)$, the A-linear ∞-category $\mathcal{C}_\eta$ is complete.

(4) We will say that $\mathcal{C}$ is *compactly generated* if, for every connective $\mathbb{E}_\infty$-ring A and every point $\eta \in X(A)$, the A-linear ∞-category $\mathcal{C}_\eta$ is compactly generated.

Remark 10.3.1.4. Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, and let $\mathcal{C}$ be a prestable quasi-coherent stack on Y. If $\mathcal{C}$ is stable (separated, complete, compactly generated), then $f^* \mathcal{C}$ is also stable (separated, complete, compactly generated). The converse holds if f induces an effective epimorphism after sheafifying with respect to the étale topology (since the conditions of being stable, separated, complete, and compactly generated can be tested locally with respect to the étale topology: see Example 10.3.0.2.

Remark 10.3.1.5. Let A be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a prestable A-linear ∞-category. Then $\mathcal{C}$ is stable (separated, complete, compactly generated) when regarded as a Grothendieck prestable ∞-category if and only if it is stable (separated, complete, compactly generated) when regarded as a prestable quasi-coherent stack on $\operatorname{Spec} A$.

Example 10.3.1.6. Let X be a spectral Deligne-Mumford stack, let $K \subseteq |\mathsf{X}|$ be a cocompact closed subset, and let $\mathcal{Q}_K^{\mathrm{cn}}$ be as in Variant 10.1.7.3. Then the prestable quasi-coherent stack $\mathcal{Q}_K \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ is compactly generated (see Proposition **??**).

Proposition 10.3.1.7. *Let $f : X \to Y$ be a representable morphism between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. Then:*

(*a*) *If $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(X)$ is stable, then $f_* \mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(Y)$ is stable.*

(*b*) *If $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(X)$ is separated, then $f_* \mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(Y)$ is separated.*

(*c*) *If $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(X)$ is complete, then $f_* \mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(Y)$ is complete.*

Proof. We will give the proof of (c); the proofs of (a) and (b) are similar. Using Proposition 10.1.5.1, we can reduce to the case where $Y = \operatorname{Spec} A$ is affine. Since f is representable, it follows that X is representable by a spectral Deligne-Mumford stack $\mathsf{X} = (\mathcal{X}, \mathcal{O}_X)$. For each object $U \in \mathcal{X}$, let $\Gamma(U; \mathcal{C})$ be as in the proof of Proposition 10.1.4.1. The construction $(U \in \mathcal{X}) \mapsto \Gamma(U; \mathcal{C})$ determines a functor $\mathcal{X}^{\mathrm{op}} \to \mathsf{Groth}_\infty^{\mathrm{lex}}$ which preserves small limits. Let $\mathcal{X}_0 \subseteq \mathcal{X}$ be the full subcategory spanned by those objects U for which the Grothendieck prestable ∞-category $\Gamma(U; \mathcal{C})$ is complete. Since the full subcategory of $\mathsf{Groth}_\infty^{\mathrm{lex}}$ spanned by the complete Grothendieck prestable ∞-categories is closed under small limits, it follows that $\mathcal{X}_0 \subseteq \mathcal{X}$ is closed under small colimits. If $\mathcal{C}$ is complete, then $\mathcal{X}_0$ contains all affine objects of $\mathcal{X}$. Applying Proposition 1.4.7.9, we deduce that $\mathcal{X}_0 = \mathcal{X}$. In particular, $\mathcal{X}_0$ contains the final object of $\mathcal{X}$, which proves that the Grothendieck prestable ∞-category $\mathrm{QCoh}(X; \mathcal{C}) \simeq \mathrm{QCoh}(Y; f_* \mathcal{C})$ is complete. Applying Remark 10.3.1.5, we deduce that $f_* \mathcal{C}$ is complete. □

If X is a quasi-geometric spectral Deligne-Mumford stack, then Theorem 10.2.0.1 guarantees that a prestable quasi-coherent stack $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ is determined by the ∞-category of global sections $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$. In this case, there is a close relationship between local and global properties of $\mathcal{C}$.

Proposition 10.3.1.8. *Let X be a spectral Deligne-Mumford stack and let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$. Then:*

(*a*) *If $\mathcal{C}$ is stable, then the Grothendieck prestable ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is stable. The converse holds if X is quasi-geometric.*

(*b*) *If $\mathcal{C}$ is separated, then the Grothendieck prestable ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is separated. The converse holds if X is quasi-geometric.*

(*c*) *If $\mathcal{C}$ is complete, then the Grothendieck prestable ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is complete. The converse holds if X is geometric.*

Remark 10.3.1.9. The analogues of Propositions 10.3.1.7 and 10.3.1.8 for compactly generated prestable quasi-coherent stacks are more subtle; we will discuss the matter in §10.3.2.

Proof of Proposition 10.3.1.8. The first parts of assertions (a) through (c) are special cases of Proposition 10.3.1.7. To prove the converse assertions, let us assume that X is quasi-geometric. In this case, Proposition 10.2.4.2 shows that we can recover the quasi-coherent stack $\mathcal{C}$ from the ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ as follows: for any map $\eta : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$, we have a canonical equivalence of ∞-categories

$$\mathcal{C}_\eta \simeq \mathrm{Mod}_A^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathrm{QCoh}(\mathsf{X}; \mathcal{C}).$$

If $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is stable, then the two-sided bar construction $\mathrm{Bar}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathrm{Mod}_A^{\mathrm{cn}}, \mathrm{QCoh}(\mathsf{X}; \mathcal{C}))_\bullet$ is stable in each degree, so its geometric realization $\mathcal{C}_\eta$ is also stable; this proves (a).

We now prove (b). Let $\eta : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$ be as above and let $\mathscr{A} \in \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{X}))$ be the direct of the structure sheaf of $\mathrm{Sp\acute{e}t}\, A$. Since X is quasi-compact, Proposition 2.4.1.5 guarantees that there exists an integer $n \geqslant 0$ such that $\mathscr{A} \in \mathrm{QCoh}(\mathsf{X})_{\geqslant -n}$. Let $\mathcal{E}$ denote the stabilization of the Grothendieck prestable ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$, so that $\mathcal{E}$ inherits a t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$ and the functor Σ^∞ induces an equivalence $\mathrm{QCoh}(\mathsf{X}; \mathcal{C}) \simeq \mathcal{E}_{\geqslant 0}$. Let us regard the ∞-category $\mathrm{LMod}_{\mathcal{A}}(\mathcal{E})$ as endowed with the t-structure of Construction 10.2.1.1, so that Proposition 10.2.1.3 supplies a t-exact equivalence $\mathcal{C}_\eta \simeq \mathrm{LMod}_{\mathscr{A}}(\mathcal{E})_{\geqslant 0}$. By definition, $\mathrm{LMod}_{\mathscr{A}}(\mathcal{E})_{\geqslant 0}$ is the smallest full subcategory of $\mathrm{LMod}_{\mathscr{A}}(\mathcal{E})$ which is closed under colimits and extensions and contains the tensor product $\mathcal{A} \otimes E$, for each object $E \in \mathcal{E}_{\geqslant 0}$. It follows that the forgetful functor $\mathrm{LMod}_{\mathscr{A}}(\mathcal{E}) \to \mathcal{E}$ carries $\mathrm{LMod}_{\mathscr{A}}(\mathcal{E})_{\geqslant k}$ into $\mathcal{E}_{\geqslant k-n}$ for each integer k. If $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is separated, then the intersection $\bigcap_{k \in \mathbf{Z}} \mathcal{E}_{\geqslant k-n}$ contains only zero objects of $\mathcal{E}$. It follows that the intersection $\bigcap_{k \in \mathbf{Z}} \mathrm{LMod}_{\mathscr{A}}(\mathcal{E})_{\geqslant k}$ contains only zero objects of $\mathrm{LMod}_{\mathscr{A}}(\mathcal{E})$, so that the Grothendieck prestable ∞-category $\mathcal{C}_\eta$ is also separated. This completes the proof of (b).

We now prove (c). Assume that X is geometric and that the Grothendieck prestable ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is complete; we wish to show that $\mathcal{C}_\eta$ is also complete, for any morphism $\eta : \mathrm{Spét}\, A \to \mathsf{X}$. The assumption that X is geometric guarantees that the algebra $\mathscr{A} \in \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{X}))$ is connective. In this case, the forgetful functor $\theta : \mathrm{LMod}_{\mathscr{A}}(\mathcal{E}) \to \mathcal{E}$ is t-exact: left t-exactness is automatic, and right t-exactness follows from the observation that the fiber product $\mathcal{E}_{\geqslant 0} \times_{\mathcal{E}} \mathrm{LMod}_{\mathscr{A}}(\mathcal{E})$ is a full subcategory of $\mathrm{LMod}_{\mathscr{A}}(\mathcal{E})$ which is closed under small colimits, extensions, and contains all objects of the form $\mathscr{A} \otimes E$ where $E \in \mathcal{E}_{\geqslant 0}$. We will complete the proof by showing that the ∞-category $\mathcal{E}_\eta \in \mathrm{LMod}_{\mathscr{A}}(\mathcal{E})_{\geqslant 0}$ satisfies the criterion of Proposition HTT.5.5.6.26 : that is, that a diagram

$$X \to \cdots \to X(3) \to X(2) \to X(1) \to X(0)$$

in $\mathcal{C}_\eta$ is a Postnikov tower if and only if it exhibits each $X(n)$ as an n-truncation of $X(n+1)$ and induces an equivalence $X \to \varprojlim_{n \geqslant 0} X(n)$. Since the forgetful functor θ is t-exact, conservative, and preserves small limits, it suffices to observe that the diagram

$$\theta X \to \cdots \to \theta X(3) \to \theta X(2) \to \theta X(1) \to \theta X(0)$$

in $\mathcal{E}_{\geqslant 0}$ is a Postnikov tower if and only if exhibit each $\theta X(n)$ as the n-truncation of $\theta X(n+1)$ and induces an equivalence $\theta X \to \varprojlim_{n \geqslant 0} \theta X(n)$. This follows from our assumption that $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is complete. □

Notation 10.3.1.10. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor. We let $\mathrm{QStk}^{\mathrm{comp}}(X)$ denote the full subcategory of $\mathrm{QStk}^{\mathrm{PSt}}(X)$ spanned by the complete prestable quasi-coherent stacks on X, and we let $\mathrm{QStk}^{\mathrm{sep}}(X)$ denote the full subcategory of $\mathrm{QStk}^{\mathrm{PSt}}(X)$ spanned by the the separated prestable quasi-coherent stacks on X.

Proposition 10.3.1.11. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be a functor. Then:*

- (a) *The inclusion functor $\mathrm{QStk}^{\mathrm{comp}}(X) \hookrightarrow \mathrm{QStk}^{\mathrm{PSt}}(X)$ admits a left adjoint which we will denote by $\mathcal{C} \mapsto \widehat{\mathcal{C}}$. Moreover, if $\mathcal{C}$ is a prestable quasi-coherent stack on X, then the canonical map $\mathcal{C} \to \widehat{\mathcal{C}}$ exhibits $\widehat{\mathcal{C}}_\eta$ as the completion of $\mathcal{C}_\eta$ for each point $\eta \in X(A)$ (see §C.3.6).*

- (b) *The inclusion functor $\mathrm{QStk}^{\mathrm{sep}}(X) \hookrightarrow \mathrm{QStk}^{\mathrm{PSt}}(X)$ admits a left adjoint which we will denote by $\mathcal{C} \mapsto \mathcal{C}^{\mathrm{sep}}$. Moreover, if $\mathcal{C}$ is a prestable quasi-coherent stack on X, then the canonical map $\mathcal{C} \to \mathcal{C}^{\mathrm{sep}}$ exhibits $\mathcal{C}^{\mathrm{sep}}_\eta$ as the separated quotient of $\mathcal{C}_\eta$ for each point $\eta \in X(A)$.*

Remark 10.3.1.12. For $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(X)$, we will refer to the quasi-coherent stacks $\widehat{\mathcal{C}}$ and $\mathcal{C}^{\mathrm{sep}}$ of Proposition 10.3.1.11 as the *completion* and *separated quotient* of $\mathcal{C}$, respectively.

Proof. We will give the proof of (a); the proof of (b) is similar. Let $\mathrm{LinCat}^{\mathrm{Add}}$ be as in Definition 10.1.1.1, let $\mathrm{LinCat}^{\mathrm{PSt}}$ be the full subcategory of $\mathrm{LinCat}^{\mathrm{Add}}$ spanned by those pairs $(A, \mathcal{C})$ where A is a connective $\mathbb{E}_\infty$-ring and $\mathcal{C}$ is a prestable A-linear ∞-category, and let $\mathrm{LinCat}^{\mathrm{comp}} \subseteq \mathrm{LinCat}^{\mathrm{PSt}}$ be the full subcategory spanned by those pairs $(A, \mathcal{C})$ where $\mathcal{C}$ is complete. Then the forgetful functor $\theta : \mathrm{LinCat}^{\mathrm{PSt}} \to \mathrm{CAlg}^{\mathrm{cn}}$ is a coCartesian fibration which restricts to a coCartesian fibration $\theta' : \mathrm{LinCat}^{\mathrm{comp}} \to \mathrm{CAlg}^{\mathrm{cn}}$ (moreover, every θ'-coCartesian morphism in $\mathrm{LinCat}^{\mathrm{comp}}$ is a θ-coCartesian morphism in $\mathrm{LinCat}^{\mathrm{PSt}}$: see Proposition D.5.1.3). It follows from Proposition C.4.6.1 that for every connective $\mathbb{E}_\infty$-ring A, the inclusion $\mathrm{LinCat}^{\mathrm{comp}}_A \hookrightarrow \mathrm{LinCat}^{\mathrm{PSt}}_A$ admits a left adjoint, given by the completion construction $\mathcal{C} \mapsto \widehat{\mathcal{C}}$. Moreover, if $f : \mathcal{C} \to \mathcal{D}$ is an A-linear functor which induces an equivalence of completions, then the induced map $f_B : B \otimes_A \mathcal{C} \to B \otimes_A \mathcal{D}$ also induces an equivalence of completions, for any $\mathbb{E}_\infty$-algebra B over A. Applying Proposition HA.7.3.2.11 , we deduce that the inclusion functor $\mathrm{LinCat}^{\mathrm{comp}} \hookrightarrow \mathrm{LinCat}^{\mathrm{PSt}}$ admits a left adjoint L relative to $\mathrm{CAlg}^{\mathrm{cn}}$ (see Definition HA.7.3.2.2). If $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ classifies a left fibration of ∞-categories $\mathcal{E} \to \mathrm{CAlg}^{\mathrm{cn}}$, then we can identify $\mathrm{QStk}^{\mathrm{PSt}}(X)$ and $\mathrm{QStk}^{\mathrm{comp}}(X)$ with the full subcategories of $\mathrm{Fun}_{\mathrm{CAlg}^{\mathrm{cn}}}(\mathcal{E}, \mathrm{LinCat}^{\mathrm{PSt}})$ and $\mathrm{Fun}_{\mathrm{CAlg}^{\mathrm{cn}}}(\mathcal{E}, \mathrm{LinCat}^{\mathrm{comp}})$ spanned by those functors which carry morphisms in $\mathcal{E}$ to θ-coCartesian morphisms in $\mathrm{LinCat}^{\mathrm{PSt}}$ and θ'-coCartesian morphisms in $\mathrm{LinCat}^{\mathrm{comp}}$, respectively. Using these identifications, we see that pointwise composition with L determines a functor $\mathrm{QStk}^{\mathrm{PSt}}(X) \to \mathrm{QStk}^{\mathrm{comp}}(X)$ having the desired properties. □

Proposition 10.3.1.7 has the following analogue for properties of morphisms between quasi-coherent stacks:

Proposition 10.3.1.13. *Let $f : X \to Y$ be a representable morphism between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ and let $u : \mathcal{C} \to \mathcal{D}$ be a morphism of prestable quasi-coherent stacks on X. Then:*

- (a) *If u is left exact, then the induced map $f_*(u) : f_* \mathcal{C} \to f_* \mathcal{D}$ is left exact.*
- (b) *If u is compact, then the induced map $f_*(u) : f_* \mathcal{C} \to f_* \mathcal{D}$ is compact.*

We now consider the converse:

Proposition 10.3.1.14. *Let X be a spectral Deligne-Mumford stack and let $u : \mathcal{C} \to \mathcal{D}$ be a morphism of prestable quasi-coherent stacks on X. Then:*

- (a) *If u is left exact, then the induced map $\mathrm{QCoh}(\mathsf{X}; \mathcal{C}) \to \mathrm{QCoh}(\mathsf{Y}; \mathcal{D})$ is left exact. The converse holds if X is quasi-geometric.*

(b) *If u is compact, then the induced map* $\mathrm{QCoh}(\mathsf{X};\mathcal{C}) \to \mathrm{QCoh}(\mathsf{Y};\mathcal{D})$ *is compact. The converse holds if* X *is quasi-geometric.*

Proof. The first parts of assertions (a) and (b) follow immediately from Proposition **??**. For the converse, assume that X is quasi-geometric and that u induces a functor $U : \mathrm{QCoh}(\mathsf{X};\mathcal{C}) \to \mathrm{QCoh}(\mathsf{X};\mathcal{D})$ which is left exact (compact); we wish to show that for each map $\eta : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$, the induced A-linear functor $u_\eta : \mathcal{C}_\eta \to \mathcal{D}_\eta$ is also left exact (compact). As in the proof of Proposition 10.3.1.8, we can identify u_η with the functor

$$\mathrm{Mod}_A^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathrm{QCoh}(\mathsf{X};\mathcal{C}) \to \mathrm{Mod}_A^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}} \mathrm{QCoh}(\mathsf{X};\mathcal{D})$$

determined by U. Assertion (a) is now a special case of Proposition 10.2.2.3. To prove (b), we can replace $\mathcal{C}$ and $\mathcal{D}$ by their stabilizations (see Proposition C.3.4.1). In this case, we can identify u_η with the functor $\mathrm{LMod}_{\mathscr{A}}(\mathrm{QCoh}(\mathsf{X};\mathcal{C})) \to \mathrm{LMod}_{\mathscr{A}}(\mathrm{QCoh}(\mathsf{X};\mathcal{D}))$ determined by U, where $\mathscr{A} \in \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{X}))$ is the direct image of the structure sheaf of $\mathrm{Sp\acute{e}t}\, A$. Let G_η denote the right adjoint to u_η, so that G_η fits into a commutative diagram

$$\begin{array}{ccc} \mathrm{LMod}_{\mathscr{A}}(\mathrm{QCoh}(\mathsf{X};\mathcal{D})) & \xrightarrow{G_\eta} & \mathrm{LMod}_{\mathscr{A}}(\mathrm{QCoh}(\mathsf{X};\mathcal{C})) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{X};\mathcal{D}) & \xrightarrow{G} & \mathrm{QCoh}(\mathsf{X};\mathcal{C}), \end{array}$$

where G is left adjoint to U. Since U is compact, the functor G commutes with filtered colimits. Since the vertical maps are conservative and commute with filtered colimits, it follows that G_η also commutes with filtered colimits. □

Corollary 10.3.1.15. *Let* X *be a quasi-geometric spectral Deligne-Mumford stack and let* $u : \mathcal{C} \to \mathcal{D}$ *be a left morphism of prestable quasi-coherent stacks on* X*. The following conditions are equivalent:*

(i) *The functor u induces an equivalence of completions* $\widehat{\mathcal{C}} \to \widehat{\mathcal{D}}$ *(see Proposition 10.3.1.11).*

(ii) *The induced map of Grothendieck prestable ∞-categories* $\mathrm{QCoh}(\mathsf{X};\mathcal{C}) \to \mathrm{QCoh}(\mathsf{X};\mathcal{D})$ *induces an equivalence of completions.*

Proof. The implication (i) $\Rightarrow$ (ii) is immediate. Conversely, suppose that (ii) is satisfied. We wish to show that for every étale morphism $\eta : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$, the A-linear functor $u_\eta : \mathcal{C}_\eta \to \mathcal{D}_\eta$ induces an equivalence of completions. Equivalently, we must show that u_η induces an equivalence on n-truncated objects for each $n \geqslant 0$. For this, it will suffice to show that the t-exact functor of stable ∞-categories $\mathrm{Sp}(u)_\eta : \mathrm{Sp}(\mathcal{C}_\eta) \to \mathrm{Sp}(\mathcal{D}_\eta)$ induces an equivalence on n-truncated objects. Let $\mathscr{A}$ be as in the proof of Proposition 10.3.1.13, so that we have canonical equivalences

$$\mathrm{Sp}(\mathcal{C}_\eta) \simeq \mathrm{LMod}_{\mathscr{A}}(\mathrm{QCoh}(\mathsf{X};\mathrm{Sp}(\mathcal{C}))) \qquad \mathrm{Sp}(\mathcal{D}_\eta) \simeq \mathrm{LMod}_{\mathscr{A}}(\mathrm{QCoh}(\mathsf{X};\mathrm{Sp}(\mathcal{D})))$$

which restrict to equivalences

$$\mathrm{Sp}(\mathcal{C}_\eta)_{\leqslant n} \simeq \mathrm{LMod}_{\mathscr{A}}(\mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C}))_{\leqslant n}) \qquad \mathrm{Sp}(\mathcal{D}_\eta) \simeq \mathrm{LMod}_{\mathscr{A}}(\mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{D})_{\leqslant n})).$$

It will therefore suffice to show that the functor u induces an equivalence of ∞-categories $\mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C}))_{\leqslant n} \to \mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{D}))_{\leqslant n}$, which follows immediately from assumption (ii). □

10.3.2 Compact Generation

Let X be a quasi-compact, quasi-separated spectral algebraic space. Proposition 9.6.1.2 asserts that the ∞-category $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ of connective quasi-coherent sheaves on X is compactly generated. Our goal in this section is to prove a relative version of this result:

Theorem 10.3.2.1. *Let X be a spectral Deligne-Mumford stack and let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ be a prestable quasi-coherent stack on X. Then:*

- (a) *If X is quasi-geometric and the ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is compactly generated, then the quasi-coherent stack $\mathcal{C}$ is compactly generated.*
- (b) *If X is a quasi-compact, quasi-separated spectral algebraic space and the quasi-coherent stack $\mathcal{C}$ is compactly generated, then the prestable ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is compactly generated.*

Remark 10.3.2.2. In the special case where $\mathcal{C}$ is the unit object of $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$, Theorem 10.3.2.1 reduces to Proposition 9.6.1.2.

Corollary 10.3.2.3. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks. Suppose that f is representable by quasi-compact, quasi-separated spectral algebraic spaces. If $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ is compactly generated, then $f_* \mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{Y})$ is compactly generated.*

Proof. Using Proposition 10.1.4.1, we can reduce to the case where Y is affine, in which case the desired result follows from Theorem 10.3.2.1. □

As a first step towards a proof of Theorem 10.3.2.1, we establish a criterion for recognizing compact objects in an ∞-category of the form $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$.

Lemma 10.3.2.4. *Let X be a spectral Deligne-Mumford stack, let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ be compactly generated, and let $C \in \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ be an object. The following conditions are equivalent:*

1. *For every map $\eta : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$, the image of C under the forgetful functor $\mathrm{QCoh}(\mathsf{X}; \mathcal{C}) \to \mathcal{C}_\eta$ is compact.*

(2) *For every étale* $\eta : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$*, the image of* C *under the forgetful functor* $\mathrm{QCoh}(\mathsf{X}; \mathcal{C}) \to \mathcal{C}_\eta$ *is compact.*

(3) *There exists a jointly surjective collection of étale maps* $\eta_\alpha : \mathrm{Sp\acute{e}t}\, A_\alpha \to \mathsf{X}$ *such that the image of* C *under each of the forgetful functors* $\mathrm{QCoh}(\mathsf{X}; \mathcal{C}) \to \mathcal{C}_{\eta_\alpha}$ *is compact.*

Proof. The implications (1) ⇒ (2) ⇒ (3) are obvious. We prove that (3) ⇒ (1). Assume that (3) is satisfied for some jointly surjective $\eta_\alpha : \mathrm{Spec}\, A_\alpha \to \mathsf{X}$, and choose any map $\xi : \mathrm{Spec}\, R \to \mathsf{X}$. Then there exists a finite collection of étale maps $\{R \to R_\beta\}$ for which the induced map $R \to \prod_\beta R_\beta$ is faithfully flat, such that each of the induced maps $\mathrm{Spec}\, R_\beta \to \mathrm{Spec}\, R$ fits into a commutative diagram

$$\begin{array}{ccc} \mathrm{Spec}\, R_\beta & \longrightarrow & \mathrm{Spec}\, A_\alpha \\ \downarrow & & \downarrow \eta_\alpha \\ \mathrm{Spec}\, R & \xrightarrow{\xi} & \mathsf{X} \end{array}$$

for some index α. It follows that the image of C in $\mathrm{Mod}_{R_\beta}(\mathcal{C}_\xi)$ is compact for every index β. Applying Remark D.5.2.3, we deduce that the image of C in $\mathcal{C}_\xi$ is compact. □

Definition 10.3.2.5. Let X be a spectral Deligne-Mumford stack and let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ be compactly generated. We will say that an object of $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is *locally compact* if it satisfies the equivalent conditions of Lemma 10.3.2.4.

We now prove a decategorified version of Theorem 10.3.2.1:

Proposition 10.3.2.6. *Let* X *be a spectral Deligne-Mumford stack, let* $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ *be compactly generated, and let* C *be an object of* $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$*. Then:*

(a) *If* X *is quasi-geometric and* C *is a compact object of* $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$*, then* C *is locally compact.*

(b) *If* X *is a quasi-compact, quasi-separated spectral algebraic space and* C *is locally compact, then* C *is a compact object of* $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$*.*

Proof. We first prove (a). Assume that X is quasi-geometric and let $\eta : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$; we wish to show that pullback along η determines a functor $f : \mathrm{QCoh}(\mathsf{X}; \mathcal{C}) \to \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A; \eta^* \mathcal{C}) = \mathcal{C}_\eta$ which preserves compact objects. In fact, we claim that the functor f is compact. To prove this, it will suffice to show that the induced map of stable ∞-categories $F : \mathrm{Sp}(\mathrm{QCoh}(\mathsf{X}; \mathcal{C})) \to \mathrm{Sp}(\mathcal{C}_\eta)$ admits a right adjoint G which commutes with small colimits (see Proposition C.3.4.1). This follows from Propositions 10.2.4.2 and 10.2.1.3, which allow us to identify G with the forgetful functor $\mathrm{LMod}_{\mathscr{A}}(\mathrm{Sp}(\mathrm{QCoh}(\mathsf{X}; \mathcal{C}))) \to \mathrm{Sp}(\mathrm{QCoh}(\mathsf{X}; \mathcal{C}))$, where $\mathscr{A} \in \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{X}))$ denotes the direct image of the structure sheaf of $\mathrm{Sp\acute{e}t}\, A$.

We now prove (b). Every object $C \in \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ determines a colimit-preserving functor $\lambda : \mathrm{Sp}^{\mathrm{cn}} \to \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ satisfying $\lambda(S) = C$ (Example C.3.1.2), which we can identify with a map of quasi-coherent stacks $\overline{\lambda} : \mathcal{Q}^{\mathrm{cn}}_{\mathsf{X}} \to \mathcal{C}$. Note that if C is locally compact, then the morphism quasi-coherent stacks $\overline{\lambda}$ is compact. Invoking Proposition 10.3.1.14, we deduce that the induced map of global sections

$$\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \simeq \mathrm{QCoh}(\mathsf{X}; \mathcal{Q}^{\mathrm{cn}}_{\mathsf{X}}) \xrightarrow{\mathrm{QCoh}(\mathsf{X}; \overline{\lambda})} \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$$

is compact. Unwinding the definitions, we see that this functor carries the structure sheaf of X to the object $C \in \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$. We are therefore reduced to proving that the structure sheaf of X is a compact object of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$, which is a special case of Proposition 9.6.1.1. □

The proof of Theorem 10.3.2.1 will require the following more elaborate version of Proposition D.5.3.4:

Lemma 10.3.2.7. *Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a compactly generated prestable R-linear ∞-category, and let $I \subseteq \pi_0 R$ be a finitely generated ideal. For each object $C \in \mathrm{Sp}(\mathcal{C})$, set $T(C) = C \oplus \Sigma(C)$. Suppose that $C \in \mathrm{Sp}(\mathcal{C})$ is an object satisfying the following condition:*

- $(*)$ *For every element $a \in I$, the localization $C[a^{-1}] = R[a^{-1}] \otimes_R C$ is a compact object of $\mathrm{LMod}_{R[a^{-1}]}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$.*

Then there exists an integer $e \geqslant 0$ and a morphism $\alpha : D \to T^e(C)$ in $\mathrm{Sp}(\mathcal{C})$, where D is a compact object of $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ and α induces an equivalence $D[a^{-1}] \to T^e(C)[a^{-1}]$ for all $a \in I$.

Proof. Since I is finitely generated, we can write $I = (a_1, \ldots, a_n)$ for some nonnegative integer n. We proceed by induction on n. If $n = 0$, then $I = (0)$ and there is nothing to prove. Otherwise, set $J = (a_1, \ldots, a_{n-1})$. Applying the inductive hypothesis, we can choose a compact object $D_0 \in \mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ and a map $\beta : D_0 \to T^d(C)$ which induces an equivalence $D_0[a^{-1}] \simeq T^d(C)[a^{-1}]$ for all $a \in J$. Replacing C by $T^d(C)$, we can assume without loss of generality that $d = 0$. Let $C' = \mathrm{cofib}(\beta)$. Then $C'[a_n^{-1}]$ is a compact object of $\mathrm{LMod}_{R[a_n^{-1}]}(\mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$. Arguing as in the proof of Proposition D.5.3.4, we deduce that $T(C'[a_n^{-1}])$ can be written as $E[a_n^{-1}]$ for some compact object $E \in \mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. Replacing C by $T(C)$, we may assume that $C'[a_n^{-1}] \simeq E[a_n^{-1}]$, where E is a compact object of $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$.

Fix $1 \leqslant i < n$. By construction, we have $C'[a_i^{-1}] \simeq 0$. Since $C'[a_n^{-1}]$ is a compact object of $\mathrm{LMod}_{R[a_n^{-1}]}(\mathrm{Sp}(\mathcal{C}))$, it follows that the map $a_i^m : C'[a_n^{-1}] \to C'[a_n^{-1}]$ is nullhomotopic for $m \gg 0$. Consequently, $T(C'[a_n^{-1}])$ is equivalent to $E'[a_n^{-1}]$, where $E' = \mathrm{cofib}(a_i^m : E \to E)$ is a compact object of $\mathcal{C}_{\geqslant 0}$ satisfying $E[a_i^{-1}] \simeq 0$. Replacing C by $T(C)$ and E by E', we can assume that $E[a_i^{-1}] \simeq 0$. Applying this argument repeatedly, we can arrange that $E[a_i^{-1}] \simeq 0$ for *all* $i \in \{1, 2, \ldots, n-1\}$.

Fix an equivalence $\gamma_0 : E[a_n^{-1}] \simeq C'[a_n^{-1}]$. Since E is a compact object of $\mathrm{Sp}(\mathcal{C})$, we may assume (after multiplying γ_0 by a suitable power of a_n) that γ_0 is induced by a morphism

$\gamma : E \to C'$ in the ∞-category $\mathrm{Sp}(\mathcal{C})$. We now define D to be the pullback $C \times_{C'} E$. The existence of a fiber sequence $D_0 \to D \to E$ shows that D is a compact object of $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. We claim that the projection map $e : D \to C$ induces an equivalence $D[a^{-1}] \to C[a^{-1}]$ whenever $a \in I$. To prove this, we observe that the condition $a \in I$ guarantees that the map $R[a^{-1}] \to \prod_{1 \leqslant i \leqslant n} R[(aa_i)^{-1}]$ is étale and faithfully flat; it will therefore suffice to show that e becomes an equivalence after tensoring with $R[a_i^{-1}]$ for $1 \leqslant i \leqslant n$. For $i < n$, this follows from the fact that both sides vanish; when $i = n$, it follows from our construction. □

Proof of Theorem 10.3.2.1. We first prove (a). Suppose that X is a quasi-geometric spectral Deligne-Mumford stack and let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ have the property that $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is compactly generated; we wish to show that the prestable quasi-coherent stack $\mathcal{C}$ is compactly generated. Fix a map $\eta : \mathrm{Spét}\, A \to \mathsf{X}$; we will show that the A-linear ∞-category $\mathcal{C}_\eta$ is compactly generated. Set $\mathcal{E} = \mathrm{Sp}(\mathrm{QCoh}(\mathsf{X}; \mathcal{C}))$, so $\mathcal{E}$ admits a t-structure $(\mathcal{E}_{\geqslant 0}, \mathcal{E}_{\leqslant 0})$ with $\mathcal{E}_{\geqslant 0} \simeq \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$. Let $\mathscr{A} \in \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{X}))$ denote the direct image of the structure sheaf of $\mathrm{Spét}\, A$ and let us regard $\mathrm{LMod}_{\mathscr{A}}(\mathcal{E})$ as equipped with the t-structure described in Construction 10.2.1.1, so that Theorem 10.2.0.1 supplies an equivalence $\mathcal{C}_\eta \simeq \mathrm{LMod}_{\mathscr{A}}(\mathcal{E})_{\geqslant 0}$. By definition, $\mathrm{LMod}_{\mathscr{A}}(\mathcal{E})_{\geqslant 0}$ is the smallest full subcategory of $\mathrm{LMod}_{\mathscr{A}}(\mathcal{E})$ which is closed under colimits and extensions and contains each tensor product $\mathscr{A} \otimes E$, where $E \in \mathcal{E}_{\geqslant 0}$. Since $\mathcal{E}_{\geqslant 0} \simeq \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is compactly generated, we can also describe $\mathrm{LMod}_{\mathscr{A}}(\mathcal{E})_{\geqslant 0}$ as the smallest full subcategory of $\mathrm{LMod}_{\mathscr{A}}(\mathcal{E})$ which is closed under colimits and extensions and contains $\mathscr{A} \otimes E$ where E is a *compact* object of $\mathcal{E}_{\geqslant 0}$. In this case, $\mathscr{A} \otimes E$ is a compact object of $\mathrm{LMod}_{\mathscr{A}}(\mathcal{E})$. Applying Proposition C.6.3.1, we deduce that the ∞-category $\mathrm{LMod}_{\mathscr{A}}(\mathcal{E})_{\geqslant 0}$ is compactly generated.

We now prove (b). Assume that X is a quasi-compact, quasi-separated spectral algebraic space and let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ be compactly generated; we wish to prove that the Grothendieck prestable ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is compactly generated. We will show that $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ satisfies the criterion of Corollary C.6.3.3: that is, for every nonzero object $N \in \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$, we will show that there exists a nonzero map $C \to N$ in $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$, where C is compact (by virtue of Proposition 10.3.2.6, this is equivalent to the requirement that C is locally compact).

Since X is a quasi-compact, quasi-separated spectral algebraic space, we can choose a scallop decomposition $\varnothing = \mathsf{U}_0 \to \mathsf{U}_1 \to \cdots \to \mathsf{U}_n \simeq \mathsf{X}$ and excision squares

$$\begin{array}{ccc} \mathsf{V}_i & \longrightarrow & \mathrm{Spét}\, R_i \\ \downarrow & & \downarrow{\scriptstyle \eta_i} \\ \mathsf{U}_{i-1} & \longrightarrow & \mathsf{U}_i; \end{array}$$

see Theorem 3.4.2.1. For $0 \leqslant i \leqslant n$, let $\mathcal{C}_{\mathsf{U}_i}$ denote the restriction of $\mathcal{C}$ to the open substack $\mathsf{U}_i \subseteq \mathsf{X}$ and let N_i denote the image of N in the ∞-category $\mathrm{QCoh}(\mathsf{U}_i; \mathcal{C}_{\mathsf{U}_i})$. Since $N \neq 0$, there exists some smallest integer i such that $N_i \neq 0$. Since $\mathsf{U}_0 = \emptyset$, we have $i > 0$, and the minimality of i guarantees that the image of N_i in $\mathrm{QCoh}(\mathsf{U}_{i-1}; \mathcal{C}_{\mathsf{U}_{i-1}})$ vanishes. It follows that N_i has nonzero image in the prestable R_i-linear ∞-category $\mathcal{C}_{\eta_i}$. Let us denote this image by N'. Our assumption that the quasi-coherent stack $\mathcal{C}$ is compactly generated guarantees that the prestable ∞-category $\mathcal{C}_{\eta_i}$ is compactly generated. Let $I \subseteq \pi_0 R_i$ be a finitely generated ideal which defines the open substack $\mathsf{V}_i \subseteq \mathrm{Spét}\, R_i$, so that the vanishing of N_{i-1} guarantees that N' is I-nilpotent. Proposition 7.1.1.12 guarantees that the collection of I-nilpotent objects of $\mathcal{C}_{\eta_i}$ form a compactly generated prestable ∞-category. It then follows from Corollary C.6.3.3 (or from the proof of Proposition 7.1.1.12) that there exists a nonzero map $\rho : M' \to N'$ in $\mathcal{C}_{\eta_i}$, where M' is compact and I-nilpotent (Proposition 7.1.1.12). Note that the domain and codomain of ρ vanish when restricted to the open substack $\mathsf{V}_i \subseteq \mathrm{Spét}\, R_i$. Using the pullback diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{U}_i; \mathcal{C}_{\mathsf{U}_i}) & \longrightarrow & \mathrm{QCoh}(\mathsf{U}_{i-1}; \mathcal{C}_{\mathsf{U}_{i-1}}) \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathrm{Spét}\, R_i; \mathcal{C}_{\eta_i}) & \longrightarrow & \mathrm{QCoh}(\mathsf{V}_i; \mathcal{C}_{\mathsf{V}_i}), \end{array}$$

we can lift the map $\rho : M' \to N'$ (in an essentially unique way) to a morphism $\rho_i : M_i \to N_i$ in the ∞-category $M_i \in \mathrm{QCoh}(\mathsf{U}_i; \mathcal{C})$, where M_i has vanishing image in $\mathrm{QCoh}(\mathsf{U}_{i-1}; \mathcal{C}_{\mathsf{U}_i})$. It follows from Lemma 10.3.2.4 that the object M_i is locally compact.

We now prove the following assertion:

($*$) For $i \leqslant j \leqslant n$, there exists a nonzero morphism $\rho_j : M_j \to N_j$ in $\mathrm{QCoh}(\mathsf{U}_j; \mathcal{C}_{\mathsf{U}_j})$, where M_j is locally compact.

The proof proceeds by induction on j, the case $j = i$ having been handled above. When $j = n$, we will obtain a nonzero morphism from a locally compact object of $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ into N, which will complete the proof of Theorem 10.3.2.1.

Let us assume that $i < j$ and that $\rho_{j-1} : M_{j-1} \to N_{j-1}$ has been constructed. We let u denote the composite map $M_{j-1} \oplus \Sigma M_{j-1} \to M_{j-1} \xrightarrow{\rho_{j-1}} N_{j-1}$, and let u_0 be the image of u in $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{V}_j; \mathcal{C}_{\mathsf{V}_j})$. Let N'' denote the image of N in $\mathrm{QCoh}(\mathrm{Spét}\, R_j; \mathcal{C}_{\eta_j})$. Using the pullback diagram

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{U}_j; \mathcal{C}_{\mathsf{U}_j}) & \longrightarrow & \mathrm{QCoh}(\mathsf{U}_{j-1}; \mathcal{C}_{\mathsf{U}_{j-1}}) \\ \downarrow & & \downarrow g^* \\ \mathrm{QCoh}(\mathrm{Spét}\, R_j; \mathcal{C}_{\eta_j}) & \xrightarrow{h^*} & \mathrm{QCoh}(\mathsf{V}_j; \mathcal{C}_{\mathsf{V}_j}), \end{array}$$

we are reduced to proving that u_0 can be lifted to a morphism $v : M'' \to N''$ in $\mathrm{QCoh}(\mathrm{Spét}\, R_j; \mathcal{C}_{\eta_j})$ for some compact object $M'' \in \mathrm{QCoh}(\mathrm{Spét}\, R_j; \mathcal{C})$.

It follows from Lemma 10.3.2.7 that, after replacing M_{j-1} by the direct sum $M_{j-1} \oplus \Sigma M_{j-1}$ finitely many times, we can assume that the object $g^* M_{j-1}$ can be lifted to a compact object

$M'' \in \mathcal{C}_{\eta_j}$. Then we can regard u_0 as a morphism from $h^* M''$ to $h^* N''$, which determines a map $v_0 : M'' \to h_* h^* N''$ in the ∞-category. Let K denote the cofiber of the unit map $N'' \to h^* h^* N''$, let Q denote the cokernel of the composite map $\pi_0 M'' \xrightarrow{v_0} \pi_0(h_* h^* N'') \to \pi_0 K$ (formed in the abelian category $\mathcal{C}_{\eta_j}^{\heartsuit}$), and let K_0 denote the fiber of the map $K \to \pi_0 K \to Q$. By construction, the object $K \in \mathcal{C}_{\eta_j}^{\heartsuit}$ is I-nilpotent (in the sense of Proposition 7.1.1.12). For each $x \in I$, we can identify $Q[x^{-1}]$ with a quotient of $\pi_0 K[x^{-1}]$. It follows that Q is also I-nilpotent, so that the fiber K_0 is I-nilpotent. Using Proposition 7.1.1.12, we can write K_0 as a filtered colimit of I-nilpotent compact objects $K_\alpha \in \mathcal{C}_\alpha$. By construction, the composite map $M'' \to h_* h^* N'' \to K$ factors K_0 and therefore (by virtue of the compactness of M'') through some K_α. Let L denote the fiber of the map $K_\alpha \to K_0$, so that L is also an I-nilpotent object of $\mathcal{C}_{\eta_j}$. Applying Proposition 7.1.1.12 again, we can write L as a filtered colimit $\varinjlim L_\beta$, where each L_β is a compact I-nilpotent object. For each β, let $P_\beta \in \mathcal{C}_{\eta_j}^{\heartsuit}$ be the cokernel of the induced map $\pi_0(M'' \oplus L_\beta) \to \pi_0 K_\alpha$. Then

$$\varinjlim P_\beta \simeq \operatorname{coker}(\pi_0(M'' \oplus L) \to \pi_0 K_\alpha) \simeq \operatorname{coker}(\pi_0(M'') \to \pi_0 K_0) \simeq 0.$$

It follows that the map $K_\alpha \to \pi_0 K_\alpha \to \varinjlim P_\beta$ is nullhomotopic. Using the compactness of K_α, we deduce that there exists an index β for which the composite map $K_\alpha \to \pi_0 K_\alpha \to P_\beta$ is nullhomotopic: that is, the map $\epsilon : M'' \oplus L_\beta \to K_\alpha$ is an epimorphism on π_0. Let F denote the fiber of ϵ, so that the fiber sequence $F \to M'' \oplus L_\beta \to K_\alpha$ remains a fiber sequence after applying the functor $\Sigma^\infty : \mathcal{C}_{\eta_j} \to \operatorname{Sp}(\mathcal{C}_{\eta_j})$. Since M'', L_β, and K_α are compact, the object F is also compact. Moreover, since the objects L_β and K_α are I-nilpotent, the map $F \to M''$ induces an equivalence $h^* F \to h^* M''$. We may therefore replace M'' by F and thereby reduce to the case where the composite map $M'' \xrightarrow{v_0} h_* h^* N'' \to K$ is nullhomotopic, so that v_0 factors through the unit map $h_* h^* N''$ as desired. □

10.3.3 Anticomplete Quasi-Coherent Stacks

We now consider some more subtle variants of Definition 10.3.1.3.

Definition 10.3.3.1. Let X be a spectral Deligne-Mumford stack and let $\mathcal{C}$ be a prestable quasi-coherent stack on X.

(1) We will say that $\mathcal{C}$ is *anticomplete* if, for every étale morphism $\eta : \operatorname{Spét} A \to \mathsf{X}$, the A-linear ∞-category $\mathcal{C}_\eta$ is anticomplete.

(2) We will say that $\mathcal{C}$ is *weakly coherent* if, for every étale morphism $\eta : \operatorname{Spét} A \to \mathsf{X}$, the A-linear ∞-category $\mathcal{C}_\eta$ is weakly coherent.

Warning 10.3.3.2. In the situation of Definition 10.3.3.1, the assumption that $\eta : \operatorname{Spét} A \to \mathsf{X}$ is étale plays an essential role: the condition that a prestable A-linear ∞-category $\mathcal{C}$ is anticomplete (weakly coherent) is not preserved by arbitrary base change. Consequently, Definition 10.3.3.1 makes sense when X is a spectral Deligne-Mumford stack, but not for an arbitrary functor $\mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$.

Remark 10.3.3.3. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks and let $\mathcal{C}$ be a prestable quasi-coherent stack on Y. Then:

- (i) Suppose that f is flat and that the diagonal map $\delta : \mathsf{X} \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ has finite Tor-amplitude. If $\mathcal{C}$ is anticomplete, then $f^* \mathcal{C}$ is anticomplete: this follows from Theorems D.5.4.1 and D.5.4.9.
- (ii) Suppose that f is locally almost of finite presentation and locally quasi-finite. If $\mathcal{C}$ is weakly coherent, then $f^* \mathcal{C}$ is weakly coherent: this follows from Theorem D.5.5.1 and Corollary D.5.5.11.

In particular, if f is étale and $\mathcal{C}$ is anticomplete (weakly coherent), then $f^* \mathcal{C}$ is also anticomplete (weakly coherent). The converse holds if f is an étale surjection (see Proposition 10.3.0.3).

Remark 10.3.3.4. Let A be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a prestable A-linear ∞-category. Then $\mathcal{C}$ is anticomplete (weakly coherent) when regarded as a Grothendieck prestable ∞-category if and only if it is anticomplete (weakly coherent) when regarded as a prestable quasi-coherent stack on $\mathrm{Sp\acute{e}t}\, A$.

We now establish a global analogue of Lemma D.5.4.5.

Proposition 10.3.3.5. *Let X be a spectral Deligne-Mumford stack, let $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{lex}}$ denote the subcategory of $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ whose morphisms are left exact, and let $\mathrm{QStk}^{\mathrm{ch}}(\mathsf{X})$ denote the full subcategory of $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{lex}}$ whose objects are anticomplete prestable quasi-coherent stacks on X (see Definition 10.3.3.1). Then:*

- (a) *The inclusion functor $\mathrm{QStk}^{\mathrm{ch}}(\mathsf{X}) \hookrightarrow \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{lex}}$ admits a right adjoint, which we will denote by $\mathcal{C} \mapsto \check{\mathcal{C}}$.*
- (b) *Let $f : \mathcal{C} \to \mathcal{D}$ be a left exact morphism of prestable quasi-coherent stacks on X. Then f induces an equivalence $\check{\mathcal{C}} \to \check{\mathcal{D}}$ if and only if, for each étale morphism $\eta : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$, the induced A-linear functor $f_\eta : \mathcal{C}_\eta \to \mathcal{D}_\eta$ induces an equivalence of completions.*

Proof. Write $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathsf{X}})$. For each object $U \in \mathcal{X}$, set $\mathsf{X}_U = (\mathcal{X}_{/U}, \mathcal{O}_{\mathsf{X}}|_U)$. Let us say that $U \in \mathcal{X}$ is *good* if the conclusions of Proposition 10.3.3.5 hold when X is replaced by X_U. By virtue of Proposition 1.4.7.9, it will suffice to prove the following:

- (i) Every affine object $U \in \mathcal{X}$ is good.

(ii) The collection of good objects of $\mathcal{X}$ is closed under small colimits.

Assertion (i) follows immediately from Lemma D.5.4.5. To prove (ii), suppose we are given a small diagram $\rho : \mathcal{J} \to \mathcal{X}$ having colimit $X \in \mathcal{X}$, where $\rho(J)$ is good for each object $J \in \mathcal{J}$. The construction $(J \in \mathcal{J}) \mapsto \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}_{\rho(J)})^{\mathrm{lex}}$ classifies a coCartesian fibration of ∞-categories $q : \mathcal{E} \to \mathcal{J}^{\mathrm{op}}$. Let us identify objects of $\mathcal{E}$ with pairs $(J, \mathcal{C})$, where $J \in \mathcal{J}$ and $\mathcal{C}$ is a prestable quasi-coherent stack on $\mathsf{X}_{\rho(J)}$. Let $\mathcal{E}^{\mathrm{ch}}$ denote the full subcategory of $\mathcal{E}$ spanned by those pairs $(J, \mathcal{C})$ where $\mathcal{C}$ is anticomplete. It follows from Remark 10.3.1.4 that the restriction $q|_{\mathcal{E}^{\mathrm{ch}}} : \mathcal{E}^{\mathrm{ch}} \to \mathcal{J}^{\mathrm{op}}$ is also a coCartesian fibration, and that the inclusion $\mathcal{E}^{\mathrm{ch}} \hookrightarrow \mathcal{E}$ carries $q|_{\mathcal{E}^{\mathrm{ch}}}$-coCartesian morphisms to q-coCartesian morphisms. Since each $\rho(J)$ is good, each of the inclusion maps $\mathcal{E}^{\mathrm{ch}} \times_{\mathcal{J}^{\mathrm{op}}} \{J\} \hookrightarrow \mathcal{E} \times_{\mathcal{J}^{\mathrm{op}}} \{J\}$ admits a right adjoint. Applying Proposition HA.7.3.2.6 , we deduce that the inclusion $\mathcal{E}^{\mathrm{ch}} \hookrightarrow \mathcal{E}$ admits a right adjoint $G : \mathcal{E} \to \mathcal{E}^{\mathrm{ch}}$ relative to $\mathcal{J}^{\mathrm{op}}$. Using the fact that each $\mathsf{X}_{\rho(J)}$ satisfies condition (b) of Proposition 10.3.3.5, we see that the functor G carries q-coCartesian morphisms of $\mathcal{E}$ to $q|_{\mathcal{E}^{\mathrm{ch}}}$-coCartesian morphisms of $\mathcal{E}^{\mathrm{ch}}$. Using Proposition HTT.3.3.3.1 , we obtain equivalences

$$\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}_X)^{\mathrm{lex}} \simeq \varprojlim_{J \in \mathcal{J}} \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}_{\rho(J)})^{\mathrm{lex}} \simeq \mathrm{Fun}'_{\mathcal{J}^{\mathrm{op}}}(\mathcal{J}^{\mathrm{op}}, \mathcal{E})$$

$$\mathrm{QStk}^{\mathrm{ch}}(\mathsf{X}_X) \simeq \varprojlim_{J \in \mathcal{J}} \mathrm{QStk}^{\mathrm{ch}}(\mathsf{X}_{\rho(J)}) \simeq \mathrm{Fun}'_{\mathcal{J}^{\mathrm{op}}}(\mathcal{J}^{\mathrm{op}}, \mathcal{E}^{\mathrm{ch}}),$$

where $\mathrm{Fun}'_{\mathcal{J}^{\mathrm{op}}}(\mathcal{J}^{\mathrm{op}}, \mathcal{E})$ denotes the full subcategory of $\mathrm{Fun}'_{\mathcal{J}^{\mathrm{op}}}(\mathcal{J}^{\mathrm{op}}, \mathcal{E})$ spanned by those functors which carry every morphism in $\mathcal{J}^{\mathrm{op}}$ to a q-coCartesian morphism in $\mathcal{E}$ and $\mathrm{Fun}'_{\mathcal{J}^{\mathrm{op}}}(\mathcal{J}^{\mathrm{op}}, \mathcal{E}^{\mathrm{ch}})$ is defined similarly. Under these equivalences, pointwise composition with G determines a functor $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}_X)^{\mathrm{lex}} \to \mathrm{QStk}^{\mathrm{ch}}(\mathsf{X}_X)$ which is a right adjoint to the inclusion, so that X_X satisfies condition (a) of Proposition 10.3.3.5. Moreover, the proof yields the following version of (b):

(b') Let $f : \mathcal{C} \to \mathcal{D}$ be a left exact morphism of prestable quasi-coherent stacks on X_X. Then f induces an equivalence $\check{\mathcal{C}} \to \check{\mathcal{D}}$ if and only if, for each étale morphism $\eta : \mathrm{Spét}\, A \to \mathsf{X}_X$ which factors through $\mathsf{X}_{\rho(J)}$ for some $J \in \mathcal{J}$, the induced A-linear functor $f_\eta : \mathcal{C}_\eta \to \mathcal{D}_\eta$ induces an equivalence of completions.

To complete the proof, it suffices to observe that if $f : \mathcal{C} \to \mathcal{D}$ satisfies the criterion of (b'), then the induced functor $f_\eta : \mathcal{C}_\eta \to \mathcal{D}_\eta$ induces an equivalence of completions for *every* étale morphism $\eta : \mathrm{Spét}\, A \to \mathsf{X}_X$, since this can be checked locally with respect to the étale topology on $\mathrm{Spét}\, A$. □

Let X be a spectral Deligne-Mumford stack on X and let $\mathcal{C}$ be a prestable quasi-coherent stack on X. Unwinding the definitions, we see that the quasi-coherent stack $\check{\mathcal{C}}$ is characterized by the following:

(i) There exists a left exact morphism $\lambda : \check{\mathcal{C}} \to \mathcal{C}$ in $\mathrm{QStk}^{\mathrm{PSt}}(\mathcal{C})$.

(ii) The morphism λ induces an equivalence of completions.

(iii) The prestable quasi-coherent stack $\check{\mathcal{C}}$ is anticomplete.

Combining this observation with Remark 10.3.3.3, we obtain the following:

Corollary 10.3.3.6. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Assume that f is flat and that the diagonal map $\delta : \mathsf{X} \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ has finite* Tor*-amplitude. Then the diagram of ∞-categories*

$$\begin{array}{ccc} \mathrm{QStk}^{\mathrm{ch}}(\mathsf{X}) & \longrightarrow & \mathrm{QStk}^{\mathrm{PSt,lex}}(\mathsf{X}) \\ \downarrow f^* & & \downarrow f^* \\ \mathrm{QStk}^{\mathrm{ch}}(\mathsf{Y}) & \longrightarrow & \mathrm{QStk}^{\mathrm{PSt,lex}}(\mathsf{Y}) \end{array}$$

is right adjointable. In other words, for every prestable quasi-coherent stack $\mathcal{C}$ on Y, the canonical map $\widetilde{f^* \mathcal{C}} \to f^*(\check{\mathcal{C}})$ is an equivalence in $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$.

We now consider local-to-global principles which are satisfied by the notions introduced in Definition 10.3.3.1.

Proposition 10.3.3.7. *Let X be a quasi-compact, quasi-separated spectral algebraic space and let $\mathcal{C}$ be a prestable quasi-coherent stack on X. The following conditions are equivalent:*

(a) The quasi-coherent stack $\mathcal{C}$ is anticomplete.

(b) The Grothendieck prestable ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is anticomplete.

Proof. Let $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{lex}}$ denote the subcategory of $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ whose morphisms are left exact and define $\mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)^{\mathrm{lex}} \subseteq \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)$ similarly. Let S be the collection of those morphisms in $\mathrm{QStk}^{\mathrm{PSt,lex}}(\mathsf{X})^{\mathrm{lex}}$ which induce equivalences of completions and define $S' \subseteq \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)^{\mathrm{lex}}$ similarly. It follows from Proposition 10.3.1.14 that the equivalence

$$\mathrm{QCoh}(\mathsf{X}; \bullet) : \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}) \to \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)$$

of Theorem 10.2.0.2 restricts to an equivalence of ∞-categories

$$\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{lex}} \simeq \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)^{\mathrm{lex}},$$

and from Corollary 10.3.1.15 that this equivalence carries S to S'. Using Proposition 10.3.3.5, we see that a prestable quasi-coherent stack $\mathcal{C}$ on X is anticomplete if and only if it is an S-local object of $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$. Similarly, since $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ is a compactly generated prestable ∞-category whose stabilization is locally rigid (see Proposition 9.6.1.2), Lemma D.5.4.5 implies that $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is anticomplete if and only if it is an S'-local object of $\mathrm{Mod}_{\mathrm{Coh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)^{\mathrm{lex}}$. □

Lemma 10.3.3.8. *Let* X *be a quasi-compact, quasi-separated spectral algebraic space and let* $\mathcal{C}$ *be a prestable quasi-coherent stack on* X*. If* $\mathcal{C}$ *is anticomplete and weakly coherent, then* $\Gamma(\mathsf{X};\mathcal{C})$ *is anticomplete and weakly coherent.*

Proof. Applying Theorem C.6.7.1 (and the quasi-compactness of X), we see that $\mathcal{C}$ is compactly generated, that the loop functor $\Omega : \mathrm{QCoh}(\mathsf{X};\mathcal{C}) \to \mathrm{QCoh}(\mathsf{X};\mathcal{C})$ carries locally compact objects to locally compact objects (Definition 10.3.2.5), and that every locally compact object of $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ is truncated. Using Theorem 10.3.2.1 and Proposition 10.3.2.6, we deduce that $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ is compactly generated and that an object of $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ is compact if and only if it is locally compact. The desired result now follows from Theorem C.6.7.1. □

Proposition 10.3.3.9. *Let* X *be a quasi-compact, quasi-separated spectral algebraic space and let* $\mathcal{C}$ *be a prestable quasi-coherent stack on* X*. If* $\mathcal{C}$ *is weakly coherent, then* $\Gamma(\mathsf{X};\mathcal{C})$ *is weakly coherent.*

Proof. Let $\check{\mathcal{C}} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ be as in Proposition 10.3.3.5. Then the canonical map $\lambda : \check{\mathcal{C}} \to \mathcal{C}$ induces an equivalence of completions. It follows from Corollary C.6.5.5 that $\check{\mathcal{C}}$ is weakly coherent, so that Lemma 10.3.3.8 implies that $\Gamma(\mathsf{X};\check{\mathcal{C}})$ is anticomplete and weakly coherent. Since the induced map $\mathrm{QCoh}(\mathsf{X};\check{\mathcal{C}}) \to \mathrm{QCoh}(\mathsf{X};\mathcal{C})$ also induces an equivalence of completions, Corollary C.6.5.5 guarantees that $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ is also weakly coherent. □

10.3.4 Complicial Quasi-Coherent Stacks

Let X be a spectral Deligne-Mumford stack and let $\mathrm{QCoh}(\mathsf{X})$ denote the ∞-category of quasi-coherent sheaves on X. Then $\mathrm{QCoh}(\mathsf{X})$ is equipped with a t-structure, whose heart $\mathrm{QCoh}(\mathsf{X})^{\heartsuit}$ is the abelian category of quasi-coherent sheaves on the underlying ordinary Deligne-Mumford stack of X (see §2.2.6). Using Theorem C.5.4.9, we see that the inclusion $\mathrm{QCoh}(\mathsf{X})^{\heartsuit} \hookrightarrow \mathrm{QCoh}(\mathsf{X})$ admits an essentially unique extension to a colimit-preserving t-exact functor

$$F : \mathcal{D}(\mathrm{QCoh}(\mathsf{X})^{\heartsuit}) \to \mathrm{QCoh}(\mathsf{X}).$$

We now consider the following:

Question 10.3.4.1. Let X be a spectral Deligne-Mumford stack. Under what conditions can we assert that the functor $F : \mathcal{D}(\mathrm{QCoh}(\mathsf{X})^{\heartsuit}) \to \mathrm{QCoh}(\mathsf{X})$ is an equivalence of ∞-categories?

In the special case where X is schematic and 0-truncated, Question 10.3.4.1 was studied by Bökstedt and Neeman. In this case, X can be identified with an ordinary scheme $(X, \mathscr{O}_X)$, and the ∞-category $\mathrm{QCoh}(\mathsf{X})$ can be identified with the full subcategory $\mathcal{D}_{\mathrm{qc}}(\mathrm{Mod}^{\heartsuit}_{\mathscr{O}_X}) \subseteq \mathcal{D}(\mathrm{Mod}^{\heartsuit}_{\mathscr{O}_X})$ spanned by chain complexes of $\mathscr{O}_X$-modules having quasi-coherent cohomology sheaves. Under the assumption that X is quasi-compact and separated, Bökstedt and Neeman show that $\mathcal{D}_{\mathrm{qc}}(\mathrm{Mod}^{\heartsuit}_{\mathscr{O}_X})$ can be recovered as the derived ∞-category of its heart.

Our goal in this section is formulate and prove a relative version of the Bökstedt-Neeman result (we recover a slight variant of their result as Corollary 10.3.4.13 below). We begin by noting that for *any* spectral Deligne-Mumford stack X, the t-structure on $\mathrm{QCoh}(\mathsf{X})$ is right and left complete and compatible with filtered colimits (Proposition 2.2.5.4). Using Remark C.5.4.11, we can reformulate Question 10.3.4.1 as follows:

Question 10.3.4.2. Let X be a spectral Deligne-Mumford stack. Under what conditions can we assert that the Grothendieck prestable ∞-category $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ is 0-complicial (see Definition C.5.3.1)?

Question 10.3.4.2 is an instance of the following more general question:

Question 10.3.4.3. Let X be a spectral Deligne-Mumford stack, let $\mathcal{C}$ be a quasi-coherent stack on X, and let $n \geqslant 0$ be an integer. Under what conditions can we assert that the Grothendieck prestable ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is n-complicial?

To address Question **??**, we will need to introduce some terminology.

Definition 10.3.4.4. Let X be a spectral Deligne-Mumford stack, let $n \geqslant 0$ be an integer, and let $\mathcal{C}$ be a prestable quasi-coherent stack on X.

(1) We will say that $\mathcal{C}$ is *weakly n-complicial* if, for every étale morphism $\eta : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$, the A-linear ∞-category $\mathcal{C}_\eta$ is weakly n-complicial.

(2) Assume that $\mathcal{C}$ is either separated or anticomplete. We will say that $\mathcal{C}$ is *n-complicial* if, for every étale morphism $\eta : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$, the A-linear ∞-category $\mathcal{C}_\eta$ is n-complicial.

Warning 10.3.4.5. We do not know if the condition that a prestable A-linear ∞-category $\mathcal{C}$ is n-complicial can be tested locally with respect to the étale topology on A. However, this is true if we restrict our attention to prestable A-linear ∞-categories which are either anticomplete or separated (Corollary D.5.7.3), which is why these conditions appear in part (2) of Definition 10.3.4.4.

Remark 10.3.4.6. Let $f : \mathsf{X} \to \mathsf{Y}$ be flat morphism of spectral Deligne-Mumford stacks and let $\mathcal{C}$ be a prestable quasi-coherent stack on Y.

(*i*) If $\mathcal{C}$ is weakly n-complicial, then $f^* \mathcal{C}$ is weakly n-complicial.

(*ii*) If $\mathcal{C}$ is separated and n-complicial, then $f^* \mathcal{C}$ is separated and n-complicial.

(*iii*) If the diagonal map $\delta : \mathsf{X} \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ has finite Tor-amplitude and $\mathcal{C}$ is anticomplete and n-complicial, then $f^* \mathcal{C}$ is anticomplete and n-complicial.

In particular, if f is étale and $\mathcal{C}$ is weakly n-complicial (separated and n-complicial, anticomplete and n-complicial), then $f^* \mathcal{C}$ is also weakly n-complicial (separated and n-complicial, anticomplete and n-complicial). The converse holds if f is an étale surjection (see Proposition 10.3.0.3).

Remark 10.3.4.7. Let A be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a prestable A-linear ∞-category. Then $\mathcal{C}$ is weakly n-complicial (separated and n-complicial, anticomplete and n-complicial) when regarded as a Grothendieck prestable ∞-category if and only if it is weakly n-complicial (separated and n-complicial, anticomplete and n-complicial) when regarded as a prestable quasi-coherent stack on Spét A.

Example 10.3.4.8. Let X be a spectral Deligne-Mumford stack and let $\mathcal{Q}_{\mathsf{X}}^{\mathrm{cn}}$ be the unit object of $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ (see Example 10.1.6.2). The following conditions are equivalent (see Proposition C.5.5.15):

(*i*) The structure sheaf $\mathscr{O}_{\mathsf{X}}$ is n-truncated.

(*ii*) The quasi-coherent stack $\mathcal{Q}_{\mathsf{X}}^{\mathrm{cn}}$ is weakly n-complicial.

(*iii*) The quasi-coherent stack $\mathcal{Q}_{\mathsf{X}}^{\mathrm{cn}}$ is separated and n-complicial.

Proposition 10.3.4.9. *Let X be a spectral Deligne-Mumford stack, let $\mathcal{C}$ be a prestable quasi-coherent stack on X, and let $n \geqslant 0$ be an integer. If X is geometric, then $\mathcal{C}$ is weakly n-complicial if and only if the ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is weakly n-complicial.*

Proof. Using Remark C.5.5.14, we can replace $\mathcal{C}$ by its completion $\widehat{\mathcal{C}}$ and thereby reduce to the case where $\mathcal{C}$ is complete. In this case, Proposition 10.3.4.9 is a special case of Proposition 10.4.6.6, which we will discuss in §10.4. □

Proposition 10.3.4.10. *Let X be a quasi-compact, quasi-separated spectral algebraic space, let $\mathcal{C}$ be a prestable quasi-coherent stack on X, and let $n \geqslant 0$. Assume that the diagonal map $\delta : \mathsf{X} \to \mathsf{X} \times \mathsf{X}$ is affine. Then $\mathcal{C}$ is anticomplete and n-complicial if and only if the Grothendieck prestable ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C}$ is anticomplete and n-complicial.*

Proof. Combine Propositions C.5.5.16, 10.3.3.7, and 10.3.4.9. □

Proposition 10.3.4.11. *Let X be a geometric spectral Deligne-Mumford stack, let $\mathcal{C}$ be a prestable quasi-coherent stack on X, and let $n \geqslant 0$. Then:*

(1) *If $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is separated and n-complicial, then $\mathcal{C}$ is separated and n-complicial.*

(2) *If X is a quasi-compact, quasi-separated spectral algebraic space and $\mathcal{C}$ is separated and n-complicial, then $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is separated and n-complicial.*

Proof. We first prove (1). Assume that $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ is separated and n-complicial. Applying Proposition 10.3.1.8, we deduce that $\mathcal{C}$ is separated. To complete the proof, it will suffice to show that for every étale morphism $\eta : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$, the prestable A-linear ∞-category $\mathcal{C}_\eta$ is n-complicial. Set $\mathscr{A} = \eta_* \mathscr{O}_{\mathrm{Sp\acute{e}t}\, A} \in \mathrm{CAlg}(\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}})$, so that Proposition 10.2.4.2 supplies an equivalence $\mathcal{C}_\eta \simeq \mathrm{LMod}_{\mathscr{A}}(\mathrm{QCoh}(\mathsf{X};\mathcal{C}))$. Let X be an object of $\mathcal{C}_\eta$, which we will identify with an $\mathscr{A}$-module object of $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$. Our assumption that $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ is n-complicial guarantees that there exists a morphism $u : Y \to X$ in $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ which is surjective on π_0, where Y is n-truncated. Extending scalars, we can identify u with a morphism $u' : \mathscr{A} \otimes Y \to X$ whose domain is also n-truncated (since $\mathscr{A} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ is flat) which is also an epimorphism on π_0. Allowing X to vary, we conclude that $\mathcal{C}_\eta \simeq \mathrm{LMod}_{\mathscr{A}}(\mathrm{QCoh}(\mathsf{X};\mathcal{C}))$ is n-complicial, which completes the proof of (1).

We now prove (2). Assume that $\mathcal{C}$ is separated and n-complicial. Let $\lambda : \check{\mathcal{C}} \to \mathcal{C}$ be as in Proposition 10.3.3.5 and $\check{\mathcal{C}}^{\mathrm{sep}}$ denote the separated quotient of $\check{\mathcal{C}}$ (see Proposition 10.3.1.11). Applying Remark C.5.5.14, we deduce that $\check{\mathcal{C}}$ is weakly n-complicial. Since $\check{\mathcal{C}}$ is anticomplete, it follows from Proposition C.5.5.16 that $\check{\mathcal{C}}$ is n-complicial. Applying Proposition C.5.3.3, we see that $\check{\mathcal{C}}^{\mathrm{sep}}$ is n-complicial. Because $\mathcal{C}$ is separated, the map λ factors as a composition $\check{\mathcal{C}} \to \check{\mathcal{C}}^{\mathrm{sep}} \xrightarrow{\mu} \mathcal{C}$. The domain and codomain of μ are both separated and n-complicial. Since μ induces an equivalence of completions, it follows from Proposition C.5.3.9 that μ is an equivalence: that is, the map λ exhibits $\mathcal{C}$ as the separated quotient of $\check{\mathcal{C}}$. Passing to global sections, we obtain an equivalence $\mathrm{QCoh}(\mathsf{X};\mathcal{C}) \simeq \mathrm{QCoh}(\mathsf{X};\check{\mathcal{C}})^{\mathrm{sep}}$. It follows from Proposition 10.3.4.10 that the ∞-category $\mathrm{QCoh}(\mathsf{X};\check{\mathcal{C}})$ is n-complicial, so that $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ is also n-complicial by virtue of Proposition C.5.3.3. We conclude the proof by observing that $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ is also separated (Proposition 10.3.1.8). □

Specializing to the case $\mathcal{C} = \mathcal{Q}^{\mathrm{cn}}_X$, we obtain the following:

Corollary 10.3.4.12. *Let X be a spectral Deligne-Mumford stack. Then:*

(1) *If X is geometric, then the structure sheaf $\mathscr{O}_{\mathsf{X}}$ is n-truncated if and only if the Grothendieck prestable ∞-category $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ is weakly n-complicial.*

(2) *If X is a geometric spectral algebraic space, then the structure sheaf $\mathscr{O}_{\mathsf{X}}$ is n-truncated if and only if the Grothendieck prestable ∞-category $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ is n-complicial.*

Proof. Combine Example 10.3.4.8, Proposition 10.3.4.9, and Proposition 10.3.4.11. □

Specializing to the case $n = 0$, we obtain the following:

Corollary 10.3.4.13. *Let X be a spectral Deligne-Mumford stack. Then:*

(1) *If X is 0-truncated and geometric, then the inclusion $\mathrm{QCoh}(\mathsf{X})^{\heartsuit} \hookrightarrow \mathrm{QCoh}(\mathsf{X})$ extends to a t-exact equivalence $\widehat{\mathcal{D}}(\mathrm{QCoh}(\mathsf{X})^{\heartsuit}) \simeq \mathrm{QCoh}(\mathsf{X})$.*

(2) *If* X *is a* 0*-truncated geometric spectral algebraic space, then the inclusion* $\mathrm{QCoh}(\mathsf{X})^{\heartsuit} \hookrightarrow \mathrm{QCoh}(\mathsf{X})$ *extends ot an equivalence* $\mathcal{D}(\mathrm{QCoh}(\mathsf{X})^{\heartsuit}) \simeq \mathrm{QCoh}(\mathsf{X})$.

Remark 10.3.4.14. In the special case where X is schematic and separated, part (2) of Corollary 10.3.4.13 was proven by Bökstedt and Neeman; see [29].

Proof of Corollary 10.3.4.13. Note that for any spectral Deligne-Mumford stack X, the t-structure on $\mathrm{QCoh}(\mathsf{X})$ is both left and right complete (Proposition 2.2.5.4). Assertion (1) now follows from Corollaries 10.3.4.12 and C.5.9.7, while (2) follows from Corollaries 10.3.4.12 and C.5.8.11. □

10.4 Complete Quasi-Coherent Stacks

Let X be a quasi-compact, quasi-separated spectral algebraic space. According to Theorem 10.2.0.2, the global sections functor $\mathcal{C} \mapsto \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ establishes an equivalence between quasi-coherent stacks on X and Grothendieck prestable ∞-categories equipped with an action of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$. Our goal in this section is to establish an analogous result in the case where X is replaced by a geometric stack $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ (Definition 9.3.0.1). More precisely, we will prove (Theorem 10.4.2.3) that for every geometric stack X, the following data are equivalent:

- Prestable quasi-coherent stacks on X which are *complete* (Definition 10.3.1.3).
- Complete Grothendieck prestable ∞-categories $\mathcal{C}$ equipped with an action of $\mathrm{QCoh}(X)^{\mathrm{cn}}$, having the additional property that tensor product with any *flat* object of $\mathrm{QCoh}(X)^{\mathrm{cn}}$ determines a left exact functor from $\mathcal{C}$ to itself.

This equivalence can be regarded as a categorification of the fact that for an affine scheme X, the category of quasi-coherent sheaves on X is equivalent to the category of modules over the commutative ring $\Gamma(X; \mathscr{O}_X)$. However, our result requires a much weaker hypothesis: we need affineness only for the diagonal $X \to X \times X$, rather than for X itself.

10.4.1 The Global Sections Functor

Let S denote the sphere spectrum. For any functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, the projection map $q : X \to \operatorname{Spec} S$ induces a pullback functor

$$\mathsf{Groth}_\infty \simeq \mathrm{QStk}^{\mathrm{PSt}}(\operatorname{Spec} S) \xrightarrow{q^*} \mathrm{QStk}^{\mathrm{PSt}}(X).$$

When X is representable by a spectral Deligne-Mumford stack, Construction 10.1.7.1 shows that this pullback functor admits a right adjoint $\mathrm{QCoh}(X; \bullet) : \mathrm{QStk}^{\mathrm{PSt}}(X) \to \mathsf{Groth}_\infty$. We would like to prove an analogous assertion in the case where X is a quasi-geometric stack.

Here we encounter a technical obstacle: if X is representable by a Deligne-Mumford stack, then we can use an étale surjection $u : \operatorname{Spec} A \to X$ and étale descent for Grothendieck prestable ∞-categories (Theorem D.4.1.2) to reduce to the case where X is affine. If X is assumed only to be a quasi-geometric stack, then we can choose a faithfully flat map $u : \operatorname{Spec} A \to X$, but we generally cannot arrange that u is étale. We do not know if the theory of Grothendieck prestable ∞-categories satisfies descent for the flat topology. Consequently, we will restrict our attention to *complete* Grothendieck prestable ∞-categories (where the requisite descent property follows from Proposition D.6.6.2).

Remark 10.4.1.1. The completeness hypotheses we use in this section can be removed if we are willing to impose some mild additional hypotheses on X, like the requirement that X admits a map $u : \operatorname{Spec} A \to X$ which both is faithfully flat and locally almost of finite presentation (this condition is satisfied, for example, if X is obtained from an Artin stack in classical algebraic geometry): in this case, we can use Theorem D.4.1.6 as a replacement for Theorem D.4.1.2. However, completeness assumptions will be needed again to characterize the essential image of the global sections functor $\operatorname{QCoh}(X; \bullet)$ (Theorem 10.4.2.3).

Notation 10.4.1.2. For each functor $X : \operatorname{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, we let $\operatorname{QStk}^{\mathrm{comp}}(X)$ denote the full subcategory of $\operatorname{QStk}^{\mathrm{PSt}}(X)$ spanned by the complete prestable quasi-coherent stacks on X. It follows from Remark **??** that we can regard the construction $X \mapsto \operatorname{QStk}^{\mathrm{comp}}(X)$ as defining a functor $\operatorname{QStk}^{\mathrm{comp}} : \operatorname{Fun}(\operatorname{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_{\infty}$.

Remark 10.4.1.3. Using Lemma 6.2.1.13, we see that the functor $\operatorname{QStk}^{\mathrm{comp}}$ can be regarded as a right Kan extension of the functor

$$\operatorname{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{C}\mathrm{at}}_{\infty} \qquad A \mapsto \operatorname{LinCat}_A^{\mathrm{comp}}$$

along the Yoneda embedding $j : \operatorname{Fun}(\operatorname{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})^{\mathrm{op}}$. Since the functor $A \mapsto \operatorname{LinCat}_A^{\mathrm{comp}}$ is a sheaf with respect to the fpqc topology (Theorem D.6.8.1), it follows that the construction $\operatorname{QStk}^{\mathrm{comp}}$ factors through the formation of sheafification for the fpqc topology. In other words, if $f : X \to Y$ is a natural transformation between functors $X, Y : \operatorname{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ which induces an equivalence after sheafification with respect to the fpqc topology, then the pullback functor $f^* \operatorname{QStk}^{\mathrm{comp}}(Y) \to \operatorname{QStk}^{\mathrm{comp}}(X)$ is an equivalence of ∞-categories.

Proposition 10.4.1.4. *Let $X : \operatorname{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a quasi-geometric stack, let S denote the sphere spectrum, and let $q : X \to \operatorname{Spec} S$ be the projection map. Then the pullback functor*

$$q^* : \mathsf{Groth}_{\infty}^{\mathrm{comp}} \simeq \operatorname{QStk}^{\mathrm{comp}}(\operatorname{Sp\acute{e}t} S) \to \operatorname{QStk}^{\mathrm{comp}}(X)$$

admits a right adjoint $\operatorname{QCoh}(X; \bullet) : \operatorname{QStk}^{\mathrm{comp}}(X) \to \mathsf{Groth}_{\infty}^{\mathrm{comp}}$.

Proof. Let X be a geometric stack and let $q : X \to \operatorname{Spec} S$ be the projection map. Fix an object $\mathcal{C} \in \mathrm{QStk}^{\mathrm{comp}}(X)$. We wish to show that the functor

$$F : \mathsf{Groth}_{\infty}^{\mathrm{comp}} \to \widehat{\mathcal{S}} \qquad \mathcal{E} \mapsto \mathrm{Map}_{\mathrm{QStk}^{\mathrm{comp}}(X)}(q^{*}\mathcal{E}, \mathcal{C})$$

is representable by an object of $\mathsf{Groth}_{\infty}^{\mathrm{comp}}$. Choose a faithfully flat map $f_0 : U_0 \to X$ where $U_0 \simeq \operatorname{Spec} A^0$ is affine and let $U_\bullet$ denote the Čech nerve of f_0. For each $n \geqslant 0$, let $f_n : U_n \to X$ be the tautological map and let $F^n : \mathsf{Groth}_{\infty}^{\mathrm{comp}} \to \widehat{\mathcal{S}}$ denote the functor given by

$$\mathcal{E} \mapsto \mathrm{Map}_{\mathrm{QStk}^{\mathrm{comp}}(U_n)}(f_n^{*} q^{*}\mathcal{E}, f_n^{*}\mathcal{C}).$$

Note that each F^n is representable by the complete Grothendieck prestable ∞-category $\mathrm{QCoh}(U_n; f_n^{*}\mathcal{C})$ of Construction 10.1.7.1.

Since the natural map $|U_\bullet| \to X$ is an equivalence after sheafification for the fpqc topology, the ∞-category $\mathrm{QStk}^{\mathrm{comp}}(X)$ can be identified with the totalization of the cosimplicial ∞-category $\mathrm{QStk}^{\mathrm{comp}}(U_\bullet)$ (see Remark 10.4.1.3), so that $F \simeq \varprojlim_{[n] \in \mathbf{\Delta}} F^n$. Consequently, to show that F is representable, it will suffice to show that the cosimplicial object $[n] \mapsto \mathrm{QCoh}(U_n; f_n^{*}\mathcal{C})$ admits a limit in the ∞-category $\mathsf{Groth}_{\infty}^{\mathrm{comp}}$. Using the right cofinality of the inclusion $\mathbf{\Delta}_s \hookrightarrow \mathbf{\Delta}$ (Lemma HTT.6.5.3.7) and the fact that $\mathsf{Groth}_{\infty}^{\mathrm{comp}}$ is closed under limits in Groth_{∞} (Proposition C.3.6.3), it will suffice to show that the underlying cosemisimplicial object of Groth_{∞} admits a limit. Note that if $\alpha : [m] \to [n]$ is a morphism in $\mathbf{\Delta}_{+}$, then the associated map $U_n \to U_m$ is flat (since it is a composition of pullbacks of the flat map $f_0 : U_0 \to X$), so that the associated pullback functor $\mathrm{QCoh}(U_m; f_m^{*}\mathcal{C}) \to \mathrm{QCoh}(U_n; f_n^{*}\mathcal{C})$ is left exact (Corollary 10.1.7.10). It follows that the construction $[n] \mapsto \mathrm{QCoh}(U_n; f_n^{*}\mathcal{C})$ determines a functor from $\mathbf{\Delta}_s$ to the subcategory $\mathsf{Groth}_{\infty}^{\mathrm{lex}} \subseteq \mathsf{Groth}_{\infty}$ of Notation C.3.2.3, so the existence of the limit $\varprojlim \mathrm{QCoh}(U_\bullet; f_\bullet^{*}\mathcal{C})$ follows from Proposition C.3.2.4. □

Example 10.4.1.5. Let X be a geometric stack and $\mathcal{C}$ be a complete quasi-coherent stack on X. The proof of Proposition 10.4.1.4 shows that the ∞-category $\mathrm{QCoh}(X; \mathcal{C})$ can be identified with the totalization $\varprojlim \mathrm{QCoh}(U_\bullet; f_\bullet^{*}\mathcal{C})$, where $f_\bullet : U_\bullet \to X$ is the Čech nerve of any faithfully flat map $f_0 : U_0 = \operatorname{Spec} A \to X$. Taking $\mathcal{C} = \mathcal{Q}_X^{\mathrm{cn}}$, we obtain an equivalence of ∞-categories

$$\mathrm{QCoh}(X; \mathcal{Q}_X^{\mathrm{cn}}) \simeq \varprojlim \mathrm{QCoh}(U_\bullet; \mathcal{Q}_{U_\bullet}^{\mathrm{cn}}) = \varprojlim \mathrm{QCoh}(U_\bullet)^{\mathrm{cn}} \simeq \mathrm{QCoh}(X)^{\mathrm{cn}}.$$

10.4.2 Recovering $\mathcal{C}$ from $\mathrm{QCoh}(X; \mathcal{C})$

Let A be a connective $\mathbb{E}_\infty$-ring and let $\mathrm{LinCat}_A^{\mathrm{comp}}$ denote the ∞-category of complete A-linear prestable ∞-categories. Then the inclusion $\mathrm{LinCat}_A^{\mathrm{comp}} \hookrightarrow \mathrm{LinCat}_A^{\mathrm{PSt}}$ admits a left adjoint L, given by the completion functor of Proposition C.3.6.3. This left adjoint is compatible with the symmetric monoidal structure of Remark D.2.3.1 (in the sense of

Definition HA.2.2.1.6). It follows that $\mathrm{LinCat}_A^{\mathrm{comp}}$ inherits a symmetric monoidal structure, whose tensor product $(\mathcal{C}, \mathcal{D}) \mapsto \mathcal{C} \widehat{\otimes}_A \mathcal{D}$ is the completion of the usual A-linear tensor product $\mathcal{C} \otimes_A \mathcal{D}$ (in the special case where A is the sphere spectrum, this is the completed tensor product of Warning C.4.6.3). We can therefore regard the construction $A \mapsto \mathrm{LinCat}_A^{\mathrm{comp}}$ as a functor from the ∞-category $\mathrm{CAlg}^{\mathrm{cn}}$ of connective $\mathbb{E}_\infty$-rings to the ∞-category $\mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty)$ of (not necessarily small) symmetric monoidal ∞-categories.

Construction 10.4.2.1. [Completed Tensor Products of Quasi-Coherent Stacks] The construction $X \mapsto \mathrm{QStk}^{\mathrm{comp}}(X)$ of Notation 10.4.1.2 can be regarded as a right Kan extension of the functor $A \mapsto \mathrm{LinCat}_A^{\mathrm{comp}}$ along the Yoneda embedding $\mathrm{CAlg}^{\mathrm{cn}} \hookrightarrow \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \widehat{\mathcal{S}})^{\mathrm{op}}$. Since the forgetful functor $\mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty) \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ commutes with limits, it commutes with the formation of right Kan extensions along j. Consequently, for every functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$, we can regard $\mathrm{QStk}^{\mathrm{comp}}(X)$ as a symmetric monoidal ∞-category.

Remark 10.4.2.2. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be any functor. The tensor product on $\mathrm{QStk}^{\mathrm{comp}}(X)$ is computed "pointwise" in the following sense: for every connective $\mathbb{E}_\infty$-ring A and every point $\eta \in X(A)$, we have a canonical equivalence of A-linear ∞-categories $(\mathcal{C} \otimes \mathcal{D})_\eta \simeq \mathcal{C}_\eta \widehat{\otimes}_A \mathcal{D}_\eta$ for any pair of complete prestable quasi-coherent stacks $\mathcal{C}, \mathcal{D} \in \mathrm{QStk}^{\mathrm{comp}}(X)$.

Suppose now that X is a quasi-geometric stack and let $q : X \to \operatorname{Spec} S$ be as in Proposition 10.4.1.4. Then the pullback functor $q^* : \mathsf{Groth}_\infty^{\mathrm{comp}} \simeq \mathrm{QStk}^{\mathrm{comp}}(\operatorname{Spec} S) \to \mathrm{QStk}^{\mathrm{comp}}(X)$ is symmetric monoidal. It follows that the global sections functor $\mathrm{QCoh}(X; \bullet) : \mathrm{QStk}^{\mathrm{comp}}(X) \to \mathsf{Groth}_\infty^{\mathrm{comp}}$ is lax symmetric monoidal. Consequently, we can promote the functor $\mathrm{QCoh}(X; \bullet)$ to a functor

$$\begin{aligned} \mathrm{QStk}^{\mathrm{comp}}(X) &\simeq \mathrm{Mod}_{\mathcal{Q}_X^{\mathrm{cn}}}(\mathrm{QStk}^{\mathrm{comp}}(X)) \\ &\xrightarrow{\mathrm{QCoh}(X;\bullet)} \mathrm{Mod}_{\mathrm{QCoh}(X;\mathcal{Q}_X^{\mathrm{cn}})}(\mathsf{Groth}_\infty^{\mathrm{comp}}) \\ &\simeq \mathrm{Mod}_{\mathrm{QCoh}(X)^{\mathrm{cn}}}(\mathsf{Groth}_\infty^{\mathrm{comp}}). \end{aligned}$$

We will abuse notation by denoting this functor also by $\mathcal{C} \mapsto \mathrm{QCoh}(X; \mathcal{C})$. We can describe the situation more informally as follows: for every complete quasi-coherent stack $\mathcal{C}$ on X, the ∞-category $\mathrm{QCoh}(X; \mathcal{C})$ of global sections of $\mathcal{C}$ is tensored over ∞-category $\mathrm{QCoh}(X)^{\mathrm{cn}}$ of connective quasi-coherent sheaves on X, and the action

$$\mathrm{QCoh}(X)^{\mathrm{cn}} \times \mathrm{QCoh}(X; \mathcal{C}) \to \mathrm{QCoh}(X; \mathcal{C})$$

preserves small colimits separately in each variable. We can now formulate the main result of this section (which we will prove in §10.4.4):

Theorem 10.4.2.3. *Let X be a geometric stack. Then the global sections functor*

$$\mathrm{QCoh}(X; \bullet) : \mathrm{QStk}^{\mathrm{comp}}(X) \to \mathrm{Mod}_{\mathrm{QCoh}(X)^{\mathrm{cn}}}(\mathsf{Groth}_\infty^{\mathrm{comp}})$$

is fully faithful. Moreover, for an object $\mathcal{E} \in \mathrm{Mod}_{\mathrm{QCoh}(X)^{\mathrm{cn}}}(\mathsf{Groth}_\infty^{\mathrm{comp}})$*, the following conditions are equivalent:*

(*i*) *The* ∞*-category* $\mathcal{E}$ *belongs to the essential image of the functor* $\mathrm{QCoh}(X; \bullet)$.

(*ii*) *For every flat quasi-coherent sheaf* $\mathscr{F} \in \mathrm{QCoh}(X)$*, the construction* $E \mapsto \mathscr{F} \otimes E$ *determines a left exact functor from* $\mathcal{E}$ *to itself.*

(*iii*) *There exists a faithfully flat map* $\eta : \operatorname{Spec} A \to X$ *for which the construction* $E \mapsto \mathscr{F} \otimes E$ *determines a left exact functor from* $\mathcal{E}$ *to itself, where* $\mathcal{F} \in \mathrm{QCoh}(X)^{\mathrm{cn}}$ *is the cofiber of the unit map* $\mathscr{O}_X \to \eta_* \mathscr{O}_{\operatorname{Spec} A}$.

10.4.3 Digression: Module Objects of Prestable ∞-Categories

Our proof of Theorem 10.4.2.3 will use the following general observation about Grothendieck prestable ∞-categories:

Proposition 10.4.3.1. *Let* $\mathcal{C}$ *and* $\mathcal{D}$ *be presentable* ∞*-categories and suppose that we are given a functor* $G : \mathcal{D} \to \mathcal{C}$ *which is conservative and preserves small limits and colimits. If* $\mathcal{C}$ *is a Grothendieck prestable* ∞*-category, then so is* $\mathcal{D}$*. Moreover, if* $\mathcal{C}$ *is stable (separated, complete), then so is* $\mathcal{D}$*.*

Example 10.4.3.2. Let $\mathcal{C}$ be a Grothendieck prestable ∞-category which is tensored over a monoidal ∞-category $\mathcal{A}$. Suppose that A is an algebra object of $\mathcal{A}$ and that the functor

$$(C \in \mathcal{C}) \mapsto (A \otimes C \in \mathcal{C})$$

commutes with small colimits. Then the forgetful functor $\mathrm{LMod}_A(\mathcal{C}) \to \mathcal{C}$ is conservative and preserves small limits and colimits (see Corollaries HA.4.2.3.3 and HA.4.2.3.5). It follows from Proposition 10.4.3.1 that $\mathrm{LMod}_A(\mathcal{C})$ is a Grothendieck prestable ∞-category, which is complete (separated, stable) whenever $\mathcal{C}$ is complete (separated, stable).

Remark 10.4.3.3. Proposition 10.4.3.1 can be deduced from Example 10.4.3.2: if $G : \mathcal{D} \to \mathcal{C}$ is a functor between presentable ∞-categories which preserves small limits and colimits, then G admits a left adjoint $F : \mathcal{C} \to \mathcal{D}$. It follows that the composition $T = G \circ F$ can be regarded as an algebra object of the monoidal ∞-category $\mathrm{Fun}(\mathcal{C}, \mathcal{C})$. If G is conservative then Theorem HA.4.7.3.5 supplies an equivalence $\mathcal{D} \simeq \mathrm{LMod}_T(\mathcal{C})$ under which G corresponds to the forgetful functor $\mathrm{LMod}_T(\mathcal{C}) \to \mathcal{C}$.

Proof of Proposition 10.4.3.1. Assume that $\mathcal{C}$ is a Grothendieck prestable ∞-category. We first prove that $\mathcal{D}$ is pointed. Let $\varnothing$ and $\mathbf{1}$ denote initial and final objects of $\mathcal{D}$, respectively, so that there is an essentially unique map $\alpha : \varnothing \to \mathbf{1}$ in $\mathcal{D}$. We wish to prove that α is an equivalence. Since G preserves small limits and colimits, it preserves initial and final objects, so that $G(\alpha)$ is a morphism from an initial object of $\mathcal{C}$ to a final object of $\mathcal{C}$. Because $\mathcal{C}$ is pointed, it follows that $G(\alpha)$ is an equivalence. Since the functor G is conservative, it follows that α is an equivalence.

We next claim that that the suspension functor $\Sigma_{\mathcal{D}} : \mathcal{D} \to \mathcal{D}$ is fully faithful. Let D be an object of $\mathcal{D}$ and let $u : D \to \Omega_{\mathcal{D}}\Sigma_{\mathcal{D}}D$ be the unit map. Since the functor G commutes with limits and colimits, we can identify $G(u)$ with the unit map $G(D) \to \Omega_{\mathcal{C}}\Sigma_{\mathcal{C}}G(D)$, which is an equivalence by virtue of prestability of $\mathcal{C}$. Since G is conservative, it follows that u is an equivalence.

We now complete the proof that $\mathcal{D}$ is prestable by verifying condition (c) of Definition **??**. Suppose we are given a morphism $f : Y \to \Sigma_{\mathcal{D}}Z$ in the ∞-category $\mathcal{D}$. We can then form a pullback diagram σ :

$$\begin{array}{ccc} X & \longrightarrow & Y \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & \Sigma_{\mathcal{D}}Z. \end{array}$$

Since G commutes with finite colimits, we can identify $G(\sigma)$ with a diagram

$$\begin{array}{ccc} G(X) & \longrightarrow & G(Y) \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & \Sigma_{\mathcal{C}}G(Z). \end{array}$$

Since G commutes with finite limits, the diagram $G(\sigma)$ is a pullback square. Using the prestability of $\mathcal{C}$, we conclude that $G(\sigma)$ is also a pushout square. Because G is conservative and commutes with pushouts, it follows that σ is a pushout square in $\mathcal{D}$. This completes the proof that $\mathcal{D}$ is prestable.

We now claim that $\mathcal{D}$ is a *Grothendieck* prestable ∞-category: that is, that filtered colimits in $\mathcal{D}$ are left exact. Let K be a finite simplicial set and let $\varprojlim_K : \mathrm{Fun}(K, \mathcal{D}) \to \mathcal{D}$ be a right adjoint to the diagonal map; we wish to show that $\varprojlim_K$ commutes with filtered colimits. Since the functor G is conservative and commutes with filtered colimits, it will suffice to show that the composite functor $\mathrm{Fun}(K, \mathcal{D}) \xrightarrow{\varprojlim_K} \mathcal{D} \xrightarrow{G} \mathcal{C}$ commutes with filtered colimits. Because G commutes with finite limits, this functor also factors as a composition $\mathrm{Fun}(K, \mathcal{D}) \xrightarrow{G\circ} \mathrm{Fun}(K, \mathcal{C}) \to \mathcal{C}$, which commutes with filtered colimits because G commutes with all colimits and filtered colimits in $\mathcal{C}$ are left exact.

Suppose that $\mathcal{C}$ is stable; we wish to show that $\mathcal{D}$ is also stable. Equivalently, we wish to show that for each object $D \in \mathcal{D}$, the counit map $v : \Sigma_{\mathcal{D}}\Omega_{\mathcal{D}}D \to D$ is an equivalence. Since the functor G commutes with limits and colimits, we can identify $G(v)$ with the counit map $\Sigma_{\mathcal{C}}\Omega_{\mathcal{C}}G(D) \to G(D)$, which is an equivalence by virtue of the stability of $\mathcal{C}$. Because G is conservative, we conclude that v is also an equivalence, as desired.

Suppose now that $\mathcal{C}$ is separated; we wish to prove that $\mathcal{D}$ is also separated. Fix an object $D \in \mathcal{D}$ satisfying $\tau_{\leqslant n} D \simeq 0$ for each $n \geqslant 0$; we wish to prove that $D \simeq 0$. For each integer $n \geqslant 0$, we have a cofiber sequence $D_{>n} \to D \to \tau_{\leqslant n} D$ in the ∞-category $\mathcal{D}$, where $D_{>n}$ belongs to the essential image of the iterated suspension functor $\Sigma^{n+1}_{\mathcal{D}}$. Because the functor G commutes with suspension, the object $GD_{>n}$ belongs to the essential image of $\Sigma^{n+1}_{\mathcal{C}}$. Because G is left exact, the object $G(\tau_{\leqslant n} D) \in \mathcal{C}$ is n-truncated. It follows that the cofiber sequence $GD_{>n} \to GD \to G(\tau_{\leqslant n} D)$ exhibits $G(\tau_{\leqslant n} D)$ as the n-truncation of the object $GD \in \mathcal{C}$. Consequently, if $\tau_{\leqslant n} D$ vanishes in $\mathcal{D}$ for each $n \geqslant 0$, then $\tau_{\leqslant n} GD$ vanishes in $\mathcal{C}$ for each $n \geqslant 0$. The separatedness of $\mathcal{C}$ then implies that $GD \simeq 0$, and the conservativity of G implies that $D \simeq 0$.

Assume now that $\mathcal{C}$ is complete; we wish to prove that $\mathcal{D}$ is also complete. Suppose we are given a tower

$$\cdots \to D(2) \to D(1) \to D(0)$$

be a tower of objects of $\mathcal{D}$ which exhibits each $D(n)$ as the n-truncation of $D(n+1)$, and set $D = \varprojlim D(n)$. We wish to show that each of the maps $D \to D(n)$ induces an equivalence $\tau_{\leqslant n} D \to D(n)$. By virtue of the fact that G is conservative, it will suffice to show that the underlying map $G(\tau_{\leqslant n} D) \to G(D(n))$ is an equivalence in $\mathcal{C}$. The preceding argument shows that the functor G commutes with n-truncation, so it will suffice to show that the natural map $D \to D(n)$ exhibits $G(D(n))$ as an n-truncation of $G(D)$. This follows from the completeness of $\mathcal{C}$, because we can identify $G(D)$ with the limit of the Postnikov tower

$$\cdots \to G(D(2)) \to G(D(1)) \to G(D(0))$$

in the ∞-category $\mathcal{C}$. □

10.4.4 The Proof of Theorem 10.4.2.3

Let X be a geometric stack and let $\mathcal{C} \in \mathrm{Mod}_{\mathrm{QCoh}(X)^{\mathrm{cn}}}(\mathsf{Groth}_{\infty})$ be a Grothendieck prestable ∞-category equipped with an action of $\mathrm{QCoh}(X)^{\mathrm{cn}}$. For every connective $\mathbb{E}_{\infty}$-ring A and every point $\eta \in X(A)$, let $\mathcal{C}_{\eta}$ denote the tensor product $\mathrm{Mod}^{\mathrm{cn}}_A \otimes_{\mathrm{QCoh}(X)^{\mathrm{cn}}} \mathcal{C}$, formed in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable ∞-categories. Our assumption that X is a geometric stack guarantees that η is an affine morphism, so that we can identify $\mathrm{Mod}^{\mathrm{cn}}_A$ with the ∞-category $\mathrm{Mod}_{\mathscr{A}}(\mathrm{QCoh}(X)^{\mathrm{cn}})$ where $\mathscr{A} \in \mathrm{CAlg}(\mathrm{QCoh}(X)^{\mathrm{cn}})$ denotes the direct image of the structure sheaf of Spét A. Applying Theorem HA.4.8.4.6 , we obtain an equivalence $\mathcal{C}_{\eta} \simeq \mathrm{LMod}_{\mathscr{A}}(\mathcal{C})$. It follows from Example 10.4.3.2 that $\mathcal{C}_{\eta}$ is an (A-linear) Grothendieck prestable ∞-category, which is complete (separated, stable) if $\mathcal{C}$ is complete (separated, stable). In particular, the construction $\mathcal{C} \mapsto \{\mathcal{C}_{\eta}\}_{\eta \in X(A)}$ determines a functor

$$\Phi^{\mathrm{comp}}_X : \mathrm{Mod}_{\mathrm{QCoh}(X)^{\mathrm{cn}}}(\mathsf{Groth}^{\mathrm{comp}}_{\infty}) \to \mathrm{QStk}^{\mathrm{comp}}(X).$$

It is not difficult to see that the functor Φ_X^{comp} is left adjoint to the global sections functor $\mathrm{QCoh}(X;\bullet) : \mathrm{QStk}^{\mathrm{comp}}(X) \to \mathrm{Mod}_{\mathrm{QCoh}(X)^{\mathrm{cn}}}(\mathsf{Groth}_\infty^{\mathrm{comp}})$.

Proof of Theorem 10.4.2.3. Let X be a geometric stack and choose a faithfully flat map $\eta : U_0 \to X$, where $U_0 \simeq \operatorname{Spec} A$ is affine. We first claim that the global sections functor

$$\mathrm{QCoh}(X;\bullet) : \mathrm{QStk}^{\mathrm{comp}}(X) \to \mathrm{Mod}_{\mathrm{QCoh}(X)^{\mathrm{cn}}}(\mathsf{Groth}_\infty^{\mathrm{comp}})$$

is fully faithful. Let $\mathcal{C}$ be a complete quasi-coherent stack on X; we wish to show that the counit map $v : \Phi_X^{\mathrm{comp}} \mathrm{QCoh}(X;\mathcal{C}) \to \mathcal{C}$ is an equivalence of quasi-coherent stacks on X. Since η is an effective epimorphism of fpqc sheaves, it will suffice to show that $\eta^*(v)$ is an equivalence (see Remark 10.4.1.3). Unwinding the definitions, we wish to prove that the canonical map $\theta : \mathrm{Mod}_A^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(X)^{\mathrm{cn}}} \mathrm{QCoh}(X;\mathcal{C}) \to \mathcal{C}_\eta$ is an equivalence of A-linear prestable ∞-categories. Let $U_\bullet$ denote the Čech nerve of η, and for each $n \geqslant 0$ let $f_n : U_n \to X$ be the canonical map. Then the proof of Proposition 10.4.1.4 supplies a canonical equivalence $\mathrm{QCoh}(X;\mathcal{C}) \simeq \varprojlim \mathrm{QCoh}(U_\bullet; f_\bullet^* \mathcal{C})$.

Set $\mathscr{A} = \eta_* \mathscr{O}_{U_0} \in \mathrm{CAlg}(\mathrm{QCoh}(X)^{\mathrm{cn}})$. Since X is a geometric stack, the map η is affine and we can identify $\mathrm{Mod}_A^{\mathrm{cn}}$ with the ∞-category $\mathrm{Mod}_{\mathscr{A}}(\mathrm{QCoh}(X)^{\mathrm{cn}})$. It follows that $\mathrm{Mod}_A^{\mathrm{cn}}$ is self-dual as an object of the ∞-category $\mathrm{Mod}_{\mathrm{QCoh}(X)^{\mathrm{cn}}}(\mathsf{Groth}_\infty^{\mathrm{comp}})$, so that the formation of tensor products with $\mathrm{Mod}_A^{\mathrm{cn}}$ commutes with limits. We therefore have canonical equivalences

$$\begin{aligned} \mathrm{Mod}_A^{\mathrm{cn}} \otimes_{\mathrm{QCoh}(X)^{\mathrm{cn}}} \mathrm{QCoh}(X;\mathcal{C}) &\simeq \mathrm{LMod}_{\mathscr{A}}(\mathrm{QCoh}(X;\mathcal{C})) \\ &\simeq \varprojlim \mathrm{LMod}_{\mathscr{A}}(\mathrm{QCoh}(U_\bullet; f_\bullet^* \mathcal{C})) \\ &\simeq \mathrm{QCoh}(U_{\bullet+1}; f_{\bullet+1}^* \mathcal{C}). \end{aligned}$$

The statement that θ is an equivalence now follows from the observation that the augmented simplicial object $\mathrm{QCoh}(U_{\bullet+1}; f_{\bullet+1}^* \mathcal{C})$ is split.

We next show that for every complete quasi-coherent stack $\mathcal{C} \in \mathrm{QStk}^{\mathrm{comp}}(X)$, the ∞-category $\mathrm{QCoh}(X;\mathcal{C})$ satisfies condition (ii) of Theorem 10.4.2.3: that is, for every flat object $\mathscr{F} \in \mathrm{QCoh}(X)^{\mathrm{cn}}$, the functor

$$F : \mathrm{QCoh}(X;\mathcal{C}) \to \mathrm{QCoh}(X;\mathcal{C}) \qquad E \mapsto \mathscr{F} \otimes E$$

is left exact. For each $n \geqslant 0$, we can write $U_n \simeq \operatorname{Spec} A^n$ for some connective $\mathbb{E}_\infty$-ring A^n. The proof of Proposition 10.4.1.4 shows that we can identify $\mathrm{QCoh}(X;\mathcal{C})$ with the totalization of the cosemisimplicial object $([n] \in \mathbf{\Delta}_s) \mapsto \mathrm{QCoh}(U_\bullet; f_\bullet^* \mathcal{C})$ of the ∞-category $\mathsf{Groth}_\infty^{\mathrm{lex}}$. It will therefore suffice to show that for each $n \geqslant 0$, tensor product with $f_n^* \mathscr{F} \in \mathrm{QCoh}(U_n)^{\mathrm{cn}}$ induces a left exact functor from $f_n^* \mathcal{C}$ to itself, where we regard $f_n^* \mathcal{C}$ as a prestable A^n-linear ∞-category. Since $\mathscr{F}$ is flat, the pullback $f_n^* \mathscr{F}$ is a flat A^n-module and can therefore be written as a filtered colimit $\varinjlim M_\alpha$, where each M_α is a free A^n-module of finite rank. Because $f_n^* \mathcal{C}$ is a Grothendieck prestable ∞-category, filtered colimits in $f_n^* \mathcal{C}$ are left exact.

It will therefore suffice to show that for each index α, tensor product with M_α determines a left exact functor from $f_n^* \mathcal{C}$ to itself. This is clear: the formation of tensor product with M_α preserves all small limits (since it admits a right adjoint, given by tensor product with the A-linear dual $M_\alpha^\vee$).

The implication $(ii) \Rightarrow (iii)$ of Theorem 10.4.2.3 is clear. We will complete the proof by showing that $(iii) \Rightarrow (i)$. Let $\mathcal{E}$ be a complete Grothendieck prestable ∞-category equipped with an action of $\mathrm{QCoh}(X)^{\mathrm{cn}}$ which satisfies the following condition:

$(*)$ Let $\mathscr{F} \in \mathrm{QCoh}(X)^{\mathrm{cn}}$ denote the cofiber of the unit map $\mathscr{O}_X \to \mathscr{A}$. Then the construction $E \mapsto \mathscr{F} \otimes E$ determines a left exact functor from $\mathcal{E}$ to itself.

We wish to show that $\mathcal{E}$ belongs to the essential image of the global sections functor

$$\mathrm{QCoh}(X; \bullet) : \mathrm{QStk}^{\mathrm{comp}}(\mathsf{X}) \to \mathrm{Mod}_{\mathrm{QCoh}(X)^{\mathrm{cn}}}(\mathsf{Groth}_\infty^{\mathrm{comp}}).$$

Equivalently, we show that if $\mathcal{E}$ satisfies condition $(*)$, then the unit map $u : \mathcal{E} \to \mathrm{QCoh}(X; \Phi_X^{\mathrm{comp}} \mathcal{E})$ is an equivalence of ∞-categories.

For each $n \geqslant 0$, let $\mathscr{A}^n \in \mathrm{CAlg}(\mathrm{QCoh}(X)^{\mathrm{cn}})$ denote the direct image of the structure sheaf of U_n, so that $f_n^* \Phi_X^{\mathrm{comp}} \mathcal{E}$ can be identified with the ∞-category $\mathcal{E}^n = \mathrm{LMod}_{\mathscr{A}^n}(\mathcal{E})$. Let us regard $\mathscr{A}^\bullet$ as an augmented cosimplicial object of $\mathrm{CAlg}(\mathrm{QCoh}(X)^{\mathrm{cn}})$ by taking $\mathscr{A}^{-1} = \mathscr{O}_X$, so that $\mathcal{E}^{-1} = \mathcal{E}$. The proof of Proposition 10.4.1.4 then supplies an identification of $\mathrm{QCoh}(X; \Phi_X^{\mathrm{comp}} \mathcal{E})$ with the totalization of the underlying cosemisimplicial object of $\mathcal{E}^\bullet$. Under this identification, the functor u is given by the natural map $\mathcal{E}^{-1} \to \varprojlim_{[n] \in \mathbf{\Delta}_s} \mathcal{E}^n$ is an equivalence in the ∞-category $\mathrm{Mod}_{\mathrm{QCoh}(X)^{\mathrm{cn}}}(\mathsf{Groth}_\infty)$. Using Corollary HA.4.2.3.3 and Proposition C.3.2.4, we see that this is equivalent to the assertion that $\mathcal{E}^{-1}$ is a limit of the diagram $\{\mathcal{E}^n\}_{[n] \in \mathbf{\Delta}_s}$ in $\widehat{\mathcal{C}\mathrm{at}}_\infty$. Let $F : \mathcal{E} = \mathcal{E}^{-1} \to \mathcal{E}^0 = \mathrm{LMod}_{\mathscr{A}}(\mathcal{E})$ be the functor given $E \mapsto \mathscr{A} \otimes E$. Since the augmented cosimplicial ∞-category $\mathcal{E}^\bullet$ satisfies the Beck-Chevalley condition of Corollary HA.4.7.5.3 , we are reduced to proving the following concrete assertions:

(a) The functor F is conservative.

(b) The functor $F : \mathcal{E} \to \mathrm{LMod}_{\mathscr{A}}(\mathcal{E})$ preserves limits of F-split cosimplicial objects.

To prove (a), it suffices to show that if $E \in \mathcal{E}$ and $F(E) \simeq 0$, then $E \simeq 0$. Note that condition $(*)$ implies that F is t-exact, so that $F(\pi_n E) \simeq 0$ for each integer $n \geqslant 0$. Condition $(*)$ then supplies a short exact sequence

$$0 \to \pi_n E \to \pi_n F(E) \to \pi_n(\mathscr{F} \otimes E) \to 0$$

in the abelian category $\mathcal{E}^\heartsuit$. It follows that $\pi_n E \simeq 0$ for all n, so that $E \simeq 0$ by virtue of our assumption that $\mathcal{E}$ is complete.

We now prove (b). Assumption $(*)$ guarantees that tensor product with $\mathscr{A}$ determines a left exact functor from $\mathcal{E}$ to itself, which restricts to an exact functor T from the abelian category $\mathcal{E}^{\heartsuit}$ to itself. Similarly, tensor product with $\mathscr{F}$ determines an exact functor T' from $\mathcal{E}^{\heartsuit}$ to itself, and we have an exact sequence of functors

$$0 \to \mathrm{id} \to T \to T' \to 0$$

In particular, the functor T is conservative (as noted in our proof of (a)).

Let $E^\bullet$ be an F-split cosimplicial object of $\mathcal{E}$. Then $\mathscr{A} \otimes E^\bullet$ is a split cosimplicial object of $\mathcal{E}$. For every integer n, we obtain a cosimplicial object $\pi_n E^\bullet$ of the abelian category $\mathcal{E}^{\heartsuit}$, which has an associated cochain complex

$$\pi_n E^0 \xrightarrow{d_n} \pi_n E^1 \to \pi_n E^2 \to \cdots$$

After applying the functor T, this cochain complex becomes a split exact resolution of $\pi_n \varprojlim(\mathscr{A} \otimes E^\bullet)$. Since T is exact and conservative, we conclude that the cochain complex above is acyclic in positive degrees. Let $E = \varprojlim E^\bullet$; since $\mathcal{E}$ is complete, Corollary HA.1.2.4.12 guarantees that the map $E \to E^0$ induces an isomorphism $\pi_n E \simeq \ker(d_n)$ for each $n \geqslant 0$ (in the abelian category $\mathcal{E}^{\heartsuit}$). We claim that the induced map $F(E) \to \varprojlim F(E^\bullet)$ is an equivalence: in other words, that $\mathscr{A} \otimes E \simeq \varprojlim(\mathscr{A} \otimes E^\bullet)$. Because the prestable ∞-category $\mathcal{E}$ is separated, it will suffice to show that the induced map $T(\pi_n E) \simeq \pi_n(\mathscr{A} \otimes E) \to \pi_n \varprojlim(\mathscr{A} \otimes E^\bullet)$ is an equivalence for each integer n. This follows immediately from Corollary HA.1.2.4.12 and the exactness of the functor T. □

10.4.5 Geometric Stacks with the Resolution Property

Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a geometric stack. Then Theorem 10.4.2.3 supplies a fully faithful embedding $\mathrm{QCoh}(X; \bullet) : \mathrm{QStk}^{\mathrm{comp}}(X) \hookrightarrow \mathrm{Mod}_{\mathrm{QCoh}(X)^{\mathrm{cn}}}(\mathsf{Groth}_\infty^{\mathrm{comp}})$. In this section, we consider two special cases in which we can prove that this functor is an equivalence of ∞-categories:

Theorem 10.4.5.1. *Let X be a geometric stack which either has the resolution property (Definition 9.3.3.2) or is locally Noetherian (Definition 9.5.1.1). Then the global sections functor*

$$\mathrm{QCoh}(X; \bullet) : \mathrm{QStk}^{\mathrm{comp}}(X) \to \mathrm{Mod}_{\mathrm{QCoh}(X)^{\mathrm{cn}}}(\mathsf{Groth}_\infty^{\mathrm{comp}})$$

of §10.4.2 is an equivalence of ∞-categories.

Theorem 10.4.5.1 is an immediate consequence of Theorem 10.4.2.3 together with the following pair of results:

Proposition 10.4.5.2. *Let X be a geometric stack with the resolution property, let $f : \operatorname{Spec} A \to X$ be a faithfully flat morphism, and let $\mathscr{F} \in \mathrm{QCoh}(X)^{\mathrm{cn}}$ be the cofiber of the unit map $\mathscr{O}_X \to f_* \mathscr{O}_{\operatorname{Spec} A}$. Suppose that $\mathcal{E}$ is a Grothendieck prestable ∞-category which* *is tensored over* $\mathrm{QCoh}(X)^{\mathrm{cn}}$*, and that the action map* $\otimes : \mathrm{QCoh}(X)^{\mathrm{cn}} \times \mathcal{E} \to \mathcal{E}$ *preserves small colimits separately in each variable. Then the construction* $E \mapsto \mathscr{F} \otimes E$ *determines a left exact functor from* $\mathcal{E}$ *to itself.*

Proposition 10.4.5.3. *Let* X *be a locally Noetherian geometric stack, let* $\mathcal{E}$ *be a separated Grothendieck prestable* ∞*-category which is tensored over* $\mathrm{QCoh}(X)^{\mathrm{cn}}$*, and suppose that the action map* $\otimes : \mathrm{QCoh}(X)^{\mathrm{cn}} \times \mathcal{E} \to \mathcal{E}$ *preserves small colimits separately in each variable. Then, for any flat object* $\mathscr{F} \in \mathrm{QCoh}(X)^{\mathrm{cn}}$*, the construction* $E \mapsto \mathscr{F} \otimes E$ *determines a left exact functor from* $\mathcal{E}$ *to itself.*

Proof of Proposition 10.4.5.2. By virtue of Proposition C.3.2.1, it will suffice to show that for every discrete object $E \in \mathcal{E}$, the tensor product $\mathscr{F} \otimes E$ is also discrete. Note that we can promote E to a module over the commutative algebra object $\pi_0 \mathscr{O}_X \in \mathrm{QCoh}(X)^{\mathrm{cn}}$. Replacing $\mathcal{E}$ by $\mathrm{LMod}_{\pi_0 \mathscr{O}_X}(\mathcal{E})$ and X by its 0-truncation (see §9.1.6), we can reduce to the case where X is 0-truncated.

Let $\mathcal{C} = \mathrm{Vect}(X) \times_{\mathrm{QCoh}(X)} \mathrm{QCoh}(X)_{/ f_* \mathscr{O}_{\mathrm{Spec}\, A}}$ be the ∞-category of vector bundles $\mathscr{G}$ on X equipped with a map $\mathscr{G} \to f_* \mathscr{O}_{\mathrm{Spec}\, A}$. According to Lemma 9.3.4.13, the ∞-category $\mathcal{C}$ is filtered. The proof of Proposition 9.3.4.11 shows that the canonical map $\varinjlim_{\mathscr{G} \in \mathcal{C}} \mathscr{G} \to f_* \mathscr{O}_{\mathrm{Spec}\, A}$ is an equivalence. Let us abuse notation by regarding the structure sheaf $\mathscr{O}_X$ as an object of $\mathcal{C}$ (by equipping it with the unit map $\mathscr{O}_X \to f_* \mathscr{O}_{\mathrm{Spec}\, A}$), so that $\mathcal{C}_{\mathscr{O}_X /}$ is also a filtered ∞-category and the projection map $\mathcal{C}_{\mathscr{O}_X /} \to \mathcal{C}$ is left cofinal. For each object $\mathscr{G} \in \mathcal{C}_{\mathscr{O}_X /}$, let $\mathscr{G}'$ denote the cofiber of the map $e : \mathscr{O}_X \to \mathscr{G}$. Note that $f^*(e)$ admits a left homotopy inverse, so that $f^* \mathscr{G}'$ is a direct summand of $f^* \mathscr{G}$. We can therefore write $\mathscr{F} = \mathrm{cofib}(\mathscr{O}_X \to f_* \mathscr{O}_{\mathrm{Spec}\, A})$ as the colimit of a filtered diagram $\{\mathscr{G}'\}_{\mathscr{G} \in \mathcal{C}_{\mathscr{O}_X /}}$. Consequently, to show that $\mathscr{F} \otimes E$ is a discrete object of $\mathcal{E}$, it will suffice to show that $\mathscr{G}' \otimes E$ is a discrete object of $\mathcal{E}$ for each $\mathscr{G}' \in \mathrm{Vect}(X)$. This is clear: every object $\mathscr{G}' \in \mathrm{Vect}(X)$ is dualizable as an object of $\mathrm{QCoh}(X)^{\mathrm{cn}}$, so the functor $E \mapsto \mathscr{G}' \otimes E$ preserves small limits (since it has a left adjoint, given by $E \mapsto \mathscr{G}'^{\vee} \otimes E$). □

We now prove Proposition **??** using the strategy outlined in §9.5.4. The main step is the following variant of Lemma 9.5.4.5:

Lemma 10.4.5.4. *Let* X *be a* 0*-truncated geometric stack, let* $\mathcal{E}$ *be a complete Grothendieck prestable* ∞*-category which is tensored over* $\mathrm{QCoh}(X)^{\mathrm{cn}}$*, and suppose that the action map* $\otimes : \mathrm{QCoh}(X)^{\mathrm{cn}} \times \mathcal{E} \to \mathcal{E}$ *preserves small colimits separately in each variable. Let* $\alpha : \mathscr{F} \to \mathscr{F}'$ *be a morphism in* $\mathrm{QCoh}(X)^{\mathrm{cn}}$*, where* $\mathscr{F}$ *is almost perfect and* $\mathscr{F}'$ *is flat. Then, for every object* $E \in \mathcal{E}^{\heartsuit}$*, the induced map* $\alpha_E : \mathscr{F} \otimes E \to \mathscr{F}' \otimes E$ *factors through an object of* $\mathcal{E}^{\heartsuit}$*.*

Proof. We proceed as in the proof of Lemma 9.5.4.5. Let $\mathscr{F}^{\vee} = \underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{O}_X) \in \mathrm{QCoh}(X)$ be defined as in §9.5.3. Since $\mathscr{F}$ is almost perfect, the structure sheaf $\mathscr{O}_X$ is 0-truncated, and $\mathscr{F}'$ has Tor-amplitude $\leqslant 0$, it follows from Corollary 9.5.3.6 that the canonical map $\rho : \mathscr{F}' \otimes \mathscr{F}^\vee \to \underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{F}')$ is an equivalence in $\mathrm{QCoh}(X)$. Let $\mathscr{G} = \tau_{\geqslant 0} \mathscr{F}^\vee$ denote the connective cover of $\mathscr{F}^\vee$. Since $\mathscr{F}'$ is flat, we can identify $\mathscr{F}' \otimes \mathscr{G}$ with the connective cover of $\mathscr{F}' \otimes \mathscr{F}^\vee$. It follows that we can choose a map $c : \mathscr{O}_X \to \mathscr{F}' \otimes \mathscr{G}$ which is determined (uniquely up to homotopy) by the requirement that the composition

$$\mathscr{O}_X \xrightarrow{c} \mathscr{F}' \otimes \mathscr{G} \to \mathscr{F}' \otimes \mathscr{F}^\vee \xrightarrow{\rho} \underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{F}')$$

classifies α. The tautological pairing $\mathscr{F}^\vee \otimes \mathscr{F} \to \mathscr{O}_X$ determines an "evaluation map" $e : \mathscr{G} \otimes \mathscr{F} \to \mathscr{O}_X$. Unwinding the definitions, we see that the composite map

$$\mathscr{F} \xrightarrow{c \otimes \mathrm{id}} \mathscr{F}' \otimes \mathscr{G} \otimes \mathscr{F} \xrightarrow{\mathrm{id} \otimes e} \mathscr{F}'$$

is homotopic to α.

Let E be a discrete object of $\mathcal{E}$. The construction $(E' \in \mathcal{E}) \mapsto \mathrm{Map}_{\mathcal{E}}(\mathscr{G} \otimes E', E)$ carries colimits in $\mathcal{E}$ to limits in $\mathcal{S}$, and is therefore representable by an object of $\mathcal{E}$ which we will denote by $\underline{\mathrm{Map}}(\mathscr{G}, E)$. The evaluation map e induces a morphism $e_E : \mathscr{G} \otimes \mathscr{F} \otimes E \to E$, which is classified by a morphism of R-modules $\beta : \mathscr{F} \otimes E \to \underline{\mathrm{Map}}(\mathscr{G}, E)$. Let γ denote the composite map

$$\underline{\mathrm{Map}}(\mathscr{G}, E) \xrightarrow{c \otimes \mathrm{id}} \mathscr{F}' \otimes \mathscr{G} \otimes \underline{\mathrm{Map}}(\mathscr{G}, E) \to \mathscr{F}' \otimes E.$$

Using the fact that $(\mathrm{id} \otimes e) \circ (c \otimes \mathrm{id})$ is homotopic to α, we deduce that the composition $\gamma \circ \beta$ is homotopic to α_E. We conclude by observing that since E is discrete, the mapping space $\mathrm{Map}_{\mathcal{E}}(\mathscr{G} \otimes E', E)$ is discrete for each $E' \in \mathcal{E}$, so that $\underline{\mathrm{Map}}(\mathscr{G}, E)$ is also discrete. □

Proof of Proposition **??**. Let X be a locally Noetherian geometric stack, let $\mathcal{E}$ be a separated Grothendieck prestable ∞-category which is tensored over $\mathrm{QCoh}(X)^{\mathrm{cn}}$, and suppose that the action map $\otimes : \mathrm{QCoh}(X)^{\mathrm{cn}} \times \mathcal{E} \to \mathcal{E}$ preserves small colimits separately in each variable. Let $\mathscr{F}$ be a flat object of $\mathrm{QCoh}(X)$. We wish to show that the functor $E \mapsto \mathscr{F} \otimes E$ is a left exact functor from $\mathcal{E}$ to itself. To prove this, it will suffice to show that if $E \in \mathcal{E}$ is discrete, then $\mathscr{F} \otimes E$ is also discrete (Proposition C.3.2.1).

Set $\mathscr{A} = \pi_0 \mathscr{O}_X$. Since E is discrete, it admits the structure of a $\mathscr{A}$-module object of $\mathcal{E}$. We may therefore replace $\mathcal{E}$ by $\mathrm{LMod}_{\mathscr{A}}(\mathcal{E})$ (which is prestable and separated by virtue of Example 10.4.3.2) and thereby reduce to the case where the action of $\mathrm{QCoh}(X)^{\mathrm{cn}}$ on $\mathcal{E}$ factors through an action of $\mathrm{Mod}_{\mathscr{A}}(\mathrm{QCoh}(X)^{\mathrm{cn}}) \simeq \mathrm{QCoh}(X_0)^{\mathrm{cn}}$, where X_0 is the 0-truncation of X (see §9.1.6). Replacing X by X_0 (and $\mathscr{F}$ by its restriction $\mathscr{F}|_{X_0}$), we can reduce to the case where X is 0-truncated.

Since X is 0-truncated and $\mathscr{F} \in \mathrm{QCoh}(X)$ is flat, the sheaf $\mathscr{F}$ is also 0-truncated. Invoking our assumption that X is locally Noetherian, we deduce that $\mathscr{F}$ can be written as a filtered colimit $\varinjlim \mathscr{F}_\alpha$ where each $\mathscr{F}_\alpha \in \mathrm{QCoh}(X)^\heartsuit$ is almost perfect (Proposition 9.5.2.3). It follows that for each $n \geqslant 0$, we have an equivalence $\pi_n(\mathscr{F} \otimes E) \simeq \varinjlim_\alpha \pi_n(\mathscr{F}_\alpha \otimes E)$ in the abelian category $\mathcal{E}^\heartsuit$. Lemma 9.5.4.5 implies that for $n > 0$, the maps $\pi_n(\mathscr{F}_\alpha \otimes E) \to$

$\pi_n(\mathscr{F} \otimes E)$ vanish for each index α. It follows that $\pi_n(\mathscr{F} \otimes E)$ vanishes for $n > 0$. Since $\mathcal{E}$ is separated, this implies that $\mathscr{F} \otimes E$ is discrete as desired. □

We close this section by discussing a variant of Theorem 10.4.5.1.

Theorem 10.4.5.5. *Let X be a geometric stack with the resolution property. Assume either that X is n-truncated for some integer $n \geqslant 0$ or that $\mathscr{O}_X$ is a compact object of $\mathrm{QCoh}(X)$. Then the global sections functor $\mathcal{C} \mapsto \mathrm{QCoh}(X; \mathcal{C})$ determines a fully faithful embedding*

$$\mathrm{QCoh}(X; \bullet) : \mathrm{QStk}^{\mathrm{comp}}(X) \to \mathrm{Mod}_{\mathrm{Vect}(X)}(\widehat{\mathcal{C}\mathrm{at}}_\infty)$$

whose essential image is spanned by those ∞-categories $\mathcal{E}$ with an action of $\mathrm{Vect}(X)$ which satisfy the following conditions:

(*i*) *The ∞-category $\mathcal{E}$ is a complete Grothendieck prestable ∞-category.*

(*ii*) *If $0 \in \mathrm{Vect}(X)$ is a zero object, then $0 \otimes E$ is a zero object of $\mathcal{E}$ for each $E \in \mathcal{E}$.*

(*iii*) *For every diagram*

$$\begin{array}{ccc} \mathscr{F}' & \longrightarrow & \mathscr{F} \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & \mathscr{F}'' \end{array}$$

in $\mathrm{Vect}(X)$ which is a cofiber sequence in $\mathrm{QCoh}(X)$ and every object $E \in \mathcal{E}$, the resulting diagram

$$\begin{array}{ccc} \mathscr{F}' \otimes E & \longrightarrow & \mathscr{F} \otimes E \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & \mathscr{F}'' \otimes E \end{array}$$

is a cofiber sequence in $\mathcal{E}$.

Proof. Let $\mathcal{C} = \mathrm{Fun}^{\pi}(\mathrm{Vect}(X)^{\mathrm{op}}, \mathcal{S})$ be the ∞-category of functors $\mathrm{Vect}(X)^{\mathrm{op}} \to \mathcal{S}$ which preserve finite products. Then $\mathcal{C}$ is a complete Grothendieck prestable ∞-category (see Proposition C.1.5.7). Since the tensor product on $\mathrm{Vect}(X)$ preserves finite direct sums in each variable, there is an essentially unique symmetric monoidal structure on $\mathcal{C}$ for which the tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves small colimits separately in each variable and the Yoneda embedding $j : \mathrm{Vect}(X) \to \mathcal{C}$ is symmetric monoidal. Moreover, composition with j induces a fully faithful embedding $\rho : \mathrm{Mod}_{\mathcal{C}}(\mathsf{Groth}_\infty^{\mathrm{comp}}) \to \mathrm{Mod}_{\mathrm{Vect}(X)}(\widehat{\mathcal{C}\mathrm{at}}_\infty)$ whose essential image consists of those complete Grothendieck prestable ∞-categories $\mathcal{E}$ with an action of $\mathrm{Vect}(X)$ for which the action map $a : \mathrm{Vect}(X) \times \mathcal{E} \to \mathcal{E}$ preserves finite coproducts in the first variable and small colimits in the second variable. Note that since every object $\mathscr{F} \in \mathrm{Vect}(X)$ is dualizable, this second condition is automatic: the construction $E \mapsto \mathscr{F} \otimes E$ automatically preserves small colimits, since it is left adjoint to the construction $E \mapsto \mathscr{F}^{\vee} \otimes E$. It follows that the essential image of ρ can be characterized as those objects $\mathcal{E} \in \mathrm{Mod}_{\mathrm{Vect}(X)}(\widehat{\mathcal{C}\mathrm{at}}_{\infty})$ which satisfy conditions (i), (ii), and the following weaker version of (iii'):

(iii') For every diagram

$$\begin{array}{ccc} \mathscr{F}' & \longrightarrow & \mathscr{F} \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & \mathscr{F}'' \end{array}$$

in $\mathrm{Vect}(X)$ which is a *split* cofiber sequence in $\mathrm{QCoh}(X)$ and every object $E \in \mathcal{E}$, the associated diagram

$$\begin{array}{ccc} \mathscr{F}' \otimes E & \longrightarrow & \mathscr{F} \otimes E \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & \mathscr{F}'' \otimes E \end{array}$$

is also a (split) cofiber sequence in $\mathcal{E}$.

Note that the inclusion functor $\mathrm{Vect}(X) \to \mathrm{QCoh}(X)^{\mathrm{cn}}$ is symmetric monoidal, and therefore admits an essentially unique extension to a symmetric monoidal functor $F : \mathcal{C} \to \mathrm{QCoh}(X)^{\mathrm{cn}}$ which preserves small colimits. To prove Theorem 10.4.5.5, we must show that composition with F induces a fully faithful embedding

$$\theta : \mathrm{Mod}_{\mathrm{QCoh}(X)^{\mathrm{cn}}}(\mathsf{Groth}_{\infty}^{\mathrm{comp}}) \to \mathrm{Mod}_{\mathcal{C}}(\mathsf{Groth}_{\infty}^{\mathrm{comp}}),$$

whose essential image is spanned by those $\mathcal{C}$-modules $\mathcal{E}$ which satisfy condition (iii).

For each $m \geqslant 0$, let Groth_m denote the ∞-category of Grothendieck abelian $(m+1)$-categories (see Definition C.5.4.1). Then Theorem C.5.4.8 supplies an equivalence of ∞-categories $\mathsf{Groth}_{\infty}^{\mathrm{comp}} \simeq \varprojlim_m \mathsf{Groth}_m$. It follows that we can identify θ with the limit of a tower of functors

$$\theta_m : \mathrm{Mod}_{\mathrm{QCoh}(X)^{\mathrm{cn}}_{\leqslant m}}(\mathsf{Groth}_m) \to \mathrm{Mod}_{\tau_{\leqslant m}\mathcal{C}}(\mathsf{Groth}_m).$$

Let $e : \mathrm{Vect}(X) \to \tau_{\leqslant m}\mathcal{C}$ be the symmetric monoidal functor given by $e(\mathscr{F}) = \tau_{\leqslant m} j(\mathscr{F})$. To complete the proof, it will suffice to show that each θ_m is a fully faithful embedding, whose essential image is spanned by those Grothendieck abelian $(m+1)$-categories $\mathcal{E}$ equipped with an action of $\tau_{\leqslant m}\mathcal{C}$ for which the induced action of $\mathrm{Vect}(X)$ on $\mathcal{E}$ (via the functor e) satisfies condition (iii).

For every commutative diagram σ :

$$\begin{array}{ccc} \mathscr{F}' & \longrightarrow & \mathscr{F} \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & \mathscr{F}'' \end{array}$$

in $\mathrm{Vect}(X)$ which is a pushout square in $\mathrm{QCoh}(X)$, let $f_\sigma : \mathrm{cofib}(e(\mathscr{F}') \to e(\mathscr{F})) \to e(\mathscr{F}')$ be the induced map in the ∞-category $\tau_{\leqslant m}\,\mathcal{C}$. Let S be the collection of all morphisms in $\tau_{\leqslant m}\,\mathcal{C}$ having the form f_σ. Unwinding the definitions, we see that an object $\mathcal{E} \in \mathrm{Mod}_{\tau_{\leqslant m}\,\mathcal{C}}(\mathsf{Groth}_m)$ satisfies condition (iii) if and only if the induced map $\tau_{\leqslant m}\,\mathcal{C} \to \mathrm{Fun}(\mathcal{E}, \mathcal{E})$ factors through the localization $S^{-1}(\tau_{\leqslant m}\,\mathcal{C})$. To complete the proof, it will suffice to show that the functor F induces an equivalence $S^{-1}(\tau_{\leqslant m}\,\mathcal{C}) \to \mathrm{QCoh}(X)^{\mathrm{cn}}_{\leqslant m}$, which is a reformulation of Proposition 9.3.7.7. □

10.4.6 Weakly Complicial Quasi-Coherent Stacks

We now generalize some of the results of §**??** to the setting of geometric stacks.

Proposition 10.4.6.1. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a quasi-geometric stack, let $\mathcal{C}$ be a quasi-coherent stack on X, and let n be a nonnegative integer. The following conditions are equivalent:*

- (a) *For every flat morphism $\eta : \mathrm{Spec}\,A \to X$, the prestable A-linear ∞-category $\mathcal{C}_\eta$ is weakly n-complicial.*
- (b) *There exists a faithfully flat morphism $\eta : \mathrm{Spec}\,A \to X$ such that $\mathcal{C}_\eta$ is weakly n-complicial.*

Proof. The implication $(a) \Rightarrow (b)$ is clear. Suppose that (b) is satisfied: that is, there exists a faithfully flat map $\eta : \mathrm{Spec}\,A \to X$ such that $\mathcal{C}_\eta$ is weakly n-complicial. Let $\eta' : \mathrm{Spec}\,A' \to X$ be any flat map. Choose a faithfully flat map $\mathrm{Spec}\,B \to \mathrm{Spec}\,A \times_X \mathrm{Spec}\,A'$. The flatness of η' guarantees that B is flat over A, so that $B \otimes_A \mathcal{C}_\eta$ is weakly n-complicial (Proposition D.5.7.1). Using the equivalence $B \otimes_A \mathcal{C}_\eta \simeq B \otimes_{A'} \mathcal{C}_{\eta'}$, we conclude that $B \otimes_{A'} \mathcal{C}_{\eta'}$ is weakly n-complicial. Since the morphism η is faithfully flat, B is faithfully flat over A'. Applying Proposition D.5.7.1 again, we deduce that $\mathcal{C}_{\eta'}$ is also weakly n-complicial. □

Definition 10.4.6.2. Let X be a quasi-geometric stack and let $\mathcal{C}$ be a prestable quasi-coherent stack on X. We will say that $\mathcal{C}$ is *weakly n-complicial* if it satisfies the equivalent conditions of Proposition 10.4.6.1.

Remark 10.4.6.3. Let X be a quasi-geometric Deligne-Mumford stack and let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$. We then $\mathcal{C}$ is weakly n-complicial in the sense of Definition 10.4.6.2 if and only if it is weakly n-complicial in the sense of Definition 10.3.4.4 (this is an elementary consequence of Proposition 10.4.6.1).

Remark 10.4.6.4. Let $f : X \to Y$ be a morphism of quasi-geometric stacks and let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(Y)$. If $\mathcal{C}$ is weakly n-complicial and f is flat, then $f^*\,\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(X)$ is weakly n-complicial. Beware that this need not be true if we drop the assumption that f is flat.

Example 10.4.6.5. Let X be a quasi-geometric stack and let $\mathcal{Q}_X^{\mathrm{cn}}$ be the unit object of $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ (see Example 10.1.6.2). Then $\mathcal{Q}_X^{\mathrm{cn}}$ is weakly n-complicial if and only if X is n-truncated, in the sense of Definition 9.1.6.2: this follows from Proposition C.5.5.15.

We now establish a local-to-global principle for Definition 10.4.6.2:

Proposition 10.4.6.6. *Let X be a geometric stack, let $\mathcal{C}$ be a complete prestable quasi-coherent stack on X, and let $n \geqslant 0$ be an integer. Then $\mathcal{C}$ is weakly n-complicial if and only if the Grothendieck prestable ∞-category $\mathrm{QCoh}(X;\mathcal{C})$ is weakly n-complicial.*

Proof. Choose a faithfully flat map $\eta : \operatorname{Spec} A \to X$ and let $\mathcal{C}_\eta$ denote the corresponding A-linear ∞-category. Since η is flat, the pullback functor $\eta^* : \mathrm{Sp}(\mathrm{QCoh}(X;\mathcal{C})) \to \mathrm{Sp}(\mathcal{C}_\eta)$ is t-exact (Corollary 10.1.7.10). Consequently, the right adjoint $\eta_* : \mathrm{Sp}(\mathcal{C}_\eta) \to \mathrm{Sp}(\mathrm{QCoh}(X;\mathcal{C}))$ carries injective objects of $\mathrm{Sp}(\mathcal{C}_\eta)_{\leqslant 0}$ to injective objects of $\mathrm{Sp}(\mathrm{QCoh}(X;\mathcal{C}))_{\leqslant 0}$ (see Definition HA.**??**).

Suppose that $\mathrm{QCoh}(X;\mathcal{C})$ is weakly n-complicial. Using Proposition C.5.7.11, we deduce that every injective object of $\mathrm{Sp}(\mathrm{QCoh}(X;\mathcal{C}))_{\leqslant 0}$ belongs to $\mathrm{Sp}(\mathrm{QCoh}(X;\mathcal{C}))_{\geqslant -n}$. It follows that if $\overline{Q}$ is an injective object of $\mathrm{Sp}(\mathcal{C}_\eta)_{\leqslant 0}$, then $\eta_* \overline{Q} \in \mathrm{Sp}(\mathrm{QCoh}(X;\mathcal{C}))_{\geqslant -n}$. Since η is affine, the pushforward functor η_* is t-exact and conservative. We therefore conclude that every injective object of $\mathrm{Sp}(\mathcal{C}_\eta)_{\leqslant 0}$ belongs to $\mathrm{Sp}(\mathcal{C}_\eta)_{\geqslant -n}$. Applying Proposition C.5.7.11 again, we conclude that $\mathcal{C}_\eta$ is weakly n-complicial, and therefore $\mathcal{C}$ is weakly n-complicial (Proposition 10.4.6.1).

To prove the converse, we will need the following:

$(*)$ Every injective object Q of $\mathrm{Sp}(\mathrm{QCoh}(X;\mathcal{C}))_{\leqslant 0}$ is a direct summand of $\eta_* \overline{Q}$, for some injective object $\overline{Q} \in \mathrm{Sp}(\mathcal{C}_\eta)_{\leqslant 0}$.

To prove $(*)$, we note that the abelian category $\mathcal{C}_\eta^\heartsuit$ has enough injectives, so there exists an injective object $I \in \mathcal{C}_\eta^\heartsuit$ and a monomorphism $\rho : \pi_0 \eta^* Q \to I$. Using Proposition HA.**??** , we can write $I = \pi_0 \overline{Q}$ for some injective object $\overline{Q} \in \mathrm{Sp}(\mathcal{C}_\eta)_{\leqslant 0}$. The injectivity of $\overline{Q}$ implies that the composite map $\pi_0 \eta^* Q \xrightarrow{\rho} I \to \overline{Q}$ can be extended to a map $\eta^* Q \to \overline{Q}$, which we can identify with a map $\rho_0 : Q \to \eta_* \overline{Q}$. By construction, $\eta^* \rho_0$ induces a monomorphism on π_0. Since η is faithfully flat, it follows that ρ_0 induces a monomorphism on π_0. Since $\eta_* \overline{Q}$ is an injective object of $\mathrm{Sp}(\mathcal{C}_\eta)_{\leqslant 0}$, it follows that ρ_0 admits a left homotopy inverse: that is, it exhibits Q as a direct summand of $\eta_* \overline{Q}$.

Now suppose that $\mathcal{C}$ is weakly n-complicial. Then every injective object of $\mathrm{Sp}(\mathcal{C}_\eta)_{\leqslant 0}$ belongs to $\mathrm{Sp}(\mathcal{C}_\eta)_{\geqslant -n}$ (Proposition C.5.7.11). Since the functor η_* is t-exact, assertion $(*)$ implies that every injective object of $\mathrm{Sp}(\mathrm{QCoh}(X;\mathcal{C}))_{\leqslant 0}$ belongs to $\mathrm{Sp}(\mathrm{QCoh}(X;\mathcal{C})_{\geqslant -n}$. Applying Proposition C.5.7.11 again, we conclude that $\mathrm{QCoh}(X;\mathcal{C})$ is weakly n-complicial. □

Specializing to the case $\mathcal{C} = \mathcal{Q}_X^{\mathrm{cn}}$, we obtain the following:

Corollary 10.4.6.7. *Let X be a geometric stack. Then X is n-truncated if and only if the Grothendieck prestable ∞-category $\mathrm{QCoh}(X)^{\mathrm{cn}}$ is weakly n-complicial.*

Proof. Combine Example 10.4.6.5 with Proposition 10.4.6.6. □

Corollary 10.4.6.8. *Let X be a geometric stack. Then the following conditions are equivalent:*

(a) *The structure sheaf $\mathscr{O}_X$ is 0-truncated.*

(b) *The inclusion $\mathrm{QCoh}(X)^{\heartsuit} \hookrightarrow \mathrm{QCoh}(X)$ extends to a t-exact equivalence of ∞-categories $\widehat{\mathcal{D}}(\mathrm{QCoh}(X)^{\heartsuit}) \simeq \mathrm{QCoh}(X)$*

Proof. Combine Corollaries 10.4.6.7 and C.5.9.7. □

Warning 10.4.6.9. In general, the completion which appears in the statement of Corollary 10.4.6.8 is necessary. For example, if G is the classifying stack of the additive group $\mathbf{G}_a$ over a field κ of characteristic $p > 0$, then the derived ∞-category $\mathcal{D}(\mathrm{QCoh}(X)^{\heartsuit})$ is not left complete (see [93]).

10.5 Locally Noetherian Quasi-Coherent Stacks

Let $\mathcal{C}$ be a Grothendieck prestable ∞-category. We say that $\mathcal{C}$ is *locally Noetherian* if the abelian category $\mathcal{C}^{\heartsuit}$ is locally Noetherian and each Noetherian object $C \in \mathcal{C}^{\heartsuit}$ is compact when viewed as an object of $\tau_{\leqslant n}\mathcal{C}$, for each $n \geqslant 0$ (see Proposition C.6.9.8). Our goal in this section is to globalize the theory of locally Noetherian prestable ∞-categories by introducing the notion of a *locally Noetherian quasi-coherent stack*.

10.5.1 On Spectral Deligne-Mumford Stacks

It follows from Propositions D.5.6.1 and D.5.6.4 that the condition that a prestable A-linear ∞-category $\mathcal{C}$ is locally Noetherian can be tested locally with respect to the étale topology on $\mathrm{Spét}\, A$. This motivates the following:

Definition 10.5.1.1. Let X be a spectral Deligne-Mumford stack and let $\mathcal{C}$ be a prestable quasi-coherent stack on X. We will say that $\mathcal{C}$ is *locally Noetherian* if, for every étale morphism $\eta : \mathrm{Spét}\, A \to \mathsf{X}$, the prestable A-linear ∞-category $\mathcal{C}_\eta$ is locally Noetherian.

Remark 10.5.1.2. Let $f : \mathsf{X} \to \mathsf{Y}$ be morphism of spectral Deligne-Mumford stacks and let $\mathcal{C}$ be a prestable quasi-coherent stack on Y. If f is locally almost of finite presentation and $\mathcal{C}$ is locally Noetherian, then $f^* \mathcal{C}$ is locally Noetherian (see Proposition D.5.6.1). Conversely, if

f is a flat covering and $f^* \mathcal{C}$ is locally Noetherian, then $\mathcal{C}$ is locally Noetherian (Proposition D.5.6.4).

Remark 10.5.1.3. Let A be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a prestable A-linear ∞-category. Then $\mathcal{C}$ is locally Noetherian when regarded as a Grothendieck prestable ∞-category if and only if it is locally Noetherian when regarded as a prestable quasi-coherent stack on Spét A.

Example 10.5.1.4. Let X be a spectral Deligne-Mumford stack and let $\mathcal{Q}_{\mathsf{X}}^{\mathrm{cn}}$ be the unit object of $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ (see Example 10.1.6.2). Then$\mathcal{Q}_{\mathsf{X}}^{\mathrm{cn}}$ is locally Noetherian if and only X is locally Noetherian (see Example C.6.9.4).

In the setting of Definition 10.5.1.1, we have the following local-to-global principle:

Proposition 10.5.1.5. *Let X be a quasi-geometric spectral Deligne-Mumford stack and let $\mathcal{C}$ be a prestable quasi-coherent stack on X. If $\mathcal{C}$ is locally Noetherian, then the Grothendieck prestable ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is locally Noetherian.*

Remark 10.5.1.6. In the statement of Proposition 10.5.1.5, the hypothesis that X is quasi-geometric can be weakened: it is enough to assume that X is ∞-quasi-compact (Definition 2.3.1.1).

Proof of Proposition 10.5.1.5. Let $\widehat{\mathcal{C}}$ be the completion of $\mathcal{C}$, so that $\mathrm{QCoh}(\mathsf{X}; \widehat{\mathcal{C}})$ is the completion of $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$. It follows from Proposition 10.5.2.7 that $\mathrm{QCoh}(\mathsf{X}; \widehat{\mathcal{C}})$ is locally Noetherian. Invoking Remark C.6.9.2, we see that $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is also locally Noetherian. □

Proposition 10.5.1.7. *Let X be a quasi-compact, quasi-separated spectral algebraic space and let $\mathcal{C}$ be a prestable quasi-coherent stack on X. If X is schematic and $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is locally Noetherian, then $\mathcal{C}$ is locally Noetherian.*

Proof. Since X is quasi-compact and schematic, it admits a finite covering by affine open substacks $\mathsf{U}_\alpha \subseteq \mathsf{X}$. By virtue of Remark 10.3.1.4, it will suffice to show that the restriction of $\mathcal{C}$ to each U_α is locally Noetherian. Using Remark 10.5.1.3, we see that this is equivalent to the assertion that each of the Grothendieck prestable ∞-categories $\mathrm{QCoh}(\mathsf{U}_\alpha; \mathcal{C}|_{\mathsf{U}_\alpha})$ is locally Noetherian. Let $j : \mathsf{U}_\alpha \to \mathsf{X}$ be the inclusion map, so that we have a pair of adjoint functors

$$\mathrm{QCoh}(\mathsf{X}; \mathcal{C}) \underset{j_*}{\overset{j^*}{\rightleftarrows}} \mathrm{QCoh}(\mathsf{U}_\alpha; \mathcal{C}|_{\mathsf{U}_\alpha})$$

which exhibit $\mathrm{QCoh}(\mathsf{U}_\alpha; \mathcal{C}|_{\mathsf{U}_\alpha})$ as a left exact localization of $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$. The desired result now follows from Proposition C.6.9.9. □

10.5.2 On Quasi-Geometric Stacks

We now adapt Definition 10.5.1.1 to the setting of quasi-geometric stacks.

Definition 10.5.2.1. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a quasi-geometric stack and let $\mathcal{C}$ be a prestable quasi-coherent stack on X. We will say that $\mathcal{C}$ is *locally Noetherian* if there exists a faithfully flat morphism $\eta : \mathrm{Spec}\, A \to X$ for which the prestable A-linear ∞-category $\mathcal{C}_\eta$ is locally Noetherian.

Warning 10.5.2.2. Let X be a quasi-geometric stack and let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(X)$ be locally Noetherian. It does *not* follow that for every faithfully flat morphism $\eta : \mathrm{Spec}\, A \to X$, the prestable A-linear ∞-category $\mathcal{C}_\eta$ is locally Noetherian. This stronger condition is never satisfied, except in trivial cases.

Remark 10.5.2.3. Let X be a quasi-geometric spectral Deligne-Mumford stack. We then have two *a priori* different notions of locally Noetherian quasi-coherent stack on X: one given by Definition 10.5.1.1 and one given by Definition 10.5.2.1. However, we will show in a moment that these definitions are equivalent: this is an immediate consequence of Corollary 10.5.2.6.

Example 10.5.2.4. Let X be a spectral Deligne-Mumford stack and let $\mathcal{Q}_X^{\mathrm{cn}}$ be the unit object of $\mathrm{QStk}^{\mathrm{PSt}}(X)$ (see Example 10.1.6.2). Then $\mathcal{Q}_X^{\mathrm{cn}}$ is locally Noetherian if and only X is locally Noetherian, in the sense of Definition 9.5.1.1: this follows immediately from Example C.6.9.4.

In spite of Warning 10.5.2.2, we have the following:

Proposition 10.5.2.5. *Let X be a quasi-geometric stack, let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(X)$ be locally Noetherian, and let $\eta : \mathrm{Spec}\, A \to X$ be a morphism which is locally almost of finite presentation. Then the prestable A-linear ∞-category $\mathcal{C}_\eta$ is locally Noetherian.*

Proof. Since $\mathcal{C}$ is locally Noetherian, we can choose a faithfully flat morphism $\eta' : \mathrm{Spec}\, A' \to X$ such that $\mathcal{C}_{\eta'}$ is locally Noetherian. Choose an étale surjection $\mathrm{Spec}\, B \to \mathrm{Spec}\, A \times_X \mathrm{Spec}\, A'$. Since η is locally almost of finite presentation, the $\mathbb{E}_\infty$-ring B is almost of finite presentation over A'. It follows from Proposition D.5.6.1 that the Grothendieck prestable ∞-category $B \otimes_{A'} \mathcal{C}_{\eta'}$ is locally Noetherian. Using the equivalence $B \otimes_{A'} \mathcal{C}_{\eta'} \simeq B \otimes_A \mathcal{C}_\eta$, we deduce that $B \otimes A\, \mathcal{C}_\eta$ is locally Noetherian. Since η' is faithully flat, the $\mathbb{E}_\infty$-ring B is faithfully flat over A. Applying Proposition D.5.6.4, we deduce that $\mathcal{C}_\eta$ is locally Noetherian. □

Corollary 10.5.2.6. *Let X be a quasi-geometric stack and let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(X)$. Suppose that there exists a morphism $\eta : \mathrm{Spec}\, A \to X$ which is faithfully flat and locally almost of finite presentation. Then $\mathcal{C}$ is locally Noetherian if and only if the prestable A-linear ∞-category $\mathcal{C}_\eta$ is locally Noetherian.*

The following result can be regarded as a relative version of Proposition 9.5.2.3:

Proposition 10.5.2.7. *Let X be a quasi-geometric stack and let $\mathcal{C}$ be a complete prestable quasi-coherent stack on X. If $\mathcal{C}$ is locally Noetherian, then the Grothendieck prestable ∞-category $\mathrm{QCoh}(X;\mathcal{C})$ is locally Noetherian.*

Proof. We proceed as in the proof of Proposition D.5.6.4 (note that when X is affine, Proposition 10.5.2.7 reduces to Proposition D.5.6.4). Choose a faithfully flat map $\eta : \operatorname{Spec} A \to X$ for which the prestable A-linear ∞-category $\mathcal{C}_\eta$ is locally Noetherian. We wish to prove that $\mathrm{QCoh}(X;\mathcal{C})$ is locally Noetherian.

We begin by showing that the abelian category $\mathrm{QCoh}(X;\mathcal{C})^{\heartsuit}$ is locally Noetherian. Note that we have a pair of adjoint functors $\mathrm{QCoh}(X;\mathcal{C}) \underset{\eta_*}{\overset{\eta^*}{\rightleftarrows}} \mathcal{C}_\eta$ which are left exact, since the morphism η is flat. Fix an object $C \in \mathrm{QCoh}(X;\mathcal{C})^{\heartsuit}$. Since the Grothendieck abelian category $\mathcal{C}_\eta^{\heartsuit}$ is locally Noetherian, we can write $\eta^* C \in \mathcal{C}_\eta^{\heartsuit}$ as a union of Noetherian subobjects $\{C'_\alpha\}$. For each index α, set $C_\alpha = C \times_{\eta_*\eta^* C} \eta_* C'_\alpha$. Since filtered colimits in $\mathrm{QCoh}(X;\mathcal{C})$ are exact, we have $C = \varinjlim C_\alpha$. We will show that each C_α is a Noetherian object of $\mathrm{QCoh}(X;\mathcal{C})^{\heartsuit}$. Note that the functor η^* induces an injection from the set of isomorphism classes of subobjects of C to the set of isomorphism classes of subobjects of $\eta^* C$. It will therefore suffice to show that $\eta^* C_\alpha$ is a Noetherian subobject of $\eta^* C$ in the abelian category $\mathcal{C}_\eta^{\heartsuit}$. This is clear, since the inclusion $\eta^* C_\alpha \hookrightarrow \eta^* C$ factors through C'_α (which is a Noetherian subobject of $\eta^* C$ by construction).

To complete the proof that $\mathrm{QCoh}(X;\mathcal{C})$ is locally Noetherian, it will suffice to show that if C is a Noetherian object of $\mathrm{QCoh}(X;\mathcal{C})^{\heartsuit}$, then C is compact when viewed as an object of $\tau_{\leqslant n} \mathrm{QCoh}(X;\mathcal{C})$ for each $n \geqslant 0$ (see Proposition C.6.9.8). Fix a filtered diagram $\{D_\alpha\}$ of n-truncated objects of $\mathcal{C}$ having colimit D; we wish to show that the canonical map $\rho : \varinjlim \mathrm{Map}_{\mathrm{QCoh}(X,\mathcal{C})}(C, D_\alpha) \to \mathrm{Map}_{\mathrm{QCoh}(X,\mathcal{C})}(C, D)$ is a homotopy equivalence. We will prove that the homotopy fibers of ρ are m-truncated for every integer $m \geqslant -2$. Note that this is trivial when $m = n$ (since the domain and codomain of ρ are both n-truncated). We will handle the general case using descending induction on m. For each index α, form a cofiber sequence $D_\alpha \to \eta_*\eta^* D_\alpha \to D'_\alpha$, and set $D' = \varinjlim D'_\alpha$. Note that since η is faithfully flat, the objects D'_α are also n-truncated. We have a commutative diagram of fiber sequences

$$\begin{array}{ccccc}
\varinjlim \mathrm{Map}_{\mathrm{QCoh}(X;\mathcal{C})}(C, D_\alpha) & \longrightarrow & \varinjlim \mathrm{Map}_{\mathrm{QCoh}(X;\mathcal{C})}(C, \eta_*\eta^* D_\alpha) & \longrightarrow & \varinjlim \mathrm{Map}_{\mathrm{QCoh}(X;\mathcal{C})}(C, D'_\alpha) \\
\downarrow \rho & & \downarrow \phi & & \downarrow \rho' \\
\mathrm{Map}_{\mathrm{QCoh}(X;\mathcal{C})}(C, D) & \longrightarrow & \mathrm{Map}_{\mathrm{QCoh}(X;\mathcal{C})}(C, \eta_*\eta^* D) & \longrightarrow & \mathrm{Map}_{\mathrm{QCoh}(X;\mathcal{C})}(C, D').
\end{array}$$

It follows from our inductive hypothesis that the map ρ' has $(m+1)$-truncated homotopy fibers. Consequently, to show that the homotopy fibers of ρ are m-truncated, it will suffice to show that ϕ is a homotopy equivalence. Unwinding the definitions, we can identify ϕ with the canonical map $\varinjlim \mathrm{Map}_{\mathcal{C}_\eta}(\eta^* C, \eta^* D_\alpha) \to \mathrm{Map}_{\mathcal{C}_\eta}(\eta^* C, \eta^* D)$. To show that this map is a homotopy equivalence, it will suffice to show that $\eta^* C$ is an almost compact object of $\mathcal{C}_\eta$. Using Proposition C.6.9.3 and Corollary C.6.8.9 (and our assumption that $\mathcal{C}_\eta$ is locally Noetherian), we are reduced to showing that $\eta^* C$ is compact as an object of $\mathcal{C}_\eta^\heartsuit$. This is clear: the functor η_* commutes with filtered colimits, so the pullback functor $\eta^* : \mathrm{QCoh}(X; \mathcal{C})^\heartsuit \to \mathcal{C}_\eta^\heartsuit$ preserves compact objects (and C is a compact object of $\mathrm{QCoh}(X; \mathcal{C})$ by virtue of Proposition C.6.8.7). □

10.5.3 Injective and Locally Injective Objects

Let A be a connective $\mathbb{E}_\infty$-ring, let $\mathcal{C}$ be a prestable A-linear ∞-category, and let Q be an object of $\mathrm{Sp}(\mathcal{C})$. If $\mathcal{C}$ is locally Noetherian, then Corollary 7.2.5.19 and Proposition 7.2.5.20 imply that the condition that Q is injective (in the sense of Definition C.5.7.2) can be tested locally with respect to the étale topology on A. Motivated by this observation, we introduce the following variant of Definition C.5.7.2:

Definition 10.5.3.1. Let X be a spectral Deligne-Mumford stack, let $\mathcal{C}$ be a locally Noetherian prestable quasi-coherent stack on X, and let $\mathscr{G}$ be an object of the ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C}))$. We will say that $\mathscr{G}$ is *locally injective* if, for every étale morphism $\eta : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$, the object $\mathscr{G}_\eta \in \mathrm{Sp}(\mathcal{C}_\eta)$ is injective.

Remark 10.5.3.2. Let A be a connective $\mathbb{E}_\infty$-ring, let $\mathcal{C}$ be a prestable A-linear ∞-category, and let Q be an object of $\mathrm{Sp}(\mathcal{C})$. Then Q is injective (in the sense of Definition C.5.7.2) if and only if it is locally injective when regarded as an object of $\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A; \mathrm{Sp}(\mathcal{C}))$ (in the sense of Definition 10.5.3.1). The “if” direction is obvious, and the converse follows from Corollary 7.2.5.19.

Remark 10.5.3.3. Let $f : \mathsf{X} \to \mathsf{Y}$ be an étale morphism between spectral Deligne-Mumford stacks, let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{Y})$ be locally Noetherian, and let $\mathscr{G} \in \mathrm{QCoh}(\mathsf{Y}; \mathrm{Sp}(\mathcal{C}))$. If $\mathscr{G}$ is locally injective, then $f^* \mathscr{G} \in \mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(f^* \mathcal{C}))$ is also locally injective. The converse holds if f is an étale surjection (this follows from Proposition 7.2.5.20).

Our goal in this section is to establish the following generalization of Remark 10.5.3.2:

Theorem 10.5.3.4. *Let X be a quasi-compact, quasi-separated spectral algebraic space, let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ be locally Noetherian, and let $\mathscr{G} \in \mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C})) \simeq \mathrm{Sp}(\mathrm{QCoh}(\mathsf{X}; \mathcal{C}))$. Then $\mathscr{G}$ is locally injective (in the sense of Definition 10.5.3.1) if and only if it is injective (in the sense of Definition C.5.7.2).*

The proof of Theorem 10.5.3.4 will require some preliminaries.

Lemma 10.5.3.5. *Let $j : \mathsf{U} \hookrightarrow \mathsf{X}$ be a quasi-compact open immersion between spectral Deligne-Mumford stacks and let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ be locally Noetherian. If $\mathscr{G} \in \mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C}))$ is locally injective, then the direct image $j_* j^* \mathscr{G}$ and the fiber $\mathrm{fib}(\mathscr{G} \to j_* j^*)$ are also locally injective objects of $\mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C}))$.*

Proof. Working locally on X, we can reduce to the case where $\mathsf{X} = \mathrm{Sp\acute{e}t}\, A$ is affine, in which case the desired result follows from Corollary 7.2.5.13. □

Lemma 10.5.3.6. *Let X be a quasi-compact, quasi-separated spectral algebraic space, let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ be locally Noetherian, and let $\mathscr{G} \in \mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C})) \simeq \mathrm{Sp}(\mathrm{QCoh}(\mathsf{X}; \mathcal{C}))$. If $\mathscr{G}$ is locally injective, then $\mathscr{G}$ is injective.*

Proof. Using Theorem 3.4.2.1, we can choose a scallop decomposition

$$\varnothing = \mathsf{U}_0 \hookrightarrow \mathsf{U}_1 \hookrightarrow \cdots \hookrightarrow \mathsf{U}_n = \mathsf{X}.$$

We will prove that $\mathscr{G}|_{\mathsf{U}_i}$ is an injective object of $\mathrm{QCoh}(\mathsf{U}_i; \mathcal{C}|_{\mathsf{U}_i})$ for $0 \leqslant i \leqslant n$. The proof proceeds by induction on i, the case $i = 0$ being trivial. To carry out the inductive step, let us assume that $i > 0$ and that $\mathscr{G}|_{\mathsf{U}_{i-1}}$ is an injective object of $\mathrm{QCoh}(\mathsf{U}_{i-1}; \mathcal{C}|_{\mathsf{U}_{i-1}})$. Choose an excision square σ :

$$\begin{array}{ccc} \mathsf{V}' & \longrightarrow & \mathsf{V} \\ \downarrow & & \downarrow q \\ \mathsf{U}_{i-1} & \xrightarrow{j} & \mathsf{U}_i, \end{array}$$

where V is affine. Form a fiber sequence $\mathscr{G}' \to \mathscr{G}|_{\mathsf{U}_i} \to j_* \mathscr{G}|_{\mathsf{U}_{i-1}}$ in the ∞-category $\mathrm{QCoh}(\mathsf{U}_i; \mathrm{Sp}(\mathcal{C}|_{\mathsf{U}_i}))$. Since the functor

$$j_* : \mathrm{QCoh}(\mathsf{U}_{i-1}; \mathrm{Sp}(\mathcal{C}|_{\mathsf{U}_{i-1}})) \to \mathrm{QCoh}(\mathsf{U}_i; \mathrm{Sp}(\mathcal{C}|_{\mathsf{U}_i}))$$

has a t-exact left adjoint (Corollary 10.1.7.10), and therefore carries injective objects to injective objects. It follows that $j_* \mathscr{G}|_{\mathsf{U}_{i-1}}$ is an injective object of $\mathrm{QCoh}(\mathsf{U}_i; \mathrm{Sp}(\mathcal{C}|_{\mathsf{U}_i}))$. Since the collection of injective objects is closed under extensions, it will suffice to show that $\mathscr{G}'$ is an injective object of $\mathrm{QCoh}(\mathsf{U}_i; \mathrm{Sp}(\mathcal{C}|_{\mathsf{U}_i}))$. Lemma 10.5.3.5 shows that $\mathscr{G}'$ is locally injective. Since V is affine, the object $q^* \mathscr{G}' \in \mathrm{QCoh}(\mathsf{V}; \mathrm{Sp}(\mathcal{C}|_{\mathsf{V}}))$ is injective. Since the functor q^* is t-exact (Corollary 10.1.7.10), the pushforward functor $q_* : \mathrm{QCoh}(\mathsf{V}; \mathrm{Sp}(\mathcal{C}|_{\mathsf{V}})) \to \mathrm{QCoh}(\mathsf{U}_i; \mathrm{Sp}(\mathcal{C}|_{\mathsf{U}_i}))$ carries injective objects to injective objects. It follows that $q_* q^* \mathscr{G}'$ is an injective object of $\mathrm{QCoh}(\mathsf{U}_i; \mathrm{Sp}(\mathcal{C}|_{\mathsf{U}_i}))$. We now complete the proof by observing that the unit map $\mathscr{G}' \to q_* q^* \mathscr{G}'$ is an equivalence (since σ is an excision square and $j^* \mathscr{G}' \simeq 0$), so that $\mathscr{G}'$ is also an injective object of $\mathrm{QCoh}(\mathsf{U}_i; \mathrm{Sp}(\mathcal{C}|_{\mathsf{U}_i}))$. □

Lemma 10.5.3.7. *Let $f : \mathsf{X} \to \mathsf{Y}$ be an étale morphism between quasi-compact, quasi-separated spectral algebraic spaces. Let $\mathcal{C}$ be a locally Noetherian prestable quasi-coherent* *stack on* Y *and let* $\mathscr{G} \in \mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(f^* \mathcal{C}))$ *be locally injective. Then* $f_* \mathscr{G} \in \mathrm{QCoh}(\mathsf{Y}; \mathrm{Sp}(\mathcal{C}))$ *is also locally injective.*

Proof. The assertion is local on Y, so we may assume without loss of generality that Y is affine. Note that $\mathscr{G}$ is an injective object of $\mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(f^* \mathcal{C}))$ by virtue of Lemma 10.5.3.6. Since the functor $f_* : \mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(f^* \mathcal{C})) \to \mathrm{QCoh}(\mathsf{Y}; \mathrm{Sp}(\mathcal{C}))$ admits a t-exact left adjoint (Corollary 10.1.7.10), it carries injective objects to injective objects. In particular, the object $f_* \mathscr{G} \in \mathrm{QCoh}(\mathsf{Y}; \mathrm{Sp}(\mathcal{C}))$ is injective, and is therefore locally injective by virtue of Remark 10.5.3.2. □

Proof of Theorem 10.5.3.4. Let X be a quasi-compact, quasi-separated spectral algebraic space, let $\mathcal{C}$ be a locally Noetherian prestable quasi-coherent stack on X, and let $\mathscr{G} \in \mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C})) \simeq \mathrm{Sp}(\mathrm{QCoh}(\mathsf{X}; \mathcal{C}))$. We wish to show that $\mathscr{G}$ is locally injective if and only if it is injective. The "only if" direction follows from Lemma 10.5.3.6. For the converse, suppose that $\mathscr{G}$ is injective. Choose an étale surjection $q : \mathsf{U} \to \mathsf{X}$, where U is affine. Choose a morphism $f : q^* \mathscr{G} \to \mathscr{G}'$ in $\mathrm{QCoh}(\mathsf{U}; \mathrm{Sp}(q^* \mathcal{C}))$ which exhibits $\mathscr{G}'$ as an injective hull of $q^* \mathscr{G}$ (see Example C.5.7.9), so that $\mathrm{cofib}(f)$ belongs to $\mathrm{QCoh}(\mathsf{U}; \mathrm{Sp}(q^* \mathcal{C}))_{\leqslant 0}$. Let f' denote the composite map

$$\mathscr{G} \xrightarrow{u} q_* q^* \mathscr{G} \xrightarrow{q_*(f)} q_* \mathscr{G}' .$$

Since q is surjective, we have $\mathrm{cofib}(u) \in \mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C}))_{\leqslant 0}$. Since q_* is right t-exact, we also have $\mathrm{cofib}(q_*(f)) \simeq q_* \mathrm{cofib}(f) \in \mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C}))_{\leqslant 0}$. It follows that $\mathrm{cofib}(f') \in \mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C}))_{\leqslant 0}$. Since $\mathscr{G}$ is an injective object of $\mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C}))$, it follows that u admits a left homotopy inverse: that is, it exhibits $\mathscr{G}$ as a direct summand of $q_* \mathscr{G}'$. Consequently, to show that $\mathscr{G}$ is locally injective, it will suffice to show that $q_* \mathscr{G}'$ is locally injective. This is an immediate consequence of Lemma 10.5.3.7 (since the object $\mathscr{G}' \in \mathrm{QCoh}(\mathsf{U}; \mathrm{Sp}(f^* \mathcal{C}))$ is locally injective by virtue of Remark 10.5.3.2). □

10.5.4 Spectral Decompositions of Injective Objects

Let A be a connective $\mathbb{E}_\infty$-ring, let $\mathcal{C}$ be a prestable A-linear ∞-category, and suppose that $\mathcal{C}$ is locally Noetherian. In §7.2.5, we saw that to every indecomposable injective object $Q \in \mathrm{Sp}(\mathcal{C})$, we can associate a unique prime ideal $\mathfrak{p} \in |\operatorname{Spec} A|$ such that Q is centered at $\mathfrak{p}$ (Proposition 7.2.5.11). Our goal in this section is to prove a global version of Proposition 7.2.5.11, replacing $\operatorname{Sp\acute{e}t} A$ by an arbitrary quasi-compact, quasi-separated spectral algebraic space X (Proposition 10.5.4.6).

