## THIAZOLOPYRIDINONE DERIVATES AS MCH RECEPTOR ANTAGONISTS

**Field of Invention**

The present invention is in the field of medicine, particularly in the treatment of obesity and diseases caused by or exacerbated by obesity. More specifically, the present invention relates to antagonists of melanin concentrating hormone useful in the prevention and treatment of obesity and related diseases.

**Background of the Invention**

The affluence of the 1990's along with the exponential increase in food production particularly in Western and Asian economies has resulted in feeding patterns that lead to obesity. Obesity is defined as being excessively overweight. Excessive weight is generally characterized by excessive body fat, because unused energy is stored in the adipose tissues as fat.

Obesity has associated with it, economic and social costs. Obese people, an increasing proportion of developed and developing societies, are regarded as having out of control feeding habits often associated with low self-esteem. Moreover, obese persons are more likely to have medical problems associated with or exacerbated by the excess body weight. Examples of medical conditions caused, exacerbated or triggered by excessive weight include bone fractures, pains in the knee joints, arthritis, increased risk of hypertension, atherosclerosis, stroke, diabetes, etc.

Melanin concentrating hormone (MCH) is a 19 amino acid neuropeptide produced in the lateral hypothalamic area and zona incerta. Although MCH-expressing neurons project to numerous regions of the brain. MCH is processed from a larger pre-prohormone that also includes a second peptide, NEI, and possibly a third, NGE (Nahon, Crit Rev in Neurobiology, 8:221-262, 1994). MCH mediates its effects through at least two G protein-coupled receptors, MCHR1 and MCHR2 (Saito et al. Nature 400: 265-269, 1999; Hill et al., J Biol Chem. 276: 20125-20129, 2001). Both receptors are expressed in regions of the brain consistent with MCH neuronal projection and known MCH physiologic function (Hervieu et al., Eur J Neuroscience 12: 1194-1216, 2000; Hill et al.,

J Biol Chem. 276: 20125-20129, 2001; Sailer et al., Proc Nat Acad Sci. 98: 7564-7569, 2001).

Extensive evidence exists to support the orexigenic activity of MCH. MCH mRNA is elevated in rodent models of obesity and in the fasted state (Qu et al., Nature 5 380: 243-247, 1996). Intra-cerebroventricularly administered MCH increases feeding and blocks the anorexic effect of  $\alpha$ -melanocyte stimulating hormone (Ludwig et al., Am J Physiol 274: E627-E633, 1998). MCH knockout mice (MCH<sup>-/-</sup> mice) are lean, hypophagic and hypometabolic (Shimada et al., Nature 396: 670-674, 1998), while MCH over-expressing transgenic mice are obese and insulin resistant (Ludwig et al., J Clin Invest 10 107: 379-386, 2001). MCHR1<sup>-/-</sup> mice have recently been reported to be lean and hypermetabolic, indicating that the R1 isoform mediates at least some of the metabolic effects of MCH (Marsh et al., Proc Nat Acad Sci 99: 3240-3245, 2002).

In addition to its effects on feeding, MCH has been implicated in regulation of the hypothalamic-pituitary-adrenal axis through modulation of CRF and ACTH release 15 (Bluet-Pajot et al., J Neuroendocrinol 7: 297-303, 1995). MCH may also play a role in the modulation of reproductive function (Murray et al., J Neuroendocrinol 12: 217-223, 2000) and memory (Monzon et al., Peptides 20: 1517-1519, 1999).

The current preferred treatment for obesity as well as Type II non-insulin dependent diabetes is diet and exercise with a view toward weight reduction and 20 improved insulin sensitivity for diabetics. Patient compliance, however, is usually poor. The problem is compounded by the fact that there are currently only two medications approved for the treatment of obesity (sibutramine, or Meridia<sup>TM</sup> and orlistat, or Xenical<sup>TM</sup>).

PCT application number WO 01/21577 (JP00/06375) filed September 19, 2000, 25 discloses compounds reportedly useful as antagonists of the MCH receptor. In particular the WO 01/21577 application claims a compound of formula A

PCT International publication WO 03/033476 A1 discloses a compound of the  
 formula (Ia) :

 derivative thereof, wherein the variables are as described therein.

Current treatments targeted at obesity have side effects. Examples of such treatments include various over-the-counter appetite suppressants. These agents have not been proven effective for all patients and for sustainable periods of time. Similarly, the approved treatments, sibutramine (Meridia™) and orlistat (Xenical™) have been associated with side effects which may compromise compliance and may preclude long term use for sustained weight loss for certain patient populations.

