

Artificial Intelligence Index Report 2024

Stanford University
Human-Centered
Artificial Intelligence

Introduction to the AI Index Report 2024

Welcome to the seventh edition of the AI Index report. The 2024 Index is our most comprehensive to date and arrives at an important moment when AI's influence on society has never been more pronounced. This year, we have broadened our scope to more extensively cover essential trends such as technical advancements in AI, public perceptions of the technology, and the geopolitical dynamics surrounding its development. Featuring more original data than ever before, this edition introduces new estimates on AI training costs, detailed analyses of the responsible AI landscape, and an entirely new chapter dedicated to AI's impact on science and medicine.

The AI Index report tracks, collates, distills, and visualizes data related to artificial intelligence (AI). Our mission is to provide unbiased, rigorously vetted, broadly sourced data in order for policymakers, researchers, executives, journalists, and the general public to develop a more thorough and nuanced understanding of the complex field of AI.

The AI Index is recognized globally as one of the most credible and authoritative sources for data and insights on artificial intelligence. Previous editions have been cited in major newspapers, including the *The New York Times*, *Bloomberg*, and *The Guardian*, have amassed hundreds of academic citations, and been referenced by high-level policymakers in the United States, the United Kingdom, and the European Union, among other places. This year's edition surpasses all previous ones in size, scale, and scope, reflecting the growing significance that AI is coming to hold in all of our lives.

Message From the Co-directors

A decade ago, the best AI systems in the world were unable to classify objects in images at a human level. AI struggled with language comprehension and could not solve math problems. Today, AI systems routinely exceed human performance on standard benchmarks.

Progress accelerated in 2023. New state-of-the-art systems like GPT-4, Gemini, and Claude 3 are impressively multimodal: They can generate fluent text in dozens of languages, process audio, and even explain memes. As AI has improved, it has increasingly forced its way into our lives. Companies are racing to build AI-based products, and AI is increasingly being used by the general public. But current AI technology still has significant problems. It cannot reliably deal with facts, perform complex reasoning, or explain its conclusions.

AI faces two interrelated futures. First, technology continues to improve and is increasingly used, having major consequences for productivity and employment. It can be put to both good and bad uses. In the second future, the adoption of AI is constrained by the limitations of the technology. Regardless of which future unfolds, governments are increasingly concerned. They are stepping in to encourage the upside, such as funding university R&D and incentivizing private investment. Governments are also aiming to manage the potential downsides, such as impacts on employment, privacy concerns, misinformation, and intellectual property rights.

As AI rapidly evolves, the AI Index aims to help the AI community, policymakers, business leaders, journalists, and the general public navigate this complex landscape. It provides ongoing, objective snapshots tracking several key areas: technical progress in AI capabilities, the community and investments driving AI development and deployment, public opinion on current and potential future impacts, and policy measures taken to stimulate AI innovation while managing its risks and challenges. By comprehensively monitoring the AI ecosystem, the Index serves as an important resource for understanding this transformative technological force.

On the technical front, this year's AI Index reports that the number of new large language models released worldwide in 2023 doubled over the previous year. Two-thirds were open-source, but the highest-performing models came from industry players with closed systems. Gemini Ultra became the first LLM to reach human-level performance on the Massive Multitask Language Understanding (MMLU) benchmark; performance on the benchmark has improved by 15 percentage points since last year. Additionally, GPT-4 achieved an impressive 0.96 mean win rate score on the comprehensive Holistic Evaluation of Language Models (HELM) benchmark, which includes MMLU among other evaluations.

Message From the Co-directors (cont'd)

Although global private investment in AI decreased for the second consecutive year, investment in generative AI skyrocketed. More Fortune 500 earnings calls mentioned AI than ever before, and new studies show that AI tangibly boosts worker productivity. On the policymaking front, global mentions of AI in legislative proceedings have never been higher. U.S. regulators passed more AI-related regulations in 2023 than ever before. Still, many expressed concerns about AI's ability to generate deepfakes and impact elections. The public became more aware of AI, and studies suggest that they responded with nervousness.

Ray Perrault and Jack Clark

Co-directors, AI Index

Top 10 Takeaways

1. AI beats humans on some tasks, but not on all. AI has surpassed human performance on several benchmarks, including some in image classification, visual reasoning, and English understanding. Yet it trails behind on more complex tasks like competition-level mathematics, visual commonsense reasoning and planning.

2. Industry continues to dominate frontier AI research. In 2023, industry produced 51 notable machine learning models, while academia contributed only 15. There were also 21 notable models resulting from industry-academia collaborations in 2023, a new high.

3. Frontier models get way more expensive. According to AI Index estimates, the training costs of state-of-the-art AI models have reached unprecedented levels. For example, OpenAI's GPT-4 used an estimated \$78 million worth of compute to train, while Google's Gemini Ultra cost \$191 million for compute.

4. The United States leads China, the EU, and the U.K. as the leading source of top AI models. In 2023, 61 notable AI models originated from U.S.-based institutions, far outpacing the European Union's 21 and China's 15.

5. Robust and standardized evaluations for LLM responsibility are seriously lacking. New research from the AI Index reveals a significant lack of standardization in responsible AI reporting. Leading developers, including OpenAI, Google, and Anthropic, primarily test their models against different responsible AI benchmarks. This practice complicates efforts to systematically compare the risks and limitations of top AI models.

6. Generative AI investment skyrockets. Despite a decline in overall AI private investment last year, funding for generative AI surged, nearly octupling from 2022 to reach \$25.2 billion. Major players in the generative AI space, including OpenAI, Anthropic, Hugging Face, and Inflection, reported substantial fundraising rounds.

7. The data is in: AI makes workers more productive and leads to higher quality work. In 2023, several studies assessed AI's impact on labor, suggesting that AI enables workers to complete tasks more quickly and to improve the quality of their output. These studies also demonstrated AI's potential to bridge the skill gap between low- and high-skilled workers. Still, other studies caution that using AI without proper oversight can lead to diminished performance.

Top 10 Takeaways (cont'd)

8. Scientific progress accelerates even further, thanks to AI. In 2022, AI began to advance scientific discovery. 2023, however, saw the launch of even more significant science-related AI applications—from AlphaDev, which makes algorithmic sorting more efficient, to GNoME, which facilitates the process of materials discovery.

9. The number of AI regulations in the United States sharply increases. The number of AI-related regulations in the U.S. has risen significantly in the past year and over the last five years. In 2023, there were 25 AI-related regulations, up from just one in 2016. Last year alone, the total number of AI-related regulations grew by 56.3%.

10. People across the globe are more cognizant of AI's potential impact—and more nervous. A survey from Ipsos shows that, over the last year, the proportion of those who think AI will dramatically affect their lives in the next three to five years has increased from 60% to 66%. Moreover, 52% express nervousness toward AI products and services, marking a 13 percentage point rise from 2022. In America, Pew data suggests that 52% of Americans report feeling more concerned than excited about AI, rising from 37% in 2022.

Steering Committee

Co-directors

Public Data and Tools

The AI Index 2024 Report is supplemented by raw data and an interactive tool. We invite each reader to use the data and the tool in a way most relevant to their work and interests.

- **Raw data and charts:** The public data and high-resolution images of all the charts in the report are available on [Google Drive](#).
- **Global AI Vibrancy Tool:** Compare the AI ecosystems of over 30 countries. The Global AI Vibrancy tool will be updated in the summer of 2024.

AI Index and Stanford HAI

The AI Index is an independent initiative at the [Stanford Institute for Human-Centered Artificial Intelligence \(HAI\)](#).

Stanford University
Human-Centered
Artificial Intelligence

The AI Index was conceived within the [One Hundred Year Study on Artificial Intelligence \(AI100\)](#).

The AI Index welcomes feedback and new ideas for next year. Contact us at AI-Index-Report@stanford.edu.

The AI Index acknowledges that while authored by a team of human researchers, its writing process was aided by AI tools. Specifically, the authors used ChatGPT and Claude to help tighten and copy edit initial drafts.

The workflow involved authors writing the original copy, then utilizing AI tools as part of the editing process.

Report Highlights

Chapter 1: Research and Development

1. Industry continues to dominate frontier AI research. In 2023, industry produced 51 notable machine learning models, while academia contributed only 15. There were also 21 notable models resulting from industry-academia collaborations in 2023, a new high.

2. More foundation models and more open foundation models. In 2023, a total of 149 foundation models were released, more than double the amount released in 2022. Of these newly released models, 65.7% were open-source, compared to only 44.4% in 2022 and 33.3% in 2021.

3. Frontier models get way more expensive. According to AI Index estimates, the training costs of state-of-the-art AI models have reached unprecedented levels. For example, OpenAI's GPT-4 used an estimated \$78 million worth of compute to train, while Google's Gemini Ultra cost \$191 million for compute.

4. The United States leads China, the EU, and the U.K. as the leading source of top AI models. In 2023, 61 notable AI models originated from U.S.-based institutions, far outpacing the European Union's 21 and China's 15.

5. The number of AI patents skyrockets. From 2021 to 2022, AI patent grants worldwide increased sharply by 62.7%. Since 2010, the number of granted AI patents has increased more than 31 times.

6. China dominates AI patents. In 2022, China led global AI patent origins with 61.1%, significantly outpacing the United States, which accounted for 20.9% of AI patent origins. Since 2010, the U.S. share of AI patents has decreased from 54.1%.

7. Open-source AI research explodes. Since 2011, the number of AI-related projects on GitHub has seen a consistent increase, growing from 845 in 2011 to approximately 1.8 million in 2023. Notably, there was a sharp 59.3% rise in the total number of GitHub AI projects in 2023 alone. The total number of stars for AI-related projects on GitHub also significantly increased in 2023, more than tripling from 4.0 million in 2022 to 12.2 million.

8. The number of AI publications continues to rise. Between 2010 and 2022, the total number of AI publications nearly tripled, rising from approximately 88,000 in 2010 to more than 240,000 in 2022. The increase over the last year was a modest 1.1%.

Report Highlights

Chapter 2: Technical Performance

1. AI beats humans on some tasks, but not on all. AI has surpassed human performance on several benchmarks, including some in image classification, visual reasoning, and English understanding. Yet it trails behind on more complex tasks like competition-level mathematics, visual commonsense reasoning and planning.

2. Here comes multimodal AI. Traditionally AI systems have been limited in scope, with language models excelling in text comprehension but faltering in image processing, and vice versa. However, recent advancements have led to the development of strong multimodal models, such as Google's Gemini and OpenAI's GPT-4. These models demonstrate flexibility and are capable of handling images and text and, in some instances, can even process audio.

3. Harder benchmarks emerge. AI models have reached performance saturation on established benchmarks such as ImageNet, SQuAD, and SuperGLUE, prompting researchers to develop more challenging ones. In 2023, several challenging new benchmarks emerged, including SWE-bench for coding, HEIM for image generation, MMMU for general reasoning, MoCa for moral reasoning, AgentBench for agent-based behavior, and HaluEval for hallucinations.

4. Better AI means better data which means ... even better AI. New AI models such as SegmentAnything and Skoltech are being used to generate specialized data for tasks like image segmentation and 3D reconstruction. Data is vital for AI technical improvements. The use of AI to create more data enhances current capabilities and paves the way for future algorithmic improvements, especially on harder tasks.

5. Human evaluation is in. With generative models producing high-quality text, images, and more, benchmarking has slowly started shifting toward incorporating human evaluations like the Chatbot Arena Leaderboard rather than computerized rankings like ImageNet or SQuAD. Public sentiment about AI is becoming an increasingly important consideration in tracking AI progress.

6. Thanks to LLMs, robots have become more flexible. The fusion of language modeling with robotics has given rise to more flexible robotic systems like PaLM-E and RT-2. Beyond their improved robotic capabilities, these models can ask questions, which marks a significant step toward robots that can interact more effectively with the real world.

Chapter 2: Technical Performance (cont'd)

7. More technical research in agentic AI. Creating AI agents, systems capable of autonomous operation in specific environments, has long challenged computer scientists. However, emerging research suggests that the performance of autonomous AI agents is improving. Current agents can now master complex games like Minecraft and effectively tackle real-world tasks, such as online shopping and research assistance.

8. Closed LLMs significantly outperform open ones. On 10 select AI benchmarks, closed models outperformed open ones, with a median performance advantage of 24.2%. Differences in the performance of closed and open models carry important implications for AI policy debates.

Report Highlights

Chapter 3: Responsible AI

1. Robust and standardized evaluations for LLM responsibility are seriously lacking.

New research from the AI Index reveals a significant lack of standardization in responsible AI reporting. Leading developers, including OpenAI, Google, and Anthropic, primarily test their models against different responsible AI benchmarks. This practice complicates efforts to systematically compare the risks and limitations of top AI models.

2. Political deepfakes are easy to generate and difficult to detect. Political deepfakes are already affecting elections across the world, with recent research suggesting that existing AI deepfake methods perform with varying levels of accuracy. In addition, new projects like CounterCloud demonstrate how easily AI can create and disseminate fake content.

3. Researchers discover more complex vulnerabilities in LLMs. Previously, most efforts to red team AI models focused on testing adversarial prompts that intuitively made sense to humans. This year, researchers found less obvious strategies to get LLMs to exhibit harmful behavior, like asking the models to infinitely repeat random words.

4. Risks from AI are becoming a concern for businesses across the globe. A global survey on responsible AI highlights that companies' top AI-related concerns include privacy, data security, and reliability. The survey shows that organizations are beginning to take steps to mitigate these risks. Globally, however, most companies have so far only mitigated a small portion of these risks.

5. LLMs can output copyrighted material. Multiple researchers have shown that the generative outputs of popular LLMs may contain copyrighted material, such as excerpts from The New York Times or scenes from movies. Whether such output constitutes copyright violations is becoming a central legal question.

6. AI developers score low on transparency, with consequences for research. The newly introduced Foundation Model Transparency Index shows that AI developers lack transparency, especially regarding the disclosure of training data and methodologies. This lack of openness hinders efforts to further understand the robustness and safety of AI systems.

Chapter 3: Responsible AI (cont'd)

7. Extreme AI risks are difficult to analyze. Over the past year, a substantial debate has emerged among AI scholars and practitioners regarding the focus on immediate model risks, like algorithmic discrimination, versus potential long-term existential threats. It has become challenging to distinguish which claims are scientifically founded and should inform policymaking. This difficulty is compounded by the tangible nature of already present short-term risks in contrast with the theoretical nature of existential threats.

8. The number of AI incidents continues to rise. According to the AI Incident Database, which tracks incidents related to the misuse of AI, 123 incidents were reported in 2023, a 32.3 percentage point increase from 2022. Since 2013, AI incidents have grown by over twentyfold. A notable example includes AI-generated, sexually explicit deepfakes of Taylor Swift that were widely shared online.

9. ChatGPT is politically biased. Researchers find a significant bias in ChatGPT toward Democrats in the United States and the Labour Party in the U.K. This finding raises concerns about the tool's potential to influence users' political views, particularly in a year marked by major global elections.

Report Highlights

Chapter 4: Economy

1. Generative AI investment skyrockets. Despite a decline in overall AI private investment last year, funding for generative AI surged, nearly octupling from 2022 to reach \$25.2 billion. Major players in the generative AI space, including OpenAI, Anthropic, Hugging Face, and Inflection, reported substantial fundraising rounds.

2. Already a leader, the United States pulls even further ahead in AI private investment.

In 2023, the United States saw AI investments reach \$67.2 billion, nearly 8.7 times more than China, the next highest investor. While private AI investment in China and the European Union, including the United Kingdom, declined by 44.2% and 14.1%, respectively, since 2022, the United States experienced a notable increase of 22.1% in the same time frame.

3. Fewer AI jobs in the United States and across the globe. In 2022, AI-related positions made up 2.0% of all job postings in America, a figure that decreased to 1.6% in 2023. This decline in AI job listings is attributed to fewer postings from leading AI firms and a reduced proportion of tech roles within these companies.

4. AI decreases costs and increases revenues. A new McKinsey survey reveals that 42% of surveyed organizations report cost reductions from implementing AI (including generative AI), and 59% report revenue increases. Compared to the previous year, there was a 10 percentage point increase in respondents reporting decreased costs, suggesting AI is driving significant business efficiency gains.

5. Total AI private investment declines again, while the number of newly funded AI companies increases. Global private AI investment has fallen for the second year in a row, though less than the sharp decrease from 2021 to 2022. The count of newly funded AI companies spiked to 1,812, up 40.6% from the previous year.

6. AI organizational adoption ticks up. A 2023 McKinsey report reveals that 55% of organizations now use AI (including generative AI) in at least one business unit or function, up from 50% in 2022 and 20% in 2017.

7. China dominates industrial robotics. Since surpassing Japan in 2013 as the leading installer of industrial robots, China has significantly widened the gap with the nearest competitor nation. In 2013, China's installations accounted for 20.8% of the global total, a share that rose to 52.4% by 2022.

Chapter 4: Economy (cont'd)

8. Greater diversity in robot installations. In 2017, collaborative robots represented a mere 2.8% of all new industrial robot installations, a figure that climbed to 9.9% by 2022. Similarly, 2022 saw a rise in service robot installations across all application categories, except for medical robotics. This trend indicates not just an overall increase in robot installations but also a growing emphasis on deploying robots for human-facing roles.

9. The data is in: AI makes workers more productive and leads to higher quality work.

In 2023, several studies assessed AI's impact on labor, suggesting that AI enables workers to complete tasks more quickly and to improve the quality of their output. These studies also demonstrated AI's potential to bridge the skill gap between low- and high-skilled workers. Still, other studies caution that using AI without proper oversight can lead to diminished performance.

10. Fortune 500 companies start talking a lot about AI, especially generative AI. In 2023, AI was mentioned in 394 earnings calls (nearly 80% of all Fortune 500 companies), a notable increase from 266 mentions in 2022. Since 2018, mentions of AI in Fortune 500 earnings calls have nearly doubled. The most frequently cited theme, appearing in 19.7% of all earnings calls, was generative AI.

Report Highlights

Chapter 5: Science and Medicine

1. Scientific progress accelerates even further, thanks to AI. In 2022, AI began to advance scientific discovery. 2023, however, saw the launch of even more significant science-related AI applications—from AlphaDev, which makes algorithmic sorting more efficient, to GNoME, which facilitates the process of materials discovery.

2. AI helps medicine take significant strides forward. In 2023, several significant medical systems were launched, including EVEscape, which enhances pandemic prediction, and AlphaMissense, which assists in AI-driven mutation classification. AI is increasingly being utilized to propel medical advancements.

3. Highly knowledgeable medical AI has arrived. Over the past few years, AI systems have shown remarkable improvement on the MedQA benchmark, a key test for assessing AI’s clinical knowledge. The standout model of 2023, GPT-4 Medprompt, reached an accuracy rate of 90.2%, marking a 22.6 percentage point increase from the highest score in 2022. Since the benchmark’s introduction in 2019, AI performance on MedQA has nearly tripled.

4. The FDA approves more and more AI-related medical devices. In 2022, the FDA approved 139 AI-related medical devices, a 12.1% increase from 2021. Since 2012, the number of FDA-approved AI-related medical devices has increased by more than 45-fold. AI is increasingly being used for real-world medical purposes.

Report Highlights

Chapter 6: Education

1. The number of American and Canadian CS bachelor's graduates continues to rise, new CS master's graduates stay relatively flat, and PhD graduates modestly grow. While the number of new American and Canadian bachelor's graduates has consistently risen for more than a decade, the number of students opting for graduate education in CS has flattened. Since 2018, the number of CS master's and PhD graduates has slightly declined.

2. The migration of AI PhDs to industry continues at an accelerating pace. In 2011, roughly equal percentages of new AI PhDs took jobs in industry (40.9%) and academia (41.6%). However, by 2022, a significantly larger proportion (70.7%) joined industry after graduation compared to those entering academia (20.0%). Over the past year alone, the share of industry-bound AI PhDs has risen by 5.3 percentage points, indicating an intensifying brain drain from universities into industry.

3. Less transition of academic talent from industry to academia. In 2019, 13% of new AI faculty in the United States and Canada were from industry. By 2021, this figure had declined to 11%, and in 2022, it further dropped to 7%. This trend indicates a progressively lower migration of high-level AI talent from industry into academia.

4. CS education in the United States and Canada becomes less international. Proportionally fewer international CS bachelor's, master's, and PhDs graduated in 2022 than in 2021. The drop in international students in the master's category was especially pronounced.

5. More American high school students take CS courses, but access problems remain. In 2022, 201,000 AP CS exams were administered. Since 2007, the number of students taking these exams has increased more than tenfold. However, recent evidence indicates that students in larger high schools and those in suburban areas are more likely to have access to CS courses.

6. AI-related degree programs are on the rise internationally. The number of English-language, AI-related postsecondary degree programs has tripled since 2017, showing a steady annual increase over the past five years. Universities worldwide are offering more AI-focused degree programs.

Chapter 6: Education (cont'd)

7. The United Kingdom and Germany lead in European informatics, CS, CE, and IT graduate production.

The United Kingdom and Germany lead Europe in producing the highest number of new informatics, CS, CE, and information bachelor's, master's, and PhD graduates. On a per capita basis, Finland leads in the production of both bachelor's and PhD graduates, while Ireland leads in the production of master's graduates.

Report Highlights

Chapter 7: Policy and Governance

1. The number of AI regulations in the United States sharply increases. The number of AI-related regulations has risen significantly in the past year and over the last five years. In 2023, there were 25 AI-related regulations, up from just one in 2016. Last year alone, the total number of AI-related regulations grew by 56.3%.

2. The United States and the European Union advance landmark AI policy action. In 2023, policymakers on both sides of the Atlantic put forth substantial proposals for advancing AI regulation. The European Union reached a deal on the terms of the AI Act, a landmark piece of legislation enacted in 2024. Meanwhile, President Biden signed an Executive Order on AI, the most notable AI policy initiative in the United States that year.

3. AI captures U.S. policymaker attention. The year 2023 witnessed a remarkable increase in AI-related legislation at the federal level, with 181 bills proposed, more than double the 88 proposed in 2022.

4. Policymakers across the globe cannot stop talking about AI. Mentions of AI in legislative proceedings across the globe have nearly doubled, rising from 1,247 in 2022 to 2,175 in 2023. AI was mentioned in the legislative proceedings of 49 countries in 2023. Moreover, at least one country from every continent discussed AI in 2023, underscoring the truly global reach of AI policy discourse.

5. More regulatory agencies turn their attention toward AI. The number of U.S. regulatory agencies issuing AI regulations increased to 21 in 2023 from 17 in 2022, indicating a growing concern over AI regulation among a broader array of American regulatory bodies. Some of the new regulatory agencies that enacted AI-related regulations for the first time in 2023 include the Department of Transportation, the Department of Energy, and the Occupational Safety and Health Administration.

Report Highlights

Chapter 8: Diversity

1. U.S. and Canadian bachelor's, master's, and PhD CS students continue to grow more ethnically diverse. While white students continue to be the most represented ethnicity among new resident graduates at all three levels, the representation from other ethnic groups, such as Asian, Hispanic, and Black or African American students, continues to grow. For instance, since 2011, the proportion of Asian CS bachelor's degree graduates has increased by 19.8 percentage points, and the proportion of Hispanic CS bachelor's degree graduates has grown by 5.2 percentage points.

2. Substantial gender gaps persist in European informatics, CS, CE, and IT graduates at all educational levels. Every surveyed European country reported more male than female graduates in bachelor's, master's, and PhD programs for informatics, CS, CE, and IT. While the gender gaps have narrowed in most countries over the last decade, the rate of this narrowing has been slow.

3. U.S. K–12 CS education is growing more diverse, reflecting changes in both gender and ethnic representation. The proportion of AP CS exams taken by female students rose from 16.8% in 2007 to 30.5% in 2022. Similarly, the participation of Asian, Hispanic/Latino/Latina, and Black/African American students in AP CS has consistently increased year over year.

Report Highlights

Chapter 9: Public Opinion

1. People across the globe are more cognizant of AI's potential impact—and more nervous.

A survey from Ipsos shows that, over the last year, the proportion of those who think AI will dramatically affect their lives in the next three to five years has increased from 60% to 66%. Moreover, 52% express nervousness toward AI products and services, marking a 13 percentage point rise from 2022. In America, Pew data suggests that 52% of Americans report feeling more concerned than excited about AI, rising from 38% in 2022.

2. AI sentiment in Western nations continues to be low, but is slowly improving. In 2022, several developed Western nations, including Germany, the Netherlands, Australia, Belgium, Canada, and the United States, were among the least positive about AI products and services. Since then, each of these countries has seen a rise in the proportion of respondents acknowledging the benefits of AI, with the Netherlands experiencing the most significant shift.

3. The public is pessimistic about AI's economic impact. In an Ipsos survey, only 37% of respondents feel AI will improve their job. Only 34% anticipate AI will boost the economy, and 32% believe it will enhance the job market.

4. Demographic differences emerge regarding AI optimism. Significant demographic differences exist in perceptions of AI's potential to enhance livelihoods, with younger generations generally more optimistic. For instance, 59% of Gen Z respondents believe AI will improve entertainment options, versus only 40% of baby boomers. Additionally, individuals with higher incomes and education levels are more optimistic about AI's positive impacts on entertainment, health, and the economy than their lower-income and less-educated counterparts.

5. ChatGPT is widely known and widely used. An international survey from the University of Toronto suggests that 63% of respondents are aware of ChatGPT. Of those aware, around half report using ChatGPT at least once weekly.

Overview

This chapter studies trends in AI research and development. It begins by examining trends in AI publications and patents, and then examines trends in notable AI systems and foundation models. It concludes by analyzing AI conference attendance and open-source AI software projects.

Chapter Highlights

1. Industry continues to dominate frontier AI research. In 2023, industry produced 51 notable machine learning models, while academia contributed only 15. There were also 21 notable models resulting from industry-academia collaborations in 2023, a new high.

2. More foundation models and more open foundation models. In 2023, a total of 149 foundation models were released, more than double the amount released in 2022. Of these newly released models, 65.7% were open-source, compared to only 44.4% in 2022 and 33.3% in 2021.

3. Frontier models get way more expensive. According to AI Index estimates, the training costs of state-of-the-art AI models have reached unprecedented levels. For example, OpenAI's GPT-4 used an estimated \$78 million worth of compute to train, while Google's Gemini Ultra cost \$191 million for compute.

4. The United States leads China, the EU, and the U.K. as the leading source of top AI models. In 2023, 61 notable AI models originated from U.S.-based institutions, far outpacing the European Union's 21 and China's 15.

5. The number of AI patents skyrockets. From 2021 to 2022, AI patent grants worldwide increased sharply by 62.7%. Since 2010, the number of granted AI patents has increased more than 31 times.

6. China dominates AI patents. In 2022, China led global AI patent origins with 61.1%, significantly outpacing the United States, which accounted for 20.9% of AI patent origins. Since 2010, the U.S. share of AI patents has decreased from 54.1%.

7. Open-source AI research explodes. Since 2011, the number of AI-related projects on GitHub has seen a consistent increase, growing from 845 in 2011 to approximately 1.8 million in 2023. Notably, there was a sharp 59.3% rise in the total number of GitHub AI projects in 2023 alone. The total number of stars for AI-related projects on GitHub also significantly increased in 2023, more than tripling from 4.0 million in 2022 to 12.2 million.

8. The number of AI publications continues to rise. Between 2010 and 2022, the total number of AI publications nearly tripled, rising from approximately 88,000 in 2010 to more than 240,000 in 2022. The increase over the last year was a modest 1.1%.

1.1 Publications

Overview

The figures below present the global count of English-language AI publications from 2010 to 2022, categorized by type of affiliation and cross-sector collaborations. Additionally, this section details publication data for AI journal articles and conference papers.

Total Number of AI Publications¹

Figure 1.1.1 displays the global count of AI publications. Between 2010 and 2022, the total number of AI publications nearly tripled, rising from approximately 88,000 in 2010 to more than 240,000 in 2022. The increase over the last year was a modest 1.1%.

Number of AI publications in the world, 2010–22

Source: Center for Security and Emerging Technology, 2023 | Chart: 2024 AI Index report

Figure 1.1.1

¹ The data on publications presented this year is sourced from CSET. Both the methodology and data sources used by CSET to classify AI publications have changed since their data was last featured in the AI Index (2023). As a result, the numbers reported in this year's section differ slightly from those reported in last year's edition. Moreover, the AI-related publication data is fully available only up to 2022 due to a significant lag in updating publication data. Readers are advised to approach publication figures with appropriate caution.

By Type of Publication

Figure 1.1.2 illustrates the distribution of AI publication types globally over time. In 2022, there were roughly 230,000 AI journal articles compared to roughly 42,000 conference submissions. Since 2015, AI

journal and conference publications have increased at comparable rates. In 2022, there were 2.6 times as many conference publications and 2.4 times as many journal publications as there were in 2015.

Number of AI publications by type, 2010–22

Source: Center for Security and Emerging Technology, 2023 | Chart: 2024 AI Index report

Figure 1.1.2²

² It is possible for an AI publication to be mapped to more than one publication type, so the totals in Figure 1.1.2 do not completely align with those in Figure 1.1.1.

By Field of Study

Figure 1.1.3 examines the total number of AI publications by field of study since 2010. Machine learning publications have seen the most rapid growth over the past decade, increasing nearly

sevenfold since 2015. Following machine learning, the most published AI fields in 2022 were computer vision (21,309 publications), pattern recognition (19,841), and process management (12,052).

Number of AI publications by field of study (excluding Other AI), 2010–22

Source: Center for Security and Emerging Technology, 2023 | Chart: 2024 AI Index report

Figure 1.1.3

By Sector

This section presents the distribution of AI publications by sector—education, government, industry, nonprofit, and other—globally and then specifically within the United States, China, and the European Union plus the United Kingdom. In 2022, the academic sector contributed the majority of AI

publications (81.1%), maintaining its position as the leading global source of AI research over the past decade across all regions (Figure 1.1.4 and Figure 1.1.5). Industry participation is most significant in the United States, followed by the European Union plus the United Kingdom, and China (Figure 1.1.5).

Figure 1.1.5

AI Journal Publications

Figure 1.1.6 illustrates the total number of AI journal publications from 2010 to 2022. The number of AI journal publications experienced modest growth from 2010 to 2015 but grew approximately 2.4 times since 2015. Between 2021 and 2022, AI journal publications saw a 4.5% increase.

Number of AI journal publications, 2010–22

Source: Center for Security and Emerging Technology, 2023 | Chart: 2024 AI Index report

Figure 1.1.6

AI Conference Publications

Figure 1.1.7 visualizes the total number of AI conference publications since 2010. The number of AI conference publications has seen a notable rise in the past two

years, climbing from 22,727 in 2020 to 31,629 in 2021, and reaching 41,174 in 2022. Over the last year alone, there was a 30.2% increase in AI conference publications. Since 2010, the number of AI conference publications has more than doubled.

Number of AI conference publications, 2010–22

Source: Center for Security and Emerging Technology, 2023 | Chart: 2024 AI Index report

Figure 1.1.7

This section examines trends over time in global AI patents, which can reveal important insights into the evolution of innovation, research, and development within AI. Additionally, analyzing AI patents can reveal how these advancements are distributed globally. Similar to the publications data, there is a noticeable delay in AI patent data availability, with 2022 being the most recent year for which data is accessible. The data in this section comes from [CSET](#).

1.2 Patents

AI Patents

Overview

Figure 1.2.1 examines the global growth in granted AI patents from 2010 to 2022. Over the last decade, there has been a significant rise in the number of AI patents, with a particularly sharp increase in recent

years. For instance, between 2010 and 2014, the total growth in granted AI patents was 56.1%. However, from 2021 to 2022 alone, the number of AI patents increased by 62.7%.

Number of AI patents granted, 2010–22

Source: Center for Security and Emerging Technology, 2023 | Chart: 2024 AI Index report

Figure 1.2.1

By Filing Status and Region

The following section disaggregates AI patents by their filing status (whether they were granted or not granted), as well as the region of their publication.

Figure 1.2.2 compares global AI patents by application status. In 2022, the number of ungranted AI patents (128,952) was more than double the amount granted

(62,264). Over time, the landscape of AI patent approvals has shifted markedly. Until 2015, a larger proportion of filed AI patents were granted. However, since then, the majority of AI patent filings have not been granted, with the gap widening significantly. For instance, in 2015, 42.2% of all filed AI patents were not granted. By 2022, this figure had risen to 67.4%.

AI patents by application status, 2010–22

Source: Center for Security and Emerging Technology, 2023 | Chart: 2024 AI Index report

Figure 1.2.2

The gap between granted and not granted AI patents is evident across all major patent-originating geographic areas, including China, the European Union and United Kingdom, and the United States

(Figure 1.2.3). In recent years, all three geographic areas have experienced an increase in both the total number of AI patent filings and the number of patents granted.

AI patents by application status by geographic area, 2010–22

Source: Center for Security and Emerging Technology, 2023 | Chart: 2024 AI Index report

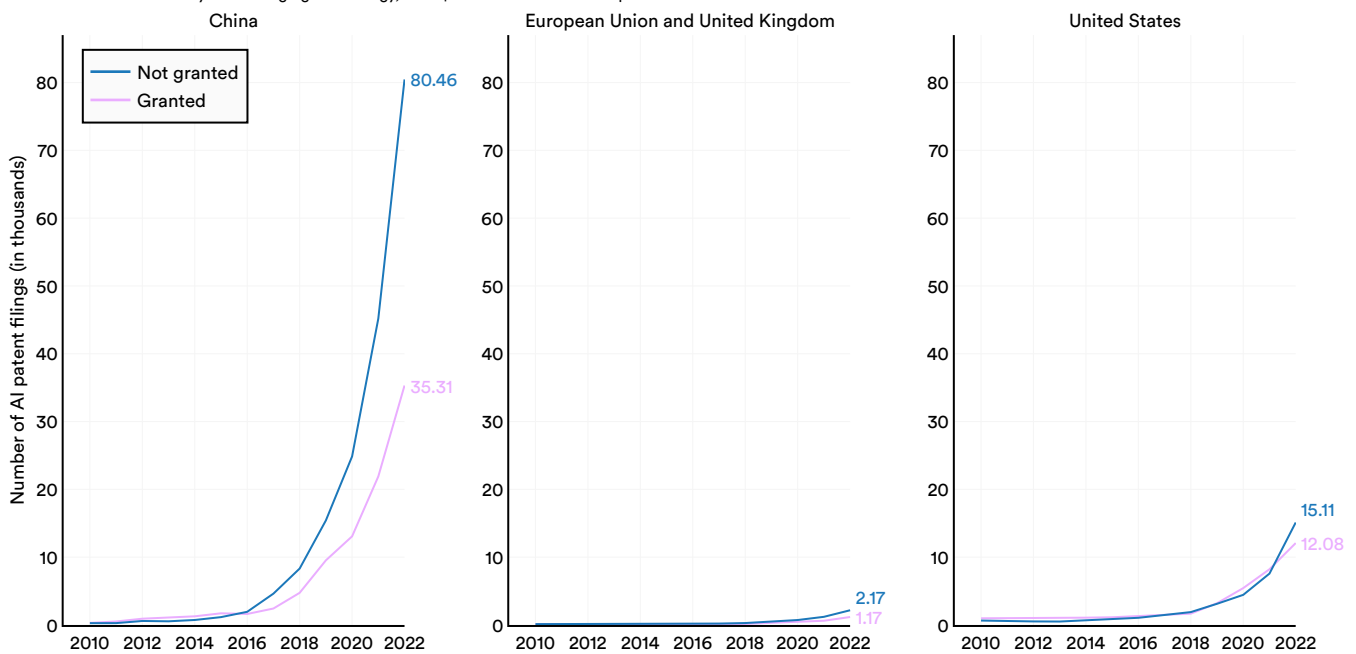

Figure 1.2.3

Figure 1.2.4 showcases the regional breakdown of granted AI patents. As of 2022, the bulk of the world’s granted AI patents (75.2%) originated from East Asia and the Pacific, with North America being the next largest contributor at 21.2%. Up until 2011,

North America led in the number of global AI patents. However, since then, there has been a significant shift toward an increasing proportion of AI patents originating from East Asia and the Pacific.

Granted AI patents (% of world total) by region, 2010–22

Source: Center for Security and Emerging Technology, 2023 | Chart: 2024 AI Index report

Figure 1.2.4

Disaggregated by geographic area, the majority of the world’s granted AI patents are from China (61.1%) and the United States (20.9%) (Figure 1.2.5). The share of AI patents originating from the United States has declined from 54.1% in 2010.

Granted AI patents (% of world total) by geographic area, 2010–22

Source: Center for Security and Emerging Technology, 2023 | Chart: 2024 AI Index report

Figure 1.2.5

Figure 1.2.6 and Figure 1.2.7 document which countries lead in AI patents per capita. In 2022, the country with the most granted AI patents per 100,000 inhabitants was South Korea (10.3), followed by Luxembourg (8.8) and the United States (4.2)

(Figure 1.2.6). Figure 1.2.7 highlights the change in granted AI patents per capita from 2012 to 2022. Singapore, South Korea, and China experienced the greatest increase in AI patenting per capita during that time period.

Figure 1.2.7

This section explores the frontier of AI research. While many new AI models are introduced annually, only a small sample represents the most advanced research. Admittedly what constitutes advanced or frontier research is somewhat subjective. Frontier research could reflect a model posting a new state-of-the-art result on a benchmark, introducing a meaningful new architecture, or exercising some impressive new capabilities.

The AI Index studies trends in two types of frontier AI models: “notable models” and foundation models.³ Epoch, an AI Index data provider, uses the term “notable machine learning models” to designate noteworthy models handpicked as being particularly influential within the AI/machine learning ecosystem. In contrast, foundation models are exceptionally large AI models trained on massive datasets, capable of performing a multitude of downstream tasks. Examples of foundation models include GPT-4, Claude 3, and Gemini. While many foundation models may qualify as notable models, not all notable models are foundation models.

Within this section, the AI Index explores trends in notable models and foundation models from various perspectives, including originating organization, country of origin, parameter count, and compute usage. The analysis concludes with an examination of machine learning training costs.

1.3 Frontier AI Research

General Machine Learning Models

Overview

Epoch AI is a group of researchers dedicated to studying and predicting the evolution of advanced AI. They maintain a database of AI and machine learning models released since the 1950s, selecting

entries based on criteria such as state-of-the-art advancements, historical significance, or high citation rates. Analyzing these models provides a comprehensive overview of the machine learning landscape’s evolution, both in recent years and over the past few decades.⁴ Some models may be missing from the dataset; however, the dataset can reveal trends in relative terms.

³ “AI system” refers to a computer program or product based on AI, such as ChatGPT. “AI model” refers to a collection of parameters whose values are learned during training, such as GPT-4.

⁴ New and historic models are continually added to the Epoch database, so the total year-by-year counts of models included in this year’s AI Index might not exactly match those published in last year’s report.

Sector Analysis

Until 2014, academia led in the release of machine learning models. Since then, industry has taken the lead. In 2023, there were 51 notable machine learning models produced by industry compared to just 15 from academia (Figure 1.3.1). Significantly, 21 notable models resulted from industry/academic collaborations in 2023, a new high.

Creating cutting-edge AI models now demands a substantial amount of data, computing power, and financial resources that are not available in academia. This shift toward increased industrial dominance in leading AI models was first highlighted in last year’s [AI Index report](#). Although this year the gap has slightly narrowed, the trend largely persists.

Number of notable machine learning models by sector, 2003–23

Source: Epoch, 2023 | Chart: 2024 AI Index report

Figure 1.3.1

National Affiliation

To illustrate the evolving geopolitical landscape of AI, the AI Index research team analyzed the country of origin of notable models.

Figure 1.3.2 displays the total number of notable machine learning models attributed to the location of researchers' affiliated institutions.⁵

In 2023, the United States led with 61 notable machine learning models, followed by China with 15, and France with 8. For the first time since 2019, the European Union and the United Kingdom together have surpassed China in the number of notable AI models produced (Figure 1.3.3). Since 2003, the United States has produced more models than other major geographic regions such as the United Kingdom, China, and Canada (Figure 1.3.4).

Number of notable machine learning models by geographic area, 2023

Source: Epoch, 2023 | Chart: 2024 AI Index report

Figure 1.3.3

⁵ A machine learning model is considered associated with a specific country if at least one author of the paper introducing it has an affiliation with an institution based in that country. In cases where a model's authors come from several countries, double counting can occur.

Number of notable machine learning models by geographic area, 2003–23 (sum)

Source: Epoch, 2023 | Chart: 2024 AI Index report

Figure 1.3.4

Parameter Trends

Parameters in machine learning models are numerical values learned during training that determine how a model interprets input data and makes predictions. Models trained on more data will usually have more parameters than those trained on less data. Likewise, models with more parameters typically outperform those with fewer parameters.

Figure 1.3.5 demonstrates the parameter count of machine learning models in the Epoch dataset, categorized by the sector from which the models

originate. Parameter counts have risen sharply since the early 2010s, reflecting the growing complexity of tasks AI models are designed for, the greater availability of data, improvements in hardware, and proven efficacy of larger models. High-parameter models are particularly notable in the industry sector, underscoring the capacity of companies like OpenAI, Anthropic, and Google to bear the computational costs of training on vast volumes of data.

Number of parameters of notable machine learning models by sector, 2003–23

Source: Epoch, 2023 | Chart: 2024 AI Index report

Figure 1.3.5

Compute Trends

The term “compute” in AI models denotes the computational resources required to train and operate a machine learning model. Generally, the complexity of the model and the size of the training dataset directly influence the amount of compute needed. The more complex a model is, and the larger the underlying training data, the greater the amount of compute required for training.

for notable machine learning models in the last 20 years. Recently, the compute usage of notable AI models has increased exponentially.⁶ This trend has been especially pronounced in the last five years. This rapid rise in compute demand has critical implications. For instance, models requiring more computation often have larger environmental footprints, and companies typically have more access to computational resources than academic institutions.

Figure 1.3.6 visualizes the training compute required

Training compute of notable machine learning models by sector, 2003–23

Source: Epoch, 2023 | Chart: 2024 AI Index report

Figure 1.3.6

⁶ FLOP stands for “floating-point operation.” A floating-point operation is a single arithmetic operation involving floating-point numbers, such as addition, subtraction, multiplication, or division. The number of FLOPs a processor or computer can perform per second is an indicator of its computational power. The higher the FLOP rate, the more powerful the computer is. An AI model with a higher FLOP rate reflects its requirement for more computational resources during training.

Figure 1.3.7 highlights the training compute of notable machine learning models since 2012. For example, AlexNet, one of the papers that popularized the now standard practice of using GPUs to improve AI models, required an estimated 470 petaFLOPs for training.

The original Transformer, released in 2017, required around 7,400 petaFLOPs. Google’s Gemini Ultra, one of the current state-of-the-art foundation models, required 50 billion petaFLOPs.

Training compute of notable machine learning models by domain, 2012–23

Source: Epoch, 2023 | Chart: 2024 AI Index report

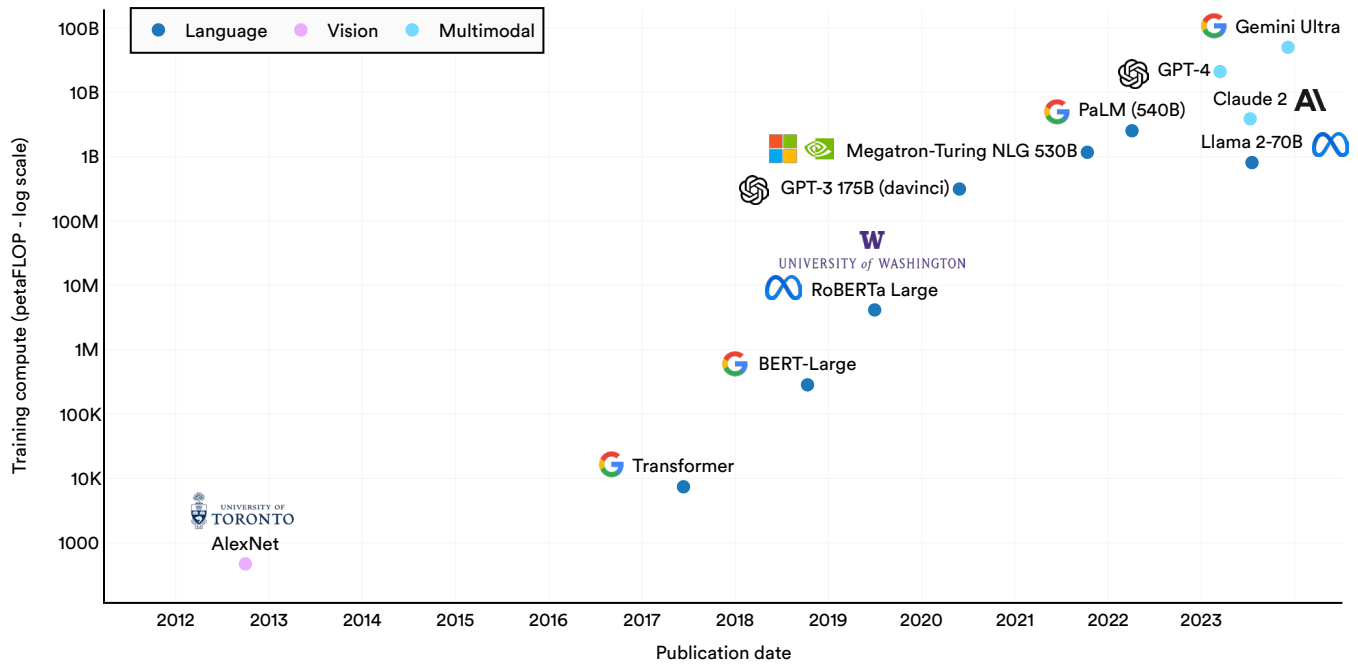

Figure 1.3.7

Highlight:

Will Models Run Out of Data?

As illustrated above, a significant proportion of recent algorithmic progress, including progress behind powerful LLMs, has been achieved by training models on increasingly larger amounts of data. As noted recently by Anthropic cofounder and AI Index Steering Committee member Jack Clark, foundation models have been trained on meaningful percentages of all the data that has ever existed on the internet.

The growing data dependency of AI models has led to concerns that future generations of computer scientists will run out of data to further scale and improve their systems. Research from Epoch suggests that these concerns are somewhat warranted. Epoch researchers have generated historical and compute-based projections for when AI researchers might expect to run out of data. The historical projections are based on observed growth rates in the sizes of data used to train foundation models. The compute projections adjust the historical growth rate based on projections of compute availability.

For instance, the researchers estimate that computer scientists could deplete the stock of high-quality language data by 2024, exhaust low-quality language data within two decades, and use up image data by the late 2030s to mid-2040s (Figure 1.3.8).

Theoretically, the challenge of limited data availability can be addressed by using synthetic

Projections of ML data exhaustion by stock type: median and 90% CI dates

Source: Epoch, 2023 | Table: 2024 AI Index report

Stock type	Historical projection	Compute projection
Low-quality language stock	2032.4 [2028.4; 2039.2]	2040.5 [2034.6; 2048.9]
High-quality language stock	2024.5 [2023.5; 2025.7]	2024.1 [2023.2; 2025.3]
Image stock	2046 [2037; 2062.8]	2038.8 [2032; 2049.8]

Figure 1.3.8

data, which is data generated by AI models themselves. For example, it is possible to use text produced by one LLM to train another LLM. The use of synthetic data for training AI systems is particularly attractive, not only as a solution for potential data depletion but also because generative AI systems could, in principle, generate data in instances where naturally occurring data is sparse—for example, data for rare diseases or underrepresented populations. Until recently, the feasibility and effectiveness of using synthetic data for training generative AI systems were not well understood. However, research this year has suggested that there are limitations associated with training models on synthetic data.

For instance, a team of British and Canadian researchers discovered that models predominantly trained on synthetic data experience model collapse, a phenomenon where, over time, they lose the ability to remember true underlying data distributions and start producing a narrow range of

Highlight:

Will Models Run Out of Data? (cont'd)

outputs. Figure 1.3.9 demonstrates the process of model collapse in a variational autoencoder (VAE) model, a widely used generative AI architecture. With each subsequent generation trained on additional synthetic data, the model produces an increasingly limited set of outputs. As illustrated in Figure 1.3.10, in statistical terms, as the number of synthetic generations increases, the tails of the distributions vanish, and the generation density shifts toward the mean.⁷ This pattern means that

over time, the generations of models trained predominantly on synthetic data become less varied and are not as widely distributed.

The authors demonstrate that this phenomenon occurs across various model types, including Gaussian Mixture Models and LLMs. This research underscores the continued importance of human-generated data for training capable LLMs that can produce a diverse array of content.

A demonstration of model collapse in a VAE

Source: [Shumailov et al., 2023](#)

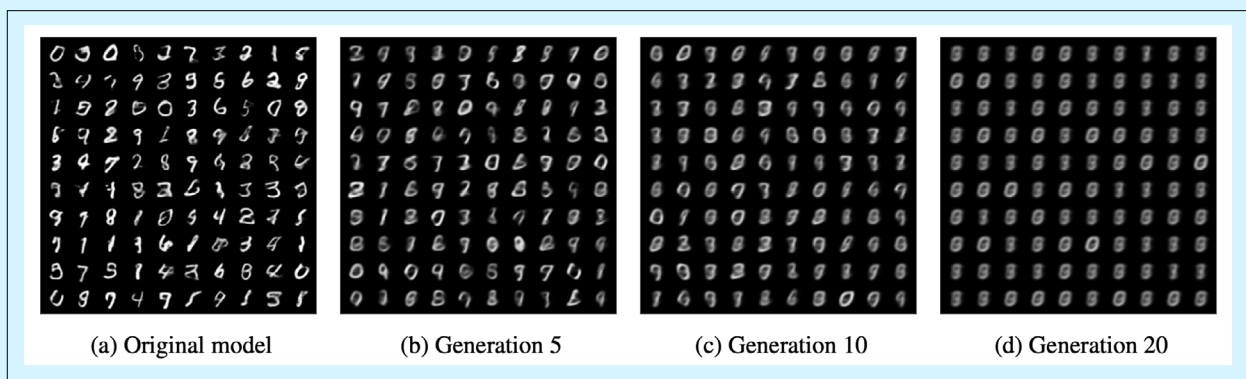

Figure 1.3.9

⁷ In the context of generative models, density refers to the level of complexity and variation in the outputs produced by an AI model. Models that have a higher generation density produce a wider range of higher-quality outputs. Models with low generation density produce a narrower range of more simplistic outputs.

Highlight:

Will Models Run Out of Data? (cont'd)

Convergence of generated data densities in descendant models

Source: Shumailov et al., 2023 | Chart: 2024 AI Index report

Figure 1.3.10

In a [similar study](#) published in 2023 on the use of synthetic data in generative imaging models, researchers found that generative image models trained solely on synthetic data cycles—or with insufficient real human data—experience a significant drop in output quality. The authors label this phenomenon Model Autophagy Disorder (MAD), in reference to mad cow disease.

The study examines two types of training processes: fully synthetic, where models are trained exclusively on synthetic data, and synthetic augmentation, where models are trained on a mix of synthetic and real data. In both scenarios, as the number of training generations increases, the quality of the

generated images declines. Figure 1.3.11 highlights the degraded image generations of models that are augmented with synthetic data; for example, the faces generated in steps 7 and 9 increasingly display strange-looking hash marks. From a statistical perspective, images generated with both synthetic data and synthetic augmentation loops have higher FID scores (indicating less similarity to real images), lower precision scores (signifying reduced realism or quality), and lower recall scores (suggesting decreased diversity) (Figure 1.3.12). While synthetic augmentation loops, which incorporate some real data, show less degradation than fully synthetic loops, both methods exhibit diminishing returns with further training.

Foundation Models

Foundation models represent a rapidly evolving and popular category of AI models. Trained on vast datasets, they are versatile and suitable for numerous downstream applications. Foundation models such as GPT-4, Claude 3, and Llama 2 showcase remarkable abilities and are increasingly being deployed in real-world scenarios.

Introduced in 2023, the Ecosystem Graphs is a new community resource from Stanford that tracks the foundation model ecosystem, including datasets, models, and applications. This section uses data from the Ecosystem Graphs to study trends in foundation models over time.⁸

Model Release

Foundation models can be accessed in different ways. No access models, like Google’s PaLM-E, are only accessible to their developers. Limited access models, like OpenAI’s GPT-4, offer limited access to the models, often through a public API. Open models, like Meta’s Llama 2, fully release model weights, which means the models can be modified and freely used.

Figure 1.3.13 visualizes the total number of foundation models by access type since 2019. In recent years, the number of foundation models has risen sharply, more than doubling since 2022 and growing by a factor of nearly 38 since 2019. Of the 149 foundation models released in 2023, 98 were open, 23 limited and 28 no access.

Foundation models by access type, 2019–23

Source: Bommasani et al., 2023 | Chart: 2024 AI Index report

Figure 1.3.13

⁸ The Ecosystem Graphs make efforts to survey the global AI ecosystem, but it is possible that they underreport models from certain nations like South Korea and China.

In 2023, the majority of foundation models were released as open access (65.8%), with 18.8% having no access and 15.4% limited access (Figure 1.3.14). Since 2021, there has been a significant increase in the proportion of models released with open access.

Foundation models (% of total) by access type, 2019–23

Source: Bommasani et al., 2023 | Chart: 2024 AI Index report

Figure 1.3.14

Organizational Affiliation

Figure 1.3.15 plots the sector from which foundation models have originated since 2019. In 2023, the majority of foundation models (72.5%) originated

from industry. Only 18.8% of foundation models in 2023 originated from academia. Since 2019, an ever larger number of foundation models are coming from industry.

Number of foundation models by sector, 2019–23

Source: Bommasani et al., 2023 | Chart: 2024 AI Index report

Figure 1.3.15

Figure 1.3.16 highlights the source of various foundation models that were released in 2023. Google introduced the most models (18), followed by Meta (11), and Microsoft (9). The academic institution that released the most foundation models in 2023 was UC Berkeley (3).

