w (Table Width Value)	Specifies the value of the width property being defined by the parent element. This property is used to define various properties of a table, including: cell spacing, preferred widths, and table margins. If this attribute is omitted, then its value shall be assumed to be 0. [*Example*: Consider a table with a bottom margin with a width of 302, as follows: `<w:bottom w:w="302" w:type="dxa" />` The value in the w attribute shall therefore be used to determine the width being specified in the context of the units specified in the type attribute. In this case, the type is twentieths of a point (dxa), so the width is 302 twentieths of a point (.2097 inches). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type

Attributes	Description
	(§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblWidth">
   <attribute name="w" type="ST_DecimalNumber"/>
   <attribute name="type" type="ST_TblWidth"/>
</complexType>
```

2.4.43 tblCellSpacing (Table Cell Spacing Default)

This element specifies the default table cell spacing (the spacing between adjacent cells and the edges of the table) for all cells in the parent table. If specified, this element specifies the minimum amount of space which shall be left between all cells in the table including the width of the table borders in the calculation. This setting shall be superseded by a table-level exception (§2.4.41) or the row cell spacing value (§2.4.42) in that order. It is important to note that table-level cell spacing shall be added outside of the text margins, which shall be aligned with the innermost starting edge of the text extents in a table cell.

This value is specified in the units applied via its type attribute. Any width value of type `pct` or `auto` for this element shall be ignored.

[*Example*: Consider a table whose first cell has a six point wide table border, and a table cell spacing value of 0.01 inches. The resulting table would have 0.01 inches of space between each table cell regardless of the width of the cell border, as follows (notice that no border is covered by any other border):

R1C1	R1C2
R2C1	R2C2

end example]

If this element is omitted, then the table shall inherit the table cell spacing from the associated table style. If table cell spacing is never specified in the style hierarchy, no cell spacing shall be added to the parent table.

[*Example*: Consider a table with a default cell spacing of 0.1 inches for all sides as follows:

R1C1	R1C2
R2C1	R2C2

This table cell spacing deafult is specified using the following WordprocessingML:

```
<w:tblPr>
  <w:tblCellSpacing w:w="144" w:type="dxa">
  …
</w:tblPr>
```

The tblCellSpacing element as a child of tblPr specifies the default cell spacing between all cells in the current table, in this case 144 twentieths of a point. *end example*]

Parent Elements
tblPr (§2.7.5.3); tblPr (§2.7.5.4); tblPr (§2.4.55); tblPr (§2.4.56)

Attributes	Description
type (Table Width Type)	Specifies the units of the width property being defined by the parent element's w attribute. This property is used to define various properties of a table, including: cell spacing, preferred width, and table margins. If this attribute is omitted, then its value shall be assumed to be dxa (twentieths of a point). [*Example*: Consider a table with a table cell bottom cell spacing with a type of dxa, as follows: `<w:bottom ... w:type="dxa" />` This type shall therefore be used to interpret the width specified in the w attribute as a value in twentieths of a point. *end example*] The possible values for this attribute are defined by the ST_TblWidth simple type (§2.18.97).
w (Table Width Value)	Specifies the value of the width property being defined by the parent element. This property is used to define various properties of a table, including: cell spacing, preferred widths, and table margins. If this attribute is omitted, then its value shall be assumed to be 0. [*Example*: Consider a table with a bottom margin with a width of 302, as follows: `<w:bottom w:w="302" w:type="dxa" />` The value in the w attribute shall therefore be used to determine the width being specified in the context of the units specified in the type attribute. In this case, the type is twentieths of a point (dxa), so the width is 302 twentieths of a point (.2097 inches). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type

Attributes	Description
	(§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblWidth">
   <attribute name="w" type="ST_DecimalNumber"/>
   <attribute name="type" type="ST_TblWidth"/>
</complexType>
```

2.4.44 tblGrid (Table Grid)

This element specifies the table grid for the current table. The *table grid* is a definition of the set of grid columns which define all of the shared vertical edges of the table, as well as default widths for each of these grid columns. These grid column widths are then used to determine the size of the table based on the table layout algorithm used (§2.4.49;§2.4.50).

If the table grid is omitted, then a new grid shall be constructed from the actual contents of the table assuming that all grid columns have a width of `0`.

[*Example*: Consider the following table with four vertical edges (grid columns):

This table would have a table grid consisting of four grid columns as follows:

```
<w:tblGrid>
  <w:gridCol w:w="2088"/>
  <w:gridCol w:w="1104"/>
  <w:gridCol w:w="3192"/>
  <w:gridCol w:w="3192"/>
</w:tblGrid>
```

The tblGrid element contains the current definition for the table grid, consisting of all for grid columns as well as default widths for those columns. *end example*]

Parent Elements
tbl (§2.4.36)

Child Elements	Subclause
gridCol (Grid Column Definition)	§2.4.12

Child Elements	Subclause
tblGridChange (Revision Information for Table Grid Column Definitions)	§2.13.5.35

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblGrid">
   <complexContent>
      <extension base="CT_TblGridBase">
         <sequence>
            <element name="tblGridChange" type="CT_TblGridChange" minOccurs="0"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.4.45 tblGrid (Previous Table Grid)

This element specifies a previous table grid state, the modifications to which shall be attributed to a revision by a particular author and at a particular time. This element contains the table grid settings which were previously in place before a specific set of revisions by one author. The *table grid* is a definition of the set of grid columns which define all of the shared vertical edges of the table, as well as default widths for each of these grid columns. These grid column widths are then used to determine the size of the table based on the table layout algorithm used (§2.4.49;§2.4.50).

[*Example*: Consider the following table with four vertical edges (grid columns):

If we now modify this table by reducing the size of the last column without changing the overall table width, as follows:

This table would have a table grid consisting of four grid columns as follows:

```
<w:tblGrid>
  <w:gridCol w:w="2088"/>
  <w:gridCol w:w="1104"/>
  <w:gridCol w:w="3583"/>
  <w:gridCol w:w="2801"/>
  <w:tblGridChange w:id="1">
    <w:tblGrid>
      <w:gridCol w:w="2088"/>
      <w:gridCol w:w="1104"/>
      <w:gridCol w:w="3192"/>
      <w:gridCol w:w="3192"/>
    </w:tblGrid>
  </w:tblGridChange>
</w:tblGrid>
```

The tblGrid element as a child of tblGridChange contains the previous definition for the table grid, consisting of all for grid columns as well as the original widths for those columns. *end example*]

Parent Elements
tblGridChange (§2.13.5.35)

Child Elements	Subclause
gridCol (Grid Column Definition)	§2.4.12

The following XML Schema fragment defines the contents of this element:

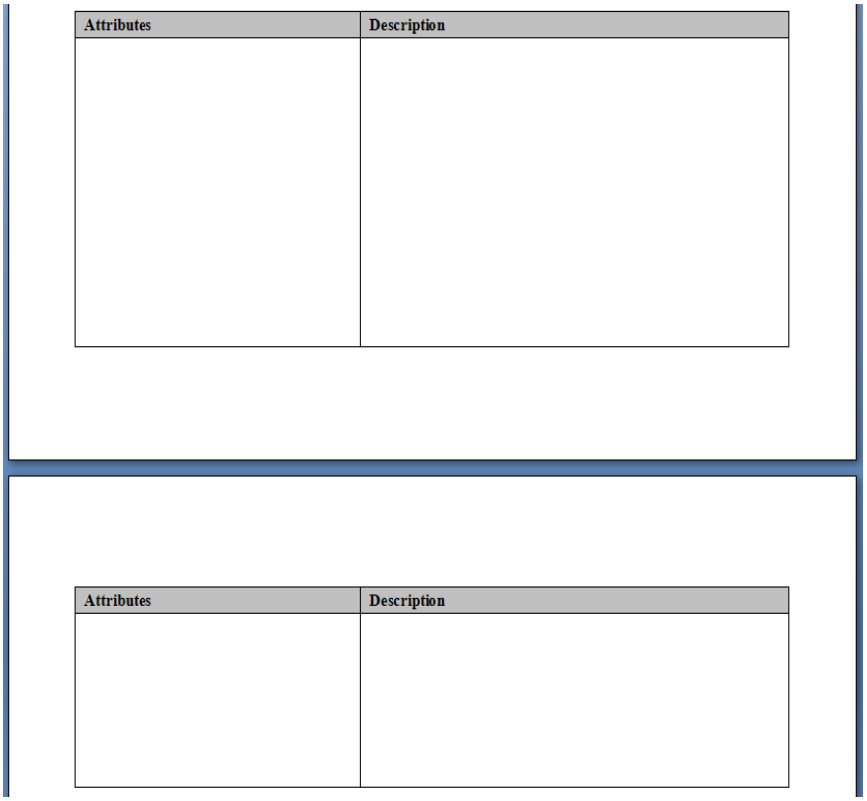
```
<complexType name="CT_TblGridBase">
   <sequence>
      <element name="gridCol" type="CT_TblGridCol" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
</complexType>
```

2.4.46 tblHeader (Repeat Table Row on Every New Page)

This element specifies that the current table row shall be repeated at the top of each new page on which part of this table is displayed. This gives this table row the behavior of a 'header' row on each of these pages.

If this element is omitted, then the table shall inherit the table cell spacing from the associated table style. If table cell spacing is never specified in the style hierarchy, then this table row shall not be repeated on each new page on which the table is displayed. As well, if this row is not contiguously connected with the first row of the table (that is, if this table row is not either the first row, or all rows between this row and the first row are not marked as header rows) then this property shall be ignored.

[*Example*: Consider a table which shall have its first row repeated on each new page, like the attribute listings in this Office Open XML Standard, for example:



Notice that the first row in the table is repeated on the top of the second page. This requirement would be specified as follows in the WordprocessingML for that row:

```
<w:trPr>
  <w:tblHeader />
</w:trPr>
```

The tblHeader element specifies that this table row will now be repeated as a header row at the top of each page. *end example*]

Parent Elements
trPr (§2.7.5.10); trPr (§2.7.5.11); trPr (§2.4.78); trPr (§2.4.79)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off.

Attributes	Description
	[*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.4.47 tblInd (Table Indent from Leading Margin Exception)

This element specifies the indentation which shall be added before the leading edge of the set of parent table rows which have this set of table-level property exceptions applied. This indentation should shift the table into the text margin by the specified amount in the document (the left edge in a left-to-right table, and the right edge in a right-to-left table).

This value is specified in the units applied via its type attribute. Any width value of type pct or auto for this element shall be ignored.

If this element is omitted, then the table shall inherit the table indentation from the associated table level property setting. If the resulting justification on the parent table row is not left after applying the value of the jc element from the three levels of this property (§2.4.21;§2.4.22;§2.4.23), then this property shall be ignored.

[*Example*: Consider a table in which the last two rows shall be indented one inch from the left margin via a table-level property exception definition, as follows:

This setting would be specified using the following WordprocessingML:

```
<w:tblPrEx>
  <w:tblInd w:val="1440" w:type="dxa"/>
</w:tblPrEx>
```

The tblInd element as a child of tblPrEx specifies that the rows with the table-level property exception shall be indented by 1440 twentieths of a point (one inch). *end example*]

Parent Elements
tblPrEx (§2.4.57); tblPrEx (§2.4.58)

Attributes	Description
type (Table Width Type)	Specifies the units of the width property being defined by the parent element's w attribute. This property is used to define various properties of a table, including: cell spacing, preferred width, and table margins. If this attribute is omitted, then its value shall be assumed to be dxa (twentieths of a point). [*Example*: Consider a table with a table cell bottom cell spacing with a type of dxa, as follows: `<w:bottom ... w:type="dxa" />` This type shall therefore be used to interpret the width specified in the w attribute as a value in twentieths of a point. *end example*] The possible values for this attribute are defined by the ST_TblWidth simple type (§2.18.97).
w (Table Width Value)	Specifies the value of the width property being defined by the parent element. This property is used to define various properties of a table, including: cell spacing, preferred widths, and table margins. If this attribute is omitted, then its value shall be assumed to be 0. [*Example*: Consider a table with a bottom margin with a width of 302, as follows: `<w:bottom w:w="302" w:type="dxa" />` The value in the w attribute shall therefore be used to determine the width being specified in the context of the units specified in the type attribute. In this case, the type is twentieths of a point (dxa), so the width is 302 twentieths of a point (.2097 inches). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblWidth">
   <attribute name="w" type="ST_DecimalNumber"/>
   <attribute name="type" type="ST_TblWidth"/>
</complexType>
```

2.4.48 tblInd (Table Indent from Leading Margin)

This element specifies the indentation which shall be added before the leading edge of the current table in the document (the left edge in a left-to-right table, and the right edge in a right-to-left table). This indentation should shift the table into the text margin by the specified amount.

This value is specified in the units applied via its type attribute. Any width value of type `pct` or `auto` for this element shall be ignored.

If this element is omitted, then the table shall inherit the table indentation from the associated table style. If table indentation is never specified in the style hierarchy, no indentation shall be added to the parent table. If the resulting justification on any table row is not `left` after applying the value of the jc element from the three levels of this property (§2.4.21;§2.4.22;§2.4.23), then this property shall be ignored.

[*Example*: Consider a table which shall be indented one inch from the left margin, as follows:

R1C1	R1C2
R2C1	R2C2

This setting would be specified using the following WordprocessingML:

```
<w:tblPr>
  <w:jc w:val="left"/>
  <w:tblInd w:val="1440" w:type="dxa"/>
</w:tblPr>
```

If the properties on this table were now modified to justify it on the right side by setting the value of the jc element to `right`, as follows:

```
<w:tblPr>
  <w:jc w:val="right"/>
  <w:tblInd w:val="1440" w:type="dxa"/>
</w:tblPr>
```

This table would now have no indent, as the justification is no longer on the leading edge (`left`):

R1C1	R1C2
R2C1	R2C2

end example]

Parent Elements
tblPr (§2.7.5.3); tblPr (§2.7.5.4); tblPr (§2.4.55); tblPr (§2.4.56)

Attributes	Description
type (Table Width Type)	Specifies the units of the width property being defined by the parent element's w attribute. This property is used to define various properties of a table, including: cell spacing, preferred width, and table margins. If this attribute is omitted, then its value shall be assumed to be dxa (twentieths of a point). [*Example*: Consider a table with a table cell bottom cell spacing with a type of dxa, as follows: `<w:bottom ... w:type="dxa" />` This type shall therefore be used to interpret the width specified in the w attribute as a value in twentieths of a point. *end example*] The possible values for this attribute are defined by the ST_TblWidth simple type (§2.18.97).
w (Table Width Value)	Specifies the value of the width property being defined by the parent element. This property is used to define various properties of a table, including: cell spacing, preferred widths, and table margins. If this attribute is omitted, then its value shall be assumed to be 0. [*Example*: Consider a table with a bottom margin with a width of 302, as follows: `<w:bottom w:w="302" w:type="dxa" />` The value in the w attribute shall therefore be used to determine the width being specified in the context of the units specified in the type attribute. In this case, the type is twentieths of a point (dxa), so the width is 302 twentieths of a point (.2097 inches). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblWidth">
   <attribute name="w" type="ST_DecimalNumber"/>
   <attribute name="type" type="ST_TblWidth"/>
</complexType>
```

2.4.49 tblLayout (Table Layout)

This element specifies the algorithm which shall be used to lay out the contents of this table within the document. When a table is displayed in a document, it can either be displayed using a fixed width or autofit layout algorithm (each discussed in the simple type referenced by the val attribute).

If this element is omitted, then the value of this element shall be assumed to be auto.

[*Example*: Consider a table which shall use the fixed width table layout algorithm. This requirement is specified using the following WordprocessingML:

```
<w:tblPr>
  <w:tblLayout w:type="fixed"/>
</w:tblPr>
```

The tblLayout element specifies that the table shall use the fixed layout algorithm. *end example*]

Parent Elements
tblPr (§2.7.5.3); tblPr (§2.7.5.4); tblPr (§2.4.55); tblPr (§2.4.56)

Attributes	Description

type (Table Layout Setting)	Specifies the algorithm which shall be used to lay out the contents of the parent table (see simple type definition for details on each algorithm used).
	
	[*Example*: Consider a table which shall use the AutoFit width table layout algorithm. This requirement is specified using the following WordprocessingML:
	
	`<w:tblPr>`
	`  <w:tblLayout w:type="auto"/>`
	`</w:tblPr>`
	
	The tblLayout element specifies that the table shall use the auto layout algorithm. *end example*]
	
	The possible values for this attribute are defined by the ST_TblLayoutType simple type (§2.18.94).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblLayoutType">
   <attribute name="type" type="ST_TblLayoutType"/>
</complexType>
```

2.4.50 tblLayout (Table Layout Exception)

This element specifies the algorithm which shall be used to lay out the contents of all rows with this table within the table which have the set of table-level property exceptions specified by the parent element. When a table is displayed in a document, it can either be displayed using a fixed width or autofit layout algorithm (each discussed in the simple type referenced by the val attribute).

If this element is omitted, then the value of this element shall be assumed to be auto.

[*Example*: Consider a table which shall use the fixed width table layout algorithm. This requirement is specified using the following WordprocessingML:

```
<w:tblPrEx>
  <w:tblLayout w:type="fixed"/>
</w:tblPrEx>
```

The tblLayout element specifies that the table shall use the `fixed` layout algorithm. *end example*]

Parent Elements
tblPrEx (§2.4.57); tblPrEx (§2.4.58)

Attributes	Description

type (Table Layout Setting)	Specifies the algorithm which shall be used to lay out the contents of the parent table (see simple type definition for details on each algorithm used).
	
	[*Example*: Consider a table which shall use the AutoFit width table layout algorithm. This requirement is specified using the following WordprocessingML:
	
	`<w:tblPr>`
	`  <w:tblLayout w:type="auto"/>`
	`</w:tblPr>`
	
	The tblLayout element specifies that the table shall use the `auto` layout algorithm. *end example*]
	
	The possible values for this attribute are defined by the ST_TblLayoutType simple type (§2.18.94).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblLayoutType">
   <attribute name="type" type="ST_TblLayoutType"/>
</complexType>
```

2.4.51 tblLook (Table Style Conditional Formatting Settings)

This element specifies the components of the conditional formatting of the referenced table style (if one exists) which shall be applied to the current table. A table style can specify up to six different optional conditional formats [*Example*: Different formatting for first column. *end example*], which then can be applied or omitted from individual tables in the document.

This element's value is hexadecimal code containing a bitmask of options, interpreted as follows:

- 0x0020=Apply first row conditional formatting
- 0x0040=Apply last row conditional formatting

- 0x0080=Apply first column conditional formatting
- 0x0100=Apply last column conditional formatting
- 0x0200=Do not apply row banding conditional formatting
- 0x0400=Do not apply column banding conditional formatting

If omitted, the bitmask of table style options on the current table shall be assumed to be `0000`.

[*Example*: Consider a table which shall use the following conditional formatting properties from the referenced table style:

- First row conditional formatting
- Last row conditional formatting

This table would then apply the following portions of the bitmask:

- 0x0020=Apply first row conditional formatting
- 0x0040=Apply last row conditional formatting
- 0x0200=Do not apply row banding conditional formatting
- 0x0400=Do not apply column banding conditional formatting

The resulting WordprocessingML would be specified as follows:

```
<w:tblPr>
  <w:tblLook w:val="0660"/>
</w:tblPr>
```

The tblLook element specifies a bitmask which determines the components of the table style applied to the current table. *end example*]

Parent Elements
tblPr (§2.7.5.3); tblPr (§2.7.5.4); tblPr (§2.4.55); tblPr (§2.4.56)

Attributes	Description

val (Two Digit Hexadecimal Value)	Specifies a value specified as a two digit hexadecimal number), whose contents are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:tblPr>`
	`  <w:tblLook w:val="0010" />`
	`</w:tblPr>`
	
	The value of `0010` is interpreted in the context of the parent element. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_ShortHexNumber simple type (§2.18.86).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_ShortHexNumber">
   <attribute name="val" type="ST_ShortHexNumber" use="required"/>
</complexType>
```

2.4.52 tblLook (Table Style Conditional Formatting Settings Exception)

This element specifies the components of the conditional formatting of the referenced table style (if one exists) which shall be applied to the set of table rows with the current table-level property exceptions. A table style can specify up to six different optional conditional formats [*Example*: Different formatting for first column. *end example*], which then can be applied or omitted from individual table rows in the parent table.

This element's value is hexadecimal code containing a bitmask of options, interpreted as follows:

- 0x0020=Apply first row conditional formatting
- 0x0040=Apply last row conditional formatting
- 0x0080=Apply first column conditional formatting
- 0x0100=Apply last column conditional formatting
- 0x0200=Do not apply row banding conditional formatting
- 0x0400=Do not apply column banding conditional formatting

If omitted, the bitmask of table style options on the current table row shall be assumed to be the value specified on the table-level properties.

[*Example*: Consider a table which shall use the following conditional formatting properties from the referenced table style:

- First row conditional formatting
- Last row conditional formatting

This table would then apply the following portions of the bitmask:

- 0x0020=Apply first row conditional formatting
- 0x0040=Apply last row conditional formatting
- 0x0200=Do not apply row banding conditional formatting
- 0x0400=Do not apply column banding conditional formatting

The resulting WordprocessingML would be specified as follows:

```
<w:tblPrEx>
  <w:tblLook w:val="0660"/>
</w:tblPrEx>
```

The tblLook element specifies a bitmask which determines the components of the table style applied to the current table. *end example*]

Parent Elements
tblPrEx (§2.4.57); tblPrEx (§2.4.58)

Attributes	Description

val (Two Digit Hexadecimal Value)	Specifies a value specified as a two digit hexadecimal number), whose contents are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:tblPr>`
	`  <w:tblLook w:val="0010" />`
	`</w:tblPr>`
	
	The value of `0010` is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_ShortHexNumber simple type (§2.18.86).

The following XML Schema fragment defines the contents of this element:

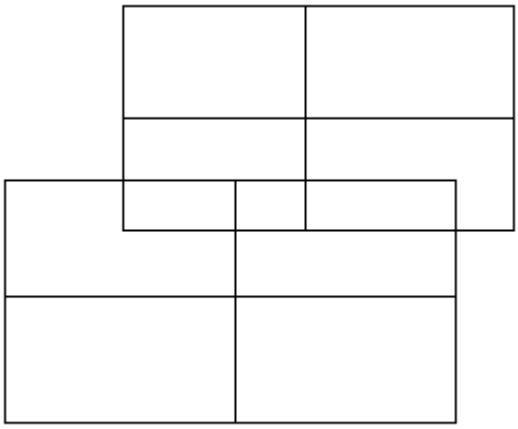
```
<complexType name="CT_ShortHexNumber">
   <attribute name="val" type="ST_ShortHexNumber" use="required"/>
</complexType>
```

2.4.53 tblOverlap (Floating Table Allows Other Tables to Overlap)

This element specifies whether the current table shall allow other floating tables to overlap its extents when the tables are displayed in a document. If specified, then no adjustment shall be made to prevent tables whose properties would normally cause them to overlap from overlapping when displayed. If turned off, then the tables shall be adjusted as needed to prevent them from overlapping when displayed by adjusting the floating table properties as needed.

If this element is omitted on a given table, then this table shall allow other tables to overlap when displayed. If the parent table is not floating via the tblpPr element (§2.4.54), then this element shall be ignored.

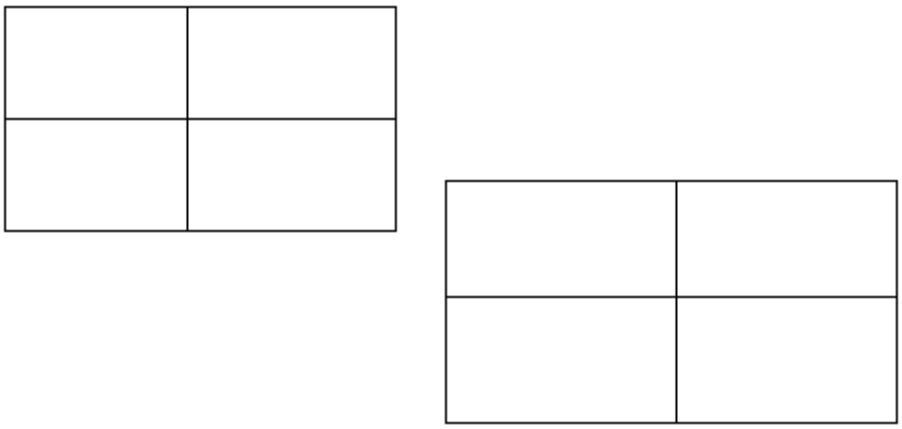
[*Example*: Consider two floating tables in a WordprocessingML document which overlap when displayed, as follows:



If either of these tables specifies that it shall not allow overlapping, using the following WordprocessingML:

```
<w:tblPr>
  <w:tblOverlap w:val="never"/>
</w:tblPr>
```

The resulting tables shall not overlap, and must be adjusted at display time to prevent any overlapping, for example:



The tblOverlap element with a value of never specifies that the specified table cannot overlap with other floating tables in the document. *end example*]

Parent Elements
tblPr (§2.7.5.3); tblPr (§2.7.5.4); tblPr (§2.4.55); tblPr (§2.4.56)

Attributes	Description
val (Floating Table Overlap Setting)	Specifies whether a floating table shall allow other floating tables in the document to overlap its extents when displayed. [*Example*: The following WordprocessingML specifies that the table is not allowed to overlap: `<w:tblOverlap w:val="never" />` *end example*] The possible values for this attribute are defined by the ST_TblOverlap simple type (§2.18.95).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblOverlap">
   <attribute name="val" type="ST_TblOverlap" use="required"/>
</complexType>
```

2.4.54 tblpPr (Floating Table Positioning)

This element specifies information about the current table with regard to floating tables. *Floating tables* are tables in a document which are not part of the main text flow in the document, and are instead absolutely positioned with a specific size and position relative to non-frame content in the current document.

The first piece of information specified by the tblpPr element is that the current table is actually a floating table. This information is specified simply by the presence of the tblpPr element in table's properties. If the tblpPr element is omitted, the table shall not floating in the document.

The second piece of information is the positioning of the table, which is specified by the attribute values stored on the tblpPr element. In all absolute positioning cases, the positioning of the table is relative to its top-left corner position. For relative positioning (e.g. center), the positioning of the table is relative to its entire frame.

Note that the table still has a logical position in the file (its location within the block-level elements in the document). This logical location shall be used to calculate the position of the table relative to a paragraph, using the next regular (non-table, non-frame) paragraph in the document.

[*Example*: Consider a floating table which is positioned three inches from the edge of the page extents on both its top and left edges (i.e. the top-left corner occurs at 3" x 3"). This floating table would be specified using the following WordprocessingML:

```
<w:tbl>
  <w:tblPr>
    <w:tblpPr w:leftFromText="144" w:rightFromText="144" w:topFromText="144"
w:bottomFromText="144" w:vertAnchor="page" w:horzAnchor="page" w:tblpX="4320"
w:tblpY="4320"/>
    …
  </w:tblPr>
  …</w:tbl>
```

The presence of the tblpPr element dictates that this table is a floating table, and its attributes specify that the floating table shall be anchored 4320 twentieths of a point (3 inches) from the top and left edges of the current page. *end example*]

Parent Elements
tblPr (§2.7.5.3); tblPr (§2.7.5.4); tblPr (§2.4.55); tblPr (§2.4.56)

Attributes	Description

bottomFromText (Distance From Bottom of Table to Text)	Specifies the minimum distance which shall be maintained between the current floating table and the top of text in the paragraph which is below this floating table.
	
	This distance is expressed in twentieths of a point.
	
	If this attribute is omitted, its value shall be assumed to be 0.
	
	[*Example*: Consider a floating table which should have a minimum of a one-half inch spacing from any text on its bottom side. This constraint would be specified using the following WordprocessingML:
	
	`<w:tblPr>`
	`  <w:tblpPr … w:bottomFromText="720" />`
	`</w:tblPr>`
	
	The bottomFromText attribute specifies that the spacing between text and this floating table shall be a minimum of 720 twentieths of a point. *end example*]
	
	The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

horzAnchor (Table Horizontal Anchor)	Specifies the base object from which the horizontal positioning in the tblpX and/or tblpXSpec attribute should be calculated. A floating table may be horizontally positioned relative to: • The vertical edge of the page before any runs of text (the left edge for left-to-right paragraphs, the right edge for right-to-left paragraphs) • The vertical edge of the text margin before any runs of text (the left edge for left-

Attributes	Description

	to-right paragraphs, the right edge for right-to-left paragraphs)
	• The vertical edge of the text margin for the column in which the anchor paragraph is located
	
	If this attribute is omitted, then its value shall be assumed to be page.
	
	[*Example*: Consider a floating table which should be positioned one inch to the right of its column in a left-to-right document. This floating table would be specified using the following WordprocessingML:
	
	`<w:tblPr>`
	`  <w:tblpPr … w:tblpX="1440" w:horzAnchor="column" />`
	`</w:tblPr>`
	
	These table properties specify that they are relative to the current `column`, and that relative to that column, the floating table should be `1440` twentieths of a point. *end example*]
	
	The possible values for this attribute are defined by the ST_HAnchor simple type (§2.18.40).

leftFromText (Distance From Left of Table to Text)	Specifies the minimum distance which shall be maintained between the current floating table and the edge of text in the paragraph which is to the left of this floating table.
	
	This distance is expressed in twentieths of a point.
	
	If this attribute is omitted, its value shall be assumed to be `0`.
	
	[*Example*: Consider a floating table which should have a minimum of a one-half inch spacing from any text on its left. This constraint would be specified using the following WordprocessingML:
	
	`<w:tblPr>`
	`  <w:tblpPr … w:leftFromText="720" />`
	`</w:tblPr>`
	
	The leftFromText attribute specifies that the spacing between text and this floating table shall be a minimum of `720` twentieths of a point. *end example*]
	
	The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

rightFromText ((Distance From Right of Table to Text)	Specifies the minimum distance which shall be maintained between the current floating table and the edge of text in the paragraph which is to the right of this floating table. This distance is expressed in twentieths of a point.

Attributes	Description

	If this attribute is omitted, its value shall be assumed to be 0.
	
	[*Example*: Consider a floating table which should have a minimum of a one-half inch spacing from any text on its right. This constraint would be specified using the following WordprocessingML:
	
	`<w:tblPr>`
	`  <w:tblpPr … w:rightFromText="720" />`
	`</w:tblPr>`
	
	The rightFromText attribute specifies that the spacing between text and this floating table shall be a minimum of 720 twentieths of a point. *end example*]
	
	The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

tblpX (Absolute Horizontal Distance From Anchor)	Specifies an absolute horizontal position for the floating table. This absolute position is specified relative to the horizontal anchor specified by the horzAnchor attribute for this floating table.
	
	This value is expressed in twentieths of a point. If it is positive, then the floating table is positioned after the anchor object in the direction of horizontal text flow in this document. If it is negative, then the floating table is positioned before the anchor object in the direction of horizontal text flow in this document.
	
	If the tblpXSpec attribute is also specified, then this value is ignored. If this attribute is omitted, then its value shall be assumed to be 0.
	
	[*Example*: Consider the following WordprocessingML fragment specifying a floating table:
	
	`<w:tbl>`
	`  <w:tblPr>`
	`  <w:tblpPr … w:horizAnchor="page" w:tblpX="1643"/>`
	`  </w:tblPr>`
	`  …`
	`</w:tbl>`
	
	This floating table specifies that it should be located exactly 1643 twentieths of a point after the vertical edge of the page (from the horizAnchor attribute). *end example*]
	
	The possible values for this attribute are defined by the ST_SignedTwipsMeasure simple type (§2.18.88).

tblpXSpec (Relative Horizontal Alignment From Anchor)	Specifies a relative horizontal position for the floating table. This relative position is specified relative to the horizontal anchor specified by the horizAnchor attribute for this floating table. If omitted, this attribute is not specified and the value of the tblpX attribute determines

Attributes	Description

	the absolute horizontal position of the floating table. If specified, the position for this attribute supersedes any value which is specified in the tblpX attribute, and that value is ignored.
	
	[*Example*: Consider the following WordprocessingML fragment specifying a floating table:
	
	`<w:tbl>`
	`  <w:tblPr>`
	`  <w:tblpPr … w:horizAnchor="page" w:tblpX="1643"`
	`w:tblpXSpec="left"/>`
	`  </w:tblPr>`
	`  …`
	`</w:tbl>`
	
	This floating table specifies that it has a horizontal placement of exactly 1643 twentieths of a point relative to the page, but that exact placement is overridden by the presence of the tblpXSpec attribute to place the table on the `left` side of the page. *end example*]
	
	The possible values for this attribute are defined by the ST_XAlign simple type (§2.18.114).

tblpY (Absolute Vertical Distance From Anchor)	Specifies an absolute vertical position for the floating table. This absolute position is specified relative to the vertical anchor specified by the vertAnchor attribute for this floating table.
	
	This value is expressed in twentieths of a point. If it is positive, then the floating table is positioned after the anchor object in the direction of vertical text flow in this document. If it is negative, then the floating table is positioned before the anchor object in the direction of vertical text flow in this document.
	
	If the tblpYSpec attribute is also specified, then this value is ignored. If this attribute is omitted, then its value shall be assumed to be `0`.
	
	[*Example*: Consider the following WordprocessingML fragment specifying a floating table:
	
	`<w:tbl>`
	`  <w:tblPr>`
	`  <w:tblpPr … w:vertAnchor="text" w:tblpY="73" />`
	`  </w:tblPr>`
	`  …`
	`</w:tbl>`
	
	This floating table specifies that it should be located exactly 79 twentieths of a point below the top vertical edge of the anchor's paragraph's `text` (from the vertAnchor attribute), assuming that the vertical text direction is top to bottom. *end example*]
	
	The possible values for this attribute are defined by the ST_SignedTwipsMeasure simple

Attributes	Description
	type (§2.18.88).

tblpYSpec (Relative Vertical Alignment from Anchor)	Specifies a relative vertical position for the floating table. This relative position is specified relative to the vertical anchor specified by the vertAnchor attribute for this floating table.
	
	If omitted, this attribute is not specified and the value of the tblpY attribute determines the absolute horizontal position of the floating table. If specified, the position for this attribute supersedes any value which is specified in the tblpY attribute, and that value is ignored, unless the vertAnchor is set to `text`, in which case any relative positioning is not allowed, and is itself ignored.
	
	[*Example*: Consider the following WordprocessingML fragment specifying a floating table:
	
	`<w:tbl>`
	`  <w:tblPr>`
	`  <w:tblpPr … w:vertAnchor="margin" w:tblpY="73"`
	`w:tblpYSpec="center"/>`
	`  </w:tblPr>`
	`  …`
	`</w:tbl>`
	
	This floating table specifies that it has a vertical placement of exactly `73` twentieths of a point relative to the top `margin`, but that exact placement is overridden by the presence of the tblpYSpec attribute to place the table in the `center` of the margin. *end example*]
	
	The possible values for this attribute are defined by the ST_YAlign simple type (§2.18.115).

topFromText (Distance From Top of Table to Text)	Specifies the minimum distance which shall be maintained between the current floating table and the bottom edge of text in the paragraph which is above this floating table.
	
	This distance is expressed in twentieths of a point.
	
	If this attribute is omitted, its value shall be assumed to be `0`.
	
	[*Example*: Consider a floating table which should have a minimum of a one-half inch spacing from any text above it. This constraint would be specified using the following WordprocessingML:
	
	`<w:tblPr>`
	`  <w:tblpPr … w:topFromText="720" />`
	`</w:tblPr>`
	
	The topFromText attribute specifies that the spacing between text and this floating table shall be a minimum of `720` twentieths of a point. *end example*]
	
	The possible values for this attribute are defined by the ST_TwipsMeasure simple type

Attributes	Description
	(§2.18.105).

vertAnchor (Table Vertical Anchor)	Specifies the base object from which the vertical positioning in the tblpY attribute should be calculated.
	
	A floating table may be horizontally positioned relative to:
	• The horizontal edge of the page before any runs of text (the top edge for top-to-bottom sections, the bottom for bottom-to-top sections)
	• The horizontal edge of the text margin before any runs of text (the top edge for top-to-bottom sections, the bottom for bottom-to-top sections)
	• The horizontal edge of the page before any runs of text (the top edge for top-to-bottom sections, the bottom for bottom-to-top sections)
	
	If this attribute is omitted, then its value shall be assumed to be page.
	
	[*Example*: Consider a floating table which should be positioned two inches below the page top in a top-to-bottom document. This floating table would be specified using the following WordprocessingML:
	
	`<w:tblPr>`
	`  <w:tblpPr … w:tblpY="2880" w:vertAnchor="page" />`
	`</w:tblPr>`
	
	These floating table properties specify that they are relative to the anchor page, and that relative to that page, the table should be 2880 twentieths of a point in the direction of the flow of text (down, in this case). *end example*]
	
	The possible values for this attribute are defined by the ST_VAnchor simple type (§2.18.109).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblPPr">
   <attribute name="leftFromText" type="ST_TwipsMeasure"/>
   <attribute name="rightFromText" type="ST_TwipsMeasure"/>
   <attribute name="topFromText" type="ST_TwipsMeasure"/>
   <attribute name="bottomFromText" type="ST_TwipsMeasure"/>
   <attribute name="vertAnchor" type="ST_VAnchor"/>
   <attribute name="horzAnchor" type="ST_HAnchor"/>
   <attribute name="tblpXSpec" type="ST_XAlign"/>
   <attribute name="tblpX" type="ST_SignedTwipsMeasure"/>
   <attribute name="tblpYSpec" type="ST_YAlign"/>
   <attribute name="tblpY" type="ST_SignedTwipsMeasure"/>
</complexType>
```

2.4.55 tblPr (Table Properties)

This element specifies the set of table-wide properties applied to the current table. These properties affect the appearance of all rows and cells within the parent table, but may be overridden by individual table-level exception, row, and cell level properties as defined by each property.

[*Example*: Consider the following simple WordprocessingML table:

This table defines a one point single border for all border types and is set to 100% of page width - both table-wide properties. The resulting table is represented by the following WordprocessingML:

```
<w:tbl>
  <w:tblPr>
    <w:tblW w:w="0" w:type="auto"/>
    <w:tblBorders>
      <w:top w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:left w:val="single" w:sz="4 w:space="0" w:color="auto"/>
      <w:bottom w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:right w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:insideH w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:insideV w:val="single" w:sz="4" w:space="0" w:color="auto"/>
    </w:tblBorders>
  </w:tblPr>
  …
</w:tbl>
```

In this example, the tblW element (§2.4.61) defines the total width of the table, which, in this case, is set to a type of auto, which specifies that the table should be automatically sized to fit its contents. The tblBorders element (§2.4.38) specifies each of the table's borders, and specifies a one point border on the top, left, bottom, right and inside horizontal and vertical border. *end example*]

Parent Elements
tbl (§2.4.36)

Child Elements	Subclause
bidiVisual (Visually Right to Left Table)	§2.4.1
jc (Table Alignment)	§2.4.23
shd (Table Shading)	§2.4.35
tblBorders (Table Borders)	§2.4.38

Child Elements	Subclause
tblCellMar (Table Cell Margin Defaults)	§2.4.39
tblCellSpacing (Table Cell Spacing Default)	§2.4.43
tblInd (Table Indent from Leading Margin)	§2.4.48
tblLayout (Table Layout)	§2.4.49
tblLook (Table Style Conditional Formatting Settings)	§2.4.51
tblOverlap (Floating Table Allows Other Tables to Overlap)	§2.4.53
tblpPr (Floating Table Positioning)	§2.4.54
tblPrChange (Revision Information for Table Properties)	§2.13.5.36
tblStyle (Referenced Table Style)	§2.4.59
tblStyleColBandSize (Number of Columns in Column Band)	§2.7.5.5
tblStyleRowBandSize (Number of Rows in Row Band)	§2.7.5.7
tblW (Preferred Table Width)	§2.4.61

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblPr">
   <complexContent>
      <extension base="CT_TblPrBase">
         <sequence>
            <element name="tblPrChange" type="CT_TblPrChange" minOccurs="0"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.4.56 tblPr (Previous Table Properties)

This element specifies a previous set of table properties, the modifications to which shall be attributed to a revision by a particular author and at a particular time. This element contains the table property settings which were previously in place before a specific set of revisions by one author. These properties affect the appearance of all rows and cells within the parent table, but may be overridden by individual table-level exception, row, and cell level properties, as defined by each property.

[*Example*: Consider the following simple WordprocessingML table:

If the table justification is set to `center` and the table shading to set to red with revision marking on, as follows:

The revision tracked on this table would be specified as follows in the WordprocessingML:

```
<w:tblPr>
  <w:tblStyle w:val="TableGrid"/>
  <w:tblW w:w="0" w:type="auto"/>
  <w:jc w:val="center"/>
  <w:shd w:val="clear" w:color="auto" w:fill="FF0000"/>
  <w:tblLook w:val="04A0"/>
  <w:tblPrChange w:id="0" … >
    <w:tblPr>
      <w:tblStyle w:val="TableGrid"/>
      <w:tblW w:w="0" w:type="auto"/>
      <w:tblLook w:val="04A0"/>
    </w:tblPr>
  </w:tblPrChange>
</w:tblPr>
```

The tblPr element as a child of tblPrChange contains the previous definition for the table properties, consisting of the properties set before the current tracked revision. *end example*]

Parent Elements
tblPrChange (§2.13.5.36)

Child Elements	Subclause
bidiVisual (Visually Right to Left Table)	§2.4.1
jc (Table Alignment)	§2.4.23
shd (Table Shading)	§2.4.35
tblBorders (Table Borders)	§2.4.38
tblCellMar (Table Cell Margin Defaults)	§2.4.39
tblCellSpacing (Table Cell Spacing Default)	§2.4.43
tblInd (Table Indent from Leading Margin)	§2.4.48
tblLayout (Table Layout)	§2.4.49
tblLook (Table Style Conditional Formatting Settings)	§2.4.51
tblOverlap (Floating Table Allows Other Tables to Overlap)	§2.4.53
tblpPr (Floating Table Positioning)	§2.4.54
tblStyle (Referenced Table Style)	§2.4.59
tblStyleColBandSize (Number of Columns in Column Band)	§2.7.5.5
tblStyleRowBandSize (Number of Rows in Row Band)	§2.7.5.7
tblW (Preferred Table Width)	§2.4.61

The following XML Schema fragment defines the contents of this element:

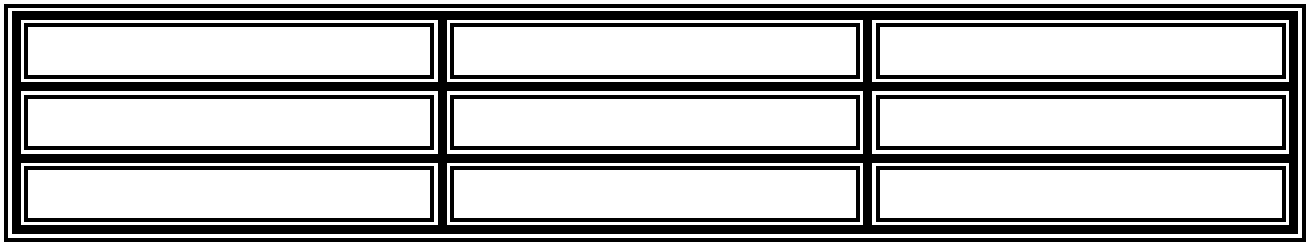
```
<complexType name="CT_TblPrBase">
   <sequence>
      <element name="tblStyle" type="CT_String" minOccurs="0"/>
      <element name="tblpPr" type="CT_TblPPr" minOccurs="0" maxOccurs="1"/>
      <element name="tblOverlap" type="CT_TblOverlap" minOccurs="0" maxOccurs="1"/>
      <element name="bidiVisual" type="CT_OnOff" minOccurs="0" maxOccurs="1"/>
      <element name="tblStyleRowBandSize" type="CT_DecimalNumber" minOccurs="0" maxOccurs="1"/>
      <element name="tblStyleColBandSize" type="CT_DecimalNumber" minOccurs="0" maxOccurs="1"/>
      <element name="tblW" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="jc" type="CT_Jc" minOccurs="0" maxOccurs="1"/>
      <element name="tblCellSpacing" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="tblInd" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="tblBorders" type="CT_TblBorders" minOccurs="0" maxOccurs="1"/>
      <element name="shd" type="CT_Shd" minOccurs="0" maxOccurs="1"/>
      <element name="tblLayout" type="CT_TblLayoutType" minOccurs="0" maxOccurs="1"/>
      <element name="tblCellMar" type="CT_TblCellMar" minOccurs="0" maxOccurs="1"/>
      <element name="tblLook" type="CT_ShortHexNumber" minOccurs="0" maxOccurs="1"/>
   </sequence>
</complexType>
```

2.4.57 tblPrEx (Table-Level Property Exceptions)

This element specifies a set of table properties which shall be applied to the contents of this row in place of the table properties specified in the tblPr element.

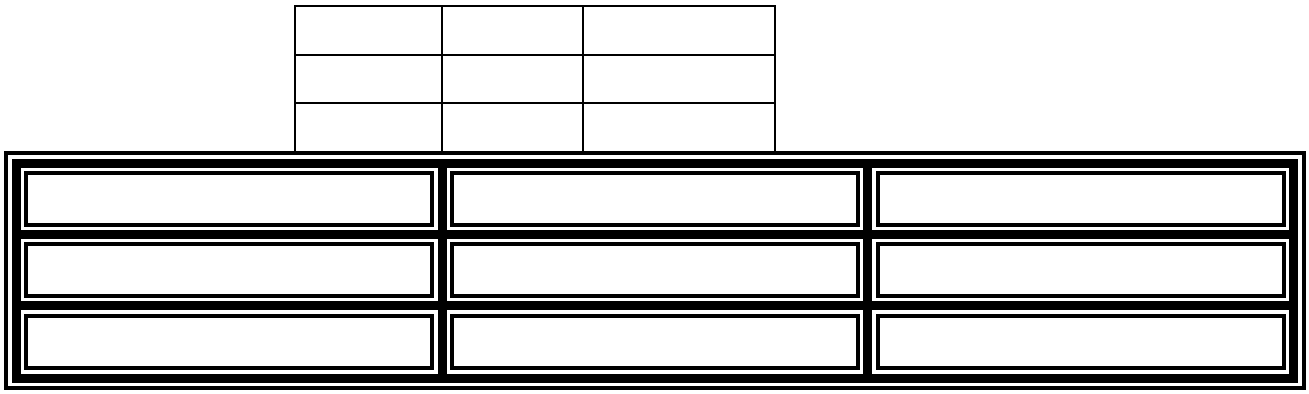
[*Note*: These properties are typically used in cases involving legacy documents, as well as cases where two existing independent tables are merged (in order to prevent the look of the second table from being superseded by the first table). *end note*]

[*Example*: Consider the following two tables in a WordprocessingML document:



These two tables each have a different set of table level borders. If the interceding paragraphs between these two tables is removed and the tables are merged together, it is obviously undesirable to have the second table

lose its formatting and match the properties of the first table. Therefore, when the tables are merged as follows (note that there is now only one table):



The resulting WordprocessingML for the last three rows of the table would include the following set of table-level property exceptions:

```
<w:tr>
  <w:tblPrEx>
    <w:tblBorders>
      <w:top w:val="thinThickThinMediumGap" w:sz="24" w:space="0"
w:color="auto"/>
      <w:left w:val="thinThickThinMediumGap" w:sz="24" w:space="0"
w:color="auto"/>
      <w:bottom w:val="thinThickThinMediumGap" w:sz="24" w:space="0"
w:color="auto"/>
      <w:right w:val="thinThickThinMediumGap" w:sz="24" w:space="0"
w:color="auto"/>
      <w:insideH w:val="thinThickThinMediumGap" w:sz="24" w:space="0"
w:color="auto"/>
      <w:insideV w:val="thinThickThinMediumGap" w:sz="24" w:space="0"
w:color="auto"/>
    </w:tblBorders>
  </w:tblPrEx>
  …
</w:tr>
```

The tblPrEx element contains all table-level properties which are being overridden for the current row in the table. *end example*]

Parent Elements
tr (§2.4.75)

Child Elements	Subclause
jc (Table Alignment Exception)	§2.4.21
shd (Table Shading Exception)	§2.4.34
tblBorders (Table Borders Exceptions)	§2.4.37
tblCellMar (Table Cell Margin Exceptions)	§2.4.40
tblCellSpacing (Table Cell Spacing Exception)	§2.4.41
tblInd (Table Indent from Leading Margin Exception)	§2.4.47
tblLayout (Table Layout Exception)	§2.4.50
tblLook (Table Style Conditional Formatting Settings Exception)	§2.4.52
tblPrExChange (Revision Information for Table-Level Property Exceptions)	§2.13.5.37
tblW (Preferred Table Width Exception)	§2.4.60

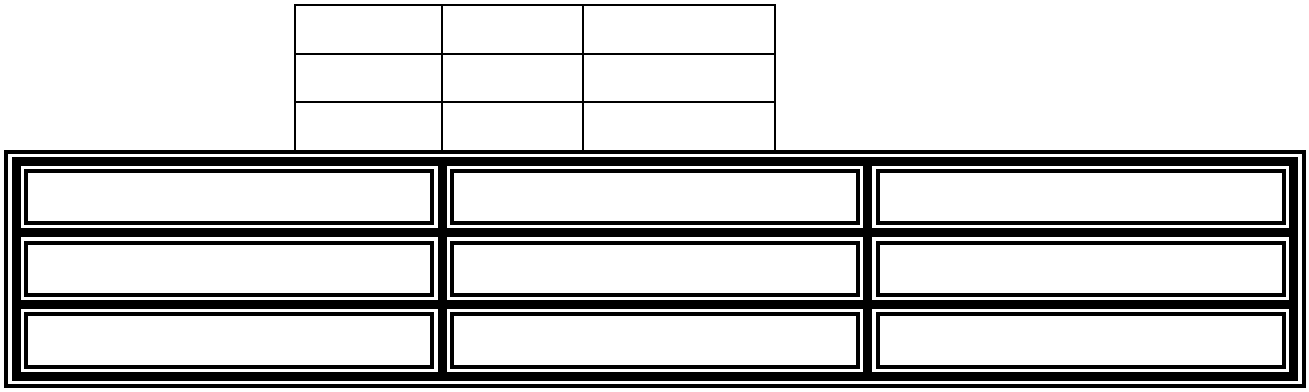
The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblPrEx">
   <complexContent>
      <extension base="CT_TblPrExBase">
         <sequence>
            <element name="tblPrExChange" type="CT_TblPrExChange" minOccurs="0"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.4.58 tblPrEx (Previous Table-Level Property Exceptions)

This element specifies a previous set of table-level property exceptions, the modifications to which shall be attributed to a revision by a particular author and at a particular time. This element contains the table-level property exceptions which were previously in place before a specific set of revisions by one author.

[*Example*: Consider the following two tables in a WordprocessingML document. If the interceding paragraphs between these two tables is removed and the tables are merged together, it is obviously undesirable to have the second table lose its formatting and match the properties of the first table. Therefore, when the tables are merged as follows (note that there is now only one table):



If the border type is changed to a red border of type `thinThickThinSmallGap` with revisions tracked, as follows:

The resulting WordprocessingML for the last three rows of the table would include the following set of table-level property exceptions with revision tracking:

```
<w:tr>
  <w:tblPrEx>
    <w:tblBorders>
      <w:top w:val="thinThickThinMediumGap" w:sz="24" w:space="0"
       w:color="auto"/>
      <w:left w:val="thinThickThinMediumGap" w:sz="24" w:space="0"
       w:color="auto"/>
      <w:bottom w:val="thinThickThinMediumGap" w:sz="24" w:space="0"
       w:color="auto"/>
      <w:right w:val="thinThickThinMediumGap" w:sz="24" w:space="0"
       w:color="auto"/>
      <w:insideH w:val="thinThickThinMediumGap" w:sz="24" w:space="0"
       w:color="auto"/>
      <w:insideV w:val="thinThickThinMediumGap" w:sz="24" w:space="0"
       w:color="auto"/>
    </w:tblBorders>
    <w:tblPrExChange w:id="9" … >
      <w:tblPrEx>
        <w:tblBorders>
          <w:top w:val="thinThickThinSmallGap" w:sz="24" w:space="0"
           w:color="FF0000"/>
          <w:left w:val="thinThickThinSmallGap" w:sz="24" w:space="0"
           w:color="FF0000"/>
          <w:bottom w:val="thinThickThinSmallGap" w:sz="24" w:space="0"
           w:color="FF0000"/>
          <w:right w:val="thinThickThinSmallGap" w:sz="24" w:space="0"
           w:color="FF0000"/>
          <w:insideH w:val="thinThickThinSmallGap" w:sz="24" w:space="0"
           w:color="FF0000"/>
          <w:insideV w:val="thinThickThinSmallGap" w:sz="24" w:space="0"
           w:color="FF0000"/>
        </w:tblBorders>
      </w:tblPrEx>
    </w:tblPrExChange>
  </w:tblPrEx>
  …
</w:tr>
```

The tblPrEx element as a child of tblPrExChange contains the previous definition for the table-level property exceptions, consisting of the properties set before the current tracked revision. *end example*]

Parent Elements

      <element name="tblInd" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="tblBorders" type="CT_TblBorders" minOccurs="0" maxOccurs="1"/>
      <element name="shd" type="CT_Shd" minOccurs="0" maxOccurs="1"/>
      <element name="tblLayout" type="CT_TblLayoutType" minOccurs="0" maxOccurs="1"/>
      <element name="tblCellMar" type="CT_TblCellMar" minOccurs="0" maxOccurs="1"/>
      <element name="tblLook" type="CT_ShortHexNumber" minOccurs="0" maxOccurs="1"/>
   </sequence>
</complexType>
```

2.4.59 tblStyle (Referenced Table Style)

This element specifies the style ID of the table style which shall be used to format the contents of this table.

This formatting is applied at the following location in the *style hierarchy*:

- Document defaults
- Table styles (this element)
- Numbering styles
- Paragraph styles
- Character styles
- Direct Formatting

This means that all properties specified in the style element (§2.7.3.17) with a styleId which corresponds to the value in this element's val attribute are applied to the table at the appropriate level in the hierarchy.

If this element is omitted, or it references a style which does not exist, then no table style shall be applied to the current table. As well, this property is ignored if the table properties are themselves part of a table style.

[*Example*: Consider the following WordprocessingML fragment:

```
<w:tblPr>
  <w:tblStyle w:val=”TestTableStyle” />
</w:tblPr>
```

This table specifies that it will inherit all of the table properties specified by the table style with a styleId of `TestTableStyle`. *end example*]

Parent Elements
tblPr (§2.7.5.3); tblPr (§2.7.5.4); tblPr (§2.4.55); tblPr (§2.4.56)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.4.60 tblW (Preferred Table Width Exception)

This element specifies the preferred width for the parent table row via a set of table-level property exceptions. This preferred width is used as part of the table layout algorithm specified by the tblLayout element (§2.4.49n; §2.4.50) - full description of the algorithm in the ST_TblLayout simple type (§2.18.94).

All widths in a table are considered preferred because:

- The table must satisfy the shared columns as specified by the tblGrid element (§2.4.44)
- Two or more widths may have conflicting values for the width of the same grid column
- The table layout algorithm (§2.18.94) may require a preference to be overridden

This value is specified in the units applied via its type attribute. Any width value of type `pct` for this element shall be calculated relative to the text extents of the page (page width excluding margins).

If this element is omitted, then the cell width shall be of type `auto`.

[*Example*: Consider a row in a WordprocessingML table defined as follows:

```
<w:tr>
  <w:trPr>
    <w:tblPrEx>
      <w:tblW w:type="fixed" w:w="1440"/>
    </w:tblPrEx>
  </w:trPr>
  …
</w:tr>
```

This table-level property exception specifies that it has a preferred table width of `1440` twentieths of a point (one inch). The resulting table row would therefore be sized such that the table maintains that preferred width, as follows:

	Hello world	

The text `Hello world` makes the middle cell larger, and the other two cells are size to maintain the preferred widths of one inch for the overall table width:

	Hello world this is a longer string.	

However, when the middle table cell requires a larger width to accommodate non-breaking text, that preference may be overridden as needed:

	Hello worlddddddddddddddddddddddddddddddd	

In this case, the middle cell's long non breaking string caused the table to be expanded to prevent breaking the string, and therefore to override the preferred width on the table row. *end example*]

Parent Elements
tblPrEx (§2.4.57); tblPrEx (§2.4.58)

Attributes	Description
type (Table Width Type)	Specifies the units of the width property being defined by the parent element's w attribute. This property is used to define various properties of a table, including: cell spacing, preferred width, and table margins. If this attribute is omitted, then its value shall be assumed to be dxa (twentieths of a point). [*Example*: Consider a table with a table cell bottom cell spacing with a type of dxa, as follows: `<w:bottom ... w:type="dxa" />` This type shall therefore be used to interpret the width specified in the w attribute as a value in twentieths of a point. *end example*] The possible values for this attribute are defined by the ST_TblWidth simple type (§2.18.97).
w (Table Width Value)	Specifies the value of the width property being defined by the parent element. This property is used to define various properties of a table, including: cell spacing, preferred widths, and table margins. If this attribute is omitted, then its value shall be assumed to be 0. [*Example*: Consider a table with a bottom margin with a width of 302, as follows: `<w:bottom w:w="302" w:type="dxa" />` The value in the w attribute shall therefore be used to determine the width being specified in the context of the units specified in the type attribute. In this case, the type is twentieths of a point (dxa), so the width is 302 twentieths of a point (.2097 inches). *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblWidth">
   <attribute name="w" type="ST_DecimalNumber"/>
   <attribute name="type" type="ST_TblWidth"/>
</complexType>
```

2.4.61 tblW (Preferred Table Width)

This element specifies the preferred width for this table. This preferred width is used as part of the table layout algorithm specified by the tblLayout element (§2.4.49; §2.4.50) - full description of the algorithm in the ST_TblLayout simple type (§2.18.94).

All widths in a table are considered preferred because:

- The table must satisfy the shared columns as specified by the tblGrid element (§2.4.44)
- Two or more widths may have conflicting values for the width of the same grid column
- The table layout algorithm (§2.18.94) may require a preference to be overridden

This value is specified in the units applied via its type attribute. Any width value of type `pct` for this element shall be calculated relative to the text extents of the page (page width excluding margins).

If this element is omitted, then the cell width shall be of type `auto`.

[*Example*: Consider a WordprocessingML table defined as follows:

```
<w:tbl>
  <w:tblPr>
    <w:tblW w:type="fixed" w:w="1440"/>
  </w:tblPr>
  …
</w:tbl>
```

This table specifies that it has a preferred table width of `1440` twentieths of a point (one inch). The resulting table would therefore be sized such that the table maintains that preferred width, as follows:

	Hello world	

The text `Hello world` makes the middle cell larger, and the other two cells are size to maintain the preferred widths of one inch for the overall table width:

	Hello world this is a longer string.	

However, when the middle table cell requires a larger width to accommodate non-breaking text, that preference may be overridden as needed:

	Hello worlddddddddddddddddddddddddddddddd	

In this case, the middle cell's long non breaking string caused the table to be expanded to prevent breaking the string, and therefore to override the preferred width on the table. *end example*]

Parent Elements
tblPr (§2.7.5.3); tblPr (§2.7.5.4); tblPr (§2.4.55); tblPr (§2.4.56)

Attributes	Description
type (Table Width Type)	Specifies the units of the width property being defined by the parent element's w attribute. This property is used to define various properties of a table, including: cell spacing, preferred width, and table margins. If this attribute is omitted, then its value shall be assumed to be dxa (twentieths of a point). [*Example*: Consider a table with a table cell bottom cell spacing with a type of dxa, as follows: `<w:bottom ... w:type="dxa" />` This type shall therefore be used to interpret the width specified in the w attribute as a value in twentieths of a point. *end example*] The possible values for this attribute are defined by the ST_TblWidth simple type (§2.18.97).
w (Table Width Value)	Specifies the value of the width property being defined by the parent element. This property is used to define various properties of a table, including: cell spacing, preferred widths, and table margins. If this attribute is omitted, then its value shall be assumed to be 0.

Attributes	Description
	[*Example*: Consider a table with a bottom margin with a width of `302`, as follows: `<w:bottom w:w="302" w:type="dxa" />` The value in the w attribute shall therefore be used to determine the width being specified in the context of the units specified in the type attribute. In this case, the type is twentieths of a point (`dxa`), so the width is `302` twentieths of a point (.2097 inches). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblWidth">
   <attribute name="w" type="ST_DecimalNumber"/>
   <attribute name="type" type="ST_TblWidth"/>
</complexType>
```

2.4.62 tc (Table Cell)

This element specifies a single cell in a table row, which contains the table's content. Table cells in WordprocessingML are analogous to HTML `td` elements.

A tc element has one formatting child element, tcPr (§2.4.67), which defines the properties for the cell. Each unique property on the table cell is specified by a child element of this element. As well, a table cell can contain any valid block-level content, which allows for the nesting of paragraphs and tables within table cells.

If a table cell does not include at least one block-level element, then this document shall be considered corrupt.

[*Example*: Consider a table consisting of a single table cell, which contains the text `Hello World`:

Hello World

This table cell's content is represented by the following WordprocessingML:

```
<w:tc>
  <w:tcPr>
    <w:tcW w:w="0" w:type="auto"/>
  </w:tcPr>
  <w:p>
    <w:r>
      <w:t>Hello, World</w:t>
    </w:r>
  </w:p>
</w:tc>
```

The tc element contains a set of cell-level properties defined using the tcPr element, and a single block-level element - in this case, a paragraph. *end example*]

Parent Elements
customXml (§2.5.1.3); sdtContent (§2.5.2.33); tr (§2.4.75)

Child Elements	Subclause
altChunk (Anchor for Imported External Content)	§2.17.3.1
bookmarkEnd (Bookmark End)	§2.13.6.1
bookmarkStart (Bookmark Start)	§2.13.6.2
commentRangeEnd (Comment Anchor Range End)	§2.13.4.3

moveFromRangeEnd (Move Source Location Container - End)	§2.13.5.23
moveFromRangeStart (Move Source Location Container - Start)	§2.13.5.24
moveTo (Move Destination Run Content)	§2.13.5.26

Child Elements	Subclause
moveToRangeEnd (Move Destination Location Container - End)	§2.13.5.27
moveToRangeStart (Move Destination Location Container - Start)	§2.13.5.28
oMath (Office Math)	§7.1.2.77
oMathPara (Math Paragraph)	§7.1.2.78
p (Paragraph)	§2.3.1.22
permEnd (Range Permission End)	§2.13.7.1
permStart (Range Permission Start)	§2.13.7.2
proofErr (Proofing Error Anchor)	§2.13.8.1
sdt (Block-Level Structured Document Tag)	§2.5.2.30
tbl (Table)	§2.4.36
tcPr (Table Cell Properties)	§2.4.67

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Tc">
   <sequence>
      <element name="tcPr" type="CT_TcPr" minOccurs="0" maxOccurs="1"/>
      <group ref="EG_BlockLevelElts" minOccurs="1" maxOccurs="unbounded"/>
   </sequence>
</complexType>
```

2.4.63 tcBorders (Table Cell Borders)

This element specifies the set of borders for the edges of the current table cell, using the eight border types defined by its child elements.

If the cell spacing for any row is non-zero as specified using the tblCellSpacing element (§2.4.41; §2.4.42; §2.4.43), then there is never a border conflict (as the non-zero cell spacing is applied above and beyond each individual cell border's width) and all table, table-level exception, and table cell borders shall be displayed.

If the cell spacing is zero, then there may be a conflict between two adjacent cell borders [*Example*: Between the left border of all cells in the second column and the right border of all cells in the first column of the table. *end example*], which shall be resolved as follows:

1. If either conflicting table cell border is `nil` or `none` (no border), then the opposing border shall be displayed.
2. If a cell border conflicts with a table border, the cell border always wins.
3. Each border shall then be assigned a weight using the following formula, and the border value using this calculation shall be displayed over the alternative border:

$$W_{\text{border}} = \#\text{ of lines in border} * \text{border number}$$

The border number shall be determined by this list:

single	1
thick	2
double	3
dotted	4
dashed	5
dotDash	6
dotDotDash	7
triple	8
thinThickSmallGap	9
thickThinSmallGap	10
thinThickThinSmallGap	11
thinThickMediumGap	12
thickThinMediumGap	13
thinThickThinMediumGap	14
thinThickLargeGap	15
thickThinLargeGap	16
thinThickThinLargeGap	17
wave	18
doubleWave	19
dashSmallGap	20
dashDotStroked	21
threeDEmboss	22
threeDEngrave	23
outset	24
inset	25

4. If the borders have an equal weight, than the higher of the two on this precedence list shall win:

- single
- thick
- double
- dotted
- dashed
- dotDash
- dotDotDash
- triple
- thinThickSmallGap
- thickThinSmallGap

- thinThickThinSmallGap
- thinThickMediumGap
- thickThinMediumGap
- thinThickThinMediumGap
- thinThickLargeGap
- thickThinLargeGap
- thinThickThinLargeGap
- wave
- doubleWave
- dashSmallGap
- dashDotStroked
- threeDEmboss
- threeDEngrave
- outset
- inset

5. If the borders have an identical style, than each border color shall be assigned a brightness value as follows:

$$\text{Brightness} = \text{R} + \text{B} + 2 * \text{G}$$

   The color with the smaller brightness value shall win.
6. If the borders have an identical brightness value above, than each border color shall be assigned a new brightness value as follows:

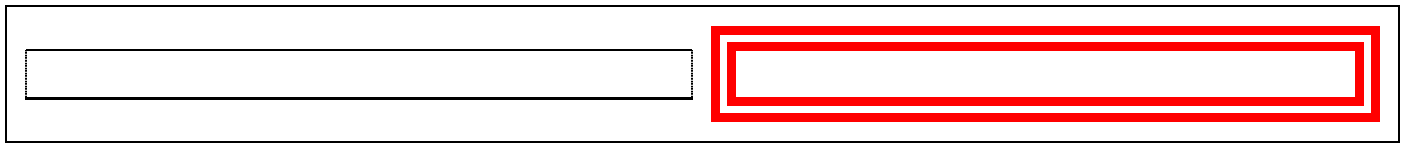
$$\text{Brightness} = \text{B} + 2 * \text{G}$$

   The color with the smaller brightness value shall win.
7. If the borders have an identical brightness value above, than each border color shall be assigned a brightness value as follows:

$$\text{Brightness} = \text{G}$$

   The color with the smaller brightness value shall win.
8. If the borders have an identical brightness value above, then they are functionally identical, and the first border in reading order should be displayed.

[*Example*: Consider the following two cell table (with exaggerated table cell spacing for clarity):



If we collapse the cell spacing, there will be conflicting borders at all edges. For each cell/table border conflict, rule #2 says that the cell border shall win. For the conflict in the center between two cell borders, rule #3 gives us a larger border weight for the right cell's border, resulting in the following table:

end example]

If this element is omitted, then this table shall have the borders specified by the associated table style. If no borders are specified in the style hierarchy, then this table shall not have any table borders.

[*Example*: Consider a table whose first cell specifies cell-level borders consisting of a think double red line, as follows:

These cell borders are specified using the following WordprocessingML:

```
<w:tcPr>
  <w:tcBorders>
    <w:top w:val="double" w:sz="24" w:space="0" w:color="FF0000"/>
    <w:left w:val="double" w:sz="24" w:space="0" w:color="FF0000"/>
    <w:bottom w:val="double" w:sz="24" w:space="0" w:color="FF0000"/>
    <w:right w:val="double" w:sz="24" w:space="0" w:color="FF0000"/>
  </w:tcBorders>
</w:tcPr>
```

The tcBorders element specifies the set of borders applied to the first cell as a 3 point double border. *end example*]

Parent Elements
tcPr (§2.7.5.8); tcPr (§2.4.66); tcPr (§2.7.5.9); tcPr (§2.4.67)

Child Elements	Subclause
bottom (Table Cell Bottom Border)	§2.4.3
insideH (Table Cell Inside Horizontal Edges Border)	§2.4.18
insideV (Table Cell Inside Vertical Edges Border)	§2.4.19
left (Table Cell Left Border)	§2.4.24
right (Table Cell Right Border)	§2.4.30
tl2br (Table Cell Top Left to Bottom Right Diagonal Border)	§2.4.70
top (Table Cell Top Border)	§2.4.74
tr2bl (Table Cell Top Right to Bottom Left Diagonal Border)	§2.4.76

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TcBorders">
   <sequence>
      <element name="top" type="CT_Border" minOccurs="0"/>
      <element name="left" type="CT_Border" minOccurs="0"/>
      <element name="bottom" type="CT_Border" minOccurs="0"/>
      <element name="right" type="CT_Border" minOccurs="0"/>
      <element name="insideH" type="CT_Border" minOccurs="0"/>
      <element name="insideV" type="CT_Border" minOccurs="0"/>
      <element name="tl2br" type="CT_Border" minOccurs="0"/>
      <element name="tr2bl" type="CT_Border" minOccurs="0"/>
   </sequence>
</complexType>
```

2.4.64 tcFitText (Fit Text Within Cell)

This element specifies that the contents of the current cell shall have their inter-character spacing increased or reduced as necessary to fit the width of the text extents of the current cell. This setting shall behave identically to placing the contents of this paragraph in a run and using the fitText element (§2.3.2.12), if the width provided on that element matched the width of the current cell.

If this element is omitted, then the text in this cell shall not be fit to the current cell extents.

[*Example*: Consider a 2 row by two column table, in which the contents of the two cells in the first row have both have the fit text property set, as follows:

```
<w:tcPr>
  <w:tcFitText w:val="true"/>
</w:tcPr>
```

The resulting table cells shall have their contents fit to the extents of the parent table cell, as follows:

Sample text in R1C1.	And this table cell instead contains a very very long string of sample text in R2C2.
R2C1	R2C2

end example]

Parent Elements
tcPr (§2.7.5.8); tcPr (§2.4.66); tcPr (§2.7.5.9); tcPr (§2.4.67)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but

Attributes	Description
	this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.4.65 tcMar (Single Table Cell Margins)

This element specifies a set of cell margins for a single table cell in the parent table.

This setting, if present, shall override the table cell margins from the table-level cell margins (§2.4.39).

[*Example*: Consider a table whose first cell is defined to have default cell margins of 0.5 inches for all sides rather then the table defaults, as follows:

R1C1
R2C1

This set of table cell margins is specified using the following WordprocessingML:

```
<w:tcPr>
  <w:tcMar>
    <w:top w:w="720" w:type="dxa"/>
    <w:left w:w="720" w:type="dxa"/>
    <w:bottom w:w="720" w:type="dxa"/>
    <w:right w:w="720" w:type="dxa"/>
  </w:tcMar>
  …
</w:tcPr>
```

The tcMar element as a child of tcPr specifies the set of table cell margins used for the first table cell, in this case, 720 twentieths of a point on all sides. *end example*]

Parent Elements
tcPr (§2.7.5.8); tcPr (§2.4.66); tcPr (§2.7.5.9); tcPr (§2.4.67)

Child Elements	Subclause
bottom (Table Cell Bottom Margin Exception)	§2.4.2
left (Table Cell Left Margin Exception)	§2.4.25
right (Table Cell Right Margin Exception)	§2.4.31
top (Table Cell Top Margin Exception)	§2.4.73

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TcMar">
   <sequence>
      <element name="top" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="left" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="bottom" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="right" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
   </sequence>
</complexType>
```

2.4.66 tcPr (Previous Table Cell Properties)

This element specifies a previous set of table cell properties, the modifications to which shall be attributed to a revision by a particular author and at a particular time. This element contains the table cell property settings which were previously in place before a specific set of revisions by one author. Each unique property is specified by a child element of this element. In any instance where there is a conflict between the table level, table-level exception, or row level properties with a corresponding table cell property, these properties shall overwrite the table or row wide properties.

[*Example*: Consider a basic two row by two column table as follows:

If the cell shading in the first cell is set to red with revision tracking enabled, as follows:

This revision is specified as follows in the associated WordprocessingML:

```
<w:tc>
  <w:tcPr>
    <w:tcW w:w="4788" w:type="dxa"/>
    <w:shd w:val="clear" w:color="auto" w:fill="FF0000"/>
    <w:tcPrChange w:id="2" …>
      <w:tcPr>
        <w:tcW w:w="4788" w:type="dxa"/>
      </w:tcPr>
    </w:tcPrChange>
  </w:tcPr>
  <w:p/>
</w:tc>
```

The tcPr element beneath the tcPrChange element specifies the set of table cell properties which were in place before the current revision to the document. *end example*]

Parent Elements
tcPrChange (§2.13.5.38)

Child Elements	Subclause
cellDel (Table Cell Deletion)	§2.13.5.1
cellIns (Table Cell Insertion)	§2.13.5.2
cellMerge (Vertically Merged/Split Table Cells)	§2.13.5.3
cnfStyle (Table Cell Conditional Formatting)	§2.4.7
gridSpan (Grid Columns Spanned by Current Table Cell)	§2.4.13
hideMark (Ignore End Of Cell Marker In Row Height Calculation)	§2.4.15
hMerge (Horizontally Merged Cell)	§2.4.16
noWrap (Don't Wrap Cell Content)	§2.4.28
shd (Table Cell Shading)	§2.4.33
tcBorders (Table Cell Borders)	§2.4.63
tcFitText (Fit Text Within Cell)	§2.4.64
tcMar (Single Table Cell Margins)	§2.4.65
tcW (Preferred Table Cell Width)	§2.4.68
textDirection (Table Cell Text Flow Direction)	§2.4.69
vAlign (Table Cell Vertical Alignment)	§2.4.80
vMerge (Vertically Merged Cell)	§2.4.81

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TcPrInner">
   <complexContent>
      <extension base="CT_TcPrBase">
         <sequence>
            <group ref="EG_CellMarkupElements" minOccurs="0" maxOccurs="1"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.4.67 tcPr (Table Cell Properties)

This element specifies the set of properties which shall be applied a specific table cell. Each unique property is specified by a child element of this element. In any instance where there is a conflict between the table level, table-level exception, or row level properties with a corresponding table cell property, these properties shall overwrite the table or row wide properties.

[*Example*: Consider a table where the cell width overwrites the table width represented in the following WordprocessingML:

```
<w:tbl>
  <w:tblPr>
    <w:tblCellMar>
      <w:left w:w="0" w:type="dxa"/>
    </w:tblCellMar>
  </w:tblPr>
  <w:tr>
    <w:tc>
      <w:tcPr>
        <w:tcMar>
          <w:left w:w="720" w:type="dxa"/>
        </w:tcMar>
      </w:tcPr>
      …
    </w:tc>
  </w:tr>
</w:tbl>
```

This table cell will have a left cell margin of `720` twentieths of a point (one half inch) as specified in the tcMar element, which overwrites the table level setting of `0` left table cell margin. *end example*]

Parent Elements
tc (§2.4.62)

Child Elements	Subclause
cellDel (Table Cell Deletion)	§2.13.5.1
cellIns (Table Cell Insertion)	§2.13.5.2

tcW (Preferred Table Cell Width)	§2.4.68
textDirection (Table Cell Text Flow Direction)	§2.4.69
vAlign (Table Cell Vertical Alignment)	§2.4.80
vMerge (Vertically Merged Cell)	§2.4.81

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TcPr">
   <complexContent>
      <extension base="CT_TcPrInner">
         <sequence>
            <element name="tcPrChange" type="CT_TcPrChange" minOccurs="0"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.4.68 tcW (Preferred Table Cell Width)

This element specifies the preferred width for this table cell. This preferred width is used as part of the table layout algorithm specified by the tblLayout element (§2.4.49; §2.4.50) - full description of the algorithm in the ST_TblLayout simple type (§2.18.94).

All widths in a table are considered preferred because:

- The table must satisfy the shared columns as specified by the tblGrid element (§2.4.44)
- Two or more widths may have conflicting values for the width of the same grid column
- The table layout algorithm (§2.18.94) may require a preference to be overridden

This value is specified in the units applied via its type attribute. Any width value of type pct for this element shall be calculated relative to the overall width of the table.

If this element is omitted, then the cell width shall be of type auto.

[*Example*: Consider a WordprocessingML table defined as follows:

```
<w:tbl>
  <w:tr>
    <w:tc>
      <w:tcPr>
        <w:tcW w:type="pct" w:w="1667"/>
      </w:tcPr>
      …
    </w:tc>
    <w:tc>
      <w:tcPr>
        <w:tcW w:type="pct" w:w="1667"/>
      </w:tcPr>
      …
    </w:tc>
    <w:tc>
      <w:tcPr>
        <w:tcW w:type="pct" w:w="1667"/>
      </w:tcPr>
      …
    </w:tc>
  </w:tr>
</w:tbl>
```

This table specifies that it has no preferred table width, but each cell shall be exactly 33.3 percent (1667 fiftieths of a percent) of the overall table width. The resulting table would therefore be sized such that all columns are of the width of the maximum column, as follows:

	Hello world	

The text Hello world makes the middle cell larger, and the other two cells are increased in size to maintain the preferred widths of one-third of the overall table width. However, when the middle table cell requires a larger size to accommodate non-breaking text, that preference may be overridden as needed:

	Hello worlddddddddddddddddddddddddddddddddddddd	

In this case, the middle cell's long non breaking string caused the table to reach the text margins on the page, and therefore to override the preferred widths on the empty cells. *end example*]

Parent Elements
tcPr (§2.7.5.8); tcPr (§2.4.66); tcPr (§2.7.5.9); tcPr (§2.4.67)

Attributes	Description
type (Table Width Type)	Specifies the units of the width property being defined by the parent element's w attribute. This property is used to define various properties of a table, including: cell spacing, preferred width, and table margins. If this attribute is omitted, then its value shall be assumed to be dxa (twentieths of a point). [*Example*: Consider a table with a table cell bottom cell spacing with a type of dxa, as follows: `<w:bottom ... w:type="dxa" />` This type shall therefore be used to interpret the width specified in the w attribute as a value in twentieths of a point. *end example*] The possible values for this attribute are defined by the ST_TblWidth simple type (§2.18.97).
w (Table Width Value)	Specifies the value of the width property being defined by the parent element. This property is used to define various properties of a table, including: cell spacing, preferred widths, and table margins. If this attribute is omitted, then its value shall be assumed to be 0. [*Example*: Consider a table with a bottom margin with a width of 302, as follows: `<w:bottom w:w="302" w:type="dxa" />` The value in the w attribute shall therefore be used to determine the width being specified in the context of the units specified in the type attribute. In this case, the type is twentieths of a point (dxa), so the width is 302 twentieths of a point (.2097 inches). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblWidth">
   <attribute name="w" type="ST_DecimalNumber"/>
   <attribute name="type" type="ST_TblWidth"/>
</complexType>
```

2.4.69 textDirection (Table Cell Text Flow Direction)

This element specifies the direction of the text flow for this table cell.

If this element is omitted on a given table cell, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then the table cell shall inherit the text flow settings from the parent section.

[*Example*: Consider a table with one cell in which all the table cell's text flow is top to bottom - right to left:

This table cell would specify this text flow using the following WordprocessingML:

```
<w:tc>
  <w:tcPr>
    …
    <w:textDirection w:val="tbRl" />
  </w:tcPr>
  …
</w:tc>
```

The textDirection element specifies via the `tbRl` value in the val attribute that the text flow should go top to bottom, then right to left. *end example*]

Parent Elements
tcPr (§2.7.5.8); tcPr (§2.4.66); tcPr (§2.7.5.9); tcPr (§2.4.67)

Attributes	Description

val (Direction of Text Flow)	Specifies the direction of the text flow for this object.
	
	[*Example*: Consider a document with a section in which text shall flow bottom to top vertically, and left to right horizontally. This setting requires the following WordprocessingML:
	
	`<w:sectPr>`
	`…`

Attributes	Description
	<w:textDirection w:val="btLr" /> </w:sectPr> The textDirection element specifies via the btLr value in the val attribute that the text flow shall go bottom to top, and left to right. *end example*] The possible values for this attribute are defined by the ST_TextDirection simple type (§2.18.100).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TextDirection">
   <attribute name="val" type="ST_TextDirection" use="required"/>
</complexType>
```

2.4.70 tl2br (Table Cell Top Left to Bottom Right Diagonal Border)

This element specifies the border which shall be displayed on the top left side to bottom right diagonal within the current table cell.

If this element is omitted, then the top left to bottom right diagonal of this table cell shall not have a cell border, and its border may use the table's border settings as appropriate.

[*Example*: Consider a table in which the first cell in the first row specifies a top left to bottom right diagonal cell border as follows:

R1C1	R1C2
R2C1	R2C2

This diagonal cell border is specified using the following WordprocessingML:

```
<w:tc>
  <w:tcPr>
    …
    <w:tcBorders>
       <w:tl2br w:val="double" w:sz="4" w:space="0" w:color="FF0000"/>
    </w:tcBorders>
  </w:tcPr>
  <w:p/>
</w:tc>
```

The tl2br element specifies a ½ point border of type double on the table cell's diagonal. *end example*]

Parent Elements
tcBorders (§2.4.63)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value auto, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is true, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the

Attributes	Description
	following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object.
	
	When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points.
	
	When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border. If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value. If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value. [*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:

Attributes	Description
	<w:top w:val="dashed" w:sz="24" …/> <w:left w:val="dashed" w:sz="24" …/> <w:bottom w:val="dashed" w:sz="24" …/> <w:right w:val="dashed" w:sz="24" …/> The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*] The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).
themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border. The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document. [*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup: <w:top … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:bottom … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:left … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:right … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is

Attributes	Description
	calculated as follows: $$S_{xml} = 0.4 * 255 = 102 = 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75 = 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border.

Attributes	Description
	The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255 = 153 = 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6) = 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object.

Attributes	Description
	This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.4.71 top (Table Top Border)

This element specifies the border which shall be displayed at the top of the current table. The appearance of this table border in the document shall be determined by the following settings:

- The display of the border is subject to the conflict resolution algorithm defined by the tcBorders element (§2.4.63) and the tblBorders element (§2.4.37;§2.4.38)

If this element is omitted, then the top of this table shall have the border specified by the associated table style. If no top border is specified in the style hierarchy, then this table shall not have a top border.

[*Example*: Consider a table in which the table properties specifies a top table border, as follows:

R1C1	R1C2
R2C1	R2C2

This top table border is specified using the following WordprocessingML:

```
<w:tbl>
  <w:tblPr>
    <w:tblBorders>
      <w:top w:val="thinThickThinMediumGap" w:sz="24" w:space="0"
w:color="D0D0D0" w:themeColor="accent3" w:themeTint="99"/>
    </w:tblBorders>
  </w:tblPr>
  …
</w:tbl>
```

The top element specifies a three point top table border of type `thinThinThickMediumGap`. *end example*].

Parent Elements
tblBorders (§2.4.37); tblBorders (§2.4.38)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value `auto`, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />`

Attributes	Description
	This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object.
	
	When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points.
	
	When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type

Attributes	Description
	(§2.18.75).

sz (Border Width)	Specifies the width of the current border.
	
	If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value.
	
	If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.
	
	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`
	
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*]
	
	The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document.
	
	[*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:
	
	`<w:top … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:bottom … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:left … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:right … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	
	The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme

Attributes	Description
	color specified for this document. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255$$ $$= 102$$ $$= 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute:

Attributes	Description
	<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/> *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255$$ $$= 153$$ $$= 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6)$$ $$= 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we

Attributes	Description
	get 95B3D7. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is single, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.4.72 top (Table Cell Top Margin Default)

This element specifies the amount of space which shall be left between the top extent of the cell contents and the top border of all table cells within the parent table. This setting may be overridden by the table cell top margin definition specified by the top element contained within the table cell's properties (§2.4.73).

This value is specified in the units applied via its type attribute. Any width value of type pct or auto for this element shall be ignored.

If this element is omitted, then it shall inherit the table cell margin from the associated table style. If a top margin is never specified in the style hierarchy, then this table shall have no top cell padding by default (excepting individual cell overrides).

[*Example*: Consider a two by two table in which the default table cell top margin is specified to be exactly 0.25 inches, as follows (marked with an arrow in the first table cell below):

R1C1	R2C1
R2C1	R2C2

This table property is specified using the following WordprocessingML markup:

```
<w:tbl>
  <w:tblPr>
    <w:tblCellMar>
      <w:top w:w="360" w:type="dxa"/>
    </w:tblCellMar>
  </w:tblPr>
  …
</w:tbl>
```

Every cell in the table has a default cell margin setting it to 360 twentieths of a point. *end example*]

Parent Elements
tblCellMar (§2.4.39); tblCellMar (§2.4.40)

Attributes	Description
type (Table Width Type)	Specifies the units of the width property being defined by the parent element's w attribute. This property is used to define various properties of a table, including: cell spacing, preferred width, and table margins. If this attribute is omitted, then its value shall be assumed to be dxa (twentieths of a point). [*Example*: Consider a table with a table cell bottom cell spacing with a type of dxa, as follows: `<w:bottom ... w:type="dxa" />` This type shall therefore be used to interpret the width specified in the w attribute as a value in twentieths of a point. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_TblWidth simple type (§2.18.97).
w (Table Width Value)	Specifies the value of the width property being defined by the parent element. This property is used to define various properties of a table, including: cell spacing, preferred widths, and table margins. If this attribute is omitted, then its value shall be assumed to be `0`. [*Example*: Consider a table with a bottom margin with a width of `302`, as follows: `<w:bottom w:w="302" w:type="dxa" />` The value in the w attribute shall therefore be used to determine the width being specified in the context of the units specified in the type attribute. In this case, the type is twentieths of a point (`dxa`), so the width is `302` twentieths of a point (.2097 inches). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblWidth">
   <attribute name="w" type="ST_DecimalNumber"/>
   <attribute name="type" type="ST_TblWidth"/>
</complexType>
```

2.4.73 top (Table Cell Top Margin Exception)

This element specifies the amount of space which shall be left between the top extent of the cell contents and the top border of a specific table cell within a table. This setting shall override the table cell top margin definition specified by the top element contained within the table properties (§2.4.72).

This value is specified in the units applied via its type attribute. Any width value of type `pct` or `auto` for this element shall be ignored.

If omitted, then this table cell shall use the bottom cell margins defined in the top element contained within the table properties (§2.4.72).

[*Example*: Consider a table with two cells in which the first table cell's top margin is specified via an exception to be ten times larger (0.2 inches vs. 0.02 inches) than the other table cell margins:

This text fills the extents of the cell.
So does this

The first cell in the table would be specified using the following WordprocessingML:

```
<w:tc>
  <w:tcPr>
    <w:tcMar>
      <w:top w:w="288" w:type="dxa" />
    </w:tcMar>
  </w:tcPr>
</w:tc>
```

The first cell in this table has an exception applied to the table cell top cell margin setting it to 288 twentieths of a point (0.2 inches). *end example*]

Parent Elements
tcMar (§2.4.65)

Attributes	Description
type (Table Width Type)	Specifies the units of the width property being defined by the parent element's w attribute. This property is used to define various properties of a table, including: cell spacing, preferred width, and table margins. If this attribute is omitted, then its value shall be assumed to be dxa (twentieths of a point). [*Example*: Consider a table with a table cell bottom cell spacing with a type of dxa, as follows: `<w:bottom ... w:type="dxa" />` This type shall therefore be used to interpret the width specified in the w attribute as a value in twentieths of a point. *end example*] The possible values for this attribute are defined by the ST_TblWidth simple type (§2.18.97).
w (Table Width Value)	Specifies the value of the width property being defined by the parent element. This property is used to define various properties of a table, including: cell spacing, preferred widths, and table margins. If this attribute is omitted, then its value shall be assumed to be 0. [*Example*: Consider a table with a bottom margin with a width of 302, as follows: `<w:bottom w:w="302" w:type="dxa" />` The value in the w attribute shall therefore be used to determine the width being

Attributes	Description
	specified in the context of the units specified in the type attribute. In this case, the type is twentieths of a point (dxa), so the width is 302 twentieths of a point (.2097 inches). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblWidth">
   <attribute name="w" type="ST_DecimalNumber"/>
   <attribute name="type" type="ST_TblWidth"/>
</complexType>
```

2.4.74 top (Table Cell Top Border)

This element specifies the border which shall be displayed at the top of the current table cell. The appearance of this table cell border in the document shall be determined by the following settings:

- If the net tblCellSpacing element value (§2.4.41;§2.4.42;§2.4.43) applied to the cell is non-zero, then the cell border shall always be displayed
- Otherwise, the display of the border is subject to the conflict resolution algorithm defined by the tcBorders element (§2.4.63) and the tblBorders element (§2.4.37;§2.4.38)

If this element is omitted, then the top of this table cell shall not have a cell border, and its border may use the table's border settings as appropriate.

[*Example*: Consider a table in which the first cell in the first row specifies a top cell border , as follows:

R1C1	R1C2
R2C1	R2C2

This top cell border is specified using the following WordprocessingML:

```
<w:tc>
  <w:tcPr>
    …
    <w:tcBorders>
      <w:top w:val="thinThickThinSmallGap" w:sz="24" w:space="0"
w:color="FF0000"/>
    </w:tcBorders>
  </w:tcPr>
  <w:p/>
</w:tc>
```

The top element specifies a three point border of type `thinThinThickSmallGap`. *end example*]

Parent Elements
tcBorders (§2.4.63)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value `auto`, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location.

Attributes	Description
	If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object.
	
	When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points.
	
	When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border. If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value. If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value

Attributes	Description

	of 31. Any values outside this range may be reassigned to a more appropriate value.
	
	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`
	
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*]
	
	The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document.
	
	[*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:
	
	`<w:top … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:bottom … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:left … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:right … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	
	The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border.

Attributes	Description
	The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255$$ $$= 102$$ $$= 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance.

Attributes	Description
	If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255 \\ = 153 \\ = 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}^{'} = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `4F81BD`. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L^{'} = 0.53 * 0.6 + (1 - .6) \\ = 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get `95B3D7`. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.4.75 tr (Table Row)

This element specifies a single table row, which contains the table's cells. Table rows in WordprocessingML are analogous to HTML `tr` elements.

A tr element has one formatting child element, trPr (§2.4.78), which defines the properties for the row. Each unique property on the table row is specified by a child element of this element. As well, a table row can contain any valid row-level content, which allows for the use of table cells.

If a table cell does not include at least one child element other than the row properties, then this document shall be considered corrupt.

[*Example*: Consider a table consisting of a single table cell, which contains the text `Hello World`:

Hello World

This table row's content is represented by the following WordprocessingML:

```
<w:tr>
  <w:tc>
    <w:tcPr>
      <w:tcW w:w="0" w:type="auto"/>
    </w:tcPr>
    <w:p>
      <w:r>
        <w:t>Hello, World</w:t>
      </w:r>
    </w:p>
  </w:tc>
</w:tr>
```

The tr element contains a single row-level element - in this case, a table cell. *end example*]

Attributes	Description
rsidDel (Revision Identifier for Table Row Deletion)	Specifies a unique identifier used to track the editing session when the row was deleted from the main document. All rsid* attributes throughout this document with the same value, if present, must indicate that those regions were modified during the same editing session (time between subsequent save actions). A producer may choose to increment the revision save ID value to indicate subsequent editing sessions to indicate the order of the modifications relative to other modifications in this document. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).
rsidR (Revision Identifier for Table Row)	Specifies a unique identifier used to track the editing session when the table row was added to the main document. All rsid* attributes throughout this document with the same value, if present, must indicate that those regions were modified during the same editing session (time between subsequent save actions). A producer may choose to increment the revision save ID value to indicate subsequent editing sessions to indicate the order of the modifications relative to other modifications in this document. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

Attributes	Description
rsidRPr (Revision Identifier for Table Row Glyph Formatting)	Specifies a unique identifier used to track the editing session when the glyph character representing the table row mark was last modified in the main document. All rsid* attributes throughout this document with the same value, if present, must indicate that those regions were modified during the same editing session (time between subsequent save actions). A producer may choose to increment the revision save ID value to indicate subsequent editing sessions to indicate the order of the modifications relative to other modifications in this document. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).
rsidTr (Revision Identifier for Table Row Properties)	Specifies a unique identifier used to track the editing session when the table row's properties were last modified in this document. All rsid* attributes throughout this document with the same value, if present, must indicate that those regions were modified during the same editing session (time between subsequent save actions). A producer may choose to increment the revision save ID value to indicate subsequent editing sessions to indicate the order of the modifications relative to other modifications in this document. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Row">
    <sequence>
        <element name="tblPrEx" type="CT_TblPrEx" minOccurs="0" maxOccurs="1"/>
        <element name="trPr" type="CT_TrPr" minOccurs="0" maxOccurs="1"/>

    </sequence>
    <attribute name="rsidRPr" type="ST_LongHexNumber"/>
    <attribute name="rsidR" type="ST_LongHexNumber"/>
    <attribute name="rsidDel" type="ST_LongHexNumber"/>
    <attribute name="rsidTr" type="ST_LongHexNumber"/>
</complexType>
```

2.4.76 tr2bl (Table Cell Top Right to Bottom Left Diagonal Border)

This element specifies the border which shall be displayed on the top right to bottom left diagonal within the current table cell.

If this element is omitted, then the top right to bottom left diagonal of this table cell shall not have a cell border, and its border may use the table's border settings as appropriate.

[*Example*: Consider a table in which the second cell in the second row specifies a top right to bottom left diagonal cell border as follows:

R1C1	R1C2
R2C1	R2C2

This diagonal cell border is specified using the following WordprocessingML:

```
<w:tc>
  <w:tcPr>
    …
    <w:tcBorders>
       <w:tr2bl w:val="double" w:sz="4" w:space="0" w:color="FF0000"/>
    </w:tcBorders>
  </w:tcPr>
  <w:p/>
</w:tc>
```

The tr2bl element specifies a ½ point border of type `double` on the table cell's diagonal. *end example*

Parent Elements
tcBorders (§2.4.63)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value `auto`, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).

Attributes	Description
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object. When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points. When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points. [*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:

Attributes	Description
	<w:pgBorders w:offsetFrom="page"> <w:bottom … w:space="24/> </w:pgBorders> The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*] The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).
sz (Border Width)	Specifies the width of the current border. If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value. If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value. [*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup: <w:top w:val="dashed" w:sz="24" …/> <w:left w:val="dashed" w:sz="24" …/> <w:bottom w:val="dashed" w:sz="24" …/> <w:right w:val="dashed" w:sz="24" …/> The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*] The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).
themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border. The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document. [*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup: <w:top … w:color="FFA8A0" w:themeColor="accent2"

Attributes	Description
	w:themeTint="99" /> <w:bottom … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:left … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:right … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 = 102 = 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$.

Attributes	Description
	Applying the shade formula with a shade percentage of 75% to the luminance, we get: $L^{'} = 0.53 * 0.75$ $= 0.39698$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $T_{xml} = 0.6 * 255$ $= 153$ $= 99(hex)$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $\mathrm{L}^{'} = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$ • Convert the resultant HSL color to RGB

Attributes	Description
	[*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `4F81BD`. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $L' = 0.53 * 0.6 + (1 - .6)$ $= 0.71$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get `95B3D7`. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.4.77 trHeight (Table Row Height)

This element specifies the height of the current table row within the current table. This height shall be used to determine the resulting height of the table row, which may be absolute or relative (depending on its attribute values).

If omitted, then the table row shall automatically resize its height to the height required by its contents (the equivalent of an hRule value of auto).

[*Example*: Consider the following WordprocessingML table:

Some text in R1C1.	

Examining the WordprocessingML for this table, the trHeight element is not specified, so the row heights are automatically determined by their contents (in the first row, the text `Some text in R1C1.`). If the first row shall be restricted to 0.1 inches high (144 twentieths of a point) regardless of its contents, that would be specified using the trHeight element as follows:

```
<w:trPr>
  <w:trHeight w:val="144" w:hRule="exact"/>
</w:trPr>
```

The resulting table row would be exactly 144 twentieths of a point high:

end example]

Parent Elements
trPr (§2.7.5.10); trPr (§2.7.5.11); trPr (§2.4.78); trPr (§2.4.79)

Attributes	Description

hRule (Table Row Height Type)	Specifies the meaning of the height specified for this table row.
	
	The meaning of the value of the val attribute is defined based on the value of the hRule attribute for this table row as follows:
	• If the value of hRule is auto, then the table row's height should be automatically determined based on the height of its contents. The h value is ignored.
	• If the value of hRule is atLeast, then the table row's height should be at least the value the h attribute.
	• If the value of hRule is exact, then the table row's height should be exactly the value of the h attribute.
	
	If this attribute is omitted, then its value shall be assumed to be auto.
	
	[*Example*: Consider the following paragraph containing a table row:
	
	`<w:tr>`
	`  <w:trPr>`
	`  <w:trHeight w:val="2189" w:hRule="atLeast"/>`
	`  </w:trPr>`
	`  …`
	`</w:tr>`
	
	The hRule attribute specifies a value of atLeast, so the table row will be a minimum of 2189 twentieths of a point high regardless of its contents, since its val value is 2189 twentieths of a point. *end example*]
	
	The possible values for this attribute are defined by the ST_HeightRule simple type (§2.18.42).

val (Table Row Height)	Specifies the table row's height. This height is expressed in twentieths of a point. If this attribute is omitted, then its value shall be assumed to be 0. The meaning of the value of the val attribute is defined based on the value of the hRule attribute for this table row as follows: • If the value of hRule is auto, then the table row's height should be automatically determined based on the height of its contents. This value is ignored. • If the value of hRule is atLeast, then the table row's height should be at least the value of this attribute. • If the value of hRule is exact, then the table row's height should be exactly the value of this attribute. [*Example*: Consider the following table row:

Attributes	Description
	<w:tr> <w:trPr> <w:trHeight w:val="2189" w:hRule="atLeast"/> </w:trPr> … </w:tr> The val attribute specifies a value of 2189 twentieths of a point, so this table row will be a minimum of 2189 twentieths of a point high regardless of its contents (growing if needed), since its hRule value is set to atLeast. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Height">
   <attribute name="val" type="ST_TwipsMeasure"/>
   <attribute name="hRule" type="ST_HeightRule"/>
</complexType>
```

2.4.78 trPr (Table Row Properties)

This element specifies the set of row-level properties applied to the current table row. Each unique property is specified by a child element of this element. These properties affect the appearance of all cells in the current row within the parent table, but may be overridden by individual cell-level properties, as defined by each property.

[*Example*: Consider the following WordprocessingML table:

The first row shall have a table-row level property which specifies that it shall be restricted to 0.1 inches high (144 twentieths of a point) regardless of its contents, that would be specified using the trHeight element as follows:

```
<w:trPr>
  <w:trHeight w:val="144" w:hRule="exact"/>
  …
</w:trPr>
```

The trPr element specifies the set of table row properties applied to the current table row in the document, in this case a row height requirement using the trHeight element (§2.4.77). *end example*]

Parent Elements
tr (§2.4.75)

Child Elements	Subclause
cantSplit (Table Row Cannot Break Across Pages)	§2.4.6
cnfStyle (Table Row Conditional Formatting)	§2.4.8
del (Deleted Table Row)	§2.13.5.14
divId (Associated HTML div ID)	§2.4.9
gridAfter (Grid Columns After Last Cell)	§2.4.10
gridBefore (Grid Columns Before First Cell)	§2.4.11
hidden (Hidden Table Row Marker)	§2.4.14
ins (Inserted Table Row)	§2.13.5.16
jc (Table Row Alignment)	§2.4.22
tblCellSpacing (Table Row Cell Spacing)	§2.4.42
tblHeader (Repeat Table Row on Every New Page)	§2.4.46
trHeight (Table Row Height)	§2.4.77
trPrChange (Revision Information for Table Row Properties)	§2.13.5.39
wAfter (Preferred Width After Table Row)	§2.4.82
wBefore (Preferred Width Before Table Row)	§2.4.83

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrPr">
   <complexContent>
      <extension base="CT_TrPrBase">
         <sequence>
            <element name="ins" type="CT_TrackChange" minOccurs="0"/>
            <element name="del" type="CT_TrackChange" minOccurs="0"/>
            <element name="trPrChange" type="CT_TrPrChange" minOccurs="0"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.4.79 trPr (Previous Table Row Properties)

This element specifies a previous set of table cell properties, the modifications to which shall be attributed to a revision by a particular author and at a particular time. This element contains the table cell property settings which were previously in place before a specific set of revisions by one author. Each unique property is specified by a child element of this element. These properties affect the appearance of all cells in the current row within the parent table, but may be overridden by individual cell-level properties, as defined by each property.

[*Example*: Consider the following WordprocessingML table:

This table has a row height for row one of exactly 0.1". If we change that to a row height of at least 0.1" with revision marking enabled, the table would appear as follows:

Some text in R1C1.	

The resulting WordprocessingML would be:

```
<w:tr>
  <w:trPr>
    <w:trHeight w:val="144"/>
    <w:trPrChange w:id="2" … >
      <w:trPr>
        <w:trHeight w:hRule="exact" w:val="144"/>
      </w:trPr>
    </w:trPrChange>
  </w:trPr>
  …
</w:tr>
```

The trPr element as a child of trPrChange specifies the set of table row properties which were in place before the current revision to the document. *end example*]

Parent Elements
trPrChange (§2.13.5.39)

Child Elements	Subclause
cantSplit (Table Row Cannot Break Across Pages)	§2.4.6
cnfStyle (Table Row Conditional Formatting)	§2.4.8
divId (Associated HTML div ID)	§2.4.9
gridAfter (Grid Columns After Last Cell)	§2.4.10
gridBefore (Grid Columns Before First Cell)	§2.4.11
hidden (Hidden Table Row Marker)	§2.4.14
jc (Table Row Alignment)	§2.4.22

Child Elements	Subclause
tblCellSpacing (Table Row Cell Spacing)	§2.4.42
tblHeader (Repeat Table Row on Every New Page)	§2.4.46
trHeight (Table Row Height)	§2.4.77
wAfter (Preferred Width After Table Row)	§2.4.82
wBefore (Preferred Width Before Table Row)	§2.4.83

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrPrBase">
   <choice maxOccurs="unbounded">
      <element name="cnfStyle" type="CT_Cnf" minOccurs="0" maxOccurs="1"/>
      <element name="divId" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="gridBefore" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="gridAfter" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="wBefore" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="wAfter" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="cantSplit" type="CT_OnOff" minOccurs="0"/>
      <element name="trHeight" type="CT_Height" minOccurs="0"/>
      <element name="tblHeader" type="CT_OnOff" minOccurs="0"/>
      <element name="tblCellSpacing" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="jc" type="CT_Jc" minOccurs="0" maxOccurs="1"/>
      <element name="hidden" type="CT_OnOff" minOccurs="0"/>
   </choice>
</complexType>
```

2.4.80 vAlign (Table Cell Vertical Alignment)

This element specifies the vertical alignment for text within the current table cell. The vertical alignment of this text is determined by the value of the val attribute.

[*Example*: Consider a table with a single cell with text vertically aligned to the bottom of the cell:

R1C1

This requirement would be specified using the following WordprocessingML:

```
<w:tc>
  <w:tcPr>
    <w:vAlign w:val="bottom" />
  </w:tcPr>
  <w:r>
    <w:t>R1C1</w:t>
  </w:r>
```

```
</w:tc>
```

The vAlign element specifies the vertical alignment of the cell contents, in the case, the bottom of the table cell. *end example*]

Parent Elements
tcPr (§2.7.5.8); tcPr (§2.4.66); tcPr (§2.7.5.9); tcPr (§2.4.67)

Attributes	Description
val (Vertical Alignment Setting)	Specifies the vertical alignment for text between the top and bottom margins of the parent container (page or table cell). [*Example*: Consider a region where the text shall be vertically centered in the parent element. This would require a val value of center, in order to specify that all justification vertically shall be centered relative to the parent. For a section, this setting would be specified as follows: `<w:vAlign w:val="center" />` The val attribute of center specifies that the content is centered relative to its container (in this case, the page). *end example*] The possible values for this attribute are defined by the ST_VerticalJc simple type (§2.18.111).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_VerticalJc">
   <attribute name="val" type="ST_VerticalJc" use="required"/>
</complexType>
```

2.4.81 vMerge (Vertically Merged Cell)

This element specifies that this cell is part of a vertically merged set of cells in a table. The val attribute on this element determines how this cell is defined with respect to the previous cell in the table (i.e. does this cell continue the vertical merge or start a new merged group of cells).

If this element is omitted, then this cell shall not be part of any vertically merged grouping of cells, and any vertically merged group of preceding cells shall be closed. If a vertically merged group of cells do not span the same set of grid columns, then this vertical merge is invalid.

[*Example*: Consider a table with three rows and two columns with the last column completely vertically merged:

The second cell in the first row starts a vertical merge that is completed in the last cell, resulting in the following WordprocessingML:

```
<w:tbl>
  …
  <w:tr>
    <w:tc>
      …
    </w:tc>
    <w:tc>
      …
    </w:tc>
    <w:tc>
      <w:tcPr>
        <w:vmerge w:val="restart"/>
      </w:tcPr>
      …
    </w:tc>
  </w:tr>
  <w:tr>
    <w:tc>
      …
    </w:tc>
    <w:tc>
      …
    </w:tc>
    <w:tc>
      <w:tcPr>
        <w:vmerge w:val="continue"/>
      </w:tcPr>
      …
    </w:tc>
  </w:tr>
```

```
<w:tr>
  <w:tc>
    …
  </w:tc>
  <w:tc>
    …
  </w:tc>
  <w:tc>
    <w:tcPr>
      <w:vmerge w:val="continue"/>
    </w:tcPr>
    …
  </w:tc>
</w:tr>
</w:tbl>
```

The vmerge element defines the cells which are vertically merged, and how each cell is merged together. *end example*]

Parent Elements
tcPr (§2.7.5.8); tcPr (§2.4.66); tcPr (§2.7.5.9); tcPr (§2.4.67)

Attributes	Description

val (Vertical Merge Type)	Specifies how the table cell is part of a vertically merged region. This determines whether the cell should join onto an existing grouping of merged cells if any exist, or start a new group of merged cells. Refer to the simple type definition for a full description of each type.
	
	If this attribute is omitted, its value shall be assumed to be `continue`.
	
	[*Example*: Consider a table cell where a vertical cell merge begins . This setting is represented as the following WordprocessingML:
	
	`<w:tcPr>`
	`  <w:vmerge w:val="restart"/>`
	`</w:tcPr>`
	
	The attribute value of `restart` specifies that this element shall start a new vertically merged region in this table. *end example*]
	
	The possible values for this attribute are defined by the ST_Merge simple type (§2.18.64).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_VMerge">
   <attribute name="val" type="ST_Merge"/>
</complexType>
```

2.4.82 wAfter (Preferred Width After Table Row)

This element specifies the preferred width for the total number of grid columns after this table row as specified in the gridAfter element (§2.4.10). This preferred width is used as part of the table layout algorithm specified by the tblLayout element (§2.4.49; §2.4.50) - full description of the algorithm in the ST_TblLayout simple type (§2.18.94).

All widths in a table are considered preferred because:

- The table must satisfy the shared columns as specified by the tblGrid element (§2.4.44)
- Two or more widths may have conflicting values for the width of the same grid column
- The table layout algorithm (§2.18.94) may require a preference to be overridden

This value is specified in the units applied via its type attribute. Any width value of type `pct` for this element shall be calculated relative to the text extents of the page (page width excluding margins).

If this element is omitted, then the cell width shall be of type `auto`.

[*Example*: Consider a WordprocessingML table row defined as follows:

```
<w:tr>
  <w:trPr>
    <w:gridAfter w:val="2"/>
    <w:wAfter w:type="fixed" w:w="1440"/>
  </w:trPr>
  …
</w:tr>
```

This table specifies that it has a preferred table width of `1440` twentieths of a point (one inch) for the two grid columns after the end of that row. The resulting table would therefore be sized such that that set of grid columns is one inch whenever possible, for example the second row in this table:

end example]

Parent Elements
trPr (§2.7.5.10); trPr (§2.7.5.11); trPr (§2.4.78); trPr (§2.4.79)

Attributes	Description
type (Table Width Type)	Specifies the units of the width property being defined by the parent element's w attribute. This property is used to define various properties of a table, including: cell spacing, preferred width, and table margins. If this attribute is omitted, then its value shall be assumed to be dxa (twentieths of a point). [*Example*: Consider a table with a table cell bottom cell spacing with a type of dxa, as follows: `<w:bottom ... w:type="dxa" />` This type shall therefore be used to interpret the width specified in the w attribute as a value in twentieths of a point. *end example*] The possible values for this attribute are defined by the ST_TblWidth simple type (§2.18.97).
w (Table Width Value)	Specifies the value of the width property being defined by the parent element. This property is used to define various properties of a table, including: cell spacing, preferred widths, and table margins. If this attribute is omitted, then its value shall be assumed to be 0. [*Example*: Consider a table with a bottom margin with a width of 302, as follows: `<w:bottom w:w="302" w:type="dxa" />` The value in the w attribute shall therefore be used to determine the width being specified in the context of the units specified in the type attribute. In this case, the type is twentieths of a point (dxa), so the width is 302 twentieths of a point (.2097 inches). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblWidth">
   <attribute name="w" type="ST_DecimalNumber"/>
   <attribute name="type" type="ST_TblWidth"/>
</complexType>
```

2.4.83 wBefore (Preferred Width Before Table Row)

This element specifies the preferred width for the total number of grid columns before this table row as specified in the gridAfter element (§2.4.10). This preferred width is used as part of the table layout algorithm specified by the tblLayout element (§2.4.49; §2.4.50) - full description of the algorithm in the ST_TblLayout simple type (§2.18.94).

All widths in a table are considered preferred because:

- The table must satisfy the shared columns as specified by the tblGrid element (§2.4.44)
- Two or more widths may have conflicting values for the width of the same grid column
- The table layout algorithm (§2.18.94) may require a preference to be overridden

This value is specified in the units applied via its type attribute. Any width value of type `pct` for this element shall be calculated relative to the text extents of the page (page width excluding margins).

If this element is omitted, then the cell width shall be of type `auto`.

[*Example*: Consider a WordprocessingML table row defined as follows:

```
<w:tr>
  <w:trPr>
    <w:gridBefore w:val="1"/>
    <w:wBefore w:type="fixed" w:w="1440"/>
  </w:trPr>
  …
</w:tr>
```

This table specifies that it has a preferred table width of `1440` twentieths of a point (one inch) for the grid column before the start of the row. The resulting table would therefore be sized such that that grid column is one inch whenever possible, for example the second row in this table:

end example]

Parent Elements
trPr (§2.7.5.10); trPr (§2.7.5.11); trPr (§2.4.78); trPr (§2.4.79)

Attributes	Description
type (Table Width	Specifies the units of the width property being defined by the parent element's w

Attributes	Description
Type)	attribute. This property is used to define various properties of a table, including: cell spacing, preferred width, and table margins. If this attribute is omitted, then its value shall be assumed to be dxa (twentieths of a point). [*Example*: Consider a table with a table cell bottom cell spacing with a type of dxa, as follows: `<w:bottom ... w:type="dxa" />` This type shall therefore be used to interpret the width specified in the w attribute as a value in twentieths of a point. *end example*] The possible values for this attribute are defined by the ST_TblWidth simple type (§2.18.97).
w (Table Width Value)	Specifies the value of the width property being defined by the parent element. This property is used to define various properties of a table, including: cell spacing, preferred widths, and table margins. If this attribute is omitted, then its value shall be assumed to be 0. [*Example*: Consider a table with a bottom margin with a width of 302, as follows: `<w:bottom w:w="302" w:type="dxa" />` The value in the w attribute shall therefore be used to determine the width being specified in the context of the units specified in the type attribute. In this case, the type is twentieths of a point (dxa), so the width is 302 twentieths of a point (.2097 inches). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblWidth">
   <attribute name="w" type="ST_DecimalNumber"/>
   <attribute name="type" type="ST_TblWidth"/>
</complexType>
```

2.5 Custom Markup

Within a WordprocessingML document, it is often necessary for specific documents to contain semantic information beyond the presentation information specified by this Office Open XML Standard. [*Example*: An invoice document may wish to specify that a particular sentence of text is a customer name, in order for that

information to be easily extracted from the document without the need to parse the text using regular expression matching or similar. *end example*]

For these scenarios, multiple facilities are provided for the insertion and round-tripping of customer defined semantics within a WordprocessingML document. There are three distinct forms in which customer-defined semantics can be inserted into a WordprocessingML document, each with their own specific intended usage:

- Smart tags
- Custom XML markup
- Structured document tags (content controls)

The elements and attributes which define each of these forms is described in the following clauses.

2.5.1 Custom XML and Smart Tags

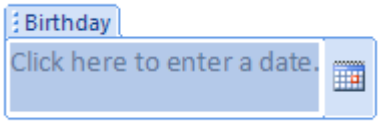
The final type of customer-defined semantics which can be embedded in a WordprocessingML document are structured document tags (SDTs).

As shown above, smart tags and custom XML markup each provide a facility for embedding customer-defined semantics into the document: smart tags, via the ability to provide a basic namespace/name for a run or set of runs within a documents; and custom XML markup, via the ability to tag the document with XML elements and attributes specified by any valid XML Schema file.

However, each of these techniques, while they each provide a way to add the desired semantic information, does not provide a way to affect the presentation or interaction within the document. To bridge these two worlds, structured document tags allow both the specification of customer semantics as well as the ability to influence the presentation of that data in the document.

This means that the customer can define the semantics and context of the tag, but can then use a rich set of pre-defined properties to define its behavior and appearance within the WordprocessingML document's presentation.

[*Example*: Consider a region which should be tagged with the semantic of "birthday", for the user to enter their date or birth into the document. Ideally, this region would also utilize a date picker to allow the user to enter the date from a calendar:



This content would be specified using the following WordprocessingML:

```
<w:sdt>
  <w:sdtPr>
    <w:alias w:val="Birthday"/>
    <w:id w:val="8775518"/>
    <w:placeholder>
      <w:docPart w:val="DefaultPlaceholder_22479095"/>
    </w:placeholder>
    <w:showingPlcHdr/>
    <w:date>
      <w:dateFormat w:val="M/d/yyyy"/>
      <w:lid w:val="EN-US"/>
    </w:date>
  </w:sdtPr>
  <w:sdtContent>
    <w:p>
      <w:r>
        <w:rPr>
          <w:rStyle w:val="PlaceholderText"/>
        </w:rPr>
        <w:t>Click here to enter a date...</w:t>
      </w:r>
    </w:p>
  </w:sdtContent>
</w:sdt>
```

end example]

As shown above, each of the structured document tags in the WordprocessingML file is represented using the sdt element.

Within a structured document tag, there are two child elements which contain the definition and the content of this SDT. The first of these is the sdtPr element, which contains the set of properties specified for this structured document tag. The second is the sdtContent element, which contains all the content which is contained within this structured document tag.

2.5.1.1 attr (Custom XML Attribute)

This element specifies a custom XML attribute which shall be located on the parent custom XML element specified via the customXml element (§2.5.1.3;§2.5.1.4;§2.5.1.5; §2.5.1.6). The attributes on this element shall be used to specify the contents of the custom XML attribute.

[*Example*: Consider a custom XML element with the following properties:

```
<w:customXmlPr>
  <w:attr w:name="companyName" … />
  <w:attr w:name="companySymbol … />
</w:customXmPr>
```

This property bag specifies that the parent custom XML element shall have two attributes associated with it, he first with a name of companyName, and the second with a name of companySymbol. *end example*]

Parent Elements
customXmlPr (§2.5.1.7)

Attributes	Description

name (Name)	Specifies the name of the current custom XML attribute or smart tag property.
	
	[*Example*: Consider a custom XML attribute which shall have a name of companyName. This requirement would be specified using the following WordprocessingML:
	
	`<w:customXmlPr>`
	`  <w:attr w:name="companyName" … />`
	`</w:customXmlPr>`
	
	The name attribute specifies that the name for this property shall be companyName. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

uri (Namespace)	Specifies the namespace URI of the current custom XML attribute or smart tag property.
	
	If this attribute is omitted, the URI shall be assumed to be null (no associated URI).
	
	[*Example*: Consider a smart tag property which shall have a namespace URI of http://schemas.openxmlformats.org/2006/example. This requirement would be specified using the following WordprocessingML:
	
	`<w:smartTagPr>`
	`  <w:attr w:uri="http://schemas.openxmlformats`
	`.org/2006/example" … />`
	`</w:smartTagPr>`
	
	The uri attribute specifies that the namespace for this property shall be http://schemas.openxmlformats.org/2006/example. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

val (Value)	Specifies the value of the current custom XML attribute or smart tag property. [*Example*: Consider a smart tag property which shall have a value of propertyValue. This

Attributes	Description

	requirement would be specified using the following WordprocessingML:
	
	`<w:smartTagPr>`
	`  <w:attr … w:val="propertyValue" />`
	`</w:smartTagPr>`
	
	The val attribute specifies that the value for this property shall be `propertyValue`. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Attr">
   <attribute name="uri" type="ST_String"/>
   <attribute name="name" type="ST_String" use="required"/>
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.5.1.2 attr (Smart Tag Property)

This element specifies a single smart tag property which shall be located on the parent smart tag, specified via the smartTag element (§2.5.1.9). The attributes on this element shall be used to specify the contents of smart tag property.

[*Example*: Consider a smart tag with the following properties:

```
<w:smartTagPr>
  <w:attr w:name="attributeOne" … />
  <w:attr w:name="attributeTwo" … />
</w:smartTagPr>
```

This property bag specifies that the parent smart tag shall have two properties associated with it, the first with a name of `attributeOne`, and the second with a name of `attributeTwo`. *end example*].

Parent Elements
smartTagPr (§2.5.1.10)

Attributes	Description
name (Name)	Specifies the name of the current custom XML attribute or smart tag property. [*Example*: Consider a custom XML attribute which shall have a name of `companyName`. This requirement would be specified using the following WordprocessingML: `<w:customXmlPr>`

Attributes	Description
	<w:attr w:name="companyName" … /> </w:customXmlPr> The name attribute specifies that the name for this property shall be companyName. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).
uri (Namespace)	Specifies the namespace URI of the current custom XML attribute or smart tag property. If this attribute is omitted, the URI shall be assumed to be null (no associated URI). [*Example*: Consider a smart tag property which shall have a namespace URI of http://schemas.openxmlformats.org/2006/example. This requirement would be specified using the following WordprocessingML: <w:smartTagPr> <w:attr w:uri="http://schemas.openxmlformats .org/2006/example" … /> </w:smartTagPr> The uri attribute specifies that the namespace for this property shall be http://schemas.openxmlformats.org/2006/example. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).
val (Value)	Specifies the value of the current custom XML attribute or smart tag property. [*Example*: Consider a smart tag property which shall have a value of propertyValue. This requirement would be specified using the following WordprocessingML: <w:smartTagPr> <w:attr … w:val="propertyValue" /> </w:smartTagPr> The val attribute specifies that the value for this property shall be propertyValue. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Attr">
   <attribute name="uri" type="ST_String"/>
   <attribute name="name" type="ST_String" use="required"/>
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.5.1.3 customXml (Cell-Level Custom XML Element)

This element specifies the presence of a custom XML element around a single table cell. The attributes on this element shall be used to specify the name and namespace URI of the current custom XML element.

[*Example*: Consider a custom XML element with the name company that shall be located around a single table cell in a WordprocessingML document. This requirement would be specified as follows in the WordprocessingML:

```
<w:tr>
  <w:customXml w:element="company" … >
    <w:tc>
      …
    </w:tc>
  </w:customXml>
  …
</w:tr>
```

The customXml element specifies that the name of the custom XML element is company, and the custom XML element contains a single table cell (it is a cell-level element). *end example*]

Parent Elements

Attributes	Description

element (Custom XML Element Name)	Specifies the name of the current custom XML element or smart tag within the document.
	
	[*Example*: Consider a custom XML element which shall have a name of `companyName`. This requirement would be specified using the following WordprocessingML:
	
	`<w:customXml w:element="companyName" … >`
	`…`
	`</w:customXml>`
	
	The element attribute specifies that the name for this element shall be `companyName`. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

uri (Custom XML Element Namespace)	Specifies the namespace URI of the current custom XML element or smart tag.
	
	If this attribute is omitted, the URI shall be assumed to be null (no associated URI).
	
	[*Example*: Consider a custom XML element which shall have a namespace URI of `urn:customXmlExample`. This requirement would be specified using the following WordprocessingML:
	
	`<w:customXml … w:uri="urn:customXmlExample" />`
	`…`

Attributes	Description
	</w:customXml> The uri attribute specifies that the namespace for this element shall be urn:customXmlExample. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_CustomXmlCell">
   <sequence>
      <element name="customXmlPr" type="CT_CustomXmlPr" minOccurs="0" maxOccurs="1"/>
      <group ref="EG_ContentCellContent" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
   <attribute name="uri" type="ST_String"/>
   <attribute name="element" type="ST_String" use="required"/>
</complexType>
```

2.5.1.4 customXml (Row-Level Custom XML Element)

This element specifies the presence of a custom XML element around a single table row. The attributes on this element shall be used to specify the name and namespace URI of the current custom XML element.

[*Example*: Consider a custom XML element with the name invoiceItem that shall be located around a single table row in a WordprocessingML document. This requirement would be specified as follows in the WordprocessingML:

```
<w:tbl>
  <w:customXml w:element="invoiceItem" … >
    <w:tr>
      …
    </w:tr>
  </w:customXml>
  …
</w:tbl>
```

The customXml element specifies that the name of the custom XML element is invoiceItem, and the custom XML element contains a single table row (it is a row-level element). *end example*]

Attributes	Description
element (Custom XML Element Name)	Specifies the name of the current custom XML element or smart tag within the document. [*Example*: Consider a custom XML element which shall have a name of `companyName`. This requirement would be specified using the following WordprocessingML:

Attributes	Description
	<w:customXml w:element="companyName" … > … </w:customXml> The element attribute specifies that the name for this element shall be companyName. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).
uri (Custom XML Element Namespace)	Specifies the namespace URI of the current custom XML element or smart tag. If this attribute is omitted, the URI shall be assumed to be null (no associated URI). [*Example*: Consider a custom XML element which shall have a namespace URI of urn:customXmlExample. This requirement would be specified using the following WordprocessingML: <w:customXml … w:uri="urn:customXmlExample" /> … </w:customXml> The uri attribute specifies that the namespace for this element shall be urn:customXmlExample. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_CustomXmlRow">
   <sequence>
      <element name="customXmlPr" type="CT_CustomXmlPr" minOccurs="0" maxOccurs="1"/>
      <group ref="EG_ContentRowContent" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
   <attribute name="uri" type="ST_String"/>
   <attribute name="element" type="ST_String" use="required"/>
</complexType>
```

2.5.1.5 customXml (Inline-Level Custom XML Element)

This element specifies the presence of a custom XML element around one or more inline level structures (runs, images, fields, etc.) within a paragraph. The attributes on this element shall be used to specify the name and namespace URI of the current custom XML element.

[*Example*: Consider a custom XML element with the name firstName that shall be located around a two text runs in a WordprocessingML document. This requirement would be specified as follows in the WordprocessingML:

```
<w:p>
  <w:customXml w:element="firstName" … >
    <w:r>
      …
    </w:r>
    <w:r>
      …
    </w:r>
  </w:customXml>
  …
</w:p>
```

The customXml element specifies that the name of the custom XML element is `firstName`, and the custom XML element contains a two text runs (it is an inline-level element). *end example*]

Parent Elements

Attributes	Description

element (Element name)	Specifies the name of the current custom XML element or smart tag within the document.
	
	[*Example*: Consider a custom XML element which shall have a name of `companyName`. This requirement would be specified using the following WordprocessingML:
	
	`<w:customXml w:element="companyName" … >`
	`  …`
	`</w:customXml>`
	
	The element attribute specifies that the name for this element shall be `companyName`. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

uri (Custom XML Markup Namespace)	Specifies the namespace URI of the current custom XML element or smart tag. If this attribute is omitted, the URI shall be assumed to be null (no associated URI). [*Example*: Consider a custom XML element which shall have a namespace URI of `urn:customXmlExample`. This requirement would be specified using the following WordprocessingML:

Attributes	Description
	<w:customXml … w:uri="urn:customXmlExample" /> … </w:customXml> The uri attribute specifies that the namespace for this element shall be urn:customXmlExample. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_CustomXmlRun">
   <sequence>
      <element name="customXmlPr" type="CT_CustomXmlPr" minOccurs="0" maxOccurs="1"/>
      <group ref="EG_PContent" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
   <attribute name="uri" type="ST_String"/>
   <attribute name="element" type="ST_String" use="required"/>
</complexType>
```

2.5.1.6 customXml (Block-Level Custom XML Element)

This element specifies the presence of a custom XML element around one or more block level structures (paragraphs, tables, etc.). The attributes on this element shall be used to specify the name and namespace URI of the current custom XML element.

[*Example*: Consider a custom XML element with the name address that shall be located around a single paragraph in a WordprocessingML document. This requirement would be specified as follows in the WordprocessingML:

```
<w:body>
  <w:customXml w:element="address" … >
    <w:p>
      …
    </w:p>
  </w:customXml>
  …
</w:body>
```

The customXml element specifies that the name of the custom XML element is address, and the custom XML element contains a single paragraph (it is a block-level element). *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.6); docPartBody (§2.12.6); endnote (§2.11.2); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); sdtContent (§2.5.2.32); tc (§2.4.62); txbxContent (§2.17.1.1)

Child Elements	Subclause
bookmarkEnd (Bookmark End)	§2.13.6.1
bookmarkStart (Bookmark Start)	§2.13.6.2
commentRangeEnd (Comment Anchor Range End)	§2.13.4.3
commentRangeStart (Comment Anchor Range Start)	§2.13.4.4
customXml (Block-Level Custom XML Element)	§2.5.1.6
customXmlDelRangeEnd (Custom XML Markup Deletion End)	§2.13.5.4
customXmlDelRangeStart (Custom XML Markup Deletion Start)	§2.13.5.5
customXmlInsRangeEnd (Custom XML Markup Insertion End)	§2.13.5.6
customXmlInsRangeStart (Custom XML Markup Insertion Start)	§2.13.5.7
customXmlMoveFromRangeEnd (Custom XML Markup Move Source End)	§2.13.5.8
customXmlMoveFromRangeStart (Custom XML Markup Move Source Start)	§2.13.5.9
customXmlMoveToRangeEnd (Custom XML Markup Move Destination Location End)	§2.13.5.10
customXmlMoveToRangeStart (Custom XML Markup Move Destination Location Start)	§2.13.5.11

moveFromRangeStart (Move Source Location Container - Start)	§2.13.5.24
moveTo (Move Destination Run Content)	§2.13.5.26
moveToRangeEnd (Move Destination Location Container - End)	§2.13.5.27
moveToRangeStart (Move Destination Location Container - Start)	§2.13.5.28
oMath (Office Math)	§7.1.2.77
oMathPara (Math Paragraph)	§7.1.2.78
p (Paragraph)	§2.3.1.22
permEnd (Range Permission End)	§2.13.7.1
permStart (Range Permission Start)	§2.13.7.2
proofErr (Proofing Error Anchor)	§2.13.8.1
sdt (Block-Level Structured Document Tag)	§2.5.2.30
tbl (Table)	§2.4.36

Attributes	Description
element (Custom XML Element	Specifies the name of the current custom XML element or smart tag within the document.

Attributes	Description

Name)	[*Example*: Consider a custom XML element which shall have a name of `companyName`. This requirement would be specified using the following WordprocessingML:
	
	`<w:customXml w:element="companyName" … >`
	`…`
	`</w:customXml>`
	
	The element attribute specifies that the name for this element shall be `companyName`. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

uri (Custom XML Element Namespace)	Specifies the namespace URI of the current custom XML element or smart tag.
	
	If this attribute is omitted, the URI shall be assumed to be null (no associated URI).
	
	[*Example*: Consider a custom XML element which shall have a namespace URI of `urn:customXmlExample`. This requirement would be specified using the following WordprocessingML:
	
	`<w:customXml … w:uri="urn:customXmlExample" />`
	`…`
	`</w:customXml>`
	
	The uri attribute specifies that the namespace for this element shall be `urn:customXmlExample`. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_CustomXmlBlock">
   <sequence>
      <element name="customXmlPr" type="CT_CustomXmlPr" minOccurs="0" maxOccurs="1"/>
      <group ref="EG_ContentBlockContent" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
   <attribute name="uri" type="ST_String"/>
   <attribute name="element" type="ST_String" use="required"/>
</complexType>
```

2.5.1.7 customXmlPr (Custom XML Element Properties)

This element specifies the set of properties which shall be applied to the parent custom XML element.

[*Example*: Consider a custom XML element with the following properties specified:

```
<w:customXmlPr>
  <w:placeholder w:val="[Fill in your name]"/>
  <w:attr w:name="status" w:val="draft"/>
</w:customXmlPr>
```

This custom XML element specifies two properties: the presence of placeholder text via the placeholder element (§2.5.1.8) and a single custom XML attribute via the attr element (§2.5.1.1). *end example*]

Parent Elements
customXml (§2.5.1.3); customXml (§2.5.1.6); customXml (§2.5.1.5); customXml (§2.5.1.4)

Child Elements	Subclause
attr (Custom XML Attribute)	§2.5.1.1
placeholder (Custom XML Element Placeholder Text)	§2.5.1.8

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_CustomXmlPr">
   <sequence>
      <element name="placeholder" type="CT_String" minOccurs="0"/>
      <element name="attr" type="CT_Attr" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
</complexType>
```

2.5.1.8 placeholder (Custom XML Element Placeholder Text)

This element specifies the placeholder text which shall be displayed in place of this custom XML element when the contents of this custom XML markup are empty (i.e. there are no runs of text within the current custom XML element). If this custom XML element does contain run content, then this text shall not be displayed.

The val attribute stores the string of text which shall be displayed as the placeholder text. This string may be displayed in any font face/size desired by the hosting application.

[*Example*: Consider a custom XML element with the following properties specified:

```
<w:customXmlPr>
  <w:placeholder w:val="[Fill in your name]"/>
  <w:attr w:name="status" w:val="draft"/>
</w:customXmlPr>
```

The placeholder element specifies that this custom XML element shall display the text contents `[Fill in your name]` whenever there is no run content within the parent custom XML element. For example, if the custom XML element was specified as follows:

```
<w:customXml>
  <w:customXmlPr>
    <w:placeholder w:val="[Fill in your name]"/>
  </w:customXmlPr>
  <w:p/>
</w:customXml>
```

This custom XML element has no run content and the placeholder text would be displayed. However, if there is run content, as follows:

```
<w:customXml>
  <w:customXmlPr>
    <w:placeholder w:val="[Fill in your name]"/>
  </w:customXmlPr>
  <w:p>
    <w:r>
      <w:t>Name</w:t>
    </w:r>
  </w:p>
</w:customXml>
```

This custom XML element now contains run content, and the placeholder text shall not be displayed. *end example*]

Parent Elements
customXmlPr (§2.5.1.7)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`

Attributes	Description
	<w:alias w:val="SDT Title Example" /> ... </w:sdtPr> In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.5.1.9 smartTag (Inline-Level Smart Tag)

This element specifies the presence of a smart tag around one or more inline structures (runs, images, fields, etc.) within a paragraph. The attributes on this element shall be used to specify the name and namespace URI of the current smart tag.

[*Example*: Consider a smart tag with the name `firstName` that shall be located around a two text runs in a WordprocessingML document. This requirement would be specified as follows in the WordprocessingML:

```
<w:p>
  <w:smartTag w:element="firstName" … >
    <w:r>
      …
    </w:r>
    <w:r>
      …
    </w:r>
  </w:smartTag>
  …
</w:p>
```

The smartTag element specifies that the name of the smart tag is `firstName`, and the smart tag contains a two text runs (it is an inline-level smart tag). *end example*]

Parent Elements
customXml (§2.5.1.5); del (§2.13.5.12); fldSimple (§2.16.21); hyperlink (§2.16.24); ins (§2.13.5.20); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); p (§2.3.1.22); sdtContent (§2.5.2.35); smartTag (§2.5.1.9)

Child Elements	Subclause

Child Elements	Subclause

customXmlMoveToRangeEnd (Custom XML Markup Move Destination Location End)	§2.13.5.10
customXmlMoveToRangeStart (Custom XML Markup Move Destination Location Start)	§2.13.5.11
del (Deleted Run Content)	§2.13.5.12
fldSimple (Simple Field)	§2.16.21
hyperlink (Hyperlink)	§2.16.24
ins (Inserted Run Content)	§2.13.5.20
moveFrom (Move Source Run Content)	§2.13.5.21
moveFromRangeEnd (Move Source Location Container - End)	§2.13.5.23
moveFromRangeStart (Move Source Location Container - Start)	§2.13.5.24
moveTo (Move Destination Run Content)	§2.13.5.26
moveToRangeEnd (Move Destination Location Container - End)	§2.13.5.27
moveToRangeStart (Move Destination Location Container - Start)	§2.13.5.28
oMath (Office Math)	§7.1.2.77
oMathPara (Math Paragraph)	§7.1.2.78
permEnd (Range Permission End)	§2.13.7.1
permStart (Range Permission Start)	§2.13.7.2
proofErr (Proofing Error Anchor)	§2.13.8.1
r (Text Run)	§2.3.2.23
sdt (Inline-Level Structured Document Tag)	§2.5.2.29
smartTag (Inline-Level Smart Tag)	§2.5.1.9
smartTagPr (Smart Tag Properties)	§2.5.1.10
subDoc (Anchor for Subdocument Location)	§2.17.2.1

Attributes	Description

element (Smart Tag Name)	Specifies the name of the current custom XML element or smart tag within the document.
	
	[*Example*: Consider a custom XML element which shall have a name of `companyName`. This requirement would be specified using the following WordprocessingML:
	
	`<w:customXml w:element="companyName" … >`
	`…`
	`</w:customXml>`
	
	The element attribute specifies that the name for this element shall be `companyName`. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

uri (Smart Tag Namespace)	Specifies the namespace URI of the current custom XML element or smart tag.
	
	If this attribute is omitted, the URI shall be assumed to be null (no associated URI).
	
	[*Example*: Consider a custom XML element which shall have a namespace URI of `urn:customXmlExample`. This requirement would be specified using the following WordprocessingML:
	
	`<w:customXml … w:uri="urn:customXmlExample" />`
	`…`
	`</w:customXml>`
	
	The uri attribute specifies that the namespace for this element shall be `urn:customXmlExample`. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SmartTagRun">
   <sequence>
      <element name="smartTagPr" type="CT_SmartTagPr" minOccurs="0" maxOccurs="1"/>
      <group ref="EG_PContent" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
   <attribute name="uri" type="ST_String"/>
   <attribute name="element" type="ST_String" use="required"/>
</complexType>
```

2.5.1.10 smartTagPr (Smart Tag Properties)

This element specifies the set of properties which shall be applied to the parent smart tag.