Therefore, there is a need for new and/or improved therapeutically effective agents useful as antagonists of melanin concentrating hormone to better control the dietary habits, minimize the preponderance of obesity and treat, prevent and/or ameliorate the effects of obesity, including for example diabetes.

### Detailed Description

For the purposes of the present invention, as disclosed and/or claimed herein, the  
25 following terms are defined below.

The term "main chain" as used herein describes the number of atoms in the shortest distance between two ends of a variable or radical or linker and includes the distance in number of atoms when traversing a straight chain, branched chain or atoms in a mono or bicyclic ring from one end of the variable or radical to the other. As used  
30 herein the radical or group -CH<sub>2</sub>CH<sub>2</sub>OCH<sub>2</sub>CH(CH<sub>2</sub>CH<sub>2</sub>CH<sub>3</sub>)CH<sub>2</sub>- has a chain length of 6.

General chemical terms used in the description of compounds herein described bear their usual meanings. For example, the term "C<sub>1-8</sub> alkyl," or "(C<sub>1</sub>-C<sub>8</sub>)alkyl" or "C<sub>1</sub>-

C<sub>8</sub> alkyl” or as indicated refers to a straight or branched aliphatic chain of 1 to 8 carbon atoms including but not limited to methyl, ethyl, propyl, iso-propyl, n-butyl, pentyl, and and the like as indicated. Unless otherwise stated, the term “alkyl” means C<sub>1</sub>-C<sub>8</sub> alkyl. Similarly, the term “C<sub>0</sub>-C<sub>8</sub> alkyl” implies an alkyl group as indicated wherein when the  
5 term C<sub>0</sub> applies, the alkyl group is not present, and the remaining groups attach directly to the substrate. For example, the group -C<sub>0</sub>-C<sub>8</sub> alkylCONR<sup>10</sup>R<sup>11</sup> implies that when C<sub>0</sub> applies, the group -C<sub>0</sub>-C<sub>8</sub> alkylCONR<sup>10</sup>R<sup>11</sup> becomes to -CONR<sup>10</sup>R<sup>11</sup>.

The invention also contemplates that the term C<sub>1</sub>-C<sub>6</sub> alkyl or C<sub>2</sub>-C<sub>6</sub> alkenyl or similar terms encompass the specified alkyl or alkenyl or similar group, which may be  
10 chiral, regio or stereoisomeric. Such chiral or regio or stereoisomeric groups are also objects of the present invention.

The term “C<sub>3</sub>-C<sub>8</sub> cycloalkyl” as used herein refers to a cyclic hydrocarbon radical or group having from 3 to 8 carbon atoms and having no double bonds. Examples of C<sub>3</sub>-C<sub>8</sub> cycloalkyl groups include but are not limited to cyclopropyl, cyclobutyl, cyclopentyl,  
15 cyclohexyl, cycloheptyl, and cyclooctyl.

The term “C<sub>3</sub>-C<sub>8</sub> cycloalkenyl” as used herein refers to a cyclic hydrocarbon radical or group having from 3 to 8 carbon atoms and having from 1 to 3 double bonds. Specific examples of C<sub>3</sub>-C<sub>8</sub> cycloalkenyl include cyclopropenyl, cyclobutenyl, cyclopentenyl, cyclohexenyl, cycloheptenyl, and cyclooctenyl.

20 The term “halo” means halogens including iodo, chloro, bromo and fluoro.

The term “C<sub>1</sub>-C<sub>4</sub> haloalkyl” refers to a C<sub>1</sub>-C<sub>4</sub> alkyl (or as indicated) group substituted with one, two three or more halogen atoms as possible and chemically appropriate. Examples of C<sub>1</sub>-C<sub>4</sub> haloalkyl include but are not limited to trifluoromethyl, chloroethyl, and 2-chloropropyl. Similarly, a “C<sub>1</sub>-C<sub>8</sub> haloalkyl” group is a C<sub>1</sub>-C<sub>8</sub> alkyl  
25 moiety substituted with up to six halo atoms, preferably one to three halo atoms.

A “C<sub>1</sub>-C<sub>8</sub> alkoxy” group is a C<sub>1</sub>-C<sub>8</sub> alkyl moiety connected through an oxy linkage. Examples of alkoxy groups include but are not limited to methoxy, ethoxy, propoxy, isopropoxy, butoxy, isobutoxy, *sec*-butoxy, pentyloxy, and hexyloxy.