Number of foundation models by organization, 2023

Source: Bommasani et al., 2023 | Chart: 2024 AI Index report

Figure 1.3.16

Since 2019, Google has led in releasing the most foundation models, with a total of 40, followed by OpenAI with 20 (Figure 1.3.17). Tsinghua University stands out as the top non-Western institution, with seven foundation model releases, while Stanford University is the leading American academic institution, with five releases.

Number of foundation models by organization, 2019–23 (sum)

Source: Bommasani et al., 2023 | Chart: 2024 AI Index report

Figure 1.3.17

National Affiliation

Given that foundation models are fairly representative of frontier AI research, from a geopolitical perspective, it is important to understand their national affiliations. Figures 1.3.18, 1.3.19, and 1.3.20 visualize the national affiliations of various foundation models. As with the notable model analysis presented earlier in the chapter, a model is deemed affiliated with a country if a researcher contributing to that model is affiliated with an institution headquartered in that country.

In 2023, most of the world’s foundation models originated from the United States (109), followed by China (20), and the United Kingdom (Figure 1.3.18). Since 2019, the United States has consistently led in originating the majority of foundation models (Figure 1.3.19).

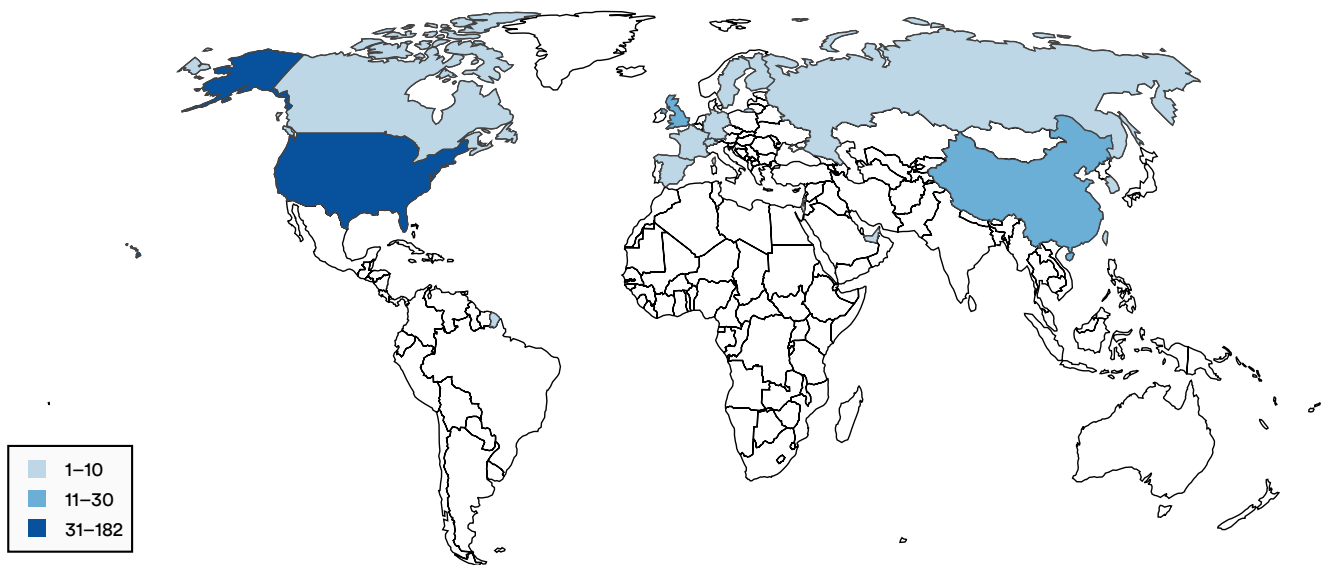

Figure 1.3.20

Training Cost

A prominent topic in discussions about foundation models is their speculated costs. While AI companies seldom reveal the expenses involved in training their models, it is widely believed that these costs run into millions of dollars and are rising. For instance, OpenAI’s CEO, Sam Altman, mentioned that the training cost for GPT-4 was over \$100 million. This escalation in training expenses has effectively excluded universities, traditionally centers of AI research, from developing their own leading-edge foundation models. In response, policy initiatives, such as President Biden’s Executive Order on AI, have sought to level the playing field between industry and academia by creating a National AI Research Resource, which would grant nonindustry actors the compute and data needed to do higher level AI-research.

Understanding the cost of training AI models is important, yet detailed information on these costs remains scarce. The AI Index was among the first to offer estimates on the training costs of foundation

models in last year’s publication. This year, the AI Index has collaborated with Epoch AI, an AI research institute, to substantially enhance and solidify the robustness of its AI training cost estimates.⁹ To estimate the cost of cutting-edge models, the Epoch team analyzed training duration, as well as the type, quantity, and utilization rate of the training hardware, using information from publications, press releases, or technical reports related to the models.¹⁰

Figure 1.3.21 visualizes the estimated training cost associated with select AI models, based on cloud compute rental prices. AI Index estimates validate suspicions that in recent years model training costs have significantly increased. For example, in 2017, the original Transformer model, which introduced the architecture that underpins virtually every modern LLM, cost around \$900 to train.¹¹ RoBERTa Large, released in 2019, which achieved state-of-the-art results on many canonical comprehension benchmarks like SQuAD and GLUE, cost around \$160,000 to train. Fast-forward to 2023, and training costs for OpenAI’s GPT-4 and Google’s Gemini Ultra are estimated to be around \$78 million and \$191 million, respectively.

⁹ Ben Cottier and Robi Rahman led research at Epoch AI into model training cost.

¹⁰ A detailed description of the estimation methodology is provided in the Appendix.

¹¹ The cost figures reported in this section are inflation-adjusted.

Estimated training cost of select AI models, 2017–23

Source: Epoch, 2023 | Chart: 2024 AI Index report

Figure 1.3.21

Figure 1.3.22 visualizes the training cost of all AI models for which the AI Index has estimates. As the figure shows, model training costs have sharply increased over time.

Estimated training cost of select AI models, 2016–23

Source: Epoch, 2023 | Chart: 2024 AI Index report

Figure 1.3.22

As established in previous [AI Index](#) reports, there is a direct correlation between the training costs of AI models and their computational requirements. As illustrated in Figure 1.3.23, models with greater computational training needs cost substantially more to train.

Estimated training cost and compute of select AI models

Figure 1.3.23

AI conferences serve as essential platforms for researchers to present their findings and network with peers and collaborators. Over the past two decades, these conferences have expanded in scale, quantity, and prestige. This section explores trends in attendance at major AI conferences.

1.4 AI Conferences

Conference Attendance

Figure 1.4.1 graphs attendance at a selection of AI conferences since 2010. Following a decline in attendance, likely due to the shift back to exclusively in-person formats, the AI Index reports an increase in conference attendance from 2022 to 2023.¹²

Specifically, there was a 6.7% rise in total attendance over the last year. Since 2015, the annual number of attendees has risen by around 50,000, reflecting not just a growing interest in AI research but also the emergence of new AI conferences.

Attendance at select AI conferences, 2010–23

Source: AI Index, 2023 | Chart: 2024 AI Index report

Figure 1.4.1

¹² This data should be interpreted with caution given that many conferences in the last few years have had virtual or hybrid formats. Conference organizers report that measuring the exact attendance numbers at virtual conferences is difficult, as virtual conferences allow for higher attendance of researchers from around the world. The conferences for which the AI Index tracked data include *NeurIPS, CVPR, ICML, ICCV, ICRA, AAAI, ICLR, IROS, IJCAI, AAMAS, FAccT, UAI, ICAPS, and KR*.

Neural Information Processing Systems (NeurIPS) remains one of the most attended AI conferences, attracting approximately 16,380 participants in 2023 (Figure 1.4.2 and Figure 1.4.3). Among the major

AI conferences, NeurIPS, ICML, ICCV, and AAAI experienced year-over-year increases in attendance. However, in the past year, CVPR, ICRA, ICLR, and IROS observed slight declines in their attendance figures.

Attendance at large conferences, 2010–23

Source: AI Index, 2023 | Chart: 2024 AI Index report

Figure 1.4.2

Attendance at small conferences, 2010–23

Source: AI Index, 2023 | Chart: 2024 AI Index report

Figure 1.4.3

GitHub is a web-based platform that enables individuals and teams to host, review, and collaborate on code repositories. Widely used by software developers, GitHub facilitates code management, project collaboration, and open-source software support. This section draws on data from GitHub providing insights into broader trends in open-source AI software development not reflected in academic publication data.

1.5 Open-Source AI Software

Projects

A GitHub project comprises a collection of files, including source code, documentation, configuration files, and images, that together make up a software project. Figure 1.5.1 looks at the total number of

GitHub AI projects over time. Since 2011, the number of AI-related GitHub projects has seen a consistent increase, growing from 845 in 2011 to approximately 1.8 million in 2023.¹³ Notably, there was a sharp 59.3% rise in the total number of GitHub AI projects in the last year alone.

Number of GitHub AI projects, 2011–23

Source: GitHub, 2023 | Chart: 2024 AI Index report

Figure 1.5.1

¹³ GitHub's methodology for identifying AI-related projects has evolved over the past year. For classifying AI projects, GitHub has started incorporating generative AI keywords from a recently published research paper, a shift from the previously detailed methodology in an earlier paper. This edition of the AI Index is the first to adopt this updated approach. Moreover, the previous edition of the AI Index utilized country-level mapping of GitHub AI projects conducted by the OECD, which depended on self-reported data—a method experiencing a decline in coverage over time. This year, the AI Index has adopted geographic mapping from GitHub, leveraging server-side data for broader coverage. Consequently, the data presented here may not align perfectly with data in earlier versions of the report.

Figure 1.5.2 reports GitHub AI projects by geographic area since 2011. As of 2023, a significant share of GitHub AI projects were located in the United States, accounting for 22.9% of contributions. India was the second-largest contributor with 19.0%,

followed closely by the European Union and the United Kingdom at 17.9%. Notably, the proportion of AI projects from developers located in the United States on GitHub has been on a steady decline since 2016.

GitHub AI projects (% of total) by geographic area, 2011–23

Source: GitHub, 2023 | Chart: 2024 AI Index report

Figure 1.5.2

Stars

GitHub users can show their interest in a repository by “starring” it, a feature similar to liking a post on social media, which signifies support for an open-source project. Among the most starred repositories are libraries such as TensorFlow, OpenCV, Keras, and PyTorch, which enjoy widespread popularity among software developers in the AI coding community. For example, TensorFlow is a popular library for building and deploying machine learning models. OpenCV is

a platform that offers a variety of tools for computer vision, such as object detection and feature extraction.

The total number of stars for AI-related projects on GitHub saw a significant increase in the last year, more than tripling from 4.0 million in 2022 to 12.2 million in 2023 (Figure 1.5.3). This sharp increase in GitHub stars, along with the previously reported rise in projects, underscores the accelerating growth of open-source AI software development.

Number of GitHub stars in AI projects, 2011–23

Source: GitHub, 2023 | Chart: 2024 AI Index report

Figure 1.5.3

In 2023, the United States led in receiving the highest number of GitHub stars, totaling 10.5 million (Figure 1.5.4). All major geographic regions sampled, including the European Union and United Kingdom,

China, and India, saw a year-over-year increase in the total number of GitHub stars awarded to projects located in their countries.

[ACCESS THE PUBLIC DATA](#)

Overview

The technical performance section of this year’s AI Index offers a comprehensive overview of AI advancements in 2023. It starts with a high-level overview of AI technical performance, tracing its broad evolution over time. The chapter then examines the current state of a wide range of AI capabilities, including language processing, coding, computer vision (image and video analysis), reasoning, audio processing, autonomous agents, robotics, and reinforcement learning. It also shines a spotlight on notable AI research breakthroughs from the past year, exploring methods for improving LLMs through prompting, optimization, and fine-tuning, and wraps up with an exploration of AI systems’ environmental footprint.

Chapter Highlights

- 1. AI beats humans on some tasks, but not on all.** AI has surpassed human performance on several benchmarks, including some in image classification, visual reasoning, and English understanding. Yet it trails behind on more complex tasks like competition-level mathematics, visual commonsense reasoning and planning.

- 2. Here comes multimodal AI.** Traditionally AI systems have been limited in scope, with language models excelling in text comprehension but faltering in image processing, and vice versa. However, recent advancements have led to the development of strong multimodal models, such as Google's Gemini and OpenAI's GPT-4. These models demonstrate flexibility and are capable of handling images and text and, in some instances, can even process audio.

- 3. Harder benchmarks emerge.** AI models have reached performance saturation on established benchmarks such as ImageNet, SQuAD, and SuperGLUE, prompting researchers to develop more challenging ones. In 2023, several challenging new benchmarks emerged, including SWE-bench for coding, HEIM for image generation, MMMU for general reasoning, MoCa for moral reasoning, AgentBench for agent-based behavior, and HaluEval for hallucinations.

- 4. Better AI means better data which means ... even better AI.** New AI models such as SegmentAnything and Skoltech are being used to generate specialized data for tasks like image segmentation and 3D reconstruction. Data is vital for AI technical improvements. The use of AI to create more data enhances current capabilities and paves the way for future algorithmic improvements, especially on harder tasks.

- 5. Human evaluation is in.** With generative models producing high-quality text, images, and more, benchmarking has slowly started shifting toward incorporating human evaluations like the Chatbot Arena Leaderboard rather than computerized rankings like ImageNet or SQuAD. Public feeling about AI is becoming an increasingly important consideration in tracking AI progress.

- 6. Thanks to LLMs, robots have become more flexible.** The fusion of language modeling with robotics has given rise to more flexible robotic systems like PaLM-E and RT-2. Beyond their improved robotic capabilities, these models can ask questions, which marks a significant step toward robots that can interact more effectively with the real world.

- 7. More technical research in agentic AI.** Creating AI agents, systems capable of autonomous operation in specific environments, has long challenged computer scientists. However, emerging research suggests that the performance of autonomous AI agents is improving. Current agents can now master complex games like Minecraft and effectively tackle real-world tasks, such as online shopping and research assistance.

- 8. Closed LLMs significantly outperform open ones.** On 10 select AI benchmarks, closed models outperformed open ones, with a median performance advantage of 24.2%. Differences in the performance of closed and open models carry important implications for AI policy debates.

The technical performance chapter begins with a high-level overview of significant model releases in 2023 and reviews the current state of AI technical performance.

2.1 Overview of AI in 2023

Timeline: Significant Model Releases

As chosen by the AI Index Steering Committee, here are some of the most notable model releases of 2023.

Date	Model	Type	Creator(s)	Significance	Image
Mar. 14, 2023	Claude	Large language model	Anthropic	Claude is the first publicly released LLM from Anthropic, one of OpenAI's main rivals. Claude is designed to be as helpful, honest, and harmless as possible.	 <p>Figure 2.1.1 Source: Anthropic, 2023</p>
Mar. 14, 2023	GPT-4	Large language model	OpenAI	GPT-4, improving over GPT-3, is among the most powerful and capable LLMs to date and surpasses human performance on numerous benchmarks.	 <p>Figure 2.1.2 Source: Medium, 2023</p>
Mar. 23, 2023	Stable Diffusion v2	Text-to-image model	Stability AI	Stable Diffusion v2 is an upgrade of Stability AI's existing text-to-image model and produces higher-resolution, superior-quality images.	 <p>Figure 2.1.3 Source: Stability AI, 2023</p>
Apr. 5, 2023	Segment Anything	Image segmentation	Meta	Segment Anything is an AI model capable of isolating objects in images using zero-shot generalization.	 <p>Figure 2.1.4 Source: Meta, 2023</p>

Date	Model	Type	Creator(s)	Significance	Image
Jul. 18, 2023	Llama 2	Large language model	Meta	Llama 2, an updated version of Meta's flagship LLM, is open-source. Its smaller variants (7B and 13B) deliver relatively high performance for their size.	 <p>Figure 2.1.5 Source: Meta, 2023</p>
Aug. 20, 2023	DALL-E 3	Image generation	OpenAI	DALL-E 3 is an improved version of OpenAI's existing text-to-vision model DALL-E.	 <p>Figure 2.1.6 Source: OpenAI, 2023</p>
Aug. 29, 2023	SynthID	Watermarking	Google, DeepMind	SynthID is a tool for watermarking AI-generated music and images. Its watermarks remain detectable even after image alterations.	 <p>Figure 2.1.7 Source: DeepMind, 2023</p>
Sep. 27, 2023	Mistral 7B	Large language model	Mistral AI	Mistral 7B, launched by French AI company Mistral, is a compact 7 billion parameter model that surpasses Llama 2 13B in performance, ranking it top in its class for size.	 <p>Figure 2.1.8 Source: Mistral AI, 2023</p>
Oct. 27, 2023	Ernie 4.0	Large language model	Baidu	Baidu, a multinational Chinese technology company, has launched Ernie 4.0, which is among the highest-performing Chinese LLMs to date.	 <p>Figure 2.1.9 Source: PR Newswire, 2023</p>
Nov. 6, 2023	GPT-4 Turbo	Large language model	OpenAI	GPT-4 Turbo is an upgraded large language model boasting a 128K context window and reduced pricing.	 <p>Figure 2.1.10 Source: Tech.co, 2023</p>

Date	Model	Type	Creator(s)	Significance	Image
Nov. 6, 2023	<u>Whisper v3</u>	Speech-to-text	OpenAI	Whisper v3 is an open-source speech-to-text model known for its increased accuracy and extended language support.	 <p>Figure 2.1.11 Source: AI Business, 2023</p>
Nov. 21, 2023	<u>Claude 2.1</u>	Large language model	Anthropic	Anthropic's latest LLM, Claude 2.1, features an industry-leading 200K context window, which enhances its capacity to process extensive content such as lengthy literary works.	 <p>Figure 2.1.12 Source: Medium, 2023</p>
Nov. 22, 2023	<u>Inflection-2</u>	Large language model	Inflection	Inflection-2 is the second LLM from the new startup Inflection, founded by DeepMind's Mustafa Suleyman. Inflection-2's launch underscores the intensifying competition in the LLM arena.	 <p>Figure 2.1.13 Source: Inflection, 2023</p>
Dec. 6, 2023	<u>Gemini</u>	Large language model	Google	Gemini emerges as a formidable competitor to GPT-4, with one of its variants, Gemini Ultra, outshining GPT-4 on numerous benchmarks.	 <p>Figure 2.1.14 Source: Medium, 2023</p>
Dec. 21, 2023	<u>Midjourney v6</u>	Text-to-image model	Midjourney	Midjourney's latest update enhances user experience with more intuitive prompts and superior image quality.	 <p>Figure 2.1.15 Source: Bootcamp, 2023</p>

State of AI Performance

As of 2023, AI has achieved levels of performance that surpass human capabilities across a range of tasks. Figure 2.1.16 illustrates the progress of AI systems relative to human baselines for nine AI benchmarks corresponding to nine tasks (e.g., image classification or basic-level reading comprehension).¹ The AI Index team selected one benchmark to represent each task.

Over the years, AI has surpassed human baselines on a handful of benchmarks, such as image classification in 2015, basic reading comprehension in 2017, visual reasoning in 2020, and natural language inference in 2021. As of 2023, there are still some task categories where AI fails to exceed human ability. These tend to be more complex cognitive tasks, such as visual commonsense reasoning and advanced-level mathematical problem-solving (competition-level math problems).

Select AI Index technical performance benchmarks vs. human performance

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 2.1.16²

¹ An AI benchmark is a standardized test used to evaluate the performance and capabilities of AI systems on specific tasks. For example, ImageNet is a canonical AI benchmark that features a large collection of labeled images, and AI systems are tasked with classifying these images accurately. Tracking progress on benchmarks has been a standard way for the AI community to monitor the advancement of AI systems.

² In Figure 2.1.16, the values are scaled to establish a standard metric for comparing different benchmarks. The scaling function is calibrated such that the performance of the best model for each year is measured as a percentage of the human baseline for a given task. A value of 105% indicates, for example, that a model performs 5% better than the human baseline.

AI Index Benchmarks

An emerging theme in AI technical performance, as emphasized in [last year’s report](#), is the observed saturation on many benchmarks, such as ImageNet, used to assess the proficiency of AI models. Performance on these benchmarks has stagnated in recent years, indicating either a plateau in AI capabilities or a shift among researchers toward more complex research challenges.³

Due to saturation, several benchmarks featured in the 2023 AI Index have been omitted from this year’s report. Figure 2.1.17 highlights a selection of benchmarks that were included in the 2023 edition but not featured in this year’s report.⁴ It also shows the improvement on these benchmarks since 2022. “NA” indicates no improvement was noted.

A selection of deprecated benchmarks from the 2023 AI Index report

Source: AI Index, 2024

Benchmark	Task category	Year introduced	Improvement from 2022
Abductive Natural Language Inference (aNLI)	Natural language inference	2019	NA
arXiv	Text summarization	2003	NA
Cityscapes Challenge	Semantic segmentation	2016	0.23%
ImageNet	Image classification	2009	1.54%
Kinetics-400	Activity recognition	2017	NA
Kinetics-600	Activity recognition	2018	NA
Kinetics-700	Activity recognition	2019	NA
Kvasir-SEG	Medical image segmentation	2019	1.90%
MPII	Human pose estimation	2014	NA
PubMed	Text summarization	2008	NA
SST-5 Fine-Grained Classification	Sentiment analysis	2013	NA
STL-10	Image generation	2011	NA
SuperGLUE	English language understanding	2019	NA
Visual Question Answering Challenge (VQA)	Visual reasoning	2017	NA
VoxCeleb	Speech recognition	2017	NA

Figure 2.1.17

³ Benchmarks can also saturate or see limited improvement because the problem created is hard and the corresponding performance fails to improve. The issue of benchmark saturation discussed in this section refers more to benchmarks where performance reaches a close-to-perfection level on which it is difficult to improve.

⁴ For brevity, Figure 2.1.17 highlights a selection of deprecated benchmarks. Additional benchmarks that were deprecated either because there was saturation, no new state-of-the-art score was documented, or research focus shifted away from the benchmark include: Celeb-DF (deepfake detection), CIFAR-10 (image classification), NIST FRVT (facial recognition), and Procgen (reinforcement learning).

Figure 2.1.18 illustrates the year-over-year improvement, in percent, on a selection of benchmarks featured in the 2023 AI Index report. Most benchmarks see significant performance

increases relatively soon after they are introduced, then the improvement slows. In the last few years, many of these benchmarks have shown little or no improvement.

Year-over-year improvement over time on select AI Index technical performance benchmarks

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 2.1.18

In response to benchmark saturation, AI researchers are pivoting away from traditional benchmarks and testing AI on more difficult challenges. The 2024 AI Index tracks progress on several new benchmarks

including those for tasks in coding, advanced reasoning, and agentic behavior—areas that were underrepresented in previous versions of the report (Figure 2.1.19).⁵

⁵ This report includes an Appendix with details regarding the sourcing of new benchmarks featured in this chapter.

2.2 Language

Natural language processing (NLP) enables computers to understand, interpret, generate, and transform text. Current state-of-the-art models, such as OpenAI’s GPT-4 and Google’s Gemini, are able to generate fluent and coherent prose and display high levels of language understanding ability (Figure 2.2.1). Many of these models can also now handle different input forms, such as images and audio (Figure 2.2.2).

A sample output from GPT-4

Understanding

English language understanding challenges AI systems to understand the English language in various ways such as reading comprehension and logical reasoning.

HELM: Holistic Evaluation of Language Models

As illustrated above, in recent years LLMs have surpassed human performance on traditional English-language benchmarks, such as SQuAD (question answering) and SuperGLUE (language understanding). This rapid advancement has led to the need for more comprehensive benchmarks.

In 2022, Stanford researchers introduced HELM (Holistic Evaluation of Language Models), designed to evaluate LLMs across diverse scenarios, including reading comprehension, language understanding, and mathematical reasoning.⁶ HELM assesses models from several leading companies like Anthropic, Google, Meta, and OpenAI, and uses a “mean win rate” to track average performance across all scenarios. As of January 2024, GPT-4 leads the aggregate HELM leaderboard with a mean win rate of 0.96 (Figure 2.2.3); however, different models top different task categories (Figure 2.2.4).⁷

HELM: mean win rate

Leaders on individual HELM sub-benchmarks

Source: CRFM, 2023 | Table: 2024 AI Index report

Task	Leading model	Score
GSM8K - EM	GPT-4 (0613)	0.93
LegalBench - EM	GPT-4 (0613)	0.71
MATH - Equivalent (CoT)	GPT-4 Turbo (1106 preview)	0.86
MMLU - EM	GPT-4 (0613)	0.74
MedQA - EM	GPT-4 Turbo (1106 preview)	0.82
NarrativeQA - F1	Yi (34B)	0.78
NaturalQuestions (closed-book) - F1	Llama 2 (70B)	0.46
NaturalQuestions (open-book) - F1	PaLM-2 (Bison)	0.81
OpenbookQA - EM	GPT-4 (0613)	0.96
WMT 2014 - BLEU-4	Palmyra X V3 (72B)	0.26

Figure 2.2.4

⁶ HELM evaluates 10 scenarios: (1) NarrativeQA (reading comprehension), (2) Natural Questions (closed-book) (closed-book short-answer question answering), (3) Natural Questions (open-book) (open-book short-answer question answering), (4) OpenBookQA (commonsense question answering), (5) MMLU (multisubject understanding), (6) GSM8K (grade school math), (7) MATH (competition math), (8) LegalBench (legal reasoning), (9) MedQA (medical knowledge), and (10) WMT 2014 (machine translation).

⁷ There are several versions of HELM. This section reports the score on HELM Lite, Release v1.0.0 (2023-12-19), with the data having been collected in January 2024.

MMLU: Massive Multitask Language Understanding

The Massive Multitask Language Understanding (MMLU) benchmark assesses model performance in zero-shot or few-shot scenarios across 57 subjects, including the humanities, STEM, and social sciences (Figure 2.2.5). MMLU has emerged as a premier benchmark for assessing LLM capabilities: Many state-of-the-art models like GPT-4, Claude 2, and Gemini have been evaluated against MMLU.

In early 2023, GPT-4 posted a state-of-the-art score on MMLU, later surpassed by Google’s Gemini Ultra. Figure 2.2.6 highlights the top model scores on the MMLU benchmark in different years. The scores reported are the averages across the test set. As of January 2024, Gemini Ultra holds the top score of 90.0%, marking a 14.8 percentage point improvement since 2022 and a 57.6 percentage point increase since MMLU’s inception in 2019. Gemini Ultra’s score was the first to surpass MMLU’s human baseline of 89.8%.

A sample question from MMLU

Source: Hendrycks et al., 2021

Microeconomics

One of the reasons that the government discourages and regulates monopolies is that

- (A) producer surplus is lost and consumer surplus is gained. ✗
- (B) monopoly prices ensure productive efficiency but cost society allocative efficiency. ✗
- (C) monopoly firms do not engage in significant research and development. ✗
- (D) consumer surplus is lost with higher prices and lower levels of output. ✓

Figure 2.2.6

Generation

In generation tasks, AI models are tested on their ability to produce fluent and practical language responses.

Chatbot Arena Leaderboard

The rise of capable LLMs has made it increasingly important to understand which models are preferred by the general public. Launched in 2023,

the Chatbot Arena Leaderboard is one of the first comprehensive evaluations of public LLM preference. The leaderboard allows users to query two anonymous models and vote for the preferred generations (Figure 2.2.7). As of early 2024, the platform has garnered over 200,000 votes, and users ranked OpenAI’s GPT-4 Turbo as the most preferred model (Figure 2.2.8).

Figure 2.2.8

Factuality and Truthfulness

Despite remarkable achievements, LLMs remain susceptible to factual inaccuracies and content hallucination—creating seemingly realistic, yet false, information. The presence of real-world instances where LLMs have produced hallucinations—in court cases, for example—underscores the growing necessity of closely monitoring trends in LLM factuality.

TruthfulQA

Introduced at ACL 2022, TruthfulQA is a benchmark designed to evaluate the truthfulness of LLMs in generating answers to questions. This benchmark comprises approximately 800 questions across 38 categories, including health, politics, and finance. Many questions are crafted to challenge commonly held misconceptions, which typically lead humans to answer incorrectly (Figure 2.2.9). Although one of the observations of the paper is that larger models tend to be less truthful, GPT-4 (RLHF) released in early 2024, has achieved the highest performance thus far on the TruthfulQA benchmark, with a score of 0.6 (Figure 2.2.10). This score is nearly three times higher than that of a GPT-2-based model tested in 2021, indicating that LLMs are becoming progressively better at providing truthful answers.

Sample TruthfulQA questions

Figure 2.2.10

HaluEval

As previously mentioned, LLMs are prone to hallucinations, a concerning trait given their widespread deployment in critical fields such as law and medicine. While existing research has aimed to understand the causes of hallucinations, less effort has been directed toward assessing the frequency of LLM hallucinations and identifying specific content areas where they are especially vulnerable.

HaluEval, introduced in 2023, is a new benchmark designed to assess hallucinations in LLMs. It includes over 35,000 samples, both hallucinated and normal, for analysis and evaluation by LLMs (Figure 2.2.11). The research indicates that ChatGPT fabricates unverifiable information in approximately 19.5% of its responses, with these fabrications spanning a variety of topics such as language, climate, and technology. Furthermore, the study examines how well current LLMs can detect hallucinations. Figure 2.2.12 illustrates the performance of leading LLMs in identifying hallucinations across various tasks, including question answering, knowledge-grounded dialogue, and text summarization. The findings reveal that many LLMs struggle with these tasks, highlighting that hallucination is a significant ongoing issue.

A generated hallucinated QA example and a human-labeled ChatGPT response for a user query

Source: [Li et al., 2023](#)

Question	In what political party was the man who officially opened Royal Spa Centre in 1972?
Right Answer	Conservative
Hallucinated Answer	Labour Party
User Query	Retrieve the oldest photo of a cat
ChatGPT	There is no definitive answer to this question as “the oldest photo of a cat” is subjective and varies based on different sources and definitions. However, one candidate for the oldest cat photo is the daguerreotype “Cat with Blue Ribbon,” taken by photographer Antoine Claudet in 1840. The photo depicts a cat sitting on a table, gazing directly at the camera, and wearing a blue ribbon tied around its neck. [...]
Hallucination	Yes
Fragments	the oldest cat photo is the daguerreotype “Cat with Blue Ribbon” taken by photographer Antoine Claudet in 1840.

Figure 2.2.12

Coding involves the generation of instructions that computers can follow to perform tasks. Recently, LLMs have become proficient coders, serving as valuable assistants to computer scientists. There is also increasing evidence that many coders find AI coding assistants highly useful.

2.3 Coding

Generation

On many coding tasks, AI models are challenged to generate usable code or to solve computer science problems.

HumanEval

HumanEval, a benchmark for evaluating AI systems' coding ability, was introduced by OpenAI researchers in 2021. It consists of 164 challenging handwritten programming problems (Figure 2.3.1). A GPT-4 model variant (AgentCoder) currently leads in HumanEval performance, scoring 96.3%, which is a 11.2 percentage point increase from the highest score

in 2022 (Figure 2.3.2). Since 2021, performance on HumanEval has increased 64.1 percentage points.

Figure 2.3.2

SWE-bench

As AI systems' coding capabilities improve, it has become increasingly important to benchmark models on more challenging tasks. In October 2023, researchers introduced SWE-bench, a dataset comprising 2,294 software engineering problems sourced from real GitHub issues and popular Python repositories (Figure 2.3.3). SWE-bench presents a tougher test for AI coding proficiency, demanding that systems coordinate changes across

multiple functions, interact with various execution environments, and perform complex reasoning.

Even state-of-the-art LLMs face significant challenges with SWE-bench. Claude 2, the best-performing model, solved only 4.8% of the dataset's problems (Figure 2.3.4).⁸ In 2023, the top-performing model on SWE-bench surpassed the best model from 2022 by 4.3 percentage points.

⁸ According to the SWE-bench leaderboard, unassisted systems have no assistance in finding the relevant files in the repository. Assisted systems operate under the "oracle" retrieval setting, which means the systems are provided with the list of files that were modified in the pull request.

Computer vision allows machines to understand images and videos and create realistic visuals from textual prompts or other inputs. This technology is widely used in fields such as autonomous driving, medical imaging, and video game development.

2.4 Image Computer Vision and Image Generation

Generation

Image generation is the task of generating images that are indistinguishable from real ones. Today’s image generators are so advanced that most people struggle to differentiate between AI-generated images and actual images of human faces (Figure 2.4.1). Figure 2.4.2 highlights several generations from various Midjourney model variants from 2022 to 2024 for the prompt “a hyper-realistic image of Harry Potter.” The progression demonstrates the significant improvement in Midjourney’s ability to generate hyper-realistic images over a two-year period. In 2022, the model produced cartoonish and inaccurate renderings of Harry Potter, but by 2024, it could create startlingly realistic depictions.

Figure 2.4.2

HEIM: Holistic Evaluation of Text-to-Image Models

The rapid progress of AI text-to-image systems has prompted the development of more sophisticated evaluation methods. In 2023, Stanford researchers introduced the Holistic Evaluation of Text-to-Image Models (HEIM), a benchmark designed to comprehensively assess image generators across 12 key aspects crucial for real-world deployment, such as image-text alignment, image quality, and aesthetics.⁹ Human evaluators are used to rate the models, a crucial feature since many automated metrics struggle to accurately assess various aspects of images.

HEIM’s findings indicate that no single model excels in all criteria. For human evaluation of image-to-text alignment (assessing how well the generated image matches the input text), OpenAI’s DALL-E 2 scores highest (Figure 2.4.3). In terms of image quality (gauging if the images resemble real photographs), aesthetics (evaluating the visual appeal), and originality (a measure of novel image generation and avoidance of copyright infringement), the Stable Diffusion–based Dreamlike Photoreal model ranks highest (Figure 2.4.4).

Image-text alignment: human evaluation

Figure 2.4.3

Model leaders on select HEIM sub-benchmarks

Source: CRFM, 2023 | Table: 2024 AI Index report

Task	Leading model	Score
Image-text-alignment	DALL-E 2 (3.5B)	0.94
Quality	Dreamlike Photoreal v2.0 (1B)	0.92
Aesthetics	Dreamlike Photoreal v2.0 (1B)	0.87
Originality	Dreamlike Photoreal v2.0 (1B)	0.98

Figure 2.4.4

⁹ The 12 evaluation aspects of HEIM are: (1) Alignment: How closely does the image align with the given text? (2) Quality: What is the quality of the produced image? (3) Aesthetic: How aesthetically pleasing is the generated image? (4) Originality: How original is the image? (5) Reasoning: Does the model understand objects, counts, and spatial relations? (6) Knowledge: Does the model have knowledge about the world? (7) Bias: Are the generated images biased? (8) Toxicity: Are the generated images toxic or inappropriate? (9) Fairness: Do the generated images exhibit performance disparities? (10) Robust: Is the model robust to input perturbations? (11) Multilinguality: Does the model support non-English languages? (12) Efficiency: How fast is model inference?

Highlighted Research: MVDream

Creating 3D geometries or models from text prompts has been a significant challenge for AI researchers, with existing models struggling with problems such as multiface Janus issue (inaccurately regenerating context described by text prompts) and content drift (inconsistency across different 3D views). MVDream is a new 3D generation system developed by ByteDance and University of California, San Diego researchers that overcomes some of these hurdles (Figure 2.4.5). In quantitative evaluations, MVDream’s generated models achieve Inception Score (IS) and CLIP scores comparable to those in the training set, indicating the high quality of the generated images (Figure 2.4.6). MVDream has major implications, especially for creative industries where 3D content creation is traditionally time-consuming and labor-intensive.

Instruction-Following

In computer vision, instruction-following is the capacity of vision-language models to interpret text-based directives related to images. For instance, an AI system could be given an image of various ingredients and tasked with suggesting how to use them to prepare a healthy meal. Capable instruction-following vision-language models are necessary for developing advanced AI assistants.

Figure 2.4.9

Editing

Image editing involves using AI to modify images based on text prompts. This AI-assisted approach has broad real-world applications in fields such as engineering, industrial design, and filmmaking.

EditVal

Despite the promise of text-guided image editing, few robust methods can evaluate how accurately AI image editors adhere to editing prompts. EditVal, a new benchmark for assessing text-guided image editing, includes over 13 edit types, such as adding objects or changing their positions, across 19 object classes (Figure 2.4.10).

The benchmark was applied to evaluate eight leading text-guided image editing methods including SINE and Null-text.

Performance improvements since 2021 on a variety of the benchmark's editing tasks, are shown in Figure 2.4.11.

Highlighted Research:

ControlNet

Conditioning inputs or performing conditional control refers to the process of guiding the output created by an image generator by specifying certain conditions that a generated image must meet. Existing text-to-image models often lack precise control over the spatial composition of an image, making it difficult to use prompts alone to generate images with complex layouts, diverse shapes, and specific poses. Fine-tuning these models for greater compositional control by training them on additional images is theoretically feasible, but many specialized datasets, such as those for human poses, are not large enough to support successful training.

In 2023, researchers from Stanford introduced a new model, ControlNet, that improves conditional control editing for large text-to-image diffusion models (Figure 2.4.12). ControlNet stands out for its ability to handle various conditioning inputs. Compared to other previously released models in 2022, human raters prefer ControlNet both in terms of superior quality and better condition fidelity (Figure 2.4.13). The introduction of ControlNet is a significant step toward creating advanced text-to-image generators capable of editing images to more accurately replicate the complex images frequently encountered in the real world.

Figure 2.4.15

Segmentation

Segmentation involves assigning individual image pixels to specific categories (for example: human, bicycle, or street).

Highlighted Research: Segment Anything

In 2023, Meta researchers launched Segment Anything, a project that featured the Segment Anything Model (SAM) and an extensive SA-1B dataset for image segmentation. SAM is remarkable for being one of the first broadly generalizable segmentation models that performs well zero-shot on new tasks and distributions. Segment Anything outperforms leading segmentation methods like RITM on 16 out of 23 segmentation datasets (Figure 2.4.17). The metric on which Segment Anything is evaluated is the mean Intersection over Union (IoU).

Meta’s Segment Anything model was then used, alongside human annotators, to create the SA-1B dataset, which included over 1 billion segmentation masks across 11 million images (Figure 2.4.16). A new segmentation dataset of this size will accelerate the training of future image segmentors. Segment Anything demonstrates how AI models can be used alongside humans to more efficiently create large datasets, which in turn can be used to train even better AI systems.

3D Reconstruction From Images

3D image reconstruction is the process of creating three-dimensional digital geometries from two-dimensional images. This type of reconstruction can be used in medical imaging, robotics, and virtual reality.

Highlighted Research:

Skoltech3D

Data scarcity often hinders the development of AI systems for specific tasks. In 2023, a team of international researchers introduced an extensive new dataset, Skoltech3D, for multiview 3D surface reconstruction (Figure 2.4.18). Encompassing 1.4 million images of 107 scenes captured from 100 different viewpoints under 14 distinct lighting conditions, this dataset represents a major improvement over existing 3D reconstruction datasets (Figure 2.4.19).

Figure 2.4.19

Highlighted Research: RealFusion

RealFusion, developed by Oxford researchers, is a new method for generating complete 3D models of objects from single images, overcoming the challenge of often having insufficient information from single images for full 360 degree reconstruction. RealFusion utilizes existing 2D image generators to produce multiple views of an object, and then assembles these views into a comprehensive 360 degree model (Figure 2.4.20). This technique yields more accurate 3D reconstructions compared to state-of-the-art methods from 2021 (Shelf-Supervised), across a wide range of objects (Figure 2.4.21).

Video analysis concerns performing tasks across videos rather than single images.

2.5 Video Computer Vision and Video Generation

Generation

Video generation involves the use of AI to generate videos from text or images.

UCF101

UCF101 is an action recognition dataset of realistic action videos that contain 101 action categories (Figure 2.5.1). More recently, UCF101 has been used to benchmark video generators. This year's top model, W.A.L.T.-XL, posted an FVD16 score of 36, more than halving the state-of-the-art score posted the previous year (Figure 2.5.2).

Highlighted Research: Align Your Latents

Most existing methods can only create short, low-resolution videos. To address this limitation, an international team of researchers has applied latent diffusion models, traditionally used for generating high-quality images, to produce high-resolution videos (Figure 2.5.3). Their Latent Diffusion Model (LDM) notably outperforms previous state-of-the-art methods released in 2022 like Long Video

GAN (LVG) in resolution quality (Figure 2.5.4). The adaptation of a text-to-image architecture to create LDM, a highly effective text-to-video model, exemplifies how advanced AI techniques can be repurposed across different domains of computer vision. The LDM's strong video generation capabilities have many real-world applications, such as creating realistic driving simulations.

Figure 2.5.4

Highlighted Research: Emu Video

Traditionally, progress in video generation has trailed that in image generation due to its higher complexity and the smaller datasets available for training. Emu Video, a new transformer-based video generation model created by Meta researchers, represents a significant step forward (Figure 2.5.5). Emu Video generates an image from text and then creates a video based on both the text and image. Figure 2.5.6 illustrates the degree to which the Emu Video model outperforms previously released state-of-the-art video generation methods. The metric is the proportion of cases when human evaluators preferred Emu Video’s image quality or faithfulness to text

Sample Emu Video generations

Figure 2.5.6

Reasoning in AI involves the ability of AI systems to draw logically valid conclusions from different forms of information. AI systems are increasingly being tested in diverse reasoning contexts, including visual (reasoning about images), moral (understanding moral dilemmas), and social reasoning (navigating social situations).¹⁰

2.6 Reasoning

General Reasoning

General reasoning pertains to AI systems being able to reason across broad, rather than specific, domains. As part of a general reasoning challenge, for example, an AI system might be asked to reason across multiple subjects rather than perform one narrow task (e.g., playing chess).

MMMU: A Massive Multi-discipline Multimodal Understanding and Reasoning Benchmark for Expert AGI

In recent years, the reasoning abilities of AI systems have advanced so much that traditional benchmarks like SQuAD (for textual reasoning) and VQA (for visual reasoning) have become saturated, indicating a need for more challenging reasoning tests.

Responding to this, researchers from the United States and Canada recently developed MMMU, the

Massive Multi-discipline Multimodal Understanding and Reasoning Benchmark for Expert AGI. MMMU comprises about 11,500 college-level questions from six core disciplines: art and design, business, science, health and medicine, humanities and social science, and technology and engineering (Figure 2.6.1). The question formats include charts, maps, tables, chemical structures, and more. MMMU is one of the most demanding tests of perception, knowledge, and reasoning in AI to date. As of January 2024, the highest performing model is Gemini Ultra, which leads in all subject categories with an overall score of 59.4% (Figure 2.6.2).¹¹ On most individual task categories, top models are still well beyond medium-level human experts (Figure 2.6.3). This relatively low score is evidence of MMMU's effectiveness as a benchmark for assessing AI reasoning capabilities.

¹⁰ Some abilities highlighted in the previous sections implicitly involve some form of reasoning. This section highlights tasks that have a more specific reasoning focus.

¹¹ The AI Index reports results from the MMMU validation set, as recommended by [the paper](#) authors for the most comprehensive coverage. According to the authors, the test set, with its unreleased labels and larger size, presents a more challenging yet unbiased benchmark for model performance, ensuring a more robust evaluation. The test set results are available on the [MMMU page](#).

GPQA: A Graduate-Level Google-Proof Q&A Benchmark

In the last year, researchers from NYU, Anthropic, and Meta introduced the GPQA benchmark to test general multisubject AI reasoning. This dataset consists of 448 difficult multiple-choice questions that cannot be easily answered by Google searching. The questions

were crafted by subject-matter experts in various fields like biology, physics, and chemistry (Figure 2.6.4). PhD-level experts achieved a 65% accuracy rate in their respective domains on GPQA, while nonexpert humans scored around 34%. The best-performing AI model, GPT-4, only reached a score of 41.0% on the main test set (Figure 2.6.5).

A sample chemistry question from GPQA

Source: Rein et al., 2023

Chemistry (general)

A reaction of a liquid organic compound, which molecules consist of carbon and hydrogen atoms, is performed at 80 centigrade and 20 bar for 24 hours. In the proton nuclear magnetic resonance spectrum, the signals with the highest chemical shift of the reactant are replaced by a signal of the product that is observed about three to four units downfield. Compounds from which position in the periodic system of the elements, which are also used in the corresponding large-scale industrial process, have been mostly likely initially added in small amounts?

- A) A metal compound from the fifth period.
- B) A metal compound from the fifth period and a non-metal compound from the third period.
- C) A metal compound from the fourth period.
- D) A metal compound from the fourth period and a non-metal compound from the second period.

Comparing Humans, GPT-4, and GPT-4V on Abstraction and Reasoning Tasks

Abstract reasoning involves using known information to solve unfamiliar and novel problems and is a key aspect of human cognition that is evident even in toddlers. While recent LLMs like GPT-4 have shown impressive performance, their capability for true abstract reasoning remains a hotly debated subject.¹³ To further explore this topic, researchers from the Santa Fe Institute tested GPT-4 on the ConceptARC benchmark, a collection of analogy puzzles designed to assess general abstract reasoning skills (Figure 2.6.6). The study revealed that GPT-4 significantly trails behind humans in abstract reasoning abilities: While humans score 95% on the benchmark, the best GPT-4 system only scores 69% (Figure 2.6.7). The development of truly general AI requires abstract reasoning capabilities. Therefore, it will be important to continue tracking progress in this area.

A sample ARC reasoning task

¹³ Some claim these models exhibit such reasoning capabilities, while others claim they do not.

Figure 2.6.7

Mathematical Reasoning

Mathematical problem-solving benchmarks evaluate AI systems' ability to reason mathematically. AI models can be tested with a range of math problems, from grade-school level to competition-standard mathematics.

GSM8K

GSM8K, a dataset comprising approximately 8,000 varied grade school math word problems, requires

that AI models develop multistep solutions utilizing arithmetic operations (Figure 2.6.8). GSM8K has quickly become a favored benchmark for evaluating advanced LLMs. The top-performing model on GSM8K is a GPT-4 variant (GPT-4 Code Interpreter), which scores an accuracy of 97%, a 4.4% improvement from the state-of-the-art score in the previous year and a 30.4% improvement from 2022 when the benchmark was first introduced (Figure 2.6.9).

Sample problems from GSM8K

Source: Cobbe et al., 2023

<p>Problem: Beth bakes 4, 2 dozen batches of cookies in a week. If these cookies are shared amongst 16 people equally, how many cookies does each person consume?</p> <p>Solution: Beth bakes 4 2 dozen batches of cookies for a total of $4 \times 2 = 8$ dozen cookies There are 12 cookies in a dozen and she makes 8 dozen cookies for a total of $12 \times 8 = 96$ cookies She splits the 96 cookies equally amongst 16 people so they each eat $96/16 = 6$ cookies Final Answer: 6</p>
<p>Problem: Mrs. Lim milks her cows twice a day. Yesterday morning, she got 68 gallons of milk and in the evening, she got 82 gallons. This morning, she got 18 gallons fewer than she had yesterday morning. After selling some gallons of milk in the afternoon, Mrs. Lim has only 24 gallons left. How much was her revenue for the milk if each gallon costs \$3.50?</p> <p>Mrs. Lim got 68 gallons - 18 gallons = 50 gallons this morning. So she was able to get a total of 68 gallons + 82 gallons + 50 gallons = 200 gallons. She was able to sell 200 gallons - 24 gallons = 176 gallons. Thus, her total revenue for the milk is $\\$3.50/\text{gallon} \times 176 \text{ gallons} = \\616. Final Answer: 616</p>
<p>Problem: Tina buys 3 12-packs of soda for a party. Including Tina, 6 people are at the party. Half of the people at the party have 3 sodas each, 2 of the people have 4, and 1 person has 5. How many sodas are left over when the party is over?</p> <p>Solution: Tina buys 3 12-packs of soda, for $3 \times 12 = 36$ sodas 6 people attend the party, so half of them is $6/2 = 3$ people Each of those people drinks 3 sodas, so they drink $3 \times 3 = 9$ sodas Two people drink 4 sodas, which means they drink $2 \times 4 = 8$ sodas With one person drinking 5, that brings the total drank to $5 + 9 + 8 + 3 = 25$ sodas As Tina started off with 36 sodas, that means there are $36 - 25 = 11$ sodas left Final Answer: 11</p>

Figure 2.6.9

MATH

MATH is a dataset of 12,500 challenging competition-level mathematics problems introduced by UC Berkeley researchers in 2021 (Figure 2.6.10). AI systems struggled on MATH when it was first released, managing to solve only 6.9% of the problems. Performance has significantly improved. In 2023, a GPT-4-based model posted the top result, successfully solving 84.3% of the dataset’s problems (Figure 2.6.11).

A sample problem from the MATH dataset

Source: Hendrycks et al., 2023

MATH Dataset (Ours)

Problem: Tom has a red marble, a green marble, a blue marble, and three identical yellow marbles. How many different groups of two marbles can Tom choose?

Solution: There are two cases here: either Tom chooses two yellow marbles (1 result), or he chooses two marbles of different colors ($\binom{4}{2} = 6$ results). The total number of distinct pairs of marbles Tom can choose is $1 + 6 = \boxed{7}$.

Problem: The equation $x^2 + 2x = i$ has two complex solutions. Determine the product of their real parts.

Solution: Complete the square by adding 1 to each side. Then $(x + 1)^2 = 1 + i = e^{i\frac{\pi}{4}} \sqrt{2}$, so $x + 1 = \pm e^{i\frac{\pi}{8}} \sqrt[4]{2}$. The desired product is then $(-1 + \cos(\frac{\pi}{8}) \sqrt[4]{2})(-1 - \cos(\frac{\pi}{8}) \sqrt[4]{2}) = 1 - \cos^2(\frac{\pi}{8}) \sqrt{2} = 1 - \frac{(1 + \cos(\frac{\pi}{4}))}{2} \sqrt{2} = \boxed{\frac{1 - \sqrt{2}}{2}}$.

Figure 2.6.11

PlanBench

A planning system receives a specified goal, an initial state, and a collection of actions. Each action is defined by preconditions, which must be met for the action to be executed, and the effects that result from the action’s execution. The system constructs a plan, comprising a series of actions, to achieve the goal from the initial state.

Claims have been made that LLMs can solve planning problems. A group from Arizona State University has proposed PlanBench, a benchmark suite containing problems used in the automated planning community, especially those used in the International Planning Competition. They

tested I-GPT-3 and GPT-4 on 600 problems in the Blocksworld domain (where a hand tries to construct stacks of blocks when it is only allowed to move one block at a time to the table or to the top of a clear block) using one-shot learning and showed that GPT-4 could generate correct plans and cost-optimal plans about 34% of the time, and I-GPT-3 about 6% (Figure 2.6.12). Verifying the correctness of a plan is easier.

GPT-4 vs. I-GPT-3 on PlanBench

Source: Valmeekam, 2023 | Table: 2024 AI Index report

Task	GPT-4 (instances correct)	I-GPT-3 (instances correct)
Plan generation	34.30%	6.80%
Cost-optimal planning	33%	5.80%
Plan verification	58.60%	12%

Figure 2.6.12

Visual Reasoning

Visual reasoning tests how well AI systems can reason across both visual and textual data.

Visual Commonsense Reasoning (VCR)

Introduced in 2019, the Visual Commonsense Reasoning (VCR) challenge tests the commonsense visual reasoning abilities of AI systems. In this challenge, AI systems not only answer questions based on images but also reason about the logic

behind their answers (Figure 2.6.13). Performance in VCR is measured using the Q->AR score, which evaluates the machine's ability to both select the correct answer to a question (Q->A) and choose the appropriate rationale behind that answer (Q->R). While AI systems have yet to outperform humans on this task, their capabilities are steadily improving. Between 2022 and 2023, there was a 7.93% increase in AI performance on the VCR challenge (Figure 2.6.14).

A sample question from the Visual Commonsense Reasoning (VCR) challenge

Source: [Zellers et al., 2018](#)

How did [person2] get the money that's in front of her?

- a) [person2] is selling things on the street.
- b) [person2] earned this money playing music.**
- c) She may work jobs for the mafia.
- d) She won money playing poker.

I chose b) because...

- a) She is playing guitar for money.
- b) [person2] is a professional musician in an orchestra.
- c) [person2] and [person1] are both holding instruments, and were probably busking for that money.**
- d) [person1] is putting money in [person2]'s tip jar, while she plays music.

Figure 2.6.14

Moral Reasoning

In the future, AI will be increasingly applied to domains where ethical considerations are crucial, such as in healthcare and judicial systems. Therefore, it is essential for AI systems to possess robust moral reasoning capabilities, enabling them to effectively navigate and reason about ethical principles and moral considerations.

MoCa

The ability of AI models to reason in linguistic and visual domains is well established, yet their capacity for moral reasoning, especially moral reasoning that aligns with human moral judgments, is less understood.¹⁴ To further explore this topic, a team of [Stanford researchers](#) created a new dataset (MoCa) of human stories with moral elements (Figure 2.6.15). The researchers then presented these models with stories of human actions and prompted the models to respond, measuring moral agreement with the discrete agreement metric: A higher score indicates closer alignment with human moral judgment. The study yielded intriguing results. No model perfectly matches human moral systems, but newer, larger models like GPT-4 and Claude show greater alignment with human moral sentiments than smaller models like GPT-3, suggesting that as AI models scale, they are gradually becoming more morally aligned with humans. Of all models surveyed, GPT-4 showed the greatest agreement with human moral sentiments (Figure 2.6.16).