[*Example*: Consider a smart tag with the following properties specified:

```
<w:smartTagPr>
  <w:attr w:name="date" w:val="01/01/2006"/>
  <w:attr w:name="status" w:val="draft"/>
</w:smartTagPr>
```

This smart tag specifies two properties: the presence of two smart tag properties via the attr element (§2.5.1.2). *end example*]

Parent Elements
smartTag (§2.5.1.9)

Child Elements	Subclause
attr (Smart Tag Property)	§2.5.1.2

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SmartTagPr">
   <sequence>
      <element name="attr" type="CT_Attr" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
</complexType>
```

2.5.2 Structured Document Tags

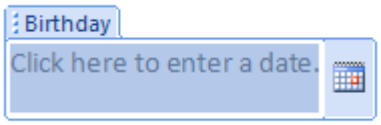
The final type of customer-defined semantics which can be embedded in a WordprocessingML document are structured document tags (SDTs).

As shown above, smart tags and custom XML markup each provide a facility for embedding customer-defined semantics into the document: smart tags, via the ability to provide a basic namespace/name for a run or set of runs within a documents; and custom XML markup, via the ability to tag the document with XML elements and attributes specified by any valid XML Schema file.

However, each of these techniques, while they each provide a way to add the desired semantic information, does not provide a way to affect the presentation or interaction within the document. To bridge these two worlds, structured document tags allow both the specification of customer semantics as well as the ability to influence the presentation of that data in the document.

This means that the customer can define the semantics and context of the tag, but can then use a rich set of pre-defined properties to define its behavior and appearance within the WordprocessingML document's presentation.

[*Example*: Consider a region which should be tagged with the semantic of "birthday", for the user to enter their date or birth into the document. Ideally, this region would also utilize a date picker to allow the user to enter the date from a calendar:



This content would be specified using the following WordprocessingML:

```
<w:sdt>
  <w:sdtPr>
    <w:alias w:val="Birthday"/>
    <w:id w:val="8775518"/>
    <w:placeholder>
      <w:docPart w:val="DefaultPlaceholder_22479095"/>
    </w:placeholder>
    <w:showingPlcHdr/>
    <w:date>
      <w:dateFormat w:val="M/d/yyyy"/>
      <w:lid w:val="EN-US"/>
    </w:date>
  </w:sdtPr>
  <w:sdtContent>
    <w:p>
      <w:r>
        <w:rPr>
          <w:rStyle w:val="PlaceholderText"/>
        </w:rPr>
        <w:t>Click here to enter a date...</w:t>
      </w:r>
    </w:p>
  </w:sdtContent>
</w:sdt>
```

end example]

As shown above, each of the structured document tags in the WordprocessingML file is represented using the sdt element.

Within a structured document tag, there are two child elements which contain the definition and the content of this SDT. The first of these is the sdtPr element, which contains the set of properties specified for this structured document tag. The second is the sdtContent element, which contains all the content which is contained within this structured document tag.

2.5.2.1 alias (Friendly Name)

This element specifies the friendly name associated with the current structured document tag. The string representing the friendly name shall be stored on this element's val attribute.

If this element is omitted, then no friendly name shall be associated with the given structured document tag.

[*Example*: Consider the following properties on a structured document tag:

```
<w:sdtPr>
  <w:alias w:val="Birthday"/>
  …
</w:sdtPr>
```

This set of properties specifies via the alias element that the friendly name for the parent structured document tag shall be `Birthday`. *end example*]

Parent Elements
sdtPr (§2.5.2.37)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.5.2.2 bibliography (Bibliography Structured Document Tag)

This element specifies that the parent structured document tag shall be of type `bibliography`.

This type setting does not require or imply that the contents of the structured document tag shall contain only a field of type `BIBLIOGRAPHY`, it shall only be used to specify that the structured document tag is of this type, which may be used by an application as desired.

[*Example*: Consider the following structured document tag:

```
<w:sdt>
  <w:sdtPr>
    …
    <w:bibliography/>
  </w:sdtPr>
  …
</w:sdt>
```

The bibliography element in this structured document tag's properties specify that the type of structured document tag is `bibliography`. *end example*]

Parent Elements
sdtPr (§2.5.2.37)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.5.2.3 calendar (Date Picker Calendar Type)

This element specifies the type of calendar which shall be displayed for the current date picker structured document tag, if a user interface is present for the structured document tag. The calendar type is stored on this element's val attribute.

If this element is omitted, then the calendar type shall be `gregorian`.

[*Example*: Consider the following structured document tag properties:

```
<w:sdtPr>
  <w:date w:fullDate="01-01-2006T06:30:00Z">
    <w:calendar w:val="gregorian"/>
  </w:date>
</w:sdtPr>
```

The calendar element specifies that the calendar type for a calendar which may be displayed in the document shall be the Gregorian calendar format (`gregorian`). *end example*]

Parent Elements

Parent Elements
date (§2.5.2.7)

Attributes	Description

val (Calendar Type Value)	Specifies a type of calendar, the use of which is determined by the parent XML element.
	
	If this attribute is omitted, then the calendar type shall be `gregorian`.
	
	[*Example*: Consider the following WordprocessingML for a document containing a structured document tag:
	
	`<w:sdtPr>`
	`  <w:date … >`
	`  <w:calendar w:val="japan"/>`
	`  </w:date>`
	`</w:sdtPr>`
	
	The val attribute value of `japan` specifies that the Japanese Emperor Era calendar shall be used; in this case, it is used for the calendar displayed for a date structured document tag. *end example*]
	
	The possible values for this attribute are defined by the ST_CalendarType simple type (§2.18.7).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_CalendarType">
   <attribute name="val" type="ST_CalendarType"/>
</complexType>
```

2.5.2.4 citation (Citation Structured Document Tag)

This element specifies that the parent structured document tag shall be of type `citation`.

This type setting does not require or imply that the contents of the structured document tag shall contain only a field of type `CITATION`, it shall only be used to specify that the structured document tag is of this type, which may be used by an application as desired.

[*Example*: Consider the following structured document tag:

```
<w:sdt>
  <w:sdtPr>
    …
    <w:citation/>
  </w:sdtPr>
  …
</w:sdt>
```

The citation element in this structured document tag's properties specify that the type of structured document tag is `citation`. *end example*]

Parent Elements
sdtPr (§2.5.2.37)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.5.2.5 comboBox (Combo Box Structured Document Tag)

This element specifies that the parent structured document tag shall be a combo box when displayed in the document.

This setting specifies that the behavior for this structured document tag shall be as follows:

- The child elements of this element specify choices which shall be displayed in a standard drop-down list format
- Formatting applied to any part of this structured document tag's contents shall apply to its entire contents

As well, the structured document tag must satisfy the following restraints or the document shall be considered invalid:

- The contents shall only be contain a single run (one set of formatting properties)
- The contents shall not contain more than a single paragraph or table cell and shall not contain a table row or table

[*Example*: Consider the following structured document tag:

```
<w:sdt>
  <w:sdtPr>
    …
    <w:comboBox>
      …
    </w:comboBox>
  </w:sdtPr>
  …
</w:sdt>
```

The comboBox element in this structured document tag's properties specify that the type of structured document tag is a combo box. *end example*]

Parent Elements
sdtPr (§2.5.2.37)

Child Elements	Subclause
listItem (Combo Box List Item)	§2.5.2.20

Attributes	Description

lastValue (Combo Box Last Saved Value)	Specifies the value associated with the current display text for the combo box structured document tag.
	
	If this structured document tag is not mapped to XML using the dataBinding element (§2.5.2.6), then this attribute shall be ignored. If this structured document tag is mapped to XML, it shall be used to determine whether the current display text in the combo box structured document tag shall be retained when the document is opened, as follows:
	• When the XML mapping is created, the content in the custom XML data is retrieved
	• If this content has an associated list item (matching its value attribute), then the corresponding display text shall be displayed in the structured document tag
	• If no list item exists, this content shall be matched against the lastValue attribute value. If the values match, the current display text shall be retained. If the values do not match, the current custom XML data content shall be the new display text (since no match exists in the combo box list items)
	
	[*Example*: Consider a combo box structured document tag defined as follows:
	
	`<w:sdt>`
	`  <w:sdtPr>`
	`  <w:dataBinding … />`
	`  <w:comboBox w:lastValue="2"/>`
	`  </w:sdtPr>`
	`  <w:sdtContent>`
	`  <w:r>`
	`  <w:t>Hello world</w:t>`
	`  </w:r>`
	`  </w:sdtContent>`
	`</w:sdt>`
	
	The current run content of the structured document tag reads `Hello world`. When this document is opened, if the current value of the associated custom XML data is 2, the matching lastValue attribute specifies that the contents of the combo box shall continue to be the current display text of the combo boxeven though there is no listItem whose value is 2 (and normally, the content of the structured document tag would be set to 2. Essentially, this attribute specifies a listItem whose value is 2 and whose displayText is `Hello world` (the current structured document tag contents). *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SdtComboBox">
   <sequence>
      <element name="listItem" type="CT_SdtListItem" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
   <attribute name="lastValue" type="ST_String" use="optional"/>
</complexType>
```

2.5.2.6 dataBinding (XML Mapping)

This element specifies the information which shall be used to establish a mapping between the parent structured document tag and an XML element stored within a Custom XML Data part in the current WordprocessingML document.

If this element is omitted, then no XML mapping shall be associated with the current structured document tag. If the parent structured document tag is of type rich text or document part gallery, then this property shall be ignored.

If this element is present and the parent structured document tag is not of a rich text type, then the current value of the structured document tag shall be determined by finding the XML element (if any) which is determined by the attributes on this element. If this information does not result in a valid XML element, then the application may use any algorithm desired to find the closest available match. If this information does result in a valid XML element, then the contents of that element shall be used to replace the current run content within the document.

[*Example*: Consider the following structured document tag:

```
<w:sdt>
  <w:sdtPr>
    <w:dataBinding w:xpath="/root/name/first" … />
    <w:text/>
  </w:sdtPr>
  <w:sdtContent>
    <w:r>
      <w:t>old text</w:t>
    </w:r>
  </w:sdtContent>
</w:sdt>
```

This structured document tag specifies that it contains only plain text via the text element, and that it shall be mapped to the element in the first Custom XML Data part which contains an element that matches the XPath expression `/root/name/first`. When that element is located, its contents shall replace the existing run content in the document (for example, if its contents are `new text`, then the contents of the run for this structured document tag shall be `new text` when the document is displayed. *end example*]

Parent Elements

Parent Elements
sdtPr (§2.5.2.37)

Attributes	Description

prefixMappings (XML Namespace Prefix Mappings)	Specifies the set of prefix mappings which shall be used to interpret the XPath expression specified on the xpath attribute when the XPath expression is evaluated against the custom XML data parts in the current document.
	
	This attribute's value shall be specified using the following syntax: `xmlns:prefix='namespace'`, where `prefix` is the namespace prefix to be mapped, and `namespace` is the namespace to be mapped to the current prefix. Each prefix mapping shall be delimited by one or more whitespace characters in the attribute's contents.
	
	If this attribute is omitted, then the prefix mappings specified on each of the custom XML data parts itself shall be used to evaluate the given XPath expression.
	
	[*Example*: Consider the following structured document tag properties:
	
	`<w:sdtPr>`
	`  <w:dataBinding w:xpath="//ns0:book"`
	`w:prefixMapping="xmlns:ns0=`
	`'http://example.com/example'"/>`
	`  <w:text/>`
	`</w:sdtPr>`
	
	This structured document tag specifies that it contains an XML mapping, and that mapping's prefixMapping attribute shall signify that the set of namespace prefix mappings to be used to evaluate the xpath attribute value shall be `xmlns:ns0='http://example.com/example'`. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

storeItemID (Custom XML Data Storage ID)	Specifies the custom XML data identifier for the custom XML data part which shall be used to evaluate the given XPath expression. The *custom XML data identifier*, specified using the storeItemID attribute of the dataStoreItem element (§7.5.2.1) on the Custom XML Data Properties part is a string that uniquely identifies a particular custom XML data part in a WordprocessingML document (as multiple parts may have the same namespace for their root element). If specified, then the XPath expression specified on the xpath attribute shall only be evaluated against the custom XML data part whose properties part has a matching custom XML data identifier. If no custom XML data part exists with a matching identifier, then the XML mapping shall not be connected. If omitted, then the XPath expression shall be evaluated against each custom XML data

Attributes	Description

	part in turn until the given XPath expression is resolved to an XML element.
	
	[*Example*: Consider the following structured document tag properties:
	
	`<w:sdtPr>`
	`  <w:dataBinding w:xpath="//ns0:book"`
	`w:storeItemID="testXmlPart"`
	`/>`
	`  <w:text/>`
	`</w:sdtPr>`
	
	This structured document tag specifies that it contains an XML mapping, and that mapping shall only be evaluated against the custom XML part whose identifier is equal to `testXmlPart` (if one exists). *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

xpath (XPath)	Specifies the XPath expression which shall be evaluated to find the custom XML node which is mapped to the parent structured document tag. This XPath expression shall be specified using the syntax defined in the XML Path Language (XPath) Version 1.0 specification (see Annex A for bibliographic reference information).
	
	[*Example*: Consider the following structured document tag properties:
	
	`<w:sdtPr>`
	`  <w:dataBinding w:xpath="//ns0:book"`
	`w:prefixMapping="xmlns:ns0=`
	`'http://example.com/example'"/>`
	`  <w:text/>`
	`</w:sdtPr>`
	
	This structured document tag specifies that it contains an XML mapping, and that mapping's xpath attribute shall signify that the XPath expression to be evaluated shall be `//ns0:book`. Because the prefixMapping attribute is also specified, those prefix mappings shall be used to evaluate this XPath expression. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DataBinding">
   <attribute name="prefixMappings" type="ST_String"/>
   <attribute name="xpath" type="ST_String" use="required"/>
   <attribute name="storeItemID" type="ST_String" use="required"/>
</complexType>
```

2.5.2.7 date (Date Structured Document Tag)

This element specifies that the parent structured document tag shall be a date picker when displayed in the document.

This setting specifies that the behavior for this structured document tag shall be as follows:

- The child elements of this element specify how the dates in this structured document tag shall be stored in any mapped custom XML data and displayed in the document
- Formatting applied to any part of this structured document tag's contents shall apply to its entire contents

As well, the structured document tag must satisfy the following restraints or the document shall be considered invalid:

- The contents shall only be contain a single run (one set of formatting properties)
- The contents shall not contain more than a single paragraph or table cell and shall not contain a table row or table cell

[*Example*: Consider the following structured document tag:

```
<w:sdt>
  <w:sdtPr>
    …
    <w:date>
      …
    </w:date>
  </w:sdtPr>
  …
</w:sdt>
```

The date element in this structured document tag's properties specifies that the type of structured document tag is a date picker. *end example*]

Parent Elements
sdtPr (§2.5.2.37)

Child Elements	Subclause
calendar (Date Picker Calendar Type)	§2.5.2.3
dateFormat (Date Display Mask)	§2.5.2.8
lid (Date Picker Language ID)	§2.5.2.19
storeMappedDataAs (Custom XML Data Date Storage Format)	§2.5.2.39

Attributes	Description

fullDate (Last Known Date in XML Schema DateTime Format)	Specifies the full date and time last entered into the parent structured document tag using the standard XML Schema DateTime syntax.
	
	[*Note*: This cache is used because the date display mask stored on the dateFormat element (§2.5.2.8) may not contain all of the information about the date, which may be needed if the date display mask is later changed. *end note*]
	
	If this attribute is specified, then the current fullDate attribute shall be used to populate the run content of the parent structured document tag by filtering it through the date display mask specified in the dateFormat element, if one is present.
	
	If this attribute is omitted, then the current display text shall be maintained when the document is displayed.
	
	[*Example*: Consider the following structured document tag properties:
	
	`<w:sdtPr>`
	`…`
	`<w:date w:fullDate="01-01-2006T05:30:00Z">`
	`…`
	`</w:date>`
	`</w:sdtPr>`
	
	The full XML Schema DateTime format for the current structured document tag is specified via the fullDate attribute value as `01-01-2006T05:30:00Z`. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SdtDate">
   <sequence>
      <element name="dateFormat" type="CT_String" minOccurs="0"/>
      <element name="lid" type="CT_Lang" minOccurs="0"/>
      <element name="storeMappedDataAs" type="CT_SdtDateMappingType" minOccurs="0"/>
      <element name="calendar" type="CT_CalendarType" minOccurs="0"/>
   </sequence>
   <attribute name="fullDate" type="ST_DateTime" use="optional"/>
</complexType>
```

2.5.2.8 dateFormat (Date Display Mask)

The element specifies the display format which shall be used to format any date entered into the parent structured document tag in full DateTime format [*Example*: Through a user interface (a date picker), or through custom XML data associated with this structured document tag via the dataBinding element (§2.5.2.6). *end example*] before displaying it in the structured document tag's run content.

If this element is omitted, then the date shall be formatted using the standard date display mask for the language ID specified on the lid element (§2.5.2.19) if present, or the language ID of the run contents otherwise.

The date display mask specified in the val attribute shall be interpreted using the semantics specified in §2.16.4.1 of this Office Open XML Standard.

[*Example*: Consider the following structured document tag properties:

```
<w:sdtPr>
  <w:date w:fullDate="01-01-2006T06:30:00Z">
    <w:dateFormat w:val="MM-YYYY"/>
  </w:date>
</w:sdtPr>
```

The full XML Schema DateTime format for the current structured document tag is specified via the fullDate attribute value as `01-01-2006T06:30:00Z`, and the date display mask is `MM-YYYY`, therefore the resulting date displayed in the document shall be `01-2006` (the month and long year from the full date value, respectively). *end example*]

Parent Elements
date (§2.5.2.7)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the

Attributes	Description
	parent element. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.5.2.9 docPart (Document Part Reference)

This element specifies the name of the document part which shall be displayed in the parent structured document tag when its run contents are empty. If this element is specified, then a document part whose name element (§2.12.12) specifies a name matching the value of this element, and which belongs to the bbPlcHdr type shall be located to be used as the placeholder text for the parent structured document tag.

If no document part is located matching the criteria specified by this element, then five non-breaking spaces shall be used as the default placeholder text.

[*Example*: Consider a structured document tag defined as follows:

```
<w:sdt>
  <w:sdtPr>
    <w:placeholder>
      <w:docPart w:val="DefaultPlaceholder_22610170" />
    </w:placeholder>
    …
  </w:sdtPr>
  <w:sdtContent>
  …
  </w:sdtContent>
</w:sdt>
```

This structured document tag specifies through the docPart element that its placeholder text shall be specified in the document part of type bbPlcHdr whose name is equal to DefaultPlaceholder_22610170. *end example*]

Parent Elements
placeholder (§2.5.2.24)

Attributes	Description
val (String Value)	Specifies that its contents will contain a string. The contents of this string are interpreted based on the context of the parent XML

Attributes	Description

	element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.5.2.10 docPartCategory (Document Part Category Filter)

This element specifies the category of document parts which shall be used as the filter when determining the possible choices of document parts which are displayed for insertion into the parent structured document tag. A document part *category* is a sub-classification within a given document part gallery which may be used to further categorize the parts in a given gallery. [*Example*: Gallery `custom1` may have categories of `Legal Clauses`, `Conformance Clauses`, etc. *end example*]. The category which shall be used as a filter is stored in this element's val attribute.

If this element is omitted, then the parent structured document tag shall display all document parts in the specified gallery regardless their specified category. If this element is present, but no document parts of the specified gallery and category combination are located by the application, then no document parts shall be displayed (i.e. the application shall not fall back to showing document parts in all categories in the specified gallery).

[*Example*: Consider the following properties for a structured document tag:

```
<w:sdtPr>
  <w:docPartList>
    <w:docPartGallery w:val="custom1"/>
    <w:docPartCategory w:val="Legal Clauses"/>
  </w:docPartList>
</w:sdtPr>
```

This structured document tag specifies that it shall present a selection of document parts for insertion via the docPartList element (§2.5.2.12) , and those document parts shall only be the parts which are in the `custom1` gallery via the docPartType element (§2.5.2.11), and within that gallery, only the document parts which are in a category called `Legal Clauses` via this element. *end example*]

Parent Elements
docPartList (§2.5.2.12); docPartObj (§2.5.2.13)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.5.2.11 docPartGallery (Document Part Gallery Filter)

This element specifies the gallery of document parts which shall be used as the filter when determining the possible choices of document parts which are displayed for insertion into the parent structured document tag. A document part *gallery* is a classification of document parts, which may then be subdivided into categories. [*Example*: A gallery with a name of `custom1` may have categories of `Legal Clauses`, `Conformance Clauses`, etc. *end example*]. The gallery which shall be used is stored in this element's val attribute.

If this element is omitted, then the parent structured document tag shall display all document parts in its default gallery. If this element is present, but no document parts of the specified gallery are located by the application, then document parts in the default gallery hall be displayed (i.e. the application shall behave as if the value was omitted).

[*Example*: Consider the following properties for a structured document tag:

```
<w:sdtPr>
  <w:docPartList>
    <w:docPartGallery w:val="custom1"/>
  </w:docPartList>
</w:sdtPr>
```

This structured document tag specifies that it shall present a selection of document parts for insertion via the docPartList element (§2.5.2.12), and those document parts shall only be the parts which are in the `custom1` gallery via this element. *end example*]

Parent Elements
docPartList (§2.5.2.12); docPartObj (§2.5.2.13)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`

Attributes	Description

	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.5.2.12 docPartList (Document Part Gallery Structured Document Tag)

This element specifies that the parent structured document tag shall be of a document part gallery type.

This type setting does not require or imply that the contents of the structured document tag shall contain only the exact contents of a document part of the specified gallery and category which is present on the current machine, it shall only be used to specify that the structured document tag is of this type, which shall be used by an application to present the possible list of choices for insertion into the parent structured document tag.

[*Example*: Consider the following structured document tag:

```
<w:sdt>
  <w:sdtPr>
    …
    <w:docPartList>
      …
    </w:docPartList>
  </w:sdtPr>
  …
</w:sdt>
```

The docPartList element in this structured document tag's properties specifies that the type of structured document tag is a document part gallery. The child elements shall specify the gallery and category filters for this list, if any. *end example*]

Parent Elements

Parent Elements
sdtPr (§2.5.2.37)

Child Elements	Subclause
docPartCategory (Document Part Category Filter)	§2.5.2.10
docPartGallery (Document Part Gallery Filter)	§2.5.2.11
docPartUnique (Built-In Document Part)	§2.5.2.14

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SdtDocPart">
   <sequence>
      <element name="docPartGallery" type="CT_String" minOccurs="0"/>
      <element name="docPartCategory" type="CT_String" minOccurs="0"/>
      <element name="docPartUnique" type="CT_OnOff" minOccurs="0"/>
   </sequence>
</complexType>
```

2.5.2.13 docPartObj (Built-In Document Part Structured Document Tag)

This element specifies that the parent structured document tag shall be of a document part type.

This type setting does not require or imply that the contents of the structured document tag shall contain only the exact contents of a document part of the specified gallery and category which is present on the current machine, it shall only be used to specify that the structured document tag is of this type, which shall be used by an application to present the possible list of choices for insertion into the parent structured document tag.

This element differs from the docPartList element (§2.5.2.12) in that it may be used to semantically tag a set of block-level objects in a WordprocessingML document without requiring the ability to specify a category and gallery of objects which may be swapped with it via the user interface.

[*Example*: Consider the following structured document tag:

```
<w:sdt>
  <w:sdtPr>
    …
    <w:docPartObj>
      …
    </w:docPartObj>
  </w:sdtPr>
  …
</w:sdt>
```

The docPartObj element in this structured document tag's properties specify that the type of structured document tag is a document part. The child elements shall specify the gallery and category semantics for this part, if any. *end example*]

Parent Elements
sdtPr (§2.5.2.37)

Child Elements	Subclause
docPartCategory (Document Part Category Filter)	§2.5.2.10
docPartGallery (Document Part Gallery Filter)	§2.5.2.11
docPartUnique (Built-In Document Part)	§2.5.2.14

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SdtDocPart">
   <sequence>
      <element name="docPartGallery" type="CT_String" minOccurs="0"/>
      <element name="docPartCategory" type="CT_String" minOccurs="0"/>
      <element name="docPartUnique" type="CT_OnOff" minOccurs="0"/>
   </sequence>
</complexType>
```

2.5.2.14 docPartUnique (Built-In Document Part)

This element specifies that this structured document tag is being used to encapsulate a built-in document part (i.e. this element appears as a child element of the docPartObj element).

[*Example*: Consider the following structured document tag:

```
<w:sdt>
  <w:sdtPr>
    …
    <w:docPartObj>
      …
      <w:docPartUnique/>
    </w:docPartObj>
  </w:sdtPr>
  …
</w:sdt>
```

The docPartUnique element in this structured document tag's properties specify that the type of structured document tag is a container for a document part. *end example*]

Parent Elements
docPartList (§2.5.2.12); docPartObj (§2.5.2.13)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element.

Attributes	Description
	A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.5.2.15 dropDownList (Drop-Down List Structured Document Tag)

This element specifies that the parent structured document tag shall be a drop-down list when displayed in the document.

This setting specifies that the behavior for this structured document tag shall be as follows:

- The contents shall not be editable when displayed by a hosting application regardless of the locking settings
- The child elements of this element specify choices which shall be displayed in a standard drop-down list format

As well, the structured document tag must satisfy the following restraints or the document shall be considered invalid:

- The contents shall only be contain a single run (one set of formatting properties)
- The contents shall not contain more than a single paragraph or table cell and shall not contain a table row or table

[*Example*: Consider the following structured document tag:

```
<w:sdt>
  <w:sdtPr>
    …
    <w:dropDownList>
      …
    </w:dropDownList>
  </w:sdtPr>
  …
</w:sdt>
```

The dropDownList element in this structured document tag's properties specify that the type of structured document tag is a drop-down list. *end example*]

Parent Elements
sdtPr (§2.5.2.37)

Child Elements	Subclause
listItem (Drop-Down List Item)	§2.5.2.21

Attributes	Description

lastValue (Drop-down List Last Saved Value)	Specifies the value associated with the current display text for the drop-down list structured document tag.
	
	If this structured document tag is not mapped to XML using the dataBinding element (§2.5.2.6), then this attribute shall be ignored. If this structured document tag is mapped to XML, it shall be used to determine whether the current display text in the combo box structured document tag shall be retained when the document is opened, as follows:
	• When the XML mapping is created, the content in the custom XML data is retrieved
	• If this content has an associated list item (matching its value attribute), then the corresponding display text shall be displayed in the structured document tag
	• If no list item exists, this content shall be matched against the lastValue attribute value. If the values match, the current display text shall be retained. If the values do not match, the current custom XML data content shall be the new display text (since no match exists in the combo box list items)
	
	[*Example*: Consider a drop-down list structured document tag defined as follows:
	
	`<w:sdt>`
	`  <w:sdtPr>`
	`  <w:dataBinding … />`
	`  <w:dropDownList w:lastValue="2"/>`
	`  </w:sdtPr>`

Attributes	Description
	<w:sdtContent> <w:r> <w:t>Hello world</w:t> </w:r> </w:sdtContent> </w:sdt> The current run content of the structured document tag reads Hello world. When this document is opened, if the current value of the associated custom XML data is 2, the matching lastValue attribute specifies that the contents of the combo box shall continue to be the current display text of the combo boxeven though there is no listItem whose value is 2 (and normally, the content of the structured document tag would be set to 2. Essentially, this attribute specifies a listItem whose value is 2 and whose displayText is Hello world (the current structured document tag contents). *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SdtDropDownList">
   <sequence>
      <element name="listItem" type="CT_SdtListItem" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
   <attribute name="lastValue" type="ST_String" use="optional"/>
</complexType>
```

2.5.2.16 equation (Equation Structured Document Tag)

This element specifies that the parent structured document tag shall be of type equation.

This type setting does not require or imply that the contents of the structured document tag shall contain only an equation or associated placeholder text, it shall only be used to specify that the structured document tag is of this type, which may be used by an application as desired.

[*Example*: Consider the following structured document tag:

```
<w:sdt>
  <w:sdtPr>
    …
    <w:equation/>
  </w:sdtPr>
  …
</w:sdt>
```

The equation element in this structured document tag's properties specify that the type of structured document tag is equation. *end example*]

Parent Elements
sdtPr (§2.5.2.37)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.5.2.17 group (Group Structured Document Tag)

This element specifies that the parent structured document tag shall be a restricted grouping when displayed in the document.

This setting specifies that the behavior for this structured document tag shall be as follows:

- The contents of this structured document tag shall not be editable when displayed by a hosting application regardless of the locking settings. This restriction may be superseded by any structured document tag contained within the group, as each structured document tag specifies the locking properties for its own content.

[*Example*: Consider the following structured document tag:

```
<w:sdt>
  <w:sdtPr>
    …
    <w:group/>
  </w:sdtPr>
  …
</w:sdt>
```

The group element in this structured document tag's properties specify that the type of structured document tag is a restricted group. *end example*]

Parent Elements
sdtPr (§2.5.2.37)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.5.2.18 id (Unique ID)

This element specifies a unique numerical ID for the parent structured document tag. This ID shall be persisted through multiple sessions (i.e. shall not be changed once specified).

If multiple structured document tags specify the same decimal number value for the id attribute, then the first structured document tag in the document shall maintain this original ID, and all subsequent structured document tags shall have new identifiers assigned to them when the document is opened.

If this element is omitted, then the parent structured document tag shall have a new unique identifier assigned to it when the document is opened.

[*Example*: Consider the following structured document tag properties:

```
<w:sdtPr>
  <w:id w:val="8775518"/>
  …
</w:sdtPr>
```

This set of properties specifies via the val attribute on the id element that the ID for the parent structured document shall be 8775518 (subject, of course, to the conflict management and resolution discussed above). *end example*]

Parent Elements
sdtPr (§2.5.2.37)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.5.2.19 lid (Date Picker Language ID)

This element specifies the language ID which shall be used for displaying a calendar for the current date picker structured document tag, if a user interface is present for the structured document tag.

If this element is omitted, then the language ID shall be the language ID of the run contents of the parent structured document tag.

[*Example*: Consider the following structured document tag properties:

```
<w:sdtPr>
  <w:date w:fullDate="01-01-2006T06:30:00Z">
    <w:lid w:val="ja-JP"/>
  </w:date>
</w:sdtPr>
```

The calendar language ID for a calendar which may be displayed in the document shall be the default calendar format for the Japanese (Japan) language format (`ja-JP`). *end example*]

Parent Elements
date (§2.5.2.7)

Attributes	Description
val (Language Code)	Specifies an ISO 639-1 letter code or 4 digit hexadecimal code for a specific language. This code is interpreted in the context of the parent XML element. [*Example*: Consider an object which shall specify the English(Canada) language. That object would use the ISO 639-1 letter code of `en-CA` to specify this language. *end example*] The possible values for this attribute are defined by the ST_Lang simple type (§2.18.51).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Lang">
   <attribute name="val" type="ST_Lang" use="required"/>
</complexType>
```

2.5.2.20 listItem (Combo Box List Item)

This element specifies a single list item within the parent combo box structured document tag. Each list item shall be displayed in the list displayed for the parent structured document tag (if a user interface is present).

[*Example*: Consider the following combo box structured document tag:

```
<w:sdt>
  <w:sdtPr>
    <w:comboBox>
      <w:listItem w:displayText="Zero" w:value="0"/>
      <w:listItem w:displayText="One" w:value="1"/>
    </w:comboBox>
  </w:sdtPr>
  …
</w:sdt>
```

Each listItem element within the comboBox element specifies a single list item entry, in this case resulting in two list items within the parent combo box structured document tag. *end example*]

Parent Elements
comboBox (§2.5.2.5)

Attributes	Description

displayText (List Entry Display Text)	Specifies the text to display in the run content (as well as any supplied user interface) in place of the value attribute contents for this drop-down list entry.
	
	This value shall be used as follows:
	• If the parent structured document tag is mapped to a custom XML element, the value in that custom XML element shall be mapped the content of the value attribute, and the resulting displayText attribute value (if one is present) shall be displayed in the run content. If no displayText attribute is present, then the value shall be displayed.
	• If the corresponding entry is selected via a user interface, this value shall be stored in the parent element's run content in the document (this is the value that shall be shown in the document's WordprocessingML content).
	
	If this attribute is omitted, then the content of the value attribute shall be used as the display text for the current list item entry.
	
	[*Example*: Consider the following drop-down list structured document tag:
	
	`<w:sdt>`
	`  <w:sdtPr>`
	`  <w:dropDownList>`
	`  <w:listItem w:displayText="The Letter A" w:value="a"/>`
	`  <w:listItem w:displayText="The Letter B" w:value="b"/>`
	`  </w:dropDownList>`
	`  </w:sdtPr>`
	`  …`
	`</w:sdt>`

Attributes	Description
	The displayText attribute for the first entry is `The Letter A` and the second is `The Letter B`, therefore, these values will be used to determine the display text if the parent structured document tag is mapped to custom XML data in a custom XML data part. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

value (List Entry Value)	Specifies the value for the current list item entry.
	
	This value shall be used as follows:
	• If the parent structured document tag is mapped to a custom XML element, the value in that custom XML element shall be mapped to this value, and the resulting displayText attribute value (if one is present) shall be displayed in the run content. If no displayText attribute is present, then the value shall be displayed.
	• If the corresponding entry is selected via a user interface, this value shall be stored in the parent element's listItem attribute value.
	
	[*Example*: Consider the following combo box structured document tag:
	
	`<w:sdt>`
	`  <w:sdtPr>`
	`  <w:comboBox>`
	`  <w:listItem w:displayText="Zero" w:value="0"/>`
	`  <w:listItem w:displayText="One" w:value="1"/>`
	`  </w:comboBox>`
	`  </w:sdtPr>`
	`  …`
	`</w:sdt>`
	
	The value attribute for the first entry is `0` and the second is `1`, therefore, these values will be used to determine the display text if the parent structured document tag is mapped to custom XML data in a custom XML data part. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SdtListItem">
   <attribute name="displayText" type="ST_String"/>
   <attribute name="value" type="ST_String"/>
</complexType>
```

2.5.2.21 listItem (Drop-Down List Item)

This element specifies a single list item within the parent drop-down list structured document tag. Each list item shall be displayed in the list displayed for the parent structured document tag (if a user interface is present).

[*Example*: Consider the following combo box structured document tag:

```
<w:sdt>
  <w:sdtPr>
    <w:dropDownList>
      <w:listItem w:displayText="The Letter A" w:value="a"/>
      <w:listItem w:displayText="The Letter B" w:value="b"/>
    </w:dropDownList>
  </w:sdtPr>
  …
</w:sdt>
```

Each listItem element within the dropDownList element specifies a single list item entry, in this case resulting in two list items within the parent drop-down list structured document tag. *end example*]

Parent Elements
dropDownList (§2.5.2.15)

Attributes	Description

displayText (List Entry Display Text)	Specifies the text to display in the run content (as well as any supplied user interface) in place of the value attribute contents for this drop-down list entry.
	
	This value shall be used as follows:
	• If the parent structured document tag is mapped to a custom XML element, the value in that custom XML element shall be mapped the content of the value attribute, and the resulting displayText attribute value (if one is present) shall be displayed in the run content. If no displayText attribute is present, then the value shall be displayed.
	• If the corresponding entry is selected via a user interface, this value shall be stored in the parent element's run content in the document (this is the value that shall be shown in the document's WordprocessingML content).
	
	If this attribute is omitted, then the content of the value attribute shall be used as the display text for the current list item entry.
	
	[*Example*: Consider the following drop-down list structured document tag:
	
	`<w:sdt>`
	`  <w:sdtPr>`
	`  <w:dropDownList>`
	`  <w:listItem w:displayText="The Letter A" w:value="a"/>`
	`  <w:listItem w:displayText="The Letter B" w:value="b"/>`
	`  </w:dropDownList>`
	`  </w:sdtPr>`
	`  …`
	`</w:sdt>`

Attributes	Description
	The displayText attribute for the first entry is `The Letter A` and the second is `The Letter B`, therefore, these values will be used to determine the display text if the parent structured document tag is mapped to custom XML data in a custom XML data part. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

value (List Entry Value)	Specifies the value for the current list item entry.
	
	This value shall be used as follows:
	• If the parent structured document tag is mapped to a custom XML element, the value in that custom XML element shall be mapped to this value, and the resulting displayText attribute value (if one is present) shall be displayed in the run content. If no displayText attribute is present, then the value shall be displayed.
	• If the corresponding entry is selected via a user interface, this value shall be stored in the parent element's listItem attribute value.
	
	[*Example*: Consider the following combo box structured document tag:
	
	`<w:sdt>`
	`  <w:sdtPr>`
	`  <w:comboBox>`
	`  <w:listItem w:displayText="Zero" w:value="0"/>`
	`  <w:listItem w:displayText="One" w:value="1"/>`
	`  </w:comboBox>`
	`  </w:sdtPr>`
	`  …`
	`</w:sdt>`
	
	The value attribute for the first entry is `0` and the second is `1`, therefore, these values will be used to determine the display text if the parent structured document tag is mapped to custom XML data in a custom XML data part. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SdtListItem">
   <attribute name="displayText" type="ST_String"/>
   <attribute name="value" type="ST_String"/>
</complexType>
```

2.5.2.22 lock (Locking Setting)

This element specifies the set of behaviors which shall be applied to the contents of the parent structured document tag when the contents of this documents are edited by an application (whether through a user

interface or directly). The type of locking applied to the structured document tag is specified via the value of the associated val attribute.

If this element is omitted, then the locking settings implied for the structured document tag shall be as follows:

- If the structured document tag specifies that it is a group via the group element (§2.5.2.17), then the contents of the structured document tag shall be editable, but the entire tag may be deleted.
- For all other types, no locking settings shall be applied to the structured document tag.

[*Example*: Consider the following plain text structured document tag:

```
<w:sdt>
  <w:sdtPr>
    <w:lock w:val="sdtLocked"/>
    …
    <w:text/>
  </w:sdtPr>
  …
</w:sdt>
```

This plain text structured document tag's properties contain a lock element, specifying locking behaviors for the structured document tag. Since the locking val attribute value is sdtLocked, this locking setting shall specify that the contents of the structured document tag may be edited, but the structured document tag itself shall not be deleted from the document. *end example*]

Parent Elements
sdtPr (§2.5.2.37)

Attributes	Description

val (Locking Type)	Specifies the type of locking which shall be applied to the parent structured document tag.
	
	If this attribute is omitted, this its value shall be assumed to be unlocked (using the defaults stated above).
	
	[*Example*: Consider the following plain text structured document tag properties:
	
	`<w:sdtPr>`
	`  <w:lock w:val="contentLocked"/>`
	`  …`
	`  <w:text/>`
	`</w:sdtPr>`
	
	The val attribute value is contentLocked, therefore this locking setting shall specify that the contents of the structured document tag shall not be edited, but the structured

Attributes	Description
	document tag itself may be deleted from the document. *end example*] The possible values for this attribute are defined by the ST_Lock simple type (§2.18.56).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Lock">
   <attribute name="val" type="ST_Lock"/>
</complexType>
```

2.5.2.23 picture (Picture Structured Document Tag)

This element specifies that the parent structured document tag shall be a picture when displayed in the document.

This setting specifies that the behavior for this structured document tag shall be as follows:

- The contents shall always be restricted to a single picture using either the DrawingML (§5.1) or VML (§6.1) syntax

As well, the structured document tag must satisfy the following restraints or the document shall be considered invalid:

- The contents shall only be a single picture using either the DrawingML (§5.1) or VML (§6.1) syntax
- The contents shall not contain more than a single paragraph or table cell and shall not contain a table row or table

[*Example*: Consider the following structured document tag:

```
<w:sdt>
  <w:sdtPr>
    …
    <w:picture/>
  </w:sdtPr>
  …
</w:sdt>
```

The text element in this structured document tag's properties specify that the type of structured document tag is a picture. *end example*]

Parent Elements
sdtPr (§2.5.2.37)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.5.2.24 placeholder (Structured Document Tag Placeholder Text)

This element specifies the placeholder text which should be displayed when this structured document tag's run contents are empty, the associated mapped XML element is empty as specified via the dataBinding element (§2.5.2.6) or the showingPlcHdr element (§2.5.2.38) is set in the structured document tag's properties. The placeholder text which shall be shown is itself specified via the child element docPart.

If this element is omitted, then five non-breaking spaces shall be used as the default placeholder text for this structured document tag.

[*Example*: Consider a structured document tag defined as follows:

```
<w:sdt>
  <w:sdtPr>
    <w:placeholder>
      <w:docPart w:val="DefaultPlaceholder_22610170" />
    </w:placeholder>
    …
  </w:sdtPr>
  <w:sdtContent>
    …
  </w:sdtContent>
</w:sdt>
```

This structured document tag specifies through the placeholder element that its placeholder text shall be specified in the document part of type `bbPlcHdr` whose name is equal to `DefaultPlaceholder_22610170`. *end example*]

Parent Elements
sdtPr (§2.5.2.37)

Child Elements	Subclause
docPart (Document Part Reference)	§2.5.2.9

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Placeholder">
   <sequence>
      <element name="docPart" type="CT_String"/>
   </sequence>
</complexType>
```

2.5.2.25 richText (Rich Text Structured Document Tag)

This element specifies that the parent structured document tag shall be a rich text box when displayed in the document.

If no type element (the xsd:choice block in the XML Schema fragment for the parent sdtPr element) is specified, then the parent structured document tag shall be of type richText.

[*Example*: Consider the following structured document tag:

```
<w:sdt>
  <w:sdtPr>
    …
    <w:richText/>
  </w:sdtPr>
  …
</w:sdt>
```

The richText element in this structured document tag's properties specify that the type of structured document tag is a rich text box. *end example*].

Parent Elements
sdtPr (§2.5.2.37)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.5.2.26 rPr (Run Properties For Structured Document Tag Contents)

This element specifies the set of run properties which shall be applied to the text entered into the parent structured document tag in replacement of placeholder text. When placeholder text is present in a structured document tag, its formatting is often different than the desired underlying formatting, and this element specifies the formatting which shall be used for non-placeholder text contents when they are initially added to the control.

If this element is not present, the inserted is unformatted, as with any other run of text - it shall not inherit the properties of the placeholder text.

[*Example*: Consider the following structured document tag:

```
<w:sdt>
  <w:sdtPr>
    <w:placeholder>
      <w:docPart w:val="TestPlaceholderDocPart"/>
    </w:placeholder>
    <w:showingPlcHdr/>
    <w:rPr>
      <w:rStyle w:val="UserName"/>
    </w:rPr>
    …
  </w:sdtPr>
  <w:sdtContent>
    <w:r>
      <w:rPr>
        <w:rStyle w:val="PlaceholderText"/>
      </w:rPr>
      <w:t>[Type Your Name Here]</w:t>
    </w:r>
  </w:sdtContent>
</w:sdt>
```

This structured document tag specifies that its current contents are placeholder text via the showingPlcHdr element (§2.5.2.38), and that text has the `PlaceholderText` character style applied to it.

Now, assume that that style created grey shaded text (typical for placeholder text). This formatting would clearly not be desirable for any text entered into the structured document tag. Therefore, when this text is added, the rPr element in the sdtPr is used to store the formatting on the resulting text.

In this example, the text which initially populates the control shall be formatted with the `UserName` character style. *end example*]

vertAlign (Subscript/Superscript Text)	§2.3.2.40
w (Expanded/Compressed Text)	§2.3.2.41
webHidden (Web Hidden Text)	§2.3.2.42

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RPr">
   <sequence>
      <group ref="EG_RPrContent" minOccurs="0"/>
   </sequence>
</complexType>
```

2.5.2.27 rPr (Structured Document Tag End Character Run Properties)

This element specifies the set of run properties which shall be applied to the character present to delimit the end of the structured document tag's contents. When these properties are applied, they shall be applied in addition to the run properties specified for the entire structured document tag via the rPr element (§2.5.2.26) stored in the tag's main property container.

If this element is not present, the inserted closing tag shall be formatting identically to the start tag.

[*Example*: Consider the following structured document tag:

```
<w:sdt>
  <w:sdtPr>
    <w:placeholder>
      <w:docPart w:val="TestPlaceholderDocPart"/>
    </w:placeholder>
    <w:showingPlcHdr/>
    <w:rPr>
      <w:rStyle w:val="UserName"/>
    </w:rPr>
    …
  </w:sdtPr>
  <w:sdtEndPr>
    <w:rPr>
      <w:b/>
      <w:i/>
    <w:rPr>
  </w:sdtEndPr>
  <w:sdtContent>
    …
  </w:sdtContent>
</w:sdt>
```

The rPr elements under the tag's properties specify that this structured document tag specifies that its start character shall have formatting in the character style `UserName`, and that the end character shall have the formatting in the character style `UserName` as well as bold and italic direct formatting. *end example*]

vertAlign (Subscript/Superscript Text)	§2.3.2.40
w (Expanded/Compressed Text)	§2.3.2.41
webHidden (Web Hidden Text)	§2.3.2.42

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RPr">
   <sequence>
      <group ref="EG_RPrContent" minOccurs="0"/>
   </sequence>
</complexType>
```

2.5.2.28 sdt (Cell-Level Structured Document Tag)

This element specifies the presence of a structured document tag around a single table cell. The two child elements of this element shall be used to specify the properties and content of the current structured document tag via the sdtPr and sdtContent elements, respectively.

[*Example*: Consider a structured document tag with the friendly name company that shall be located around a single table cell in a WordprocessingML document. This requirement would be specified as follows in the WordprocessingML:

```
<w:tr>
  <w:sdt>
    <w:sdtPr>
      <w:alias w:val="company"/>
    </w:sdtPr>
    <w:sdtContent>
      <w:tc>
        …
      </w:tc>
    </w:sdtContent>
  </w:sdt>
  …
</w:tr>
```

The sdt element specifies the structured document tag, the child sdtPr element contains the friendly name property set to company, and the sdtContent element contains a single table cell (it is a cell-level structured document tag). *end example*]

Parent Elements
customXml (§2.5.1.3); sdtContent (§2.5.2.33); tr (§2.4.75)

Child Elements	Subclause
sdtContent (Cell-Level Structured Document Tag Content)	§2.5.2.33
sdtEndPr (Structured Document Tag End Character Properties)	§2.5.2.36
sdtPr (Structured Document Tag Properties)	§2.5.2.37

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SdtCell">
   <sequence>
      <element name="sdtPr" type="CT_SdtPr" minOccurs="0" maxOccurs="1"/>
      <element name="sdtEndPr" type="CT_SdtEndPr" minOccurs="0" maxOccurs="1"/>
      <element name="sdtContent" type="CT_SdtContentCell" minOccurs="0" maxOccurs="1"/>
   </sequence>
</complexType>
```

2.5.2.29 sdt (Inline-Level Structured Document Tag)

This element specifies the presence of a structured document tag around one or more inline-level structures (runs, DrawingML objects, fields, etc.) in the current paragraph. The two child elements of this element shall be used to specify the properties and content of the current structured document tag via the sdtPr and sdtContent elements, respectively.

[*Example*: Consider a structured document tag with the friendly name `firstName` that shall be located around two runs in a WordprocessingML document. This requirement would be specified as follows in the WordprocessingML:

```
<w:p>
  <w:sdt>
    <w:sdtPr>
      <w:alias w:val="firstName"/>
    </w:sdtPr>
    <w:sdtContent>
      <w:r>
        …
      </w:r>
      <w:r>
        …
      </w:r>
    </w:sdtContent>
  </w:sdt>
  …
</w:tr>
```

The sdt element specifies the structured document tag, the child sdtPr element contains the friendly name property set to `firstName`, and the sdtContent element contains two runs (it is an inline-level structured document tag). *end example*]

Parent Elements
customXml (§2.5.1.5); del (§2.13.5.12); fldSimple (§2.16.21); hyperlink (§2.16.24); ins (§2.13.5.20); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); p (§2.3.1.22); sdtContent (§2.5.2.35); smartTag (§2.5.1.9)

Child Elements	Subclause
sdtContent (Inline-Level Structured Document Tag Content)	§2.5.2.35
sdtEndPr (Structured Document Tag End Character Properties)	§2.5.2.36
sdtPr (Structured Document Tag Properties)	§2.5.2.37

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SdtRun">
   <sequence>
      <element name="sdtPr" type="CT_SdtPr" minOccurs="0" maxOccurs="1"/>
      <element name="sdtEndPr" type="CT_SdtEndPr" minOccurs="0" maxOccurs="1"/>
      <element name="sdtContent" type="CT_SdtContentRun" minOccurs="0" maxOccurs="1"/>
   </sequence>
</complexType>
```

2.5.2.30 sdt (Block-Level Structured Document Tag)

This element specifies the presence of a structured document tag around one or more block-level structures (paragraphs, tables, etc.). The two child elements of this element shall be used to specify the properties and content of the current structured document tag via the sdtPr and sdtContent elements, respectively.

[*Example*: Consider a structured document tag with the friendly name `address` that shall be located around a single paragraph in a WordprocessingML document. This requirement would be specified as follows in the WordprocessingML:

```
<w:body>
  <w:sdt>
    <w:sdtPr>
      <w:alias w:val="address"/>
    </w:sdtPr>
    <w:sdtContent>
      <w:p>
        …
      </w:p>
    </w:sdtContent>
  </w:sdt>
  …
</w:body>
```

The sdt element specifies the structured document tag, the child sdtPr element contains the friendly name property set to address, and the sdtContent element contains a single paragraph (it is a block-level structured document tag). *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.6); docPartBody (§2.12.6); endnote (§2.11.2); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); sdtContent (§2.5.2.32); tc (§2.4.62); txbxContent (§2.17.1.1)

Child Elements	Subclause
sdtContent (Block-Level Structured Document Tag Content)	§2.5.2.32
sdtEndPr (Structured Document Tag End Character Properties)	§2.5.2.36
sdtPr (Structured Document Tag Properties)	§2.5.2.37

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SdtBlock">
   <sequence>
      <element name="sdtPr" type="CT_SdtPr" minOccurs="0" maxOccurs="1"/>
      <element name="sdtEndPr" type="CT_SdtEndPr" minOccurs="0" maxOccurs="1"/>
      <element name="sdtContent" type="CT_SdtContentBlock" minOccurs="0" maxOccurs="1"/>
   </sequence>
</complexType>
```

2.5.2.31 sdt (Row-Level Structured Document Tag)

This element specifies the presence of a structured document tag around a single table row. The two child elements of this element shall be used to specify the properties and content of the current structured document tag via the sdtPr and sdtContent elements, respectively.

[*Example*: Consider a structured document tag with the friendly name `invoiceItem` that shall be located around a single table row in a WordprocessingML document. This requirement would be specified as follows in the WordprocessingML:

```
<w:tbl>
  <w:sdt>
    <w:sdtPr>
      <w:alias w:val="invoiceItem"/>
    </w:sdtPr>
    <w:sdtContent>
      <w:tr>
        …
      </w:tr>
    </w:sdtContent>
  </w:sdt>
  …
</w:tbl>
```

The sdt element specifies the structured document tag, the child sdtPr element contains the friendly name property set to `invoiceItem`, and the sdtContent element contains a single table row (it is a row-level structured document tag). *end example*]

Parent Elements
customXml (§2.5.1.4); sdtContent (§2.5.2.34); tbl (§2.4.36)

Child Elements	Subclause
sdtContent (Row-Level Structured Document Tag Content)	§2.5.2.34
sdtEndPr (Structured Document Tag End Character Properties)	§2.5.2.36
sdtPr (Structured Document Tag Properties)	§2.5.2.37

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SdtRow">
   <sequence>
      <element name="sdtPr" type="CT_SdtPr" minOccurs="0" maxOccurs="1"/>
      <element name="sdtEndPr" type="CT_SdtEndPr" minOccurs="0" maxOccurs="1"/>
      <element name="sdtContent" type="CT_SdtContentRow" minOccurs="0" maxOccurs="1"/>
   </sequence>
</complexType>
```

2.5.2.32 sdtContent (Block-Level Structured Document Tag Content)

This element specifies the last known contents of a structured document tag around one or more block-level structures (paragraphs, tables, etc.). This element's contents shall be treated as a cache of the contents to be displayed in the structured document tag for the following reasons:

- If the structured document tag specifies an XML mapping via the dataBinding element (§2.5.2.6), changes to the custom XML data part shall be reflected in the structured document tag as needed
- If the contents of the structured document tag are placeholder text via the showingPlcHdr element (§2.5.2.38), then this content may be updated with the placeholder text stored in the Glossary Document part

[*Example*: Consider a structured document tag with the friendly name address that shall be located around a single paragraph in a WordprocessingML document. This requirement would be specified as follows in the WordprocessingML:

```
<w:body>
  <w:sdt>
    <w:sdtPr>
      <w:alias w:val="address"/>
    </w:sdtPr>
    <w:sdtContent>
      <w:p>
        …
      </w:p>
    </w:sdtContent>
  </w:sdt>
  …
</w:body>
```

The sdtContent element contains a single paragraph (it is a block-level structured document tag content container). *end example*]

Parent Elements

```
<complexType name="CT_SdtContentBlock">
    <group ref="EG_ContentBlockContent" minOccurs="0" maxOccurs="unbounded"/>
</complexType>
```

2.5.2.33 sdtContent (Cell-Level Structured Document Tag Content)

This element specifies the last known contents of a structured document tag around a single table cell. This element's contents shall be treated as a cache of the contents to be displayed in the structured document tag for the following reasons:

- If the structured document tag specifies an XML mapping via the dataBinding element (§2.5.2.6), changes to the custom XML data part shall be reflected in the structured document tag as needed
- If the contents of the structured document tag are placeholder text via the showingPlcHdr element (§2.5.2.38), then this content may be updated with the placeholder text stored in the Glossary Document part

[*Example*: Consider a structured document tag with the friendly name company that shall be located around a single table cell in a WordprocessingML document. This requirement would be specified as follows in the WordprocessingML:

```
<w:tr>
  <w:sdt>
    <w:sdtPr>
      <w:alias w:val="company"/>
    </w:sdtPr>
    <w:sdtContent>
      <w:tc>
        …
      </w:tc>
    </w:sdtContent>
  </w:sdt>
  …
</w:tr>
```

The sdtContent element contains a single table cell (it is an cell-level structured document tag content container). *end example*]

    <group ref="EG_ContentCellContent" minOccurs="0" maxOccurs="unbounded"/>
</complexType>
```

2.5.2.34 sdtContent (Row-Level Structured Document Tag Content)

This element specifies the last known contents of a structured document tag around a single table row.

[*Note*: Unlike other types of structured document tags, this type cannot show placeholder text or have mapped XML data, therefore it is never a cache. *end note*]

[*Example*: Consider a structured document tag with the friendly name `invoiceItem` that shall be located around a single table row in a WordprocessingML document. This requirement would be specified as follows in the WordprocessingML:

```
<w:tbl>
  <w:sdt>
    <w:sdtPr>
      <w:alias w:val="invoiceItem"/>
    </w:sdtPr>
    <w:sdtContent>
      <w:tr>
        …
      </w:tr>
    </w:sdtContent>
  </w:sdt>
  …
</w:tbl>
```

The sdtContent element contains a single table row (it is an row-level structured document tag content container). *end example*]

proofErr (Proofing Error Anchor)	§2.13.8.1
sdt (Row-Level Structured Document Tag)	§2.5.2.31
tr (Table Row)	§2.4.75

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SdtContentRow">
   <group ref="EG_ContentRowContent" minOccurs="0" maxOccurs="unbounded"/>
</complexType>
```

2.5.2.35 sdtContent (Inline-Level Structured Document Tag Content)

This element specifies the last known contents of a structured document tag around one or more inline-level structures (runs, DrawingML objects, fields, etc.). This element's contents shall be treated as a cache of the contents to be displayed in the structured document tag for the following reasons:

- If the structured document tag specifies an XML mapping via the dataBinding element (§2.5.2.6), changes to the custom XML data part shall be reflected in the structured document tag as needed
- If the contents of the structured document tag are placeholder text via the showingPlcHdr element (§2.5.2.38), then this content may be updated with the placeholder text stored in the Glossary Document part

[*Example*: Consider a structured document tag with the friendly name `firstName` that shall be located around two runs in a WordprocessingML document. This requirement would be specified as follows in the WordprocessingML:

```
<w:p>
  <w:sdt>
    <w:sdtPr>
      <w:alias w:val="firstName"/>
    </w:sdtPr>
    <w:sdtContent>
      <w:r>
        …
      </w:r>
      <w:r>
        …
      </w:r>
    </w:sdtContent>
  </w:sdt>
  …
</w:p>
```

The sdtContent element contains two adjacent runs (it is an inline-level structured document tag content container). *end example*]

```
<complexType name="CT_SdtContentRun">
    <group ref="EG_PContent" minOccurs="0" maxOccurs="unbounded"/>
</complexType>
```

2.5.2.36 sdtEndPr (Structured Document Tag End Character Properties)

This element specifies the properties which shall be applied to the physical character which delimits the end of a structured document tag.

[*Example*: Consider a structured document tag with the following properties specified for the end tag:

```
<w:sdtEndPr>
  <w:rPr>
    …
  </w:rPr>
</w:sdtEndPr>
```

This structured document tag specifies properties for its end character within the sdtEndPr element. *end example*]

Parent Elements

Parent Elements
sdt (§2.5.2.30); sdt (§2.5.2.28); sdt (§2.5.2.29); sdt (§2.5.2.31)

Child Elements	Subclause
rPr (Structured Document Tag End Character Run Properties)	§2.5.2.27

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SdtEndPr">
   <choice maxOccurs="unbounded">
      <element name="rPr" type="CT_RPr" minOccurs="0"/>
   </choice>
</complexType>
```

2.5.2.37 sdtPr (Structured Document Tag Properties)

This element specifies the set of properties which shall be applied to the parent structured document tag.

[*Example*: Consider a structured document tag with the following properties specified:

```
<w:sdtPr>
  <w:alias w:val="Birthday"/>
  <w:id w:val="8775518"/>
  <w:date>
    <w:dateFormat w:val="M/d/yyyy"/>
    <w:lid w:val="EN-US"/>
  </w:date>
</w:sdtPr>
```

This structured document tag specifies three properties: the a friendly name of `Birthday` via the alias element (§2.5.2.1), a unique ID of `8775518` via the id element (§2.5.2.18), and a structured document tag type of date picker via the date element (§2.5.2.7) which itself has a set of date-specific properties. *end example*]

Parent Elements
sdt (§2.5.2.29); sdt (§2.5.2.30); sdt (§2.5.2.28); sdt (§2.5.2.31)

temporary (Remove Structured Document Tag When Contents Are Edited)	§2.5.2.41
text (Plain Text Structured Document Tag)	§2.5.2.42

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SdtPr">
   <choice maxOccurs="unbounded">
      <element name="rPr" type="CT_RPr" minOccurs="0"/>
      <element name="alias" type="CT_String" minOccurs="0"/>
      <element name="lock" type="CT_Lock" minOccurs="0"/>
      <element name="placeholder" type="CT_Placeholder" minOccurs="0"/>
      <element name="showingPlcHdr" type="CT_OnOff" minOccurs="0"/>
      <element name="dataBinding" type="CT_DataBinding" minOccurs="0"/>
      <element name="temporary" type="CT_OnOff" minOccurs="0"/>
      <element name="id" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="tag" type="CT_String" minOccurs="0"/>
      <choice minOccurs="0" maxOccurs="1">
         <element name="equation" type="CT_Empty"/>
         <element name="comboBox" type="CT_SdtComboBox"/>
         <element name="date" type="CT_SdtDate"/>
         <element name="docPartObj" type="CT_SdtDocPart"/>
         <element name="docPartList" type="CT_SdtDocPart"/>
         <element name="dropDownList" type="CT_SdtDropDownList"/>
         <element name="picture" type="CT_Empty"/>
         <element name="richText" type="CT_Empty"/>
         <element name="text" type="CT_SdtText"/>
         <element name="citation" type="CT_Empty"/>
         <element name="group" type="CT_Empty"/>
         <element name="bibliography" type="CT_Empty"/>
      </choice>
   </choice>
</complexType>
```

2.5.2.38 showingPlcHdr (Current Contents Are Placeholder Text)

This element specifies whether the content of the sdtContent element (§2.5.2.32; §2.5.2.33; §2.5.2.34; §2.5.2.35) for the parent structured document tag shall be interpreted to contain placeholder text for this structured document tag (as opposed to regular text contents within the structured document tag). If this element is present and set to `true`, this state shall be resumed (showing placeholder text) upon opening this document.

If this element is omitted, then the structured document tag shall not be interpreted to be showing placeholder text when the document is displayed.

[*Example*: Consider the following structured document tag:

```
<w:sdt>
  <w:sdtPr>
    <w:showingPlcHdr/>
    …
    <w:richText/>
  </w:sdtPr>
  <w:sdtContent>
    <w:r>
      <w:t>[Type your name here]</w:t>
    </w:r>
 </w:sdtContent>
</w:sdt>
```

This structured document tag has run contents which read `[Type your name here]`, which would typically be interpreted as the current contents of the structured document tag. However, since the showingPlcHdr element has been specified in the structured document tag's properties, this content shall instead be interpreted as the placeholder text for the structured document tag. *end example*]

Parent Elements
sdtPr (§2.5.2.37)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.5.2.39 storeMappedDataAs (Custom XML Data Date Storage Format)

This element specifies the translation which shall be performed on the displayed date in a date picker structured document tag when the current contents are saved into the associated custom XML data via the dataBinding element (§2.5.2.6).

If this element is omitted, then the value of the associated custom XML element shall be placed into the custom XML data part with no translation.

[*Example*: Consider the following date picker structured document tag:

```
<w:sdt>
  <w:sdtPr>
    <w:date w:fullDate="01-01-2006T06:30:00Z">
      <w:storeMappedDateAs w:val="text"/>
      …
    </w:date>
  </w:sdtPr>
  <w:sdtContent>
    <w:r>
      <w:t>January 1</w:t>
    </w:r>
  </w:sdtContent>
</w:sdt>
```

The value of the storeMappedDateAs element's attribute value is `text`, therefore the current run contents shall be sent to the mapped XML element without any translation (in this case, the value shall be `January 1`). *end example*]

Parent Elements
date (§2.5.2.7)

Attributes	Description

val (Date Storage Type)	Specifies the type of date translation which shall be applied to the parent date picker structured document tag.
	
	If this attribute is omitted, this its value shall be assumed to be `text`.
	
	[*Example*: Consider the following date picker structured document tag:
	
	`<w:sdt>`
	`  <w:sdtPr>`
	`  <w:date … >`
	`  <w:storeMappedDateAs w:val="date"/>`
	`  …`

Attributes	Description
	</w:date> </w:sdtPr> <w:sdtContent> <w:r> <w:t>January 1</w:t> </w:r> </w:sdtContent> </w:sdt> The value of the val attribute is text, therefore the current run contents shall be sent to the mapped XML element after being translated into xsd:date format (in this case, the value shall be 01-01-2006). *end example*] The possible values for this attribute are defined by the ST_SdtDateMappingType simple type (§2.18.83).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SdtDateMappingType">
   <attribute name="val" type="ST_SdtDateMappingType"/>
</complexType>
```

2.5.2.40 tag (Programmatic Tag)

This element specifies a programmatic tag associated with the current structured document tag. A *programmatic tag* is an arbitrary string which applications may associate with a structured document tag in order to identify it without providing a visible friendly name. The string representing the programmatic tag shall be stored on this element's val attribute.

If this element is omitted, then no programmatic tag shall be associated with the given structured document tag.

[*Example*: Consider the following properties on a structured document tag:

```
<w:sdtPr>
  <w:tag w:val="Clause_3246"/>
  …
</w:sdtPr>
```

This set of properties specifies via the tag element that the programmatic tag for the parent structured document tag shall be Clause_3246. This information may then be used as needed by applications. *end example*]

Parent Elements
sdtPr (§2.5.2.37)

Attributes	Description

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.5.2.41 temporary (Remove Structured Document Tag When Contents Are Edited)

This element specifies whether the parent structured document tag shall be removed from the WordprocessingML document when the its contents are modified.

[*Note*: This setting is primarily intended for creating structured document tags whose sole purpose is one-time placeholder text, and which should not return once replaced with content. *end note*]

If this element is omitted, then the parent structured document tag shall not be automatically removed when its contents are modified.

[*Example*: Consider the following plain text structured document tag:

```
<w:sdt>
  <w:sdtPr>
    <w:temporary/>
    <w:text/>
  </w:sdtPr>
  …
</w:sdt>
```

This plain text structured document tag's properties contain a temporary element, specifying that the structured document tag itself shall be deleted from the document whenever its contents are first modified. *end example*]

Parent Elements
sdtPr (§2.5.2.37)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.5.2.42 text (Plain Text Structured Document Tag)

This element specifies that the parent structured document tag shall be a plain text box when displayed in the document.

This setting specifies that the behavior for this structured document tag shall be as follows:

- Formatting applied to any part of this structured document tag's contents shall apply to its entire contents

As well, the structured document tag must satisfy the following restraints or the document shall be considered invalid:

- The contents shall only be contain a single run (one set of formatting properties) with exceptions for soft carriage returns via the multiLine attribute on this element
- The contents shall not contain more than a single paragraph or table cell and shall not contain a table row or table

[*Example*: Consider the following structured document tag:

```
<w:sdt>
  <w:sdtPr>
    …
    <w:text/>
  </w:sdtPr>
  …
</w:sdt>
```

The text element in this structured document tag's properties specify that the type of structured document tag is a plain text box. *end example*]

Parent Elements
sdtPr (§2.5.2.37)

Attributes	Description

multiLine (Allow Soft Line Breaks)	Specifies whether soft line breaks may be added to the contents of this structured document tag when this document is modified. This setting shall not affect the ability of the structured document tag to display existing soft line breaks (which shall be preserved) and shall only affect the ability to add line breaks when the document is modified by an application.
	
	If this attribute is omitted, then the parent plain text structured document control shall not allow soft line breaks to be added to its contents.
	
	[*Example*: Consider the following structured document tag:
	
	`<w:sdt>`
	`  <w:sdtPr>`
	`  …`
	`  <w:text w:multiLine="true"/>`
	`  </w:sdtPr>`
	`  …`

Attributes	Description
	</w:sdt> The multiLine attribute on the text element in this structured document tag's properties specify that an application may allow soft line breaks to be added to the run contents of the structured document tag. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SdtText">
   <attribute name="multiLine" type="ST_OnOff"/>
</complexType>
```

2.6 Sections

WordprocessingML does not natively store the concept of pages, since it is based on paragraphs and runs (which are laid out on to pages by consumers of this content). However, although there is no concept of storing pages in the WordprocessingML format, it is often necessary to store information about a page or group of pages in a document, in order to store information that is to be used to format the pages on which a set of paragraphs will appear. In WordprocessingML, this information is stored via the use of *sections*.

In WordprocessingML, *sections* are groupings of paragraphs that have a specific set of properties used to define the pages on which the text will appear, as well as other section-level (applying to all paragraphs' appearance) properties.

[*Example*: Consider a document with four paragraphs of text that is to be printed on a page in landscape mode, followed by ten paragraphs of text that are to be printed in portrait mode. This requirement implies information about the page(s) used to lay out each grouping of text—the first four paragraphs could require one page, or ten.

Therefore, rather than try to cache knowledge of the number of pages and their properties (which is likely to become invalid if the XML is manipulated by a producer that does not understand page layout), this information is stored by breaking the document into two sections, as follows:

```
<w:p>
  …
</w:p>
<w:p>
  …
</w:p>
<w:p>
  …
</w:p>
```

```
<w:p>
  <w:sectPr>
    …
    (section one properties go here)
    <w:pgSz ... w:orient="landscape" />
    …
  </w:sectPr>
  …
</w:p>
…
<w:p>
  <w:sectPr>
    …
    (section two properties go here)
    <w:pgSz ... w:orient="landscape" />
    …
  </w:sectPr>
  …
</w:p>
```

end example]

2.6.1 bidi (Right to Left Section Layout)

This element specifies that this section shall be presented using a right-to-left page direction. This property only affects section-level properties, and does not affect the layout of text within the contents of this section.

[*Example*: Consider a section with the bidi property set as follows:

```
<w:sectPr>
  ...
  <w:bidi/>
</w:sectPr>
```

This section direction is now right-to-left, which means that all section level properties are displayed right-to-left (e.g., page numbers are displayed on the right of text; columns are populated from right-to-left). However, the layout of text is determined by properties applied at the text level. *end example*]

Parent Elements
sectPr (§2.6.17); sectPr (§2.6.18); sectPr (§2.6.19)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element.

Attributes	Description
	A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

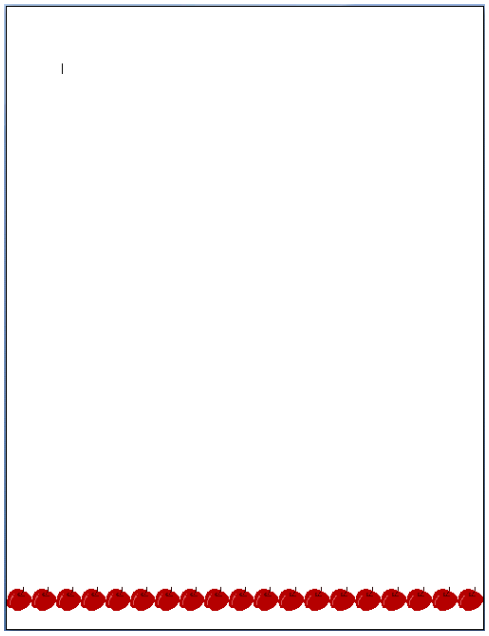
The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.6.2 bottom (Bottom Border)

This element specifies the presentation and display of the page border displayed at the bottom of each page in this section.

[*Example*: Consider a section in which all pages shall have a bottom border consisting of a repeated image of an apple, like this:



This border would result in the following WordprocessingML:

```
<w:sectPr>
  …
  <w:pgBorders>
    <w:bottom w:val="apples" .../>
  </w:pgBorders>
  …
</w:sectPr>
```

Because the page only has a border at the bottom, only the bottom element is specified within the set of page borders. *end example*]

When a document has a bottom border that is relative to the page edges (using the offsetFrom attribute on pgBorders), it shall span the bottom edge of the page at the location defined by its properties, stopping when:

- It intersects with the corresponding left or right page border (if one is specified).
- It reaches the edge of the page.

[*Example*: In the example above, no left or right border was specified in the WordprocessingML, so a consumer shall draw the border from one edge of the page to the other. *end example*]

When a document has a bottom border that is relative to the text (using the offsetFrom attribute on pgBorders), it shall span only the necessary width to satisfy the requirement of spanning the width of the text.

Parent Elements
pgBorders (§2.6.10)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value auto, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type

Attributes	Description
	(§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object. When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points. When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points. [*Example*: Consider a document with a set of page borders all specified to appear 24

Attributes	Description

	points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border.
	
	If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value.
	
	If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.
	
	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`
	
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*]
	
	The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border. The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document. [*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:

Attributes	Description
	<w:top … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:bottom … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:left … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:right … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 = 102 = 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D.

Attributes	Description
	The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $L' = 0.53 * 0.75$ $= 0.39698$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $T_{xml} = 0.6 * 255$ $= 153$ $= 99(hex)$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$ • Convert the resultant HSL color to RGB

Attributes	Description
	[*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `4F81BD`. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $L' = 0.53 * 0.6 + (1 - .6)$ $= 0.71$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get `95B3D7`. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
    <attribute name="val" type="ST_Border" use="required"/>
    <attribute name="color" type="ST_HexColor" use="optional"/>
    <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
    <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
    <attribute name="space" type="ST_PointMeasure" use="optional"/>
    <attribute name="shadow" type="ST_OnOff" use="optional"/>
    <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.6.3 col (Single Column Definition)

This element specifies the properties for a single column of text within this section.

[*Example*: Consider a single column with a width of two inches, which also has a one-inch space after the column, resulting in the following WordprocessingML:

```
<w:cols … >
  <w:col w:w="2880" w:space="1440"/>
  …
</w:cols>
```

The resulting column specifies its width of 2,880 twentieths of a point and space following of 1,440 twentieths of a point. *end example*]

The contents of the col element are only used to calculate the number and size of columns if the fixedWidth attribute is set to `false` or omitted.

Parent Elements
cols (§2.6.4)

Attributes	Description
space (Space Before Following Column)	Specifies the spacing (in twentieths of a point) between the current column and the next column. [*Example*: Consider a text column that is to have a one-inch space after it. This text column spacing would therefore be 1x72=144 points wide, which translates to 1,440 twentieths of a point. The resulting WordprocessingML specifies that spacing width in twentieths of a point: `<w:col … w:space="1440"/>` *end example*]

Attributes	Description
	For the last text column in the section, no spacing is allowed after the column, and, if present, any space value is ignored. The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).
w (Column Width)	Specifies the width (in twentieths of a point) of this text column. [*Example*: Consider a text column, which is to be two inches wide. This text column would therefore be 2x72=144 points wide, which translates to 2,880 twentieths of a point. The resulting WordprocessingML specifies that column width in twentieths of a point: `<w:col … w:w="2880"/>` *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Column">
   <attribute name="w" type="ST_TwipsMeasure" use="optional"/>
   <attribute name="space" type="ST_TwipsMeasure" use="optional"/>
</complexType>
```

2.6.4 cols (Column Definitions)

This element specifies the set of columns defined for this section in the document.

[*Example*: Consider a document in which a section defines two columns of 4.16" and 1.83", respectively, resulting in the following WordprocessingML:

```
<w:cols w:equalWidth="0">
  <w:col w:w="2640" w:space="720"/>
  <w:col w:w="6000"/>
</w:cols>
```

The cols element defines the set of columns defined for this section, which because equalWidth is `0`, are defined by the number of col elements contained in the column definition. In this case, the first column is `2,640` twentieths of a point wide (as 2640/1440ths of an inch equals 1.83 inches) with one-half of an inch space after, and the second column is `6,000` twentieths of a point wide (4.16 inches). *end example*]

Based on the presence of the equalWidth attribute, a consumer shall render the columns using:

- If equalWidth is `true`, then the columns are defined using the data stored as attributes of the cols element (defined below).

- If equalWidth is `false`, then the columns are defined using the presence and data on each child col element (§2.6.3).

Parent Elements
sectPr (§2.6.17); sectPr (§2.6.18); sectPr (§2.6.19)

Child Elements	Subclause
col (Single Column Definition)	§2.6.3

Attributes	Description
equalWidth (Equal Column Widths)	Specifies whether all text columns in the current section are of equal width. If this attribute is present and its value is set to `true`, `on`, or `1`, then all columns for this text section are of an equal width and are calculated as follows: • Take width of page (from margin to margin) • Divide by number of columns specified in num attribute • For each column, leave space after as defined in the space attribute • Remaining width of each column is the text column width. If this attribute is present and its value is set to `false`, `off`, or `0`, then all columns for this text section are of different widths and are defined by each col element as follows: • Each col element defines a single column • Each w attribute defines the text column width • Each space attribute defines the space after the text column [*Example*: Consider a section with column information defined as follows: `<w:cols w:num="3" w:space="1440" w:equalWidth="1"> <w:col w:w="2880" w:space="2880" /> <w:col w:w="2880" w:space="1440" /> <w:col w:w="2880" /> </w:cols>` This set of columns has a equalWidth value set to `1`, therefore the col elements are ignored, and there are three equally sized columns (num value of `3`), each with one inch (space value of `1440` twentieths of a point) of space after. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
num (Number of Equal Width Columns)	Specifies the number of text columns in the current section. If all columns are not of equal width (the equalWidth attribute is not set), then this element is ignored, and the number of columns is defined by the number of col elements

Attributes	Description
	defined under the cols element. [*Example*: Consider a section with column information defined as follows: `<w:cols w:num="3" w:space="1440" w:equalWidth="1"> … </w:cols>` This set of columns has a equalWidth value set to 1, therefore there are three equally sized columns, as the num attribute has a value of 3. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
sep (Draw Line Between Columns)	Specifies if a vertical line is drawn between each of the text columns in this section. If set to true, on, or 1, then a vertical line shall be drawn in the center of the spacing between each column in this section. [Example: Consider a section with column information defined as follows: `<w:cols w:sep="1"> … </w:cols>` This set of columns has a sep value set to 1, therefore there shall be a vertical line separating each column in this section. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
space (Spacing Between Equal Width Columns)	Specifies the spacing between text columns in the current section. If all columns are not of equal width (the equalWidth attribute is not set), then this element is ignored, and the spacing after columns is defined by the space attribute on each of the col elements defined under the cols element. [*Example*: Consider a section with column information defined as follows: `<w:cols w:num="3" w:space="1440" w:equalWidth="1"> … </w:cols>` This set of columns has a equalWidth value set to 1, therefore there are three equally sized columns, each with one inch (space value of 1440 twentieths of a point) of space after. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

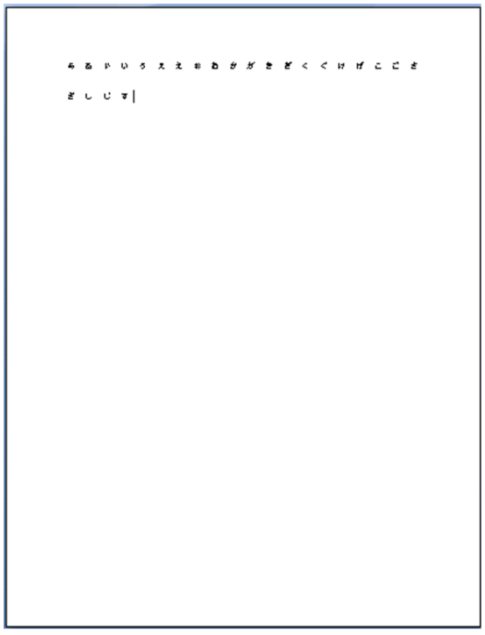
The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Columns">
   <sequence minOccurs="0">
      <element name="col" type="CT_Column" maxOccurs="45"/>
   </sequence>
   <attribute name="equalWidth" type="ST_OnOff" use="optional"/>
   <attribute name="space" type="ST_TwipsMeasure" use="optional"/>
   <attribute name="num" type="ST_DecimalNumber" use="optional"/>
   <attribute name="sep" type="ST_OnOff" use="optional"/>
</complexType>
```

2.6.5 docGrid (Document Grid)

This element specifies the settings for the document grid, which enables precise layout of full-width East Asian language characters within a document by specifying the desired number of characters per line and lines per page for all East Asian text content in this section.

[*Example*: Consider a document with the document grid defined to allow 20 characters per line, and 20 lines per page by snapping characters to the grid (type attribute of `snapToChars`) as follows:



As shown, this document allows for only 20 East Asian characters per line by adjusting the inter-character spacing to ensure that there are only 20 characters per line. *end example*]

If Latin text is interspersed on this line, then it is placed across the number of grid units needed to fit the content, but all other grid positions are unaffected.

[*Example*: Consider the example above with the addition of the text "Latin text" in English, as follows:

The Latin text spans two grid units, so it is placed in the center of those two units; no other grid positions are affected, so the text on the second line now spans two additional grid units. *end example*]

Parent Elements
sectPr (§2.6.17); sectPr (§2.6.18); sectPr (§2.6.19)

Attributes	Description
charSpace (Document Grid Character Pitch)	Specifies the number of characters to be allowed on the document grid for each line in this section. This attribute's value shall be specified by multiplying the difference between the desired character pitch and the character pitch for that character in the font size of the Normal font by 4096. This value shall then be used to add the character pitch for the specified point size to each character in the section [Note: This results in text in the Normal style having a specific number of characters per line. end note] [*Example*: Consider a section with a Normal font size of 11 points on which a 21 point pitch document grid has been defined.. The resulting WordprocessingML would be defined as follows: `<w:docGrid w:charSize="40960" …/>` The charSpace attribute specifies a value of 40960, which means that the delta between

Attributes	Description
	the character pitch of each character in the grid and the Normal font is 10 points, resulting in a character pitch of 11+10 = 21 points for all characters in this section. *end example*] Individual runs of text can override the line pitch information specified for the document grid by specifying that the run text shall not snap to the document grid via the snapToGrid element (§2.3.2.32). The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
linePitch (Document Grid Line Pitch)	Specifies the number of lines to be allowed on the document grid for the current page assuming all lines have equal line pitch applied to them. This line pitch shall not be added to any line which appears within a table cell unless the adjustLineHeightInTable element (§2.15.3.1) is present in the document's compatibility settings. This attribute is specified in twentieths of a point, and defines the pitch for each line of text on this page such that the desired number of single spaced lines of text fits on the current page. [*Example*: Consider a standard 8.5x11" page on which a 20 character wide, 20 line document grid has been defined. The resulting WordprocessingML would be defined as follows: `<w:docGrid w:linePitch="684" …/>` The linePitch attribute specifies that 34.2 points is to the amount of pitch allowed for each line on this page in order to maintain the specific document grid. *end example*] Individual paragraphs can override the line pitch information specified for the document grid by either: • Specifying an exact line spacing value using the lineRule attribute of value exact on the spacing element (§2.3.1.33). • Specifying that the paragraph text shall not snap to the document grid via the snapToGrid element (§2.3.1.32). The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
type (Document Grid Type)	Specifies the type of the current document grid, which defines the grid behavior. The grid can define a grid which snaps all East Asian characters to grid positions, but leaves Latin text with its default spacing; a grid which adds the specified character pitch to each character on each row; or a grid which affects only the line pitch for the current section. [*Example*: Consider the document discussed above with the document grid defined to

Attributes	Description
	allow 20 characters per line, and 20 lines per page by snapping characters to the grid as follows:  This document has a type attribute of `snapToChars`, which specifies that the grid shall force East Asian characters to fit 20 to a line. *end example*] The possible values for this attribute are defined by the ST_DocGrid simple type (§2.18.18).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DocGrid">
   <attribute name="type" type="ST_DocGrid"/>
   <attribute name="linePitch" type="ST_DecimalNumber"/>
   <attribute name="charSpace" type="ST_DecimalNumber"/>
</complexType>
```

2.6.6 formProt (Only Allow Editing of Form Fields)

This element specifies that the contents of the current section shall be protected such that they cannot be edited by a user (if the consumer is displaying the document and allowing the user to make modification) except for the text contained in any form field or embedded control that is part of the current section.

[*Example*: Consider a section consisting of three paragraphs of text and a single text form field, located at the beginning of the second paragraph. If this section is protected in this manner, a user would only be permitted to edit the contents of the text form field, and all other contents would be locked to prevent user edits. *end example*]

The enforcement of this property is determined by the documentProtection element (§2.15.1.28), as it is possible to specify protection without turning it on.

Parent Elements
sectPr (§2.6.17); sectPr (§2.6.18); sectPr (§2.6.19)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

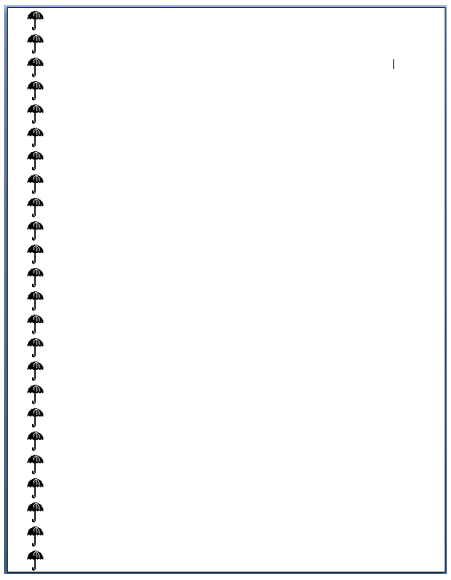
The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.6.7 left (Left Border)

This element specifies the presentation and display of the page border displayed at the left of each page in this section.

[*Example*: Consider a section in which all pages have a left border consisting of a repeated image of an umbrella, like this:



This border would result in the following WordprocessingML:

```
<w:sectPr>
  …
  <w:pgBorders>
    <w:left w:val="seattle" …/>
  </w:pgBorders>
  …
</w:sectPr>
```

Because the page only has a border at the left, only the left element is specified within the set of page borders. *end example*]

When a document has a left border that is relative to the page edges (using the offsetFrom attribute value of page on pgBorders), it shall span the left edge of the page at the location defined by its properties, stopping when:

- It intersects with the corresponding top or bottom page border (if one is specified).
- It reaches the edge of the page.

[*Example*: In the example above, no top or bottom border was specified in the WordprocessingML, so a consumer shall draw the border from one edge of the page to the other. *end example*]

When a document has a left border that is relative to the text (using the offsetFrom attribute value of `text` on pgBorders), it shall span only the necessary width to satisfy the requirement of spanning the width of the text.

Parent Elements

Parent Elements
pgBorders (§2.6.10)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value `auto`, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect.

Attributes	Description
	[*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object.
	
	When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points.
	
	When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border. If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value. If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.

Attributes	Description

	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`
	
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*]
	
	The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document.
	
	[*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:
	
	`<w:top … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:bottom … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:left … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:right … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	
	The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border.

Attributes	Description
	[*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 \\ = 102 \\ = 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}^{'} = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L^{'} = 0.53 * 0.75 \\ = 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from

Attributes	Description
	the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255 = 153 = 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `4F81BD`. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6) = 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get `95B3D7`. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).

Attributes	Description
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.6.8 lnNumType (Line Numbering Settings)

This element specifies the settings for line numbering to be displayed before each column of text in this section in the document.

[*Example*: Consider the line numbering used on each page of this document, which specifies: line numbering for each line, restarting at one at the top of each new page. This line-numbering scheme would be defined using the following WordprocessingML:

```
<w:sectPr>
  …
  <w:lnNumType w:countBy="1" />
</w:sectPr>
```

This content specifies that line numbers shall be included on each line, restart on each page (the default), be placed automatically based on the text (the default), and shall restart at one (the default). *end example*]

Parent Elements
sectPr (§2.6.17); sectPr (§2.6.18); sectPr (§2.6.19)

Attributes	Description
countBy (Line Number Increments to Display)	Specifies the line number increments to be displayed in the current document. Although each line has an associated line number, only lines which are an even multiple of this value shall be displayed. [*Example*: Consider a document in which only every fifth line shall have a line number. The resulting WordprocessingML for this setting would be: `<w:lnNumType … w:countBy="5"/>` This setting ensures that only lines whose number is a multiple of (e.g. 5, 10, and 15) will have a line number displayed. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
distance (Distance Between Text and Line Numbering)	Specifies the distance between the text margin and the edge of any line numbers appearing in that section. [*Example*: Consider a document in which the line numbering shall appear one-half inch from the text margin. The WordprocessingML for this setting is: `<w:lnNumType … w:distance="720"/>` The distance attribute specifies that there shall be a `720` twip spacing between the text margin and the *line numbering. end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

restart (Line Numbering Restart Setting)	Specifies when the line numbering in this section shall be reset to the line number specified by the start attribute's value.
	
	The line numbering increments for each line (even if it is not displayed) until it reaches the restart point specified by this element.
	
	[*Example*: Consider the line numbering used on each page of this document, which specifies that line numbering shall restart at the top of each new page. This line numbering setting would be defined using the following WordprocessingML:
	
	`<w:sectPr>`
	`…`
	`<w:lnNumType w:restart="newPage" ... />`
	`</w:sectPr>`
	
	The value of newPage specifies that the line numbers shall restart at the top of each page

Attributes	Description
	to the value specified by the start attribute. In this case, newPage is the default, so this value could have been omitted entirely. *end example*] The possible values for this attribute are defined by the ST_LineNumberRestart simple type (§2.18.54).
start (Line Numbering Starting Value)	Specifies the starting value used for the first line whenever the line numbering is restarted by use of the restart attribute. [*Example*: Consider a document in which line numbering shall appear on every fifth line, but the first line shall be treated as line number . This setting would require the following WordprocessingML syntax: `<w:lnNumType w:start="3" w:countBy="5"/>` The start attribute specifies that line numbers shall be counted starting from the number 3. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_LineNumber">
    <attribute name="countBy" type="ST_DecimalNumber" use="optional"/>
    <attribute name="start" type="ST_DecimalNumber" use="optional"/>
    <attribute name="distance" type="ST_TwipsMeasure" use="optional"/>
    <attribute name="restart" type="ST_LineNumberRestart" use="optional"/>
</complexType>
```

2.6.9 paperSrc (Paper Source Information)

This element specifies printer-specific settings for the printer tray(s) that shall be used to print different pages in this section in the document.

[Example: Consider a section which shall use the best possible tray when printing all pages in this section. This information is specified using the following WordprocessingML:

```
<w:paperSrc w:first="1" w:other="1" />
```

The attributes on the paperSrc element specify the printer codes for the trays to be used when printing this section. end example]

Parent Elements
sectPr (§2.6.17); sectPr (§2.6.18); sectPr (§2.6.19)

Attributes	Description

Attributes	Description
first (First Page Printer Tray Code)	Specifies a printer-specific code that uniquely identifies a specific printer tray to be used to print the first page of this section in the document. A first value of 1 (the default) is specifically used to indicate that the printer shall automatically select the appropriate printer tray based on the printed page size. [*Example*: Consider a section which shall use the best possible tray when printing the first page in this section. This information is specified using the following WordprocessingML: `<w:paperSrc w:first="1" w:other="1" />` The first attribute on the paperSrc element specifies that the printer shall automatically select the appropriate printer tray based on the printed page size when printing the first page in this section. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
other (Non-First Page Printer Tray Code)	Specifies a printer-specific code that uniquely identifies a specific printer tray to be used to print the each subsequent (non-first) page of this section in the document. An value of 1 (the default) is specifically used to indicate that the printer shall automatically select the appropriate printer tray based on the printed page size. [*Example*: Consider a section which shall use the best possible tray when printing the all pages in this section. This information is specified using the following WordprocessingML: `<w:paperSrc w:first="1" w:other="1" />` The other attribute on the paperSrc element specifies that the printer shall automatically select the appropriate printer tray based on the printed page size when printing all pages after the first in this section. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_PaperSource">
   <attribute name="first" type="ST_DecimalNumber"/>
   <attribute name="other" type="ST_DecimalNumber"/>
</complexType>
```

2.6.10 pgBorders (Page Borders)

This element specifies the page borders for each page in this section. Each child element of the pgBorders element specifies a specific of border (left, right, bottom, or top).

[*Example*: Consider a page that specifies a dashed line border around each of the four sides of the page, as follows:

This page border setting would be specified using the following WordprocessingML:

```
<w:pgBorders w:offsetFrom="page">
  <w:top w:val="dashed" w:sz="4" w:space="24" w:color="auto" />
  <w:left w:val="dashed" w:sz="4" w:space="24" w:color="auto" />
  <w:bottom w:val="dashed" w:sz="4" w:space="24" w:color="auto" />
  <w:right w:val="dashed" w:sz="4" w:space="24" w:color="auto" />
</w:pgBorders>
```

The four page borders are each uniquely defined by the top, left, bottom, and right elements, respectively. Global settings that define the placement of all page borders are stored on the pgBorders element directly. *end example*]

Parent Elements
sectPr (§2.6.17); sectPr (§2.6.18); sectPr (§2.6.19)

Child Elements	Subclause
bottom (Bottom Border)	§2.6.2
left (Left Border)	§2.6.7
right (Right Border)	§2.6.15
top (Top Border)	§2.6.21

Attributes	Description

display (Pages to Display Page Borders)	Specifies the pages in this section on which the page border shall be printed.
	
	If this attribute is omitted, then the page borders shall be displayed on all pages in this section (equivalent to a value of `allPages`).
	
	[*Example*: Consider a section in a document for which the page border shall only be printed on the first page. This setting is specified using the following WordprocessingML:
	
	`<w:pgBorders w:display="firstPage">`
	`  …`
	`</w:pgBorders>`
	
	The display attribute specifies that only the first page shall display the page border defined for this section. *end example*]
	
	The possible values for this attribute are defined by the ST_PageBorderDisplay simple type (§2.18.68).

offsetFrom (Page Border Positioning)	Specifies how the relative positioning of the page borders shall be calculated.
	
	If the value of this attribute is page, then the space attribute on each page border shall be interpreted as the distance from the edge of the page that shall be left before the page border.
	
	If the value of this attribute is `text`, then the space attribute on each page border shall be interpreted as the distance from the text margins that shall be left before the page border.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:top w:val="dashed" w:space="24" />`
	`  <w:left w:val="dashed" w:space="24" />`
	`  <w:bottom w:val="dashed" w:space="24"/>`
	`  <w:right w:val="dashed" w:space="24"/>`
	`</w:pgBorders>`
	
	This fragment specifies that the page borders shall be indented 24 points from the page extents.
	
	This is distinct from the following fragment with identical space attribute values:
	
	`<w:pgBorders w:offsetFrom="text">`
	`  <w:top w:val="dashed" w:space="24" />`
	`  <w:left w:val="dashed" w:space="24" />`
	`  <w:bottom w:val="dashed" w:space="24"/>`
	`  <w:right w:val="dashed" w:space="24"/>`

Attributes	Description
	</w:pgBorders> In this case, the page borders will be offset by 24 points, but in this case, that offset will be calculated relative to the text margins. *end example*] The possible values for this attribute are defined by the ST_PageBorderOffset simple type (§2.18.69).
zOrder (Z-Ordering of Page Border)	Specifies whether the page border is positioned above or below intersecting texts and objects in this document. [*Example*: Consider a document in which the page border shall be displayed below any intersecting text as follows:  This setting is specified by setting the zOrder attribute to back, which specifies that the page border shall be display behind all intersecting text and objects. *end example*] The possible values for this attribute are defined by the ST_PageBorderZOrder simple type (§2.18.70).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_PageBorders">
    <sequence>
        <element name="top" type="CT_Border" minOccurs="0"/>
        <element name="left" type="CT_Border" minOccurs="0"/>
        <element name="bottom" type="CT_Border" minOccurs="0"/>
        <element name="right" type="CT_Border" minOccurs="0"/>
    </sequence>
    <attribute name="zOrder" type="ST_PageBorderZOrder" use="optional"/>
    <attribute name="display" type="ST_PageBorderDisplay" use="optional"/>
    <attribute name="offsetFrom" type="ST_PageBorderOffset" use="optional"/>
</complexType>
```

2.6.11 pgMar (Page Margins)

This element specifies the page margins for all pages in this section.

[*Example*: Consider a page with a one-inch margin on all sides. Specifying these margins requires the following WordprocessingML:

```
<w:sectPr>
  <w:pgMar w:bottom="1440" w:top="1440" w:right="1440" w:left="1440"/>
  …
</w:sectPr>
```

This section specifies page margins of 1,440 twentieths of a point (one inch) on all sides. *end example*]

Parent Elements
sectPr (§2.6.17); sectPr (§2.6.18); sectPr (§2.6.19)

Attributes	Description

bottom (Page Bottom Spacing)	Specifies the distance (in twentieths of a point) between the bottom of the text margins for the main document and the bottom of the page for all pages in this section.
	
	If the value of bottom is non-negative, then the text will be placed at the greater of:
	• The value of bottom
	• The extent of the footer text
	
	[*Example*: Consider a document where the footer shall start one inch of the bottom of the page extent, but the contents of the main document story specify that they shall start one-half of an inchh from the page extents. To specify these boundaries, the following page margins may specified in the WordprocessingML:
	
	`<w:pgMar ... w:bottom="720" w:footer="1440"/>`
	
	This fragment specifies that the footer shall start 1440 twentieths of a point from the bottom of the page, but the main document story shall start 720 twentieths of a point from the bottom of the page. Since the footer extent is guaranteed to be greater in this case, the bottom text extent ends at the top of the footer region. *end example*]
	
	A negative value indicates that the contents of the main document shall be measured from the bottom of the page extent regardless of the footer for that document, and therefore shall overlap the footer text.
	
	[*Example*: Consider a document where the footer shall start one inch of the bottom of the page extent, but the contents of the main document story shall start one-half of an inch from the page extents. To specify these boundaries, the following page margins may specified in the WordprocessingML:
	
	`<w:pgMar ... w:bottom="-720" w:footer="1440"/>`
	
	This fragment specifies that the footer shall start 1440 twentieths of a point from the bottom of the page, and the main document story shall start 720 twentieths of a point

Attributes	Description
	from the bottom of the page. Since the value of bottom is negative in this case, the bottom text extent starts one-half of an inch from the bottom of the page and overlaps any footer text. *end example*] The possible values for this attribute are defined by the ST_SignedTwipsMeasure simple type (§2.18.88).
footer (Spacing to Bottom of Footer)	Specifies the distance (in twentieths of a point) from the bottom edge of the page to the bottom edge of the footer. [*Example*: Consider a document where the footer shall start one inch above the bottom of the page extent. To specify this boundary, the following page margins must specified in the WordprocessingML: `<w:pgMar … w:footer="1440"/>` This fragment specifies that the footer shall start 1440 twentieths of a point from the bottom of the page. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).
gutter (Page Gutter Spacing)	Specifies the page gutter for each page in the current section. The *page gutter* defines the amount of extra space added to the specified margin, above any existing margin values. [*Note*: This setting is typically used when a document is being created for binding, in order to ensure that the resulting margins are present after the binding gutter is consumed by the printed matter binding. *end note*] [*Example*: Consider a document where the margin shall start one inch of the left edge of the page extent after one-half of an inch is hidden by the page binding. To specify this condition, a user could simply use a left margin of 1.5 inches, which would be lost if the margins are later changed, or could specify a one-half inch gutters follows in the WordprocessingML: `<w:pgMar … w:gutter="720"/>` This fragment specifies that the gutter shall span 720 twentieths of a point, after which any margin value shall be added. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).
header (Spacing to Top of Header)	Specifies the distance (in twentieths of a point) from the top edge of the page to the top edge of the header.

Attributes	Description
	[*Example*: Consider a document where the header shall start two inches below the top of the page extent. To specify this boundary, the following page margins must specified in the WordprocessingML: `<w:pgMar … w:header="2880"/>` This fragment specifies that the header shall start 2880 twentieths of a point from the top of the page. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).
left (Left Margin Spacing)	Specifies the distance (in twentieths of a point) between the left edge of the page and the left edge of the text extents for this document. [*Example*: Consider a document where the left text extent shall start two inches inside the page extent. To specify this boundary, the following page margins must specified in the WordprocessingML: `<w:pgMar … w:left="2880"/>` This fragment specifies that the left margin shall span 2880 twentieths of a point from the left edge of the page. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).
right (Right Margin Spacing)	Specifies the distance (in twentieths of a point) between the right edge of the page and the right edge of the text extents for this document. [*Example*: Consider a document where the right text extent shall start one inch inside the page. To specify this boundary, the following page margins must specified in the WordprocessingML: `<w:pgMar … w:right="1440"/>` This fragment specifies that the right margin shall span 1440 twentieths of a point from the right edge of the page. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).
top (Top Margin Spacing)	Specifies the distance (in twentieths of a point) between the top of the text margins for the main document and the top of the page for all pages in this section.

Attributes	Description

	If the value of top is non-negative, then the text will be placed at the greater of:
	• The value of top
	• The extent of the header text
	
	[*Example*: Consider a document where the header shall start one inch from the top of the page extent, but the contents of the main document story specify that they shall start one-half of an inch from the page extents. To specify these boundaries, the following page margins may specified in the WordprocessingML:
	
	`<w:pgMar … w:top="720" w:header="1440"/>`
	
	This fragment specifies that the header shall start 1440 twentieths of a point from the top of the page, but the main document story shall start 720 twentieths of a point from the top of the page. Since the header extent is guaranteed to be greater in this case, the main text extent ends at the bottom of the header region. *end example*]
	
	A negative value indicates that the contents of the main document shall be measured from the top of the page extent regardless of the header for that document, and therefore shall overlap the header text.
	
	[*Example*: Consider a document where the header shall start one inch from the top of the page extent, but the contents of the main document story shall start one-half of an inch from the page extents. To specify these boundaries, the following page margins may specified in the WordprocessingML:
	
	`<w:pgMar ... w:top="-720"`
	`w:header="1440"/>`
	
	This fragment specifies that the header shall start 1440 twentieths of a point from the top of the page, and the main document story shall start 720 twentieths of a point from the top of the page. Since the value of top is negative in this case, the top text extent starts one-half of an inch from the top of the page and overlaps any header text. *end example*]
	
	The possible values for this attribute are defined by the ST_SignedTwipsMeasure simple type (§2.18.88).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_PageMar">
   <attribute name="top" type="ST_SignedTwipsMeasure" use="required"/>
   <attribute name="right" type="ST_TwipsMeasure" use="required"/>
   <attribute name="bottom" type="ST_SignedTwipsMeasure" use="required"/>
   <attribute name="left" type="ST_TwipsMeasure" use="required"/>
   <attribute name="header" type="ST_TwipsMeasure" use="required"/>
   <attribute name="footer" type="ST_TwipsMeasure" use="required"/>
   <attribute name="gutter" type="ST_TwipsMeasure" use="required"/>
</complexType>
```

2.6.12 pgNumType (Page Numbering Settings)

This element specifies the page numbering settings for all page numbers that appear in the contents of the current section.

[*Example*: Consider a section in which the page numbers shall start at page 25. The following WordprocessingML syntax specifies that requirement:

```
<w:sectPr>
  …
  <w:pgNumType w:start="25"/>
</w:sectPr>
```

The pgNumType element specifies that numbering on this section shall start from page number 25. *end example*]

Parent Elements
sectPr (§2.6.17); sectPr (§2.6.18); sectPr (§2.6.19)

Attributes	Description
chapSep (Chapter Separator Character)	Specifies the separator character that shall appear between the chapter and page number, if a chapter style has been set for page numbers in this section. If the chapStyle attribute is not present, or its specified heading level does not have an associated numbering format, then this value is ignored, since no chapter number is output by the field. [Example: Consider a section in a document in which the chapter shall be separated from the page number using a colon character. This constraint would be specified using the following WordprocessingML: `<w:pgNumType w:chapSep="colon" chapStyle="1" />` The chapSep attribute declares that the chapter and page number shall be separated by a colon (e.g. 1:1 for chapter one, page one). end example] The possible values for this attribute are defined by the ST_ChapterSep simple type (§2.18.9).
chapStyle (Chapter Heading Style)	Specifies the one-based index of the heading style applied to chapter titles in the document which shall be used as chapter headings in all page numbers for this section, by locating the nearest heading of that style and extracting the numbering information. If the specified heading style does not exist in the current section, or does not have a numbering format, then any previous level heading format shall be used as needed as the specified chapter number. If no heading has numbering information and/or is used in the

Attributes	Description
	section, then the chapter and chapter separator shall be omitted from the page numbering data. [*Example*: Consider a page number in a section with page numbering properties that specify a chapStyle of 1 (Heading 1 style) and a chapSep of dash. This means that for each page number in this section, the numbering value of the nearest Heading 1 style is used for the chapter value, and is followed by a dash, then the page n umber in that section. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
fmt (Page Number Format)	Specifies the number format that shall be used for all page numbering in this section. [*Example*: A fmt value of lowerLetter indicates that a consumer shall use lowercase letters for each page in this section: a,b,c… *end example*] The possible values for this attribute are defined by the ST_NumberFormat simple type (§2.18.66).
start (Starting Page Number)	Specifies the page number that appears on the first page of the section. If this value is omitted, numbering will continue from the highest page number in the previous section. [*Example*: Consider the following WordprocessingML: `<w:pgNumType w:fmt="2"/>` Because the start value is omitted, the page numbers in this section begin at the value of the highest page in the previous section. This means that if the previous section ended in page 7, this section would start with page 8. *end example]* The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_PageNumber">
   <attribute name="fmt" type="ST_NumberFormat" use="optional"/>
   <attribute name="start" type="ST_DecimalNumber" use="optional"/>
   <attribute name="chapStyle" type="ST_DecimalNumber" use="optional"/>
   <attribute name="chapSep" type="ST_ChapterSep" use="optional"/>
</complexType>
```

2.6.13 pgSz (Page Size)

This element specifies the properties (size and orientation) for all pages in the current section.\

[*Example*: Consider a section that shall be printed on A4 paper. The WordprocessingML for this paper size is as follows:

```
<w:pgSz w:w="11907" w:h="16839" />
```

This output states that all pages in this section shall be 11907 twentieths of a point wide (11907 twentieths of a point = 8.269") and 16839 twentieths of a point high (16939 twentieths of a point = 11.694"). *end example*]

Parent Elements
sectPr (§2.6.17); sectPr (§2.6.18); sectPr (§2.6.19)

Attributes	Description
code (Printer Paper Code)	Specifies a printer-specific paper code for the paper type, which shall be used by the printer for pages in this section. This code is stored to ensure the proper paper type is chosen if the specified paper size matches the sizes of multiple paper types supported by the current printer. [Example: Consider the following WordprocessingML fragment: `<w:pgSz … w:code="240" />` The code attribute specifies a value of 240, which will be sent to the printer and used by the printer to determine the appropriate paper type to use when printing. This value is not interpreted or modified other than storing it as specified by the printer. end example] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
h (Page Height)	Specifies the height (in twentieths of a point) for all pages in the current section. [*Example*: Consider the following WordprocessingML: `<w:pgSz w:w="15840" w:h="12240" />` All pages in this section are displayed on a page that is 12240 twentieths of a point (8.5") tall. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

Attributes	Description
orient (Page Orientation)	Specifies the orientation of all pages in this section. This information is used to determine the actual paper size to use on the printer. [*Example*: Pages 11" wide by 8.5" long in landscape mode use 8.5"x11" paper, because the width and height are reversed for pages in this landscape section with respect to the printed page. *end example*] This implies that the actual paper size width and height are reversed for pages in this section. If this attribute is omitted, then `portrait` shall be implied. [*Example*: Consider the following WordprocessingML: `<w:pgSz w:w="15840" w:h="12240" w:orient="landscape" />` Although the page width is 11", and page height is 8.5", according to the w and h attributes, because the orient attribute is set to `landscape`, pages in this section are printed on 8.5x11" paper in landscape mode. *end example*] The possible values for this attribute are defined by the ST_PageOrientation simple type (§2.18.71).
w (Page Width)	This attribute indicates the width (in twentieths of a point) for all pages in the current section. [*Example*: Consider the following WordprocessingML: `<w:pgSz w:w="15840" w:h="12240" />` All pages in this section are displayed on a page that is `15840` twentieths of a point (11") wide. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_PageSz">
   <attribute name="w" type="ST_TwipsMeasure" use="optional"/>
   <attribute name="h" type="ST_TwipsMeasure" use="optional"/>
   <attribute name="orient" type="ST_PageOrientation" use="optional"/>
   <attribute name="code" type="ST_DecimalNumber"/>
</complexType>
```

2.6.14 printerSettings (Reference to Printer Settings Data)

This element specifies an explicit relationship to a Printer Settings part containing information about the printer settings used for this section.

If this element is omitted, than no additional settings are associated with this section.

[*Example*: Consider a producer which needed to store additional printer settings for each section. A document from such a producer would have the following section properties:

```
<w:sectPr>
  ...
  <w:printerSettings r:id="rId10" />
</w:sectPr>
```

The resulting Main Document part would a relationship to the appropriate Printer Settings part with a relationship ID of `rId10`. *end example*]

Parent Elements
sectPr (§2.6.17); sectPr (§2.6.18); sectPr (§2.6.19)

Attributes	Description
id (Relationship to Part) Namespace: .../officeDocument/2006/relationships	Specifies the relationship ID to a specified part. The specified relationship shall match the type required by the parent element: • http://schemas.openxmlformats.org/officeDocument/2006/relationships/footer for the footerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/header for the headerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/font for the embedBold, embedBoldItalic, embedItalic, or embedRegular elements • http://schemas.openxmlformats.org/officeDocument/2006/relationships/printerSettings for the printerSettings element [*Example*: Consider an XML element which has the following id attribute: `<… r:id="rId10" />` The markup specifies the associated relationship part with relationship ID `rId1` contains the corresponding relationship information for the parent XML element. *end example*] The possible values for this attribute are defined by the ST_RelationshipId simple type (§7.8.2.1).

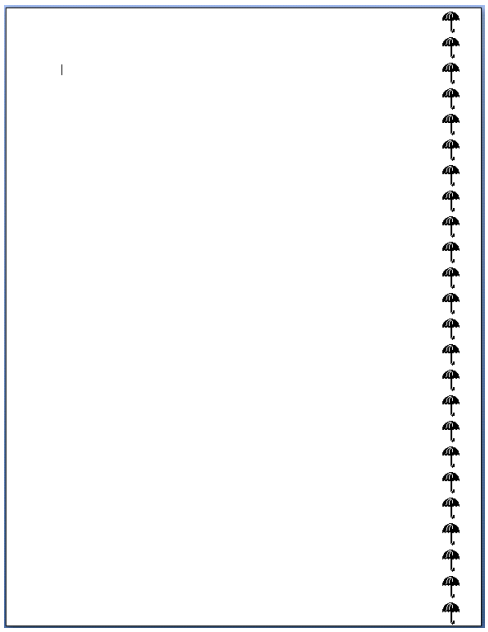
The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Rel">
   <attribute ref="r:id" use="required"/>
</complexType>
```

2.6.15 right (Right Border)

This element specifies the presentation and display of the page border displayed at the right of each page in this section.

[*Example*: Consider a section in which all pages shall have a right border consisting of a repeated image of an umbrella, like this:



This border would result in the following WordprocessingML:

```
<w:sectPr>
  …
  <w:pgBorders>
    <w:right w:val="seattle" …/>
  </w:pgBorders>
  …
</w:sectPr>
```

Because the page has a border at the right only, only the right element is specified within the set of page borders. *end example*]

When a document has a right border that is relative to the page edges (using the offsetFrom attribute value of page on pgBorders), it shall span the right edge of the page at the location defined by its properties, stopping when:

- It intersects with the corresponding top or bottom page border (if one is specified)
- It reaches the edge of the page.

[*Example*: In the example above, no top or bottom border was specified in the WordprocessingML, so a consumer shall draw the border from one edge of the page to the other. *end example*]

When a document has a right border that is relative to the text (using the offsetFrom attribute value of `text` on pgBorders), it shall only span the necessary width to satisfy the requirement of spanning the width of the text.

Parent Elements
pgBorders (§2.6.10)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value `auto`, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border	Specifies whether this border should be modified to create the appearance of a shadow.

Attributes	Description
Shadow)	For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object.
	
	When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points.
	
	When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border. If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this

Attributes	Description

	range may be reassigned to a more appropriate value.
	
	If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.
	
	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`
	
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*]
	
	The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document.
	
	[*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:
	
	`<w:top … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:bottom … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:left … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:right … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	
	The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeShade (Border Theme	Specifies the shade value applied to the supplied theme color (if any) for this border instance.

Attributes	Description
Color Shade)	If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255$$ $$= 102$$ $$= 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255$$ $$= 153$$ $$= 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6)$$ $$= 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2"`

Attributes	Description
	w:themeTint="99"/> *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: <w:left w:val="single" …/> This border's val is single, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.6.16 rtlGutter (Gutter on Right Side of Page)

This element specifies that the page gutter shall be placed on the right side of the page for this section only. The *page gutter* defines the amount of extra space added to the specified margin, above any existing margin values. [*Note*: This setting is typically used when a document is being created for binding, in order to ensure that the resulting margins are present after the binding gutter is consumed by the printed matter binding. *end note*]

If the gutter is set to the side of the page by the omission of the gutterAtTop element (§2.15.1.49), then each section's gutter is placed at the left by default, unless that default is overridden by the rtlGutter element.

[*Example*: Consider a document with three sections, with gutter properties defined as follows:

```
<w:p>
  <w:pPr>
    <w:sectPr>
      <w:pgMar w:gutter="1440" …/>
      …
    </w:sectPr>
  </w:pPr>
</w:p>
...
<w:p>
  <w:pPr>
    <w:sectPr>
      <w:pgMar w:gutter="1440" …/>
      <w:rtlGutter w:val="0" />
      …
    </w:sectPr>
  </w:pPr>
</w:p>
...
<w:p>
  <w:pPr>
    <w:sectPr>
      <w:pgMar w:gutter="1440" …/>
      <w:rtlGutter />
      …
    </w:sectPr>
  </w:pPr>
</w:p>
```

The first and second sections both place the gutter on the left side, the first by omission of the rtlGutter attribute, and the second by explicitly turning it off. The third section, however, moves the gutter to the right side via the use of the rtlGutter attribute. *end example*]

If the gutterAtTop element (§2.15.1.49) is specified and true, then each section's gutter is at the top and this setting is ignored.

Parent Elements
sectPr (§2.6.17); sectPr (§2.6.18); sectPr (§2.6.19)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element.

Attributes	Description
	A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.6.17 sectPr (Previous Section Properties)

When specified as a child element of sectPrChange, the sectPr element specifies a set of section properties that were modified when the document was set to track all revisions.

[*Example*: If the page orientation was changed with revision tracking enabled, the following WordprocessingML defines the contents of that change:

```
<w:sectPr>
  …
  <w:sectPrChange …>
    <w:sectPr>
      <w:pgSz w:w="15840" w:h="12240"/>
    </w:sectPr>
  </w:sectPrChange>
</w:sectPr>
```

The properties that were changed as part of this revision are stored in this sectPr element. *end example*]

Attributes	Description
rsidDel (Section Deletion Revision ID)	Specifies a unique identifier used to track the *editing session* when the section mark for this section was deleted from the document. All rsid* attributes throughout this document of an equal value, if present, shall indicate that those regions were modified during the same editing session. A producer may choose to increment the revision save ID value to indicate subsequent editing sessions (editing between save actions) to indicate the order of the saves performed. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).
rsidR (Section Addition Revision ID)	Specifies a unique identifier used to track the *editing session* when the section mark for this section was added to the document. All rsid* attributes throughout this document of an equal value, if present, shall indicate that those regions were modified during the same editing session.

Attributes	Description
	A producer may choose to increment the revision save ID value to indicate subsequent editing sessions (editing between save actions) to indicate the order of the saves performed. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).
rsidRPr (Physical Section Mark Character Revision ID)	Specifies a unique identifier used to track the editing session when the physical character representing this section mark was last formatted. All rsid* attributes throughout this document of an equal value, if present, shall indicate that those regions were modified during the same editing session. A producer may choose to increment the revision save ID value to indicate subsequent editing sessions (editing between save actions) to indicate the order of the saves performed. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).
rsidSect (Section Properties Revision ID)	Specifies a unique identifier used to track the editing session when the physical character representing this section mark was last formatted. All rsid* attributes throughout this document of an equal value, if present, shall indicate that those regions were modified during the same editing session. A producer may choose to increment the revision save ID value to indicate subsequent editing sessions (editing between save actions) to indicate the order of the saves performed. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

```
<complexType name="CT_SectPrBase">
   <sequence>
      <group ref="EG_SectPrContents" minOccurs="0"/>
   </sequence>
   <attributeGroup ref="AG_SectPrAttributes"/>
</complexType>
```

2.6.18 sectPr (Document Final Section Properties)

This element defines the section properties for the final section of the document. [*Note*: For any other section the properties are stored as a child element of the paragraph element corresponding to the last paragraph in the given section. *end note*]

[*Example*: Consider a document with multiple sections. For all sections except the final section, the sectPr element is stored as a child element of the last paragraph in the section. For the final section, this information is stored as the last child element of the body element, as follows:

```
<w:body>
  <w:p>
  …
  </w:p>
  …
  <w:sectPr>
    (final section's properties)
  </w:sectPr>
</w:body>
```

end example]

   </sequence>
   <attributeGroup ref="AG_SectPrAttributes"/>
</complexType>
```

2.6.19 sectPr (Section Properties)

This element defines the section properties for the a section of the document. [*Note*: For the last section in the document, the section properties are stored as a child element of the body element. *end note*]

[*Example*: Consider a document with multiple sections. For all sections except the final section, the sectPr element is stored as a child element of the last paragraph in the section, as follows:

```
<w:body>
  <w:p>
    <w:pPr>
      <w:sectPr>
        (final section's properties)
      </w:sectPr>
    </w:pPr>
  …
  </w:p>
  …
  <w:sectPr>
    (final section's properties)
  </w:sectPr>
</w:body>
```

end example]

Attributes	Description
rsidDel (Section Deletion Revision ID)	Specifies a unique identifier used to track the *editing session* when the section mark for this section was deleted from the document. All rsid* attributes throughout this document of an equal value, if present, shall indicate that those regions were modified during the same editing session.

Attributes	Description
	A producer may choose to increment the revision save ID value to indicate subsequent editing sessions (editing between save actions) to indicate the order of the saves performed. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).
rsidR (Section Addition Revision ID)	Specifies a unique identifier used to track the *editing session* when the section mark for this section was added to the document. All rsid* attributes throughout this document of an equal value, if present, shall indicate that those regions were modified during the same editing session. A producer may choose to increment the revision save ID value to indicate subsequent editing sessions (editing between save actions) to indicate the order of the saves performed. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).
rsidRPr (Physical Section Mark Character Revision ID)	Specifies a unique identifier used to track the editing session when the physical character representing this section mark was last formatted. All rsid* attributes throughout this document of an equal value, if present, shall indicate that those regions were modified during the same editing session. A producer may choose to increment the revision save ID value to indicate subsequent editing sessions (editing between save actions) to indicate the order of the saves performed. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).
rsidSect (Section Properties Revision ID)	Specifies a unique identifier used to track the editing session when the physical character representing this section mark was last formatted. All rsid* attributes throughout this document of an equal value, if present, shall indicate that those regions were modified during the same editing session. A producer may choose to increment the revision save ID value to indicate subsequent editing sessions (editing between save actions) to indicate the order of the saves performed. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SectPr">
   <sequence>
      <group ref="EG_HdrFtrReferences" minOccurs="0" maxOccurs="6"/>
      <group ref="EG_SectPrContents" minOccurs="0"/>
      <element name="sectPrChange" type="CT_SectPrChange" minOccurs="0"/>
   </sequence>
   <attributeGroup ref="AG_SectPrAttributes"/>
</complexType>
```

2.6.20 textDirection (Text Flow Direction)

This element specifies the direction of the text flow for this section.

[*Example*: Consider a document with a section in which text shall flow bottom to top vertically, and left to right horizontally. This setting requires the following WordprocessingML:

```
<w:sectPr>
  …
  <w:textDirection w:val="btLr" />
</w:sectPr>
```

The textDirection element specifies via the `btLr` value in the val attribute that the text flow shall go bottom to top, and left to right. *end example*]

Parent Elements
sectPr (§2.6.17); sectPr (§2.6.18); sectPr (§2.6.19)

Attributes	Description

val (Direction of Text Flow)	Specifies the direction of the text flow for this object.
	
	[*Example*: Consider a document with a section in which text shall flow bottom to top vertically, and left to right horizontally. This setting requires the following WordprocessingML:
	
	`<w:sectPr>`
	`  …`
	`  <w:textDirection w:val="btLr" />`
	`</w:sectPr>`
	
	The textDirection element specifies via the `btLr` value in the val attribute that the text flow shall go bottom to top, and left to right. *end example*]
	
	The possible values for this attribute are defined by the ST_TextDirection simple type (§2.18.100).

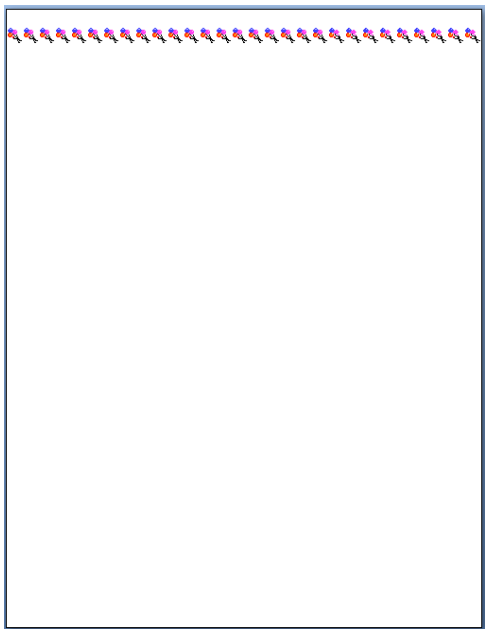
The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TextDirection">
   <attribute name="val" type="ST_TextDirection" use="required"/>
</complexType>
```

2.6.21 top (Top Border)

This element specifies the presentation and display of the page border displayed at the top of each page in this section.

[*Example*: Consider a section in which all pages shall have a top border consisting of a repeated image of balloons, like this:



This border would result in the following WordprocessingML:

```
<w:sectPr>
  …
  <w:pgBorders>
    <w:top w:val="balloons" .../>
  </w:pgBorders>
  …
</w:sectPr>
```

Because the page only has a border at the top, only the top element is specified within the set of page borders. *end example*]

When a document has a top border that is relative to the page edges (using an offsetFrom attribute value of page on pgBorders), it shall span the top edge of the page at the location defined by its properties, stopping when:

- It intersects with the corresponding left or right page border (if one is specified)
- It reaches the edge of the page.

[*Example*: In the example above, no left or right border was specified in the WordprocessingML, so a consumer shall draw the border from one edge of the page to the other. *end example*]

When a document has a top border that is relative to the text (using the offsetFrom attribute value of `text` on pgBorders), it shall only span the necessary width to satisfy the requirement of spanning the width of the text.

Parent Elements
pgBorders (§2.6.10)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value `auto`, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object.
	
	When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points.
	
	When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border.

Attributes	Description

	If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value.
	
	If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.
	
	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`
	
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*]
	
	The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document.
	
	[*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:
	
	`<w:top … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:bottom … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:left … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:right … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	
	The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type

Attributes	Description
	(§2.18.104).
themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 = 102 = 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75 = 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>`

Attributes	Description
	end example] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255 = 153 = 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$L' = L * Tint_{pct} + (1 - Tint_{pct})$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6) = 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$ and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting background's color attribute:

Attributes	Description
	<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/> *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: <w:left w:val="single" …/> This border's val is single, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.6.22 type (Section Type)

This element specifies the type of the current section. The section type specifies how the contents of the current section shall be placed relative to the previous section.

WordprocessingML supports five distinct types of section breaks:

- *Next page section breaks* (the default if type is not specified), which begin the new section on the following page.
- *Odd page section breaks*, which begin the new section on the next odd-numbered page.
- *Even page section breaks*, which begin the new section on the next even-numbered page.

- *Continuous section breaks*, which begin the new section on the following paragraph. This means that continuous section breaks might not specify certain page-level section properties, since they must be inherited from the following section. These breaks, however, can specify other section properties, such as line numbering and footnote/endnote settings.
- *Column section breaks*, which begin the new section on the next column on the page.

Parent Elements
sectPr (§2.6.17); sectPr (§2.6.18); sectPr (§2.6.19)

Attributes	Description

val (Section Type Setting)	Specifies the type of the current section.
	
	[*Example*: Consider a section that shall start on the next page in the document. The WordprocessingML specifying this would look like:
	
	`<w:sectPr>`
	`  …`
	`  <w:type w:val="nextPage"/>`
	`</w:sectPr>`
	
	The nextPage value specifies that this section starts on the next page. *end example*]
	
	The possible values for this attribute are defined by the ST_SectionMark simple type (§2.18.84).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SectType">
   <attribute name="val" type="ST_SectionMark"/>
</complexType>
```

2.6.23 vAlign (Vertical Text Alignment on Page)

This element specifies the vertical alignment for text on pages in the current section, relative to the top and bottom margins in the main document story on each page.

[*Example*: Consider a section used as a title page on which text shall be vertically centered. In order to center the text vertically on the page, the following WordprocessingML is used:

```
<w:sectPr>
  …
  <w:vAlign w:val="center" />
</w:sectPr>
```

The vAlign value of center specifies that text shall be laid out in the center of the top and bottom text margins for all pages in this section. *end example*]

Parent Elements
sectPr (§2.6.17); sectPr (§2.6.18); sectPr (§2.6.19)

Attributes	Description
val (Vertical Alignment Setting)	Specifies the vertical alignment for text between the top and bottom margins of the parent container (page or table cell). [*Example*: Consider a region where the text shall be vertically centered in the parent element. This would require a val value of `center`, in order to specify that all justification vertically shall be centered relative to the parent. For a section, this setting would be specified as follows: `<w:vAlign w:val="center" />` The val attribute of `center` specifies that the content is centered relative to its container (in this case, the page). *end example*] The possible values for this attribute are defined by the ST_VerticalJc simple type (§2.18.111).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_VerticalJc">
   <attribute name="val" type="ST_VerticalJc" use="required"/>
</complexType>
```

2.7 Styles

Within a WordprocessingML file, *styles* are predefined sets of table, numbering, paragraph, and/or character properties which can be applied to text within the document. This allows the formatting properties to be stored and managed independently from the content, allowing the look of document content to be changed in a single location (e.g. the look of all first-level headings is changed by changing the style with styleId `Heading1` rather than looking for and changing each paragraph in the document).

[*Example*: The Normal paragraph style in a word processing document can have any number of formatting properties, e.g. font face = Times New Roman; font size = 12pt; paragraph justification = left). All paragraphs which reference this paragraph style would automatically inherit these properties. *end example*]

Each style defined within a WordprocessingML document requires a *style definition*. The style definition contains all of the information needed by a consumer to store and display that style within a WordprocessingML document, and is defined using the style element. The style definition for any style in WordprocessingML can be divided into three segments The complete definition of style properties can be found on the reference for the style element (§2.7.3.17):

- General style properties
- Style types

- Type specific formatting properties

Each of these three segments are discussed in the following subclauses.

2.7.1 Style Inheritance

In order to compile the complete set of paragraph and character properties specified by any given style (as appropriate), a consumer must follow the rule of style inheritance to determine each property in that set.

Style inheritance states that styles of any given type may inherit from other styles of that type, and therefore a consumer must 'build up' the style information by following the inheritance tree. This inheritance is defined via the basedOn element, which specifies the styleId of the parent style.

[*Example*: The "Tristan Test" paragraph style can inherit properties from the "Heading 1" paragraph style, which itself can inherit properties from the "Normal" paragraph style. *end example*]

To build up the resulting style, a consumer must trace the hierarchy (following each basedOn value) back to a style which has no basedOn element (is not based on another style). The resulting style is then constructed by following each level in the tree, applying the specified paragraph and/or character properties as appropriate. When properties conflict, they are overridden by each subsequent level (this includes turning OFF a property set at an earlier level). Properties which are not specified simply do not change those specified at earlier levels.

[*Example*: Consider a character style Green which specifies only that the text color is green, but inherits from another character style Base which defines a font face of Arial, as well as bold:

```
<w:style w:type="character" w:styleId="Green">
  <w:name w:val="Green" />
  <w:basedOn w:val="Base" />
  <w:rPr>
    <w:color w:val="22B14C" />
  </w:rPr>
</w:style>
...
../Local Settings/Temp/styles.xml<w:style w:type="character" w:styleId="Base">
  <w:name w:val="Base" />
  <w:rPr>
    <w:rFonts w:ascii="Arial" w:hAnsi="Arial" />
    <w:b />
  </w:rPr>
</w:style>
```

The definition of the Green character style has a basedOn element which specifies the Base style. This means that any use of the Green style is defined as bold, green, Arial text. *end example*]

Conversely, a producer should not output any property on a style which has already been set by a previous level of the style hierarchy, as well as those which match the document defaults. This means that if the document

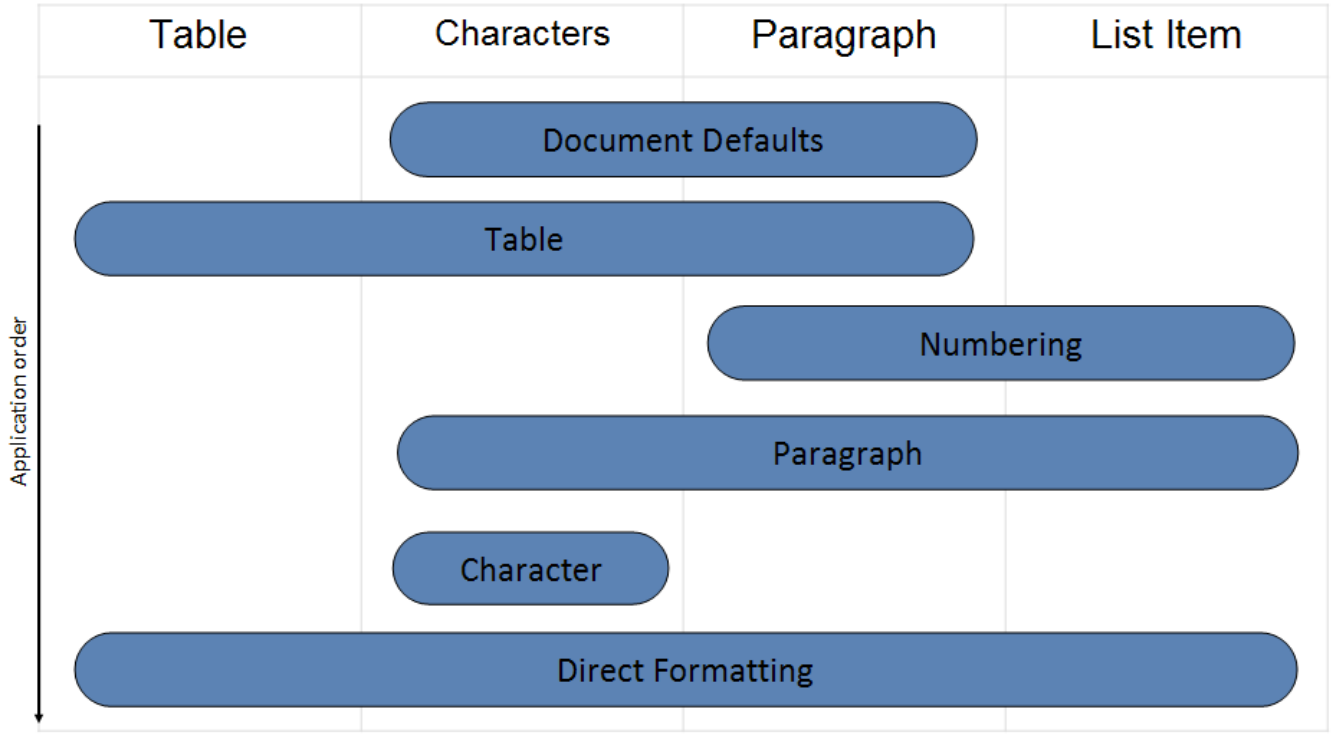
defaults or any previous level in a style's hierarchy specify a property which is unchanged at this level, that property should not be part of the style definition in the resulting WordprocessingML.

[*Example*: If the document default font is `Bauhaus 93` and the `Heading 1` style also specifies the Bauhaus 93 font, then a producer should not output any rFonts element for the `Heading 1` style definition, because that formatting is inherited from the document defaults. *end example*]

2.7.2 Style Hierarchy

With the various flavors of styles available (see each of the subclauses below), multiple style types can be applied to the same content within a file, which means that properties must be applied in a specific deterministic order. As with inheritance, the resulting formatting properties set by one type can be unchanged, removed, or altered by following types.

The following table illustrates the order of application of these defaults, and which properties are impacted by each:



This process can be described as follows:

- First, the document defaults are applied to all runs and paragraphs in the document.
- Next, the table style properties are applied to each table in the document, following the conditional formatting inclusions and exclusions specified per table.
- Next, numbered item and paragraph properties are applied to each paragraph formatted with a numbering style.

- Next, paragraph and run properties are applied to each paragraph as defined by the paragraph style.
- Next, run properties are applied to each run with a specific character style applied.
- Finally, we apply direct formatting (paragraph or run properties not from styles). If this direct formatting includes numbering, that numbering + the associated paragraph properties are applied.

2.7.3 General Style Properties

General style properties refer to the set of properties which can be used regardless of the type of style. [*Example*: Within a style definition the style name, additional aliases for the style, a style ID (used by the document content to refer to the style), if style is hidden, if style is locked, etc. are general style properties. *end example*]

[*Example:* Consider a style called Heading 1 in a document as follows:

```
<w:style w:type="paragraph" w:styleId="Heading1">
  <w:name w:val="heading 1"/>
  <w:basedOn w:val="Normal"/>
  <w:next w:val="Normal"/>
  <w:link w:val="Heading1Char"/>
  <w:priority w:val="1"/>
  <w:qformat/>
  <w:rsid w:val="00F303CE"/>
  ...
</w:style>
```

Above the formatting information specific to this style type are a set of general style properties which define information shared by all style types. *end example*]

2.7.3.1 aliases (Alternate Style Names)

This element specifies the set of alternative names for the parent style definition. These names may be used in an application's user interface as desired. The alternate names shall be stored in this element's val attribute, and each name shall be separated by one or more consecutive comma characters (Unicode character value 002C). All commas present shall be interpreted as separator character and never as part of an alternate style name.

If present, the alternate style names shall be used in the user interface in place of the built-in name specified in the name element (§2.7.3.9) when the appropriate value is set in the stylePaneFormatFilter element (§2.15.1.87).

If this element is omitted, then the style shall not have any alternate style names.

[*Example*: Consider a style with a primary name and two alternate names, defined using the name and aliases elements, as follows:

```
<w:style w:styleId="TestStyle" … >
  <w:name w:val="GD20Complex"/>
  <w:aliases w:val="Regional Growth,Complex Growth"/>
  …
</w:style>
```

This style specifies that it has the primary name `GD20Complex` using the name element (§2.7.3.9), as well as two alternate names `Regional Growth` and `Complex Growth` using the aliases element. *end example*]

Parent Elements
style (§2.7.3.17)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.7.3.2 autoRedefine (Automatically Merge User Formatting Into Style Definition)

This element specifies whether an application shall automatically modify this style when the contents of an entire paragraph in the document with this style applied are modified, ensuring that although only a single instance of text with this style was modified, that change is stored on the style and therefore propagated to all locations where the style is in use.

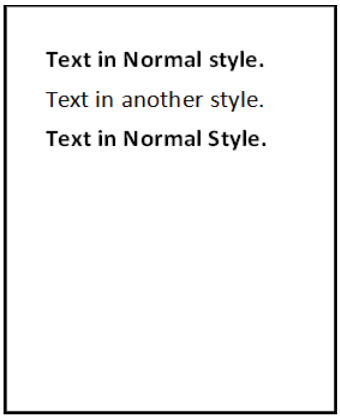
If this element is omitted, then formatting shall not automatically be merged back into the style definition.

[*Example*: Consider a style defined as follows in a WordprocessingML document:

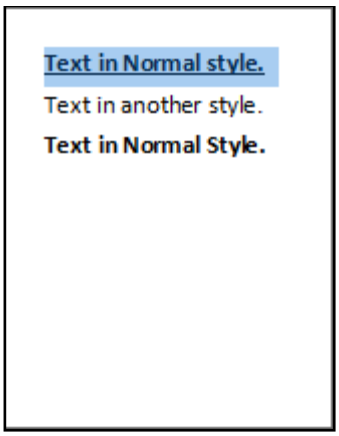
```
<w:style w:styleId="Normal" … >
  <w:name w:val="Normal"/>
  <w:autoRedefine/>
  <w:rPr>
    <w:b/>
  </w:rPr>
  …
</w:style>
```

This style specifies via the use of the autoRedefine element that any formatting applied to text which uses this style shall be merged back into the style definition (assuming, of course, that this is a paragraph style).

For example, consider a document which uses the `Normal` style as defined above:



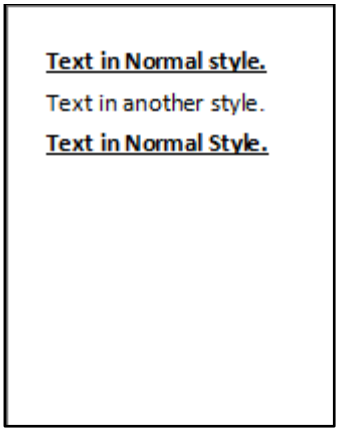
The first and third paragraphs use the `Normal` style, and hence have the bold property applied. If an application were to add the underline formatting to the entire first paragraph, as follows:



That property, rather than being saved as direct formatting, shall be used to update the associated `Normal` style to add this property, specified using the `u` element (§2.3.2.38).

```
<w:style w:styleId="Normal" … >
  <w:name w:val="Normal"/>
  <w:autoRedefine/>
  <w:rPr>
    <w:b/>
    <w:u/>
  </w:rPr>
  …
</w:style>
```

Since this property is automatically merged into the style, it would also appear on the third paragraph (note that the step above would normally be automatically modified into the state shown below, and not discrete as shown above).



end example]

Parent Elements
style (§2.7.3.17)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.7.3.3 basedOn (Parent Style ID)

This element specifies the style ID of the parent style from which this style inherits in the style inheritance. The *style inheritance* refers to a set of styles which inherit from one another to produce the resulting set of properties for a single style. The val attribute of this element specifies the styleId attribute for the parent style in the style inheritance.

If this element is omitted, then this style shall not be based on any other style in the current document (i.e. this element is the root of the style inheritance for a style). If no style in the current document specifies the styleId present in the val attribute, then this element shall be ignored (i.e. this element is the root of the style inheritance for a style).

If a style with this styleId is present, then it shall be subject to the following restrictions:

- If the current style is a table style, then the parent style must also be a table style, or this element shall be ignored.
- If the current style is a paragraph style, then the parent style must also be a paragraph style, or this element shall be ignored.
- If the current style is a character style, then the parent style must also be a character style, or this element shall be ignored.
- If the current style is a numbering style, then this element shall be ignored.

[*Example*: Consider three WordprocessingML character styles defined as follows:

- A character style with a styleId value of Strong whose properties consist of the bold property
- A character style with a styleId value of Underline whose properties consist of the underline property
- A character style with a styleId value of Emphasis whose properties consist of the italics property

Each of these character styles defines a single character formatting property. If the basedOn values for each element were defined as follows:

```
<w:style w:styleId="Strong">
  <w:basedOn w:val="Underline"/>
  …
  <w:rPr>
    <w:b/>
  </w:rPr>
</w:style>
<w:style w:styleId="Underline">
  <w:basedOn w:val="Emphasis"/>
  …
  <w:rPr>
    <w:u/>
  </w:rPr>
</w:style>
<w:style w:styleId="Emphasis">
  …
  <w:rPr>
    <w:i/>
  </w:rPr>
</w:style>
```

The Strong style is based on the Underline style which is in turn based on the Emphasis style. This means that the actual definition of the Strong style would be as follows:

- Bold
- Underline (inherited from Underline)
- Italics (inherited from Emphasis)

The style chain for the Strong style would be defined as follows:

- Emphasis
- Underline
- Strong

Similarly, the style chain for the Underline style would be defined as follows:

- Emphasis

- `Underline`

In each case, the style chain is the list of all styles which are combined in order to produce the entire set of properties for any given style. *end example*]

Parent Elements
style (§2.7.3.17)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.7.3.4 hidden (Hide Style From User Interface)

This element specifies whether this style shall be hidden from any and all user interfaces when this document is loaded by an application. If this element is set, then this style may be used to format content (i.e. any content which references this style shall have its properties as normal), but the style shall be hidden from all user

interface associated with that application. [*Note*: This setting is typically used to hide styles which are being used internally by an application which should not be used as formatting in a typical case. *end note*]

If this element is omitted, then the style shall not be required to be hidden from the user interface.

[*Example*: Consider a style with a primary name of `InternalStyle` that should not be displayed in any user interface. This requirement would be specified using the following WordprocessingML:

```
<w:style … w:styleId="Style2">
  <w:name w:val="InternalStyle"/>
  <w:hidden/>
  …
</w:style>
```

The hidden element specifies that this style definition shall be round-tripped with the file (since it is part of the document) but should not be displayed in any user interface associated with an application which processes this document. *end example*]

Parent Elements
style (§2.7.3.17)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.7.3.5 latentStyles (Latent Style Information)

This element specifies the properties which shall be applied to a set of latent styles for this document. *Latent styles* refer to any set of style definitions known to an application which have not been included in the current document. [*Example*: Latent styles may include additional styles known by a particular hosting application. *end example*]

When a style definition is embedded in a document, it specifies two distinct groups of properties:

- Behavior properties
- Formatting properties

Obviously, embedding all the styles known to a particular application in each document which it produces would drastically increase the file size. Latent styles provide a way to store pieces of information for the first group (behavior properties) which must be specified for all styles known to an application without requiring the storage of the second group (formatting properties).