Definition 10.5.4.1. Let X be a quasi-compact, quasi-separated spectral algebraic space, let $\mathcal{C}$ be a stable quasi-coherent stack on X, and let x be a point of the underlying topological space $|\mathsf{X}|$. We will say that an object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is *centered at x* if the following condition is satisfied:

(∗) Let $U \subseteq |\mathsf{X}|$ be a quasi-compact open subset corresponding to an open immersion $j : \mathsf{U} \hookrightarrow \mathsf{X}$. If $x \in U$, then the unit map $\mathscr{F} \to j_* j^* \mathscr{F}$ is an equivalence. If $x \notin U$, then the pullback $j^* \mathscr{F}$ is a zero object of $\mathrm{QCoh}(\mathsf{U}; \mathcal{C}|_{\mathsf{U}})$.

Example 10.5.4.2. In the situation of Definition 10.5.4.1, suppose that $\mathsf{X} = \mathrm{Sp\acute{e}t}\, A$ is affine and that $x \in |\mathsf{X}|$ corresponds to a prime ideal $\mathfrak{p} \subseteq \pi_0 A$. Then $\mathscr{F}$ is centered at x (in the sense of Definition 10.5.4.1) if and only if it is centered at $\mathfrak{p}$ (in the sense of Definition 7.2.5.6).

Remark 10.5.4.3. In the situation of Definition 10.5.4.1, suppose that $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is nonzero. Then there is at most one point $x \in |\mathsf{X}|$ such that $\mathscr{F}$ is centered at x. To prove this, we note that if x and y are two distinct points of $|\mathsf{X}|$, then we can choose a quasi-compact open subset $U \subseteq |\mathsf{X}|$ which contains one but not the other. In this case, the assumption that $\mathscr{F}$ is centered at both x and y guarantees that the unit map $u : \mathscr{F} \to j_* j^* \mathscr{F}$ is an equivalence and that the codomain of u vanishes; here $j : \mathsf{U} \hookrightarrow \mathsf{X}$ denotes the open immersion corresponding to U. This contradicts our assumption that $\mathscr{F}$ is nonzero.

Remark 10.5.4.4. Let X be a quasi-compact, quasi-separated spectral algebraic space, let $\mathcal{C}$ be a stable quasi-coherent stack on X, and let x be a point of the underlying topological space $|\mathsf{X}|$. The collection of those objects $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ which are centered at x is a stable subcategory of $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ which is closed under suspensions.

Remark 10.5.4.5. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism between quasi-compact, quasi-separated spectral algebraic spaces, let $\mathcal{C}$ be a stable quasi-coherent stack on Y, and let $x \in |\mathsf{X}|$ be a point having image $y = f(x) \in |\mathsf{Y}|$. If $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X}; f^* \mathcal{C})$ is centered at x, then $f_* \mathscr{F} \in \mathrm{QCoh}(\mathsf{Y}; \mathcal{C})$ is centered at y.

Proposition 10.5.4.6. *Let X be a quasi-compact, quasi-separated spectral algebraic space, let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ be locally Noetherian, and let $\mathscr{F}$ be an indecomposable injective object of $\mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C}))$. Then there exists a unique point $x \in |\mathsf{X}|$ such that $\mathscr{F}$ is centered at x.*

Corollary 10.5.4.7. *Let X be a quasi-compact, quasi-separated spectral algebraic space, let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ be locally Noetherian, and let $\mathscr{F}$ be an injective object of $\mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C}))$. Then $\mathscr{F}$ can be written as a coproduct $\bigoplus_{x \in |\mathsf{X}|} \mathscr{F}_x$, where each $\mathscr{F}_x$ is an injective object of $\mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C}))$ which is centered at x.*

Proof. It follows from Proposition 10.5.1.5 that the Grothendieck prestable ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is locally Noetherian. Consequently, every injective object $\mathscr{F} \in \mathrm{Sp}(\mathrm{QCoh}(\mathsf{X}; \mathcal{C})) \simeq \mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C}))$ can be written as a direct sum of indecomposable injective objects of $\mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C}))$ (Proposition C.6.10.6). We can therefore reduce to the case where $\mathscr{F}$ is indecomposable, in which case the desired result follows from Proposition 10.5.4.6. □

Warning 10.5.4.8. In the situation of Corollary 10.5.4.7, one can show that the summands $\mathscr{F}_x$ are determined by $\mathscr{F}$ up to equivalence. However, the decomposition $\mathscr{F} \simeq \bigoplus_{x \in |\mathsf{X}|} \mathscr{F}_x$ is not unique, since objects of the form $\bigoplus_{x \in |\mathsf{X}|} \mathscr{F}_x$ can admit automorphisms which do not preserve their direct sum decomposition.

Proof of Proposition 10.5.4.6. We proceed as in the proof of Lemma 10.5.3.6. Using Theorem 3.4.2.1, we can choose a scallop decomposition

$$\varnothing = \mathsf{U}_0 \hookrightarrow \mathsf{U}_1 \hookrightarrow \cdots \hookrightarrow \mathsf{U}_n = \mathsf{X}.$$

Let m be the smallest integer for which the restriction $\mathscr{F}|_{\mathsf{U}_m}$ is nonzero and let $j : \mathsf{U}_m \hookrightarrow \mathsf{X}$ denote the inclusion map. Form a fiber sequence $\mathscr{F}' \to \mathscr{F} \to j_* j^* \mathscr{F}$ in the ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C}))$. Using Theorem 10.5.3.4 and Lemma 10.5.3.5, we deduce that $\mathscr{F}'$ and $j_* j^* \mathscr{F}$ are also injective objects of $\mathrm{QCoh}(\mathsf{X}; \mathrm{Sp}(\mathcal{C}))$. It follows that $\mathscr{F}$ splits as a direct sum $\mathscr{F}' \oplus j_* j^* \mathscr{F}$, where the second summand does not vanish (by virtue of our assumption that $\mathscr{F}|_{\mathsf{U}_m} \neq 0$). The indecomposability of $\mathscr{F}$ now guarantees that $\mathscr{F}' \simeq 0$, so that the unit map $u : \mathscr{F} \to j_* j^* \mathscr{F}$ is an equivalence.

Choose an excision square σ :

$$\begin{array}{ccc} \mathsf{V}' & \longrightarrow & \mathsf{V} \\ \downarrow & & \downarrow q \\ \mathsf{U}_{m-1} & \longrightarrow & \mathsf{U}_m, \end{array}$$

where V is affine. The minimality of m implies that $\mathscr{F}|_{\mathsf{U}_{m-1}} \simeq 0$, so that the unit map $u' : \mathscr{F}|_{\mathsf{U}_m} \to q_* \mathscr{F}|_{\mathsf{V}}$ is an equivalence. Theorem 10.5.3.4 guarantees that $\mathscr{F}|_{\mathsf{V}}$ is an injective object of $\mathrm{QCoh}(\mathsf{V}; \mathrm{Sp}(\mathcal{C}|_{\mathsf{V}}))$. Applying Corollary 7.2.5.12, we deduce that $\mathscr{F}|_{\mathsf{V}}$ splits as a coproduct $\bigoplus_{v \in |\mathsf{V}|} \mathscr{G}_v$, where each $\mathscr{G}_v$ is centered at $v \in |\mathsf{V}|$. It follows that $\mathscr{F} \simeq j_* q_* \mathscr{F}|_{\mathsf{V}}$ splits as a direct sum $\bigoplus_{v \in |\mathsf{V}|} \mathscr{F}_v$ where $\mathscr{F}_v = j_* q_* \mathscr{G}_v$. The indecomposability of $\mathscr{F}$ now guarantees that exactly one of these summands does not vanish: that is, we have $\mathscr{F} \simeq j_* q_* \mathscr{G}_v$ for some point $v \in |\mathsf{V}|$. Applying Remark 10.5.4.5, we deduce that $\mathscr{F}$ is centered at x, where x denotes the image of v under the continuous map $|\mathsf{V}| \xrightarrow{j \circ q} |\mathsf{X}|$. □

10.6 Abelian Quasi-Coherent Stacks

Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a geometric stack. In §10.4, we proved that a complete prestable quasi-coherent stack $\mathcal{C}$ on X can be recovered from its global sections $\mathrm{QCoh}(X; \mathcal{C})$, regarded as an ∞-category tensored over $\mathrm{QCoh}(X)^{\mathrm{cn}}$ (Theorem 10.4.2.3). Our primary goal in this section is to prove an analogous statement in the setting of abelian quasi-coherent stacks. Our main results can be summarized as follows:

- Let $q : X \to \operatorname{Spec} S$ be the projection map. Then the pullback functor
$$q^* : \mathsf{Groth}_{\mathrm{ab}} \simeq \mathrm{QStk}^{\mathrm{Ab}}(\operatorname{Spec} S) \to \mathrm{QStk}^{\mathrm{Ab}}(X)$$
admits a right adjoint $\mathrm{QCoh}(X; \bullet) : \mathrm{QStk}^{\mathrm{Ab}}(X) \to \mathsf{Groth}_{\mathrm{ab}}$, which we will refer to as the *global sections functor* (Proposition 10.6.1.1).

- For every abelian quasi-coherent stack $\mathcal{C}$ on X, the Grothendieck abelian category $\mathrm{QCoh}(X; \mathcal{C})$ is equipped with an action of the abelian category $\mathrm{QCoh}(X)^{\heartsuit}$. This action depends functorially on $\mathcal{C}$: that is, we can regard the construction $\mathcal{C} \mapsto \mathrm{QCoh}(X; \mathcal{C})$ as a functor from the ∞-category $\mathrm{QStk}^{\mathrm{Ab}}(X)$ to the ∞-category $\mathrm{Mod}_{\mathrm{QCoh}(X)^{\heartsuit}}(\mathsf{Groth}_{\mathrm{ab}})$.

- The construction $\mathrm{QCoh}(X; \bullet) : \mathrm{QStk}^{\mathrm{Ab}}(X) \to \mathrm{Mod}_{\mathrm{QCoh}(X)^{\heartsuit}}(\mathsf{Groth}_{\mathrm{ab}})$ is fully faithful, and its essential image admits a simple description (see Theorem 10.6.2.1).

- The theory of abelian quasi-coherent stacks on X is closely related to the theory of prestable quasi-coherent stacks on X. More precisely, there is a full subcategory $\mathrm{QStk}^{\%}(X) \subseteq \mathrm{QStk}^{\mathrm{PSt}}(X)$ whose objects we will refer to as *complicial* quasi-coherent stacks (Definition **??**), for which the composite functor
$$\mathrm{QStk}^{\%}(X) \hookrightarrow \mathrm{QStk}^{\mathrm{PSt}}(X) \xrightarrow{\heartsuit} \mathrm{QStk}^{\mathrm{Ab}}(X)$$
induces a homotopy equivalence $\mathrm{QStk}^{\%}(X)^{\heartsuit} \to \mathrm{QStk}^{\mathrm{Ab}}(X)^{\heartsuit}$ (Proposition **??**).

Remark 10.6.0.1. According to Remark 10.1.2.6, the ∞-category $\mathrm{QStk}^{\mathrm{Ab}}(X)$ of abelian quasi-coherent stacks on X depends only on the restriction of X to the category of ordinary commutative rings (which we can regard as a full subcategory of the ∞-category $\mathrm{CAlg}^{\mathrm{cn}}$). Consequently, the results of this section can be viewed as belonging to classical algebraic geometry, rather than spectral algebraic geometry.

Remark 10.6.0.2. Many of the results we prove in this section for abelian quasi-coherent stacks can be deduced from their counterparts for (complete) prestable quasi-coherent stacks using the equivalence $\mathrm{QStk}^{\%}(X)^{\simeq} \to \mathrm{QStk}^{\mathrm{Ab}}(X)^{\simeq}$ of Proposition **??**. However, this approach is unnecessarily convoluted: it will be easier to instead to give direct proofs by imitating the arguments used in §10.4.

10.6.1 Global Sections of Abelian Quasi-Coherent Stacks

We begin by establishing an analogue of Proposition 10.4.1.4:

Proposition 10.6.1.1. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a quasi-geometric stack, let S denote the sphere spectrum, and let $q : X \to \operatorname{Spec} S$ be the projection map. Then the pullback functor $q^* : \mathsf{Groth}_{\mathrm{ab}} \simeq \mathrm{QStk}^{\mathrm{Ab}}(\operatorname{Spec} S) \to \mathrm{QStk}^{\mathrm{Ab}}(X)$ admits a right adjoint* $\mathrm{QCoh}(X; \bullet) : \mathrm{QStk}^{\mathrm{Ab}}(X) \to \mathsf{Groth}_{\mathrm{ab}}$.

Proof. Fix an object $\mathcal{C} \in \mathrm{QStk}^{\mathrm{Ab}}(X)$. We wish to show that the functor

$$F : \mathsf{Groth}_{\mathrm{ab}} \to \widehat{\mathcal{S}} \qquad \mathcal{E} \mapsto \mathrm{Map}_{\mathrm{QStk}^{\mathrm{Ab}}(X)}(q^* \mathcal{E}, \mathcal{C})$$

is representable by an object of $\mathsf{Groth}_{\mathrm{ab}}$.

Choose a faithfully flat map $f_0 : U_0 \to X$ where $U_0 \simeq \operatorname{Spec} A$ is affine, and let $U_\bullet$ denote the Čech nerve of f_0. For each $n \geqslant 0$, let $f_n : U_n \to X$ be the tautological map and let $F^n : \mathsf{Groth}_{\mathrm{ab}} \to \widehat{\mathcal{S}}$ denote the functor given by

$$\mathcal{E} \mapsto \mathrm{Map}_{\mathrm{QStk}^{\mathrm{Ab}}(U_n)}(f_n^* q^* \mathcal{E}, f_n^* \mathcal{C}).$$

Since each U_n is representable by a spectral Deligne-Mumford stack, each of the functors F^n is representable by the Grothendieck abelian category $\mathrm{QCoh}(U_n; f_n^* \mathcal{C})$ of Construction 10.1.7.1.

Since the natural map $|U_\bullet| \to X$ is an equivalence after sheafification for the fpqc topology, the ∞-category $\mathrm{QStk}^{\mathrm{Ab}}(X)$ can be identified with the totalization of the cosimplicial ∞-category $\mathrm{QStk}^{\mathrm{Ab}}(U_\bullet)$ (see Remark 10.1.2.11), so that $F \simeq \varprojlim_{[n] \in \mathbf{\Delta}} F^n$. Consequently, to show that F is representable, it will suffice to show that the cosimplicial object $[n] \mapsto f_n^* \mathcal{C}$ admits a limit in the ∞-category $\mathsf{Groth}_{\mathrm{ab}}$. Using the right cofinality of the inclusion $\mathbf{\Delta}_s \hookrightarrow \mathbf{\Delta}$ (Lemma HTT.6.5.3.7), it will suffice to show that the underlying cosemisimplicial object of $\mathsf{Groth}_{\mathrm{ab}}$ admits a limit. Note that if $\alpha : [m] \to [n]$ is a morphism in $\mathbf{\Delta}_+$, then the associated map $U_n \to U_m$ is flat (since it is a composition of pullbacks of the flat map $f_0 : U_0 \to X$). Using Corollary 10.1.7.10, we see that the natural map $\mathrm{QCoh}(U_m; f_m^* \mathcal{C}) \to \mathrm{QCoh}(U_n; f_n^* \mathcal{C})$ is left exact. It follows that the construction $[n] \mapsto f_n^*$ determines a functor from $\mathbf{\Delta}_s$ to the subcategory $\mathsf{Groth}_{\mathrm{ab}}^{\mathrm{lex}} \subseteq \mathsf{Groth}_{\mathrm{ab}}$ of Definition C.5.4.1, so the existence of the limit $\varprojlim f_\bullet^* \mathcal{C}$ follows from Proposition C.5.4.21. □

Example 10.6.1.2. Let X be a quasi-geometric stack and $\mathcal{C}$ be an abelian quasi-coherent stack on X. The proof of Proposition 10.6.1.1 shows that the ∞-category $\mathrm{QCoh}(X; \mathcal{C})$ can be identified with the totalization $\varprojlim \mathrm{QCoh}(U_\bullet; f_\bullet^* \mathcal{C})$, where $f_\bullet : U_\bullet \to X$ is the Čech nerve of any faithfully flat map $f_0 : U_0 = \operatorname{Spec} A \to X$. Taking $\mathcal{C} = \mathcal{Q}_X^\heartsuit$, we obtain an equivalence of Grothendieck abelian categories

$$\mathrm{QCoh}(X; \mathcal{Q}_X^\heartsuit) \simeq \varprojlim \mathrm{QCoh}(U_\bullet; \mathcal{Q}_{U_\bullet}^\heartsuit) = \varprojlim \mathrm{QCoh}(U_\bullet)^\heartsuit \simeq \mathrm{QCoh}(X)^\heartsuit.$$

10.6.2 Recovering $\mathcal{C}$ from $\mathrm{QCoh}(X; \mathcal{C})$

Let X be a quasi-geometric stack and let $q : X \to \operatorname{Spec} S$ be the projection map. Then the pullback functor

$$q^* : \mathsf{Groth}_{\mathrm{ab}} \simeq \mathrm{QStk}^{\mathrm{Ab}}(\operatorname{Spec} S) \to \mathrm{QStk}^{\mathrm{Ab}}(X)$$

is symmetric monoidal. It follows that the global sections functor $\mathrm{QCoh}(X;\bullet)$ of Proposition 10.6.1.1 is lax symmetric monoidal. We can therefore promote $\mathrm{QCoh}(X;\bullet)$ to a functor

$$\begin{aligned}\mathrm{QStk}^{\mathrm{Ab}}(X) &\simeq \mathrm{Mod}_{\mathcal{Q}_X^{\heartsuit}}(\mathrm{QStk}^{\mathrm{Ab}}(X)) \\ &\xrightarrow{\mathrm{QCoh}(X;\bullet)} \mathrm{Mod}_{\mathrm{QCoh}(X;\mathcal{Q}_X^{\heartsuit})}(\mathsf{Groth}_{\mathrm{ab}}) \\ &\simeq \mathrm{Mod}_{\mathrm{QCoh}(X)^{\heartsuit}}(\mathsf{Groth}_{\mathrm{ab}}).\end{aligned}$$

We will abuse notation by denoting this functor also by $\mathcal{C} \mapsto \mathrm{QCoh}(X;\mathcal{C})$. We can describe the situation more informally as follows: for every abelian quasi-coherent stack $\mathcal{C}$ on X, the Grothendieck abelian category $\mathrm{QCoh}(X;\mathcal{C})$ is tensored over the Grothendieck abelian category $\mathrm{QCoh}(X)^{\heartsuit}$ of discrete quasi-coherent sheaves on X, and the action

$$\mathrm{QCoh}(X)^{\heartsuit} \times \mathrm{QCoh}(X;\mathcal{C}) \to \mathrm{QCoh}(X;\mathcal{C})$$

preserves small colimits separately in each variable.

We can now formulate the main result of this section.

Theorem 10.6.2.1. *Let X be a geometric stack. Then the global sections functor*

$$\mathrm{QCoh}(X;\bullet) : \mathrm{QStk}^{\mathrm{Ab}}(X) \to \mathrm{Mod}_{\mathrm{QCoh}(X)^{\heartsuit}}(\mathsf{Groth}_{\mathrm{ab}})$$

is a fully faithful embedding, whose essential image is spanned by those $\mathcal{E} \in \mathrm{Mod}_{\mathrm{QCoh}(X)^{\heartsuit}}(\mathsf{Groth}_{\mathrm{ab}})$ which satisfy the following additional conditions:

- $(*)$ *Let $\mathscr{F} \in \mathrm{QCoh}(X)^{\heartsuit}$. If $\mathscr{F}$ can be written as $\pi_0 \mathscr{G}$ where $\mathscr{G} \in \mathrm{QCoh}(X)$ is flat, then the construction $E \mapsto \mathscr{F} \otimes E$ determines a left exact functor from the Grothendieck abelian category $\mathcal{E}$ to itself.*

- $(*')$ *Suppose we are given an exact sequence*

$$0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0$$

in the abelian category $\mathrm{QCoh}(X)^{\heartsuit}$. If $\mathscr{F}'' \simeq \pi_0 \mathscr{G}$ where $\mathscr{G} \in \mathrm{QCoh}(X)$ is flat, then for every object $E \in \mathcal{E}$ the sequence

$$0 \to \mathscr{F}' \otimes E \to \mathscr{F} \otimes E \to \mathscr{F}'' \otimes E \to 0$$

is also exact.

10.6.3 Digression: Module Objects of Grothendieck Abelian Categories

Our proof of Theorem 10.6.2.1 will require the following standard fact about Grothendieck abelian categories:

Proposition 10.6.3.1. *Let $\mathcal{C}$ and $\mathcal{D}$ be presentable categories and suppose we are given a functor $G : \mathcal{D} \to \mathcal{C}$ which is conservative and preserves small limits and colimits. If $\mathcal{C}$ is a Grothendieck abelian category, then so is $\mathcal{D}$.*

Example 10.6.3.2. Let $\mathcal{C}$ be a Grothendieck abelian category which is tensored over a monoidal ∞-category $\mathcal{A}$. Suppose that A is an algebra object of $\mathcal{A}$ and that the functor $(C \in \mathcal{C}) \mapsto (A \otimes C \in \mathcal{C})$ commutes with small colimits. Then the forgetful functor $\mathrm{LMod}_A(\mathcal{C}) \to \mathcal{C}$ is conservative and preserves small limits and colimits (Corollaries HA.4.2.3.3 and HA.4.2.3.5). It follows from Proposition 10.6.3.1 that $\mathrm{LMod}_A(\mathcal{C})$ is also Grothendieck abelian category.

Proof of Proposition 10.6.3.1. We proceed as in the proof of Proposition 10.4.3.1. The first step is to show that $\mathcal{D}$ is pointed. Let $\varnothing$ and $\mathbf{1}$ denote initial and final objects of $\mathcal{D}$, respectively, so that there is a unique map $\alpha : \varnothing \to \mathbf{1}$ in $\mathcal{D}$. We wish to prove that α is an isomorphism. Since G preserves small limits and colimits, it preserves initial and final objects, so that $G(\alpha)$ is a morphism from an initial object of $\mathcal{C}$ to a final object of $\mathcal{C}$. Because $\mathcal{C}$ is pointed, it follows that $G(\alpha)$ is an equivalence. Since the functor G is conservative, it follows that α is an equivalence.

We next claim that $\mathcal{D}$ is semiadditive: that is, for every pair of objects $D, D' \in \mathcal{D}$, the map

$$\begin{pmatrix} \mathrm{id}_D & 0 \\ 0 & \mathrm{id}_{D'} \end{pmatrix} : D \amalg D' \to D \times D'$$

is an isomorphism. Since the functor G preserves small limits and colimits, we can identify $G \begin{pmatrix} \mathrm{id}_D & 0 \\ 0 & \mathrm{id}_{D'} \end{pmatrix}$ with the natural map

$$\begin{pmatrix} \mathrm{id}_{G(D)} & 0 \\ 0 & \mathrm{id}_{G(D')} \end{pmatrix} : G(D) \amalg G(D') \to G(D) \times G(D'),$$

which is an isomorphism by virtue of the fact that $\mathcal{C}$ is semiadditive. Since G is conservative, it follows that the map $\begin{pmatrix} \mathrm{id}_D & 0 \\ 0 & \mathrm{id}_{D'} \end{pmatrix}$ is an isomorphism in $\mathcal{D}$.

To complete the proof that $\mathcal{D}$ is additive, it will suffice to show that for every object $D \in \mathcal{D}$, the "shearing" map

$$\begin{pmatrix} \mathrm{id}_D & \mathrm{id}_D \\ 0 & \mathrm{id}_D \end{pmatrix} : D \oplus D \to D \oplus D$$

is an isomorphism (see the proof of Theorem C.4.1.1). This follows from the fact that G is conservative, since the map

$$G\begin{pmatrix} \mathrm{id}_D & \mathrm{id}_D \\ 0 & \mathrm{id}_D \end{pmatrix} = \begin{pmatrix} \mathrm{id}_{G(D)} & \mathrm{id}_{G(D)} \\ 0 & \mathrm{id}_{G(D)} \end{pmatrix} : G(D) \oplus G(D) \to G(D) \oplus G(D)$$

is an isomorphism by virtue of our assumption that the category $\mathcal{C}$ is additive.

We next show that $\mathcal{D}$ is abelian. Let $f : D \to D'$ be a morphism in $\mathcal{D}$; we wish to show that the natural map $\alpha : \mathrm{coim}(f) \to \mathrm{im}(f)$ is an isomorphism in $\mathcal{D}$. Since the functor G preserves limits and colimits, it commutes with the formation of images and coimages. Consequently, we can identify $G(\alpha)$ with the canonical map from coimage of $G(f)$ to the image of $G(f)$. Since $\mathcal{C}$ is an abelian category, it follows that $G(\alpha)$ is an isomorphism. Using the fact that G is conservative, we conclude that α is an isomorphism.

We now complete the proof by showing that the abelian category $\mathcal{D}$ is Grothendieck. Since $\mathcal{D}$ is assumed to be presentable, it will suffice to show that the collection of monomorphisms in $\mathcal{D}$ is closed under filtered colimits. Suppose we are given a filtered diagram $\{f_\alpha : D_\alpha \to D'_\alpha\}$ of monomorphisms in $\mathcal{D}$ having a colimit $f : D \to D'$. Since G commutes with limits, it is left exact. Consequently, each $G(f_\alpha)$ is a monomorphism in $\mathcal{C}$. Using the assumption that $\mathcal{C}$ is a Grothendieck abelian category, we deduce that the colimit $\varinjlim G(f_\alpha)$ is also a monomorphism in $\mathcal{C}$. Because G commutes with colimits, we can identify $\varinjlim G(f_\alpha)$ with $G(f)$. Using the left exactness of G, we deduce that $G(\ker(f)) \simeq \ker(G(f)) \simeq 0$. Since G is conservative, it follows that $\ker(f) \simeq 0$, so that f is a monomorphism. □

10.6.4 The Proof of Theorem 10.6.2.1

Let X be a geometric stack and let $\mathcal{C} \in \mathrm{Mod}_{\mathrm{QCoh}(X)^\heartsuit}(\mathsf{Groth}_{\mathrm{ab}})$ be a Grothendieck abelian ∞-category equipped with an action of $\mathrm{QCoh}(X)^\heartsuit$. For every connective $\mathbb{E}_\infty$-ring A and every point $\eta \in X(A)$, let $\mathcal{C}_\eta$ denote the tensor product $\mathrm{Mod}_A^\heartsuit \otimes_{\mathrm{QCoh}(X)^\heartsuit} \mathcal{C}$, formed in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ of presentable ∞-categories. Our assumption that X is a geometric stack guarantees that η is an affine morphism, so that we can identify $\mathrm{Mod}_A^\heartsuit$ with the ∞-category

$$\mathrm{Mod}_{\mathscr{A}}(\mathrm{QCoh}(X))^\heartsuit \simeq \mathrm{Mod}_{\pi_0 \mathscr{A}}(\mathrm{QCoh}(X)^\heartsuit)$$

where $\mathscr{A} = \eta_* \mathscr{O}_{\mathrm{Spec}\, A} \in \mathrm{CAlg}(\mathrm{QCoh}(X)^{\mathrm{cn}})$. Applying Theorem HA.4.8.4.6 , we obtain an equivalence $\mathcal{C}_\eta \simeq \mathrm{LMod}_{\pi_0 \mathscr{A}}(\mathcal{C})$. It follows from Example 10.6.3.2 that $\mathcal{C}_\eta$ is an (A-linear) Grothendieck abelian category.

The construction $\mathcal{C} \mapsto \{\mathcal{C}_\eta\}_{\eta \in X(A)}$ determines a functor

$$\Phi_X^{\mathrm{Ab}} : \mathrm{Mod}_{\mathrm{QCoh}(X)^\heartsuit}(\mathsf{Groth}_{\mathrm{ab}}) \to \mathrm{QStk}^{\mathrm{Ab}}(X).$$

It is not difficult to see that the functor Φ_X^{Ab} is left adjoint to the global sections functor $\mathrm{QCoh}(X; \bullet) : \mathrm{QStk}^{\mathrm{Ab}}(X) \to \mathrm{Mod}_{\mathrm{QCoh}(X)^\heartsuit}(\mathsf{Groth}_{\mathrm{ab}})$ appearing in the statement of Theorem 10.6.2.1.

Proof of Theorem 10.6.2.1. Let X be a geometric stack and choose a faithfully flat map $\eta : U_0 \to X$, where $U_0 \simeq \operatorname{Spec} A$ is affine. We first show that the global sections functor

$$\mathrm{QCoh}(X; \bullet) : \mathrm{QStk}^{\mathrm{Ab}}(X) \to \mathrm{Mod}_{\mathrm{QCoh}(X)^{\heartsuit}}(\mathsf{Groth}_{\mathrm{ab}})$$

is fully faithful. Let $\mathcal{C}$ be an abelian quasi-coherent stack on X; we wish to show that the counit map $v : \Phi_X^{\mathrm{Ab}} \mathrm{QCoh}(X; \mathcal{C}) \to \mathcal{C}$ is an equivalence of abelian quasi-coherent stacks on X. Since η is an effective epimorphism of fpqc sheaves, it will suffice to show that $\eta^*(v)$ is an equivalence of A-linear abelian categories (Remark 10.1.2.11).

Unwinding the definitions, we wish to prove that the canonical map

$$\theta : \mathrm{Mod}_A^{\heartsuit} \otimes_{\mathrm{QCoh}(X)^{\heartsuit}} \mathrm{QCoh}(X; \mathcal{C}) \to \mathcal{C}_\eta$$

is an equivalence of A-linear abelian categories. Let $U_\bullet$ denote the Čech nerve of η, so that we can write $U_\bullet \simeq \operatorname{Spec} A^\bullet$ for some cosimplicial $\mathbb{E}_\infty$-ring $A^\bullet$. For each $n \geqslant 0$, let $f_n : U_n \to X$ be the canonical map, and let us abuse notation by identifying each pullback $f_n^* \mathcal{C}$ with the corresponding (A^n-linear) Grothendieck abelian category. Then the proof of Proposition 10.6.1.1 supplies a canonical equivalence $\mathrm{QCoh}(X; \mathcal{C}) \simeq \varprojlim f_\bullet^* \mathcal{C}$. Let $\mathscr{A} \in \mathrm{CAlg}(\mathrm{QCoh}(X)^{\mathrm{cn}})$ denote the direct image under η of the structure sheaf of $\operatorname{Spec} A$. Since X is a geometric stack, the map η is affine and we can identify $\mathrm{Mod}_A^{\heartsuit}$ with the ∞-category $\mathrm{Mod}_{\mathscr{A}}(\mathrm{QCoh}(X))^{\heartsuit} \simeq \mathrm{Mod}_{\pi_0 \mathscr{A}}(\mathrm{QCoh}(X)^{\heartsuit})$. It follows that $\mathrm{Mod}_A^{\heartsuit}$ is self-dual as an object of the ∞-category $\mathrm{Mod}_{\mathrm{QCoh}(X)^{\heartsuit}}(\mathsf{Groth}_{\mathrm{ab}})$, so that the formation of tensor products with $\mathrm{Mod}_A^{\heartsuit}$ commutes with limits. We therefore have canonical equivalences

$$\begin{aligned} \mathrm{Mod}_A^{\heartsuit} \otimes_{\mathrm{QCoh}(X)^{\heartsuit}} \mathrm{QCoh}(X; \mathcal{C}) &\simeq \mathrm{LMod}_{\pi_0 \mathscr{A}}(\mathrm{QCoh}(X; \mathcal{C})) \\ &\simeq \varprojlim \mathrm{LMod}_{\mathscr{A}}(\mathrm{QCoh}(U_\bullet; f_\bullet^* \mathcal{C})) \\ &\simeq \mathrm{QCoh}(U_{\bullet+1}; f_{\bullet+1}^* \mathcal{C}). \end{aligned}$$

The statement that θ is an equivalence now follows from the observation that the augmented simplicial object $\mathrm{QCoh}(U_{\bullet+1}; f_{\bullet+1}^* \mathcal{C})$ is split.

We next show that for every abelian quasi-coherent stack $\mathcal{C} \in \mathrm{QStk}^{\mathrm{Ab}}(X)$, the Grothendieck abelian category $\mathrm{QCoh}(X; \mathcal{C})$ satisfies conditions $(*)$ and $(*')$ of Theorem 10.6.2.1. We first verify $(*)$. Let $\mathscr{F} \in \mathrm{QCoh}(X)^{\heartsuit}$, and suppose that we can write $\mathscr{F} = \pi_0 \mathscr{G}$ where $\mathscr{G} \in \mathrm{QCoh}(X)$ is flat. Let $F : \mathrm{QCoh}(X; \mathcal{C}) \to \mathrm{QCoh}(X; \mathcal{C})$ be the functor given by tensor product with $\mathscr{F}$. We wish to prove that the functor F is exact. Recall that we can identify $\mathrm{QCoh}(X; \mathcal{C})$ with the inverse limit of the cosemisimplicial object $f_\bullet^* \mathcal{C}$ in the ∞-category $\mathsf{Groth}_{\mathrm{ab}}^{\mathrm{lex}}$ (see the proof of Proposition 10.6.1.1); consequently, the functor F is exact if and only if each of the composite functors $\mathrm{QCoh}(X; \mathcal{C}) \xrightarrow{F} \mathrm{QCoh}(X; \mathcal{C}) \xrightarrow{f_n^*} f_n^* \mathcal{C}$ is exact. Rewriting this functor as a composition $\mathrm{QCoh}(X; \mathcal{C}) \xrightarrow{f_n^*} f_n^* \mathcal{C} \xrightarrow{(f_n^* \mathscr{F}) \otimes} f_n^* \mathcal{C}$, we are reduced to proving that tensor product with the object $f_n^* \mathscr{F} \in \mathrm{QCoh}(U_n)^{\heartsuit} \simeq \mathrm{Mod}_{A^n}^{\heartsuit}$ determines an exact functor F_n from the abelian category $f_n^* \mathcal{C}$ to itself. To see this, we observe that we can identify $f_n^* \mathscr{F}$ with $\pi_0(f_n^* \mathscr{G})$. Since $\mathscr{G}$ is flat, Proposition HA.7.2.2.15 implies that we can write f_n^* as a filtered colimit of free A^n-modules of finite rank. Consequently, the functor F_n can be written as a filtered colimit of endofunctors of $f_n^* \mathcal{C}$ having the form $C \mapsto C^k$, and is therefore exact.

We now prove that $\mathrm{QCoh}(X; \mathcal{C})$ satisfies condition $(*')$. Suppose we are given an exact sequence $0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0$ in the abelian category $\mathrm{QCoh}(X)^{\heartsuit}$, where $\mathscr{F}'' \simeq \pi_0 \mathscr{G}$ for some flat object $\mathscr{G} \in \mathrm{QCoh}(X)$. We wish to show that for each object $C \in \mathrm{QCoh}(X; \mathcal{C})$, the sequence

$$0 \to \mathscr{F}' \otimes E \to \mathscr{F} \otimes E \to \mathscr{F}'' \otimes E \to 0$$

is exact. Arguing as above, it will suffice to show that the sequence σ :

$$0 \to f_n^*(\mathscr{F}' \otimes E) \to f_n^*(\mathscr{F} \otimes E) \to f_n^*(\mathscr{F}'' \otimes E) \to 0$$

is exact in the Grothendieck abelian category $f_n^* \mathcal{C}$ for each $n \geqslant 0$. Let E^n denote the image of E in $f_n^* \mathcal{C}$, so that we can rewrite the sequence σ as

$$0 \to f_n^* \mathscr{F}' \otimes_{A^n} E^n \to f_n^* \mathscr{F} \otimes_{A^n} E^n \to f_n^* \mathscr{F}'' \otimes_{A^n} E^n \to 0.$$

Note that we can identify $f_n^* \mathscr{F}''$ with $\pi_0 f_n^* \mathscr{G}$. Since the quasi-coherent sheaf $\mathscr{G}$ is flat, Proposition HA.7.2.2.15 implies that we can write $f_n^* \mathscr{G}$ as a filtered colimit of free A^n-modules of finite rank. Consequently, we can write $f_n^* \mathscr{F}''$ as a filtered colimit $\varinjlim M_\alpha$, where each M''_α is a free module over $\pi_0 A^n$. Set $M_\alpha = f_n^* \mathscr{F} \times_{f_n^* \mathscr{F}''} M''_\alpha$, so that we can write σ as a filtered colimit of complexes σ_α:

$$0 \to f_n^* \mathscr{F}' \otimes_{A^n} E^n \to M_\alpha \otimes_{A^n} E^n \to M''_\alpha \otimes_{A^n} E^n \to 0.$$

Since $f_n^* \mathcal{C}$ is a Grothendieck abelian category, the collection of exact sequences in $f_n^* \mathcal{C}$ is closed under filtered colimits. Consequently, to prove that the sequence σ is exact, it will suffice to prove that each of the sequences σ_α is exact. In fact, we claim that σ_α is split exact. This follows from the observation that σ_α is obtained by tensoring the object $E^n \in f_n^* \mathcal{C}$ with the exact sequence

$$0 \to f_n^* \mathscr{F}' \to M_\alpha \to M''_\alpha \to 0$$

in $\mathrm{Mod}_{A^n}^{\heartsuit}$, which is split by virtue of the fact that M''_α is a free module over the commutative ring $\pi_0 A^n$.

To complete the proof of Theorem 10.6.2.1, we must show that if $\mathcal{E}$ is a Grothendieck abelian category equipped with an action of $\mathrm{QCoh}(X)^{\heartsuit}$ satisfying conditions $(*)$ and $(*')$, then $\mathcal{E}$ belongs to the essential image of the global sections functor

$$\mathrm{QCoh}(X; \bullet) : \mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X}) \to \mathrm{Mod}_{\mathrm{QCoh}(X)^{\heartsuit}}(\mathsf{Groth}_{\mathrm{ab}}).$$

Equivalently, we show that $\mathcal{E}$ satisfies conditions $(*)$ and $(*')$, then the unit map $u : \mathcal{E} \to \mathrm{QCoh}(X; \Phi_X^{\mathrm{Ab}} \mathcal{E})$ is an equivalence of abelian categories.

For each $n \geqslant 0$, let $\mathscr{A}^n \in \mathrm{CAlg}(\mathrm{QCoh}(X))$ denote the direct image of the structure sheaf of U_n, so that $f_n^* \Phi_X^{\mathrm{Ab}} \mathcal{E}$ can be identified with the abelian category $\mathcal{E}^n = \mathrm{LMod}_{\pi_0 \mathscr{A}^n}(\mathcal{E})$. Let us regard $\mathscr{A}^\bullet$ as an augmented cosimplicial object of $\mathrm{CAlg}(\mathrm{QCoh}(X))$ by taking $\mathscr{A}^{-1} = \mathscr{O}_X$, so that $\mathcal{E}^{-1} = \mathcal{E}$. The proof of Proposition 10.6.1.1 then supplies an identification of $\mathrm{QCoh}(X; \Phi_X^{\mathrm{Ab}} \mathcal{E})$ with the totalization of the underlying cosemisimplicial object of $\mathcal{E}^\bullet$. Under this identification, the functor u is given by the natural map $\mathcal{E}^{-1} \to \varprojlim_{[n] \in \mathbf{\Delta}_s} \mathcal{E}^n$ is an equivalence in the ∞-category $\mathrm{Mod}_{\mathrm{QCoh}(X)^\heartsuit}(\mathsf{Groth}_{\mathrm{ab}})$. Using Corollary HA.4.2.3.3 and Proposition C.5.4.21, we see that this map is an equivalence if and only if $\mathcal{E}^{-1}$ is a limit of the diagram $\{\mathcal{E}^n\}_{[n] \in \mathbf{\Delta}_s}$ in $\widehat{\mathcal{C}\mathrm{at}}_\infty$. Let $F : \mathcal{E} = \mathcal{E}^{-1} \to \mathcal{E}^0 = \mathrm{LMod}_{\pi_0 \mathscr{A}}(\mathcal{E})$ be the functor given $E \mapsto (\pi_0 \mathscr{A}) \otimes E$. Since the augmented cosimplicial ∞-category $\mathcal{E}^\bullet$ satisfies the Beck-Chevalley condition of Corollary HA.4.7.5.3 , we are reduced to proving the following concrete assertions:

- (a) The functor F is conservative.
- (b) The functor $F : \mathcal{E} \to \mathrm{LMod}_{\pi_0 \mathscr{A}}(\mathcal{E})$ preserves totalizations of F-split cosimplicial objects.

We first prove (b). Note that $\mathcal{E}$ and $\mathrm{LMod}_{\pi_0 \mathscr{A}}(\mathcal{E})$ are ordinary categories, so that the limit of a cosimplicial object $E^\bullet$ (in either setting) can be described as the equalizer of the pair of coface maps $d^0, d^1 : E^0 \to E^1$. Consequently, to prove that condition (b) is satisfied, it will suffice to show that the functor F preserves finite limits. Since the forgetful functor $G : \mathrm{LMod}_{\pi_0 \mathscr{A}}(\mathcal{E}) \to \mathcal{E}$ is conservative and preserves finite limits, we are reduced to proving that the composite functor $G \circ F$ preserves finite limits. This follows from condition $(*)$, applied to the object $\pi_0 \mathscr{A} \in \mathrm{QCoh}(X)^\heartsuit$.

To prove (a), let $e : \mathscr{O}_X \to \mathscr{A}$ denote the unit map of the algebra $\mathscr{A} \in \mathrm{CAlg}(\mathrm{QCoh}(X))$. Since the map η is faithfully flat, the cofiber $\mathrm{cofib}(e) \in \mathrm{QCoh}(X)$ is flat. We have an exact sequence

$$0 \to \pi_0 \mathscr{O}_X \to \pi_0 \mathscr{A} \to \pi_0 \mathrm{cofib}(e) \to 0$$

in the abelian category $\mathrm{QCoh}(X)^\heartsuit$. If $\mathcal{E}$ satisfies condition $(*)$, then for every object $E \in \mathcal{E}$ the sequence

$$0 \to E \to (\pi_0 \mathscr{A}) \otimes E \to (\pi_0 \mathrm{cofib}(e)) \otimes E \to 0$$

is also exact. Consequently, if $E \in \mathcal{E}$ is annihilated by the functor F, then $E \simeq 0$. Applying this observation to the kernel and cokernel of a morphism $\alpha : X \to Y$ in $\mathcal{E}$ (and using the exactness of F established above), we deduce that if $F(\alpha)$ is an equivalence, then α is an equivalence. □

10.6.5 The Resolution Property

For geometric stacks with the resolution property (see Definition 9.3.3.2), the statement of Theorem 10.6.2.1 can be simplified:

Theorem 10.6.5.1. *Let X be a geometric stack with the resolution property. Then the global sections functor* $\mathrm{QCoh}(X; \bullet) : \mathrm{QStk}^{\mathrm{Ab}}(X) \to \mathrm{Mod}_{\mathrm{QCoh}(X)^{\heartsuit}}(\mathsf{Groth}_{\mathrm{ab}})$ *is an equivalence of ∞-categories.*

Proof. Without loss of generality, we may assume that X is 0-truncated. By virtue of Theorem **??**, it will suffice to show that for every object $\rho : \mathcal{E} \in \mathrm{Mod}_{\mathrm{QCoh}(X)^{\heartsuit}}(\mathsf{Groth}_{\mathrm{ab}})$, the unit map $u : \mathcal{E} \to \mathrm{QCoh}(X; \Phi_X^{\mathrm{Ab}} \mathcal{E})$ is an equivalence of categories. Choose a faithfully flat map $f : U \to X$, where U is affine, and set $\mathscr{A} = f_* \mathscr{O}_U$. Let $F : \mathcal{E} \to \mathrm{LMod}_{\pi_0 \mathscr{A}}(\mathcal{E})$ be a left adjoint to the forgetful functor. Arguing as in the proof of Theorem **??**, we see that ρ is an equivalence if and only if the following conditions are satisfied:

(a) The functor F is conservative.

(b) The functor $F : \mathcal{E} \to \mathrm{LMod}_{\pi_0 \mathscr{A}}(\mathcal{E})$ preserves totalizations of F-split cosimplicial objects.

We first prove (b). Note that $\mathcal{E}$ and $\mathrm{LMod}_{\pi_0 \mathscr{A}}(\mathcal{E})$ are ordinary categories, so that the limit of a cosimplicial object $E^{\bullet}$ (in either setting) can be described as the equalizer of the pair of coface maps $d^0, d^1 : E^0 \to E^1$. Consequently, to prove that condition (b) is satisfied, it will suffice to show that the functor F preserves finite limits. Since the forgetful functor $G : \mathrm{LMod}_{\pi_0 \mathscr{A}}(\mathcal{E}) \to \mathcal{E}$ is conservative and preserves finite limits, we are reduced to proving that the composite functor $G \circ F$, given by $E \mapsto (\pi_0 \mathscr{A}) \otimes E$, preserves finite limits.

We now proceed as in the proof of Proposition 10.4.5.2. Let $\mathcal{C} = \mathrm{Vect}(X) \times_{\mathrm{QCoh}(X)} \mathrm{QCoh}(X)_{/\mathscr{A}}$ be the ∞-category of vector bundles $\mathscr{F}$ on X equipped with a map $\mathscr{F} \to \mathscr{A}$. According to Lemma 9.3.4.13, the ∞-category $\mathcal{C}$ is filtered. The proof of Proposition 9.3.4.11 shows that the canonical map $\varinjlim_{\mathscr{F} \in \mathcal{C}} \mathscr{F} \to \mathscr{A}$ is an equivalence. It follows that we can write $G \circ F$ as the colimit of a filtered diagram of functors of the form $E \mapsto (\pi_0 \mathscr{F}) \otimes E$ for $\mathscr{F} \in \mathrm{Vect}(X)$. Each of these functors is left exact, since it admits a left adjoint (given by the construction $E \mapsto (\pi_0 \mathscr{F}^{\vee}) \otimes E$).

We now prove (a). Since F is an exact functor, it will suffice to show that any object $E \in \mathcal{E}$ satisfying $F(E) \simeq 0$ must itself be a zero object of $\mathcal{E}$. Let us regard the structure sheaf $\mathscr{O}_X$ as an object of $\mathcal{C}$ (by equipping it with the unit map $e : \mathscr{O}_X \to \mathscr{A}$), so that $\mathcal{C}_{\mathscr{O}_X /}$ is also a filtered ∞-category and the projection map $\mathcal{C}_{\mathscr{O}_X /} \to \mathcal{C}$ is left cofinal. It follows that e can be written as the colimit of a filtered diagram of maps $e_\alpha : \mathscr{O}_X \to \mathscr{F}_\alpha$ in $\mathrm{Vect}(X)$, so that the unit map $u_E : E \to (G \circ F)(E)$ can be computed as a filtered colimit of maps $u_\alpha : E \to (\pi_0 \mathscr{F}_\alpha) \otimes E$. Note that $f^*(e_\alpha)$ admits a left homotopy inverse, so that

$f^* \operatorname{cofib}(e_\alpha)$ is a direct summand of $f^* \mathscr{F}_\alpha$ and therefore belongs to $\operatorname{Vect}(U)$. It follows that the dual map $e_\alpha^\vee : \mathscr{F}_\alpha^\vee \to \mathscr{O}_X$ is an epimorphism on π_0. Unwinding the definitions, we see that the composite map

$$(\pi_0 \mathscr{F}_\alpha^\vee) \otimes \ker(u_\alpha) \xrightarrow{e_\alpha^\vee \otimes \mathrm{id}} \ker(u_\alpha) \to E$$

vanishes. Since $e_\alpha^\vee \otimes \mathrm{id}$ is an epimorphism, it follows that the map $\ker(u_\alpha) \to E$ vanishes, so that u_α is a monomorphism. Because filtered colimits in $\mathcal{E}$ are left exact, we conclude that the unit map $u_E : E \to (G \circ F)(E)$ is also a monomorphism. Since $(G \circ F)(E)$ vanishes by assumption, we conclude that $E \simeq 0$ as desired. □

We also have an abelian analogue of Theorem 10.4.5.5:

Theorem 10.6.5.2. *Let X be a 0-truncated geometric stack with the resolution property. Then the global sections functor $\mathcal{C} \mapsto \operatorname{QCoh}(X; \mathcal{C})$ determines a fully faithful embedding*

$$\operatorname{QCoh}(X; \bullet) : \operatorname{QStk}^{\mathrm{Ab}}(X) \to \operatorname{Mod}_{\operatorname{Vect}(X)}(\widehat{\mathcal{C}\mathrm{at}})$$

whose essential image is spanned by those $\operatorname{Vect}(X)$-modules $\mathcal{E}$ satisfying the following conditions:

(i) The category $\mathcal{E}$ is Grothendieck abelian.

(ii) If $0 \in \operatorname{Vect}(X)$ is a zero object, then $0 \otimes E$ is a zero object of $\mathcal{E}$ for each $E \in \mathcal{E}$.

(iii) For every diagram $0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0$ in $\operatorname{Vect}(X)$ which is exact in the abelian category $\operatorname{QCoh}(X)^\heartsuit$ and every object $E \in \mathcal{E}$, the sequence

$$\mathscr{F}' \otimes E \to \mathscr{F} \otimes E \to \mathscr{F}'' \otimes E \to 0$$

is exact in the abelian category $\mathcal{E}$.

*Proof of Theorem **??**.* Let $\mathcal{C} = \tau_{\leqslant 0} \mathcal{P}_\Sigma(\operatorname{Vect}(X)) = \operatorname{Fun}^\pi(\operatorname{Vect}(X)^{\mathrm{op}}, \mathcal{S}\mathrm{et})$ be the abelian category of functors $\operatorname{Vect}(X)^{\mathrm{op}} \to \mathcal{S}\mathrm{et}$ which preserve finite products. Let us abuse notation by identifying $\operatorname{Vect}(X)$ with its essential image under the Yoneda embedding $\operatorname{Vect}(X) \hookrightarrow \mathcal{C}$. Since X has the resolution property, the Gabriel-Popescu theorem (Theorem C.2.2.1) implies that the inclusion $\operatorname{Vect}(X) \hookrightarrow \operatorname{QCoh}(X)^\heartsuit$ extends to an exact functor $F : \mathcal{C} \to \operatorname{QCoh}(X)^\heartsuit$ which admits a fully faithful right adjoint G. Using Proposition 9.3.7.7, we see that G induces an equivalence from $\operatorname{QCoh}(X)^\heartsuit$ to the full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ spanned by those functors $\lambda : \operatorname{Vect}(X)^{\mathrm{op}} \to \mathcal{S}\mathrm{et}$ which preserve finite products and satisfy the following additional condition:

$(\star)$ For every diagram $0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0$ in $\operatorname{Vect}(X)$ which is exact in the abelian category $\operatorname{QCoh}(X)^\heartsuit$, the diagram $0 \to \lambda(\mathscr{F}'') \to \lambda(\mathscr{F}) \to \lambda(\mathscr{F}')$ is exact (in the category of abelian groups).

Since the tensor product on $\mathrm{Vect}(X)$ preserves finite direct sums in each variable, it admits an essentially unique extension to a symmetric monoidal structure on $\mathcal{C}$ for which the tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves small colimits separately in each variable. Moreover, composition with the inclusion $\mathrm{Vect}(X) \hookrightarrow \mathcal{C}$ determines a fully faithful functor $\rho : \mathrm{Mod}_{\mathcal{C}}(\mathsf{Groth}_{\mathrm{ab}}) \to \mathrm{Mod}_{\mathrm{Vect}(X)}(\widehat{\mathcal{C}\mathrm{at}})$ whose essential image consists of those objects which satisfy conditions (i), (ii), and the following weaker version of (iii'):

(iii') For every diagram $0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0$ in $\mathrm{Vect}(X)$ which is split exact in the abelian category $\mathrm{QCoh}(X)^{\heartsuit}$ and every object $E \in \mathcal{E}$, the sequence

$$\mathscr{F}' \otimes E \to \mathscr{F} \otimes E \to \mathscr{F}'' \otimes E \to 0$$

is exact in the abelian category $\mathcal{E}$.

Let $\mathrm{Mod}^0_{\mathcal{C}}(\mathsf{Groth}_{\mathrm{ab}})$ denote the full subcategory of $\mathrm{Mod}_{\mathcal{C}}(\mathsf{Groth}_{\mathrm{ab}})$ spanned by those $\mathcal{C}$-modules $\mathcal{E}$ for which $\rho(\mathcal{E})$ satisfies condition (iii). Using Theorem 10.6.5.1, we see that Theorem 10.6.5.2 is equivalent to the statement that F induces an equivalence of ∞-categories $\mathrm{Mod}_{\mathrm{QCoh}(X)^{\heartsuit}}(\mathsf{Groth}_{\mathrm{ab}}) \to \mathrm{Mod}^0_{\mathcal{C}}(\mathsf{Groth}_{\mathrm{ab}})$. We are therefore reduced to showing that a monoidal functor $\mathcal{C} \to \mathrm{LFun}(\mathcal{E}, \mathcal{E})$ factors through F if and only if the induced action of $\mathrm{Vect}(X)$ on $\mathcal{E}$ satisfies condition (iii), which follows immediately from $(\star)$. □

10.6.6 Comparison with Prestable Quasi-Coherent Stacks

We now study the relationship between abelian and prestable quasi-coherent stacks in greater detail. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ be an arbitrary functor. Then the construction $\mathcal{C} \mapsto \mathcal{C}^{\heartsuit}$ determines a functor $\mathrm{QStk}^{\mathrm{PSt}}(X) \to \mathrm{QStk}^{\mathrm{Ab}}(X)$ (see Construction 10.1.2.8). This functor carries left exact morphisms to left exact morphisms, and therefore restricts to a functor $\mathrm{QStk}^{\mathrm{PSt}}(X)^{\mathrm{lex}} \to \mathrm{QStk}^{\mathrm{Ab}}(X)^{\mathrm{lex}}$; here $\mathrm{QStk}^{\mathrm{PSt}}(X)^{\mathrm{lex}}$ is the subcategory of $\mathrm{QStk}^{\mathrm{PSt}}(X)^{\mathrm{lex}}$ whose morphisms are left exact and $\mathrm{QStk}^{\mathrm{Ab}}(X)^{\mathrm{lex}}$ is defined similarly. We now prove a relative version of Proposition C.5.5.20:

Theorem 10.6.6.1. *Let X be a spectral Deligne-Mumford stack. Then Construction 10.1.2.8 determines a functor*

$$\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{lex}} \to \mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X})^{\mathrm{lex}} \qquad \mathcal{C} \mapsto \mathcal{C}^{\heartsuit}$$

which admits a fully faithful left adjoint $\check{\mathcal{D}}$. The essential image of $\check{\mathcal{D}}$ consists of those prestable quasi-coherent stacks on X which are anticomplete and 0-complicial.

The proof of Theorem 10.6.6.1 will proceed by reduction to the case where X is affine, in which case the desired result is a consequence of the following more general assertion:

Lemma 10.6.6.2. *Let R be a connective $\mathbb{E}_\infty$-ring and let n be a nonnegative integer. Then:*

(a) *Suppose that $\mathcal{A}$ is a Grothendieck abelian $(n+1)$-category (Definition C.5.4.1) equipped with an action of R. Then there exists an R-linear Grothendieck prestable ∞-category $\mathcal{C}$ and an R-linear equivalence $\mathcal{A} \simeq \tau_{\leqslant n}\mathcal{C}$, where $\mathcal{C}$ is anticomplete and n-complicial.*

(b) *Let $\mathcal{C}$ and $\mathcal{D}$ be R-linear Grothendieck prestable ∞-categories, let $\mathrm{LFun}^{\mathrm{lex}}_R(\mathcal{C},\mathcal{D})$ denote the ∞-category of left exact R-linear functors from $\mathcal{C}$ to $\mathcal{D}$, and define the ∞-category $\mathrm{LFun}^{\mathrm{lex}}_R(\tau_{\leqslant n}\mathcal{C},\tau_{\leqslant n}\mathcal{D})$ similarly. If $\mathcal{C}$ is anticomplete and n-complicial, then the restriction map $\mathrm{LFun}^{\mathrm{lex}}_R(\mathcal{C},\mathcal{D}) \to \mathrm{LFun}^{\mathrm{lex}}_R(\tau_{\leqslant n}\mathcal{C},\tau_{\leqslant n}\mathcal{D})$ is an equivalence of ∞-categories.*

Proof. We first prove (a). Let $\mathcal{A}$ be a Grothendieck abelian $(n+1)$-category. Using Proposition C.5.4.5, we deduce that there exists a Grothendieck prestable ∞-category $\mathcal{C}$ which is anticomplete and n-complicial and an equivalence $\mathcal{A} \simeq \tau_{\leqslant n}\mathcal{C}$. It then follows from Proposition C.5.5.19 that the restriction functor $\rho : \mathrm{LFun}^{\mathrm{lex}}(\mathcal{C},\mathcal{C}) \to \mathrm{LFun}^{\mathrm{lex}}(\mathcal{A},\mathcal{A})$ is an equivalence of monoidal ∞-categories. An action of R on $\mathcal{A}$ can be identified with a monoidal functor $\mathrm{Mod}^{\mathrm{ff}}_R \to \mathrm{LFun}^{\mathrm{lex}}(\mathcal{A},\mathcal{A})$ (see Definition D.1.1.1). Composing with a homotopy inverse to ρ, we obtain a compatible action of R on the Grothendieck prestable ∞-category $\mathcal{C}$.

We now prove (b). Let $F : \mathrm{LinCat}^{\mathrm{Add}}_R = \mathrm{Mod}_{\mathrm{Mod}^{\mathrm{cn}}_R}(\mathcal{P}\mathrm{r}^{\mathrm{Add}}) \to \mathcal{P}\mathrm{r}^{\mathrm{Add}}$ be the forgetful functor. Then F admits a right adjoint $G : \mathcal{P}\mathrm{r}^{\mathrm{Add}} \to \mathrm{LinCat}^{\mathrm{Add}}_R$, given by the construction

$$F(\mathcal{C}) = \mathrm{LFun}(\mathrm{Mod}^{\mathrm{cn}}_R, \mathcal{C}) \simeq \mathrm{LMod}_R(\mathcal{C}),$$

where the equivalence is given by Theorem HA.4.8.4.1 . The functor F is conservative (by construction) and preserves small limits (Corollary HA.4.2.3.3). Applying Theorem HA.4.7.3.5 , we see that the adjunction $\mathrm{LinCat}^{\mathrm{Add}}_R \underset{G}{\overset{F}{\rightleftarrows}} \mathcal{P}\mathrm{r}^{\mathrm{Add}}$ is comonadic: that is, it exhibits $\mathrm{LinCat}^{\mathrm{Add}}_R$ as the ∞-category of comodules over the comonad $U = F \circ G : \mathcal{P}\mathrm{r}^{\mathrm{Add}} \to \mathcal{P}\mathrm{r}^{\mathrm{Add}}$. Note that an additive R-linear ∞-category $\mathcal{C}$ is prestable if and only if its image under F is prestable and that an R-linear functor is left exact if and only if its image under F is left exact. Consequently, F and G restrict to a comonadic adjunction

$$\mathrm{LinCat}^{\mathrm{PSt,lex}}_R \underset{G_0}{\overset{F_0}{\rightleftarrows}} \mathsf{Groth}^{\mathrm{lex}}_{\infty}.$$

. In particular, every object $\mathcal{D} \in \mathrm{LinCat}^{\mathrm{PSt,lex}}_R$ can be written as a limit of objects which belong to the essential image of the functor G_0 (see Proposition HA.4.7.3.14). Consequently, to prove (b), we may assume without loss of generality that $\mathcal{D} = G_0(\mathcal{D}_0)$ for some Grothendieck prestable ∞-category $\mathcal{D}_0$. In this case, we are reduced to proving that the restriction map $\mathrm{LFun}^{\mathrm{lex}}(\mathcal{C},\mathcal{D}_0) \to \mathrm{LFun}^{\mathrm{lex}}(\tau_{\leqslant n}\mathcal{C},\tau_{\leqslant n}\mathcal{D}_0)$ is an equivalence of ∞-categories, which follows from Proposition C.5.3.9. □

Proof of Theorem 10.6.6.1. Write $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$. For each object $U \in \mathcal{X}$, let X_U denote the spectral Deligne-Mumford stack $(\mathcal{X}_{/U}, \mathscr{O}_{\mathsf{X}}|_U)$, and let $\mathcal{E}_U$ denote the full subcategory of $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}_U)^{\mathrm{lex}}$ spanned by those prestable quasi-coherent stacks on X_U which are anticomplete and 0-complicial. It follows from Corollary D.5.7.3 that the construction $U \mapsto \mathcal{E}_U$ is (contravariantly) functorial in U. Moreover, for each $U \in \mathcal{X}$, the construction $\mathcal{C} \mapsto \mathcal{C}^{\heartsuit}$ determines a functor $\theta_U : \mathcal{E}_U \to \mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X}_U)^{\mathrm{lex}}$, which also depends functorially on U.

Let $\mathcal{X}_0 \subseteq \mathcal{X}$ be the full subcategory spanned by those objects $U \in \mathcal{X}$ for which the functor θ_U is an equivalence of ∞-categories. Since the condition of being anticomplete and 0-complicial can be tested locally with respect to the étale topology (Corollary D.5.7.3), the construction $U \mapsto \theta_U$ carries colimits in $\mathcal{X}$ to limits in the ∞-category $\mathrm{Fun}(\Delta^1, \widehat{\mathcal{C}\mathrm{at}}_\infty)$. It follows that $\mathcal{X}_0$ is closed under small colimits. Moreover, Lemma 10.6.6.2 shows that θ_U is an equivalence whenever U is affine. Applying Proposition 1.4.7.9, we deduce that $\mathcal{X}_0 = \mathcal{X}$. In particular, $\mathcal{X}_0$ contains a final object $\mathbf{1} \in \mathcal{X}$.

Let $\check{\mathcal{D}} : \mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X})^{\mathrm{lex}} \to \mathcal{E}_{\mathbf{1}} \subseteq \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{lex}}$ be a homotopy inverse to the equivalence $\theta_{\mathbf{1}}$. To complete the proof, it will suffice to show that the identification $\mathrm{id}_{\mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X})^{\mathrm{lex}}} \simeq \check{\mathcal{D}}(\bullet)^{\heartsuit}$ is the unit of an adjunction. In other words, it will suffice to show that for every abelian quasi-coherent stack $\mathcal{A}$ on X and every prestable quasi-coherent stack $\mathcal{C}$ on X, the canonical map

$$\rho : \mathrm{Map}_{\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{lex}}}(\check{\mathcal{D}}(\mathcal{A}), \mathcal{C}) \to \mathrm{Map}_{\mathrm{QStk}^{\mathrm{Ab}}}(\mathsf{X})^{\mathrm{lex}}(\mathcal{A}, \mathcal{C}^{\heartsuit})$$

is a homotopy equivalence. For every object $U \in \mathcal{X}$, we have an analogous map

$$\rho_U : \mathrm{Map}_{\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}_U)^{\mathrm{lex}}}(\check{\mathcal{D}}(\mathcal{A})|_{\mathsf{X}_U}, \mathcal{C}|_{\mathsf{X}_U}) \to \mathrm{Map}_{\mathrm{QStk}^{\mathrm{Ab}}}(\mathsf{X}_U)^{\mathrm{lex}}(\mathcal{A}|_{\mathsf{X}_U}, \mathcal{C}^{\heartsuit}|_{\mathsf{X}_U}).$$

Let $\mathcal{X}_1 \subseteq \mathcal{X}$ be the full subcategory spanned by those objects for which ρ_U is a homotopy equivalence. Since the construction $U \mapsto \rho_U$ carries colimits in $\mathcal{X}$ to limits in the ∞-category $\mathrm{Fun}(\Delta^1, \widehat{\mathcal{S}})$, the full subcategory $\mathcal{X}_1$ is closed under small colimits. Lemma 10.6.6.2 shows that $\mathcal{X}_1$ contains all affine objects of $\mathcal{X}$, so that $\mathcal{X}_1 = \mathcal{X}$ by virtue of Proposition 1.4.7.9. In particular, $\mathcal{X}_1$ contains a final object of $\mathcal{X}$, which shows that ρ is a homotopy equivalence as desired. □

The functor $\mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X})^{\mathrm{lex}} \to \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{lex}}$ can be regarded as a global version of the construction $\mathcal{A} \mapsto \check{\mathcal{D}}(\mathcal{A})$ studied in §C.5.8. We now consider analogous globalizations of the related constructions $\mathcal{A} \mapsto \mathcal{D}(\mathcal{A})$ and $\mathcal{A} \mapsto \widehat{\mathcal{D}}(\mathcal{A})$:

Corollary 10.6.6.3. *Let X be a spectral Deligne-Mumford stack and let $\mathrm{QStk}^{\mathrm{sep}}(\mathsf{X})^{\mathrm{lex}}$ denote the full subcategory of $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{lex}}$ spanned by the separated prestable quasi-coherent stacks on X. Then Construction 10.1.2.8 determines a functor*

$$\mathrm{QStk}^{\mathrm{sep}}(\mathsf{X})^{\mathrm{lex}} \to \mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X})^{\mathrm{lex}} \qquad \mathcal{C} \mapsto \mathcal{C}^{\heartsuit}$$

which admits a fully faithful left adjoint $\mathcal{D}$. The essential image of $\mathcal{D}$ consists of those prestable quasi-coherent stacks on X which are separated and 0-complicial.

Proof. Let $\check{\mathcal{D}} : \mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X})^{\mathrm{lex}} \to \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{lex}}$ be as in Theorem 10.6.6.1. Note that the inclusion $\mathrm{QStk}^{\mathrm{sep}}(\mathsf{X})^{\mathrm{lex}} \hookrightarrow \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{lex}}$ admits a left adjoint, given by the construction $\mathcal{C} \mapsto \mathcal{C}^{\mathrm{sep}}$ of Proposition 10.3.1.11. It follows that the construction

$$(\mathcal{A} \in \mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X})^{\mathrm{lex}}) \mapsto (\check{\mathcal{D}}(\mathcal{A})^{\mathrm{sep}} \in \mathrm{QStk}^{\mathrm{sep}}(\mathsf{X})^{\mathrm{lex}})$$

is a left adjoint to the functor $\mathcal{C} \mapsto \mathcal{C}^{\heartsuit}$. To show that this functor is fully faithful, we must show that for every abelian quasi-coherent stack $\mathcal{A} \in \mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X})^{\mathrm{lex}}$, the composite map

$$\mathcal{A} \xrightarrow{u} \check{\mathcal{D}}(\mathcal{A})^{\heartsuit} \xrightarrow{v} (\check{\mathcal{D}}(\mathcal{A})^{\mathrm{sep}})^{\heartsuit}$$

is an equivalence of abelian quasi-coherent stacks. Here u is the unit map for the adjunction of Theorem 10.6.6.1, which is an equivalence since the functor $\check{\mathcal{D}}$ is fully faithful. The map u' is also an, equivalence because the canonical map $\mathcal{C} \to \mathcal{C}^{\mathrm{sep}}$ induces an equivalence on hearts for any $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$.

Note that if $\mathcal{A}$ is an abelian quasi-coherent stack on X, then the prestable quasi-coherent stack $\check{\mathcal{D}}(\mathcal{A})$ is 0-complicial (Theorem 10.6.6.1), so the separated quotient $\check{\mathcal{D}}(\mathcal{A})^{\mathrm{sep}}$ is separated and 0-complicial (Proposition C.5.3.3). Conversely, suppose that $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{lex}}$ is separated and 0-complicial. Then the counit map $v : \check{\mathcal{D}}(\mathcal{C}^{\heartsuit})^{\mathrm{sep}} \to \mathcal{C}$ is left exact and induces an equivalence on hearts. Since the domain and codomain of v are separated and 0-complicial, it follows from Proposition C.5.4.5 that v is an equivalence, so that $\mathcal{C}$ belongs to the essential image of the functor $\mathcal{A} \mapsto \check{\mathcal{D}}(\mathcal{A})^{\mathrm{sep}}$. □

Corollary 10.6.6.4. *Let X be a spectral Deligne-Mumford stack and let $\mathrm{QStk}^{\mathrm{comp}}(\mathsf{X})^{\mathrm{lex}}$ denote the full subcategory of $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{lex}}$ spanned by the complete prestable quasi-coherent stacks on X. Then Construction 10.1.2.8 determines a functor*

$$\mathrm{QStk}^{\mathrm{comp}}(\mathsf{X})^{\mathrm{lex}} \to \mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X})^{\mathrm{lex}} \qquad \mathcal{C} \mapsto \mathcal{C}^{\heartsuit}$$

which admits a fully faithful left adjoint $\widehat{\mathcal{D}}$. The essential image of $\widehat{\mathcal{D}}$ consists of those prestable quasi-coherent stacks on X which are complete and weakly 0-complicial.

Proof. Let $\check{\mathcal{D}} : \mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X})^{\mathrm{lex}} \to \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{lex}}$ be as in Theorem 10.6.6.1. Note that the inclusion $\mathrm{QStk}^{\mathrm{sep}}(\mathsf{X})^{\mathrm{lex}} \hookrightarrow \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{lex}}$ admits a left adjoint, given by the construction $\mathcal{C} \mapsto \widehat{\mathcal{C}}$ of Proposition 10.3.1.11. Composing these left adjoints, we obtain a functor $\widehat{\mathcal{D}} : \mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X})^{\mathrm{lex}} \to \mathrm{QStk}^{\mathrm{comp}}(\mathsf{X})^{\mathrm{lex}}$ which is left adjoint to the formation of hearts. To show that this functor is fully faithful, we must show that for every abelian quasi-coherent stack $\mathcal{A} \in \mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X})^{\mathrm{lex}}$, the composite map $\mathcal{A} \xrightarrow{u} \check{\mathcal{D}}(\mathcal{A})^{\heartsuit} \xrightarrow{u'} \widehat{\mathcal{D}}(\mathcal{A})^{\heartsuit}$ is an equivalence of abelian quasi-coherent stacks. Here u is the unit map for the adjunction of Theorem 10.6.6.1, which is an equivalence since the functor $\check{\mathcal{D}}$ is fully faithful, and the map u' is evidently an equivalence as well.

Note that if $\mathcal{A}$ is an abelian quasi-coherent stack on X, then the prestable quasi-coherent stack $\check{\mathcal{D}}(\mathcal{A})$ is weakly 0-complicial (Theorem 10.6.6.1), so its completion $\hat{\mathcal{D}}(\mathcal{A})$ is complete and weakly 0-complicial (Remark C.5.5.14). Conversely, suppose that $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{lex}}$ is complete and weakly 0-complicial. Then the counit map $v : \widehat{\mathcal{D}}(\mathcal{C}^{\heartsuit}) \to \mathcal{C}$ is left exact and induces an equivalence on hearts. Since the domain and codomain of v are complete and weakly 0-complicial, it follows from Proposition C.5.9.3 that v is an equivalence, so that $\mathcal{C}$ belongs to the essential image of the functor $\widehat{\mathcal{D}}$. □

Warning 10.6.6.5. The constructions $\check{\mathcal{D}}, \mathcal{D}, \widehat{\mathcal{D}} : \mathrm{QStk}^{\mathrm{Ab}}(\mathsf{X})^{\mathrm{lex}} \to \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})^{\mathrm{lex}}$ of Theorem 10.6.6.1 and Corollaries 10.6.6.3 and 10.6.6.4 are in general not compatible with base change. If $\mathcal{A}$ is an abelian quasi-coherent stack on X and $f : \mathsf{Y} \to \mathsf{X}$ is a morphism of spectral Deligne-Mumford stacks, then we have canonical maps

$$\check{v} : \check{\mathcal{D}}(f^* \mathcal{A}) \to f^* \check{\mathcal{D}}(\mathcal{A}) \qquad v : \mathcal{D}(f^* \mathcal{A}) \to f^* \mathcal{D}(\mathcal{A}) \qquad \hat{v} : \widehat{\mathcal{D}}(f^* \mathcal{A}) \to f^* \widehat{\mathcal{D}}(\mathcal{A}).$$

in $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{Y})^{\mathrm{lex}}$ which induce equivalences after passing to hearts. Using Remark 10.3.4.6, we obtain the following:

- (i) The morphism $\check{v}$ is an equivalence if and only if $f^* \check{\mathcal{D}}(\mathcal{A})$ is anticomplete and 0-complicial. This condition is satisfied whenever f is étale (or, more generally, when f is flat and the diagonal map $\mathsf{Y} \to \mathsf{Y} \times_{\mathsf{X}} \mathsf{Y}$ has finite Tor-amplitude).
- (ii) The morphism v is an equivalence if and only if $f^* \mathcal{D}(\mathcal{A})$ is separated and 0-complicial. This condition is satisfied whenever f is flat.
- (iii) The morphism $\hat{v}$ is an equivalence if and only if $f^* \widehat{\mathcal{D}}(\mathcal{A})$ is complete and and weakly 0-complicial. This condition is satisfied whenever f is flat.

Because the constructions of Theorem 10.6.6.1 and Corollaries 10.6.6.3 and 10.6.6.4 are not stable under arbitrary base change, they do not extend to quasi-coherent stacks on an arbitrary functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$. However, Corollary **??** has an analogue for quasi-geometric stacks:

Corollary 10.6.6.6. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a quasi-geometric stack and let $\mathrm{QStk}^{\mathrm{comp}}(X)^{\mathrm{lex}}$ be defined as in Corollary 10.6.6.4. Then Construction 10.1.2.8 determines a functor*

$$\mathrm{QStk}^{\mathrm{comp}}(X)^{\mathrm{lex}} \to \mathrm{QStk}^{\mathrm{Ab}}(X)^{\mathrm{lex}} \qquad \mathcal{C} \mapsto \mathcal{C}^{\heartsuit}$$

which admits a fully faithful left adjoint $\widehat{\mathcal{D}}$. The essential image of $\widehat{\mathcal{D}}$ consists of those prestable quasi-coherent stacks on X which are complete and weakly 0-complicial.

Proof. We proceed as in the proof of Theorem 10.6.6.1. For every quasi-geometric stack Y, let $\mathrm{QStk}^{(0)}(Y)^{\mathrm{lex}}$ denote the full subcategory of $\mathrm{QStk}^{\mathrm{comp}}(Y)^{\mathrm{lex}}$ spanned by those prestable quasi-coherent stacks on Y which are complete and weakly 0-complicial. Note that the construction $Y \mapsto \mathrm{QStk}^{(0)}(Y)^{\mathrm{lex}}$ is contravariantly functorial for *flat* maps between quasi-geometric stacks (Remark 10.4.6.4).

We first prove that the construction $\mathcal{C} \mapsto \mathcal{C}^{\heartsuit}$ induces an equivalence of ∞-categories $\theta_X : \mathrm{QStk}^{(0)}(X)^{\mathrm{lex}} \to \mathrm{QStk}^{\mathrm{Ab}}(X)^{\mathrm{lex}}$. Choose a faithfully flat $u : X_0 \to X$, where $X_0 \simeq \operatorname{Spec} A$ is affine, and let $X_\bullet$ denote the Čech nerve of u. Then the construction $[n] \mapsto \theta_{X_n}$ determines a cosemisimplicial object of $\mathrm{Fun}(\Delta^1, \widehat{\mathcal{C}\mathrm{at}_\infty})$. Since each X_n is representable by a (quasi-affine) spectral Deligne-Mumford stack, Corollary 10.6.6.4 guarantees that each of the functors θ_{X_n} is an equivalence of ∞-categories. It follows that $\theta_X \simeq \mathrm{Tot}(\theta_{X_\bullet})$ is also an equivalence of ∞-categories. In particular, θ_X admits a homotopy inverse $\widehat{\mathcal{D}} : \mathrm{QStk}^{\mathrm{Ab}}(X)^{\mathrm{lex}} \to \mathrm{QStk}^{(0)}(X)^{\mathrm{lex}} \subseteq \mathrm{QStk}^{\mathrm{comp}}(X)^{\mathrm{lex}}$. To complete the proof, it will suffice to show that the natural map $\mathrm{id}_{\mathrm{QStk}^{\mathrm{Ab}}(X)^{\mathrm{lex}}} \to \widehat{\mathcal{D}}(\bullet)^{\heartsuit}$ is the unit of an adjunction. In other words, it will suffice to show that if $\mathcal{A}$ is an abelian quasi-coherent stack on X and $\mathcal{C}$ is complete prestable quasi-coherent stack on X, then the canonical map

$$\rho : \mathrm{Map}_{\mathrm{QStk}^{\mathrm{PSt}}(X)^{\mathrm{lex}}}(\widehat{\mathcal{D}}(\mathcal{A}), \mathcal{C}) \to \mathrm{Map}_{\mathrm{QStk}^{\mathrm{Ab}}(X)^{\mathrm{lex}}}(\mathcal{A}, \mathcal{C}^{\heartsuit})$$

is a homotopy equivalence. Note that ρ can be realized as the totalization of a map of cosimplicial spaces

$$\rho^\bullet : \mathrm{Map}_{\mathrm{QStk}^{\mathrm{PSt}}(X_\bullet)^{\mathrm{lex}}}(\widehat{\mathcal{D}}(\mathcal{A})|_{X_\bullet}, \mathcal{C}\,|_{X_\bullet}) \to \mathrm{Map}_{\mathrm{QStk}^{\mathrm{Ab}}(X)^{\mathrm{lex}}}(\mathcal{A}\,|_{X_\bullet}, \mathcal{C}^{\heartsuit}\,|_{X_\bullet}).$$

It will therefore suffice to show that each of the maps ρ^n is a homotopy equivalence, which follows from Corollary 10.6.6.4. □

Chapter 11

Smooth and Proper Linear ∞-Categories

Let X be a Noetherian scheme. A theorem of Gabriel ([74]) implies that X can be recovered, up to canonical isomorphism, from the abelian category $\mathrm{Coh}(X)$ of coherent sheaves on X (this result has been extended to non-Noetherian schemes by Rosenberg). In particular, any geometric condition on X can, at least in principle, be reformulated as a condition on the category $\mathrm{Coh}(X)$.

Example 11.0.0.1. Let X be a quasi-projective variety over a field κ. Then X is projective if and only if, for every pair of coherent sheaves $\mathscr{F}, \mathscr{G} \in \mathrm{Coh}(X)$, the vector space $\mathrm{Hom}_{\mathrm{Coh}(X)}(\mathscr{F}, \mathscr{G})$ has finite dimension over κ. The "only if" direction is a fundamental finiteness theorem of Serre. The converse follows from the observation that if X is not projective, then there exists a closed 1-dimensional subvariety $C \subseteq X$ which is not projective, so that the vector space $\mathrm{Hom}_{\mathrm{Coh}(X)}(\mathscr{O}_X, \mathscr{O}_C)$ is isomorphic to the ring of functions on C (and is therefore infinite-dimensional as a vector space over κ).

By a slight abuse of notation, we can regard every scheme X as a spectral algebraic space and consider the stable ∞-category $\mathrm{QCoh}(X)$ introduced in Chapter 2. Let us assume for simplicity that X is quasi-compact and separated, so that $\mathrm{QCoh}(X)$ is the derived category of usual abelian category $\mathrm{QCoh}(X)^{\heartsuit}$ of quasi-coherent sheaves on X (Corollary 10.3.4.13). It follows from Theorem 9.6.0.1 that we can recover X (up to canonical isomorphism) from the ∞-category $\mathrm{QCoh}(X)$, together with its symmetric monoidal structure. However, the symmetric monoidal structure is now essential:

Example 11.0.0.2. Let X be an abelian variety dimension > 0 over a field κ and let $X^{\vee}$ be the dual abelian variety. Then the Fourier-Mukai transform (see [158]) determines an equivalence of ∞-categories $\alpha : \mathrm{QCoh}(X) \simeq \mathrm{QCoh}(X^{\vee})$ which is not induced by an isomorphism of schemes $X \simeq X^{\vee}$ (for example, α is not t-exact).

In general, the existence of an equivalence of stable ∞-categories $\mathrm{QCoh}(X) \simeq \mathrm{QCoh}(Y)$ need not imply that X and Y are isomorphic. However, it *does* imply that X and Y have many common geometric features. For example, if X and Y are quasi-projective varieties over a field κ and there exists a κ-linear equivalence $\mathrm{QCoh}(X) \simeq \mathrm{QCoh}(Y)$, then X is projective if and only if Y is projective. This is a consequence of the following slight variant of Example 11.0.0.1:

Example 11.0.0.3. Let X be a quasi-projective variety over a field κ. Then X is projective if and only if, for every pair of compact objects $\mathscr{F}, \mathscr{G} \in \mathrm{QCoh}(X)$, the mapping object $\underline{\mathrm{Map}}_{\mathrm{QCoh}(X)}(\mathscr{F}, \mathscr{G}) \in \mathrm{Mod}_\kappa$ is perfect (see Notation D.7.1.1).

Example illustrates one of the basic insights of (homological) *non-commutative geometry*: important geometric features of an algebro-geometric object X can be reformulated as conditions on the stable ∞-category $\mathrm{QCoh}(X)$. Such reformulations allow us to apply geometric ideas in the study of stable ∞-categories which do not arise (directly) from algebraic geometry. Though we will not delve deeply into the theory of non-commutative geometry in this book, we devote this chapter to investigating some of the simplest examples of this paradigm.

We begin in §11.1 by introducing the notion of a *proper R-linear ∞-category*, where R is an arbitrary $\mathbb{E}_\infty$-ring (or every $\mathbb{E}_2$-ring; see Definition 11.1.0.1). The definition is motivated by Example 11.0.0.3: we say that $\mathcal{C}$ is proper if it is compactly generated and, for every pair of compact objects $C, D \in \mathcal{C}$, the R-module $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$ is perfect. Our main goal is to establish the following more precise version of Example 11.0.0.3: if R is connective and X is a spectral algebraic space which is quasi-compact, separated, and locally almost of finite presentation over R, then $\mathrm{QCoh}(\mathsf{X})$ is a proper R-linear ∞-category if and only if X is proper and of finite Tor-amplitude over R (Theorem 11.1.4.1).

Another essential notion from classical algebraic geometry is *smoothness*. Recall that a map of schemes $f : X \to Y$ is said to be *smooth* if it is locally of finite presentation and satisfies the "infinitesimal lifting property":

$(*)$ If $\phi : B \to \overline{B}$ is a surjective morphism of commutative rings whose kernel $\ker(\phi)$ is a nilpotent ideal of B, then every lifting problem

$$\begin{array}{ccc} \operatorname{Spec} \overline{B} & \longrightarrow & X \\ \downarrow & \nearrow & \downarrow f \\ \operatorname{Spec} B & \longrightarrow & Y \end{array}$$

admits a solution.

In §11.2, we will study some analogues of condition $(*)$ in the setting of spectral algebraic geometry. Here the situation is more complicated: there are (at least) two useful notions of smooth morphism, depending on whether one requires condition $(*)$ to hold only for homomorphisms ϕ between ordinary commutative rings (and demand that f be flat), or require the analogue of $(*)$ for more general $\mathbb{E}_\infty$-rings (which is generally incompatible with the requirement that f be flat). These notions are equivalent in characteristic zero but otherwise distinct; we will refer to them as *fiber smoothness* and *differential smoothness*, respectively.

Let R be a connective $\mathbb{E}_\infty$-ring and let $q : \mathsf{X} \to \operatorname{Sp\acute{e}t} R$ be a morphism of spectral algebraic spaces. In §11.3, we show that (under some mild additional hypotheses) the condition that q is fiber smooth depends only on the structure of $\mathrm{QCoh}(\mathsf{X})$ as an R-linear ∞-category. More precisely, we introduce the notion of a *smooth R-linear ∞-category* (Definition 11.3.1.1) and show that $\mathrm{QCoh}(\mathsf{X})$ is smooth if and only if q is fiber smooth (Theorem 11.3.6.1).

The hypotheses of smoothness and properness for R-linear ∞-categories are very powerful when used in conjunction with one another. In §11.4, we will show that if X is a quasi-compact, quasi-separated spectral algebraic space over R, then $\mathrm{QCoh}(\mathsf{X})$ is smooth and proper if and only if the structure map $q : \mathsf{X} \to \operatorname{Sp\acute{e}t} R$ is proper and fiber smooth (Theorem 11.4.2.1). In particular, the requirement that $\mathrm{QCoh}(\mathsf{X})$ is smooth and proper guarantees that X is almost of finite presentation over R.

One way to guarantee that a (compactly generated) R-linear ∞-category $\mathcal{C}$ be smooth and proper is to assume that it is *invertible*: that is, that there exists another R-linear ∞-category $\mathcal{C}^{-1}$ such that $\mathcal{C} \otimes_R \mathcal{C}^{-1} \simeq \mathrm{Mod}_R$. The collection of all equivalences classes of (compactly generated) invertible R-linear ∞-categories can be organized into an abelian group $\mathrm{Br}^\dagger(R)$, which we will refer to as the *extended Brauer group* of R. In §11.5, we will investigate the structure of invertible R-linear ∞-categories and the extended Brauer group $\mathrm{Br}^\dagger(R)$. In particular, we will show that every invertible R-linear ∞-category is locally equivalent to Mod_R with respect to the étale topology (Theorem 11.5.5.1) and that $\mathrm{Br}^\dagger(R)$ depends only on the commutative ring $\pi_0 R$ (Proposition 11.5.5.6).

Remark 11.0.0.4. The notions of smooth and proper R-linear ∞-categories were introduced by Kontsevich (at least when R is an ordinary commutative ring), using the language of differential graded categories. They have subsequently been studied by a number of authors: see, for example, [31], [207], [208], [211], [123], [212], and [163]. See also [2] for a discussion in the setting where R is a structured ring spectrum, which has considerable overlap with the material of this chapter.

Contents

11.1 Properness for Linear ∞-Categories and Quasi-Coherent Stacks

Let R be an $\mathbb{E}_2$-ring and let $\mathcal{C}$ be a stable R-linear ∞-category (Definition D.1.4.1). For every pair of objects $C, D \in \mathcal{C}$, we let $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$ denote the R-module of morphisms from

C to D (see Example D.7.1.2), which is characterized by the following universal property: for every left R-module M, we have a canonical homotopy equivalence

$$\mathrm{Map}_{\mathrm{LMod}_R}(M, \underline{\mathrm{Map}}_{\mathcal{C}}(C, D)) \simeq \mathrm{Map}_{\mathcal{C}}(M \otimes_R C, D).$$

Definition 11.1.0.1. Let R be an $\mathbb{E}_2$-ring and let $\mathcal{C}$ be a stable R-linear ∞-category. We will say that $\mathcal{C}$ is *proper* if the following conditions are satisfied:

(1) The ∞-category $\mathcal{C}$ is compactly generated.

(2) For every pair of compact objects $C, D \in \mathcal{C}$, the left R-module $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$ is perfect.

When restricted to R-linear ∞-categories of the form LMod_A for $A \in \mathrm{Alg}_R$, Definition 11.1.0.1 recovers the notion of proper R-algebra studied in §HA.4.6.4 :

Proposition 11.1.0.2. *Let R be an $\mathbb{E}_2$-ring and let A be an $\mathbb{E}_1$-algebra over R. The following conditions are equivalent:*

(1) *The algebra A is perfect when regarded as a left R-module (that is, the object $A \in \mathrm{Alg}_R$ is proper).*

(2) *The stable R-linear ∞-category LMod_A is proper.*

Proof. Let $\mathcal{C} = \mathrm{LMod}_A$. Then we can regard A as a compact object of $\mathcal{C}$, with $\underline{\mathrm{Map}}_{\mathcal{C}}(A, A) \simeq A$. It follows immediately that (2) $\Rightarrow$ (1). Conversely, suppose that (1) is satisfied. We must show that if C and D are compact objects of $\mathcal{C}$, then $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$ is a perfect R-module. If we regard D as fixed, then the collection of those objects $C \in \mathcal{C}$ for which $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$ is perfect is a stable subcategory of $\mathcal{C}$ which is closed under retracts. Consequently, to prove that $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$ is perfect for every compact object $C \in \mathcal{C}$, it will suffice to treat the case $C = A$. Similarly, we may reduce to the case $N = A$, so that $\underline{\mathrm{Map}}_{\mathcal{C}}(M, N) \simeq A$ is perfect provided that condition (1) is satisfied. □

Our goal in this section is to study a relative version of Definition 11.1.0.1. We begin in §11.1.1 by showing that the condition that a stable R-linear ∞-category $\mathcal{C}$ is proper can be tested locally with respect to the étale topology (Proposition 11.1.1.1). Consequently, there is a robust notion of proper quasi-coherent stacks on an arbitrary spectral Deligne-Mumford stack X (Definition 11.1.1.3). Our main objective is to establish the following direct image theorem: if $f : \mathsf{X} \to \mathsf{Y}$ is a morphism which is proper, locally almost of finite presentation, and of finite Tor-amplitude, then the pushforward functor $f_* : \mathrm{QStk}^{\mathrm{St}}(\mathsf{X}) \to \mathrm{QStk}^{\mathrm{St}}(\mathsf{Y})$ carries proper quasi-coherent stacks on X to proper quasi-coherent stacks on Y (Theorem 11.1.4.1).

11.1.1 Proper Quasi-Coherent Stacks

Our next goal is to show collection of proper R-linear ∞-categories is stable under base change and satisfies étale descent.

Proposition 11.1.1.1. *Let R be an $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a stable R-linear ∞-category. Then:*

(1) *If $\mathcal{C}$ is proper as an R-linear ∞-category and $R \to R'$ is an arbitrary morphism of $\mathbb{E}_\infty$-rings, then the tensor product $R' \otimes_R \mathcal{C} = \mathrm{LMod}_{R'}(\mathcal{C})$ is a proper R'-linear ∞-category.*

(2) *Suppose there exists a finite collection of étale morphisms $\{R \to R_\alpha\}$ such that the induced map $R \to \prod_\alpha R_\alpha$ is faithfully flat. If R is connective and each $R_\alpha \otimes_R \mathcal{C}$ is a proper R_α-linear ∞-category, then $\mathcal{C}$ is a proper R-linear ∞-category.*

Remark 11.1.1.2. Proposition 11.1.1.1 remains true (with an essentially identical proof) in the setting of linear ∞-categories over $\mathbb{E}_2$-rings.

Proof of Proposition 11.1.1.1. We first prove (1). If $\mathcal{C}$ is proper, then it is compactly generated and therefore $\mathrm{LMod}_{R'}(\mathcal{C})$ is compactly generated (Example **??**). We must show that for every pair of compact objects $C, D \in \mathrm{LMod}_{R'}(\mathcal{C})$, the R'-module $\underline{\mathrm{Map}}_{\mathrm{LMod}_{R'}(\mathcal{C})}(C, D)$ is perfect. Let us first regard Y as fixed, and let $\mathcal{X} \subseteq \mathrm{LMod}_{R'}(\mathcal{C})$ be the full subcategory spanned by those compact objects X for which $\underline{\mathrm{Map}}_{\mathrm{LMod}_{R'}(\mathcal{C})}(C, D)$ is perfect. Then $\mathcal{X}$ is an idempotent complete, stable subcategory of $\mathrm{LMod}_{R'}(\mathcal{C})$. To show that it contains every compact object of $\mathrm{LMod}_{R'}(\mathcal{C})$, it will suffice to show that it contains every object of the form $R' \otimes_R C_0$, where C_0 is a compact object of $\mathcal{C}$. Let us now regard C_0 as fixed; we wish to show that $\underline{\mathrm{Map}}_{\mathrm{LMod}_{R'}(\mathcal{C})}(R' \otimes_R C_0, D) \simeq \underline{\mathrm{Map}}_{\mathcal{C}}(C_0, D)$ is a perfect R'-module for every compact object $D \in \mathrm{LMod}_{R'}(\mathcal{C})$. Arguing as above, we may suppose that $D \simeq R' \otimes_R D$ for some compact object $D \in \mathcal{C}$. Using the compactness of C_0, we obtain an equivalence of R'-modules $R' \otimes_R \underline{\mathrm{Map}}_{\mathcal{C}}(C_0, D_0) \to \underline{\mathrm{Map}}_{\mathrm{LMod}_{R'}(\mathcal{C})}(C, D)$. It will therefore suffice to show that $\underline{\mathrm{Map}}_{\mathcal{C}}(C_0, D_0)$ is a perfect R-module, which follows from our assumption that $\mathcal{C}$ is proper.

We now prove (2). Assume that R is connective $\mathbb{E}_\infty$-ring and that each $R_\alpha \otimes_R \mathcal{C}$ is a proper R_α-linear ∞-category, for some étale covering $\{R \to R_\alpha\}$. Using Theorem D.5.3.1, we conclude that $\mathcal{C}$ is a compactly generated ∞-category. Fix compact objects $C, D \in \mathcal{C}$. For every index α, the tensor product

$$R_\alpha \otimes_R \underline{\mathrm{Map}}_{\mathcal{C}}(C, D) \simeq \underline{\mathrm{Map}}_{\mathrm{LMod}_{R_\alpha}(\mathcal{C})}(R_\alpha \otimes C, R_\alpha \otimes D)$$

is a perfect module over R_α. Applying Proposition 2.8.4.2, we deduce that $\underline{\mathrm{Map}}_{\mathcal{C}}(C, D)$ is a perfect R-module. $\square$

Proposition 11.1.1.1 asserts that the condition of properness can be tested locally for the étale topology. This motivates the following:

Definition 11.1.1.3. Let X be a spectral Deligne-Mumford stack and let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{St}}(\mathsf{X})$ be an stable quasi-coherent stack on X. We will say that $\mathcal{C}$ is *proper* if, for every connective $\mathbb{E}_\infty$-ring R and every morphism $\eta : \mathrm{Sp\acute{e}t}\, R \to \mathsf{X}$, the stable R-linear ∞-category $\mathcal{C}_\eta$ is proper.

Example 11.1.1.4. Let $\mathsf{X} \simeq \mathrm{Sp\acute{e}t}\, R$ be an affine spectral Deligne-Mumford stack and let $\mathcal{C}$ be a stable quasi-coherent stack on X. Then $\mathcal{C}$ is proper as a quasi-coherent stack on X if and only if it is proper as an R-linear ∞-category: this follows immediately from the first assertion of Proposition 11.1.1.1.

Proposition 11.1.1.1 immediately implies the following:

Proposition 11.1.1.5. *Let X be a spectral Deligne-Mumford stack and let $\mathcal{C}$ be a stable quasi-coherent stack on X. Then:*

(1) *Let $f : \mathsf{Y} \to \mathsf{X}$ be any map of spectral Deligne-Mumford stacks. If $\mathcal{C}$ is proper, then $f^* \mathcal{C} \in \mathrm{QStk}^{\mathrm{St}}(\mathsf{Y})$ is proper.*

(2) *Suppose we are given a collection of étale maps $\{f_\alpha : \mathsf{X}_\alpha \to \mathsf{X}\}$ which induce an étale surjection $\coprod_\alpha \mathsf{X}_\alpha \to \mathsf{X}$. If each pullback $f_\alpha^* \mathcal{C} \in \mathrm{QStk}^{\mathrm{St}}(\mathsf{X}_\alpha)$ is proper, then $\mathcal{C}$ is proper.*

11.1.2 Digression: Perfect Objects with Prescribed Support

Let X be a quasi-separated spectral algebraic space. We say that a closed subset $K \subseteq |\mathsf{X}|$ is *cocompact* if the complementary open set $|\mathsf{X}| - K$ is quasi-compact. According to Proposition 7.1.5.5, the support $\mathrm{Supp}(\mathscr{F}) \subseteq |\mathsf{X}|$ is a cocompact closed set for every perfect object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$. We will need the following converse:

Proposition 11.1.2.1. *Let X be a quasi-compact, quasi-separated spectral algebraic space, and let K be a cocompact closed subset of $|\mathsf{X}|$. Then there exists a perfect object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ such that $K = \mathrm{Supp}(\mathscr{F})$.*

We first treat the case where X is affine.

Lemma 11.1.2.2. *Let A be a connective $\mathbb{E}_\infty$-ring, and let K be a cocompact closed subset of $|\mathrm{Spec}\, A|$. Then there exists a perfect A-module M such that $\mathrm{Supp}(\mathscr{F}) = K$, where $\mathscr{F}$ denotes the image of M under the equivalence of ∞-categories $\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A) \simeq \mathrm{Mod}_A$.*

Proof. Since K is cocompact, we can write K as the vanishing locus of an ideal $I \subseteq \pi_0 A$ generated by finitely many elements $x_1, \ldots, x_n \in \pi_0 A$. We can now take M to be the tensor product of the cofibers of the maps $x_i : A \to A$. □

Proof of Proposition 11.1.2.1. Using Theorem 3.4.2.1, we can choose a scallop decomposition

$$\varnothing = \mathsf{U}_0 \hookrightarrow \cdots \hookrightarrow \mathsf{U}_n = \mathsf{X}.$$

For $0 \leqslant m \leqslant n$, let K_m denote the inverse image of K in $|\,\mathsf{U}_m\,|$. We will prove by induction on m that there exists a perfect object $\mathscr{F}_m \in \mathrm{QCoh}(\mathsf{U}_m)$ with $\mathrm{Supp}(\mathscr{F}_m) = K_m$. The case $m = 0$ is trivial. To carry out the inductive step, suppose that $\mathscr{F}_m$ has been constructed for $m < n$ and choose an excision square

$$\begin{array}{ccc} \mathsf{V} & \xrightarrow{j} & \mathsf{Y} \\ \downarrow{\scriptstyle \phi} & & \downarrow{\scriptstyle \psi} \\ \mathsf{U}_m & \longrightarrow & \mathsf{U}_{m+1} \end{array}$$

where Y is affine and j is a quasi-compact open immersion. Let K' denote the inverse image of K in $|\,\mathsf{Y}\,|$. Using the argument of Theorem **??** (applied to the quasi-coherent stack $\mathcal{Q}_K$), we deduce that there exists an object $\mathscr{G} \in \mathrm{QCoh}_{K'}(\mathsf{Y})$ with $j^* \mathscr{G} \simeq \phi^*(\mathscr{F}_m \oplus \Sigma \mathscr{F}_m)$, so that $\mathscr{G}$ and $\mathscr{F}_m \oplus \Sigma \mathscr{F}_m$ can be glued to obtain a perfect object $\mathscr{F}' \in \mathrm{QCoh}_{K_{m+1}}(\mathsf{U}_{m+1})$ whose support contains K_m. Let $Z = K_{m+1} - K_m$, so that Z is a closed subset of $|\,\mathsf{U}_{m+1}\,|$ which does not intersect $|\,\mathsf{U}_m\,|$. Let Z' denote the inverse image of Z in $|\,\mathsf{Y}\,|$. It follows from descent that the pullback functor ψ^* induces an equivalence of ∞-categories

$$\mathrm{QCoh}_Z(\mathsf{U}_{m+1}) \to \mathrm{QCoh}_{Z'}(\mathsf{Y}).$$

Applying Lemma 11.1.2.2, we deduce the existence of a perfect object $\mathscr{F}'' \in \mathrm{QCoh}_Z(\mathsf{U}_{m+1})$ such that $\mathrm{Supp}(\psi^* \mathscr{F}'') = Z'$. We now complete the proof by setting $\mathscr{F}_{m+1} = \mathscr{F}' \oplus \mathscr{F}''$. □

11.1.3 Properness and Dualizability

Let X be a quasi-compact, quasi-separated spectral algebraic space. Combining Theorem 10.2.0.2 with Proposition D.5.1.1, we deduce that the construction $\mathcal{C} \mapsto \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ induces an equivalence of ∞-categories

$$\mathrm{QCoh}(\mathsf{X}; \bullet) : \mathrm{QStk}^{\mathrm{St}}(\mathsf{X}) \to \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})}(\mathcal{P}\mathrm{r}^{\mathrm{St}});$$

here $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ denotes the ∞-category of presentable stable ∞-categories. Consequently, if $\mathcal{C}$ is a stable quasi-coherent stack on X, then the condition that $\mathcal{C}$ is proper (in the sense of Definition 11.1.1.3) depends only on the ∞-category $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ (as an ∞-category tensored over $\mathrm{QCoh}(\mathsf{X})$). We now make this observation more explicit.

Construction 11.1.3.1. Let X be a quasi-compact, quasi-separated spectral algebraic space, and let $\mathcal{C}$ be a stable quasi-coherent stack on X. Assume that $\mathcal{C}$ is compactly generated.

Then the ∞-category $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ is compactly generated (Theorem 10.3.2.1). Since the ∞-category $\mathrm{QCoh}(\mathsf{X})$ is locally rigid (Proposition 9.6.1.2), it follows that $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ is dualizable as a module over $\mathrm{QCoh}(\mathsf{X})$ (Proposition D.7.5.1 and Proposition HA.4.6.5.11). Let us denote the its dual by ${}^{\vee}\mathrm{QCoh}(\mathsf{X};\mathcal{C})$, so that we have a duality datum

$$e : \mathrm{QCoh}(\mathsf{X};\mathcal{C}) \otimes_{\mathrm{QCoh}(\mathsf{X})} {}^{\vee}\mathrm{QCoh}(\mathsf{X};\mathcal{C}) \to \mathrm{QCoh}(\mathsf{X}).$$

Moreover, if $\lambda : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{Sp}$ denotes the global sections functor, then the composition

$$\mathrm{QCoh}(\mathsf{X};\mathcal{C}) \otimes {}^{\vee}\mathrm{QCoh}(\mathsf{X};\mathcal{C}) \to \mathrm{QCoh}(\mathsf{X};\mathcal{C}) \otimes_{\mathrm{QCoh}(\mathsf{X})} {}^{\vee}\mathrm{QCoh}(\mathsf{X};\mathcal{C}) \xrightarrow{e} \mathrm{QCoh}(\mathsf{X}) \xrightarrow{\lambda} \mathrm{Sp}$$

exhibits ${}^{\vee}\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ as a dual of $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ in the symmetric monoidal ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{St}}$. We may therefore use Proposition D.7.2.3 to identify ${}^{\vee}\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ with the ∞-category $\mathrm{Ind}((\mathrm{QCoh}(\mathsf{X};\mathcal{C})_c^{\mathrm{op}})$, where $\mathrm{QCoh}(\mathsf{X};\mathcal{C})_c$ denotes the full subcategory of $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ spanned by the compact objects.

Unwinding the definitions, we see that e restricts to a functor

$$\underline{\mathrm{Map}}_{\mathcal{C}} : \mathrm{QCoh}(\mathsf{X};\mathcal{C})_c^{\mathrm{op}} \times \mathrm{QCoh}(\mathsf{X};\mathcal{C}) \to \mathrm{QCoh}(\mathsf{X}),$$

$$(\mathscr{F},\mathscr{G}) \mapsto \underline{\mathrm{Map}}_{\mathcal{C}}(\mathscr{F},\mathscr{G}),$$

which is characterized by the universal property

$$\mathrm{Map}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{E},\underline{\mathrm{Map}}_{\mathcal{C}}(\mathscr{F},\mathscr{G})) \simeq \mathrm{Map}_{\mathrm{QCoh}(\mathsf{X};\mathcal{C})}(\mathscr{E}\otimes\mathscr{F},\mathscr{G}).$$

Remark 11.1.3.2. Let X be a quasi-compact, quasi-separated spectral algebraic space and let $\mathcal{C}$ be a stable quasi-coherent stack on X. Assume that $\mathcal{C}$ is compactly generated and let ${}^{\vee}\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ be as in Construction 11.1.3.1. Since the functor $\mathrm{QCoh}(\mathsf{X};\bullet) : \mathrm{QStk}^{\mathrm{St}}(\mathsf{X}) \to \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})}(\mathcal{P}\mathrm{r}^{\mathrm{St}})$ is a symmetric monoidal equivalence, we can write ${}^{\vee}\mathrm{QCoh}(\mathsf{X};\mathcal{C}) \simeq \mathrm{QCoh}(\mathsf{X};{}^{\vee}\mathcal{C})$, where ${}^{\vee}\mathcal{C}$ is a dual of $\mathcal{C}$ in the symmetric monoidal ∞-category $\mathrm{QStk}^{\mathrm{St}}(\mathsf{X})$.

Proposition 11.1.3.3. *Let X be a quasi-compact, quasi-separated spectral algebraic space and let $\mathcal{C}$ be a stable quasi-coherent stack on X. Assume that $\mathcal{C}$ is compactly generated, so that $\mathcal{C}$ admits a dual ${}^{\vee}\mathcal{C}$ in $\mathrm{QStk}^{\mathrm{St}}(\mathsf{X})$. The following conditions are equivalent:*

(a) *The stable quasi-coherent stack $\mathcal{C}$ is proper (in the sense of Definition 11.1.1.3).*

(b) *The evaluation map $e : \mathcal{C}\otimes{}^{\vee}\mathcal{C} \to \mathcal{Q}_{\mathsf{X}}$ is compact (in the sense of Definition 10.1.3.1).*

(c) *The evaluation map $e' : \mathrm{QCoh}(\mathsf{X};\mathcal{C}) \otimes_{\mathrm{QCoh}(\mathsf{X})} {}^{\vee}\mathrm{QCoh}(\mathsf{X};\mathcal{C}) \to \mathrm{QCoh}(\mathsf{X})$ is compact (in the sense of Definition C.3.4.2).*

(d) *For every pair of compact objects $\mathscr{F},\mathscr{G} \in \mathrm{QCoh}(\mathsf{X};\mathcal{C})$, the object $\underline{\mathrm{Map}}_{\mathcal{C}}(\mathscr{F},\mathscr{G})$ (see Construction 11.1.3.1) is perfect.*

Proof. The equivalence of (b) and (c) follows from Proposition 10.3.1.14, and the equivalence of (b) and (c) follows from the observation that the ∞-category of compact objects of $\mathrm{QCoh}(\mathsf{X};\mathcal{C})\otimes_{\mathrm{QCoh}(\mathsf{X})}{}^{\vee}\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ is generated (under finite colimits and retracts) by objects of the form $\mathscr{F}\otimes\mathscr{G}$, where $\mathscr{F}\in\mathrm{QCoh}(\mathsf{X};\mathcal{C})_c$ and $\mathscr{G}\in\mathrm{QCoh}(\mathsf{X};\mathcal{C})_c^{\mathrm{op}}$ (see Construction 11.1.3.1). To prove the equivalence of (a) and (b), we can work locally on X and thereby reduce to the case where $\mathsf{X}=\mathrm{Sp\acute{e}t}\,R$ is affine. In this case, the desired result reduces to the equivalence $(b)\Leftrightarrow(d)$. □

Remark 11.1.3.4. The equivalence $(a)\Leftrightarrow(b)$ of Proposition 11.1.3.3 is valid for *any* spectral Deligne-Mumford stack X.

11.1.4 Direct Images of Proper Quasi-Coherent Stacks

We now consider the relationship between properness of quasi-coherent stacks and proper morphisms between spectral algebraic spaces.

Theorem 11.1.4.1. *Let $f:\mathsf{X}\to\mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Assume that f is quasi-compact, separated, and locally almost of finite presentation. Then the following conditions are equivalent:*

(1) *The map f is proper and locally of* Tor*-amplitude $\leqslant n$, for some integer n.*

(2) *For every proper object $\mathcal{C}\in\mathrm{QStk}^{\mathrm{St}}(\mathsf{X})$, the pushforward $f_*\,\mathcal{C}$ is also proper.*

(3) *The pushforward $f_*\,\mathcal{Q}_{\mathsf{X}}\in\mathrm{QStk}^{\mathrm{St}}(\mathsf{Y})$ is proper (here $\mathcal{Q}_{\mathsf{X}}$ denotes the unit object of $\mathrm{QStk}^{\mathrm{St}}(\mathsf{X})$).*

In the situation of Theorem 11.1.4.1, the implication $(2)\Rightarrow(3)$ is immediate, and the implication $(1)\Rightarrow(3)$ is a reformulation of Theorem 6.1.3.2. The remaining implications are consequences of the following three results:

Proposition 11.1.4.2. *Let R be a connective $\mathbb{E}_\infty$-ring, let X be a spectral algebraic space which is proper, locally almost of finite presentation, and of finite* Tor*-amplitude over R. If $\mathcal{C}\in\mathrm{QStk}^{\mathrm{St}}(\mathsf{X})$ is a proper quasi-coherent stack on X, then $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ is a proper R-linear ∞-category.*

Proposition 11.1.4.3. *Let R be a connective $\mathbb{E}_\infty$-ring, let X be a quasi-compact separated spectral algebraic space which is locally almost of finite presentation over R, and suppose that $\mathrm{QCoh}(\mathsf{X})$ is a proper R-linear ∞-category. Then X is proper over R.*

Proposition 11.1.4.4. *Let R be a connective $\mathbb{E}_\infty$-ring, let X be a quasi-compact, quasi-separated spectral algebraic space which is locally almost of finite presentation over R, and suppose that $\mathrm{QCoh}(\mathsf{X})$ is a proper R-linear ∞-category. Then X has* Tor*-amplitude $\leqslant n$ over R, for some $n\geqslant 0$.*

Proof of Proposition 11.1.4.2. Let X be a spectral algebraic space which is proper, locally almost of finite presentation, and locally of Tor-amplitude $\leqslant n$ over a connective $\mathbb{E}_\infty$-ring R, and let $\mathcal{C}$ be a proper quasi-coherent stack on X. It follows from Theorem 10.3.2.1 that $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is a compactly generated R-linear ∞-category, and Proposition 10.3.2.6 implies that an object of $\mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ is compact if and only if it is locally compact. It will therefore suffice to prove that if $\mathscr{F}, \mathscr{G} \in \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$ are locally compact, then the R-module $\underline{\mathrm{Map}}_{\mathrm{QCoh}(\mathsf{X};\mathcal{C})}(\mathscr{F}, \mathscr{G}) \in \mathrm{Mod}_R$ is perfect. Unwinding the definitions, we see that $\underline{\mathrm{Map}}_{\mathrm{QCoh}(\mathsf{X};\mathcal{C})}(\mathscr{F}, \mathscr{G})$ can be identified with the R-module of global sections of the quasi-coherent sheaf $\underline{\mathrm{Map}}_{\mathcal{C}}(\mathscr{F}, \mathscr{G}) \in \mathrm{QCoh}(\mathsf{X})$ described in Construction 11.1.3.1. The assumption that $\mathcal{C}$ is proper guarantees that $\underline{\mathrm{Map}}_{\mathcal{C}}(\mathscr{F}, \mathscr{G})$ is a perfect object of $\mathrm{QCoh}(\mathsf{X})$, so that the desired result reduces to Theorem 6.1.3.2. □

The proof of Proposition 11.1.4.3 will require some preliminaries.

Lemma 11.1.4.5. *Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ be a spectral Deligne-Mumford stack, let $\mathscr{A}$ be an algebra object of $\mathrm{QCoh}(\mathsf{X})$, and let $A = \Gamma(\mathcal{X}; \mathscr{A}) \in \mathrm{Alg}$ denote the $\mathbb{E}_1$-algebra of global sections of $\mathscr{A}$. Then $\mathscr{A} \simeq 0$ if and only if $A \simeq 0$.*

Proof. The "only if" direction is obvious. The converse follows from the observation that $\mathscr{A}$ is a sheaf of A-module spectra on $\mathcal{X}$, which automatically vanishes if $A \simeq 0$. □

Lemma 11.1.4.6. *Let R be a connective $\mathbb{E}_\infty$-ring, let X be a spectral algebraic space over R which is quasi-compact and quasi-separated, and assume that the R-linear ∞-category $\mathrm{QCoh}(\mathsf{X})$ is proper. Then the map of topological spaces $\phi : |\mathsf{X}| \to |\operatorname{Spec} R|$ is closed.*

Proof. Let K be a closed subset of $|\mathsf{X}|$; we wish to show that $\phi(K) \subseteq |\operatorname{Spec} R|$ is closed. Let $U = |\mathsf{X}| - K$, and write U as a union of quasi-compact open subsets U_α. For each index α, let U_α be the corresponding open substack of X. Since X is quasi-separated, each of the maps $\mathsf{U}_\alpha \to \mathsf{X}$ is quasi-compact, so that the closed sets $K_\alpha = |\mathsf{X}| - U_\alpha$ are cocompact. Since the fibers of ϕ are quasi-compact topological spaces, we have $\phi(K) = \bigcap_\alpha \phi(K_\alpha)$. It will therefore suffice to show that each $\phi(K_\alpha)$ is a closed subset of $|\operatorname{Spec} R|$. Replacing K by K_α, we may reduce to the case where K is cocompact, so that $K = \mathrm{Supp}(\mathscr{F})$ for some perfect object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ (Proposition 11.1.2.1). Replacing $\mathscr{F}$ by $\mathrm{End}(\mathscr{F})$ if necessary, we may suppose that $\mathscr{F}$ is an algebra object of $\mathrm{QCoh}(\mathsf{X})$ (Corollary 7.1.5.6). Let $A \in \mathrm{Alg}(\mathrm{Mod}_R)$ denote the R-module of global sections of $\mathscr{F}$. Since $\mathrm{QCoh}(\mathsf{X})$ is proper, the algebra $A = \underline{\mathrm{Map}}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{O}, \mathscr{F})$ is a perfect R-module. We will complete the proof by showing that $\phi(K) = \mathrm{Supp}(A)$ (where we abuse notation by identifying A with the corresponding quasi-coherent sheaf on $\operatorname{Spét} R$). Equivalently, we show that for any field κ and any map of $\mathbb{E}_\infty$-rings $R \to \kappa$, the tensor product $\kappa \otimes_R A$ vanishes if and only if the pullback of $\mathscr{F}$ to $\mathsf{X}_0 = \operatorname{Spét} \kappa \times_{\operatorname{Spét} R} \mathsf{X}$ vanishes. Replacing R by κ and X by X_0, we deduce the desired result from Lemma 11.1.4.5. □

Proof of Proposition 11.1.4.3. Let X be a spectral algebraic space which is separated and locally almost finite presentation over a connective $\mathbb{E}_\infty$-ring R, and suppose that $\mathrm{QCoh}(\mathsf{X})$ is a proper R-linear ∞-category. We wish to prove that X is proper over R. Equivalently, we must show that every pullback diagram

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow \\ \mathrm{Sp\acute{e}t}\, R' & \longrightarrow & \mathrm{Sp\acute{e}t}\, R, \end{array}$$

induces a closed map of topological spaces $|\mathsf{X}'| \to |\mathrm{Spec}\, R'|$. This follows from Lemma 11.1.4.6, since $\mathrm{QCoh}(\mathsf{X}') \simeq \mathrm{Mod}_{R'}(\mathrm{QCoh}(\mathsf{X}))$ is a proper R'-linear ∞-category (Proposition 11.1.1.1). □

We now turn to the proof of Proposition 11.1.4.4.

Lemma 11.1.4.7. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of quasi-compact, quasi-separated spectral algebraic spaces. Suppose that the pushforward functor f_* carries $\mathrm{QCoh}(\mathsf{X})^{\mathrm{perf}}$ into $\mathrm{QCoh}(\mathsf{Y})^{\mathrm{perf}}$, and let $f_+ : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{Y})$ be as in Proposition 6.4.5.4. Then there exists an integer n such that f_+ carries $\mathrm{QCoh}(\mathsf{X})_{\geqslant 0}$ into $\mathrm{QCoh}(\mathsf{Y})_{\geqslant -n}$.*

Proof. Choose a perfect object $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})$ satisfying the requirements of Proposition 9.6.3.1. Then $f_+ \mathscr{F}$ is a perfect object of $\mathrm{QCoh}(\mathsf{Y})$. Since Y is quasi-compact, there exists an integer n such that $f_+ \mathscr{F} \in \mathrm{QCoh}(\mathsf{Y})_{\geqslant -n}$. The collection of those objects $\mathscr{G} \in \mathrm{QCoh}(\mathsf{X})$ such that $f_+ \mathscr{G} \in \mathrm{QCoh}(\mathsf{Y})_{\geqslant -n}$ contains $\mathscr{F}$ and is closed under colimits and extensions, and therefore contains $\mathrm{QCoh}(\mathsf{X})_{\geqslant 0}$. □

Lemma 11.1.4.8. *Let R be a connective $\mathbb{E}_\infty$-ring, let X be a quasi-compact, quasi-separated spectral algebraic space over R, and suppose that $\mathrm{QCoh}(\mathsf{X})$ is a proper R-linear ∞-category. Then there exists an integer c with the following property:*

- $(*)$ *Let $\phi : R \to R'$ be a map of connective $\mathbb{E}_\infty$-rings, let $\mathsf{X}' = \mathrm{Sp\acute{e}t}\, R' \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X}$, and let $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X}')$ be perfect. If $\mathscr{F}$ has* Tor*-amplitude $\leqslant n$, then the R'-module $\Gamma(\mathsf{X}'; \mathscr{F})$ has* Tor*-amplitude $\leqslant n + c$.*

Proof. According to Lemma **??**, there exists an integer n such that the functor f_+ : $\mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, R) \simeq \mathrm{Mod}_R$ carries $\mathrm{QCoh}(\mathsf{X})_{\geqslant 0}$ into $(\mathrm{Mod}_R)_{\geqslant -c}$. We claim that c has the desired property. For any map of connective $\mathbb{E}_\infty$-rings $R \to R'$, form a pullback diagram

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{X}') & \xrightarrow{g'} & \mathrm{QCoh}(\mathsf{X}) \\ \downarrow{\scriptstyle f'} & & \downarrow \\ \mathrm{Sp\acute{e}t}\, R' & \longrightarrow & \mathrm{Sp\acute{e}t}\, R. \end{array}$$

The map g' is affine, so that g'_* is right t-exact. It follows that the composite functor $f_+ \circ g'_*$ carries $\mathrm{QCoh}(\mathsf{X}')_{\geqslant 0}$ into $(\mathrm{Mod}_R)_{\geqslant -c}$. Using Remark 6.4.5.7, we deduce that $g_* f'_+$ carries $\mathrm{QCoh}(\mathsf{X}')_{\geqslant 0}$ into $(\mathrm{Mod}_R)_{\geqslant -c}$, so that f'_+ carries $\mathrm{QCoh}(\mathsf{X}')_{\geqslant 0}$ into $(\mathrm{Mod}_{R'})_{\geqslant -c}$. If $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X}')$ is perfect of Tor-amplitude $\leqslant n$, then $\mathscr{F}^\vee \in \mathrm{QCoh}(\mathsf{X}')_{\geqslant -n}$, so that $(f_+ \mathscr{F}^\vee) \simeq (f_* \mathscr{F})^\vee \in (\mathrm{Mod}_{R'})_{\geqslant -n-c}$, and therefore $f_* \mathscr{F}$ has Tor-amplitude $\leqslant n + c$. □

Proof of Proposition 11.1.4.4. Let R be a connective $\mathbb{E}_\infty$-ring, let X be a quasi-compact, quasi-separated spectral algebraic space which is locally almost of finite presentation over R, and assume that $\mathrm{QCoh}(\mathsf{X})$ is proper as an R-linear ∞-category. We wish to prove that X has finite Tor-amplitude over R. Since X is quasi-compact, we can choose an étale surjection $\mathrm{Spét}\, A \to \mathsf{X}$. Our assumption that X is locally almost of finite presentation over R guarantees that $\pi_0 A$ is finitely generated as a commutative algebra over $\pi_0 R$. Choose a finite collection of elements $x_1, \ldots, x_d \in \pi_0 A$ which generate $\pi_0 A$ as an algebra over $\pi_0 R$, and choose an integer c satisfying condition $(*)$ of Lemma 11.1.4.8. We will prove that X has Tor-amplitude $\leqslant c + d$ over R. By virtue of Corollary 6.1.4.8, it will suffice to show that for every field κ and every map $R \to \kappa$, the fiber product $\mathrm{Spét}\, \kappa \times_{\mathrm{Spét}\, R} \mathsf{X}$ is $(c + d)$-truncated. Replacing R by κ, we may suppose that R is a field.

Using Theorem 3.4.2.1, we can choose a scallop decomposition

$$\varnothing = \mathsf{U}_0 \hookrightarrow \mathsf{U}_1 \hookrightarrow \cdots \hookrightarrow \mathsf{U}_n = \mathsf{X}$$

of X. We will prove that each U_i is $(c + d)$-truncated, using induction on i. The case $i = 0$ is trivial. To carry out the inductive step, assume that $1 \leqslant i \leqslant n$ and that U_{i-1} is $(c + d)$-truncated; we wish to show that U_i is $(c + d)$-truncated. Choose an excision square σ :

$$\begin{array}{ccc} \mathsf{V} & \xrightarrow{f} & \mathrm{Spét}\, B \\ \downarrow & & \downarrow u \\ \mathsf{U}_{i-1} & \longrightarrow & \mathsf{U}_i . \end{array}$$

The map f is an open immersion whose image is an open subset $V \subseteq |\mathrm{Spec}\, B|$. Since U_{i-1} and $\mathrm{Spét}\, B$ constitute an étale covering of U_i, it will suffice to show that B is $(c + d)$-truncated. Fix $k > c + d$; we will show that $\pi_k B \simeq 0$. For this, it will suffice to show that the localization $\pi_k B_{\mathfrak{m}} \simeq 0$, for every maximal ideal $\mathfrak{m} \subseteq \pi_0 B$. Without loss of generality, we may assume that $\mathfrak{m} \in |\mathrm{Spec}\, B|$ does not belong to V (otherwise, the desired result follows from our inductive hypothesis).

Our choice of c guarantees that the commutative ring $\pi_0 B$ has Krull dimension at most c, so we can choose a sequence of elements $y_1, \ldots, y_d$ belonging to the maximal ideal of $\pi_0 B_{\mathfrak{m}}$, having the property that $(\pi_0 B_{\mathfrak{m}})/(y_1, \ldots, y_d)$ is a finite-dimensional vector space over κ. For $1 \leqslant i \leqslant d$, let M_i denote the $B_{\mathfrak{m}}$-module given by the cofiber of the map $y_i : B_{\mathfrak{m}} \to B_{\mathfrak{m}}$, and let M denote the tensor product $\bigotimes_{1 \leqslant i \leqslant d} M_i$ (formed in the ∞-category $\mathrm{Mod}_{B_{\mathfrak{m}}}$). Then M is a perfect $B_{\mathfrak{m}}$-module, which has Tor-amplitude $\leqslant d$ over $B_{\mathfrak{m}}$. Moreover, M is supported at the closed point of $|\operatorname{Spec} B_{\mathfrak{m}}|$, so that each homotopy group $\pi_i M$ is finite-dimensional as a vector space over κ. It follows that M is almost perfect as a B-module (Proposition HA.7.2.4.17). Since $B_{\mathfrak{m}}$ is flat over B, M has Tor-amplitude $\leqslant c$ as a B-module (Lemma 6.1.1.6). It follows that M is perfect as a B-module (Proposition HA.7.2.4.23). By construction, the support of M (as a B-module) is contained in the closed subset $\overline{K} = |\operatorname{Spec} B| - V$.

Let K be the closed subset of $|\mathsf{U}_i|$ complementary to the open immersion $\mathsf{U}_{i-1} \hookrightarrow \mathsf{U}_i$. Since σ is an excision square, the adjoint functors

$$\operatorname{QCoh}_K(\mathsf{U}_i) \underset{u_*}{\overset{u^*}{\rightleftarrows}} \operatorname{QCoh}_{\overline{K}}(\operatorname{Sp\acute{e}t} B)$$

are mutually inverse equivalence of ∞-categories. In particular, we can write M as the image of some sheaf $\mathscr{F}_i \in \operatorname{QCoh}_K(\mathsf{U}_i)$ under the composite functor

$$\operatorname{QCoh}_K(\mathsf{U}_i) \xrightarrow{u^*} \operatorname{QCoh}_{\overline{K}}(\operatorname{Sp\acute{e}t} B) \subseteq \operatorname{QCoh}(\operatorname{Sp\acute{e}t} B) \simeq \operatorname{Mod}_B .$$

For $j \geqslant i$, let $\mathscr{F}_j$ denote the direct image of $\mathscr{F}_i$ under the open immersion $\mathsf{U}_i \to \mathsf{U}_j$. We will prove by induction on j that each $\mathscr{F}_j$ is a perfect object of $\operatorname{QCoh}(\mathsf{U}_j)$ of Tor-amplitude $\leqslant d$. In the case $j = i$, we observe that $\operatorname{Sp\acute{e}t} B$ and U_{i-1} comprise an étale cover of U_i. Since $\mathscr{F}|_{\mathsf{U}_i} \simeq 0$, it suffices to show that $u^* \mathscr{F}$ is a perfect object of Tor-amplitude $\leqslant c$, which follows from our construction. To carry out the inductive step, suppose that $i < j \leqslant n$, and that $\mathscr{F}_{j-1}$ is perfect of Tor-amplitude $\leqslant d$. We have an excision square τ :

$$\begin{array}{ccc} \mathsf{V}' & \xrightarrow{g'} & \operatorname{Sp\acute{e}t} C \\ \downarrow{\scriptstyle v'} & & \downarrow{\scriptstyle v} \\ \mathsf{U}_{j-1} & \xrightarrow{g} & \mathsf{U}_j . \end{array}$$

To prove that $\mathscr{F}_j \simeq g_* \mathscr{F}_{j-1}$ is perfect of Tor-amplitude $\leqslant d$, it will suffice to show that $g^* g_* \mathscr{F}_{j-1} \simeq \mathscr{F}_{j-1}$ and $v^* g_* \mathscr{F}_{j-1} \simeq g'_* v'^* \mathscr{F}_{j-1}$ are perfect of Tor-amplitude $\leqslant d$. In the former case, this follows from the inductive hypothesis. To handle the latter case, let $Y \subseteq |\mathsf{V}'|$ be the support of $v'^* \mathscr{F}_{j-1}$, and let $\overline{Y}$ denote the closure of Y in $|\operatorname{Spec} C|$. Then $g'_* v'^* \mathscr{F}_{j-1}$ vanishes on the complement of $\overline{Y}$ and is perfect of Tor-amplitude $\leqslant d$ on V'. We are therefore reduced to proving that V' contains $\overline{Y}$: that is, that Y is closed in $|\operatorname{Spec} C|$. Form a pullback diagram

$$\begin{array}{ccc} \mathsf{Y} & \xrightarrow{h'} & \mathsf{V}' \\ \downarrow{\scriptstyle v''} & & \downarrow{\scriptstyle v'} \\ \operatorname{Sp\acute{e}t} B & \xrightarrow{h} & \mathsf{U}_{j-1} \end{array} .$$

Then

$$v'^* \mathscr{F}_{j-1} \simeq v'^* h_* u^* \mathscr{F}_i \simeq h'_* v''^* u^* \mathscr{F}_i .$$

Since $u^* \mathscr{F}_i$ is supported on the set $\{\mathfrak{m}\} \subseteq |\operatorname{Spec} B|$, $v'^* \mathscr{F}_{j-1}$ is supported on the closure of $v''(h'^{-1}\{\mathfrak{m}\})$. However, v'' is a quasi-compact étale map, so $h^{-1}\{\mathfrak{m}\}$ consists of finitely many points whose residue fields are finite extensions of κ. It follows that Y consists of finitely many points of $|\mathsf{V}'|$, whose residue fields are finite extensions of κ, and therefore Y is a closed subset of $|\operatorname{Spec} C|$. This completes the proof the proof that each $\mathscr{F}_j$ is perfect of Tor-amplitude $\leqslant d$. In particular, $\mathscr{F}_n \in \operatorname{QCoh}(\mathsf{X})$ is perfect of Tor-amplitude $\leqslant d$. It follows that $M \simeq \Gamma(\mathsf{X}; \mathscr{F})$ has Tor-amplitude $\leqslant c + d$ as a module over κ. In particular, we have $\pi_k M \simeq 0$.

For $1 \leqslant a \leqslant d$, let $M(a)$ denote the tensor product $\bigotimes_{1 \leqslant i \leqslant a} M_i$ (formed in the ∞-category $\operatorname{Mod}_{B_{\mathfrak{m}}}$. We then have fiber sequences

$$M(a) \xrightarrow{y_{a+1}} M(a) \to M(a+1),$$

hence short exact sequences

$$\pi_k M(a) \overset{y_{a+1}}{\to} \pi_k M(a) \to \pi_k M(a+1).$$

Since $\pi_k M(d) \simeq 0$, it follows by descending induction on a (using Nakayama's lemma) that $\pi_k M(a) \simeq 0$ for all a. Taking $a = 0$, we deduce that $\pi_k B_{\mathfrak{m}} \simeq 0$, as desired. □

11.1.5 Serre Functors and Relative Dualizing Sheaves

Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks which is proper, locally almost of finite presentation, and locally of finite Tor-amplitude. Theorem **??** implies that the direct image $f_* \mathcal{Q}_{\mathsf{X}}$ is a proper quasi-coherent stack on Y. In this section, we show that the relative dualizing sheaf $\omega_{\mathsf{X}/\mathsf{Y}}$ of Definition 6.4.2.4 admits a categorical interpretation: it controls the *Serre functor* of the quasi-coherent stack $f_* \mathcal{Q}_{\mathsf{X}}$ (see Construction 11.1.5.1 below). To simplify the exposition, we will assume throughout this section that the spectral Deligne-Mumford stack Y is affine (though all constructions we consider can be globalized).

Construction 11.1.5.1 (The Serre Functor)**.** Let A be an $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a proper A-linear ∞-category. In particular, $\mathcal{C}$ is compactly generated and is therefore dualizable as an object of $\operatorname{LinCat}^{\operatorname{St}}_A$. Choose an A-linear functor $e : \mathcal{C} \otimes_A \mathcal{C}^\vee \to \operatorname{Mod}_A$ which exhibits $\mathcal{C}^\vee$ as a dual of $\mathcal{C}$ in the symmetric monoidal ∞-category $\operatorname{LinCat}^{\operatorname{St}}_A$. Let $e^R : \operatorname{Mod}_A \to \mathcal{C} \otimes_A \mathcal{C}^\vee$ be a right adjoint of e. Our assumption that $\mathcal{C}$ is proper guarantees that the functor e preserves compact objects (Proposition 11.1.3.3), so that the functor e^R commutes with filtered colimits (Proposition HTT.5.5.7.2). Applying Remark D.1.5.3, we can regard e^R as an A-linear functor from Mod_A to $\mathcal{C} \otimes_A \mathcal{C}^\vee$, which we can identify with an A-linear functor

$S_{\mathcal{C}} : \mathcal{C} \to \mathcal{C}$. We will refer to $S_{\mathcal{C}}$ as the *Serre functor of* $\mathcal{C}$; it can be described as the composition

$$\mathcal{C} \simeq \mathrm{Mod}_A \otimes_A \mathcal{C} \xrightarrow{e^R \otimes \mathrm{id}} \mathcal{C} \otimes_A \mathcal{C}^\vee \otimes_A \mathcal{C} \xrightarrow{\mathrm{id} \otimes e} \mathcal{C} \otimes_A \mathrm{Mod}_A \simeq \mathcal{C}.$$

Remark 11.1.5.2. In the situation of Construction 11.1.5.1, the Serre functor $S_{\mathcal{C}}$ has the following property: for every pair of compact objects $C, D \in \mathcal{C}$, there is a canonical equivalence of A-modules $\underline{\mathrm{Map}}_{\mathcal{C}}(C, S_{\mathcal{C}}(D)) \simeq \underline{\mathrm{Map}}_{\mathcal{C}}(D, C)^\vee$. Note that this description *essentially* characterizes the functor $S_{\mathcal{C}}$ (if we ignore issues of A-linearity), by virtue of our assumption that $\mathcal{C}$ is compactly generated.

We now specialize Construction 11.1.5.1 to the geometric setting:

Proposition 11.1.5.3. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral algebraic spaces which is proper, locally almost of finite presentation, and locally of finite* Tor*-amplitude. Assume that* $\mathsf{Y} = \mathrm{Sp\acute{e}t}\, A$*, so that* $\mathrm{QCoh}(\mathsf{X})$ *is a proper A-linear ∞-category (Proposition 11.1.4.2), and let* $S : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{X})$ *be its Serre functor (Construction 11.1.5.1). Then S is given by the construction $\mathscr{F} \mapsto \mathscr{F} \otimes \omega_{\mathsf{X}/\mathsf{Y}}$, where $\omega_{\mathsf{X}/\mathsf{Y}}$ denotes the relative dualizing sheaf of f (Definition 6.4.2.4).*

Remark 11.1.5.4. Combining Remark 11.1.5.2 with Proposition 11.1.5.3, we see that for $\mathscr{F}, \mathscr{G} \in \mathrm{QCoh}(\mathsf{Y})^{\mathrm{perf}}$, we have a canonical equivalence of A-modules

$$\underline{\mathrm{Map}}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{F}, \mathscr{G} \otimes \omega_{\mathsf{X}/\mathsf{Y}}) \simeq \underline{\mathrm{Map}}_{\mathrm{QCoh}(\mathsf{X})}(\mathscr{G}, \mathscr{F})^\vee.$$

In the special case where $\mathscr{G} = \mathscr{O}_{\mathsf{X}}$, this reduces to Serre-Grothendieck duality (which, in the present setting, is essentially immediate from our definition of $\omega_{\mathsf{X}/\mathsf{Y}}$). The terminology of Construction 11.1.5.1 is motivated by this observation: for a general proper A-linear ∞-category $\mathcal{C}$, the functor $S_{\mathcal{C}}$ controls the "twist" which needs to be added for $\mathcal{C}$ to enjoy some analogue of Serre-Grothendieck duality.

Proof of Proposition 11.1.5.3. Note that the A-linear ∞-category $\mathrm{QCoh}(\mathsf{X})$ is canonically self-dual via the evaluation map $e : \mathrm{QCoh}(\mathsf{X}) \otimes_A \mathrm{QCoh}(\mathsf{X}) \to \mathrm{Mod}_A$ given by the composition

$$\mathrm{QCoh}(\mathsf{X}) \otimes_A \mathrm{QCoh}(\mathsf{X}) \xrightarrow{\otimes} \mathrm{QCoh}(\mathsf{X}) \xrightarrow{\Gamma(\mathsf{X}; \bullet)} \mathrm{Mod}_A.$$

For each $n \geqslant 0$, let $\mathsf{X}^{(n)}$ denote the n-fold fiber power of X over Y. In what follows, we will use Corollary 9.4.3.8 to identify $\mathrm{QCoh}(\mathsf{X}^{(n)})$ with the n-fold tensor power of $\mathrm{QCoh}(\mathsf{X})$ in the ∞-category $\mathrm{LinCat}_A^{\mathrm{St}}$. Under this identification, the evaluation functor e corresponds to the composition $\mathrm{QCoh}(\mathsf{X}^{(2)}) \xrightarrow{\delta^*} \mathrm{QCoh}(\mathsf{X}) \xrightarrow{f_*} \mathrm{QCoh}(\mathsf{Y})$, where $\delta : \mathsf{X} \to \mathsf{X}^{(2)}$ denotes the diagonal map. It follows that the right adjoint e^R is given by the composition $\mathrm{QCoh}(\mathsf{Y}) \xrightarrow{f^!}$

$\mathrm{QCoh}(\mathsf{X}) \xrightarrow{\delta_*} \mathrm{QCoh}(\mathsf{X}^{(2)})$. Let $\pi : \mathsf{X}^{(2)} \to \mathsf{X}$ denote the projection onto the second factor, so that we have a commutative diagram of stable A-linear ∞-categories

$$\begin{array}{ccccccccc} & & & & \mathrm{QCoh}(\mathsf{X}) & & & & \\ & & & \nearrow^{\delta^*} & & \searrow^{\delta_*} & & & \\ & & \mathrm{QCoh}(\mathsf{X}^{(2)}) & & & & \mathrm{QCoh}(\mathsf{X}^{(2)}) & & \\ & \nearrow^{\pi^!} & & \searrow^{(\mathrm{id}\times\delta)_*} & & \nearrow^{(\delta\times\mathrm{id})^*} & & \searrow^{\pi_*} & \\ \mathrm{QCoh}(\mathsf{X}) & & & & \mathrm{QCoh}(\mathsf{X}^{(3)}) & & & & \mathrm{QCoh}(\mathsf{X}). \end{array}$$

Unwinding the definitions, we see that the Serre functor $S_{\mathrm{QCoh}(\mathsf{X})} = (\mathrm{id} \otimes e) \circ (e^R \otimes \mathrm{id})$ can be described as the composition of the four lower arrows in this diagram. Using the commutativity of the diagram (and the observation that $\pi_* \circ \delta_* \simeq (\pi \circ \delta)_*$ is equivalent to the identity functor), we see that the Serre functor $S_{\mathrm{QCoh}(\mathsf{X})}$ can be identified with the composition $\delta^* \circ \pi^!$, which is given by $\mathscr{F} \mapsto \mathscr{F} \otimes \omega_{\mathsf{X}/\mathsf{Y}}$ by virtue of Corollary 6.4.2.7 and Remark 6.4.2.6. $\square$

11.2 Smooth Morphisms in Spectral Algebraic Geometry

Let $f : X \to Y$ be a morphism of schemes. Recall that f is said to be *smooth* if it is locally of finite presentation and satisfies the following additional condition:

$(*)$ If $\phi : B \to \overline{B}$ is a surjective morphism of commutative rings whose kernel $\ker(\phi)$ is a nilpotent ideal of B, then every lifting problem

$$\begin{array}{ccc} \operatorname{Spec} \overline{B} & \longrightarrow & X \\ \downarrow & \nearrow & \downarrow f \\ \operatorname{Spec} B & \longrightarrow & Y \end{array}$$

admits a solution.

Suppose that we wish to consider an analogous theory of smoothness in the setting of spectral algebraic geometry. We first ask: in the formulation of condition $(*)$, what is a reasonable analogue of the hypothesis that $\ker(\phi)$ is nilpotent, if we allow ϕ to be a morphism of $\mathbb{E}_\infty$-rings? Motivated by the philosophy that the spectrum of a connective $\mathbb{E}_\infty$-ring B should be regarded as a infinitesimal enlargement the ordinary scheme $\operatorname{Spec} \pi_0 B$, let us say that a map of connective $\mathbb{E}_\infty$-rings $B \to \overline{B}$ is a *nilpotent thickening* if it induces a surjection $\pi_0 B \to \pi_0 \overline{B}$ whose whose kernel is a nilpotent ideal of $\pi_0 B$. We might then demand that the lifting criterion $(*)$ is satisfied whenever $\phi : B \to \overline{B}$ is an infinitesimal thickening of

$\mathbb{E}_\infty$-rings. This leads to the notion of a *differentially smooth* morphism $f : \mathsf{X} \to \mathsf{Y}$ between spectral Deligne-Mumford stacks.

A fundamental feature of classical algebraic geometry is that any morphism of schemes $f : X \to Y$ which is of finite presentation and satisfies condition $(*)$ is automatically flat (see Proposition 11.2.4.1 below). In the setting of spectral algebraic geometry, the analogous statement is false: a differentially smooth morphism of spectral Deligne-Mumford stacks $f : \mathsf{X} \to \mathsf{Y}$ is usually not flat. For example, if R is a commutative ring and $R\{x\}$ denotes the free $\mathbb{E}_\infty$-algebra over R on one generator, then the induced map $\operatorname{Spét} R\{x\} \to \operatorname{Spét} R$ is differentially smooth, but is flat only if $\pi_0 R$ is an algebra over the field $\mathbf{Q}$ of rational numbers.

If $f : \mathsf{X} \to \mathsf{Y}$ is a flat morphism of spectral Deligne-Mumford stacks, then it is generally not reasonable to exact that f satisfies the lifting criterion $(*)$ for an arbitrary infinitesimal thickening $B \to \overline{B}$ (unless f is étale or we work in characteristic zero). However, there is a large class of flat morphisms which satisfy $(*)$ in the special case where B and $\overline{B}$ are discrete, which we will refer to as *fiber smooth* morphisms.

Our goal in this section is to introduce the notions of differential smoothness and fiber smoothness and to describe their relationships to one another (and to smoothness in classical algebraic geometry). We will focus our attention primarily on the affine case, postponing global definitions until §11.2.5 (see Definition 11.2.5.5).

11.2.1 Formally Smooth Morphisms of $\mathbb{E}_\infty$-Rings

Our first step is to formulate an infinitesimal lifting criterion in the setting of spectral algebraic geometry.

Definition 11.2.1.1. Let $f : R \to A$ be a map of connective $\mathbb{E}_\infty$-rings. We will say that f is *formally smooth* if the following condition is satisfied: for every morphism $B \to \overline{B}$ in $\mathrm{CAlg}^{\mathrm{cn}}_R$, if the underlying map $\pi_0 B \to \pi_0 \overline{B}$ is a surjection whose kernel is a nilpotent ideal of $\pi_0 B$, the induced map

$$\mathrm{Map}_{\mathrm{CAlg}_R}(A, B) \to \mathrm{Map}_{\mathrm{CAlg}_R}(A, \overline{B})$$

is surjective on connected components.

Formal smoothness can be characterized in terms of the cotangent complex:

Proposition 11.2.1.2. *Let $\phi : R \to A$ be a morphism of connective $\mathbb{E}_\infty$-algebras. The following conditions are equivalent:*

(1) *The morphism ϕ is formally smooth, in the sense of Definition 11.2.1.1.*

(2) *The relative cotangent complex $L_{A/R}$ is a projective A-module (Definition HA.7.2.2.4).*

Proof. Assume first that ϕ is formally smooth; we wish to show that $L_{A/R}$ is projective. By virtue of Proposition HA.7.2.2.6 , it will suffice to show that for every cofiber sequence $N' \to N \to N''$ of connective A-modules, the induced map $\theta : \mathrm{Map}_{\mathrm{Mod}_A}(L_{A/R}, N) \to \mathrm{Map}_{\mathrm{Mod}_A}(L_{A/R}, N'')$ is surjective on connected components: in other words, we wish to show that the homotopy fibers of θ are nonempty. Fix a map $L_{A/k} \to N''$, corresponding to a section of s the projection map $A \oplus N'' \to A$. Invoking the definition of $L_{A/R}$, we see that the homotopy fiber of θ over s can be identified with the homotopy fiber of the map

$$\theta' : \mathrm{Map}_{\mathrm{CAlg}_R}(A, A \oplus N) \to \mathrm{Map}_{\mathrm{CAlg}_R}(A, A \oplus N'').$$

Since the map $A \oplus N \to A \oplus N''$ induces a surjection $\pi_0(A \oplus N) \to \pi_0(A \oplus N'')$ with nilpotent kernel, the homotopy fibers of θ' are nonempty by virtue of (1).

Now suppose that $L_{A/R}$ is projective. We wish to prove that ϕ is formally smooth. Let $B \to \overline{B}$ be a map of connective $\mathbb{E}_\infty$-algebras over R which induces a surjection $\pi_0 B \to \pi_0 \overline{B}$ having nilpotent kernel, and let $\eta \in \mathrm{Map}_{\mathrm{CAlg}_R}(A, \overline{B})$; we wish to show that η can be lifted to a point of $\mathrm{Map}_{\mathrm{CAlg}_R}(A, B)$. We define a tower of B-algebras

$$\ldots \to B(2) \to B(1) \to B(0) = \overline{B}$$

by induction as follows. Assume that $B(i)$ has been constructed, set $M(i) = L_{B(i)/B}$, and let $d : B(i) \to B(i) \oplus M(i)$ be the tautological map. By construction, we have a commutative diagram

$$\begin{array}{ccc} B & \longrightarrow & B(i) \\ \downarrow & & \downarrow {\scriptstyle d_0} \\ B(i) & \xrightarrow{d} & B(i) \oplus M(i); \end{array}$$

here d_0 corresponds to the trivial derivation. We now define $B(i+1)$ to be the fiber product $B(i) \times_{B(i) \oplus M(i)} B(i)$.

Let $I \subseteq \pi_0 B$ be the kernel of the surjection $\pi_0 B \to \pi_0 \overline{B}$. We first claim:

($*$) For every integer $n \geqslant 0$, the algebra $B(n)$ is connective. Moreover, the map $\pi_0 B \to \pi_0 B(n)$ is a surjection, whose kernel is the ideal I^{2^n}.

The proof of ($*$) proceeds by induction on n. Assume that ($*$) holds for $B(n)$, and let K denote the fiber of the map $B \to B(n)$. Condition ($*$) guarantees that K is connective, and that the image of the map $\pi_0 K \to \pi_0 B$ is the ideal $J = I^{2^n}$. We have a map of fiber sequences

$$\begin{array}{ccccc} K & \longrightarrow & B & \longrightarrow & B(n) \\ \downarrow & & \downarrow & & \downarrow \\ \Sigma^{-1} M(n) & \longrightarrow & B(n+1) & \longrightarrow & B(n), \end{array}$$

so the fiber K' of the map $B \to B(n+1)$ can be identified with the fiber of the composition

$$K \xrightarrow{\beta} K \otimes_B B(n) \xrightarrow{\alpha} \Sigma^{-1} M(n).$$

To prove $(*)$, it will suffice to show that K' is connective and the image of the map $\pi_0 K' \to \pi_0 B$ is J^2. We have a fiber sequence $\mathrm{fib}(\beta) \to K' \to \mathrm{fib}(\alpha)$. Since K is connective, Theorem HA.7.4.3.1 guarantees that $\mathrm{fib}(\alpha)$ is 1-connective. It follows that the maps $\pi_i \mathrm{fib}(\beta) \to \pi_i K'$ are surjective for $i \leqslant 0$. To complete the proof, it will therefore suffice to show that $\mathrm{fib}(\beta)$ is connective and the map $\pi_0 \mathrm{fib}(\beta) \to \pi_0 B$ has image J^2. This follows from the observation that $\mathrm{fib}(\beta) \simeq K \times_B K$, so that $\pi_0 \mathrm{fib}(\beta) \simeq \mathrm{Tor}_0^{\pi_0 B}(\pi_0 K, \pi_0 K)$. Under this identification, the map $\pi_0 \mathrm{fib}(\beta) \to \pi_0 B$ corresponds to the bilinear multiplication map

$$\pi_0 K \times \pi_0 K \to J \times J \to \pi_0 B,$$

whose image generates the ideal $J^2 \subseteq \pi_0 B$. This completes the proof of $(*)$.

Choose any map of R-algebras $A \to B(n)$. Since $L_{A/R}$ is projective, the mapping space $\mathrm{Map}_{\mathrm{Mod}_A}(L_{A/R}, M(n))$ is connected. It follows that the homotopy fibers of the projection map

$$\mathrm{Map}_{\mathrm{CAlg}_R}(A, B(n) \oplus M(n)) \to \mathrm{Map}_{\mathrm{CAlg}_R}(A, B(n))$$

are connected. Consequently, for any derivation $d : B(n) \to B(n) \oplus M(n)$, the homotopy fibers of the induced map

$$\mathrm{Map}_{\mathrm{CAlg}_R}(A, B(n)) \to \mathrm{Map}_{\mathrm{CAlg}_R}(A, B(n) \oplus M(n))$$

are nonempty. It follows that the map $\mathrm{Map}_{\mathrm{CAlg}_R}(A, B(n+1)) \to \mathrm{Map}_{\mathrm{CAlg}_R}(A, B(n))$ also has nonempty homotopy fibers. Consequently, to prove that a point $\eta \in \mathrm{Map}_{\mathrm{CAlg}_R}(A, \overline{B}) = \mathrm{Map}_{\mathrm{CAlg}_R}(A, B(0))$ can be lifted to $\mathrm{Map}_{\mathrm{CAlg}_R}(A, B)$, we are free to replace $\overline{B}$ by $B(n)$, for any integer $n \geqslant 0$. Since I is nilpotent, condition $(*)$ implies that $\pi_0 B \simeq \pi_0 B(n)$ for $n \gg 0$. We may therefore reduce to the case where $\pi_0 \overline{B} = \pi_0 B$.

We now return to our analysis of the tower

$$\ldots \to B(2) \to B(1) \to B(0)$$

defined above, and prove the following strengthening of $(*)$:

$(*')$ For $n \geqslant 0$, the fiber of the map $B \to B(n)$ is 2^n-connective.

The proof of $(*')$ proceeds by induction on n, the case $n = 0$ being obvious. Assume therefore that $B \to B(n)$ is 2^n-connective, and let K and K' be as in the proof of $(*)$. We wish to prove that K' is 2^{n+1}-connective. As before, we have a fiber sequence

$$\mathrm{fib}(\alpha) \to K' \to \mathrm{fib}(\beta).$$

Here $\mathrm{fib}(\beta) \simeq K \otimes_B K$, and is therefore 2^{n+1}-connective since K is 2^n-connective by the inductive hypothesis. The map α is $(2^{n+1}+1)$-connective by Theorem HA.7.4.3.1 .

As before, each of the maps $\mathrm{Map}_{\mathrm{CAlg}_R}(A, B(n+1)) \to \mathrm{Map}_{\mathrm{CAlg}_R}(A, B(n))$ is surjective on connected components, so we can lift η to a point of $\varprojlim \mathrm{Map}_{\mathrm{CAlg}_R}(A, B(n)) \simeq \mathrm{Map}_{\mathrm{CAlg}_R}(A, \varprojlim B(n))$. To complete, the proof, it suffices to show that the canonical map $B \to \varprojlim B(n)$ is an equivalence. This follows from $(*')$, since the ∞-category $\mathrm{CAlg}_R^{\mathrm{cn}}$ is Postnikov complete (in the sense of Definition A.7.2.1; see Proposition HA.7.1.3.19). □

11.2.2 Differentially Smooth Morphisms of $\mathbb{E}_\infty$-Rings

We now combine Definition 11.2.1.1 with a mild finiteness condition.

Proposition 11.2.2.1. *Let $\phi : R \to A$ be a map of connective $\mathbb{E}_\infty$-rings, and suppose that ϕ exhibits $\pi_0 A$ as a finitely presented commutative algebra over $\pi_0 R$. The following conditions are equivalent:*

(1) *The map ϕ is formally smooth.*

(2) *The relative cotangent complex $L_{A/R}$ is a projective A-module.*

(3) *The relative cotangent complex $L_{A/R}$ is a projective A-module of finite rank.*

(4) *There exist elements $a_1, \ldots, a_n \in \pi_0 A$ which generate the unit ideal of $\pi_0 A$ and a collection of étale maps $R\{x_1, \ldots, x_{m_i}\} \to A[a_i^{-1}]$.*

Here $R\{x_1, \ldots, x_k\} = \mathrm{Sym}_R^*(R^k)$ denotes the free $\mathbb{E}_\infty$-algebra over R on k generators.

Proof. The equivalence (1) ⇔ (2) follows from Proposition 11.2.1.2, the implication (3) ⇒ (2) is obvious, and the implication (2) ⇒ (3) follows from the observation that $\pi_0 L_{A/R}$ is the module of Kähler differentials of $\pi_0 A$ over $\pi_0 R$ (Proposition HA.7.4.3.9) and therefore finitely presented over $\pi_0 A$.

We will complete the proof by showing that (4) ⇔ (3). Assume first that (4) is satisfied. The condition that $L_{A/R}$ is a projective A-module of finite rank is local with respect to the étale topology on A (see Proposition 2.8.4.2); we may therefore assume that $A = R\{x_1, \ldots, x_m\}$ for some integer m, in which case the result is obvious.

Now suppose that (3) is satisfied; we will prove (4). Suppose that the module $\pi_0 L_{A/R}$ is projective and of finite rank over $\pi_0 A$. Then there exist elements $a_1, \ldots, a_n$ generating the unit ideal in $\pi_0 A$ such that each of the modules $(\pi_0 L_{A/R})[a_i^{-1}]$ is a free module of some rank m_i over $(\pi_0 A)[a_i^{-1}]$. Replacing A by $A[a_i^{-1}]$, we may suppose that $\pi_0 L_{A/R}$ is a free module of some rank $m \geqslant 0$. Proposition HA.7.4.3.9 allows us to identify $\pi_0 L_{A/R}$ with the module of Kähler differentials of $\pi_0 A$ over $\pi_0 R$. In particular, $\pi_0 L_{A/R}$ is generated (as an A-module) by finitely many differentials $\{dx_p\}_{1 \leqslant p \leqslant q}$. The identification $\pi_0 L_{A/k} \simeq (\pi_0 A)^m$ allows us to view the differentials $\{dx_q\}_{1 \leqslant p \leqslant q}$ as an m-by-q matrix M. Let $\{b_j\}$ be the collection of all determinants of m-by-m square submatrices appearing in M. Since the elements $\{dx_p\}_{1 \leqslant p \leqslant q}$ generate $(\pi_0 A)^m$, the matrix M has rank m so that the elements b_j generate the unit ideal in A. It therefore suffices to prove that (4) is satisfied by each of the algebras $A[b_j^{-1}]$. We may therefore assume (after discarding some of the elements x_i) that $q = m$ and that $\pi_0 L_{A/R}$ is freely generated by the elements dx_i. The choice of elements $x_1, \ldots, x_m \in \pi_0 A$ determines a map $R\{x_1, \ldots, x_m\} \to A$. The fiber sequence

$$A \otimes_{R\{x_1,\ldots,x_n\}} L_{R\{x_1,\ldots,x_m\}/R} \to L_{A/R} \to L_{A/R\{x_1,\ldots,x_m\}}$$

shows that the relative cotangent complex $L_{A/R\{x_1,\ldots,x_m\}}$ vanishes. It follows from Lemma B.1.3.3 that A is étale over $R\{x_1, \ldots, x_m\}$. □

Definition 11.2.2.2. Let $\phi : R \to A$ be a map of connective $\mathbb{E}_\infty$-rings. We will say that ϕ is *differentially smooth* if it satisfies the equivalent conditions of Proposition 11.2.2.1. That is, ϕ is differentially smooth if it is formally smooth and the commutative ring $\pi_0 A$ is finitely presented as an algebra over $\pi_0 R$.

Remark 11.2.2.3. Let $\phi : R \to A$ be a differentially smooth morphism of connective $\mathbb{E}_\infty$-rings. Then ϕ is locally of finite presentation: that is, ϕ exhibits A as a compact object of CAlg_R. This follows immediately from characterization (4) of Proposition 11.2.2.1.

Conversely, suppose that ϕ is almost of finite presentation. Then ϕ is differentially smooth if and only if $L_{A/R}$ is a flat A-module (Proposition HA.7.2.4.20).

Remark 11.2.2.4. Suppose we are given a pushout diagram of connective $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc} R & \longrightarrow & R' \\ \downarrow{\scriptstyle \phi} & & \downarrow{\scriptstyle \phi'} \\ A & \longrightarrow & A'. \end{array}$$

If ϕ is differentially smooth, then ϕ' is differentially smooth.

Example 11.2.2.5. Any étale morphism of connective $\mathbb{E}_\infty$-rings is differentially smooth.

Differential smoothness can be tested fiberwise:

Proposition 11.2.2.6. *Let $\phi : R \to A$ be a morphism of connective $\mathbb{E}_\infty$-rings, and suppose that ϕ is almost of finite presentation. Then ϕ is differentially smooth if and only if, for every field κ and every morphism $R \to \kappa$, the tensor product $\kappa \otimes_R A$ is differentially smooth over κ.*

Lemma 11.2.2.7. *Let A be a connective $\mathbb{E}_\infty$-ring, and let M be an A-module which is connective and almost perfect. The following conditions are equivalent:*

(a) *The module M is projective of finite rank.*

(b) *For every field κ and every morphism $A \to \kappa$, the tensor product $\kappa \otimes_A M$ is discrete.*

Proof. It is clear that $(a) \Rightarrow (b)$. Conversely, suppose that (b) is satisfied. To prove that M is projective of finite rank, it will suffice to show that M is flat (Proposition HA.7.2.4.20). That is, we must show that if N is a discrete A-module, then $M \otimes_A N$ is also discrete. For this, it suffices to show that the localization $(M \otimes_A N)_{\mathfrak{p}}$ is discrete, for each prime ideal $\mathfrak{p} \subseteq A$. Replacing A by the localization $A_{\mathfrak{p}}$, we may assume that A is local. Let κ denote the residue field of A, and choose a collection of elements $x_1, \ldots, x_n \in M$ whose images form a basis for $\pi_0(\kappa \otimes_A M)$. These elements determine a map of A-modules $f : A^n \to M$. By construction, f induces a map $\kappa^n \to \kappa \otimes_A M$ which is an isomorphism on π_0, and therefore a homotopy equivalence (since condition (b) implies that $\pi_i(\kappa \otimes_A M) \simeq 0$ for $i \neq 0$). Let $K = \mathrm{fib}(f)$. We claim that $K \simeq 0$, so that f is an equivalence and therefore $M \simeq A^n$ is projective. Assume otherwise. Then, since K is almost perfect, there exists a smallest integer d such that $\pi_d K \neq 0$. In this case, Nakayama's lemma implies that $\pi_d(\kappa \otimes_A K) \simeq \mathrm{Tor}_0^{\pi_0 A}(\kappa, \pi_d K) \neq 0$ and we obtain a contradiction. □

Proof of Proposition 11.2.2.6. Since A is almost of finite presentation over R, the relative cotangent complex $L_{A/R}$ is connective and almost perfect (Theorem HA.7.4.3.18). Consequently, to prove that $L_{A/R}$ is a projective A-module of finite rank, it will suffice to show that $\kappa \otimes_A L_{A/R}$ is discrete, for every field κ and every map $A \to \kappa$. Replacing A by $\kappa \otimes_R A$, we can reduce to the case where R is a field, in which case the desired result follows from our assumption that $\kappa \otimes_R A$ is differentially smooth over κ. □

Corollary 11.2.2.8. *Let $\phi : R \to A$ be a morphism of connective $\mathbb{E}_\infty$-rings. Then ϕ is differentially smooth if and only if the induced map $\phi_0 : \pi_0 R \to (\pi_0 R) \otimes_R A$ is differentially smooth.*

Proof. The "only if" direction is clear. Conversely, suppose that ϕ_0 is differentially smooth. Then ϕ_0 is almost of finite presentation, so that ϕ is almost of finite presentation (Proposition 4.1.3.4). The desired result now follows immediately from Proposition 11.2.2.6. □

Proposition 11.2.2.9. *Let $\phi : A \to B$ and $\psi : B \to C$ be morphisms of connective $\mathbb{E}_\infty$-rings. If ϕ and ψ are formally smooth (differentially smooth), then $\psi \circ \phi$ is also formally smooth (differentially smooth).*

Proof. Suppose first that ϕ and ψ are formally smooth. Using Proposition 11.2.1.2, we deduce that $L_{C/B}$ and $C \otimes_B L_{B/A}$ are projective C-modules. It follows that the fiber sequence

$$C \otimes_B L_{B/A} \to L_{C/A} \to L_{C/B}$$

splits, so that $L_{C/A} \simeq L_{C/B} \oplus (C \otimes_B L_{B/A})$ is also a projective C-module, and therefore $\psi \circ \phi$ is formally smooth (Proposition 11.2.1.2). If, in addition, ϕ and ψ are differentially smooth, then ϕ and ψ are almost of finite presentation, so that $\psi \circ \phi$ is also almost finite presentation and therefore differentially smooth. □

11.2.3 Fiber Smooth Morphisms of $\mathbb{E}_\infty$-Rings

From the perspective of classical algebraic geometry, the notion of differential smoothness (Definition 11.2.2.2) suffers from two (closely related) defects:

(*a*) A differentially smooth morphism of $\mathbb{E}_\infty$-rings need not be flat.

(*b*) A morphism of commutative rings which is smooth (in the sense of classical commutative algebra) need not be differentially smooth (when regarded as a morphism of $\mathbb{E}_\infty$-rings).

We now consider a different notion of smoothness, which does not suffer from either of these problems.

Definition 11.2.3.1. Let $f : A \to B$ be a map of connective $\mathbb{E}_\infty$-rings. We will say that f is *fiber smooth* if the following conditions are satisfied:

(1) The morphism f is flat.

(2) The morphism f is almost of finite presentation.

(3) For every field κ and every morphism $B \to \kappa$, the vector space $\pi_1(\kappa \otimes_B L_{B/A})$ vanishes.

Example 11.2.3.2. Let $f : A \to B$ be an étale morphism between connective $\mathbb{E}_\infty$-rings. Then f is fiber smooth.

Remark 11.2.3.3. Let $f : A \to B$ be a morphism of $\mathbb{E}_\infty$-rings which is faithfully flat and almost of finite presentation. Then f is a universal descent morphism (this follows from Proposition D.3.3.1, since $\pi_0 B$ is countably presented as a module over $\pi_0 A$). In particular, if f is faithfully flat and fiber smooth, then f is a universal descent morphism.

We now establish some basic formal properties of fiber smoothness.

Proposition 11.2.3.4. (1) *Let $f : A \to B$ and $g : B \to C$ be morphisms of connective $\mathbb{E}_\infty$-rings. If f and g are fiber smooth, then $g \circ f$ is fiber smooth.*

(2) *Suppose we are given a pushout diagram of $\mathbb{E}_\infty$-rings*

$$\begin{array}{ccc} A & \longrightarrow & A' \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f'} \\ B & \longrightarrow & B'. \end{array}$$

If f is fiber smooth, then f' is fiber smooth.

Proof. Assertion (2) follows immediately from the definitions. We will prove (1). Suppose that $f : A \to B$ and $g : B \to C$ are fiber smooth. It is clear that $g \circ f$ is almost of finite presentation and flat. Using the fiber sequence

$$C \otimes_B L_{B/A} \to L_{C/A} \to L_{C/B},$$

we deduce that for every field κ and every map $C \to \kappa$ there is an exact sequence

$$\pi_1(\kappa \otimes_B L_{B/A}) \to \pi_1(\kappa \otimes_C L_{C/A}) \to \pi_1(\kappa \otimes_C L_{C/B}),$$

from which we deduce that $\pi_1(\kappa \otimes_C L_{C/A}) \simeq 0$. □

Remark 11.2.3.5. Let $f : R \to A$ be a map of connective $\mathbb{E}_\infty$-rings, and form a pushout diagram

$$\begin{array}{ccc} R & \longrightarrow & \pi_0 R \\ \downarrow f & & \downarrow f' \\ A & \longrightarrow & \pi_0 R \otimes_R A. \end{array}$$

Then f is fiber smooth if and only if f' is fiber smooth. The "only if" direction follows from Proposition 11.2.3.4, and the converse follows from Remarks 6.1.2.6 and Corollary 4.1.3.5.

We first show that fiber smoothness can be interpreted as a regularity condition on the (geometric) fibers of a morphism.

