Table S2: List of random forest hyperparameters that underwent optimization during model's training using RandomForestRegression function in Python.

Parameters	Description	Range
<i>n_estimators</i>	The number of trees in the forest.	400, 450, 500, 550, 600
<i>max_features</i>	The number of features to consider when looking for the best split.	None, 'sqrt'
<i>max_samples</i>	The number of samples to draw from the training dataset to train each base estimator.	0.5, 0.625, 0.75, None
<i>min_samples_leaf</i>	The minimum number of samples required to be at a leaf node. This may have the effect of smoothing the model, especially in regression.	3, 5, 7, 10

Table S3: Prediction accuracy of random forest models for each parameter during training. The value for each goodness metrics reflects the average accuracy of multiple models from the modelling scheme. The n is the amount of data for testing, RMSE = root mean square error (in parameter's unit), R² = coefficient of determinant (unitless).

Parameters	Unit	Peatland region	n	RMSE	R ²
Thickness	m	A—North America	1,425	1.10	0.65
		B—Europe and Russia	13,245	0.54	0.79
		C—Latin America	1,499	0.35	0.83
		D—Africa	122	0.57	0.86
		E—South and Southeast Asia	1,245	1.05	0.86
		F—Australia and New Zealand	577	0.52	0.89
		peat layers (cm depth)			
Bulk density	Mg m ⁻³	0 - 15	9,544	0.05	0.84