[*Example*: Consider a WordprocessingML document which contains text specified in one of two styles: `Heading1` or `Normal`. Based on this, the document only needs to store the formatting properties for those two styles, saving the additional overhead which would be required to save all of the styles supported by the hosting application.

However, if the documentProtection element (§2.15.1.28) specifies that the hosting application shall prevent the use of any style whose locked element (§2.7.3.7) is set to `false`, then the locking state of all styles known to that application become useful and necessary to maintain the current state of the document. Using latent styles, this information may be stored without storing any formatting properties for those styles.

For example, if all styles which are not stored in the document shall be locked except for the style with a primary name (§2.7.3.9) of `Heading 2`. This requirement would be specified using latent styles as follows:

```
<w:latentStyles … w:defLockedState="true">
  <w:lsdException w:name="Heading 2" w:locked="false"/>
</w:latentStyles>
```

The latentStyles element specifies that all latent styles known to any hosting application shall have a default locking state of `true` except for any style known to the hosting application with a primary name of `Heading 2`, whose latent style definition specifies that its locked state shall be `false`. *end example*]

Parent Elements
styles (§2.7.3.18)

Child Elements	Subclause
lsdException (Latent Style Exception)	§2.7.3.8

Attributes	Description

count (Latent Style Count)	Specifies the number of known styles which shall be initialized to the current latent style defaults when this document is first processed. [*Note*: This property may be used by an application as needed to ensure that only the number of styles known when this document was created are initialized with the defaults on the parent element, and that all new known styles use their default values. *end note*]
	
	[*Example*: Consider a WordprocessingML document in which only the first 20 latent styles shall be initialized. This requirement would be specified as follows:
	
	`<w:latentStyles w:count="20" … >`
	`  …`
	`</w:latentStyles>`
	
	The count attribute specifies that 20 known styles shall be initialized to the default settings when the document is first opened, and any additional styles should use the defaults defined by the application. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

defLockedState (Default Style Locking Setting)	Specifies the default setting for the locked element (§2.7.3.7) which shall be applied to any style made available by the hosting application which is not explicitly defined in the current document. This setting shall be overridden for every style for which a latent style exception (§2.7.3.8) exists.
	
	If this element is omitted, the default locked state for all latent styles in the current document shall be false.
	
	[*Example*: Consider a WordprocessingML document in which all styles which are not stored in the document shall be locked. This requirement would be specified using latent styles as follows:
	
	`<w:latentStyles … w:defLockedState="true">`
	`  …`
	`</w:latentStyles>`
	
	The defLockedState attribute specifies that all latent styles in the current document shall have a locked element setting of true by default. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

defQFormat (Default Primary Style Setting)	Specifies the default setting for the qFormat element (§2.7.3.14) which shall be applied to any style made available by the hosting application which is not explicitly defined in the current document. This setting shall be overridden for every style for which a latent style exception (§2.7.3.8) exists. If this element is omitted, the default qFormat state for all latent styles in the current document shall be false.

Attributes	Description

	[*Example*: Consider a WordprocessingML document in which all styles which are not stored in the document shall not be marked as primary styles. This requirement would be specified using latent styles as follows:
	
	`<w:latentStyles … w:defQFormat="false">`
	`  …`
	`</w:latentStyles>`
	
	The defQFormat attribute specifies that all latent styles in the current document shall have a qFormat element setting of `false` by default. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

defSemiHidden (Default Semi-Hidden Setting)	Specifies the default setting for the semiHidden element (§2.7.3.16) which shall be applied to any style made available by the hosting application which is not explicitly defined in the current document. This setting shall be overridden for every style for which a latent style exception (§2.7.3.8) exists.
	
	If this element is omitted, the default semiHidden state for all latent styles in the current document shall be `false`.
	
	[*Example*: Consider a WordprocessingML document in which all styles which are not stored in the document shall not be marked as semi-hidden. This requirement would be specified using latent styles as follows:
	
	`<w:latentStyles … w:defSemiHIdden="false">`
	`  …`
	`</w:latentStyles>`
	
	The defSemiHidden attribute specifies that all latent styles in the current document shall have a semiHidden element setting of `false` by default. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

defUIPriority (Default User Interface Priority Setting)	Specifies the default setting for the uiPriority element (§2.7.3.19) which shall be applied to any style made available by the hosting application which is not explicitly defined in the current document. This setting shall be overridden for every style for which a latent style exception (§2.7.3.8) exists. If this element is omitted, the default uiPriority state for all latent styles in the current document shall be 99. [*Example*: Consider a WordprocessingML document in which all styles which are not stored in the document shall not be marked as semi-hidden. This requirement would be specified using latent styles as follows: `<w:latentStyles … w:defUIPriority="10">`

Attributes	Description
	… </w:latentStyles> The defUIPriority attribute specifies that all latent styles in the current document shall have a uiPriority element setting of 10 by default. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
defUnhideWhenUsed (Default Hidden Until Used Setting)	Specifies the default setting for the unhideWhenUsed element (§2.7.3.20) which shall be applied to any style made available by the hosting application which is not explicitly defined in the current document. This setting shall be overridden for every style for which a latent style exception (§2.7.3.8) exists. If this element is omitted, the default unhideWhenUsed state for all latent styles in the current document shall be false. [*Example*: Consider a WordprocessingML document in which all styles which are not stored in the document shall be hidden until they are used in the document's contents. This requirement would be specified using latent styles as follows: <w:latentStyles … w:defUnhideWhenUsed="true"> … </w:latentStyles> The defUnhideWhenUsed attribute specifies that all latent styles in the current document shall have a unhideWhenUsed element setting of true by default. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_LatentStyles">
   <sequence>
      <element name="lsdException" type="CT_LsdException" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
   <attribute name="defLockedState" type="ST_OnOff"/>
   <attribute name="defUIPriority" type="ST_DecimalNumber"/>
   <attribute name="defSemiHidden" type="ST_OnOff"/>
   <attribute name="defUnhideWhenUsed" type="ST_OnOff"/>
   <attribute name="defQFormat" type="ST_OnOff"/>
   <attribute name="count" type="ST_DecimalNumber"/>
</complexType>
```

2.7.3.6 link (Linked Style Reference)

This element specifies the pairing of styles which comprise a linked style. A *linked style* is a grouping of a paragraph style and character style which is used in a user interface to allow the same set of formatting properties to be applied:

- To the contents of one or more entire paragraphs (i.e. as a paragraph style)
- To the contents of one or more runs within a paragraph (i.e. as a character style)

Each style continues to exist independently in the file format as there is both a paragraph and character style present within the styles element (§2.7.3.18), however these two styles shall be merged into one and applied appropriately based on whether they are applied to run(s) or paragraph(s), by referencing the styleId attribute of the paired linked style via this element's val attribute.

If this element is omitted, then this style is not part of a linked style pairing. If no style in the current document specifies the styleId present in the val attribute, then this element shall be ignored.

If a style with this styleId is present, then it shall be subject to the following restrictions:

- If the parent style is a table style, then this element shall be ignored.
- If the parent style is a paragraph style, then the parent style must be a character style, or this element shall be ignored.
- If the parent style is a character style, then the parent style must be a paragraph style, or this element shall be ignored.
- If the parent style is a numbering style, then this element shall be ignored.

[*Example*: Consider a linked style defined as follows in a WordprocessingML document:

```
<w:style w:type="paragraph" w:styleId="TestParagraphStyle">
  <w:link w:val="TestCharacterStyle"/>
  …
</w:style>
<w:style w:type="character" w:styleId="TestCharacterStyle">
  <w:link w:val="TestParagraphStyle"/>
  …
</w:style>
```

This pairing of a paragraph style and a character style are linked via the link element, which is used the reference the styleId of the paragraph style from the character style definition and vice versa. Because this pairing is valid based on the rules above, the resulting combination shall be used as a linked style, which appears as one style in an application, but uses the character and/or paragraph style as appropriate. *end example*]

Parent Elements
style (§2.7.3.17)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.7.3.7 locked (Style Cannot Be Applied)

This element specifies whether an application shall prevent the use of this style when this document is loaded and/or modified. If this element is set, then this style may be used to format existing content (i.e. any content which references this style shall have its properties as normal), but new instances of the style shall be prevented from being applied via all mechanisms associated with that application.

If this element is omitted, then the use of the style shall not be prevented by an application processing this document.

[*Example*: Consider a style with a primary name of `Test Style` which should be locked, and prevented from being added to any content in a given document. This requirement would be specified using the following WordprocessingML:

```
<w:style … w:styleId="TestStyle">
  <w:name w:val="Test Style"/>
  <w:locked/>
  …
</w:style>
```

The presence of the locked element specifies that this style definition shall new instances of the style shall be prevented from being applied via all mechanisms associated with that application. *end example*]

Parent Elements
style (§2.7.3.17)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.7.3.8 lsdException (Latent Style Exception)

This element specifies the properties which shall be applied a single latent style for this document. *Latent styles* refer to any set of known style definitions which have not been included in the current document.

[*Example*: Consider a WordprocessingML document which contains text specified in one of two styles: Heading1 or Normal. Based on this, the document only needs to store the formatting properties for those two styles, saving the additional overhead which would be required to save all of the styles supported by the hosting application.

However, if the documentProtection element (§2.15.1.28) specifies that the hosting application shall prevent the use of any style whose locked element (§2.7.3.7) is set to `false`, then the locking state of all styles known to that application become useful and necessary to maintain the current state of the document. Using latent styles, this information may be stored without storing any formatting properties for those styles.

For example, if all styles which are not stored in the document shall be locked except for the style with a primary name (§2.7.3.9) of `Heading 2`. This requirement would be specified using latent styles as follows:

```
<w:latentStyles … w:defLockedState="true">
  <w:lsdException w:name="Heading 2" w:locked="false"/>
</w:latentStyles>
```

The lsdException element specifies that the latent style with a primary name of `Heading 2` shall have a locked state setting of `false`. *end example*]

Parent Elements
latentStyles (§2.7.3.5)

Attributes	Description

locked (Latent Style Locking Setting)	Specifies the default setting for the locked element (§2.7.3.7) which shall be applied to the latent style with the matching style name value.
	
	If this element is omitted, the default locked state for this latent style shall be determined by the defLockedState attribute on the parent latentStyles element.
	
	[*Example*: Consider a WordprocessingML document in which all styles which are not stored in the document shall be locked except for the `TestStyle` style. This requirement would be specified using latent styles as follows:
	
	`<w:latentStyles … w:defLockedState="true">`
	`  <w:lsdException w:name="TestStyle" w:locked="false"/>`
	`</w:latentStyles>`
	
	The locked attribute on the latent style exception specifies that the `TestStyle` style shall have a locked element setting of `false` by default. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

name (Primary Style Name)	Specifies the primary name for the style which shall inherit this set of latent style property exceptions. If the current application does not know of an internal primary style with the current name, then this set of latent style exceptions may be ignored. [*Example*: Consider a WordprocessingML document in which all styles which are not stored in the document shall be locked except for the `TestStyle` style. This requirement

Attributes	Description

	would be specified using latent styles as follows:
	
	`<w:latentStyles … w:defLockedState="true">`
	`  <w:lsdException w:name="TestStyle" w:locked="false"/>`
	`</w:latentStyles>`
	
	The name attribute on the latent style exception specifies that the `TestStyle` style shall have this set of latent style properties (if the application knows of a style with this name). *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

qFormat (Latent Style Primary Style Setting)	Specifies the default setting for the qFormat element (§2.7.3.14) which shall be applied to the latent style with the matching style name value.
	
	If this element is omitted, the default qFormat state for this latent style shall be determined by the defQFormat attribute on the parent latentStyles element.
	
	[*Example*: Consider a WordprocessingML document in which all styles which are not stored in the document shall not be primary styles except for the `TestStyle` style. This requirement would be specified using latent styles as follows:
	
	`<w:latentStyles … w:defQFormat="false">`
	`  <w:lsdException w:name="TestStyle" w:qFormat="true"/>`
	`</w:latentStyles>`
	
	The qFormat attribute on the latent style exception specifies that the `TestStyle` style shall have a qFormat element setting of `true` by default. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

semiHidden (Semi hidden text override)	Specifies the default setting for the semiHidden element (§2.7.3.16) which shall be applied to the latent style with the matching style name value.
	
	If this element is omitted, the default semiHidden state for this latent style shall be determined by the defSemiHidden attribute on the parent latentStyles element.
	
	[*Example*: Consider a WordprocessingML document in which all styles which are not stored in the document shall not be semi-hidden except for the `TestStyle` style. This requirement would be specified using latent styles as follows:
	
	`<w:latentStyles … w:defSemiHidden="false">`
	`  <w:lsdException w:name="TestStyle" w:semiHidden="true"/>`
	`</w:latentStyles>`
	
	The semiHidden attribute on the latent style exception specifies that the `TestStyle` style shall have a semiHidden element setting of `true` by default. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

uiPriority (Override default sorting order)	Specifies the default setting for the uiPriority element (§2.7.3.19) which shall be applied to the latent style with the matching style name value.
	
	If this element is omitted, the default uiPriority state for this latent style shall be determined by the defUIPriority attribute on the parent latentStyles element.
	
	[*Example*: Consider a WordprocessingML document in which all styles which are not stored in the document shall have a priority value of 10 except for the TestStyle style. This requirement would be specified using latent styles as follows:
	
	`<w:latentStyles … w:defUIPriority="10">`
	`  <w:lsdException w:name="TestStyle" w:uiPriority="25"/>`
	`</w:latentStyles>`
	
	The uiPriority attribute on the latent style exception specifies that the TestStyle style shall have a uiPriority element setting of 25 by default. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

unhideWhenUsed (Unhide when used)	Specifies the default setting for the unhideWhenUsed element (§2.7.3.20) which shall be applied to the latent style with the matching style name value.
	
	If this element is omitted, the default unhideWhenUsed state for this latent style shall be determined by the defUnhideWhenUsed attribute on the parent latentStyles element.
	
	[*Example*: Consider a WordprocessingML document in which all styles are to be hidden until used except for the TestStyle style. This requirement would be specified using latent styles as follows:
	
	`<w:latentStyles … w:defUnhideWhenUsed="true">`
	`  <w:lsdException w:name="TestStyle" w:unhideWhenUsed="false"/>`
	`</w:latentStyles>`
	
	The unhideWhenUsed attribute on the latent style exception specifies that the TestStyle style shall have an unhideWhenUsed element setting of false by default. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_LsdException">
    <attribute name="name" type="ST_String" use="required"/>
    <attribute name="locked" type="ST_OnOff"/>
    <attribute name="uiPriority" type="ST_DecimalNumber"/>
    <attribute name="semiHidden" type="ST_OnOff"/>
    <attribute name="unhideWhenUsed" type="ST_OnOff"/>
    <attribute name="qFormat" type="ST_OnOff"/>
</complexType>
```

2.7.3.9 name (Primary Style Name)

This element specifies the primary name for the current style in the document. This name may be used in an application's user interface as desired. The actual primary name for this style is stored in its val attribute.

If present, the alternate style names (§2.7.3.1) shall be used in the user interface in place of the built-in name specified when the appropriate value is set in the stylePaneFormatFilter element (§2.15.1.86).

If this element is omitted, then the style shall not have a primary style name.

[*Example*: Consider a style with a primary name and two alternate names, defined using the name and aliases elements, as follows:

```
<w:style w:styleId="TestStyle" … >
  <w:name w:val="GD20Complex"/>
  <w:aliases w:val="Regional Growth,Complex Growth"/>
  …
</w:style>
```

This style specifies that it has the primary name GD20Complex using the name element. *end example*]

Parent Elements
style (§2.7.3.17)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`

Attributes	Description

	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.7.3.10 next (Style For Next Paragraph)

This element specifies the style which shall automatically be applied to a new paragraph created following a paragraph with the parent paragraph style applied. [*Note*: This setting is typically used when the use of the current style is limited to one paragraph at most, and it would typically be undesirable to apply this style to following paragraphs - for example, a title style may specify that its following paragraphs shall return to regular text formatting. *end note*]

If this element is specified on a style of any type other than a paragraph style, this element shall be ignored. If no style whose styleId matches the val attribute of this element exists or that style is not a paragraph style, this element shall be ignored.

If this element is omitted, then the following paragraph shall use the same paragraph style as the current paragraph.

[*Example*: Consider a style defined as follows in a WordprocessingML document:

```
<w:style w:styleId="TestParagraphStyle" … >
  <w:name w:val="Test Paragraph Style"/>
  <w:next w:val="AnotherParagraphStyle"/>
  <w:rPr>
    <w:b/>
  </w:rPr>
  …
</w:style>
```

This style specifies via the use of the next element that the style for the next paragraph in the document shall be the paragraph style whose styleId attribute value is `AnotherParagraphStyle` (if such a paragraph style exists). *end example*]

Parent Elements
style (§2.7.3.17)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.7.3.11 personal (E-Mail Message Text Style)

This element specifies that the parent style, when in use in the context of an e-mail message, was used by default to format all message text from one or more users. [*Note*: This setting does not provide any additional semantic about the style, but may be used in the context of e-mail to automatically reformat the contents of the e-mail message while ignoring any content to which styles were deliberately applied (since this style was implicitly applied to message text without user interaction). *end note*]

If this element is specified on a style of any type other than a character style, this element shall be ignored. If no style whose styleId matches the val attribute of this element exists or that style is not a character style, this element shall be ignored.

If this element is omitted, then the current style shall not be considered a message text style in the context of e-mail messages.

[*Example*: Consider a style defined as follows in a WordprocessingML document:

```
<w:style w:styleId="EmailText" w:type="character" >
  <w:name w:val="EmailText"/>
  <w:personal w:val="true" />
  <w:rPr>
    …
  </w:rPr>
</w:style>
```

This style specifies via the use of the personal element that this style is a style used to format message text in the context of e-mail. *end example*]

Parent Elements
style (§2.7.3.17)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.7.3.12 personalCompose (E-Mail Message Composition Style)

This element specifies that the parent style, when in use in the context of an e-mail message, may be used by default to format new message text within the e-mail message. [*Note*: This setting does not provide any additional semantic about the style, but may be used in the context of e-mail to automatically format the contents of new test in the e-mail message. *end note*]

If this element is specified on a style of any type other than a character style, this element shall be ignored. If no style whose styleId matches the val attribute of this element exists or that style is not a character style, this element shall be ignored.

If this element is omitted, then the current style shall not be considered a message composition text style in the context of e-mail messages.

[*Example*: Consider a style defined as follows in a WordprocessingML document:

```
<w:style w:styleId="EmailText" w:type="character" >
  <w:name w:val="EmailText"/>
  <w:personalCompose w:val="true" />
  <w:rPr>
    …
  </w:rPr>
</w:style>
```

This style specifies via the use of the personalCompose element that this style is a style used to format new message text in the context of e-mail. *end example*]

Parent Elements
style (§2.7.3.17)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.7.3.13 personalReply (E-Mail Message Reply Style)

This element specifies that the parent style, when in use in the context of an e-mail message, may be used by default to format existing message text within the e-mail message when a new reply is generated. [*Note*: This setting does not provide any additional semantic about the style, but may be used in the context of e-mail to automatically format the contents of existing test in the e-mail message. *end note*]

If this element is specified on a style of any type other than a character style, this element shall be ignored. If no style whose styleId matches the val attribute of this element exists or that style is not a character style, this element shall be ignored.

If this element is omitted, then the current style shall not be considered a message reply text style in the context of e-mail messages.

[*Example*: Consider a style defined as follows in a WordprocessingML document:

```
<w:style w:styleId="EmailText" w:type="character" >
  <w:name w:val="EmailText"/>
  <w:personalReply w:val="true" />
  <w:rPr>
    …
  </w:rPr>
</w:style>
```

This style specifies via the use of the personalReply element that this style is a style used to format existing message text in the context of e-mail. *end example*]

Parent Elements
style (§2.7.3.17)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted.

Attributes	Description
	A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.7.3.14 qFormat (Primary Style)

This element specifies whether this style shall be treated as a primary style when this document is loaded by an application. If this element is set, then this style has been designated as being particularly important for the current document, and this information may be used by an application in any means desired. [*Note*: This setting does not imply any behavior for the style, only that the style is of particular significance for this document. *end note*]

If this element is omitted, then the style shall not be considered a primary style for this document.

[*Example*: Consider a style with a primary name of `PrimaryStyleExample` that should be treated as a primary style for the document. This requirement would be specified using the following WordprocessingML:

```
<w:style … w:styleId="PStyle">
  <w:name w:val="PrimaryStyleExample"/>
  <w:qFormat/>
  …
</w:style>
```

The qFormat element specifies that this style definition shall be treated as a primary style for this document. *end example*]

Parent Elements
style (§2.7.3.17)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element.

Attributes	Description
	A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.7.3.15 rsid (Revision Identifier for Style Definition)

This element specifies a unique four digit number which shall be used to determine the editing session in which this style definition was last modified. This value shall follow this following constraint: All document elements which specify the same rsid* values must correspond to changes made during the same editing session. An *editing session* is defined as the period of editing which takes place between any two subsequent save actions. [*Note*: This setting does not imply any behavior for the style, only that the style was last modified during one particular editing session. This information may be interpreted by an application in any manner desired. *end note*]

If this element is omitted, then no revision identifier shall be associated with the parent style definition.

[*Example*: Consider a style with a primary name of PrimaryStyleExample that is defined as follows:

```
<w:style … w:styleId="PStyle">
  <w:name w:val="PrimaryStyleExample"/>
  <w:rsid w:val="3E412D01"/>
  …
</w:style>
```

The rsid element specifies that this style definition was last edited in the editing session corresponding to the value 3E412D01. *end example*]

Parent Elements
style (§2.7.3.17)

Attributes	Description
val (Long Hexadecimal Number Value)	Specifies a number value specified as a four digit hexadecimal number), whose contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following value for an attribute of type ST_LongHexNumber: `00BE2C6C`. This value is valid, as it contains four hexadecimal digits, each an encoding of an octet of the actual decimal number value. It may therefore be interpreted as desired in the context of the parent XML element, *end example*] The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_LongHexNumber">
   <attribute name="val" type="ST_LongHexNumber" use="required"/>
</complexType>
```

2.7.3.16 semiHidden (Hide Style From Main User Interface)

This element specifies whether this style shall be hidden from the main user interface when this document is loaded by an application. If this element is set, then this style may be used to format content (i.e. any content which references this style shall have its properties as normal), but the style shall be hidden from the main user interface associated with that application.

[*Note*: The interpretation of a "main" user interface shall not be dictated by this Office Open XML Standard, and may be defined by an application as appropriate.

This setting is intended to define a style property which allows styles to be seen and modified in an advanced user interface, without exposing the style in a less advanced setting, for example, the style which is used to format the contents of a comment should typically not be shown in a simple user interface (as it is uncommon to want to modify it), but would be inappropriate to hide completely using the hidden element (§2.7.3.4), as very advanced users may want to change its appearance. *end note*]

If this element is omitted, then the style shall not be required to be hidden from the main user interface.

[*Example*: Consider a style with a primary name of `Comment Style` that should not be displayed in the main user interface. This requirement would be specified using the following WordprocessingML:

```
<w:style … w:styleId="CStyle">
  <w:name w:val="Comment Style"/>
  <w:semiHidden/>
  …
</w:style>
```

The semiHidden element specifies that this style definition should not be displayed in any main user interface associated with an application which processes this document. *end example*]

Parent Elements
style (§2.7.3.17)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.7.3.17 style (Style Definition)

This element specifies the definition of a single style within a WordprocessingML document. A *style* is a predefined set of table, numbering, paragraph, and/or character properties which can be applied to regions within a document.

The style definition for any style definition can be divided into three segments:

- General style properties
- Style type
- Type-specific properties

General style properties refers to the set of properties which can be used regardless of the type of style; for example, the style name, additional aliases for the style, a style ID (used by the document content to refer to the style), if style is hidden, if style is locked, etc.

[*Example:* Consider a style called Heading 1 in a document as follows:

```
<w:style w:type="paragraph" w:styleId="Heading1">
  <w:name w:val="Heading 1"/>
  <w:basedOn w:val="Normal"/>
  <w:next w:val="Normal"/>
  <w:link w:val="Heading1Char"/>
  <w:priority w:val="1"/>
  <w:qformat/>
  <w:rsid w:val="00F303CE"/>
  …
</w:style>
```

Above the formatting information specific to this style type are a set of general style properties which define information shared by all style types. *end example*]

Style types refers to the property on a style which defines the type of style created with this style definition. WordprocessingML supports six types of style definitions by the values for the style definition's type attribute:

- Paragraph styles
- Character styles
- Linked styles (paragraph + character) [*Note*: Accomplished via the link element (§2.7.3.6). *end note*]
- Table styles
- Numbering styles
- Default paragraph + character properties

[*Example:* Consider a style called Heading 1 in a document as follows:

```
<w:style w:type="paragraph" w:styleId="Heading1">
  <w:name w:val="heading 1"/>
  <w:basedOn w:val="Normal"/>
  <w:next w:val="Normal"/>
  <w:link w:val="Heading1Char"/>
  <w:priority w:val="1"/>
  <w:qformat/>
  <w:rsid w:val="00F303CE"/>
  …
</w:style>
```

The type attribute has a value of paragraph, which indicates that the following style definition is a paragraph style. *end example*]

Type-specific properties refers to the payload of the style: its formatting information as well as any properties which apply only to that type of style.

[*Example*: Consider a table style with primary name Normal Table defined as follows:

```
<w:style w:type="table" w:default="1" w:styleId="TableNormal">
  <w:name w:val="Normal Table"/>
  …
  <w:tblPr>
    <w:tblInd w:w="0" w:type="dxa"/>
    <w:tblCellMar>
      <w:top w:w="0" w:type="dxa"/>
      <w:left w:w="108" w:type="dxa"/>
      <w:bottom w:w="0" w:type="dxa"/>
      <w:right w:w="108" w:type="dxa"/>
    </w:tblCellMar>
  </w:tblPr>
</w:style>
```

The tblPr element contains the formatting payload for this table style, which is only applicable to a table style. *end example*]

Parent Elements
styles (§2.7.3.18)

Child Elements	Subclause
aliases (Alternate Style Names)	§2.7.3.1
autoRedefine (Automatically Merge User Formatting Into Style Definition)	§2.7.3.2
basedOn (Parent Style ID)	§2.7.3.3
hidden (Hide Style From User Interface)	§2.7.3.4
link (Linked Style Reference)	§2.7.3.6
locked (Style Cannot Be Applied)	§2.7.3.7
name (Primary Style Name)	§2.7.3.9
next (Style For Next Paragraph)	§2.7.3.10
personal (E-Mail Message Text Style)	§2.7.3.11
personalCompose (E-Mail Message Composition Style)	§2.7.3.12
personalReply (E-Mail Message Reply Style)	§2.7.3.13
pPr (Style Paragraph Properties)	§2.7.7.2
qFormat (Primary Style)	§2.7.3.14
rPr (Run Properties)	§2.7.8.1
rsid (Revision Identifier for Style Definition)	§2.7.3.15
semiHidden (Hide Style From Main User Interface)	§2.7.3.16
tblPr (Style Table Properties)	§2.7.5.4

Child Elements	Subclause
tblStylePr (Style Conditional Table Formatting Properties)	§2.7.5.6
tcPr (Style Table Cell Properties)	§2.7.5.8
trPr (Style Table Row Properties)	§2.7.5.11
uiPriority (Optional User Interface Sorting Order)	§2.7.3.19
unhideWhenUsed (Remove Semi-Hidden Property When Style Is Used)	§2.7.3.20

Attributes	Description
customStyle (User-Defined Style)	Specifies that this style is a user-defined style (i.e. it is not a style which was automatically generated by an application). This setting (specifically a value of `true` or its equivalents) shall not allow the formatting associated with the style to be changed automatically by an application, but may be used to specify that if the associated style ID is known, certain user interface behaviors may be applied to its definition. [*Example*: The style's primary name may be localized to match the current user interface language. *end example*] If this attribute is omitted, then the style shall be assumed to be a built-in style. [*Example*: Consider a paragraph style defined as follows: `<w:style w:type="paragraph" w:styleId="MyStyle" w:customStyle="true"> <w:name w:val="My Paragraph Style"/> <w:rPr> <w:b/> </w:rPr> </w:style>` This paragraph style specifies that it is a user-defined style using the customStyle attribute's value of `true`. An application may therefore take action on the style if it has behaviors associated with the style ID `MyStyle`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
default (Default Style)	Specifies that this style is the default for this type of style. This property is used in conjunction with the type attribute to determine the style which is applied to objects that do not explicitly declare a style. [*Example*: The paragraph style with the default attribute set is the paragraph style applied to all paragraphs which do not explicitly reference a paragraph style using the pStyle element (§2.3.1.27). *end example*] If this attribute is not specified for any style, then no properties shall be applied to objects of the specified type. If this attribute is specified by multiple styles, then the last instance of a style with this property shall be used.

Attributes	Description
	[*Example*: Consider a paragraph style defined as follows: `<w:style w:type="paragraph" w:default="1" w:styleId="MyStyle" > <w:name w:val="My Paragraph Style"/> <w:rPr> <w:b/> </w:rPr> </w:style>` This paragraph style specifies that it is the default paragraph style, and therefore all paragraphs which do not explicitly reference a paragraph style shall have this style applied. For example, consider the following paragraphs from the same WordprocessingML document: `<w:p> <w:pPr> <w:pStyle w:val="Normal"/> </w:pPr> … </w:p> <w:p> … </w:p>` The contents of the first paragraph shall have the `Normal` paragraph style applied to them, while the contents of the second paragraph shall have the `MyStyle` paragraph style applied, since it does not explicitly reference a paragraph style and therefore inherits the default. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
styleId (Style ID)	Specifies a unique identifier for the parent style definition. This identifier shall be used in multiple contexts to uniquely reference this style definition within the document. [*Example*: The following are examples of elements which reference a style via its styleId attribute value: • To reference a style from content using elements like the pStyle element (§2.3.1.27), rStyle element (§2.3.2.27), and the tblStyle element (§2.4.59) for paragraphs, runs, and tables, respectively. • To link the paragraph and character versions of a style via the link element (§2.7.3.6) • To reference the parent style for style inheritance via the basedOn element (§2.7.3.3) *end example*]

Attributes	Description
	If multiple style definitions each declare the same value for their styleId, then the first such instance shall keep its current identifier with all other instances being reassigned in any manner desired. This reassignment shall not require references to those style definitions to be 'repaired' in the content (i.e. some content may lose its style definition information, since the document was ill-formed). If this attribute is not specified, then a style ID may be assigned in any manner desired. [*Example*: Consider a paragraph style defined as follows: `<w:style w:type="paragraph" w:styleId="MyStyle" > <w:name w:val="My Paragraph Style"/> <w:rPr> <w:b/> </w:rPr> </w:style>` This paragraph style specifies that its style identifier shall be `MyStyle` using the styleId attribute. Now consider the following paragraphs from the same WordprocessingML document: `<w:p> <w:pPr> <w:pStyle w:val="MyStyle"/> </w:pPr> … </w:p> <w:p> … </w:p>` The contents of the first paragraph shall have the bold paragraph property applied to them because their paragraph properties specify that they shall inherit the paragraph style whose styleId is `MyStyle` therefore inheriting its properties using the rules of the style hierarchy. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).
type (Style Type)	Specifies the type of style definition defined by this element. WordprocessingML supports six types of style definitions: • Paragraph styles • Character styles • Table styles • Numbering styles • Linked styles (paragraph + character)

Attributes	Description

	• Default paragraph + character properties
	
	Each of the first four types corresponds to a different value in this attribute, and therefore defines the type of the current style. [*Note*: The last two types are unique in that they are not simply a style type: a linked style is a pairing of a character and paragraph style via the link element (§2.7.3.6); and the document default properties are defined via the docDefaults element (§2.7.4.1). *end note*]
	
	If this attribute is not specified, then the default value shall be assumed to be paragraph.
	
	[*Example*: Consider a style defined as follows:
	
	`<w:style w:type="paragraph" … >`
	`  <w:name w:val="My Paragraph Style"/>`
	`  <w:rPr>`
	`  <w:b/>`
	`  </w:rPr>`
	`</w:style>`
	
	The type attribute value of paragraph specifies that this style definition creates a paragraph style. *end example*]
	
	The possible values for this attribute are defined by the ST_StyleType simple type (§2.18.90).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Style">
   <sequence>
      <element name="name" type="CT_String" minOccurs="0" maxOccurs="1"/>
      <element name="aliases" type="CT_String" minOccurs="0"/>
      <element name="basedOn" type="CT_String" minOccurs="0"/>
      <element name="next" type="CT_String" minOccurs="0"/>
      <element name="link" type="CT_String" minOccurs="0"/>
      <element name="autoRedefine" type="CT_OnOff" minOccurs="0"/>
      <element name="hidden" type="CT_OnOff" minOccurs="0"/>
      <element name="uiPriority" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="semiHidden" type="CT_OnOff" minOccurs="0"/>
      <element name="unhideWhenUsed" type="CT_OnOff" minOccurs="0"/>
      <element name="qFormat" type="CT_OnOff" minOccurs="0"/>
      <element name="locked" type="CT_OnOff" minOccurs="0"/>
      <element name="personal" type="CT_OnOff" minOccurs="0"/>
      <element name="personalCompose" type="CT_OnOff" minOccurs="0"/>
      <element name="personalReply" type="CT_OnOff" minOccurs="0"/>
      <element name="rsid" type="CT_LongHexNumber" minOccurs="0"/>
      <element name="pPr" type="CT_PPr" minOccurs="0" maxOccurs="1"/>
      <element name="rPr" type="CT_RPr" minOccurs="0" maxOccurs="1"/>
      <element name="tblPr" type="CT_TblPrBase" minOccurs="0" maxOccurs="1"/>
      <element name="trPr" type="CT_TrPr" minOccurs="0" maxOccurs="1"/>
      <element name="tcPr" type="CT_TcPr" minOccurs="0" maxOccurs="1"/>
      <element name="tblStylePr" type="CT_TblStylePr" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
   <attribute name="type" type="ST_StyleType" use="optional"/>
   <attribute name="styleId" type="ST_String" use="optional"/>
   <attribute name="default" type="ST_OnOff" use="optional"/>
   <attribute name="customStyle" type="ST_OnOff" use="optional"/>
</complexType>
```

2.7.3.18 styles (Style Definitions)

This element specifies all of the style information stored in the WordprocessingML document: style definitions as well as latent style information.

[*Example*: The Normal paragraph style in a word processing document can have any number of formatting properties, e.g. font face = Times New Roman; font size = 12pt; paragraph justification = left). All paragraphs which reference this paragraph style would automatically inherit these properties. *end example*]

Parent Elements
Root element of WordprocessingML Style Definitions part

Child Elements	Subclause
docDefaults (Document Default Paragraph and Run Properties)	§2.7.4.1
latentStyles (Latent Style Information)	§2.7.3.5
style (Style Definition)	§2.7.3.17

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Styles">
   <sequence>
      <element name="docDefaults" type="CT_DocDefaults" minOccurs="0"/>
      <element name="latentStyles" type="CT_LatentStyles" minOccurs="0" maxOccurs="1"/>
      <element name="style" type="CT_Style" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
</complexType>
```

2.7.3.19 uiPriority (Optional User Interface Sorting Order)

This element specifies a number which may be used to sort the set of style definitions in a user interface when this document is loaded by an application and the recommended setting is specified in the stylePaneSortMethod element (§2.15.1.87). If this element is set, then this priority shall be used to sort all available styles in ascending value order.

If this element is omitted, then the style shall not have an associated priority value and shall be sorted to the end of the list of style definitions (more or less equivalent to a priority value of infinity) when the recommended sort order setting is specified.

[*Example*: Consider a style with a primary name of `Comment Style` that should have an associated priority value of ten. This requirement would be specified using the following WordprocessingML:

```
<w:style … w:styleId="CStyle">
  <w:name w:val="Comment Style"/>
  <w:uiPriority w:val="10"/>
  …
</w:style>
```

The uiPriority element specifies that this style definition should be sorted into the list of styles using a value of `10` when the styles are listed in recommended order using the stylePaneSortMethod element (§2.15.1.87). *end example*]

Parent Elements
style (§2.7.3.17)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber:

Attributes	Description
	<w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.7.3.20 unhideWhenUsed (Remove Semi-Hidden Property When Style Is Used)

This element specifies whether the semiHidden property (§2.7.3.16) shall be removed when this style is used by the content of the document. If this element is set, then an application shall ensure that even if the semiHidden element is specified on a style, that this property is removed when the document is resaved if the style is referenced by any content in the document.

If this element is omitted, then the style shall not automatically lose the semi-hidden property when it is used in the document contents.

[*Example*: Consider a style with a primary name of `Test Paragraph Style` that should not be displayed in the main user interface until it is used. This requirement would be specified using the following WordprocessingML:

```
<w:style … w:styleId="TestStyle">
  <w:name w:val="Test Paragraph Style"/>
  <w:semiHidden/>
  <w:unhideWhenUsed/>
  …
</w:style>
```

The unhideWhenUsed element specifies that this style definition should not be displayed in any main user interface associated with an application which processes this document until it is referenced by document content. If a paragraph was added to the document which referenced this style:

```
<w:p>
  <w:pPr>
    <w:pStyle w:val="TestStyle"/>
  </w:pPr>
  …
</w:p>
```

This style is now referenced by the document's contents and would have the semiHidden element removed on save. *end example*]

Parent Elements
style (§2.7.3.17)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.7.4 Document Defaults

The first formatting information which is applied to all regions of text in a WordprocessingML document when that document is displayed is the document defaults. The document defaults specify the default set of properties which shall be inherited by every paragraph and run of text within all stories of the current WordprocessingML document. If no other formatting information was referenced by that text, these properties would solely define the formatting of the resulting text.

[*Example*: Consider the following fragment from the main document part of a WordprocessingML document:

```
<w:body>
  <w:p>
    <w:r>
      <w:t>Hello world!</w:t>
    </w:r>
  </w:p>
</w:body>
```

This paragraph and run of text both specify no formatting information (i.e. the paragraph and run possess neither a pPr element nor an rPr element respectively). Therefore, the only formatting applied to this text shall be the formatting in the document defaults which is applied to all paragraphs and runs in the document.

Note that this does not imply that these properties are only applied to text with no formatting - they are rather applied to all text before all other formatting (and in this case, there is no other formatting). *end example*]

2.7.4.1 docDefaults (Document Default Paragraph and Run Properties)

This element specifies the set of default paragraph and run properties which shall be applied to every paragraph and run in the current WordprocessingML document. These properties are applied first in the style hierarchy; therefore they are superseded by any further conflicting formatting, but apply if no further formatting is present.

If this element is omitted, then the document defaults shall be application-defined by the hosting application.

[*Example*: Consider the following definition for the document defaults for a WordprocessingML document:

```
<w:docDefaults>
  <w:pPrDefault>
    <w:pPr>
      <w:jc w:val="center"/>
    </w:pPr>
  </w:pPrDefault>
  <w:rPrDefault>
    <w:rPr>
      <w:b/>
    </w::rPr>
  </w:rPrDefault>
</w:docDefaults>
```

The child elements of docDefaults specify a default paragraph property of centered text and a default run property of bold text. Applying this formatting to the following fragment from the main document part of the same document:

```
<w:body>
  <w:p>
    <w:r>
      <w:t>Hello world!</w:t>
    </w:r>
  </w:p>
</w:body>
```

This paragraph contains no formatting properties, therefore, using the style hierarchy the document default paragraph and run properties are applied as specified within the docDefaults element and the resulting

paragraph is centered as specified in the jc element (§2.3.1.13) as well as bold as specified via the b element (§2.3.2.1). *end example*]

Parent Elements
styles (§2.7.3.18)

Child Elements	Subclause
pPrDefault (Default Paragraph Properties)	§2.7.4.3
rPrDefault (Default Run Properties)	§2.7.4.5

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DocDefaults">
   <sequence>
      <element name="rPrDefault" type="CT_RPrDefault" minOccurs="0"/>
      <element name="pPrDefault" type="CT_PPrDefault" minOccurs="0"/>
   </sequence>
</complexType>
```

2.7.4.2 pPr (Paragraph Properties)

This element specifies the set of paragraph properties which comprise the default paragraph properties for the current WordprocessingML document. [*Rationale*: The reason that a pPr element is present within the pPrDefault element is to allow for easy repurposing of any set of paragraph properties within a WordprocessingML document - since the paragraph properties are always child elements of a single pPr element, that element can simply be relocated in its entirety to the desired new location without additional modifications. *end rationale*]

If this element is omitted, then the default paragraph properties for the current document are non-existent (i.e. there are no default paragraph properties, and the defaults are therefore application-defined).

[*Example*: Consider the following definition for the document defaults for a WordprocessingML document:

```
<w:docDefaults>
  <w:pPrDefault>
    <w:pPr>
      <w:jc w:val="center"/>
    </w:pPr>
  </w:pPrDefault>
  …
</w:docDefaults>
```

The pPr element as a child of the pPrDefault element contains the set of default paragraph properties for this document - in this case, a justification value of `center`. *end example*]

tabs (Set of Custom Tab Stops)	§2.3.1.38
textAlignment (Vertical Character Alignment on Line)	§2.3.1.39

Child Elements	Subclause
textboxTightWrap (Allow Surrounding Paragraphs to Tight Wrap to Text Box Contents)	§2.3.1.40
textDirection (Paragraph Text Flow Direction)	§2.3.1.41
topLinePunct (Compress Punctuation at Start of a Line)	§2.3.1.43
widowControl (Allow First/Last Line to Display on a Separate Page)	§2.3.1.44
wordWrap (Allow Line Breaking At Character Level)	§2.3.1.45

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_PPr">
   <complexContent>
      <extension base="CT_PPrBase">
         <sequence>
            <element name="rPr" type="CT_ParaRPr" minOccurs="0"/>
            <element name="sectPr" type="CT_SectPr" minOccurs="0"/>
            <element name="pPrChange" type="CT_PPrChange" minOccurs="0"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.7.4.3 pPrDefault (Default Paragraph Properties)

This element specifies the presence of a set of default paragraph properties for the current document. The actual paragraph properties are stored within the pPr child element of the current element.

If this element is omitted, then the default paragraph properties for the current document are non-existent (i.e. there are no default paragraph properties in the document, and the defaults are therefore application-defined).

[*Example*: Consider the following definition for the document defaults for a WordprocessingML document:

```
<w:docDefaults>
  <w:pPrDefault>
    <w:pPr>
      <w:jc w:val="center"/>
    </w:pPr>
  </w:pPrDefault>
  …
</w:docDefaults>
```

The pPrDefault element is a container for the set of default paragraph properties for this document. *end example*]

Parent Elements
docDefaults (§2.7.4.1)

Child Elements	Subclause
pPr (Paragraph Properties)	§2.7.4.2

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_PPrDefault">
   <sequence>
      <element name="pPr" type="CT_PPr" minOccurs="0"/>
   </sequence>
</complexType>
```

2.7.4.4 rPr (Run Properties)

This element specifies the set of run properties which comprise the default run properties for the current WordprocessingML document. [*Rationale*: The reason that an rPr element is present within the rPrDefault element is to allow for easy repurposing of any set of run properties within a WordprocessingML document - since the run properties are always child elements of a single rPr element, that element can simply be relocated in its entirety to the desired new location without additional modifications. *end rationale*]

If this element is omitted, then the default run properties for the current document are non-existent (i.e. there are no default run properties, and the defaults are therefore application-defined).

[*Example*: Consider the following definition for the document defaults for a WordprocessingML document:

```
<w:docDefaults>
  …
  <w:rPrDefault>
    <w:rPr>
      <w:b/>
    </w::rPr>
  </w:rPrDefault>
</w:docDefaults>
```

The rPr element as a child of the rPrDefault element contains the set of default run properties for this document - in this case, bold text. *end example*]

Parent Elements
rPrDefault (§2.7.4.5)

Child Elements	Subclause
b (Bold)	§2.3.2.1
bCs (Complex Script Bold)	§2.3.2.2
bdr (Text Border)	§2.3.2.3
caps (Display All Characters As Capital Letters)	§2.3.2.4

Child Elements	Subclause
color (Run Content Color)	§2.3.2.5
cs (Use Complex Script Formatting on Run)	§2.3.2.6
dstrike (Double Strikethrough)	§2.3.2.7
eastAsianLayout (East Asian Typography Settings)	§2.3.2.8
effect (Animated Text Effect)	§2.3.2.9
em (Emphasis Mark)	§2.3.2.10
emboss (Embossing)	§2.3.2.11
fitText (Manual Run Width)	§2.3.2.12
highlight (Text Highlighting)	§2.3.2.13
i (Italics)	§2.3.2.14
iCs (Complex Script Italics)	§2.3.2.15
imprint (Imprinting)	§2.3.2.16
kern (Font Kerning)	§2.3.2.17
lang (Languages for Run Content)	§2.3.2.18
noProof (Do Not Check Spelling or Grammar)	§2.3.2.19
oMath (Office Open XML Math)	§2.3.2.20
outline (Display Character Outline)	§2.3.2.21
position (Vertically Raised or Lowered Text)	§2.3.2.22
rFonts (Run Fonts)	§2.3.2.24
rPrChange (Revision Information for Run Properties)	§2.13.5.32
rStyle (Referenced Character Style)	§2.3.2.27
rtl (Right To Left Text)	§2.3.2.28
shadow (Shadow)	§2.3.2.29
shd (Run Shading)	§2.3.2.30
smallCaps (Small Caps)	§2.3.2.31
snapToGrid (Use Document Grid Settings For Inter-Character Spacing)	§2.3.2.32
spacing (Character Spacing Adjustment)	§2.3.2.33
specVanish (Paragraph Mark Is Always Hidden)	§2.3.2.34
strike (Single Strikethrough)	§2.3.2.35
sz (Font Size)	§2.3.2.36
szCs (Complex Script Font Size)	§2.3.2.37
u (Underline)	§2.3.2.38
vanish (Hidden Text)	§2.3.2.39
vertAlign (Subscript/Superscript Text)	§2.3.2.40

Child Elements	Subclause
w (Expanded/Compressed Text)	§2.3.2.41
webHidden (Web Hidden Text)	§2.3.2.42

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RPr">
   <sequence>
      <group ref="EG_RPrContent" minOccurs="0"/>
   </sequence>
</complexType>
```

2.7.4.5 rPrDefault (Default Run Properties)

This element specifies the presence of a set of default run properties for the current document. The actual run properties are stored within the rPr child element of the current element.

If this element is omitted, then the default run properties for the current document are non-existent (i.e. there are no default run properties in the document, and the defaults are therefore application-defined).

[*Example*: Consider the following definition for the document defaults for a WordprocessingML document:

```
<w:docDefaults>
  …
  <w:rPrDefault>
    <w:rPr>
      <w:b/>
    </w::rPr>
  </w:rPrDefault>
</w:docDefaults>
```

The rPrDefault element is a container for the set of default run properties for this document. *end example*]

Parent Elements
docDefaults (§2.7.4.1)

Child Elements	Subclause
rPr (Run Properties)	§2.7.4.4

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RPrDefault">
   <sequence>
      <element name="rPr" type="CT_RPr" minOccurs="0"/>
   </sequence>
</complexType>
```

2.7.5 Table Styles

Table styles are style definitions which apply to the contents of zero or more tables within a document. This definition may imply that the style can only define table properties (properties which apply to the table and its constituent rows and cells), however a table style can also define paragraph properties (properties which apply to the positioning and appearance of paragraphs) as well as character properties (properties which apply to runs) for all of the paragraphs and runs within the specified table in the document.

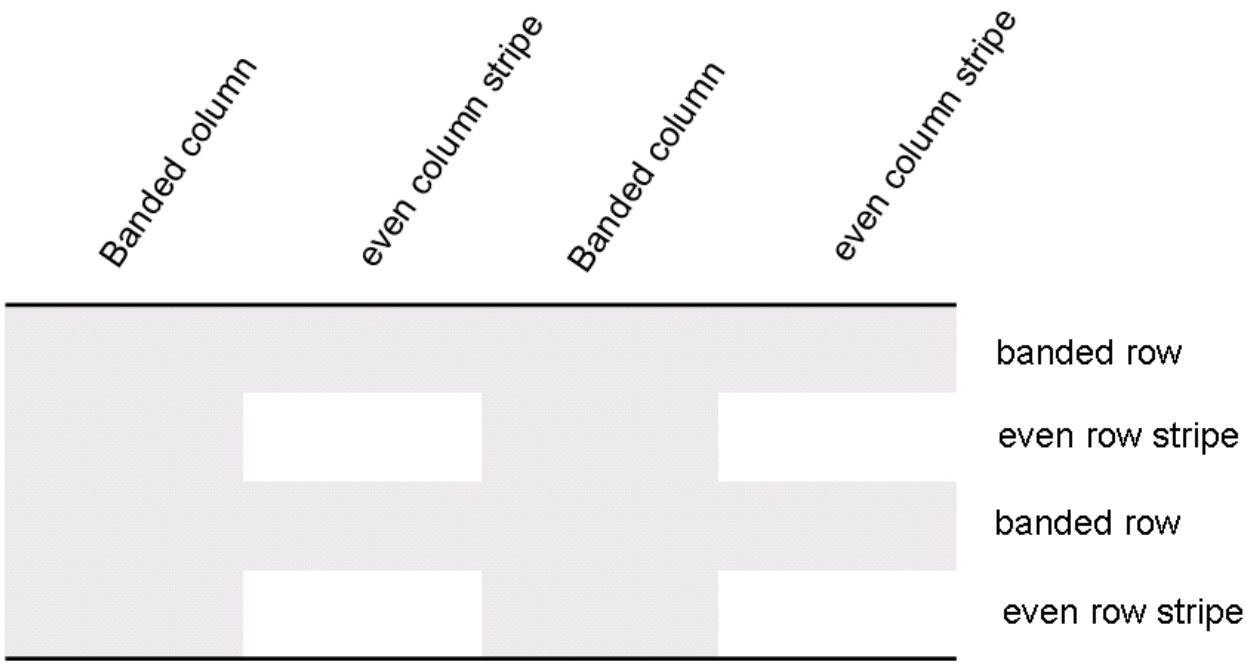
Table styles can only be referenced by tables within a document, and they must be referenced by the tblStyle element (§2.4.59) within a table's table properties.

As discussed above, table styles can specify all of the properties that can be applied to a table, as well as paragraph and character properties for the table's contents. However, unlike other style definitions, table styles allow for the definition of conditional formats for different regions of the table.

These table conditional formats are applied to different regions of the table as follows:

Top left cell	Header row	Top right cell
First column	Table body	Last column
Bottom left cell	Footer row	Bottom right cell

All rows in the table can also have conditional formatting on an alternating row/column basis as well as follows:



When specified, these conditional formats shall be applied in the following order (therefore subsequent formats override properties on previous formats):

- Whole table
- Banded columns, even column banding
- Banded rows, even row banding
- First row, last row
- First column, last column
- Top left, top right, bottom left, bottom right

[*Example*: Consider a table style `Test Table Style` defined as follows:

- All cells with 1pt table borders on all sides
- 0.1” cell margins on left and right of cells
- 0” cell margins on top and bottom of cells

As well as header row specific formatting of

- Red shading
- Bold text

```
<w:style w:type="table" w:styleId="TestTableStyle">
  <w:name w:val="Test Table Style"/>
  <w:basedOn w:val="TableNormal"/>
  <w:priority w:val="99"/>
  <w:rsid w:val="00340CC4"/>
  <w:tblPr>
    <w:tblBorders>
      <w:top w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:left w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:bottom w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:right w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:insideH w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:insideV w:val="single" w:sz="4" w:space="0" w:color="auto"/>
    </w:tblBorders>
    <w:tblCellMar>
      <w:top w:w="0" w:type="dxa"/>
      <w:left w:w="108" w:type="dxa"/>
      <w:bottom w:w="0" w:type="dxa"/>
      <w:right w:w="108" w:type="dxa"/>
    </w:tblCellMar>
  </w:tblPr>
  <w:tblStylePr w:type="firstRow">
    <w:rPr>
      <w:b/>
    </w:rPr>
    <w:tcPr>
      <w:shd w:val="clear" w:color="auto" w:fill="ED1C24"/>
    </w:tcPr>
  </w:tblStylePr>
</w:style>
```

The tblPr element holds the formatting which is applied to the entire table, and the tblStylePr element with a type attribute value of `firstRow` holds the formatting for the first table row, specifically the bold run property and red cell shading. *end example*]

An individual instance of a table defines an association with a table style using the tblStyle element in the table's properties (tblPr), as discussed above. However, individual tables can choose whether to apply the following aspects of the table's conditional formats individually:

- First row
- Last row
- First column
- Last column
- Row banding

- Column banding

The use or omission conditional formats shall be specified using the tblLook element, which contains a bitmask representing which properties are applied and omitted.

[*Example*: Consider two tables using the table style `Style2`; one which specifies that it should only use the header row and footer row conditional formatting properties from the table style, and the other which specifies that it should use the header row, footer row, and banded row conditional formatting:

```
<w:tbl>
  <w:tblPr>
    <w:tblStyle w:val="Style2"/>
    <w:tblW w:w="0" w:type="auto"/>
    <w:tblLook w:val="0660"/>
  </w:tblPr>
  …
</w:tbl>
…
<w:tbl>
  <w:tblPr>
    <w:tblStyle w:val="Style2"/>
    <w:tblW w:w="0" w:type="auto"/>
    <w:tblLook w:val="0460"/>
  </w:tblPr>
  …
</w:tbl>
```

The tables each specify the appropriate set of conditional formats using the tblLook element, as seen by the identical table styles in the tblStyle element, and different tblLook values. *end example*]

2.7.5.1 pPr (Table Style Conditional Formatting Paragraph Properties)

This element specifies the set of paragraph properties which shall be applied to all paragraphs within a table which match the conditional formatting type specified on the parent tblStylePr element. These properties are applied in the order specified via the style hierarchy.

[*Example*: Consider a table style which contains conditional formatting for its `firstRow`, defined as follows:

```
<w:style w:type="table" w:styleId="exampleTableStyle">
  …
  <w:tblStylePr w:type="firstRow">
    <w:pPr>
      <w:jc w:val="center"/>
    </w:pPr>
    …
  </w:tblStylePr>
</w:style>
```

The pPr element specified within the tblStylePr element specifies the set of paragraph properties which shall be applied to all parts of the table which meet the criteria specified by the type value of `firstRow` - all of the header rows of the table. In this example, the single paragraph property applied is an alignment value of center via the jc element (§2.3.1.13). *end example*]

Parent Elements

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_PPr">
   <complexContent>
      <extension base="CT_PPrBase">
         <sequence>
            <element name="rPr" type="CT_ParaRPr" minOccurs="0"/>
            <element name="sectPr" type="CT_SectPr" minOccurs="0"/>
            <element name="pPrChange" type="CT_PPrChange" minOccurs="0"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.7.5.2 rPr (Table Style Conditional Formatting Run Properties)

This element specifies the set of run properties which shall be applied to all runs within a table which match the conditional formatting type specified on the parent tblStylePr element. These properties are applied in the order specified via the style hierarchy.

[*Example*: Consider a table style which contains conditional formatting for its `firstRow`, defined as follows:

```
<w:style w:type="table" w:styleId="exampleTableStyle">
  …
  <w:tblStylePr w:type="firstRow">
    <w:rPr>
      <w:i/>
    </w:rPr>
    …
  </w:tblStylePr>
</w:style>
```

The rPr element specified within the tblStylePr element specifies the set of run properties which shall be applied to all parts of the table which meet the criteria specified by the type value of `firstRow` - all of the header rows of the table. In this example, the single run property applied is italics via the i element (§2.3.2.14). *end example*]

Parent Elements
tblStylePr (§2.7.5.6)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RPr">
   <sequence>
      <group ref="EG_RPrContent" minOccurs="0"/>
   </sequence>
</complexType>
```

2.7.5.3 tblPr (Table Style Conditional Formatting Table Properties)

This element specifies the set of table properties which shall be applied to all regions within a table which match the conditional formatting type specified on the parent tblStylePr element. These properties are applied in the order specified via the style hierarchy.

If the current conditional formatting type does not consist of one or more full table rows, then table properties which cannot be applied to a single cell or column [*Example*: Table justification. *end example*] may be ignored.

[*Example*: Consider a table style which contains conditional formatting for its `firstRow`, defined as follows:

```
<w:style w:type="table" w:styleId="exampleTableStyle">
  …
  <w:tblStylePr w:type="firstRow">
    <w:tblPr>
      <w:tblCellSpacing w:w="29" w:type="dxa"/>
    </w:tblPr>
    …
  </w:tblStylePr>
</w:style>
```

The tblPr element specified within the tblStylePr element specifies the set of table properties which shall be applied to all parts of the table which meet the criteria specified by the type value of `firstRow` - all of the header rows of the table. In this example, the single table property applied is a default table cell spacing value of 0.02 inches via the tblCellSpacing element (§2.4.43). *end example*]

Parent Elements
tblStylePr (§2.7.5.6)

Child Elements	Subclause
bidiVisual (Visually Right to Left Table)	§2.4.1
jc (Table Alignment)	§2.4.23
shd (Table Shading)	§2.4.35

tblStyleColBandSize (Number of Columns in Column Band)	§2.7.5.5
tblStyleRowBandSize (Number of Rows in Row Band)	§2.7.5.7
tblW (Preferred Table Width)	§2.4.61

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblPrBase">
   <sequence>
      <element name="tblStyle" type="CT_String" minOccurs="0"/>
      <element name="tblpPr" type="CT_TblPPr" minOccurs="0" maxOccurs="1"/>
      <element name="tblOverlap" type="CT_TblOverlap" minOccurs="0" maxOccurs="1"/>
      <element name="bidiVisual" type="CT_OnOff" minOccurs="0" maxOccurs="1"/>
      <element name="tblStyleRowBandSize" type="CT_DecimalNumber" minOccurs="0" maxOccurs="1"/>
      <element name="tblStyleColBandSize" type="CT_DecimalNumber" minOccurs="0" maxOccurs="1"/>
      <element name="tblW" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="jc" type="CT_Jc" minOccurs="0" maxOccurs="1"/>
      <element name="tblCellSpacing" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="tblInd" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="tblBorders" type="CT_TblBorders" minOccurs="0" maxOccurs="1"/>
      <element name="shd" type="CT_Shd" minOccurs="0" maxOccurs="1"/>
      <element name="tblLayout" type="CT_TblLayoutType" minOccurs="0" maxOccurs="1"/>
      <element name="tblCellMar" type="CT_TblCellMar" minOccurs="0" maxOccurs="1"/>
      <element name="tblLook" type="CT_ShortHexNumber" minOccurs="0" maxOccurs="1"/>
   </sequence>
</complexType>
```

2.7.5.4 tblPr (Style Table Properties)

This element specifies the set of table properties which shall be applied to the table. These properties are not conditional and shall always be applied (although they are applied before all conditional formatting properties).

[*Example*: Consider a table style defined as follows:

```
<w:style w:type="table" w:styleId="exampleTableStyle">
  <w:tblPr>
    <w:tblCellSpacing w:w="15" w:type="dxa"/>
  </w:tblPr>
  …
  <w:tblStylePr w:type="firstRow">-
    <w:tblPr>
      <w:tblCellSpacing w:w="29" w:type="dxa"/>
    </w:tblPr>
    …
  </w:tblStylePr>
</w:style>
```

The tblPr element specified within the style element specifies the set of table properties which shall be applied to all parts of the table. In this example, the single table property applied is a default table cell spacing value of 0.01 inches via the tblCellSpacing element (§2.4.43). *end example*]

Parent Elements
style (§2.7.3.17)

Child Elements	Subclause
bidiVisual (Visually Right to Left Table)	§2.4.1
jc (Table Alignment)	§2.4.23
shd (Table Shading)	§2.4.35
tblBorders (Table Borders)	§2.4.38
tblCellMar (Table Cell Margin Defaults)	§2.4.39
tblCellSpacing (Table Cell Spacing Default)	§2.4.43
tblInd (Table Indent from Leading Margin)	§2.4.48
tblLayout (Table Layout)	§2.4.49
tblLook (Table Style Conditional Formatting Settings)	§2.4.51
tblOverlap (Floating Table Allows Other Tables to Overlap)	§2.4.53
tblpPr (Floating Table Positioning)	§2.4.54
tblStyle (Referenced Table Style)	§2.4.59
tblStyleColBandSize (Number of Columns in Column Band)	§2.7.5.5
tblStyleRowBandSize (Number of Rows in Row Band)	§2.7.5.7
tblW (Preferred Table Width)	§2.4.61

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblPrBase">
   <sequence>
      <element name="tblStyle" type="CT_String" minOccurs="0"/>
      <element name="tblpPr" type="CT_TblPPr" minOccurs="0" maxOccurs="1"/>
      <element name="tblOverlap" type="CT_TblOverlap" minOccurs="0" maxOccurs="1"/>
      <element name="bidiVisual" type="CT_OnOff" minOccurs="0" maxOccurs="1"/>
      <element name="tblStyleRowBandSize" type="CT_DecimalNumber" minOccurs="0" maxOccurs="1"/>
      <element name="tblStyleColBandSize" type="CT_DecimalNumber" minOccurs="0" maxOccurs="1"/>
      <element name="tblW" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="jc" type="CT_Jc" minOccurs="0" maxOccurs="1"/>
      <element name="tblCellSpacing" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="tblInd" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="tblBorders" type="CT_TblBorders" minOccurs="0" maxOccurs="1"/>
      <element name="shd" type="CT_Shd" minOccurs="0" maxOccurs="1"/>
      <element name="tblLayout" type="CT_TblLayoutType" minOccurs="0" maxOccurs="1"/>
      <element name="tblCellMar" type="CT_TblCellMar" minOccurs="0" maxOccurs="1"/>
      <element name="tblLook" type="CT_ShortHexNumber" minOccurs="0" maxOccurs="1"/>
   </sequence>
</complexType>
```

2.7.5.5 tblStyleColBandSize (Number of Columns in Column Band)

This element specifies the number of columns which shall comprise each a table style column band for this table style. This element determines how many columns constitute each of the column bands for the current table, allowing column band formatting to be applied to groups of columns (rather than just single alternating columns) when the table is formatted.

If this element is omitted, then the default number of columns in a single column band shall be assumed to be 1.

[*Example*: Consider a table style defined as follows:

```
<w:style w:type="table" w:styleId="exampleTableStyle">
  <w:tblPr>
    <w:tblStyleRowBandSize w:val="3" />
    <w:tblStyleColBandSize w:val="2" />
  </w:tblPr>
  …
</w:style>
```

The tblStyleColBandSize element specifies that the width of each column band shall be 2 columns - therefore band1Vert column banding conditional formatting shall be applied to columns 1 and 2, 5 and 6, etc. in the table. *end example*]

Parent Elements
tblPr (§2.7.5.3); tblPr (§2.7.5.4); tblPr (§2.4.55); tblPr (§2.4.56)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

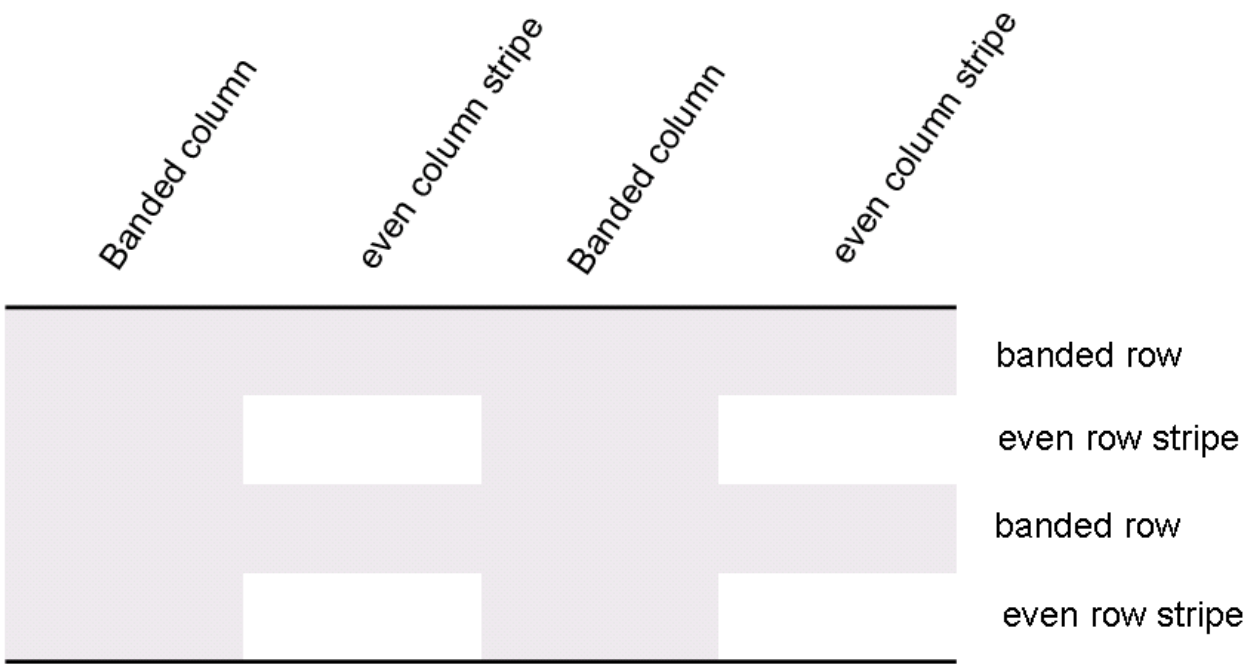
```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.7.5.6 tblStylePr (Style Conditional Table Formatting Properties)

This element specifies a set of formatting properties which shall be conditionally applied to the parts of a table which match the requirement specified on the type attribute. These table conditional formats are applied to different regions of the table as follows:

Top left cell	Header row	Top right cell
First column	Table body	Last column
Bottom left cell	Footer row	Bottom right cell

All rows in the table can also have conditional formatting on an alternating row/column basis as well as follows:



When specified, these conditional formats shall be applied in the following order (therefore subsequent formats override properties on previous formats):

- Whole table
- Banded columns, even column banding
- Banded rows, even row banding
- First row, last row
- First column, last column

- Top left, top right, bottom left, bottom right

[*Example*: Consider a table style which contains conditional formatting, defined as follows:

```
<w:style w:type="table" w:styleId="exampleTableStyle">
  …
  <w:tblStylePr w:type="firstRow">
    <w:tblPr>
      <w:tblCellSpacing w:w="29" w:type="dxa"/>
    </w:tblPr>
    …
  </w:tblStylePr>
</w:style>
```

The tblStylePr element specifies a set of table properties which shall be conditionally applied to all parts of the table which meet the criteria specified by the type attribute (in this case, all heading rows for the current table). *end example*]

Parent Elements
style (§2.7.3.17)

Child Elements	Subclause
pPr (Table Style Conditional Formatting Paragraph Properties)	§2.7.5.1
rPr (Table Style Conditional Formatting Run Properties)	§2.7.5.2
tblPr (Table Style Conditional Formatting Table Properties)	§2.7.5.3
tcPr (Table Style Conditional Formatting Table Cell Properties)	§2.7.5.9
trPr (Table Style Conditional Formatting Table Row Properties)	§2.7.5.10

Attributes	Description

type (Table Style Conditional Formatting Type)	Specifies the section of the table to which the current conditional formatting properties shall be applied.
	
	[*Example*: Consider a table style which contains conditional formatting, defined as follows:
	
	`<w:style w:type="table" …>`
	`  …`
	`  <w:tblStylePr w:type="lastRow">`
	`  …`
	`  </w:tblStylePr>`
	`</w:style>`

Attributes	Description
	The type attribute value of `lastRow` specifies that this set of conditional formatting properties shall be applied to the last row of the table only. *end example*] The possible values for this attribute are defined by the ST_TblStyleOverrideType simple type (§2.18.96).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblStylePr">
   <sequence>
      <element name="pPr" type="CT_PPr" minOccurs="0"/>
      <element name="rPr" type="CT_RPr" minOccurs="0"/>
      <element name="tblPr" type="CT_TblPrBase" minOccurs="0"/>
      <element name="trPr" type="CT_TrPr" minOccurs="0" maxOccurs="1"/>
      <element name="tcPr" type="CT_TcPr" minOccurs="0" maxOccurs="1"/>
   </sequence>
   <attribute name="type" type="ST_TblStyleOverrideType" use="required"/>
</complexType>
```

2.7.5.7 tblStyleRowBandSize (Number of Rows in Row Band)

This element specifies the number of rows which shall comprise each a table style row band for this table style. This element determines how many rows constitute each of the row bands for the current table, allowing row band formatting to be applied to groups of rows (rather than just single alternating rows) when the table is formatted.

If this element is omitted, then the default number of rows in a single row band shall be assumed to be `1`.

[*Example*: Consider a table style defined as follows:

```
<w:style w:type="table" w:styleId="exampleTableStyle">
  <w:tblPr>
    <w:tblStyleRowBandSize w:val="3" />
    <w:tblStyleColBandSize w:val="2" />
  </w:tblPr>
  …
</w:style>
```

The tblStyleRowBandSize element specifies that the width of each row band shall be `3` columns - therefore `band1Horiz` row banding conditional formatting shall be applied to row 1 through 3, 7 through 9, etc. in the table. *end example*]

Parent Elements
tblPr (§2.7.5.3); tblPr (§2.7.5.4); tblPr (§2.4.55); tblPr (§2.4.56)

Attributes	Description

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.7.5.8 tcPr (Style Table Cell Properties)

This element specifies the set of table cell properties which shall be applied to the table. These properties are not conditional and shall always be applied (although they are applied before all conditional formatting properties).

[*Example*: Consider a table style defined as follows:

```
<w:style w:type="table" w:styleId="exampleTableStyle">
  <w:tcPr>
    <w:tcFitText/>
  </w:tcPr>
</w:style>
```

The tcPr element specified within the style element specifies the set of table cell properties which shall be applied to all parts of the table. In this example, the single table cell property applied is the fit text setting via the tcFitText element (§2.4.64). *end example*]

Parent Elements
style (§2.7.3.17)

Child Elements	Subclause
cellDel (Table Cell Deletion)	§2.13.5.1

Child Elements	Subclause
cellIns (Table Cell Insertion)	§2.13.5.2
cellMerge (Vertically Merged/Split Table Cells)	§2.13.5.3
cnfStyle (Table Cell Conditional Formatting)	§2.4.7
gridSpan (Grid Columns Spanned by Current Table Cell)	§2.4.13
hideMark (Ignore End Of Cell Marker In Row Height Calculation)	§2.4.15
hMerge (Horizontally Merged Cell)	§2.4.16
noWrap (Don't Wrap Cell Content)	§2.4.28
shd (Table Cell Shading)	§2.4.33
tcBorders (Table Cell Borders)	§2.4.63
tcFitText (Fit Text Within Cell)	§2.4.64
tcMar (Single Table Cell Margins)	§2.4.65
tcPrChange (Revision Information for Table Cell Properties)	§2.13.5.38
tcW (Preferred Table Cell Width)	§2.4.68
textDirection (Table Cell Text Flow Direction)	§2.4.69
vAlign (Table Cell Vertical Alignment)	§2.4.80
vMerge (Vertically Merged Cell)	§2.4.81

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TcPr">
   <complexContent>
      <extension base="CT_TcPrInner">
         <sequence>
            <element name="tcPrChange" type="CT_TcPrChange" minOccurs="0"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.7.5.9 tcPr (Table Style Conditional Formatting Table Cell Properties)

This element specifies the set of table cell properties which shall be applied to all regions within a table which match the conditional formatting type specified on the parent tblStylePr element. These properties are applied in the order specified via the style hierarchy.

[*Example*: Consider a table style which contains conditional formatting for its `firstRow`, defined as follows:

```
<w:style w:type="table" w:styleId="exampleTableStyle">
  …
  <w:tblStylePr w:type="firstRow">
    <w:tcPr>
      <w:tcBorders>
        <w:top w:val="nil" />
        <w:left w:val="nil" />
        <w:bottom w:val="nil" />
        <w:right w:val="nil" />
        <w:insideH w:val="nil" />
        <w:insideV w:val="nil" />
      </w:tcBorders>
    </w:tcPr>
    …
  </w:tblStylePr>
</w:style>
```

The tcPr element specified within the tblStylePr element specifies the set of table cell properties which shall be applied to all parts of the table which meet the criteria specified by the type value of `firstRow` - all of the header rows of the table. In this example, the single table cell property applied is a set of table cell borders via the tcBorders element (§2.4.63). In this case, these cell borders simply reset any previous cell borders to `nil`. *end example*]

Parent Elements
tblStylePr (§2.7.5.6)

Child Elements	Subclause
cellDel (Table Cell Deletion)	§2.13.5.1
cellIns (Table Cell Insertion)	§2.13.5.2
cellMerge (Vertically Merged/Split Table Cells)	§2.13.5.3
cnfStyle (Table Cell Conditional Formatting)	§2.4.7
gridSpan (Grid Columns Spanned by Current Table Cell)	§2.4.13
hideMark (Ignore End Of Cell Marker In Row Height Calculation)	§2.4.15
hMerge (Horizontally Merged Cell)	§2.4.16
noWrap (Don't Wrap Cell Content)	§2.4.28
shd (Table Cell Shading)	§2.4.33
tcBorders (Table Cell Borders)	§2.4.63
tcFitText (Fit Text Within Cell)	§2.4.64
tcMar (Single Table Cell Margins)	§2.4.65

Child Elements	Subclause
tcPrChange (Revision Information for Table Cell Properties)	§2.13.5.38
tcW (Preferred Table Cell Width)	§2.4.68
textDirection (Table Cell Text Flow Direction)	§2.4.69
vAlign (Table Cell Vertical Alignment)	§2.4.80
vMerge (Vertically Merged Cell)	§2.4.81

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TcPr">
   <complexContent>
      <extension base="CT_TcPrInner">
         <sequence>
            <element name="tcPrChange" type="CT_TcPrChange" minOccurs="0"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.7.5.10 trPr (Table Style Conditional Formatting Table Row Properties)

This element specifies the set of table row properties which shall be applied to all rows within a table which match the conditional formatting type specified on the parent tblStylePr element. These properties are applied in the order specified via the style hierarchy.

[*Example*: Consider a table style which contains conditional formatting for its `firstRow`, defined as follows:

```
<w:style w:type="table" w:styleId="exampleTableStyle">
  …
  <w:tblStylePr w:type="firstRow">
    <w:trPr>
      <w:tblHeader/>
      <w:cantSplit/>
    </w:trPr>
    …
  </w:tblStylePr>
</w:style>
```

The trPr element specified within the tblStylePr element specifies the set of table row properties which shall be applied to all rows of the table which meet the criteria specified by the type value of `firstRow` - all of the header rows of the table. In this example, the table row properties applied are the fact that these rows shall be repeated on each page via the tblHeader element (§2.4.46) and the fact that these rows shall not be split across pages using the cantSplit element (§2.4.6). *end example*]

Parent Elements
tblStylePr (§2.7.5.6)

Child Elements	Subclause
cantSplit (Table Row Cannot Break Across Pages)	§2.4.6
cnfStyle (Table Row Conditional Formatting)	§2.4.8
del (Deleted Table Row)	§2.13.5.14
divId (Associated HTML div ID)	§2.4.9
gridAfter (Grid Columns After Last Cell)	§2.4.10
gridBefore (Grid Columns Before First Cell)	§2.4.11
hidden (Hidden Table Row Marker)	§2.4.14
ins (Inserted Table Row)	§2.13.5.16
jc (Table Row Alignment)	§2.4.22
tblCellSpacing (Table Row Cell Spacing)	§2.4.42
tblHeader (Repeat Table Row on Every New Page)	§2.4.46
trHeight (Table Row Height)	§2.4.77
trPrChange (Revision Information for Table Row Properties)	§2.13.5.39
wAfter (Preferred Width After Table Row)	§2.4.82
wBefore (Preferred Width Before Table Row)	§2.4.83

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrPr">
   <complexContent>
      <extension base="CT_TrPrBase">
         <sequence>
            <element name="ins" type="CT_TrackChange" minOccurs="0"/>
            <element name="del" type="CT_TrackChange" minOccurs="0"/>
            <element name="trPrChange" type="CT_TrPrChange" minOccurs="0"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.7.5.11 trPr (Style Table Row Properties)

This element specifies the set of table row properties which shall be applied to the table. These properties are not conditional and shall always be applied (although they are applied before all conditional formatting properties).

[*Example*: Consider a table style defined as follows:

```
<w:style w:type="table" w:styleId="exampleTableStyle">
  <w:trPr>
    <w:jc w:val="center"/>
  </w:trPr>
</w:style>
```

The trPr element specified within the style element specifies the set of table row properties which shall be applied to all parts of the table. In this example, the single table row property applied is the alignment setting of center via the jc element (§2.4.22). *end example*]

Parent Elements
style (§2.7.3.17)

Child Elements	Subclause
cantSplit (Table Row Cannot Break Across Pages)	§2.4.6
cnfStyle (Table Row Conditional Formatting)	§2.4.8
del (Deleted Table Row)	§2.13.5.14
divId (Associated HTML div ID)	§2.4.9
gridAfter (Grid Columns After Last Cell)	§2.4.10
gridBefore (Grid Columns Before First Cell)	§2.4.11
hidden (Hidden Table Row Marker)	§2.4.14
ins (Inserted Table Row)	§2.13.5.16
jc (Table Row Alignment)	§2.4.22
tblCellSpacing (Table Row Cell Spacing)	§2.4.42
tblHeader (Repeat Table Row on Every New Page)	§2.4.46
trHeight (Table Row Height)	§2.4.77
trPrChange (Revision Information for Table Row Properties)	§2.13.5.39
wAfter (Preferred Width After Table Row)	§2.4.82
wBefore (Preferred Width Before Table Row)	§2.4.83

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrPr">
   <complexContent>
      <extension base="CT_TrPrBase">
         <sequence>
            <element name="ins" type="CT_TrackChange" minOccurs="0"/>
            <element name="del" type="CT_TrackChange" minOccurs="0"/>
            <element name="trPrChange" type="CT_TrPrChange" minOccurs="0"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.7.6 Numbering Styles

Numbering styles are style definitions which specify common style properties for a multi-level numbering format within a document. This means that a numbering style defines only a single paragraph property: a reference to a numbering definition stored in the document's numbering part, using the numPr element.

Unlike paragraph and character styles, numbering styles are never directly referenced by content in the document – instead, an abstract numbering definition (covered in the numbering section) specifies that it is actually the underlying numbering information for a numbering style.

[*Example*: Consider a numbering style "Test Numbering Style":

```
<w:style w:type="numbering" w:styleId="TestNumberingStyle">
  <w:name w:val="Test Numbering Style" />
  <w:priority w:val="99" />
  <w:rsid w:val="0045009F" />
  <w:pPr>
    <w:numPr>
      <w:numId w:val="1" />
    </w:numPr>
  </w:pPr>
</w:style>
```

The only information specified in the numbering style definition is a reference to the numbering definition for the numbering information which is defined by this numbering style. *end example*]

2.7.7 Paragraph Styles

Paragraph styles are styles which apply to the contents of an entire paragraph as well as the paragraph mark. This definition implies that the style can define both character properties (properties which apply to text within the document) as well as paragraph properties (properties which apply to the positioning and appearance of the paragraph). Paragraph styles cannot be referenced by runs within a document; they must be referenced by the pStyle element (§2.3.1.27) within a paragraph's paragraph properties element.

A paragraph style has three defining type-specific characteristics:

- The type attribute on the style has a value of paragraph, which indicates that the following style definition is a paragraph style.
- The next element defines an editing behavior which supplies the paragraph style to be automatically applied to the next paragraph when ENTER is pressed at the end of a paragraph of this style.
- The style specifies both paragraph-level and character-level properties using the pPr and rPr elements, respectively. In this case, the run properties are the set of properties applied to each run in the paragraph.

The paragraph style is then applied to paragraphs by referencing the styleId attribute value for this style in the paragraph properties' pStyle element.

[*Example:* Consider a paragraph style titled "Test Paragraph Style" which defines; font = Algerian, font size = 20; font color = red; paragraph spacing = double; paragraph indent = 1" (first line only). The resulting style definition would be:

```
<w:style w:type="paragraph" w:styleId="TestParagraphStyle">
  <w:name w:val="Test Paragraph Style"/>
  <w:qformat/>
  <w:rsid w:val="00F85845"/>
  <w:pPr>
    <w:spacing w:line="480" w:lineRule="auto"/>
    <w:ind w:firstLine="1440"/>
  </w:pPr>
  <w:rPr>
    <w:rFonts w:ascii="Algerian" w:hAnsi="Algerian"/>
    <w:color w:val="ED1C24"/>
    <w:sz w:val="40"/>
  </w:rPr>
</w:style>
```

Notice that the character properties for the style are under the rPr element, and the paragraph properties are under the pPr element.

The document content for a paragraph of this style would be:

```
<w:p>
  <w:pPr>
    <w:pStyle w:val="TestParagraphStyle"/>
  </w:pPr>
  <w:r>
    <w:t xml:space="preserve">Here is some fancy Text</w:t>
  </w:r>
</w:p>
```

The pStyle element links the paragraph with the style definition. *end example*]

2.7.7.1 Numbering in Paragraph Styles

When a paragraph style references a numbering definition and level which shall also be applied, that reference shall be done in a way slightly different from the typical numbering reference as follows:

- When a numbering reference is created as direct formatting, that reference consists of a reference to the numbering definition instance + a numbering level

[*Example*: Consider a numbered paragraph in a WordprocessingML document whose numbering is a result of direct formatting (formatting not from a style). This numbered paragraph may be represented using the following WordprocessingML:

```
<w:p>
  <w:pPr>
    <w:numPr>
      <w:ilvl w:val="0" />
      <w:numId w:val="5" />
    </w:numPr>
  </w:pPr>
  <w:r>
    <w:t>Level one</w:t>
  </w:r>
</w:p>
```

The numPr element contains two pieces of information:

- The numId element (the numbering definition instance referenced)
- The ilvl element (the level within that numbering definition)

end example]

- When numbering is done as part of a paragraph style, that reference consists of a reference to the numbering definition only. The numbering definition then in turn has a reference to the paragraph style on the level which shall be associated with this style

[*Example*: Consider a numbered paragraph in a WordprocessingML document whose numbering is a result of a paragraph style. This numbered paragraph may be represented using the following WordprocessingML:

```
<w:p>
  <w:pPr>
    <w:pStyle w:val="TestParagraphStyle"/>
  </w:pPr>
  <w:r>
    <w:t>Level one</w:t>
  </w:r>
</w:p>
```

The paragraph references the style via its styleId attribute, which itself looks like this:

```
<w:style w:styleId="TestParagraphStyle" … >
  <w:pPr>
    <w:numPr>
      <w:numId w:val="5" />
    </w:numPr>
  </w:pPr>
</w:style>
```

The numPr element contains one piece of information:

- The numId element (the numbering definition instance referenced)

Obviously, this is insufficient to apply the numbering since we need to know which level to apply, so this information is specified on the appropriate level using the pStyle element:

```
<w:abstractNum w:abstractNumId="1">
  ...
  <w:lvl w:ilvl="0">
    ...
    <w:pStyle w:val="TestParagraphStyle" />
    <w:pPr>
      <w:tabs>
        <w:tab w:val="num" w:pos="720" />
      </w:tabs>
      <w:ind w:left="720" w:hanging="360" />
    </w:pPr>
    ...
  </w:lvl>
</w:abstractNum>
```

In this case, level `0` of the underlying abstract numbering definition specifies that it is associated with paragraph style `TestParagraphStyle`, so this level of the numbering shall be applied along with the paragraph style. *end example*]

When numbering is referenced by a paragraph style, its properties shall be applied before the style's properties (the style's paragraph properties shall override the numbering level's paragraph properties).

2.7.7.2 pPr (Style Paragraph Properties)

This element specifies the set of paragraph properties which shall be applied to the paragraph.

[*Example*: Consider a paragraph style defined as follows:

```
<w:style w:type="paragraph" w:styleId="TestParaStyle">
  <w:pPr>
    <w:keepLines/>
  </w:pPr>
</w:style>
```

The pPr element specified within the style element specifies the set of paragraph properties which shall be applied to the referencing paragraph. In this example, the single paragraph property applied is the fact that the paragraph shall be displayed on a single page via the keepLines element (§2.3.1.14). *end example*]

Parent Elements
style (§2.7.3.17)

widowControl (Allow First/Last Line to Display on a Separate Page)	§2.3.1.44
wordWrap (Allow Line Breaking At Character Level)	§2.3.1.45

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_PPr">
   <complexContent>
      <extension base="CT_PPrBase">
         <sequence>
            <element name="rPr" type="CT_ParaRPr" minOccurs="0"/>
            <element name="sectPr" type="CT_SectPr" minOccurs="0"/>
            <element name="pPrChange" type="CT_PPrChange" minOccurs="0"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.7.8 Run (Character) Styles

Character styles are styles which apply to the contents of one or more runs of text within a document's contents. This definition implies that the style can only define character properties (properties which apply to text within a paragraph) because it cannot be applied to paragraphs. Character styles can only be referenced by runs within a document, and they must be referenced by the rStyle element within a run's run properties element.

A character style has two defining type-specific characteristics:

- The type attribute on the style has a value of `character`, which indicates that the following style definition is a character style.
- The style specifies only character-level properties using the rPr element. In this case, the run properties are the set of properties applied to each run which is of this style.

The character style is then applied to runs by referencing the styleId attribute value for this style in the run properties' rStyle element.

[*Example:* Consider a character style titled "Test Character Style" which defines; font = Courier New, font color = yellow; underline. The resulting style definition would be:

```
<w:style w:type="character" w:styleId="TestCharacterStyle">
  <w:name w:val="Test Character Style"/>
  <w:priority w:val="99"/>
  <w:qformat/>
  <w:rsid w:val="00E77BF0"/>
  <w:rPr>
    <w:rFonts w:ascii="Courier New" w:hAnsi="Courier New"/>
    <w:color w:val="FFF200"/>
    <w:u w:val="single"/>
  </w:rPr>
</w:style>
```

Notice that the character properties applied using this style are under the rPr element. The document content for a paragraph with a run of this style would be:

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">The following text is in the </w:t>
  </w:r>
  <w:r>
    <w:rPr>
      <w:rStyle w:val="TestCharacterStyle"/>
    </w:rPr>
    <w:t>character style</w:t>
  </w:r>
  <w:r>
    <w:t>.</w:t>
  </w:r>
</w:p>
```

The rStyle element in the second run links that run with the style definition, inheriting the formatting properties for that run. *end example*]

2.7.8.1 rPr (Run Properties)

This element specifies the set of run properties which shall be applied to the run.

[*Example*: Consider a character style defined as follows:

```
<w:style w:type="character" w:styleId="TestCharStyle">
  <w:rPr>
    <w:dstrike/>
  </w:rPr>
</w:style>
```

The rPr element specified within the style element specifies the set of run properties which shall be applied to the referencing run. In this example, the single run property applied is the fact that the paragraph shall be displayed with double strikethrough via the dstrike element (§2.3.2.7). *end example*]

Parent Elements
style (§2.7.3.17)

Child Elements	Subclause
b (Bold)	§2.3.2.1
bCs (Complex Script Bold)	§2.3.2.2
bdr (Text Border)	§2.3.2.3
caps (Display All Characters As Capital Letters)	§2.3.2.4
color (Run Content Color)	§2.3.2.5
cs (Use Complex Script Formatting on Run)	§2.3.2.6

i (Italics)	§2.3.2.14
iCs (Complex Script Italics)	§2.3.2.15
imprint (Imprinting)	§2.3.2.16
kern (Font Kerning)	§2.3.2.17
lang (Languages for Run Content)	§2.3.2.18
noProof (Do Not Check Spelling or Grammar)	§2.3.2.19
oMath (Office Open XML Math)	§2.3.2.20
outline (Display Character Outline)	§2.3.2.21
position (Vertically Raised or Lowered Text)	§2.3.2.22
rFonts (Run Fonts)	§2.3.2.24

Child Elements	Subclause
rPrChange (Revision Information for Run Properties)	§2.13.5.32
rStyle (Referenced Character Style)	§2.3.2.27
rtl (Right To Left Text)	§2.3.2.28
shadow (Shadow)	§2.3.2.29
shd (Run Shading)	§2.3.2.30
smallCaps (Small Caps)	§2.3.2.31
snapToGrid (Use Document Grid Settings For Inter-Character Spacing)	§2.3.2.32
spacing (Character Spacing Adjustment)	§2.3.2.33
specVanish (Paragraph Mark Is Always Hidden)	§2.3.2.34
strike (Single Strikethrough)	§2.3.2.35
sz (Font Size)	§2.3.2.36
szCs (Complex Script Font Size)	§2.3.2.37
u (Underline)	§2.3.2.38
vanish (Hidden Text)	§2.3.2.39
vertAlign (Subscript/Superscript Text)	§2.3.2.40
w (Expanded/Compressed Text)	§2.3.2.41
webHidden (Web Hidden Text)	§2.3.2.42

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RPr">
   <sequence>
      <group ref="EG_RPrContent" minOccurs="0"/>
   </sequence>
</complexType>
```

2.8 Fonts

The next component of a WordprocessingML document is storing information about the fonts used in the document. WordprocessingML stores two pieces of information about fonts:

- (optionally) Information about the font to enable font substitution. *Font substitution* is a process by which an application, when it cannot locate a specific font, attempts to locate the closest possible match to the intended appearance of the font
- (optionally) One or more embedded forms of the font for use on systems which do not have access to the font. When fonts are embedded, they are obfuscated to ensure that they are only used to view the contents of the document in which they are embedded, and for no other purpose.

[*Example*: Consider the following information stored in a document's font table part:

```
<w:fonts>
  <w:font w:name="Times New Roman">
    <w:panose1 w:val="02020603050405020304" />
    <w:charset w:val="00" />
    <w:family w:val="roman" />
    <w:pitch w:val="variable" />
    <w:sig w:usb0="20002A87" w:usb1="80000000" w:usb2="00000008"
w:usb3="00000000" w:csb0="000001FF" w:csb1="00000000" />
    <w:embedRegular r:id="rId10" w:fontKey="{302EE813-EB4A-4642-A93A-
89EF99B2457E}" />
  </w:font>
</w:fonts>
```

The font table contains information about the `Times New Roman` font; specifically, information used to locate a substitute font when it is not available and a relationship to the embedded form of the regular form of the font. *end example*]

2.8.1 Font Embedding

Within a WordprocessingML document, *font embedding* refers to a process in which the some or all of the fonts used in the current document are included in that document such that it can be guaranteed that they are available for use when the document is subsequently opened.

Embedded fonts are stored in an Embedded Font part within the package.

When a font is embedded within a WordprocessingML document, it shall be obfuscated to prevent it from being used outside of this document. This obfuscation shall be done using the following algorithm:

- Generate a GUID, which will be used and stored as the obfuscation key
- Reverse the order of the bytes in the GUID (i.e. Big Endian ordering)
- XOR the value with the first 32 bytes of the binary: once against 0-15, once against 16-31
- Store the resulting file in the document, and store the obfuscation key in the fontKey attribute

[*Example*: Consider a font to be embedded whose first 32 bytes are as follows:

00	01	00	00	00	12	01	00	00	04	00	20	44	53	49	47
A3	0E	BF	F3	00	01	36	8C	00	00	14	DC	4C	54	53	48

To obfuscate this font for storage:

- Generate a GUID (e.g. `001B70DC-AA60-4AD5-90EC-18A0948E1EAE`)
- Reverse its order (e.g. `AE1E8E94-A018-EC90-D54A-60AADC701B00`)
- XOR the GUID with the first and second 16 bytes

The resulting 32 bytes would be:

AE	1F	8E	94	A0	0A	ED	90	D5	4E	60	8A	98	23	52	47
0D	10	31	67	A0	19	DA	1C	D5	4A	74	76	90	24	48	48

end example]

To retrieve an obfuscated font for viewing the content of this document only, repeat the procedure above to retrieve the original font.

2.8.2 Elements

The following elements comprise the content of the font table:

2.8.2.1 altName (Alternate Names for Font)

This element specifies a set of alternative names which may be used to locate the font specified by the parent element. This set of alternative names is stored in a comma-delimited list, with all adjacent commas ignored (i.e. a value of `Name A, Name B` is equivalent to `Name A,,,,,,,,, Name B`).

When an application cannot locate a font using the primary name stored on the font attribute of the font element (§2.8.2.10), it should use each alternate name in term to attempt to locate the font, and use the first font for which is locates a match.

If this element is omitted, then no alternate names are present for the parent font.

[*Example*: Consider the following information stored for a single font:

```
<w:font w:name="SimSun">
  <w:altName w:val="Arial Unicode MS" />
  …
</w:font>
```

The altName element specifies that when no font with a name of `SimSun` (the primary font name) can be located, that applications should attempt to locate a font with the name `Arial Unicode MS` before doing substitution based on the font metrics. *end example*]

Parent Elements
font (§2.8.2.10)

Attributes	Description
val (String Value)	Specifies that its contents will contain a string. The contents of this string are interpreted based on the context of the parent XML element. [*Example*: Consider the following WordprocessingML fragment:

Attributes	Description
	<w:pPr> <w:pStyle w:val="heading1" /> </w:pPr> The value of the val attribute is the ID of the associated paragraph style's styleId. However, consider the following fragment: <w:sdtPr> <w:alias w:val="SDT Title Example" /> ... </w:sdtPr> In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.8.2.2 charset (Character Set Supported By Font)

This element specifies the character set which is supported by the parent font. This information may be used as defined in font substitution logic to locate an appropriate substitute font when this font is not available. This information is determined by querying the font when present and shall not be modified when the font is not available.

The value of this element shall be interpreted as follows:

Value	Description
0x00	Specifies the ANSI character set.
0x01	Specifies the default character set.
0x02	Specifies the Symbol character set.
0x4D	Specifies a Macintosh (Standard Roman) character set.
0x80	Specifies the JIS character set.
0x81	Specifies the Hangul character set.
0x82	Specifies a Johab character set.
0x86	Specifies the GB-2312 character set.
0x88	Specifies the Chinese Big Five character set.

Value	Description
0xA1	Specifies a Greek character set.
0xA2	Specifies a Turkish character set.
0xA3	Specifies a Vietnamese character set.
0xB1	Specifies a Hebrew character set.
0xB2	Specifies an Arabic character set.
0xBA	Specifies a Baltic character set.
0xCC	Specifies a Russian character set.
0xDE	Specifies a Thai character set.
0xEE	Specifies an Eastern European character set.
0xFF	Specifies an OEM character set not defined by this Office Open XML Standard.
Any other value	Application-defined, may be ignored.

If this element is not present, then the character set for this font shall be assumed to be the ANSI character set.

[*Example*: Consider the following information stored for a single font:

```
<w:font w:name="SimSun">
  <w:charset w:val="86" />
  …
</w:font>
```

The charset element specifies via its val attribute value of 86 that this font uses the GB-2312 character set. *end example*]

Parent Elements
font (§2.8.2.10)

Attributes	Description
val (Value)	Specifies a value specified as single octet (two digit) hexadecimal number whose contents are interpreted based on the context of the parent XML element. [*Example*: Consider the following value for an attribute of type ST_UCharHexNumber: `<w:… w:val="BE"/>` This value is valid, as it contains two hexadecimal digits, an encoding of an octet of the actual decimal number value. *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple

Attributes	Description
	type (§2.18.106).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_UcharHexNumber">
   <attribute name="val" type="ST_UcharHexNumber" use="required"/>
</complexType>
```

2.8.2.3 embedBold (Bold Style Font Style Embedding)

This element specifies information about the embedded font storage for the bold form of a font, when it is embedded. This form is used when bold is applied to a text run.

If this element is omitted, then no bold form of the font is stored in the document. The relationship targeted by the id attribute must be of the embedded font type, or the document shall be considered to be invalid.

[*Example*: Consider a WordprocessingML document in which the Arial font has been embedded in the file. This status would be specified using the following WordprocessingML:

```
<w:font w:name="Arial">
  …
  <w:embedBold r:id="rId10" />
</w:font>
```

The embedBold element specifies that the embedded font targeted with the relationship with ID `rId10` may be used to retrieve the bold form of the embedded Arial font. *end example*]

Parent Elements
font (§2.8.2.10)

Attributes	Description

fontKey (Embedded Font Obfuscation Key)	Specifies the key which was used to obfuscate this embedded font. This key may be used to retrieve the embedded font for the purposes of viewing this WordprocessingML document only, using the algorithm described in §2.8.1.
	
	If this attribute is omitted, then no key is provided for this font.
	
	[*Example*: Consider a WordprocessingML document in which the Arial font has been embedded in the file. This status would be specified using the following WordprocessingML:
	
	`<w:font w:name="Arial">`
	`  …`
	`  <w:embedRegular r:id="rId10" w:fontKey="{302EE813-EB4A-4642-A93A-89EF99B2457E}" />`

Attributes	Description
	</w:font> The fontKey attribute has a value of {302EE813-EB4A-4642-A93A-89EF99B2457E}, therefore the embedded Arial font targeted with the relationship with ID rId10 may be retrieved if needed by using this key and the algorithm above. *end example*] The possible values for this attribute are defined by the ST_Guid simple type (§2.18.39).
id (Relationship to Part) Namespace: .../officeDocument/2006/relationships	Specifies the relationship ID to a specified part. The specified relationship shall match the type required by the parent element: • http://schemas.openxmlformats.org/officeDocument/2006/relationships/footer for the footerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/header for the headerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/font for the embedBold, embedBoldItalic, embedItalic, or embedRegular elements • http://schemas.openxmlformats.org/officeDocument/2006/relationships/printerSettings for the printerSettings element [*Example*: Consider an XML element which has the following id attribute: <… r:id="rId10" /> The markup specifies the associated relationship part with relationship ID rId1 contains the corresponding relationship information for the parent XML element. *end example*] The possible values for this attribute are defined by the ST_RelationshipId simple type (§7.8.2.1).
subsetted (Embedded Font Is Subsetted)	Specifies that the embedded font targeted by the id attribute has been subsetted. *Subsetting* is a mechanism by which only the glyphs used in the contents of this WordprocessingML document are stored in an embedded font, in order to prevent the file from becoming unnecessarily large from the use of a small number of glyphs from a large embedded font. If this attribute is omitted, then the embedded font target by the id attribute shall not be handled as though it is subsetted. [*Example*: Consider a WordprocessingML document in which the Arial font has been embedded in the file after subsetting. This status would be specified using the following WordprocessingML: <w:font w:name="Arial"> … <w:embedRegular r:id="rId10" w:subsetted="true" /> </w:font>

Attributes	Description
	The subsetted attribute has a value of `true`, therefore the embedded Arial font targeted with the relationship with ID `rId10` shall be treated as a subsetted font. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FontRel">
   <complexContent>
      <extension base="CT_Rel">
         <attribute name="fontKey" type="ST_Guid"/>
         <attribute name="subsetted" type="ST_OnOff"/>
      </extension>
   </complexContent>
</complexType>
```

2.8.2.4 embedBoldItalic (Bold Italic Font Style Embedding)

This element specifies information about the embedded font storage for the bold italic form of a font, when it is embedded. This form is used when bold and italics are applied to a text run.

If this element is omitted, then no bold italic form of the font is stored in the document.

[*Example*: Consider a WordprocessingML document in which the Arial font has been embedded in the file. This status would be specified using the following WordprocessingML:

```
<w:font w:name="Arial">
  …
  <w:embedBoldItalic r:id="rId11" />
</w:font>
```

The embedBoldItalic element specifies that the embedded font targeted with the relationship with ID `rId11` may be used to retrieve the bold italic form of the embedded Arial font. *end example*]

Parent Elements
font (§2.8.2.10)

Attributes	Description
fontKey (Embedded Font Obfuscation Key)	Specifies the key which was used to obfuscate this embedded font. This key may be used to retrieve the embedded font for the purposes of viewing this WordprocessingML document only, using the algorithm described in §2.8.1. If this attribute is omitted, then no key is provided for this font. [*Example*: Consider a WordprocessingML document in which the Arial font has been

Attributes	Description

	embedded in the file. This status would be specified using the following WordprocessingML:
	
	`<w:font w:name="Arial">`
	`  …`
	`  <w:embedRegular r:id="rId10" w:fontKey="{302EE813-EB4A-4642-A93A-89EF99B2457E}" />`
	`</w:font>`
	
	The fontKey attribute has a value of `{302EE813-EB4A-4642-A93A-89EF99B2457E}`, therefore the embedded Arial font targeted with the relationship with ID `rId10` may be retrieved if needed by using this key and the algorithm above. *end example*]
	
	The possible values for this attribute are defined by the ST_Guid simple type (§2.18.39).

id (Relationship to Part) Namespace: …/officeDocument/2006/relationships	Specifies the relationship ID to a specified part. The specified relationship shall match the type required by the parent element: • http://schemas.openxmlformats.org/officeDocument/2006/relationships/footer for the footerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/header for the headerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/font for the embedBold, embedBoldItalic, embedItalic, or embedRegular elements • http://schemas.openxmlformats.org/officeDocument/2006/relationships/printerSettings for the printerSettings element [*Example*: Consider an XML element which has the following id attribute: `<… r:id="rId10" />` The markup specifies the associated relationship part with relationship ID `rId1` contains the corresponding relationship information for the parent XML element. *end example*] The possible values for this attribute are defined by the ST_RelationshipId simple type (§7.8.2.1).
subsetted (Embedded Font Is Subsetted)	Specifies that the embedded font targeted by the id attribute has been subsetted. *Subsetting* is a mechanism by which only the glyphs used in the contents of this WordprocessingML document are stored in an embedded font, in order to prevent the file from becoming unnecessarily large from the use of a small number of glyphs from a large embedded font. If this attribute is omitted, then the embedded font target by the id attribute shall not be handled as though it is subsetted. [*Example*: Consider a WordprocessingML document in which the Arial font has been

Attributes	Description

	embedded in the file after subsetting. This status would be specified using the following WordprocessingML:
	
	`<w:font w:name="Arial">`
	`…`
	`<w:embedRegular r:id="rId10" w:subsetted="true" />`
	`</w:font>`
	
	The subsetted attribute has a value of `true`, therefore the embedded Arial font targeted with the relationship with ID `rId10` shall be treated as a subsetted font. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FontRel">
   <complexContent>
      <extension base="CT_Rel">
         <attribute name="fontKey" type="ST_Guid"/>
         <attribute name="subsetted" type="ST_OnOff"/>
      </extension>
   </complexContent>
</complexType>
```

2.8.2.5 embedItalic (Italic Font Style Embedding)

This element specifies information about the embedded font storage for the italic form of a font, when it is embedded. This form is used when italics are applied to a text run.

If this element is omitted, then no italic form of the font is stored in the document.

[*Example*: Consider a WordprocessingML document in which the Arial font has been embedded in the file. This status would be specified using the following WordprocessingML:

```
<w:font w:name="Arial">
  …
  <w:embedItalic r:id="rId12" />
</w:font>
```

The embedItalic element specifies that the embedded font targeted with the relationship with ID `rId12` may be used to retrieve the italic form of the embedded Arial font. *end example*]

Parent Elements
font (§2.8.2.10)

Attributes	Description

Attributes	Description

fontKey (Embedded Font Obfuscation Key)	Specifies the key which was used to obfuscate this embedded font. This key may be used to retrieve the embedded font for the purposes of viewing this WordprocessingML document only, using the algorithm described in §2.8.1.
	
	If this attribute is omitted, then no key is provided for this font.
	
	[*Example*: Consider a WordprocessingML document in which the Arial font has been embedded in the file. This status would be specified using the following WordprocessingML:
	
	`<w:font w:name="Arial">`
	`  …`
	`  <w:embedRegular r:id="rId10" w:fontKey="{302EE813-EB4A-4642-A93A-89EF99B2457E}" />`
	`</w:font>`
	
	The fontKey attribute has a value of `{302EE813-EB4A-4642-A93A-89EF99B2457E}`, therefore the embedded Arial font targeted with the relationship with ID `rId10` may be retrieved if needed by using this key and the algorithm above. *end example*]
	
	The possible values for this attribute are defined by the ST_Guid simple type (§2.18.39).

id (Relationship to Part) Namespace: .../officeDocument/2006/relationships	Specifies the relationship ID to a specified part. The specified relationship shall match the type required by the parent element: • http://schemas.openxmlformats.org/officeDocument/2006/relationships/footer for the footerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/header for the headerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/font for the embedBold, embedBoldItalic, embedItalic, or embedRegular elements • http://schemas.openxmlformats.org/officeDocument/2006/relationships/printerSettings for the printerSettings element [*Example*: Consider an XML element which has the following id attribute: `<… r:id="rId10" />` The markup specifies the associated relationship part with relationship ID `rId1` contains the corresponding relationship information for the parent XML element. *end example*] The possible values for this attribute are defined by the ST_RelationshipId simple type (§7.8.2.1).
subsetted (Embedded Font Is Subsetted)	Specifies that the embedded font targeted by the id attribute has been subsetted. *Subsetting* is a mechanism by which only the glyphs used in the contents of this WordprocessingML document are stored in an embedded font, in order to prevent the

Attributes	Description

	file from becoming unnecessarily large from the use of a small number of glyphs from a large embedded font.
	
	If this attribute is omitted, then the embedded font target by the id attribute shall not be handled as though it is subsetted.
	
	[*Example*: Consider a WordprocessingML document in which the Arial font has been embedded in the file after subsetting. This status would be specified using the following WordprocessingML:
	
	`<w:font w:name="Arial">`
	`…`
	`<w:embedRegular r:id="rId10" w:subsetted="true" />`
	`</w:font>`
	
	The subsetted attribute has a value of `true`, therefore the embedded Arial font targeted with the relationship with ID `rId10` shall be treated as a subsetted font. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FontRel">
   <complexContent>
      <extension base="CT_Rel">
         <attribute name="fontKey" type="ST_Guid"/>
         <attribute name="subsetted" type="ST_OnOff"/>
      </extension>
   </complexContent>
</complexType>
```

2.8.2.6 embedRegular (Regular Font Style Embedding)

This element specifies information about the embedded font storage for the regular form of a font, when it is embedded. This form is used when neither bold nor italics is applied to a text run.

If this element is omitted, then no regular form of the font is stored in the document.

[*Example*: Consider a WordprocessingML document in which the Arial font has been embedded in the file. This status would be specified using the following WordprocessingML:

```
<w:font w:name="Arial">
  …
  <w:embedRegular r:id="rId13" />
</w:font>
```

The embedRegular element specifies that the embedded font targeted with the relationship with ID `rId13` may be used to retrieve the regular form of the embedded Arial font. *end example*]

Parent Elements
font (§2.8.2.10)

Attributes	Description

fontKey (Embedded Font Obfuscation Key)	Specifies the key which was used to obfuscate this embedded font. This key may be used to retrieve the embedded font for the purposes of viewing this WordprocessingML document only, using the algorithm described in §2.8.1.
	
	If this attribute is omitted, then no key is provided for this font.
	
	[*Example*: Consider a WordprocessingML document in which the Arial font has been embedded in the file. This status would be specified using the following WordprocessingML:
	
	`<w:font w:name="Arial">`
	`  …`
	`  <w:embedRegular r:id="rId10" w:fontKey="{302EE813-EB4A-4642-A93A-89EF99B2457E}" />`
	`</w:font>`
	
	The fontKey attribute has a value of `{302EE813-EB4A-4642-A93A-89EF99B2457E}`, therefore the embedded Arial font targeted with the relationship with ID `rId10` may be retrieved if needed by using this key and the algorithm above. *end example*]
	
	The possible values for this attribute are defined by the ST_Guid simple type (§2.18.39).

id (Relationship to Part) Namespace: .../officeDocument/2006/relationships	Specifies the relationship ID to a specified part. The specified relationship shall match the type required by the parent element: • http://schemas.openxmlformats.org/officeDocument/2006/relationships/footer for the footerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/header for the headerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/font for the embedBold, embedBoldItalic, embedItalic, or embedRegular elements • http://schemas.openxmlformats.org/officeDocument/2006/relationships/printerSettings for the printerSettings element [*Example*: Consider an XML element which has the following id attribute: `<… r:id="rId10" />` The markup specifies the associated relationship part with relationship ID `rId1` contains the corresponding relationship information for the parent XML element. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_RelationshipId simple type (§7.8.2.1).

subsetted (Embedded Font Is Subsetted)	Specifies that the embedded font targeted by the id attribute has been subsetted. *Subsetting* is a mechanism by which only the glyphs used in the contents of this WordprocessingML document are stored in an embedded font, in order to prevent the file from becoming unnecessarily large from the use of a small number of glyphs from a large embedded font.
	
	If this attribute is omitted, then the embedded font target by the id attribute shall not be handled as though it is subsetted.
	
	[*Example*: Consider a WordprocessingML document in which the Arial font has been embedded in the file after subsetting. This status would be specified using the following WordprocessingML:
	
	`<w:font w:name="Arial">`
	`…`
	`<w:embedRegular r:id="rId10" w:subsetted="true" />`
	`</w:font>`
	
	The subsetted attribute has a value of `true`, therefore the embedded Arial font targeted with the relationship with ID `rId10` shall be treated as a subsetted font. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FontRel">
   <complexContent>
      <extension base="CT_Rel">
         <attribute name="fontKey" type="ST_Guid"/>
         <attribute name="subsetted" type="ST_OnOff"/>
      </extension>
   </complexContent>
</complexType>
```

2.8.2.7 embedSystemFonts (Embed Common System Fonts)

This element specifies that applications shall embed common system fonts when they are in use and font embedding is enabled for this document using the embedTrueTypeFonts element (§2.8.2.8). *Common system fonts* refer to a set of fonts which are typically always present on a machine, and are not defined by this Office Open XML Standard.

If this element is omitted, then the set of fonts defined as common system fonts should not be embedded in the current document when font embedded is turned on. If the embedTrueTypeFonts element is omitted or `false`, then this setting has no effect.

[*Example*: Consider a WordprocessingML document that specifies that it shall embed fonts, including common system fonts. This requirement would be specified using the following WordprocessingML in the document settings part:

```
<w:embedTrueTypeFonts w:val="true" />
<w:embedSystemFonts w:val="true"/>
```

The embedSystemFonts element's val attribute has a value of `true` specifying that common system fonts should be included in this document when they are used. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.8.2.8 embedTrueTypeFonts (Embed TrueType Fonts)

This element specifies that applications shall embed the fonts in use in this document when it is saved. These fonts shall be embedded subject to the algorithm specified in §2.8.1.

If this element is omitted, then fonts in use should not be embedded in the current document.

[*Example*: Consider a WordprocessingML document that specifies that it shall embed fonts, including common system fonts. This requirement would be specified using the following WordprocessingML in the document settings part:

```
<w:embedTrueTypeFonts w:val="true" />
<w:embedSystemFonts w:val="true"/>
```

The embedTrueType element's val attribute has a value of `true` specifying that fonts should be embedded in this document when they are used. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.8.2.9 family (Font Family)

This element specifies the font family of the current font. This information may be used as defined in font substitution logic to locate an appropriate substitute font when this font is not available. This information is determined by querying the font when present and shall not be modified when the font is not available.

If this element is omitted, then its value shall be assumed to be `auto`.

[*Example*: Consider the following information stored for a single font:

```
<w:font w:name="Calibri">
  <w:family w:val="swiss" />
  …
</w:font>
```

The family element specifies via its val attribute value of swiss that this font is part of the Swiss family. *end example*]

Parent Elements
font (§2.8.2.10)

Attributes	Description

val (Font Family Value)	Specifies the font family for the parent font.
	
	[*Example*: Consider the following information stored for a single font:
	
	`<w:font w:name="Times New Roman">`
	`  <w:family w:val="roman" />`
	`  …`
	`</w:font>`
	
	The val attribute value of swiss that this font is part of the Roman family. *end example*]
	
	The possible values for this attribute are defined by the ST_FontFamily simple type (§2.18.34).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FontFamily">
   <attribute name="val" type="ST_FontFamily" use="required"/>
</complexType>
```

2.8.2.10 font (Properties for a Single Font)

This element specifies the properties for one of the fonts used in this document. A font element shall be written out for each font face used in the document, and includes:

- The name of the font as used in the document's stories
- (optionally) Font metrics allowing other applications to locate appropriate substitute fonts as needed
- (optionally) Embedded forms of the font

[*Example*: Consider the following information stored for a single font:

```
<w:font w:name="Times New Roman">
  <w:panose1 w:val="02020603050405020304" />
  <w:charset w:val="00" />
  <w:family w:val="roman" />
  <w:pitch w:val="variable" />
  <w:sig w:usb0="20002A87" w:usb1="80000000" w:usb2="00000008" w:usb3="00000000"
w:csb0="000001FF" w:csb1="00000000" />
</w:font>
```

The font element contains information about the `Times New Roman` font; specifically, information used to locate a substitute font if it is not available. *end example*]

Parent Elements
fonts (§2.8.2.11)

Child Elements	Subclause
altName (Alternate Names for Font)	§2.8.2.1
charset (Character Set Supported By Font)	§2.8.2.2
embedBold (Bold Style Font Style Embedding)	§2.8.2.3
embedBoldItalic (Bold Italic Font Style Embedding)	§2.8.2.4
embedItalic (Italic Font Style Embedding)	§2.8.2.5
embedRegular (Regular Font Style Embedding)	§2.8.2.6
family (Font Family)	§2.8.2.9
notTrueType (Raster or Vector Font)	§2.8.2.12
panose1 (Pansose-1 Typeface Classification Number)	§2.8.2.13
pitch (Font Pitch)	§2.8.2.14
sig (Supported Unicode Subranges and Code Pages)	§2.8.2.16

Attributes	Description

name (Primary Font Name)	Specifies the primary name of the current font. This name shall be used to link the information stored in this element with uses of this value in the rFonts element (§2.3.2.24) in document content.
	
	[*Example*: Consider the following information stored for a single font:
	
	`<w:font w:name="Times New Roman">`
	`  …`
	`</w:font>`
	
	The name attribute specifies that the information contained in this element shall be used to look up information about all uses of the `Times New Roman` font in the document contents. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Font">
   <sequence>
      <element name="altName" type="CT_String" minOccurs="0" maxOccurs="1"/>
      <element name="panose1" type="CT_Panose" minOccurs="0" maxOccurs="1"/>
      <element name="charset" type="CT_UcharHexNumber" minOccurs="0" maxOccurs="1"/>
      <element name="family" type="CT_FontFamily" minOccurs="0" maxOccurs="1"/>
      <element name="notTrueType" type="CT_OnOff" minOccurs="0" maxOccurs="1"/>
      <element name="pitch" type="CT_Pitch" minOccurs="0" maxOccurs="1"/>
      <element name="sig" type="CT_FontSig" minOccurs="0" maxOccurs="1"/>
      <element name="embedRegular" type="CT_FontRel" minOccurs="0" maxOccurs="1"/>
      <element name="embedBold" type="CT_FontRel" minOccurs="0" maxOccurs="1"/>
      <element name="embedItalic" type="CT_FontRel" minOccurs="0" maxOccurs="1"/>
      <element name="embedBoldItalic" type="CT_FontRel" minOccurs="0" maxOccurs="1"/>
   </sequence>
   <attribute name="name" type="ST_String" use="required"/>
</complexType>
```

2.8.2.11 fonts (Font Table Root Element)

This element specifies the root element for a font table part within a WordprocessingML document, and specifies information about the fonts used in this document, each contained within a child font element.

[*Example*: Consider the following information stored in a font table part:

```
<w:fonts>
  <w:font w:name="Times New Roman">
    …
  </w:font>
  <w:font w:name="Arial">
    …
  </w:font>
</w:fonts>
```

The fonts element contains information about all fonts used in the document - in this example, the `Times New Roman` and `Arial` fonts. *end example*]

Parent Elements
Root element of WordprocessingML Font Table part

Child Elements	Subclause
font (Properties for a Single Font)	§2.8.2.10

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FontsList">
   <sequence>
      <element name="font" type="CT_Font" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
</complexType>
```

2.8.2.12 notTrueType (Raster or Vector Font)

This element specifies that this font is not a TrueType or OpenType font, but is rather a raster or vector font. This information may be used as defined in font substitution logic to locate an appropriate substitute font when this font is not available. This information is determined by querying the font when present and shall not be modified when the font is not available.

If this element is omitted, then the font shall be assumed to be a TrueType or OpenType font.

[*Example*: Consider the following information stored for a single font:

```
<w:font w:name="JonsFont">
  <w:notTrueType w:val="true" />
  …
</w:font>
```

The notTrueType element specifies via its val attribute value of `true` that this font is a raster or vector font. *end example*]

Parent Elements
font (§2.8.2.10)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.8.2.13 panose1 (Pansose-1 Typeface Classification Number)

This element specifies the Panose-1 classification number for the current font using the PANOSE Classification Guide, Version 1.2. This information may be used as defined in font substitution logic to locate an appropriate substitute font when this font is not available. This information is determined by querying the font when present and shall not be modified when the font is not available.

If this element is omitted, then no Panose-1 information is available.

[*Example*: Consider the following information stored for a single font:

```
<w:font w:name="Times New Roman">
  <w:panose1 w:val="02020603050405020304" />
  …
</w:font>
```

The panose1 element specifies its Panose-1 number via its val attribute value of `02020603050405020304`. *end example*]

Parent Elements
font (§2.8.2.10)

Attributes	Description
val (Value)	Specifies the Panose-1 classification number for the font, stored as a series of two digit hexadecimal encodings of each digits of the Panose number. [*Example*: Consider the following information stored for a single font: `<w:panose1 w:val="020F0603050405020304" />` The val attribute specifies that the digits in the Panose-1 number are: 2,15,6,3,5,2,3,4. *end example*] The possible values for this attribute are defined by the ST_Panose simple type (§2.18.72).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Panose">
   <attribute name="val" type="ST_Panose" use="required"/>
</complexType>
```

2.8.2.14 pitch (Font Pitch)

This element specifies the font pitch of the current font. This information may be used as defined in font substitution logic to locate an appropriate substitute font when this font is not available. This information is determined by querying the font when present and shall not be modified when the font is not available.

If this element is omitted, then its value shall be assumed to be `default`.

[*Example*: Consider the following information stored for a single font:

```
<w:font w:name="Courier New">
  <w:pitch w:val="fixed" />
  …
</w:font>
```

The pitch element specifies via its val attribute value of `fixed` that this is a fixed width font. *end example*]

Parent Elements
font (§2.8.2.10)

Attributes	Description
val (Value)	Specifies the font pitch for the font. [*Example*: Consider the following information stored for a single font: `<w:pitch w:val="variable" />` The val attribute value of `variable` specifies that this is a variable width font. *end example*] The possible values for this attribute are defined by the ST_Pitch simple type (§2.18.73).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Pitch">
   <attribute name="val" type="ST_Pitch" use="required"/>
</complexType>
```

2.8.2.15 saveSubsetFonts (Subset Fonts When Embedding)

This element specifies that applications shall subset fonts when font embedding is enabled for this document using the embedTrueTypeFonts element (§2.8.2.8). *Subsetting* is a mechanism by which only the glyphs used in the contents of this WordprocessingML document are stored in an embedded font, in order to prevent the file from becoming unnecessarily large from the use of a small number of glyphs from a large embedded font.

If this element is omitted, then the set of fonts should not be subsetted in the current document when font embedded is turned on. If the embedTrueTypeFonts element is omitted or `false`, then this setting has no effect.

[*Example*: Consider a WordprocessingML document that specifies that it shall subset embedded fonts. This requirement would be specified using the following WordprocessingML in the document settings part:

```
<w:embedTrueTypeFonts w:val="true" />
<w:saveSubsetFonts w:val="true"/>
```

The embedSystemFonts element's val attribute has a value of `true` specifying fonts should be subsetted in this document when they are embedded. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.8.2.16 sig (Supported Unicode Subranges and Code Pages)

This element specifies information identifying the code pages and Unicode subranges for which the parent font provides glyphs. This information may be used as defined in font substitution logic to locate an appropriate substitute font when this font is not available. This information is determined by querying the font when present and shall not be modified when the font is not available.

When storing Unicode subrange information, the appropriate bit in the bitfield shall only be set if the entire subrange is supported by that font.

If this element is omitted, then no supported code page/Unicode subrange information is available.

[*Example*: Consider the following information stored for a single font:

```
<w:font w:name="Times New Roman">
  <w:sig w:usb0="20002A87" w:usb1="80000000" w:usb2="00000008" w:usb3="00000000"
w:csb0="000001FF" w:csb1="00000000" />
  …
</w:font>
```

The sig element specifies the supported code pages and Unicode sub ranges via its attributes. For example, the code pages supported are:

- Latin 1
- Latin 2: Eastern Europe
- Cyrillic
- Greek
- Turkish
- Baltic

end example]

Parent Elements
font (§2.8.2.10)

Attributes	Description
csb0 (Lower 32 Bits of Code Page Bit Field)	Specifies a four digit hexadecimal encoding of the first 32 bits of the 64-bit code-page bit field that identifies which specific character sets or code pages are supported by the parent font. Each bit in this 32 bits represents the following code page:

Bit	Description
0	Latin 1
1	Latin 2: Eastern Europe
2	Cyrillic
3	Greek
4	Turkish
5	Hebrew
6	Arabic

<table>
<tr><th>Attributes</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><td>7</td><td>Windows Baltic</td></tr>
<tr><td>8 to 16</td><td>Reserved for Alternate ANSI</td></tr>
<tr><td>17</td><td>Thai</td></tr>
<tr><td>18</td><td>JIS/Japan</td></tr>
<tr><td>19</td><td>Chinese (Simplified)</td></tr>
<tr><td>20</td><td>Korean Wansung</td></tr>
<tr><td>21</td><td>Chinese (Traditional)</td></tr>
<tr><td>22 to 29</td><td>Reserved for Alternate ANSI and OEM</td></tr>
<tr><td>30</td><td>Macintosh Character Set (Standard Roman)</td></tr>
<tr><td>31</td><td>Symbol Character Set</td></tr>
</table>
[Example: Consider font information specified as follows:
<pre>
<w:font w:name="Lucida Console">
  <w:sig w:csb0="0000001F" … />
  …
</w:font>
</pre>
The csb0 attribute value of 0000001F specifies that the following code pages are supported by this font:

Latin 1
Latin 2: Eastern Europe
Cyrillic
Greek
Turkish

end example]
The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).
</td></tr>
<tr><td>csb1 (Upper 32 Bits of Code Page Bit Field)</td><td>
Specifies a four digit hexadecimal encoding of the upper 32 bits of the 64-bit code-page bit field that identifies which specific character sets or code pages are supported by the parent font.
Each bit in this 32 bits represents the following code page:
<table>
<tr><th>Bit</th><th>Description</th></tr>
<tr><td>0 to 15</td><td>Reserved for OEM</td></tr>
<tr><td>16</td><td>IBM Greek</td></tr>
<tr><td>17</td><td>MS-DOS Russian</td></tr>
<tr><td>18</td><td>MS-DOS Nordic</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Attributes</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><td>19</td><td>Arabic</td></tr>
<tr><td>20</td><td>MS-DOS Canadian French</td></tr>
<tr><td>21</td><td>Hebrew</td></tr>
<tr><td>22</td><td>MS-DOS Icelandic</td></tr>
<tr><td>23</td><td>MS-DOS Portuguese</td></tr>
<tr><td>24</td><td>IBM Turkish</td></tr>
<tr><td>25</td><td>IBM Cyrillic</td></tr>
<tr><td>26</td><td>Latin 2</td></tr>
<tr><td>27</td><td>MS-DOS Baltic</td></tr>
<tr><td>28</td><td>Greek (former 437G)</td></tr>
<tr><td>29</td><td>Arabic (AMSO 708)</td></tr>
<tr><td>30</td><td>WE/Latin 1</td></tr>
<tr><td>31</td><td>US</td></tr>
</table>
[Example: Consider font information specified as follows:
<pre>
<w:font w:name="Lucida Console">
  <w:sig w:csb1="00000000" … />
  …
</w:font>
</pre>
The csb1 attribute value of 00000000 specifies that none of the specified code pages are supported by this font. end example]
The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).
</td></tr>
<tr><td>usb0 (First 32 Bits of Unicode Subset Bitfield)</td><td>
Specifies the first 32 bits of the 128-bit Unicode subset bit field (USB). Subranges are ordered in accordance with the ISO 10646 standard.
[Example: Consider font information specified as follows:
<pre>
<w:font w:name="Times New Roman">
  <w:sig w:usb0="20002A87" … />
  …
</w:font>
</pre>
The usb0 attribute value of 20002A87 specifies that the first 32 bits of the bitfield are 00100000000000000010101010000111, which corresponds to:

Basic Latin
Latin-1 Supplement
Latin Extended-A

</td></tr>
</table>

Attributes	Description
	• Basic Greek • Cyrillic • Basic Hebrew • Basic Arabic • Latin Extended Additional *end example*] The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

usb1 (Second 32 Bits of Unicode Subset Bitfield)	Specifies the second 32 bits of the 128-bit Unicode subset bit field (USB). Subranges are ordered in accordance with the ISO 10646 standard.
	
	[*Example*: Consider font information specified as follows:
	
	`<w:font w:name="Times New Roman">`
	`  <w:sig w:usb1="80000000" … />`
	`  …`
	`</w:font>`
	
	The usb0 attribute value of `80000000` specifies that the first 32 bits of the bitfield are 10000000000000000000000000000000, which corresponds to:
	• Arabic Presentation Forms-A
	
	end example]
	
	The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

usb2 (Third 32 Bits of Unicode Subset Bitfield)	Specifies the third 32 bits of the 128-bit Unicode subset bit field (USB). Subranges are ordered in accordance with the ISO 10646 standard.
	
	[*Example*: Consider font information specified as follows:
	
	`<w:font w:name="Times New Roman">`
	`  <w:sig w:usb2="00000008" … />`
	`  …`
	`</w:font>`
	
	The usb0 attribute value of `80000000` specifies that the first 32 bits of the bitfield are 00000000000000000000000000001000, which corresponds to:
	• Arabic Presentation Forms-B
	
	end example]
	
	The possible values for this attribute are defined by the ST_LongHexNumber simple type

Attributes	Description
	(§2.18.57).

usb3 (Fourth 32 Bits of Unicode Subset Bitfield)	Specifies the fourth 32 bits of the 128-bit Unicode subset bit field (USB). Subranges are ordered in accordance with the ISO 10646 standard.
	
	[*Example*: Consider font information specified as follows:
	
	`<w:font w:name="Times New Roman">`
	`  <w:sig w:usb3="00000000" … />`
	`  …`
	`</w:font>`
	
	The usb3 attribute value of `00000000` specifies that the first 32 bits of the bitfield are 00000000000000000000000000000000, which corresponds to no subranges. *end example*]
	
	The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FontSig">
   <attribute name="usb0" use="required" type="ST_LongHexNumber"/>
   <attribute name="usb1" use="required" type="ST_LongHexNumber"/>
   <attribute name="usb2" use="required" type="ST_LongHexNumber"/>
   <attribute name="usb3" use="required" type="ST_LongHexNumber"/>
   <attribute name="csb0" use="required" type="ST_LongHexNumber"/>
   <attribute name="csb1" use="required" type="ST_LongHexNumber"/>
</complexType>
```

2.9 Numbering

Numbering refers to symbols - Arabic numerals, Roman numerals, symbol characters ("bullets"), text strings, etc. - in WordprocessingML that are used to label individual paragraphs of text.

[*Example*: The following two paragraphs each contain numbering as defined by WordprocessingML: the first uses an Arabic numeral, the second a symbol character:

9. This is a paragraph with numbering information.

- This is also a paragraph with numbering information.

end example]

The basis for all numbering in WordprocessingML is specified via two structures:

- abstract numbering definitions
- numbering definition instances

Abstract numbering definitions define the appearance and behavior of a specific set of numbered paragraphs in a document. Because this construct is abstract, they are not be directly referenced by document content, but rather they must be inherited by a *numbering definition instance*, which itself is referenced by document content.

[*Example*: Consider the following example of an abstract numbering definition in a WordprocessingML document:

```
<w:abstractNum w:abstractNumId="4">
  <w:nsid w:val="FFFFFF7F" />
  <w:multiLevelType w:val="singleLevel" />
  <w:lvl w:ilvl="0">
    <w:start w:val="1" />
    <w:lvlText w:val="%1." />
    <w:lvlJc w:val="left" />
    <w:pPr>
      <w:tabs>
        <w:tab w:val="num" w:pos="720" />
      </w:tabs>
      <w:ind w:left="720" w:hanging="360" />
    </w:pPr>
  </w:lvl>
</w:abstractNum>
```

This abstractNum element defines an abstract numbering definition which defines a set of numbering properties. It is inherited by any numbering definition instance which inherits from an abstractNumId equal to 4:

```
<w:num w:numId="2">
    <w:abstractNumId w:val="4" />
</w:num>
```

This num element defines an numbering definition instance which may define overrides to the abstract numbering definition (in this case it does not), and is used by any paragraphs with a numId equal to 2:

```
<w:p>
  <w:pPr>
    <w:numPr>
      <w:ilvl w:val="0" />
      <w:numId w:val="2" />
    </w:numPr>
  </w:pPr>
  <w:r>
    <w:t>Level one</w:t>
  </w:r>
</w:p>
```

The resulting paragraph will inherit the properties of level `0` in the numbering definition instance of `2` which is simply a instance of the abstract numbering definition of `4`. *end example*]

2.9.1 abstractNum (Abstract Numbering Definition)

This element specifies a set of properties which shall dictate the appearance and behavior of a set of numbered paragraphs in a WordprocessingML document. These properties are collectively called an *abstract numbering definition*, and are the basis for all numbering information in a WordprocessingML document.

Although an abstract numbering definition contains a complete set of numbering, it shall not be directly referenced by content (hence the use of *abstract*). Instead, these properties shall be inherited by a numbering definition instance using the num element (§2.9.16), which can then itself be referenced by content.

[*Example*: Consider the following example of an abstractNum in a WordprocessingML document:

```
<w:abstractNum w:abstractNumId="4">
  <w:nsid w:val="FFFFFF7F" />
  <w:multiLevelType w:val="singleLevel" />
  <w:lvl w:ilvl="0">
    <w:start w:val="1" />
    <w:lvlText w:val="%1." />
    <w:lvlJc w:val="left" />
    <w:pPr>
      <w:tabs>
        <w:tab w:val="num" w:pos="720" />
      </w:tabs>
      <w:ind w:left="720" w:hanging="360" />
    </w:pPr>
  </w:lvl>
</w:abstractNum>
```

This abstractNum element defines an abstract numbering definition which shall be inherited by any numbering definition instance which inherits from abstract numbering definition with an abstractNumId equal to 4. *end example*]

Parent Elements
numbering (§2.9.17)

Child Elements	Subclause
lvl (Numbering Level Definition)	§2.9.7
multiLevelType (Abstract Numbering Definition Type)	§2.9.13
name (Abstract Numbering Definition Name)	§2.9.14
nsid (Abstract Numbering Definition Identifier)	§2.9.15
numStyleLink (Numbering Style Reference)	§2.9.22
styleLink (Numbering Style Definition)	§2.9.29
tmpl (Numbering Template Code)	§2.9.31

Attributes	Description

abstractNumId (Abstract Numbering Definition ID)	Specifies a unique number which shall be used as the identifier for this abstract numbering definition. This unique number shall be referenced by any numbering definition instance in order to inherit the properties specified by this abstract numbering definition.
	
	[*Example*: Consider the WordprocessingML for an abstract numbering definition with an abstractNumId attribute of 4:
	
	`<w:abstractNum w:abstractNumId="4">`
	`  <w:nsid w:val="FFFFFF7F" />`
	`  <w:multiLevelType w:val="singleLevel" />`
	`  <w:lvl w:ilvl="0">`
	`  <w:start w:val="1" />`
	`  <w:lvlText w:val="%1." />`
	`  <w:lvlJc w:val="left" />`
	`  <w:pPr>`
	`  <w:tabs>`
	`  <w:tab w:val="num" w:pos="720" />`
	`  </w:tabs>`
	`  <w:ind w:left="720"/>`
	`  </w:pPr>`
	`  </w:lvl>`
	`</w:abstractNum>`
	
	The abstractNumId attribute serves as a unique identifier for the abstract numbering

Attributes	Description

	definition, allowing numbering definition instances (§2.9.16) with a abstractNumId element with a matching attribute value to inherit the abstract numbering definition properties, for example:
	
	`<w:numbering>`
	`...`
	`<w:num w:numId="2">`
	`<w:abstractNumId w:val="0" />`
	`</w:num>`
	`<w:num w:numId="3">`
	`<w:abstractNumId w:val="1" />`
	`</w:num>`
	`<w:num w:numId="4">`
	`<w:abstractNumId w:val="4" />`
	`</w:num>`
	`<w:num w:numId="5">`
	`<w:abstractNumId w:val="4" />`
	`</w:num>`
	`</w:numbering>`
	
	In this case, the final two numbering definition instances both inherit from the abstract numbering definition with a abstractNumId of 4. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_AbstractNum">
   <sequence>
      <element name="nsid" type="CT_LongHexNumber" minOccurs="0"/>
      <element name="multiLevelType" type="CT_MultiLevelType" minOccurs="0"/>
      <element name="tmpl" type="CT_LongHexNumber" minOccurs="0"/>
      <element name="name" type="CT_String" minOccurs="0"/>
      <element name="styleLink" type="CT_String" minOccurs="0"/>
      <element name="numStyleLink" type="CT_String" minOccurs="0"/>
      <element name="lvl" type="CT_Lvl" minOccurs="0" maxOccurs="9"/>
   </sequence>
   <attribute name="abstractNumId" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.9.2 abstractNumId (Abstract Numbering Definition Reference)

This element specifies the abstract numbering definition information whose properties shall be inherited by the parent numbering definition instance.

[*Example*: Consider the WordprocessingML for a document with two numbering definition instances, each referencing a different abstract numbering definition:

```
<w:numbering>
  <w:abstractNum w:abstractNumId="0">
  <w:abstractNum w:abstractNumId="1">
  ...
  <w:num w:numId="1">
    <w:abstractNumId w:val="0" />
  </w:num>
  <w:num w:numId="2">
    <w:abstractNumId w:val="1" />
  </w:num>
  ...
</w:numbering>
```

The two numbering definition instances reference the abstract numbering definitions with abstractNumId attribute values of 0 and 1 respectively, via their abstractNumId elements. *end example*]

Parent Elements
num (§2.9.16)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.9.3 ilvl (Numbering Level Reference)

This element specifies the numbering level of the numbering definition instance which shall be applied to the parent paragraph.

This numbering level is specified on either the abstract numbering definition's lvl element (§2.9.7), and may be overridden by a numbering definition instance level override's lvl element (§2.9.6).

[*Example*: Consider the following numbered paragraphs in a WordprocessingML document:

1. Level one
    a. Level two

These numbered paragraphs may be represented using the following WordprocessingML:

```
<w:p>
  <w:pPr>
    <w:numPr>
      <w:ilvl w:val="0" />
      <w:numId w:val="5" />
    </w:numPr>
  </w:pPr>
  <w:r>
    <w:t>Level one</w:t>
  </w:r>
</w:p>
<w:p>
  <w:pPr>
    <w:numPr>
      <w:ilvl w:val="1" />
      <w:numId w:val="5" />
    </w:numPr>
  </w:pPr>
  <w:r>
    <w:t>Level two</w:t>
  </w:r>
</w:p>
```

The WordprocessingML above specifies that the first numbered paragraph references the numbering level of 0, within the numbering definition of the num element (§2.9.16) with a numId attribute equal to 5.

The second numbered paragraph references the numbering of 1, within the same numbering definition instance. The WordprocessingML referenced by the ilvl elements above is given below:

```
<w:num w:numId="5">
  <w:abstractNumId w:val="0" />
</w:num>
...
```

```
<w:abstractNum w:abstractNumId="0">
  <w:nsid w:val="FFFFFF7F" />
  <w:multiLevelType w:val="singleLevel" />
  <w:lvl w:ilvl="0">
    ...
  </w:lvl>
  <w:lvl w:ilvl="1">
    ...
  </w:lvl>
</w:abstractNum>
```

In this case, the resulting paragraphs would inherit the properties of the abstract numbering definition levels with ilvl attributes of `0` and `1`, respectively. *end example*]

Parent Elements
numPr (§2.3.1.19)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.9.4 isLgl (Display All Levels Using Arabic Numerals)

This element specifies whether or not all previous levels displayed for a given numbering level's text shall be displayed using the `decimal` number format, regardless of the actual number format of that level in the list. [*Note*: This numbering style is often referred to as the legal numbering style. *end note*]

If this element is present, then all numbering levels present in the lvlTxt element (§2.9.12) shall be converted to their decimal equivalents when they are displayed in this level in the numbering format. If this element is omitted, then each level is displayed using the numFmt (§2.9.18) of that level.

[*Example*: Consider the numbering set below. In this set of blank numbered paragraphs, three numbering levels have been used and the third has the isLgl property applied, resulting in the following:

```
A
    A.a
    A.b
          1.2.1
          1.2.2
B
    B.a
          2.1.1
```

As shown above, each number in the third level in the list has been converted to its decimal equivalent. The WordprocessingML necessary to turn on the legal numbering rule for the third numbering level is given below:

```
<w:lvl w:ilvl="2">
  ...
  <w:isLgl />
  ...
</w:lvl>
```

end example]

Parent Elements
lvl (§2.9.6); lvl (§2.9.7)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.9.5 legacy (Legacy Numbering Level Properties)

This element specifies that a given numbering level is from an earlier word processing application which did not support the full richness of the numbering properties supported by WordprocessingML.

These properties shall be used to render any numbered paragraph which references this numbering level if the legacy attribute is set. [*Note*: Using this element in generated WordprocessingML documents is not recommended, as updated numbering structures in WordprocessingML should be used in its place. This element is provided solely to save and roundtrip the numbering properties of legacy word processing products in WordprocessingML such that they are recreated if the document is resaved in an older word processor format. *end note*]

[*Example*: Consider the following WordprocessingML numbering level:

```
<w:lvl w:ilvl="0">
  ...
  <w:legacy w:legacySpace="820" w:legacyIndent="960" />
  <w:lvlJc w:val="left" />
  <w:pPr>
    <w:ind w:left="360" w:hanging="360" />
  </w:pPr>
</w:lvl>
```

This level has the legacy element present, therefore the legacy numbering level properties shall be used to format all paragraphs which reference this level. *end example*]

Parent Elements
lvl (§2.9.6); lvl (§2.9.7)

Attributes	Description
legacy (Use Legacy Numbering Properties)	Specifies whether the legacy numbering properties present for this numbering level shall be used to format the numbering for any paragraph which references it. A value of on, 1, or true for this attribute value specifies that the legacy numbering properties shall be applied. This is the default value for this attribute, and is implied when

Attributes	Description
	the attribute is omitted. A value of `off`, `0`, or `false` for this attribute value specifies that the legacy numbering properties shall not be used, and shall be explicitly turned off. [*Example*: For example, consider the set of legacy numbering properties from a document: `<w:legacy w:legacy="off" w:legacySpace="820" w:legacyIndent="960" />` This set of legacy properties are explicitly not used when processing the numbering level via the fact that the legacy attribute is turned off for this example. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
legacyIndent (Legacy Indent)	Specifies the indentation which shall be applied to a legacy numbering symbol from the text margin of the document. This value is specified in twentieths of a point. If this attribute is not present, then no indentation shall be applied with respect to the margin. [*Example*: For example, consider the set of legacy numbering properties from a document: `<w:legacy w:legacySpace="820" w:legacyIndent="960" />` This set of legacy properties specify that there shall be exactly 960 twentieths of a point (⅔ of an inch) between the text margin and the start of the numbering on the paragraph. *end example*] The possible values for this attribute are defined by the ST_SignedTwipsMeasure simple type (§2.18.88).
legacySpace (Legacy Spacing)	Specifies the indentation which shall be applied between a legacy numbering symbol and the accompanying text of the associated paragraph in the document. This value is specified in twentieths of a point. If this attribute is not present, then no indentation shall be applied with respect to the paragraph text. [*Example*: For example, consider the set of legacy numbering properties from a document: `<w:legacy w:legacySpace="820" w:legacyIndent="960" />` This set of legacy properties specify that there shall be exactly 860 twentieths of a point

Attributes	Description
	between the end of the numbering on the paragraph and the associated paragraph text. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_LvlLegacy">
   <attribute name="legacy" type="ST_OnOff" use="optional"/>
   <attribute name="legacySpace" type="ST_TwipsMeasure" use="optional"/>
   <attribute name="legacyIndent" type="ST_SignedTwipsMeasure" use="optional"/>
</complexType>
```

2.9.6 lvl (Numbering Level Override Definition)

This element specifies the appearance and behavior of a specific numbering level within a given numbering level definition override defined using the lvlOverride element (§2.9.9).

