Abstract

This document presents the specification of a primitive datatype for the plain literals of RDF.

Status of this Document

May Be Superseded

This section describes the status of this document at the time of its publication. Other documents may supersede this document. A list of current W3C publications and the latest revision of this technical report can be found in the [W3C technical reports index](#) at <http://www.w3.org/TR/>.

Summary of Changes

There have been no [substantive](#) changes since the [previous version](#). For details on the minor changes see the [change log](#) and [color-coded diff](#).

Please Send Comments

Please send any comments to public-owl-comments@w3.org ([public archive](#)). Although work on this document by the [OWL Working Group](#) and the [Rule Interchange Format \(RIF\) Working Group](#) is complete, comments may be addressed in the [errata](#) or in future revisions. Open discussion among developers is welcome at public-owl-dev@w3.org ([public archive](#)).

Endorsed By W3C

This document has been reviewed by W3C Members, by software developers, and by other W3C groups and interested parties, and is endorsed by the Director as a W3C Recommendation. It is a stable document and may be used as reference material or cited from another document. W3C's role in making the Recommendation is to draw attention to the specification and to promote its widespread deployment. This enhances the functionality and interoperability of the Web.

Patents

This document was produced by a group operating under the [5 February 2004 W3C Patent Policy](#). W3C maintains a [public list of any patent disclosures](#) made in connection with the deliverables of the group; that page also includes instructions for disclosing a patent.

1 Introduction

The Resource Description Framework [RDF] is defined to have an extensible system of [typed literals](#), based on XML Schema datatypes [XSD], and also to have [plain literals](#). In the RDF specification, plain literals differ from typed literals in that plain literals have no datatype and can optionally have a language tag, indicating the natural language of the content. (See [Tags for Identifying Languages \[BCP 47\]](#)). These options for expressing RDF literals complicate specifications which interact with RDF, such as RIF and OWL. Furthermore, RDF does not provide a name for the set of all plain literals, which, for example, prevents one from stating in RDFS or OWL that the range of some property must be a plain literal.

In response, this specification introduces a datatype called `rdf:PlainLiteral`. The datatype is in the "rdf:" namespace because it refers to parts of the conceptual model of RDF. This extension, however, does not change that conceptual model, and thus does not affect specifications that depend on it, such as SPARQL [SPARQL]. The value space of `rdf:PlainLiteral` consists of all data values represented by RDF plain literals, which allows RDF applications to explicitly refer to this set (e.g., in `rdfs:range` assertions).

Because RDF plain literals are already a part of RDF and SPARQL syntaxes, `rdf:PlainLiteral` literals are written as RDF plain literals in RDF and SPARQL syntaxes.

As with plain literals, this datatype can associate language tags with Unicode strings, but it does not provide its own facilities for representing natural language utterances. Unicode [bidirectional control characters \[BIDI\]](#) may be used within these literals, like all other Unicode characters. (Richer, XML-based representations such as [XHTML \[XHTML\]](#) and [Ruby annotations \[RUBY\]](#) can be expressed using the [rdf:XMLLiteral](#) datatype.)

2 Preliminaries

A *character* is an atomic unit of text. Each character has a Universal Character Set (UCS) code point [ISO/IEC 10646] (or, equivalently, a Unicode code point [UNICODE]) that must match the [Char](#) production from XML [XML] thus ensuring compatibility with XML Schema Datatypes [XML Schema Datatypes]. Code points are sometimes represented in this document as U+ followed by a four-digit hexadecimal value of the code point.

A *string* is a finite sequence of zero or more characters. The *length* of a string is the number of characters in it. Strings are written in this specification by enclosing them in double quotes. Two strings are identical if and only if they contain exactly the same characters in exactly the same sequence.

Example:

UCS [ISO/IEC 10646] and Unicode [UNICODE] provide for 1,114,112 different code points. The [Char](#) production from XML [XML], however, excludes the surrogate code points and the code points U+FFFE and U+FFFF. Thus, `rdf:PlainLiteral` provides a total of 1,112,033 different characters. This number is important, as it can affect the satisfiability of an OWL 2 ontology. Consider the following example:

```
ClassAssertion( MinCardinality( n a:property DatatypeRestriction( xs:string xs:length 1 ) ) a:i )
```

This OWL 2 axiom states that the individual `a:i` is connected by the property `a:property` to at least `n` different strings of length one. The number of such strings is limited to 1,112,033 by the above definitions, so this ontology is satisfiable if and only if `n` is smaller than or equal to 1,112,033.