Proposition 11.2.3.6. *Let $f : R \to A$ be a map of connective $\mathbb{E}_\infty$-rings which is almost of finite presentation. Then the following conditions are equivalent:*

(1) *The morphism f is fiber smooth.*

(2) *For every algebraically closed field κ and every map $R \to \kappa$, the tensor product $\kappa \otimes_R A$ is discrete, and is regular when regarded as a commutative ring.*

Corollary 11.2.3.7. *Every fiber smooth morphism of connective $\mathbb{E}_\infty$-rings is geometrically reduced (see Definition 8.6.2.4).*

Remark 11.2.3.8. Let $f : R \to A$ be a morphism of connective $\mathbb{E}_\infty$-rings which is almost of finite presentation. It follows from Proposition **??** that f is fiber smooth if and only if, for every residue field κ of A, the induced map $\kappa \to \kappa \otimes_A B$ is fiber smooth.

Lemma 11.2.3.9. *Let R be a local Noetherian commutative ring with residue field κ. The following conditions are equivalent:*

(a) *The local ring R is regular. That is, the maximal ideal $\mathfrak{m} \subseteq R$ is generated by a regular sequence $x_1, \ldots, x_n \in \mathfrak{m}$.*

(b) *The vector space* $\pi_2 L_{\kappa/R}$ *vanishes.*

Proof. Choose a sequence of elements $x_1, \ldots, x_n \in \mathfrak{m}$ which form a basis for $\mathfrak{m}/\mathfrak{m}^2$ as a vector space over κ. Let $R[X_1, \ldots, X_n]$ be a polynomial ring over R on n variables, and define $\phi_0, \phi : R[X_1, \ldots, X_n] \to R$ by the formulas

$$\phi(X_i) = x_i \qquad \phi_0(X_i) = 0.$$

Form a pushout diagram

$$\begin{array}{ccc} R[X_1, \ldots, X_n] & \xrightarrow{\phi} & R \\ \downarrow{\scriptstyle \phi_0} & & \downarrow \\ R & \longrightarrow & A \end{array}$$

in the ∞-category CAlg_R, so that we have a canonical $A \to \kappa$ which induces an isomorphism $\pi_0 A \simeq \kappa$.

Let $B = R\{X_1, \ldots, X_n\}$ denote the free $\mathbb{E}_\infty$-algebra over R on n-variables, so that $\pi_0 B \simeq R[X_1, \ldots, X_n]$. Then $L_{B/R} \simeq B^n$, so that

$$\pi_i(\kappa \otimes_B L_{B/R}) \simeq \begin{cases} \kappa^n & \text{if } i = 0 \\ 0 & \text{if } i > 0. \end{cases}$$

The truncation map $B \to R[X_1, \ldots, X_n]$ has 2-connective cofiber. Applying Corollary HA.7.4.3.2 , we deduce that $L_{R[X_1,\ldots,X_n]/B}$ is 2-connective. Using the fiber sequence

$$\kappa \otimes_B L_{B/R} \to \kappa \otimes_{R[X_1,\ldots,X_n]} L_{R[X_1,\ldots,X_n]/R} \to \kappa \otimes_{R[X_1,\ldots,X_n]} L_{R[X_1,\ldots,X_n]/B},$$

we conclude that

$$\pi_i(\kappa \otimes_{R[X_1,\ldots,X_n]} L_{R[X_1,\ldots,X_n]/R}) \simeq \begin{cases} \kappa^n & \text{if } i = 0 \\ 0 & \text{if } i = 1. \end{cases}$$

Using the fiber sequence

$$\kappa \otimes_{R[X_1,\ldots,X_n]} L_{R[X_1,\ldots,X_n]/R} \to \kappa \otimes_R L_{R/R} \to \kappa \otimes_R L_{R/R[X_1,\ldots,X_n]},$$

we obtain isomorphisms

$$\begin{aligned} \pi_i(\kappa \otimes_A L_{A/R}) &\simeq \pi_i(\kappa \otimes_R L_{R/R[X_1,\ldots,X_n]}) \\ &\simeq \pi_{i-1}(\kappa \otimes_{R[X_1,\ldots,X_n]} L_{R[X_1,\ldots,X_n]/R}) \\ &\simeq \begin{cases} \kappa^n & \text{if } i = 1 \\ 0 & \text{if } i = 2. \end{cases} \end{aligned}$$

Since the map $A \to \kappa$ has 2-connective cofiber, $L_{\kappa/A}$ is 2-connective. Using the fiber sequence

$$\kappa \otimes_A L_{A/R} \to L_{\kappa/R} \to L_{\kappa/A},$$

we obtain a short exact sequence

$$0 \to \pi_2 L_{\kappa/R} \xrightarrow{\alpha} \pi_2 L_{\kappa/A} \to \kappa^n \xrightarrow{\beta} \pi_1 L_{\kappa/R} \to \pi_1 L_{\kappa/A} = 0.$$

Theorem HA.7.4.3.1 supplies an isomorphism $\pi_1 L_{\kappa/R} \simeq \mathfrak{m}/\mathfrak{m}^2$, so that $\pi_1 L_{\kappa/R}$ is an n-dimensional vector space over κ. Since β is a surjection between vector spaces of the same dimension, it is also injective. It follows that α is an isomorphism.

Suppose now that (a) is satisfied. Then $x_1, \ldots, x_n$ is a regular sequence on R, so that $A \simeq \kappa$. It follows that $\pi_2 L_{\kappa/R} \simeq \pi_2 L_{\kappa/A} \simeq 0$.

We now prove the converse. Suppose that (b) is satisfied, so that $\pi_2 L_{\kappa/R} \simeq 0$. Then we also have $\pi_2 L_{\kappa/A} \simeq 0$. Applying Corollary HA.7.4.3.2 , we deduce that $\pi_1 A \simeq 0$. For $1 \leqslant i \leqslant n$, let M_i denote the cofiber of the map $x_i : R \to R$ in Mod_R, and for $0 \leqslant i \leqslant n$ let $M(i)$ denote the tensor product $\bigotimes_{j \leqslant i} M_i$ in Mod_R. Then $M(n) \simeq A$, so that $\pi_1 M(n) \simeq 0$. To prove that $x_1, \ldots, x_n$ is a regular sequence in R, it suffices to show that each $M(i)$ is discrete. Suppose otherwise, and choose a minimal integer i such that $M(i)$ is not discrete. Using the fiber sequence

$$M(i-1) \xrightarrow{x_i} M(i-1) \to M(i),$$

we deduce that $M(i)$ is 1-truncated and therefore $\pi_1 M(i) \neq 0$. Using the exact sequences

$$\pi_1 M(j) \xrightarrow{x_{j+1}} \pi_1 M(j) \to \pi_1 M(j+1),$$

and the fact that each $\pi_1 M(j)$ is a finitely generated R-module, we deduce that $\pi_1 M(j) \neq 0$ for $j \geqslant i$. It follows that $\pi_1 M(n) = \pi_1 A \neq 0$, a contradiction. □

Proof of Proposition 11.2.3.6. Suppose first that $f : R \to A$ is fiber smooth, and that we are given a morphism $R \to \kappa$, where κ is an algebraically closed field. Since f is flat, A_κ is discrete. By assumption f is almost of finite presentation, so that A_κ is finitely generated as an algebra over κ (and in particular Noetherian). We wish to show that A_κ is regular. Let $\mathfrak{m}$ be a maximal ideal of A_κ. It follows from Hilbert's Nullstellensatz that the composite map $\kappa \to A_\kappa \to A_\kappa/\mathfrak{m}$ is an isomorphism. The fiber sequence

$$\kappa \otimes_{A_\kappa} L_{A_\kappa/\kappa} \to L_{\kappa/\kappa} \to L_{\kappa/A_\kappa}$$

therefore yields an isomorphism

$$\pi_1(\kappa \otimes_A L_{A/R}) \simeq \pi_1(\kappa \otimes_{A_\kappa} L_{A_\kappa/\kappa}) \simeq \pi_2 L_{\kappa/A_\kappa}.$$

Since f is fiber smooth, we conclude that $\pi_2 L_{\kappa/A_\kappa} \simeq 0$, so that A_κ is regular at $\mathfrak{m}$ by Lemma 11.2.3.9.

Conversely, suppose that f satisfies condition (2); we wish to show that f is fiber smooth. The flatness of f follows from Proposition **??**. To complete the proof, it will suffice to show that for every field κ and every map $A \rightarrow \kappa$, the vector space $\pi_1(\kappa \otimes_A L_{A/R})$ vanishes. We may assume without loss of generality that κ is algebraically closed, define A_κ as above, and let $\mathfrak{m}$ denote the maximal ideal of A_κ given by the kernel of the canonical map $A_\kappa \rightarrow \kappa$. Then we have a canonical isomorphism

$$\pi_1(\kappa \otimes_A L_{A/R}) \simeq \pi_1(\kappa \otimes_{A_\kappa} L_{A_\kappa/\kappa}) \simeq \pi_2 L_{\kappa/A_\kappa}.$$

Since A_κ is a regular Noetherian ring, $\pi_2 L_{\kappa/A_\kappa}$ vanishes by Lemma 11.2.3.9. □

11.2.4 Smoothness in Commutative Algebra

If we restrict our attention to ordinary commutative rings, then fiber smoothness reduces to the classical notion of smooth morphism in commutative algebra. This admits several alternative characterizations:

Proposition 11.2.4.1. *Let $f : R \rightarrow A$ be a morphism of commutative rings which exhibits A as a finitely presented algebra over R. The following conditions are equivalent:*

(1) *When regarded as a map of connective $\mathbb{E}_\infty$-rings, f is fiber smooth.*

(2) *For every field κ and every map $A \rightarrow \kappa$, the vector space $\pi_1(\kappa \otimes_A L_{A/R})$ vanishes.*

(3) *The A-module $\pi_0 L_{A/R}$ is projective and $\pi_1 L_{A/R}$ vanishes.*

(4) *For every commutative R-algebra B and every nilpotent ideal $I \subseteq B$, the canonical map $\mathrm{Hom}_R(A, B) \rightarrow \mathrm{Hom}_R(A, B/I)$ is surjective (here the* Hom*-sets are computed in the category of commutative R-algebras).*

(5) *There exists a finite collection of elements $a_\alpha \in A$ which generate the unit ideal, such that each localization $A[a_\alpha^{-1}]$ admits an étale map $R[x_1, \ldots, x_{n_\alpha}] \rightarrow A[a_\alpha^{-1}]$.*

Proof. The implication (1) ⇒ (2) is obvious. We next show that (2) ⇒ (3). Since A is finitely presented as a commutative algebra over R, the map $f : R \rightarrow A$ is of finite generation to order 1 (Remark 4.1.1.9), so that $L_{A/R}$ is perfect to order 1. It follows that $P = \pi_0 L_{A/R}$ is a finitely presented A-module. We wish to show that P is projective. This assertion is local on $|\operatorname{Spec} A|$ with respect to the Zariski topology. It will therefore suffice to show that for each maximal ideal $\mathfrak{m} \subseteq A$, there exists an element $a \in A - \mathfrak{m}$ such that $P[a^{-1}]$ is projective as a module over $M[a^{-1}]$. Choose elements $x_1, \ldots, x_n \in P$ which form a basis for the vector space $P/\mathfrak{m}P$ over $A/\mathfrak{m}$. The elements x_i determine an A-module homomorphism $\theta : A^n \rightarrow P$. Using Nakayama's lemma, we see that this map is surjective after localization at $\mathfrak{m}$. Replacing A by a localization if necessary, we may suppose that θ is surjective. Let $\kappa = A/\mathfrak{p}$. Using the exact sequence

$$\pi_1(\kappa \otimes_A L_{A/R}) \to \pi_1(\kappa \otimes_A P) \to \pi_0(\kappa \otimes_A \tau_{\geqslant 1} L_{A/R})$$

and (2), we deduce that $\pi_1(\kappa \otimes_A P) \simeq 0$, so that we have an exact sequence

$$0 \to \pi_0(\kappa \otimes_A \ker(\theta)) \to \pi_0(\kappa \otimes_A A^n) \to \pi_0(\kappa \otimes_A P) \to 0.$$

It follows that $\pi_0(\kappa \otimes_A \ker(\theta)) \simeq 0$. Since P is finitely presented, $\ker(\theta)$ is a finitely generated A-module. Using Nakayama's lemma, we deduce that $\ker(\theta)_{\mathfrak{m}} \simeq 0$ and therefore, after replacing A by a localization, we may suppose that $\ker(\theta) = 0$: that is, that θ is an isomorphism. This completes the proof that P is projective. It follows that $L_{A/R}$ splits as a direct sum $P \oplus \tau_{\geqslant 1} L_{A/R}$. In particular, $\tau_{\geqslant 1} L_{A/R}$ is perfect to order 1, so that $Q = \pi_1 L_{A/R}$ is a finitely generated A-module. For every maximal ideal $\mathfrak{m}$ of A, the quotient $Q/\mathfrak{m}Q \simeq \pi_1(A/\mathfrak{m} \otimes_A \tau_{\geqslant 1} L_{A/R})$ is a direct summand of $\pi_1(A/\mathfrak{m} \otimes_A L_{A/R})$, and therefore vanishes. It follows from Nakayama's lemma that $Q \simeq 0$. This completes the proof that $(2) \Rightarrow (3)$.

We next prove that $(3) \Rightarrow (4)$. Assume that (3) is satisfied, let B be a commutative ring with a map $R \to B$, and let $I \subseteq B$ be an ideal with $I^k = 0$; we wish to show that the map $\mathrm{Hom}_R(A, B) \to \mathrm{Hom}_R(A, B/I)$ is surjective. Proceeding by induction on k, we can reduce to the case where $I^2 = 0$. Fix an R-algebra map $\phi_0 : A \to B/I$; we wish to show that ϕ_0 can be lifted to an R-algebra map $\phi : A \to B$. Replacing B by the pullback $A \times_{B/I} B$, we can assume that ϕ_0 is an isomorphism, so that B is a square-zero extension of A by some (discrete) B-module M, classified by a map $\eta : L_{A/R} \to \Sigma M$. Using (3), we deduce that $L_{A/R}$ splits as a direct sum $P \oplus \tau_{\geqslant 2} L_{A/R}$. Since $\mathrm{Map}_{\mathrm{Mod}_A}(\tau_{\geqslant 2} L_{A/R}, \Sigma M)$ is contractible and $\mathrm{Map}_{\mathrm{Mod}_A}(P, \Sigma M)$ is connected, we conclude that η is nullhomotopic, so that the square-zero extension $B \to A$ admits a section.

We next prove that $(4) \Rightarrow (2)$. Suppose that (4) is satisfied; we wish to show that for every field κ and every map $A \to \kappa$, we have $\pi_1(\kappa \otimes_A L_{A/R}) \simeq 0$. Suppose otherwise: then there exists a nonzero map of κ-modules $\kappa \otimes_A L_{A/R} \to \Sigma\kappa$, which classifies a nonzero map of A-modules $L_{A/R} \to \Sigma\kappa$. This map classifies a square-zero extension $\overline{A}$ of A by κ (in the category of R-modules). It follows that the reduction map $\mathrm{Hom}_R(A, \overline{A}) \to \mathrm{Hom}_R(A, A)$ is not surjective, contradicting assumption (4).

We next show that $(5) \Rightarrow (1)$. Since the assertion that A is fiber smooth over R is local with respect to the Zariski topology (Proposition 11.2.5.4), we may assume that there exists an étale map $\psi : R[x_1, \ldots, x_n] \to A$, for some integer n. The map ψ is fiber smooth (Example 11.2.3.2). Using Proposition 11.2.3.4, we are reduced to proving that $R[x_1, \ldots, x_n]$ is fiber smooth over R. Using Proposition 11.2.3.4 again, we can reduce to the case where R is Noetherian. In this case, Proposition HA.7.2.4.31 implies that $R[x_1, \ldots, x_n]$ is almost of finite presentation as an object of CAlg_R. Using Remark 11.2.3.8, we may further reduce to the case where R is a field κ, and using Proposition 11.2.5.3 we may suppose that κ is algebraically closed. It is clear that $\kappa[x_1, \ldots, x_n]$ is flat over κ. Moreover, the Nullstellensatz guarantees that every maximal ideal $\kappa[x_1, \ldots, x_n]$ is generated by a regular sequence of the form $x_1 - c_1, \ldots, x_n - c_n$, for some scalars $c_i \in \kappa$.

We now complete the proof by showing that (3) ⇒ (5). Suppose that (3) is satisfied; in particular, this implies that $\pi_0 L_{A/R}$ is a projective A-module of finite rank. Note that $\pi_0 L_{A/R}$ can be identified with the module of Kähler differentials $\Omega_{A/R}$; in particular, it is generated by the set of elements $\{da\}_{a \in A}$ (Proposition HA.7.4.3.9). Assertion (5) is local with respect to the Zariski topology on $|\operatorname{Spec} A|$. We may therefore assume without loss of generality that there exist $y_1, \ldots, y_n \in A$ such that the elements dy_i freely generate $\pi_0 L_{A/R}$ as a module over A. Let $A_0 = R[Y_1, \ldots, Y_n]$, so that there is a unique R-algebra homomorphism $\xi : A_0 \to A$ satisfying $\xi(Y_i) = y_i$. We will complete the proof by showing that ξ is étale.

We have a fiber sequence $A \otimes_{A_0} L_{A_0/R} \xrightarrow{\alpha} L_{A/R} \to L_{A/A_0}$. By construction, the map α induces an isomorphism on π_0. Since $\pi_1 L_{A/R} \simeq 0$, we conclude that $\pi_0 L_{A/A_0} \simeq \pi_1 L_{A/A_0} \simeq 0$. Using Lemma B.1.3.2, we deduce that ξ factors as a composition $A_0 \xrightarrow{\xi'} A_1 \xrightarrow{\xi''} A$, where ξ' is étale and $\mathrm{fib}(\xi'')$ is 2-connective. Since A_0 is discrete and ξ' is étale, we conclude that A_1 is discrete. Then ξ'' is a map between discrete $\mathbb{E}_\infty$-rings which induces an isomorphism $\pi_0 A' \to \pi_0 A$, and is therefore an equivalence. It follows that $\xi = \xi'' \circ \xi'$ is étale, as desired. □

Corollary 11.2.4.2. *Let $\phi : R \to A$ be a morphism of connective $\mathbb{E}_\infty$-rings. Suppose that ϕ is flat and that ϕ exhibits $\pi_0 A$ as a finitely presented commutative algebra over $\pi_0 R$. Then the following conditions are equivalent:*

(1) *The morphism ϕ is fiber smooth.*

(2) *For every surjective map of commutative rings $B \to \overline{B}$ with nilpotent kernel, every lifting problem*

$$\begin{array}{ccc} R & \longrightarrow & B \\ \downarrow & \nearrow & \downarrow \\ A & \longrightarrow & \overline{B} \end{array}$$

admits a solution.

(3) *For every discrete A-module M, the abelian group $\pi_1(M \otimes_A L_{A/R})$ vanishes.*

(4) *For every field κ and every morphism $A \to \kappa$, the vector space $\pi_1(\kappa \otimes_A L_{A/R})$ vanishes.*

Proof. Using Remark 11.2.3.5, we can replace R by $\pi_0 R$ and A by $A \otimes_R \pi_0 R$, and thereby reduce to the case where R is discrete. Since A is flat over R, it is also discrete. The equivalence of (1), (2), and (4) follows from Proposition 11.2.4.1, and the implication (3) ⇒ (4) is immediate. We complete the proof by showing that (1) ⇒ (3). If (1) is satisfied, then $\pi_1 L_{A/R} \simeq 0$ and $\pi_0 L_{A/R}$ is a flat A-module. It follows that the abelian groups $\mathrm{Tor}_0^A(M, \pi_1 L_{A/R})$ and $\mathrm{Tor}_1^A(M, \pi_0 L_{A/R})$ vanish. Using the exact sequence

$$\mathrm{Tor}_0^A(M, \pi_1 L_{A/R}) \to \pi_1(M \otimes_A L_{A/R}) \to \mathrm{Tor}_1^A(M, \pi_0 L_{A/R}),$$

we see that $\pi_1(M \otimes_A L_{A/R})$ vanishes as well. □

We now consider the relationship between differential smoothness and fiber smoothness.

Proposition 11.2.4.3. *Let $\phi : R \to A$ be a morphism of connective $\mathbb{E}_\infty$-rings. If ϕ is differentially smooth, then the induced map of commutative rings $\pi_0 R \to \pi_0 A$ is fiber smooth.*

Proof. This follows immediately from the criteria for smoothness provided by part (4) of Proposition 11.2.2.1 and part (5) of Proposition 11.2.4.1. □

In characteristic zero, fiber smoothness is equivalent to differential smoothness:

Proposition 11.2.4.4. *Let $\phi : R \to A$ be a morphism of connective $\mathbb{E}_\infty$-rings, and suppose that $\pi_0 R$ is an algebra over the field $\mathbf{Q}$ of rational numbers. Then ϕ is fiber smooth if and if ϕ is differentially smooth.*

Proof. Using Corollary 11.2.2.8 and Remark 11.2.3.5, we can reduce to the case where R is discrete. By virtue of the criteria provided by part (4) of Proposition 11.2.2.1 and part (5) of Proposition 11.2.4.1, it will suffice to show that for every integer $n \geqslant 0$, the canonical map $\theta : R\{x_1, \ldots, x_n\} \to R[x_1, \ldots, x_n]$ is an equivalence in CAlg_R. This follows from Proposition HA.7.1.4.20 . □

11.2.5 Smooth Morphisms of Spectral Deligne-Mumford Stacks

Let $\phi : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings. Then the condition that ϕ is differentially smooth (fiber smooth) is local with respect to the étale topology on Spét B, and local with respect to the flat topology on Spét A:

Proposition 11.2.5.1. *Let $\phi : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings, and suppose we are given a finite collection of étale B-algebras B_α such that the induced map $B \to \prod_\alpha B_\alpha$ is faithfully flat. Then ϕ is differentially smooth if and only if each of the induced maps $\phi_\alpha : A \to B_\alpha$ is differentially smooth.*

Proof. If ϕ is differentially smooth, then it follows immediately from Proposition 11.2.2.9 and Example 11.2.2.5 that each ϕ_α is differentially smooth. Conversely, suppose that each ϕ_α is differentially smooth. Using Proposition 4.1.4.1 we deduce that ϕ is almost of finite presentation. Consequently, we are reduced to proving that the relative cotangent complex $L_{B/A}$ is flat over B (Remark 11.2.2.3). By virtue of Proposition 2.8.4.2, it will suffice to show that each tensor product $B_\alpha \otimes_B L_{B/A}$ is flat over B_α. This is clear, since $B_\alpha \otimes_B L_{B/A} \simeq L_{B_\alpha/A}$, and B_α is assumed to be differentially smooth over A. □

Proposition 11.2.5.2. *Let $\phi : A \to B$ be a morphism of connective $\mathbb{E}_\infty$-rings, and suppose we are given a finite collection of A-algebras B_α such that the induced map $A \to \prod_\alpha A_\alpha$ is faithfully flat. If each of the induced maps $\phi_\alpha : A_\alpha \to A_\alpha \otimes_A B$ is differentially smooth, then ϕ is differentially smooth.*

Proof. It follows from Proposition 4.1.4.3 that ϕ is locally almost of finite presentation. We wish to prove that $L_{B/A}$ is flat over B (Remark 11.2.2.3). It now suffices to note that the flatness of $L_{B/A}$ can be tested locally with respect to the flat topology (Proposition 2.8.4.2). □

Proposition 11.2.5.3. *Let $\phi : A \to B$ be a map of connective $\mathbb{E}_\infty$-rings. Suppose that there exists a finite collection of A-algebras A_α, such that $\prod_\alpha A_\alpha$ is faithfully flat over A. If each tensor product $A_\alpha \otimes_A B$ is fiber smooth over B, then B is fiber smooth over A.*

Proof. It follows from Proposition 4.2.1.5 that B is almost of finite presentation over A, and from Proposition 2.8.4.2 that B is flat over A. To complete the proof that B is fiber smooth over A, it will suffice to show that for every field κ and every morphism $B \to \kappa$, the vector space $\pi_1(\kappa \otimes_B L_{B/A})$ vanishes. Enlarging κ if necessary, we may assume that the composite map $A \to B \to \kappa$ factors through some A_α. Let $B_\alpha = A_\alpha \otimes_A B$. Then we have a canonical isomorphism $\pi_1(\kappa \otimes_B L_{B/A}) \simeq \pi_1(\kappa \otimes_{B_\alpha} L_{B_\alpha/A_\alpha})$, so the desired result follows from our assumption that B_α is fiber smooth over A_α. □

Proposition 11.2.5.4. *Let $\phi : A \to B$ be a map of connective $\mathbb{E}_\infty$-rings. Suppose that there exists a finite collection of flat morphisms $B \to B_\alpha$ which are almost of finite presentation, such that $\prod_\alpha B_\alpha$ is faithfully flat over B and each B_α is fiber smooth over A. Then B is fiber smooth over A.*

Proof. Set $B' = \prod_\alpha B_\alpha$. Then B' is fiber smooth over A, and the map $B \to B'$ is almost of finite presentation and faithfully flat. Applying Corollary 6.1.6.5, we deduce that B is almost of finite presentation over A. We wish to prove that B is fiber smooth over A. Using Remark 11.2.3.8, we can reduce to the case where $A = \kappa$ is a field. Using Proposition 11.2.5.3, we can reduce to the case where κ is algebraically closed. Since B' is fiber smooth over κ, it is discrete. The faithful flatness of B' over B guarantees that B is also discrete. Note that B is finitely generated as an algebra over κ; we wish to show that B is regular. Let $\mathfrak{m}$ be a maximal ideal of B; we will show that $B/\mathfrak{m}$ is perfect as a B-module (see Lemma 11.3.3.3). Since B is Noetherian and $B/\mathfrak{m}$ is a finitely generated B-module, it is almost perfect (Proposition HA.7.2.4.17). We are therefore reduced to proving that $B/\mathfrak{m}$ has finite Tor-amplitude as a B-module (Proposition HA.7.2.4.23).

Since B' is faithfully flat over B, the map $|\operatorname{Spec} B'| \to |\operatorname{Spec} B|$ is surjective. We may therefore choose a maximal ideal $\mathfrak{m}'$ of B' lying over $\mathfrak{m}$. Since κ is algebraically closed, both $B'/\mathfrak{m}'$ and $B/\mathfrak{m}$ are isomorphic to κ, so that the natural map $B/\mathfrak{m} \to B'/\mathfrak{m}'$ is an isomorphism. Since B' is flat over B, we are reduced to proving that $B'/\mathfrak{m}'$ has finite Tor-amplitude as a B'-module (Lemma 6.1.1.6). This follows from Lemma 11.3.3.3, since B' is a regular Noetherian ring. □

Motivated by the preceding results, we introduce global versions of Definitions 11.2.2.2 and 11.2.3.1:

Definition 11.2.5.5. Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. We will say that f is *differentially smooth* (*fiber smooth*) if, for every commutative diagram of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \operatorname{Sp\acute{e}t} B & \longrightarrow & \mathsf{X} \\ \downarrow & & \downarrow f \\ \operatorname{Sp\acute{e}t} A & \longrightarrow & \mathsf{Y} \end{array}$$

where the horizontal maps are étale, the underlying map of connective $\mathbb{E}_\infty$-rings $A \to B$ is differentially smooth (fiber smooth).

Remark 11.2.5.6. Differential smoothness and fiber smoothness for maps of spectral Deligne-Mumford stacks can also be defined in terms of infinitesimal lifting properties. We defer a proof until §17 (see Proposition 17.3.9.4), where we will develop the global theory of the cotangent complex.

Example 11.2.5.7. Let R be a connective $\mathbb{E}_\infty$-ring and let $\mathbf{P}^n_R$ be projective space of dimension n over R (see Construction 5.4.1.3). Then the projection map $\mathbf{P}^n_R \to \operatorname{Sp\acute{e}t} R$ is fiber smooth.

Remark 11.2.5.8. Let $f : \mathsf{X} \to \mathsf{Y}$ be a fiber smooth morphism of spectral Deligne-Mumford stacks. Then f is Gorenstein, in the sense of Definition 6.6.6.1. To prove this, we first observe that f is flat and locally almost of finite presentation, so we may assume without loss of generality that $\mathsf{Y} = \operatorname{Sp\acute{e}t} \kappa$ for some field κ. The assertion is local on X, so we may assume that $\mathsf{X} = \operatorname{Sp\acute{e}t} A$ for some finitely generated (discrete) κ-algebra A. The fiber smoothness of A over κ guarantees that A is a regular Noetherian ring (Proposition 11.2.3.6), and therefore Gorenstein (Example **??**).

We now summarize some formal properties of Definition 11.2.5.5:

Proposition 11.2.5.9. (1) *The condition that a morphism $f : \mathsf{X} \to \mathsf{Y}$ of spectral Deligne-Mumford stacks be differentially smooth (fiber smooth) is local on the target with respect to the flat topology, and local on the source with respect to the étale topology.*

(2) *The collection of differentially smooth (fiber smooth) morphisms is closed under composition.*

(3) *Suppose are given a pullback diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y}. \end{array}$$

If f is differentially smooth (fiber smooth), so is f'.

Proof. Assertion (1) follows from Propositions 11.2.5.3, 11.2.5.4, 11.2.5.1, and 11.2.5.2 (see Remarks 2.8.1.3 and 6.3.1.3). Assertion (2) follows from Propositions 11.2.2.9 and 11.2.3.4, and assertion (3) follows from Proposition 11.2.3.4 and Remark 11.2.2.4. □

Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Since the property of being fiber smooth is local on the source with respect to the étale topology, there exists a largest open substack $\mathsf{U} \subseteq \mathsf{X}$ for which the restriction $f|_{\mathsf{U}} : \mathsf{U} \to \mathsf{Y}$ is fiber smooth. We will refer to $\mathsf{U} \subseteq \mathsf{X}$ as the *smooth locus* of the morphism f. Note that if we are given any pullback diagram

$$\begin{array}{ccc} \mathsf{X}' & \longrightarrow & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y}, \end{array}$$

then we can identify $\mathsf{U} \times_{\mathsf{X}} \mathsf{X}'$ with an open substack of X', and the restriction of f' to this open substack is also fiber smooth (Proposition 11.2.5.9). It follows that $\mathsf{U} \times_{\mathsf{X}} \mathsf{X}'$ is contained in the smooth locus of f'. In good cases, we have equality:

Proposition 11.2.5.10 (Universality of the Smooth Locus)**.** *Suppose we are given a pullback diagram of spectral Deligne-Mumford stacks*

$$\begin{array}{ccc} \mathsf{X}' & \xrightarrow{g} & \mathsf{X} \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ \mathsf{Y}' & \longrightarrow & \mathsf{Y} \end{array}$$

where f and f' are flat and locally almost of finite presentation. If $\mathsf{U} \subseteq \mathsf{X}$ is the smooth locus of f, then $\mathsf{U} \times_{\mathsf{X}} \mathsf{X}'$ is the smooth locus of f'.

Proof. Without loss of generality, we may assume that $\mathsf{Y} \simeq \operatorname{Sp\acute{e}t} A$ and $\mathsf{Y}' \simeq \operatorname{Sp\acute{e}t} A'$ are affine. Similarly, we may assume that $\mathsf{X} \simeq \operatorname{Sp\acute{e}t} B$ is affine, so that $\mathsf{X}' \simeq \operatorname{Sp\acute{e}t} B'$ for $B' = A' \otimes_A B$. Let $x' \in |\operatorname{Spec} B'|$ be a point which belongs to the smooth locus of f'; we wish to show that $x = g(x') \in |\operatorname{Spec} B|$ belongs to the smooth locus of f. Let $\kappa(x')$ denote the residue field of B' at x' and let $\kappa(x)$ denote the residue field of B at x. Then $\pi_0(\kappa(x') \otimes_B L_{B/A})$ is generated as a vector space over $\kappa(x')$ by the image of $\pi_0 L_{B/A}$. We can therefore choose a collection of elements $u_1, \ldots, u_d \in \pi_0 L_{B/A}$ whose images form a basis for $\pi_0(\kappa(x') \otimes_B L_{B/A})$. Let us identify the set $\{u_i\}_{1 \leqslant i \leqslant d}$ with a morphism of B-modules $u : B^d \to L_{B/A}$. Our assumption that x' belongs to the smooth locus of f' guarantees that $\kappa(x') \otimes_B \operatorname{cofib}(u)$ is 2-connective, so that $\kappa(x) \otimes_B \operatorname{cofib}(u)$ is 2-connective. The cofiber $\operatorname{cofib}(u)$ is almost perfect, so Proposition 2.7.4.1 guarantees the existence of an element $b \in \pi_0 B$ which does not vanish at x such that $\operatorname{cofib}(u)[b^{-1}]$ is 2-connective. Then $f|_{\operatorname{Sp\acute{e}t} B[b^{-1}]} : \operatorname{Sp\acute{e}t} B[b^{-1}] \to \operatorname{Sp\acute{e}t} A$ is smooth, so that x is contained in the smooth locus of f as desired. □

11.3 Smoothness for Linear ∞-Categories

Let R be a connective $\mathbb{E}_\infty$-ring, and let X be a spectral algebraic space over R. We will say that X is *fiber smooth* over R if the map $\mathsf{X} \to \operatorname{Sp\acute{e}t} R$ is fiber smooth, in the sense of Definition 11.2.5.5. Our goal in this section is to show that (under some mild hypotheses) the hypothesis that X is fiber smooth over R depends only on the R-linear ∞-category $\operatorname{QCoh}(\mathsf{X})$. For this end, we will introduce the notion of a *smooth* R-linear ∞-category (Definition 11.3.1.1). Our main result asserts that if X is quasi-compact, quasi-separated, locally almost of finite presentation, and of finite Tor-amplitude over R, then $\operatorname{QCoh}(\mathsf{X})$ is smooth if and only if X is separated and fiber smooth over R (Theorem 11.3.6.1).

11.3.1 Definition of Smoothness

We begin with some general remarks.

Definition 11.3.1.1. Let R be an $\mathbb{E}_2$-ring and let $\mathcal{C}$ be a stable R-linear ∞-category. We will say that $\mathcal{C}$ is *smooth* if the following conditions are satisfied:

(1) The ∞-category $\mathcal{C}$ is compactly generated and is therefore left dualizable as a left LMod_R-module object of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ (Corollary D.7.7.4). Let us denote its left dual by ${}^\vee\mathcal{C}$.

(2) Let $c : \mathrm{Sp} \to {}^\vee\mathcal{C} \otimes_R \mathcal{C}$ be a morphism in $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ which exhibits ${}^\vee\mathcal{C}$ as a left dual of $\mathcal{C}$. Then the functor c preserves compact objects.

Warning 11.3.1.2. The condition that a stable R-linear ∞-category $\mathcal{C}$ be smooth depends not only on the underlying stable ∞-category, but also on the action of Mod_R on $\mathcal{C}$. We will sometimes emphasize this dependence by saying that $\mathcal{C}$ is *smooth over* R if it satisfies the requirements of Definition 11.3.1.1.

Remark 11.3.1.3. In the situation of Definition 11.3.1.1, condition (2) is equivalent to the *a priori* weaker hypothesis that the functor $c : \mathrm{Sp} \to {}^{\vee}\mathcal{C} \otimes_R \mathcal{C}$ carries the sphere spectrum S to a compact object of ${}^{\vee}\mathcal{C} \otimes_R \mathcal{C}$.

Remark 11.3.1.4. Let R be an $\mathbb{E}_2$-ring, let $\mathcal{C}$ be an R-linear ∞-category, and let $R \to R'$ be a morphism of $\mathbb{E}_2$-rings. Then $R' \otimes_R \mathcal{C}$ is a compactly generated R'-linear ∞-category (Corollary **??**), whose left dual can be identified with the ∞-category

$$ {}^{\vee}\mathcal{C} \otimes_R R' = {}^{\vee}\mathcal{C} \otimes_{\mathrm{LMod}_R} \mathrm{LMod}_{R'} . $$

Moreover, the canonical map

$$ {}^{\vee}\mathcal{C} \otimes_R \mathcal{C} \to {}^{\vee}\mathcal{C} \otimes_R \mathrm{LMod}_{R'} \otimes_R \mathcal{C} \simeq ({}^{\vee}\mathcal{C} \otimes_R R') \otimes_{R'} (R' \otimes_R \mathcal{C}) $$

preserves compact objects. It follows that if $\mathcal{C}$ is smooth over R, then $R' \otimes_R \mathcal{C}$ is smooth over R'.

11.3.2 Comparison with Smooth Algebras

Let R be an $\mathbb{E}_2$-ring and let A be an $\mathbb{E}_1$-algebra over R. Then we can regard RMod_A is a stable R-linear ∞-category. We now show that the condition that RMod_A is smooth over R admits a more concrete formulation in terms of the structure of A as an R-algebra (Proposition 11.3.2.3).

Definition 11.3.2.1. Let R be an $\mathbb{E}_2$-ring and let A be an $\mathbb{E}_1$-algebra over R. We will say that A is *smooth over* R if it is compact when viewed as an object of the stable ∞-category ${}_A\mathrm{BMod}_A(\mathrm{LMod}_R)$ of A-A bimodule objects of LMod_R.

Remark 11.3.2.2. Suppose that R is an $\mathbb{E}_\infty$-ring, let A be an $\mathbb{E}_1$-algebra over R, and let A^{rev} denote the opposite algebra (Remark HA.4.1.1.7). Then we have an equivalence of ∞-categories ${}_A\mathrm{BMod}_A(\mathrm{Mod}_R) \simeq \mathrm{LMod}_{A \otimes_R A^{\mathrm{rev}}}$, so that the algebra A is compact when viewed as an object of ${}_A\mathrm{BMod}_A(\mathrm{Mod}_R)$ if and only if it is perfect when regarded as left module over $A \otimes_R A^{\mathrm{rev}}$. In other words, the algebra A is smooth in the sense of Definition 11.3.2.1 if and only if it is a smooth algebra object of Mod_R, in the sense of Definition HA.4.6.4.13 .

Proposition 11.3.2.3. *Let R be an $\mathbb{E}_2$-ring and let A be an $\mathbb{E}_1$-algebra over R. The following conditions are equivalent:*

(a) *The R-linear ∞-category RMod_A is smooth over R (in the sense of Definition 11.3.1.1).*

(b) *The algebra A is smooth over R (in the sense of Definition 11.3.2.1). That is, A is a compact object of the ∞-category ${}_A\mathrm{BMod}_A(\mathrm{LMod}_R)$.*

Proof. Using Theorem HA.4.8.4.6 , we can identify the tensor product $\mathrm{LMod}_A \otimes_R \mathrm{RMod}_A$ with the ∞-category ${}_A\mathrm{BMod}_A(\mathrm{LMod}_R)$. Under this identification, the coevaluation functor

$$c : \mathrm{Sp} \to \mathrm{LMod}_A \otimes_R \mathrm{RMod}_A$$

carries the sphere spectrum $S \in \mathrm{Sp}$ to the spectrum A, regarded as a bimodule over itself. □

Proposition 11.3.2.3 asserts in particular that if $A \in \mathrm{Alg}_R$ is smooth, then the ∞-category RMod_A is smooth over R. In fact, all smooth R-linear ∞-categories arise in this way:

Proposition 11.3.2.4. *Let R be an $\mathbb{E}_2$-ring and let $\mathcal{C}$ be a stable R-linear ∞-category. The following conditions are equivalent:*

(1) *The ∞-category $\mathcal{C}$ is smooth over R.*

(2) *There exists an R-linear equivalence $\mathcal{C} \simeq \mathrm{RMod}_A$, where $A \in \mathrm{Alg}_R$ is smooth.*

Proof. The implication (2) ⇒ (1) follows from Proposition 11.3.2.3. We now prove the converse. Let $\mathcal{C}$ be a smooth R-linear ∞-category. We will show that there exists a single compact object $C \in \mathcal{C}$ which generates $\mathcal{C}$. It will then follow from Corollary D.7.6.4 that $\mathcal{C} \simeq \mathrm{RMod}_A$, where A is the endomorphism algebra of C. Proposition 11.3.2.3 then implies that $A \in \mathrm{Alg}_R$ is smooth, so that (2) is satisfied.

We now prove the existence of C. By assumption, the ∞-category $\mathcal{C}$ is compactly generated. Choose a set $\{C_t\}_{t \in T}$ of compact generators for $\mathcal{C}$. For every finite subset $T' \subseteq T$, let $\mathcal{C}_{T'}$ denote the smallest stable subcategory of $\mathcal{C}$ which contains the objects of T' and is closed under small colimits. Fix an object $X \in \mathcal{C}_{T'}$, and let $\mathcal{D}_X$ be the full subcategory of Mod_R spanned by those left R-modules M for which $M \otimes C$ belongs to $\mathcal{C}_{T'}$. Since $\mathcal{C}_{T'}$ is stable and closed under small colimits in $\mathcal{C}$, $\mathcal{D}_C$ is stable and closed under small colimits in Mod_R. Since $R \in \mathcal{D}_{T'}$, we conclude that $\mathcal{D}_{T'} = \mathrm{LMod}_R$: that is, the action of LMod_R on $\mathcal{C}$ carries $\mathcal{C}_{T'}$ into itself. We may therefore regard each $\mathcal{C}_{T'}$ itself as an R-linear ∞-category.

We next claim that the canonical map $\theta : \varinjlim_{T' \subseteq S} \mathcal{C}_{T'} \to \mathcal{C}$ is an equivalence in $\mathrm{LinCat}_R^{\mathrm{St}}$; here the colimit is taken over the collection of all finite subsets $T' \subseteq T$. Since the forgetful functor $\mathrm{LinCat}_R^{\mathrm{St}} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ preserves small colimits, we are reduced to proving that $\mathcal{C}$ is a colimit of the diagram $\{\mathcal{C}_{T'}\}_{T' \subseteq T}$ in $\mathcal{P}\mathrm{r}^{\mathrm{L}}$. For each finite subset $T' \subseteq T$, let $\mathcal{C}^0_{T'}$ denote the smallest stable subcategory of $\mathcal{C}$ containing T'. Similarly, let $\mathcal{C}^0$ be the smallest stable subcategory of $\mathcal{C}$ containing T. Let $\mathcal{C}\mathrm{at}_\infty^{\mathrm{Ex}}$ denote the subcategory of $\mathcal{C}\mathrm{at}_\infty$ whose objects are (small) stable ∞-categories and whose morphisms are exact functors. Since each $\mathcal{C}^0_{T'}$ consists of compact objects of $\mathcal{C}$, the inclusion $\mathcal{C}^0_{T'} \hookrightarrow \mathcal{C}$ extends to a fully faithful embedding $\mathrm{Ind}(\mathcal{C}^0_{T'}) \to \mathcal{C}$ which preserves small colimits. The essential image of this embedding is the full subcategory of $\mathcal{C}$ generated by $\mathcal{C}^0_{T'}$ under small colimits, and therefore coincides with $\mathcal{C}_{T'}$. Similarly, we can identify $\mathcal{C}$ with $\mathrm{Ind}(\mathcal{C}^0_{T'})$. We may therefore identify θ with the canonical map

$$\varinjlim_{T' \subseteq T} \mathrm{Ind}(\mathcal{C}^0_{T'}) \to \mathrm{Ind}(\mathcal{C}^0).$$

Since the functor $\mathrm{Ind} : \mathcal{C}\mathrm{at}_\infty^{\mathrm{Ex}} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ preserves small colimits, we are reduced to showing that $\mathcal{C}^0$ is the colimit of the diagram $\{\mathcal{C}^0_{T'}\}_{T' \subseteq T}$, which follows immediately from the definitions (note that the forgetful functor $\mathcal{C}\mathrm{at}_\infty^{\mathrm{Ex}} \to \mathcal{C}\mathrm{at}_\infty$ preserves filtered colimits).

Note that for every finite subset $T' \subseteq T$, the inclusion $\iota : \mathcal{C}_{T'} \hookrightarrow \mathcal{C}$ preserves compact objects, and therefore admits a right adjoint G which preserves filtered colimits. Using Remark D.1.5.3, we can regard G as an R-linear functor, and the unit map $u : \mathrm{id}_{\mathcal{C}_{T'}} \to G \circ \iota$ as an R-linear natural transformation. Since ι is fully faithful, u is an equivalence. Let $c : \mathrm{Sp} \to {}^\vee\mathcal{C} \otimes_R \mathcal{C}$ be the duality datum appearing in Definition 11.3.1.1. Then we can identify the codomain of c with the colimit

$$\varinjlim_{T' \subseteq T} {}^\vee\mathcal{C} \otimes_R \mathcal{C}_{T'}.$$

Let $S \in \mathrm{Sp}$ be the sphere specturm. Since $\mathcal{C}$ is smooth, $c(S)$ is a compact object of the tensor product ${}^\vee\mathcal{C} \otimes_R \mathcal{C}$ and can therefore be lifted to a compact object of ${}^\vee\mathcal{C} \otimes_R \mathcal{C}_{T'}$ for some finite subset $T' \subseteq T$ (Lemma HA.7.3.5.11). This object determines a map $\overline{c} : \mathrm{Sp} \to {}^\vee\mathcal{C} \otimes_R \mathcal{C}_{T''}$ which classifies an R-linear functor $\mathcal{C} \to \mathcal{C}_{T'}$ which is right homotopy inverse to the identity. It follows that $\mathcal{C}_{T'} = \mathcal{C}$. We now complete the proof by observing that the object $C = \bigoplus_{t \in T'} C_t$ is a compact generator of $\mathcal{C}$. □

11.3.3 Relationship with Fiber Smoothness

Let $f : R \to A$ be a morphism of $\mathbb{E}_\infty$-rings. Then, by neglect of structure, we can regard A as an $\mathbb{E}_1$-algebra over R. We now show that the smoothness of A as an $\mathbb{E}_1$-algebra is closely related to the fiber smoothness of the morphism f:

Proposition 11.3.3.1. *Let $f : R \to A$ be a morphism of connective $\mathbb{E}_\infty$-rings. Then f is fiber smooth if and only if it satisfies the following conditions:*

(1) *The morphism f has finite* Tor*-amplitude.*

(2) *The morphism f is almost of finite presentation.*

(3) *The algebra A is smooth as an $\mathbb{E}_1$-algebra over R (Definition 11.3.2.1). That is, A is perfect when regarded as a module over $A \otimes_R A$.*

Warning 11.3.3.2. Hypothesis (1) of Proposition 11.3.3.1 is necessary. For example, let $\mathbf{Q}$ denote the field of rational numbers (regarded as a discrete $\mathbb{E}_\infty$-ring) and let $A = \mathrm{Sym}^*_{\mathbf{Q}}(\Sigma^2\, \mathbf{Q})$ denote the free $\mathbb{E}_\infty$-algebra over $\mathbf{Q}$ on one generator in homological degree 2. Then A is smooth over $\mathbf{Q}$ in the sense of Definition 11.3.2.1, but is not fiber smooth over $\mathbf{Q}$ (since it is not flat over $\mathbf{Q}$).

Lemma 11.3.3.3. *[Serre's Criterion] Let R be a local Noetherian $\mathbb{E}_\infty$-ring with residue field κ. Assume that R is n-truncated for some integer n and that κ is perfect when regarded as an R-module. Then $\pi_0 R$ is a regular local ring and $\pi_m R \simeq 0$ for $m > 0$.*

Proof. If $R \simeq 0$ there is nothing to prove. Otherwise, our assumption that R is truncated guarantees the existence of a largest integer n such that $\pi_n R \neq 0$. We will prove that R is discrete by showing that $n = 0$. The regularity of $\pi_0 R$ will then follow from Serre's criterion (see, for example, [148]).

If κ is a perfect R-module, then it has Tor-amplitude $\leqslant d$ for some integer d. It follows that for every discrete R-module M, we have $\pi_{d+1}(\kappa \otimes_R M) \simeq 0$. Using Corollary 6.1.4.7, we deduce that if M is finitely generated as a module over $\pi_0 R$, then M also has Tor-amplitude $\leqslant d$.

Assume for a contradiction that $n > 0$. Since R is Noetherian, $\pi_n R$ is a finitely generated module over $\pi_0 R$. Let $\mathfrak{p} \subseteq \pi_0 R$ be a minimal prime ideal belonging to the support of $\pi_0 R$, so that $\pi_n R_{\mathfrak{p}} \neq 0$. Note that the quotient $M = \pi_0 R/\mathfrak{p}$ has Tor-amplitude $\leqslant d$ as an R-module. Then $M_{\mathfrak{p}}$ can be identified with the fraction field of $R_{\mathfrak{p}}$, and therefore has Tor-amplitude $\leqslant d$ as an $R_{\mathfrak{p}}$-module. We may therefore replace R by $R_{\mathfrak{p}}$, and thereby reduce to the case where $\pi_n R$ is supported at the maximal ideal $\mathfrak{m} \subseteq R$ (and is therefore an R-module of finite length). In particular, we may assume that there exists a nonzero element $x \in \pi_n R$ which is annihilated by $\mathfrak{m}$.

To obtain a contradiction, it will suffice to prove the following:

$(*)$ Let N be a nonzero perfect R-module which is connective and of Tor-amplitude $\geqslant k$. Then $\pi_{n+k} N \neq 0$.

We prove $(*)$ using induction on k. If $k = 0$, then N is a projective R-module, so that $\pi_n N \simeq (\pi_n R) \otimes_{\pi_0 R} (\pi_0 N) \neq 0$. Assume that $k > 0$, and choose a finite collection of elements $x_1, \ldots, x_m \in \pi_0 N$ which generate $\pi_0(\kappa \otimes_R N)$ as a vector space over κ. These elements determine a fiber sequence of R-modules $N' \xrightarrow{\phi} R^m \to N$. It follows from Nakayama's lemma that the map $\pi_0 R^m \to \pi_0 N$ is surjective. Since N has Tor-amplitude $\geqslant k > 0$, the R-module N' is nonzero and has Tor-amplitude $> k-1$. We have a short exact sequence of abelian groups $\pi_{n+k} N \to \pi_{n+k-1} N' \xrightarrow{\psi} \pi_{n+k-1} R^m$. It will therefore suffice to show that the map ψ is not injective. If $k > 1$ this is clear, since $\pi_{n+k-1} N' \neq 0$ by the inductive hypothesis, and $\pi_{n+k-1} R \simeq 0$. In the case $k = 1$, N' is a projective R-module. Since R is local, we have $R^a \simeq N'$ for some integer $a > 0$. Then ϕ is given (up to homotopy) by a matrix of coefficients $\{\phi_{i,j} \in \pi_0 R\}_{1 \leqslant i \leqslant a, 1 \leqslant j \leqslant m}$. By construction, the map $(\pi_0 R^m)/\mathfrak{m}(\pi_0 R^m) \to N/\mathfrak{m}N$ is injective, so that the image of $\pi_0 N'$ under ϕ is contained in $\mathfrak{m}^m \subseteq (\pi_0 R)^m$. It follows that each of the coefficients $\phi_{i,j}$ belongs to $\mathfrak{m}$, and therefore ψ annihilates the nonzero element $(x, x, \ldots, x) \in \pi_n R^a \simeq \pi_n N'$. □

Proof of Proposition 11.3.3.1. Suppose first that $f : R \to A$ is fiber smooth. Then f is almost of finite presentation and of finite Tor-amplitude (in fact, it is flat). We must show that A is smooth in the sense of Definition 11.3.2.1: that is, that it is perfect when regarded as a module over $A \otimes_R A$. We first note that since A is almost of finite presentation over R, the tensor product $A \otimes_R A$ is also almost of finite presentation over R, and therefore A is almost of finite presentation over $A \otimes_R A$. Using Corollary 5.2.2.2, we deduce that A is almost perfect as a module over $A \otimes_R A$. To prove that A is perfect over $A \otimes_R A$, it will suffice to show that A has finite Tor-amplitude over $A \otimes_R A$ (Proposition HA.7.2.4.23). Choose a finite collection of elements $x_1, \ldots, x_d \in \pi_0 A$ which generate $\pi_0 A$ as a commutative algebra over $\pi_0 R$. We will show that A has Tor-amplitude $\leqslant d$ over $A \otimes_R A$. Using Proposition **??**, we are reduced to proving that for every algebraically closed field κ and every morphism $\theta : A \otimes_R A \to \kappa$, the tensor product $B = A \otimes_{A \otimes_R A} \kappa$ is d-truncated. After replacing R by κ, we can identify θ with a pair of morphisms $\phi_0, \phi_1 : A \to \kappa$ in CAlg_κ, and B with the pushout $\kappa \otimes_A \kappa$. To verify that B is d-truncated, it will suffice to show that κ has Tor-amplitude $\leqslant d$ when regarded as an A-module (via either ϕ_0). Let $\mathfrak{m}$ denote the maximal ideal of A given by the kernel of ϕ_0. Since f is fiber smooth, the ring $A_\mathfrak{m}$ is regular, so that κ has Tor-amplitude n as a module over $A_\mathfrak{m}$, where n is the Krull dimension of A_κ. The inequality $n \leqslant d$ follows from the fact that A is generated by $\leqslant d$ elements as a commutative algebra over κ.

Now suppose that $f : R \to A$ is a morphism of $\mathbb{E}_\infty$-rings which satisfies conditions (1), (2), and (3); we wish to show that f is fiber smooth. Using Propositions **??** and 11.2.3.6, we are reduced to proving that for every algebraically closed field κ and every morphism $R \to \kappa$, the tensor product $\kappa \otimes_R A$ is discrete and regular. Replacing R by κ, we may suppose that A is almost of finite presentation over κ (and therefore Noetherian) and d-truncated for some integer d. To prove that A is discrete and regular, it suffices to show that the localization $A_\mathfrak{m}$ is discrete and regular, for every maximal ideal $\mathfrak{m} \subseteq \pi_0 A$. Since κ is algebraically closed, the residue field $\pi_0 A/\mathfrak{m}$ is isomorphic to κ and is therefore dualizable when regarded as a κ-module. Since A is smooth as an object of Alg_κ, it follows that $(\pi_0 A)/\mathfrak{m}$ is also dualizable as an A-module (Proposition HA.4.6.4.12). The desired result now follows from Lemma 11.3.3.3. □

11.3.4 Smooth Quasi-Coherent Stacks

The condition of smoothness can be tested locally with respect to the étale topology:

Proposition 11.3.4.1. *Let R be an $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a stable R-linear ∞-category. Suppose that there exists a finite collection of étale maps $R \to R_\alpha$ such that $\prod_\alpha R_\alpha$ is faithfully flat over R, and each of the ∞-categories $R_\alpha \otimes_R \mathcal{C}$ is smooth over R_α. Then $\mathcal{C}$ is smooth over R.*

Proof. It follows from Proposition **??** that the ∞-category $\mathcal{C}$ is compactly generated. Let $c : \mathrm{Sp} \to {}^\vee\mathcal{C} \otimes_R \mathcal{C}$ be as in Definition 11.3.1.1; we wish to show that $c(S)$ is a compact object of the R-linear ∞-category $\mathcal{D} = {}^\vee\mathcal{C} \otimes_R \mathcal{C}$. Since each $\mathrm{LMod}_{R_\alpha}(\mathcal{C})$ is smooth over R_α, we conclude that the image of $c(S)$ is compact in each of the ∞-categories $\mathrm{LMod}_{R_\alpha}(\mathcal{D})$. Applying Proposition **??**, we conclude that $c(S)$ itself is compact. □

Corollary 11.3.4.2. *For every $\mathbb{E}_\infty$-ring R, let $\mathrm{LinCat}_R^{\mathrm{sm}}$ denote the full subcategory of $\mathrm{LinCat}_R^{\mathrm{St}}$ spanned by the smooth R-linear ∞-categories. Then the functor $R \mapsto \mathrm{LinCat}_R^{\mathrm{sm}}$ is a sheaf with respect to the étale topology on CAlg_R.*

Proof. Combine Theorem **??** with Proposition 11.3.4.1. □

We now introduce a global version of Definition 11.3.1.1.

Definition 11.3.4.3. Let X be a spectral Deligne-Mumford stack and let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{St}}(\mathsf{X})$ be a quasi-coherent stack on X. We will say that $\mathcal{C}$ is *smooth* if it is stable and, for every map $\eta : \mathrm{Spét}\, R \to \mathsf{X}$, the pullback $\eta^* \mathcal{C} \in \mathrm{LinCat}_R$ is a smooth R-linear ∞-category.

Remark 11.3.4.4. Let $\mathsf{X} \simeq \mathrm{Spét}\, R$ be an affine spectral Deligne-Mumford stack and let $\mathcal{C}$ be a quasi-coherent stack on X. Then $\mathcal{C}$ is smooth (as a quasi-coherent stack on X) if and only if the corresponding stable R-linear ∞-category is stable and smooth over R, in the sense of Definition 11.3.1.1: this follows from Remark 11.3.1.4.

Using Proposition 11.3.4.1, we deduce the following:

Proposition 11.3.4.5. *Let X be a spectral Deligne-Mumford stack and let $\mathcal{C}$ be a quasi-coherent stack on X. Then:*

(1) *Let $f : \mathsf{Y} \to \mathsf{X}$ be any map of spectral Deligne-Mumford stacks. If $\mathcal{C}$ is smooth, then $f^* \mathcal{C} \in \mathrm{QStk}(\mathsf{Y})$ is smooth.*

(2) *Suppose we are given a collection of étale maps $\{f_\alpha : \mathsf{X}_\alpha \to \mathsf{X}\}$ which induce an étale surjection $\coprod_\alpha \mathsf{X}_\alpha \to \mathsf{X}$. If each pullback $f_\alpha^* \mathcal{C} \in \mathrm{QStk}(\mathsf{X}_\alpha)$ is smooth, then $\mathcal{C}$ is smooth.*

Remark 11.3.4.6. Let X be a spectral Deligne-Mumford stack and let $\mathcal{C} \in \mathrm{QStk}^{\mathrm{St}}(\mathsf{X})$ be a stable quasi-coherent stack on X. Assume that $\mathcal{C}$ is compactly generated, so that it is dualizable as an object of the symmetric monoidal ∞-category $\mathrm{QStk}^{\mathrm{St}}(\mathsf{X})$ (see Corollary D.7.7.4). Let $c : \mathcal{Q}_{\mathsf{X}} \to \mathcal{C} \otimes \mathcal{C}^{\vee}$ be a duality datum in the symmetric monoidal ∞-category. $\mathrm{QStk}^{\mathrm{St}}(\mathsf{X})$. Then $\mathcal{C}$ is smooth if and only if c is a compact morphism of quasi-coherent stacks, in the sense of Definition 10.1.3.1.

Combining Remark 11.3.4.6, Theorem 10.2.0.2, and Proposition 10.3.1.14, we obtain the following:

Proposition 11.3.4.7. *Let X be a quasi-compact, quasi-separated spectral algebraic space and let $\mathcal{C}$ be a stable quasi-coherent stack on X, so that $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ is a dualizable $\mathrm{QCoh}(\mathsf{X})$-module of $\mathcal{P}\mathrm{r}^{\mathrm{St}}$ (see Construction 11.1.3.1). Then $\mathcal{C}$ is smooth if and only if the coevaluation functor $c : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{X};\mathcal{C}) \otimes_{\mathrm{QCoh}(\mathsf{X})} \mathrm{QCoh}(\mathsf{X};\mathcal{C})^{\vee}$ preserves compact objects.*

Remark 11.3.4.8. In the situation of Proposition 11.3.4.7, it suffices to show that the functor c carries the structure sheaf $\mathscr{O}_{\mathsf{X}}$ to a compact object of the ∞-category $\mathrm{QCoh}(\mathsf{X};\mathcal{C}) \otimes_{\mathrm{QCoh}(\mathsf{X})} \mathrm{QCoh}(\mathsf{X};\mathcal{C})^{\vee} \simeq \mathrm{QCoh}(\mathsf{X};\mathcal{C} \otimes \mathcal{C}^{\vee})$.

11.3.5 Global Sections of Smooth Quasi-Coherent Stacks

We now establish a local-to-global principle for smooth quasi-coherent stacks.

Proposition 11.3.5.1. *Let R be a connective $\mathbb{E}_{\infty}$-ring, and let X be a spectral algebraic space over R which is quasi-compact, separated, and fiber smooth over R. Let $\mathcal{C}$ be a smooth quasi-coherent stack on X. Then $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ is a smooth R-linear ∞-category.*

The proof of Proposition 11.3.5.1 will require some preliminaries.

Lemma 11.3.5.2. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a fiber smooth morphism of spectral Deligne-Mumford stacks. Then the diagonal map $\delta : \mathsf{X} \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ is locally of finite* Tor*-amplitude.*

Proof. The assertion is local on X and Y; we may therefore assume without loss of generality that $\mathsf{Y} = \mathrm{Sp\acute{e}t}\, R$ and $\mathsf{X} = \mathrm{Sp\acute{e}t}\, A$ are affine. Using Remark 6.1.2.6, we can reduce to the case where R is discrete. Using Proposition 11.2.4.1 (and the fact that the assertion is local on X with respect to the étale topology) we can further reduce to the case where $A = R[x_1, \ldots, x_n]$ is a polynomial ring over R. In this case, we observe that A has Tor-amplitude $\leqslant n$ as a module over $A \otimes_R A$. □

Lemma 11.3.5.3. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a map of spectral Deligne-Mumford stacks which is separated and fiber smooth, and let $\delta : \mathsf{X} \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ be the diagonal map. Then the pushforward functor δ_* carries perfect objects of $\mathrm{QCoh}(\mathsf{X})$ to perfect objects of $\mathrm{QCoh}(\mathsf{X} \times_{\mathsf{Y}} \mathsf{X})$.*

Proof. Since f is separated, δ is a closed immersion, and therefore a proper map. Since f is fiber smooth, it is locally almost of finite presentation, so that δ is also locally almost of finite presentation. Lemma 11.3.5.2 implies that δ is locally of finite Tor-amplitude, so the desired result follows from Theorem 6.1.3.2. □

Proof of Proposition 11.3.5.1. Let $\Gamma : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{Mod}_R$ be the global sections functor. We first claim that Γ exhibits $\mathrm{QCoh}(\mathsf{X})$ as a Frobenius algebra object of LinCat_R: that is, that the canonical map

$$e : \mathrm{QCoh}(\mathsf{X}) \otimes_R \mathrm{QCoh}(\mathsf{X}) \xrightarrow{\otimes} \mathrm{QCoh}(\mathsf{X}) \xrightarrow{\Gamma} \mathrm{Mod}_R$$

is a duality datum in LinCat_R. Since $\mathrm{QCoh}(\mathsf{X})$ is compactly generated, it is dualizable as an R-linear ∞-category (Theorem D.7.0.7). Let us denote its dual by $\mathrm{QCoh}(\mathsf{X})^\vee$, so that we have a duality datum $\overline{e} : \mathrm{QCoh}(\mathsf{X})^\vee \otimes_R \mathrm{QCoh}(\mathsf{X}) \to \mathrm{Mod}_R$. The universal property of $\overline{e}$ implies that e factors as a composition

$$\mathrm{QCoh}(\mathsf{X}) \otimes_R \mathrm{QCoh}(\mathsf{X}) \xrightarrow{u \otimes \mathrm{id}} \mathrm{QCoh}(\mathsf{X})^\vee \otimes_R \mathrm{QCoh}(\mathsf{X}) \xrightarrow{\overline{e}} \mathrm{Mod}_R .$$

We wish to prove that $u : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{X})^\vee$ is an equivalence. According to Remark D.7.7.6, the composite map

$$\mathrm{QCoh}(\mathsf{X})^\vee \otimes \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{X})^\vee \otimes_R \mathrm{QCoh}(\mathsf{X}) \xrightarrow{\overline{e}} \mathrm{Mod}_R \to \mathrm{Sp}$$

is a duality datum in $\mathcal{P}\mathrm{r}^{\mathrm{St}}$. It will therefore suffice to show that

$$\mathrm{QCoh}(\mathsf{X}) \otimes \mathrm{QCoh}(\mathsf{X}) \to \mathrm{QCoh}(\mathsf{X}) \otimes_R \mathrm{QCoh}(\mathsf{X}) \xrightarrow{e} \mathrm{Mod}_R \to \mathrm{Sp}$$

is also a duality datum in $\mathcal{P}\mathrm{r}^{\mathrm{St}}$. This follows from Proposition D.7.5.1, since the ∞-category $\mathrm{QCoh}(\mathsf{X})$ is locally rigid (Corollary **??**).

Set $\mathcal{D} = \mathrm{QCoh}(\mathsf{X}; \mathcal{C})$. Arguing as in Construction 11.1.3.1, we see that $\mathcal{D}$ is dualizable as a module over $\mathrm{QCoh}(\mathsf{X})$. Let $\beta : \mathcal{D}^\vee \otimes_{\mathrm{QCoh}(\mathsf{X})} \mathcal{D} \to \mathrm{QCoh}(\mathsf{X})$ be a duality datum. Applying Corollary HA.4.6.5.14 , we deduce that the composite map

$$\mathcal{D}^\vee \otimes_R \mathcal{D} \xrightarrow{\alpha} \mathcal{D}^\vee \otimes_{\mathrm{QCoh}(\mathsf{X})} \mathcal{D} \xrightarrow{\beta} \mathrm{QCoh}(\mathsf{X}) \xrightarrow{\Gamma} \mathrm{Mod}_R$$

is a duality datum in LinCat_R.

We wish to prove that $\mathcal{D}$ is a smooth R-linear ∞-category. Equivalently, we wish to show that the composition $\gamma \circ \beta \circ \alpha$ is dual to an R-linear functor which preserves compact objects. To prove this, we will show that α, β, and Γ are each R-linear duals of functors which preserve compact objects:

(α) Let $\mathcal{E} = \mathrm{QCoh}(\mathsf{X}) \otimes_R \mathrm{QCoh}(\mathsf{X})$. According to Corollary ??, the canonical map

$$\mathcal{E} \to \mathrm{QCoh}(\mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X})$$

is an equivalence of symmetric monoidal ∞-categories. In particular, $\mathcal{E}$ is locally rigid. Note that α is obtained from a map $\alpha_0 : \mathcal{E} \to \mathrm{QCoh}(\mathsf{X})$ of $\mathcal{E}$-modules by tensoring over $\mathcal{E}$ with $\mathcal{D}^\vee \otimes_R \mathcal{D}$. Since $\mathcal{E}$ is locally rigid, α_0 is a morphism between dualizable $\mathcal{E}$-modules, and therefore admits a $\mathcal{E}$-linear dual $\alpha_0^\vee$. It follows that the dual of α is given by tensoring $\alpha_0^\vee$ over $\mathcal{E}$ with $\mathcal{D}^\vee \otimes_R \mathcal{D}$. Consequently, to show that the dual of α preserves compact objects, it will suffice to show that $\alpha_0^\vee$ preserves compact objects.

Since X is separated, the diagonal map $\delta : \mathsf{X} \to \mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X}$ is a closed immersion, and in particular an affine map. Let $\mathscr{A} \in \mathrm{CAlg}(\mathcal{E})$ denote the direct image of the structure sheaf of X, so that $\mathrm{QCoh}(\mathsf{X}) \simeq \mathrm{LMod}_{\mathscr{A}}(\mathcal{E})$. Then α_0 can be identified with the free module functor from $\mathcal{E}$ to $\mathrm{LMod}_{\mathscr{A}}(\mathcal{E})$. It follows that the dual $\alpha_0^\vee$ can be identified with the forgetful functor $\mathrm{RMod}_{\mathscr{A}}(\mathcal{E}) \to \mathcal{E}$: that is, with the pushforward functor δ_*. Since X is fiber smooth over R, this functor preserves compact objects by Lemma 11.3.5.3.

(β) The stable ∞-category $\mathcal{D}^\vee$ is tensored over $\mathrm{QCoh}(\mathsf{X})$ and can therefore be written as $\mathrm{QCoh}(\mathsf{X}; \mathcal{C}^\vee)$ for some stable quasi-coherent stack $\mathcal{C}^\vee \in \mathrm{QStk}(\mathsf{X})$ (Theorem 10.2.0.2). Since the equivalence of Theorem 10.2.0.2 is symmetric monoidal, the quasi-coherent stack $\mathcal{C}^\vee$ is a dual of $\mathcal{C}$ in $\mathrm{QStk}^{\mathrm{St}}(\mathsf{X})$; in particular, $\mathcal{C}^\vee$ is smooth. Let $c : \mathcal{Q}_{\mathsf{X}} \to \mathcal{C} \otimes \mathcal{C}^\vee$ be the associated coevaluation map, so that β is dual to the map

$$\mathrm{QCoh}(\mathsf{X}) \simeq \mathrm{QCoh}(\mathsf{X}; \mathcal{Q}_{\mathsf{X}}) \to \mathrm{QCoh}(\mathsf{X}; \mathcal{C} \otimes \mathcal{C}^\vee)$$

determined by c. Since $\mathcal{C}$ is smooth, this functor carries perfect objects of $\mathrm{QCoh}(\mathsf{X})$ to locally compact objects of $\mathrm{QCoh}(\mathsf{X}; \mathcal{C} \otimes \mathcal{C}^\vee)$. It follows from Proposition 10.3.2.6 that $\beta^\vee$ preserves compact objects.

(Γ) Since the global sections functor $\Gamma : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{Mod}_R$ exhibits $\mathrm{QCoh}(\mathsf{X})$ as a Frobenius algebra object of LinCat_R, it follows immediately from the definitions that the dual of Γ can be identified with the unit map $\mathrm{Mod}_R \to \mathrm{QCoh}(\mathsf{X})$. Since perfect objects of $\mathrm{QCoh}(\mathsf{X})$ are compact, the dual of Γ preserves compact objects.

□

Remark 11.3.5.4. Let R be a connective $\mathbb{E}_\infty$-ring and suppose that X is a quasi-compact, quasi-separated spectral algebraic space over R. The proof of Proposition 11.3.5.1 shows that the global sections functor $\Gamma : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{Mod}_R$ exhibits X as a Frobenius algebra object of LinCat_R. That is, the composite map

$$\mathrm{QCoh}(\mathsf{X}) \otimes_R \mathrm{QCoh}(\mathsf{X}) \xrightarrow{\otimes} \mathrm{QCoh}(\mathsf{X}) \xrightarrow{\Gamma} \mathrm{Mod}_R$$

is a duality datum in LinCat_R. Using Proposition 2.5.4.5, we see that a compatible coevaluation map is given by the composition

$$\mathrm{Mod}_R \to \mathrm{QCoh}(\mathsf{X}) \xrightarrow{\delta_*} \mathrm{QCoh}(\mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X}) \simeq \mathrm{QCoh}(\mathsf{X}) \otimes_R \mathrm{QCoh}(\mathsf{X})$$

(where $\delta : \mathsf{X} \to \mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X}$ denotes the diagonal map).

Suppose that $f : \mathsf{X} \to \mathsf{Y}$ is a map of quasi-compact, quasi-separated spectral algebraic spaces over R, so that $f^* : \mathrm{QCoh}(\mathsf{Y}) \to \mathrm{QCoh}(\mathsf{X})$ is an R-linear functor. Using the duality data described above, we can identify $\mathrm{QCoh}(\mathsf{X})$ and $\mathrm{QCoh}(\mathsf{Y})$ with their own duals in LinCat_R. Then the dual of f^* is an R-linear functor from $\mathrm{QCoh}(\mathsf{X})$ to $\mathrm{QCoh}(\mathsf{Y})$. Repeatedly using Corollary **??**, we can identify this dual with the composition

$$\begin{aligned} \mathrm{QCoh}(\mathsf{X}) &\xrightarrow{\pi^*} \mathrm{QCoh}(\mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{Y}) \\ &\xrightarrow{\delta_*} \mathrm{QCoh}(\mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{Y} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{Y}) \\ &\xrightarrow{f'^*} \mathrm{QCoh}(\mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{Y}) \\ &\xrightarrow{\delta'^*} \mathrm{QCoh}(\mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{Y}) \\ &\xrightarrow{\pi'_*} \mathrm{QCoh}(\mathsf{Y}) \end{aligned}$$

where π and π' denote the projection maps from $\mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{Y}$ onto the first and second factor, δ and δ' are given by the diagonal embeddings, and f' is the product of f with the identity maps on X and Y. We have a pullback diagram of spectral algebraic spaces

$$\begin{array}{ccc} \mathsf{X} & \xrightarrow{\mathrm{id} \times f} & \mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{Y} \\ \downarrow{\scriptstyle \mathrm{id} \times f} & & \downarrow{\scriptstyle f' \circ \delta'} \\ \mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{Y} & \xrightarrow{\delta} & \mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{Y} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{Y} \end{array}$$

Using Proposition 2.5.4.5, we can identify the dual of f^* with the functor given by composing pullback along the composition $\mathsf{X} \xrightarrow{\mathrm{id} \times f} \mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{Y} \xrightarrow{\pi} \mathsf{X}$ with pushforward along the composition $\mathsf{X} \xrightarrow{\mathrm{id} \times f} \mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{Y} \xrightarrow{\pi'} \mathsf{Y}$. The first composition is given by the identity map from X to itself, and the second agrees with f. It follows that the dual of f^* is given by f_*, as an R-linear functor from $\mathrm{QCoh}(\mathsf{X})$ to $\mathrm{QCoh}(\mathsf{Y})$.

11.3.6 Direct Images of Smooth Quasi-Coherent Stacks

We can now formulate the main result of this section:

Theorem 11.3.6.1. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Assume that f is a quasi-compact, quasi-separated, locally almost of finite presentation, locally of finite* Tor*-amplitude, and a relative spectral algebraic space. Then the following conditions are equivalent:*

(1) *The morphism f is separated and fiber smooth.*

(2) *For every smooth object $\mathcal{C} \in \mathrm{QStk}(\mathsf{X})$, the direct image $f_* \mathcal{C} \in \mathrm{QStk}(\mathsf{Y})$ is smooth.*

(3) *The quasi-coherent stack $f_* \mathcal{Q}_{\mathsf{X}} \in \mathrm{QStk}^{\mathrm{St}}(\mathsf{Y})$ is smooth.*

(4) *Let $\delta : \mathsf{X} \to \mathsf{X} \times_{\mathsf{Y}} \mathsf{X}$ be the diagonal map. Then the direct image $\delta_* \mathscr{O}_{\mathsf{X}}$ is perfect.*

The main content of Theorem 11.3.6.1 is contained in Proposition 11.3.5.1, which we proved in §11.3.5. We will also need the following:

Lemma 11.3.6.2. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a quasi-affine morphism of spectral Deligne-Mumford stacks. Suppose that $f_* \mathscr{O}_{\mathsf{X}}$ is perfect. Then f is affine. Suppose, in addition, that f satisfies the following condition:*

($*$) *For every discrete $\mathbb{E}_\infty$-ring B, the map*

$$\mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, B, \mathsf{X}) \to \mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, B, \mathsf{Y})$$

has (-1)-truncated homotopy fibers.

Then f is a closed immersion.

Proof. The assertion is local on Y. We may therefore assume without loss of generality that $\mathsf{Y} = \mathrm{Sp\acute{e}t}\, R$ is affine. Let us identify $f_* \mathscr{O}_{\mathsf{X}}$ with an object $A \in \mathrm{CAlg}_R$. Assume first that A is perfect; we wish to show that X is affine. According to Proposition **??**, the canonical map $\mathrm{Map}_{\mathrm{SpDM}}(\mathrm{Sp\acute{e}t}\, B, \mathsf{X}) \to \mathrm{Map}_{\mathrm{CAlg}}(A, B)$ is a homotopy equivalence for every connective $\mathbb{E}_\infty$-ring B. It follows that if A is connective, then $\mathsf{X} \simeq \mathrm{Sp\acute{e}t}\, A$ is affine.

Suppose, for a contradiction, that A is not connective. Then there exists an integer $n < 0$ such that $\pi_n A \neq 0$. Since A is perfect, there exists a smallest such integer n. Then $\pi_n A$ is a finitely generated module over $\pi_0 R$. Using Nakayama's lemma, we deduce that there exists a maximal ideal $\mathfrak{m} \subseteq \pi_0 R$ such that $\mathrm{Tor}_0^{\pi_0 R}(\pi_n A, \kappa) \neq 0$, where κ denotes the residue field $(\pi_0 R)/\mathfrak{m}$. Then $\pi_n(A \otimes_R \kappa) \neq 0$. Replacing R by κ, we can reduce to the case where R is a field. In this case, since A is perfect over κ, $\pi_0 A$ is a finite-dimensional vector space over κ. It follows that $|\operatorname{Spec} A|$ is a finite set equipped with the discrete topology. In particular, any open subset of $|\operatorname{Spec} A|$ is also closed. Using Proposition 2.4.1.3, we deduce that X is an open substack of $\mathrm{Sp\acute{e}t}\, A$, and therefore affine. It follows that $A = \Gamma(\mathcal{X}; \mathscr{O}_{\mathsf{X}})$ is connective, contradicting our assumption that $\pi_n A \neq 0$.

Now suppose that ($*$) is satisfied; we wish to show that f is a closed immersion. Since A is perfect and connective as an R-module, $\pi_0 A$ is a finitely generated as a module over $\pi_0 R$. We wish to prove that the unit map $\pi_0 R \to \pi_0 A$ is surjective. Using Nakayama's lemma, we are reduced to proving that the unit map $\kappa \to \mathrm{Tor}_0^{\pi_0 R}(\pi_0 A, \kappa)$ is surjective, for every residue field κ of R. Replacing R by κ, we may suppose that $R = \kappa$. Let $B = \pi_0 A \otimes_\kappa \pi_0 A$. Then

B is a discrete $\mathbb{E}_\infty$-ring, equipped with two R-algebra maps $\phi, \phi' : A \to B$. It follows from $(*)$ that ϕ and ϕ' are homotopic. In particular, for each $x \in \pi_0 A$, we have $x \otimes 1 = 1 \otimes x$ in $\pi_0 A \otimes_\kappa \pi_0 A$, so that x is a scalar multiple of the identity. □

Proof of Theorem 11.3.6.1. The implication (1) ⇒ (2) follows from Proposition 11.3.5.1, and the implication (2) ⇒ (3) is obvious. Assume next that (3) is satisfied; we will prove (4). The assertion is local on Y; we may therefore suppose without loss of generality that $\mathsf{Y} = \operatorname{Spét} R$ is affine. The proof of Proposition 11.3.5.1 shows that the composition

$$\mathrm{QCoh}(\mathsf{X}) \otimes_{\mathrm{Mod}_R} \mathrm{QCoh}(\mathsf{X}) \xrightarrow{\otimes} \mathrm{QCoh}(\mathsf{X}) \xrightarrow{f_*} \mathrm{Mod}_R$$

is a duality datum in LinCat_R. Using Remark 11.3.5.4 and Corollary **??**, we can identify the dual of this map with the composition

$$\mathrm{Mod}_R \xrightarrow{f^*} \mathrm{QCoh}(\mathsf{X}) \xrightarrow{\delta_*} \mathrm{QCoh}(\mathsf{X} \times_{\operatorname{Spét} R} \mathsf{X}).$$

If condition (3) is satisfied, then this functor preserves compact objects. In particular $\delta_* \mathscr{O}_{\mathsf{X}} \simeq \delta_*(f^* R)$ is perfect, so that condition (4) is satisfied.

We now prove that (4) ⇒ (1). Assume that $\delta_* \mathscr{O}_{\mathsf{X}}$ is perfect. It follows from Theorem 3.3.0.2 that δ is quasi-affine, so that Lemma 11.3.6.2 implies that δ is is a closed immersion. This proves that X is separated.

We now prove that f is fiber smooth. The assertion is local on Y; we may therefore assume that $\mathsf{Y} = \operatorname{Spét} R$ is affine. Choose an étale map $u : \operatorname{Spét} A \to \mathsf{X}$; we will prove that A is fiber smooth over R. Form a pullback diagram

$$\begin{array}{ccc} \operatorname{Spét} A \times_{\mathsf{X}} \operatorname{Spét} A & \xrightarrow{\delta'} & \operatorname{Spét} A \times_{\operatorname{Spét} R} \operatorname{Spét} A \\ \downarrow & & \downarrow \\ \mathsf{X} & \longrightarrow & \mathsf{X} \times_{\operatorname{Spét} R} \mathsf{X}. \end{array}$$

Let $\mathscr{O}$ denote the structure sheaf of $\operatorname{Spét} A \times_{\mathsf{X}} \operatorname{Spét} A$. It follows from (3) that $\delta'_* \mathscr{O}$ is perfect when regarded as a module over $A \otimes_R A$. Since u is separated and étale, the diagonal map $\operatorname{Spét} A \to \operatorname{Spét} A \times_{\mathsf{X}} \operatorname{Spét} A$ is a clopen immersion. It follows that $\delta'_* \mathscr{O}$ contains A as a direct summand, so that A is perfect when regarded as a module over $A \otimes_R A$. That is, A is a smooth R-algebra in the sense of Definition HA.4.6.4.13. Since X is assumed to be locally almost of finite presentation and of finite Tor-amplitude over R, Proposition 11.3.3.1 implies that A is fiber smooth over R. □

11.4 Smooth and Proper Linear ∞-Categories

Let Y be a spectral Deligne-Mumford stack. In §11.3 and §11.1 we introduced the notions of smooth and proper quasi-coherent stacks $\mathcal{C} \in \mathrm{QStk}^{\mathrm{St}}(\mathsf{Y})$. In this section, we will study quasi-coherent stacks which possess both of these properties.

Notation 11.4.0.1. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor and let $\mathrm{QStk}^{\mathrm{St}}(X)$ be the ∞-category of stable quasi-coherent stacks on X. We let $\mathrm{QStk}^{\mathrm{cg}}(X)$ denote the full subcategory of $\mathrm{QStk}^{\mathrm{St}}(X)$ whose objects are compactly generated stable quasi-coherent stacks (Definition 10.3.1.3) and whose morphisms are compact morphisms of quasi-coherent stacks (Definition 10.1.3.1). It follows from Lemma D.5.3.3 that the subcategory $\mathrm{QStk}^{\mathrm{cg}}(X) \subseteq \mathrm{QStk}^{\mathrm{St}}(X)$ is closed under the tensor product of Proposition 10.1.6.4, and therefore inherits the structure of a symmetric monoidal ∞-category.

Proposition 11.4.0.2. *Let X be a spectral Deligne-Mumford stack. Then a stable quasi-coherent stack $\mathcal{C} \in \mathrm{QStk}^{\mathrm{St}}(\mathsf{X})$ is smooth and proper if and only if it is a dualizable object of the symmetric monoidal ∞-category $\mathrm{QStk}^{\mathrm{cg}}(\mathsf{X})$.*

Proof. It follows from Theorem D.7.0.7 that $\mathcal{C}$ is dualizable as an object of the larger symmetric monoidal ∞-category $\mathrm{QStk}^{\mathrm{St}}(\mathsf{X})$: that is, there exists a stable quasi-coherent stack $\mathcal{C}^\vee$ on X and compatible maps

$$e : \mathcal{C}^\vee \otimes \mathcal{C} \to \mathcal{Q}_{\mathsf{X}} \qquad c : \mathcal{Q}_{\mathsf{X}} \to \mathcal{C} \otimes \mathcal{C}^\vee$$

which exhibit $\mathcal{C}^\vee$ as a dual of $\mathcal{C}$. Note that $\mathcal{C}^\vee$ is compactly generated (Remark D.7.7.6). It follows from Proposition 11.1.3.3 and Remark 11.3.4.6 that the maps c and e are compact if and only if $\mathcal{C}$ is smooth and proper. □

Our main goal is to give a proof of the following result:

Theorem 11.4.0.3. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Assume that f is quasi-compact, quasi-separated, and that $\mathrm{Sp\acute{e}t}\, R \times_{\mathsf{Y}} \mathsf{X}$ is a spectral algebraic space for every map $\mathrm{Sp\acute{e}t}\, R \to \mathsf{Y}$. The following conditions are equivalent:*

(1) *The morphism f is proper and fiber smooth.*

(2) *The functor $f_* : \mathrm{QStk}^{\mathrm{St}}(\mathsf{X}) \to \mathrm{QStk}^{\mathrm{St}}(\mathsf{Y})$ carries smooth objects of $\mathrm{QStk}^{\mathrm{St}}(\mathsf{X})$ to smooth objects of $\mathrm{QStk}^{\mathrm{St}}(\mathsf{Y})$ and proper objects of $\mathrm{QStk}^{\mathrm{St}}(\mathsf{X})$ to proper objects of $\mathrm{QStk}^{\mathrm{St}}(\mathsf{Y})$.*

(3) *The functor $f_* : \mathrm{QStk}^{\mathrm{cg}}(\mathsf{X}) \to \mathrm{QStk}^{\mathrm{cg}}(\mathsf{Y})$ carries dualizable objects of $\mathrm{QStk}^{\mathrm{cg}}(\mathsf{X})$ to dualizable objects of $\mathrm{QStk}^{\mathrm{cg}}(\mathsf{Y})$, where $\mathrm{QStk}^{\mathrm{cg}}(\mathsf{X})$ and $\mathrm{QStk}^{\mathrm{cg}}(\mathsf{Y})$ are defined as in Notation 11.4.0.1.*

(4) *The quasi-coherent stack $f_* \mathcal{Q}_{\mathsf{X}} \in \mathrm{QStk}^{\mathrm{St}}(\mathsf{Y})$ is smooth and proper.*

The implication (1) ⇒ (2) of Theorem 11.4.0.3 follows from Propositions 11.3.5.1 and 11.1.4.2, and the implications (2) ⇒ (3) ⇒ (4) follow from Proposition 11.4.0.2. It will therefore suffice to show that (4) ⇒ (1). This is a consequence of Theorem 11.4.2.1, which we will prove in §11.4.2.

11.4.1 Digression: Compactness Conditions on Associative Algebras

We now collect some auxiliary results (Propositions 11.4.1.1 and 11.4.1.3) which will be needed to complete our proof of Theorem 11.4.0.3.

Proposition 11.4.1.1. *Let R be a connective $\mathbb{E}_\infty$-ring, and let $A \in \mathrm{CAlg}^{\mathrm{cn}}_R$. Suppose that A is almost compact when viewed as an object of $\mathrm{Alg}^{\mathrm{cn}}_R$: that is, for every integer $n \geqslant 0$, the truncation $\tau_{\leqslant n} A$ is a compact object of $\tau_{\leqslant n} \mathrm{Alg}^{\mathrm{cn}}_R$. Then A is almost of finite presentation over R.*

Lemma 11.4.1.2. *Let R be a connective $\mathbb{E}_\infty$-ring, and suppose that $A, B \in \mathrm{Alg}^{\mathrm{cn}}_R$ are almost compact. Then the tensor product $A \otimes_R B \in \mathrm{Alg}^{\mathrm{cn}}_R$ is almost compact.*

Proof. Write A as a filtered colimit $\varinjlim A_\alpha$ of compact objects of $\mathrm{Alg}^{\mathrm{cn}}_R$, and similarly write B as a filtered colimit $\varinjlim B_\beta$. We wish to show that, for each $n \geqslant 0$, the tensor product $\tau_{\leqslant n}(A \otimes_R B)$ is a compact object of $\tau_{\leqslant n} \mathrm{Alg}^{\mathrm{cn}}_R$. Since $\tau_{\leqslant n} A$ is a compact object of $\tau_{\leqslant n} \mathrm{Alg}^{\mathrm{cn}}_R$, the equivalence $\tau_{\leqslant n} A \simeq \varinjlim_\alpha (\tau_{\leqslant n} A_\alpha)$ guarantees that $\tau_{\leqslant n} A$ is a retract of $\tau_{\leqslant n} A_\alpha$, for some index α. Similarly, $\tau_{\leqslant n} B$ is a retract of some $\tau_{\leqslant n} B_\beta$. Then $\tau_{\leqslant n}(A \otimes_R B) \simeq \tau_{\leqslant n}(\tau_{\leqslant n} A \otimes_R \tau_{\leqslant n} B)$ is a retract of $\tau_{\leqslant n}(A_\alpha \otimes_R B_\alpha) \simeq \tau_{\leqslant n}(\tau_{\leqslant n} A_\alpha \otimes_R \tau_{\leqslant n} B_\beta)$. We may therefore replace A by A_α and B by B_β, and thereby reduce to the case where A and B are compact. In this case, the desired result follows from Corollary HA.5.3.1.17 . □

Proof of Proposition 11.4.1.1. Let $\mathcal{C} = \tau_{\leqslant n} \mathrm{Alg}^{\mathrm{cn}}_R$. We will regard $\mathcal{C}$ as a symmetric monoidal ∞-category, so that we have equivalences $\mathrm{CAlg}(\mathcal{C}) \simeq \tau_{\leqslant n} \mathrm{CAlg}(\mathrm{Alg}^{\mathrm{cn}}_R) \simeq \tau_{\leqslant n} \mathrm{CAlg}^{\mathrm{cn}}_R$. It will therefore suffice to show that $\tau_{\leqslant n} A$ is compact when regarded as a commutative algebra object of $\mathcal{C}$. Since A is almost compact as an object of $\mathrm{Alg}^{\mathrm{cn}}_R$, Lemma 11.4.1.2 implies that each $\tau_{\leqslant n} A^{\otimes m}$ is compact as an object of $\mathcal{C}$. The desired result now follows from Lemma 5.2.2.6. □

Proposition 11.4.1.3. *Let X be a quasi-compact, quasi-separated spectral algebraic space over a connective $\mathbb{E}_\infty$-ring R, let $u : \mathsf{U} \to \mathsf{X}$ be a map which is affine and étale. For each $B \in \mathrm{Alg}_R$, let $T(B)$ denote the full subcategory of $\mathrm{LMod}_B(\mathrm{QCoh}(\mathsf{U}))$ spanned by those objects $\mathscr{F}$ such that $u_* \mathscr{F}$ is compact as an object of $\mathrm{LMod}_B(\mathrm{QCoh}(\mathsf{X}))$. Then the construction $B \mapsto T(B)^{\simeq}$ determines a functor $\mathrm{Alg}_R \to \mathcal{S}$ which commutes with filtered colimits.*

Lemma 11.4.1.4. *Let $\phi : R \to A$ be an étale morphism of $\mathbb{E}_\infty$-rings. Then A is compact when viewed as an object of Alg_R.*

Proof. Let $L^{(1)}_A$ denote the cotangent complex of A regarded as an associative algebra object of Alg_R, so that $L^{(1)}_A$ is an object of $\mathrm{Sp}((\mathrm{Alg}_R)_{/A}) \simeq {}_A\mathrm{BMod}_A(R)$. Theorem HA.7.3.5.1 supplies a fiber sequence $L^{(1)}_A \to A \otimes_R A \to A$. Since A is étale over R, this sequence splits, so that $L^{(1)}_A$ can be regarded as a direct summand of $A \otimes_R A$.

For every object $B \in \mathrm{Alg}_R^{\mathrm{cn}}$ and every integer $n > 0$, we can regard $\tau_{\leqslant n} B$ as a square-zero extension of $\tau_{\leqslant n-1} B$ by $\Sigma^n(\pi_n B)$ (Theorem HA.7.4.1.23), so that we have a fiber sequence of spaces

$$\mathrm{Map}_{\mathrm{Alg}_R}(A, \tau_{\leqslant n} B) \xrightarrow{\phi} \mathrm{Map}_{\mathrm{Alg}_R}(A, \tau_{\leqslant n-1} B) \to \mathrm{Map}_{{}_A\mathrm{BMod}_A(\mathrm{Mod}_R)}(L_A^{(1)}, \Sigma^{n+1}\pi_n B).$$

Since $L_A^{(1)}$ is a direct summand of $A \otimes_R A$, the space $\mathrm{Map}_{{}_A\mathrm{BMod}_A(\mathrm{Mod}_R)}(L_A^{(1)}, \Sigma^{n+1}\pi_n B)$ is a direct factor of an Eilenberg-MacLane space $K(\pi_n B, n+1)$. It follows that the map ϕ has n-connective homotopy fibers. Since $\mathrm{Map}_{\mathrm{Alg}_R}(A, B)$ can be identified with the homotopy limit of the tower

$$\cdots \to \mathrm{Map}_{\mathrm{Alg}_R}(A, \tau_{\leqslant 2} B) \to \mathrm{Map}_{\mathrm{Alg}_R}(A, \tau_{\leqslant 1} B) \to \mathrm{Map}_{\mathrm{Alg}_R}(A, \tau_{\leqslant 0} B),$$

we conclude that each of the maps $\mathrm{Map}_{\mathrm{Alg}_R}(A, B) \to \mathrm{Map}_{\mathrm{Alg}_R}(A, \tau_{\leqslant n} B)$ has $(n+1)$-connective homotopy fibers, and therefore induces a homotopy equivalence

$$\tau_{\leqslant n} \mathrm{Map}_{\mathrm{Alg}_R}(A, B) \to \tau_{\leqslant n} \mathrm{Map}_{\mathrm{Alg}_R}(A, \tau_{\leqslant n} B).$$

Now suppose that we are given a filtered diagram $\{B_\alpha\}$ in Alg_R having colimit B; we wish to show that the induced map

$$\theta : \varinjlim \mathrm{Map}_{\mathrm{Alg}_R}(A, B_\alpha) \to \mathrm{Map}_{\mathrm{Alg}_R}(A, B)$$

is a homotopy equivalence. Without loss of generality, we may assume that each B_α is connective. It will suffice to show that for each $m \geqslant 0$, the map

$$\varinjlim \tau_{\leqslant m} \mathrm{Map}_{\mathrm{Alg}_R}(A, B_\alpha) \to \tau_{\leqslant m} \mathrm{Map}_{\mathrm{Alg}_R}(A, B)$$

is a homotopy equivalence. We may therefore replace each B_α by $\tau_{\leqslant m} B_\alpha$, and thereby reduce to the case where there exists an integer $n = 0$ such that each B_α is n-truncated.

We now proceed by induction on n. In the case $n = 0$, each B_α is discrete. The desired result is therefore equivalent to the fact that $\pi_0 A$ is finitely presented when regarded as an associative algebra over $\pi_0 R$. Let us therefore assume that $n > 0$. We have a diagram of fiber sequences

$$\begin{array}{ccc}
\varinjlim \mathrm{Map}_{\mathrm{Alg}_R}(A, B_\alpha) & \xrightarrow{\theta} & \mathrm{Map}_{\mathrm{Alg}_R}(A, B) \\
\downarrow & & \downarrow \\
\varinjlim \mathrm{Map}_{\mathrm{Alg}_R}(A, \tau_{\leqslant n-1} B_\alpha) & \xrightarrow{\theta'} & \mathrm{Map}_{\mathrm{Alg}_R}(A, \tau_{\leqslant n-1} B) \\
\downarrow & & \downarrow \\
\varinjlim \mathrm{Map}_{{}_A\mathrm{BMod}_A(\mathrm{Mod}_R)}(L_A^{(1)}, \Sigma^{n+1}\pi_n B_\alpha) & \xrightarrow{\theta''} & \mathrm{Map}_{{}_A\mathrm{BMod}_A(\mathrm{Mod}_R)}(L_A^{(1)}, \Sigma^{n+1}\pi_n B).
\end{array}$$

The inductive hypothesis implies that θ' is a homotopy equivalence. Consequently, to show that θ is a homotopy equivalence, it suffices to show that θ'' is a homotopy equivalence. This follows from the observation that $L^{(1)}_A$ is a direct summand of $A \otimes_R A$, and therefore a compact object of ${}_A\mathrm{BMod}_A(\mathrm{Mod}_R)$. □

Proof of Proposition 11.4.1.3. Let $u : \mathsf{U} \to \mathsf{X}$ be an affine étale morphism between quasi-compact, quasi-separated spectral algebraic spaces over R. Write $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$. For each $U \in \mathcal{X}$, let $\mathsf{X}_U = (\mathcal{X}_{/U}, \mathscr{O}_{\mathsf{X}}|_U)$, let U_U denote the fiber product $\mathsf{X}_U \times_{\mathsf{X}} \mathsf{U}$. Let $T_U : \mathrm{Alg}_R \to \mathcal{C}\mathrm{at}_\infty$ be the functor which assigns to each $B \in \mathrm{Alg}_R$ the full subcategory of $\mathrm{LMod}_B(\mathrm{QCoh}(\mathsf{U}_U))$ spanned by those objects whose direct image in $\mathrm{LMod}_B(\mathsf{X}_U)$ is locally compact (when viewed as section over the quasi-coherent stack given by $V \mapsto \mathrm{LMod}_B(\mathrm{QCoh}(\mathsf{X}_V))$). The construction $U \mapsto T_U(B)^{\simeq}$ carries colimits in $\mathcal{X}$ to limits of ∞-categories. Let $\mathcal{X}_0$ denote the full subcategory of $\mathcal{X}$ spanned by those objects U for which the functor $B \mapsto T_U(B)^{\simeq}$ preserves filtered colimits. Then $\mathcal{X}_0$ is closed under finite colimits in $\mathcal{X}$. We wish to show that $\mathcal{X}_0$ contains the final object of $\mathcal{X}$. Note that X admits a scallop decomposition (Theorem 3.4.2.1). Using Corollary 2.5.3.6, we are reduced to proving that $\mathcal{X}_0$ contains all affine objects $U \in \mathcal{X}$. Replacing X by X_U, we may reduce to the case where X is affine. Replacing R by the $\mathbb{E}_\infty$-ring of global sections of the structure sheaf of X if necessary, we may suppose that $\mathsf{X} = \mathrm{Sp\acute{e}t}\, R$. In this case, we can write $\mathsf{U} = \mathrm{Sp\acute{e}t}\, A$, where A is étale over R.

Suppose we are given a diagram $\{B_\alpha\}$ in Alg_R which is indexed by a filtered partially ordered sets and having colimit B. We have a commutative diagram of spaces

$$\begin{array}{ccc} \varinjlim T(B_\alpha)^{\simeq} & \longrightarrow & T(B)^{\simeq} \\ \downarrow & & \downarrow \\ \varinjlim (\mathrm{LMod}^{\mathrm{perf}}_{B_\alpha})^{\simeq} & \longrightarrow & (\mathrm{LMod}^{\mathrm{perf}}_{B})^{\simeq}, \end{array}$$

where the bottom horizontal map is a homotopy equivalence by virtue of Proposition HA.4.6.3.11 . To show that the top horizontal map is a homotopy equivalence, it will suffice to show that it induces a homotopy equivalence after passing to the homotopy fibers of the vertical maps over any point $\eta \in \varinjlim (\mathrm{LMod}^{\mathrm{perf}}_{B_\alpha})^{\simeq}$, represented by an index α and a perfect left B_α-module M_α. For each $\beta \geqslant \alpha$, let $M_\beta = A_\beta \otimes_{A_\alpha} M_\alpha$, and let $M = B \otimes_{B_\alpha} M_\alpha$. Unwinding the definitions, we are reduced to proving that the map

$$\theta : \varinjlim_{\beta \geqslant \alpha} {}_{B_\beta}\mathrm{BMod}_A(\mathrm{Mod}_R) \times_{\mathrm{LMod}_{B_\beta}} \{M_\beta\} \to {}_B\mathrm{BMod}_A(\mathrm{Mod}_R) \times_{\mathrm{LMod}_B} \{M\}$$

is a homotopy equivalence.

For each $\beta \geqslant \alpha$, let $E_\beta \in \mathrm{Alg}_R$ denote the endomorphism algebra of M_β (where we regard M_β as an object of the R-linear ∞-category LMod_{B_β}, and let $E \in \mathrm{Alg}_R$ denote the endomorphism algebra of M. Using Corollary HA.4.7.1.40 , we can identify θ with the canonical map

$$\varinjlim_{\beta \geqslant \alpha} \mathrm{Map}_{\mathrm{Alg}_R}(A, E_\beta) \to \mathrm{Map}_{\mathrm{Alg}_R}(A, E).$$

It follows from Proposition HA.4.6.3.11 that the natural map $\varinjlim_{\beta \geqslant \alpha} E_\beta \to E$ is an equivalence in Alg_R. We now conclude by observing that A is compact as an object of Alg_R (Lemma 11.4.1.4). □

11.4.2 The Proof of Theorem 11.4.0.3

We now complete the proof of Theorem 11.4.0.3 by establishing the following:

Theorem 11.4.2.1. *Let $f : \mathsf{X} \to \mathrm{Sp\acute{e}t}\, R$ be a morphism of quasi-compact, quasi-separated spectral algebraic spaces. If* $\mathrm{QCoh}(\mathsf{X})$ *is smooth and proper as an R-linear ∞-category, then the morphism f is proper and fiber smooth.*

Proof. Since $\mathrm{QCoh}(\mathsf{X})$ is a smooth R-linear ∞-category, the proof of Theorem 11.3.6.1 shows that pushforward along the diagonal map $\delta : \mathsf{X} \to \mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X}$ carries the structure sheaf of X to a perfect quasi-coherent sheaf on $\mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X}$. Lemma 11.3.6.2 implies that δ is a closed immersion, so that X is separated. Suppose, for the moment, that f is locally almost of finite presentation. Since $\mathrm{QCoh}(\mathsf{X})$ is a proper R-linear ∞-category, Theorem 11.1.4.1 guarantees that f is proper and has Tor-amplitude $\leqslant n$, for some integer n. Applying Theorem 11.3.6.1, we deduce that f is fiber smooth, thereby completing the proof of Theorem 11.4.2.1.

It remains to prove that f is locally almost of finite presentation. Choose an étale map $u : \mathrm{Sp\acute{e}t}\, A \to \mathsf{X}$. We wish to prove that A is locally almost of finite presentation over R. By virtue of Proposition 11.4.1.1, it will suffice to show that A is compact when regarded as an object of Alg_R.

For every morphism $\phi : A \to B$ in Alg_R, we can regard B as an object of the ∞-category ${}_B\mathrm{BMod}_A(\mathrm{Mod}_R) \simeq \mathrm{LMod}_B(\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A))$. Let $\mathscr{F}_\phi \in \mathrm{LMod}_B(\mathrm{QCoh}(\mathsf{X}))$ denote the image of this object under the pushforward functor u_*. We claim that $\mathscr{F}_\phi$ is a compact object of $\mathrm{LMod}_B(\mathrm{QCoh}(\mathsf{X}))$. To prove this, it will suffice (by Theorem **??**) to show that for every étale map $v : \mathrm{Sp\acute{e}t}\, A' \to \mathsf{X}$, the pullback $v^* \mathscr{F}_\phi$ is a compact object of $\mathrm{LMod}_B(\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A')) \simeq {}_B\mathrm{BMod}_{A'}(\mathrm{Mod}_R)$. Since X is separated, we can write $\mathrm{Sp\acute{e}t}\, A' \times_{\mathsf{X}} \mathrm{Sp\acute{e}t}\, A$ as $\mathrm{Sp\acute{e}t}\, A''$, for some $A'' \in \mathrm{Mod}_R$. Unwinding the definitions, we can identify $v^* \mathscr{F}_\phi$ with the tensor product $B \otimes_A A''$. Since δ_* carries the structure sheaf of X to a perfect object of $\mathrm{QCoh}(\mathsf{X} \times_{\mathrm{Sp\acute{e}t}\, R} \mathsf{X})$, the $\mathbb{E}_\infty$-ring A'' is perfect when regarded as a module over $A \otimes_R A'$, so that $B \otimes_A A''$ is perfect when regarded as a module over $B \otimes_R A'$.

For every algebra object $B \in \mathrm{Alg}_R$, let $\mathcal{C}_B$ denote the full subcategory of

$${}_B\mathrm{BMod}_A(\mathrm{Mod}_R) \simeq \mathrm{LMod}_B(\mathrm{QCoh}(\mathrm{Sp\acute{e}t}\, A))$$

spanned by those objects have compact image in $\mathrm{LMod}_B(\mathrm{QCoh}(\mathsf{X}))$ under the pushforward functor u_*. Since $\mathrm{QCoh}(\mathsf{X})$ is proper, the global sections functor $\Gamma : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{Mod}_R$ preserves compact objects, so that the induced functor $\Gamma_B : \mathrm{LMod}_B(\mathrm{QCoh}(\mathsf{X})) \simeq \mathrm{LMod}_B \otimes_{\mathrm{Mod}_R} \mathrm{QCoh}(\mathsf{X}) \to \mathrm{LMod}_B$ also preserves compact objects. It follows that the composite functor

$$_B\mathrm{BMod}_A(\mathrm{Mod}_R) \xrightarrow{u_*} \mathrm{LMod}_B(\mathrm{QCoh}(\mathsf{X})) \xrightarrow{\Gamma_B} \mathrm{LMod}_B$$

carries $\mathcal{C}_B$ into $\mathrm{LMod}_B^{\mathrm{perf}}$. Applying Corollary HA.4.8.5.6 , we see that the construction

$$(\phi : A \to B) \mapsto \mathscr{F}_\phi$$

induces a homotopy equivalence of Kan complexes

$$\mathrm{Map}_{\mathrm{Alg}_R}(A, B) \to \mathcal{C}_B^{\simeq} \times_{\mathrm{LMod}_B^{\mathrm{perf}}} \{B\}.$$

According to Proposition HA.4.6.3.11 , the construction $B \mapsto \mathrm{LMod}_B^{\mathrm{perf}}$ commutes with filtered colimits. To prove that A is compact as an object of Alg_R, it will suffice to show that the construction $B \mapsto \mathcal{C}_B^{\simeq}$ also preserves filtered colimits, which follows from Proposition 11.4.1.3. □

11.4.3 Variant: Dualizability and Affineness

Let R be an $\mathbb{E}_\infty$-ring and let X be a quasi-compact, quasi-separated spectral algebraic space over R. According to Theorem 11.4.2.1 Proposition 11.4.0.2, the spectral algebraic space X is proper and fiber smooth over R if and only if $\mathrm{QCoh}(\mathsf{X})$ is dualizable as an object of the ∞-category of compactly generated stable R-linear ∞-categories (whose morphisms are functors which preserve small colimits and compact objects). We now consider a variant of this result, where we focus our attention on the *prestable* R-linear ∞-category $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$:

Theorem 11.4.3.1. *Let $f : \mathsf{X} \to \mathsf{Y}$ be a morphism of spectral Deligne-Mumford stacks. Assume that f is quasi-compact, quasi-separated, and that* $\mathrm{Sp\acute{e}t}\, R \times_{\mathsf{Y}} \mathsf{X}$ *is a spectral algebraic space for every map* $\mathrm{Sp\acute{e}t}\, R \to \mathsf{Y}$*. The following conditions are equivalent:*

(1) *The morphism f is affine.*

(2) *The pushforward functor $f_* : \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}) \to \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{Y})$ (see Corollary 10.3.2.3) carries dualizable objects of* $\mathrm{QStk}(\mathsf{X})$ *to dualizable objects of* $\mathrm{QStk}(\mathsf{Y})$*.*

(3) *The quasi-coherent stack $f_* \mathcal{Q}_{\mathsf{X}}^{\mathrm{cn}} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{Y})$ is a dualizable object of* $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{Y})$*.*

We will deduce Theorem 11.4.3.2 from Serre's affineness criterion (Proposition 9.6.5.1) together with following observation:

Remark 11.4.3.2. Let R be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a prestable R-linear ∞-category. Then the forgetful functor $\mathrm{Mod}_R^{\mathrm{cn}} \to \mathrm{Sp}^{\mathrm{cn}}$ exhibits $\mathrm{Mod}_R^{\mathrm{cn}}$ as a symmetric Frobenius algebra object of the symmetric monoidal ∞-category $\mathrm{Mod}_{\mathrm{Sp}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ (see Remark HA.4.6.5.7). It follows that $\mathcal{C}$ is dualizable as an object $\mathrm{Mod}_{\mathrm{Mod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ if and only if it is dualizable as an object of $\mathrm{Mod}_{\mathrm{Sp}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$. Moreover, if these conditions are satisfied, then the dual of $\mathcal{C}$ as an object of $\mathrm{Mod}_{\mathrm{Mod}_R^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ is equivalent to the dual of $\mathcal{C}$ as an object of $\mathrm{Mod}_{\mathrm{Sp}^{\mathrm{cn}}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$. It follows that $\mathcal{C}$ is dualizable in $\mathrm{LinCat}_R^{\mathrm{PSt}}$ if and only if it is dualizable in Groth_∞.

Proof of Theorem 11.4.3.1. We first show that (1) implies (2). Assume that $f : \mathsf{X} \to \mathsf{Y}$ is affine and that $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ is dualizable; we wish to show that $f_* \mathcal{C}$ is dualizable in $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{Y})$. To prove this, we can work locally on Y and thereby reduce to the case where $\mathsf{Y} \simeq \mathrm{Spét}\, A$ is affine. In this case, our assumption that f is affine guarantees that $\mathsf{X} \simeq \mathrm{Spét}\, B$ is also affine. In this case, $\mathcal{C}$ with a B-linear prestable ∞-category. By assumption, $\mathcal{C}$ admits a dual in the ∞-category $\mathrm{LinCat}_B^{\mathrm{PSt}}$ and we wish to show that the image of $\mathcal{C}$ in $\mathrm{LinCat}_A^{\mathrm{PSt}}$ is also dualizable. This follows from Remark 11.4.3.2: both conditions are equivalent to the requirement that $\mathcal{C}$ is dualizable as an object of Groth_∞.

The implication (2) ⇒ (3) is tautological. To prove that (3) ⇒ (1), we can again reduce to the case where $\mathsf{Y} \simeq \mathrm{Spét}\, R$ is affine. We will prove that X is also affine by verifying that the global sections functor $\Gamma(\mathsf{X}; \bullet) : \mathrm{QCoh}(\mathsf{X}) \to \mathrm{Sp}$ is t-exact (see Proposition 9.6.5.1).

Condition (3) guarantees that $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ admits a dual in the ∞-category $\mathrm{LinCat}_R^{\mathrm{PSt}}$. Applying Remark 11.4.3.2, we deduce that $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ is dualizable as an object of Groth_∞. Then we can choose a Grothendieck prestable ∞-category $\mathcal{C}$ and (compatible) functors

$$e : \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \otimes \mathcal{C} \to \mathrm{Sp}^{\mathrm{cn}} \qquad c : \mathrm{Sp}^{\mathrm{cn}} \to \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \otimes \mathcal{C}$$

which exhibit $\mathcal{C}$ as a dual of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ in the ∞-category Groth_∞. Since the stabilization functor $\mathrm{Sp}(\bullet) : \mathsf{Groth}_\infty \to \mathcal{P}\mathrm{r}^{\mathrm{St}}$ is symmetric monoidal, the induced maps

$$\mathrm{Sp}(e) : \mathrm{QCoh}(\mathsf{X}) \otimes \mathrm{Sp}(\mathcal{C}) \to \mathrm{Sp} \qquad \mathrm{Sp}(c) : \mathrm{Sp} \to \mathrm{QCoh}(\mathsf{X}) \otimes \mathrm{Sp}(\mathcal{C})$$

exhibit $\mathrm{Sp}(\mathcal{C})$ as the dual of $\mathrm{QCoh}(\mathsf{X})$ as a presentable stable ∞-category. Since X is a quasi-compact, quasi-separated spectral algebraic space, the monoidal stable ∞-category $\mathrm{QCoh}(\mathsf{X})$ is locally rigid. Applying Proposition **??**, we deduce that the composite functor

$$e' : \mathrm{QCoh}(\mathsf{X}) \otimes \mathrm{QCoh}(\mathsf{X}) \xrightarrow{\otimes} \mathrm{QCoh}(\mathsf{X}) \xrightarrow{\Gamma(\mathsf{X};\bullet)} \to \mathrm{Sp}$$

exhibits $\mathrm{QCoh}(\mathsf{X})$ as a dual of itself in $\mathcal{P}\mathrm{r}^{\mathrm{St}}$. We can therefore choose an equivalence $\alpha : \mathrm{Sp}(\mathcal{C}) \simeq \mathrm{QCoh}(\mathsf{X})$ for which the functor $\mathrm{Sp}(c)$ is given by

$$\mathrm{QCoh}(\mathsf{X}) \otimes \mathrm{Sp}(\mathcal{C}) \xrightarrow{\alpha} \mathrm{QCoh}(\mathsf{X}) \otimes \mathrm{QCoh}(\mathsf{X}) \xrightarrow{\otimes} \mathrm{QCoh}(\mathsf{X}) \xrightarrow{\Gamma(\mathsf{X};\bullet)} \mathrm{Sp}\,.$$

Let us identify $\mathcal{C}$ with a full subcategory of $\mathrm{QCoh}(\mathsf{X})$ via the fully faithful embedding $\mathcal{C} \xrightarrow{\Sigma^\infty} \mathrm{Sp}(\mathcal{C}) \xrightarrow{\alpha} \mathrm{QCoh}(\mathsf{X})$. Using the commutativity of the diagram

$$\begin{array}{ccc} \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \otimes \mathcal{C} & \xrightarrow{e} & \mathrm{Sp}^{\mathrm{cn}} \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{X}) \otimes \mathrm{QCoh}(\mathsf{X}) & \xrightarrow{e'} & \mathrm{Sp}, \end{array}$$

we deduce that the spectrum $\Gamma(\mathsf{X}; \mathscr{F} \otimes \mathscr{G})$ is connective whenever $\mathscr{F} \in \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ and $\mathscr{G} \in \mathcal{C}$. Consequently, to prove that $\Gamma(\mathsf{X}; \bullet)$ is right t-exact, it will suffice to show that the structure sheaf $\mathscr{O}_{\mathsf{X}}$ of X is contained in $\mathcal{C}$. Since $\Gamma(\mathsf{X}; \bullet)$ is automatically left t-exact, this will complete the proof of (c).

Note that the action of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ on itself induces an action of $\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}$ on its dual $\mathcal{C}$. Using the equivalence $\mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X}) \simeq \mathrm{Mod}_{\mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}}}(\mathsf{Groth}_\infty)$ of Theorem 10.2.0.2, we can write $\mathcal{C} = \mathrm{QCoh}(\mathsf{X}; \mathcal{E})$ for some prestable quasi-coherent stack $\mathcal{E} \in \mathrm{QStk}^{\mathrm{PSt}}(\mathsf{X})$ whose stabilization is $\mathcal{Q}_{\mathsf{X}}$. To show that $\mathscr{O}_{\mathsf{X}}$ belongs to $\mathcal{C}$, it will suffice to show that the unit map $\mathcal{Q}_{\mathsf{X}}^{\mathrm{cn}} \to \mathcal{Q}_{\mathsf{X}}$ factors through $\mathcal{E}$. This assertion is local on X: it amounts to the assertion that, for every étale map $\eta : \mathsf{U} \to \mathsf{X}$ where $\mathsf{U} = (\mathcal{U}, \mathscr{O}_{\mathsf{U}})$ is affine, the structure sheaf $\mathscr{O}_{\mathsf{U}}$ belongs to the essential image of the inclusion $\mathcal{E}_\eta \subseteq (\mathcal{Q}_{\mathsf{X}})_\eta \simeq \mathrm{QCoh}(\mathsf{U})$. Let $q_{\mathsf{U}} : \mathsf{U} \times \mathsf{U} \to \mathsf{U}$ denote the projection onto the first factor. Since $\mathsf{U} \simeq \mathrm{Spét}\, A$ is affine, the direct image functor $q_{\mathsf{U}*} : \mathrm{QCoh}(\mathsf{U} \times \mathsf{U}) \to \mathrm{QCoh}(\mathsf{U})$ carries the full subcategory

$$\mathrm{LMod}_A(\mathcal{E}_\eta) \simeq \mathcal{E}_\eta \otimes \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \subseteq \mathrm{QCoh}(\mathsf{U}) \otimes \mathrm{QCoh}(\mathsf{U}) \simeq \mathrm{QCoh}(\mathsf{U} \times \mathsf{U})$$

into $\mathcal{E}_\eta \subseteq \mathrm{QCoh}(\mathsf{U})$.

Write $\mathsf{U} \times_{\mathsf{X}} \mathsf{U} = (\mathcal{Y}, \mathscr{O}_{\mathsf{Y}})$ so that the diagonal map $\delta : \mathsf{U} \to \mathsf{U} \times \mathsf{U}$ factors as a composition $\mathsf{U} \xrightarrow{\delta'} (\mathcal{Y}, \mathscr{O}_{\mathsf{Y}}) \xrightarrow{\delta''} \mathsf{U} \times \mathsf{U}$. Since η is étale and separated, the diagonal map δ' is a clopen immersion so that $\delta'_* \mathscr{O}_{\mathsf{U}}$ is a direct summand of $\mathscr{O}_{\mathsf{Y}}$. It follows that $\mathscr{O}_{\mathsf{Y}} \simeq q_{\mathsf{U}*} \delta_* \mathscr{O}_{\mathsf{U}} \simeq q_{\mathsf{U}*} \delta''_* \delta'_* \mathscr{O}_{\mathsf{U}}$ is a direct summand of $q_{\mathsf{U}*} \delta'_* \mathscr{O}_{\mathsf{Y}}$. We are therefore reduced to proving that $\delta'_* \mathscr{O}_{\mathsf{Y}} \in \mathrm{QCoh}(\mathsf{U} \times \mathsf{U})$ belongs to the essential image of the inclusion $\mathcal{E}_\eta \otimes \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \hookrightarrow \mathrm{QCoh}(\mathsf{U} \times \mathsf{U})$. Note that we can identify $\delta'_* \mathscr{O}_{\mathsf{Y}}$ with the pullback $(\eta \times \eta)^* \epsilon_* \mathscr{O}_{\mathsf{X}}$, where $\epsilon : \mathsf{X} \to \mathsf{X} \times \mathsf{X}$ is the diagonal map of X. Using the commutativity of the diagram

$$\begin{array}{ccc} \mathcal{C} \otimes \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} & \longrightarrow & \mathcal{E}_\eta \otimes \mathrm{QCoh}(\mathsf{U})^{\mathrm{cn}} \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(\mathsf{X} \times \mathsf{X}) & \xrightarrow{(\eta \times \eta)^*} & \mathrm{QCoh}(\mathsf{U} \times \mathsf{U}), \end{array}$$

we see that it will suffice to show that $\epsilon_* \mathscr{O}_{\mathsf{X}}$ belongs to the essential image of the inclusion $\mathcal{C} \otimes \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \hookrightarrow \mathrm{QCoh}(\mathsf{X} \times \mathsf{X})$. The evaluation map $e' : \mathrm{QCoh}(\mathsf{X}) \otimes \mathrm{QCoh}(\mathsf{X}) \to \mathrm{Sp}$ admits a compatible coevaluation $c' : \mathrm{Sp} \to \mathrm{QCoh}(\mathsf{X}) \otimes \mathrm{QCoh}(\mathsf{X}) \simeq \mathrm{QCoh}(\mathsf{X} \times \mathsf{X})$, which carries the sphere spectrum S to the sheaf $\epsilon_* \mathscr{O}_{\mathsf{X}}$. The desired result now follows from the commutativity of the diagram

$$\begin{array}{ccc} \mathrm{Sp}^{\mathrm{cn}} & \xrightarrow{c} & \mathrm{QCoh}(\mathsf{X})^{\mathrm{cn}} \otimes \mathcal{C} \\ \downarrow & & \downarrow \\ \mathrm{Sp} & \xrightarrow{c'} & \mathrm{QCoh}(\mathsf{X}) \otimes \mathrm{QCoh}(\mathsf{X}). \end{array}$$

□

11.4.4 Deforming Objects of R-Linear ∞-Categories

We conclude this section with some convergence results concerning the deformation theory of objects of smooth and proper R-linear ∞-categories. In what follows, if $\mathcal{C}$ is a compactly generated stable R-linear ∞-category and A is an $\mathbb{E}_1$-algebra over R, we let $\mathrm{LMod}_A(\mathcal{C})^c$ denote the full subcategory of $\mathrm{LMod}_A(\mathcal{C}) \simeq \mathrm{LMod}_A \otimes_{\mathrm{Mod}_R} \mathcal{C}$ spanned by the compact objects. Our goal is to prove the following:

Theorem 11.4.4.1. *Let R be the limit of a tower of $\mathbb{E}_\infty$-rings*

$$\cdots \to R_2 \to R_1 \to R_0$$

satisfying the following conditions:

(1) *Each R_n is connective.*

(2) *Each of the maps $R_n \to R_{n-1}$ induces a surjection of commutative rings $\pi_0 R_n \to \pi_0 R_{n-1}$, whose kernel is a nilpotent ideal in $\pi_0 R_n$.*

(3) *The canonical map $\pi_0 R \to \lim^0\{\pi_0 R_n\}$ is an isomorphism. Equivalently, the abelian group $\lim^1\{\pi_1 R_n\}$ vanishes.*

Let $\mathcal{C}$ be a compactly generated stable R-linear ∞-category. If $\mathcal{C}$ is proper, then the canonical map $\theta : \mathcal{C}^c \to \varprojlim \mathrm{LMod}_{R_n}(\mathcal{C})^c$ is fully faithful. If $\mathcal{C}$ is smooth and proper, then θ is an equivalence of ∞-categories.

Example 11.4.4.2. Let R be an arbitrary connective $\mathbb{E}_\infty$-ring. Then the Postnikov tower

$$\cdots \to \tau_{\leqslant 2} R \to \tau_{\leqslant 1} R \to \tau_{\leqslant 0} R$$

satisfies the hypotheses of Theorem 11.4.4.1. It follows that for every smooth and proper R-linear ∞-category $\mathcal{C}$, the canonical map $\mathcal{C}^c \to \varprojlim \mathrm{LMod}_{\tau_{\leqslant n} R}(\mathcal{C})^c$ is an equivalence of ∞-categories.

Example 11.4.4.3. Let R be a Noetherian commutative ring which is complete with respect to an ideal $I \subseteq R$. Then the tower

$$\cdots \to R/I^3 \to R/I^2 \to R/I$$

satisfies the hypotheses of Theorem 11.4.4.1. It follows that for every smooth and proper R-linear ∞-category $\mathcal{C}$, the canonical map $\mathcal{C}^c \to \varprojlim \mathrm{LMod}_{R/I^n}(\mathcal{C})^c$ is an equivalence of ∞-categories.

Example 11.4.4.4. Let R be a commutative ring, let p be a prime number which vanishes in R, and let $W(R)$ denote the ring of (p-typical) Witt vectors of R. Then $W(R)$ is the limit of a tower of commutative rings

$$\cdots \to W_3(R) \to W_2(R) \to W_1(R) \simeq R$$

which satisfies the hypotheses of Theorem 11.4.4.1. It follows that if $\mathcal{C}$ is a smooth and proper $W(R)$-linear ∞-category, then the canonical map $\mathcal{C}^c \to \varprojlim \mathrm{LMod}_{W_n(R)}(\mathcal{C})^c$ is an equivalence of ∞-categories.

We begin by proving Theorem 11.4.4.1 in the special case $\mathcal{C} = \mathrm{Mod}_R$.

Lemma 11.4.4.5. *Let R be an associative ring, let $I \subseteq R$ be a nilpotent two-sided ideal, and let e be an endomorphism of the left R-module $(R/I)^k$ such that $e = e^2$. Then e can be lifted to an endomorphism $\overline{e}$ of R^k satisfying $\overline{e}^2 = \overline{e}$.*

Proof. Without loss of generality, we may suppose that $I^2 = 0$. Let e' be an arbitrary endomorphism of R^k lifting e, so that $e'^2 = e' + q$, where q is an endomorphism of R^k whose image belongs to I^k. Then $e'^2 + e'q = e'^3 = e'^2 + qe'$, so that $qe' = e'q$. Using this, a simple calculation shows that $\overline{e} = e' + q - 2e'q$ has the desired property. □

Lemma 11.4.4.6. *Let R be the limit of a tower of $\mathbb{E}_1$-rings*

$$\cdots \to R_2 \to R_1 \to R_0$$

satisfying the following conditions:

(1) *Each R_n is connective.*

(2) *Each of the maps $R_n \to R_{n-1}$ induces a surjection of associative rings $\pi_0 R_n \to \pi_0 R_{n-1}$, whose kernel is a nilpotent ideal in $\pi_0 R_n$.*

Then the canonical map $F : \mathrm{LMod}_R^{\mathrm{perf}} \to \varprojlim \mathrm{LMod}_{R_n}^{\mathrm{perf}}$ is an equivalence of ∞-categories.

Proof. Let $\mathcal{C}$ denote the inverse limit $\varprojlim \mathrm{LMod}^{\mathrm{perf}}_{R_n}$. We will identify objects of $\mathcal{C}$ with inverse systems $\vec{M} = \{M_n \in \mathrm{LMod}^{\mathrm{perf}}_{R_n}\}_{n \geqslant 0}$ satisfying $R_{n-1} \otimes_{R_n} M_n \simeq M_{n-1}$ for $n > 0$. Let us say that such an inverse system $\vec{M}$ is *connective* if M_0 is connective.

We define a functor $G : \mathcal{C} \to \mathrm{Mod}_R$ by the formula $G(\vec{M}) = \varprojlim M_n$. Note that G is a right adjoint to F, in the sense that we have homotopy equivalences

$$\mathrm{Map}_{\mathrm{LMod}_R}(N, G(\vec{M})) \simeq \mathrm{Map}_{\mathcal{C}}(F(N), \vec{M})$$

depending functorially on $\vec{M} \in \mathcal{C}$, $N \in \mathrm{LMod}^{\mathrm{perf}}_R$. Moreover, if $N \in \mathrm{LMod}_R$ is perfect, then the unit map $N \to (G \circ F)(N)$ can be identified with the tensor product of N with the natural map $R \to \varprojlim R_n$, and is therefore an equivalence. It follows that the functor F is fully faithful.

We next claim that if $\vec{M} \in \mathcal{C}$ is connective, then each M_n is a connective module over R_n. Suppose otherwise: then there exists some smallest integer $m < 0$ such that $\pi_m M_n \neq 0$. Then we have an isomorphism $\mathrm{Tor}^{\pi_0 R_n}_0(\pi_0 R_0, \pi_m M_n) \simeq \pi_m M_0 \simeq 0$. Since the map $\pi_0 R_n \to \pi_0 R_0$ is a surjection with nilpotent kernel, we obtain a contradiction.

It follows that if $\vec{M} \in \mathcal{C}$ is connective, then the inverse system

$$\cdots \to \pi_0 M_2 \to \pi_0 M_1 \to \pi_0 M_0$$

consists of surjective maps. It follows that for any projective left R-module P, the maps

$$\cdots \to \mathrm{Map}_{\mathrm{LMod}_R}(P, M_2) \to \mathrm{Map}_{\mathrm{LMod}_R}(P, M_1) \to \mathrm{Map}_{\mathrm{LMod}_R}(P, M_0)$$

are surjective on connected components, so that any map of R-modules $P \to M_0$ can be lifted to a map $F(P) \to \vec{M}$ in the ∞-category $\mathcal{C}$.

We now prove that the functor F is essentially surjective. Fix an object $\vec{M} \in \mathcal{C}$; we wish to show that $\vec{M}$ belongs to the essential image of F. Replacing $\vec{M}$ by a suspension if necessary, we may suppose that $\vec{M}$ is connective. Since M_0 is perfect as a left module over R_0, it has Tor-amplitude $\leqslant k$ for some integer $k \geqslant 0$. We proceed by induction on k. Suppose first that $k > 0$. Since M_0 is perfect and connective, $\pi_0 M_0$ is finitely generated as a module over $\pi_0 R_0$. We may therefore choose a map of left R-modules $R^k \to M_0$ which induces a surjection on π_0. Using the preceding arguments, we can lift this to a map $\alpha : F(R^k) \to \vec{M}$ in the ∞-category $\mathcal{C}$. Consequently, to show that $\vec{M}$ belongs to the essential of F, it will suffice to show that $\mathrm{fib}(\alpha)$ belongs to the essential image of F. This follows from the inductive hypothesis, since $\mathrm{fib}(\alpha)$ is connective and has Tor-amplitude $\leqslant k - 1$.

It remains to treat the case where $k = 0$: that is, the case where M_0 is a finitely generated projective module over R_0. In particular, we can write $\pi_0 M_0$ as the image of an idempotent endomorphism e_0 of $(\pi_0 R_0)^k$, for some integer k. Applying Lemma 11.4.4.5 repeatedly, we lift e_0 to idempotent endomorphisms e_n of $(\pi_0 R_n)^k$, for each integer $n \geqslant 0$. The inverse system $\{e_n\}_{n \geqslant 0}$ determines an idempotent endomorphism of A^k, where $A = \varprojlim \pi_0 R_n$. Note that the map $\pi_0 R \to A$ is a surjection, whose kernel I can be identified with $\lim^1\{\pi_1 R_n\}$. The action of $\pi_0 R$ on I factors through A, so that I is nilpotent. Using Lemma 11.4.4.5 again, we can lift $\{e_n\}_{n \geqslant 0}$ to an idempotent endomorphism e of $(\pi_0 R)^k$, whose image P_0 is a projective left module of finite rank over $\pi_0 R$. Applying Corollary HA.7.2.2.19 , we can lift P_0 to a projective left R-module P of finite rank. By construction, we have a a map of R-modules $P \to M_0$, which we can lift to a map $\beta : F(P) \to \vec{M}$. Replacing $\vec{M}$ by $\mathrm{cofib}(\beta)$, we can reduce to the case where $M_0 \simeq 0$. Then $\Sigma^k \vec{M}$ is a connective object of $\mathcal{C}$ for each integer k. It follows that $\Sigma^k M_n$ is a connective left R_n-module for every integer k, so that each M_n is zero and $\vec{M} \simeq 0$ belongs to the essential image of F, as desired. □

Proof of Theorem 11.4.4.1. We first show that canonical map $\theta : \mathcal{C}^c \to \varprojlim_n \mathrm{LMod}_{R_n}(\mathcal{C})^c$ is fully faithful. Let $X, Y \in \mathcal{C}$ be compact objects. Unwinding the definitions, we wish to show that θ induces a homotopy equivalence

$$\Omega^\infty \underline{\mathrm{Map}}_{\mathcal{C}}(X, Y) \to \varprojlim \Omega^\infty \underline{\mathrm{Map}}_{\mathrm{LMod}_{R_n}(\mathcal{C})}(R_n \otimes X, R_n \otimes Y).$$

In fact, we claim that the map

$$\phi : \underline{\mathrm{Map}}_{\mathcal{C}}(X, Y) \to \varprojlim \underline{\mathrm{Map}}_{\mathrm{LMod}_{R_n}(\mathcal{C})}(R_n \otimes X, R_n \otimes Y) \simeq \varprojlim \underline{\mathrm{Map}}_{\mathcal{C}}(X, R_n \otimes Y)$$

is an equivalence of R-modules. Since $X \in \mathcal{C}$ is compact, we can identify ϕ with the canonical map $R \otimes_R \underline{\mathrm{Map}}_{\mathcal{C}}(X, Y) \to \varprojlim(R_n \otimes_R \underline{\mathrm{Map}}_{\mathcal{C}}(X, Y))$. Since $\mathcal{C}$ is proper, $\underline{\mathrm{Map}}_{\mathcal{C}}(X, Y)$ is a perfect R-module, so tensor product with $\underline{\mathrm{Map}}_{\mathcal{C}}(X, Y)$ commutes with limits. We are therefore reduced to proving that the canonical map $R \to \varprojlim R_n$ is an equivalence, which is true by hypothesis.

We now prove that θ is essentially surjective. Since $\mathcal{C}$ is a smooth R-linear ∞-category, we can write $\mathcal{C} \simeq \mathrm{RMod}_A$ for some smooth $\mathbb{E}_1$-algebra A over R (Proposition 11.3.2.4). It follows from Proposition 11.1.0.2 that A is also a proper $\mathbb{E}_1$-algebra over R, so that an object of $\mathcal{C} \simeq \mathrm{RMod}_A$ is compact if and only if its image in Mod_R is compact. We therefore have a commutative diagram

$$\begin{array}{ccc} \mathcal{C}^c & \xrightarrow{\theta} & \varprojlim \mathrm{LMod}_{\tau_{\leqslant n} R}(\mathcal{C})^c \\ \downarrow & & \downarrow \\ \mathrm{Mod}_R^{\mathrm{perf}} & \xrightarrow{\theta'} & \varprojlim_n \mathrm{Mod}^{\mathrm{perf}}_{\tau_{\leqslant n} R} . \end{array}$$

The map θ' is an equivalence of ∞-categories by Lemma 11.4.4.6. Consequently, to prove that θ is essentially surjective, it will suffice to show that θ induces an essentially surjective map

$$\phi : \mathcal{C}^c \times_{\mathrm{Mod}_R^{\mathrm{perf}}} \{M\} \to (\varprojlim \mathrm{LMod}_{R_n}(\mathcal{C})^c) \times_{\varprojlim_n \mathrm{Mod}_{R_n}^{\mathrm{perf}}} \{M\}$$

for every perfect R-module M. Using Theorem HA.4.7.1.34, we can identify ϕ with the canonical map

$$\begin{aligned} \mathrm{Map}_{\mathrm{Alg}_R}(A^{\mathrm{rev}}, \mathrm{End}(M)) &\rightarrow \varprojlim \mathrm{Map}_{\mathrm{Alg}_{R_n}}(R_n \otimes_R A^{\mathrm{rev}}, \mathrm{End}(R_n \otimes_R M)) \\ &\simeq \varprojlim \mathrm{Map}_{\mathrm{Alg}_R}(A^{\mathrm{rev}}, R_n \otimes \mathrm{End}(M)). \end{aligned}$$

To prove that this map is a homotopy equivalence, it suffices to observe that the canonical map $\mathrm{End}(M) \to \varprojlim(R_n \otimes_R \mathrm{End}(M))$ is an equivalence. Since $\mathrm{End}(M)$ is a perfect R-module, this again follows from our assumption that the map $R \to \varprojlim R_n$ is an equivalence. □

11.5 Brauer Groups in Spectral Algebraic Geometry

For every associative ring A, we let $\mathfrak{Z}(A)$ denote the center of A (that is, the subalgebra consisting of those elements $a \in A$ such that $ab = ba$ for all $b \in A$). Recall that a *division algebra* is a nonzero associative ring A such that every nonzero element $a \in A$ is invertible.

Let κ be a field. A *central division algebra* over κ is a division algebra A equipped with an isomorphism $\iota : \kappa \simeq \mathfrak{Z}(A)$ which exhibits A as a finite-dimensional vector space over κ. Let $\mathrm{Br}(\kappa)$ denote the set of isomorphism classes of central division algebras over κ. We refer to $\mathrm{Br}(\kappa)$ as the *Brauer group* of the field κ. It is naturally endowed with the structure of an abelian group, whose multiplication is characterized by the following requirement:

(∗) Let A, B, and C be central division algebras over κ and denote their isomorphism classes by $[A], [B], [C] \in \mathrm{Br}(\kappa)$. Then $[A][B] = [C]$ if and only if there is a κ-linear algebra isomorphism $A \otimes_\kappa B \simeq M_n(C)$; here $M_n(C)$ denotes the algebra of n-by-n matrices over C.

The theory of the Brauer group was extended to the setting of arbitrary commutative rings by Auslander and Goldman ([9]), following earlier work of Azumaya in the case of local commutative rings ([10]). It was generalized further by Grothendieck, who associated a Brauer group to an arbitrary scheme X ([91]). In fact, there are at least two natural candidates for such an extension:

- The *Brauer-Grothendieck group* $\mathrm{Br}_{\mathsf{Groth}}(X)$, whose elements are isomorphism classes of quasi-coherent sheaves of Azumaya algebras on X.

- The *cohomological Brauer group* $\mathrm{Br}_{\mathrm{coh}}(X)$, given by the étale cohomology group $\mathrm{H}^2_{\text{ét}}(X; \mathbf{G}_m)$.

These groups are related as follows:

(a) For any scheme X, there is a canonical monomorphism $\rho : \mathrm{Br}_{\mathsf{Groth}}(X) \hookrightarrow \mathrm{Br}_{\mathrm{coh}}(X)$.

(*b*) If X is a quasi-compact separated scheme equipped with an ample line bundle $\mathscr{L}$, then a theorem of Gabber asserts that the image of ρ is the torsion subgroup of $\mathrm{Br}_{\mathrm{coh}}(X)$ (see [47]).

(*c*) If X is a regular Noetherian scheme, then the cohomological Brauer group $\mathrm{Br}_{\mathrm{coh}}(X)$ is a torsion group.

In general, the map ρ need not be an isomorphism: that is, a general element $\alpha \in \mathrm{H}^2_{\text{ét}}(X; \mathbf{G}_m)$ need not be representable by an Azumaya algebra on X. To address this point, Toën introduced a mild enlargement of the cohomological Brauer group $\mathrm{Br}_{\mathrm{coh}}(X)$, which we will refer to here as the *extended Brauer group* and denote by $\mathrm{Br}^{\dagger}(X)$. This group admits three different descriptions:

(*i*) For any scheme X, the extended Brauer group $\mathrm{Br}^{\dagger}(X)$ can be defined as the group of equivalence classes of stable quasi-coherent stacks on X (in the sense of Chapter 10) which are invertible and compactly generated.

(*ii*) For any scheme X, the extended Brauer group $\mathrm{Br}^{\dagger}(X)$ admits a cohomological interpretation: it is canonically isomorphic to the Cartesian product $\mathrm{H}^2_{\text{ét}}(X; \mathbf{G}_m) \times \mathrm{H}^1_{\text{ét}}(X; \mathbf{Z})$. In particular, if the group $\mathrm{H}^1_{\text{ét}}(X; \mathbf{Z})$ vanishes (for example, if X is a normal Noetherian scheme), then the extended Brauer group $\mathrm{Br}^{\dagger}(X)$ agrees with the cohomological Brauer group $\mathrm{Br}_{\mathrm{coh}}(X)$.

(*iii*) If X is quasi-compact and quasi-separated, then $\mathrm{Br}^{\dagger}(X)$ can be defined as the group of equivalence classes of *derived Azumaya algebras* on X (see Definition 11.5.3.1).

In [211], Toën proved the equivalence of (*i*), (*ii*), and (*iii*) in the setting of derived algebraic geometry (based on simplicial commutative rings). His results were generalized to the setting of spectral algebraic geometry (based on $\mathbb{E}_\infty$-rings) by Antieau-Gepner (see [2]). In this section, we give an overview of the work of Antieau-Gepner and discuss an analogue of the equivalence of (*i*) and (*ii*) for the (non-extended) cohomological Brauer group (see Theorem 11.5.7.11 and the accompanying discussion).

11.5.1 The Brauer Group of a Field

We begin by reviewing the classical theory of the Brauer group in the case of a field.

Definition 11.5.1.1. Let κ be a field and let $A \in \mathrm{Alg}^{\heartsuit}_{\kappa}$ be an associative algebra over κ. We will say that A is *central simple* if it satisfies the following conditions:

(*i*) The structural map $\kappa \to \mathfrak{Z}(A)$ is an isomorphism (that is, κ is the center of A).

(*ii*) The algebra A is finite-dimensional as a vector space over κ.

(*iii*) The algebra A is simple: that is, any nonzero two-sided ideal $I \subseteq A$ is equal to A.

Definition 11.5.1.1 admits several convenient reformulations:

Proposition 11.5.1.2. *Let κ be a field and let A be an associative algebra over κ. The following conditions are equivalent:*

(1) *The algebra A is central simple over κ.*

(2) *There exists an isomorphism $A \simeq M_k(D)$, where D is a central division algebra over κ and $M_k(D)$ denotes the algebra of k-by-k matrices over D.*

Proof. We first show that (1) implies (2). Assume that A is central simple over κ. Then A is nonzero and is finite-dimensional as a vector space over κ. Let $I \subseteq A$ be a nonzero right ideal whose dimension over κ is minimal. Choose a collection of elements $\{a_1, \ldots, a_k\}$ which is maximal among those for which each $a_i I$ is nonzero and the collection of right ideals $\{a_i I\}_{1 \leqslant i \leqslant k}$ is linearly independent over κ. Set $J = a_1 I + \cdots + a_k I$. Then J is a nonzero right ideal of A. For each element $b \in A$, the maximality of $\{a_1, \ldots, a_k\}$ implies that either $bI = 0$ or $bI \cap J \neq 0$. In the latter case, we have $\dim_\kappa(bI \cap J) \leqslant \dim_\kappa(bI) \leqslant \dim_\kappa(I)$. The minimality of $\dim_\kappa(I)$ then guarantees that equality must hold, so that $bI \subseteq J$. Allowing b to vary, we deduce that J is also a left ideal of A. Our assumption that A is simple then guarantees that $J = A$.

Note that for $1 \leqslant i \leqslant k$, right multiplication by a_i determines a surjective A-module homomorphism $\alpha_i : I \to a_i I$. We then have $0 < \dim_\kappa(a_i I) \leqslant \dim_\kappa(I)$, so the minimality of I guarantees that α_i is an isomorphism. Consequently, the homomorphisms $\{\alpha_i\}_{1 \leqslant i \leqslant k}$ induce a right A-module isomorphism $\alpha : I^k \to A$. We can therefore identify A with the endomorphism ring of I^k as a right A-module, which is given by $M_k(D)$ where D is the endomorphism ring of I as a right A-module.

Note that if $f : I \to I$ is a nonzero element of D, then $\mathrm{im}(f)$ is a nonzero right ideal of A which is contained in I. It follows from the minimality of $\dim_\kappa(I)$ that $\mathrm{im}(f) = I$: that is, the map f is surjective. Since I is finite-dimensional as a vector space over κ, it follows that f is bijective: that is, it is an invertible element of D. This proves that D is a division algebra, and the isomorphism $\mathfrak{Z}(A) \simeq \mathfrak{Z}(M_k(D)) \simeq \mathfrak{Z}(D)$ shows that D is central over κ. This completes the proof of the implication (1) $\Rightarrow$ (2).

We now show that (2) $\Rightarrow$ (1). Suppose that we are given an isomorphism $A \simeq M_k(D)$, where D is a central division algebra over κ. It is then clear that $\mathfrak{Z}(A) \simeq \mathfrak{Z}(M_k(D)) \simeq \mathfrak{Z}(D) \simeq \kappa$ and that A is finite-dimensional as a vector space over κ. To complete the proof, it will suffice to show that A is central. Let us identify A with the endomorphism ring $\mathrm{End}_D(V)$, where V is a right D-module with basis $\{v_1, \ldots, v_k\}$. Let $I \subseteq A$ be a nonzero two-sided ideal; we wish to show that $I = A$. Choose elements $f \in I$ and $x \in V$ such that

$f(x) \neq 0$. For $w \in V$ and $1 \leqslant i \leqslant k$, we can choose elements $g_w, h_i \in A$ such that

$$g_w(f(x)) = w \qquad h_i(v_j) = \begin{cases} x & \text{if } i = j \\ 0 & \text{otherwise.} \end{cases}.$$

Then for any $f' \in A$, we have $f' = \sum_{1 \leqslant i \leqslant k} g_{f'(v_i)} \circ f \circ h_i \in I$. □

Remark 11.5.1.3. In the situation of Proposition 11.5.1.2, the division algebra D is well-defined up to isomorphism: it can be recovered as the endomorphism ring of any simple right A-module.

Proposition 11.5.1.4. *Let κ be a field and let A and B be central simple algebras over κ. Then $A \otimes_\kappa B$ is also a central simple algebra over κ.*

Proof. Let x be an element of the center $\mathfrak{Z}(A \otimes_\kappa B)$. Choose a representation $x = a_1 \otimes b_1 + \cdots + a_n \otimes b_n$ where n is minimal, so that the set $\{b_1, \ldots, b_n\}$ is linearly independent over κ. For each $a \in A$, we have

$$0 = ax - xa = \sum (aa_i - a_i a) \otimes b_i.$$

The linear independence of the set $\{b_1, \ldots, b_n\}$ then implies that we must have $aa_i = a_i a$. Allowing a to vary, we deduce that each a_i belongs to the center $\mathfrak{Z}(A) \simeq \kappa$. It follows that x belongs to $\mathfrak{Z}(A) \otimes_\kappa B \simeq B$. Since $\mathfrak{Z}(B) \simeq \kappa$, we deduce that x is a scalar.

It is clear that $A \otimes_\kappa B$ is finite-dimensional as a vector space over κ. To complete the proof, it will suffice to show that every nonzero two-sided ideal $I \subseteq A \otimes_\kappa B$ coincides with $A \otimes_\kappa B$. To prove this, choose a nonzero element $x = a_1 \otimes b_1 + \cdots + a_n \otimes b_n \in I$ where n is chosen as small as possible. Then $a_1 \neq 0$. Our assumption that A is simple guarantees that we can write $1 = \sum a'_j a_1 a''_j$ for some elements $a'_j, a''_j \in A$. Replacing x by $\sum a'_j x a''_j$, we can assume that $a_1 = 1$. For each $a \in A$, we then have

$$ax - xa = (aa_2 - a_2 a) \otimes b_2 + \cdots + (aa_n - a_n a) \otimes b_n \in I.$$

It follows from the minimality of n (and the linear independence of $\{b_2, \ldots, b_n\}$) that we have $aa_i - a_i a = 0$ for each i. Using our assumption that A is central over κ, we conclude that each a_i belongs to κ. The linear independence of $\{a_1, \ldots, a_n\}$ then implies that $n = 1$: that is, the element x has the form $1 \otimes b$ for some nonzero element $b \in B$. The simplicity of B then gives $B = BbB$, so that $I = A \otimes_\kappa B$. □

Proposition 11.5.1.5. *Let κ be a field and let A be an associative algebra over κ which is nonzero and finite-dimensional as a vector space over κ. The following conditions are equivalent:*

(1) *The algebra A is central simple over κ.*

(2) *The left and right actions of A on itself induce an isomorphism $\rho : A \otimes_\kappa A^{\mathrm{rev}} \to \mathrm{End}_\kappa(A)$; here A^{rev} denotes the opposite algebra of A.*

Proof. Suppose first that (1) is satisfied. It follows from Proposition 11.5.1.4 that $A \otimes_\kappa A^{\mathrm{rev}}$ is a central simple algebra over κ. Consequently, the two-sided ideal $\ker(\rho) \subseteq A \otimes_\kappa A^{\mathrm{rev}}$ must be zero, so that ρ is injective. Since the domain and codomain of ρ are vector spaces of the same (finite) dimension over κ, the map ρ is an isomorphism.

Now suppose that (2) is satisfied. An element $x \in A$ belongs to the center $\mathfrak{Z}(A)$ if and only if $\rho(x \otimes 1 - 1 \otimes x) = 0$. Since ρ is injective, we then conclude that $x \otimes 1 - 1 \otimes x$ vanishes in $A \otimes_\kappa A^{\mathrm{rev}}$, so that x belongs to κ. To complete the proof, it will suffice to show that A is simple. Let $I \subseteq A$ be a two-sided ideal. Then $\mathrm{im}(\rho)$ is contained in the subspace of $\mathrm{End}_\kappa(A)$ consisting of those maps $f : A \to A$ satisfying $f(I) = I$. Since ρ is surjective, it follows that I is stable under every endomorphism of A as a κ-vector space, so that either $I = 0$ or $I = A$. □

Proposition 11.5.1.6. *Let κ be a field and let A and B be central simple algebras over κ. The following conditions are equivalent:*

(1) *There is a central division algebra D over κ and isomorphisms $A \simeq M_m(D)$ and $B \simeq M_n(D)$ for $m, n \geqslant 1$.*

(2) *The tensor product $A \otimes_\kappa B^{\mathrm{rev}}$ is isomorphic to a matrix algebra over κ.*

Proof. To show that $(1) = (2)$, we may assume without loss of generality that $m = n$, in which case the desired result follows immediately from Proposition 11.5.1.5. For the converse, we may assume that $A = M_m(D)$ and $B = M_n(D')$ for some central division algebras $D, D' \in \mathrm{Alg}_\kappa^\heartsuit$ (Proposition 11.5.1.2). Proposition 11.5.1.4 guarantees that $D \otimes_\kappa D'^{\mathrm{rev}}$ is central simple over κ, and is therefore isomorphic to $M_d(D'')$ for some central division algebra D'' over κ. We then have $A \otimes_\kappa B^{\mathrm{rev}} \simeq M_{dmn}(D'')$, so condition (2) guarantees that $D'' \simeq \kappa$. We then have an isomorphism $\rho : D \otimes_\kappa D'^{\mathrm{rev}} \simeq \mathrm{End}_\kappa(V)$ where V is a vector space of dimension d over κ. Let us regard V as a D-D' bimodule via the map ρ. We then have $\dim_D(V) \dim_\kappa(D) = \dim_\kappa(V) = \dim_{D'}(V) \dim_\kappa(D')$. Since ρ is an isomorphism, we also have $\dim_\kappa(D) \dim_\kappa(D') = \dim_\kappa(\mathrm{End}_\kappa(V)) = \dim_\kappa(V)^2$. It follows that $\dim_D(V) = \dim_{D'}(V) = 1$, so that $\dim_\kappa(D) = \dim_{\kappa'}(D') = d$. Moreover, the equality $\dim_{D'}(V) = 1$ ensures that the endomorphism algebra of V as a right D'-module is isomorphic to D', so that ρ determines a κ-algebra homomorphism $\beta : D \to D'$. This map is automatically injective (since D is a division algebra), and is therefore an isomorphism (since the domain and codomain of β have the same dimension over κ). □

Definition 11.5.1.7. Let κ be a field and let $A, B \in \mathrm{Alg}_\kappa^\heartsuit$ be central simple algebras over κ. We will say that A and B are *Morita equivalent* if the equivalent conditions of Proposition

11.5.1.6 are satisfied. We let $\mathrm{Br}(\kappa)$ denote the set of Morita equivalence classes of central simple algebras over κ. We will refer to $\mathrm{Br}(\kappa)$ as the *Brauer group* of κ.

Remark 11.5.1.8. Let κ be a field. It follows immediately from characterization (1) of Proposition 11.5.1.6 (together with Remark 11.5.1.3) that Morita equivalence defines an equivalence relation on the collection of all (isomorphism classes of) central simple algebras over κ. Moreover, we can also identify $\mathrm{Br}(\kappa)$ with the set of all isomorphism classes of central division algebras over κ.

Notation 11.5.1.9. Let κ be a field and let A be a central simple algebra over κ. We let $[A]$ denote the Morita equivalence class of A, which we regard as an element of the Brauer group $\mathrm{Br}(\kappa)$.

Proposition 11.5.1.10. *Let κ be a field. Then $\mathrm{Br}(\kappa)$ has the structure of an abelian group, with multiplication given by $[A][B] = [A \otimes_\kappa B]$.*

Proof. It follows immediately from the definition that the construction $[A], [B] \mapsto [A \otimes_\kappa B]$ determines a multiplication $\mathrm{Br}(\kappa) \times \mathrm{Br}(\kappa) \to \mathrm{Br}(\kappa)$ which is commutative and associative. Moreover, it has a unit given by the Morita equivalence class $[\kappa]$. For every central simple algebra A over κ, Proposition 11.5.1.5 gives $[A][A^{\mathrm{rev}}] = [A \otimes_\kappa A^{\mathrm{rev}}] = [\mathrm{End}_\kappa(A)] = [\kappa]$, so that $[A^{\mathrm{rev}}]$ is an inverse of $[A]$ in $\mathrm{Br}(\kappa)$. □

Remark 11.5.1.11 (Functoriality)**.** Let $f : \kappa \to \kappa'$ be a homomorphism of fields. It follows from Proposition 11.5.1.5 that if A is an associative algebra over κ, then A is central simple over κ if and only if $A' = \kappa' \otimes_\kappa A$ is central simple over κ'. Consequently, the construction $A \mapsto \kappa' \otimes_\kappa A$ determines an abelian group homomorphism $\mathrm{Br}(\kappa) \to \mathrm{Br}(\kappa')$.

Proposition 11.5.1.12. *Let κ be a separably closed field. Then the Brauer group $\mathrm{Br}(\kappa)$ is trivial.*

Proof. Let D be a central division algebra over κ. We wish to show that $D = \kappa$. Assume otherwise: then there exists an element $x \in D$ which does not belong to κ. Let D_0 be the κ-subalgebra of D generated by x. Then D_0 is commutative, and is therefore a finite algebraic extension field of κ. Since κ is separably closed, the extension $\kappa \hookrightarrow D_0$ is purely inseparable. It follows that κ has characteristic $p > 0$ and that $x^{p^n} \in \kappa$ for $n \gg 0$. Choose n as small as possible. Replacing x by $x^{p^{n-1}}$, we can assume that $x^p \in \kappa$.

Let $f : D \to D$ be the function given by $f(y) = xy - yx$. Then $f^k(y) = \sum_{i=0}^{k} (-1)^i \binom{k}{i} x^{k-i} y x^i$. Since κ has characteristic p and $x^p \in \kappa$, we have $f^p(y) = x^p y - y x^p = 0$ for each $y \in D$. However, the map f is nonzero (since $x \notin \kappa = \mathfrak{Z}(D)$). We can therefore choose an element $y \in D$ such that $f(y) \neq 0$ but $f^2(y) = 0$. Set $u = y f(y)^{-1} x$. Since $f(y)^{-1}$ commutes with x, we obtain $x u x^{-1} = x y f(y)^{-1} = (yx + f(y)) f(y)^{-1} = y f(y)^{-1} x + 1 = u + 1$.

Let $D_1 \subseteq D$ be the κ-subalgebra generated by u. Since D_1 is commutative, it is also a purely inseparable algebraic extension of κ, so that $u^{p^m} \in \kappa$ for $m \gg 0$. In particular, u^{p^m} commutes with x for $m \gg 0$, so that we obtain the contradiction

$$u^{p^m} = xu^{p^m}x^{-1} = (xux^{-1})^{p^m} = (u+1)^{p^m} = u^{p^m} + 1.$$

□

We conclude this section by recording another standard fact about associative algebras which will be needed in §11.5.3.

Proposition 11.5.1.13. *Let κ be a field and let $A \in \mathrm{Alg}_\kappa^\heartsuit$ be an associative algebra over κ which is finite-dimensional as a vector space over κ. Then there are only finitely many isomorphism classes of simple left A-modules.*

Proof. Let $M_1, M_2, \ldots, M_n \in \mathrm{Mod}_A^\heartsuit$ be a collection of simple left A-modules which are pairwise nonisomorphic. Choose a nonzero element $x_i \in M_i$ for $1 \leqslant i \leqslant n$, and set $x = \{x_i\}_{1 \leqslant i \leqslant n} \in \bigoplus_{1 \leqslant i \leqslant n} M_i$. Let $N \subseteq \bigoplus_{1 \leqslant i \leqslant n} M_i$ be the cyclic submodule generated by x. We claim that $N = \bigoplus_{1 \leqslant i \leqslant n} M_i$. The proof proceeds by induction on n, the case $n = 0$ being trivial. Assume that $n > 0$, and consider the composite map $\phi : N \hookrightarrow \bigoplus_{1 \leqslant i \leqslant n} M_i \to \bigoplus_{1 \leqslant i < n} M_i$. We have a diagram of short exact sequences

$$\begin{array}{ccccccccc} 0 & \to & \ker(\phi) & \to & N & \to & \mathrm{im}(\phi) & \to & 0 \\ & & \downarrow{\scriptstyle\alpha} & & \downarrow{\scriptstyle\beta} & & \downarrow{\scriptstyle\gamma} & & \\ 0 & \to & M_n & \to & \bigoplus_{1 \leqslant i \leqslant n} M_i & \to & \bigoplus_{1 \leqslant i < n} M_i & \to & 0 \end{array}$$

where the vertical maps are injective. Our inductive hypothesis guarantees that γ is surjective. Consequently, to show that β is an isomorphism, it will suffice to show that α is surjective. Assume otherwise. Then, since M_n is simple, the map α vanishes, so that $\ker(\phi) \simeq 0$. It follows that ϕ is an isomorphism, so that the construction $\bigoplus_{1 \leqslant i < n} M_i \xrightarrow{\phi^{-1}} N \to M_n$ determines a nonzero A-module homomorphism from $\bigoplus_{1 \leqslant i < n} M_i$ to M_n. It follows that there exists a nonzero map $\alpha : M_i \to M_n$ for some $i < n$. Since M_i and M_n are simple, the map α is an isomorphism, contradicting our assumption that the modules $\{M_i\}$ are pairwise nonisomorphic.

It follows from the above argument that if $M_1, M_2, \ldots, M_n$ are pairwise nonisomorphic simple left A-modules, then we have $\sum \dim_\kappa(M_i) \leqslant \dim_\kappa(A)$. In particular, there are at most $\dim_\kappa(A)$ isomorphism classes of simple left A-modules. □

11.5.2 The Extended Brauer Group

We now introduce our main objects of interest in this section.

Definition 11.5.2.1. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor and let $\mathrm{QStk}^{\mathrm{cg}}(X)$ be the ∞-category of compactly generated stable quasi-coherent stacks on X (Notation 11.4.0.1). We let $\mathscr{B}\mathrm{r}^{\dagger}(X)$ denote the full subcategory of $\mathrm{QStk}^{\mathrm{cg}}(X)^{\simeq}$ spanned by the invertible objects of $\mathrm{QStk}^{\mathrm{cg}}(X)$. We will refer to $\mathscr{B}\mathrm{r}^{\dagger}(X)$ as the *extended Brauer space* of X. We let $\mathrm{Br}^{\dagger}(X)$ denote the set $\pi_0 \mathscr{B}\mathrm{r}^{\dagger}(X)$. We will refer to $\mathrm{Br}^{\dagger}(X)$ as the *extended Brauer group* of X.

If X is a spectral Deligne-Mumford stack. we let $\mathrm{Br}^{\dagger}(\mathsf{X})$ and $\mathscr{B}\mathrm{r}^{\dagger}(\mathsf{X})$ denote the extended Brauer group and extended Brauer space of the functor $\mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ represented by X. If R is a connective $\mathbb{E}_\infty$-ring, we let $\mathrm{Br}^{\dagger}(R)$ and $\mathscr{B}\mathrm{r}^{\dagger}(R)$ denote extended Brauer group and extended Brauer space of the functor $\mathrm{Spec}\, R : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ corepresented by R.

Remark 11.5.2.2. We will see below that if κ is a field, then the extended Brauer group $\mathrm{Br}^{\dagger}(\kappa)$ of Definition 11.5.2.1 coincides with the classical Brauer group $\mathrm{Br}(\kappa)$ of Definition 11.5.1.7 (see Theorem 11.5.3.18).

Warning 11.5.2.3. In the situation of Definition 11.5.2.1, the ∞-category $\mathrm{QStk}^{\mathrm{cg}}(X)$ need not be small (and the ∞-category $\mathrm{QStk}^{\mathrm{St}}(X)$ need not even be locally small). Consequently, it is not obvious from the definition that the extended Brauer space $\mathscr{B}\mathrm{r}^{\dagger}(X)$ is essentially small, or that the extended Brauer group $\mathrm{Br}^{\dagger}(X)$ is small. We will later see that these invariants are small under some mild assumptions on X (see Remark 11.5.3.13 and Construction 11.5.5.3).

Example 11.5.2.4 (The Dualizing Gerbe)**.** Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ be a Noetherian spectral algebraic space. Let us say that an object $U \in \mathcal{X}$ is *good* if U is affine and the spectral algebraic space $\mathsf{X}_U = (\mathcal{X}_{/U}, \mathscr{O}_{\mathsf{X}}|_U)$ admits a dualizing sheaf (Definition 6.6.1.1). In this case, we let $\mathcal{C}(U)$ denote the full subcategory of $\mathrm{QCoh}(\mathsf{X}_U)$ spanned by those objects which are coherent, truncated, and of finite injective dimension. If ω_U is a dualizing sheaf for X_U, then Corollary 6.6.1.11 implies that the construction $\mathscr{F} \mapsto \mathscr{F} \otimes \omega_U$ induces an equivalence $\mathrm{QCoh}(\mathsf{X}_U)^{\mathrm{perf}} \simeq \mathcal{C}(U)$, which extends to a $\mathscr{O}_{\mathsf{X}}(U)$-linear equivalence of ∞-category $\mathrm{Mod}_{\mathscr{O}_{\mathsf{X}}(U)} \simeq \mathrm{Ind}(\mathcal{C}(U))$.

Suppose that $\mathcal{X}$ is covered by good objects: that is, that X admits a dualizing sheaf *locally*. In this case, the construction $U \mapsto \mathrm{Ind}(\mathcal{C}(U))$ extends to a quasi-coherent stack on X which is compactly generated and invertible, and can therefore be identified with an object of $\mathscr{B}\mathrm{r}^{\dagger}(\mathsf{X})$. We will refer to this object as the *dualizing gerbe* of X. The associated element of $\mathrm{Br}^{\dagger}(\mathsf{X})$ vanishes if and only if X admits a dualizing sheaf ω_{X}.

Remark 11.5.2.5. Let R be a connective $\mathbb{E}_\infty$-ring and let $\mathcal{C}$ be a compactly generated stable R-linear ∞-category. Then $\mathcal{C}$ is a dualizable object of $\mathrm{LinCat}_R^{\mathrm{St}}$ (Theorem D.7.0.7). Let us denote its dual by $\mathcal{C}^{\vee}$, so that we have evaluation and coevaluation maps

$$e : \mathcal{C}^{\vee} \otimes_R \mathcal{C} \to \mathrm{Mod}_R \qquad c : \mathrm{Mod}_R \to \mathcal{C} \otimes_R \mathcal{C}^{\vee}.$$

Then the following conditions are equivalent:

(a) The functor e is an equivalence of R-linear ∞-categories.

(b) The functor c is an equivalence of R-linear ∞-categories.

(c) As an object of $\mathrm{LinCat}_R^{\mathrm{St}}$, $\mathcal{C}$ is invertible.

Moreover, if these conditions are satisfied, then the inverse $\mathcal{C}^{-1}$ of $\mathcal{C}$ in $\mathrm{LinCat}_R^{\mathrm{St}}$ is also compactly generated (see Remark D.7.7.6), so that $\mathcal{C} \in \mathscr{B}\mathrm{r}^{\dagger}(R) \subseteq \mathrm{LinCat}_R$. In this case, the functors e and c preserve compact objects, so that $\mathcal{C}$ is both smooth and proper as an R-linear ∞-category.

Remark 11.5.2.6. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor. Since every invertible morphism in $\mathrm{QStk}^{\mathrm{St}}(X)$ is compact, we can identify $\mathscr{B}\mathrm{r}^{\dagger}(X)$ with the full subcategory of $\mathrm{QStk}^{\mathrm{St}}(X)^{\simeq}$ spanned by those stable quasi-coherent stacks $\mathcal{C}$ on X which are compactly generated and invertible as objects of $\mathrm{QStk}^{\mathrm{St}}(X)$ (the inverse of $\mathcal{C}$ is then automatically compactly generated as well; see Remark 11.5.2.5). We do not know if there exist invertible objects of $\mathrm{QStk}^{\mathrm{St}}(X)$ which are not compactly generated.

Remark 11.5.2.7. For every functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, the symmetric monoidal structure on $\mathrm{QStk}(X)$ restricts to a symmetric monoidal structure on $\mathscr{B}\mathrm{r}^{\dagger}(X)$: that is, we may regard $\mathscr{B}\mathrm{r}^{\dagger}(X)$ as a commutative monoid object of the ∞-category $\widehat{\mathcal{S}}$ of (not necessarily small) spaces. By construction, this commutative monoid is grouplike. Neglecting issues of size, we can regard $\mathscr{B}\mathrm{r}^{\dagger}(X)$ as the zeroth space of a connective spectrum (see §HA.5.2.6), so that $\mathrm{Br}^{\dagger}(X) = \pi_0 \mathscr{B}\mathrm{r}^{\dagger}(X)$ has the structure of an abelian group.

Remark 11.5.2.8 (Functoriality)**.** Let $f : X \to Y$ be a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$. Then the pullback functor $f^* : \mathrm{QStk}^{\mathrm{St}}(Y) \to \mathrm{QStk}^{\mathrm{St}}(X)$ restricts to a map $\mathscr{B}\mathrm{r}^{\dagger}(Y) \to \mathscr{B}\mathrm{r}^{\dagger}(X)$, and therefore induces a homomorphism of extended Brauer groups $\mathrm{Br}^{\dagger}(Y) \to \mathrm{Br}^{\dagger}(X)$.

Remark 11.5.2.9. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor. The condition that an object $\mathcal{C} \in \mathrm{QStk}^{\mathrm{St}}(X)$ belong to $\mathscr{B}\mathrm{r}^{\dagger}(X)$ can be tested pointwise: that is, $\mathcal{C} \in \mathscr{B}\mathrm{r}^{\dagger}(X)$ if and only if, for every connective $\mathbb{E}_\infty$-ring R and every point $\eta \in X(R)$, we have $\eta^* \mathcal{C} \in \mathscr{B}\mathrm{r}^{\dagger}(R) \subseteq \mathrm{LinCat}_R^{\mathrm{St}}$. The "only if" direction is obvious, and the "if" direction follows from Remark 11.5.2.5.