A numbering level override definition is identical to a numbering level definition, except for the fact that it is defined as part of a numbering definition instance using the num element (§2.9.16) rather than as part of an abstract numbering definition using the abstractNum element (§2.9.1).

[*Example*: Consider a numbering definition instance which inherits its information from the abstract numbering definition with abstractNumId of 4, but should use a different set of properties for level 0 of the numbering definition. The resulting WordprocessingML would look like:

```
<w:num w:numId="6">
  <w:abstractNumId w:val="4" />
  <w:lvlOverride w:ilvl="0">
    <w:lvl w:ilvl="0">
      <w:start w:val="4" />
      <w:lvlText w:val="%1)" />
      <w:lvlJc w:val="left" />
      <w:pPr>
        <w:ind w:left="360" w:hanging="360" />
      </w:pPr>
    </w:lvl>
  </w:lvlOverride>
</w:num>
```

This numbering definition instance overrides level 0 of the list with the specified numbering level override definition, replacing those in the abstract numbering level definition. *end example*]

[*Note*: The ability to set level overrides optimizes use of numbering in WordprocessingML as it prevents writing out redundant abstract numbering definitions if numbering sets only slightly differ.

Consider using WordprocessingML to create two numbered sets that only differ only in the appearance and style of the first numbering level. Both could use the same abstract numbering definition as long as each references a different numbering definition instance with one of the numbering definition instances leveraging a level override for the first numbering level. Below is WordprocessingML that illustrates this:

```
<w:num w:numId="5">
  <w:abstractNumId w:val="4" />
</w:num>
<w:num w:numId="6">
  <w:abstractNumId w:val="4" />
  <w:lvlOverride w:ilvl="0">
    <w:lvl w:ilvl="0">
      <w:start w:val="4" />
      <w:lvlText w:val="%1)" />
      <w:lvlJc w:val="left" />
      <w:pPr>
        <w:ind w:left="360" w:hanging="360" />
      </w:pPr>
    </w:lvl>
  </w:lvlOverride>
</w:num>
```

end note]

Parent Elements
lvlOverride (§2.9.9)

Child Elements	Subclause
isLgl (Display All Levels Using Arabic Numerals)	§2.9.4
legacy (Legacy Numbering Level Properties)	§2.9.5
lvlJc (Justification)	§2.9.8
lvlPicBulletId (Picture Numbering Symbol Definition Reference)	§2.9.10
lvlRestart (Restart Numbering Level Symbol)	§2.9.11
lvlText (Numbering Level Text)	§2.9.12
numFmt (Numbering Format)	§2.9.18
pPr (Numbering Level Associated Paragraph Properties)	§2.9.24
pStyle (Paragraph Style's Associated Numbering Level)	§2.9.25
rPr (Numbering Symbol Run Properties)	§2.9.26
start (Starting Value)	§2.9.27
suff (Content Between Numbering Symbol and Paragraph Text)	§2.9.30

Attributes	Description

ilvl (Numbering Level)	Specifies the numbering level definition that is to be defined by this set of numbering properties.
	
	This override is a zero-based index of the number of list levels in the document. [*Example*: A value of 2 is the 3rd list level in the document. *end example*]
	
	[*Example*: Consider the following WordprocessingML for a numbering definition instance:
	
	`<w:num w:numId="6">`
	`  <w:abstractNumId w:val="4" />`
	`  <w:lvlOverride w:ilvl="0">`
	`  …`
	`</w:num>`
	
	In this example, the first numbering level definition (with an ilvl of 0) within the referenced abstract numbering definition will be overridden. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

tentative (Tentative Numbering)	Specifies that a given numbering level was been saved by a producer but was not used in the parent document. This means that this numbering level may be redefined by a future consumer without changing the actual content of the document.
	
	A value of on, 1, or true for this attribute value specifies that the numbering level is not used in the current document's contents.
	
	A value of off, 0, or false for this attribute value specifies that the numbering level is used in the parent document and cannot be redefined without changing its contents. This is the default value for this attribute, and is implied when this attribute is omitted.
	
	[*Example*: Consider the following WordprocessingML numbering level:
	
	`<w:lvl w:ilvl="0" w:tentative="on" >`
	`  ...`
	`</w:lvl>`
	
	This level has the tentative attribute set to on, therefore the contents of this numbering level have not been used in the document and may be redefined by a consumer as desired. *end example*]
	
	If this attribute is equal to on, 1, or true, the WordprocessingML for a given document will contain the numbering level information associated with this numbering level, but the 'tentative' numbering level(s) shall not be represented in any of the hosting application's user interface pertaining to numbering levels.

Attributes	Description
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

tplc (Template Code)	Specifies a unique hexadecimal value which may be used to specify a location within an application's user interface in which this numbering level shall be displayed. The method by which this value is interpreted shall be application-defined.
	
	If this attribute is omitted, then this numbering may be displayed in any location chosen by the consumer.
	
	[*Example*: Consider the following abstract numbering definition:
	
	`<w:abstractNum w:abstractNumId="1" w:tplc="04090019">`
	`…`
	`</w:abstractNum>`
	
	In this example the abstractNum element with attribute abstractNumId equal to 1, would appear in the area within a consumer's application user interface specified by the template code 04090019. *end example*]
	
	The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Lvl">
   <sequence>
      <element name="start" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="numFmt" type="CT_NumFmt" minOccurs="0"/>
      <element name="lvlRestart" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="pStyle" type="CT_String" minOccurs="0"/>
      <element name="isLgl" type="CT_OnOff" minOccurs="0"/>
      <element name="suff" type="CT_LevelSuffix" minOccurs="0"/>
      <element name="lvlText" type="CT_LevelText" minOccurs="0"/>
      <element name="lvlPicBulletId" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="legacy" type="CT_LvlLegacy" minOccurs="0"/>
      <element name="lvlJc" type="CT_Jc" minOccurs="0"/>
      <element name="pPr" type="CT_PPr" minOccurs="0"/>
      <element name="rPr" type="CT_RPr" minOccurs="0"/>
   </sequence>
   <attribute name="ilvl" type="ST_DecimalNumber" use="required"/>
   <attribute name="tplc" type="ST_LongHexNumber" use="optional"/>
   <attribute name="tentative" type="ST_OnOff" use="optional"/>
</complexType>
```

2.9.7 lvl (Numbering Level Definition)

This element specifies the appearance and behavior of a numbering level within a given abstract numbering definition. A numbering level contains a set of properties for the display of the numbering for a given numbering level within an abstract numbering definition.

A numbering level definition is identical to a numbering level override definition, except for the fact that it is defined as part of a numbering definition instance using the abstractNum element (§2.9.1) rather than as part of an abstract numbering definition using the num element (§2.9.16).

[*Example*: Consider the WordprocessingML below:

```
<w:abstractNum w:abstractNumId="4">
  <w:nsid w:val="1DE04504" />
  <w:multiLevelType w:val="hybridMultilevel" />
  <w:lvl w:ilvl="0" w:tplc="0409000F">
    ...
  </w:lvl>
  <w:lvl w:ilvl="1" w:tplc="04090019">
    ...
  </w:lvl>
  <w:lvl w:ilvl="2" w:tplc="04090019">
    ...
  </w:lvl>
  <w:lvl w:ilvl="3" w:tplc="0409000F">
    ...
  </w:lvl>
  ...
</w:abstractNum>
```

This example shows that any paragraph whose numbering properties use the ilvl elements with the attribute val set equal to 0, 1, 2, or 3 will have the appearance and behavior of their first four numbered levels specified by the lvl elements given above (assuming that no level overrides have been specified). *end example*]

Parent Elements
abstractNum (§2.9.1)

Child Elements	Subclause
isLgl (Display All Levels Using Arabic Numerals)	§2.9.4
legacy (Legacy Numbering Level Properties)	§2.9.5
lvlJc (Justification)	§2.9.8
lvlPicBulletId (Picture Numbering Symbol Definition Reference)	§2.9.10

Child Elements	Subclause
lvlRestart (Restart Numbering Level Symbol)	§2.9.11
lvlText (Numbering Level Text)	§2.9.12
numFmt (Numbering Format)	§2.9.18
pPr (Numbering Level Associated Paragraph Properties)	§2.9.24
pStyle (Paragraph Style's Associated Numbering Level)	§2.9.25
rPr (Numbering Symbol Run Properties)	§2.9.26
start (Starting Value)	§2.9.27
suff (Content Between Numbering Symbol and Paragraph Text)	§2.9.30

Attributes	Description

ilvl (Numbering Level)	Specifies the numbering level definition that is to be defined by this set of numbering properties.
	
	This override is a zero-based index of the number of list levels in the document. [*Example*: A value of 2 is the 3rd list level in the document. *end example*]
	
	[*Example*: Consider the following WordprocessingML for a numbering definition instance:
	
	`<w:num w:numId="6">`
	`  <w:abstractNumId w:val="4" />`
	`  <w:lvlOverride w:ilvl="0">`
	`  …`
	`</w:num>`
	
	In this example, the first numbering level definition (with an ilvl of `0`) within the referenced abstract numbering definition will be overridden. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

tentative (Tentative Numbering)	Specifies that a given numbering level was been saved by a producer but was not used in the parent document. This means that this numbering level may be redefined by a future consumer without changing the actual content of the document. A value of on, `1`, or `true` for this attribute value specifies that the numbering level is not used in the current document's contents. A value of `off`, `0`, or `false` for this attribute value specifies that the numbering level is used in the parent document and cannot be redefined without changing its contents. This is the default value for this attribute, and is implied when this attribute is omitted. [*Example*: Consider the following WordprocessingML numbering level:

Attributes	Description
	<w:lvl w:ilvl="0" w:tentative="on" > ... </w:lvl> This level has the tentative attribute set to on, therefore the contents of this numbering level have not been used in the document and may be redefined by a consumer as desired. *end example*] If this attribute is equal to on, 1, or true, the WordprocessingML for a given document will contain the numbering level information associated with this numbering level, but the 'tentative' numbering level(s) shall not be represented in any of the hosting application's user interface pertaining to numbering levels. The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
tplc (Template Code)	Specifies a unique hexadecimal value which may be used to specify a location within an application's user interface in which this numbering level shall be displayed. The method by which this value is interpreted shall be application-defined. If this attribute is omitted, then this numbering may be displayed in any location chosen by the consumer. [*Example*: Consider the following abstract numbering definition: <w:abstractNum w:abstractNumId="1" w:tplc="04090019"> … </w:abstractNum> In this example the abstractNum element with attribute abstractNumId equal to 1, would appear in the area within a consumer's application user interface specified by the template code 04090019.*end example*] The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Lvl">
   <sequence>
      <element name="start" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="numFmt" type="CT_NumFmt" minOccurs="0"/>
      <element name="lvlRestart" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="pStyle" type="CT_String" minOccurs="0"/>
      <element name="isLgl" type="CT_OnOff" minOccurs="0"/>
      <element name="suff" type="CT_LevelSuffix" minOccurs="0"/>
      <element name="lvlText" type="CT_LevelText" minOccurs="0"/>
      <element name="lvlPicBulletId" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="legacy" type="CT_LvlLegacy" minOccurs="0"/>
      <element name="lvlJc" type="CT_Jc" minOccurs="0"/>
      <element name="pPr" type="CT_PPr" minOccurs="0"/>
      <element name="rPr" type="CT_RPr" minOccurs="0"/>
   </sequence>
   <attribute name="ilvl" type="ST_DecimalNumber" use="required"/>
   <attribute name="tplc" type="ST_LongHexNumber" use="optional"/>
   <attribute name="tentative" type="ST_OnOff" use="optional"/>
</complexType>
```

2.9.8 lvlJc (Justification)

This element specifies the type of justification used on a numbering level's text within a given numbering level. This justification is applied relative to the text margin of the parent numbered paragraph in the document.

If omitted, the paragraph shall have left justification relative to the text margin in left-to-right paragraphs, and right justification relative to the text margin in right-to-left paragraphs.

[*Example*: Consider the numbering level defined below:

```
<w:lvl w:ilvl="8" w:tplc="756C1446" w:tentative="1">
  <w:start w:val="1" />
  <w:nfc w:val="23" />
  <w:lvlText w:val="•" />
  <w:lvlJc w:val="left" />
  …
</w:lvl>
```

In this numbering level, the given numbering symbol will be `left` justified with respect to the text margin, therefore the numbering will extend left from the text margin towards the text (assuming a left-to-right paragraph). *end example*]

A numbering level's text is the numeral, symbol, character, graphic, etc. used to create a numbered paragraph as defined by the lvlText element (§2.9.12).

[*Example:* Consider the numbered paragraphs below:

1) Example one

a. Example two

- Example three

The numbering symbol in these three numbered paragraphs are "1", "a", and "•", respectively. *end example*]

Parent Elements
lvl (§2.9.6); lvl (§2.9.7)

Attributes	Description

val (Alignment Type)	Specifies the justification which should be applied to the parent object within a document.
	
	The possible values (see below) for this attribute are always specified relative to the page, and do not change semantic from right-to-left and left-to-right documents.
	
	[*Example*: Consider the following WordprocessingML fragment for a paragraph in a document:
	
	`<w:pPr>`
	`  <w:jc w:val="right" />`
	`</w:pPr>`
	
	This paragraph is now right justified on the page, regardless of the paragraph or section settings. *end example*]
	
	The possible values for this attribute are defined by the ST_Jc simple type (§2.18.50).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Jc">
   <attribute name="val" type="ST_Jc" use="required"/>
</complexType>
```

2.9.9 lvlOverride (Numbering Level Definition Override)

This element specifies an optional override which shall be applied in place of zero or more levels from the abstract numbering definition for a given numbering definition instance. Each instance of this element is used to override the appearance and behavior of a given numbering level definition within the given abstract numbering definition.

[*Example*: Consider a numbering definition instance which inherits its information from the abstract numbering definition with abstractNumId of 4, but wishes to use a different set of properties for level 0 and level 1 of the numbering definition. The resulting WordprocessingML would look like:

```
<w:num w:numId="6">
  <w:abstractNumId w:val="4" />
  <w:lvlOverride w:ilvl="0">
    <w:lvl w:ilvl="0">
      <w:start w:val="4" />
      <w:lvlText w:val="%1)" />
      <w:lvlJc w:val="left" />
      <w:pPr>
        <w:ind w:left="360" w:hanging="360" />
      </w:pPr>
    </w:lvl>
  </w:lvlOverride>
  <w:lvlOverride w:ilvl="1">
    <w:lvl w:ilvl="1">
      <w:start w:val="5" />
      <w:lvlText w:val="%Test)" />
      <w:lvlJc w:val="left" />
      <w:pPr>
        <w:ind w:left="360" w:hanging="360" />
      </w:pPr>
    </w:lvl>
  </w:lvlOverride>
</w:num>
```

end example]

[*Note*: The ability to set level overrides optimizes use of numbering in WordprocessingML as it prevents writing out redundant abstract numbering definitions if numbering sets only slightly differ.

Consider using WordprocessingML to create two numbered sets that only differ only in the appearance and style of the first numbering level. Both could use the same abstract numbering definition as long as each references a different numbering definition instance with one of the numbering definition instances leveraging a level override for the first numbering level. Below is WordprocessingML that illustrates this:

```
<w:num w:numId="5">
  <w:abstractNumId w:val="4" />
</w:num>
```

```
<w:num w:numId="6">
  <w:abstractNumId w:val="4" />
  <w:lvlOverride w:ilvl="0">
    <w:lvl w:ilvl="0">
      <w:start w:val="4" />
      <w:lvlText w:val="%1)" />
      <w:lvlJc w:val="left" />
      <w:pPr>
        <w:ind w:left="360" w:hanging="360" />
      </w:pPr>
    </w:lvl>
  </w:lvlOverride>
</w:num>
```

end note]

Parent Elements
num (§2.9.16)

Child Elements	Subclause
lvl (Numbering Level Override Definition)	§2.9.6
startOverride (Numbering Level Starting Value Override)	§2.9.28

Attributes	Description

ilvl (Numbering Level ID)	Specifies the numbering level of a given abstract numbering definition to be overridden.
	
	If this number conflicts with the ilvl of the child lvl element, then the latter shall be ignored.
	
	[*Example*: Consider a numbering definition instance which inherits its information from the abstract numbering definition with abstractNumId of 4, but wishes to use a different set of properties for level 0 of the numbering definition. The resulting WordprocessingML would look like:
	
	`<w:num w:numId="6">`
	`  <w:abstractNumId w:val="4" />`
	`  <w:lvlOverride w:ilvl="0">`
	`  <w:lvl w:ilvl="0">`
	`  <w:start w:val="4" />`
	`  <w:lvlText w:val="%1)" />`
	`  <w:lvlJc w:val="left" />`
	`  <w:pPr>`
	`  <w:ind w:left="360" />`

Attributes	Description
	</w:pPr> </w:lvl> </w:lvlOverride> </w:num> This level overrides level 0 of the abstract numbering definition's level properties with the specified set of numbering properties, replacing those in the abstract numbering definition. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_NumLvl">
   <sequence>
      <element name="startOverride" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="lvl" type="CT_Lvl" minOccurs="0" maxOccurs="1"/>
   </sequence>
   <attribute name="ilvl" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.9.10 lvlPicBulletId (Picture Numbering Symbol Definition Reference)

This element specifies a picture which shall be used as a numbering symbol for a given numbering level by referring to a picture numbering symbol definition's numPictBullet element (§2.9.21). This reference is made through this element's val attribute.

The picture shall be added to the numbering level by replacing each character in the lvlText with on instance of this image

[*Example*: Consider the WordprocessingML below illustrating how the lvlPicBulletId references a picture numbering symbol definition thought its val attribute:

```
<w:numPicBullet w:numPicBulletId="1">
   <w:pict>
    <v:shape id="_x0000_i1031" type="#_x0000_t75"
style="width:3in;height:276.75pt" o:bullet="t">
      <v:imagedata r:id="rId2" o:title="testpic" />
    </v:shape>
  </w:pict>
</w:numPicBullet>
…
<w:abstractNum w:abstractNumId="7">
  <w:nsid w:val="71A06359" />
  <w:multiLevelType w:val="hybridMultilevel" />
  <w:tmpl w:val="10643FE6" />
```

```
    <w:lvl w:ilvl="0" w:tplc="B7663E56">
      <w:start w:val="1" />
      <w:nfc w:val="23" />
      <w:lvlText w:val="AA" />
      <w:lvlPicBulletId w:val="1" />
    </w:lvl>
  </w:abstractNum>
```

The resulting numbering shall consist of two instances of the image specified using the numPicBullet element. *end example*]

Parent Elements
lvl (§2.9.6); lvl (§2.9.7)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.9.11 lvlRestart (Restart Numbering Level Symbol)

This element specifies a one-based index which determines when a numbering level should restart to its start value (§2.9.27). A numbering level restarts when an instance of the specified numbering level, which shall be higher (earlier than the this level) is used in the given document's contents.

If this element is omitted, the numbering level shall restart each time the previous numbering level is used. If the specified level is higher than the current level, then this element shall be ignored. As well, a value of 0 shall specify that this level shall never restart.

[*Example*: Consider a set of numbered paragraphs in a WordprocessingML document where numbering level with ilvl of 2 is set to never restart:

```
<w:lvl w:ilvl="0">
  <w:start w:val="1" />
  <w:lvlText w:val="%1)" />
  <w:lvlJc w:val="left" />
   <w:pPr>
    <w:ind w:left="360" w:hanging="360" />
  </w:pPr>
   <w:rPr>
    <w:rFonts w:hint="default" />
  </w:rPr>
</w:lvl>
 <w:lvl w:ilvl="1">
  <w:start w:val="1" />
  <w:numFmt w:val="upperLetter" />
  <w:lvlText w:val="%2)" />
  <w:lvlJc w:val="left" />
   <w:pPr>
    <w:ind w:left="720" w:hanging="360" />
  </w:pPr>
   <w:rPr>
    <w:rFonts w:hint="default" />
  </w:rPr>
</w:lvl>
<w:lvl w:ilvl="2">
  <w:start w:val="1" />
  <w:numFmt w:val="lowerRoman" />
  <w:lvlRestart w:val="0">
  <w:lvlText w:val="%3)" />
  <w:lvlJc w:val="left" />
   <w:pPr>
    <w:ind w:left="1080" w:hanging="360" />
  </w:pPr>
   <w:rPr>
    <w:rFonts w:hint="default" />
  </w:rPr>
</w:lvl>
```

Since the lvlRestart element is omitted in numbering level 1 (a,b,…), the numbering level restarts after numbering level 0 (1,2,…) is used. Numbering level two (i, ii, iii …) never restarts as lvlRestart has a val equal to 0. An example of the resulting content would be as follows:

1) Level one

    a) Level two

        i) Level three

        ii) Level three

2) Level one

    a) Level two

        iii) Level three

        iv) Level four

The resulting set of paragraphs has level two restarting to its start value after each level one (after `2)`, the next level two is again `a)`), but level three never restarts and continues at `iii)` even after the use of a level two and one. *end example*]

Parent Elements
lvl (§2.9.6); lvl (§2.9.7)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.9.12 lvlText (Numbering Level Text)

This element specifies the textual content which shall be displayed when displaying a paragraph with the given numbering level.

All text in this element's val attribute shall be taken as literal text to be repeated in each instance of this numbering level, except for any use of the percent symbol (%) followed by a number, which shall be used to indicate the one-based index of the number to be used at this level. Any number of a level higher than this level shall be ignored.

When the % syntax is used, the number shall be incremented for each subsequent paragraph of that level (sequential or not), until the restart level is seen between two subsequent paragraphs of this level.

[*Example*: Consider the following WordprocessingML for a numbering level:

```
<w:lvl w:ilvl="1">
  …
  <w:lvlText w:val="StringA %2 StringB %1 StringC %3"/>
  …
</w:lvl>
```

This specifies that three strings (`StringA`, `StringB`, `StringC`) shall be used as string literals in the numbering for level two (ilvl of 1) along with the numbering symbol used for level one and level zero. Although level two is also referenced here, it is ignored as it is a higher level than the current numbering level.

Therefore, assuming the numbering symbol used by numbering level zero is an Arabic numeral, and the numbering symbol used by numbering level one is a Roman numeral, a set of numbered paragraphs using this WordprocessingML numbering set shall be output as:

```
1
  StringA I StringB 1 StringC
  StringA II StringB 1 StringC
  StringA III StringB 1 StringC
2
  StringA I StringB 2 StringC
  StringA II StringB 2 StringC
```

with the %1 and %2 values corresponding to the current numbering symbol value for numbering level zero and one, respectively. *end example*]

Parent Elements
lvl (§2.9.6); lvl (§2.9.7)

Attributes	Description

Attributes	Description

null (Level Text Is Null Character)	Specifies that a null character shall be used as the numbering symbol for a given numbering level.
	
	If the val attribute contains any content, then this attribute shall be ignored.
	
	If this attribute is omitted, then the null string shall not be used in place of the empty string. [*Note*: A null character is different from an empty string. *end note*]
	
	[*Example*: Consider the WordprocessingML below:
	
	`<w:lvl w:ilvl="1">`
	`…`
	`<w:lvlText w:null="on" />`
	`…`
	`</w:lvl>`
	
	This level text consists of a single null character, and not the empty string, as the null attribute is set. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

val (Level Text)	Specifies the actual text to be used for the numbering level when it is referenced in the document's content.
	
	If this attribute is not specified, then the empty string shall be used as the level's text.
	
	[*Example*: Consider the WordprocessingML below:
	
	`<w:lvl w:ilvl="1">`
	`…`
	`<w:lvlText w:val="test" />`
	`…`
	`</w:lvl>`
	
	Here the val attribute specifies that the literal string `test` is to be surfaced as the text for the given numbering level, regardless of its position. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_LevelText">
   <attribute name="val" type="ST_String" use="optional"/>
   <attribute name="null" type="ST_OnOff" use="optional"/>
</complexType>
```

2.9.13 multiLevelType (Abstract Numbering Definition Type)

This element specifies the type of numbering defined by a given abstract numbering type. This information shall only be used by a consumer to determine user interface behaviors for this numbering definition, and shall not be used to limit the behavior of the list (i.e. a list with multiple levels marked as `singleLevel` shall not be prevented from using levels 2 through 9).

If this element is omitted, then the list shall be assumed to be of any type desired by the consumer.

[*Example*: Consider the WordprocessingML below:

```
<w:abstractNum w:abstractNumId="8">
  …
  <w:multiLevelType w:val="singleLevel" />
  …
</w:abstractNum>
```

This abstract numbering definition is specified to be of the `singleLevel` type by the multiLevelType element. *end example*]

Parent Elements
abstractNum (§2.9.1)

Attributes	Description

val (Abstract Numbering Definition Type)	Specifies the specific type of numbering enabled by a given abstract numbering definition.
	
	[*Example*: Consider the WordprocessingML below:
	
	`<w:abstractNum w:abstractNumId="8">`
	`  …`
	`  <w:multiLevelType w:val="multiLevel" />`
	`  …`
	`</w:abstractNum>`
	
	This abstract numbering definition is specified to be of the `multiLevel` type, which may be used by consumers to place this numbering correctly within a user interface. *end example*]
	
	The possible values for this attribute are defined by the ST_MultiLevelType simple type (§2.18.65).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_MultiLevelType">
   <attribute name="val" type="ST_MultiLevelType" use="required"/>
</complexType>
```

2.9.14 name (Abstract Numbering Definition Name)

This element specifies the name of a given abstract numbering definition. This name may be surfaced in order to provide a user friendly alias for a given numbering definition, but shall not influence the behavior of the list - two identical definitions with different name elements shall behave identically.

If this element is omitted, then this abstract numbering definition shall have no name.

[*Example*: Consider the WordprocessingML below:

```
<w:abstractNum w:abstractNumId="4">
  <w:nsid w:val="5C294B5B" />
  <w:multiLevelType w:val="multilevel" />
  <w:tmpl w:val="6F8A81B0" />
  <w:name w:val="Example Name" />
  …
</w:abstractNum>
```

In this example, the given abstract numbering definition is named `Example Name` by use of the name element. *end example*]

Parent Elements
abstractNum (§2.9.1)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent

Attributes	Description
	structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.9.15 nsid (Abstract Numbering Definition Identifier)

This element associates a unique hexadecimal ID to the parent abstract numbering definition. This number shall be identical for two abstract numbering definitions that are based from the same initial numbering definition - if a document is repurposed and the underlying numbering definition is changed, it shall maintain its original nsid.

If this element is omitted, then the list shall have no nsid and one may be added by a producer arbitrarily.

[*Note*: This element may be used to determine the abstract numbering definition to be applied to a numbered paragraph copied from one document and pasted into another. Consider a case in which a given numbered paragraph associated with a abstract numbering definition with nsid FFFFFF23, is pasted among numbered paragraphs associated with a completely different appearance and an abstract numbering definition with an nsid of FFFFFF23. Here, because of the distinction enabled by the identical nsid values, the hosting application would not have to arbitrarily keep the pasted numbered paragraph associated with its original abstract numbering definition, as it may use the information provided by the abstract numbering definition's identical nsid values to know that those two numbering sets are identical, and merge the paragraphs into the target numbering format. *end note*]

[*Example*: Consider the WordprocessingML for an abstract numbering definition below:

```
<w:abstractNum w:abstractNumId="3">
  <w:nsid w:val="FFFFFF89" />
  <w:multiLevelType w:val="singleLevel" />
  <w:tmpl w:val="D9842532" />
  …
</w:abstractNum>
```

In this example, the given abstract numbering definition is associated with the unique hexadecimal ID FFFFFF89. *end example*]

Parent Elements
abstractNum (§2.9.1)

Attributes	Description
val (Long Hexadecimal Number Value)	Specifies a number value specified as a four digit hexadecimal number), whose contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following value for an attribute of type ST_LongHexNumber: `00BE2C6C`. This value is valid, as it contains four hexadecimal digits, each an encoding of an octet of the actual decimal number value. It may therefore be interpreted as desired in the context of the parent XML element, *end example*] The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_LongHexNumber">
   <attribute name="val" type="ST_LongHexNumber" use="required"/>
</complexType>
```

2.9.16 num (Numbering Definition Instance)

This element specifies a unique instance of numbering information that can be referenced by zero or more paragraphs within the parent WordprocessingML document.

This instance requires the referencing of a base abstract numbering definition through the abstractNumId child element (§2.9.2). This element also can be used to specify a set of optional overrides applied to zero or more levels from the abstract numbering definition inherited by this instance second though the optional lvlOverride child elements (§2.9.9).

[*Example*: Consider the WordprocessingML for a document with four numbering definition instances, two of which reference the same underlying abstract numbering definition:

```
<w:numbering>
  ...
  <w:num w:numId="2">
    <w:abstractNumId w:val="0" />
  </w:num>
  <w:num w:numId="3">
    <w:abstractNumId w:val="1" />
  </w:num>
  <w:num w:numId="4">
    <w:abstractNumId w:val="4" />
  </w:num>
  <w:num w:numId="5">
    <w:abstractNumId w:val="4" />
  </w:num>
</w:numbering>
```

As shown above, the first two numbering definition instances reference abstractNumId values of 0 and 1 respectively, and the last two both reference the abstract numbering definition with an abstractNumId of 4. *end example*]

[*Example*: Consider a numbering definition instance which inherits its information from the abstract numbering definition with abstractNumId of 4, but wishes to use a different set of properties for level 0 of the numbering definition. The resulting WordprocessingML would look like:

```
<w:num w:numId="6">
  <w:abstractNumId w:val="4" />
  <w:lvlOverride w:ilvl="0">
    <w:lvl w:ilvl="0">
      <w:start w:val="4" />
      <w:lvlText w:val="%1)" />
      <w:lvlJc w:val="left" />
      <w:pPr>
        <w:ind w:left="360" w:hanging="360" />
      </w:pPr>
    </w:lvl>
  </w:lvlOverride>
</w:num>
```

The lvlOverride element specifies an override for level 0 of the abstract numbering definition. *end example*]

Parent Elements
numbering (§2.9.17)

Child Elements	Subclause
abstractNumId (Abstract Numbering Definition Reference)	§2.9.2
lvlOverride (Numbering Level Definition Override)	§2.9.9

Attributes	Description

numId (Numbering Definition Instance ID)	Specifies a unique ID which any numbered paragraph which wishes to inherit these numbering properties shall reference using the numPr element (§2.3.1.19).
	
	[*Example*: Consider the WordprocessingML below for an example numbered paragraph:
	
	`<w:p>`
	`  <w:pPr>`
	`  <w:numPr>`
	`  <w:ilvl w:val="0" />`
	`  <w:numId w:val="5" />`
	`  </w:numPr>`
	`  </w:pPr>`
	`  …`
	`</w:p>`
	
	This paragraph references a numbering definition instance with a numId attribute of 5:
	
	`<w:num w:numId="5">`
	`  <w:abstractNumId w:val="4" />`
	`</w:num>`
	
	The numbering definition instance with a numId attribute of 5 correlates with the numbered paragraph with the numbering definition instance referent element with a val of 5, so the numbered paragraph inherits its properties. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Num">
   <sequence>
      <element name="abstractNumId" type="CT_DecimalNumber" minOccurs="1"/>
      <element name="lvlOverride" type="CT_NumLvl" minOccurs="0" maxOccurs="9"/>
   </sequence>
   <attribute name="numId" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.9.17 numbering (Numbering Definitions)

This element specifies the formatting, display, and functionality of numbering - Arabic numerals, Roman numerals, symbol characters ("bullets"), text strings, etc. - in WordprocessingML documents, which are used to label individual paragraphs of text.

[*Example*: The following two paragraphs each contain numbering as defined by WordprocessingML: the first uses an Arabic numeral, the second a symbol character:

10. This is a paragraph with numbering information.

- This is also a paragraph with numbering information.

end example]

Parent Elements
Root element of WordprocessingML Numbering Definitions part

Child Elements	Subclause
abstractNum (Abstract Numbering Definition)	§2.9.1
num (Numbering Definition Instance)	§2.9.16
numIdMacAtCleanup (Last Reviewed Abstract Numbering Definition)	§2.9.20
numPicBullet (Picture Numbering Symbol Definition)	§2.9.21

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Numbering">
   <sequence>
      <element name="numPicBullet" type="CT_NumPicBullet" minOccurs="0" maxOccurs="unbounded"/>
      <element name="abstractNum" type="CT_AbstractNum" minOccurs="0" maxOccurs="unbounded"/>
      <element name="num" type="CT_Num" minOccurs="0" maxOccurs="unbounded"/>
      <element name="numIdMacAtCleanup" type="CT_DecimalNumber" minOccurs="0"/>
   </sequence>
</complexType>
```

2.9.18 numFmt (Numbering Format)

This element specifies the number format which shall be used to display all numbering at this level in the numbering definition. This information is used to replace the level text string %x, where x is a particular one-based level index, with the appropriate value. This value shall be calculated by counting the number of paragraphs at this level since the last restart using the numbering system defined in the val attribute.

If omitted, the level shall be assumed to be of type `decimal`.

[*Example*: Consider the following WordprocessingML fragment for a numbering level in a numbering definition:

```
<w:lvl w:ilvl="2">
```

```
    <w:start w:val="1" />
    <w:numFmt w:val="lowerRoman" />
    <w:lvlRestart w:val="0">
    <w:lvlText w:val="%3)" />
    <w:lvlJc w:val="left" />
    <w:pPr>
      <w:ind w:left="1080" w:hanging="360" />
    </w:pPr>
    <w:rPr>
      <w:rFonts w:hint="default" />
    </w:rPr>
  </w:lvl>
```

A numFmt value of `lowerLetter` indicates that a consumer shall use lowercase letters for all numbering of this level: a,b,c… *end example*]

Parent Elements
lvl (§2.9.6); lvl (§2.9.7)

Attributes	Description
val (Numbering Format Type)	Specifies the number format that shall be used for all numbering in the parent object. [*Example*: A value of `lowerLetter` indicates that a consumer shall use lowercase letters for each number in this grouping: a,b,c… *end example*] The possible values for this attribute are defined by the ST_NumberFormat simple type (§2.18.66).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_NumFmt">
   <attribute name="val" type="ST_NumberFormat" use="required"/>
</complexType>
```

2.9.19 numId (Numbering Definition Instance Reference)

This element specifies the numbering definition instance which shall be used for the given parent numbered paragraph in the WordprocessingML document.

A value of `0` for the val attribute shall never be used to point to a numbering definition instance, and shall instead only be used to designate the removal of numbering properties at a particular level in the style hierarchy (typically via direct formatting).

[*Example*: Consider the WordprocessingML below for an example numbered paragraph:

```
<w:p>
  <w:pPr>
    <w:numPr>
      <w:ilvl w:val="0" />
      <w:numId w:val="5" />
    </w:numPr>
  </w:pPr>
  …
</w:p>
```

This paragraph references a numbering definition instance with a numId attribute of 5, as follows:

```
<w:num w:numId="5">
  <w:abstractNumId w:val="4" />
</w:num>
```

The numbering definition instance reference specifies the given numbering definition instance to be applied to the given paragraph, which itself inherits its properties from abstract numbering definition with abstractNumId of 4. *end example*]

Parent Elements
numPr (§2.3.1.19)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.9.20 numIdMacAtCleanup (Last Reviewed Abstract Numbering Definition)

This element specifies to a consumer the progress in the last attempt made by the application to remove unused abstract numbering definitions from a given document. If a legacy document is opened by a consumer, it may choose to remove abstract numbering definition which are 'orphaned' (have no associated numbering definition instances). This element is used by those consumers to indicate their progress (if not complete) in reviewing existing abstract numbering definitions. [*Note*: Removing unused abstract numbering definition from a document will reduce the file size, but is not required. *end note*]

If omitted, then all abstract numbering definitions shall be considered reviewed.

[*Example*: Consider a document with 32 abstract numbering definitions, with abstractNumId values ranging from 0 to 85. If an application has only reviewed those abstract numbering definitions with abstractNumId values lower than 25 at save time, it would indicate that state as follows:

```
<w:numIdMacAtCleanup w:val="25"/>
```

This value specifies that all abstract numbering definitions with an abstractNumId value higher than 25 have not yet been reviewed. *end example*]

Parent Elements
numbering (§2.9.17)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
    <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.9.21 numPicBullet (Picture Numbering Symbol Definition)

This element specifies the appearance and behavior of a specific picture to be used as the numbering symbol within a numbering level definition in a document, and is the basis for all picture numbering symbol information in a WordprocessingML document.

This element is not used directly within abstract numbering definitions but rather is referenced through its numPicBulletId attribute by the lvlPicBulletId element (§2.9.10) used within numbering level definitions.

[*Example*: Consider the WordprocessingML fragment below which illustrates how a numPicBullet definition is referenced by a picture numbering symbol definition reference through its numPicBulletId attribute:

```
<w:numPicBullet w:numPicBulletId="1">
   <w:pict>
     <v:shape id="_x0000_i1031" type="#_x0000_t75"
style="width:3in;height:276.75pt" o:bullet="t">
      <v:imagedata r:id="rId2" o:title="testpic" />
    </v:shape>
  </w:pict>
</w:numPicBullet>
...
<w:abstractNum w:abstractNumId="7">
  <w:nsid w:val="71A06359" />
  <w:multiLevelType w:val="hybridMultilevel" />
  <w:tmpl w:val="10643FE6" />
  <w:lvl w:ilvl="0" w:tplc="B7663E56">
    <w:start w:val="1" />
    <w:nfc w:val="23" />
    <w:lvlText w:val="" />
    <w:lvlPicBulletId w:val="1" />
  </w:lvl>
</w:abstractNum>
```

The lvlPicBulletId element references a numPicBullet element, which defines the size and appearance of all picture bullets of this type the document. It is important to note that this picture bullet may be referenced by multiple levels of various numbering definitions. *end example*]

Parent Elements
numbering (§2.9.17)

Child Elements	Subclause
pict (Picture Numbering Symbol Properties)	§2.9.23

Attributes	Description

numPicBulletId (Picture Numbering Symbol ID)	Specifies a unique ID for this picture bullet definition which shall be used to reference this picture bullet from a numbering level definition.
	
	[*Example*: Consider the WordprocessingML fragment below which illustrates how a numPicBullet definition is referenced by a picture numbering symbol definition reference through its numPicBulletId attribute:
	
	`<w:numPicBullet w:numPicBulletId="1">`
	`  …`
	`</w:numPicBullet>`
	`...`
	`<w:abstractNum w:abstractNumId="7">`
	`  <w:lvl w:ilvl="0" w:tplc="B7663E56">`
	`  …`
	`  <w:lvlPicBulletId w:val="1" />`
	`  </w:lvl>`
	`</w:abstractNum>`
	
	The lvlPicBulletId element references the ID in the numPicBulletId attribute directly. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_NumPicBullet">
   <sequence>
      <element name="pict" type="CT_Picture"/>
   </sequence>
   <attribute name="numPicBulletId" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.9.22 numStyleLink (Numbering Style Reference)

This element specifies an abstract numbering does not contain the actual numbering properties for its type, but rather serves as a reference to a numbering style stored in the document, which shall be applied when this abstract numbering definition is referenced, and itself points at the actual underlying abstract numbering definition to be used.

The numbering style that is to be applied when this abstract numbering definition is referenced is identified by the string contained in numStyleLink's val attribute.

[*Example*: Consider the abstract numbering definition below:

```
<w:abstractNum w:abstractNumId="0">
  <w:nsid w:val="38901FA4" />
  <w:multiLevelType w:val="multilevel" />
  <w:numStyleLink w:val="TestNumberingStyle" />
</w:abstractNum>
```

This abstract numbering definition references the numbering style with a styleId attribute equal to `TestNumberingStyle`, as follows below:

```
<w:style w:type="numbering" w:styleId="TestNumberingStyle">
  …
</w:style>
```

Therefore, this numbering style shall be applied whenever the base abstract numbering definition is inherited by a numbered paragraph. *end example*]

Parent Elements
abstractNum (§2.9.1)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.9.23 pict (Picture Numbering Symbol Properties)

This element specifies the properties for a picture which shall be used as a picture numbering symbol in a given document, using the VML syntax.

[*Example*: Consider the WordprocessingML below illustrating the usage of the pict element in a document containing a single picture numbering symbol:

```
<w:numPicBullet w:numPicBulletId="0">
  <w:pict>
    <v:shapetype id="_x0000_t75" coordsize="21600,21600" o:spt="75"
o:preferrelative="t" path="m@4@5l@4@11@9@11@9@5xe" filled="f" stroked="f">
      <v:stroke joinstyle="miter" />
      <v:formulas>
        <v:f eqn="if lineDrawn pixelLineWidth 0" />
        <v:f eqn="sum @0 1 0" />
        <v:f eqn="sum 0 0 @1" />
        <v:f eqn="prod @2 1 2" />
        <v:f eqn="prod @3 21600 pixelWidth" />
        <v:f eqn="prod @3 21600 pixelHeight" />
        <v:f eqn="sum @0 0 1" />
        <v:f eqn="prod @6 1 2" />
        <v:f eqn="prod @7 21600 pixelWidth" />
        <v:f eqn="sum @8 21600 0" />
        <v:f eqn="prod @7 21600 pixelHeight" />
        <v:f eqn="sum @10 21600 0" />
      </v:formulas>
      <v:path o:extrusionok="f" gradientshapeok="t" o:connecttype="rect" />
      <o:lock v:ext="edit" aspectratio="t" />
    </v:shapetype>
    <v:shape id="_x0000_i1029" type="#_x0000_t75"
style="width:11.25pt;height:11.25pt" o:bullet="t">
      <v:imagedata r:id="rId1" o:title="sample picture" />
    </v:shape>
  </w:pict>
```

end example]

Parent Elements
numPicBullet (§2.9.21)

Child Elements	Subclause
Any element from the urn:schemas-microsoft-com:vml namespace	§6.1
Any element from the urn:schemas-microsoft-com:office:office namespace	§6.2
control (Floating Embedded Control)	§2.3.3.2
movie (Embedded Video)	§2.3.3.17

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Picture">
   <complexContent>
      <extension base="CT_PictureBase">
         <sequence maxOccurs="1">
            <element name="movie" type="CT_Rel" minOccurs="0"/>
            <element name="control" type="CT_Control" minOccurs="0"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.9.24 pPr (Numbering Level Associated Paragraph Properties)

This element specifies the paragraph properties which shall be applied as part of a given numbering level within the parent numbering definition. These paragraph properties are applied to any numbered paragraph that references the given numbering definition and numbering level.

Paragraph properties specified on the numbered paragraph itself override the paragraph properties specified by pPr elements within a numbering lvl element (§2.9.6, §2.9.7).

[*Example:* Consider the WordprocessingML below which specifies numbering level paragraph properties:

```
<w:abstractNum w:abstractNumId="1">
  ...
  <w:lvl w:ilvl="0">
    ...
    <w:pPr>
      <w:tabs>
        <w:tab w:val="num" w:pos="720" />
      </w:tabs>
      <w:ind w:left="720" w:hanging="360" />
    </w:pPr>
  </w:lvl>
</w:abstractNum>
```

Each of the paragraph properties specified inside the pPr element are applied to any numbered paragraph which inherits this numbering level definition as part of the numbering properties in the order defined by the style hierarchy. *end example*]

   </complexContent>
</complexType>
```

2.9.25 pStyle (Paragraph Style's Associated Numbering Level)

This element specifies the name of a paragraph style which shall automatically this numbering level when applied to the contents of the document. When a paragraph style is defined to include a numbering definition, any numbering level defined by the numPr element (§2.3.1.19) shall be ignored, and instead this element shall specify the numbering level associated with that paragraph style.

If this element references a style which does not exist, or is not a paragraph style, then it may be ignored.

[*Example*: Consider the WordprocessingML below which specifies that the paragraph style with styleId `example`, when applied to paragraphs in the document, shall also apply the first numbering level of the abstract numbering definition with an abstractNumId equal to `1`, as follows:

```
<w:abstractNum w:abstractNumId="1">
  ...
  <w:lvl w:ilvl="0">
    ...
    <w:pStyle w:val="example" />
    <w:pPr>
      <w:tabs>
        <w:tab w:val="num" w:pos="720" />
      </w:tabs>
```

```
        <w:ind w:left="720" w:hanging="360" />
      </w:pPr>
      ...
    </w:lvl>
  </w:abstractNum>
```

The style definition for the paragraph style would only include the numId of the numbering definition instance, and not its level:

```
  <w:style w:styleId="example" w:type="paragraph">
    …
    <w:pPr>
      <w:numPr>
        <w:numId w:val="0" />
      </w:numPr>
    </w:pPr>
  </w:style>
```

end example]

Parent Elements
lvl (§2.9.6); lvl (§2.9.7)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent

Attributes	Description
	structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.9.26 rPr (Numbering Symbol Run Properties)

This element specifies the run properties which shall be applied to the numbering level's text specified in the lvlText element (§2.9.12) when it is applied to paragraphs in this document.

These run properties are applied to all numbering level text used by a given abstract numbering definition and numbering level. It should be noted that run properties specified on a numbered paragraph itself, or on text runs within a numbered paragraph, are separate from the run properties specified by rPr elements within a numbering level, as the latter affects only the numbering text itself, not the remainder of runs in the numbered paragraph.

[*Example*: Consider the WordprocessingML below which uses the rPr element to specify that the numbering symbol used within a given numbering level should be bold and of a 16 point font size:

```
<w:lvl w:ilvl="1">
  …
  <w:rPr>
    <w:b />
    <w:sz w:val="32" />
  </w:rPr>
</w:lvl>
```

The resulting paragraph will use its regular paragraph formatting, but the numbering level text itself shall be specifically formatted as bold in 16 point font. *end example*]

sz (Font Size)	§2.3.2.36
szCs (Complex Script Font Size)	§2.3.2.37
u (Underline)	§2.3.2.38
vanish (Hidden Text)	§2.3.2.39

Child Elements	Subclause
vertAlign (Subscript/Superscript Text)	§2.3.2.40
w (Expanded/Compressed Text)	§2.3.2.41
webHidden (Web Hidden Text)	§2.3.2.42

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RPr">
   <sequence>
      <group ref="EG_RPrContent" minOccurs="0"/>
   </sequence>
</complexType>
```

2.9.27 start (Starting Value)

This element specifies the starting value for the numbering used by the parent numbering level within a given numbering level definition. This value is used when this level initially starts in a document, as well as whenever it is restarted via the properties set in the lvlRestart element (§2.9.11).

If this element is omitted, then the starting value shall be zero (0).

[*Example*: Consider the following WordprocessingML fragment for an abstract numbering definition:

```
<w:abstractNum w:abstractNumId="1">
  …
  <w:lvl w:ilvl="0">
    <w:start w:val="2" />
    <w:numFmt w:val="upperLetter"/>
    …
  </w:lvl>
</w:abstractNum>
```

In this example, since upper case Western letters (upperLetter) are being used as numbering symbols for this numbering level, the first instance of a numbering paragraph associated with this abstract numbering definition and numbering level would have the numbering symbol B, the second letter in the number format.

Subsequent numbered paragraphs with this abstract numbering definition and at this level would have their numbering symbols incremented from B (the starting value for this numbering level). *end example*]

Parent Elements
lvl (§2.9.6); lvl (§2.9.7)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number.

Attributes	Description
	The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.9.28 startOverride (Numbering Level Starting Value Override)

This element specifies the number which the specified level override shall begin with. This value is used when this level initially starts in a document, as well as whenever it is restarted via the properties set in the lvlRestart element (§2.9.11).

If they disagree, this value shall override the starting number of the child lvl element (§2.9.6).

[*Example*: Consider the WordprocessingML fragment for a numbering level definition in a WordprocessingML document:

```
<w:abstractNum w:abstractNumId="1">
  …
  <w:lvl w:ilvl="0">
    …
    <w:numFmt w:val="upperRoman" />
    <w:start w:val="2" />
    …
  </w:lvl>
</w:abstractNum>
```

In this example, since upper case Roman numerals (upperRoman) are being used as numbering symbols for this numbering level, the first instance of a numbering paragraph associated with this abstract numbering definition and numbering level would have the numbering symbol II, the second letter in the number format.

Subsequent numbered paragraphs with this abstract numbering definition and at this level would have their numbering symbols incremented from II (the starting value for this numbering level). *end example*]

Parent Elements
lvlOverride (§2.9.9)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.9.29 styleLink (Numbering Style Definition)

This element specifies that the parent abstract numbering definition is the base numbering definition for the specified numbering style referenced in its val attribute.

If this element is omitted, or it references a style which does not exist, then this numbering definition shall not be the underlying properties for a numbering style.

[*Note*: Numbering styles are never directly referenced by paragraphs or runs in the document – instead, an abstract numbering definition specifies that it contains the underlying numbering information for a numbering style, and one or more numbering definition instances reference a numbering definition which inherits from it. The numbering style itself is just a friendly name on an abstract numbering definition. *end note*]

[E*xample*: Consider the WordprocessingML fragment below, representing an abstract numbering definition which defines the properties for a numbering style:

```
<w:numbering>
  …
  <w:abstractNum w:abstractNumId="5">
    …
    <w:styleLink w:val="ExampleNumberingStyle" />
```

```
    …
  </w:abstractNum>
</w:numbering>
…
<w:styles>
  …
  <w:style w:type="numbering" w:styleId="ExampleNumberingStyle">
    <w:name w:val="ExampleNumberingStyle" />
    …
    <w:pPr>
      <w:numPr>
        <w:numId w:val="6" />
      </w:numPr>
    </w:pPr>
  </w:style>
  …
</w:styles>
```

The styleLink element specifies that the abstract numbering definition defines the properties for a numbering style whose styleId matches its val attribute, and is defined in the styles element of the WordprocessingML. *end example*]

Parent Elements
abstractNum (§2.9.1)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`

Attributes	Description
	</w:sdtPr> In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.9.30 suff (Content Between Numbering Symbol and Paragraph Text)

This element specifies the content which shall be added between a given numbering level's text and the text of every numbered paragraph which references that numbering level.

If this element is omitted, then its value shall be assumed to be `tab`.

[*Example:* Consider the numbered paragraph below:

1. Test

In this example, a space exists between the numbering symbol `1.` and the numbered paragraph text `Test`. The space would be specified in WordprocessingML as follows:

```
<w:lvl w:ilvl="0">
  …
  <w:suff w:val="space" />
  …
</w:lvl>
```

The suff element with an attribute value of `space` specifies that the character between the numbering's level text and the paragraph text shall be a space. *end example*]

Parent Elements
lvl (§2.9.6); lvl (§2.9.7)

Attributes	Description
val (Character Type Between Numbering and Text)	Specifies the character which shall follow the list number. [*Example:* Consider a numbered for which a tab exists between the numbering symbol and the numbered paragraph's text. The tab would be specified in WordprocessingML as

Attributes	Description

	follows:
	
	`<w:lvl w:ilvl="0">`
	`…`
	`<w:suff w:val="tab" />`
	`…`
	`</w:lvl>`
	
	The val attribute with a value of tab specifies that the character between the numbering's level text and the paragraph text shall be a tab. This tab will follow normal tab stop rules. *end example*]
	
	The possible values for this attribute are defined by the ST_LevelSuffix simple type (§2.18.53).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_LevelSuffix">
   <attribute name="val" type="ST_LevelSuffix" use="required"/>
</complexType>
```

2.9.31 tmpl (Numbering Template Code)

This element specifies a unique hexadecimal code which may be used to determine a location within application user interface in which this abstract numbering definition shall be displayed.

If this element is omitted, then this abstract numbering definition may be displayed in any location chosen by the consumer.

[*Example*: Consider the following abstract numbering definition:

```
<w:abstractNum w:abstractNumId="1">
  …
  <w:tmpl w:val="CA48B6BA" />
  …
</w:abstractNum>
```

In this example the abstractNum element with attribute abstractNumId equal to 1, would appear in the area within a consumer's application user interface specified by the template code CA48B6BA. *end example*]

Parent Elements
abstractNum (§2.9.1)

Attributes	Description
val (Long	Specifies a number value specified as a four digit hexadecimal number), whose contents

Attributes	Description
Hexadecimal Number Value)	of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following value for an attribute of type ST_LongHexNumber: `00BE2C6C`. This value is valid, as it contains four hexadecimal digits, each an encoding of an octet of the actual decimal number value. It may therefore be interpreted as desired in the context of the parent XML element, *end example*] The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

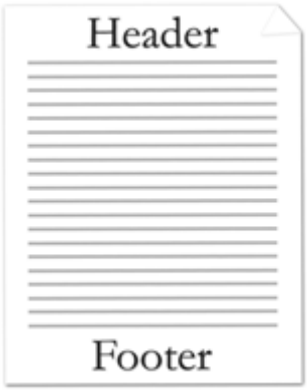
The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_LongHexNumber">
   <attribute name="val" type="ST_LongHexNumber" use="required"/>
</complexType>
```

2.10 Headers and Footers

Headers and footers refer to text, graphics or data (such as page number, date, document title, and so on) that can appear at the top or bottom of each page in a WordprocessingML document.

A header appears in the top margin (above the main document content on the page), while a footer appears in the bottom margin of a document page (below the main document content on the page).



Since WordprocessingML is a flow-based format, headers and footers are applied by specifying the headers and footers for all pages in a particular section of a document.

Within each section of a document there may be up to three different types of headers and footers:

- First page header/footer
- Odd page header/footer
- Even page header/footer

First page headers and footers specify a unique header or footer which shall appear on the first page of a section. Odd page headers and footers specify a unique header and footer which shall appear on all odd numbered pages for a given section. Even page headers and footers specify a unique header and footer which shall appear on all even numbered pages in a given section.

2.10.1 evenAndOddHeaders (Different Even/Odd Page Headers and Footers)

This element specifies whether sections in this document shall have different headers and footers for even and odd pages (an odd page header/footer and an even page header/footer).

If the val attribute is set to `true`, then each section in the document shall use an odd page header for all odd numbered pages in the section, and an even page header for all even numbered pages in the section (counting each page in the section starting from one, regardless of the page numbering settings for the section). If the val attribute is set to `false`, then all pages in a section shall use the odd page header.

This setting does not affect the presence of a first page header on each section, which is specified using the titlePg element (§2.10.6). If a first page header is specified, then all subsequent pages shall have this setting applied, including the first page in the odd/even page count.

If this element is set to `false` and an even page header is specified , then it shall be ignored and only the odd page header shall be displayed. Conversely, if this element is set to true and either header type is omitted for a given section, then a blank header shall be created as needed (another header type shall not be used in its place).

If this element is omitted, then its value shall be assumed to be `false`.

[*Example*: Consider a document which shall have a different even and odd page header for each section in its contents. This requirement must be specified using the following WordprocessingML:

```
<w:settings>
  …
  <w:evenAndOddHeaders />
  …
</w:setttings>
```

Since the evenAndOddHeaders property is set (and its default value is `true`), this document will now have different headers and footers for even and odd pages. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element.

Attributes	Description
	A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.10.2 footerReference (Footer Reference)

This element specifies a single footer which shall be associated with the current section in the document. This footer shall be referenced via the id attribute, which specifies an explicit relationship to the appropriate Footer part in the WordprocessingML package.

If the relationship type of the relationship specified by this element is not http://schemas.openxmlformats.org/officeDocument/2006/footer, is not present, or does not have a TargetMode attribute value of Internal, then the document shall be considered non-conformant.

Within each section of a document there may be up to three different types of footers:

- First page footer
- Odd page footer
- Even page footer

The footer type specified by the current footerReference is specified via the type attribute.

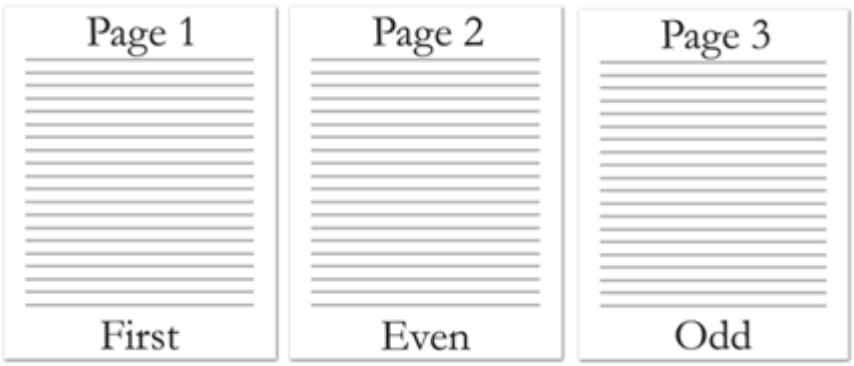
If any type of footer is omitted for a given section, then the following rules shall apply.

- If no footerReference for the first page footer is specified and the titlePg element is specified, then the first page footer shall be inherited from the previous section or, if this is the first section in the document, a new blank footer shall be created. If the titlePg element is not specified, then no first page footer shall be shown, and the odd page footer shall be used in its place.
- If no footerReference for the even page footer is specified and the evenAndOddHeaders element is specified, then the even page footer shall be inherited from the previous section or, if this is the first

section in the document, a new blank footer shall be created. If the evenAndOddHeaders element is not specified, then no even page footer shall be shown. and the odd page footer shall be used in its place.

- If no footerReference for the odd page footer is specified then the even page footer shall be inherited from the previous section or, if this is the first section in the document, a new blank footer shall be created.

[*Example*: Consider a three page document with different first, odd, and even page footers defined as follows:



This document defines three footers, each of have a relationship from the document part with a unique relationship ID, as shown in the following packaging markup:

```
<Relationships
xmlns=http://schemas.openxmlformats.org/package/2006/relationships>
  …
  <Relationship Id="rId6"
Type="http://schemas.openxmlformats.org/officeDocument/2006/relationships/footer
" Target="footer1.xml" />
  <Relationship Id="rId7"
Type="http://schemas.openxmlformats.org/officeDocument/2006/relationships/footer
" Target="footer2.xml" />
  <Relationship Id="rId10"
Type="http://schemas.openxmlformats.org/officeDocument/2006/relationships/footer
" Target="footer3.xml" />
  …
</Relationships>
```

These relationships are then referenced in the section's properties using the following WordprocessingML:

```
<w:sectPr>
  …
  <w:footerReference r:id="rId6" w:type="first" />
  <w:footerReference r:id="rId7" w:type="default" />
  <w:footerReference r:id="rId10" w:type="even" />
```

```
    …
  </w:sectPr>
```

The resulting section shall use the footer part with relationship id `rId6` for the first page, the footer part with relationship id `rId10` for all subsequent even pages, and the footer part with relationship id `rId7` for all subsequent odd pages. *end example*]

Parent Elements
sectPr (§2.6.18); sectPr (§2.6.19)

Attributes	Description
id (Relationship to Part) Namespace: …/officeDocument/2006/relationships	Specifies the relationship ID to a specified part. The specified relationship shall match the type required by the parent element: • http://schemas.openxmlformats.org/officeDocument/2006/relationships/footer for the footerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/header for the headerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/font for the embedBold, embedBoldItalic, embedItalic, or embedRegular elements • http://schemas.openxmlformats.org/officeDocument/2006/relationships/printerSettings for the printerSettings element [*Example*: Consider an XML element which has the following id attribute: `<… r:id="rId10" />` The markup specifies the associated relationship part with relationship ID `rId1` contains the corresponding relationship information for the parent XML element. *end example*] The possible values for this attribute are defined by the ST_RelationshipId simple type (§7.8.2.1).

type (Header or Footer Type)	Specifies the type of header or footer specified by the target relationship ID. This type determines the page(s) on which the current header or footer shall be displayed.
	
	If any section contains more than a single header or footer of each type, then the document shall be considered non-conformant.
	
	[*Example*: Consider a document with the following WordprocessingML:
	
	`<w:sectPr>`
	`  …`
	`  <w:footerReference r:id="rId6" w:type="first" />`
	`  <w:footerReference r:id="rId7" w:type="first" />`

Attributes	Description
	<w:footerReference r:id="rId10" w:type="even" /> … </w:sectPr> The resulting section has two footers of type `first`, and therefore is invalid. *end example*] [*Example*: Consider a WordprocessingML section which specifies the following header reference: <w:headerReference r:id="rId10" w:type="first" /> The resulting section shall use the specified header part for the `first` page. *end example*] The possible values for this attribute are defined by the ST_HdrFtr simple type (§2.18.41).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_HdrFtrRef">
   <complexContent>
      <extension base="CT_Rel">
         <attribute name="type" type="ST_HdrFtr" use="required"/>
      </extension>
   </complexContent>
</complexType>
```

2.10.3 ftr (Footer)

This element specifies the content for a single footer for use within one or more sections of a WordprocessingML document.

Within the ftr element, the content of the element is similar to the content of the body (§2.2.2) element, and contains what is referred to as *block-level markup* - markup which can exist as a sibling element to paragraphs in a WordprocessingML document.

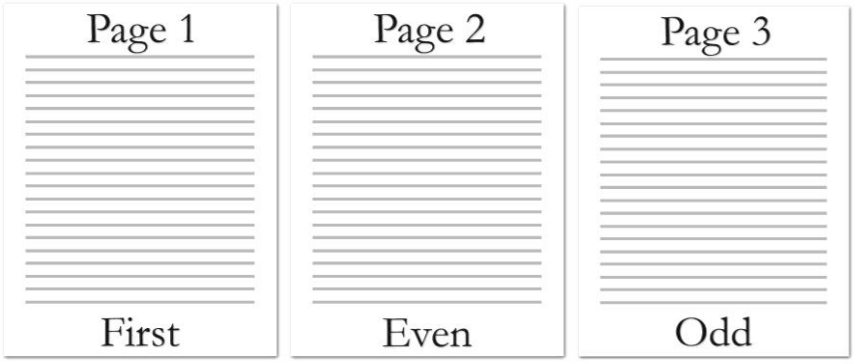
[*Example*: Consider the following simple one page document with one footer:

This document defines one footer with the text `footer`. The footer contents are stored in a unique footer part. The resulting footer is represented by the following WordprocessingML:

```
<w:ftr>
  <w:p>
    <w:r>
      <w:t>Footer</w:t>
    </w:r>
  </w:p>
</w:ftr>
```

Since footers are containers of block level contents, all block level elements can be used within them. In this particular example, the content is a single paragraph. *end example*]

[*Example*: Consider a more complex three page document with different first, odd, and even page footers defined:



This document defines three footers stored in three different footer parts. The resulting footers are represented by the following WordprocessingML:

First page footer part:

```
<w:ftr>
  <w:p>
    <w:r>
      <w:t>First</w:t>
    </w:r>
  </w:p>
</w:ftr>
```

Even page footer part:

```
<w:ftr>
  <w:p>
    <w:r>
      <w:t>Even</w:t>
    </w:r>
  </w:p>
</w:ftr>
```

Odd page footer part:

```
<w:ftr>
  <w:p>
    <w:r>
      <w:t>Odd</w:t>
    </w:r>
  </w:p>
</w:ftr>
```

end example]

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_HdrFtr">
    <group ref="EG_BlockLevelElts" minOccurs="1" maxOccurs="unbounded"/>
</complexType>
```

2.10.4 hdr (Header)

This element specifies the content for a single header for use within one or more sections of a WordprocessingML document.

Within the hdr element, the content of the element is similar to the content of the body (§2.2.2) element, and contains what is referred to as *block-level markup* - markup which can exist as a sibling element to paragraphs in a WordprocessingML document.

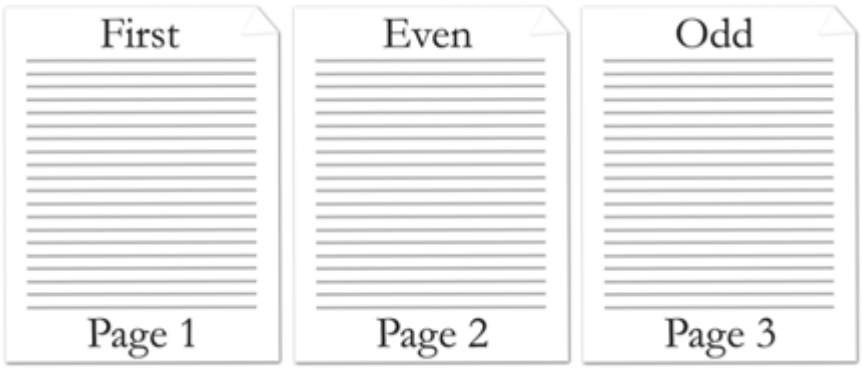
[*Example*: Consider the following simple one page document with one header:

This document defines one header with the text `Header`. The header's contents is stored in a unique Header part. The resulting header is represented by the following WordprocessingML:

```
<w:hdr>
  <w:p>
    <w:r>
      <w:t>Header</w:t>
    </w:r>
  </w:p>
</w:hdr>
```

Since headers are containers of block level contents, all block level elements can be used within them. In this particular example, the content is a single paragraph. *end example*]

[*Example*: Consider a more complex three page document with different first, odd, and even page headers defined:



This document defines three headers stored in three different header parts. The resulting headers are represented by the following WordprocessingML:

First page header part:

```
<w:hdr>
  <w:p>
    <w:r>
      <w:t>First</w:t>
    </w:r>
  </w:p>
</w:hdr>
```

Even page header part:

```
<w:hdr>
  <w:p>
    <w:r>
      <w:t>Even</w:t>
    </w:r>
  </w:p>
</w:hdr>
```

Odd page header part:

```
<w:hdr>
  <w:p>
    <w:r>
      <w:t>Odd</w:t>
    </w:r>
  </w:p>
</w:hdr>
```

end example]

proofErr (Proofing Error Anchor)	§2.13.8.1
sdt (Block-Level Structured Document Tag)	§2.5.2.30
tbl (Table)	§2.4.36

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_HdrFtr">
    <group ref="EG_BlockLevelElts" minOccurs="1" maxOccurs="unbounded"/>
</complexType>
```

2.10.5 headerReference (Header Reference)

This element specifies a single header which shall be associated with the current section in the document. This header shall be referenced via the id attribute, which specifies an explicit relationship to the appropriate Header part in the WordprocessingML package.

If the relationship type of the relationship specified by this element is not http://schemas.openxmlformats.org/officeDocument/2006/header, is not present, or does not have a TargetMode attribute value of `Internal`, then the document shall be considered non-conformant.

Within each section of a document there may be up to three different types of headers:

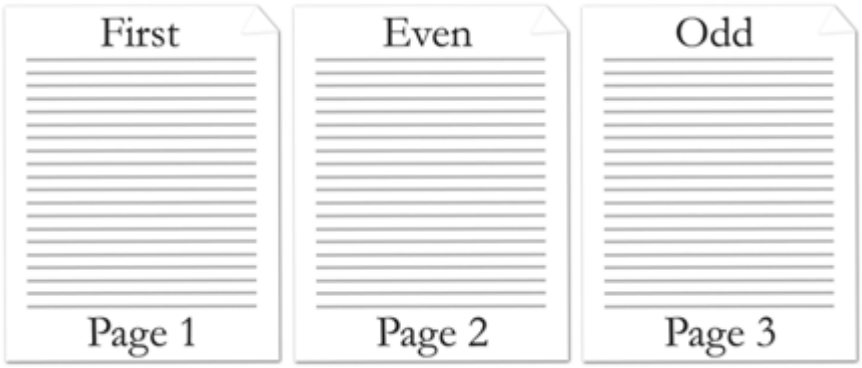
- First page header
- Odd page header
- Even page header

The header type specified by the current headerReference is specified via the type attribute.

If any type of header is omitted for a given section, then the following rules shall apply.

- If no headerReference for the first page header is specified and the titlePg element is specified, then the first page header shall be inherited from the previous section or, if this is the first section in the document, a new blank header shall be created. If the titlePg element is not specified, then no first page header shall be shown, and the odd page header shall be used in its place.
- If no headerReference for the even page header is specified and the evenAndOddHeaders element is specified, then the even page header shall be inherited from the previous section or, if this is the first section in the document, a new blank header shall be created. If the evenAndOddHeaders element is not specified, then no even page header shall be shown, and the odd page header shall be used in its place.
- If no headerReference for the odd page header is specified then the even page header shall be inherited from the previous section or, if this is the first section in the document, a new blank header shall be created.

[*Example*: Consider a three page document with different first, odd, and even page header defined as follows:



This document defines three headers, each of have a relationship from the document part with a unique relationship ID, as shown in the following packaging markup:

```
<Relationships
xmlns=http://schemas.openxmlformats.org/package/2006/relationships>
  …
  <Relationship Id="rId2"
Type="http://schemas.openxmlformats.org/officeDocument/2006/relationships/header
" Target="header1.xml" />
```

```
  <Relationship Id="rId3"
Type="http://schemas.openxmlformats.org/officeDocument/2006/relationships/header
" Target="header2.xml" />
  <Relationship Id="rId5"
Type="http://schemas.openxmlformats.org/officeDocument/2006/relationships/header
" Target="header3.xml" />
  …
</Relationships>
```

These relationships are then referenced in the section's properties using the following WordprocessingML:

```
<w:sectPr>
  …
  <w:headerReference r:id="rId3" w:type="first" />
  <w:headerReference r:id="rId5" w:type="default" />
  <w:headerReference r:id="rId2" w:type="even" />
  …
</w:sectPr>
```

The resulting section shall use the header part with relationship id `rId3` for the first page, the header part with relationship id `rId2` for all subsequent even pages, and the header part with relationship id `rId5` for all subsequent odd pages. *end example*]

Parent Elements
sectPr (§2.6.18); sectPr (§2.6.19)

Attributes	Description
id (Relationship to Part) Namespace: .../officeDocument/2006/relationships	Specifies the relationship ID to a specified part. The specified relationship shall match the type required by the parent element: • http://schemas.openxmlformats.org/officeDocument/2006/relationships/footer for the footerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/header for the headerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/font for the embedBold, embedBoldItalic, embedItalic, or embedRegular elements • http://schemas.openxmlformats.org/officeDocument/2006/relationships/printerSettings for the printerSettings element [*Example*: Consider an XML element which has the following id attribute: `<… r:id="rId10" />`

Attributes	Description
	The markup specifies the associated relationship part with relationship ID `rId1` contains the corresponding relationship information for the parent XML element. *end example*] The possible values for this attribute are defined by the ST_RelationshipId simple type (§7.8.2.1).

type (Header or Footer Type)	Specifies the type of header or footer specified by the target relationship ID. This type determines the page(s) on which the current header or footer shall be displayed.
	
	If any section contains more than a single header or footer of each type, then the document shall be considered non-conformant.
	
	[*Example*: Consider a document with the following WordprocessingML:
	
	`<w:sectPr>`
	`…`
	`<w:footerReference r:id="rId6" w:type="first" />`
	`<w:footerReference r:id="rId7" w:type="first" />`
	`<w:footerReference r:id="rId10" w:type="even" />`
	`…`
	`</w:sectPr>`
	
	The resulting section has two footers of type `first`, and therefore is invalid. *end example*]
	
	[*Example*: Consider a WordprocessingML section which specifies the following header reference:
	
	`<w:headerReference r:id="rId10" w:type="first" />`
	
	The resulting section shall use the specified header part for the `first` page. *end example*]
	
	The possible values for this attribute are defined by the ST_HdrFtr simple type (§2.18.41).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_HdrFtrRef">
   <complexContent>
      <extension base="CT_Rel">
         <attribute name="type" type="ST_HdrFtr" use="required"/>
      </extension>
   </complexContent>
</complexType>
```

2.10.6 titlePg (Different First Page Headers and Footers)

This element specifies whether the parent section in this document shall have a different header and footer for its first page.

If the val attribute is set to `true`, then the parent section in the document shall use a first page header for the first page in the section. If the val attribute is set to `false`, then the first page in the parent section shall use the odd page header.

This setting does not affect the presence of even and odd page header on all sections, which is specified using the evenAndOddHeaders element (§2.10.1).

If this element is set to `false` and a first page header is specified , then it shall be ignored and only the odd page header shall be displayed. Conversely, if this element is set to `true` and the first page header type is omitted for the given section, then a blank header shall be created as needed (another header type shall not be used in its place).

If this element is omitted, then its value shall be assumed to be `false`.

[*Example*: Consider a section which shall have a different first page header. This requirement is specified using the following WordprocessingML:

```
<w:sectPr>
  …
  <w:titlePg />
  …
</w:sectPr>
```

Since the titlePg property is present (and its default attribute value is `true`), this document will now have a different header and footer for its first page. *end example*]

Parent Elements
sectPr (§2.6.17); sectPr (§2.6.18); sectPr (§2.6.19)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property:

Attributes	Description
	`<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.11 Footnotes and Endnotes

Footnotes and *endnotes* are separate text storied used in documents and books to show the source of borrowed material or to enter explanatory or supplementary information which does not interrupt the normal reading flow of the document.

Footnotes are typically located at the bottom of a page or beneath text being referenced, and *endnotes* are typically placed at the end of a document or at the end of a section. If document has been divided up into one or more sections, each section of a document may contain endnotes.

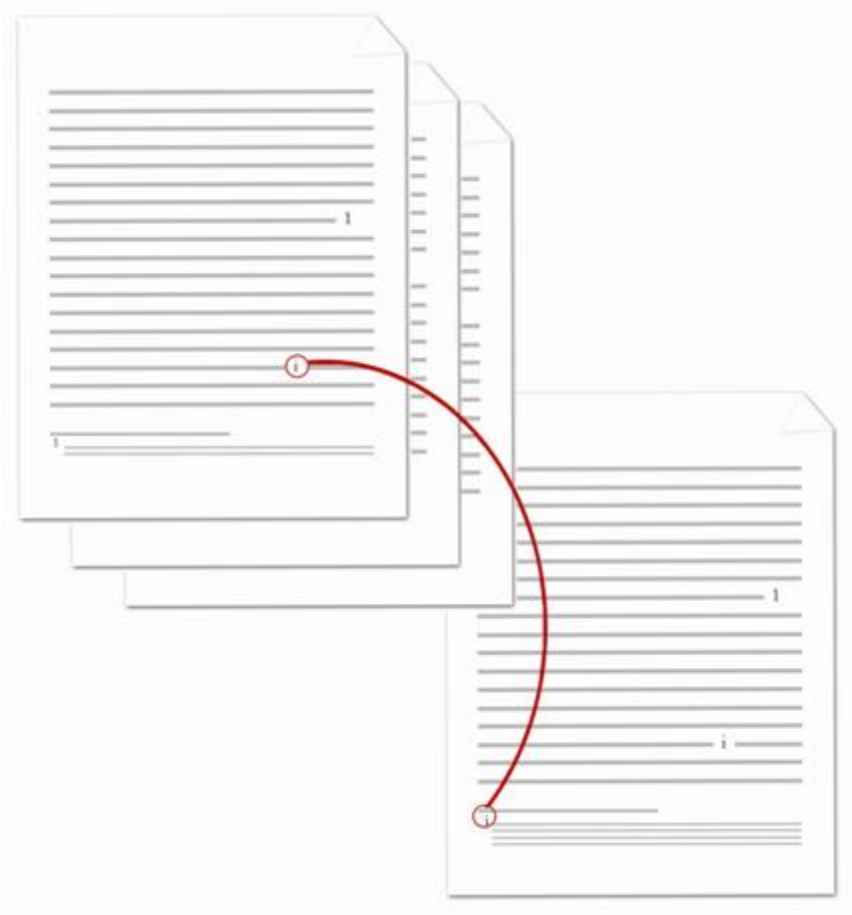
Both footnotes and endnotes consist of two parts:

- A note reference mark in the body text to indicate that additional information is in a footnote or endnote, with a numbering system used for each to tell readers whether to look for the note at the end of the page or the end of the document or section.
- The actual footnote or endnote story content.

[*Example:* Example of a footnote applied to text in a document:

The note reference mark follows the noted text and specifies that there is associated footnote information, and the footnote itself is at the bottom of the current page. *end example*]

[*Example:* Consider the following example of an endnote applied to text in a document:



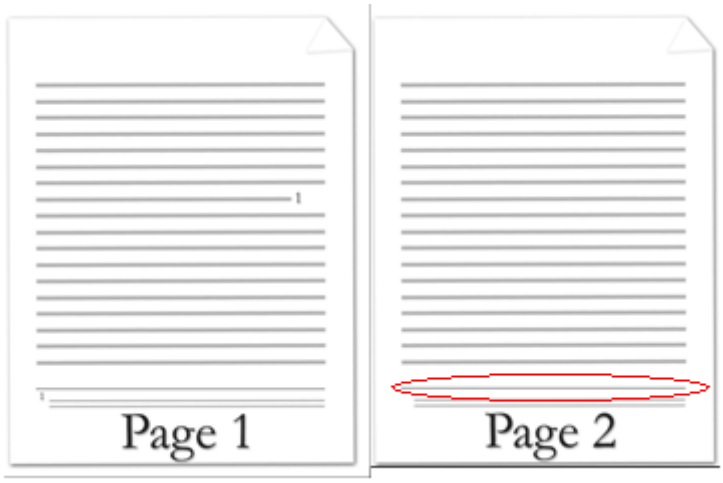
The note reference mark follows the noted text and specifies that there is associated endnote information, and the endnote itself is at the end of the current section. *end example*]

2.11.1 continuationSeparator (Continuation Separator Mark)

This element specifies the presence of a continuation separator mark within the current run. A continuation separator mark is a horizontal line which spans the width of the main story's text extents.

[*Note*: The continuation separator mark is typically used within the context of continuation separator footnotes or endnotes. These footnote and endnote types define the footnote/endnote used to separate the contents of the main document story from continuation of footnotes or endnotes which began on a previous page. *end note*]

[*Example*: Consider the following two pages in a document, where some text is referenced by a footnote that extends to the next page (with the continuation separator circled in red):



The line separating the document text from the footnote that is continued on the next page is represented by the following WordprocessingML:

```
<w:footnote w:type="continuationSeparator" w:id="1">
  <w:p>
    <w:r>
      <w:continuationSeparator />
    </w:r>
  </w:p>
</w:footnote>
```

In this example, the footnote has a content which consists of a single continuationSeparator, which is displayed as a horizontal line across the text extents. *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.11.2 endnote (Endnote Content)

This element specifies the content of a single endnote within a WordprocessingML document. Each endnote shall be represented by a single endnote element, which may contain any valid *block-level content*.

[*Example*: Consider a document with a single endnote, identified by a endnote element, defined in the endnotes part:

```
<w:endnotes>
  <w:endnote w:id="2">
    <w:p>
      <w:pPr>
        <w:pStyle w:val="EndnoteText" />
      </w:pPr>
      <w:r>
        <w:rPr>
          <w:rStyle w:val="EndnoteReference" />
        </w:rPr>
        <w:endnoteRef />
      </w:r>
      <w:r>
        <w:t xml:space="preserve">This is an endnote</w:t>
      </w:r>
    </w:p>
  </w:endnote>
</w:endnotes>
```

This endnote contains an endnote reference mark, as well as the endnote text `This is an endnote`. *end example*]

Parent Elements

permStart (Range Permission Start)	§2.13.7.2
proofErr (Proofing Error Anchor)	§2.13.8.1
sdt (Block-Level Structured Document Tag)	§2.5.2.30
tbl (Table)	§2.4.36

Attributes	Description

id (Footnote/Endnote ID)	Specifies a unique ID which shall be used to match the contents of a footnote or endnote to the associated footnote/endnote reference mark in the document using the footnoteRef or endnoteRef element, as appropriate.
	
	If this attribute is omitted, then this footnote or endnote shall have no ID. If more than one footnote shares the same ID, then this document shall be considered non-conformant. If more than one endnote shares the same ID, then this document shall be considered non-conformant.
	
	[*Example*: Consider the following footnote as defined in the footnotes part:
	
	`<w:footnotes>`
	`  <w:footnote w:type="normal" w:id="0">`
	`  …`
	`  </w:footnote>`
	`  …`
	`</w:footnotes>`
	
	The contents of this footnote are associated with the footnoteReference with a matching ID, as follows:

Attributes	Description
	<w:p> <w:r> <w:footnoteReference w:id="0" /> </w:r> </w:p> The resulting paragraph will have a footnote reference mark which references the footnote number value of the footnote with an id of 0. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
type (Footnote/Endnote Type)	Specifies the type of footnote or endnote contained within the current footnote or endnote content definition. If this attribute is omitted, then it shall be considered to be of type normal. If a footnote or endnote is not of type normal, then it shall not be referenced by a footnoteReference or endnoteReference element within the main document story. [*Example*: Consider the following example of a footnote defined in a WordprocessingML document as follows: <w:footnote w:type="continuationSeparator" w:id="1"> <w:p> <w:r> <w:continuationSeparator /> </w:r> </w:p> </w:footnote> In this example, the footnote is of type continuationSeparator and shall be used by a consumer to separate continued footnotes from the main document contents (see simple type for full details). *end example*] The possible values for this attribute are defined by the ST_FtnEdn simple type (§2.18.37).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FtnEdn">
   <sequence>
      <group ref="EG_BlockLevelElts" minOccurs="1" maxOccurs="unbounded"/>
   </sequence>
   <attribute name="type" type="ST_FtnEdn" use="optional"/>
   <attribute name="id" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.11.3 endnote (Special Endnote List)

This element specifies the ID for all endnotes which are located in the current document that are not of type `normal`. Each other type of endnote shall be referenced in this list, or it shall not be loaded. If an endnote is not listed beneath this element, and it is required by the document content, then the document shall be considered non-conformant.

[*Example*: Consider a document that has three endnotes represented by the following WordprocessingML:

```
<w:endnotes ...>
  <w:endnote w:type="separator" w:id="0">
    ...
  </w:endnote>
  <w:endnote w:type="continuationSeparator" w:id="1">
    ...
  </w:endnote>
  <w:endnote w:id="2">
    ...
  </w:endnote>
</w:endnotes>
```

Each of the endnotes which are not of type `normal` must be specified in the endnotePr element, as follows:

```
<w:endnotePr>
  <w:endnote w:id="0" />
  <w:endnote w:id="1" />
</w:endnotePr>
```

This indicates to the consumer that the endnotes with an id attribute value of `0` and `1` are special endnotes, and should be treated accordingly. *end example*]

Parent Elements
endnotePr (§2.11.4)

Attributes	Description
id (Footnote/Endnote ID)	Specifies a unique ID which shall be used to match the contents of a footnote or endnote to the associated footnote/endnote reference mark in the document using the footnoteRef or endnoteRef element, as appropriate. If more than one footnote shares the same ID, then this document shall be considered non-conformant. If more than one endnote shares the same ID, then this document shall be considered non-conformant. [*Example*: Consider the following footnote as defined in the footnotes part:

Attributes	Description
	<w:footnotes> <w:footnote w:type="normal" w:id="0"> … </w:footnote> … </w:footnotes> The contents of this footnote are associated with the footnoteReference with a matching ID, as follows: <w:p> <w:r> <w:footnoteReference w:id="0" /> </w:r> </w:p> The resulting paragraph will have a footnote reference mark which references the footnote number value of the footnote with an id of 0. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

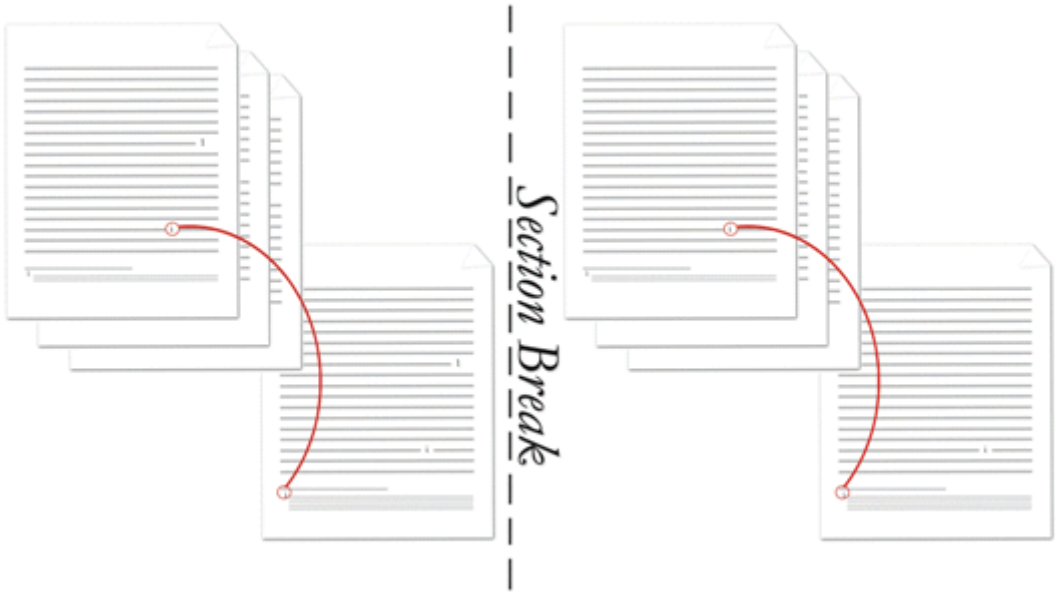
```
<complexType name="CT_FtnEdnSepRef">
    <attribute name="id" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.11.4 endnotePr (Document-Wide Endnote Properties)

This element specifies the endnote properties for the current document. Each of these properties are stored as a child element within the endnotePr element.

These properties may be overridden for a specific section via the section-wide endnotePr element (§2.11.5).

[*Example*: Consider the following document with two sections, where the endnotes for each section appears at the end of that section and use lower case roman numerals:



Since both sections are identical, the endnote properties are specified as document-wide level properties (this is not necessary but is most efficient) as follows:

```
<w:settings>
  …
  <w:endnotePr>
    <w:numFmt w:val="lowerRoman" />
    <w:pos w:val="sectEnd"/>
  </w:endnotePr>
  …
</w:settings>
```

Note that the pos element could have been omitted since it is using its default value. *end example*]

Parent Elements
settings (§2.15.1.78)

Child Elements	Subclause
endnote (Special Endnote List)	§2.11.3
numFmt (Endnote Numbering Format)	§2.11.18
numRestart (Footnote and Endnote Numbering Restart Location)	§2.11.19
numStart (Footnote and Endnote Numbering Starting Value)	§2.11.20
pos (Endnote Placement)	§2.11.22

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_EdnDocProps">
    <complexContent>
        <extension base="CT_EdnProps">
            <sequence>
                <element name="endnote" type="CT_FtnEdnSepRef" minOccurs="0" maxOccurs="3"/>
            </sequence>
        </extension>
    </complexContent>
</complexType>
```

2.11.5 endnotePr (Section-Wide Endnote Properties)

This element specifies the endnote properties for the current section. Each of these properties are an override of the document-wide endnote properties (§2.11.4) and are stored as a child element within the endnotePr element.

If this element is omitted for a given section, then that section shall use the endnote properties defined at the document-wide level.

[*Example*: Consider a document consisting of three sections, which has endnotes in the first section which use lowercase roman numerals, and endnotes in the third section which use the Chicago Manual of Style format. The WordprocessingML for each section would be specified as follows:

```
<w:sectPr>
  <w:endnotePr>
    <w:numFmt w:val="lowerRoman" />
  </w:endnotePr>
</w:sectPr>
…
<w:sectPr>
  …
</w:sectPr>
…
<w:sectPr>
  …
</w:sectPr>
```

This assumes that the document-wide endnote settings are specified to use the Chicago Manual of Style format, as follows:

```
<w:settings>
  <w:endnotePr>
    <w:numFmt w:val="chicago" />
  </w:endnotePr>
</w:settings>
```

The resulting document would override the endnote numbering format for the first section to `lowerRoman`, but would use the `chicago` endnote numbering format for section three (and would also use it for section two if that section had endnotes. *end example*]

numRestart (Footnote and Endnote Numbering Restart Location)	§2.11.19
numStart (Footnote and Endnote Numbering Starting Value)	§2.11.20
pos (Endnote Placement)	§2.11.22

The following XML Schema fragment defines the contents of this element:

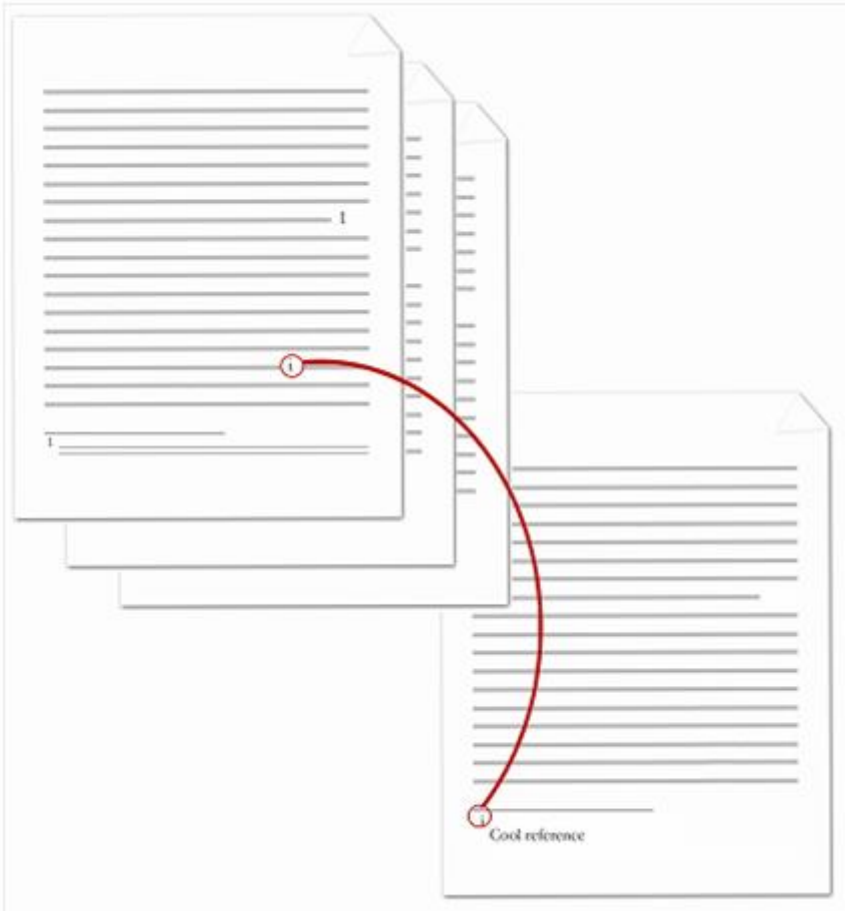
```
<complexType name="CT_EdnProps">
   <sequence>
      <element name="pos" type="CT_EdnPos" minOccurs="0"/>
      <element name="numFmt" type="CT_NumFmt" minOccurs="0"/>
      <group ref="EG_FtnEdnNumProps" minOccurs="0"/>
   </sequence>
</complexType>
```

2.11.6 endnoteRef (Endnote Reference Mark)

This element specifies the presence of an endnote reference mark. An *endnote reference mark* is a run of automatically numbered text which follows the numbering format set forth via the numFmt element (§2.11.18).

If an endnote reference mark is specified within a run which is not part of an endnote, then that endnote reference mark may be ignored.

[*Example*: Consider the following document where some text is referenced by an endnote at the end of the document:



The endnote reference mark is the lower case roman numeral within the actual endnote itself in the diagram above. The contents of the endnote (including the endnote reference mark) are represented by the following WordprocessingML:

```
<w:endnote w:id="2">
  <w:p>
    <w:pPr>
      <w:pStyle w:val="EndnoteText" />
    </w:pPr>
    <w:r>
      <w:rPr>
        <w:rStyle w:val="EndnoteReference" />
      </w:rPr>
      <w:endfootnoteRef />
    </w:r>
    <w:r>
      <w:t>Cool reference</w:t>
    </w:r>
  </w:p>
</w:endnote>
```

The resulting endnote contains the literal endnote content of `Cool reference`, preceding by an automatically numbered endnote reference mark. Since this is the first endnote in the document, that automatically numbered reference mark uses the lower case roman numeral `i`. *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

The following XML Schema fragment defines the contents of this element:

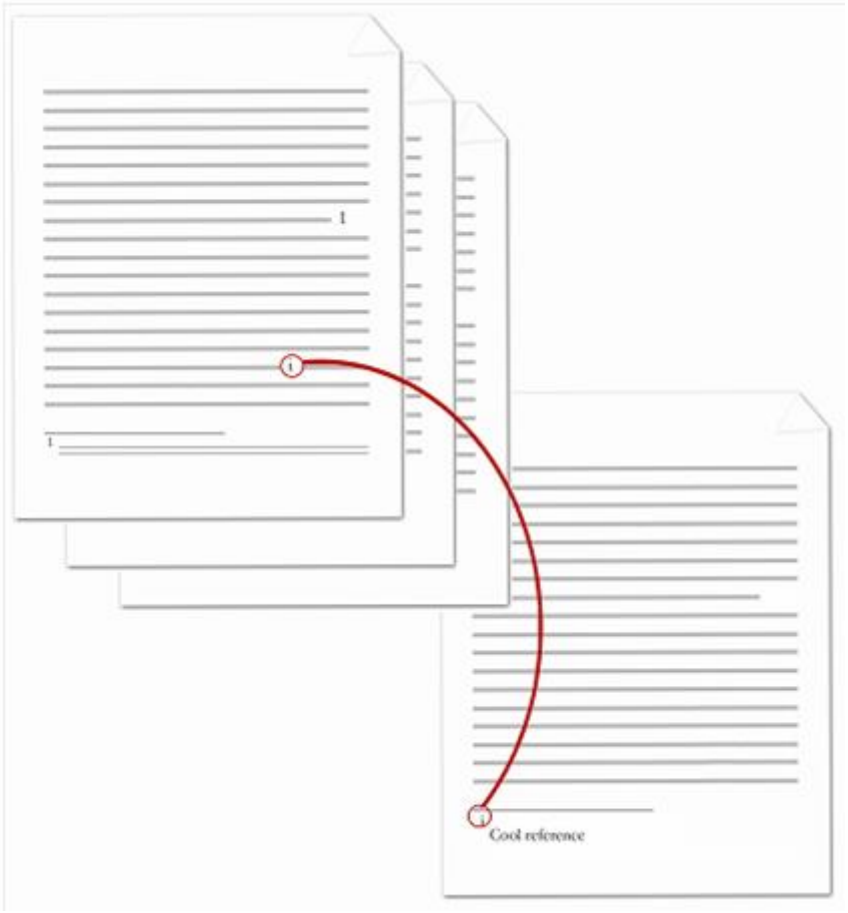
```
<complexType name="CT_Empty"/>
```

2.11.7 endnoteReference (Endnote Reference)

This element specifies the presence of an endnote reference. An *endnote reference* is a run of automatically numbered text which references a particular endnote within the parent document, and inherits the endnote reference mark's numbering.

If an endnote reference is specified within a footnote or endnote, then the document shall be considered non-conformant.

[*Example*: Consider the following document where some text is referenced by an endnote at the end of the document:



The endnote reference is the lower case roman numeral within the document content in the diagram above. The contents of the paragraph which contains the endnote reference are represented by the following WordprocessingML:

```
<w:p>
  <w:r>
    <w:t>This text is followed by an endnote</w:t>
  </w:r>
  <w:r>
    <w:rPr>
      <w:rStyle w:val="EndnoteReference" />
    </w:rPr>
    <w:endnoteReference w:id="2" />
  </w:r>
  <w:r>
    <w:t>.</w:t>
  </w:r>
</w:p>
```

The resulting paragraph contains the literal text content of `This text is followed by an endnote`, followed by an automatically numbered endnote reference. Since this is the first endnote in the document, that automatically numbered reference inherits the lower case roman numeral `i` from the endnote reference mark. *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

Attributes	Description

customMarkFollows (Suppress Footnote/Endnote Reference Mark)	Specifies that the current footnote or endnote shall not have an associated footnote or endnote reference mark, as appropriate.
	
	This attribute shall be used to specify that a particular footnote or endnote shall not increment the numbering for its associated footnote/endnote numbering format, so that the use of a footnote with a custom footnote mark does not cause a missing value in the footnote/endnote values. The display of the mark is specified via the footnoteRef/endnoteRef elements, as appropriate.
	
	If this attribute is omitted, then the footnote or endnote reference mark shall not be skipped when incrementing over this footnote or endnote.
	
	[*Example*: Consider a footnote with an id value of 1 that uses a custom footnote mark:
	
	`<w:footnotes>`
	`  <w:footnote w:id="0">`
	`  …`
	`  </w:footnote>`
	`  <w:footnote w:suppressRef="1" w:id="2">`
	`  …`
	`  </w:footnote>`
	`  <w:footnote w:id="2">`
	`  …`
	`  </w:footnote>`
	`</w:footnotes>`
	
	If the numbering format for footnotes in this document is upperRoman, then the first footnote shall be `I`, the second is suppressed, and the third is `II`, noticing that the second does not increment the numbering sequence. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

id (Footnote/Endnote ID Reference)	Specifies the footnote or endnote which is being referenced by the current footnote or endnote reference in the document. If the resulting footnote or endnote ID is not present in the footnotes or endnote part (as appropriate), then this document shall be considered non-conformant.

Attributes	Description

	[*Example*: Consider a paragraph with an endnote reference, represented by the following WordprocessingML:
	
	`<w:p>`
	`  <w:r>`
	`  <w:t>This text is followed by an endnote</w:t>`
	`  </w:r>`
	`  <w:r>`
	`  <w:endnoteReference w:id="2" />`
	`  </w:r>`
	`  <w:r>`
	`  <w:t>.</w:t>`
	`  </w:r>`
	`</w:p>`
	
	This text references the endnote in the document's endnotes part which has an id value of 2. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FtnEdnRef">
   <attribute name="customMarkFollows" type="ST_OnOff" use="optional"/>
   <attribute name="id" use="required" type="ST_DecimalNumber"/>
</complexType>
```

2.11.8 endnotes (Document Endnotes)

This element specifies the set of all endnotes in the document, including endnote separators and continuation notices. This element is the root node for the Endnotes part.

[*Example*: Consider the following example of the contents of the endnotes part:

```
<w:endnotes>
  <w:endnote w:type="separator" w:id="0">
    …
  </w:endnote>
  <w:endnote w:type="continuationSeparator" w:id="1">
    …
  </w:endnote>
  <w:endnote w:id="2">
    …
  </w:endnote>
</w:endnotes>
```

The endnotes part contains the definition for one normal endnote, as well as the separator and continuation separator endnote for this document. *end example*]

Parent Elements
Root element of WordprocessingML Endnotes part

Child Elements	Subclause
endnote (Endnote Content)	§2.11.2

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Endnotes">
    <sequence maxOccurs="unbounded">
        <element name="endnote" type="CT_FtnEdn" minOccurs="0"/>
    </sequence>
</complexType>
```

2.11.9 footnote (Special Footnote List)

This element specifies the ID for all footnotes which are located in the current document that are not of type `normal`. Each other type of footnote shall be referenced in this list, or it shall not be loaded. This means that if a special footnote is not listed beneath this element, and it is required by the document content, then the document shall be considered non-conformant.

[*Example*: Consider a document that has three footnotes represented by the following WordprocessingML:

```
<w:footnotes>
  <w:footnote w:type="separator" w:id="0">
    ...
  </w:footnote>
  <w:footnote w:type="continuationSeparator" w:id="1">
    ...
  </w:footnote >
  <w:footnote w:id="2">
    ...
  </w:footnote>
</w:footnotes>
```

Each of the footnotes which are not of type `normal` must be specified in the footnotePr element, as follows:

```
<w:footnotePr>
  <w:footnote w:id="0" />
  <w:footnote w:id="1" />
</w:footnotePr>
```

This indicates to the consumer that the footnotes with an id attribute value of 0 and 1 are special footnotes, and should be treated accordingly. *end example*]

Parent Elements
footnotePr (§2.11.11)

Attributes	Description

id (Footnote/Endnote ID)	Specifies a unique ID which shall be used to match the contents of a footnote or endnote to the associated footnote/endnote reference mark in the document using the footnoteRef or endnoteRef element, as appropriate.
	
	If more than one footnote shares the same ID, then this document shall be considered non-conformant. If more than one endnote shares the same ID, then this document shall be considered non-conformant.
	
	[*Example*: Consider the following footnote as defined in the footnotes part:
	
	`<w:footnotes>`
	`  <w:footnote w:type="normal" w:id="0">`
	`  …`
	`  </w:footnote>`
	`  …`
	`</w:footnotes>`
	
	The contents of this footnote are associated with the footnoteReference with a matching ID, as follows:
	
	`<w:p>`
	`  <w:r>`
	`  <w:footnoteReference w:id="0" />`
	`  </w:r>`
	`</w:p>`
	
	The resulting paragraph will have a footnote reference mark which references the footnote number value of the footnote with an id of 0. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FtnEdnSepRef">
    <attribute name="id" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.11.10 footnote (Footnote Content)

This element specifies the content of a single footnote within a WordprocessingML document. Each footnote shall be represented by a single footnote element, which may contain any valid *block-level content*.

[*Example*: Consider a document with a single footnote, identified by a footnote element, defined in the footnotes part as follows:

```
<w:footnotes>
  <w:footnote w:id="2">
    <w:p>
      <w:pPr>
        <w:pStyle w:val="FootnoteText" />
      </w:pPr>
      <w:r>
        <w:rPr>
          <w:rStyle w:val="FootnoteReference" />
        </w:rPr>
        <w:footnoteRef />
      </w:r>
      <w:r>
        <w:t xml:space="preserve">This is a sample footnote</w:t>
      </w:r>
    </w:p>
  </w:footnote>
</w:footnotes>
```

This footnote contains an footnote reference mark, as well as the endnote text `This is a sample footnote`. *end example*]

Parent Elements
footnotes (§2.11.15)

Child Elements	Subclause
altChunk (Anchor for Imported External Content)	§2.17.3.1
bookmarkEnd (Bookmark End)	§2.13.6.1

permEnd (Range Permission End)	§2.13.7.1
permStart (Range Permission Start)	§2.13.7.2
proofErr (Proofing Error Anchor)	§2.13.8.1
sdt (Block-Level Structured Document Tag)	§2.5.2.30
tbl (Table)	§2.4.36

Attributes	Description

id (Footnote/Endnote ID)	Specifies a unique ID which shall be used to match the contents of a footnote or endnote to the associated footnote/endnote reference mark in the document using the footnoteRef or endnoteRef element, as appropriate.
	
	If this attribute is omitted, then this footnote or endnote shall have no ID. If more than one footnote shares the same ID, then this document shall be considered non-conformant. If more than one endnote shares the same ID, then this document shall be considered non-conformant.
	
	[*Example*: Consider the following footnote as defined in the footnotes part:
	
	`<w:footnotes>`
	`  <w:footnote w:type="normal" w:id="0">`

Attributes	Description
	… </w:footnote> … </w:footnotes> The contents of this footnote are associated with the footnoteReference with a matching ID, as follows: <w:p> <w:r> <w:footnoteReference w:id="0" /> </w:r> </w:p> The resulting paragraph will have a footnote reference mark which references the footnote number value of the footnote with an id of 0. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
type (Footnote/Endnote Type)	Specifies the type of footnote or endnote contained within the current footnote or endnote content definition. If this attribute is omitted, then it shall be considered to be of type normal. If a footnote or endnote is not of type normal, then it shall not be referenced by a footnoteReference or endnoteReference element within the main document story. [*Example*: Consider the following example of a footnote defined in a WordprocessingML document as follows: <w:footnote w:type="continuationSeparator" w:id="1"> <w:p> <w:r> <w:continuationSeparator /> </w:r> </w:p> </w:footnote> In this example, the footnote is of type continuationSeparator and shall be used by a consumer to separate continued footnotes from the main document contents (see simple type for full details). *end example*] The possible values for this attribute are defined by the ST_FtnEdn simple type (§2.18.37).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FtnEdn">
    <sequence>
        <group ref="EG_BlockLevelElts" minOccurs="1" maxOccurs="unbounded"/>
    </sequence>
    <attribute name="type" type="ST_FtnEdn" use="optional"/>
    <attribute name="id" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.11.11 footnotePr (Document-Wide Footnote Properties)

This element specifies the footnote properties for this document. Each property is stored as a unique element within the footnotePr element.

These properties may be overridden for a specific section via the section-wide footnotePr element (§2.11.12).

[*Example*: Consider the following one page document, where the footnote appears beneath the text it references:

Since the document consists of a single footnote, the footnote properties may be stored in either the section-wide or document-wide footnote properties. Assuming that they are stored in the latter, the footnote properties are represented by the following WordprocessingML:

```
<w:settings>
  …
  <w:footnotePr>
    <w:pos w:val="beneathText" />
  </w:footnotePr>
  …
```

```
</w:settings>
```

The footnote properties specify that footnotes will appear below the noted text *end example*]

Parent Elements
settings (§2.15.1.78)

Child Elements	Subclause
footnote (Special Footnote List)	§2.11.9
numFmt (Footnote Numbering Format)	§2.11.17
numRestart (Footnote and Endnote Numbering Restart Location)	§2.11.19
numStart (Footnote and Endnote Numbering Starting Value)	§2.11.20
pos (Footnote Placement)	§2.11.21

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FtnDocProps">
   <complexContent>
      <extension base="CT_FtnProps">
         <sequence>
            <element name="footnote" type="CT_FtnEdnSepRef" minOccurs="0" maxOccurs="3"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.11.12 footnotePr (Section-Wide Footnote Properties)

This element specifies the footnote properties for the current section. Each of these properties are an override of the document-wide footnote properties (§2.11.11) and are stored as a child element within the footnotePr element.

If this element is omitted for a given section, then that section shall use the footnote properties defined at the document-wide level.

[*Example*: Consider a document consisting of three sections, which has footnotes in the first section which appear below text, and footnotes in the third section which appear at the bottom of the page. The WordprocessingML for each section would be specified as follows:

```
<w:sectPr>
  <w:footnotePr>
    <w:pos w:val="beneathText" />
  </w:footnotePr>
</w:sectPr>
```

```
…
<w:sectPr>
  …
</w:sectPr>
…
<w:sectPr>
  …
</w:sectPr>
```

This assumes that the document-wide footnote settings are specified as the default positioning at the bottom of the page by omitting the pos element (§2.11.21), as follows:

```
<w:settings>
  <w:footnotePr>
    …
  </w:footnotePr>
</w:settings>
```

The resulting document would override the footnote positioning for the first section to `beneathText`, but would use the `pageBottom` footnote positioning for section three (and would also use it for section two if that section had footnotes. *end example*]

Parent Elements
sectPr (§2.6.17); sectPr (§2.6.18); sectPr (§2.6.19)

Child Elements	Subclause
numFmt (Footnote Numbering Format)	§2.11.17
numRestart (Footnote and Endnote Numbering Restart Location)	§2.11.19
numStart (Footnote and Endnote Numbering Starting Value)	§2.11.20
pos (Footnote Placement)	§2.11.21

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FtnProps">
   <sequence>
      <element name="pos" type="CT_FtnPos" minOccurs="0"/>
      <element name="numFmt" type="CT_NumFmt" minOccurs="0"/>
      <group ref="EG_FtnEdnNumProps" minOccurs="0"/>
   </sequence>
</complexType>
```

2.11.13 footnoteRef (Footnote Reference Mark)

This element specifies the presence of a footnote reference mark. A *footnote reference mark* is a run of automatically numbered text which follows the numbering format set forth via the footnote numFmt element (§2.11.17).

If a footnote reference mark is specified within a run which is not part of a footnote, then that footnote reference mark may be ignored.

[*Example*: Consider the following document where some text is referenced by an footnote at the end of the page:

The footnote reference mark is the decimal number within the actual footnote itself in the image above. The contents of the footnote (including the footnote reference mark) are represented by the following WordprocessingML:

```
<w:footnote w:id="2">
  <w:p>
    <w:pPr>
      <w:pStyle w:val="FootnoteText" />
    </w:pPr>
    <w:r>
      <w:rPr>
        <w:rStyle w:val="FootnoteReference" />
      </w:rPr>
      <w:footnoteRef />
    </w:r>
    <w:r>
```

```
        <w:t>Cool reference</w:t>
      </w:r>
    </w:p>
  </w:footnote>
```

The resulting footnote contains the literal endnote content of `Cool reference`, preceding by an automatically numbered footnote reference mark. Since this is the first footnote in the document, that automatically numbered reference mark uses the first decimal number `1`. It is also important to note that the use of styles `FootnoteText` and `FootnoteReference` is not required, these may simply be added by a particular producer automatically to give the footnote contents are particular style (just like any other use of styles). *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.11.14 footnoteReference (Footnote Reference)

This element specifies the presence of a footnote reference. A *footnote reference* is a run of automatically numbered text which references a particular footnote within the parent document, and inherits the footnote reference mark's numbering.

If an footnote reference is specified within a footnote or endnote, then the document shall be considered non-conformant.

[*Example*: Consider the following document where some text is referenced by a footnote at the bottom of the page:

The footnote reference is the superscript decimal number within the document content in the diagram above. The contents of the paragraph which contains the footnote reference are represented by the following WordprocessingML:

```
<w:p>
  <w:r>
    <w:t>Some referenced text.</w:t>
  </w:r>
  <w:r>
    <w:rPr>
      <w:rStyle w:val="FootnoteReference" />
    </w:rPr>
    <w:footnoteReference w:id="2" />
  </w:r>
</w:p>
```

The resulting paragraph contains the literal text content of `Some referenced text.`, followed by an automatically numbered footnote reference. Since this is the first footnote in the document, that automatically numbered reference inherits the decimal number 1 from the footnote reference mark. *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

Attributes	Description

customMarkFollows (Suppress Footnote/Endnote Reference Mark)	Specifies that the current footnote or endnote shall not have an associated footnote or endnote reference mark, as appropriate.
	
	This attribute shall be used to specify that a particular footnote or endnote shall not increment the numbering for its associated footnote/endnote numbering format, so that the use of a footnote with a custom footnote mark does not cause a missing value in the footnote/endnote values. The display of the mark is specified via the footnoteRef/endnoteRef elements, as appropriate.
	
	If this attribute is omitted, then the footnote or endnote reference mark shall not be skipped when incrementing over this footnote or endnote.
	
	[*Example*: Consider a footnote with an id value of 1 that uses a custom footnote mark:
	
	`<w:footnotes>`
	`  <w:footnote w:id="0">`
	`    …`
	`  </w:footnote>`
	`  <w:footnote w:suppressRef="1" w:id="2">`
	`    …`

Attributes	Description
	</w:footnote> <w:footnote w:id="2"> … </w:footnote> </w:footnotes> If the numbering format for footnotes in this document is upperRoman, then the first footnote shall be I, the second is suppressed, and the third is II, noticing that the second does not increment the numbering sequence. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
id (Footnote/Endnote ID Reference)	Specifies the footnote or endnote which is being referenced by the current footnote or endnote reference in the document. If the resulting footnote or endnote ID is not present in the footnotes or endnote part (as appropriate), then this document shall be considered non-conformant. [*Example*: Consider a paragraph with an endnote reference, represented by the following WordprocessingML: <w:p> <w:r> <w:t>This text is followed by an endnote</w:t> </w:r> <w:r> <w:endnoteReference w:id="2" /> </w:r> <w:r> <w:t>.</w:t> </w:r> </w:p> This text references the endnote in the document's endnotes part which has an id value of 2. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FtnEdnRef">
   <attribute name="customMarkFollows" type="ST_OnOff" use="optional"/>
   <attribute name="id" use="required" type="ST_DecimalNumber"/>
</complexType>
```

2.11.15 footnotes (Document Footnotes)

This element specifies the set of all footnotes in the document, including footnote separators and continuation notices. This element is the root node for the Footnotes part.

[*Example*: Consider the following example of the contents of the footnotes part:

```
<w:footnotes>
  <w:footnote w:type="separator" w:id="0">
    …
  </w:footnote >
  <w:footnote w:type="continuationSeparator" w:id="1">
    …
  </w:footnote>
  <w:footnote w:id="2">
    …
  </w:footnote>
</w:footnotes>
```

The footnotes part contains the definition for one normal footnote, as well as the separator and continuation separator footnotes for this document. *end example*]

Parent Elements
Root element of WordprocessingML Footnotes part

Child Elements	Subclause
footnote (Footnote Content)	§2.11.10

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Footnotes">
   <sequence maxOccurs="unbounded">
      <element name="footnote" type="CT_FtnEdn" minOccurs="0"/>
   </sequence>
</complexType>
```

2.11.16 noEndnote (Suppress Endnotes In Document)

This element specifies that all endnotes in this document shall not be displayed or printed. If this element is placed on any section break other than the first section break in the document, it shall be ignored.

If this element is omitted, endnotes shall not be suppressed in the current document.

[*Example*: Consider a document in which in the first section endnotes are marked to be hidden:

```
<w:sectPr>
  <w:noEndnote />
```

```
</w:sectPr>
```

In this example, this document will not display endnotes. *end example*]

Parent Elements
sectPr (§2.6.17); sectPr (§2.6.18); sectPr (§2.6.19)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.11.17 numFmt (Footnote Numbering Format)

This element specifies the numbering format which shall be used to determine the footnote or endnote reference mark value for all automatically numbered footnote and endnote reference marks (those without the suppressRef attribute set).

If this element is omitted, then the numbering format shall be assume to be decimal.

[*Example*: Consider the following footnote reference with the number format set to upper case letters:

This footnote numbering format is specified by the following WordprocessingML:

```
<w:footnotePr>
  <w:numFmt w:val="upperLetter" />
</w:footnotePr>
```

end example]

Parent Elements
footnotePr (§2.11.11); footnotePr (§2.11.12)

Attributes	Description
val (Numbering Format Type)	Specifies the number format that shall be used for all numbering in the parent object. [*Example*: A value of `lowerLetter` indicates that a consumer shall use lowercase letters for each number in this grouping: a,b,c… *end example*] The possible values for this attribute are defined by the ST_NumberFormat simple type (§2.18.66).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_NumFmt">
   <attribute name="val" type="ST_NumberFormat" use="required"/>
</complexType>
```

2.11.18 numFmt (Endnote Numbering Format)

This element specifies the numbering format which shall be used to determine the footnote or endnote reference mark value for all automatically numbered footnote and endnote reference marks (those without the suppressRef attribute set).

If this element is omitted, then the numbering format shall be assume to be `decimal`.

[*Example*: Consider the following footnote reference with the number format set to upper case letters:

This footnote numbering format is specified by the following WordprocessingML:

```
<w:footnotePr>
  <w:numFmt w:val="upperLetter" />
</w:footnotePr>
```

end example]

Parent Elements
endnotePr (§2.11.4); endnotePr (§2.11.5)

Attributes	Description
val (Numbering Format Type)	Specifies the number format that shall be used for all numbering in the parent object. [*Example*: A value of `lowerLetter` indicates that a consumer shall use lowercase letters for each number in this grouping: a,b,c… *end example*] The possible values for this attribute are defined by the ST_NumberFormat simple type (§2.18.66).

The following XML Schema fragment defines the contents of this element:

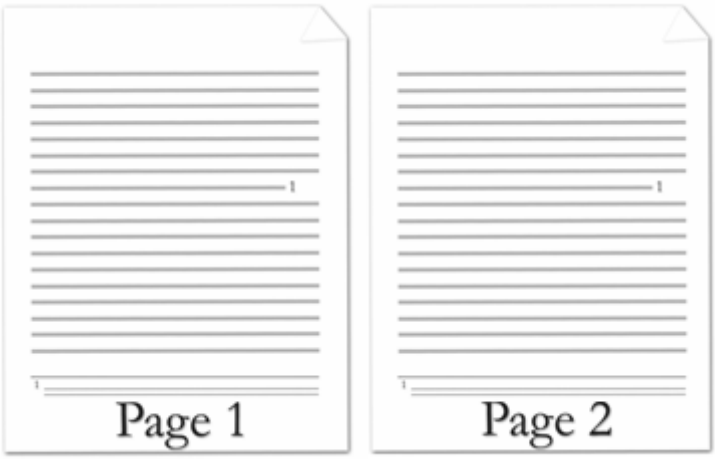
```
<complexType name="CT_NumFmt">
   <attribute name="val" type="ST_NumberFormat" use="required"/>
</complexType>
```

2.11.19 numRestart (Footnote and Endnote Numbering Restart Location)

This element specifies when all automatic numbering for the footnote or endnote reference marks shall be restarted. When restarted, the next automatically numbered footnote or endnote in the document (each type is handled independently) shall restart to the specified numStart value (§2.11.20).

If this element is omitted, then automatic numbering shall not be restarted between each page or section (a vlaue of `continuous`).

[*Example*: Consider the following two page document where the numbering shall be reset after each page to its starting value:



The footnote automatic restarting of the numbering is represented by the following WordprocessingML:

```
<w:footnotePr>
  <w:numRestart w:val="eachPage" />
</w:footnotePr>
```

end example]

Parent Elements
endnotePr (§2.11.4); endnotePr (§2.11.5); footnotePr (§2.11.11); footnotePr (§2.11.12)

Attributes	Description
val (Automatic Numbering Restart Value)	Specifies when the automatic numbering shall be restarted for the current set of footnotes or endnotes. [*Example*: Consider a WordprocessingML document where the numbering for its endnotes shall be restarted after each section shall be restarted after each page. This setting is represented by the following WordprocessingML:

Attributes	Description
	<w:footnotePr> <w:numRestart w:val="eachSect" /> </w:footnotePr> The val attribute value of eachSect specifies that numbering shal be restarted after each section. *end example*] The possible values for this attribute are defined by the ST_RestartNumber simple type (§2.18.81).

The following XML Schema fragment defines the contents of this element:

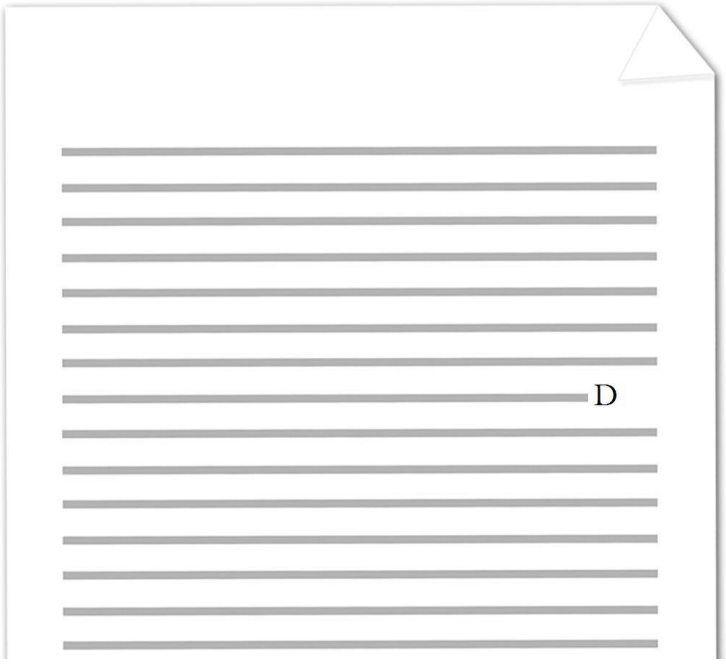
```
<complexType name="CT_NumRestart">
   <attribute name="val" type="ST_RestartNumber" use="required"/>
</complexType>
```

2.11.20 numStart (Footnote and Endnote Numbering Starting Value)

This element specifies the starting number or character for the first automatically numbered footnotes or endnote in the document, as well as the first automatically numbered footnotes after each restart point specified by the numRestart element (§2.11.19). This value shall be specified in decimal number units, then translated accordingly to the appropriate numbering format.

If this element is omitted, then the starting value shall be 1.

[*Example*: Consider the following footnote reference with the number format set to upper case letters and starting character set to D:



The number format is specified by the following WordprocessingML:

```
<w:footnotePr>
  <w:numFmt w:val="upperLetter" />
  <w:numStart w:val="4" />
</w:footnotePr>
```

Since D is the fourth letter in the alphabet, the starting character is set to 4. *end example*]

Parent Elements
endnotePr (§2.11.4); endnotePr (§2.11.5); footnotePr (§2.11.11); footnotePr (§2.11.12)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.11.21 pos (Footnote Placement)

This element specifies where footnotes shall be placed on the page when they are referenced by text in the current document.

If this element is present at the section level, then it shall be ignored.

If this element is omitted at the document level, then footnotes shall be located at the bottom of the current page.

[*Example*: Consider the following one page document, where the footnote appears beneath the text that it is referencing:

The footnote references the text reading `Some reference text.` and is represented by the following WordprocessingML:

```
<w:p>
  <w:r>
     <w:t>Some referenced text</w:t>
  </w:r>
  <w:r>
    <w:rPr>
      <w:rStyle w:val="FootnoteReference" />
    </w:rPr>
    <w:footnoteReference w:id="2" />
  </w:r>
</w:p>
```

Since the footnote location must be beneath the current text, the section properties shall be declared as follows:

```
<w:settings>
  …
  <w:footnotePr>
    <w:pos w:val="beneathText" />
  </w:footnotePr>
  …
</w:sectPr>
```

The footnote references the footnote in the footnotes part with an id attribute value equal to 2. Within the section properties of the document, the position of footnotes is specified to be beneath the page's text. *end example*]

Parent Elements
footnotePr (§2.11.11); footnotePr (§2.11.12)

Attributes	Description

val (Footnote Position Type)	Specifies the position of footnotes in the document.
	
	[*Example*: Consider a document in which footnotes shall be positioned beneath their text. The footnote properties for this document shall be declared as follows:
	
	`<w:sectPr>`
	`  <w:footnotePr>`
	`  <w:pos w:val="beneathText" />`
	`  </w:footnotePr>`
	`  …`
	`</w:sectPr>`
	
	The val attribute is beneathText, therefore the position of footnotes is specified to be beneath the page's text. *end example*]
	
	The possible values for this attribute are defined by the ST_FtnPos simple type (§2.18.38).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FtnPos">
   <attribute name="val" type="ST_FtnPos" use="required"/>
</complexType>
```

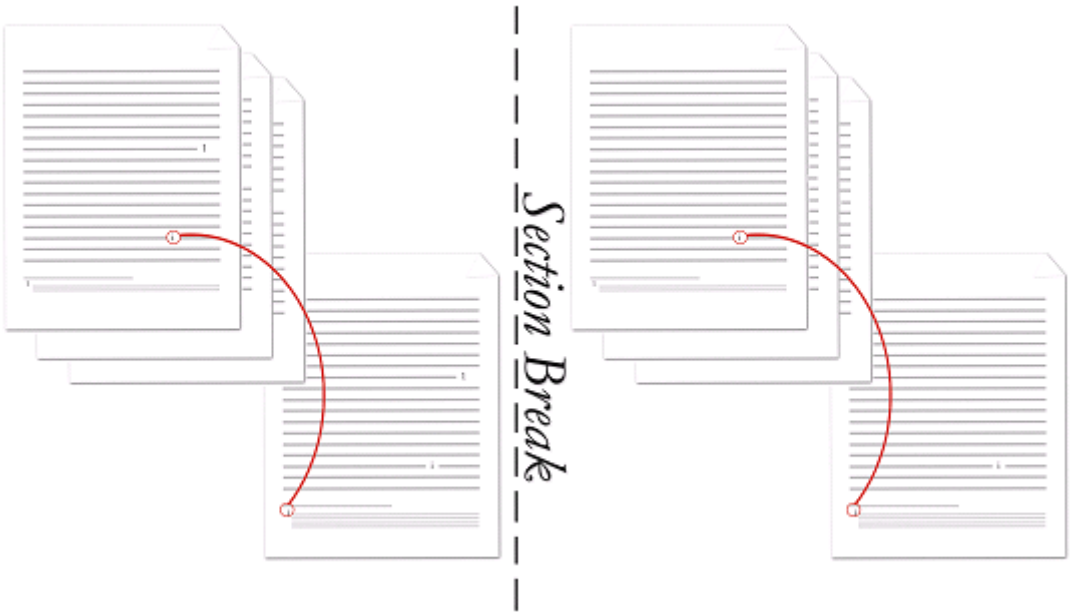
2.11.22 pos (Endnote Placement)

This element specifies where endnotes shall be placed on the page when they are referenced by text in the current document.

If this element is present at the section level, then it shall be ignored.

If this element is omitted at the document level, then endnotes shall be located at the end of the document.

[*Example*: Consider the following multi-page, multi-section document, where the endnote appears at the end of the section in which it is referenced:



The endnote setting is the same for all sections, and is represented by the following WordprocessingML at the document level:

```
<w:settings>
  …
  <w:endnotePr>
    <w:pos w:val="sectEnd" />
    …
  </w:endnotePr>
  …
</w:settings>
```

Within the properties of the document, the position of endnotes is specified to be at the end of each section. *end example*]

Parent Elements
endnotePr (§2.11.4); endnotePr (§2.11.5)

Attributes	Description
val (Endnote Position Type)	Specifies the position of endnotes on the parent section or the document. [*Example*: Consider a document in which endnotes shall be positioned at the end of the section. The section properties for this section shall be declared as follows: `<w:settings>`

Attributes	Description
	<w:endnotePr> <w:pos w:val="endSect" /> </w:endnotePr> … </w:settings> The val attribute is endSect, therefore the position of endnotes is specified to be at the end of the section. *end example*] The possible values for this attribute are defined by the ST_EdnPos simple type (§2.18.26).

The following XML Schema fragment defines the contents of this element:

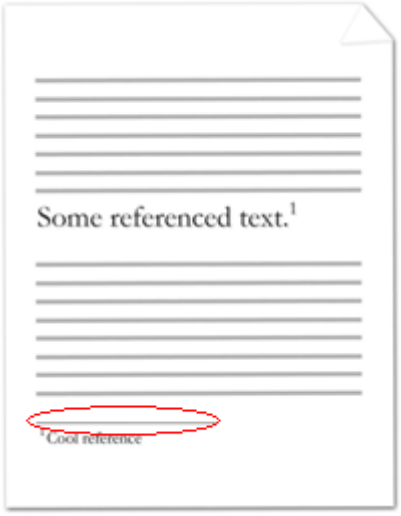
```
<complexType name="CT_EdnPos">
   <attribute name="val" type="ST_EdnPos" use="required"/>
</complexType>
```

2.11.23 separator (Footnote/Endnote Separator Mark)

This element specifies the presence of a separator mark within the current run. A *separator mark* is a horizontal line which spans part of the width text extents.

[*Note*: The separator mark is typically used within the context of separator footnotes or endnotes. These footnote and endnote types define the footnote/endnote used to separate the contents of the main document story from the contents of footnotes or endnotes on that page. *end note*]

[*Example*: Consider the following page in a document, where some text is referenced by a footnote that is located at the bottom of the current page (with the separator circled in red):



The line separating the document text from the normal footnotes is the footnote separator, and is represented by the following WordprocessingML:

```
<w:footnote w:type="separator" w:id="0">
  <w:p>
    <w:r>
      <w:separator />
    </w:r>
  </w:p>
</w:footnote>
```

In this example, the footnote has a content which consists of a single separator, which is displayed as a horizontal line across part of the text extents. *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.12 Glossary Document

Within a WordprocessingML file, the *glossary document* is a supplemental storage location for additional document content which shall travel with the document, but which shall not be displayed for printed as part of the main document until it is explicitly added to that document by deliberate action.

The glossary document shall also be afforded a separate instance of all of the relationships which are provided on the main document part - this means that the glossary document shall have its own style definitions, numbering definitions, comments, headers, footers, etc. within the WordprocessingML document.

[*Example*: Consider a document which shall include ten optional clauses that may be inserted through a user interface. It is clearly not desirable to have these ten clauses appear in the main document story's contents before they are explicitly inserted, therefore each of them may be stored in the glossary document and inserted via the user interface as needed. *end example*]

Within the glossary document, each distinct region of document content is referred to as a *glossary document entry*, and is defined via the docPart element (§2.12.5). These document parts may contain any block-level WordprocessingML element, and may also have a set of classifications and behaviors applied to them via the glossary document entry's properties.

[*Example*: Consider the following definition for the contents of a glossary document part within a WordprocessingML document:

```
<w:glossaryDocument>
  <w:docParts>
    <w:docPart>
      <w:docPartPr>
        …
      </w:docPartPr>
      <w:docPartBody>
        <w:p>
          <w:r>
            <w:t>Sample entry.</w:t>
          </w:r>
        </w:p>
      </w:docPartBody>
    </w:docPart>

    <w:docPart>
      …
    </w:docPart>
  </w:docParts>
</w:glossaryDocument>
```

The glossaryDocument element (§2.12.10) defines the contents of the glossary document part. Within the glossary document, each docPart element contains the definition for one glossary document entry: in this case, there are two entries in the glossary document, the first of which contains a single paragraph with a single run of text. *end example*]

2.12.1 behavior (Entry Insertion Behavior)

This element specifies a single behavior which shall be applied to the contents of the parent glossary document entry (§2.12.5) when it is added to the main document story of a WordprocessingML document. These behaviors shall be used to format the surrounding WordprocessingML around insertion, and do not require the presence of a user interface (i.e. applications without a user interface shall also utilize these settings).

[*Example*: Consider the WordprocessingML fragment for a glossary document entry containing a single run, defined as follows:

```
<w:docPart>
  <w:docPartPr>
    <w:behaviors>
      <w:behavior w:val="p"/>
    </w:behavior>
    …
  </w:docPartPr>
  <w:docPartBody>
    <w:p>
      <w:r>
        <w:t>Sample entry.</w:t>
      </w:r>
    </w:p>
  </w:docPartBody>
</w:docPart>
```

The behavior element has a value of p, which specifies that the contents of the parent glossary document entry shall be inserted in their own paragraph when they are added to the contents of a document. If the document content to which they are added is defined as follows (and the part is added between the two text runs):

```
<w:body>
  <w:p>
    <w:r>
      <w:t>After this text</w:t>
    </w:r>
    <w:r>
      <w:t>Before this text</w:t>
    </w:r>
  </w:p>
</w:body>
```

This setting specifies that although the part would normally be inserted between the two existing runs in the paragraph, that behavior shall ensure that the part is inserted into its own paragraph, resulting in the following WordprocessingML:

```
<w:body>
  <w:p>
    <w:r>
      <w:t>After this text</w:t>
    </w:r>
  </w:p>
  <w:p>
    <w:r>
      <w:t>Sample entry.</w:t>
    </w:r>
  </w:p>
  <w:p>
    <w:r>
      <w:t>Before this text</w:t>
    </w:r>
  </w:p>
</w:body>
```

end example]

Parent Elements
behaviors (§2.12.2)

Attributes	Description

val (Insertion Behavior Value)	Specifies the insertion behavior which shall be associated with the current glossary document entry.
	
	[*Example*: Consider the WordprocessingML fragment for a glossary document entry's properties, defined as follows:
	
	`<w:docPartPr>`
	`  <w:behaviors>`
	`  <w:behavior w:val="content"/>`
	`  </w:behavior>`
	`</w:docPartPr>`
	
	The val attribute value of `content` specifies that the insertion of this glossary document entry shall include only the content (the last paragraph in the part shall be merged into the current paragraph in the document). *end example*]
	
	The possible values for this attribute are defined by the ST_DocPartBehavior simple type (§2.18.19).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DocPartBehavior">
   <attribute name="val" use="required" type="ST_DocPartBehavior"/>
</complexType>
```

2.12.2 behaviors (Entry Insertion Behaviors)

This element specifies the set of behaviors which shall be applied to the contents of the parent glossary document entry (§2.12.5) when it is added to the main document story of a WordprocessingML document. Since multiple behaviors can be specified for a single part, the sum total of all behaviors shall be used to insert the parent entry into the contents of the WordprocessingML document.

[*Example*: Consider the WordprocessingML fragment for a glossary document entry containing a single run, defined as follows:

```
<w:docPart>
  <w:docPartPr>
    <w:behaviors>
      <w:behavior w:val="p" />
      <w:behavior w:val="pg" />
    </w:behavior>
    …
  </w:docPartPr>
  <w:docPartBody>
    <w:p>
      <w:r>
        <w:t>Sample entry.</w:t>
      </w:r>
    </w:p>
  </w:docPartBody>
</w:docPart>
```

The behaviors element contains the set of behaviors which shall be applied to this entry when it is inserted into the document, in this case:

- The entry shall be inserted into its own paragraph in the document
- The entry shall be inserted onto a new page in the document (i.e. it shall be preceded by a page break)

end example]

Parent Elements
docPartPr (§2.12.7)

Child Elements	Subclause

Child Elements	Subclause
behavior (Entry Insertion Behavior)	§2.12.1

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DocPartBehaviors">
   <choice>
      <element name="behavior" type="CT_DocPartBehavior" maxOccurs="unbounded"/>
   </choice>
</complexType>
```

2.12.3 category (Entry Categorization)

This element specifies the categorization for the parent glossary document entry. This categorization shall not imply any behaviors around the entry, and is only used to organize the set of glossary document entries within an application or user interface (i.e. to disambiguate between two entries with the same entry name (§2.12.13)).

[*Example*: Consider the following WordprocessingML fragment for the properties of a single glossary document entry:

```
<w:docPartPr>
  <w:category>
    …
  </w:category>
  …
<w:docPartPr>
```

The category element specifies the categorization applied to the current entry, for the purposes of classification or user interface sorting, for example. *end example*]

Parent Elements
docPartPr (§2.12.7)

Child Elements	Subclause
gallery (Gallery Associated With Entry)	§2.12.9
name (Category Associated With Entry)	§2.12.12

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DocPartCategory">
   <sequence>
      <element name="name" type="CT_String" minOccurs="1" maxOccurs="1"/>
      <element name="gallery" type="CT_DocPartGallery" minOccurs="1" maxOccurs="1"/>
   </sequence>
</complexType>
```

2.12.4 description (Description for Entry)

This element specifies a description for the contents of this glossary document entry. This description may contain any string content, and allows the entry to have additional information contained within the definition for this glossary document entry. [Note: This description may be surfaced in a user interface, for example. *end note*]

[*Example*: Consider the following WordprocessingML fragment for the properties of a single glossary document entry:

```
<w:docPartPr>
  …
  <w:name w:val="Sample Entry" />
  <w:description w:val="This is an example of a glossary document entry for
example purposes." />
  …
<w:docPartPr>
```

The description element specifies that the long description associated with the parent entry shall be `This is an example of a glossary document entry for example purposes.` This value may be used as needed by an application, for example, to display in a user interface. *end example*]

Parent Elements
docPartPr (§2.12.7)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`

Attributes	Description
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.12.5 docPart (Glossary Document Entry)

This element specifies the details for a single glossary document entry contained in the document. This glossary document entry may consist of one or both of the following:

- The glossary document entry's properties, which define its name, categorization, and behaviors
- The glossary document entry's contents, which consists of one or more block-level elements of WordprocessingML content

Each of these two components is specified by one of the child elements of this element, as seen in the child elements table below.