A *language tag* is a string matching the `langtag` production from BCP 47 [BCP 47]. Furthermore, note that this definition corresponds to the *well-formed* rather than the *valid* class of conformance in BCP 47. A language tag may contain subtags that are not registered in the IANA Language Subtag Registry, although an `rdf:PlainLiteral` implementation may also choose to reject such invalid language tags.

Example:

The language tag "en-fubar" is not registered with the IANA Language Subtag Registry, so an `rdf:PlainLiteral` implementation is allowed to reject it. This string, however, matches the `langtag` production from BCP 47, so it is a perfectly valid language tag for the purpose of this specification. Consequently, the value space of `rdf:PlainLiteral` (see [Section 3](#) for its definition) contains, say, the pair < "some string" , "en-fubar" >.

This specification uses Uniform Resource Identifiers (URIs), which are defined in RFC 3986 [RFC 3986], for naming datatypes and their components. For readability, URI prefixes are often abbreviated using a short prefix name according to the convention of RDF [RDF]. The following prefix names are used throughout this document:

- the prefix name `xs:` stands for `http://www.w3.org/2001/XMLSchema#`
- the prefix name `rdf:` stands for `http://www.w3.org/1999/02/22-rdf-syntax-ns#`

The names of the built-in functions defined in Section 5 are QNames, as defined in the XML namespaces specification [XML Namespaces]. The following namespace abbreviations are used in Section 5:

- `fn` stands for the `http://www.w3.org/2005/xpath-functions` namespace
- `plfn` stands for the `http://www.w3.org/2009/rdf-PlainLiteral-functions` namespace

Whether an expression of the form `pr:ln` denotes an abbreviated URI or a QName should be clear from the context: only the names of the built-in functions in Section 5 are QNames; all other such expressions denote abbreviated URIs.

Datatypes are defined in this document along the lines of XML Schema Datatypes [XML Schema Datatypes]. Each datatype is identified by a URI and is described by the following components:

- The *value space* is a set determining the set of values of the datatype. Elements of the value space are called *data values*.
- The *lexical space* is a set of strings that can be used to refer to data values. Each member of the lexical space is called a *lexical form*, and it is mapped to a particular data value.
- The *facet space* is a set of facet pairs of the form (`F v`), where `F` is a URI called a *constraining facet*, and `v` is an arbitrary data value called a *constraining value*. Each such facet pair is mapped to a subset of the value space of the datatype.

A *plain literal* is a string with an optional language tag [RDF]. A plain literal without a language tag is interpreted in an RDF interpretation [RDF Semantics] by itself. A plain literal with a language tag can be written as `"abc"@LangTag`, and is interpreted in an RDF interpretation as a pair < "abc" , "LangTag" >.

A *typed literal* consists of a string and a datatype URI [RDF] and can be written as `"abc"^^datatypeURI`. Given an RDF datatype identified by `datatypeURI`, an RDF datatype interpretation that includes the datatype interprets the typed literal as the data value that the datatype assigns to the lexical form "abc".

The italicized keywords *must*, *must not*, *should*, *should not*, and *may* specify certain aspects of the normative behavior of tools implementing this specification, and are interpreted as specified in RFC 2119 [RFC 2119].

3 Definition of the `rdf:PlainLiteral` Datatype

The datatype identified by the URI `http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral` (abbreviated `rdf:PlainLiteral`) is defined as follows.

Value Space. The value space of `rdf:PlainLiteral` consists of

- all strings, and
- all pairs of the form < "abc" , "lc-langtag" > where "abc" is a string and "lc-langtag" is a lowercase language tag.

Lexical Space. An `rdf:PlainLiteral` lexical form is a string of the form `"abc@LangTag"` where "abc" is an arbitrary (possibly empty) string, and "LangTag" is either the empty string or a (not necessarily lowercase) language tag. Each such lexical form is mapped to a data value `dv` as follows:

- If "LangTag" is empty, then `dv` is equal to the string "abc" and

- If "*langTag*" is not empty, then *dv* is equal to the pair < "*abc*" , "*lc-langtag*" > where "*lc-langtag*" is "*langTag*" normalized to lowercase.

Example:

The following table shows several `rdf:PlainLiteral` lexical forms and their corresponding data values.