The term “haloalkoxy”, “C<sub>1</sub>-C<sub>8</sub> haloalkyloxy”, -OC<sub>1</sub>-C<sub>8</sub> haloalkyl” or  
30 “halogenated C<sub>1</sub>-C<sub>8</sub> alkoxy” means an alkoxy group having halogen substituents at one or more carbon atoms of the group. The term encompasses groups including for example, difluoromethoxy, trifluoromethoxy, 2-haloethoxy, 2,2,2-trifluoroethoxy, 4,4,4-

trifluorobutoxy, up to and including the like groups having the indicated number of carbon atoms.

The term "cyclic" as used herein refers to substituted or unsubstituted aromatic (including heteroaromatic) and non-aromatic, carbocyclic or heterocyclic ring structures. Cyclic groups may also be monocyclic or bicyclic unless otherwise specified. Aromatic groups include, for example, benzene, thiophene, furan, pyrrole, imidazole, pyrazole, thiazole, isothiazole, oxazole, isoxazole, pyridine, pyrimidine, pyrazine, pyrimidine, pyridazine, naphthyl, 1,2,4-oxadiazole, 1,3,4-oxadiazole, 1,2,4,-thiadiazole, 1,3,4-thiadiazole, pyrrolidine, imidazoline, imidazolidine, pyrazoline, pyrazolidine, tetrahydrothiazole, tetrahydroisothiazole, tetrahydrooxazole, tetrahydroisoxazole, piperidine, tetrahydropyridine, dihydropyridine, piperazine, morpholine, thiomorpholine, tetrahydropyrimidine, tetrahydropyridazine, and hexamethyleneimine. Examples of bicyclic groups within the ambit of cyclic groups as used herein include benzofuran, benzimidazole, benzoxazole, benzothiophene, benzothiazole, benzisothiazole, naphtho[2,3-b]thiophene, naphthyl, isoquinoline, quinoline, indole, indazole, quinoxaline, phenanthridine, phenothiazine, phenoxathin, phenoxazine, naphthylidene, quinazoline, carbazole,  $\beta$ -carboline, acridine, phenazine, phthalimide, and thioxanthene each of which may be optionally substituted. **Preparing Compounds of the Invention**

Scheme 1 shows a synthetic route for preparing a common intermediate VI generally utilized in the preparation of compounds of the invention.

## Scheme 1

Preparation of the intermediate VI starts with the condensation of thioamide I and  
 5 β-keto ester II as shown in step 1. This can be achieved in polar solvent (such as MeOH, EtOH or DMF) from about 2 to 24 hours (h) at a temperature range from about room temperature to 80 °C to give a thiazole of formula III.

In step 2, reduction of the ester III to the alcohol IV can be achieved using one of  
 10 several methods well known in the literature. For example, ester III can be reduced with DIBAL (or other suitable reducing agent like LiAlH<sub>4</sub>, NaBH<sub>4</sub>, and LiBH<sub>4</sub>) in THF (or other aprotic solvent such as ether or toluene) from about 1 to 8h at a temperature range from about -78°C to 60 °C. Compound IV is isolated by aqueous work-up and purified by means known in the art.

As shown in step 3, carboxylic acid V can be prepared from alcohol IV by  
 15 dissolving in THF (or ether) at about -78 °C, slowly treating with a solution of *n*-BuLi (or other suitable base such as LDA or HMDA) over about 2 to 4 hours, then treating with a solution of CO<sub>2</sub> (g) in THF (or ether). Compound V is isolated by precipitation from a dilute aqueous solution and purified by means known in the art.

The use of a Dean-Stark trap accelerates the reaction by removing H<sub>2</sub>O as it is produced.

20 Step 4 involves lactone formation to give VI using anhydrous conditions. For example, a solution of alcohol V in anhydrous toluene (or THF, benzene, etc.) is treated with an acid catalyst (ex. *para*-toluenesulfonic acid) and heated to reflux for 4 to 24 hours

to cyclize to **VI**. The use of a Dean-Stark trap accelerates the reaction by removing H<sub>2</sub>O as it is produced.

5 **Scheme 2. Synthesis of lactam compounds of formula XIII (Route 1).**

Lactone **VI** can be elaborated to provide compounds of formula **XIII** as shown in Scheme 2. In step 5, a nitro compound of formula **VII** that contains a free OH or NH group is protected with an appropriate group, to give compound of formula **VIII** that can be removed later in the synthetic sequence. For example, 2-methoxy-4-nitro-phenol is  
 10 protected as a silyl ether by dissolving the phenol in a polar solvent such as DMF or THF, treating with a base such as sodium hydride, and then adding triisopropylsilyl triflate (or similar silyl reagent like TBSCl, TIPSCl, or TBSOTf). The reaction is stirred within a temperature range of about RT to 50°C for 1 to 24 hours then isolated via aqueous work-up and purified by means known in the art. Other protecting groups for an OH or NH  
 15 group can be employed and are familiar to those skilled in the art (see Philip J. Kocienski, "Protecting Groups," Thieme: New York 1994 or Theodora W. Green, "Protective Groups in Organic Synthesis," John Wiley and Sons: New York, 1981 for additional examples).