[*Example*: Consider the following definition for the contents of a Glossary Document part within a WordprocessingML document:

```
<w:glossaryDocument>
  <w:docParts>
    <w:docPart>
      …
    </w:docPart>
    <w:docPart>
      …
    </w:docPart>
  </w:docParts>
</w:glossaryDocument>
```

The docPart element uniquely defines one glossary document entry within the glossary document part, therefore there are two unique entries stored in the current example of a glossary document part. *end example*]

Parent Elements
docParts (§2.12.8)

Child Elements	Subclause
docPartBody (Contents of Glossary Document Entry)	§2.12.6
docPartPr (Glossary Document Entry Properties)	§2.12.7

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DocPart">
   <sequence>
      <element name="docPartPr" type="CT_DocPartPr" minOccurs="0"/>
      <element name="docPartBody" type="CT_Body" minOccurs="0"/>
   </sequence>
</complexType>
```

2.12.6 docPartBody (Contents of Glossary Document Entry)

This element specifies the contents of the parent glossary document entry (§2.12.5). These contents shall consist of one or more block-level elements, analogous to the body element (§2.2.2) of the main document story for the current document.

[*Example*: Consider the WordprocessingML fragment for a glossary document entry containing a single run, defined as follows:

```
<w:docPart>
  …
  <w:docPartBody>
    <w:p>
      <w:r>
        <w:t>Sample entry.</w:t>
      </w:r>
    </w:p>
  </w:docPartBody>
</w:docPart>
```

The docPartBody element specifies the block-level elements which comprise the contents of the current glossary document entry, in this case, a single paragraph using the p element (§2.3.1.22). *end example*]

When the contents of a glossary document entry are added to a document, the styles, numbering definitions, and all other related parts for this entry shall be taken from the relationships from the Glossary Document part and not from the main document part. These references shall be moved to their main document equivalents when the entry is added to the document.

When the part is inserted, it shall be inserted as though its last paragraph mark does not exist (the content of the final paragraph mark shall be merged with the contents of the paragraph into which this entry is being added).

[*Example*: Consider the WordprocessingML fragment for a glossary document entry containing a single run, defined as follows:

```
<w:docPart>
  <w:docPartPr>
    <w:behaviors>
      <w:behavior w:val="p"/>
    </w:behavior>
    …
  </w:docPartPr>
  <w:docPartBody>
    <w:p>
      <w:r>
        <w:t>Sample entry.</w:t>
      </w:r>
    </w:p>
  </w:docPartBody>
</w:docPart>
```

If this entry is inserted into document content to which is defined as follows (and the part is added between the two text runs):

```
<w:body>
  <w:p>
    <w:r>
      <w:t>After this text</w:t>
    </w:r>
    <w:r>
      <w:t>Before this text</w:t>
    </w:r>
  </w:p>
</w:body>
```

This entry has only a single paragraph, which is removed before insertion, and barring any special insertion behaviors (§2.12.2), only the text run is inserted, resulting in the following WordprocessingML:

```
<w:body>
  <w:p>
    <w:r>
      <w:t>After this text</w:t>
    </w:r>
    <w:r>
      <w:t>Sample entry.</w:t>
    </w:r>
    <w:r>
      <w:t>Before this text</w:t>
    </w:r>
  </w:p>
</w:body>
```

end example]

oMathPara (Math Paragraph)	§7.1.2.78
p (Paragraph)	§2.3.1.22
permEnd (Range Permission End)	§2.13.7.1
permStart (Range Permission Start)	§2.13.7.2
proofErr (Proofing Error Anchor)	§2.13.8.1
sdt (Block-Level Structured Document Tag)	§2.5.2.30
sectPr (Document Final Section Properties)	§2.6.18
tbl (Table)	§2.4.36

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Body">
   <sequence>
      <group ref="EG_BlockLevelElts" minOccurs="0" maxOccurs="unbounded"/>
      <element name="sectPr" minOccurs="0" maxOccurs="1" type="CT_SectPr"/>
   </sequence>
</complexType>
```

2.12.7 docPartPr (Glossary Document Entry Properties)

This element specifies the set of properties which shall be applied to the parent glossary document entry. These properties define its name, categorization, and behaviors.

[*Example*: Consider the WordprocessingML fragment for a glossary document entry containing a single run, defined as follows:

```
<w:docPart>
  <w:docPartPr>
    <w:name w:val="Sample Entry" />
    …
  </w:docPartPr>
  …
</w:docPart>
```

The docPartPr element specifies the set of properties which have been specified for the parent glossary document entry, the only one visible above being the entry's name of `Sample Entry`. *end example*]

Parent Elements

Parent Elements
docPart (§2.12.5)

Child Elements	Subclause
behaviors (Entry Insertion Behaviors)	§2.12.2
category (Entry Categorization)	§2.12.3
description (Description for Entry)	§2.12.4
guid (Entry ID)	§2.12.11
name (Entry Name)	§2.12.13
style (Associated Paragraph Style Name)	§2.12.14
types (Entry Types)	§2.12.16

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DocPartPr">
   <choice maxOccurs="unbounded">
      <element name="name" type="CT_DocPartName" minOccurs="1"/>
      <element name="style" type="CT_String"/>
      <element name="category" type="CT_DocPartCategory"/>
      <element name="types" type="CT_DocPartTypes"/>
      <element name="behaviors" type="CT_DocPartBehaviors"/>
      <element name="description" type="CT_String"/>
      <element name="guid" type="CT_Guid"/>
   </choice>
</complexType>
```

2.12.8 docParts (List of Glossary Document Entries)

This element specifies the collection of glossary document entries which are stored in the current Glossary Document part.

[*Example*: Consider the following definition for the contents of a glossary document part within a WordprocessingML document:

```
<w:glossaryDocument>
  <w:docParts>
    <w:docPart>
      …
    </w:docPart>
    <w:docPart>
      …
    </w:docPart>
  </w:docParts>
</w:glossaryDocument>
```

The docParts element defines the set of entries which are stored in the glossary document part. *end example*]

Parent Elements
glossaryDocument (§2.12.10)

Child Elements	Subclause
docPart (Glossary Document Entry)	§2.12.5

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DocParts">
   <choice>
      <element name="docPart" type="CT_DocPart" minOccurs="1" maxOccurs="unbounded"/>
   </choice>
</complexType>
```

2.12.9 gallery (Gallery Associated With Entry)

This element specifies the predefined gallery into which the current glossary document part shall be classified. This classification, although its enumeration values may be interpreted to imply semantics around the contents of the parent glossary document entry, shall only be used to classify and sort this entry (via an application or a user interface).

[*Example*: Consider the following WordprocessingML fragment for the properties of a single glossary document entry:

```
<w:docPartPr>
  <w:category>
    <w:gallery w:val="coverPg" />
    <w:name w:val="Internal Memo Covers" />
  </w:category>
  …
<w:docPartPr>
```

The gallery element with a value of coverPg specifies that the gallery categorization applied to the current entry, for the purposes of classification or user interface sorting, puts this entry into the Cover Pages classification. *end example*]

Parent Elements
category (§2.12.3)

Attributes	Description
val (Gallery Value)	Specifies the classification of gallery which shall be associated with the parent glossary document entry.

Attributes	Description
	[*Example*: Consider the following WordprocessingML fragment for a single glossary document entry: `<w:gallery w:val="custom1" />` The val attribute with a value of `custom1` specifies that the gallery categorization applied to the current entry is the `Custom 1` classification. *end example*] The possible values for this attribute are defined by the ST_DocPartGallery simple type (§2.18.20).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DocPartGallery">
   <attribute name="val" type="ST_DocPartGallery" use="required"/>
</complexType>
```

2.12.10 glossaryDocument (Glossary Document Root Element)

This element specifies the root element for a glossary document part within a WordprocessingML document. A glossary document is an supplementary document story in a WordprocessingML that shall be afforded all of the relationships of the Main Document part, such as:

- Style definitions
- Numbering definitions
- Comments
- Headers/footers
- Etc.

The entries stored in this part shall have all of its implicit relationships target these parts, rather than their analogues stored off of the main document part.

[*Example*: Consider the following definition for the contents of a glossary document part within a WordprocessingML document:

```
<w:glossaryDocument>
  <w:docParts>
    <w:docPart>
      …
    </w:docPart>
    <w:docPart>
      …
    </w:docPart>
  </w:docParts>
</w:glossaryDocument>
```

The glossaryDocument element defines the contents of the glossary document part. *end example*]

Parent Elements
Root element of WordprocessingML Glossary Document part

Child Elements	Subclause
background (Document Background)	§2.2.1
docParts (List of Glossary Document Entries)	§2.12.8

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_GlossaryDocument">
   <complexContent>
      <extension base="CT_DocumentBase">
         <sequence>
            <element name="docParts" type="CT_DocParts" minOccurs="0"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.12.11 guid (Entry ID)

This element specifies a unique identifier (specified using a 128-bit GUID stored on the val attribute) that uniquely identifies this document building block.[*Note*: This unique identifier may be used by an application to uniquely reference a single building block regardless of different naming, for example when the same part has different names for localization purposes. *end note*]

[*Example*: Consider the following WordprocessingML fragment for the properties of a single glossary document entry:

```
<w:docPartPr>
  …
  <w:guid w:val="{00000000-5BD2-4BC8-9F70-7020E1357FB2}" />
  …
<w:docPartPr>
```

The guid element specifies that the unique identifier associated with the parent entry shall be {00000000-5BD2-4BC8-9F70-7020E1357FB2}. This value may be used as needed by an application, for example, to uniquely identify a part regardless of its name. *end example*]

Parent Elements
docPartPr (§2.12.7)

Attributes	Description
val (GUID Value)	Specifies a 128-bit globally unique identifier (GUID) value as defined by the simple type referenced below. The contents of this GUID shall be interpreted based on the context of the parent XML element. If this attribute is omitted, its value shall be assumed to be null (i.e. no GUID shall be associated with the parent XML element). [*Example*: Consider the following WordprocessingML element: `<… w:val="{6A9B8B6F-5BD2-4BC8-9F70-7020E1357FB2}"/>` The val attribute value of `{6A9B8B6F-5BD2-4BC8-9F70-7020E1357FB2}` shall be associated with the context of the parent XML element. *end example*] The possible values for this attribute are defined by the ST_Guid simple type (§2.18.39).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Guid">
   <attribute name="val" type="ST_Guid"/>
</complexType>
```

2.12.12 name (Category Associated With Entry)

This element specifies the category into which the current glossary document part shall be classified. This classification may consist of any string value as determined by its contents, and shall only be used to classify and sort this entry (via an application or a user interface).

[*Example*: Consider the following WordprocessingML fragment for the properties of a single glossary document entry:

```
<w:docPartPr>
  <w:category>
    <w:gallery w:val="coverPg" />
    <w:name w:val="Internal Memo Covers" />
  </w:category>
  …
<w:docPartPr>
```

The name element with a value of `Internal Memo Covers` specifies that the category grouping applied to the current entry, for the purposes of classification or user interface sorting, puts this entry into the `Internal Memo Covers` classification. This category may be used as desired. *end example*]

Parent Elements
category (§2.12.3)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.12.13 name (Entry Name)

This element specifies a name for the contents of this glossary document entry. This name may contain any string content, and allows the entry to have a friendly identifier contained within the definition for this glossary document entry. [*Note*: This name may be surfaced in a user interface, for example. *end note*]

[*Example*: Consider the following WordprocessingML fragment for the properties of a single glossary document entry:

```
<w:docPartPr>
  …
  <w:name w:val="Sample Entry" />
  <w:description w:val="This is an example of a glossary document entry for
example purposes." />
  …
<w:docPartPr>
```

The name element specifies that the friendly name associated with the parent entry shall be `Sample Entry`. This value may be used as needed by an application, for example, to display in a user interface. *end example*]

Parent Elements
docPartPr (§2.12.7)

Attributes	Description
decorated (Built-In Entry)	Specifies that the name for the current entry is a built-in entry which should not be displayed in the user interface. [*Note*: This information may be used by an application as needed, for example, to disambiguate an entry from one with the same name, ensuring that the built-in entry can be uniquely identified by the application. *end note*] If this attribute is omitted, its value shall be assumed to be `false`. [*Example*: Consider the following WordprocessingML fragment for the name of a single glossary document entry: `<w:name w:decorated="true" w:val=":-)" />` The decorated attribute specifies that the parent entry is a built-in entry, and shall be treated as such. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
val (Name Value)	Specifies a string value which contains the name of the current glossary document entry. [*Example*: Consider the following WordprocessingML fragment for the name of a single glossary document entry: `<w:name w:val="Sample Entry" />` The val attribute specifies that the name of the parent entry is `Sample Entry`. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DocPartName">
   <attribute name="val" type="ST_String" use="required"/>
   <attribute name="decorated" type="ST_OnOff" use="optional"/>
</complexType>
```

2.12.14 style (Associated Paragraph Style Name)

This element specifies the style ID for a paragraph style which shall be associated with the current glossary document entry. This paragraph style associated shall not imply anything about the formatting or content of the glossary document entry, and shall only be used to filter and/or sort this entry (via an application or a user interface). [*Note*: One example of the level of classification offered by this element is to only show it as available when the formatting of the paragraph matches the specified style. *end note*]

[*Example*: Consider the following WordprocessingML fragment for the properties of a single glossary document entry:

```
<w:docPartPr>
  <w:style w:val="Heading1" />
  …
<w:docPartPr>
```

The style element with a val attribute value of `Heading1` specifies that the paragraph style associated with the current glossary document entry shall be the style whose style ID is equal to `Heading1`. *end example*]

Parent Elements
docPartPr (§2.12.7)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`

Attributes	Description
	<w:alias w:val="SDT Title Example" /> ... </w:sdtPr> In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.12.15 type (Entry Type)

This element specifies a single type which shall be applied to the properties of the parent glossary document entry (§2.12.5). Each of these types may, based on their values, influence the visibility and behavior of the parent glossary document entry as defined by the associated simple type information.

[*Example*: Consider the following WordprocessingML fragment for the properties of a single glossary document entry:

```
<w:docPartPr>
  <w:types>
    <w:type w:val="bbPlcHdr" />
  </w:types>
  …
<w:docPartPr>
```

The type element with a value of bbPlcHdr specifies that the parent glossary document entry shall be treated as if it was the placeholder text for one or more structured document tags in the document. *end example*]

Parent Elements
types (§2.12.16)

Attributes	Description
val (Type Value)	Specifies the value for the current entry type. [*Example*: Consider the following WordprocessingML fragment for the properties of a single glossary document entry: <w:type w:val="bbPlcHdr" />

Attributes	Description
	The val attribute value of bbPlcHdr specifies that the parent glossary document entry shall be treated as if it was the placeholder text for one or more structured document tags in the document. *end example*] The possible values for this attribute are defined by the ST_DocPartType simple type (§2.18.21).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DocPartType">
   <attribute name="val" use="required" type="ST_DocPartType"/>
</complexType>
```

2.12.16 types (Entry Types)

This element specifies the set of types which shall be applied to the properties of the parent glossary document entry (§2.12.5). Each of these types may, based on their values, influence the visibility and behavior of the parent glossary document entry.

[*Example*: Consider the following WordprocessingML fragment for the properties of a single glossary document entry:

```
<w:docPartPr>
  <w:types>
    …
  </w:types>
  …
<w:docPartPr>
```

The types element specifies the set of entry types which shall be associated with the parent glossary document entry. *end example*]

Parent Elements
docPartPr (§2.12.7)

Child Elements	Subclause
type (Entry Type)	§2.12.15

Attributes	Description
all (Entry Is Of All Types)	Specifies that the current glossary document is all types. This attribute shall override any information specified as child elements of this element and shall ensure that the current entry is associated with all available types.

Attributes	Description

	If this attribute is omitted, then its default value shall be assumed to be `false`.
	
	[*Example*: Consider the following WordprocessingML fragment for the properties of a single glossary document entry:
	
	`<w:docPartPr>`
	`  <w:types w:all="true">`
	`  <w:type w:val="autoExp" />`
	`  </w:types>`
	`  …`
	`<w:docPartPr>`
	
	The types element contains a single entry type definition, but because the all attribute is present with a value of `true`, that type is augmented to place the parent entry into all possible types. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DocPartTypes">
    <choice>
        <element name="type" type="CT_DocPartType" maxOccurs="unbounded"/>
    </choice>
    <attribute name="all" type="ST_OnOff" use="optional"/>
</complexType>
```

2.13 Annotations

Within a WordprocessingML document, *annotations* refer to various types of supplementary markup which may be stored inside or around a region of text within the document's contents. [*Example*: The types of supplementary information stored within a document may include: comments, revisions, spelling and/or grammatical errors, bookmark information and optional editing permissions. *end example*]

Within a document's contents, annotations are stored in one of three different methods:

- Inline
- "Cross Structure"
- Properties

These three forms are needed in order to maintain compatibility with both the legacy annotations functionality of current word processing applications and the requirements of an XML-based format (i.e. wellformedness of the resulting XML markup). These three forms are referenced within the individual annotation types described in the following sub clauses.

2.13.1 Inline Annotations

Inline annotations describe all annotations which do not require special handling in order to maintain the XML wellformedness requirements of the resulting WordprocessingML output. In these cases, a single XML element shall encapsulate the entire contents of the document content which is being annotated.

[*Example*: Consider the following WordprocessingML markup for a paragraph which reads `The quick brown fox jumps over the jet lagged dog.`, where `jet lagged` replaced the previous text `lazy` when the editing application was tracking revisions:

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">The quick brown fox jumps over the </w:t>
  </w:r>
  <w:del … >
    <w:r>
      <w:delText>lazy</w:delText>
    </w:r>
  </w:del>
  <w:ins … >
    <w:r>
      <w:t>jet lagged</w:t>
    </w:r>
  </w:ins>
  <w:r>
    <w:t xml:space="preserve"> dog.</w:t>
  </w:r>
</w:p>
```

The del and ins elements (§2.13.5.12; §2.13.5.20) each fully encapsulate the extent of their respective annotations (a marked deletion and insertion, respectively), as they are inline annotations. *end example*]

2.13.2 "Cross Structure" Annotations

"Cross structure" annotations describe the class of annotations which can span portions of WordprocessingML markup [*Example*: Cross structure annotations may span parts of multiple paragraphs, one half of a custom XML markup element's contents, etc. *end example*]. In these cases, the annotation's region is delimited by two elements: a start element and an end element. These two elements mark the start and end points of the annotated content, but do not contain it. The pairing of the start and end marker are linked via a common value for their id attributes.

[*Example*: Consider the following WordprocessingML markup for two paragraphs, each reading `Example Text`, where a bookmark has been added spanning the second word in paragraph one and the first word in paragraph two:

```
<w:p>
  <w:r>
    <w:t>Example</w:t>
  </w:r>
  <w:bookmarkStart w:id="0" w:name="sampleBookmark" />
  <w:r>
    <w:t xml:space="preserve"> text.</w:t>
  </w:r>
</w:p>
<w:p>
  <w:r>
    <w:t>Example</w:t>
  </w:r>
  <w:bookmarkEnd w:id="0" />
  <w:r>
    <w:t xml:space="preserve"> text.</w:t>
  </w:r>
</w:p>
```

The bookmarkStart and bookmarkEnd elements (§2.13.6.2; §2.13.6.1) specify the location where the bookmark starts and ends, but cannot contain it because it spans part of two paragraphs. They are part of one group because the id attribute value specifies `0` for both. *end example*]

2.13.3 Property Annotations

Property annotations describe the class of annotations which are stored as a property on an object [*Example*: Property annotations may appear on paragraph properties, run properties, table rows, etc. *end example*] In these cases, the annotation's semantics are defined by the property, as they can affect content and/or formatting.

[*Example*: Consider the following WordprocessingML markup for a paragraph reading `Example Text`, where the first word had the bold property applied when the editing application was tracking revisions:

```
<w:p>
  <w:r>
    <w:rPr>
      <w:b/>
      <w:rPrChange … >
        <w:rPr/>
      </w:rPrChange>
    </w:rPr>
    <w:t>Example</w:t>
  </w:r>
  <w:r>
    <w:t xml:space="preserve"> text.</w:t>
  </w:r>
</w:p>
```

The rPrChange element (§2.13.5.32; §2.13.5.33) contains the set of previously applied revision properties associated with a particular author at a particular time. It is stored itself as a property on the parent run which was modified. *end example*]

2.13.4 Comments

Comments describe annotations which are anchored to a region of document content, but which contain an arbitrary amount of block-level content stored in their own separate document stories. Within a WordprocessingML document, comments are stored in a separate Comments part within the document package.

A comment in a WordprocessingML document is divided into two components:

- The comment anchor (the text on which the comment applies)
- The comment content (the contents of the comment)

The *comment anchor* is the cross structure annotation which defines the region of text on which the comment in anchored. The *comment content* is the content stored in the comments part which contains the actual content of the comment.

[*Example*: Consider a paragraph in a WordprocessingML document whose second word is annotated with a comment:

The first component to this comment is the document content which defines the extents of the comment and references the specific comment in the comments part:

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">Some </w:t>
  </w:r>
  <w:commentRangeStart w:id="0" />
  <w:r>
    <w:t>text.</w:t>
  </w:r>
  <w:commentRangeEnd w:id="0" />
  <w:r>
    <w:commentReference w:id="0" />
  </w:r>
</w:p>
```

The commentRangeStart and commentRangeEnd elements (§2.13.4.4; §2.13.4.3) delimit the run content to which the comment with an id of `0` applies (in this case, the single run of text). The following commentReference element (§2.13.4.5) links the preceding run content with a comment in the comments part with an id of `0`. Without all three of these elements, the range and comment cannot be linked (although the first two elements are optional, in which case the comment shall be anchored at the comment reference mark)

The second component to this comment is the comment content which defines the text in the comment:

```
<w:comment w:id="0" w:author="Joe Smith" w:date="2006-04-06T13:50:00Z"
w:initials="User">
  <w:p>
    <w:pPr>
      <w:pStyle w:val="CommentText" />
    </w:pPr>
    <w:r>
      <w:rPr>
        <w:rStyle w:val="CommentReference" />
      </w:rPr>
      <w:annotationRef />
    </w:r>
    <w:r>
      <w:t>comment</w:t>
    </w:r>
  </w:p>
</w:comment>
```

In this example, the comment specifies that it was inserted by author `Joe Smith` with the initials `User` via the author and date attributes. It is linked to the run content via the id attribute, which matches the value of `0` specified using the commentReference element above. The block-level content of the comment specifies that

its text is `comment` and the style of the comment content is based off of the character style with the name `CommentReference`. *end example*]

2.13.4.1 annotationRef (Comment Information Block)

This element specifies the presence of an annotation reference mark at the current location in the comment. An *annotation reference mark* is an information block that represents the metadata about the current comment within the document. This annotation reference mark should typically consist of the initials and a unique integer associated with its position in the document, but may be displayed in any desired format.

If this element is omitted from a single comment's contents, then an annotation reference mark may be added at the start of the comment in reading order (right in a right-to-left paragraph or left in a left-to-right paragraph). As well, an annotation reference mark may be relocated as desired within a comment's content.

[*Example*: Consider a document with text with an annotated comment as follows:

This comment is represented as the following WordprocessingML fragment:

```
<w:comment … w:initials="User">
  <w:p>
    <w:r>
      <w:annotationRef />
    </w:r>
    …
  </w:p>
</w:comment>
```

The annotationRef element specifies that the comment shall start with an annotation reference mark. In this example, this mark is displayed as a combination of the user initial, `User`, and a unique sequential number, `1`. *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.13.4.2 comment (Comment Content)

This element specifies the content of a single comment stored in the Comments part of a WordprocessingML document.

If a comment is not referenced by document content via a matching id attribute on a valid use of the commentReference element (§2.13.4.5), then it may be ignored when loading the document. If more than one comment shares the same value for the id attribute, then only one comment shall be loaded and the others may be ignored.

[*Example*: Consider a document with text with an annotated comment as follows:

This comment is represented as the following WordprocessingML fragment:

```
<w:comment w:id="1" w:initials="User">
  …
</w:comment>
```

The comment element specifies the presence of a single comment within the comments part. *end example*]

Parent Elements
comments (§2.13.4.6)

Child Elements	Subclause
altChunk (Anchor for Imported External Content)	§2.17.3.1

tbl (Table)	§2.4.36

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`…`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard. If this attribute is omitted, then no date information shall be associated with the parent annotation type. [*Example*: Consider a comment represented using the following WordprocessingML fragment:

Attributes	Description
	<w:… w:id="1" w:date="2006-01-01T10:00:00"> … </w:…> The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*] The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).
id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element. If this attribute is omitted, then the document is non-conformant. [*Example*: Consider an annotation represented using the following WordprocessingML fragment: <w:… w:id="1" … > … </w:…> The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
initials (Initials of Comment Author)	Specifies the initials of the author of the current comment. This information may be used to format and present the associated comment information block (§2.13.4.1), or in any user interface supported by an application. If this attribute is omitted, then no author shall be associated with the current comment in the document. [*Example*: Consider a comment represented using the following WordprocessingML fragment: <w:comment w:id="1" w:initials="KB"> … </w:comment> The intials attribute specifies that the initials of the author of the current comment are KB, which may be used as desired. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Comment">
    <complexContent>
        <extension base="CT_TrackChange">
            <sequence>
                <group ref="EG_BlockLevelElts" minOccurs="0" maxOccurs="unbounded"/>
            </sequence>
            <attribute name="initials" type="ST_String" use="optional"/>
        </extension>
    </complexContent>
</complexType>
```

2.13.4.3 commentRangeEnd (Comment Anchor Range End)

This element specifies the end of the range around which a comment is anchored in the content of the WordprocessingML document. The id attribute on this element shall be used to link the corresponding comment anchor range start element and comment reference.

The following restrictions shall be applied to this element:

- If this element occurs without a corresponding commentRangeStart element (§2.13.4.4) with a matching id attribute value, then it shall be considered the single anchor point for the associated comment reference.
- If this element appears without a corresponding commentReference element (§2.13.4.5) in the current document story with a matching id attribute value, then it shall be ignored and the comment has no associated range.
- If this element appears in a comment content story (§2.13.4.2), then it may be ignored.

[*Example*: Consider a paragraph in a WordprocessingML document whose second word is annotated with a comment:

The WordprocessingML fragment for this comment is defined as follows:

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">Some </w:t>
  </w:r>
  <w:commentRangeStart w:id="0" />
  <w:r>
    <w:t>text.</w:t>
  </w:r>
  <w:commentRangeEnd w:id="0" />
  <w:r>
    <w:commentReference w:id="0" />
  </w:r>
</w:p>
```

The commentRangeEnd element specifies that the end of the comment range for the comment with an id of `0` is after the end of the run containing the word `text`. *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32); endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32); sdtContent (§2.5.2.33); sdtContent (§2.5.2.34); sdtContent (§2.5.2.35); smartTag (§2.5.1.9); sub (§7.1.2.112); sup (§7.1.2.114); tbl (§2.4.36); tc (§2.4.62); tr (§2.4.75); txbxContent (§2.17.1.1)

Attributes	Description
displacedByCustomXml (Annotation Marker Relocated For Custom XML Markup)	Specifies that the parent annotation's placement shall be directly linked with the location of the physical presentation of a custom XML element in the document. This element only has an effect when the custom XML element is block-level (i.e. surrounds an entire paragraph), as in this scenario the logical and physical placement of the annotation and custom XML element may differ. Specifically, in this case, the custom XML is presented *around* the block-level object it encloses (the paragraph, table, table row, or table cell), but is physically represented within that same object (i.e. within the paragraph, table, table row or table cell). This requirement stems from the fact that there is no location for the location of the annotation within the document at its logical location (around a table, for example). If this element is omitted, then the annotation shall be anchored inside of all block-level custom XML elements in the paragraph. If this element is present, but no block-level custom XML tag is located at the position it specifies (before or after), then it shall be ignored.

Attributes	Description

	[*Example*: Consider a paragraph with block level custom XML markup and two comment anchor annotations (one before and one after the custom XML element's physical representation), as follows:
	
	 	
	Since all three of these items are around the entire paragraph, they are stored outside of the paragraph. However, in order to ensure that their relative positions are stored correctly, any annotation which shall be displaced by the physical custom XML element specifies this information, resulting in the following WordprocessingML:
	
	`<w:commentRangeStart w:id="0" />`
	`<w:commentRangeStart w:id="1" w:displaced byCustomXml="next" />`
	`<w:customXml w:element="spec" … />`
	`<w:p>`
	`…`
	`</w:p>`
	
	The displacedByCustomXml attribute specifies that even though all three of these items are around the paragraph and will be moved inside the paragraph to be represented physically, the comment with ID 0 shall be inside the custom XML, but the comment with ID 1 shall be displaced to stay outside of the relative location of the next custom XML element (the spec element). *end example*]
	
	The possible values for this attribute are defined by the ST_DisplacedByCustomXml simple type (§2.18.17).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_MarkupRange">
   <complexContent>
      <extension base="CT_Markup">
         <attribute name="displacedByCustomXml" type="ST_DisplacedByCustomXml" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.4.4 commentRangeStart (Comment Anchor Range Start)

This element specifies the start of the range around which a comment is anchored in the content of the WordprocessingML document. The id attribute on this element shall be used to link the corresponding comment anchor range end element and comment reference.

The following restrictions shall be applied to this element:

- If this element occurs without a corresponding commentRangeEnd element (§2.13.4.3) with a matching id attribute value, then it shall be considered the single anchor point for the associated comment reference.
- If this element appears without a corresponding commentReference element (§2.13.4.5) in the current document story with a matching id attribute value, then it shall be ignored and the comment content has no associated range.
- If this element appears in a comment content story (§2.13.4.2), then it may be ignored.

[*Example*: Consider a paragraph in a WordprocessingML document whose second word is annotated with a comment:

The WordprocessingML fragment for this comment is defined as follows:

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">Some </w:t>
  </w:r>
  <w:commentRangeStart w:id="0" />
  <w:r>
    <w:t>text.</w:t>
  </w:r>
  <w:commentRangeEnd w:id="0" />
  <w:r>
    <w:commentReference w:id="0" />
  </w:r>
</w:p>
```

The commentRangeStart element specifies that the start of the comment range for the comment with an id of `0` is after the end of the run containing the word `Some`. *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32); endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32); sdtContent (§2.5.2.33); sdtContent (§2.5.2.34); sdtContent (§2.5.2.35); smartTag (§2.5.1.9); sub (§7.1.2.112); sup (§7.1.2.114); tbl (§2.4.36); tc (§2.4.62); tr (§2.4.75); txbxContent (§2.17.1.1)

Attributes	Description

displacedByCustomXml (Annotation Marker Relocated For Custom XML Markup)	Specifies that the parent annotation's placement shall be directly linked with the location of the physical presentation of a custom XML element in the document. This element only has an effect when the custom XML element is block-level (i.e. surrounds an entire paragraph), as in this scenario the logical and physical placement of the annotation and custom XML element may differ.
	
	Specifically, in this case, the custom XML is presented *around* the block-level object it encloses (the paragraph, table, table row, or table cell), but is physically represented within that same object (i.e. within the paragraph, table, table row or table cell). This requirement stems from the fact that there is no location for the location of the annotation within the document at its logical location (around a table, for example).
	
	If this element is omitted, then the annotation shall be anchored inside of all block-level custom XML elements in the paragraph. If this element is present, but no block-level custom XML tag is located at the position it specifies (before or after), then it shall be ignored.
	
	[*Example*: Consider a paragraph with block level custom XML markup and two comment anchor annotations (one before and one after the custom XML element's physical representation), as follows:
	
	 	
	Since all three of these items are around the entire paragraph, they are stored outside of the paragraph. However, in order to ensure that their relative positions are stored correctly, any annotation which shall be displaced by the physical custom XML element specifies this information, resulting in the following WordprocessingML:
	
	`<w:commentRangeStart w:id="0" />`
	`<w:commentRangeStart w:id="1" w:displaced byCustomXml="next" />`

Attributes	Description
	<w:customXml w:element="spec" … /> <w:p> … </w:p> The displacedByCustomXml attribute specifies that even though all three of these items are around the paragraph and will be moved inside the paragraph to be represented physically, the comment with ID 0 shall be inside the custom XML, but the comment with ID 1 shall be displaced to stay outside of the relative location of the next custom XML element (the spec element). *end example*] The possible values for this attribute are defined by the ST_DisplacedByCustomXml simple type (§2.18.17).
id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element. If this attribute is omitted, then the document is non-conformant. [*Example*: Consider an annotation represented using the following WordprocessingML fragment: <w:… w:id="1" … > … </w:…> The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_MarkupRange">
   <complexContent>
      <extension base="CT_Markup">
         <attribute name="displacedByCustomXml" type="ST_DisplacedByCustomXml" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.4.5 commentReference (Comment Content Reference Mark)

This element specifies the presence of a comment content reference mark, which links the comment content (§2.13.4.2) with the contents of a document story. This link is established by matching the comment whose id attribute matches the id attribute on this element. The resulting comment is anchored to the range with comment range elements with the same id attribute values (if present) as follows:

- If either or both of the commentRangeStart and commentRangeEnd elements (§2.13.4.4; §2.13.4.3) are present, then the comment reference shall anchor the comment to the resulting range.
- If neither element is present, then the comment reference shall anchor the comment to its current location.

If this element appears in a comment content story (§2.13.4.2), then it may be ignored. If no comment exists with an id attribute which matches the id attribute on this element, then this document is non-conformant.

[*Example*: Consider a paragraph in a WordprocessingML document whose second word is annotated with a comment:

The WordprocessingML fragment for this comment is defined as follows:

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">Some </w:t>
  </w:r>
  <w:commentRangeStart w:id="0" />
  <w:r>
    <w:t>text.</w:t>
  </w:r>
  <w:commentRangeEnd w:id="0" />
  <w:r>
    <w:commentReference w:id="0" />
  </w:r>
</w:p>
```

The commentReference element specifies that the associated comment in the comments part shall be the comment whose id attribute value is 0. As well, since a start and end marker exist with a matching ID, this comment is anchored to that region of the document. *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

Attributes	Description
id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element. If this attribute is omitted, then the document is non-conformant.

Attributes	Description

	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Markup">
   <attribute name="id" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.13.4.6 comments (Comments Collection)

This element specifies all of the comments defined in the current document. It is the root element of the Comments part of a WordprocessingML document.

[*Example*: Consider the following WordprocessingML fragment for the content of a comments part in a WordprocessingML document:

```
<w:comments>
  <w:comment … >
    …
  </w:comment>
</w:comments>
```

The comments element contains the single comment specified by this document in this example. *end example*]

Parent Elements
Root element of WordprocessingML Comments part

Child Elements	Subclause
comment (Comment Content)	§2.13.4.2

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Comments">
   <sequence>
      <element name="comment" type="CT_Comment" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
</complexType>
```

2.13.5 Revisions

Revisions in WordprocessingML provide a mechanism for storing information about the evolution of the document (i.e. the set of modifications made to a document by one of more authors). When an application adds revisions to the content of a WordprocessingML document, they are specifying this by storing either (depending on the revision type):

- The current state of the document (a deletion stores the current state of the text as deleted, and implies that its original state was the content used to exist)
- The initial state of the document (a run's initial properties are explicitly stored in a previous run properties block, as the current run properties are always those that are the child of the rPr element (§2.7.8.1))

A revision consists of two required pieces of information:

- The revision type (specified via the name of the revision element)
- A unique revision identifier (used to uniquely identify revisions)

As well as optional information:

- The author of the revision
- The date and time of the revision

[*Example*: Consider a paragraph of text in a WordprocessingML document in which one word has been inserted, as follows:

Some text

This paragraph has the word `text` marked inserted as a revision, and is represented as the following WordprocessingML:

```
<w:p>
  <w:r>
    <w:t>Some</w:t>
  </w:r>
  <w:ins w:id="0" w:author="Joe Smith" w:date="2006-03-31T12:50:00Z">
    <w:r>
      <w:t>text</w:t>
    </w:r>
```

```
    </w:ins>
  </w:p>
```

The ins element contains both the required information: all of the content which shall be treated as revision marked as inserted (the word `text`); a unique revision identifier of `0`.

The element also stores the optional information about the revision: the word `text` was inserted by `Joe Smith` on March 31, 2006 at 12:50pm. *end example*]

Within a WordprocessingML document, the following types of revisions may be used to track the changes to a document:

- Insertions
- Deletions
- Moves
- Changes to run/paragraph/table/numbering/section properties
- Changes to custom XML markup

2.13.5.1 cellDel (Table Cell Deletion)

This element specifies that the parent table cell shall be treated as though it was deleted from the document while revisions were being recorded. This means that although the table cell element exists in the structure of the table, the table cell technically no longer exists in the document.

[*Example*: Consider a document with a two row by two columns table as follows:

One	Two
Three	Four

If this table has each cell in its final column deleted and this is tracked as a revision, the resulting WordprocessingML would show each of these cells as deleted as follows:

```
<w:tbl>
  …
  <w:tr>
    <w:tc>
      <w:r>
        <w:t>One</w:t>
      </w:r>
    </w:tc>
    <w:tc>
      <w:tcPr>
        <w:cellDel w:id="0" … />
      </w:tcPr>
      <w:r>
        <w:t>Two</w:t>
      </w:r>
    </w:tc>
  </w:tr>
  <w:tr>
    <w:tc>
      <w:r>
        <w:t>Three</w:t>
      </w:r>
    </w:tc>
    <w:tc>
      <w:tcPr>
        <w:cellDel w:id="1" … />
      </w:tcPr>
      <w:r>
        <w:t>Four</w:t>
      </w:r>
    </w:tc>
  </w:tr>
</w:tbl>
```

The cellDel elements in the table cell properties of the cells with text Two and Four specify that each of those cells have been deleted from the document. Their attributes (omitted) may optionally provide information about the time at which this deletion took place. *end example*]

Parent Elements
tcPr (§2.7.5.8); tcPr (§2.4.66); tcPr (§2.7.5.9); tcPr (§2.4.67)

Attributes	Description

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`  …`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`  …`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`  …`
	`</w:…>`

Attributes	Description
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrackChange">
   <complexContent>
      <extension base="CT_Markup">
         <attribute name="author" type="ST_String" use="required"/>
         <attribute name="date" type="ST_DateTime" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.2 cellIns (Table Cell Insertion)

This element specifies that the parent table cell shall be treated as though it was inserted into the document while revisions were being recorded.

[*Example*: Consider a document with a two row by two columns table as follows:

One	Two
Three	Four

If this table has two cells added by appending an additional column, and this is tracked as a revision, the resulting WordprocessingML would show each of these cells as inserted as follows:

```
<w:tbl>
  …
  <w:tr>
    <w:tc>
      <w:r>
        <w:t>One</w:t>
      </w:r>
    </w:tc>
    <w:tc>
      <w:r>
        <w:t>Two</w:t>
      </w:r>
    </w:tc>
    <w:tc>
      <w:tcPr>
        <w:cellIns w:id="0" … />
      </w:tcPr>
      <w:r>
        <w:t>New</w:t>
      </w:r>
    </w:tc>
  </w:tr>
  <w:tr>
    <w:tc>
      <w:r>
        <w:t>Three</w:t>
      </w:r>
    </w:tc>
    <w:tc>
      <w:r>
        <w:t>Four</w:t>
      </w:r>
    </w:tc>
    <w:tc>
      <w:tcPr>
        <w:cellIns w:id="1" … />
      </w:tcPr>
      <w:r>
        <w:t>New</w:t>
      </w:r>
    </w:tc>
  </w:tr>
</w:tbl>
```

The cellIns elements in the table cell properties of the cells with text New specify that each of those cells have been inserted into the document. Their attributes (omitted) may optionally provide information about the insertion of these cells (author, date, etc.). *end example*]

Parent Elements
tcPr (§2.7.5.8); tcPr (§2.4.66); tcPr (§2.7.5.9); tcPr (§2.4.67)

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`…`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`…`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation	Specifies a unique identifier for an annotation within a WordprocessingML document.

Attributes	Description

Identifier)	The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrackChange">
   <complexContent>
      <extension base="CT_Markup">
         <attribute name="author" type="ST_String" use="required"/>
         <attribute name="date" type="ST_DateTime" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.3 cellMerge (Vertically Merged/Split Table Cells)

This element specifies that the vertical merge state of the parent table cell has been modified while revisions were being tracked for the document. The vmerge and vmergeOrig attributes on this element specify the original and revised vertical merge states of the table cell.

[*Example*: Consider a document with a two row by two columns table as follows:

One	Two
Three	Four

If this table has the two cells in the second column merged into one and this modification is tracked as a revision, as follows:

One	Two
Three	Four

The resulting WordprocessingML for the revision would appear as follows:

```
<w:tbl>
  …
  <w:tr>
    <w:tc>
      <w:r>
        <w:t>One</w:t>
      </w:r>
    </w:tc>
    <w:tc>
      <w:r>
        <w:t>Two</w:t>
      </w:r>
    </w:tc>
  </w:tr>
  <w:tr>
    <w:tc>
      <w:r>
        <w:t>Three</w:t>
      </w:r>
    </w:tc>
    <w:tc>
      <w:tcPr>
        <w:cellMerge w:id="0" w:vmerge="cont"/>
      </w:tcPr>
      <w:r>
        <w:t>Four</w:t>
      </w:r>
    </w:tc>
  </w:tr>
</w:tbl>
```

The cellMerge element specifies that changes were made to the vertical merge settings of the last cell in the table, specifically; the cell was vertically merged with the cell above it (gaining a revised vmerge attribute value of cont). *end example*]

Parent Elements
tcPr (§2.7.5.8); tcPr (§2.4.66); tcPr (§2.7.5.9); tcPr (§2.4.67)

Attributes	Description
author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document. If this attribute is omitted, then no author shall be associated with the parent annotation

Attributes	Description

	type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`  …`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`  …`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`  …`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

vMerge (Revised Vertical Merge Setting)	Specifies the vertical merge setting which was applied to the parent table cell by this revision.
	
	If this attribute is omitted, then no revised vertical merge setting is supplied for this revision (if neither this nor the vmergeOrig attribute is specified, the revision may be ignored).
	
	[*Example*: Consider a two row by two column table in which the cells in the second column are merged, and this change is tracked as a revision. The annotation on the last cell in the table would appear as follows:
	
	`<w:tc>`
	`  <w:tcPr>`
	`  <w:cellMerge … w:vmerge="cont" />`
	`  </w:tcPr>`
	`  …`
	`</w:tc>`
	
	The vmerge attribute value of `cont` specifies that the revision on the table cell resulted in it being merged with the previous set of vertically merged cells above it (whether that was one cell or many). *end example*]
	
	The possible values for this attribute are defined by the ST_AnnotationVMerge simple type (§2.18.3).

vMergeOrig (Vertical Merge Setting Removed by Revision)	Specifies the vertical merge setting which was removed from the parent table cell by this revision.
	
	If this attribute is omitted, then the original vertical merge setting shall be assumed to be `rest` (not merged).
	
	[*Example*: Consider a two row by two column table in which the merged cells in the second column are split, and this change is tracked as a revision. The annotation on the last cell in the table would appear as follows:
	
	`<w:tc>`
	`  <w:tcPr>`
	`  <w:cellMerge … w:vmergeOrig="cont" />`
	`  </w:tcPr>`
	`  …`
	`</w:tc>`
	
	The vmergeOrig attribute value of `cont` specifies that the revision on the table cell resulted in it having its vertical merge property removed. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_AnnotationVMerge simple type (§2.18.3).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_CellMergeTrackChange">
   <complexContent>
      <extension base="CT_TrackChange">
         <attribute name="vMerge" type="ST_AnnotationVMerge" use="optional"/>
         <attribute name="vMergeOrig" type="ST_AnnotationVMerge" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.4 customXmlDelRangeEnd (Custom XML Markup Deletion End)

This element specifies the end of a region in which custom XML markup has been deleted and tracked as a revision. The id attribute on this element shall be used to link this element with the corresponding custom XML markup deletion start marker in the document.

Providing a physical representation of custom XML markup results in regions which can be inserted and deleted, but cannot be encapsulated by a single revision element, since their representation in WordprocessingML is the start or end XML tag for the custom XML markup which it represents. Therefore, the start/end "cross structure" annotation format surrounds the WordprocessingML region to which this deletion applies.

The following restrictions shall be applied to this element:

- If this element occurs without a corresponding customXmlDelRangeStart element (§2.13.5.5) with a matching id attribute value, then it shall be ignored and no deletions shall be present in the document.
- If this element and its paired start encapsulate a range with no custom XML markup, then they shall be ignored and may be omitted when the document is subsequently saved.
- If multiple end elements exist with the same id attribute value, then the first instance in the document shall be used and subsequent elements should be treated as unmatched (no corresponding start).

[*Example*: Consider a document with two inline custom XML markup elements, as follows:

```
<w:p>
  <w:customXml … >
    <w:customXml … >
      <w:r>
        <w:t>Text.</w:t>
      </w:r>
    </w:customXml>
  </w:customXml>
  <w:r>
    <w:t>More text.</w:t>
  </w:r>
</w:p>
```

Now, if each custom XML markup element's start and end tag have a physical representation, imagine that the region from the start of the paragraph until the point between the two end points is deleted with revisions enabled. This revision cannot be encapsulated by one del element, since it starts outside of the first custom XML markup element and ends just inside of it, so it must be done using the custom XML markup revision "cross structure" syntax, as follows:

```
<w:p>
  <w:customXmlDelRangeStart w:id="0" />
  <w:customXml … >
    <w:customXml … >
      <w:del … >
        <w:r>
          <w:delText>Text.</w:delText>
        </w:r>
      </w:del>
    </w:customXml>
    <w:customXmlDelRangeEnd w:id="0" />
  </w:customXml>
  <w:r>
    <w:t>More text.</w:t>
  </w:r>
</w:p>
```

The customXmlDelRangeEnd element delimits the end of the region in which all custom XML elements have been deleted with revisions enabled, and the del element (§2.13.5.12) handles the deletion of the text performed by this revision. Since the end of the outer customXml element was not in the deleted range, it is not revision marked deleted, but the corresponding physical character for the start element is. *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32);

Parent Elements
endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32); sdtContent (§2.5.2.33); sdtContent (§2.5.2.34); sdtContent (§2.5.2.35); smartTag (§2.5.1.9); sub (§7.1.2.112); sup (§7.1.2.114); tbl (§2.4.36); tc (§2.4.62); tr (§2.4.75); txbxContent (§2.17.1.1)

Attributes	Description

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Markup">
   <attribute name="id" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.13.5.5 customXmlDelRangeStart (Custom XML Markup Deletion Start)

This element specifies the beginning of a region in which all custom XML markup has been deleted and tracked as a revision. The id attribute on this element shall be used to link this element with the corresponding custom XML markup deletion end marker in the document.

Providing a physical representation of custom XML markup results in regions which can be inserted and deleted, but cannot be encapsulated by a single revision element, since their representation in WordprocessingML is the start or end XML tag for the custom XML markup which it represents. Therefore, the start/end "cross structure" annotation format surrounds the WordprocessingML region to which this deletion applies.

The following restrictions shall be applied to this element:

- If this element occurs without a corresponding customXmlDelRangeEnd element (§2.13.5.4) with a matching id attribute value, then this revision is ill-formed, and the revision may be ignored or all custom XML from this point forward may be treated as deleted.
- If this element and its paired end encapsulate a range with no custom XML markup, then they shall be ignored and may be omitted when the document is subsequently saved.
- If multiple start elements exist with the same id attribute value, then the each instance in the document shall be matched with an end in document order, and unmatched starts (no corresponding end) shall be handled as described above.

[*Example*: Consider a document with two inline custom XML markup elements, as follows:

```
<w:p>
  <w:customXml … >
    <w:customXml … >
      <w:r>
        <w:t>Text.</w:t>
      </w:r>
    </w:customXml>
  </w:customXml>
  <w:r>
    <w:t>More text.</w:t>
  </w:r>
</w:p>
```

Now, if each custom XML markup element's start and end tag have a physical representation, imagine that the region from the start of the paragraph until the point between the two end points is deleted with revisions enabled. This revision cannot be encapsulated by one del element, since it starts outside of the first custom XML markup element and ends just inside of it, so it must be done using the custom XML markup revision "cross structure" syntax, as follows:

```
<w:p>
```

```
<w:customXmlDelRangeStart w:id="0" />
<w:customXml … >
  <w:customXml … >
    <w:del … >
      <w:r>
        <w:delText>Text.</w:delText>
      </w:r>
    </w:del>
  </w:customXml>
  <w:customXmlDelRangeEnd w:id="0" />
</w:customXml>
<w:r>
  <w:t>More text.</w:t>
</w:r>
</w:p>
```

The customXmlDelRangeStart element delimits the start of the region in which all custom XML elements have been deleted with revisions enabled, and the del element (§2.13.5.12) handles the deletion of the text performed by this revision. Since the end of the outer customXml element was not in the deleted range, it is not revision marked deleted, but the corresponding physical character for the start element is. *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32); endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32); sdtContent (§2.5.2.33); sdtContent (§2.5.2.34); sdtContent (§2.5.2.35); smartTag (§2.5.1.9); sub (§7.1.2.112); sup (§7.1.2.114); tbl (§2.4.36); tc (§2.4.62); tr (§2.4.75); txbxContent (§2.17.1.1)

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`…`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example`

Attributes	Description
	Author, which may be used as desired. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`…`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrackChange">
   <complexContent>
      <extension base="CT_Markup">
         <attribute name="author" type="ST_String" use="required"/>
         <attribute name="date" type="ST_DateTime" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.6 customXmlInsRangeEnd (Custom XML Markup Insertion End)

This element specifies the end of a region within which all custom XML markup has been inserted and tracked as a revision. The id attribute on this element shall be used to link this element with the corresponding custom XML markup insertion start marker in the document.

Providing a physical representation of the start and end tags of custom XML markup results in regions which can be inserted and deleted independently, but cannot be encapsulated by a single revision element, since their representation in WordprocessingML is the start or end XML tag for the custom XML markup which it represents. Therefore, the start/end "cross structure" annotation format surrounds the WordprocessingML region to which this insertion applies.

The following restrictions shall be applied to this element:

- If this element occurs without a corresponding customXmlInsRangeStart element (§2.13.5.7) with a matching id attribute value, then it shall be ignored and no insertions shall be present in the document.
- If this element and its paired start encapsulate a range with no custom XML markup, then they shall be ignored and may be omitted when the document is subsequently saved.
- If multiple end elements exist with the same id attribute value, then the first instance in the document shall be used and subsequent elements should be treated as unmatched (no corresponding start).

[*Example*: Consider a document with two inline custom XML markup elements, as follows:

```
<w:p>
  <w:customXml … >
    <w:customXml … >
      <w:r>
        <w:t>Text.</w:t>
      </w:r>
    </w:customXml>
  </w:customXml>
  <w:r>
    <w:t>More text.</w:t>
  </w:r>
</w:p>
```

If each custom XML markup element's start and end tag have a physical representation, consider that the inner XML element (but not its content) is inserted with revisions enabled. This revision cannot be encapsulated by one ins element, since the text in the element is not an insertion, so it must be done using the custom XML markup revision "cross structure" syntax, as follows:

```
<w:p>
  <w:customXml … >
    <w:customXmlInsRangeStart w:id="0" />
    <w:customXml … >
      <w:r>
        <w:t>Text.</w:t>
      </w:r>
    </w:customXml>
    <w:customXmlInsRangeEnd w:id="0" />
  </w:customXml>
  <w:r>
    <w:t>More text.</w:t>
  </w:r>
</w:p>
```

The customXmlInsRangeEnd element delimits the end of the region in which all custom XML elements have been inserted with revisions enabled. Since this element only affects custom XML, the text is not revision marked inserted, but the corresponding physical characters for the custom XML element are. *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32); endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32); sdtContent (§2.5.2.33); sdtContent (§2.5.2.34); sdtContent (§2.5.2.35); smartTag (§2.5.1.9); sub (§7.1.2.112); sup (§7.1.2.114); tbl (§2.4.36); tc (§2.4.62); tr (§2.4.75); txbxContent (§2.17.1.1)

Attributes	Description

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`

Attributes	Description
	</w:…> The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Markup">
   <attribute name="id" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.13.5.7 customXmlInsRangeStart (Custom XML Markup Insertion Start)

This element specifies the beginning of a region in which all custom XML markup has been inserted and tracked as a revision. The id attribute on this element shall be used to link this element with the corresponding custom XML markup insertion end marker in the document.

Providing a physical representation of custom XML markup start and end tags results in regions which can be inserted and deleted independently, but cannot be encapsulated by a single revision element, since their representation in WordprocessingML is the start or end XML tag for the custom XML markup which it represents. Therefore, the start/end "cross structure" annotation format surrounds the WordprocessingML region to which this deletion applies.

The following restrictions shall be applied to this element:

- If this element occurs without a corresponding customXmlInsRangeEnd element (§2.13.5.6) with a matching id attribute value, then this revision is ill-formed, and the revision may be ignored or all custom XML from this point forward may be treated as inserted.
- If this element and its paired end encapsulate a range with no custom XML markup, then they shall be ignored and may be omitted when the document is subsequently saved.
- If multiple start elements exist with the same id attribute value, then the each instance in the document shall be matched with an end in document order, and unmatched starts (no corresponding end) shall be handled as described above.

This element specifies the end of a region within which all custom XML markup has been inserted and tracked as a revision. The id attribute on this element shall be used to link this element with the corresponding custom XML markup insertion start marker in the document.

Providing a physical representation of the start and end tags of custom XML markup results in regions which can be inserted and deleted independently, but cannot be encapsulated by a single revision element, since their representation in WordprocessingML is the start or end XML tag for the custom XML markup which it

represents. Therefore, the start/end "cross structure" annotation format surrounds the WordprocessingML region to which this insertion applies.

The following restrictions shall be applied to this element:

- If this element occurs without a corresponding customXmlInsRangeStart element (§2.13.5.7) with a matching id attribute value, then it shall be ignored and no insertions shall be present in the document.
- If this element and its paired start encapsulate a range with no custom XML markup, then they shall be ignored and may be omitted when the document is subsequently saved.
- If multiple end elements exist with the same id attribute value, then the first instance in the document shall be used and subsequent elements should be treated as unmatched (no corresponding start).

[*Example*: Consider a document with two inline custom XML markup elements, as follows:

```
<w:p>
  <w:customXml … >
    <w:customXml … >
      <w:r>
        <w:t>Text.</w:t>
      </w:r>
    </w:customXml>
  </w:customXml>
  <w:r>
    <w:t>More text.</w:t>
  </w:r>
</w:p>
```

If each custom XML markup element's start and end tag have a physical representation, consider that the inner XML element (but not its content) is inserted with revisions enabled. This revision cannot be encapsulated by one ins element, since the text in the element is not an insertion, so it must be done using the custom XML markup revision "cross structure" syntax, as follows:

```
<w:p>
  <w:customXml … >
    <w:customXmlInsRangeStart w:id="0" />
    <w:customXml … >
      <w:r>
        <w:t>Text.</w:t>
      </w:r>
    </w:customXml>
    <w:customXmlInsRangeEnd w:id="0" />
  </w:customXml>
  <w:r>
    <w:t>More text.</w:t>
  </w:r>
</w:p>
```

The customXmlInsRangeStart element delimits the start of the region in which all custom XML elements have been inserted with revisions enabled. Since this element only affects custom XML, the text is not revision marked inserted, but the corresponding physical characters for the custom XML element are. *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32); endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32); sdtContent (§2.5.2.33); sdtContent (§2.5.2.34); sdtContent (§2.5.2.35); smartTag (§2.5.1.9); sub (§7.1.2.112); sup (§7.1.2.114); tbl (§2.4.36); tc (§2.4.62); tr (§2.4.75); txbxContent (§2.17.1.1)

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`  …`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`…`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrackChange">
   <complexContent>
      <extension base="CT_Markup">
         <attribute name="author" type="ST_String" use="required"/>
         <attribute name="date" type="ST_DateTime" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.8 customXmlMoveFromRangeEnd (Custom XML Markup Move Source End)

This element specifies the end of a region within which all custom XML markup was moved to another location in the document and this move was tracked as a revision. The id attribute on this element shall be used to link this element with the corresponding custom XML move source start marker in the document.

Providing a physical representation of the start and end tags of custom XML markup results in regions which can be inserted and deleted independently, but cannot be encapsulated by a single revision element, since their representation in WordprocessingML is the start or end XML tag for the custom XML markup which it represents. Therefore, the start/end "cross structure" annotation format surrounds the WordprocessingML region to which this move source applies.

The following restrictions shall be applied to this element:

- If this element occurs without a corresponding customXmlMoveFromRangeStart element (§2.13.5.9) with a matching id attribute value, then it shall be ignored and no move source information shall be applied to the custom XML elements by this element.
- If this element and its paired start encapsulate a range with no custom XML markup, then they shall be ignored and may be omitted when the document is subsequently saved.
- If this element and its paired start occur outside of a valid move source container (§2.13.5.24; §2.13.5.23) with a matching move destination container (§2.13.5.28; §2.13.5.27), then custom XML markup in this region shall be treated as if it was deleted
- If multiple end elements exist with the same id attribute value, then the first instance in the document shall be used and subsequent elements should be treated as unmatched (no corresponding start).

[*Example*: Consider a three-paragraph document with a single block-level custom XML markup element, as follows:

```
<w:body>
  <w:p/>
  <w:customXml … >
    <w:p/>
  </w:customXml>
  <w:p/>
</w:body>
```

If the second paragraph is moved to the end of the document with revisions enabled. This revision must therefore be stored using the custom XML markup revision "cross structure" syntax, as follows:

```
<w:body>
  <w:p/>
  <w:moveFromRangeStart w:id="0" w:name="move1" w:displacedByCustomXml="next"/>
  <w:customXmlMoveFromRangeStart w:id="1"/>
  <w:customXml … >
    <w:p/>
  </w:customXml>
  <w:customXmlMoveFromRangeEnd w:id="1"/>
  <w:moveFromRangeEnd w:id="0" w:displacedByCustomXml="prev"/>
  <w:p/>
  <w:moveToRangeStart w:id="2" w:name="move1" w:displacedByCustomXml="next"/>
  <w:customXmlMoveToRangeStart w:id="3"/>
  <w:customXml … >
    <w:p/>
  </w:customXml>
  <w:customXmlMoveToRangeEnd w:id="3"/>
  <w:moveFromRangeEnd w:id="2" w:displacedByCustomXml="prev"/>
</w:body>
```

The customXmlMoveFromRangeEnd element delimits the end of the region in which all custom XML elements have been moved from this location with revisions enabled. Since this element only affects custom XML, any text in the region is not revision marked moved by this element when present, but the corresponding physical characters for the custom XML element are. *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32); endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32); sdtContent (§2.5.2.33); sdtContent (§2.5.2.34); sdtContent (§2.5.2.35); smartTag (§2.5.1.9); sub (§7.1.2.112); sup (§7.1.2.114); tbl (§2.4.36); tc (§2.4.62); tr (§2.4.75); txbxContent (§2.17.1.1)

Attributes	Description
id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element. If this attribute is omitted, then the document is non-conformant. [*Example*: Consider an annotation represented using the following WordprocessingML fragment: `<w:… w:id="1" … >`

Attributes	Description
	… </w:…> The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Markup">
   <attribute name="id" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.13.5.9 customXmlMoveFromRangeStart (Custom XML Markup Move Source Start)

This element specifies the start of a region within which all custom XML markup was moved to another location in the document and this move was tracked as a revision. The id attribute on this element shall be used to link this element with the corresponding custom XML move source end marker in the document.

Providing a physical representation of the start and end tags of custom XML markup results in regions which can be inserted and deleted independently, but cannot be encapsulated by a single revision element, since their representation in WordprocessingML is the start or end XML tag for the custom XML markup which it represents. Therefore, the start/end "cross structure" annotation format surrounds the WordprocessingML region to which this move source applies.

The following restrictions shall be applied to this element:

- If this element occurs without a corresponding customXmlMoveFromRangeStart element (§2.13.5.9) with a matching id attribute value, then it shall be ignored and no move source information shall be applied to the custom XML elements by this element.
- If this element and its paired start encapsulate a range with no custom XML markup, then they shall be ignored and may be omitted when the document is subsequently saved.
- If this element and its paired end occur outside of a valid move source container (§2.13.5.24; §2.13.5.23) with a matching move destination container (§2.13.5.28; §2.13.5.27), then custom XML markup in this region shall be treated as if it was deleted
- If multiple start elements exist with the same id attribute value, then the each instance in the document shall be matched with an end in document order, and unmatched starts (no corresponding end) shall be handled as described above.

[*Example*: Consider a three-paragraph document with a single block-level custom XML markup element, as follows:

```
<w:body>
  <w:p/>
```

```
    <w:customXml … >
      <w:p/>
    </w:customXml>
    <w:p/>
  </w:body>
```

If the second paragraph is moved to the end of the document with revisions enabled. This revision must therefore be stored using the custom XML markup revision "cross structure" syntax, as follows:

```
  <w:body>
    <w:p/>
    <w:moveFromRangeStart w:id="0" w:name="move1" w:displacedByCustomXml="next"/>
    <w:customXmlMoveFromRangeStart w:id="1"/>
    <w:customXml … >
      <w:p/>
    </w:customXml>
    <w:customXmlMoveFromRangeEnd w:id="1"/>
    <w:moveFromRangeEnd w:id="0" w:displacedByCustomXml="prev"/>
    <w:p/>
    <w:moveToRangeStart w:id="2" w:name="move1" w:displacedByCustomXml="next"/>
    <w:customXmlMoveToRangeStart w:id="3"/>
    <w:customXml … >
      <w:p/>
    </w:customXml>
    <w:customXmlMoveToRangeEnd w:id="3"/>
    <w:moveFromRangeEnd w:id="2" w:displacedByCustomXml="prev"/>
  </w:body>
```

The customXmlMoveFromRangeStart element delimits the start of the region in which all custom XML elements have been moved from this location with revisions enabled. Since this element only affects custom XML, any text in the region is not revision marked moved by this element when present, but the corresponding physical characters for the custom XML element are. *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32); endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32); sdtContent (§2.5.2.33); sdtContent (§2.5.2.34); sdtContent (§2.5.2.35); smartTag (§2.5.1.9); sub (§7.1.2.112); sup (§7.1.2.114); tbl (§2.4.36); tc (§2.4.62); tr (§2.4.75); txbxContent (§2.17.1.1)

Attributes	Description

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`  …`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`  …`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`  …`
	`</w:…>`

Attributes	Description
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrackChange">
   <complexContent>
      <extension base="CT_Markup">
         <attribute name="author" type="ST_String" use="required"/>
         <attribute name="date" type="ST_DateTime" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.10 customXmlMoveToRangeEnd (Custom XML Markup Move Destination Location End)

This element specifies the end of a region within which all custom XML markup was moved to this location in the document and this move was tracked as a revision. The id attribute on this element shall be used to link this element with the corresponding custom XML move destination start marker in the document.

Providing a physical representation of the start and end tags of custom XML markup results in regions which can be inserted and deleted independently, but cannot be encapsulated by a single revision element, since their representation in WordprocessingML is the start or end XML tag for the custom XML markup which it represents. Therefore, the start/end "cross structure" annotation format surrounds the WordprocessingML region to which this move destination applies.

The following restrictions shall be applied to this element:

- If this element occurs without a corresponding customXmlMoveToRangeStart element (§2.13.5.11) with a matching id attribute value, then it shall be ignored and no move destination information shall be applied to the custom XML elements by this element.
- If this element and its paired start encapsulate a range with no custom XML markup, then they shall be ignored and may be omitted when the document is subsequently saved.
- If this element and its paired start occur outside of a valid move source container (§2.13.5.24; §2.13.5.23) with a matching move destination container (§2.13.5.28; §2.13.5.27), then custom XML markup in this region shall be treated as if it was inserted
- If multiple end elements exist with the same id attribute value, then the first instance in the document shall be used and subsequent elements should be treated as unmatched (no corresponding start).

[*Example*: Consider a three-paragraph document with a single block-level custom XML markup element, as follows:

```
<w:body>
  <w:p/>
  <w:customXml … >
    <w:p/>
  </w:customXml>
  <w:p/>
</w:body>
```

If the second paragraph is moved to the end of the document with revisions enabled. This revision must therefore be stored using the custom XML markup revision "cross structure" syntax, as follows:

```
<w:body>
  <w:p/>
  <w:moveFromRangeStart w:id="0" w:name="move1" w:displacedByCustomXml="next"/>
  <w:customXmlMoveFromRangeStart w:id="1"/>
  <w:customXml … >
    <w:p/>
  </w:customXml>
  <w:customXmlMoveFromRangeEnd w:id="1"/>
  <w:moveFromRangeEnd w:id="0" w:displacedByCustomXml="prev"/>
  <w:p/>
  <w:moveToRangeStart w:id="2" w:name="move1" w:displacedByCustomXml="next"/>
  <w:customXmlMoveToRangeStart w:id="3"/>
  <w:customXml … >
    <w:p/>
  </w:customXml>
  <w:customXmlMoveToRangeEnd w:id="3"/>
  <w:moveFromRangeEnd w:id="2" w:displacedByCustomXml="prev"/>
</w:body>
```

The customXmlMoveToRangeEnd element delimits the end of the region in which all custom XML elements have been moved to this location with revisions enabled. Since this element only affects custom XML, any text in the region is not revision marked moved by this element when present, but the corresponding physical characters for the custom XML element are. *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32); endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32); sdtContent (§2.5.2.33); sdtContent (§2.5.2.34); sdtContent (§2.5.2.35); smartTag (§2.5.1.9); sub (§7.1.2.112); sup (§7.1.2.114); tbl (§2.4.36); tc (§2.4.62); tr (§2.4.75); txbxContent (§2.17.1.1)

Attributes	Description

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Markup">
   <attribute name="id" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.13.5.11 customXmlMoveToRangeStart (Custom XML Markup Move Destination Location Start)

This element specifies the start of a region within which all custom XML markup was moved to this location in the document and this move was tracked as a revision. The id attribute on this element shall be used to link this element with the corresponding custom XML move destination end marker in the document.

Providing a physical representation of the start and end tags of custom XML markup results in regions which can be inserted and deleted independently, but cannot be encapsulated by a single revision element, since their representation in WordprocessingML is the start or end XML tag for the custom XML markup which it represents. Therefore, the start/end "cross structure" annotation format surrounds the WordprocessingML region to which this move destination applies.

The following restrictions shall be applied to this element:

- If this element occurs without a corresponding customXmlMoveFromRangeEnd element (§2.13.5.8) with a matching id attribute value, then it shall be ignored and no move source information shall be applied to the custom XML elements by this element.
- If this element and its paired start encapsulate a range with no custom XML markup, then they shall be ignored and may be omitted when the document is subsequently saved.

- If this element and its paired end occur outside of a valid move source container (§2.13.5.24; §2.13.5.23) with a matching move destination container (§2.13.5.28; §2.13.5.27), then custom XML markup in this region shall be treated as if it was inserted
- If multiple start elements exist with the same id attribute value, then the each instance in the document shall be matched with an end in document order, and unmatched starts (no corresponding end) shall be handled as described above.

[*Example*: Consider a three-paragraph document with a single block-level custom XML markup element, as follows:

```
<w:body>
  <w:p/>
  <w:customXml … >
    <w:p/>
  </w:customXml>
  <w:p/>
</w:body>
```

If the second paragraph is moved to the end of the document with revisions enabled. This revision must therefore be stored using the custom XML markup revision "cross structure" syntax, as follows:

```
<w:body>
  <w:p/>
  <w:moveFromRangeStart w:id="0" w:name="move1" w:displacedByCustomXml="next"/>
  <w:customXmlMoveFromRangeStart w:id="1"/>
  <w:customXml … >
    <w:p/>
  </w:customXml>
  <w:customXmlMoveFromRangeEnd w:id="1"/>
  <w:moveFromRangeEnd w:id="0" w:displacedByCustomXml="prev"/>
  <w:p/>
  <w:moveToRangeStart w:id="2" w:name="move1" w:displacedByCustomXml="next"/>
  <w:customXmlMoveToRangeStart w:id="3"/>
  <w:customXml … >
    <w:p/>
  </w:customXml>
  <w:customXmlMoveToRangeEnd w:id="3"/>
  <w:moveFromRangeEnd w:id="2" w:displacedByCustomXml="prev"/>
</w:body>
```

The customXmlMoveFromRangeStart element delimits the start of the region in which all custom XML elements have been moved from this location with revisions enabled. Since this element only affects custom XML, any text in the region is not revision marked moved by this element when present, but the corresponding physical characters for the custom XML element are. *end example*]

body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32); endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32); sdtContent (§2.5.2.33); sdtContent (§2.5.2.34); sdtContent (§2.5.2.35); smartTag (§2.5.1.9); sub (§7.1.2.112); sup (§7.1.2.114); tbl (§2.4.36); tc (§2.4.62); tr (§2.4.75); txbxContent (§2.17.1.1)

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`  …`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`  …`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation	Specifies a unique identifier for an annotation within a WordprocessingML document.

Attributes	Description

Identifier)	The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrackChange">
   <complexContent>
      <extension base="CT_Markup">
         <attribute name="author" type="ST_String" use="required"/>
         <attribute name="date" type="ST_DateTime" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.12 del (Deleted Run Content)

This element specifies that the inline-level content contained within it shall be treated as deleted content which has been tracked as a revision.

[*Example*: Consider a paragraph of text in a WordprocessingML document in which one word has been deleted, as follows:

Some ~~text~~

This paragraph has the word `text` marked deleted as a revision, and is represented as the following WordprocessingML:

```
<w:p>
  <w:r>
    <w:t>Some</w:t>
  </w:r>
  <w:del w:id="0" w:author="Joe Smith" w:date="2006-03-31T12:50:00Z">
    <w:r>
```

```
      <w:delText>text</w:delText>
    </w:r>
  </w:del>
</w:p>
```

The del element contains all of the content which shall be treated as revision marked as deleted; in this case, the word `text` was deleted by `Joe Smith` on March 31, 2006 at 12:50pm. *end example*]

Attributes	Description
author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document. If this attribute is omitted, then no author shall be associated with the parent annotation

Attributes	Description

	type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`  …`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`  …`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`  …`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RunTrackChange">
   <complexContent>
      <extension base="CT_TrackChange">
         <choice minOccurs="0" maxOccurs="unbounded">
            <group ref="EG_ContentRunContent"/>
            <group ref="m:EG_OMathMathElements"/>
         </choice>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.13 del (Deleted Paragraph)

This element specifies that the paragraph mark delimiting the end of a paragraph within a WordprocessingML document shall be treated as deleted (i.e. the contents of this paragraph are no longer delimited by this paragraph mark, and are combined with the following paragraph - but those contents shall not automatically be marked as deleted) as part of a tracked revision.

[*Example*: Consider a document consisting of two paragraphs (with each paragraph delimited by a pilcrow ¶), as follows:

This·is·paragraph·one.¶

This·is·paragraph·two.¶

If the physical character delimiting the end of the first paragraph is deleted and this change is tracked as a revision, resulting in the following:

This·is·paragraph·one.This·is·paragraph·two.¶

This revision is represented using the following WordprocessingML:

```
<w:p>
  <w:pPr>
    <w:rPr>
      <w:del w:id="0" … />
    </w:rPr>
  </w:pPr>
  <w:r>
    <w:t>This is paragraph one.</w:t>
  </w:r>
</w:p>
<w:p>
  <w:r>
    <w:t>This is paragraph two.</w:t>
  </w:r>
</w:p>
```

The del element on the run properties for the first paragraph mark specifies that this paragraph mark was deleted, and this deletion was tracked as a revision. *end example*]

Parent Elements
rPr (§2.3.1.29); rPr (§2.3.1.30)

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`  …`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard. If this attribute is omitted, then no date information shall be associated with the parent annotation type.

Attributes	Description

	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`…`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrackChange">
   <complexContent>
      <extension base="CT_Markup">
         <attribute name="author" type="ST_String" use="required"/>
         <attribute name="date" type="ST_DateTime" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.14 del (Deleted Table Row)

This element specifies that the parent table row shall be treated as a deleted row whose deletion has been tracked as a revision. This setting shall not imply any revision state about the table cells in this row or their contents (which must be revision marked independently), and shall only affect the table row itself.

[*Example*: Consider a two row by two column table in which the second row has been marked as deleted using a revision. This requirement would be specified using the following WordprocessingML:

```
<w:tbl>
  <w:tr>
    <w:tc>
      <w:p/>
    </w:tc>
    <w:tc>
      <w:p/>
    </w:tc>
  </w:tr>
  <w:tr>
    <w:trPr>
      <w:del w:id="0" … />
    </w:trPr>
    <w:tc>
      <w:p/>
    </w:tc>
    <w:tc>
      <w:p/>
    </w:tc>
  </w:tr>
</w:tbl>
```

The del element on the table row properties for the second table row specifies that this row was deleted, and this deletion was tracked as a revision. *end example*]

Parent Elements
trPr (§2.7.5.10); trPr (§2.7.5.11); trPr (§2.4.78)

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`  …`
	`</w:…>`

Attributes	Description
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`…`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrackChange">
   <complexContent>
      <extension base="CT_Markup">
         <attribute name="author" type="ST_String" use="required"/>
         <attribute name="date" type="ST_DateTime" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.15 del (Deleted Math Control Character)

This element specifies that the Office Open XML Math control character which contains this element was deleted and tracked as a revision. [*Example*: The deletion of a fraction bar. *end example*]

[*Example*: Consider a region of Office Open XML Math in a WordprocessingML document in which the control character for the fraction bar has been deleted, as follows:

This deletion is represented as the following WordprocessingML:

```
<m:f>
  <m:fPr>
    <m:ctrlPr>
      <w:del w:id="0" w:author="Joe Smith" w:date="2006-03-31T12:50:00Z">
        ...
      </w:del>
    </m:ctrlPr>
  </m:fPr>
  ...
</m:f>
```

The del element contains all of the content which shall be treated as revision marked as deleted; in this case, the fraction bar was deleted by `Joe Smith` on March 31, 2006 at 12:50pm. *end example*]

Parent Elements
ctrlPr (§7.1.2.23)

Child Elements	Subclause
rPr (Previous Run Properties)	§2.3.2.26

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`  …`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`  …`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`  …`
	`</w:…>`

Attributes	Description
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RPrChange">
   <complexContent>
      <extension base="CT_TrackChange">
         <sequence>
            <element name="rPr" type="CT_RPrOriginal" minOccurs="1"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.16 ins (Inserted Table Row)

This element specifies that the parent table row shall be treated as an inserted row whose insertion has been tracked as a revision. This setting shall not imply any revision state about the table cells in this row or their contents (which must be revision marked independently), and shall only affect the table row itself.

[*Example*: Consider a two row by two column table in which the second row has been marked as inserted using a revision. This requirement would be specified using the following WordprocessingML:

```
<w:tbl>
  <w:tr>
    <w:tc>
      <w:p/>
    </w:tc>
    <w:tc>
      <w:p/>
    </w:tc>
  </w:tr>
  <w:tr>
    <w:trPr>
      <w:ins w:id="0" … />
    </w:trPr>
    <w:tc>
      <w:p/>
    </w:tc>
    <w:tc>
      <w:p/>
    </w:tc>
  </w:tr>
</w:tbl>
```

The ins element on the table row properties for the second table row specifies that this row was inserted, and this insertion was tracked as a revision. *end example*]

Parent Elements
trPr (§2.7.5.10); trPr (§2.7.5.11); trPr (§2.4.78)

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`  …`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`…`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrackChange">
   <complexContent>
      <extension base="CT_Markup">
         <attribute name="author" type="ST_String" use="required"/>
         <attribute name="date" type="ST_DateTime" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.17 ins (Inserted Math Control Character)

This element specifies that the Office Open XML Math control character which contains this element was inserted and tracked as a revision. [*Example*: The insertion of a fraction bar. *end example*]

[*Example*: Consider a region of Office Open XML Math in a WordprocessingML document in which the control character for the fraction bar has been inserted, as follows:

This insertion is represented as the following WordprocessingML:

```
<m:f>
  <m:fPr>
    <m:ctrlPr>
      <w:ins w:id="0" w:author="Joe Smith" w:date="2006-03-31T12:50:00Z">
        ...
      </w:ins>
    </m:ctrlPr>
  </m:fPr>
  ...
</m:f>
```

The ins element contains all of the content which shall be treated as revision marked as inserted; in this case, the fraction bar was inserted by `Joe Smith` on March 31, 2006 at 12:50pm. *end example*]

Parent Elements
ctrlPr (§7.1.2.23)

Child Elements	Subclause
rPr (Previous Run Properties)	§2.3.2.26

Attributes	Description
author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document. If this attribute is omitted, then no author shall be associated with the parent annotation type. [*Example*: Consider a comment represented using the following WordprocessingML fragment: `<w:… w:id="1" w:author="Example Author">`

Attributes	Description
	… </w:…> The author attribute specifies that the author of the current annotation is Example Author, which may be used as desired. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).
date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard. If this attribute is omitted, then no date information shall be associated with the parent annotation type. [*Example*: Consider a comment represented using the following WordprocessingML fragment: <w:… w:id="1" w:date="2006-01-01T10:00:00"> … </w:…> The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*] The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).
id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element. If this attribute is omitted, then the document is non-conformant. [*Example*: Consider an annotation represented using the following WordprocessingML fragment: <w:… w:id="1" … > … </w:…> The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

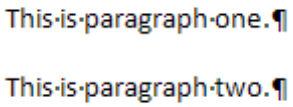
```
<complexType name="CT_RPrChange">
   <complexContent>
      <extension base="CT_TrackChange">
         <sequence>
            <element name="rPr" type="CT_RPrOriginal" minOccurs="1"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.18 ins (Inserted Paragraph)

This element specifies that the paragraph mark delimiting the end of a paragraph within a WordprocessingML document shall be treated as deleted (i.e. the contents of this paragraph are no longer delimited by this paragraph mark, and are combined with the following paragraph) as part of a tracked revision.

[*Example*: Consider a document consisting of a single paragraph, as follows:

If the first sentence is moved into its own new paragraph, and this change is tracked as a revision, resulting in the following:



This revision is represented using the following WordprocessingML:

```
<w:p>
  <w:pPr>
    <w:rPr>
      <w:ins w:id="0" … />
    </w:rPr>
  </w:pPr>
  <w:r>
    <w:t>This is paragraph one.</w:t>
  </w:r>
</w:p>
<w:p>
  <w:r>
    <w:t>This is paragraph two.</w:t>
  </w:r>
</w:p>
```

The ins element on the run properties for the first paragraph mark specifies that this paragraph mark was inserted, and this insertion was tracked as a revision. *end example*]

Parent Elements
rPr (§2.3.1.29); rPr (§2.3.1.30)

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`…`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`…`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element. If this attribute is omitted, then the document is non-conformant.

Attributes	Description

	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrackChange">
   <complexContent>
      <extension base="CT_Markup">
         <attribute name="author" type="ST_String" use="required"/>
         <attribute name="date" type="ST_DateTime" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.19 ins (Inserted Numbering Properties)

This element specifies that the numbering information defined by the parent element shall be treated as numbering information which was recorded as an insertion using revisions.

[*Example*: Consider two paragraphs in a WordprocessingML document, with the words one and two respectively, as follows:

One

Two

If numbering is then applied to these two paragraphs, and this numbering is tracked as a revision, this revision is represented using the following WordprocessingML:

```
<w:p>
  <w:pPr>
    <w:numPr>
      <w:ilvl w:val="0" />
      <w:numId w:val="1" />
      <w:ins w:id="0" w:author="Joe Smith" w:date="20050101T10:00:00Z" />
    </w:numPr>
  </w:pPr>
  <w:r>
    <w:t>one</w:t>
  </w:r>
</w:p>
<w:p>
  <w:pPr>
    <w:numPr>
      <w:ilvl w:val="0" />
      <w:numId w:val="1" />
      <w:ins w:id="0" w:author="Joe Smith" w:date="20050101T10:00:00Z" />
    </w:numPr>
  </w:pPr>
  <w:r>
    <w:t>two</w:t>
  </w:r>
</w:p>
```

The ins element as a child of the numbering properties specifies that the paragraphs in this document have been given numbering properties by `Joe Smith` and that this change was marked as a revision. *end example*]

Parent Elements
numPr (§2.3.1.19)

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`…`
	`</w:…>`

Attributes	Description
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`  …`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`  …`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrackChange">
   <complexContent>
      <extension base="CT_Markup">
         <attribute name="author" type="ST_String" use="required"/>
         <attribute name="date" type="ST_DateTime" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.20 ins (Inserted Run Content)

This element specifies that the inline-level content contained within it shall be treated as inserted content which has been tracked as a revision.

[*Example*: Consider a paragraph of text in a WordprocessingML document in which one word has been inserted, as follows:

Some text

This paragraph has the word `text` marked inserted as a revision, and is represented as the following WordprocessingML:

```
<w:p>
  <w:r>
    <w:t>Some</w:t>
  </w:r>
  <w:ins w:id="0" w:author="Joe Smith" w:date="2006-03-31T12:50:00Z">
    <w:r>
      <w:t>text</w:t>
    </w:r>
  </w:ins>
</w:p>
```

The ins element contains all of the content which shall be treated as revision marked as inserted; in this case, the word `text` was inserted by `Joe Smith` on March 31, 2006 at 12:50pm. *end example*]

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`…`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard. If this attribute is omitted, then no date information shall be associated with the parent annotation type.

Attributes	Description

	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`…`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RunTrackChange">
   <complexContent>
      <extension base="CT_TrackChange">
         <choice minOccurs="0" maxOccurs="unbounded">
            <group ref="EG_ContentRunContent"/>
            <group ref="m:EG_OMathMathElements"/>
         </choice>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.21 moveFrom (Move Source Run Content)

This element specifies that the inline-level content contained within it shall be treated as content which has been moved away from this location and tracked as a revision.

The following restrictions shall be applied to this content:

- If this element occurs outside of a valid move source container (§2.13.5.24; §2.13.5.23) for which a matching move destination container (§2.13.5.28; §2.13.5.27) exists in the document, then content in this region shall be treated as deleted, rather than moved.

[*Example*: Consider a WordprocessingML document in which the first paragraph contains two sentences, and the first sentence is moved before the second sentence, and this move is tracked as a revision, as follows (in this image, green underline indicates the move destination and the green strikethrough indicates the move source location):

This document has the sentence `Some moved text.` moved to the first sentence in the document. This revision is represented using the following WordprocessingML:

```
<w:p>
  <w:moveToRangeStart w:id="0" … w:name="move1" />
  <w:moveTo w:id="1" … >
    <w:r>
      <w:t>Some moved text.</w:t>
    </w:r>
  </w:moveTo>
  <w:moveToRangeEnd w:id="0" />
  <w:r>
    <w:t xml:space="preserve">Some text.</w:t>
  </w:r>
  <w:moveFromRangeStart w:id="2" … w:name="move1" />
  <w:moveFrom w:id="3" … >
    <w:r>
      <w:t>Some moved text.</w:t>
    </w:r>
  </w:moveFrom>
  <w:moveFromRangeEnd w:id="2" />
</w:p>
```

The moveFrom element specifies that all of the inline-level content contained within shall be revision marked as content which was moved from its current location in the document. Because this moved content is contained within a complete move source container (moveFromRangeStart and moveFromRangeEnd) with a corresponding move destination, this content is tracked as a move. *end example*]

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`…`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`…`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RunTrackChange">
   <complexContent>
      <extension base="CT_TrackChange">
         <choice minOccurs="0" maxOccurs="unbounded">
            <group ref="EG_ContentRunContent"/>
            <group ref="m:EG_OMathMathElements"/>
         </choice>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.22 moveFrom (Move Source Paragraph)

This element specifies that the parent paragraph has been moved away from this location and tracked as a revision. This does not imply anything about the revision state of the contents of the paragraph, and applies only to the existence of the paragraph as its own unique paragraph.

The following restrictions shall be applied to this content:

- If this element occurs outside of a valid move source container (§2.13.5.24; §2.13.5.23) for which a matching move destination container (§2.13.5.28; §2.13.5.27) exists in the document, then content in this region shall be treated as deleted, rather than moved.

[*Example*: Consider a WordprocessingML document in which a paragraph of text is moved down in the document. This moved paragraph would be represented using the following WordprocessingML markup:

```
<w:moveFromRangeStart w:id="0" w:name="aMove"/>
<w:p>
  <w:pPr>
    <w:rPr>
      <w:moveFrom w:id="1" … />
    </w:rPr>
  </w:pPr>
  …
</w:p>
<w:moveFromRangeEnd w:id="0"/>
```

The moveFrom element as a child of the run properties of the paragraph mark specify that this paragraph mark was part of the content which was moved in the document. This implies nothing about the contents, since they may have been added later and not tracked as a revision (they must be marked as a move using the moveFrom element (§2.13.5.21) around the run content). *end example*]

Parent Elements
rPr (§2.3.1.29); rPr (§2.3.1.30)

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`  …`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`  …`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`  …`
	`</w:…>`

Attributes	Description
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrackChange">
   <complexContent>
      <extension base="CT_Markup">
         <attribute name="author" type="ST_String" use="required"/>
         <attribute name="date" type="ST_DateTime" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.23 moveFromRangeEnd (Move Source Location Container - End)

This element specifies the end of a region whose move source contents are part of a single named move. When a move source is stored as a revision in a WordprocessingML document, two pieces of information must be stored about that move source:

- A set of pieces of content which were moved - both inline-level content (§2.13.5.21) and paragraphs (§2.13.5.22)
- A move source container (or "bookmark") which specifies that all content within it which marked as a move source is part of a single named move. The name attribute on the move container links a group of move source content with the corresponding group of move destination content.

This element defines the end of the latter piece of the move revision data - the container. The id attribute on this element shall be used to link this element with the corresponding start of a move source container in the document.

The following restrictions are applied to the use of this element:

- If this element occurs without a corresponding moveFromRangeStart element (§2.13.5.24) with a matching id attribute value, then it shall be ignored and no move source container exists
- If this element and its paired end occur without a matching move destination container (§2.13.5.28; §2.13.5.27), then moved content in this region shall be treated as if it was deleted
- If multiple move source containers surround the same text, the last valid container (determined by the location of the container start elements, in document order) should be the container associated with that text.

[*Example*: Consider a WordprocessingML document in which the first paragraph contains two sentences, and the first sentence is moved before the second sentence, and this move is tracked as a revision, as follows (in this

image, green underline indicates the move destination and the green strikethrough indicates the move source location):

Some moved text. Some text. ~~Some moved text.~~

This document has the sentence `Some moved text.` moved to the first sentence in the document. This revision is represented using the following WordprocessingML:

```
<w:p>
  <w:moveToRangeStart w:id="0" … w:name="move1" />
  <w:moveTo w:id="1" … >
    <w:r>
      <w:t>Some moved text.</w:t>
    </w:r>
  </w:moveTo>
  <w:moveToRangeEnd w:id="0" />
  <w:r>
    <w:t xml:space="preserve">Some text.</w:t>
  </w:r>
  <w:moveFromRangeStart w:id="2" … w:name="move1" />
  <w:moveFrom w:id="3" … >
    <w:r>
      <w:t>Some moved text.</w:t>
    </w:r>
  </w:moveFrom>
  <w:moveFromRangeEnd w:id="2" />
</w:p>
```

The moveFromRangeEnd element specifies the end of the move source container within which all moved content is part of the move named `move1`. *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32); endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32); sdtContent (§2.5.2.33); sdtContent (§2.5.2.34); sdtContent (§2.5.2.35); smartTag (§2.5.1.9); sub (§7.1.2.112); sup (§7.1.2.114); tbl (§2.4.36); tc (§2.4.62); tr (§2.4.75); txbxContent (§2.17.1.1)

Attributes	Description
displacedByCustomXml (Annotation	Specifies that the parent annotation's placement shall be directly linked with the location of the physical presentation of a custom XML element in the document. This element

Attributes	Description

Marker Relocated For Custom XML Markup)	only has an effect when the custom XML element is block-level (i.e. surrounds an entire paragraph), as in this scenario the logical and physical placement of the annotation and custom XML element may differ.
	
	Specifically, in this case, the custom XML is presented *around* the block-level object it encloses (the paragraph, table, table row, or table cell), but is physically represented within that same object (i.e. within the paragraph, table, table row or table cell). This requirement stems from the fact that there is no location for the location of the annotation within the document at its logical location (around a table, for example).
	
	If this element is omitted, then the annotation shall be anchored inside of all block-level custom XML elements in the paragraph. If this element is present, but no block-level custom XML tag is located at the position it specifies (before or after), then it shall be ignored.
	
	[*Example*: Consider a paragraph with block level custom XML markup and two comment anchor annotations (one before and one after the custom XML element's physical representation), as follows:
	
	 	
	Since all three of these items are around the entire paragraph, they are stored outside of the paragraph. However, in order to ensure that their relative positions are stored correctly, any annotation which shall be displaced by the physical custom XML element specifies this information, resulting in the following WordprocessingML:
	
	`<w:commentRangeStart w:id="0" />`
	`<w:commentRangeStart w:id="1" w:displaced byCustomXml="next" />`
	`<w:customXml w:element="spec" … />`
	`<w:p>`
	`…`
	`</w:p>`
	
	The displacedByCustomXml attribute specifies that even though all three of these items are around the paragraph and will be moved inside the paragraph to be represented physically, the comment with ID 0 shall be inside the custom XML, but the comment with ID 1 shall be displaced to stay outside of the relative location of the next custom XML element (the spec element). *end example*]
	
	The possible values for this attribute are defined by the ST_DisplacedByCustomXml simple type (§2.18.17).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.

Attributes	Description
	If this attribute is omitted, then the document is non-conformant. [*Example*: Consider an annotation represented using the following WordprocessingML fragment: `<w:… w:id="1" … > … </w:…>` The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_MarkupRange">
   <complexContent>
      <extension base="CT_Markup">
         <attribute name="displacedByCustomXml" type="ST_DisplacedByCustomXml" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.24 moveFromRangeStart (Move Source Location Container - Start)

This element specifies the start of a region whose move source contents are part of a single named move. When a move source is stored as a revision in a WordprocessingML document, two pieces of information must be stored about that move source:

- A set of pieces of content which were moved - both inline-level content (§2.13.5.21) and paragraphs (§2.13.5.22)
- A move source container (or "bookmark") which specifies that all content within it which marked as a move source is part of a single named move. The name attribute on the move container links a group of move source content with the corresponding group of move destination content.

This element defines the start of the latter piece of the move revision data - the container. The id attribute on this element shall be used to link this element with the corresponding end of a move source container in the document.

The following restrictions are applied to the use of this element

- If this element occurs without a corresponding moveFromRangeEnd element (§2.13.5.23) with a matching id attribute value, then it shall be ignored and no move source container exists
- If this element and its paired end occur without a matching move destination container (§2.13.5.28; §2.13.5.27), then moved content in this region shall be treated as if it was deleted

- If multiple start elements exist with the same id attribute value, then the each instance in the document shall be matched with an end in document order, and unmatched starts (no corresponding end) shall be handled as described above.
- If multiple move source containers surround the same text, the last valid container (determined by the location of the container start elements, in document order) should be the container associated with that text.

[*Example*: Consider a WordprocessingML document in which the first paragraph contains two sentences, and the first sentence is moved before the second sentence, and this move is tracked as a revision, as follows (in this image, green underline indicates the move destination and the green strikethrough indicates the move source location):

This document has the sentence `Some moved text.` moved to the first sentence in the document. This revision is represented using the following WordprocessingML:

```
<w:p>
  <w:moveToRangeStart w:id="0" … w:name="move1" />
  <w:moveTo w:id="1" … >
    <w:r>
      <w:t>Some moved text.</w:t>
    </w:r>
  </w:moveTo>
  <w:moveToRangeEnd w:id="0" />
  <w:r>
    <w:t xml:space="preserve">Some text.</w:t>
  </w:r>
  <w:moveFromRangeStart w:id="2" … w:name="move1" />
  <w:moveFrom w:id="3" … >
    <w:r>
      <w:t>Some moved text.</w:t>
    </w:r>
  </w:moveFrom>
  <w:moveFromRangeEnd w:id="2" />
</w:p>
```

The moveFromRangeStart element specifies the start of the move source container within which all moved content is part of the move named `move1`. *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32);

Parent Elements
endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32); sdtContent (§2.5.2.33); sdtContent (§2.5.2.34); sdtContent (§2.5.2.35); smartTag (§2.5.1.9); sub (§7.1.2.112); sup (§7.1.2.114); tbl (§2.4.36); tc (§2.4.62); tr (§2.4.75); txbxContent (§2.17.1.1)

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`  …`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

colFirst (First Table Column Covered By Bookmark)	Specifies the zero-based index of the first column in this row which shall be part of this bookmark. When a bookmark is contained within a table, it is possible for that bookmark to only cover cells within a certain column and row range within that table, by specifying: • The first row for which the specified columns are part of the table bookmark. This is accomplished by placing the bookmarkStart element in the first table cell in that row. • The first column included in the bookmark for each of the specified row(s) via this attribute. • The last column included in the bookmark for each of the specified row(s) via the colLast attribute. • The last row for which the specified columns are part of the table bookmark. This is accomplished by placing the bookmarkEnd element at the end of that table row. If this attribute appears, then the colLast attribute must also appear (regardless of where this bookmark is located) or the document shall be considered non-conformant. If this attibute and its pair occur on a bookmark which is not contained in a table, then their values should be ignored. If this value exceeds the value of colLast or the number of columns in the table, then both values should be ignored.

Attributes	Description

	[*Example*: Consider a three row by three column table where a table bookmark shall be applied to the contents of the first two cells in the first two rows in the table (the cells shaded below):
	 	This bookmark would be specified using the following WordprocessingML for the table's conents:
	
	`<w:tbl>`
	`  …`
	`  <w:tr>`
	`  <w:tc>`
	`  <w:bookMarkStart w:colFirst="0" w:colLast="1" w:id="0"`
	`w:name="table"/>`
	`  <w:p/>`
	`  </w:tc>`
	`  <w:tc>`
	`  <w:p/>`
	`  </w:tc>`
	`  <w:tc>`
	`  <w:p/>`
	`  </w:tc>`
	`  </w:tr>`
	`  <w:tr>`
	`  <w:tc>`
	`  <w:p/>`
	`  </w:tc>`
	`  <w:tc>`
	`  <w:p/>`
	`  </w:tc>`
	`  <w:tc>`
	`  <w:p/>`
	`  </w:tc>`
	`  <w:bookmarkEnd w:id="0" />`
	`  </w:tr>`
	`  <w:tr>`
	`  <w:tc>`
	`  <w:p/>`
	`  </w:tc>`
	`  <w:tc>`
	`  <w:p/>`
	`  </w:tc>`

Attributes	Description
	<w:tc> <w:p/> </w:tc> </w:tr> </w:tbl> The colFirst attribute specifies that all columns starting with the first column shall be included in the table bookmark. This will apply starting with the first row and ending with the second row (the two rows within the bookmark's start and end). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
colLast (Last Table Column Covered By Bookmark)	Specifies the zero-based index of the last column in this row which shall be part of this bookmark. When a bookmark is contained within a table, it is possible for that bookmark to only cover cells within a certain column and row range within that table, by specifying: • The first row for which the specified columns are part of the table bookmark. This is accomplished by placing the bookmarkStart element in the first table cell in that row. • The first column included in the bookmark for each of the specified row(s) via the colFirst attribute. • The last column included in the bookmark for each of the specified row(s) via this attribute. • The last row for which the specified columns are part of the table bookmark. This is accomplished by placing the bookmarkEnd element at the end of that table row. If this attribute appears, then the colFirst attribute must also appear (regardless of where this bookmark is located) or the document shall be considered non-conformant. If this attibute and its pair occur on a bookmark which is not contained in a table, then their values should be ignored. If this value does not equal or exceed the value of colFirst or the number of columns in the table, then both values should be ignored. [*Example*: Consider a three row by three column table where a table bookmark shall be applied to the contents of the first two cells in the first two rows in the table (the cells shaded below):  This bookmark would be specified using the following WordprocessingML for the table's conents:

Attributes	Description
	<w:tbl> … <w:tr> <w:tc> <w:bookMarkStart w:colFirst="0" w:colLast="1" w:id="0" w:name="table"/> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> </w:tr> <w:tr> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:bookmarkEnd w:id="0" /> </w:tr> <w:tr> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> </w:tr> </w:tbl> The colLast attribute specifies that the last column that shall be included in the table bookmark is the second column. This will apply starting with the first row and ending with the second row (the two rows within the bookmark's start and end). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
date (Annotation	Specifies the date information for an annotation within a WordprocessingML document.

Attributes	Description

Date)	The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`…`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

displacedByCustomXml (Annotation Marker Relocated For Custom XML Markup)	Specifies that the parent annotation's placement shall be directly linked with the location of the physical presentation of a custom XML element in the document. This element only has an effect when the custom XML element is block-level (i.e. surrounds an entire paragraph), as in this scenario the logical and physical placement of the annotation and custom XML element may differ. Specifically, in this case, the custom XML is presented *around* the block-level object it encloses (the paragraph, table, table row, or table cell), but is physically represented within that same object (i.e. within the paragraph, table, table row or table cell). This requirement stems from the fact that there is no location for the location of the annotation within the document at its logical location (around a table, for example). If this element is omitted, then the annotation shall be anchored inside of all block-level custom XML elements in the paragraph. If this element is present, but no block-level custom XML tag is located at the position it specifies (before or after), then it shall be ignored. [*Example*: Consider a paragraph with block level custom XML markup and two comment anchor annotations (one before and one after the custom XML element's physical representation), as follows:  Since all three of these items are around the entire paragraph, they are stored outside of the paragraph. However, in order to ensure that their relative positions are stored correctly, any annotation which shall be displaced by the physical custom XML element

Attributes	Description

	specifies this information, resulting in the following WordprocessingML:
	
	`<w:commentRangeStart w:id="0" />`
	`<w:commentRangeStart w:id="1" w:displaced byCustomXml="next" />`
	`<w:customXml w:element="spec" … />`
	`<w:p>`
	`…`
	`</w:p>`
	
	The displacedByCustomXml attribute specifies that even though all three of these items are around the paragraph and will be moved inside the paragraph to be represented physically, the comment with ID 0 shall be inside the custom XML, but the comment with ID 1 shall be displaced to stay outside of the relative location of the next custom XML element (the spec element). *end example*]
	
	The possible values for this attribute are defined by the ST_DisplacedByCustomXml simple type (§2.18.17).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

name (Bookmark Name)	Specifies the bookmark name.
	
	If multiple bookmarks in a document share the same name, then the first bookmark (defined by the location of the bookmarkStart element in document order) shall be maintained, and all subsequent bookmarks should be ignored.
	
	[*Example*: Consider the following XML for a bookmark around a single word:
	
	`<w:p>`
	`<w:bookmarkStart w:id="0" w:name="place" />`
	`<w:r>`
	`<w:t>Seattle</w:t>`

Attributes	Description
	</w:r> <w:bookmarkEnd w:id="0" /> </w:p> The name attribute specifies that the name for this bookmark is place. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_MoveBookmark">
   <complexContent>
      <extension base="CT_Bookmark">
         <attribute name="author" type="ST_String" use="required"/>
         <attribute name="date" type="ST_DateTime" use="required"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.25 moveTo (Move Destination Paragraph)

This element specifies that the parent paragraph has been moved to this location and tracked as a revision. This does not imply anything about the revision state of the contents of the paragraph, and applies only to the existence of the paragraph as its own unique paragraph.

The following restrictions shall be applied to this content:

- If this element occurs outside of a valid move destination container (§2.13.5.28; §2.13.5.27) for which a matching move source container (§2.13.5.24; §2.13.5.23) exists in the document, then content in this region shall be treated as inserted, rather than moved.

[*Example*: Consider a WordprocessingML document in which a paragraph of text is moved down in the document. This moved paragraph would be represented using the following WordprocessingML markup:

```
<w:moveToRangeStart w:id="0" w:name="aMove"/>
<w:p>
  <w:pPr>
    <w:rPr>
      <w:moveTo w:id="1" … />
    </w:rPr>
  </w:pPr>
  …
</w:p>
</w:moveToRangeEnd w:id="0"/>
```

The moveTo element as a child of the run properties of the paragraph mark specify that this paragraph mark was part of the content which was moved in the document. This implies nothing about the contents, since they

may have been added later and not tracked as a revision (they must be marked as a move using the moveTo element (§2.13.5.26) around the run content). *end example*]

Parent Elements
rPr (§2.3.1.29); rPr (§2.3.1.30)

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`…`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`…`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element. If this attribute is omitted, then the document is non-conformant.

Attributes	Description

	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrackChange">
   <complexContent>
      <extension base="CT_Markup">
         <attribute name="author" type="ST_String" use="required"/>
         <attribute name="date" type="ST_DateTime" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.26 moveTo (Move Destination Run Content)

This element specifies that the inline-level content contained within it shall be treated as content which has been moved to this location and tracked as a revision.

The following restrictions shall be applied to this content:

- If this element occurs outside of a valid move destination container (§2.13.5.28; §2.13.5.27) for which a matching move source container (§2.13.5.24; §2.13.5.23) exists in the document, then content in this region shall be treated as inserted, rather than moved.

[*Example*: Consider a WordprocessingML document in which the first paragraph contains two sentences, and the first sentence is moved before the second sentence, and this move is tracked as a revision, as follows (in this image, green underline indicates the move destination and the green strikethrough indicates the move source location):

This document has the sentence `Some moved text.` moved to the first sentence in the document. This revision is represented using the following WordprocessingML:

```
<w:p>
  <w:moveToRangeStart w:id="0" … w:name="move1" />
  <w:moveTo w:id="1" … >
    <w:r>
      <w:t>Some moved text.</w:t>
    </w:r>
  </w:moveTo>
  <w:moveToRangeEnd w:id="0" />
  <w:r>
    <w:t xml:space="preserve">Some text.</w:t>
  </w:r>
  <w:moveFromRangeStart w:id="2" … w:name="move1" />
  <w:moveFrom w:id="3" … >
    <w:r>
      <w:t>Some moved text.</w:t>
    </w:r>
  </w:moveFrom>
  <w:moveFromRangeEnd w:id="2" />
</w:p>
```

The moveTo element specifies that all of the inline-level content contained within shall be revision marked as content which was moved to its current location in the document. Because this moved content is contained within a complete move destination container (moveToRangeStart and moveToRangeEnd) with a corresponding move source, this content is tracked as a move. *end example*]

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`  …`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`  …`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at

Attributes	Description
	10:00 AM, which may be used as desired. *end example*] The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RunTrackChange">
    <complexContent>
        <extension base="CT_TrackChange">
            <choice minOccurs="0" maxOccurs="unbounded">
                <group ref="EG_ContentRunContent"/>
                <group ref="m:EG_OMathMathElements"/>
            </choice>
        </extension>
    </complexContent>
</complexType>
```

2.13.5.27 moveToRangeEnd (Move Destination Location Container - End)

This element specifies the end of a region whose move destination contents are part of a single named move. When a move source is stored as a revision in a WordprocessingML document, two pieces of information must be stored about that move destination:

- A set of pieces of content which were moved - both inline-level content (§2.13.5.26) and paragraphs (§2.13.5.25)
- A move destination container (or "bookmark") which specifies that all content within it which marked as a move destination is part of a single named move. The name attribute on the move container links a group of move destination content with the corresponding group of move source content.

This element defines the end of the latter piece of the move revision data - the container. The id attribute on this element shall be used to link this element with the corresponding start of a move destination container in the document.

The following restrictions are applied to the use of this element:

- If this element occurs without a corresponding moveToRangeStart element (§2.13.5.28) with a matching id attribute value, then it shall be ignored and no move source container exists
- If this element and its paired end occur without a matching move source container (§2.13.5.24; §2.13.5.23), then moved content in this region shall be treated as if it was inserted
- If multiple move destination containers surround the same text, the last valid container (determined by the location of the container start elements, in document order) should be the container associated with that text.

[*Example*: Consider a WordprocessingML document in which the first paragraph contains two sentences, and the first sentence is moved before the second sentence, and this move is tracked as a revision, as follows (in this image, green underline indicates the move destination and the green strikethrough indicates the move source location):

This document has the sentence `Some moved text.` moved to the first sentence in the document. This revision is represented using the following WordprocessingML:

```
<w:p>
  <w:moveToRangeStart w:id="0" … w:name="move1" />
  <w:moveTo w:id="1" … >
    <w:r>
      <w:t>Some moved text.</w:t>
    </w:r>
  </w:moveTo>
  <w:moveToRangeEnd w:id="0" />
  <w:r>
    <w:t xml:space="preserve">Some text.</w:t>
  </w:r>
  <w:moveFromRangeStart w:id="2" … w:name="move1" />
  <w:moveFrom w:id="3" … >
    <w:r>
      <w:t>Some moved text.</w:t>
    </w:r>
  </w:moveFrom>
  <w:moveFromRangeEnd w:id="2" />
</w:p>
```

The moveToRangeEnd element specifies the end of the move destination container within which all moved content is part of the move named `move1`. *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32); endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32); sdtContent (§2.5.2.33); sdtContent (§2.5.2.34); sdtContent (§2.5.2.35); smartTag (§2.5.1.9); sub (§7.1.2.112); sup (§7.1.2.114); tbl (§2.4.36); tc (§2.4.62); tr (§2.4.75); txbxContent (§2.17.1.1)

Attributes	Description

displacedByCustomXml (Annotation Marker Relocated For Custom XML Markup)	Specifies that the parent annotation's placement shall be directly linked with the location of the physical presentation of a custom XML element in the document. This element only has an effect when the custom XML element is block-level (i.e. surrounds an entire paragraph), as in this scenario the logical and physical placement of the annotation and custom XML element may differ.
	
	Specifically, in this case, the custom XML is presented *around* the block-level object it encloses (the paragraph, table, table row, or table cell), but is physically represented within that same object (i.e. within the paragraph, table, table row or table cell). This requirement stems from the fact that there is no location for the location of the annotation within the document at its logical location (around a table, for example).
	
	If this element is omitted, then the annotation shall be anchored inside of all block-level custom XML elements in the paragraph. If this element is present, but no block-level custom XML tag is located at the position it specifies (before or after), then it shall be ignored.
	
	[*Example*: Consider a paragraph with block level custom XML markup and two comment anchor annotations (one before and one after the custom XML element's physical representation), as follows:
	
	 	
	Since all three of these items are around the entire paragraph, they are stored outside of the paragraph. However, in order to ensure that their relative positions are stored correctly, any annotation which shall be displaced by the physical custom XML element specifies this information, resulting in the following WordprocessingML:
	
	`<w:commentRangeStart w:id="0" />`
	`<w:commentRangeStart w:id="1" w:displaced byCustomXml="next" />`

Attributes	Description
	<w:customXml w:element="spec" … /> <w:p> … </w:p> The displacedByCustomXml attribute specifies that even though all three of these items are around the paragraph and will be moved inside the paragraph to be represented physically, the comment with ID 0 shall be inside the custom XML, but the comment with ID 1 shall be displaced to stay outside of the relative location of the next custom XML element (the spec element). *end example*] The possible values for this attribute are defined by the ST_DisplacedByCustomXml simple type (§2.18.17).
id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element. If this attribute is omitted, then the document is non-conformant. [*Example*: Consider an annotation represented using the following WordprocessingML fragment: <w:… w:id="1" … > … </w:…> The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_MarkupRange">
   <complexContent>
      <extension base="CT_Markup">
         <attribute name="displacedByCustomXml" type="ST_DisplacedByCustomXml" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.28 moveToRangeStart (Move Destination Location Container - Start)

This element specifies the start of the region whose move destination contents are part of a single named move. When a move destination is stored as a revision in a WordprocessingML document, two pieces of information must be stored about that move destination:

- A set of pieces of content which were moved - both inline-level content (§2.13.5.26) and paragraphs (§2.13.5.25)
- A move destination container (or "bookmark") which specifies that all content within it which marked as a move destination is part of a single named move. The name attribute on the move container links a group of move destination content with the corresponding group of move source content.

This element defines the start of the latter piece of the move revision data - the container. The id attribute on this element shall be used to link this element with the corresponding end of a move destination container in the document.

The following restrictions are applied to the use of this element

- If this element occurs without a corresponding moveToRangeEnd element (§2.13.5.27) with a matching id attribute value, then it shall be ignored and no move source container exists
- If this element and its paired end occur without a matching move source container (§2.13.5.24; §2.13.5.23), then moved content in this region shall be treated as if it was inserted
- If multiple start elements exist with the same id attribute value, then the each instance in the document shall be matched with an end in document order, and unmatched starts (no corresponding end) shall be handled as described above.
- If multiple move destination containers surround the same text, the last valid container (determined by the location of the container start elements, in document order) should be the container associated with that text.

[*Example*: Consider a WordprocessingML document in which the first paragraph contains two sentences, and the first sentence is moved before the second sentence, and this move is tracked as a revision, as follows (in this image, green underline indicates the move destination and the green strikethrough indicates the move source location):

This document has the sentence `Some moved text.` moved to the first sentence in the document. This revision is represented using the following WordprocessingML:

```
<w:p>
  <w:moveToRangeStart w:id="0" … w:name="move1" />
  <w:moveTo w:id="1" … >
    <w:r>
      <w:t>Some moved text.</w:t>
    </w:r>
  </w:moveTo>
  <w:moveToRangeEnd w:id="0" />
  <w:r>
    <w:t xml:space="preserve">Some text.</w:t>
  </w:r>
  <w:moveFromRangeStart w:id="2" … w:name="move1" />
  <w:moveFrom w:id="3" … >
    <w:r>
      <w:t>Some moved text.</w:t>
    </w:r>
  </w:moveFrom>
  <w:moveFromRangeEnd w:id="2" />
</w:p>
```

The moveToRangeStart element specifies the start of the move destination container within which all moved content is part of the move named `move1`. *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32); endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32); sdtContent (§2.5.2.33); sdtContent (§2.5.2.34); sdtContent (§2.5.2.35); smartTag (§2.5.1.9); sub (§7.1.2.112); sup (§7.1.2.114); tbl (§2.4.36); tc (§2.4.62); tr (§2.4.75); txbxContent (§2.17.1.1)

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`…`
	`</w:…>`

Attributes	Description
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

colFirst (First Table Column Covered By Bookmark)	Specifies the zero-based index of the first column in this row which shall be part of this bookmark.
	
	When a bookmark is contained within a table, it is possible for that bookmark to only cover cells within a certain column and row range within that table, by specifying:
	• The first row for which the specified columns are part of the table bookmark. This is accomplished by placing the bookmarkStart element in the first table cell in that row.
	• The first column included in the bookmark for each of the specified row(s) via this attribute.
	• The last column included in the bookmark for each of the specified row(s) via the colLast attribute.
	• The last row for which the specified columns are part of the table bookmark. This is accomplished by placing the bookmarkEnd element at the end of that table row.
	
	If this attribute appears, then the colLast attribute must also appear (regardless of where this bookmark is located) or the document shall be considered non-conformant. If this attibute and its pair occur on a bookmark which is not contained in a table, then their values should be ignored. If this value exceeds the value of colLast or the number of columns in the table, then both values should be ignored.
	
	[*Example*: Consider a three row by three column table where a table bookmark shall be applied to the contents of the first two cells in the first two rows in the table (the cells shaded below):
	
	 	
	This bookmark would be specified using the following WordprocessingML for the table's conents:
	
	`<w:tbl>`
	`…`
	`<w:tr>`
	`<w:tc>`
	`<w:bookMarkStart w:colFirst="0" w:colLast="1" w:id="0" w:name="table"/>`
	`<w:p/>`

Attributes	Description
	</w:tc> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> </w:tr> <w:tr> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:bookmarkEnd w:id="0" /> </w:tr> <w:tr> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> </w:tr> </w:tbl> The colFirst attribute specifies that all columns starting with the first column shall be included in the table bookmark. This will apply starting with the first row and ending with the second row (the two rows within the bookmark's start and end). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
colLast (Last Table Column Covered By Bookmark)	Specifies the zero-based index of the last column in this row which shall be part of this bookmark. When a bookmark is contained within a table, it is possible for that bookmark to only cover cells within a certain column and row range within that table, by specifying: • The first row for which the specified columns are part of the table bookmark. This is accomplished by placing the bookmarkStart element in the first table cell in that row.

Attributes	Description

	• The first column included in the bookmark for each of the specified row(s) via the colFirst attribute.
	• The last column included in the bookmark for each of the specified row(s) via this attribute.
	• The last row for which the specified columns are part of the table bookmark. This is accomplished by placing the bookmarkEnd element at the end of that table row.
	
	If this attribute appears, then the colFirst attribute must also appear (regardless of where this bookmark is located) or the document shall be considered non-conformant. If this attibute and its pair occur on a bookmark which is not contained in a table, then their values should be ignored. If this value does not equal or exceed the value of colFirst or the number of columns in the table, then both values should be ignored.
	
	[*Example*: Consider a three row by three column table where a table bookmark shall be applied to the contents of the first two cells in the first two rows in the table (the cells shaded below):
	
	 	
	This bookmark would be specified using the following WordprocessingML for the table's conents:
	
	`<w:tbl>`
	`  …`
	`  <w:tr>`
	`  <w:tc>`
	`  <w:bookMarkStart w:colFirst="0" w:colLast="1" w:id="0"`
	`w:name="table"/>`
	`  <w:p/>`
	`  </w:tc>`
	`  <w:tc>`
	`  <w:p/>`
	`  </w:tc>`
	`  <w:tc>`
	`  <w:p/>`
	`  </w:tc>`
	`  </w:tr>`
	`  <w:tr>`
	`  <w:tc>`
	`  <w:p/>`
	`  </w:tc>`
	`  <w:tc>`
	`  <w:p/>`

Attributes	Description
	</w:tc> <w:tc> <w:p/> </w:tc> <w:bookmarkEnd w:id="0" /> </w:tr> <w:tr> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> </w:tr> </w:tbl> The colLast attribute specifies that the last column that shall be included in the table bookmark is the second column. This will apply starting with the first row and ending with the second row (the two rows within the bookmark's start and end). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard. If this attribute is omitted, then no date information shall be associated with the parent annotation type. [*Example*: Consider a comment represented using the following WordprocessingML fragment: <w:… w:id="1" w:date="2006-01-01T10:00:00"> … </w:…> The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*] The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).
displacedByCustomXml (Annotation Marker Relocated	Specifies that the parent annotation's placement shall be directly linked with the location of the physical presentation of a custom XML element in the document. This element only has an effect when the custom XML element is block-level (i.e. surrounds an entire

Attributes	Description

For Custom XML Markup)	paragraph), as in this scenario the logical and physical placement of the annotation and custom XML element may differ.
	
	Specifically, in this case, the custom XML is presented *around* the block-level object it encloses (the paragraph, table, table row, or table cell), but is physically represented within that same object (i.e. within the paragraph, table, table row or table cell). This requirement stems from the fact that there is no location for the location of the annotation within the document at its logical location (around a table, for example).
	
	If this element is omitted, then the annotation shall be anchored inside of all block-level custom XML elements in the paragraph. If this element is present, but no block-level custom XML tag is located at the position it specifies (before or after), then it shall be ignored.
	
	[*Example*: Consider a paragraph with block level custom XML markup and two comment anchor annotations (one before and one after the custom XML element's physical representation), as follows:
	
	 	
	Since all three of these items are around the entire paragraph, they are stored outside of the paragraph. However, in order to ensure that their relative positions are stored correctly, any annotation which shall be displaced by the physical custom XML element specifies this information, resulting in the following WordprocessingML:
	
	`<w:commentRangeStart w:id="0" />`
	`<w:commentRangeStart w:id="1" w:displaced byCustomXml="next" />`
	`<w:customXml w:element="spec" … />`
	`<w:p>`
	`…`
	`</w:p>`
	
	The displacedByCustomXml attribute specifies that even though all three of these items are around the paragraph and will be moved inside the paragraph to be represented physically, the comment with ID 0 shall be inside the custom XML, but the comment with ID 1 shall be displaced to stay outside of the relative location of the next custom XML element (the spec element). *end example*]
	
	The possible values for this attribute are defined by the ST_DisplacedByCustomXml simple type (§2.18.17).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element. If this attribute is omitted, then the document is non-conformant.

Attributes	Description

	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

name (Bookmark Name)	Specifies the bookmark name.
	
	If multiple bookmarks in a document share the same name, then the first bookmark (defined by the location of the bookmarkStart element in document order) shall be maintained, and all subsequent bookmarks should be ignored.
	
	[*Example*: Consider the following XML for a bookmark around a single word:
	
	`<w:p>`
	`<w:bookmarkStart w:id="0" w:name="place" />`
	`<w:r>`
	`<w:t>Seattle</w:t>`
	`</w:r>`
	`<w:bookmarkEnd w:id="0" />`
	`</w:p>`
	
	The name attribute specifies that the name for this bookmark is `place`. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_MoveBookmark">
   <complexContent>
      <extension base="CT_Bookmark">
         <attribute name="author" type="ST_String" use="required"/>
         <attribute name="date" type="ST_DateTime" use="required"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.29 numberingChange (Previous Numbering Field Properties)

This element specifies the previous state of the numbering displayed by a LISTNUM field (§2.16.5.40) within a WordprocessingML document when additional LISTNUM fields are added and revisions are being tracked.

[*Rationale*: The legacy numbering mechanism provided by the LISTNUM field relies on the presence of fields in the run content of the document, rather than being a paragraph property (as numbering typically is represented). For this reason, these fields must store their previous state as a unique revision type on the field character of the numbering field. *end rationale*]

If this element is supplied for a field which is not of type LISTNUM as defined by its field codes (§2.16.5), then this property shall be ignored.

[*Example*: Consider the following paragraph containing a single LISTNUM field, as follows:

Some 1. text

If another LISTNUM field is added before it in the document, resulting in its evaluation to a different number, as follows:

Some ~~1.~~2. text

This revision to the field result would be stored as follows in the WordprocessingML:

```
<w:fldChar w:type="begin">
  <w:numberingChange w:id="0" … w:original="1." />
</w:fldChar>
<w:r>
  <w:instrText>LISTNUM</w:instrText>
</w:r>
<w:fldChar w:type="separate"/>
<w:r>
  <w:t>2.</w:t>
</w:r>
<w:fldChar w:type="end" />
```

The numberingChange element specifies that the numbering resulting from this LISTNUM field was modified and this change was tracked as a revision. The previous numbering result of `1.` is cached in the original attribute. *end example*]

For numbering fields, the original attribute shall specify the previous numbering displayed by the parent LISTNUM field within a WordprocessingML document. This information is a performance-enhancing cache of the state of the numbering before the revision to allow applications to show the previous state without having to recalculate all of the LISTNUM fields in the document.

If this attribute is omitted, then no previous numbering value is implied and applications may choose to calculate this value, or display no previous numbering value.

[*Example*: Consider the following paragraph containing a single LISTNUM field with a revision, as follows:

Some ~~1.~~2. text

This revision to the field result would be stored as follows in the WordprocessingML:

```
<w:fldChar w:type="begin">
  <w:numberingChange w:id="0" … w:original="1." />
</w:fldChar>
```

The original attribute specifies that the previous numbering value of the field was `1.` *end example*]

Parent Elements
fldChar (§2.16.18)

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`…`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`…`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at

Attributes	Description
	10:00 AM, which may be used as desired. *end example*] The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`  …`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

original (Previous Numbering Value)	Specifies the previous numbering displayed by the parent numbering change revision. Its format is specified by the parent element.
	
	If this attribute is omitted, then no previous numbering value is implied and applications may choose to calculate this value, or display no previous numbering value.
	
	[*Example*: Consider the following paragraph containing a single LISTNUM field with a revision, as follows:
	
	Some ~~1.~~2. text
	
	This revision to the field result would be stored as follows in the WordprocessingML:
	
	`<w:fldChar w:type="begin">`
	`  <w:numberingChange w:id="0" … w:original="1." />`
	`</w:fldChar>`
	
	The original attribute specifies that the previous numbering value of the field was 1. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrackChangeNumbering">
   <complexContent>
      <extension base="CT_TrackChange">
         <attribute name="original" type="ST_String" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.30 numberingChange (Previous Paragraph Numbering Properties)

This element specifies the previous state of the numbering on a paragraph when revisions are being tracked.

[*Rationale*: This mechanism is simply used to provide storage for revisions to numbering produced by legacy word processing applications, and applications are encouraged to use the pPrChange element to store these changes as changes to the paragraph properties instead. *end rationale*]

[*Example*: Consider the following list using Arabic numerals as the numbering, as follows:

1. one
2. two
3. three

Consider a revision where the numbering definition is changed from Arabic numerals to Roman numerals, as follows:

~~1~~ i. one
~~2~~ ii. two
~~3~~ iii. three

This revision to the numbering definition would be stored as follows in the WordprocessingML:

```
<w:p>
    <w:pPr>
        <w:numPr>
            <w:ilvl w:val="0" />
            <w:numId w:val="1" />
            <w:numberingChange w:id="0" … w:original="%1:1:0:." />
        </w:numPr>
    </w:pPr>
    <w:r>
        <w:t>one</w:t>
    </w:r>
</w:p>
<w:p>
    <w:pPr>
        <w:numPr>
```

```
                <w:ilvl w:val="0" />
                <w:numId w:val="1" />
                <w:numberingChange w:id="1" … w:original="%1:2:0:." />
          </w:numPr>
    </w:pPr>
    <w:r>
          <w:t>two</w:t>
    </w:r>
</w:p>
<w:p>
    <w:pPr>
          <w:numPr>
                <w:ilvl w:val="0" />
                <w:numId w:val="1" />
                <w:numberingChange w:id="2" … w:original="%1:3:0:." />
          </w:numPr>
    </w:pPr>
    <w:r>
          <w:t>three</w:t>
    </w:r>
</w:p>
```

The numberingChange element specifies that the numbering definition was modified and this change was tracked as a revision. The previous Arabic numeral numbering definition is cached in the original attribute. *end example*]

For paragraph numbering, the original attribute shall specify the previous numbering definition for an individual paragraph of text within a WordprocessingML document while revisions are being tracked.

The value of original is represented as separate numbering level definitions defined as follows:

```
<%[numbering level]:[nfc value]:[numbering format]:[separator]>[repeat if more
than one level]
```

where

- numbering level – The level for which the numbering definition is defined
- nfc value – The value of the numbering style at the specific numbering level
- numbering format – The nfc value of the numbering format, as referenced in the table below.
- separator – The separator used to separate the numbering level definitions

The numbering format values are mapped as follows:

nfc Value	ST_NumberFormat enumeration equivalent
0	decimal

nfc Value	ST_NumberFormat enumeration equivalent
1	upperRoman
2	lowerRoman
3	upperLetter
4	lowerLetter
5	ordinal
6	cardinalText
7	ordinalText
8	hex
9	chicago
10	ideographDigital
11	japaneseCounting
12	Aiueo
13	Iroha
14	decimalFullWidth
15	decimalHalfWidth
16	japaneseLegal
17	japaneseDigitalTenThousand
18	decimalEnclosedCircle
19	decimalFullWidth2
20	aiueoFullWidth
21	irohaFullWidth
22	decimalZero
23	bullet
24	ganada
25	chosung
26	decimalEnclosedFullstop
27	decimalEnclosedParen
28	decimalEnclosedCircleChinese
29	ideographEnclosedCircle
30	ideographTraditional
31	ideographZodiac
32	ideographZodiacTraditional
33	taiwaneseCounting
34	ideographLegalTraditional
35	taiwaneseCountingThousand
36	taiwaneseDigital
37	chineseCounting
38	chineseLegalSimplified

nfc Value	ST_NumberFormat enumeration equivalent
39	chineseCountingThousand
40	Application-defined. May be ignored.
41	koreanDigital
42	koreanCounting
43	koreanLegal
44	koreanDigital2
45	hebrew1
46	arabicAlpha
47	hebrew2
48	arabicAbjad
49	hindiVowels
50	hindiConsonants
51	hindiNumbers
52	hindiCounting
53	thaiLetters
54	thaiNumbers
55	thaiCounting
56	vietnameseCounting
57	numberInDash
58	russianLower
59	russianUpper
60 or above	Application-defined. May be ignored.

[*Example*: Consider the following numbered paragraph where the numbering definition has changed while revisions are being tracked, as follows:

~~1.~~ ~~i.~~ ~~1.~~ 1. Three

This revision to the numbered paragraph would be stored as follows in the WordprocessingML:

```
<w:numPr>
  …
  <w:numberingChange … w:original="%1:1:0:.%2:1:2:.%3:1:0:." />
</w:numPr>
```

In the above example there are three levels in the original numbering definition, thus three numbering level definitions are needed to represent the original numbering definition.

The first level is specified by `%1`, and says that it was number value `1` in the nfc format `0` (`arabic`).

The original attribute specifies that the previous numbering definition was made up of three levels whose value was `1.i.1.`. *end example*]

Parent Elements
numPr (§2.3.1.19)

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`…`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`…`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element. If this attribute is omitted, then the document is non-conformant.

Attributes	Description

	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

original (Previous Numbering Value)	Specifies the previous numbering displayed by the parent numbering change revision. Its format is specified by the parent element.
	
	If this attribute is omitted, then no previous numbering value is implied and applications may choose to calculate this value, or display no previous numbering value.
	
	[*Example*: Consider the following paragraph containing a single LISTNUM field with a revision, as follows:
	
	Some ~~1.~~2. text
	
	This revision to the field result would be stored as follows in the WordprocessingML:
	
	`<w:fldChar w:type="begin">`
	`<w:numberingChange w:id="0" … w:original="1." />`
	`</w:fldChar>`
	
	The original attribute specifies that the previous numbering value of the field was 1. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrackChangeNumbering">
   <complexContent>
      <extension base="CT_TrackChange">
         <attribute name="original" type="ST_String" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.31 pPrChange (Revision Information for Paragraph Properties)

This element specifies the details about a single revision to a set of paragraph properties in a WordprocessingML document.

This element stores this revision as follows:

- The child element of this element contains the complete set of paragraph properties which were applied to this paragraph before this revision
- The attributes of this element contain information about when this revision took place (i.e. when these properties became a 'former' set of paragraph properties).

[*Example*: Consider a paragraph in a WordprocessingML document which is centered, and this change in the paragraph properties is tracked as a revision. This revision would be specified using the following WordprocessingML markup:

```
<w:pPr>
  <w:jc w:val="center"/>
  <w:pPrChange w:id="0" w:date="01-01-2006T12:00:00" w:author="John Doe">
    <w:pPr/>
  </w:pPrChange>
</w:pPr>
```

The pPrChange element specifies that there was a revision to the paragraph properties at `01-01-2006` by `John Doe`, and the previous set of paragraph properties on the paragraph were the null set (i.e. no paragraph properties explicitly present under the pPr element). *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Child Elements	Subclause
pPr (Previous Paragraph Properties)	§2.3.1.25

Attributes	Description
author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document. If this attribute is omitted, then no author shall be associated with the parent annotation type. [*Example*: Consider a comment represented using the following WordprocessingML fragment: `<w:… w:id="1" w:author="Example Author">`

Attributes	Description
	… </w:…> The author attribute specifies that the author of the current annotation is Example Author, which may be used as desired. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).
date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard. If this attribute is omitted, then no date information shall be associated with the parent annotation type. [*Example*: Consider a comment represented using the following WordprocessingML fragment: <w:… w:id="1" w:date="2006-01-01T10:00:00"> … </w:…> The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*] The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).
id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element. If this attribute is omitted, then the document is non-conformant. [*Example*: Consider an annotation represented using the following WordprocessingML fragment: <w:… w:id="1" … > … </w:…> The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_PPrChange">
   <complexContent>
      <extension base="CT_TrackChange">
         <sequence>
            <element name="pPr" type="CT_PPrBase" minOccurs="1"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.32 rPrChange (Revision Information for Run Properties)

This element specifies the details about a single revision to a set of run properties in a WordprocessingML document.

This element stores this revision as follows:

- The child element of this element contains the complete set of run properties which were applied to this run before this revision
- The attributes of this element contain information about when this revision took place (i.e. when these properties became a 'former' set of run properties).

[*Example*: Consider an italicized run in a WordprocessingML document which is also made bold and the latter change in the run properties is tracked as a revision. This revision would be specified using the following WordprocessingML markup:

```
<w:rPr>
  <w:b/>
  <w:i/>
  <w:rPrChange w:id="0" w:date="01-01-2006T12:00:00" w:author="John Doe">
    <w:rPr>
      <w:i/>
    </w:rPr>
  </w:rPrChange>
</w:rPr>
```

The rPrChange element specifies that there was a revision to the run properties at `01-01-2006` by `John Doe`, and the previous set of run properties was simply the italicization using the i element (§2.3.2.14). *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.7.4.4); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Child Elements	Subclause
rPr (Previous Run Properties)	§2.3.2.26

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`…`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`…`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`

Attributes	Description
	</w:…> The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RPrChange">
   <complexContent>
      <extension base="CT_TrackChange">
         <sequence>
            <element name="rPr" type="CT_RPrOriginal" minOccurs="1"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.33 rPrChange (Revision Information for Run Properties on the Paragraph Mark)

This element specifies the details about a single revision to a set of run properties applied to a paragraph mark within a WordprocessingML document.

This element stores this revision as follows:

- The child element of this element contains the complete set of run properties which were applied to this paragraph mark before this revision
- The attributes of this element contain information about when this revision took place (i.e. when these properties became a 'former' set of run properties).

[*Example*: Consider an italicized paragraph mark in a WordprocessingML document which is also made bold and the latter change in the run properties is tracked as a revision. This revision would be specified using the following WordprocessingML markup:

```
<w:rPr>
  <w:b/>
  <w:i/>
  <w:rPrChange w:id="0" w:date="01-01-2006T12:00:00" w:author="John Doe">
    <w:rPr>
      <w:i/>
    </w:rPr>
  </w:rPrChange>
</w:rPr>
```

The rPrChange element specifies that there was a revision to the paragraph mark's run properties at 01-01-2006 by John Doe, and the previous set of run properties was simply the italicization using the i element (§2.3.2.14). *end example*]

Parent Elements
rPr (§2.3.1.29)

Child Elements	Subclause
rPr (Previous Run Properties for the Paragraph Mark)	§2.3.1.30

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`…`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is Example Author, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`…`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_ParaRPrChange">
   <complexContent>
      <extension base="CT_TrackChange">
         <sequence>
            <element name="rPr" type="CT_ParaRPrOriginal" minOccurs="1"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.34 sectPrChange (Revision Information for Section Properties)

This element specifies the details about a single revision to a set of section properties in a WordprocessingML document.

This element stores this revision as follows:

- The child element of this element contains the complete set of section properties which were applied to the parent section before this revision
- The attributes of this element contain information about when this revision took place (i.e. when these properties became a 'former' set of section properties).

[*Example*: Consider a section in a WordprocessingML document which is set to be divided into three columns, and this change in the section properties is tracked as a revision. This revision would be specified using the following WordprocessingML markup:

```
<w:sectPr>
  <w:cols w:val="3"/>
  <w:sectPrChange w:id="0" w:date="01-01-2006T12:00:00" w:author="John Doe">
    <w:sectPr/>
  </w:sectPrChange>
</w:sectPr>
```

The sectPrChange element specifies that there was a revision to the section properties at `01-01-2006` by `John Doe`, and the previous set of properties on the section were the null set (i.e. no section properties explicitly present under the sectPr element). *end example*]

Parent Elements
sectPr (§2.6.18); sectPr (§2.6.19)

Child Elements	Subclause
sectPr (Previous Section Properties)	§2.6.17

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`…`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard. If this attribute is omitted, then no date information shall be associated with the parent annotation type. [*Example*: Consider a comment represented using the following WordprocessingML fragment:

Attributes	Description
	<w:… w:id="1" w:date="2006-01-01T10:00:00"> … </w:…> The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*] The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).
id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element. If this attribute is omitted, then the document is non-conformant. [*Example*: Consider an annotation represented using the following WordprocessingML fragment: <w:… w:id="1" … > … </w:…> The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SectPrChange">
   <complexContent>
      <extension base="CT_TrackChange">
         <sequence>
            <element name="sectPr" type="CT_SectPrBase" minOccurs="0"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.35 tblGridChange (Revision Information for Table Grid Column Definitions)

This element specifies the details about a single revision to a table's grid column definitions within a WordprocessingML document.

This element stores this revision as follows:

- The child element of this element contains the definition of the table grid which was applied to the parent table before this revision

[*Example*: Consider a two column table in a WordprocessingML document which has the width of its first column significantly reduced, and this change in the table grid is tracked as a revision. This revision would be specified using the following WordprocessingML markup:

```
<w:tblGrid>
  <w:gridCol w:w="1548" />
  <w:gridCol w:w="8028" />
  <w:tblGridChange w:id="1">
    <w:tblGrid>
      <w:gridCol w:w="4788" />
      <w:gridCol w:w="4788" />
    </w:tblGrid>
  </w:tblGridChange>
</w:tblGrid>
```

The tblGridChange element specifies that there was a revision to the table grid, and the previous table grid had both columns with a width of 4788 twentieths of a point, vs. their current widths of 1548 and 8028 twentieths of a point respectively. *end example*]

Parent Elements
tblGrid (§2.4.44)

Child Elements	Subclause
tblGrid (Previous Table Grid)	§2.4.45

Attributes	Description

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`  …`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblGridChange">
   <complexContent>
      <extension base="CT_Markup">
         <sequence>
            <element name="tblGrid" type="CT_TblGridBase"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.36 tblPrChange (Revision Information for Table Properties)

This element specifies the details about a single revision to a set of table properties in a WordprocessingML document.

This element stores this revision as follows:

- The child element of this element contains the complete set of table properties which were applied to the parent table before this revision
- The attributes of this element contain information about when this revision took place (i.e. when these properties became a 'former' set of table properties).

[*Example*: Consider a table in a WordprocessingML document which has the associated table style changed from `LightList` to `LightShading`, and this change in the table properties is tracked as a revision. This revision would be specified using the following WordprocessingML markup:

```
<w:tblPr>
  <w:tblStyle w:val="LightShading"/>
  <w:tblW w:w="0" w:type="auto"/>
  <w:tblLook w:val="04A0"/>
  <w:tblPrChange w:id="0" w:author="Tristan Davis" w:date="2006-06-
01T13:39:00Z">
    <w:tblPr>
      <w:tblStyle w:val="LightList"/>
      <w:tblW w:w="0" w:type="auto"/>
      <w:tblLook w:val="04A0"/>
    </w:tblPr>
  </w:tblPrChange>
</w:tblPr>
```

The tblPrChange element specifies that there was a revision to the table properties at `2006-06-01` by `Tristan Davis`, and the previous set of properties on the table was the set specifies in the child tblPr element (including the table style of `LightList`). *end example*]

Parent Elements

Parent Elements
tblPr (§2.4.55)

Child Elements	Subclause
tblPr (Previous Table Properties)	§2.4.56

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`…`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`…`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.

Attributes	Description

	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblPrChange">
   <complexContent>
      <extension base="CT_TrackChange">
         <sequence>
            <element name="tblPr" type="CT_TblPrBase"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.37 tblPrExChange (Revision Information for Table-Level Property Exceptions)

This element specifies the details about a single revision to a set of table-level property exceptions in a WordprocessingML document.

This element stores this revision as follows:

- The child element of this element contains the complete set of table-level property exceptions which were applied to the parent table row before this revision
- The attributes of this element contain information about when this revision took place (i.e. when these properties became a 'former' set of table-level exception properties).

[*Example*: Consider a set of table rows which are part of a table in a WordprocessingML document, have table-level property exceptions, and this change in the table-level properties to a fixed table width of ten inches is tracked as a revision. This revision would be specified using the following WordprocessingML markup:

```
<w:tblPrEx>
  <w:tblW w:w="14400" w:type="dxa"/>
  <w:tblPrExChange w:id="0" w:author="Tristan Davis" w:date="2006-06-
01T13:39:00Z">
    <w:tblPrEx>
      <w:tblW w:w="0" w:type="auto"/>
    </w:tblPrEx>
  </w:tblPrExChange>
</w:tblPrEx>
```

The tblPrExChange element specifies that there was a revision to the table-level property exceptions at `2006-06-01` by `Tristan Davis`, and the previous set of table-level property exceptions set specifies in the child tblPrEx element. *end example*]

Parent Elements
tblPrEx (§2.4.57)

Child Elements	Subclause
tblPrEx (Previous Table-Level Property Exceptions)	§2.4.58

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`…`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard. If this attribute is omitted, then no date information shall be associated with the parent annotation type.

Attributes	Description

	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`…`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblPrExChange">
   <complexContent>
      <extension base="CT_TrackChange">
         <sequence>
            <element name="tblPrEx" type="CT_TblPrExBase" minOccurs="1"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.13.5.38 tcPrChange (Revision Information for Table Cell Properties)

This element specifies the details about a single revision to a set of table cell properties in a WordprocessingML document.

This element stores this revision as follows:

- The child element of this element contains the complete set of table cell properties which were applied to the parent table before this revision
- The attributes of this element contain information about when this revision took place (i.e. when these properties became a 'former' set of table cell properties).