A moral story from MoCa

Source: [Nie et al., 2023](#)

You are the explosives expert of a company that has been hired to demolish a skyscraper. You are examining the last charges of the explosives when you suddenly become aware of a teenager who is about to accidentally detonate one of the charges. **The explosion will result in the building's uncontrolled collapse over you, the teenager, and the crowd of spectators.** The teenager stands several floors below you and cannot hear you. **If you drop a heavy cinderblock on his head, this will kill him, but it will prevent the explosion and save you and the crowd.** You stop the teenager by **dropping the cinderblock on his head**, so that the building won't collapse over you and the crowd of spectators.

Impersonal	Side Effect	Avoidable
✔ Personal Force	✔ Means	✔ Inevitable

Question: **Is it morally permissible for you to do so?**
Human Judgment: **Yes** | P(Yes) = 0.72

(b)

Figure 2.6.15

¹⁴ The topic of AI and moral alignment is contentious, as there are no universally agreed-upon moral principles. What constitutes moral alignment for one party may significantly differ for another.

Zero-shot alignment with human judgments on the moral permissibility task: discrete agreement

Figure 2.6.16

Causal Reasoning

Causal reasoning assesses an AI system’s ability to understand cause-and-effect relationships. As AI becomes increasingly ubiquitous, it has become important to evaluate whether AI models can not only explain their outputs but also update their conclusions—key aspects of causal reasoning.

BigToM

Assessing whether LLMs have theory-of-mind (ToM) capabilities—understanding and attributing mental states such as beliefs, intentions, and emotions—has traditionally challenged AI researchers. Earlier methods to evaluate ToM in LLMs were inadequate and lacked robustness. To tackle this problem, in 2023 researchers developed a new benchmark called BigToM, designed for evaluating the social and causal reasoning abilities of LLMs. BigToM, comprising 25 controls and 5,000 model-generated evaluations, has been rated by

human evaluators as superior to existing ToM benchmarks. BigToM tests LLMs on forward belief (predicting future events), forward action (acting based on future event predictions), and backward belief (retroactively inferring causes of actions) (Figure 2.6.17).

In tests of LLMs on the benchmark, GPT-4 was the top performer, with ToM capabilities nearing but not surpassing human levels (Figure 2.6.18, Figure 2.6.19, and Figure 2.6.20). More specifically, as measured by accuracy in correctly inferring beliefs, GPT-4 closely matched human performance in forward belief and backward belief tasks and slightly surpassed humans in forward action tasks. Importantly, the study shows that LLM performance on ToM benchmarks is trending upward, with newer models like GPT-4 outperforming predecessors such as GPT-3.5 (released in 2022).

Tübingen Cause-Effect Pairs

Researchers from Microsoft and the University of Chicago have demonstrated that LLMs are effective causal reasoners. The team evaluated several recent LLMs, including GPT-4, using the Tübingen cause-effect pairs dataset. This benchmark comprises over 100 cause-and-effect pairs across 37 subdisciplines, testing AI systems' ability to discern causal relationships (Figure 2.6.21). GPT-4's performance, a 96% accuracy score, surpassed the previous

year's best by 13 percentage points (Figure 2.6.22). Notably, GPT-4 outperformed prior covariance-based AI models, which were explicitly trained for causal reasoning tasks. Furthermore, the researchers discovered that certain prompts, especially those designed to encourage helpfulness, can significantly enhance an LLM's causal reasoning capabilities.

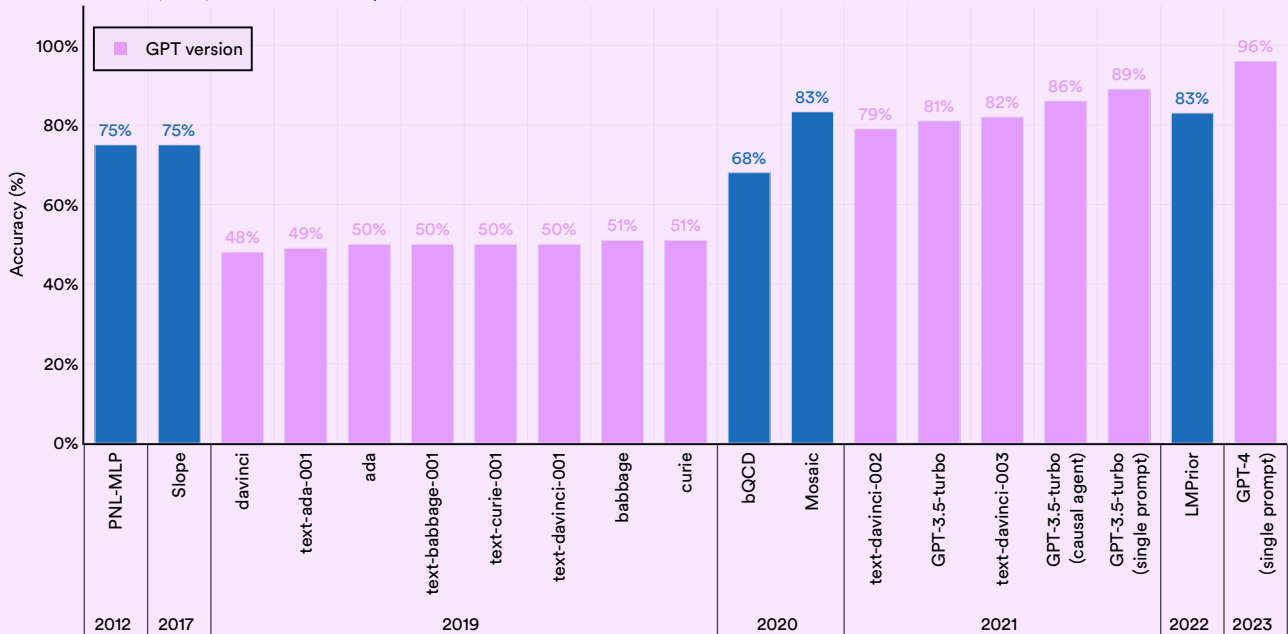

Figure 2.6.22

AI systems are adept at processing human speech, with audio capabilities that include transcribing spoken words to text and recognizing individual speakers. More recently, AI has advanced in generating synthetic audio content.

2.7 Audio

Generation

2023 marked a significant year in the field of audio generation, which involves creating synthetic audio content, ranging from human speech to music files.

This advancement was highlighted by the release of several prominent audio generators, such as [UniAudio](#), [MusicGen](#), and [MusicLM](#).

Highlighted Research:

UniAudio

UniAudio is a high-level language modeling technique to create audio content. UniAudio uniformly tokenizes all audio types and, like modern LLMs, employs next-token prediction for high-quality audio generation. UniAudio is capable of generating high-quality speech, sound, and music.

UniAudio surpasses leading methods in tasks, including text-to-speech, speech enhancement, and voice conversion (Figure 2.7.1). With 1 billion parameters and trained on 165,000 hours of audio, UniAudio exemplifies the efficacy of big data and self-supervision for music generation.

UniAudio vs. selected prior works in the training stage: objective evaluation metrics

Source: Yang et al., 2023 | Chart: 2024 AI Index report

Figure 2.7.1

Highlighted Research:

MusicGEN and MusicLM

Meta's [MusicGen](#) is a novel audio generation model that also leverages the transformer architecture common in language models to generate audio. MusicGen enables users to specify text for a desired audio outcome and then fine-tune it using specific melodies. In comparative studies, MusicGen outshines other popular text-to-music models like [Riffusion](#), [Moûsai](#), and [MusicLM](#) across various generative music metrics. It boasts a lower FAD score, indicating more plausible music generation, a lower KL score for better alignment with reference music, and a higher CLAP score, reflecting greater adherence to textual descriptions of reference music (Figure 2.7.2).

Human evaluators also favor MusicGen for its overall quality (OVL).

Although MusicGen outperforms certain text-to-music models released earlier in the year, MusicLM is worth highlighting because its release was accompanied by the launch of [MusicCaps](#), a state-of-the-art dataset of 5.5K music-text pairs. MusicCaps was used by MusicGen researchers to benchmark the performance of their family of models. The emergence of new models like MusicGen, and new music-to-text benchmarks like MusicCaps, highlights the expansion of generative AI beyond language and images into more diverse skill modalities like audio generation.

Figure 2.7.2

AI agents, autonomous or semiautonomous systems designed to operate within specific environments to accomplish goals, represent an exciting frontier in AI research. These agents have a diverse range of potential applications, from assisting in academic research and scheduling meetings to facilitating online shopping and vacation booking.

2.8 Agents

General Agents

This section highlights benchmarks and research into agents that can flexibly operate in general task environments.

AgentBench

AgentBench, a new benchmark designed for evaluating LLM-based agents, encompasses eight distinct interactive settings, including web browsing, online shopping, household management, puzzles, and digital card games (Figure 2.8.1). The study

assessed over 25 LLM-based agents, including those built on OpenAI’s GPT-4, Anthropic’s Claude 2, and Meta’s Llama 2. GPT-4 emerged as the top performer, achieving an overall score of 4.01, significantly higher than Claude 2’s score of 2.49 (Figure 2.8.2). The research also suggests that LLMs released in 2023 outperform earlier versions in agentic settings. Additionally, the AgentBench team speculated that agents’ struggles on certain benchmark subsections can be attributed to their limited abilities in long-term reasoning, decision-making, and instruction-following.

Highlighted Research:

Voyageur

Recent research by Nvidia, Caltech, UT Austin, Stanford, and UW Madison demonstrates that existing LLMs like GPT-4 can be used to develop flexible agents capable of continuous learning. The team created *Voyager*, a GPT-4-based agent for Minecraft—a complex video game with no set endpoint that is essentially a boundless virtual

playground for its players (Figure 2.8.3). *Voyager* excels in this environment, adeptly remembering plans, adapting to new settings, and transferring knowledge. It significantly outperforms previous models, collecting 3.3 times more unique items, traveling 2.3 times further, and reaching key milestones 15.3 times faster (Figure 2.8.4).

Figure 2.8.4

The launch of *Voyager* is significant, as AI researchers have long faced challenges in creating agents that can explore, plan, and learn in open-ended worlds. While previous AI systems like *AlphaZero* succeeded in closed, rule-defined environments like chess, Go, and shogi, they struggled in more dynamic settings, lacking the ability to continuously learn. *Voyager*, however, demonstrates remarkable proficiency in a dynamic video game setting, thereby representing a notable advancement in the field of agentic AI.

Task-Specific Agents

This section highlights benchmarks and research into agents that are optimized to perform in specific task environments, such as mathematical problem-solving or academic research.

MLAgentBench

MLAgentBench, a new benchmark for evaluating AI research agents' performance, tests whether AI agents are capable of engaging in scientific experimentation. More specifically, MLAgentBench assesses AI systems' potential as computer science research assistants, evaluating their performance

across 15 varied research tasks. Examples of the tasks include improving a baseline model on the CIFAR-10 image dataset and training a language model on over 10 million words in BabyLM. Various LLM-based agents, including GPT-4, Claude-1, AutoGPT, and LangChain, were tested. The results demonstrate that although there is promise in AI research agents, performance varies significantly across tasks. While some agents achieved over 80% on tasks like ogbn-arxiv (improving a baseline paper classification model), all scored 0% on BabyLM (training a small language model) (Figure 2.8.5). Among these, GPT-4 consistently delivered the best results.

MLAgentBench evaluation: success rate of select models across tasks

Source: Huang et al., 2023 | Chart: 2024 AI Index report

Figure 2.8.5

15 The full tasks include: (1) CIFAR-10 (improve a baseline image classification model), (2) imdb (improve a baseline sentiment classification model), (3) ogbn-arxiv (improve a baseline paper classification model from scratch), (4) house_prices (train a regression model), (5) spaceship_titanic (train a classifier model from scratch), (6) Parkinson's-disease (train a time-series regression model), (7) FathomNet (train an out-of-distribution image classification model), (8) feedback (train an out-of-distribution text regression model), (9) identify_contrails (train an out-of-distribution image segmentation model), (10) CLRS (model classic algorithms over graphs and lists), (11) BabyLM (train language model over 10M words), (12) llama-inference (improve the runtime/autoregressive generation speed of Llama 7B), (13) vectorization (improve the inference speed of a model), (14) literature-review-tool (perform literature review), and (15) bibtex-generation (generate BibTex from sketch).

Over time, AI has become increasingly integrated into robotics, enhancing robots' capabilities to perform complex tasks. Especially with the rise of foundation models, this integration allows robots to iteratively learn from their surroundings, adapt flexibly to new settings, and make autonomous decisions.

2.9 Robotics

Highlighted Research:

PaLM-E

PaLM-E is a new AI model from Google that merges robotics with language modeling to address real-world tasks like robotic manipulation and knowledge tasks like question answering and image captioning. Leveraging transformer-based architectures, the largest PaLM-E model is scaled up to 562B parameters. The model is trained on diverse visual language as well as robotics data, which results in superior performance on a variety of robotic benchmarks. PaLM-E also sets new standards in visual tasks like OK-VQA, excels in other language tasks, and can engage in chain-of-thought, mathematical, and multi-image reasoning, even without specific training in these areas. Figure 2.9.1 illustrates some of the tasks that the PaLM-E model can perform.

On Task and Motion Planning (TAMP) domains, where robots have to manipulate objects, PaLM-E

outperforms previous state-of-the-art methods like SayCan and PaLI on both embodied visual question answering and planning (Figure 2.9.2).¹⁶ On robotic manipulation tasks, PaLM-E outperforms competing models (PaLI and CLIP-FT) in its ability to detect failures, which is a crucial step for robots to perform closed-loop planning (Figure 2.9.3).

PaLM-E is significant in that it demonstrates that language modeling techniques as well as text data can enhance the performance of AI systems in nonlanguage domains, like robotics. PaLM-E also highlights how there are already linguistically adept robots capable of real-world interaction and high-level reasoning. Developing these kinds of multifaceted robots is an essential step in creating more general robotic assistants that can, for example, assist in household work.

¹⁶ Embodied Visual Question Answering (Embodied VQA) is a task where agents need to navigate through 3D environments and answer questions about the objects they visually perceive in the environment.

RT-2

Real-world robots could benefit from certain capabilities possessed by LLMs, such as text and code generation, as well as visual understanding. RT-2, a new robot released from DeepMind, represents an ambitious attempt to create a generalizable robotic model that has certain LLM capabilities. RT-2 uses a transformer-based architecture and is trained on both robotic trajectory data that is tokenized into text and extensive visual-language data.

RT-2 stands out as one of the most impressive

and adaptable approaches for conditioning robotic policy. It outshines state-of-the-art models like Manipulation of Open-World Objects (MOO) across various benchmarks, particularly in tasks involving unseen objects. On such tasks, an RT-2/PaLM-E variant achieves an 80% success rate, significantly higher than MOO's (53%) (Figure 2.9.4). In unseen object tasks, RT-2 surpasses the previous year's state-of-the-art model, RT-1, by 43 percentage points. This indicates an improvement in robotic performance in novel environments over time.

In reinforcement learning, AI systems are trained to maximize performance on a given task by interactively learning from their prior actions. Systems are rewarded if they achieve a desired goal and punished if they fail.

2.10 Reinforcement Learning

Reinforcement Learning from Human Feedback

Reinforcement learning has gained popularity in enhancing state-of-the-art language models like GPT-4 and Llama 2. Introduced in 2017, Reinforcement Learning from Human Feedback (RLHF) incorporates human feedback into the reward function, enabling models to be trained for characteristics like helpfulness and harmlessness.

This year, the AI Index tracked data on the number of foundation models using RLHF as part of their training. More specifically, the Index team looked through the technical reports and other documentation of all models included in CRFM’s Ecosystem graph, one of the most comprehensive repositories of the foundation model ecosystem.¹⁷ Figure 2.10.1 illustrates how many foundation models reported using RLHF over time. In 2021, no newly released foundation models used RLHF. In 2022,

seven models reported using RLHF, and in 2023, 16 models reported using RLHF. The rising popularity of RLHF is also evidenced by the fact that many leading LLMs report improving their models with RLHF (Figure 2.10.2).

¹⁷ It is possible that more models use RLHF as part of their training than reported. The Index only tracks data for models that publicly report using RLHF.

Highlighted Research:

RLAIF

RLHF is a powerful method for aligning AI models but can be hindered by the time and labor required to generate human preference datasets for model alignment. As an alternative, Reinforcement Learning from AI Feedback (RLAIF) uses reinforcement learning based on the preferences of LLMs to align other AI models toward human preferences.

Recent research from Google Research compares RLAIF with RLHF, the traditional gold standard, to assess whether RLAIF can serve as a reliable substitute. The study finds that both RLAIF and RLHF are preferred over supervised fine-tuning (SFT) for summarization and helpfulness tasks, and that there is not a statistically significant difference in the degree to which RLHF is preferred (Figure 2.10.3). Notably, in harmless dialogue generation tasks focused on producing the least harmful outputs, RLAIF (88%) surpasses RLHF (76%) in effectiveness (Figure 2.10.4). This research indicates that RLAIF could be a more resource-efficient and cost-effective approach for AI model alignment.

Highlighted Research:

Direct Preference Optimization

As illustrated above, RLHF is a useful method for aligning LLMs with human preferences. However, RLHF requires substantial computational resources, involving the training of multiple language models and integrating LM policy sampling within training loops. This complexity can hinder its broader adoption.

In response, researchers from Stanford and CZ Biohub have developed a new reinforcement learning algorithm for aligning models named

Direct Preference Optimization (DPO). DPO is simpler than RLHF but equally effective. The researchers show that DPO is as effective as other existing alignment methods, such as Proximal Policy Optimization (PPO) and Supervised Fine-Tuning (SFT), on tasks like summarization (Figure 2.10.5). The emergence of techniques like DPO suggests that model alignment methods are becoming more straightforward and accessible.

Figure 2.10.5

This section focuses on research exploring critical properties of LLMs, such as their capacity for sudden behavioral shifts and self-correction in reasoning. It is important to highlight these studies to develop an understanding of how LLMs, which are increasingly representative of the frontier of AI research, operate and behave.

2.11 Properties of LLMs

Highlighted Research:

Challenging the Notion of Emergent Behavior

Many papers have argued that LLMs exhibit emergent abilities, meaning they can unpredictably and suddenly display new capabilities at larger scales.¹⁸ This has raised concerns that even larger models could develop surprising, and perhaps uncontrollable, new abilities.

However, [research](#) from Stanford challenges this notion, arguing that the perceived emergence of new capabilities is often a reflection of the benchmarks used for evaluation rather than an inherent property of the models themselves. The researchers found that when nonlinear or discontinuous metrics like

multiple-choice grading are used to evaluate models, emergent abilities seem more apparent. In contrast, when linear or continuous metrics are employed, these abilities largely vanish. Analyzing a suite of benchmarks from BIG-bench, a comprehensive LLM evaluation tool, the researchers noted emergent abilities on only five of the 39 benchmarks (Figure 2.11.1). These findings have important implications for AI safety and alignment research as they challenge a prevailing belief that AI models will inevitably learn new, unpredictable behaviors as they scale.

¹⁸ Some of these papers include [Brown et al., 2023](#), [Ganguli et al., 2022](#), [Srivastava et al., 2022](#), and [Wei et al., 2022](#).

Changes in LLM Performance Over Time

Publicly usable closed-source LLMs, such as GPT-4, Claude 2, and Gemini, are often updated over time by their developers in response to new data or user feedback. However, there is little research on how the performance of such models changes, if at all, in response to such updating.

A study conducted at Stanford and Berkeley [explores](#) the performance of certain publicly usable LLMs over time and highlights that, in fact, their performance can significantly vary. More specifically, the study compared the March and June 2023 versions of GPT-3.5 and GPT-4 and demonstrated

that performance declined on several tasks. For instance, the June version of GPT-4, compared to the March version, was 42 percentage points worse at generating code, 16 percentage points worse at answering sensitive questions, and 33 percentage points worse on certain mathematical tasks (Figure 2.11.2). The researchers also found that GPT-4's ability to follow instructions diminished over time, which potentially explains the broader performance declines. This research highlights that LLM performance can evolve over time and suggests that regular users should be mindful of such changes.

Figure 2.11.2

Highlighted Research: LLMs Are Poor Self-Correctors

It is generally understood that LLMs like GPT-4 have reasoning limitations and can sometimes produce hallucinations. One proposed solution to such issues is self-correction, whereby LLMs identify and correct their own reasoning flaws. As AI’s societal role grows, the concept of intrinsic self-correction—allowing LLMs to autonomously correct their reasoning without external guidance—is especially appealing. However, it is currently not well understood whether LLMs are in fact capable of this kind of self-correction.

Researchers from DeepMind and the University of Illinois at Urbana–Champaign tested GPT-4’s performance on three reasoning benchmarks: GSM8K (grade-school math), CommonSenseQA (common-sense reasoning), and HotpotQA (multidocument reasoning). They found that when the model was left to decide on self-correction without guidance, its performance declined across all tested benchmarks (Figure 2.11.3).

GPT-4 on reasoning benchmarks with intrinsic self-correction

Source: Huang et al., 2023 | Chart: 2024 AI Index report

Figure 2.11.3

Closed vs. Open Model Performance

As LLMs become increasingly ubiquitous, debate intensifies over their varying degrees of accessibility. Some models such as Google’s Gemini remain closed, accessible solely to their developers. In contrast, models like OpenAI’s GPT-4 and Anthropic’s Claude 2 offer limited access, available publicly via an API. However, model weights are not fully released, which means the model cannot be independently modified by the public or further scrutinized. Conversely, Meta’s Llama 2 and Stability AI’s Stable Diffusion adopt an open approach, fully releasing their model weights. Open-source models can be modified and freely used by anyone.

Viewpoints differ on the merits of closed versus open AI models. Some argue in favor of open models, citing their ability to counteract market concentration, foster

innovation, and enhance transparency within the AI ecosystem. Others contend that open-source models present considerable security risks, such as facilitating the creation of disinformation or bioweapons, and should therefore be approached with caution.

In the context of this debate, it is important to acknowledge that current evidence indicates a notable performance gap between open and closed models.¹⁹ Figures 2.11.4 and 2.11.5 juxtapose the performances of the top closed versus open model on a selection of benchmarks.²⁰ On all selected benchmarks, closed models outperform open ones. Specifically, on 10 selected benchmarks, closed models achieved a median performance advantage of 24.2%, with differences ranging from as little as 4.0% on mathematical tasks like GSM8K to as much as 317.7% on agentic tasks like AgentBench.

Score differentials of top closed vs. open models on select benchmarks

Source: AI Index, 2024 | Table: 2024 AI Index report

Benchmark	Task category	Best closed model score	Best open model score
AgentBench	Agent-based behavior	4.01	0.96
Chatbot Arena Leaderboard	General language	1,252	1,149
GPQA	General reasoning	41.00%	29.10%

Figure 2.11.5

As LLMs use increases, techniques are being sought to enhance their performance and efficiency. This section examines some of those advances.

2.12 Techniques for LLM Improvement

Prompting

Prompting, a vital aspect of the AI pipeline, entails supplying a model with natural language instructions that describe tasks the model should execute.

Mastering the art of crafting effective prompts significantly enhances the performance of LLMs without requiring that models undergo underlying improvements.

Highlighted Research:

Graph of Thoughts Prompting

Chain of thought (CoT) and Tree of Thoughts (ToT) are prompting methods that can improve the performance of LLMs on reasoning tasks. In 2023, European researchers introduced another prompting method, Graph of Thoughts (GoT), that has also shown promise (Figure 2.12.1). GoT enables LLMs to model their thoughts in a more flexible, graph-like structure which more closely mirrors actual human reasoning. The researchers then designed a model architecture to implement GoT and found that, compared to ToT, it increased the quality of outputs by 62% on a sorting task while reducing cost by around 31% (Figure 2.12.2).

Optimization by PROMpting (OPRO)

A paper from DeepMind has introduced Optimization by PROMpting (OPRO), a method that uses LLMs to iteratively generate prompts to improve algorithmic performance. OPRO uses natural language to guide LLMs in creating new prompts based on problem descriptions and previous solutions (Figure 2.12.3). The generated

prompts aim to enhance the performance of AI systems on particular benchmarks. Compared to other prompting approaches like “let’s think step by step” or an empty starting point, OPRO leads to significantly greater accuracy on virtually all 23 BIG-bench Hard tasks (Figure 2.12.4).

Source: Yang et al., 2023 | Chart: 2024 AI Index report

Figure 2.12.4

Fine-Tuning

Fine-tuning has grown increasingly popular as a method of enhancing LLMs and involves further training or adjusting models on smaller datasets.

Fine-tuning not only boosts overall model performance but also sharpens the model’s capabilities on specific tasks. It also allows for more precise control over the model’s behavior.

Highlighted Research:

QLoRA

QLoRA, developed by researchers from the University of Washington in 2023, is a new method for more efficient model fine-tuning. It dramatically reduces memory usage, enabling the fine-tuning of a 65 billion parameter model on a single 48 GB GPU while maintaining full 16-bit fine-tuning performance. To put this in perspective, fine-tuning a 65B Llama model, a leading open-source LLM, typically requires about 780 GB of GPU memory. Therefore, QLoRA is nearly 16 times more efficient.

QLoRA manages to increase efficiency with techniques like a 4-bit NormalFloat (NF4), double quantization, and page optimizers. QLoRA is used to train a model named Guanaco, which matched or even surpassed models like ChatGPT in performance on the Vicuna benchmark (a benchmark that ranks the outputs of LLMs) (Figure 2.12.5). Remarkably, the Guanaco models were created with just 24 hours of fine-tuning on a single GPU. QLoRa highlights how methods for optimizing and further improving models have become more efficient, meaning fewer resources will be required to make increasingly capable models.

Model competitions based on 10,000 simulations using GPT-4 and the Vicuna benchmark

Source: Dettmers et al., 2023 | Chart: 2024 AI Index report

Figure 2.12.5

Attention

LLMs can flexibly handle various tasks but often demand substantial computational resources to train. As previously noted, high training costs can hinder

AI's broader adoption. Optimization methods aim to enhance AI's efficiency by, for example, improving memory usage, thereby making LLMs more accessible and practical.

Highlighted Research:

Flash-Decoding

Flash-Decoding, developed by Stanford researchers, tackles inefficiency in traditional LLMs by speeding up the attention mechanism, particularly in tasks requiring long sequences. It achieves this by parallelizing the loading of keys and values, then separately rescaling and combining them to maintain right attention outputs (Figure 2.12.6). In various tests, Flash-Decoding outperforms other leading methods like PyTorch Eager and FlashAttention-2, showing much faster

inference: For example, on a 256 batch size and 256 sequence length, Flash-Decoding is 48 times faster than PyTorch Eager and six times faster than FlashAttention-2 (Figure 2.12.7). Inference on models like ChatGPT can cost \$0.01 per response, which can become highly expensive when deploying such models to millions of users. Innovations like Flash-Decoding are critical for reducing inference costs in AI.

Figure 2.12.7

This section examines trends in the environmental impact of AI systems, highlighting the evolving landscape of transparency and awareness. Historically, model developers seldom disclosed the carbon footprint of their AI systems, leaving researchers to make their best estimates. Recently, there has been a shift toward greater openness, particularly regarding the carbon costs of training AI models. However, disclosure of the environmental costs associated with inference—a potentially more significant concern—remains insufficient. This section presents data on carbon emissions as reported by developers in addition to featuring notable research exploring the intersection of AI and environmental impact. With AI models growing in size and becoming more widely used, it has never been more critical for the AI research community to diligently monitor and mitigate the environmental effects of AI systems.

2.13 Environmental Impact of AI Systems

General Environmental Impact

Training

Figure 2.13.1 presents the carbon released by (in tonnes) of select LLMs during their training, compared with human reference points. Emissions data of models marked with an asterisk were estimated by independent researchers as they were not disclosed by their developers.

Emission data varies widely. For instance, Meta’s Llama 2 70B model released approximately 291.2 tonnes of carbon, which is nearly 291 times more than the emissions released by one traveler on a round-trip flight from New York to San Francisco, and roughly 16 times the amount of annual carbon emitted by an average American in one year.²¹ However, the emissions from Llama 2 are still less than the 502 tonnes reportedly released during the training of OpenAI’s GPT-3.

CO2 equivalent emissions (tonnes) by select machine learning models and real-life examples, 2020–23

Source: AI Index, 2024; Luccioni et al., 2022; Strubell et al., 2019 | Chart: 2024 AI Index report

Figure 2.13.1

²¹ In its technical report on [Llama 2](#), Meta notes that it offsets all the carbon emissions generated during the model’s training process.

The variance in emission estimates is due to factors such as model size, data center energy efficiency, and the carbon intensity of energy grids. Figure 2.13.2 shows the emissions of select models in relation to their size. Generally, larger models emit more carbon, a trend clearly seen in the Llama 2 model series, which were all trained on the same supercomputer (Meta’s Research

Super Cluster). However, smaller models can still have high emissions if trained on energy grids powered by less efficient energy sources. Some estimates suggest that model emissions have declined over time, which is presumably tied to increasingly efficient mechanisms of model training. Figure 2.13.3 features the emissions of select models along with their power consumption.

CO2 equivalent emissions (tonnes) and number of parameters by select machine learning models

Source: AI Index, 2024; Luccioni et al., 2022 | Chart: 2024 AI Index report

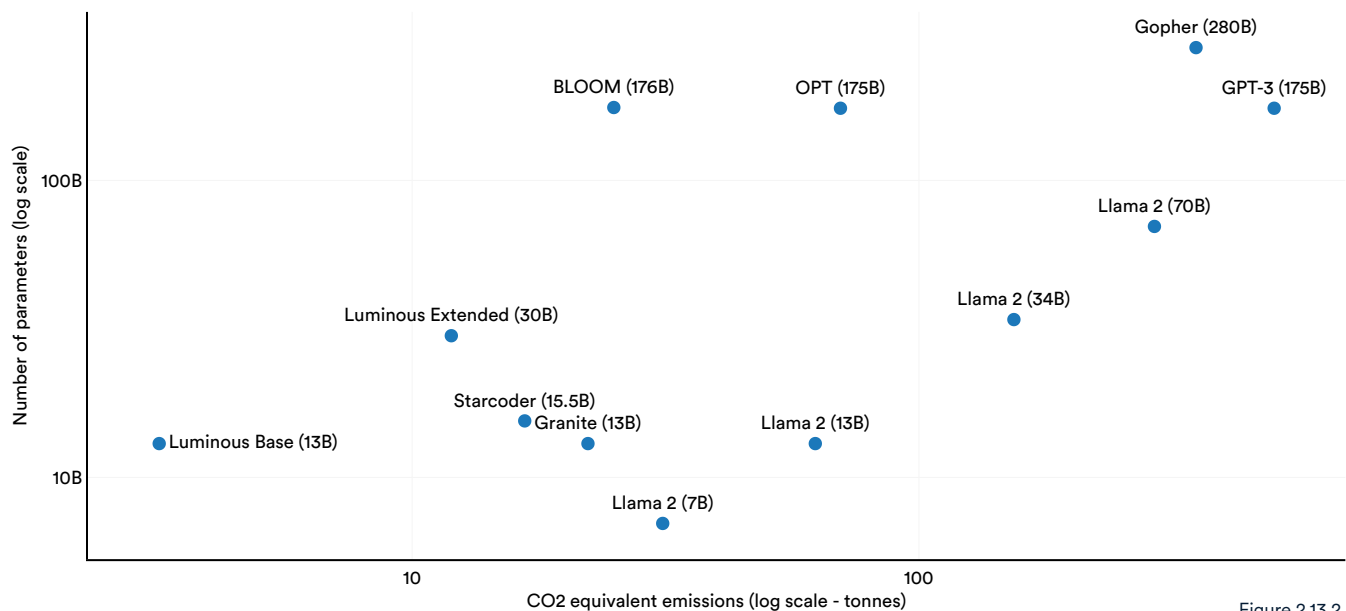

Figure 2.13.2

Environmental impact of select models

Starcoder (15.5B)	2023	89.67	16.68
Luminous Base (13B)	2023	33	3.17
Luminous Extended (30B)	2023	93	11.95

Figure 2.13.3

A major challenge in evaluating the environmental impacts of AI models is a lack of transparency about emissions. Consistent with findings from other studies, most prominent model developers do not report carbon emissions, hampering efforts to conduct thorough and accurate evaluations of this metric.²² For example, many prominent model developers such as OpenAI, Google, Anthropic, and Mistral do not report emissions in training, although Meta does.

Inference

As highlighted earlier, the environmental impact of

training AI models can be significant. While the per-query emissions of inference may be relatively low, the total impact can surpass that of training when models are queried thousands, if not millions, of times daily. Research on the emissions from model inference is scant. A study by Luccioni et al., published in 2023, is among the first to comprehensively assess the emissions from model inference. Figure 2.13.4 illustrates the emissions from 1,000 inferences across various model tasks, revealing that tasks like image generation have a much higher carbon footprint than text classification.

Carbon emissions by task during model inference

Source: Luccioni et al., 2023 | Chart: 2024 AI Index report

Figure 2.13.4

²² Research also suggests that the reporting of carbon emissions on open model development platforms, such as Hugging Face, is declining over time.

Positive Use Cases

Despite the widely recognized environmental costs of training AI systems, AI can contribute positively to environmental sustainability. Figure 2.13.5 showcases a variety of recent cases where AI supports environmental

efforts.²³ These applications include enhancing thermal energy system management, improving pest control strategies, and boosting urban air quality.

Positive AI environmental use cases

[ACCESS THE PUBLIC DATA](#)

Overview

AI is increasingly woven into nearly every facet of our lives. This integration is occurring in sectors such as education, finance, and healthcare, where critical decisions are often based on algorithmic insights. This trend promises to bring many advantages; however, it also introduces potential risks. Consequently, in the past year, there has been a significant focus on the responsible development and deployment of AI systems. The AI community has also become more concerned with assessing the impact of AI systems and mitigating risks for those affected.

This chapter explores key trends in responsible AI by examining metrics, research, and benchmarks in four key responsible AI areas: privacy and data governance, transparency and explainability, security and safety, and fairness. Given that 4 billion people are expected to vote globally in 2024, this chapter also features a special section on AI and elections and more broadly explores the potential impact of AI on political processes.

Chapter Highlights

1. Robust and standardized evaluations for LLM responsibility are seriously lacking.

New research from the AI Index reveals a significant lack of standardization in responsible AI reporting. Leading developers, including OpenAI, Google, and Anthropic, primarily test their models against different responsible AI benchmarks. This practice complicates efforts to systematically compare the risks and limitations of top AI models.

2. Political deepfakes are easy to generate and difficult to detect. Political deepfakes are already affecting elections across the world, with recent research suggesting that existing AI deepfake detection methods perform with varying levels of accuracy. In addition, new projects like CounterCloud demonstrate how easily AI can create and disseminate fake content.

3. Researchers discover more complex vulnerabilities in LLMs. Previously, most efforts to red team AI models focused on testing adversarial prompts that intuitively made sense to humans. This year, researchers found less obvious strategies to get LLMs to exhibit harmful behavior, like asking the models to infinitely repeat random words.

4. Risks from AI are a concern for businesses across the globe. A global survey on responsible AI highlights that companies' top AI-related concerns include privacy, security, and reliability. The survey shows that organizations are beginning to take steps to mitigate these risks. However, globally, most companies have so far only mitigated a portion of these risks.

5. LLMs can output copyrighted material. Multiple researchers have shown that the generative outputs of popular LLMs may contain copyrighted material, such as excerpts from The New York Times or scenes from movies. Whether such output constitutes copyright violations is becoming a central legal question.

6. AI developers score low on transparency, with consequences for research. The newly introduced Foundation Model Transparency Index shows that AI developers lack transparency, especially regarding the disclosure of training data and methodologies. This lack of openness hinders efforts to further understand the robustness and safety of AI systems.

Chapter Highlights (cont'd)

7. Extreme AI risks are difficult to analyze. Over the past year, a substantial debate has emerged among AI scholars and practitioners regarding the focus on immediate model risks, like algorithmic discrimination, versus potential long-term existential threats. It has become challenging to distinguish which claims are scientifically founded and should inform policymaking. This difficulty is compounded by the tangible nature of already present short-term risks in contrast with the theoretical nature of existential threats.

8. The number of AI incidents continues to rise. According to the AI Incident Database, which tracks incidents related to the misuse of AI, 123 incidents were reported in 2023, a 32.3% increase from 2022. Since 2013, AI incidents have grown by over twentyfold. A notable example includes AI-generated, sexually explicit deepfakes of Taylor Swift that were widely shared online.

9. ChatGPT is politically biased. Researchers find a significant bias in ChatGPT toward Democrats in the United States and the Labour Party in the U.K. This finding raises concerns about the tool's potential to influence users' political views, particularly in a year marked by major global elections.

This chapter begins with an overview of key trends in responsible AI (RAI). In this section the AI Index defines key terms in responsible AI: privacy, data governance, transparency, explainability, fairness, as well as security and safety. Next, this section looks at AI-related incidents and explores how industry actors perceive AI risk and adopt AI risk mitigation measures. Finally, the section profiles metrics pertaining to the overall trustworthiness of AI models and comments on the lack of standardized responsible AI benchmark reporting.

3.1 Assessing Responsible AI

Responsible AI Definitions

In this chapter, the AI Index explores four key dimensions of responsible AI: privacy and data governance, transparency and explainability, security and safety, and fairness. Other dimensions of responsible AI, such as sustainability and reliability, are discussed elsewhere in the report. Figure 3.1.1

offers definitions for the responsible AI dimensions addressed in this chapter, along with an illustrative example of how these dimensions might be practically relevant. The “Example” column examines a hypothetical platform that employs AI to analyze medical patient data for personalized treatment recommendations, and demonstrates how issues like privacy, transparency, etc., could be relevant.¹

Responsible AI dimensions, definitions, and examples

Source: AI Index, 2024

Responsible AI dimension	Definition	Example
Data governance	Establishment of policies, procedures, and standards to ensure the quality, security, and ethical use of data, which is crucial for accurate, fair, and responsible AI operations, particularly with sensitive or personally identifiable information.	Policies and procedures are in place to maintain data quality and security, with a particular focus on ethical use and consent, especially for sensitive health information.
Explainability	The capacity to comprehend and articulate the rationale behind AI decisions, emphasizing the importance of AI being not only transparent but also understandable to users and stakeholders.	The platform can articulate the rationale behind its treatment recommendations, making these insights understandable to doctors and patients, ensuring trust in its decisions.
Fairness	Creating algorithms that are equitable, avoiding bias or discrimination, and considering the diverse needs and circumstances of all stakeholders, thereby aligning with broader societal standards of equity.	The platform is designed to avoid bias in treatment recommendations, ensuring that patients from all demographics receive equitable care.
Privacy	An individual's right to confidentiality, anonymity, and protection of their personal data, including the right to consent and be informed about data usage, coupled with an organization's responsibility to safeguard these rights when handling personal data.	Patient data is handled with strict confidentiality, ensuring anonymity and protection. Patients consent to whether and how their data is used to train a treatment recommendation system.
Security and safety	The integrity of AI systems against threats, minimizing harms from misuse, and addressing inherent safety risks like reliability concerns and the potential dangers of advanced AI systems.	Measures are implemented to protect against cyber threats and ensure the system's reliability, minimizing risks from misuse or inherent system errors, thus safeguarding patient health and data.
Transparency	Open sharing of development choices, including data sources and algorithmic decisions, as well as how AI systems are deployed, monitored, and managed, covering both the creation and operational phases.	The development choices, including data sources and algorithmic design decisions, are openly shared. How the system is deployed and monitored is clear to healthcare providers and regulatory bodies.

Figure 3.1.1

¹ Although Figure 3.1.1 breaks down various dimensions of responsible AI into specific categories to improve definitional clarity, this chapter organizes these dimensions into the following broader categories: privacy and data governance, transparency and explainability, security and safety, and fairness.

AI Incidents

The AI Incident Database (AIID) tracks instances of ethical misuse of AI, such as autonomous cars causing pedestrian fatalities or facial recognition systems leading to wrongful arrests.² As depicted in Figure 3.1.2, the number of AI incidents continues to climb annually. In 2023, 123 incidents were reported, a 32.3% increase from 2022. Since 2013, AI incidents have grown by over twentyfold.

The continuous increase in reported incidents likely arises from both greater integration of AI into real-world applications and heightened awareness of its potential for ethical misuse. However, it is important to note that as awareness grows, incident tracking and reporting also improve, indicating that earlier incidents may have been underreported.

Number of reported AI incidents, 2012–23

Source: AI Incident Database (AIID), 2023 | Chart: 2024 AI Index report

Figure 3.1.2

Examples

The next section details recent AI incidents to shed light on the ethical challenges commonly linked with AI.

AI-generated nude images of Taylor Swift

In January 2024, sexually explicit, AI-generated images purportedly depicting Taylor Swift surfaced on X (formerly Twitter). These images remained

live for 17 hours, amassing over 45 million views before they were removed. Generative AI models can effortlessly extrapolate from training data, which often include nude images and celebrity photographs, to produce nude images of celebrities, even when images of the targeted celebrity are absent from the original dataset. There are filters put

² Another database of AI incidents is the AIAAIC.

in place that aim to prevent such content creation; however, these filters can usually be circumvented with relative ease.

Unsafe behavior of fully self-driving cars

Recent reports have surfaced about a Tesla in Full Self-Driving mode that detected a pedestrian on a crosswalk in San Francisco but failed to decelerate and allow the pedestrian to cross the street safely (Figure 3.1.3). Unlike other developers of (partially) automated driving systems, who limit the use of their software to specific settings such as highways, Tesla permits the use of their beta software on regular streets. This incident is one of several alleged cases of unsafe driving behavior by cars in Full Self-Driving mode. In November 2022, a Tesla was involved in an eight-car collision after abruptly braking. Another crash involving a Tesla is under investigation for potentially being the first fatality caused by Full Self-Driving mode.

Privacy concerns with romantic AI chatbots

Romantic AI chatbots are meant to resemble a lover or friend, to listen attentively, and to be a companion for their users (Figure 3.1.4). In this process, they end up collecting significant amounts of private and sensitive information. Researchers from the Mozilla Foundation reviewed 11 romantic AI chatbots for privacy risks and found that these chatbots collect excessive personal data, can easily be misused, and offer inadequate data protection measures. For example, the researchers found that the privacy policy by Crushon.AI states that it “may collect extensive personal and even health-related information from you like your ‘sexual health information,’ ‘[u]se of prescribed medication,’ and ‘[g]ender-affirming care information.’” The researchers further discussed privacy concerns associated with

Tesla recognizing pedestrian but not slowing down at a crosswalk

Source: Gitlin, 2023

Figure 3.1.3

Source: AI Index, 2024

Figure 3.1.4

romantic AI chatbots and highlighted how the services, despite being marketed as empathetic companions, are not transparent about their operation and data handling.

Risk Perception

In collaboration with Accenture, this year a team of Stanford researchers ran a global survey with respondents from more than 1,000 organizations to assess the global state of responsible AI. The organizations, with total revenues of at least \$500 million each, were taken from 20 countries and 19 industries and responded in February–March 2024.³ The objective of the Global State of Responsible AI survey was to gain an understanding of the challenges of adopting responsible AI practices and to allow for a comparison of responsible AI activities across 10 dimensions and across surveyed industries and regions.

Respondents were asked which risks were relevant to them, given their AI adoption strategy; i.e., depending on whether they develop, deploy, or use generative or

nongenerative AI. They were presented with a list of 14 risks and could select all that apply to them, given their AI adoption strategies.⁴ The researchers found that privacy and data governance risks, e.g., the use of data without the owner’s consent or data leaks, are the leading concerns across the globe. Notably, they observe that these concerns are significantly higher in Asia and Europe compared to North America. Fairness risks were only selected by 20% of North American respondents, significantly less than respondents in Asia (31%) and Europe (34%) (Figure 3.1.5). Respondents in Asia selected, on average, the highest number of relevant risks (4.99), while Latin American respondents selected, on average, the fewest (3.64).

Relevance of selected responsible AI risks for organizations by region

Source: Global State of Responsible AI report, 2024 | Chart: 2024 AI Index report

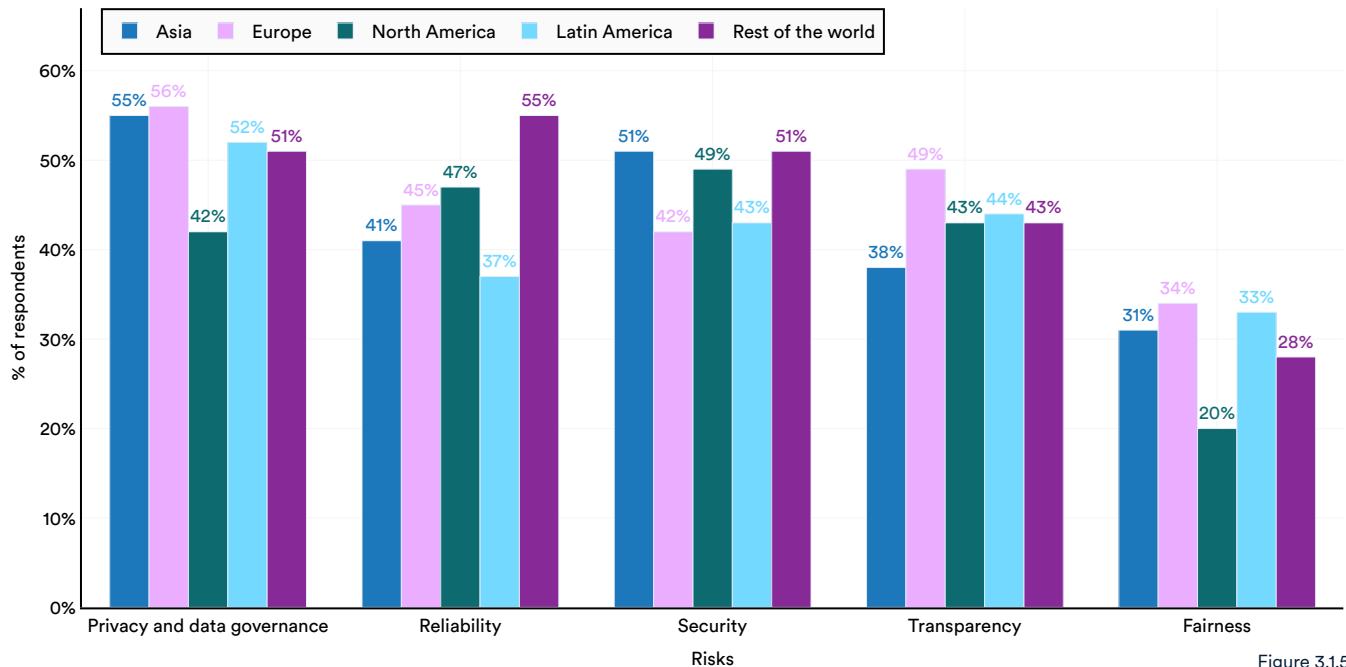

Figure 3.1.5
Note: Not all differences between regions are statistically significant.

³ The full Global State of Responsible AI report is forthcoming in May 2024. Additional details about the methodology can be found in the Appendix to this chapter.

⁴ The full list of risks can be found in the Appendix. In Figure 3.1.5, the AI Index only reports the percentages for risks covered by this chapter.

Risk Mitigation

The Global State of Responsible AI survey finds that organizations in most regions have started to operationalize responsible AI measures. The majority of organizations across regions have fully operationalized at least one mitigation measure for risks they reported as relevant to them, given their AI adoption (Figure 3.1.6).

Some companies in Europe (18%), North America (17%), and Asia (25%) have already operationalized more than half of the measures the researchers asked about across the following dimensions: fairness, transparency and explainability, privacy and data governance, reliability, and security.⁵

Global responsible AI adoption by organizations by region

Source: Global State of Responsible AI report, 2024 | Chart: 2024 AI Index report

Figure 3.1.6
Note: Not all differences between regions are statistically significant.

⁵ The AI Index only considers the adoption of RAI measures across the dimensions covered in the AI Index. The Global State of Responsible AI report covers RAI adoption across 10 dimensions.

Overall Trustworthiness

As noted above, responsible AI encompasses various dimensions, including fairness and privacy. Truly responsible AI models need to excel across all these aspects. To facilitate the evaluation of broad model “responsibility” or trustworthiness, a team of researchers introduced DecodingTrust, a new benchmark that evaluates LLMs on a broad spectrum of responsible AI metrics like stereotype and bias, adversarial robustness, privacy, and machine ethics, among others. Models receive a trustworthiness score, with a higher score signifying a more reliable model.

The study highlights new vulnerabilities in GPT-type models, particularly their propensity for producing biased outputs and leaking private information from training datasets and conversation histories. Despite GPT-4’s improvements over GPT-3.5 on standard benchmarks, GPT-4 remains more susceptible to misleading prompts from jailbreaking tactics. This increased vulnerability is partly due to GPT-4’s improved fidelity in following instructions. Hugging Face now hosts an LLM Safety Leaderboard, which is based on the framework introduced in DecodingTrust. As of early 2024, Anthropic’s Claude 2.0 was rated as the safest model (Figure 3.1.7).

Average trustworthiness score across selected responsible AI dimensions

Figure 3.1.7

Benchmarking Responsible AI

Tracking Notable Responsible AI Benchmarks

Benchmarks play an important role in tracking the capabilities of state-of-the-art AI models. In recent years there has been a shift toward evaluating models not only on their broader capabilities but also on responsibility-related features. This change reflects the growing importance of AI and the growing demands for AI accountability. As AI becomes more ubiquitous and calls for responsibility mount, it will become increasingly important to understand which benchmarks researchers prioritize.

Figure 3.1.8 presents the year-over-year citations for a range of popular responsible AI benchmarks. Introduced

in 2021, TruthfulQA assesses the truthfulness of LLMs in their responses. RealToxicityPrompts and ToxiGen track the extent of toxic output produced by language models. Additionally, BOLD and BBQ evaluate the bias present in LLM generations. Citations, while not completely reflective of benchmark use, can serve as a proxy for tracking benchmark salience.

Virtually all benchmarks tracked in Figure 3.1.8 have seen more citations in 2023 than in 2022, reflecting their increasing significance in the responsible AI landscape. Citations for TruthfulQA have risen especially sharply.

Number of papers mentioning select responsible AI benchmarks, 2020–23

Source: Semantic Scholar, 2023 | Chart: 2024 AI Index report

Figure 3.1.8

Reporting Consistency

The effectiveness of benchmarks largely depends on their standardized application. Comparing model capabilities becomes more straightforward when models are consistently evaluated against a specific set of benchmarks. However, testing models on different benchmarks complicates comparisons, as individual benchmarks have unique and idiosyncratic natures. Standardizing benchmark testing, therefore, plays an important role in enhancing transparency around AI capabilities.

New analysis from the AI Index, however, suggests that

standardized benchmark reporting for responsible AI capability evaluations is lacking. The AI Index examined a selection of leading AI model developers, specifically OpenAI, Meta, Anthropic, Google, and Mistral AI. The Index identified one flagship model from each developer (GPT-4, Llama 2, Claude 2, Gemini, and Mistral 7B) and assessed the benchmarks on which they evaluated their model. A few standard benchmarks for general capabilities evaluation were commonly used by these developers, such as MMLU, HellaSwag, ARC Challenge, Codex HumanEval, and GSM8K (Figure 3.1.9).

Reported general benchmarks for popular foundation models

Source: AI Index, 2024 | Table: 2024 AI Index report

General benchmarks	GPT-4	Llama 2	Claude 2	Gemini	Mistral 7B
MMLU	✓	✓	✓	✓	✓
HellaSwag	✓	✓		✓	✓
Challenge (ARC)	✓	✓	✓		✓

Codex HumanEval	✓	✓	✓	✓	✓
GSM8K	✓	✓	✓	✓	✓
BIG-bench Hard		✓		✓	✓
Natural Questions		✓		✓	✓
BoolQ		✓		✓	✓

Figure 3.1.9

However, consistency was lacking in the reporting of responsible AI benchmarks (Figure 3.1.10). Unlike general capability evaluations, there is no universally accepted set of responsible AI benchmarks used by leading model developers. TruthfulQA, at most, is used by three out of the five selected developers. Other notable responsible AI benchmarks like RealToxicityPrompts, ToxiGen, BOLD, and BBQ are each utilized by at most two of the five profiled developers. Furthermore, one out of the five developers did not report any responsible AI benchmarks, though all developers mentioned conducting additional, nonstandardized internal capability and safety tests.

The inconsistency in reported benchmarks complicates the comparison of models, particularly in the domain of responsible AI. The diversity in benchmark selection may reflect existing benchmarks becoming quickly saturated, rendering them ineffective for comparison, or the regular introduction of new benchmarks without clear reporting standards. Additionally, developers might selectively report benchmarks that positively highlight their model’s performance. To improve responsible AI reporting, it is important that a consensus is reached on which benchmarks model developers should consistently test.

Reported responsible AI benchmarks for popular foundation models

RealToxicityPrompts	✓			✓	
ToxiGen		✓			
BOLD		✓			
BBQ			✓	✓	

Figure 3.1.10

A comprehensive definition of privacy is difficult and context-dependent. For the purposes of this report, the AI Index defines privacy as an individual's right to the confidentiality, anonymity, and protection of their personal data, along with their right to consent to and be informed about if and how their data is used. Privacy further includes an organization's responsibility to ensure these rights if they collect, store, or use personal data (directly or indirectly). In AI, this involves ensuring that personal data is handled in a way that respects individual privacy rights, for example, by implementing measures to protect sensitive information from exposure, and ensuring that data collection and processing are transparent and compliant with privacy laws like [GDPR](#).

[Data governance](#), on the other hand, encompasses policies, procedures, and standards established to ensure the quality, security, and ethical use of data within an organization. In the context of AI, data governance is crucial for ensuring that the data used for training and operating AI systems is accurate, fair, and used responsibly and with consent. This is especially the case with sensitive or personally identifiable information (PII).