Remark 11.5.2.10. Using Theorem **??**, we see that the functor $R \mapsto \mathscr{B}\mathrm{r}^{\dagger}(R)$ is a sheaf with respect to the étale topology. Moreover, the functor $\mathscr{B}\mathrm{r}^{\dagger} : \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})^{\mathrm{op}} \to \widehat{\mathcal{S}}$ is a right Kan extension of the functor $R \mapsto \mathscr{B}\mathrm{r}^{\dagger}(R)$ along the Yoneda embedding $\mathrm{CAlg}^{\mathrm{cn}} \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{cn}}, \mathcal{S})^{\mathrm{op}}$. It follows that if $\alpha : X \to Y$ is a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$ which induces an equivalence after sheafification with respect to the étale topology, then the pullback map $\alpha^* : \mathscr{B}\mathrm{r}^{\dagger}(Y) \to \mathscr{B}\mathrm{r}^{\dagger}(X)$ is a homotopy equivalence.

Remark 11.5.2.11. Let R be an $\mathbb{E}_\infty$-ring. Every R-linear functor F from Mod_R to itself is given by tensor product by an object $M \in \mathrm{Mod}_R$, and F is an equivalence of ∞-categories if and only if M is an invertible object of Mod_R. We therefore have a homotopy equivalence

$$\Omega\,\mathscr{B}\mathrm{r}^\dagger(R) \simeq \mathscr{P}\mathrm{ic}^\dagger(R).$$

This homotopy equivalence depends functorially on R, and so globalizes to give an equivalence $\Omega\,\mathscr{B}\mathrm{r}^\dagger(X) \simeq \mathscr{P}\mathrm{ic}^\dagger(X)$ for any functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \widehat{\mathcal{S}}$; here $\mathscr{P}\mathrm{ic}^\dagger(X)$ denotes the full subcategory of $\mathrm{QCoh}(X)^{\simeq}$ spanned by the invertible objects.

Remark 11.5.2.12. The extended Brauer group $\mathrm{Br}^\dagger(R)$ of Definition 11.5.2.1 makes sense for $\mathbb{E}_\infty$-rings R which are not connective. However, we will restrict our attention to the connective setting in what follows.

11.5.3 Azumaya Algebras

Let R be a connective $\mathbb{E}_\infty$-ring and let $\mathrm{Br}^\dagger(R)$ be the extended Brauer group of R (Definition 11.5.2.1). By definition, the elements of $\mathrm{Br}^\dagger(R)$ are equivalence classes of invertible compactly generated stable R-linear ∞-categories. Our next goal is to make this definition more explicit by describing concrete representatives for extended Brauer classes. Recall that when R is a field, the classical Brauer group $\mathrm{Br}(R)$ can be described as the set of Morita equivalence classes of central simple algebras over R (Definition 11.5.1.7). The theory of central simple algebras was generalized by Azumaya to the setting of local commutative rings ([10]). We consider here a further generalization of Azumaya's theory to the setting of ring spectra, introduced by Toën in the setting of simplicial commutative rings and Antieau-Gepner in the setting of $\mathbb{E}_\infty$-rings:

Definition 11.5.3.1. Let R be a connective $\mathbb{E}_\infty$-ring and let A be an $\mathbb{E}_1$-algebra over R. We will say that A is an *Azumaya algebra over* R if it satisfies the following conditions:

(1) The algebra A is a compact generator of Mod_R.

(2) The left and right actions of A on itself induce an equivalence $A \otimes_R A^{\mathrm{rev}} \to \mathrm{End}_R(A)$.

Warning 11.5.3.2. In the case where R is an ordinary commutative ring, Definition 11.5.3.1 does not reduce to the usual notion of Azumaya algebra in commutative algebra because we do not require A to be a projective R-module (see Proposition 11.5.3.3 below). For this reason, Toën refers to an algebra $A \in \mathrm{Alg}_R$ satisfying the requirements of Definition 11.5.3.1 as a *derived Azumaya algebra*. Other variants have appeared in the literature; see [133] and [11].

Proposition 11.5.3.3. *Let R be an $\mathbb{E}_\infty$-ring and let A be an Azumaya algebra over R. The following conditions are equivalent:*

(a) *The algebra A is connective.*

(b) *The algebra A is a locally free of finite rank as an R-module.*

Proof. The implication $(b) \Rightarrow (a)$ is obvious. For the converse, suppose that (a) is satisfied. Then A is a connective perfect R-module. To show that A is locally free of finite rank, it will suffice to show that it has Tor-amplitude $\leqslant 0$ (Remark 2.9.1.2). Equivalently, we must show that the dual $A^\vee$ is connective. Using Corollary 2.7.4.3, we can reduce to the case where $R = \kappa$ is a field. In this case, our assumption that A is an Azumaya algebra supplies an isomorphism of graded vector spaces

$$(\pi_* A) \otimes_\kappa (\pi_* A^{\mathrm{rev}}) \simeq \pi_*(A \otimes_\kappa A^{\mathrm{rev}}) \simeq \pi_* \mathrm{End}_\kappa(A) \simeq (\pi_* A) \otimes (\pi_* A^\vee).$$

Since the left hand side is concentrated in nonnegative degrees, the right hand side must also be concentrated in nonnegative degrees, from which it follows that $A^\vee$ is connective. □

The next result highlights the relevance of Definition 11.5.3.1 to the theory of Brauer groups:

Proposition 11.5.3.4. *Let R be a connective $\mathbb{E}_\infty$-ring and let $A \in \mathrm{Alg}_R$. Then A is an Azumaya algebra over R if and only if the stable R-linear ∞-category RMod_A is an invertible object of $\mathrm{LinCat}_R^{\mathrm{St}}$.*

The proof of Proposition 11.5.3.4 will require a few preliminaries.

Lemma 11.5.3.5. *Let R be an $\mathbb{E}_\infty$-ring and let M be a perfect R-module. The following conditions are equivalent:*

(1) *The object M is a compact generator of Mod_R.*

(2) *Let $\mathcal{C}$ be the smallest stable subcategory of Mod_R which contains M and is idempotent complete. Then $\mathcal{C} = \mathrm{Mod}_R^{\mathrm{perf}}$.*

(3) *The R-linear dual $M^\vee$ is a compact generator of Mod_R.*

Proof. Let $\mathcal{C}$ be as in (2). Since M is perfect, $\mathcal{C} \subseteq \mathrm{Mod}_R^{\mathrm{perf}}$, so the inclusion $\mathcal{C} \hookrightarrow \mathrm{Mod}_R^{\mathrm{perf}}$ extends to a fully faithful embedding $\theta : \mathrm{Ind}(\mathcal{C}) \to \mathrm{Ind}(\mathrm{Mod}_R^{\mathrm{perf}}) \simeq \mathrm{Mod}_R$. Condition (1) is equivalent to the requirement that θ is an equivalence of ∞-categories. Since $\mathcal{C}$ is idempotent complete, this is equivalent to condition (2).

Let $\mathcal{C}^\vee = \{N^\vee : N \in \mathcal{C}\}$. Then $\mathcal{C} = \mathrm{Mod}_R^{\mathrm{perf}}$ if and only if $\mathcal{C}^\vee = \mathrm{Mod}_R^{\mathrm{perf}}$. Since $\mathcal{C}^\vee$ is the smallest stable subcategory of Mod_R which contains $M^\vee$ and is idempotent complete, we deduce that $(2) \Leftrightarrow (3)$. □

Lemma 11.5.3.6. *Let R be an $\mathbb{E}_\infty$-ring, let $A \in \mathrm{Alg}_R$, and let $X \in \mathrm{RMod}_A$. Let $G : \mathrm{Mod}_R \to \mathrm{RMod}_A$ be the R-linear functor given by $G(M) = M \otimes_R X$. The following conditions are equivalent:*

(1) *The functor G is an equivalence of ∞-categories.*

(2) *The image of X under the forgetful functor $\mathrm{RMod}_A \to \mathrm{Mod}_R$ is a compact generator of Mod_R. Moreover, the right action of A on X induces an equivalence $A^{\mathrm{rev}} \to \mathrm{End}_R(X)$ of $\mathbb{E}_1$-algebras over R.*

Proof. Suppose first that (1) is satisfied, and let $F : \mathrm{RMod}_A \to \mathrm{Mod}_R$ be a homotopy inverse of G (so that F is also an R-linear functor). Let $Y = F(A) \in \mathrm{Mod}_R$. According to Theorem HA.4.8.4.1 , we can regard Y as a left A-module object of Mod_R, and the functor F is given by the formula $F(M) = M \otimes_A Y$. Since A is a compact generator of RMod_A and F is an equivalence of ∞-categories, the object Y is a compact generator of Mod_R. In particular, Y is dualizable as an R-module. Let us regard its R-linear dual $Y^\vee$ as a left A-module. Then the construction $P \mapsto P \otimes_R Y^\vee$ determines an R-linear functor $\mathrm{Mod}_R \to \mathrm{RMod}_A$ which is left adjoint to G, and therefore equivalent to F. In particular, we obtain an equivalence of right A-modules $X = F(R) \simeq R \otimes_R Y^\vee \simeq Y^\vee$. Since Y is a compact generator of Mod_R, Lemma 11.5.3.5 implies that $X \simeq Y^\vee$ is also a compact generator of Mod_R. Moreover, the assertion that the right action of A on X induces an equivalence $A^{\mathrm{rev}} \to \mathrm{End}_R(X)$ is equivalent to the assertion that the left action of A on Y induces an equivalence $A \to \mathrm{End}_R(Y)$. Since F is an equivalence of ∞-categories, this follows from the observation that A is a classifying object for endomorphisms of itself, regarded as an object of RMod_A.

We now show that (2) $\Rightarrow$ (1). Suppose that X is a compact generator of Mod_R, and let $A = \mathrm{End}_R(X)^{\mathrm{op}}$, so that we can regard X as a right A-module. We wish to show that the functor $M \mapsto M \otimes_R X$ induces an equivalence $G : \mathrm{Mod}_R \to \mathrm{RMod}_A$. Let Y denote the R-linear dual of X, so that we can regard Y as a left A-module, and let $F : \mathrm{RMod}_A \to \mathrm{Mod}_R$ be given by $F(N) = N \otimes_A Y$. Then F is left adjoint to G; it will therefore suffice to show that F is an equivalence of ∞-categories. We first claim that F is fully faithful. Let P and Q be right A-modules; we wish to show that the canonical map

$$\mu_{P,Q} : \mathrm{Map}_{\mathrm{RMod}_A}(P, Q) \to \mathrm{Map}_{\mathrm{Mod}_R}(P \otimes_A Y, Q \otimes_A Y)$$

is a homotopy equivalence. If we fix P, the collection of those objects $P \in \mathrm{RMod}_A$ for which $\mu_{P,Q}$ is a homotopy equivalence is closed under small colimits. We may therefore reduce to the case where $P = \Sigma^d A$ for some integer d. In particular, P is a compact of RMod_A. Since $P \otimes_A M \simeq \Sigma^d Y$ is a compact object of Mod_R, we conclude that the collection of those Q for which $\mu_{P,Q}$ is an equivalence is closed under filtered colimits in Q. We may therefore reduce to the case where Q is perfect. Since the collection of those Q for which $\mu_{P,Q}$ is an equivalence is closed under finite limits, we may further reduce to the case where $Q = \Sigma^{d'} A$. In this case, we must show that the canonical map

$$\mathrm{Map}_{\mathrm{RMod}_A}(\Sigma^d A, \Sigma^{d'} A) \to \mathrm{Map}_{\mathrm{Mod}_R}(\Sigma^d Y, \Sigma^{d'}_Y)$$

is a homotopy equivalence, which follows immediately from our assumption that the map $A \simeq \mathrm{End}_R(X)^{\mathrm{rev}} \simeq \mathrm{End}_R(Y)$ is an equivalence.

It remains to show that the functor F is essentially surjective. Because F is fully faithful, the essential image of F is a full subcategory of Mod_R which is closed under small colimits. Since $F(A) \simeq Y = X^\vee$ is a compact generator of Mod_R (Lemma 11.5.3.5), we conclude that $F(\mathrm{RMod}_A) = \mathrm{Mod}_R$. □

Proof of Proposition 11.5.3.4. Let A be an arbitrary $\mathbb{E}_1$-algebra over R. According to Remark HA.4.8.4.8, the R-linear ∞-category RMod_A is a dualizable object of $\mathrm{LinCat}^{\mathrm{St}}_R$, whose dual is given by LMod_A. More precisely, we can identify the tensor product $\mathrm{LMod}_A \otimes_R \mathrm{RMod}_A$ with the ∞-category ${}_A\mathrm{BMod}_A(\mathrm{Mod}_R)$ of A-A bimodule objects of Mod_R. The unit object $A \in {}_A\mathrm{BMod}_A(\mathrm{Mod}_R)$ determines an R-linear functor

$$c : \mathrm{Mod}_R \to \mathrm{LMod}_A \otimes_R \mathrm{RMod}_A,$$

which exhibits LMod_A as a dual of RMod_A in $\mathrm{LinCat}^{\mathrm{St}}_R$. Consequently, RMod_A is an invertible object of $\mathrm{LinCat}^{\mathrm{St}}_R$ if and only if the functor c is an equivalence. Proposition 11.5.3.4 now follows by applying Lemma 11.5.3.6 to the ∞-category

$$\mathrm{LMod}_A \otimes \mathrm{RMod}_A \simeq {}_A\mathrm{BMod}_A(\mathrm{Mod}_R) \simeq \mathrm{RMod}_{A \otimes_R A^{\mathrm{rev}}}.$$

□

We now use Proposition 11.5.3.4 to give a concrete description of the extended Brauer group $\mathrm{Br}^\dagger(\mathsf{X})$, where X is a quasi-compact, quasi-separated spectral algebraic space. First, we need a global version of Definition 11.5.3.1.

Definition 11.5.3.7. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor and let $\mathscr{A}$ be an associative algebra object of the ∞-category $\mathrm{QCoh}(X)$. We will say that $\mathscr{A}$ is an *Azumaya algebra* if, for every connective $\mathbb{E}_\infty$-ring R and every point $\eta \in X(R)$, the object $\mathscr{A}_\eta \in \mathrm{Alg}_R$ is an Azumaya algebra over R.

Example 11.5.3.8. Let R be a connective $\mathbb{E}_\infty$-ring and let $\mathscr{A} \in \mathrm{Alg}(\mathrm{QCoh}(\mathrm{Spec}\, R))$. Then $\mathscr{A}$ is an Azumaya algebra (in the sense of Definition 11.5.3.7) if and only if its image under the equivalence $\mathrm{Alg}(\mathrm{QCoh}(\mathrm{Spec}\, R)) \simeq \mathrm{Alg}_R$ is an Azumaya algebra over R (in the sense of Definition 11.5.3.1).

Construction 11.5.3.9 (The Extended Brauer Class of an Azumaya Algebra)**.** Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor and let $\mathscr{A} \in \mathrm{Alg}(\mathrm{QCoh}(X))$ be an Azumaya algebra. Then the construction

$$(\eta \in X(R)) \mapsto (\mathrm{RMod}_{\mathscr{A}_\eta} \in \mathrm{LinCat}_R^{\mathrm{St}})$$

determines a compactly generated stable quasi-coherent stack on X. It follows from Proposition 11.5.3.4 that this quasi-coherent stack is an invertible object of $\mathrm{LinCat}_R^{\mathrm{St}}$, and can therefore be identified with a point of the extended Brauer space $\mathscr{B}\mathrm{r}^\dagger(X)$. We let $[\mathscr{A}] \in \mathrm{Br}^\dagger(X)$ denote the equivalence class of this quasi-coherent stack. We will refer to $[\mathscr{A}]$ as the *extended Brauer class of* $\mathscr{A}$.

In good cases, every element of $\mathrm{Br}^\dagger(X)$ can be represented by an Azumaya algebra:

Proposition 11.5.3.10. *Let* X *be a spectral algebraic space which is quasi-compact and quasi-separated. Then every element of* $\mathrm{Br}^\dagger(\mathsf{X})$ *has the form* $[\mathscr{A}]$*, for some Azumaya algebra* $\mathscr{A} \in \mathrm{Alg}(\mathrm{QCoh}(\mathsf{X}))$*.*

Proof. Let u be an element of $\mathrm{Br}^\dagger(\mathsf{X})$. Choose a compactly generated invertible object $\mathcal{C} \in \mathrm{QStk}^{\mathrm{St}}(\mathsf{X})$ which represents u. It follows from Theorem 10.3.2.1 that the ∞-category $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ is compactly generated. Choose a set of compact generators $\{C_i\}_{i\in I}$ for $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$. Since X is quasi-compact, there exists an étale surjection $\eta : \mathrm{Sp\acute{e}t}\, R \to \mathsf{X}$. For each $i \in I$, let $\eta^* C_i$ denote the image of C_i in the stable R-linear ∞-category $\mathcal{C}_\eta$. It follows from Remark 11.5.2.5 that $\mathcal{C}_\eta$ is smooth over R. It follows from the proof of Proposition 11.3.2.4 that we can choose a finite subset $I_0 \subseteq I$ such that the objects $\{\eta^* C_i\}_{i\in I_0}$ generate $\mathcal{C}_\eta$. Set $C = \bigoplus_{i\in I_0} C_i$.

Let us regard the ∞-category $\mathrm{QCoh}(\mathsf{X};\mathcal{C})$ as tensored over $\mathrm{QCoh}(\mathsf{X})$, and let $\mathscr{A} \in \mathrm{Alg}(\mathrm{QCoh}(\mathsf{X}))$ be the endomorphism algebra of C. Let $\mathcal{C}' \in \mathrm{QStk}^{\mathrm{St}}(\mathsf{X})$ be the stable quasi-coherent stack on X given by the construction $(\eta' : \mathrm{Sp\acute{e}t}\, R' \to \mathsf{X}) \mapsto (\mathrm{RMod}_{\eta'^* \mathscr{A}} \in \mathrm{LinCat}_{R'}^{\mathrm{St}})$. The operation $\bullet \otimes_{\mathscr{A}} C$ determines a morphism of quasi-coherent stacks $F : \mathcal{C}' \to \mathcal{C}$. Since $\eta^* C$ is a compact generator of $\mathcal{C}_\eta$, the induced map functor $F_\eta : \mathcal{C}'_\eta \to \mathcal{C}_\eta$ is an equivalence of R-linear ∞-categories. In particular, the R-linear ∞-category $\mathrm{RMod}_{\eta^* \mathscr{A}} \simeq \mathcal{C}'_\eta \simeq \mathcal{C}_\eta$ is an invertible object of $\mathrm{LinCat}_R^{\mathrm{St}}$, so that Proposition 11.5.3.4 implies that $\eta^* \mathscr{A} \in \mathrm{Alg}_R$ is an Azumaya algebra over R. Since the map η is an étale surjection, it follows that $\mathscr{A}$ is an Azumaya algebra on X and that F is an equivalence, so that $u = [\mathscr{A}]$. □

In the situation of Proposition 11.5.3.10, the Azumaya algebra $\mathscr{A}$ is not determined by its Brauer class $[\mathscr{A}]$. However, the failure of uniqueness is addressed by the following:

Proposition 11.5.3.11. *Let* $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ *be a functor and let* $\mathscr{A} \in \mathrm{Alg}(\mathrm{QCoh}(X))$*. The following conditions are equivalent:*

(1) *The object* $\mathscr{A}$ *is an Azumaya algebra and the extended Brauer class* $[\mathscr{A}] \in \mathrm{Br}^\dagger(X)$ *vanishes.*

(2) *There exists an equivalence* $\mathscr{A} \simeq \operatorname{End}(\mathscr{F}) = \mathscr{F} \otimes \mathscr{F}^\vee$, *where* $\mathscr{F} \in \operatorname{QCoh}(X)$ *has the property that for each point* $\eta \in X(R)$, *the object* $\eta^* \mathscr{F}$ *is a compact generator of* Mod_R.

Proof. Let $\mathcal{C}$ denote the stable quasi-coherent stack on X given by the construction $(\eta \in X(R)) \mapsto (\operatorname{RMod}_{\eta^* \mathscr{A}} \in \operatorname{LinCat}_R^{\operatorname{St}})$. Using Proposition 11.5.3.4, we see that condition (1) is equivalent to the following:

(1′) There exists a map $\rho : \mathcal{Q}_X^{\operatorname{St}} \to \mathcal{C}$ which is an equivalence of quasi-coherent stacks.

Note that giving a map of quasi-coherent stacks $\rho : \mathcal{Q}_X^{\operatorname{St}} \to \mathcal{C}$ is equivalent to giving an object $\mathscr{G} \in \operatorname{QCoh}(X; \mathcal{C}) \simeq \operatorname{RMod}_{\mathscr{A}}(\operatorname{QCoh}(X))$. Using Lemma **??**, we see that the map ρ is an equivalence if and only if $\mathscr{G}$ satisfies the following additional pair of conditions:

(i) For each point $\eta \in X(R)$, the R-module $\eta^* \mathscr{G}$ is a compact generator of Mod_R.

(ii) The right action of $\mathscr{A}$ on $\mathscr{G}$ induces an equivalence $\mathscr{A} \to \operatorname{End}(\mathscr{G})^{\operatorname{rev}} \simeq \operatorname{End}(\mathscr{G}^\vee)$.

Setting $\mathscr{F} = \mathscr{G}^\vee$ (and applying Lemma 11.5.3.5), we see that conditions (1) and (2) are equivalent. □

Remark 11.5.3.12. Let $X : \operatorname{CAlg}^{\operatorname{cn}} \to \mathcal{S}$ be a functor. We can summarize Construction **??**, Proposition **??**, and Proposition 11.5.3.11 as follows:

(a) Every Azumaya algebra $\mathscr{A}$ on X determines an element $[\mathscr{A}] \in \operatorname{Br}^\dagger(X)$. If X is (representable by) a quasi-compact, quasi-separated spectral algebraic space, then every element of $\operatorname{Br}^\dagger(X)$ is obtained in this way.

(b) The collection of elements of $\operatorname{Br}^\dagger(X)$ having the form $[\mathscr{A}]$ comprise a subgroup of $\operatorname{Br}^\dagger(X)$. More explicitly, the multiplication on $\operatorname{Br}^\dagger(X)$ is given by $[\mathscr{A}][\mathscr{B}] = [\mathscr{A} \otimes \mathscr{B}]$, the identity element of $\operatorname{Br}^\dagger(X)$ is given by $[\mathscr{O}_X]$, and the inverse of $[\mathscr{A}]$ is given by $[\mathscr{A}^{\operatorname{rev}}]$ (the last assertion follows from Proposition 11.5.3.11 together with the equivalence $\mathscr{A} \otimes \mathscr{A}^{\operatorname{rev}} \simeq \operatorname{End}(\mathscr{A})$ supplied by our assumption that $\mathscr{A}$ is an Azumaya algebra).

(c) Given Azumaya algebras $\mathscr{A}, \mathscr{B} \in \operatorname{Alg}(\operatorname{QCoh}(X))$, we have $[\mathscr{A}] = [\mathscr{B}]$ in $\operatorname{Br}^\dagger(X)$ if and only if there is an equivalence $\mathscr{A} \otimes \mathscr{B}^{\operatorname{rev}} \simeq \operatorname{End}(\mathscr{F})$ for some $\mathscr{F} \in \operatorname{QCoh}(X)^{\operatorname{perf}}$ having the property that $\eta^* \mathscr{F} \in \operatorname{Mod}_R$ is a compact generator for each $\eta \in X(R)$ (in this case, we can regard $\mathscr{F}$ as a $\mathscr{A}$-$\mathscr{B}$ bimodule object of $\operatorname{QCoh}(X)$).

Remark 11.5.3.13. Let X be a spectral algebraic space which is quasi-compact and quasi-separated. It follows from Proposition 11.5.3.10 that the Brauer group $\operatorname{Br}^\dagger(\mathsf{X})$ is small. Combining this observation with Remarks **??** and 2.9.5.2, we deduce that the extended Brauer space $\mathscr{B}\mathrm{r}^\dagger(R)$ is essentially small. In fact, these assertions are valid for *any* spectral Deligne-Mumford stack (see Construction 11.5.5.3).

We now use Proposition 11.5.3.11 to relate the extended Brauer group of Definition 11.5.2.1 to the classical Brauer group of Definition 11.5.1.7. The key observation is the following:

Proposition 11.5.3.14. *Let κ be a field and let $A \in \mathrm{Alg}_\kappa$. Then:*

- (a) *The algebra A is an Azumaya algebra over κ (in the sense of Definition 11.5.3.1) if and only if $B = \pi_* A$ is a central simple algebra over κ (in the sense of Definition 11.5.1.1).*
- (b) *The algebra A is a connective Azumaya algebra over κ (in the sense of Definition 11.5.3.1) if and only A is discrete and is a central simple algebra over κ (in the sense of Definition 11.5.1.1).*

Warning 11.5.3.15. Assertion (b) of Proposition 11.5.3.14 follows immediately from Propositions 11.5.3.3 and 11.5.1.5. However, the proof of (a) is a bit more subtle. Let A be an $\mathbb{E}_1$-algebra over a field κ which is perfect as a κ-module. Then we can regard $B = \pi_* A$ as a finite-dimensional associative algebra over κ. Using the left and right actions of A and B on themselves, we obtain maps

$$\rho_A : A \otimes_\kappa A^{\mathrm{rev}} \to \mathrm{End}_\kappa(A) \qquad \rho_B : B \otimes_\kappa B^{\mathrm{rev}} \to \mathrm{End}_\kappa(B).$$

On homotopy groups, ρ_A induces a map $\overline{\rho}_A : (\pi_* A) \otimes_\kappa (\pi_* A^{\mathrm{rev}}) \to \mathrm{End}_\kappa(\pi_* A)$ which does *not* agree with the map ρ_B. Given elements $x \in \pi_a A$, $y \in \pi_b A^{\mathrm{rev}}$, $z \in \pi_c A$, we have

$$\overline{\rho}_A(x \otimes y)(z) = (-1)^{bc} xzy \qquad \rho_B(x \otimes y)(z) = xzy.$$

In order to address the difficulties described in Warning 11.5.3.15, we will need a few auxiliary results.

Lemma 11.5.3.16. *Let κ be a field, let $B = \oplus_{n \in \mathbf{Z}} B_n$ be a graded associative algebra over κ which is finite-dimensional as a vector space over κ, and let $M \in \mathrm{LMod}_B^{\heartsuit}$ be a left B-module. Assume that M is absolutely simple (that is, the tensor product $\overline{\kappa} \otimes_\kappa M$ is a simple module over $\overline{\kappa} \otimes_\kappa B$, where $\overline{\kappa}$ is an algebraic closure of κ). Then M admits the structure of a graded left module over B (that is, there exists a decomposition $M = \bigoplus_{n \in \mathbf{Z}} M_n$ satisfying $bx \in M_{m+n}$ for $b \in B_m$ and $x \in M_n$).*

Proof. For every commutative κ-algebra R, let $G(R)$ denote the subgroup of $R^\times \times \mathrm{Aut}_R(R \otimes_\kappa M)$ consisting of those pairs (λ, f) which satisfy the identity $f(bx) = \lambda^n b f(x)$ for all $b \in B_n$ and $x \in M$. The construction $R \mapsto G(R)$ determines an affine group scheme over κ, which we can regard as a closed subgroup of the product $\mathbf{G}_m \times \mathrm{GL}_d$ for $d = \dim_\kappa(M)$. Let $\pi : G \to \mathbf{G}_m$ be the projection map onto the first factor (given on R-valued points by $\pi(\lambda, f) = \lambda$).

Set $\overline{B} = \overline{\kappa} \otimes_{\kappa} B$ and $\overline{M} = \overline{\kappa} \otimes_{\kappa} M$. For each $\lambda \in \overline{\kappa}^{\times}$, we define a left $\overline{B}$-module $\overline{M}_{\lambda}$ by the following requirement: there exists an isomorphism of $\overline{\kappa}$-vector spaces $\alpha : \overline{M} \to \overline{M}_{\lambda}$, and the actions of $\overline{B}$ on $\overline{M}$ and $\overline{M}_{\lambda}$ are related by the formula $\alpha(bx) = \lambda^n b\alpha(x)$ for $b \in B_n$. Note that $\lambda \in \overline{\kappa}^{\times}$ belongs to the image of the map $\pi : G(\overline{\kappa}) \to \mathbf{G}_m(\overline{\kappa})$ if and only if $\overline{M}$ and $\overline{M}_{\lambda}$ are isomorphic. Since there are only finitely many isomorphism classes of simple $\overline{B}$-modules (Proposition 11.5.1.13), the image of the map $G(\overline{\kappa}) \to \overline{\kappa}^{\times}$ is a finite-index subgroup of $\overline{\kappa}^{\times}$, and is therefore dense in the Zariski topology.

Our assumption that M is absolutely simple guarantees that the kernel $\ker(\pi)$ is isomorphic to the multiplicative group $\mathbf{G}_m$. We therefore have an exact sequence $0 \to \mathbf{G}_m \to G \xrightarrow{\pi} \mathbf{G}_m \to 0$ in the category of affine group schemes over κ. It follows that π admits a section, which determines a grading of M which is compatible with the action of B. □

Lemma 11.5.3.17. *Let κ be a field and let $A \in \mathrm{Alg}_{\kappa}$. Suppose that there exists a finite-dimensional graded vector space V over κ and an isomorphism of graded rings $\pi_* A \simeq \mathrm{End}_{\kappa}(V)$. Then there is a perfect κ-module $\overline{V}$ and an equivalence $A \simeq \mathrm{End}_{\kappa}(\overline{V})$ of $\mathbb{E}_1$-algebras over κ.*

Proof. Let $\{v_1, \ldots, v_n\}$ be a basis for V as a κ-vector space, where each v_i is a homogeneous element of degree d_i. For $1 \leqslant i, j \leqslant n$, let $e_{i,j} \in \mathrm{End}_{\kappa}(V)$ be the endomorphism given by

$$e_{i,j}(v_l) = \begin{cases} v_j & \text{if } i = l \\ 0 & \text{otherwise,} \end{cases}$$

so that $e_{i,j}$ is homogeneous of degree $d_j - d_i$. Let us abuse notation by identifying each $e_{i,j}$ with its image under the isomorphism $\mathrm{End}_{\kappa}(V) \simeq \pi_* A$.

For $1 \leqslant i \leqslant n$, left multiplication by the element $e_{i,i} \in \pi_0 A$ determines an idempotent map from A to itself in the ∞-category RMod_A. We let $e_{i,i}A$ denote the corresponding direct factor of A, so that we have an equivalence $A \simeq \bigoplus e_{i,i}A$ in RMod_A. Note that each $e_{i,i}A$ is a summand of A, and therefore a compact object of RMod_A. Moreover, the elements $e_{i,j} \in \pi_{d_j - d_i} A$ induce equivalences $e_{j,j}A \simeq \Sigma^{d_i - d_j} e_{i,i}A$. It follows that each $e_{i,i}A$ is a compact generator of RMod_A. Note that the unit map $\kappa \to \pi_* \mathrm{End}_{\mathrm{RMod}_A}(e_{i,i}A) \simeq e_{i,i}(\pi_* A)e_{i,i}$ is an isomorphism, so that the construction $\kappa \mapsto e_{i,i}A$ extends to an equivalence of κ-linear stable ∞-categories $\phi : \mathrm{Mod}_{\kappa} \to \mathrm{RMod}_A$. Then $\phi^{-1}(A)$ is a compact object of Mod_{κ}, and we have an equivalence of $\mathbb{E}_1$-algebras $A \simeq \mathrm{End}_{\mathrm{RMod}_A}(A) \simeq \mathrm{End}_{\mathrm{Mod}_{\kappa}}(\phi^{-1}A)$. □

Proof of Proposition 11.5.3.14. Since assertion (b) follows from Propositions 11.5.3.3 and 11.5.1.5, it will suffice to prove (a) (alternatively, we note that (b) is an easy consequence of (a)). Let $A \in \mathrm{Alg}_{\kappa}$ and let $B = \pi_* A$, which we regard as an associative algebra over κ. We wish to show that A is an Azumaya algebra if and only if B is central simple. Without loss of generality, we may assume that κ is algebraically closed (see Remark 11.5.1.11).

Assume first that A is an Azumaya algebra. Then B is finite-dimensional as a vector space over κ. Let M be a simple left B-module. Using Lemma 11.5.3.16, we can choose a grading on M which is compatible with the grading on B. In this case, the left action of B on M determines a map of graded rings $f : B \to \mathrm{End}_\kappa(M)$. Since κ is algebraically closed and M is a simple B-module, the morphism f is surjective. We will complete the proof by showing that that the graded two-sided ideal $I = \ker(f)$ vanishes. Let $\overline{\rho}_A : B \otimes_\kappa B^{\mathrm{rev}} \to \mathrm{End}_\kappa(B)$ be the map appearing in Warning 11.5.3.15. Note that $\overline{\rho}_A$ is an algebra homomorphism, if we regard $B \otimes_\kappa B^{\mathrm{rev}}$ as equipped with the multiplication law given by

$$(x \otimes y)(x' \otimes y') = (-1)^{ij+ik}(xx' \otimes y'y),$$

where y, x', and y' are homogeneous elements of degree i, j, and k respectively. With respect to this multiplication, the tensor product $I \otimes_\kappa B^{\mathrm{rev}}$ is a two-sided ideal in $B \otimes_\kappa B^{\mathrm{rev}}$. Our assumption that A is an Azumaya algebra guarantees that $\overline{\rho}_A$ is an isomorphism, so that $B \otimes_\kappa B^{\mathrm{rev}}$ is central simple over κ (Proposition 11.5.1.2). Since $I \neq B$, it follows that $I = 0$ as desired.

Now suppose that B is central simple. Using Proposition 11.5.1.12 (and our assumption that κ is algebraically closed), we deduce that there exists an isomorphism $\alpha : B \simeq \mathrm{End}_\kappa(V)$, where V is a finite-dimensional vector space over κ. Applying Lemma 11.5.3.17, we conclude that $A \simeq \mathrm{End}_\kappa(\overline{V})$ for some perfect object $\overline{V} \in \mathrm{Mod}_\kappa$, so that A is an Azumaya algebra by virtue of Proposition 11.5.3.11. □

Theorem 11.5.3.18. *Let κ be a field. Then there is a canonical isomorphism from the Brauer group $\mathrm{Br}(\kappa)$ (Definition **??**) to the extended Brauer group $\mathrm{Br}^\dagger(\kappa)$ (Definition 11.5.2.1), which carries the equivalence class $[A] \in \mathrm{Br}(\kappa)$ of a central simple algebra A over κ to class $[A] = \mathrm{RMod}_A \in \mathrm{Br}^\dagger(\kappa)$ of Construction 11.5.3.9.*

Proof. Let A and B be central simple algebras over κ. Using Proposition 11.5.3.11, we see that the identity $[A] = [B]$ holds in $\mathrm{Br}^\dagger(\kappa)$ if and only if the tensor product $A \otimes_\kappa B$ can be identified with the endomorphism algebra $\mathrm{End}_\kappa(V)$ for some nonzero object $V \in \mathrm{Mod}_\kappa^{\mathrm{perf}}$. Note that in this case V must be discrete, so the equality $[A] = [B]$ holds in $\mathrm{Br}^\dagger(\kappa)$ if and only if it holds in $\mathrm{Br}(\kappa)$. We therefore obtain a well-defined monomorphism $\phi : \mathrm{Br}(\kappa) \to \mathrm{Br}^\dagger(\kappa)$.

We now complete the proof by showing that ϕ is surjective. According to Proposition 11.5.3.10, every element of $\mathrm{Br}^\dagger(\kappa)$ has the form $[A]$, where $A \in \mathrm{Alg}_\kappa$ is an Azumaya algebra over κ. Set $B = \pi_* A$, which we regard as a (discrete) associative algebra over κ. Proposition 11.5.3.14 implies that B is central simple. We then have canonical isomorphisms

$$\pi_*(A \otimes_\kappa B^{\mathrm{rev}}) \simeq (\pi_* A) \otimes_\kappa B^{\mathrm{rev}} \simeq B \otimes_\kappa B^{\mathrm{rev}} \simeq \mathrm{End}_\kappa(B).$$

Using Lemma 11.5.3.17, we deduce that $[A] = [B]$ in $\mathrm{Br}^\dagger(\kappa)$. □

Warning 11.5.3.19. Let κ be a field and let $\phi : \mathrm{Br}(\kappa) \to \mathrm{Br}^{\dagger}(\kappa)$ be the isomorphism of Theorem 11.5.3.18. The proof of Theorem 11.5.3.18 shows that the inverse isomorphism $\phi^{-1} : \mathrm{Br}^{\dagger}(\kappa) \to \mathrm{Br}(\kappa)$ is given by the construction $[A] \mapsto [\pi_* A]$. In particular, if A and B are Azumaya algebras over κ, then the κ-algebras $\pi_*(A \otimes_{\kappa} B)$ and $(\pi_* A) \otimes_{\kappa} (\pi_* B)$ are Morita equivalent (and therefore isomorphic, since they have the same dimension over κ). This is not *a priori* obvious: beware that the canonical identification $\pi_*(A \otimes_{\kappa} B) \simeq (\pi_* A) \otimes_{\kappa} (\pi_* B)$ is usually *not* an isomorphism of algebras.

11.5.4 Extended Brauer Groups of Direct and Inverse Limits

By virtue of Remark 11.5.2.8, we can regard the construction $R \mapsto \mathrm{Br}^{\dagger}(R)$ as a functor from the ∞-category $\mathrm{CAlg}^{\mathrm{cn}}$ of connective $\mathbb{E}_{\infty}$-rings to the ordinary category of abelian groups. We now study the compatibility of this functor with direct and inverse limits.

Proposition 11.5.4.1. *The construction $R \mapsto \mathrm{Br}^{\dagger}(R)$ commutes with filtered colimits.*

The proof of Proposition 11.5.4.1 will require some preliminaries.

Remark 11.5.4.2. Let R be a connective $\mathbb{E}_{\infty}$-ring and let $A \in \mathrm{Alg}_R$ be an Azumaya algebra. Then A is smooth and proper over R (Remark 11.5.2.5), and is therefore a compact object of Alg_R (Proposition HA.**??**).

Lemma 11.5.4.3. *For each $\mathbb{E}_2$-ring R, let Alg^c_R denote the full subcategory of Alg_R spanned by the compact objects. Then the construction $R \mapsto \mathrm{Alg}^c_R$ commutes with filtered colimits.*

Proof. Let $\{R_{\alpha}\}$ be a filtered diagram of $\mathbb{E}_2$-rings with colimit R. We wish to show that the canonical map $\theta : \varinjlim \mathrm{Alg}^c_{R_{\alpha}} \to \mathrm{Alg}^c_R$ is an equivalence of ∞-categories. It follows from Lemma HA.**??** that the domain and codomain of θ are both idempotent complete. Using Lemma HA.5.3.2.9 , we are reduced to proving that θ exhibits $\mathrm{Ind}(\mathrm{Alg}^c_R)$ as a colimit of the diagram $\{\mathrm{Ind}(\mathrm{Alg}^c_{R_{\alpha}})\}$ in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$. In other words, we must show that Alg_R is a colimit of the diagram $\{\mathrm{Alg}_{R_{\alpha}}\}$ in $\mathcal{P}\mathrm{r}^{\mathrm{L}}$. Using Theorem HTT.5.5.3.18 , we are reduced to showing that the forgetful functors $\mathrm{Alg}_R \to \mathrm{Alg}_{R_{\alpha}}$ exhibit Alg_R as a limit $\varprojlim \mathrm{Alg}_{R_{\alpha}}$ in the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_{\infty}$. For this, it will suffice to prove that the canonical map $\mathrm{LMod}_R \to \varprojlim \mathrm{LMod}_{R_{\alpha}}$ is an equivalence in $\widehat{\mathcal{C}\mathrm{at}}_{\infty}$, which follows from Proposition HA.**??** (and Theorem HTT.5.5.3.18). □

Lemma 11.5.4.4. *Let R be an $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a compactly generated R-linear ∞-category, and let $\chi : \mathrm{Alg}_R \to \mathcal{C}\mathrm{at}_{\infty}$ be the functor given by $\chi(A) = \mathrm{LMod}_A(\mathcal{C})^c$, where $\mathrm{LMod}_A(\mathcal{C})^c$ denotes the full subcategory of $\mathrm{LMod}_A(\mathcal{C})$ spanned by the compact objects. Then χ preserves filtered colimits.*

Proof. Let $\{A_\alpha\}$ be a filtered diagram in Alg_R with colimit A. We wish to show that the canonical map $\theta : \varinjlim \mathrm{LMod}_{A_\alpha}(\mathcal{C})^c \to \mathrm{LMod}_A(\mathcal{C})^c$ is an equivalence of ∞-categories. It follows from Lemma HA.**??** that the domain and codomain of θ are both idempotent complete. Using Lemma HA.5.3.2.9 , we are reduced to proving that the $\mathrm{LMod}_A(\mathcal{C})$ is a colimit of the diagram $\{\mathrm{LMod}_{A_\alpha}(\mathcal{C})\}$ in the ∞-category $\mathcal{P}\mathrm{r}^{\mathrm{L}}$. Using Theorem HA.4.8.4.6 , we are reduced to proving that $\mathrm{LMod}_A \otimes \mathcal{C}$ is a colimit of the diagram $\{\mathrm{LMod}_{A_\alpha} \otimes_R \mathcal{C}\}$ in the ∞-category LinCat_R, which follows from Proposition HA.**??** (since the tensor product in LinCat_R preserves small colimits separately in each variable). □

Proof of Proposition 11.5.4.1. Let $\{R_\alpha\}$ be a diagram of $\mathbb{E}_\infty$-rings indexed by a filtered partially ordered set, having colimit $R = \varinjlim R_\alpha$. We wish to show that the canonical map $\theta : \varinjlim \mathrm{Br}^\dagger(R_\alpha) \to \mathrm{Br}^\dagger(R)$ is an isomorphism. We first show that θ is injective. Fix an index α and an Azumaya algebra A_α over R_α, and let $A = R \otimes_{R_\alpha} A_\alpha$. Suppose that $[A]$ is trivial in $\mathrm{Br}(R)$. Then we can write $A = \mathrm{End}_R(X)$, where X is a compact generator of Mod_R. Enlarging α if necessary, we can use Lemma 11.5.4.4 to write $X = R \otimes_{R_\alpha} X_\alpha$ for some perfect R_α-module X_α. Let $\mathcal{C} \subseteq \mathrm{Mod}_{R_\alpha}$ be the smallest stable subcategory of Mod_{R_α} which contains X_α and is closed under small colimits. For each $\beta \geqslant \alpha$, we can identify $\mathrm{Mod}_{R_\beta} \otimes_{\mathrm{Mod}_{R_\alpha}} \mathcal{C}$ with the smallest stable subcategory of Mod_{R_β} which contains $X_\beta = R_\beta \otimes_{R_\alpha} X_\alpha$ and is closed under small colimits. Since X is a compact generator of Mod_R, we conclude that $\varinjlim_{\beta \geqslant \alpha} \mathrm{LMod}_{R_\beta}(\mathcal{C}) \simeq \mathrm{Mod}_R$. Using Lemma 11.5.4.4, we conclude that there exists an index $\beta \geqslant \alpha$ and a compact object $Y_\beta \in \mathcal{C}_\beta$ such that $R \otimes_{R_\beta} Y_\beta \simeq R$. Using Lemma 11.5.4.4 again, we may suppose (after enlarging β) that $Y_\beta \simeq R$, so that $\mathrm{LMod}_{R_\beta}(\mathcal{C}) = \mathrm{Mod}_{R_\beta}$. Replacing α by β, we may reduce to the case where X_α is a compact generator of Mod_{R_α}, so that $B_\alpha = \mathrm{End}_{R_\alpha}(X_\alpha)$ is an Azumaya algebra. Remark 11.5.4.2 implies that A_α and B_α are compact objects of Alg_{R_α}. Since the images of A_α and B_α in Alg_R are equivalent, Lemma 11.5.4.3 implies that there exists $\gamma \geqslant \alpha$ such that $R_\gamma \otimes_{R_\alpha} A_\alpha$ and $R_\gamma \otimes_{R_\alpha} B_\alpha$ are equivalent in Alg_{R_γ}. It follows that the image of $[A_\alpha]$ vanishes in $\mathrm{Br}^\dagger(R_\gamma)$, and therefore represents the trivial element in the domain of θ.

We now prove that θ is surjective. According to Proposition 11.5.3.10, every element of $\mathrm{Br}^\dagger(R)$ can be written as $[A]$, where A is an Azumaya algebra over R. Then A is a compact object of Alg_R (Remark 11.5.4.2), so we can write $A = R \otimes_{R_\alpha} A_\alpha$ for some index α and some compact object $A_\alpha \in \mathrm{Alg}_{R_\alpha}$. Using the preceding argument, we may assume (after enlarging α if necessary) that A_α is a compact generator of Mod_{R_α}. The left and right actions of A_α on itself induce a map $u : A_\alpha \otimes_{R_\alpha} A_\alpha^{\mathrm{op}} \to \mathrm{End}_{R_\alpha}(A_\alpha)$. We can regard u as a morphism between perfect R_α-modules. Since A is Azumaya, the image of u in Mod_R is an equivalence. Using Lemma 11.5.4.4, we deduce that there exists an index $\beta \geqslant \alpha$ such that the image of u in Mod_{R_β} is an equivalence. Then $A_\beta = R_\beta \otimes_{R_\alpha} A_\alpha$ is an Azumaya algebra over R_β, so that $[A]$ belongs to the image of the map $\mathrm{Br}^\dagger(R_\beta) \to \mathrm{Br}(R)$. □

We now study the compatibility of the functor $R \mapsto \mathrm{Br}^{\dagger}(R)$ with (certain) inverse limits.

Proposition 11.5.4.5. *Let R be a Noetherian commutative ring which is complete with respect to an ideal I. Then the map $\mathrm{Br}^{\dagger}(R) \to \mathrm{Br}^{\dagger}(R/I)$ is injective.*

Proposition 11.5.4.6. *Let R be a connective $\mathbb{E}_{\infty}$-ring. Then the map $\mathrm{Br}^{\dagger}(R) \to \mathrm{Br}^{\dagger}(\pi_0 R)$ is injective.*

Remark 11.5.4.7. We will show later that the canonical map $\mathrm{Br}^{\dagger}(R) \to \mathrm{Br}^{\dagger}(\pi_0 R)$ is an isomorphism: see Proposition 11.5.5.6.

To prove Propositions 11.5.4.5 and 11.5.4.6, we will need a variant of Proposition 11.5.3.11 which can be used to verify the vanishing of an element $\eta \in \mathrm{Br}^{\dagger}(R)$.

Definition 11.5.4.8. Let R be a connective $\mathbb{E}_{\infty}$-ring, and let $\mathcal{C} \in \mathscr{B}\mathrm{r}^{\dagger}(R)$ be an invertible R-linear ∞-category. We will say that a compact object $X \in \mathcal{C}$ is a *neutralization* of $\mathcal{C}$ if the unit map $R \to \underline{\mathrm{Map}}_{\mathcal{C}}(X, X)$ is an equivalence.

Proposition 11.5.4.9. *Let R be a connective $\mathbb{E}_{\infty}$-ring, let $\mathcal{C} \in \mathscr{B}\mathrm{r}^{\dagger}(R)$, and let $X \in \mathcal{C}$ be a compact object, so that X classifies an R-linear functor $F : \mathrm{Mod}_R \to \mathcal{C}$. The following conditions are equivalent:*

(1) *The map F is an equivalence of ∞-categories.*

(2) *The object X is a neutralization of $\mathcal{C}$.*

Proof. The implication (1) ⇒ (2) is clear. Conversely, suppose that (2) is satisfied. Since F preserves small colimits and compact objects, it admits an R-linear right adjoint G (Remark D.1.5.3). Since X is a neutralization of $\mathcal{C}$, the functor F is fully faithful, so that the unit map $u : \mathrm{id} \to G \circ F$ is an equivalence. Let $F' : \mathcal{C}^{-1} \to \mathrm{Mod}_R$ be the functor obtained by tensoring F over Mod_R with $\mathcal{C}^{-1}$. It follows that F' admits an R-linear right adjoint G', and that the unit map $u' : \mathrm{id} \to G' \circ F'$ is fully faithful. In particular, the functor F' is fully faithful and preserves compact objects. Let Y be a compact generator of $\mathcal{C}^{-1}$, and let $M = F'(Y) \in \mathrm{Mod}_R^{\mathrm{perf}}$. Since F' is fully faithful, the canonical map $\underline{\mathrm{Map}}_{\mathcal{C}^{-1}}(Y, Y) \to \mathrm{End}(M)$ is an equivalence in Alg_R. It follows from Proposition 11.5.3.4 that $\mathrm{End}(M)$ is an Azumaya algebra over R. In particular, $\mathrm{End}(M)$ is a compact generator of Mod_R. Since $\mathrm{End}(M) \simeq M^{\vee} \otimes_R M \simeq F'(M^{\vee} \otimes Y)$ belongs to the essential image of F', we deduce that F' is an equivalence of ∞-categories. We conclude that the functor F is also an equivalence. □

Corollary 11.5.4.10. *Let R be a connective $\mathbb{E}_{\infty}$-ring and let $\mathcal{C} \in \mathscr{B}\mathrm{r}^{\dagger}(R)$. Then $[\mathcal{C}] = 0$ in $\mathrm{Br}^{\dagger}(R)$ if and only if there exists a neutralization of $\mathcal{C}$.*

The proofs of Propositions 11.5.4.6 and 11.5.4.5 will also require a bit of deformation theory.

Lemma 11.5.4.11. *Suppose we are given a pullback diagram of connective $\mathbb{E}_\infty$-rings σ :*

$$\begin{array}{ccc} R & \longrightarrow & R_0 \\ \downarrow & & \downarrow \\ R_1 & \longrightarrow & R_{01}, \end{array}$$

where the underlying maps of commutative rings $\pi_0 R_0 \to \pi_0 R_{01} \leftarrow \pi_0 R_1$ are surjective. Let $\mathcal{C}$ be an R-linear ∞-category which is smooth and proper. Then the canonical map

$$\theta : \mathcal{C}^c \to \mathrm{LMod}_{R_0}(\mathcal{C})^c \times_{\mathrm{LMod}_{R_{01}}(\mathcal{C})} \mathrm{LMod}_{R_1}(\mathcal{C})^c$$

is an equivalence of ∞-categories.

Proof. We proceed as in the proof of Theorem 11.4.4.1. Since $\mathcal{C}$ is a smooth R-linear ∞-category, we can write $\mathcal{C} \simeq \mathrm{RMod}_A$ for some smooth $\mathbb{E}_1$-algebra A over R (Proposition 11.3.2.4). It follows from Proposition 11.1.0.2 that A is also a proper $\mathbb{E}_1$-algebra over R, so that an object of $\mathcal{C} \simeq \mathrm{RMod}_A$ is compact if and only if its image in Mod_R is compact. Let $A_0 = R_0 \otimes_R A$, and define A_1 and A_{01} similarly. We have a commutative diagram

$$\begin{array}{ccc} \mathrm{RMod}_A^{\mathrm{perf}} & \xrightarrow{\theta} & \mathrm{RMod}_{A_0}^{\mathrm{perf}} \times_{\mathrm{RMod}_{A_{01}}^{\mathrm{perf}}} \mathrm{RMod}_{A_1}^{\mathrm{perf}} \\ \downarrow & & \downarrow \\ \mathrm{Mod}_R^{\mathrm{perf}} & \xrightarrow{\theta'} & \mathrm{Mod}_{R_0}^{\mathrm{perf}} \times_{\mathrm{Mod}_{R_{01}}^{\mathrm{perf}}} \mathrm{Mod}_{R_1}^{\mathrm{perf}} . \end{array}$$

Proposition 16.2.1.1 implies that θ is fully faithful. Moreover, Theorem 16.2.0.2 and Proposition 16.2.3.1 guarantee θ' is an equivalence of ∞-categories. Consequently, to prove that θ is an equivalence, it will suffice to show that θ induces an essentially surjective map

$$\phi : \mathrm{RMod}_A^{\mathrm{perf}} \times_{\mathrm{Mod}_R^{\mathrm{perf}}} \{M\} \to (\mathrm{RMod}_{A_0}^{\mathrm{perf}} \times_{\mathrm{RMod}_{A_{01}}^{\mathrm{perf}}} \mathrm{RMod}_{A_1}^{\mathrm{perf}}) \times_{\mathrm{Mod}_R^{\mathrm{perf}}} \{M\}$$

for every perfect R-module M. Let $M_0 = R_0 \otimes_R M \in \mathrm{Mod}_{R_0}^{\mathrm{perf}}$, and define M_1 and M_{01}

similarly. Using Theorem HA.4.7.1.34 , we can identify ϕ with the canonical map

$$\begin{array}{c}
\mathrm{Map}_{\mathrm{Alg}_R}(A^{\mathrm{rev}}, \mathrm{End}(M)) \\
\downarrow \\
\mathrm{Map}_{\mathrm{Alg}_{R_0}}(A_0^{\mathrm{rev}}, \mathrm{End}(M_0)) \times_{\mathrm{Map}_{\mathrm{Alg}_{R_{01}}}(A_{01}^{\mathrm{rev}}, \mathrm{End}(M_{01}))} \mathrm{Map}_{\mathrm{Alg}_{R_1}}(A_1^{\mathrm{rev}}, \mathrm{End}(M_1)) \\
\downarrow \\
\mathrm{Map}_{\mathrm{Alg}_R}(A^{\mathrm{rev}}, \mathrm{End}(M_0)) \times_{\mathrm{Map}_{\mathrm{Alg}_R}(A^{\mathrm{rev}}, \mathrm{End}(M_{01}))} \mathrm{Map}_{\mathrm{Alg}_R}(A^{\mathrm{rev}}, \mathrm{End}(M_1)) \\
\downarrow \\
\mathrm{Map}_{\mathrm{Alg}_R}(A^{\mathrm{rev}}, \mathrm{End}(M_0) \times_{\mathrm{End}(M_{01})} \mathrm{End}(M_1)) \\
\downarrow \\
\mathrm{Map}_{\mathrm{Alg}_R}(A^{\mathrm{rev}}, (R_0 \times_{R_{01}} R_1) \otimes_R M).
\end{array}$$

Since σ is a pullback diagram, this map is an equivalence. □

Lemma 11.5.4.12. *Let R be a connective $\mathbb{E}_\infty$-ring, let $\overline{R}$ be a square-zero extension of R by a connective R-module M, and let $\mathcal{C} \in \mathscr{B}\mathrm{r}^\dagger(\overline{R})$. Then any neutralization of $\mathrm{LMod}_R(\mathcal{C})$ can be lifted to a neutralization of $\mathcal{C}$.*

Proof. Since $\overline{R}$ is a square-zero extension of R by M, we have a pullback diagram of $\mathbb{E}_\infty$-rings

$$\begin{array}{ccc}
\overline{R} & \longrightarrow & R \\
\downarrow & & \downarrow \\
R & \longrightarrow & R \oplus \Sigma M.
\end{array}$$

Applying Lemma 11.5.4.11, we obtain a pullback diagram of ∞-categories

$$\begin{array}{ccc}
\mathcal{C}^c & \longrightarrow & \mathrm{LMod}_R(\mathcal{C})^c \\
\downarrow & & \downarrow \beta \\
\mathrm{LMod}_R(\mathcal{C})^c & \xrightarrow{\alpha} & \mathrm{LMod}_{R \oplus \Sigma M}(\mathcal{C})^c.
\end{array}$$

Let $X \in \mathrm{LMod}_R(\mathcal{C})^c$ be a neutralization. We first claim that X can be lifted to a compact object $\overline{X} \in \mathcal{C}$. For this, it suffices to show that $\alpha(X)$ lies in the essential image of β. Using Corollary 11.5.4.10, we can choose an R-linear equivalence $\mathrm{LMod}_R(\mathcal{C}) \simeq \mathrm{Mod}_R$, which induces an equivalence $\mathrm{LMod}_{R \oplus \Sigma M}(\mathcal{C}) \simeq \mathrm{Mod}_{R \oplus \Sigma M}$. Under the latter equivalence, we can identify $\alpha(X)$ with an invertible module L over $R \oplus \Sigma M$. Proposition 2.9.6.2 guarantees that the base change map $\mathrm{Pic}^\dagger(R) \to \mathrm{Pic}^\dagger(R \oplus \Sigma M)$ is an isomorphism of abelian groups, so that L belongs to the essential image of α.

It remains to prove that $\overline{X}$ is a neutralization of $\mathcal{C}$. Let $u : \overline{R} \to \underline{\mathrm{Map}}_{\mathcal{C}}(\overline{X}, \overline{X})$ be the unit map; we wish to show that u is an equivalence. Suppose otherwise. Then $\mathrm{cofib}(u)$

is a nonzero perfect module over $\overline{R}$. It follows that there is a smallest integer m such that $\pi_m \operatorname{cofib}(u) \neq 0$. Using Nakayama's lemma, we deduce that $\pi_m(R \otimes_{\overline{R}} \operatorname{cofib}(u)) \neq 0$, contradicting our assumption that X is a neutralization of $\mathrm{LMod}_R(\mathcal{C})$. □

Proof of Proposition 11.5.4.5. Let $\mathcal{C} \in \mathscr{B}\mathrm{r}^{\dagger}(R)$, and suppose that $\mathrm{LMod}_{R/I}(\mathcal{C})$ represents the zero element of $\mathrm{Br}^{\dagger}(R/I)$. Corollary 11.5.4.10 implies that there exists a neutralization X_1 of $\mathrm{LMod}_{R/I}(\mathcal{C})$. Applying Lemma 11.5.4.12 repeatedly, we can choose a compatible family of neutralizations $X_n \in \mathrm{LMod}_{R/I^n}(\mathcal{C})$. It follows from Theorem 11.4.4.1 that we can write $X_n \simeq R/I^n \otimes X$ for some compact object $X \in \mathcal{C}$. We will complete the proof by showing that X is a neutralization of $\mathcal{C}$. Let $u : R \to \underline{\mathrm{Map}}_{\mathcal{C}}(X, X)$ be the unit map; we wish to prove that $\operatorname{cofib}(u) \simeq 0$. Suppose otherwise. Since $\operatorname{cofib}(u)$ is a perfect R-module, there exists some smallest integer m such that $\pi_m \operatorname{cofib}(u) \neq 0$. Then $\pi_m \operatorname{cofib}(u)$ is a finitely generated module over R, and $\mathrm{Tor}_0^R(R/I, \pi_m \operatorname{cofib}(u)) \simeq \pi_m(R/I \otimes_R \operatorname{cofib}(u)) \simeq 0$. Since R is I-adically complete, it follows that $\pi_m \operatorname{cofib}(u) \simeq 0$, contrary to our choice of m. □

Proof of Proposition 11.5.4.6. Let $\mathcal{C} \in \mathscr{B}\mathrm{r}^{\dagger}(R)$, and suppose that $\mathrm{LMod}_{\pi_0 R}(\mathcal{C})$ represents the zero element of $\mathrm{Br}^{\dagger}(\pi_0 R)$. Corollary 11.5.4.10 implies that there exists a neutralization X_0 of $\mathrm{LMod}_{\pi_0 R}(\mathcal{C})$. Applying Lemma 11.5.4.12 repeatedly, we can choose a compatible family of neutralizations $X_n \in \mathrm{LMod}_{\tau_{\leqslant n} R}(\mathcal{C})$. It follows from Theorem 11.4.4.1 that we can write $X_n \simeq (\tau_{\leqslant n} R) \otimes X$ for some compact object $X \in \mathcal{C}$. We will complete the proof by showing that X is a neutralization of $\mathcal{C}$. Let $u : R \to \underline{\mathrm{Map}}_{\mathcal{C}}(X, X)$ be the unit map; we wish to prove that $\operatorname{cofib}(u) \simeq 0$. Suppose otherwise. Since $\operatorname{cofib}(u)$ is a perfect R-module, there exists some smallest integer m such that $\pi_m \operatorname{cofib}(u) \neq 0$. Then

$$0 \neq \pi_m \operatorname{cofib}(u) \simeq \pi_m(\pi_0 R \otimes_R \operatorname{cofib}(u)) \simeq 0$$

and we obtain a contradiction. □

11.5.5 Cohomological Interpretation of the Extended Brauer Group

We can now formulate the main result of this section:

Theorem 11.5.5.1. *Let X be a spectral Deligne-Mumford stack, and let $u \in \mathrm{Br}^{\dagger}(\mathsf{X})$. Then there exists an étale surjection $f : \mathsf{U} \to \mathsf{X}$ such that $f^* u = 0$ in $\mathrm{Br}^{\dagger}(\mathsf{U})$.*

Remark 11.5.5.2. Theorem 11.5.5.1 was proven by Toën in the setting of simplicial commutative rings ([211]) and by Antieau-Gepner in general ([2]). The proof we present here is slightly different: it avoids theory of higher algebraic stacks in the setting of spectral algebraic geometry, but relies on nontrivial input from commutative algebra (namely, Popescu's smoothing theorem; see Theorem **??**).

Proof of Theorem 11.5.5.1. Let X be a spectral Deligne-Mumford stack and let $u \in \mathrm{Br}^{\dagger}(\mathsf{X})$; we wish to show that u vanishes after passing to an étale cover of X. Without loss of generality that $\mathsf{X} = \mathrm{Spét}\, R$ for some connective $\mathbb{E}_{\infty}$-ring R. Using Proposition 11.5.4.6 (and Theorem HA.7.5.0.6), we can replace R by $\pi_0 R$ and thereby reduce to the case where R is discrete. Write R as a union of its finitely generated subalgebras R_{α}. Using Proposition 11.5.4.1, we may assume that u is the image of some class $u_{\alpha} \in \mathrm{Br}(R_{\alpha})$. Replacing R by R_{α}, we may suppose that R is finitely generated commutative ring.

Let $\mathfrak{m} \subseteq R$ be a maximal ideal. We will show that there exists an étale map $R \to R(\mathfrak{m})$ such that the image of u in $\mathrm{Br}^{\dagger}(R(\mathfrak{m}))$ vanishes, and $\mathfrak{m}$ lies in the image of the induced map $\theta_{\mathfrak{m}} : |\operatorname{Spec} R(\mathfrak{m})| \to |\operatorname{Spec} R|$. Assuming this, the union of the images of the maps $\theta_{\mathfrak{m}}$ is an open subset of $|\operatorname{Spec} R|$ which contains all maximal ideals, and is therefore the whole of $|\operatorname{Spec} R|$. Since $|\operatorname{Spec} R|$ is quasi-compact, we can choose a finite collection of maximal ideals $\mathfrak{m}_1, \ldots, \mathfrak{m}_n$ such that $|\operatorname{Spec} R| = \bigcup_{1 \leqslant i \leqslant n} \theta_{\mathfrak{m}_i}(|\operatorname{Spec} R(\mathfrak{m}_i)|)$. We may then complete the proof by taking $R' = \prod_{1 \leqslant i \leqslant n} R(\mathfrak{m}_i)$.

Let $\kappa = R/\mathfrak{m}$ and let $\overline{\kappa}$ be a separable closure of κ. Using Theorem 11.5.3.18 and Proposition 11.5.1.12, we deduce that the image of u in $\mathrm{Br}^{\dagger}(\overline{\kappa})$ vanishes. It follows from Proposition 11.5.4.1 that there exists a separable extension κ' of κ having degree $d < \infty$, such that the image of u in $\mathrm{Br}^{\dagger}(\kappa')$ vanishes. Using the primitive element theorem, we can write $\kappa' = \kappa[x]/(f(x))$, where f is a separable monic polynomial of degree d. Choose a monic polynomial $\overline{f} \in R[x]$ of degree d lifting f. Replacing R by a localization if necessary, we may suppose that $R[x]/(f(x))$ is an étale R-algebra. Replacing R by $R[x]/(f(x))$, we may reduce to the case where the image of u in $\mathrm{Br}^{\dagger}(\kappa)$ vanishes.

Let $R_{\mathfrak{m}}$ denote the localization of R at $\mathfrak{m}$, and let $R^{\wedge}_{\mathfrak{m}}$ denote the completion of $R_{\mathfrak{m}}$ with respect to its maximal ideal. It follows from Proposition 11.5.4.5 that the image of u in $\mathrm{Br}^{\dagger}(R^{\wedge}_{\mathfrak{m}})$ vanishes. Since R is a finitely generated commutative ring, it is a Grothendieck ring (Theorem **??**). It follows that the map $R \to R^{\wedge}_{\mathfrak{m}}$ is geometrically regular, so that we can write $R^{\wedge}_{\mathfrak{m}} = \varinjlim A_{\beta}$, where each A_{β} is fiber smooth over R (Theorem **??**) Using Proposition 11.5.4.1, we deduce that there exists an index β such that the image of u in $\mathrm{Br}^{\dagger}(A_{\beta})$ vanishes. Replacing R by a localization if necessary, we may suppose that the map of affine schemes $\operatorname{Spec} A_{\beta} \to \operatorname{Spec} R$ is smooth and faithfully flat, and therefore admits an étale section. That is, we can find a map $A_{\beta} \to R'$, where R' is étale and faithfully flat over R. By construction the image of u vanishes in $\mathrm{Br}^{\dagger}(R')$. □

Let us now describe some consequences of Theorem 11.5.5.1.

Construction 11.5.5.3 (The Extended Brauer Sheaf)**.** Let $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathsf{X}})$ be a spectral Deligne-Mumford stack. For each object $U \in \mathcal{X}$, let X_U denote the spectral Deligne-Mumford stack $(\mathcal{X}_{/U}, \mathcal{O}_{\mathsf{X}}|_U)$. The construction $U \mapsto \mathscr{B}\mathrm{r}(\mathsf{X}_U)$ determines a functor $\mathcal{X}^{\mathrm{op}} \to \widehat{\mathcal{S}}$ which preserves small limits. Note that if U is affine, then Remark 11.5.3.13 implies that $\mathscr{B}\mathrm{r}(\mathsf{X}_U)$

is essentially small. It follows that $\mathscr{B}\mathrm{r}(\mathsf{X}_U)$ is essentially small for each $U \in \mathcal{X}$, so that that the functor $U \mapsto \mathscr{B}\mathrm{r}^{\dagger}(\mathsf{X}_U)$ is representable by an object $\underline{\mathscr{B}\mathrm{r}}^{\dagger}_{\mathsf{X}} \in \mathcal{X}$. We will refer to $\underline{\mathscr{B}\mathrm{r}}^{\dagger}_{\mathsf{X}}$ as the *extended Brauer sheaf* of X.

Note that $\underline{\mathscr{B}\mathrm{r}}^{\dagger}_{\mathsf{X}}$ is a group-like commutative monoid of $\mathcal{X}$. In particular, we can view each homotopy group $\pi_n \underline{\mathscr{B}\mathrm{r}}^{\dagger}_{\mathsf{X}}$ as an abelian group object in the topos $\mathcal{X}^{\heartsuit}$ of discrete objects of $\mathcal{X}$. Using Theorem 11.5.5.1, Remark 11.5.2.11, and Remark 2.9.5.8, we obtain isomorphisms

$$\pi_n \underline{\mathscr{B}\mathrm{r}}^{\dagger}_{\mathsf{X}} = \begin{cases} 0 & \text{if } n = 0 \\ \underline{\mathbf{Z}} & \text{if } n = 1 \\ (\pi_0 \mathscr{O}_{\mathsf{X}})^{\times} & \text{if } n = 2 \\ \pi_{n-2} \mathscr{O}_{\mathsf{X}} & \text{if } n > 2, \end{cases}$$

where $\underline{\mathbf{Z}}$ denotes the constant sheaf associated to the abelian group $\mathbf{Z}$.

Remark 11.5.5.4. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ be a spectral Deligne-Mumford stack. Then the invertible sheaf $\Sigma\,\mathscr{O}_{\mathsf{X}}$ determines a global section of the sheaf $\Omega \underline{\mathscr{B}\mathrm{r}}^{\dagger}_{\mathsf{X}}$, which we can identify with a map $\alpha : K(\underline{\mathbf{Z}}, 1) \to \underline{\mathscr{B}\mathrm{r}}^{\dagger}_{X}$ of pointed objects of $\mathcal{X}$; here $K(\underline{\mathbf{Z}}, 1)$ denotes the constant sheaf on X whose value is the space $K(\mathbf{Z}, 1) \simeq S^1$. Note that α can be identified with a section of the truncation map $\underline{\mathscr{B}\mathrm{r}}^{\dagger}_{\mathsf{X}} \to \tau_{\leqslant 1} \underline{\mathscr{B}\mathrm{r}}^{\dagger}_{\mathsf{X}} \simeq K(\underline{\mathbf{Z}}, 1)$. Using the monoid structure on $\underline{\mathscr{B}\mathrm{r}}^{\dagger}_{\mathsf{X}}$, we see that α determines an equivalence

$$\tau_{\geqslant 2} \underline{\mathscr{B}\mathrm{r}}^{\dagger}_{\mathsf{X}} \times K(\underline{Z}, 1) \to \underline{\mathscr{B}\mathrm{r}}^{\dagger}_{\mathsf{X}}.$$

Beware that this equivalence is *not* compatible with the monoid structure on $\underline{\mathscr{B}\mathrm{r}}^{\dagger}_{\mathsf{X}}$, because the map α is not multiplicative.

Example 11.5.5.5. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ be a spectral Deligne-Mumford stack, and suppose that the structure sheaf $\mathscr{O}_{\mathsf{X}}$ is 0-truncated. Then we can identify $\mathscr{O}_{\mathsf{X}}$ with a commutative ring object of the topos of discrete objects of $\mathcal{X}$; let $\mathscr{O}_{\mathsf{X}}^{\times}$ denote its group of units. Combining the analysis of Construction 11.5.5.3 with Remark 11.5.5.4, we obtain an equivalence $\underline{\mathscr{B}\mathrm{r}}^{\dagger}_{\mathsf{X}} \simeq K(\mathscr{O}_{\mathsf{X}}^{\times}, 2) \times K(\underline{\mathbf{Z}}, 1)$ in the ∞-topos $\mathcal{X}$. Passing to global sections, we obtain a bijection $\mathrm{Br}^{\dagger}(\mathsf{X}) \simeq \mathrm{H}^2(\mathcal{X}; \mathscr{O}_{\mathsf{X}}^{\times}) \times \mathrm{H}^1(\mathcal{X}; \underline{\mathbf{Z}})$. It is not hard to see that this bijection is an isomorphism of abelian groups. In particular, if $\mathrm{H}^1(\mathcal{X}; \underline{\mathbf{Z}})$ vanishes (for example, if X is a quasi-compact, quasi-separated spectral algebraic space which is normal and locally Noetherian; see Theorem **??**), then we obtain an isomorphism $\mathrm{Br}^{\dagger}(\mathsf{X}) \simeq \mathrm{H}^2(\mathcal{X}; \mathscr{O}_{\mathsf{X}}^{\times})$.

Using Theorem 11.5.5.1, we can prove the following refinement of Proposition 11.5.4.6:

Proposition 11.5.5.6. *Let R be a connective $\mathbb{E}_{\infty}$-ring. Then the canonical map $\mathrm{Br}^{\dagger}(R) \to \mathrm{Br}^{\dagger}(\pi_0 R)$ is an isomorphism.*

Proof. Let $\mathcal{X} = \mathcal{S}\mathrm{hv}_R^{\text{ét}}$. For each integer n, let $\mathscr{F}_n$ denote the Brauer sheaf of $\operatorname{Sp\acute{e}t} \tau_{\leqslant n} R$, and regard $\mathscr{F}_n$ as a grouplike commutative monoid object of $\mathcal{X}$. Let $\mathscr{F}$ denote the Brauer sheaf of $\operatorname{Sp\acute{e}t} R$, and let $\mathscr{F}_\infty = \varprojlim \mathscr{F}_n$, so that we have maps

$$\mathscr{F} \xrightarrow{\alpha} \mathscr{F}_\infty \xrightarrow{\beta} \mathscr{F}_0 .$$

We will prove the following:

(a) For every étale R-algebra R', the map β induces an isomorphism $\pi_0(\mathscr{F}_\infty(R')) \to \pi_0(\mathscr{F}_0(R'))$.

(b) The map α is an equivalence.

Assuming (a) and (b), we deduce that the composition of α and β induces an isomorphism

$$\mathrm{Br}^\dagger(R) \simeq \pi_0 \mathscr{F}(R) \xrightarrow{\alpha} \pi_0 \mathscr{F}_\infty(R) \xrightarrow{\beta} \pi_0 \mathscr{F}_0(R) \simeq \mathrm{Br}^\dagger(\pi_0 R).$$

We first prove (a). Note that we have an exact sequence

$$\lim{}^1\{\pi_1 \mathscr{F}_n(R')\} \to \pi_0 \mathscr{F}_\infty(R') \to \lim{}^0\{\pi_0 \mathscr{F}_n(R')\} \to 0$$

where the left hand side vanishes by virtue of Proposition 2.9.6.2. Consequently, to prove (a), it will suffice to show that each of the maps $\theta : \pi_0 \mathscr{F}_n(R') \to \pi_0 \mathscr{F}_{n-1}(R')$ is an isomorphism. Enlarging R if necessary, we may suppose that $R' = R$. Let $\mathscr{O}$ denote the structure sheaf of $\operatorname{Sp\acute{e}t} R$. Using the description of the homotopy sheaves of $\mathscr{F}_n$ and $\mathscr{F}_{n-1}$ supplied by Construction 11.5.5.3, we deduce the existence of a fiber sequence

$$\mathscr{F}_n \to \mathscr{F}_{n-1} \to K(\pi_n \mathscr{O}, n+3)$$

in the ∞-topos $\mathcal{X}$, so that we have a short exact sequence

$$\mathrm{H}^{n+2}(\mathcal{X}; \pi_n \mathscr{O}) \to \pi_0 \mathscr{F}_n(R) \xrightarrow{\theta} \pi_0 \mathscr{F}_{n-1}(R) \to \mathrm{H}^{n+3}(\mathcal{X}; \pi_n \mathscr{O}).$$

The desired result now follows from the vanishing of $\mathrm{H}^i(\mathcal{X}; \pi_n \mathscr{O}) \simeq 0$ for $i > 0$.

We now prove (b). Using (a), we deduce that $\pi_0 \mathscr{F}_\infty \simeq \pi_0 \mathscr{F}_0$. The map α induces an isomorphism $\pi_0 \mathscr{F} \to \pi_0 \mathscr{F}_\infty$ (both sides vanish by Theorem 11.5.5.1). Consequently, to prove that α is an equivalence, it will suffice to show that α induces an equivalence of loop objects $\Omega \mathscr{F} \to \Omega \mathscr{F}_\infty \simeq \varprojlim \Omega \mathscr{F}_n$. This follows immediately from Remark 11.5.2.11 and Corollary 2.9.6.3. □

11.5.6 Digression: Connectivity of Compact Objects

Let R be a connective $\mathbb{E}_\infty$-ring and let M be an R-module spectrum. If M is connective, then the fiber $\kappa \otimes_R M \in \mathrm{Mod}_\kappa$ is connective for every residue field κ of R. If M is a perfect R-module, then the converse holds: if M is not connective, then there exists some largest integer $n > 0$ such that $\pi_{-n} M \neq 0$. Then $\pi_{-n} M$ is a finitely generated module over $\pi_0 R$, so Nakayama's lemma implies that there exists a residue field κ of R for which $0 \neq \mathrm{Tor}_0^{\pi_0 R}(\kappa, \pi_{-n} M) \simeq \pi_{-n}(\kappa \otimes_R M)$. We close this section by establishing a "relative version" of this observation, which will be useful in §11.5.7:

Theorem 11.5.6.1. *Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be a compactly generated prestable R-linear ∞-category, and let $C \in \mathrm{Sp}(\mathcal{C})$ be a compact object. Assume that the commutative ring $\pi_0 R$ is Noetherian. Then the following conditions are equivalent:*

(1) *The object C belongs to $\mathrm{Sp}(\mathcal{C})_{\geq 0}$.*

(2) *For every residue field κ of $\pi_0 R$, the object $\kappa \otimes_R C$ belongs to $(\kappa \otimes_R \mathrm{Sp}(\mathcal{C}))_{\geq 0}$.*

The proof of Theorem 11.5.6.1 will require some preliminaries. We first show that (under very mild assumptions) the question can be reduced to the case where R is discrete:

Proposition 11.5.6.2. *Let R be a connective $\mathbb{E}_2$-ring, let $\mathcal{C}$ be an R-linear prestable ∞-category, and set $\mathcal{C}' = (\pi_0 R) \otimes_R \mathcal{C}$. Let C be an object of $\mathrm{Sp}(\mathcal{C})$ which belongs to $\mathrm{Sp}(\mathcal{C})_{\geq -n}$ for some integer n. Then C belongs to $\mathrm{Sp}(\mathcal{C})_{\geq 0}$ if and only if the image of C in $\mathrm{Sp}(\mathcal{C}')$ belongs to $\mathrm{Sp}(\mathcal{C}')_{\geq 0}$.*

Remark 11.5.6.3. In the situation of Proposition 11.5.6.2, the assumption that C belongs to $\mathrm{Sp}(\mathcal{C})_{\geq -n}$ for some integer n is automatically satisfied if C is a compact object of $\mathrm{Sp}(\mathcal{C})$: the right completeness of $\mathrm{Sp}(\mathcal{C})$ guarantees that C can be realized as the colimit of the sequence of truncations

$$\cdots \rightarrow \tau_{\geq 0} C \rightarrow \tau_{\geq -1} C \rightarrow \tau_{\geq -2} C \rightarrow \cdots,$$

so that the compactness of C implies that C is a retract of $\tau_{\geq -n} C$ for some n.

Proof of Proposition 11.5.6.2. The "only if" direction is obvious. To prove the converse, we show that $C \in \mathrm{Sp}(\mathcal{C})_{\geq -m}$ for every nonnegative integer m using descending induction on m. To carry out the inductive step, we note if $C \in \mathrm{Sp}(\mathcal{C})_{\geq -m}$, then $(\tau_{\geq 1} R) \otimes_R C$ belongs to $\mathrm{Sp}(\mathcal{C})_{\geq 1-m}$, so that we have an exact sequence (in the abelian category $\mathcal{C}^{\heartsuit}$)

$$0 = \pi_{-m}((\tau_{\geq 1} R) \otimes_R C) \rightarrow \pi_{-m} C \rightarrow \pi_{-m}((\pi_0 R) \otimes_R C).$$

Our hypothesis guarantees that $(\pi_0 R) \otimes_R C$ belongs to $\mathrm{Sp}(\mathcal{C})_{\geq 0}$, so that $\pi_{-m}((\pi_0 R) \otimes_R C)$ vanishes for $m > 0$. it follows that $\pi_{-m} C \simeq 0$ and therefore $C \in \mathcal{C}_{\geq 1-m}$. □

Proposition 11.5.6.4. *Let R be a commutative ring (which we regard as a discrete $\mathbb{E}_2$-ring), let $\mathcal{C}$ be a compactly generated prestable R-linear ∞-category. Let $C \in \mathrm{Sp}(\mathcal{C})$ be a compact object and let x be an element of R. Then C belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ if and only if both of the objects $R[x^{-1}] \otimes_R C$ and $R/(x) \otimes_R C$ belong to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$.*

Proof. The "only if" direction is clear. Conversely, suppose that both $R[x^{-1}] \otimes_R C$ and $R/(x) \otimes_R C$ belong to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. For every object $D \in \mathrm{Sp}(\mathcal{C})$, set $D[x^{-1}] = R[x^{-1}] \otimes_R D \in \mathrm{LMod}_{R[x^{-1}]}(\mathrm{Sp}(\mathcal{C}))$. Note that the object C belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ if and only if the direct sum $C \oplus \Sigma C$ belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. Using our assumption that $C[x^{-1}]$ is a compact object of $\mathrm{LMod}_{R[x^{-1}]}(\mathcal{C})$, we see that (after replacing C by $C \oplus \Sigma C$ if necessary) we may assume that there exists a compact object $D \in \mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ with $\alpha : D[x^{-1}] \simeq C[x^{-1}]$ (Proposition D.5.3.4). Arguing as in Proposition D.5.3.4, we see that after multipliying the equivalence α by a suitable power of x, we can arrange that α arises from a morphism $\alpha_0 : D \to C$ in $\mathrm{Sp}(\mathcal{C})$. Since the full subcategory $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ is closed under extensions, it will suffice to prove that $\mathrm{cofib}(\alpha_0)$ belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. Replacing C by $\mathrm{cofib}(\alpha_0)$, we can reduce to the case where $C[x^{-1}] \simeq 0$.

The assumption that $C[x^{-1}] \simeq 0$ implies that the canonical map $C \to C[x^{-1}]$ is nullhomotopic. Since C is a compact object of $\mathrm{Sp}(\mathcal{C})$, it follows that the map $x^n : C \to C$ is nullhomotopic for $n \gg 0$. Let $M \in \mathrm{Mod}_R$ denote the cofiber of the map $x^n : R \to R$. Then

$$M \otimes_R C \simeq \mathrm{cofib}(x^n : C \to C) \simeq C \oplus \Sigma(C).$$

It will therefore suffice to show that $M \otimes_R C$ belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. Note that M can be written as a successive extension of finitely many copies of $\mathrm{cofib}(x : R \to R)$. We may therefore reduce to the case $n = 1$. Note that $M \simeq R \otimes_{R[X]} R$ has the structure of a connective $\mathbb{E}_\infty$-algebra over R, with $\pi_0 M \simeq R/(x)$. Our assumption that $R/(x) \otimes_R C$ belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ implies that $M \otimes_R C$ belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ by virtue of Proposition 11.5.6.2. □

Proof of Theorem 11.5.6.1. Using Proposition 11.5.6.2 (and Remark 11.5.6.3), we can reduce to the case where R is discrete. Suppose that $C \notin \mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. Since R is Noetherian, there exists an ideal which is maximal among those ideals I for which $R/I \otimes_R C$ does not belong to $(R/I \otimes_R \mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$. Replacing R by R/I, we may assume that $I = (0)$.

If $R \simeq 0$, there is nothing to prove. Otherwise, we can choose an associated prime ideal $\mathfrak{p}$ of R which appears as the annihilator of a nonzero element $x \in R$. In this case, we have a short exact sequence of discrete R-modules $0 \to R/\mathfrak{p} \to R \to R/(x) \to 0$. It follows from our inductive hypothesis that $R/(x) \otimes_R C$ belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. Since $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ is closed under extensions, we are reduced to proving that $R/\mathfrak{p} \otimes_R C$ belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. This follows from our inductive hypothesis unless $\mathfrak{p} = (0)$. We may therefore assume without loss of generality that R is an integral domain.

Let κ denote the fraction field of R, so that $\kappa \otimes_R C$ is belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. Let $\mathcal{E} \subseteq (\kappa \otimes_R \mathcal{C})$ denote the full subcategory spanned by objects of the form $\kappa \otimes_R D$, where D is a compact object of $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. Note that if D is a compact object of $\mathrm{Sp}(\mathcal{C})$ and $D' \in \mathrm{Sp}(\mathcal{C})$ is arbitrary, then the mapping space

$$\mathrm{Map}_{\kappa \otimes_R \mathrm{Sp}(\mathcal{C})}(\kappa \otimes_R D, \kappa \otimes_R D') \simeq \mathrm{Map}_{\mathcal{C}}(D, \kappa \otimes_R D')$$

can be identified with a filtered colimit of copies of the mapping space $\mathrm{Map}_{\mathrm{Sp}(\mathcal{C})}(D, D')$, indexed by the nonzero elements of R. Arguing as in the proof of Proposition D.5.3.4, we see that $\mathcal{E}$ is closed under the formation of cofibers and extensions, so that every compact object of $\kappa \otimes_R \mathrm{Sp}(\mathcal{C}))_{\geqslant 0}$ can be written as a retract of an object of $\mathcal{E}$. In particular, we can write $(\kappa \otimes_R C) \oplus E \simeq \kappa \otimes_R D$ for some compact object $D \in \mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. Let f be the endomorphism of $\kappa \otimes_R D$ which is nullhomotopic on $\kappa \otimes_R C$ and an equivalence on E. Since D is compact, we may assume that f is induced by an endomorphism $f_0 : D \to D$ in the ∞-category $\mathrm{Sp}(\mathcal{C})$. Then $\kappa \otimes_R \mathrm{cofib}(f_0) \simeq \kappa \otimes_R (C \oplus \Sigma(C))$.

Replacing C by $C \oplus \Sigma(C)$, we may reduce to the case where there exists a compact object $C' \in \mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ and an equivalence $g : \kappa \otimes_R C' \simeq \kappa \otimes_R C$. Since C' is compact, we can assume (after multiplying g by a nonzero element of R) that g is induced by a map $g_0 : C' \to C$. Form a fiber sequence $C' \xrightarrow{g_0} C \to C''$. Then C belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ if and only if C'' belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$. Replacing C by C'', we may assume that $\kappa \otimes_R C \simeq 0$. It follows that the natural map $C \to \kappa \otimes_R C$ is nullhomotopic. Since C is compact, it follows that there exists a nonzero element $x \in R$ such that the map $x : C \to C$ is nullhomotopic. In this case, C can be identified with a direct summand of $R/(x) \otimes_R C \simeq C \oplus \Sigma(C)$, which belongs to $\mathrm{Sp}(\mathcal{C})_{\geqslant 0}$ by virtue of our inductive hypothesis. □

11.5.7 The Brauer Group

Let X be a spectral Deligne-Mumford stack. In §11.5.2 we introduced the *extended Brauer space* $\mathscr{B}\mathrm{r}^{\dagger}(\mathsf{X})$, an infinite loop space whose first homotopy group $\pi_1 \mathscr{B}\mathrm{r}^{\dagger}(\mathsf{X})$ can be identified with the extended Picard group $\mathrm{Pic}^{\dagger}(\mathsf{X})$ of invertible objects of $\mathrm{QCoh}(\mathsf{X})$. In this section, we will discuss a variant of $\mathscr{B}\mathrm{r}^{\dagger}(\mathsf{X})$ which bears an analogous relation to the usual Picard group $\mathrm{Pic}(\mathsf{X})$ of line bundles on X.

Definition 11.5.7.1. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor and let $\mathrm{QStk}^{\mathrm{PSt}}(X)$ denote the ∞-category of prestable quasi-coherent stacks on X. We let $\mathscr{B}\mathrm{r}(X)$ denote the full subcategory of $\mathrm{QStk}^{\mathrm{PSt}}(X)^{\simeq}$ spanned by the invertible quasi-coherent stacks $\mathcal{C} \in \mathrm{QStk}^{\mathrm{PSt}}(X)$ for which $\mathcal{C}$ and $\mathcal{C}^{-1}$ are compactly generated. We will refer to $\mathscr{B}\mathrm{r}(X)$ as the *Brauer space* of X. We let $\mathrm{Br}(X)$ denote the set $\pi_0 \mathscr{B}\mathrm{r}(X)$, which we will refer to as the *Brauer group* of X.

If X is a spectral Deligne-Mumford stack representing a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$, we will denote the Brauer space $\mathscr{B}\mathrm{r}(X)$ and the Brauer group $\mathrm{Br}(X)$ by $\mathscr{B}\mathrm{r}(\mathsf{X})$ and $\mathrm{Br}(\mathsf{X})$, respectively. If R is a connective $\mathbb{E}_\infty$-ring, we will denote $\mathscr{B}\mathrm{r}(\mathrm{Spét}\, R)$ and $\mathrm{Br}(\mathrm{Spét}\, R)$ by $\mathscr{B}\mathrm{r}(R)$ and $\mathrm{Br}(R)$, respectively.

Remark 11.5.7.2. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor. Then the Brauer space $\mathscr{B}\mathrm{r}(X)$ admits the structure of a symmetric monoidal ∞-category in which every object and every morphism is invertible. In other words, it is a grouplike $\mathbb{E}_\infty$-space. In particular, the set $\mathrm{Br}(X) = \pi_0 \mathscr{B}\mathrm{r}(X)$ has the structure of an abelian group.

Remark 11.5.7.3. Let R be a connective $\mathbb{E}_\infty$-ring. Then the stabilization construction $\mathcal{C} \mapsto \mathrm{Sp}(\mathcal{C})$ determines a symmetric monoidal functor $\mathrm{LinCat}_R^{\mathrm{PSt}} \to \mathrm{LinCat}_R^{\mathrm{St}}$ which preserves compactly generated objects, and therefore induces a map of $\mathbb{E}_\infty$-spaces $\theta : \mathscr{B}\mathrm{r}(R) \to \mathscr{B}\mathrm{r}^\dagger(R)$.

Let $\mathcal{C}$ be a stable R-linear ∞-category which is compactly generated and invertible. Using Proposition C.3.1.1, we see that the homotopy fiber $\theta^{-1}\{\mathcal{C}\}$ is discrete: more precisely, it can be identified with the collection of all t-structures $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ on $\mathcal{C}$ satisfying the following conditions:

- (i) The t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ is right complete and compatible with filtered colimits.
- (ii) The Grothendieck prestable ∞-category $\mathcal{C}_{\geqslant 0}$ is an invertible object of $\mathrm{LinCat}_R^{\mathrm{PSt}}$.
- (iii) The Grothendieck prestable ∞-category $\mathcal{C}_{\geqslant 0}$ and its inverse $\mathcal{C}_{\geqslant 0}^{-1}$ are compactly generated.

Note that condition (iii) implies that $\mathcal{C}_{\geqslant 0}$ is determined by its intersection with the ∞-category of compact objects of $\mathcal{C}$. In particular, we deduce that the homotopy fibers of θ are essentially small. Since $\mathscr{B}\mathrm{r}^\dagger(R)$ is essentially small (Remark 11.5.3.13), it follows that the Brauer space $\mathscr{B}\mathrm{r}(R)$ is essentially small.

Remark 11.5.7.4. Let X be a spectral Deligne-Mumford stack. Then the canonical equivalence $\Omega \mathscr{B}\mathrm{r}^\dagger(\mathsf{X}) \simeq \mathscr{P}\mathrm{ic}^\dagger(\mathsf{X})$ induces a map $\Omega \mathscr{B}\mathrm{r}(\mathsf{X}) \to \mathscr{P}\mathrm{ic}^\dagger(\mathsf{X})$ which exhibits $\Omega \mathscr{B}\mathrm{r}(\mathsf{X})$ as a summand of $\mathscr{P}\mathrm{ic}^\dagger(\mathsf{X})$. Unwinding the definitions, we see that this summand consists of those invertible quasi-coherent sheaves $\mathscr{L} \in \mathrm{QCoh}(\mathsf{X})$ having the property that for every map $\eta : \mathrm{Sp\acute{e}t}\, R \to \mathsf{X}$, tensor product with $\eta^* \mathscr{L}$ induces a t-exact equivalence from the ∞-category $\mathrm{Mod}_R^{\mathrm{cn}}$ to itself. We therefore obtain a homotopy equivalence $\Omega \mathscr{B}\mathrm{r}(\mathsf{X}) \simeq \mathscr{P}\mathrm{ic}(\mathsf{X})$, where $\mathscr{P}\mathrm{ic}(\mathsf{X})$ is the Picard space of X (see Definition 2.9.4.1). In particular, we can identify $\pi_1 \mathscr{B}\mathrm{r}(\mathsf{X})$ with the Picard group $\mathrm{Pic}(\mathsf{X})$.

In §11.5.3, we studied the relationship between the extended Brauer group $\mathrm{Br}^\dagger(X)$ and the theory of Azumaya algebras on X. There is an analogous (but somewhat weaker) connection between $\mathrm{Br}(X)$ and connective Azumaya algebras. We begin with an analogue of Proposition 11.5.3.4.

Lemma 11.5.7.5. *Let R be a connective $\mathbb{E}_\infty$-ring, let $A \in \mathrm{Alg}_R^{\mathrm{cn}}$, and let M be a connective right A-module. Let $G : \mathrm{Mod}_R^{\mathrm{cn}} \to \mathrm{RMod}_A^{\mathrm{cn}}$ be the R-linear functor given by $G(N) = N \otimes_R M$. The following conditions are equivalent:*

(1) *The functor G is an equivalence of ∞-categories.*

(2) *As an R-module, M is locally free of rank > 0 and the action of A on M induces an equivalence $A^{\mathrm{rev}} \to \mathrm{End}_R(M)$.*

Proof. Suppose first that (2) is satisfied. Then M is a compact generator of the stable ∞-category Mod_R. Applying Lemma **??**, we deduce that the construction $N \mapsto N \otimes_R M$ induces an equivalence of stable ∞-categories $\mathrm{Mod}_R \simeq \mathrm{RMod}_A$. Since an R-module N is connective if and only if $N \otimes_R M$ is connective, it follows that G is an equivalence of ∞-categories.

Now suppose that (1) is satisfied. Then the induced map $\mathrm{Sp}(G) : \mathrm{Mod}_R \to \mathrm{RMod}_A$ is an equivalence of stable ∞-categories. Applying Lemma **??**, we deduce that M is a perfect R-module and that the canonical map $A^{\mathrm{rev}} \to \mathrm{End}_R(M)$ is an equivalence. We will complete the proof by showing that the R-module M is locally free of rank > 0. By virtue of Proposition 2.9.3.2, it will suffice to show that $\kappa \otimes_R M$ is locally free of rank > 0, for every residue field κ of R. We may therefore replace R by κ and thereby reduce to the case where $R = \kappa$ is a field.

Note that R does not belong to the essential image of the suspension functor $\Sigma : \mathrm{Mod}_R^{\mathrm{cn}} \to \mathrm{Mod}_R^{\mathrm{cn}}$. Using assumption (1), we deduce that $M = G(R)$ does not belong to the essential image of the suspension functor $\Sigma : \mathrm{RMod}_A^{\mathrm{cn}} \to \mathrm{RMod}_A^{\mathrm{cn}}$. It follows that $\pi_0 M \neq 0$. If M is not locally free as an R-module, then we must have $\pi_n M \neq 0$ for some $n > 0$. It then follows that $\pi_{-n}(M^\vee) \simeq (\pi_n M)^\vee \neq 0$ and therefore $\pi_{-n}(M \otimes_\kappa M^\vee) \neq 0$. This is a contradiction, since the tensor product $M \otimes_\kappa M^\vee \simeq A^{\mathrm{rev}}$ is connective by assumption. □

Proposition 11.5.7.6. *Let R be a connective $\mathbb{E}_\infty$-ring and let $A \in \mathrm{Alg}_R^{\mathrm{cn}}$. Then A is an Azumaya algebra if and only if $\mathrm{RMod}_A^{\mathrm{cn}}$ is an invertible object of $\mathrm{LinCat}_R^{\mathrm{PSt}}$.*

Proof. If $\mathrm{RMod}_A^{\mathrm{cn}}$ is an invertible object of $\mathrm{LinCat}_R^{\mathrm{PSt}}$, then $\mathrm{Sp}(\mathrm{RMod}_A^{\mathrm{cn}}) \simeq \mathrm{RMod}_A$ is an invertible object of $\mathrm{LinCat}_R^{\mathrm{St}}$, so that A is an Azumaya algebra by virtue of Proposition 11.5.3.4. Conversely, if suppose that A is an Azumaya algebra. Then we have an equivalence $\mathrm{RMod}_A^{\mathrm{cn}} \simeq \mathrm{RMod}_{A^{\mathrm{rev}}}^{\mathrm{cn}} \simeq \mathrm{RMod}_{A \otimes_R A^{\mathrm{rev}}}^{\mathrm{cn}} \simeq \mathrm{RMod}_{\mathrm{End}_R(A)}^{\mathrm{cn}}$. Since A is a locally free R-module of rank > 0 (Proposition 11.5.3.3), Lemma 11.5.7.5 supplies an R-linear equivalence $\mathrm{RMod}_{\mathrm{End}_R(A)}^{\mathrm{cn}} \simeq \mathrm{Mod}_R^{\mathrm{cn}}$. □

We now introduce a connective analogue of Construction 11.5.7.7:

Construction 11.5.7.7 (The Brauer Class of a Connective Azumaya Algebra)**.** Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor and let $\mathscr{A} \in \mathrm{Alg}(\mathrm{QCoh}(X)^{\mathrm{cn}})$ be a connective Azumaya algebra. Then the construction

$$(\eta \in X(R)) \mapsto (\mathrm{RMod}_{\mathscr{A}_\eta}^{\mathrm{cn}} \in \mathrm{LinCat}_R^{\mathrm{PSt}})$$

determines a compactly generated prestable quasi-coherent stack on X. It follows from Proposition 11.5.7.6 that this quasi-coherent stack is an invertible object of $\mathrm{LinCat}_R^{\mathrm{PSt}}$ (whose inverse is also compactly generated), and can therefore be identified with a point of the Brauer space $\mathscr{B}\mathrm{r}(X)$. We let $[\mathscr{A}] \in \mathrm{Br}(X)$ denote the equivalence class of this quasi-coherent stack. We will refer to $[\mathscr{A}]$ as the *Brauer class of $\mathscr{A}$*.

Warning 11.5.7.8. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor and let $\mathscr{A}$ be a connective Azumaya algebra on X. We have now assigned two different meanings to the symbol $[\mathscr{A}]$: it can be regarded as an element of the extended Brauer group $\mathrm{Br}^{\dagger}(X)$ (Construction 11.5.3.9) or as an element of the Brauer group $\mathrm{Br}(X)$ (Construction **??**). In practice, there is little danger of ambiguity: the canonical map $\mathrm{Br}(X) \to \mathrm{Br}^{\dagger}(X)$ (see Remark 11.5.7.3) carries the Brauer class of $\mathscr{A}$ to the extended Brauer class of $\mathscr{A}$.

Proposition 11.5.7.9. *Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor and let $\mathscr{A} \in \mathrm{Alg}(\mathrm{QCoh}(X))$. The following conditions are equivalent:*

(1) *The object $\mathscr{A}$ is a connective Azumaya algebra and the Brauer class $[\mathscr{A}] \in \mathrm{Br}(X)$ vanishes.*

(2) *There exists an equivalence $\mathscr{A} \simeq \mathrm{End}(\mathscr{E}) = \mathscr{E} \otimes \mathscr{E}^{\vee}$, where $\mathscr{E} \in \mathrm{Vect}(X)$ is a vector bundle on X of rank > 0.*

Proof. We proceed as in the proof of Proposition 11.5.3.11. Let $\mathcal{C}$ denote the prestable quasi-coherent stack on X given by the construction $(\eta \in X(R)) \mapsto (\mathrm{RMod}^{\mathrm{cn}}_{\eta^* \mathscr{A}} \in \mathrm{LinCat}_R^{\mathrm{PSt}})$. Using Proposition 11.5.7.6, we see that condition (1) is equivalent to the following:

(1′) There exists a map $\rho : \mathcal{Q}_X^{\mathrm{PSt}} \to \mathcal{C}$ which is an equivalence of prestable quasi-coherent stacks on X.

Note that giving a map of quasi-coherent stacks $\rho : \mathcal{Q}_X^{\mathrm{PSt}} \to \mathcal{C}$ is equivalent to giving an object $\mathscr{G} \in \mathrm{QCoh}(X; \mathcal{C}) \simeq \mathrm{RMod}^{\mathrm{cn}}_{\mathscr{A}}(\mathrm{QCoh}(X))$. Using Lemma 11.5.7.5, we see that the map ρ is an equivalence if and only if $\mathscr{G}$ is a vector bundle of rank > 0 on X and ρ induces an equivalence $\mathscr{A} \simeq \mathrm{End}(\mathscr{G})^{\mathrm{rev}} \simeq \mathrm{End}(\mathscr{G}^{\vee})$. Setting $\mathscr{E} = \mathscr{G}^{\vee}$, we see that conditions (1) and (2) are equivalent. □

Remark 11.5.7.10. Let $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ be a functor. Using Construction 11.5.3.9 and Proposition 11.5.7.9, we arrive at the following analogue of Remark **??**:

(a) Every connective Azumaya algebra $\mathscr{A}$ on X determines an element $[\mathscr{A}] \in \mathrm{Br}(X)$.

(b) The collection of elements of $\mathrm{Br}(X)$ having the form $[\mathscr{A}]$ comprise a subgroup of $\mathrm{Br}(X)$. More explicitly, the multiplication on $\mathrm{Br}(X)$ is given by $[\mathscr{A}][\mathscr{B}] = [\mathscr{A} \otimes \mathscr{B}]$, the identity element of $\mathrm{Br}^{\dagger}(X)$ is given by $[\mathscr{O}_X]$, and the inverse of $[\mathscr{A}]$ is given by $[\mathscr{A}^{\mathrm{rev}}]$.

(c) Given connective Azumaya algebras $\mathscr{A}, \mathscr{B} \in \mathrm{Alg}(\mathrm{QCoh}(X))$, we have $[\mathscr{A}] = [\mathscr{B}]$ in $\mathrm{Br}(X)$ if and only if there is an equivalence $\mathscr{A} \otimes \mathscr{B}^{\mathrm{rev}} \simeq \mathrm{End}(\mathscr{E})$ for some vector bundle $\mathscr{E} \in \mathrm{Vect}(X)$ of positive rank (in this case, we can regard $\mathscr{E}$ as a $\mathscr{A}$-$\mathscr{B}$ bimodule object of $\mathrm{Vect}(X)$).

In contrast with Remark **??**, it is generally not true that every element of $\mathrm{Br}(X)$ has the form $[\mathscr{A}]$ for some connective Azumaya algebra $\mathscr{A} \in \mathrm{Alg}(\mathrm{QCoh}(X))$, even if we assume that X is affine. For example, if X is an ordinary scheme, then the subgroup described in (b) coincides with the Brauer-Grothendieck group of X, while the group $\mathrm{Br}(X)$ agrees with the cohomological Brauer group $\mathrm{H}^2_{\text{ét}}(X; \mathbf{G}_m)$ (see Example 11.5.7.15).

Our main result is the following analogue of Theorem 11.5.5.1:

Theorem 11.5.7.11. *Let X be a spectral Deligne-Mumford stack, and let $u \in \mathrm{Br}(\mathsf{X})$. Then there exists an étale surjection $f : \mathsf{U} \to \mathsf{X}$ such that $f^* u = 0$ in $\mathrm{Br}(\mathsf{U})$.*

Before giving the proof of Theorem 11.5.7.11, let us describe some of its consequences.

Corollary 11.5.7.12. *Let X be a spectral Deligne-Mumford stack and let $\mathscr{A} \in \mathrm{Alg}(\mathrm{QCoh}(\mathsf{X}))$ be a connective Azumaya algebra on X. Then there exists an étale surjection $f : \mathsf{U} \to \mathsf{X}$ and an equivalence $f^* \mathscr{A} \simeq \mathrm{End}(\mathscr{E})$, where $\mathscr{E}$ is a vector bundle on U of rank > 0.*

Proof. Combine Theorem 11.5.7.11 with Proposition 11.5.7.9. □

Construction 11.5.7.13 (The Brauer Sheaf)**.** Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ be a spectral Deligne-Mumford stack. For each object $U \in \mathcal{X}$, let X_U denote the spectral Deligne-Mumford stack $(\mathcal{X}_{/U}, \mathscr{O}_{\mathsf{X}}|_U)$. The construction $U \mapsto \mathscr{B}\mathrm{r}(\mathsf{X}_U)$ determines a functor $\mathcal{X}^{\mathrm{op}} \to \widehat{\mathcal{S}}$ which preserves small limits. Remark 11.5.7.3 implies that $\mathscr{B}\mathrm{r}(\mathsf{X}_U)$ is essentially small whenever U is affine, so that $\mathscr{B}\mathrm{r}(\mathsf{X}_U)$ is essentially small for all objects $U \in \mathcal{X}$. It follows that the construction $U \mapsto \mathscr{B}\mathrm{r}(\mathsf{X}_U)$ is representable by an object $\underline{\mathscr{B}\mathrm{r}}_{\mathsf{X}} \in \mathcal{X}$. We will refer to $\underline{\mathscr{B}\mathrm{r}}_{\mathsf{X}}$ as the *Brauer sheaf* of X.

Note that $\underline{\mathscr{B}\mathrm{r}}_{\mathsf{X}}$ is a grouplike commutative monoid of $\mathcal{X}$. In particular, we can each homotopy group $\pi_n \underline{\mathscr{B}\mathrm{r}}_{\mathsf{X}}$ as an abelian group object in the topos $\mathcal{X}^{\heartsuit}$. Using Theorem 11.5.7.11 and Remark 11.5.7.4, we obtain isomorphisms

$$\pi_n \underline{\mathscr{B}\mathrm{r}}_{\mathsf{X}} = \begin{cases} 0 & \text{if } n \leqslant 1 \\ (\pi_0 \mathscr{O}_{\mathsf{X}})^{\times} & \text{if } n = 2 \\ \pi_{n-2} \mathscr{O}_{\mathsf{X}} & \text{if } n > 2. \end{cases}$$

Remark 11.5.7.14. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ be a spectral Deligne-Mumford stack. The forgetful functor $\mathscr{B}\mathrm{r} \to \mathscr{B}\mathrm{r}^{\dagger}$ determines a map of Brauer sheaves $\underline{\mathscr{B}\mathrm{r}}_{\mathsf{X}} \to \underline{\mathscr{B}\mathrm{r}}^{\dagger}_{\mathsf{X}}$. Combining the analyses of Construction 11.5.5.3 and **??**, we see that this map exhibits $\underline{\mathscr{B}\mathrm{r}}_{\mathsf{X}}$ as the 2-connective cover of $\underline{\mathscr{B}\mathrm{r}}^{\dagger}_{\mathsf{X}}$. In particular, we have a canonical fiber sequence $\underline{\mathscr{B}\mathrm{r}}_{\mathsf{X}} \to \underline{\mathscr{B}\mathrm{r}}^{\dagger}_{\mathsf{X}} \to K(\underline{\mathbf{Z}}, 1)$ of grouplike commutative monoid objects of $\mathcal{X}$ (which admits a non-multiplicative splitting; see Remark 11.5.5.4). Passing to global sections, we obtain a (split) short exact sequence of abelian groups $0 \to \mathrm{Br}(\mathsf{X}) \to \mathrm{Br}^{\dagger}(\mathsf{X}) \to \mathrm{H}^1(\mathcal{X}; \underline{\mathbf{Z}}) \to 0$.

Example 11.5.7.15. Let $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathsf{X}})$ be a spectral Deligne-Mumford stack, and suppose that $\mathscr{O}_{\mathsf{X}}$ is 0-truncated. Then we can identify $\mathscr{O}_{\mathsf{X}}$ with a commutative ring object of the topos of discrete objects of $\mathcal{X}$; let $\mathscr{O}^{\times}_{\mathsf{X}}$ denote its group of units. For each $U \in \mathcal{X}$, $\mathscr{P}\mathrm{ic}(\mathsf{X}_U)$ is equivalent to the nerve of a groupoid, so that the extended Brauer space $\mathscr{B}\mathrm{r}(\mathsf{X}_U)$ is 2-truncated. It follows that the Brauer sheaf $\underline{\mathscr{B}\mathrm{r}}_{\mathsf{X}}$ is 2-truncated, so that the analysis of Construction 11.5.7.13 supplies an equivalence $\underline{\mathscr{B}\mathrm{r}}_{\mathsf{X}} \simeq K(\mathscr{O}^{\times}_{\mathsf{X}}, 2)$. Passing to global sections, we obtain an isomorphism $\mathrm{Br}(\mathsf{X}) \simeq \mathrm{H}^2(\mathcal{X}; \mathscr{O}^{\times}_{\mathsf{X}})$. In other words, the Brauer group $\mathrm{Br}(\mathsf{X})$ of Definition 11.5.7.1 agrees with the classical *cohomological Brauer group* of X.

Corollary 11.5.7.16. *Let R be a connective $\mathbb{E}_\infty$-ring. Then the canonical map $\mathrm{Br}(R) \to \mathrm{Br}(\pi_0 R)$ is an isomorphism of abelian groups.*

Proof. Combine Proposition 11.5.5.6 with Remark 11.5.7.14. □

We now turn to the proof of Theorem 11.5.7.11. We will need a few preliminary results.

Lemma 11.5.7.17. *For every $\mathbb{E}_\infty$-ring R, let $\mathrm{Alg}^{\mathrm{c}}_R$ denote the full subcategory of Alg_R spanned by the compact objects. Then the construction $R \mapsto \mathrm{Alg}^{\mathrm{c}}_R$ commutes with filtered colimits (when regarded as a functor from CAlg to $\mathcal{C}\mathrm{at}_\infty$).*

Proof. The construction $R \mapsto \mathrm{Alg}_R$ carries each $\mathbb{E}_\infty$-ring R to a compactly generated ∞-category and each morphism $R \to R'$ to an extension-of-scalars functor $\mathrm{Alg}_R \to \mathrm{Alg}_{R'}$ which preserves compact objects. By virtue of Lemma HA.7.3.5.11 , it will suffice to show that the construction $R \mapsto \mathrm{Alg}_R$ determines a functor $\rho : \mathrm{CAlg} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ which commutes with filtered colimits. Using Corollary **??**, we can identify ρ with a functor $\rho' : \mathrm{CAlg}^{\mathrm{op}} \to \mathcal{P}\mathrm{r}^{\mathrm{R}}$, which carries an $\mathbb{E}_\infty$-ring R to the ∞-category $\mathrm{Alg}(\mathrm{Mod}_R)$ and a morphism $R \to R'$ to the restriction-of-scalars functor $\mathrm{Alg}(\mathrm{Mod}_{R'}) \to \mathrm{Alg}(\mathrm{Mod}_R)$. To show that ρ' commutes with filtered limits, it will suffice to show that the construction $R \mapsto \mathrm{Mod}_R$ carries filtered colimits in CAlg to filtered limits in $\mathcal{P}\mathrm{r}^{\mathrm{R}}$, which follows from Proposition 4.5.1.2. □

Lemma 11.5.7.18. *Let R be a connective $\mathbb{E}_\infty$-ring and let M be a connective perfect R-module. Suppose that:*

(a) *For every residue field κ of R, the vector space $\pi_0(\kappa \otimes_R M)$ is nonzero.*

(b) *The R-module M generates Mod_R as a presentable stable ∞-category: in other words, if $\mathcal{C} \subseteq \mathrm{Mod}_R$ is a full stable subcategory which is closed under small colimits, then $\mathcal{C} = \mathrm{Mod}_R$.*

Then M generates $(\mathrm{Mod}_R)_{\geqslant 0}$ under small colimits and extensions.

Proof. Write R as a colimit $\varinjlim_{\alpha \in A} R_\alpha$ indexed by a filtered partially ordered set A, where each R_α is a compact object of $\mathrm{CAlg}^{\mathrm{cn}}$ (and, in particular, a Noetherian $\mathbb{E}_\infty$-ring). Using Lemma 11.5.7.17, we can choose an index α, a connective perfect R_α-module M_α, and an equivalence $M \simeq R \otimes_{R_\alpha} M_\alpha$. Then $\pi_0 M_\alpha$ is a finitely generated module over $\pi_0 R_\alpha$. Let $I \subseteq \pi_0 R_\alpha$ denote its annihilator ideal. Since R_α is Noetherian, the ideal I is finitely generated. Using (a), we see that the image of I in $\pi_0 R$ is nilpotent. Enlarging α if necessary, we may assume that I is nilpotent.

For each $\beta \geqslant \alpha$, let $M_\beta = R_\beta \otimes_{R_\alpha} M_\alpha$, and let $\mathcal{E}_\beta$ denote the smallest stable subcategory of Mod_{R_β} which contains M_β. Then $\mathcal{E} = \varinjlim \mathcal{E}_\beta$ is the smallest stable subcategory of Mod_R which contains M. Since M is perfect, the inclusion $\mathcal{E} \hookrightarrow \mathrm{Mod}_R$ extends to a fully faithful embedding $\mathrm{Ind}(\mathcal{E}) \to \mathrm{Mod}_R$, and condition (b) implies that this functor is an equivalence of ∞-categories. In particular, since $R \in \mathrm{Mod}_R$ is compact, the $\mathbb{E}_\infty$-ring R itself can be written as a retract of an object of $\mathcal{E}$. It follows that there exists $\beta \geqslant \alpha$ for which R_β can be written as a retract of some object of $\mathcal{E}_\beta$. Consequently, the module $M_\beta \in \mathrm{Mod}_{R_\beta}$ satisfies conditions (a) and (b). We may therefore replace R by R_β and thereby reduce to the case where R is Noetherian.

Let $\mathcal{C}_{\geqslant 0} \subseteq \mathrm{Mod}_R$ be the full subcategory generated by M under small colimits and extensions. We wish to prove that $\mathcal{C}_{\geqslant 0} = (\mathrm{Mod}_R)_{\geqslant 0}$. Since M is connective, we clearly have $\mathcal{C}_{\geqslant 0} \subseteq (\mathrm{Mod}_R)_{\geqslant 0}$. To prove the reverse inclusion, it will suffice to show that $\mathcal{C}_{\geqslant 0}$ contains R. It follows from Proposition C.6.3.1 that $\mathcal{C}_{\geqslant 0}$ is a compactly generated prestable ∞-category. Moreover, the action of $\mathrm{Mod}_R^{\mathrm{cn}}$ on itself restricts to an action of $\mathrm{Mod}_R^{\mathrm{cn}}$ on $\mathcal{C}_{\geqslant 0}$. Applying Theorem 11.5.6.1, we are reduced to proving that $\mathcal{C}_{\geqslant 0}$ contains each residue field κ of R. This is clear, since condition (a) guarantees that κ is a retract of the tensor product $\kappa \otimes_R M$. □

Proof of Theorem 11.5.7.11. Without loss of generality, we may assume that $\mathsf{X} = \mathrm{Spét}\, R$ is affine, so that $u \in \mathrm{Br}(\mathsf{X})$ classifies a compactly generated prestable R-linear ∞-category $\mathcal{C}_{\geqslant 0} \in \mathrm{LinCat}_R^{\mathrm{PSt}}$ which admits a compactly generated inverse $\mathcal{D}_{\geqslant 0} \in \mathrm{LinCat}_R^{\mathrm{PSt}}$. Using Theorem 11.5.5.1, we can further assume that $\mathrm{Sp}(\mathcal{C}_{\geqslant 0}) \simeq \mathrm{Mod}_R$. Without loss of generality, we can identify $\mathcal{C}_{\geqslant 0}$ with its essential image under the full faithful embedding

$$\Sigma^\infty : \mathcal{C}_{\geqslant 0} \simeq \mathrm{Sp}(\mathcal{C}_{\geqslant 0}) \simeq \mathrm{Mod}_R$$

and thereby reduce to the case where $\mathcal{C}_{\geqslant 0}$ is the connective part of a t-structure $(\mathcal{C}_{\geqslant 0}, \mathcal{C}_{\leqslant 0})$ on Mod_R; similarly, we may identify $\mathcal{D}_{\geqslant 0}$ with the connective part of a t-structure $(\mathcal{D}_{\geqslant 0}, \mathcal{D}_{\leqslant 0})$ on Mod_R. Because $\mathcal{C}_{\geqslant 0}$ and $\mathcal{D}_{\geqslant 0}$ are compactly generated, we can choose compact objects $\{C_\alpha\}_{\alpha \in A}$ and $\{D_\beta\}_{\beta \in B}$ of Mod_R which generate $\mathcal{C}_{\geqslant 0}$ and $\mathcal{D}_{\geqslant 0}$ under small colimits. Then the collection of tensor products $C_\alpha \otimes D_\beta$ generates $\mathcal{C}_{\geqslant 0} \otimes \mathcal{D}_{\geqslant 0} \simeq \mathrm{Mod}_R^{\mathrm{cn}}$ under small colimits. For every pair of subsets $A_0 \subseteq A$, $B_0 \subseteq B$, let $\mathcal{E}_{A_0, B_0}$ be the smallest full subcategory of Mod_R which contains each tensor product $\{C_\alpha \otimes_R D_\beta\}_{\alpha \in A_0, \beta \in B_0}$ and is closed under finite colimits and extensions. Using Proposition C.6.3.1, we deduce that the inclusion $\mathcal{E}_{A,B} \hookrightarrow \mathrm{Mod}_R$ extends to an equivalence of ∞-categories $\mathrm{Ind}(\mathcal{E}_{A,B}) \simeq \mathrm{Mod}_R^{\mathrm{cn}}$. It follows that the module R appears as a direct summand of some object $E \in \mathcal{E}_{A,B}$. Note that $\mathcal{E}_{A,B}$ can be written as a union $\bigcup_{A_0} \mathcal{E}_{A_0,B}$, where A_0 ranges over all finite subsets of A. We can therefore choose a finite subset $A_0 \subseteq A$ such that $E \in \mathcal{E}_{A_0,B}$. Let $\mathcal{C}'_{\geqslant 0}$ denote the full subcategory of Mod_R generated by the objects $\{C_\alpha\}_{\alpha \in A_0}$ under small colimits and extensions. Enlarging A_0 if necessary, we may assume that $\mathcal{C}'_{\geqslant 0}$ contains $\Sigma^n R$ for $n \gg 0$. Applying Proposition C.6.3.1, we deduce that $\mathcal{C}'_{\geqslant 0}$ is a compactly generated prestable ∞-category with stabilization Mod_R. It follows that the tensor product $\mathcal{C}'_{\geqslant 0} \otimes_R \mathcal{D}_{\geqslant 0}$ is also a Grothendieck prestable ∞-category (Theorem C.4.2.1), so it embeds fully faithfully into its stabilization

$$\mathrm{Sp}(\mathcal{C}'_{\geqslant 0} \otimes_R \mathcal{D}_{\geqslant 0}) \simeq \mathrm{Sp}(\mathcal{C}'_{\geqslant 0}) \otimes_R \mathrm{Sp}(\mathcal{D}_{\geqslant 0}) \simeq \mathrm{Mod}_R .$$

By construction, the essential image of this embedding contains R, so that the natural map

$$\mathcal{C}'_{\geqslant 0} \otimes_R \mathcal{D}_{\geqslant 0} \to \mathcal{C}_{\geqslant 0} \otimes_R \mathcal{D}_{\geqslant 0}$$

is an equivalence of R-linear Grothenieck prestable ∞-categories. Using the invertibility of $\mathcal{D}_{\geqslant 0}$ as an object of $\mathrm{LinCat}_R^{\mathrm{PSt}}$, we deduce that the inclusion $\mathcal{C}'_{\geqslant 0} \hookrightarrow \mathcal{C}_{\geqslant 0}$ is an equivalence: that is, the ∞-category $\mathcal{C}_{\geqslant 0}$ is generated under colimits and extensions by a single perfect R-module $C = \bigoplus_{\alpha \in A_0} C_\alpha$. Similarly, the ∞-category $\mathcal{D}_{\geqslant 0}$ is generated under colimits and extensions by a perfect R-module $D \in \mathcal{D}_{\geqslant 0}$.

Let $\mathfrak{p}$ be a prime ideal of the commutative ring $\pi_0 R$ and let $\kappa(\mathfrak{p})$ denote the residue field of R at $\mathfrak{p}$. Since C generates Mod_R under shifts and colimits, the tensor product $\kappa(\mathfrak{p}) \otimes_R C$ is a nonzero perfect $\kappa(\mathfrak{p})$-module. We let $d_C(\mathfrak{p})$ denote the smallest integer n such that $\pi_n(\kappa(x) \otimes_R C) \neq 0$. We can then regard d_C as a $\mathbf{Z}$-valued function on $|\operatorname{Spec} R|$. We claim that d_C is lower semicontinuous. To prove that, fix a point $\mathfrak{p} \in |\operatorname{Spec} R|$ such that $d_C(\mathfrak{p}) = n$. We claim that there exists an element $a \in (\pi_0 R) - \mathfrak{p}$ such that $C[a^{-1}]$ is n-connective (so that $d_C(\mathfrak{q}) \geqslant n$ for all $\mathfrak{q} \in |\operatorname{Spec} R|$ which do not contain A). To prove this, we argue by induction on $m \leqslant n$ that we can choose $a_m \in (\pi_0 R) - \mathfrak{p}$ for which $C[a_m^{-1}]$ is m-connective. For $m \ll 0$ we can take $a_m = 1$ (since C is perfect). In the general case, we can use the inductive hypothesis to reduce to the case where C is $(m-1)$-connective. In this case, $\pi_{m-1} C$ is a finitely generated $(\pi_0 R)$-module M satisfying $\mathrm{Tor}_0^{\pi_0 R}(\kappa(\mathfrak{p}), M) \simeq 0$, so that $M[a^{-1}] \simeq 0$ for some $a \notin \mathfrak{p}$ by virtue of Nakayama's lemma.

Define functions $d_D, d_{C \otimes D} : |\operatorname{Spec} R| \to \mathbf{Z}$ similarly, so that we have

$$d_C + d_D = d_{C \otimes D}.$$

Since $C \otimes D$ is a connective R-module which generates $(\mathrm{Mod}_R)_{\geqslant 0}$ under colimits and extensions, the function $d_{C \otimes D}$ vanishes, so that $d_C(\mathfrak{p}) = -d_D(\mathfrak{p})$. It follows from the above argument that d_D is lower semi-continuous, so that d_C is upper semi-continuous and therefore continuous. Passing to a étale cover of $\operatorname{Spec} R$, we can assume that d_C is the constant function taking some value n. It now follows from Lemma 11.5.7.18 that $\mathcal{C}_{\geqslant 0} = (\mathrm{Mod}_R)_{\geqslant n}$, which implies that $u = 0 \in \mathrm{Br}(R)$. □

Part IV

Formal Moduli Problems

The following thesis plays a central role in deformation theory:

(∗) If X is a moduli space defined over a field κ of characteristic zero, then a formal neighborhood of any point $x \in X$ can be described by a differential graded Lie algebra over κ.

This idea has been developed in unpublished work of Deligne, Drinfeld, and Feigin, and has powerfully influenced subsequent contributions of Hinich, Kontsevich-Soibelman, Manetti, Pridham, and many others. Our goal in Part IV is to give a precise formulation (and proof) of (∗), together with some of its generalizations.

The first step in formulating (∗) is to decide exactly what we mean by a moduli space. For simplicity, let us work for now over the field $\mathbf{C}$ of complex numbers. We will adopt Grothendieck's "functor of points" philosophy, and identify an algebro-geometric object X (for example, a scheme) with the functor

$$R \mapsto X(R) = \mathrm{Hom}(\mathrm{Spec}\, R, X).$$

This suggests a very general definition:

Definition 11.5.0.1. Let $\mathrm{CAlg}^{\heartsuit}_{\mathbf{C}}$ denote the category of commutative $\mathbf{C}$-algebras and let $\mathcal{S}\mathrm{et}$ denote the category of sets. A *classical moduli problem* is a functor $X : \mathrm{CAlg}^{\heartsuit}_{\mathbf{C}} \to \mathcal{S}\mathrm{et}$.

Unfortunately, Definition 11.5.0.1 is not adequate four our needs. First of all, Definition 11.5.0.1 requires that the functor X take values in the category of sets. In many applications, one would like to consider functors X which assign to each commutative ring R some collection of geometric objects parametrized by the affine scheme $\mathrm{Spec}\, R$. In such cases, it is important to retain information about *automorphisms* of geometric objects.

Example 11.5.0.2. For every commutative $\mathbf{C}$-algebra R, let $X(R)$ denote the category of elliptic curves $E \to \mathrm{Spec}\, R$ (morphisms in the category $X(R)$ are given by isomorphisms of elliptic curves). Then F determines a functor from $\mathrm{CAlg}^{\heartsuit}_{\mathbf{C}}$ to Gpd, where Gpd denotes the 2-category of *groupoids*. In this case, X determines an underlying set-valued functor, which assigns to each commutative ring R the set $\pi_0 X(R)$ of isomorphism classes of elliptic curves over R. However, the groupoid-valued functor $X : \mathrm{CAlg}^{\heartsuit}_{\mathbf{C}} \to \mathrm{Gpd}$ is much better behaved than the set-valued functor $\pi_0 X : \mathrm{CAlg}^{\heartsuit}_{\mathbf{C}} \to \mathcal{S}\mathrm{et}$. For example, the functor X satisfies descent (with respect to the flat topology on the category of commutative rings), while the functor $\pi_0 X$ does not: two elliptic curves which are locally isomorphic need not be globally isomorphic.

Because the functor X of Example 11.5.0.2 is not $\mathcal{S}$et-valued, it cannot be represented by a scheme. However, it is nevertheless a reasonable geometric object: it is representable by a Deligne-Mumford stack. To accommodate Example 11.5.0.2, we would like to adjust Definition 11.5.0.1 to allow groupoid-valued functors.

Variant 11.5.0.3. Let $\mathcal{C}$ be an ∞-category. A *$\mathcal{C}$-valued classical moduli problem* is a functor of ∞-categories $X : \mathrm{CAlg}^{\heartsuit}_{\mathbf{C}} \to \mathcal{C}$.

Remark 11.5.0.4. We recover Definition 11.5.0.1 as a special case of Variant 11.5.0.3, by taking the ∞-category $\mathcal{C}$ to be the ordinary category of sets. In practice, we will be most interested in the special case where $\mathcal{C}$ is the ∞-category $\mathcal{S}$ of spaces.

The next step in formulating $(*)$ is to decide what we mean by a formal neighborhood of a point x in a moduli space X. Suppose, for example, that $X = \operatorname{Spec} A$ is an affine algebraic variety over the field $\mathbf{C}$ of complex numbers. Then a closed point $x \in X$ is determined by a $\mathbf{C}$-algebra homomorphism $\phi : A \to \mathbf{C}$, which is determined a choice of maximal ideal $\mathfrak{m} = \ker(\phi) \subseteq A$. One can define the *formal completion* of X at the point x to be the functor $X^{\wedge} : \mathrm{CAlg}^{\heartsuit}_{\mathbf{C}} \to \mathcal{S}$et given by the formula

$$X^{\wedge}(R) = \{f \in X(R) : f(\operatorname{Spec} R) \subseteq \{x\} \subseteq \operatorname{Spec} A\}.$$

In other words, $X^{\wedge}(R)$ is the collection of commutative ring homomorphisms $\phi : A \to R$ having the property that ϕ carries each element of $\mathfrak{m}$ to a nilpotent element of R. Since $\mathfrak{m}$ is finitely generated, this is equivalent to the condition that ϕ annihilates $\mathfrak{m}^n$ for some integer $n \gg 0$, so that the image of ϕ is a quotient of A by some $\mathfrak{m}$-primary ideal.

Definition 11.5.0.5. Let R be a commutative algebra over the field $\mathbf{C}$ of complex numbers. We will say that R is a *local Artinian* if it is finite dimensional as a $\mathbf{C}$-vector space and has a unique maximal ideal $\mathfrak{m}_R$. The collection of local Artinian $\mathbf{C}$-algebras forms a category, which we will denote by $\mathrm{CAlg}^{\heartsuit\,\mathrm{art}}_{\mathbf{C}}$.

The above analysis shows that if X is an affine algebraic variety over $\mathbf{C}$ containing a point x, then the formal completion $X^{\wedge}$ can be recovered from its values on local Artinian $\mathbf{C}$-algebras. This motivates the following definition:

Definition 11.5.0.6. Let $\mathcal{C}$ be an ∞-category. A *$\mathcal{C}$-valued classical formal moduli problem* is a functor $\mathrm{CAlg}^{\heartsuit\,\mathrm{art}}_{\mathbf{C}} \to \mathcal{C}$.

If X is a set-valued classical moduli problem and we are given a point $\eta \in X(\mathbf{C})$, we can define a set-valued classical formal moduli problem $X^{\wedge}$ by the formula

$$X^{\wedge}(R) = X(R) \times_{X(R/\mathfrak{m}_R)} \{\eta\}.$$

We will refer to $X^\wedge$ as the *completion of X at the point η*. If X is groupoid-valued, the same formula determines a groupoid-valued classical formal moduli problem $X^\wedge$ (in this case, we must interpret $X(R) \times_{X(R/\mathfrak{m}_R)} \{\eta\}$ as the *homotopy fiber product* of the relevant groupoids).

Example 11.5.0.7. For every commutative $\mathbf{C}$-algebra R, let $X(R)$ denote the groupoid whose objects are smooth proper R-schemes and whose morphisms are isomorphisms of R-schemes. Suppose we are given a point $\eta \in X(\mathbf{C})$, corresponding to smooth and proper algebraic variety Z over $\mathbf{C}$. The formal completion $X^\wedge$ assigns to every local Artinian $\mathbf{C}$-algebra R the groupoid $X^\wedge(R)$ of *deformations over Z* over R: that is, smooth proper morphisms $f : \overline{Z} \to \operatorname{Spec} R$ which fit into a pullback diagram

$$\begin{array}{ccc} Z & \longrightarrow & \overline{Z} \\ \downarrow & & \downarrow \\ \operatorname{Spec} \mathbf{C} & \longrightarrow & \operatorname{Spec} R. \end{array}$$

Example 11.5.0.7 is a typical example of the kind of formal moduli problem we would like to study (see §**??**). Let us recall some well-known features of the functor $X^\wedge$ (see Propositions 0.1.3.1 and 0.1.3.4):

(*a*) The functor $X^\wedge$ carries the ring $\mathbf{C}[\epsilon]/(\epsilon^2)$ to the groupoid of first-order deformations of the variety Z. Every first order deformation of Z has an automorphism group which is canonically isomorphic to $\mathrm{H}^0(Z; T_Z)$, where T_Z denotes the tangent bundle of Z.

(*b*) The collection of isomorphism classes of first order deformations of Z can be canonically identified with the cohomology group $\mathrm{H}^1(Z; T_Z)$.

(*c*) To every first order deformation $\overline{Z}$ of Z, we can assign an *obstruction class* $\rho(\overline{Z}) \in \mathrm{H}^2(Z; T_Z)$ which vanishes if and only if $\overline{Z}$ can be extended to a second-order deformation of Z.

As we mentioned in §0.1.3, assertion (*c*) has a natural interpretation in the language of spectral algebraic geometry. More precisely, the spectral language allows us to enlarge the category on which functor X of Example 11.5.0.7 is defined. For every connective $\mathbb{E}_\infty$-algebra R over $\mathbf{C}$, we can define $X(R)$ to be the underlying ∞-groupoid of the ∞-category of spectral schemes which are proper and differentially smooth over R. If R is equipped with an augmentation $\epsilon : R \to \mathbf{C}$, we let $X^\wedge(R)$ denote the fiber product $X(R) \times_{X(\mathbf{C})} \{\eta\}$, which we can think of as a classifying space for *deformations of Z* over $\operatorname{Spec} R$. In the special case where R is a (discrete) local Artinian $\mathbf{C}$-algebra, this agrees with the groupoid described in Example 11.5.0.7. However, we can obtain more information by evaluating the functor $X^\wedge$ on $\mathbb{E}_\infty$-algebras over $\mathbf{C}$ which are not discrete. For example, let $\mathbf{C}[\delta]$ denote the trivial square-zero extension $\mathbf{C} \oplus \Sigma\, \mathbf{C}$. According to As we will see later (Remark 19.4.3.5), there is a canonical isomorphism $\mathrm{H}^2(Z; T_Z) \simeq \pi_0 X^\wedge(\mathbf{C}[\delta])$ (as we promised in Proposition 0.1.3.5). The ordinary commutative ring $\mathbf{C}[\epsilon]/(\epsilon^3)$ is a square-zero extension of $\mathbf{C}[\epsilon]/(\epsilon^2)$ by the ideal $\mathbf{C}\,\epsilon^2$, and therefore fits into a pullback diagram of $\mathbb{E}_\infty$-algebras σ :

$$\begin{array}{ccc} \mathbf{C}[\epsilon]/(\epsilon^3) & \longrightarrow & \mathbf{C}[\epsilon]/(\epsilon^2) \\ \downarrow & & \downarrow \\ \mathbf{C} & \longrightarrow & \mathbf{C}[\delta]. \end{array}$$

In §16.3, we will show that this pullback square determines a pullback diagram of spaces

$$\begin{array}{ccc} X(\mathbf{C}[\epsilon]/(\epsilon^3)) & \longrightarrow & X(\mathbf{C}[\epsilon]/(\epsilon^2)) \\ \downarrow & & \downarrow \\ X(\mathbf{C}) & \longrightarrow & X(\mathbf{C}[\delta]), \end{array}$$

and therefore a fiber sequence

$$X^\wedge(\mathbf{C}[\epsilon]/(\epsilon^3)) \to X^\wedge(\mathbf{C}[\epsilon]/(\epsilon^2)) \xrightarrow{\rho} X^\wedge(\mathbf{C}[\delta]).$$

Passing to connected components, we obtain the obstruction class map $\rho : \mathrm{H}^1(Z; T_Z) \to \mathrm{H}^2(Z; T_Z)$ which vanishes on precisely those elements of $\mathrm{H}^1(Z; T_Z)$ classifying first-order deformations of Z which can be extended to second-order deformations.

The preceding analysis of Example 11.5.0.7 cannot be carried out for an arbitrary classical formal moduli problem (in the sense of Definition 11.5.0.6): it depends crucially on the fact that we can extend the domain of the functor $X^\wedge$ to $\mathbb{E}_\infty$-rings which are not discrete (such as $\mathbf{C}[\delta] = \mathbf{C} \oplus \Sigma\,\mathbf{C}$). Moreover, this extended functor needs to be reasonably well-behaved: for example, it should carry the diagram σ to a pullback diagram of spaces. This motivates another variant of Definition 11.5.0.1:

Definition 11.5.0.8. Let R be an $\mathbb{E}_\infty$-algebra over $\mathbf{C}$. We will say that R is *Artinian* if it is connective, $\pi_* R$ is a finite-dimensional vector space over $\mathbf{C}$, and $\pi_0 R$ is a local ring. Let $\mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}}$ denote the ∞-category whose objects are $\mathbb{E}_\infty$-algebras R over $\mathbf{C}$

A *formal moduli problem over* $\mathbf{C}$ is a functor $X : \mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}} \to \mathcal{S}$ which satisfies the following pair of conditions:

(1) The space $X(\mathbf{C})$ is contractible.

(2) For every pullback diagram

$$\begin{array}{ccc} R & \longrightarrow & R_0 \\ \downarrow & & \downarrow \\ R_1 & \longrightarrow & R_{01} \end{array}$$

in $\mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}}$ for which the underlying ring homomorphisms $\pi_0 R_0 \to \pi_0 R_{01} \leftarrow \pi_0 R_1$ are surjective, the diagram

$$\begin{array}{ccc} X(R) & \longrightarrow & X(R_0) \\ \downarrow & & \downarrow \\ X(R_1) & \longrightarrow & X(R_{01}) \end{array}$$

is a pullback square.

Warning 11.5.0.9. The terminology of Definition 11.5.0.8 is potentially misleading: it might be more appropriate to refer to an object $R \in \mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}}$ as a *local Artinian* $\mathbb{E}_\infty$-algebra over $\mathbf{C}$. However, we will abuse terminology throughout Part IV by referring to such an $\mathbb{E}_\infty$-algebra simply as *Artinian* (since we will have no cause to consider Artinian algebras which are not local). See Warning 12.1.2.6.

Remark 11.5.0.10. Let $\mathrm{CAlg}^{\mathrm{cn}}_{\mathbf{C}}$ denote the ∞-category of connective $\mathbb{E}_\infty$-algebras over the field $\mathbf{C}$ of complex numbers, and let $X : \mathrm{CAlg}^{\mathrm{cn}}_{\mathbf{C}} \to \mathcal{S}$ be a functor. Given a point $x \in X(\mathbf{C})$, we define the *completion of* X *at the point* x to be the functor $X^\wedge : \mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}} \to \mathcal{S}$ given by the formula $X^\wedge(R) = X(R) \times_{X(\mathbf{C})} \{x\}$. The functor $X^\wedge$ automatically satisfies condition (1) of Definition 11.5.0.8. Condition (2) is not automatic, but holds for a wide variety of functors; for example, it is satisfied whenever X is representable by a spectral Deligne-Mumford stack (see Corollary **??**).

Remark 11.5.0.11. Let $X : \mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}} \to \mathcal{S}$ be a formal moduli problem. Then X determines a functor between ordinary categories $X_0 : \mathrm{hCAlg}^{\mathrm{art}}_{\mathbf{C}} \to \mathcal{S}\mathrm{et}$, where $\mathrm{hCAlg}^{\mathrm{art}}_{\mathbf{C}}$ denotes the homotopy category of $\mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}}$, given by the formula $X_0(A) = \pi_0 X(A)$. It follows from condition (2) of Definition 11.5.0.8 that if we are given maps of Artinian $\mathbb{E}_\infty$-algebras $R_0 \to R_{01} \leftarrow R_1$ which induce surjections $\pi_0 R_0 \to \pi_0 R_{01} \leftarrow \pi_0 R_1$, then the induced map

$$X_0(R_0 \times_{R_{01}} R_1) \to X_0(R_0) \times_{X_0(R_{01})} X_0(R_1)$$

is a surjection of sets. There is a substantial literature on set-valued moduli functors of this type; see, for example, [146] and [122].

Warning 11.5.0.12. If X is a formal moduli problem over $\mathbf{C}$, then X determines a classical formal moduli problem (with values in the ∞-category $\mathcal{S}$) simply by restricting the functor X to the subcategory of $\mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}}$ consisting of ordinary local Artinian $\mathbf{C}$-algebras (which are precisely the discrete objects of $\mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}}$).

If $\mathsf{X} = (\mathcal{X}, \mathcal{O})$ is a spectral Deligne-Mumford stack over $\mathbf{C}$ equipped with a point $\eta : \mathrm{Spec}^{\text{ét}}\,\mathbf{C} \to \mathsf{X}$ and X is defined as in Remark 11.5.0.10, then the restriction $X_0 = X|_{\mathrm{CAlg}^{\heartsuit\,\mathrm{art}}_{\mathbf{C}}}$ depends only on the pair $(\mathcal{X}, \pi_0\,\mathcal{O})$. In particular, the functor X cannot be recovered from X_0.

In general, if we are given a classical formal moduli problem $X_0 : \mathrm{CAlg}_{\mathbf{C}}^{\heartsuit\,\mathrm{art}} \to \mathcal{S}$, there may or may not exist a formal moduli problem X such that $X_0 = X|_{\mathrm{CAlg}_{\mathbf{C}}^{\heartsuit\,\mathrm{art}}}$. Moreover, if X exists, then it need not be unique. Nevertheless, classical formal moduli problems X_0 which arise naturally are often equipped with a natural extension $X : \mathrm{CAlg}_{\mathbf{C}}^{\mathrm{art}} \to \mathcal{S}$ (as in our discussion of Example 11.5.0.7 above), which can be quite useful in the study of X_0.

We are now ready to articulate a precise version of $(*)$:

Theorem 11.5.0.13. *Let* $\mathrm{Moduli}_{\mathbf{C}}$ *denote the full subcategory of* $\mathrm{Fun}(\mathrm{CAlg}_{\mathbf{C}}^{\mathrm{art}}, \mathcal{S})$ *spanned by the formal moduli problems, and let* $\mathrm{Lie}_{\mathbf{C}}^{\mathrm{dg}}$ *denote the category of differential graded Lie algebras over* $\mathbf{C}$ *(see §13.1). Then there is a functor* $\theta : \mathrm{Lie}_{\mathbf{C}}^{\mathrm{dg}} \to \mathrm{Moduli}$ *with the following universal property: for any* ∞*-category* $\mathcal{C}$*, composition with* θ *induces a fully faithful embedding* $\mathrm{Fun}(\mathrm{Moduli}, \mathcal{C}) \to \mathrm{Fun}(\mathrm{Lie}_{\mathbf{C}}^{\mathrm{dg}}, \mathcal{C})$*, whose essential image is the collection of all functors* $F : \mathrm{Lie}_{\mathbf{C}}^{\mathrm{dg}} \to \mathcal{C}$ *which carry quasi-isomorphisms of differential graded Lie algebras to equivalences in* $\mathcal{C}$*.*

Remark 11.5.0.14. An equivalent version of Theorem 11.5.0.13 has been established by Pridham; we refer the reader to [165] for details.

Remark 11.5.0.15. Let W be the collection of all quasi-isomorphisms in the category $\mathrm{Lie}_{\mathbf{C}}^{\mathrm{dg}}$, and let $\mathrm{Lie}_{\mathbf{C}}^{\mathrm{dg}}[W^{-1}]$ denote the ∞-category obtained from $\mathrm{Lie}_{\mathbf{C}}^{\mathrm{dg}}$ by formally inverting the morphisms in W. Theorem 11.5.0.13 asserts that there is an equivalence of ∞-categories $\mathrm{Lie}_{\mathbf{C}}^{\mathrm{dg}}[W^{-1}] \simeq \mathrm{Moduli}$. In particular, every differential graded Lie algebra over $\mathbf{C}$ determines a formal moduli problem, and two differential graded Lie algebras $\mathfrak{g}_*$ and $\mathfrak{g}'_*$ determine equivalent formal moduli problems if and only if they can be joined by a chain of quasi-isomorphisms.

Theorem 11.5.0.13 articulates a sense in which the theories of commutative algebras and Lie algebras are closely related. In concrete terms, this relationship is controlled by the *Chevalley-Eilenberg* functor, which associates to a differential graded Lie algebra $\mathfrak{g}_*$ a cochain complex of vector spaces $C^*(\mathfrak{g}_*)$. The cohomology of this cochain complex is the *Lie algebra cohomology* of the Lie algebra $\mathfrak{g}_*$, and is endowed with a commutative multiplication. In fact, this multiplication is defined at the level of cochains: the construction $\mathfrak{g}_* \mapsto C^*(\mathfrak{g}_*)$ determines a functor C^* from the (opposite of) the category $\mathrm{Lie}_{\mathbf{C}}^{\mathrm{dg}}$ of differential graded Lie algebras over $\mathbf{C}$ to the category $\mathrm{CAlg}_{\mathbf{C}}^{\mathrm{dg}}$ of commutative differential graded algebras over $\mathbf{C}$. This functor carries quasi-isomorphisms to quasi-isomorphisms, and therefore induces a functor of ∞-categories

$$C^* : \mathrm{Lie}_{\mathbf{C}}^{\mathrm{dg}}[W^{-1}]^{\mathrm{op}} \to \mathrm{CAlg}_{\mathbf{C}}^{\mathrm{dg}}[W'^{-1}];$$

here W is the collection of quasi-isomorphisms in $\mathrm{Lie}_{\mathbf{C}}^{\mathrm{dg}}$ (as in Remark 11.5.0.15) and W' is the collection of quasi-isomorphisms in $\mathrm{CAlg}_{\mathbf{C}}^{\mathrm{dg}}$ (here the ∞-category $\mathrm{CAlg}_{\mathbf{C}}^{\mathrm{dg}}[W'^{-1}]$

can be identified $\mathrm{CAlg}_{\mathbf{C}}$ of $\mathbb{E}_\infty$-algebras over $\mathbf{C}$: see Proposition HA.7.1.4.11). Every differential graded Lie algebra $\mathfrak{g}_*$ admits a canonical map $\mathfrak{g}_* \to 0$, so that its Chevalley-Eilenberg complex is equipped with an augmentation $C^*(\mathfrak{g}_*) \to C^*(0) \simeq \mathbf{C}$. We may therefore refine C^* to a functor $\mathrm{Lie}^{\mathrm{dg}}_{\mathbf{C}}[W^{-1}]^{\mathrm{op}} \to \mathrm{CAlg}^{\mathrm{aug}}_{\mathbf{C}}$ taking values in the ∞-category $\mathrm{CAlg}^{\mathrm{aug}}_{\mathbf{C}}$ of *augmented* $\mathbb{E}_\infty$-algebras over $\mathbf{C}$. We will see that this functor admits a left adjoint $\mathfrak{D} : \mathrm{CAlg}^{\mathrm{aug}}_{\mathbf{C}} \to \mathrm{Lie}^{\mathrm{dg}}_{\mathbf{C}}[W^{-1}]^{\mathrm{op}}$ (Theorem 13.3.0.1). The functor $\theta : \mathrm{Lie}^{\mathrm{dg}}_{\mathbf{C}} \to \mathrm{Moduli}$ appearing in the statement of Theorem 11.5.0.13 can then be defined by the formula

$$\theta(\mathfrak{g}_*)(R) = \mathrm{Map}_{\mathrm{Lie}^{\mathrm{dg}}_{\mathbf{C}}[W^{-1}]}(\mathfrak{D}(R), \mathfrak{g}_*).$$

In more abstract terms, the relationship between commutative algebras and Lie algebras suggested by Theorem 11.5.0.13 is an avatar of *Koszul duality*. More specifically, Theorem 11.5.0.13 reflects the fact that the commutative operad is Koszul dual to the Lie operad (see [114]). This indicates that should be many other versions of Theorem 11.5.0.13, where we replace commutative and Lie algebras by algebras over some other pair of Koszul dual operads. For example, the Koszul self-duality of the $\mathbb{E}_n$-operads (see [68]) suggests an analogue of Theorem 11.5.0.13 in the setting of “noncommutative” derived algebraic geometry, which we will also prove here (see Theorems 14.0.0.5 and 15.0.0.9).

Let us now outline the contents of Part IV. In Chapter 12, we will introduce the general notion of a *deformation theory*: a functor of ∞-categories $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$ satisfying a suitable list of axioms (see Definitions 12.3.1.1 and 12.3.3.2). We will then prove an abstract version of Theorem 11.5.0.13: every deformation theory $\mathfrak{D}$ determines an equivalence $\mathbf{B} \simeq \mathrm{Moduli}^{\mathbf{A}}$, where $\mathrm{Moduli}^{\mathbf{A}}$ is a suitably defined ∞-category of formal moduli problems (Theorem 12.3.3.5). This result is not very difficult in itself: it can be regarded as a distillation of the purely formal ingredients needed for the proof of results like Theorem 11.5.0.13. In practice, the hard part is to construct the functor $\mathfrak{D}$ and to prove that it satisfies the axioms of Definitions 12.3.1.1 and 12.3.3.2. We will give a detailed treatment of three special cases:

(a) In Chapter 13, we treat the case where $\mathbf{A}$ is the ∞-category $\mathrm{CAlg}^{\mathrm{aug}}_{\kappa}$ of augmented $\mathbb{E}_\infty$-algebras over a field κ of characteristic zero, and use Theorem 12.3.3.5 to prove a version of Theorem 11.5.0.13 (Theorem 13.0.0.2).

(b) In Chapter 14, we treat the case where $\mathbf{A}$ is the ∞-category $\mathrm{Alg}^{\mathrm{aug}}_{\kappa}$ of augmented $\mathbb{E}_1$-algebras over a field κ (of arbitrary characteristic), and use Theorem 12.3.3.5 to prove a noncommutative analogue of Theorem 11.5.0.13 (Theorem 14.0.0.5).

(c) In Chapter 15, we treat the case where $\mathbf{A}$ is the ∞-category $\mathrm{Alg}^{(n),\mathrm{aug}}_{\kappa}$ of augmented $\mathbb{E}_n$-algebras over a field κ (again of arbitrary characteristic), and use Theorem 12.3.3.5 to prove a more general noncommutative analogue of Theorem 11.5.0.13 (Theorem 15.0.0.9).

In each case, the relevant deformation functor $\mathfrak{D}$ is given by some version of Koszul duality, and our main result gives an algebraic model for the ∞-category of formal moduli problems $\mathrm{Moduli}^{\mathbf{A}}$. In Chapter 16, we will use these results to study some concrete examples of formal moduli problems which arise naturally in deformation theory.

Remark 11.5.0.16. The notion that differential graded Lie algebras should play an important role in the description of moduli spaces goes back to Quillen's work on rational homotopy theory ([220]), and was developed further in unpublished work of Deligne, Drinfeld, and Feigin. Many other mathematicians have subsequently taken up these ideas: see, for example, the book of Kontsevich and Soibelman ([122]).

Chapter 12

Deformation Theories: Axiomatic Approach

Our in Part IV is to prove several variants of Theorem 11.5.0.13, which supply algebraic descriptions of various ∞-categories of formal moduli problems. Here is a basic prototype for the kind of result we are after:

$(*)$ Let $\mathbf{A}$ be an ∞-category of algebraic objects, let $\mathbf{A}^{\mathrm{art}} \subseteq \mathbf{A}$ be a full subcategory of "Artinian" objects, and let $\mathrm{Moduli}^{\mathbf{A}} \subseteq \mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$ be the ∞-category of functors $X : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ which satisfy a suitable gluing condition (as in Definition 11.5.0.8). Then there is an equivalence of ∞-categories $\mathrm{Moduli}^{\mathbf{A}} \simeq \mathbf{B}$, where $\mathbf{B}$ is some other ∞-category of algebraic objects.

Our goal in this section is to flesh out assertion $(*)$. We begin in §12.1 by introducing the notion of a *deformation context* (Definition 12.1.1.1). A deformation context is a presentable ∞-category $\mathbf{A}$ equipped with some additional data (namely, a collection of spectrum objects $E_\alpha \in \mathrm{Sp}(\mathbf{A})$). Using this data, we define a full subcategory $\mathbf{A}^{\mathrm{art}} \subseteq \mathbf{A}$ of *Artinian* objects of $\mathbf{A}$ (Definition 12.1.2.4) and a full subcategory $\mathrm{Moduli}^{\mathbf{A}} \subseteq \mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$ of *formal moduli problems* (Definition 12.1.3.1). Our definition is quite general, but nevertheless sufficient to guarantee the existence of a reasonable *differential* theory of formal moduli problems. In §12.2 we will explain how to associate to every formal moduli problem X a collection of spectra $X(E_\alpha)$, which we call the *tangent complex*(es) of X. The construction is functorial: every map between formal moduli problems $u : X \to Y$ can be differentiated to obtain maps of spectra $X(E_\alpha) \to Y(E_\alpha)$. Moreover, if each of these maps is a homotopy equivalence, then u is an equivalence (Proposition 12.2.2.6).

In §12.3, we will formulate a general version of $(*)$. For this, we will introduce the notion of a *deformation theory*. A deformation theory is a functor $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$ satisfying a collection of axioms (see Definitions 12.3.1.1 and 12.3.3.2). Our main result (Theorem 12.3.3.5) can then be stated as follows: if $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$ is a deformation theory, then $\mathfrak{D}$ determines an equivalence of ∞-categories $\mathbf{B} \simeq \mathrm{Moduli}^{\mathbf{A}}$. The proof of this result will be given in §12.5, using an ∞-categorical variant of Quillen's small object argument which we review in §12.4.

Our work in this section should be regarded as providing a sort of formal outline for proving results like Theorem 11.5.0.13. For practical purposes, the main difficulty is not in proving Theorem 12.3.3.5 but in verifying its hypotheses: that is, in constructing a functor $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$ which satisfies the axioms listed in Definitions 12.3.1.1 and 12.3.3.2. The later chapters of Part IV are devoted to carrying this out in special cases (we will treat the case of commutative algebras in Chapter 13, associative algebras in Chapter 14, and $\mathbb{E}_n$-algebras in Chapter 15).

Contents

12.1 Formal Moduli Problems

In this section, we introduce a general axiomatic paradigm for the study of deformation theory. Let us begin by outlining the basic idea. We are ultimately interesting in studying some class of algebro-geometric objects (such as schemes, or algebraic stacks, or their spectral analogues). Using the functor of points philosophy, we will view these geometric objects with functors $X : \mathbf{A} \to \mathcal{S}$, where $\mathbf{A}$ denotes some ∞-category of "test objects". The main example of interest (which we will study in detail in Chapter 13) is the case where $\mathbf{A}$ to be the ∞-category $\mathrm{CAlg}^{\mathrm{aug}}_{\kappa} = (\mathrm{CAlg}_{\kappa})_{/\kappa}$ of augmented $\mathbb{E}_{\infty}$-algebras over a field κ of characteristic zero. In any case, we will always assume that $\mathbf{A}$ contains a final object $*$; we can then define a *point* of a functor $X : \mathbf{A} \to \mathcal{S}$ to be a point of the space $X(*)$. Suppose that we wish to study a *formal neighborhood* of X around some chosen point $x \in X(*)$. This formal neighborhood should encode information about the homotopy fiber products $X(A) \times_{X(*)} \{x\}$ for every object $A \in \mathbf{A}$ which is sufficiently "close" to the final object $*$. In order to make this idea precise, we need to introduce some terminology.

12.1.1 Deformation Contexts

Let $\mathbf{A}$ be a presentable ∞-category. We let $\mathrm{Sp}(\mathbf{A})$ denote the ∞-category of spectrum objects of $\mathbf{A}$: that is, the full subcategory of $\mathrm{Fun}(\mathcal{S}^{\mathrm{fin}}_{*}, \mathbf{A})$ spanned by the reduced and excisive functors (see Definition HA.1.4.2.8). For each integer n, we we let $\Omega^{\infty-n} : \mathrm{Sp}(\mathbf{A}) \to \mathbf{A}$ denote the forgetful functor, given concretely by the formula $\Omega^{\infty-n}(X) = \Omega^{m} X(S^{n+m})$ for any $m \geqslant -n$. We recall that $\mathrm{Sp}(\mathbf{A})$ can also be described as the homotopy limit of the tower of ∞-categories

$$\cdots \to \mathbf{A}_{*} \xrightarrow{\Omega} \mathbf{A}_{*} \xrightarrow{\Omega} \mathbf{A}_{*} \to \cdots ,$$

where $\mathbf{A}_{*}$ denotes the ∞-category of pointed objects of $\mathbf{A}$.

Definition 12.1.1.1. A *deformation context* is a pair $(\mathbf{A}, \{E_{\alpha}\}_{\alpha \in T})$, where $\mathbf{A}$ is a presentable ∞-category and $\{E_{\alpha}\}_{\alpha \in T}$ is a set of objects of the ∞-category $\mathrm{Sp}(\mathbf{A})$.

Example 12.1.1.2. Let κ be an $\mathbb{E}_{\infty}$-ring, and let $\mathbf{A} = \mathrm{CAlg}^{\mathrm{aug}}_{\kappa} = (\mathrm{CAlg}_{\kappa})_{/\kappa}$ denote the ∞-category of augmented $\mathbb{E}_{\infty}$-algebras over κ. Using Theorem HA.7.3.4.13 , we can identify $\mathrm{Sp}(\mathbf{A})$ with the ∞-category Mod_{κ} of modules over κ. Let $E \in \mathrm{Sp}(\mathbf{A})$ be the object which corresponds to $\kappa \in \mathrm{Mod}_{\kappa}$ under this identification, so that for every integer n we can identify $\Omega^{\infty-n} E$ with the trivial square-zero extension $\kappa \oplus \Sigma^{n}(\kappa)$ of κ. Then the pair $(\mathrm{CAlg}^{\mathrm{aug}}_{\kappa}, \{E\})$ is a deformation context.

12.1.2 Artinian Objects

Let κ be a field and let $A \in \mathrm{CAlg}^{\mathrm{aug}}_{\kappa}$ be a local augmented $\mathbb{E}_{\infty}$-algebra over κ. We will say that A is said to be *Artinian* if A is connective and $\pi_{*} A$ is a finite-dimensional vector space over κ. Our next goal is to show that the class of (local) Artinian objects of $\mathrm{CAlg}_\kappa^{\mathrm{aug}}$ is determined by the deformation context of Example 12.1.1.2 (see Proposition 12.1.2.9).

Definition 12.1.2.1. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context. We will say that a morphism $\phi : A' \to A$ in $\mathbf{A}$ is *elementary* if there exists an index $\alpha \in T$, an integer $n > 0$, and a pullback diagram

$$\begin{array}{ccc} A' & \longrightarrow & * \\ \downarrow{\scriptstyle \phi} & & \downarrow{\scriptstyle \phi_0} \\ A & \longrightarrow & \Omega^{\infty - n} E_\alpha. \end{array}$$

Here ϕ_0 corresponds to the image of E_α under the forgetful functor $\mathrm{Sp}(\mathbf{A}) \xrightarrow{\Omega_*^{\infty-n}} \mathbf{A}_*$.

Example 12.1.2.2. Let κ be a field and let $(\mathbf{A}, \{E\})$ be the deformation context described in Example 12.1.1.2. Suppose that $\phi : A' \to A$ is a map between connective objects of $\mathbf{A} = \mathrm{CAlg}_\kappa^{\mathrm{aug}}$. Using Theorem HA.7.4.1.26 , we deduce that ϕ is elementary if and only if the following conditions are satisfied:

(a) There exists an integer $n \geqslant 0$ and an equivalence $\mathrm{fib}(\phi) \simeq \Sigma^n(\kappa)$ in the ∞-category $\mathrm{Mod}_{A'}$ (here we regard κ as an object of $\mathrm{Mod}_{A'}$ via the augmentation map $A' \to \kappa$).

(b) If $n = 0$, then the multiplication map $\pi_0 \,\mathrm{fib}(\phi) \otimes \pi_0 \,\mathrm{fib}(\phi) \to \pi_0 \,\mathrm{fib}(\phi)$ vanishes.

If (a) is satisfied for $n = 0$, then we can choose a generator $\overline{x}$ for $\pi_0 \,\mathrm{fib}(\phi)$ having image $x \in \pi_0 A'$. Condition (b') is automatic if $x = 0$. If $a \neq 0$, then the map $\pi_0 \,\mathrm{fib}(\phi) \to \pi_0 A'$ is injective, so condition (b) is equivalent to the requirement that $x^2 = 0$ in $\pi_0 A'$.

Remark 12.1.2.3. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context, and suppose we are given an object $A \in \mathbf{A}$. Every elementary map $A' \to A$ in $\mathbf{A}$ is given by the fiber of a map $A \to \Omega^{\infty-n} E_\alpha$ for some $n > 0$ and some $\alpha \in T$. It follows that the collection of equivalence classes of elementary maps $A' \to A$ is bounded in cardinality.

Definition 12.1.2.4. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context. We will say that a morphism $\phi : A' \to A$ in $\mathbf{A}$ is *small* if it can be written as a composition of finitely many elementary morphisms $A' \simeq A_0 \to A_1 \to \cdots \to A_n \simeq A$. We will say that an object $A \in \mathbf{A}$ is *Artinian* if the map $A \to *$ (which is uniquely determined up to homotopy) is small. We let $\mathbf{A}^{\mathrm{art}}$ denote the full subcategory of $\mathbf{A}$ spanned by the Artinian objects.

Warning 12.1.2.5. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context. The collection of Artinian objects of $\mathbf{A}$ depends not only on the underlying ∞-category $\mathbf{A}$, but also on the collection of spectrum objects $\{E_\alpha\}_{\alpha \in T}$.

Warning 12.1.2.6. The terminology of Definition 12.1.2.4 is motivated by the observation that, if κ is a field, then the class of Artinian objects of $\mathrm{CAlg}^{\mathrm{aug}}_{\kappa}$ (in the sense of Definition 12.1.2.4) can be regarded as a "derived" version of the theory of augmented local Artinian κ-algebras (in the sense of commutative algebra): see Proposition 12.1.2.9 below. However, our terminology is potentially confusing for two reasons:

(a) If A is an augmented commutative algebra over a field κ which is Artinian in the sense of classical commutative algebra, then A will not be Artinian in the the sense of Definition 12.1.2.4 unless it is local. For example, the product $A = \kappa \times \kappa$ is not Artinian in the sense of Definition 12.1.2.4. (To avoid this confusion, it might be more appropriate to refer to the objects of $\mathbf{A}^{\mathrm{art}}$ as the *local Artinian* objects of $\mathbf{A}$; however, we would prefer to avoid unnecessarily convoluted language: see Warning 11.5.0.9)

(b) If κ is a commutative ring which is not a field, then we can still regard $\mathbf{A} = \mathrm{CAlg}^{\mathrm{aug}}_{\kappa}$ as a deformation context (as in Example 12.1.1.2), but the condition that an augmented commutative κ-algebra A belongs to $\mathbf{A}^{\mathrm{art}}$ is generally unrelated to the condition that A is Artinian (for example, the commutative ring κ itself is always Artinian in the sense of Definition 12.1.2.4). In practice, this will not concern us: we will only consider the deformation context of Example 12.1.1.2 in the case where κ is a field (usually of characteristic zero).

Example 12.1.2.7. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context. For every integer $n \geqslant 0$ and every index $\alpha \in T$, we have a pullback diagram

$$\begin{array}{ccc} \Omega^{\infty-n} E_\alpha & \longrightarrow & * \\ \downarrow & & \downarrow \\ * & \longrightarrow & \Omega^{\infty-n-1} E_\alpha. \end{array}$$

It follows that the left vertical map is elementary. In particular, $\Omega^{\infty-n} E_\alpha$ is an Artinian object of $\mathbf{A}$.

Remark 12.1.2.8. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context. It follows from Remark 12.1.2.3 that the subcategory $\mathbf{A}^{\mathrm{art}} \subseteq \mathbf{A}$ is essentially small.

Proposition 12.1.2.9. *Let κ be a field and let $(\mathbf{A}, \{E\})$ be the deformation context of Example 12.1.1.2. Then an object $A \in \mathbf{A} = \mathrm{CAlg}^{\mathrm{aug}}_{\kappa}$ is Artinian (in the sense of Definition 12.1.2.4) if and only if the following conditions are satisfied:*

(1) *The homotopy groups $\pi_n A$ vanish for $n < 0$ and $n \gg 0$.*

(2) *Each homotopy group $\pi_n A$ is finite-dimensional as a vector space over κ.*

(3) *The commutative ring* $\pi_0 A$ *is local.*

Proof. Suppose first that A is Artinian, so that there there exists a finite sequence of maps

$$A = A_0 \to A_1 \to \cdots \to A_n \simeq \kappa$$

where each A_i is a square-zero extension of A_{i+1} by $\Sigma^{m_i}(\kappa)$, for some $n_i \geqslant 0$. We prove that each A_i satisfies conditions (1), (2), and (3) using descending induction on i. The case $i = n$ is obvious, so let us assume that $i < n$ and that A_{i+1} is known to satisfy conditions (1), (2), and (3). We have a fiber sequence of κ-module spectra

$$\Sigma^{m_i}(\kappa) \to A_i \to A_{i+1}$$

which immediately implies that A_i satisfies (1) and (2). The map $\phi : \pi_0 A_i \to \pi_0 A_{i+1}$ is surjective and $\ker(\phi)^2 = 0$, from which it follows immediately that $\pi_0 A_i$ is local.

Now suppose that A satisfies conditions (1), (2), and (3). We will prove that A is Artinian by induction on the dimension of the κ-vector space $\pi_* A$. Let n be the largest integer for which $\pi_n A$ does not vanish. We first treat the case $n = 0$. We will abuse notation by identifying A with the underlying commutative ring $\pi_0 A$. Condition (3) asserts that A is a local ring; let $\mathfrak{m}$ denote its maximal ideal. Since A is a finite dimensional algebra over κ, we have $\mathfrak{m}^{i+1} \simeq 0$ for $i \gg 0$. Choose i as small as possible. If $i = 0$, then $\mathfrak{m} \simeq 0$ and $A \simeq \kappa$, in which case there is nothing to prove. Otherwise, we can choose a nonzero element $x \in \mathfrak{m}^i \subseteq \mathfrak{m}$. Let A' denote the quotient ring $A/(x)$. It follows from Example 12.1.2.2 that the quotient map $A \to A'$ is elementary. Since A' is Artinian by the inductive hypothesis, we conclude that A is Artinian.

Now suppose that $n > 0$ and let $M = \pi_n A$, so that M has the structure of a module over the ring $\pi_0 A$. Let $\mathfrak{m} \subseteq \pi_0 A$ be as above, and let i be the least integer such that $\mathfrak{m}^{i+1} M \simeq 0$. Let $x \in \mathfrak{m}^i M$ and let M' be the quotient of M by x, so that we have an exact sequence

$$0 \to \kappa \xrightarrow{x} M \to M' \to 0$$

of modules over $\pi_0 A$. We will abuse notation by viewing this sequence as a fiber sequence of A''-modules, where $A'' = \tau_{\leqslant n-1} A$. It follows from Theorem HA.7.4.1.26 that there is a pullback diagram

$$\begin{array}{ccc} A & \longrightarrow & \kappa \\ \downarrow & & \downarrow \\ A'' & \longrightarrow & \kappa \oplus \Sigma^{n+1}(M). \end{array}$$

Set $A' = A'' \times_{\kappa \oplus \Sigma^{n+1}(M')} \kappa$. Then $A \simeq A' \times_{\kappa \oplus \Sigma^{n+1}(\kappa)} \kappa$ so we have an elementary map $A \to A'$. Using the inductive hypothesis we deduce that A' is Artinian, so that A is also Artinian. □

Remark 12.1.2.10. Let κ be a field and suppose that $A \in \mathrm{CAlg}_{\kappa}^{\mathrm{cn}}$ has the property that $\pi_* A$ is a finite-dimensional vector space over κ and that $\pi_0 A$ is a local ring with residue field κ. Then the mapping space $\mathrm{Map}_{\mathrm{CAlg}_{\kappa}}(A, \kappa)$ is contractible. In particular, A can be promoted (in an essentially unique way) to an Artinian object of $\mathbf{A} = \mathrm{CAlg}_{\kappa}^{\mathrm{aug}}$. Moreover, the forgetful functor $\mathrm{CAlg}_{\kappa}^{\mathrm{aug}} \to \mathrm{CAlg}_{\kappa}$ is fully faithful when restricted to the full subcategory $\mathbf{A}^{\mathrm{art}} \subseteq \mathbf{A}$. We will denote the essential image of this restriction by $\mathrm{CAlg}_{\kappa}^{\mathrm{art}}$. We refer to $\mathrm{CAlg}_{\kappa}^{\mathrm{art}}$ as the *∞-category of Artinian $\mathbb{E}_{\infty}$-algebras over κ*. In the case where $\kappa = \mathbf{C}$, this recovers the definition of $\mathrm{CAlg}_{\mathbf{C}}^{\mathrm{art}}$ appearing in Definition 11.5.0.8.