In step 6, a compound of formula **VIII** is prepared by reduction of the nitro group  
 20 to give an amine of formula **IX** by treatment with 5-10% Pd/C under H<sub>2</sub> atmosphere (1atm) in a suitable solvent (like THF, EtOAc, EtOH or MeOH) from about 2 to 24 hours at room temperature. Several other nitro reduction techniques known in the art can be employed.

Amide formation, as shown in step 7, is accomplished using a typical Weinreb  
 25 protocol (see Basha, Anwer; Lipton, M.; Weinreb, Steven M. Tetrahedron Letters, 1977,

48, 4171-4174). For example, amine **IX** is dissolved in an aprotic solvent (such as CH<sub>2</sub>Cl<sub>2</sub> or toluene) and treated with a 2–2.5M solution of Me<sub>3</sub>Al in hexanes. The resulting solution is stirred at a temperature from about 0 °C to room temperature for about 5 to 60 minutes, and then treated with lactone **VI**. The resulting solution is stirred  
5 at a range of between about room temperature and 110 °C for about 3 to 24 hours to give amide **X** which is isolated by aqueous work-up and purified by trituration with ether or by flash chromatography.

In step 8, lactam **XI** is prepared under Mitsunobu conditions (Maligres, P. E.; Waters, M. S.; Weissman, S. A.; McWilliams, J. C.; Lewis, S.; Cowen, J.; Reamer, R. A.;  
10 Volante, R. P.; Reider, P. J.; Askin, D. *J. Het. Chem.* 2003, 40(2), 229-241). For example, amide **X** is dissolved in a suitable anhydrous solvent (ex. THF, CH<sub>2</sub>Cl<sub>2</sub>, toluene, etc.) and treated with a trialkyl- or triarylphosphine (ex. Me<sub>3</sub>P, Bu<sub>3</sub>P, or Ph<sub>3</sub>P) and dialkylazo-dicarboxylate (ex. DEAD or DIAD) at a suitable temperature (about 0 °C to RT) for about 4 to 24 hours. Compound **XI** is isolated by aqueous workup and  
15 chromatographic purification.

In step 9, the protecting group that was installed in Step 5 is removed using conditions that are appropriate for the type of protecting group used to give compound of formula **XII**. For example, removal of a silyl ether, such as a triisopropylsilyl group, is achieved by dissolving the silyl ether in a polar solvent like THF or CH<sub>2</sub>Cl<sub>2</sub> and treating  
20 with a fluoride source such as nBu<sub>4</sub>NF or HF•pyridine. The reaction is stirred from about 15 minutes to 4 hours at a temperature within a range of about 0 to 50°C and is isolated by aqueous work-up and purified by means known in the art.

Compounds of formula **XIII** can be prepared by the alkylation of an NH or OH group (see step 10) by dissolving in a polar solvent (like THF, DMF, DMSO, and NMP) and treating with a base such as NaH or K<sub>2</sub>CO<sub>3</sub> and an electrophile (e.g. alkyl halide, alkyl  
25 mesylate, or alkyl tosylate). The reaction is stirred within a range of about room temperature to about 100 °C from 4-24 hours and then isolated by aqueous work-up and purified by means known in the art.

23

### Scheme 3. Synthesis of lactam compounds of formula XIII (Route 2).

Scheme 3 shows an alternative route to compounds of formula XIII. In this approach, the alkylation of an NH or OH group occurs early in the synthetic sequence.

For example, alkylation of VII as shown in Step 11 occurs under conditions similar to step 8 above to give compounds of formula XIV.

In step 13, the nitro group is reduced to an amine as described in step 5. Also, step 13 and 14 proceed under similar conditions as described in steps 7 and 8, respectively, to ultimately provide compounds of formula XIII.

10

### Scheme 4. Synthesis of pyridone compounds of formula XIX (Route 1).

Schemes 4 and 5 show synthetic routes for preparing thiazole-pyridone compounds of the invention and/or precursors thereof.