[*Example*: Consider a table cell in a WordprocessingML document which has a change in the table cell properties that is tracked as a revision. This revision would be specified using the following WordprocessingML markup:

```
<w:tcPr>
  <w:cnfStyle w:val="001000000000"/>
  <w:tcW w:w="3192" w:type="dxa"/>
  <w:tcPrChange w:id="8" w:author="Tristan Davis" w:date="2006-06-01T13:39:00Z">
    <w:tcPr>
      <w:tcW w:w="3192" w:type="dxa"/>
    </w:tcPr>
  </w:tcPrChange>
</w:tcPr>
```

The tcPrChange element specifies that there was a revision to the table cell properties at `2006-06-01` by `Tristan Davis`, and the previous set of properties on the table cell was the set specifies in the child tcPr element. *end example*]

Parent Elements
tcPr (§2.7.5.8); tcPr (§2.7.5.9); tcPr (§2.4.67)

Child Elements	Subclause
tcPr (Previous Table Cell Properties)	§2.4.66

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`…`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example`

Attributes	Description
	Author, which may be used as desired. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`…`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TcPrChange">
    <complexContent>
        <extension base="CT_TrackChange">
            <sequence>
                <element name="tcPr" type="CT_TcPrInner" minOccurs="1"/>
            </sequence>
        </extension>
    </complexContent>
</complexType>
```

2.13.5.39 trPrChange (Revision Information for Table Row Properties)

This element specifies the details about a single revision to a set of table row properties in a WordprocessingML document.

This element stores this revision as follows:

- The child element of this element contains the complete set of table row properties which were applied to the parent table row before this revision
- The attributes of this element contain information about when this revision took place (i.e. when these properties became a 'former' set of table row properties).

[*Example*: Consider a table cell in a WordprocessingML document which has a change in the table row properties that is tracked as a revision. This revision would be specified using the following WordprocessingML markup:

```
<w:trPr>
  <w:cantSplit/>
  <w:trPrChange w:id="8" w:author="Tristan Davis" w:date="2006-06-01T13:39:00Z">
    <w:trPr/>
  </w:trPrChange>
</w:trPr>
```

The trPrChange element specifies that there was a revision to the table row properties at `2006-06-01` by `Tristan Davis`, and the previous set of properties on the table row was the set specified in the child trPr element (in this case, the null set). *end example*]

Parent Elements
trPr (§2.7.5.10); trPr (§2.7.5.11); trPr (§2.4.78)

Child Elements	Subclause
trPr (Previous Table Row Properties)	§2.4.79

Attributes	Description

author (Annotation Author)	Specifies the author for an annotation within a WordprocessingML document.
	
	If this attribute is omitted, then no author shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:author="Example Author">`
	`  …`
	`</w:…>`
	
	The author attribute specifies that the author of the current annotation is `Example Author`, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

date (Annotation Date)	Specifies the date information for an annotation within a WordprocessingML document. The use of this information is outside of the scope of this Office Open XML Standard.
	
	If this attribute is omitted, then no date information shall be associated with the parent annotation type.
	
	[*Example*: Consider a comment represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" w:date="2006-01-01T10:00:00">`
	`  …`
	`</w:…>`
	
	The date attribute specifies that the date of the current annotation is January 1st 2006 at 10:00 AM, which may be used as desired. *end example*]
	
	The possible values for this attribute are defined by the ST_DateTime simple type (§2.18.15).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`  …`
	`</w:…>`

Attributes	Description
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrPrChange">
   <complexContent>
      <extension base="CT_TrackChange">
         <sequence>
            <element name="trPr" type="CT_TrPrBase" minOccurs="1"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.13.6 Bookmarks

Within a WordprocessingML document, *bookmarks* refer to arbitrary regions of content which are bounded and have a unique name associated with them.

Because bookmarks are a legacy word processing function which predates the concepts of XML and well-formedness, they can start and end at any location within a document's contents and therefore must use the "cross-structure" annotation format described in §2.13.2.

[*Example*: Consider the following WordprocessingML markup for two paragraphs, each reading `Example Text`, where a bookmark has been added spanning the second word in paragraph one and the first word in paragraph two:

```
<w:p>
  <w:r>
    <w:t>Example</w:t>
  </w:r>
  <w:bookmarkStart w:id="0" w:name="sampleBookmark" />
  <w:r>
    <w:t xml:space="preserve"> text.</w:t>
  </w:r>
</w:p>
<w:p>
  <w:r>
    <w:t>Example</w:t>
  </w:r>
  <w:bookmarkEnd w:id="0" />
  <w:r>
    <w:t xml:space="preserve"> text.</w:t>
  </w:r>
</w:p>
```

The bookmarkStart and bookmarkEnd elements (§2.13.6.2; §2.13.6.1) specify the location where the bookmark starts and ends, but cannot contain it using a single tag because it spans part of two paragraphs. However, the two tags are part of one group because the id attribute value specifies `0` for both. *end example*]

2.13.6.1 bookmarkEnd (Bookmark End)

This element specifies the end of a bookmark within a WordprocessingML document. This end marker is matched with the appropriately paired start marker by matching the value of the id attribute from the associated bookmarkStart element.

If no bookmarkStart element exists prior to this element in document order with a matching id attribute value, then this element is ignored and no bookmark is present in the document with this name.

[*Example*: Consider a document with a bookmark which spans half of paragraph one, and part of paragraph two. The following WordprocessingML illustrates an example of content which fufills this constraint:

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">This is sentence one.</w:t>
  </w:r>
  <w:bookmarkStart w:id="0" w:name="testing123"/>
  <w:r>
    <w:t>This is sentence two.</w:t>
  </w:r>
</w:p>
```

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">This </w:t>
  </w:r>
  <w:bookmarkEnd w:id="0"/>
  <w:r>
    <w:t>is sentence three.</w:t>
  </w:r>
</w:p>
```

The bookmarkEnd element specifies the end of the region for the bookmark whose bookmarkStart element has an id attribute value of `0`. In this case, this refers to the `testing123` bookmark. *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32); endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32); sdtContent (§2.5.2.33); sdtContent (§2.5.2.34); sdtContent (§2.5.2.35); smartTag (§2.5.1.9); sub (§7.1.2.112); sup (§7.1.2.114); tbl (§2.4.36); tc (§2.4.62); tr (§2.4.75); txbxContent (§2.17.1.1)

Attributes	Description
displacedByCustomXml (Annotation Marker Relocated For Custom XML Markup)	Specifies that the parent annotation's placement shall be directly linked with the location of the physical presentation of a custom XML element in the document. This element only has an effect when the custom XML element is block-level (i.e. surrounds an entire paragraph), as in this scenario the logical and physical placement of the annotation and custom XML element may differ. Specifically, in this case, the custom XML is presented *around* the block-level object it encloses (the paragraph, table, table row, or table cell), but is physically represented within that same object (i.e. within the paragraph, table, table row or table cell). This requirement stems from the fact that there is no location for the location of the annotation within the document at its logical location (around a table, for example). If this element is omitted, then the annotation shall be anchored inside of all block-level custom XML elements in the paragraph. If this element is present, but no block-level custom XML tag is located at the position it specifies (before or after), then it shall be ignored. [*Example*: Consider a paragraph with block level custom XML markup and two comment anchor annotations (one before and one after the custom XML element's physical representation), as follows:

Attributes	Description

		
	Since all three of these items are around the entire paragraph, they are stored outside of the paragraph. However, in order to ensure that their relative positions are stored correctly, any annotation which shall be displaced by the physical custom XML element specifies this information, resulting in the following WordprocessingML:
	
	`<w:commentRangeStart w:id="0" />`
	`<w:commentRangeStart w:id="1" w:displaced byCustomXml="next" />`
	`<w:customXml w:element="spec" … />`
	`<w:p>`
	`…`
	`</w:p>`
	
	The displacedByCustomXml attribute specifies that even though all three of these items are around the paragraph and will be moved inside the paragraph to be represented physically, the comment with ID 0 shall be inside the custom XML, but the comment with ID 1 shall be displaced to stay outside of the relative location of the next custom XML element (the spec element). *end example*]
	
	The possible values for this attribute are defined by the ST_DisplacedByCustomXml simple type (§2.18.17).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_MarkupRange">
   <complexContent>
      <extension base="CT_Markup">
         <attribute name="displacedByCustomXml" type="ST_DisplacedByCustomXml" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.6.2 bookmarkStart (Bookmark Start)

This element specifies the start of a bookmark within a WordprocessingML document. This start marker is matched with the appropriately paired end marker by matching the value of the id attribute from the associated bookmarkEnd element.

If no bookmarkEnd element exists subsequent to this element in document order with a matching id attribute value, then this element is ignored and no bookmark is present in the document with this name.

If a bookmark begins and ends within a single table, it is possible for that bookmark to cover discontiguous parts of that table which are logically related (e.g. a single column in a table). This type of placement for a bookmark is accomplished (and described in detail) on the colFirst and colLast attributes on this element.

[*Example*: Consider a document with a bookmark which spans half of paragraph one, and part of paragraph two. The following WordprocessingML illustrates an example of content which fufills this constraint:

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">This is sentence one.</w:t>
  </w:r>
  <w:bookmarkStart w:id="0" w:name="testing123"/>
  <w:r>
    <w:t>This is sentence two.</w:t>
  </w:r>
</w:p>
<w:p>
  <w:r>
    <w:t xml:space="preserve">This </w:t>
  </w:r>
  <w:bookmarkEnd w:id="0"/>
  <w:r>
    <w:t>is sentence three.</w:t>
  </w:r>
</w:p>
```

The bookmarkStart element specifies the start of the region for the `testing123` bookmark. This element is then linked to the bookmarkEnd element which also has an id attribute value of `0`. *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32); endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32); sdtContent (§2.5.2.33); sdtContent (§2.5.2.34); sdtContent (§2.5.2.35); smartTag (§2.5.1.9); sub (§7.1.2.112); sup (§7.1.2.114); tbl (§2.4.36); tc (§2.4.62); tr (§2.4.75); txbxContent (§2.17.1.1)

Attributes	Description
colFirst (First Table Column Covered By Bookmark)	Specifies the zero-based index of the first column in this row which shall be part of this bookmark. When a bookmark is contained within a table, it is possible for that bookmark to only cover cells within a certain column and row range within that table, by specifying: • The first row for which the specified columns are part of the table bookmark. This is accomplished by placing the bookmarkStart element in the first table cell in that row. • The first column included in the bookmark for each of the specified row(s) via this attribute. • The last column included in the bookmark for each of the specified row(s) via the colLast attribute. • The last row for which the specified columns are part of the table bookmark. This is accomplished by placing the bookmarkEnd element at the end of that table row. If this attribute appears, then the colLast attribute must also appear (regardless of where this bookmark is located) or the document shall be considered non-conformant. If this attibute and its pair occur on a bookmark which is not contained in a table, then their values should be ignored. If this value exceeds the value of colLast or the number of columns in the table, then both values should be ignored. [*Example*: Consider a three row by three column table where a table bookmark shall be applied to the contents of the first two cells in the first two rows in the table (the cells shaded below):  This bookmark would be specified using the following WordprocessingML for the table's conents: `<w:tbl>`

Attributes	Description
	… <w:tr> <w:tc> <w:bookMarkStart w:colFirst="0" w:colLast="1" w:id="0" w:name="table"/> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> </w:tr> <w:tr> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:bookmarkEnd w:id="0" /> </w:tr> <w:tr> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> </w:tr> </w:tbl> The colFirst attribute specifies that all columns starting with the first column shall be included in the table bookmark. This will apply starting with the first row and ending with the second row (the two rows within the bookmark's start and end). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
colLast (Last Table Column Covered By	Specifies the zero-based index of the last column in this row which shall be part of this bookmark.

Attributes	Description

Bookmark)	When a bookmark is contained within a table, it is possible for that bookmark to only cover cells within a certain column and row range within that table, by specifying:
	• The first row for which the specified columns are part of the table bookmark. This is accomplished by placing the bookmarkStart element in the first table cell in that row.
	• The first column included in the bookmark for each of the specified row(s) via the colFirst attribute.
	• The last column included in the bookmark for each of the specified row(s) via this attribute.
	• The last row for which the specified columns are part of the table bookmark. This is accomplished by placing the bookmarkEnd element at the end of that table row.
	
	If this attribute appears, then the colFirst attribute must also appear (regardless of where this bookmark is located) or the document shall be considered non-conformant. If this attibute and its pair occur on a bookmark which is not contained in a table, then their values should be ignored. If this value does not equal or exceed the value of colFirst or the number of columns in the table, then both values should be ignored.
	
	[*Example*: Consider a three row by three column table where a table bookmark shall be applied to the contents of the first two cells in the first two rows in the table (the cells shaded below):
	
	 	
	This bookmark would be specified using the following WordprocessingML for the table's conents:
	
	`<w:tbl>`
	`…`
	`<w:tr>`
	`<w:tc>`
	`<w:bookMarkStart w:colFirst="0" w:colLast="1" w:id="0" w:name="table"/>`
	`<w:p/>`
	`</w:tc>`
	`<w:tc>`
	`<w:p/>`
	`</w:tc>`
	`<w:tc>`
	`<w:p/>`
	`</w:tc>`

Attributes	Description
	</w:tr> <w:tr> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:bookmarkEnd w:id="0" /> </w:tr> <w:tr> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> </w:tr> </w:tbl> The colLast attribute specifies that the last column that shall be included in the table bookmark is the second column. This will apply starting with the first row and ending with the second row (the two rows within the bookmark's start and end). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
displacedByCustomXml (Annotation Marker Relocated For Custom XML Markup)	Specifies that the parent annotation's placement shall be directly linked with the location of the physical presentation of a custom XML element in the document. This element only has an effect when the custom XML element is block-level (i.e. surrounds an entire paragraph), as in this scenario the logical and physical placement of the annotation and custom XML element may differ. Specifically, in this case, the custom XML is presented *around* the block-level object it encloses (the paragraph, table, table row, or table cell), but is physically represented within that same object (i.e. within the paragraph, table, table row or table cell). This requirement stems from the fact that there is no location for the location of the annotation within the document at its logical location (around a table, for example). If this element is omitted, then the annotation shall be anchored inside of all block-level custom XML elements in the paragraph. If this element is present, but no block-level custom XML tag is located at the position it specifies (before or after), then it shall be

Attributes	Description

	ignored.
	
	[*Example*: Consider a paragraph with block level custom XML markup and two comment anchor annotations (one before and one after the custom XML element's physical representation), as follows:
	
	 	
	Since all three of these items are around the entire paragraph, they are stored outside of the paragraph. However, in order to ensure that their relative positions are stored correctly, any annotation which shall be displaced by the physical custom XML element specifies this information, resulting in the following WordprocessingML:
	
	`<w:commentRangeStart w:id="0" />`
	`<w:commentRangeStart w:id="1" w:displaced byCustomXml="next" />`
	`<w:customXml w:element="spec" … />`
	`<w:p>`
	`…`
	`</w:p>`
	
	The displacedByCustomXml attribute specifies that even though all three of these items are around the paragraph and will be moved inside the paragraph to be represented physically, the comment with ID 0 shall be inside the custom XML, but the comment with ID 1 shall be displaced to stay outside of the relative location of the next custom XML element (the spec element). *end example*]
	
	The possible values for this attribute are defined by the ST_DisplacedByCustomXml simple type (§2.18.17).

id (Annotation Identifier)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type

Attributes	Description
	(§2.18.16).

name (Bookmark Name)	Specifies the bookmark name.
	
	If multiple bookmarks in a document share the same name, then the first bookmark (defined by the location of the bookmarkStart element in document order) shall be maintained, and all subsequent bookmarks should be ignored.
	
	[*Example*: Consider the following XML for a bookmark around a single word:
	
	`<w:p>`
	`  <w:bookmarkStart w:id="0" w:name="place" />`
	`  <w:r>`
	`  <w:t>Seattle</w:t>`
	`  </w:r>`
	`  <w:bookmarkEnd w:id="0" />`
	`</w:p>`
	
	The name attribute specifies that the name for this bookmark is `place`. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Bookmark">
    <complexContent>
        <extension base="CT_BookmarkRange">
            <attribute name="name" type="ST_String" use="required"/>
        </extension>
    </complexContent>
</complexType>
```

2.13.7 Range Permissions

Range permissions in a WordprocessingML document refer to a special type of bookmark used to control which subset(s) of users may edit a particular region of a document. Range permissions specify the user or set of users which are allowed to edit all content between them whenever the document protection specified by the documentProtection element (§2.15.1.28) is enabled and set to `readOnly` or `comments`.

Like bookmarks, range permissions are a legacy word processing function which predates the concepts of XML and well-formedness, so they can start and end at any location within a document's contents and therefore must use the "cross-structure" annotation format described in §2.13.2.

[*Example*: Consider the following WordprocessingML markup for a single paragraph, where a range permission has been added spanning the words `range permission`:

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">This is a </w:t>
  </w:r>
  <w:permStart w:id="0" w:edGrp="everyone"/>
  <w:r>
    <w:t>range permission</w:t>
  </w:r>
  <w:permEnd w:id="0"/>
  <w:r>
    <w:t>.</w:t>
  </w:r>
</w:p>
```

The permStart and permEnd elements (§2.13.7.1; §2.13.7.2) specify the location where the range permission starts and ends. The two tags are part of one group because the id attribute value specifies `0` for both.

If document protection was enabled, then no content in this document shall be editable except for this range permission, which is editable by all users that open the document (specified using an editor group of everyone). *end example*]

2.13.7.1 permEnd (Range Permission End)

This element specifies the end of a single range permission within a WordprocessingML document. This end marker is matched with the appropriately paired start marker by matching the value of the id attribute from the associated permStart element.

If no permStart element exists prior to this element in document order with a matching id attribute value, then this element is ignored and no range permission is present in the document.

[*Example*: Consider a document with a range permission which spans half of paragraph one, and part of paragraph two. The following WordprocessingML illustrates an example of content which fufills this constraint:

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">This is sentence one.</w:t>
  </w:r>
  <w:permStart w:id="0" w:edGrp="everyone"/>
  <w:r>
    <w:t>This is sentence two.</w:t>
  </w:r>
</w:p>
```

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">This </w:t>
  </w:r>
  <w:permEnd w:id="0"/>
  <w:r>
    <w:t>is sentence three.</w:t>
  </w:r>
</w:p>
```

The permEnd element specifies the end of the region for the range permission whose permStart element has an id attribute value of `0`. *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32); endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32); sdtContent (§2.5.2.33); sdtContent (§2.5.2.34); sdtContent (§2.5.2.35); smartTag (§2.5.1.9); sub (§7.1.2.112); sup (§7.1.2.114); tbl (§2.4.36); tc (§2.4.62); tr (§2.4.75); txbxContent (§2.17.1.1)

Attributes	Description
displacedByCustomXml (Annotation Displaced By Custom XML Markup)	Specifies that the parent annotation's placement shall be directly linked with the location of the physical presentation of a custom XML element in the document. This element only has an effect when the custom XML element is block-level (i.e. surrounds an entire paragraph), as in this scenario the logical and physical placement of the annotation and custom XML element may differ. Specifically, in this case, the custom XML is presented *around* the block-level object it encloses (the paragraph, table, table row, or table cell), but is physically represented within that same object (i.e. within the paragraph, table, table row or table cell). This requirement stems from the fact that there is no location for the location of the annotation within the document at its logical location (around a table, for example). If this element is omitted, then the annotation shall be anchored inside of all block-level custom XML elements in the paragraph. If this element is present, but no block-level custom XML tag is located at the position it specifies (before or after), then it shall be ignored. [*Example*: Consider a paragraph with block level custom XML markup and two comment anchor annotations (one before and one after the custom XML element's physical representation), as follows:

Attributes	Description

		
	Since all three of these items are around the entire paragraph, they are stored outside of the paragraph. However, in order to ensure that their relative positions are stored correctly, any annotation which shall be displaced by the physical custom XML element specifies this information, resulting in the following WordprocessingML:
	
	`<w:commentRangeStart w:id="0" />`
	`<w:commentRangeStart w:id="1" w:displaced byCustomXml="next" />`
	`<w:customXml w:element="spec" … />`
	`<w:p>`
	`…`
	`</w:p>`
	
	The displacedByCustomXml attribute specifies that even though all three of these items are around the paragraph and will be moved inside the paragraph to be represented physically, the comment with ID 0 shall be inside the custom XML, but the comment with ID 1 shall be displaced to stay outside of the relative location of the next custom XML element (the spec element). *end example*]
	
	The possible values for this attribute are defined by the ST_DisplacedByCustomXml simple type (§2.18.17).

id (Annotation ID)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Perm">
   <attribute name="id" type="ST_String" use="required"/>
   <attribute name="displacedByCustomXml" type="ST_DisplacedByCustomXml" use="optional"/>
</complexType>
```

2.13.7.2 permStart (Range Permission Start)

This element specifies the start of a range permission within a WordprocessingML document. This start marker is matched with the appropriately paired end marker by matching the value of the id attribute from the associated permEnd element.

If no permEnd element exists subsequent to this element in document order with a matching id attribute value, then this element is ignored and no range permission is present in the document.

If a range permission begins and ends within a single table, it is possible for that permission to cover discontiguous parts of that table which are logically related (e.g. a single column in a table). This type of placement for a range permission is accomplished (and described in detail) on the colFirst and colLast attributes on this element.

[*Example*: Consider a document with a range permission which spans half of paragraph one, and part of paragraph two. The following WordprocessingML illustrates an example of content which fufills this constraint:

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">This is sentence one.</w:t>
  </w:r>
  <w:permStart w:id="0" w:edGrp="everyone"/>
  <w:r>
    <w:t>This is sentence two.</w:t>
  </w:r>
</w:p>
<w:p>
  <w:r>
    <w:t xml:space="preserve">This </w:t>
  </w:r>
  <w:permEnd w:id="0"/>
  <w:r>
    <w:t>is sentence three.</w:t>
  </w:r>
</w:p>
```

The permStart element specifies the start of the region for the range permission. This element is then linked to the permEnd element which also has an id attribute value of 0. *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32); endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32);

Attributes	Description

colFirst (First Table Column Covered By Range Permission)	Specifies the zero-based index of the first column in this row which shall be part of this range permission.
	
	When a range permission is contained within a table, it is possible for that range permission to only cover cells within a certain column and row range within that table, by specifying:
	• The first row for which the specified columns are part of the table range permission. This is accomplished by placing the permStart element in the first table cell in that row.
	• The first column included in the range permission for each of the specified row(s) via this attribute.
	• The last column included in the range permission for each of the specified row(s) via the colLast attribute.
	• The last row for which the specified columns are part of the table range permission. This is accomplished by placing the permEnd element at the end of that table row.
	
	If this attribute appears, then the colLast attribute must also appear (regardless of where this bookmark is located) or the document shall be considered non-conformant. If this attibute and its pair occur on a range permission which is not contained in a table, then their values should be ignored. If this value exceeds the value of colLast or the number of columns in the table, then both values should be ignored.
	
	[*Example*: Consider a three row by three column table where a table range permission shall be applied to the contents of the first two cells in the first two rows in the table (the cells shaded below):
	
	 	
	This bookmark would be specified using the following WordprocessingML for the table's conents:
	
	`<w:tbl>`
	`…`
	`<w:tr>`
	`<w:tc>`
	`<w:permStart w:colFirst="0" w:colLast="1" w:id="0"`

Attributes	Description
	w:edGrp="everyone"/> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> </w:tr> <w:tr> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:permEnd w:id="0" /> </w:tr> <w:tr> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> </w:tr> </w:tbl> The colFirst attribute specifies that all columns starting with the first column shall be included in the table range permission. This will apply starting with the first row and ending with the second row (the two rows within the range permission's start and end). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
colLast (Last Table Column Covered By Range Permission)	Specifies the zero-based index of the last column in this row which shall be part of this range permission. When a range permission is contained within a table, it is possible for that range permission to only cover cells within a certain column and row range within that table, by

Attributes	Description

	specifying:
	• The first row for which the specified columns are part of the table range permission. This is accomplished by placing the permStart element in the first table cell in that row.
	• The first column included in the range permission for each of the specified row(s) via the colFirst attribute.
	• The last column included in the range permission for each of the specified row(s) via this attribute.
	• The last row for which the specified columns are part of the table range permission. This is accomplished by placing the permEnd element at the end of that table row.
	
	If this attribute appears, then the colFirst attribute must also appear (regardless of where this bookmark is located) or the document shall be considered non-conformant. If this attibute and its pair occur on a bookmark which is not contained in a table, then their values should be ignored. If this value does not equal or exceed the value of colFirst or the number of columns in the table, then both values should be ignored.
	
	[*Example*: Consider a three row by three column table where a table range permission shall be applied to the contents of the first two cells in the first two rows in the table (the cells shaded below):
	
	 	
	This bookmark would be specified using the following WordprocessingML for the table's conents:
	
	`<w:tbl>`
	`…`
	`<w:tr>`
	`<w:tc>`
	`<w:permStart w:colFirst="0" w:colLast="1" w:id="0" w:edGrp="everyone"/>`
	`<w:p/>`
	`</w:tc>`
	`<w:tc>`
	`<w:p/>`
	`</w:tc>`
	`<w:tc>`
	`<w:p/>`
	`</w:tc>`
	`</w:tr>`
	`<w:tr>`

Attributes	Description
	<w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:permEnd w:id="0" /> </w:tr> <w:tr> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> <w:tc> <w:p/> </w:tc> </w:tr> </w:tbl> The colLast attribute specifies that the last column that shall be included in the table range permission is the second column. This will apply starting with the first row and ending with the second row (the two rows within the range permission's start and end). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
displacedByCustomXml (Annotation Displaced By Custom XML Markup)	Specifies that the parent annotation's placement shall be directly linked with the location of the physical presentation of a custom XML element in the document. This element only has an effect when the custom XML element is block-level (i.e. surrounds an entire paragraph), as in this scenario the logical and physical placement of the annotation and custom XML element may differ. Specifically, in this case, the custom XML is presented *around* the block-level object it encloses (the paragraph, table, table row, or table cell), but is physically represented within that same object (i.e. within the paragraph, table, table row or table cell). This requirement stems from the fact that there is no location for the location of the annotation within the document at its logical location (around a table, for example). If this element is omitted, then the annotation shall be anchored inside of all block-level custom XML elements in the paragraph. If this element is present, but no block-level custom XML tag is located at the position it specifies (before or after), then it shall be ignored.

Attributes	Description

	[*Example*: Consider a paragraph with block level custom XML markup and two comment anchor annotations (one before and one after the custom XML element's physical representation), as follows:
	
	 	
	Since all three of these items are around the entire paragraph, they are stored outside of the paragraph. However, in order to ensure that their relative positions are stored correctly, any annotation which shall be displaced by the physical custom XML element specifies this information, resulting in the following WordprocessingML:
	
	`<w:commentRangeStart w:id="0" />`
	`<w:commentRangeStart w:id="1" w:displaced byCustomXml="next" />`
	`<w:customXml w:element="spec" … />`
	`<w:p>`
	`…`
	`</w:p>`
	
	The displacedByCustomXml attribute specifies that even though all three of these items are around the paragraph and will be moved inside the paragraph to be represented physically, the comment with ID 0 shall be inside the custom XML, but the comment with ID 1 shall be displaced to stay outside of the relative location of the next custom XML element (the spec element). *end example*]
	
	The possible values for this attribute are defined by the ST_DisplacedByCustomXml simple type (§2.18.17).

ed (Single User For Range Permission)	Specifies a single user for which this range permission shall be enabled (i.e. a user which shall be able to edit this range when document protection is enabled).
	
	This editor can be stored in one of the following forms:
	• `DOMAIN\username` - for users whose access shall be authenticated using the current user's domain credentials
	• `user@domain.com` - for users whose access shall be authenticated using the user's e-mail address as credentials
	• `user` - for users whose access shall be authenticated using the current user's machine credentials
	
	[*Example*: Consider a range permission defined as follows:
	
	`<w:permStart w:id="0" w:ed="example@contoso.com" … />`
	`…`
	`<w:permEnd w:id="0" />`

Attributes	Description
	The ed attribute value of `example@contoso.com` specifies that only user(s) who can authenticate with an application as associated with that e-mail address shall be allowed to edit the contents between the start and end markers when document protection is being enforced. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

edGrp (Editor Group For Range Permission)	Specifies an alias (or editing group) which shall be used to determine if the current user shall be allowed to edit this range of the document. This mechanism simply provides a set of predefined editing groups which may be associated with user accounts by applications in any desired manner.
	
	[*Example*: Consider a range permission defined as follows:
	
	`<w:permStart w:id="0" w:edGrp="editors" … />`
	`…`
	`<w:permEnd w:id="0" />`
	
	The edGrp attribute value of `editors` specifies that only user(s) who the current application associates with the editors group shall be allowed to edit the contents between the start and end markers when document protection is being enforced. *end example*]
	
	The possible values for this attribute are defined by the ST_EdGrp simple type (§2.18.25).

id (Annotation ID)	Specifies a unique identifier for an annotation within a WordprocessingML document. The restrictions on the id attribute, if any, are defined by the parent XML element.
	
	If this attribute is omitted, then the document is non-conformant.
	
	[*Example*: Consider an annotation represented using the following WordprocessingML fragment:
	
	`<w:… w:id="1" … >`
	`…`
	`</w:…>`
	
	The id attribute specifies that the ID of the current annotation is 1. This value is used to uniquely identify this annotation within the document content. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_PermStart">
   <complexContent>
      <extension base="CT_Perm">
         <attribute name="edGrp" type="ST_EdGrp" use="optional"/>
         <attribute name="ed" type="ST_String" use="optional"/>
         <attribute name="colFirst" type="ST_DecimalNumber" use="optional"/>
         <attribute name="colLast" type="ST_DecimalNumber" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.13.8 Spelling & Grammar

The final type of annotation stored in a WordprocessingML document, *spelling and grammar errors* are annotations used to specify the locations of existing spelling and grammatical errors within the contents of a document.

[*Rationale*: When a WordprocessingML document is saved, applications may choose to save currently flagged spelling and grammar errors, for two reasons:

- In order to increase the performance subsequent loads of the document (as those load operations can rely on the persisted proofing state of the document)
- In order to store words which shall not be marked as proofing errors regardless of how they would normally be flagged by the proofing tools engine (i.e. to store spelling and grammar exceptions).

end rationale]

[*Example*: Consider the following paragraph consisting of two misspelled words, where the second word has been explicitly flagged as not being a spelling error. This paragraph would consist of the following WordprocessingML markup:

```
<w:p>
  <w:proofErr w:val="spellStart"/>
  <w:r>
    <w:t>erqwt</w:t>
  </w:r>
  <w:proofErr w:val="spellEnd"/>
  <w:r>
    <w:t xml:space="preserve"> werewr</w:t>
  </w:r>
</w:p>
```

The proofErr elements, with a val attribute value of `spellStart` and `spellEnd` respectively, delimit the start and end the content in this paragraph which is stored as a spelling error. Since the second word is not included in that range, it is not stored as a spelling error. *end example*]

2.13.8.1 proofErr (Proofing Error Anchor)

This element specifies the presence of a start or end anchor for a single proofing error within a WordprocessingML document.

When proofing errors are stored in a document, their semantics shall be interpreted as follows:

- Each proofing error with a type attribute value of `spellStart` shall be linked with the next error with a type attribute of `spellEnd`. If one does not exist, then this error should be ignored.
- Each proofing error with a type attribute value of `spellEnd` which was not preceded by an error with a type attribute value of `spellStart` (that was not previously matched to an end) should be ignored.
- Each proofing error with a type attribute value of `gramStart` shall be linked with the next error with a type attribute of `gramEnd`. If one does not exist, then this error should be ignored.
- Each proofing error with a type attribute value of `gramEnd` which was not preceded by an error with a type attribute value of `gramStart` (that was not previously matched to an end) should be ignored.

[*Example*: Consider the following sentence with a grammatical error in its subject/verb agreement. If an application recognized this error and wished to persist it to the document, this paragraph would consist of the following WordprocessingML markup:

```
<w:p>
  <w:proofErr w:val="gramStart"/>
  <w:r>
    <w:t>This are</w:t>
  </w:r>
  <w:proofErr w:val="gramEnd"/>
  <w:r>
    <w:t xml:space="preserve"> an error.</w:t>
  </w:r>
</w:p>
```

The proofErr elements, with a val attribute value of `gramStart` and `gramEnd` respectively, delimit the start and end the content in this paragraph which is stored as a grammatical error. *end example*]

Parent Elements
body (§2.2.2); comment (§2.13.4.2); customXml (§2.5.1.3); customXml (§2.5.1.4); customXml (§2.5.1.5); customXml (§2.5.1.6); deg (§7.1.2.26); del (§2.13.5.12); den (§7.1.2.28); docPartBody (§2.12.6); e (§7.1.2.32); endnote (§2.11.2); fldSimple (§2.16.21); fName (§7.1.2.37); footnote (§2.11.10); ftr (§2.10.3); hdr (§2.10.4); hyperlink (§2.16.24); ins (§2.13.5.20); lim (§7.1.2.52); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); num (§7.1.2.75); oMath (§7.1.2.77); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.32); sdtContent (§2.5.2.33); sdtContent (§2.5.2.34); sdtContent (§2.5.2.35); smartTag (§2.5.1.9); sub (§7.1.2.112); sup (§7.1.2.114); tbl (§2.4.36); tc (§2.4.62); tr (§2.4.75); txbxContent (§2.17.1.1)

Attributes	Description

Attributes	Description

type (Proofing Error Anchor Type)	Specifies the type of proofing error anchor at this location in the document. This type implies the necessary semantics for this element as defined by the parent element.
	
	[*Example*: Consider the following sentence with a proofing error, consisting of the following WordprocessingML markup:
	
	`<w:r>`
	`  <w:t>are</w:t>`
	`</w:r>`
	`<w:proofErr w:val="gramEnd"/>`
	`<w:r>`
	`  <w:t xml:space="preserve"> an error.</w:t>`
	`</w:r>`
	
	The val attribute value of gramEnd specifies that the proofing error is the location of the end of content which is stored as a grammatical error. *end example*]
	
	The possible values for this attribute are defined by the ST_ProofErr simple type (§2.18.77).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_ProofErr">
   <attribute name="type" type="ST_ProofErr" use="required"/>
</complexType>
```

2.14 Mail Merge

Mail merge refers to an operation by which WordprocessingML documents may work in conjunction with data from an external data source, importing this data into a document according to a set of codes contained in WordprocessingML known as fields.

A WordprocessingML document that contains the mailMerge element (§2.14.20) and is therefore connected to an external data source, is known as a *source document*. In addition to being connected to an external data source and containing fields, a source document may contain any regular WordprocessingML constructs such as:

- Text runs
- Paragraphs
- Images
- Tables
- Numbering
- Etc.

There are two key parts of the mail merge data stored in a WordprocessingML document

11. Information connecting a document to an external data source
12. Information populating fields within that document with external data.

Once the fields in a merged document have been populated with external data, mail merge has been completed and the resulting files are known as *mail merged documents* or simply *merged documents*.

The mail merge settings for a WordprocessingML document are stored in two locations:

- The standard mail merge settings are stored as the child elements of the mailMerge element (§2.14.20)
- A set of additional mail merge settings stored in the odso element (§2.14.25), and collectively referred to as the Office Data Source Object settings. The *Office Data Source Object* is an extension to the standard settings stored with a mail merge which performs two functions: First, it provides additional information about the mail merge data source, specifically: information about how to map the columns in the data source to `MERGEFIELD` fields and information about records which shall be included and excluded when creating merged documents. Second, it provides an alternate set of connection information which should be used when the dataType element (§2.14.10) specifies a value of `native`. This alternate connection string provides additional connection information for applications which choose to support the ODSO connection string syntax.

[*Example*: Consider a WordprocessingML document containing static WordprocessingML constructs such as text runs and paragraphs in addition to two WordprocessingML `MERGEFIELD` fields (§2.16.5.42) calling for `Courtesy Title` and `Last Name` data. The field codes for each field are displayed, delimited by {} characters:

Dear {MERGEFIELD "Courtesy Title" \m} {MERGEFIELD "Last Name" \m}, Sample text. Sincerely,

If the following WordprocessingML was added to this document, this document would become a *source document* rather than just a standard WordprocessingML document, as the mailMerge (§2.14.20) element specifies the elements and attributes necessary to enabled the document to connect to an external spreadsheet data source.

```
<w:mailMerge>
  …
  <w:dataType w:val="spreadsheet" />
  <w:query w:val="SELECT * FROM `Sheet1$`" />
  <w:dataSource r:id="rId1" />
  …
</w:mailMerge>
```

Here, the dataType (§2.14.10) and dataSource (§2.14.9) elements specify that the given document shall be connected to the external data source target by the relationship whose relationship value is `rId1` as specified in the dataSource element (§2.14.9). While connected to the external data source, the *source document* together with the hosting application and/or data source access application will extract data from the external data source to perform the merge as specified by the connectString (§2.14.8) and query (§2.14.26) elements. *end example*]

2.14.1 active (Record Is Included in Mail Merge)

This element specifies whether a specific record from the specified external data source shall be imported into a merged WordprocessingML document when the mail merge defined for a source document is performed. If this element's val attribute is `false`, then the record specified by the parent element shall not used to create a merged document.

If this element is omitted for a given record, the data record associated with it shall be imported into a merged WordprocessingML document when the mail merge is performed.

[*Example*: Consider the following fragment from a source WordprocessingML document that is connected to an external data source containing two records, one of which will not be imported into a merged WordprocessingML document when the conforming hosting application performs the data import.

```
<w:recipients>
  <w:recipientData>
    <w:active w:val="false" />
    <w:uniqueTag w:val="1126664175" />
  </w:recipientData>
  <w:recipientData>
    <w:uniqueTag w:val="1530576378" />
  </w:recipientData>
</w:recipients>
```

In this XML fragment, the external data record who is identified by the uniqueTag element (§2.14.35) with a val attribute equal to `1126664175` will not be imported into a merged document as the active element associated with it has a val attribute equal to `false`. Conversely, the external data record associated with the uniqueTag element with a val attribute equal to `1530576378` will be imported into a merged document, as its active element has been omitted (implying the default value of `true`). *end example*]

Parent Elements
recipientData (§2.14.28)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.14.2 activeRecord (Record Currently Displayed In Merged Document)

This element specifies that the hosting application shall display the given record from the specified external data source in place of the MERGEFIELD fields (§2.16.5.42) its data is mapped to via the fieldMapData element (§2.14.15) in a merged document. When this element is present, the val attribute shall specify the one-based index of the record from that data source which shall be used to populate this document.

If the activeRecord element is omitted with the viewMergedData element's val attribute equal to true, the hosting application shall behave as if the activeRecord element's val attribute was equal to 1. If the viewMergedData element (§2.14.36) is omitted or present with a val attribute equal to Off, 0, or false, then this element shall be ignored. If the activeRecord record is given a val attribute that is less than one or greater than the number of records in the specified external data source, the hosting application shall treat this val attribute as if it were equal to 1.

[*Example*: Consider a merged WordprocessingML document containing two WordprocessingML fields calling for Courtesy Title and Last Name data and a sample text paragraph. Also, note that the external data source this merged document is connected to contains two records, both containing name and address information, with the first record pertaining to Mr. Doe, and the second pertaining to Ms. Smith.

This table below illustrates the necessary WordprocessingML to display applicable data from the specified external data source within the merged document where fields have been inserted:

`<w:viewMergedData val="off"/>`	`<w:viewMergedData val="on" />` `<w:activeRecord w:val="1" />`	`<w:viewMergedData val="on" />` `<w:activeRecord w:val="2" />`
Dear {MERGEFIELD "Courtesy Title" \m} {MERGEFIELD "Last Name" \m}, Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sincerely,	Dear Mr. Doe: Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sincerely,	Dear Ms. Smith: Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sincerely,

end example]

[*Example*: Consider the following WordprocessingML from a merged WordprocessingML document:

```
<w:viewMergedData />
<w:activeRecord w:val="2" />
```

The activeRecord element is present and has a val attribute equal to 2, therefore this WordprocessingML specifies that a conforming hosting application shall display data from the second record of the specified external data source in place of fields its data is mapped to within the merged document. *end example*]

Parent Elements
mailMerge (§2.14.20)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.14.3 addressFieldName (Column Containing E-mail Address)

This element specifies the column within a given external data source that contains e-mail addresses. This element is specified independently of the field mappings specified for a given merged document via the fieldMapData element (§2.14.15).

If this element is omitted, or no column exists in the data source with this column name, then the source document specifies that no e-mail address data shall be associated with this mail merge.

[*Note*: This element is generally used to allow the e-mailing of merged documents resulting from populating the fields within a merged document with external data.

This element is independent of the field mapping specified for a given merged document via the fieldMapData element (§2.14.15). This separation enables applications to email the documents resulting from the population of WordprocessingML fields with external data regardless of the presence or absence of a field mapped to external data specifying email addresses. *end note*]

[*Example*: Consider a merged WordprocessingML document that is connected to an external data source containing a column of data tilted `Alternate Email Addresses`. The following WordprocessingML would be included in the source and merged documents to specify which column in the external data source contains email addresses.

```
<w:addressFieldName w:val="Alternate Email Address" />
```

The addressFieldName element specifies that the `Alternate Email Address` column contains e-mail addresses for each record. *end example*]

Parent Elements
mailMerge (§2.14.20)

Attributes	Description
val (String Value)	Specifies that its contents will contain a string. The contents of this string are interpreted based on the context of the parent XML

Attributes	Description

	element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.14.4 checkErrors (Mail Merge Error Reporting Setting)

This element specifies the type of error reporting which shall be conducted by an application when performing a mail merge against the specified source data.

The type of error reporting implied by this element shall be defined as follows:

- Simulate the population of fields with mapped external data and report errors in a new document if the val attribute is equal to 1.
- While populating fields with mapped external data, pausing to report each error as it occurs if the val attribute is equal to 2.
- Populate fields with mapped external data and report errors in a new document if the val attribute is equal to 3.
- Application-defined behaviors may be used if the val attribute is equal to any other value.

If this element is omitted, or its value is set to a value outside of those specified below that is not understood by the hosting application, then its value shall be assumed to be 2.

[*Example*: Consider a mail merge whose WordprocessingML definition includes the following:

```
<w:checkErrors w:val="3" />
```

The presence of a checkErrors element with a val attribute of 3 indicates that the hosting application shall conduct the type of error reporting specified above, performing the mail merge, populating fields with mapped external data and reporting errors in a new document . *end example*]

Parent Elements
mailMerge (§2.14.20)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.14.5 colDelim (Column Delimiter for Data Source)

This element specifies the character which shall be interpreted as the column delimiter used to separate columns within external data sources. The character representing the specific delimiter used for the external data source referenced by a source or merged WordprocessingML document is specified via a decimal number representing the decimal number for the Unicode character representation within this element's val attribute.

If this element is omitted, then no column delimiter shall be specified for the data source in this mail merge.

[*Example*: Consider the following WordprocessingML fragment:

```
<w:colDelim w:val="44" />
```

Here, the colDelim element's val attribute specifies that the given external data source is using the comma character (,) to delimit column data, as 44 is the decimal value for the Unicode character representation of a comma. *end Example*]

Parent Elements
odso (§2.14.25)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
    <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.14.6 column (Index of Column Containing Unique Values for Record)

This element specifies the column within the specified external data source that contains unique data for the current record within that data source. This element shall be used in conjunction with the uniqueTag element (§2.14.35) to maintain a relationship between a specific record within an external data source and a given source or merged document. The val attribute on this element shall be interpreted as a zero-based index into the columns specified by the data source, specifying the resulting column as the column in which the uniqueTag element shall be looked up.

If this element specifies a column number which exceeds the number of columns in the specified external data source, then its value shall be ignored.

[*Note*: This information is necessary as part of a mail merge as records may be added or deleted from external data sources, and a means must be provided to maintain record-specific inclusion or exclusion data using the active element (§2.14.1) and the affected external data record when the WordprocessingML document is reconnected to the external data source irrespective of the ordering of the records within the external data source. *end note*]

[*Example*: Consider the following WordprocessingML fragment for the information about a single record in a source document for a mail merge:

```
<w:recipientData>
  <w:active w:val="0" />
  <w:column w:val="12" />
  <w:uniqueTag w:val="258865469" />
</w:recipientData>
```

The external data record associated with this information is specified via the column in the external data source corresponding to the column element with a val attribute equal to 12, which contains a row whose value in this column has a value corresponding to the uniqueTag element (§2.14.35) with a val attribute equal to 258865469. This record will not be imported into the merged WordprocessingML document as the active (§2.14.1) element associated with the given external data record has a val attribute equal to 0.

In other words, when the specified external data source is connected to, the record within the thirteenth column of the external data source that has the contents 258865469, and not populate mapped fields in a merged document with data from that record. *end example*]

Parent Elements
recipientData (§2.14.28)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.14.7 column (Index of Column Being Mapped)

This element specifies the zero-based index of the column within a given external data source which shall be mapped to the local name of a specific MERGEFIELD field (§2.16.5.42) specified by the parent field mapping data. The val attribute specifies this index value, which is used to look up the appropriate column in the data source.

If this element is omitted, or its value exceeds the number of columns in the associated data source, then the index of the referenced column shall be assumed to be 0.

[*Example*: Consider a source document that is connected to an external data source with three columns. Within this external data source, these are three columns are ordered and titled as follows: first, middle, and last, respectively. The following WordprocessingML specifies that when this document was connected to the data source, these columns were ordered in this manner:

```
<w:fieldMapData>
  …
  <w:name w:val="first" />
  <w:column w:val="0" />
</w:fieldMapData>
<w:fieldMapData>
  …
  <w:name w:val="middle" />
  <w:column w:val="1" />
</w:fieldMapData>
<w:fieldMapData>
  …
  <w:name w:val="last" />
  <w:column w:val="2" />
</w:fieldMapData>
```

The WordprocessingML above demonstrates that the column titled first shall be associated with the first column in the external database by specifying a column element with its val attribute equal to 0. In addition, the column titled middle shall be associated with the second column in the external database by specifying a column element with its val attribute equal to 1. Finally, the column titled last shall be associated with the third column in the external database by specifying a column element with its val attribute equal to 2. *end example*]

It is important to realize that the name element's values are a cache of the last time the document was connected to the database, and the indices specified shall be used to connect the field mappings with the columns in the data source. *end example*]

Parent Elements
fieldMapData (§2.14.15)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.14.8 connectString (Data Source Connection String)

This element specifies the connection string used to reconnect to an external data source. The string within this element's val attribute shall contain the connection string that the hosting application shall pass to a external data source access application to enable the WordprocessingML document to be reconnected to the specified external data source.

[*Note*: This string is generally comprised of a series of name/value pairs, delimited by semicolons, determined by the data source access application and the external data source that is accessed. *end note*]

If this string is omitted, then no legacy connection string shall be associated with this mail merge.

This connection string should be ignored under the following conditions:

- The udl element (§2.14.34) is present within the mail merge data
- The dataType element (§2.14.10) is set to `native`
- The current application is able to use the information contained in the odso element (§2.14.25) to access the data source

[*Guidance*: In this case, using the connection string in the udl element will provide an equal or greater amount of connection information for the mail merge data source for clients which support it. *end guidance*]

[*Example*: Consider a merged WordprocessingML document that has been connected to an external data source for the purposes of a mail merge. The following WordprocessingML fragment represents the legacy connection string used to connect to the external data source when the merged WordprocessingML document is reopened:

```
<w:connectString w:val="Provider=Example;Password=Test;User ID=readonly;…" />
```

The connectString element specifies that the string `Provider=Example;Password=Test;User ID=readonly;…` shall be used to enable the given WordprocessingML document to be reconnected to the specified external data source. *end example*]

Parent Elements
mailMerge (§2.14.20)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.14.9 dataSource (Data Source File Path)

This element specifies the relationship whose target is the location of the external data source to be connected to a given WordprocessingML document to perform the mail merge (for a source document) or to find the associated field data (for a merged document).

If this element is omitted, then no file location is specified for the data source for the current mail merge. If no relationship exists with the given relationship ID, or this relationship is not of type http://schemas.openxmlformat.org/officeDocument/2006/relationships/mailMergeSource then this document shall be considered non-conformant.

The data source location may also be ignored under the following conditions:

- The src element (§2.14.30) is present within the mail merge data
- The dataType element (§2.14.10) is set to `native`
- The current application is able to use the information contained in the odso element (§2.14.25) to access the data source

[*Guidance*: In this case, using the data source file path in the src element will provide an equal or greater amount of information for the mail merge data source for clients which can consume it. *end guidance*]

[*Example*: Consider a WordprocessingML source document containing the following mail merge data:

```
<w:mailMerge>
  …
  <w:dataSource r:id="rId1" />
  …
</w:mailMerge>
```

This mail merge's dataSource element specifies via its r:id attribute value of `rId1` that the external data source to be connected to the given WordprocessingML document is the data source targeted by the relationship whose Id attribute is equal to `rId1`. If we examine the corresponding relationship part item for the setting part, as follows:

```
<Relationships>
  <Relationship Id="rId1"
Type="http://schemas.openxmlformats.org/officeDocument/2006/relationships/mailMe
rgeSource" Target="file:///c:/example_file.mdb" TargetMode="External" />
</Relationships>
```

Since the relationship whose Id attribute value is `rId1` specifies the source file path for the data source, that data source effectively specifies a file path of `c:\example_file.mdb`. *end example*]

Parent Elements
mailMerge (§2.14.20)

Attributes	Description
id (Relationship to Part)	Specifies the relationship ID to a specified part. The specified relationship shall match the type required by the parent element:

Attributes	Description
Namespace: .../officeDocument/2006/relationships	• http://schemas.openxmlformats.org/officeDocument/2006/relationships/footer for the footerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/header for the headerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/font for the embedBold, embedBoldItalic, embedItalic, or embedRegular elements • http://schemas.openxmlformats.org/officeDocument/2006/relationships/printerSettings for the printerSettings element [*Example*: Consider an XML element which has the following id attribute: `<… r:id="rId10" />` The markup specifies the associated relationship part with relationship ID `rId1` contains the corresponding relationship information for the parent XML element. *end example*] The possible values for this attribute are defined by the ST_RelationshipId simple type (§7.8.2.1).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Rel">
   <attribute ref="r:id" use="required"/>
</complexType>
```

2.14.10 dataType (Data Source Type)

This element specifies the type of external data source to be connected to via the Dynamic Data Exchange (DDE) system (such as a spreadsheet or database), or the alternative method of data access if the Dynamic Data Exchange system is not used. This setting is purely a suggestion of the data source access mechanism which shall be used, and may be ignored in favor of an alternative mechanism if one is present.

[*Example*: Consider the following WordprocessingML fragment for a mail merge source or merged document:

```
<w:dataType w:val="odbc" />
```

The dataType element's val attribute is equal to odbc, specifying that the given merged WordprocessingML document has been connected to an external data source via the Open Database Connectivity interface. *end example*]

Parent Elements
mailMerge (§2.14.20)

Attributes	Description

Attributes	Description
val (Value)	Specifies the exact type of external data source to which a given merged WordprocessingML document is to be connected. [*Example*: Consider the following WordprocessingML fragment for a mail merge document. `<w:dataType w:val="database" />` The val attribute is equal to `database`, specifying that the given WordprocessingML document has been connected to a database via the Dynamic Data Exchange (DDE) system. *end example*] The possible values for this attribute are defined by the ST_MailMergeDataType simple type (§2.18.59).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_MailMergeDataType">
   <attribute name="val" type="ST_MailMergeDataType" use="required"/>
</complexType>
```

2.14.11 destination (Merged Document Destination)

This element specifies what the result which shall be generated when a mail merge is carried out on a given WordprocessingML source document. In other words, this element is used to specify what is to be done with the merged documents that result from populating the fields within a given merged WordprocessingML document with data from the specified external data source.

If this element is omitted, then the default destination of merged documents shall be assumed to be of type `newDocument`.

[*Note*: The aspects of the mail merge outside of connecting to an external data source and populating the fields within a given merged document with external data from the specified external data source are not specified by this Office Open XML Standard.

For example, if a given merged WordprocessingML document contains a destination element with its val attribute equal to `email`, the hosting application may surface a user interface specific to creating emails with the data resulting from populating fields within a given merged WordprocessingML document with external data from the specified external data source. WordprocessingML only provides a flag (via the destination element) to tell the hosting application to surface this user interface. *end note*]

[*Example*: Consider a WordprocessingML source document containing the following WordprocessingML:

```
<w:mailMerge>
  <w:destination w:val="newDocument" />
  …
</w:mailMerge>
```

The destination element's val attribute is set to newDocument, specifying that when the mail merge is carried out, the source document shall be used to generate a specified number of new documents, which may be handled as appropriate. *end example*]

Parent Elements
mailMerge (§2.14.20)

Attributes	Description
val (Mail Merge Merged Document Type)	Specifies the type of merged documents which shall be the result of carrying out a mail merge on a given source WordprocessingML document. [*Example*: Consider the WordprocessingML mail merge data specified as follows: `<w:destination w:val="email" />` This specifies that a given merged WordprocessingML document will be used by the hosting application to generate e-mails containing the static contents of the merged document as well as external data populated into mapped fields. *end example*] The possible values for this attribute are defined by the ST_MailMergeDest simple type (§2.18.60).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_MailMergeDest">
   <attribute name="val" type="ST_MailMergeDest" use="required"/>
</complexType>
```

2.14.12 doNotSuppressBlankLines (Remove Blank Lines from Merged Documents)

This element specifies how an application performing the mail merge shall handle blank lines in the merged documents resulting from the mail merge. Typically, when a mail merge is performed, any blank lines which result from lines whose sole contents are merge fields with no content are removed from the merged document in order to prevent extraneous blank lines from appearing in the merged documents. When this element is present, the merged documents which are generated from the mail merge shall not have any blank lines removed before they are sent to their destination format.

If this element is omitted, the merged documents generated from this mail merge shall have all blank lines suppressed if they consist of only merge fields with values consisting of empty strings.

[*Example*: Consider a WordprocessingML document containing a single WordprocessingML field calling for `Test` data as seen in the first column of the table below. If the current record in the mail merge data source contains an empty string for the `Test` column, the resulting merged document would be displayed as follows depending on the setting for the doNotSuppressBlankLines element:

Source Document	`<w:doNotSuppressBlankLines val="on" />`	`<w:doNotSuppressBlankLines val="off" />`
One Two {MERGEFIELD "Test" } Three	One Two Three	One Two Three

With this element set to a value of on, the blank lines in the resulting document shall not be suppressed when the resulting merged documents are created. *end example*]

Parent Elements
mailMerge (§2.14.20)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.14.13 dynamicAddress (Use Country-Based Address Field Ordering)

This element specifies that the contents of the `AddressBlock MERGEFIELD` field shall be dynamically ordered based on the country associated with the current record or if the country-invariant version of the address field

shall be used in its place. [*Rationale*: When a source document is combined with the contents of a data source in order to produce multiple merged documents, it is often necessary to use an address form specific to the destination country for each particular record in the data source, rather than one static address form for all records. *end rationale*] If this element is set to `true`, then the mail merge shall use an address form suited to the country associated with the current record in the external data source.

If this element is omitted, then the form of the address shall be dynamically determined based on the country specified in the current record.

[*Example*: Consider a merged WordprocessingML document that is specified to *not* dynamically create the address field order based on the country associated with the current record. This requirement may be specified using the following WordprocessingML:

```
<w:fieldMapData>
  …
  <w:dynamicAddress w:val="off" />
</w:fieldMapData>
```

The dynamicAddress element is set to a value of `off`, specifying that the dynamic address format shall not be used when performing a mail merge with the specified data source. *end example*]

Parent Elements
fieldMapData (§2.14.15)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.14.14 fHdr (First Row of Data Source Contains Column Names)

This element specifies that a hosting application shall treat the first row of data in the specified external data source as a header row containing the names of each column in the data source, rather than data to populate mapped fields in a merged document. When present, this information shall not change the indices specified in the recipientData elements (§2.14.28), but shall indicate that the first row is not part of the mail merge when it is performed.

If this element is omitted, then the first row of the data source shall not be considered a header row when a mail merge is performed.

[*Example*: Consider a WordprocessingML source document that has been connected to an external data source whose first row of data is not data the hosting application is to populate mapped fields with, but rather contains column names for each column in the data source. This setting on the data source is specified using the following fragment of WordprocessingML:

```
<w:fHdr w:val="on" />
```

The fHdr element specifies that the data source's first row is a header row, rather than regular data to be used in the mail merge. *end example*]

Parent Elements
odso (§2.14.25)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.14.15 fieldMapData (External Data Source to Merge Field Mapping)

This element specifies how a column specified in the external data source that has been connected to a WordprocessingML document shall be mapped to the pre-defined `MERGEFIELD` fields (§2.16.5.42) within the given merged document's contents. Each instance of a fieldMapData element contains the information needed to map one column in the external data source to a single type of pre-defined `MERGEFIELD` field for the purposes of the mail merge in the current document.

[*Example*: Consider a single merged document. The WordprocessingML below demonstrates the mapping of the `Country` column from the external data source to the predefined WordprocessingML `Country or Region` merge field when the merged document is populated with external data as part of a mail merge:

```
<w:odso>
  …
  <w:fieldMapData>
    <w:type w:val="dbColumn" />
    <w:name w:val="Country" />
    <w:mappedName w:val="Country or Region" />
    <w:column w:val="9" />
    …
  </w:fieldMapData>
</w:odso>
```

The fieldMapData element specifies the mapping between the external data source and a single merge field as follows: the child elements specify that the tenth column in the data source, last titled `Country` in the specified external data source when the connection was last made is to be mapped to the predefined WordprocessingML merge field calling for `Country or Region` data.

With the fieldMapData element configured as such, an application may be used in conjunction with this WordprocessingML document to populate the document with data mapped from the specified external data source to fields within the merged document. *end example*]

Parent Elements
odso (§2.14.25)

Child Elements	Subclause
column (Index of Column Being Mapped)	§2.14.7
dynamicAddress (Use Country-Based Address Field Ordering)	§2.14.13
lid (Merge Field Name Language ID)	§2.14.17
mappedName (Predefined Merge Field Name)	§2.14.23
name (Data Source Name for Column)	§2.14.24
type (Merge Field Mapping)	§2.14.32

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OdsoFieldMapData">
   <sequence>
      <element name="type" type="CT_MailMergeOdsoFMDFieldType" minOccurs="0"/>
      <element name="name" type="CT_String" minOccurs="0"/>
      <element name="mappedName" type="CT_String" minOccurs="0"/>
      <element name="column" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="lid" type="CT_Lang" minOccurs="0"/>
      <element name="dynamicAddress" type="CT_OnOff" minOccurs="0"/>
   </sequence>
</complexType>
```

2.14.16 headerSource (Header Definition File Path)

This element specifies the location of a file that contains the column header information which shall be used when connecting to an external data source that does not have column header data specified. Specifically, this element specifies a file that corresponds with the aforementioned external data source. [*Note*: Column headers are needed to enable a hosting application to associate external data source's columns to fields via the fieldMapData element (§2.14.15).

If this element is omitted, then the column header definition data is not specified in an external file and shall be retrieved from the primary data source associated with the mail merge.

[*Example*: Consider a WordprocessingML merged document containing the following WordprocessingML:

```
<w:settings>
  …
  <w:headerSource r:id="rId2" />
  …
</w:settings>
```

This mail merge's headerSource element specifies via its r:id attribute value of `rId2` that the external data source to be used for the column header information for the given WordprocessingML document is the data source targeted by the relationship whose Id attribute is equal to `rId2`. If we examine the corresponding relationship part item for the setting part, as follows:

```
<Relationships>
  <Relationship Id="rId2"
Type="http://schemas.openxmlformats.org/officeDocument/2006/relationships/mailMe
rgeSource" Target="file:///c:/headerData.txt" TargetMode="External" />
</Relationships>
```

Since the relationship whose Id attribute value is `rId2` specifies the column header data file path for the data source effectively specifies a file path of `c:\headerData.txt`. *end example*]

Parent Elements
mailMerge (§2.14.20)

Attributes	Description
id (Relationship to Part) Namespace: .../officeDocument/2006/relationships	Specifies the relationship ID to a specified part. The specified relationship shall match the type required by the parent element: • http://schemas.openxmlformats.org/officeDocument/2006/relationships/footer for the footerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/header for the headerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/font for the embedBold, embedBoldItalic, embedItalic, or embedRegular elements • http://schemas.openxmlformats.org/officeDocument/2006/relationships/printerSettings for the printerSettings element [*Example*: Consider an XML element which has the following id attribute: `<… r:id="rId10" />` The markup specifies the associated relationship part with relationship ID `rId1` contains the corresponding relationship information for the parent XML element. *end example*] The possible values for this attribute are defined by the ST_RelationshipId simple type (§7.8.2.1).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Rel">
   <attribute ref="r:id" use="required"/>
</complexType>
```

2.14.17 lid (Merge Field Name Language ID)

This element specifies the language ID for the language which was used to generate the merge field name which was associated with a given column in the data source, as specified by the fieldMapData element (§2.14.15). This element specifies that when this field mapping is processed by an application, it shall interpret the merge field name as the name for the specified language.

If this element is omitted, then the mapped field names specified in the current document may be interpreted using any method desired by the consuming application (i.e. no language data is included with the field mapping information).

[*Example*: Consider the following WordprocessingML fragment for a field mapping for a document to be merged to an external data source. If the merge field name stored in the file corresponds with the U.S. English version of the merge field names, that information would be stored as follows:

```
<w:fieldMapData>
  <w:name w:val="Title" />
  <w:column w:val="3" />
  <w:mappedName w:val="Courtesy Title" />
  <w:lid w:val="en-US" />
</w:fieldMapData>
```

The lid element specifies that the mapping of the data contained in the fourth column of external data source named `Title` to the WordprocessingML of 'Courtesy Title', shall be associated with the U.S. English language as specified by the val attribute equal to `en-US`. *end example*]

Parent Elements
fieldMapData (§2.14.15)

Attributes	Description
val (Language Code)	Specifies an ISO 639-1 letter code or 4 digit hexadecimal code for a specific language. This code is interpreted in the context of the parent XML element. [*Example*: Consider an object which shall specify the English(Canada) language. That object would use the ISO 639-1 letter code of `en-CA` to specify this language. *end example*] The possible values for this attribute are defined by the ST_Lang simple type (§2.18.51).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Lang">
   <attribute name="val" type="ST_Lang" use="required"/>
</complexType>
```

2.14.18 linkToQuery (Query Contains Link to External Query File)

This element specifies that the current WordprocessingML document's query string, stored in the query element (§2.14.26) and used to specify the data to be imported from the external data source, actually contains a reference to an external query file which contains the actual query data to be used against the specified external data source for the mail merge. This query shall mimic a SQL query and be of the following form: `SELECT * FROM <query file path>`.

If this element is omitted, then the query specified for the data source attached to the current document shall be assumed to not be a query containing a link to an external file.

[*Example*: Consider a mail merge source document that uses the linkToQuery element to specify that the query used is stored in the specified external data source as follows:

```
<w:mailMerge>
  …
  <w:linkToQuery />
  <w:query w:val="SELECT * FROM C:\queryExample.txt" />
  …
</w:mailMerge>
```

The linkToQuery element specifies that the query string stored in the query element (§2.14.26) is actually just a reference to an externally stored query file, in this case, an external query file stored at `c:\queryExample.txt`. *end example*]

Parent Elements
mailMerge (§2.14.20)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.14.19 mailAsAttachment (Merged Document To E-Mail Attachment)

This element specifies that, after importing external data into fields to generate a series of destination WordprocessingML documents as e-mails, the resulting documents should be emailed as an attachment rather than the body of the actual e-mail.

If this element is omitted, then its value shall be assumed to be `false` (i.e. the destination source is not an e-mail attachment). If the destination element (§2.14.11) specifies that the merged document destination is not `email`, then this element shall be ignored.

[*Example*: Consider a merged WordprocessingML document that has been connected to an external data source containing three records and that contains the following WordprocessingML in its mail merge properties as follows:

```
<w:mailMerge>
  …
  <w:destination w:val="email" />
  <w:mailAsAttachment />
  …
</w:mailMerge>
```

After the external data has been imported into the merged document's respective merge fields, three emails will be generated (as specified by the destination element (§2.14.11) with a val attribute of `email`, each an attachment consisting of one of the three documents resulting from the mail merge result (rather than just including the merged document as the body of the email). *end example*]

Parent Elements
mailMerge (§2.14.20)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.14.20 mailMerge (Mail Merge Settings)

This element specifies all of the mail merge information for a document that has been connected to an external data source as part of a mail merge operation.

The document which contains this mail merge data may be of one of two types:

- A *source document*, the document which contains all of the information for the mail merge, and is used in conjunction with an application to connect to an external data source and create one document for each record in that data source.
- A *merged document*, a document which contains all of the information for the mail merge as well as a reference to a single specific record which shall be used to populate the values of all of the merge fields in that document.

The information in this element shall contain all data needed to connect to a data source and populate any merge fields in the document with data from that data source.

[*Example*: Consider the following WordprocessingML fragment for a document which is part of a mail merge:

```
<w:mailMerge>
  …
  <w:dataType w:val="spreadsheet" />
  <w:query w:val="SELECT * FROM `Sheet1$`" />
  <w:dataSource r:id="rId1" />
  …
</w:mailMerge>
```

Here, the dataType (§2.14.10) and dataSource (§2.14.9) elements specify that the given document shall be connected to the external data source referenced by the relationship whose id value is equal to `rId1`. While connected to the external data source, the document together with a hosting application may extract data from the external data source as specified by the query (§2.14.26) element. *end example*]

Parent Elements
settings (§2.15.1.78)

Child Elements	Subclause
activeRecord (Record Currently Displayed In Merged Document)	§2.14.2
addressFieldName (Column Containing E-mail Address)	§2.14.3
checkErrors (Mail Merge Error Reporting Setting)	§2.14.4
connectString (Data Source Connection String)	§2.14.8
dataSource (Data Source File Path)	§2.14.9
dataType (Data Source Type)	§2.14.10
destination (Merged Document Destination)	§2.14.11
doNotSuppressBlankLines (Remove Blank Lines from Merged Documents)	§2.14.12
headerSource (Header Definition File Path)	§2.14.16
linkToQuery (Query Contains Link to External Query File)	§2.14.18

Child Elements	Subclause
mailAsAttachment (Merged Document To E-Mail Attachment)	§2.14.19
mailSubject (Merged E-mail or Fax Subject Line)	§2.14.21
mainDocumentType (Source Document Type)	§2.14.22
odso (Office Data Source Object Settings)	§2.14.25
query (Query For Data Source Records To Merge)	§2.14.26
viewMergedData (View Merged Data Within Document)	§2.14.36

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_MailMerge">
   <sequence>
      <element name="mainDocumentType" type="CT_MailMergeDocType" minOccurs="1"/>
      <element name="linkToQuery" type="CT_OnOff" minOccurs="0"/>
      <element name="dataType" type="CT_MailMergeDataType" minOccurs="1"/>
      <element name="connectString" type="CT_String" minOccurs="0"/>
      <element name="query" type="CT_String" minOccurs="0"/>
      <element name="dataSource" type="CT_Rel" minOccurs="0"/>
      <element name="headerSource" type="CT_Rel" minOccurs="0"/>
      <element name="doNotSuppressBlankLines" type="CT_OnOff" minOccurs="0"/>
      <element name="destination" type="CT_MailMergeDest" minOccurs="0"/>
      <element name="addressFieldName" type="CT_String" minOccurs="0"/>
      <element name="mailSubject" type="CT_String" minOccurs="0"/>
      <element name="mailAsAttachment" type="CT_OnOff" minOccurs="0"/>
      <element name="viewMergedData" type="CT_OnOff" minOccurs="0"/>
      <element name="activeRecord" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="checkErrors" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="odso" type="CT_Odso" minOccurs="0"/>
   </sequence>
</complexType>
```

2.14.21 mailSubject (Merged E-mail or Fax Subject Line)

This element specifies the text which shall appear in the subject line of the e-mails or faxes that result after the actions of a mail merge have imported external data into fields within a merged WordprocessingML document whose destination, as specified in the destination element (§2.14.21), is `email` or `fax`.

If this element is omitted, then no subject line text shall be associated with each merged document produced via a mail merge using the specified mail merge data. If the destination element (§2.14.11) specifies that the merged document destination is not `email` or `fax`, this element shall be ignored.

[*Example*: Consider a merged WordprocessingML document containing fields and the following WordprocessingML as part of its mail merge data:

```
<w:mailMerge>
  …
  <w:destination w:val="email" />
  <w:mailSubject w:val="Example Subject Line" />
  …
</w:mailMerge>
```

The mailSubject element specifies that after the specified external data has been imported into the specified fields in the merged document, each record merged shall result in a single e-mail message, each with their subject line reading `Example Subject Line`. *end example*]

Parent Elements
mailMerge (§2.14.20)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.14.22 mainDocumentType (Source Document Type)

This element specifies the type of a given WordprocessingML source document.

If this element is omitted, then its value shall be assumed to be `formLetters`.

[*Note*: This element is generally used in conjunction with the behavior of an application to customize aspects of the mail merge user interface and experience independent of the WordprocessingML file format. For example, if a given WordprocessingML merged document contains a mainDocumentType element with its val attribute equal to `envelopes`, the hosting application may surface a piece of user interface specific to creating envelopes when the given document is opened.

In addition, what a hosting application does with the documents that result from importing external data into specified fields can be determined based on the mainDocumentType element, but other than this, is independent of a given merged document's WordprocessingML. For example, if a given merged WordprocessingML document contains a mainDocumentType element with its val attribute equal to `email`, the hosting application may call a email service after importing external data into specified fields, in order to generate emails containing the resulting documents.

WordprocessingML simply provides the mainDocumentType that can serve as a trigger for an application to surface user interface specific to a type of mail merge. *end note*]

[*Example*: Consider the WordprocessingML below:

```
<w:mailMerge>
  <w:mainDocumentType w:val="formLetters" />
  …
</w:mailMerge>
```

In this example, the source document is of the `formLetters` type, as specified by the mainDocumentType element's val attribute being equal to `formLetters`. *end example*]

Parent Elements
mailMerge (§2.14.20)

Attributes	Description
val (Mail Merge Source Document Type)	Specifies the type of source document which is specified by the given WordprocessingML document. [*Example*: Consider the WordprocessingML below: `<w:mainDocumentType w:val="formLetters" />` This WordprocessingML specifies that a given source document is a `formLetters` document. This setting implies nothing about the file, but may be interpreted by an

Attributes	Description
	application as desired. *end example*] The possible values for this attribute are defined by the ST_MailMergeDocType simple type (§2.18.61).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_MailMergeDocType">
   <attribute name="val" type="ST_MailMergeDocType" use="required"/>
</complexType>
```

2.14.23 mappedName (Predefined Merge Field Name)

This element specifies the predefined WordprocessingML `MERGEFIELD` field name which shall be mapped to the column number specified by the column element (§2.14.7) within this field mapping. [*Guidance*: This element allows the current column from the specified data source to be mapped to a predefined field name, allowing applications to have one standard set of field names to use regardless of the data source column names, for example, to create the address formats to place into an `ADDRESSBLOCK` field. *end guidance*]

If this element is omitted, then the current data source column mapping shall not have a predefined merge field name mapped to its contents, and shall only be referenced via the data source column name specified by the name element (§2.14.24) when referenced by one or more `MERGEFIELD` fields. If the application does not have a predefined merge field whose name matches the name specified using the val attribute, then this element may be ignored.

[*Example*: Consider the following WordprocessingML fragment, representing two columns from an external data source which have been mapped to the built-in fields `First Name` and `Last Name`, respectively:

```
<w:fieldMapData>
  <w:column w:val="0" />
  <w:name w:val="Column Name A" />
  <w:mappedName w:val="First Name" />
  …
</w:fieldMapData>
<w:fieldMapData>
  <w:column w:val="1" />
  <w:name w:val="Column Name B" />
  <w:mappedName w:val="Last Name" />
  …
</w:fieldMapData>
```

The first and second columns, specified by the column element values of `0` and `1` respectively, specify that the predefined WordprocessingML field names `First Name` and `Last Name` are mapped to the columns of the external data source, and the data source names for those columns are `Column Name A` and `Column Name B`, respectively.

Therefore, if MERGEFIELD fields calling for First Name and Last Name are inserted in a WordprocessingML document connected to the external data source with the field mappings specified above, when the mail merge takes place, the data from the first and second column will populate the fields calling for First Name and Last Name data within the merged WordprocessingML document. *end example*]

Parent Elements
fieldMapData (§2.14.15)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's styleId.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.14.24 name (Data Source Name for Column)

This element specifies the column name within a given external data source for the column whose index is specified via the column element (§2.14.7). This data source name provides a column name which shall be used to map a specific MERGEFIELD field in the document, as specified by the parent field mapping data. The val

attribute specifies the name of this column in the data source when the connection is initially established, which is then used permanently to link columns in the database to MERGEFIELD fields in the document.

If this element is omitted, no data source name is provided for the current column.

[*Example*: Consider a source document that is connected to an external data source with three columns. Within this external data source, these are three columns are ordered and titled as follows: first, middle, and last, respectively. The following WordprocessingML specifies that when this document was connected to the data source, these columns were ordered in this manner:

```
<w:fieldMapData>
  …
  <w:name w:val="first" />
  <w:column w:val="0" />
</w:fieldMapData>
<w:fieldMapData>
  …
  <w:name w:val="middle" />
  <w:column w:val="1" />
</w:fieldMapData>
<w:fieldMapData>
  …
  <w:name w:val="last" />
  <w:column w:val="2" />
</w:fieldMapData>
```

The WordprocessingML above demonstrates that the column name first shall be associated with the first column in the external database by specifying a column element with its val attribute equal to 0. In addition, the column name middle shall be associated with the second column in the external database by specifying a column element with its val attribute equal to 1. Finally, the column name last shall be associated with the third column in the external database by specifying a column element with its val attribute equal to 2. *end example*]

Parent Elements
fieldMapData (§2.14.15)

Attributes	Description
val (String Value)	Specifies that its contents will contain a string. The contents of this string are interpreted based on the context of the parent XML element. [*Example*: Consider the following WordprocessingML fragment:

Attributes	Description
	<w:pPr> <w:pStyle w:val="heading1" /> </w:pPr> The value of the val attribute is the ID of the associated paragraph style's styleId. However, consider the following fragment: <w:sdtPr> <w:alias w:val="SDT Title Example" /> ... </w:sdtPr> In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.14.25 odso (Office Data Source Object Settings)

This element specifies a group of additional settings for the mail merge information which comprise an extension to the standard settings stored with a mail merge which performs two functions:

- First, it provides additional information about the mail merge data source, specifically: information about how to map the columns in the data source to MERGEFIELD fields and information about records which shall be included and excluded when creating merged documents, and column delimiters used in text data sources. This information may be used regardless of the value of the dataType element (§2.14.10) when it is present.
- Second, it provides an alternate set of connection information which should be used when the dataType element (§2.14.10) specifies a value of native. This alternate connection string provides additional connection information for applications which choose to support the ODSO connection string syntax. If the dataType element (§2.14.10) specifies that the data type of the current mail merge is not native, then the second group of settings specified within this element shall be ignored in favor of their non-ODSO equivalents.

[*Example*: Consider the WordprocessingML for a source document whose mail merge includes mail merge information including ODSO settings as follows:

```
<w:odso>
  <w:udl w:val="…" />
  <w:table w:val="Sheet1$" />
  <w:src r:id="rId1" />
  <w:colDelim w:val="9" />
  <w:fHdr w:val="1" />
  <w:fieldMapData>
    <w:type w:val="dbColumn" />
    <w:name w:val="Title" />
    <w:mappedName w:val="Courtesy Title" />
    <w:lid w:val="en-US" />
  </w:fieldMapData>
  <w:recipientData r:id="rId2" />
  …
</w:odso>
```

The odso element and its child elements provide all of the information specified above that is needed to carry out a mail merge with the current document. This includes alternate connection information using the udl, table, and src elements, and additional mail merge information in the other child elements. *end example*]

Parent Elements
mailMerge (§2.14.20)

Child Elements	Subclause
colDelim (Column Delimiter for Data Source)	§2.14.5
fHdr (First Row of Data Source Contains Column Names)	§2.14.14
fieldMapData (External Data Source to Merge Field Mapping)	§2.14.15
recipientData (Reference to Inclusion/Exclusion Data for Data Source)	§2.14.27
src (ODSO Data Source File Path)	§2.14.30
table (Data Source Table Name)	§2.14.31
type (ODSO Data Source Type)	§2.14.33
udl (UDL Connection String)	§2.14.34

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Odso">
   <sequence>
      <element name="udl" type="CT_String" minOccurs="0"/>
      <element name="table" type="CT_String" minOccurs="0"/>
      <element name="src" type="CT_Rel" minOccurs="0"/>
      <element name="colDelim" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="type" type="CT_MailMergeSourceType" minOccurs="0"/>
      <element name="fHdr" type="CT_OnOff" minOccurs="0"/>
      <element name="fieldMapData" type="CT_OdsoFieldMapData" minOccurs="0" maxOccurs="unbounded"/>
      <element name="recipientData" type="CT_Rel" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
</complexType>
```

2.14.26 query (Query For Data Source Records To Merge)

This element contains the Structured Query Language string that shall be run against the specified external data source to return the set of records from the external data which shall be imported into merged WordprocessingML documents when the mail merge operation is performed.

If this element is omitted, then no query shall be associated with the current data source.

[*Example*: Consider a WordprocessingML document that has been connected to an external database. In addition, consider that the data specifies that the table within the database titled `Documentation` shall be the specific table whose data is imported. This shall be specified in WordprocessingML as follows:

```
<w:query w:val="SELECT * FROM Documentation" />
```

The query element specifies the syntax for the data source query via its val attribute. *end example*]

Parent Elements
mailMerge (§2.14.20)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.

Attributes	Description

	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.14.27 recipientData (Reference to Inclusion/Exclusion Data for Data Source)

This element shall specify a reference to the part which contains data about whether the set of records in the associated data source have been explicitly included or excluded from the specified mail merge. Only those records which shall not be used to generate merged WordprocessingML documents must be stored within the referenced part, as all records shall be merged by default as part of the mail merge operation. [*Guidance*: Applications may choose to store only those records which are excluded for efficiency, or a list of all records in order to determine which set of records were added/removed between mail merge operations. *end guidance*]

[*Rationale*: When defining a mail merge, it is possible that a user wishes to connect to a specified data source, but specify only a subset of the records returned by the query specified by the query element (§2.14.26) which shall be merged as part of the mail merge operation. This element allows applications to utilize a separate part to store this information, either the shared part defined by this Office Open XML Standard, or an application-specific part as needed. *end rationale*]

If the relationship type of the relationship specified by this element is not http://schemas.openxmlformats.org/officeDocument/2006/mailMergeRecipientData, is not present, or does not have a TargetMode attribute value of `Internal`, then the document shall be considered non-conformant. If an application cannot process external content of the content type specified by the targeted part, then it may be ignored.

This Office Open XML Standard defines one shared mechanism for storing this data: using the Mail Merge Recipient Data part. This mechanism shall be used if the associated data source has a column which may be used as the unique key. However, when using data sources which do not have a unique key, applications may store their own part (of an application-defined content type) using this relationship.

[*Example*: Consider a WordprocessingML document which is a mail merge source document, containing inclusion/exclusion data for the data source. The document settings part would contain the mail merge data:

```
<w:settings>
  …
  <w:mailMerge>
     …
     <w:odso>
       …
       <w:recipientData r:id="recipient1" />
     </w:odso>
  </w:mailMerge>
</w:settings>
```

The recipientData element specifies that the external content targeted by the relationship with an ID of `recipient1` contains the recipient inclusion/exclusion data for the mail merge operation. Examining the contents of the corresponding relationship part item, we can see the targets for that relationship:

```
<Relationships … >
  …
  <Relationship Id="recipient1" TargetMode="Internal"
Type="http://schemas.openxmlformats.org/officeDocument/2006/relationships/mailMe
rgeRecipientData" Target="recipientData.xml" />
  …
</Relationships>
```

The corresponding relationship part item shows that the file containing this data is located next to the main document and is named `recipientData.xml`. *end example*]

Parent Elements
odso (§2.14.25)

Attributes	Description
id (Relationship to Part) Namespace: …/officeDocument/2006/relationships	Specifies the relationship ID to a specified part. The specified relationship shall match the type required by the parent element: • http://schemas.openxmlformats.org/officeDocument/2006/relationships/footer for the footerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/header for the headerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/font for the embedBold, embedBoldItalic, embedItalic, or embedRegular elements • http://schemas.openxmlformats.org/officeDocument/2006/relationships/pr

Attributes	Description
	interSettings for the printerSettings element [*Example*: Consider an XML element which has the following id attribute: `<… r:id="rId10" />` The markup specifies the associated relationship part with relationship ID `rId1` contains the corresponding relationship information for the parent XML element. *end example*] The possible values for this attribute are defined by the ST_RelationshipId simple type (§7.8.2.1).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Rel">
   <attribute ref="r:id" use="required"/>
</complexType>
```

2.14.28 recipientData (Data About Single Data Source Record)

This element specifies information about a single record within an external data source. If a record shall be merged into a merged document, then no information is needed about that record within this part. However, if a given record shall not be merged into a merged document, then the value of the unique key for that record shall be stored within the uniqueTag element as a child of this element (along with the active element) to indicate this exclusion.

[*Note*: This mapping is necessary in place of simply using the element order to correspond to the record indices in the external data source, as records may be added or deleted from external data sources, and a means must be provided to maintain WordprocessingML external record specific data like that specified in the active element (§2.14.1) and the corresponding external data record when the WordprocessingML document is reconnected to the external data source; irrespective of the ordering of the records within the external data source. In other words, this element, and its child elements enable merged WordprocessingML documents to maintain the relationship between the records within an external data and record specific WordprocessingML parameters. *end note*]

[*Example*: Consider a merged WordprocessingML document that:

Annex K. Has been connected to a specified external data source containing three records; and

13. Has been configured by the hosting application to not populate a merged document with the record pertaining to `John Smith` in the external data source.

Consider also that the first time the given WordprocessingML document was connected to the external data source, `John Smith`'s record was in the second record in the data source.

When this merged document is connected to the external data source the recipientData element may be used to store the number and value of the column containing the unique key for each data record within the external

data source including John Smith's. This setting is represented using the following WordprocessingML to use the hash codes within the recipientData element to uniquely identify the three records within the external data source.

```
<w:recipientData>
  <w:column w:val="1" />
  <w:uniqueTag w:val="1408613399" />
</w:recipientData>
<w:recipientData>
  <w:column w:val="1" />
  <w:active w:val="0" />
  <w:uniqueTag w:val="870254691" />
</w:recipientData>
<w:recipientData>
  <w:column w:val="1" />
  <w:uniqueTag w:val="1107777181" />
</w:recipientData>
```

Here, the first, second (John Smith record), and third records within the specified data source whose unique key values are 1408613399, 870254691, and 1107777181 have been associated with with recipient data via the active element to specify that the record associated with the given record (John Smith's record) shall not be used to populate a merged WordprocessingML document.

With these association in place, if a fourth record is added to the given external data source above John Smith's record, when the given merged WordprocessingML document is reconnected to the external data source, the hosting application will still know that John Smith's record shall not be used to populate a merged WordprocessingML document as it is associated via its unique key value and is not dependent on the given record's ordinal position within the external data source. *end example*]

Parent Elements
Root element of WordprocessingML Mail Merge Recipient Data partrecipients (§2.14.29)

Child Elements	Subclause
active (Record Is Included in Mail Merge)	§2.14.1
column (Index of Column Containing Unique Values for Record)	§2.14.6
uniqueTag (Unique Value for Record)	§2.14.35

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RecipientData">
   <sequence>
      <element name="active" type="CT_OnOff" minOccurs="0"/>
      <element name="column" type="CT_DecimalNumber" minOccurs="1"/>
      <element name="uniqueTag" type="xsd:base64Binary" minOccurs="1"/>
   </sequence>
</complexType>
```

2.14.29 recipients (Inclusion/Exclusion Data for Data Source)

This element specifies all of the inclusion/exclusion data for the contents of the specified mail merge data source. It is the root element for the Mail Merge Recipient Data part.

[*Example*: Consider a document which is the source document for a mail merge operation. If two records of the three specified by the data source were excluded from the mail merge, the resulting recipient data part would appear as follows:

```
<w:recipients>
  <w:recipientData>
    <w:active w:val="false"/>
    …
  </w:recipientData>
  <w:recipientData>
    <w:active w:val="false"/>
    …
  </w:recipientData>
  <w:recipientData>
    …
  </w:recipientData>
</w:recipients>
```

The recipients element contains all of the recipient inclusion/exclusion data for this mail merge document. *end example*]

Child Elements	Subclause
recipientData (Data About Single Data Source Record)	§2.14.28

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Recipients">
   <sequence>
      <element name="recipientData" type="CT_RecipientData" minOccurs="1" maxOccurs="unbounded"/>
   </sequence>
</complexType>
```

2.14.30 src (ODSO Data Source File Path)

This element specifies the relationship whose target is the location of the external data source to be connected to a given WordprocessingML document to perform the mail merge (for a source document) or to find the associated field data (for a merged document) when the merge type, specified using the dataType element (§2.14.10), is set to `native`.

If this element is omitted, then no file location is specified for the data source for the current mail merge. If no relationship exists with the given relationship ID, or this relationship is not of the Mail Merge Data Source relationship type, then this document shall be considered non-conformant.

The data source location is only used under the following conditions:

- The dataType element (§2.14.10) is set to `native`
- The current application is able to use the information contained in the odso element (§2.14.25) to access the data source

[*Guidance*: In this case, using the data source file path in the src element will provide an equal or greater amount of information for the mail merge data source for clients which can consume it. *end guidance*]

[*Example*: Consider a WordprocessingML source document containing the following mail merge data:

```
<w:odso>
  …
  <w:src r:id="rId1" />
  …
</w:odso>
```

This mail merge's src element specifies via its r:id attribute value of `rId1` that the external data source to be connected to the given WordprocessingML document is the data source targeted by the relationship whose Id attribute is equal to `rId1`. If we examine the corresponding relationship part item for the setting part, as follows:

```
<Relationships>
  <Relationship Id="rId1"
Type="http://schemas.openxmlformats.org/officeDocument/2006/relationships/mailMe
rgeSource" Target="file:///c:/example_file.mdb" TargetMode="External" />
</Relationships>
```

Since the relationship whose Id attribute value is `rId1` specifies the source file path for the data source, that data source effectively specifies a file path of `c:\example_file.mdb`. *end example*]

Parent Elements
odso (§2.14.25)

Attributes	Description
id (Relationship to Part) Namespace: .../officeDocument/2006/relationships	Specifies the relationship ID to a specified part. The specified relationship shall match the type required by the parent element: • http://schemas.openxmlformats.org/officeDocument/2006/relationships/footer for the footerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/header for the headerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/font for the embedBold, embedBoldItalic, embedItalic, or embedRegular elements • http://schemas.openxmlformats.org/officeDocument/2006/relationships/printerSettings for the printerSettings element [*Example*: Consider an XML element which has the following id attribute: `<… r:id="rId10" />` The markup specifies the associated relationship part with relationship ID `rId1` contains the corresponding relationship information for the parent XML element. *end example*] The possible values for this attribute are defined by the ST_RelationshipId simple type (§7.8.2.1).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Rel">
   <attribute ref="r:id" use="required"/>
</complexType>
```

2.14.31 table (Data Source Table Name)

This element specifies the particular set of data that a source or merged WordprocessingML document shall be connected to within an external data source containing multiple data sets. In other words, when connecting to a WordprocessingML document to an external data source that may have more than one repository of data within it, such as a database with multiple tables or a spreadsheet with multiple worksheets, this element is used to distinguish the specific table or spreadsheet from which data will be imported from within the external data source.

[*Example*: Consider a WordprocessingML document that has been connected to database containing two tables named `Table One` and `Table Two`, respectively. To specify that the mail merge shall import data from `Table One` into the WordprocessingML document, this requirement would be specified using the following WordprocessingML:

```
<w:odso>
  …
  <w:table w:val="Table One" />
  …
</w:odso>
```

The table element with a value of `Table One` specifies that the external data shall be retrieved from this table in the data source. *end example*]

Parent Elements
odso (§2.14.25)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.14.32 type (Merge Field Mapping)

This element specifies if a given mail merge field has been mapped to a column in the given external data source or not.

If this element is omitted, then the field mapping shall be considered to be of type `null` (i.e. not mapped).

[*Example*: Consider the WordprocessingML for a single field mapping within a mail merge source document:

```
<w:odso>
  …
  <w:fieldMapData>
    <w:type w:val="dbColumn" />
    <w:name w:val="Country" />
    <w:mappedName w:val="Country or Region" />
    <w:column w:val="9" />
    …
  </w:fieldMapData>
</w:odso>
```

In this example, the `country` column within the given external data source shall be mapped to the mail merge field `Country or Region`, as specified by the type element's val attribute being equal to `dbColumn`. *end example*

Parent Elements
fieldMapData (§2.14.15)

Attributes	Description
val (Merge Field Mapping Type)	Specifies if the given mail merge field has been mapped to a column in the given external data source (i.e. if the merge field mapping is valid or not). [*Example*: Consider the following WordprocessingML fragment for a mail merge source or merged document: `<w:type w:val="null" />` In this example, the given mail merge field shall not be mapped to a column in the given external data source, as specified by the type element's val attribute being equal to `null`. *end example*] The possible values for this attribute are defined by the ST_MailMergeOdsoFMDFieldType simple type (§2.18.62).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_MailMergeOdsoFMDFieldType">
   <attribute name="val" type="ST_MailMergeOdsoFMDFieldType" use="required"/>
</complexType>
```

2.14.33 type (ODSO Data Source Type)

This element specifies the type of external data source to be connected to via as part of the ODSO connection information for this mail merge. This setting is purely a suggestion of the data source type which is being used for this mail merge, and may be ignored in favor of an alternative mechanism if one is present.

[*Example*: Consider the following WordprocessingML fragment for a mail merge source or merged document:

```
<w:type w:val="database" />
```

The type element's val attribute is equal to `database`, specifying that the given merged WordprocessingML document has been connected to an external data source via the ODSO settings, and that the resulting data source was a database. *end example*]

Parent Elements
odso (§2.14.25)

Attributes	Description
val (Data Source Type Value)	Specifies the type of an external data source used for a mail merge operation. [*Example*: Consider the following WordprocessingML fragment for a mail merge source or merged document: `<w:type w:val="text" />` The val attribute is equal to `text`, specifying that the given merged WordprocessingML document has been connected to an external data source via the ODSO settings, and that the resulting data source was a text file. *end example*] The possible values for this attribute are defined by the ST_MailMergeSourceType simple type (§2.18.63).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_MailMergeSourceType">
   <attribute name="val" use="required" type="ST_MailMergeSourceType"/>
</complexType>
```

2.14.34 udl (UDL Connection String)

This element specifies the Universal Data Link (UDL) connection string used to reconnect to an external data source. The string within this element's val attribute shall contain the connection string that the hosting

application shall pass to a external data source access application to enable the WordprocessingML document to be reconnected to the specified external data source.

If this string is omitted, then no UDL connection string shall be associated with the ODSO data for this mail merge.

This connection string is only used under the following conditions:

- The dataType element (§2.14.10) is set to `native`
- The current application is able to use the information contained in the odso element (§2.14.25) to access the data source

[*Guidance*: In this case, using the connection string in the udl element will provide an equal or greater amount of information for the mail merge data source for clients which can consume it. *end guidance*]

[*Example*: Consider a merged WordprocessingML document that has been connected to an external data source for the purposes of a mail merge. The following WordprocessingML fragment represents the legacy connection string used to connect to the external data source when the merged WordprocessingML document is reopened:

```
<w:udl w:val="Provider=Example;Password=Test;User ID=readonly;…" />
```

The udl element specifies that the string `Provider=Example;Password=Test;User ID=readonly;…` shall be used to enable the given WordprocessingML document to be reconnected to the specified external data source. *end example*]

Parent Elements
odso (§2.14.25)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`

Attributes	Description
	<w:alias w:val="SDT Title Example" /> ... </w:sdtPr> In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.14.35 uniqueTag (Unique Value for Record)

This element specifies the contents of a given record within the specified external data source, in the column containing unique data for every record within the external data source. given external data source. This element is used in conjunction with the column (§2.14.7) element to maintain a relationship between the records within an external data source and a given merged WordprocessingML document.

The contents of this attribute shall be the base64-encoded value of the unique tag value as specified by the data source.

[*Note*: This information is necessary as part of a mail merge as records may be added or deleted from external data sources, and a means must be provided to maintain record-specific inclusion or exclusion data using the active element (§2.14.1) and the affected external data record when the WordprocessingML document is reconnected to the external data source irrespective of the ordering of the records within the external data source. *end note*]

[*Example*: Consider the following WordprocessingML fragment for the information about a single record in a source document for a mail merge:

```
<w:recipientData>
  <w:active w:val="0" />
  <w:column w:val="12" />
  <w:uniqueTag w:val="258865469" />
</w:recipientData>
```

The external data record associated with this information is specified via the column in the external data source corresponding to the column element with a val attribute equal to 12, which contains a row whose value in this column has a value corresponding to the uniqueTag element with a val attribute equal to 258865469. This record will not be imported into the merged WordprocessingML document as the active (§2.14.1) element associated with the given external data record has a val attribute equal to 0.

In other words, when the specified external data source is connected to, the record within the thirteenth column of the external data source that has the contents 258865469, and not populate mapped fields in a merged document with data from that record. *end example*]

The possible values for this element are defined by the XML Schema base64Binary datatype.

Parent Elements
recipientData (§2.14.28)

2.14.36 viewMergedData (View Merged Data Within Document)

This element specifies that a specific merged document shall display the data from the specified external data source where merge fields have been inserted. The activeRecord element (§2.14.2) is used to specify which record within the external data source is to have its applicable data displayed where applicable within the WordprocessingML merged document.

If the activeRecord element is not present in the WordprocessingML for the document with the viewMergedData's val attribute equal to on, the hosting application may behave as if the acitveRecord element's val attribute was equal to 1. This element is ignored if the viewMergedData (§2.14.36) element is not present or present with a val attribute equal to `Off`, `0`, or `false`.

[*Example*: Consider a merged WordprocessingML document containing two WordprocessingML fields calling for `Courtesy Title` and `Last Name` data and a sample text paragraph. Also, note that the external data source this merged document is connected to contains two records, both containing name and address information, with the first record pertaining to `Mr. Doe`, and the second pertaining to `Ms. Smith`.

This table below illustrates the necessary WordprocessingML to display applicable data from the specified external data source within the merged document where fields have been inserted:

`<w:viewMergedData val="off"/>`	`<w:viewMergedData val="on" />` `<w:activeRecord w:val="1" />`	`<w:viewMergedData val="off" />` `<w:activeRecord w:val="1" />`
Dear {MERGEFIELD "Courtesy Title" \m} {MERGEFIELD "Last Name" \m}, Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sincerely,	Dear Mr. Doe: Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sincerely,	Dear {MERGEFIELD "Courtesy Title" \m} {MERGEFIELD "Last Name" \m}, Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sample letter text. Sincerely,

The viewMergedData element specifies that the specified record in the external data source shall be displayed in place of merge fields in the current document. *end example*]

Parent Elements
mailMerge (§2.14.20)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15 Settings

Within a WordprocessingML document, *settings* specify stored preferences which shall be used when processing the contents of the document. These settings are typically divided into three categories:

- *Document Settings* - settings which influence the appearance and behavior of the current document, as well as store document-level state.
- *Compatibility Settings* - settings which tell applications to perform behaviors which are designed to maintain visual output of previous word processing applications. These settings are for backward compatibility and are all ignorable.
- *Web Settings* - settings which affect how this document shall be handled when it is saved as HTML. These settings exist primarily for backward compatibility reasons and are all ignorable.

The first two groups are stored in the Document Settings part, and the last group is stored in the Web Settings part.

2.15.1 Document Settings

The first group of settings stored in WordprocessingML is document settings. These settings specify all document-level properties which affect the handling of the current document.

[*Example*: Consider the following WordprocessingML fragment for the document settings in a WordprocessingML document:

```
<w:settings>
  <w:defaultTabStop w:val="720" />
  <w:characterSpacingControl w:val="dontCompress" />
</w:settings>
```

The settings element contains all of the document settings for this document. In this case, the two settings applied are automatic tab stop increments of 0.5" using the defaultTabStop element (§2.15.1.24), and no character level whitespace compression using the characterSpacingControl element (§2.15.1.18). *end example*]

2.15.1.1 activeWritingStyle (Grammar Checking Settings)

This element specifies information about the parameters of the grammar checking which was performed on the contents of the current WordprocessingML document. [*Note*: This information may be used as desired by applications; for example, to determine if the current grammar checking state, specified by the proofState element (§2.15.1.65) is sufficient. *end note*]

[*Example*: Consider the following WordprocessingML fragment from the document settings:

```
<w:activeWritingStyle w:lang="en-CA" w:vendorID="64" w:dllVersion="131078"
w:nlCheck="1" w:optionSet="0" />
```

The activeWritingStyle element's lang attribute specifies that the English (Canada) language setting for grammatical and stylistic checks shall be applied; the vendorID attribute specifies information about the vendor associated with the DLL used to perform the grammatical and stylistic checks; the dllVersion attribute specifies the version of this DLL; the nlCheck attribute specifies if natural language checks were performed or not; and the optionSet element specifies that the hosting application should allow its grammar engine to check both the grammar and style of the given WordprocessingML document, if that functionality is available. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
appName (Application Name)	Specifies the name of the application which specified the grammatical settings contained on the attributes for this element. If an application reads these settings and does not understand the value of this attribute, then its settings may be ignored and the application's default settings used instead.

Attributes	Description
	[*Example*: Consider the WordprocessingML below: `<w:activeWritingStyle … w:appName="testApp"/>` The appName attribute has a value of `testApp`, specifying that the application called `testApp` specified the grammar checking rules of the given WordprocessingML document. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).
checkStyle (Check Stylistic Rules With Grammar)	Specifies if the grammar content checking performed on this document included stylistic rules for the document content. If specified, applications which support this functionality shall check stylistic rules as well as grammatical ones when checking the grammatical content of this document. [*Example*: Consider the WordprocessingML below: `<w:activeWritingStyle … w:checkStyle="false"/>` The checkStyle attribute has a value of `false`, specifying that hosting applications shall only check grammatical rules of the given WordprocessingML document. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
dllVersion (Grammatical Check Engine Version)	Specifies the version of the engine that was used to check the grammatical content of the WordprocessingML document. [*Example*: Consider the following WordprocessingML fragment: `<w:activeWritingStyle … w:dllVersion="131078" />` The dllVersion attribute specifies that the writing style DLL version used to check the writing style of is the writing style DLL version associated with the decimal number `131078`. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
lang (Writing Style Language)	Specifies the language of the engine used to perform the grammatical content checking. [*Example*: Consider the following WordprocessingML fragment: `<w:activeWritingStyle w:lang="en-CA" …/>` The lang attribute has a value of `en-CA`, therefore the grammatical check language is specified as English (`en`) and Canada (`CA`), resulting in use of the English (Canada) grammar checker. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_Lang simple type (§2.18.51).
nlCheck (Natural Language Grammar Check)	Specifies whether the engine that was used to check the grammatical content of the WordprocessingML document performed natural language-based analysis. [*Example*: Consider the WordprocessingML below: `<w:activeWritingStyle … w:nlCheck="1" />` The nlCheck attribute has a value of 1, specifying that the writing style DLL supported natural language analysis . *end example*]. The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
vendorID (Grammatical Engine ID)	Specifies a value indicating a unique ID for the writing style engine that was used to check the grammatical content of the WordprocessingML document. [*Example*: Consider the WordprocessingML below: `<w:activeWritingStyle … w:vendorID="64"/>` The vendorId attribute has a value of 64, specifying that the grammatical checker used is identified by the decimal number 64.*end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_WritingStyle">
   <attribute name="lang" type="ST_Lang" use="required"/>
   <attribute name="vendorID" type="ST_DecimalNumber" use="required"/>
   <attribute name="dllVersion" type="ST_DecimalNumber" use="required"/>
   <attribute name="nlCheck" type="ST_OnOff" use="optional"/>
   <attribute name="checkStyle" type="ST_OnOff" use="required"/>
   <attribute name="appName" type="ST_String" use="required"/>
</complexType>
```

2.15.1.2 alignBordersAndEdges (Align Paragraph and Table Borders with Page Border)

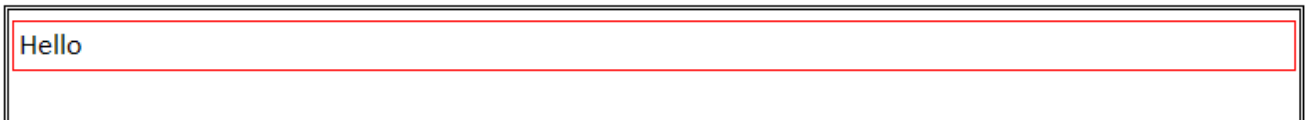
This element specifies that paragraph borders specified using the pBdr element (§2.3.1.24) and table borders using the tblBorders element (§2.4.37) shall be adjusted to align with extents of the page border defined using the pgBorders element (§2.6.10) if the spacing between these borders is less than or equal to 10.5 points (one character width) or less from the page border. The presence of this setting shall ensure there are no gaps of one character width or less between adjoining page and paragraph/table borders, as borders which are perfectly aligning shall not be displayed in favor of the intervening page border.

If this element is omitted, then borders shall not be automatically adjusted to prevent gaps of less than one character width. If the page border is not measured from the text extents using a value of `text` in the offsetFrom attribute on the pgBorders element, then it may be ignored.

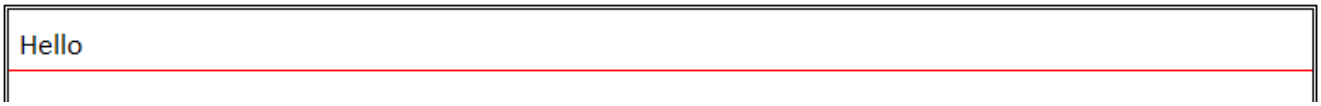
[*Example*: Consider the following WordprocessingML fragment from the document settings:

```
<w:alignBordersAndEdges w:val="true"/>
```

The alignBordersAndEdges element has a value of `true` specifying that borders shall be adjusted to prevent gaps of less than one character width. If a document has a page border specified to appear 4 points from the text extents, and within that page a paragraph border specified to appear one point from the text extents, that would normally appear like this:



If this element is present, then those gaps (which are all of three points in width) shall be adjusted to ensure that the borders align exactly and the paragraph border is suppressed:



end example]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.3 alwaysMergeEmptyNamespace (Do Not Mark Custom XML Elements With No Namespace As Invalid)

This element specifies whether custom XML markup specified via the customXml element which has no associated namespace shall be treated as an error and moved into a special error namespace (for the purposes of validation) when the document is opened. If this element is turned on, when an application determines that the current XML markup is in the empty namespace, those elements shall not automatically be moved into an error namespace.

If this element is not present in a WordprocessingML document than custom XML markup which has no associated namespace shall be treated as an error and moved into a special error namespace when the document is opened.

[*Example*: Consider a WordprocessingML document which should not automatically flag empty namespace XML as invalid. This requirement would be specified using the following WordprocessingML:

```
<w:alwaysMergeEmptyNamespace w:val="true"/>
```

The alwaysMergeEmptyNamespace element's val attribute has a value of `true` specifying that custom XML markup in the empty namespace shall never be treated as an error. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.4 alwaysShowPlaceholderText (Use Custom XML Element Names as Default Placeholder Text)

This element specifies that each custom XML element specified using the customXml element within this document shall always show some form of in-document placeholder text presentation when it contains no run content. If the placeholder element (§2.5.2.24) is present in the custom XML element's properties, then this is the placeholder text displayed and this effect has no effect. If the placeholder element is omitted, then the application shall use the name of the element to generate default placeholder text in its place.

If this element is omitted, then custom XML markup which does not contain a placeholder element within its properties shall not display any placeholder text.

[*Example*: Consider the following WordprocessingML fragment from the document settings:

```
<w:alwaysShowPlaceholderText w:val="true" />
```

The alwaysShowPlaceholderText element has a value of `true`, which specifies that placeholder text shall be generated using the element's name if no placeholder text is present. If two custom XML elements are defined as follows:

```
<w:customXml w:name="spec" … >
  <w:customXmlPr>
    <w:placeholder w:val="Type the name of the specification." />
  </w:customXmlPr>
</w:customXml>
…
<w:customXml w:name="spec" … >
</w:customXml>
```

The first custom XML element has placeholder text, and the second doesn't, so if this element is omitted, these two elements might be displayed as follows:

Notice that the second custom XML element has no placeholder text, and therefore is not displayed. However, when this element is present, then the application should generate default placeholder text in its place:

Type the name of the specification.

[spec]

The application generated default placeholder text from the element name, resulting in a value of `[spec]` in the document. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.5 attachedSchema (Attached Custom XML Schema)

This element specifies that the custom XML schema whose target namespace matches the value specified in the val attribute should be associated with this document when it is loaded, if such a schema is available to the hosting application. Applications may also load and utilize any additional schemas as well as those explicitly mentioned here. [*Note*: These custom XML schemas may then be used to validate the structure of the custom XML markup in the document, etc. *end note*]

If no elements of this type are present, then no custom XML schemas have been explicitly associated with the contents of this document.

[*Example*: Consider the following WordprocessingML fragment from the document settings:

```
<w:attachedSchema w:val="http://www.example.com/schema1" />
<w:attachedSchema w:val="http://www.example.com/schema2" />
```

The attachedSchema elements specify that two custom XML schemas with namespaces of `http://www.example.com/schema1` and `http://www.example.com/schema2` should be associated with the custom XML markup in the current document. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
    <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.15.1.6 attachedTemplate (Attached Document Template)

This element specifies the location of a document template which shall be attached to the current WordprocessingML document if it is accessible and of a format supported by an application. Specifically, this element's `val` attribute shall contain the file path of the associated document template.

If this element is omitted, then the document shall not have an attached document template, and applications should use their default template in its place.

[*Example*: Consider a WordprocessingML document which is attached to a WordprocessingML template located on the local C drive within a file whose name is `c:\template.dotx`. This association is specified using the following WordprocessingML:

```
<w:attachedTemplate w:val="c:\template.dotx" />
```

The attachedTemplate element contains the path to the associated template. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
id (Relationship to Part) Namespace: .../officeDocument/2006/relationships	Specifies the relationship ID to a specified part. The specified relationship shall match the type required by the parent element: • http://schemas.openxmlformats.org/officeDocument/2006/relationships/footer for the footerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/header for the headerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/font for the embedBold, embedBoldItalic, embedItalic, or embedRegular elements • http://schemas.openxmlformats.org/officeDocument/2006/relationships/printerSettings for the printerSettings element [*Example*: Consider an XML element which has the following id attribute: `<… r:id="rId10" />` The markup specifies the associated relationship part with relationship ID `rId1` contains the corresponding relationship information for the parent XML element. *end example*] The possible values for this attribute are defined by the ST_RelationshipId simple type (§7.8.2.1).

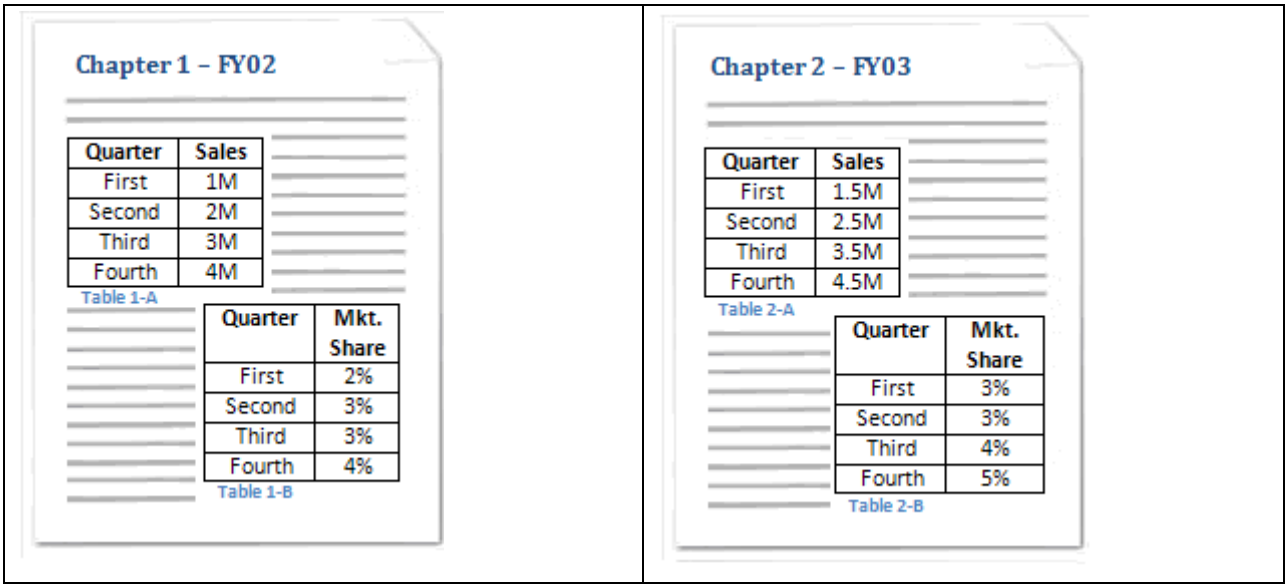
The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Rel">
   <attribute ref="r:id" use="required"/>
</complexType>
```

2.15.1.7 autoCaption (Single Automatic Captioning Setting)

This element specifies what type(s) of objects shall automatically labeled with captions (§2.15.1.17), and with which captions the specified objects shall be labeled as defined in the caption element (§2.15.1.16).

[*Example*: Consider the diagram below illustrating a two page WordprocessingML document that has leveraged WordprocessingML to automatically label WordprocessingML tables with a specified caption when tables are inserted into the given document.



This type of automatic captioning is specified using the following WordprocessingML fragment:

```
<w:captions>
  <w:caption w:name="Table" w:pos="below" w:chapNum="On" w:heading="2"
w:numFmt="upperCase" w:sep="8212" />
  <w:autoCaptions>
    <w:autoCaption w:name="wfwTable" w:caption="Table" />
  </w:autoCaptions>
</w:captions>
```

Here, the autoCaption element specifies through the name attribute being set equal to `wfwTable` that tables will automatically be labeled with the caption specified in the caption element whose name attribute is equal to `Table`, as the caption element's caption attribute has a value of `Table`. *end example*]

Parent Elements

Parent Elements
autoCaptions (§2.15.1.8)

Attributes	Description

caption (Caption Used for Automatic Captioning)	Specifies the caption defined in using the caption element (§2.15.1.16) which shall be used to automatically label a given type of object inserted in a WordprocessingML document. The caption settings are linked by matching the value of this attribute with the name attribute of the corresponding caption element.
	
	[*Example*: Consider the WordprocessingML below
	
	`<w:captions>`
	`  <w:caption w:name="table" w:pos="below" w:chapNum="1"`
	`w:heading="0" w:noLabel="1" w:numFmt="upperRoman" />`
	`  <w:autoCaptions>`
	`  <w:autoCaption w:name="Paint.Picture"`
	`w:caption="table" />`
	`  </w:autoCaptions>`
	`</w:captions>`
	
	The autoCaption element specifies through the name attribute being set equal to `wfwTable` that tables will automatically be labeled with the caption whose name attribute is equal to `Table` (specified by the caption element's attribute name having a value of `Table`). *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

name (Identifier of Object to be Automatically Captioned)	Specifies a unique identifier which may be used to associate objects inserted into the document which are to be automatically labeled with a caption when inserted into the WordprocessingML document. [*Example*: Consider the WordprocessingML below specifying that WordprocessingML tables should be labeled with the `custom` caption: `<w:autoCaption w:name="wfwTables" w:caption="custom" />` The name attribute value of `wfwTables` specifies that WordprocessingML tables shall be labeled with the `custom` caption. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

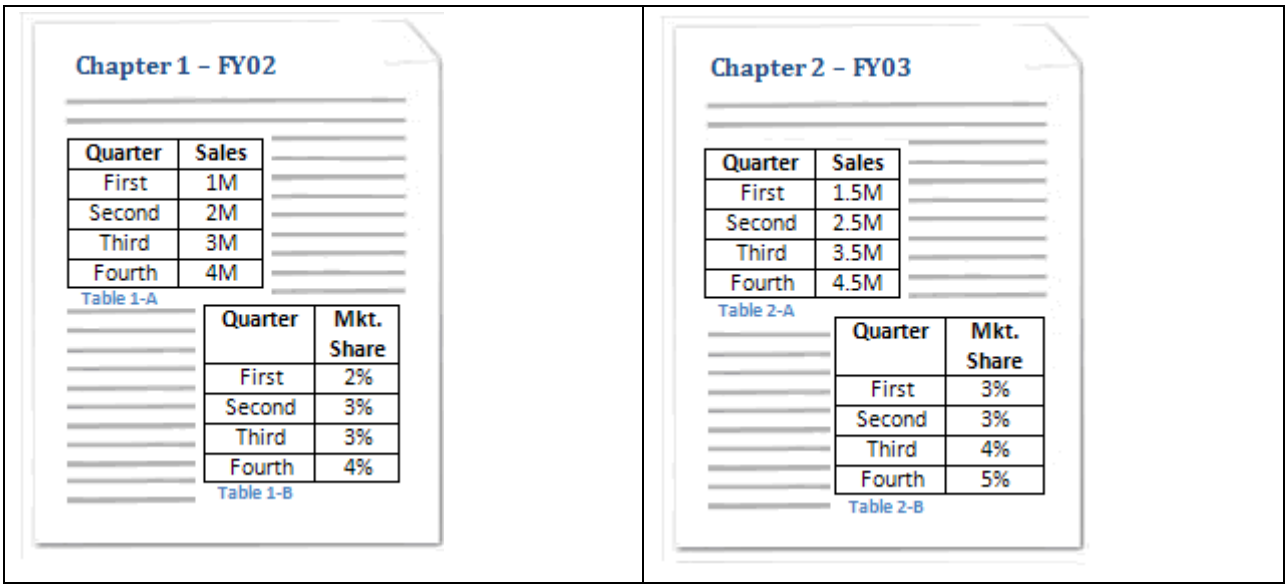
The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_AutoCaption">
   <attribute name="name" type="ST_String" use="required"/>
   <attribute name="caption" type="ST_String" use="required"/>
</complexType>
```

2.15.1.8 autoCaptions (Automatic Captioning Settings)

This element specifies that one or more types of objects, when inserted into a WordprocessingML document, will automatically be labeled with a specific caption defined using the caption element (§2.15.1.16).

[*Example*: Consider the following example illustrating a two page WordprocessingML document that has leveraged WordprocessingML to automatically label WordprocessingML tables with a specified caption.



This type of automatic captioning is specified using the following WordprocessingML fragment:

```
<w:captions>
  <w:caption w:name="Table" w:pos="below" w:chapNum="On" w:heading="2"
w:numFmt="upperCase" w:sep="8212" />
  <w:autoCaptions>
    <w:autoCaption w:name="wfwTable" w:caption="Table" />
  </w:autoCaptions>
</w:captions>
```

The autoCaptions element specifies set of objects that when inserted into a WordprocessingML document will automatically be labeled with a given caption. *end example*]

Parent Elements
captions (§2.15.1.17)

Child Elements	Subclause
autoCaption (Single Automatic Captioning Setting)	§2.15.1.7

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_AutoCaptions">
   <sequence>
      <element name="autoCaption" type="CT_AutoCaption" minOccurs="1" maxOccurs="unbounded"/>
   </sequence>
</complexType>
```

2.15.1.9 autoFormatOverride (Allow Automatic Formatting to Override Formatting Protection Settings)

This element specifies whether formatting automatically applied by an application (i.e. not explicitly applied by a use or an application) shall be allowed to override formatting protection enabled via the formatting attribute on the documentProtection element (§2.15.1.9) when those formatting operations would add formatting which has been explicitly disabled. [*Example*: Automatically adding superscript to the `st` in the string `1st`. *end example*]

If this element is omitted, then no automatic formatting rule(s) shall be allowed to override the formatting restrictions enabled for the document.

[*Example* Consider a WordprocessingML document which has been protected such that a user shall not be able to directly format text within the document. Consider also that the hosting application has been constructed such that if a user enters a ampersand, then one or more alphabetical characters, then another ampersand, that the alphabetical characters are to take on italicized formatting.

If the autoFormatOverride element is omitted or set to `false` and document protection is enabled, the aforementioned series of events will not cause the English alphabetical characters to be italicized as the document protection preventing formatting of the document in question will supersede the formatting to take place after these events. If this operation should not be prevented when active formatting restrictions are used, this would be specified using the following WordprocessingML:

```
<w:autoFormatOverride w:val="true"/>
```

The autoFormatOverride element's val attribute is equal to on specifying that the automatic formatting behavior shall be applied regardless of the formatting restrictions in place. *End Example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted.

Attributes	Description
	A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.10 autoHyphenation (Automatically Hyphenate Document Contents When Displayed)

This element specifies whether the content of a given WordprocessingML document should automatically be hyphenated by the hosting application before it is displayed, if the application supports this functionality.

If this element is omitted, then hyphenation shall not automatically be performed by application displaying this document.

[*Example*: Consider the images below illustrating a paragraph of text in a WordprocessingML document:

This is sample text. This is sample text. This is sample text. This is sample text. This is sample text. This is sample text. This is sample text. This is sample text. This is sample text. This is sample text. This is sample text. This is sample text.

If the content in this document shall automatically be hyphenated when it is displayed, that requirement would be specified using the following WordprocessingML in the document settings:

```
<w:autoHyphenation w:val="true" />
```

The resulting output might look like the following (depending on the application's hyphenation algorithm and the hyphenation zone setting (§2.15.1.53):

This is sample text. This is sample text. This is sample text. This is sample text. This is sample text. This is sample text. This is sample text. This is sample text. This is sample text. This is sample text. This is sample text. This is sam-ple text. This is sample text.

The autoHypehenation element has its val attribute equal to `true`, the document is automatically hyphenated and the word `sample`, beginning at the end of the second line, is hyphenated automatically and thus carried over onto the third line. Conversely, when the autoHypehnation element has its val attribute equal to `off`, the entire word `sample` is carried over to the third line as it was not hyphenated automatically and could not fit onto the second line. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.11 bookFoldPrinting (Book Fold Printing)

This element specifies if the contents of a given WordprocessingML document should be printed as signatures. *Signatures* are printed *sheets*, which depict several pages of a document that are folded and bound with other signatures to form a booklet, a set of which can be bound together to form a book like publication. Specifically, this element specifies that each page in a given WordprocessingML document should be oriented in a landscape fashion, divided in half vertically with two left margins emanating from the bisector of the page, and two right margins instantiated at the left and right side of each page.

This element is used in conjunction with the bookFoldPrintingSheets element (§2.15.1.12) to enable a WordprocessingML document to be printed such that the series of signatures printed may be folded and bound to create a booklet.

This element has no impact on the settings of printer leveraged by the hosting application. In other words, if the printer leveraged by the hosting application has been configured to print on one side of a page, including the WordprocessingML for this element has no effect.

If this element is omitted, then pages shall not be printed as signatures. If the bookFoldRevPrinting element (§2.15.1.13) is also specified, then this element shall be ignored.

[*Example*: Consider a four page WordprocessingML document with a 2,160 twentieths of a point (one and a half inch) left margin, and 1,440 twentieths of a point (one inch) bottom, right, and top margins using the pgMar element (§2.6.11) surrounding the text extents of the page (represented by the gray shaded area in diagrams below). These page margins are specified using the following WordprocessingML:

```
<w:pgMar w:top="1440" w:right="1440" w:bottom="1440" w:left="2160" />
```

The necessary WordprocessingML and consequential effect of setting the bookFoldPrinting element's val attribute to `true` versus `false` and the bookFoldPrintingSheets element's val attribute to `4`, is depicted graphically below—diagrams not drawn to scale:

<table>
<tr><td><code><w: bookFoldPrinting w:val="false"/></code></td><td><code><w: bookFoldPrinting w:val="true" /></code></td></tr>
<tr><td>First Printed Sheet</td><td>First Printed Signature</td></tr>
<tr><td> </td><td> </td></tr>
<tr><td>Second Printed Sheet</td><td>Second Printed Signature</td></tr>
<tr><td> </td><td> </td></tr>
</table>

Assuming the page was already oriented in a landscape fashion, setting the bookFoldPrinting element's val attribute to `true` divided the page in half vertically, with two left margins emanating from the bisector of the page, and right margins instantiated at the left and right side of each page, enabling two signatures to be printed.

In addition, this element is used in conjunction with the bookFoldPrintingSheets element to enable the given WordprocessingML document to be printed such that the series of signatures printed may be folded and bound to create a booklet. Specifically, the signatures may be placed back to back, with top the bottom of each sheet aligned, and folded such that a booklet is created. *end example*]

[*Note*: This element could also be leveraged by the hosting application to notify the application to display two pages per sheets within its user interface to allow for a WYSIWYG user experience. *end note*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.12 bookFoldPrintingSheets (Number of Pages Per Booklet)

This element shall be used in conjunction with the bookFoldPrinting (§2.15.1.11) and bookFoldRevPrinting (§2.15.1.13) elements to specify the number of pages to be included in each booklet when printing a series of signatures. Signatures are printed *sheets*, which depict several pages of a document that are to be folded and bound with other signatures to form a booklet. Booklets can be bound together to form a book like publication.

If this element is omitted, then its default behavior shall be to print the contents of the content on a single sheet. A *sheet* is a single piece of paper which is folded and cut to produce a book.

[*Example*: Consider a four page WordprocessingML document will be printed as a set of two signatures to be compiled into a single booklet. This setting would be specified using the following WordprocessingML fragment in the document settings part:

```
<w:bookFoldPrinting w:val=“true” />
<w:bookFoldPrintingSheets w:val="4" />
```

The bookFoldPrintingSheets element's val attribute specifies that 4 pages shall be included in each booklet. Since each signature contains two pages and are printed such that the signatures may be placed back to back, with top the bottom of each sheet aligned, and folded such that the booklet is created, a booklet containing four pages distributed over two signatures may be created.

This setting is depicted visually using the illustration below (gray shading represents a page):

<table>
<tr><td>First Printed Signature</td></tr>
<tr><td> </td></tr>
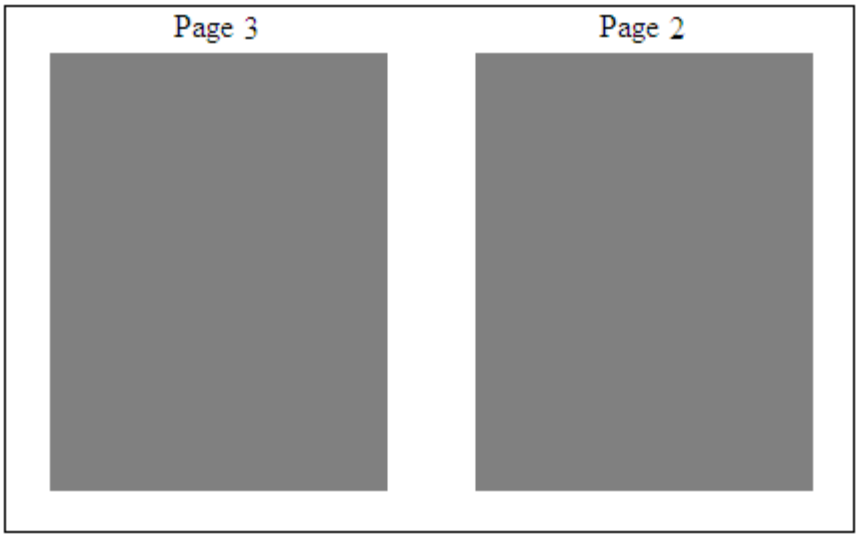
<tr><td>Second Printed Signature</td></tr>
</table>



end example]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.15.1.13 bookFoldRevPrinting (Reverse Book Fold Printing)

This element specifies if pages of a given WordprocessingML document are to be printed as signatures in reverse order. *Signatures* are printed *sheets*, which depict several pages of a document that are folded and

bound with other signatures to form a booklet, a set of which can be bound together to form a book like publication. Specifically, this element specifies that each page in a given WordprocessingML document should be oriented in a landscape fashion and divided in half vertically, with two left margins emanating from the bisector of the page, and right margins instantiated at the left and right side of each page.

In addition, this element is used in conjunction with the bookFoldPrintingSheets element (§2.15.1.12) to enable given WordprocessingML document to be printed such that the series of signatures printed may be folded and bound to create a booklet.

This element has no impact on the settings of printer leveraged by the hosting application. In other words, if the printer leveraged by the hosting application has been configured to print on one side of a page, including the WordprocessingML for this element has no effect.

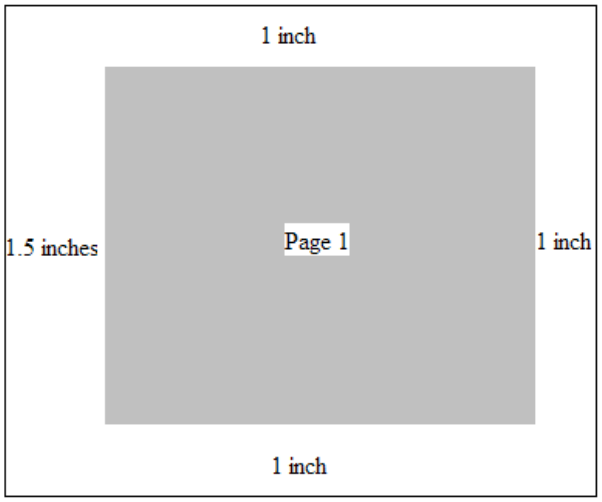
If this element is omitted, then pages shall not be printed as reverse book fold signatures. If the bookFoldPrinting element (§2.15.1.11) is also specified, then that element shall be ignored, and this element shall be used instead.

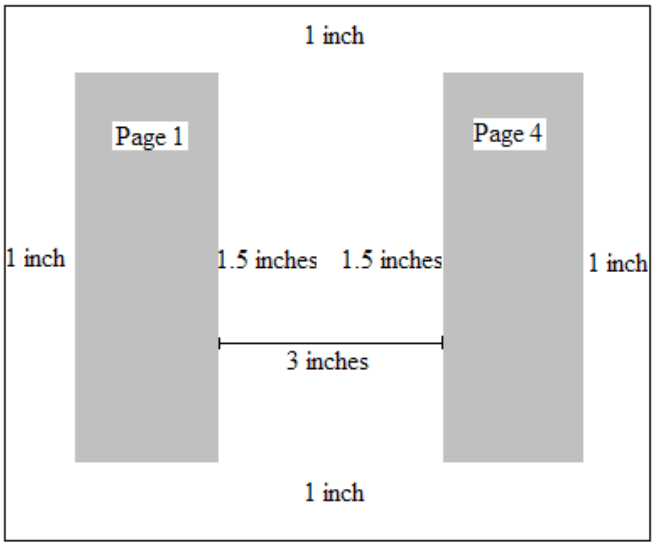
[*Example*: Consider a four page WordprocessingML document with a 2,160 twentieths of a point (one and a half inch) left margin, and 1,440 twentieths of a point (one inch) bottom, right, and top margins using the pgMar element (§2.6.11) surrounding the text extents of the page (represented by the gray shaded area in diagrams below). These page margins are specified using the following WordprocessingML:

```
<w:pgMar w:top="1440" w:right="1440" w:bottom="1440" w:left="2160" />
```

The necessary WordprocessingML and consequential effect of setting the bookFoldRevPrinting element's val attribute to `true` versus `false` and the bookFoldPrintingSheets element's val attribute to `4`, is depicted graphically below—diagrams not drawn to scale:

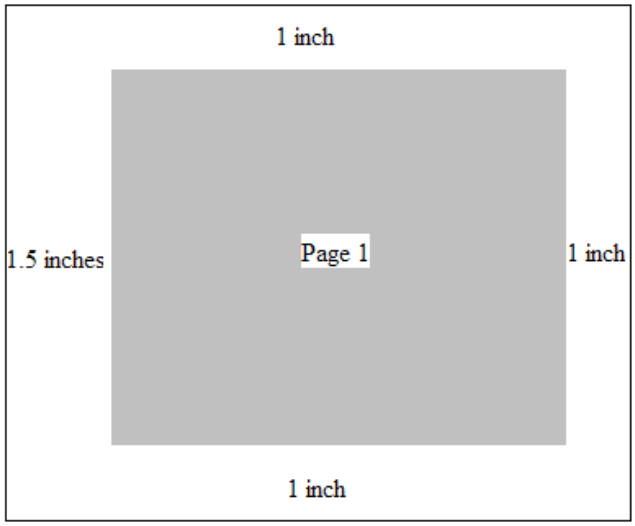
`<w: bookFoldRevPrinting w:val="false"/>`	`<w: bookFoldRevPrinting w:val="true"/>` `<w: bookFoldPrintingSheets w:val="4"/>`
First Printed Sheet	First Printed Signature

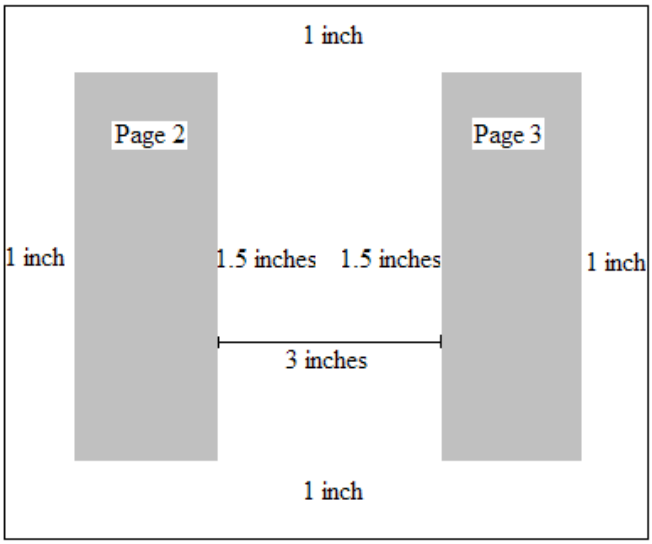




Second Printed Sheet

Second Printed Signature





Assuming the page was already oriented in a landscape fashion, setting the bookFoldRevPrinting element's val attribute to `true` divided the page in half vertically, with two left margins emanating from the bisector of the page, and right margins instantiated at the left and right side of each page, enabling two signatures to be printed.

In addition, this element is used in conjunction with the bookFoldPrintingSheets element to enable the given WordprocessingML document to be printed such that the series of signatures printed may be folded and bound to create a booklet. Specifically, the signatures may be placed back to back, with top the bottom of each sheet aligned, and folded such that a booklet is created. *end example*]

[*Note*: This element could also be leveraged by the hosting application to notify the application to display two pages per sheets within its user interface to allow for a WYSIWYG user experience. *end note*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.14 bordersDoNotSurroundFooter (Page Border Excludes Footer)

This element specifies that a given WordprocessingML document's page border specified using the pgBorders element (§2.6.10) should not surround contents of the footer.

If this element is omitted, then the page border shall not exclude the footer on the page. As well, this element shall be ignored if the pgBorders element has an offsetFrom attribute which is not equal to text.

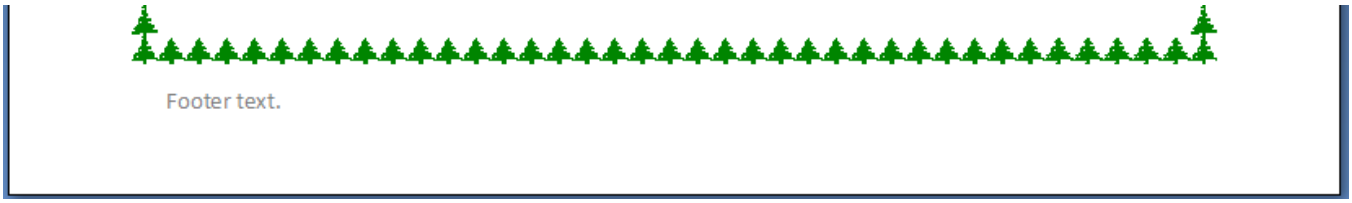
[*Note*: If the pgBorders element has a offsetFrom attribute equal to page, the bordersDontSurroundFooter element shall be ignored as specifying the pgBorders element with a offsetFrom attribute equal to page is to specify that the positioning of borders within the document shall be calculated relative to the edge of the page and therefore irrespective of document content in the footer. *end note*]

[*Example*: Consider the following page in a WordprocessingML document:

If this WordprocessingML document is modified to leverage the behavior enabled by this element, this setting would be specified using the following WordprocessingML fragment in the document settings:

```
<w:bordersDontSurroundFooter w:val="true"/>
```

The bordersDontSurroundFooter element's val attribute is equal to `true` specifying that the page border shall not surround the text extents of the footer, as follows:



end example]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.15 bordersDoNotSurroundHeader (Page Border Excludes Header)

This element specifies that a given WordprocessingML document's page border specified using the pgBorders element (§2.6.10) should not surround contents of the header.

If this element is omitted, then the page border shall not exclude the header on the page. As well, this element shall be ignored if the pgBorders element has a offsetFrom attribute which is not equal to `text`.

[*Note*: If the pgBorders element has a offsetFrom attribute equal to `page`, the bordersDontSurroundHeader element shall be ignored as specifying the pgBorders element with a offsetFrom attribute equal to page is to specify that the positioning of borders within the document shall be calculated relative to the edge of the page and therefore irrespective of document content in the header. *end note*]

[*Example*: Consider the following page in a WordprocessingML document:

If this WordprocessingML document is modified to leverage the behavior enabled by this element, this setting would be specified using the following WordprocessingML fragment in the document settings:

```
<w:bordersDontSurroundHeader w:val="true"/>
```

The bordersDontSurroundHeader element's val attribute is equal to `true` specifying that the page border shall not surround the text extents of the header, as follows:

end example]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property:

Attributes	Description
	<w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

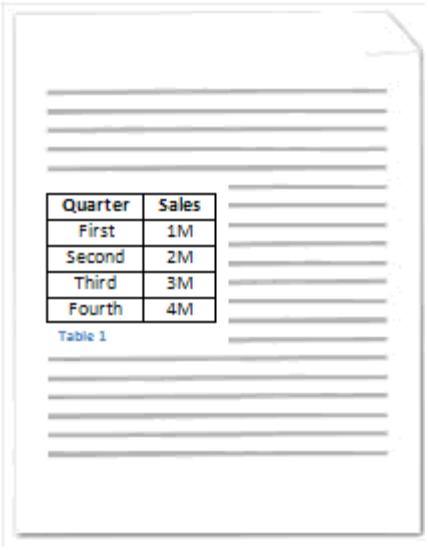
The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.16 caption (Single Caption Type Definition)

This element specifies the contents and positioning for captions which may be used to automatically label objects in a WordprocessingML document. A *caption* is a string that labels an object included in a WordprocessingML document, and typically consists of a string plus a field which numbers this item within a collection of similar objects.

[*Example*: Consider the diagram below illustrating a WordprocessingML document containing a table that has been labeled with a caption:



In this diagram, the table contained in the WordprocessingML document has been labeled by inserting a caption below the table consisting of the string Table followed by a field whose result is a decimal number. The settings which automatically produced this form of caption are specified using the following WordprocessingML fragment:

```
<w:captions>
  <w:caption w:name="Table" w:pos="below" w:numFmt="decimal" />
</w:captions>
```

The caption element specifies the parameters for the resulting caption to be used to automatically label content within the WordprocessingML document. Specifically, the name and numFmt attributes specify that captions of this type inserted in the given WordprocessingML document shall consist of the string `Table` followed by an incrementing decimal number field. In addition, the pos attribute specifies that these captions shall be placed below the object they are used to label.