Lexical form	Corresponding data value
"Family Guy@en"	< "Family Guy" , "en" >
"Family Guy@EN"	< "Family Guy" , "en" >
"Family Guy@FOX@en"	< "Family Guy@FOX" , "en" >
"Family Guy@"	"Family Guy"
"Family Guy@FOX@"	"Family Guy@FOX"

The following table shows several of strings that are not `rdf:PlainLiteral` lexical forms.

String	The reason for not being an <code>rdf:PlainLiteral</code> lexical form
"Family Guy"	does not contain at least one @ (U+0040) character
"Family Guy@12"	"12" is not a language tag according to BCP 47

Facet Space. The facet space of `rdf:PlainLiteral` is defined as shown in Table 1.

Table 1. The Facet Space of `rdf:PlainLiteral`

A facet pair (<i>F v</i>) is in the facet space of <code>rdf:PlainLiteral</code> if...	Each such facet pair is mapped to the subset of the value space of <code>rdf:PlainLiteral</code> containing...
... <i>F</i> is <code>xs:length</code> , <code>xs:minLength</code> , <code>xs:maxLength</code> , <code>xs:pattern</code> , <code>xs:enumeration</code> , or <code>xs:assertion</code> and (<i>F v</i>) is in the facet space of <code>xs:string</code>all strings of the form " <i>abc</i> " and all pairs of the form < " <i>abc</i> " , " <i>lc-langtag</i> " > such that " <i>abc</i> " is contained in the subset of the value space of <code>xs:string</code> determined by (<i>F v</i>) as specified by XML Schema Datatypes [XML Schema Datatypes].
... <i>F</i> is <code>rdf:langRange</code> and <i>v</i> is an <i>extended language range</i> as specified in Section 2.2 of [RFC4647].	...all pairs of the form < " <i>abc</i> " , " <i>lc-langtag</i> " > such that " <i>lc-langtag</i> " matches <i>v</i> under <i>extended filtering</i> as specified in Section 3.3.2 of [RFC4647].

Example:

The facet `xs:length` can be used to refer to a subset of strings of a particular length regardless of whether they have a language tag or not. Thus, the subset of the value space of `rdf:PlainLiteral` corresponding to the facet pair (`xs:length 3`) contains the string "abc", as well as the pairs < "abc" , "en" > and < "abc" , "de" >.

Example:

The facet `rdf:langRange` can be used to refer to a subset of strings containing the language tag. Note that the language range need not be in lowercase, and that the matching algorithm is case-insensitive. Thus, the subset of the value space of `rdf:PlainLiteral` corresponding to the facet pair (`rdf:langRange "de-DE"`) contains the pairs < "abc" , "de-de" > and < "abc" , "de-de-1996" > (because these match the language range "de-DE" according to RFC 4647), but not the string "abc" (because it is not a pair with a language tag) or the pairs < "abc" , "de-deva" > and < "abc" , "de-latn-de" > (because these do not match the language range "de-DE" according to RFC 4647).

Example:

The facet pair (`rdf:langRange "*"`) is mapped to the subset of the value space of `rdf:PlainLiteral` containing all pairs of the form < "*abc*" , "*lc-langtag*" >. In languages such as OWL 2, this can be used to specify that a data value must contain a language tag.

4 Syntax for `rdf:PlainLiteral` Literals

It follows from the above that in datatyped interpretations that include the `rdf:PlainLiteral` datatype, the value space of `rdf:PlainLiteral` contains exactly all data values assigned to plain literals (with or without a language tag). The `rdf:PlainLiteral` datatype thus provides an explicit way of referring to this set.

To eliminate another source of syntactic redundancy and to retain a large degree of interoperability with applications that do not understand the `rdf:PlainLiteral` datatype, the form of `rdf:PlainLiteral` literals in syntaxes for RDF graphs and for SPARQL is the already existing syntax for the corresponding plain literal, not the syntax for a typed literal. Therefore, typed literals with `rdf:PlainLiteral` as the datatype are considered by this specification to be not valid in syntaxes for RDF graphs or SPARQL.

To implement this design and provide this interoperability, applications that employ this datatype *must* use plain literals (instead of `rdf:PlainLiteral` typed literals) whenever a syntax for plain literals is provided, such as in existing syntaxes for RDF graphs and SPARQL results.

Additionally, systems may need similar restrictions for non-syntactic public interfaces. For instance, in [extended SPARQL basic graph matching](#), the results of matching SPARQL basic graph patterns in an entailment regime that understands `rdf:PlainLiteral` *must* provide variable bindings in existing RDF plain literal form.