Remark 12.1.2.11. Let $(\mathbf{A}, \{E_{\alpha}\}_{\alpha \in T})$ be a deformation context. Then the collection of small morphisms in $\mathbf{A}$ is closed under composition. Consequently, if $\phi : A' \to A$ is small and A is Artinian, then A' is also Artinian. In particular, if there exists a pullback diagram

$$\begin{array}{ccc} B' & \longrightarrow & A' \\ \downarrow & & \downarrow \phi \\ B & \longrightarrow & A \end{array}$$

where B is Artinian and ϕ is small, then B' is also Artinian.

12.1.3 Formal Moduli Problems

We are now ready to introduce the main objects of study in Part IV.

Definition 12.1.3.1. Let $(\mathbf{A}, \{E_{\alpha}\}_{\alpha \in T})$ be a deformation context. A *formal moduli problem* is a functor $X : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ satisfying the following pair of conditions:

(a) The space $X(*)$ is contractible (here $*$ denotes a final object of $\mathbf{A}$).

(b) Let σ :

$$\begin{array}{ccc} A' & \longrightarrow & B' \\ \downarrow & & \downarrow \phi \\ A & \longrightarrow & B \end{array}$$

be a diagram in $\mathbf{A}^{\mathrm{art}}$. If σ is a pullback diagram and ϕ is small, then $X(\sigma)$ is a pullback diagram in $\mathcal{S}$.

We let $\mathrm{Moduli}^{\mathbf{A}}$ denote the full subcategory of $\mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$ spanned by the formal moduli problems. We will refer to $\mathrm{Moduli}^{\mathbf{A}}$ as the *∞-category of formal moduli problems*.

Condition (b) of Definition 12.1.3.1 has a number of equivalent formulations:

Proposition 12.1.3.2. *Let $(\mathbf{A}, \{E_{\alpha}\}_{\alpha \in T})$ be a deformation context, and let $X : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ be a functor. The following conditions are equivalent:*

(1) *Let* σ :

$$\begin{array}{ccc} A' & \longrightarrow & B' \\ \downarrow & & \downarrow \phi \\ A & \longrightarrow & B \end{array}$$

be a diagram in $\mathbf{A}^{\mathrm{art}}$*. If* σ *is a pullback diagram and* ϕ *is small, then* $X(\sigma)$ *is a pullback diagram in* $\mathcal{S}$*.*

(2) *Let* σ *be as in* (1)*. If* σ *is a pullback diagram and* ϕ *is elementary, then* $X(\sigma)$ *is a pullback diagram in* $\mathcal{S}$*.*

(3) *Let* σ *be as in* (1)*. If* σ *is a pullback diagram and* ϕ *is the base point morphism* $* \to \Omega^{\infty-n}E_\alpha$ *for some* $\alpha \in T$ *and* $n > 0$*, then* $X(\sigma)$ *is a pullback diagram in* $\mathcal{S}$*.*

Proof. The implications $(a) \Rightarrow (b) \Rightarrow (c)$ are clear. The reverse implications follow from Lemma HTT.4.4.2.1 . □

Example 12.1.3.3. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context, and let $A \in \mathbf{A}$ be an object. Let $\mathrm{Spf}(A) : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ be the functor corepresented by A, given on Artinian objects of $\mathbf{A}$ by the formula $\mathrm{Spf}(A)(B) = \mathrm{Map}_{\mathbf{A}}(A, B)$. Then $\mathrm{Spf}(A)$ is a formal moduli problem. We will refer to $\mathrm{Spf}(A)$ as the *formal spectrum* of A. Moreover, the construction $A \mapsto \mathrm{Spf}(A)$ determines a functor $\mathrm{Spf} : \mathbf{A}^{\mathrm{op}} \to \mathrm{Moduli}^{\mathbf{A}}$.

Warning 12.1.3.4. The notion of formal spectrum Spf A of Example 12.1.3.3 is different from the notion of formal spectrum studied in Chapter 8. However, in many situations where both notions are defined, they are interchangeable: see §**??**.

Remark 12.1.3.5. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context. The ∞-category $\mathbf{A}^{\mathrm{art}} \subseteq \mathbf{A}$ is essentially small. It follows from Lemmas HTT.5.5.4.19 and HTT.5.5.4.18 that the ∞-category $\mathrm{Moduli}^{\mathbf{A}}$ is an accessible localization of the ∞-category $\mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$. In particular, the ∞-category $\mathrm{Moduli}^{\mathbf{A}}$ is presentable.

Remark 12.1.3.6. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context, and let $X : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ be a functor which satisfies the equivalent conditions of Proposition 12.1.3.2. For every point $\eta \in X(*)$, define a functor $X_\eta : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ by the formula $X_\eta(A) = X(A) \times_{X(*)} \{\eta\}$. Then X_η is a formal moduli problem. We may therefore identify X as a family of formal moduli problems parametrized by the space $X(*)$. Consequently, condition (a) of Definition 12.1.3.1 should be regarded as a harmless simplifying assumption.

In the special case where $\mathbf{A} = \mathrm{CAlg}^{\mathrm{aug}}_{\mathbf{C}}$, Definition 12.1.3.1 agrees with Definition 11.5.0.8. This is an immediate consequence of the following result:

Proposition 12.1.3.7. *Let κ be a field and let $X : \mathrm{CAlg}^{\mathrm{art}}_{\kappa} \to \mathcal{S}$ be a functor. Then conditions* (1)*,* (2)*, and* (3) *of Proposition 12.1.3.2 are equivalent to the following:*

($*$) *For every pullback diagram*

$$\begin{array}{ccc} R & \longrightarrow & R_0 \\ \downarrow & & \downarrow \\ R_1 & \longrightarrow & R_{01} \end{array}$$

in $\mathrm{CAlg}^{\mathrm{art}}_{\kappa}$ for which the underlying maps $\pi_0 R_0 \to \pi_0 R_{01} \leftarrow \pi_0 R_1$ are surjective, the diagram

$$\begin{array}{ccc} X(R) & \longrightarrow & X(R_0) \\ \downarrow & & \downarrow \\ X(R_1) & \longrightarrow & X(R_{01}) \end{array}$$

is a pullback square.

The proof of Proposition 12.1.3.7 will require the following elaboration on Proposition 12.1.2.9:

Lemma 12.1.3.8. *Let κ be a field and let $f : A \to B$ be a morphism in $\mathrm{CAlg}^{\mathrm{art}}_{\kappa}$. Then f is small (when regarded as a morphism in $\mathrm{CAlg}^{\mathrm{aug}}_{\kappa}$) if and only if it induces a surjection of commutative rings $\pi_0 A \to \pi_0 B$.*

Proof. Let K be the fiber of f, regarded as an A-module. If $\pi_0 A \to \pi_0 B$ is surjective, then K is connective. We will prove that f is small by induction on the dimension of the graded vector space $\pi_* K$. If this dimension is zero, then $K \simeq 0$ and f is an equivalence. Assume therefore that $\pi_* K \neq 0$, and let n be the smallest integer such that $\pi_n K \neq 0$. Let $\mathfrak{m}$ denote the maximal ideal of $\pi_0 A$. Then $\mathfrak{m}$ is nilpotent, so $\mathfrak{m}(\pi_n K) \neq \pi_n K$ and we can choose a map of $\pi_0 A$-modules $\phi : \pi_n K \to \kappa$. According to Theorem HA.7.4.3.1 , we have $(2n+1)$-connective map $K \otimes_A B \to \Sigma^{-1}(L_{B/A})$. In particular, we have an isomorphism $\pi_{n+1} L_{B/A} \simeq \mathrm{Tor}_0^{\pi_0 A}(\pi_0 B, \pi_n K)$ so that ϕ determines a map $L_{B/A} \to \Sigma^{n+1}(\kappa)$. We can interpret this map as a derivation $B \to B \oplus \Sigma^{n+1}(\kappa)$; let $B' = B \times_{B \oplus \Sigma^{n+1}(\kappa)} \kappa$. Then f factors as a composition

$$A \xrightarrow{f'} B' \xrightarrow{f''} B.$$

Since the map f'' is elementary, it will suffice to show that f' is small, which follows from the inductive hypothesis. □

Proof of Proposition 12.1.3.7. The implication $(*) \Rightarrow (3)$ is obvious, and the implication $(1) \Rightarrow (*)$ follows from Lemma 12.1.3.8. □

Remark 12.1.3.9. The proof of Proposition 12.1.3.7 shows that condition $(*)$ is equivalent to the *a priori* stronger condition that the diagram

$$\begin{array}{ccc} R & \longrightarrow & R_0 \\ \downarrow & & \downarrow \\ R_1 & \longrightarrow & R_{01} \end{array}$$

is a pullback square whenever *one* of the maps $\pi_0 R_0 \to \pi_0 R_{01}$ or $\pi_0 R_1 \to \pi_0 R_{01}$ is surjective.

12.2 The Tangent Complex

Let X be an algebraic variety over the field $\mathbf{C}$ of complex numbers, and let $x : \operatorname{Spec} \mathbf{C} \to X$ be a point of X. A *tangent vector* to X at the point x is a dotted arrow rendering the diagram

$$\begin{array}{ccc} \operatorname{Spec} \mathbf{C} & \xrightarrow{x} & X \\ \downarrow & \nearrow & \downarrow \\ \operatorname{Spec} \mathbf{C}[\epsilon]/(\epsilon^2) & \longrightarrow & \operatorname{Spec} \mathbf{C} \end{array}$$

commutative. The collection of tangent vectors to X at x comprise a vector space $T_{X,x}$, which we call the *Zariski tangent space* of X at x. If $\mathcal{O}_{X,x}$ denotes the local ring of X at the point x and $\mathfrak{m} \subseteq \mathcal{O}_{X,x}$ its maximal ideal, then there is a canonical isomorphism of vector spaces $T_{X,\eta} \simeq (\mathfrak{m}/\mathfrak{m}^2)^\vee$.

The tangent space $T_{X,x}$ is among the most basic and useful invariants one can use to study the local structure of an algebraic variety X near a point x. Our goal in this section is to generalize the construction of $T_{X,x}$ to the setting of an arbitrary formal moduli problem, in the sense of Definition 12.1.3.1. Let us identify X with its functor of points, given by $X(A) = \operatorname{Hom}(\operatorname{Spec} A, X)$ for every $\mathbf{C}$-algebra A (here the Hom is computed in the category of schemes over $\mathbf{C}$). Then $T_{X,x}$ can be described as the fiber of the map $X(\mathbf{C}[\epsilon]/(\epsilon^2)) \to X(\mathbf{C})$ over the point $x \in X(\mathbf{C})$. Note that the commutative ring $\mathbf{C}[\epsilon]/(\epsilon^2)$ is given by $\Omega^\infty E$, where E is the spectrum object of $\mathrm{CAlg}^{\mathrm{aug}}_{\mathbf{C}}$ appearing in Example 12.1.1.2. This suggests a possible generalization:

Definition 12.2.0.1. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context, and let $Y : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ be a formal moduli problem. For each $\alpha \in T$, the *tangent space of Y at α* is the space $Y(\Omega^\infty E_\alpha)$.

12.2.1 Delooping the Tangent Space

There is a somewhat unfortunate aspect to the terminology of Definition 12.2.0.1. By definition, a formal moduli problem Y is a $\mathcal{S}$-valued functor, so the evaluation of X on any object $A \in \mathbf{A}^{\mathrm{art}}$ might be called a “space”. The term “tangent space” in algebraic geometry has a different meaning: if X is a complex algebraic variety with a base point x, then we refer to $T_{X,x}$ as the tangent *space* of X not because it is equipped with a topology, but because it has the structure of a vector space over $\mathbf{C}$. In particular, $T_{X,x}$ is equipped with an addition which is commutative and associative. This phenomenon is quite general: for any formal moduli problem $Y : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$, each tangent space $Y(\Omega^{\infty} E_\alpha)$ of Y is an infinite loop space, and therefore equipped with a composition law which is commutative and associative up to coherent homotopy.

Recall that if $\mathcal{C}$ is an ∞-category which admits finite limits, then the ∞-category $\mathrm{Sp}(\mathcal{C})$ of *spectrum objects of* $\mathcal{C}$ is defined to be the full subcategory of $\mathrm{Fun}(\mathcal{S}_*^{\mathrm{fin}}, \mathcal{C})$ spanned by those functors which are reduced and excisive (Definition HA.1.4.2.8).

Proposition 12.2.1.1. *Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context. For each $\alpha \in T$, we identify $E_\alpha \in \mathrm{Sp}(\mathbf{A})$ with the corresponding functor $\mathcal{S}_*^{\mathrm{fin}} \to \mathbf{A}$. Then:*

(1) *For every map $f : K \to K'$ of pointed finite spaces which induces a surjection $\pi_0 K \to \pi_0 K'$, the induced map $E_\alpha(K) \to E_\alpha(K')$ is a small morphism in $\mathbf{A}$.*

(2) *For every pointed finite space K, the object $E_\alpha(K) \in \mathbf{A}$ is Artinian.*

Proof. We will prove (1); assertion (2) follows by applying (1) to the constant map $K \to *$. Note that f is equivalent to a composition of maps

$$K = K_0 \to K_1 \to \cdots \to K_n = K',$$

where each K_i is obtained from K_{i-1} by attaching a single cell of dimension n_i. Since $\pi_0 K$ surjects onto $\pi_0 K'$, we may assume that each n_i is positive. It follows that we have pushout diagrams of finite pointed spaces

$$\begin{array}{ccc} K_{i-1} & \longrightarrow & K_i \\ \downarrow & & \downarrow \\ * & \longrightarrow & S^{n_i}. \end{array}$$

Since E_α is excisive, we obtain a pullback square

$$\begin{array}{ccc} E_\alpha(K_{i-1}) & \longrightarrow & E_\alpha(K_i) \\ \downarrow & & \downarrow \\ * & \longrightarrow & \Omega^{n_i} E_\alpha, \end{array}$$

so that each of the maps $E_\alpha(K_{i-1}) \to E_\alpha(K_i)$ is elementary. □

It follows from Proposition 12.2.1.1 that if $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ is a deformation context, then each E_α can be regarded as a functor from $\mathcal{S}_*^{\mathrm{fin}}$ to the full subcategory $\mathbf{A}^{\mathrm{art}} \subseteq \mathbf{A}$ spanned by the Artinian objects. It therefore makes sense to compose E_α with any formal moduli problem.

Proposition 12.2.1.2. *Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context and let $Y : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ be a formal moduli problem. For every $\alpha \in T$, the composite functor*

$$\mathcal{S}_*^{\mathrm{fin}} \xrightarrow{E_\alpha} \mathbf{A}^{\mathrm{art}} \xrightarrow{Y} \mathcal{S}$$

is reduced and excisive.

Proof. It is obvious that $Y \circ E_\alpha$ carries initial objects of $\mathcal{S}_*^{\mathrm{fin}}$ to contractible spaces. Suppose we are given a pushout diagram

$$\begin{array}{ccc} K & \longrightarrow & K' \\ \downarrow & & \downarrow \\ L & \longrightarrow & L' \end{array}$$

of pointed finite spaces; we wish to show that the diagram σ :

$$\begin{array}{ccc} Y(E_\alpha(K)) & \longrightarrow & Y(E_\alpha(K')) \\ \downarrow & & \downarrow \\ Y(E_\alpha(L)) & \longrightarrow & Y(E_\alpha(L')) \end{array}$$

is a pullback square in $\mathcal{S}$. Let K'_+ denote the union of those connected components of K' which meet the image of the map $K \to K'$. There is a retraction of K' onto K'_+, which carries the other connected components of K' to the base point. Define L'_+ and the retraction $L' \to L'_+$ similarly. We have a commutative diagram of pointed finite spaces

$$\begin{array}{ccccc} K & \longrightarrow & K' & \longrightarrow & K'_+ \\ \downarrow & & \downarrow & & \downarrow \\ L & \longrightarrow & L' & \longrightarrow & L'_+ \end{array}$$

where each square is a pushout, hence a diagram of spaces

$$\begin{array}{ccccc} Y(E_\alpha(K)) & \longrightarrow & Y(E_\alpha(K')) & \longrightarrow & Y(E_\alpha(K'_+)) \\ \downarrow & & \downarrow & & \downarrow \\ Y(E_\alpha(L)) & \longrightarrow & Y(E_\alpha(L')) & \longrightarrow & Y(E_\alpha(L'_+)). \end{array}$$

To prove that the left square is a pullback diagrams, it will suffice to show that the right square and the outer rectangle are pullback diagrams. We may therefore reduce to the case where the map $\pi_0 K \to \pi_0 K'$ is surjective. Then the map $\pi_0 L \to \pi_0 L'$ is surjective, so that $E_\alpha(L) \to E_\alpha(L')$ is a small morphism in $\mathbf{A}^{\mathrm{art}}$ (Proposition 12.2.1.1). Since E_α is excisive, the diagram

$$\begin{array}{ccc} E_\alpha(K) & \longrightarrow & E_\alpha(K') \\ \downarrow & & \downarrow \\ E_\alpha(L) & \longrightarrow & E_\alpha(L') \end{array}$$

is a pullback square in $\mathbf{A}$. Using the assumption that Y is a formal moduli problem, we deduce that σ is a pullback square of spaces. □

12.2.2 The Tangent Complex

Proposition 12.2.1.2 motivates the following:

Definition 12.2.2.1. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context, and let $Y : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ be a formal moduli problem. For each $\alpha \in T$, we let $Y(E_\alpha)$ denote the composite functor

$$\mathcal{S}^{\mathrm{fin}}_* \xrightarrow{E_\alpha} \mathbf{A}^{\mathrm{art}} \xrightarrow{Y} \mathcal{S}.$$

We will view $Y(E_\alpha)$ as an object in the ∞-category $\mathrm{Sp} = \mathrm{Sp}(\mathcal{S})$ of spectra, and refer to $Y(E_\alpha)$ as the *tangent complex to* Y at α.

Remark 12.2.2.2. In the situation of Definition 12.2.2.1, suppose that T has a single element, so that $\{E_\alpha\}_{\alpha \in T} = \{E\}$ for some $E \in \mathrm{Sp}(\mathbf{A})$ (this condition is satisfied in all of the main examples we will study in this paper). In this case, we will omit mention of the index α and simply refer to $Y(E)$ as the *tangent complex* to the formal moduli problem Y.

Remark 12.2.2.3. Let $Y : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ be as in Definition 12.2.2.1. For every index α, we can identify the tangent space $Y(\Omega^\infty E_\alpha)$ at α with the 0th space of the tangent complex $Y(E_\alpha)$. More generally, there are canonical homotopy equivalences $Y(\Omega^{\infty-n} E_\alpha) \simeq \Omega^{\infty-n} Y(E_\alpha)$ for $n \geqslant 0$.

Example 12.2.2.4. Let $X = \mathrm{Spec}\, R$ be an affine algebraic variety over the field $\mathbf{C}$ of complex numbers, and suppose we are given a point x of X (corresponding to an augmentation $\epsilon : R \to \mathbf{C}$ of the $\mathbf{C}$-algebra R). Then X determines a formal moduli problem $X^\wedge = \mathrm{Spf}\, R : \mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}} \to \mathcal{S}$, given by the formula $X^\wedge(A) = \mathrm{Map}_{\mathrm{CAlg}^{\mathrm{aug}}_{\mathbf{C}}}(R, A)$ (here we work in the deformation context $(\mathrm{CAlg}^{\mathrm{aug}}_{\mathbf{C}}, \{E\})$ of Example 12.1.1.2). Unwinding the definitions, we see that the tangent complex $X^\wedge(E)$ can be identified with the spectrum $\mathrm{Mor}_{\mathrm{Mod}_R}(L_{R/\mathbf{C}}, \mathbf{C})$ classifying maps from the cotangent complex $L_{R/\mathbf{C}}$ into $\mathbf{C}$ (regarded as an R-module via the augmentation ϵ). In particular, the homotopy groups of $X^\wedge(E)$ are given by

$$\pi_i X^\wedge(E) \simeq (\pi_{-i}(\mathbf{C} \otimes_R L_{R/\mathbf{C}}))^\vee.$$

It follows that $\pi_i X^\wedge(E)$ vanishes for $i > 0$, and that $\pi_0 X^\wedge(E)$ is isomorphic to the Zariski tangent space $(\mathfrak{m}/\mathfrak{m}^2)^\vee$ of X at the point x. If X is smooth at the point x, then the negative homotopy groups of $\pi_i X^\wedge(E)$ vanish. In general, the homotopy groups $\pi_i X^\wedge(E)$ encode information about the nature of the singularity of X at the point x. One of our goals in Part IV is to articulate a sense in which the tangent complex $X^\wedge(E)$ encodes *complete* information about the local structure of X near the point x.

Warning 12.2.2.5. The terminology of Definition 12.2.2.1 is potentially misleading. For a general deformation context $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ and formal moduli problem $Y : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$, the tangent complexes $Y(E_\alpha)$ are spectra. If κ is a field and $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T}) = (\mathrm{CAlg}^{\mathrm{aug}}_\kappa, \{E\})$ is the deformation context of Example 12.1.1.2, one can show that the tangent complex $Y(E)$ admits the structure of a κ-module spectrum, and can therefore be identified with a chain complex of vector spaces over κ. This observation motivates our use of the term "tangent complex." In the general case, it might be more appropriate to refer to $Y(E_\alpha)$ as a "tangent spectrum" to the formal moduli problem Y.

The tangent complex of a formal moduli problem Y is a powerful invariant of Y. We close this section with a simple illustration:

Proposition 12.2.2.6. *Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context and let $u : X \to Y$ be a map of formal moduli problems. Suppose that u induces an equivalence of tangent complexes $X(E_\alpha) \to Y(E_\alpha)$ for each $\alpha \in T$. Then u is an equivalence.*

Proof. Consider an arbitrary object $A \in \mathbf{A}^{\mathrm{art}}$, so that there exists a sequence of elementary morphisms

$$A = A_0 \to A_1 \to \cdots \to A_n \simeq *$$

in $\mathbf{A}$. We prove that the map $u(A_i) : X(A_i) \to Y(A_i)$ is a homotopy equivalence using descending induction on i, the case $i = n$ being trivial. Assume therefore that $i < n$ and that $u(A_{i+1})$ is a homotopy equivalence. Since $A_i \to A_{i+1}$ is elementary, we have a fiber sequence of maps

$$u(A_i) \to u(A_{i+1}) \to u(\Omega^{\infty - n} E_\alpha)$$

for some $n > 0$ and $\alpha \in T$. To prove that $u(A_i)$ is a homotopy equivalence, it suffices to show that $u(\Omega^{\infty - n} E_\alpha)$ is a homotopy equivalence, which follows immediately from our assumption that u induces an equivalence $X(E_\alpha) \to Y(E_\alpha)$. □

12.3 Deformation Theories

Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context. Our main goal in Part IV is to show that, in many cases of interest, the ∞-category $\mathrm{Moduli}^{\mathbf{A}} \subseteq \mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$ admits a concrete algebraic description. To prove this, we will need to be able to address the following question:

(Q) Given an ∞-category $\mathbf{B}$, how can we recognize the existence of an equivalence $\mathrm{Moduli}^{\mathbf{A}} \simeq \mathbf{B}$?

12.3.1 Weak Deformation Theories

We take our first cue from Example 12.1.3.3. If $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T}$ is a deformation context, then to every object $A \in \mathbf{A}$ we can associate a formal moduli problem $\operatorname{Spf} A \in \mathrm{Moduli}^{\mathbf{A}}$ using the formula $(\operatorname{Spf} A)(R) = \mathrm{Map}_{\mathbf{A}}(A, R)$. Composing this construction with a prospective equivalence $\mathrm{Moduli}^{\mathbf{A}} \simeq \mathbf{B}$, we obtain a functor $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$. We begin by axiomatizing the expected properties of such a functor:

Definition 12.3.1.1. A *weak deformation theory* for a deformation context $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ is a functor $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$ satisfying the following axioms:

($D1$) The ∞-category $\mathbf{B}$ is presentable.

($D2$) The functor $\mathfrak{D}$ admits a left adjoint $\mathfrak{D}' : \mathbf{B} \to \mathbf{A}^{\mathrm{op}}$.

($D3$) There exists a full subcategory $\mathbf{B}_0 \subseteq \mathbf{B}$ satisfying the following conditions:

- (a) For every object $K \in \mathbf{B}_0$, the unit map $K \to \mathfrak{D}\mathfrak{D}'K$ is an equivalence.
- (b) The full subcategory $\mathbf{B}_0$ contains the initial object $\varnothing \in \mathbf{B}$. It then follows from ($a$) that $\varnothing \simeq \mathfrak{D}\mathfrak{D}'\varnothing \simeq \mathfrak{D}(*)$, where $*$ denotes the final object of $\mathbf{A}$.
- (c) For every index $\alpha \in T$ and every $n \geqslant 1$, there exists an object $K_{\alpha,n} \in \mathbf{B}_0$ and an equivalence $\Omega^{\infty-n} E_\alpha \simeq \mathfrak{D}' K_{\alpha,n}$. It follows that the base point of $\Omega^{\infty-n} E_\alpha$ determines a map

$$v_{\alpha,n} : K_{\alpha,n} \simeq \mathfrak{D}\mathfrak{D}' K_{\alpha,n} \simeq \mathfrak{D}(\Omega^{\infty-n} E_\alpha) \to \mathfrak{D}(*) \simeq \varnothing.$$

- (d) For every pushout diagram

$$\begin{array}{ccc} K_{\alpha,n} & \longrightarrow & K \\ \big\downarrow{\scriptstyle v_{\alpha,n}} & & \big\downarrow \\ \varnothing & \longrightarrow & K' \end{array}$$

where $\alpha \in T$ and $n > 0$, if K belongs to to $\mathbf{B}_0$ then K' also belongs to $\mathbf{B}_0$.

Definition 12.3.1.1 might seem a bit complicated at a first glance. We can summarize axioms ($D2$) and ($D3$) informally by saying that the functor $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$ is not far from being an equivalence. Axiom ($D2$) requires that there exists an adjoint $\mathfrak{D}'$ to $\mathfrak{D}$, and axiom ($D3$) requires that $\mathfrak{D}'$ behave as a homotopy inverse to $\mathfrak{D}$, at least on a subcategory $\mathbf{B}_0 \subseteq \mathbf{B}$ with good closure properties.

Example 12.3.1.2. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context. The functor $\mathrm{Spf} : \mathbf{A}^{\mathrm{op}} \to \mathrm{Moduli}^{\mathbf{A}}$ of Example 12.1.3.3 satisfies conditions $(D1)$, $(D2)$ and $(D3)$ of Definition 12.3.1.1, and therefore defines a weak deformation theory (we can define the full subcategory $\mathrm{Moduli}^{\mathbf{A}}_0 \subseteq \mathrm{Moduli}^{\mathbf{A}}$ whose existence is required by $(D3)$ to be spanned by objects of the form $\mathrm{Spf}(A)$, where $A \in \mathbf{A}^{\mathrm{art}}$).

Example 12.3.1.3. Let κ be a field of characteristic zero and let $(\mathrm{CAlg}^{\mathrm{aug}}_\kappa, \{E\})$ be the deformation context described in Example 12.1.1.2. In Chapter 13, we will construct a weak deformation theory $\mathfrak{D} : (\mathrm{CAlg}^{\mathrm{aug}}_\kappa)^{\mathrm{op}} \to \mathrm{Lie}_\kappa$, where Lie_κ denotes the ∞-category of differential graded Lie algebras over κ (Definition 13.1.4.1). Here the adjoint functor $\mathfrak{D}' : \mathrm{Lie}_\kappa \to (\mathrm{CAlg}^{\mathrm{aug}}_\kappa)^{\mathrm{op}}$ assigns to each differential graded Lie algebra $\mathfrak{g}_*$ its cohomology Chevalley-Eilenberg complex $C^*(\mathfrak{g}_*)$ (see Construction 13.2.5.1). In fact, the functor $\mathfrak{D} : (\mathrm{CAlg}^{\mathrm{aug}}_\kappa)^{\mathrm{op}} \to \mathrm{Lie}_\kappa$ is even a *deformation theory*: it satisfies condition $(D4)$ appearing in Definition 12.3.3.2 below.

Remark 12.3.1.4. By virtue of Corollary HTT.5.5.2.9 and Remark HTT.5.5.2.10 , condition $(D2)$ of Definition 12.3.1.1 is equivalent to the requirement that the functor $\mathfrak{D}$ preserves small limits.

Remark 12.3.1.5. In the situation of Definition 12.3.1.1, the objects $K_{\alpha,n} \in \mathbf{B}_0$ are determined up to canonical equivalence: it follows from (a) that they are given by $K_{\alpha,n} \simeq \mathfrak{D}\mathfrak{D}' K_{\alpha,n} \simeq \mathfrak{D}(\Omega^{\infty-n} E_\alpha)$. In particular, Definition 12.3.1.1 requires that the objects $\Omega^{\infty-n} E_\alpha$ belong to $\mathbf{B}_0$.

12.3.2 Formal Moduli Problems from Weak Deformation Theories

Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$. According to Example 12.3.1.2, we can always regard the formal spectrum construction $\mathrm{Spf} : \mathbf{A}^{\mathrm{op}} \to \mathrm{Moduli}^{\mathbf{A}}$ as a weak deformation theory. Our next goal is to show that the functor Spf is actually *universal* with respect to this property:

Proposition 12.3.2.1. *Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context, let $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$ a weak deformation theory, and let $j : \mathbf{B} \to \mathrm{Fun}(\mathbf{B}^{\mathrm{op}}, \mathcal{S})$ denote the Yoneda embedding. Then:*

(a) *For every object $B \in \mathbf{B}$, the composition*

$$\mathbf{A}^{\mathrm{art}} \subseteq \mathbf{A} \xrightarrow{\mathfrak{D}} \mathbf{B}^{\mathrm{op}} \xrightarrow{j(B)} \mathcal{S}$$

is a formal moduli problem.

(b) *The construction $(B \in \mathbf{B}) \mapsto (j(B) \circ \mathfrak{D})|_{\mathbf{A}^{\mathrm{art}}}$ determines a functor $\Psi : \mathbf{B} \to \mathrm{Moduli}^{\mathbf{A}}$.*

(*c*) *The diagram*

$$\begin{array}{ccc} \mathbf{A}^{\mathrm{op}} & \xrightarrow{\mathrm{Spf}} & \mathrm{Moduli}^{\mathbf{A}} \\ & \searrow^{\mathfrak{D}} \quad \nearrow_{\Psi} & \\ & \mathbf{B} & \end{array}$$

commutes up to (canonical) homotopy.

Proposition 12.3.2.1 is an easy consequence of the following result, which summarizes some of the formal properties of Definition 12.3.1.1:

Proposition 12.3.2.2. *Let* $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ *be a deformation context and* $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$ *a weak deformation theory. Let* $\mathbf{B}_0 \subseteq \mathbf{B}$ *be a full subcategory which is stable under equivalence and satisfies condition* (3) *of Definition 12.3.1.1. Then:*

(1) *The functor* $\mathfrak{D}$ *carries final objects of* $\mathbf{A}$ *to initial objects of* $\mathbf{B}$.

(2) *Let* $A \in \mathbf{A}$ *be an object having the form* $\mathfrak{D}'(K)$, *where* $K \in \mathbf{B}_0$. *Then the unit map* $A \to \mathfrak{D}'\mathfrak{D}(A)$ *is an equivalence in* $\mathbf{A}$.

(3) *If* $A \in \mathbf{A}$ *is Artinian, then* $\mathfrak{D}(A) \in \mathbf{B}_0$ *and the unit map* $A \to \mathfrak{D}'\mathfrak{D}A$ *is an equivalence in* $\mathbf{A}$.

(4) *Suppose we are given a pullback diagram* σ :

$$\begin{array}{ccc} A' & \longrightarrow & B' \\ \downarrow & & \downarrow{\scriptstyle \phi} \\ A & \longrightarrow & B \end{array}$$

in $\mathbf{A}$, *where* A *and* B *are Artinian and the morphism* ϕ *is small. Then* $\mathfrak{D}(\sigma)$ *is a pushout diagram in* $\mathbf{B}$.

Proof of Proposition 12.3.2.1. Part (*a*) is an immediate consequence of assertions (1) and (4) of Proposition 12.3.2.2, and (*b*) is a restatement of (*a*). To prove (*c*), we note that for $A \in \mathbf{A}$ and $A' \in \mathbf{A}^{\mathrm{art}}$, we have canonical homotopy equivalences

$$\begin{array}{rcl} \Psi(\mathbf{D}(A))(A') & = & \mathrm{Map}_{\mathbf{B}}(\mathfrak{D}(A'), \mathfrak{D}(A)) \\ & \simeq & \mathrm{Map}_{\mathbf{A}}(A, \mathfrak{D}'\mathfrak{D}(A')) \\ & \xleftarrow{\sim} & \mathrm{Map}_{\mathbf{A}}(A, A') \\ & = & (\mathrm{Spf}\, A)(A') \end{array}$$

where the displayed arrow is a homotopy equivalence by virtue of assertion (3) of Proposition 12.3.2.2. $\square$

Proof of Proposition 12.3.2.2. Let $\varnothing$ denote an initial object of $\mathbf{B}$. Then $\varnothing \in \mathbf{B}_0$ so that the adjunction map $\varnothing \to \mathfrak{D}\mathfrak{D}'\varnothing$ is an equivalence. Since $\mathfrak{D}' : \mathbf{B} \to \mathbf{A}^{\mathrm{op}}$ is left adjoint to $\mathfrak{D}$, it carries $\varnothing$ to a final object $* \in \mathbf{A}$. This proves (1). To prove (2), suppose that $A = \mathfrak{D}'(K)$ for $K \in \mathbf{B}_0$. Then the unit map $u : A \to \mathfrak{D}'\mathfrak{D}A$ has a left homotopy inverse, given by applying $\mathfrak{D}'$ to the the map $v : K \to \mathfrak{D}\mathfrak{D}'K$ in $\mathbf{B}$. Since v is an equivalence (part (a) of Definition 12.3.1.1), we conclude that u is an equivalence.

We now prove (3). Let $A \in \mathbf{A}$ be Artinian, so that there exists a sequence of elementary morphisms

$$A = A_0 \to A_1 \to \cdots \to A_n \simeq *.$$

We will prove that $\mathfrak{D}A_i \in \mathbf{B}_0$ using descending induction on i. If $i = n$, the desired result follows from (1). Assume therefore that $i < n$, so that the inductive hypothesis guarantees that $\mathfrak{D}(A_{i+1}) \in \mathbf{B}_0$. Choose a pullback diagram σ :

$$\begin{array}{ccc} A_i & \longrightarrow & * \\ \downarrow & & \downarrow{\scriptstyle \phi} \\ A_{i+1} & \xrightarrow{\psi} & \Omega^{\infty-n}E_\alpha \end{array}$$

where $n > 0$, $\alpha \in T$, and ϕ is the base point of $\Omega^{\infty-n}E_\alpha$. Form a pushout diagram τ :

$$\begin{array}{ccc} \mathfrak{D}(\Omega^{\infty-n}E_\alpha) & \xrightarrow{\mathfrak{D}\psi} & \mathfrak{D}A_{i+1} \\ \downarrow{\scriptstyle \mathfrak{D}\phi} & & \downarrow \\ \mathfrak{D}(*) & \longrightarrow & X \end{array}$$

in $\mathbf{B}$. There is an evident transformation $\xi : \sigma \to \mathfrak{D}'(\tau)$ of diagrams in $\mathbf{A}$. Since both σ and $\mathfrak{D}'(\tau)$ are pullback diagrams and the objects A_{i+1}, $\Omega^{\infty-n}E_\alpha$, and $*$ belong to the essential image of $\mathfrak{D}'|_{\mathbf{B}_0}$, it follows from assertion (2) that ξ is an equivalence, so that $A_i \simeq \mathfrak{D}'(X)$. Assumption (d) of Definition 12.3.1.1 guarantees that $X \in \mathbf{B}_0$, so that A_i lies in the essential image of $\mathfrak{D}'|_{\mathbf{B}_0}$.

We now prove (4). The class of morphisms ϕ for which the conclusion holds (for an arbitrary morphism $A \to B$ between Artinian objects of $\mathbf{A}$) is evidently stable under composition. We may therefore reduce to the case where ϕ is elementary, and further to the case where ϕ is the base point map $* \to \Omega^{\infty-n}E_\alpha$ for some $\alpha \in T$ and some $n > 0$. Arguing as above, we deduce that the pullback diagram σ :

$$\begin{array}{ccc} A' & \longrightarrow & * \\ \downarrow & & \downarrow{\scriptstyle \phi} \\ A & \longrightarrow & \Omega^{\infty-n}E_\alpha \end{array}$$

is equivalent to $\mathfrak{D}'(\tau)$, where τ is a diagram in $\mathbf{B}_0$ which is a pushout square in $\mathbf{B}$. Then $\mathfrak{D}(\sigma) \simeq \mathfrak{D}\mathfrak{D}'(\tau) \simeq \tau$ is a pushout diagram, by virtue of condition (a) of Definition 12.3.1.1. □

12.3.3 Deformation Theories

Our next goal is to formulate an additional hypothesis on a weak deformation theory $\mathbf{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$ which is sufficient (but not necessary: see Warning 12.3.3.3) to guarantee that the functor $\Psi : \mathbf{B} \to \mathrm{Moduli}^{\mathbf{A}}$ is an equivalence of ∞-categories. First, we note the following immediate consequence of Propositions 12.3.2.1 and 12.2.1.2:

Proposition 12.3.3.1. *Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context and $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$ a weak deformation theory. For each $\alpha \in T$ and each $K \in \mathbf{B}$, the composite map*

$$\mathcal{S}_*^{\mathrm{fin}} \xrightarrow{E_\alpha} \mathbf{A} \xrightarrow{\mathfrak{D}} \mathbf{B}^{\mathrm{op}} \xrightarrow{j(K)} \mathcal{S}$$

is reduced and excisive, and can therefore be identified with a spectrum which we will denote by $e_\alpha(K)$. This construction determines a functor $e_\alpha : \mathbf{B} \to \mathrm{Sp} = \mathrm{Sp}(\mathcal{S}) \subseteq \mathrm{Fun}(\mathcal{S}_*^{\mathrm{fin}}, \mathcal{S})$.

Definition 12.3.3.2. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context. A *deformation theory* for $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ is a weak deformation theory $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$ which satisfies the following additional condition:

$(D4)$ For each $\alpha \in T$, let $e_\alpha : \mathbf{B} \to \mathrm{Sp}$ be the functor described in Proposition 12.3.3.1. Then e_α preserves small sifted colimits. Moreover, a morphism f in $\mathbf{B}$ is an equivalence if and only if each $e_\alpha(f)$ is an equivalence of spectra.

Warning 12.3.3.3. Let $(\mathbf{A}, \{X_\alpha\}_{\alpha \in T})$ be a deformation context, and let $\mathrm{Spf} : \mathbf{A}^{\mathrm{op}} \to \mathrm{Moduli}^{\mathbf{A}}$ be given by the Yoneda embedding (see Example 12.3.1.2). The resulting functors $e_\alpha : \mathrm{Moduli}^{\mathbf{A}} \to \mathrm{Sp}$ are then given by evaluation on the spectrum objects $E_\alpha \in \mathrm{Sp}(\mathbf{A})$, and are therefore jointly conservative (Proposition 12.2.2.6) and preserve filtered colimits. However, it is not clear that Spf is a deformation theory, since the tangent complex constructions $X \mapsto X(E_\alpha)$ do not obviously commute with sifted colimits.

Remark 12.3.3.4. Let $(\mathbf{A}, \{E\})$ be a deformation context, let $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$ be a deformation theory for $\mathbf{A}$, and let $e : \mathbf{B} \to \mathrm{Sp}$ be as in Proposition 12.3.3.1. The functor e preserves small limits, and condition $(D4)$ of Definition 12.3.3.2 implies that e preserves sifted colimits. It follows that e admits a left adjoint $F : \mathrm{Sp} \to \mathbf{B}$. The composite functor $e \circ F$ has the structure of a monad U on Sp. Since e is conservative and commutes with sifted colimits, Theorem HA.4.7.3.5 gives us an equivalence of ∞-categories $\mathbf{B} \simeq \mathrm{LMod}_U(\mathrm{Sp})$ with the ∞-category of algebras over the monad U. In other words, we can think of $\mathbf{B}$ as an

∞-category whose objects are spectra which are equipped some additional structure (namely, a left action of the monad U).

More generally, if $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ is a deformation context equipped with a deformation theory $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$, the same argument supplies an equivalence $\mathbf{B} \simeq \mathrm{LMod}_U(\mathrm{Sp}^T)$: that is, we can think of objects of $\mathbf{B}$ as determines by a collection of spectra (indexed by T), together with some additional structure.

We can now formulate the main result of this section:

Theorem 12.3.3.5. *Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context and let $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$ be a deformation theory. Then the functor $\Psi : \mathbf{B} \to \mathrm{Moduli}^{\mathbf{A}}$ of Proposition 12.3.2.1 is an equivalence of ∞-categories.*

The proof of Theorem 12.3.3.5 will be given in §12.5.

Remark 12.3.3.6. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context and let $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$ a deformation theory. Using the commutativity of the diagram

$$\begin{array}{ccc} \mathbf{A}^{\mathrm{op}} & \xrightarrow{\mathrm{Spf}} & \mathrm{Moduli}^{\mathbf{A}} \\ & {\scriptstyle \mathfrak{D}} \searrow \quad \nearrow {\scriptstyle \Psi} & \\ & \mathbf{B} & \end{array}$$

(see Proposition 12.3.2.1) and Theorem 12.3.3.5, we see that $\mathfrak{D}$ can be identified (in an essentially unique way) with the formal spectrum functor $\mathrm{Spf} : \mathbf{A}^{\mathrm{op}} \to \mathrm{Moduli}^{\mathbf{A}}$. In other words, if the deformation context $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T}$ admits a deformation theory, then that deformation theory is essentially unique. The existence is not automatic (see Warning 12.3.3.3): it is equivalent to the requirement that each of the tangent complex functors $\mathrm{Moduli}^{\mathbf{A}} \to \mathrm{Sp}$ commutes with sifted colimits.

Remark 12.3.3.7. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context. Then the ∞-category $\mathbf{A}^{\mathrm{art}}$ admits finite products. Let $\mathcal{P}_\Sigma(\mathbf{A}^{\mathrm{art,op}})$ be the full subcategory of $\mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$ spanned by those functors which preserve finite products. Using Proposition HTT.5.5.8.15 , we deduce that for each index $\alpha \in T$, there is an essentially unique functor $F_\alpha : \mathcal{P}_\Sigma(\mathbf{A}^{\mathrm{art,op}}) \to \mathrm{Sp}$ which preserves sifted colimits, having the property that the composite functor

$$\mathbf{A}^{\mathrm{art,op}} \xhookrightarrow{j} \mathcal{P}_\Sigma(\mathbf{A}^{\mathrm{art,op}}) \xrightarrow{F_\alpha} \mathrm{Sp}$$

is given by $A \mapsto (\mathrm{Spf}(A))(E_\alpha)$; here j denotes the Yoneda embedding. Note that the ∞-category $\mathcal{P}_\Sigma(\mathbf{A}^{\mathrm{art,op}})$ contains $\mathrm{Moduli}^{\mathbf{A}}$, and that each of the functors F_α is a left Kan extension of its restriction to the full subcategory of $\mathrm{Moduli}^{\mathbf{A}}$ spanned by those formal moduli problems of the form $\mathrm{Spf}(A)$, where $A \in \mathbf{A}^{\mathrm{art}}$. In particular, for every formal moduli problem X, we have a canonical map $\theta_X : F_\alpha(X) \to X(E_\alpha)$. We claim that each of these maps is an equivalence. To prove this, choose a smooth hypercovering $X_\bullet$ of X, where each X_n is prorepresentable. Then θ_X is a colimit of the maps θ_{X_n}, each of which is a filtered colimit of a collection of maps of the form $\theta_{\mathrm{Spf}(A)}$, hence an equivalence.

Let $L : \mathcal{P}_\Sigma(\mathbf{A}^{\mathrm{art,op}}) \to \mathrm{Moduli}^{\mathbf{A}}$ denote a left adjoint to the inclusion. We claim that the following conditions are equivalent:

(1) For each $\alpha \in T$, the functor F_α carries L-equivalences to equivalences in the ∞-category Sp (in other words, each of the functors F_α factors through L, up to homotopy).

(2) For each $\alpha \in T$, the construction $X \mapsto X(E_\alpha)$ determines a functor $\mathrm{Moduli}^{\mathbf{A}} \to \mathrm{Sp}$ which commutes with sifted colimits.

(3) The deformation context $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ admits a deformation theory $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$.

The equivalence (2) $\Leftrightarrow$ (3) follows from Remark 12.3.3.6. Note that (2) is equivalent to the requirement that each of the constructions $X \mapsto (LX)(E_\alpha)$ determines a functor $F'_\alpha : \mathcal{P}_\Sigma(\mathbf{A}^{\mathrm{art,op}}) \to \mathrm{Sp}$ which commutes with sifted colimits. Note that F_α and F'_α agree on objects of the form $\mathrm{Spf}(A)$, so there is a canonical natural transformation $\mu_\alpha : F_\alpha \to F'_\alpha$. Conditions (1) and (2) are both equivalent to the requirement that each μ_α is an equivalence.

12.4 Digression: The Small Object Argument

Let $\mathcal{C}$ be a category containing a collection of morphisms $\{f_\alpha : C_\alpha \to D_\alpha\}$, and let $g : X \to Z$ be another morphism in $\mathcal{C}$. Under some mild hypotheses, Quillen's *small object argument* can be used to produce a factorization $X \xrightarrow{g'} Y \xrightarrow{g''} Z$ where g' is "built from" the morphisms f_α, and g'' has the right lifting property with respect to the morphisms f_α (see §HTT.A.1.2 for a more detailed discussion). The small object argument was used by Grothendieck to prove that every Grothendieck abelian category has enough injective objects (see [87] or Corollary HA.1.3.5.7). It is now a basic tool in the theory of model categories. Our goal in this section is to formulate an ∞-categorical version of the small object argument (Proposition 12.4.2.1).

12.4.1 Lifting Properties and Saturation

We begin by introducing some terminology.

Definition 12.4.1.1. Let $\mathcal{C}$ be an ∞-category. Let $f : C \to D$ and $g : X \to Y$ be morphisms in $\mathcal{C}$. We will say that g has the *right lifting property* with respect to f if every commutative

diagram

$$\begin{array}{ccc} C & \longrightarrow & X \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle g} \\ D & \longrightarrow & Y \end{array}$$

can be extended to a 3-simplex of $\mathcal{C}$, as depicted by the diagram

$$\begin{array}{ccc} C & \longrightarrow & X \\ \downarrow{\scriptstyle f} & \nearrow & \downarrow{\scriptstyle g} \\ D & \longrightarrow & Y. \end{array}$$

In this case, we will also say that f has the *left lifting property* with respect to g.

More generally, if S is any set of morphisms in $\mathcal{C}$, we will say that a morphism g has the *right lifting property* with respect to S if it has the right lifting property with respect to every morphism in S, and that a morphism f has the *left lifting property* with respect to S if f has the left lifting property with respect to every morphism in S.

Definition 12.4.1.2. Let $\mathcal{C}$ be an ∞-category and let S be a collection of morphisms in $\mathcal{C}$. We will say that a morphism f in $\mathcal{C}$ is a *transfinite pushout of morphisms in* S if there exists an ordinal α and a diagram $F : [\alpha] \to \mathcal{C}$ (here $[\alpha]$ denotes the linearly ordered set of ordinals $\{\beta : \beta \leqslant \alpha\}$) with the following properties:

(1) For every nonzero limit ordinal $\lambda \leqslant \alpha$, the restriction $F|_{[\lambda]}$ is a colimit diagram in $\mathcal{C}$.

(2) For every ordinal $\beta < \alpha$, the morphism $F(\beta) \to F(\beta + 1)$ is a pushout of a morphism in S.

(3) The morphism $F(0) \to F(\alpha)$ coincides with f.

Remark 12.4.1.3. Let $\mathcal{C}$ be an ∞-category, and let S and T be collections of morphisms in $\mathcal{C}$. Suppose that every morphism belonging to T is a transfinite pushout of morphisms in S. If f is a transfinite pushout of morphisms in T, then f is a transfinite pushout of morphisms in S.

Definition 12.4.1.4. Let $\mathcal{C}$ be an ∞-category and let S be a collection of morphisms in $\mathcal{C}$. We will say that S is *weakly saturated* if it has the following properties:

(1) If f is a morphism in $\mathcal{C}$ which is a transfinite pushout of morphisms in S, then $f \in S$.

(2) The set S is closed under retracts. In other words, if we are given a commutative diagram

$$\begin{array}{ccccc} C & \longrightarrow & C' & \longrightarrow & C \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ D & \longrightarrow & D' & \longrightarrow & D \end{array}$$

in which both horizontal compositions are the identity and f' belongs to S, then so does f.

Remark 12.4.1.5. If $\mathcal{C}$ is the nerve of an ordinary category (which admits small colimits), then Definition 12.4.1.4 reduces to Definition HTT.A.1.2.2 .

Remark 12.4.1.6. Let S be a weakly saturated collection of morphisms in an ∞-category $\mathcal{C}$. Any identity map in $\mathcal{C}$ can be written as a transfinite composition of morphisms in S (take $\alpha = 0$ in Definition 12.4.1.2). Condition (2) of Definition 12.4.1.4 guarantees that the class of morphisms is stable under equivalence; it follows that every equivalence in $\mathcal{C}$ belongs to S. Condition (1) of Definition 12.4.1.4 also implies that S is closed under composition (take $\alpha = 2$ in Definition 12.4.1.2).

12.4.2 The Small Object Argument for ∞-Categories

We can now formulate our main result:

Proposition 12.4.2.1 (Small Object Argument)**.** *Let $\mathcal{C}$ be a presentable ∞-category and let S be a small collection of morphisms in $\mathcal{C}$. Then every morphism $f : X \to Z$ admits a factorizaton $X \xrightarrow{f'} Y \xrightarrow{f''} Z$ where f' is a transfinite pushout of morphisms in S and f'' has the right lifting property with respect to S.*

Warning 12.4.2.2. In contrast with the ordinary categorical setting (see Proposition HTT.A.1.2.5), the factorization $X \xrightarrow{f'} Y \xrightarrow{f''} Z$ of Proposition 12.4.2.1 cannot generally be chosen to depend functorially on f.

Proof of Proposition 12.4.2.1. Let $S = \{g_i : C_i \to D_i\}_{i \in I}$. Choose a regular cardinal κ such that each of the objects C_i is κ-compact. We construct a diagram $F : [\kappa] \to \mathcal{C}_{/Z}$ as the union of maps $\{F_\alpha : [\alpha] \to \mathcal{C}_{/Z}\}_{\alpha \leqslant \kappa}$; here $[\alpha]$ denotes the linearly ordered set of ordinals $\{\beta : \beta \leqslant \alpha\}$. The construction proceeds by induction: we let F_0 be the morphism $f : X \to Z$, and for a nonzero limit ordinal $\lambda \leqslant \kappa$ we let F_λ be a colimit of the diagram obtained by amalgamating themaps $\{F_\alpha\}_{\alpha < \lambda}$. Assume that $\alpha < \kappa$ and that F_α been constructed. Then $F_\alpha(\alpha)$ corresponds to a map $X' \to Z$. Let $T(\alpha)$ be a set of representantives for all equivalence classes of diagrams equivalence classes of diagrams σ_t :

$$\begin{array}{ccc} C_t & \longrightarrow & X' \\ \big\downarrow{\scriptstyle g_t} & & \big\downarrow \\ D_t & \longrightarrow & Z, \end{array}$$

where g_t is a morphism belonging to S. Choose a pushout diagram

$$\begin{array}{ccc} \amalg_{t \in T(\alpha)} C_t & \longrightarrow & X' \\ \downarrow & & \downarrow \\ \amalg_{t \in T(\alpha)} D_t & \longrightarrow & X'' \end{array}$$

in $\mathcal{C}_{/Z}$. We regard X'' as an object of $\mathcal{C}_{X'//Z}$. Since the map $(\mathcal{C}_{/Z})_{F_\alpha/} \to \mathcal{C}_{X'//Z}$ is a trivial Kan fibration, we can lift X' to an object of $(\mathcal{C}_{/Z})_{F_\alpha/}$, which determines the desired map $F_{\alpha+1}$.

For each $\alpha \leqslant \kappa$, let $f_\alpha : Y_\alpha \to Z$ be the image $F(\alpha) \in \mathcal{C}_{/Z}$. Let $Y = Y_\kappa$ and $f'' = f_\kappa$. We claim that f'' has the right lifting property with respect to every morphism in S. In other words, we wish to show that for each $i \in I$ and every map $D_i \to Z$, the induced map

$$\mathrm{Map}_{\mathcal{C}_{/Z}}(D_i, Y) \to \mathrm{Map}_{\mathcal{C}_{/Z}}(C_i, Y)$$

is surjective on connected components. Choose a point $\eta \in \mathrm{Map}_{\mathcal{C}_{/Z}}(C_i, Y)$. Since C_i is κ-compact, the space $\mathrm{Map}_{\mathcal{C}_{/Z}}(C_i, Y)$ can be realized as the filtered colimit of mapping spaces $\varinjlim_\alpha \mathrm{Map}_{\mathcal{C}_{/Z}}(C_i, Y_\alpha)$, so we may assume that η is the image of a point $\eta_\alpha \in \mathrm{Map}_{\mathcal{C}_{/Z}}(C_i, Y_\alpha)$ for some $\alpha < \kappa$. The point η_α determines a commutative diagram

$$\begin{array}{ccc} C_i & \longrightarrow & Y_\alpha \\ \downarrow{\scriptstyle g_i} & & \downarrow \\ D_i & \longrightarrow & Z \end{array}$$

which is equivalent to σ_t for some $t \in T(\alpha)$. It follows that the image of η_α in $\mathrm{Map}_{\mathcal{C}_{/Z}}(C_i, Y_{\alpha+1})$ extends to D_i, so that η lies in the image of the map $\mathrm{Map}_{\mathcal{C}_{/Z}}(D_i, Y_{\alpha+1}) \to \mathrm{Map}_{\mathcal{C}_{/Z}}(C_i, Y)$.

The morphism $F(0) \to F(\kappa)$ in $\mathcal{C}_{/Z}$ induces a morphism $f' : X \to Y$ in $\mathcal{C}$; we will complete the proof by showing that f' is a transfinite pushout of morphisms in S. Using Remark 12.4.1.3, we are reduced to showing that for each $\alpha < \kappa$, the map $Y_\alpha \to Y_{\alpha+1}$ is a transfinite pushout of morphisms in S. To prove this, choose a well-ordering of $T(\alpha)$ having order type β. For $\gamma < \beta$, let t_γ denote the corresponding element of $T(\alpha)$. We define a functor $G : [\beta] \to \mathcal{C}$ so that, for each $\beta' \leqslant \beta$, we have a pushout diagram

$$\begin{array}{ccc} \amalg_{\gamma < \beta'} C_{t_\gamma} & \longrightarrow & Y_\alpha \\ \downarrow & & \downarrow \\ \amalg_{\gamma < \beta'} D_{t_\gamma} & \longrightarrow & G(\beta'). \end{array}$$

It is easy to see that G satisfies the conditions of Definition 12.4.1.2 and therefore exhibits $Y_\alpha \to Y_{\alpha+1}$ as a transfinite pushout of morphisms in S. □

12.4.3 Applications of the Small Object Argument

To apply Proposition 12.4.2.1, the following observation is often useful:

Proposition 12.4.3.1. *Let $\mathcal{C}$ be an ∞-category and let T be a collection of morphisms in $\mathcal{C}$. Let S denote the collection of all morphisms in $\mathcal{C}$ which have the left lifting property with respect to T. Then S is weakly saturated.*

Proof. Since the intersection of a collection of weakly saturated collections is weakly saturated, it will suffice to treat the case where T consists of a single morphism $g : X \to Y$. Note that a morphism $f : C \to D$ has the left lifting property with respect to g if and only if, for every lifting of Y to $\mathcal{C}_{f/}$, the induced map $\theta_f : \mathcal{C}_{f//Y} \to \mathcal{C}_{C//Y}$ is surjective on objects which lie over $g \in \mathcal{C}_{/Y}$. Since θ_f is a left fibration, it is a categorical fibration; it therefore suffices to show that object of $\mathcal{C}_{C//Y}$ which lies over g is in the essential image of θ_f. We begin by showing that S is stable under pushouts. Suppose we are given a pushout diagram σ :

$$\begin{array}{ccc} C' & \xrightarrow{f'} & D' \\ \downarrow{\scriptstyle \lambda} & & \downarrow \\ C & \xrightarrow{f} & D \end{array}$$

in $\mathcal{C}$, where $f' \in S$. We wish to prove that $f \in S$. Consider a lifting of Y to $\mathcal{C}_{f/}$ which we can lift further to $\mathcal{C}_{\sigma/}$. The map θ_f is equivalent to the left fibration $\mathcal{C}_{\sigma//Y} \to \mathcal{C}_{\lambda/Y}$. Since σ is a pushout diagram, this is equivalent to the map $\theta : \mathcal{C}_{f'//Y} \times_{\mathcal{C}_{C'//Y}} \mathcal{C}_{\lambda//Y} \to \mathcal{C}_{\lambda//Y}$. It will therefore suffice to show that every lifting of g to $\mathcal{C}_{\lambda//Y}$ lies in the essential image of θ, which follows from our assumption that every lifting of g to $\mathcal{C}_{C'//Y}$ lies in the essential image of $\theta_{f'}$.

We now verify condition (1) of Definition 12.4.1.4. Fix an ordinary α and a diagram $F : [\alpha] \to \mathcal{C}$ satisfying the hypotheses of Definition 12.4.1.2, and let $f : F(0) \to F(\alpha)$ be the induced map. Choose a lifting of Y to $\mathcal{C}_{f/}$ which we can lift further to $\mathcal{C}_{F/}$. Then θ_f is equivalent to the map $\theta : \mathcal{C}_{F//Y} \to \mathcal{C}_{F(0)//Y}$. It will therefore suffice to show that every lift of g to an object of $\overline{X} \in \mathcal{C}_{F(0)//Y}$ lies in the image of θ. For each $\beta < \alpha$, we let $F_\beta = F|_{[\beta]}$; we will construct a compatible sequence of objects $\overline{X}_\beta \in \mathcal{C}_{F_\beta//Y}$ by induction on β. If $\beta = 0$, we take $\overline{X}_\beta = \overline{X}$. If β is a nonzero limit ordinal, then our assumption that F_β is a colimit diagram guarantees that the map $\mathcal{C}_{F_\beta//Y} \to \varprojlim_{\gamma<\beta} \mathcal{C}_{F_\gamma//Y}$ is a trivial Kan fibration so that $\overline{X}_\beta$ can be defined. It remains to treat the case of a successor ordinal: let $\beta < \alpha$ and assume that $\overline{X}_\beta$ has been defined; we wish to show that the vertex $\overline{X}_\beta$ lies in the image of the map $\theta_\beta : \mathcal{C}_{F_{\beta+1}//Y} \to \mathcal{C}_{F_\beta//Y}$. Let $u : F(\beta) \to F(\beta+1)$ be the morphism determined by F, so that θ_β is equivalent to the map θ_u. Since the image of $\overline{X}_\beta$ in $\mathcal{C}_{F(\beta)//Y}$ lies over g, the existence of the desired lifting follows from our assumption that $u \in S$.

We now verify (2). Consider a diagram $\sigma : \Delta^2 \times \Delta^1 \to \mathcal{C}$, given by

$$\begin{array}{ccccc} C & \xrightarrow{\lambda} & C' & \longrightarrow & C \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ D & \longrightarrow & D' & \longrightarrow & D. \end{array}$$

Assume that $f' \in S$; we wish to prove $f \in S$. Choose a lifting of Y to $\mathcal{C}_{f/}$, and lift Y further to $\mathcal{C}_{\sigma/}$ (here we identify f with $\sigma|_{\{2\} \times \Delta^1}$. Let $\overline{X}$ be a lifting of g to $\mathcal{C}_{C//Y}$; we wish to show that $\overline{X}$ lies in the image of θ_f. We can lift $\overline{X}$ further to an object $\widetilde{X} \in \mathcal{C}_{\sigma_0//Y}$, where $\sigma_0 = \sigma|_{\Delta^2 \times \{0\}}$. Let $\sigma' = \sigma|_{\Delta^1 \times \Delta^1}$. The forgetful functor $\theta : \mathcal{C}_{\sigma'//Y} \to \mathcal{C}_{\lambda//Y}$ is equivalent to $\theta_{f'}$, so that the image of $\widetilde{X}$ in $\mathcal{C}_{\lambda//Y}$ lies in the image of θ. It follows immediately that $\overline{X}$ lies in the image of θ_f. □

Corollary 12.4.3.2. *Let $\mathcal{C}$ be a presentable ∞-category, let S be a small collection of morphisms of $\mathcal{C}$, let T be the collection of all morphisms in $\mathcal{C}$ which have the right lifting property with respect to every morphism in S, and let $S^\vee$ be the collection of all morphisms in $\mathcal{C}$ which have the left lifting property with respect to every morphism in T. Then $S^\vee$ is the smallest weakly saturated collection of morphisms which contains S.*

Proof. Proposition 12.4.3.1 implies that $S^\vee$ is weakly saturated, and it is obvious that $S^\vee$ contains S. Suppose that $\overline{S}$ is any weakly saturated collection of morphisms which contains S; we will show that $S^\vee \subseteq \overline{S}$. Let $f : X \to Z$ be a morphism in $S^\vee$, and choose a factorization

$$X \xrightarrow{f'} Y \xrightarrow{f''} Z$$

as in Proposition 12.4.2.1, so that $f' \in \overline{S}$ and $f'' \in T$. Since $f \in S^\vee$, the diagram

$$\begin{array}{ccc} X & \xrightarrow{f'} & Y \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f''} \\ Z & \xrightarrow{\mathrm{id}} & Z \end{array}$$

can be extended to a 3-simplex

$$\begin{array}{ccc} X & \xrightarrow{f'} & Y \\ \downarrow{\scriptstyle f} & \nearrow{\scriptstyle g} & \downarrow{\scriptstyle f''} \\ Z & \xrightarrow{\mathrm{id}} & Z. \end{array}$$

We therefore obtain a commutative diagram

$$\begin{array}{ccccc} X & \xrightarrow{\mathrm{id}} & X & \longrightarrow & X \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Z & \xrightarrow{g} & Y & \xrightarrow{f''} & Z \end{array}$$

which shows that f is a retract of f' and therefore belongs to $\overline{S}$ as desired. $\square$

Recall that if $\mathcal{C}$ is an ∞-category which admits finite limits and colimits, then every simplicial object $X_\bullet$ of $\mathcal{C}$ determines *latching* and *matching* objects $L_n(X_\bullet), M_n(X_\bullet)$ for $n \geqslant 0$ (see Remark HTT.A.2.9.16). The following result will play an important role in our proof of Theorem 12.3.3.5:

Corollary 12.4.3.3. *Let $\mathcal{C}$ be a presentable ∞-category and let S be a small collection of morphisms in $\mathcal{C}$. Let Y be any object of $\mathcal{C}$, and let $\phi : \mathcal{C}_{/Y} \to \mathcal{C}$ be the forgetful functor. Then there exists a simplicial object $X_\bullet$ of $\mathcal{C}_{/Y}$ with the following properties:*

(1) *For each $n \geqslant 0$, let $u_n : L_n(X_\bullet) \to X_n$ be the canonical map. Then $\phi(u_n)$ is a transfinite pushout of morphisms in S.*

(2) *For each $n \geqslant 0$, let $v_n : X_n \to M_n(X_\bullet)$ be the canonical map in $\mathcal{C}_{/Y}$. Then $\phi(v_n)$ has the right lifting property with respect to every morphism in S.*

Proof. We construct $X_\bullet$ as the union of a compatible family of diagrams $X_\bullet^{(n)} : \mathbf{\Delta}^{\mathrm{op}}_{\leqslant n} \to \mathcal{C}_{/Y}$, which we construct by induction on n. The case $n = -1$ is trivial (since $\mathbf{\Delta}_{\leqslant -1}$ is empty). Assume that $n \geqslant 0$ and that $X_\bullet^{(n-1)}$ has been constructed, so that the matching and latching objects $L_n(X)$, $M_n(X)$ are defined and we have a map $t : L_n(X) \to M_n(X)$. Using Proposition HTT.A.2.9.14 , we see that it suffices to construct a commutative diagram

$$\begin{array}{ccccc} & & X_n & & \\ & \overset{u_n}{\nearrow} & & \overset{v_n}{\searrow} & \\ L_n(X_\bullet) & & \xrightarrow{\quad t \quad} & & M_n(X_\bullet) \end{array}$$

in $\mathcal{C}_{/Y}$. Since the map $\mathcal{C}_{/Y} \to \mathcal{C}$ is a right fibration, this is equivalent to the problem of producing a commutative diagram

$$\begin{array}{ccccc} & & K_n & & \\ & \overset{u}{\nearrow} & & \searrow & \\ \phi(L_n(X_\bullet)) & & \xrightarrow{\quad \phi(t) \quad} & & \phi(M_n(X_\bullet)) \end{array}$$

in the ∞-category $\mathcal{C}$. Proposition 12.4.2.1 guarantees that we are able to make these choices in such a way that (1) and (2) are satisfied. $\square$

Remark 12.4.3.4. In the situation of Corollary 12.4.3.3, let $\varnothing$ denote the initial object of $\mathcal{C}$. Then for each $n \geqslant 0$, the canonical map $w : \varnothing \to \phi(X_n)$ is a transfinite pushout of morphisms in S. To prove this, we let P denote the full subcategory of $\mathbf{\Delta}_{[n]/}$ spanned by the surjective maps $[n] \to [m]$; we will regard P as a partially ordered set. For each upward-closed subset $P_0 \subseteq P$, we let $Z(P_0)$ denote a colimit of the induced diagram

$$P_0^{\mathrm{op}} \longrightarrow \mathbf{\Delta}^{\mathrm{op}} \xrightarrow{X_\bullet} \mathcal{C}_{/Y} \xrightarrow{\phi} \mathcal{C}\,.$$

Then $Z(\emptyset) \simeq \emptyset$ and $Z(P) \simeq \phi(X_n)$. It will therefore suffice to show that if $P_1 \subseteq P$ is obtained from P_0 by adjoining a new element given by $\alpha : [n] \to [m]$, then the induced map $\theta : Z(P_0) \to Z(P_1)$ is a transfinite pushout of morphisms in S. This follows from assertion (1) of Corollary 12.4.3.3, since θ is a pushout of the map $\phi(u_n) : \phi(L_m(X_\bullet)) \to \phi(X_m)$.

12.5 Proof of the Main Theorem

Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context which admits a deformation theory $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$. Our goal in this section is to prove Theorem 12.3.3.5, which asserts that the construction $K \mapsto \mathrm{Map}_{\mathbf{B}}(\mathfrak{D}(\bullet), K)$ induces an equivalence of ∞-categories $\Psi : \mathbf{B} \to \mathrm{Moduli}^{\mathbf{A}}$. The key step is to prove that every formal moduli problem X admits a "smooth atlas" (Proposition 12.5.3.3).

12.5.1 Digression: Atlases in Algebraic Geometry

We have seen that if X is an algebraic variety over the field $\mathbf{C}$ of complex numbers and $x : \mathrm{Spec}\,\mathbf{C} \to X$ is a point, then X determines a formal moduli problem $X^\wedge : \mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}} \to \mathcal{S}$ (Example 12.2.2.4). However, Definition 12.1.3.1 is far more inclusive than this. For example, we can also obtain formal moduli problems by extracting the formal completions of algebraic stacks.

Example 12.5.1.1. Let $n \geqslant 0$ be an integer, and let A be a connective $\mathbb{E}_\infty$-ring. We say that an A-module M is *projective of rank* n if $\pi_0 M$ is a projective module over $\pi_0 A$ of rank n, and M is flat over A. Let $X(A)$ denote the subcategory of Mod_A whose objects are modules which are locally free of rank n, and whose morphisms are equivalences of modules. It is not difficult to see that the ∞-category $X(A)$ is an essentially small Kan complex. Consequently, the construction $A \mapsto X(A)$ determines a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$.

Let η denote the point of $X(\mathbf{C})$ corresponding to the complex vector space $\mathbf{C}^n$. We define the *formal completion of* X *at* η to be the functor $X^\wedge : \mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}} \to \mathcal{S}$ given by $X^\wedge(R) = X(R) \times_{X(\mathbf{C})} \{\eta\}$. More informally, $X^\wedge(R)$ is a classifying space for projective R-modules M of rank n equipped with a trivialization $\mathbf{C} \otimes_R M \simeq \mathbf{C}^n$. Then $X^\wedge$ is a formal moduli problem (we will prove a more general statement to this effect in §16.5).

If A is a local commutative ring, then every projective A-module of rank of n is isomorphic to A^n. If X is the functor of Example 12.5.1.1, we deduce that $X(A)$ can be identified with the classifying space for the group $\mathrm{GL}_n(A)$ of automorphisms of A^n as an A-module.

For this reason, the functor X is often denoted by BGL_n. It can be described as the geometric realization (in the ∞-category of functors $F : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$ which are sheaves with respect to the Zariski topology) of a simplicial functor $F_\bullet$, given by the formula $F_m(A) = \mathrm{GL}_n(A)^m$, where $\mathrm{GL}_n(A)$ denotes the subspace of $\mathrm{Map}_{\mathrm{Mod}_A}(A^n, A^n)$ spanned by the invertible morphisms. Similarly, the formal completion $X^\wedge$ can be described as the geometric realization of a simplicial functor $F^\wedge_\bullet$, given by $F^\wedge_m(R) = \mathrm{fib}(\mathrm{GL}_n(R) \to \mathrm{GL}_n(\mathbf{C}))$ for $R \in \mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}}$ (after passing to formal completions, there is no need to sheafify with respect to the Zariski topology: if $R \in \mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}}$, then $\pi_0 R$ is a local Artin ring, so that every projective R-module of rank n is automatically free).

Remark 12.5.1.2. Example 12.5.1.1 can be generalized. Suppose that X is an arbitrary Artin stack over $\mathbf{C}$. Then X can be presented by an atlas, which is a (smooth) groupoid object

$$\cdots \rightrightarrows U_1 \rightrightarrows U_0.$$

in the category of $\mathbf{C}$-schemes. Let $\eta_0 : \mathrm{Spec}\,\mathbf{C} \to U_0$ be any point, so that η_0 determines points $\eta_n : \mathrm{Spec}\,\mathbf{C} \to U_n$ for every integer n. We can then define formal moduli problems $U^\wedge_n : \mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}} \to \mathcal{S}$ by formally completing each U_n at the point η_n. This gives a simplicial object $U^\wedge_\bullet$ in the ∞-category $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}}, \mathcal{S})$. The geometric realization $|U^\wedge_\bullet| \in \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}}, \mathcal{S})$ is also a formal moduli problem which we will denote by $X^\wedge$. One can show that it is canonically independent (up to equivalence) of the atlas $U_\bullet$ chosen.

Our first goal in this section is to formulate a converse to Remark 12.5.1.2. Roughly speaking, we would like to assert that every formal moduli problem $Y : \mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}} \to \mathcal{S}$ admits a description that resembles the formal completion of an algebraic stack. However, the precise context of Remark 12.5.1.2 is too restrictive in several respects:

- (a) We can associate formal completions not only to algebraic stacks, but also to *higher* algebraic stacks. Consequently, rather than trying to realize Y as the geometric realization of a groupoid object $Y_\bullet$ of $\mathrm{Moduli} \subseteq \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}}, \mathcal{S})$, we will allow more general simplicial objects $Y_\bullet$ of Moduli.

- (b) We would like to exhibit Y as the geometric realization of a simplicial object $Y_\bullet$ where each Y_m resembles the formal completion of a $\mathbf{C}$-scheme near some point (which, without loss of generality, we may take to be an affine scheme of the form $\mathrm{Spét}\,R$). Since the construction of the formal completion makes sense not only for schemes but also for spectral Deligne-Mumford stacks (Remark 11.5.0.10), we should allow the possibility that R is a nondiscrete $\mathbb{E}_\infty$-algebra over $\mathbf{C}$.

- (c) If R is an augmented $\mathbb{E}_\infty$-algebra over $\mathbf{C}$, then A determines a formal moduli problem $\mathrm{Spf}\,R : \mathrm{CAlg}^{\mathrm{art}}_{\mathbf{C}} \to \mathcal{S}$ given by the formula $A \mapsto \mathrm{Map}_{\mathrm{CAlg}^{\mathrm{aug}}_{\mathbf{C}}}(R, A)$. This functor is perhaps better understood (at least in the case where R is Noetherian) as the formal spectrum of $R^{\wedge}$, where $R^{\wedge}$ denotes the completion of R along the augmentation ideal in $\pi_0 R$. To incorporate a wider class of examples, we should allow arbitrary (possibly infinite-dimensional) affine formal schemes, not only those which arise as the formal completions of actual schemes.

12.5.2 Smooth Morphisms

We now translate some of the ideas of Remark 12.5.1.2 to the setting of an arbitrary deformation context.

Proposition 12.5.2.1. *Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context, and let $u : X \to Y$ be a map of formal moduli problems $X, Y : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$. The following conditions are equivalent:*

(1) *For every small map $\phi : A \to B$ in $\mathbf{A}^{\mathrm{art}}$, u has the right lifting property with respect to $\mathrm{Spf}(\phi) : \mathrm{Spf}(B) \to \mathrm{Spf}(A)$.*

(2) *For every small map $\phi : A \to B$ in $\mathbf{A}^{\mathrm{art}}$, the induced map $X(A) \to X(B) \times_{Y(B)} Y(A)$ is surjective on connected components.*

(3) *For every elementary map $\phi : A \to B$ in $\mathbf{A}^{\mathrm{art}}$, the induced map $X(A) \to X(B) \times_{Y(B)} Y(A)$ is surjective on connected components.*

(4) *For every $\alpha \in T$ and every $n > 0$, the homotopy fiber of the map $X(\Omega^{\infty-n} E_\alpha) \to Y(\Omega^{\infty-n} E_\alpha)$ (taken over the point determined by the base point of $\Omega^{\infty-n} E_\alpha$) is connected.*

(5) *For every $\alpha \in T$, the map of spectra $X(E_\alpha) \to Y(E_\alpha)$ is connective (that is, it has a connective homotopy fiber).*

Proof. The equivalence (1) $\Leftrightarrow$ (2) is tautological, and the implications (2) $\Rightarrow$ (3) $\Rightarrow$ (4) are evident. Let S be the collection of all small morphisms $A \to B$ in $\mathbf{A}^{\mathrm{art}}$ for which the map $X(A) \to X(B) \times_{Y(B)} Y(A)$ is surjective on connected components. The implication (3) $\Rightarrow$ (2) follows from the observation that S is closed under composition, and the implication (4) $\Rightarrow$ (3) from the observation that S is stable under the formation of pullbacks. The equivalence (4) $\Leftrightarrow$ (5) follows from fact that a map of $M \to M'$ of spectra is connective if and only if the induced map $\Omega^{\infty-n} M \to \Omega^{\infty-n} M'$ has connected homotopy fibers for each $n > 0$. $\square$

Definition 12.5.2.2. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context, and let $u : X \to Y$ be a map of formal moduli problems. We will say that u is *smooth* if it satisfies the equivalent conditions of Proposition 12.5.2.1. We will say that a formal moduli problem X is smooth if the map $X \to *$ is smooth, where $*$ denotes the final object of $\mathrm{Moduli}^{\mathbf{A}}$ (that is, the constant functor $\mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ taking the value $* \in \mathcal{S}$).

Remark 12.5.2.3. We can regard condition (5) of Proposition 12.5.2.1 as providing a differential criterion for smoothness: a map of formal moduli problems $X \to Y$ is smooth if and only if it induces a connective map of tangent complexes $X(E_\alpha) \to Y(E_\alpha)$. This should be regarded as an analogue of the condition that a map of smooth algebraic varieties $f : X \to Y$ induce a surjective map of tangent sheaves $T_X \to f^* T_Y$.

12.5.3 Existence of Smooth Hypercoverings

Our next goal is to show that in the setting of an arbitrary deformation context, every formal moduli problem admits a smooth hypercovering by "affine" objects.

Definition 12.5.3.1. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context. We let $\mathrm{Pro}(\mathbf{A}^{\mathrm{art}})$ denote the ∞-category of pro-objects of $\mathbf{A}^{\mathrm{art}}$: that is, the smallest full subcategory of $\mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})^{\mathrm{op}}$ which contains all corepresentable functors and is closed under filtered colimits. We will say that a functor $X : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ is *prorepresentable* if it belongs to the full subcategory $\mathrm{Pro}(\mathbf{A}^{\mathrm{art}}) \subseteq \mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})^{\mathrm{op}}$.

Remark 12.5.3.2. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context. Since filtered colimits in $\mathcal{S}$ are left exact (Example HTT.7.3.4.4), the full subcategory $\mathrm{Moduli}^{\mathbf{A}}$ is stable under filtered colimits in $\mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$. Since every corepresentable functor is a formal moduli problem (Example 12.1.3.3), we conclude that $\mathrm{Pro}(\mathbf{A}^{\mathrm{art}})^{\mathrm{op}}$ is contained in $\mathrm{Moduli}^{\mathbf{A}}$ (as a full subcategory of $\mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$). That is, every prorepresentable functor $\mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ is a formal moduli problem.

Proposition 12.5.3.3. *Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context and let $X : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$ be a formal moduli problem. Then there exists a simplicial object $X_\bullet$ in $\mathrm{Moduli}^{\mathbf{A}}_{/X}$ with the following properties:*

(1) *Each X_n is prorepresentable.*

(2) *For each $n \geqslant 0$, let $M_n(X_\bullet)$ denote the nth matching object of the simplicial object $X_\bullet$ (computed in the ∞-category $\mathrm{Moduli}^{\mathbf{A}}_{/X}$). Then the canonical map $X_n \to M_n(X_\bullet)$ is smooth.*

In particular, X is equivalent to the geometric realization $|X_\bullet|$ in $\mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$.

The proof of Proposition 12.5.3.3 will use the following simple observation:

Lemma 12.5.3.4. *Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context, and let S be the collection of all morphisms in the ∞-category $\mathrm{Moduli}^{\mathbf{A}}$ of the form $\mathrm{Spf}(B) \to \mathrm{Spf}(A)$, where the* *underlying map $A \to B$ is a small morphism in $\mathbf{A}^{\mathrm{art}}$. Let $f : X \to Y$ be a morphism in $\mathrm{Moduli}^{\mathbf{A}}$, and suppose that f is a transfinite pushout of morphisms in S. If X is prorepresentable, then Y is prorepresentable.*

Proof. Since the collection of prorepresentable objects of $\mathrm{Moduli}^{\mathbf{A}}$ is closed under filtered colimits, it will suffice to prove the following:

(∗) If $\phi : A \to B$ is a small morphism in $\mathrm{Moduli}^{\mathbf{A}}$ and we are given a pushout diagram

$$\begin{array}{ccc} \mathrm{Spf}(B) & \longrightarrow & X \\ \Big\downarrow{\scriptstyle \mathrm{Spf}(\phi)} & & \Big\downarrow{\scriptstyle f} \\ \mathrm{Spf}(A) & \longrightarrow & Y \end{array}$$

where X is prorepresentable, then Y is also prorepresentable.

To prove (∗), we note that X can be regarded as an object of $\mathrm{Pro}(\mathbf{A}^{\mathrm{art}})^{\mathrm{op}}_{\mathrm{Spf}(B)/} \simeq \mathrm{Ind}((\mathbf{A}^{\mathrm{art}}_{/B})^{\mathrm{op}})$. In other words, we have $X \simeq \varinjlim_\beta \mathrm{Spf}(B_\beta)$ for some filtered diagram $\{B_\beta\}$ in $\mathbf{A}^{\mathrm{art}}_{/B}$. Then

$$Y \simeq \varinjlim (\mathrm{Spf}(B_\beta) \amalg_{\mathrm{Spf}(B)} \mathrm{Spf}(A)).$$

For any formal moduli problem Z, we have

$$\mathrm{Map}_{\mathrm{Moduli}^{\mathbf{A}}}(\mathrm{Spf}(B_\beta) \amalg_{\mathrm{Spf}(B)} \mathrm{Spf}(A), Z) \simeq Z(B_\beta) \times_{Z(B)} Z(A) \simeq Z(B_\beta \times_B A)$$

(since the map $\phi : A \to B$ is small), so that $\mathrm{Spf}(B_\beta) \amalg_{\mathrm{Spf}(B)} \mathrm{Spf}(A) \simeq \mathrm{Spf}(B_\beta \times_B A)$ is corepresented by an object $B_\beta \times_B A$. It follows that Y is prorepresentable, as desired. □

Proof of Proposition 12.5.3.3. Let X be an arbitrary formal moduli problem. Applying Proposition **??**, we can choose a simplicial object $X_\bullet$ of $\mathrm{Moduli}^{\mathbf{A}}_{/X}$ such that each of the maps $X_n \to M_n(X_\bullet)$ is smooth, and each of the maps $L_n(X_\bullet) \to X_n$ is a transfinite pushout of morphisms of the form $\mathrm{Spf}\, B \to \mathrm{Spf}\, A$, where $A \to B$ is an elementary morphism in $\mathbf{A}^{\mathrm{art}}$. Using Remark 12.4.3.4 and Lemma 12.5.3.4, we conclude that each X_n is prorepresentable. This proves (1) and (2). To prove that $X \simeq |X_\bullet|$ in $\mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$, it suffices to observe that condition (2) implies that $X_\bullet(A)$ is a hypercovering of $X(A)$ for every $A \in \mathbf{A}^{\mathrm{art}}$. □

12.5.4 The Proof of Theorem 12.3.3.5

Our proof of Theorem 12.3.3.5 will make use of the following:

Lemma 12.5.4.1. *Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context and let $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$ be a deformation theory. For every Artinian object $A \in \mathbf{A}^{\mathrm{art}}$, $\mathfrak{D}(A)$ is a compact object of the ∞-category $\mathbf{B}$.*

Proof. Since A is Artinian, there exists a sequence of elementary morphisms

$$A = A_0 \to A_1 \to \cdots \to A_n \simeq *$$

in $\mathbf{A}$. We will prove that $\mathfrak{D}(A_i)$ is a compact object of $\mathbf{B}$ by descending induction on i. When $i = n$, the desired result follows from the observation that $\mathfrak{D}$ carries final objects of $\mathbf{A}$ to initial objects of $\mathbf{B}$ (Proposition 12.3.2.2). Assume therefore that $i < n$ and that $\mathfrak{D}(A_{i+1}) \in \mathbf{B}$ is compact. Since the map $A_i \to A_{i+1}$ is elementary, we have a pullback diagram σ :

$$\begin{array}{ccc} A_i & \longrightarrow & * \\ \downarrow & & \downarrow \\ A_{i+1} & \longrightarrow & \Omega^{\infty-n} E_\alpha \end{array}$$

for some $\alpha \in T$ and some $n > 0$. It follows from Proposition 12.3.2.2 that $\mathfrak{D}(\sigma)$ is a pushout square in $\mathbf{B}$. Consequently, to show that $\mathfrak{D}(A_i)$ is a compact object of $\mathbf{B}$, it will suffice to show that $\mathfrak{D}(A_{i+1})$, $\mathfrak{D}(*)$, and $\mathfrak{D}(\Omega^{\infty-n} E_\alpha)$ are compact objects of $\mathbf{B}$. In the first two cases, this follows from the inductive hypothesis. For the third, we note that the functor corepresented by $\mathfrak{D}(\Omega^{\infty-n} E_\alpha)$ is given by the composition $\mathbf{B} \xrightarrow{e_\alpha} \mathrm{Sp} \xrightarrow{\Omega^{\infty-n}} \mathcal{S}$, where e_α is the functor described in Proposition 12.3.3.1. Our assumption that $\mathfrak{D}$ is a deformation theory guarantees that e_α commutes with sifted colimits. The functor $\Omega^{\infty-n} : \mathrm{Sp} \to \mathcal{S}$ commutes with filtered colimits, so the composite functor $\mathbf{B} \to \mathcal{S}$ commutes with filtered colimits which implies that $\Omega^{\infty-n} E_\alpha$ is a compact object of $\mathbf{B}$. $\square$

Proof of Theorem 12.3.3.5. Let $(\mathbf{A}, \{E_\alpha\}_{\alpha \in T})$ be a deformation context, let $\mathfrak{D} : \mathbf{A}^{\mathrm{op}} \to \mathbf{B}$ be a deformation theory, and let $\Psi : \mathbf{B} \to \mathrm{Moduli}^{\mathbf{A}} \subseteq \mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$ denote the functor given by the formula $\Psi(K)(A) = \mathrm{Map}_{\mathbf{B}}(\mathfrak{D}(A), K)$. We wish to prove that Ψ is an equivalence of ∞-categories. It is clear that Ψ preserves small limits. It follows from Lemma 12.5.4.1 that Ψ preserves filtered colimits and is therefore accessible. Using Corollary HTT.5.5.2.9 we conclude that Ψ admits a left adjoint Φ. To prove that Ψ is an equivalence, it will suffice to show:

- (a) The functor Ψ is conservative.
- (b) The unit transformation $u : \mathrm{id}_{\mathrm{Moduli}} \to \Psi \circ \Phi$ is an equivalence.

We begin with the proof of (a). Suppose we are given a morphism $f : K \to K'$ in $\mathbf{B}$ have that $\Psi(f)$ is an equivalence. In particular, for each $\alpha \in T$ and each $n \geqslant 0$, we have homotopy equivalences

$$\begin{aligned} \mathrm{Map}_{\mathbf{B}}(\mathfrak{D}(\Omega^{\infty-n} E_\alpha), K) &\simeq \Psi(K)(\mathfrak{D}\Omega^{\infty-n} E_\alpha) \\ &\to \Psi(K')(\mathfrak{D}\Omega^{\infty-n} E_\alpha) \\ &\simeq \mathrm{Map}_{\mathbf{B}}(\mathfrak{D}(\Omega^{\infty-n} E_\alpha), K'). \end{aligned}$$

It follows that $e_\alpha(K) \simeq e_\alpha(K')$, where $e_\alpha : \mathbf{B} \to \mathrm{Sp}$ is the functor described in Proposition 12.3.3.1. Since the functors e_α are jointly conservative (Definition 12.3.3.2), we conclude that f is an equivalence.

We now prove (b). Let $X \in \mathrm{Moduli}^{\mathbf{A}}$ be a formal moduli problem; we wish to show that u induces an equivalence $X \to (\Psi \circ \Phi)(X)$. According to Proposition 12.2.2.6, it suffices to show that for each $\alpha \in T$, the induced map

$$\theta : X(E_\alpha) \to (\Psi \circ \Phi)(X)(E_\alpha) \simeq e_\alpha(\Phi X)$$

is an equivalence of spectra. To prove this, choose a simplicial object $X_\bullet$ of $\mathrm{Moduli}^{\mathbf{A}}_{/X}$ satisfying the requirements of Proposition 12.5.3.3. For every object $A \in \mathbf{A}^{\mathrm{art}}$, the simplicial space $X_\bullet(A)$ is a hypercovering of $X(A)$ so that the induced map $|X_\bullet(A)| \to X(A)$ is a homotopy equivalence. It follows that X is a colimit of the diagram $X_\bullet$ in the ∞-category $\mathrm{Fun}(\mathbf{A}^{\mathrm{art}}, \mathcal{S})$ and therefore also in the ∞-category $\mathrm{Moduli}^{\mathbf{A}}$. Similarly, $X(E_\alpha)$ is equivalent to the geometric realization $|X_\bullet(E_\alpha)|$ in the ∞-category $\mathrm{Fun}(\mathcal{S}^{\mathrm{fin}}_*, \mathcal{S})$ and therefore also in the ∞-category of spectra. Since Φ preserves small colimits and e_α preserves sifted colimits, we have

$$e_\alpha(\Phi(X)) \simeq e_\alpha(\Phi|X_\bullet|) \simeq |e_\alpha(\Phi X_\bullet)|.$$

It follows that θ is a geometric realization of a simplicial morphism $\theta_\bullet : X_\bullet(E_\alpha) \to e_\alpha(\Phi X_\bullet)$. It will therefore suffice to prove that each θ_n is an equivalence, which is equivalent to the requirement that u induces an equivalence $X_n \to (\Psi \circ \Phi)(X_n)$. In other words, we may replace X by X_n, and thereby reduce to the case where X is prorepresentable. Since the functors Φ and Ψ both commute with filtered colimits, we may further reduce to the case where $X = \mathrm{Spf}(A)$ for some $A \in \mathbf{A}^{\mathrm{art}}$. Since $\Phi(\mathrm{Spf}(A)) = \mathfrak{D}(A)$, it suffices to show that for each $B \in \mathbf{A}^{\mathrm{art}}$, the map

$$\mathrm{Map}_{\mathbf{A}}(A, B) \to \mathrm{Map}_{\mathbf{B}}(\mathfrak{D}(B), \mathfrak{D}(A)) \simeq \mathrm{Map}_{\mathbf{A}}(A, \mathfrak{D}'\mathfrak{D}(B))$$

is a homotopy equivalence, which follows immediately from Proposition 12.3.2.2. □

Chapter 13

Moduli Problems for Commutative Algebras

Let κ be a field of characteristic zero. We will say that an augmented $\mathbb{E}_\infty$-algebra $A \in \mathrm{CAlg}_\kappa^{\mathrm{aug}}$ is *Artinian* if it satisfies the conditions of Proposition 12.1.2.9: that is, if A is connective, $\pi_* A$ is a finite dimensional vector space over κ, and $\pi_0 A$ is a local ring (note that this terminology is slightly misleading, since it includes the hypothesis that A is local: see Warning 12.1.2.6). We let $\mathrm{CAlg}_\kappa^{\mathrm{art}}$ denote the full subcategory of $\mathrm{CAlg}_\kappa^{\mathrm{aug}}$ spanned by the Artinian $\mathbb{E}_\infty$-algebra over κ (which we can also identify with a full subcategory of the ∞-category CAlg_κ: see Remark 12.1.2.10).

Recall that a functor $X : \mathrm{CAlg}_\kappa^{\mathrm{art}} \to \mathcal{S}$ is called a *formal moduli problem* if it satisfies the following pair of conditions (see Proposition 12.1.3.7):

(*a*) The space $X(\kappa)$ is contractible.

(*b*) For every pullback square

$$\begin{array}{ccc} R & \longrightarrow & R_0 \\ \downarrow & & \downarrow \\ R_1 & \longrightarrow & R_{01} \end{array}$$

in $\mathrm{CAlg}_\kappa^{\mathrm{art}}$, if both the maps $\pi_0 R_0 \to \pi_0 R_{01} \leftarrow \pi_0 R_1$ are surjective, then the diagram of spaces

$$\begin{array}{ccc} X(R) & \longrightarrow & X(R_0) \\ \downarrow & & \downarrow \\ X(R_1) & \longrightarrow & X(R_{01}) \end{array}$$

is also a pullback square.

In this section, we will study the full subcategory $\mathrm{Moduli}_\kappa \subseteq \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{art}}_\kappa, \mathcal{S})$ spanned by the formal moduli problems.

We begin by applying the general formalism of §12.2. To every formal moduli problem $X \in \mathrm{Moduli}_\kappa$, we can associate a spectrum $T_X \in \mathrm{Sp}$, which is given informally by the formula $\Omega^{\infty-n} T_X = X(\kappa \oplus \Sigma^n(\kappa))$ for $n \geqslant 0$. In particular, we can identify the 0th space $\Omega^\infty T_X$ with $X(\kappa[\epsilon]/(\epsilon^2))$, an analogue of the classical Zariski tangent space. We refer to T_X as the *tangent complex* of the formal moduli problem X.

The construction $X \mapsto T_X$ commutes with finite limits. In particular, we have a homotopy equivalence of spectra $\Sigma^{-1} T_X \simeq T_{\Omega X}$, where ΩX denotes the formal moduli problem given by the formula $(\Omega X)(R) = \Omega X(R)$ (note that a choice of point η in the contractible space $X(\kappa)$ determines a base point of each $X(R)$, so the loop space $\Omega X(R)$ is well-defined). The formal moduli problem ΩX is equipped with additional structure: it can be regarded as a group object of Moduli_κ. It is therefore natural to expect that the tangent complex $T_{\Omega X}$ should behave somewhat like the tangent space to an algebraic group. We can formulate this expectation more precisely as follows:

(∗) Let $X \in \mathrm{Moduli}_\kappa$ be a formal moduli problem. Then the shifted tangent complex $\Sigma^{-1} T_X \simeq T_{\Omega X}$ can be identified with the underlying spectrum of a differential graded Lie algebra over κ.

Example 13.0.0.1. Suppose that A is a commutative κ-algebra equipped with an augmentation $\epsilon : A \to \kappa$. Then R defines a formal moduli problem X over κ, which carries a Artinian $\mathbb{E}_\infty$-algebra R over κ to the mapping space $\mathrm{Map}_{\mathrm{CAlg}^{\mathrm{aug}}_\kappa}(A, R)$. When κ is of characteristic zero, the tangent complex T_X can be identified with the complex of Andre-Quillen cochains taking values in κ. In this case, the existence of a natural differential graded Lie algebra structure on $\Sigma^{-1} T_X$ is proven in [183].

Assertion (∗) has a converse: every differential graded Lie algebra $\mathfrak{g}_*$ arises (up to quasi-isomorphism) as the shifted tangent complex $\Sigma^{-1} T_X$ of some $X \in \mathrm{Moduli}_\kappa$. Moreover, the formal moduli problem X is determined by $\mathfrak{g}_*$ up to equivalence. More precisely, we have the following stronger version of Theorem 11.5.0.13:

Theorem 13.0.0.2. *Let κ be a field of characteristic zero and let Lie_κ denote the ∞-category of differential graded Lie algebras over κ (see Definition 13.1.4.1). Then there is an equivalence of ∞-categories $\Psi : \mathrm{Lie}_\kappa \to \mathrm{Moduli}_\kappa$. Moreover, the functor $\mathfrak{g}_* \mapsto \Sigma^{-1} T_{\Psi(\mathfrak{g}_*)}$ is equivalent to the forgetful functor $\mathrm{Lie}_\kappa \to \mathrm{Sp}$ (which carries a differential graded Lie algebra $\mathfrak{g}_*$ to the generalized Eilenberg-MacLane spectrum determined by its underlying chain complex).*

Our main goal in this section is to prove Theorem 13.0.0.2. The first step is to construct the functor $\Psi : \mathrm{Lie}_\kappa \to \mathrm{Moduli}_\kappa$. Let $\mathfrak{g}_*$ be a differential graded Lie algebra over κ, and let $R \in \mathrm{CAlg}_\kappa^{\mathrm{art}}$. Since κ has characteristic zero, we can identify R with an (augmented) commutative differential graded algebra over κ; let us denote its augmentation ideal by $\mathfrak{m}_R$. The tensor product $\mathfrak{m}_R \otimes_\kappa \mathfrak{g}_*$ then inherits the structure of a differential graded Lie algebra over κ. Heuristically, $\Psi(\mathfrak{g}_*)(R)$ can be described as the space of *Maurer-Cartan elements* of the differential graded Lie algebra $\mathfrak{m}_R \otimes_\kappa \mathfrak{g}_*$: that is, the space of solutions to the Maurer-Cartan equation $dx = [x, x]$. There does not seem to be a homotopy-invariant definition for the space $\mathrm{MC}(\mathfrak{g}_*)$ of Maurer-Cartan elements of an arbitrary differential graded Lie algebra over κ: the well-definedness of $\mathrm{MC}(\mathfrak{m}_R \otimes_\kappa \mathfrak{g}_*)$ relies on the nilpotence properties of the tensor product $\mathfrak{m}_R \otimes_\kappa \mathfrak{g}_*$ (which result from our assumption that R is Artinian). Nevertheless, there is a well-defined *bifunctor* $\mathrm{MC} : \mathrm{CAlg}_\kappa^{\mathrm{aug}} \times \mathrm{Lie}_\kappa \to \mathcal{S}$ which is given heuristically by $(R, \mathfrak{g}_*) \mapsto \mathrm{MC}(\mathfrak{m}_R \otimes_\kappa \mathfrak{g}_*)$. This functor can be defined rigorously by the formula $\mathrm{MC}(R, \mathfrak{g}_*) = \mathrm{Map}_{\mathrm{Lie}_\kappa}(\mathfrak{D}(R), \mathfrak{g}_*)$, where $\mathfrak{D} : (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Lie}_\kappa$ is the *Koszul duality* functor that we will describe in §13.3. Roughly speaking, the Koszul dual of an augmented $\mathbb{E}_\infty$-algebra R is a differential graded Lie algebra $\mathfrak{D}(R) \in \mathrm{Lie}_\kappa$ which *corepresents* the functor $\mathfrak{g}_* \mapsto \mathrm{MC}(\mathfrak{m}_R \otimes_\kappa \mathfrak{g}_*)$. However, it will be more convenient for us to describe $\mathfrak{D}(R)$ instead by the functor that *represents*. We will define $\mathfrak{D}$ as the right adjoint to the functor $C^* : \mathrm{Lie}_\kappa \to (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}}$, which assigns to each differential graded Lie algebra $\mathfrak{g}_*$ the commutative differential graded algebra $C^*(\mathfrak{g}_*)$ of Lie algebra cochains on $\mathfrak{g}_*$ (see Construction 13.2.5.1).

Remark 13.0.0.3. For our purposes, the Maurer-Cartan equation $dx = [x, x]$ (and the associated space $\mathrm{MC}(\mathfrak{g}_*)$ of Maurer-Cartan elements of a differential graded Lie algebra $\mathfrak{g}_*$) are useful heuristics for understanding the functor Ψ appearing in Theorem 13.0.0.2. However, they will play no further role in our discussion. For a construction of the functor Ψ which makes direct use of the Maurer-Cartan equation, we refer the reader to the work of Hinich (see [95]). We also refer the reader to the work of Goldman and Millson ([82] and [83]).

Let us now outline the contents of this section. We begin in §13.1 with a brief review of the theory of differential graded Lie algebras and a definition of the ∞-category Lie_κ. In §13.2, we will review the homology and cohomology of (differential graded) Lie algebras, which are computed by the Chevalley-Eilenberg constructions $\mathfrak{g}_* \mapsto C_*(\mathfrak{g}_*)$ and $\mathfrak{g}_* \mapsto C^*(\mathfrak{g}_*)$. The functor C^* carries quasi-isomorphisms of differential graded Lie algebras to quasi-isomorphisms between (augmented) commutative differential graded algebras, and therefore descends to a functor from the ∞-category Lie_κ to the ∞-category $(\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}}$. We will show that this functor admits a right adjoint $\mathfrak{D}$ and study its properties. The main point is to show that $\mathfrak{D}$ is a deformation theory (in the sense of Definition 12.3.3.2) on the deformation context $(\mathrm{CAlg}_\kappa^{\mathrm{aug}}, \{E\})$ of Example 12.1.1.2. We will use this fact in §13.3 to deduce Theorem 13.0.0.2 from Theorem 12.3.3.5.

To every formal modui problem $X : \mathrm{CAlg}_\kappa^{\mathrm{art}} \to \mathcal{S}$, we can introduce an ∞-category

QCoh(X) of *quasi-coherent sheaves* on X. It follows from Theorem 13.0.0.2 that X is completely determined by a differential graded Lie algebra $\mathfrak{g}_*$ (which is well-defined up to quasi-isomorphism). In §13.4, we will show that QCoh(X) can be identified with a full subcategory of the ∞-category of (differential graded) representations of $\mathfrak{g}_*$ (Theorem 13.4.0.1).

Contents

13.1 Differential Graded Lie Algebras

Let κ be a field of characteristic zero. Theorem 13.0.0.2 asserts that the ∞-category Moduli_{κ} of formal moduli problems over κ is equivalent to the ∞-category Lie_{κ} of differential graded Lie algebras over κ. Our goal in this section is to explain the definition of Lie_κ and establish some of its basic properties. Along the way, we will introduce some of the notation and constructions which will play a role in our proof of Theorem 13.0.0.2.

13.1.1 Chain Complexes of Vector Spaces

We begin by reviewing some terminology.

Notation 13.1.1.1. Let κ be a field. We let $\mathrm{Vect}_\kappa^{\mathrm{dg}}$ denote the category of differential graded vector spaces over κ: that is, the category whose objects are chain complexes

$$\cdots \to V_1 \to V_0 \to V_{-1} \to \cdots$$

and whose morphisms are maps of chain complexes. We will regard $\mathrm{Vect}_\kappa^{\mathrm{dg}}$ as a symmetric monoidal category with respect to the tensor product of chain complexes described by the formula

$$(V \otimes W)_p = \bigoplus_{p=p'+p''} V_{p'} \otimes_\kappa W_{p''},$$

and the symmetry isomorphism $V \otimes W \simeq W \otimes V$ is the sum of the isomorphisms $V_{p'} \otimes_\kappa W_{p''} \simeq W_{p''} \otimes_\kappa V_{p'}$, multiplied by the factor $(-1)^{p'p''}$.

Recall that the category $\mathrm{Vect}_\kappa^{\mathrm{dg}}$ admits a model structure, where:

(C) A map of chain complexes $f : V_* \to W_*$ is a cofibration it is degreewise monic: that is, each of the induced maps $V_n \to W_n$ is injective.

(F) A map of chain complexes $f : V_* \to W_*$ is a fibration it is degreewise epic: that is, each of the induced maps $V_n \to W_n$ is surjective.

(W) A map of chain complexes $f : V_* \to W_*$ is a weak equivalence if it is a *quasi-isomorphism*: that is, if it induces an isomorphism of homology groups $\mathrm{H}_n(V) \to \mathrm{H}_n(W)$ for every integer n.

Moreover, the underlying ∞-category of $\mathrm{Vect}_\kappa^{\mathrm{dg}}$ can be identified with the ∞-category Mod_κ of κ-module spectra (see Remark HA.7.1.1.16).

Notation 13.1.1.2. Let V be a graded vector space over κ. We let $V^\vee$ denote the graded dual of V, given by $(V^\vee)_p = \mathrm{Hom}_\kappa(V_{-p}, \kappa)$. For each integer n, we let $V[n]$ denote the same vector space with grading shifted by n, so that $V[n]_p = V_{p-n}$.

Definition 13.1.1.3. We let $\mathrm{Alg}_\kappa^{\mathrm{dg}}$ denote the category of associative algebra objects of $\mathrm{Vect}_\kappa^{\mathrm{dg}}$, and $\mathrm{CAlg}_\kappa^{\mathrm{dg}}$ the category of commutative algebra objects of $\mathrm{Vect}_\kappa^{\mathrm{dg}}$. We will refer to objects of $\mathrm{Alg}_\kappa^{\mathrm{dg}}$ as *differential graded algebras* over κ and objects of $\mathrm{CAlg}_\kappa^{\mathrm{dg}}$ as *commutative differential graded algebras over* κ. According to Propositions HA.4.1.8.3 and HA.4.5.4.6 ,

$\mathrm{Alg}_\kappa^{\mathrm{dg}}$ and $\mathrm{CAlg}_\kappa^{\mathrm{dg}}$ admit combinatorial model structures, where a map $f : A_* \to B_*$ of (commutative) differential graded algebras is a weak equivalence or fibration if the underlying map of chain complexes is a weak equivalence or fibration.

Remark 13.1.1.4. In more concrete terms, a differential graded algebra A is a chain complex (A_*, d) together with a unit $1 \in A_0$ and a collection of κ-bilinear multiplication maps $A_p \times A_q \to A_{p+q}$ satisfying

$$1x = x1 = x \qquad x(yz) = (xy)z \qquad d(xy) = dxy + (-1)^p xdy$$

for $x \in A_p$, $y \in A_q$, and $z \in A_r$. The differential graded algebra A is commutative if $xy = (-1)^{pq} yx$ for $x \in A_p$, $y \in A_q$.

13.1.2 The Ordinary Category of Differential Graded Lie Algebras

We now introduce our main objects of interest.

Definition 13.1.2.1. A *differential graded Lie algebra* over κ is a chain complex $(\mathfrak{g}_*, d)$ of κ-vector spaces equipped with a Lie bracket $[,] : \mathfrak{g}_p \otimes_\kappa \mathfrak{g}_q \to \mathfrak{g}_{p+q}$ satisfying the following conditions:

(1) For $x \in \mathfrak{g}_p$ and $y \in \mathfrak{g}_q$, we have $[x, y] + (-1)^{pq}[y, x] = 0$.

(2) For $x \in \mathfrak{g}_p$, $y \in \mathfrak{g}_q$, and $z \in \mathfrak{g}_r$, we have

$$(-1)^{pr}[x, [y, z]] + (-1)^{pq}[y, [z, x]] + (-1)^{qr}[z, [x, y]] = 0.$$

(3) The differential d is a derivation with respect to the Lie bracket. That is, for $x \in \mathfrak{g}_p$ and $y \in \mathfrak{g}_q$, we have $d[x, y] = [dx, y] + (-1)^p[x, dy]$.

Given a pair of differential graded Lie algebras $(\mathfrak{g}_*, d)$ and $(\mathfrak{g}'_*, d')$, a *morphism of differential graded Lie algebras* from $(\mathfrak{g}_*, d)$ to $(\mathfrak{g}'_*, d')$ is a map of chain complexes $F : (\mathfrak{g}_*, d) \to (\mathfrak{g}'_*, d')$ such that $F([x, y]) = [F(x), F(y)]$ for $x \in \mathfrak{g}_p$, $y \in \mathfrak{g}_q$. With this notion of morphism, we can regard the collection of differential graded Lie algebras over κ as a category which we will denote by $\mathrm{Lie}_\kappa^{\mathrm{dg}}$.

Example 13.1.2.2. Let A_* be a (possibly nonunital) differential graded algebra over κ. Then A_* has the structure of a differential graded Lie algebra, where the Lie bracket $[,] : A_p \otimes_\kappa A_q \to A_{p+q}$ is given by the graded commutator $[x, y] = xy - (-1)^{pq} yx$.

Remark 13.1.2.3. The construction of Example 13.1.2.2 determines a forgetful functor $\mathrm{Alg}_\kappa^{\mathrm{dg}} \to \mathrm{Lie}_\kappa^{\mathrm{dg}}$. This functor admits a left adjoint $U : \mathrm{Lie}_\kappa^{\mathrm{dg}} \to \mathrm{Alg}_\kappa^{\mathrm{dg}}$, which assigns to every differential graded Lie algebra $\mathfrak{g}_*$ its *universal enveloping algebra* $U(\mathfrak{g}_*)$. The universal enveloping algebra $U(\mathfrak{g}_*)$ can be described as the quotient of the tensor algebra $\bigoplus_{n \geqslant 0} \mathfrak{g}_*^{\otimes n}$ by the two-sided ideal generated by all expressions of the form $(x \otimes y) - (-1)^{pq}(y \otimes x) - [x, y]$, where $x \in \mathfrak{g}_p$ and $y \in \mathfrak{g}_q$. The collection of such expressions is stable under the differential on $\bigoplus_{n \geqslant 0} \mathfrak{g}_*^{\otimes n}$, so that $U(\mathfrak{g}_*)$ inherits the structure of a differential graded algebra.

The universal enveloping algebra $U(\mathfrak{g}_*)$ admits a natural filtration

$$U(\mathfrak{g}_*)^{\leqslant 0} \subseteq U(\mathfrak{g}_*)^{\leqslant 1} \subseteq \cdots,$$

where $U(\mathfrak{g}_*)^{\leqslant n}$ is the image of $\bigoplus_{0 \leqslant i \leqslant n} \mathfrak{g}_*^{\otimes i}$ in $U(\mathfrak{g}_*)$. The associated graded algebra of $U(\mathfrak{g}_*)$ is commutative (in the graded sense), so that the canonical map $\mathfrak{g}_* \to U(\mathfrak{g}_*)^{\leqslant 1}$ induces a map of differential graded algebras $\theta : \mathrm{Sym}_\kappa^* \mathfrak{g}_* \to \mathrm{gr}\, U(\mathfrak{g}_*)$. According to the Poincare-Birkhoff-Witt theorem, the map θ is an isomorphism (see Theorem 2.3 of [220] for a proof in the setting of differential graded Lie algebras).

Remark 13.1.2.4. Let $\mathfrak{g}_*$ be a differential graded Lie algebra over κ. For each integer n, we let $\psi : \mathfrak{g}_*^{\otimes n} \to U(\mathfrak{g}_*)$ denote the multiplication map. For every permutation σ of the set $\{1, 2, \ldots, n\}$, let ϕ_σ denote the induced automorphism of $\mathfrak{g}_*^{\otimes n}$. The map $\frac{1}{n!} \sum_\sigma \psi \circ \phi_\sigma$ is invariant under precomposition with each of the maps ϕ_σ, and therefore factors as a composition $\mathfrak{g}_*^{\otimes n} \to \mathrm{Sym}_\kappa^n(\mathfrak{g}_*) \xrightarrow{\Psi_n} U(\mathfrak{g}_*)^{\leqslant n} \subseteq U(\mathfrak{g}_*)$. We observe that the composite map $\mathrm{Sym}_\kappa^n(\mathfrak{g}_*) \xrightarrow{\Psi_n} U(\mathfrak{g}_*)^{\leqslant n} \to \mathrm{gr}^n U(\mathfrak{g}_*)$ coincides with the isomorphism of Remark 13.1.2.3. It follows that the direct sum of the maps Ψ_n determines an isomorphism of chain complexes $\overline{\theta} : \mathrm{Sym}_\kappa^*(\mathfrak{g}_*) \to U(\mathfrak{g}_*)$.

13.1.3 The Model Structure on $\mathrm{Lie}_\kappa^{\mathrm{dg}}$

We now show that the category of differential graded Lie algebras over a field κ of characteristic zero admits a model structure.

Definition 13.1.3.1. Let $f : \mathfrak{g}_* \to \mathfrak{g}'_*$ be a map of differential graded Lie algebras over κ. We will say that f is a *quasi-isomorphism* if the underlying map of chain complexes is a quasi-isomorphism: that is, if F induces an isomorphism on homology.

Proposition 13.1.3.2. *Let κ be a field of characteristic zero. Then the category $\mathrm{Lie}_\kappa^{\mathrm{dg}}$ of differential graded Lie algebras over κ has the structure of a left proper combinatorial model category, where:*

- (W) *A map of differential graded Lie algebras $f : \mathfrak{g}_* \to \mathfrak{g}'_*$ is a weak equivalence if and only if it is a quasi-isomorphism (Definition 13.1.3.1).*

- (F) *A map of differential graded Lie algebras $f : \mathfrak{g}_* \to \mathfrak{g}'_*$ is a fibration if and only if it is a fibration of chain complexes: that is, if and only if each of the induced maps $\mathfrak{g}_p \to \mathfrak{g}'_p$ is a surjective map of vector spaces over κ.*

(C) *A map of differential graded Lie algebras $f : \mathfrak{g}_* \to \mathfrak{g}'_*$ is a cofibration if and only if it has the left lifting property with respect to every map of differential graded Lie algebras which is simultaneously a fibration and a weak equivalence.*

Remark 13.1.3.3. In the situation of Proposition 13.1.3.2, the forgetful functor $\mathrm{Alg}_\kappa^{\mathrm{dg}} \to \mathrm{Lie}_\kappa^{\mathrm{dg}}$ of Example 13.1.2.2 preserves fibrations and weak equivalences, and is therefore a right Quillen functor. It follows that the universal enveloping algebra functor $U : \mathrm{Lie}_\kappa^{\mathrm{dg}} \to \mathrm{Alg}_\kappa^{\mathrm{dg}}$ is a left Quillen functor.

Lemma 13.1.3.4. *Let $f : \mathfrak{g}_* \to \mathfrak{g}'_*$ be a map of differential graded Lie algebras over κ. The following conditions are equivalent:*

(1) *The map f is a quasi-isomorphism.*

(2) *The induced map $U(\mathfrak{g}_*) \to U(\mathfrak{g}'_*)$ is a quasi-isomorphism of differential graded algebras.*

Proof. We note that if $g : V_* \to W_*$ is any map of chain complexes of κ-vector spaces, then g is a quasi-isomorphism if and only if g induces a quasi-isomorphism $\mathrm{Sym}_\kappa^*(V_*) \to \mathrm{Sym}_\kappa^*(W_*)$. The desired assertion now follows immediately from Remark 13.1.2.4. □

Proof of Proposition 13.1.3.2. The forgetful functor $\mathrm{Lie}_\kappa^{\mathrm{dg}} \to \mathrm{Vect}_\kappa^{\mathrm{dg}}$ has a left adjoint (the free Lie algebra functor), which we will denote by $\mathrm{Free} : \mathrm{Vect}_\kappa^{\mathrm{dg}} \to \mathrm{Lie}_\kappa^{\mathrm{dg}}$. For every integer n, let $E(n)_*$ denote the acyclic chain complex

$$\cdots \to 0 \to 0 \to \kappa \simeq \kappa \to 0 \to 0 \to \cdots$$

which is nontrivial only in degrees n and $(n-1)$, and let $\partial\, E(n)_*$ be the subcomplex of $E(n)_*$ which is nontrivial only in degree $(n-1)$. Let C_0 be the collection of morphisms in $\mathrm{Lie}_k^{\mathrm{dg}}$ of the form $\mathrm{Free}(\partial\, E(n)_*) \to \mathrm{Free}(E(n)_*)$, and let W be the collection of all quasi-isomorphisms in $\mathrm{Lie}_\kappa^{\mathrm{dg}}$. We claim that the collection of morphisms C_0 and W satisfy the hypotheses of Proposition HTT.A.2.6.15:

(1) The collection W of quasi-isomorphisms is perfect, in the sense of Definition HTT.A.2.6.12 . This follows immediately from Corollary HTT.A.2.6.14 , applied to the forgetful functor $\mathrm{Lie}_\kappa^{\mathrm{dg}} \to \mathrm{Vect}_\kappa^{\mathrm{dg}}$.

(2) The collection of weak equivalences is stable under pushouts of morphisms in C_0. In other words, if $f : \mathfrak{g}_* \to \mathfrak{g}'_*$ is a quasi-isomorphism of differential graded Lie algebras over κ and $x \in \mathfrak{g}_{n-1}$ is a cycle classifying a map $\mathrm{Free}(\partial\, E(n)_*) \to \mathfrak{g}_*$, we must show that the induced map

$$\mathfrak{g}_* \amalg_{\mathrm{Free}(\partial\, E(n)_*)} \mathrm{Free}(E(n)_*) \to \mathfrak{g}'_* \amalg_{\mathrm{Free}(\partial\, E(n)_*)} \mathrm{Free}(E(n)_*)$$

is also a quasi-isomorphism of differential graded Lie algebras. Let $A_* = U(\mathfrak{g}_*)$, let $A'_* = U(\mathfrak{g}'_*)$, and let $F : A_* \to A'_*$ be the map induced by f. We will abuse notation and identify x with its image in A_{n-1}. Using Lemma 13.1.3.4, we see that F is a quasi-isomorphism, and we are reduced to showing that F induces a quasi-isomorphism $B_* \to B'_*$, where B_* is the differential graded algebra obtained from A_* by adjoining a class y in degree n with $dy = x$, and B'_* is defined similarly. To prove this, we note that B_* admits an exhaustive filtration

$$A_* \simeq B_*^{\leqslant 0} \subseteq B_*^{\leqslant 1} \subseteq B_*^{\leqslant 2} \subseteq \cdots$$

where $B^{\leqslant m}$ is the subspace of B spanned by all expressions of the form $a_0 y a_1 y \cdots y a_k$, where $k \leqslant m$ and each a_i belongs to the image of A_* in B_*. Similarly, we have a filtration

$$A'_* \simeq B_*'^{\leqslant 0} \subseteq B_*'^{\leqslant 1} \subseteq B_*'^{\leqslant 2} \subseteq \cdots$$

of B'_*. Since the collection of quasi-isomorphisms is stable under filtered colimits, it will suffice to show that for each $m \geqslant 0$, the map of chain complexes $B_*^{\leqslant m} \to B_*'^{\leqslant m}$ is a quasi-isomorphism. The proof proceeds by induction on m, the case $m = 0$ being true by assumption. If $m > 0$, we have a diagram of short exact sequences of chain complexes

$$\begin{array}{ccccccccc} 0 & \to & B_*^{\leqslant m-1} & \to & B_*^{\leqslant m} & \to & B_*^{\leqslant n}/B_*^{\leqslant m-1} & \to & 0 \\ & & \downarrow & & \downarrow & & \downarrow{\scriptstyle \phi} & & \\ 0 & \to & B_*'^{\leqslant m-1} & \to & B_*'^{\leqslant m} & \to & B_*'^{\leqslant m}/B_*'^{\leqslant m-1} & \to & 0. \end{array}$$

The inductive hypothesis implies that the left vertical map is a quasi-isomorphism. To complete the inductive step, it will suffice to show that ϕ is a quasi-isomorphism. For this, we observe that the construction $a_0 \otimes \cdots \otimes a_n \mapsto a_0 y a_1 y \cdots y a_m$ determines an isomorphism of chain complexes $A_*^{\otimes m+1} \to B_*^{\leqslant m}/B_*^{\leqslant m-1}$, and similarly we have an isomorphism $A_*'^{\otimes m+1} \to B_*'^{\leqslant m}/B_*'^{\leqslant m-1}$. Under these isomorphisms, ϕ corresponds to the map $A_*^{\otimes m+1} \to A_*'^{\otimes m+1}$ given by the $(m+1)$st tensor power of F, which is a quasi-isomorphism by assumption.

(3) Let $f : \mathfrak{g}_* \to \mathfrak{g}'_*$ be a map of differential graded Lie algebras which has the right lifting property with respect to every morphism in C_0. We claim that f is a quasi-isomorphism. To prove this, we must show that f induces an isomorphism $\theta_n : \mathrm{H}_n(\mathfrak{g}_*) \to \mathrm{H}_n(\mathfrak{g}'_*)$ for every integer n (here $\mathrm{H}_n(\mathfrak{h}_*)$ denotes the homology of the underlying chain complex of $\mathfrak{h}_*$). We first show that θ_n is surjective. Choose a class $\eta \in \mathrm{H}_n(\mathfrak{g}'_*)$, represented by a cycle $x \in \mathfrak{g}'_n$. Then x determines a map $u : \mathrm{Free}(E(n)_*) \to \mathfrak{g}'_*$ which vanishes on $\mathrm{Free}(\partial\, E(n)_*)$. It follows that $u = f \circ v$, where $v : \mathrm{Free}(E(n)_*) \to \mathfrak{g}_*$ is a map of

differential graded Lie algebras which vanishes on $\mathrm{Free}(\partial\, E(n-1)_*)$. The map v is determined by a cycle $\overline{x} \in \mathfrak{g}_n$ which represents a homology class lifting η.

We now prove that θ_n is injective. Let $\eta \in \mathrm{H}_n(\mathfrak{g}_*)$ be a class whose image in $\mathrm{H}_n(\mathfrak{g}'_*)$ vanishes. Then η is represented by a cycle $x \in \mathfrak{g}_n$ such that $f(x) = dy$, for some $y \in \mathfrak{g}'_{n+1}$. Then y determines a map of differential graded Lie algebras $u : \mathrm{Free}(E(n+1)_*) \to \mathfrak{g}'$ such that $u|_{\mathrm{Free}(\partial\, E(n+1)_*)}$ lifts to $\mathfrak{g}_*$. It follows that $u = f \circ v$, for some map of differential graded Lie algebras $\mathrm{Free}(E(n+1)_*) \to \mathfrak{g}_*$ such that $v|_{\mathrm{Free}(\partial\, E(n+1)_*)}$ classifies x. It follows that x is a boundary, so that $\eta = 0$.

It follows from Proposition HTT.A.2.6.15 that $\mathrm{Lie}^{\mathrm{dg}}_{\kappa}$ admits a left proper combinatorial model structure having W as the class of weak equivalences and C_0 as a class of generating cofibrations. To complete the proof, it will suffice to show that a morphism $u : \mathfrak{g}_* \to \mathfrak{g}'_*$ in $\mathrm{Lie}^{\mathrm{dg}}_{\kappa}$ is a fibration if and only if it is degreewise surjective. Suppose first that u is a fibration. For each integer n, let $i_n : 0 \to \mathrm{Free}(E(n)_*)$ be the evident map of differential graded Lie algebras. Then i_n factors as a composition

$$0 \to 0 \amalg_{\mathrm{Free}(\partial\, E(n-1)_*)} \mathrm{Free}(E(n-1)_*) \simeq \mathrm{Free}(\partial\, E(n)_*) \to \mathrm{Free}(E(n)_*),$$

and is therefore a cofibration. The unit map $\kappa \simeq U(0) \to U(\mathrm{Free}(E(n)_*)) \simeq \bigoplus_{m \geqslant 0} E(n)_*^{\otimes m}$ is a quasi-isomorphism (since $E(n)$ is acyclic and therefore each $E(n)_*^{\otimes m}$ is acyclic for $m > 0$). It follows that i_n is a trivial cofibration, so that u has the right lifting property with respect to i_n. Unwinding the definitions, we conclude that the map $\mathfrak{g}_n \to \mathfrak{g}'_n$ is surjective.

Now suppose that u is degreewise surjective; we wish to show that u is a fibration. Let S be the collection of all trivial cofibrations in $\mathrm{Lie}^{\mathrm{dg}}_{\kappa}$ which have the left lifting property with respect to u. Let $f : \mathfrak{h}_* \to \mathfrak{h}''_*$ be a trivial cofibration in $\mathrm{Lie}^{\mathrm{dg}}_{k}$; we will prove that $f \in S$. Note that f contains each of the trivial cofibrations $i_n : 0 \to \mathrm{Free}(E(n)_*)$ above. Using the small object argument, we can factor f as a composition $\mathfrak{h}_* \xrightarrow{f'} \mathfrak{h}'_* \xrightarrow{f''} \mathfrak{h}''_*$ where $f' \in S$ and f'' has the right lifting property with respect to each of the morphisms i_n: that is, f'' is degreewise surjective. Since f and f' are quasi-isomorphisms, we conclude that f'' is a quasi-isomorphism. It follows that f'' is a trivial fibration in the category of chain complexes and therefore a trivial fibration in the category $\mathrm{Lie}^{\mathrm{dg}}_{\kappa}$. Because f is a cofibration, the lifting problem

$$\begin{array}{ccc} \mathfrak{h}_* & \xrightarrow{f'} & \mathfrak{h}'_* \\ \downarrow{\scriptstyle f} & \nearrow & \downarrow{\scriptstyle f''} \\ \mathfrak{g}''_* & \xrightarrow{\mathrm{id}} & \mathfrak{g}''_* \end{array}$$

admits a solution. We conclude that f is a retract of f', and therefore also belongs to S. $\square$

13.1.4 The ∞-Category of Differential Graded Lie Algebras

For our purposes, it will be convenient to view the collection of differential graded Lie algebras (over a field κ of characteristic zero) not as an ordinary category or as a model category, but as an ∞-category.

Definition 13.1.4.1. Let κ be a field of characteristic zero. We let Lie_κ denote the underlying ∞-category of the model category $\mathrm{Lie}_k^{\mathrm{dg}}$. More precisely, Lie_κ denotes an ∞-category equipped with a functor $u : \mathrm{Lie}_\kappa^{\mathrm{dg}} \to \mathrm{Lie}_\kappa$ having the following universal property: for every ∞-category $\mathcal{C}$, composition with u induces an equivalence from $\mathrm{Fun}(\mathrm{Lie}_\kappa, \mathcal{C})$ to the full subcategory of $\mathrm{Fun}(\mathrm{Lie}_\kappa^{\mathrm{dg}}, \mathcal{C})$ spanned by those functors $F : \mathrm{Lie}_\kappa^{\mathrm{dg}} \to \mathcal{C}$ which carry quasi-isomorphisms in $\mathrm{Lie}_\kappa^{\mathrm{dg}}$ to equivalences in $\mathcal{C}$ (see Definition HA.1.3.4.15 and Remark HA.1.3.4.16). We will refer to Lie_κ as the *∞-category of differential graded Lie algebras over κ.*

Remark 13.1.4.2. Using Proposition HA.7.1.1.15 , we conclude that the underlying ∞-category of the model category $\mathrm{Vect}_\kappa^{\mathrm{dg}}$ can be identified with the ∞-category $\mathrm{Mod}_\kappa = \mathrm{Mod}_\kappa(\mathrm{Sp})$ of κ-module spectra. The forgetful functor $\mathrm{Lie}_\kappa^{\mathrm{dg}} \to \mathrm{Vect}_\kappa^{\mathrm{dg}}$ preserves quasi-isomorphisms, and therefore induces a forgetful functor $\mathrm{Lie}_\kappa \to \mathrm{Mod}_\kappa$.

Proposition 13.1.4.3. *Let $\mathcal{J}$ be a small category which is sifted (when viewed as an ∞-category). The forgetful functor $G : \mathrm{Lie}_\kappa^{\mathrm{dg}} \to \mathrm{Vect}_\kappa^{\mathrm{dg}}$ preserves $\mathcal{J}$-indexed homotopy colimits.*

Proof. Let $G' : \mathrm{Alg}_\kappa^{\mathrm{dg}} \to \mathrm{Vect}_\kappa^{\mathrm{dg}}$ be the forgetful functor. It follows from Remark 13.1.2.4 that the functor G is a retract of $G' \circ U$. It will therefore suffice to show that $G' \circ U$ preserves $\mathcal{J}$-indexed homotopy colimits. The functor U is a left Quillen functor (Remark 13.1.3.3) and therefore preserves all homotopy colimits. We are therefore reduced to showing that G' preserves $\mathcal{J}$-indexed homotopy colimits, which is a special case of Lemma HA.4.1.8.13 . □

Proposition 13.1.4.4. *The ∞-category Lie_κ is presentable, and the forgetful functor $\theta : \mathrm{Lie}_\kappa \to \mathrm{Mod}_\kappa$ of Remark 13.1.4.2 preserves small sifted colimits.*

Proof. The first assertion follows from Proposition HA.1.3.4.22 . Using Propositions HA.1.3.4.24 , HA.1.3.4.25 , and 13.1.4.3, we conclude that θ preserves colimits indexed by small categories $\mathcal{J}$ which are sifted (when viewed as ∞-categories). Since any filtered ∞-category $\mathcal{I}$ admits a left cofinal map $A \to \mathcal{I}$ where A is a filtered partially ordered set (Proposition HTT.5.3.1.18), we conclude that θ preserves small filtered colimits. Since θ also preserves geometric realizations of simplicial objects, it preserves all small sifted colimits (Corollary HTT.5.5.8.17). □

Remark 13.1.4.5. The forgetful functor $\theta : \mathrm{Lie}_\kappa \to \mathrm{Mod}_\kappa$ is monadic: that is, θ admits a left adjoint $\mathrm{Free} : \mathrm{Mod}_\kappa \to \mathrm{Lie}_\kappa$, and induces an equivalence of Lie_κ with $\mathrm{LMod}_T(\mathrm{Mod}_\kappa)$, where T is the monad on Mod_κ given by the composition $\theta \circ \mathrm{Free}$. This follows from Theorem HA.4.7.0.3 and Proposition 13.1.4.4.

13.2 Homology and Cohomology of Lie Algebras

Throughout this section, we fix a field κ, which we will assume to be of characteristic zero unless otherwise specified. Let $\mathfrak{g}$ be a Lie algebra over κ and let $U(\mathfrak{g})$ denote its universal enveloping algebra. We can regard κ as a (left or right) module over $U(\mathfrak{g})$, with each element of $\mathfrak{g}$ acting trivially on κ. The *homology and cohomology* groups of $\mathfrak{g}$ are defined by

$$\mathrm{H}_n(\mathfrak{g}) = \mathrm{Tor}_n^{U(\mathfrak{g})}(\kappa, \kappa) \qquad \mathrm{H}^n(\mathfrak{g}) = \mathrm{Ext}^n_{U(\mathfrak{g})}(\kappa, \kappa).$$

These groups can be described more explicitly as the homology groups of chain complexes $C_*(\mathfrak{g})$ and $C^*(\mathfrak{g})$, called the (homological and cohomological) *Chevalley-Eilenberg complexes* of $\mathfrak{g}$. In this section, we will review the definition of these chain complexes (in the more general setting of differential graded algebras) and establish some of their basic properties. These constructions will play an important role in the construction of the deformation theory $\mathfrak{D} : (\mathrm{CAlg}^{\mathrm{aug}}_\kappa)^{\mathrm{op}} \to \mathrm{Lie}_\kappa$ required for the proof of Theorem 13.0.0.2.

13.2.1 The Homological Chevalley-Eilenberg Complex

Suppose that $\mathfrak{g}$ is a Lie algebra over κ. To obtain a concrete description of the homology and cohomology groups $\mathrm{H}_*(\mathfrak{g})$ and $\mathrm{H}^*(\mathfrak{g})$, it is convenient to choose explicit resolution of the ground field κ as a (left) module over the universal enveloping algebra $U(\mathfrak{g})$. We can obtain such a resolution by taking the universal enveloping algebra of an acyclic differential graded Lie algebra which contains $\mathfrak{g}$.

Construction 13.2.1.1. Let $\mathfrak{g}_*$ be a differential graded Lie algebra over κ. We define another differential graded Lie algebra $\mathrm{Cn}(\mathfrak{g})_*$ as follows:

(1) For each $n \in \mathbf{Z}$, the vector space $\mathrm{Cn}(\mathfrak{g})_*$ is given by $\mathfrak{g}_n \oplus \mathfrak{g}_{n-1}$. We will denote the elements of $\mathrm{Cn}(\mathfrak{g})_n$ by $x + \epsilon y$, where $x \in \mathfrak{g}_n$ and $y \in \mathfrak{g}_{n-1}$.

(2) The differential on $\mathrm{Cn}(\mathfrak{g})_*$ is given by the formula $d(x + \epsilon y) = dx + y - \epsilon dy$.

(3) The Lie bracket on $\mathrm{Cn}(\mathfrak{g})_*$ is given by $[x+\epsilon y, x'+\epsilon y'] = [x, x']+\epsilon([y, x']+(-1)^p[x, y'])$, where $x \in \mathfrak{g}_p$.

We will refer to $\mathrm{Cn}(\mathfrak{g})_*$ as the *cone* on $\mathfrak{g}_*$.

Remark 13.2.1.2. Let $\mathfrak{g}_*$ be a differential graded Lie algebra over κ. Then the underlying chain complex $\mathrm{Cn}(\mathfrak{g})_*$ can be identified with the mapping cone for the identity $\mathrm{id} : \mathfrak{g}_* \to \mathfrak{g}_*$. It follows that $\mathrm{Cn}(\mathfrak{g})_*$ is a contractible chain complex. In particular, the map $0 \to \mathrm{Cn}(\mathfrak{g})_*$ is a quasi-isomorphism of differential graded Lie algebras.

Construction 13.2.1.3. Let $\mathfrak{g}_*$ be a differential graded Lie algebra over κ. The zero map $\mathfrak{g}_* \to 0$ induces a morphism of differential graded algebras $U(\mathfrak{g}_*) \to U(0) \simeq \kappa$. There is an evident map of differential graded Lie algebras $\mathfrak{g}_* \to \mathrm{Cn}(\mathfrak{g})_*$. We let $C_*(\mathfrak{g}_*)$ denote the chain complex given by the tensor product $U(\mathrm{Cn}(\mathfrak{g})_*) \otimes_{U(\mathfrak{g}_*)} \kappa$. We will refer to $C_*(\mathfrak{g}_*)$ as the *homological Chevalley-Eilenberg complex of* $\mathfrak{g}_*$.

Remark 13.2.1.4. Let $\mathfrak{g}_*$ be a differential graded Lie algebra over a field κ, and regard the shifted chain complex $\mathfrak{g}_*[1]$ as a graded Lie algebra with a vanishing Lie bracket. There is an evident map of graded Lie algebras (without differential) $\mathfrak{g}_*[1] \to \mathrm{Cn}(\mathfrak{g})_*$. This map induces a map of graded vector spaces $\mathrm{Sym}^*_\kappa(\mathfrak{g}_*[1]) \simeq U(\mathfrak{g}_*[1]) \to U(\mathrm{Cn}(\mathfrak{g})_*)$. Using the Poincare-Birkhoff-Witt theorem, we obtain an isomorphism of graded right $U(\mathfrak{g}_*)$-modules

$$U(\mathrm{Cn}(\mathfrak{g})_*) \simeq \mathrm{Sym}^*_\kappa(\mathfrak{g}_*[1]) \otimes_\kappa U(\mathfrak{g}_*),$$

hence an isomorphism of graded vector spaces $\phi : \mathrm{Sym}^*_\kappa(\mathfrak{g}_*[1]) \to C_*(\mathfrak{g}_*)$. We will often identify $C_*(\mathfrak{g}_*)$ with the symmetric algebra $\mathrm{Sym}^*_\kappa(\mathfrak{g}_*[1])$ using the isomorphism ϕ. Note that ϕ is not an isomorphism of differential graded vector spaces. Unwinding the definitions, we see that the differential on $C_*(\mathfrak{g}_*)$ is given by the formula

$$\begin{aligned} D(x_1 \dots x_n) &= \sum_{1 \leqslant i \leqslant n} (-1)^{p_1 + \cdots + p_{i-1}} x_1 \dots x_{i-1} dx_i x_{i+1} \dots x_n + \\ & \sum_{1 \leqslant i < j \leqslant n} (-1)^{p_i(p_{i+1} + \cdots + p_{j-1})} x_1 \dots x_{i-1} x_{i+1} \dots x_{j-1} [x_i, x_j] x_{j+1} \dots x_n. \end{aligned}$$

Remark 13.2.1.5. Let $\mathfrak{g}_*$ be a differential graded Lie algebra over κ. The filtration of $\mathrm{Sym}^*_\kappa(\mathfrak{g}_*)$ by the subspaces $\mathrm{Sym}^{\leqslant n}_\kappa(\mathfrak{g}_*) \simeq \bigoplus_{i \leqslant n} \mathrm{Sym}^i_\kappa(\mathfrak{g}_*)$ determines a filtration

$$\kappa \simeq C^{\leqslant 0}_*(\mathfrak{g}_*) \hookrightarrow C^{\leqslant 1}_*(\mathfrak{g}_*) \hookrightarrow C^{\leqslant 2}_*(\mathfrak{g}_*) \hookrightarrow \cdots$$

Using the formula for the differential on $C_*(\mathfrak{g}_*)$ given in Remark 13.2.1.4, we deduce the existence of canonical isomorphisms $C^{\leqslant n}_*(\mathfrak{g}_*)/C^{\leqslant n-1}_*(\mathfrak{g}_*) \simeq \mathrm{Sym}^n_\kappa(\mathfrak{g}_*)$ in the category of differential graded vector spaces over κ.

13.2.2 Lie Algebra Homology

If $\mathfrak{g}_*$ is a differential graded Lie algebra, we will refer to the homology groups of the chain complex $C_*(\mathfrak{g}_*)$ as the *Lie algebra homology groups* of $\mathfrak{g}_*$. This is a quasi-isomorphism invariant:

Proposition 13.2.2.1. *Let $f : \mathfrak{g}_* \to \mathfrak{g}'_*$ be a quasi-isomorphism between differential graded Lie algebras over κ. Then the induced map $C_*(\mathfrak{g}_*) \to C_*(\mathfrak{g}'_*)$ is a quasi-isomorphism of chain complexes.*

Proof. Since the collection of quasi-isomorphisms is closed under filtered colimits, it will suffice to show that the induced map $\theta_n : C_*^{\leqslant n}(\mathfrak{g}_*) \to C_*^{\leqslant n}(\mathfrak{g}'_*)$ is a quasi-isomorphism for each $n \geqslant 0$. We proceed by induction on n. When $n = 0$, the map θ is an isomorphism and there is nothing to prove. Assume therefore that $n > 0$, so that we have a commutative diagram of short exact sequences

$$\begin{array}{ccccccccc} 0 & \longrightarrow & C_*^{\leqslant n-1}(\mathfrak{g}_*) & \longrightarrow & C_*^{\leqslant n}(\mathfrak{g}_*) & \longrightarrow & \mathrm{Sym}^n_\kappa(\mathfrak{g}_*[1]) & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle \theta_{n-1}} & & \downarrow{\scriptstyle \theta_n} & & \downarrow{\scriptstyle \phi} & & \\ 0 & \longrightarrow & C_*^{\leqslant n-1}(\mathfrak{g}'_*) & \longrightarrow & C_*^{\leqslant n}(\mathfrak{g}'_*) & \longrightarrow & \mathrm{Sym}^n_\kappa(\mathfrak{g}'_*[1]) & \longrightarrow & 0 \end{array}$$

Using the inductive hypothesis, we are reduced to showing that the map ϕ is a quasi-isomorphism. Since κ is a field of characteristic zero, the map ϕ is a retract of the map $\mathfrak{g}_*^{\otimes n}[n] \to \mathfrak{g}_*'^{\otimes n}[n]$, which is a quasi-isomorphism by virtue of our assumption that f is a quasi-isomorphism. □

Remark 13.2.2.2. Let $\mathfrak{g}_*$ be a differential graded Lie algebra over κ. Then $U(\mathrm{Cn}(\mathfrak{g})_*)$ can be regarded as a cofibrant replacement for κ in the model category of differential graded right modules over $U(\mathfrak{g}_*)$. The tensor product functor $M_* \mapsto M_* \otimes_{U(\mathfrak{g}_*)} \kappa$ is a left Quillen functor. It follows that $C_*(\mathfrak{g}_*)$ is an explicit model for the left derived tensor product $\kappa \otimes^L_{U(\mathfrak{g}_*)} \kappa$. Equivalently, the image of $C_*(\mathfrak{g}_*)$ in Mod_κ can be identified with the ∞-categorical relative tensor product $\kappa \otimes_A \kappa$, where $A \in \mathrm{Alg}_\kappa$ is the image of $U(\mathfrak{g}_*)$ under the functor $\mathrm{Alg}^{\mathrm{dg}}_\kappa \to \mathrm{Alg}_\kappa$.

13.2.3 The Case of a Free Algebra

If $\mathfrak{g}_*$ is a free differential graded Lie algebra, then the homology of $\mathfrak{g}_*$ is easy to describe.

Proposition 13.2.3.1. *Let V_* be a differential graded vector spaces over κ and let $\mathfrak{g}_*$ be free differential graded Lie algebra generated by V_*. Then the inclusion of chain complexes*

$$\xi : \kappa \oplus V_*[1] \hookrightarrow \kappa \oplus \mathfrak{g}_*[1] \simeq C_*^{\leqslant 1}(\mathfrak{g}_*) \hookrightarrow C_*(\mathfrak{g}_*)$$

is a quasi-isomorphism.

To prove Proposition 13.2.3.1, we will need some general observations about differential graded algebras and their modules.

Lemma 13.2.3.2. *Let A_* be a differential graded algebra over a field κ (not necessarily assumed to be of characteristic zero), and let $f : M_* \to N_*$ be a map of differential graded right modules over A_*. Assume that:*

(1) *The differential graded module M_* can be written as a union of submodules*

$$0 = M(0)_* \subseteq M(1)_* \subseteq M(2)_* \subseteq \cdots$$

where each successive quotient $M(n)_*/M(n-1)_*$ is isomorphic (as a differential graded A_*-module) to a free differential graded module of the form $\bigoplus_\alpha A_*[e_\alpha]$.

(2) *The chain complex N_* is acyclic.*

Then the map f is nullhomotopic. That is, there exists a map of graded A_*-modules $h : M_* \to N_{*+1}$ satisfying $dh + hd = f$.

Proof. We construct a compatible family of nullhomotopies $h(n) : M(n)_* \to N_{*+1}$ for the maps $f(n) = f|_{M(n)_*}$. When $n = 0$, such a nullhomotopy exists and is unique (since $M(0)_* \simeq 0$). Assume therefore that $n > 0$ and that $h(n-1)$ has been constructed. Condition (1) guarantees that $M(n)_*/M(n-1)_*$ is freely generated (as an A_*-module) by generators $\overline{x}_\alpha \in (M(n)/M(n-1))_{e_\alpha}$. Choose $x_\alpha \in M(n)_{e_\alpha}$ representing $\overline{x}_\alpha$. We compute

$$d(f(x_\alpha) - h(n-1)dx_\alpha) = f(dx_\alpha) - d(h(n-1)dx_\alpha) = h(n-1)d^2x_\alpha = 0.$$

Since N_* is acyclic, we can choose $y_\alpha \in N_{e_\alpha+1}$ with $dy_\alpha = f(x_\alpha) - h(n-1)dx_\alpha$. We now define $h(n)$ to be the unique map of graded A_*-modules from $M(n)_*$ to N_{*+1} which extends $h(n-1)$ and carries x_α to y_α; it is easy to see that $h(n)$ has the desired properties. □

Lemma 13.2.3.3. *Let A_* be a differential graded algebra over a field κ (not necessarily assumed to be of chracteristic zero), and let M_* be a chain complex of differential graded right modules over A_*. Assume that M_* is acyclic and satisfies condition* (1) *of Lemma 13.2.3.2. Then, for any differential graded left A_*-module N_*, the tensor product $M_* \otimes_{A_*} N_*$ is acyclic.*

Proof. It follows from Lemma 13.2.3.2 that identity map $\mathrm{id} : M_* \to M_*$ is chain homotopic to zero: that is, there exists a map $h : M_* \to M_{*+1}$ such that $dh + hd = \mathrm{id}$. Then h determines a contracting homotopy for $M_* \otimes_{A_*} N_*$, so that $M_* \otimes_{A_*} N_*$ is also acyclic. □

Proof of Proposition 13.2.3.1. Note that the universal enveloping algebra $U(\mathfrak{g}_*)$ can be identified with the tensor algebra $T(V_*) \simeq \bigoplus_{n \geqslant 0} V_*^{\otimes n}$. Let $M_* \subseteq U(\mathrm{Cn}(\mathfrak{g})_*)$ be the right $T(V_*)$-submodule generated by $\kappa \oplus V_*[1]$. Unwinding the definitions, we see that M_* is isomorphic (as a chain complex) to the direct sum $\kappa \oplus M'_*$, where M'_* is isomorphic to mapping cone of the identity map from $\bigoplus_{n \geqslant 1} V_*^{\otimes n}$ to itself. It follows that the inclusion $\kappa \hookrightarrow M_*$ is a quasi-isomorphism. The composite inclusion $\kappa \hookrightarrow M_* \to U(\mathrm{Cn}(\mathfrak{g})_*)$ is given by applying the universal enveloping algebra functor U to the inclusion of differential graded Lie algebras $0 \to \mathrm{Cn}(\mathfrak{g})_*$, and is therefore a quasi-isomorphism by Remark 13.2.1.2 and

Lemma 13.1.3.4. It follows that the inclusion $M_* \subseteq U(\mathrm{Cn}(\mathfrak{g})_*)$ is a quasi-isomorphism, so that the quotient $Q_* = U(\mathrm{Cn}(\mathfrak{g})_*)/M_*$ is acyclic. It is not difficult to see that Q_* satisfies hypothesis (1) of Lemma 13.2.3.2; in particular, Q_* is free as a graded A_*-module. It follows that we have an exact sequence of chain complexes

$$0 \to M_* \otimes_{T(V_*)} \kappa \xrightarrow{\theta} U(\mathrm{Cn}(\mathfrak{g})_*) \otimes_{T(V_*)} \kappa \to Q_* \otimes_{T(V_*)} \kappa \to 0.$$

Lemma 13.2.3.3 guarantees that $Q_* \otimes_{T(V_*)} \kappa$ is acyclic, so that θ determines a quasi-isomorphism $\kappa \oplus V_*[1] \to C_*(\mathfrak{g}_*)$. □

13.2.4 Compatibility with Colimits

It follows from Proposition 13.2.2.1 that the Chevalley-Eilenberg construction $C_* : \mathrm{Lie}_\kappa^{\mathrm{dg}} \to \mathrm{Vect}_\kappa^{\mathrm{dg}}$ induces a functor of ∞-categories $\mathrm{Lie}_\kappa \to \mathrm{Mod}_\kappa$, which we will also denote by C_*. Note that C_* carries the initial object $0 \in \mathrm{Lie}_\kappa$ to $C_*(0) \simeq \kappa$, and therefore induces a functor $\mathrm{Lie}_\kappa \to (\mathrm{Mod}_\kappa)_{\kappa/}$. We will abuse notation by denoting this functor also by C_*.

Proposition 13.2.4.1. *The functor of ∞-categories $C_* : \mathrm{Lie}_\kappa \to (\mathrm{Mod}_\kappa)_{\kappa/}$ preserves small colimits.*

Proof. By virtue of Corollary HTT.4.2.3.11 and Lemma HA.1.3.3.10 , it will suffice to show that C_* preserves finite coproducts and small sifted colimits. We begin by showing that C_* preseres small sifted colimits. Using Lemma HTT.4.4.2.8 and Proposition HTT.4.3.1.5 , we are reduced to showing that the composite functor $\mathrm{Lie}_\kappa \to (\mathrm{Mod}_\kappa)_{\kappa/} \to \mathrm{Mod}_\kappa$ preserves small sifted colimits. The proof of Proposition 13.2.2.1 shows that for each $n \geqslant 0$, the functor $C_*^{\leqslant n}$ preserves quasi-isomorphisms and therefore induces a functor of ∞-categories $\mathrm{Lie}_\kappa \to \mathrm{Mod}_\kappa$. Since the collection of quasi-isomorphisms in $\mathrm{Vect}_\kappa^{\mathrm{dg}}$ is closed under filtered colimits, every colimit diagram in $\mathrm{Vect}_\kappa^{\mathrm{dg}}$ indexed by a filtered category determines a homotopy colimit diagram in $\mathrm{Vect}_\kappa^{\mathrm{dg}}$ and therefore a colimit diagram in Mod_κ (Proposition HA.1.3.4.24). It follows that the functor $C_* : \mathrm{Lie}_\kappa \to \mathrm{Mod}_\kappa$ is a colimit of the functors $C_*^{\leqslant n} : \mathrm{Lie}_\kappa \to \mathrm{Mod}_\kappa$. Using Proposition HTT.5.5.2.3 , we are reduced to proving that each of the functors $C_*^{\leqslant n}$ preserves small sifted colimits. We proceed by induction on n, the case $n < 0$ being trivial. Since the field κ has characteristic zero, the construction $V_* \mapsto \mathrm{Sym}_\kappa^n V_*$ preserves quasi-isomorphisms and therefore induces a functor $\mathrm{Sym}_\kappa^n : \mathrm{Mod}_\kappa \to \mathrm{Mod}_\kappa$. Let $\theta : \mathrm{Lie}_\kappa \to \mathrm{Mod}_\kappa$ be the forgetful functor. Using Remark 13.2.1.5 and Corollary HA.1.3.2.16 , we obtain a fiber sequence of functors

$$C_*^{\leqslant n-1} \to C_*^{\leqslant n} \to \mathrm{Sym}_\kappa^n \circ \theta[1]$$

from Lie_κ to Mod_κ. Since $C_*^{\leqslant n-1}$ preserves sifted colimits by the inductive hypothesis and $\theta[1]$ preserves sifted colimits by Proposition 13.1.4.4, it will suffice to show that the functor Sym_κ^n preserves sifted colimits. Since the characteristic of κ is zero, the functor Sym_κ^n is a retract of the functor $V_* \mapsto V_*^{\otimes n}$, which evidently preserves sifted colimits.

We now prove that $C_* : \mathrm{Lie}_\kappa \to (\mathrm{Mod}_\kappa)_{\kappa/}$ preserves finite coproducts. Since C_* preserves initial objects by construction, it will suffice to show that C_* preserves pairwise coproducts. That is, we must show that for every pair of differential graded Lie algebras $\mathfrak{g}_*$ and $\mathfrak{g}'_*$ having a coproduct $\mathfrak{g}''_*$ in Lie_κ, the diagram σ :

$$\begin{array}{ccc} \kappa & \longrightarrow & C_*(\mathfrak{g}_*) \\ \downarrow & & \downarrow \\ C_*(\mathfrak{g}'_*) & \longrightarrow & C_*(\mathfrak{g}''_*) \end{array}$$

is a pushout square in Mod_κ.

Let $\mathrm{Free} : \mathrm{Mod}_\kappa \to \mathrm{Lie}_\kappa$ be a left adjoint to the forgetful functor. Using Proposition HA.4.7.3.14 and Proposition 13.1.4.4, we deduce that $\mathfrak{g}_*$ can be obtained as the geometric realization of a simplicial object $(\mathfrak{g}_*)_\bullet$ of Lie_κ, where each $(\mathfrak{g}_*)_n$ lies in the essential image of Free. Similarly, we can write $\mathfrak{g}'_*$ as the geometric realization of a simplicial object $(\mathfrak{g}'_*)_\bullet$. Then $(\mathfrak{g}''_*)_\bullet$ is the geometric realization of a simplicial object $(\mathfrak{g}''_*)_\bullet$ of Lie_κ, given by $[n] \mapsto (\mathfrak{g}_*)_n \amalg (\mathfrak{g}'_*)_n$. Since the functor C_* commutes with geometric realization of simplicial objects, it will suffice to show that the diagram

$$\begin{array}{ccc} \kappa & \longrightarrow & C_*((\mathfrak{g}_*)_n) \\ \downarrow & & \downarrow \\ C_*((\mathfrak{g}'_*)_n) & \longrightarrow & C_*((\mathfrak{g}''_*)_n) \end{array}$$

is a pushout square in Mod_κ, for each $n \geqslant 0$. We may therefore reduce to the case where $\mathfrak{g}_* \simeq \mathrm{Free}(V_*)$, $\mathfrak{g}'_* \simeq \mathrm{Free}(V'_*)$ for some objects $V_*, V'_* \in \mathrm{Mod}_\kappa$. Then $\mathfrak{g}''_* \simeq \mathrm{Free}(V_* \oplus V'_*)$. Using Proposition 13.2.3.1, we can identify σ with the diagram

$$\begin{array}{ccc} \kappa & \longrightarrow & \kappa \oplus V_*[1] \\ \downarrow & & \downarrow \\ \kappa \oplus V'_*[1] & \longrightarrow & \kappa \oplus V_*[1] \oplus V'_*[1], \end{array}$$

which is evidently a pushout square in the ∞-category Mod_κ. □

13.2.5 The Cohomological Chevalley-Eilenberg Complex

We now turn our attention to the cohomology of (differential graded) Lie algebras.

Construction 13.2.5.1. Let $\mathfrak{g}_*$ be a differential graded Lie algebra over κ. We let $C^*(\mathfrak{g}_*)$ denote the linear dual of the chain complex dual to $C_*(\mathfrak{g}_*)$. We will refer to $C^*(\mathfrak{g}_*)$ as the *cohomological Chevalley-Eilenberg complex* of $\mathfrak{g}_*$. We will identify elements $\lambda \in C^n(\mathfrak{g}_*)$ with the dual space of the degree n part of the graded vector space $\mathrm{Sym}^*_\kappa(\mathfrak{g}_*[1])$.

There is a natural multiplication on $C^*(\mathfrak{g}_*)$, which carries $\lambda \in C^p(\mathfrak{g}_*)$ and $\mu \in C^q(\mathfrak{g}_*)$ to the element $\lambda\mu \in C^{p+q}(\mathfrak{g}_*)$ characterized by the formula

$$(\lambda\mu)(x_1 \ldots x_n) = \sum_{S,S'} \epsilon(S,S')\lambda(x_{i_1} \ldots x_{i_m})\mu(x_{j_1} \ldots x_{j_{n-m}}).$$

Here $x_i \in \mathfrak{g}_{r_i}$ denotes a sequence of homogeneous elements of $\mathfrak{g}_*$, the sum is taken over all disjoint sets $S = \{i_1 < \ldots < i_m\}$ and $S' = \{j_1 < \ldots < j_{n-m}\}$ range with $S \cup S' = \{1, \ldots, n\}$ and $r_{i_1} + \cdots + r_{i_m} = p$, and $\epsilon(S,S') = \prod_{i \in S', j \in S, i<j} (-1)^{r_i r_j}$. With this multiplication, $C^*(\mathfrak{g}_*)$ has the structure of a commutative differential graded algebra over κ.

Remark 13.2.5.2. Let $\mathfrak{g}_*$ be a differential graded Lie algebra over κ. Unwinding the definitions, we can identify $C^*(\mathfrak{g}_*)$ with the chain complex of right $U(\mathfrak{g}_*)$-linear maps from $U(\mathrm{Cn}(\mathfrak{g})_*)$ into κ. Arguing as in Remark 13.2.2.2, we see that $C^*(\mathfrak{g}_*)$ is a model for the right derived mapping complex of right $U(\mathfrak{g}_*)$-module maps from κ to itself.

Remark 13.2.5.3. Let κ be a field of characteristic zero, let V_* be a chain complex of vector spaces over κ, and let $\mathfrak{g}_*$ be the free differential graded Lie algebra generated by V_*. The quasi-isomorphism $\kappa \oplus V_*[1] \to C_*(\mathfrak{g}_*)$ of Proposition 13.2.3.1 induces a quasi-isomorphism of chain complexes $C^*(\mathfrak{g}_*) \to \kappa \oplus V_*^\vee[-1]$, where $V_*^\vee$ denote the dual of the chain complex V_*. In fact, this map is a quasi-isomorphism of commutative differential graded algebras (where we regard $\kappa \oplus V_*^\vee[-1]$ as a trivial square-zero extension of κ).

Notation 13.2.5.4. If the field κ has characteristic zero, Proposition 13.2.2.1 implies that the construction $\mathfrak{g}_* \mapsto C^*(\mathfrak{g}_*)$ carries quasi-isomorphisms of differential graded Lie algebras to quasi-isomorphisms of commutative differential graded algebras. Consequently, we obtain a functor between ∞-categories $\mathrm{Lie}_\kappa \to \mathrm{CAlg}_\kappa^{\mathrm{op}}$, which we will also denote by C^*.

Note that the functor C^* carries the initial object $0 \in \mathrm{Lie}_\kappa$ to the final object $\kappa \in \mathrm{CAlg}_\kappa^{\mathrm{op}}$. We therefore obtain a functor $\mathrm{Lie}_\kappa \to (\mathrm{CAlg}_\kappa^{\mathrm{op}})_{\kappa/} \simeq (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}}$, where $\mathrm{CAlg}_\kappa^{\mathrm{aug}} = (\mathrm{CAlg}_\kappa)_{/\kappa}$ denotes the ∞-category of augmented $\mathbb{E}_\infty$-algebras over κ. We will abuse notation by denoting this functor also by C^*.

Proposition 13.2.5.5. *The functor* $C^* : \mathrm{Lie}_\kappa \to (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}}$ *preserves small colimits.*

Proof. Using Corollary HA.3.2.2.5 , we are reduced to proving that the composite functor

$$\mathrm{Lie}_\kappa \xrightarrow{C^*} (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \longrightarrow (\mathrm{Mod}_\kappa^{\mathrm{op}})_{\kappa/}$$

preserves small colimits. We note that this composition can be identified with the functor

$$\mathrm{Lie}_\kappa \xrightarrow{C_*} (\mathrm{Mod}_\kappa)_{\kappa/} \xrightarrow{D} (\mathrm{Mod}_\kappa^{\mathrm{op}})_{\kappa/},$$

where D is induced by the κ-linear duality functor $V_* \mapsto V_*^\vee$ from $\mathrm{Vect}_\kappa^{\mathrm{dg}}$ to itself. According to Proposition 13.2.4.1, it will suffice to show that D preserves small colimits. Using

Propositions HA.1.3.4.23 , HA.1.3.4.24 , and HA.1.3.4.25 , we are reduced to the problem of showing that the functor $V_* \mapsto V_*^\vee$ carries homotopy colimits in $\mathrm{Vect}_\kappa^{\mathrm{dg}}$ to homotopy limits in $\mathrm{Vect}_\kappa^{\mathrm{dg}}$, which is clear. □

13.3 Koszul Duality

Let κ be a field of characteristic zero and let $C^* : \mathrm{Lie}_\kappa \to (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}}$ be the functor constructed in Notation 13.2.5.4. Proposition 13.2.5.5 implies that C^* preserves small colimits. Since the ∞-category Lie_κ is presentable (Proposition 13.1.4.4), Corollary HTT.5.5.2.9 (and Remark HTT.5.5.2.10) imply that C^* admits a right adjoint $\mathfrak{D} : (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Lie}_\kappa$. We will refer to the functor $\mathfrak{D}$ as *Koszul duality.* The main goal of this section is to prove the following result:

Theorem 13.3.0.1. *Let κ be a field of characteristic zero and let $(\mathrm{CAlg}_\kappa^{\mathrm{aug}}, \{E\})$ be the deformation context of Example 12.1.1.2. Then the Koszul duality functor $\mathfrak{D} : (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Lie}_\kappa$ is a deformation theory (see Definition 12.3.3.2).*

We will then deduce Theorem 13.0.0.2 by combining Theorems 13.3.0.1 and 12.3.3.5.

Remark 13.3.0.2. Let us temporarily distinguish in notation between the functor of ∞-categories $C^* : \mathrm{Lie}_\kappa \to (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}}$ and the functor of ordinary categories $\mathrm{Lie}_\kappa^{\mathrm{dg}} \to (\mathrm{CAlg}_\kappa^{\mathrm{dg}})^{\mathrm{op}}_{/\kappa}$ of Construction **??**, denoting the latter by C^*_{dg}. It follows from Proposition 13.2.5.5 and the adjoint functor theorem that the functor C^* admits a right adjoint, the Koszul duality functor $\mathfrak{D} : (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Lie}_\kappa$. Consequently, the functor C^*_{dg} descends to a functor from the homotopy category of $\mathrm{Lie}_\kappa^{\mathrm{dg}}$ to the homotopy category of $(\mathrm{CAlg}_\kappa^{\mathrm{dg}})^{\mathrm{op}}_{/\kappa}$ which admits a right adjoint. However, the functor C^*_{dg} itself does not admit a right adjoint; in particular, it is not a left Quillen functor. Consequently, it is not so easy to give a concrete description of the functor $\mathfrak{D}$ using the formalism of differential graded Lie algebras. To obtain a more explicit construction of $\mathfrak{D}$, it is convenient to work in the setting of L_∞-algebras. Since we will not need this construction, we do not describe it here.

Remark 13.3.0.3. We will often abuse notation by identifying the Koszul duality functor $\mathfrak{D} : (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Lie}_\kappa$ with the induced functor between opposite ∞-categories $\mathrm{CAlg}_\kappa^{\mathrm{aug}} \to \mathrm{Lie}_\kappa^{\mathrm{op}}$.

13.3.1 The Double Dual

To prove Theorem 13.3.0.1, we must show that the adjunction $\mathrm{Lie}_\kappa \underset{\mathfrak{D}}{\overset{C^*}{\rightleftarrows}} (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}}$ is not too far from being an equivalence of ∞-categories. More precisely, we have the following result:

Proposition 13.3.1.1. *Let $\mathfrak{g}_*$ be a differential graded Lie algebra over a field κ of characteristic zero. Assume that:*

(a) *For every integer n, the vector space $\mathfrak{g}_n$ is finite dimensional.*

(b) *The vector space $\mathfrak{g}_n$ is trivial for $n \geqslant 0$.*

Then the unit map $u : \mathfrak{g}_* \to \mathfrak{D}C^*(\mathfrak{g})$ is an equivalence in Lie_κ.

The proof of Proposition 13.3.1.1 will require some preliminaries.

Notation 13.3.1.2. Let $F : (\mathrm{Vect}_\kappa^{\mathrm{dg}})^{\mathrm{op}} \to \mathrm{Vect}_\kappa^{\mathrm{dg}}$ be the functor between ordinary categories which carries each chain complex (V_*, d) to the dual chain complex $(V_*^\vee, d^\vee)$, where $V_n^\vee = \mathrm{Hom}_\kappa(V_{-n}, \kappa)$ and the differential $d^\vee$ is characterized by the formula $d^\vee(\lambda)(v) + (-1)^n \lambda(dv) = 0$ for $\lambda \in V_n^\vee$. The construction $V_* \mapsto V_*^\vee$ preserves quasi-isomorphisms and therefore induces a functor $\mathrm{Mod}_\kappa^{\mathrm{op}} \to \mathrm{Mod}_\kappa$, which we will denote by $V \mapsto V^\vee$. We will refer to this functor as *κ-linear duality.*

Remark 13.3.1.3. For every pair of κ-module spectra $V, W \in \mathrm{Mod}_\kappa$, we have canonical homotopy equivalences

$$\mathrm{Map}_{\mathrm{Mod}_\kappa}(V, W^\vee) \simeq \mathrm{Map}_{\mathrm{Mod}_\kappa}(V \otimes W, \kappa) \simeq \mathrm{Map}_{\mathrm{Mod}_\kappa}(W, V^\vee).$$

It follows that κ-linear duality, when regarded as a functor $\mathrm{Mod}_\kappa \to \mathrm{Mod}_\kappa^{\mathrm{op}}$, is canonically equivalent to the left adjoint of the κ-linear duality functor $\mathrm{Mod}_\kappa^{\mathrm{op}} \to \mathrm{Mod}_\kappa$.

Let us now study the composite functor $(\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \xrightarrow{\mathfrak{D}} \mathrm{Lie}_\kappa \xrightarrow{\theta} \mathrm{Mod}_\kappa$, where θ denotes the forgetful functor. This composition admits a left adjoint $\mathrm{Mod}_\kappa \xrightarrow{\mathrm{Free}} \mathrm{Lie}_\kappa \xrightarrow{C^*} (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}}$, which is in turn induced by the map of ordinary categories $\mathrm{Vect}_\kappa^{\mathrm{dg}} \to \mathrm{CAlg}_\kappa^{\mathrm{dg}}$ given by $V_* \mapsto C^*(\mathrm{Free}(V_*))$. Remark 13.2.5.3 supplies a (functorial) quasi-isomorphism of commutative differential graded algebras $C^*(\mathrm{Free}(V_*)) \to \kappa \oplus V_*^\vee[-1]$. It follows that the underlying functor of ∞-categories $\mathrm{Mod}_\kappa \to (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}}$ is given by composing the κ-linear duality functor $\mathrm{Mod}_\kappa \to \mathrm{Mod}_\kappa^{\mathrm{op}}$ with the functor $\mathrm{Mod}_\kappa^{\mathrm{op}} \to (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}}$ given by the formation of square-zero extensions $M \mapsto \kappa \oplus \Sigma^{-1} M$. Both of these functors admit left adjoints: in the first case, the left adjoint is given by κ-linear duality (Remark 13.3.1.3), and in the second it is given by the formation of the relative cotangent complex $A \mapsto \Sigma^{-1}(L_{A/\kappa} \otimes_A \kappa) \simeq L_{\kappa/A}$ respectively. We have proven:

Proposition 13.3.1.4. *Let κ be a field of characteristic zero and let $\theta : \mathrm{Lie}_\kappa \to \mathrm{Mod}_\kappa$ be the forgetful functor. Then the composite functor $(\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \xrightarrow{\mathfrak{D}} \mathrm{Lie}_\kappa \xrightarrow{\theta} \mathrm{Mod}_\kappa$ is given on objects by $A \mapsto L_{\kappa/A}^\vee$.*

To prove Proposition 13.3.1.1, we need to analyze the unit map $\mathfrak{g}_* \to \mathfrak{D}C^*(\mathfrak{g}_*)$ associated to a differential graded Lie algebra $\mathfrak{g}_*$. We begin with a few preliminary remarks regarding explicit models for the cotangent fiber of a commutative differential graded algebra.

Definition 13.3.1.5. Let A_* be a commutative differential graded algebra over κ equipped with an augmentation $u : A_* \to \kappa$. The kernel of u is an ideal $\mathfrak{m}_A \subseteq A_*$. We let $\mathrm{Indec}(A)_*$ denote the quotient $\mathfrak{m}_A/\mathfrak{m}_A^2$, which we regard as a complex of κ-vector spaces. We will refer to $\mathrm{Indec}(A)_*$ as the *chain complex of indecomposables in* A_*.