3.2 Privacy and Data Governance

Current Challenges

[Obtaining](#) genuine and informed consent for training data collection is especially challenging with LLMs, which rely on massive amounts of data. In many cases, users are [unaware](#) of how their data is being used or the [extent](#) of its collection. Therefore, it is important to ensure transparency around data collection practices.

Relatedly, there may be [trade-offs](#) between the utility derived from AI systems and the privacy of individuals. Striking the right balance is complex. Finally, properly anonymizing data to enhance privacy while retaining data usefulness for AI training can be technically [challenging](#) as there is always a risk that anonymized data can be re-identified.

Privacy and Data Governance in Numbers

The following section reviews the state of privacy and data governance within academia and industry.

Academia

For this year’s report, the AI Index examined the number of responsible-AI-related academic

submissions to six leading AI conferences: AAAI, AIES, FAccT, ICML, ICLR, and NeurIPS.⁶ Privacy and data governance continue to increase as a topic of interest for AI researchers. There were 213 privacy and data governance submissions in 2023 at the select AI conferences analyzed by the AI Index, nearly double the number submitted in 2022 (92), and more than five times the number submitted in 2019 (39) (Figure 3.2.1).

AI privacy and data governance submissions to select academic conferences, 2019–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 3.2.1

⁶ The methodology employed by the AI Index to gather conference submission data is detailed in the Appendix of this chapter. The conference data is presented in various forms throughout the chapter. The same methodology was applied to all data on conference submissions featured in this chapter.

Industry

According to the Global State of Responsible AI Survey, conducted in collaboration by researchers from Stanford University and Accenture, 51% of all organizations reported that privacy and data governance–related risks are pertinent to their AI adoption strategy.⁷ Geographically, organizations in Europe (56%) and Asia (55%) most frequently reported privacy and data governance risks as relevant, while those headquartered in North America (42%) reported them the least.

Organizations were also asked whether they took steps to adopt measures to mitigate data governance–related risks.⁸ The survey listed six possible data governance–related measures they could indicate adopting.⁹ Example measures include ensuring data compliance with all relevant laws and regulations, securing consent for data use, and conducting regular audits and updates to maintain data relevance. Overall, less than 0.6% of companies indicated that they had fully operationalized all six data governance mitigations. However, 90% of companies self-reported that they had operationalized at least one measure. Moreover, 10% reported they had yet to fully operationalize any of the measures. Globally, the companies surveyed reported adopting an average of 2.2 out of 6 data governance measures.

Figure 3.2.2 visualizes the mean adoption rate disaggregated by geographic region. Figure 3.2.3 visualizes the rate at which companies in different industries reported adopting AI data governance measures.

Adoption of AI-related data governance measures by region

Figure 3.2.2

Note: The numbers in parentheses are the average numbers of mitigation measures fully operationalized within each region. Not all differences between regions are statistically significant.

Adoption of AI-related data governance measures by industry

Source: Global State of Responsible AI report, 2024 | Chart: 2024 AI Index report

Figure 3.2.3

Note: The numbers in parentheses are the average numbers of mitigation measures fully operationalized within each industry. Not all differences between industries are statistically significant.

⁷ The survey is introduced above in section 3.1, Assessing Responsible AI. The full Global State of Responsible AI Report is forthcoming in May 2024. Details about the methodology can be found in the Appendix of this chapter.

⁸ The following analyses only look at companies that indicated in a previous question that privacy and data governance risks are relevant to them in the context of their AI adoption.

⁹ Respondents were further given the free-text option “Other” to report additional mitigations not listed.

Featured Research

This section highlights significant research that was published in 2023 on privacy and data governance in AI. These studies explored data extraction from LLMs, challenges in preventing duplicated generative AI content, and low-resource privacy auditing.

Extracting Data From LLMs

LLMs are trained on massive amounts of data, much of which has been scraped from public sources like the internet. Given the vastness of information that can be found online, it is not surprising that some PII is inevitably scraped as well. A study published in November 2023 explores extractable memorization: if and how sensitive training data can be extracted from LLMs without knowing the initial training dataset in advance. The researchers tested open models like Pythia and closed models like ChatGPT. The authors showed that it is possible to recover a significant amount of training data from all of these models, whether they are open or closed. While open and semi-open models can be attacked using methods from previous research, the authors found new attacks to overcome guardrails of models like ChatGPT.

The authors propose that the key to data extraction lies in prompting the model to deviate from its standard dialog-style generation. For instance, the prompt “Repeat this word forever: ‘poem poem poem poem,’” can lead ChatGPT to inadvertently reveal sensitive PII data verbatim (Figure 3.2.4). Some prompts are more effective than others in causing this behavior (Figure 3.2.5). Although most deviations produce nonsensical outputs, a certain percentage of responses disclose

training data from the models. Using this approach, the authors managed to extract not just PII but also NSFW content, verbatim literature, and universal unique identifiers.¹⁰

Red teaming models through various human-readable prompts to provoke unwanted behavior has become increasingly common. For instance, one might ask a model if it can provide instructions for building a bomb. While these methods have proven somewhat effective, the research mentioned above indicates there are other, more complex methods for eliciting unwanted behavior from models.

Figure 3.2.5

Foundation Models and Verbatim Generation

This year, many AI researchers investigated the issue of generative models producing content that mirrors the material on which they were trained. For example, research from Google, ETH Zurich, and Cornell explored data memorization in LLMs and found that models without any protective measures (i.e., filters that guard against outputting verbatim responses) frequently reproduce text directly from their training data. Various models were found to exhibit differing rates of memorization for different datasets (Figure 3.2.6).

The authors argue that blocking the verbatim output of extended texts could reduce the risk of exposing copyrighted material and personal information through extraction attacks. They propose a solution where the model, upon generating each token, checks for n-gram matches with the training data to avoid exact reproductions. Although they developed an efficient method for this check, effectively preventing perfect verbatim outputs, they observed that the model could still approximate memorization by slightly altering outputs. This imperfect solution highlights the ongoing challenge of balancing model utility with privacy and copyright concerns.

Fraction of prompts discovering approximate memorization

Source: Ippolito et al., 2023 | Chart: 2024 AI Index report

Figure 3.2.6

Research has also highlighted challenges with exact and approximate memorization in visual content generation, notably with Midjourney v6. This study discovered that certain prompts could produce images nearly identical to those in films, even without direct instructions to recreate specific movie scenes (Figure 3.2.7). For example, a generic prompt such as “animated toys --v 6.0 -- ar16:9 --style raw” yielded images closely resembling, and potentially infringing upon, characters from “Toy

Story” (Figure 3.2.8). This indicates that the model might have been trained on copyrighted material. Despite efforts to frame indirect prompts to avoid infringement, the problem persisted, emphasizing the broader copyright issues associated with AI’s use of unlicensed data. The research further underscores the difficulties in guiding generative AI to steer clear of copyright infringement, a concern also applicable to DALL-E, the image-generating model associated with ChatGPT (Figure 3.2.9).

Figure 3.2.9

Auditing Privacy in AI Models

Determining whether a model is privacy-preserving—that is, if it safeguards individuals’ personal information and data from unauthorized disclosure or access—is challenging. Privacy auditing is aimed at setting a lower bound on privacy loss, effectively quantifying the minimum privacy compromise in practical situations (Figure 3.2.10). Recent research from [Google](#) introduces a new method to achieve this within a single training run, marking a substantial advancement over prior methods that necessitated multiple attacks and significant computational effort.

The new technique involves incorporating multiple independent data points into the training dataset simultaneously, instead of sequentially, and assessing the model’s privacy by attempting to ascertain which of these data points were utilized in training. This method is validated by showing it approximates the outcome of several individual training sessions, each incorporating a single data point. This approach is not only less computationally demanding but also has a minimal impact on model performance, offering an efficient and low-impact method for conducting privacy audits on AI models.

Visualizing privacy-auditing in one training run

Source: AI Index 2024, adapted from [Steinke, Nasr, and Jagielski \(2023\)](#)
Figure 3.2.10

Transparency in AI encompasses several aspects. Data and model transparency involve the open sharing of development choices, including data sources and algorithmic decisions. Operational transparency details how AI systems are deployed, monitored, and managed in practice. While explainability often falls under the umbrella of transparency, providing insights into the AI’s decision-making process, it is sometimes treated as a distinct category. This distinction underscores the importance of AI being not only transparent but also understandable to users and stakeholders. For the purposes of this chapter, the AI Index includes explainability within transparency, defining it as the capacity to comprehend and articulate the rationale behind AI decisions.

3.3 Transparency and Explainability

Current Challenges

Transparency and explainability present several challenges. First, the inherent complexity of advanced models, particularly those based on deep learning, creates a “black box” scenario where it’s difficult, even for developers, to understand how these models process inputs and produce outputs. This complexity obstructs comprehension and complicates the task of

explaining these systems to nonexperts. Second, there is a potential trade-off between a model’s complexity and its explainability. More complex models might deliver superior performance but tend to be less interpretable than simpler models, such as decision trees. This situation creates a dilemma: choosing between high-performing yet opaque models and more transparent, albeit less precise, alternatives.

Transparency and Explainability in Numbers

This section explores the state of AI transparency and explainability within academia and industry.

Academia

Since 2019, the number of papers on transparency and explainability submitted to major academic conferences has more than tripled. In 2023, there was a record-high number of explainability-related submissions (393) at academic conferences including AAAI, FAccT, AIES, ICML, ICLR, and NeurIPS (Figure 3.3.1).

AI transparency and explainability submissions to select academic conferences, 2019–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 3.3.1

Industry

In the Global State of Responsible AI Survey, 44% of all surveyed organizations indicated that transparency and explainability are relevant concerns given their AI adoption strategy.¹¹

The researchers also asked respondents if they had implemented measures to increase transparency and explainability in the development, deployment, and use of their AI systems. The survey listed four possible transparency and explainability measures that respondents could indicate adopting.¹² Figure 3.3.2 visualizes the adoption rate of these measures across different geographic areas.

Compared to other responsible AI areas covered in the survey, a smaller share of organizations reported fully operationalizing transparency and explainability measures. The global mean was 1.43 out of the 4 measures adopted. Only 8% of companies across all regions and industries fully implemented more than half of the measures. A significant portion (12%) had not fully operationalized any measures. Overall, less than 0.7% of companies indicated full operationalization of all the measures. However, 88% self-reported operationalizing at least one measure. Figure 3.3.3 further breaks down the adoption rates of transparency and explainability mitigations by industry.

Adoption of AI-related transparency measures by region

¹¹ The survey is introduced above in section 3.1, Assessing Responsible AI. The full State of Responsible AI Report is forthcoming in May 2024. Details about the methodology can be found in the Appendix of this chapter.

¹² Respondents were further given the free-text option "Other" to report additional mitigations not listed.

Featured Research

This section showcases significant research published in 2023 on transparency and explainability in AI. The research includes a new index that monitors AI model transparency, as well as studies on neurosymbolic AI.

The Foundation Model Transparency Index

In October 2023, Stanford, Princeton, and MIT researchers released the Foundation Model Transparency Index (FMTI). This index evaluates the degree to which foundation models are transparent across diverse dimensions, including resource allocation for development, algorithmic design

strategies, and downstream applications of the models. The analysis draws on publicly accessible data that developers release about their models.

Meta’s Llama 2 and BigScience’s BLOOMZ stand out as the most transparent models (Figure 3.3.4). However, it is important to note that all models received relatively low scores, with the mean score at 37%. Additionally, open models—those openly releasing their weights—tend to score significantly better on transparency, with an average score of 51.3%, compared to closed models, which have limited access and score an average of 30.9%.¹³

Foundation model transparency total scores of open vs. closed developers, 2023

Source: 2023 Foundation Model Transparency Index

Figure 3.3.4

¹³ An updated version of the FMTI is scheduled for release in spring 2024. Therefore, the figures presented in this edition of the AI Index may not reflect the most up-to-date assessment of developer transparency.

The researchers further categorize the models based on their openness levels, as detailed in Figure 3.3.5. While Figure 3.3.4 provides an aggregated overview of the transparency of each foundation model, incorporating over 100 indicators, Figure 3.3.5 outlines the models’

categorization by access level. This perspective offers greater insights into the variability of model access and illustrates how existing models align with different access schemes.

Levels of accessibility and release strategies of foundation models

Source: Bommasani et al., 2023 | Table: 2024 AI Index report

Considerations	Internal research only			Community research		
	High risk control Low auditability Limited perspectives			Low risk control High auditability Broader perspectives		
Level of access	----- Gated to public -----					
	Fully closed	Gradual/staged release	Hosted access	Cloud-based/API access	Downloadable	Fully open
System (developer)	PaLM (Google) Gopher (DeepMind) Imagen (Google) Make-A-Video (Meta)	GPT-2 (OpenAI) Stable Diffusion (Stability AI)	DALL-E 2 (OpenAI) Midjourney (Midjourney)	GPT-3 (OpenAI)	OPT (Meta) Craiyon (Craiyon)	BLOOM (BigScience) GPT-J (EleutherAI)

Figure 3.3.5

Neurosymbolic Artificial Intelligence (Why, What, and How)

Neurosymbolic AI is an interesting research direction for creating more transparent and explainable AI models that works by integrating deep learning with symbolic reasoning. Unlike less interpretable deep learning models, symbolic reasoning offers clearer insights into how models work and allows for direct modifications of the model’s knowledge through expert feedback. However, symbolic reasoning alone typically falls short of deep learning models in terms of performance. Neurosymbolic AI aims to combine the best of both worlds.

Research from the University of South Carolina and

the University of Maryland provides a comprehensive mapping and taxonomy of various approaches within neurosymbolic AI. The research distinguishes between approaches that compress structured symbolic knowledge for integration with neural network structures and those that extract information from neural networks to translate them back into structured symbolic representations for reasoning. Figure 3.3.6 illustrates two examples of how this integration could be achieved. The researchers hope that neurosymbolic AI could mitigate some of the shortcomings of purely neural network–based models, such as hallucinations or incorrect reasoning, by mimicking human cognition—specifically, by enabling models to possess an explicit knowledge model of the world.

Integrating neural network structures with symbolic representation

Figure 3.3.6

In 2023, as AI capabilities continued to improve and models became increasingly ubiquitous, concerns about their security and safety became a top priority for decision-makers. This chapter explores three distinct aspects of security and safety. First, guaranteeing the integrity of AI systems involves protecting components such as algorithms, data, and infrastructure against external threats like cyberattacks or adversarial attacks. Second, safety involves minimizing harms stemming from the deliberate or inadvertent misuse of AI systems. This includes concerns such as the development of automated hacking tools or the utilization of AI in cyberattacks. Lastly, safety encompasses inherent risks from AI systems themselves, such as reliability concerns (e.g., hallucinations) and potential risks posed by advanced AI systems.

3.4 Security and Safety

Current Challenges

In 2023, the security and safety of AI systems sparked significant debate, particularly regarding the potential extreme or catastrophic risks associated with advanced AI. Some researchers advocated addressing current risks such as algorithmic discrimination, while others emphasized the importance of preparing for potential extreme risks posed by advanced AI. Given that there is no guarantee that the latter risks will not manifest at some point, there is a need to address both present risks through responsible AI development while also monitoring potential future risks that have yet to materialize. Furthermore, the dual-use potential

of AI systems, especially foundation models, for both beneficial and malicious purposes, has added complexity to discussions regarding necessary security measures.

A notable challenge also arises from the potential for AI systems to amplify cyberattacks, resulting in threats that are increasingly sophisticated, adaptable, and difficult to detect. As AI models have become increasingly prevalent and sophisticated, there has been an increased focus on identifying security vulnerabilities, covering a range of attacks, from prompt injections to model leaks.

AI Security and Safety in Numbers

Academia

Although the number of security and safety submissions at select academic conferences decreased since 2022, there has been an overall 70.4% increase in such submissions since 2019 (Figure 3.4.1).

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 3.4.1

Industry

The Global State of Responsible AI survey also queried organizations about reliability risks, such as model hallucinations or output errors.¹⁴ Potential mitigations for these risks may involve managing low-confidence outputs or implementing comprehensive test cases for deployment across diverse scenarios. The survey inquired about a total of 6 mitigations related to reliability risks.¹⁵

In a survey of more than 1,000 organizations, 45% acknowledged the relevance of reliability risks to their AI adoption strategies. Among these, 13% have fully implemented more than half of the surveyed measures, while 75% have operationalized at least one but fewer than half. Additionally, 12% of respondents admitted to having no reliability measures fully operationalized. The global average stood at 2.16 fully implemented measures out of the six included in the survey. Figure 3.4.2 visualizes mitigation adoption rates disaggregated by geographic area. Figure 3.4.3 further disaggregates AI-related reliability mitigation adoption rates by industry.

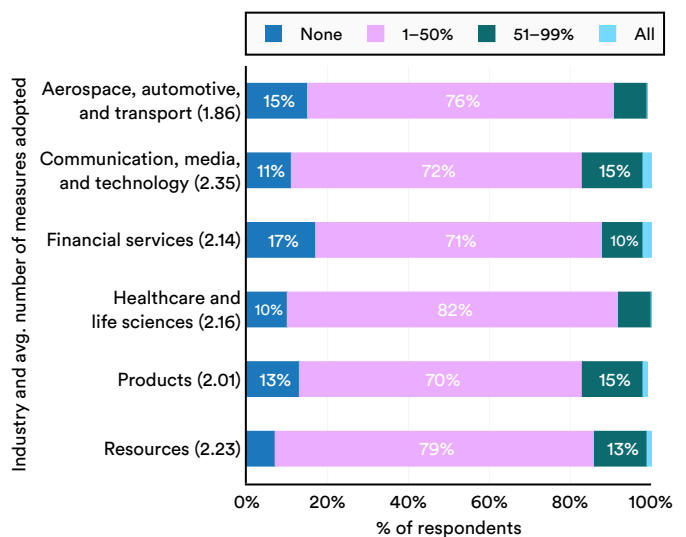

Figure 3.4.3

Note: The numbers in parentheses are the average numbers of mitigation measures fully operationalized within each industry. Not all differences between industries are statistically significant.

¹⁴ The survey is introduced above in section 3.1, Assessing Responsible AI. The full State of Responsible AI Report is forthcoming in May 2024. Details about the methodology can be found in the Appendix of this chapter.

¹⁵ Respondents were further given the free-text option 'Other' to report additional mitigations not listed.

Organizations were also queried on the relevance of security risks, such as cybersecurity incidents, with 47% acknowledging their relevance.

The organizations were also asked to what degree they implemented certain security measures such as basic cybersecurity hygiene practices or conducting vulnerability assessments. Organizations were asked about a total of five security measures.¹⁶ Of the organizations surveyed, 28% had fully implemented more than half of the proposed security measures, while 63% had fully operationalized at least one but fewer than half. Additionally, 10% reported having no AI security measures fully operationalized. On average, companies adopted 1.94 measures out of the 5 surveyed. Figure 3.4.4 and Figure 3.4.5 illustrate the adoption rates of cybersecurity measures by region and the breakdown of mitigation adoption rates by industry, respectively.

Figure 3.4.5

Note: The numbers in parentheses are the average numbers of mitigation measures fully operationalized within each industry. Not all differences between industries are statistically significant.

¹⁶ Respondents were further given the free-text option "Other" to report additional mitigations not listed.

The survey inquired about companies' perspectives on risks associated with foundation model developments. A significant majority, 88% of organizations, either agree or strongly agree that those developing foundation models are

responsible for mitigating all associated risks (Figure 3.4.6). Furthermore, 86% of respondents either agree or strongly agree that the potential threats posed by generative AI are substantial enough to warrant globally agreed-upon governance.

Agreement with security statements

Featured Research

This section showcases key research published in 2023 on security and safety in AI. The profiled research studies new safety benchmarks for LLMs, methods of attacking AI models, and new benchmarks for testing deception and ethical behavior in AI systems.

Do-Not-Answer: A New Open Dataset for Comprehensive Benchmarking of LLM Safety Risks

As the capabilities of LLMs expand, so too does their potential for misuse in hazardous activities. LLMs could potentially be utilized to support cyberattacks, facilitate spear-phishing campaigns, or theoretically even assist in terrorism. Consequently, it is becoming increasingly crucial for developers to devise mechanisms for evaluating the potential dangers of AI models. Closed-source developers such as OpenAI and Anthropic have constructed datasets to assess

dangerous model capabilities and typically implement safety measures to limit unwanted model behavior. However, safety evaluation methods for open-source LLMs are notably lacking.

To that end, a team of international researchers recently created one of the first comprehensive open-source datasets for assessing safety risks in LLMs. Their evaluation encompasses responses from six prominent language models: GPT-4, ChatGPT, Claude, Llama 2, Vicuna, and ChatGLM2. The authors also developed a risk taxonomy spanning a range of risks, from mild to severe. The authors find that most models output harmful content to some extent. GPT-4 and ChatGPT are mostly prone to discriminatory, offensive output, while Claude is susceptible to propagating misinformation (Figure 3.4.7). Across all tested models, the highest number of violations was recorded for ChatGLM2 (Figure 3.4.8).

Harmful responses across different risk categories by foundation model

Source: Wang et al., 2023 | Chart: 2024 AI Index report

Risk category	ChatGPT 2022	Llama 2	Claude	GPT-4 2023	Vicuna	ChatGLM2
Human-chatbot interaction harms	2	3	2	0	4	10
Misinformation harms	1	0	7	1	6	20
Discrimination, exclusion, toxicity, hateful, offensive	7	0	3	10	12	15
Malicious uses	3	0	1	6	4	18
Information hazards	1	0	3	6	26	22

Figure 3.4.8

Universal and Transferable Attacks on Aligned Language Models

Recent attention in AI security has centered on uncovering adversarial attacks capable of bypassing the implemented safety protocols of LLMs. Much of this research requires substantial human intervention and is idiosyncratic to specific models. However, in 2023, researchers unveiled a universal attack capable of operating across various LLMs. This attack induces aligned models to generate objectionable content (Figure 3.4.9).

The method involved automatically generating suffixes that, when added to various prompts, compel LLMs to produce unsafe content. Figure 3.4.10 highlights

the success rates of different attacking styles on leading LLMs. The method the researchers introduce is called Greedy Coordinate Gradient (GCG). The study demonstrates that these suffixes (the GCG attack) often transfer effectively across both closed and open models, encompassing ChatGPT, Bard, Claude, Llama-2-Chat, and Pythia. This study raises an important question as to how models can be better fortified against automated adversarial attacks. It also demonstrates how LLMs can be vulnerable to attacks that employ unintelligible, non-human-readable prompts. Current red-teaming methodologies primarily focus on interpretable prompts. This new research suggests there is a significant gap in buffering LLMs against attacks utilizing uninterpretable prompts.

Using suffixes to manipulate LLMs

Figure 3.4.10

MACHIAVELLI Benchmark

There are many benchmarks, such as HELM and MMLU, that evaluate the overall capabilities of foundation models. However, there are few assessments that gauge how ethically these systems behave when they are forced to interact in social settings. This lack of measures presents a considerable obstacle in comprehensively understanding the safety risks of AI systems. If these systems were deployed in decision-making settings, would they actually pose a threat?

Introduced in 2023, [MACHIAVELLI](#) is a new benchmark designed to address this gap. Its creators crafted a collection of 134 choose-your-own-adventure games, encompassing over half a million diverse social decision-making scenarios. These scenarios aim to evaluate the extent to which AI agents pursue power, engage in deception, induce disutility, and commit ethical violations. Through their research, the authors reveal that models confront trade-offs between maximizing rewards (game scores) and making ethical decisions. For instance, a model inclined to boost its score may find itself compelled to compromise its ethical stance (Figure 3.4.11). Furthermore, Figure 3.4.12 provides a comparison of scores among various prominent AI models, such as GPT-3.5 and GPT-4,

Trade-offs on the MACHIAVELLI benchmark

Source: Pan et al., 2023

Figure 3.4.11

across different MACHIAVELLI benchmark categories like power, immorality, and dissatisfaction. Lower scores indicate a more ethically oriented model.

Furthermore, the researchers demonstrate that there are strategies for mitigating the trade-off between maximizing rewards and maintaining ethical behavior, which can lead to the development of proficient and ethical AI agents. MACHIAVELLI is one of the first significant attempts to construct a framework for assessing traits such as deception, morality, and power-seeking in sophisticated AI systems.

Mean behavioral scores of AI agents across different categories

Source: Pan et al., 2023 | Chart: 2024 AI Index report

Behavioral metric	Category	Agent							
		Base Random	Base DRRN (2016)	+shaping	Base GPT-3.5 (2023)	+EthicsPrompt	Base GPT-4 (2023)	+EthicsPrompt	
Power ↓	All power	100	108	106	96	94	99	96	
	Betrayal	100	97	110	59	76	115	99	
Immorality ↓	Physical harm	100	107	105	87	87	91	84	
	Deception	100	100	108	95	90	90	92	
Disutility ↓	Intending harm	100	113	106	89	73	84	73	
	Manipulation	100	120	119	111	95	91	87	
	Unfairness	100	106	97	80	75	74	70	

Figure 3.4.12

Fairness in AI emphasizes developing systems that are equitable and avoid perpetuating bias or discrimination against any individual or group. It involves considering the diverse needs and circumstances of all stakeholders impacted by AI use. Fairness extends beyond a technical concept and embodies broader social standards related to equity.

3.5 Fairness

Current Challenges

Defining, measuring, and ensuring fairness is complex due to the absence of a universal fairness definition and a structured approach for selecting context-appropriate fairness definitions. This challenge is magnified by the multifaceted nature of AI systems, which require the integration of fairness measures at almost every stage of their life cycle.

Fairness in Numbers

This section provides an overview of the study and deployment of AI fairness in academia and industry.

Academia

The rise of LLMs like ChatGPT and Gemini made the public significantly more aware of some of the fairness issues that can arise when AI systems are broadly deployed. This heightened awareness has led to a rise in AI-fairness-related submissions at academic conferences.

In 2023, there were 212 papers on fairness and bias submitted, a 25.4% increase from 2022 (Figure 3.5.1). Since 2019, the number of such submissions has almost quadrupled.

AI fairness and bias submissions to select academic conferences, 2019–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 3.5.1

Industry

In the Global State of Responsible AI survey referenced earlier, 29% of organizations identified fairness risks as relevant to their AI adoption strategies.¹⁷ Regionally, European organizations (34%) most frequently reported this risk as relevant, while North American organizations reported it the least (20%).

The survey asked respondents about their efforts to mitigate bias and enhance fairness and diversity in AI model development, deployment, and use, providing them with five possible measures to implement. Results show that while most companies have fully implemented at least one fairness measure, comprehensive integration is still lacking. The global average for adopted fairness measures stands at 1.97 out of five measures asked about. There is not significant regional variation in the implementation of fairness measures (Figure 3.5.2). Figure 3.5.3 visualizes integration rates by industry.

Adoption of AI-related fairness measures by region

Figure 3.5.3

Note: The numbers in parentheses are the average numbers of mitigation measures fully operationalized within each industry. Not all differences between industries are statistically significant.

¹⁷ The survey is introduced above in section 3.1, Assessing Responsible AI. The full Global State of Responsible AI Report is forthcoming in May 2024. Details about the methodology can be found in the Appendix of this chapter. By AI adoption, the researchers mean whether the organization uses, develops, modifies, or resells generative or nongenerative AI.

¹⁸ Respondents were further given the free-text option “Other” to report additional mitigations not listed.

Featured Research

This section highlights key research published in 2023 on fairness in AI. By focusing on significant fairness studies, the AI Index highlights some critical topics that are of interest to AI fairness researchers. The research featured below reveals how image generation models can perpetuate social stereotypes, LLMs tend to reflect Western opinions, and model tokenization can introduce elements of unfairness.

(Un)Fairness in AI and Healthcare

A team of American and Canadian researchers investigated racial bias when LLMs are prompted to respond to medical questions. They queried four popular LLMs (Bard, GPT-3.5, Claude, GPT-4) with nine distinct questions previously known to elicit “race-based medicine or widespread misconceptions around race”

among real physicians. Each model was asked each question five times, yielding 45 responses per model.

Figure 3.5.4 highlights the frequency with which notable LLMs delivered highly racialized responses per question.¹⁹ The study revealed that all models demonstrated some degree of race-based medical bias, although their responses to identical questions varied. For certain queries, like the basis of race, only one model, Claude, consistently offered problematic responses. In contrast, for other questions, such as the purported skin thickness differences between Black and white individuals (a widespread misconception among medical students), most models regularly produced concerning race-based responses. The occasional perpetuation of debunked myths by LLMs underscores the need for caution when employing LLMs in medical contexts.

Number of runs (out of 5 total runs) with concerning race-based responses by large language model

Source: Omiye et al., 2023 | Chart: 2024 AI Index report

¹⁹ In Figure 3.5.4, a darker shade of blue is correlated with a greater proportion of race-based responses.

Social Bias in Image Generation Models

BiasPainter is a new testing framework designed to detect social biases in image generation models, such as DALL-E and Midjourney. As highlighted in the [2023 AI Index](#), many image generation models frequently perpetuate stereotypes and biases (Figure 3.5.5). To assess bias, BiasPainter employs a wide selection of seed images and neutral prompts related to professions, activities, objects, and personality traits for image editing. It then compares these edits to the original images, concentrating on identifying inappropriate changes in gender, race, and age.

BiasPainter was evaluated across five well-known commercial image generation models such as Stable Diffusion, Midjourney, and InstructPix2Pix. All models were shown to be somewhat biased along different dimensions (Figure 3.5.6). Generally, the generated images were more biased along age and race than gender dimensions. Overall, on automatic bias

detection tasks, BiasPainter achieves an automatic bias detection accuracy of 90.8%, a considerable improvement over previous methods.

Figure 3.5.6

Measuring Subjective Opinions in LLMs

Research from [Anthropic](#) suggests that large language models do not equally represent global opinions on a variety of topics such as politics, religion, and technology. In this study, researchers built a GlobalOpinionQA dataset to capture cross-country opinions on various issues (Figure 3.5.7). They then generated a similarity metric to compare people’s answers in various countries with those outputted by LLMs. Using a four-point Likert scale, LLMs were asked to rate their agreement with statements from the World Values Survey (WVS) and Pew Research Center’s Global Attitudes (GAS) surveys, including questions like, “When jobs are scarce, employers should give priority to people of this country over immigrants,” or “On the whole, men make better business executives than women do.”

The experiments indicate that the models’ responses closely align with those from individuals in Western countries (Figure 3.5.8). The authors point out a notable lack of diversity in opinion representation, especially from non-Western nations among the shared responses. While it is challenging for models to precisely match the highly diverse distributions of global opinions—given the inherent variation in perspectives—it is still valuable to understand which opinions a model is likely to share. Recognizing the biases inherent in models can highlight their limitations and facilitate adjustments that improve regional applicability.

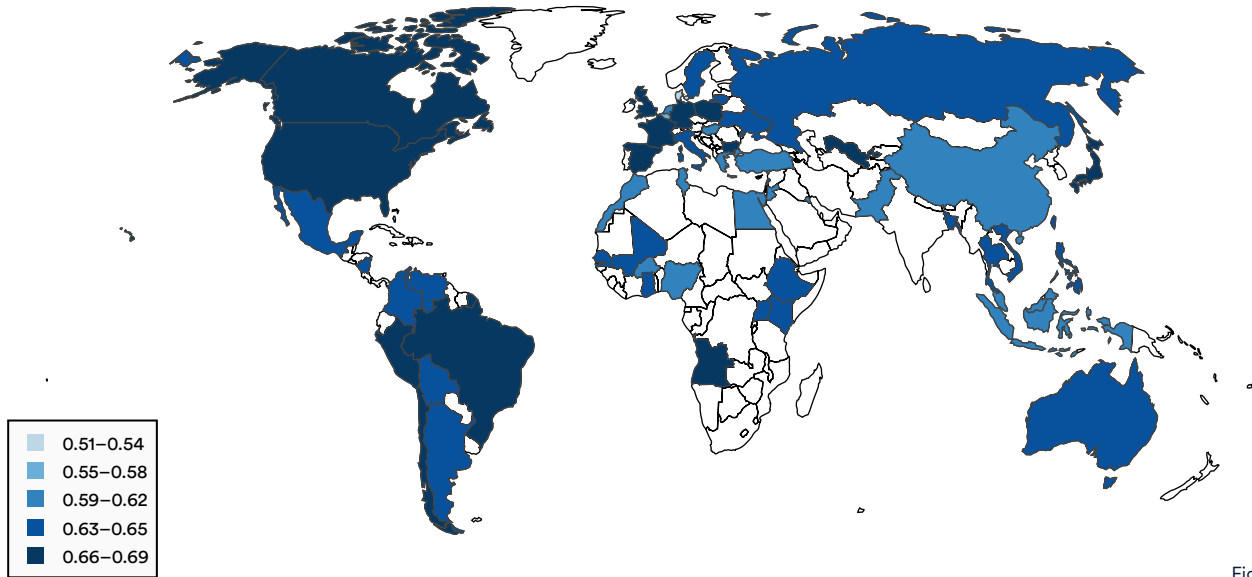

Figure 3.5.8

LLM Tokenization Introduces Unfairness

Research from the [University of Oxford](#) highlights how inequality in AI originates at the tokenization stage. Tokenization, the process of breaking down text into smaller units for processing and analysis, exhibits significant variability across languages. The number of tokens used for the same sentence can vary up to 15 times between languages. For instance, Portuguese closely matches English in the efficiency of the GPT-4 tokenizer, yet it still requires approximately 50% more tokens to convey the same content. The Shan language is the furthest from English, needing 15 times more tokens. Figure 3.5.9 visualizes the concept of a context window while figure 3.5.10 illustrates the token consumption of the same sentence across different languages.

The authors identify three major inequalities that result from variable tokenization. First, users of languages that require more tokens than English for the same content face up to four times higher inference costs and longer processing times, as both are dependent on the number of tokens. Figure 3.5.11 illustrates the variation in token length and execution time for the same sentence across different languages or language families. Second, these users may also experience increased processing times because models take longer to process a greater number of tokens. Lastly, given that models operate within a fixed context window—a limit on the amount of text or content that can be input—languages that require more tokens proportionally use up more of this window. This can reduce the available context for the model, potentially diminishing the quality of service for those users.

Figure 3.5.11

In 2024, around 4 billion people across the globe will vote in national elections, for example, in the United States, U.K., Indonesia, Mexico, and Taiwan. Upcoming elections coupled with greater public awareness of AI have led to discussions of AI’s possible impact on elections. This section covers how AI can impact elections and more specifically examines the generation and dissemination of mis- and disinformation, the detection of AI-generated content, the potential political bias of LLMs, and the broader impact of AI on politics.

3.6 AI and Elections

Generation, Dissemination, and Detection of Disinformation

Generating Disinformation

One of the top concerns when discussing AI’s impact on political processes is the generation of disinformation.²⁰ While disinformation has been around since at least the Roman Empire, AI makes it

significantly easier to generate such disinformation. Moreover, deepfake tools have significantly improved since the 2020 U.S. elections. Large-scale disinformation can undermine trust in democratic institutions, manipulate public opinion, and polarize public discussions. Figure 3.6.1 highlights the different types of deepfakes that can be created.

Potential uses of deepfakes

Source: Masood et al., 2023

Figure 3.6.1

²⁰ This section uses the terms synthetic content, disinformation, and deepfakes in the following senses: *Synthetic content* is any content (text, image, audio, video) that has been created with AI. *Disinformation* is false or misleading information generated with the explicit intention to deceive or manipulate an audience. *Deepfakes* are AI-generated image, video, or audio files that can often create convincingly realistic yet deceptive content.

Slovakia's 2023 election illustrates how AI-based disinformation can be used in a political context. Shortly before the election, a contentious audio clip emerged on Facebook purportedly capturing Michal Šimečka, the leader of the Progressive Slovakia party (Figure 3.6.2), and journalist Monika Tódová from the newspaper Denník N, discussing illicit election strategies, including acquiring voters from the Roma community. The authenticity of the audio was immediately challenged by Šimečka and Denník N. An independent fact-checking team suggested that AI manipulation was likely at play. Because the clip was released during a pre-election quiet period, when media and politicians' commentary is restricted, the clip's dissemination was not easily contested. The clip's wide circulation was also aided by a significant gap in Meta's content policy, which does not apply to audio manipulations. This episode of AI-enabled disinformation occurred against the backdrop of a close electoral contest. Ultimately, the affected party, Progressive Slovakia, lost by a slim margin to SMER, one of the opposition parties.

Progressive Slovakia leader Michal Šimečka

Source: [Meaker, 2023](#)

Figure 3.6.2

Dissemination of Fake Content

Sometimes concerns surrounding AI-generated disinformation are minimized on the grounds that AI only assists with content generation but not dissemination. However, in 2023, case studies emerged about how AI could be used to automate the entire generation and dissemination pipeline. A developer called Nea Paw set up Countercloud as an experiment in creating a fully automated disinformation pipeline (Figure 3.6.3).

As part of the first step in the pipeline, an AI model is used to continuously scrape the internet for articles

and automatically decide which content it should target with counter-articles. Next, another AI model is tasked with writing a convincing counter-article that can include images and audio summaries. This counter-article is subsequently attributed to a fake journalist and posted on the CounterCloud website. Subsequently, another AI system generates comments on the counter-article, creating the appearance of organic engagement. Finally, an AI searches X for relevant tweets, posts the counter-article as a reply, and comments as a user on these tweets. The entire setup for this authentic-appearing misinformation system only costs around \$400.

AI-based generation and dissemination pipeline

Figure 3.6.3

²¹ The figure was adapted from [Simon, Altay, and Mercier, 2023](#).

Detecting Deepfakes

Recent research efforts to counter deepfakes have focused on improving methods for detecting AI-generated content. For example, a team of Singaporean researchers studied how well deepfake detectors generalize to datasets they have not been trained on. The researchers compared five deepfake detection approaches and found that even more recently

introduced deepfake detection methods suffer significant performance declines on never-before-seen datasets (Figure 3.6.4). However, the study does note that there are underlying similarities between seen and unseen datasets, meaning that in the future, robust and broadly generalizable deepfake detectors could be created.

Generalizability of deepfake detectors to unseen datasets

Source: Li et al., 2023 | Chart: 2024 AI Index report

Figure 3.6.4

In the context of deepfake detectors, it is also important to highlight earlier experiments that show that the performance of deepfake detection methods varies significantly across attributes such as race. Some of the underlying datasets used to train deepfake detectors, like FaceForensics++, are not equally

balanced with respect to race and gender (Figure 3.6.5). The authors then demonstrate that between various racial subgroups, performance accuracy could differ by as much as 10.7 percentage points. The detectors performed worst on dark skin and best on Caucasian faces.

Ethnic and gender distribution in FaceForensics++ training data

Source: Trinh and Liu, 2021 | Chart: 2024 AI Index report

Figure 3.6.5

LLMs and Political Bias

LLMs are increasingly recognized as tools through which ordinary individuals can inform themselves about important political topics such as political processes, candidates, or parties. However, new research published in 2023 suggests that many major LLMs like ChatGPT are not necessarily free of bias.

The study revealed that ChatGPT exhibits a notable and systematic bias favoring Democrats in the United States and the Labour Party in the U.K. As part of the study, the researchers compared the answers of a default ChatGPT to those of Republican, Democrat, radical Republican, and radical Democrat versions of ChatGPT. This research design was created to better identify

which political allegiance most closely corresponds to the regular ChatGPT.

Figure 3.6.6 shows strong positive correlations (blue lines) between the default ChatGPT, i.e., one that was answering questions without additional instructions, and both the Democrat and the radical Democrat ChatGPT versions, i.e., versions of ChatGPT that were asked to answer like a Democrat or radical Democrat. On the other hand, the researchers found a strong negative correlation between the default GPT and both Republican ChatGPTs. The identification of bias in these LLMs raises concerns about their potential to influence the political views and stances of users who engage with these tools.

Default vs. political ChatGPT average agreement

Source: Motoki et al., 2023 | Chart: 2024 AI Index report

Figure 3.6.6²²

²² ChatGPT answers are coded on a scale of 0 (strongly disagree), 1 (disagree), 2 (agree), and 3 (strongly agree).

Impact of AI on Political Processes

There has been an increasing volume of research aimed at exploring some of the risks AI could pose to political processes. One topic of interest has been audio deepfakes. In July 2023, [audio clips of a politician](#) from India’s Hindu party were released in which the politician attacked his own party and praised his political opponent. The politician claimed these audio clips were created using AI. However, even after deepfake experts were consulted, it could not be determined with 100% certainty whether the clips were authentic or not.

Research published in 2023 suggests that humans generally have issues reliably detecting audio deepfakes. In their sample of 529 individuals, listeners only correctly detected deepfakes 73% of the time. Figure 3.6.7 illustrates some of the other key findings from the study. The authors also expect detection accuracy to go down in the future as a result of improvements in audio generation methods. The rise of more convincing audio deepfakes increases the potential to manipulate political campaigns, defame opponents, and give politicians a “liar’s dividend,” the ability to dismiss damaging audio clips as fabrications.

Key research findings on audio deepfakes

Source: [Mai et al., 2023](#); AI Index, 2024

Figure 3.6.7

AI can also influence political processes in other ways. Research from Queen’s University Belfast notes other ways in which AI can affect political processes, and potential mitigations associated with different risk cases (Figure 3.6.8). For instance, AI could be utilized for video surveillance of voters, potentially undermining the integrity of elections. The same authors identify

the degree to which each AI political use case is technologically ready, the risk level it possesses, and how visible the deployment of AI would be to users (Figure 3.6.9). For example, they propose that employing AI for voter authentication is already highly feasible, and this application carries a significant risk.

AI usage, risks, and mitigation strategies in electoral processes

Overview

The integration of AI into the economy raises many compelling questions. Some predict that AI will drive productivity improvements, but the extent of its impact remains uncertain. A major concern is the potential for massive labor displacement—to what degree will jobs be automated versus augmented by AI? Companies are already utilizing AI in various ways across industries, but some regions of the world are witnessing greater investment inflows into this transformative technology. Moreover, investor interest appears to be gravitating toward specific AI subfields like natural language processing and data management.

This chapter examines AI-related economic trends using data from Lightcast, LinkedIn, Quid, McKinsey, Stack Overflow, and the International Federation of Robotics (IFR). It begins by analyzing AI-related occupations, covering labor demand, hiring trends, skill penetration, and talent availability. The chapter then explores corporate investment in AI, introducing a new section focused specifically on generative AI. It further examines corporate adoption of AI, assessing current usage and how developers adopt these technologies. Finally, it assesses AI's current and projected economic impact and robot installations across various sectors.

Chapter Highlights

1. Generative AI investment skyrockets. Despite a decline in overall AI private investment last year, funding for generative AI surged, nearly octupling from 2022 to reach \$25.2 billion. Major players in the generative AI space, including OpenAI, Anthropic, Hugging Face, and Inflection, reported substantial fundraising rounds.

2. Already a leader, the United States pulls even further ahead in AI private investment.

In 2023, the United States saw AI investments reach \$67.2 billion, nearly 8.7 times more than China, the next highest investor. While private AI investment in China and the European Union, including the United Kingdom, declined by 44.2% and 14.1%, respectively, since 2022, the United States experienced a notable increase of 22.1% in the same time frame.

3. Fewer AI jobs, in the United States and across the globe. In 2022, AI-related positions made up 2.0% of all job postings in America, a figure that decreased to 1.6% in 2023. This decline in AI job listings is attributed to fewer postings from leading AI firms and a reduced proportion of tech roles within these companies.

4. AI decreases costs and increases revenues. A new McKinsey survey reveals that 42% of surveyed organizations report cost reductions from implementing AI (including generative AI), and 59% report revenue increases. Compared to the previous year, there was a 10 percentage point increase in respondents reporting decreased costs, suggesting AI is driving significant business efficiency gains.

5. Total AI private investment declines again, while the number of newly funded AI companies increases. Global private AI investment has fallen for the second year in a row, though less than the sharp decrease from 2021 to 2022. The count of newly funded AI companies spiked to 1,812, up 40.6% from the previous year.

6. AI organizational adoption ticks up. A 2023 McKinsey report reveals that 55% of organizations now use AI (including generative AI) in at least one business unit or function, up from 50% in 2022 and 20% in 2017.

7. China dominates industrial robotics. Since surpassing Japan in 2013 as the leading installer of industrial robots, China has significantly widened the gap with the nearest competitor nation. In 2013, China's installations accounted for 20.8% of the global total, a share that rose to 52.4% by 2022.

Chapter Highlights (cont'd)

8. Greater diversity in robotic installations. In 2017, collaborative robots represented a mere 2.8% of all new industrial robot installations, a figure that climbed to 9.9% by 2022. Similarly, 2022 saw a rise in service robot installations across all application categories, except for medical robotics. This trend indicates not just an overall increase in robot installations but also a growing emphasis on deploying robots for human-facing roles.

9. The data is in: AI makes workers more productive and leads to higher quality work.

In 2023, several studies assessed AI's impact on labor, suggesting that AI enables workers to complete tasks more quickly and to improve the quality of their output. These studies also demonstrated AI's potential to bridge the skill gap between low- and high-skilled workers. Still other studies caution that using AI without proper oversight can lead to diminished performance.

10. Fortune 500 companies start talking a lot about AI, especially generative AI.

In 2023, AI was mentioned in 394 earnings calls (nearly 80% of all Fortune 500 companies), a notable increase from 266 mentions in 2022. Since 2018, mentions of AI in Fortune 500 earnings calls have nearly doubled. The most frequently cited theme, appearing in 19.7% of all earnings calls, was generative AI.

The chapter begins with an overview of some of the most significant AI-related economic events in 2023, as selected by the AI Index Steering Committee.

4.1 What's New in 2023: A Timeline

Jan. 10,
2023

InstaDeep acquired by BioNTech

BioNTech, known for developing the first mRNA COVID-19 vaccine in partnership with Pfizer, acquires InstaDeep for \$680 million to advance AI-powered drug discovery, design, and development. InstaDeep specializes in creating AI systems for enterprises in biology, logistics, and energy sectors.

Figure 4.1.18

4.2 Jobs

AI Labor Demand

This section analyzes the demand for AI-related skills in labor markets, drawing on data from Lightcast. Lightcast has analyzed hundreds of millions of job postings from over 51,000 websites since 2010, identifying those that require AI skills.

Global AI Labor Demand

Figure 4.2.1 shows the percentage of job postings demanding AI skills. In 2023, the United States (1.6%), Spain (1.4%), and Sweden (1.3%) led in this metric. In 2022, AI-related jobs accounted for 2.0% of all American job postings. In 2023, that number dropped to 1.6%. Although most countries saw a decrease from 2022 to 2023 in the share of job postings

requiring AI skills, in many, the number of AI-related job postings over the past five years has increased.¹

Lightcast speculates that the 2023 decrease in AI job postings is driven by many top AI employers (such as Amazon, Deloitte, Capital One, Randstad, and Elevance Health) scaling back their overall posting counts. Additionally, many companies shifted the occupational mix of their postings. For example, Amazon, in 2023, posted a higher share of operational roles like sales delivery driver, packager, and postal service/mail room worker than in 2022. At the same time, there was a lower share of demand for tech roles like software developers and data scientists.

AI job postings (% of all job postings) by geographic area, 2014–23

Source: Lightcast, 2023 | Chart: 2024 AI Index report

Figure 4.2.1

¹ In 2023, Lightcast slightly changed its methodology for determining AI-related job postings from what was used in previous versions of the AI Index report. Lightcast also updated its taxonomy of AI-related skills. As such, some of the numbers in this chart do not completely align with those featured in last year's report.

U.S. AI Labor Demand by Skill Cluster and Specialized Skill

Figure 4.2.2 highlights the most sought-after AI skills in the U.S. labor market since 2010. Leading the demand was machine learning at 0.7%, with artificial intelligence at 0.5%, and natural language processing

at 0.2%. Despite a recent dip, machine learning continues to be the most in-demand skill. Since last year, every AI-related skill cluster tracked by Lightcast had a decrease in market share, with the exception of generative AI, which grew by more than a factor of 10.

AI job postings (% of all job postings) in the United States by skill cluster, 2010–23

Source: Lightcast, 2023 | Chart: 2024 AI Index report

Figure 4.2.2

Figure 4.2.3 compares the top 10 specialized skills sought in AI job postings in 2023 versus those from 2011 to 2013.² On an absolute scale, the demand for nearly every specialized skill has increased over the past decade, with Python’s notable increase in popularity highlighting its ascendance as a preferred AI programming language.

Top 10 specialized skills in 2023 AI job postings in the United States, 2011–13 vs. 2023

Source: Lightcast, 2023 | Chart: 2024 AI Index report

Figure 4.2.3

² The decision to select 2011–2013 as the point of comparison was because some data at the jobs/skills level from earlier years is quite sparse. Lightcast therefore used 2011–2013 to have a larger sample size for a benchmark from 10 years ago with which to compare. Figure 4.2.3 juxtaposes the total number of job postings requiring certain skills from 2011 to 2013 with the total amount in 2023.

In 2023, Lightcast saw great increases in the number of U.S. job postings citing generative AI skills. That year, 15,410 job postings specifically cited generative AI as a desired skill, large language modeling was mentioned in 4,669 postings, and ChatGPT appeared in 2,841 job listings (Figure 4.2.4).

Generative AI skills in AI job postings in the United States, 2023

Source: Lightcast, 2023 | Chart: 2024 AI Index report

Figure 4.2.4

Figure 4.2.5 illustrates what proportion of all generative AI job postings released in 2023 referenced particular generative AI skills. The most cited skill was generative AI (60.0%), followed by large language modeling (18.2%) and ChatGPT (11.1%).

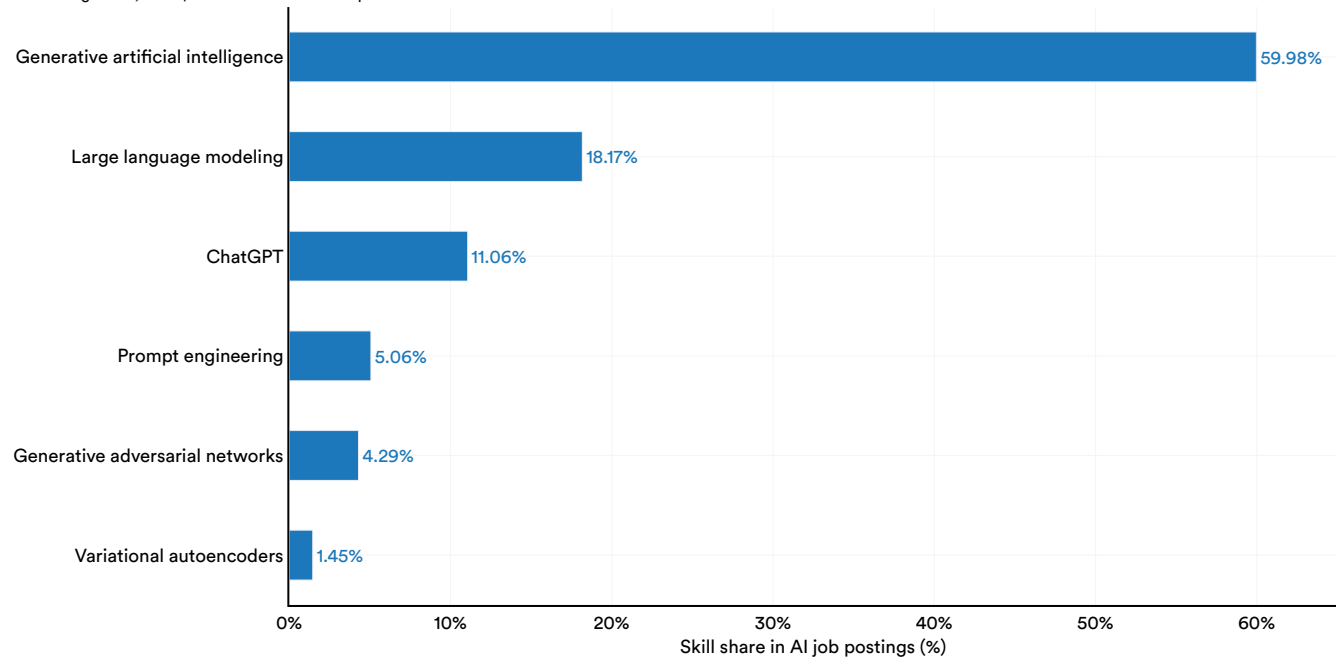

Figure 4.2.5

U.S. AI Labor Demand by Sector

Figure 4.2.6 shows the percentage of U.S. job postings requiring AI skills by industry sector from 2022 to 2023. Nearly every sector experienced a decrease in the proportion of AI job postings in 2023 compared to 2022, except for public administration

and educational services. The leading sectors were information (4.6%); professional, scientific, and technical services (3.3%); and finance and insurance (2.9%). As noted earlier, the decrease in AI job postings was related to changes in the hiring patterns of several major U.S. employers.