15

In step 13 of scheme 4, pyridone **XVII** is prepared in one step by the oxidation of intermediate alcohol **X**. For example compound **X** is dissolved in a suitable polar solvent (e.g. CH<sub>2</sub>Cl<sub>2</sub>, THF) and treated with an oxidizing reagent (e.g. Dess-Martin periodinane, pyridine•SO<sub>3</sub>, PDC, or under Swern-oxidation conditions). Oxidation conditions are abundantly known to those skilled in the art and can be found in *Comprehensive Organic Transformations*, by R.C. Larock, VCH Publishers, 1989, p. 604-614. Dess-Martin periodinane is the reagent of choice for this transformation and the oxidation is performed at about 0 °C to room temperature from about 1 hour to 3 days. Pyridone **XVII** is isolated by aqueous workup and chromatographic purification.

In step 14, analogous to step 9 above, removal of the protecting group to reveal an NH or OH group is achieved under similar conditions and the compound of formula **XVIII** is isolated by aqueous work-up and purified by means known in the art.

Alkylation of the OH or NH group of **XVIII** (step 15) can occur under basic conditions with an alkylating reagent, as described in step 10 above, or under Mitsunobu conditions to provide compounds of formula **XIX**.

Alternatively, and as shown in step 16 of Scheme 5, intermediate **XVI** can be oxidized with the sidechain already installed using similar conditions as described in step 13 above to afford thiazole-pyridone compounds of formula **XIX**.

Scheme 5. Synthesis of pyridone compounds of formula **XIX** (Route 2).

Scheme 6 shows a synthetic route for preparing compounds of the invention from an intermediate acetal wherein L<sup>1</sup> is an alkylene of varying carbon chain lengths.

**Scheme 6. Synthesis of amines of formula XXII.**

5

If groups A, B and D (Compound XIII) together define an acetal group (such as A= CH and B=D=OMe or OEt), then hydrolysis to an aldehyde group is performed according to conditions recognized by persons skilled in the art (Scheme 6). For example, in step 17 acetal XX is dissolved in a suitable solvent (e.g. THF, acetone, MeOH) and treated with water and an acid catalyst (e.g. *p*-toluenesulfonic acid) at reflux for about 4 to 24 hours to give aldehyde XXI. Reductive amination (step 18) is performed by dissolving the aldehyde XXI in dichloroethane or another suitable solvent such as for example, CH<sub>2</sub>Cl<sub>2</sub> or THF and treated with an 1° or 2° amine and a reducing reagent such as for example NaCNBH<sub>3</sub>, or NaBH(OAc)<sub>3</sub>. The mixture is stirred at about RT to 80 °C from about 30 min to 8 hours. Amines of formula XXII are isolated by aqueous workup and purified by means known in the art.

Scheme 7 shows an alternative synthetic route for preparing compounds of the invention and/or precursors thereof. In step 19, lactone VI is treated with a protected amine using conditions previously described in step 7 to give amide XXIII. In step 19, Lactam XXIV is prepared using conditions previously described in step 8. The lactam nitrogen is deprotected, as shown in step 21, using conditions consistent with the type of protecting group that is used. For example, a 3,4-dimethoxy benzyl group is removed

under acidic conditions (e.g. *p*-toluene sulfonic acid or TFA) in a solvent such as toluene at a temperature range of RT to reflux for 0.5 to 4h. Lactam **XXIV** is isolated by precipitation from water and purified by means known in the art.

In step 22, the lactam is coupled to an aryl bromide using catalytic cross-coupling conditions such as Buchwald arylation of an amide (see Yin, J.; Buchwald, S.J. *J. Am. Chem. Soc.* **2002**, *124* (21), 6043-6048). For example, lactam of formula **XXIV** is coupled to bromide **XXV** (where P2 is a protecting group for an OH or NH group) using a base such as for example, Cs<sub>2</sub>CO<sub>3</sub>, a palladium reagent such as Pd<sub>2</sub>dba<sub>3</sub>, and a phosphine ligand such as Xantphos<sup>TM</sup> in a non-protic solvent (ex. dioxane, toluene, benzene etc.). The reaction is performed at a temperature range of about RT to reflux from about 3 to 24h and is then isolated by aqueous work-up and purified by means known in the art.

As shown in step 23, the protecting group of **XXVII** is removed using conditions consistent with the type of protecting group that is used. For example, a silyl ether is removed using a Bu<sub>4</sub>NF. In addition, a *p*-toluene sulfonate ester is removed under basic conditions using for example, LiOH in 2:1 dioxane water, to afford a compound of formula **XII**.

In step 24, alkylation of the free NH or OH group of **XII** is achieved using conditions previously described in step 8 to afford a compound of formula **XIII**.

**Scheme 7. Synthesis of lactam compounds of formula XIII (Route 3).**

Scheme 8 shows the preferred synthesis of substituted morpholines that are used as reagents in the synthesis of compounds of the invention.