Remark 13.3.1.6. The construction $V_* \mapsto \kappa \oplus V_*$ determines a right Quillen functor from $\mathrm{Vect}_\kappa^{\mathrm{dg}}$ to $(\mathrm{CAlg}_\kappa^{\mathrm{dg}})_{/\kappa}$, whose left adjoint is given by $A_* \mapsto \mathrm{Indec}(A)_*$. It follows that the functor $\mathrm{Indec}(A)_*$ preserves weak equivalences between cofibrant objects of $(\mathrm{CAlg}_\kappa^{\mathrm{dg}})_{/\kappa}$, and induces a functor of ∞-categories $\mathrm{CAlg}_\kappa^{\mathrm{aug}} \to \mathrm{Mod}_\kappa$. This functor is evidently left adjoint to the formation of trivial square-zero extensions, and is therefore given by $A \mapsto L_{A/\kappa} \otimes_A \kappa \simeq \Sigma^{-1} L_{\kappa/A}$. It follows that for every cofibrant augmented commutative differential graded algebra A_*, the canonical map $A_* \to \kappa \oplus \mathrm{Indec}(A)_*$ induces an equivalence $\Sigma^{-1} L_{\kappa/A_*} \simeq L_{A_*/\kappa} \otimes_{A_*} \kappa \to \mathrm{Indec}(A)_*$ in Mod_κ (here we abuse notation by identifying A_* with its image in the ∞-category $\mathrm{CAlg}_\kappa^{\mathrm{aug}}$).

Proof of Proposition 13.3.1.1. Let $\mathfrak{g}_*$ be a differential graded Lie algebra which is concentrated in negative degrees and finite-dimensional in each degree. We wish to show that the unit map $\mathfrak{g}_* \to \mathfrak{D}C^*(\mathfrak{g})$ is an equivalence in the ∞-category Lie_κ. Since the forgetful functor $\mathrm{Lie}_\kappa \to \mathrm{Mod}_\kappa$ is conservative, it will suffice to show that u induces an equivalence $\mathfrak{g}_* \to L^\vee_{\kappa/C^*(\mathfrak{g}_*)}$ in Mod_κ (see Proposition 13.3.1.4). This map admits a predual $u^\vee : L_{C^*(\mathfrak{g}_*)/\kappa} \otimes_{C^*(\mathfrak{g})} \kappa \to \Sigma^{-1} \mathfrak{g}_*^\vee$. We will prove that $u^\vee$ is an equivalence.

Consider the isomorphism of graded vector spaces $C^*(\mathfrak{g}_*) \simeq \prod_{n \geqslant 0} (\mathrm{Sym}^n_\kappa \mathfrak{g}_*[1])^\vee$. Choose a basis $\{y_1, \ldots, y_p\}$ for the vector space $\mathfrak{g}_{-1}$, and let $\{x_1, \ldots, x_p\}$ be the dual basis for $\mathfrak{g}_1^\vee$, so that $C^0(\mathfrak{g}_*)$ can be identified with the power series ring $\kappa[[x_1, \ldots, x_p]]$. Let $A_* = \bigoplus_{n \geqslant 0} (\mathrm{Sym}^n_\kappa(\mathfrak{g}_*[1]))^\vee$, and regard A_* as a graded subalgebra of $C^*(\mathfrak{g}_*)$. It is easy to see that A_* is a differential graded subalgebra of $C^*(\mathfrak{g}_*)$, and that A_0 contains the polynomial ring $\kappa[x_1, \ldots, x_p]$. Using (a) and (b), we deduce that A_* is a graded polynomial ring generated by $g_*^\vee[-1]$, and that the natural map

$$A_* \otimes_{\kappa[x_1, \ldots, x_p]} \kappa[[x_1, \ldots, x_p]] \to C^*(\mathfrak{g}_*)$$

is an isomorphism of commutative differential graded algebras. Since $\kappa[[x_1, \ldots, x_p]]$ is flat over $\kappa[x_1, \ldots, x_p]$, it follows that for each $n \in \mathbf{Z}$ we have an isomorphism in homology

$$\mathrm{H}_n(A_*) \otimes_{\kappa[x_1, \ldots, x_p]} \kappa[[x_1, \ldots, x_p]] \to \mathrm{H}_n(C^*(\mathfrak{g}_*)),$$

so that the diagram

$$\begin{array}{ccc} \kappa[x_1, \ldots, x_p] & \longrightarrow & \kappa[[x_1, \ldots, x_p]] \\ \downarrow & & \downarrow \\ A_* & \longrightarrow & C^*(\mathfrak{g}_*) \end{array}$$

is a pushout square in the ∞-category CAlg_κ. We therefore obtain equivalences

$$L_{C^*(\mathfrak{g}_*)/A_*} \otimes_{C^*(\mathfrak{g}_*)} \kappa \simeq L_{\kappa[[x_1,\ldots,x_p]]/\kappa[x_1,\ldots,x_p]} \otimes_{\kappa[[x_1,\ldots,x_p]]} \kappa \simeq L_{R/\kappa} \simeq 0.$$

where R denotes the tensor product $\kappa[[x_1, \ldots, x_p]] \otimes_{\kappa[x_1,\ldots,x_p]} \kappa \simeq \kappa$. It follows that u can be identified with the map $L_{A_*/\kappa} \otimes_{A_*} \kappa \to \Sigma^{-1}\mathfrak{g}_*^\vee$ which classifies the morphism $A_* \to \kappa \oplus \mathfrak{g}_*^\vee[-1] \simeq \kappa \oplus \mathrm{Indec}(A)_*$. Since A_* is a cofibrant differential graded algebra, Remark 13.3.1.6 implies that u is an equivalence in Mod_κ. □

13.3.2 The Main Theorem

The first step in our proof of Theorem 13.3.0.1 is to show that the Koszul duality functor $\mathfrak{D} : (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Lie}_\kappa$ is a weak deformation theory: that is, it satisfies axioms $(D1)$, $(D2)$, and $(D3)$ of Definition 12.3.1.1. Axioms $(D1)$ and $(D2)$ are easy: we have already seen that Lie_κ is presentable (Proposition 13.1.4.4), and the functor $\mathfrak{D}$ admits a left adjoint by construction. Axiom $(D3)$ is a consequence of the following more precise assertion:

Proposition 13.3.2.1. *Let κ be a field of characteristic zero and let $\mathfrak{g}_*$ be a differential graded Lie algebra over κ. We will say that $\mathfrak{g}_*$ is good if it is cofibrant (with respect to the model structure on $\mathrm{Lie}_\kappa^{\mathrm{dg}}$ described in Proposition 13.1.3.2) and there exists a graded vector subspace $V_* \subseteq \mathfrak{g}_*$ satisfying the following conditions:*

(i) For every integer n, the vector space V_n is finite dimensional.

(ii) For every nonnegative integer n, the vector space V_n is trivial.

(iii) The graded vector space V_* freely generates $\mathfrak{g}_*$ as a graded Lie algebra.

Let $\mathcal{C}$ be the full subcategory of Lie_κ spanned by those objects which can be represented by good objects of $\mathrm{Lie}_\kappa^{\mathrm{dg}}$. Then $\mathcal{C}$ satisfies conditions (a), (b), (c), and (d) of Definition 12.3.1.1.

Proof. We verify each condition in turn:

(a) Let $\mathfrak{g}_* \in \mathcal{C}$; we wish to prove that the unit map $\mathfrak{g}_* \to \mathfrak{D}C^*(\mathfrak{g})$ is an equivalence in Lie_κ. We may assume without loss of generality that $\mathfrak{g}_*$ is good, so there is a graded subspace $V_* \subseteq \mathfrak{g}_*$ satisfying conditions (i), (ii), and (iii). As a graded vector space, $\mathfrak{g}_*$ is isomorphic to a direct summand of the augmentation ideal in $U(\mathfrak{g}) \simeq \bigoplus_{n \geqslant 0} V_*^{\otimes n}$. It follows that each $\mathfrak{g}_n$ is finite dimensional, and that $\mathfrak{g}_n \simeq 0$ for $n \geqslant 0$. The desired result now follows from Proposition 13.3.1.1.

(b) The initial object $0 \in \mathrm{Lie}_\kappa$ obviously belongs to $\mathcal{C}$.

(c) We must show that for each $n \geqslant 0$, the square-zero algebra $\kappa \oplus \Sigma^n(\kappa) \in \mathrm{CAlg}_\kappa^{\mathrm{aug}}$ is equivalent to $C^*(\mathfrak{g})$ for some object $\mathfrak{g}_* \in \mathcal{C}$. In fact, we can take $\mathfrak{g}_*$ to be the differential graded Lie algebra freely generated by the complex $\kappa[-n-1]$ (see Remark 13.2.5.3).

(d) Suppose that $n \leqslant -2$ and that we are given a pushout diagram

$$\begin{array}{ccc} \mathrm{Free}(\kappa[n]) & \xrightarrow{\alpha} & \mathfrak{g}_* \\ \downarrow{\scriptstyle v} & & \downarrow \\ 0 & \longrightarrow & \mathfrak{g}'_* \end{array}$$

in the ∞-category Lie_κ. Here $\mathrm{Free} : \mathrm{Mod}_\kappa \to \mathrm{Lie}_\kappa$ denotes the left adjoint to the forgetful functor. We wish to show that if $\mathfrak{g}_* \in \mathcal{C}$, then $\mathfrak{g}'_* \in \mathcal{C}$. We may assume without loss of generality that $\mathfrak{g}_*$ is good. Since $\mathrm{Free}(\kappa[n])$ is a cofibrant object of $\mathrm{Lie}_\kappa^{\mathrm{dg}}$ and $\mathfrak{g}_*$ is fibrant, we can assume that α is given by a morphism $\mathrm{Free}(\kappa[n]) \to \mathfrak{g}_*$ in the category $\mathrm{Lie}_\kappa^{\mathrm{dg}}$ (determined by a cycle $x \in \mathfrak{g}_n$). The morphism v in $\mathrm{Lie}\,\kappa$ is represented by the cofibration of differential graded Lie algebras $j : \mathrm{Free}(\partial\, E(n+1)_*) \hookrightarrow \mathrm{Free}(E(n+1)_*)$ (see the proof of Proposition 13.1.3.2). Form a pushout diagram σ :

$$\begin{array}{ccc} \mathrm{Free}(\partial\, E(n)_*) & \longrightarrow & \mathfrak{g}_* \\ \downarrow{\scriptstyle j} & & \downarrow{\scriptstyle j'} \\ \mathrm{Free}(E(n+1)_*) & \longrightarrow & \mathfrak{h}_*. \end{array}$$

Since j is a cofibration and $\mathfrak{g}_*$ is cofibrant, σ is a homotopy pushout diagram in $\mathrm{Lie}_\kappa^{\mathrm{dg}}$, so that $\mathfrak{h}_*$ and $\mathfrak{g}'_*$ are equivalent in Lie_κ (Proposition HA.1.3.4.24). It will therefore suffice to show that the object $\mathfrak{h}_* \in \mathrm{Lie}_\kappa^{\mathrm{dg}}$ is good.

The differential graded Lie algebra $\mathfrak{h}_*$ is cofibrant by construction. Let $V_* \subseteq \mathfrak{g}$ be a subspace satisfying conditions (i), (ii), and (iii), and let $y \in \mathfrak{h}_{n+1}$ be the image of a generator of $E(n+1)_{n+1}$. Let V'_* be the graded subspace of $\mathfrak{h}_*$ generated by V_* and y. It is trivial to verify that V'_* satisfies conditions (i), (ii), and (iii).

□

Proof of Theorem 13.3.0.1. Proposition 13.3.2.1 shows that the functor $\mathfrak{D} : (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Lie}_\kappa$ is a weak deformation theory. We will show that it satisfies axiom (D4) of Definition 12.3.3.2. Let $E \in \mathrm{Sp}(\mathrm{CAlg}_\kappa^{\mathrm{aug}})$ be the spectrum object of Example 12.1.1.2, so that $\Omega^{\infty-n}E \simeq \kappa \oplus \Sigma^n(\kappa)$. The proof of Proposition 13.3.2.1 shows that $\mathfrak{D}(E)$ is given by the infinite loop object $\{\mathrm{Free}(\kappa[-n-1])\}_{n\geqslant 0}$ in $\mathrm{Lie}_\kappa^{\mathrm{op}}$; here $\mathrm{Free} : \mathrm{Mod}_\kappa \to \mathrm{Lie}_\kappa$ denotes a left adjoint to the forgetful functor $\theta : \mathrm{Lie}_\kappa \to \mathrm{Mod}_\kappa$. It follows that the functor $e : \mathrm{Lie}_\kappa \to \mathrm{Sp}$

appearing in Definition 12.3.3.2 is given by $\Sigma(F \circ \theta)$, where $F : \mathrm{Mod}_\kappa = \mathrm{Mod}_\kappa(\mathrm{Sp}) \to \mathrm{Sp}$ and $\theta : \mathrm{Lie}_\kappa \to \mathrm{Mod}_\kappa$ are the forgetful functors. Since F is conservative and commutes with all colimits, it will suffice to observe that θ is conservative (which is obvious) and preserves sifted colimits (Proposition 13.1.4.4). □

Proof of Theorem 13.0.0.2. Let κ be a field of characteristic zero, and let $\Psi : \mathrm{Lie}_\kappa \to \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{art}}_\kappa, \mathcal{S})$ denote the functor given on objects by the formula

$$\Psi(\mathfrak{g}_*)(R) = \mathrm{Map}_{\mathrm{Lie}_\kappa}(\mathfrak{D}(R), \mathfrak{g}_*).$$

Combining Theorems 13.3.0.1 and 12.3.3.5, we deduce that Ψ is a fully faithful embedding whose essential image is the full subcategory $\mathrm{Moduli}_\kappa \subseteq \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{art}}_\kappa, \mathcal{S})$ spanned by the formal moduli problems. Let $X \mapsto T_X$ denote tangent complex functor $\mathrm{Moduli}_\kappa \to \mathrm{Sp}$, given by evaluation on the spectrum object $E \in \mathrm{Sp}(\mathrm{CAlg}^{\mathrm{art}}_\kappa)$ appearing in Example 12.1.1.2. Then the functor $\mathfrak{g}_* \mapsto \Sigma^{-1} T_{\Psi(\mathfrak{g}_*)}$ coincides with the functor $\Sigma^{-1} e$, where $e : \mathrm{Lie}_\kappa \to \mathrm{Sp}$ is the functor appearing in Definition 12.3.3.2. The proof of Theorem 13.3.0.1 supplies an equivalence of $\Sigma^{-1} e$ with the forgetful functor $\mathrm{Lie}_\kappa \to \mathrm{Mod}_\kappa = \mathrm{Mod}_\kappa(\mathrm{Sp}) \to \mathrm{Sp}$. □

13.3.3 Classification of Prorepresentable Formal Moduli Problems

We close this section with an application of Theorem 13.3.0.1.

Proposition 13.3.3.1. *Let κ be a field of characteristic zero and let $X : \mathrm{CAlg}^{\mathrm{art}}_\kappa \to \mathcal{S}$ be a formal moduli problem. Then following conditions are equivalent:*

(1) *The formal moduli problem X is prorepresentable (see Definition 12.5.3.1).*

(2) *Let T_X denote the tangent complex of X. Then $\pi_i T_X \simeq 0$ for $i > 0$.*

Proof. Suppose first that X is prorepresentable; we wish to show that the homotopy groups $\pi_i T_X$ vanish for $i > 0$. The construction $X \mapsto \pi_i T_X$ commutes with filtered colimits. It will therefore suffice to show that $\pi_i T_X \simeq 0$ when $X = \mathrm{Spf}\, A$ is the the functor corepresented by an object $A \in \mathrm{CAlg}^{\mathrm{art}}_\kappa$. This is clear: the homotopy group $\pi_i T_X \simeq \pi_i \mathrm{Map}_{\mathrm{CAlg}^{\mathrm{aug}}_\kappa}(A, \kappa[\epsilon]/(\epsilon^2))$ vanishes because A is connective and $\kappa[\epsilon]/(\epsilon^2)$ is discrete.

We now prove the converse. Let X be a formal moduli problem such that $\pi_i T_X \simeq 0$ for $i > 0$; we wish to prove that X is prorepresentable. Let $\Psi : \mathrm{Lie}_\kappa \to \mathrm{Moduli}_\kappa$ be the equivalence of ∞-categories of Theorem 13.0.0.2. Then we can assume that $X = \Psi(\mathfrak{g}_*)$ for some differential graded Lie algebra $\mathfrak{g}_*$ satisfying $\mathrm{H}_i(\mathfrak{g}_*) \simeq 0$ for $i \geqslant 0$ (here we let $\mathrm{H}_i(\mathfrak{g}_*)$ denote the ith homology group of the underlying chain complex of $\mathfrak{g}_*$, rather than the Lie algebra homology of $\mathfrak{g}_*$ computed by the Chevalley-Eilenberg complex $C_*(\mathfrak{g}_*)$ of §13.2).

We will construct a sequence of differential graded Lie algebras

$$0 = \mathfrak{g}(0)_* \to \mathfrak{g}(1)_* \to \mathfrak{g}(2)_* \to \cdots$$

equipped with maps $\phi(i) : \mathfrak{g}(i)_* \to \mathfrak{g}_*$. For every integer n, choose a graded subspace $V_n \subseteq \mathfrak{g}_n$ consisting of cycles which maps isomorphically onto the homology $\mathrm{H}_n(\mathfrak{g}_*)$. Then we can regard V_* as a differential graded vector space with trivial differential. Let $\mathfrak{g}(1)_*$ denote the free differential graded Lie algebra generated by V_*, and $\phi(1) : \mathfrak{g}(1)_* \to \mathfrak{g}_*$ the canonical map. Assume now that $i \geqslant 1$ and that we have constructed a map $\phi(i) : \mathfrak{g}(i)_* \to \mathfrak{g}_*$ extending $\phi(1)$. Then $\phi(i)$ induces a surjection $\theta : \mathrm{H}_n(\mathfrak{g}(i)_*) \to \mathrm{H}_*(\mathfrak{g}_*)$. Choose a collection of cycles $x_\alpha \in \mathfrak{g}(i)_{n_\alpha}$ whose images form a basis for $\ker(\theta)$. Then we can write $\phi(i)(x_\alpha) = dy_\alpha$ for some $y_\alpha \in \mathfrak{g}_{n_\alpha+1}$. Let $\mathfrak{g}(i+1)_*$ be the differential graded Lie algebra obtained from $\mathfrak{g}(i)_*$ by freely adjoining elements Y_α (in degrees $n_\alpha + 1$) satisfying $dY_\alpha = x_\alpha$. We let $\phi(i+1) : \mathfrak{g}(i+1)_* \to \mathfrak{g}_*$ denote the unique extension of $\phi(i)$ satisfying $\phi(i+1)(Y_\alpha) = y_\alpha$.

We will establish the following assertion for each integer $i \geqslant 1$:

$(*_i)$ The inclusion $V_{-1} \hookrightarrow \mathfrak{g}(i)_{-1}$ induces an isomorphism $V_{-1} \to \mathrm{H}_{-1}(\mathfrak{g}(i)_*)$, and the groups $\mathfrak{g}(i)_n$ vanish for $n \geqslant 0$.

Assertion $(*_i)$ is easy when $i = 1$. Let us assume that $(*_i)$ holds, and let θ be defined as above. Then θ is an isomorphism in degrees $\geqslant -1$, so that $\mathfrak{g}(i+1)_*$ is obtained from $\mathfrak{g}(i)_*$ by freely adjoining generators Y_α in degrees $\leqslant -1$. It follows immediately that $\mathfrak{g}(i+1)_n \simeq 0$ for $n \geqslant 0$. Moreover, we can write $\mathfrak{g}(i+1)_{-1} \simeq \mathfrak{g}(i)_{-1} \oplus W$, where W is the subspace spanned by elements of the form Y_α where $n_\alpha = -2$. By construction, the differential on $\mathfrak{g}(i+1)_*$ induces a monomorphism from W to the quotient $\mathfrak{g}(i)_{-2}/d\mathfrak{g}(i)_{-1} \subseteq \mathfrak{g}(i+1)_{-2}/d\mathfrak{g}(i)_{-1}$, so that the Lie algebras $\mathfrak{g}(i+1)_*$ and $\mathfrak{g}(i)_*$ have the same homology in degree -1.

Let $\mathfrak{g}'_*$ denote the colimit of the sequence $\{\mathfrak{g}(i)_*\}_{i \geqslant 0}$. The evident map $\mathfrak{g}'_* \to \mathfrak{g}_*$ is surjective on homology (since the map $\mathfrak{g}(1)_* \to \mathfrak{g}_*$ is surjective on homology). If $\eta \in \ker(\mathrm{H}_*(\mathfrak{g}'_*) \to \mathrm{H}_*(\mathfrak{g}_*)$, then η is represented by a class $\overline{\eta} \in \ker(\mathrm{H}_*(\mathfrak{g}(i)_*) \to \mathrm{H}_*(\mathfrak{g}_*))$ for $i \gg 0$. By construction, the image of $\overline{\eta}$ vanishes in $\mathrm{H}_*(\mathfrak{g}(i+1)_*)$, so that $\eta = 0$. It follows that the map $\mathfrak{g}'_* \to \mathfrak{g}_*$ is a quasi-isomorphism. Since the collection of quasi-isomorphisms in $\mathrm{Lie}_\kappa^{\mathrm{dg}}$ is closed under filtered colimits, we conclude that $\mathfrak{g}_*$ is a homotopy colimit of the sequence $\{\mathfrak{g}(i)_*\}_{i \geqslant 0}$ in the model category $\mathrm{Lie}_\kappa^{\mathrm{dg}}$, and therefore a colimit of $\{\mathfrak{g}(i)_*\}_{i \geqslant 0}$ in the ∞-category Lie_κ. Setting $X(i) = \Psi(\mathfrak{g}(i)_*) \in \mathrm{Moduli}_\kappa$, we deduce that $X \simeq \varinjlim X(i)$. To prove that X is prorepresentable, it will suffice to show that each $X(i)$ is prorepresentable.

We now proceed by induction on i, the case $i = 0$ being trivial. To carry out the inductive step, we note that each of the Lie algebras $\mathfrak{g}(i+1)_*$ is obtained from $\mathfrak{g}(i)_*$ by freely adjoining a set of generators $\{Y_\alpha\}_{\alpha \in A}$ of degrees $n_\alpha + 1 \leqslant -1$, satisfying $dY_\alpha = x_\alpha \in \mathfrak{g}(i)_{n_\alpha}$ (this is obvious when $i = 0$, and follows from $(*_i)$ when $i > 0$). Choose a well-ordering of the set A. For each $\alpha \in A$, we let $\mathfrak{g}_*^{<\alpha}$ denote the Lie subalgebra of $\mathfrak{g}(i+1)_*$ generated by $\mathfrak{g}(i)_*$ and the elements Y_β for $\beta < \alpha$, and let $\mathfrak{g}_*^{\leqslant\alpha}$ be defined similarly. Set $X^{<\alpha} = \Psi(\mathfrak{g}_*^{<\alpha})$ and $X^{\leqslant\alpha} = \Psi(\mathfrak{g}_*^{\leqslant\alpha})$. For each $\alpha \in A$, we have a homotopy pushout diagram of differential graded

Lie algebras

$$\begin{array}{ccc} \mathrm{Free}(\partial E(n_\alpha+1)_*) & \longrightarrow & \mathrm{Free}(E(n_\alpha+1)_*) \\ \downarrow & & \downarrow \\ \mathfrak{g}_*^{<\alpha} & \longrightarrow & \mathfrak{g}_*^{\leqslant\alpha}, \end{array}$$

hence a pushout diagram of formal moduli problems

$$\begin{array}{ccc} \mathrm{Spf}(\kappa \oplus \Sigma^{n_\alpha+1}\kappa) & \longrightarrow & \mathrm{Spf}(\kappa) \\ \downarrow & & \downarrow \\ X^{<\alpha} & \longrightarrow & X^{\leqslant\alpha}. \end{array}$$

It follows that the map $X(i) \to X(i+1)$ satisfies the criterion of Lemma 12.5.3.4. Since $X(i)$ is prorepresentable, we conclude that $X(i+1)$ is prorepresentable. □

13.4 Quasi-Coherent Sheaves

Let κ be a field and let $X : \mathrm{CAlg}_\kappa^{\mathrm{art}} \to \mathcal{S}$ be a formal moduli problem over κ. Following the ideas introduced in §6.2, we can define a symmetric monoidal ∞-category $\mathrm{QCoh}(X)$ of *quasi-coherent sheaves* on X. Roughly speaking, a quasi-coherent sheaf $\mathscr{F}$ on X is a rule which assigns to each point $\eta \in X(R)$ an R-module $\eta^* \mathscr{F} \in \mathrm{Mod}_R$, which is functorial in the following sense: if $\phi : R \to R'$ is a morphism in $\mathrm{CAlg}_\kappa^{\mathrm{art}}$ and η' denotes the image of η in $X(R')$, then there is an equivalence $\eta'^* \mathscr{F} \simeq R' \otimes_R \eta^* \mathscr{F}$ in the ∞-category $\mathrm{Mod}_{R'}$.

If the field κ has characteristic zero, Theorem 13.0.0.2 provides an equivalence of ∞-categories $\Psi : \mathrm{Lie}_\kappa \to \mathrm{Moduli}_\kappa$. In particular, every formal moduli problem X is equivalent to $\Psi(\mathfrak{g}_*)$, for some differential graded Lie algebra $\mathfrak{g}_*$ which is well-defined up to quasi-isomorphism. In this section, we will explore the relationship between $\mathfrak{g}_*$ and the ∞-category $\mathrm{QCoh}(X)$. Our main result is the following:

Theorem 13.4.0.1. *Let κ be a field of characteristic zero, let $\mathfrak{g}_*$ be a differential graded Lie algebra over κ, and let $X = \Psi(\mathfrak{g}_*)$ be the associated formal moduli problem. Then there is a fully faithful symmetric monoidal embedding $\mathrm{QCoh}(X) \hookrightarrow \mathrm{Rep}_{\mathfrak{g}_*}$, where $\mathrm{Rep}_{\mathfrak{g}_*}$ denotes the ∞-category of representations of $\mathfrak{g}_*$ (see Notation 13.4.1.4).*

Remark 13.4.0.2. It follows from Theorem 13.4.0.1 that the ∞-category $\mathrm{Rep}_{\mathfrak{g}_*}$ can be regarded as a (symmetric monoidal) *enlargement* of the ∞-category $\mathrm{QCoh}(X)$ of quasi-coherent sheaves on the formal moduli problem determined by $\mathfrak{g}_*$. This enlargement can be described geometrically as the ∞-category of Ind-coherent sheaves on X. We refer the reader to §14.5 for a discussion of Ind-coherent sheaves in the noncommutative setting, and to §14.6 for a noncommutative analogue of Theorem 13.4.0.1.

13.4.1 Representations of Lie Algebras

We begin by reviewing some definitions.

Definition 13.4.1.1. Let κ be a field of characteristic zero and let $\mathfrak{g}_*$ be a differential graded Lie algebra over κ. A *representation* of $\mathfrak{g}_*$ is a differential graded vector space V_* equipped with a map $\mathfrak{g}_* \otimes_\kappa V_* \to V_*$ satisfying the identity $[x,y]v = x(yv) + (-1)^{pq} y(xv)$ for all $x \in \mathfrak{g}_p$, $y \in \mathfrak{g}_q$, and $v \in V_r$. The representations of $\mathfrak{g}_*$ form a category which we will denote by $\mathrm{Rep}^{\mathrm{dg}}_{\mathfrak{g}_*}$.

Example 13.4.1.2. For every differential graded vector space V_*, the zero map $\mathfrak{g}_* \otimes_\kappa V_* \to V_*$ exhibits V_* as a representation of $\mathfrak{g}_*$. In particular, taking $V_* = \kappa$ (regarded as a graded vector space concentrated in degree zero), we obtain a representation of $\mathfrak{g}_*$ on κ which we call the *trivial representation*.

Note that a representation of a differential graded Lie algebra $\mathfrak{g}_*$ is the same data as a (left) module over the universal enveloping algebra $U(\mathfrak{g}_*)$. Using Proposition HA.4.3.3.15 , we deduce the following:

Proposition 13.4.1.3. *Let $\mathfrak{g}_*$ be a differential graded Lie algebra over a field κ. Then the category $\mathrm{Rep}^{\mathrm{dg}}_{\mathfrak{g}_*}$ of representations of $\mathfrak{g}_*$ admits a combinatorial model structure, where:*

(W) *A map $f : V_* \to W_*$ of representations of $\mathfrak{g}_*$ is a weak equivalence if and only if it induces an isomorphism on homology.*

(F) *A map $f : V_* \to W_*$ of representations of $\mathfrak{g}_*$ is a fibration if and only if it is degreewise surjective.*

Notation 13.4.1.4. If $\mathfrak{g}_*$ is a differential graded Lie algebra over a field κ, we let $W_{\mathfrak{g}_*}$ denote the collection of all weak equivalences in $\mathrm{Rep}^{\mathrm{dg}}_{\mathfrak{g}_*}$, and we let $\mathrm{Rep}_{\mathfrak{g}_*} = \mathrm{Rep}^{\mathrm{dg}}_{\mathfrak{g}_*}[W^{-1}_{\mathfrak{g}_*}]$ denote the ∞-category obtained from $\mathrm{Rep}^{\mathrm{dg}}_{\mathfrak{g}_*}$ by formally inverting all quasi-isomorphisms: that is, the underlying ∞-category of the model category described in Proposition 13.4.1.3.

It follows from Theorem HA.4.3.3.17 that we can identify $\mathrm{Rep}_{\mathfrak{g}_*}$ with the ∞-category $\mathrm{LMod}_{U(\mathfrak{g}_*)}$ of left modules over the universal enveloping algebra $U(\mathfrak{g}_*)$ (which we regard as an $\mathbb{E}_1$-ring). In particular, $\mathrm{Rep}_{\mathfrak{g}_*}$ is a stable ∞-category.

13.4.2 Cohomology with Coefficients

Let $\mathfrak{g}_*$ be a differential graded Lie algebra over a field κ and let V_* be a representation of $\mathfrak{g}_*$. We let $C^*(\mathfrak{g}_*; V_*)$ denote the differential graded vector space of $U(\mathfrak{g}_*)$-module maps from $U(\mathrm{Cn}(\mathfrak{g})_*)$ into V_*. We will refer to $C^*(\mathfrak{g}_*; V_*)$ as the *cohomological Chevalley-Eilenberg complex of $\mathfrak{g}_*$ with coefficients in V_*.*

Remark 13.4.2.1. Unwinding the definitions, we see that the graded pieces $C^n(\mathfrak{g}_*; V_*)$ can be identified with the set of graded vector space maps $\mathrm{Sym}^*_\kappa(\mathfrak{g}_*[1]) \to V_*[-n]$.

We note that $C^*(\mathfrak{g}_*; V_*)$ has the structure of a module over the differential graded algebra $C^*(\mathfrak{g}_*)$. The action is given by κ-bilinear maps

$$C^p(\mathfrak{g}_*) \times C^q(\mathfrak{g}_*; V_*) \to C^{p+q}(\mathfrak{g}_*; V_*),$$

which carries a class $\lambda \in C^p(\mathfrak{g}_*)$ and $\mu \in C^q(\mathfrak{g}_*; V_*)$ to the element $\lambda\mu \in C^{p+q}(\mathfrak{g}_*; V_*)$ given by the formula

$$(\lambda\mu)(x_1 \ldots x_n) = \sum_{S,S'} \epsilon(S, S')\lambda(x_{i_1} \ldots x_{i_m})\mu(x_{j_1} \ldots x_{j_{n-m}}),$$

as in Construction 13.2.5.1.

Remark 13.4.2.2. It follows from general nonsense that the (differential graded) endomorphism ring of the functor $C^*(\mathfrak{g}_*; \bullet) : \mathrm{Rep}^{\mathrm{dg}}_{\mathfrak{g}_*} \to \mathrm{Mod}^{\mathrm{dg}}_\kappa$ is isomorphic to the (differential graded) endomorphism ring of $U(\mathrm{Cn}(\mathfrak{g})_*)$ (regarded as a representation of $\mathfrak{g}_*$). In particular, the action of $C^*(\mathfrak{g}_*)$ on $C^*(\mathfrak{g}_*; \bullet)$ arises from an action of $C^*(\mathfrak{g}_*)$ on $U(\mathrm{Cn}(\mathfrak{g})_*)$, which commutes with the left action of $U(\mathfrak{g}_*)$. For an alternative description of this action, we refer the reader to the proof of Proposition 14.3.2.2.

Proposition 13.4.2.3. *Let $\mathfrak{g}_*$ be a differential graded Lie algebra over a field κ of characteristic zero. Then the functor $V_* \mapsto C^*(\mathfrak{g}_*; V_*)$ preserves quasi-isomorphisms.*

Proof. For each $n \geqslant 0$ and each $V_* \in \mathrm{Rep}^{\mathrm{dg}}_{\mathfrak{g}_*}$, we let $F_n(V_*)$ denote the quotient of $C^*(\mathfrak{g}_*; V_*)$ given by maps from $\mathrm{Sym}^{\leqslant n}_\kappa(\mathfrak{g}_*[1])$ into V_*. Then $C^*(\mathfrak{g}_*; V_*)$ is given by the inverse limit of a tower of fibrations

$$\cdots \to F_2(V_*) \to F_1(V_*) \to F_0(V_*).$$

It will therefore suffice to show that each of the functors F_n preserves quasi-isomorphisms. We proceed by induction on n. If $n = 0$, then F_n is the identity functor and the result is obvious. Assume therefore that $n > 0$. Let $K : \mathrm{Rep}^{\mathrm{dg}}_{\mathfrak{g}_*} \to \mathrm{Mod}^{\mathrm{dg}}_\kappa$ be the functor given by the kernel of the surjection $F_n \to F_{n-1}$, so that we have a short exact sequence of functors

$$0 \to K \to F_n \to F_{n-1} \to 0.$$

It will therefore suffice to show that the functor K preserves quasi-isomorphisms. Unwinding the definitions, we see that K carries a representation V_* to the chain complex of Σ_n-equivariant maps from $(\mathfrak{g}_*[1])^{\otimes n}$ into V_*, regarded as objects of $\mathrm{Mod}^{\mathrm{dg}}_\kappa$. Since κ has characteristic zero, the functor K is a direct summand of the functor $K' : \mathrm{Rep}^{\mathrm{dg}}_{\mathfrak{g}_*} \to \mathrm{Mod}^{\mathrm{dg}}_\kappa$, which carries V_* to the chain complex of maps from $(\mathfrak{g}_*[1])^{\otimes n}$ into V_*. This functor evidently preserves quasi-isomorphisms. □

Remark 13.4.2.4. Let $\mathfrak{g}_*$ be a differential graded Lie algebra over a field κ of characteristic zero, and let $\mathrm{Mod}^{\mathrm{dg}}_{C^*(\mathfrak{g}_*)}$ denote the category of differential graded modules over $C^*(\mathfrak{g}_*)$. The functor $C^*(\mathfrak{g}_*; \bullet) : \mathrm{Rep}^{\mathrm{dg}}_{\mathfrak{g}_*} \to \mathrm{Mod}^{\mathrm{dg}}_{C^*(\mathfrak{g}_*)}$ preserves weak equivalences and fibrations. Moreover, it has a left adjoint F, given by $M_* \mapsto U(\mathrm{Cn}(\mathfrak{g})_*) \otimes_{C^*(\mathfrak{g}_*)} M_*$ (see Remark 13.4.2.2). It follows that $C^*(\mathfrak{g}_*; \bullet)$ is a right Quillen functor, which induces a map between the underlying ∞-categories $\mathrm{Rep}_{\mathfrak{g}_*} \to \mathrm{Mod}_{C^*(\mathfrak{g}_*)}$. We will generally abuse notation by denoting this functor also by $C^*(\mathfrak{g}_*; \bullet)$. It admits a left adjoint $f : \mathrm{Mod}_{C^*(\mathfrak{g}_*)} \to \mathrm{Rep}_{\mathfrak{g}_*}$ (given by the left derived functor of F).

13.4.3 Koszul Duality with Coefficients

In good cases, there is a close relationship between the representations of a differential graded Lie algebra $\mathfrak{g}_*$ and the modules over its Chevalley-Eilenberg complex $C^*(\mathfrak{g}_*)$.

Proposition 13.4.3.1. *Let κ be a field of characteristic zero and let $\mathfrak{g}_*$ be a differential graded Lie algebra over κ. Assume that the underlying graded Lie algebra is freely generated by a finite sequence of homogeneous elements $x_1, \ldots, x_n$ such that each dx_i belongs to the Lie subalgebra of $\mathfrak{g}_*$ generated by $x_1, \ldots, x_{i-1}$. Let $f : \mathrm{Mod}_{C^*(\mathfrak{g}_*)} \to \mathrm{Rep}_{\mathfrak{g}_*}$ denote the left adjoint to the functor $C^*(\mathfrak{g}_*; \bullet)$ (see Remark 13.4.2.4). Then f is a fully faithful embedding.*

Lemma 13.4.3.2. *Let κ be a field and let A_* be an augmented differential graded algebra over κ; we will abuse notation by identifying A_* with its image in Mod_κ. Assume that A_* is freely generated (as a graded algebra) by a finite sequence of homogeneous elements $x_1, \ldots, x_n$, such that each dx_i lies in the subalgebra generated by $x_1, \ldots, x_{i-1}$. Then the field κ is a compact object of the stable ∞-category LMod_{A_*}.*

Proof. Adding scalars to the elements x_i if necessary, we may assume that the augmentation $A_* \to \kappa$ annihilates each x_i. For $0 \leqslant i \leqslant n$, let $M(i)_*$ denote the quotient of A_* by the left ideal generated by the elements $x_1, \ldots, x_i$. We will prove that each $M(i)_*$ is perfect as a left A_*-module; taking $i = n$, this will imply the desired result. The proof proceeds by induction on i. If $i = 0$, then $M(i)_* \simeq A_*$ and the result is obvious. If $i > 0$, then the image of x_i in $M(i-1)_*$ is a cycle. It follows that right multiplication by x_i induces a map of left A_*-modules $A_* \to M(i-1)_*$, fitting into an exact sequence

$$0 \to A_* \xrightarrow{x_i} M(i-1)_* \to M(i)_* \to 0.$$

Since $M(i-1)_*$ is perfect by the inductive hypothesis, we deduce that $M(i)_*$ is perfect. □

Proof of Proposition 13.4.3.1. We first show that f is fully faithful when restricted to the full subcategory $\mathrm{Mod}^{\mathrm{perf}}_{C^*(\mathfrak{g}_*)} \subseteq \mathrm{Mod}_{C^*(\mathfrak{g}_*)}$ spanned by the perfect $C^*(\mathfrak{g}_*)$-modules. Let M and N be perfect $C^*(\mathfrak{g}_*)$-modules. We wish to show that f induces an isomorphism

$$\theta : \mathrm{Ext}^*_{C^*(\mathfrak{g}_*)}(M, N) \to \mathrm{Ext}^*_{U(\mathfrak{g}_*)}(fM, fN).$$

Regard M as fixed. The collection of those modules N for which θ is an isomorphism is closed under retracts, shifts, and extensions. To prove that θ is an isomorphism for each $N \in \mathrm{Mod}^{\mathrm{perf}}_{C^*(\mathfrak{g}_*)}$, it will suffice to prove that θ is an isomorphism for $N = C^*(\mathfrak{g}_*)$. By the same reasoning, we can reduce to the case where $M = C^*(\mathfrak{g}_*)$. Then $fM \simeq U(\mathrm{Cn}(\mathfrak{g})_*)$ and $fN \simeq U(\mathrm{Cn}(\mathfrak{g}_*) \simeq \kappa$, so that $\mathrm{Ext}^*_{U(\mathfrak{g}_*)}(fM, fN) \simeq \mathrm{Ext}^*_{U(\mathfrak{g}_*)}(U(\mathrm{Cn}(\mathfrak{g})_*), \kappa)$ is canonically isomorphic to the Lie algebra cohomology of $\mathfrak{g}_*$. Under this isomorphism, θ corresponds to the identity map.

We now prove that f is fully faithful in general. Since $\mathrm{Mod}_{C^*(\mathfrak{g}_*)} \simeq \mathrm{Ind}(\mathrm{Mod}^{\mathrm{perf}}_{C^*(\mathfrak{g}_*)})$ and the functor f preserves filtered colimits, it will suffice to show that f carries objects $\mathrm{Mod}^{\mathrm{perf}}_{C^*(\mathfrak{g}_*)}$ to perfect $U(\mathfrak{g}_*)$-modules. The collection of those $M \in \mathrm{Mod}_{C^*(\mathfrak{g}_*)}$ for which fM is perfect is closed under extensions, shifts, and retracts. It will therefore suffice to show that $fC^*(\mathfrak{g}_*) \simeq \kappa$ is perfect as a $U(\mathfrak{g}_*)$-module, which follows from Lemma 13.4.3.2. □

Notation 13.4.3.3. Let $\mathfrak{g}_*$ be a differential graded Lie algebra and let V_* be a representation of $\mathfrak{g}_*$. We will say that V_* is *connective* if its image in Mod_κ is connective: that is, if the homology groups of the chain complex V_* are concentrated in non-negative degrees. We let $\mathrm{Rep}^{\mathrm{cn}}_{\mathfrak{g}_*}$ denote the full subcategory of $\mathrm{Rep}_{\mathfrak{g}_*}$ spanned by the connective $\mathfrak{g}_*$-modules.

Proposition 13.4.3.4. *Let $\mathfrak{g}_*$ be as in the statement of Proposition 13.4.3.1, and assume that each of the generators x_i of $\mathfrak{g}_*$ has negative homological degree. Then the fully faithful embedding $f : \mathrm{Mod}_{C^*(\mathfrak{g}_*)} \to \mathrm{Rep}_{\mathfrak{g}_*}$ induces an equivalence of ∞-categories $\mathrm{Mod}^{\mathrm{cn}}_{C^*(\mathfrak{g}_*)} \to \mathrm{Rep}^{\mathrm{cn}}_{\mathfrak{g}_*}$.*

Lemma 13.4.3.5. *Let κ be a field and let A be a coconnective $\mathbb{E}_1$-algebra over κ (see Definition 14.1.3.1), equipped with an augmentation $\epsilon : A \to \kappa$. Let $\mathcal{C} \subseteq \mathrm{LMod}_A$ be a full subcategory which contains κ (regarded as a left A-module via the augmentation ϵ) and is closed under colimits and extensions. Then $\mathcal{C}$ contains every left A-module whose underlying spectrum is connective.*

Proof. Let M be a left A-module whose underlying spectrum is connective. We will construct a sequence of objects $0 = M(0) \to M(1) \to M(2) \to \cdots$ in $\mathcal{C}$ and a compatible family of maps $\theta(i) : M(i) \to M$ with the following property:

- $(*)$ The groups $\pi_j M(i)$ vanish unless $0 \leqslant j < i$, and the maps $\pi_j M(j) \to \pi_j M$ are isomorphisms for $0 \leqslant j < i$.

Assume that $i \geqslant 0$ and that we have already constructed a map $\theta(i)$ satisfying $(*)$. Let $M' = \mathrm{fib}(\theta(i))$, so that $\pi_j M' \simeq 0$ for $j < i-1$. Using Proposition 14.1.4.1, we can construct a map of left A-modules $N \to M'$ which induces an isomorphism $\pi_{i-1}N \to \pi_{i-1}M'$, with $\pi_j N \simeq 0$ for $j \neq i-1$. Let $M(i+1)$ denote the cofiber of the composite map $N \to M' \to M(i)$. There is an evident map $\theta(i+1) : M(i+1) \to M$ satisfying $(*)$. We will complete the proof by showing that $M(i+1) \in \mathcal{C}$. We have a fiber sequence $M(i) \to M(i+1) \to \Sigma N$. Lemma **??** implies that ΣN is equivalent to a direct sum of copies of $\Sigma^i(\kappa)$. Since $\mathcal{C}$ contains κ and is closed under colimits, we conclude that $\Sigma N \in \mathcal{C}$. The module $M(i)$ belong to $\mathcal{C}$ by the inductive hypothesis. Since $\mathcal{C}$ is closed under extensions, we deduce that $M(i+1) \in \mathcal{C}$. □

Proof of Proposition 13.4.3.4. Since $C^*(\mathfrak{g}_*)$ is connective, we can characterize as the smallest full subcategory of $\mathrm{Mod}^{\mathrm{cn}}_{C^*(\mathfrak{g}_*)}$ which contains $C^*(\mathfrak{g}_*)$ and is closed under colimits and extensions. It follows that f induces an equivalence from $\mathrm{Mod}^{\mathrm{cn}}_{C^*(\mathfrak{g}_*)}$ to the smallest full subcategory of $\mathrm{Rep}^{\mathrm{cn}}_{\mathfrak{g}_*}$ which contains $fC^*(\mathfrak{g}_*) \simeq \kappa$ and is closed under colimits and extensions. It is clear that this full subcategory is contained in $\mathrm{Rep}^{\mathrm{cn}}_{\mathfrak{g}_*}$, and the reverse inclusion follows from Lemma 13.4.3.5. □

13.4.4 Tensor Products of Lie Algebra Representations

If $\mathfrak{g}_*$ is a differential graded Lie algebra over a field κ, then the category $\mathrm{Rep}^{\mathrm{dg}}_{\mathfrak{g}_*}$ of representations of $\mathfrak{g}_*$ has a natural symmetric monoidal structure: if V_* and W_* are representations of $\mathfrak{g}_*$, then the tensor product $V_* \otimes_\kappa W_*$ can also be regarded as a representation of $\mathfrak{g}_*$, with action given by the formula

$$x(v \otimes w) = (xv) \otimes w + (-1)^{pq} v \otimes (xw)$$

for homogeneous elements $x \in \mathfrak{g}_p$, $v \in V_q$, and $w \in W_r$. For fixed $V_* \in \mathrm{Rep}^{\mathrm{dg}}_{\mathfrak{g}_*}$, the construction $W_* \mapsto V_* \otimes_\kappa W_*$ preserves quasi-isomorphisms. It follows from Proposition HA.4.1.7.4 that the underlying ∞-category $\mathrm{Rep}_{\mathfrak{g}_*} = \mathrm{Rep}^{\mathrm{dg}}_{\mathfrak{g}_*}[W^{-1}_{\mathfrak{g}_*}]$ inherits a symmetric monoidal structure.

Remark 13.4.4.1. Let $\mathfrak{g}_*$ be a differential graded Lie algebra over a field κ. Then the diagram

$$\begin{array}{ccc} \mathrm{Rep}_{\mathfrak{g}_*} \times \mathrm{Rep}_{\mathfrak{g}_*} & \xrightarrow{\otimes} & \mathrm{Rep}_{\mathfrak{g}_*} \\ \downarrow & & \downarrow \\ \mathrm{Mod}_\kappa \times \mathrm{Mod}_\kappa & \xrightarrow{\otimes} & \mathrm{Mod}_\kappa \end{array}$$

commutes up to equivalence. It follows that the tensor product functor $\otimes : \mathrm{Rep}_{\mathfrak{g}_*} \times \mathrm{Rep}_{\mathfrak{g}_*} \to \mathrm{Rep}_{\mathfrak{g}_*}$ preserves small colimits separately in each variable.

To discuss the functorial dependence of the symmetric monoidal structure of Remark 13.4.4.1 on $\mathfrak{g}_*$, it is convenient to introduce the following more elaborate construction:

Construction 13.4.4.2. Let κ be a field. We define a category $\mathrm{Rep}^{\otimes}_{\mathrm{dg}}$ as follows:

(1) An object of $\mathrm{Rep}^{\otimes}_{\mathrm{dg}}$ is a tuple $(\mathfrak{g}_*, V^1_*, \ldots, V^n_*)$, where $\mathfrak{g}_*$ is a differential graded Lie algebra over κ and each V^i_* is a representation of $\mathfrak{g}_*$.

(2) Given a pair of objects $(\mathfrak{g}_*, V^1_*, \ldots, V^m_*), (\mathfrak{h}_*, W^1_*, \ldots, W^n_*) \in \mathrm{Rep}^{\otimes}_{\mathrm{dg}}$, a morphism

$$(\mathfrak{g}_*, V^1_*, \ldots, V^m_*) \to (\mathfrak{h}_*, W^1_*, \ldots, W^n_*)$$

is given by a map $\alpha : \langle m \rangle \to \langle n \rangle$ of pointed finite sets, a morphism $\phi : \mathfrak{h}_* \to \mathfrak{g}_*$ of differential graded Lie algebras, and, for each $1 \leqslant j \leqslant n$, a map $\bigotimes_{\alpha(i)=j} V^i_* \to W^j_*$ of representations of $\mathfrak{h}_*$ (here we regard each V^i_* as a representation of $\mathfrak{h}_*$ via the morphism ϕ).

The category $\mathrm{Rep}^{\otimes}_{\mathrm{dg}}$ is equipped with an evident forgetful functor $\mathrm{Rep}^{\otimes}_{\mathrm{dg}} \to (\mathrm{Lie}^{\mathrm{dg}}_{\kappa})^{\mathrm{op}} \times \mathcal{F}\mathrm{in}_*$, which induces a coCartesian fibration $\mathrm{Rep}^{\otimes}_{\mathrm{dg}} \to (\mathrm{Lie}^{\mathrm{dg}}_{\kappa})^{\mathrm{op}} \times \mathcal{F}\mathrm{in}_*$.

For our applications of Construction 13.4.4.2, we will need the following general result:

Proposition 13.4.4.3. *Let $p : \mathcal{C} \to \mathcal{D}$ be a coCartesian fibration of ∞-categories. Suppose that we are given, for each $D \in \mathcal{D}$, a collection of morphisms W_D in the fiber $\mathcal{C}_D$. Suppose further that for each morphism $D \to D'$ in $\mathcal{D}$, the induced functor $\mathcal{C}_D \to \mathcal{C}_{D'}$ carries W_D into $W_{D'}$. Let $W = \bigcup_{D \in \mathcal{D}} W_D$. Since p carries each morphism of W to an equivalence in $\mathcal{D}$, it factors as a composition $\mathcal{C} \xrightarrow{\theta} \mathcal{C}[W^{-1}] \xrightarrow{q} \mathcal{D}$. Replacing $\mathcal{C}[W^{-1}]$ by an equivalent ∞-category if necessary, we may assume that q is a categorical fibration. Then:*

(1) *The map q is a coCartesian fibration.*

(2) *The functor θ carries p-coCartesian morphisms in $\mathcal{C}$ to q-coCartesian morphisms in $\mathcal{C}[W^{-1}]$.*

(3) *For each $D \in \mathcal{D}$, the map θ induces an equivalence $\mathcal{C}[W_D^{-1}] \to (\mathcal{C}[W^{-1}])_D$.*

Corollary 13.4.4.4. *Let κ be a field and let W be the collection of all morphisms in $\mathrm{Rep}^{\otimes}_{\mathrm{dg}}$ of the form $\alpha : (\mathfrak{g}_*, V^1_*, \ldots, V^n_*) \to (\mathfrak{g}_*, V'^1_*, \ldots, V'^n_*)$ where the image of α in both $\mathrm{Lie}^{\mathrm{dg}}_{\kappa}$ and $\mathcal{F}\mathrm{in}_*$ is an identity map, and α induces a quasi-isomorphism $V^i_* \to V'^i_*$ for $1 \leqslant i \leqslant n$. Then we have a coCartesian fibration $\mathrm{Rep}^{\otimes}_{\mathrm{dg}}[W^{-1}] \to (\mathrm{Lie}^{\mathrm{dg}}_{\kappa})^{\mathrm{op}} \times \mathcal{F}\mathrm{in}_*$. For every differential graded Lie algebra $\mathfrak{g}_*$ over κ, we can identify the fiber $\mathrm{Rep}^{\otimes}_{\mathrm{dg}}[W^{-1}]_{\mathfrak{g}_*, \langle 1 \rangle}$ with the ∞-category $\mathrm{Rep}^{\otimes}_{\mathfrak{g}_*}$.*

Proof of Proposition 13.4.4.3. Let $\chi : \mathcal{D} \to \mathcal{C}\mathrm{at}_{\infty}$ classify the Cartesian fibration p. For each $D \in \mathcal{D}$, we have a canonical equivalence $\chi(D) \simeq \mathcal{C}_D$; let W'_D denote the collection of morphisms in $\chi(D)$ whose in $\mathcal{C}_D$ are equivalent to morphisms belonging to W_D. Then the construction $D \mapsto (\chi(D), W)$ determines a functor $\chi_W : \mathcal{D} \to \mathcal{W}\mathcal{C}\mathrm{at}_{\infty}$, where $\mathcal{W}\mathcal{C}\mathrm{at}_{\infty}$ is defined as in Construction HA.4.1.7.1 . Composing with the left adjoint to the inclusion $\mathcal{C}\mathrm{at}_{\infty} \to \mathcal{W}\mathcal{C}\mathrm{at}_{\infty}$, we obtain a new functor $\chi' : \mathcal{D} \to \mathcal{C}\mathrm{at}_{\infty}$, given on objects by $\chi'(D) = \chi(D)[W'^{-1}_D] \simeq \mathcal{C}_D[W_D^{-1}]$. The functor χ' classifies a coCartesian fibration $p' : \mathcal{C}' \to \mathcal{D}$. We have an evident natural transformation $\chi \to \chi'$, which determines a functor $\phi \in \mathrm{Fun}_{\mathcal{D}}(\mathcal{C}, \mathcal{C}')$

which carries p-coCartesian morphisms to p'-coCartesian morphisms. To complete the proof, it will suffice to show that ϕ induces an equivalence $\mathcal{C}[W^{-1}] \to \mathcal{C}'$. Equivalently, we must show that for any ∞-category $\mathcal{E}$, composition with ϕ induces a fully faithful embedding $v : \mathrm{Fun}(\mathcal{C}', \mathcal{E})^{\simeq} \to \mathrm{Fun}(\mathcal{C}, \mathcal{E})^{\simeq}$ whose essential image consists of those functors $F : \mathcal{C} \to \mathcal{E}$ which carry each morphism of W to an equivalence in $\mathcal{E}$.

Evaluation at the vertex $0 \in \Delta^1$ induces a Cartesian fibration $\mathrm{Fun}(\Delta^1, \mathcal{D}) \to \mathcal{D}$. We define a new simplicial set $\mathcal{E}'$ with a map $r : \mathcal{E}' \to \mathcal{D}$ so that the following universal property is satisfied: for every map of simplicial sets $K \to \mathcal{D}$, we have a canonical bijection

$$\mathrm{Hom}_{(\mathcal{S}\mathrm{et}_{\Delta})_{/\mathcal{D}}}(K, \mathcal{E}') = \mathrm{Hom}_{\mathcal{S}\mathrm{et}_{\Delta}}(K \times_{\mathrm{Fun}(\{0\},\mathcal{D})} \mathrm{Fun}(\Delta^1, \mathcal{D}), \mathcal{E}).$$

Using Corollary HTT.3.2.2.12 , we deduce that the map $r : \mathcal{E}' \to \mathcal{D}$ is a coCartesian fibration. The diagonal inclusion $\mathcal{D} \to \mathrm{Fun}(\Delta^1, \mathcal{D})$ induces a map $K \to K \times_{\mathrm{Fun}(\{0\},\mathcal{D})} \mathrm{Fun}(\Delta^1, \mathcal{D})$ for every map $K \to \mathcal{D}$. Composition with these maps gives a functor $u : \mathcal{E}' \to \mathcal{E}$. We claim:

($*$) Let $\mathrm{Fun}'_{\mathcal{D}}(\mathcal{C}, \mathcal{E}')$ denote the full subcategory of $\mathrm{Fun}_{\mathcal{D}}(\mathcal{C}, \mathcal{E}')$ spanned by those functors which carry p-coCartesian morphisms to r-coCartesian morphisms. Then composition with u induces a trivial Kan fibration $\mathrm{Fun}'_{\mathcal{D}}(\mathcal{C}, \mathcal{E}') \to \mathrm{Fun}(\mathcal{C}, \mathcal{E})$

To prove ($*$), we note that $\mathrm{Fun}_{\mathcal{D}}(\mathcal{C}, \mathcal{E}')$ can be identified with the ∞-category

$$\mathrm{Fun}(\mathcal{C} \times_{\mathrm{Fun}(\{0\},\mathcal{D})} \mathrm{Fun}(\Delta^1, \mathcal{D}), \mathcal{E}).$$

Under this identification, $\mathrm{Fun}'_{\mathcal{D}}(\mathcal{C}, \mathcal{E}')$ corresponds to the full subcategory spanned by those functors F which are right Kan extensions of their restrictions to $\mathcal{C} \hookrightarrow \mathcal{C} \times_{\mathrm{Fun}(\{0\},\mathcal{D})} \mathrm{Fun}(\Delta^1, \mathcal{D})$. Assertion ($*$) now follows from Proposition HTT.4.3.2.15 . A similar argument gives:

($*$) Let $\mathrm{Fun}'_{\mathcal{D}}(\mathcal{C}', \mathcal{E}')$ denote the full subcategory of $\mathrm{Fun}_{\mathcal{D}}(\mathcal{C}', \mathcal{E}')$ spanned by those functors which carry p'-coCartesian morphisms to r-coCartesian morphisms. Then composition with u induces a trivial Kan fibration $\mathrm{Fun}'_{\mathcal{D}}(\mathcal{C}', \mathcal{E}') \to \mathrm{Fun}(\mathcal{C}', \mathcal{E})$.

It follows that we can identify v with the map $\mathrm{Fun}'_{\mathcal{D}}(\mathcal{C}', \mathcal{E}')^{\simeq} \to \mathrm{Fun}'_{\mathcal{D}}(\mathcal{C}, \mathcal{E}')^{\simeq}$. Let $\nu : \mathcal{D} \to \mathcal{C}\mathrm{at}_{\infty}$ classify the coCartesian fibration r, so that v is given by the map $\mathrm{Map}_{\mathrm{Fun}(\mathcal{D},\mathcal{C}\mathrm{at}_{\infty})}(\chi', \nu) \to \mathrm{Map}_{\mathrm{Fun}(\mathcal{D},\mathcal{C}\mathrm{at}_{\infty})}(\chi, \nu)$ given by composition with the natural transformation α. The desired result now follows from the construction of the natural transformation χ'. $\square$

13.4.5 Tensor Products and Cohomology

Let $\mathfrak{g}_*$ be a differential graded Lie algebra over a field κ. Then the Chevalley-Eilenberg construction $V_* \mapsto C^*(\mathfrak{g}_*; V_*)$ is a lax symmetric monoidal functor: for every pair of representations $V_*, W_* \in \mathrm{Rep}^{\mathrm{dg}}_{\mathfrak{g}_*}$, there is a canonical map

$$C^*(\mathfrak{g}_*; V_*) \otimes_{\kappa} C^*(\mathfrak{g}_*; W_*) \to C^*(\mathfrak{g}_*; V_* \otimes_{\kappa} W_*),$$

which classifies bilinear maps $C^p(\mathfrak{g}_*; V_*) \times C^q(\mathfrak{g}_*; W_*) \to C^{p+q}(\mathfrak{g}_*; V_* \otimes_\kappa W_*)$ carrying classes $\lambda \in C^p(\mathfrak{g}_*; V_*)$ and $\mu \in C^q(\mathfrak{g}_*; W_*)$ to the product $\lambda\mu \in C^{p+q}(\mathfrak{g}_*; V_* \otimes_\kappa W_*)$ given by

$$(\lambda\mu)(x_1 \ldots x_n) = \sum_{S,S'} \epsilon(S, S')\lambda(x_{i_1} \ldots x_{i_m}) \otimes \mu(x_{j_1} \ldots x_{j_{n-m}}).$$

Remark 13.4.5.1. Taking V_* and W_* to be the trivial representation of $\mathfrak{g}_*$, we recover the multiplication on $C^*(\mathfrak{g}_*)$ described in Construction 13.2.5.1. Taking V_* to be the trivial representation, we recover the action of $C^*(\mathfrak{g}_*)$ on $C^*(\mathfrak{g}_*; W_*)$ described in Remark 13.4.2.1. It follows from general nonsense that the multiplication maps

$$C^*(\mathfrak{g}_*; V_*) \otimes_\kappa C^*(\mathfrak{g}_*; W_*) \to C^*(\mathfrak{g}_*; V_* \otimes_k W_*)$$

are $C^*(\mathfrak{g}_*)$-bilinear, and therefore descend to give maps

$$C^*(\mathfrak{g}_*; V_*) \otimes_{C^*(\mathfrak{g}_*)} C^*(\mathfrak{g}_*; W_*) \to C^*(\mathfrak{g}_*; V_* \otimes_\kappa W_*).$$

Notation 13.4.5.2. Let $\mathcal{C}$ be a symmetric monoidal ∞-category. We let $\mathrm{Mod}(\mathcal{C})^{\otimes} = \mathrm{Mod}^{\mathrm{Comm}}(\mathcal{C})^{\otimes}$ be as in Definition HA.3.3.3.8: more informally, the objects of $\mathrm{Mod}(\mathcal{C})^{\otimes}$ are given by tuples $(A, M_1, \ldots, M_n)$ where $A \in \mathrm{CAlg}(\mathcal{C})$ and each M_i is a module over A. Note that if $\mathcal{C}$ is (equivalent to) an ordinary symmetric monoidal category, then $\mathrm{Mod}(\mathcal{C})^{\otimes}$ is also (equivalent to) an ordinary category.

The lax symmetric monoidal structure on the functor $C^*(\mathfrak{g}_*; \bullet)$, and its dependence on $\mathfrak{g}_*$, are encoded by a map of categories $\mathrm{Rep}^{\otimes}_{\mathrm{dg}} \to \mathrm{Mod}(\mathrm{Mod}^{\mathrm{dg}}_\kappa)^{\otimes}$, given on objects by $(\mathfrak{g}_*, V^1_*, \ldots, V^n_*) \mapsto (C^*(\mathfrak{g}_*), C^*(\mathfrak{g}_*; V^1_*), \ldots, C^*(\mathfrak{g}_*; V^n_*))$. Composing this with the map of symmetric monoidal functor $\mathrm{Mod}^{\mathrm{dg}}_\kappa \to \mathrm{Mod}_\kappa$, we obtain a map $\mathrm{Rep}^{\otimes}_{\mathrm{dg}} \to \mathrm{Mod}(\mathrm{Mod}_\kappa)^{\otimes}$. If the field κ has characteristic zero, then Proposition 13.4.2.3 implies that this functor carries morphisms of W (where W is defined as in Corollary 13.4.4.4) to equivalences in $\mathrm{Mod}(\mathrm{Mod}_\kappa)^{\otimes}$, and therefore induces a lax symmetric monoidal functor

$$G : \mathrm{Rep}^{\otimes}_{\mathrm{dg}}[W^{-1}] \to (\mathrm{Lie}^{\mathrm{dg}}_\kappa)^{\mathrm{op}} \times_{\mathrm{CAlg}_\kappa} \mathrm{Mod}(\mathrm{Mod}_\kappa)^{\otimes}.$$

Proposition 13.4.5.3. *Let κ be a field of characteristic zero, and consider the commutative diagram*

$$\begin{array}{ccc} \mathrm{Rep}^{\otimes}_{\mathrm{dg}}[W^{-1}] & \xrightarrow{G} & (\mathrm{Lie}^{\mathrm{dg}}_\kappa)^{\mathrm{op}} \times_{\mathrm{CAlg}_\kappa} \mathrm{Mod}(\mathrm{Mod}_\kappa)^{\otimes} \\ & {\scriptstyle p} \searrow \quad \swarrow {\scriptstyle q} & \\ & (\mathrm{Lie}^{\mathrm{dg}}_\kappa)^{\mathrm{op}} \times \mathcal{F}\mathrm{in}_* . & \end{array}$$

Then:

(1) *The functor G admits a left adjoint F relative to $(\mathrm{Lie}_\kappa^{\mathrm{dg}})^{\mathrm{op}} \times \mathcal{F}\mathrm{in}_*$ (see Definition HA.7.3.2.2).*

(2) *The functor F carries q-coCartesian morphisms to p-coCartesian morphisms.*

Remark 13.4.5.4. We can summarize Proposition 13.4.5.3 more informally as follows. For every differential graded Lie algebra $\mathfrak{g}_*$ over κ, the construction $V_* \mapsto C^*(\mathfrak{g}_*; V_*)$ determines a lax symmetric monoidal functor from $\mathrm{Rep}_{\mathfrak{g}_*}$ to $\mathrm{Mod}_{C^*(\mathfrak{g}_*)}$. This functor admits a symmetric monoidal left adjoint $f : \mathrm{Mod}_{C^*(\mathfrak{g}_*)} \to \mathrm{Rep}_{\mathfrak{g}_*}$. Moreover, the functor f depends functorially on the differential graded Lie algebra $\mathfrak{g}_*$.

Proof of Proposition 13.4.5.3. We will prove the existence of F; since F admits a right adjoint relative to $(\mathrm{Lie}_\kappa^{\mathrm{dg}})^{\mathrm{op}} \times \mathcal{F}\mathrm{in}_*$, it will follow automatically that F carries q-coCartesian morphisms to p-coCartesian morphisms (see Proposition HA.7.3.2.6). To prove the existence of F, we will check that G satisfies the criterion of Proposition HA.7.3.2.11 . For each differential graded Lie algebra $\mathfrak{g}_*$ and each $\langle n \rangle \in \mathcal{F}\mathrm{in}_*$, the induced functor

$$G_{\mathfrak{g}_*, \langle n \rangle} : \mathrm{Rep}_{\mathrm{dg}}^{\otimes}[W^{-1}]_{\mathfrak{g}_*, \langle n \rangle} \to (\mathrm{Mod}_{C^*(\mathfrak{g}_*)})^{\otimes}_{\langle n \rangle}$$

is equivalent to a product of n copies of the functor $C^*(\mathfrak{g}_*; \bullet) : \mathrm{Rep}_{\mathfrak{g}_*} \to \mathrm{Mod}_{C^*(\mathfrak{g}_*)}$, and therefore admits a left adjoint $f_{\mathfrak{g}_*}$ by Remark 13.4.2.4. Unwinding the definitions, we are reduced to proving that for every finite sequence of $C^*(\mathfrak{g}_*)$-modules $M_1, \ldots, M_n$, and every map of differential graded Lie algebras $\mathfrak{h}_* \to \mathfrak{g}_*$, the canonical map

$$f_{\mathfrak{h}_*}(C^*(\mathfrak{h}_*) \otimes_{C^*(\mathfrak{g}_*)} M_1 \otimes_{C^*(\mathfrak{g}_*)} \cdots \otimes_{C^*(\mathfrak{g}_*)} M_n) \to f_{\mathfrak{g}_*}(M_1) \otimes_\kappa \cdots \otimes_\kappa f_{\mathfrak{g}_*}(M_n)$$

is an equivalence. We observe that both sides are compatible with colimits in each M_i (see Remark 13.4.4.1). Since $\mathrm{Mod}_{C^*(\mathfrak{g}_*)}$ is generated under small colimits by the modules $\Sigma^k C^*(\mathfrak{g}_*)$ for $k \in \mathbf{Z}$, we can reduce to the case where $M_i = C^*(\mathfrak{g}_*)$ for $1 \leqslant i \leqslant n$. In this case, the result is obvious. □

13.4.6 Quasi-Coherent Sheaves on a Formal Moduli Problem

We now define the stable ∞-category $\mathrm{QCoh}(X)$ associated to a formal moduli problem $X : \mathrm{CAlg}_\kappa^{\mathrm{art}} \to \mathcal{S}$.

Construction 13.4.6.1. Let κ be a field. The coCartesian fibration $\mathrm{Mod}(\mathrm{Mod}_\kappa)^{\otimes} \to \mathrm{CAlg}_\kappa \times \mathcal{F}\mathrm{in}_*$ is classified by a map $\chi : \mathrm{CAlg}_\kappa \to \mathrm{Mon}_{\mathrm{Comm}}(\widehat{\mathcal{C}\mathrm{at}}_\infty) \simeq \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty)$, which carries an $\mathbb{E}_\infty$-algebra A over κ to Mod_A, regarded as a symmetric monoidal ∞-category. Let χ^{art} denote the restriction of χ to the full subcategory $\mathrm{CAlg}_\kappa^{\mathrm{art}} \subseteq \mathrm{CAlg}_\kappa$ spanned by the Artinian $\mathbb{E}_\infty$-algebras over κ. Applying Theorem HTT.5.1.5.6 , we deduce that χ^{art} admits an essentially unique factorization as a composition

$$\mathrm{CAlg}_\kappa^{\mathrm{art}} \xrightarrow{j} \mathrm{Fun}(\mathrm{CAlg}_\kappa^{\mathrm{art}}, \mathcal{S})^{\mathrm{op}} \xrightarrow{\mathrm{QCoh}} \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty),$$

where the functor QCoh preserves small limits. For every functor $X : \mathrm{CAlg}_\kappa^{\mathrm{art}} \to \mathcal{S}$, we will regard $\mathrm{QCoh}(X) \in \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty)$ as a symmetric monoidal ∞-category, which we call the *∞-category of quasi-coherent sheaves on X.*

Remark 13.4.6.2. Let $\mathcal{P}\mathrm{r}^{\mathrm{L}} \subseteq \widehat{\mathcal{C}\mathrm{at}}_\infty$ denote the subcategory whose objects are presentable ∞-categories and whose morphisms are colimit preserving functors, and regard $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ as a symmetric monoidal ∞-category as explained in §HA.4.8.1 . Note that the functor χ of Construction 13.4.6.1 factors through $\mathrm{CAlg}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \subseteq \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty)$. Since this inclusion preserves small limits, we deduce that the functor

$$\mathrm{QCoh} : \mathrm{Fun}(\mathrm{CAlg}_\kappa^{\mathrm{art}}, \mathcal{S})^{\mathrm{op}} \to \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty)$$

also factors through $\mathrm{CAlg}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$. In other words:

- (a) For every functor $X : \mathrm{CAlg}_\kappa^{\mathrm{art}} \to \mathcal{S}$, the ∞-category $\mathrm{QCoh}(X)$ is presentable.
- (b) For every functor $X : \mathrm{CAlg}_\kappa^{\mathrm{art}} \to \mathcal{S}$, the tensor product $\otimes : \mathrm{QCoh}(X) \times \mathrm{QCoh}(X) \to \mathrm{QCoh}(X)$ preserves small colimits separately in each variable.
- (c) For every natural transformation $f : X \to Y$ of functors $X, Y : \mathrm{CAlg}_\kappa^{\mathrm{art}} \to \mathcal{S}$, the pullback functor $f^* : \mathrm{QCoh}(Y) \to \mathrm{QCoh}(X)$ preserves small colimits.

Remark 13.4.6.3. Let κ be a field and let $X : \mathrm{CAlg}_\kappa^{\mathrm{art}} \to \mathcal{S}$ be a functor which classifies a right fibration $\mathcal{X} \to \mathrm{CAlg}_\kappa^{\mathrm{art}}$. Then $\mathrm{QCoh}(X)$ can be identified with the ∞-category coCartesian sections of the coCartesian fibration $\mathcal{X} \times_{\mathrm{CAlg}_\kappa} \mathrm{Mod}(\mathrm{Mod}_\kappa) \to \mathcal{X}$. More informally, an object $\mathscr{F} \in \mathrm{QCoh}(X)$ is a rule which assigns to every point $\eta \in X(A)$ an A-module $\mathscr{F}_\eta$, and to every morphism $f : A \to A'$ carrying η to $\eta' \in X(A')$ an equivalence $\mathscr{F}_{\eta'} \simeq A' \otimes_A \mathscr{F}_\eta$.

We now consider a variant of Construction 13.4.6.1:

Construction 13.4.6.4. Let κ be a field of characteristic zero. The coCartesian fibration $\mathrm{Rep}_{\mathrm{dg}}^{\otimes}[W^{-1}] \to (\mathrm{Lie}_\kappa^{\mathrm{dg}})^{\mathrm{op}} \times \mathcal{F}\mathrm{in}_*$ of Corollary 13.4.4.4 classifies a functor $\overline{\chi}_0 : (\mathrm{Lie}_\kappa^{\mathrm{dg}})^{\mathrm{op}} \to \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty)$, given on objects by $\mathfrak{g}_* \mapsto \mathrm{Rep}_{\mathfrak{g}_*}$. If $\phi : \mathfrak{h}_* \to \mathfrak{g}_*$ is a quasi-isomorphism of differential graded Lie algebras, then the induced map $U(\mathfrak{h}_*) \to U(\mathfrak{g}_*)$ is an equivalence in Alg_κ, so that the forgetful functor $\mathrm{Rep}_{\mathfrak{g}_*} \to \mathrm{Rep}_{\mathfrak{h}_*}$ is an equivalence of ∞-categories. It follows that $\overline{\chi}_0$ induces a functor $\overline{\chi} : \mathrm{Lie}_\kappa^{\mathrm{op}} \to \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty)$.

We let $\chi_!^{\mathrm{art}} : \mathrm{CAlg}_\kappa^{\mathrm{art}} \to \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty)$ denote the composition of $\overline{\chi}$ with the Koszul duality functor $\mathfrak{D} : (\mathrm{CAlg}_\kappa^{\mathrm{art}})^{\mathrm{op}} \to \mathrm{Lie}_\kappa$ studied in §13.3. Applying Theorem HTT.5.1.5.6 , we deduce that $\chi_!^{\mathrm{art}}$ admits an essentially unique factorization as a composition

$$\mathrm{CAlg}_\kappa^{\mathrm{art}} \xrightarrow{j} \mathrm{Fun}(\mathrm{CAlg}_k^{\mathrm{art}}, \mathcal{S})^{\mathrm{op}} \xrightarrow{\mathrm{QCoh}^!} \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty),$$

where j denotes the Yoneda embedding and the functor $\mathrm{QCoh}^!$ preserves small limits.

Remark 13.4.6.5. If $f : X \to Y$ is a natural transformation between functors $X, Y : \mathrm{CAlg}^{\mathrm{art}}_{\kappa} \to \mathcal{S}$, we will denote the induced functor $\mathrm{QCoh}^!(Y) \to \mathrm{QCoh}^!(X)$ by $f^!$.

The functor $\chi^{\mathrm{art}}_!$ appearing in Construction 13.4.6.4 factors through the subcategory $\mathrm{CAlg}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \subseteq \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_{\infty})$. As in Remark 13.4.6.2, we deduce that the functor $\mathrm{QCoh}^!$ factors through $\mathrm{CAlg}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$. That is, each of the ∞-categories $\mathrm{QCoh}^!(X)$ is presentable, each of the functors $f^! : \mathrm{QCoh}^!(Y) \to \mathrm{QCoh}^!(X)$ preserves small colimits, and the tensor product functors $\mathrm{QCoh}^!(X) \times \mathrm{QCoh}^!(X) \to \mathrm{QCoh}^!(X)$ preserve small colimits separately in each variable.

Remark 13.4.6.6. For $A \in \mathrm{Alg}^{\mathrm{art}}_{\kappa}$, the biduality map $A \to C^*(\mathfrak{D}(A))$ is an equivalence. It follows that the functor χ^{art} of Construction 13.4.6.1 is given by the composition

$$\mathrm{CAlg}^{\mathrm{art}}_{\kappa} \xrightarrow{\mathfrak{D}} \mathrm{Lie}^{\mathrm{op}}_{\kappa} \xrightarrow{C^*} \mathrm{CAlg}^{\mathrm{aug}}_{\kappa} \to \mathrm{CAlg}_{\kappa} \xrightarrow{\chi} \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_{\infty}).$$

The functor F of Proposition 13.4.5.3 induces a natural transformation $\chi^{\mathrm{art}} \to \chi^{\mathrm{art}}_!$, and therefore a natural transformation $\mathrm{QCoh} \to \mathrm{QCoh}^!$ of functors $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{art}}_{\kappa}, \mathcal{S})^{\mathrm{op}} \to \mathrm{CAlg}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$.

Let $A \in \mathrm{CAlg}^{\mathrm{art}}_{\kappa}$ and let $\mathfrak{g}_* = \mathfrak{D}(A)$ be its Koszul dual. Since A is Artinian, there exists a sequence of maps $A = A_n \to A_{n-1} \to \cdots \to A_0 = \kappa$, where each A_i is a square-zero extension of A_{i-1} by $\Sigma^{n_i}(\kappa)$ for some $n_i \geqslant 0$. We therefore have a sequence of differential graded Lie algebras

$$0 = \mathfrak{D}(A_0) \to \mathfrak{D}(A_1) \to \cdots \to \mathfrak{D}(A_n) \simeq \mathfrak{g}_*,$$

where each $\mathfrak{D}(A_i)$ is obtained from $\mathfrak{D}(A_{i-1})$ by adjoining a cell in dimension $-n_i - 1$. It follows that, up to quasi-isomorphism, $\mathfrak{g}_*$ satisfies the hypotheses of Proposition 13.4.3.1 and Proposition 13.4.3.4. We conclude that the natural transformation $\chi^{\mathrm{art}} \to \chi^{\mathrm{art}}_!$ induces a (symmetric monoidal) fully faithful embedding

$$\chi^{\mathrm{art}}(A) \simeq \mathrm{Mod}_A \simeq \mathrm{Mod}_{C^*(\mathfrak{g}_*)} \to \mathrm{Rep}_{\mathfrak{g}_*} \simeq \chi^{\mathrm{art}}_!(A),$$

which restricts to an equivalence of ∞-categories $\mathrm{Mod}^{\mathrm{cn}}_A \to \mathrm{Rep}^{\mathrm{cn}}_{\mathfrak{g}_*}$. It follows that the natural transformation $\mathrm{QCoh} \to \mathrm{QCoh}^!$ determines a (symmetric monoidal) fully faithful embedding $\mathrm{QCoh}(X) \to \mathrm{QCoh}^!(X)$ for each $X \in \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{art}}_{\kappa}, \mathcal{S})$.

13.4.7 The Proof of Theorem 13.4.0.1

Let κ be a field of characteristic zero and let $X : \mathrm{CAlg}^{\mathrm{art}}_{\kappa} \to \mathcal{S}$ be a formal moduli problem, given by $\Psi(\mathfrak{g}_*)$ for some differential graded Lie algebra $\mathfrak{g}_*$. Remark 13.4.6.6 supplies a symmetric monoidal fully faithful embedding $\mathrm{QCoh}(X) \hookrightarrow \mathrm{QCoh}^!(X)$. To prove Theorem 13.4.0.1, it will suffice to establish the following:

Proposition 13.4.7.1. *Let κ be a field of characteristic zero, let $\mathfrak{g}_*$ be a differential graded Lie algebra over κ and let $X = \Psi(\mathfrak{g}_*)$ be the formal moduli problem given by $X(R) = \mathrm{Map}_{\mathrm{Lie}_\kappa}(\mathfrak{D}(R), \mathfrak{g}_*)$. Then there is a canonical equivalence of symmetric monoidal ∞-categories $\mathrm{QCoh}^!(X) \simeq \mathrm{Rep}_{\mathfrak{g}_*}$.*

Lemma 13.4.7.2. *Let κ be a field and let $\nu : \mathrm{Alg}_\kappa^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ classify the Cartesian fibration $\mathrm{LMod}(\mathrm{Mod}_\kappa) \to \mathrm{Alg}_\kappa$ (so that ν is given by the formula $\nu(A) = \mathrm{LMod}_A$). Then ν preserves K-indexed limits for every weakly contractible simplicial set K.*

Proof. Let $\mathcal{P}\mathrm{r}^{\mathrm{R}}$ denote the subcategory of $\widehat{\mathcal{C}\mathrm{at}}_\infty$ whose objects are presentable ∞-categories and whose morphisms are functors which admit left adjoints, and define $\mathcal{P}\mathrm{r}^{\mathrm{L}} \subseteq \widehat{\mathcal{C}\mathrm{at}}_\infty$ similarly. Note that the functor ν factors through $\mathcal{P}\mathrm{r}^{\mathrm{R}}$, and that the inclusion $\mathcal{P}\mathrm{r}^{\mathrm{R}} \subseteq \widehat{\mathcal{C}\mathrm{at}}_\infty$ preserves small limits (Theorem HTT.5.5.3.18). It will therefore suffice to show that if K is weakly contractible, then ν carries K-indexed limits in $\mathrm{Alg}_\kappa^{\mathrm{op}}$ to K-indexed limits in $\mathcal{P}\mathrm{r}^{\mathrm{R}}$. Using the equivalence $\mathcal{P}\mathrm{r}^{\mathrm{L}} \simeq (\mathcal{P}\mathrm{r}^{\mathrm{R}})^{\mathrm{op}}$ of Corollary HTT.5.5.3.4 , we can identify ν with a functor $\mu : \mathrm{Alg}_\kappa \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ (the functor μ classifies the coCartesian fibration $\mathrm{LMod}(\mathrm{Mod}_\kappa) \to \mathrm{Alg}_\kappa$). Theorem HA.4.8.5.11 implies that the functor $\mathrm{Alg}_\kappa \simeq (\mathrm{Alg}_\kappa)_{\kappa/} \to (\mathcal{P}\mathrm{r}^{\mathrm{L}})_{\mathrm{Mod}_\kappa /}$ admits a right adjoint, and therefore preserves all small colimits. It therefore suffices to verify that the forgetful functor $(\mathcal{P}\mathrm{r}^{\mathrm{L}})_{\mathrm{Mod}_\kappa /} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ preserves K-indexed colimits, which follows from Proposition HTT.4.4.2.9 . □

Lemma 13.4.7.3. *Let κ be a field of characteristic zero, and let $\overline{\chi} : \mathrm{Lie}_\kappa^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ be as in Construction 13.4.6.4. Then $\overline{\chi}$ preserves K-indexed limits for every weakly contractible simplicial set K.*

Proof. The functor $\overline{\chi}$ factors as a composition $\mathrm{Lie}_\kappa^{\mathrm{op}} \xrightarrow{U} \mathrm{Alg}_\kappa^{\mathrm{op}} \xrightarrow{\nu} \widehat{\mathcal{C}\mathrm{at}}_\infty$, where ν preserves K-indexed limits by Lemma 13.4.7.2, and U preserves all small limits (since it is right adjoint to the forgetful functor $\mathrm{Alg}_\kappa^{\mathrm{op}} \to \mathrm{Lie}_\kappa^{\mathrm{op}}$). □

Proof of Proposition 13.4.7.1. Let $\Psi : \mathrm{Lie}_\kappa \to \mathrm{Moduli}_\kappa$ be the equivalence of ∞-categories appearing in Theorem 13.0.0.2, and let Ψ^{-1} denote a homotopy inverse to Ψ. Let $L : \mathrm{Fun}(\mathrm{CAlg}_\kappa^{\mathrm{art}}, \mathcal{S}) \to \mathrm{Moduli}_\kappa$ denote a left adjoint to the inclusion functor $\mathrm{Moduli}_\kappa \subseteq \mathrm{Fun}(\mathrm{CAlg}_\kappa^{\mathrm{art}}, \mathcal{S})$ (see Remark 12.1.3.5), and let $\widehat{\mathfrak{D}} : \mathrm{Fun}(\mathrm{CAlg}_\kappa^{\mathrm{art}}, \mathcal{S}) \to \mathrm{Lie}_\kappa$ be the composition $\Psi^{-1} \circ L$. The functor $\widehat{\mathfrak{D}}$ preserves small colimits, and the composition of $\widehat{\mathfrak{D}}$ with the Yoneda embedding $(\mathrm{CAlg}_\kappa^{\mathrm{art}})^{\mathrm{op}} \to \mathrm{Fun}(\mathrm{CAlg}_\kappa^{\mathrm{art}}, \mathcal{S})$ can be identified with the Koszul duality functor $\mathfrak{D} : (\mathrm{CAlg}_\kappa^{\mathrm{art}})^{\mathrm{op}} \to \mathrm{Lie}_\kappa$. Let $\overline{\chi} : \mathrm{Lie}_\kappa^{\mathrm{op}} \to \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty)$ be as in Construction 13.4.6.4 (given on objects by $\overline{\chi}(\mathfrak{g}_*) = \mathrm{Rep}_{\mathfrak{g}_*}$), and let $F : \mathrm{Fun}(\mathrm{CAlg}_\kappa^{\mathrm{art}}, \mathcal{S})^{\mathrm{op}} \to \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty)$ denote the composite functor

$$\mathrm{Fun}(\mathrm{CAlg}_\kappa^{\mathrm{art}}, \mathcal{S})^{\mathrm{op}} \xrightarrow{\widehat{\mathfrak{D}}} \mathrm{Lie}_\kappa^{\mathrm{op}} \xrightarrow{\overline{\chi}} \mathrm{CAlg}(\widehat{\mathcal{C}\mathrm{at}}_\infty).$$

Let $\mathcal{C}$ denote the full subcategory of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{art}}_{\kappa}, \mathcal{S})$ spanned by the corepresentable functors. By construction, the functors F and $\mathrm{QCoh}^{!}$ agree on the ∞-category $\mathcal{C}$, and by construction $\mathrm{QCoh}^{!}$ is a right Kan extension of its restriction to $\mathcal{C}$. We therefore have a canonical natural transformation $\alpha : F \to \mathrm{QCoh}^{!}$. We will prove the following:

$(*)$ If $X : \mathrm{CAlg}^{\mathrm{art}}_{\kappa} \to \mathcal{S}$ is a formal moduli problem, then α induces an equivalence of ∞-categories $F(X) \to \mathrm{QCoh}^{!}(X))$.

Taking $X = \Psi(\mathfrak{g}_*)$ for $A \in \mathrm{Alg}^{\mathrm{aug}}_{\kappa}$, we see that $(*)$ guarantees an equivalence of symmetric monoidal ∞-categories $\mathrm{Rep}_{\mathfrak{g}_*} \simeq F(X) \to \mathrm{QCoh}^{!}(X)$.

It remains to prove $(*)$. Let $\mathcal{E} \subseteq \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{art}}_{\kappa}, \mathcal{S})$ be the full subcategory spanned by those functors X for which α induces an equivalence of ∞-categories $F(X) \to \mathrm{QCoh}^{!}(X)$. The localization functor $L : \mathrm{Fun}(\mathrm{CAlg}^{\mathrm{art}}_{\kappa}, \mathcal{S}) \to \mathrm{Moduli}_{\kappa}$, the equivalence $\Psi^{-1} : \mathrm{Moduli}_{\kappa} \to \mathrm{Lie}_{\kappa}$ both preserve small colimits. It follows from Lemma 13.4.7.3 that the functor $\overline{\chi} : \mathrm{Lie}^{\mathrm{op}}_{\kappa} \to \widehat{\mathcal{C}\mathrm{at}}_{\infty}$ preserves sifted limits, so that F preserves sifted limits. Since the functor $\mathrm{QCoh}^{!}$ preserves small limits, the ∞-category $\mathcal{E}$ is closed under sifted colimits in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{art}}_{\kappa}, \mathcal{S})$. Since $\mathcal{E}$ contains all corepresentable functors and is closed under filtered colimits, it contains it contains all prorepresentable formal moduli problems (see Definition 12.5.3.1). Proposition 12.5.3.3 implies that every formal moduli problem X can be obtained as the geometric realization of a simplicial object $X_{\bullet}$ of $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{art}}_{\kappa}, \mathcal{S})$, where each X_n is prorepresentable. Since $\mathcal{E}$ is closed under geometric realizations in $\mathrm{Fun}(\mathrm{CAlg}^{\mathrm{art}}_{\kappa}, \mathcal{S})$, we conclude that $X \in \mathcal{E}$ as desired. □

13.4.8 Connectivity Conditions

Let $X : \mathrm{CAlg}^{\mathrm{art}}_{\kappa} \to \mathcal{S}$ be a formal moduli problem and let $\mathscr{F} \in \mathrm{QCoh}(X)$ be a quasi-coherent sheaf on X, so that $\mathscr{F}$ determines an A-module $\mathscr{F}_{\eta}$ for every $\eta \in X(A)$ (see Remark 13.4.6.3). We will say that $\mathscr{F}$ is *connective* if each $\mathscr{F}_{\eta} \in \mathrm{Mod}_A$ is connective. We let $\mathrm{QCoh}(X)^{\mathrm{cn}}$ denote the full subcategory of $\mathrm{QCoh}(X)$ spanned by the connective objects. It is easy to see that $\mathrm{QCoh}(X)^{\mathrm{cn}}$ is a presentable ∞-category which is closed under colimits and extensions in $\mathrm{QCoh}(X)$, and therefore determines an accessible t-structure on $\mathrm{QCoh}(X)$ (see Proposition HA.1.4.4.11).

Proposition 13.4.8.1. *Let κ be a field of characteristic zero, let $\mathfrak{g}_*$ be a differential graded Lie algebra over κ and let $X = \Psi(\mathfrak{g}_*)$ be the associated formal moduli problem. Then the fully faithful embedding $\theta : \mathrm{QCoh}(X) \to \mathrm{Rep}_{\mathfrak{g}_*}$ induces an equivalence of ∞-categories* $\mathrm{QCoh}(X)^{\mathrm{cn}} \to \mathrm{Rep}^{\mathrm{cn}}_{\mathfrak{g}_*}$.

Proof. If $\phi : \mathfrak{h}_* \to \mathfrak{g}_*$ is a map of differential graded Lie algebras over κ inducing a map of formal moduli problems $Y \to X$, then the diagram

$$\begin{array}{ccc} \mathrm{QCoh}(X) & \longrightarrow & \mathrm{Rep}_{\mathfrak{g}_*} \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(Y) & \longrightarrow & \mathrm{Rep}_{\mathfrak{g}_*} \end{array}$$

commutes up to canonical homotopy. Taking $\mathfrak{h}_* = 0$, we deduce that the composite functor $\mathrm{QCoh}(X) \to \mathrm{Rep}_{\mathfrak{g}_*} \to \mathrm{Mod}_\kappa$ is given by evaluation at the base point $\eta_0 \in X(\kappa)$. In particular, we deduce that θ carries $\mathrm{QCoh}(X)^{\mathrm{cn}}$ into $\mathrm{Rep}^{\mathrm{cn}}_{\mathfrak{g}_*} = \mathrm{Rep}_{\mathfrak{g}_*} \times_{\mathrm{Mod}_\kappa} \mathrm{Mod}^{\mathrm{cn}}_\kappa$. To complete the proof, it will suffice to show that if $V \in \mathrm{Mod}^{\mathrm{cn}}_{\mathfrak{g}_*}$, then V_* belongs to the essential image of θ. To prove this, it suffices to show that for every point $\eta \in X(A)$ classified by a map of differential graded Lie algebras $\mathfrak{D}(A) \to \mathfrak{g}_*$, the image of V in $\mathrm{Rep}_{\mathfrak{D}(A)}$ belongs to the essential image of the functor $\mathrm{QCoh}(\mathrm{Spf}\, A) \to \mathrm{Rep}_{\mathfrak{D}(A)}$. Since V is connective, this follows from Proposition 13.4.3.4 (note that $\mathfrak{D}(A)$ satisfies the hypotheses of Propositions 13.4.3.1 and 13.4.3.4; see Remark 13.4.6.6. $\square$

Chapter 14

Moduli Problems for Associative Algebras

Let A be a connective $\mathbb{E}_\infty$-ring. Recall that an A-module spectrum M is *projective of rank n* if the following conditions are satisfied:

(1) The group $\pi_0 M$ is a projective $\pi_0 A$-module of rank n.

(2) For every integer n, the canonical map $\mathrm{Tor}_0^{\pi_0 A}(\pi_n A, \pi_0 M) \to \pi_n M$ is an isomorphism (that is, M is flat over A).

Let $X(A)$ denote the subcategory of Mod_A whose objects are A-modules which are projective of rank n, and whose morphisms are equivalences. Then $X(A)$ is an essentially small Kan complex. The construction $A \mapsto X(A)$ determines a functor $X : \mathrm{CAlg}^{\mathrm{cn}} \to \mathcal{S}$.

Fix a field κ and a point $\eta \in X(\kappa)$, corresponding to a vector space V of dimension n over κ. The formal completion of X (at the point η) is the functor $X^\wedge : \mathrm{CAlg}^{\mathrm{art}}_\kappa \to \mathcal{S}$ given by $X^\wedge(A) = X(A) \times_{X(\kappa)} \{\eta\}$. More informally, $X^\wedge(A)$ is a classifying space for pairs (M, α), where M is a projective A-module of rank n and $\alpha : \kappa \otimes_A M \simeq V$ is an isomorphism of κ-vector spaces. It is not difficult to see that the functor $X^\wedge : \mathrm{CAlg}^{\mathrm{art}}_\kappa \to \mathcal{S}$ is a formal moduli problem (we will give a proof of a stronger assertion in §16.5).

Assume now that κ is a field of characteristic zero. According to Theorem 13.0.0.2, the functor $X^\wedge : \mathrm{CAlg}^{\mathrm{art}}_\kappa \to \mathcal{S}$ is determined (up to equivalence) by a differential graded Lie algebra $\mathfrak{g}_*$. Let $T_{X^\wedge}$ denote the tangent complex of $X^\wedge$, so that $\Sigma^{-1} T_{X^\wedge}$ can be identified with the spectrum underlying the chain complex of vector spaces $\mathfrak{g}_*$. Then $\Omega^\infty T_{X^\wedge} \simeq X^\wedge(\kappa[\epsilon]/(\epsilon^2))$ is a classifying space for the groupoid of order deformations of the vector space V: that is, projective $\kappa[\epsilon]/(\epsilon^2)$-modules M equipped with an isomorphism $M/\epsilon M \simeq V$. Since any basis of V can be lifted to a basis for M, this groupoid has only one isomorphism class of objects (which is represented by the module $\kappa[\epsilon]/(\epsilon^2) \otimes_\kappa V$). We conclude that $\Omega^\infty T_{X^\wedge}$ is homotopy equivalent to the classifying space BG, where G is the group of automorphisms of $\kappa[\epsilon]/(\epsilon^2) \otimes_\kappa V$ which reduce to the identity automorphism modulo ϵ. Every such automorphism can be written uniquely as $1 + \epsilon M$, where $M \in \mathrm{End}(V)$ is an endomorphism of V. From this we deduce that the homology of the chain complex $\mathfrak{g}_*$ is isomorphic to $\mathrm{End}(V)$ in degree zero and vanishes in positive degrees. It also vanishes in negative degrees: this follows from the observation that each of the spaces $X^\wedge(\kappa \oplus \Sigma^n(\kappa))$ is connected (any basis for V can be lifted to a basis for any $(\kappa \oplus \Sigma^n(\kappa))$-module deforming V). It follows that $\mathfrak{g}_*$ is quasi-isomorphic to an ordinary Lie algebra $\mathfrak{g}$ over κ (concentrated in degree zero), whose underlying abelian group is isomorphic to $\mathrm{End}(V)$. With more effort, we can show that the isomorphism $\mathfrak{g} \simeq \mathrm{End}(V)$ is an isomorphism of Lie algebras: that is, the Lie bracket on $\mathfrak{g}$ can be identified with the usual commutator bracket $[A, B] = AB - BA$ of κ-linear endomorphisms of V (see Example 16.5.4.3).

However, there is more to the story. If $R \in \mathrm{CAlg}^{\mathrm{art}}_\kappa$, then any connective R-module M equipped with an equivalence $\kappa \otimes_R M \simeq V$ is automatically projective of rank n. We can therefore identify $X^\wedge(R)$ with the fiber product $\mathrm{LMod}^{\mathrm{cn}}_R \times_{\mathrm{LMod}^{\mathrm{cn}}_\kappa} \{V\}$. This description of $X^\wedge(R)$ makes no reference to the commutativity of R. We can therefore extend $X^\wedge$ to a functor $X^\wedge_+ : \mathrm{Alg}^{\mathrm{art}}_\kappa \to \mathcal{S}$, where $\mathrm{Alg}^{\mathrm{art}}_\kappa$ denotes the ∞-category of Artinian $\mathbb{E}_1$-algebras over κ (see Definition 14.0.0.1 below). The existence of the extension $X^\wedge_+$ is a special property enjoyed by the formal moduli problem $X^\wedge$. Since $X^\wedge$ is completely determined by the Lie algebra $\mathrm{End}(V)$, we should expect that the existence of $X^\wedge_+$ reflects a special property of $\mathrm{End}(V)$. In fact, there *is* something special about $\mathrm{End}(V)$: it is the underlying Lie algebra of an associative algebra. We will see that this is a general phenomenon: if $\mathfrak{g}_*$ is a differential graded Lie algebra and $Y : \mathrm{CAlg}^{\mathrm{art}}_\kappa \to \mathcal{S}$ is the associated formal moduli problem for $\mathbb{E}_\infty$-algebras over κ, then Y extends to a formal moduli problem $Y_+ : \mathrm{Alg}^{\mathrm{art}}_\kappa \to \mathcal{S}$ for $\mathbb{E}_1$-algebras over κ if and only if $\mathfrak{g}_*$ is quasi-isomorphic to the underlying Lie algebra of a (nonunital) differential graded algebra A_* (see Example 13.1.2.2).

Our main goal in this section is to prove an analogue of Theorem 13.0.0.2 in the setting of noncommutative geometry. Before we can state our result, we need to introduce a bit of terminology.

Definition 14.0.0.1. Let κ be a field. We let Alg_κ denote the ∞-category of $\mathbb{E}_1$-algebras over κ. We will say that an object $A \in \mathrm{Alg}_\kappa$ is *Artinian* if it satisfies the following conditions:

(a) The algebra A is connective: that is, $\pi_i A \simeq 0$ for $i < 0$.

(b) The algebra A is truncated: that is, we have $\pi_i A \simeq 0$ for $i \gg 0$.

(c) Each of the homotopy groups $\pi_i A$ is finite dimensional when regarded as a vector space over field κ.

(d) Let $\mathfrak{n}$ denote the radical of the ring $\pi_0 A$. Then the canonical map $\kappa \to (\pi_0 A)/\mathfrak{n}$ is an isomorphism.

We let $\mathrm{Alg}_\kappa^{\mathrm{art}}$ denote the full subcategory of Alg_κ spanned by the Artinian κ-algebras.

Warning 14.0.0.2. Let κ be a field and let A be a discrete κ-algebra. If A is Artinian in the sense of Definition 14.0.0.1, then A is left (and right) Artinian in the usual sense of noncommutative algebra: that is, the collection of left ideals of A satisfies the descending chain condition. However, the converse is false: for example, the ring $M_2(\kappa)$ of 2-by-2 matrices over κ does not satisfy condition (d) of Definition 14.0.0.1. One should instead regard Definition 14.0.0.1 as a noncommutative (and derived) analogue of the condition that a commutative κ-algebra A be a local Artinian ring with residue field κ: see Warning 12.1.2.6.

Remark 14.0.0.3. Let κ be a field and let $A \in \mathrm{Alg}_\kappa^{\mathrm{art}}$. It follows from conditions (a) and (d) of Definition 14.0.0.1 that the mapping space $\mathrm{Map}_{\mathrm{Alg}_\kappa}(A, \kappa)$ is contractible: that is, A admits an essentially unique augmentation. Consequently, the projection map $\mathrm{Alg}_\kappa^{\mathrm{art}} \times_{\mathrm{Alg}_\kappa} \mathrm{Alg}_\kappa^{\mathrm{aug}} \to \mathrm{Alg}_\kappa^{\mathrm{art}}$ is an equivalence of ∞-categories; here $\mathrm{Alg}_\kappa^{\mathrm{aug}} = (\mathrm{Alg}_\kappa)_{/\kappa}$ denotes the ∞-category of augmented $\mathbb{E}_1$-algebras over κ. Because of this, we will often abuse notation by identifying $\mathrm{Alg}_\kappa^{\mathrm{art}}$ with its inverse image in $\mathrm{Alg}_\kappa^{\mathrm{aug}}$.

Definition 14.0.0.4. Let κ be a field and let $X : \mathrm{Alg}_\kappa^{\mathrm{art}} \to \mathcal{S}$ be a functor. We will say that X is a *formal* $\mathbb{E}_1$*-moduli problem* if it satisfies the following conditions:

(1) The space $X(\kappa)$ is contractible.

(2) For every pullback diagram

$$\begin{array}{ccc} R & \longrightarrow & R_0 \\ \downarrow & & \downarrow \\ R_1 & \longrightarrow & R_{01} \end{array}$$

in $\mathrm{Alg}_\kappa^{\mathrm{art}}$ for which the underlying maps $\pi_0 R_0 \to \pi_0 R_{01} \leftarrow \pi_0 R_1$ are surjective, the diagram

$$\begin{array}{ccc} X(R) & \longrightarrow & X(R_0) \\ \downarrow & & \downarrow \\ X(R_1) & \longrightarrow & X(R_{01}) \end{array}$$

is a pullback square.

We let $\mathrm{Moduli}_\kappa^{(1)}$ denote the full subcategory of $\mathrm{Fun}(\mathrm{Alg}_\kappa^{\mathrm{art}}, \mathcal{S})$ spanned by the formal $\mathbb{E}_1$-moduli problems.

We can now state our main result:

Theorem 14.0.0.5. *Let κ be a field. Then there is an equivalence of ∞-categories $\Psi : \mathrm{Alg}_\kappa^{\mathrm{aug}} \to \mathrm{Moduli}_\kappa^{(1)}$.*

Remark 14.0.0.6. Unlike Theorem 13.0.0.2, Theorem 14.0.0.5 does not require any assumptions on the characteristic of the field κ.

Like Theorem 13.0.0.2, Theorem 14.0.0.5 is a reflection of Koszul duality: this time in the setting of associative algebras. In §14.1, we will introduce the Koszul duality functor $\mathfrak{D}^{(1)} : (\mathrm{Alg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{\mathrm{aug}}$. Roughly speaking, if $\epsilon : A \to \kappa$ is an augmented $\mathbb{E}_1$-algebra over κ, then the Koszul dual $\mathfrak{D}^{(1)}(A)$ is the (derived) endomorphism algebra of κ as a (left) A-module. In §14.2, we will show that $\mathfrak{D}^{(1)}$ is a deformation theory (in the sense of Definition 12.3.3.2). We will then deduce Theorem 14.0.0.5 from Theorem 12.3.3.5, using the functor $\Psi : \mathrm{Alg}_\kappa^{\mathrm{aug}} \to \mathrm{Moduli}_\kappa^{(1)}$ given by

$$\Psi(A)(R) = \mathrm{Map}_{\mathrm{Alg}_\kappa^{\mathrm{aug}}}(\mathfrak{D}^{(1)}(R), A).$$

For every field κ, there is an evident forgetful functor $\mathrm{CAlg}_\kappa^{\mathrm{art}} \to \mathrm{Alg}_\kappa^{\mathrm{art}}$. Composition with this forgetful functor determines a map $\theta : \mathrm{Moduli}_\kappa^{(1)} \to \mathrm{Moduli}_\kappa$. In §14.3, we will show that if the characteristic of κ is zero, then θ fits into a commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{Alg}_\kappa^{\mathrm{aug}} & \longrightarrow & \mathrm{Moduli}_\kappa^{(1)} \\ \downarrow{\scriptstyle \theta'} & & \downarrow{\scriptstyle \theta} \\ \mathrm{Lie}_\kappa & \longrightarrow & \mathrm{Moduli}_\kappa, \end{array}$$

where the upper horizontal map is the equivalence of Theorem 14.0.0.5 and the lower horizontal map is the equivalence of Theorem 13.0.0.2. Here θ' is a functor which assigns to each augmented $\mathbb{E}_1$-algebra $\epsilon : A \to \kappa$ its augmentation ideal $\mathfrak{m}_A = \mathrm{fib}(\epsilon)$, equipped with the commutator bracket (Proposition 14.3.1.1).

If X is a formal $\mathbb{E}_1$-moduli problem over κ, then we can associate to X a pair of ∞-categories $\mathrm{QCoh}_L(X)$ and $\mathrm{QCoh}_R(X)$, which we call the *∞-categories of (left and right) quasi-coherent sheaves on X*. Roughly speaking, an object $\mathscr{F} \in \mathrm{QCoh}_L(X)$ is a rule which assigns to each point $\eta \in X(A)$ a left A-module $\mathscr{F}_\eta$, depending functorially on η (and $\mathrm{QCoh}_R(X)$ is defined similarly, using right modules in place of left). In §14.5, we will construct fully faithful embeddings

$$\mathrm{QCoh}_L(X) \hookrightarrow \mathrm{QCoh}^!_L(X) \qquad \mathrm{QCoh}_R(X) \hookrightarrow \mathrm{QCoh}^!_R(X),$$

where $\mathrm{QCoh}^!_L(X)$ and $\mathrm{QCoh}^!_R(X)$ are the (left and right) ∞-categories of Ind-*coherent sheaves on X*. Our construction requires a "fiberwise" version of the construction of opposite categories $\mathcal{C} \mapsto \mathcal{C}^{\mathrm{op}}$, which we review in §14.4. In §14.6, we will use these constructions to formulate and prove a noncommutative analogue of Theorem 13.4.0.1: if $X = \Psi(A)$ is the formal moduli problem associated to an augmented $\mathbb{E}_1$-algebra A over κ, then there are canonical equivalences of ∞-categories

$$\mathrm{QCoh}^!_L(X) \simeq \mathrm{RMod}_A \qquad \mathrm{QCoh}^!_R(X) \simeq \mathrm{LMod}_A$$

(Theorem 14.6.0.1). In particular, this gives fully faithful embeddings

$$\mathrm{QCoh}_L(X) \hookrightarrow \mathrm{RMod}_A \qquad \mathrm{QCoh}_R(X) \hookrightarrow \mathrm{LMod}_A,$$

which are equivalences when restricted to connective objects (Proposition 14.6.3.1).

14.1 Koszul Duality for Associative Algebras

Let κ be a field, let A be an associative algebra over κ, and let M be a left A-module. The *commutant* B of A in $\mathrm{End}_\kappa(M)$ is defined to be the set of A-linear endomorphisms of M. Then B can be regarded as an associative algebra over κ, and M admits an action of the tensor product $A \otimes_\kappa B$. In many cases, one can show that the relationship between A and B is symmetric. For example, if A is a finite dimensional central simple algebra over κ and M is nonzero and of finite dimension over κ, then we can recover A as the commutant of B in $\mathrm{End}_\kappa(M)$.

In this section, we will discuss the operation of Koszul duality in the setting of (augmented) $\mathbb{E}_1$-algebras over a field κ. Roughly speaking, Koszul duality can be regarded as a derived version of the formation of commutants. Suppose that A is an $\mathbb{E}_1$-algebra over κ equipped with an augmentation $\epsilon : A \to \kappa$. Then ϵ determines an action of A on the κ-module $M = \kappa$. The *Koszul dual* of A is an $\mathbb{E}_1$-algebra B over κ which classifies A-linear maps from M to itself. We have commuting actions of A and B on M, which can be encoded by a map $\mu : A \otimes_\kappa B \to \kappa$ extending the augmentation ϵ. This suggests the following definition:

($*$) Let A be an augmented $\mathbb{E}_1$-algebra over a field κ. Then the *Koszul dual* of A is universal among $\mathbb{E}_1$-algebras B equipped with an augmentation $\mu : A \otimes_\kappa B \to \kappa$ extending the augmentation on A.

Our first goal in this section is to make ($*$) more precise, and show that it determines a (contravariant) functor $\mathfrak{D}^{(1)}$ from the ∞-category $\mathrm{Alg}^{\mathrm{aug}}_\kappa$ of augmented $\mathbb{E}_1$-algebras over κ to itself. Every augmentation $\mu : A \otimes_\kappa B \to \kappa$ restricts to augmentations on A and B, and is classified by a map of augmented $\mathbb{E}_1$-algebras $\alpha : B \to \mathfrak{D}^{(1)}(A)$. We will say that μ *exhibits B as a Koszul dual of A* if the map α is an equivalence. The main results of this section establish some basic formal properties of Koszul duality:

(a) Let $\mu : A \otimes_\kappa B \to \kappa$ be an augmentation which exhibits B as the Koszul dual of A. Under some mild hypotheses, there is a close relationship between the ∞-categories LMod_A and LMod_B of (left) modules over A and B, respectively (Theorem 14.1.3.2).

(*b*) Let $\mu : A \otimes_\kappa B \to \kappa$ be an augmentation which exhibits B as the Koszul dual of A. Under some mild hypotheses, it follows that μ also exhibits A as a Koszul dual of B (Corollary 14.1.3.3). In other words, the double commutant map $A \to \mathfrak{D}^{(1)}\mathfrak{D}^{(1)}(A)$ is often an equivalence.

14.1.1 The Self-Pairing of $\mathrm{Alg}_\kappa^{\mathrm{aug}}$

We begin by reviewing some terminology. If $\mathcal{C}$ and $\mathcal{D}$ are ∞-categories, a *pairing* of $\mathcal{C}$ with $\mathcal{D}$ is an ∞-category $\mathcal{M}$ equipped with a right fibration $\lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D}$ (see §HA.**??**). We say that such a pairing is *left representable* if, for each object $C \in \mathcal{C}$, there exists a final object of the fiber $\mathcal{M} \times_{\mathcal{C}} \{C\}$. In this case, we let $\mathfrak{D}_\lambda(C)$ denote the image of that final object in $\mathcal{D}$; the construction $C \mapsto \mathfrak{D}_\lambda(C)$ determines a functor from $\mathcal{C}^{\mathrm{op}}$ to $\mathcal{D}$, which we will refer to as the *duality functor* associated to the pairing $(\lambda : \mathcal{M} \to \mathcal{C} \times \mathcal{D})$. Similarly, we see that λ is *right representable* if, for each $D \in \mathcal{D}$, the fiber $\mathcal{M} \times_{\mathcal{D}} \{D\}$ has a final object; in this case, we let $\mathcal{D}'_\lambda(C)$ denote the image of that final object in $\mathcal{C}$. If λ is both right and left representable, then the duality functors $\mathbb{D}_\lambda$ and $\mathbb{D}'_\lambda$ are mutually adjoint (see Construction HA.5.2.1.9).

Let us now specialize to the main example of interest.

Construction 14.1.1.1. Let κ be a field, let $\mathrm{Alg}_\kappa = \mathrm{Alg}(\mathrm{Mod}_\kappa)$ denote the ∞-category of associative algebra objects of Mod_κ, and let $\mathrm{Alg}_\kappa^{\mathrm{aug}} = (\mathrm{Alg}_\kappa)_{/\kappa}$ denote the ∞-category of augmented associative algebra objects of Mod_κ. We will regard Alg_κ as a symmetric monoidal ∞-category (where the tensor product operation is computed pointwise). Let $m : \mathrm{Alg}_\kappa \times \mathrm{Alg}_\kappa \to \mathrm{Alg}_\kappa$ denote the tensor product functor, and let $p_0, p_1 : \mathrm{Alg}_\kappa \times \mathrm{Alg}_\kappa \to \mathrm{Alg}_\kappa$ denote the projection onto the first and second factor, respectively. Since the unit object of Alg_κ is initial, we have natural transformations $p_0 \xrightarrow{\alpha_0} m \xleftarrow{\alpha_1} p_1$, which determine a map $\mathrm{Alg}_\kappa \times \mathrm{Alg}_\kappa \to \mathrm{Fun}(\Lambda^2_2, \mathrm{Alg}_\kappa)$. We let $\mathcal{M}^{(1)}$ denote the fiber product

$$(\mathrm{Alg}_\kappa \times \mathrm{Alg}_\kappa) \times_{\mathrm{Fun}(\Lambda^2_2, \mathrm{Alg}_\kappa)} \mathrm{Fun}(\Lambda^2_2, \mathrm{Alg}_\kappa^{\mathrm{aug}}).$$

More informally, the objects of $\mathcal{M}^{(1)}$ can be identified with triples (A, B, ϵ), where A and B are $\mathbb{E}_1$-algebras over κ, and $\epsilon : A \otimes_\kappa B \to \kappa$ is an augmentation on the tensor product $A \otimes_\kappa B$ (which then induces augmentations on A and B, respectively). Note that evaluation on the vertices $0, 1 \in \Lambda^2_2$ induces a right fibration $\lambda : \mathcal{M}^{(1)} \to \mathrm{Alg}_\kappa^{\mathrm{aug}} \times \mathrm{Alg}_\kappa^{\mathrm{aug}}$.

Proposition 14.1.1.2. *Let κ be a field and let $\lambda : \mathcal{M}^{(1)} \to \mathrm{Alg}_\kappa^{\mathrm{aug}} \times \mathrm{Alg}_\kappa^{\mathrm{aug}}$ be the pairing of ∞-categories described in Construction 14.1.1.1. Then λ is both left and right representable.*

Proof. We will prove that λ is left representable; the proof of right representability is similar. Fix an object $A \in \mathrm{Alg}_\kappa^{\mathrm{aug}}$, and let $F : (\mathrm{Alg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathcal{S}$ be the functor given by

$$F(B) = \mathrm{fib}(\mathrm{Map}_{\mathrm{Alg}_\kappa}(A \otimes_\kappa B, \kappa) \to \mathrm{Map}_{\mathrm{Alg}_\kappa}(A, \kappa) \times \mathrm{Map}_{\mathrm{Alg}_\kappa}(B, \kappa)).$$

We wish to show that the functor F is representable by an object of $\mathrm{Alg}_\kappa^{\mathrm{aug}}$. Define $F' : \mathrm{Alg}_\kappa^{\mathrm{op}} \to \mathcal{S}$ by the formula

$$F'(B) = \mathrm{fib}(\mathrm{Map}_{\mathrm{Alg}_\kappa}(A \otimes_\kappa B, \kappa) \to \mathrm{Map}_{\mathrm{Alg}_\kappa}(A, \kappa)).$$

Corollary HA.5.3.1.15 implies that the functor F' is corepresented by an object $B_0 \in \mathrm{Alg}_\kappa$, given by a centralizer of the augmentation $\epsilon : A \to \kappa$. In particular, we have a point of $\eta \in F'(B_0)$, which determines an augmentation $\mu : A \otimes_\kappa B_0 \to \kappa$. Let us regard B_0 as an augmented algebra object via the composite map $B_0 \to A \otimes_\kappa B_0 \xrightarrow{\mu} \kappa$, so that η lifts to a point $\overline{\eta} \in F(B_0)$. To complete the proof, it will suffice to show that for each $B \in \mathrm{Alg}_\kappa^{\mathrm{aug}}$, evaluation on $\overline{\eta}$ induces a homotopy equivalence $\theta : \mathrm{Map}_{\mathrm{Alg}_\kappa^{\mathrm{aug}}}(B, B_0) \to F(B)$. This map fits into a map of fiber sequences

$$\begin{array}{ccccc} \mathrm{Map}_{\mathrm{Alg}_\kappa^{\mathrm{aug}}}(B, B_0) & \longrightarrow & \mathrm{Map}_{\mathrm{Alg}_\kappa}(B, B_0) & \longrightarrow & \mathrm{Map}_{\mathrm{Alg}_\kappa}(B, \kappa) \\ \downarrow & & \downarrow{\scriptstyle \theta'} & & \downarrow{\scriptstyle \theta''} \\ F(B) & \longrightarrow & F'(B) & \longrightarrow & \mathrm{Map}_{\mathrm{Alg}_\kappa}(B, \kappa), \end{array}$$

where θ' and θ'' are homotopy equivalences (in the first case, this follows from our assumption that η exhibits F' as the functor represented by B_0). □

Definition 14.1.1.3. Let κ be a field. We let $\mathfrak{D}^{(1)} : (\mathrm{Alg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{\mathrm{aug}}$ denote the functor obtained by applying Construction **??** to the left representable pairing $\lambda : \mathcal{M}^{(1)} \to \mathrm{Alg}_\kappa^{\mathrm{aug}} \times \mathrm{Alg}_\kappa^{\mathrm{aug}}$ of Construction 14.1.1.1. We will refer to the functor $\mathfrak{D}^{(1)}$ as *Koszul duality*.

Remark 14.1.1.4. Since the pairing $\lambda : \mathcal{M}^{(1)} \to \mathrm{Alg}_\kappa^{\mathrm{aug}} \times \mathrm{Alg}_\kappa^{\mathrm{aug}}$ of Construction 14.1.1.1 is both left and right representable, it determines two functors $(\mathrm{Alg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{\mathrm{aug}}$. It follows by symmetry considerations that these functors are (canonically) equivalent to one another; hence there is no risk of confusion if we denote them both by $\mathfrak{D}^{(1)} : (\mathrm{Alg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{\mathrm{aug}}$. Using Construction HA.5.2.1.9 we see that $\mathfrak{D}^{(1)}$ is self-adjoint: more precisely, the functor $\mathfrak{D}^{(1)} : (\mathrm{Alg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{\mathrm{aug}}$ is right adjoint to the induced map between opposite ∞-categories $\mathrm{Alg}_\kappa^{\mathrm{aug}} \to (\mathrm{Alg}_\kappa^{\mathrm{aug}})^{\mathrm{op}}$. More concretely, for any pair of objects $A, B \in \mathrm{Alg}_\kappa^{\mathrm{aug}}$ we have a canonical homotopy equivalence

$$\mathrm{Map}_{\mathrm{Alg}_\kappa^{\mathrm{aug}}}(A, \mathfrak{D}^{(1)}(B)) \simeq \mathrm{Map}_{\mathrm{Alg}_\kappa^{\mathrm{aug}}}(B, \mathfrak{D}^{(1)}(A)).$$

In fact, both of these spaces can be identified with the homotopy fiber of the canonical map

$$\mathrm{Map}_{\mathrm{Alg}_\kappa}(A \otimes_\kappa B, \kappa) \to \mathrm{Map}_{\mathrm{Alg}_\kappa}(A, \kappa) \times \mathrm{Map}_{\mathrm{Alg}_\kappa}(B, \kappa).$$

Remark 14.1.1.5. Let κ be a field and let $\mu : A \otimes_\kappa B \to \kappa$ be a morphism in Alg_κ, which we can identify with an object of the ∞-category $\mathcal{M}^{(1)}$ of Construction 14.1.1.1. We say that μ *exhibits B as a Koszul dual of A* if it is left universal in the sense of Definition **??**: that is, if it induces an equivalence $B \to \mathfrak{D}^{(1)}(A)$. Similarly, we say that μ *exhibits A as a Koszul dual of B* if it is right universal: that is, if it induces an equivalence $A \to \mathfrak{D}^{(1)}(B)$.

14.1.2 The Pairing on Modules

We now discuss a linearized version of Koszul duality.

Construction 14.1.2.1. Let κ be a field and let $\mu : A \otimes_\kappa B \to \kappa$ be a morphism in Alg_κ. Then extension of scalars along μ induces a functor

$$\mathrm{LMod}_A \times \mathrm{LMod}_B \to \mathrm{LMod}_\kappa \simeq \mathrm{Mod}_\kappa .$$

We let LPair_μ denote the fiber product $(\mathrm{LMod}_A \times \mathrm{LMod}_B) \times_{\mathrm{Mod}_\kappa} (\mathrm{Mod}_\kappa)_{/\kappa}$. We can think of the objects of LPair_μ as triples (M, N, ϵ), where M is a left module over A, N is a left module over B, and $\epsilon : M \otimes_\kappa N \to \kappa$ is a map of left modules over $A \otimes_\kappa B$. The projection map $\lambda : \mathrm{LPair}_\mu \to \mathrm{LMod}_A \times \mathrm{LMod}_B$ is a right fibration, so that we can regard LPair_μ as a pairing of ∞-categories.

Proposition 14.1.2.2. *Let κ be a field, let $\mu : A \otimes_\kappa B \to \kappa$ be a morphism in Alg_κ, and let $\lambda : \mathrm{LPair}_\mu \to \mathrm{LMod}_A \times \mathrm{LMod}_B$ be the pairing of ∞-categories of Construction 14.1.2.1. Then λ is both left and right representable.*

Proof. We will prove that λ is left representable; the proof of right representability is similar. Fix an object $M \in \mathrm{LMod}_A$; we wish to show that that the functor $N \mapsto \mathrm{Map}_{\mathrm{LMod}_{A \otimes_\kappa B}}(M \otimes_\kappa N, \kappa)$ is representable by an object of LMod_B. Let us denote this functor by F. According to Proposition HTT.5.5.2.2 , it will suffice to show that the functor F carries colimits in LMod_B to limits in $\mathcal{S}$. This follows from the observation that the construction $N \mapsto M \otimes_\kappa N$ determines a functor $\mathrm{LMod}_B \to \mathrm{LMod}_{A \otimes_\kappa B}$ which commutes with small colimits. □

Notation 14.1.2.3. Let κ be a field and let $\mu : A \otimes_\kappa B \to \kappa$ be a morphism in Alg_κ. Combining Proposition 14.1.2.2 with Construction **??**, we obtain duality functors

$$\mathrm{LMod}_A^{\mathrm{op}} \xrightarrow{\mathfrak{D}_\mu} \mathrm{LMod}_B \qquad \mathrm{LMod}_B^{\mathrm{op}} \xrightarrow{\mathfrak{D}'_\mu} \mathrm{LMod}_A .$$

By construction, we have canonical homotopy equivalences

$$\mathrm{Map}_{\mathrm{LMod}_A}(M, \mathfrak{D}'_\mu N) \simeq \mathrm{Map}_{\mathrm{LMod}_{A \otimes_\kappa B}}(M \otimes_\kappa N, \kappa) \simeq \mathrm{Map}_{\mathrm{LMod}_B}(N, \mathfrak{D}_\mu M).$$

Remark 14.1.2.4. Let κ be a field and let $\mu : A \otimes_\kappa B \to \kappa$ be a morphism in Alg_κ. The proof of Theorem HA.5.3.1.14 shows that μ exhibits B as a Koszul dual of A if and only if μ exhibits B as a classifying object for morphisms from A to κ in $\mathrm{Mod}_A^{\mathrm{Assoc}}(\mathrm{Mod}_\kappa) \simeq {}_A\mathrm{BMod}_A(\mathrm{Mod}_\kappa)$ (here we regard ${}_A\mathrm{BMod}_A(\mathrm{Mod}_\kappa)$ as left-tensored over the ∞-category Mod_κ). This is equivalent to the condition that ϵ exhibit B as a classifying object for morphisms from $\kappa \simeq A \otimes_A \kappa$ to itself in ${}_A\mathrm{BMod}_\kappa(\mathrm{Mod}_\kappa) \simeq \mathrm{LMod}_A$: that is, that μ induces an equivalence of left B-modules $B \to \mathfrak{D}_\mu \mathfrak{D}'_\mu(B) \simeq \mathfrak{D}_\mu(\kappa)$. Similarly, μ exhibits A as a Koszul dual of B if and only if it induces an equivalence $A \to \mathfrak{D}'_\mu(\kappa)$ of left A-modules.

14.1.3 Biduality

We would like to use Remark 14.1.2.4 to verify (in good cases) that the relation of Koszul duality is symmetric. For this, we need to understand the linear duality functors $\mathfrak{D}_\mu$ and $\mathfrak{D}'_\mu$ associated to a pairing $\mu : A \otimes_\kappa B \to \kappa$.

Definition 14.1.3.1. Let κ be a field. An object $A \in \mathrm{Alg}_\kappa$ is *coconnective* if the unit map $\kappa \to A$ exhibits κ as a connective cover A. Equivalently, A is coconnective if $\pi_0 A$ is a 1-dimensional vector space over κ generated by the unit element, and $\pi_n A \simeq 0$ for $n > 0$.

If $M \in \mathrm{Mod}_\kappa$, we will say that M is *locally finite* if each of the homotopy groups $\pi_n M$ is finite dimensional as a vector space over κ. We will say that an object $A \in \mathrm{Alg}_\kappa$ is *locally finite* if it is locally finite when regarded as an object of Mod_κ.

Our analysis of the Koszul duality functor rests on the following result, which we will prove at the end of this section:

Theorem 14.1.3.2. *Let κ be a field and let $\mu : A \otimes_\kappa B \to \kappa$ be a morphism in Alg_κ. Assume that A is coconnective and that μ exhibits B as a Koszul dual of A. Then:*

(1) *Let M be a left A-module such that $\pi_n M \simeq 0$ for $n > 0$. Then $\pi_n \mathfrak{D}_\mu(M) \simeq 0$ for $n < 0$.*

(2) *The $\mathbb{E}_1$-algebra B is connective.*

(3) *Let N be a connective B-module. Then $\pi_n \mathfrak{D}'_\mu(N) \simeq 0$ for $n > 0$.*

(4) *Let M be as in (1) and assume that M is locally finite. Then the canonical map $M \to \mathfrak{D}'_\mu \mathfrak{D}_\mu M$ is an equivalence in LMod_A.*

Corollary 14.1.3.3. *Let κ be a field, and let $A \in \mathrm{Alg}^{\mathrm{aug}}_\kappa$ be coconnective and locally finite. Then the canonical map $A \to \mathfrak{D}^{(1)}\mathfrak{D}^{(1)}(A)$ is an equivalence. In other words, if $\mu : A \otimes_\kappa B \to \kappa$ exhibits B as a Koszul dual of A, then μ also exhibits A as a Koszul dual of B.*

Proof. Let $\mu : A \otimes_\kappa B \to \kappa$ be a map which exhibits B as a Koszul dual of A. We wish to prove that μ exhibits A as the Koszul dual of B. According to Remark 14.1.2.4, it will suffice to show that the unit map $A \to \mathfrak{D}'_\mu \mathfrak{D}_\mu(A)$ is an equivalence of left A-modules. Since A is coconnective and locally finite, this follows from Theorem 14.1.3.2. □

14.1.4 Free Resolutions of Coconnective Modules

If A is a connective $\mathbb{E}_1$-ring, then the free A-modules of finite rank comprise compact projective generators for the ∞-category $\mathrm{LMod}^{\mathrm{cn}}_A$ of connective left A-modules. It follows that every connective A-module M can be written as the geometric realization of a simplicial object $M_\bullet$ of $\mathrm{LMod}_A^{\mathrm{cn}}$, where each M_k is free. Our next goal is to prove an analogous (but in some sense dual) result in the case where A is a coconnective $\mathbb{E}_1$-algebra over a field κ (see Definition 14.1.3.1). This result will play an important role in our proof of Theorem 14.1.3.2:

Proposition 14.1.4.1. *Let A be a coconnective $\mathbb{E}_1$-algebra over a field κ and let M be a left A-module. Then there exists a sequence of left A-modules*

$$0 = M(0) \to M(1) \to M(2) \to \cdots$$

with the following properties:

(a) *For each $n \geqslant 0$, there exists a κ-module spectrum $V(n)$ such that $\pi_i V(n) \simeq 0$ for $i \geqslant 0$ and a cofiber sequence of left A-modules*

$$A \otimes_\kappa V(n) \to M(n) \to M(n+1).$$

(b) *There exists a map $\theta : \varinjlim M(n) \to M$ which induces an isomorphism $\pi_m \varinjlim M(n) \to \pi_m M$ for $m \leqslant 0$.*

Remark 14.1.4.2. In the situation of Proposition 14.1.4.1, it follows easily by induction on n that $\pi_m M(n)$ vanishes for $m > 0$, so that the map $\theta : \varinjlim M(n) \to M$ is an equivalence if and only if $\pi_m M \simeq 0$ for $m > 0$.

Proof. Let M' be the underlying κ-module spectrum of M, and let $V(1) = \tau_{\leqslant 0} M'$. Since κ is a field, the canonical map $M' \to V(1)$ admits a section s. Set $M(1) = A \otimes_\kappa V(1)$, so that s determines a map of left A-modules $M(1) \to M$. By construction, the map $\pi_m M(1) \to \pi_m M$ is surjective for $m \leqslant 0$ and bijective for $m = 0$. We construct $M(n) \in (\mathrm{LMod}_A)_{/M}$ for $n > 1$ by induction on n. Assume that we have already constructed $M(n-1) \in (\mathrm{LMod}_A)_{/M}$, and that the map $e_m : \pi_m M(n-1) \to \pi_m M$ is bijective for $m = 0$ and surjective for $m < 0$. Let W_m denote the kernel of e_m (as a vector space over κ), and let $V(n) = \bigoplus_{m<0} \Sigma^m(W_m)$ (as a κ-module spectrum). We have an evident map of κ-modules $V(n) \to \mathrm{fib}(M(n-1) \to M)$, hence a map of left A-modules $f : (A \otimes_\kappa V(n)) \to \mathrm{fib}(M(n-1) \to M)$. Let $M(n)$ denote the cofiber of the map $A \otimes_\kappa V(n) \to M(n-1)$, so that f determines a map $M(n-1) \to M(n)$ in $(\mathrm{LMod}_A)_{/M}$ and we have a cofiber sequence

$$A \otimes_\kappa V(n) \to M(n-1) \to M(n).$$

For each $m \in \mathbf{Z}$, let $e'_m : \pi_m M(n) \to \pi_m M$ be the evident map. It is clear that e'_m is surjective for $m < 0$ (since e_m factors through e'_m). We claim that e'_m is bijective when

$m = 0$. To prove this, it suffices to show that the evident map $\pi_0 M(n-1) \to \pi_0 M(n)$ is bijective. We have a long exact sequence

$$\pi_1(A \otimes_\kappa V(n)) \to \pi_0 M(n-1) \xrightarrow{e'_n} \pi_0 M(n) \to \pi_0(A \otimes_\kappa V(n)) \xrightarrow{\phi} \pi_{-1} M(n-1).$$

Since A is coconnective and $\pi_m V(n) \simeq 0$ for $m > 0$, the vector space $\pi_1(A \otimes_\kappa V(n))$ is trivial and $\pi_0(A \otimes_\kappa V(n)) \simeq \pi_0 V(n) \simeq \ker(\pi_{-1} M(n-1) \to \pi_{-1} M)$. It follows that ϕ is injective so that e'_0 is an isomorphism.

It remains to prove that the map $\theta : \varinjlim M(n) \to M$ induces an isomorphism on π_m for $m \leqslant 0$. It is clear that the map $\vec{e}_m : \pi_m \varinjlim M(n) \to \pi_m M$ is surjective for $m \leqslant 0$. If η belongs to the kernel of $\vec{e}_m$, then η can be represented by an element of $\pi_m M(n-1)$ belonging to the kernel of e_m for some $n \gg 0$. By construction, the image of this class in $\pi_m M(n)$ vanishes, so that $\eta = 0$. □

Corollary 14.1.4.3. *Let A be a coconnective $\mathbb{E}_1$-algebra over a field κ, let M be a left A-module, and let N be a right A-module. Suppose that $\pi_i M \simeq \pi_i N \simeq 0$ for $i > 0$. Then $\pi_i(N \otimes_A M) \simeq 0$ for $i > 0$. Moreover, the map $(\pi_0 N) \otimes_\kappa (\pi_0 M) \to \pi_0(N \otimes_\kappa M)$ is injective.*

Proof. Let $\{M(n)\}_{n \geqslant 0}$ be as in the proof of Proposition 14.1.4.1, so that $M \simeq \varinjlim M(n)$ by Remark 14.1.4.2. Then $\pi_i(N \otimes_A M) \simeq \varinjlim \pi_i(N \otimes_A M(n))$, and we have $M(1) \simeq A \otimes_\kappa M$ so that

$$\pi_0(N \otimes_A M(1)) \simeq \pi_0(N \otimes_\kappa M) \simeq (\pi_0 N) \otimes_\kappa (\pi_0 M).$$

It will therefore suffice to show that $\pi_i(N \otimes_A M(1)) \simeq 0$ for each $i > 0$ and that the maps $\pi_0(N \otimes_A M(1)) \to \pi_0(N \otimes_A M(n))$ are injective, for which we use induction on n. When $n = 1$, the result is obvious. Otherwise, we have a cofiber sequence

$$A \otimes_\kappa V(n) \to M(n-1) \to M(n)$$

where $V(n) \in (\mathrm{Mod}_\kappa)_{\leqslant -1}$, whence a cofiber sequence of spectra

$$N \otimes_\kappa V(n) \to N \otimes_A M(n-1) \to N \otimes_A M(n).$$

The desired result now follows from the inductive hypothesis, since $\pi_i(N \otimes_\kappa V(n)) \simeq 0$ for $i \geqslant 0$. □

Corollary 14.1.4.4. *Let κ be a field and let $\phi : A \to B$ be a map of coconnective $\mathbb{E}_1$-algebras over κ. Let M be a left A-module such that $\pi_i M \simeq 0$ for $i > 0$. Then the homotopy groups $\pi_i(B \otimes_A M)$ vanish for $i > 0$, and the map $\pi_0 M \to \pi_0(B \otimes_A M)$ is injective.*

Corollary 14.1.4.5. *Let κ be a field and let $\phi : A \to B$ be a map of coconnective $\mathbb{E}_1$-algebras over κ. Let M be a left A-module such that $\pi_i M \simeq 0$ for $i > 0$. If $B \otimes_A M \simeq 0$, then $M \simeq 0$.*

14.1.5 Connectivity and Mapping Spaces

Let A be a connective $\mathbb{E}_1$-ring. Then the ∞-category LMod_A of left A-modules admits a t-structure $((\mathrm{LMod}_A)_{\geqslant 0}, (\mathrm{LMod}_A)_{\leqslant 0})$, where a left A-module M belongs to $(\mathrm{LMod}_A)_{\geqslant 0}$ if and only if the homotopy groups of M are concentrated in degrees $\geqslant 0$, and a left A-module N belongs to $(\mathrm{LMod}_A)_{\leqslant 0}$ if and only if the homotopy groups of N are concentrated in degrees $\leqslant 0$ (see Proposition **??**). In particular, if $M, N \in \mathrm{LMod}_A$ are left A-modules and there exists an integer m for which the groups $\pi_* M$ vanish for $* < m$ and the groups $\pi_* N$ vanish for $* \geqslant m$, then any morphism $M \to N$ is automatically nullhomotopic. We now prove an analogous (but dual) result in the case where A is a coconnective $\mathbb{E}_1$-algebra over a field.

Proposition 14.1.5.1. *Let A be a coconnective $\mathbb{E}_1$-algebra over a field κ. Let M and N be left A-modules. Assume that $\pi_m M \simeq 0$ for $m > 0$ and that $\pi_m N \simeq 0$ for $m \leqslant 0$. Then any map $f : M \to N$ is nullhomotopic.*

Proof. Let $\{M(n)\}_{n \geqslant 0}$ be as in the proof of Proposition 14.1.4.1, so that $M \simeq \varinjlim M(n)$ by Remark 14.1.4.2. We may therefore identify $\mathrm{Map}_{\mathrm{LMod}_A}(M, N)$ with the homotopy limit of the tower

$$\cdots \to \mathrm{Map}_{\mathrm{LMod}_A}(M(1), N) \to \mathrm{Map}_{\mathrm{LMod}_A}(M(0), N).$$

To prove that $\mathrm{Map}_{\mathrm{LMod}_A}(M, N)$ is connected, it will suffice to show that each of the mapping spaces $\mathrm{Map}_{\mathrm{LMod}_A}(M(n), N)$ is connected, and that each map

$$\pi_1 \mathrm{Map}_{\mathrm{LMod}_A}(M(n), N) \to \pi_1 \mathrm{Map}_{\mathrm{LMod}_A}(M(n-1), N)$$

is surjective. We proceed by induction on n. Using the cofiber sequence

$$A \otimes_\kappa V(n) \to M(n-1) \to M(n),$$

we obtain a fiber sequence of spaces

$$\mathrm{Map}_{\mathrm{LMod}_A}(M(n), N) \to \mathrm{Map}_{\mathrm{LMod}_A}(M(n-1), N) \to \mathrm{Map}_{\mathrm{LMod}_\kappa}(V(n), N).$$

It will therefore suffice to show that $\pi_1 \mathrm{Map}_{\mathrm{LMod}_\kappa}(V(n), N) \simeq 0$. Since κ is a field, this follows immediately from the our assumptions that $\pi_m V(n) \simeq 0$ for $m \geqslant 0$ and $\pi_m N \simeq 0$ for $m \leqslant 0$. $\square$

Corollary 14.1.5.2. *Let A be a coconnective $\mathbb{E}_1$-algebra over a field κ. Let M and N be left A-modules such that $\pi_m M \simeq 0$ for $m > 0$ and $\pi_m N \simeq 0$ for $m < 0$. Then the canonical map $\theta : \mathrm{Ext}^0_A(M, N) \to \mathrm{Hom}_\kappa(\pi_0 M, \pi_0 N)$ is surjective.*

Proof. We have an evident map of κ-module spectra $\pi_0 M \to M$, which determines a map of left A-modules $A \otimes_\kappa (\pi_0 M) \to M$. Let K denote the fiber of this map, so that we have a fiber sequence of spaces

$$\mathrm{Map}_{\mathrm{LMod}_A}(M, N) \xrightarrow{\phi} \mathrm{Map}_{\mathrm{Mod}_\kappa}(\pi_0 M, N) \to \mathrm{Map}_{\mathrm{LMod}_A}(K, N).$$

Since $\pi_m K \simeq 0$ for $m \geqslant 0$, Proposition 14.1.5.1 implies that the mapping space $\mathrm{Map}_{\mathrm{LMod}_A}(K, N)$ is connected. It follows that ϕ induces a surjection

$$\mathrm{Ext}^0_A(M, N) \to \mathrm{Ext}^0_A(\pi_0 M, N) \simeq \mathrm{Hom}_\kappa(\pi_0 M, \pi_0 N).$$

□

Corollary 14.1.5.3. *Let A be a coconnective $\mathbb{E}_1$-algebra over a field κ, and let M be a left A-module such that $\pi_m M \simeq 0$ for $m \neq 0$. Suppose we are given a map of $\mathbb{E}_1$-algebras $A \to \kappa$. Then M lies in the essential image of the forgetful functor $\theta : \mathrm{Mod}_\kappa \simeq \mathrm{LMod}_\kappa \to \mathrm{LMod}_A$.*

Proof. Let $V = \pi_0 M$, and regard V as a discrete κ-module spectrum. Corollary 14.1.5.2 implies that the evident isomorphism $\pi_0 \theta(V) \simeq \pi_0 M$ can be lifted to a map of left A-modules $\theta(V) \to M$, which is evidently an equivalence. □

14.1.6 The Proof of Theorem 14.1.3.2

Let κ be a field and let $\mu : A \otimes_\kappa B \to \kappa$ be a morphism in Alg_κ. Assume that A is coconnective and that μ exhibits B as a Koszul dual of A. We will verify each of the assertions of Theorem 14.1.3.2:

(1) Let M be a left A-module satisfying $\pi_m M \simeq 0$ for $m > 0$. We wish to show that $\pi_n \mathfrak{D}_\mu(M) \simeq 0$ for $n < 0$. Using Proposition 14.1.4.1 and Remark 14.1.4.2, we can write M as the colimit of a sequence of A-modules

$$0 = M(0) \to M(1) \to M(2) \to \cdots,$$

where each $M(n)$ fits into a cofiber sequence $A \otimes_\kappa V(n) \to M(n) \to M(n+1)$ for $V(n) \in (\mathrm{Mod}_\kappa)_{\leqslant -1}$. Then $\mathfrak{D}_\mu(M)$ is a limit of the tower $\{\mathfrak{D}_\mu(M(n))\}_{n \geqslant 0}$. It will therefore suffice to prove that $\pi_m \mathfrak{D}_\mu(M(n)) \simeq 0$ for $m < 0$ and that each of the maps $\pi_0 \mathfrak{D}_\mu(M(n)) \to \pi_0 \mathfrak{D}_\mu(M(n-1))$ is surjective. Using the fiber sequences

$$\mathfrak{D}_\mu(M(n)) \to \mathfrak{D}_\mu(M(n-1)) \to \mathfrak{D}_\mu(A \otimes_\kappa V(n)),$$

we are reduced to showing that the groups $\pi_m \mathfrak{D}_\mu(A \otimes_\kappa V(n))$ vanish for $m \leqslant 0$. Unwinding the definitions, we must show that if $m \leqslant 0$, then any map of $A \otimes_\kappa B$-modules from $(A \otimes_\kappa V(n)) \otimes_\kappa \Sigma^m(B)$ to κ is nullhomotopic. This is equivalent to the assertion that every map of κ-module spectra from $\Sigma^m V(n)$ into κ is nullhomotopic. Since κ is a field, this follows from the observation that $\pi_0 \Sigma^m V(n) \simeq \pi_{-m} V(n) \simeq 0$.

(2) Since $\mu : A \otimes_\kappa B \to \kappa$ exhibits B as a Koszul dual of A, the augmentation on B gives a map $\kappa \otimes_\kappa B \to \kappa$ which induces an equivalence $B \to \mathfrak{D}_\mu(\kappa)$. It follows from (1) that B is connective.

(3) Let N be a connective B-module. We wish to show that the homotopy groups $\pi_n \mathfrak{D}'_\mu(N)$ vanish for $n > 0$. Let $\mathcal{C}$ be the full subcategory of LMod_B spanned by those objects N for which $\pi_n \mathfrak{D}'_\mu(N) \simeq 0$ for $n > 0$. Since $\mathfrak{D}'_\mu : \mathrm{LMod}_B^{\mathrm{op}} \to \mathrm{LMod}_A$ preserves small limits, the ∞-category $\mathcal{C}$ is stable under small colimits in LMod_B. Consequently, to prove that $\mathcal{C}$ contains all connective left B-modules, it will suffice to show that $B \in \mathcal{C}$. This is clear, since $\mathfrak{D}'_\mu(B) \simeq \kappa$.

(4) Let M be a left A-module which is locally finite and satisfies $\pi_* M \simeq 0$ for $* > 0$. We wish to show that the canonical map $u_M : M \to \mathfrak{D}'_\mu \mathfrak{D}_\mu M$ is an equivalence in LMod_A. It follows from (1) that $\mathfrak{D}_\mu(M)$ is connective, so that $\pi_n \mathfrak{D}'_\mu \mathfrak{D}_\mu(M) \simeq 0$ for $n > 0$ by virtue of (3). Set $K_M = \mathrm{fib}(u_M)$, so that $\pi_n K_M \simeq 0$ for $n > 0$. We prove that $\pi_n K_M \simeq 0$ for all n, using descending induction on n. Using Proposition 14.1.4.1, we can choose a map of left A-modules $v : M' \to M$ which induces an isomorphism $\pi_m M' \to \pi_m M$ for $m < 0$ and satisfies $\pi_m M' \simeq 0$ for $m \geqslant 0$. Let M'' denote the cofiber of v, so that $\pi_m M'' \simeq 0$ for $m \neq 0$ and therefore Corollary 14.1.5.3 guarantees that M'' is a direct sum of (finitely many) copies of κ. The condition that μ exhibits B as a Koszul dual of A guarantees that $B \simeq \mathfrak{D}_\mu(\kappa)$ and therefore the unit map $u_\kappa : \kappa \simeq \mathfrak{D}'_\mu(B) \to \mathfrak{D}'_\mu \mathfrak{D}_\mu(\kappa)$ is an equivalence. It follows that $u_{M''}$ is an equivalence. The cofiber sequence $M \to M'' \to \Sigma M'$ induces an equivalence $K_M \simeq \Sigma^{-1} K_{\Sigma M'}$. The inductive hypothesis implies that $\pi_{n+1} K_{\Sigma M'} \simeq 0$, so that $\pi_n K_M \simeq 0$ as desired.

14.1.7 Koszul Duality and Tensor Products

In Chapter 15, we will need the following slightly stronger version of Corollary 14.1.3.3:

Proposition 14.1.7.1. *Let κ be a field and suppose given a finite collection of maps $\{\mu_i : A_i \otimes_\kappa B_i \to \kappa\}_{1 \leqslant i \leqslant m}$ in Alg_κ. Assume that each A_i is coconnective and locally finite and that each μ_i exhibits B_i as a Koszul dual of A_i. Let $A = \bigotimes_i A_i$, $B = \bigotimes_i B_i$, and let $\mu : A \otimes_\kappa B \to \kappa$ be the tensor product of the maps μ_i. Then μ exhibits A as the Koszul dual of B.*

Warning 14.1.7.2. In the situation of Proposition 14.1.7.1, it is not necessarily true that μ exhibits B as the Koszul dual of A. For example, suppose that $m = 2$ and that $A_1 = A_2 = \kappa \oplus \Sigma^{-1}(\kappa)$, endowed with the square-zero algebra structure. In this case, the Koszul dual of A_1 can be identified with the power series ring $\kappa[[x_1]]$, regarded as a discrete $\mathbb{E}_1$-algebra. Similarly, the Koszul dual of A_2 can be identified with $\kappa[[x_2]]$, and the Koszul dual of the tensor product $A_1 \otimes_\kappa A_2$ is given by $\kappa[[x_1, x_2]]$. The canonical map

$\theta : \kappa[[x_1]] \otimes_\kappa \kappa[[x_2]] \to \kappa[[x_1, x_2]]$ is not an isomorphism: however, Proposition 14.1.7.1 guarantees that θ induces an equivalence after applying the Koszul duality functor.

Proof. For $1 \leqslant i \leqslant m$, let $\mathfrak{D}_i : \mathrm{LMod}_{A_i}^{\mathrm{op}} \to \mathrm{LMod}_{B_i}$ be the duality functor determined by μ_i, and let $\mathfrak{D}'_\mu : \mathrm{LMod}_B^{\mathrm{op}} \to \mathrm{LMod}_A$ be the duality functor associated to μ. For every sequence of objects $\vec{M} = \{M_i \in \mathrm{LMod}_{A_i}\}$, we have a canonical map $u_{\vec{M}} : M_1 \otimes_\kappa \cdots \otimes_\kappa M_m \to \mathfrak{D}'_\mu(\mathfrak{D}_1 M_1 \otimes_\kappa \cdots \otimes_\kappa \mathfrak{D}_m M_m)$. We will prove the following:

$(*)$ If $\vec{M} = \{M_i\}_{1 \leqslant i \leqslant m} \in \prod_i \mathrm{LMod}_{A_i}$ is such that the homotopy groups $\pi_n M_i \simeq 0$ vanish for $i > 0$ and each M_i is locally finite, then $u_{\vec{M}}$ is an equivalence.

Fix $0 \leqslant m' \leqslant m$. We will show that assertion $(*)$ holds under the additional assumption that $M_i \simeq \kappa$ for $i > m'$. The proof proceeds by induction on m'. If $m' = 0$, then each $M_i \simeq \kappa$ and the desired result follows immediately from our assumption that each μ_i exhibits B_i as a Koszul dual of A_i. Let us therefore assume that $m' > 0$ and that condition $(*)$ holds whenever $M_i \simeq \kappa$ for $i < m'$.

Note that if $\vec{M}$ satisfies the hypotheses of $(*)$, then Theorem 14.1.3.2 guarantees that each $\mathfrak{D}_i(M_i)$ is connective and therefore that $\pi_n \mathfrak{D}'_\mu(\mathfrak{D}_1 M_1 \otimes_\kappa \cdots \otimes_\kappa \mathfrak{D}_m M_m) \simeq 0$ for $n > 0$. Let $K_{\vec{M}}$ denote the fiber of $u_{\vec{M}}$, so that $\pi_n K_{\vec{M}} \simeq 0$ for $n > 0$. We prove that $\pi_n K_{\vec{M}} \simeq 0$ for all n, using descending induction on n. Using Proposition 14.1.4.1, we can choose a map of left A-modules $v : M' \to M_{m'}$ which induces an isomorphism $\pi_p M' \to \pi_p M_{m'}$ for $p < 0$ and satisfies $\pi_p M' \simeq 0$ for $p \geqslant 0$. Let M'' denote the cofiber of v, so that $\pi_p M'' \simeq 0$ for $p \neq 0$ and therefore Corollary 14.1.5.3 guarantees that M'' is a direct sum of (finitely many) copies of κ. Let $\vec{M}''$ be the sequence of modules obtained from $\vec{M}$ by replacing $M_{m'}$ with M'', and let $\vec{N}$ be the sequence of modules obtained from $\vec{M}$ by replacing $M_{m'}$ with $\Sigma M'$. The inductive hypothesis implies that $K_{\vec{M}''} \simeq 0$. Using the cofiber sequence $M_{m'} \to M'' \to \Sigma M'$, we obtain an equivalence $K_{\vec{M}} \simeq \Sigma^{-1} K_{\vec{N}}$, so that $\pi_n K_{\vec{M}} \simeq \pi_{n+1} K_{\vec{N}}$ is trivial by the other inductive hypothesis. □

14.2 Formal Moduli Problems for Associative Algebras

Let κ be a field. In this section, we will use the Koszul duality functor $\mathfrak{D}^{(1)}$ of §14.1 to construct an equivalence of ∞-categories $\mathrm{Alg}_\kappa^{\mathrm{aug}} \simeq \mathrm{Moduli}_\kappa^{(1)}$, and thereby obtain a proof of Theorem 14.0.0.5. The main point is to show that the functor $\mathfrak{D}^{(1)}$ is a deformation theory (in the sense of Definition 12.3.3.2).

14.2.1 Associative Algebras as a Deformation Context

We begin by discussing a variant of Example 12.1.1.2:

Construction 14.2.1.1. Let κ be a field. Theorem HA.7.3.4.13 gives an equivalence between $\mathrm{Sp}(\mathrm{Alg}_\kappa^{\mathrm{aug}})$ and the ∞-category ${}_\kappa\mathrm{BMod}_\kappa(\mathrm{Mod}_\kappa) \simeq \mathrm{Mod}_\kappa$ of κ-module spectra. Let $E \in \mathrm{Sp}(\mathrm{Alg}_\kappa^{\mathrm{aug}})$ correspond to the unit object $\kappa \in \mathrm{Mod}_\kappa$ under this equivalence (so we have $\Omega^{\infty-n}E \simeq \kappa \oplus \Sigma^n(\kappa)$ for every integer n). We regard $(\mathrm{Alg}_\kappa^{\mathrm{aug}}, \{E\})$ as a deformation context (see Definition 12.1.1.1).

We begin by showing that the deformation context $(\mathrm{Alg}_\kappa^{\mathrm{aug}}, \{E\})$ of Construction 14.2.1.1 allows us to recover the notion of Artinian κ-algebra and formal $\mathbb{E}_1$-moduli problem via the general formalism laid out in §12.1.

Proposition 14.2.1.2. *Let κ be a field and let $(\mathrm{Alg}_\kappa^{\mathrm{aug}}, \{E\})$ be the deformation context of Construction 14.2.1.1. Then an object $A \in \mathrm{Alg}_\kappa^{\mathrm{aug}}$ is Artinian (in the sense of Definition 12.1.2.4) if and only if its image in Alg_κ is Artinian (in the sense of Definition 14.0.0.1); that is, if and only if A satisfies the following conditions:*

(a) *The algebra A is connective: that is, $\pi_i A \simeq 0$ for $i < 0$.*

(b) *The algebra A is truncated: that is, we have $\pi_i A \simeq 0$ for $i \gg 0$.*

(c) *Each of the homotopy groups $\pi_i A$ is finite dimensional when regarded as a vector space over field κ.*

(d) *Let $\mathfrak{n}$ denote the radical of the ring $\pi_0 A$ (which is a finite-dimensional associative algebra over κ). Then the canonical map $\kappa \to (\pi_0 A)/\mathfrak{n}$ is an isomorphism.*

Proof. Suppose first that there there exists a finite sequence of maps

$$A = A_0 \to A_1 \to \cdots \to A_n \simeq \kappa$$

where each A_i is a square-zero extension of A_{i+1} by $\Sigma^{n_i}(\kappa)$, for some $n_i \geqslant 0$. We prove that each A_i satisfies conditions (a) through (d) using descending induction on i. The case $i = n$ is obvious, so let us assume that $i < n$ and that A_{i+1} is known to satisfy conditions (a) through (d). We have a fiber sequence of κ-module spectra

$$\Sigma^{n_i}(\kappa) \to A_i \to A_{i+1}$$

which immediately implies that A_i satisfies (a), (b), and (c). To prove (d), we note that the map $\phi : \pi_0 A_i \to \pi_0 A_{i+1}$ is surjective and $\ker(\phi)^2 = 0$, so that the quotient of $\pi_0 A_i$ by its radical agrees with the quotient of $\pi_0 A_{i+1}$ by its radical.

Now suppose that A satisfies conditions (a) through (d). We will prove that A is Artinian by induction on the dimension of the κ-vector space $\pi_* A$. Let n be the largest integer for which $\pi_n A$ does not vanish. We first treat the case $n = 0$. We will abuse notation by identifying A with the underlying associative ring $\pi_0 A$. Let $\mathfrak{n}$ denote the radical of A. If

$\mathfrak{n} = 0$, then condition (d) implies that $A \simeq \kappa$ so there is nothing to prove. Otherwise, we can view $\mathfrak{n}$ as a nonzero module over the associative algebra $A \otimes_{\kappa} A^{\mathrm{op}}$. It follows that there exists a nonzero element $x \in \mathfrak{n}$ which is annihilated by $\mathfrak{n} \otimes_{\kappa} \mathfrak{n}$. Using (d) again, we deduce that the subspace $\kappa x \subseteq A$ is a two-sided ideal of A. Let A' denote the quotient ring $A/\kappa x$. Theorem HA.7.4.1.23 implies that A is a square-zero extension of A' by κ. The inductive hypothesis implies that A' is Artinian, so that A is also Artinian.

Now suppose that $n > 0$ and let $M = \pi_n A$. Then M is a nonzero bimodule over the finite dimensional κ-algebra $\pi_0 A$. It follows that there is a nonzero element $x \in M$ which is annihilated (on both sides) by the action of the radical $\mathfrak{n} \subseteq \pi_0 A$. Let M' denote the quotient of M by the bimodule generated by x (which, by virtue of (d), coincides with κx), and let $A'' = \tau_{\leqslant n-1} A$. It follows from Theorem HA.7.4.1.23 that there is a pullback diagram

$$\begin{array}{ccc} A & \longrightarrow & \kappa \\ \downarrow & & \downarrow \\ A'' & \longrightarrow & \kappa \oplus \Sigma^{n+1}(M). \end{array}$$

Set $A' = \kappa \times_{\kappa \oplus \Sigma^{n+1}(M')} A''$. Then $A \simeq \kappa \times_{\kappa \oplus \Sigma^{n+1}(\kappa)} A'$ so we have an elementary map $A \to A'$. Using the inductive hypothesis we deduce that A' is Artinian, so that A is also Artinian. □

We will also need a noncommutative analogue of Lemma 12.1.3.8:

Proposition 14.2.1.3. *Let κ be a field and let $f : A \to B$ be a morphism in $\mathrm{Alg}_{\kappa}^{\mathrm{art}}$. Then f is small (when regarded as a morphism in $\mathrm{Alg}_{\kappa}^{\mathrm{aug}}$) if and only if it induces a surjection of associative rings $\pi_0 A \to \pi_0 B$.*

Proof. The "only if" direction is obvious. For the converse, suppose that $\pi_0 A \to \pi_0 B$ is surjective, so that the fiber $I = \mathrm{fib}(f)$ is connective. We will prove that f is small by induction on the dimension of the graded vector space $\pi_* I$. If this dimension is zero, then $I \simeq 0$ and f is an equivalence. Assume therefore that $\pi_* I \neq 0$, and let n be the smallest integer such that $\pi_n I \neq 0$. Let $L_{B/A}$ denote the relative cotangent complex of B over A in the setting of $\mathbb{E}_1$-algebras, regarded as an object of ${}_B\mathrm{BMod}_B(\mathrm{Mod}_{\kappa})$. Remark HA.7.4.1.12 supplies a fiber sequence $L_{B/A} \to B \otimes_A B \to B$. In the ∞-category LMod_B, this sequence splits; we therefore obtain an equivalence of left B-modules

$$L_{B/A} \simeq \mathrm{cofib}(B \to B \otimes_A B) \simeq B \otimes_A \mathrm{cofib}(A \to B) \simeq B \otimes_A \Sigma(I).$$

The kernel of the map $\pi_0 A \to \pi_0 B$ is contained in the radical of $\pi_0 A$ and is therefore a nilpotent ideal. It follows that $\pi_{n+1} L_{B/A} \simeq \mathrm{Tor}_0^{\pi_0 B}(\pi_0 A, \pi_n I)$ is a nonzero quotient of of $\pi_n I$. Let us regard $\pi_{n+1} L_{B/A}$ as a bimodule over $\pi_0 B$, and let $\mathfrak{n}$ be the radical of $\pi_0 B$. Since $\mathfrak{n}$ is nilpotent, the two-sided submodule $\mathfrak{n}(\pi_{n+1} L_{B/A}) + (\pi_{n+1} L_{B/A})\mathfrak{n}$ does not coincide with $\pi_{n+1} L_{B/A}$. It follows that there exists a map of $\pi_0 B$-bimodules $\pi_{n+1} L_{B/A} \to \kappa$, which determines a map $L_{B/A} \to \Sigma^{n+1}(\kappa)$ in the ∞-category ${}_B\mathrm{BMod}_B(\mathrm{Mod}_\kappa)$. We can interpret this map as a derivation $B \to B \oplus \Sigma^{n+1}(\kappa)$. Let $B' = B \times_{B \oplus \Sigma^{n+1}(\kappa)} \kappa$ be the associated square-zero extension of B by $\Sigma^n(\kappa)$. Then f factors as a composition $A \xrightarrow{f'} B' \xrightarrow{f''} B$. Since the map f'' is elementary, it will suffice to show that f' is small, which follows from the inductive hypothesis. □

Corollary 14.2.1.4. *Let κ be a field and let $X : \mathrm{Alg}_\kappa^{\mathrm{art}} \to \mathcal{S}$ be a functor. Then X belongs to the full subcategory $\mathrm{Moduli}_\kappa^{(1)}$ of Definition 14.0.0.4 if and only if it is a formal moduli problem in the sense of Definition 12.1.3.1.*

Proof. The "if" direction follows immediately from Proposition 14.2.1.3. For the converse, suppose that X satisfies the conditions of Definition 14.0.0.4; we wish to show that X is a formal moduli problem. According to Proposition 12.1.3.2, it will suffice to show that for every $n > 0$ and every pullback diagram

$$\begin{array}{ccc} A & \longrightarrow & B \\ \downarrow & & \downarrow \\ \kappa & \longrightarrow & \kappa \oplus \Sigma^n(\kappa) \end{array}$$

in the ∞-category $\mathrm{Alg}_\kappa^{\mathrm{art}}$, the associated diagram of spaces

$$\begin{array}{ccc} X(A) & \longrightarrow & X(B) \\ \downarrow & & \downarrow \\ X(\kappa) & \longrightarrow & X(\kappa \oplus \Sigma^n(\kappa)) \end{array}$$

is also a pullback square. This follows immediately from condition (2) of Definition 14.0.0.4. □

14.2.2 Koszul Duality as a Deformation Theory

We can now formulate our main result:

Theorem 14.2.2.1. *Let κ be a field. Then the Koszul duality functor*

$$\mathfrak{D}^{(1)} : (\mathrm{Alg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{\mathrm{aug}}$$

is a deformation theory (on the deformation context $(\mathrm{Alg}_\kappa^{\mathrm{aug}}, \{E\})$ of Construction 14.2.1.1).

Proof of Theorem 14.0.0.5. Let κ be a field, and let $\Psi : \mathrm{Alg}_\kappa^{\mathrm{aug}} \to \mathrm{Fun}(\mathrm{Alg}_\kappa^{\mathrm{art}}, \mathcal{S})$ be the functor given on objects by the formula $\Psi(A)(R) = \mathrm{Map}_{\mathrm{Alg}_\kappa^{\mathrm{aug}}}(\mathfrak{D}^{(1)}(R), A)$. Combining

Theorems 14.2.2.1 and 12.3.3.5, we deduce that Ψ is a fully faithful embedding whose essential image is the full subcategory $\mathrm{Moduli}_{\kappa}^{(1)} \subseteq \mathrm{Fun}(\mathrm{Alg}_{\kappa}^{\mathrm{art}}, \mathcal{S})$ spanned by the formal $\mathbb{E}_1$-moduli problems. □

Proof of Theorem 14.2.2.1. The ∞-category $\mathrm{Alg}_{\kappa}^{\mathrm{aug}}$ is presentable by Corollary HA.3.2.3.5 , and $\mathfrak{D}^{(1)}$ admits a left adjoint by Remark 14.1.1.4. Let $\mathbf{B}_0 \subseteq \mathrm{Alg}_{\kappa}^{\mathrm{aug}}$ be the full subcategory spanned by those algebras which are coconnective and locally finite (see Definition 14.1.3.1). We will complete the proof that $\mathfrak{D}^{(1)}$ is a weak deformation theory by showing that the subcategory $\mathbf{B}_0$ satisfies conditions (a) thorugh (d) of Definition 12.3.1.1:

(a) For every object $A \in \mathbf{B}_0$, the unit map $A \to \mathfrak{D}^{(1)}\mathfrak{D}^{(1)}(A)$ is an equivalence. This follows from Corollary 14.1.3.3.

(b) The full subcategory $\mathbf{B}_0$ contains the initial object $\kappa \in \mathrm{Alg}_{\kappa}^{\mathrm{aug}}$. This is clear from the definitions.

(c) For each $n \geqslant 1$, there exists an object $K_n \in \mathbf{B}_0$ and an equivalence $\kappa \oplus \Sigma^n(\kappa) \simeq \mathfrak{D}^{(1)}(K_n)$. In fact, we can take K_n to be the free algebra $\bigoplus_{m \geqslant 0} V^{\otimes m}$ generated by $V = \Sigma^{-n-1}(\kappa)$ (this is a consequence of Proposition 15.3.2.1, but is also not difficult to verify by direct calculation).

(d) Let $n \geqslant 1$ and suppose we are given a pushout diagram σ :

$$\begin{array}{ccc} K_n & \longrightarrow & \kappa \\ \downarrow{\scriptstyle \phi} & & \downarrow \\ A & \longrightarrow & A' \end{array}$$

in $\mathrm{Alg}_{\kappa}^{\mathrm{aug}}$, where K_n is as in (c). We must show that if $A \in \mathbf{B}_0$, then $A' \in \mathbf{B}_0$. Note that σ is also a pushout diagram in Alg_{κ}. We will make use of the fact that Alg_{κ} is the underlying ∞-category of the model category $\mathrm{Alg}_{\kappa}^{\mathrm{dg}}$ of differential graded algebras over κ (for a different argument which does not use the theory of model categories, we refer the reader to the proof of Theorem 15.3.3.1). Choose a cofibrant differential graded algebra A_* representing A, and let B_* denote the free differential graded algebra generated by a class x in degree $(-n-1)$. Since B_* is cofibrant and A_* is fibrant, the map $\phi : K_n \to A$ can be represented by a map $\phi_0 : B_* \to A_*$ of differential graded algebras, which is determined by the element $x' = \phi_0(x) \in A_{-n-1}$. Let B'_* denote the free differential graded algebra generated by the chain complex $E(-n)_*$ (see the proof of Proposition 13.1.3.2): in other words, B'_* is obtained from B_* by freely adjoining an element $y \in B'_{-n}$ satisfying $dy = x$. Then B'_* is quasi-isomorphic to the ground field κ.

Let $\psi_0 : B_* \to B'_*$ be the evident inclusion, and form a pushout diagram σ_0 :

$$\begin{array}{ccc} B_* & \xrightarrow{\psi_0} & B'_* \\ \downarrow{\scriptstyle \phi_0} & & \downarrow \\ A_* & \longrightarrow & A'_* \end{array}$$

in the category $\mathrm{Alg}^{\mathrm{dg}}_\kappa$. Since A_* is cofibrant and ψ_0 is a cofibration, the diagram σ_0 is also a homotopy pushout square, so that the image of σ_0 in Alg_κ is equivalent to the diagram σ. It follows that the differential graded algebra A'_* represents A'. We can describe A'_* explicitly as the differential graded algebra obtained from A_* by adjoining an element y' in degree $-n$ satisfying $dy' = x'$. As a chain complex, A'_* can be written as a union of an increasing family of subcomplexes

$$A_* = A'^0_* \subseteq A'^1_* \subseteq A'^2_* \subseteq \cdots ,$$

where A'^m_* denote the graded subspace of A'_* generated by products of the form $a_0 y a_1 y \cdots a_{m_1} y a_m$. The successive quotients for this filtration are given by $A'^m_* / A'^{m-1}_* \simeq A_*^{\otimes m+1}[-nm]$. It follows that the homology groups of A'_*/A_* can be computed by means of a (convergent) spectral sequence $\{E_r^{p,q}, d_r\}_{r \geqslant 2}$ with

$$E_2^{p,q} \simeq \begin{cases} 0 & \text{if } p \leqslant 0 \\ (\mathrm{H}_*(A_*)^{\otimes p+1})_{q+p+np} & \text{if } p \geqslant 1. \end{cases}$$

Since A is coconnective and $n > 0$, the groups $E_2^{p,q}$ vanish unless $p + q \leqslant -np < 0$. It follows that each homology group $\mathrm{H}_m(A'_*/A_*)$ admits a finite filtration by subquotients of the vector spaces $E_2^{p,q}$ with $p + q = m$, each of which is finite dimensional (since A is locally finite), and that the groups $\mathrm{H}_m(A'_*/A_*)$ vanish for $m \geqslant 0$. Using the long exact seuqence

$$\cdots \to \mathrm{H}_m(A_*) \to \mathrm{H}_m(A'_*) \to \mathrm{H}_m(A'_*/A_*) \to \mathrm{H}_{m-1}(A_*) \to \cdots ,$$

we deduce that $\mathrm{H}_m(A'_*)$ is finite dimensional for all m and isomorphic to $\mathrm{H}_m(A_*)$ for $m \geqslant 0$, from which it follows immediately that $A' \in \mathbf{B}_0$.