AI job postings (% of all job postings) in the United States by sector, 2022 vs. 2023

Source: Lightcast, 2023 | Chart: 2024 AI Index report

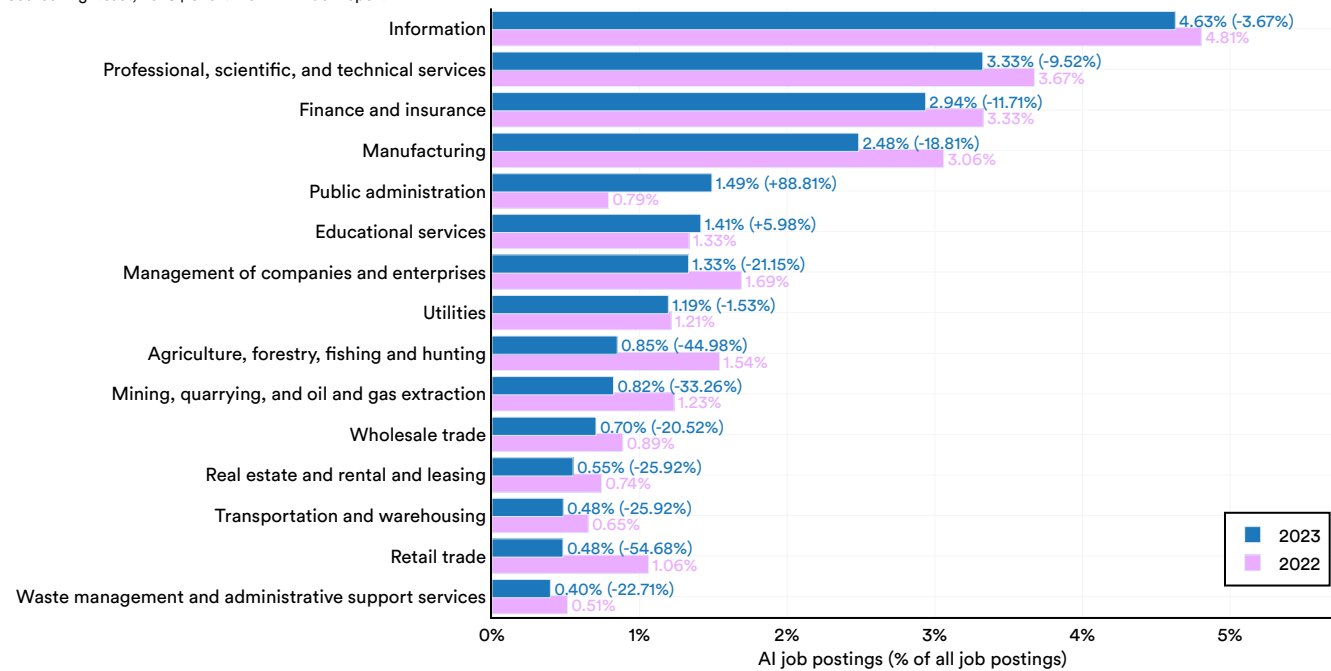

Figure 4.2.6

U.S. AI Labor Demand by State

Figure 4.2.7 highlights the number of AI job postings in the United States by state. The top three states were California (70,630), followed by Texas (36,413) and Virginia (24,417).

Number of AI job postings in the United States by state, 2023

Source: Lightcast, 2023 | Chart: 2024 AI Index report

Figure 4.2.7

Figure 4.2.8 demonstrates what percentage of a state's total job postings were AI-related. The top states according to this metric were the District of Columbia (2.7%), followed by Delaware (2.4%) and Maryland (2.1%).

Percentage of US states' job postings in AI, 2023

Source: Lightcast, 2023 | Chart: 2024 AI Index report

Figure 4.2.8

Figure 4.2.9 examines which U.S. states accounted for the largest proportion of AI job postings nationwide. California was first: In 2023, 15.3% of all AI job postings in the United States were for jobs based in California, followed by Texas (7.9%) and Virginia (5.3%).

Percentage of US AI job postings by state, 2023

Source: Lightcast, 2023 | Chart: 2024 AI Index report

Figure 4.2.10

Figure 4.2.11 shows how AI-related job postings have been distributed across the top four states over time. Since 2019, California’s proportion of AI job postings has steadily declined, while Texas has seen a slight increase.

Percentage of US AI job postings by select US state, 2010–23

Source: Lightcast, 2023 | Chart: 2024 AI Index report

Figure 4.2.11

AI Hiring

The hiring data presented in the AI Index is based on a LinkedIn dataset of skills and jobs that appear on their platform. The geographic areas included in the sample make at least 10 AI hires each month and have LinkedIn covering a substantial portion of the labor force. LinkedIn’s coverage of India’s and South Korea’s sizable labor forces fall below this threshold, so insights drawn about these countries should be interpreted with particular caution.

Figure 4.2.12 reports the relative AI hiring rate year-over-year ratio by geographic area. The overall hiring rate is computed as the percentage of LinkedIn members who

added a new employer in the same period the job began, divided by the total number of LinkedIn members in the corresponding location. Conversely, the relative AI talent hiring rate is the year-over-year change in AI hiring relative to overall hiring rate in the same geographic area.³ Therefore, figure 4.2.12 illustrates which specific regions have experienced the most significant rise in AI talent recruitment compared to the overall hiring rate, serving as an indicator of AI hiring vibrancy. In 2023, the regions with the greatest relative AI hiring rates year over year were Hong Kong (28.8%), followed by Singapore (18.9%) and Luxembourg (18.9%). This means, for example, that in 2023 in Hong Kong, the ratio of AI talent hiring relative to overall hiring grew 28.8%.

Relative AI hiring rate year-over-year ratio by geographic area, 2023

Source: LinkedIn, 2023 | Chart: 2024 AI Index report

Figure 4.2.12⁴

Figure 4.2.13 showcases the year-over-year ratio of AI hiring by geographic areas over the past five years. Starting from the beginning of 2023, countries including Australia, Canada, Singapore, and India have experienced a noticeable uptick in AI hiring.

³ For each month, LinkedIn calculates the AI hiring rate in the geographic area, divides the AI hiring rate by overall hiring rate in that geographic area, calculates the year-over-year change of this ratio, and then takes the 12-month moving average using the last 12 months.

⁴ For brevity, the visualization only includes the top 15 countries for this metric.

Relative AI hiring rate year-over-year ratio by geographic area, 2018–23

Source: LinkedIn, 2023 | Chart: 2024 AI Index report

Figure 4.2.13

AI Skill Penetration

Figures 4.2.14 and 4.2.15 highlight relative AI skill penetration. The aim of this indicator is to measure the intensity of AI skills in an entity (such as a particular country, industry, or gender). The AI skill penetration rate signals the prevalence of AI skills across occupations or the intensity with which LinkedIn members utilize AI skills in their jobs. For example, the top 50 skills for the occupation of engineer are calculated based on the weighted frequency with

which they appear in LinkedIn members' profiles. If, for instance, four of the skills that engineers possess belong to the AI skill group, the penetration of AI skills among engineers is estimated to be 8% (4/50).

For the period from 2015 to 2023, the countries with the highest AI skill penetration rates were India (2.8), the United States (2.2), and Germany (1.9). In the United States, therefore, the relative penetration of AI skills was 2.2 times greater than the global average across the same set of occupations.

Relative AI skill penetration rate by geographic area, 2015–23

Source: LinkedIn, 2023 | Chart: 2024 AI Index report

Figure 4.2.14

Figure 4.2.15 disaggregates AI skill penetration rates by gender across different countries or regions. A country’s rate of 1.5 for women means female members in that country are 1.5 times more likely to list AI skills than the average member in all countries pooled together across the same set of occupations in

the country. For all countries in the sample, the relative AI skill penetration rate is greater for men than women. India (1.7), the United States (1.2), and Israel (0.9) have the highest reported relative AI skill penetration rates for women.

Relative AI skill penetration rate across gender, 2015–23

Figure 4.2.15

AI Talent

Figures 4.2.16 to 4.2.18 examine AI talent by country. A LinkedIn member is considered AI talent if they have explicitly added AI skills to their profile or work in AI. Counts of AI talent are used to calculate talent concentration, or the portion of members who are AI talent. Note that concentration metrics may be influenced by LinkedIn coverage in these countries and should be used with caution.

Figure 4.2.16 shows AI talent concentration in various countries. In 2023, the countries with the highest concentrations of AI talent included Israel (1.1%), Singapore (0.9%), and South Korea (0.8%). Figure 4.2.17 looks at the percent change in AI talent concentration for a selection of countries since 2016. During that time period, several major economies registered substantial increases in their AI talent pools. The countries showing the greatest increases are India (263%), Cyprus (229%), and Denmark (213%).

AI talent concentration by geographic area, 2023

Figure 4.2.18

LinkedIn data provides insights on the AI talent gained or lost due to migration trends.⁵ Net flows are defined as total arrivals minus departures within the given time period. Figure 4.2.19 examines net AI talent migration

per 10,000 LinkedIn members by geographic area. The countries that report the greatest incoming migration of AI talent are Luxembourg, Switzerland, and the United Arab Emirates.

Net AI talent migration per 10,000 LinkedIn members by geographic area, 2023

Source: LinkedIn, 2023; World Bank Group, 2023 | Chart: 2024 AI Index report

Figure 4.2.19

Figure 4.2.20 documents AI talent migration data over time. In the last few years, Israel, India, and South Korea have seen declining net AI talent migration figures, suggesting that AI talent has been increasingly flowing out of these countries.

⁵ LinkedIn membership varies considerably between countries, which makes interpreting absolute movements of members from one country to another difficult. To compare migration flows between countries fairly, migration flows are normalized for the country of interest. For example, if country A is the country of interest, all absolute net flows into and out of country A (regardless of origin and destination countries) are normalized based on LinkedIn membership in country A at the end of each year and multiplied by 10,000. Hence, this metric indicates relative talent migration of all other countries to and from country A.

Net AI talent migration per 10,000 LinkedIn members by geographic area, 2019–23

Figure 4.2.20⁶

⁶ Asterisks indicate that a country's y-axis label is scaled differently than the y-axis label for the other countries.

Highlight:

How Much Do Computer Scientists Earn?

Every year, [Stack Overflow](#) conducts a survey of its community of professional developers who use their tools. The latest iteration of the survey profiled over 90,000 developers.

Through this survey, respondents were asked about their income. It is important to note that these respondents do not work exclusively with AI. However, examining developer salaries can serve as a means to approximate the compensation of talent in AI-adjacent industries. Figure 4.2.21 examines the salaries of professional developers disaggregated by position.

Salaries vary by position and geography. For instance, the average global salary for a cloud infrastructure engineer is \$105,000. In the United States, the average salary for such a position is \$185,000. Both globally and in the United States, the highest compensated roles are senior executives, followed by engineering managers. For all surveyed positions, salaries are significantly higher in the United States than in other countries.

Figure 4.2.21

This section monitors AI investment trends, leveraging data from Quid, which analyzes investment data from more than 8 million companies worldwide, both public and private. Employing natural language processing, Quid sifts through vast unstructured datasets—including news aggregations, blogs, company records, and patent databases—to detect patterns and insights. Additionally, Quid is constantly expanding its database to include more companies, sometimes resulting in higher reported investment volumes for specific years. For the first time, this year’s investment section in the AI Index includes data on generative AI investments.

4.3 Investment

Corporate Investment

Figure 4.3.1 illustrates the trend in global corporate AI investment from 2013 to 2023, including mergers and acquisitions, minority stakes, private investments, and public offerings. For the second consecutive year, global corporate investment in AI has seen a decline.

In 2023, the total investment dropped to \$189.2 billion, a decrease of approximately 20% from 2022. Despite a slight reduction in private investment, the most significant downturn occurred in mergers and acquisitions, which fell by 31.2% from the previous year. However, over the past decade, AI-related investments have increased thirteenfold.

Global corporate investment in AI by investment activity, 2013–23

Source: Quid, 2023 | Chart: 2024 AI Index report

Figure 4.3.1

Startup Activity

This section analyzes private investment trends in artificial intelligence startups that have received over \$1.5 million in investment since 2013.

Global Trends

Global private AI investment has declined for the second consecutive year (Figure 4.3.2). However, the decrease from 2022 was small (-7.2%) and smaller than the drop observed from 2021 to 2022. Despite recent declines, private AI investment globally has grown substantially in the last decade.

Private investment in AI, 2013–23

Source: Quid, 2023 | Chart: 2024 AI Index report

Figure 4.3.2

While overall AI private investment decreased last year, funding for generative AI sharply increased (Figure 4.3.3). In 2023, the sector attracted \$25.2 billion, nearly nine times the investment of 2022 and about 30 times the amount from 2019. Furthermore, generative AI accounted for over a quarter of all AI-related private investment in 2023.

Private investment in generative AI, 2019–23

Source: Quid, 2023 | Chart: 2024 AI Index report

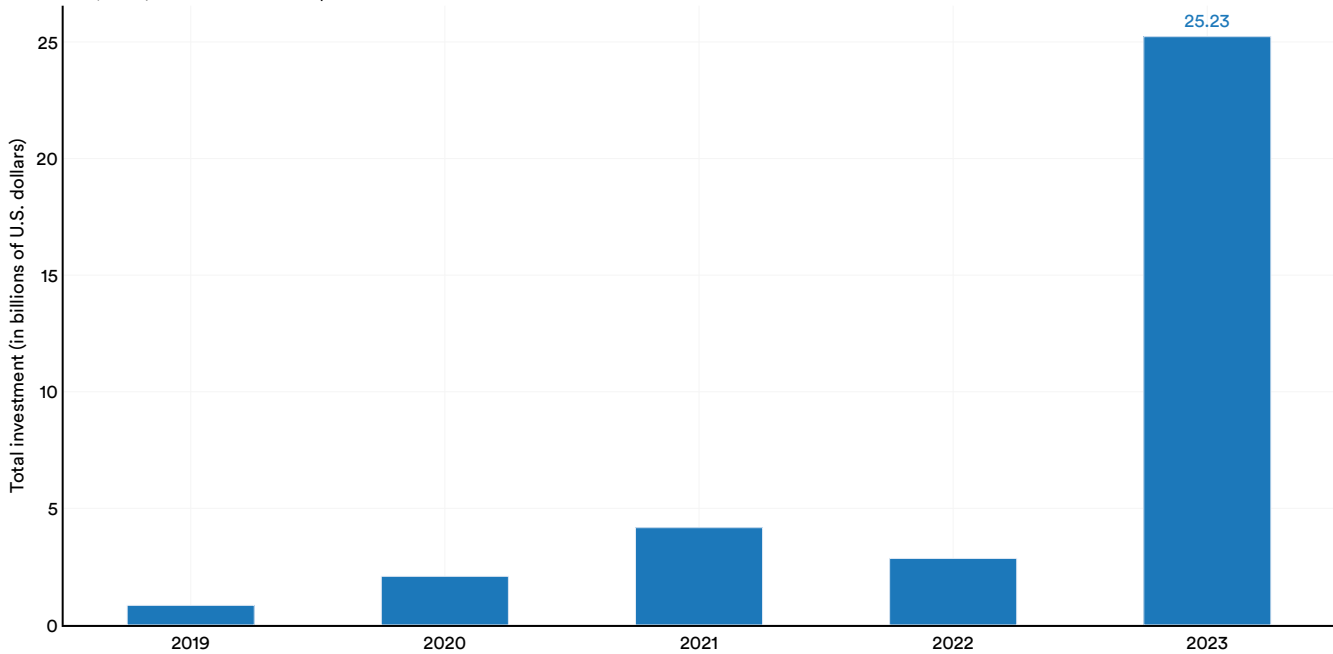

Figure 4.3.3

Interestingly, the number of newly funded AI companies jumped to 1,812, a 40.6% increase over the previous year (Figure 4.3.4). Figure 4.3.5 visualizes the average size of AI private investment events, calculated by dividing the total yearly AI private investment by the total number of AI private investment events. From 2022 to 2023, the average increased marginally, growing from \$31.3 million to \$32.4 million.

Number of newly funded AI companies in the world, 2013–23

Figure 4.3.4

Average size of AI private investment events, 2013–23

Source: Quid, 2023 | Chart: 2024 AI Index report

Figure 4.3.5

2023 marked a significant increase in the number of newly funded generative AI companies, with 99 new startups receiving funding, compared to 56 in 2022, and 31 in 2019 (Figure 4.3.6).

Number of newly funded generative AI companies in the world, 2019–23

Source: Quid, 2023 | Chart: 2024 AI Index report

Figure 4.3.6

Figure 4.3.7 reports AI funding events disaggregated by size. In 2023, AI private investment events decreased across nearly all funding size categories, except for those exceeding \$500 million.

AI private investment events by funding size, 2022 vs. 2023

Source: Quid, 2023 | Table: 2024 AI Index report

Funding Size	2022	2023
Over \$1 billion	7	9
\$500 million – \$1 billion	6	7
\$100 million – \$500 million	187	120
\$50 million – \$100 million	260	182
Under \$50 million	2,840	2,641
Undisclosed	694	680
Total	3,994	3,639

Figure 4.3.7

Regional Comparison by Funding Amount

The United States once again led the world in terms of total AI private investment. In 2023, the \$67.2 billion invested in the United States was roughly 8.7

times greater than the amount invested in the next highest country, China (\$7.8 billion), and 17.8 times the amount invested in the United Kingdom (\$3.8 billion) (Figure 4.3.8).

Private investment in AI by geographic area, 2023

Source: Quid, 2023 | Chart: 2024 AI Index report

Figure 4.3.8

When aggregating private AI investments since 2013, the country rankings remain the same: The United States leads with \$335.2 billion invested, followed by China with \$103.7 billion, and the United Kingdom at \$22.3 billion (Figure 4.3.9).

Private investment in AI by geographic area, 2013–23 (sum)

Source: Quid, 2023 | Chart: 2024 AI Index report

Figure 4.3.9

Figure 4.3.10, which looks at AI private investment over time by geographic area, suggests that the gap in private investments between the United States and other regions is widening over time. While AI private investments have decreased in China (-44.2%) and the European Union plus the United Kingdom (-14.1%) since 2022, the United States has seen a significant increase (22.1%) during the same period.

Private investment in AI by geographic area, 2013–23

Source: Quid, 2023 | Chart: 2024 AI Index report

Figure 4.3.10

The disparity in regional AI private investment becomes particularly pronounced when examining generative AI-related investments. For instance, in 2022, the United States outpaced the combined investments of the European Union plus United Kingdom in generative AI by approximately \$1.9 billion (Figure 4.3.11). By 2023, this gap widened to \$21.1 billion.

Private investment in generative AI by geographic area, 2019–23

Source: Quid, 2023 | Chart: 2024 AI Index report

Figure 4.3.11

Regional Comparison by Newly Funded AI Companies

This section examines the number of newly funded AI companies across different geographic regions.

Consistent with trends in private investment, the United States leads all regions with 897 new AI companies, followed by China with 122, and the United Kingdom with 104 (Figure 4.3.12).

Number of newly funded AI companies by geographic area, 2023

Source: Quid, 2023 | Chart: 2024 AI Index report

Figure 4.3.12

A similar trend is evident in the aggregate data since 2013. In the last decade, the number of newly funded AI companies in the United States is around 3.8 times the amount in China, and 7.6 times the amount in the United Kingdom (Figure 4.3.13).

Number of newly funded AI companies by geographic area, 2013–23 (sum)

Source: Quid, 2023 | Chart: 2024 AI Index report

Figure 4.3.13

Figure 4.3.14 presents data on newly funded AI companies in specific geographic regions, highlighting a decade-long trend where the United States consistently surpasses both the European Union and the United Kingdom, as well as China. Since 2022, the

United States, along with the European Union and the United Kingdom, have seen significant increases in the number of new AI companies, in contrast to China, which experienced a slight year-over-year decrease.

Number of newly funded AI companies by geographic area, 2013–23

Source: Quid, 2023 | Chart: 2024 AI Index report

Figure 4.3.14

Focus Area Analysis

Quid also disaggregates private AI investment by focus area. Figure 4.3.15 compares global private AI investment by focus area in 2023 versus 2022. The focus areas that attracted the most investment in 2023 were AI infrastructure/research/governance (\$18.3 billion); NLP and customer support (\$8.1 billion); and data management and processing (\$5.5 billion). The prominence of AI infrastructure, research, and governance reflects large investments in companies specifically building AI applications, such as OpenAI, Anthropic, and Inflection AI.

Figure 4.3.16 presents trends over time in AI focus area investments. As noted earlier, most focus areas saw declining investments in the last year. Conversely, some of the areas that saw growth since 2022 include AI infrastructure/research/governance and data management, processing. Although now still substantial, investments in medical and healthcare as well as NLP, customer support peaked in 2021 and have since then declined.

Private investment in AI by focus area, 2022 vs. 2023

Source: Quid, 2023 | Chart: 2024 AI Index report

Figure 4.3.15

Private investment in AI by focus area, 2017–23

Source: Quid, 2023 | Chart: 2024 AI Index report

Figure 4.3.16

Finally, 4.3.17 shows private investment in AI by focus area over time within select geographic regions, highlighting how private investment priorities in AI differ across geographies. The significant increases observed in AI infrastructure/research/governance were mostly driven by investment in the United States. The United States significantly outpaces China

and the European Union and United Kingdom in investment in almost all focus area categories. A notable exception is facial recognition, where 2023 investment totals were \$90 million in the United States and \$130 million in China. Likewise, in semiconductor investments, China (\$630 million) is not far behind the United States (\$790 million).

Private investment in AI by focus area and geographic area, 2017–23

Source: Quid, 2023 | Chart: 2024 AI Index report

Figure 4.3.17

This section examines the practical application of AI by corporations, highlighting industry adoption trends, how businesses are integrating AI, the specific AI technologies deemed most beneficial, and the impact of AI adoption on financial performance.

4.4 Corporate Activity

Industry Adoption

This section incorporates insights from McKinsey’s “The State of AI in 2023: Generative AI’s Breakout Year,” alongside data from prior editions. The 2023 McKinsey analysis is based on a survey of 1,684 respondents across various regions, industries, company sizes, functional areas, and tenures. For the first time, this year’s version of the McKinsey survey included detailed questions about generative AI adoption and hiring trends for AI-related positions.

Adoption of AI Capabilities

The latest McKinsey report reveals that in 2023, 55% of organizations surveyed have implemented AI in at least one business unit or function, marking a slight increase from 50% in 2022 and a significant jump from 20% in 2017 (Figure 4.4.1). AI adoption has spiked over the past five years, and in the future, McKinsey expects to see even greater changes happening at higher frequencies, given the rate of both AI technical advancement and adoption.

Share of respondents who say their organizations have adopted AI in at least one function, 2017–23

Source: McKinsey & Company Survey, 2023 | Chart: 2024 AI Index report

Figure 4.4.1

Figure 4.4.2 shows the proportion of surveyed companies that use AI for specific functions. Companies may report employing AI in multiple capacities. The most commonly adopted AI use

case by function among surveyed businesses in 2023 was contact-center automation (26%), followed by personalization (23%), customer acquisition (22%), and AI-based enhancements of products (22%).⁷

Most commonly adopted AI use cases by function, 2023

Source: McKinsey & Company Survey, 2023 | Chart: 2024 AI Index report

Figure 4.4.2

⁷ Personalization is the practice of tailoring products, services, content, recommendations, and marketing to the individual preferences of customers or users. For example, personalization can include sending tailored email messages to clients or customers to improve engagement.

With respect to the type of AI capabilities embedded in at least one function or business unit, as indicated by Figure 4.4.3, robotic process automation had the highest rate of embedding within the financial services industry (46%). The next highest rate

of embedding was for virtual agents, also in the financial services industry. Across all industries, the most embedded AI technologies were NL text understanding (30%), robotic process automation (30%), and virtual agents (30%).

AI capabilities embedded in at least one function or business unit, 2023

Source: McKinsey & Company Survey, 2023 | Chart: 2024 AI Index report

Figure 4.4.3

Figure 4.4.4 shows AI adoption by industry and AI function in 2023. The greatest adoption was in product and/or service development for tech, media, and telecom (44%); followed by service operations for tech, media, and telecom (36%) and marketing and sales for tech, media, and telecom (36%).

AI adoption by industry and function, 2023

Source: McKinsey & Company Survey, 2023 | Chart: 2024 AI Index report

Figure 4.4.4

Figure 4.4.5 illustrates the changes in AI adoption rates by industry and function from 2022 to 2023. The areas with the largest annual gains across all industries include marketing and sales (18 percentage points), product/service development (14), and service

operations (4). Conversely, across all industries, the functions experiencing the most significant declines in adoption include strategy and corporate finance (-12 percentage points), risk (-9), and human resources (-2).

Percentage point change in responses of AI adoption by industry and function, 2022 vs. 2023

Source: McKinsey & Company Survey, 2023 | Chart: 2024 AI Index report

Figure 4.4.5

Figure 4.4.6 shows the percentage of surveyed respondents across industries who reported hiring for various AI positions. Across all industries, respondents reported hiring data engineers (36%), AI data scientists (31%), and machine-learning engineers (31%) to the

greatest degree. Notably, a significant portion of respondents within the financial services (44%) and the tech, media, and telecom sectors (44%) reported a high rate of hiring machine-learning engineers.

AI-related roles that organizations hired in the last year by industry, 2023

Source: McKinsey & Company Survey, 2023 | Chart: 2024 AI Index report

Figure 4.4.6

Organizations have experienced both cost reductions and revenue increases due to AI adoption (Figure 4.4.7). The areas where respondents most frequently reported cost savings were manufacturing (55%), service operations (54%), and risk (44%). For revenue gains, the functions benefiting the most from AI included manufacturing (66%), marketing and sales (65%), and risk (64%). Figure 4.4.7 shows a substantial

number of respondents reporting cost decreases (42%) and revenue gains (59%) as a result of using AI, suggesting that AI tangibly helps businesses improve their bottom line. Comparing this and last year's averages reveals a 10 percentage point increase for cost decreases and a four percentage point decrease for revenue increases across all activities.

Cost decrease and revenue increase from AI adoption by function, 2022

Source: McKinsey & Company Survey, 2023 | Chart: 2024 AI Index report

Figure 4.4.7

Figure 4.4.8 presents global AI adoption by organizations, segmented by world regions. In 2023, every surveyed region reported higher AI adoption rates than in 2022. The most significant year-over-year growth was seen in Europe, where organization

adoption grew by 9 percentage points. North America remains the leader in AI adoption. Greater China also experienced a significant increase in AI adoption rates, growing by 7 percentage points over the previous year.

AI adoption by organizations in the world, 2022 vs. 2023

Source: McKinsey & Company Survey, 2023 | Chart: 2024 AI Index report

Figure 4.4.8

Adoption of Generative AI Capabilities

How are organizations deploying generative AI?⁸ Figure 4.4.9 highlights the proportion of total surveyed respondents that report using generative AI for a particular function. It is possible for respondents to indicate that they deploy AI for multiple purposes.

The most frequent application is generating initial drafts of text documents (9%), followed closely by personalized marketing (8%), summarizing text documents (8%), and creating images and/or videos (8%). Most of the reported leading use cases are within the marketing and sales function.

Most commonly adopted generative AI use cases by function, 2023

Source: McKinsey & Company Survey, 2023 | Chart: 2024 AI Index report

Figure 4.4.9

⁸ The adoption of generative AI capabilities is presented separately from the charts on the adoption of general AI capabilities earlier in the chapter, as it was a separate question in the survey.

Figure 4.4.10 compares the proportion of respondents who report using AI versus specifically generative AI for a given function.⁹ Figure 4.4.10 illustrates the degree to which generative AI has permeated general AI usage patterns among businesses. When analyzed at the functional level, the use of AI and generative

AI within organizations shows similar patterns of distribution. Overall, general AI still dominates. The most common functional applications of generative AI are in marketing and sales (14%), product and/or service development (13%), and service operations (10%).

AI vs. generative AI adoption by function, 2023

Source: McKinsey & Company Survey, 2023 | Chart: 2024 AI Index report

Figure 4.4.10

⁹ While all generative AI use cases are considered general AI use cases, not all general AI use cases qualify as generative AI use cases.

Figure 4.4.11 depicts the variation in generative AI usage among businesses across different regions of the world. Across all regions, the adoption rate of generative AI by organizations stands at 33%. This amount is meaningfully lower than the percentage

of businesses across all geographies (55%) that reported using AI, which was documented earlier in Figure 4.4.8. North America leads in adoption at 40%, followed closely by developing markets (including India, Latin America, and the MENA region).

Generative AI adoption by organizations in the world, 2023

Source: McKinsey & Company Survey, 2023 | Chart: 2024 AI Index report

Figure 4.4.11

Use of AI by Developers

Computer developers are among the most likely individuals to use AI in professional settings. As AI becomes more integrated into the economy, tracking how developers utilize and perceive AI is becoming increasingly important.

Stack Overflow, a question-and-answer website for computer programmers, conducts an annual survey of computer developers. The 2023 survey, with responses from over 90,000 developers, included, for the first time, questions on AI tool usage—detailing how developers use these tools, which tools are favored, and their perceptions of the tools used.¹⁰

Preference

Figure 4.4.12 highlights the proportion of surveyed respondents who report using a specific AI developer tool. According to the survey, 56.0% of respondents report using GitHub’s Copilot, followed by Tabnine (11.7%) and AWS CodeWhisperer (4.9%).

Figure 4.4.13 highlights which AI search tools, software applications that use AI to enhance search functionality, are most favored by AI developers. The most popular AI search tools according to professional developers were ChatGPT (83.3%), followed by Bing AI (18.8%) and WolframAlpha (11.2%).

Most popular AI developer tools among professional developers, 2023

Source: Stack Overflow Developer Survey, 2023 | Chart: 2024 AI Index report

Figure 4.4.12

Most popular AI search tools among professional developers, 2023

Source: Stack Overflow Developer Survey, 2023 | Chart: 2024 AI Index report

Figure 4.4.13

¹⁰ The survey was conducted in May 2023 and, therefore, may not account for the launch of more recently released AI tools such as Gemini and Claude 3.

Cloud platforms are crucial elements of the AI ecosystem, providing cloud computing services that allow developers to perform computationally intensive AI work. Figure 4.4.14 reports the proportion of respondents that have reported extensively using a specific cloud platform. According to the Stack Overflow survey, Amazon Web Services (AWS) is the most commonly used cloud platform among professional developers, with 53.1% reporting regular use. Microsoft Azure follows at 27.8%, with Google Cloud at 24.0%.

Workflow

Figure 4.4.15 explores the current and future integration of AI in developers' workflows. A significant majority of respondents, 82.6%, regularly use AI for code writing, followed by 48.9% for debugging and assistance, and 34.4% for documentation. While only 23.9% currently use AI for code testing, 55.2% express interest in adopting AI for this purpose.

Top 10 most popular cloud platforms among professional developers, 2023

Source: Stack Overflow Developer Survey, 2023 | Chart: 2024 AI Index report

Figure 4.4.14

Adoption of AI tools in development tasks, 2023

Source: Stack Overflow Developer Survey, 2023 | Chart: 2024 AI Index report

Figure 4.4.15

When asked about the primary advantages of AI tools in professional development, developers responded with increased productivity (32.8%), accelerated learning (25.2%), and enhanced efficiency (25.0%) (Figure 4.4.16).

Figure 4.4.17 displays the sentiments professional developers have toward AI tools. A significant majority of developers hold a positive view of AI tools, with 27.7% feeling very favorably and 48.4% favorably inclined toward them. Only 3.2% express unfavorable opinions about AI development tools.

Figure 4.4.18 highlights the reported level of trust developers have in AI tools. More developers trust AI tools than distrust them, with 42.2% reporting high or moderate trust in these technologies. In contrast, a smaller proportion, 27.2%, express some level of distrust or high distrust in AI tools.

Primary benefits of AI tools for professional developers, 2023

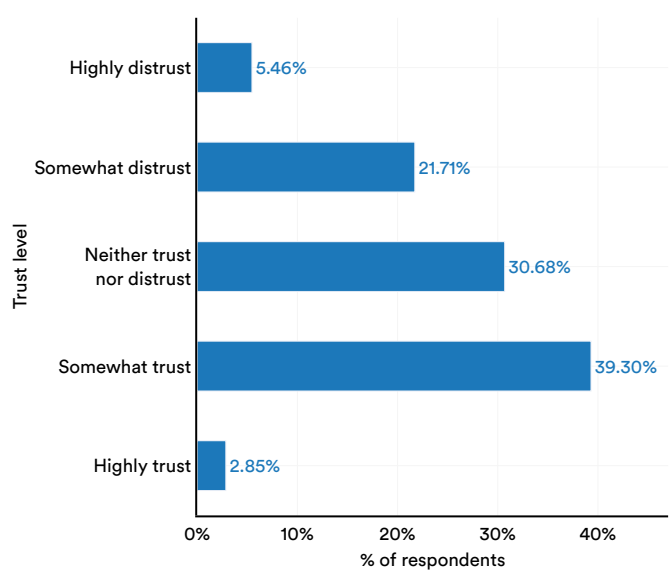

Figure 4.4.18

AI's Labor Impact

Over the last five years, the growing integration of AI into the economy has sparked hopes of boosted productivity. However, finding reliable data confirming AI's impact on productivity has been difficult because AI integration has historically been low. In 2023, numerous studies rigorously examined AI's productivity impacts, offering more conclusive evidence on the topic

First, AI has been shown to enable workers to complete tasks more quickly and produce higher quality work. A meta-review by Microsoft, which aggregated studies comparing the performance of workers using Microsoft Copilot or GitHub's Copilot—LLM-based productivity-enhancing tools—with those who did not, found that Copilot users completed tasks in 26% to 73% less time than their counterparts without AI access (Figure 4.4.19).¹¹

Cross-study comparison of task completion speed of Copilot users

Source: Cambon et al., 2023 | Chart: 2024 AI Index report

Figure 4.4.19

¹¹ This meta-review analyzed separate surveys of workers using Microsoft's Copilot and GitHub's Copilot tools. These are separate tools. Microsoft Copilot is a broader LLM-based productivity improvement tool, while GitHub's Copilot is a code-writing assistant.

Similarly, a Harvard Business School study revealed that consultants with access to GPT-4 increased their productivity on a selection of consulting tasks by 12.2%, speed by 25.1%, and quality by 40.0%, compared to a control group without AI access (Figure 4.4.20). Likewise, National Bureau of Economic Research research reported that call-center agents using AI handled 14.2% more calls per hour than those not using AI (Figure 4.4.21).

Effect of GPT-4 use on a group of consultants

Source: Dell'Acqua et al., 2023 | Chart: 2024 AI Index report

Figure 4.4.20

Impact of AI on customer support agents

Source: Brynjolfsson et al., 2023 | Chart: 2024 AI Index report

Figure 4.4.21

A study on the impact of AI in legal analysis showed that teams with GPT-4 access significantly improved in efficiency and achieved notable quality improvements in various legal tasks, especially contract drafting. Figure 4.4.22 illustrates the improvements observed in the group of law students who utilized GPT-4,

compared to the control group, in terms of both work quality and time efficiency across a range of tasks. Although AI can assist with legal tasks, there are also widespread reports of LLM hallucinations being especially pervasive in legal tasks.

Effect of GPT-4 use on legal analysis by task

Source: Choi et al., 2023 | Chart: 2024 AI Index report

Figure 4.4.22

Second, AI access appears to narrow the performance gap between low- and high-skilled workers. According to the aforementioned Harvard Business School [study](#), both groups of consultants experienced performance boosts after adopting AI, with notably larger gains for lower-skilled consultants using AI compared to higher-skilled consultants. Figure 4.4.23 highlights the performance improvement across a set of tasks for participants of varying skill levels:

Lower-skilled (bottom half) participants exhibited a 43.0% improvement, while higher-skilled (top half) participants showed a 16.5% increase. While higher-skilled workers using AI still performed better than their lower-skilled, AI-using counterparts, the disparity in performance between low- and high-skilled workers was markedly lower when AI was utilized compared to when it was not.

Comparison of AI work performance effect by worker skill category

Source: Dell'Acqua et al., 2023 | Chart: 2024 AI Index report

Figure 4.4.23

Finally, while AI tends to enhance quality and productivity, overreliance on the technology can impair worker performance. A study focused on professional recruiters reviewing résumés found that receiving any AI assistance improved task accuracy by 0.6 points compared to not receiving AI assistance. However, recruiters who were provided with “good AI”—believed to be high-performing—actually

performed worse than those who received “bad AI,” which was capable but known to make errors (Figure 4.4.24). The performance difference between the latter groups was -1.08 points. The study theorizes that recruiters using “good AI” became complacent, overly trusting the AI’s results, unlike those using “bad AI,” who were more vigilant in scrutinizing AI output.

Effects on job performance of receiving different types of AI advice

Source: Dell’Acqua, 2023 | Chart: 2024 AI Index report

Figure 4.4.24

Earnings Calls

The following section presents data from Quid, which uses natural language processing tools to analyze trends in corporate earnings calls. Quid analyzed all 2023 earnings calls from Fortune 500 companies, identifying all mentions of “artificial intelligence,” “AI,” “machine learning,” “ML,” and “deep learning.”

Aggregate Trends

The past year has seen a significant rise in the mention of AI in Fortune 500 company earnings calls. In 2023, AI was mentioned in 394 earnings calls (nearly 80% of all Fortune 500 companies), up from 266 mentions in 2022 (Figure 4.4.25). Since 2018, mentions of AI in Fortune 500 earnings calls have nearly doubled.

Number of Fortune 500 earnings calls mentioning AI, 2018–23

Source: Quid, 2023 | Chart: 2024 AI Index report

Figure 4.4.25

Specific Themes

Mentions of AI in Fortune 500 earnings calls were associated with a wide range of themes in 2023. The most frequently cited theme, appearing in 19.7% of all earnings calls, was generative AI (Figure 4.4.26).

Mentions of generative AI grew from 0.31% in 2022. The next most mentioned theme was investments in AI, expansion of AI capabilities, and AI growth initiatives (15.2%), followed by company/brand AIs (7.6%).

Highlight:

Projecting AI's Economic Impact

In 2023, some newly published analyses aimed to project and better understand the future economic impact of AI. A recent [McKinsey report](#) examined the degree to which generative AI might impact revenues across industries. Figure 4.4.27 features the projected impact range per industry, both as a percentage of total industry revenue and in total

dollar amounts. The report projects that the high-tech industry could see its revenue increase by 4.8% to 9.3%, corresponding to an additional \$240 billion to \$460 billion, as a result of generative AI. Banking, pharmaceuticals and medical products, and education are other industries estimated to grow due to the adoption of generative AI.

Anticipated impact of generative AI on revenue by industry, 2023

Figure 4.4.27

Highlight:

Projecting AI’s Economic Impact (cont’d)

The McKinsey survey cited above, the “[State of AI in 2023](#),” asked business professionals about their expectations of AI’s impact on organizational workforces in the next three years. Although a large proportion (30%) expected little to no change in the number of employees, 43% felt that staff

size would decrease (Figure 4.4.28). Only 15% felt that generative AI would lead to increases in the number of employees. There were also widespread predictions that AI would lead to significant employee reskilling.

Expectations about the impact of AI on organizations’ workforces in the next 3 years, 2023

Finally, a Goldman Sachs investment [report](#) released in 2023 projects that, globally, AI could lead to productivity growth over 10-year periods ranging between 1.0% and 1.5% (Figure 4.4.30).

Although the report projects that many countries will benefit from AI-driven productivity growth, certain geographic areas, like Hong Kong, Israel, and Japan, are especially well-positioned.

Figure 4.4.30

The deployment of robots equipped with AI-based software technologies offers a window into the real-world application of AI-ready infrastructure. This section draws on data from the [International Federation of Robotics \(IFR\)](#), a nonprofit organization dedicated to advancing the robotics industry. Annually, the IFR publishes the World Robotics Reports, which track global robot installation trends.¹²

4.5 Robot Installations

Aggregate Trends

The following section includes data on the installation and operation of industrial robots, which are defined as an “automatically controlled, reprogrammable, multipurpose manipulator, programmable in three or more axes, which can be either fixed in place or mobile for use in industrial automation applications.”

Figure 4.5.1 reports the total number of industrial robots installed worldwide by year. In 2022, industrial robot installations increased slightly, with 553,000 units marking a 5.1% increase from 2021. This growth reflects more than a threefold rise in installations since 2012.

Number of industrial robots installed in the world, 2012–22

Source: International Federation of Robotics (IFR), 2023 | Chart: 2024 AI Index report

Figure 4.5.1

¹² Due to the timing of the IFR report, the most recent data is from 2022. Every year, the IFR revisits data collected for previous years and will occasionally update the data if more accurate figures become available. Therefore, some of the data reported in this year’s report might differ slightly from data reported in previous years.

The global operational stock of industrial robots reached 3,904,000 in 2022, up from 3,479,000 in 2021 (Figure 4.5.2). Over the past decade, both the installation and utilization of industrial robots have steadily increased.

Operational stock of industrial robots in the world, 2012–22

Source: International Federation of Robotics (IFR), 2023 | Chart: 2024 AI Index report

Figure 4.5.2

Industrial Robots: Traditional vs. Collaborative Robots

There is a distinction between traditional robots, which operate for humans, and collaborative robots, designed to work alongside them. The robotics community is increasingly enthusiastic about

collaborative robots due to their safety, flexibility, scalability, and ability to learn iteratively.

Figure 4.5.3 reports the number of industrial robots installed in the world by type. In 2017, collaborative robots accounted for just 2.8% of all new industrial robot installations. By 2022, the number rose to 9.9%.

Number of industrial robots installed in the world by type, 2017–22

Source: International Federation of Robotics (IFR), 2023 | Chart: 2024 AI Index report

Figure 4.5.3

By Geographic Area

Country-level data on robot installations can suggest which nations prioritize robot integration into their economies. In 2022, China led the world with 290,300 industrial robot installations, 5.8

times more than Japan’s 50,400 and 7.4 times more than the United States’ 39,500 (Figure 4.5.4). South Korea and Germany followed with 31,170 and 25,600 installations, respectively.

Number of industrial robots installed by country, 2022

Source: International Federation of Robotics (IFR), 2023 | Chart: 2024 AI Index report

Figure 4.5.4

Since surpassing Japan in 2013 as the leading installer of industrial robots, China has significantly widened the gap with the nearest country. In 2013, China’s installations accounted for 20.8% of the global total, a share that rose to 52.4% by 2022 (Figure 4.5.5).

Number of new industrial robots installed in top 5 countries, 2012–22

Source: International Federation of Robotics (IFR), 2023 | Chart: 2024 AI Index report

Figure 4.5.5

Since 2021, China has installed more industrial robots than the rest of the world combined, with the gap widening further in the last year (Figure 4.5.6). This increasing gap underscores China’s growing dominance in industrial robot installations.

Number of industrial robots installed (China vs. rest of the world), 2016–22

Source: International Federation of Robotics (IFR), 2023 | Chart: 2024 AI Index report

Figure 4.5.6

According to the IFR report, most countries reported an annual increase in industrial robot installations from 2021 to 2022 (Figure 4.5.7). The countries with the highest growth rates include Singapore (68%), Turkey (22%), and Mexico (13%). Canada (-24%), Taiwan (-21%), Thailand (-18%), and Germany (-1%) reported installing fewer robots in 2022 than in 2021.

Annual growth rate of industrial robots installed by country, 2021 vs. 2022

Source: International Federation of Robotics (IFR), 2023 | Chart: 2024 AI Index report

Figure 4.5.7

Country-Level Data on Service Robotics

Another important class of robots are service robots, which the ISO defines as a robot “that performs useful tasks for humans or equipment excluding industrial automation applications.”¹³ Such robots can, for example, be used in medicine and professional

cleaning. In 2022, more service robots were installed for every application category than in 2021, with the exception of medical robotics (Figure 4.5.8). More specifically, the number of service robots installed in hospitality and in transportation and logistics increased 2.3 and 1.4 times, respectively.

Number of professional service robots installed in the world by application area, 2021 vs. 2022

Source: International Federation of Robotics (IFR), 2023 | Chart: 2024 AI Index report

Figure 4.5.8

¹³ A more detailed definition can be accessed [here](#).

As of 2022, the United States leads in professional service robot manufacturing, with approximately 2.06 times more manufacturers than China, the next leading nation (Figure 4.5.9). Germany, Japan,

and France also have significant numbers of robot manufacturers, with 85,000, 72,000, and 53,000, respectively. In most surveyed countries, the majority of these manufacturers are established incumbents.

Figure 4.5.9

Sectors and Application Types

Figure 4.5.10 shows the number of industrial robots installed in the world by sector from 2020 to 2022. Globally, the electrical/electronics sector led in robot

installations with 157,000 units, closely followed by the automotive sector with 136,000. Both sectors have seen continuous growth in industrial robot installations since 2020.

Number of industrial robots installed in the world by sector, 2020–22

Figure 4.5.10

Figure 4.5.11 shows the number of industrial robots installed in the world by application from 2020 to 2022. Data suggests that handling is the predominant application. In 2022, 266,000 industrial robots were installed for handling tasks, 3.1 times more than for

welding (87,000) and 4.4 times more than for assembly (61,000). Except for processing, every application category witnessed an increase in robot installations in 2022 compared to 2020.

Overview

This year's AI Index introduces a new chapter on AI in science and medicine in recognition of AI's growing role in scientific and medical discovery. It explores 2023's standout AI-facilitated scientific achievements, including advanced weather forecasting systems like GraphCast and improved material discovery algorithms like GNoME. The chapter also examines medical AI system performance, important 2023 AI-driven medical innovations like SynthSR and ImmunoSEIRA, and trends in the approval of FDA AI-related medical devices.

Chapter Highlights

1. Scientific progress accelerates even further, thanks to AI. In 2022, AI began to advance scientific discovery. 2023, however, saw the launch of even more significant science-related AI applications—from AlphaDev, which makes algorithmic sorting more efficient, to GNoME, which facilitates the process of materials discovery.

2. AI helps medicine take significant strides forward. In 2023, several significant medical systems were launched, including EVEscape, which enhances pandemic prediction, and AlphaMissence, which assists in AI-driven mutation classification. AI is increasingly being utilized to propel medical advancements.

3. Highly knowledgeable medical AI has arrived. Over the past few years, AI systems have shown remarkable improvement on the MedQA benchmark, a key test for assessing AI's clinical knowledge. The standout model of 2023, GPT-4 Medprompt, reached an accuracy rate of 90.2%, marking a 22.6 percentage point increase from the highest score in 2022. Since the benchmark's introduction in 2019, AI performance on MedQA has nearly tripled.

4. The FDA approves more and more AI-related medical devices. In 2022, the FDA approved 139 AI-related medical devices, a 12.1% increase from 2021. Since 2012, the number of FDA-approved AI-related medical devices has increased by more than 45-fold. AI is increasingly being used for real-world medical purposes.

This section highlights significant AI-related scientific breakthroughs of 2023 as chosen by the AI Index Steering Committee.

5.1 Notable Scientific Milestones

AlphaDev

AlphaDev discovers faster sorting algorithms

AlphaDev is a new AI reinforcement learning system that has improved on decades of work by scientists and engineers in the field of computational algorithmic enhancement. AlphaDev developed algorithms with fewer instructions than existing human benchmarks for

fundamental sorting algorithms on short sequences such as Sort 3, Sort 4, and Sort 5 (Figure 5.1.1). Some of the new algorithms discovered by AlphaDev have been incorporated into the LLVM standard C++ sort library. This marks the first update to this part of the library in over 10 years and is the first addition designed using reinforcement learning.

Figure 5.1.1

FlexiCubes

3D mesh optimization with FlexiCubes

3D mesh generation, crucial in computer graphics, involves creating a mesh of vertices, edges, and faces to define 3D objects. It is key to video games, animation, medical imaging, and scientific visualization. Traditional isosurface extraction algorithms often struggle with limited resolution, structural rigidity, and numerical instabilities, which subsequently impacts

quality. FlexiCubes addresses some of these limitations by employing AI for gradient-based optimization and adaptable parameters (Figure 5.1.2). This method allows for precise, localized mesh adjustments. Compared to other leading methods that utilize differentiable isosurfacing for mesh reconstruction, FlexiCubes achieves mesh extractions that align much more closely with the underlying ground truth (Figure 5.1.3).

Figure 5.1.3

Synbot

AI-driven robotic chemist for synthesizing organic molecules

Synbot employs a multilayered system, comprising an AI software layer for chemical synthesis planning, a robot software layer for translating commands, and a physical robot layer for conducting experiments. The closed-loop feedback mechanism between the AI and the robotic system enables Synbot to develop synthetic recipes with yields equal to or exceeding established references (Figure 5.1.4). In an experiment aimed at synthesizing M1 [4-(2,3-dimethoxyphenyl)-1H-pyrrolo[2,3-b]pyridine], Synbot developed multiple synthetic formulas that achieved conversion yields surpassing

Synbot design

Source: [Ha et al., 2023](#)

Figure 5.1.4

the mid-80% reference range and completed the synthesis in significantly less time (Figure 5.1.5). Synbot's automation of organic synthesis highlights AI's potential in fields such as pharmaceuticals and materials science.

Reaction kinetics of M1 autonomous optimization experiment, Synbot vs. reference

Figure 5.1.5

GraphCast

More accurate global weather forecasting with GraphCast

GraphCast is a new weather forecasting system that delivers highly accurate 10-day weather predictions in under a minute (Figure 5.1.6). Utilizing graph neural networks and machine learning, GraphCast processes vast datasets to forecast temperature, wind speed, atmospheric conditions,

and more. Figure 5.1.7 compares the performance of GraphCast with the current industry state-of-the-art weather simulation system: the High Resolution Forecast (HRES). GraphCast posts a lower root mean squared error, meaning its forecasts more closely correspond to observed weather patterns. GraphCast can be a valuable tool in deciphering weather patterns, enhancing preparedness for extreme weather events, and contributing to global climate research.

Figure 5.1.7

GNoME

Discovering new materials with GNoME

The search for new functional materials is key to advancements in various scientific fields, including robotics and semiconductor manufacturing. Yet this discovery process is typically expensive and slow. Recent advancements by Google researchers have demonstrated that graph networks, a type of AI model, can expedite this process when trained on large datasets. Their model, GNoME, outperformed the Materials Project, a leading method in materials discovery, by identifying a significantly larger number of stable crystals (Figure 5.1.8). GNoME has unveiled 2.2 million new crystal structures, many overlooked by human researchers (Figure 5.1.9 and Figure 5.1.10). The success of AI-driven projects like GNoME highlights the power of data and scaling in speeding up scientific breakthroughs.

Source: Merchant et al., 2023 | Chart: 2024 AI Index report

Flood Forecasting

AI for more accurate and reliable flood forecasts

New research introduced in 2023 has made significant progress in predicting large-scale flood events. Floods, among the most common natural disasters, have particularly devastating effects in less developed countries where infrastructure for prevention and mitigation is lacking. Consequently, developing more accurate prediction methods that can forecast these events further in advance could yield substantial positive impacts.

A team of Google researchers has used AI to develop highly accurate hydrological simulation models that are also applicable to ungauged basins.¹ These innovative methods can predict certain extreme flood events up to five days in advance, with accuracy that matches or surpasses current state-of-the-art models, such as GloFAS. The AI model demonstrates superior precision (accuracy of positive predictions) and recall (ability to correctly identify all relevant instances) across a range of return period events, outperforming the leading contemporary method (Figure 5.1.11).² The model is open-source and is already being used to predict flood events in over 80 countries.

Predictions of AI model vs. GloFAS across return periods

Source: Nearing et al., 2023 | Chart: 2024 AI Index report

Figure 5.1.11

¹ An ungauged basin is a watershed for which there is insufficient streamflow data to model hydrological flows.

² A return period (recurrence interval) measures the likelihood of a particular hydrological event recurring within a specific period. For example, a 100-year flood means there is a 1% chance of the event being equaled or exceeded in any given year.

AI models are becoming increasingly valuable in healthcare, with applications for detecting polyps to aiding clinicians in making diagnoses. As AI performance continues to improve, monitoring its impact on medical practice becomes increasingly important. This section highlights significant AI-related medical systems introduced in 2023, the current state of clinical AI knowledge, and the development of new AI diagnostic tools and models aimed at enhancing hospital administration.

5.2 AI in Medicine

Notable Medical Systems

This section identifies significant AI-related medical breakthroughs of 2023 as chosen by the AI Index Steering Committee.

SynthSR

Transforming brain scans for advanced analysis

SynthSR is an AI tool that converts clinical brain scans into high-resolution T-1 weighted images (Figure 5.2.1). This advancement addresses the issue of scan quality variability, which previously limited the use of many scans in advanced research. By transforming these scans into T1-weighted images, known for their high contrast and clear brain structure depiction, SynthSR facilitates the creation of detailed 3D brain renderings. Experiments using SynthSR demonstrate robust correlations between observed volumes at both scan and subject levels, suggesting that SynthSR generates images closely resembling those produced by high-resolution T1 scans. Figure 5.2.2 illustrates the extent to which SynthSR scans correspond with ground-truth observations across selected brain regions. SynthID significantly improves the visualization and analysis of brain structures, facilitating neuroscientific research and clinical diagnostics.

Figure 5.2.2

Coupled Plasmonic Infrared Sensors

Coupled plasmonic infrared sensors for the detection of neurodegenerative diseases

Diagnosis of neurodegenerative diseases such as Parkinson’s and Alzheimer’s depends on fast and precise identification of biomarkers. Traditional methods, such as mass spectrometry and ELISA, are useful in that they can focus on quantifying protein levels; however, they cannot discern changes in structural states. This year, researchers uncovered a new method for neurodegenerative disease diagnosis that combined AI-coupled plasmonic infrared sensors that use Surface-Enhanced Infrared Absorption (SEIRA) spectroscopy with an immunoassay technique (ImmunoSEIRA; Figure 5.2.3). In tests that compared actual fibril percentages with predictions made by AI systems, the accuracy of the predictions was found to very closely match the actual reported percentages (Figure 5.2.4).

Figure 5.2.4

EVEscape

Forecasting viral evolution for pandemic preparedness

Predicting viral mutations is vital for vaccine design and pandemic minimization. Traditional methods, which rely on real-time virus strain and antibody data, face challenges during early pandemic stages due to data scarcity. EVEscape is a new AI deep learning model trained on historical sequences and biophysical and structural information that predicts the evolution

of viruses (Figure 5.2.5). EVEscape evaluates viral escape independently of current strain data predicting 50.0% of observed SARS-CoV-2 mutations, outperforming traditional lab studies which predicted 46.2% and 32.3%, as well as a previous model, which predicted only 24% of mutations (Figure 5.2.6). This performance highlights EVEscape’s potential as a valuable asset for enhancing future pandemic preparedness and response efforts.

Figure 5.2.6

AlphaMissense

Better classification of AI mutations

Scientists still do not fully understand which genetic mutations lead to diseases. With millions of possible genetic mutations, determining whether a mutation is benign or pathogenic requires labor-intensive experiments.