5 Functions on `rdf:PlainLiteral` Data Values

This section defines functions that construct and operate on `rdf:PlainLiteral` data values. The terminology used and the way in which these functions are described are in accordance with the XQuery 1.0 and XPath 2.0 Functions and Operators [XPathFunc]. Each function is identified by a QName [XML Namespaces]. The error codes used in this section are given in Appendix G of the XPath 2.0 specification [XPath20] and Appendix C of XQuery and XPath function specification [XPathFunc].

5.1 Functions for Assembling and Disassembling `rdf:PlainLiteral` Data Values

5.1.1 `plfn:PlainLiteral-from-string-lang`

```
plfn:PlainLiteral-from-string-lang( $arg1 as xs:string, $arg2 as xs:string) as rdf:PlainLiteral
```

Summary: returns the data value < \$arg1, lowercase(\$arg2) > if \$arg2 is present, and returns the data value \$arg1 otherwise. Both arguments must be of type xs:string or one of its subtypes, and \$arg2 — if present — must be a (nonempty) language tag; otherwise, this function raises type error [err:FORG0006](#). Note that, since in the value space of rdf:PlainLiteral language tags are in lowercase, this function converts \$arg2 to lowercase.

5.1.2 plfn:string-from-PlainLiteral

```
plfn:string-from-PlainLiteral( $arg as rdf:PlainLiteral ) as xs:string
```

Summary: returns the string part s if \$arg is a rdf:PlainLiteral data value of the form < s, l > or of the form s. If \$arg is not of type rdf:PlainLiteral, this function raises type error [err:FORG0006](#).

5.1.3 plfn:lang-from-PlainLiteral

```
plfn:lang-from-PlainLiteral( $arg as rdf:PlainLiteral ) as xs:language
```

Summary: returns the language tag l if \$arg is an rdf:PlainLiteral data value of the form < s, l >, and returns the empty string if \$arg is an rdf:PlainLiteral data value of the form s. If \$arg is not of type rdf:PlainLiteral, this function raises type error [err:FORG0006](#).

5.2 The Comparison of rdf:PlainLiteral Data Values

The notion of collations used in this section is taken from [Section 7.3.1](#) of XPath and XQuery function specification [[XPathFunc](#)].

5.2.1 plfn:compare

```
plfn:compare( $comparand1 as rdf:PlainLiteral?, $comparand2 as rdf:PlainLiteral? ) as xs:integer?
```

```
plfn:compare( $comparand1 as rdf:PlainLiteral?, $comparand2 as rdf:PlainLiteral?, $collation as xs:string ) as xs:integer?
```

Summary: if either \$comparand1 or \$comparand2 is not of type rdf:PlainLiteral, or if \$collation is specified but is not of type xs:string, this function raises type error [err:FORG0006](#). Otherwise, the function returns the empty sequence if one of the arguments is empty, if one of \$comparand1 and \$comparand2 has a language tag and the other one does not, or if the language parts of \$comparand1 and \$comparand2 are unequal; otherwise, this function returns -1, 0, or 1 depending on whether the value of the string-part of \$comparand1 (or \$comparand1 itself if it has no language tag) is respectively less than, equal to, or greater than the value of the string-part of \$comparand2 (or \$comparand2 itself if it has no language tag). The collation used by the invocation of this function is determined according to the rules in Section 7.3.1 of the XPath and XQuery functions specification [[XPathFunc](#)].

The first version of this function enables the comparison of rdf:PlainLiteral values using the XQuery operators "eq", "ne", "gt", "lt", "le", and "ge".

The two functions may be viewed as declared XQuery functions with the following definitions:

```
declare function plfn:compare( $comparand1 as rdf:PlainLiteral?, $comparand2 as rdf:PlainLiteral? ) as xs:integer?
{
  return
    if ( fn:empty($comparand1) ) then $comparand1
    else if ( fn:empty($comparand2) ) then $comparand2
    else if ( fn:compare ( plfn:lang-from-PlainLiteral( $comparand1 ), plfn:lang-from-PlainLiteral( $comparand2 ) ) = 0 ) then
      fn:compare ( plfn:string-from-PlainLiteral( $comparand1 ), plfn:string-from-PlainLiteral( $comparand2 ) )
}
```

```
declare function plfn:compare( $comparand1 as rdf:PlainLiteral?, $comparand2 as rdf:PlainLiteral? $collation as xs:string ) as xs:integer?
{
  return
    if ( fn:empty($comparand1) ) then $comparand1
    else if ( fn:empty($comparand2) ) then $comparand2
    else if ( fn:compare ( plfn:lang-from-PlainLiteral( $comparand1 ), plfn:lang-from-PlainLiteral( $comparand2 ) ) = 0 ) then
      fn:compare ( plfn:string-from-PlainLiteral( $comparand1 ), plfn:string-from-PlainLiteral( $comparand2 ), $collation )
}
```