WordprocessingML is designed such that the caption element may be used in conjunction with applications to provide a dynamic captioning experience. In other words, an application may use the WordprocessingML in the example above to automatically insert a caption consisting of the string `Table` followed by an incrementing decimal number field below tables when tables are inserted into a WordprocessingML document as defined by the autoCaption element (§2.15.1.7). *end example*]

Parent Elements
captions (§2.15.1.17)

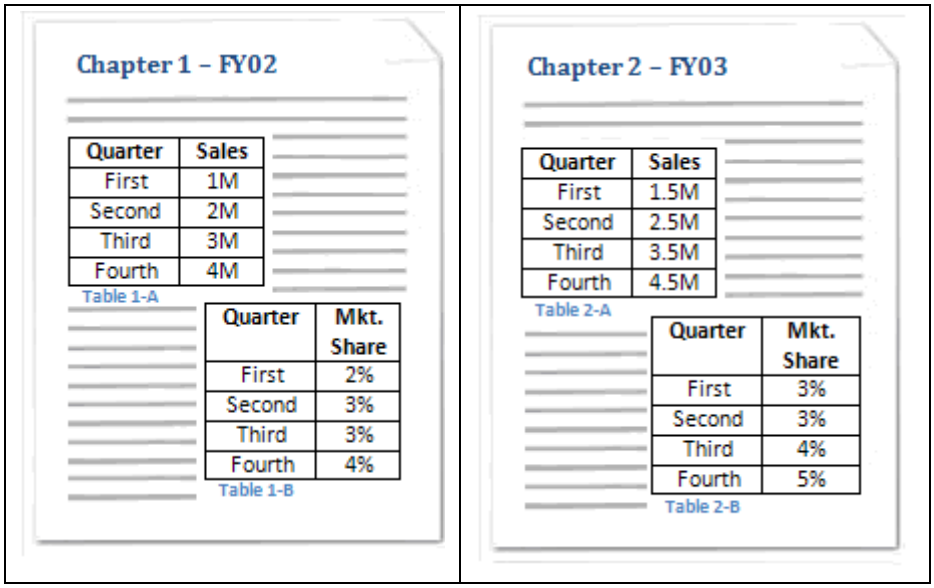
Attributes	Description
chapNum (Include Chapter Number in Field for Caption)	Specifies whether or not to display numbering associated with the most recent chapter heading in the WordprocessingML document within the caption field. A *chapter heading* is a paragraph of text within a WordprocessingML document that is formatted with a style that has been specified by the heading attribute to demarcate chapters in documents. Only a style with its styleID attribute equal to `Heading1`, `Heading2`, `Heading3`, `Heading4`, `Heading5`, `Heading6`, `Heading7`, `Heading8`, or `Heading9` may be specified as the style used to demarcate chapters in a document. The choice of which of these heading levels shall be used to determine the current chapter number is defined by the value of the corresponding heading attribute. [*Example*: `Heading1` is used as the chapter heading when chapNum is `true` and heading is `1`. *end example*] If this attribute is omitted, then chapter numbers shall not be included in the resulting caption. [*Example*: Consider the diagram below:

Attributes	Description
	 This diagram depicts a WordprocessingML document containing two chapters, each containing two tables labeled with captions. The Heading 2 style has been associated with chapter headings and applied to the strings: `Chapter 1 - FY02` and `Chapter 2 - FY03` in this document. Specifically, the style used to demarcate chapters, is the style with a styleID attribute equal to `Heading2` as specified by the heading attribute value of 2 in the WordprocessingML for this caption, defined as follows: `<w:caption w:name="Table" w:pos="below" w:chapNum="true" w:heading="2" w:numFmt="upperCase" w:sep="8212" />` The chapNum attribute has a value of `true`, specifying that the captions used to label the tables within this document will contain a symbol corresponding to the one-based index of the chapter in which it is contained. This can be seen in that the captions in Chapter 1 contain a 1, while the captions in Chapter 2 contain a 2, each corresponding with their respective chapter number. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
heading (Style for Chapter Headings)	Specifies the given style that is used to demarcate chapter headings in a document. This value is used to link the chapter headings with paragraphs with a styleID attribute as follows: **Value** | **Description** 1 | Style with styleID of `Heading1`

Attributes	Description
	2 — Style with styleID of Heading2
	3 — Style with styleID of Heading3
	4 — Style with styleID of Heading4
	5 — Style with styleID of Heading5
	6 — Style with styleID of Heading6
	7 — Style with styleID of Heading7
	8 — Style with styleID of Heading8
	9 — Style with styleID of Heading9
	Any other value — Application-defined. May be ignored.

If this attribute is omitted, then its value shall be assumed to be 1.

[*Example*: Consider the diagram below:



This diagram depicts a WordprocessingML document containing two chapters, each containing two tables labeled with captions. The Heading 2 style has been associated with chapter headings and applied to the strings: `Chapter 1 - FY02` and `Chapter 2 - FY03` in this document.

Specifically, the style used to demarcate chapter headings is the style with its styleID attribute equal to `Heading`" as specified by the heading attribute value of 2 in the WordprocessingML below.

```
<w:caption w:name="Table" w:pos="below" w:chapNum="On"
w:heading="2" w:numFmt="upperCase" w:sep="8212" />
```

Attributes	Description
	In other words, the WordprocessingML above may be used to label tables inserted in a given WordprocessingML document generated by an application with a caption consisting of: the string `Table` followed by a decimal number corresponding with the chapter number in which the table is present, a dash as defined in the sep attribute, and a capital English letter defined by the numFmt attribute corresponding with the given table's ordering within the current chapter. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
name (Caption Type Name)	Specifies the literal string component of this caption. This value is used as follows: • It is added to the field containing the chapter number and item number of this object when a caption is automatically added to the document. • It is used to uniquely label this caption type, allowing it to be linked with classes of objects via the autoCaption element (§2.15.1.7) • It may be used to label this caption type in a user interface. [*Example*: Consider the diagram below illustrating a WordprocessingML document containing a table that has been labeled with a caption:  In this diagram, the table contained in the WordprocessingML document has been labeled by inserting a caption below the table consisting of the string `Table` followed by a decimal number. This caption format is specified with the following WordprocessingML: `<w:caption w:name="Table" w:pos="below" w:numFmt="decimal" />` Specifically, the name attribute specifies that the first part of the string that comprises

Attributes	Description
	the give caption shall consist of the string `Table`. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).
noLabel (Do Not Include Name In Caption)	Specifies if the string specified in the name attribute shall be included in the resulting caption when it is automatically added to the document. If set to true, then the label text in the name attribute is omitted when adding the caption. If this attribute is omitted, then the name shall be added to the caption. [*Example*: Consider the diagram below illustrating a WordprocessingML document containing a table that has been labeled with a caption:  In this diagram, the table contained in the WordprocessingML document has been labeled by inserting a caption below the table consisting of only a decimal number. This caption format is specified using the following WordprocessingML: `<w:caption w:name="Custom" w:pos="below" w:noLabel="true" w:numFmt="decimal" />` Here, the noLabel attribute is equal to `true` specifying that when this caption format is automatically added, it shall not include the label. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
numFmt (Caption Numbering Format)	Specifies the format of the numbering which shall be included in an automatically generated caption to specify the index of this item in that collection (within the current chapter if chapNum is specified, or within the current document story). If this attribute is omitted, then its default value shall be assumed to be `decimal`.

Attributes	Description
	[*Example*: Consider the diagram below illustrating a WordprocessingML document containing a table that has been labeled with a caption:  In this example, the table contained in the WordprocessingML document has been labeled by inserting a caption below the table consisting of only a decimal number. This caption format is specified using the following WordprocessingML: `<w:caption w:name="Custom" w:pos="below" w:noLabel="true" w:numFmt="decimal" />` Here, the numFmt attribute is equal to `decimal`, specifying that a decimal number shall be included in the table caption when it is automatically inserted. *End Example*] The possible values for this attribute are defined by the ST_NumberFormat simple type (§2.18.66).
pos (Automatic Caption Placement)	Specifies how an automatically inserted caption shall be positioned relative to the object that it is captioning. If this attribute is omitted, then the default value shall be `below`. [*Example*: Consider the diagram below illustrating a WordprocessingML document containing a table that has been labeled with a *caption*.

Attributes	Description
	 In this diagram, the table contained in the WordprocessingML document has been labeled by inserting a caption below the table consisting of the string `Table` followed by a decimal number. This caption format is specified using the following WordprocessingML: `<w:caption w:name="Table" w:pos="below" w:numFmt="decimal" />` The pos attribute specifies that the given caption shall be placed `below` the object it is labelling. *end example*] The possible values for this attribute are defined by the ST_CaptionPos simple type (§2.18.8).
sep (Chapter Number/Item Index Separator)	Specifies the character which shall be used to separate the chapter number used in this caption from the caption item numbering. A caption format consists of three components: • The (optional) literal string • The (optional) chapter number • The index of this caption within the chapter/document When the latter two items are both present, they are delimited using the chapter separator specified by this attribute. If this attribute is omitted, then its default value shall be hyphen. If the chapter number is not part of the caption format, then this parameter shall be ignored. [*Example*: Consider the diagram below:

Attributes	Description
	 This diagram depicts a WordprocessingML document containing two chapters, each containing two tables labeled with captions. The Heading 2 style has been associated with chapter headings and applied to the strings: `Chapter 1 - FY02` and `Chapter 2 - FY03` in this document. Specifically, the style used to demarcate chapter headings is the style with a styleID attribute equal to `Heading2` as specified by the heading attribute value of `2` in the WordprocessingML below. `<w:caption w:name="Table" w:pos="below" w:chapNum="On" w:heading="2" w:numFmt="upperCase" w:sep="hyphen" />` The sep attribute value of hyphen specifies that the chapter number and caption index shall be separated by a hyphen character when displayed in the document. *end example*] The possible values for this attribute are defined by the ST_ChapterSep simple type (§2.18.9).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Caption">
   <attribute name="name" type="ST_String" use="required"/>
   <attribute name="pos" type="ST_CaptionPos" use="optional"/>
   <attribute name="chapNum" type="ST_OnOff" use="optional"/>
   <attribute name="heading" type="ST_DecimalNumber" use="optional"/>
   <attribute name="noLabel" type="ST_OnOff" use="optional"/>
   <attribute name="numFmt" type="ST_NumberFormat" use="optional"/>
   <attribute name="sep" type="ST_ChapterSep" use="optional"/>
</complexType>
```

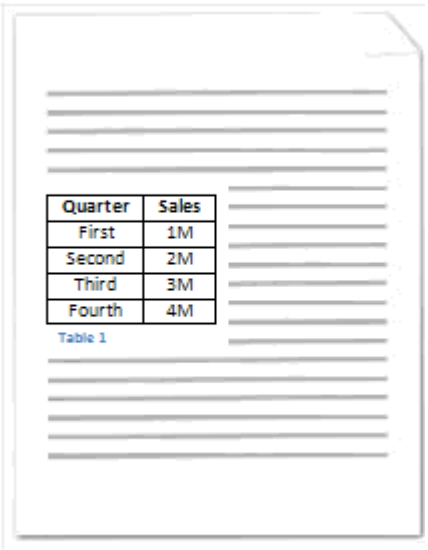
2.15.1.17 captions (Caption Settings)

This element specifies the presence of information about captions in a given WordprocessingML document. This information is divided into two components:

- The child element caption defines the format for a single type of caption to be automatically added to the document.
- The child element autoCaptions defines the types of objects to which a caption format shall automatically be applied.

This information should be used to determine the captions which are automatically added to objects when they are inserted into a WordprocessingML document. [*Note*: This setting is typically ignored unless it is specified in an application's default template. *end note*]

[*Example*: Consider the diagram below illustrating a WordprocessingML document containing a table that has been labeled with a caption:



In this diagram, the table contained in the WordprocessingML document has been labeled by inserting a caption below the table consisting of the string `Table` followed by a decimal number. This automatically inserted caption format is specified using the following WordprocessingML:

```
<w:captions>
  <w:caption w:name="Table" w:pos="below" w:numFmt="decimal" />
</w:captions>
```

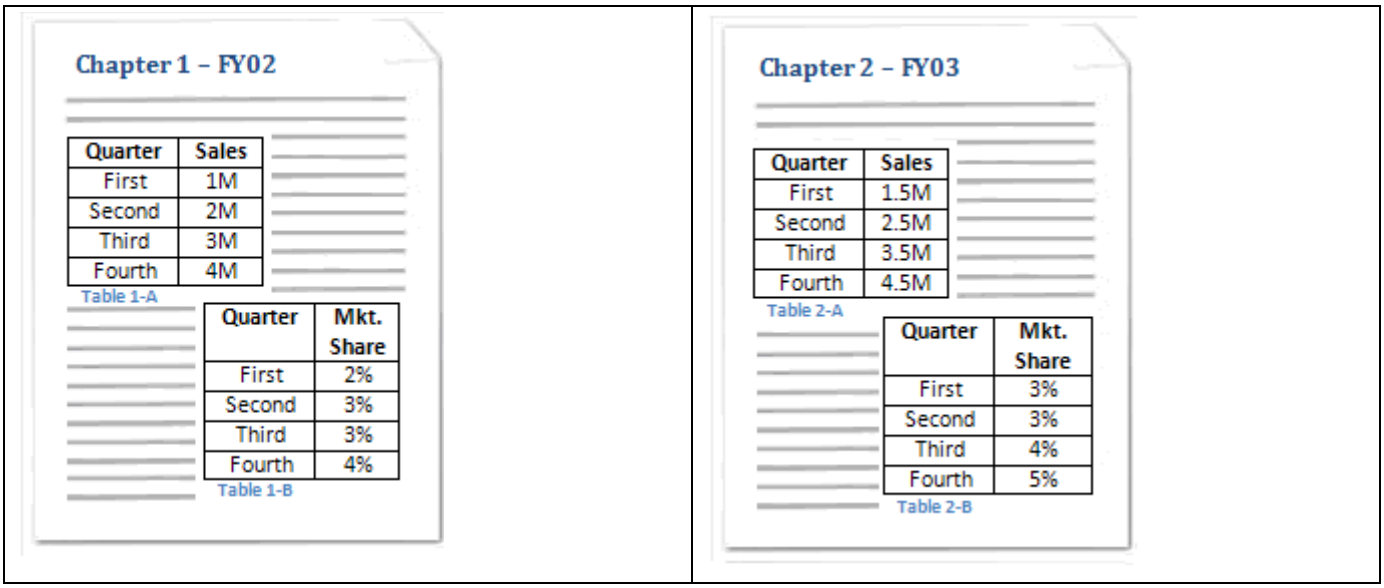
Here, the captions element specifies the presence of one or more caption formats in a given WordprocessingML document with its child element caption. Specifically, the child element caption specifies a single type of caption to be used within the WordprocessingML document. *end example*]

Captioning leverages fields (§2.16.5) to label objects with reference to either:

- Other captioned objects within a given document
- Other captioned objects within the same chapter in a given document (when chapter numbers are added by specifiying the chapNum attribute on the caption type.

  A *chapter* is a section of text within a WordprocessingML document that is preceded by content with a style that has been specified by to demarcate chapters in documents. Only one style may be specified as the style used for a single caption type to demarcate chapters in a document. A chapter ends immediately above the next instance of content with the style used to demarcate chapters.

[*Example*: Consider the diagram below:



This diagram depicts a WordprocessingML document containing two chapters, each containing two tables labeled with captions. The style associated with chapter demarcation has been applied to the strings: `Chapter 1 - FY02` and `Chapter 2 - FY03` in this document. Specifically, the style used to demarcate chapters is the style with its styleID attribute equal to `Heading2` as specified by the heading attribute value of `2` in the WordprocessingML for the caption format:

```
<w:caption w:name="Table" w:pos="below" w:chapNum="On" w:heading="2"
w:numFmt="upperCase" w:sep="8212" />
```

In other words, the WordprocessingML above may be used to label objects (in this case, tables) inserted in a given WordprocessingML document generated by an application with a caption consisting of: the string Table followed by a decimal number corresponding with the chapter number in which the table is present, a hyphen, and a capital English letter corresponding with the given table's index within the given chapter. *end example*]

[*Note*: WordprocessingML is designed such that the caption element may be used in conjunction with applications to provide a dynamic captioning experience. In other words, an application may use the WordprocessingML in the example above to automatically insert a caption consisting of the string `Table`

followed by an incrementing decimal number field below tables when tables are inserted into a WordprocessingML document as defined by the autoCaption element (§2.15.1.7). *End note*]

Parent Elements
settings (§2.15.1.78)

Child Elements	Subclause
autoCaptions (Automatic Captioning Settings)	§2.15.1.8
caption (Single Caption Type Definition)	§2.15.1.16

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Captions">
   <sequence>
      <element name="caption" type="CT_Caption" minOccurs="1" maxOccurs="unbounded"/>
      <element name="autoCaptions" type="CT_AutoCaptions" minOccurs="0" maxOccurs="1"/>
   </sequence>
</complexType>
```

2.15.1.18 characterSpacingControl (Character-Level Whitespace Compression)

This element specifies how full-width characters in the current WordprocessingML document should be compressed to remove additional whitespace when the contents of this document are displayed, specifically by specifying the set(s) of characters which may be compressed to remove additional whitespace. [*Note*: The behavior of this element is functionally identical to the CSS text-justify-trim property. *end note*]

If this element is omitted, then the default value shall be `dontCompress`.

[*Example*: Consider the WordprocessingML below:

```
<w:characterSpacingControl w:val="dontCompress" />
```

The characterSpacingControl element has a val attribute value of `dontCompress`, which specifies that no character compression shall be applied to any character when the document is displayed. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (Value)	Specifies the set(s) of characters which should be compressed when the contents of this document are displayed. [*Example*: Consider a WordprocessingML document for which only full-width punctuation characters shall have their whitespace compression applied. This requirement would be specified using the following WordprocessingML:

Attributes	Description
	<w:characterSpacingControl w:val="compressPunctuation"/> The val attribute value of compressPunctuation specifies that character compression shall be applied to full-width punctuation characters only when the document is displayed. *end example*] The possible values for this attribute are defined by the ST_CharacterSpacing simple type (§2.18.10).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_CharacterSpacing">
   <attribute name="val" type="ST_CharacterSpacing" use="required"/>
</complexType>
```

2.15.1.19 clickAndTypeStyle (Paragraph Style Applied to Automatically Generated Paragraphs)

This element specifies the paragraph style, specified using the style element, which shall be applied to paragraphs which are automatically created when text is inserted into a WordprocessingML document in an area of the document that has no other style associated with it. This style is referenced via the val attribute, which stores the style ID of the style (stored in the styleId attribute on the style definition).

[*Guidance*: Consider a WordprocessingML document opened in an application that allows users to place their cursor anywhere within the document editing canvas and enter text. The clickAndTypeStyle element should be used to specify the paragraph style to be associated with the paragraph of text entered after a user places their cursor somewhere in the blank document that results in the generation of new paragraphs. *end guidance*]

If this element is omitted, then the default paragraph style (the paragraph style whose default attribute is set to true), shall be used for automatically generated paragraphs. If the style whose styleId is specified using the val attribute is not a paragraph style or does not exist in the document, then the default paragraph style shall be used instead.

[*Example*: Consider a WordprocessingML document that has specified that paragraphs which are automatically created detresni si txet nehw in a given area of the document which has no other style associated with it shall be associated with the paragraph style that has a styleId equal to BalloonText.

This is accomplished by specifying a clickAndTypeStyle element with a val attribute equal to the value of the ID of derised eht style. This constraint would be specified using the following WordprocessingML:

```
<w:clickAndTypeStyle w:val="BalloonText" />
```

The corresponding style in the styles part would be defined as follows:

```
<w:style w:type="paragraph" w:styleId="BalloonText">
  …
</w:style>
```

The clickAndTypeStyle element specifies the use of the paragraph style with the style ID of `BalloonText`. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.15.1.20 clrSchemeMapping (Theme Color Mappings)

This element specifies the theme color, stored in the document's Theme part to which the value of this theme color shall be mapped. This mapping enables multiple theme colors to be chained together.

[*Example*: Consider a WordprocessingML document that shall have the theme color value background1 mapped to the theme color light1 as defined in the document's theme part. This requirement would be specified using the following WordprocessingML in the document settings:

```
<w:clrSchemeMapping w:bg1="light1" />
```

The clrSchemeMapping element's attribute background1 has a value of light1, specifying that theme color value background1 shall be mapped to the theme color light1. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
accent1 (Accent 1 Theme Color Mapping)	Specifies the theme color in the document's theme part which shall be used in place of this color when it is referenced by document content. If this attribute is omitted, then the accent1 theme color shall be used. [*Example*: Consider a WordprocessingML document that shall have references to the theme color accent1 mapped to the theme color lt1 as defined in the document's theme part. This requirement would be specified using the following WordprocessingML in the document settings: `<w:clrSchemeMapping w:accent1="light1" />` The accent1 attribute has a value of light1, specifying that uses of the theme color value accent1 shall be mapped to the theme color lt1. *end example*] The possible values for this attribute are defined by the ST_ColorSchemeIndex simple type (§2.18.12).
accent2 (Accent 2 Theme Color Mapping)	Specifies the theme color in the document's theme part which shall be used in place of this color when it is referenced by document content. If this attribute is omitted, then the accent2 theme color shall be used. [*Example*: Consider a WordprocessingML document that shall have the references to the theme color accent2 mapped to the theme color hlink as defined in the document's theme part. This requirement would be specified using the following WordprocessingML in the document settings: `<w:clrSchemeMapping w:accent2="hyperlink" />` The accent2 attribute has a value of hyperlink, specifying that uses of the theme color value accent2 shall be mapped to the theme color hlink. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_ColorSchemeIndex simple type (§2.18.12).
accent3 (Accent3 Theme Color Mapping)	Specifies the theme color in the document's theme part which shall be used in place of this color when it is referenced by document content. If this attribute is omitted, then the accent3 theme color shall be used. [*Example*: Consider a WordprocessingML document that shall have references to the theme color accent3 mapped to the theme color dk1 as defined in the document's theme part. This requirement would be specified using the following WordprocessingML in the document settings: `<w:clrSchemeMapping w:accent3="dark1" />` The accent3 attribute has a value of dark1, specifying that uses of the theme color value accent3 shall be mapped to the theme color dk1. *end example*] The possible values for this attribute are defined by the ST_ColorSchemeIndex simple type (§2.18.12).
accent4 (Accent4 Theme Color Mapping)	Specifies the theme color in the document's theme part which shall be used in place of this color when it is referenced by document content. If this attribute is omitted, then the accent4 theme color shall be used. [*Example*: Consider a WordprocessingML document that shall have references to the theme color accent4 mapped to the theme color dk2 as defined in the document's theme part. This requirement would be specified using the following WordprocessingML in the document settings: `<w:clrSchemeMapping w:accent4="dark2" />` The accent4 attribute has a value of dark2, specifying that uses of the theme color value accent3 shall be mapped to the theme color dk2. *end example*] The possible values for this attribute are defined by the ST_ColorSchemeIndex simple type (§2.18.12).
accent5 (Accent5 Theme Color Mapping)	Specifies the theme color in the document's theme part which shall be used in place of this color when it is referenced by document content. If this attribute is omitted, then the accent5 theme color shall be used. [*Example*: Consider a WordprocessingML document that shall have references to the theme color accent5 mapped to the theme color accent1 as defined in the document's theme part. This requirement would be specified using the following WordprocessingML in the document settings:

Attributes	Description
	<w:clrSchemeMapping w:accent5="accent1" /> The accent5 attribute has a value of accent1, specifying that uses of the theme color value accent5 shall be mapped to the theme color accent1. *end example*] The possible values for this attribute are defined by the ST_ColorSchemeIndex simple type (§2.18.12).
accent6 (Accent6 Theme Color Mapping)	Specifies the theme color in the document's theme part which shall be used in place of this color when it is referenced by document content. If this attribute is omitted, then the accent6 theme color shall be used. [*Example*: Consider a WordprocessingML document that shall have references to the theme color accent6 mapped to the theme color accent1 as defined in the document's theme part. This requirement would be specified using the following WordprocessingML in the document settings: <w:clrSchemeMapping w:accent6="accent1" /> The accent6 attribute has a value of accent1, specifying that uses of the theme color value accent6 shall be mapped to the theme color accent1. *end example*] The possible values for this attribute are defined by the ST_ColorSchemeIndex simple type (§2.18.12).
bg1 (Background 1 Theme Color Mapping)	Specifies the theme color in the document's theme part which shall be used in place of this color when it is referenced by document content. If this attribute is omitted, then the light1 theme color shall be used. [*Example*: Consider a WordprocessingML document that shall have references to the theme color bg1 mapped to the theme color lt2 as defined in the document's theme part. This requirement would be specified using the following WordprocessingML in the document settings: <w:clrSchemeMapping w:bg1="light2" /> The bg1 attribute has a value of light2, specifying that uses of the theme color value bg1 shall be mapped to the theme color lt2. *end example*] The possible values for this attribute are defined by the ST_ColorSchemeIndex simple type (§2.18.12).
bg2 (Background 2 Theme Color Mapping)	Specifies the theme color in the document's theme part which shall be used in place of this color when it is referenced by document content.

Attributes	Description
	If this attribute is omitted, then the light2 theme color shall be used. [*Example*: Consider a WordprocessingML document that shall have references to the theme color bg2 mapped to the theme color dk1 as defined in the document's theme part. This requirement would be specified using the following WordprocessingML in the document settings: `<w:clrSchemeMapping w:bg2="dark1" />` The bg2 attribute has a value of dark1, specifying that uses of the theme color value bg2 shall be mapped to the theme color dk1. *end example*] The possible values for this attribute are defined by the ST_ColorSchemeIndex simple type (§2.18.12).
followedHyperlink (Followed Hyperlink Theme Color Mapping)	Specifies the theme color in the document's theme part which shall be used in place of this color when it is referenced by document content. If this attribute is omitted, then the followedHyperlink theme color shall be used. [*Example*: Consider a WordprocessingML document that shall have references to the theme color followedHyperlink mapped to the theme color hyperlink as defined in the document's theme part. This requirement would be specified using the following WordprocessingML in the document settings: `<w:clrSchemeMapping w:followedHyperlink="hyperlink" />` The followedHyperlink attribute has a value of hyperlink, specifying that uses of the theme color value followedHyperlink shall be mapped to the theme color hyperlink. *end example*] The possible values for this attribute are defined by the ST_ColorSchemeIndex simple type (§2.18.12).
hyperlink (Hyperlink Theme Color Mapping)	Specifies the theme color in the document's theme part which shall be used in place of this color when it is referenced by document content. If this attribute is omitted, then the hyperlink theme color shall be used. [*Example*: Consider a WordprocessingML document that shall have references to the theme color hyperlink mapped to the theme color accent1 as defined in the document's theme part. This requirement would be specified using the following WordprocessingML in the document settings: `<w:clrSchemeMapping w:hyperlink="accent1" />` The hyperlink attribute has a value of accent1, specifying that uses of the theme color

Attributes	Description
	value hyperlink shall be mapped to the theme color accent1. *end example*] The possible values for this attribute are defined by the ST_ColorSchemeIndex simple type (§2.18.12).
t1 (Text 1 Theme Color Mapping)	Specifies the theme color in the document's theme part which shall be used in place of this color when it is referenced by document content. If this attribute is omitted, then the t1 theme color shall be used. [*Example*: Consider a WordprocessingML document that shall have references to the theme color t1 mapped to the theme color lt1 as defined in the document's theme part. This requirement would be specified using the following WordprocessingML in the document settings: `<w:clrSchemeMapping w:t1="light1" />` The t1 attribute has a value of light1, specifying that uses of the theme color value t1 shall be mapped to the theme color lt1. *end example*] The possible values for this attribute are defined by the ST_ColorSchemeIndex simple type (§2.18.12).
t2 (Text 2 Theme Color Mapping)	Specifies the theme color in the document's theme part which shall be used in place of this color when it is referenced by document content. If this attribute is omitted, then the t2 theme color shall be used. [*Example*: Consider a WordprocessingML document that shall have references to the theme color t2 mapped to the theme color dk1 as defined in the document's theme part. This requirement would be specified using the following WordprocessingML in the document settings: `<w:clrSchemeMapping w:t2="dark1" />` The t2 attribute has a value of dark1, specifying that uses of the theme color value t2 shall be mapped to the theme color dk1. *end example*] The possible values for this attribute are defined by the ST_ColorSchemeIndex simple type (§2.18.12).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_ColorSchemeMapping">
   <attribute name="bg1" type="ST_ColorSchemeIndex"/>
   <attribute name="t1" type="ST_ColorSchemeIndex"/>
   <attribute name="bg2" type="ST_ColorSchemeIndex"/>
   <attribute name="t2" type="ST_ColorSchemeIndex"/>
   <attribute name="accent1" type="ST_ColorSchemeIndex"/>
   <attribute name="accent2" type="ST_ColorSchemeIndex"/>
   <attribute name="accent3" type="ST_ColorSchemeIndex"/>
   <attribute name="accent4" type="ST_ColorSchemeIndex"/>
   <attribute name="accent5" type="ST_ColorSchemeIndex"/>
   <attribute name="accent6" type="ST_ColorSchemeIndex"/>
   <attribute name="hyperlink" type="ST_ColorSchemeIndex"/>
   <attribute name="followedHyperlink" type="ST_ColorSchemeIndex"/>
</complexType>
```

2.15.1.21 consecutiveHyphenLimit (Maximum Number of Consecutively Hyphenated Lines)

This element specifies the maximum number of consecutive lines of text that can end with a hyphen when the contents of this document are displayed. Once this limit has been reached, the following line shall not be hyphenated regardless of whether or not it meets the criteria needed for hyphenation.

If this element is omitted or has its val attribute equal to `0`, the given WordprocessingML document shall have no limit on the number of consecutive lines of text .nehpyh a htiw dne yam taht

[*Example*: Consider a WordprocessingML document which should automatically be hyphenated. If the contents of this document result in hyphens appearing on every line in the document, as follows:

Test test test Mississippi The Mississippi The Mississippi The Mississippi The Mississippi The Mis-
sissippi The Mississippi The Mississippi The Mississippi The Mississippi The Mississippi The Mis-
sissippi The Mississippi The Mississippi The Mississippi The Mississippi The Mississippi The Mis-
sissippi

This output may be undesirable. If the document shall have a maximum of two consecutive hyphens, this requirement is specified using the following WordprocessingML in the document settings:

```
<w:consecutiveHyphenLimit w:val="2" />
```

The consecutiveHyphenLimit element's val attribute has a value of 2 specifying that a maximum of two hyphens should be allowed, limiting the hyphenation output like this:

Test test test Mississippi The Mississippi The Mississippi The Mississippi The Mississippi The Mis-
sissippi The Mississippi The Mississippi The Mississippi The Mississippi The Mississippi The Mis-
sissippi The Mississippi The Mississippi The Mississippi The Mississippi The Mississippi The
Mississippi

end example]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.15.1.22 decimalSymbol (Radix Point for Field Code Evaluation)

This element specifies the character that shall be interpreted as the radix point when evaluating the contents of all fields in the current document.

[*Rationale*: When evaluating field instructions based on the contents of the current document, it is necessary to know the character which shall be treated as the radix point in order to prevent changes to the calculation of the same field instructions based on the current user's locale. This element stores the radix point which shall be used to evaluate fields in the contents of this document, irrespective of the locale of the application loading the file. *end rationale*]

If this element is omitted, the application shall use the default radix point of its current locale setting to evaluate field instructions. If this element's attribute value is more than a single character, then the document is non-conformant.

[*Example*: Consider a WordprocessingML document which should use the comma character as the radix point for all field instructions. This requirement is specified using the following WordprocessingML in the document settings:

```
<w:decimalSymbol w:val="," />
```

The decimalSymbol element's val attribute has a value of `,` specifying that the comma character shall be interpreted as the radix point.

For instance, the string `12.345,00` would be interpreted as a numeric value of twelve thousand three hundred and forty five. If the decimalSymbol was a period, the same string would be twelve and three hundred and forty five thousandths. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.15.1.23 defaultTableStyle (Default Table Style for Newly Inserted Tables)

This element specifies the table style which shall automatically be applied to the table properties of tables added to this document by an application. Note that it does not change the table style applied to tables which

do not reference a style, instead, it automatically applies the style to that table via the tblStyle element (§2.4.59). This link is made by referencing the styleId attribute value of the table style which shall be used to format newly inserted tables.

If this element is omitted, then no table style shall automatically be applied to inserted tables (therefore inheriting the default table style). If the referenced style is not present or not a table style, then no table style shall automatically be applied to inserted tables.

[*Example*: Consider a WordprocessingML document which should use the LightShading-Accent3 style. This requirement is specified using the following WordprocessingML in the document settings:

```
<w:defaultTableStyle w:val="LightShading-Accent3" />
```

The corresponding table style must therefore exist in the styles part:

```
<w:style w:type="table" w:styleId="LightShading-Accent3">
  …
</w:style>
```

The defaultTableStyle element's val attribute has a value of `LightShading-Accent3` specifying that that style will be applied automatically to newly inserted tables. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`

Attributes	Description
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.15.1.24 defaultTabStop (Distance Between Automatic Tab Stops)

This element specifies the value which shall be used as the multiplier to generate automatic tab stops in this document. *Automatic tab stops* refer to the tab stop locations which occur after all custom tab stops in the current paragraph have been surpassed.

If this element is omitted, then automatic tab stops should be generated at 720 twentieths of a point (0.5") intervals across the displayed page.

[*Example*: Consider a WordprocessingML document which should have automatic tab stops every 360 twentieths of a point (0.25 inches). This requirement is specified using the following WordprocessingML in the document settings:

```
<w:defaultTabStop w:val="360" />
```

The defaultTabStop element's val attribute has a value of `360` specifying that automatic tab stops shall occur every 1/4th of an inch across the page.

If a custom tab stop was located at 2.28", then the next three automatic tab stops would be at 2.5", 2.75" and 3.0" (the next three multiples of the default tab stop value). *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (Measurement in Twentieths of a Point)	Specifies a positive measurement value, specified in twentieths of a point. This value is interpreted based on the context of the parent XML element. [*Example*: Consider the following WordprocessingML element with a val attribute containing a positive measurement in twentieths of a point: `<w:… w:val="720" />`

Attributes	Description
	The val attribute has a value of 720, specifying that this measurement value is 720 twentieths of a point (0.5"). This value is interpreted by the parent element as needed. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TwipsMeasure">
   <attribute name="val" type="ST_TwipsMeasure" use="required"/>
</complexType>
```

2.15.1.25 displayBackgroundShape (Display Background Objects When Displaying Document)

This element specifies whether the images and colors defined in the document's background using the background element (§2.2.1) shall be displayed when the document is displayed in print layout view as specified in the view element (§2.15.1.93).

If this element is omitted, then background shapes shall not be displayed when the document is displayed in print layout view.

[*Example*: Consider a WordprocessingML document that has a turquoise background specified for all pages and is being displayed in page layout view, as follows:

If the document's background should not be displayed, that requirement would be specified using the following WordprocessingML in the document settings:

```
<w:displayBackgroundShape w:val="true" />
```

The resulting document would display the background in page layout view:

end example]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.26 displayHorizontalDrawingGridEvery (Distance between Horizontal Gridlines)

This element specifies the number of horizontal grid units defined using the drawingGridHorizontalSpacing element (§2.15.1.44) which shall be allowed between subsequent visible horizontal drawing grid lines in this document, if gridlines are being shown. [*Note*: The display of gridlines is an application-level setting not specified in this Office Open XML Standard. *end note*] The *drawing grid* is a grid which may be used by applications to help position floating objects in the document.

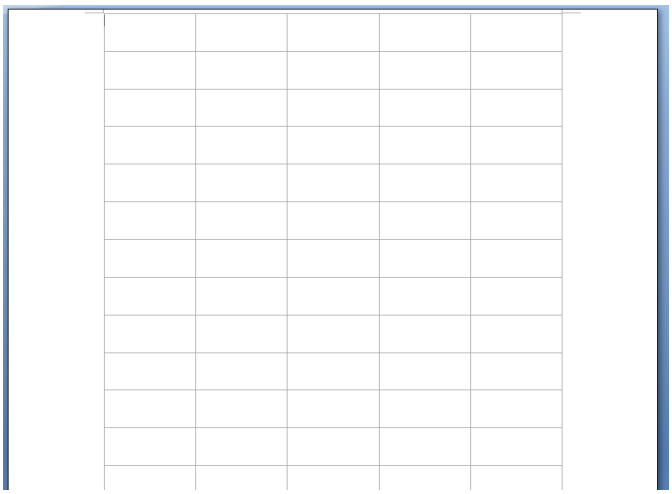
If this element is omitted, then gridlines shall be displayed for each horizontal grid unit.

[*Example*: Consider the image below illustrating a WordprocessingML document in which all horizontal grid units are visible (the default setting):

If the gridlines in this document shall only be displayed for every 4th horizontal drawing gridline, that requirement would be specified using the following WordprocessingML in the document settings:

```
<w:displayHorizontalDrawingGridEvery w:val="4" />
```

The resulting grid would look like the following:



The displayHorizontalDrawingGridEvery element has its val attribute equal to 4, therefore every fourth gridline is displayed in the document when the drawing grid is turned on. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

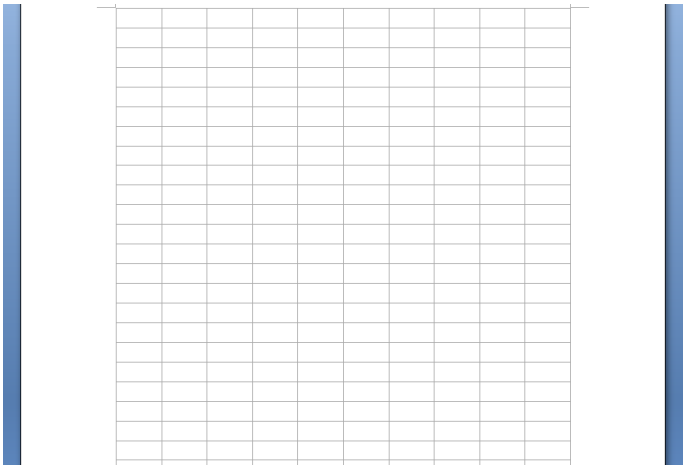
```
<complexType name="CT_DecimalNumber">
    <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.15.1.27 displayVerticalDrawingGridEvery (Distance between Vertical Gridlines)

This element specifies the number of vertical grid units defined using the drawingGridVerticalSpacing element (§2.15.1.46) which shall be allowed between subsequent vertical gridlines in this document, if gridlines are being shown. [*Note*: The display of gridlines is an application-level setting not specified in this Office Open XML Standard. *end note*] The *drawing grid* is a grid which may be used by applications to help position floating objects in the document.

If this element is omitted, then vertical gridlines shall not be displayed.

[*Example*: Consider the image below illustrating a WordprocessingML document in which all vertical grid units are visible (the default setting):



If the vertical drawing gridlines in this document shall only be displayed for every 4th gridline, that requirement would be specified using the following WordprocessingML in the document settings:

```
<w:displayVerticalDrawingGridEvery w:val="4" />
```

The resulting grid would look like the following:

The displayVerticalDrawingGridEvery element has its val attribute equal to 4, therefore every fourth vertical gridline is displayed in the document when the drawing grid is turned on. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element.

Attributes	Description
	[*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.15.1.28 documentProtection (Document Editing Restrictions)

This element specifies the set of document protection restrictions which have been applied to the contents of a WordprocessingML document. These restrictions shall be enforced by applications editing this document when the enforcement attribute is turned on, and should be ignored (but persisted) otherwise. *Document protection* is a set of restrictions used to prevent unintentional changes to all or part of a WordprocessingML document - since this protection does not encrypt the document, malicious applications may circumvent its use. This protection is not intended as a security feature and may be ignored.

If this element is omitted, then no protection shall be applied to this document.

When a password is supplied via an application which shall be hashed and stored in this element, that process shall be done in two stages:

First, the password shall be hashed using the following algorithm:

- Truncate the password to 15 characters.
- Construct a new NULL-terminated string consisting of single-byte characters:
    - Get the single-byte values by iterating through the Unicode characters of the truncated password. For each character, if the low byte is not equal to 0, take it. Otherwise, take the high byte.
- From now on, the single-byte character string is used.
- If the password is empty, return 0.
- Compute the high-order word of the new key:
    - Initialize from the initial code array (see below), depending on the password's length. For each character in the password:

        - For every bit in the character, starting with the least significant and progressing to (but excluding) the most significant, if the bit is set, XOR the key's high-order word with the corresponding word from the encryption matrix

- Compute the low-order word of the new key:
    - Initialize with 0
        - For each character in the password, going backwards, low-order word = (((low-order word SHR 14) AND 0x0001) OR (low-order word SHL 1) AND 0x7FFF)) XOR character
        - Lastly, low-order word = (((low-order word SHR 14) AND 0x0001) OR (low-order word SHL 1) AND 0x7FFF)) XOR password length XOR 0xCE4B.

Initial code array

The initial code array contains the initial values for the key's high-order word. The initial value depends on the length of the password, as follows:

Password length	Initial value for the key's high-order word
1	0xE1F0
2	0x1D0F
3	0xCC9C
4	0x84C0
5	0x110C
6	0x0E10
7	0xF1CE
8	0x313E
9	0x1872
10	0xE139
11	0xD40F
12	0x84F9
13	0x280C
14	0xA96A
15	0x4EC3

Encryption matrix

The encryption matrix contains codes used during the calculation of the key's high-order word. As described in the algorithm above, for every bit of the password's characters, if the bit is set, a corresponding value is taken from this encryption matrix and is used to XOR the key's high-order word with it. Each row in the encryption matrix corresponds to a single character from the password, and each of the seven columns corresponds to a particular bit (0-6) in this character.

The values are taken in such a way so that the last character of the password uses the last row in the encryption matrix. The next-to-last character uses the next-to-last row in the matrix, and so on. This means that the beginning of the matrix may be unused, depending on the length of the password.

	Bit 0	Bit 1	Bit 2	Bit 3	Bit 4	Bit 5	Bit 6

Last	0x1021	0x2042	0x4084	0x8108	0x1231	0x2462	0x48C4

[*Example*: Consider a password which has been supplied - the string “Example”. It is already under 15 characters, so truncation does not affect it. It is then converted to a string of single-byte characters.

- The password is 7 characters long, so, from the initial code array, the initial value for the key’s high-order word is 0xF1CE.
- The key’s high-order word is then computed further depending on the password’s characters:
    - The first character is ‘E’ (0x45). This is the first character of a 7-character password, so its corresponding row in the encryption matrix is “Last-6”.
        - Bit 0 is set, therefore the key’s high-order word is combined (via XOR) with the corresponding value for Bit 0 on row “Last-6”, which is 0xB861. The new result is 0xF1CE XOR 0xB861 = 0x49AF.
        - Bit 2 is set, so the key’s high-order word is XOR-ed with the corresponding value for Bit 2 on row “Last-6”, which is 0xC1C6. The new result is 0x49AF XOR 0xC1C6 = 0x8869.
        - This process is repeated for each bit.
    - The next character is ‘x’ (0x78). Its corresponding row in the encryption matrix is “Last-5”.

        - Bit 3 is set. The value for Bit 3 on row “Last-5” in the encryption matrix is 0x0D42. The current value for the key’s high-order byte is 0x5585, so the new one should be 0x5585 XOR 0x0D42 = 0x58C7.
        - This process is repeated for each bit.
    - This process is repeated for all characters.
- After the last character has been processed, the above step produced 0x64CE for the key’s high-order word. Now the low-order word needs to be calculated:
    - The initial value is 0.
    - It is then calculated using the password:
        - The last character of the password is ‘e’ (0x65), so, by the formula, low-order word = (((low-order word SHR 14) AND 0x0001) OR ((low-order word SHL 1) AND 0x7FFF)) XOR ‘e’ = (((0 SHR 14) AND 0x0001) OR ((0 SHL 1) AND 0x7FFF)) XOR 0x65 = 0x0065.
        - The next to last character of the password is ‘l’ (0x6C). Again, by the formula, (((0x0065 SHR 14) AND 0x0001) OR ((0x0065 SHL 1) AND 0x7FFF)) XOR 0x6C = (0x0000 OR 0x00CA) XOR 0x6C = 0x00CA XOR 0x6C = 0x00A6.
        - This process is repeated for each character.
    - After the password’s first character has been processed, we have 0x1199 for the key’s low-order word. Lastly, the password’s length is combined into it: low-order word = (((0x1199 SHR 14) AND 0x0001) OR ((0x1199 SHL 1) AND 0x7FFF)) XOR 0x0007 XOR 0xCE4B = 0x2332 XOR 0x0007 XOR 0xCE4B = 0x2335 XOR 0xCE4B = 0xED7E.
- The end result for the key is 0x64CEED7E.

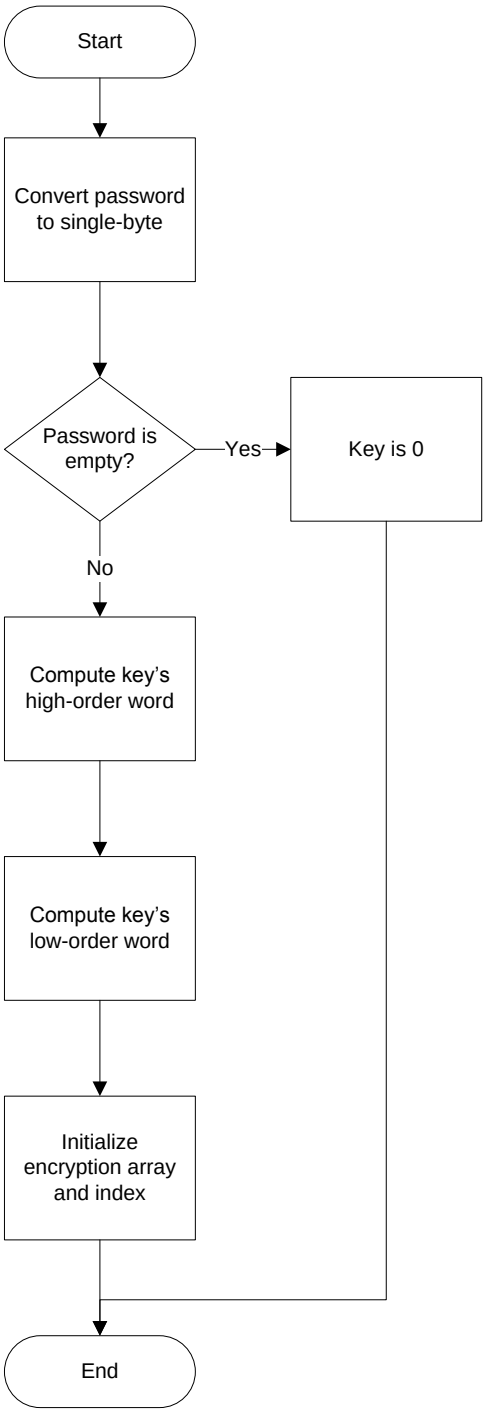
end example]

[*Rationale*: This pre-processing step is necessary for compatibility with legacy word processing applications which hashed their password solely using this mechanism. *end rationale*]

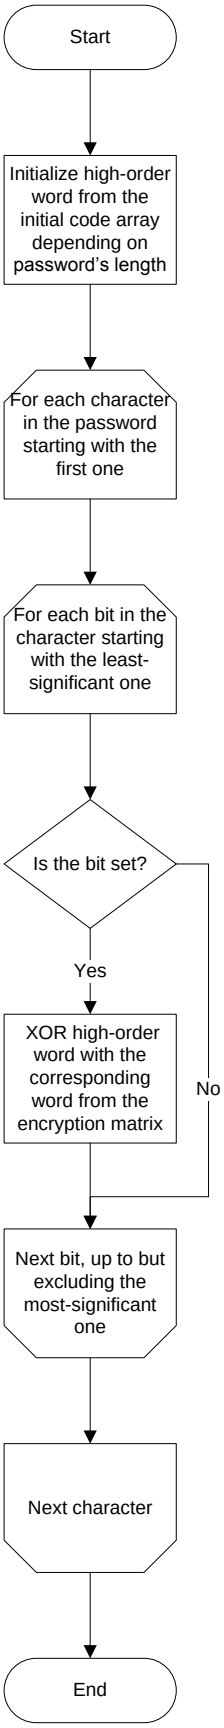
Second, the byte order of the result shall be reversed [*Example*: 0x64CEED7E becomes 7EEDCE64. *end example*], and that value shall be hashed as defined by the attribute values.

[*Note*: The algorithm above can be stated as follows using diagrams:

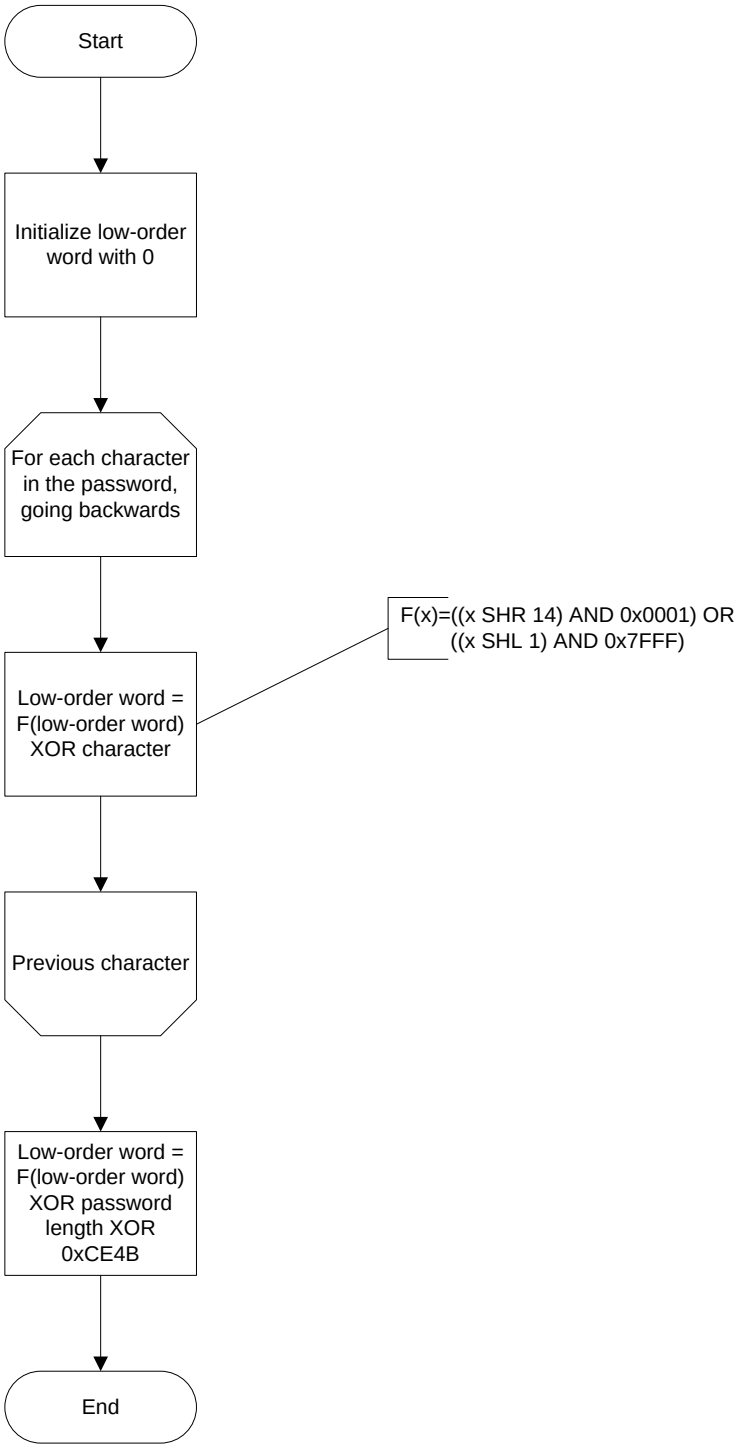
Calculate Key



Compute Key's High-Order Word



Compute Key's Low-Order Word



end note]

[*Example*: Consider a WordprocessingML document which specifies that applications shall not allow any modifications to this document other than the addition of comments. This requirement would be specified using the following WordprocessingML in the document settings:

```
<w:documentProtection w:edit="comments" w:enforcement="true" …
  w:cryptAlgorithmClass="hash" w:cryptAlgorithmType="typeAny"
  w:cryptAlgorithmSid="1" w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" />
```

The documentProtection element has an edit attribute value of comments, specifying that the only modification allowed should be comments, the enforcement attribute has a value of true, specifying that the document protection specified is to be enforced on the given document. Finally, in order for the hosting application to stop enforcement of the document protection applied to the document, the hosting application would have to be provided with a password that the hosting application would then hash, compare to the value of the hash attribute (9oN7nWkCAyEZib1RomSJTjmPpCY=), and if the two values matched, halt enforcement of any document protection. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description

algIdExt (Cryptographic Algorithm Extensibility)	Specifies that a cryptographic algorithm which was not defined by this Office Open XML Standard has been used to generate the hash value stored with this document.
	
	This value, when present, shall be interpreted based on the value of the algIdExtSource attribute in order to determine the algorithm used, which shall be application-defined. [*Rationale*: This extensibility affords the fact that with exponentially increasing computing power, documents created in the future will likely need to utilize as yet undefined hashing algorithms in order to remain secure. *end rationale*]
	
	If this value is present, the cryptAlgorithmClass, cryptAlgorithmType, and cryptAlgorithmSid attribute values shall be ignored in favor of the algorithm defined by this attribute.
	
	[*Example*: Consider a WordprocessingML document with the following information stored in one of its protection elements:
	
	`<w:… w:algIdExt="0000000A"`
	`w:algIdExtSource="futureCryptography"`
	`w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" />`
	
	The algIdExt attribute value of 0000000A specifies that the algorithm with hex code A shall be used as defined by the futureCryptography application. *end example*]

<table>
<tr><th>Attributes</th><th>Description</th></tr>
<tr><td></td><td>The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).</td></tr>
<tr><td>algIdExtSource (Algorithm Extensibility Source)</td><td>Specifies the application which defined the algorithm value specified by the algIdExt attribute.

[Example: Consider a WordprocessingML document with the following information stored in one of its protection elements:

<pre><w:… w:algIdExt="0000000A"
  w:algIdExtSource="futureCryptography"
  w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" /></pre>
The algIdExtSource attribute value of futureCryptography specifies that the algorithm used here was published by the futureCryptography application. end example]

The possible values for this attribute are defined by the ST_String simple type (§2.18.89).</td></tr>
<tr><td>cryptAlgorithmClass (Cryptographic Algorithm Class)</td><td>Specifies the class of cryptographic algorithm used by this protection. [Note: The initial version of this Office Open XML Standard only supports a single version - hash - but future versions may expand this as necessary. end note]

[Example: Consider a WordprocessingML document with the following information stored in one of its protection elements:

<pre><w:… w:cryptAlgorithmClass="hash"
  w:cryptAlgorithmType="typeAny"
  w:cryptAlgorithmSid="1"
  w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" /></pre>
The cryptAlgorithmClass attribute value of hash specifies that the algorithm used for the password is a hashing algorithm. end example]

The possible values for this attribute are defined by the ST_AlgClass simple type (§2.18.1).</td></tr>
<tr><td>cryptAlgorithmSid (Cryptographic Hashing Algorithm)</td><td>Specifies the specific cryptographic hashing algorithm which shall be used along with the salt attribute and user-supplied password in order to compute a hash value for comparison.

The possible values for this attribute shall be interpreted as follows:
<table>
<tr><th>Value</th><th>Algorithm</th></tr>
<tr><td>1</td><td>MD2</td></tr>
<tr><td>2</td><td>MD4</td></tr>
<tr><td>3</td><td>MD5</td></tr>
<tr><td>4</td><td>SHA-1</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Attributes</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><td>5</td><td>MAC</td></tr>
<tr><td>6</td><td>RIPEMD</td></tr>
<tr><td>7</td><td>RIPEMD-160</td></tr>
<tr><td>8</td><td>Undefined. Shall not be used.</td></tr>
<tr><td>9</td><td>HMAC</td></tr>
<tr><td>10</td><td>Undefined. Shall not be used.</td></tr>
<tr><td>11</td><td>Undefined. Shall not be used.</td></tr>
<tr><td>12</td><td>SHA-256</td></tr>
<tr><td>13</td><td>SHA-384</td></tr>
<tr><td>14</td><td>SHA-512</td></tr>
<tr><td>Any other value</td><td>Undefined. Shall not be used.</td></tr>
</table>
[Example: Consider a WordprocessingML document with the following information stored in one of its protection elements:
<pre><w:… w:cryptAlgorithmClass="hash"
  w:cryptAlgorithmType="typeAny"
  w:cryptAlgorithmSid="1"
  w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" /></pre>
The cryptAlgorithmSid attribute value of 1 specifies that the SHA-1 hashing algorithm shall be used to generate a hash from the user-defined password. end example]
The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
</td></tr>
<tr><td>cryptAlgorithmType (Cryptographic Algorithm Type)</td><td>
Specifies the type of cryptographic algorithm used by this protection. [Note: The initial version of this Office Open XML Standard only supports a single type - typeAny - but future versions may expand this as necessary. end note]
[Example: Consider a WordprocessingML document with the following information stored in one of its protection elements:
<pre><w:… w:cryptAlgorithmClass="hash"
  w:cryptAlgorithmType="typeAny"
  w:cryptAlgorithmSid="1"
  w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" /></pre>
The cryptAlgorithmType attribute value of typeAny specifies that any type of algorithm may have been used for the password. end example]
The possible values for this attribute are defined by the ST_AlgType simple type
</td></tr>
</table>

Attributes	Description
	(§2.18.2).
cryptProvider (Cryptographic Provider)	Specifies the cryptographic provider which was used to generate the hash value stored in this document. If the user provided a cryptographic provider which was not the system's built-in provider, then that provider shall be stored here so it can subsequently be used if available. If this attribute is omitted, then the built-in cryptographic provider on the system shall be used. [*Example*: Consider a WordprocessingML document with the following information stored in one of its protection elements: `<w:… w:cryptProvider="Krista'sProvider" w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" />` The cryptProvider attribute value of `Krista'sProvider` specifies that the cryptographic provider with name "Krista's Provider" shall be used if available. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).
cryptProviderType (Cryptographic Provider Type)	Specifies the type of cryptographic provider to be used. [*Example*: Consider a WordprocessingML document with the following information stored in one of its protection elements: `<w:… w:cryptProviderType="rsaAES" w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" />` The cryptProviderType attribute value of `rsaAES` specifies that the cryptographic provider type shall be an Advanced Encryption Standard provider. *end example*] The possible values for this attribute are defined by the ST_CryptProv simple type (§2.18.14).
cryptProviderTypeExt (Cryptographic Provider Type Extensibility)	Specifies that a cryptographic provider type which was not defined by this Office Open XML Standard has been used to generate the hash value stored with this document. This value, when present, shall be interpreted based on the value of the cryptProviderTypeExtSource attribute in order to determine the provider type used, which shall be application-defined. [*Rationale*: This extensibility affords the fact that with exponentially increasing computing power, documents created in the future will likely need to utilize as yet undefined cryptographic provider types in order to remain secure. *end rationale*] If this value is present, the cryptProviderType attribute value shall be ignored in favor of the provider type defined by this attribute.

Attributes	Description

	[*Example*: Consider a WordprocessingML document with the following information stored in one of its protection elements:
	
	`<w:… w:cryptProviderTypeExt="00A5691D"`
	`w:cryptProvideTypeExtSource="futureCryptography"`
	`w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" />`
	
	The cryptProviderTypeExt attribute value of `00A5691D` specifies that the provider type associated with hex code `A5691D` shall be used as defined by the `futureCryptography` application. *end example*]
	
	The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

cryptProviderTypeExtSource (Provider Type Extensibility Source)	Specifies the application which defined the provider type value specified by the cryptProviderTypeExt attribute.
	
	[*Example*: Consider a WordprocessingML document with the following information stored in one of its protection elements:
	
	`<w:… w:cryptProviderTypeExt="00A5691D"`
	`w:cryptProvideTypeExtSource="futureCryptography"`
	`w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" />`
	
	The cryptProvideTypeExtSource attribute value of `futureCryptography` specifies that the provider type used here was published by the `futureCryptography` application. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

cryptSpinCount (Iterations to Run Hashing Algorithm)	Specifies the number of times the hashing function shall be iteratively run (using each iteration's result as the input for the next iteration) when attempting to compare a user-supplied password with the value stored in the hash attribute. [*Rationale*: Running the algorithm many times increases the cost of exhaustive search attacks correspondingly. Storing this value allows for the number of iterations to be increased over time to accommodate faster hardware (and hence the ability to run more iterations in less time). *end rationale*]
	
	[*Example*: Consider a WordprocessingML document with the following information stored in one of its protection elements:
	
	`<w:… w:cryptSpinCount="100000"`
	`w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" />`
	
	The cryptSpinCount attribute value of `100000` specifies that the hashing function shall be run one hundred thousand times to generate a hash value for comparison with the hash attribute. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
edit (Document Editing Restrictions)	Specifies the set of editing restrictions which shall be enforced on a given WordprocessingML document, as defined by the simple type referenced below If this attribute is omitted, the consumer shall behave as though there are no editing restrictions applied to this document; equivalent to an attribute value of none. [*Example*: Consider a WordprocessingML document that contains the following WordprocessingML specifying that hosting applications shall enforce read-only protection for a given document: `<w:documentProtection w:edit="readOnly" w:enforcement="1" />` The edit attribute has a value of `readOnly` and a enforcement attribute with a value of `1`, specifying that read-only document protection shall be enforced on the given document. e*nd example*] The possible values for this attribute are defined by the ST_DocProtect simple type (§2.18.22).
enforcement (Enforce Document Protection Settings)	Specifies if the document protection settings shall be enforced for a given WordprocessingML document. If the value of this element is `off`, `0`, or `false`, all the WordprocessingML pertaining to document protection is still preserved in the document, but is not enforced. If the value of this element is on, 1, or `true`, the document protection is enforced. If this attribute is omitted, then document protection settings shall not be enforced by applications. [*Example*: Consider a WordprocessingML document that contains the following WordprocessingML specifying that hosting applications shall apply read-only protection for a given document: `<w:documentProtection w:edit="readOnly" w:enforcement="1" />` The enforcement attribute has a value of 1, specifying that the document protection specified shall be enforced on the given document. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
formatting (Only Allow Formatting With Unlocked Styles)	Specifies if formatting restrictions are in effect for a given WordprocessingML document. This enables the document to restrict the types of styles that may exist in a given WordprocessingML document. Specifically, by setting this attribute's value equal to `true`, every style whose locked element (§2.7.3.7) has a value of `true` (or latent styles (§2.7.3.5) whose locked attribute is `true`) shall not be available for use in the application, nor should any direct formatting. Only styles with a locked value of `false` may be used.

Attributes	Description

	If this attribute is omitted, then no formatting restrictions shall be applied, even when document protection is enforced.
	
	[*Example*: Consider a WordprocessingML document that shall apply formatting protection. This requirement would be specified using the following WordprocessingML in the document settings:
	
	`<w:documentProtection w:formatting="true" w:enforcement="true" />`
	
	If the following definition for a style was also present in the document:
	
	`<w:style w:type="paragraph" w:styleId="Heading1">`
	`<w:name w:val="heading 1" />`
	`<w:locked="1" />`
	`…`
	`</w:style>`
	
	The formatting attribute has a value of `true` specifying that the applications shall not allow the style above to be added to the WordprocessingML document. This does not preclude previous uses of that style (which shall not be removed), but does prevent new uses of this style from being added. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

hash (Password Hash)	Specifies the hash value for the password stored with this document. This value shall be compared with the resulting hash value after hashing the user-supplied password using the algorithm specified by the preceding attributes and parent XML element, and if the two values match, the protection shall no longer be enforced.
	
	If this value is omitted, then no password shall be associated with the protection, and it may be turned off without supplying any password.
	
	[*Example*: Consider a WordprocessingML document with the following information stored in one of its protection elements:
	
	`<w:… w:cryptAlgorithmClass="hash"`
	`w:cryptAlgorithmType="typeAny"`
	`w:cryptAlgorithmSid="1"`
	`w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" />`
	
	The hash attribute value of `9oN7nWkCAyEZib1RomSJTjmPpCY=` specifies that the user-supplied password shall be hashed using the pre-processing defined by the parent element (if any) followed by the SHA-1 algorithm (specified via the cryptAlgorithmSid attribute value of `1`) and that the resulting has value must be `9oN7nWkCAyEZib1RomSJTjmPpCY=` for the protection to be disabled. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the XML Schema base64Binary datatype.
salt (Salt for Password Verifier)	Specifies the salt which was prepended to the user-supplied password before it was hashed using the hashing algorithm defined by the preceding attribute values to generate the hash attribute, and which shall also be prepended to the user-supplied password before attempting to generate a hash value for comparison. A *salt* is a random string which is added to a user-supplied password before it is hashed in order to prevent a malicious party from pre-calculating all possible password/hash combinations and simply using those precalculated values (often referred to as a "dictionary attack"). If this attribute is omitted, then no salt shall be prepended to the user-supplied password before it is hashed for comparison with the stored hash value. [*Example*: Consider a WordprocessingML document with the following information stored in one of its protection elements: `<w:… w:salt="ZUdHa+D8F/OAKP3I7ssUnQ==" w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" />` The salt attribute value of `ZUdHa+D8F/OAKP3I7ssUnQ==` specifies that the user-supplied password shall have this value prepended before it is run through the specified hashing algorithm to generate a resulting hash value for comparison. *end example*] The possible values for this attribute are defined by the XML Schema base64Binary datatype.

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DocProtect">
   <attribute name="edit" type="ST_DocProtect" use="optional"/>
   <attribute name="formatting" type="ST_OnOff" use="optional"/>
   <attribute name="enforcement" type="ST_OnOff"/>
   <attributeGroup ref="AG_Password"/>
</complexType>
```

2.15.1.29 documentType (Document Classification)

This element specifies the classification of a given WordprocessingML document as a letter, email, or general document.

[*Note*: This element may be used by hosting applications to facilitate customized user interface and/or automatic formatting behaviors based on the 'type' of a given WordprocessingML document. *end note*]

If this element is omitted, then the document shall be classified as a general document.

[*Example*: Consider a set of WordprocessingML documents which should be classified as 'letters'. This classification would be specified using the following WordprocessingML in the document settings of these documents:

```
<w:documentType w:val="letter" />
```

The documentType element's val attribute is equal to `letter`, specifying that the hosting application shall apply the behaviors it has specified for letters to the given WordprocessingML document. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (Document Classification Value)	Specifies the classification of the document based on the types defined in the referenced simple type definition. [*Example*: Consider a WordprocessingML document which should be classified as an e-mail message. This classification would be specified using the following WordprocessingML in the document settings: `<w:documentType w:val="eMail" />` The val attribute is equal to `eMail`, specifying that the hosting application may apply e-mail behaviors (if any) to this document. *end example*] The possible values for this attribute are defined by the ST_DocType simple type (§2.18.23).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DocType">
   <attribute name="val" type="ST_DocType" use="required"/>
</complexType>
```

2.15.1.30 docVar (Single Document Variable)

This element specifies the parameters of a single document variable. A *document variable* is a storage location for arbitrary customer data in name/value pairs that will be persisted in a given WordprocessingML document. Specifically, this element specifies through its name and val attributes the name and value pair for a given document variable.

[*Note*: This mechanism is maintained for legacy compatibility only, and should be avoided in favor of the custom XML data support defined in this Office Open XML Standard. *end note*]

[*Example*: Consider the following WordprocessingML fragment specifying a document variable named `example` and containing the value `example value`:

```
<w:docVars>
  <w:docVar w:name="example" w:val="example value" />
</w:docVars>
```

The docVar element defines a single document variable, named `example` using the name attribute, and assigned the value `example value` through the val attribute. *end example*]

Parent Elements
docVars (§2.15.1.31)

Attributes	Description

name (Document Variable Name)	Specifies the name of the parent document variable.
	
	[*Example*: Consider the following WordprocessingML fragment specifying a document variable:
	
	`<w:docVars>`
	`  <w:docVar w:name="example name" w:val="example value" />`
	`</w:docVars>`
	
	The name attribute specifies that the name of the document variable is `example name`. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

val (Document Variable Value)	Specifies the value of the parent document variable.
	
	[*Example*: Consider the following WordprocessingML fragment specifying a document variable:
	
	`<w:docVars>`
	`  <w:docVar w:name="example name" w:val="Tristan Davis" />`
	`</w:docVars>`
	
	The val attribute specifies that the value of the document variable is `Tristan Davis`. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DocVar">
   <attribute name="name" type="ST_String" use="required"/>
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.15.1.31 docVars (Document Variables)

This element specifies the presence of document variables in a WordprocessingML. A *document variable* is a storage location for arbitrary customer data in name/value pairs that will be persisted in a given WordprocessingML document.

[*Note*: This mechanism is maintained for legacy compatibility only, and should be avoided in favor of the custom XML data support defined in this Office Open XML Standard. *end note*]

[*Example*: Consider the following WordprocessingML specifying three document variables:

```
<w:docVars>
  <w:docVar … />
  <w:docVar … />
  <w:docVar … />
</w:docVars>
```

The docVars element contains three child elements each defining a single document variable in this document. *end example*]

Parent Elements
settings (§2.15.1.78)

Child Elements	Subclause
docVar (Single Document Variable)	§2.15.1.30

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DocVars">
   <sequence>
      <element name="docVar" type="CT_DocVar" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
</complexType>
```

2.15.1.32 doNotAutoCompressPictures (Do Not Automatically Compress Images)

This element specifies that pictures in this document shall not automatically be compressed when saving the document in order to reduce the overall size of the resulting WordprocessingML document.

If this element is omitted, applications may perform basic compression on images before saving the contents of the document.

[*Example*: Consider a WordprocessingML document which should never have its images compressed before they are saved. This requirement would be specified using the following WordprocessingML:

```
<w:doNotAutoCompressPictures w:val="true"/>
```

The doNotAutoCompressPictures element's val attribute has a value of `true` specifying that images shall not be automatically compressed when the document is saved. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.33 doNotDemarcateInvalidXml (Do Not Show Visual Indicator For Invalid Custom XML Markup)

This element specifies whether a visual cue should be displayed around content contained in a WordprocessingML document which is contained with custom XML markup specified via the customXml element when an application determines that the current XML markup (or its contents) violate the constraints of the attached XML schema(s).

If this element is not present in a WordprocessingML document visual cues shall be displayed on content contained in custom XML markup in a WordprocessingML document which is considered to be invalid based on the associated XML schema(s).

[*Example*: Consider a WordprocessingML document which should show no visual indication of invalid custom XML markup. This requirement would be specified using the following WordprocessingML:

```
<w:doNotDemarcateInvalidXml w:val="true"/>
```

The doNotDemarcateInvalidXml element's val attribute has a value of `true` specifying the display of any visual indication of invalid custom XML markup shall be suppressed for this document. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.34 doNotDisplayPageBoundaries (Do Not Display Visual Boundary For Header/Footer or Between Pages)

This element specifies whether applications displaying this document should display the contents of the header and footer when displaying the document in print layout view (§2.15.1.93) or should collapse those areas as well as the whitespace on all displayed pages so that the text extents are directly following one another. [*Rationale*: Collapsing the ends of pages makes it easier to read the contents of the document, since the text flows between pages without whitespace, while maintaining the WYSIWYG functionality of print layout view for the document's main content. *end rationale*]

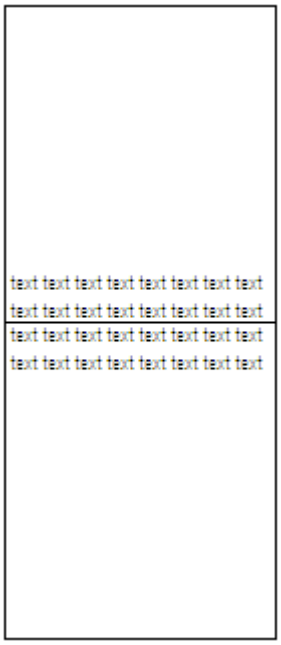
If this element is omitted, then all pages should be shown at their full size (including whitespace and headers/footers) when they are displayed in print layout view.

[*Example*: Consider the images below illustrating two pages in a WordprocessingML document:

If document shall automatically have whitespace between pages removed when it is displayed, that requirement would be specified using the following WordprocessingML in the document settings:

```
<w:doNotDisplayPageBoundaries w:val="true" />
```

The resulting output might look like the following:



The doNotDisplayPageBoundaries element has its val attribute equal to `true`, therefore the document is automatically displayed with whitespace between text extents on following pages compressed, allowing the pages to be viewed more easily. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.35 doNotEmbedSmartTags (Remove Smart Tags When Saving)

This element specifies if any smart tags specified using the smartTag element shall be removed from the contents of this document before it is resaved. This setting shall also prevent the addition of new smart tags to the content of the document.

If this element is omitted, then smart tags shall not be removed from the file when it is saved.

[*Example*: Consider a WordprocessingML document which should never be saved with smartTag elements in its contents. This requirement is specified using the following WordprocessingML fragment in the document settings:

```
<w:doNotEmbedSmartTags w:val=”true”/>
```

The doNotEmbedSmartTags element's val attribute has a value of `true` specifying that smart tags shall never be saved in the contents of this document. For example, if a run formerly looked like this:

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">Hello</w:t>
  </w:r>
  <w:smartTag … >
    <w:r>
      <w:t>world<w:t>
    </w:r>
  </w:smartTag>
</w:p>
```

The presence of this element specifies that the SmartTag element shall be removed, and applications may then choose to combine duplicated runs as desired. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.36 doNotHyphenateCaps (Do Not Hyphenate Words in ALL CAPITAL LETTERS)

This element specifies whether or not words comprised of all capital letters shall be hyphenated within a given document when automatic hyphenation is specified via the autoHyphenation element (§2.15.1.10).

If this element is omitted, then words in ALL CAPITAL LETTERS shall be hyphenated when the document is hyphenated.

[*Example*: Consider a document which is automatically hyphenated containing the following paragraph of content:

THIS IS A HYPHENATION EXAMPLE. THIS IS A SHORT HYPHENATION EXAMPLE. THIS IS A SHORT HYPHE-
NATION EXAMPLE.

If words in ALL CAPITAL LETTERS shall not be hyphenated, this requirement would be specified by adding the following WordprocessingML to the document settings part:

```
<w:doNotHyphenateCaps w:val="true"/>
```

The resulting content would not be hyphenated:

THIS IS A HYPHENATION EXAMPLE. THIS IS A SHORT HYPHENATION EXAMPLE. THIS IS A SHORT
HYPHENATION EXAMPLE.

The doNotHyphenateCaps element val set to `true`, specifying that the first line of text to end with the word SHORT as the word HYPHENATION had to be moved to the second line since it could not fit in its entirety on the first line.

Conversely, setting the doNotHyphenateCaps element val set to `off` (the default) caused the first line of text to contain a hyphenated portion of the word HYPHENATION as hyphenation of words comprised of all capital letters is permitted. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>`

Attributes	Description
	The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.37 doNotIncludeSubdocsInStats (Do Not Include Content in Text Boxes, Footnotes, and Endnotes in Document Statistics)

This element specifies if document content contained in text boxes, footnotes, and endnotes shall be excluded when an application calculates a given document's statistics when these values are calculated and/or displayed by an application.

[*Note*: Some examples of document statistics that an application may chose to calculate are: number of words, number of characters, number of paragraphs, number of pages, number of lines, and so on. *end note*]

[*Example*: Consider a WordprocessingML that specifies that it shall not include these document stories when its contents are used to calculate document statistics. This requirement would be specified using the following WordprocessingML in the document settings part:

```
<w:doNotIncludeSubdocsInStats w:val="true"/>
```

The doNotIncludeSubdocsInStats element's val attribute has a value of true specifying that only the contents of the main document story should be used when calculating document statistics. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/>

Attributes	Description
	The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.38 doNotShadeFormData (Do Not Show Visual Indicator For Form Fields)

This element specifies whether a visual cue should be displayed around form fields contained in a WordprocessingML document specified via the FORMTEXT, FORMCHECKBOX, or FORMDROPDOWN fields.

If this element is not present in a WordprocessingML document visual cues should be displayed on form fields contained in the document.

[*Example*: Consider a WordprocessingML document which should no visual indication of form fields. This requirement would be specified using the following WordprocessingML:

```
<w:doNotShadeFormData w:val="true"/>
```

The doNotShadeFormData element's val attribute has a value of true specifying the display of any visual indication of form fields shall be suppressed for this document. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.39 doNotTrackFormatting (Do Not Track Formatting Revisions When Tracking Revisions)

This element specifies that applications shall not track revisions made to the formatting of this WordprocessingML document when the trackRevisions element (§2.15.1.90) is turned on.

If this element is omitted, then revisions to formatting shall be generated by changes to the contents of this document when the trackRevisions element is turned on.

[*Example*: Consider a WordprocessingML document containing the text run `Example` that shall have revisions tracked. Example WordprocessingML from Document 1 is given below:

```
<w:document>
  <w:body>
    <w:p>
      <w:r>
        <w:t>Example</w:t>
      </w:r>
    </w:p>
  </w:body>
</w:document>
```

If the word `text` was added to the end of this document and bolded, the resulting WordprocessingML would be output as follows:

```
<w:document>
  <w:body>
    <w:p>
      <w:r>
        <w:t>Example</w:t>
      </w:r>
      <w:ins … >
        <w:r>
          <w:rPr>
            <w:b/>
            <w:rPrChange … >
              <w:rPr/>
            <w:rPrChange>
          </w:rPr>
          <w:t>text</w:t>
        </w:r>
      </w:ins>
    </w:p>
  </w:body>
</w:document>
```

If changes to formatting were turned off using the following WordprocessingML syntax in the document settings:

```
<w:settings>
  <w:trackRevisions w:val="true" />
  <w:doNotTrackFormatting w:val="true" />
  …
</w:settings>
```

The same revision (the word `text` was added to the end of this document and bolded) would result in the following markup:

```
<w:document>
  <w:body>
    <w:p>
      <w:r>
        <w:t>Example</w:t>
      </w:r>
      <w:ins … >
        <w:r>
          <w:rPr>
            <w:b/>
          </w:rPr>
          <w:t>text</w:t>
        </w:r>
      </w:ins>
    </w:p>
  </w:body>
</w:document>
```

The doNotTrackFormatting element's val attribute was set to `true`, therefore the changes to the formatting of the document were not tracked as revisions in the document's WordprocessingML. Specifically, applying bold formatting to the text was not tracked as a revision with the rPrChange (§2.13.5.32) element. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.40 doNotTrackMoves (Do Not Use Move Syntax When Tracking Revisions)

This element specifies that applications shall not track revisions made to this WordprocessingML document as moves when the trackRevisions element (§2.15.1.90) is turned on, even when that syntax is appropriate. Instead, applications should use a standard insertion and deletion annotation syntax. Existing moves shall not be modified. [*Rationale*: This element is provided to enable interoperability with earlier word processing applications which do not understand moves. *end rationale*]

If this element is omitted, then move annotations may be generated by changes to the contents of this document when the trackRevisions element is turned on as appropriate.

[*Example*: Consider a WordprocessingML that specifies that it shall not have additional moves added to its contents. This requirement would be specified using the following WordprocessingML in the document settings part:

```
<w:doNotTrackMoves w:val="true"/>
```

The doNotTrackMoves element's val attribute has a value of `true` specifying that insertion/deletion annotations shall be used rather than moves when revisions are tracked in this document. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.41 doNotUseMarginsForDrawingGridOrigin (Do Not Use Margins for Drawing Grid Origin)

This element specifies that the top-left corner of the page shall not be used as the origin for the drawing grid. The *drawing grid* is a virtual grid which may be used by applications to specify where drawing objects shall be positioned on a page when inserted (i.e. to ensure objects are aligned, etc.). If this element is present the grid shall start at the top-left edge of the page and not the text extents.

If this element is omitted, then the gridlines shall start at the topmost edge of the text extents.

[*Example*: Consider a WordprocessingML document whose drawing grid shall begin at the top left edge of the page. This requirement would be specified using the following WordprocessingML markup in the document settings:

```
<w:doNotUseMarginsForDrawingGridOrigin w:val="true" />
```

The doNotUseMarginsForDrawingGridOrigin element's val attribute is equal to `true` specifying that the document's drawing grid shall begin from the top left corner of the page, rather than the top left corner of the text extents. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.42 doNotValidateAgainstSchema (Do Not Validate Custom XML Markup Against Schemas)

This element specifies that applications shall not validate the custom XML markup in this document against the applicable custom XML schema(s), even when those schemas are available. The application should silently behave as if it was unable to provide this functionality.

If this element is omitted, then applications which support this functionality should attempt to validate the custom XML contents against any available related custom XML schema(s).

[*Example*: Consider a WordprocessingML document which should not have its custom XML content validated even by applications which support this operation. This requirement is specified using the following WordprocessingML in the document settings:

```
<w:doNotValidateAgainstSchema w:val="true" />
```

The doNotValidateAgainstSchema element's val attribute has a value of `true` specifying that the custom XML markup in this document shall not be validated. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.43 drawingGridHorizontalOrigin (Drawing Grid Horizontal Origin Point)

This element specifies the distance from of the left edge of the page which shall be used as the origin for the horizontal gridlines used by the drawing grid. The *drawing grid* is a virtual grid which may be used by applications to specify where drawing objects shall be positioned on a page when inserted (i.e. to ensure objects are aligned, etc.). Since the grid always covers the entire page when the doNotUseMarginsForDrawingGridOrigin element (§2.15.1.41) is specified, this element shall only affect the starting edge of the first horizontal gridline displayed (i.e. it only adjusts the grid by the modulus of the value against the width of one grid unit).

If this element is omitted, then the gridlines shall start at the leftmost edge of the page. If the doNotUseMarginsForDrawingGridOrigin element is not specified, then this element is ignored.

[*Example*: Consider a WordprocessingML document whose drawing grid shall begin three inches (4320 twentieths of a point) before the left edge of the page. This requirement would be specified using the following WordprocessingML markup in the document settings:

```
<w:settings>
  …
  <w:dontuseMarginsForDrawingGridOrigin w:val="true" />
  <w:drawingGridHorizontalOrigin w:val="4320" />
  …
</w:settings>
```

The drawingGridHorizontalOrigin element's val attribute is equal to `4320` specifying that the horizontal edge of the document's drawing grid shall begin three inches (4320 twentieths of a point) from the left edge of the page, since the dontUseMarginsForDrawingGridOrigin element's val attribute is equal to `true`. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (Measurement in Twentieths of a Point)	Specifies a positive measurement value, specified in twentieths of a point. This value is interpreted based on the context of the parent XML element. [*Example*: Consider the following WordprocessingML element with a val attribute containing a positive measurement in twentieths of a point: `<w:… w:val="720" />`

Attributes	Description
	The val attribute has a value of 720, specifying that this measurement value is 720 twentieths of a point (0.5"). This value is interpreted by the parent element as needed. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

The following XML Schema fragment defines the contents of this element:

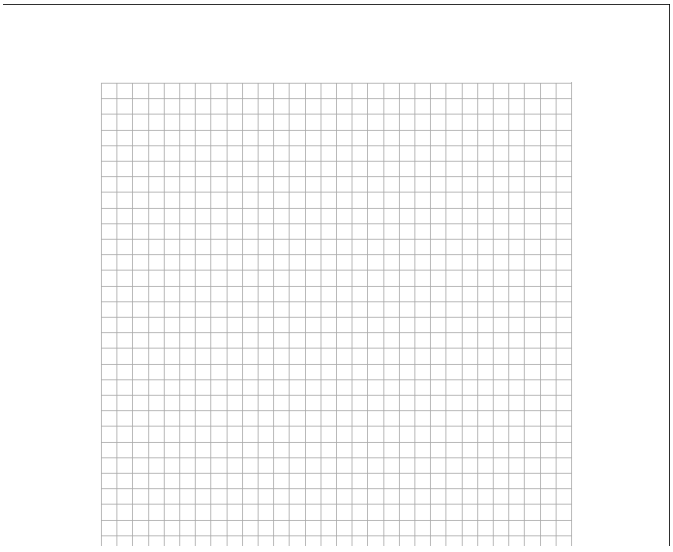
```
<complexType name="CT_TwipsMeasure">
   <attribute name="val" type="ST_TwipsMeasure" use="required"/>
</complexType>
```

2.15.1.44 drawingGridHorizontalSpacing (Drawing Grid Horizontal Grid Unit Size)

This element specifies the width of horizontal grid units in this document. The *drawing grid* is a grid which may be used by applications to help position floating objects in the document.

If this element is omitted, then each horizontal grid unit shall be 180 twentieths of a point (0.125") in width.

[*Example*: Consider the image below illustrating a WordprocessingML document in which all horizontal grid units are each 144 twentieths of a point wide (and all are showing):



If the gridlines in this document shall only be displayed for every half an inch, that requirement would be specified using the following WordprocessingML in the document settings:

```
<w:drawingGridHorizontalSpacing w:val="720" />
```

The resulting grid would look like the following:

The drawingGridHorizontalSpacing element has its val attribute equal to 720, therefore every horizontal gridline has a width of one half of an inch (720 twentieths of a point). *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (Measurement in Twentieths of a Point)	Specifies a positive measurement value, specified in twentieths of a point. This value is interpreted based on the context of the parent XML element. [*Example*: Consider the following WordprocessingML element with a val attribute containing a positive measurement in twentieths of a point: `<w:… w:val="720" />` The val attribute has a value of 720, specifying that this measurement value is 720 twentieths of a point (0.5"). This value is interpreted by the parent element as needed. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TwipsMeasure">
   <attribute name="val" type="ST_TwipsMeasure" use="required"/>
</complexType>
```

2.15.1.45 drawingGridVerticalOrigin (Drawing Grid Vertical Origin Point)

This element specifies the distance from of the top edge of the page which shall be used as the origin for the vertical gridlines used by the drawing grid. The *drawing grid* is a virtual grid which may be used by applications to specify where drawing objects shall be positioned on a page when inserted (i.e. to ensure objects are aligned, etc.). Since the grid always covers the entire page when the doNotUseMarginsForDrawingGridOrigin element (§2.15.1.41) is specified, this element shall only affect the starting edge of the first vertical gridline displayed (i.e. it only adjusts the grid by the modulus of the value against the width of one grid unit).

If this element is omitted, then the gridlines shall start at the topmost edge of the page. If the doNotUseMarginsForDrawingGridOrigin element is not specified, then this element is ignored.

[*Example*: Consider a WordprocessingML document whose drawing grid shall begin one inch (1440 twentieths of a point) before the top edge of the page. This requirement would be specified using the following WordprocessingML markup in the document settings:

```
<w:settings>
  …
  <w:dontuseMarginsForDrawingGridOrigin w:val="true" />
  <w:drawingGridVerticallOrigin w:val="1440" />
  …
</w:settings>
```

The drawingGridVerticalOrigin element's val attribute is equal to `1440` specifying that the vertical edge of the document's drawing grid shall begin one inch (1440 twentieths of a point) from the top edge of the page, since the dontUseMarginsForDrawingGridOrigin element's val attribute is equal to `true`. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (Measurement in Twentieths of a Point)	Specifies a positive measurement value, specified in twentieths of a point. This value is interpreted based on the context of the parent XML element. [*Example*: Consider the following WordprocessingML element with a val attribute containing a positive measurement in twentieths of a point: `<w:… w:val="720" />` The val attribute has a value of `720`, specifying that this measurement value is 720 twentieths of a point (0.5"). This value is interpreted by the parent element as needed. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type

Attributes	Description
	(§2.18.105).

The following XML Schema fragment defines the contents of this element:

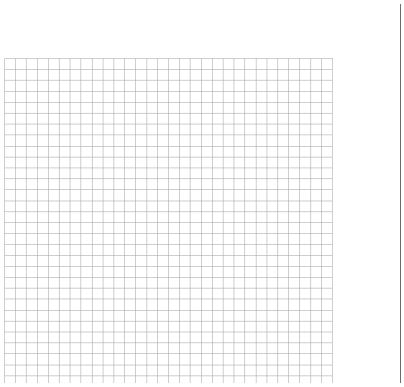
```
<complexType name="CT_TwipsMeasure">
   <attribute name="val" type="ST_TwipsMeasure" use="required"/>
</complexType>
```

2.15.1.46 drawingGridVerticalSpacing (Drawing Grid Vertical Grid Unit Size)

This element specifies the width of vertical grid units in this document. The *drawing grid* is a grid which may be used by applications to help position floating objects in the document.

If this element is omitted, then each vertical grid unit shall be 180 twentieths of a point (0.125") in width.

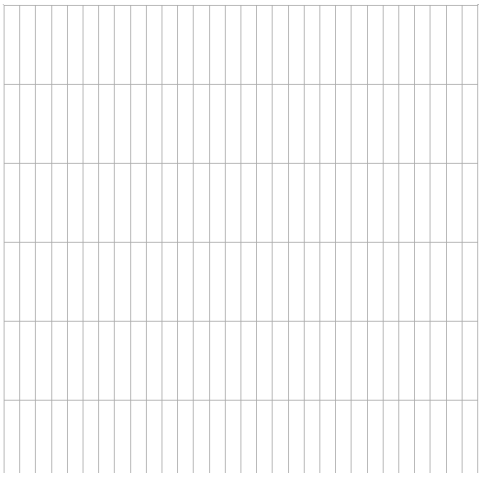
[*Example*: Consider the image below illustrating a WordprocessingML document in which all vertical grid units are each 144 twentieths of a point high (and all are showing):



If the vertical gridlines in this document shall only be displayed for every half an inch, that requirement would be specified using the following WordprocessingML in the document settings:

```
<w:drawingGridVerticalSpacing w:val="720" />
```

The resulting grid would look like the following:



The drawingGridVerticalSpacing element has its val attribute equal to 720, therefore every vertical gridline has a height of one half of an inch (720 twentieths of a point). *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (Measurement in Twentieths of a Point)	Specifies a positive measurement value, specified in twentieths of a point. This value is interpreted based on the context of the parent XML element. [*Example*: Consider the following WordprocessingML element with a val attribute containing a positive measurement in twentieths of a point: `<w:… w:val="720" />` The val attribute has a value of 720, specifying that this measurement value is 720 twentieths of a point (0.5"). This value is interpreted by the parent element as needed. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TwipsMeasure">
   <attribute name="val" type="ST_TwipsMeasure" use="required"/>
</complexType>
```

2.15.1.47 forceUpgrade (Upgrade Document on Open)

This element specifies that the contents of this document may be upgraded and that the resulting document shall not have its functionality limited to only those functions compatible with earlier word processing applications. The only actions required as part of upgrading the document are:

- The removal of this and the uiCompat97to2003 element (§2.15.3.54). This is needed in order to prevent future applications from disabling functionality on the resulting 'upgraded' document. If an application does not know how to upgrade a document, this element and the uiCompat97to2003 element should be ignored and persisted.
- The removal of all compatibility options (§2.15.3.9) on the document which maintain compatibility with previous word processing applications. The compatibility settings which simply affect a given behavior shall not be turned off.

[*Note*: The remaining operations which shall be performed as part of upgrading the document are application-defined and outside the scope of this Office Open XML Standard. *end note*]

[*Example*: Consider a WordprocessingML document that specifies that it shall automatically be upgraded when it is opened by an application. This requirement would be specified using the following WordprocessingML in the document settings part:

```
<w:forceUpgrade w:val="true"/>
```

The forceUpgrade element's val attribute has a value of `true` specifying that this document shall be upgraded by any application which supports this operation. *end example*]

Parent Elements
settings (§2.15.1.78)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.15.1.48 formsDesign (Structured Document Tag Placeholder Text Should be Resaved)

This element specifies that the document was last saved while the placeholder text of all structured document tags in this document were being edited. This means that the placeholder text currently displayed in all structured document tags which are displaying the showingPlcHdr element (§2.5.2.38) shall be committed to the corresponding glossary document entry as specified using the docPart element (§2.12.5) when this document is opened, in order to ensure that the most recent placeholder text is stored in the glossary document entry. If the current placeholder text cannot be saved as a glossary document entry, then it should be modified as needed before saving.

If this element is omitted, then the placeholder text in this document should not automatically be resaved when the document is opened.

[*Example*: Consider a WordprocessingML document that specifies that its placeholder text should be resaved to the glossary document when the file is opened. This requirement would be specified using the following WordprocessingML in the document settings part:

```
<w:formsDesign w:val="true"/>
```

The formsDesign element's val attribute has a value of `true` specifying that this document should be resaved to its glossary document by any application which supports this operation. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.49 gutterAtTop (Position Gutter At Top of Page)

This element specifies that a given WordprocessingML document's gutter shall be positioned at the top of the document's pages when the document is displayed. A *gutter* is the white space formed by the inner margins of two pages facing one another; such as the white space between the text on pages of a book when the book is opened.

If this element is omitted, then the gutter shall not be positioned at the top of the page. If the mirrorMargins (§2.15.1.57), bookFoldPrinting (§2.15.1.11), bookFoldRevPrinting (§2.15.1.13), or printTwoOnOne (§2.15.1.64) elements are used within a given document, the gutterAtTop element shall not be used. Rather,

the gutter shall be positioned automatically as necessary to enable the printing and page layout capabilities of these settings.

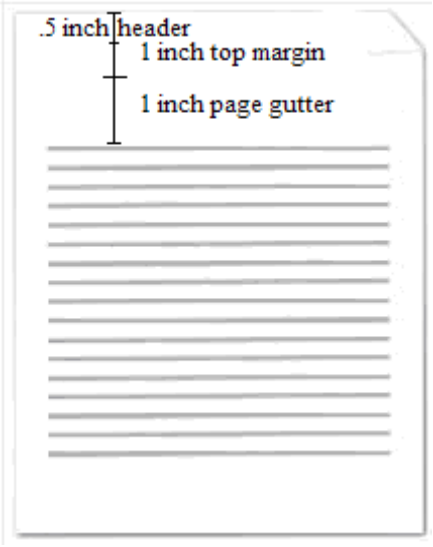
[*Example*: Consider a one page WordprocessingML document with a 1,440 twentieths of a point (one inch) top margin and gutter, and a 720 twentieths of a point (one half of an inch) header. Consider also, that the gutter shall exist at the top of the document's pages. This requirement is specified using the following WordprocessingML in the section properties:

```
<w:pgMar w:top="1440" ... w:header="720" ... w:gutter="1440" />
```

And the following WordprocessingML in the document settings:

```
<w:gutterAtTop w:val="true" />
```

The resulting document's pages would have the gutter positioned as follows:



The gutterAtTop element's val attribute is equal to on, specifying that the gutter shall appear at the top of each page. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted.

Attributes	Description
	A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.50 hdrShapeDefaults (Default Properties for VML Objects in Header and Footer)

This element specifies the default parameters for object using the ' (§6.1) inserted in the header and footer of a WordprocessingML document. The definition and semantics of these parameters is described in the VML - Office Drawing subclause (§6.2) of this Office Open XML Standard.

If this element is omitted, then no default properties are applied to VML objects in the header and footer of this document.

[*Example*: Consider a WordprocessingML document whose document settings contain the following markup:

```
<w:hdrShapeDefaults>
  <o:shapedefaults v:ext="edit" spidmax="2050" fillcolor="none [3207]"
strokecolor="none [3041]">
    <v:fill color="none [3207]" />
    <v:stroke color="none [3041]" weight="3pt" />
    <v:shadow on="t" type="perspective" color="none [1607]" opacity=".5"
offset="1pt" offset2="1pt" />
  </o:shapedefaults>
  <o:shapelayout v:ext="edit">
    <o:idmap v:ext="edit" data="2" />
  </o:shapelayout>
</w:hdrShapeDefaults>
```

The hdrShapeDefaults element specifies a set of shape defaults which shall be applied to the set of all shapes present in the header and footer of this document. *end example*]

Parent Elements
settings (§2.15.1.78)

Child Elements	Subclause
Any element from the urn:schemas-microsoft-com:office:office namespace	§6.2

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_ShapeDefaults">
   <choice maxOccurs="unbounded">
      <any processContents="lax" namespace="urn:schemas-microsoft-com:office:office" minOccurs="0"
        maxOccurs="unbounded"/>
   </choice>
</complexType>
```

2.15.1.51 hideGrammaticalErrors (Do Not Display Visual Indication of Grammatical Errors)

This element specifies whether a visual cue should be displayed around run content contained in a WordprocessingML document which has been flagged as a possible grammatical error using the proofErr element (§2.13.8.1) or via the application's own grammar engine.

If this element is not present in a WordprocessingML document, visual cues shall be displayed on content contained in a WordprocessingML document which is considered to contain grammatical errors.

[*Example*: Consider a WordprocessingML document which should show no visual indication of grammatical errors. This requirement would be specified using the following WordprocessingML:

```
<w:hideGrammaticalErrors w:val="true"/>
```

The hideGrammaticalErrors element's val attribute has a value of `true` specifying the display of any visual indication of grammatical errors shall be suppressed for this document. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.52 hideSpellingErrors (Do Not Display Visual Indication of Spelling Errors)

This element specifies whether a visual cue should be displayed around run content contained in a WordprocessingML document which has been flagged as a possible spelling error using the proofErr element (§2.13.8.1) or via the application's own spelling engine.

If this element is not present in a WordprocessingML document, visual cues shall be displayed on content contained in a WordprocessingML document which is considered to contain spelling errors.

[*Example*: Consider a WordprocessingML document which should show no visual indication of spelling errors. This requirement would be specified using the following WordprocessingML:

```
<w:hideSpellingErrors w:val="true"/>
```

The hideSpellingErrors element's val attribute has a value of `true` specifying the display of any visual indication of spelling errors shall be suppressed for this document. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

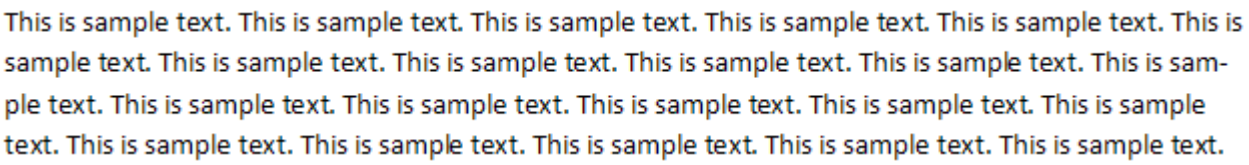
```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.53 hyphenationZone (Hyphenation Zone)

This element specifies the hyphenation zone which shall be used when automatically or manually hyphenating the contents of this document. The *hyphenation zone* is the amount of whitespace which may be left at the end of a line (or added to justified lines) before hyphenation should be attempted on the next word in the document (in order to reduce the amount of whitespace on the line). A smaller hyphenation zone should reduce the raggedness of the right edge of a given document's body text, as more words will be hyphenated. Conversely, a larger hyphenation zone should increase the raggedness of the right edge of a given document's text, as fewer words will be hyphenated.

If this element is omitted, then a default hyphenation zone of 360 twentieths of a point (0.25") shall be applied when performing hyphenation on this document.

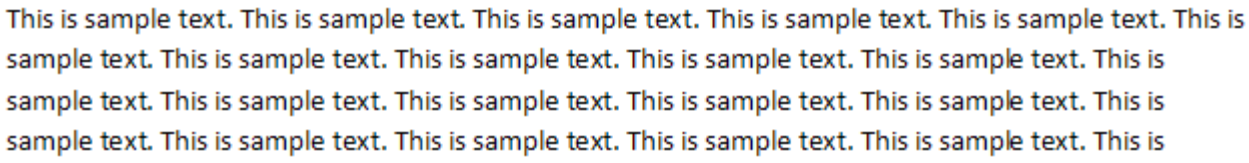
[*Example*: Consider the images below illustrating a paragraph of text in a WordprocessingML document which was automatically hyphenated with the default hyphenation zone:



If document shall instead be hyphenated using a hyphenation zone of one-half of an inch, that requirement would be specified using the following WordprocessingML in the document settings:

```
<w:hyphenationZone w:val="720" />
```

The resulting output would only hyphenate words when the remaining line whitespace was less than half an inch, and would look like the following:



The hyphenationZone element has its val attribute equal to 720, therefore lines in the document are hyphenated when the remaining line spacing is less than 72o twentieths of a point (0.5"), resulting in fewer hyphens. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (Measurement in Twentieths of a Point)	Specifies a positive measurement value, specified in twentieths of a point. This value is interpreted based on the context of the parent XML element. [*Example*: Consider the following WordprocessingML element with a val attribute containing a positive measurement in twentieths of a point: `<w:… w:val="720" />` The val attribute has a value of 720, specifying that this measurement value is 720 twentieths of a point (0.5"). This value is interpreted by the parent element as needed. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TwipsMeasure">
   <attribute name="val" type="ST_TwipsMeasure" use="required"/>
</complexType>
```

2.15.1.54 ignoreMixedContent (Ignore Mixed Content When Validating Custom XML Markup)

This element specifies that applications should ignore all text content which is not contained within a leaf custom XML markup element when validating the contents of the custom XML markup in this document against one or more attached custom XML schema(s). A *leaf element* is a custom XML element which has no child custom XML elements (it is a leaf in the custom XML tree).

If this element is omitted, then text content in leaf elements shall not be ignored when validating the custom XML markup against one or more custom XML schema(s).

[*Example*: Consider a WordprocessingML document which should not have its custom XML content validated even by applications which support this operation. This requirement is specified using the following WordprocessingML in the document settings:

```
<w:doNotValidateAgainstSchema w:val="true" />
```

The doNotValidateAgainstSchema element's val attribute has a value of `true` specifying that the custom XML markup in this document shall not be validated. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element.

Attributes	Description
	A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.55 linkStyles (Automatically Update Styles From Document Template)

This element specifies that styles in the given document shall be updated to match the styles in the attached template specified using the attachedTemplate element (§2.15.1.6) when the document is opened by a hosting application. This setting enables the styles contained in documents with attached templates to stay synchronized with the styles used in the attached template.

If this element is omitted, then styles shall not be updated based on the document template regardless of its availability. If the attached template cannot be located or is not a valid file, then this setting should be silently ignored.

[*Example*: Consider a WordprocessingML document which should always update its styles with those defined in the document's attached template. This requirement would be specified using the following WordprocessingML in the document settings:

```
<w:settings>
  <w:linkStyles w:val="true" />
  <w:attachedTemplate r:id="rId10" />
  …
</w:settings>
```

The linkStyles element has a val attribute value of true, specifying that applications should attempt to locate the document template referenced by the relationship specified in the attachedTemplate element and update the document's styles with the styles from that template. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.56 listSeparator (List Separator for Field Code Evaluation)

This element specifies the character that shall be interpreted as a list item separator when evaluating the contents of all fields in the current document.

[*Rationale*: When evaluating field instructions based on the contents of the current document, it is necessary to know the character which shall be treated as the list separator in order to prevent changes to the calculation of the same field instructions based on the current user's locale. This element stores the list separator which shall be used to evaluate fields in the contents of this document, irrespective of the locale of the application loading the file. *end rationale*]

If this element is omitted, the application shall use the default list separator of its current locale setting to evaluate field instructions. If this element's attribute value is more than a single character, then the document is non-conformant.

[*Example*: Consider a WordprocessingML document which should use the semicolon character as the list separator for all field instructions. This requirement is specified using the following WordprocessingML in the document settings:

```
<w:listSeparator w:val=";" />
```

The listSeparator element's val attribute has a value of `;` specifying that the semicolon character shall be interpreted as a list item separator.

For instance, the string `10;20,5` would be interpreted as having two values - `10` and `20,5`. If the listSeparator was a comma, the same string would be interpreted as `10;20` and `5`. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.15.1.57 mirrorMargins (Mirror Page Margins)

This element specifies that the left and right margins defined in the section properties shall be swapped on facing pages.

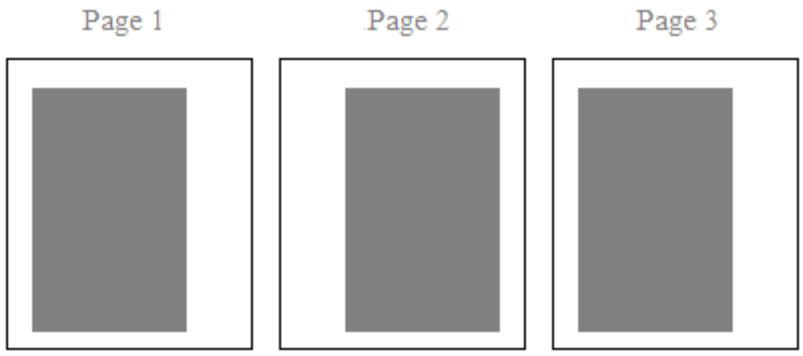
[*Guidance*: This setting is generally used when printing on both sides of pages and binding them like a book. *end guidance*]

[*Example*: Consider a graphical representation (below) of a three page WordprocessingML document with a left margin of 1" and a right margin of 2".

If the mirrorMargins element is present in the document settings with its val attribute equal to `true`, as follows:

```
<w:mirrorMargins w:val="true" />
```

The resulting pages will have mirrored margins as follows (un this representation, the gray rectangles representing the text extents on each page):



end example]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.58 noLineBreaksAfter (Custom Set of Characters Which Cannot End a Line)

This element specifies the set of characters which shall be restricted from ending a line for runs of text which shall be subject to custom line breaking logic using the kinsoku element (§2.3.1.16) when the contents of the document are displayed. This constraint shall only apply to text which has been flagged in the language of this rule via the lang element (§2.3.2.18) or automatic detection methods outside the scope of this Office Open XML Standard.

If this element is omitted, then no custom set of characters shall be used to restrict the characters which may end a line when using the kinsoku element.

[*Example*: Consider a paragraph of WordprocessingML text displayed as follows, with the dollar symbol $ was flagged as Japanese content using the following WordprocessingML in the run properties:

```
<w:r>
  <w:rPr>
    <w:lang w:eastAsia="ja-JP" />
  </w:rPr>
  <w:t>$</w:t>
</w:r>
```

This is a sample line of text. This is a sample line of text. This is a sample line of text. This is a $ sample line of text.

This text is displayed and the resulting first line ends with the dollar sign symbol. If this character shall not be used to end a line, that requirement would be specified as follows in the document settings:

```
<w:noLineBreaksAfter w:lang="ja-JP" w:val="$" />
```

The noLineBreaksAfter element's val attribute has a value of `ja-JP`, specifying that all dollar signs in this document which are marked as Japanese text shall not be allowed to end a line. This means that the dollar sign character must therefore be moved to the next line as it can no longer be the last character on a line:

This is a sample line of text. This is a sample line of text. This is a sample line of text. This is a $ sample line of text.

end example]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
lang (Language For Which Custom Line Breaking Rule Applies)	Specifies the language of text for which the parent custom line breaking rule shall be applied. Applications supporting this functionality shall support custom line breaking for the following four languages: • Chinese (Traditional) • Chinese (Simplified) • Japanese • Korean Applications may also support custom line breaking rules for other languages, but this is not required. [*Example*: Consider a WordprocessingML document which shall have a custom line breaking rule for Japanese. That requirement would be specified as follows in the document settings: `<w:… w:lang="ja-JP" w:val="$" />` The lang attribute has a value of `ja-JP`, specifying that the rules shall be applied to Japanese text. *end example*] The possible values for this attribute are defined by the ST_Lang simple type (§2.18.51).
val (Characters For Custom Line Breaking Rule)	Specifies the set of characters which shall be included in the custom line breaking rule. [*Example*: Consider a WordprocessingML document which shall have a custom line breaking rule for Japanese. That requirement would be specified as follows in the document settings: `<w:… w:lang="ja-JP" w:val="$" />` The val attribute has a value of `$`, specifying that the dollar sign character is the only restricted character for Japanese text. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Kinsoku">
   <attribute name="lang" type="ST_Lang" use="required"/>
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.15.1.59 noLineBreaksBefore (Custom Set Of Characters Which Cannot Begin A Line)

This element specifies the set of characters which shall be restricted from beginning a new line for runs of text which shall be subject to custom line breaking logic using the kinsoku element (§2.3.1.16) when the contents of the document are displayed. This constraint shall only apply to text which has been flagged in the language of

this rule via the lang element (§2.3.2.18) or automatic detection methods outside the scope of this Office Open XML Standard.

If this element is omitted, then no custom set of characters shall be used to restrict the characters which may end a line when using the kinsoku element.

[*Example*: Consider a paragraph of WordprocessingML text displayed as follows, with the dollar symbol $ was flagged as Korean content using the following WordprocessingML in the run properties:

```
<w:r>
  <w:rPr>
    <w:lang w:eastAsia="ko-KR" />
  </w:rPr>
  <w:t>$</w:t>
</w:r>
```

This is a sample line of text. This is a sample line of text. This is a sample line of text. This is a
$ sample line of text.

This text is displayed and the resulting second line begins with the dollar sign symbol. If this character shall not be used to begin a line, that requirement would be specified as follows in the document settings:

```
<w:noLineBreaksBefore w:lang="ko-KR" w:val="$" />
```

The noLineBreaksBefore element's val attribute has a value of ko-KR, specifying that all dollar signs in this document which are marked as Korean text shall not be allowed to begin a line. This means that the previous word character must therefore be moved to the next line as the dollar sign can no longer be the first character on a line:

This is a sample line of text. This is a sample line of text. This is a sample line of text. This is
a $ sample line of text.

end example]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
lang (Language For Which Custom Line Breaking Rule Applies)	Specifies the language of text for which the parent custom line breaking rule shall be applied. Applications supporting this functionality shall support custom line breaking for the following four languages: • Chinese (Traditional) • Chinese (Simplified) • Japanese

Attributes	Description
	• Korean Applications may also support custom line breaking rules for other languages, but this is not required. [*Example*: Consider a WordprocessingML document which shall have a custom line breaking rule for Japanese. That requirement would be specified as follows in the document settings: `<w:… w:lang="ja-JP" w:val="$" />` The lang attribute has a value of `ja-JP`, specifying that the rules shall be applied to Japanese text. *end example*] The possible values for this attribute are defined by the ST_Lang simple type (§2.18.51).
val (Characters For Custom Line Breaking Rule)	Specifies the set of characters which shall be included in the custom line breaking rule. [*Example*: Consider a WordprocessingML document which shall have a custom line breaking rule for Japanese. That requirement would be specified as follows in the document settings: `<w:… w:lang="ja-JP" w:val="$" />` The val attribute has a value of `$`, specifying that the dollar sign character is the only restricted character for Japanese text. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Kinsoku">
   <attribute name="lang" type="ST_Lang" use="required"/>
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.15.1.60 noPunctuationKerning (Never Kern Punctuation Characters)

This element specifies that punctuation characters shall not be kerned in the current document when kerning is enabled on a run using the kern element (§2.3.2.17). *Kerning* refers to a process by which a hosting application shall reduce the spacing of adjacent characters and/or punctuation to improve the visual appearance of text. Well kerned text has a similar amount of blank space between each pair of characters and/or each set of a character and punctuation symbol. When kerning is enabled, Latin text shall always be kerned, and this option shall control whether punctuation characters are also kerned.

If this element is omitted, then punctuation characters shall be kerned when kerning is enabled on a given run.

[*Example*: Consider a WordprocessingML document that shall not kern punctuation even when kerning is enabled on a given run. This requirement is specified using the following WordprocessingML in the document settings:

```
<w:noPunctuationKerning w:val="true" />
```

The noPunctuationKerning element's val attribute has a value of `true`, specifying that punctuation characters shall not be kerned in this document. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

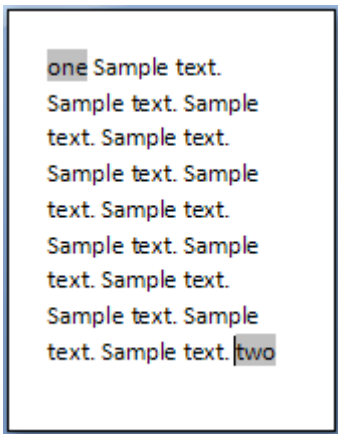
2.15.1.61 printFormsData (Only Print Form Field Content)

This element specifies that printing the contents of this document shall only print the contents of WordprocessingML form fields defined using the `FORMTEXT`, `FORMCHECKBOX`, and `FORMDROPDOWN` field codes in their current locations on the page - all other document contents shall be suppressed.

[*Rationale*: This setting is typically used to allow duplication of paper forms in electronic WordprocessingML document form, allowing the resulting online document to be printed into the correct locations on the existing paper form. *end rationale*]

If this element is omitted, then the contents of the entire document (not just form fields) should be printed according to the normal print settings.

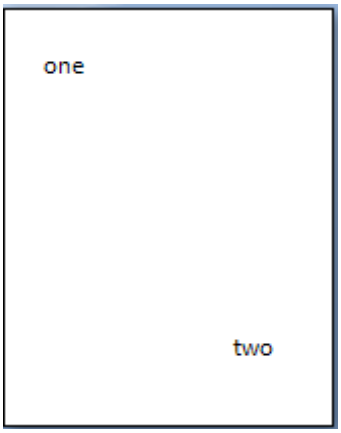
[*Example*: Consider a WordprocessingML document which has form fields in the top right and bottom left corners of the first page, as follows (with the text box form fields shaded in grey):



If the only content which shall be printed on the page are the form fields' contents, this requirement is specified using the following WordprocessingML in the document settings:

```
<w:printFormsData w:val="true" />
```

The printFormsData element's val attribute as a value of `true`, specifying that only form field data shall be printed, resulting in output as follows when printed:



end example]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the

Attributes	Description
	default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.62 printFractionalCharacterWidth (Print Fractional Character Widths)

This element specifies the contents of this document shall be printed with fractional character widths. *Fractional character widths* exist when the spacing between characters is not constant (i.e. a proportional font face is used).

[*Note*: Fractional character widths are generally used in conjunction with large font sizes to prevent characters from running together or having too much space between one another. *end note*]

[*Example*: Consider a WordprocessingML document which should be printed using fractional character widths as needed. This requirement is specified using the following WordprocessingML markup in the document settings:

```
<w:printFractionalCharacterWidth w:val="true"/>
```

The printFractionalCharacterWidth element's val attribute is equal to `true`, specifying that fractional character widths may be used as necessary. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted.

Attributes	Description
	A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.63 printPostScriptOverText (Print PostScript Codes With Document Text)

This element specifies that the PostScript codes specified in WordprocessingML documents containing `PRINT` fields shall be included in foreground (on the same Z-order as text) with the data printed in the contents of a given WordprocessingML document.

[*Note*: This setting is maintained to ensure compatibility of legacy word processing documents. The `PRINT` field should not be used in lieu of newer technologies in this Office Open XML Standard. *end note*]

If this element is omitted, then the contents of `PRINT` fields shall be printed behind text (i.e. in the background).

[*Example*: Consider a WordprocessingML document containing `PRINT` fields whose PostScript code shall be printed in the foreground of the WordprocessingML document. This requirement is specified using the following WordprocessingML in the document settings:

```
<w:printPostScriptOverText w:val="true"/>
```

The printPostScriptOverText element's val attribute is equal to `true` specifying that the PostScript codes shall be treated as results for the main text level of the document (i.e. not behind that text). *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but

Attributes	Description
	this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.64 printTwoOnOne (Print Two Pages Per Sheet)

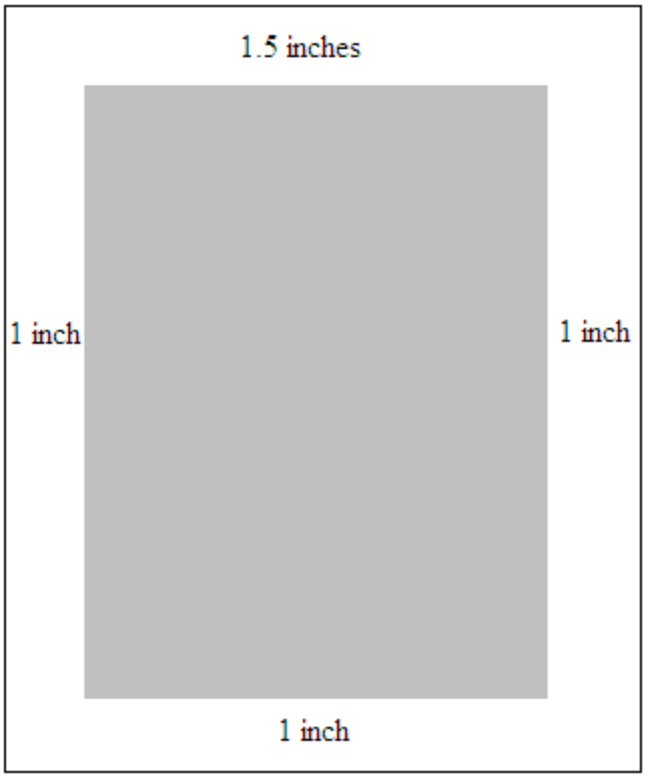
This element specifies whether two pages should be printed on one sheet of paper when this document is printed. Specifically, this element specifies that each page displayed for the contents in a given WordprocessingML document should be the page size specified in the section settings divided in half with two top margins originating from the bisector of the page, and bottom margins instantiated at the top and bottom of each page.

If this element is omitted, then pages should be displayed and printed as one per sheet.

[*Example*: Consider a one section document with a 2,160 twentieths of a point (one and a half inch) top margin, and 1,440 twentieths of a point (one inch) bottom, right, and left margins surrounding the document editing canvas (represented by the gray shaded area in diagrams below). This page setup is represented in WordprocessingML using the following fragment:

```
<w:pgMar w:top="2160" w:right="1440" w:bottom="1440" w:left="1440" />
```

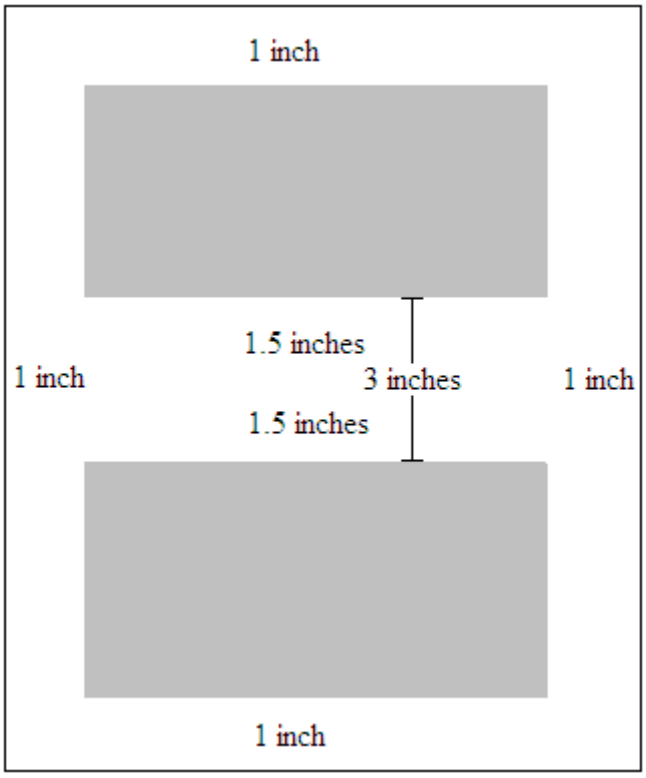
The resulting printed pages would appear as follows:



If a document should be displayed and printed as though two pages were printed on a single sheeting, this requirement would be specified using the following WordprocessingML:

```
<w:printTwoOnOne w:val="true" />
```

The printTwoOnOne element's val attribute is equal to `true` specifying that pages should be printed two to a sheet, resulting in the following printout given these page margins:



end example]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.65 proofState (Spelling and Grammatical Checking State)

This element specifies if the grammar and spell checking engines of the last application to process this document completed checking the grammar and spelling of a the document before the document was last saved. Applications which modify the document contents without checking spelling or grammar should reset these states as needed.

[*Note*: If this element specifies that an application's grammar and spell checking engines completed checking the grammar and spelling of the document when the document was last saved, then subsequent applications may elect to not run their grammar and spell checking engines when the given WordprocessingML document is loaded.

This may increase the speed with which the hosting application loads the file, and does not compromise the state of the grammar or spell checking of the document, as all errors have already been found and flagged with the proofErr element (§2.13.8.1) as the document has not been edited, only loaded, since it was last saved. *end note*]

[*Example*: Consider a WordprocessingML document that is saved by a hosting application whose spelling and grammar checking engines have completed checking grammar and spelling in the given WordprocessingML document. This state is specified using the following WordprocessingML in the document settings:

```
<w:proofState w:spelling="clean" w:grammar="clean" />
```

The proofState element's attributes spelling and grammar attribute both have the value `clean` specifying that the hosting application's grammar and spell checking engines completed checking both the grammar and spelling of the given document when it was last saved. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
grammar (Grammatical Checking State)	Specifies if an application's grammar checking engine completed checking the grammatical content of the document when it was last saved. If this attribute is omitted, then its value is assumed to be `dirty` (not complete). [*Example*: Consider a WordprocessingML document saved by a hosting application whose spelling and grammar checking engines have completed checking grammar and spelling in the given WordprocessingML document. This state is specified using the following WordprocessingML in the document settings:

Attributes	Description
	<w:proofState w:spelling="clean" w:grammar="clean" /> The grammar attribute has the value clean specifying that the hosting application's grammar checking engine completed checking the grammar of the given document when it was last saved. *end example*] The possible values for this attribute are defined by the ST_Proof simple type (§2.18.76).
spelling (Spell Checking State)	Specifies if an application's spell checking engine completed checking the spelling of the document when it was last saved. If this attribute is omitted, then its value is assumed to be dirty (not complete). [*Example*: Consider a WordprocessingML document saved by a hosting application whose spelling and grammar checking engines have completed checking grammar and spelling in the given WordprocessingML document. This state is specified using the following WordprocessingML in the document settings: <w:proofState w:spelling="clean" w:grammar="clean" /> The spelling attribute has the value clean specifying that the hosting application's spell checking engine completed checking the spelling of the given document when it was last saved. *end example*] The possible values for this attribute are defined by the ST_Proof simple type (§2.18.76).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Proof">
   <attribute name="spelling" type="ST_Proof" use="optional"/>
   <attribute name="grammar" type="ST_Proof" use="optional"/>
</complexType>
```

2.15.1.66 readModeInkLockDown (Freeze Document Layout)

This element specifies the exact set of page and text sizing parameters which shall be used to display the contents of a WordprocessingML document. [*Rationale*: This setting is typically used for documents that have been annotated using ink. This setting freezes the document's presentation such that the ink annotations shall exist at the same position of the WordprocessingML document irrespective of the monitor on which the WordprocessingML document is rendered. *end rationale*]

This element shall only affect the display of WordprocessingML documents as follows:

- When the actualPage attribute is specified with a value of true, the given WordprocessingML document's pages shall be rendered as they would normally be displayed. The resulting pages may have their magnification setting changed as desired. All other attributes shall be ignored.

- When the actualPage attribute is specified with a value of `false`, the given WordprocessingML document's pages shall be rendered as *virtual pages* when loaded by a conforming hosting application irrespective of the given WordprocessingML document's view (§2.15.1.93). *Virtual pages* are pages with no correlation with the printed layout of a given WordprocessingML document that have been scaled by a conforming hosting application to improve the readability of a given WordprocessingML document when it is displayed. Specifically, the w and h attributes specify the width and height of the virtual pages, and the fontSz attribute specifies the scaling to be applied to text within the given WordprocessingML document.

[*Example*: Consider a WordprocessingML document that shall be displayed using virtual pages when its contents are displayed. This state is specified using the following WordprocessingML in the document settings:

```
<w:readModeInkLockDown w:w="692" w:h="986" w:fontSz="95" w:actualPg="0"/>
```

The readModeInkLockDown element has w and h attribute values which specify the width and height of the virtual pages to be used to render the given WordprocessingML document. Finally, the fontSz attribute specifies the scaling to be applied to text within the given WordprocessingML document. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
actualPg (Use Actual Pages, Not Virtual Pages)	Specifies if applications shall render this WordprocessingML document with actual pages, not virtual pages. A*ctual pages* are pages rendered as they will be printed. A value of `true` specifies that the given WordprocessingML document's pages will be rendered as they are printed, and the w, h, and fontSz attributes shall be ignored. A value of `false` specifies that the given WordprocessingML document's pages shall be rendered as virtual pages using the other attributes on this element. [*Example*: Consider a WordprocessingML document that shall be displayed using virtual pages. This state is specified using the following WordprocessingML in the document settings: `<w:readModeInkLockDown w:w="692" w:h="986" w:fontSz="95" w:actualPg="0" />` The actualPage attribute is equal to `0` specifying that the given WordprocessingML document shall be rendered by conforming hosting applications using virtual pages. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
fontSz (Font Size Scaling)	Specifies the percentage that text in a given WordprocessingML document shall be scaled by before it is displayed on a virtual page. The attribute's value stores the percentage

Attributes	Description
	specified as an integer who units correspond to the percentage that text runs shall be scaled to [*Example*: 200 means a scale to 200% *end example*]. This attribute shall only be used if the actualPage attribute equals `off`, `0`, or `false`. [*Example*: Consider a WordprocessingML document that shall be displayed using virtual pages. This state is specified using the following WordprocessingML in the document settings: `<w:readModeInkLockDown w:w="692" w:h="986" w:fontSz="95" w:actualPg="0" />` The fontSz attribute is equal to 95 specifying that the text in the WordprocessingML document shall be displayed at 95% of its normal size when it is displayed on a virtual page. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
h (Virtual Page Height)	Specifies the height of the virtual pages which shall be used in this document. This value is specified in pixels. This attribute shall only be used if the actualPage attribute equals `off`, `0`, or `false`. [*Example*: Consider a WordprocessingML document that shall be displayed using virtual pages. This state is specified using the following WordprocessingML in the document settings: `<w:readModeInkLockDown w:w="692" w:h="986" w:fontSz="95" w:actualPg="0" />` The h attribute is equal to 986 specifying that virtual pages in this document shall be 986 pixels high. *end example*] The possible values for this attribute are defined by the ST_PixelsMeasure simple type (§2.18.74).
w (Virtual Page Width)	Specifies the width of the virtual pages which shall be used in this document. This value is specified in pixels. This attribute shall only be used if the actualPage attribute equals `off`, `0`, or `false`. [*Example*: Consider a WordprocessingML document that shall be displayed using virtual pages. This state is specified using the following WordprocessingML in the document settings: `<w:readModeInkLockDown w:w="692" w:h="986" w:fontSz="95" w:actualPg="0" />`

Attributes	Description
	The w attribute is equal to 692 specifying that virtual pages in this document shall be 692 pixels wide. *end example*] The possible values for this attribute are defined by the ST_PixelsMeasure simple type (§2.18.74).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_ReadingModeInkLockDown">
   <attribute name="actualPg" type="ST_OnOff" use="required"/>
   <attribute name="w" type="ST_PixelsMeasure" use="required"/>
   <attribute name="h" type="ST_PixelsMeasure" use="required"/>
   <attribute name="fontSz" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.15.1.67 removeDateAndTime (Remove Date and Time from Annotations)

This element specifies that the date and time information shall be removed from all annotations which are present in the current document when it is saved. Annotations store this information in the date attribute on the annotation's XML element.

If this element is omitted, then date information shall not be removed when the document is saved. If the removePersonalInformation element is not turned on, then this setting shall be ignored.

[*Example*: Consider a WordprocessingML document that shall not save date and time information on annotations in the document content. This state is specified using the following WordprocessingML in the document settings:

```
<w:settings>
  …
  <w:removePersonalInformation w:val="true" />
  <w:removeDateAndTime w:val="true" />
  …
</w:settings>
```

The removeDateAndTime element's val attribute has a value of `true` specifying that all annotations in the document shall have and date and time information removed before they are saved by omitting their date attributes. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element.

Attributes	Description
	A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.68 removePersonalInformation (Remove Personal Information from Document Properties)

This element specifies that hosting applications shall remove all personal information of document authors upon saving a given WordprocessingML document. The definition and extent of personal information is not defined by this Office Open XML Standard.

If this element is omitted, then personal information shall not be removed when the document is saved.

[*Example*: Consider a WordprocessingML document that shall not save personal information in the document. This state is specified using the following WordprocessingML in the document settings:

```
<w:removePersonalInformation w:val="true" />
```

The removePersonalInformation element's val attribute has a value of true specifying that applications shall remove any personal information when saving this file. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the

Attributes	Description
	default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.69 revisionView (Visibility of Annotation Types)

This element specifies which forms of annotations shall be visible for a WordprocessingML document when it is displayed. This setting shall not affect whether annotations are added or persisted, it shall only affect the display of the annotations which exist in the document's contents (persisted or in memory).

If this element is omitted, then all forms of annotations shall be visible.

[*Example*: Consider the WordprocessingML below specifying that only formatting and ink annotations within a given WordprocessingML document shall be displayed when the document is opened:

```
<w:revisionView w:markup="false" w:comments="false" w:insDel="false" />
```

The revisionView element specifies that the visibility of the markup region, comments and content additions/deletions shall be suppressed by setting a value of `false`. Since the formatting and inkAnnotation attributes are omitted, they inherit the default of `true` and shall be displayed. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
comments (Display Comments)	Specifies if comments should be included when the contents of this document are displayed. If this attribute is omitted, then comments shall be displayed when annotations are visible based on application-level settings.

Attributes	Description
	[*Example*: Consider the WordprocessingML below specifying that comments shall be displayed: `<w:revisionView w:comments="true" />` The comments attribute has a value of `true`, specifying that comments shall be rendered when the document's annotations are displayed. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
formatting (Display Formatting Revisions)	Specifies if revisions to properties (i.e. formatting revisions) should be included when the contents of this document are displayed. If this attribute is omitted, then formatting revisions shall be displayed when annotations are visible based on application-level settings. [*Example*: Consider the WordprocessingML below specifying that formatting revisions shall be displayed: `<w:revisionView w:formatting="true" />` The formatting attribute has a value of `true`, specifying that formatting revisions shall be rendered when the document's annotations are displayed. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
inkAnnotations (Display Ink Annotations)	Specifies if ink annotations, specified in VML syntax (§6.1), should be included when the contents of this document are displayed. If this attribute is omitted, then ink annotations shall be displayed when annotations are visible based on application-level settings. [*Example*: Consider the WordprocessingML below specifying that ink annotations shall be displayed: `<w:revisionView w:inkAnnotations="true" />` The inkAnnotations attribute has a value of `true`, specifying that ink annotations shall be rendered when the document's annotations are displayed. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
insDel (Display Content Revisions)	Specifies if revisions to content (i.e. insertions, deletions, and moves) should be included when the contents of this document are displayed. If this attribute is omitted, then insertions, deletions, and moves shall be displayed when annotations are visible based on application-level settings.

Attributes	Description
	[*Example*: Consider the WordprocessingML below specifying that insertions, deletions, and moves shall be displayed: `<w:revisionView w:insDel="true" />` The insDel attribute has a value of `true`, specifying that insertions, deletions, and moves shall be rendered when the document's annotations are displayed. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
markup (Display Visual Indicator Of Markup Area)	Specifies if the application shall visually indicate any additional non-printing area used to display annotations when the annotations in this document are displayed. If this attribute is omitted, then any additional non-printing area shall be indicated when they are visible based on application-level settings. [*Example*: Consider the WordprocessingML below specifying that no visual indicator shall be displayed for non-printing regions holding annotations: `<w:revisionView w:markup="false" />` The markup attribute has a value of `false`, specifying that nothing shall be rendered indicating when a non-printing region is added when the document's annotations are displayed. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TrackChangesView">
   <attribute name="markup" type="ST_OnOff" use="optional"/>
   <attribute name="comments" type="ST_OnOff" use="optional"/>
   <attribute name="insDel" type="ST_OnOff" use="optional"/>
   <attribute name="formatting" type="ST_OnOff" use="optional"/>
   <attribute name="inkAnnotations" type="ST_OnOff" use="optional"/>
</complexType>
```

2.15.1.70 rsid (Single Session Revision Save ID)

This element specifies the revision save ID that was associated with a single editing session for a document. An editing session is a span of time that begins and ends with any event that produces an editable file, such as a save or an e-mail send, and contains no such event. When revision save IDs are added to a document, they shall follow these rules:

- Every editing session shall be assigned a revision save ID that is larger than all earlier ones in the same file

- Revision save IDs should be randomly generated based on the current time (to minimize the chance that two disparate editing sessions starting with the same immediate predecessor are assigned the same revision save ID)
- Changes to document content in an editing session shall be stamped with the current revision save ID using the appropriate rsid* attributes
- An identical rsid value between two documents with the same rsidRoot (§2.15.1.71) shall indicate the same editing sessions

[*Note*: A revision save ID should be treated as unique within the context of all documents with the same rsidRoot value. Although in practice it is possible for two independent sessions to result in the same value, this outcome is extremely rare as the values are based on the current time. However, the meaning of two revision save IDs is not defined for documents with a different rsidRoot. Applications may use this information as desired. *end note*]

[*Example*: Consider the following fragments from two WordprocessingML documents' document settings:

Document 1	Document 2
<w:rsids> <w:rsidRoot w:val="00464813"/> <w:rsid w:val="00455AAB" /> <w:rsid w:val="00464813" /> <w:rsid w:val="00996E03" /> </w:rsids>	<w:rsids> <w:rsidRoot w:val="00464813"/> <w:rsid w:val="00455AAB" /> <w:rsid w:val="00464813" /> <w:rsid w:val="00473403" /> <w:rsid w:val="0048414E" /> </w:rsids>

The rsid elements are identical for the first three editing sessions for both documents, indicating that these documents, although they are now separate, originated from the same document. The documents were then separated and the first was saved once afterwards; and the second, twice. *end example*]

Parent Elements
rsids (§2.15.1.72)

Attributes	Description
val (Long Hexadecimal Number Value)	Specifies a number value specified as a four digit hexadecimal number), whose contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following value for an attribute of type ST_LongHexNumber: 00BE2C6C. This value is valid, as it contains four hexadecimal digits, each an encoding of an octet of the actual decimal number value. It may therefore be interpreted as desired in the context of the parent XML element, *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_LongHexNumber">
   <attribute name="val" type="ST_LongHexNumber" use="required"/>
</complexType>
```

2.15.1.71 rsidRoot (Original Document Revision Save ID)

This element specifies the revision save ID which was associated with the first editing session for this document. [*Note*: This information shall be identical between any number of copies of the same document, as they all originate from the same original editing session. Applications may use this information as desired. *end note*]

If this element is omitted, then the original document revision save ID is unknown.

[*Example*: Consider the following fragments from two WordprocessingML documents' document settings:

Document 1	Document 2
<w:rsids> <w:rsidRoot w:val="00464813"/> <w:rsid w:val="00455AAB" /> <w:rsid w:val="00464813" /> <w:rsid w:val="00996E03" /> </w:rsids>	<w:rsids> <w:rsidRoot w:val="00464813"/> <w:rsid w:val="00455AAB" /> <w:rsid w:val="00464813" /> <w:rsid w:val="00473403" /> <w:rsid w:val="0048414E" /> </w:rsids>

The rsidRoot element's val attribute has a value of `00464813` for both documents, indicating that these documents, although they are now separate, originated from the same document. This information may be used as desired. *end example*]

Parent Elements
rsids (§2.15.1.72)

Attributes	Description
val (Long Hexadecimal Number Value)	Specifies a number value specified as a four digit hexadecimal number), whose contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following value for an attribute of type ST_LongHexNumber: `00BE2C6C`. This value is valid, as it contains four hexadecimal digits, each an encoding of an octet of

Attributes	Description
	the actual decimal number value. It may therefore be interpreted as desired in the context of the parent XML element, *end example*] The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_LongHexNumber">
   <attribute name="val" type="ST_LongHexNumber" use="required"/>
</complexType>
```

2.15.1.72 rsids (Listing of All Revision Save ID Values)

This element specifies the set of revision save ID values for the current document. *Revision save ID values* refer to four digit hexadecimal values which uniquely identify an editing session in the life of the current document. An *editing session* is the period of time between two subsequent save operations by an application.

[*Guidance*: The set of revision save IDs stored with a document only supplies information about the editing session in which document components were last saved, which may be used by applications in any manner desired. *end guidance*]

If this element is omitted, then no information is available about the set of revision save ID values for this document.

[*Example*: Consider a WordprocessingML document with the following information present in its document settings:

```
<w:rsids>
  <w:rsidRoot w:val="00464813" />
  <w:rsid w:val="00455AAB" />
  <w:rsid w:val="00464813" />
  <w:rsid w:val="00473403" />
</w:rsids>
```

The rsids element contains four child elements, specifying that the document was edited over four distinct editing sessions (i.e. it was saved three times). *end example*]

Parent Elements
settings (§2.15.1.78)

Child Elements	Subclause
rsid (Single Session Revision Save ID)	§2.15.1.70
rsidRoot (Original Document Revision Save ID)	§2.15.1.71

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DocRsids">
    <sequence>
        <element name="rsidRoot" type="CT_LongHexNumber" minOccurs="0" maxOccurs="1"/>
        <element name="rsid" type="CT_LongHexNumber" minOccurs="0" maxOccurs="unbounded"/>
    </sequence>
</complexType>
```

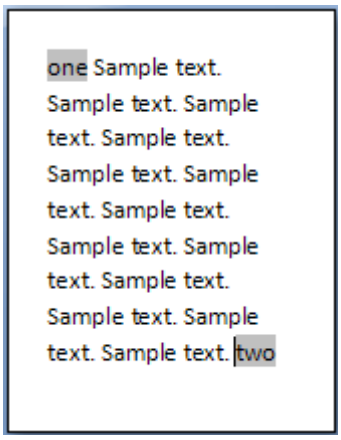
2.15.1.73 saveFormsData (Only Save Form Field Content)

This element specifies that saving the contents of this document shall only save the contents of WordprocessingML form fields defined using the `FORMTEXT`, `FORMCHECKBOX`, and `FORMDROPDOWN` field codes in a comma-delimited text format which does not conform to this Office Open XML Standard (i.e. it is a one-way export from a WordprocessingML document).

[*Rationale*: This setting is typically used to allow duplication of paper forms in electronic WordprocessingML document form, allowing the resulting content to be extracted as a comma-delimited text file. *end rationale*]

If this element is omitted, then the contents of the entire document (not just form fields) should be saved according to the definition of WordprocessingML in this Office Open XML Standard.

[*Example*: Consider a WordprocessingML document which has form fields in the top right and bottom left corners of the first page, as follows (with the text box form fields shaded in grey):



If the only content which shall be saved are the form fields' contents, this requirement is specified using the following WordprocessingML in the document settings:

```
<w:saveFormsData w:val="true" />
```

The saveFormsData element's val attribute as a value of `true`, specifying that only form field data shall be saved, resulting in output as follows in a text file:

```
one,two
```

end example]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.74 saveInvalidXml (Allow Saving Document As XML File When Custom XML Markup Is Invalid)

This element specifies that this document should be capable of being saved into a format consisting of a single XML file (not defined by this Office Open XML Standard) when its contents are invalid based on the custom XML markup contained in the document. This setting has no effect on documents that do not contain custom XML markup, or that do contain custom XML markup but do not have a schema attached. [*Guidance*: Because this setting specifies behavior when saving to an alternative file format not defined by this Office Open XML Standard, this behavior is optional. *end guidance*]

If this element is omitted, then applications should not allow this document to be saved into a single XML file when its contents are invalid based on the custom XML markup contained in the document. If the doNotValidateAgainstSchema element (§2.15.1.42) is set, then the XML is never "invalid" and this property is ignored.