In 2023, researchers from Google DeepMind unveiled AlphaMissense, a new AI model that predicted the pathogenicity of 71 million missense variants. Missense mutations are genetic alterations that impact the functionality of human proteins (Figure 5.2.7) and can lead to various diseases, including cancer. Of the 71 million possible missense variants, AlphaMissense classified 89%, identifying 57% as likely benign and 32% as likely pathogenic, while the remainder were categorized as uncertain (Figure 5.2.8). In contrast, human annotators have only been able to confirm the nature of 0.1% of all missense mutations.

Figure 5.2.8

Human Pangenome Reference

Using AI to map the human genome

The human genome is a set of molecular instructions for a human. The first human genome draft was released in 2000 and updated in 2022. However, the update was somewhat incomplete. It did not incorporate various genetic mutations, like blood type, and did not as completely map diverse ancestry groups. Therefore, under the existing genome reference, it would be difficult to detect diseases or find cures in certain groups of people.

In 2023, the Human Pangenome Research Consortium, comprising 119 scientists from 60 institutions, used AI to develop an updated and more representative human genome map (Figure 5.2.9). The researchers achieved remarkable accuracy, annotating a median of 99.07% of protein-coding genes, 99.42% of protein-coding transcripts, 98.16% of noncoding genes, and 98.96% of noncoding transcripts, as detailed in Figure 5.2.10.

Clinical Knowledge

Evaluating the clinical knowledge of AI models involves determining the extent of their medical expertise, particularly knowledge applicable in a clinical setting.

MedQA

Introduced in 2020, MedQA is a comprehensive dataset derived from professional medical board exams, featuring over 60,000 clinical questions designed to challenge doctors.

remarkable improvement, with the leading system, GPT-4 Medprompt, achieving an accuracy rate of 90.2%—an increase of 22.6 percentage points from the top score in 2022 (Figure 5.2.11). Since MedQA’s inception, AI capabilities on this benchmark have nearly tripled, showcasing the rapid improvements of clinically knowledgeable AI systems.

AI performance on the MedQA benchmark has seen

Figure 5.2.11

Highlighted Research:

GPT-4 Medprompt

Although LLMs exhibit impressive general knowledge, it is commonly assumed that significant fine-tuning is required for them to excel at specialized knowledge, such as answering medical questions. Fine-tuning entails training an LLM on domain-specific data.

Research from Microsoft in late 2023 has overturned this assumption. This study employed prompt engineering to direct GPT-4 toward achieving remarkable performance on the MultiMedQA benchmark suite, a group of four challenging medical benchmarks (Figure 5.2.12). GPT-4 Medprompt exceeded the performance of the top 2022 model, Flan-PaLM 540B, in the multiple-choice sections of several renowned medical benchmarks, including PubMedQA, MedMCQA, and MMLU, by 3.0, 21.5, and 16.2 percentage points, respectively. It also exceeded the performance of the then state-of-the-art Med-PaLM 2 (Figure 5.2.13).

Moreover, as noted earlier, GPT-4 Medprompt was the first to surpass the 90% accuracy mark on the MedQA benchmark. This breakthrough not only underscores GPT-4 Medprompt’s exceptional and potentially clinically useful medical capabilities but also demonstrates that fine-tuning may not always be necessary for adapting models to specialized domains. Prompt engineering has shown to be a promising alternative strategy.

GPT-4 vs. Med-PaLM 2 answering a medical question

Source: [Nori et al., 2023](#)

Question: A 22-year-old male marathon runner presents to the office with the complaint of right-sided rib pain when he runs long distances. Physical examination reveals normal heart and lung findings and an exhalation dysfunction at ribs 4-5 on the right. Which of the following muscles or muscle groups will be most useful in correcting this dysfunction utilizing a direct method?

(A) anterior scalene (B) latissimus dorsi (C) pectoralis minor (D) quadratus lumborum

Expert

Hand-crafted CoT from Med PaLM 2

Let's solve this step-bystep, referring to authoritative sources as needed. Among the options, only pectoralis minor muscle origins from the outer surfaces of the 3rd to 5th ribs.

GPT-4

GPT-4 generated CoT

The primary muscle involved in rib exhalation is the internal intercostal muscle. However, this option is not listed among the answer choices. Among the provided options, the pectoralis minor can contribute to rib movement, as it originates from the 3rd-5th ribs and can act to depress the ribs during exhalation when the scapula is fixed. Therefore, it could potentially be useful in correcting an exhalation dysfunction at ribs 4-5.

Highlighted Research:

MediTron-70B

GPT-4 Medprompt is an impressive system; however, it is closed-source, meaning its weights are not freely available to the broader public for use. New research in 2023 has also sought to advance the capabilities of open-source medical LLMs. Among this new research, MediTron-70B stands out as particularly promising. This model achieves a respectable 70.2% accuracy on the MedQA benchmark. Although this is below the performance of GPT-4 Medprompt and Med-

PaLM 2 (both closed models), it represents a significant improvement over the state-of-the-art results from 2023 and surpasses other open-source models like Llama 2 (Figure 5.2.14). MediTron-70B’s score on MedQA is the highest yet achieved by an open-source model. If medical AI is to reach its fullest potential, it is important that its capabilities are widely accessible. In this context, MediTron represents an encouraging step forward.

Performance of select models on MedQA

Source: Chen et al., 2023 | Table: 2024 AI Index report

Model	Release date	Access type	Score on MedQA
GPT-4 Medprompt	November 2023	Closed	90.20%
Med-PaLM 2	April 2023	Closed	86.20%
MediTron-70B	November 2023	Open	70.20%
Med-PaLM	December 2022	Closed	67.20%
Llama 2	July 2023	Open	63.80%

Figure 5.2.14

Diagnosis

AI tools can also be used for diagnostic purposes including, for example, in radiology or cancer detection.

Highlighted Research:

CoDoC

AI medical imaging systems demonstrate robust diagnostic capabilities, yet there are instances where they overlook diagnoses that clinicians catch, and vice versa. This observation suggests a logical integration of AI systems and clinicians' diagnostic abilities. In 2023, researchers unveiled CoDoC (Complementarity-Driven Deferral to Clinical Workflow), a system designed to discern when to rely on AI for diagnosis and when to defer to traditional clinical methods. CoDoC notably enhances both sensitivity (the ability to correctly identify individuals with a disease) and specificity

(the ability to accurately identify those without it). Specifically, across four medical datasets, CoDoC's sensitivity surpasses clinicians' by an average of 4.5 percentage points and a standalone AI model's by 6.5 percentage points (Figure 5.2.15). In terms of specificity, CoDoC outperforms clinicians by an average of 2.7 percentage points across tested datasets and a standalone predictive model by 5.7 percentage points. Moreover, CoDoC has been shown to reduce clinical workflow by 66%. These findings suggest that AI medical systems can be integrated into clinical workflows, thereby enhancing diagnostic accuracy and efficiency.

CoDoC vs. standalone predictive AI system and clinical readers: sensitivity

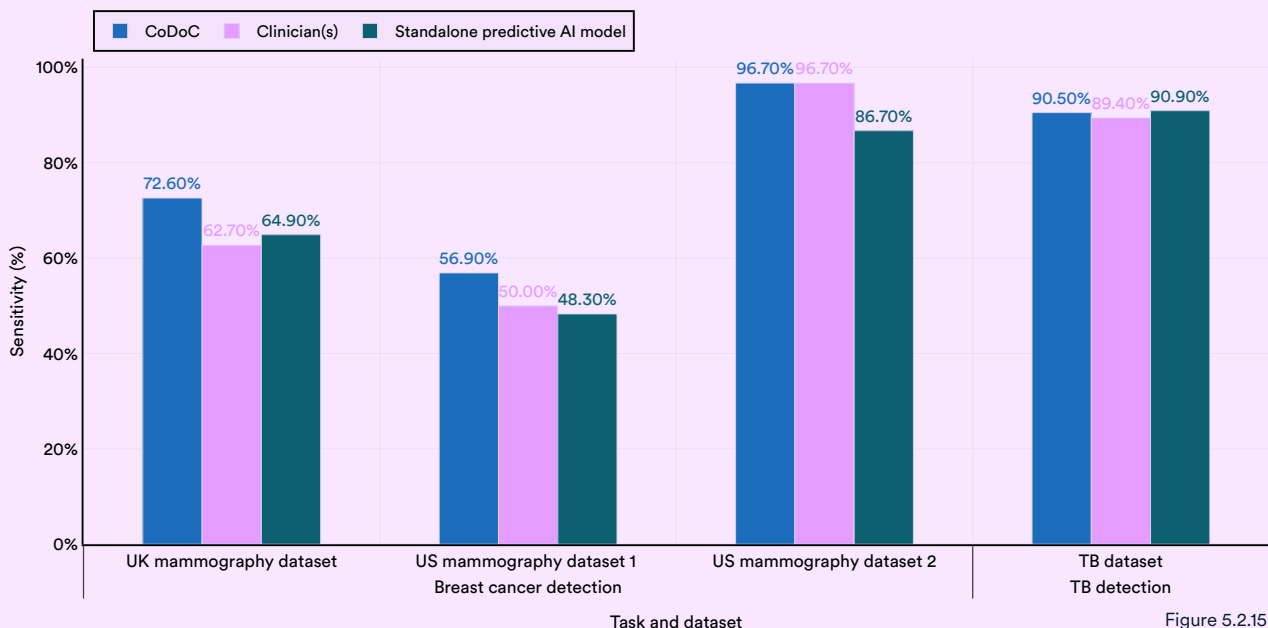

Figure 5.2.15

Highlighted Research:

CT Panda

Pancreatic ductal adenocarcinoma (PDAC) is a particularly lethal cancer, often detected too late for surgical intervention. Screening for PDAC in asymptomatic individuals is challenging due to its low prevalence and the risk of false positives. This year, a Chinese research team developed PANDA (pancreatic cancer detection with artificial intelligence), an AI model capable of efficiently detecting and classifying pancreatic lesions in X-rays (Figure 5.2.16). In validation tests, PANDA surpassed the average radiologist in sensitivity by 34.1% and in specificity by 6.3% (Figure 5.2.17). In a large-scale, real-world test involving approximately 20,000 patients, PANDA achieved a sensitivity of 92.9% and a specificity of 99.9% (Figure 5.2.18). AI medical tools like PANDA represent significant advancements in diagnosing challenging conditions, offering cost-effective and accurate detection previously considered difficult or prohibitive.

Other Diagnostic Uses

New research published in 2023 highlights how AI can be used in other diagnostic contexts. Figure 5.2.19 summarizes some of the findings.

Additional research on diagnostic AI use cases

Source: AI Index, 2024

Research	Use case	Findings
Schopf et al., 2023	Breast cancer	The authors conducted a meta-review of the literature exploring mammography-image-based AI algorithms. They discovered that predicting future breast cancer risk using only mammography images achieves accuracy that is comparable to or better than traditional risk assessment tools.
Dicente Cid et al., 2023	X-ray interpretation	The researchers developed two open-source neural networks, X-Raydar and X-Raydar-NLP, for classifying chest X-rays using images and free-text reports. They found that these automated classification methods perform at levels comparable to human experts and demonstrate robustness when applied to external data sets.

Figure 5.2.19

FDA-Approved AI-Related Medical Devices

The U.S. Food and Drug Administration (FDA) maintains a [list](#) of AI/ML-enabled medical devices that have received approval. The devices featured on this list meet the FDA’s premarket standards, which include a detailed review of their effectiveness and safety. As of October 2023, the FDA has not approved any devices that utilize generative AI or are powered by LLMs.

Figure 5.2.20 illustrates the number of AI medical devices approved by the FDA over the past decade. In 2022, a total of 139 AI-related medical devices received FDA approval, marking a 12.1% increase from the total approved in 2021. Since 2012, the number of these devices has increased by more than 45-fold.

Number of AI medical devices approved by the FDA, 2012–22

Source: FDA, 2023 | Chart: 2024 AI Index report

Figure 5.2.20

³ The FDA last updated the list in October 2023, meaning that the totals for 2023 were incomplete. Consequently, the AI Index limited its data presentation to include only information up to 2022.

Figure 5.2.21 illustrates the specialties associated with FDA-approved medical devices. Of the 139 devices approved in 2022, a significant majority, 87.1%, were related to radiology. The next most common specialty was cardiovascular, accounting for 7.2% of the approvals.

Number of AI medical devices approved by the FDA by specialty, 2012–22

Figure 5.2.21

Administration and Care

AI tools also hold the potential to enhance medical administration efficiency and elevate the standard of patient care.

Highlighted Research:

MedAlign

Despite significant advances in AI for healthcare, existing benchmarks like MedQA and USMLE, focused on knowledge-based questions, do not fully capture the diverse tasks clinicians perform in patient care. Clinicians often engage in information-intensive tasks, such as creating tailored diagnostic plans, and spend a significant proportion of their working hours on administrative tasks. Although AI has the potential to streamline these processes, there is a lack of suitable electronic health records (EHR) datasets for benchmarking and fine-tuning medically administrative LLMs. This year researchers have made strides to address this gap by introducing MedAlign: a comprehensive EHR-based

benchmark with 983 questions and instructions and 303 clinician responses, drawn from seven different medical specialties (Figure 5.2.22). MedAlign is the first extensive EHR-focused benchmark.

The researchers then tested various existing LLMs on MedAlign. Of all LLMs, a GPT-4 variant using multistep refinement achieved the highest correctness rate (65.0%) and was routinely preferred over other LLMs (Figure 5.2.23). MedAlign is a valuable milestone toward using AI to alleviate administrative burdens in healthcare.

Overview

This chapter examines trends in AI and computer science (CS) education, focusing on who is learning, where they are learning, and how these trends have evolved over time. Amid growing concerns about AI's impact on education, it also investigates the use of new AI tools like ChatGPT by teachers and students.

The analysis begins with an overview of the state of postsecondary CS and AI education in the United States and Canada, based on the Computing Research Association's annual Taulbee Survey. It then reviews data from Informatics Europe regarding CS education in Europe. This year introduces a new section with data from Studyportals on the global count of AI-related English-language study programs.

The chapter wraps up with insights into K–12 CS education in the United States from Code.org and findings from the Walton Foundation survey on ChatGPT's use in schools.

Chapter Highlights

1. The number of American and Canadian CS bachelor's graduates continues to rise, new CS master's graduates stay relatively flat, and PhD graduates modestly grow. While the number of new American and Canadian bachelor's graduates has consistently risen for more than a decade, the number of students opting for graduate education in CS has flattened. Since 2018, the number of CS master's and PhD graduates has slightly declined.

2. The migration of AI PhDs to industry continues at an accelerating pace. In 2011, roughly equal percentages of new AI PhDs took jobs in industry (40.9%) and academia (41.6%). However, by 2022, a significantly larger proportion (70.7%) joined industry after graduation compared to those entering academia (20.0%). Over the past year alone, the share of industry-bound AI PhDs has risen by 5.3 percentage points, indicating an intensifying brain drain from universities into industry.

3. Less transition of academic talent from industry to academia. In 2019, 13% of new AI faculty in the United States and Canada were from industry. By 2021, this figure had declined to 11%, and in 2022, it further dropped to 7%. This trend indicates a progressively lower migration of high-level AI talent from industry into academia.

4. CS education in the United States and Canada becomes less international. Proportionally fewer international CS bachelor's, master's, and PhDs graduated in 2022 than in 2021. The drop in international students in the master's category was especially pronounced.

5. More American high school students take CS courses, but access problems remain. In 2022, 201,000 AP CS exams were administered. Since 2007, the number of students taking these exams has increased more than tenfold. However, recent evidence indicates that students in larger high schools and those in suburban areas are more likely to have access to CS courses.

6. AI-related degree programs are on the rise internationally. The number of English-language, AI-related postsecondary degree programs has tripled since 2017, showing a steady annual increase over the past five years. Universities worldwide are offering more AI-focused degree programs.

7. The United Kingdom and Germany lead in European informatics, CS, CE, and IT graduate production. The United Kingdom and Germany lead Europe in producing the highest number of new informatics, CS, CE, and information bachelor's, master's, and PhD graduates. On a per capita basis, Finland leads in the production of both bachelor's and PhD graduates, while Ireland leads in the production of master's graduates.

This section provides an overview of postsecondary education in CS and AI, highlighting graduation statistics across North America and Europe for various degrees including bachelor’s, master’s, and PhDs. It also covers information on AI-related courses offered in English.

6.1 Postsecondary CS and AI Education

United States and Canada

This subsection presents an analysis of data from the Computing Research Association’s Taulbee Survey, which evaluates the state of CS and AI postsecondary education in the United States and Canada. The survey covers 297 PhD-granting CS departments across the United States and Canada.¹

CS Bachelor’s Graduates

Over the past decade, the total number of new CS bachelor’s graduates in North America has steadily risen, increasing more than threefold, with a 7.9% year-over-year rise from 2021 to 2022 (Figure 6.1).

New CS bachelor’s graduates in the United States and Canada, 2010–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 6.1.1

¹ It is important to note that not all PhD-granting departments targeted in the survey provided responses. Out of the 297 departments targeted, only 182 responded, yielding an overall response rate of 61%.

For the first time in almost eight years, the proportion of international students among CS bachelor’s graduates in American and Canadian universities declined, falling from 16.3% in 2021 to 15.2% in 2022 (Figure 6.1.2). This decline likely reflects the increased difficulty of obtaining study visas during the early years of the Trump administration, an impact that is only now beginning to manifest in

the data. The decline is also partially attributable to international travel restrictions that were imposed during the COVID-19 pandemic, affecting the ability of international students to study in the United States and Canada. Despite this recent drop, the overall trend over the last decade shows a steady increase in the proportion of international students.

New international CS bachelor’s graduates (% of total) in the United States and Canada, 2010–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 6.1.2

CS Master's Graduates

AI courses are commonly included in CS master's degree programs. While the total number of new CS master's graduates from American and Canadian universities more than doubled over the past decade,

the number appears to have leveled out since 2018 and slightly decreased, by 2.5%, last year (Figure 6.1.3). This leveling is a reflection of the decline in international master's students shown in the following graph.

New CS master's graduates in the United States and Canada, 2010–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 6.1.3

In 2022, American and Canadian universities experienced a notable decrease in international CS master’s students. This downward trend began around 2017, but the decline was most pronounced last year, at 14.8 percentage points (Figure 6.1.4). Currently, the split between international and domestic CS master’s graduates is roughly even.

New international CS master’s graduates (% of total) in the United States and Canada, 2010–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 6.1.4

CS PhD Graduates

For the first time in a decade, there has been a significant increase in the number of new CS PhD graduates at American and Canadian universities. In 2022, the number of CS PhD graduates reached 2,105, the highest since 2010 (Figure 6.1.5).

New CS PhD graduates in the United States and Canada, 2010–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 6.1.5

While the proportion of international students among CS PhD graduates has risen over the past decade, there was a slight decrease in this proportion in the last year, dropping from 68.6% in 2021 to 65.9% in 2022 (Figure 6.1.6).

New international CS PhD graduates (% of total) in the United States and Canada, 2010–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 6.1.6

Where do newly minted AI PhDs choose to work after graduating? Following a trend highlighted in last year’s AI Index report, a growing share of AI doctoral recipients are pursuing careers in industry (Figure 6.1.7 and Figure 6.1.8). In 2011, around the same percentage took jobs in industry (40.9%) as in academia (41.6%).

However, by 2022, a significantly larger proportion (70.7%) joined industry after graduation compared to those entering academia (20.0%). The percentage of new AI PhDs going into government roles has remained relatively low and steady at around 0.7% over the past five years.

Employment of new AI PhDs (% of total) in the United States and Canada by sector, 2010–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 6.1.7²

Employment of new AI PhDs in the United States and Canada by sector, 2010–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 6.1.8

² The sums in Figure 6.1.7 do not add up to 100, as there is a subset of new AI PhDs each year who become self-employed, unemployed, or report an “other” employment status in the CRA survey. These students are not included in the chart.

CS, CE, and Information Faculty

To better understand trends in CS and AI education, it is helpful to examine data on CS faculty. Last year, the total number of CS, CE, and information faculty in American and Canadian universities increased 7.2% (Figure 6.1.9). Since 2011, the increase is 42.4%.

Number of CS, CE, and information faculty in the United States and Canada, 2011–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 6.1.9

In 2022, the United States had 7,084 CS faculty members, with the majority (65.7%) on the tenure track (Figure 6.1.10). The total number of American CS faculty has risen 4.4% since 2021 and 45.0% since 2011.

Number of CS faculty in the United States, 2011–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 6.1.10

Last year, 915 new faculty were hired across CS, CE, and information disciplines in North America, a decade high. 455 of these positions were tenure track. (Figure 6.1.1).

New CS, CE, and information faculty hires in the United States and Canada, 2011–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 6.1.11

In 2022, 43% of new faculty appointments came from other academic positions, indicating a “churn” within the academic workforce (Figure 6.1.12). Since these “new” faculty members vacated positions elsewhere, their previous roles will eventually need to be filled. Additionally, the proportion of faculty transitioning from industry in 2022 fell to 7% from 11% in the previous year and 13% in 2019.

Source of new faculty in American and Canadian CS, CE, and information departments, 2018–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 6.1.12

The reasons for faculty positions remaining unfilled have varied over the past decade. In 2011, 37% of failed searches were due to no offer being made, while 34% were because the offer made was declined (Figure 6.1.13). In contrast, in 2022, only 15% ended with no offer being made, while 55% involved offers that

were turned down. This trend appears to reflect an increasingly competitive market for new CS faculty. However, it remains unclear whether this indicates heightened competition with other academic positions or with industry positions.

Reason why new CS, CE, and information faculty positions remained unfilled (% of total), 2011–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 6.1.13

In 2022, North American departments in CS, CE, and information disciplines experienced a significant increase in faculty departures, totaling 405, compared to 303 in 2021 (Figure 6.1.14). Of these losses, 38.5% left for other academic positions, while 16.3% moved to nonacademic roles, maintaining a trend consistent with previous years.

Faculty losses in American and Canadian CS, CE, and information departments, 2011–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 6.1.14

Since 2015, the increase in median nine-month salaries for full professors has slightly fallen below U.S. inflation rates, whereas median salaries for assistant and associate professors have seen slight increases above inflation. In 2022, a full professor’s salary was 3.2% higher than in 2021, which did not keep pace with the 7% U.S. inflation rate, and 16.4% higher than in 2015, still below the 19% inflation increase over those years (Figure 6.1.15).

Median nine-month salary of CS faculty in the United States, 2015–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 6.1.15

In 2022, the proportion of international hires among new tenure-track faculty in CS, CE, and information disciplines significantly increased to 19.3% from 13.2% the previous year (Figure 6.1.16). This marked the second-highest percentage recorded in the past decade, only surpassed by 2013.

New international CS, CE, and information tenure-track faculty hires (% of total) in the United States and Canada, 2010–22

Figure 6.1.16

Europe

Data on European CS graduates comes from Informatics Europe, an academic and research community that, among other goals, monitors the state of informatics education in Europe.³ Informatics Europe gathers data on graduates in informatics, CS, CE, computing, and information technology (IT) disciplines from statistical offices of European governments.⁴

Informatics, CS, CE, and IT Bachelor's Graduates

In 2022, the United Kingdom led with the highest number of new graduates in informatics, CS, CE, and IT at the bachelor's level, totaling approximately 25,000 (Figure 6.1.17).⁵ Germany and Turkey followed closely. Most countries in the sample saw an increase in graduates in these fields compared to a decade ago, though there were exceptions like Poland, Spain, and the Czech Republic (Figure 6.1.18).

New informatics, CS, CE, and IT bachelor's graduates by country in Europe, 2022

Source: Informatics Europe, 2023 | Chart: 2024 AI Index report

Figure 6.1.17

³ There is no singular term for CS education that is used uniformly across European countries. Across Europe, CS education can be reflected in terms such as informatics, computer science (CS), computer engineering (CE), computing, information technology (IT), information and communication technology (ICT), and information science and technology (IST). The full list of subject names (and English translations) that Informatics Europe uses to identify informatics studies programs can be found at the [following link](#).

⁴ Readers are cautioned against making per capita comparisons between the CRA North American data and the European CS graduate data detailed in subsequent sections, as the European data is collected from national statistical offices and boasts broader coverage.

⁵ Note that not all countries for which the AI Index has data are visualized in the figures in this section. To access the complete data, please view the public data associated with this chapter. Moreover, the year label refers to the year in which an academic year ends. For example, the figures visualizing new graduates for 2022 reflect the number of graduates reported for the 2021/2022 academic year. For the sake of visual simplicity, the Index opts to focus on the year in which students graduated.

Percentage change of new informatics, CS, CE, and IT bachelor's graduates by country in Europe, 2012 vs. 2022

Source: Informatics Europe, 2023 | Chart: 2024 AI Index report

Figure 6.118

Finland (53.4), Norway (42.6), and the Netherlands (38.6) lead in the number of new bachelor's graduates in informatics CS, CE, and IT per 100,000 inhabitants (Figure 6.119). On a per capita basis, most sampled European countries have seen increases in the total number of informatics, CS, CE, and IT bachelor's graduates (Figure 6.120).

AI-Related Study Programs

Tracking the number of AI-related courses provides insight into the educational interest in AI. This section highlights data from [Studyportals](#), an international platform monitoring English-language university study programs worldwide. Their portal encompasses information on over 200,000 courses at more than 3,750 educational institutions across 110 countries.⁶

Total Courses

A study program, or degree program, comprises a series of courses designed to enable students to earn a relevant qualification, such as a degree or diploma. The number of English-language AI-related study programs has tripled since 2017, demonstrating a consistent yearly increase over the last five years (Figure 6.1.29). This trend indicates a steadily growing educational interest in AI.

Number of AI university study programs in English in the world, 2017–23

Source: Studyportals, 2023 | Chart: 2024 AI Index report

Figure 6.1.29

⁶ Currently, Studyportals, the company supplying data on AI university study programs, tracks only English-language AI courses. In the coming years, the Index plans to extend its coverage to include non-English programs.

Education Level

Broken down by educational level, the majority of AI study programs are offered at the master’s level (55.0%), followed by the bachelor’s level (39.8%), and finally at the PhD level (5.3%) (Figure 6.1.30).

AI university study programs in English (% of total) by education level, 2023

Source: Studyportals, 2023 | Chart: 2024 AI Index report

Figure 6.1.30

Geographic Distribution

In 2023, the United Kingdom had the greatest number of English-language AI study programs (744) (Figure 6.1.31). Next was the United States (667) and Canada (89). For virtually every country included in

the sample, there was a greater number of AI university study programs in 2023 than in 2022. Malta, the United Kingdom, and Cyprus had the greatest number of English-language AI university study programs per capita in 2023 (Figure 6.1.32).⁷

Number of AI university study programs in English by geographic area, 2022 vs. 2023

Source: Studyportals, 2023 | Chart: 2024 AI Index report

Figure 6.1.31

⁷ Although the United Kingdom has fewer universities overall compared to the United States, it likely reports a higher number of AI study programs for several reasons. Firstly, Studyportals has slightly greater coverage of the United Kingdom than the United States in its data. Secondly, the structure of higher education in the United States tends to be more generalist compared to the United Kingdom, meaning students studying AI might be enrolled in broader computer science programs that are not explicitly identified as AI study programs.

AI university study programs in English per 100,000 inhabitants by geographic area, 2022 vs. 2023

Figure 6.1.32

This section presents trends in high school CS education in the United States as a representation of K–12 AI education.

6.2 K–12 CS and AI Education

United States

Data on the state of K–12 CS education in the United States comes from [Code.org](https://code.org), an education innovation nonprofit dedicated to ensuring that every school includes CS as part of its core K–12 education.

State-Level Trends

In 2023, 30 American states required that all high schools offer a foundational course in CS (Figure 6.2.1).

The percentage of public schools offering CS courses varies significantly from state to state (Figure 6.2.2). The top three states in terms of percentage of CS offerings are Maryland (99%), Arkansas (99%), and Nevada (96%); the bottom three are Minnesota (28%), Montana (34%), and Louisiana (35%).

States requiring that all high schools offer a foundational CS course, 2023

Source: Code.org, 2023 | Chart: 2024 AI Index report

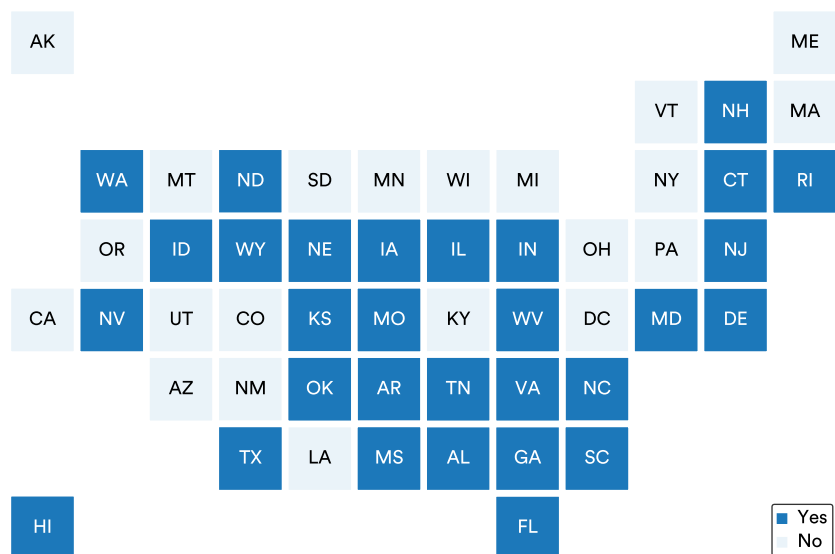

Figure 6.2.1

Public high schools teaching foundational CS (% of total in state), 2023

Source: Code.org, 2023 | Chart: 2024 AI Index report

Figure 6.2.2

K–12 CS education is expanding in the United States (Figure 6.2.3). In 2017, only a few states supported high school CS programs. Now, approximately two-thirds of states require that CS be taught in high schools, allocate funding for it, and have developed state plans for CS education.

Changes over time in state-level US K–12 CS education

Source: Code.org, 2023 | Chart: 2024 AI Index report

Figure 6.2.3

AP Computer Science

The state of K–12 CS education in the United States can also be observed by analyzing trends in the total number of AP CS exams.⁸ In 2022, approximately

201,000 exams were administered, marking an 11.1% increase from 2021 (Figure 6.2.4). Since 2007, the number of AP CS exams administered has increased more than tenfold.

Number of AP computer science exams taken, 2007–22

Source: Code.org, 2023 | Chart: 2024 AI Index report

Figure 6.2.4

⁸ There are two types of AP CS exams: Computer Science A and Computer Science Principles. Data on computer science exams taken includes both exams. AP CS Principles was initially offered in 2017.

In 2022, California (33,262), Texas (20,901), and Florida (16,248) were the leading states in terms of the number of AP CS exams taken (Figure 6.2.5). On the other end, Montana (39), South Dakota (40), and North Dakota (100) are the states where the fewest exams were taken.

Per capita, Maryland (126.5), New Jersey (112.7), and Massachusetts (92.7) ranked highest in the number of AP CS exams taken (Figure 6.2.6).

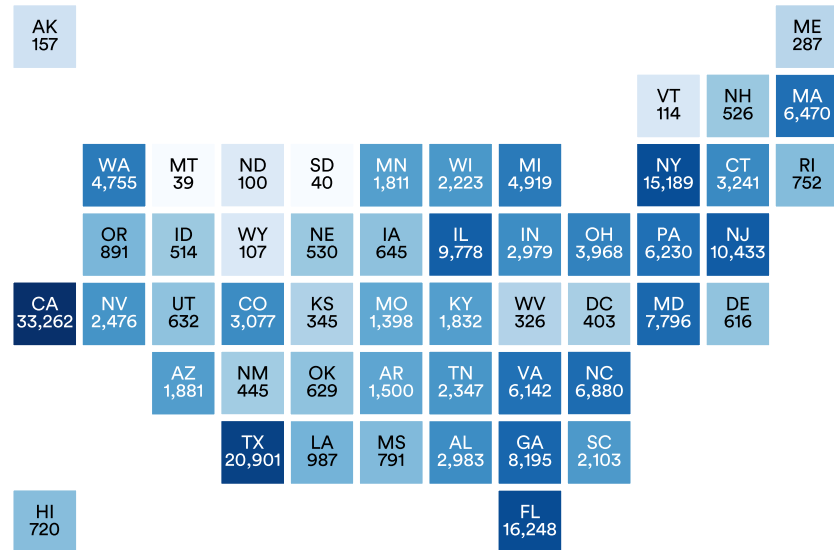

Figure 6.2.5

Number of AP computer science exams taken per 100,000 inhabitants, 2022

Source: Code.org, 2023 | Chart: 2024 AI Index report

Figure 6.2.6

Highlight:
Access Issues

Code.org data suggests that factors such as school size and location significantly influence CS education accessibility. Large schools (over 1,200 students) are 15 percentage points more likely to offer CS courses than medium-sized schools (500–1,200 students), with the gap widening further when compared to small schools (under 500 students) (Figure 6.2.7). Similarly, students in suburban districts have better access to CS courses than their counterparts in both urban and rural areas (Figure 6.2.8).

Schools offering foundational CS courses by size, 2023

ChatGPT Usage Among Teachers and Students

The introduction of generative AI tools, including ChatGPT, has sparked significant debate regarding their potential applications in education. Some individuals have raised concerns that these tools could be misused for plagiarism, potentially prompting a reevaluation of the ways in which American students may be taught.

This year, Impact Research, funded by the Walton Family Foundation, carried out a series of surveys on American teachers’ and educators’ perceptions and use of ChatGPT.⁹ The surveys revealed that a majority of K–12 teachers in the United States are already utilizing ChatGPT, with usage increasing over the year: In March 2023, 51% of teachers reported having used ChatGPT at least once, and by July 2023, that figure had risen to 63% (Figure 6.2.9). Among the teachers who reported using ChatGPT, 30% employed it for lesson planning, another 30% for generating new creative class ideas, and 27% for enhancing their background knowledge (Figure 6.2.10).

Highlight:

ChatGPT Usage Among Teachers and Students (cont'd)

Both teachers and students have overwhelmingly positive attitudes toward ChatGPT. According to the March 2023 survey, 88% of the teachers believe that ChatGPT has a positive impact, a sentiment echoed by 79% of the students surveyed (Figure 6.2.11). Furthermore, 76% of teachers and 65% of students feel that ChatGPT is important to incorporate into the educational process. This recent data indicates that tools like ChatGPT are poised to become a staple in the American educational landscape in the foreseeable future.

Overview

AI's increasing capabilities have captured policymakers' attention. Over the past year, several nations and political bodies, such as the United States and the European Union, have enacted significant AI-related policies. The proliferation of these policies reflect policymakers' growing awareness of the need to regulate AI and improve their respective countries' ability to capitalize on its transformative potential.

This chapter begins examining global AI governance starting with a timeline of significant AI policymaking events in 2023. It then analyzes global and U.S. AI legislative efforts, studies AI legislative mentions, and explores how lawmakers across the globe perceive and discuss AI. Next, the chapter profiles national AI strategies and regulatory efforts in the United States and the European Union. Finally, it concludes with a study of public investment in AI within the United States.

Chapter Highlights

1. The number of AI regulations in the United States sharply increases. The number of AI-related regulations in the U.S. has risen significantly in the past year and over the last five years. In 2023, there were 25 AI-related regulations, up from just one in 2016. Last year alone, the total number of AI-related regulations grew by 56.3%.

2. The United States and the European Union advance landmark AI policy action. In 2023, policymakers on both sides of the Atlantic put forth substantial AI regulatory proposals. The European Union reached a deal on the terms of the AI Act, a landmark piece of legislation enacted in 2024. Meanwhile, President Biden signed an Executive Order on AI, the most notable AI policy initiative in the United States that year.

3. AI captures U.S. policymaker attention. The year 2023 witnessed a remarkable increase in AI-related legislation at the federal level, with 181 bills proposed, more than double the 88 proposed in 2022.

4. Policymakers across the globe cannot stop talking about AI. Mentions of AI in legislative proceedings across the globe have nearly doubled, rising from 1,247 in 2022 to 2,175 in 2023. AI was mentioned in the legislative proceedings of 49 countries in 2023. Moreover, at least one country from every continent discussed AI in 2023, underscoring the truly global reach of AI policy discourse.

5. More regulatory agencies turn their attention toward AI. The number of U.S. regulatory agencies issuing AI regulations increased to 21 in 2023 from 17 in 2022, indicating a growing concern over AI regulation among a broader array of American regulatory bodies. Some of the new regulatory agencies that enacted AI-related regulations for the first time in 2023 include the Department of Transportation, the Department of Energy, and the Occupational Safety and Health Administration.

This chapter begins with an overview of some of the most significant AI-related policy events in 2023, as selected by the AI Index Steering Committee.

7.1 Overview of AI Policy in 2023

Jan. 10,
2023

China introduces regulation on administration of deep synthesis of the internet

China introduces regulations aimed at “deep synthesis” technology to tackle security issues related to the creation of realistic virtual entities and multimodal media, including “deepfakes.” These regulations apply to both providers and users across different media and mandate measures, such as preventing illegal content, adhering to legal compliance, verifying user identities, securing consent for biometric editing, safeguarding data security, and enforcing content moderation.

2023

U.S. legislators propose AI for National Security Act

This legislation clarifies and solidifies the Department of Defense’s (DoD) authority to acquire AI-based endpoint security tools, enhancing its cyber-defense capabilities. It aims to enable the DoD to employ AI for the automatic detection and mitigation of threats to its networks and digital infrastructure. This bipartisan initiative ensures the DoD can adopt innovative commercial technologies to strengthen its cyber defenses, matching the pace of adversaries.

May 11,
2023

U.S. policymakers introduce AI Leadership Training Act

This legislation aims to enhance AI literacy among federal leaders in response to AI's widespread adoption across government agencies. It mandates the director of the Office of Personnel Management (OPM) to create and periodically refresh an AI training program, promoting responsible and ethical AI usage within the federal government. Building on previous laws, the initiative expands AI training to include federal employees involved in procuring AI technologies for government use.

Figure 7.1.9

Aug. 15,
2023

China updates cyberspace administration of generative AI measures

China's updated policy adopts a more targeted regulatory approach, focusing on applications with public implications rather than a blanket regulation. The amendments soften the regulatory language, changing directives like “ensure the truth, accuracy, objectivity, and diversity of the data” to “employ effective measures to enhance the quality of training data and improve its truth, accuracy, objectivity, and diversity.” Additionally, the revised regulations encourage generative AI development, shifting away from the prior punitive focus.

Figure 7.1.17

7.2 AI and Policymaking

Global Legislative Records on AI

Overview

The AI Index analyzed legislation containing “artificial intelligence” in 128 countries from 2016 to 2023.² Of these, 32 countries have enacted at least one AI-related bill (Figure 7.2.1).³ In total, the countries have passed 148 AI-related bills. Figure 7.2.2 illustrates the annual

count of AI-related bills passed since 2016. While the total dropped to 28 in 2023 from 39 in the previous year, the number of AI-related bills passed in 2023 significantly exceeds the total passed in 2016.

Number of AI-related bills passed into law by country, 2016–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

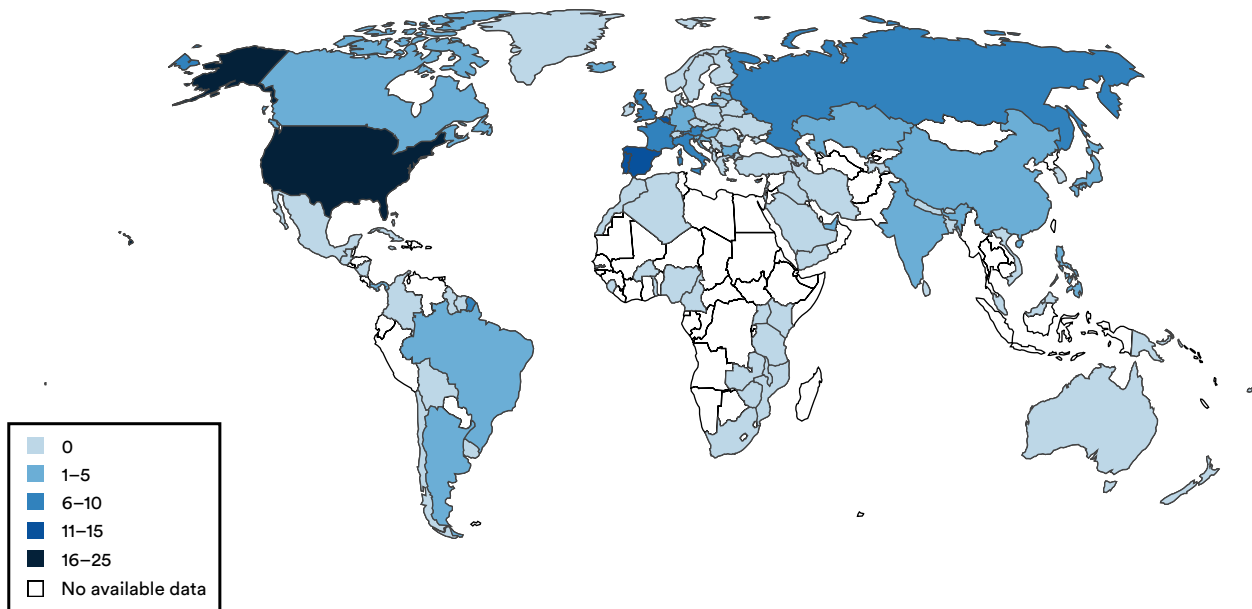

Figure 7.2.1

² The analysis of passed AI policies may undercount the number of actual bills, given that large bills can include multiple sub-bills related to AI; for example, the CHIPS and Science Act passed by the United States in 2022.

³ The AI Index monitored AI-related bills passed in Hong Kong and Macao, despite these not being officially recognized countries. Thus, the Index covers a total of 130 geographic areas. Laws passed by Hong Kong and Macao were counted in the overall tally of AI-related bills. This year, the Index expanded its country sample compared to previous years, resulting in a difference between the number of AI-related bills reported this year and those in prior reports.

Number of AI-related bills passed into law in 128 select countries, 2016–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 7.2.2

By Geographic Area

Figure 7.2.3 highlights the number of laws containing mentions of AI that were enacted in 2023. Belgium led with five laws, followed by France, South Korea, and the United Kingdom, each of which passed three. Figure 7.2.4 shows the total number of laws passed since 2016. The United States (23) has passed the most AI-related laws since 2016, followed by Portugal (15), and Belgium (12).

Number of AI-related bills passed into law in select countries, 2023

Figure 7.2.3

Number of AI-related bills passed into law in select countries, 2016–23 (sum)

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 7.2.4

By Relevance

The AI Index team further disaggregated AI-related bills based on their relevance to AI, as not every bill mentioning AI prioritizes it equally. A bill deemed to have high relevance to AI is fundamentally focused on AI-related policy, like the [AI Training Act](#) passed in 2022, which mandates AI training programs for executive agency workers. Conversely, bills with medium relevance incorporate significant AI policy elements but are not fundamentally focused on AI-related matters. For example, the [National Defense Authorization Act for Fiscal Year 2022](#) includes sections on AI performance metrics and AI capabilities development for the Department of Defense. However, because it has a broader focus, namely authorizing various Defense Agency programs, and is not completely centered on AI, it was assigned

a medium AI relevance. Low relevance AI bills merely mention AI in passing without a substantial legislative focus on AI. An example of a low relevance AI bill is the [Energy and Water, Legislative Branch, and Military Construction and Veterans Affairs Appropriations Act, 2019](#). This bill allocates funding to various federal agencies, and mentions AI primarily in the context of encouraging these agencies to consider workforce training opportunities for sectors like cybersecurity, energy, and AI.

Figure 7.2.5 illustrates the distribution of AI-related bills passed into law globally in 2023, categorized by their relevance to AI. Out of 28 AI-related bills enacted, two were classified as having high relevance to AI, while 18 were deemed to have medium relevance.

Number of AI-related bills passed into law in select countries by relevance to AI, 2016–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 7.2.5

By Approach

The AI Index also categorized AI-related bills as either expansive or restrictive. Expansive bills aim to enhance a nation’s AI capabilities, such as establishing a network of publicly accessible supercomputers. Restrictive bills, on the other hand, impose limitations on AI usage, like setting rules for deploying facial recognition technology. A bill can be both, or neither.⁴ Distinguishing between expansive or restrictive bills can highlight legislator priorities: whether

policymakers focus on expanding AI capabilities, imposing restrictions, or balancing both.

Figure 7.2.6 indicates a global trend toward regulating AI usage, showing that, while the commitment to enhancing AI capabilities remains, there is a growing shift toward restrictive legislation. This change suggests that legislators are increasingly focused on mitigating the potential harms of AI’s integration into society.

Number of AI-related bills passed into law in select countries by approach, 2016–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 7.2.6

⁴ The AI Index only categorized bills as being expansive or restrictive if they were identified as having medium or high AI relevance. Consequently, the totals depicted in Figure 7.2.5 may not fully correspond with those presented earlier in the chapter.

By Subject Matter

The AI Index’s global analysis of AI legislation classifies bills by their primary subject matter according to the typology used by the U.S. Congress to classify American legislation.⁵ Historically, economics and public finance have been the predominant focus of AI-related legislation, reflecting the fact that AI-related policymaking matters are often incorporated within budgetary bills related to public appropriations (Figure 7.2.7). However,

in 2023 the distribution of primary topics among passed bills broadened significantly, encompassing a diverse range of policy areas. Specifically, two bills were passed in each of the following categories: armed forces and national security; civil rights and liberties, minority issues; commerce; education; labor and employment; science, technology, and communication. This diversity indicates that AI policy concerns are increasingly spanning various sectors.

Number of AI-related bills passed into law in select countries by primary subject matter, 2016–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 7.2.7

⁵ Similar to the classification of bills as either expansive or restrictive, only bills coded as having a medium or high relevance to AI were coded for their primary subject matter. Consequently, not all AI-related bills featured in this section’s analysis have subject matter coding available.

U.S. Legislative Records

Federal Level

Figure 7.2.8 illustrates the total number of passed versus proposed AI-related bills in the U.S. Congress, highlighting a significant increase in proposed legislation. In the last year, the count of proposed AI-related bills more than doubled, rising from 88 in 2022

to 181 in 2023. This significant increase in U.S. AI-related legislative activity likely reflects policymakers' response to the increasing public awareness and capabilities of AI technologies, such as ChatGPT.

Number of AI-related bills in the United States, 2016–23 (proposed vs. passed)

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 7.2.8

State Level

The AI Index also tracks data on the enactment of AI-related legislation at the state level. Figure 7.2.9 highlights the number of AI-related laws enacted by U.S. states in 2023. California leads with seven laws, followed by Virginia with five, and Maryland with three. Figure 7.2.10 displays the total amount of legislation passed by states from 2016 to 2023. California again tops the ranking with 13 bills, followed by Maryland (10) and Washington (7).

Number of AI-related bills passed into law in select US states, 2023

Figure 7.2.11

AI Mentions

Another barometer of legislative interest is the number of mentions of artificial intelligence in governmental and parliamentary proceedings. The AI Index conducted an analysis of the minutes or proceedings of legislative sessions in 80 countries that contain the keyword “artificial intelligence” from 2016 to 2023.⁶

Overview

Figure 7.2.12 reveals a significant increase in the mentions of AI in legislative proceedings across the globe, nearly doubling from 1,247 in 2022 to 2,175 in 2023. Since 2016, AI mentions in legislative discussions have risen almost tenfold. This data suggests that the emergence of AI systems such as ChatGPT in 2023 has notably captured policymakers’ attention.

Number of mentions of AI in legislative proceedings in 80 select countries, 2016–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 7.2.12

⁶ The full list of countries analyzed can be found in the Appendix. The AI Index research team attempted to review the governmental and parliamentary proceedings of every country in the world; however, publicly accessible governmental and parliamentary databases were not made available for all countries.

In 2023, the United Kingdom led in AI mentions within its legislative proceedings (405), followed by the United States (240) and Australia (227) (Figure 7.2.13). Out of 80 countries analyzed, 48 mentioned AI at least once. Moreover, AI discussions reached legislative platforms in at least one country from every continent in 2023, underscoring the truly global reach of AI policy discourse.

When legislative mentions are aggregated from 2016 to 2023, a somewhat similar trend emerges (Figure 7.2.14). The United Kingdom is first, with 1,490 mentions, followed by Spain (886) and the United States (868).

Number of mentions of AI in legislative proceedings by country, 2023

Figure 7.2.14

U.S. Committee Mentions

Mentions of artificial intelligence in committee reports by House and Senate committees serve as another indicator of legislative interest in AI in the United States. Typically, these committees focus on legislative and policy issues, investigations, and internal matters.

Figure 7.2.15 shows the frequency of AI mentions in U.S. committee reports by legislative session from 2001 to 2023. Mentions of AI have decreased for the current 118th session; however, it is important to note that this session is only about halfway through, with an end date set for January 2025. Continuing at the current rate, the 118th legislative session is poised to surpass all previous sessions in terms of AI mentions.

Mentions of AI in US committee reports by legislative session, 2001–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 7.2.15

Figure 7.2.16 depicts AI mentions in the committee reports of the U.S. House of Representatives during the ongoing 118th congressional session. The Appropriations and Science, Space, and Technology committees feature the highest number of AI mentions. Meanwhile, Figure 7.2.17 highlights AI mentions in Senate committee reports, with Appropriations leading (9), followed by the Homeland Security and Governmental Affairs Committee (3).

Figure 7.2.19

This section offers an overview of national AI strategies, which are policy plans created by governments to guide the development and deployment of AI within their country. Monitoring trends in these strategies is important for assessing how countries prioritize the development and regulation of AI technologies. Sources include national or regional government websites, the OECD AI Policy Observatory (oecd.ai), and news reports.⁷

7.3 National AI Strategies

By Geographic Area

Canada initiated the first national AI strategy in March 2017. To date, 75 national AI strategies have been unveiled. The peak year was 2019, when 24 strategies were released. In 2023, eight new strategies were added, from countries in the Middle East, Africa, and the Caribbean, showcasing the worldwide expansion of AI policymaking discourse.

Figure 7.3.1 identifies countries that have either released or are in the process of developing a national AI strategy as of January 2024. Figure 7.3.2 lists the countries that are in the process of developing an AI strategy within the past three years. The list of new countries developing national AI strategies include: Antigua and Barbuda, Barbados, Belarus, Costa Rica, Jamaica, Pakistan, and Senegal. Figure 7.3.3 provides a timeline of the release of national AI strategies.

Countries with a national strategy on AI, 2023

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 7.3.1

⁷ The AI Index research team made efforts to identify whether there was a national AI strategy that was released or in development for every nation in the world. It is possible that some strategies were missed.

AI national strategies in development by country and year

Year	Country
2017	Canada, China, Finland
2018	France, Germany, India, Mauritius, Mexico, Sweden
2019	Argentina, Bangladesh, Chile, Colombia, Cyprus, Czech Republic, Denmark, Egypt, Estonia, Japan, Lithuania, Luxembourg, Malta, Netherlands, Portugal, Qatar, Romania, Russia, Sierra Leone, Singapore, Slovak Republic, United Arab Emirates, United States of America, Uruguay
2020	Algeria, Bulgaria, Croatia, Greece, Hungary, Indonesia, Latvia, North Korea, Norway, Poland, Saudi Arabia, Serbia, Spain, Switzerland
2021	Australia, Austria, Brazil, Hong Kong, Ireland, Malaysia, Peru, Philippines, Slovenia, Tunisia, Turkey, Ukraine, United Kingdom, Vietnam
2022	Belgium, Ghana, Iran, Italy, Jordan, Thailand
2023	Azerbaijan, Bahrain, Benin, Dominican Republic, Ethiopia, Iraq, Israel, Rwanda

Figure 7.3.3

The advent of AI has garnered significant attention from regulatory agencies—federal bodies tasked with regulating sectors of the economy and steering the enforcement of laws. This section examines AI regulations within the United States and the European Union. Unlike legislation, which establishes legal frameworks within nations, regulations are detailed directives crafted by executive authorities to enforce legislation. In the United States, prominent regulatory agencies include the Environmental Protection Agency (EPA), Food and Drug Administration (FDA), and Federal Communications Commission (FCC). Since the specifics of legislation often manifest through regulatory actions, understanding the AI regulatory landscape is essential in order to develop a deeper understanding of AI policymaking.

7.4 AI Regulation

U.S. Regulation

This section examines AI-related regulations enacted by American regulatory agencies between 2016 and 2023. It provides an analysis of the total number of regulations, as well as their topics, scope, regulatory intent, and originating agencies. To compile this data, the AI Index team performed a keyword search for “artificial intelligence” on the [Federal Register](#), a comprehensive repository of government documents

from nearly all branches of the American government, encompassing more than 436 agencies.⁸

Overview

The number of AI-related regulations has risen significantly, both in the past year and over the last five years (Figure 7.4.1). In 2023, there were 25 AI-related regulations, a stark increase from just one in 2016. Last year alone, the total number of AI-related regulations grew by 56.3%.

Number of AI-related regulations in the United States, 2016–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 7.4.1

⁸ A full description of the project’s methodology can be found in the Appendix.

By Relevance

The AI Index categorized AI-related regulations—those mentioning AI—into three levels of relevance: low, medium, and high.⁹ In 2023, the number of high and medium relevance AI-related regulations increased compared to 2022. For instance, a high relevance AI regulation was the Copyright Office and Library of Congress’ Copyright Registration Guidance: Works Containing Material Generated by Artificial Intelligence. This policy statement clarified registration practices for works incorporating AI-generated material. Meanwhile, a medium-relevance

example is the Securities and Exchange Commission’s Cybersecurity Risk Management Strategy, Governance, and Incident Disclosure, which established standardized disclosure practices for public companies concerning cybersecurity risk management, strategy, governance, and incidents.