We now complete the proof of Theorem 14.2.2.1 by showing that the weak deformation theory $\mathfrak{D}^{(1)}$ satisfies axiom $(D4)$ of Definition 12.3.3.2. For $n \geqslant 1$, and $A \in \mathrm{Alg}^{\mathrm{aug}}_\kappa$, we have a canonical homotopy equivalence

$$\begin{aligned} \Psi(A)(\Omega^{\infty-n}(E)) &= \mathrm{Map}_{\mathrm{Alg}^{\mathrm{aug}}_\kappa}(\mathfrak{D}^{(1)}(\kappa \oplus \Sigma^n(\kappa)), A) \\ &\simeq \mathrm{Map}_{\mathrm{Alg}^{\mathrm{aug}}_\kappa}(K_n, A) \\ &\simeq \Omega^{\infty-n-1}\,\mathrm{fib}(A \to \kappa). \end{aligned}$$

These maps determine an equivalence from the functor $e : \mathrm{Alg}_\kappa^{\mathrm{aug}} \to \mathrm{Sp}$ with $\Sigma(I)$, where $I : \mathrm{Alg}_\kappa^{\mathrm{aug}} \to \mathrm{Sp}$ denotes the functor which assigns to each augmented algebra $\epsilon : A \to \kappa$ its augmentation ideal $\mathrm{fib}(\epsilon)$. This functor is evidently conservative, and preserves sifted colimits by virtue of Proposition HA.3.2.3.1 . □

Remark 14.2.2.2. Let κ be a field, let $\epsilon : A \to \kappa$ be an object of $\mathrm{Alg}_\kappa^{\mathrm{aug}}$, and let $X = \Psi(A)$ denote the formal $\mathbb{E}_1$-moduli problem associated to A via the equivalence of Theorem 14.0.0.5. The proof of Theorem 14.2.2.1 shows that the shifted tangent complex $\Sigma^{-1} X(E) \in \mathrm{Sp}$ can be identified with the augmentation ideal $\mathrm{fib}(\epsilon)$ of A.

14.2.3 Application: Prorepresentability

We close this section by proving a noncommutative analogue of Proposition 13.3.3.1.

Proposition 14.2.3.1. *Let κ be a field and let $X : \mathrm{Alg}_\kappa^{\mathrm{art}} \to \mathcal{S}$ be a formal $\mathbb{E}_1$-moduli problem over κ. The following conditions are equivalent:*

(1) *The functor X is prorepresentable (see Definition 12.5.3.1).*

(2) *Let $X(E)$ denote the tangent complex of X. Then $\pi_i X(E) \simeq 0$ for $i > 0$.*

(3) *The functor X has the form $\Psi(A)$, where $A \in \mathrm{Alg}_\kappa^{\mathrm{aug}}$ is coconnective and $\Psi : \mathrm{Alg}_\kappa^{\mathrm{aug}} \to \mathrm{Moduli}_\kappa^{(1)}$ is the equivalence of Theorem 14.0.0.5.*

Proof. The equivalence of (2) and (3) follows from Remark 14.2.2.2. We next prove that (1) ⇒ (2). Since the construction $X \mapsto X(E)$ commutes with filtered colimits, it will suffice to show that $\pi_i X(E) \simeq 0$ for $i > 0$ in the case when $X = \mathrm{Spf}\, R$ is representable by an object $R \in \mathrm{Alg}_\kappa^{\mathrm{art}}$. In this case, we can write $X = \Psi(A)$ where $A = \mathbb{D}^{(1)}(R)$ belongs to the full subcategory $\mathbf{B}_0 \subseteq \mathrm{Alg}_\kappa^{\mathrm{aug}}$ appearing in the proof of Theorem 14.2.2.1. In particular, A is coconnective, so that X satisfies condition (3) (and therefore also condition (2)).

We now complete the proof by showing that (3) ⇒ (1). Let $A \in \mathrm{Alg}_\kappa^{\mathrm{aug}}$ be coconnective. Choose a representative of A by a cofibrant differential graded algebra $A_* \in \mathrm{Alg}_\kappa^{\mathrm{dg}}$. Since A_* is cofibrant, we may assume that the augmentation of A is determined by an augmentation of A_*. We now construct a sequence of differential graded algebras

$$\kappa = A(-1)_* \to A(0)_* \to A(1)_* \to A(2)_* \to \cdots$$

equipped with maps $\phi(i) : A(i)_* \to A_*$. For each $n < 0$, choose a graded subspace $V_n \subseteq A_n$ consisting of cycles which maps isomorphically onto the homology $\mathrm{H}_n(A_*)$. We regard V_* as a differential graded vector space with trivial differential (which vanishes in nonnegative degrees). Let $A(0)_*$ denote the free differential graded Lie algebra generated by V_*, and $\phi(0) : A(0)_* \to A_*$ the evident map. Assume now that we have constructed a map

$\phi(i) : A(i)_* \to A_*$ extending $\phi(1)$. Since A is coconnective, the map $\theta : \mathrm{H}_n(A(i)_*) \to \mathrm{H}_*(A_*)$ is surjective. Choose a collection of cycles $x_\alpha \in A(i)_{n_\alpha}$ whose images form a basis for $\ker(\theta)$. Then we can write $\phi(i)(x_\alpha) = dy_\alpha$ for some $y_\alpha \in A_{n_\alpha+1}$. Let $A(i+1)_*$ be the differential graded algebra obtained from $A(i)_*$ by freely adjoining elements Y_α (in degrees $n_\alpha + 1$) satisfying $dY_\alpha = x_\alpha$. We let $\phi(i+1) : A(i+1)_* \to A_*$ denote the unique extension of $\phi(i)$ satisfying $\phi(i+1)(Y_\alpha) = y_\alpha$.

We now prove the following assertion for each integer $i \geqslant 0$:

$(*_i)$ The inclusion $V_{-1} \hookrightarrow A(i)_{-1}$ induces an isomorphism $V_{-1} \to \mathrm{H}_{-1}(A(i)_*)$, the unit map $\kappa \to A(i)_0$ is an isomorphism, and $A(i)_j \simeq 0$ for $j > 0$.

Assertion $(*_i)$ is obvious when $i = 0$. Let us assume that $(*_i)$ holds, and let θ be defined as above. Then θ is an isomorphism in degrees $\geqslant -1$, so that $A(i+1)_*$ is obtained from $A(i)_*$ by freely adjoining generators Y_α in degrees $\leqslant -1$. It follows immediately that $A(i+1)_j \simeq 0$ for $j > 0$ and that the unit map $\kappa \to A(i+1)_0$ is an isomorphism. Moreover, we can write $A(i+1)_{-1} \simeq A(i)_{-1} \oplus W$, where W is the subspace spanned by elements of the form Y_α where $n_\alpha = -2$. By construction, the differential on $A(i+1)_*$ induces a monomorphism from W to the quotient $A(i)_{-2}/dA(i)_{-1} \subseteq A(i+1)_{-2}/dA(i)_{-1}$, so that the differential graded algebras $A(i+1)_*$ and $A(i)_*$ have the same homology in degree -1.

Let A'_* denote the colimit of the sequence $\{A(i)_*\}_{i \geqslant 0}$. The evident map $\mathfrak{g}'_* \to \mathfrak{g}_*$ is surjective on homology (since the map $A(0)_* \to \mathfrak{g}_*$ is surjective on homology). If $\eta \in \ker(\mathrm{H}_*(A'_*) \to \mathrm{H}_*(A_*))$, then η is represented by a class $\overline{\eta} \in \ker(\mathrm{H}_*(A(i)_*) \to \mathrm{H}_*(A_*))$ for $i \gg 0$. By construction, the image of $\overline{\eta}$ vanishes in $\mathrm{H}_*(A(i+1)_*)$, so that $\eta = 0$. It follows that the map $A'_* \to A_*$ is a quasi-isomorphism. Since the collection of quasi-isomorphisms in $\mathrm{Alg}^{\mathrm{dg}}_\kappa$ is closed under filtered colimits, we conclude that A_* is a homotopy colimit of the sequence $\{A(i)_*\}_{i \geqslant 0}$ in the model category $\mathrm{Alg}^{\mathrm{dg}}_\kappa$. Let $A(i) \in \mathrm{Alg}^{\mathrm{aug}}_\kappa$ be the image of the differential graded algebra $A(i)_*$ (equipped with the augmentation determined by the map $\phi(i) : A(i)_* \to A_*$), so that $A \simeq \varinjlim A(i)$ in $\mathrm{Alg}^{\mathrm{aug}}_\kappa$. Setting $X(i) = \Psi(A(i)_*) \in \mathrm{Moduli}^{(1)}_\kappa$, we deduce that $X \simeq \varinjlim X(i)$. To prove that X is prorepresentable, it will suffice to show that each $X(i)$ is prorepresentable.

We now proceed by induction on i, the case $i = -1$ being trivial. To carry out the inductive step, we note that each of the Lie algebras $A(i+1)_*$ is obtained from $A(i)_*$ by freely adjoining a set of generators $\{Y_\alpha\}_{\alpha \in S}$ of degrees $n_\alpha + 1 \leqslant -1$, satisfying $dY_\alpha = x_\alpha \in A(i)_{n_\alpha}$. Choose a well-ordering of the set S. For each $\alpha \in S$, we let $A^{<\alpha}_*$ denote the Lie subalgebra of $A(i+1)_*$ generated by $A(i)_*$ and the elements Y_β for $\beta < \alpha$, and let $A^{\leqslant \alpha}_*$ be defined similarly. Set $X^{<\alpha} = \Psi(A^{<\alpha}_*)$ and $X^{\leqslant\alpha} = \Psi(A^{\leqslant\alpha}_*)$. For each integer n, let $B(n)_*$ be the free differential graded algebra generated by a class x in degree n and $B'(n)_*$ the free differential graded algebra generated by a class x in degree n and a class y in degree $n+1$ satisfying

$dy = x$. For each $\alpha \in S$, we have a homotopy pushout diagram of differential graded algebras

$$\begin{array}{ccc} B(n)_* & \longrightarrow & B'(n)_* \\ \downarrow & & \downarrow \\ A_*^{<\alpha} & \longrightarrow & A_*^{\leqslant\alpha}, \end{array}$$

hence a pushout diagram diagram of formal $\mathbb{E}_1$-moduli problems

$$\begin{array}{ccc} \mathrm{Spf}(\kappa \oplus \Sigma^{n_\alpha+1}(\kappa)) & \longrightarrow & \mathrm{Spf}(\kappa) \\ \downarrow & & \downarrow \\ X^{<\alpha} & \longrightarrow & X^{\leqslant\alpha}. \end{array}$$

It follows that the map $X(i) \to X(i+1)$ satisfies the criterion of Lemma 12.5.3.4. Since $X(i)$ is prorepresentable, we conclude that $X(i+1)$ is prorepresentable. □

14.3 Comparison with the Commutative Case

For every field κ, the forgetful functor $\mathrm{CAlg}_\kappa \to \mathrm{Alg}_\kappa$ carries Artinian $\mathbb{E}_\infty$-algebras over κ to Artinian $\mathbb{E}_1$-algebras over κ and therefore induces a forgetful functor $\theta : \mathrm{CAlg}_\kappa^{\mathrm{art}} \to \mathrm{Alg}_\kappa^{\mathrm{art}}$. If $X : \mathrm{Alg}_\kappa^{\mathrm{art}} \to \mathcal{S}$ is a formal $\mathbb{E}_1$-moduli problem over κ, then the composition $(X \circ \theta) : \mathrm{CAlg}_\kappa^{\mathrm{art}} \to \mathcal{S}$ is a formal moduli problem over κ. Consequently, composition with θ determines a functor $\phi : \mathrm{Moduli}_\kappa^{(1)} \to \mathrm{Moduli}_\kappa$.

Suppose now that the field κ has characteristic zero. Theorems 14.0.0.5 and 13.0.0.2 supply equivalences of ∞-categories

$$\mathrm{Alg}_\kappa^{\mathrm{aug}} \simeq \mathrm{Moduli}_\kappa^{(1)} \qquad \mathrm{Lie}_\kappa \simeq \mathrm{Moduli}_\kappa,$$

so that we can identify ϕ with a functor $\phi' : \mathrm{Alg}_\kappa^{\mathrm{aug}} \to \mathrm{Lie}_\kappa$. Our goal in this section is to give an explicit description of the functor ϕ'.

Recall that the ∞-category Alg_κ of $\mathbb{E}_1$-algebras over κ can be identified with the underlying ∞-category of the model category $\mathrm{Alg}_\kappa^{\mathrm{dg}}$ of differential graded algebras over κ (Proposition HA.7.1.4.6). Let $(\mathrm{Alg}_\kappa^{\mathrm{dg}})_{/\kappa}$ denote the category of *augmented* differential graded algebras over κ. Then $(\mathrm{Alg}_\kappa^{\mathrm{dg}})_{/\kappa}$ inherits a model structure, and (because $\kappa \in \mathrm{Alg}_\kappa^{\mathrm{dg}}$ is fibrant) the underlying ∞-category of $(\mathrm{Alg}_\kappa^{\mathrm{dg}})_{/\kappa}$ can be identified with $\mathrm{Alg}_\kappa^{\mathrm{aug}}$. For every object $\epsilon : A_* \to \kappa$ of $(\mathrm{Alg}_\kappa^{\mathrm{dg}})_{/\kappa}$, we let $\mathfrak{m}_{A_*} = \ker(\epsilon)$ denote the augmentation ideal of A_*. Then $\mathfrak{m}_{A_*}$ inherits the structure of a nonunital differential graded algebra over κ. In particular, we can view $\mathfrak{m}_{A_*}$ as a differential graded Lie algebra over κ (see Example 13.1.2.2). The construction $A_* \mapsto \mathfrak{m}_{A_*}$ determines a functor $(\mathrm{Alg}_\kappa^{\mathrm{dg}})_{/\kappa} \to \mathrm{Lie}_\kappa^{\mathrm{dg}}$, which carries quasi-isomorphisms to quasi-isomorphisms. We therefore obtain an induced functor of ∞-categories $\psi : \mathrm{Alg}_\kappa^{\mathrm{aug}} \to \mathrm{Lie}_\kappa$. We will prove that the functors $\psi, \phi' : \mathrm{Alg}_\kappa^{\mathrm{aug}} \to \mathrm{Lie}_\kappa$ are equivalent to one another. We can state this result more precisely as follows:

Theorem 14.3.0.1. *Let κ be a field of characteristic zero. The diagram of ∞-categories*

$$\begin{array}{ccc} \mathrm{Alg}_\kappa^{\mathrm{aug}} & \xrightarrow{\psi} & \mathrm{Lie}_\kappa \\ \downarrow & & \downarrow \\ \mathrm{Moduli}_\kappa^{(1)} & \xrightarrow{\phi} & \mathrm{Moduli}_\kappa \end{array}$$

commutes (up to canonical homotopy). Here ϕ and ψ are the functors described above, and the vertical maps are the equivalences provided by Theorems 13.0.0.2 and 14.0.0.5.

14.3.1 Comparison of Koszul Duality Functors

To prove Theorem 14.3.0.1, we need to construct a homotopy between two functors $\mathrm{Alg}_\kappa^{\mathrm{aug}} \to \mathrm{Moduli}_\kappa \subseteq \mathrm{Fun}(\mathrm{CAlg}_\kappa^{\mathrm{art}}, \mathcal{S})$. Equivalently, we must construct a homotopy between the functors $F, F' : \mathrm{Alg}_\kappa^{\mathrm{aug}} \times \mathrm{CAlg}_\kappa^{\mathrm{art}} \to \mathcal{S}$ given by

$$F(A, R) = \mathrm{Map}_{\mathrm{Lie}_\kappa}(\mathfrak{D}(R), \psi(A)) \qquad F'(A, R) = \mathrm{Map}_{\mathrm{Alg}_\kappa^{\mathrm{aug}}}(\mathfrak{D}^{(1)}(R), A).$$

Composing the Koszul duality functor $\mathfrak{D} : (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Lie}_\kappa$ with the equivalence of ∞-categories $\mathrm{Lie}_\kappa \simeq \mathrm{Moduli}_\kappa$, we obtain the functor $\mathrm{Spf} : (\mathrm{CAlg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Moduli}_\kappa$ of Example 12.1.3.3. It follows from Yoneda's lemma that this functor is fully faithful when restricted to $(\mathrm{CAlg}_\kappa^{\mathrm{art}})^{\mathrm{op}}$, so that $\mathfrak{D}$ induces an equivalence from $(\mathrm{CAlg}_\kappa^{\mathrm{art}})^{\mathrm{op}}$ onto its essential image $\mathcal{C} \subseteq \mathrm{Lie}_\kappa$. The inverse of this equivalence is given by $\mathfrak{g}_* \mapsto C^*(\mathfrak{g}_*)$. It follows that we can identify F and F' with functors $G, G' : \mathrm{Alg}_\kappa^{\mathrm{aug}} \times \mathcal{C}^{\mathrm{op}} \to \mathcal{S}$, given by the formulas

$$G(A, \mathfrak{g}_*) = \mathrm{Map}_{\mathrm{Lie}_\kappa}(\mathfrak{g}_*, \psi(A)) \qquad G'(A, \mathfrak{g}_*) = \mathrm{Map}_{\mathrm{Alg}_\kappa^{\mathrm{aug}}}(\mathfrak{D}^{(1)} C^*(\mathfrak{g}_*), A).$$

Note that the forgetful functor $(\mathrm{Alg}_\kappa^{\mathrm{dg}})_{/\kappa} \to \mathrm{Lie}_\kappa^{\mathrm{dg}}$ is a right Quillen functor, with left adjoint given by the universal enveloping algebra construction $\mathfrak{g}_* \mapsto U(\mathfrak{g}_*)$ of Remark 13.1.2.3. It follows that the functor ψ admits a left adjoint $\mathrm{Lie}_\kappa \to \mathrm{Alg}_\kappa^{\mathrm{aug}}$, which we will also denote by U. Then the functor $G : \mathrm{Alg}_\kappa^{\mathrm{aug}} \times \mathcal{C}^{\mathrm{op}} \to \mathcal{S}$ can be described by the formula $G(A, \mathfrak{g}_*) = \mathrm{Map}_{\mathrm{Alg}_\kappa^{\mathrm{aug}}}(U(\mathfrak{g}_*), A)$. To show that this functor is equivalent to G', it will suffice to show that there is a canonical equivalence $U(\mathfrak{g}_*) \simeq \mathfrak{D}^{(1)} C^*(\mathfrak{g}_*)$ for $\mathfrak{g}_* \in \mathcal{C}$. Note that $\mathfrak{g}_* \in \mathcal{C}$ guarantees that $U(\mathfrak{g}_*)$ is coconnective and locally finite, so that the biduality map $U(\mathfrak{g}_*) \to \mathfrak{D}^{(1)}\mathfrak{D}^{(1)} U(\mathfrak{g}_*)$ is an equivalence (Corollary 14.1.3.2). It will therefore suffice to show that there exists a canonical equivalence of augmented $\mathbb{E}_1$-algebras $\mathfrak{D}^{(1)} U(\mathfrak{g}_*) \simeq C^*(\mathfrak{g}_*)$. In fact, such an equivalence can be defined for *all* $\mathfrak{g}_* \in \mathrm{Lie}_\kappa$:

Proposition 14.3.1.1. *Let κ be a field of characteristic zero. Then the diagram of ∞-categories*

$$\begin{array}{ccc} (\mathrm{Lie}_\kappa)^{\mathrm{op}} & \xrightarrow{C^*} & \mathrm{CAlg}_\kappa^{\mathrm{aug}} \\ \downarrow{\scriptstyle U} & & \downarrow \\ (\mathrm{Alg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} & \xrightarrow{\mathfrak{D}^{(1)}} & \mathrm{Alg}_\kappa^{\mathrm{aug}} \end{array}$$

commutes up to canonical homotopy.

14.3.2 Twisted Arrow ∞-Categories

Before giving our proof of Proposition 14.3.1.1, we need to recall a bit of terminology (see §HA.5.2.1).

Construction 14.3.2.1. Let $\mathcal{C}$ be a category. We define a new category $\mathrm{TwArr}(\mathcal{C})$ as follows:

(*a*) An object of $\mathrm{TwArr}(\mathcal{C})$ is given by a triple (C, D, ϕ), where $\phi : C \to D$ is a morphism in $\mathcal{C}$.

(*b*) Given a pair of objects $(C, D, \phi), (C', D', \phi') \in \mathrm{TwArr}(\mathcal{C})$, a morphism from (C, D, ϕ) to (C', D', ϕ') consists of a pair of morphisms $\alpha : C \to C'$, $\beta : D' \to D$ for which the diagram

$$\begin{array}{ccc} C & \xrightarrow{\phi} & D \\ \downarrow{\scriptstyle\alpha} & & \uparrow{\scriptstyle\beta} \\ C' & \xrightarrow{\phi'} & D' \end{array}$$

commutes.

(*c*) Given a pair of morphisms

$$(C, D, \phi) \xrightarrow{(\alpha,\beta)} (C', D', \phi') \xrightarrow{(\alpha',\beta')} (C'', D'', \phi'')$$

in $\mathrm{TwArr}(\mathcal{C})$, the composition of (α', β') with (α, β) is given by $(\alpha' \circ \alpha, \beta \circ \beta')$.

We will refer to $\mathrm{TwArr}(\mathcal{C})$ as the *twisted arrow category* of $\mathcal{C}$. The construction $(C, D, \phi) \mapsto (C, D)$ determines a forgetful functor $\lambda : \mathrm{TwArr}(\mathcal{C}) \to \mathcal{C} \times \mathcal{C}^{\mathrm{op}}$ which exhibits $\mathrm{TwArr}(\mathcal{C})$ as fibered in sets over $\mathcal{C} \times \mathcal{C}^{\mathrm{op}}$ (the fiber of λ over an object $(C, D) \in \mathcal{C} \times \mathcal{C}^{\mathrm{op}}$ can be identified with the set $\mathrm{Hom}_{\mathcal{C}}(C, D)$). In particular, λ is a pairing of ∞-categories. This pairing is both left and right representable, and the associated duality functors

$$\mathfrak{D}_\lambda : \mathcal{C}^{\mathrm{op}} \to \mathcal{C}^{\mathrm{op}} \qquad \mathfrak{D}'_\lambda : \mathcal{C} \to \mathcal{C}$$

are equivalent to the identity.

Proposition 14.3.2.2. *Let κ be a field of characteristic zero and let $\mathcal{M}^{(1)} \to \mathrm{Alg}^{\mathrm{aug}}_\kappa \times \mathrm{Alg}^{\mathrm{aug}}_\kappa$ be the pairing of ∞-categories of Construction 14.1.1.1. There exists a left representable map of pairings of ∞-categories*

$$\begin{array}{ccc} \mathrm{TwArr}(\mathrm{Lie}^{\mathrm{dg}}_\kappa) & \xrightarrow{T} & \mathcal{M}^{(1)} \\ \downarrow{\scriptstyle\lambda} & & \downarrow \\ \mathrm{Lie}^{\mathrm{dg}}_\kappa \times (\mathrm{Lie}^{\mathrm{dg}}_\kappa)^{\mathrm{op}} & \xrightarrow{U \times C^*} & \mathrm{Alg}^{\mathrm{aug}}_\kappa \times \mathrm{Alg}^{\mathrm{aug}}_\kappa . \end{array}$$

Here U and C^* denote the (covariant and contravariant) functors from $\mathrm{Lie}_\kappa^{\mathrm{dg}}$ *to* $\mathrm{Alg}_\kappa^{\mathrm{aug}}$ *induced by the universal enveloping algebra and cohomological Chevalley-Eilenberg constructions, respectively.*

We first observe that Proposition 14.3.2.2 implies Proposition 14.3.1.1:

Proof of Proposition 14.3.1.1. As noted in Construction 14.3.2.1, the pairing of ∞-categories

$$\mathrm{TwArr}(\mathrm{Lie}_\kappa^{\mathrm{dg}}) \to \mathrm{Lie}_\kappa^{\mathrm{dg}} \times (\mathrm{Lie}_\kappa^{\mathrm{dg}})^{\mathrm{op}}$$

induces the identity functor $\mathrm{id} : (\mathrm{Lie}_\kappa^{\mathrm{dg}})^{\mathrm{op}} \to (\mathrm{Lie}_\kappa^{\mathrm{dg}})^{\mathrm{op}}$. Applying Proposition **??** to the morphism of pairings T of Proposition 14.3.2.2, we obtain an equivalence between the functors $C^* \circ \mathrm{id}, \mathfrak{D}^{(1)} \circ U : (\mathrm{Lie}_\kappa^{\mathrm{dg}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{\mathrm{aug}}$. Since the canonical map

$$\mathrm{Fun}(\mathrm{Lie}_\kappa^{\mathrm{op}}, \mathrm{Alg}_\kappa^{\mathrm{op}}) \to \mathrm{Fun}((\mathrm{Lie}_\kappa^{\mathrm{dg}})^{\mathrm{op}}, \mathrm{Alg}_\kappa^{\mathrm{aug}})$$

is fully faithful, we obtain an equivalence between the functors $C^*, \mathfrak{D}^{(1)} \circ U : \mathrm{Lie}_\kappa^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{\mathrm{aug}}$. □

14.3.3 The Proof of Proposition 14.3.2.2

Let $\mathfrak{g}_*$ be a differential graded Lie algebra over κ and let $\mathrm{Cn}(\mathfrak{g})_*$ be as in Construction 13.2.1.1. The universal enveloping algebra $U(\mathrm{Cn}(\mathfrak{g})_*)$ has the structure of a (differential graded) Hopf algebra, where the comultiplication is determined by the requirement that the image of $\mathrm{Cn}(\mathfrak{g})_*$ consists of primitive elements. In particular, we have a counit map $\epsilon : \mathrm{Cn}(\mathfrak{g})_* \to \kappa$. Let $\mathrm{End}(U\,\mathrm{Cn}(\mathfrak{g})_*)$ denote the chain complex of $U(\mathrm{Cn}(\mathfrak{g})_*)$-comodule maps from $U(\mathrm{Cn}(\mathfrak{g})_*)$ to itself. Since $U(\mathrm{Cn}(\mathfrak{g})_*)$ is cofree as a comodule over itself, composition with the counit map $\epsilon : U(\mathrm{Cn}(\mathfrak{g})_*) \to \kappa$ induces an isomorphism θ from $\mathrm{End}(U\,\mathrm{Cn}(\mathfrak{g})_*)$ to the κ-linear dual of $U\,\mathrm{Cn}(\mathfrak{g})_*$. We regard $\mathrm{End}(U\,\mathrm{Cn}(\mathfrak{g})_*)$ as endowed with the *opposite* of the evident differential graded Lie algebra structure, so that $U\,\mathrm{Cn}(\mathfrak{g})_*$ has the structure of a right module over $\mathrm{End}(U\,\mathrm{Cn}(\mathfrak{g})_*)$. Let $\mathrm{End}_{\mathfrak{g}}(U\,\mathrm{Cn}(\mathfrak{g})_*)$ denote the subcomplex of $\mathrm{End}(U\,\mathrm{Cn}(\mathfrak{g})_*)$ consisting of right $U(\mathfrak{g}_*)$-module maps, so that θ restricts to an isomorphism from $\mathrm{End}_{\mathfrak{g}}(U\,\mathrm{Cn}(\mathfrak{g})_*)$ to the κ-linear dual $C^*(\mathfrak{g}_*)$ of $C_*(\mathfrak{g}_*) \simeq U\,\mathrm{Cn}(\mathfrak{g})_* \otimes_{U(\mathfrak{g}_*)} \kappa$. It is not difficult to verify that this isomorphism is compatible with the multiplication on $C^*(\mathfrak{g})$ described in Construction 13.2.5.1. It follows that $U\,\mathrm{Cn}(\mathfrak{g})_*$ is equipped with a right action of $C^*(\mathfrak{g}_*)$, which is compatible with the right action of $U(\mathfrak{g}_*)$ on $U\,\mathrm{Cn}(\mathfrak{g})_*$. Let $M_*(\mathfrak{g}_*)$ denote the κ-linear dual of $U\,\mathrm{Cn}(\mathfrak{g})_*$. Then M_* is a contravariant functor, which carries a differential graded Lie algebra $\mathfrak{g}_*$ to a chain complex equipped with commuting right actions of $U(\mathfrak{g}_*)$ and $C^*(\mathfrak{g}_*)$. Moreover, the unit map $\kappa \to UE(\mathfrak{g}_*)$ determines a quasi-isomorphism $\epsilon_{\mathfrak{g}_*} : M_*(\mathfrak{g}_*) \to \kappa$.

Note that the initial object $\kappa \in \mathrm{Alg}_\kappa^{(1)}$ can be identified with a classifying object for endomorphisms of the unit object $\kappa \in \mathrm{Mod}_\kappa$. Using Theorem HA.4.7.1.34 and Proposition

HA.4.7.1.39 , we can identify $\mathrm{Alg}^{\mathrm{aug}}_{\kappa}$ with the fiber product $\mathrm{LMod}(\mathrm{Mod}_{\kappa}) \times_{\mathrm{Mod}_{\kappa}} \{\kappa\}$. Let $\mathcal{X} \subseteq (\mathrm{Mod}_{\kappa})_{/\kappa}$ denote the full subcategory spanned by the final objects, so that we have an equivalence of ∞-categories

$$\alpha : \mathcal{M}^{(1)} \simeq (\mathrm{Alg}_{\kappa} \times \mathrm{Alg}_{\kappa}) \times_{\mathrm{Alg}_{\kappa}} \mathrm{LMod}(\mathrm{Mod}_{\kappa}) \times_{\mathrm{Mod}_{\kappa}} \mathcal{X}.$$

We define a more rigid analogue of $\mathcal{M}^{(1)}$ as follows: let $\mathcal{Y} \subseteq (\mathrm{Vect}^{\mathrm{dg}}_{\kappa})_{\kappa/}$ be the full subcategory spanned by the quasi-isomorphisms of chain complexes $V_* \to \kappa$ and let $\mathcal{C}$ denote the category

$$\mathrm{Alg}^{\mathrm{dg}}_{\kappa} \times \mathrm{Alg}^{\mathrm{dg}}_{\kappa} \times_{\mathrm{Alg}^{\mathrm{dg}}_{\kappa}} \mathrm{LMod}(\mathrm{Vect}^{\mathrm{dg}}_{\kappa}) \times_{\mathrm{Vect}^{\mathrm{dg}}_{\kappa}} \mathcal{Y},$$

so that α determines a functor $T'' : \mathcal{C} \to \mathcal{M}^{(1)}$. We will define T as a composition $\mathrm{TwArr}(\mathrm{Lie}^{\mathrm{dg}}_{\kappa}) \xrightarrow{T'} \mathcal{C} \xrightarrow{T''} \mathcal{M}^{(1)}$. Here the functor T' assigns to each map $\gamma : \mathfrak{h}_* \to \mathfrak{g}_*$ of differential graded Lie algebras the object of $\mathcal{C}$ given by $(U(\mathfrak{h}_*), C^*(\mathfrak{g}_*), M_*(\mathfrak{g}_*), \epsilon_{\mathfrak{g}_*})$, where $M_*(\mathfrak{g}_*)$ is regarded as a left module over $U(\mathfrak{h}_*) \otimes_{\kappa} C^*(\mathfrak{g}_*)$ by combining the commuting left actions of $U(\mathfrak{g}_*)$ and $C^*(\mathfrak{g}_*)$ on $M_*(\mathfrak{g}_*)$ (and composing with the map γ).

We now claim that the diagram σ :

$$\begin{array}{ccc} \mathrm{TwArr}(\mathrm{Lie}^{\mathrm{dg}}_{\kappa}) & \xrightarrow{T} & \mathcal{M}^{(1)} \\ \downarrow{\lambda} & & \downarrow \\ \mathrm{Lie}^{\mathrm{dg}}_{\kappa} \times (\mathrm{Lie}^{\mathrm{dg}}_{\kappa})^{\mathrm{op}} & \xrightarrow{U \times C^*} & \mathrm{Alg}^{\mathrm{aug}}_{\kappa} \times \mathrm{Alg}^{\mathrm{aug}}_{\kappa} \end{array}$$

commutes up to canonical homotopy. Consider first the composition of T with the map $\mathcal{M}^{(1)} \to \mathrm{Alg}^{\mathrm{aug}}_{\kappa}$ given by projection onto the first factor. Unwinding the definitions, we see that this map is given by the composing the equivalence $\xi : \mathrm{LMod}(\mathrm{Mod}_{\kappa}) \times_{\mathrm{Mod}_{\kappa}} \mathcal{X} \simeq \mathrm{Alg}^{\mathrm{aug}}_{\kappa}$ with the functor $T'_0 : \mathrm{TwArr}(\mathrm{Lie}^{\mathrm{dg}}_{\kappa}) \to \mathrm{LMod}(\mathrm{Mod}_{\kappa}) \times_{\mathrm{Mod}_{\kappa}} \mathcal{X}$ given by

$$T'_0(\gamma : \mathfrak{h}_* \to \mathfrak{g}_*) = (U(\mathfrak{h}_*), M_*(\mathfrak{g}_*), \epsilon_{\mathfrak{g}_*}).$$

The counit map $U(\mathfrak{g}_*) \to \kappa$ determines a quasi-isomorphism of $U(\mathfrak{h}_*)$-modules $\kappa \to M_*(\mathfrak{g}_*)$, so that T'_0 is equivalent to the functor $\overline{T}'_0$ given by $\overline{T}'_0(\gamma : \mathfrak{h}_* \to \mathfrak{g}_*) = (U(\mathfrak{h}_*), \kappa, \mathrm{id}_{\kappa})$, which (after composing with ξ) can be identified with the map $\mathrm{TwArr}(\mathrm{Lie}^{\mathrm{dg}}_{\kappa}) \to \mathrm{Lie}^{\mathrm{dg}}_{\kappa} \xrightarrow{U} \mathrm{Alg}^{\mathrm{aug}}_{\kappa}$. Now consider the composition of T with the map $\mathcal{M}^{(1)} \to \mathrm{Alg}^{\mathrm{aug}}_{\kappa}$ given by projection onto the second factor. This functor is given by composing the equivalence ξ with the functor $T'_1 : \mathrm{TwArr}(\mathrm{Lie}^{\mathrm{dg}}_{\kappa}) \to \mathrm{LMod}(\mathrm{Mod}_{\kappa}) \times_{\mathrm{Mod}_{\kappa}} \mathcal{X}$ given by $T'_1(\gamma : \mathfrak{h}_* \to \mathfrak{g}_*) = (C^*(\mathfrak{g}), M_*(\mathfrak{g}_*), \epsilon_{\mathfrak{g}_*})$. Note that $\epsilon_{\mathfrak{g}}$ is a map of $C^*(\mathfrak{g})$-modules and therefore determines an equivalence of T'_1 with the functor $\overline{T}'_1$ given by $\overline{T}'_1(\gamma : \mathfrak{h}_* \to \mathfrak{g}_*) = (C^*(\mathfrak{g}), \kappa, \mathrm{id}_{\kappa})$. It follows that the composition of T'_1 with ξ can be identified with the composition

$$\mathrm{TwArr}(\mathrm{Lie}^{\mathrm{dg}}_{\kappa}) \to (\mathrm{Lie}^{\mathrm{dg}}_{\kappa})^{\mathrm{op}} \xrightarrow{C^*} \mathrm{Alg}^{\mathrm{aug}}_{\kappa}.$$

This proves the homotopy commutativity of the diagram σ. After replacing T by an equivalent functor, we can assume that the diagram σ is commutative.

It remains to show that σ determines a left representable map between pairings of ∞-categories. Let $\mathfrak{g}_*$ be a differential graded Lie algebra, and let $\mathrm{End}(M_*(\mathfrak{g}_*))$ denote the differential graded algebra of endomorphisms of the chain complex $M_*(\mathfrak{g}_*)$. Since $M_*(\mathfrak{g}_*)$ is quasi-isomorphic to κ, the unit map $\kappa \to \mathrm{End}(M_*(\mathfrak{g}_*))$ is a quasi-isomorphism of differential graded algebras. Unwinding the definitions, we must show that the map $\theta : U(\mathfrak{g}_*) \otimes_\kappa C^*(\mathfrak{g}_*) \to \mathrm{End}(M_*(\mathfrak{g}))$ exhibits $C^*(\mathfrak{g}_*)$ as Koszul dual (as an $\mathbb{E}_1$-algebra) to $U(\mathfrak{g}_*)$. Let A_* denote the differential graded algebra of endomorphisms of $U\,\mathrm{Cn}(\mathfrak{g})_*$ (as a chain complex). Then θ factors as a composition

$$U(\mathfrak{g}_*) \otimes_\kappa C^*(\mathfrak{g}_*) \xrightarrow{\theta'} A_* \xrightarrow{\theta''} \mathrm{End}(M_*(\mathfrak{g}_*))$$

where θ'' is a quasi-isomorphism. It will therefore suffice to show that θ' exhibits $C^*(\mathfrak{g}_*)$ as Koszul dual to $U(\mathfrak{g}_*)$. Since $UE_*(\mathfrak{g}_*)$ is a free $U(\mathfrak{g}_*)$-module, this is equivalent to the requirement that θ' induces a quasi-isomorphism $\phi : C^*(\mathfrak{g}_*) \to W_*$, where W_* is the differential graded algebra of right $U(\mathfrak{g}_*)$-module maps from $U\,\mathrm{Cn}(\mathfrak{g})_*$ to itself. This is clear, since ϕ admits a left inverse which given by composition with the quasi-isomorphism $U\,\mathrm{Cn}(\mathfrak{g})_* \to \kappa$.

14.4 Digression: Opposites of Cartesian Fibrations

For every ∞-category $\mathcal{C}$, the opposite simplicial set $\mathcal{C}^{\mathrm{op}}$ is again an ∞-category. For many purposes, it is convenient to have a relative version of this construction. Suppose we are given a Cartesian fibration of simplicial sets $q : X \to S$, so that the fibers X_s of q are ∞-categories. Can we construct a new Cartesian fibration $q' : X' \to S$, whose fibers are X'_s are equivalent to the opposites of the ∞-categories X_s? In this section, we will consider two approaches to this question, the first abstract and the second more concrete.

14.4.1 Opposites of ∞-Categories

As explained in §HTT.3.3.2 , homotopy equivalence classes of Cartesian fibrations $q : X \to S$ are in bijection with homotopy classes of maps $S^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty$. By general nonsense, it follows that every (functorial) procedure for converting one Cartesian fibration $q : X \to S$ into another Cartesian fibration $q' : X' \to S$ is given by a functor $\mathcal{C}\mathrm{at}_\infty \to \mathcal{C}\mathrm{at}_\infty$. Consequently, our problem is equivalent to that of showing there is a functor $\mathcal{C}\mathrm{at}_\infty \to \mathcal{C}\mathrm{at}_\infty$ which carries each ∞-category to its opposite. The following theorem of Toën asserts that such a functor exists and is unique up to contractible ambiguity:

Theorem 14.4.1.1. *[Toën] Let $\mathcal{E}$ denote the full subcategory of* $\mathrm{Fun}(\mathcal{C}\mathrm{at}_\infty, \mathcal{C}\mathrm{at}_\infty)$ *spanned by those functors which are equivalences. Then $\mathcal{E}$ is equivalent to the (nerve of the) discrete category $\{\mathrm{id}, r\}$, where $r : \mathcal{C}\mathrm{at}_\infty \to \mathcal{C}\mathrm{at}_\infty$ is a functor which associates to every ∞-category its opposite.*

To prove Theorem 14.4.1.1, we will study an autoequivalence of $\mathcal{C}\mathrm{at}_\infty$ by analyzing its restriction to the full subcategory spanned by objects of the form $\mathrm{N}(P)$, where P is a partially ordered set. The first step is to show that this full subcategory admits an intrinsic description:

Proposition 14.4.1.2. *Let $\mathcal{C}$ be an ∞-category. The following conditions are equivalent:*

(1) *The ∞-category $\mathcal{C}$ is equivalent to the nerve of a partially ordered set P.*

(2) *For every ∞-category $\mathcal{D}$ and every pair of functors $F, F' : \mathcal{D} \to \mathcal{C}$ such that $F(x) \simeq F'(x)$ for each object $x \in \mathcal{D}$, the functors F and F' are equivalent as objects of* $\mathrm{Fun}(\mathcal{D}, \mathcal{C})$.

(3) *For every ∞-category $\mathcal{D}$, the map of sets*

$$\pi_0 \mathrm{Map}_{\mathcal{C}\mathrm{at}_\infty}(\mathcal{D}, \mathcal{C}) \to \mathrm{Hom}_{\mathcal{S}\mathrm{et}}(\pi_0 \mathrm{Map}_{\mathcal{C}\mathrm{at}_\infty}(\Delta^0, \mathcal{D}), \pi_0 \mathrm{Map}_{\mathcal{C}\mathrm{at}_\infty}(\Delta^0, \mathcal{C}))$$

is injective.

Proof. The implication (1) ⇒ (2) is obvious, and (3) is just a restatement of (2). Assume (2); we will show that (1) is satisfied. Let P denote the collection of equivalence classes of objects of $\mathcal{C}$, where $x \leqslant y$ if the space $\mathrm{Map}_{\mathcal{C}}(x, y)$ is nonempty. There is a canonical functor $\mathcal{C} \to \mathrm{N}(P)$. To prove that this functor is an equivalence, it will suffice to show the following:

($*$) For every pair of objects $x, y \in \mathcal{C}$, the space $\mathrm{Map}_{\mathcal{C}}(x, y)$ is either empty or contractible.

To prove ($*$), we may assume without loss of generality that $\mathcal{C}$ is the nerve of a fibrant simplicial category $\overline{\mathcal{C}}$. Let x and y be objects of $\overline{\mathcal{C}}$ such that the Kan complex $K = \mathrm{Map}_{\overline{\mathcal{C}}}(x, y)$ is nonempty. We define a new (fibrant) simplicial category $\overline{\mathcal{D}}$ so that $\overline{\mathcal{D}}$ consists of a pair of objects $\{x', y'\}$, with

$$\mathrm{Map}_{\overline{\mathcal{D}}}(x', y') \simeq K \quad \mathrm{Map}_{\overline{\mathcal{D}}}(x', x') \simeq \Delta^0 \simeq \mathrm{Map}_{\overline{\mathcal{D}}}(y', y') \quad \mathrm{Map}_{\overline{\mathcal{D}}}(y', x') \simeq \varnothing.$$

We let $\overline{F}, \overline{F}' : \overline{\mathcal{D}} \to \overline{\mathcal{C}}$ be simplicial functors such that $\overline{F}(x') = \overline{F}'(x') = x$, $\overline{F}(y') = \overline{F}'(y') = y$, where $\overline{F}$ induces the identity map from $\mathrm{Map}_{\overline{\mathcal{D}}}(x', y') = K = \mathrm{Map}_{\overline{\mathcal{C}}}(x, y)$ to itself, while $\overline{F}'$ induces a constant map from K to itself. Then $\overline{F}$ and $\overline{F}'$ induce functors F and F' from $\mathrm{N}(\overline{\mathcal{D}})$ to $\mathcal{C}$. It follows from assumption (2) that the functors F and F' are equivalent, which implies that the identity map from K to itself is homotopic to a constant map; this proves that K is contractible. □

Corollary 14.4.1.3. *Let $\sigma : \mathcal{C}\mathrm{at}_\infty \to \mathcal{C}\mathrm{at}_\infty$ be an equivalence of ∞-categories, and let $\mathcal{C}$ be an ∞-category (which we regard as an object of $\mathcal{C}\mathrm{at}_\infty$). Then $\mathcal{C}$ is equivalent to the nerve of a partially ordered set if and only if $\sigma(\mathcal{C})$ is equivalent to the nerve of a partially ordered set.*

Lemma 14.4.1.4. *Let $\sigma, \sigma' \in \{\mathrm{id}_{\mathbf{\Delta}}, r\} \subseteq \mathrm{Fun}(\mathbf{\Delta}, \mathbf{\Delta})$, where r denotes the reversal functor from $\mathbf{\Delta}$ to itself. Then*

$$\mathrm{Hom}_{\mathrm{Fun}(\mathbf{\Delta},\mathbf{\Delta})}(\sigma, \sigma') = \begin{cases} \emptyset & \textit{if } \sigma = \sigma' \\ \{\mathrm{id}\} & \textit{if } \sigma = \sigma'. \end{cases}$$

Proof. Note that σ and σ' are both the identity at the level of objects. Let $\alpha : \sigma \to \sigma'$ be a natural transformation. Then, for each $n \geqslant 0$, $\alpha_{[n]}$ is a map from $[n]$ to itself. We claim that $\alpha_{[n]}$ is given by the formula

$$\alpha_{[n]}(i) = \begin{cases} i & \text{if } \sigma = \sigma' \\ n - i & \text{if } \sigma \neq \sigma'. \end{cases}$$

To prove this, we observe that a choice of $i \in [n]$ determines a map $[0] \to [n]$, which allows us to reduce to the case $n = 0$ (where the result is obvious) by functoriality.

It follows from the above argument that the natural transformation α is uniquely determined, if it exists. Moreover, α is a well-defined natural transformation if and only if each $\alpha_{[n]}$ is an order-preserving map from $[n]$ to itself; this is true if and only if $\sigma = \sigma'$. □

Proposition 14.4.1.5. *Let $\mathcal{P}$ denote the category of partially ordered sets, and let $\sigma : \mathcal{P} \to \mathcal{P}$ be an equivalence of categories. Then σ is isomorphic either to the identity functor $\mathrm{id}_{\mathcal{P}}$ or the functor r which carries every partially ordered set X to the same set with the opposite ordering.*

Proof. Since σ is an equivalence of categories, it carries the final object $[0] \in \mathcal{P}$ to itself (up to canonical isomorphism). It follows that for every partially ordered set X, we have a canonical bijection of sets

$$\eta_X : X \simeq \mathrm{Hom}_{\mathcal{P}}([0], X) \simeq \mathrm{Hom}_{\mathcal{P}}(\sigma([0]), \sigma(X)) \simeq \mathrm{Hom}_{\mathcal{P}}([0], \sigma(X)) \simeq \sigma(X).$$

We next claim that $\sigma([1])$ is isomorphic to $[1]$ as a partially ordered set. Since $\eta_{[1]}$ is bijective, the partially ordered set $\sigma([1])$ has precisely two elements. Thus $\sigma([1])$ is isomorphic either to $[1]$ or to a partially ordered set $\{x, y\}$ with two elements, neither larger than the other. In the second case, the set $\mathrm{Hom}_{\mathcal{P}}(\sigma([1]), \sigma([1]))$ has four elements. This is impossible, since σ is an equivalence of categories and $\mathrm{Hom}_{\mathcal{P}}([1], [1])$ has only three elements. Let $\alpha : \sigma([1]) \to [1]$ be an isomorphism (automatically unique, since the ordered set $[1]$ has no automorphisms in $\mathcal{P}$).

The map $\alpha \circ \eta_{[1]}$ is a bijection from the set $[1]$ to itself. We will assume that this map is the identity, and prove that σ is isomorphic to the identity functor $\mathrm{id}_{\mathcal{P}}$. The same argument, applied to $\sigma \circ r$, will show that if $\alpha \circ \eta_{[1]}$ is not the identity, then σ is isomorphic to r.

To prove that σ is equivalent to the identity functor, it will suffice to show that for every partially ordered set X, the map η_X is an isomorphism of partially ordered sets. In other words, we must show that both η_X and η_X^{-1} are maps of partially ordered sets. We will prove that η_X is a map of partially ordered sets; the same argument, applied to an inverse to the equivalence σ, will show that η_X^{-1} is a map of partially ordered sets. Let $x, y \in X$ satisfy $x \leqslant y$; we wish to prove that $\eta_X(x) \leqslant \eta_X(y)$ in $\sigma(X)$. The pair (x, y) defines a map of partially ordered sets $[1] \to X$. By functoriality, we may replace X by $[1]$, and thereby reduce to the problem of proving that $\eta_{[1]}$ is a map of partially ordered sets. This follows from our assumption that $\alpha \circ \eta_{[1]}$ is the identity map. □

Proof of Theorem 14.4.1.1. Let $\mathcal{C}$ be the full subcategory of $\mathcal{C}\mathrm{at}_\infty$ spanned by those ∞-categories which are equivalent to the nerves of partially ordered sets, and let $\mathcal{C}^0$ denote the full subcategory of $\mathcal{C}$ spanned by the objects $\{\Delta^n\}_{n \geqslant 0}$. Corollary 14.4.1.3 implies that every object $\sigma \in \mathcal{E}$ restricts to an equivalence from $\mathcal{C}$ to itself. According to Proposition 14.4.1.5, $\sigma|_{\mathcal{C}}$ is equivalent either to the identity functor, or to the restriction $r|_{\mathcal{C}}$. In either case, we conclude that σ also induces an equivalence from $\mathcal{C}^0$ to itself.

It follows from Proposition HA.A.7.10 that the full subcategory $\mathcal{C}^0 \subseteq \mathcal{C}\mathrm{at}_\infty$ is dense (see Definition 20.4.1.7), so that the restriction functor $\mathcal{E} \to \mathrm{Fun}(\mathcal{C}^0, \mathcal{C}^0)$ is fully faithful (see Remark 20.4.1.6). In particular, any object $\sigma \in \mathcal{E}$ is determined by the restriction $\sigma|_{\mathcal{C}}$, so that σ is equivalent to either id or r by virtue of Proposition 14.4.1.5. Since $\mathcal{C}^0$ is equivalent to the nerve of the category $\mathbf{\Delta}$, Lemma 14.4.1.4 implies the existence of a fully faithful embedding from $\mathcal{E}$ to the nerve of the discrete category $\{\mathrm{id}, r\}$. To complete the proof, it will suffice to show that this functor is essentially surjective. In other words, we must show that there exists a functor $R : \mathcal{C}\mathrm{at}_\infty \to \mathcal{C}\mathrm{at}_\infty$ whose restriction to $\mathcal{C}$ is equivalent to r.

To carry out the details, it is convenient to replace $\mathcal{C}\mathrm{at}_\infty$ by an equivalent ∞-category with a slightly more elaborate definition. Recall that $\mathcal{C}\mathrm{at}_\infty$ is defined to be the simplicial nerve of a simplicial category $\mathcal{C}\mathrm{at}_\infty^\Delta$, whose objects are ∞-categories, where $\mathrm{Map}_{\mathcal{C}\mathrm{at}_\infty^\Delta}(X, Y)$ is the largest Kan complex contained in $\mathrm{Fun}(X, Y)$. We would like to define R to be induced by the functor $X \mapsto X^{\mathrm{op}}$, but this is not a simplicial functor from $\mathcal{C}\mathrm{at}_\infty^\Delta$ to itself; instead we have a canonical isomorphism $\mathrm{Map}_{\mathcal{C}\mathrm{at}_\infty^\Delta}(X^{\mathrm{op}}, Y^{\mathrm{op}}) \simeq \mathrm{Map}_{\mathcal{C}\mathrm{at}_\infty^\Delta}(X, Y)^{\mathrm{op}}$. However, if we let $\mathcal{C}\mathrm{at}_\infty^{\mathcal{T}\mathrm{op}}$ denote the topological category obtained by geometrically realizing the morphism spaces in $\mathcal{C}\mathrm{at}_\infty^\Delta$, then i induces an autoequivalence of $\mathcal{C}\mathrm{at}_\infty^{\mathcal{T}\mathrm{op}}$ as a topological category (via the natural homeomorphisms $|K| \simeq |K^{\mathrm{op}}|$, which is defined for every simplicial set K). We now define $\mathcal{C}\mathrm{at}'_\infty$ to be the topological nerve of $\mathcal{C}\mathrm{at}_\infty^{\mathcal{T}\mathrm{op}}$ (see Definition HTT.1.1.5.5). Then $\mathcal{C}\mathrm{at}'_\infty$ is an ∞-category equipped with a canonical equivalence $\mathcal{C}\mathrm{at}_\infty \to \mathcal{C}\mathrm{at}'_\infty$, and the involution i induces an involution I on $\mathcal{C}\mathrm{at}'_\infty$, which carries each object $\mathcal{D} \in \mathcal{C}\mathrm{at}'_\infty$ to the opposite ∞-category $\mathcal{D}^{\mathrm{op}}$. We now define R to be the composition

$$\mathcal{C}\mathrm{at}_\infty \to \mathcal{C}\mathrm{at}'_\infty \xrightarrow{I} \mathcal{C}\mathrm{at}'_\infty \to \mathcal{C}\mathrm{at}_\infty,$$

where the last map is a homotopy inverse to the equivalence $\mathcal{C}\mathrm{at}_\infty \to \mathcal{C}\mathrm{at}'_\infty$. It is easy to see that R has the desired properties (moreover, we note that for every object $\mathcal{D} \in \mathcal{C}\mathrm{at}_\infty$, the image $R\mathcal{D}$ is canonically equivalent with the opposite ∞-category $\mathcal{D}^{\mathrm{op}}$). □

14.4.2 Duals of Cartesian Fibrations

Let $q : X \to S$ be a Cartesian fibration of simplicial sets, let $\chi : S^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty$ be a diagram classifying q, and let $r : \mathcal{C}\mathrm{at}_\infty \to \mathcal{C}\mathrm{at}_\infty$ be the nontrivial equivalence of Theorem 14.4.1.1. Then $r \circ \chi$ classifies a Cartesian fibration $q' : X' \to S$, whose fibers are equipped with equivalences $X'_s \simeq X_s^{\mathrm{op}}$. The Cartesian fibration q' is determined uniquely up to equivalence. However, for many applications it is useful to have a more concrete description of X' (which is well-defined up to isomorphism rather than equivalence). We now sketch such a construction (for an alternative approach having a more combinatorial flavor, we refer the reader to [14]).

Construction 14.4.2.1. Let $p : X \to S$ be a map of simplicial sets. We define a new simplicial set $\mathrm{Dl}(p)$ equipped with a map $\mathrm{Dl}(p) \to S$ so that the following universal property is satisfied: for every map of simplicial sets $K \to S$, we have a bijection

$$\mathrm{Hom}_{(\mathcal{S}\mathrm{et}_\Delta)_{/S}}(K, \mathrm{Dl}(p)) \simeq \mathrm{Hom}_{\mathcal{S}\mathrm{et}_\Delta}(K \times_S X, \mathcal{S}).$$

Note that for each vertex $s \in S$, the fiber $\mathrm{Dl}(p)_s = \mathrm{Dl}(p) \times_S \{s\}$ is canonically isomorphic to the presheaf ∞-category $\mathrm{Fun}(X_s, \mathcal{S})$.

Assume that p is an inner fibration. We let $\mathrm{Dl}^0(p)$ the full simplicial subset of $\mathrm{Dl}(p)$ spanned by those vertices which correspond to corepresentable functors $X_s \to \mathcal{S}$, for some $s \in S$. If each of the ∞-categories X_s admits finite limits, we let $\mathrm{Dl}^{\mathrm{lex}}(p)$ denote the full simplicial subset of $\mathrm{Dl}(p)$ spanned by those vertices which correspond to left exact functors $X_s \to \mathcal{S}$, for some vertex $s \in S$,

Remark 14.4.2.2. Let $p : X \to S$ be an inner fibration and assume that each of the fibers X_s is an ∞-category which admits finite limits. Then for each vertex $s \in S$, we have a canonical isomorphism $\mathrm{Dl}^{\mathrm{lex}}(p)_s \simeq \mathrm{Ind}(X_s^{\mathrm{op}})$.

The next result summarizes some of the essential features of Construction 14.4.2.1.

Proposition 14.4.2.3. *Let $p : X \to S$ be a map of simplicial sets. Then:*

(1) *If p is a Cartesian fibration, then the map $\mathrm{Dl}(p) \to S$ is a coCartesian fibration. Moreover, for every edge $e : s \to s'$ in S, the induced functor*

$$\mathrm{Fun}(X_s, \mathcal{S}) \simeq \mathrm{Dl}(p)_s \to \mathrm{Dl}(p)_{s'} \simeq \mathrm{Fun}(X_{s'}, \mathcal{S})$$

is given by composition with the pullback functor $e^* : X_{s'} \to X_s$ determined by p.

(2) *If p is a coCartesian fibration, then the map $\mathrm{Dl}(p) \to S$ is a Cartesian fibration. Moreover, for every edge $e : s \to s'$ in S, the induced functor*

$$\mathrm{Fun}(X_{s'}, \mathcal{S}) \simeq \mathrm{Dl}(p)_{s'} \to \mathrm{Dl}(p)_s \simeq \mathrm{Fun}(X_s, \mathcal{S})$$

is given by composition with the functor $e_! : X_s \to X_{s'}$ determined by p.

(3) *Suppose p is a Cartesian fibration, that each fiber X_s of p admits finite limits and that for every edge $e : s \to s'$ in S, the pullback functor $e^* : X_{s'} \to X_s$ is left exact. Then the map $\mathrm{Dl}^{\mathrm{lex}}(p) \to S$ is a coCartesian fibration. Moreover, for every edge $e : s \to s'$ in S, the induced functor*

$$\mathrm{Ind}(X_s^{\mathrm{op}}) \simeq \mathrm{Dl}^{\mathrm{lex}}(p)_s \to \mathrm{Dl}^{\mathrm{lex}}(p)_{s'} \simeq \mathrm{Ind}(X_{s'}^{\mathrm{op}})$$

is given by composition with the pullback functor e^*.

(4) *If p is a coCartesian fibration, then the canonical map $q : \mathrm{Dl}(p) \to S$ is a coCartesian fibration, which restricts to a coCartesian fibration $\mathrm{Dl}^0(p) \to S$. If each fiber X_s admits finite limits, then q also restricts to a coCartesian fibration $\mathrm{Dl}^{\mathrm{lex}}(p) \to S$.*

Proof. Assertion (1) and (3) follow from Corollary HTT.3.2.2.12 . The implication (1) ⇒ (2) is immediate. We now prove (4). Assume that p is a coCartesian fibration. Then (2) implies that $\mathrm{Dl}(p) \to S$ is a Cartesian fibration, and that each edge $e : s \to s'$ induces a pullback functor $\mathrm{Dl}(p)_{s'} \to \mathrm{Dl}(p)_s$ which preserves small limits and filtered colimits Using Corollary HTT.5.5.2.9 , we deduce that this pullback functor admits a left adjoint $\mathrm{Fun}(X_s, \mathcal{S}) \to \mathrm{Fun}(X_{s'}, \mathcal{S})$, which is given by left Kan extension along the functor $e_! : X_s \to X_{s'}$. Corollary HTT.5.2.2.5 implies that the forgetful functor $q : \mathrm{Dl}(p) \to S$ is also a coCartesian fibration. Since the operation of left Kan extension carries corepresentable functors to corepresentable functors, we conclude that q restricts to a coCartesian fibration $q_0 : \mathrm{Dl}^0(p) \to S$ (and that a morphism in $\mathrm{Dl}^0(p)$ is q_0-coCartesian if and only if it is q-coCartesian). Now suppose that each fiber X_s of p admits finite limits. For each $s \in S$, the ∞-category $\mathrm{Dl}^{\mathrm{lex}}(p)_s = \mathrm{Ind}(X_s^{\mathrm{op}})$ can be identified with the full subcategory of $\mathrm{Dl}(p)_s = \mathcal{P}(X_s^{\mathrm{op}})$ generated by $\mathrm{Dl}^0(p)_s$ under filtered colimits. If $e : s \to s'$ is an edge of S, then the functor $e_! : \mathrm{Dl}(p)_s \to \mathrm{Dl}(p)_{s'}$ preserves small filtered colimits and carries $\mathrm{Dl}^0(p)_s$ into $\mathrm{Dl}^0(p)_{s'}$, and therefore carries $\mathrm{Dl}^{\mathrm{lex}}(p)_s$ into $\mathrm{Dl}^{\mathrm{lex}}(p)_{s'}$. It follows that q restricts to a coCartesian fibration $\mathrm{Dl}^{\mathrm{lex}}(p) \to S$. □

Proposition 14.4.2.4. *Let $q : X \to S$ be a Cartesian fibration of simplicial sets with essentially small fibers, so that q is classified by a functor $\chi : S^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty$, and let $\chi' : S^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty$ classify the induced Cartesian fibration $q' : \mathrm{Dl}^0(q) \to S$. Then $\chi' \simeq \chi \circ r$, where $r : \mathcal{C}\mathrm{at}_\infty \to \mathcal{C}\mathrm{at}_\infty$ is the functor which associates to each ∞-category its opposite.*

Proof. It suffices to treat the universal case where $S = \mathcal{C}\mathrm{at}_\infty^{\mathrm{op}}$ and χ is the identity map. Then we can identify χ' with a functor $\mathcal{C}\mathrm{at}_\infty^{\mathrm{op}} \to \mathcal{C}\mathrm{at}_\infty^{\mathrm{op}}$; we wish to show that χ' is equivalent to r. We first show that χ'^2 is equivalent to the identity. For this, it suffices to construct an equivalence $X \to \mathrm{Dl}^0(q')$ of Cartesian fibrations over S; this equivalence is classified by the tautological map

$$X \times_S \mathrm{Dl}^0(q) \hookrightarrow X \times_S \mathrm{Dl}(q) \to \mathcal{S}.$$

It follows that χ' is an equivalence of $\mathcal{C}\mathrm{at}_\infty^{\mathrm{op}}$ with itself. Note that $\chi'(s) \simeq \mathrm{Dl}(q)^0_s \simeq X_s^{\mathrm{op}}$ for each $s \in S$. Choosing $s \in S$ so that X_s is not equivalent to its opposite, we conclude that χ' is not equivalent to the identity functor. Using Theorem 14.4.1.1, we deduce that χ' is equivalent to r. □

14.4.3 The Compactly Generated Case

We conclude this section with a result which will be useful in §14.5:

Proposition 14.4.3.1. *Let $p : X \to S$ be a coCartesian fibration of simplicial sets. Assume that:*

- *(a) For each $s \in S$, the fiber X_s is compactly generated.*
- *(b) For every morphism edge $e : s \to s'$ in S, the induced functor $X_s \to X_{s'}$ preserves compact objects and small colimits.*

Let X^c denote the full simplicial subset of X spanned by those vertices which are compact objects of X_s for some $s \in S$. Let $p^{\mathrm{op}} : X^{\mathrm{op}} \to S^{\mathrm{op}}$ be the induced map between opposite simplicial sets, and let $p_c^{\mathrm{op}} : (X^c)^{\mathrm{op}} \to S^{\mathrm{op}}$ be the restriction of p^{op}. Then the restriction map $\phi : \mathrm{Dl}^0(p^{\mathrm{op}}) \subseteq \mathrm{Dl}^{\mathrm{lex}}(p^{\mathrm{op}}) \to \mathrm{Dl}^{\mathrm{lex}}(p_c^{\mathrm{op}})$ is an equivalence of coCartesian fibrations over S^{op}.

Proof. It follows from (a) and (b) that each of the functors $e_! : X_s \to X_{s'}$ admits a right adjoint e^*, so that p is a Cartesian fibration and therefore p^{op} is a coCartesian fibration. Applying Proposition 14.4.2.3, we conclude that the projection map $q : \mathrm{Dl}^0(p^{\mathrm{op}}) \to S^{\mathrm{op}}$ is a coCartesian fibration. It follows from (b) that the projection $X^c \to S$ is a coCartesian fibration whose fibers admit finite colimits, and that for every edge $e : s \to s'$ in S the induced functor $X^c_s \to X^c_{s'}$ preserves finite colimits. Applying Proposition 14.4.2.3 again, we deduce that the map $q' : \mathrm{Dl}^{\mathrm{lex}}(p_c^{\mathrm{op}}) \to S^{\mathrm{op}}$ is a coCartesian fibration. We next claim that ϕ

carries q-coCartesian morphisms to q'-coCartesian morphisms. Unwinding the definitions, this amounts to the following claim: if $\overline{e} : x \to x'$ is a p-Cartesian edge lifting $e : s \to s'$, then $\overline{e}$ induces an equivalence $h_{x'} \circ e_! \to h_x$ of functors $X_s^{\mathrm{op}} \to \mathcal{S}$, where $h_x : X_s^{\mathrm{op}} \to \mathcal{S}$ is the functor represented by x and $h_{x'} : X_{s'}^{\mathrm{op}} \to \mathcal{S}$ is the functor represented by x'. This is an immediate consequence of the definitions.

To complete the proof, it will suffice to show that for every vertex $s \in S$, the functor ϕ induces an equivalence of ∞-categories $\mathrm{Dl}^0(p^{\mathrm{op}})_s \to \mathrm{Dl}^{\mathrm{lex}}(p_c^{\mathrm{op}})$. That is, we must show that the composite functor

$$\psi : X_s \to \mathrm{Fun}(X_s^{\mathrm{op}}, \mathcal{S}) \to \mathrm{Fun}((X_s^c)^{\mathrm{op}}, \mathcal{S}) = \mathrm{Ind}(X_s^c)$$

is an equivalence of ∞-categories. This is clear, since ψ is right adjoint to the canonical map $\mathrm{Ind}(X_s^c) \to X_s$ (which is an equivalence by virtue of our assumption that X_s is compactly generated). □

14.5 Quasi-Coherent and Ind-Coherent Sheaves

Let κ be a field and let $X : \mathrm{CAlg}_\kappa^{\mathrm{art}} \to \mathcal{S}$ be a formal moduli problem. In §13.4, we introduced a symmetric monoidal ∞-category $\mathrm{QCoh}(X)$ of quasi-coherent sheaves on X. Our goal in this section is to study analogous definitions in the noncommutative setting. In this case, it is important to distinguish between left and right modules. Consequently, if $X : \mathrm{Alg}_\kappa^{\mathrm{art}} \to \mathcal{S}$ is a formal $\mathbb{E}_1$-moduli problem, then there are two natural analogues of the ∞-category $\mathrm{QCoh}(X)$. We will denote these ∞-categories by $\mathrm{QCoh}_L(X)$ and $\mathrm{QCoh}_R(X)$, and refer to them as the ∞-categories of (left and right) *quasi-coherent sheaves* on X. We will also study noncommutative counterparts of the fully faithful embedding $\mathrm{QCoh}(X) \to \mathrm{QCoh}^!(X)$ of Remark 13.4.6.6.

We will devote most of our attention to the case where $X = \mathrm{Spf}\, A$ is corepresented by an Artinian $\mathbb{E}_1$-algebra A over κ. At the end of this section, we will explain how to extrapolate our discussion to the general case (Construction 14.5.5.1).

14.5.1 Artinian Modules

Let κ be a field. We will say that an object $M \in \mathrm{Mod}_\kappa$ is *Artinian* if it is perfect as a κ-module: that is, if $\pi_* M$ has finite dimension over κ. If R is an $\mathbb{E}_1$-algebra over κ and M is a right or left module over R, we will say that M is *Artinian* if it is Artinian when regarded as an object of Mod_κ. We let $\mathrm{LMod}_R^{\mathrm{art}}$ denote the full subcategory of LMod_R spanned by the Artinian left R-modules, and $\mathrm{RMod}_R^{\mathrm{art}}$ the full subcategory of RMod_R spanned by the Artinian right R-modules.

Remark 14.5.1.1. Let κ be a field, let R be an augmented $\mathbb{E}_1$-algebra over κ. Assume that R is connective and that the kernel I of the augmentation map $\pi_0 R \to \kappa$ is a nilpotent ideal in $\pi_0 R$. Then an object $M \in \mathrm{LMod}_R$ is Artinian if and only if it belongs to the smallest stable full subcategory $\mathcal{C} \subseteq \mathrm{LMod}_R$ which contains $\kappa \simeq (\pi_0 R)/I$ and is closed under equivalence. The "if" direction is obvious (and requires no assumptions on R), since the full subcategory $\mathrm{LMod}_R^{\mathrm{art}} \subseteq \mathrm{LMod}_R$ is stable, closed under retracts, and contains κ. For the converse, suppose that M is Artinian; we prove that $M \in \mathcal{C}$ using induction on the dimension of the κ-vector space $\pi_* M$. If $M \simeq 0$ there is nothing to prove. Otherwise, there exists some largest integer n such that $\pi_n M$ is nonzero. Since I is nilpotent, there exists a nonzero element $x \in \pi_n M$ which is annihilated by I. Then multiplication by x determines a map of discrete R-modules $\kappa \to \pi_n M$, which in turn determines a fiber sequence of R-modules $\Sigma^n(\kappa) \to M \to M'$. The inductive hypothesis guarantees that $M' \in \mathcal{C}$ and it is clear that $\Sigma^n(\kappa) \in \mathcal{C}$, so that $M \in \mathcal{C}$ as desired.

We now show that if R is an $\mathbb{E}_1$-algebra over a field κ, then κ-linear duality determines a contravariant equivalence between the ∞-categories $\mathrm{LMod}_R^{\mathrm{art}}$ and $\mathrm{RMod}_R^{\mathrm{art}}$.

Proposition 14.5.1.2. *Let κ be a field and let R be an $\mathbb{E}_1$-algebra over κ. Define a functor $\lambda : \mathrm{RMod}_R^{\mathrm{op}} \times \mathrm{LMod}_R^{\mathrm{op}} \to \mathcal{S}$ by the formula $\lambda(M,N) = \mathrm{Map}_{\mathrm{Mod}_\kappa}(M \otimes_R N, \kappa)$. Then:*

(1) *For every right R-module M, let $\lambda_M : \mathrm{LMod}_R^{\mathrm{op}} \to \mathcal{S}$ be the restriction of λ to $\{M\} \times \mathrm{LMod}_R^{\mathrm{op}}$. Then λ_M is a representable functor.*

(1′) *Let $\mu : \mathrm{RMod}_R^{\mathrm{op}} \to \mathrm{Fun}(\mathrm{LMod}_R^{\mathrm{op}}, \mathcal{S})$ be given by $\mu(M)(N) = \lambda(M,N)$. Then μ is homotopic to a composition $\mathrm{RMod}_R^{\mathrm{op}} \xrightarrow{\mu_0} \mathrm{LMod}_R \xrightarrow{j} \mathrm{Fun}(\mathrm{LMod}_R^{\mathrm{op}}, \mathcal{S})$, where j denotes the Yoneda embedding.*

(2) *For every left R-module M, let $\lambda_N : \mathrm{RMod}_R^{\mathrm{op}} \to \mathcal{S}$ be the restriction of λ to $\mathrm{RMod}_R^{\mathrm{op}} \times \{N\}$. Then λ_N is a representable functor.*

(2′) *Let $\mu' : \mathrm{LMod}_R^{\mathrm{op}} \to \mathrm{Fun}(\mathrm{RMod}_R^{\mathrm{op}}, \mathcal{S})$ be given by $\mu'(N)(M) = \lambda(M,N)$. Then μ' is homotopic to a composition $\mathrm{LMod}_R^{\mathrm{op}} \xrightarrow{\mu'_0} \mathrm{RMod}_R \xrightarrow{j} \mathrm{Fun}(\mathrm{RMod}_R^{\mathrm{op}}, \mathcal{S})$, where j denotes the Yoneda embedding.*

(3) *The functors μ_0 and μ'_0 determine mutually inverse equivalences between the ∞-categories $\mathrm{RMod}_R^{\mathrm{art}}$ and $(\mathrm{LMod}_R^{\mathrm{art}})^{\mathrm{op}}$.*

Proof. We first note that (1′) and (2′) are reformulations of (1) and (2). We will prove (1); the proof of (2) is similar. Let $M \in \mathrm{RMod}_R$; we wish to show that λ_M is a representable functor. Since LMod_R is a presentable ∞-category, it will suffice to show that the functor λ_M preserves small limits (Proposition HTT.5.5.2.2). This is clear, since the functor $N \mapsto M \otimes_R N$ preserves small colimits.

Let $\mu_0 : \mathrm{RMod}_R^{\mathrm{op}} \to \mathrm{LMod}_R$ and $\mu_0' : \mathrm{LMod}_R^{\mathrm{op}} \to \mathrm{RMod}_R$ be as in $(1')$ and $(2')$. We note that μ_0' can be identified with the right adjoint to μ_0^{op}. Let $M \in \mathrm{RMod}_R$. For every integer n, we have canonical isomorphisms

$$\pi_n \mu_0(M) \simeq \pi_0 \mathrm{Map}_{\mathrm{RMod}_R}(\Sigma^n(R), \mu_0(M)) \simeq \pi_0 \mathrm{Map}_{\mathrm{Mod}_\kappa}(M \otimes_R \Sigma^n(R), \kappa) \simeq (\pi_{-n} M)^\vee,$$

where $(\pi_{-n}M)^\vee$ denotes the κ-linear dual of the vector space $\pi_{-n}M$. It follows that μ_0 carries $(\mathrm{RMod}_R^{\mathrm{art}})^{\mathrm{op}}$ into $\mathrm{LMod}_R^{\mathrm{art}}$. Similarly, μ_0' carries $(\mathrm{LMod}_R^{\mathrm{art}})^{\mathrm{op}}$ into $\mathrm{RMod}_R^{\mathrm{art}}$. To prove (3), it will suffice to show that for every pair of objects $M \in \mathrm{RMod}_R^{\mathrm{art}}$, $N \in \mathrm{LMod}_R^{\mathrm{art}}$, the unit maps $M \to \mu_0'\mu_0(M)$ and $N \to \mu_0\mu_0'(N)$ are equivalences in RMod_R and LMod_R, respectively. Passing to homotopy groups, we are reduced to proving that the biduality maps $\pi_n M \to ((\pi_n M)^\vee)^\vee$ and $\pi_n N \to ((\pi_n N)^\vee)^\vee$ are isomorphisms for every integer n. This follows from the finite-dimensionality of the vector spaces $\pi_n M$ and $\pi_n N$ over κ. $\square$

14.5.2 Ind-Coherent Modules

Let κ be a field and let $R \in \mathrm{Alg}_\kappa$. If R is Artinian (in the sense of Definition 14.0.0.1), then every perfect (left or right) R-module is perfect when viewed as a κ-module: that is, we can regard $\mathrm{LMod}_R^{\mathrm{art}}$ and $\mathrm{RMod}_R^{\mathrm{art}}$ as enlargements of the ∞-categories $\mathrm{LMod}_R^{\mathrm{perf}}$ and $\mathrm{RMod}_R^{\mathrm{perf}}$, respectively. We now introduce analogous enlargements of the ∞-categories LMod_R and RMod_R.

Definition 14.5.2.1. Let κ be a field and let $R \in \mathrm{Alg}_\kappa^{\mathrm{art}}$ be a Artinian $\mathbb{E}_1$-algebra over κ. We let $\mathrm{LMod}_R^!$ denote the full subcategory of $\mathrm{Fun}(\mathrm{RMod}_R^{\mathrm{art}}, \mathcal{S})$ spanned by the left exact functors, and $\mathrm{RMod}_R^!$ the full subcategory of $\mathrm{Fun}(\mathrm{LMod}_R^{\mathrm{art}}, \mathcal{S})$ spanned by the left exact functors. We will refer to $\mathrm{LMod}_R^!$ as the *∞-category of* Ind-*coherent left R-modules*, and $\mathrm{RMod}_R^!$ as the *∞-category of* Ind-*coherent right R-modules*.

Remark 14.5.2.2. Using the equivalence $\mathrm{RMod}_R^{\mathrm{art}} \simeq (\mathrm{LMod}_R^{\mathrm{art}})^{\mathrm{op}}$ of Proposition 14.5.1.2, we obtain equivalences of ∞-categories $\mathrm{LMod}_R^! \simeq \mathrm{Ind}(\mathrm{LMod}_R^{\mathrm{art}})$ and $\mathrm{RMod}_R^! \simeq \mathrm{Ind}(\mathrm{RMod}_R^{\mathrm{art}})$.

Our next goal is to study the dependence of the ∞-categories $\mathrm{LMod}_R^!$ and $\mathrm{RMod}_R^!$ on the choice of algebra $R \in \mathrm{Alg}_\kappa^{\mathrm{art}}$.

Construction 14.5.2.3. Let κ be a field and let $\mathrm{LMod}(\mathrm{Mod}_\kappa)$ and $\mathrm{RMod}(\mathrm{Mod}_\kappa)$ denote the ∞-categories of left and right module objects of the symmetric monoidal ∞-category Mod_κ. That is, $\mathrm{LMod}(\mathrm{Mod}_\kappa)$ is an ∞-category whose objects are pairs (R, M), where $R \in \mathrm{Alg}_\kappa$ and M is a left R-module, and $\mathrm{RMod}(\mathrm{Mod}_\kappa)$ is an ∞-category whose objects are pairs (R, M) where $R \in \mathrm{Alg}_\kappa$ and M is a left R-module. We let $\mathrm{LMod}^{\mathrm{art}}(\mathrm{Mod}_\kappa)$ denote the full subcategory of $\mathrm{LMod}(\mathrm{Mod}_\kappa)$ spanned by those pairs (R, M) where $R \in \mathrm{Alg}_\kappa^{\mathrm{art}}$ and $M \in \mathrm{LMod}_R^{\mathrm{art}}$, and define $\mathrm{RMod}^{\mathrm{art}}(\mathrm{Mod}_\kappa) \subseteq \mathrm{RMod}(\mathrm{Mod}_\kappa)$ similarly. We have evident forgetful functors

$$\mathrm{LMod}^{\mathrm{art}}(\mathrm{Mod}_\kappa) \xrightarrow{q} \mathrm{Alg}_\kappa^{\mathrm{art}} \xleftarrow{q'} \mathrm{RMod}^{\mathrm{art}}(\mathrm{Mod}_\kappa).$$

We define $\mathrm{RMod}^!(\mathrm{Mod}_\kappa) = \mathrm{Dl}^{\mathrm{lex}}(q)$ and $\mathrm{LMod}^!(\mathrm{Mod}_\kappa) = \mathrm{Dl}^{\mathrm{lex}}(q')$, so that we have evident forgetful functors

$$\mathrm{RMod}^!(\mathrm{Mod}_\kappa) \to \mathrm{Alg}_\kappa^{\mathrm{art}} \leftarrow \mathrm{LMod}^!(\mathrm{Mod}_\kappa).$$

Remark 14.5.2.4. It follows from Proposition 14.4.2.3 that the forgetful functors

$$\mathrm{LMod}^!(\mathrm{Mod}_\kappa) \to \mathrm{Alg}_\kappa^{\mathrm{art}} \leftarrow \mathrm{RMod}^!(\mathrm{Mod}_\kappa)$$

are coCartesian fibrations. For every object $R \in \mathrm{Alg}_\kappa^{\mathrm{art}}$, we can identify the fiber product $\mathrm{RMod}^!(\mathrm{Mod}_\kappa) \times_{\mathrm{Alg}_\kappa^{\mathrm{art}}} \{R\}$ with the ∞-category $\mathrm{RMod}_R^!$ of Definition 14.5.2.1, and the fiber product $\mathrm{LMod}^!(\mathrm{Mod}_\kappa) \times_{\mathrm{Alg}_\kappa^{\mathrm{art}}} \{R\}$ with the ∞-category $\mathrm{LMod}_R^!$ of Definition 14.5.2.1. If $f : R \to R'$ is a morphism in $\mathrm{Alg}_\kappa^{\mathrm{art}}$, then f induces functors $\mathrm{RMod}_R^! \to \mathrm{RMod}_{R'}^!$ and $\mathrm{LMod}_R^! \to \mathrm{LMod}_{R'}^!$, both of which we will denote by $f^!$.

14.5.3 Functoriality

Let κ be a field and let R be an Artinian κ-algebra (in the sense of Definition 14.0.0.1). Then the inclusion $\mathrm{RMod}_R^{\mathrm{perf}} \subseteq \mathrm{RMod}_R^{\mathrm{art}}$ induces a fully faithful embedding

$$\Phi_R : \mathrm{RMod}_R \simeq \mathrm{Ind}(\mathrm{RMod}_R^{\mathrm{perf}}) \hookrightarrow \mathrm{Ind}(\mathrm{RMod}_R^{\mathrm{art}}) \simeq \mathrm{RMod}_R^!.$$

However, this construction is badly behaved in some respects. For example, if $f : R \to R'$ is a morphism in $\mathrm{Alg}_\kappa^{\mathrm{art}}$, then the diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{RMod}_R & \xrightarrow{f^*} & \mathrm{RMod}_{R'} \\ \downarrow{\scriptstyle \Phi_R} & & \downarrow{\scriptstyle \Phi_{R'}} \\ \mathrm{RMod}_R^! & \xrightarrow{f^!} & \mathrm{RMod}_{R'}^! \end{array}$$

generally does not commute up to homotopy (here f^* denotes the base change functor $M \mapsto M \otimes_R R'$). In what follows, we will instead consider the fully faithful embeddings $\Psi_R : \mathrm{RMod}_R \to \mathrm{RMod}_R^!$ given by the composition

$$\begin{aligned} \mathrm{RMod}_R &\simeq \mathrm{Ind}(\mathrm{RMod}_R^{\mathrm{perf}}) \\ &\simeq \mathrm{Ind}((\mathrm{LMod}_R^{\mathrm{perf}})^{\mathrm{op}}) \\ &\hookrightarrow \mathrm{Ind}((\mathrm{LMod}_R^{\mathrm{art}})^{\mathrm{op}}) \\ &\simeq \mathrm{Ind}(\mathrm{RMod}_R^{\mathrm{art}}) \\ &\simeq \mathrm{RMod}_R^!. \end{aligned}$$

Our next goal is to give a construction of this functor which is manifestly functorial in $R \in \mathrm{Alg}_\kappa^{\mathrm{art}}$.

Construction 14.5.3.1. Let κ be a field, and let $\lambda : \mathrm{RMod}(\mathrm{Mod}_\kappa) \times_{\mathrm{Alg}_\kappa} \mathrm{LMod}^{\mathrm{art}}(\mathrm{Mod}_\kappa) \to \mathcal{S}$ be the functor given by

$$\lambda(M, R, N) = \mathrm{Map}_{\mathrm{Mod}_\kappa}(\kappa, M \otimes_R N).$$

If we fix M and R, then the functor $N \mapsto \mathrm{Map}_{\mathrm{Mod}_\kappa}(\kappa, M \otimes_R N)$ is left exact. It follows that λ is determines a functor $\Psi : \mathrm{RMod}(\mathrm{Mod}_\kappa) \times_{\mathrm{Alg}_\kappa} \mathrm{Alg}_\kappa^{\mathrm{art}} \to \mathrm{RMod}^!(\mathrm{Mod}_\kappa)$.

Proposition 14.5.3.2. *Let κ be a field, and consider the diagram*

$$\begin{array}{ccc} \mathrm{RMod}(\mathrm{Mod}_\kappa) \times_{\mathrm{Alg}_\kappa} \mathrm{Alg}_\kappa^{\mathrm{art}} & \xrightarrow{\Psi} & \mathrm{RMod}^!(\mathrm{Mod}_\kappa) \\ & {\scriptstyle p}\searrow \quad \swarrow{\scriptstyle q} & \\ & \mathrm{Alg}_\kappa^{\mathrm{art}} & \end{array}$$

where p and q are the forgetful functors and Ψ is defined as in Construction 14.5.3.1. Then:

(1) *The functor Ψ carries p-coCartesian morphisms to q-coCartesian morphisms.*

(2) *For every object $R \in \mathrm{Alg}_\kappa^{\mathrm{art}}$, the induced functor $\Psi_R : \mathrm{RMod}_R \to \mathrm{RMod}^!_R$ preserves small colimits.*

(3) *The functor Ψ is fully faithful.*

Proof. We first prove (1). Let $\alpha : (M, R) \to (M', R')$ be a p-coCartesian morphism in $\mathrm{RMod}(\mathrm{Mod}_\kappa)$. We wish to prove that $\Psi(\alpha)$ is q-coCartesian. Unwinding the definitions, we must show that for every Artinian R'-module N, the canonical map

$$\mathrm{Map}_{\mathrm{Mod}_\kappa}(\kappa, M \otimes_R N) \to \mathrm{Map}_{\mathrm{Mod}_\kappa}(\kappa, M' \otimes_{R'} N)$$

is an equivalence. This is clear, since the map $M \otimes_R N \to M' \otimes_{R'} N$ is an equivalence.

We now prove (2). Fix an object $R \in \mathrm{Alg}_\kappa^{\mathrm{art}}$. For every $N \in \mathrm{LMod}_R^{\mathrm{art}}$, the functor $M \mapsto \mathrm{Map}_{\mathrm{Mod}_\kappa}(\kappa, M \otimes_R N)$ commutes with filtered colimits and finite limits. It follows that Ψ_R commutes with filtered colimits and finite limits. Since Ψ_R is a left exact functor between stable ∞-categories, it is also right exact. We conclude that Ψ_R commutes with filtered colimits and finite colimits, and therefore with all small colimits.

We now prove (3). By virtue of (1), it will suffice to prove that for $R \in \mathrm{Alg}_\kappa^{\mathrm{art}}$ the functor $\Psi_R : \mathrm{RMod}_R \to \mathrm{RMod}^!_R$ is fully faithful. Using (2) and Proposition HTT.5.3.5.11 , we are reduced to proving that the restriction $\Psi_R|_{\mathrm{RMod}_R^{\mathrm{perf}}}$ is fully faithful. Note that if M be a perfect right R-module and $M^\vee$ its R-linear dual (regarded as a perfect left R-module), then $\Psi_R(M)$ is the functor corepresented by $M^\vee \in \mathrm{LMod}_R^{\mathrm{perf}} \subseteq \mathrm{LMod}_R^{\mathrm{art}}$. We can therefore identify $\Psi_R|_{\mathrm{RMod}_R^{\mathrm{perf}}}$ with the composition of fully faithful embeddings

$$\mathrm{RMod}_R^{\mathrm{perf}} \simeq (\mathrm{LMod}_R^{\mathrm{perf}})^{\mathrm{op}} \subseteq (\mathrm{LMod}_R^{\mathrm{art}})^{\mathrm{op}} \xhookrightarrow{j} \mathrm{RMod}^!_R,$$

(here j denotes the Yoneda embedding). □

Remark 14.5.3.3. Construction 14.5.3.1 and Proposition 14.5.3.2 have evident dual versions, which give a fully faithful embedding $\mathrm{LMod}(\mathrm{Mod}_\kappa) \times_{\mathrm{Alg}_\kappa} \mathrm{Alg}_\kappa^{\mathrm{art}} \to \mathrm{LMod}^!(\mathrm{Mod}_\kappa)$.

14.5.4 Connective Ind-Coherent Modules

Our next goal is to say something about the essential image of the functor $\Psi_R : \mathrm{RMod}_R \to \mathrm{RMod}_R^!$ of Proposition 14.5.3.2.

Definition 14.5.4.1. Let R be an Artinian $\mathbb{E}_1$-algebra over a field κ, and let $\epsilon : R \to \kappa$ be the augmentation. We will say that an object $M \in \mathrm{RMod}_R^!$ is *connective* if $\epsilon^! M$ is a connective object of $\mathrm{Mod}_\kappa \simeq \mathrm{Mod}_\kappa^!$. We let $\mathrm{RMod}_R^{!,\mathrm{cn}}$ denote the full subcategory of $\mathrm{RMod}_R^!$ spanned by the connective objects. Similarly, we define a full subcategory $\mathrm{LMod}_R^{!,\mathrm{cn}} \subseteq \mathrm{LMod}_R^!$.

Remark 14.5.4.2. Let R be an Artinian $\mathbb{E}_1$-algebra over a field κ. It follows from Proposition HTT.5.4.6.6 that $\mathrm{RMod}_R^{!,\mathrm{cn}}$ is an accessible subcategory of $\mathrm{RMod}_R^!$, which is evidently closed under small colimits and extensions. Applying Proposition HA.1.4.4.11 , we conclude that there exists a t-structure on the stable ∞-category $\mathrm{RMod}_R^!$ with $(\mathrm{RMod}_R^!)_{\geq 0} = \mathrm{RMod}_R^{!,\mathrm{cn}}$.

Proposition 14.5.4.3. *Let κ be a field, let $R \in \mathrm{Alg}_\kappa^{\mathrm{art}}$. Then the fully faithful embedding $\Psi_R : \mathrm{RMod}_R \to \mathrm{RMod}_R^!$ of Proposition 14.5.3.2 restricts to an equivalence of ∞-categories $\mathrm{RMod}_R^{\mathrm{cn}} \hookrightarrow \mathrm{RMod}_R^{!,\mathrm{cn}}$.*

Proof. Let $\epsilon : R \to \kappa$ be the augmentation map and let $M \in \mathrm{RMod}_R^!$. We wish to show that $\epsilon^! M$ is connective if and only if $M \simeq \Psi_R(M')$ for some $M' \in \mathrm{RMod}_R^{\mathrm{cn}}$. The "if" direction is clear: if $M \simeq \Psi_R(M')$, we have equivalences

$$\epsilon^! M \simeq \epsilon^! \Psi_R(M') \simeq \Psi_\kappa(\epsilon^* M') \simeq \kappa \otimes_R M'.$$

For the converse, assume that $\epsilon^! M$ is connective. Let $\mathcal{C} \subseteq \mathrm{RMod}_R^!$ denote the essential image of $\Psi_R|_{\mathrm{RMod}_R^{\mathrm{cn}}}$; we wish to prove that $M \in \mathcal{C}$. It follows from Remark 14.5.4.2 that $\mathcal{C}$ is closed under colimits and extensions in $\mathrm{RMod}_R^!$.

We begin by constructing a sequence of objects

$$0 = M(0) \to M(1) \to M(2) \to \cdots$$

in $\mathcal{C}$ and a compatible family of maps $\theta(i) : M(i) \to M$ with the following property:

- $(*)$ The groups $\pi_j \epsilon^! M(i)$ vanish unless $0 \leqslant j < i$, and the maps $\pi_j \epsilon^! M(j) \to \pi_j \epsilon^! M$ are isomorphisms for $0 \leqslant j < i$.

Assume that $i \geqslant 0$ and that we have already constructed a map $\theta(i)$ satisfying $(*)$. Let $M' = \mathrm{cofib}(\theta(i))$, so that $\pi_j \epsilon^! M' \simeq 0$ for $j < i$. Let us regard M' as a functor $\mathrm{LMod}_R^{\mathrm{art}} \to \mathcal{S}$, so that $M'(\Sigma^m(\kappa))$ is $(m+i)$-connective for every integer i. It follows by induction that for every m-connective object $N \in \mathrm{LMod}^{\mathrm{art}}_R$, the space $M'(N)$ is $(m+i)$-connective. In particular, $M'(N)$ is connected when N denotes the cofiber of the map $\Sigma^{-i}(R) \to \Sigma^{-i}(\kappa)$. Using the fiber sequence

$$M'(\Sigma^{-i}(R)) \to M'(\Sigma^{-i}(\kappa)) \to M'(\mathrm{cofib}(\Sigma^{-i}(R) \to \Sigma^{-i}(\kappa))),$$

we deduce that the map $\pi_0 M'(\Sigma^{-i}(R)) \to \pi_0 M'(\Sigma^{-i}(\kappa))$ is surjective. Let $K = \Psi_R(R) \in \mathrm{RMod}^!_R$. Then $\Sigma^i(K) = \Psi_R(\Sigma^i(R))$ can be identified with the functor corepresented by $\Sigma^{-i}(R)$. We have proven the following:

$(*')$ For every point $\eta \in \pi_i \epsilon^! M' \simeq \pi_0 M'(\Sigma^{-i}(\kappa))$, there exists a map $\Sigma^i(K) \to M$ such that η belongs to the image of the induced map $\kappa \simeq \pi_i \epsilon^! \Sigma^i(K) \to \pi_i \epsilon^! M'$.

Choose a basis $\{v_\alpha\}_{\alpha \in S}$ for the κ-vector space $\pi_i \epsilon^! M' \simeq \pi_i \epsilon^! M$. Applying $(*')$ repeatedly, we obtain a map $v : \bigoplus_{\alpha \in S} \Sigma^i(K) \to M'$. Let $M'' = \mathrm{cofib}(v)$ and let $M(i+1)$ denote the fiber of the composite map $M \to M' \to M''$. We have a fiber sequence

$$M(i) \to M(i+1) \to \bigoplus_{\alpha \in S} \Sigma^i(K).$$

Since $\mathcal{C}$ is closed under colimits and extensions (and contains $\Sigma^i(K) \simeq \Psi_R \Sigma^i(R)$), we conclude that $M(i+1) \in \mathcal{C}$. Using the long exact sequence of homotopy groups

$$\pi_j \epsilon^! M(i) \to \pi_j \epsilon^! M(i+1) \to \pi_j \epsilon^! \bigoplus_{\alpha \in S} \Sigma^i(K) \to \pi_{j-1} \epsilon^! M(i),$$

we deduce that the canonical map $M(i+1) \to M$ satisfies condition $(*)$.

Let $M(\infty) = \varinjlim M(i)$ and let $w : M(\infty) \to M$ be the tautological map. Since $\mathcal{C}$ is closed under colimits, we deduce that $M(\infty) \in \mathcal{C}$. Using $(*)$ (and the vanishing of the groups $\pi_j \epsilon^! M$ for $j < 0$), we deduce that w induces an equivalence $\epsilon^! M(\infty) \to \epsilon^! M$. Identifying M and $M(\infty)$ with left exact functors $\mathrm{LMod}^{\mathrm{art}}_R \to \mathcal{S}$, we conclude that w induces a homotopy equivalence $M(\infty)(\Sigma^j(\kappa)) \to M(\Sigma^j(\kappa))$ for every integer j. Since M and $M(\infty)$ are left exact, the collection of those objects $N \in \mathrm{LMod}^{\mathrm{art}}_R$ for which $M(\infty)(N) \to M(N)$ is a homotopy equivalence is closed under finite limits. Using Remark 14.5.1.1, we deduce that every object $N \in \mathrm{LMod}^{\mathrm{art}}_R$ has this property, so that w is an equivalence and $M \simeq M(\infty) \in \mathcal{C}$ as desired. □

Remark 14.5.4.4. Let R be an Artinian $\mathbb{E}_1$-algebra over a field κ. The natural t-structure on the ∞-category RMod_R is right complete. It follows from Proposition 14.5.4.3 that the fully faithful embedding $\Psi_R : \mathrm{RMod}_R \to \mathrm{RMod}^!_R$ induces an equivalence from RMod_R to the right completion of $\mathrm{RMod}^!_R$.

14.5.5 Sheaves on Formal Moduli Problems

We now consider global analogues of the preceding constructions.

Construction 14.5.5.1. Let κ be a field. The coCartesian fibrations

$$\mathrm{RMod}(\mathrm{Mod}_\kappa) \times_{\mathrm{Alg}_\kappa} \mathrm{Alg}^{\mathrm{art}}_\kappa \xrightarrow{p_R} \mathrm{Alg}^{\mathrm{art}}_\kappa \xleftarrow{q_R} \mathrm{RMod}^!(\mathrm{Mod}_\kappa)$$

are classified by functors $\chi, \chi_! : \mathrm{Alg}^{\mathrm{art}}_\kappa \to \widehat{\mathcal{C}\mathrm{at}}_\infty$. Since $\widehat{\mathcal{C}\mathrm{at}}_\infty$ admits small limits, Theorem HTT.5.1.5.6 implies that χ and $\chi_!$ admit (essentially unique) factorizations as compositions

$$\mathrm{Alg}^{\mathrm{art}}_\kappa \xrightarrow{j} \mathrm{Fun}(\mathrm{Alg}^{\mathrm{art}}_\kappa, \mathcal{S})^{\mathrm{op}} \xrightarrow{\mathrm{QCoh}_R} \widehat{\mathcal{C}\mathrm{at}}_\infty \qquad \mathrm{Alg}^{\mathrm{art}}_\kappa \xrightarrow{j} \mathrm{Fun}(\mathrm{Alg}^{\mathrm{art}}_\kappa, \mathcal{S})^{\mathrm{op}} \xrightarrow{\mathrm{QCoh}^!_R} \widehat{\mathcal{C}\mathrm{at}}_\infty$$

where j denotes the Yoneda embedding and the functors QCoh_R and $\mathrm{QCoh}^!_R$ preserve small limits. Similarly, the coCartesian fibrations

$$\mathrm{LMod}(\mathrm{Mod}_\kappa) \times_{\mathrm{Alg}_\kappa} \mathrm{Alg}^{\mathrm{art}}_\kappa \to \mathrm{Alg}^{\mathrm{art}}_\kappa \leftarrow \mathrm{LMod}^!(\mathrm{Mod}_\kappa)$$

are classified by maps $\chi', \chi'_! : \mathrm{Alg}^{\mathrm{art}}_\kappa \to \widehat{\mathcal{C}\mathrm{at}}_\infty$, which admit factorizations

$$\mathrm{Alg}^{\mathrm{art}}_\kappa \xrightarrow{j} \mathrm{Fun}(\mathrm{Alg}^{\mathrm{art}}_\kappa, \mathcal{S})^{\mathrm{op}} \xrightarrow{\mathrm{QCoh}_L} \widehat{\mathcal{C}\mathrm{at}}_\infty \qquad \mathrm{Alg}^{\mathrm{art}}_\kappa \xrightarrow{j} \mathrm{Fun}(\mathrm{Alg}^{\mathrm{art}}_\kappa, \mathcal{S})^{\mathrm{op}} \xrightarrow{\mathrm{QCoh}^!_L} \widehat{\mathcal{C}\mathrm{at}}_\infty.$$

For each functor $X : \mathrm{Alg}^{\mathrm{art}}_\kappa \to \mathcal{S}$, we will refer to $\mathrm{QCoh}_L(X)$ and $\mathrm{QCoh}_R(X)$ as the ∞-categories of (left and right) *quasi-coherent sheaves on* X. Similarly, we will refer to $\mathrm{QCoh}^!_L(X)$ and $\mathrm{QCoh}^!_R(X)$ as the ∞-categories of (left and right) Ind-*coherent sheaves on* X.

Remark 14.5.5.2. For every functor $X : \mathrm{Alg}^{\mathrm{art}}_\kappa \to \mathcal{S}$, the ∞-categories $\mathrm{QCoh}_L(X)$, $\mathrm{QCoh}_R(X)$, $\mathrm{QCoh}^!_L(X)$, and $\mathrm{QCoh}^!_R(X)$ are presentable and stable.

Remark 14.5.5.3. Let κ be a field, let $X : \mathrm{Alg}^{\mathrm{art}}_\kappa \to \mathcal{S}$ be a functor which classifies a right fibration $\mathcal{X} \to \mathrm{Alg}^{\mathrm{art}}_\kappa$. Then $\mathrm{QCoh}_R(X)$ and $\mathrm{QCoh}^!_R(X)$ can be identified with the ∞-categories of coCartesian sections of the coCartesian fibrations

$$\mathcal{X} \times_{\mathrm{Alg}_\kappa} \mathrm{RMod}(\mathrm{Mod}_\kappa) \to \mathcal{X} \leftarrow \mathcal{X} \times_{\mathrm{Alg}^{\mathrm{art}}_\kappa} \mathrm{RMod}^!(\mathrm{Mod}_\kappa).$$

More informally, an object $\mathscr{F} \in \mathrm{QCoh}_R(X)$ is a rule which assigns to every point $\eta \in X(A)$ a right A-module $\mathscr{F}_\eta$, and to every morphism $f : A \to A'$ carrying η to $\eta' \in X(A')$ an equivalence $\mathscr{F}_{\eta'} \simeq \mathscr{F}_\eta \otimes_A A'$. Similarly, an object of $\mathscr{G} \in \mathrm{QCoh}^!_R(X)$ is a rule which assigns to every point $\eta \in X(A)$ an Ind-coherent right R-module $\mathscr{G}_\eta \in \mathrm{RMod}^!_A$, and to every morphism $f : A \to A'$ carrying η to $\eta' \in X(R')$ an equivalence $\mathscr{G}_{\eta'} \simeq f^! \mathscr{G}_\eta$. The ∞-categories $\mathrm{QCoh}_L(X)$ and $\mathrm{QCoh}^!_L(X)$ admit similar descriptions, using left modules in place of right modules.

Notation 14.5.5.4. By construction, the ∞-categories $\mathrm{QCoh}_R(X)$, $\mathrm{QCoh}_L(X)$, $\mathrm{QCoh}^!_R(X)$, and $\mathrm{QCoh}^!_L(X)$ depend contravariantly on the object $X \in \mathrm{Fun}(\mathrm{Alg}^{\mathrm{art}}_\kappa, \mathcal{S})$. If $\alpha : X \to Y$ is a natural transformation, we will denote the resulting functors by

$$\alpha^* : \mathrm{QCoh}_R(Y) \to \mathrm{QCoh}_R(X) \qquad \alpha^! : \mathrm{QCoh}^!_R(Y) \to \mathrm{QCoh}^!_R(X)$$

$$\alpha^* : \mathrm{QCoh}_L(Y) \to \mathrm{QCoh}_L(X) \qquad \alpha^! : \mathrm{QCoh}^!_L(Y) \to \mathrm{QCoh}^!_L(X).$$

Remark 14.5.5.5. Let κ be a field. The fully faithful embedding Ψ of Proposition 14.5.3.2 induces a natural transformation $\mathrm{QCoh}_R \to \mathrm{QCoh}^!_R$ of functors $\mathrm{Fun}(\mathrm{Alg}^{\mathrm{art}}_\kappa, \mathcal{S}) \to \widehat{\mathcal{C}\mathrm{at}}_\infty$. For every functor $X : \mathrm{Alg}^{\mathrm{art}}_\kappa \to \mathcal{S}$, we obtain a fully faithful embedding $\mathrm{QCoh}_R(X) \to \mathrm{QCoh}^!_R(X)$ which preserves small colimits. Moreover, if $\alpha : X \to Y$ is a natural transformation of functors, we obtain a diagram of ∞-categories

$$\begin{array}{ccc} \mathrm{QCoh}_R(Y) & \longrightarrow & \mathrm{QCoh}^!_R(Y) \\ \downarrow{\scriptstyle \alpha^*} & & \downarrow{\scriptstyle \alpha^!} \\ \mathrm{QCoh}_R(X) & \longrightarrow & \mathrm{QCoh}^!_R(X) \end{array}$$

which commutes up to canonical homotopy. Similarly, we have fully faithful embedding $\mathrm{QCoh}_L(X) \to \mathrm{QCoh}^!_L(X)$, which depend functorially on X in the same sense.

Notation 14.5.5.6. Let κ be a field and let $X : \mathrm{Alg}^{\mathrm{art}}_\kappa \to \mathcal{S}$ be a functor. We will say that an object $\mathscr{F} \in \mathrm{QCoh}_R(X)$ is *connective* if $\mathscr{F}_\eta \in \mathrm{RMod}_A$ is connective for every point $\eta \in X(A)$ (see Notation 14.5.5.3). We let $\mathrm{QCoh}_R(X)^{\mathrm{cn}}$ denote the full subcategory of $\mathrm{QCoh}_R(X)$ spanned by the connective right quasi-coherent sheaves, and define a full subcategory $\mathrm{QCoh}_L(X)^{\mathrm{cn}} \subseteq \mathrm{QCoh}_L(X)$ similarly.

We will say that an object $\mathscr{G} \in \mathrm{QCoh}^!_R$ is *connective* if, for every point $\eta \in X(\kappa)$, the object $\mathscr{G}_\eta \in \mathrm{RMod}^!_\kappa \simeq \mathrm{Mod}_\kappa$ is connective. We let $\mathrm{QCoh}^!_R(X)^{\mathrm{cn}}$ denote the full subcategory of $\mathrm{QCoh}^!_R(X)$ spanned by the connective objects, and define $\mathrm{QCoh}^!_L(X)^{\mathrm{cn}} \subseteq \mathrm{QCoh}^!_L(X)$ similarly.

Remark 14.5.5.7. Let $X : \mathrm{Alg}^{\mathrm{art}}_\kappa \to \mathcal{S}$ be a functor. The full subcategories

$$\mathrm{QCoh}_L(X)^{\mathrm{cn}} \subseteq \mathrm{QCoh}_L(X) \qquad \mathrm{QCoh}_R(X)^{\mathrm{cn}} \subseteq \mathrm{QCoh}_R(X)$$

$$\mathrm{QCoh}^!_L(X)^{\mathrm{cn}} \subseteq \mathrm{QCoh}^!_L(X) \qquad \mathrm{QCoh}^!_R(X)^{\mathrm{cn}} \subseteq \mathrm{QCoh}^!_R(X)$$

of Notation 14.5.5.6 are presentable and closed under extensions and small colimits. It follows from Proposition HA.1.4.4.11 that they determine t-structures on $\mathrm{QCoh}_L(X)$, $\mathrm{QCoh}_R(X)$, $\mathrm{QCoh}^!_L(X)$, and $\mathrm{QCoh}^!_R(X)$.

Using Proposition 14.5.4.3, we immediately deduce the following:

Proposition 14.5.5.8. *Let κ be a field and let $X : \mathrm{Alg}_\kappa^{\mathrm{art}} \to \mathcal{S}$ be a functor. Then the fully faithful embeddings*

$$\mathrm{QCoh}_L(X) \hookrightarrow \mathrm{QCoh}^!_L(X) \qquad \mathrm{QCoh}_R(X) \hookrightarrow \mathrm{QCoh}^!_R(X)$$

of Remark 14.5.5.5 induce equivalences of ∞-categories

$$\mathrm{QCoh}_L(X)^{\mathrm{cn}} \simeq \mathrm{QCoh}^!_L(X)^{\mathrm{cn}} \qquad \mathrm{QCoh}_R(X)^{\mathrm{cn}} \simeq \mathrm{QCoh}^!_R(X)^{\mathrm{cn}}.$$

14.6 Koszul Duality for Modules

Our goal in this section is to prove the following non-commutative analogue of Theorem 13.4.0.1:

Theorem 14.6.0.1. *Let κ be a field, let $A \in \mathrm{Alg}_\kappa^{\mathrm{aug}}$, and let $X : \mathrm{Alg}_\kappa^{\mathrm{art}} \to \mathcal{S}$ be the formal $\mathbb{E}_1$-moduli problem associated to A (see Theorem 14.0.0.5). Then there are canonical equivalences of ∞-categories*

$$\mathrm{QCoh}^!_L(X) \simeq \mathrm{RMod}_A \qquad \mathrm{QCoh}^!_R(X) \simeq \mathrm{LMod}_A\,.$$

In particular, we have fully faithful embeddings

$$\mathrm{QCoh}_L(X) \hookrightarrow \mathrm{RMod}_A \qquad \mathrm{QCoh}_R(X) \hookrightarrow \mathrm{LMod}_A\,.$$

Remark 14.6.0.2 (Comparison with the Commutative Case)**.** Let κ be a field of characteristic zero and let $\theta : \mathrm{CAlg}_\kappa^{\mathrm{art}} \to \mathrm{Alg}_\kappa^{\mathrm{art}}$ denote the forgetful functor. Let $X : \mathrm{Alg}_\kappa^{\mathrm{art}} \to \mathcal{S}$ be a formal $\mathbb{E}_1$-moduli problem over κ, so that $X \circ \theta$ is a formal moduli problem over κ. For each $R \in \mathrm{CAlg}_\kappa^{\mathrm{art}}$, we have a canonical equivalence of ∞-categories $\mathrm{Mod}_R \simeq \mathrm{RMod}_{\theta(R)}$. Passing to the inverse limit over points $\eta \in X(\theta(R))$, we obtain a functor $\mathrm{QCoh}_R(X) \to \mathrm{QCoh}(X \circ \theta)$. According to Theorem 14.0.0.5, there exists an augmented $\mathbb{E}_1$-algebra A over κ such that X is given by the formula $X(R) = \mathrm{Map}_{\mathrm{Alg}_\kappa^{\mathrm{aug}}}(\mathfrak{D}^{(1)}(R), A)$. Let $\mathfrak{m}_A$ denote the augmentation ideal of A. Regard $\mathfrak{m}_A$ as an object of Lie_κ, so that $X \circ \theta$ is given by the formula

$$(X \circ \theta)(R) = \mathrm{Map}_{\mathrm{Lie}_\kappa}(\mathfrak{D}(R), \mathfrak{m}_A)$$

(see Theorem 14.3.0.1). Theorems 13.4.0.1 and 14.6.0.1 determine fully faithful embeddings

$$\mathrm{QCoh}_R(X) \hookrightarrow \mathrm{LMod}_A \qquad \mathrm{QCoh}(X \circ \theta) \hookrightarrow \mathrm{Rep}_{\mathfrak{m}_A}\,.$$

We have an evident map of $\mathbb{E}_1$-algebras $U(\mathfrak{m}_A) \to A$, which determines a forgetful functor $\mathrm{LMod}_A \to \mathrm{LMod}_{U(\mathfrak{m}_A)} \simeq \mathrm{Rep}_{\mathfrak{m}_A}$. With some additional effort, one can show that the diagram

$$\begin{array}{ccc} \mathrm{QCoh}_R(X) & \longrightarrow & \mathrm{LMod}_A \\ \downarrow & & \downarrow \\ \mathrm{QCoh}(X \circ \theta) & \longrightarrow & \mathrm{Rep}_{\mathfrak{m}_A} \end{array}$$

commutes up to canonical homotopy. That is, the algebraic models for quasi-coherent sheaves provided by Theorems 13.4.0.1 and 14.6.0.1 in the commutative and noncommutative settings are compatible with one another.

14.6.1 Reduction to the Representable Case

We will deduce Theorem 14.6.0.1 from the following:

Proposition 14.6.1.1. *Let κ be a field, and let $\chi_! : \mathrm{Alg}_\kappa^{\mathrm{art}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ be the functor given by $\chi_!(R) = \mathrm{RMod}_R^!$ (see Construction 14.5.5.1), and let $\chi' : \mathrm{Alg}_\kappa^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ given by $\chi'(R) = \mathrm{LMod}_R$ (so that χ' classifies the Cartesian fibration $\mathrm{LMod}(\mathrm{Mod}_\kappa) \to \mathrm{Alg}_\kappa$). Then $\chi_!$ is homotopic to the composition*

$$\mathrm{Alg}_\kappa^{\mathrm{art}} \hookrightarrow \mathrm{Alg}_\kappa^{\mathrm{aug}} \xrightarrow{\mathfrak{D}^{(1)}} (\mathrm{Alg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{\mathrm{op}} \xrightarrow{\chi'} \widehat{\mathcal{C}\mathrm{at}}_\infty.$$

More informally: for every object $R \in \mathrm{Alg}_\kappa^{\mathrm{art}}$, there is a canonical equivalence of ∞-categories $\mathrm{RMod}_R^! \simeq \mathrm{LMod}_{\mathfrak{D}^{(1)}(R)}$.

Before giving the proof of Proposition 14.6.1.1, let us explain how it leads to a proof of Theorem 14.6.0.1.

Proof of Theorem 14.6.0.1. Let $X : \mathrm{Alg}_\kappa^{\mathrm{art}} \to \mathcal{S}$ be the formal $\mathbb{E}_1$-moduli problem associated to an object $A \in \mathrm{Alg}_\kappa^{\mathrm{aug}}$. We will construct the equivalence $\mathrm{QCoh}_R^!(X) \simeq \mathrm{LMod}_A$; the construction of the equivalence $\mathrm{QCoh}_L^!(X) \simeq \mathrm{RMod}_A$ is similar. Let κ be a field and let $\mathrm{QCoh}_R^! : \mathrm{Fun}(\mathrm{Alg}_\kappa^{\mathrm{art}}, \mathcal{S})^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ be as in Construction 14.5.5.1. Let $\Psi : \mathrm{Alg}_\kappa^{\mathrm{aug}} \to \mathrm{Moduli}_\kappa^{(1)}$ be the equivalence of ∞-categories provided by Theorem 14.0.0.5, and let Ψ^{-1} denote a homotopy inverse to Ψ. Let $L : \mathrm{Fun}(\mathrm{Alg}_\kappa^{\mathrm{art}}, \mathcal{S}) \to \mathrm{Moduli}_\kappa^{(1)}$ denote a left adjoint to the inclusion functor $\mathrm{Moduli}_\kappa^{(1)} \subseteq \mathrm{Fun}(\mathrm{Alg}_\kappa^{\mathrm{art}}, \mathcal{S})$ (see Remark 12.1.3.5), and let $\widehat{\mathfrak{D}}^{(1)} : \mathrm{Fun}(\mathrm{Alg}_\kappa^{\mathrm{art}}, \mathcal{S}) \to \mathrm{Alg}_\kappa^{\mathrm{aug}}$ be the composition of $\Psi^{-1} \circ L$. The functor $\widehat{\mathfrak{D}}^{(1)}$ preserves small colimits, and the composition of $\widehat{\mathfrak{D}}^{(1)}$ with the Yoneda embedding $(\mathrm{Alg}_\kappa^{\mathrm{art}})^{\mathrm{op}} \to \mathrm{Fun}(\mathrm{Alg}_\kappa^{\mathrm{art}}, \mathcal{S})$ can be identified with the Koszul duality functor $\mathfrak{D}^{(1)} : (\mathrm{Alg}_\kappa^{\mathrm{art}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{\mathrm{aug}}$. Let $\chi' : \mathrm{Alg}_\kappa^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ be as in Proposition 14.6.1.1 (given on objects by $\chi'(A) = \mathrm{LMod}_A$), and let $F : \mathrm{Fun}(\mathrm{Alg}_\kappa^{\mathrm{art}}, \mathcal{S})^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ denote the composite functor

$$\mathrm{Fun}(\mathrm{Alg}_\kappa^{\mathrm{art}}, \mathcal{S})^{\mathrm{op}} \xrightarrow{\widehat{\mathfrak{D}}^{(1)}} (\mathrm{Alg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{\mathrm{op}} \xrightarrow{\chi'} \widehat{\mathcal{C}\mathrm{at}}_\infty.$$

Let $\mathcal{C}$ denote the full subcategory of $\mathrm{Fun}(\mathrm{Alg}_\kappa^{\mathrm{art}}, \mathcal{S})$ spanned by the corepresentable functors. Proposition 14.6.1.1 implies that there is an equivalence of functors $\alpha_0 : F|_{\mathcal{C}^{\mathrm{op}}} \to \mathrm{QCoh}_R^!|_{\mathcal{C}^{\mathrm{op}}}$. Since $\mathrm{QCoh}_R^!$ is a right Kan extension of its restriction to $\mathcal{C}^{\mathrm{op}}$, the equivalence α_0 extends to a natural transformation $F \to \mathrm{QCoh}_R^!$. We will prove:

$(*)$ If $X : \mathrm{Alg}_\kappa^{\mathrm{art}} \to \mathcal{S}$ is a formal $\mathbb{E}_1$-moduli problem, then α induces an equivalence of ∞-categories $F(X) \to \mathrm{QCoh}^!_R(X)$.

Taking $X = \Psi(A)$ for $A \in \mathrm{Alg}_\kappa^{\mathrm{aug}}$, we see that $(*)$ supplies an equivalence of ∞-categories

$$\beta_A : \mathrm{LMod}_A \simeq \chi'(\Psi^{-1}\Psi(A)) \simeq F(\Psi(A)) \to \mathrm{QCoh}^!_R(X).$$

It remains to prove $(*)$. Let $\mathcal{E} \subseteq \mathrm{Fun}(\mathrm{Alg}_\kappa^{\mathrm{art}}, \mathcal{S})$ be the full subcategory spanned by those functors X for which α induces an equivalence of ∞-categories $F(X) \to \mathrm{QCoh}^!_R(X)$. The localization functor $L : \mathrm{Fun}(\mathrm{Alg}_\kappa^{\mathrm{art}}, \mathcal{S}) \to \mathrm{Moduli}_\kappa^{(1)}$, the equivalence $\Psi^{-1} : \mathrm{Moduli}_\kappa^{(1)} \to \mathrm{Alg}_\kappa^{\mathrm{aug}}$, and the forgetful functor $\mathrm{Alg}_\kappa^{\mathrm{aug}} \to \mathrm{Alg}_\kappa$ preserve small colimits. Lemma 13.4.7.2 implies that the functor $\chi' : \mathrm{Alg}_\kappa^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ preserves sifted limits. It follows that the functor F preserves sifted limits. Since $\mathrm{QCoh}^!_R$ preserves small limits, the ∞-category $\mathcal{E}$ is closed under sifted colimits in $\mathrm{Fun}(\mathrm{Alg}_\kappa^{\mathrm{art}}, \mathcal{S})$. Since $\mathcal{E}$ contains all corepresentable functors and is closed under filtered colimits, it contains all prorepresentable formal moduli problems (see Definition 12.5.3.1). Proposition 12.5.3.3 implies that every formal $\mathbb{E}_1$-moduli problem X can be obtained as the geometric realization of a simplicial object $X_\bullet$ of $\mathrm{Fun}(\mathrm{Alg}_\kappa^{\mathrm{art}}, \mathcal{S})$, where each X_n is prorepresentable. Since $\mathcal{E}$ is closed under geometric realizations in $\mathrm{Fun}(\mathrm{Alg}_\kappa^{\mathrm{art}}, \mathcal{S})$, we conclude that $X \in \mathcal{E}$ as desired. □

14.6.2 The Proof of Proposition 14.6.1.1

Let κ be a field, and let $\chi' : \mathrm{Alg}_\kappa^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ be a functor which classifies the Cartesian fibration $p : \mathrm{LMod}(\mathrm{Mod}_\kappa) \to \mathrm{Alg}_\kappa$. Using Proposition 14.4.2.4, we see that χ' also classifies the coCartesian fibration $\mathrm{Dl}^0(p^{\mathrm{op}}) \to \mathrm{Alg}_\kappa^{\mathrm{op}}$. Let $\mathrm{LMod}^{\mathrm{perf}}(\mathrm{Mod}_\kappa)$ denote the full subcategory of $\mathrm{LMod}(\mathrm{Mod}_\kappa)$ spanned by those pairs (A, M), where $A \in \mathrm{Alg}_\kappa$ and M is a perfect left module over A. Let p_{perf} denote the restriction of p to $\mathrm{LMod}^{\mathrm{perf}}(\mathrm{Mod}_\kappa)$. Proposition 14.4.3.1 supplies an equivalence of $\mathrm{Dl}^0(p^{\mathrm{op}}) \simeq \mathrm{Dl}^{\mathrm{lex}}(p_{\mathrm{perf}}^{\mathrm{op}})$ of coCartesian fibrations over $\mathrm{Alg}_\kappa^{\mathrm{op}}$. By construction, $\chi_! : \mathrm{Alg}_\kappa^{\mathrm{art}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$ classifies the coCartesian fibration $\mathrm{RMod}^!(\mathrm{Mod}_\kappa) = \mathrm{Dl}^{\mathrm{lex}}(q) \to \mathrm{Alg}_\kappa^{\mathrm{art}}$, where q denotes the Cartesian fibration $\mathrm{LMod}^{\mathrm{art}}(\mathrm{Mod}_\kappa) \to \mathrm{Alg}_\kappa^{\mathrm{art}}$. Consequently, Proposition 14.6.1.1 is a consequence of the following:

Proposition 14.6.2.1. *Let κ be a field and let $\mathfrak{D} : \mathrm{Alg}_\kappa^{\mathrm{art}} \to \mathrm{Alg}_\kappa^{\mathrm{op}}$ denote the composition*

$$\mathrm{Alg}_\kappa^{\mathrm{art}} \hookrightarrow \mathrm{Alg}_\kappa^{\mathrm{aug}} \xrightarrow{\mathfrak{D}^{(1)}} (\mathrm{Alg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{\mathrm{op}},$$

where $\mathfrak{D}^{(1)}$ is the Koszul duality functor of Definition 14.1.1.3. Then there is a pullback *diagram of ∞-categories*

$$\begin{array}{ccc} \mathrm{LMod}^{\mathrm{art}}(\mathrm{Mod}_\kappa) & \xrightarrow{\mathfrak{D}'} & \mathrm{LMod}^{\mathrm{perf}}(\mathrm{Mod}_\kappa)^{\mathrm{op}} \\ \downarrow & & \downarrow \\ \mathrm{Alg}_\kappa^{\mathrm{art}} & \xrightarrow{\mathfrak{D}} & \mathrm{Alg}_\kappa^{\mathrm{op}}. \end{array}$$

We now proceed to construct the diagram appearing in the statement of Proposition 14.6.2.1.

Construction 14.6.2.2. Fix a field κ. We let $\mathcal{M}^{(1)} \to \mathrm{Alg}_\kappa^{\mathrm{aug}} \times \mathrm{Alg}_\kappa^{\mathrm{aug}}$ be the pairing of ∞-categories defined in Construction 14.1.1.1. The objects of $\mathcal{M}^{(1)}$ are given by triple (A, B, ϵ), where $A, B \in \mathrm{Alg}_\kappa$ and $\epsilon : A \otimes_\kappa B \to \kappa$ is an augmentation on $A \otimes_\kappa B$ (which then determines augmentations on A and B). Set

$$\overline{\mathcal{M}} = \mathrm{LMod}(\mathrm{Mod}_\kappa) \times_{\mathrm{Alg}_\kappa} \mathcal{M}^{(1)} \times_{\mathrm{Alg}_\kappa} \mathrm{LMod}(\mathrm{Mod}_\kappa),$$

so that $\overline{\mathcal{M}}$ is an ∞-category whose objects can be identified with quintuples (A, B, ϵ, M, N), where $A, B \in \mathrm{Alg}_\kappa$, $\epsilon : A \otimes_\kappa B \to \kappa$ is an augmentation, $M \in \mathrm{LMod}_A$, and $N \in \mathrm{LMod}_B$. There is an evident functor $\chi : \overline{\mathcal{M}}^{\mathrm{op}} \to \mathcal{S}$, given on objects by the formula $\chi(A, B, \epsilon, M, N) = \mathrm{Map}_{\mathrm{LMod}_{A \otimes_\kappa B}}(M \otimes_\kappa N, \kappa)$. Then χ classifies a right fibration $\mathcal{M}^{\mathcal{LM}} \to \overline{\mathcal{M}}$. Let $\mathrm{LMod}^{\mathrm{aug}}(\mathrm{Mod}_\kappa)$ denote the fiber product $\mathrm{LMod}(\mathrm{Mod}_\kappa) \times_{\mathrm{Alg}_\kappa} \mathrm{Alg}_\kappa^{\mathrm{aug}}$, so that the forgetful functor $\mathcal{M}^{\mathcal{LM}} \to \mathrm{LMod}^{\mathrm{aug}}(\mathrm{Mod}_\kappa) \times \mathrm{LMod}^{\mathrm{aug}}(\mathrm{Mod}_\kappa)$ is a right fibration and therefore determines a pairing of $\mathrm{LMod}^{\mathrm{aug}}(\mathrm{Mod}_\kappa)$ with itself.

Proposition 14.6.2.3. *Let κ be a field, let $\lambda : \mathcal{M}^{(1)} \to \mathrm{Alg}_\kappa^{\mathrm{aug}} \times \mathrm{Alg}_\kappa^{\mathrm{aug}}$ be the pairing of Construction 14.1.1.1 and $\lambda' : \mathcal{M}^{\mathcal{LM}} \to \mathrm{LMod}^{\mathrm{aug}}(\mathrm{Mod}_\kappa) \times \mathrm{LMod}^{\mathrm{aug}}(\mathrm{Mod}_\kappa)$ the pairing of Construction 14.6.2.2. Then λ' is both left and right representable. Moreover, the forgetful functor $\mathcal{M}^{\mathcal{LM}} \to \mathcal{M}^{(1)}$ is both left and right representable.*

Proof. We will show that λ' is left representable and $\mathcal{M}^{\mathcal{LM}} \to \mathcal{M}^{(1)}$ is left representable; the corresponding assertions for right representability will follow by symmetry. Fix an object $A \in \mathrm{Alg}_\kappa^{\mathrm{aug}}$ and a left A-module M. Let $B = \mathfrak{D}^{(1)}(A)$ be the Koszul dual of A and $\epsilon : A \otimes_\kappa B \to \kappa$ the canonical map. Proposition 14.1.2.2 implies that ϵ determines a duality functor $\mathfrak{D}_\epsilon : \mathrm{LMod}_A^{\mathrm{op}} \to \mathrm{LMod}_B$. We let $N = \mathfrak{D}_\epsilon(M)$, so that there is a canonical map of left $A \otimes_\kappa B$-modules $\mu : M \otimes_\kappa N \to \kappa$. The quintuple (A, B, ϵ, M, N) is an object of the ∞-category $\overline{\mathcal{M}}$ of Construction 14.6.2.2, and μ determines a lifting to an object $X \in \mathcal{M}^{\mathcal{LM}}$. We complete the proof by observing that X is left universal and has left universal image in $\mathcal{M}^{(1)}$. □

It follows from Proposition 14.6.2.3 that the pairing

$$\mathcal{M}^{\mathcal{LM}} \to \mathrm{LMod}^{\mathrm{aug}}(\mathrm{Mod}_\kappa) \times \mathrm{LMod}^{\mathrm{aug}}(\mathrm{Mod}_\kappa)$$

determines a duality functor $\mathfrak{D}^{\mathcal{LM}} : \mathrm{LMod}^{\mathrm{aug}}(\mathrm{Mod}_\kappa) \to \mathrm{LMod}^{\mathrm{aug}}(\mathrm{Mod}_\kappa)^{\mathrm{op}}$. Let $\mathfrak{D}'$ denote the composite map

$$\mathrm{LMod}^{\mathrm{art}}(\mathrm{Mod}_\kappa) \to \mathrm{LMod}^{\mathrm{aug}}(\mathrm{Mod}_\kappa) \xrightarrow{\mathfrak{D}^{\mathcal{LM}}} \mathrm{LMod}^{\mathrm{aug}}(\mathrm{Mod}_\kappa)^{\mathrm{op}} \to \mathrm{LMod}(\mathrm{Mod}_\kappa)^{\mathrm{op}}.$$

By construction, we have a commutative diagram σ :

$$\begin{array}{ccc} \mathrm{LMod}^{\mathrm{art}}(\mathrm{Mod}_\kappa) & \xrightarrow{\mathfrak{D}'} & \mathrm{LMod}(\mathrm{Mod}_\kappa)^{\mathrm{op}} \\ \downarrow{\scriptstyle p} & & \downarrow{\scriptstyle q} \\ \mathrm{Alg}_\kappa^{\mathrm{art}} & \xrightarrow{\mathfrak{D}} & \mathrm{Alg}_\kappa^{\mathrm{op}} . \end{array}$$

We next claim that the functor $\mathfrak{D}'$ carries p-Cartesian morphisms to q-Cartesian morphisms. Unwinding the definitions, we must show that if $f : R \to R'$ is a morphism in $\mathrm{Alg}_\kappa^{\mathrm{art}}$ and M is an Artinian left R'-module, then the canonical map

$$\theta_M : \mathfrak{D}^{(1)}(R) \otimes_{\mathfrak{D}^{(1)}(R')} \mathfrak{D}_{\mu'}(M) \to \mathfrak{D}_\mu(M)$$

is an equivalence, where $\mathfrak{D}_\mu : \mathrm{LMod}_R^{\mathrm{op}} \to \mathrm{LMod}_{\mathfrak{D}^{(1)}(R)}$ and $\mathfrak{D}_{\mu'} : \mathrm{LMod}_{R'}^{\mathrm{op}} \to \mathrm{LMod}_{\mathfrak{D}^{(1)}(R')}$ are the duality functors determined by the pairings $\mu : R \otimes_\kappa \mathfrak{D}^{(1)}(R) \to \kappa$ and $\mu' : R' \otimes_\kappa \mathfrak{D}^{(1)}(R') \to \kappa$. The modules $M \in \mathrm{LMod}_{R'}$ for which θ_M is an equivalence span a stable subcategory of $\mathrm{LMod}_{R'}$ which includes κ, and therefore contains all Artinian R'-modules (Lemma 14.5.1.1).

To complete the proof of Proposition 14.6.2.1, it suffices to show that the functor $\mathfrak{D}'$ carries $\mathrm{LMod}^{\mathrm{art}}(\mathrm{Mod}_\kappa)$ into $\mathrm{LMod}^{\mathrm{perf}}(\mathrm{Mod}_\kappa)^{\mathrm{op}}$ and induces an equivalence of ∞-categories

$$\mathrm{LMod}^{\mathrm{art}}(\mathrm{Mod}_\kappa) \to \mathrm{LMod}^{\mathrm{perf}}(\mathrm{Mod}_\kappa)^{\mathrm{op}} \times_{\mathrm{Alg}_\kappa^{\mathrm{op}}} \mathrm{Alg}_\kappa^{\mathrm{art}} .$$

Using Corollary HTT.2.4.4.4 , we are reduced to proving that $\mathfrak{D}'$ induces an equivalence of ∞-categories from $\mathrm{LMod}_R^{\mathrm{art}}$ to the opposite of $\mathrm{LMod}_{\mathfrak{D}^{(1)}(R)}^{\mathrm{perf}}$, for every $R \in \mathrm{Alg}_\kappa^{\mathrm{art}}$. This is a consequence of Remark 14.5.1.1 together with the following more general assertion:

Proposition 14.6.2.4. *Let κ be a field and let $\mu : A \otimes_\kappa B \to \kappa$ be a map of $\mathbb{E}_1$-algebras over κ which exhibits B as a Koszul dual of A. Then the duality functor $\mathfrak{D}_\mu : \mathrm{LMod}_A^{\mathrm{op}} \to \mathrm{LMod}_B$ restricts to an equivalence $\mathcal{C} \to \mathrm{LMod}_B^{\mathrm{perf}}$, where $\mathcal{C}$ denotes the smallest stable subcategory of LMod_A which contains κ (regarded as a left A-module via the augmentation $A \to A \otimes_\kappa B \xrightarrow{\mu} \kappa$) and is closed under retracts.*

Proof. Let $\mathfrak{D}'_\mu : \mathrm{LMod}_B^{\mathrm{op}} \to \mathrm{LMod}_A$ be as in Notation 14.1.2.3, and let $\mathcal{D}$ denote the full subcategory of LMod_A spanned by those objects M for which the unit map $M \to \mathfrak{D}'_\mu \mathfrak{D}_\mu(M)$ is an equivalence in LMod_A. It is clear that $\mathcal{D}$ is a stable subcategory of LMod_A which is closed under retracts. Since μ exhibits B as a Koszul dual of A, the subcategory $\mathcal{D}$ contains κ so that $\mathcal{C} \subseteq \mathcal{D}$. It follows that the functor $\mathfrak{D}_\mu|_{\mathcal{C}}$ is fully faithful. Moreover, the essential image of $\mathfrak{D}_\mu|_{\mathcal{C}}$ is the smallest stable full subcategory of LMod_B which contains $\mathfrak{D}_\mu(\kappa) \simeq B$ and is closed under retracts: this is the full subcategory $\mathrm{LMod}_B^{\mathrm{perf}} \subseteq \mathrm{LMod}_B$. □

14.6.3 Connectivity Conditions

Let κ be a field, let $A \in \mathrm{Alg}^{\mathrm{aug}}_{\kappa}$, and let $X : \mathrm{Alg}^{\mathrm{art}}_{\kappa} \to \mathcal{S}$ be the formal $\mathbb{E}_1$-moduli problem associated to A (see Theorem 14.0.0.5). We conclude this section with a discussion of the exactness properties of equivalences $\mathrm{QCoh}^!_L(X) \simeq \mathrm{RMod}_A$ and $\mathrm{QCoh}^!_R(X) \simeq \mathrm{LMod}_A$ appearing in Theorem 14.6.0.1. Let $\mathrm{RMod}^{\mathrm{cn}}_A$ and $\mathrm{LMod}^{\mathrm{cn}}_A$ denote the full subcategories spanned by those right and left A-modules whose underlying spectra are connective. Note that the equivalences of Theorem 14.6.0.1 depend functorially on A, and when $A = \kappa$ they are equivalent to the identity functor from the ∞-category Mod_{κ} to itself. Let $*$ denote the final object of $\mathrm{Moduli}^{(1)}_{\kappa}$, so that we have a canonical map of formal moduli problems $* \to X$ (induced by the map of augmented $\mathbb{E}_1$-algebras $\kappa \to A$). It follows that Theorem 14.6.0.1 gives an equivalence

$$\begin{aligned} \mathrm{QCoh}^!_L(X)^{\mathrm{cn}} &\simeq \mathrm{QCoh}^!_L(X) \times_{\mathrm{QCoh}^!_L(*)} \mathrm{QCoh}^!_L(*)^{\mathrm{cn}} \\ &\simeq \mathrm{RMod}_A \times_{\mathrm{RMod}_{\kappa}} \mathrm{RMod}^{\mathrm{cn}}_{\kappa} \\ &\simeq \mathrm{RMod}^{\mathrm{cn}}_A \end{aligned}$$

and, by symmetry, an equivalence $\mathrm{QCoh}^!_R(X)^{\mathrm{cn}} \simeq \mathrm{LMod}^{\mathrm{cn}}_A$. Combining this observation with Proposition 14.5.5.8, we obtain the following result:

Proposition 14.6.3.1. *Let κ be a field, let $A \in \mathrm{Alg}^{\mathrm{aug}}_{\kappa}$, and let $X : \mathrm{Alg}^{\mathrm{art}}_{\kappa} \to \mathcal{S}$ be the formal $\mathbb{E}_1$-moduli problem associated to A (see Theorem 14.0.0.5). Then the fully faithful embeddings*

$$\mathrm{QCoh}_L(X) \hookrightarrow \mathrm{RMod}_A \qquad \mathrm{QCoh}_R(X) \hookrightarrow \mathrm{LMod}_A .$$

of Theorem 14.6.0.1 restrict to equivalences of ∞-categories

$$\mathrm{QCoh}_L(X)^{\mathrm{cn}} \simeq \mathrm{RMod}^{\mathrm{cn}}_A \qquad \mathrm{QCoh}_R(X)^{\mathrm{cn}} \simeq \mathrm{LMod}^{\mathrm{cn}}_A .$$

Warning 14.6.3.2. If A is an arbitrary $\mathbb{E}_1$-ring, then the full subcategories

$$\mathrm{LMod}^{\mathrm{cn}}_A = \mathrm{LMod}_A \times_{\mathrm{Sp}} \mathrm{Sp}^{\mathrm{cn}} \subseteq \mathrm{LMod}_A \qquad \mathrm{RMod}^{\mathrm{cn}}_A = \mathrm{RMod}_A \times_{\mathrm{Sp}} \mathrm{Sp}^{\mathrm{cn}} \subseteq \mathrm{RMod}_A$$

are presentable, closed under small colimits, and closed under extensions. It follows from Proposition HA.1.4.4.11 that the ∞-categories LMod_A and RMod_A admit t-structures with $(\mathrm{LMod}_A)_{\geqslant 0} = \mathrm{LMod}^{\mathrm{cn}}_A$ and $(\mathrm{RMod}_A)_{\geqslant 0} = \mathrm{RMod}^{\mathrm{cn}}_A$. However, it is often difficult to describe the subcategories $(\mathrm{LMod}_A)_{\leqslant 0} \subseteq \mathrm{LMod}_A$ and $(\mathrm{RMod}_A)_{\leqslant 0} \subseteq \mathrm{RMod}_A$. In particular, they generally do not coincide with the subcategories $\mathrm{LMod}_A \times_{\mathrm{Sp}} \mathrm{Sp}_{\leqslant 0} \subseteq \mathrm{LMod}_A$ and $\mathrm{RMod}_A \times_{\mathrm{Sp}} \mathrm{Sp}_{\leqslant 0} \subseteq \mathrm{RMod}_A$ unless the $\mathbb{E}_1$-ring A is connective.

Chapter 15

Moduli Problems for $\mathbb{E}_n$-Algebras

Let κ be a field. In Chapters 13 and 14 we studied the ∞-categories Moduli_κ and $\mathrm{Moduli}_\kappa^{(1)}$ consisting of formal moduli problems defined for commutative and associative algebras over κ, respectively. In the ∞-categorical context, there is a whole hierarchy of algebraic notions lying between these two extremes. Recall that the commutative ∞-operad can be identified with the colimit of a sequence

$$\mathrm{Assoc}^{\otimes} \simeq \mathbb{E}_1^{\otimes} \to \mathbb{E}_2^{\otimes} \to \mathbb{E}_3^{\otimes} \to \cdots ,$$

where $\mathbb{E}_n^{\otimes}$ denotes the Boardman-Vogt ∞-operad of little n-cubes (see Corollary HA.5.1.1.5). Consequently, the ∞-category CAlg_κ of $\mathbb{E}_\infty$-algebras over κ can be identified with the limit of a tower of ∞-categories

$$\cdots \to \mathrm{Alg}_\kappa^{(3)} \to \mathrm{Alg}_\kappa^{(2)} \to \mathrm{Alg}_\kappa^{(1)} \simeq \mathrm{Alg}_\kappa,$$

where $\mathrm{Alg}_\kappa^{(n)}$ denotes the ∞-category of $\mathbb{E}_n$-algebras over κ. Our goal in this section is to prove a generalization of Theorem 14.0.0.5 in the setting of $\mathbb{E}_n$-algebras, for an arbitrary integer $n \geqslant 0$. To formulate our result, we need a bit of terminology.

Definition 15.0.0.1. Let κ be a field, let $n \geqslant 1$, and let A be an $\mathbb{E}_n$-algebra over κ. We will say that A is *Artinian* if its image in Alg_κ is Artinian, in the sense of Definition 14.0.0.1. We let $\mathrm{Alg}_\kappa^{(n),\mathrm{art}}$ denote the full subcategory of $\mathrm{Alg}_\kappa^{\mathrm{art}}$ spanned by the Artinian $\mathbb{E}_n$-algebras over κ.

Warning 15.0.0.2. The terminology of Definition 15.0.0.1 is potentially confusing: when A is discrete and $n \geqslant 2$, it corresponds to the condition that A is a local Artinian ring with residue field κ, rather than merely an Artinian ring. See Warnings 12.1.2.6 and 14.0.0.2.

Remark 15.0.0.3. Let $n \geqslant 1$ and let A be an $\mathbb{E}_n$-algebra over κ. Then A is Artinian if and only if it is connective, $\pi_* A$ is finite-dimensional over κ, and the unit map $\kappa \to (\pi_0 A)/\mathfrak{m}$ is an isomorphism, where $\mathfrak{m}$ denotes the radical of $\pi_0 A$.

Remark 15.0.0.4. Let κ be a field and let A be an $\mathbb{E}_n$-algebra over κ, for $n \geqslant 0$. An *augmentation* on A is a map of $\mathbb{E}_n$-algebras $\epsilon : A \to \kappa$. We let $\mathrm{Alg}_\kappa^{(n),\mathrm{aug}} = (\mathrm{Alg}_\kappa^{(n)})_{/\kappa}$ denote the ∞-category of augmented $\mathbb{E}_n$-algebras over κ. Note that if $n \geqslant 1$ and $A \in \mathrm{Alg}_\kappa^{(n)}$ is Artinian, then the space $\mathrm{Map}_{\mathrm{Alg}_\kappa^{(n)}}(A, \kappa)$ of augmentations on A is contractible. It follows that the projection map $\mathrm{Alg}_\kappa^{(n),\mathrm{aug}} \times_{\mathrm{Alg}_\kappa^{(n)}} \mathrm{Alg}_\kappa^{(n),\mathrm{art}} \to \mathrm{Alg}_\kappa^{(n),\mathrm{art}}$ is an equivalence of ∞-categories. We will henceforth abuse notation by using this equivalence to identify $\mathrm{Alg}_\kappa^{(n),\mathrm{art}}$ with its inverse image in $\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$.

Remark 15.0.0.5. It will be convenient to have a version of Definition 14.0.0.1 also in the case $n = 0$. We therefore adopt the following convention: we will say that an augmented $\mathbb{E}_0$-algebra A over κ is *Artinian* if A is connective and $\pi_* A$ is a finite dimensional vector space over κ. We let $\mathrm{Alg}_\kappa^{(0),\mathrm{art}}$ denote the full subcategory of $\mathrm{Alg}_\kappa^{(0),\mathrm{aug}}$ spanned by the Artinian augmented $\mathbb{E}_0$-algebras over κ.

Notation 15.0.0.6. Let κ be a field, let $n \geqslant 0$, and let $\epsilon : A \to \kappa$ be an augmented $\mathbb{E}_n$-algebra over κ. We let $\mathfrak{m}_A$ denote the fiber of the map ϵ in the stable ∞-category Mod_κ. We will refer to $\mathfrak{m}_A$ as the *augmentation ideal* of A. The construction $(\epsilon : A \to \kappa) \mapsto \mathfrak{m}_A$ determines a functor $\mathfrak{m} : \mathrm{Alg}_\kappa^{(n),\mathrm{aug}} \to \mathrm{Mod}_\kappa$. In the case $n = 0$, this functor is an equivalence of ∞-categories.

Definition 15.0.0.7. Let κ be a field, let $n \geqslant 0$ be an integer and let $X : \mathrm{Alg}_\kappa^{(n),\mathrm{art}} \to \mathcal{S}$ be a functor. We will say that X is a *formal* $\mathbb{E}_n$*-moduli problem* if it satisfies the following conditions:

(1) The space $X(\kappa)$ is contractible.

(2) For every pullback diagram

$$\begin{array}{ccc} R & \longrightarrow & R_0 \\ \downarrow & & \downarrow \\ R_1 & \longrightarrow & R_{01} \end{array}$$

in $\mathrm{Alg}_\kappa^{\mathrm{art}}$ for which the underlying maps $\pi_0 R_0 \to \pi_0 R_{01} \leftarrow \pi_0 R_1$ are surjective, the diagram

$$\begin{array}{ccc} X(R) & \longrightarrow & X(R_0) \\ \downarrow & & \downarrow \\ X(R_1) & \longrightarrow & X(R_{01}) \end{array}$$

is a pullback square.

We let $\mathrm{Moduli}_\kappa^{(n)}$ denote the full subcategory of $\mathrm{Fun}(\mathrm{Alg}_\kappa^{(n),\mathrm{art}}, \mathcal{S})$ spanned by the formal $\mathbb{E}_n$-moduli problems.

Example 15.0.0.8. It is not difficult to show that a functor $X : \mathrm{Alg}_{\kappa}^{(0),\mathrm{art}} \to \mathcal{S}$ is a formal $\mathbb{E}_0$ moduli problem if and only if it is reduced and excisive (see Definition HA.1.4.2.1): that is, if and only if X carries the initial object of $\mathrm{Alg}_{\kappa}^{(0),\mathrm{art}}$ to a final object of $\mathcal{S}$, and carries pushout squares to pullback squares.

We can now state the main result of this section:

Theorem 15.0.0.9. *Let κ be a field and let $n \geqslant 0$ be an integer. Then there is an equivalence of ∞-categories $\Psi : \mathrm{Alg}_{\kappa}^{(n),\mathrm{aug}} \to \mathrm{Moduli}_{\kappa}^{(n)}$. Moreover, the diagram*

$$\begin{array}{ccc} \mathrm{Alg}_{\kappa}^{(n),\mathrm{aug}} & \xrightarrow{\Psi} & \mathrm{Moduli}_{\kappa}^{(n)} \\ \downarrow{\scriptstyle \mathfrak{m}} & & \downarrow{\scriptstyle \Sigma^{-n}T} \\ \mathrm{Mod}_{\kappa} & \longrightarrow & \mathrm{Sp} \end{array}$$

commutes up to canonical homotopy, where $T : \mathrm{Moduli}_{\kappa}^{(n)} \to \mathrm{Sp}$ denotes the tangent complex functor (so that $\Omega^{\infty - m} T_X \simeq X(\kappa \oplus \Sigma^m(\kappa))$ for $m \geqslant 0$) and $\mathfrak{m} : \mathrm{Alg}_{\kappa}^{(n),\mathrm{aug}} \to \mathrm{Mod}_{\kappa}$ denotes the augmentation ideal functor of Notation 15.0.0.6.

Example 15.0.0.10. When $n = 1$, Theorem 15.0.0.9 follows from Theorem 14.0.0.5 and Remark 14.2.2.2.

Remark 15.0.0.11. Suppose that κ is a field of characteristic zero. For each $n \geqslant 0$, there is an evident forgetful functor $\mathrm{CAlg}_{\kappa}^{\mathrm{art}} \to \mathrm{Alg}_{\kappa}^{(n),\mathrm{art}}$, which induces a forgetful functor $\theta : \mathrm{Moduli}_{\kappa}^{(n)} \to \mathrm{Moduli}_{\kappa}$. Using the equivalences

$$\mathrm{Lie}_{\kappa} \simeq \mathrm{Moduli}_{\kappa} \qquad \mathrm{Moduli}_{\kappa}^{(n)} \simeq \mathrm{Alg}_{\kappa}^{(n),\mathrm{aug}}$$

of Theorems 13.0.0.2 and 15.0.0.9, we can identify θ with a functor from $\mathrm{Alg}_{\kappa}^{(n),\mathrm{aug}}$ to Lie_{κ}. We can summarize the situation informally as follows: if A is an augmented $\mathbb{E}_n$-algebra over κ, then the shifted augmentation ideal $\Sigma^{n-1}\mathfrak{m}_A$ inherits the structure of a differential graded Lie algebra over κ. In particular, at the level of homotopy groups we obtain a Lie bracket operation

$$[,] : \pi_p \mathfrak{m}_A \times \pi_q \mathfrak{m}_A \to \pi_{p+q+n-1} \mathfrak{m}_A.$$

One can show that this Lie bracket is given by the *Browder operation* on $\mathfrak{m}_A$. If $\mathrm{Free} : \mathrm{Mod}_{\kappa} \to \mathrm{Alg}_{\kappa}^{(n)}$ denotes the free algebra functor (left adjoint to the forgetful functor $\mathrm{Alg}_{\kappa}^{(n)} \to \mathrm{Mod}_{\kappa}$), then the Browder operation is universally represented by the the map ϕ appearing in the cofiber sequence of augmented $\mathbb{E}_n$-algebras

$$\mathrm{Free}(\Sigma^{p+q+n-1}(\kappa)) \xrightarrow{\phi} \mathrm{Free}(\Sigma^p(\kappa) \oplus \Sigma^q(\kappa)) \to \mathrm{Free}(\Sigma^p(\kappa)) \otimes_{\kappa} \mathrm{Free}(\Sigma^q(\kappa))$$

supplied by Theorem HA.5.3.3.3 .

The appearance of the theory of $\mathbb{E}_n$-algebras on both sides of the equivalence

$$\mathrm{Alg}_\kappa^{(n),\mathrm{aug}} \simeq \mathrm{Moduli}_\kappa^{(n)} \subseteq \mathrm{Fun}(\mathrm{Alg}_\kappa^{(n),\mathrm{art}}, \mathcal{S})$$

is somewhat striking: it is a reflection of the Koszul self-duality of the little cubes operads $\mathbb{E}_n^{\otimes}$ (see [68]). In particular, there is a Koszul duality functor $\mathfrak{D}^{(n)} : (\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$. This functor is not difficult to define directly : if A is an augmented $\mathbb{E}_n$-algebra over κ, then $\mathfrak{D}^{(n)}(A)$ is universal among $\mathbb{E}_n$-algebras over κ for which the tensor product $A \otimes_\kappa \mathfrak{D}^{(n)}(A)$ admits an augmentation extending the augmentation on A. The equivalence Ψ appearing in the statement of Theorem 15.0.0.9 carries an augmented $\mathbb{E}_n$-algebra A to the functor X given by the formula $X(R) = \mathrm{Map}_{\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}}(\mathfrak{D}^{(n)}(R), A)$.

In §15.3, we will prove that the Koszul duality functor $\mathfrak{D}^{(n)}$ is a deformation theory (in the sense of Definition 12.3.3.2), so that Theorem 15.0.0.9 is a consequence of Theorem 12.3.3.5. The main point is to produce a full subcategory $\mathbf{B}_0 \subseteq \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$ which satisfies axiom $(D3)$ of Definition 12.3.1.1. We will define $\mathbf{B}_0$ to be the full subcategory of $\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$ spanned by those augmented $\mathbb{E}_n$-algebras A which satisfy suitable finiteness and coconnectivity conditions. We will then need to prove two things:

- (a) The full subcategory $\mathbf{B}_0 \subseteq \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$ has good closure properties.
- (b) For every object $A \in \mathbf{B}_0$, the biduality map $A \to \mathfrak{D}^{(n)}\mathfrak{D}^{(n)}(A)$ is an equivalence.

The verification of (a) comes down to connectivity properties of free algebras over the $\mathbb{E}_n$-operad. We will establish these properties in §15.1, using topological properties of configuration spaces of points in Euclidean space. We will prove (b) in §15.2. Our strategy is to use the description of Koszul duality in terms of iterated bar constructions (see §HA.5.2.3) to reduce to the case $n = 1$, which was analyzed in detail in Chapter 14.

15.1 Coconnective $\mathbb{E}_n$-Algebras

Let κ be a field and let $n \geqslant 0$ be an integer. Our goal in this section is to study some finiteness and coconnectivity conditions on $\mathbb{E}_n$-algebras over κ which will be relevant to our proof of Theorem 15.0.0.9.

Definition 15.1.0.1. Let κ be a field and let A be an $\mathbb{E}_0$-algebra over κ: that is, a κ-module equipped with a unit map $e : \kappa \to A$. Let m be an integer. We will say that A is *m-coconnective* if the homotopy groups $\pi_i \operatorname{cofib}(e)$ vanish for $i > -m$.

More generally, if A is an $\mathbb{E}_n$-ring equipped with a map of $\mathbb{E}_n$-rings $\kappa \to A$, we will say that A is *m-coconnective* if it is m-coconnective when regarded as an $\mathbb{E}_0$-algebra over κ (here we need not require that A is an $\mathbb{E}_n$-algebra over κ, though this will always be satisfied in cases of interest to us).

Remark 15.1.0.2. If A is an $\mathbb{E}_1$-algebra over a field κ, then A is coconnective (in the sense of Definition 14.1.3.1) if and only if it is 1-coconnective (in the sense of Definition 15.1.0.1).

Remark 15.1.0.3. If $m > 0$, then an $\mathbb{E}_n$-algebra A over κ is m-coconnective if and only if the unit map $\kappa \to A$ induces an isomorphism $\kappa \to \pi_0 A$ and the homotopy groups $\pi_i A$ vanish for $i > 0$ and $-m < i < 0$.

Notation 15.1.0.4. Let κ be a field and let $n \geqslant 0$ be an integer. We let $\operatorname{Free}^{(n)} : \operatorname{Mod}_\kappa \to \operatorname{Alg}_\kappa^{(n)}$ denote a left adjoint to the forgetful functor $\operatorname{Alg}_\kappa^{(n)} \to \operatorname{Mod}_\kappa$. For any object $V \in \operatorname{Mod}_\kappa$, the free algebra $\operatorname{Free}^{(n)}(V)$ is equipped with a canonical augmentation $\epsilon : \operatorname{Free}^{(n)}(V) \to \kappa$, corresponding to the zero morphism $V \to \kappa$ in $\operatorname{Mod}_\kappa$.

Our main result can be stated as follows:

Theorem 15.1.0.5. *Let κ be a field, let A be an $\mathbb{E}_n$-algebra over κ, and let $m \geqslant n$ be an integer. Suppose we are given a map $\phi : V \to A$ in $\operatorname{Mod}_\kappa$, where $\pi_i V \simeq 0$ for $i \geqslant -m$, and form a pushout diagram*

$$\begin{array}{ccc} \operatorname{Free}^{(n)}(V) & \xrightarrow{\phi'} & A \\ \downarrow{\scriptstyle \epsilon} & & \downarrow \\ \kappa & \longrightarrow & A' \end{array}$$

where ϕ' is the map of $\mathbb{E}_n$-algebras determined by ϕ and ϵ is the augmentation of Notation 15.1.0.4. If A is m-coconnective, then A' is also m-coconnective.

Our proof of Theorem 15.1.0.5 is somewhat indirect, and will require several digressions.

15.1.1 Dimensions of Configuration Spaces

Theorem 15.1.0.5 relies on having a good understanding of the free algebra functor $\mathrm{Free}^{(n)} : \mathrm{Mod}_\kappa \to \mathrm{Alg}_\kappa^{(n)}$. Recall that for $V \in \mathrm{Mod}_\kappa$, the underlying κ-module spectrum of $\mathrm{Free}^{(n)}(V)$ is given by $\bigoplus_{m \geqslant 0} \mathrm{Sym}^m_{\mathbb{E}_n}(V)$, where $\mathrm{Sym}^m_{\mathbb{E}_n}(V)$ is the colimit of a diagram indexed by the full subcategory $K_{m,n} \subseteq (\mathbb{E}_n^{\otimes})_{/\langle 1 \rangle}$ spanned by the active morphisms $\langle m \rangle \to \langle 1 \rangle$ in the ∞-operad $\mathbb{E}_n^{\otimes}$ (see Proposition HA.3.1.3.13). The geometric input to our proof of Theorem 15.1.0.5 is the following geometric fact about the Kan complexes $K_{m,n}$:

Proposition 15.1.1.1. *Let m and n be positive integers. Then the Kan complex $K_{m,n}$ defined above is homotopy equivalent to $\mathrm{Sing}(X)$, where X is a finite CW complex of dimension $\leqslant (m-1)(n-1)$.*

Remark 15.1.1.2. The Kan complex $K_{m,n}$ appearing in Proposition 15.1.1.1 is homotopy equivalent to the labelled configuration space $\mathrm{Conf}_m(\mathbf{R}^n)$ parametrizing m-tuples of distinct points in $\mathbf{R}^n$. This space is contractible if $m = 1$, and otherwise admits a fibration $\mathrm{Conf}_m(\mathbf{R}^n) \to \mathrm{Conf}_{m-1}(\mathbf{R}^n)$ whose fibers are homotopy equivalent to a bouquet of spheres having dimension $(n-1)$. One can use this observation to prove Proposition 15.1.1.1 using induction on m. We will give a different argument below, which uses induction on n rather than m.

Lemma 15.1.1.3. *Fix an integer $b \geqslant 0$, and let Q_b denote the set of sequences $(I_1, \ldots, I_b)$, where each $I_j \subseteq (-1, 1)$ is a closed interval, and we have $x < y$ whenever $x \in I_i$, $y \in I_j$, and $i < j$. We regard Q as a partially ordered set, where $(I_1, \ldots, I_b) \leqslant (I'_1, \ldots, I'_b)$ if $I_j \subseteq I'_j$ for $1 \leqslant i \leqslant j$. Then the nerve $\mathrm{N}(Q_b)$ is weakly contractible.*

Proof. The proof proceeds by induction on b. If $b = 0$, then Q_b has a single element and there is nothing to prove. Otherwise, we observe that "forgetting" the last coordinate induces a Cartesian fibration $q : \mathrm{N}(Q_b) \to \mathrm{N}(Q_{b-1})$. We will prove that the fibers of q are weakly contractible, so q is left cofinal (Lemma HTT.4.1.3.2) and therefore a weak homotopy equivalence. Fix an element $x = ([t_1, t'_1], [t_2, t'_2], \ldots, [t_{b-1}.t'_{b-1}]) \in Q_{b-1}$. Then $q^{-1}\{x\}$ can be identified with the nerve of the partially ordered set $Q' = \{(t_b, t'_b) : t'_{b-1} < t_b < t'_b < 1\}$, where $(t_b, t'_b) \leqslant (s_b, s'_b)$ if $t_b \geqslant s_b$ and $t'_b \leqslant s'_b$.

The map $(t_b, t'_b) \mapsto t'_b$ is a monotone map from Q' to the open interval $(t'_{b-1}, 1)$. This map determines a coCartesian fibration $q' : \mathrm{N}(Q') \to \mathrm{N}(t'_{b-1}, 1)$. The fiber of q' over a point s can be identified with the *opposite* of the nerve of the interval (t'_{b-1}, s), and is therefore weakly contractible. It follows that q' is a weak homotopy equivalence, so that $\mathrm{N}(Q')$ is weakly contractible as desired. □

Proof of Proposition 15.1.1.1. For every topological space X, let $\mathrm{Sym}^m(X)$ denote the quotient of X^m by the action of the symmetric group Σ_m, and let $\mathrm{Conf}_m(X)$ denote the subspace of $\mathrm{Sym}^m(X)$ corresponding to m-tuples of *distinct* points in X. Let $\square^n = (-1,1)^n$ denote an open cube of dimension n. Using Lemma HA.5.1.1.3 , we obtain a homotopy equivalence $K_{m,n} \simeq \mathrm{Sing}(\mathrm{Conf}_m(\square^n))$. It will therefore suffice to show that the configuration space $\mathrm{Conf}_m(\square^n)$ is homotopy equivalent to a finite CW complex of dimension $\leqslant (m-1)(n-1)$. If $n = 1$, then $\mathrm{Conf}_m(\square^n)$ is contractible and there is nothing to prove. We prove the result in general by induction on n. Let us therefore assume that $K_{m',n-1}$ is equivalent to the singular complex of a CW complex of dimension $\leqslant (m'-1)(n-2)$ for every integer $m' \geqslant 1$.

Let us identify $\square^n$ with a product $\square^{n-1} \times (-1,1)$, and let $p_0 : \square^n \to \square^{n-1}$ and $p_1 : \square^n \to (-1,1)$ be the projection maps. If $I \subseteq (-1,1)$ is a disjoint union of finitely many closed intervals (with nonempty interiors), we let $[t] \in \pi_0 I$ denote the connected component containing t for each $t \in I$. Then $\pi_0 I$ inherits a linear ordering, with $[t] < [t']$ if and only if $t < t'$ and $[t] \neq [t']$. Let P denote the partially ordered set of triples $(I, \sim, \mu)$, where $I \subseteq (-1,1)$ is a nonempty disjoint union of finitely many closed intervals, $\sim$ is an equivalence relation on $\pi_0 I$ such that $x < y < z$ and $x \sim z$ implies $x \sim y \sim z$, and $\mu : \pi_0 I \to \mathbf{Z}_{>0}$ is a positive integer-valued function such that $\sum_{x \in \pi_0 I} \mu(x) = m$. We regard $(I, \sim, \mu)$ as a partially ordered set, with $(I, \sim, \mu) \leqslant (I', \sim', \mu')$ if $I \subseteq I'$, $\mu'(x) = \sum_y \mu(y)$ where the sum is taken over all $y \in \pi_0 I$ contained in x, and $[s] \sim' [t]$ implies $[s] \sim [t]$ for all $s, t \in I$. For every pair $(I, \sim, \mu) \in P$, we let $Z(I, \sim, \mu)$ be the open subset of $\mathrm{Conf}_m(\square^n)$ consisting of subsets $S \subseteq \square^n$ which are contained in $\square^{n-1} \times I^{\circ}$ (here I° denotes the interior of I), have the property that if $s, s' \in S$ and $[p_1(s)] \sim [p_1(s')]$, then either $s = s'$ or $p_0(s) \neq p_0(s')$, and satisfy $\mu(x) = |\{s \in S : p_1(s) \in x\}|$ for $x \in \pi_0 I$.

We next claim:

$(*)$ The Kan complex $\mathrm{Sing}(\mathrm{Conf}_m(\square^n))$ is a homotopy colimit of the diagram of simplicial sets
$$\{\mathrm{Sing}(Z(I, \sim, \mu))\}_{(I, \sim, \mu) \in P}.$$

To prove this, it will suffice (by Theorem HA.A.3.1) to show that for each point $S \in \mathrm{Conf}_m(\square^n)$, the partially ordered set $P_S = \{(I, \sim, \mu) \in P : S \in Z(I, \sim, \mu)\}$ has weakly contractible nerve. Let Q denote the collection of all equivalence relations $\sim$ on S with the following properties:

(i) If $p_1(s) \leqslant p_1(s') \leqslant p_1(s'')$ and $s \sim s''$, then $s \sim s' \sim s''$.

(ii) If $s \sim s'$, then either $s = s'$ or $p_0(s) \neq p_0(s')$.

We regard Q as a partially ordered set with respect to refinement. Pullback of equivalence relations determines a forgetful functor $\phi : \mathrm{N}(P_S) \to \mathrm{N}(Q)^{\mathrm{op}}$. It is easy to see that μ is a Cartesian fibration. The simplicial set $\mathrm{N}(Q)$ is weakly contractible, since Q has a smallest element (given by the equivalence relation where $s \sim s'$ if and only if $s = s'$). We will complete the proof of $(*)$ by showing that the fibers of ϕ are weakly contractible, so that ϕ is left cofinal (Lemma HTT.4.1.3.2) and therefore a weak homotopy equivalence.

Fix an equivalence relation $\sim \in Q$. Unwinding the definitions, we see that $\phi^{-1}\{\sim\}$ can be identified with the nerve of the partially ordered set R consisting of those subsets $I \subseteq (-1, 1)$ satisfying the following conditions:

(a) The set I is a disjoint union of closed intervals in $(-1, 1)$.

(b) The set I contains $p_1(S)$, and p_1 induces a surjection $S \to \pi_0 I$.

(c) If $p_1(s)$ and $p_1(s')$ belong to the same connected component of I, then $s \sim s'$.

To see that $\mathrm{N}(R)$ is contractible, it suffices to observe that the partially ordered set R^{op} is filtered: it has a cofinal subset given by sets of the form $\bigcup_{s \in S}[p_1(s) - \epsilon, p_1(s) + \epsilon]$ for $\epsilon > 0$. This completes the proof of $(*)$.

We define a category $\mathcal{J}$ as follows:

- An object of $\mathcal{J}$ is a triple $([a], \sim, \mu)$ where $[a] \in \mathbf{\Delta}$, $\sim$ is an equivalence relation on $[a]$ such that $i < j < k$ and $i \sim k$ implies that $i \sim j \sim k$, and $\mu : [a] \to \mathbf{Z}_{>0}$ is a function satisfying $m = \sum_{0 \leqslant i \leqslant a} \mu(i)$.

- A morphism from $([a], \sim, \mu)$ to $([a'], \sim', \mu')$ in $\mathcal{J}$ is a nondecreasing map $\alpha : [a] \to [a']$ such that $\alpha(j) \sim \alpha(j')$ implies $j \sim j'$ and $\mu'(j) = \sum_{\alpha(i)=j} \mu(i)$.

There is an evident forgetful functor $q : P \to \mathcal{J}$, which carries a pair $(I, \sim, \mu)$ to $(\pi_0 I, \sim, \mu)$ where we abuse notation by identifying $\pi_0 I$ with the linearly ordered set $[a]$ for some $a \geqslant 0$. Let $Z' : \mathcal{J} \to \mathcal{S}\mathrm{et}_{\Delta}$ be a homotopy left Kan extension of Z along q. For each object $([a], \sim, \mu) \in \mathcal{J}$, we can identify $Z'([a], \sim, \mu)$ with the homotopy colimit of the diagram $Z|_{P_{[a],\sim,\mu}}$, where $P_{[a],\sim,\mu}$ denotes the partially ordered set of quadruples $(I, \lambda, \sim', \mu')$ where $I \subseteq (-1, 1)$ is a disjoint union of closed intervals, $\lambda : \pi_0 I \to [a]$ is nondecreasing surjection, $\sim'$ is an equivalence relation on $\pi_0 I$ such that $\lambda([t]) \sim \lambda([t'])$ implies $[t] \sim' [t']$, and $\mu' : \pi_0 I \to \mathbf{Z}_{>0}$ is a map satisfying $\mu(i) = \sum_{\lambda(x)=i} \mu'(x)$ for $0 \leqslant i \leqslant a$. Let $P'_{[a],\sim,\mu}$ be the subset of $P_{[a],\sim,\mu}$ consisting of those quadruples $(I, \lambda, \sim', \mu')$ where λ is a bijection and $\sim'$ is the pullback of $\sim$ along λ. The inclusion $\mathrm{N}(P'_{[a],\sim,\mu}) \to \mathrm{N}(P_{[a],\sim,\mu})$ admits a left adjoint and is therefore left cofinal. It follows that $Z'([a], \sim, \mu)$ can be identified with a homotopy colimit of the diagram $Z|_{P'_{[a],\sim,\mu}}$. Note that Z carries each morphism in $P'_{[a],\sim,\mu}$ to a homotopy equivalence of Kan complexes. Since $P'_{[a],\sim}$ is weakly contractible (Lemma 15.1.1.3), we conclude that the map $Z(I, \sim', \mu') \to Z'([a], \sim, \mu)$ is a weak homotopy equivalence for any $(I, \lambda, \sim', \mu') \in P'_{[a],\sim,\mu}$.