5.3 Other Functions on rdf:PlainLiteral Data Values

5.3.1 plfn:length

```
plfn:length($arg as rdf:PlainLiteral) as xs:integer
```

Summary: returns the number of characters in the string part s if \$arg is an rdf:PlainLiteral data value of the form < s, l > or a string value s, respectively. If \$arg is not of type rdf:PlainLiteral, this function raises type error [err:FORG0006](#).

This function may be viewed as a declared XQuery function with the following definition:

```
declare function plfn:length($arg as rdf:PlainLiteral?) as xs:integer
{
  return
    fn:string-length ( plfn:string-from-PlainLiteral( $arg ) )
}
```

5.3.2 plfn:matches-language-range

```
plfn:matches-language-range($arg as rdf:PlainLiteral?, $range as xs:string) as xs:boolean
```

Summary: This function is only defined if \$arg is a sequence of length 0 or 1 of literals of type rdf:PlainLiteral and \$range is of type xs:string; if the parameters do not satisfy these typing conditions, the function raises a type error [err:FORG0006](#). If the typing conditions are fulfilled, the function returns true in case \$arg is an rdf:PlainLiteral data value of the form < s, l > with l a language tag that matches the extended language range \$range as specified by the extended filtering algorithm for "Matching of Language Tags" [[BCP-47](#)]; otherwise, it returns false. This means that the function returns false if the argument \$arg is a string rdf:PlainLiteral data value. An empty input sequence is treated as a rdf:PlainLiteral data value consisting of the empty string, and accordingly on such input this function also returns false.

6 Acknowledgments

The RIF and OWL Working Groups made parallel efforts to support strings with associated language tags, as found in RDF. This specification is the outcome of a collaboration between the two groups, and it is based on the work on the datatypes `rif:text` and `owl:internationalizedString`.

In addition to members and chairs of both Working Groups, the editors would like to thank Addison Phillips, C. Michael Sperberg-McQueen, Eric Prud'hommeaux, Andy Seaborne, and Pat Hayes, along with other participants of the [public-rdf-text](#) mailing list, for their assistance in working out the details of this specification.

8 Appendix: Change Log (Informative)

8.1 Changes Since Recommendation

This section summarizes the changes to this document since the [Recommendation of 27 October, 2009](#).

- With the publication of the XML Schema Definition Language (XSD) 1.1 Part 2: Datatypes [Recommendation of 5 April 2012](#), the elements of OWL 2 which are based on XSD 1.1 are now considered required, and the note detailing the optional dependency on the XSD 1.1 [Candidate Recommendation of 30 April, 2009](#) has been removed from the "Status of this Document" section.

8.2 Changes Since Proposed Recommendation

This section summarizes the changes to this document since the [Proposed Recommendation](#) of 22 September, 2009.

- Several editorial clarifications and improvements were made.

8.3 Changes Since Candidate Recommendation

This section summarizes the changes to this document since the [Candidate Recommendation](#) of 11 June, 2009.

- The "At Risk" warnings were removed. The indicated features remain in the document.
- An error in the order of parameters in an example was corrected
- `xs:assertions` and `xs:lang` were corrected to `xs:assertion` and `xs:language`
- The references to XML Schema Datatypes were rephrased to account for version 1.1 not yet being a Recommendation

8.4 Changes Since Last Call

Since the [last call draft](#) of 21 April 2009, the following changes have been made:

- The name of the datatype was changed from `rdf:text` to `rdf:PlainLiteral`, to clarify the role and purpose of the datatype
- The names of the builtins and their namespace were changed to match the change in the name of the datatype
- The introduction and section 4 were rewritten to reframe this datatype as having a special relationship to RDF plain literals.
- The notion of an entailment relationship between plain literals and `rdf:PlainLiteral` typed literals was removed, since `rdf:PlainLiteral`s are now more clearly understood to not occur in RDF graph syntaxes.
- The characters used to delimit pairs was changed, since problems were reported with `⟨` and `⟩` in some browsers