**Scheme 8. Synthesis of substituted morpholine analogs.**

In step 25, the amino group of methallyl amine (**XXVIII**) is protected with a benzyl group via a reductive amination. Amine **XXVIII** is dissolved in a polar aprotic solvent like and treated with benzaldehyde. The imine intermediate is then reduced with a reducing reagent like  $\text{NaBH}_4$  for 10-24 hours at a temperature range of room temperature to  $50^\circ\text{C}$  to give an amine of formula **XXIX** that is isolated by aqueous work-up and purified by means known in the art.

In step 26, an amine of formula **XXIX** is alkylated by treating with an epoxide (for example, isobutylene oxide) and Lewis acid such as  $\text{LiBr}$  at a temperature range from room temperature to  $60^\circ\text{C}$  for 1 to 8 hours to give alcohol of formula **XXX**. The product is isolated by aqueous work-up and purified by means known in the art.

In step 27, the preferred method for forming the substituted morpholine is via halo-etherification methodology. In this approach, an alcohol of formula **XXX** is treated with iodine. The reaction is performed in a biphasic mixture of a nonpolar aprotic solvent, such as MTBE, and an aqueous basic solution (for example,  $1\text{M NaHCO}_3$ ) for 12 to 24h. The iodide of formula **XXXI** is then isolated by aqueous work-up and purified by means known in the art.

In step 28, the iodide is removed under reducing conditions to give the benzyl morpholine of formula **XXXII**. Typical conditions to remove an alkyl iodide group are to dissolve the iodide **XXXI** in a polar solvent such as DMSO and treat with a reducing

reagent like NaBH<sub>4</sub> for 2 to 6 hours. Morpholine of formula **XXXII** is isolated by aqueous work-up and purified by means known in the art.

In step 29, the benzyl protecting group is removed under typical reductive conditions that are recognized by persons skilled in the art. For example, compound of formula **XXXII** is dissolved in suitable solvent (example THF, ETOH), treated with 3% palladium on activated carbon under hydrogen atmosphere that is pressurized up to 60psi at 40°C for up to 24h. Morpholine of formula **XXXIII** is purified by means known in the art and can be isolated as the hydrochloride salt by treating with an HCl source (ex. 1.0M HCl in ether).

### Demonstration of Function

In order to demonstrate that compounds of the present invention have the capacity to bind to and inhibit the function of MCHR1, binding and functional assays were established. All ligands, radioligands, solvents and reagents employed in these assays are readily available from commercial sources or can be readily prepared by those skilled in the art.

The full-length cDNA for human MCHR1 was cloned from a human adult brain cDNA library (Edge Biosystems, Cat. 38356) by standard polymerase chain reaction (PCR) methodology employing the following primers: sense, 5'-GCCACCATGGACCT GGAAGCCTCGCTGC-3'; anti-sense, 5'-TGGTGCCCTGACTTGGAGGTGTGC-3'. The PCR reaction was performed in a final volume of 50 µl containing 5 µl of a 10x stock solution of PCR buffer, 1 µl of 10 mM dNTP mixture (200 µM final), 2 µl of 50 mM Mg(SO<sub>4</sub>) (2 mM final), 0.5 µl of 20 µM solutions of each primer (0.2 µM final), 5 µl of template cDNA containing 0.5 ng DNA, 0.5 µl of Platinum Taq High Fidelity DNA polymerase (Gibco Life Technologies) and 36 µl of H<sub>2</sub>O. PCR amplification was performed on a Perkin Elmer 9600 thermocycler. After denaturation for 90 sec at 94 °C, the amplification sequence consisting of 94 °C for 25 sec, 55 °C for 25 sec and 72 °C for 2 min was repeated 30 times, followed by a final elongation step at 72 °C for 10 min. The desired PCR product (1.1 Kb) was confirmed by agarose gel electrophoresis and the band was extracted from the gel by GeneClean (Bio101) following the manufacturer's instructions. Following extraction, the cDNA fragment was cloned into pCR2.1-TOPO plasmid (Invitrogen Corp) to confirm the identity and sequence.

30

In order to generate cell lines stably expressing MCHR1, the insert was then subcloned into the Xba I and Not I sites of pcDNA(+)-3.1-neomycin (Invitrogen). After purification by Qiagen Maxi-prep kit (QIAGEN, Inc.), the plasmid was transfected by Fugene 6 (Roche Applied Science) into AV12 cells that had been previously transfected  
5 with the promiscuous G protein  $G_{\alpha 15}$ . The transfected cells were selected by G418 (800  $\mu\text{g}/\text{ml}$ ) for 10-14 days and single colonies were isolated from culture plates. The G418-resistant colonies were further selected for MCHR1 expression by measuring MCH-stimulated  $\text{Ca}^{2+}$  transients with a fluorometric imaging plate reader (FLIPR, Molecular Devices).