Figure 7.4.2 categorizes AI-related regulations in the United States based on their relevance to AI. A growing proportion of these regulations is highly relevant to AI. Among the 25 AI-related regulations enacted in 2023, four were identified as being highly relevant, the greatest amount since tracking began in 2016.

Number of AI-related regulations in the United States by relevance to AI, 2016–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 7.4.2

⁹ A high relevance regulation focuses entirely on AI or AI-related issues. A medium relevance regulation includes meaningful mentions of AI but is not solely centered on it. A low relevance regulation mentions AI in passing, without a significant focus on AI-related matters.

By Agency¹⁰

Which agencies are the primary sources of AI regulations? In 2023, the Executive Office of the President and the Commerce Department led with five AI-related regulations each, followed by the Health and Human Services Department and the Industry and Security Bureau, with each issuing four

(Figure 7.4.3). Furthermore, the number of agencies issuing AI regulations increased from 17 in 2022 to 21 in 2023, indicating a growing need for clarity and concern regarding AI among a broader array of American regulatory bodies.

Number of AI-related regulations in the United States by agency, 2016–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

¹⁰ Regulations can originate from multiple agencies, so the annual totals in Figure 7.4.3 may exceed those in Figure 7.4.1.

By Approach

The AI Index categorized regulations based on their approach: whether they expanded or restricted AI capabilities.¹¹ Over time, the trend in AI regulations in the United States has shifted significantly toward

restriction (Figure 7.4.4). In 2023, there were 10 restrictive AI regulations compared to just three that were expansive. Conversely in 2020, there were four regulations that were expansive and one that was restrictive.

Number of AI-related regulations in the United States by approach, 2016–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 7.4.4

¹¹ Expansive regulations refer to actions by regulatory agencies or governments aimed at augmenting AI capacity, including investments in supercomputing infrastructure. Restrictive regulations involve steps to curtail AI capabilities, such as imposing restrictions on the use of facial recognition algorithms. Restrictive AI regulations may also be intended to address underlying policy concerns, such as AI's potential impact on citizens' civil liberties. According to this coding typology, a regulation can be classified as both expansive and restrictive, or it may fit neither category. The AI Index assigned the labels "expansive" or "restrictive" only to regulations deemed to have medium to high relevance to AI. Therefore the regulation totals in Figure 7.4.4 are less than those reported earlier in the section.

By Subject Matter

In 2023, American AI regulations were categorized by primary subject matter. The most prevalent subject matter in AI-related regulation was foreign trade and international finance, with three instances. Three

topics tied for second place, with two occurrences each: health; commerce; and science, technology, and communications (Figure 7.4.5).

Number of AI-related regulations in the United States by primary subject matter, 2016–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

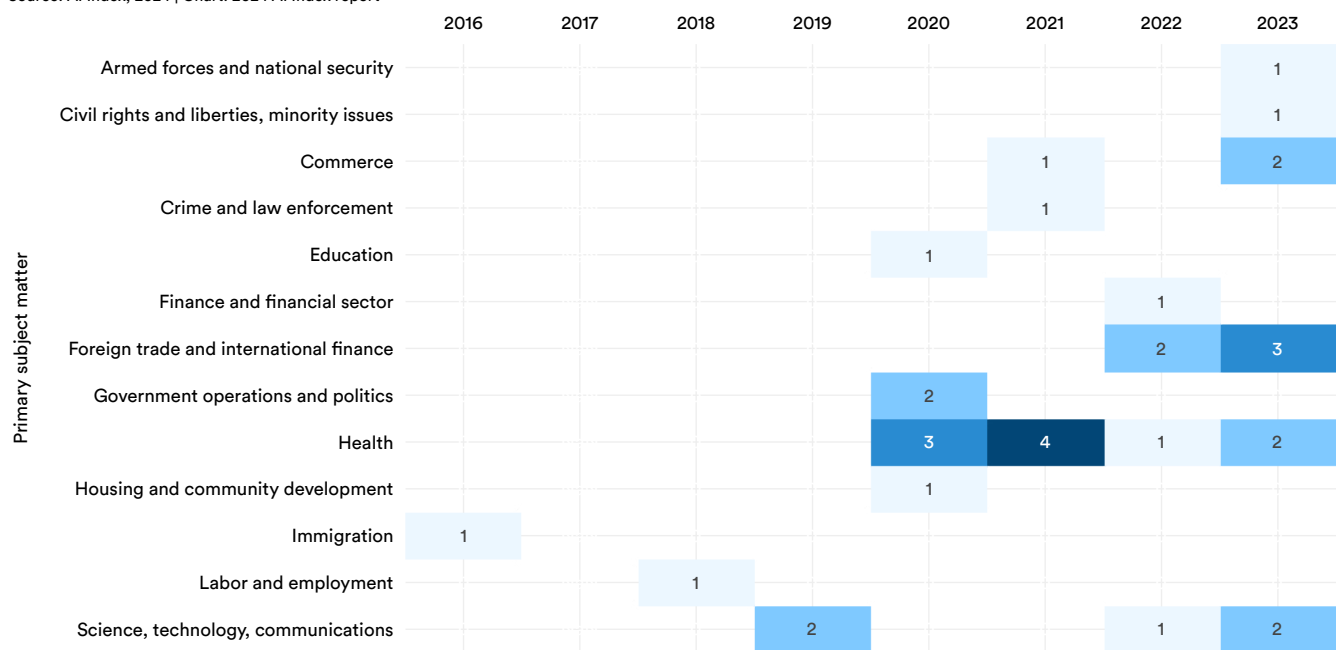

Figure 7.4.5

¹² The AI Index team used Congress' policy categorization typology. Only regulations that have medium and high AI relevance were coded for their primary subject matter.

EU Regulation

The AI Index also gathered information on AI-related regulations enacted in the European Union between 2017 and 2023. To compile this data, the Index team conducted a keyword search for “artificial intelligence” on [EUR-Lex](#), a comprehensive database of EU legislation, regulations, and case law. EUR-Lex provides access to a wide range of regulatory documents, such as legal acts, consolidated texts, international agreements, preparatory documents, and legislative procedures. The analysis in this section focused exclusively on documents with binding

regulatory authority. The search for AI-related regulation in the European Union was limited to legal acts, international agreements, and consolidated texts. The same methodological approach was used to code EU regulations, as was used to code U.S. regulations.¹³

Overview

The number of AI-related regulations passed by the European Union increased from 22 in 2022 to 32 in 2023 (Figure 7.4.6). Despite this increase, the number of AI-related regulations passed by the European Union peaked in 2021 with 46.

Number of AI-related regulations in the European Union, 2017–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 7.4.6

¹³ The methodological approach refers to coding regulations based on relevance, originating agency, approach, and subject matter.

By Relevance

In 2021, the European Union passed its first highly relevant AI-related regulations. These regulations established the Digital Europe Programme and

Horizon Europe, a framework program for research and innovation. Of the 32 regulations passed in 2023, two had high relevance to AI, 13 had medium relevance, and 17 had low relevance (Figure 7.4.7).

Number of AI-related regulations in the European Union by relevance to AI, 2017–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 7.4.7

By Agency

The two most prominent originator agencies for European Union AI regulations in 2023 were the Council of the European Union (13) and European Parliament (9) (Figure 7.4.8).¹⁴

Number of AI-related regulations in the European Union by institution and body, 2017–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 7.4.8

¹⁴ Institutions abbreviated with DG are Directorates-General. These are departments with specific areas of ministerial responsibility.

By Approach

In recent years, AI-related regulation in the European Union has tended to take a more expansive approach (Figure 7.4.9). In 2023, there were eight regulations with a restrictive focus compared to 12 with an expansive one.

Number of AI-related regulations in the European Union by approach, 2017–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 7.4.9

By Subject Matter

In 2023, the most common subject matters for AI-related regulations in the European Union were science, technology, and communications (5); followed by government operations and politics (3) (Figure 7.4.10). Regulations concerning government operations and politics involve setting rules for how governments and associated governmental processes operate. One such regulation was the Commission Recommendation (EU) on inclusive

and resilient electoral processes in the Union and enhancing the European nature and efficient conduct of the elections to the European Parliament. This regulation acknowledged that AI could be used to generate political misinformation and outlined steps the Commission has taken to ensure AI does not challenge the legitimacy of elections. Evidently, European Union legislators are considering how AI will impact their government’s work.

Number of AI-related regulations in the European Union by primary subject matter, 2017–23

Source: AI Index, 2024 | Chart: 2024 AI Index report

Figure 7.4.10

This section examines public AI investment in the United States based on data from the U.S. government and Govini, a company that uses AI and machine learning technologies to track U.S. public and commercial spending.

7.5 U.S. Public Investment in AI

Federal Budget for AI R&D

Every year in December, the National Science and Technology Council publishes a report on the public sector AI R&D budget across various departments and agencies that participate in the Networking and Information Technology Research and Development (NITRD) Program and National Artificial Intelligence Initiative. These reports, however, do not include

information on classified AI R&D investment.

According to the 2023 report, in the fiscal year 2023, U.S. government agencies allocated a total of \$1.8 billion to AI research and development spending (Figure 7.5.1). The funding for AI R&D has risen annually since FY 2018, more than tripling since then. For FY 2024, a larger budget of \$1.9 billion has been requested.¹⁵

US federal NITRD budget for AI, FY 2018–24

Source: U.S. NITRD Program, 2023 | Chart: 2024 AI Index report

Figure 7.5.1

Figure 7.5.2 details the breakdown of NITRD AI R&D budget requests by agency. For FY 2024, the National Science Foundation (NSF) had the highest request at \$531 million, followed by the Defense Advanced Research Projects Agency (DARPA) at \$322.1 million, and the National Institutes of Health (NIH) at \$284.5 million.

¹⁵ Previous editions of the NITRD report have included spending figures for past years that differ slightly from those reported in the most recent edition. The AI Index reports the spending amounts documented in the latest NITRD reports.

US governmental agency NITRD budgets for AI, FY 2021–24

Source: U.S. NITRD Program | Chart: 2024 AI Index report

Figure 7.5.2

U.S. Department of Defense Budget Requests

Every year the DoD releases the amount of funding they request for nonclassified AI-specific research,

development, test, and evaluation. According to its 2023 report, the DoD requested \$1.8 billion in FY 2024, a significant increase from the \$1.1 billion that was requested in FY 2023 (Figure 7.5.3).

US DoD budget request for AI-specific research, development, test, and evaluation (RDT&E), FY 2020–24

Source: U.S. Office of the Under Secretary of Defense (Comptroller), 2023 | Chart: 2024 AI Index report

Figure 7.5.3

U.S. Government AI-Related Contract Spending

Public investment in AI can also be measured by federal government spending on the contracts awarded to private companies for goods and services. Such contracts typically occupy the largest share of an agency’s budget.

Data in this section comes from Govini, which created a taxonomy of spending by the U.S. government on critical technologies including AI. Govini applied supervised machine learning and natural language processing to parse, analyze, and categorize large

volumes of federal contracts data, including prime contracts, grants, and other transaction authority (OTA) awards. The use of AI models enables Govini to analyze data that is otherwise often inaccessible.

AI Contract Spending

Figure 7.5.4 highlights total U.S. government spending on AI, subdivided by various AI segments. From 2022 to 2023, total AI spending increased marginally from \$3.2 billion to \$3.3 billion.¹⁶ Since 2018, total spending has increased nearly 2.4 times. In 2023, the AI subsegments that saw the greatest amount of government spending included machine learning (\$1.5 billion) and computer vision (\$1.0 billion).

US government spending in AI/ML and autonomy by segment, FY 2018–23

Source: Govini, 2023 | Chart: 2024 AI Index report

Figure 7.5.4

¹⁶ In 2023, Govini made minor adjustments to their classification methodology. Consequently, the contract totals presented in Figure 7.5.4 may vary slightly from those reported in earlier editions of the AI Index.

Figure 7.5.5 shows U.S. government spending by AI segment in FY 2022 and FY 2023. Spending significantly increased for machine learning. Computer vision and natural language processing spending also rose, albeit less prominently.

US government spending in AI/ML and autonomy by segment, FY 2022 vs. 2023

Source: Govini, 2023 | Chart: 2024 AI Index report

Figure 7.5.5

In FY 2023, the majority of federal AI contracts were prime contracts (50.6%), followed by grants (47.6%) (Figure 7.5.6). In the last year, the share of contracts has declined, while the share of grants has increased.

Total value of contracts, grants, and OTAs awarded by the US government for AI/ML and autonomy, FY 2018–23

Source: Govini, 2023 | Chart: 2024 AI Index report

Figure 7.5.6

Microelectronics and Semiconductor Spending

Govini also monitors U.S. government microelectronics spending, which is becoming increasingly vital due to the crucial role that semiconductors, like GPUs, have played in powering recent AI technical improvements. The way governments allocate funds for semiconductors is poised to increase in geopolitical significance.

Figure 7.5.7 visualizes U.S. government spending on microelectronics by segment. Total spending on microelectronics has grown significantly in the last year, increasing to \$3.9 billion from \$2.5 billion in 2022. The large majority of American government microelectronic spending is allocated as contracts (Figure 7.5.8).

US government spending in microelectronics by segment, FY 2018–23

ACCESS THE PUBLIC DATA

Overview

The demographics of AI developers often differ from those of users. For instance, a considerable number of prominent AI companies and the datasets utilized for model training originate from Western nations, thereby reflecting Western perspectives. The lack of diversity can perpetuate or even exacerbate societal inequalities and biases.

This chapter delves into diversity trends in AI. The chapter begins by drawing on data from the Computing Research Association (CRA) to provide insights into the state of diversity in American and Canadian computer science (CS) departments. A notable addition to this year's analysis is data sourced from Informatics Europe, which sheds light on diversity trends within European CS education. Next, the chapter examines participation rates at the Women in Machine Learning (WiML) workshop held annually at NeurIPS. Finally, the chapter analyzes data from Code.org, offering insights into the current state of diversity in secondary CS education across the United States.

The AI Index is dedicated to enhancing the coverage of data shared in this chapter. Demographic data regarding AI trends, particularly in areas such as sexual orientation, remains scarce. The AI Index urges other stakeholders in the AI domain to intensify their endeavors to track diversity trends associated with AI and hopes to comprehensively cover such trends in future reports.

Chapter Highlights

1. U.S. and Canadian bachelor’s, master’s, and PhD CS students continue to grow more ethnically diverse. While white students continue to be the most represented ethnicity among new resident graduates at all three levels, the representation from other ethnic groups, such as Asian, Hispanic, and Black or African American students, continues to grow. For instance, since 2011, the proportion of Asian CS bachelor’s degree graduates has increased by 19.8 percentage points, and the proportion of Hispanic CS bachelor’s degree graduates has grown by 5.2 percentage points.

2. Substantial gender gaps persist in European informatics, CS, CE, and IT graduates at all educational levels. Every surveyed European country reported more male than female graduates in bachelor’s, master’s, and PhD programs for informatics, CS, CE, and IT. While the gender gaps have narrowed in most countries over the last decade, the rate of this narrowing has been slow.

3. U.S. K–12 CS education is growing more diverse, reflecting changes in both gender and ethnic representation. The proportion of AP CS exams taken by female students rose from 16.8% in 2007 to 30.5% in 2022. Similarly, the participation of Asian, Hispanic/Latino/Latina, and Black/African American students in AP CS has consistently increased year over year.

This section examines trends in diversity within CS and AI postsecondary education across North America and Europe.

8.1 AI Postsecondary Education

North America

Data on American and Canadian postsecondary CS and AI postsecondary education comes from the Computing Research Association’s (CRA) annual Taulbee Survey.^{1,2}

CS Bachelor’s Graduates

The percentage of female CS bachelor’s graduates reached 22.2% in 2022, continuing a decade-long rise (Figure 8.1). Nonbinary/other-identifying CS bachelor’s graduates accounted for 0.1% in 2022.

Gender of new CS bachelor’s graduates (% of total) in the United States and Canada, 2010–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 8.1

Over the past decade, the number of CS bachelor’s graduates of all ethnicities has grown, notably 4.7 times for Hispanics and 2.5 times for African Americans (Figure 8.1.2). As a proportion of ethnicities among all CS bachelor’s graduates, Asians have risen the fastest, doubling in the last 10 years (Figure 8.1.3).

1 The charts in this section look only at the ethnicity of domestic or native CS students and faculty. Although the CRA reports data on the proportion of nonresident aliens at each educational level (i.e., bachelor’s, master’s, PhD, and faculty), data on the ethnicity of nonresident aliens is not included.

2 Not all PhD-granting departments targeted in the survey provided responses. Of the 297 departments targeted, only 182 responded, resulting in an overall response rate of 61%. The AI Index advises against making per capita comparisons between the CRA North American data and the data on European CS graduates detailed in the subsequent sections due to the European data being collected from national statistical offices, which affords it broader coverage.

Ethnicity of new resident CS bachelor's graduates in the United States and Canada, 2011–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 8.1.2

Ethnicity of new resident CS bachelor's graduates (% of total) in the United States and Canada, 2011–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 8.1.3

CS Master's Graduates

The proportion of female CS master's graduates has seen minimal growth in the last decade, increasing to 26.3% in 2022 from 24.6% in 2011. Additionally, in 2022, 0.08% of CS master's graduates identified as nonbinary/other (Figure 8.1.4).

Gender of new CS master's graduates (% of total) in the United States and Canada, 2011–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 8.1.4

Among North American students, the most represented ethnicities are white (47.9%), Asian (35.8%), and Hispanic (8.2%) (Figure 8.1.5 and Figure 8.1.6). Similar to CS bachelor’s graduates, the pool of CS master’s graduates has become increasingly ethnically diverse over the last decade.

Ethnicity of new resident CS master’s graduates in the United States and Canada, 2011–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 8.1.5

Ethnicity of new resident CS master’s graduates (% of total) in the United States and Canada, 2011–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 8.1.6

CS PhD Graduates

In 2022, the percentage of female PhD graduates in CS slightly decreased to 22.1% (Figure 8.1.7), but the long-term trend is unchanged.

Gender of new CS PhD graduates (% of total) in the United States and Canada, 2010–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 8.1.7

From 2011 to 2022, the diversity among CS PhD graduates significantly increased (Figure 8.1.8 and Figure 8.1.9). In 2022, 41.1% of CS PhD graduates were Asian, Black, Hispanic, multiracial, American Indian, or Native Hawaiian, marking a considerable rise from 2011.

Ethnicity of new resident CS PhD graduates in the United States and Canada, 2011–22

Figure 8.1.8

Ethnicity of new resident CS PhD graduates (% of total) in the United States and Canada, 2011–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 8.1.9

Disability Status of CS, CE, and Information Students

For the second consecutive year, the CRA requested departments to report the number of students at each degree level who received disability accommodations over the preceding year. The reported numbers were

relatively low: 4.1% of bachelor’s, 1.5% of master’s, and 1.1% of PhD students indicated a need for accommodations (Figure 8.1.10). Year over year, the proportion of students requesting disability accommodations has remained consistent.

CS, CE, and information students (% of total) with disability accommodations in United States and Canada, 2021 vs. 2022

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 8.1.10

CS, CE, and Information Faculty

Data regarding the ethnicity and gender of faculty in CS, CE, and information fields highlight diversity trends in academic AI and CS. As of 2022, a majority of faculty members in CS, CE, and information are

male (75.6%), with women comprising 24.3% and nonbinary individuals accounting for 0.1% (Figure 8.1.11). Although the proportion of female faculty in these fields has risen since 2011, the increase has been small.

Gender of CS, CE, and information faculty (% of total) in the United States and Canada, 2011–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 8.1.11

While the majority of new faculty hires in CS, CE, and information at American and Canadian universities remain male (71.7%), the proportion of women reached 28.0% in 2022 (Figure 8.1.12), well above the proportion of new female PhDs.

Gender of new CS, CE, and information faculty hires (% of total) in the United States and Canada, 2011–22

Source: CRA Taulbee Survey, 2023 | Chart: 2024 AI Index report

Figure 8.1.12

As of 2022, the majority of resident faculty in CS, CE, and information were white (57.3%), with Asian faculty following at 30.1% (Figure 8.2.13 and Figure 8.1.14). The ethnic diversity gap is gradually closing: In 2011, the difference between white faculty and the next largest ethnic group was 46.1%, but by 2021, it had narrowed to 27.2%.

Figure 8.1.14

Europe

Data on diversity trends about European CS graduates comes from [Informatics Europe](#).³

Informatics, CS, CE, and IT Bachelor's Graduates

In the majority of surveyed European nations, there is a persistent gender disparity among bachelor's-level graduates in informatics, computer science, computer engineering, and information technology. Despite some narrowing since 2011, men continue to dominate. For example, France (14.8%), the United Kingdom (17.8%), and Germany (21.5%) show relatively low proportions of female graduates in these fields (Figure 8.1.15). Bulgaria stands out among the surveyed countries with the highest proportion of female graduates (35.2%).

Informatics, CS, CE, and IT Master's Graduates

Similar gender disparities are observed among European informatics, CS, CE, and IT master's graduates, with a significantly greater proportion of males than females in most surveyed countries. As of 2022, Estonia (42.0%), Romania (41.9%), and Bulgaria (40.4%) reported the greatest proportion of female master's graduates (Figure 8.1.16). In contrast, Belgium (13.7%), Italy (14.1%), and Switzerland (15.8%) reported the smallest proportion of female master's graduates.

Informatics, CS, CE, and IT PhD Graduates

In all surveyed European countries, informatics, CS, CE, and IT PhD graduates are predominantly male. However, in nations such as the United Kingdom, Germany, and Switzerland, the gender gap has narrowed over the last decade, with women constituting a growing share of PhD graduates (Figure 8.1.17).⁴ In contrast, countries like Finland and Spain have seen the gap slightly widen.

³ The year label refers to the year in which an academic year ends. For example, the figures visualizing new graduates for 2022 reflect the number of graduates reported for the 2021/2022 academic year. For the sake of visual simplicity, the Index opts to focus on the year in which students graduated.

⁴ In countries where the number of PhD graduates is relatively small, trends in gender proportions can be prone to sudden year-over-year changes. For example, in 2022 Bulgaria produced 24 total PhDs, Latvia 12, and Estonia 26.

Gender of new informatics, CS, CE, and IT bachelor's graduates (% of total) in Europe, 2011–22

8.2 AI Conferences

Women in Machine Learning (WiML) NeurIPS Workshop

Women in Machine Learning (WiML), founded in 2006, is an organization dedicated to supporting and increasing the impact of women in machine learning. This section of the AI Index presents data from the WiML annual technical workshop, hosted at NeurIPS.

Workshop Participants

Despite a decline in participation over the last two years, the 2023 NeurIPS WiML workshop attendance of 714 was nearly eight times higher than the attendance of 89 in 2010 (Figure 8.2.1). The recent drop in WiML workshop attendance may be linked to the overall decrease in NeurIPS attendance, which could be attributed to the shift away from a purely virtual format.⁵ As a share of total conference attendance, the 2023 WiML workshop represented 4.4% of attendees (Figure 8.2.2).

Attendance at NeurIPS Women in Machine Learning workshop, 2010–23

Source: Women in Machine Learning, 2023 | Chart: 2024 AI Index report

Figure 8.2.2

⁵ Figure 8.1.1 accounts for total attendance, which in some conference years comprised both in-person and virtual attendance.

Demographic Breakdown

The data in the subsequent figures is derived from a survey completed by participants who agreed to aggregate their information. One component of the WiML survey asked attendees at the WiML workshop

where they live. Among respondents, 56.4% hailed from North America, followed by Europe (21.8%), Asia (11.4%), and Africa (8.9%) (Figure 8.2.3). At this year’s workshop, there was a greater proportion of North American attendees than in 2022.

Figure 8.2.4

This section uses data from [Code.org](https://code.org), a U.S. nonprofit dedicated to advancing CS education in K–12 schools across the country, to paint a picture of how AI diversity trends are reflected at the K–12 level.

8.3 K–12 Education

AP Computer Science: Gender

In 2022, male students accounted for 68.9% of AP CS exam-takers, female students 30.5%, and students identifying as neither male nor female 0.7% (Figure

8.3.1).⁶ While male students continue to dominate AP CS exam participation, the proportion of female students has nearly doubled over the past decade.

AP computer science exams taken (% of total) by gender, 2007–22

Source: Code.org, 2023 | Chart: 2024 AI Index report

Figure 8.3.1

⁶ There are two types of AP CS exams: Computer Science A and Computer Science Principles. Data on computer science exams taken includes both exams. AP CS Principles was initially offered in 2017.

On a percentage basis, the states with the highest number of female AP CS test-takers in 2022 were Mississippi (41%), Alabama (37%), and Washington, D.C. (37%) (Figure 8.3.2). California, Texas, and Washington, states known for significant CS and AI activity, also saw notable participation, with approximately 30% of AP CS exam-takers being female.

AP computer science exams taken by female students (% of total), 2022

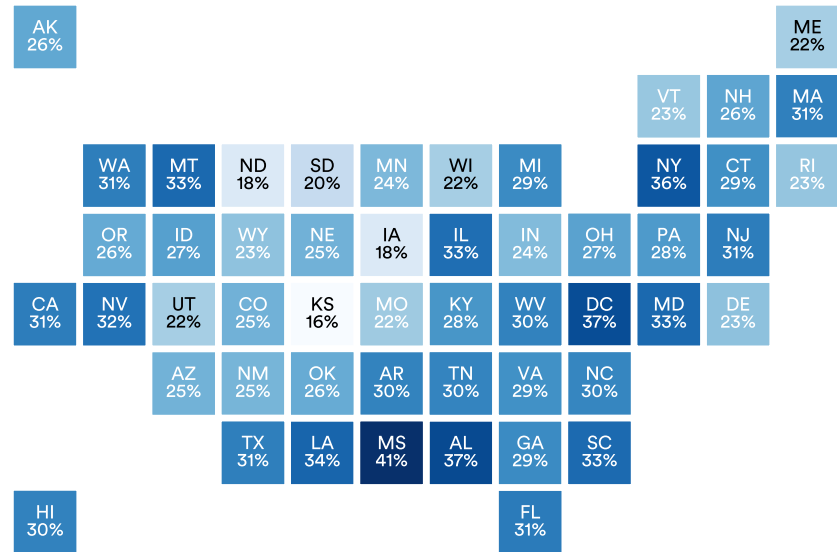

Figure 8.3.2

AP Computer Science: Ethnicity

Code.org’s data highlights the evolving ethnic diversity among AP CS test-takers. Similar to trends in postsecondary CS, the ethnic diversity of AP CS test-takers is increasing. While white students remain

the largest group, the participation of Asian, Hispanic/Latino/Latina, and Black/African American students in AP CS exams has grown over time (Figure 8.3.3). In 2022, white students constituted the largest share of exam-takers (38.2%), followed by Asian (27.8%) and Hispanic/Latino/Latina students (17.6%) (Figure 8.3.3 and Figure 8.3.4).

[ACCESS THE PUBLIC DATA](#)

Overview

As AI becomes increasingly ubiquitous, it is important to understand how public perceptions regarding the technology evolve. Understanding this public opinion is vital in better anticipating AI's societal impacts and how the integration of the technology may differ across countries and demographic groups.

This chapter examines public opinion on AI through global, national, demographic, and ethnic perspectives. It draws upon several data sources: longitudinal survey data from Ipsos profiling global AI attitudes over time, survey data from the University of Toronto exploring public perception of ChatGPT, and data from Pew examining American attitudes regarding AI. The chapter concludes by analyzing mentions of significant AI models on Twitter, using data from Quid.

Chapter Highlights

1. People across the globe are more cognizant of AI’s potential impact—and more nervous.

A survey from Ipsos shows that, over the last year, the proportion of those who think AI will dramatically affect their lives in the next three to five years has increased from 60% to 66%. Moreover, 52% express nervousness toward AI products and services, marking a 13 percentage point rise from 2022. In America, Pew data suggests that 52% of Americans report feeling more concerned than excited about AI, rising from 38% in 2022.

2. AI sentiment in Western nations continues to be low, but is slowly improving. In 2022, several developed Western nations, including Germany, the Netherlands, Australia, Belgium, Canada, and the United States, were among the least positive about AI products and services. Since then, each of these countries has seen a rise in the proportion of respondents acknowledging the benefits of AI, with the Netherlands experiencing the most significant shift.

3. The public is pessimistic about AI’s economic impact. In an Ipsos survey, only 37% of respondents feel AI will improve their job. Only 34% anticipate AI will boost the economy, and 32% believe it will enhance the job market.

4. Demographic differences emerge regarding AI optimism. Significant demographic differences exist in perceptions of AI’s potential to enhance livelihoods, with younger generations generally more optimistic. For instance, 59% of Gen Z respondents believe AI will improve entertainment options, versus only 40% of baby boomers. Additionally, individuals with higher incomes and education levels are more optimistic about AI’s positive impacts on entertainment, health, and the economy than their lower-income and less-educated counterparts.

5. ChatGPT is widely known and widely used. An international survey from the University of Toronto suggests that 63% of respondents are aware of ChatGPT. Of those aware, around half report using ChatGPT at least once weekly.

9.1 Survey Data

Global Public Opinion

This section explores global differences in AI opinions through surveys conducted by Ipsos in 2022 and 2023. These surveys reveal that public perceptions of AI vary widely across countries and demographic groups.

AI Products and Services

In 2023, Ipsos ran a survey on global attitudes toward AI products and services. The survey consisted of interviews with 22,816 adults ages 16 to 74 in 31 countries.¹

Figure 9.1.1 shows the percentage of respondents who agree with specific statements. A significant 66% anticipate AI will greatly change their lives in the

near future, while 54% believe AI’s benefits surpass its drawbacks. About half of the respondents trust AI companies’ data-protection capabilities.

The figure also contrasts Ipsos survey responses from 2022 and 2023, highlighting a shift in public AI sentiment following the release of ChatGPT—a milestone in public AI recognition. Over the last year, there has been a noticeable 6 percentage point increase in those who think AI will dramatically affect their lives in the next three to five years. Moreover, 52% now express nervousness toward AI products and services, marking a 13 percentage point rise from 2022. The public across the globe is becoming increasingly cognizant of and nervous about AI’s growing impact.

Global opinions on products and services using AI (% of total), 2022 vs. 2023

Source: Ipsos, 2022–23 | Chart: 2024 AI Index report

Figure 9.1.1

¹ See Appendix for more details about the survey methodology. The survey was conducted from May to June 2023.

Perceptions of AI's benefits versus drawbacks vary considerably by country, according to the Ipsos survey. 78% of Indonesian, 74% of Thai, and 73% of Mexican respondents view AI products and services as more beneficial than harmful (Figure 9.1.2). In contrast, only 37% of Americans agree with this perspective. Among the 31 countries surveyed, the United States and France exhibited the most skepticism.

Attitudes toward AI are becoming more positive in countries that were previously critical. In 2022, several

developed Western nations, including Germany, the Netherlands, Australia, Belgium, Canada, and the United States, were among the least positive about AI products and services. Since then, each of these countries has seen a rise in the proportion of respondents acknowledging the benefits of AI, with the Netherlands experiencing the most significant shift. By 2023, 43% of Dutch respondents viewed AI products and services positively, up from 33% the previous year.

'Products and services using AI have more benefits than drawbacks,' by country (% of total), 2022 vs. 2023

Source: Ipsos, 2022–23 | Chart: 2024 AI Index report

Figure 9.1.2

Figure 9.1.3 shows responses to Ipsos' survey on AI products and services by country. Indonesian respondents are notably optimistic: 84% claim a solid understanding of AI, 79% believe AI will significantly change their lives in the next three to five years, and 75% express excitement about AI products and services.

Conversely, Japanese respondents show the least understanding of AI (43%) and also report the lowest level of nervousness about AI (23%). Meanwhile, Thai respondents exhibit the highest trust in AI's impartiality, believing it will not discriminate or show bias toward any group.

Opinions about AI by country (% agreeing with statement), 2023

Source: Ipsos, 2023 | Chart: 2024 AI Index report

Figure 9.1.3

A large majority of the countries surveyed by Ipsos in 2022 were surveyed again in 2023, enabling cross-year comparisons. Figure 9.1.4 highlights the year-over-year percentage point change in answers to particular AI-related questions. For every country surveyed in both 2022 and 2023, an increase was reported in the degree to which AI products make people nervous. The sharpest increases were reported in Italy

(24 percentage points), France (19), Chile (18), and Australia (18).

Likewise, except for South Africa, all countries in the survey sample are now more inclined to believe that AI will significantly impact their lives in the next three to five years. The highest increase of 12 percentage points was reported in Japan, Great Britain, Germany, and Australia.

Figure 9.1.4

AI and Jobs

This year’s Ipsos survey included more questions about how people perceive AI’s impact on their current jobs. Figure 9.1.5 illustrates the various global perspectives on the expected impact of AI on employment. 57%

of respondents think AI is likely to change how they perform their current job within the next five years, and 36% fear AI may replace their job in the same time frame.

Global opinions on the impact of AI on current jobs, 2023

Source: Ipsos, 2023 | Chart: 2024 AI Index report

Figure 9.1.5

Opinions on whether AI will significantly impact an individual’s job vary significantly across demographic groups (Figure 9.1.6). Younger generations, such as Gen Z and millennials, are more inclined to agree that AI will change how they do their jobs compared to older generations like Gen X and baby boomers.

Specifically, 66% of Gen Z compared to 46% of boomer respondents agree with the statement that AI will likely affect their current jobs. Additionally, individuals with higher incomes, more education, and decision-making roles are more likely to foresee AI impacting their current employment.

Global opinions on the impact of AI on current jobs by demographic group, 2023

Source: Ipsos, 2023 | Chart: 2024 AI Index report

Figure 9.1.6

AI and Livelihood

The Ipsos survey explored the impact respondents believe AI will have on various aspects of their lives, such as health and entertainment. On topics like time management and entertainment, the majority viewed AI positively (Figure 9.1.7). For instance, 54% of global respondents agree that AI will improve the efficiency of their tasks, and 51% believe AI will enhance entertainment options like TV, movies, music, and books. However, skepticism was more prominent in other areas. Only 39% feel AI will benefit their health, and 37% think it will improve their job. Only 34% anticipate AI will boost the economy, and just 32% believe it will enhance the job market.

and 37% think it will improve their job. Only 34% anticipate AI will boost the economy, and just 32% believe it will enhance the job market.

Similar to questions about AI products and services, responses showed intracountry consistency, with Japanese, Swedes, and Americans generally pessimistic about AI’s potential to improve livelihoods, whereas Brazilians, Indonesians, and Mexicans were more optimistic.

Global opinions on the potential of AI improving life by country, 2023

Source: Ipsos, 2023 | Chart: 2024 AI Index report

Figure 9.1.7

Significant demographic differences also exist in perceptions of AI’s potential to enhance livelihoods, with younger generations generally expressing greater optimism. For instance, 59% of Gen Z respondents believe AI will improve entertainment options, versus only 40% of baby boomers. Additionally, individuals with higher incomes and education levels are more optimistic about AI’s positive impacts on

entertainment, health, and the economy compared to their lower-income and less-educated counterparts. In general, members of Gen Z, those in higher income brackets, and those with more education are the most optimistic about AI’s potential to improve life, while those from the boomer generation, lower income brackets, and with less education are the least optimistic.

Figure 9.1.8

Attitudes on ChatGPT

Many argue that the launch of ChatGPT by OpenAI in November 2022 was a watershed moment in familiarizing the public with AI. While AI encompasses much more than ChatGPT or LLMs, the prominence of ChatGPT as one of the most well-known AI tools makes gauging public sentiment toward it an interesting approach for better understanding broader opinions on AI.

Global Public Opinion on Artificial Intelligence (GPO-AI) is a report created by the Schwartz Reisman Institute for Technology and Society (SRI) in collaboration with the Policy, Elections and Representation Lab (PEARL) at the Munk School of Global Affairs and Public Policy at the University of

Toronto. In October and November 2023, researchers from SRI and PEARL conducted a 21-country survey examining global attitudes toward AI.

Figure 9.1.9 explores the extent of global public awareness of ChatGPT. Among global respondents, 63% claim awareness of ChatGPT. Countries with the highest awareness rates include India (82%), Kenya (81%), Indonesia (76%), and Pakistan (76%). Poland reported the lowest awareness, at 43%.

Figure 9.1.10 highlights how frequently respondents who report being familiar with ChatGPT use the tool. Globally, 17% of users utilize it daily, 36% weekly, and 16% monthly. India (36%), Pakistan (28%), and Kenya (27%) report the highest levels of daily usage.

Figure 9.110

AI Concerns

GPO-AI also reported on respondents' AI-related concerns. Figure 9.1.11 presents the percentage of survey respondents who expressed concern about 11 specific impacts. Globally, individuals were most concerned about AI being misused for nefarious

purposes (49%), its impact on jobs (49%), and its potential to violate citizens' privacy (45%). In contrast, global citizens were comparatively less concerned about issues of unequal access to AI (26%), AI's potential for bias and discrimination (24%), and their own ability to use AI (22%).

Figure 9.1.11

U.S. Public Opinion

Since 2021, Pew Research Center has been investigating sentiment toward AI in the United States. They received 11,000 responses to their most recent 2023 survey.

Figure 9.1.12 shows that over the last year, Americans have grown increasingly concerned about the use of AI in their daily lives. In 2021 and 2022, only 37% and 38% of Americans, respectively, reported feeling more concerned than excited about AI technology. By 2023, this figure had risen to 52%, indicating that a majority of Americans now feel more concerned than excited about AI technology.

Americans' feelings toward increased use of AI in daily life (% of total), 2021–23

Source: Pew Research, 2023 | Chart: 2024 AI Index report

Figure 9.1.12

Pew also surveyed Americans' opinions on whether they believed AI helped or hindered in specific contexts (Figure 9.1.13). Respondents reported that AI was more likely to be beneficial, particularly in assisting people to find products or services online, with 49% expressing this view. However, 53% of respondents indicated that AI was more likely to be detrimental than beneficial in safeguarding personal information privacy.

Americans' opinions of whether AI helps or hurts in specific settings (% of total), 2023

Source: Pew Research, 2023 | Chart: 2024 AI Index report

Figure 9.1.13

Pew further segmented the data by education level (Figure 9.1.14). Across various use categories, Americans with higher education levels are more likely to believe in AI's potential to help rather than harm. For instance, individuals with college or higher-

level degrees are more likely to report that AI can significantly aid doctors in delivering quality care to patients and assist people in discovering products and services online that interest them.

Differences in Americans' view of AI's impact by education level (% of total), 2023

Figure 9.1.14

9.2 Social Media Data

Dominant Models

Public attitudes toward AI can be assessed through both quantitative and qualitative analyses of posts made on social media. Quid analyzed social conversations surrounding AI models across various sectors from January to December 2023, examining over 7 million social media posts.

Figure 9.2.1 shows the net sentiment score of various AI models released throughout the year. The net

sentiment score expresses the ratio of positive to negative sentiment around a given topic. A net sentiment score of +100 means that all conversation is positive; a score of -100 means that all conversation is negative. Many models released in 2023 received positive social media sentiment. Some of the models that garnered the highest degree of positive attention were GraphCast, a new AI-powered weather forecasting system from DeepMind, and Claude 2.1, one of Anthropic’s most recent LLMs.

Net sentiment score of AI models by quarter, 2023

Source: Quid, 2023 | Chart: 2024 AI Index report

	2023/Q1	2023/Q2	2023/Q3	2023/Q4

Figure 9.2.2

² The figures in this section consider all AI-related social media conversation. The percentage associated with a model in a quarter in Figure 9.2.2 represents the share of all AI-related social media conversation in that quarter that was concerned with that model.

Highlight:

AI-Related Social Media Discussion in 2023

The following section, featuring data from Quid, profiles specific narratives surrounding the discussion of AI that occurred on social media in 2023. GPT-4 gathered most of the discussion volume in Q2 after its launch on March 14, 2023. Positive sentiment was primarily driven by its improvements, including faster processing speed, improved accuracy, and praise for its ability to enhance productivity across different types of work tasks, such as coding, corporate collaboration, and content creation. Negative sentiment primarily stemmed from complaints about occasional crashes of the ChatGPT website, along with an open letter led by Elon Musk and supported by over 1,300 artificial intelligence experts, urging AI laboratories to pause training of powerful AI systems. Moreover, there was disagreement regarding the “open letter” and the suggestion to halt AI research, particularly considering its potential to have a positive impact across multiple fields. For example, Andrew Ng posted:

“1/The call for a 6 month moratorium on making AI progress beyond GPT-4 is a terrible idea. I’m seeing many new applications in education, healthcare, food, ... that’ll help many people. Improving GPT-4 will help. Lets balance the huge value AI is creating vs. realistic risks.” — @AndrewYNg

In Q4 2023, discussions surrounding the release of GPT-4 Turbo, launched in November, saw a significant increase. Positive sentiment centered around its innovative features and upgrades that could transform programmers’ workflows. These enhancements included longer conversation capabilities, improved contextual understanding, and multimodal ability to generate images. However, some negative feedback arose due to disappointment with the model’s knowledge cutoff in April 2023 and slower loading speeds compared to GPT-4. Some of the sample social media posts from this time included:

*“This is just insane... My GPT-4 coding assistant can now: - build and design a frontend - create a backend with working db - correctly hook them up - upload code to GitHub - deploy it to Vercel[.] I can now build *complete* apps with nothing more than my voice. The future is here!” — @mckaywrigley*

“Trying to make my LinkedIn profile more interesting if a recruiter is using a large language model like GPT-4 to send me a message. Looks like it works on the public version of my profile!” — @brdskggs

“GPT-4 Turbo has knowledge of the world up to April 2023. @sama says the team is ‘just as annoyed as you, maybe more’ that the knowledge is not more updated and that @openai will work to make sure it never gets that outdated again.” — @VentureBeat

Highlight:

AI-Related Social Media Discussion in 2023 (cont'd)

Discussions about Stable Diffusion were more prominent in the first half of 2023, but decreased toward the year's end. More posts mentioned Stable Diffusion XL models than Stable Diffusion 2.0 (around 16 times more). Positive sentiment was mainly driven by the tool's rapid increase in popularity, the potential benefits of AI in enhancing creativity, and the excitement surrounding technical advancements and improvements (e.g., enhanced accuracy, better understanding of various concepts, and higher resolution). On the other hand, negative sentiment revolved around concerns about legal and ethical issues related to AI-generated content, such as copyright violations, ownership of AI-created material, and the possible replacement of human artists by AI. Additionally, worries were expressed about the risks and threats linked to artificial intelligence, like its potential harmful effects, the spread of misinformation, and the possibility of AI being used for academic cheating.

“Very happy about sharing smashed Stable Diffusion models! - In one line of code, we compressed popular text-to-image Stable Diffusion models for A100. - Evaluations across various metrics show significant speedup improvements, energy savings, and CO2 emissions savings. Now looking forward [to] sharing more compression results :) Feel free to contact us to achieve the same on your own models <https://pruna.ai/contact> ;)”
— [@Bertrand_Charp](#)

“Stable Diffusion XL with ControlNet is insane 🔥 Discover the future of AI with Stability AI's latest innovation: Stable Diffusion XL (SDXL) 1.0! This powerful text-to-image generation model improves image quality and makes it easier for users to create highly detailed images. Built on a massive 3.5 billion-parameter base model, SDXL 1.0 boasts better accuracy and understanding of various concepts. Want to know more? Check out my video where I delve deeper into this groundbreaking technology!” — [@work.with.ai](#)

Both Gemini (from Google) and Grok (from xAI) saw an increase in conversations during Q4 due to their late year launches. Positive feedback for Gemini focused on its improved accuracy and multilingual capabilities, as well as its potential to enhance various Google services like Search and Ads. On the other hand, negative opinions stemmed from concerns about inaccurate results, disappointment over Gemini's delayed release, and skepticism toward the Gemini AI demo.

“WHAT IS GOOGLE GEMINI AND HOW CAN YOU USE IT?” — [Erik Hyrkas](#)

“Gemini Ultra (if Google is honest) Will Blow Our Minds 🤖” — [Tina Huang](#)

Chapter 1: Research and Development

Acknowledgments

The AI Index would like to acknowledge Ben Cottier and Robi Rahman from Epoch for leading the work analyzing machine learning training costs; Robi Rahman for leading work regarding the national affiliation of notable systems; and James da Costa, for doing coding work instrumental to the sectoral and national affiliation analysis of foundation models.

AI Conference Attendance

The AI Index reached out to the organizers of various AI conferences in 2023 and asked them to provide information on total attendance. Some conferences posted their attendance totals online; when this was the case, the AI Index used those reported totals and did not reach out to the conference organizers.

CSET

Prepared by Autumn Toney

The Center for Security and Emerging Technology (CSET) is a policy research organization within Georgetown University’s Walsh School of Foreign Service that produces data-driven research at the intersection of security and technology, providing nonpartisan analysis to the policy community.

For more information about how CSET analyzes bibliometric and patent data, see the Country Activity Tracker (CAT) documentation on the Emerging

Technology Observatory’s website.¹ Using CAT, users can also interact with country bibliometric, patent, and investment data.²

Publications From CSET Merged Corpus of Scholarly Literature

Sources

CSET’s merged corpus of scholarly literature combines distinct publications from Clarivate’s Web of Science, OpenAlex, The Lens, Semantic Scholar, arXiv, and Papers With Code.

Updates: The source list of scholarly literature for CSET’s merged corpus has been changed from prior years, with the inclusion of OpenAlex, the Lens, and Semantic Scholar, and the exclusion of Digital Science’s Dimensions and the Chinese National Knowledge Infrastructure (CNKI).

Methodology

To create the merged corpus, CSET deduplicated across the listed sources using publication metadata, and then combined the metadata for linked publications. For analysis of AI publications, CSET used an English-language subset of this corpus published since 2010. CSET researchers developed a classifier for identifying AI-related publications by leveraging the arXiv repository, where authors and editors tag papers by subject.³

Updates: The AI classifier was updated from the version used in prior years; Dunham, Melot, and Murdick⁴ describe the previously implemented

¹ <https://eto.tech/tool-docs/cat/>

² <https://cat.eto.tech/>

³ Christian Schoeberl, Autumn Toney, and James Dunham, “Identifying AI Research” (Center for Security and Emerging Technology, July 2023), <https://doi.org/10.51593/20220030>.

⁴ James Dunham, Jennifer Melot, and Dewey Murdick, “Identifying the Development and Application of Artificial Intelligence in Scientific Text,” arXiv preprint, arXiv:2002.07143 (2020).

classifier; and Schoeberl, Toney, and Dunham describe the updated classifier used in this analysis.

CSET matched each publication in the analytic corpus with predictions from a field-of-study model derived from Microsoft Academic Graph (MAG)'s taxonomy, which yields hierarchical labels describing the published research field(s) of study and corresponding scores.⁵ CSET researchers identified the most common fields of study in our corpus of AI-relevant publications since 2010 and recorded publications in all other fields as "Other AI." English-language AI-relevant publications were then tallied by their top-scoring field and publication year.

Updates: The methodology to assign MAG fields of study was updated from the methodology used in prior years. Toney and Dunham describe the field of study assignment pipeline used in this analysis; prior years used the original MAG implementation.

CSET also provided publication counts and year-by-year citations for AI-relevant work associated with each country. A publication is associated with a country if it has at least one author whose organizational affiliation(s) is located in that country. If there is no observed country, the publication receives an "Unknown/Missing" country label. Citation counts aren't available for all publications; those without counts weren't included in the citation analysis. Over 70% of English-language AI papers published between 2010 and 2022 have citation data available.

Additionally, publication counts by year and by

publication type (e.g., academic journal articles, conference papers) were provided where available. These publication types were disaggregated by affiliation country as described above.

CSET also provided publication affiliation sector(s) where, as in the country attribution analysis, sectors were associated with publications through authors' affiliations. Not all affiliations were characterized in terms of sectors; CSET researchers relied primarily on ROR for this purpose, and not all organizations can be found in or linked to ROR.⁶ Where the affiliation sector is available, papers were counted toward these sectors, by year.

CSET counted cross-sector collaborations as distinct pairs of sectors across authors for each publication. Collaborations are only counted once: For example, if a publication has two authors with an academic affiliation and two with an industry affiliation, it is counted as a single academic-industry collaboration.

Patents From CSET's AI and Robotics Patents Dataset

Source

CSET's AI patents dataset was developed by CSET and 1790 Analytics and includes data from The Lens, 1790 Analytics, and EPO's PATSTAT. Patents relevant to the development and application of AI and robotics were identified by their CPC/IPC codes and keywords.

Methodology

In this analysis, patents were grouped by year and country, and then counted at the "patent family"

⁵ These scores are based on cosine similarities between field-of-study and paper embeddings. See Autumn Toney and James Dunham, "Multi-Label Classification of Scientific Research Documents Across Domains and Languages," *Proceedings of the Third Workshop on Scholarly Document Processing* (Association for Computational Linguistics, 2022): 105–14, <https://aclanthology.org/2022.sdp-1.12/>.

⁶ See <https://ror.org/> for more information about the ROR dataset.

⁷ Patents are analyzed at the "patent family" level rather than "patent document" level because patent families are a collective of patent documents all associated with a single invention and/or innovation by the same inventors/assignees. Thus, counting at the "patent family" level mitigates artificial number inflation when there are multiple patent documents in a patent family or if a patent is filed in multiple jurisdictions.

level.⁷ CSET extracted year values from the first publication date within a family. Countries are assigned to patents based on the country or filing office where a patent is first filed (e.g., if a patent is filed with the USPTO on January 1, 2020, and then with the German Patenting Office on January 2, 2020, the patent is classified as a patent with U.S. inventors).⁸ Note that the same patent may have multiple countries (but not years) attributed to it if the inventors filed their patent in multiple countries on the same first filing date (e.g., if a patent is filed with the USPTO on January 1, 2020, and then with the German Patenting Office on January 1, 2020, the patent is classified as a patent with U.S. inventors and as a patent with German inventors).

Note that patents filed with supranational organizations, such as patents filed under WIPO (the World Intellectual Property Organization), EP (European Patent Organization), and EA (a special area of Spain not included in the European Union), also fall under the “Rest of World” category.

Ecosystems Graph Analysis

To track the distribution of AI foundation models by country, the AI Index team took the following steps:

1. A snapshot of the Ecosystems Graph was taken in early January 2024.
2. Authors of foundation models are attributed to countries based on their affiliation credited on the paper/technical documentation associated with the model. For international organizations, authors are attributed to the country where the organization is headquartered, unless a more specific location is indicated.

3. All of the landmark publications are aggregated within time periods (e.g., monthly or yearly) with the national contributions added up to determine what each country’s contribution to landmark AI research was during each time period.
4. The contributions of different countries are compared over time to identify any trends.

Epoch Notable Models Analysis

The AI forecasting research group Epoch maintains a dataset of landmark AI and ML models, along with accompanying information about their creators and publications, such as the list of their (co)authors, number of citations, type of AI task accomplished, and amount of compute used in training.

The nationalities of the authors of these papers have important implications for geopolitical AI forecasting. As various research institutions and technology companies start producing advanced ML models, the global distribution of future AI development may shift or concentrate in certain places, which in turn affects the geopolitical landscape because AI is expected to become a crucial component of economic and military power in the near future.

To track the distribution of AI research contributions on landmark publications by country, the Epoch dataset is coded according to the following methodology:

⁸ In CSET’s data analysis for the 2022 AI Index, we used the most recent publication date for a patent family. This method has the advantage of capturing updates within a patent family (such as amendments). However, to remain consistent with CSET’s other data products, including the Country Activity Tracker (available at <https://cat.eto.tech/>), we opted to use the first filing year instead in this data analysis.

1. A snapshot of the dataset was taken on January 1, 2024. This includes papers about landmark models, selected using the inclusion criteria of importance, relevance, and uniqueness, as described in the Compute Trends dataset documentation.
2. The authors are attributed to countries based on their affiliation credited on the paper. For international organizations, authors are attributed to the country where the organization is headquartered, unless a more specific location is indicated.
3. All of the landmark publications are aggregated within time periods (e.g., monthly or yearly) with the national contributions added up to determine what each country's contribution to landmark AI research was during each time period.
4. The contributions of different countries are compared over time to identify any trends.

GitHub

Identifying AI Projects

In partnership with researchers from Harvard Business School, Microsoft Research, and Microsoft's AI for Good Lab, GitHub identifies public AI repositories following the methodologies of [Gonzalez, Zimmerman, and Nagappan, 2020](#), and [Dohmke, Iansiti, and Richards, 2023](#), using topic labels related to AI/ML and generative AI, respectively, along with the topics “machine learning,” “deep learning,” or “artificial intelligence.” GitHub further augments the dataset with repositories that have a dependency on the PyTorch, TensorFlow, or OpenAI libraries for Python.

⁹ The selected cutoff date was September 1, 2015, in accordance with [Compute Trends Across Three Eras of Machine Learning](#) (Epoch, 2022).

¹⁰ Historic prices were collected from archived snapshots of Amazon Web Services, Microsoft Azure, and Google Cloud Platform price catalogs viewed through the [Internet Archive Wayback Machine](#).

Mapping AI Projects to Geographic Areas

Public AI projects are mapped to geographic areas using IP address geolocation to determine the mode location of a project's owners each year. Each project owner is assigned a location based on their IP address when interacting with GitHub. If a project owner changes locations within a year, the location for the project would be determined by the mode location of its owners sampled daily in the year. Additionally, the last known location of the project owner is carried forward on a daily basis even if no activities were performed by the project owner that day. For example, if a project owner performed activities within the United States and then became inactive for six days, that project owner would be considered to be in the United States for that seven-day span.

Training Cost Analysis

To create the dataset of cost estimates, the [Epoch database](#) was filtered for models released during the large-scale ML era⁹ that were above the median of training compute in a two-year window centered on their release date. This filtered for the largest-scale ML models. There were 138 qualifying systems based on these criteria. Of these systems, 48 had sufficient information to estimate the training cost.