It follows from condition $(*)$ that $\mathrm{Sing}(K_{m,n})$ can be identified with a homotopy colimit of the diagram Z'. We may assume without loss of generality that Z' takes values in Kan complexes, so that Z' determines a functor of ∞-categories $\mathcal{J} \to \mathcal{S}$. We will abuse notation by denoting this map also by Z'. Note that if $([a], \sim, \mu) \in \mathcal{J}$, then $m = \sum_{0 \leqslant i \leqslant a} \mu(i) \geqslant a + 1$. For each object $([a], \sim, \mu) \in \mathcal{J}$, we define the *complexity* $d([a], \sim, \mu)$ to be the sum $|[a]/\sim| + \sum_{0 \leqslant i \leqslant a}(\mu(i) - 1)$. Since $[a]/\sim$ has at least one element, $d([a], \sim, \mu)$ is bounded below by 1 and bounded above by $|[a]| + \sum_{0 \leqslant i \leqslant a} \mu(i) - 1 = \sum_{0 \leqslant i \leqslant a} \mu(i) = m$. Note that for every nonidentity morphism $J \to J'$ in $\mathcal{J}$, we have $d(J) < d(J')$. From this, we deduce that every nondegenerate simplex in the nerve $\mathrm{N}(\mathcal{J})$, corresponding to a sequence of nonidentity morphisms $J_0 \to \cdots \to J_b$ in $\mathcal{J}$, is bounded in length by $b \leqslant m - 1$. It follows immediately that the simplicial set $\mathrm{N}(\mathcal{J})$ has only finitely many nondegenerate simplices. We will prove that for every finite simplicial subset $A \subseteq \mathrm{N}(\mathcal{J})$, the colimit of the diagram $Z'|_A$ is homotopy equivalent to the singular complex of finite CW complex of dimension $\leqslant (n-1)(m-1)$. This is obvious when $A = \emptyset$, and when $A = \mathrm{N}(\mathcal{J})$ it implies the desired result. To carry out the inductive step, assume that A is nonempty so that there is a pushout diagram

$$\begin{array}{ccc} \partial \Delta^b & \longrightarrow & \Delta^b \\ \downarrow & & \downarrow \sigma \\ A_0 & \longrightarrow & A \end{array}$$

for some smaller simplicial subset $A_0 \subseteq \mathrm{N}(\mathcal{J})$. The simplex σ carries the initial vertex $0 \in \Delta^b$ to an object $([a], \sim, \mu) \in \mathcal{J}$, and we have a pushout diagram

$$\begin{array}{ccc} Z'([a], \sim, \mu) \times \partial \Delta^b & \longrightarrow & Z'([a], \sim, \mu) \times \Delta^b \\ \downarrow & & \downarrow \\ \varinjlim(Z'|_{A_0}) & \longrightarrow & \varinjlim(Z'|_A) \end{array}$$

where $\varinjlim(Z'|_{A_0})$ is homotopy equivalent to the singular complex of a finite CW complex of dimension $\leqslant (n-1)(m-1)$. Let $I \subseteq (-1, 1)$ be a finite union of $a + 1$ closed intervals and identify $\pi_0 I$ with $[a]$, so that $Z'([a], \sim, \mu) \simeq Z(I, \sim, \mu)$ is homotopy equivalent to the product $\prod_{x \in [a]/\sim} \mathrm{Conf}_{\mu_x}(\square^{n-1})$, where $\mu_x = \sum_{i \in x} \mu(i)$. Using the inductive hypothesis, we deduce that $Z'([a], \sim, \mu)$ is homotopy equivalent to the nerve of a CW complex of dimension $(m-d)(n-2)$, where d is the cardinality of the quotient $[a]/\sim$. It follows that $\varinjlim(Z'|_A)$ is homotopy equivalent to the singular complex of a CW complex having dimension at most the maximum of $(m-1)(n-1)$ and $(m-d)(n-2)+b \leqslant (m-1)(n-2)+(m-1) = (m-1)(n-1)$, as desired. $\square$

Remark 15.1.1.4. Let $\mathcal{C}$ be a presentable ∞-category equipped with an $\mathbb{E}_n$-monoidal structure, and if $n > 0$ assume that the tensor product on $\mathcal{C}$ preserves coproducts separately in each variable.

Suppose now that $X \in \mathcal{C}$ is a coproduct of objects $\{X_s\}_{s \in S}$. Let $\mathcal{J}$ be the subcategory of $\mathcal{F}\mathrm{in}_*$ consisting of the object $\langle m \rangle$ and its automorphisms. Let $\mathcal{J}(S)$ be the category whose objects are maps of sets $\{1, \ldots, m\} \to S$, and whose morphisms are given by commutative diagrams

$$\begin{array}{ccc} \{1,\ldots,m\} & \xrightarrow{\nu} & \{1,\ldots,m\} \\ & \searrow \quad \swarrow & \\ & S & \end{array}$$

where ν is bijective. There is an evident forgetful functor $q : \mathcal{J}(S) \to \mathcal{J}$. Let $K_{m,n}$ be as in the statement of Proposition 15.1.1.1, and let $K_{m,n}(S)$ denote the fiber product $K_{m,n} \times_{\mathrm{N}(\mathcal{J})} \mathrm{N}(\mathcal{J}(S))$.

According to Proposition HA.3.1.3.13 , the free algebra functor $\mathrm{Free}^{(n)} : \mathcal{C} \to \mathrm{Alg}_{/\mathbb{E}_n}(\mathcal{C})$ carries an object $X \in \mathcal{C}$ to the coproduct $\amalg_{m \geqslant 0} \mathrm{Sym}^{(n)}_{\mathbb{E}_n}(X)$, where $\mathrm{Sym}^{(n)}_{\mathbb{E}_n}(X)$ denotes the colimit of a diagram $\phi_X : K_{m,n} \to \mathcal{C}$.

Then ϕ_X can be identified with the left Kan extension (along q) of a functor $\phi_{\{X_s\}_{s \in S}} : \mathcal{J}(S) \to \mathcal{J}$, where $\overline{\beta}$ carries an operation $\gamma : \langle m \rangle \to \langle 1 \rangle$ in $\mathbb{E}_n^{\otimes}$ and a map $\alpha : \langle m \rangle^{\circ} \to S$ to the object $\gamma_!(X_{\alpha(1)}, \ldots, X_{\alpha(m)}) \in \mathcal{C}$ (here $\gamma_! : \mathcal{C}^m \to \mathcal{C}$ denotes the functor determined by the $\mathbb{E}_n$-monoidal structure on $\mathcal{C}$).

For every map $\mu : S \to \mathbf{Z}_{\geqslant 0}$ satisfying $\sum_{s \in S} \mu(s) = m < \infty$, let $\mathcal{J}(S, \mu)$ denote the full subcategory of $\mathcal{J}(S)$ spanned by those maps $\alpha : \langle m \rangle^{\circ} \to S$ such that $\alpha^{-1}\{s\}$ has cardinality $\mu(s)$, and let $K_{m,n}(S, \mu)$ denote the fiber product $K_{m,n}(S) \times_{\mathrm{N}(\mathcal{J}(S))} \mathrm{N}(\mathcal{J}(S, \mu))$. Then $K_{m,n}(S)$ is a disjoint union of the Kan complexes $K_{m,n}(S, \mu)$. It follows that $\mathrm{Sym}^m_{\mathbb{E}_n}(X)$ is a coproduct $\amalg_\mu \varinjlim \overline{\beta}|_{K_{m,n}(\mu)}$. Note that if $T \subseteq S$ and $\mu(s) = 0$ for $s \notin T$, then there is a canonical equivalence

$$\phi_{\{X_s\}_{s \in S}}|_{K_{m,n}(S,\mu)} \simeq \phi_{\{X_s\}_{s \in T}}|_{K_{m,n}(T,\mu|_T)}.$$

It follows that if the cardinality of S is larger than m, then $\mathrm{Sym}^m_{\mathbb{E}_n}(X)$ can be written as a coproduct of objects, each of which is a summand of $\mathrm{Sym}^m_{\mathbb{E}_n}(\amalg_{t \in S - \{s\}} X_t)$ for some $s \in S$.

15.1.2 Local Finiteness of Tensor Products

Let κ be a field. Recall that we say that an object $M \in \mathrm{Mod}_\kappa$ is *locally finite* if each homotopy group $\pi_i M$ is a finite-dimensional vector space over κ (Definition 14.1.3.1). We will need the following closure property of locally finite modules under tensor products:

Proposition 15.1.2.1. *Let A be a coconnective $\mathbb{E}_1$-algebra over a field κ such that $\pi_{-1}A \simeq 0$. Let M be a left A-module, let N be a right A-module. Suppose that A, M, and N are locally finite, and that $\pi_i M \simeq \pi_i N \simeq 0$ for $i > 0$. Then $N \otimes_A M$ is locally finite.*

Our proof of Proposition 15.1.2.1 will make use of the following:

Lemma 15.1.2.2. *Let A be a coconnective $\mathbb{E}_1$-algebra over a field κ such that $\pi_{-1}A \simeq 0$, and let M be a left A-module such that $\pi_i M \simeq 0$ for $i > 0$. Assume that A and M are locally finite. Then there exists a sequence of left A-modules*

$$0 = M(0) \to M(1) \to M(2) \to \cdots$$

with the following properties:

(1) *For each $n > 0$, there exists a locally finite object $V(n) \in (\mathrm{Mod}_\kappa)_{\leqslant -n}$ and a cofiber sequence of left A-modules $A \otimes_\kappa V(n) \to M(n-1) \to M(n)$.*

(2) *There exists an equivalence $\theta : \varinjlim M(n) \simeq M$.*

Proof. We construct $M(n)$ using induction on n, beginning with the case $n = 0$ where we set $M(0) = 0$. Assume that $M(n-1) \in (\mathrm{LMod}_A)_{/M}$ has been constructed, and let $V(n)$ denote the underlying κ-module of the fiber of the map $M(n-1) \to M$. We then define $M(n)$ to be the cofiber of the induced map $A \otimes_\kappa V(n) \to M(n-1)$. This construction produces a sequence of objects $M(0) \to M(1) \to M(2) \to \cdots$ in $(\mathrm{LMod}_A)_{/M}$, hence a map $\theta : \varinjlim M(n) \to M$. We claim that θ is an equivalence of left A-modules. To prove this, it suffices to show that θ is an equivalence in Mod_κ. As an object of Mod_κ, we can identify $\varinjlim M(n)$ with the direct limit of the sequence

$$M(0) \to M(0)/V(1) \to M(1) \to M(1)/V(2) \to \cdots$$

It therefore suffices to show that the map $\varinjlim M(i)/V(i+1) \to M$ is an equivalence in Mod_κ, which is clear (since each cofiber $M(i)/V(i+1)$ is equivalent to M). This proves (2). We next prove the following by a simultaneous induction on n:

(a_n) The map $M(n) \to M$ induces an isomorphism $\pi_i M(n) \to \pi_i M$ for $i > -n$ and an injection for $i = -n$.

(b_n) Each $M(n)$ is locally finite.

(a'_n) The κ-module $V(n+1)$ belongs to $(\mathrm{Mod}_\kappa)_{\leqslant -n-1}$.

(b'_n) The κ-module $V(n+1)$ is locally finite.

Assertions (a_0) and (b_0) are obvious, and the equivalences $(a_n) \Leftrightarrow (a'_n)$ and $(b_n) \Leftrightarrow (b'_n)$ follow from the existence of a long exact sequence

$$\cdots \to \pi_i V(n+1) \to \pi_i M(n) \to \pi_i M \to \pi_{i-1} V(n+1) \to \cdots$$

We will complete the proof by showing that (a'_n) and (b'_n) imply (a'_{n+1}) and (b_{n+1}). Assertion (b_{n+1}) follows from (b'_n) by virtue of the existence of an exact sequence

$$\cdots \to \pi_i(A \otimes_\kappa V(n+1)) \to \pi_i M(n) \to \pi_i M(n+1) \to \pi_{i-1}(A \otimes_\kappa V(n+1)) \to \cdots$$

To prove (a_{n+1}), we note that the identification $M \simeq M(n)/V(n)$ gives a fiber sequence

$$(A/\kappa) \otimes_\kappa V(n) \to M \xrightarrow{\lambda} M(n+1)$$

in Mod_κ, where λ is a right inverse to the A-module map $M(n+1) \to M$. We therefore have an equivalence $M(n+1) \simeq M \oplus ((A/\kappa) \otimes_\kappa \Sigma(V(n))$ in Mod_κ so that $V(n+1) \simeq \Sigma(A/\kappa) \otimes_\kappa V(n)$. Since $\pi_i A/\kappa \simeq 0$ for $i \geqslant -1$, it follows immediately that $(a'_n) \Rightarrow (a'_{n+1})$. □

Proof of Proposition 15.1.2.1. Let κ be a field, let A be a coconnective $\mathbb{E}_1$-algebra over κ satisfying $\pi_1 A \simeq 0$, and let $M \in \mathrm{LMod}_A$ and $N \in \mathrm{RMod}_A$. Suppose that A, M, and N are locally finite, and that $\pi_i M \simeq \pi_i N \simeq 0$ for $i > 0$. We wish to show that $N \otimes_A M$ is also locally finite. Choose $\{M(n)\}_{n \geqslant 0}$ be as in Lemma 15.1.2.2. Then $\pi_i(N \otimes_A M) \simeq \varinjlim \pi_i(N \otimes_A M(n))$. We have cofiber sequences $A \otimes_\kappa V(n) \to M(n-1) \to M(n)$ where $V(n) \in (\mathrm{Mod}_\kappa)_{\leqslant -n}$, hence also cofiber sequences $N \otimes_\kappa V(n) \to N \otimes_A M(n-1) \to N \otimes_A M(n)$ in Mod_κ. Since each $\pi_i V(n)$ is finite-dimensional, the homotopy groups of $N \otimes_\kappa V(n)$ are finite-dimensional. It follows by induction on n that $N \otimes_A M(n)$ is locally finite. Since $\pi_i(N \otimes_\kappa V(n)) \simeq 0$ for $i > -n$, the maps $\pi_i(N \otimes_A M(n-1)) \to \pi_i(N \otimes_A M(n))$ are bijective for $i > -n+1$. It follows that $\pi_i(N \otimes_A M) \simeq \varinjlim \pi_i(N \otimes_A M(n))$ is also a finite dimensional vector space over κ. □

15.1.3 The Algebra $\int A$

To prove Theorem 15.1.0.5, it will be convenient to introduce a device which can be used to translate certain questions about $\mathbb{E}_n$-algebras to questions about $\mathbb{E}_1$-algebras (which can then be analyzed using ideas from Chapter 14).

Construction 15.1.3.1. Let κ be a field and let A be an $\mathbb{E}_n$-algebra over κ. We let $\mathrm{Mod}_A^{\mathbb{E}_n} = \mathrm{Mod}_A^{\mathbb{E}_n}(\mathrm{Mod}_\kappa)$ denote the ∞-category of $\mathbb{E}_n$-modules over A (see §HA.3.3.3). Note that $\mathrm{Mod}_A^{\mathbb{E}_n}$ is a presentable ∞-category (Theorem HA.3.4.4.2) and the forgetful functor $\theta : \mathrm{Mod}_A^{\mathbb{E}_n} \to \mathrm{Mod}_\kappa$ is conservative and preserves small limits and colimits (Corollaries HA.3.4.3.3 , HA.3.4.3.6 , and HA.3.4.4.6). It follows that $\mathrm{Mod}_A^{\mathbb{E}_n}$ is a stable ∞-category. The composite functor

$$\mathrm{Mod}_A^{\mathbb{E}_n} \xrightarrow{\theta} \mathrm{Mod}_\kappa \to \mathrm{Sp} \xrightarrow{\Omega^\infty} \mathcal{S}$$

preserves small limits and filtered colimits, and is therefore corepresentable by an object $M \in \mathrm{Mod}_A^{\mathbb{E}_n}$ (Proposition HTT.5.5.2.7). Since θ is conservative, the object M generates $\mathrm{Mod}_A^{\mathbb{E}_n}$ in the following sense: an object $N \in \mathrm{Mod}_A^{\mathbb{E}_n}$ vanishes if and only if the abelian groups $\mathrm{Ext}^n_{\mathrm{Mod}_A^{\mathbb{E}_n}}(M, N)$ vanish for every integer n. Applying Theorem HA.7.1.2.1 (and its proof), we see that there exists an $\mathbb{E}_1$-ring $\int A$ and an equivalence of ∞-categories $\mathrm{LMod}_{\int A} \simeq \mathrm{Mod}_A^{\mathbb{E}_n}$ carrying $\int A$ to the module M (this latter condition is equivalent to the requirement that the composition

$$\mathrm{LMod}_{\int A} \simeq \mathrm{Mod}_A^{\mathbb{E}_n} \to \mathrm{Mod}_k \to \mathrm{Sp}$$

is equivalent to the forgetful functor $\mathrm{LMod}_{\int A} \to \mathrm{Sp}$). The $\mathbb{E}_1$-ring $\int A$ can be characterized (up to equivalence) as the $\mathbb{E}_1$-ring of endomorphisms of M in the stable ∞-category $\mathrm{Mod}_A^{\mathbb{E}_n}$.

Remark 15.1.3.2 (Functoriality)**.** In the situation of Construction 15.1.3.1, let $\mathrm{Mod}^{\mathbb{E}_n}$ denote the ∞-category of pairs (A, M), where A is an $\mathbb{E}_n$-algebra over κ and M is an $\mathbb{E}_n$-module over A. We have a presentable fibration $\mathrm{Mod}^{\mathbb{E}_n} \to \mathrm{Alg}_\kappa^{(n)}$, classified by a functor $\chi : \mathrm{Alg}_\kappa^{(n)} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$; here $\mathcal{P}\mathrm{r}^{\mathrm{L}}$ denotes the ∞-category whose objects are presentable ∞-categories and whose morphisms are functors which preserve small colimits. Since each $\mathrm{Mod}_A^{\mathbb{E}_n}$ is stable, the functor χ factors as a composition

$$\mathrm{Alg}_\kappa^{(n)} \xrightarrow{\chi'} \mathrm{Mod}_{\mathrm{Sp}}(\mathcal{P}\mathrm{r}^{\mathrm{L}}) \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$$

(see Proposition HA.4.8.2.15). Since χ carries the inital object $\kappa \in \mathrm{Alg}_\kappa^{(n)}$ to Mod_κ (see Proposition HA.3.4.2.1), the canonical map $\mathrm{Sp} \to \mathrm{Mod}_\kappa$ allows us to factor χ through a functor $\chi'' : \mathrm{Alg}_\kappa^{(n)} \to \mathrm{Mod}_{\mathrm{Sp}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})_{\mathrm{Sp}/}$. According to Theorem HA.4.8.5.5 , the construction $B \mapsto \mathrm{LMod}_B$ determines a fully faithful embedding $\mathrm{Alg}(\mathrm{Sp}) \to \mathrm{Mod}_{\mathrm{Sp}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})_{\mathrm{Sp}/}$, and the argument of Construction 15.1.3.1 implies that the functor χ'' factors through the essential image of this embedding. It follows that we can regard the construction $A \mapsto \int A$ as a functor $\int : \mathrm{Alg}_\kappa^{(n)} \to \mathrm{Alg}(\mathrm{Sp})$.

Remark 15.1.3.3. Let κ be a field, and regard κ as an $\mathbb{E}_n$-algebra over itself. Then the forgetful functor $\mathrm{Mod}_\kappa^{\mathbb{E}_n} \to \mathrm{Mod}_\kappa$ is an equivalence of ∞-categories (Proposition HA.3.4.2.1), so that we have a canonical equivalence of $\mathbb{E}_1$-rings $\kappa \simeq \int \kappa$. For any $\mathbb{E}_n$-algebra A over κ, the unit map $\kappa \to A$ is a map of $\mathbb{E}_n$-algebras, and therefore induces a map of $\mathbb{E}_1$-rings $\kappa \simeq \int \kappa \to \int A$. In particular, the homotopy groups $\pi_* A$ can be regarded as vector spaces over the field κ.

With more effort, one can show that the map $\kappa \to \int A$ is central: that is, $\int A$ can be regarded as an $\mathbb{E}_1$-algebra over κ. We will not need this fact.

Example 15.1.3.4. If $n = 0$ and A is an $\mathbb{E}_n$-algebra over κ, then the forgetful functor $\mathrm{Mod}_A^{\mathbb{E}_n} \to \mathrm{Mod}_\kappa$ is an equivalence Proposition HA.3.3.3.19). It follows that the map $\kappa \to \int A$ of Remark 15.1.3.3 is an equivalence. That is, $\int : \mathrm{Alg}_\kappa^{(0)} \to \mathrm{Alg}^{(1)}$ can be identified with the constant functor taking the value κ.

Example 15.1.3.5. If $n = 1$ and $A \in \mathrm{Alg}_\kappa^{(n)}$, then there is a canonical equivalence of ∞-categories $\mathrm{Mod}_A^{\mathbb{E}_1} \simeq {}_A\mathrm{BMod}_A(\mathrm{Mod}_\kappa)$ (Theorem HA.4.4.1.28). Using Corollary HA.**??** , we obtain a canonical equivalence of $\mathbb{E}_1$-rings $\int A \simeq A \otimes_\kappa A^{\mathrm{rev}}$, where A^{rev} denotes the $\mathbb{E}_1$-algebra A equipped with the opposite multiplication.

More generally, for any integer $n \geqslant 1$, the inclusion of ∞-operads $\mathbb{E}_1^{\otimes} \to \mathbb{E}_n^{\otimes}$ determines a forgetful functor $\mathrm{Alg}_A^{\mathbb{E}_n} \to \mathrm{Alg}_A^{\mathbb{E}_1}$ which induces a map of $\mathbb{E}_1$-rings $A \otimes_\kappa A^{\mathrm{rev}} \to \int A$. We may therefore regard $\int A$ as an A-A bimodule object of Mod_κ.

Remark 15.1.3.6. Let A be an $\mathbb{E}_n$-algebra over a field κ. Theorem HA.7.3.5.1 supplies a fiber sequence $\Sigma^{n-1} L_{A/\kappa} \to \int A \to A$ of $\mathbb{E}_n$-modules over A, where $L_{A/\kappa}$ denotes the relative cotangent complex of A over κ in the setting of $\mathbb{E}_n$-algebras. If A is connective, then $L_{A/\kappa}$ is also connective. For $n \geqslant 1$, it follows that $\int A$ is also connective (this is also true for $n = 0$; see Example 15.1.3.4), so that the ∞-category $\mathrm{Mod}_A^{\mathbb{E}_n}(\mathrm{Mod}_\kappa) \simeq \mathrm{Mod}_{\int A}$ inherits a t-structure from the t-structure on Mod_κ. For $n \geqslant 2$, we deduce also that the map $\pi_0 \int A \to \pi_0 A$ is an isomorphism, so that the forgetful functor $\mathrm{Mod}_A^{\mathbb{E}_n}(\mathrm{Mod}_\kappa) \to \mathrm{LMod}_A$ induces an equivalence of abelian categories $\mathrm{Mod}_A^{\mathbb{E}_n}(\mathrm{Mod}_\kappa)^{\heartsuit} \simeq \mathrm{LMod}_A^{\heartsuit}$.

Let κ be a field and let A be an $\mathbb{E}_n$-algebra over κ. One can show that the $\mathbb{E}_1$-ring $\int A$ is given by the topological chiral homology $\int_{\mathbf{R}^n - \{0\}} A$ defined in §HA.5.5.2). In what follows, we will not use this description directly. However, we will need the following consequence, for which we supply a direct proof:

Proposition 15.1.3.7. *Let κ be a field and let $n \geqslant 0$. The functor $\int : \mathrm{Alg}_\kappa^{(n)} \to \mathrm{Alg}^{(1)}$ preserves small sifted colimits.*

Proof. Let $\Theta : \mathrm{Alg}^{(1)} \to \mathrm{Mod}_{\mathrm{Sp}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})_{\mathrm{Sp}/}$ be the fully faithful embedding $B \mapsto \mathrm{LMod}_B$ of Theorem HA.4.8.5.5 . To prove that the functor $\int$ preseves small sifted colimits, it will suffice to show that the composite functor $\Theta \circ \int$ preserves small sifted colimits. Since every sifted simplicial set is contractible, it suffices to show that the induced map $\mathrm{Alg}_\kappa^{(n)} \to \mathrm{Mod}_{\mathrm{Sp}}(\mathcal{P}\mathrm{r}^{\mathrm{L}})$ preserves small sifted colimits (Proposition HTT.4.4.2.9). Using Theorem HA.7.3.4.13 , we see that this functor classifies the stable envelope of the Cartesian fibration $\theta : \mathrm{Fun}(\Delta^1, \mathrm{Alg}_\kappa^{(n)}) \to \mathrm{Fun}(\{1\}, \mathrm{Alg}_\kappa^{(n)})$, classified by the functor $\xi : \mathrm{Alg}_\kappa^{(n)} \to \mathcal{P}\mathrm{r}^{\mathrm{L}}$ given informally by $A \mapsto (\mathrm{Alg}_\kappa^{(n)})_{/A}$. It will therefore suffice to show that ξ preserves small sifted colimits. Using Theorem HTT.5.5.3.18 , we are reduced to showing that the composite functor $\mathrm{Alg}_\kappa^{(n)} \xrightarrow{\xi} \mathcal{P}\mathrm{r}^{\mathrm{L}} \simeq \mathcal{P}\mathrm{r}^{\mathrm{R}^{\mathrm{op}}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty^{\mathrm{op}}$ preserves small sifted colimits. This functor also classifies the forgetful functor θ (this time as a Cartesian fibration). Fix a sifted ∞-category K and a colimit diagram $\overline{f} : K^{\triangleright} \to \mathrm{Alg}_\kappa^{(n)}$; we wish to show that the Cartesian fibration $\theta' : \mathrm{Fun}(\Delta^1, \mathrm{Alg}_\kappa^{(n)}) \times_{\mathrm{Fun}(\{1\}, \mathrm{Alg}_\kappa^{(n)})} K^{\triangleright}$ is classified by limit diagram $(K^{\triangleright})^{\mathrm{op}} \to \widehat{\mathcal{C}\mathrm{at}}_\infty$. Let $A \in \mathrm{Alg}_\kappa^{(n)}$ denote the image under $\overline{f}$ of the cone point of $K^{\triangleright}$, and for each vertex $v \in K$ let $A_v = \overline{f}(v)$. According to Proposition **??**, it will suffice to verify the following:

(a) The pullback functors $q_v : (\mathrm{Alg}^{(n)}_\kappa)_{/A} \to (\mathrm{Alg}^{(n)}_\kappa)_{/A_v}$, given by $B \mapsto A_v \times_A B$, are jointly conservative. Since K is nonempty, it will suffice to show that for each $v \in K$, the pullback q_v is conservative. To this end, suppose we are given a map $\alpha : B \to B'$ in $(\mathrm{Alg}^{(n)}_\kappa)_{/A}$ such that $q_v(\alpha)$ is an equivalence. Since the fiber of α (as a map of spectra) is equivalent to the fiber of $q_v(\alpha)$ (by virtue of Corollary HA.3.2.2.5), we conclude that α is an equivalence as well.

(b) Let $h \in \mathrm{Fun}_{\mathrm{Alg}^{(n)}_\kappa}(K, \mathrm{Fun}(\Delta^1, \mathrm{Alg}^{(n)}_\kappa))$ be a map which carries each edge of K to a θ-Cartesian morphism in the ∞-category $\mathrm{Fun}(\Delta^1, \mathrm{Alg}^{(n)}_\kappa)$, corresponding to a natural transformation $\{B_v \to A_v\}_{v \in K}$, and let $\overline{h} \in \mathrm{Fun}_{\mathrm{Alg}^{(n)}_\kappa}(K^{\triangleright}, \mathrm{Alg}^{(n)}_\kappa)$ be an θ-colimit diagram extending h; we wish to show that $\overline{h}$ carries each edge of $K^{\triangleright}$ to a θ-Cartesian morphism in $\mathrm{Fun}(\Delta^1, \mathrm{Alg}^{(n)}_\kappa)$. Unwinding the definitions, we must show that if $B = \varinjlim B_v$, then for each $v \in K$ the diagram σ :

$$\begin{array}{ccc} B_v & \longrightarrow & B \\ \downarrow & & \downarrow \\ A_v & \longrightarrow & A \end{array}$$

is a pullback square in $\mathrm{Alg}^{(n)}_\kappa$. For each $v \in K$, let I_v denote the fiber of the map $B_v \to A_v$ in Mod_κ, and let I be the fiber of the map $B \to A$; we wish to show that each of the canonical maps $I_v \to I$ is an equivalence in Mod_κ. Our assumption on h guarantees that the diagram $v \mapsto I_v$ carries each edge of K to an equivalence in Mod_κ. It will therefore suffice to show that the canonical map $\varinjlim I_v \to I$ is an equivalence in Mod_κ. Since Mod_κ is stable, the formation of fibers commutes with colimits; it will therefore suffice to show that A and B are colimits of the diagrams $\{A_v\}_{v \in K}$ and $\{B_v\}_{v \in K}$ in Mod_κ, respectively. Since K is sifted, this follows because the forgetful functor $\mathrm{Alg}^{(n)}_\kappa \to \mathrm{Mod}_\kappa$ preserves sifted colimits (Proposition HA.3.2.3.1).

□

15.1.4 The Main Step

We are now ready to prove a special case of Theorem 15.1.0.5:

Proposition 15.1.4.1. *Let κ be a field, let A be an $\mathbb{E}_n$-algebra over κ, and let $m \geqslant n$ be an integer. Suppose we are given a map $\phi : V \to A$ in Mod_κ, where $\pi_i V \simeq 0$ for $i \geqslant -m$, and form a pushout diagram*

$$\begin{array}{ccc} \mathrm{Free}^{(n)}(V) & \xrightarrow{\phi'} & A \\ \downarrow{\scriptstyle \epsilon} & & \downarrow \\ \kappa & \longrightarrow & A' \end{array}$$

where ϕ' is the map of $\mathbb{E}_n$-algebras determined by ϕ and ϵ is the augmentation of Notation 15.1.0.4. Assume that A is m-coconnective and that $\int A$ is $(m+1-n)$-coconnective. Then A' is m-coconnective, and $\int A'$ is $(m+1-n)$-coconnective. Moreover, if A, $\int A$, and V are locally finite, then A' and $\int A'$ are locally finite (see Definition 14.1.3.1).

Remark 15.1.4.2. We will show in a moment that the hypothesis $\int A$ is $(m+1-n)$-connective is automatic (Proposition 15.1.5.1).

Proof of Proposition 15.1.4.1. We will assume $n > 0$ (otherwise the result is trivial). Let $\phi'_0 : \mathrm{Free}^{(n)}(V) \to A$ be the map of $\mathbb{E}_n$-algebras induced by the zero map $V \to A$, so that A' can be identified with the colimit of the coequalizer diagram $\mathrm{Free}^{(n)}(V) \underset{\phi'_0}{\overset{\phi'}{\rightrightarrows}} A$ classified by a functor $u_0 : \mathbf{\Delta}^{\mathrm{op}}_{s,\leqslant 1} \to \mathrm{Alg}^{(n)}_\kappa$. Let $u : \mathbf{\Delta}^{\mathrm{op}} \to \mathrm{Alg}^{(n)}_\kappa$ be a left Kan extension of u_0 along the inclusion $\mathbf{\Delta}^{\mathrm{op}}_{s,\leqslant 1} \hookrightarrow \mathbf{\Delta}^{\mathrm{op}}$, so that u determines a simplicial object $A_\bullet$ in $\mathrm{Alg}^{(n)}_\kappa$ with $A' \simeq |A_\bullet|$ and $A_p \simeq A \amalg \mathrm{Free}(V^p)$ for all $p \geqslant 0$. Let $R = \int A$ so that $\mathrm{LMod}_R \simeq \mathrm{Mod}^{\mathbb{E}_n}_A(\mathrm{Mod}_\kappa)$ is equipped with an $\mathbb{E}_n$-monoidal structure, where the tensor product is given by the relative tensor product over A. We will need the following estimate:

$(*)$ For each integer $a > 0$, the iterated tensor product $R^{\otimes a}$ belongs to $(\mathrm{Mod}_\kappa)_{\leqslant 0}$. Moreover, if A and $\int A$ are locally finite, then $R^{\otimes a}$ is locally finite.

Suppose first that $n = 1$, so that $R \simeq A \otimes_\kappa A^{\mathrm{rev}}$ (Example 15.1.3.5). Then $R^{\otimes a}$ can be identified with an iterated tensor product $A \otimes_\kappa A \otimes_\kappa \cdots \otimes_\kappa A$ and assertion $(*)$ is obvious. We may therefore assume that $n \geqslant 2$. In this case, A is $m \geqslant n \geqslant 2$-coconnective, so the desired result follows from Corollary 14.1.4.3 and Proposition 15.1.2.1.

Let $V' = R \otimes_\kappa V$ denote the image of V in $\mathrm{Mod}^{\mathbb{E}_n}_A$. For each $p \geqslant 0$, Corollary HA.3.4.1.5 allows us to identify A_p with the free $\mathbb{E}_n$-algebra generated by V' in the $\mathbb{E}_n$-monoidal ∞-category $\mathrm{Mod}^{\mathbb{E}_n}_A$. Using Proposition HA.3.1.3.13 , we obtain an equivalence $A_p \simeq \bigoplus_{a \geqslant 0} \mathrm{Sym}^a_{\mathbb{E}_n} V'^p$ (where the symmetric powers are computed in $\mathrm{Mod}^{\mathbb{E}_n}_A$). Let Q denote the cofiber of the map $A \to A'$ in the stable ∞-category $\mathrm{Mod}^{\mathbb{E}_n}_A(\mathrm{Mod}_\kappa)$, so that Q is given by the geometric realization of a simplicial object $Q_\bullet$ with $Q_p \simeq \bigoplus_{a>0} \mathrm{Sym}^a_{\mathbb{E}_n} V'^p$. To show that A' is m-coconnective, it will suffice to show that $\pi_i Q \simeq 0$ for $i > -m$.

Using Remark HA.1.2.4.4 , we obtain a spectral sequence $\{E^{p,q}_r\}_{r \geqslant 1}$ converging to $\pi_{p+q} Q$, where $E^{*,q}_1$ is the normalized chain complex associated to the simplicial κ-vector space $[p] \mapsto \bigoplus_{a>0} \pi_q \mathrm{Sym}^a_{\mathbb{E}_n}(V'^p)$. It follows from Remark 15.1.1.4 that the summand $\pi_q \mathrm{Sym}^a_{\mathbb{E}_n}(V'^p)$ lies in the image of the degeneracy maps of this simplicial vector space whenever $p > a$.

Note that $\mathrm{Sym}^a_{\mathbb{E}_n}(V'^p)$ is the colimit of a diagram $\phi_{V'} : K_{a,n} \to \mathrm{Mod}^{\mathbb{E}_n}_A(\mathrm{Mod}_\kappa)$ whose value on each vertex is given by $(V'^p)^{\otimes a}$, where $K_{a,n}$ is the Kan complex appearing in the statement of Proposition 15.1.1.1. Since $\pi_i V \simeq 0$ for $i > -m-1$, condition $(*)$ guarantees that $\pi_i (V'^p)^{\otimes a} \simeq 0$ for $i > (-m-1)a$, and that the homotopy groups of $(V'^p)^{\otimes a}$ are finitely generated vector spaces over κ provided that A and R are locally finite. Combining this with Proposition 15.1.1.1, we deduce that if $a > 0$, then $\pi_q \operatorname{Sym}^a_{\mathbb{E}_n}(V'^p)$ vanishes for

$$q > (a-1)(n-1) + (-m-1)a = 1 - 2a - m + (n-m)(a-1)$$

and thus for $q > 1 - 2a - m$.

If the vector space $E_1^{p,q}$ is nonzero, there must be an integer $a > 0$ such that $p \leqslant a$ and $q \leqslant 1 - 2a - m$, so that $p + q \leqslant 1 - a - m \leqslant -m$. This proves that $\pi_i Q \simeq 0$ for $i > p + q$, so that A' is m-coconnective. For any integer i, the inequality $i = p + q \leqslant 1 - a - m$ implies that a is bounded above by $1 - m - i$, so that $\pi_i Q$ admits a finite filtration whose associated graded vector space consists of subquotients of $\pi_{i-p} \operatorname{Sym}^a_{\mathbb{E}_n} V'^p$ where $a \leqslant 1 - m - i$ and $p \leqslant a$. It follows that if A and R are locally finite, then Q is also locally finite, so that A' is locally finite.

To complete the proof, we must show that $\int A'$ is $(1 + m - n)$-coconnective, and that $\int A'$ is locally finite if A and $\int A$ are locally finite. According to Proposition 15.1.3.7, $\int A'$ can be identified with the geometric realization of the simplicial $\mathbb{E}_1$-ring $\int A_\bullet$. Let B be an arbitrary $\mathbb{E}_n$-ring, let $W \in \operatorname{Mod}_\kappa$ and let $W' = (\int B) \otimes_\kappa W$ denote the image of W in $\operatorname{Mod}^{\mathbb{E}_n}_B \simeq \operatorname{LMod}_{\int B}$. Then the coproduct $B \amalg \operatorname{Free}^{(n)}(W)$ can be identified with the free $\mathbb{E}_n$-algebra in $\operatorname{Mod}^{\mathbb{E}_n}_B$ generated by W', which is given by $\bigoplus_{a \geqslant 0} \operatorname{Sym}^a_{\mathbb{E}_n}(W')$. If we let $Z(W)$ denote the cofiber in $\operatorname{Mod}_\kappa$ of the map $B \to B \amalg \operatorname{Free}^{(n)}(W)$, then we obtain an equivalence $\int B \simeq \varinjlim_{b \mapsto \infty} \Omega^b Z(\Sigma^b \kappa)$. Taking $B = A_p$, we obtain an equivalence

$$\int A_p \simeq \varinjlim_{b \mapsto \infty} \Omega^b (\bigoplus_{a \geqslant 0} \operatorname{Sym}^a_{\mathbb{E}_n}(V'^p \oplus \Sigma^b \kappa)) / (\bigoplus_{a \geqslant 0} \operatorname{Sym}^a_{\mathbb{E}_n}(V'^p)).$$

Remark 15.1.1.4 gives a canonical decomposition

$$\operatorname{Sym}^a_{\mathbb{E}_n}(V'^p \oplus \Sigma^b \kappa) \simeq \bigoplus_{a = a' + a''} F_{a', a''}(V'^p, \Sigma^b \kappa).$$

Note that $F_{a-1,1}$ is an exact functor of the second variable, and that if $a'' \geqslant 2$, then the colimit $\varinjlim \Omega^b F_{a', a''}(V'^p, \Sigma^b \kappa)$ vanishes. We therefore obtain an equivalence $\int A_p \simeq \bigoplus_{a > 0} F_{a-1,1}(V'^p, \kappa)$. Unwinding the definitions, we see that $F_{a-1,1}(X, Y)$ is given by the colimit of a diagram $\widetilde{K}_{a,n} \to \operatorname{Mod}^{\mathbb{E}_n}_A(\operatorname{Mod}_\kappa)$, which carries each vertex to the iterated tensor product $(V'^p)^{\otimes a-1} \otimes_A R$, here $\widetilde{K}_{a,n}$ is a finite-sheeted covering space of $K_{m,n}$ and therefore equivalent to the singular complex of a finite CW complex of dimension $\leqslant (a-1)(n-1)$ (Proposition 15.1.1.1). Since condition $(*)$ implies that $\pi_i (V'^p)^{\otimes a-1} \otimes_A R$ vanishes for $i > (-m-1)(a-1)$, we conclude that $\pi_q F_{a-1,1}(V'^p, \kappa) \simeq 0$ for $q > (-m-1)(a-1) + (n-1)(a-1) = (n-m-2)(a-1)$ and therefore for $q > 2 - 2a$. Moreover, if A, V, and $\int A$ are locally finite, then each $\pi_q F_{a-1,1}(V'^p, \kappa)$ is a finite dimensional vector space over κ.

Let Q' denote the spectrum given by the cofiber of the map $\int A \to \int A'$, so that Q' is the geometric realization of a simplicial spectrum $Q'_\bullet$ given by $Q'_p \simeq \bigoplus_{a \geqslant 2} F_{a-1,1}(V'^p, \kappa)$. Using

Remark HA.1.2.4.4 , we obtain a spectral sequence $\{E_r'^{p,q}\}_{r\geqslant 1}$ converging to $\pi_{p+q}Q'$, where $E_1'^{*,q}$ is the normalized chain complex associated to the simplicial κ-vector space $[p] \mapsto \bigoplus_{a\geqslant 2} \pi_q F_{a-1,1}(V'^p, \kappa)$. Arguing as above, we deduce that the summand $\pi_q F_{a-1,1}(V'^p, \kappa)$ lies in the image of the degeneracy maps of this vector space whenever $p \geqslant a$. It follows that if $E_1'^{p,q}$ is nonzero, then there exists an integer $a \geqslant 2$ such that $p < a$ and $q \leqslant 2-2a$, so that $p + q < 2 - a \leqslant 0$. It follows that $\pi_i Q' \simeq 0$ for $i \geqslant 0$, from which we immediately conclude that $\int A'$ is 1-coconnective. For any integer i, the inequality $i = p + q \leqslant 2 - a$ implies that a is bounded above by $2 - i$, so that $\pi_i Q'$ admits a finite filtration whose associated graded vector space consists of subquotients of $\pi_{i-p} F_{a-1,1}(V'^p, \kappa)$ where $2 \leqslant a \leqslant 2 - i$ and $p < a$. If A and $\int A$ are locally finite, then these subquotients are necessarily finite dimensional, so that each $\pi_i Q'$ is a finite dimensional vector space. It then follows that $\int A'$ is locally finite as desired. □

15.1.5 The Proof of Theorem 15.1.0.5

Let κ be a field and let A be an m-connective $\mathbb{E}_n$-algebra over κ, for some integers $m \geqslant n \geqslant 0$. If the algebra $\int A$ is $(m + 1 - n)$-coconnective, then the conclusion of Theorem 15.1.0.5 follows from Proposition 15.1.4.1. Consequently, to prove Theorem 15.1.0.5 in general, it will suffice to establish the following:

Proposition 15.1.5.1. *Let A be an $\mathbb{E}_n$-algebra over a field κ, and assume that A is m-coconnective for $m \geqslant n$. Then the $\mathbb{E}_1$-ring $\int A$ is $(m + 1 - n)$-coconnective.*

Proof. Let A be an $\mathbb{E}_n$-algebra over a field κ, and assume that A is m-coconnective for $m \geqslant n$. We wish to show that $\int A$ is $(m - n + 1)$-coconnective. The result is trivial if $n = 0$ (Example 15.1.3.4); we will therefore assume that $n \geqslant 1$. We construct a sequence of maps $A(0) \to A(1) \to \cdots$ in $(\mathrm{Alg}_\kappa^{(n)})_{/A}$ by induction. Let $A(0) = \kappa$. Assuming that $A(i)$ has already been defined, we let $V(i)$ denote the fiber of the map $A(i) \to A$ (in Mod_κ) and define $A(i + 1)$ so that there is a pushout square

$$\begin{array}{ccc} \mathrm{Free}^{(n)}(V(i)) & \xrightarrow{\phi'} & A(i) \\ \downarrow{\scriptstyle \epsilon} & & \downarrow \\ \kappa & \longrightarrow & A(i+1) \end{array}$$

as in the statement of Proposition 15.1.4.1. We prove the following statements by induction on i:

(a_i) The $\mathbb{E}_n$-algebra $A(i)$ is m-coconnective.

(b_i) The map $\pi_{-m}A(i) \to \pi_{-m}A$ is injective.

(c_i) The $\mathbb{E}_1$-algebra $\int A$ is $(m+1-n)$-coconnective.

(d_i) We have $\pi_j V(i) \simeq 0$ for $j \geqslant -m$.

It is clear that conditions (a_0), (b_0), and (c_0) are satisfied. Note that (a_i) and (b_i) imply (d_i) and that (a_i), (c_i) and (d_i) imply (a_{i+1}) and (c_{i+1}) by Proposition 15.1.4.1. It will therefore suffice to show that (a_i), (b_i), (c_i), and (d_i) imply condition (b_{i+1}). As in the proof of Proposition 15.1.4.1, we can identify $A(i+1)$ with the geometric realization of a simplicial object $A_\bullet$ of $\mathrm{Alg}_\kappa^{(n)}$, with $A_p \simeq A(i) \amalg \mathrm{Free}^{(n)}(V(i)^p)$. Let Q denote the cofiber of the map $A(i) \to A(i+1)$ (as an object of $\mathrm{Mod}_{A_i}^{\mathbb{E}_n}(\kappa)$) we have a canonical map $\phi : Q \to \mathrm{cofib}(A(i) \to A) \simeq \Sigma V(i)$. We wish to prove that ϕ induces an injection $\pi_{-n} Q \to \pi_{-n-1} V(i)$, which follows immediately by inspecting the spectral sequence $\{E_r^{p,q}\}_{r \geqslant 1}$ appearing in the proof of Proposition 15.1.4.1.

We now claim that the canonical map $\theta : \varinjlim A(i) \to A$ is an equivalence. Combining this with assertions (c_i) and Proposition 15.1.3.7, we conclude that $\int A \simeq \varinjlim \int A(i)$ is $(m+1-n)$-connective as desired. To prove that θ is an equivalence, we note that the image of $A(i)$ in Mod_κ can be identified with the colimit of the sequence

$$\kappa \simeq A(0) \to A(0)/V(0) \to A(1) \to A(1)/V(1) \to \cdots,$$

where each cofiber $A(i)/V(i)$ is equivalent to A. □

15.2 Koszul Duality for $\mathbb{E}_n$-Algebras

Our goal in this section is to study the operation of Koszul duality in the setting of augmented $\mathbb{E}_n$-algebras over a field κ. More precisely, we will construct a self-adjoint functor

$$\mathfrak{D}^{(n)} : (\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}.$$

Our main result asserts that for large class of augmented $\mathbb{E}_n$-algebras A, the unit map $A \to \mathfrak{D}^{(n)}\mathfrak{D}^{(n)} A$ is an equivalence (Theorem 15.2.2.1).

15.2.1 The Definition of Koszul Duality

We begin with the definition of the Koszul duality functor $\mathfrak{D}^{(n)}$. Let A be an $\mathbb{E}_n$-algebra over a field κ. An *augmentation* on A is a map of $\mathbb{E}_n$-algebras $A \to \kappa$. We let $\mathrm{Aug}(A) = \mathrm{Map}_{\mathrm{Alg}_\kappa^{(n)}}(A, \kappa)$ denote the space of augmentations on A. If we are given a pair of augmented $\mathbb{E}_n$-algebras $\epsilon : A \to \kappa$ and $\epsilon' : B \to \kappa$, we let $\mathrm{Pair}(A, B)$ denote the homotopy fiber of the map $\mathrm{Aug}(A \otimes_\kappa B) \to \mathrm{Aug}(A) \times \mathrm{Aug}(B)$, taken over the point (ϵ, ϵ'). More informally, we can describe $\mathrm{Pair}(A, B)$ as the space of augmentations on $A \otimes_\kappa B$ which extend the given augmentations on A and B. We will refer to the points of $\mathrm{Pair}(A, B)$ as *pairings* of A with B. The starting point for our discussion of Koszul duality is the following fact, which is a special case of Proposition HA.5.2.5.1 :

Proposition 15.2.1.1. *Let κ be a field, $n \geqslant 0$ an integer, and A be an augmented $\mathbb{E}_n$-algebra over κ. Then the construction $B \mapsto \mathrm{Pair}(A, B)$ determines a representable functor from $(\mathrm{Alg}_{\kappa}^{(n),\mathrm{aug}})^{\mathrm{op}}$ into $\mathcal{S}$. That is, there exists an augmented $\mathbb{E}_n$-algebra $\mathfrak{D}^{(n)}(A)$ and a pairing $\nu : A \otimes_{\kappa} \mathfrak{D}^{(n)}(A) \to \kappa$ with the following universal property: for every augmented $\mathbb{E}_n$-algebra B, composition with ν induces a homotopy equivalence*

$$\mathrm{Map}_{\mathrm{Alg}_{\kappa}^{(n),\mathrm{aug}}}(B, \mathfrak{D}^{(n)}(A)) \to \mathrm{Pair}(A, B).$$

In the situation of Proposition, we will refer to $\mathfrak{D}^{(n)}(A)$ as the *Koszul dual* of A. The construction $A \mapsto \mathfrak{D}^{(n)}(A)$ determines a functor $\mathfrak{D}^{(n)} : (\mathrm{Alg}_{\kappa}^{(n),\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_{\kappa}^{(n),\mathrm{aug}}$, which we will refer to as *Koszul duality.*

Remark 15.2.1.2. If A is an augmented $\mathbb{E}_n$-algebra over a field κ, then the Koszul dual $\mathfrak{D}^{(n)}(A)$ can be identified (using the formalism of §HA.5.3.1) with a centralizer of the augmentation map $\epsilon : A \to \kappa$ (see Example HA.5.3.1.5).

Example 15.2.1.3. Suppose that $n = 0$. Then the construction $V \mapsto \kappa \oplus V$ defines an equivalence from the ∞-category Mod_{κ} of κ-module spectra to the ∞-category $\mathrm{Alg}_{\mathrm{aug}}^{(n)}$. If V and W are objects of Mod_{κ}, then a pairing of V with W is a κ-linear map

$$\phi : (\kappa \oplus V) \otimes_{\kappa} (\kappa \oplus W) \simeq \kappa \oplus V \oplus W \oplus (V \otimes_{\kappa} W) \to \kappa$$

equipped with homotopies $\phi|_{\kappa} \simeq \mathrm{id}$, $\phi|_V \simeq 0 \simeq \phi|_W$. It follows that we can identify $\mathrm{Pair}(\kappa \oplus V, \kappa \oplus W)$ with the space $\mathrm{Map}_{\mathrm{Mod}_{\kappa}}(V \otimes_{\kappa} W, \kappa)$. It follows that the Koszul duality functor $\mathfrak{D}^{(0)}$ is given by $\kappa \oplus V \mapsto \kappa \oplus V^{\vee}$, where $V^{\vee}$ is the κ-linear dual of V (with homotopy groups given by $\pi_i V^{\vee} \simeq \mathrm{Hom}_{\kappa}(\pi_{-i} V, \kappa)$).

Example 15.2.1.4. When $n = 1$, the Koszul duality functor $\mathfrak{D}^{(1)} : (\mathrm{Alg}_{\kappa}^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_{\kappa}^{\mathrm{aug}}$ agrees with the functor studied in §14.1.

Remark 15.2.1.5. The construction $A, B \mapsto \mathrm{Pair}(A, B)$ is symmetric in A and B. Consequently, for any pair of augmented $\mathbb{E}_n$-algebras A and B, we have homotopy equivalences

$$\mathrm{Hom}_{\mathrm{Alg}_{\kappa}^{(n),\mathrm{aug}}}(B, \mathfrak{D}^{(n)}(A)) \simeq \mathrm{Pair}(A, B) \simeq \mathrm{Pair}(B, A) \simeq \mathrm{Hom}_{\mathrm{Alg}_{\kappa}^{(n),\mathrm{aug}}}(A, \mathfrak{D}^{(n)}(B)).$$

In particular, the tautological pairing $A \otimes_{\kappa} \mathfrak{D}^{(n)}(A) \to \kappa$ can be identified with a point of $\mathrm{Pair}(\mathfrak{D}^{(n)}(A), A)$, which is classified by a *biduality map* $u_A : A \to \mathfrak{D}^{(n)}\mathfrak{D}^{(n)}(A)$. Our main goal in this section is to study conditions which guarantee that u_A is an equivalence.

15.2.2 Koszul Biduality

We can now formulate the main result of this section:

Theorem 15.2.2.1. *Let $n \geqslant 0$ and let A be an augmented $\mathbb{E}_n$-algebra over a field κ. If A is n-coconnective and locally finite, then the biduality map $u_A : A \to \mathfrak{D}^{(n)}\mathfrak{D}^{(n)}(A)$ is an equivalence of augmented $\mathbb{E}_n$-algebras over κ.*

Remark 15.2.2.2. In the case $n = 0$, Theorem 15.2.2.1 reduces to the statement that for every finite-dimensional vector space V over κ, the biduality map $V \to V^{\vee\vee}$ is an isomorphism (see Example 15.2.2.6 below). In the case $n = 1$, Theorem 15.2.2.1 reduces to Corollary 14.1.3.3.

Let A be an augmented $\mathbb{E}_n$-algebra over a field κ which is n-coconnective and locally finite. To establish Theorem 15.2.2.1, we must show that the biduality map $A \to \mathfrak{D}^{(n)}\mathfrak{D}^{(n)}(A)$ is an equivalence. This is equivalent to the requirement that, for every augmented $\mathbb{E}_n$-algebra B over κ, the canonical map

$$\mathrm{Map}_{\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}}(B, A) \to \mathrm{Map}_{\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}}(B, \mathfrak{D}^{(n)}\mathfrak{D}^{(n)}(A)) \simeq \mathrm{Map}_{\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}}(\mathfrak{D}^{(n)}(A), \mathfrak{D}^{(n)}(B))$$

is a homotopy equivalence. Our strategy is to prove this using induction on n. To make the induction work, we will need to strengthen our inductive hypothesis. Note that the Koszul duality functor $\mathfrak{D}^{(n)} : (\mathrm{Alg}_\kappa^{(n)})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{(n)}$ is lax symmetric monoidal (see Remark HA.5.2.2.25). We will actually prove the following result, which immediately implies Theorem 15.2.2.1:

Proposition 15.2.2.3. *Let κ be a field, let $n \geqslant 0$ be an integer, and suppose we are given a finite collection $\{A_1, \ldots, A_m\}$ of augmented $\mathbb{E}_n$-algebras over κ. Let B be an arbitrary augmented $\mathbb{E}_n$-algebra over κ. If each A_i is n-coconnective and locally finite, then the canonical map*

$$\mathrm{Map}_{\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}}(B, A_1 \otimes_\kappa \cdots \otimes_\kappa A_m) \to \mathrm{Map}_{\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}}(\mathfrak{D}^{(n)}A_1 \otimes_\kappa \cdots \otimes_\kappa \mathfrak{D}^{(n)}A_m, \mathfrak{D}^{(n)}B)$$

is a homotopy equivalence.

Remark 15.2.2.4. The statement Proposition 15.2.2.3 can be reformulated as saying that the canonical map

$$A_1 \otimes_\kappa \cdots \otimes_\kappa A_m \to \mathfrak{D}^{(n)}(\mathfrak{D}^{(n)}A_1 \otimes_\kappa \cdots \otimes_\kappa \mathfrak{D}^{(n)}A_m)$$

is an equivalence of augmented $\mathbb{E}_n$-algebras over κ, provided that the $\mathbb{E}_n$-algebras A_i are coconnective and locally finite.

Warning 15.2.2.5. In the situation of Proposition 15.2.2.3, the tensor product $A = A_1 \otimes_\kappa \cdots \otimes_\kappa A_m$ is also a locally finite n-coconnective augmented $\mathbb{E}_n$-algebra over κ, so that (by virtue of Theorem 15.2.2.1) the biduality map $A \to \mathfrak{D}^{(n)}\mathfrak{D}^{(n)}A$ is an equivalence. It follows that the natural map

$$A_1 \otimes_\kappa \cdots \otimes_\kappa A_m \to \mathfrak{D}^{(n)}(\mathfrak{D}^{(n)}A_1 \otimes_\kappa \cdots \otimes_\kappa \mathfrak{D}^{(n)}A_m)$$

can be identified with the Koszul dual of a map

$$\theta : \mathfrak{D}^{(n)}A_1 \otimes_\kappa \cdots \otimes_\kappa \mathfrak{D}^{(n)}A_m \to \mathfrak{D}^{(n)}(A).$$

With some further assumptions, one can show that θ is an equivalence (and thereby deduce Proposition 15.2.2.3 from Theorem 15.2.2.1). For example, θ is an equivalence if each A_i is $(n+1)$-coconnective. However, θ is not an equivalence in general.

Example 15.2.2.6. For every vector space V over κ, let $V^\vee = \mathrm{Hom}_\kappa(V, \kappa)$ denote the dual vector space. For any object $A \in \mathrm{Alg}_\kappa^{(0),\mathrm{aug}}$, we have canonical isomorphisms $\pi_p \mathfrak{D}^{(0)}(A) \simeq (\pi_{-p}A)^\vee$ (see Example 15.2.1.3). It follows that if $\{A_i\}_{1 \leqslant i \leqslant m}$ is a finite collection of locally finite 0-connective objects of $\mathrm{Alg}_\kappa^{(0),\mathrm{aug}}$, then canonical map

$$\bigoplus_{p = p_1 + \cdots + p_m} \bigotimes_i (\pi_{p_i} A_i) \to \Big(\bigoplus_{p = p_1 + \cdots + p_m} (\bigotimes_i (\pi_{p_i} A_i)^\vee) \Big)^\vee$$

is an isomorphism for every integer p (since $\pi_{p_i} A_i \simeq 0$ for $p_i > 0$, each of the direct sums is essentially finite, and the desired result follows immediately because each $\pi_{p_i} A_i$ is a finite dimensional vector space over κ). Using Remark 15.2.2.4, we deduce that Proposition 15.2.2.3 is true when $n = 0$.

15.2.3 Categorical Generalities

Our proof of Proposition 15.2.2.3 will use the following general observation (which we formulate using the language of ∞-operads developed in [139]):

Proposition 15.2.3.1. *Let $F : \mathcal{C}^\otimes \to \mathcal{D}^\otimes$ be a lax symmetric monoidal functor between symmetric monoidal ∞-categories $p : \mathcal{C}^\otimes \to \mathrm{N}(\mathcal{F}\mathrm{in}_*)$ and $q : \mathcal{D}^\otimes \to \mathrm{N}(\mathcal{F}\mathrm{in}_*)$. Let $\mathcal{C}_0$ be a full subcategory of $\mathcal{C}$ satisfying the following condition:*

- $(*)$ *For every sequence of objects $\{C_i\}_{1 \leqslant i \leqslant m}$ of $\mathcal{C}_0$ and every object $C' \in \mathcal{C}$, the canonical map*

  $$\mathrm{Map}_{\mathcal{C}}(\bigotimes_i C_i, C') \to \mathrm{Map}_{\mathcal{D}}(\bigotimes_i F(C_i), F(C'))$$

  is a homotopy equivalence.

Let $\mathcal{O}^{\otimes}$ be an ∞-operad, and suppose we are given a sequence of algebra objects $\{A_i \in \mathrm{Alg}_{\mathcal{O}}(\mathcal{C})\}_{1 \leqslant i \leqslant n}$ such that, for each $X \in \mathcal{O}$ and $1 \leqslant i \leqslant n$, we have $A_i(X) \in \mathcal{C}_0$. Then for every object $B \in \mathrm{Alg}_{\mathcal{O}}(\mathcal{C})$, the canonical map

$$\mathrm{Map}_{\mathrm{Alg}_{\mathcal{O}}(\mathcal{C})}(\bigotimes_i A_i, B) \to \mathrm{Map}_{\mathrm{Alg}_{\mathcal{O}}(\mathcal{D})}(\bigotimes_i F(A_i), F(B))$$

is a homotopy equivalence.

Proof. Let $\Delta^1 \to \mathrm{N}(\mathcal{F}\mathrm{in}_*)$ classify the unique active morphism $\langle n \rangle \to \langle 1 \rangle$, and let $\overline{\mathcal{C}} = \mathrm{Fun}_{\mathrm{N}(\mathcal{F}\mathrm{in}_*)}(\Delta^1, \mathcal{C}^{\otimes})$. In what follows, we will abuse notation by identifying $\mathcal{C}^{\otimes}_{\langle n \rangle}$ with $\mathcal{C}^n$. The ∞-category $\overline{\mathcal{C}}$ inherits a symmetric monoidal structure from $\mathcal{C}$, and we have symmetric monoidal forgetful functors $(\mathcal{C}^n)^{\otimes} \leftarrow \overline{\mathcal{C}}^{\otimes} \to \mathcal{C}^{\otimes}$. The sequence $(A_1, \ldots, A_n)$ can be identified with a $\mathcal{O}$-algebra object of $\mathcal{C}^n$, and B determines a map $\mathcal{O}^{\otimes} \to \mathcal{C}^{\otimes}$. We let $\mathcal{C}'^{\otimes} = \overline{\mathcal{C}}^{\otimes} \times_{(\mathcal{C}^n)^{\otimes} \times \mathcal{C}^{\otimes}} \mathcal{O}^{\otimes}$, so that we have a fibration of ∞-operads $\mathcal{C}'^{\otimes} \to \mathcal{O}^{\otimes}$ and $\mathrm{Alg}_{/\mathcal{O}}(\mathcal{C}')$ can be identified with the mapping space $\mathrm{Map}_{\mathrm{Alg}_{\mathcal{O}}(\mathcal{C})}(\bigotimes_i A_i, B)$. We define a fibration of ∞-operads $\mathcal{D}'^{\otimes} \to \mathcal{O}^{\otimes}$ similarly, so that $\mathrm{Map}_{\mathrm{Alg}_{\mathcal{O}}(\mathcal{D})}(\bigotimes_i F(A_i), F(B)) \simeq \mathrm{Alg}_{/\mathcal{O}}(\mathcal{D}')$. We wish to show that F induces a homotopy equivalence of Kan complexes $\mathrm{Alg}_{/\mathcal{O}}(\mathcal{C}') \to \mathrm{Alg}_{/\mathcal{O}}(\mathcal{D}')$. For this, it suffices to show that for every map of simplicial sets $K \to \mathcal{O}^{\otimes}$, the induced map $\theta : \mathrm{Fun}_{\mathcal{O}^{\otimes}}(K, \mathcal{C}'^{\otimes}) \to \mathrm{Fun}_{\mathcal{O}^{\otimes}}(K, \mathcal{D}'^{\otimes})$ is a homotopy equivalence of Kan complexes. Working simplex-by-simplex, we can assume that $K = \Delta^p$. Then the inclusion $K' = \Delta^{\{0,1\}} \amalg_{\{1\}} \cdots \amalg_{\{p-1\}} \Delta^{\{p-1,p\}} \hookrightarrow K$ is a categorical equivalence; we may therefore replace K by K'. Working simplex-by-simplex again, we can assume that $K = \Delta^p$ for $p = 0$ or $p = 1$. When $p = 0$, the desired result follows immediately from $(*)$. In the case $p = 1$, the map $\Delta^p \to \mathcal{O}^{\otimes}$ determines a morphism $\overline{\alpha} : X \to Y$ in $\mathcal{O}^{\otimes}$. Let $\alpha : \langle m \rangle \to \langle m' \rangle$ be the image of $\overline{\alpha}$ in $\mathrm{N}(\mathcal{F}\mathrm{in}_*)$, so that $X \simeq \bigoplus_{j \in \langle m \rangle^{\circ}} X_j$ and $Y = \bigoplus_{j' \in \langle m' \rangle^{\circ}} Y_{j'}$ for some objects $X_j, Y_{j'} \in \mathcal{O}$. Unwinding the definitions, we see that $\mathrm{Fun}_{\mathcal{O}^{\otimes}}(\Delta^p, \mathcal{C}'^{\otimes})$ is given by the homotopy limit of the diagram

$$\begin{array}{ccc} \prod_{j \in \langle m \rangle^{\circ}} \mathrm{Map}_{\mathcal{C}}(\bigotimes_{1 \leqslant i \leqslant n} A_i(X_j), B(X_j)) & & \prod_{j' \in \langle m' \rangle^{\circ}} \mathrm{Map}_{\mathcal{C}}(\bigotimes_{1 \leqslant i \leqslant n} A_i(Y_{j'}), B(Y_{j'})) \\ & \searrow \quad \swarrow & \\ & \prod_{j' \in \langle m' \rangle^{\circ}} \mathrm{Map}_{\mathcal{C}}(\bigotimes_{1 \leqslant i \leqslant n, \alpha(j) = j'} A_i(X_j), B(Y_{j'})). & \end{array}$$

Similarly, $\mathrm{Fun}_{\mathcal{O}^{\otimes}}(\Delta^p, \mathcal{D}'^{\otimes})$ can be identified with the homotopy limit of the diagram

$$\begin{array}{ccc} \prod_{j \in \langle m \rangle^{\circ}} \mathrm{Map}_{\mathcal{D}}(\bigotimes_{1 \leqslant i \leqslant n} FA_i(X_j), FB(X_j)) & & \prod_{j' \in \langle m' \rangle^{\circ}} \mathrm{Map}_{\mathcal{D}}(\bigotimes_{1 \leqslant i \leqslant n} FA_i(Y_{j'}), FB(Y_{j'})) \\ & \searrow \quad \swarrow & \\ & \prod_{j' \in \langle m' \rangle^{\circ}} \mathrm{Map}_{\mathcal{D}}(\bigotimes_{1 \leqslant i \leqslant n, \alpha(j) = j'} FA_i(X_j), FB(Y_{j'})) & \end{array}$$

It now follows from $(*)$ that θ is a homotopy equivalence as desired. $\square$

15.2.4 Proof of Proposition 15.2.2.3

Let κ be a field, let $n \geqslant 0$ be an integer, and suppose we are given a finite collection $\{A_1, \ldots, A_m, B\}$ of augmented $\mathbb{E}_n$-algebras over κ. We wish to show that if each A_i is n-coconnective and locally finite, then the canonical map

$$\mathrm{Map}_{\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}}(B, A_1 \otimes_\kappa \cdots \otimes_\kappa A_m) \to \mathrm{Map}_{\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}}(\mathfrak{D}^{(n)} A_1 \otimes_\kappa \cdots \otimes_\kappa \mathfrak{D}^{(n)} A_m, \mathfrak{D}^{(n)} B)$$

is a homotopy equivalence. We will proceed by induction on n. When $n = 0$ the result is trivial (see Example 15.2.2.6), and when $n = 1$ it follows from Proposition 14.1.7.1. Let us therefore assume that $n \geqslant 1$ and that Proposition 15.2.2.3 is valid for $\mathbb{E}_n$-algebras; we wish to show that it is also valid for $\mathbb{E}_{n+1}$-algebras.

Using Theorem HA.5.1.2.2 , we can identify $\mathrm{Alg}_\kappa^{(n+1),\mathrm{aug}}$ with the ∞-category $\mathrm{Alg}(\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})$. of algebra objects of $\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$. Applying Example HA.5.2.3.13 , we see that under this identification, the Koszul duality functor $\mathfrak{D}^{(n+1)}$ corresponds to the composition

$$\mathrm{Alg}(\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})^{\mathrm{op}} \xrightarrow{G} \mathrm{Alg}((\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})^{\mathrm{op}}) \xrightarrow{G'} \mathrm{Alg}(\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})$$

where G is given by the bar construction of §HA.5.2.2 (given on objects by $G(A) = \kappa \otimes_A \kappa$) and G' is induced by the (lax monoidal) functor $\mathfrak{D}^{(n)} : (\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$.

Assume that $A \in \mathrm{Alg}_\kappa^{(n+1),\mathrm{aug}}$ is $(n+1)$-coconnective and locally finite. We have a cofiber sequence of A-modules $A \to \kappa \to Q$ where $\pi_i Q \simeq 0$ for $i > -n$. Using Corollary 14.1.4.3, we deduce that $\pi_i(\kappa \otimes_A Q) \simeq 0$ for $i > -n$ so that $G(A)$ is n-coconnective. Moreover, Proposition 15.1.2.1 shows that $G(A)$ is locally finite (here we use our assumption that $n \geqslant 1$).

Using the inductive hypothesis together with Proposition 15.2.3.1, we deduce that for any sequence $\{A_i\}_{1 \leqslant i \leqslant m}$ of $(n+1)$-connective, locally finite objects of $\mathrm{Alg}_\kappa^{(n+1),\mathrm{aug}}$ and any object $C \in \mathrm{Alg}((\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})^{\mathrm{op}})$, the canonical map

$$\begin{array}{c} \mathrm{Map}_{\mathrm{Alg}((\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})^{\mathrm{op}})}(G(A_1) \otimes \cdots G(A_m), C) \\ \downarrow \\ \mathrm{Map}_{\mathrm{Alg}(\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})}((G'G)(A_1) \otimes \cdots \otimes (G'G)(A_m), G'(C)) \end{array}$$

is a homotopy equivalence. Consequently, to prove Proposition 15.2.2.3, it will suffice to show that for each $B \in \mathrm{Alg}_\kappa^{(n+1),\mathrm{aug}} \simeq \mathrm{Alg}(\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})$, the functor G induces a homotopy equivalence

$$\begin{array}{c} \mathrm{Map}_{\mathrm{Alg}(\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})}(B, A_1 \otimes \cdots \otimes A_m) \\ \downarrow \\ \mathrm{Map}_{\mathrm{Alg}((\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})^{\mathrm{op}})}(G(A_1) \otimes \cdots \otimes G(A_m), G(B)). \end{array}$$

The formula $G(A) \simeq \kappa \otimes_A \kappa$ shows that G is a monoidal functor, so that $G(A_1)\otimes\cdots\otimes G(A_m) \simeq G(A)$ with $A \simeq A_1 \otimes \cdots \otimes A_m$. Note that A is locally finite and $(n+1)$-coconnective. Let F denote a left adjoint to G (given by the cobar construction; see Theorem HA.5.2.2.17). Using Remark 15.2.2.4, we are reduced to proving that the counit map $(F \circ G)(A) \to A$ is an equivalence in $\mathrm{Alg}(\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})^{\mathrm{op}}$.

The monoidal ∞-category $\mathrm{Alg}_\kappa^{(0),\mathrm{aug}}$ admits geometric realizations and totalizations and the unit object is a zero object, so Theorem HA.5.2.2.17 implies that the bar and cobar constructions yield adjoint functors

$$\mathrm{Alg}((\mathrm{Alg}_\kappa^{(0),\mathrm{aug}})^{\mathrm{op}}) \underset{G_0}{\overset{F_0}{\rightleftarrows}} \mathrm{Alg}(\mathrm{Alg}_\kappa^{(0),\mathrm{aug}})^{\mathrm{op}}.$$

Let $\phi : \mathrm{Alg}_\kappa^{(n),\mathrm{aug}} \to \mathrm{Alg}_\kappa^{(0),\mathrm{aug}}$ denote the forgetful functor. Then ϕ is a (symmetric) monoidal functor which preserves geometric realizations of simplicial objects and totalizations of cosimplicial objects, so that ϕ is compatible with the bar and cobar constructions (Example HA.5.2.3.11). It will therefore suffice to show that the counit map $(F_0 \circ G_0)(\phi A) \to \phi(A)$ is an equivalence in $\mathrm{Alg}(\mathrm{Alg}_\kappa^{(0),\mathrm{aug}})^{\mathrm{op}}$. Equivalently, it suffices to show that for each $B \in \mathrm{Alg}(\mathrm{Alg}_\kappa^{(0),\mathrm{aug}})$, the canonical map

$$\mathrm{Map}_{\mathrm{Alg}(\mathrm{Alg}_\kappa^{(0),\mathrm{aug}})}(B, \phi A) \to \mathrm{Map}_{\mathrm{Alg}((\mathrm{Alg}_\kappa^{(0),\mathrm{aug}})^{\mathrm{op}})}(G_0(\phi A), G_0(B))$$

is a homotopy equivalence. Let $G_0' : \mathrm{Alg}((\mathrm{Alg}_\kappa^{(0),\mathrm{aug}})^{\mathrm{op}}) \to \mathrm{Alg}(\mathrm{Alg}_\kappa^{(0),\mathrm{aug}})$ be the functor given by composition with the lax monoidal functor $\mathfrak{D}^{(0)}$. Using Example 15.2.2.6 and Proposition 15.2.3.1, we deduce that G_0' induces a homotopy equivalence

$$\mathrm{Map}_{\mathrm{Alg}((\mathrm{Alg}_\kappa^{(0),\mathrm{aug}})^{\mathrm{op}})}(G_0(\phi A), G_0(B)) \to \mathrm{Map}_{\mathrm{Alg}(\mathrm{Alg}_\kappa^{(0),\mathrm{aug}})}((G_0'G_0)(\phi A), (G_0'G_0)(B)).$$

It will therefore suffice to show that the composite map

$$\begin{aligned} \mathrm{Map}_{\mathrm{Alg}(\mathrm{Alg}_\kappa^{(0),\mathrm{aug}})}(B, \phi A) &\to \mathrm{Map}_{\mathrm{Alg}(\mathrm{Alg}_\kappa^{(0),\mathrm{aug}})}((G_0'G_0)(\phi_A), (G_0'G_0)(B)) \\ &\simeq \mathrm{Map}_{\mathrm{Alg}_\kappa^{(1),\mathrm{aug}}}(\mathfrak{D}^{(1)}(\phi A), \mathfrak{D}^{(1)}(B)) \end{aligned}$$

is a homotopy equivalence. This follows from our inductive hypothesis, since ϕA is 1-connective (in fact, $(n+1)$-coconnective) and locally finite.

15.3 Deformation Theory for $\mathbb{E}_n$-Algebras

Let κ be a field. Our goal in this section is to prove Theorem 15.0.0.9, which asserts that the ∞-category $\mathrm{Moduli}_\kappa^{(n)}$ of formal $\mathbb{E}_n$-moduli problems over κ is equivalent to the ∞-category $\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$ of augmented $\mathbb{E}_n$-algebras over κ. We first introduce a suitable deformation context, and show that our discussion fits into the general paradigm described in §12.1. We will then prove that the Koszul duality functor $\mathfrak{D}^{(n)} : (\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$ of §15.2 is a deformation theory, in the sense of Definition 12.3.3.2 (Theorem 15.3.3.1). We will then use this result to deduce Theorem 15.0.0.9 from Theorem 12.3.3.5.

15.3.1 Augmented $\mathbb{E}_n$-Algebras as a Deformation Context

Let κ be a field and let $n \geqslant 0$ be an integer. Using Theorem HA.7.3.4.13 and Proposition HA.3.4.2.1 , we obtain equivalences of ∞-categories

$$\mathrm{Sp}(\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}) \simeq \mathrm{Mod}_\kappa^{\mathbb{E}_n}(\mathrm{Mod}_\kappa) \simeq \mathrm{Mod}_\kappa .$$

In particular, we can identify the unit object $\kappa \in \mathrm{Mod}_\kappa$ with a spectrum object $E \in \mathrm{Sp}(\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})$, given informally by the formula $\Omega^{\infty-m} E = \kappa \oplus \Sigma^m(\kappa)$. We regard the pair $(\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}, \{E\})$ as a deformation context.

We will need the following generalization of Proposition 14.2.1.2:

Proposition 15.3.1.1. *Let κ be a field, let $n \geqslant 1$, and let $(\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}, \{E\})$ be the deformation context defined above. Then an object $A \in \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$ is Artinian in the sense of Definition 12.1.2.4 if and only if its image in $\mathrm{Alg}_\kappa^{(n)}$ is Artinian in the sense of Definition 15.0.0.1: that is, if and only if A satisfies the following conditions:*

- (a) *The algebra A is connective: that is, $\pi_i A \simeq 0$ for $i < 0$.*
- (b) *The algebra A is truncated: that is, we have $\pi_i A \simeq 0$ for $i \gg 0$.*
- (c) *Each of the homotopy groups $\pi_i A$ is finite dimensional when regarded as a vector space over field κ.*
- (d) *Let $\mathfrak{n}$ denote the radical of the ring $\pi_0 A$ (which is a finite-dimensional associative algebra over κ). Then the canonical map $\kappa \to (\pi_0 A)/\mathfrak{n}$ is an isomorphism.*

Remark 15.3.1.2. Proposition 15.3.1.1 is also valid in the case $n = 0$, provided that we adopt the convention of Remark 15.0.0.5. That is, an object $A \in \mathrm{Alg}_\kappa^{(0),\mathrm{aug}}$ is Artinian (in the sense of Definition 12.1.2.4) if and only if it connective and $\pi_* A$ is a finite-dimensional vector space over κ.

Proof. The "only if" direction follows from Proposition 14.2.1.2 (note that if A is Artinian as an augmented $\mathbb{E}_n$-algebra, then its image in $\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$ is also Artinian). To prove the converse, suppose that $A \in \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$ satisfies conditions (a) through (d). We wish to prove that there exists a finite sequence of maps $A = A_0 \to A_1 \to \cdots \to A_d \simeq \kappa$, where each A_i is a square-zero extension of A_{i+1} by $\Sigma^{m_i}(\kappa)$, for some $m_i \geqslant 0$. If $n = 1$, this follows from

Proposition 14.2.1.2. Let us therefore assume that $n \geqslant 2$. We proceed by induction on the dimension of the κ-vector space $\pi_* A$.

Let m be the largest integer for which $\pi_m A$ does not vanish. We first treat the case $m = 0$. We will abuse notation by identifying A with the underlying commutative ring $\pi_0 A$. Let $\mathfrak{n}$ denote the radical of A. If $\mathfrak{n} = 0$, then condition (d) implies that $A \simeq \kappa$ so there is nothing to prove. Otherwise, we can view $\mathfrak{n}$ as a nonzero module over the commutative ring A. It follows that there exists a nonzero element $x \in \mathfrak{n}$ which is annihilated by $\mathfrak{n}$. Using (d) again, we deduce that the subspace $\kappa x \subseteq A$ is an ideal of A. Let A' denote the quotient ring $A/\kappa x$. Theorem HA.7.4.1.26 implies that A is a square-zero extension of A' by κ. The inductive hypothesis implies that A' is Artinian, so that A is also Artinian.

Now suppose that $m > 0$ and let $M = \pi_m A$. Then M is a nonzero module over the finite dimensional κ-algebra $\pi_0 A$. It follows that there is a nonzero element $x \in M$ which is annihilated by the action of the radical $\mathfrak{n} \subseteq \pi_0 A$. Let M' denote the quotient of M by the submodule generated by x (which, by virtue of (d), coincides with κx), and let $A'' = \tau_{\leqslant n-1} A$. It follows from Theorem HA.7.4.1.26 that there is a pullback diagram

$$\begin{array}{ccc} A & \longrightarrow & \kappa \\ \downarrow & & \downarrow \\ A'' & \longrightarrow & \kappa \oplus \Sigma^{m+1}(M). \end{array}$$

Set $A' = \kappa \times_{\kappa \oplus \Sigma^{m+1}(M')} A''$. Then $A \simeq \kappa \times_{\kappa \oplus \Sigma^{m+1}(\kappa)} A'$, so we have an elementary map $A \to A'$. Using the inductive hypothesis we deduce that A' is Artinian, so that A is also Artinian. □

Proposition 15.3.1.3. *Let κ be a field and let $f : A \to B$ be a morphism in $\mathrm{Alg}_\kappa^{(n),\mathrm{art}}$. Then f is small (when regarded as a morphism in $\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$) if and only if it induces a surjection $\pi_0 A \to \pi_0 B$.*

Proof. If $n = 1$, the desired result follows from Proposition 14.2.1.3. We will assume that $n \geqslant 2$, and leave the case $n = 0$ to the reader. The "only if" direction follows from Proposition 14.2.1.3 (note that if f is small, then the induced map between the underlying $\mathbb{E}_1$-algebras is also small). We first treat the case where $B \simeq A \oplus \Sigma^j(M)$, for some $M \in \mathrm{Mod}_A^{\mathbb{E}_n}(\mathrm{Mod}_\kappa)^\heartsuit$ and some $j \geqslant 1$. According to Remark 15.1.3.6, the abelian category $\mathrm{Mod}_A^{\mathbb{E}_n}(\mathrm{Mod}_\kappa)^\heartsuit$ is equivalent to the category of modules over the commutative ring $\pi_0 B$. Since M is finite dimensional as a vector space over κ, it admits a finite filtration

$$0 = M_0 \subseteq M_1 \subseteq \cdots \subseteq M_m = M,$$

where each of the successive quotients M_i / M_{i-1} is isomorphic to κ. This filtration determines a factorization of f as a composition

$$A \simeq A \oplus \Sigma^j(M_0) \to A \oplus \Sigma^j(M_1) \to \cdots \to A \oplus \Sigma^j(M_m) = B.$$

Each of the maps $A \oplus \Sigma^j(M_i) \to A \oplus \Sigma^j(M_{i+1})$ is elementary, so that f is small.

We now treat the general case. Note that the map $\pi_0 A \times_{\pi_0 B} B \to B$ is a pullback of the map $\pi_0 A \to \pi_0 B$ and therefore small (the map $\pi_0 A \to \pi_0 B$ is even small as a morphism of $\mathbb{E}_\infty$-algebras over κ, by Lemma 12.1.3.8). It will therefore suffice to show that the map $A \to \pi_0 A \times_{\pi_0 B} B$ is small. We will prove that each of the maps

$$\tau_{\leqslant j} A \times_{\tau_{\leqslant j} B} B \to \pi_0 A \times_{\pi_0 B} B$$

is small; taking $j \gg 0$ we will obtain the desired result. The proof proceeds by induction on j, the case $j = 0$ being trivial. Assume that $j > 0$; by the inductive hypothesis, we are reduced to proving that the map $\theta : \tau_{\leqslant j} A \times_{\tau_{\leqslant j} B} B \to \tau_{\leqslant j-1} A \times_{\tau_{\leqslant j-1} B} B$ is small.

Factor θ as a composition $\tau_{\leqslant j} A \times_{\tau_{\leqslant j} B} B \xrightarrow{\theta'} \tau_{\leqslant j} A \times_{\tau_{\leqslant j-1} B} B \xrightarrow{\theta''} \tau_{\leqslant j-1} A \times_{\tau_{\leqslant j-1} B} B$. The map θ'' is a pullback of the truncation map $u : \tau_{\leqslant j} A \to \tau_{\leqslant j-1} A$. It follows from Corollary HA.7.4.1.28 that u exhibits $\tau_{\leqslant j} A$ as a square-zero extension of $\tau_{\leqslant j-1} A$, so that we have a pullback square

$$\begin{array}{ccc} \tau_{\leqslant j} A & \xrightarrow{u} & \tau_{\leqslant j-1} A \\ \downarrow & & \downarrow \\ \tau_{\leqslant j-1} A & \xrightarrow{u_0} & (\tau_{\leqslant j-1} A) \oplus \Sigma^{j+1}(\pi_j A). \end{array}$$

Here the map u_0 is small by the argument given above, so that u is small and therefore θ'' is small. We will complete the proof by showing that θ' is small. Note that θ' is a pullback of the diagonal map $\delta : \tau_{\leqslant j} B \to \tau_{\leqslant j} B \times_{\tau_{\leqslant j-1} B} \tau_{\leqslant j} B$. Since $\tau_{\leqslant j} B$ is a square-zero extension of $\tau_{\leqslant j-1} B$ by $\Sigma^j(\pi_j B)$ (Corollary HA.7.4.1.28), the truncation map $\tau_{\leqslant j} B \to \tau_{\leqslant j-1} B$ is a pullback of the canonical map $\tau_{\leqslant j-1} B \to \tau_{\leqslant j-1} B \oplus \Sigma^{j+1}(\pi_j B)]$. It follows that δ' is a pullback of the map

$$\delta' : \tau_{\leqslant j-1} B \to \tau_{\leqslant j-1} B \times_{\tau_{\leqslant j-1} B \oplus \Sigma^{j+1}(\pi_j B)} \tau_{\leqslant j-1} B \simeq \tau_{\leqslant j-1} B \oplus \Sigma^j(\pi_j B).$$

Since $j \geqslant 1$, the first part of the proof shows that δ' is small. □

Corollary 15.3.1.4. *Let κ be a field, let $n \geqslant 0$ be an integer, and let and let $X : \mathrm{Alg}_\kappa^{(n),\mathrm{art}} \to \mathcal{S}$ be a functor. Then X belongs to the full subcategory $\mathrm{Moduli}_\kappa^{(n)}$ of Definition 15.0.0.7 if and only if it is a formal moduli problem in the sense of Definition 12.1.3.1.*

Proof. The "if" direction follows immediately from Proposition 15.3.1.3. For the converse, suppose that X satisfies the conditions of Definition 15.0.0.7; we wish to show that X is a formal moduli problem. According to Proposition 12.1.3.2, it will suffice to show that for every pullback diagram in $\mathrm{Alg}_\kappa^{(n),\mathrm{art}}$

$$\begin{array}{ccc} A & \longrightarrow & B \\ \downarrow & & \downarrow \\ \kappa & \longrightarrow & \kappa \oplus \Sigma^m(\kappa) \end{array}$$

satisfying $m > 0$, the associated diagram of spaces

$$\begin{array}{ccc} X(A) & \longrightarrow & X(B) \\ \downarrow & & \downarrow \\ X(\kappa) & \longrightarrow & X(\kappa \oplus \Sigma^m(\kappa)) \end{array}$$

is also a pullback square. This follows immediately from condition (2) of Definition 15.0.0.7. □

15.3.2 Digression: The Koszul Dual of a Free Algebra

Let κ be a field, and let $\mathrm{Free}^{(n)} : \mathrm{Mod}_\kappa \to \mathrm{Alg}_\kappa^{(n)}$ be a left adjoint to the forgetful functor (so that $\mathrm{Free}^{(n)}$ assigns to every κ-module spectrum V the free $\mathbb{E}_n$-algebra $\bigoplus_{n \geqslant 0} \mathrm{Sym}^n_{\mathbb{E}_\kappa}(V)$). Note that $\mathrm{Free}^{(n)}(0) \simeq \kappa$, so that $\mathrm{Free}^{(n)}$ determines a functor

$$\mathrm{Free}^{\mathrm{aug}} : \mathrm{Mod}_\kappa \simeq (\mathrm{Mod}_\kappa)_{/0} \to (\mathrm{Alg}_\kappa^{(n)})_{/\kappa} \simeq \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}.$$

Proposition 15.3.2.1. *Let κ be a field and let $\mathfrak{D}^{(n)} : (\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$ be the Koszul duality functor. Then the composition $\mathfrak{D}^{(n)} \circ \mathrm{Free}^{\mathrm{aug}}$ is equivalent to the functor $\mathrm{Mod}_\kappa^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$ given by $V \mapsto \kappa \oplus \Sigma^{-n}(V^\vee)$, where $V^\vee$ denotes the κ-linear dual of V.*

Proof. The functor $\mathfrak{D}^{(n)} \circ \mathrm{Free}^{\mathrm{aug}}$ admits a left adjoint and is therefore left exact. Since the ∞-category Mod_κ is stable, Proposition HA.1.4.2.22 implies that $\mathfrak{D}^{(n)} \circ \mathrm{Free}^{(n)}$ factors as a composition

$$\mathrm{Mod}_\kappa^{\mathrm{op}} \xrightarrow{T} \mathrm{Sp}(\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}) \xrightarrow{\Omega^\infty} \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}.$$

Note that $\mathrm{Sp}(\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})$ is equivalent to Mod_κ, and that under this equivalence the functor $\Omega^\infty : \mathrm{Sp}(\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}) \to \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$ is given by the formation of square-zero extensions $V \mapsto \kappa \oplus V$ (Theorem HA.7.3.4.7). It follows that we can identify T with the functor $\mathrm{Mod}_\kappa^{\mathrm{op}} \to \mathrm{Mod}_\kappa$ given by the composition

$$\mathrm{Mod}_\kappa^{\mathrm{op}} \xrightarrow{\mathrm{Free}^{\mathrm{aug}}} (\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})^{\mathrm{op}} \xrightarrow{\mathfrak{D}^{(n)}} \mathrm{Alg}_\kappa^{(n),\mathrm{aug}} \xrightarrow{I} \mathrm{Mod}_\kappa,$$

where I denotes the functor which carries each augmented $\mathbb{E}_n$-algebra A to its augmentation ideal. The composition $I \circ \mathfrak{D}^{(n)}$ assigns to each augmented $\mathbb{E}_n$-algebra B its shifted tangent fiber $\underline{\mathrm{Map}}_{\mathrm{Mod}_B^{\mathbb{E}_n}}(\Sigma^n(L_{B/\kappa}), \kappa)$ (see Example HA.7.3.5.7), so that the composition $I \circ \mathfrak{D}^{(n)} \circ \mathrm{Free}^{(n)}$ is given by $V \mapsto (\Sigma^n(V))^\vee \simeq \Sigma^{-n}(V^\vee)$. □

15.3.3 Koszul Duality as a Deformation Theory

We can now formulate the main result of this section.

Theorem 15.3.3.1. *Let κ be a field and let $n \geqslant 0$ be an integer. Then the Koszul duality functor $\mathfrak{D}^{(n)} : (\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$ is a deformation theory (in the sense of Definition 12.3.3.2).*

Proof. We show that the Koszul duality functor $\mathfrak{D}^{(n)} : \mathfrak{D}^{(n)} : (\mathrm{Alg}_\kappa^{(n),\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$ satisfies axioms $(D1)$ through $(D4)$ of Definitions 12.3.1.1 and 12.3.3.2:

$(D1)$ The ∞-category $\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$ is presentable: this follows from Corollary HA.3.2.3.5 .

$(D2)$ The functor $\mathfrak{D}^{(n)}$ admits a left adjoint. In fact, this left adjoint is given by the opposite of $\mathfrak{D}^{(n)}$ (see Remark 15.2.1.5).

$(D3)$ Let $\mathbf{B}_0 \subseteq \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$ be the full subcategory spanned by those augmented $\mathbb{E}_n$-algebras A over κ, where A is coconnective and both A and $\int A$ are locally finite. We will verify that this subcategory satisfies the requirements of Definition 12.3.1.1:

- (a) For every object $A \in \mathbf{B}_0$, the biduality map $A \to \mathfrak{D}^{(n)}\mathfrak{D}^{(n)}(A)$ is an equivalence. This follows from Theorem 15.2.2.1.
- (b) The subcategory $\mathbf{B}_0$ contains the initial object $\kappa \in \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$.
- (c) For each $m \geqslant 1$, there exists an object $K_m \in \mathbf{B}_0$ and an equivalence $\alpha : \kappa \oplus \Sigma^m(\kappa) \simeq \mathfrak{D}^{(n)} K_m$. In fact, we can take K_m to be the free $\mathbb{E}_n$-algebra generated by $\Sigma^{-m-n}(\kappa)$. This belongs to $\mathbf{B}_0$ by virtue of Proposition 15.1.4.1, and Proposition 15.3.2.1 supplies the equivalence α.
- (d) For every pushout diagram

$$\begin{array}{ccc} K_m & \longrightarrow & A \\ \downarrow{\scriptstyle \epsilon} & & \downarrow \\ \kappa & \longrightarrow & A', \end{array}$$

  where $A \in \mathbf{B}_0$ and ϵ is the canonical augmentation on K_m, the object A' also belongs to $\mathbf{B}_0$. This follows immediately from Propositions 15.1.5.1 and 15.1.4.1.

$(D4)$ Arguing as in the proof of Theorem 15.0.0.9, we see that the functor $e : \mathrm{Alg}_\kappa^{(n),\mathrm{aug}} \to \mathrm{Sp}$ appearing in Definition 12.3.3.2 is given by $A \mapsto \Sigma^n \mathfrak{m}_A$, where $\mathfrak{m}_A$ denotes the augmentation ideal of A. This functor is obviously conservative, and preserves sifted colimits by Proposition HA.3.2.3.1 .

□

Proof of Theorem 15.0.0.9. Let κ be a field and let $n \geqslant 0$ be an integer. Define a functor $\Psi : \mathrm{Alg}_\kappa^{(n),\mathrm{aug}} \to \mathrm{Fun}(\mathrm{Alg}_\kappa^{(n),\mathrm{art}}, \mathcal{S})$ by the formula $\Psi(A)(R) = \mathrm{Map}_{\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}}(\mathfrak{D}^{(n)}(R), A)$. Combining Theorem 15.3.3.1, Theorem 12.3.3.5, and Corollary 15.3.1.4, we deduce that

Ψ is a fully faithful embedding whose essential image is the full subcategory $\mathrm{Moduli}_\kappa^{(n)} \subseteq \mathrm{Fun}(\mathrm{Alg}_\kappa^{(n),\mathrm{art}}, \mathcal{S})$ spanned by the formal moduli problems. If $m \geqslant 0$, then Proposition 15.1.4.1 implies that $\mathrm{Free}^{\mathrm{aug}}(\Sigma^{-m-n}(\kappa))$ is n-coconnective and locally finite, so the the biduality map

$$\mathrm{Free}^{\mathrm{aug}}(\Sigma^{-m-n}(\kappa)) \to \mathfrak{D}^{(n)}\mathfrak{D}^{(n)}\,\mathrm{Free}^{\mathrm{aug}}(\Sigma^{-m-n}(\kappa))$$

is an equivalence (Theorem 15.2.2.1). Using Proposition 15.3.2.1, we obtain canonical homotopy equivalences

$$\begin{aligned}
\Psi(A)(\kappa \oplus \Sigma^m(\kappa)) &\simeq \Psi(A)(\mathfrak{D}^{(n)}\,\mathrm{Free}^{\mathrm{aug}}(\Sigma^{-m-n}(\kappa)))\\
&\to \mathrm{Map}_{\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}}(\mathfrak{D}^{(n)}\mathfrak{D}^{(n)}\,\mathrm{Free}^{\mathrm{aug}}(\Sigma^{-m-n}(\kappa)), A)\\
&\to \mathrm{Map}_{\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}}(\mathrm{Free}^{\mathrm{aug}}(\Sigma^{-m-n}(\kappa)), A)\\
&\simeq \Omega^{\infty-m-n}\mathfrak{m}_A,
\end{aligned}$$

where $\mathfrak{m}_A$ denotes the augmentation ideal of A. These equivalences are natural in m, and therefore give rise to an equivalence of spectra $T_{\Psi(A)} \simeq \Sigma^n \mathfrak{m}_A$ (depending functorially on A). □

Example 15.3.3.2. Suppose that $n = 0$ in the situation of Theorem 15.0.0.9. Then the Koszul duality functor $\mathfrak{D}^{(0)} : (\mathrm{Alg}_\kappa^{(0),\mathrm{aug}})^{\mathrm{op}} \mapsto \mathrm{Alg}_\kappa^{(0),\mathrm{aug}}$ is given by $\kappa \oplus V \mapsto \kappa \oplus V^\vee$ (see Example 15.2.1.3). It follows that the functor $\Psi : \mathrm{Alg}_\kappa^{(0),\mathrm{aug}} \to \mathrm{Moduli}_\kappa^{(0)}$ is given by

$$\begin{aligned}
\Psi(\kappa \oplus W)(\kappa \oplus V) &= \mathrm{Map}_{\mathrm{Alg}_\kappa^{(0),\mathrm{aug}}}(\kappa \oplus V^\vee, \kappa \oplus W)\\
&\simeq \mathrm{Map}_{\mathrm{Mod}_\kappa}(V^\vee, W)\\
&\simeq \Omega^\infty(V \otimes_\kappa W).
\end{aligned}$$

Here the last equivalence follows from the observation that V is a dualizable object of Mod_κ.

We can summarize the situation as follows: every object $W \in \mathrm{Mod}_\kappa$ determines a formal $\mathbb{E}_0$-moduli problem, given by the formula $\kappa \oplus V \mapsto \Omega^\infty(V \otimes_\kappa W)$. Moreoever, every formal $\mathbb{E}_0$-moduli problem arises in this way, up to equivalence.

15.3.4 Application: Prorepresentable Formal $\mathbb{E}_n$-Moduli Problems

We close this section by proving a generalization of Proposition 14.2.3.1:

Proposition 15.3.4.1. *Let κ be a field and let $X : \mathrm{Alg}_\kappa^{(n),\mathrm{art}} \to \mathcal{S}$ be a formal $\mathbb{E}_n$-moduli problem over κ. The following conditions are equivalent:*

(1) *The functor X is prorepresentable (see Definition 12.5.3.1).*

(2) *Let $X(E)$ denote the tangent complex of X. Then $\pi_i X(E) \simeq 0$ for $i > 0$.*

(3) *The functor X has the form $\Psi(A)$, where $A \in \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$ is n-coconnective coconnective and $\Psi : \mathrm{Alg}_\kappa^{(n),\mathrm{aug}} \to \mathrm{Moduli}_\kappa^{(n)}$ is the equivalence of Theorem 15.0.0.9.*

Lemma 15.3.4.2. *Let A be an augmented $\mathbb{E}_n$-algebra over a field κ. If A is connective, then the Koszul dual $\mathfrak{D}^{(n)}(A)$ is n-coconnective.*

Proof. Let $\mathrm{Mod}_A^{\mathbb{E}_n}$ denote the ∞-category of $\mathbb{E}_n$-modules over A in the ∞-category Mod_κ, and regard $\mathrm{Mod}_A^{\mathbb{E}_n}$ as tensored over Mod_κ. As an object of Mod_κ, we can identify $\mathfrak{D}^{(n)}(A)$ as a classifying object (in Mod_κ) for morphisms from A to κ in $\mathrm{Mod}_A^{\mathbb{E}_n}$ (see Example HA.5.3.1.5 and Theorem HA.5.3.1.30). Theorem HA.7.3.5.1 supplies fiber sequence

$$\int A \to A \to \Sigma^n L_{A/\kappa}$$

in the ∞-category $\mathrm{Mod}_A^{\mathbb{E}_n}$, where $L_{A/\kappa}$ denote the relative cotangent complex of A over κ as an $\mathbb{E}_n$-algebra. We therefore obtain a fiber sequence

$$\underline{\mathrm{Map}}_{\mathrm{Mod}_A^{\mathbb{E}_n}}(\Sigma^n L_{A/\kappa}, \kappa) \to \mathfrak{D}^{(n)}(A) \xrightarrow{\epsilon_A} \kappa$$

in the ∞-category Mod_κ. The map ϵ_A depends functorially on A and is an equivalence in the case $A = \kappa$, and can therefore be identified with the augmentation on $\mathfrak{D}^{(n)}(A)$. We may therefore identify the augmentation ideal $\mathfrak{m}_{\mathfrak{D}^{(n)}(A)}$ with a classifying object for morphisms from $\Sigma^n L_{A/\kappa}$ to κ in $\mathrm{Mod}_A^{\mathbb{E}_n}$. To prove that $\mathfrak{D}^{(n)}(A)$ is n-coconnective, it suffices to show that the mapping space

$$\mathrm{Map}_{\mathrm{Mod}_A^{\mathbb{E}_n}}(L_{A/\kappa}, \kappa) \simeq \mathrm{Map}_{\mathrm{Alg}_\kappa^{(n),\mathrm{aug}}}(A, \kappa[\epsilon]/(\epsilon^2))$$

is discrete. This is clear, since A is connective and $\kappa[\epsilon]/(\epsilon^2)$ is discrete. □

Proof of Proposition 15.3.4.1. The equivalence of (2) and (3) follows from the observation that for $X = \Psi(A)$, we have $\pi_i X(E) \simeq \pi_{i-n}\mathfrak{m}_A$, where $\mathfrak{m}_A$ is the augmentation ideal of A. We next prove that (1) $\Rightarrow$ (2). Since the construction $X \mapsto X(E)$ commutes with filtered colimits, we may reduce to the case where $X = \mathrm{Spf}\, R$ is representable by an object $R \in \mathrm{Alg}_\kappa^{(n),\mathrm{art}}$. Then R is connective and the desired result follows from Lemma 15.3.4.2.

We now complete the proof by showing that (3) $\Rightarrow$ (1). Let $A \in \mathrm{Alg}_\kappa^{(n),\mathrm{aug}}$ be n-coconnective, and choose a sequence of maps

$$\kappa = A(0) \to A(1) \to A(2) \to \cdots$$

as in the proof of Proposition 15.1.5.1. Then $A = \varinjlim A(i)$, so that $X \simeq \varinjlim X(i)$ with $X(i) = \Psi(A(i))$. To prove that X is prorepresentable, it will suffice to show that each $X(i)$ is prorepresentable. We proceed by induction on i, the case $i = 0$ being trivial.

Assume that $X(i)$ is prorepresentable. By construction, we have a pushout diagram

$$\begin{array}{ccc} \mathrm{Free}^{(n)}(V) & \longrightarrow & A(i) \\ \downarrow & & \downarrow \\ \kappa & \longrightarrow & A(i+1) \end{array}$$

where $\pi_j V \simeq 0$ for $j \geqslant -n$. For $m \geqslant n$, form a pushout diagram

$$\begin{array}{ccc} \mathrm{Free}^{(n)}(\tau_{\geqslant -m} V) & \longrightarrow & A(i) \\ \downarrow & & \downarrow \\ \kappa & \longrightarrow & A(i,m), \end{array}$$

so that $A(i+1) \simeq \varinjlim_m A(i,m)$. Then $X(i+1) \simeq \varinjlim_m \Psi(A(i,m))$, so we are reduced to proving that each $\Psi(A(i,m))$ is prorepresentable. We proceed by induction on m. If $m = n$, then $A(i,m) \simeq A(i)$ and the desired result follows from our inductive hypothesis. Assume that $m > n$ and that $\Psi(A(i,m-1))$ is prorepresentable. Let $W = \pi_{-m} V$, so that we have a pushout diagram

$$\begin{array}{ccc} \mathrm{Free}^{(n)}(\Sigma^{-m} W) & \longrightarrow & A(i,m-1) \\ \downarrow & & \downarrow \\ \kappa & \longrightarrow & A(i,m). \end{array}$$

Write W as a union of its finite-dimensional subspaces $\{W_\alpha\}$. For every finite dimensional subspace $W_\alpha \subseteq W$, form a pushout diagram

$$\begin{array}{ccc} \mathrm{Free}^{(n)}(\Sigma^{-m} W_\alpha) & \longrightarrow & A(i,m-1) \\ \downarrow & & \downarrow \\ \kappa & \longrightarrow & A(i,W_\alpha). \end{array}$$

Then $\Psi(A(i,m))$ is a filtered colimit of the objects $\Psi(A(i,W_\alpha))$. It will therefore suffice to show that each $\Psi(A(i,W_\alpha))$ is prorepresentable. We proceed by induction on the dimension of W_α; if that dimension is zero, then $A(i,W_\alpha) \simeq A(i,m-1)$ and the result is clear. If W_α has positive dimension, then we can choose a subspace W'_α of codimension 1. Then we have a pushout diagram

$$\begin{array}{ccc} \mathrm{Free}^{(n)}(\Sigma^{-m}(\kappa)) & \longrightarrow & A(i,W'_\alpha) \\ \downarrow & & \downarrow \\ \kappa & \longrightarrow & A(i,W_\alpha), \end{array}$$

hence a pushout diagram of formal moduli problems

$$\begin{array}{ccc} \mathrm{Spf}(\kappa \oplus \Sigma^{m-n}(\kappa)) & \longrightarrow & A(i, W'_\alpha) \\ \downarrow & & \downarrow \\ \mathrm{Spf}(\kappa) & \longrightarrow & \Psi(A(i, W_\alpha)). \end{array}$$

We conclude the proof by invoking Lemma 12.5.3.4. $\square$

Chapter 16

Examples of Formal Moduli Problems

In this section, we will illustrate our theory of formal moduli problems by considering some examples which arise naturally in algebraic geometry. We begin by considering the formal deformation theory of algebraic varieties. Let Z be an algebraic variety defined over a field κ. If R is a local Artin ring with residue field κ, then a *deformation* of Z over R is a pair (Z_R, α), where Z is a flat R-scheme and α is an isomorphism of Z with the fiber product $Z_R \times_{\operatorname{Spec} R} \operatorname{Spec} \kappa$ (see Example 11.5.0.7). The condition that Z_R be flat over R is equivalent to the requirement that the diagram

$$\begin{array}{ccc} Z & \longrightarrow & Z_R \\ \downarrow & & \downarrow \\ \operatorname{Spec} \kappa & \longrightarrow & \operatorname{Spec} R \end{array}$$

be a pullback square not only in the category of schemes, but also in the ∞-category of spectral algebraic spaces. This suggests the following more general definition: given a connective $\mathbb{E}_\infty$-ring R equipped with a map $R \to \kappa$, a *deformation* of Z over R is a spectral algebraic space Z_R over R, equipped with an equivalence $\mathsf{Z} \simeq \mathsf{Z}_R \times_{\operatorname{Sp\acute{e}t} R} \operatorname{Sp\acute{e}t} \kappa$, where Z denotes the spectral algebraic space over κ determined by Z (see Proposition **??**). The collection of all deformations of Z over R can be organized into an ∞-groupoid $M(R)$. The construction $R \mapsto M(R)$ determines a functor $M : \mathrm{CAlg}^{\mathrm{art}}_\kappa \to \mathcal{S}$. In this situation, we will show that the functor M is a formal moduli problem over κ (in the sense of Definition

12.1.3.1). In other words, we will show that for every pullback diagram

$$\begin{array}{ccc} R & \longrightarrow & R_0 \\ \downarrow & & \downarrow \\ R_1 & \longrightarrow & R_{01} \end{array}$$

in $\mathrm{CAlg}^{\mathrm{art}}_{\kappa}$, if the maps $\pi_0 R_0 \rightarrow \pi_0 R_{01} \leftarrow \pi_0 R_1$ are surjective, then $M(R)$ can be identified with the fiber product $M(R_0) \times_{M(R_{01})} M(R_1)$ in the ∞-category of spaces. More concretely, this means that giving a deformation Z_R of Z over R is equivalent to giving deformations Z_0 and Z_1 over R_0 and R_1 respectively, together with an equivalence between the resulting deformations of Z over R_{01}. We will verify this in §16.3, using the fact that any such deformation Z_R can be reconstructed as the pushout $\mathsf{Z}_0 \amalg_{\mathsf{Z}_{01}} \mathsf{Z}_1$, where $\mathsf{Z}_{01} = \mathrm{Sp\acute{e}t}\, R_{01} \times_{\mathrm{Sp\acute{e}t}\, R_0} \mathsf{Z}_0 \simeq \mathrm{Sp\acute{e}t}\, R_{01} \times_{\mathrm{Sp\acute{e}t}\, R_1} \mathsf{Z}_1$. The proof will use some general facts about pushouts of spectral Deligne-Mumford stacks along closed immersions which we establish in §16.1, together with an analysis of the ∞-category of quasi-coherent sheaves on a pushout which we carry out in §16.2.

Another important class of formal moduli problems arises from studying the deformation theory of (quasi)-coherent sheaves on algebraic varieties. Let $Z \rightarrow \mathrm{Spec}\, \kappa$ be as above, and suppose we are given a (discrete) quasi-coherent sheaf $\mathscr{F}$ on Z. If R is a local Artinian κ-algebra with residue field κ, a *deformation* of over R is a quasi-coherent sheaf $\mathscr{F}_R$ over the R-scheme $Z_R = \mathrm{Spec}\, R \times_{\mathrm{Spec}\, \kappa} Z$ which is flat over R, together with an isomorphism $\mathscr{F} \simeq \alpha^* \mathscr{F}_R$, where $\alpha : Z \rightarrow Z_R$ denotes the map of schemes determined by the augmentation $R \rightarrow \kappa$. Once again, the flatness of $\mathscr{F}_R$ over R admits a natural formulation in the language of spectral algebraic geometry: it is equivalent to the requirement that $\mathscr{F}$ be given by the pullback of $\mathscr{F}_R$ along α not only in the abelian category $\mathrm{QCoh}(Z)^{\heartsuit}$, but also in the stable ∞-category $\mathrm{QCoh}(Z)$ studied in Chapter I (here we abuse notation slightly by identifying Z with the associated spectral algebraic space). By virtue of Corollary **??**, we can identify deformations of $\mathscr{F}$ with inverse images of $\mathscr{F}$ under the extension-of-scalars functor $\mathrm{LMod}_R(\mathrm{QCoh}(Z)) \rightarrow \mathrm{LMod}_{\kappa}(\mathrm{QCoh}(Z)) \simeq \mathrm{QCoh}(Z)$, where we regard $\mathrm{QCoh}(Z)$ as a κ-linear ∞-category.

More generally, let κ be a field and let $\mathcal{C}$ be any prestable κ-linear ∞-category (see Definition D.1.4.1). We can associate to $\mathcal{C}$ several deformation-theoretic problems:

(a) Fix an object $C \in \mathcal{C}$, and let $R \in \mathrm{CAlg}^{\mathrm{art}}_{\kappa}$ be an Artinian $\mathbb{E}_{\infty}$-algebra over κ. A *deformation of* C *over* R is an object $C_R \in \mathrm{LMod}_R(\mathcal{C})$, together with an equivalence $C \simeq \kappa \otimes_R C_R$. Let $X(R)$ denote the ∞-category $\mathrm{LMod}_R(\mathcal{C}) \times_{\mathcal{C}} \{C\}$ of deformations of C over R.

(b) For $R \in \mathrm{CAlg}^{\mathrm{art}}_{\kappa}$, a *deformation of* $\mathcal{C}$ *over* R is a prestable R-linear ∞-category $\mathcal{C}_R$

equipped with an equivalence $\mathcal{C} \simeq \kappa \otimes_R \mathcal{C}_R$. Let $Y(R) = \mathrm{LinCat}_R^{\mathrm{PSt}} \times_{\mathrm{LinCat}_\kappa^{\mathrm{PSt}}} \{\mathcal{C}\}$ denote the ∞-category of deformations of $\mathcal{C}$ over R.

We will see later that for every object $R \in \mathrm{CAlg}_\kappa^{\mathrm{art}}$, the ∞-categories $X(R)$ and $Y(R)$ are essentially small Kan complexes. Consequently, we can view X and Y as functors from the ∞-category $\mathrm{CAlg}_\kappa^{\mathrm{art}}$ to the ∞-category $\mathcal{S}$ of spaces. Our goal in the latter part of this section is to analyze the behavior of these functors. We immediately encounter an obstacle: the functors X and Y need not be formal moduli problems, in the sense of Definition 12.1.3.1. Suppose, for example, that we are given a pullback diagram σ :

$$\begin{array}{ccc} R & \longrightarrow & R_0 \\ \downarrow & & \downarrow \\ R_1 & \longrightarrow & R_{01} \end{array}$$

in $\mathrm{CAlg}_\kappa^{\mathrm{art}}$, where the maps $\pi_0 R_0 \to \pi_0 R_{01} \leftarrow \pi_0 R_1$ are surjective. If $C \in \mathcal{C}$ and C_R is a deformation of C over R, then we will see that C_R is uniquely determined by the objects $C_0 = R_0 \otimes_R C_R$, $C_1 = R_1 \otimes_R C_{R_1}$, together with the evident equivalence

$$R_{01} \otimes_{R_0} C_0 \simeq R_{01} \otimes_R C_R \simeq R_{01} \otimes_{R_1} C_1$$

(see Proposition 16.5.2.2). More precisely, the functor X described in (a) determines a fully faithful embedding (of Kan complexes)

$$X(R) \to X(R_0) \times_{X(R_{01})} X(R_1),$$

but this map need not be essentially surjective (see Warning 16.2.0.3). The functor Y described in (b) is even more problematic: the map

$$Y(R) \to Y(R_0) \times_{Y(R_{01})} Y(R_1)$$

need not be fully faithful in general, but always has discrete homotopy fibers (Proposition 16.6.2.1): that is, we can regard $Y(R)$ as a covering space of $Y(R_0) \times_{Y(R_{01})} Y(R_1)$. To accommodate these examples, it is useful to introduce a weaker version of the axiomatics developed in Chapter 12. For every integer $n \geqslant 0$, we will define the notion of a *n-proximate formal moduli problem* (Definition 16.4.1.5). When $n = 0$, we recover the notion of formal moduli problem introduced in Definition 12.1.3.1. The requirement that a functor Z be an n-proximate formal moduli problem becomes increasingly weak as n grows. Nonetheless, we will show that an n-proximate formal moduli problem Z is not far from being a formal moduli problem: namely, there exists an (essentially unique) formal moduli problem $Z^\wedge$ and a natural transformation $Z \to Z^\wedge$ such that, for every test algebra R, the map of spaces $Z(R) \to Z^\wedge(R)$ has $(n-1)$-truncated homotopy fibers (Theorem 16.4.2.1).

In §16.5, we will turn our attention to the functor X described above, which classifies the deformations of a fixed object $C \in \mathcal{C}$. We begin by observing that the definition of $X(R)$ does not require the assumption that R is commutative. Rather, the functor X is naturally defined on the ∞-category $\mathrm{Alg}_\kappa^{\mathrm{art}}$ of Artinian $\mathbb{E}_1$-algebras over κ. We may therefore regard the construction $R \mapsto X(R)$ as a functor $X : \mathrm{Alg}_\kappa^{\mathrm{art}} \to \mathcal{S}$, which we will prove is a 1-proximate formal moduli problem (Corollary 16.5.3.2). Using Theorem 16.4.2.1, we can choose an embedding of X into a formal moduli problem $\overline{X} : \mathrm{Alg}_\kappa^{\mathrm{art}} \to \mathcal{S}$. According to Theorem 14.0.0.5 (and its proof), the functor $\overline{X}$ is given by $\overline{X}(R) = \mathrm{Map}_{\mathrm{Alg}_\kappa^{\mathrm{aug}}}(\mathfrak{D}^{(1)}(R), A)$, for some augmented $\mathbb{E}_1$-algebra A over κ. Our main result (Theorem 16.5.4.1) characterizes this algebra: the augmentation ideal $\mathfrak{m}_A$ can be identified (as a nonunital $\mathbb{E}_1$-algebra) with the endomorphism algebra of the object $C \in \mathcal{C}$.

Remark 16.0.0.1. Efimov, Lunts, and Orlov have made an extensive study of a variant of the deformation functor X described above. We refer the reader to [56], [57], and [58] for details. The global structure of moduli spaces of objects of (well-behaved) differential graded categories is treated in [212].

In §16.6, we will study the functor Y which classifies deformations of∞-category $\mathcal{C}$ itself. Once again, the definition of the space $Y(R)$ does not require the assumption that R is commutative: it requires only the ability to talk about prestable R-linear ∞-category. We can therefore regard the construction $R \mapsto Y(R)$ as a functor $Y : \mathrm{Alg}_\kappa^{(2),\mathrm{art}} \to \mathcal{S}$, which we will prove to be a 2-proximate formal moduli problem (Corollary 16.6.2.4). Using Theorem 16.4.2.1, we deduce the existence of a formal moduli problem $\overline{Y} : \mathrm{Alg}_\kappa^{(2),\mathrm{art}} \to \mathcal{S}$ and a natural transformation $Y \to \overline{Y}$ which induces a covering map $Y(R) \to \overline{Y}(R)$ for each $R \in \mathrm{Alg}_\kappa^{(2),\mathrm{art}}$. According to Theorem 15.0.0.9 (and its proof), the functor $\overline{Y}$ is given by $\overline{Y}(R) = \mathrm{Map}_{\mathrm{Alg}_\kappa^{(2),\mathrm{aug}}}(\mathfrak{D}^{(2)}(R), A)$ for some augmented $\mathbb{E}_2$-algebra A over κ. Once again, our main result gives an explicit description of the algebra A: its augmentation ideal $\mathfrak{m}_A$ can be identified (as a nonunital $\mathbb{E}_2$-algebra) with the Hochschild cochain complex $\mathrm{HC}^*(\mathcal{C})$ of the ∞-category $\mathcal{C}$ (Theorem 16.6.3.8).

Remark 16.0.0.2. For a more extensive discussion of the deformation theory of differential graded categories, we refer the reader to [115]. See also [135] and [136].

Remark 16.0.0.3. It is possible to treat the functors X and Y introduced above simultaneously. Let $\mathbf{A}$ denote the ∞-category whose objects are pairs (A_1, A_2), where A_2 is an augmented $\mathbb{E}_2$-algebra over κ and A_1 is an $\mathbb{E}_1$-algebra over A_2 equipped with a map $A_1 \to \kappa$ of $\mathbb{E}_1$-algebras over A_2. We have spectrum objects $E_1, E_2 \in \mathrm{Sp}(\mathbf{A})$, given by

$$\Omega^{\infty-n} E_1 = (\kappa \oplus \Sigma^n(\kappa), \kappa) \qquad \Omega^{\infty-n} E_2 = (\kappa, \kappa \oplus \Sigma^n(\kappa)).$$

Let us regard $(\mathbf{A}, \{E_1, E_2\})$ as a deformation context (in the sense of Definition 12.1.1.1).

Let $\mathcal{C}$ be a κ-linear ∞-category and let $C \in \mathcal{C}$ be an object. Given a pair $(R_1, R_2) \in \mathbf{A}$, we let $Z(R_1, R_2)$ denote a classifying space for pairs $(C_1, \mathcal{C}_2)$, where $\mathcal{C}_2$ is an R_2-linear ∞-category deforming $\mathcal{C}$, and $C_1 \in \mathrm{LMod}_{R_1}(\mathcal{C}_2)$ is an object deforming C. The construction $(R_1, R_2) \mapsto Z(R_1, R_2)$ determines a 2-proximate formal moduli problem. Using Theorem 16.4.2.1 we can complete Z to a formal moduli problem $\overline{Z} : \mathbf{A}^{\mathrm{art}} \to \mathcal{S}$.

Using a generalization of the techniques studied in Chapters 14 and 15, one can combine the Koszul duality functors

$$\mathfrak{D}^{(1)} : (\mathrm{Alg}_\kappa^{\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{\mathrm{aug}} \qquad \mathfrak{D}^{(2)} : (\mathrm{Alg}_\kappa^{(2),\mathrm{aug}})^{\mathrm{op}} \to \mathrm{Alg}_\kappa^{(2),\mathrm{aug}}$$

to obtain a deformation theory $\mathfrak{D} : (\mathbf{A})^{\mathrm{op}} \to \mathbf{A}$. Using Theorem 12.3.3.5, we see that the formal moduli problem $\overline{Z}$ is determined by an object $(A_1, A_2) \in \mathbf{A}$. One can show that the augmentation ideals $\mathfrak{m}_{A_1}$ and $\mathfrak{m}_{A_2}$ are given by the endomorphism algebra $\mathrm{End}(C)$ and the Hochschild cochain complex $\mathrm{HC}^*(\mathcal{C})$ of $\mathcal{C}$, respectively (note that $\mathrm{HC}^*(\mathcal{C})$ acts centrally on $\mathrm{End}(C)$).

At the cost of a bit of information, we can be much more concrete. The construction $R \mapsto \overline{Z}(R, R)$ determines a formal $\mathbb{E}_2$-moduli problem $F : \mathrm{Alg}_\kappa^{(2),\mathrm{aug}} \to \mathcal{S}$; for each $R \in \mathrm{Alg}_\kappa^{(2),\mathrm{art}}$ we have a fiber sequence $\overline{X}(R) \to F(R) \to \overline{Y}(R)$, where $\overline{X}$ and $\overline{Y}$ are the formal $\mathbb{E}_1$ and $\mathbb{E}_2$-moduli problems described above. Applying Theorem 15.0.0.9, we deduce that F is given by the formula $F(R) = \mathrm{Map}_{\mathrm{Alg}_\kappa^{(2),\mathrm{aug}}}(\mathfrak{D}^{(2)}(R), A)$ for some augmented $\mathbb{E}_2$-algebra A over κ. Then the augmentation ideal $\mathfrak{m}_A$ can be identified with the fiber of the natural map $\mathrm{HC}^*(\mathcal{C}) \to \mathrm{End}(C)$.

Contents

16.1 Gluing along Closed Immersions

Let $f : (\mathcal{X}, \mathscr{O}_{\mathcal{X}}) \to (\mathcal{Y}, \mathscr{O}_{\mathcal{Y}})$ be a morphism of spectral Deligne-Mumford stacks. Recall that f is said to be a *closed immersion* if the underlying geometric morphism $f_* : \mathcal{X} \to \mathcal{Y}$ is a closed immersion of ∞-topoi and the map of structure sheaves $f^{-1}\mathscr{O}_{\mathcal{Y}} \to \mathscr{O}_{\mathcal{X}}$ induces an epimorphism on π_0 (see Definition **??**). In this section, we will study the operation of gluing spectral Deligne-Mumford stacks along closed immersions. Our main result can be formulated as follows:

Theorem 16.1.0.1. *Suppose we are given a pair of closed immersions of spectral Deligne-Mumford stacks $f : \mathsf{X} \to \mathsf{Y}$ and $g : \mathsf{X} \to \mathsf{X}'$, and form a pushout diagram σ :*

$$\begin{array}{ccc} \mathsf{X} & \xrightarrow{f} & \mathsf{Y} \\ \downarrow{\scriptstyle g} & & \downarrow{\scriptstyle f'} \\ \mathsf{X}' & \xrightarrow{g'} & \mathsf{Y}' \end{array}$$

in the ∞-category $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ of spectrally ringed ∞-topoi. Then:

(1) *The pushout Y' is a spectral Deligne-Mumford stack.*

(2) *The diagram σ is also a pushout square in the subcategory $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}} \subseteq \infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ of locally spectrally ringed ∞-topoi (in particular, it is a pushout square in the ∞-category* SpDM *of spectral Deligne-Mumford stacks).*

(3) *The maps f' and g' are closed immersions.*

(4) *If X' and Y are affine, then Y' is also affine.*

Remark 16.1.0.2. Theorem 16.1.0.1 has an analogue in the setting of spectral schemes, which can be proven in more or less the same way; we leave the details to the reader.

16.1.1 Closed Immersions of ∞-Topoi

We begin with some generalities about gluing ∞-topoi along closed immersions. Recall that if U is an object of an ∞-topos $\mathcal{X}$, then $\mathcal{X}/U$ denotes the full subcategory of $\mathcal{X}$ spanned by those objects V for which the projection map $U \times V \to U$ is an equivalence (see §HTT.7.3.2). We refer to $\mathcal{X}/U$ as the *closed subtopos of $\mathcal{X}$ complementary to U.*

Proposition 16.1.1.1. *Let $\mathcal{X}$ be an ∞-topos, let U be a subobject of the final object of $\mathcal{X}$, and let $\mathcal{X}/U$ be the corresponding closed subtopos of $\mathcal{X}$. Suppose we are given a geometric morphism $f_* : \mathcal{X}/U \to \mathcal{Y}$, and form a pushout diagram*

$$\begin{array}{ccc} \mathcal{X}/U & \xrightarrow{g_*} & \mathcal{X} \\ \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f'_*} \\ \mathcal{Y} & \xrightarrow{g'_*} & \mathcal{Z} \end{array}$$

in the ∞-category $\infty\mathcal{T}\mathrm{op}$ of ∞-topoi. Let $V = f'_*(U) \in \mathcal{Z}$. Then:

(1) *The functor f'_* induces an equivalence $\mathcal{X}_{/U} \simeq \mathcal{Z}_{/V}$.*

(2) *The functor g'_* is fully faithful and its essential image is $\mathcal{Z}/V$. In particular, g'_* is a closed immersion.*

Proof. According to Proposition HTT.6.3.2.3 , we can identify $\mathcal{Z}$ with the homotopy fiber product of $\mathcal{X}$ with $\mathcal{Y}$ over $\mathcal{X}/U$ (along the functors $g^* : \mathcal{X} \to \mathcal{X}/U$ and $f^* : \mathcal{Y} \to \mathcal{X}/U$ adjoint to g_* and f_*). Since g^*U is an initial object of $\mathcal{X}/U$, there exists an object $V' \in \mathcal{Z}$ such that $f'^*V' \simeq U$ and g'^*V' is an initial object of $\mathcal{Y}$. For each $Z \in \mathcal{Z}$, we have a homotopy pullback diagram of spaces

$$\begin{array}{ccc} \mathrm{Map}_{\mathcal{Z}}(Z, V') & \longrightarrow & \mathrm{Map}_{\mathcal{X}}(f'^*Z, U) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathcal{Y}}(g'^*Z, g'^*V') & \longrightarrow & \mathrm{Map}_{\mathcal{X}/U}(g^*f'^*Z, g^*U). \end{array}$$

It follows that $\mathrm{Map}_{\mathcal{Z}}(Z, V')$ is contractible if g'^*Z is an initial object of $\mathcal{Y}$, and empty otherwise. Consequently, the equivalence $f'^*V' \simeq U$ is adjoint to an equivalence $V' \to V$. We may therefore assume without loss of generality that $V' = V$.

We now prove (1). Note that the projection map $\mathcal{Z}_{/V} \to \mathcal{Z}$ is a fully faithful embedding, whose essential image is the full subcategory $\mathcal{Z}_0 \subseteq \mathcal{Z}$ spanned by those objects $Z \in \mathcal{Z}$ such that g'^*Z is an initial object of $\mathcal{Y}$. Similarly, the projection $\mathcal{X}_{/U} \to \mathcal{X}$ is a fully faithful embedding whose essential image is the full subcategory $\mathcal{X}_0 \subseteq \mathcal{X}$ spanned by those objects X such that g^*X is an initial object of $\mathcal{X}/U$. It will therefore suffice to prove that the functor f'^* induces an equivalence of $\mathcal{Z}_0$ with $\mathcal{X}_0$, which follows immediately from Proposition HTT.6.3.2.3 .

We now prove (2). We first claim that g'_* carries $\mathcal{Y}$ into $\mathcal{Z}/V$. That is, we claim that if $Y \in \mathcal{Y}$, then the projection map $(g'_*Y) \times V \to V$ is an equivalence. Let $Z \in \mathcal{Z}$ be an object; we wish to show that the map

$$\mathrm{Map}_{\mathcal{Z}}(Z, g'_*Y \times V) \simeq \mathrm{Map}_{\mathcal{Y}}(g'^*Z, Y) \times \mathrm{Map}_{\mathcal{Z}}(Z, V) \to \mathrm{Map}_{\mathcal{Z}}(Z, V)$$

is a homotopy equivalence. If $Z \notin \mathcal{Z}_0$, then both sides are empty and the result is obvious. If $Z \in \mathcal{Z}_0$, then the result follows since $g'*Z$ is an initial object of $\mathcal{Y}$.

Now suppose $Z \in \mathcal{Z}/V$. We claim that the unit map $u : Z \to g'_*g'^*Z$ is an equivalence in $\mathcal{Z}$. To prove this, we show that for each $Z' \in \mathcal{Z}$, composition with u induces a homotopy equivalence

$$\mathrm{Map}_{\mathcal{Z}}(Z', Z) \to \mathrm{Map}_{\mathcal{Z}}(Z', g'_*g'^*Z) \simeq \mathrm{Map}_{\mathcal{Y}}(g'^*Z', g'^*Z).$$

This map fits into a homotopy pullback diagram

$$\begin{array}{ccc} \mathrm{Map}_{\mathcal{Z}}(Z', Z) & \longrightarrow & \mathrm{Map}_{\mathcal{Y}}(g'^*Z', g'^*Z) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{\mathcal{X}}(f'^*Z', f'^*Z) & \longrightarrow & \mathrm{Map}_{\mathcal{X}/U}(g^*f'^*Z', g^*f'^*Z). \end{array}$$

It therefore suffices to show that the bottom horizontal map is a homotopy equivalence. In other words, we are reduced to showing that the unit map $f'^{*}Z \to g_* g^* f'^{*} Z$ is an equivalence in $\mathcal{X}$, which follows from the observation that $f'^{*} \in \mathcal{X}/U$.

The argument of the preceding paragraph shows that g'^{*} induces a fully faithful embedding $\mathcal{Z}/V \to \mathcal{Y}$. To complete the proof, we show the functor $g'^{*}|_{\mathcal{Z}/V}$ is essentially surjective. Fix an object $Y \in \mathcal{Y}$, and let $X = f^* Y \in \mathcal{X}/U$. Since g_* is fully faithful, the counit map $g^* g_* X \to X$ is an equivalence. It follows that there exists an object $Z \in \mathcal{Z}$ such that $g'^{*} Z \simeq Y$ and $f'^{*} Z \simeq g_* X$. It remains only to verify that $Z \in \mathcal{Z}/V$: that is, that the projection map $Z \times V \to V$ is an equivalence. Using (1), we are reduced to proving that the map $f'^{*}(Z \times V) \to f'^{*} V \simeq U$ is an equivalence. In other words, we are reduced to proving that $f'^{*} Z \simeq g_* X$ belongs to $\mathcal{X}/U$, which is clear. □

Corollary 16.1.1.2. *Suppose we are given a pushout diagram*

$$\begin{array}{ccc} \mathcal{X} & \xrightarrow{g'_*} & \mathcal{Y} \\ \downarrow{\scriptstyle f'_*} & & \downarrow{\scriptstyle f_*} \\ \mathcal{X}' & \xrightarrow{g_*} & \mathcal{Y}' \end{array}$$

in the ∞-category $\infty\mathcal{T}\mathrm{op}$ of ∞-topoi. If f_* and g_* are closed immersions, then f'_* and g'_* are closed immersions.

Lemma 16.1.1.3. *Let $\mathcal{X}$ be an ∞-topos containing a pair of (-1)-truncated objects U and V. Suppose that $U \times V$ is an initial object of $\mathcal{X}$. Then the coproduct $U \amalg V$ is also a (-1)-truncated object of $\mathcal{X}$.*

Proof. We must prove that the diagonal map

$$U \amalg V \to (U \amalg V) \times (U \amalg V) \simeq (U \times U) \amalg (U \times V) \amalg (V \times U) \amalg (V \times V)$$

is an equivalence. This map factors as as a composition

$$U \amalg V \to (U \times U) \amalg (V \times V) \to (U \times U) \amalg (U \times V) \amalg (V \times U) \amalg (V \times V)$$

where the first map is an equivalence since U and V are (-1)-truncated, and the second is an equivalence since $U \times V \simeq V \times U$ is an initial object of $\mathcal{X}$. □

Proposition 16.1.1.4. *Let $\mathcal{X}$ be an ∞-topos containing a pair of (-1)-truncated object U and V whose product $U \times V$ is an initial object of $\mathcal{X}$. Then the diagram*

$$\begin{array}{ccc} \mathcal{X}/(U \amalg V) & \longrightarrow & \mathcal{X}/U \\ \downarrow & & \downarrow \\ \mathcal{X}/V & \longrightarrow & \mathcal{X} \end{array}$$

is a pushout square in $\infty\mathcal{T}\mathrm{op}$.

Proof. Let $f^* : \mathcal{X} \to \mathcal{X}_{/U}$, $g^* : \mathcal{X} \to \mathcal{X}_{/V}$ and $h^* : \mathcal{X} \to \mathcal{X}_{/(U \amalg V)}$ be the associated pullback functors. Form a pushout diagram

$$\begin{array}{ccc} \mathcal{X}_{/(U \amalg V)} & \longrightarrow & \mathcal{X}_{/U} \\ \downarrow & & \downarrow \\ \mathcal{X}_{/V} & \longrightarrow & \mathcal{Y} \end{array}$$

in $\infty\mathcal{T}\mathrm{op}$; we wish to prove that the induced geometric morphism $\phi_* : \mathcal{Y} \to \mathcal{X}$ is an equivalence of ∞-topoi. We first claim that the pullback functor ϕ^* is conservative. In other words, we claim that a morphism $u : X \to X'$ in $\mathcal{X}$ is an equivalence provided that both $f^*(u)$ and $g^*(u)$ are equivalences. Indeed, either of these conditions guarantees that $h^*(u)$ is an equivalence, so (by Lemma HA.A.5.11) it will suffice to show that u induces an equivalence $X \times (U \amalg V) \to X' \times (U \amalg V)$. Since colimits in $\mathcal{X}$ are universal, it suffices to show that $u_U : X \times U \to X' \times U$ and $u_V : X \times V \to X' \times V$ are equivalences. We prove that u_U is an equivalence; the proof that u_V is an equivalence is similar. We have a commutative diagram

$$\begin{array}{ccc} X \times U & \xrightarrow{v} & (g_* g^* X) \times U \\ \downarrow & & \downarrow \\ X' \times U & \xrightarrow{v'} & (g_* g^* X') \times U. \end{array}$$

Since the right vertical map is an equivalence, it will suffice to show that v and v' are equivalences. We will prove that v is an equivalence; the roof that v' is an equivalence is similar. Since g_* is fully faithfully, the map $g^*(v)$ is an equivalence. Using Lemma HA.A.5.11 again, we are reduced to proving that the map $X \times U \times V \to (g_* g^* X) \times U \times V$ is an equivalence. This is clear, since both $X \times U \times V$ and $(g_* g^* X) \times U \times V$ are initial objects of $\mathcal{X}$.

To complete the proof that ϕ_* is an equivalence, it suffices to show that the counit map $\phi^* \phi_* Y \to Y$ is an equivalence for each object $Y \in \mathcal{Y}$. Using Proposition HTT.6.3.2.3 , we can identify the ∞-category $\mathcal{Y}$ with the fiber product $\mathcal{X}_{/U} \times_{\mathcal{X}_{/(U \amalg V)}} \mathcal{X}_{/V}$. Thus $Y \in \mathcal{Y}$ corresponds to a pair of objects $Y_0 \in \mathcal{X}_{/U}$, $Y_1 \in \mathcal{X}_{/V}$ together with an equivalence $g^* Y_0 \simeq f^* Y_1 = Y_{01} \in \mathcal{X}_{/(U \amalg V)}$. Unwinding the definitions, we see that the pushforward functor ϕ_* is given by the formula $\phi_* Y = f_* Y_0 \times_{h_* Y_{01}} g_* Y_1$. Since a morphism in $\mathcal{Y}$ is an equivalence if and only if its pullbacks to $\mathcal{X}_{/U}$ and $\mathcal{X}_{/V}$ are equivalences, we are reduced to proving that the projection maps

$$\alpha : f^*(f_* Y_0 \times_{h_* Y_{01}} g_* Y_1) \to Y_0 \qquad \beta : g^*(f_* Y_0 \times_{h_* Y_{01}} g_* Y_1) \to Y_1$$

are equivalences in $\mathcal{X}_{/U}$ and $\mathcal{X}_{/V}$, respectively. We prove that α is an equivalence; the proof for β is similar. The map α factors as a composition

$$f^*(f_* Y_0 \times_{h_* Y_{01}} g_* Y_1) \xrightarrow{\alpha'} f^* f_* Y_0 \xrightarrow{\alpha''} Y_0.$$

Since f_* is fully faithful, the counit map α'' is an equivalence; it will therefore suffice to show that α is an equivalence. Since f^* is left exact, the map α' is a pullback of $\gamma : f^* g_* Y_1 \to f^* h_* Y_{01}$. It will therefore suffice to show that γ is an equivalence in $\mathcal{X}/U$, which is an immediate translation of the condition that $Y_{01} \simeq f^* Y_1 \in \mathcal{X}/(U \amalg V) \subseteq \mathcal{X}/U$. $\square$

16.1.2 Spectrally Ringed ∞-Topoi

Let $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ denote the ∞-category of spectrally ringed ∞-topoi (see Construction 1.4.1.3). The ∞-category $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ admits small colimits: given a diagram of spectrally ringed ∞-topoi $\{(\mathcal{X}_\alpha, \mathcal{O}_\alpha)\}$, the colimit is given by $(\mathcal{X}, \mathcal{O})$, where $\mathcal{X} \simeq \varinjlim \mathsf{X}_\alpha$ is the colimit of the diagram $\{\mathsf{X}_\alpha\}$ in the ∞-category $\infty\mathcal{T}\mathrm{op}$ of ∞-topoi (which coincides with the *limit* of the associated diagram of left adjoint functors in the ∞-category $\widehat{\mathcal{C}\mathrm{at}}_\infty$), and $\mathcal{O}$ denotes the limit $\varprojlim \phi_{\alpha *} \mathcal{O}_\alpha$ in the ∞-category $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$; here $\phi_{\alpha *} : \mathcal{X} \to \mathcal{X}_\alpha$ denotes the tautological map.

In particular, given a diagram of spectrally ringed ∞-topoi

$$(\mathcal{X}, \mathcal{O}_\mathcal{X}) \xrightarrow{f} (\mathcal{Z}, \mathcal{O}_\mathcal{Z}) \xleftarrow{g} (\mathcal{Y}, \mathcal{O}_\mathcal{Y}),$$

the pushout in $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ is given by $(\mathcal{X} \times_\mathcal{Z} \mathcal{Y}, g'_* \mathcal{O}_\mathcal{X} \times_{h_* \mathcal{O}_\mathcal{Z}} f'_* \mathcal{O}_\mathcal{Y})$ (here the fiber product $\mathcal{X} \times_\mathcal{Z} \mathcal{Y}$ is formed in $\widehat{\mathcal{C}\mathrm{at}}_\infty$), the functors f'_* and g'_* are the right adjoints to the projections of $\mathcal{X} \times_\mathcal{Z} \mathcal{Y}$ onto $\mathcal{Y}$ and $\mathcal{X}$, and h_* $\mathcal{Z} \to \mathcal{X} \times_\mathcal{Z} \mathcal{Y}$ is defined similarly. We will primarily be interested in the case where f and g are closed immersions:

Proposition 16.1.2.1. *Let $f : \mathsf{X} \to \mathsf{Y}$ and $g : \mathsf{X} \to \mathsf{X}'$ be closed immersions in the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$, and form a pushout diagram σ :*

$$\begin{array}{ccc} \mathsf{X} & \xrightarrow{g} & \mathsf{Y} \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f'} \\ \mathsf{X}' & \xrightarrow{g'} & \mathsf{Y}' \end{array}$$

in the ∞-category $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$. Then:

(1) *The diagram σ is also a pushout square in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$.*

(2) *The maps f' and g' are closed immersions.*

(3) *Suppose that the structure sheaves of Y and X' are strictly Henselian. Then the structure sheaf of Y' is also strictly Henselian.*

Proof. We first prove (2). Without loss of generality, it will suffice to show that f' is a closed immersion. Using Proposition 16.1.1.1, we see that f' induces a closed immersion at the level of the underlying ∞-topoi. To complete the proof, we must show that the map

$\theta : f'^{*} \mathscr{O}_{\mathsf{Y}'} \to \mathscr{O}_{\mathsf{Y}}$ has connective fiber. Set $h = f' \circ g \simeq g' \circ f$, so that $\mathscr{O}_{\mathsf{Y}'}$ is given by the fiber product

$$f'_* \mathscr{O}_{\mathsf{Y}} \times_{h_* \mathscr{O}_{\mathsf{X}}} g'_* \mathscr{O}_{\mathsf{X}'}.$$

Under this identification, θ is given by composing the equivalence $f'^{*} f'_* \mathscr{O}_{\mathsf{Y}} \to \mathscr{O}_{\mathsf{Y}}$ with the pullback of the projection map $\theta' : f'_* \mathscr{O}_{\mathsf{Y}} \times_{h_* \mathscr{O}_{\mathsf{X}}} g'_* \mathscr{O}_{\mathsf{X}'} \to f'_* \mathscr{O}_{\mathsf{Y}}$. It will therefore suffice to show that θ' has connective fiber. Equivalently, we must show that the map $g'_* \mathscr{O}_{\mathsf{X}'} \to h_* \mathscr{O}_{\mathsf{X}}$ has connective fiber. This is clear, since the map $\mathscr{O}_{\mathsf{X}'} \to f_* \mathscr{O}_{\mathsf{X}}$ has connective fiber (by virtue of our assumption that f is a closed immersion), and the pushforward functor g'_* is right t-exact (since g' is a closed immersion on the level of ∞-topoi). This completes the proof of (2).

We next claim that the structure sheaf $\mathscr{O}_{\mathsf{Y}'}$ is local. To prove this, it will suffice to show that $f'^{ast} \mathscr{O}_{\mathsf{Y}'}$ and $g'^{*} \mathscr{O}_{\mathsf{Y}'}$ are local, respectively. We will show that $f'^{*} \mathscr{O}_{\mathsf{Y}'}$ is local; the proof of the other case is similar. Write $\mathsf{Y} = (\mathcal{Y}, \mathscr{O}_{\mathsf{Y}})$ and $\mathsf{X} = (\mathcal{X}, \mathscr{O}_{\mathcal{X}})$. Since g is a closed immersion, the geometric morphism g_* induces an equivalence $\mathcal{X} \simeq \mathcal{Y}/U$ for some (-1)-truncated object $U \in \mathcal{Y}$. Because $f'^{*} \mathscr{O}_{\mathsf{Y}'}|_U \simeq \mathscr{O}_{\mathsf{Y}}|_U$ is local by assumption, it will suffice to show that the restriction of $g^* f'^{*} \mathscr{O}_{\mathsf{Y}'} = h^* \mathscr{O}_{\mathsf{Y}'} \in \mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathcal{X})$ is local. We have a pullback diagram

$$\begin{array}{ccc} h^* \mathscr{O}_{\mathsf{Y}'} & \longrightarrow & g^* \mathscr{O}_{\mathsf{Y}} \\ \downarrow & & \downarrow \\ f^* \mathscr{O}_{\mathsf{X}'} & \longrightarrow & \mathscr{O}_{\mathsf{X}} \end{array}$$

of CAlg-valued sheaves on X. Since f is a morphism in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$, the lower horizontal map in this diagram is local. It follows that the upper horizontal map is also local, so that the locality of $g^* \mathscr{O}_{\mathsf{Y}}$ implies that $h^* \mathscr{O}_{\mathsf{Y}'}$ is local (see Proposition 1.2.1.8), as desired.

We now complete the proof of (1) by showing that Y' is a pushout of X' and Y over X in the ∞-category $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$. Equivalently, we must show that if $\mathsf{Z} = (\mathcal{Z}, \mathscr{O})$ is an object of $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ and $r : \mathsf{Y}' \to \mathsf{Z}$ is a morphism in $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$, then r is a morphism in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$ if and only if $r \circ f'$ and $r \circ g'$ are morphisms in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$. That is, we must show that the map $r^* \mathscr{O} \to \mathscr{O}_{\mathsf{Y}'}$ is local if and only if the induced maps $(r \circ f')^* \mathscr{O} \to \mathscr{O}_{\mathsf{X}'}$ and $(r \circ g')^* \mathscr{O} \to \mathscr{O}_{\mathsf{Y}}$ are local. This follows immediately from the observation that a section of $\pi_0 \mathscr{O}_{\mathsf{Y}'}$ is invertible if and only if the resulting sections of $\pi_0 \mathscr{O}_{\mathsf{X}'}$ and $\pi_0 \mathscr{O}_{\mathsf{Y}}$ are invertible.

We now prove (3). Assume that $\mathscr{O}_{\mathsf{X}}$, $\mathscr{O}_{\mathsf{X}'}$, and $\mathscr{O}_{\mathsf{Y}}$ are strictly Henselian; we wish to prove that $\mathscr{O}_{\mathsf{Y}'}$ is strictly Henselian. That is, we wish to show that if R is a finitely generated commutative ring and $\{R \to R_\alpha\}$ is a finite collection of étale morphisms which determine a faithfully flat map $R \to \prod_\alpha R_\alpha$, then the induced map $\amalg_\alpha \mathcal{S}\mathrm{ol}_{R_\alpha}(\pi_0 \mathscr{O}_{\mathsf{Y}'}) \to \mathcal{S}\mathrm{ol}_R(\pi_0 \mathscr{O}_{\mathsf{Y}'})$ is an effective epimorphism. We have a fiber sequence $\mathscr{O}_{\mathsf{Y}'} \to g'_* \mathscr{O}_{\mathsf{X}'} \oplus f'_* \mathscr{O}_{\mathsf{Y}} \to h_* \mathscr{O}_{\mathsf{X}}$, which determines a short exact sequence of homotopy sheaves

$$h_*(\pi_1 \mathscr{O}_{\mathsf{X}}) \to \pi_0 \mathscr{O}_{\mathsf{Y}'} \xrightarrow{\nu} g'_*(\pi_0 \mathscr{O}_{\mathsf{X}'}) \times_{h_*(\pi_0 \mathscr{O}_{\mathsf{X}})} f'_*(\pi_0 \mathscr{O}_{\mathsf{Y}}) \to 0$$

In particular, ν is an epimorphism whose kernel is a square-zero ideal sheaf contained in $\pi_0 \mathscr{O}_{\mathsf{Y}'}$. For each index α, the assumption that R_α is étale over R guarantees that the diagram

$$\begin{array}{ccc} \mathcal{S}\mathrm{ol}_{R_\alpha}(\pi_0 \mathscr{O}_{\mathsf{Y}'}) & \longrightarrow & \mathcal{S}\mathrm{ol}_{R_\alpha}(g'_*(\pi_0 \mathscr{O}_{\mathsf{X}'}) \times_{h_*(\pi_0 \mathscr{O}_{\mathsf{X}})} f'_*(\pi_0 \mathscr{O}_{\mathsf{Y}})) \\ \downarrow & & \downarrow \\ \mathcal{S}\mathrm{ol}_{R}(\pi_0 \mathscr{O}_{\mathsf{Y}'}) & \longrightarrow & \mathcal{S}\mathrm{ol}_{R}(g'_*(\pi_0 \mathscr{O}_{\mathsf{X}'}) \times_{h_*(\pi_0 \mathscr{O}_{\mathsf{X}})} f'_*(\pi_0 \mathscr{O}_{\mathsf{Y}})) \end{array}$$

is a pullback square. We may therefore replace $\mathscr{O}_{\mathsf{Y}}$, $\mathscr{O}_{\mathsf{X}'}$, and $\mathscr{O}_{\mathsf{X}}$ by their truncations $\pi_0 \mathscr{O}_{\mathsf{Y}}$, $\pi_0 \mathscr{O}_{\mathsf{X}'}$, and $\pi_0 \mathscr{O}_{\mathsf{X}}$, and thereby reduce to the case where the structure sheaves of X, Y, and X' are discrete (from which it follows that the structure sheaf of Y' is also discrete).

We wish to prove that the map

$$\theta : \amalg_\alpha \mathcal{S}\mathrm{ol}_{R_\alpha}(g'_* \mathscr{O}_{\mathsf{X}'} \times_{h_* \mathscr{O}_{\mathsf{X}}} f'_* \mathscr{O}_{\mathsf{Y}}) \to \mathcal{S}\mathrm{ol}_{R}(g'_* \mathscr{O}_{\mathsf{X}'} \times_{h_* \mathscr{O}_{\mathsf{X}}} f'_* \mathscr{O}_{\mathsf{Y}})$$

is an effective epimorphism. Let $\mathcal{Y}'$ denote the underlying ∞-topos of Y', and let $\mathcal{U}$ denote the open subtopos of $\mathcal{Y}'$ complementary to the image of the closed immersion f'. Then the restriction of θ to $\mathcal{U}$ can be identified with the restriction of the effective epimorphism $\amalg_\alpha \mathcal{S}\mathrm{ol}_{R_\alpha}(\mathscr{O}_{\mathsf{X}'}) \to \mathcal{S}\mathrm{ol}_{R}(\mathscr{O}_{\mathsf{Y}'})$. A similar argument shows that θ is an effective epimorphism when restricted to the complement of the closed immersion g'. It will therefore suffice to show that $h^*(\theta)$ is an effective epimorphism. Unwinding the definitions, we can identify $h^*(\theta)$ with the canonical map

$$\amalg_\alpha \mathcal{S}\mathrm{ol}_{R_\alpha}(f^* \mathscr{O}_{\mathsf{X}'}) \times_{\mathcal{S}\mathrm{ol}_{R_\alpha}(\mathscr{O}_{\mathsf{X}})} \mathcal{S}\mathrm{ol}_{R_\alpha}(g^* \mathscr{O}_{\mathsf{Y}}) \to \mathcal{S}\mathrm{ol}_{R}(f^* \mathscr{O}_{\mathsf{X}'}) \times_{\mathcal{S}\mathrm{ol}_{R}(\mathscr{O}_{\mathsf{X}})} \mathcal{S}\mathrm{ol}_{R}(g^* \mathscr{O}_{\mathsf{Y}}).$$

It follows from Proposition 1.2.2.12 that this map is a pullback of $\amalg_\alpha \mathcal{S}\mathrm{ol}_{R_\alpha}(\mathscr{O}_{\mathsf{X}}) \to \mathcal{S}\mathrm{ol}_{R}(\mathscr{O}_{\mathsf{X}})$, hence an effective epimorphism (since $\mathscr{O}_{\mathsf{X}}$ is assumed to be strictly Henselisan). □

16.1.3 Pushouts in the Affine Case

We now establish a special case of Theorem 16.1.0.1.

Proposition 16.1.3.1. *Suppose we are given a pullback diagram of $\mathbb{E}_\infty$-rings*

$$\begin{array}{ccc} A' & \longrightarrow & A \\ \downarrow & & \downarrow f \\ B' & \xrightarrow{g} & B \end{array}$$

where A, B, and B' are connective and the maps f and g induce surjective ring homomorphisms $\pi_0 A \to \pi_0 B$ and $\pi_0 B' \to \pi_0 B$. Then:

(1) *The $\mathbb{E}_\infty$-ring A' is connective.*

(2) *The maps $\pi_0 A' \to \pi_0 A$ and $\pi_0 B' \to \pi_0 B$ are surjective.*

(3) *The induced diagram of spectral Deligne-Mumford stacks σ :*

$$\begin{array}{ccc} \operatorname{Sp\acute{e}t} B & \longrightarrow & \operatorname{Sp\acute{e}t} B' \\ \downarrow & & \downarrow \\ \operatorname{Sp\acute{e}t} A & \longrightarrow & \operatorname{Sp\acute{e}t} A' \end{array}$$

is a pushout diagram in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$.

Proof. Assertions (1) and (2) are obvious. For every $\mathbb{E}_\infty$-ring R, let $\mathcal{X}_R$ denote the underlying ∞-topos of Spét R (that is, the ∞-topos of étale sheaves on $\mathrm{CAlg}^{\text{ét}}_R$), and let $\mathscr{O}_R$ denote the structure sheaf of Spét R. By virtue of Proposition 16.1.2.1, it will suffice to show that σ is a pushout square in $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$. That is, we must show the following:

($3'$) The diagram of ∞-topoi

$$\begin{array}{ccc} \mathcal{X}_B & \longrightarrow & \mathcal{X}_{B'} \\ \downarrow & \overset{h_*}{\searrow} & \downarrow f_* \\ \mathcal{X}_A & \xrightarrow{g_*} & \mathcal{X}_{A'} \end{array}$$

is a pushout square in $\infty\mathcal{T}\mathrm{op}$.

($3''$) The diagram

$$\begin{array}{ccc} \mathscr{O}_{A'} & \longrightarrow & g_* \mathscr{O}_A \\ \downarrow & & \downarrow \\ f_* \mathscr{O}_{B'} & \longrightarrow & h_* \mathscr{O}_B \end{array}$$

is a pullback square in $\mathcal{S}\mathrm{hv}_{\mathrm{CAlg}}(\mathsf{X}_{A'})$.

We first prove ($3'$). Using (2) and Proposition 3.1.4.1, we deduce the existence of equivalences

$$\mathcal{X}_{B'} \simeq \mathcal{X}_{A'}/U \qquad \mathcal{X}_A \simeq \mathcal{X}_{A'}/V \qquad \mathcal{X}_B \simeq \mathcal{X}_{A'}/W$$

for (-1)-truncated objects $U, V, W \in \mathcal{X}_{A'}$. Under the equivalence $\mathcal{X}_{A'} \simeq \mathcal{S}\mathrm{hv}^{\text{ét}}_{A'} \subseteq \mathrm{Fun}(\mathrm{CAlg}^{\text{ét}}_{A'}, \mathcal{S})$, the objects U, V, and W are given by the formulae

$$U(R) = \begin{cases} \Delta^0 & \text{if } R \otimes_{A'} B' \simeq 0 \\ \emptyset & \text{otherwise} \end{cases} \quad V(R) = \begin{cases} \Delta^0 & \text{if } R \otimes_{A'} A \simeq 0 \\ \emptyset & \text{otherwise} \end{cases} \quad W(R) = \begin{cases} \Delta^0 & \text{if } R \otimes_{A'} B \simeq 0 \\ \emptyset & \text{otherwise.} \end{cases}$$

For any A-algebra R, we have a pullback diagram τ_R :

$$\begin{array}{ccc} R & \longrightarrow & R \otimes_{A'} A \\ \downarrow & & \downarrow \\ R \otimes_{A'} B' & \longrightarrow & R \otimes_{A'} B. \end{array}$$

It follows that if $R \otimes_{A'} A \simeq R \otimes_{A'} B' \simeq 0$, then $R \simeq 0$; this proves that $U \times V$ is an initial object of $\mathcal{X}_{A'}$. According to Lemma 16.1.1.3, the coproduct $U \amalg V$ in $\mathcal{X}_{A'}$ is (-1)-truncated. There is an evident map $j : U \amalg V \to W$. We will prove that j is an equivalence, so that assertion (3′) follows from Proposition 16.1.1.4. We must show that if R is an étale A'-algebra such that $W(R)$ is nonempty, then $(U \amalg V)(R)$ is nonempty. Indeed, if $W(R)$ is nonempty then we have $R \otimes_{A'} B \simeq 0$, so that the pullback diagram $\tau_{R'}$ shows that $R \simeq R_0 \times R_1$ with $R_0 = R \otimes_{A'} A$ and $R_1 = R \otimes_{A'} B'$). Then R_0 and R_1 are also étale A'-algebras, and we have $(U \amalg V)(R) \simeq (U \amalg V)(R_0) \times (U \amalg V)(R_1)$. It will therefore suffice to show that both $(U \amalg V)(R_0)$ and $(U \amalg V)(R_1)$ are nonempty. We will prove that $(U \amalg V)(R_0)$ is nonempty; the proof in the other case is similar. Since we have a map $U(R_0) \to (U \amalg V)(R_0)$, it is sufficient to show that $U(R_0)$ is nonempty: that is, that $R_0 \otimes_{A'} B' \simeq 0$. Let $I \subseteq \pi_0 A'$ be the kernel of the map $\pi_0 A' \to \pi_0 B'$, and $J \subseteq \pi_0 A'$ the kernel of the map $\pi_0 A' \to \pi_0 A$, so that the ideal $I + J$ is the kernel of the map $\pi_0 A' \to \pi_0 B$. We now compute

$$\begin{aligned} \pi_0(R_0 \otimes_{A'} B') &\simeq (\pi_0 R_0)/(I \pi_0 R_0) \\ &\simeq (\pi_0 R / J \pi_0 R)/I \pi_0 R_0 \\ &\simeq (\pi_0 R)/(I + J)\pi_0 R \\ &\simeq \pi_0(R \otimes_{A'} B) \\ &\simeq 0. \end{aligned}$$

It remains to prove (3″). Unwinding the definitions, we are reduced to the evident observation that if $R \in \mathrm{CAlg}^{\text{ét}}_{A'}$, then the diagram

$$\begin{array}{ccc} R & \longrightarrow & R \otimes_{A'} A \\ \downarrow & & \downarrow \\ R \otimes_{A'} B' & \longrightarrow & R \otimes_{A'} B \end{array}$$

is a pullback square of $\mathbb{E}_\infty$-rings. □

Example 16.1.3.2. Let X be an object of $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$, and suppose we are given a morphism $\epsilon : \mathrm{Sp\acute{e}t}\,\kappa \to \mathsf{X}$, where κ is a field. Let $X : \mathrm{CAlg}^{\mathrm{art}}_{\kappa} \to \widehat{\mathcal{S}}$ denote the functor given by the formula

$$X(R) = \mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathrm{Sp\acute{e}t}\,R, \mathsf{X}) \times_{\mathrm{Map}_{\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}}(\mathrm{Sp\acute{e}t}\,R, \mathsf{X})} \{\epsilon\}.$$

It follows from Proposition 16.1.3.1 that for every pullback diagram

$$\begin{array}{ccc} R & \longrightarrow & R_0 \\ \downarrow & & \downarrow \\ R_1 & \longrightarrow & R_{01} \end{array}$$

in $\mathrm{CAlg}_\kappa^{\mathrm{art}}$ for which the ring homomorphisms $\pi_0 R_0 \to \pi_0 R_{01} \leftarrow \pi_0 R_1$ are surjective, the associated diagram of spectral Deligne-Mumford stacks

$$\begin{array}{ccc} \operatorname{Spét} R & \longleftarrow & \operatorname{Spét} R_0 \\ \uparrow & & \uparrow \\ \operatorname{Spét} R_1 & \longleftarrow & \operatorname{Spét} R_{01} \end{array}$$

is a pushout square in $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}^{\mathrm{loc}}$ (in fact, this is easier than Proposition 16.1.3.1, since the underlying ∞-topoi of these spectral Deligne-Mumford stacks are all the same). It follows that the diagram of spaces

$$\begin{array}{ccc} X(R) & \longrightarrow & X(R_0) \\ \downarrow & & \downarrow \\ X(R_1) & \longrightarrow & X(R_{01}) \end{array}$$

is a pullback square. Since $X(\kappa)$ is evidently contractible, it follows that the functor X is a formal moduli problem (modulo the technicality that the values of X might not be essentially small: this issue does not arise in most cases of interest, for example if X is a spectral Deligne-Mumford stack).

16.1.4 The Proof of Theorem 16.1.0.1

We now turn to the proof of our main result.

Lemma 16.1.4.1. *Suppose we are given a closed immersion $f : (\mathcal{X}, \mathcal{O}_\mathcal{X}) \to (\mathcal{Y}, \mathcal{O}_\mathcal{Y})$ of spectral Deligne-Mumford stacks, where $(\mathcal{Y}, \mathcal{O}_\mathcal{Y})$ is affine. Let $U \in \mathcal{X}$ be an object such that $(\mathcal{X}_{/U}, \mathcal{O}_\mathcal{X}|_U)$ is also an affine Deligne-Mumford stack. Then there exists an equivalence $U \simeq f^* V$ for some affine object $V \in \mathcal{Y}$.*

Proof. Let $(\mathcal{Y}, \mathcal{O}_\mathcal{Y}) \simeq \operatorname{Spét} A$ for some connective $\mathbb{E}_\infty$-ring A. Then $(\mathcal{X}, \mathcal{O}_\mathcal{X}) \simeq \operatorname{Spét} B$ for some connective A-algebra B such that $\pi_0 A \to \pi_0 B$ is surjective. Using Theorem 1.4.10.2, we see that the object $U \in \mathcal{X}$ corresponds to an étale B-algebra B'. Using Proposition B.1.1.3, we can write $B' \simeq A' \otimes_A B$ for some étale A-algebra A', which determines an object $V \in \mathcal{Y}$ with the desired properties. □

Proof of Theorem 16.1.0.1. Suppose we are given a pushout diagram σ :

$$\begin{array}{ccc} \mathsf{X} & \xrightarrow{f} & \mathsf{Y} \\ \downarrow{\scriptstyle g} & & \downarrow{\scriptstyle f'} \\ \mathsf{X}' & \xrightarrow{g'} & \mathsf{Y}' \end{array}$$

in the ∞-category $\infty\mathcal{T}\mathrm{op}_{\mathrm{CAlg}}$ of spectrally ringed ∞-topoi. Assume that X, Y, and X' are spectral Deligne-Mumford stacks, and that f and g are closed immersions. It follows from Proposition 16.1.2.1 that f' and g' are closed immersions and that σ is also pushout diagram in $\infty\mathcal{T}\mathrm{op}^{\mathrm{loc}}_{\mathrm{CAlg}}$. We wish to prove that Y' is a spectral Deligne-Mumford stack.

Write $\mathsf{X} = (\mathcal{X}, \mathcal{O}_{\mathcal{X}})$, $\mathsf{Y} = (\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$, $\mathsf{X}' = (\mathcal{X}', \mathcal{O}_{\mathcal{X}'})$, and $\mathsf{Y}' = (\mathcal{Y}', \mathcal{O}_{\mathcal{Y}'})$. The assertion that $(\mathcal{Y}', \mathcal{O}_{\mathcal{Y}'})$ is a spectral Deligne-Mumford stack is local on $\mathcal{Y}'$. Let $\mathcal{Y}'_0$ be the full subcategory of $\mathcal{Y}'$ spanned by those objects Y for which $(\mathcal{Y}'_{/Y}, \mathcal{O}_{\mathcal{Y}'}|_Y)$ is a spectral Deligne-Mumford stack; it will suffice to show that there exists an effective epimorphism $\amalg Y_i \to \mathbf{1}_{\mathcal{Y}'}$, where each $Y_i \in \mathcal{Y}'_0$ and $\mathbf{1}_{\mathcal{Y}'}$ denotes a final object of $\mathcal{Y}'$. Since f' and g' are closed immersions, we can write $\mathcal{X}' \simeq \mathcal{Y}'/U$ and $\mathcal{Y} \simeq \mathcal{Y}'/V$ for some (-1)-truncated objects $U, V \in \mathcal{Y}'$. Then

$$(\mathcal{Y}'_{/U}, \mathcal{O}_{\mathcal{Y}'}|_U) \simeq (\mathcal{Y}_{/f'^*U}, \mathcal{O}_{\mathcal{Y}}|_{f'^*U}) \qquad (\mathcal{Y}'_{/V}, \mathcal{O}_{\mathcal{Y}'}|_V) \simeq (\mathcal{X}'_{/g'^*V}, \mathcal{O}_{\mathcal{X}'}|_{g'^*V})$$

are spectral Deligne-Mumford stacks, so that $U, V \in \mathcal{Y}'_0$. Let $h^* = f^* \circ g'^* : \mathcal{Y}' \to \mathcal{X}$. Using Lemma 3.1.3.2, we are reduced to proving the existence of an effective epimorphism $\amalg X_i \to \mathbf{1}_{\mathcal{X}}$, where each X_i belongs to the essential image $h^* \mathcal{Y}'_0 \subseteq \mathcal{X}$ and $\mathbf{1}_{\mathcal{X}}$ denotes the final object of $\mathcal{X}$.

Let $\mathcal{X}_0$ be the full subcategory of $\mathcal{X}$ spanned by those objects $X \in \mathcal{X}$ with the following properties:

(a) There exists an object $Y \in \mathcal{Y}$ such that $f^*Y \simeq X$ and $(\mathcal{Y}_{/Y}, \mathcal{O}_{\mathcal{Y}}|_Y)$ is affine.

(b) There exists an object $X' \in \mathcal{X}'$ such that $g^*X' \simeq X$ and $(\mathcal{X}'_{/X'}, \mathcal{O}_{\mathcal{X}'}|'_X)$ is affine.

Using Proposition HTT.6.3.2.3 , we see that every object $X \in \mathcal{X}_0$ has the form h^*Y' for some $Y' \in \mathcal{Y}$ such that $(\mathcal{X}'_{/g'^*Y'}, \mathcal{O}_{\mathcal{X}'}|_{g'^*Y'})$ and $(\mathcal{Y}_{/f'^*Y'}, \mathcal{O}_{\mathcal{Y}}|_{f'^*Y'})$ are affine. It then follows from Proposition 16.1.3.1 that $Y' \in \mathcal{Y}_0$, so that $X \in h^* \mathcal{Y}'_0$. It will therefore suffice to show that there exists an effective epimorphism $\amalg X_i \to \mathbf{1}_{\mathcal{X}}$, where each $X_i \in \mathcal{X}_0$.

Since $(\mathcal{Y}, \mathcal{O}_{\mathcal{Y}})$ is a spectral Deligne-Mumford stack, there exists an effective epimorphism $\amalg_i X_i \to \mathbf{1}_{\mathcal{X}}$ where each $X_i \in \mathcal{X}$ satisfies condition (i). Using our assumption that $(\mathcal{X}', \mathcal{O}_{\mathcal{X}'})$ is a spectral Deligne-Mumford stack, we can choose for each index i an effective epimorphism $\theta_i : \amalg_j X'_{i,j} \to g_* X_i$ in $\mathcal{X}'$. Set $X_{i,j} = g^* X'_j$, so that the maps θ_i induce effective epimorphisms

$$\amalg_{i,j} X_{i,j} \to \amalg_i X_i \to \mathbf{1}_{\mathcal{X}}.$$

It will therefore suffice to show that each $X_{i,j}$ satisfies conditions (a) and (b). Condition (b) is evident from the construction, and condition (a) follows from Lemma 16.1.4.1 (together with our assumption that X_i satisfies (a)). This completes the proof that Y' is a spectral Deligne-Mumford stack.

We conclude the proof by observing that if X' and Y are affine (so that X is also affine, by virtue of Theorem 3.1.2.1), then Proposition 16.1.3.1 implies that Y' is also affine.

□

16.2 Clutching of Quasi-Coherent Sheaves

Suppose we are a diagram of spectral Deligne-Mumford stacks $\mathsf{X}_0 \overset{f}{\hookleftarrow} \mathsf{X}_{01} \overset{g}{\hookrightarrow} \mathsf{X}_1$, where f and g are closed immersions. In §16.1, we proved that there exists a pushout diagram

$$\begin{array}{ccc} \mathsf{X}_{01} & \xrightarrow{f} & \mathsf{X}_0 \\ \downarrow{g} & & \downarrow{g'} \\ \mathsf{X}_1 & \xrightarrow{f'} & \mathsf{X} \end{array}$$