10 Typically, individual clones are plated out in 96-well plates at 60,000 cells per well in 100  $\mu\text{l}$  of growth medium (Dulbecco's modified Eagle's medium (DMEM), 5% fetal bovine serum, 2 mM L-glutamine, 10 mM HEPES, 1 mM sodium pyruvate, 0.5 mg/ml Zeocin, and 0.5 mg/ml Geneticin). After 24 hrs at 37°C, medium is removed and replaced with 50  $\mu\text{l}$  of dye loading buffer (Hank's balanced salt solution (HBSS)  
15 containing 25 mM HEPES, 0.04% Plurionate 127 and 8  $\mu\text{M}$  Fluo3 Both from Molecular Probes)). After a 60 min loading period at room temperature, dye loading buffer is aspirated and replaced with 100  $\mu\text{l}$  of HEPES/HBBS. Plate is placed in FLIPR and basal readings are taken for 10 sec, at which point 100  $\mu\text{l}$  of buffer containing 2  $\mu\text{M}$  MCH (1  $\mu\text{M}$  final) is added and measurements are taken over 105 sec. To correct for variations  
20 between clones in numbers of cells per well, the MCH response is normalized to the response induced by epinephrine.

Both the  $^{125}\text{I}$ -MCH binding and functional  $\text{GTP}\gamma^{35}\text{S}$  binding assays employed membranes isolated from a clone designated as clone 43. Typically, cells from 20  
25 confluent T225 flasks were processed by washing the monolayers in cold phosphate-buffered saline (PBS), scraping the cells into same and re-suspending the cell pellet in 35 ml of 250 mM Sucrose, 50 mM HEPES, pH 7.5, 1 mM  $\text{MgCl}_2$ , 24  $\mu\text{g}/\text{ml}$  DNase I, and protease inhibitors (1 Complete® tablet, per 50 ml of buffer prepared, Roche Diagnostics). Alternatively, greater levels of cells could be generated by adapting cell  
30 growth to suspension culture in 20 L stirred vessel bioreactors. After incubation on ice for 5 min, cells were disrupted with 20-25 strokes of a Teflon/Glass homogenizer attached to an overhead motorized stirrer, and the homogenate was centrifuged at 40,000 rpm in

Beckman Type 70.1 Ti rotor. The pellets were re-suspended in 250 mM Sucrose, 50 mM HEPES, pH 7.5, 1.5 mM CaCl<sub>2</sub>, 1 mM MgSO<sub>4</sub> and protease inhibitors by Teflon/Glass homogenization to achieve a protein concentration of ~3-5 mg/ml (Pierce BCA assay with Bovine serum albumin as standard). Aliquots were stored at -70°C.

5 Binding of compounds to MCHR1 was assessed in a competitive binding assay employing <sup>125</sup>I-MCH, compound and clone 43 membranes. Briefly, assays are carried out in 96-well Costar 3632 white opaque plates in a total volume of 200 µl containing 25 mM HEPES, pH 7.0, 10 mM CaCl<sub>2</sub>, 2 mg/ml bovine serum albumin, 0.5% dimethyl sulfoxide (DMSO), 5 µg of clone 43 membranes, 200 pM <sup>125</sup>I-MCH (NEN), 0.625 mg/ml of wheat  
10 germ agglutinin scintillation proximity assay beads (WGA-SPA beads, Amersham Inc., now GE Healthcare) and a graded dose of test compound. Non-specific binding is assessed in the presence of 0.1 µM unlabeled MCH. Bound <sup>125</sup>I-MCH is determined by placing sealed plates in a Microbeta Trilux (Perkin Elmer Life and Analytical Sciences Inc.) and counting after a 12 hr delay.

15 IC<sub>50</sub> values (defined as the concentration of test compound required to reduce specific binding of <sup>125</sup>I-MCH by 50%) are determined by fitting the concentration-response data to a 4-parameter model (max response, min response, Hill coefficient, IC<sub>50</sub>) using Excel<sup>®</sup> (Microsoft Corp.). K<sub>i</sub> values are calculated from IC<sub>50</sub> values using the Cheng-Prusoff approximation as described by Cheng *et al.* (Relationship between the  
20 inhibition constant (K<sub>i</sub>) and the concentration of inhibitor which causes 50% inhibition (IC<sub>50</sub>) of an enzymatic reaction, *Biochem. Pharmacol.*, 22: 3099-3108 (1973)). The K<sub>d</sub> for <sup>125</sup>I-MCH is determined independently from a saturation binding isotherm. Exemplified compounds showed a K<sub>i</sub> of < 1 µM under the binding assay conditions. Specifically, a sample of observed K<sub>i</sub> values is provided in Table 1 (below) for  
25 demonstration purposes only.