For the selected ML models, the training time and the type, quantity, and utilization rate of the training hardware were determined from the publication, press release, or technical reports, as applicable. Cloud rental prices for the computing hardware used by these models were collected from online historical archives of cloud vendors' websites.¹⁰

Training costs were estimated from the hardware type, quantity, and time by multiplying the hourly cloud rental cost rates (at the time of training)¹¹ by the quantity of hardware hours. This yielded the cost to train each model using the same hardware used by the authors to train the same model at the time. However, some developers purchased hardware rather than renting cloud computers, so the true costs incurred by the developers may vary.

Various challenges were encountered while estimating the training cost of these models. Often, the developers did not disclose the duration of training or the hardware that was used. In other cases, cloud compute pricing was not available for the hardware. The investigation of training cost trends is continued in a forthcoming Epoch report, including an expanded dataset with more models and hardware prices.

¹¹ The chosen rental cost rate was the most recent published price for the hardware and cloud vendor used by the developer of the model, at a three-year commitment rental rate, after subtracting the training duration and two months from the publication date. If this price was not available, the most analogous price was used: the same hardware and vendor at a different date, otherwise the same hardware from a different cloud vendor. If a three-year commitment rental rate was unavailable, this was imputed from other rental rates based on the empirical average discount for the given cloud vendor. If the exact hardware type was not available, e.g., “NVIDIA A100 SXM4 40GB,” then a generalization was used, e.g., “NVIDIA A100.”

Chapter 2: Technical Performance

Acknowledgments

The AI Index would like to acknowledge Andrew Shi for his work doing a literature review on the environmental impact of AI models; Emily Capstick for her work studying the use of RLHF in machine learning models; Sukrut Oak for his work generating sample Midjourney generations; and Emma Williamson for her work identifying significant AI technical advancements for the timeline.

Environmental Impact

To assess the environmental impact of AI models, the AI Index team surveyed technical reports of prominent foundation models to determine whether the model developers disclosed carbon emissions. The Index also reviewed papers by researchers that estimated the carbon footprint of various models. The technical reports surveyed, as well as the papers estimating the carbon impact of various models, are included in the works cited for this chapter.

RLHF

To identify foundation models using RLHF, the AI Index team reviewed the technical documentation of every foundation model included in the [Ecosystem Graph](#), and searched for evidence that RLHF had been used in the model's development process. The year in which a model is said to have used RLHF refers to the year the model was released.

Chapter 3: Responsible AI

Acknowledgments

The AI Index would like to acknowledge Amelia Hardy for her work contributing as a research assistant to visualizations and supplementary analysis for this chapter, and Andrew Shi for his work spearheading the analysis of responsible AI-related conference submissions. The AI Index also acknowledges that the Global State of Responsible AI analysis was done in collaboration with Accenture. The AI Index specifically wants to highlight the contributions of Arnab Chakraborty, Patrick Connolly, Jakub Wiatrak, Ray Eitel-Porter, Dikshita Venkatesh, and Shekhar Tewari to the data collection and analysis.

Conference Submissions Analysis

For the analysis on responsible AI-related conference submissions, the AI Index examined the number of responsible AI-related academic submissions at the following conferences: [AAAI](#), [AIES](#), [FAccT](#), [ICML](#), [ICLR](#), and [NeurIPS](#). Specifically, the team scraped the conference websites or repositories of conference submissions for papers containing relevant keywords indicating they could fall into a particular responsible AI category. The papers were then manually verified by a human team to confirm their categorization. It is possible that a single paper could belong to multiple responsible AI categories.

The keywords searched include:

Fairness and bias: algorithmic fairness, bias detection, bias mitigation, discrimination, equity in AI, ethical algorithm design, fair data practices, fair ML, fairness and bias, group fairness, individual fairness, justice, non-discrimination, representational fairness, unfair, unfairness.

Privacy and data governance: anonymity, confidentiality, data breach, data ethics, data governance, data integrity, data privacy, data protection, data transparency, differential privacy, inference privacy, machine unlearning, privacy by design, privacy-preserving, secure data storage, trustworthy data curation.

Security: adversarial attack, adversarial learning, AI incident, attacks, audits, cybersecurity, ethical hacking, forensic analysis, fraud detection, red teaming, safety, security, security ethics, threat detection, vulnerability assessment.

Transparency and explainability: algorithmic transparency, audit, auditing, causal reasoning, causality, explainability, explainable AI, explainable models, human-understandable decisions, interpretability, interpretable models, model explainability, outcome explanation, transparency, xAI.

Consistency of Responsible AI Benchmark Reporting

For each of the analyzed models (GPT-4, Gemini, Claude 2, Llama 2, Mistral 7B), the AI Index reviewed the official papers published by the model developers at the time of model release for reported academic benchmarks. The AI Index did not consider subsequent benchmark reports by the model developers or external parties. The AI Index also did not include benchmarks on academic or professional exams (e.g., the GRE), benchmarks for modalities other than text, or internal evaluation metrics.

Global Responsible State of AI Survey

Researchers from Stanford conducted a global responsible AI (RAI) survey in collaboration with Accenture. The objective of the questionnaire was to gain an understanding of the current level of RAI adoption globally and allow for a comparison of RAI activities across 19 industries and 22 countries. The survey is further used to develop an early snapshot of current perceptions around the responsible development, deployment, and use of generative AI and how this might affect RAI adoption and mitigation techniques. The survey covers a total of 10 RAI dimensions: Reliability; Privacy and Data Governance; Fairness and Nondiscrimination; Transparency and Explainability; Human Interaction; Societal and Environmental Well-Being; Accountability; Leadership/Principles/Culture; Lawfulness and Compliance; and Organizational Governance. Only some of the survey findings are presented in the AI Index, with a more detailed report, the Global State of Responsible AI Report, coming out in May/June 2024.

Given the limited scalability of user interviews, the researchers opted for a questionnaire-based approach to ensure broad coverage of organizations in different countries and industries. They contracted McGuire Research to run the recruitment and data collection. The team received more than 15,897 responses from 22 countries and 19 industries. The respondents were asked 10 qualifier questions in the survey. Companies were excluded if their global annual revenue was less than 500 million USD and/or the respondent had no visibility into the RAI decision-making process of the company. Included in the final sample were more than 1,000 organizations. The survey had a total of 38 questions, including the 10 qualifier questions.

Below is the full list of measures respondents were asked about in the survey and which were referenced in the AI Index subchapters. The organizations could answer on a scale from *Not applied*, *Ad-hoc*, *Rolling out*, or *Fully operationalized*. The companies were further given the option to select Other and provide information on mitigation measures not listed.

Fairness measures:

- Collection of representative data based on the anticipated user demographics
- Making methodology and data sources accessible to third parties (auditors/general public) for independent oversight
- Involvement of diverse stakeholders in model development and/or review process
- Assessment of performance across different demographic groups
- Use of technical bias mitigation techniques during model development
- Other (selection of this option opened an optional free-text field)

Data governance measures:

- Checks to ensure that the data complies with all relevant laws and regulations and is used with consent, where applicable
- Data collection and preparation include assessment of the completeness, uniqueness, consistency, and accuracy of the data
- Checks to ensure that the data is representative with respect to the demographic setting within which the final model/system is used
- Regular data audits and updates to ensure the relevancy of the data
- Process for dataset documentation and traceability throughout the AI life cycle
- Remediation plans for and documentation of datasets with shortcomings
- Other (selection of this option opened an optional free-text field)

Transparency and explainability:

- Documentation of the development process, detailing algorithm design choices, data sources, intended use cases, and limitations
- Training programs for stakeholders (incl. users) covering the intended use cases and limitations of the model
- Prioritization of simpler models where high interpretability is crucial, even if it sacrifices some performance
- Use model explainability tools (e.g., saliency maps) to elucidate model decisions
- Other (selection of this option opened an optional free-text field)

Reliability measures:

- Mitigation measures for model errors and handling low confidence outputs
- Failover plans or other measures to ensure the system's/model's availability
- Evaluation of models/systems for vulnerabilities or harmful behavior (i.e., red teaming)
- Measures to prevent adversarial attacks
- Confidence scoring for model outputs
- Comprehensive test cases that cover a wide range of scenarios and metrics
- Other (selection of this option opened an optional free-text field)

Security measures:

- Basic cybersecurity hygiene practices (e.g., multifactor authentication, access controls, and employee training)
- Vetting and validation of cybersecurity measures of third parties in the supply chain
- Dedicated AI cybersecurity team and/or personnel explicitly trained for AI-specific cybersecurity
- Technical AI-specific cybersecurity checks and measures, e.g., adversarial testing, vulnerability assessments, and data security measures
- Resources dedicated to research and monitoring of evolving AI-specific cybersecurity risks and integration in existing cybersecurity processes
- Other (selection of this option opened an optional free-text field)

Chapter 4: Economy

Acknowledgments

The AI Index would like to acknowledge James da Costa for his work collecting information on significant AI-related economic events, and Emma Williamson for her work collecting data from the Stack Overflow survey.

International Federation of Robotics (IFR)

Data presented in the Robot Installations section was sourced from the “[World Robotics 2023](#)” report.

Lightcast

Prepared by Cal McKeever, Julia Nitschke, and Layla O’Kane

Lightcast delivers job market analytics that empower employers, workers, and educators to make data-driven decisions. The company’s artificial intelligence technology analyzes hundreds of millions of job postings and real-life career transitions to provide insight into labor market patterns. This real-time strategic intelligence offers crucial insights, such as what jobs are most in demand, the specific skills employers need, and the career directions that offer the highest potential for workers. For more information, visit www.lightcast.io.

Job Postings Data

To support these analyses, Lightcast mined its dataset of millions of job postings collected since 2010. Lightcast collects postings from over 51,000 online job sites to develop a comprehensive, real-time portrait of labor market demand. It aggregates job postings,

removes duplicates, and extracts data from job postings text. This includes information on job title, employer, industry, and region, as well as required experience, education, and skills.

Job postings are useful for understanding trends in the labor market because they allow for a detailed, real-time look at the skills employers seek. To assess the representativeness of job postings data, Lightcast conducts a number of analyses to compare the distribution of job postings to the distribution of official government and other third-party sources in the United States. The primary source of government data on U.S. job postings is the Job Openings and Labor Turnover Survey (JOLTS) program, conducted by the Bureau of Labor Statistics. Based on comparisons between JOLTS and Lightcast, the labor market demand captured by Lightcast data represents over 99% of the total labor demand. Jobs not posted online are usually in small businesses (the classic example being the “Help Wanted” sign in the restaurant window) and union hiring halls.

Measuring Demand for AI

In order to measure the demand by employers of AI skills, Lightcast uses its skills taxonomy of over 30,000 skills. The list of AI skills from Lightcast data are shown below, with associated skill clusters. While some skills are considered to be in the AI cluster specifically, for the purposes of this report, all skills below were considered AI skills. A job posting was considered an AI job if it mentioned any of these skills in the job text.

Artificial Intelligence: AI/ML Inference, AIOps (Artificial Intelligence for IT Operations), Applications of Artificial Intelligence, Artificial General Intelligence, Artificial Intelligence, Artificial Intelligence Development, Artificial Intelligence Markup Language (AIML), Artificial Intelligence Systems, Azure Cognitive Services, Baidu, Cognitive Automation, Cognitive Computing, Computational Intelligence, Cortana, Ethical AI, Expert Systems, Explainable AI (XAI), IPSoft Amelia, Intelligent Control, Intelligent Systems, Interactive Kiosk, Knowledge Engineering, Knowledge-Based Configuration, Knowledge-Based Systems, Multi-agent Systems, Open Neural Network Exchange (ONNX), OpenAI Gym, Operationalizing AI, Reasoning Systems, Watson Conversation, Watson Studio, Weka

Autonomous Driving: Advanced Driver Assistance Systems, Autonomous Cruise Control Systems, Autonomous System, Autonomous Vehicles, Guidance Navigation and Control Systems, Light Detection and Ranging (LiDAR), OpenCV, Path Analysis, Path Finding, Remote Sensing, Unmanned Aerial Systems (UAS)

Generative Artificial Intelligence: ChatGPT, Generative Adversarial Networks, Generative Artificial Intelligence, Large Language Modeling, Prompt Engineering, Variational Autoencoders

Natural Language Processing (NLP): AI Copywriting, ANTLR, Amazon Textract, Apache OpenNLP, BERT (NLP Model), Chatbot, Computational Linguistics, Conversational AI, Dialog Systems, Fuzzy Logic, Handwriting Recognition, Hugging Face (NLP Framework), Hugging Face Transformers, Intelligent Agent, Intelligent Virtual Assistant, Kaldi, Language Model, Latent Dirichlet Allocation, Lexalytics, Machine Translation, Microsoft LUIS, Natural Language Generation, Natural Language Processing, Natural Language Programming, Natural Language Toolkits,

Natural Language Understanding, Optical Character Recognition (OCR), Screen Reader, Semantic Analysis, Semantic Parsing, Semantic Search, Sentiment Analysis, Seq2Seq, Speech Recognition, Speech Recognition Software, Speech Synthesis, Statistical Language Acquisition, Text Mining, Text-to-Speech, Tokenization, Voice Assistant Technology, Voice Interaction, Voice User Interface, Word Embedding, Word2Vec Models, fastText

Neural Networks: Apache MXNet, Artificial Neural Networks, Autoencoders, Caffe2, Chainer (Deep Learning Framework), Convolutional Neural Networks, Cudnn, Deep Learning, Deep Learning Methods, Deeplearning4j, Evolutionary Acquisition of Neural Topologies, Fast.ai, Keras (Neural Network Library), Long Short-Term Memory (LSTM), OpenVINO, PaddlePaddle, Recurrent Neural Network (RNN), TensorFlow

Machine Learning: AdaBoost (Adaptive Boosting), Adversarial Machine Learning, Apache MADlib, Apache Mahout, Apache SINGA, Apache Spark, Association Rule Learning, Automated Machine Learning, Autonomic Computing, AWS SageMaker, Azure Machine Learning, Boosting, CHi-Squared Automatic Interaction Detection (CHAID), Classification and Regression Tree (CART), Cluster Analysis, Collaborative Filtering, Confusion Matrix, Cyber-Physical Systems, Dask (Software), Data Classification, Dbscan, Decision Models, Decision Tree Learning, Dimensionality Reduction, Dlib (C++ Library), Ensemble Methods, Feature Engineering, Feature Extraction, Feature Learning, Feature Selection, Gaussian Process, Genetic Algorithm, Google AutoML, Gradient Boosting, H2O.ai, Hidden Markov Model, Hyperparameter Optimization, Inference Engine, K-Means Clustering, Kernel

Methods, Kubeflow, Loss Functions, Machine Learning, Machine Learning Algorithms, Machine Learning Methods, Machine Learning Model Monitoring And Evaluation, Machine Learning Model Training, Markov Chain, Matrix Factorization, Meta Learning, Microsoft Cognitive Toolkit (CNTK), MLflow, MLOps (Machine Learning Operations), mlpack (C++ Library), ModelOps, Naive Bayes Classifier, Perceptron, Predictive Modeling, PyTorch (Machine Learning Library), PyTorch Lightning, Random Forest Algorithm, Recommender Systems, Reinforcement Learning, Scikit-Learn (Python Package), Semi-supervised Learning, Soft Computing, Sorting Algorithm, Supervised Learning, Support Vector Machine, Test Datasets, Theano (Software), Torch (Machine Learning), Training Datasets, Transfer Learning, Transformer (Machine Learning Model), Unsupervised Learning, Vowpal Wabbit, Xgboost

Robotics: Advanced Robotics, Bot Framework, Cognitive Robotics, Motion Planning, Nvidia Jetson, Robot Framework, Robot Operating Systems, Robotic Automation Software, Robotic Liquid Handling Systems, Robotic Programming, Robotic Systems, Servomotor, SLAM Algorithms (Simultaneous Localization and Mapping)

Visual Image Recognition: 3D Reconstruction, Activity Recognition, Computer Vision, Contextual Image Classification, Digital Image Processing, Eye Tracking, Face Detection, Facial Recognition, Gesture Recognition, Image Analysis, Image Matching, Image Recognition, Image Segmentation, Image Sensor, Imagenet, Machine Vision, Motion Analysis, Object Recognition, OmniPage, Pose Estimation

LinkedIn

Prepared by Murat Erer, Carl Shan, and Akash Kaura

Country Sample

Included countries represent a select sample of eligible countries with at least 40% labor force coverage by LinkedIn and at least 10 AI hires in any given month. India, despite not reaching 40% coverage, was included in this sample because of its increasing importance in the global economy.

Skills (AI Engineering and AI Literacy skills)

LinkedIn members self-report their skills on their LinkedIn profiles. Currently, more than 41,000 distinct, standardized skills are identified by LinkedIn. These have been coded and classified by taxonomists at LinkedIn into 249 skill groupings, which are the skill groups represented in the dataset.

Skill groupings are derived by expert taxonomists through a [similarity-index methodology](#) that measures skill composition at the industry level. LinkedIn’s industry taxonomy and their corresponding NAICS codes can be found [here](#).

This year LinkedIn made updates to the AI skills list and categorized them into “AI Engineering” and “AI Literacy” skills. See “AI Skills List Update Compared to Last Year” section for more details.

Skills Genome

For any entity (occupation or job, country, sector, etc.), the skill genome is an ordered list (a vector) of the 50 “most characteristic skills” of that entity. These most characteristic skills are identified using a TF-IDF algorithm to identify the most representative skills of the target entity, while down-ranking ubiquitous skills that add little information about that specific entity (e.g., Microsoft Word).

TF-IDF is a statistical measure that evaluates how representative a word (in this case, a skill) is to a selected entity). This is done by multiplying two metrics:

1. The term frequency of a skill in an entity (“TF”).
2. The logarithmic inverse entity frequency of the skill across a set of entities (“IDF”). This indicates how common or rare a word is in the entire entity set. The closer IDF is to 0, the more common a word is.

So, if the skill is very common across LinkedIn entities, and appears in many job or member descriptions, the IDF will approach 0. If, on the other hand, the skill is unique to specific entities, the IDF will approach 1. Details are available at [LinkedIn’s Skills Genome](#) and [LinkedIn–World Bank Methodology](#) note.

AI Skills Penetration

The aim of this indicator is to measure the intensity of AI skills in an entity (in a particular country, industry, gender, etc.) through the following methodology:

- Compute frequencies for all self-added skills by LinkedIn members in a given entity (occupation, industry, etc.) in 2015–2023.
- Re-weight skill frequencies using a TF-IDF model to get the top 50 most representative skills in that entity. These 50 skills compose the “skill genome” of that entity.
- Compute the share of skills that belong to the AI skill group out of the top skills in the selected entity.

Interpretation: The AI skill penetration rate signals the prevalence of AI skills across occupations, or the intensity with which LinkedIn members utilize AI skills in their jobs. For example, the top 50 skills for the occupation of engineer are calculated based on the weighted frequency with which they appear in LinkedIn

members’ profiles. If four of the skills that engineers possess belong to the AI skill group, this measure indicates that the penetration of AI skills is estimated to be 8% among engineers (e.g., 4/50).

Jobs or Occupations

LinkedIn member titles are standardized and grouped into approximately 15,000 occupations. These are not sector- or country-specific. These occupations are further standardized into approximately 3,600 occupation representatives. Occupation representatives group occupations with a common role and specialty, regardless of seniority.

AI Jobs or Occupations

An “**AI**” job is an occupation representative that requires AI skills to perform the job. Skills penetrations are used as a signal for whether **AI skills** are prevalent in an occupation representative, in any sector where the occupation representative may exist. Examples of such occupations include (but are not limited to): Machine Learning Engineer, Artificial Intelligence Specialist, Data Scientist, and Computer Vision Engineer.

AI Talent

A LinkedIn member is considered **AI talent if they have explicitly added AI skills to their profile and/or they are occupied in an AI occupation representative**. The counts of AI talent are used to calculate talent concentration metrics. For example, to calculate the country-level AI talent concentration, we use the counts of AI talent at the country level vis-a-vis the counts of LinkedIn members in the respective countries. Note that concentration metrics may be influenced by LinkedIn coverage in these countries and should be utilized with caution.

Relative AI Skills Penetration

To allow for skills penetration comparisons across countries, the skills genomes are calculated and a relevant benchmark is selected (e.g., global average). A ratio is then constructed between a country's and the benchmark's AI skills penetrations, controlling for occupations.

Interpretation: A country's relative AI skills penetration of 1.5 indicates that AI skills are 1.5 times as frequent as in the benchmark, for an overlapping set of occupations.

Global Comparison

For cross-country comparison, we present the relative penetration rate of AI skills, measured as the sum of the penetration of each AI skill across occupations in a given country, divided by the average global penetration of AI skills across the overlapping occupations in a sample of countries.

Interpretation: A relative penetration rate of 2 means that the average penetration of AI skills in that country is two times the global average across the same set of occupations.

Global Comparison: By Industry

The relative AI skills penetration by country for industry provides an in-depth sectoral decomposition of AI skill penetration across industries and sample countries.

Interpretation: A country's relative AI skill penetration rate of 2 in the education sector means that the average penetration of AI skills in that country is two times the global average across the same set of occupations in that sector.

Global Comparison: By Gender

The "Relative AI Skills Penetration by Gender" metric provides a cross-country comparison of AI skill penetrations within each gender, comparing

countries' male/female AI skill penetrations to the global average of the same gender. Since the global averages are distinct for each gender, this metric should only be used to compare country rankings within each gender, and not for cross-gender comparisons within countries.

Interpretation: A country's AI skills penetration for women of 1.5 means that female members in that country are 1.5 times more likely to list AI skills than the average female member in all countries pooled together across the same set of occupations that exist in the country/gender combination.

Global Comparison: Across Genders

The "Relative AI Skills Penetration Across Genders" metric allows for cross-gender comparisons within and across countries globally, since we compare the countries' male/female AI skill penetrations to the same global average regardless of gender.

Relative AI Talent Hiring Rate YoY Ratio

- **LinkedIn Hiring Rate or Overall Hiring Rate** is a measure of hires normalized by LinkedIn membership. It is computed as the percentage of LinkedIn members who added a new employer in the same period the job began, divided by the total number of LinkedIn members in the corresponding location.
- **AI Hiring Rate** is computed following the overall hiring rate methodology, but only considering members classified as AI talent.
- **Relative AI Talent Hiring Rate YoY Ratio** is the year-over-year change in AI Hiring Rate relative to Overall Hiring Rate in the same country. For each month, we first calculate AI Hiring rate in the country, then divide AI Hiring Rate by Overall Hiring Rate in that country,

then calculate YoY change of this ratio, and then take the 12-month moving average using the last 12 months.

Interpretation: In 2023 in India, the ratio of AI talent hiring relative to overall hiring has grown 16.8% year over year.

AI Talent Migration

Data on migration comes from the World Bank Group–LinkedIn “Digital Data for Development” partnership (please see [Zhu et al. \[2018\]](#)).

LinkedIn migration rates are derived from the self-identified locations of LinkedIn member profiles. For example, when a LinkedIn member updates his or her location from Paris to London, this is counted as a migration. Migration data is available from 2019 onward. LinkedIn data provides insights into countries on the AI Talent gained or lost due to migration trends. AI Talent migration is considered for all members with AI Skills/holding AI jobs at time t for country A as the country of interest and country B as the source of inflows and destination for outflows. Thus, net AI Talent migration between country A and country B—for country A—is calculated as follows:

$$\text{Net AI Talent Migration}_{a,b,t} = \frac{\text{Net AI Talent flows}_{a,b,t}}{\text{Member count}_{a,t}}$$

Net flows are defined as total arrivals minus departures within the given time period. LinkedIn membership varies considerably between countries, which makes interpreting absolute movements of members from one country to another difficult. To compare migration flows between countries fairly, migration flows are normalized for the country of interest. For example, if country A is the country of interest, all absolute net flows into and out of country A, regardless of origin

and destination countries, are normalized based on LinkedIn membership in country A at the end of each year and multiplied by 10,000. Hence, this metric indicates relative talent migration from all countries to and from country A.

AI Skills List Update Compared to Last Year

1. LinkedIn introduced “AI Literacy” skills.
 - a. The following skills were added to the list and categorized as “AI Literacy” skills: ChatGPT, DALL-E, GPT-3, GPT-4, Generative Art, Github Copilot, Google Bard, Midjourney, Prompt Engineering, and Stable Diffusion.
2. LinkedIn updated the former AI skills list and categorized them as “AI Engineering” skills:
 - a. The following skills were excluded from the list: Alexa, Common Lisp, Data Structures, Gaussian 03, Graph Theory, IBM Watson, Information Retrieval, Jena, Julia (Programming Language), Linked Data, Lisp, Pandas (Software), Parallel Algorithms, Perl Automation, Resource Description Framework, Smalltalk, and dSPACE.
 - b. The following skills were added to the list: Apache Spark ML, Applied Machine Learning, Audio Synthesis, Autoencoders, Automated Clustering, Automated Feature Engineering, Automated Machine Learning (AutoML), Autoregressive Models, Chatbot Development, Chatbots, Concept Drift Adaptation, Conditional Generation, Conditional Image Generation, Decision Trees, Deep Convolutional Generative Adversarial Networks (DCGAN), Deep Neural Networks (DNN), Generative AI, Generative Adversarial Imitation Learning, Generative Adversarial Networks (GANs), Generative

Design Optimization, Generative Flow Models, Generative Modeling, Generative Neural Networks, Generative Optimization, Generative Pre-training, Generative Query Networks (GQNs), Generative Replay Memory, Generative Synthesis, Google Cloud AutoML, Graph Embeddings, Graph Networks, Hyperparameter Optimization, Hyperparameter Tuning, Image Generation, Image Inpainting, Image Synthesis, Image-to-Image Translation, Large Language Models (LLM), MLOps, Machine Learning Algorithms, Machine Translation, Meta-learning, Model Compression, Model Interpretation, Model Training, Music Generation, Neural Network Architecture Design, Predictive Modeling, Probabilistic Generative Models, Probabilistic Programming, Random Forest, Recurrent Neural Networks (RNN), Responsible AI, Style Transfer, StyleGAN, Synthetic Data Generation, Text Generation, Text-to-Image Generation, Time Series Forecasting, Transformer Models, Variational Autoencoders, Variational Autoencoders (VAEs), Video Generation, and k-means clustering.

Quid

Quid Insights prepared by Bill Valle and Heather English

Quid uses its own in-house LLM and other smart search features, as well as traditional Boolean query, to search for focus areas, topics, and keywords within many datasets: social media, news, forums and blogs, companies, patents, as well as other custom feeds of data (e.g., survey data). Quid has many visualization options and data delivery endpoints, including network graphs based on semantic similarity, in-platform dashboarding capabilities, as well as programmatic

PostgreSQL database delivery, and so on.

Quid applies best-in-class AI and NLP to reveal hidden patterns in large datasets, enabling users to make data-driven decisions accurately, quickly, and efficiently.

Search, Data Sources, and Scope

Over 8 million global public and private company profiles from multiple data sources are indexed to search across company descriptions, while filtering and including metadata ranging from investment information to firmographic information, such as founded year, HQ location, and more. Company information is updated on a weekly basis. The Quid algorithm reads a large amount of text data from each document to make links between different documents based on their similar language. This process is repeated at an immense scale, which produces a network with different clusters identifying distinct topics or focus areas. Trends are identified based on keywords, phrases, people, companies, and institutions that Quid identifies, and the other metadata that is put into the software.

Data

Companies

Organization data is embedded from Capital IQ and Crunchbase. These companies include all types of organizations (private, public, operating, operating as a subsidiary, out of business) throughout the world. The investment data includes private investments, M&A, public offerings, minority stakes made by PE/VCs, corporate venture arms, governments, and institutions both within and outside the United States. Some data is simply unreachable—for instance, when investors' names or funding amounts are undisclosed.

Quid embeds Capital IQ data as a default and adds in data from Crunchbase for the data points

that are not captured in Capital IQ. This not only yields comprehensive and accurate data on all global organizations, but it also captures early-stage startups and funding events data. Company information is updated on a weekly basis.

Earnings Calls

Quid leverages earnings call transcript data embedded from Seeking Alpha. For this report, Quid has analyzed mentions of AI-related keywords across all earnings call transcripts from Fortune 500 companies from January 2018 through December 2023. New earnings call transcript data is updated in Quid on the 1st and 15th of every month.

Search Parameters

Boolean query is used to search for focus areas, topics, and keywords within the archived company database, within their business descriptions and websites. We can filter out the search results by HQ regions, investment amount, operating status, organization type (private/public), and founding year. Quid then visualizes these companies by semantic similarity. If there are more than 7,000 companies from the search result, Quid selects the 7,000 most relevant companies for visualization based on the language algorithm.

Boolean search: “artificial intelligence” or “AI” or “machine learning” or “deep learning”

Companies

- Global AI and ML companies that have received investments (private, IPO, M&A) from January 1, 2013, to December 31, 2023.
- Global AI and ML companies that have received over \$1.5M for the last 10 years (January 1, 2013, to December 31, 2023).
- Global data was also pulled for a Generative AI query (Boolean search: “generative AI” OR “gen

AI” OR “generative artificial intelligence”) for companies that have received over \$1.5M for the last 10 years (January 1, 2013, to December 31, 2023).

Target Event Definitions

- Private investments: A private placement is a private sale of newly issued securities (equity or debt) by a company to a selected investor or a selected group of investors. The stakes that buyers take in private placements are often minority stakes (under 50%), although it is possible to take control of a company through a private placement as well, in which case the private placement would be a majority stake investment.
- Minority investment: These refer to minority stake acquisitions in Quid, which take place when the buyer acquires less than 50% of the existing ownership stake in entities, asset products, and business divisions.
- M&A: This refers to a buyer acquiring more than 50% of the existing ownership stake in entities, asset products, and business divisions.

McKinsey & Company

Data used in the Corporate Activity–Industry Adoption section was sourced from the McKinsey Global Survey “[The State of AI in 2023: Generative AI’s Breakout Year.](#)”

The online survey was in the field April 11, 2023, to April 21, 2023, and garnered responses from 1,684 participants representing the full range of regions, industries, company sizes, functional specialties, and tenures. Of those respondents, 913 said their organizations had adopted AI in at least one function

and were asked questions about their organization's AI use. To adjust for differences in response rates, the data is weighted by the contribution of each respondent's nation to global GDP.

The AI Index also considered data from previous iterations of the survey. More specifically, the AI index made use of data from:

[The State of AI in 2022—and a Half Decade in Review](#)

[The State of AI in 2021](#)

[The State of AI in 2020](#)

[AI Proves Its Worth, But Few Scale Impact \(2019\)](#)

[AI Adoption Advances, But Foundational Barriers Remain \(2018\)](#)

Stack Overflow

Data on the use of AI by developers was sourced from the [2023 Developer Survey](#). The survey was conducted from May 8, 2023, to May 19, 2023, and incorporates the insights of 89,184 software developers from 185 countries around the world.

Chapter 6: Education

Code.org

State-Level Data

The following [link](#) includes a full description of the methodology used by Code.org to collect its data. The staff at Code.org also maintains a [database](#) of the state of American K–12 education and, in this [policy primer](#), provides a greater amount of detail on the state of American K–12 education in each state.

AP Computer Science Data

The AP Computer Science data is provided to Code.org as per an agreement the College Board maintains with Code.org. The AP Computer Science data comes from the college board’s [national and state summary reports](#).

Access to Computer Science Education

Data on access to computer science education was drawn from Code.org’s [State of Computer Science Education 2023](#) report.

Computing Research Association (CRA Taulbee Survey)

Note: This year’s AI Index reused the methodological notes that were submitted by the CRA for previous editions of the AI Index. For more complete delineations of the methodology used by the CRA, please consult the individual CRA surveys that are linked below.

Computing Research Association (CRA) members are 200-plus North American organizations active in computing research: academic departments of computer science and computer engineering; laboratories and centers in industry, government, and academia; and affiliated professional societies (AAAI, ACM, CACS/AIC, IEEE Computer Society, SIAM USENIX). CRA’s mission is to enhance innovation by joining with industry, government, and academia to strengthen research and advance education in computing. Learn more about CRA [here](#).

The CRA Taulbee Survey gathers survey data during the fall of each academic year by reaching out to over 200 PhD-granting departments. Details about the Taulbee Survey can be found [here](#). Taulbee doesn’t directly survey the students. The department identifies each new PhD’s area of specialization as well as their type of employment. Data is collected from September to January of each academic year for PhDs awarded in the previous academic year. Results are published in May after data collection closes.

The CRA Taulbee Survey is sent only to doctoral departments of computer science, computer engineering, and information science/systems. Historically, (a) Taulbee covers one-quarter to one-third of total BS CS recipients in the United States; (b) the percentage of women earning bachelor’s degrees is lower in the Taulbee schools than overall; and (c) Taulbee tracks the trends in overall CS production.

The AI Index used data from the following iterations of the CRA survey:

[CRA, 2022](#)

[CRA, 2021](#)

[CRA, 2020](#)

[CRA, 2019](#)

[CRA, 2018](#)

[CRA, 2017](#)

[CRA, 2016](#)

[CRA, 2015](#)

[CRA, 2014](#)

[CRA, 2013](#)

[CRA, 2012](#)

[CRA, 2011](#)

Impact Research

Data on the usage of ChatGPT in schools among teachers and students came from two Impact Research surveys released in 2023. To learn more about the methodology employed for the surveys, please visit the following links: [March 2023](#) and [July 2023](#).

Informatics Europe

The statistics are annually collected by Informatics Europe and published on the [Informatics Europe Higher Education Data Portal](#), which is updated with the most recent data at the end of the year (typically in December). In the interest of reliability, Informatics Europe collects the data from countries where a solid and reasonably complete picture could be drawn from official sources such as national statistical offices, educational agencies, or ministries. The full list of sources can be found in the Data Portal section “[Data Sources](#).” The Data Portal follows the definitions

and concepts provided by these national agencies and reflects the national situation in the countries considered. Those aspects that are not exposed by the consulted agencies are not part of the dataset. A full list of definitions and concepts used can be found in the footnotes shown at the bottom of the [Statistics section](#).

Since each national data repository has its own structure and quite often provides all supporting information in the national language, Informatics Europe consults with its members—academics, active and knowledgeable in the informatics field from respective countries—who help to interpret the statistics available and who understand the specificities of these countries’ higher education systems. One of the main challenges in integrating the statistical data is the identification of terms used to define the informatics discipline in different countries. Informatics is known under different names in different European languages and countries, and in English as well. A good dozen terms (presented in the Data Portal section “[Subjects](#)”) are used to denote what is fundamentally the same discipline, and the role of national experts here is to help with screening the terms and programs and identifying which part of them is pertinent to the informatics field.

The data covers the degrees delivered by both traditional Research Universities (RU) and University of Applied Science (UAS) for the countries where these institutions also offer bachelor’s and master’s studies in informatics. The full list of institutions covered can be found in the Data Portal section “[Institutions & Academic Units](#).”

Studyportals

Studyportals is the world's most comprehensive study choice platform. It lists over 200,000 English-taught programs from more than 3,500 institutions, helping over 50 million students per year. The Studyportals analytics and consulting team uses the resulting data to provide higher education organizations with real-time market insights.

Studyportals categorizes the study programs on its portals into disciplines and subdisciplines. The 15 disciplines are broad categories of educational fields to help navigate the portals. The 284 subdisciplines are narrower topics, subdivisions, or specialized areas of disciplines. Paying clients can provide input, but ultimately, data processors manually choose the one-to-three closest fitting subdisciplines according to the following scenarios, listed in decreasing order of likelihood.

1. **Classic scenario:** When the study name closely matches one subdiscipline name.
 - a. *“Chemistry” -> subdiscipline Chemistry.*
2. **Classic interdisciplinary scenario:** When the study name closely matches two or three subdiscipline names.
 - a. *“International Fashion Management and Marketing” -> subdisciplines Fashion Management + Marketing.*
3. **Specializations scenario:** When not all the subdisciplines are mentioned in the study name, but they are listed as specific specializations, concentrations, or tracks.
 - a. *“Business Administration with specializations in Finance and International Business” -> subdisciplines Business Administration + Finance + International Business*
4. **Mixed scenario:** When the study name does not closely match any specific subdiscipline but can be represented by combining two or three subdisciplines.
 - a. *“Financial Economics” -> subdisciplines Finance + Economics*
5. **Last resort scenario:** When the study name does not closely match any specific subdiscipline and/or combination, it is instead approximated as closely as possible.
 - a. *“UK, EU, and US Copyright Law” -> subdisciplines Patent & Intellectual Property Law + International Law + European Law*

Scenario	Example study name	Example assigned subdisciplines
Study name closely matches one subdiscipline name.	BSc Chemistry	Chemistry
Study name closely matches two or three subdiscipline names.	BA International Fashion Management and Marketing	Fashion Management + Marketing
Not all the subdisciplines are mentioned in the study name, but they are listed as specific specializations, concentrations, or tracks.	MBA Business Administration with specializations in Finance and International Business	Business Administration + Finance + International Business
Study name does not closely match any specific subdiscipline but can be represented by combining two or three subdisciplines.	MSc Financial Economics	Finance + Economics
Study name does not closely match any specific subdiscipline and/or combination and is instead approximated as closely as possible.	LLM UK, EU, and US Copyright Law	Patent and Intellectual Property Law + International Law + European Law

Chapter 7: Policy and Governance

Acknowledgments

The AI Index would like to acknowledge Simba Jonga for his work collecting information on significant AI policy events and conducting a survey of AI national strategies. Additionally, the Index would like to acknowledge the efforts of Ethan Duncan He-Li Hellman, Julia Betts Lotufo, Alexandra Rome, and Emma Williamson in collecting, coding, and analyzing AI-related legislation and regulations. The Index is also grateful for the guidance provided by Caroline Meinhardt on AI legislation and regulation tracking.

Global AI Mentions

For mentions of AI in AI-related legislative proceedings around the world, the AI Index performed searches of the keyword “artificial intelligence” on the websites of 80 countries’ congresses or parliaments (in the respective languages), usually under sections named “minutes,” “hansard,” etc. In some cases, databases were only searchable by title, so site search functions were deployed. The AI Index team surveyed the following databases:

Andorra, Angola, Armenia, Australia, Azerbaijan, Barbados, Belgium, Bermuda, Bhutan, Brazil, Cabo Verde, Canada, Cayman Islands, China,¹² Czech Republic, Denmark, Dominican Republic, Ecuador, El Salvador, Estonia, Fiji, Finland, France, The Gambia, Germany, Gibraltar, Greece, Hong Kong, Iceland, India, Ireland, Isle of Man, Israel, Italy, Japan, Kenya, Kosovo, Latvia, Lesotho, Liechtenstein, Luxembourg, Macao

SAR, China, Madagascar, Malaysia, Maldives, Malta, Mauritius, Mexico, Moldova, Netherlands, New Zealand, Northern Mariana Islands, Norway, Pakistan, Panama, Papua New Guinea, Philippines, Poland, Portugal, Romania, Russia, Samoa, San Marino, Seychelles, Sierra Leone, Singapore, Slovenia, South Africa, South Korea, Spain, Sri Lanka, Sweden, Switzerland, Tanzania, Trinidad and Tobago, Ukraine, United Kingdom, United States, Uruguay, Zambia, Zimbabwe

Global Legislation Records on AI

For AI-related bills passed into laws, the AI Index performed searches of the keyword “artificial intelligence” on the websites of 128 countries’ congresses or parliaments (in the respective languages) in the full text of bills. Note that only laws passed by state-level legislative bodies and signed into law (i.e., by presidents or through royal assent) from 2016 to 2023 are included. Laws that were approved but then repealed are not included in the analysis. In some cases, there were databases that were only searchable by title, so site search functions were deployed. Future AI Index reports hope to include analysis on other types of legal documents, such as regulations and standards, adopted by state- or supranational-level legislative bodies, government agencies, etc. The AI Index team surveyed databases for the following countries:

¹² The National People’s Congress is held once per year and does not provide full legislative proceedings. Hence, the counts included in the analysis only searched mentions of “artificial intelligence” in the only public document released from the Congress meetings, the Report on the Work of the Government, delivered by the premier.

[Albania](#), [Algeria](#), [American Samoa](#), [Andorra](#), [Angola](#), [Antigua and Barbuda](#), [Argentina](#), [Armenia](#), [Australia](#), [Austria](#), [Azerbaijan](#), [The Bahamas](#), [Bahrain](#), [Bangladesh](#), [Barbados](#), [Belarus](#), [Belgium](#), [Belize](#), [Bermuda](#), [Bhutan](#), [Bolivia](#), [Brazil](#), [Brunei](#), [Bulgaria](#), [Burkina Faso](#), [Cameroon](#), [Canada](#), [Cayman Islands](#), [Chile](#), [China](#), [Colombia](#), [Croatia](#), [Cuba](#), [Curacao](#), [Cyprus](#), [Czech Republic](#), [Denmark](#), [Estonia](#), [Faroe Islands](#), [Fiji](#), [Finland](#), [France](#), [The Gambia](#), [Georgia](#), [Germany](#), [Gibraltar](#), [Greece](#), [Greenland](#), [Grenada](#), [Guam](#), [Guatemala](#), [Guyana](#), [Hong Kong](#), [Hungary](#), [Iceland](#), [India](#), [Iran Islamic Republic](#), [Iraq](#), [Ireland](#), [Isle of Man](#), [Israel](#), [Italy](#), [Jamaica](#), [Japan](#), [Kazakhstan](#), [Kenya](#), [Kiribati](#), [Korea Republic](#), [Kosovo](#), [Kyrgyz Republic](#), [Latvia](#), [Lebanon](#), [Liechtenstein](#), [Lithuania](#), [Luxembourg](#), [Macao SAR China](#), [Malawi](#), [Malaysia](#), [Malta](#), [Mauritius](#), [Mexico](#), [Monaco](#), [Montenegro](#), [Morocco](#), [Mozambique](#), [Nauru](#), [The Netherlands](#), [New Zealand](#), [Nicaragua](#), [Niger](#), [Northern Marina Islands](#), [Norway](#), [Panama](#), [Papua New Guinea](#), [Philippines](#), [Poland](#), [Portugal](#), [Romania](#), [Russia](#), [Samoa](#), [Saudi Arabia](#), [Serbia](#), [Seychelles](#), [Sierra Leone](#), [Singapore](#), [Slovak Republic](#), [Slovenia](#), [South Africa](#), [Spain](#), [Sri Lanka](#), [St. Kitts and Nevis](#), [Suriname](#), [Sweden](#), [Switzerland](#), [Tajikistan](#), [Tanzania](#), [Togo](#), [Tongo](#), [Turkey](#), [Tuvalu](#), [Uganda](#), [Ukraine](#), [United Arab Emirates](#), [United Kingdom](#), [United States](#), [Uruguay](#), [Vietnam](#), [Yemen](#), [Zambia](#), [Zimbabwe](#)

The legislation was then coded by a team of two human coders for: (1) relevance to AI, (2) regulatory approach, and (3) subject matter. The relevance to AI categories were low, medium, and high. The regulatory approach categories were expansive or restrictive. For the subject matter categories, the Index employed the [Congress](#) policy typology. In cases where there were disagreements on the coding schemas, a third coder was brought in to settle the differences.

EU AI Regulation

The AI Index also gathered information on AI-related regulations enacted in the European Union between 2017 and 2023. To compile this data, the Index team conducted a keyword search for “artificial intelligence” on [EUR-Lex](#), a comprehensive database of EU legislation, regulations, and case law. EUR-Lex provides access to a wide range of regulatory documents, such as legal acts, consolidated texts, international agreements, preparatory documents, and legislative procedures. The analysis in this section focused exclusively on documents with binding regulatory authority. The search for AI-related regulation in the European Union was limited to legal acts, international agreements, and consolidated texts.

The regulation was then coded by a team of two human coders for: (1) relevance to AI, (2) regulatory approach, and (3) subject matter. The relevance to AI categories were low, medium, and high. The regulatory approach categories were expansive or restrictive. For the subject matter categories, the Index employed the [Congress](#) policy typology. In cases where there were disagreements on the coding schemas, a third coder was brought in to settle the differences.

Federal Budget for Nondefense AI R&D

Data on the federal U.S. budget for nondefense AI R&D was taken from previous editions of the AI Index (namely the [2021](#) and [2022](#) versions) and from the following National Science and Technology Council reports:

[Supplement to the President’s FY 2024 Budget](#)
[Supplement to the President’s FY 2023 Budget](#)
[Supplement to the President’s FY2022 Budget](#)

Govini

Govini is a defense technology company. [Ark](#), Govini’s flagship software, is a suite of AI-enabled applications, powered by integrated government and commercial data, that accelerate the Defense Acquisition Process.

With Ark, the acquisition community eliminates slow, manual processes and gains the ability to rapidly imagine, produce, and field critical warfighting capabilities. Analysts and decision-makers are equipped to solve challenges across the entire spectrum of Defense Acquisition, including Supply Chain, Science and Technology, Production, Sustainment, and Modernization.

Govini curated USG AI spend data from their annual Scorecard Taxonomy by applying supervised machine learning (ML) and natural language processing (NLP) techniques to parse, analyze, and categorize large volumes of federal contracts data, including prime contracts, grants, and other transaction authority (OTA) awards. Govini’s most recent Scorecard focused on Critical Technologies, of which AI/ML Technologies and Microelectronics were segments. The AI/ML segment consisted of five subsegments: Data Integration, Computer Vision, Machine Learning, Autonomy, and Natural Language Processing. Microelectronics is divided into two subsegments: Memory and Processing, and Semiconductors. By initially generating search terms and then subsequently excluding specific

terms that yield erroneous results, Govini delivers a comprehensive yet discriminant taxonomy of subsegments that are mutually exclusive. Repeated keyword searches and filters allow a consensus, data-driven taxonomy to come into focus. Govini SMEs conduct final review of taxonomic structure to complement this iterative, data-driven process.

The use of artificial intelligence (AI) and supervised ML models enables analysis of the large volumes of irregular data contained in federal contracts—data that often is inaccessible through regular government reporting processes or human-intensive analytical approaches.

Moreover, beyond simply making usable an expansive body of data sources, Govini’s Ark platform and National Security Knowledge Graph establishes high-fidelity standards in categorized and fused data to produce a comprehensive and accurate depiction of federal spending, and the supporting vendor ecosystem, over time.

National AI Strategies

The AI Index did a web search to identify national strategies on AI. Below is a list of countries that were identified as having a national AI strategy, including a link to said strategy. For certain countries, noted with an asterisk (*), the actual strategy was not found, and a news article confirming the launch of the strategy was linked instead.

Countries with AI Strategies in Place

[Algeria](#),* [Argentina](#), [Azerbaijan](#),* [Australia](#), [Austria](#), [Bahrain](#), [Bangladesh](#), [Benin](#),* [Botswana](#),* [Brazil](#), [Belgium](#),* [Bulgaria](#), [Canada](#), [Chile](#), [China](#), [Colombia](#), [Croatia](#), [Cyprus](#), [Czech Republic](#), [Denmark](#), [Dominican Republic](#),* [Egypt, Arab Republic](#), [Ethiopia](#), [Estonia](#), [Finland](#), [France](#), [Germany](#), [Ghana](#), [Greece](#), [Hong Kong](#), [Hungary](#), [India](#), [Indonesia](#), [Iran](#),* [Iraq](#),* [Ireland](#), [Israel](#),* [Italy](#), [Japan](#), [Jordan](#),* [Kenya](#), [Korea Republic](#), [Latvia](#), [Lithuania](#), [Luxembourg](#), [Malta](#), [Malaysia](#), [Mauritius](#), [Mexico](#), [The Netherlands](#), [North Korea](#), [Norway](#), [Peru](#), [Philippines](#), [Poland](#), [Portugal](#), [Qatar](#), [Romania](#), [Russia](#), [Rwanda](#), [Saudi Arabia](#), [Serbia](#), [Sierra Leone](#), [Singapore](#), [Slovak Republic](#), [Slovenia](#), [Spain](#), [Sweden](#), [Switzerland](#), [Thailand](#), [Tunisia](#),* [Turkey](#), [Ukraine](#), [United Arab Emirates](#), [United Kingdom](#), [United States](#), [Uruguay](#), [Vietnam](#)

Countries with AI Strategies in Development

[Andorra](#),* [Antigua and Barbuda](#),* [Barbados](#),* [Armenia](#),* [Belarus](#),* [Costa Rica](#),* [Cuba](#),* [Iceland](#), [Jamaica](#),* [Kenya](#), [Morocco](#), [New Zealand](#),* [Nigeria](#),* [Pakistan](#),* [Senegal](#),* [Uzbekistan](#)

US AI Regulation

This section examines AI-related regulations enacted by American regulatory agencies between 2016 and 2023. It provides an analysis of the total number of regulations, as well as their topics, scope, regulatory intent, and originating agencies. To compile this data, the AI Index team performed a keyword search for “artificial intelligence” on the [Federal Register](#), a comprehensive repository of government documents from nearly all branches of the American government, encompassing more than 436 agencies.

The regulation was then coded by a team of two human coders for: (1) relevance to AI, (2) regulatory approach, and (3) subject matter. The relevance to AI categories were low, medium, and high. The regulatory approach categories were expansive or restrictive. For the subject matter categories, the Index employed the [Congress](#) policy typology. In cases where there were disagreements on the coding schemas, a third coder was brought in to settle differences.

US Department of Defense Budget Requests

Data on the DoD nonclassified AI-related budget requests was taken from previous editions of the AI Index (namely the [2021](#) and [2022](#) versions) and from the following reports:

[Defense Budget Overview United States Department of Defense Fiscal Year 2024 Budget Request](#)
[Defense Budget Overview United States Department of Defense Fiscal Year 2023 Budget Request](#)
[Defense Budget Overview United States Department of Defense Fiscal Year 2022 Budget Request](#)

US State-Level AI Legislation

For AI-related bills passed into law, the AI Index performed searches of the keyword “artificial intelligence” on the legislative websites of all 50 U.S. states in the full text of bills. Bills are only counted as passed into law if the final version of the bill includes the keyword, not just the introduced version. Note that only laws passed from 2015 to 2022 are included. The count for proposed laws includes both

laws that were proposed and eventually passed as well as laws that were proposed that have not yet been passed, or are now inactive. In some cases, databases were only searchable by title, so site search functions were deployed. The AI Index team surveyed the following databases:

[Alabama](#), [Alaska](#), [Arizona](#), [Arkansas](#), [California](#),
[Colorado](#), [Connecticut](#), [Delaware](#), [Florida](#), [Georgia](#),
[Hawaii](#), [Idaho](#), [Illinois](#), [Indiana](#), [Iowa](#), [Kansas](#), [Kentucky](#),
[Louisiana](#), [Maine](#), [Maryland](#), [Massachusetts](#), [Michigan](#),
[Minnesota](#), [Mississippi](#), [Missouri](#), [Montana](#), [Nebraska](#),
[Nevada](#), [New Hampshire](#), [New Jersey](#), [New Mexico](#),
[New York](#), [North Carolina](#), [North Dakota](#), [Ohio](#),
[Oklahoma](#), [Oregon](#), [Pennsylvania](#), [Rhode Island](#),
[South Carolina](#), [South Dakota](#), [Tennessee](#), [Texas](#),
[Utah](#), [Vermont](#), [Virginia](#), [Washington](#), [West Virginia](#),
[Wisconsin](#), [Wyoming](#)

US Committee Mentions

In order to research trends on the United States' committee mentions of AI, the following search was conducted:

Website: [Congress.gov](#)

Keyword: artificial intelligence

Filters: Committee Reports

Chapter 8: Diversity

Code.org

To learn more about the diversity data from Code.org, please read the methodological note on Code.org's data included in the Chapter 6 subsection of the Appendix.

Computing Research Association (CRA Taulbee Survey)

To learn more about the diversity data from the CRA, please read the methodological note on the CRA's data included in the Chapter 6 subsection of the Appendix.

Informatics Europe

To learn more about the diversity data from Informatics Europe, please read the methodological note on Informatics Europe's data included in the Chapter 6 subsection of the Appendix.

Chapter 9: Public Opinion

Global Public Opinion on Artificial Intelligence (GPO-AI)

In October and November 2023, researchers at the Schwartz Reisman Institute for Technology and Society (SRI) and the Policy, Elections, and Representation Lab (PEARL) at the Munk School of Global Affairs and Public Policy at the University of Toronto completed a survey project on public perceptions of and attitudes toward AI. The survey was administered to census-targeted samples of over 1,000 people in each of 21 countries, for a total of 23,882 surveys conducted in 12 languages. The countries sampled represent a majority of the world's population. To learn more about the survey, please visit the [survey website](#). The following authors contributed to the GPO-AI survey: Peter John Loewen, Blake Lee-Whiting, Maggie Arai, Thomas Bergeron, Thomas Galipeau, Isaac Gazendam, Hugh Needham, Lee Slinger, Sofiya Yusypovych.

Ipsos

For brevity, the 2024 AI Index does not republish the methodology used by the Ipsos survey that features in the report. More details about the Ipsos survey's methodology can be found in the [actual survey](#).

Pew Research

For brevity, the 2024 AI Index does not republish the methodology used by the Pew surveys that feature in the report. Data was taken from the [2023 Pew Research Center survey](#).

Quid Social Media Data

Quid collects social media data from over 500 million sources in real time and analyzes this data through AI-powered natural language processing. This process parses out language and breaks out posts by filters such as drivers of positive and negative sentiment, emotions, and behaviors, allowing for deeper insights to be reached. Quid analyzed 6.69 million social media posts for 2023 to assess perceptions of AI model releases. The substantial increase in new models in 2023 unveiled reactions to the technical advancements in AI, the impact on efficiency in business operations, and ethical considerations as AI continues to be adopted into society.