Functional antagonism of MCH activity is assessed by measuring the ability of test compound to inhibit MCH-stimulated binding of  $\text{GTP}\gamma^{35}\text{S}$  to clone 43 membranes. Briefly, assays are carried out in Costar 3632 white opaque plates in a total volume of 200  $\mu\text{l}$  containing 50 mM Hepes, pH 7.4, 5 mM  $\text{MgCl}_2$ , 10  $\mu\text{g/ml}$  saponin, 1.0 mg/ml bovine serum albumin, 100 mM NaCl, 3  $\mu\text{M}$  GDP, 0.3 nM  $\text{GTP}\gamma^{35}\text{S}$ , 10 nM MCH (approximately equal to  $\text{EC}_{90}$ ), 20  $\mu\text{g}$  of clone 43 membranes, 5.0 mg/ml of wheat germ agglutinin scintillation proximity assay beads (WGA-SPA beads, Amersham Inc., now GE Healthcare) and a graded dose of test compound. The plates are sealed and left for 16-18 hrs at 4°C. After a 1 hr delay to allow plates to equilibrate to ambient temperature, bound  $\text{GTP}\gamma^{35}\text{S}$  is determined by counting in a Microbeta Trilux (Perkin Elmer Life and Analytical Sciences Inc).

$\text{IC}_{50}$  values (defined as the concentration of test compound required to reduce MCH-stimulated  $\text{GTP}\gamma^{35}\text{S}$  binding by 50%) are determined by fitting the concentration-response data to a 4-parameter model (max response, min response, Hill coefficient,  $\text{IC}_{50}$ ) using Excel (Microsoft). After verifying competitive antagonism by Schild analysis,  $K_b$  values are calculated from the  $\text{IC}_{50}$  values for each antagonist and the  $\text{EC}_{50}$  for MCH (determined independently) using a modification of the Cheng-Prusoff approximation as described by Leff and Dougal (*Trends Pharmacol. Sci.* (1993) 14: 110-112). Exemplified compounds showed  $\text{IC}_{50}$  values of  $< 1 \mu\text{M}$  under the functional assay conditions disclosed herein.

In order to demonstrate in vivo efficacy, compounds of the invention were administered by oral gavage to diet-induced obese male Long-Evans rats (Harlan, IN) weighing 500-550g. Vehicle consisted of 1% CMC and 0.25% PS-80 in water.

Animals were individually housed in a temperature regulated room (24°C) with a reverse 12 hour light/dark cycle (dark 10:00/22:00). Water and food (Teklad 95217, Harlan, WI) were available *ad libitum*. Compounds were dosed orally once a day before onset of dark for 3 days. Daily food intake and body weight change were measured for the 3 day period. Exemplified compounds tested at 10 mg/kg showed reduction of 3 day cumulative body weight gain when compared with vehicle-treated controls. Specifically,

a sample of observed 3 day cumulative body weight reduction, relative to control, is provided in Table 2 (below) for demonstration purposes only.

The compositions of the invention may be formulated so as to provide quick, sustained or delayed release of the active ingredient after administration to the patient.

### Dose

The specific dose administered is determined by the particular circumstances surrounding each situation. These circumstances include, the route of administration, the prior medical history of the patient, the pathological condition or symptom being treated, the severity of the condition/symptom being treated, and the age and sex of the recipient. However, it will be understood that the therapeutic dosage administered will be determined by the physician in the light of the relevant circumstances, or by the veterinarian for non-human recipients.

Generally, an effective minimum daily dose of a compound of formula I is about 20 to 200 mg. Typically, an effective maximum dose is about 200 to 1000 mg. The exact dose may be determined, in accordance with the standard practice in the medical arts of "dose titrating" the recipient; that is, initially administering a low dose of the compound, and gradually increasing the dose until the desired therapeutic effect is observed.

15

### Route of Administration

When a compound of formula I is used contemporaneously with one or more other drugs, a pharmaceutical unit dosage form containing such other drugs in addition to the compound of formula I is preferred. Accordingly, the pharmaceutical compositions of the present  
10 invention include those that also contain one or more other active ingredients, in addition to a compound of formula I.