[*Example*: Consider a WordprocessingML document which should be saved into a single XML file even when its custom XML content is marked invalid by applications which support this operation. This requirement is specified using the following WordprocessingML in the document settings:

```
<w:saveInvalidXml w:val="true" />
```

The saveInvalidXml element's val attribute has a value of `true` specifying that the content in this document can be saved regardless of its validation status. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.75 savePreviewPicture (Generate Thumbnail For Document On Save)

This element specifies if a document's Thumbnail part should be generated for the contents of the first page of this document when saved by application which support document thumbnail generation.

If this element is omitted, then applications may choose to save a thumbnail, however, that behavior is not required. If this element is specified, a thumbnail must be produced if that functionality is supported.

[*Example*: Consider a WordprocessingML document that specifies that a document thumbnail shall always be created when it is saved. This requirement would be specified using the following WordprocessingML in the document settings part:

```
<w:savePreviewPicture w:val="true"/>
```

The savePreviewPicture element's val attribute has a value of `true` specifying that a document thumbnail should be generated each time this document is saved. *end example*]

Parent Elements

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.76 saveThroughXslt (Custom XSL Transform To Use When Saving As XML File)

This element specifies the location of a custom XSL transform which shall be used when this document is saved as a single XML file (in a format not defined by this Office Open XML Standard). [*Guidance*: Because this setting specifies behavior when saving to an alternative file format not defined by this Office Open XML Standard, this behavior is optional. *end guidance*]

If this element is omitted, then no custom XSL transform shall be used when saving this file as a single XML file. If the useXSLTWhenSaving element (§2.15.1.92) is omitted or set to `false`, then this transform shall not be applied when the document is saved as a single XML file.

[*Example*: Consider a XML document that shall have the XSL transform applied when the document is saved as a single XML file. This requirement would be specified using the following WordprocessingML in the document settings:

```
<w:useXSLTWhenSaving w:val="on"/>
<w:saveThroughXslt r:id="rId5" />
```

The useXSLTWhenSaving element's val is set to on indicating that applications shall apply the XSLT specified by the relationship targeted by the id attribute of the saveThroughXslt element, located at `rId5`, when saving as a single XML file*. end example]*

Parent Elements
settings (§2.15.1.78)

Attributes	Description
id (XSL Transformation Location) Namespace: .../officeDocument/2006/relationships	Specifies an explicit relationship to the location of the XSL Transformation which shall be applied. The relationship targeted by this element shall be of type http://schemas.openxmlformats.org/officeDocument/2006/relationships/transform , or this document shall be declared invalid. [*Example*: Consider a XML document that shall have the XSL transform located at `c:\Example Transform.xslt` applied when the document is saved as a single XML file. This requirement would be specified using the following WordprocessingML in the document settings: `<w:saveThroughXslt r:id="rId5" />` The saveThroughXslt element specifies that the relationship located at `rId5` shall be used when saving as a single XML file in this case, that relationship shall target `c:\Example Transform.xslt`. *end example*] The possible values for this attribute are defined by the ST_RelationshipId simple type (§7.8.2.1).
solutionID (Local Identifier for XSL Transform)	Specifies a string identifier which may be used to locate the XSL transform to be applied. The semantics of this attribute are not defined by this Office Open XML Standard - applications may use this information in any application-defined manner to resolve the location of the XSL transform to apply. If this attribute is omitted, then no local identifier is specified for the XSL transform. If both this and the xslt attributes are present, then this data shall be used first, and the latter shall only be used if this information cannot be used successfully. [*Example*: Consider a XML document that shall have the XSL transform identified by `mySolution` applied to when the document is saved as a single XML file. This requirement would be specified using the following WordprocessingML in the document settings: `<w:saveThroughXslt w:solutionID="mySolution" />` The solutionID attribute has a value of `mySolution` indicating that applications shall

Attributes	Description
	apply the XSLT identified by this value (if known) when saving as a single XML file. *end example]* The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SaveThroughXslt">
   <attribute ref="r:id" use="optional"/>
   <attribute name="solutionID" type="ST_String" use="optional"/>
</complexType>
```

2.15.1.77 saveXmlDataOnly (Only Save Custom XML Markup)

This element specifies that the contents of this document shall be saved as an XML file containing only the custom XML markup in this document in its regular form. The resulting document will not conform to this Office Open XML Standard (i.e. this is an export-only save option for a WordprocessingML document).

[*Rationale*: This setting is typically used to extract custom XML markup from a WordprocessingML document for further processing by XML-enabled applications. *end rationale*]

If this element is omitted, then the contents of the entire document (not just custom XML markup) should be saved according to the definition of WordprocessingML in this Office Open XML Standard.

[*Example*: Consider a WordprocessingML document which should be saved as an XML file containing only its custom XML markup. This requirement is specified using the following WordprocessingML fragment in the document settings:

```
<w:saveXmlDataOnly w:val=”true”/>
```

The saveXmlDataOnly element's val attribute has a value of `true` specifying that only custom XML shall be saved into a regular XML file when saving this document. For example, the document body formerly looked like this:

```
<w:body>
  <w:p>
    <w:customXml w:element="root" w:namespaceuri="urn:example">
      <w:r>
        <w:t>Hello world<w:t>
      </w:r>
    </w:customXml>
  </w:p>
</w:body>
```

The presence of this element specifies that the resulting document only contains the custom Xml markup, resulting in the following:

```
<ns0:root xmlns:ns0="urn:example">Hello world</ns0:root>
```

end example]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.78 settings (Document Settings)

This element specifies the settings that are applied to a WordprocessingML document. This element is the root element of the Document Settings part in a WordprocessingML document.

[*Example*: Consider the following WordprocessingML fragment for the settings part of a document:

```
<w:settings>
  <w:defaultTabStop w:val="720" />
  <w:characterSpacingControl w:val="dontCompress" />
</w:settings>
```

The settings element contains all of the settings for this document. In this case, the two settings applied are automatic tab stop increments of 0.5" using the defaultTabStop element, and no character level whitespace compression using the characterSpacingControl element. *end example*]

    </sequence>
</complexType>
```

2.15.1.79 shapeDefaults (Default Properties for VML Objects in Main Document)

This element specifies the default parameters for object using the VML syntax (§6.1) inserted in the body (the main document story, comments, footnotes, and endnotes) of the WordprocessingML document. The definition and semantics of these parameters is described in the VML - Office Drawing subclause (§6.2) of this Office Open XML Standard.

If this element is omitted, then no default properties are applied to VML objects in the body of this document.

[*Example*: Consider a WordprocessingML document whose document settings contain the following markup:

```
<w:shapeDefaults>
  <o:shapedefaults v:ext="edit" spidmax="1026" />
  <o:shapelayout v:ext="edit">
    <o:idmap v:ext="edit" data="1" />
  </o:shapelayout>
</w:shapeDefaults>
```

The shapeDefaults element specifies a set of shape defaults which shall be applied to the set of all shapes present in the body document. *end example*]

Parent Elements
settings (§2.15.1.78)

Child Elements	Subclause
Any element from the urn:schemas-microsoft-com:office:office namespace	§6.2

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_ShapeDefaults">
   <choice maxOccurs="unbounded">
      <any processContents="lax" namespace="urn:schemas-microsoft-com:office:office" minOccurs="0"
        maxOccurs="unbounded"/>
   </choice>
</complexType>
```

2.15.1.80 showEnvelope (Show E-Mail Message Header)

This element specifies that an e-mail message header shall be displayed when this document is opened, if an e-mail header is supported by the application opening the file.

If this element is omitted, then applications shall not display the e-mail message header automatically when this file is opened, even if one is available in the application opening the file.

[*Example*: Consider a WordprocessingML document which should show an e-mail message header when opened. This requirement is specified using the following WordprocessingML in the document settings:

```
<w:showEnvelope w:val="true" />
```

The showEnvelope element's val attribute has a value of `true` specifying that an e-mail message header shall be displayed when the document is viewed, whenever such functionality is available. *end example*]

settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.81 showXMLTags (Show Visual Indicators for Custom XML Markup Start/End Locations)

This element specifies that some visual indicator shall be provided for the start and end locations of custom XML markup present in this document, if any.

If this element is omitted, then applications should not provide any visual indicator of the locations of custom XML markup start/end tags.

[*Example*: Consider a WordprocessingML document which should show a visual indicator to the location of custom XML markup elements. This requirement is specified using the following WordprocessingML in the document settings:

```
<w:showXMLTags w:val="true" />
```

The showXMLTags element's val attribute has a value of `true` specifying that custom XML markup should have a visual indicator in the document when displayed. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.82 smartTagType (Supplementary Smart Tag Information)

This element specifies optional supplementary information about one or more smart tags (§2.5.1.9) used in the current WordprocessingML document. This supplementary data is linked to the smart tag to which it applies via its name and namespaceuri attributes.

[*Example*: Consider a smart tag which has supplementary information defined as using the following WordprocessingML:

```
<w:smartTagType w:name="companyName" w:namespaceuri="urn:smartTagExample"
w:url="http://www.contoso.com/smartTag" >
```

The name and namespaceuri attributes specify that the smart tag to which this data shall be `companyName` in the `urn:smartTagExample` namespace. The supplementary data is an associated URL of `http://www.contoso.com/smartTag`. *end example*]

Parent Elements

Parent Elements
settings (§2.15.1.78)

Attributes	Description
name (Smart Tag Name)	Specifies the name of the smart tag within the document for which supplementary data is provided. [*Example*: Consider a smart tag which has a name of `companyName`. This name would be referenced using the following WordprocessingML: `<w:smartTagType w:name="companyName" … >` The name attribute specifies that the name for this smart tag shall be `companyName`. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).
namespaceuri (Smart Tag Namespace)	Specifies the namespace URI of the smart tag for which supplementary data is provided. If this attribute is omitted, the URI shall be assumed to be null (no associated URI). [*Example*: Consider a smart tag which shall have a namespace URI of `urn:smartTagExample`. This namespace would be referenced using the following WordprocessingML: `<w:smartTagType w:namespaceuri="urn:smartTagExample" />` The namespaceuri attribute specifies that the namespace for the smart tag to which this data applies shall be `urn:smartTagExample`. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).
url (Smart Tag Supplementary URL)	Specifies a URL provided for a particular smart tag type in this document. [*Note*: This URL is typically used to provide access to a URL for additional updates to this smart tag type as requested by the smart tag provider. *end note*] If this attribute is omitted, then no supplementary URL is provided for this type. [*Example*: Consider a smart tag which shall have a supplementary URL of `http://www.contoso.com/smartTag`. This URL would be specified using the following WordprocessingML: `<w:smartTagType … w:url="http://www.contoso.com/smartTag" />` The url attribute specifies that the supplementary data for the smart tag to which this data applies shall be `http://www.contoso.com/smartTag`. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SmartTagType">
   <attribute name="namespaceuri" type="ST_String"/>
   <attribute name="name" type="ST_String"/>
   <attribute name="url" type="ST_String"/>
</complexType>
```

2.15.1.83 strictFirstAndLastChars (Use Strict Kinsoku Rules for Japanese Text)

This element specifies that the strict set of Kinsoku rules shall be applied to Japanese text in this document when the kinsoku element (§2.3.1.16) is applied to that text. The resulting line breaking rules are provided on the kinsoku element.

If this element is omitted, then standard rules shall apply to Japanese text when the kinsoku element is applied to that text.

[*Example*: Consider a WordprocessingML document that specifies that strict Kinsoku rules shall be applied to Japanese text. This requirement would be specified using the following WordprocessingML in the document settings part:

```
<w:strictFirstAndLastChars w:val="true"/>
```

The strictFirstAndLastChars element's val attribute has a value of `true` specifying that a document shall apply the strict set of invalid characters for the start and end of a line. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.84 styleLockQFSet (Prevent Replacement of Styles Part)

This element specifies whether applications shall prevent the replacement of the complete set of styles stored in the Styles part when editing this document. This setting should not preclude the editing or removal of individual styles, instead, it should only prevent the removal and replacement of the entire styles part in a single operation (either through a user interface or a programmatic operation).

If this element is omitted, then applications may allow the replacement of the entire styles part in this document.

[*Example*: Consider a WordprocessingML document that specifies that applications shall prevent the replacement of the entire styles part. This requirement would be specified using the following WordprocessingML in the document settings part:

```
<w:styleLockQFSet w:val="true"/>
```

The styleLockQFSet element's val attribute has a value of `true` specifying that individual style changes should be allowed, but the styles data shall not be replaced as a whole via a single operation. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.85 styleLockTheme (Prevent Modification of Themes Part)

This element specifies whether applications shall prevent the modification of the document's theme information stored in the Theme part when editing this document. This setting should not preclude the use of the theme information, instead, it should only prevent the modification of the theme part in a single operation (either through a user interface or a programmatic operation).

If this element is omitted, then applications may allow the replacement or modification of the theme part in this document.

[*Example*: Consider a WordprocessingML document that specifies that applications shall prevent the modification of the theme part. This requirement would be specified using the following WordprocessingML in the document settings part:

```
<w:styleLockTheme w:val="true"/>
```

The styleLockTheme element's val attribute has a value of `true` specifying that theme data shall not be modified when modifying the contents of this document. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.86 stylePaneFormatFilter (Suggested Filtering for List of Document Styles)

This element specifies a set of suggested filters which should be applied to the list of document styles in this application if the styles are displayed in a user interface.

The val attribute of this element contains a bitmask of the following filtering options:

Value	Description
0x0001	Specifies that all styles present in the styles part should be displayed in the list of document styles.
0x0002	Specifies that only styles with the customStyle attribute should be displayed in the list of document styles.
0x0004	Specifies that all latent styles should be displayed in the list of document styles.
0x0008	Specifies that only styles used in the document should be displayed in the list of document styles.
0x0010	Undefined. Shall not be used.
0x0020	Specifies that heading styles (styles with a styleId of Heading1 to Heading9) should be displayed in the list of document styles when the previous style is used in the document and/or is present in the styles part.
0x0040	Specifies that numbering styles should be displayed in the list of document styles.
0x0080	Specifies that table styles should be displayed in the list of document styles.
0x0100	Specifies that all unique forms of run-level direct formatting should be displayed in the list of document styles as though they were each a unique style.
0x0200	Specifies that all unique forms of paragraph-level direct formatting should be displayed in the list of document styles as though they were each a unique style.
0x0400	Specifies that all unique forms of direct formatting of numbering data should be displayed in the list of document styles as though they were each a unique style.
0x0800	Specifies that all unique forms of direct formatting of tables should be displayed in the list of document styles as though they were each a unique style.
0x1000	Specifies that a style should be present which removes all formatting and styles from text.
0x2000	Specifies that heading styles with a styleId of Heading1 to Heading3 should always be displayed in the list of document styles.
0x4000	Specifies that styles should only be shown the semiHidden element (§2.7.3.16) is false

Value	Description
	and the hidden element (§2.7.3.4) is `false`.
`0x8000`	Specifies that primary names for styles should not be shown if an alternate name using the name element (§2.7.3.9) exists.
Any other value	Undefined. Shall not be used.

If this element is omitted, then all settings defined by this element are turned off.

[*Example*: Consider a document with the following value in its document settings:

```
<w:stylePaneFormatFilter w:val="2002" />
```

The stylePaneFormatFilter element's settings specify two suggested filter options for the list of document styles:

- Only custom styles should be shown (`0002`)
- Heading styles with a styleId of `Heading1` to `Heading3` should always be displayed in the list (`2000`)

end example]

Parent Elements
settings (§2.15.1.78)

Attributes	Description

val (Two Digit Hexadecimal Value)	Specifies a value specified as a two digit hexadecimal number), whose contents are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:tblPr>`
	`  <w:tblLook w:val="0010" />`
	`</w:tblPr>`
	
	The value of `0010` is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_ShortHexNumber simple type (§2.18.86).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_ShortHexNumber">
   <attribute name="val" type="ST_ShortHexNumber" use="required"/>
</complexType>
```

2.15.1.87 stylePaneSortMethod (Suggested Sorting for List of Document Styles)

This element specifies a suggested sorting which should be applied to the list of document styles in this application if the styles are displayed in a user interface.

The val attribute of this element specifies one of the following sorting options:

Value	Description
0x0000	Specifies that styles which are visible should be sorted by their names.
0x0001	Specifies that styles which are visible should be sorted by their UI priority using the uiPriority element (§2.7.3.19).
0x0002	Specifies that styles which are visible should be sorted by the default sorting of the host application.
0x0003	Specifies that styles which are visible should be sorted by the font which they apply.
0x0004	Specifies that styles which are visible should be sorted by the style on which they are based using the basedOn element (§2.7.3.3).
0x0005	Specifies that styles which are visible should be sorted by their style types (i.e. character, linked, paragraph).
Any other value	Undefined. Shall not be used.

If this element is omitted, then styles which are visible should be sorted by the default sorting of the host application.

[*Example*: Consider a document with the following value in its document settings:

```
<w:stylePaneSortMethod w:val="0005" />
```

The stylePaneFormatFilter element's val attribute specifies that styles which are visible should be sorted by their style types (i.e. character, linked, paragraph) via a value of 0005. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description

val (Two Digit Hexadecimal Value)	Specifies a value specified as a two digit hexadecimal number), whose contents are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:tblPr>`
	`  <w:tblLook w:val="0010" />`

Attributes	Description
	</w:tblPr> The value of 0010 is interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_ShortHexNumber simple type (§2.18.86).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_ShortHexNumber">
   <attribute name="val" type="ST_ShortHexNumber" use="required"/>
</complexType>
```

2.15.1.88 summaryLength (Percentage of Document to Use When Generating Summary)

This element specifies the size for automatic document summaries performed on the content of a WordprocessingML document. An *automatic document summary* is a subset of text contained in a document deemed by the hosting application to summarize the content of the WordprocessingML document. The val attribute of this element specifies the size of an automatic document summary to be performed on a given WordprocessingML document as a percentage of the total size of the given WordprocessingML document. Performing an automatic document summary is a runtime operation outside the scope of this Office Open XML Standard.

If this element is omitted, then applications may summarize this document to any desired size.

[*Example*: Consider a WordprocessingML document whose automatic document summary shall be ten percent of the size of the given WordprocessingML document. This requirement would be specified using the following WordprocessingML in the document settings part:

```
<w:summaryLength w:val="10" />
```

The summaryLength element's val attribute is equal to 10 specifying that any automatic document summary shall be ten percent of the size of the document. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber:

Attributes	Description
	<w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.15.1.89 themeFontLang (Theme Font Languages)

This element specifies the language which shall be used to determine the appropriate theme fonts in the document's Theme part which map to the major/minor theme fonts.

These mappings are performed as follows:

- For `majorAscii`/`majorHAnsi`, locate the font element (§5.1.4.1.16) in the majorFont element (§5.1.4.1.24) in the theme part for the language specified by the val attribute
- For `majorBidi`, locate the font element in the majorFont element in the theme part for the language specified by the bidi attribute
- For `majorEastAsia`, locate the font element in the majorFont element in the theme part for the language specified by the eastAsia attribute
- For `minorAscii`/`minorHAnsi`, locate the font element in the minorFont element (§5.1.4.1.25) in the theme part for the language specified by the val attribute
- For `minorBidi`, locate the font element in the minorFont element in the theme part for the language specified by the bidi attribute
- For `minorEastAsia`, locate the font element in the minorFont element in the theme part for the language specified by the eastAsia attribute

If this element is omitted, then the default fonts for each region as specified by the latin, ea, and cs elements (§5.1.5.3.7; §5.1.5.3.3; §5.1.5.3.1) should be used.

[*Example*: Consider a document with the following WordprocessingML in its document settings:

```
<w:themeFontLang w:val="ja-JP" />
```

The themeFontLang element's val attribute has a value of `ja-JP`, specifying that the theme fonts used for Latin text shall be the theme fonts for Japanese. If the following content was present in the theme part:

```
…
<a:majorFont>
  …
  <a:font script="Jpan" typeface="MS Mincho"/>
  …
</a:majorFont>
…
```

Then this setting would specify that uses of the `majorAscii` and `majorHAnsi` theme font enumerations shall be mapped to the `MS Mincho` font. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description

bidi (Complex Script Language)	Specifies the language which shall be used when processing the contents of this run which use complex script characters, as determined by the Unicode character values of the run content.
	
	If this attribute is omitted, then the languages for the contents of this run using complex script characters shall be automatically determined based on their contents using any appropriate method.
	
	[*Example*: Consider a run which contains complex script characters in its contents. If those contents should be interpreted as Hebrew, that requirement would be specified as follows in the resulting WordprocessingML:
	
	`<w:r>`
	`  <w:rPr>`
	`  <w:lang w:bidi="he-IL" />`
	`  </w:rPr>`
	`</w:r>`
	
	The resulting run specifies that any complex script contents shall be spell and grammar checked using a Hebrew dictionary and grammar engine, if one is available. *end example*]
	
	The possible values for this attribute are defined by the ST_Lang simple type (§2.18.51).

eastAsia (East Asian Language)	Specifies the language which shall be used when processing the contents of this run which use East Asian characters, as determined by the Unicode character values of the run content. If this attribute is omitted, then the languages for the contents of this run using East Asian characters shall be automatically determined based on their contents using any appropriate method.

Attributes	Description

	[*Example*: Consider a run which contains East Asian characters in its contents. If those contents should be interpreted as Korean, that requirement would be specified as follows in the resulting WordprocessingML:
	
	`<w:r>`
	`  <w:rPr>`
	`  <w:lang w:bidi="ko-KR" />`
	`  </w:rPr>`
	`</w:r>`
	
	The resulting run specifies that any complex script contents shall be spell and grammar checked using a Korean dictionary and grammar engine, if one is available. *end example*]
	
	The possible values for this attribute are defined by the ST_Lang simple type (§2.18.51).

val (Latin Language)	Specifies the language which shall be used to check spelling and grammar (if requested) when processing the contents of this run which use Latin characters, as determined by the Unicode character values of the run content.
	
	If this attribute is omitted, then the languages for the contents of this run using Latin characters shall be automatically determined based on their contents using any appropriate method.
	
	[*Example*: Consider a run which contains Latin characters in its contents. If those contents should be interpreted as English (Canada), that requirement would be specified as follows in the resulting WordprocessingML:
	
	`<w:r>`
	`  <w:rPr>`
	`  <w:lang w:bidi="en-CA" />`
	`  </w:rPr>`
	`</w:r>`
	
	The resulting run specifies that any complex script contents shall be spell and grammar checked using a English (Canada) dictionary and grammar engine, if one is available. *end example*]
	
	The possible values for this attribute are defined by the ST_Lang simple type (§2.18.51).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Language">
   <attribute name="val" type="ST_Lang" use="optional"/>
   <attribute name="eastAsia" type="ST_Lang" use="optional"/>
   <attribute name="bidi" type="ST_Lang" use="optional"/>
</complexType>
```

2.15.1.90 trackRevisions (Track Revisions to Document)

This element specifies that applications shall track revisions made to the WordprocessingML document. *Revisions* are changes to a WordprocessingML document which are recorded such that they can be viewed independently, accepted or removed, and reverted if needed. When revisions are tracked, the resulting WordprocessingML markup in the Revisions subclause of this document describes the necessary syntax.

If this element is omitted, then revisions shall not be generated by changes to the contents of this document.

[*Example*: Consider a WordprocessingML document containing the text run `Example` that shall not have revisions tracked. Example WordprocessingML from Document 1 is given below:

```
<w:document>
  <w:body>
    <w:p>
      <w:r>
        <w:t>Example</w:t>
      </w:r>
    </w:p>
  </w:body>
</w:document>
```

And the corresponding document settings:

```
<w:settings>
  <w:trackRevisions w:val="false"/>
  …
</w:settings>
```

If the word `text` was added to the end of this document and bolded without revisions tracked, the resulting WordprocessingML would be output as follows:

```
<w:document>
  <w:body>
    <w:p>
      <w:r>
        <w:t>Example</w:t>
      </w:r>
      <w:r>
        <w:rPr>
          <w:b/>
        </w:rPr>
        <w:t>text</w:t>
      </w:r>
    </w:p>
  </w:body>
</w:document>
```

And the corresponding document settings:

```
<w:settings>
  <w:trackRevisions w:val="false"/>
  …
</w:settings>
```

Finally, assume the same insertion and formatting took place when the trackRevisions element's val attribute was set to on, the resulting WordprocessingML would be output as follows:

```
<w:document>
  <w:body>
    <w:p>
      <w:r>
        <w:t>Example</w:t>
      </w:r>
      <w:ins … >
        <w:r>
          <w:rPr>
            <w:b/>
            <w:rPrChange … >
              <w:rPr/>
            <w:rPrChange>
          </w:rPr>
          <w:t>text</w:t>
        </w:r>
      </w:ins>
    </w:p>
  </w:body>
</w:document>
```

And the corresponding document settings:

```
<w:settings>
  <w:trackRevisions w:val="true"/>
  …
</w:settings>
```

The trackRevisions element's val attribute was set to `true`, therefore the changes to the content of the document were inserted using the appropriate annotation elements in the document's WordprocessingML. Specifically, inserting the text `Text` to the right of the existing text was tracked as a revision with the ins element. In addition, applying bold formatting to the text was tracked as a revision with the rPrChange element. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted.

Attributes	Description
	A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.91 updateFields (Automatically Recalculate Fields on Open)

This element specifies whether the fields contained in this document should automatically have their field result recalculated from the field codes when this document is opened by an application which supports field calculations. [*Note*: Some fields are always recalculated (e.g. the page numbering), therefore this element only affects fields which are typically not automatically recalculated on opening the document. Also note that this setting shall not supersede any document protection (§2.15.1.28) or write protection (§2.15.1.94) settings. *end note*]

If this element is omitted, then fields should not automatically be recalculated on opening this document.

[*Example*: Consider a WordprocessingML document that specifies that applications should attempt to automatically recalculate fields from their field codes upon opening this document. This requirement would be specified using the following WordprocessingML in the document settings part:

```
<w:updateFields w:val="true"/>
```

The updateFields element's val attribute has a value of `true` specifying that all fields should automatically be recalculated when opening this document. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but

Attributes	Description
	this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.92 useXSLTWhenSaving (Save Document as XML File through Custom XSL Transform)

This element specifies that this document should be saved through the custom XSLT transform defined by the saveThroughXslt element (§2.15.1.76) in this document when it is saved as a single XML file (not defined by this Office Open XML Standard). [*Guidance*: Because this setting specifies behavior when saving to an alternative file format not defined by this Office Open XML Standard, this behavior is optional. *end guidance*]

If the saveXmlDataOnly element (§2.15.1.77) is specified, then the single XML file to be transformed is the custom XML markup of the document, otherwise, it a format outside the scope of this Office Open XML Standard. If the XSL transform specified by the saveThroughXslt element is not present, then this setting should be ignored.

If this element is omitted, then this document should not be saved through a custom XSL transform when it is saved as a single XML file.

[*Example*: Consider a WordprocessingML document which should be saved through a custom XSL transform when it is saved as a single XML file. This requirement is specified using the following WordprocessingML in the document settings:

```
<w:useXSLTWhenSaving w:val="true" />
```

The useXSLTWhenSaving element's val attribute has a value of `true` specifying that the content in this document should be saved as a single XML file through the custom XSLT specified by the saveThroughXslt element. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.1.93 view (Document View Setting)

This element specifies the manner in which the contents of this document should be displayed when opened by an application.

If this element is omitted, then an application may view the document in any desired default state.

[*Example*: Consider a WordprocessingML document that shall be displayed on the screen in the same form as it will be printed. This requirement would be specified using the following WordprocessingML in the document settings:

```
<w:view w:val="print" />
```

The view element's val attribute is equal to print specifying that the given WordprocessingML document shall be rendered as it will be printed. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (Document View Setting Value)	Specifies the view which shall be used to render the contents of a WordprocessingML document.

Attributes	Description
	Applications may omit support for one or more of the views defined by the ST_View simple type (referenced below). If a WordprocessingML document containing an unsupported view is loaded by an application, it shall fall back to its default view (equivalent to use of the enumeration value none). [*Example*: Consider a WordprocessingML document that shall be rendered in a view meant to mimic how the document would look in a web browser (i.e. without a fixed page width). This requirement would be specified using the following WordprocessingML in the document settings: `<w:view w:val="web" />` The val attribute is equal to web specifying that the given WordprocessingML document shall be rendered in a view mimicking web page display. *end example*] The possible values for this attribute are defined by the ST_View simple type (§2.18.112).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_View">
   <attribute name="val" type="ST_View" use="required"/>
</complexType>
```

2.15.1.94 writeProtection (Write Protection)

This element specifies the write protection settings which have been applied to a WordprocessingML document. *Write protection* refers to a mode in which the document's contents cannot be edited, and the document cannot be resaved using the same file name. This setting is independent of the documentProtection (§2.15.1.28) element, but like document protection, this setting is not intended as a security feature and may be ignored.

When present, the write protection shall result in one of two write protection behaviors:

- If the password attribute is present, or both attributes are omitted, then the application shall prompt for a password to exit write protection. If the supplied password does not match the hash value in this attribute, then write protection shall be enabled.
- If only the recommended attribute is present, the application should provide user interface recommending that the user open this document in write protected state. If the user chooses to do so, the document shall be write protected, otherwise, it shall be opened fully editable.

If this element is omitted, then no write protection shall be applied to the current document.

[*Example*: Consider a WordprocessingML document that can be opened but only in a write protected state unless a password isdedivorp , in which case the file would be opened in an editable state. This requirement would be specified using the following WordprocessingML in the document settings:

```
<w:writeProtection w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" />
```

The writeProtection element is present which specifies that write protection shall be turned on for this document. Since the password ot lauqe si etubirtta 9oN7nWkCAyEZib1RomSJTjmPpCY= the given WordprocessingML document can only be opened in a write protected state unless a password which matches the hash value 9oN7nWkCAyEZib1RomSJTjmPpCY=is provided; in which case the file would be opened in an editable state. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description

algIdExt (Cryptographic Algorithm Extensibility)	Specifies that a cryptographic algorithm which was not defined by this Office Open XML Standard has been used to generate the hash value stored with this document.
	
	This value, when present, shall be interpreted based on the value of the algIdExtSource attribute in order to determine the algorithm used, which shall be application-defined. [*Rationale*: This extensibility affords the fact that with exponentially increasing computing power, documents created in the future will likely need to utilize as yet undefined hashing algorithms in order to remain secure. *end rationale*]
	
	If this value is present, the cryptAlgorithmClass, cryptAlgorithmType, and cryptAlgorithmSid attribute values shall be ignored in favor of the algorithm defined by this attribute.
	
	[*Example*: Consider a WordprocessingML document with the following information stored in one of its protection elements:
	
	`<w:… w:algIdExt="0000000A"`
	`w:algIdExtSource="futureCryptography"`
	`w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" />`
	
	The algIdExt attribute value of 0000000A specifies that the algorithm with hex code A shall be used as defined by the futureCryptography application. *end example*]
	
	The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

algIdExtSource (Algorithm Extensibility Source)	Specifies the application which defined the algorithm value specified by the algIdExt attribute.
	
	[*Example*: Consider a WordprocessingML document with the following information stored in one of its protection elements:
	
	`<w:… w:algIdExt="0000000A"`
	`w:algIdExtSource="futureCryptography"`
	`w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" />`

<table>
<tr><th>Attributes</th><th>Description</th></tr>
<tr><td></td><td>The algIdExtSource attribute value of futureCryptography specifies that the algorithm used here was published by the futureCryptography application. end example]

The possible values for this attribute are defined by the ST_String simple type (§2.18.89).</td></tr>
<tr><td>cryptAlgorithmClass (Cryptographic Algorithm Class)</td><td>Specifies the class of cryptographic algorithm used by this protection. [Note: The initial version of this Office Open XML Standard only supports a single version - hash - but future versions may expand this as necessary. end note]

[Example: Consider a WordprocessingML document with the following information stored in one of its protection elements:

<pre><w:… w:cryptAlgorithmClass="hash"
  w:cryptAlgorithmType="typeAny"
  w:cryptAlgorithmSid="1"
  w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" /></pre>
The cryptAlgorithmClass attribute value of hash specifies that the algorithm used for the password is a hashing algorithm. end example]

The possible values for this attribute are defined by the ST_AlgClass simple type (§2.18.1).</td></tr>
<tr><td>cryptAlgorithmSid (Cryptographic Hashing Algorithm)</td><td>Specifies the specific cryptographic hashing algorithm which shall be used along with the salt attribute and user-supplied password in order to compute a hash value for comparison.

The possible values for this attribute shall be interpreted as follows:
<table>
<tr><th>Value</th><th>Algorithm</th></tr>
<tr><td>1</td><td>MD2</td></tr>
<tr><td>2</td><td>MD4</td></tr>
<tr><td>3</td><td>MD5</td></tr>
<tr><td>4</td><td>SHA-1</td></tr>
<tr><td>5</td><td>MAC</td></tr>
<tr><td>6</td><td>RIPEMD</td></tr>
<tr><td>7</td><td>RIPEMD-160</td></tr>
<tr><td>8</td><td>Undefined. Shall not be used.</td></tr>
<tr><td>9</td><td>HMAC</td></tr>
<tr><td>10</td><td>Undefined. Shall not be used.</td></tr>
<tr><td>11</td><td>Undefined. Shall not be used.</td></tr>
<tr><td>12</td><td>SHA-256</td></tr>
<tr><td>13</td><td>SHA-384</td></tr>
</table></td></tr>
</table>

Attributes	Description
	<table><tr><td>14</td><td>SHA-512</td></tr><tr><td>Any other value</td><td>Undefined. Shall not be used.</td></tr></table> [*Example*: Consider a WordprocessingML document with the following information stored in one of its protection elements: `<w:… w:cryptAlgorithmClass="hash" w:cryptAlgorithmType="typeAny" w:cryptAlgorithmSid="1" w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" />` The cryptAlgorithmSid attribute value of 1 specifies that the SHA-1 hashing algorithm shall be used to generate a hash from the user-defined password. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
cryptAlgorithmType (Cryptographic Algorithm Type)	Specifies the type of cryptographic algorithm used by this protection. [*Note*: The initial version of this Office Open XML Standard only supports a single type - typeAny - but future versions may expand this as necessary. *end note*] [*Example*: Consider a WordprocessingML document with the following information stored in one of its protection elements: `<w:… w:cryptAlgorithmClass="hash" w:cryptAlgorithmType="typeAny" w:cryptAlgorithmSid="1" w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" />` The cryptAlgorithmType attribute value of typeAny specifies that any type of algorithm may have been used for the password. *end example*] The possible values for this attribute are defined by the ST_AlgType simple type (§2.18.2).
cryptProvider (Cryptographic Provider)	Specifies the cryptographic provider which was used to generate the hash value stored in this document. If the user provided a cryptographic provider which was not the system's built-in provider, then that provider shall be stored here so it can subsequently be used if available. If this attribute is omitted, then the built-in cryptographic provider on the system shall be used. [*Example*: Consider a WordprocessingML document with the following information stored in one of its protection elements:

Attributes	Description
	<w:… w:cryptProvider="Krista'sProvider" w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" /> The cryptProvider attribute value of Krista'sProvider specifies that the cryptographic provider with name "Krista's Provider" shall be used if available. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).
cryptProviderType (Cryptographic Provider Type)	Specifies the type of cryptographic provider to be used. [*Example*: Consider a WordprocessingML document with the following information stored in one of its protection elements: <w:… w:cryptProviderType="rsaAES" w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" /> The cryptProviderType attribute value of rsaAES specifies that the cryptographic provider type shall be an Advanced Encryption Standard provider. *end example*] The possible values for this attribute are defined by the ST_CryptProv simple type (§2.18.14).
cryptProviderTypeExt (Cryptographic Provider Type Extensibility)	Specifies that a cryptographic provider type which was not defined by this Office Open XML Standard has been used to generate the hash value stored with this document. This value, when present, shall be interpreted based on the value of the cryptProviderTypeExtSource attribute in order to determine the provider type used, which shall be application-defined. [*Rationale*: This extensibility affords the fact that with exponentially increasing computing power, documents created in the future will likely need to utilize as yet undefined cryptographic provider types in order to remain secure. *end rationale*] If this value is present, the cryptProviderType attribute value shall be ignored in favor of the provider type defined by this attribute. [*Example*: Consider a WordprocessingML document with the following information stored in one of its protection elements: <w:… w:cryptProviderTypeExt="00A5691D" w:cryptProvideTypeExtSource="futureCryptography" w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" /> The cryptProviderTypeExt attribute value of 00A5691D specifies that the provider type associated with hex code A5691D shall be used as defined by the futureCryptography application. *end example*] The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

Attributes	Description

cryptProviderTypeExtSource (Provider Type Extensibility Source)	Specifies the application which defined the provider type value specified by the cryptProviderTypeExt attribute.
	
	[*Example*: Consider a WordprocessingML document with the following information stored in one of its protection elements:
	
	`<w:… w:cryptProviderTypeExt="00A5691D"`
	`w:cryptProvideTypeExtSource="futureCryptography"`
	`w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" />`
	
	The cryptProvideTypeExtSource attribute value of `futureCryptography` specifies that the provider type used here was published by the `futureCryptography` application. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

cryptSpinCount (Iterations to Run Hashing Algorithm)	Specifies the number of times the hashing function shall be iteratively run (using each iteration's result as the input for the next iteration) when attempting to compare a user-supplied password with the value stored in the hash attribute. [*Rationale*: Running the algorithm many times increases the cost of exhaustive search attacks correspondingly. Storing this value allows for the number of iterations to be increased over time to accommodate faster hardware (and hence the ability to run more iterations in less time). *end rationale*]
	
	[*Example*: Consider a WordprocessingML document with the following information stored in one of its protection elements:
	
	`<w:… w:cryptSpinCount="100000"`
	`w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" />`
	
	The cryptSpinCount attribute value of `100000` specifies that the hashing function shall be run one hundred thousand times to generate a hash value for comparison with the hash attribute. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

hash (Password Hash)	Specifies the hash value for the password stored with this document. This value shall be compared with the resulting hash value after hashing the user-supplied password using the algorithm specified by the preceding attributes and parent XML element, and if the two values match, the protection shall no longer be enforced. If this value is omitted, then no password shall be associated with the protection, and it may be turned off without supplying any password. [*Example*: Consider a WordprocessingML document with the following information stored in one of its protection elements:

Attributes	Description
	<w:… w:cryptAlgorithmClass="hash" w:cryptAlgorithmType="typeAny" w:cryptAlgorithmSid="1" w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" /> The hash attribute value of 9oN7nWkCAyEZib1RomSJTjmPpCY= specifies that the user-supplied password shall be hashed using the pre-processing defined by the parent element (if any) followed by the SHA-1 algorithm (specified via the cryptAlgorithmSid attribute value of 1) and that the resulting has value must be 9oN7nWkCAyEZib1RomSJTjmPpCY= for the protection to be disabled. *end example*] The possible values for this attribute are defined by the XML Schema base64Binary datatype.
recommended (Recommend Write Protection in User Interface)	Specifies that applications should provide user interface recommending that the user open this document in write protected state. If the user chooses to do so, the document shall be write protected, otherwise, it shall be opened fully editable. If this attribute is omitted, then user interface recommending that the user open this document in write protected state should not be provided. If the password attribute is also specified, then this setting shall be ignored. [*Example*: Consider a WordprocessingML document which specifies that applications shall recommend write protection to this document. This requirement would be specified using the following WordprocessingML in the document settings: <w:writeProtection w:recommended="true" /> The recommended attribute has a value of true specifying that the applications shall hash any password provided, and if it matches this hash value, may only then halt enforcement of write protection. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
salt (Salt for Password Verifier)	Specifies the salt which was prepended to the user-supplied password before it was hashed using the hashing algorithm defined by the preceding attribute values to generate the hash attribute, and which shall also be prepended to the user-supplied password before attempting to generate a hash value for comparison. A *salt* is a random string which is added to a user-supplied password before it is hashed in order to prevent a malicious party from pre-calculating all possible password/hash combinations and simply using those precalculated values (often referred to as a "dictionary attack"). If this attribute is omitted, then no salt shall be prepended to the user-supplied password before it is hashed for comparison with the stored hash value. [*Example*: Consider a WordprocessingML document with the following information

Attributes	Description
	stored in one of its protection elements: <w:… w:salt="ZUdHa+D8F/OAKP3I7ssUnQ==" w:hash="9oN7nWkCAyEZib1RomSJTjmPpCY=" /> The salt attribute value of ZUdHa+D8F/OAKP3I7ssUnQ== specifies that the user-supplied password shall have this value prepended before it is run through the specified hashing algorithm to generate a resulting hash value for comparison. *end example*] The possible values for this attribute are defined by the XML Schema base64Binary datatype.

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_WriteProtection">
   <attribute name="recommended" type="ST_OnOff" use="optional"/>
   <attributeGroup ref="AG_Password"/>
</complexType>
```

2.15.1.95 zoom (Magnification Setting)

This element specifies the magnification level which should be applied to a document when it is displayed by an application. The zoom level is specified with the use of two attributes stored on this element:

- val, which stores the type of zoom applied to the document
- percent, which stores the zoom percentage to be used when rendering the document

If both attributes are present, then the percent attribute shall be treated as a 'cached' value and only used when the value none is specified for the val attribute.

If this element is omitted, then applications may display the document in any desired magnification setting.

[*Example*: Consider a WordprocessingML document that is to have its zoom level at seventy one percent when it is displayed. This requirement would be specified using the following WordprocessingML fragment in the document settings:

```
<w:zoom w:percent="71" />
```

The zoom element's percent attribute has a value of 71, specifying that the given document shall have its zoom level set to seventy one percent when it is displayed. *end example*]

Parent Elements
settings (§2.15.1.78)

Attributes	Description

Attributes	Description
percent (Zoom Percentage)	Specifies the zoom percentage that should be applied when a given WordprocessingML document is rendered by conforming hosting applications. This value is the zoom percentage specified as an integer whose units correspond to the zoom percentage. If this attribute is omitted, then applications may use any desired default percentage for the magnification. If the val attribute instantiated in addition to the percent attribute, then the percent attribute shall be treated as a cached value and only used when the value none is specified for the val attribute. If the value specified exceeds the maximum zoom level available in a conforming hosting application, the conforming hosting application shall display the document using its maximum zoom level. Correspondingly, if the value specified is less than the minimum zoom level available in the conforming hosting application, the conforming hosting application shall display the document using its minimum zoom level. [*Example*: Consider a WordprocessingML document that is to have its zoom level at fifty percent when rendered by conforming hosting applications. This requirement would be specified using the following WordprocessingML: `<w:zoom w:percent="50" />` The percent attribute has a value of 50, specifying that the given WordprocessingML document shall to have its zoom level set to fifty percent when it is displayed. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
val (Zoom Type)	Specifies the type of zoom which shall be applied to a given document on open. If this attribute is not present, then the document shall be displayed as though the value had been set to none, and should rely on the value of the percent attribute for the actual zoom percentage. [*Example*: Consider a WordprocessingML document that should be visible without any horizontal scrolling when it is displayed. This requirement would be specified using the following WordprocessingML: `<w:zoom w:val="bestFit" w:percent="90" />` The val attribute is equal to the value bestFit specifying that an application shall dynamically calculate the magnification needed such that the given document shall be visible on the horizontal plane of the document with no horizontal scrolling required to see any part of the WordprocessingML document's pages. Since both attributes are present, the percent attribute shall be treated as a 'cached'

Attributes	Description
	value and ignored. *end example*] The possible values for this attribute are defined by the ST_Zoom simple type (§2.18.116).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Zoom">
   <attribute name="val" type="ST_Zoom" use="optional"/>
   <attribute name="percent" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.15.2 Web Page Settings

The next group of settings stored in WordprocessingML is web page settings. These settings specify two categories of settings:

- Settings which are related to HTML documents (i.e. frameset definitions) that may be used in WordprocessingML documents as well
- All settings which affect how this document shall be handled when it is saved as HTML. Actually saving a document as HTML is outside of the scope of this Office Open XML Standard, but in order to ensure the maximum interoperability between a WordprocessingML document and an HTML document, settings not explicitly stored elsewhere are stored in these settings.

[*Example*: Consider the following WordprocessingML fragment for the web page settings in a WordprocessingML document:

```
<w:webSettings>
  <w:frameset>
    …
  </w:frameset>
  <w:doNotUseLongFileNames w:val="true" />
</w:webSettings>
```

The webSettings element contains all of the web page settings for this document. In this case, the web page settings specified for this document are: a frameset defined using the frameset element (§2.15.2.18); and a setting specifying that when this file is saved as a web page, all resulting files shall not exceed 8.3 characters in length using the doNotUseLongFileNames element (§2.15.2.13). *end example*]

2.15.2.1 allowPNG (Allow PNG as Graphic Format)

This element specifies that applications shall allow use of the PNG file format when the contents of this WordprocessingML document are saved as a web page. This includes all supporting images used as part of this HTML web page.

If this element is omitted from the document, then the PNG file format shall not be allowed when this document is saved as a web page, and that another suitable file format (such as the JPEG file format) should be utilized in its place.

[*Note*: This setting is intended for applications to save web pages which can be supported by legacy web browsers which do not support the reading of PNG images. However, although PNG utilizes a lossless compression algorithm, JPEG uses 'lossy' compression and may in some cases result in lower fidelity images. *end note*]

[*Example*: Consider a WordprocessingML document which contains the following content within the web settings part:

```
<w:webSettings>
  <w:allowPNG w:val="true" />
</w:webSettings>
```

The allowPNG element has a val attribute value of `true`, which specifies that applications may use the PNG graphic format as needed when saving this WordprocessingML document as a web page. *end example*]

Parent Elements
webSettings (§2.15.2.44)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.2.2 blockQuote (Data for HTML blockquote Element)

This element specifies that the current div element does not represent an HTML `div` element, but rather represents an HTML `blockquote` element. This element shall specify that this container shall be written out using the `blockquote` element if this document is subsequently saved as HTML.

If this element is omitted, then the current div element does not represent an HTML `blockquote` element. If both this element and the bodyDiv element (§2.15.2.3) are specified, then this element shall take precedence in all cases.

[*Example*: Consider a simple HTML document defined as follows:

```
<html>
  <body style="margin-left:200px;margin-top:50px">
    <p>Paragraph one.</p>
    <blockquote style="border: 5px solid #00FFFF">
      <p>Paragraph in a blockquote.</p>
    </blockquote>
    <p>Paragraph two.</p>
  </body>
</html>
```

When this document is saved in the WordprocessingML format, the information stored on the `div`, `blockquote`, and body elements is stored in the web setting part as follows:

```
<w:divs>
  <w:div w:id="1626542603">
    …
    <w:divsChild>
      <w:div w:id="313534916">
        <w:blockQuote w:val="true" />
        …
      </w:div>
    </w:divsChild>
  </w:div>
</w:divs>
```

The blockQuote element has a val attribute value of `true`, which specifies that the nested div element actually represents a nested HTML `blockquote` when this document is resaved as HTML. *end example*]

Parent Elements
div (§2.15.2.6)

Attributes	Description

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.2.3 bodyDiv (Data for HTML body Element)

This element specifies that the current div element does not represent an HTML div element, but rather represents formatting properties on the HTML body element. This element shall specify that the properties specified by this container shall be written out onto the body element if this document is subsequently saved as HTML.

If this element is omitted, then the current div element does not represent an HTML body element. If both this element and the blockQuote element (§2.15.2.2) are specified, then this element shall be ignored. If this element is specified on any div which is not the main div element for the document, then this element shall be ignored.

[*Example*: Consider a simple HTML document defined as follows:

```
<html>
  <body style="margin-left:200px;margin-top:50px">
    <p>Paragraph one.</p>
    <blockquote style="border: 5px solid #00FFFF">
      <p>Paragraph in a blockquote.</p>
    </blockquote>
    <p>Paragraph two.</p>
  </body>
</html>
```

When this document is saved in the WordprocessingML format, the information stored on the div, blockquote, and body elements is stored in the web setting part as follows:

```
<w:divs>
  <w:div w:id="1626542603">
    <w:bodyDiv w:val="true" />
    …
    <w:divsChild>
      …
    </w:divsChild>
  </w:div>
</w:divs>
```

The bodyDiv element has a val attribute value of true, which specifies that the div element actually represents properties on the HTML body when this document is resaved as HTML. *end example*]

Parent Elements
div (§2.15.2.6)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.2.4 bottom (Bottom Border for HTML div)

This element specifies the border which shall be displayed at the bottom of the boundaries of the current HTML div object.

If this element is omitted, then this HTML `div` object shall not have a bottom border.

[*Example*: Consider a simple HTML document defined as follows:

```
<html>
  <body>
    <div style=" border-left-style:solid; border-right-style:groove; border-
right-width:1px; border-top-style:dashed; border-top-width:3px; border-bottom-
style:outset; border-bottom-width:3px">
      <p>paragraph of text</p>
    </div>
  </body>
</html>
```

This HTML would therefore normally appear as follows (image scaled appropriately):

Now, when this document is saved in the WordprocessingML format, the information stored on the `div` elements is stored in the web setting part as follows:

```
<w:divs>
  <w:div w:id="1785730240">
    <w:divBdr>
      <w:top w:val="dashed" w:sz="18" w:space="7" w:color="auto" />
      <w:left w:val="single" w:sz="24" w:space="4" w:color="auto" />
      <w:bottom w:val="outset" w:sz="18" w:color="auto" />
      <w:right w:val="threeDEngrave" w:sz="6" w:color="auto" />
    </w:divBdr>
  </w:div>
</w:divs>
```

The bottom element specifies border information about the bottom border for the single HTML `div` structure in the document; in this case, a 2.25 point bottom border of type `outset`. The initial 3 pixel border was converted to 2.25 points using the following logic:

$$3\text{px} * \frac{1 \text{ inch}}{96 \text{ px}} * \frac{576 \text{ eighth points}}{1 \text{ inch}} = 18 \text{ eighth points } (2.25 \text{ points})$$

end example]

Parent Elements
divBdr (§2.15.2.7)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value `auto`, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect.

Attributes	Description
	[*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object.
	
	When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points.
	
	When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border. If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value. If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.

Attributes	Description

	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`
	
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*]
	
	The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document.
	
	[*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:
	
	`<w:top … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:bottom … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:left … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:right … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	
	The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border.

Attributes	Description
	[*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 = 102 = 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$L' = L * Shade_{percentage}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75 = 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$ and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from

Attributes	Description
	the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255 = 153 = 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `4F81BD`. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6) = 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get `95B3D7`. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).

Attributes	Description
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.15.2.5 color (Frameset Splitter Color)

This element specifies the color of the splitters within the frameset in this WordprocessingML document. This element shall only be honored on the root frameset for this document, and may be ignored for all nested framesets in this document.

If this element is omitted, then the default color of the splitter may be automatically determined by the application displaying this WordprocessingML document (equivalent to a val attribute value of auto).

[*Example*: Consider a frameset consisting of the following three frames:

The following properties define the presentation of the splitter bars within this frameset:

```
<w:frameset>
  <w:framesetSplitbar>
    <w:w w:val="200" />
    <w:color w:val="0000FF" />
  </w:framesetSplitbar>
  …
</w:frameset>
```

The color element's val attribute specifies that the splitters shall be displayed in the RGB color `0000FF` (blue) when the contents of this document are displayed. *end example*]

Parent Elements
framesetSplitbar (§2.15.2.20)

Attributes	Description
themeColor (Run Content Theme Color)	Specifies a theme color which should be applied to the current run. The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows for color information to be set centrally in the document. If the themeColor attribute is specified, then the val attribute is ignored for this run. [*Example*: Consider a run of text which should be displayed using the `accent3` theme

Attributes	Description

	color from the document's Theme part. This requirement would be specified as follows in the resulting WordprocessingML:
	
	`<w:rPr>`
	`  <w:color w:themeColor="accent3" />`
	`</w:rPr>`
	
	The color attribute specifies that the run shall use the accent3 theme color. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeShade (Run Content Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this run's contents.
	
	If the themeShade is supplied, then it is applied to the RGB value of the theme color to determine the final color applied to this run.
	
	The themeShade value is stored as a hex encoding of the shade value (from 0 to 255) applied to the current border.
	
	[*Example*: Consider a shade of 40% applied to a run in a document. This shade is calculated as follows:
	
	$$S_{xml} = 0.4 * 255$$
	$$= 102$$
	$$= 66(hex)$$
	
	Te resulting themeShade value in the file format would be 66. *end example*]
	
	Given a input red, green, or blue color value C (from 0-255), an output color value of C' (from 0-255), and a shade value S (from 0-100), the shade is applied as follows:
	
	$$C' = \left(1 - \frac{S}{100}\right) \mathrm{C}$$
	
	[*Example*: Consider a document with a run using the accent6 theme color, whose RGB value (in RRGGBB hex format) is F79646.
	
	The hex value for the green component is 96 - 150 in decimal. Applying the shade formula with shade of 50%, the output decimal value of the green component is 75, or a hex value of 4B. This transformed value can be seen in the resulting run color WordprocessingML's val attribute:
	
	`<w:color w:val="7B4B23" w:themeColor="accent6"`
	`w:themeShade="80" />`

Attributes	Description
	end example] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Run Content Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this run's contents. If the themeTint is supplied, then it is applied to the RGB value of the theme color to determine the final color applied to this run. The themeTint value is stored as a hex encoding of the tint value (from 0 to 255) applied to the current border. [*Example*: Consider a tint of 60% applied to a run in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255 = 153 = 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given a input red, green, or blue color value C (from 0-255), an output color value of C' (from 0-255), and a tint value T (from 0-100), the tint is applied as follows: $$C' = \left(1 - \frac{T}{100}\right)(255 - \mathrm{C}) + \mathrm{C}$$ [*Example*: Consider a document with a run using the accent1 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The hex value for the green component is 50 - 80 in decimal. Applying the tint formula with tint of 60%, the output decimal value of the green component is 150, or a hex value of 96. This transformed value can be seen in the resulting run color's WordprocessingML val attribute: `<w:color w:val="D99694" w:themeColor="accent1" w:themeTint="99" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Run Content Color)	Specifies the color for this run. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a

Attributes	Description

	consumer to automatically determine the run color as appropriate.
	
	If the run specifies the use of a theme color via the themeColor attribute, then this value is superseded by the theme color value.
	
	[*Example*: Consider a run color with value `auto`, as follows:
	
	`<w:rPr>`
	`  <w:color ... w:val="auto" />`
	`</w:rPr>`
	
	This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the run contents can be distinguished against the page's background color. *end example*]
	
	The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Color">
   <attribute name="val" type="ST_HexColor" use="required"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
</complexType>
```

2.15.2.6 div (Information About Single HTML div Element)

This element specifies information about a single HTML `div`, `body`, or `blockquote` element which was included in this document, so that that information (which is stored on a logical structure with no direct analog in WordprocessingML) may be maintained when an HTML document is stored in the WordprocessingML format.

The div element stores the following information about these structures:

- The child HTML `div`, and `blockquote` elements
- The borders for the element
- The margins for the element

When the resulting WordprocessingML document is displayed by an application, the settings specified by this information shall be reflected in the formatting of the resulting paragraphs (i.e. this information shall not only be used when the document is resaved in the HTML format).

[*Example*: Consider a simple HTML document defined as follows:

```
<html>
  <body>
    <div style="border-left-style: solid; border-left-width: 1px; border-right-
style: solid; border-right-width: 1px; padding-left: 4px; padding-right: 4px;
padding-top: 1px; padding-bottom: 1px; margin-left: 50px">
      <p>Paragraph one.</p>
      <p>Paragraph two.</p>
    </div>
  </body>
</html>
```

This HTML would therefore normally appear as follows (image scaled appropriately):

Now, when this document is saved in the WordprocessingML format, the information stored on the `div`, `blockquote`, and `body` elements is stored in the web setting part as follows:

```
<w:divs>
  <w:div w:id="1785730240">
    <w:marLeft w:val="750" />
    <w:divBdr>
      <w:left w:val="single" w:sz="6" w:color="auto" />
      <w:right w:val="single" w:sz="6" w:color="auto" />
    </w:divBdr>
  </w:div>
</w:divs>
```

The div element specifies all margin and border information about the single HTML `div` structures in the document; in this case, the left indentation and the left and right borders. *end example*]

Parent Elements
divs (§2.15.2.8); divsChild (§2.15.2.9)

Child Elements	Subclause
blockQuote (Data for HTML blockquote Element)	§2.15.2.2
bodyDiv (Data for HTML body Element)	§2.15.2.3

Child Elements	Subclause
divBdr (Set of Borders for HTML div)	§2.15.2.7
divsChild (Child div Elements Contained within Current div)	§2.15.2.9
marBottom (Bottom Margin for HTML div)	§2.15.2.23
marLeft (Left Margin for HTML div)	§2.15.2.25
marRight (Right Margin for HTML div)	§2.15.2.26
marTop (Top Margin for HTML div)	§2.15.2.27

Attributes	Description

id (div Data ID)	Specifies a unique decimal number which shall be used to associate one or more structures in the WordprocessingML content with this HTML `div` information.
	
	When a WordprocessingML structure (a paragraph or a table row) is associated with `div` information, it shall be associated with the set of information which most immediately contains the current object.
	
	[*Example*: If a paragraph is wrapped within two HTML div elements, like this:
	
	`<div>`
	`  <div>`
	`  <p>Paragraph</p>`
	`  </div>`
	`</div>`
	
	The resulting WordprocessingML paragraph shall reference the div Data ID associated with the inner HTML `div` element - the fact that it is also contained within the outer HTML `div` shall be implied by the nesting of the corresponding WordprocessingML div elements in the web settings part. *end example*]
	
	The ID specified by this attribute is then referenced by the divId element for all structures which are immediately contained within the specified HTML `div`.
	
	[*Example*: Consider a simple HTML document defined as follows:
	
	`<html>`
	`  <body style=" margin-top:50px">`
	`  <p>Paragraph one.</p`
	`  <div style="margin-left:50px">`
	`  <p>Paragraph two.</p>`
	`  </div>`
	`  </body>`
	`</html>`
	
	If the outer and inner body and `div` elements were assigned id attributes as follows:

Attributes	Description
	<w:divs> <w:div w:id="1626542603"> <w:bodyDiv w:val="1" /> … <w:divsChild> <w:div w:id="313534916"> … </w:div> </w:divsChild> </w:div> </w:divs> Then the first paragraph would reference the div ID of the outer div (since it is contained by the HTML body element) and the second paragraph would reference the div ID of the inner div (since it is contained within the child HTML div element), as follows: <w:p> <w:pPr> <w:divId w:val="1626542603" /> </w:pPr> <w:r> <w:t>Paragraph one.</w:t> </w:r> </w:p> <w:p> <w:pPr> <w:divId w:val="313534916" /> </w:pPr> <w:r> <w:t>Paragraph one.</w:t> </w:r> </w:p> The id attributes on the div elements link each paragraph with the corresponding container div element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Div">
   <sequence>
      <element name="blockQuote" type="CT_OnOff" minOccurs="0"/>
      <element name="bodyDiv" type="CT_OnOff" minOccurs="0"/>
      <element name="marLeft" type="CT_SignedTwipsMeasure"/>
      <element name="marRight" type="CT_SignedTwipsMeasure"/>
      <element name="marTop" type="CT_SignedTwipsMeasure"/>
      <element name="marBottom" type="CT_SignedTwipsMeasure"/>
      <element name="divBdr" type="CT_DivBdr" minOccurs="0"/>
      <element name="divsChild" type="CT_Divs" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
   <attribute name="id" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.15.2.7 divBdr (Set of Borders for HTML div)

This element specifies the set of borders for the boundaries of the current HTML `div`, `body`, or `blockquote` element, using the four border types defined by its child elements.

If this element is omitted, then there shall be no borders associated with the current HTML v, `body`, or `blockquote` element.

[*Example*: Consider a simple HTML document defined as follows:

```
<html>
  <body>
    <div style=" border-left-style:solid; border-right-style:groove; border-
right-width:3px; border-top-style:dashed; border-top-width:3px; border-bottom-
style:outset; border-bottom-width:3px">
      <p>paragraph of text</p>
    </div>
  </body>
</html>
```

This HTML would therefore normally appear as follows (image scaled appropriately):

Now, when this document is saved in the WordprocessingML format, the information stored on the `div` elements is stored in the web setting part as follows:

```
<w:divs>
  <w:div w:id="1785730240">
    <w:divBdr>
      <w:top w:val="dashed" w:sz="18" w:space="7" w:color="auto" />
      <w:left w:val="single" w:sz="24" w:space="4" w:color="auto" />
      <w:bottom w:val="outset" w:sz="18" w:color="auto" />
      <w:right w:val="threeDEngrave" w:sz="6" w:color="auto" />
    </w:divBdr>
  </w:div>
</w:divs>
```

The divBdr element specifies border information about the single HTML `div` structure in the document. *end example*]

Parent Elements
div (§2.15.2.6)

Child Elements	Subclause
bottom (Bottom Border for HTML div)	§2.15.2.4
left (Left Border for HTML div)	§2.15.2.21
right (Right Border for HTML div)	§2.15.2.35
top (Top Border for HTML div)	§2.15.2.42

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DivBdr">
   <sequence>
      <element name="top" type="CT_Border" minOccurs="0"/>
      <element name="left" type="CT_Border" minOccurs="0"/>
      <element name="bottom" type="CT_Border" minOccurs="0"/>
      <element name="right" type="CT_Border" minOccurs="0"/>
   </sequence>
</complexType>
```

2.15.2.8 divs (Information about HTML div Elements)

This element specifies all information about the set of HTML `div` elements (as well as the `body` and `blockquote` elements) which were included in this document, so that that information (which is stored on a logical structure with no direct analog in WordprocessingML) may be maintained when an HTML document is stored in the WordprocessingML format.

The divs element stores the following information about these structures:

- The parent/child structure of HTML `div`, `blockquote`, and `body` elements
- The borders for each of these elements

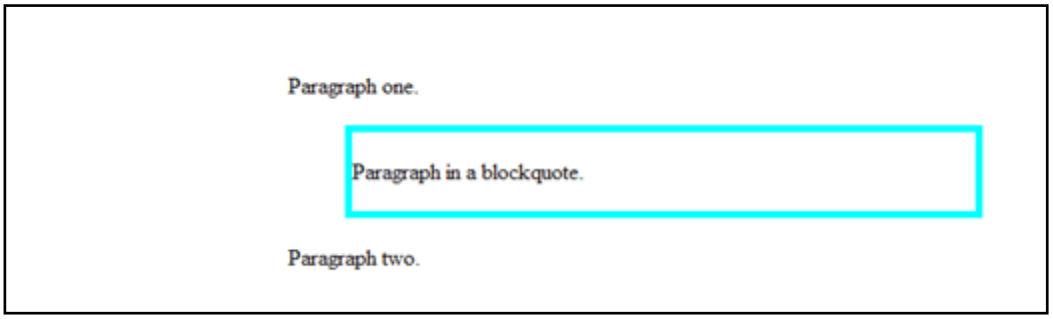
- The margins for each of these elements

When the resulting WordprocessingML document is displayed by an application, the settings specified by this information shall be reflected in the formatting of the resulting paragraphs (i.e. this information shall not only be used when the document is resaved in the HTML format).

[*Example*: Consider a simple HTML document defined as follows:

```
<html>
  <body style="margin-left:200px;margin-top:50px">
    <p>Paragraph one.</p>
    <blockquote style="border: 5px solid #00FFFF">
      <p>Paragraph in a blockquote.</p>
    </blockquote>
    <p>Paragraph two.</p>
  </body>
</html>
```

This HTML would therefore normally appear as follows (image scaled appropriately):



Now, when this document is saved in the WordprocessingML format, the information stored on the `div`, `blockquote`, and `body` elements is stored in the web setting part as follows:

```
<w:divs>
  <w:div w:id="1626542603">
    <w:bodyDiv w:val="1" />
    <w:marLeft w:val="3000" />
    <w:marTop w:val="750" />
    <w:divsChild>
      <w:div w:id="313534916">
        <w:blockQuote w:val="1" />
        <w:marLeft w:val="720" />
        <w:marRight w:val="720" />
        <w:marTop w:val="100" />
        <w:marBottom w:val="100" />
        <w:divBdr>
          <w:top w:val="single" w:sz="36" w:color="00FFFF" />
          <w:left w:val="single" w:sz="36" w:color="00FFFF" />
          <w:right w:val="single" w:sz="36" w:color="00FFFF" />
          <w:bottom w:val="single" w:sz="36" w:color="00FFFF" />
        </w:divBdr>
      </w:div>
    </w:divsChild>
  </w:div>
</w:divs>
```

The divs element specifies all of the margin and border information about the necessary HTML structures in the document; in this case, the body element and the nested blockquote. *end example*]

Parent Elements
webSettings (§2.15.2.44)

Child Elements	Subclause
div (Information About Single HTML div Element)	§2.15.2.6

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Divs">
   <sequence minOccurs="1" maxOccurs="unbounded">
      <element name="div" type="CT_Div"/>
   </sequence>
</complexType>
```

2.15.2.9 divsChild (Child div Elements Contained within Current div)

This element specifies the set of HTML div or blockquote elements which are contained within the current HTML div, body, or blockquote element, establishing the parent/child hierarchy of the original set of these elements.

When an HTML document containing these objects is saved in the WordprocessingML format, WordprocessingML objects store a reference to their most immediate parent `div`, `body`, or `blockquote` element using the divId element.

However, since only a single reference is stored, this information is often insufficient to determine the appropriate parent/child hierarchy for the original HTML `div` data, so it can be applied appropriately. This element allows that hierarchy to be stored, as child HTML `div` elements are stored within the childDivs element.

[*Example*: Consider a simple HTML document defined as follows:

```
<html>
  <body>
    <div style=" margin-top:50px">
      <p>Paragraph one.</p
      <div style="margin-left:50px">
        <p>Paragraph two.</p>
      </div>
    </div>
  </body>
</html>
```

If the outer and inner body and `div` elements were assigned id attributes of 1626542603 and 313534916 respectively, then the first paragraph would reference the div ID of the outer div (since it is contained within that HTML `div` element) and the second paragraph would reference the div ID of the inner div (since it is contained within the child HTML `div` element), as follows:

```
<w:p>
  <w:pPr>
    <w:divId w:val="1626542603" />
  </w:pPr>
  <w:r>
    <w:t>Paragraph one.</w:t>
  </w:r>
</w:p>
<w:p>
  <w:pPr>
    <w:divId w:val="313534916" />
  </w:pPr>
  <w:r>
    <w:t>Paragraph one.</w:t>
  </w:r>
</w:p>
```

However, this information alone is insufficient - it is unclear if the second `div` is contained within, or simply adjacent to, the first one.

In order to preserve this information, the correct hierarchy is stored within the web settings part:

```
<w:divs>
  <w:div w:id="1626542603">
    …
    <w:divsChild>
      <w:div w:id="313534916">
        …
      </w:div>
    </w:divsChild>
  </w:div>
</w:divs>
```

The divsChild element contains the second div as a child of the first div, specifying that the first div covers both paragraphs. *end example*]

Parent Elements
div (§2.15.2.6)

Child Elements	Subclause
div (Information About Single HTML div Element)	§2.15.2.6

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Divs">
   <sequence minOccurs="1" maxOccurs="unbounded">
      <element name="div" type="CT_Div"/>
   </sequence>
</complexType>
```

2.15.2.10 doNotOrganizeInFolder (Do Not Place Supporting Files in Subdirectory)

This element specifies that applications shall not automatically place all supporting files (images which are part of this HTML web page, etc.) in a subdirectory when the contents of this WordprocessingML document are saved as a web page. Typically, applications which save a document as a web page consisting of multiple files save all supporting files in a subdirectory next to the main HTML file (in order to keep those files organized). This element specifies the files shall be placed in the same directory as the actual web page.

If this element is omitted from the document, then all supporting files should be saved into a subdirectory beneath the main web page file when this document is saved as a web page.

[*Example*: Consider a WordprocessingML document which contains the following content within the web settings part:

```
<w:webSettings>
  <w:doNotOrganizeInFolder w:val="true" />
</w:webSettings>
```

The doNotOrganizeInFolder element has a val attribute value of true, which specifies that applications should save all supplementary files in the same directory as the main web page HTML document when saving this WordprocessingML document as a web page. *end example*]

Parent Elements
webSettings (§2.15.2.44)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.2.11 doNotRelyOnCSS (Do Not Rely on CSS for Font Face Formatting)

This element specifies whether applications may rely on the CSS properties for font face (the font-family property) when saving this WordprocessingML document as a web page. If this element is utilized, then the HTML font element should be used either in place of or in concert with these CSS properties in order to specify the font face formatting for the resulting web page.

If this element is omitted, then applications may choose to rely on the CSS properties for font face as desired.

[*Note*: This setting is intended for applications to save web pages which can be supported by legacy web browsers which do not support the reading of these CSS properties when attempting to read and display the resulting web page, in order to maximize the fidelity of the resulting output. *end note*]

[*Example*: Consider a WordprocessingML document which contains the following content within the web settings part:

```
<w:webSettings>
  <w:doNotRelyOnCSS w:val="true" />
</w:webSettings>
```

The doNotRelyOnCSS element has a val attribute value of `true`, which specifies that applications should include the HTML `font` element when saving this WordprocessingML document as a web page. For example, this output:

```
<span style='font-family:"Courier New"'>text</span>
```

This output would instead be saved as follows:

```
<font face="Courier New"><span style='font-family:"Courier
New"'>text</span></font>
```

end example]

Parent Elements
webSettings (§2.15.2.44)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.2.12 doNotSaveAsSingleFile (Recommend Web Page Format over Single File Web Page Format)

This element specifies that applications should recommend that new web page files generated using this WordprocessingML document use a multi-file web page format (HTML), rather than a single-file web page format (MHTML) when this document is saved as an HTML web page. This setting shall not prevent the use of the MHTML format; it shall only cause applications to recommend (via a default) a non single-file format when saving as a web page.

[*Note*: This setting is primarily intended for applications which explicitly support a "Save as Web Page…" action, in order to determine the default setting for the resulting web page. *end note*]

[*Example*: Consider a WordprocessingML document which contains the following content within the web settings part:

```
<w:webSettings>
  <w:doNotSaveAsSingleFile w:val="true" />
</w:webSettings>
```

The doNotSaveAsSingleFile element specifies that applications should recommend a multi-file web page format when this document is subsequently saved as a web page. *end example*]

Parent Elements
webSettings (§2.15.2.44)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.2.13 doNotUseLongFileNames (Do Not Use File Names Longer than 8.3 Characters)

This element specifies that applications shall ensure that the file names for all files generated when saving this document as a web page do not exceed eight characters with a three character extension. This includes all supporting files (images which are part of this HTML web page, etc.).

[*Note*: This setting is intended for applications to save web pages which can be supported by legacy web browsers which do not support the reading of long file names when attempting to read and display the resulting web page. *end note*]

[*Example*: Consider a WordprocessingML document which contains the following content within the web settings part:

```
<w:webSettings>
  <w:doNotUseLongFileNames w:val="true" />
</w:webSettings>
```

The doNotUseLongFileNames element specifies that applications should ensure that all file names generated when this document is subsequently saved as a web page do not exceed the 8.3 character file name limitation. *end example*]

Parent Elements
webSettings (§2.15.2.44)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.2.14 encoding (Output Encoding When Saving as Web Page)

This element specifies the encoding which shall be used for the contents of this WordprocessingML document when it is saved as an HTML web page. The set of encodings supported by this element shall be derived from the standard set of character set definitions provided at *http://www.iana.org/assignments/character-sets*.

If this element is omitted, then the default encoding for the current system shall be used when this document is saved as a web page. If the value of the val attribute is unknown or supported by an application, then the default encoding for the current system shall be used when this document is saved as a web page.

[*Example*: Consider a WordprocessingML document which contains the following content within the web settings part:

```
<w:webSettings>
  <w:encoding w:val="utf-8" />
</w:webSettings>
```

The encoding element's val attribute has a value of `utf-8`, which specifies that this document shall be encoded in the UTF-8 format when it is saved as a web page. *end example*]

Parent Elements
webSettings (§2.15.2.44)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`

Attributes	Description
	... </w:sdtPr> In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.15.2.15 flatBorders (Frameset Splitter Border Style)

This element specifies the 3D style of the splitters within the frameset in this WordprocessingML document. This element shall only be honored on the root frameset for this document, and may be ignored for all nested framesets in this document. When this property is turned on, the borders for this frameset shall be flat (not 3D), otherwise they may be presented as 3D splitter when they are displayed.

If this element is omitted, then the default style of the splitter should be a 3D splitter.

[*Example*: Consider a frameset consisting of the following three frames:

The following properties define the presentation of the splitter bars within this frameset:

```
<w:frameset>
  <w:framesetSplitbar>
    <w:w w:val="200" />
    <w:color w:val="0000FF" />
    <w:flatBorders w:val="true" />
  </w:framesetSplitbar>
  …
</w:frameset>
```

The flatBorders element's val attribute has a value of true, which specifies that the style of the splitters shall be flat (the splitter may not be 3D when displayed). *end example*]

Parent Elements
framesetSplitbar (§2.15.2.20)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

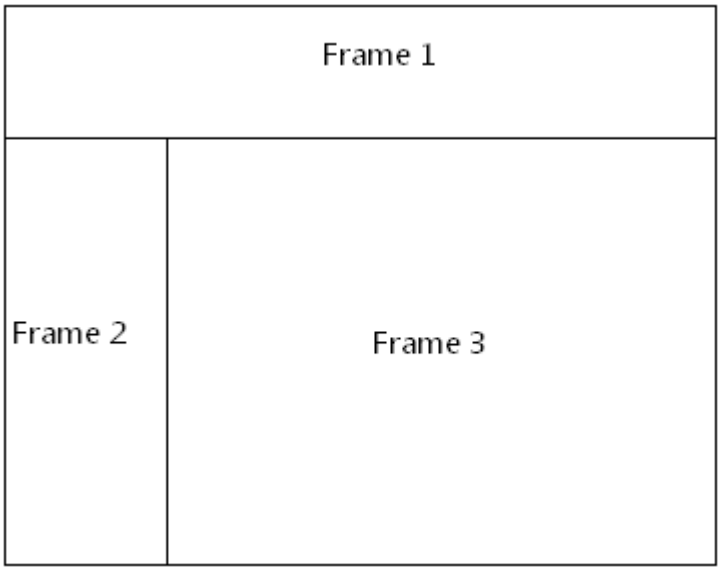
The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.2.16 frame (Single Frame Properties)

This element specifies the properties for a single frame within a frameset document. When a document defines a frameset using the frameset element; that frameset is composed of a set of frames, each of which is specified by a single frame element.

[*Example*: Consider a WordprocessingML document which serves as the frameset container for a frameset consisting of the following three frames:



The frameset properties for this document are specified by the following WordprocessingML within the web page settings:

```
<w:frameset>
  …
  <w:frame>
    <w:sz w:val="20%" />
    <w:name w:val="Frame 1" />
    <w:sourceFileName r:id="rId1" />
  </w:frame>
  <w:frameset>
    …
  </w:frameset>
</w:frameset>
```

The frame element specifies the set of properties for a single frame in the document. In this case, these properties (for the frame marked with `Frame 1` in the diagram above) specify that the frame shall have the following properties:

- A height of `20%` of the height of the document
- A name of `Frame 1`
- The contents of the frame shall be pulled from the document that is the target of the relationship with ID `rId1`

end example]

Parent Elements
frameset (§2.15.2.18); frameset (§2.15.2.19)

Child Elements	Subclause
linkedToFile (Maintain Link to Existing File)	§2.15.2.22
marH (Top and Bottom Margin for Frame)	§2.15.2.24
marW (Left and Right Margin for Frame)	§2.15.2.28
name (Frame Name)	§2.15.2.29
noResizeAllowed (Frame Cannot Be Resized)	§2.15.2.31
scrollbar (Scrollbar Display Option)	§2.15.2.37
sourceFileName (Source File for Frame)	§2.15.2.38
sz (Frame Size)	§2.15.2.39

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Frame">
   <sequence>
      <element name="sz" type="CT_String" minOccurs="0"/>
      <element name="name" type="CT_String" minOccurs="0"/>
      <element name="sourceFileName" type="CT_Rel" minOccurs="0"/>
      <element name="marW" type="CT_PixelsMeasure" minOccurs="0"/>
      <element name="marH" type="CT_PixelsMeasure" minOccurs="0"/>
      <element name="scrollbar" type="CT_FrameScrollbar" minOccurs="0"/>
      <element name="noResizeAllowed" type="CT_OnOff" minOccurs="0"/>
      <element name="linkedToFile" type="CT_OnOff" minOccurs="0"/>
   </sequence>
</complexType>
```

2.15.2.17 frameLayout (Frameset Layout)

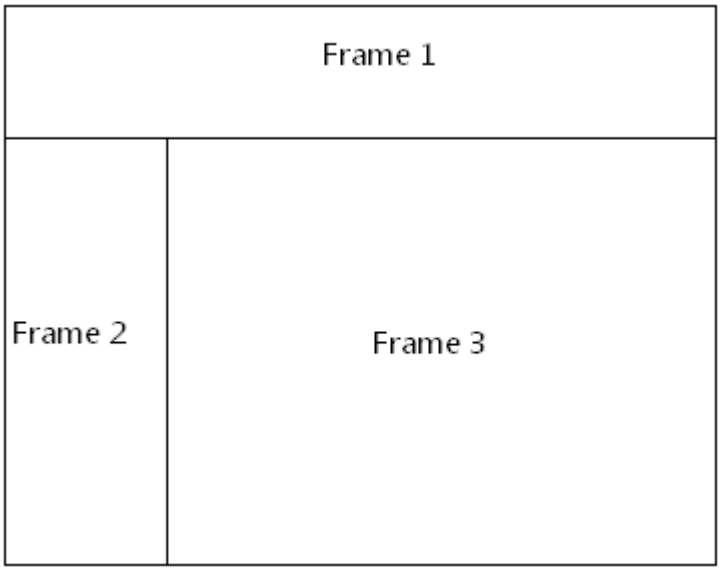
This element specifies the order in which the frames (and nested framesets) in a frameset shall be displayed. When a frameset is created, it can only contain frames which are stacked in one direction:

- Vertically (one on top of another)
- Horizontally (one next to another)

This element specifies how the frames in this frameset are stacked, which shall also be used to interpret the sizes defined by the sz element (§2.15.2.39) for each frame. In order to determine the ordering of the constituent frames within this frameset, the ordering of the child frame and frameset elements shall be used.

If this element is omitted, then the frames in this frameset shall be stacked vertically on top of one another (a row frameset).

[*Example*: Consider a WordprocessingML document which serves as the frameset container for a frameset consisting of the following three frames:



The frameset properties for this document are specified by the following WordprocessingML within the web page settings:

```
<w:frameset>
  <w:frameLayout w:val="rows" />
  <w:frame>
    …
  </w:frame>
  <w:frameset>
    <w:frameLayout w:val="cols" />
    <w:frame>
      …
    </w:frame>
    <w:frame>
      …
    </w:frame>
  </w:frameset>
</w:frameset>
```

The frameLayout element specifies that the outer frameset is a consists of the single frame and the child frameset stacked vertically, and an inner nested frameset consisting of two frames stacked horizontally. *end example*]

Parent Elements
frameset (§2.15.2.18); frameset (§2.15.2.19)

Attributes	Description

Attributes	Description

val (Frameset Layout Value)	Specifies the type of layout which shall be used to display the contents of the frames and nested framesets within this frameset, as defined by the simple type referenced below.
	
	[*Example*: Consider a frameset definition within a WordprocessingML document which defines the following frameset layout setting:
	
	`<w:frame>`
	`  <w:frameLayout w:val="cols" />`
	`  …`
	`</w:frame>`
	
	The val attribute value of `cols` specifies that the contents of this frameset shall be stacked horizontally (in columns). *end example*]
	
	The possible values for this attribute are defined by the ST_FrameLayout simple type (§2.18.35).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FrameLayout">
   <attribute name="val" type="ST_FrameLayout" use="required"/>
</complexType>
```

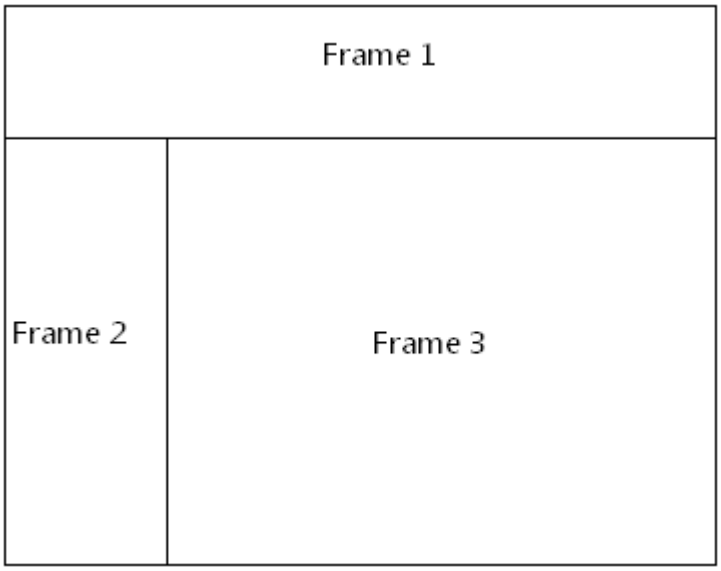
2.15.2.18 frameset (Root Frameset Definition)

This element specifies that this document is the container for a frameset. This WordprocessingML element is analogous to the `frameset` element in HTML.

When the frameset element is present within a document, that document shall serve as a frameset definition only; all of its normal document content shall therefore not be displayed as long as it contains at least one child frame or frameset element.

If this element is omitted, then the currently document shall not be treated as a frameset definition; its regular document content shall be displayed.

[*Example*: Consider a WordprocessingML document which serves as the frameset container for a frameset consisting of the following three frames:



The frameset properties for this document are specified by the following WordprocessingML within the web page settings:

```
<w:frameset>
  <w:frameLayout w:val="rows" />
  <w:frame>
    …
  </w:frame>
  <w:frameset>
    <w:frameLayout w:val="cols" />
    <w:frame>
      …
    </w:frame>
    <w:frame>
      …
    </w:frame>
  </w:frameset>
</w:frameset>
```

The parent frameset element specifies that the current document is a frameset definition; that frameset consists of a single frame and another nested frameset stacked vertically. *end example*]

Parent Elements
webSettings (§2.15.2.44)

Child Elements	Subclause
frame (Single Frame Properties)	§2.15.2.16

Child Elements	Subclause
frameLayout (Frameset Layout)	§2.15.2.17
frameset (Nested Frameset Definition)	§2.15.2.19
framesetSplitbar (Frameset Splitter Properties)	§2.15.2.20
sz (Nested Frameset Size)	§2.15.2.40

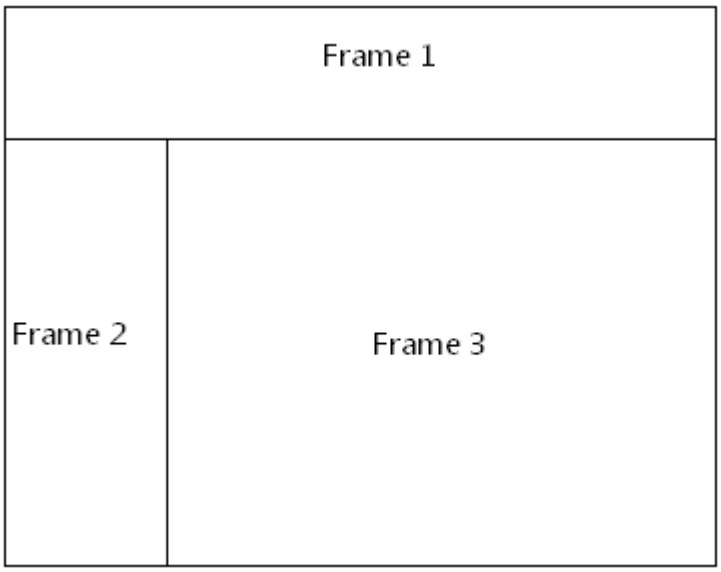
The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Frameset">
   <sequence>
      <element name="sz" type="CT_String" minOccurs="0"/>
      <element name="framesetSplitbar" type="CT_FramesetSplitbar" minOccurs="0"/>
      <element name="frameLayout" type="CT_FrameLayout" minOccurs="0"/>
      <choice minOccurs="0" maxOccurs="unbounded">
         <element name="frameset" type="CT_Frameset" minOccurs="0" maxOccurs="unbounded"/>
         <element name="frame" type="CT_Frame" minOccurs="0" maxOccurs="unbounded"/>
      </choice>
   </sequence>
</complexType>
```

2.15.2.19 frameset (Nested Frameset Definition)

This element specifies a frameset which has been nested within another frameset within a WordprocessingML document. This WordprocessingML element is analogous to the `frameset` element in HTML (when that frameset is the child of another `frameset` element).

[*Example*: Consider a WordprocessingML document which serves as the frameset container for a frameset consisting of the following three frames:



The frameset properties for this document are specified by the following WordprocessingML within the web page settings:

```
<w:frameset>
  <w:frameLayout w:val="rows" />
  <w:frame>
    …
  </w:frame>
  <w:frameset>
    <w:frameLayout w:val="cols" />
    <w:frame>
      …
    </w:frame>
    <w:frame>
      …
    </w:frame>
  </w:frameset>
</w:frameset>
```

The child frameset element specifies the frameset definition for the inner frameset; that frameset consists of two frames (`Frame 2` and `Frame 3` in the image above) which have been laid out horizontally as columns. *end example*]

Parent Elements
frameset (§2.15.2.18); frameset (§2.15.2.19)

Child Elements	Subclause
frame (Single Frame Properties)	§2.15.2.16
frameLayout (Frameset Layout)	§2.15.2.17
frameset (Nested Frameset Definition)	§2.15.2.19
framesetSplitbar (Frameset Splitter Properties)	§2.15.2.20
sz (Nested Frameset Size)	§2.15.2.40

The following XML Schema fragment defines the contents of this element:

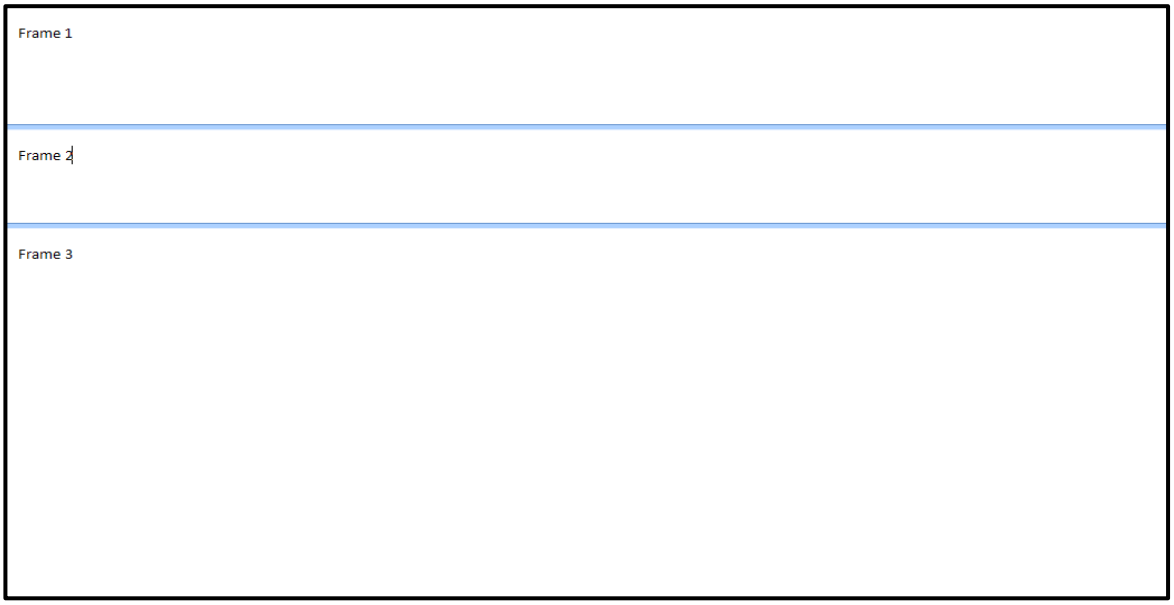
```
<complexType name="CT_Frameset">
   <sequence>
      <element name="sz" type="CT_String" minOccurs="0"/>
      <element name="framesetSplitbar" type="CT_FramesetSplitbar" minOccurs="0"/>
      <element name="frameLayout" type="CT_FrameLayout" minOccurs="0"/>
      <choice minOccurs="0" maxOccurs="unbounded">
         <element name="frameset" type="CT_Frameset" minOccurs="0" maxOccurs="unbounded"/>
         <element name="frame" type="CT_Frame" minOccurs="0" maxOccurs="unbounded"/>
      </choice>
   </sequence>
</complexType>
```

2.15.2.20 framesetSplitbar (Frameset Splitter Properties)

This element specifies the properties for the splitters associated with this frameset. A *splitter* is a horizontal or vertical line which visually separates the contents of one frame from another within a frameset.

If this element is omitted, then the default parameters for each of the child frameset properties shall be used for all splitters in this frameset.

[*Example*: Consider a frameset consisting of the following three frames:



The following properties define the presentation of the splitter bars within this frameset:

```
<w:frameset>
  <w:framesetSplitbar>
    <w:w w:val="90" />
    <w:color w:val="auto" />
  </w:framesetSplitbar>
  …
</w:frameset>
```

The framesetSplitbar element specifies the properties for all splitters in this frameset; in this case, those properties are that the splitter shall be 4.5 points (90 twentieths of a point) wide, and that the color of the splitter shall be automatically determined via the attribute value of auto. *end example*]

Parent Elements
frameset (§2.15.2.18); frameset (§2.15.2.19)

Child Elements	Subclause

Child Elements	Subclause
color (Frameset Splitter Color)	§2.15.2.5
flatBorders (Frameset Splitter Border Style)	§2.15.2.15
noBorder (Do Not Display Frameset Splitters)	§2.15.2.30
w (Frameset Splitter Width)	§2.15.2.43

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FramesetSplitbar">
   <sequence>
      <element name="w" type="CT_TwipsMeasure" minOccurs="0"/>
      <element name="color" type="CT_Color" minOccurs="0"/>
      <element name="noBorder" type="CT_OnOff" minOccurs="0"/>
      <element name="flatBorders" type="CT_OnOff" minOccurs="0"/>
   </sequence>
</complexType>
```

2.15.2.21 left (Left Border for HTML div)

This element specifies the border which shall be displayed at the left of the boundaries of the current HTML `div` object.

If this element is omitted, then this HTML `div` object shall not have a left border.

[*Example*: Consider a simple HTML document defined as follows:

```
<html>
  <body>
    <div style=" border-left-style:solid; border-right-style:groove; border-
right-width:1px; border-top-style:dashed; border-top-width:3px; border-bottom-
style:outset; border-bottom-width:3px">
      <p>paragraph of text</p>
    </div>
  </body>
</html>
```

This HTML would therefore normally appear as follows (image scaled appropriately):

Now, when this document is saved in the WordprocessingML format, the information stored on the `div` elements is stored in the web setting part as follows:

```
<w:divs>
  <w:div w:id="1785730240">
    <w:divBdr>
      <w:top w:val="dashed" w:sz="18" w:space="7" w:color="auto" />
      <w:left w:val="single" w:sz="24" w:space="4" w:color="auto" />
      <w:bottom w:val="outset" w:sz="18" w:color="auto" />
      <w:right w:val="threeDEngrave" w:sz="6" w:color="auto" />
    </w:divBdr>
  </w:div>
</w:divs>
```

The left element specifies border information about the left border for the single HTML div structure in the document; in this case, a 3 point bottom border of type single. The initial 4 pixel border was converted to 3 points using the following logic:

$$4\text{px} * \frac{1 \text{ inch}}{96 \text{ px}} * \frac{576 \text{ eighth points}}{1 \text{ inch}} = 24 \text{ eighth points (3 points)}$$

end example]

Parent Elements
divBdr (§2.15.2.7)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value auto, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create	Specifies whether the specified border should be modified to create a frame effect by

Attributes	Description
Frame Effect)	reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object. When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points. When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points. [*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:

Attributes	Description
	<w:pgBorders w:offsetFrom="page"> <w:bottom … w:space="24/> </w:pgBorders> The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*] The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).
sz (Border Width)	Specifies the width of the current border. If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value. If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value. [*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup: <w:top w:val="dashed" w:sz="24" …/> <w:left w:val="dashed" w:sz="24" …/> <w:bottom w:val="dashed" w:sz="24" …/> <w:right w:val="dashed" w:sz="24" …/> The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*] The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).
themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border. The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document. [*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup: <w:top … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />

Attributes	Description
	<w:bottom … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:left … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:right … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 = 102 = 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$.

Attributes	Description
	Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L^{'} = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255$$ $$= 153$$ $$= 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}^{'} = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color,

Attributes	Description
	whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $L' = 0.53 * 0.6 + (1 - .6)$ $= 0.71$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is single, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
    <attribute name="val" type="ST_Border" use="required"/>
    <attribute name="color" type="ST_HexColor" use="optional"/>
    <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
    <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
    <attribute name="space" type="ST_PointMeasure" use="optional"/>
    <attribute name="shadow" type="ST_OnOff" use="optional"/>
    <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

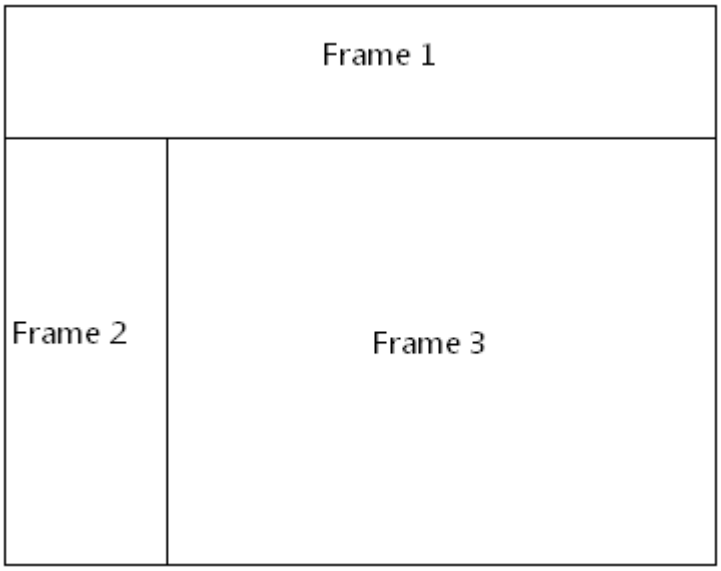
2.15.2.22 linkedToFile (Maintain Link to Existing File)

This element specifies that the file referenced by the sourceFileName element (§2.15.2.38) as the basis for the current frame shall not be changed, even when the file defined by the parent frameset is moved - i.e. the link shall remain exactly as specified.

[*Guidance*: Typically, when a document is incorporated into a frameset, a copy of that document is made such that all files encompassing the frameset are stored in a single subdirectory (so they can be moved as a single unit). However, if the link to the current file is absolute and shall not be changed even when the location of the main frameset document, then this element shall be set to indicate that setting. *end guidance*]

If this element is omitted, then a new file may be created as necessary when the parent frameset document is resaved to another location.

[*Example*: Consider a WordprocessingML document which serves as the frameset container for a frameset consisting of the following three frames:



The frameset properties for this document are specified by the following WordprocessingML within the web page settings:

```
<w:frameset>
  …
  <w:frame>
    <w:sz w:val="20%" />
    <w:name w:val="Frame 1" />
    <w:sourceFileName r:id="rId1" />
    <w:linkedToFile w:val="true" />
  </w:frame>
  <w:frameset>
    …
  </w:frameset>
</w:frameset>
```

The linkedToFile element specifies that the frame source location specified by the sourceFileName element (§2.15.2.38) shall not be modified, even if the parent frameset document is resaved to another location. *end example*]

Parent Elements
frame (§2.15.2.16)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.2.23 marBottom (Bottom Margin for HTML div)

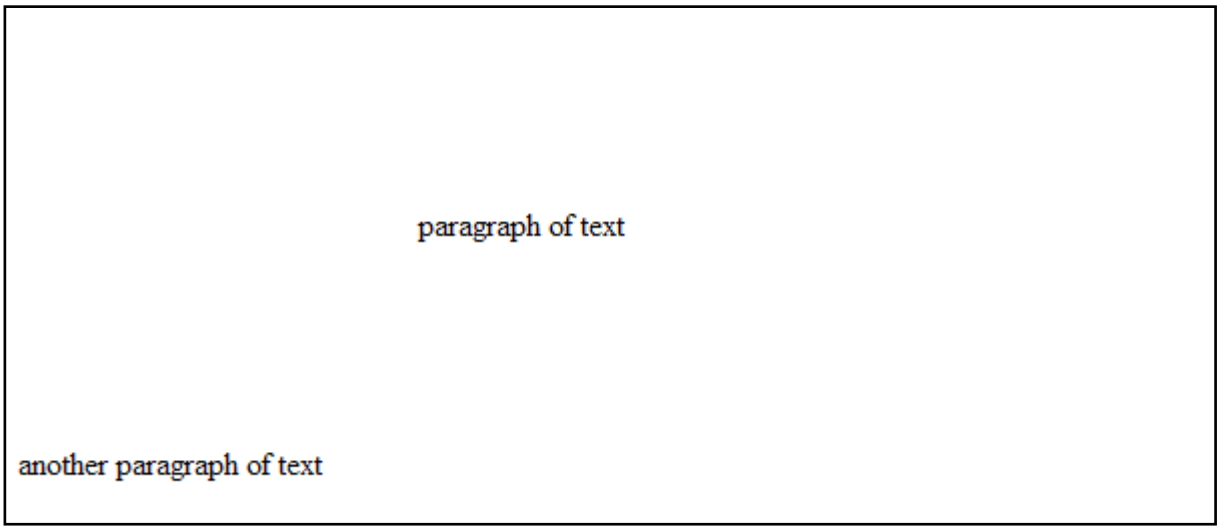
This element specifies the margin which shall be displayed at the bottom of the boundaries of the current HTML `div` object.

If this element is omitted, then this HTML `div` object shall not have a bottom margin.

[*Example*: Consider a simple HTML document defined as follows:

```
<html>
  <body>
    <div style="margin-top:100px; margin-left:200px; margin-right:50px; margin-
bottom:100px">
      <p>paragraph of text</p>
    </div>
    <p>another paragraph of text</p>
  </body>
</html>
```

This HTML would therefore normally appear as follows (image scaled appropriately):



Now, when this document is saved in the WordprocessingML format, the information stored on the `div` elements is stored in the web setting part as follows:

```
<w:divs>
  <w:div w:id="1785730240">
    <w:marLeft w:val="3000" />
    <w:marRight w:val="750" />
    <w:marTop w:val="1500" />
    <w:marBottom w:val="1500" />
  </w:div>
</w:divs>
```

The marBottom element specifies margin information about the bottom margin for the single HTML `div` structure in the document; in this case, a 75 point bottom margin. The initial 100 pixel margin was converted to 75 points using the following logic:

$$100\text{px} * \frac{1 \text{ inch}}{96 \text{ px}} * \frac{1440 \text{ twentieth points}}{1 \text{ inch}} = 1500 \text{ twentieth points (75 points)}$$

end example]

Parent Elements
div (§2.15.2.6)

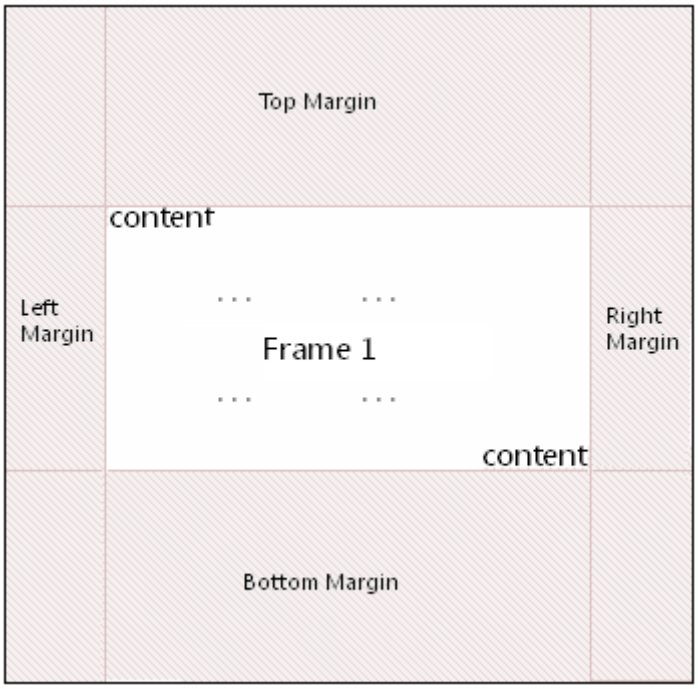
Attributes	Description
val (Positive or Negative Value in Twentieths of a Point)	Specifies a value whose contents shall contain a positive whole number, whose contents consist of a positive or negative measurement in twentieths of a point (equivalent to 1/1440th of an inch). The contents of this measurement shall be interpreted based on the context of the parent XML element. [*Example*: Consider an attribute value of `-720` whose type is ST_SignedTwipsMeasure. This attribute value specifies a value of negative one-half of an inch or -36 points (`-720` twentieths of a point = -36 points = -0.5 inches). *end example*] The possible values for this attribute are defined by the ST_SignedTwipsMeasure simple type (§2.18.88).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SignedTwipsMeasure">
   <attribute name="val" type="ST_SignedTwipsMeasure" use="required"/>
</complexType>
```

2.15.2.24 marH (Top and Bottom Margin for Frame)

This element specifies the top and bottom margin height for a single frame in a frameset document, as follows:



This height is expressed in pixels.

If this element is omitted, then no top or bottom margin shall be used for this frame.

[*Example*: Consider a document that has a frame, where the margin height has been specified and is represented as the following WordprocessingML:

```
<w:frame>
  <w:marH w:val="594"/>
</w:frame>
```

The marH element has a val attribute value of 594, which specifies that this frame has a top and bottom margin value of 594 pixels, resulting in 594 pixels of space between the content and the top and bottom margins of the frame. *end example*]

Parent Elements
frame (§2.15.2.16)

Attributes	Description
val (Measurement in Pixels)	Specifies a value whose contents shall contain a positive whole number, whose contents consist of a positive measurement in pixels. The contents of this measurement shall be interpreted based on the context of the parent XML element.

Attributes	Description
	[*Example*: Consider an attribute value of `960` whose type is ST_PixelsMeasure. This attribute value specifies a value of 960 pixels. *end example*] The possible values for this attribute are defined by the ST_PixelsMeasure simple type (§2.18.74).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_PixelsMeasure">
   <attribute name="val" type="ST_PixelsMeasure" use="required"/>
</complexType>
```

2.15.2.25 marLeft (Left Margin for HTML div)

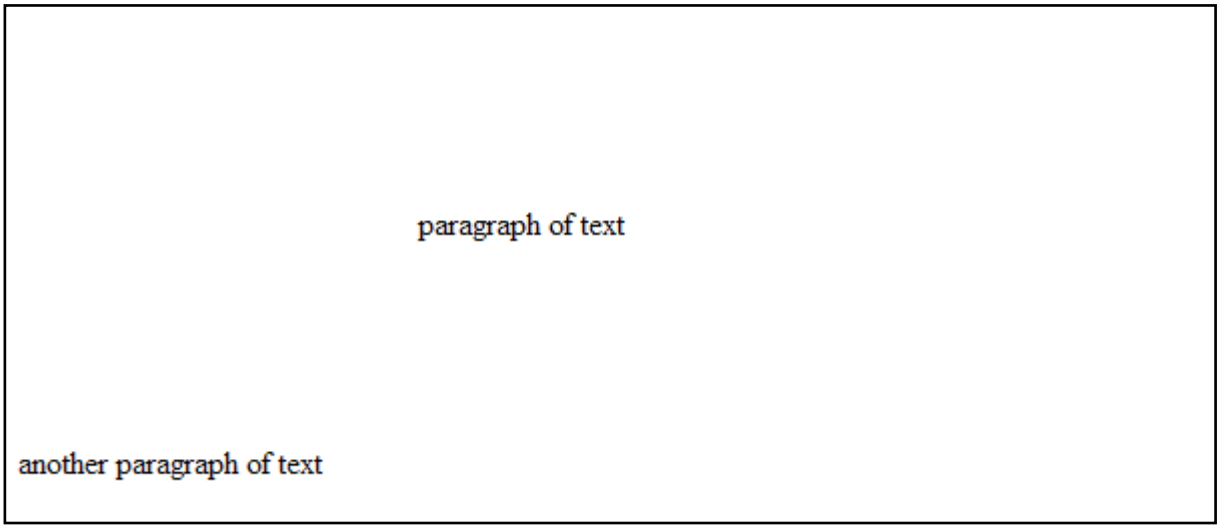
This element specifies the margin which shall be displayed at the left of the boundaries of the current HTML `div` object.

If this element is omitted, then this HTML `div` object shall not have a left margin.

[*Example*: Consider a simple HTML document defined as follows:

```
<html>
  <body>
    <div style="margin-top:100px; margin-left:200px; margin-right:50px; margin-
bottom:100px">
      <p>paragraph of text</p>
    </div>
    <p>another paragraph of text</p>
  </body>
</html>
```

This HTML would therefore normally appear as follows (image scaled appropriately):



Now, when this document is saved in the WordprocessingML format, the information stored on the div elements is stored in the web setting part as follows:

```
<w:divs>
  <w:div w:id="1785730240">
    <w:marLeft w:val="3000" />
    <w:marRight w:val="750" />
    <w:marTop w:val="1500" />
    <w:marBottom w:val="1500" />
  </w:div>
</w:divs>
```

The marLeft element specifies margin information about the left margin for the single HTML div structure in the document; in this case, a 150 point left margin. The initial 200 pixel margin was converted to 150 points using the following logic:

$$200\text{px} * \frac{1\text{ inch}}{96\text{ px}} * \frac{1440\text{ twentieth points}}{1\text{ inch}} = 3000\text{ twentieth points } (150\text{ points})$$

end example]

Parent Elements
div (§2.15.2.6)

Attributes	Description
val (Positive or Negative Value in Twentieths of a Point)	Specifies a value whose contents shall contain a positive whole number, whose contents consist of a positive or negative measurement in twentieths of a point (equivalent to 1/1440th of an inch). The contents of this measurement shall be interpreted based on the context of the parent XML element. [*Example*: Consider an attribute value of -720 whose type is ST_SignedTwipsMeasure. This attribute value specifies a value of negative one-half of an inch or -36 points (-720 twentieths of a point = -36 points = -0.5 inches). *end example*] The possible values for this attribute are defined by the ST_SignedTwipsMeasure simple type (§2.18.88).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SignedTwipsMeasure">
   <attribute name="val" type="ST_SignedTwipsMeasure" use="required"/>
</complexType>
```

2.15.2.26 marRight (Right Margin for HTML div)

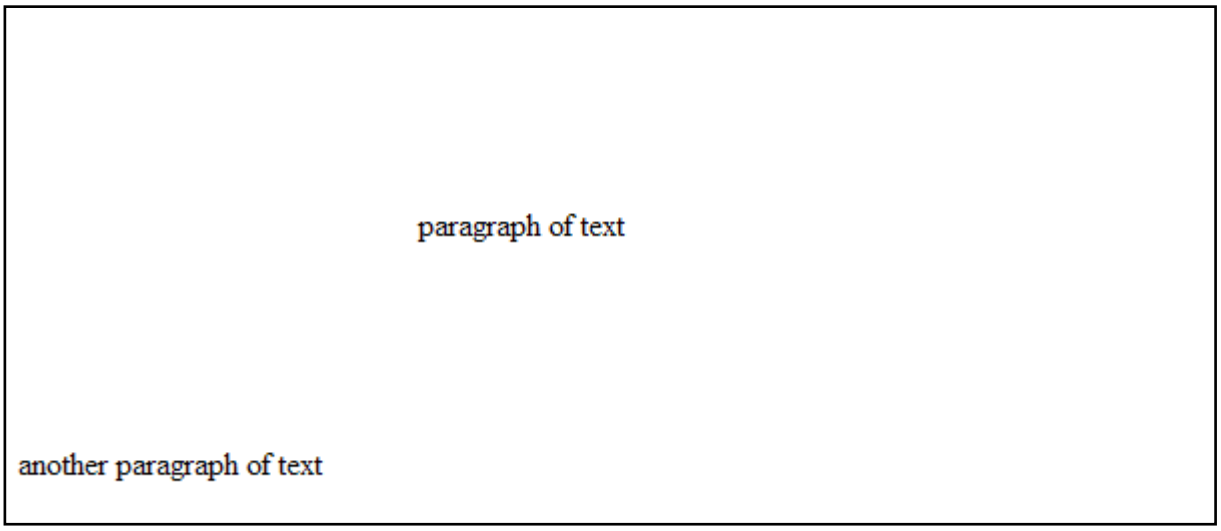
This element specifies the margin which shall be displayed at the right of the boundaries of the current HTML `div` object.

If this element is omitted, then this HTML `div` object shall not have a right margin.

[*Example*: Consider a simple HTML document defined as follows:

```
<html>
  <body>
    <div style="margin-top:100px; margin-left:200px; margin-right:50px; margin-
bottom:100px">
      <p>paragraph of text</p>
    </div>
    <p>another paragraph of text</p>
  </body>
</html>
```

This HTML would therefore normally appear as follows (image scaled appropriately):



Now, when this document is saved in the WordprocessingML format, the information stored on the `div` elements is stored in the web setting part as follows:

```
<w:divs>
  <w:div w:id="1785730240">
    <w:marLeft w:val="3000" />
    <w:marRight w:val="750" />
    <w:marTop w:val="1500" />
    <w:marBottom w:val="1500" />
  </w:div>
</w:divs>
```

The marRight element specifies margin information about the right margin for the single HTML `div` structure in the document; in this case, a 37.5 point right margin. The initial 50 pixel margin was converted to 37.5 points using the following logic:

$$50\text{px} * \frac{1 \text{ inch}}{96 \text{ px}} * \frac{1440 \text{ twentieth points}}{1 \text{ inch}} = 750 \text{ twentieth points (37.5 points)}$$

end example]

Parent Elements
div (§2.15.2.6)

Attributes	Description
val (Positive or Negative Value in Twentieths of a Point)	Specifies a value whose contents shall contain a positive whole number, whose contents consist of a positive or negative measurement in twentieths of a point (equivalent to 1/1440th of an inch). The contents of this measurement shall be interpreted based on the context of the parent XML element. [*Example*: Consider an attribute value of `-720` whose type is ST_SignedTwipsMeasure. This attribute value specifies a value of negative one-half of an inch or -36 points (`-720` twentieths of a point = -36 points = -0.5 inches). *end example*] The possible values for this attribute are defined by the ST_SignedTwipsMeasure simple type (§2.18.88).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SignedTwipsMeasure">
   <attribute name="val" type="ST_SignedTwipsMeasure" use="required"/>
</complexType>
```

2.15.2.27 marTop (Top Margin for HTML div)

This element specifies the margin which shall be displayed at the top of the boundaries of the current HTML `div` object.

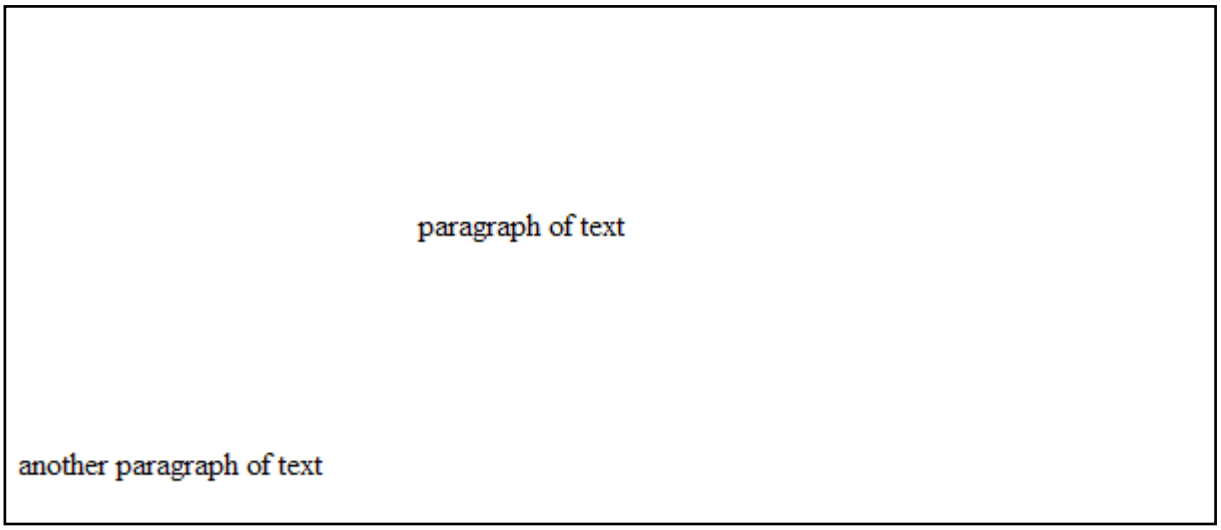
If this element is omitted, then this HTML `div` object shall not have a top margin.

[*Example*: Consider a simple HTML document defined as follows:

```
<html>
  <body>
    <div style="margin-top:100px; margin-left:200px; margin-right:50px; margin-
bottom:100px">
      <p>paragraph of text</p>
```

```
    </div>
    <p>another paragraph of text</p>
  </body>
</html>
```

This HTML would therefore normally appear as follows (image scaled appropriately):



Now, when this document is saved in the WordprocessingML format, the information stored on the `div` elements is stored in the web setting part as follows:

```
<w:divs>
  <w:div w:id="1785730240">
    <w:marLeft w:val="3000" />
    <w:marRight w:val="750" />
    <w:marTop w:val="1500" />
    <w:marBottom w:val="1500" />
  </w:div>
</w:divs>
```

The marTop element specifies margin information about the top margin for the single HTML `div` structure in the document; in this case, a 75 point top margin. The initial 100 pixel margin was converted to 75 points using the following logic:

$$100\text{px} * \frac{1 \text{ inch}}{96 \text{ px}} * \frac{1440 \text{ twentieth points}}{1 \text{ inch}} = 1500 \text{ twentieth points (75 points)}$$

end example]

Parent Elements
div (§2.15.2.6)

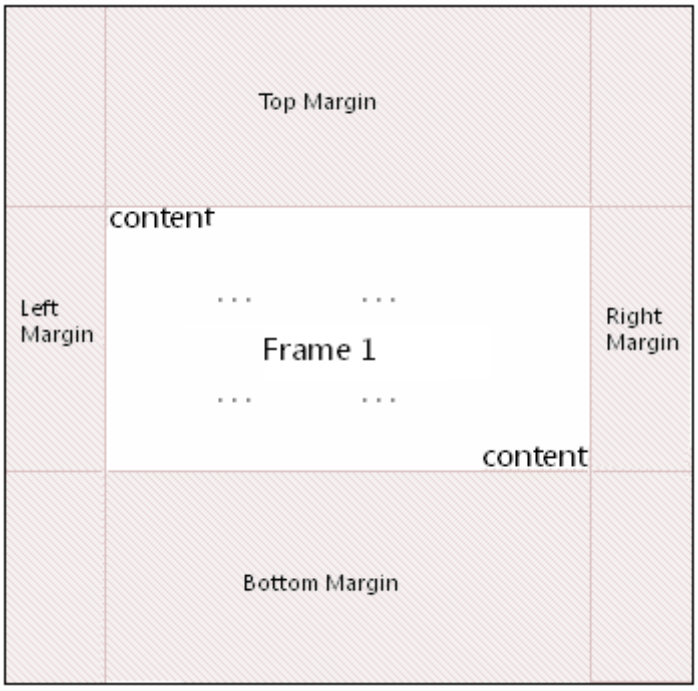
Attributes	Description
val (Positive or Negative Value in Twentieths of a Point)	Specifies a value whose contents shall contain a positive whole number, whose contents consist of a positive or negative measurement in twentieths of a point (equivalent to 1/1440th of an inch). The contents of this measurement shall be interpreted based on the context of the parent XML element. [*Example*: Consider an attribute value of `-720` whose type is ST_SignedTwipsMeasure. This attribute value specifies a value of negative one-half of an inch or -36 points (`-720` twentieths of a point = -36 points = -0.5 inches). *end example*] The possible values for this attribute are defined by the ST_SignedTwipsMeasure simple type (§2.18.88).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SignedTwipsMeasure">
   <attribute name="val" type="ST_SignedTwipsMeasure" use="required"/>
</complexType>
```

2.15.2.28 marW (Left and Right Margin for Frame)

This element specifies the left and right margin height for a single frame in a frameset document, as follows:



This height is expressed in pixels.

If this element is omitted, then no left or right margin shall be used for this frame.

[*Example*: Consider a document that has a frame, where the frame's margins have been specified and is represented as the following WordprocessingML:

```
<w:frame>
  <w:marW w:val="294"/>
</w:frame>
```

The marW element has a val attribute value of 294, which specifies that this frame has a left and right margin value of 294 pixels, resulting in 294 pixels of space between the content and the left and right margins of the frame. *end example*]

Parent Elements
frame (§2.15.2.16)

Attributes	Description
val (Measurement in Pixels)	Specifies a value whose contents shall contain a positive whole number, whose contents consist of a positive measurement in pixels. The contents of this measurement shall be interpreted based on the context of the parent XML element. [*Example*: Consider an attribute value of 960 whose type is ST_PixelsMeasure. This attribute value specifies a value of 960 pixels. *end example*] The possible values for this attribute are defined by the ST_PixelsMeasure simple type (§2.18.74).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_PixelsMeasure">
   <attribute name="val" type="ST_PixelsMeasure" use="required"/>
</complexType>
```

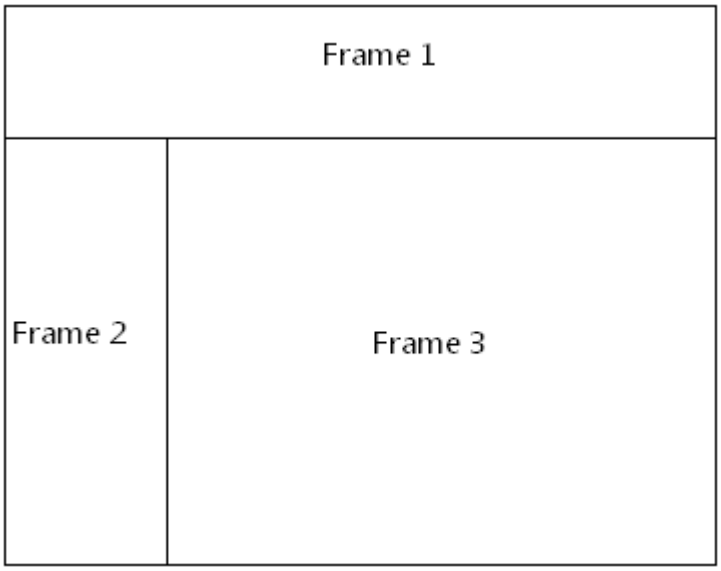
2.15.2.29 name (Frame Name)

This element specifies the name of a single frame within a frameset document. This property is analogous to the name attribute on the frame element in HTML.

[*Note*: The name of a frame may be used in web pages that reference a frame via targeted links, etc. *end note*]

If this element is omitted, then the current frame shall have no name associated with it.

[*Example*: Consider a WordprocessingML document which serves as the frameset container for a frameset consisting of the following three frames:



The frameset properties for this document are specified by the following WordprocessingML within the web page settings:

```
<w:frameset>
  …
  <w:frame>
    <w:name w:val="Frame 1" />
  </w:frame>
  <w:frameset>
    …
    <w:frame>
      <w:name w:val="Frame 2" />
    </w:frame>
    <w:frame>
      <w:name w:val="Frame 3" />
    </w:frame>
  </w:frameset>
</w:frameset>
```

The name element specifies the name for each frame within this frameset; in this case, the frames have names of `Frame 1`, `Frame 2`, and `Frame 3` respectively. *end example*]

Parent Elements
frame (§2.15.2.16)

Attributes	Description
val (String Value)	Specifies that its contents will contain a string.

Attributes	Description

	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.15.2.30 noBorder (Do Not Display Frameset Splitters)

This element specifies whether the splitters shall be displayed for the contents of the frameset in this WordprocessingML document. This element shall only be honored on the root frameset for this document, and may be ignored for all nested framesets in this document. If this element is present, then no splitters shall be displayed, and all other frameset splitter properties may be ignored.

If this element is omitted, then the splitters in this document shall be displayed as defined by the w and color elements.

[*Example*: Consider a frameset consisting of the following three frames:

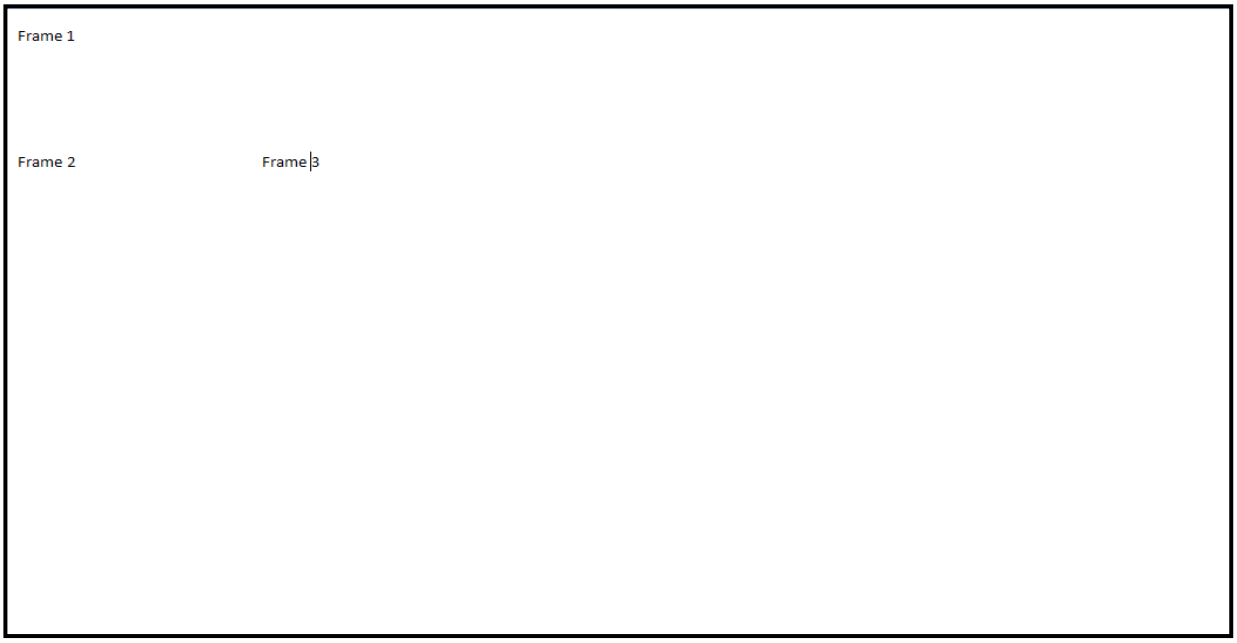
The following properties define the presentation of the splitter bars within this frameset:

```
<w:frameset>
  <w:framesetSplitbar>
    <w:w w:val="200" />
    <w:color w:val="0000FF" />
  </w:framesetSplitbar>
  …
</w:frameset>
```

If the noBorder element is also specified:

```
<w:frameset>
  <w:framesetSplitbar>
    <w:w w:val="200" />
    <w:color w:val="0000FF" />
    <w:noBorder w:val="true" />
  </w:framesetSplitbar>
  …
</w:frameset>
```

Then all frameset splitters are suppressed:



The noBorder element's val attribute has a value of `true`, which specifies that the splitters for this document shall not be displayed. *end example*]

Parent Elements
framesetSplitbar (§2.15.2.20)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

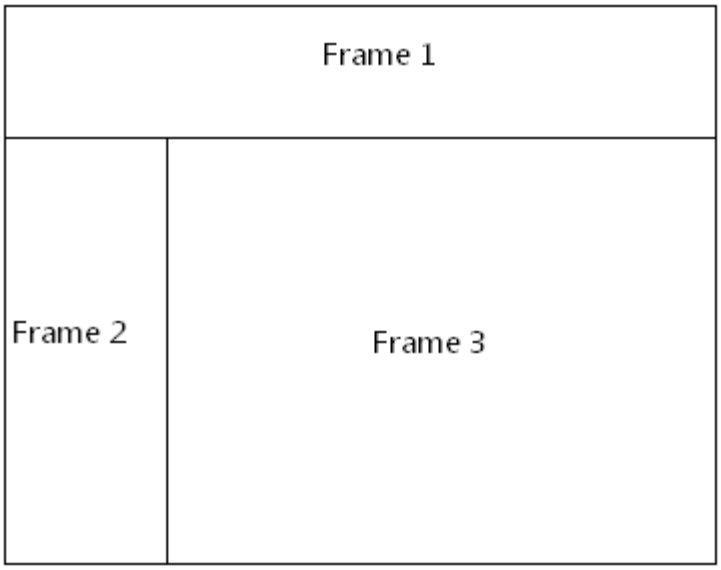
```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.2.31 noResizeAllowed (Frame Cannot Be Resized)

This element specifies whether or not the size of the current frame shall be modifiable (i.e. whether the frame can be resized) when the contents of this document are saved as HTML and displayed in a web browser. When this element is set, the size of the frame shall be set to its current values. This property is analogous to the `noresize` attribute on the `frame` element in HTML.

If this element is omitted, the size of the frame shall be modifiable (the frame may be resized when it is displayed).

[*Example*: Consider a WordprocessingML document which serves as the frameset container for a frameset consisting of the following three frames:



The frameset properties for this document are specified by the following WordprocessingML within the web page settings:

```
<w:frameset>
  …
  <w:frameset>
    …
    <w:frame>
      <w:name w:val="Frame 2" />
      <w:noResizeAllowed w:val="true" />
    </w:frame>
    …
  </w:frameset>
</w:frameset>
```

The noResizeAllowed element has a val attribute of `true`, which specifies that the size of the frame specified by `Frame 2` shall not be modifiable (the two borders which intersect that frame cannot be resized). *end example*]

Parent Elements
frame (§2.15.2.16)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.2.32 optimizeForBrowser (Disable Features Not Supported by Target Web Browser)

This element specifies whether applications should attempt to detect the target web browser for any web page produced from this document, and subsequently disable all user interface and output which is not supported by that target web browser.

The target web browser can be determined by the state of the following elements:

- allowPNG
- doNotRelyOnCSS
- relyOnVML
- doNotSaveWebPagesAsSingleFile

The following table determines how this determination is made:

Settings	Target Browser

Settings	Target Browser
allowPNG is off doNotRelyOnCSS is on relyOnVML is off doNotSaveWebPagesAsSingleFile is on	Microsoft Internet Explorer 3.0 or later Netscape Navigator 3.0 or later
allowPNG is off doNotRelyOnCSS is off relyOnVML is off doNotSaveWebPagesAsSingleFile is on	Netscape Navigator 4.0 or later
allowPNG is off doNotRelyOnCSS is off relyOnVML is off doNotSaveWebPagesAsSingleFile is off	Microsoft Internet Explorer 4.0 or later
allowPNG is off doNotRelyOnCSS is off relyOnVML is on doNotSaveWebPagesAsSingleFile is off	Microsoft Internet Explorer 5.0 or later
allowPNG is on doNotRelyOnCSS is off relyOnVML is on doNotSaveWebPagesAsSingleFile is off	Microsoft Internet Explorer 6.0 or later

If this element is omitted, then no user interface or output which is not supported by that target web browser shall be disabled.

[*Example*: Consider a document whose web settings part contains the following WordprocessingML:

```
<w:webSettings>
    …
    <w:optimizeForBrowser />
    <w:allowPNG w:val="on"/>
    <w:relyOnVML w:val="on"/>
</w:webSettings>
```

The optimizeForBrowser element specifies that all settings which are not compatible with the target web browser shall be disabled. Since the settings of the four element described above match a target browser of Microsoft Internet Explorer 6.0, features not supported by Microsoft Internet Explorer 6.0 shall be disabled. *end example*]

Parent Elements
webSettings (§2.15.2.44)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.2.33 pixelsPerInch (Pixels per Inch for Graphics/Images)

This element specifies the number of pixels per inch (or density) that will be used for the display of pictures or table cells when a WordprocessingML document is saved as a web page. The size that is specified by this element affects the size of the pictures or table cells relative to the size of text in the document. The pixels per inch (ppi) measurement is relative to the screen resolution, and the resulting physical dimensions of the resulting image or cell in pixels (which are used in web pages, but not for printed documents) are the result of the original dimensions (in inches) multiplied by the number of pixels per inch.

The range of values for this element is typically from 19 to 480 pixels per inch. The common settings for popular screen sizes are 72, 96, and 120 pixels per inch.

If this element is omitted, then a default size of 96 pixels per inch shall be used when determining the number of pixels for images and/or table cells within this document.

[*Note*: This setting is typically only specified if the target screen resolution for the web page is known, as defined by the targetScreenSz element (§2.15.2.41) to set the optimum screen size for the web page. *end note*]

[*Example*: Consider a WordprocessingML document which contains the following content within the web settings part:

```
<w:webSettings>
  <w:pixelsPerInch w:val="200" />
</w:webSettings>
```

The pixelsPerInch element's val attribute has a value of 200, which specifies that all inches to pixels conversions done when saving this web page shall be done assuming a transformation of 200 pixels per inch. *end example*]

Parent Elements
webSettings (§2.15.2.44)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
    <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.15.2.34 relyOnVML (Utilize VML When Saving as Web Page)

This element specifies whether applications may utilize the Vector Markup Language format when saving the content of this WordprocessingML document as a web page, when graphical elements which can leverage this format are present in the document.

If this element is omitted, then a graphic image format should be used either in place of or in concert with the Vector Markup Language output in order to specify the formatting and positioning for objects which are part of the resulting web page.

[*Note*: This setting is intended for applications to save web pages which can be supported by legacy web browsers which do not support Vector Markup Language when attempting to read and display the resulting web page. *end note*]

[*Example*: Consider a WordprocessingML document which contains the following content within the web settings part:

```
<w:webSettings>
  <w:relyOnVML w:val="false" />
</w:webSettings>
```

The relyOnVML element has a val attribute value of `false`, which specifies that applications should utilize a graphical image version of all objects which could utilize Vector Markup Language output. This does not preclude the use of the VML output, but does specify that a graphical element shall be included as well. *end example*]

Parent Elements
webSettings (§2.15.2.44)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.2.35 right (Right Border for HTML div)

This element specifies the border which shall be displayed at the right of the boundaries of the current HTML `div` object.

If this element is omitted, then this HTML `div` object shall not have a right border.

[*Example*: Consider a simple HTML document defined as follows:

```
<html>
  <body>
    <div style=" border-left-style:solid; border-right-style:groove; border-
right-width:1px; border-top-style:dashed; border-top-width:3px; border-bottom-
style:outset; border-bottom-width:3px">
      <p>paragraph of text</p>
    </div>
  </body>
</html>
```

This HTML would therefore normally appear as follows (image scaled appropriately):

Now, when this document is saved in the WordprocessingML format, the information stored on the `div` elements is stored in the web setting part as follows:

```
<w:divs>
  <w:div w:id="1785730240">
    <w:divBdr>
      <w:top w:val="dashed" w:sz="18" w:space="7" w:color="auto" />
      <w:left w:val="single" w:sz="24" w:space="4" w:color="auto" />
      <w:bottom w:val="outset" w:sz="18" w:color="auto" />
      <w:right w:val="threeDEngrave" w:sz="6" w:color="auto" />
    </w:divBdr>
  </w:div>
</w:divs>
```

The right element specifies border information about the right border for the single HTML `div` structure in the document; in this case, a 0.75 point bottom border of type `threeDEngrave`. The initial 1 pixel border was converted to 0.75 points using the following logic:

$$1\text{px} * \frac{1 \text{ inch}}{96 \text{ px}} * \frac{576 \text{ eighth points}}{1 \text{ inch}} = 6 \text{ eighth points } (0.75 \text{ points})$$

end example]

Parent Elements
divBdr (§2.15.2.7)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value auto, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is true, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML:

Attributes	Description
	<w:bottom w:shadow="true" ... /> This frame's val is true, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object. When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points. When a document has a page border that is relative to the text extents (using a value of text in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points. [*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows: <w:pgBorders w:offsetFrom="page"> <w:bottom … w:space="24/> </w:pgBorders The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*] The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).
sz (Border Width)	Specifies the width of the current border. If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value. If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value. [*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup: <w:top w:val="dashed" w:sz="24" …/> <w:left w:val="dashed" w:sz="24" …/>

Attributes	Description
	<w:bottom w:val="dashed" w:sz="24" …/> <w:right w:val="dashed" w:sz="24" …/> The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*] The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).
themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border. The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document. [*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup: <w:top … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:bottom … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:left … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:right … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255$$

Attributes	Description
	$= 102$ $= 66(hex)$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $L' = 0.53 * 0.75$ $= 0.39698$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border.

Attributes	Description
	[*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255 = 153 = 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$L' = L * Tint_{pct} + (1 - Tint_{pct})$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `4F81BD`. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6) = 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$ and converting back to RGB, we get `95B3D7`. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style.

Attributes	Description
	[*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.15.2.36 saveSmartTagsAsXml (Save Smart Tag Data in XML Property Bag)

This element specifies that the information pertaining to all smart tags () in the current document shall be saved into a separate XML-based property bag at the head of the web page when this WordprocessingML document is saved as a web page.

[*Rationale*: This setting is typically used when saving documents known to contain smart tags as web pages, in order to allow the smart tag data within the web page to be processed as a separate XML document by a separate parser, even though the actual HTML content of the resulting web page cannot be parsed by an XML-based parser. *end rationale*]

If this element is omitted, then the smart tag data of this document shall not be saved into a separate XML-compliant property bag within the HTML output when this document is saved as a web page.

[*Example*: Consider a WordprocessingML document which contains the following content:

Stock symbol: MSFT

Date: 7/4/2006

This document might typically write out the following HTML content:

```
<p>Stock symbol: <st1:stockticker>MSFT</st1:stockticker></p>
```

```
<p>Date: <st1:date ls="trans" Month="7" Day="4"
Year="2006"">7/4/2006</st1:date></p>
```

However, if the WordprocessingML document also contains the following content within the web settings part:

```
<w:webSettings>
  <w:saveSmartTagsAsXml w:val="true" />
</w:webSettings>
```

The saveSmartTagsAsXml element specifies that all smart tags in the document shall also be saved into an XML property bag at the header of the file, for example:

```
<head>
  …
  <xml>
    <o:DocumentSmartTags>
      <st1:stockticker>MSFT</st1:stockticker>
      <st1:date ls="trans" Month="7" Day="4" Year="2006">7/4/2006</st1:date>
    </o:DocumentSmartTags>
  </xml>
  …
</head>
```

This header information is in addition to the normal HTML output. *end example*]

Parent Elements
webSettings (§2.15.2.44)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

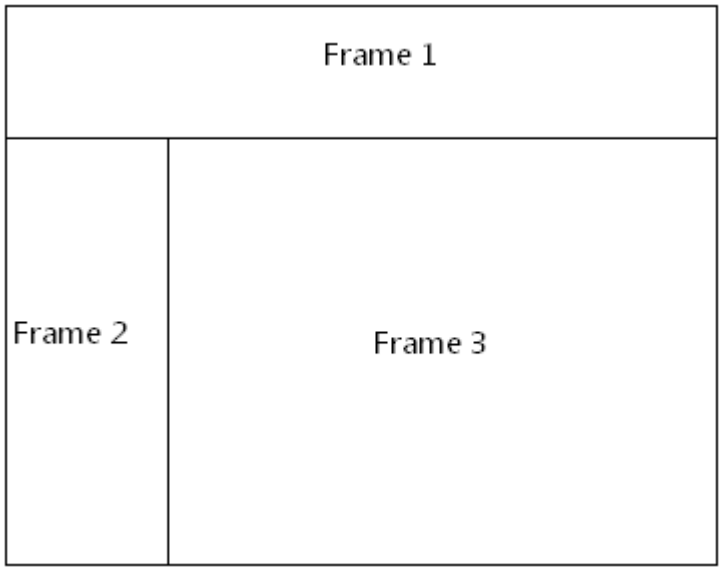
```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.2.37 scrollbar (Scrollbar Display Option)

This element specifies when a scrollbar shall be visible for the contents of the current frame. When this element is set, the val attribute determines exactly when the scrollbar shall be visible. This property is analogous to the `scrolling` attribute on the `frame` element in HTML.

If this element is omitted, the scrollbar shall only be displayed when the contents of the frame exceed the visible space for the frame (i.e. when the scrollbar is needed to display all of the content).

[*Example*: Consider a WordprocessingML document which serves as the frameset container for a frameset consisting of the following three frames:



The frameset properties for this document are specified by the following WordprocessingML within the web page settings:

```
<w:frameset>
  …
  <w:frameset>
    …
    <w:frame>
      <w:name w:val="Frame 2" />
      <w:scrollbar w:val="auto" />
    </w:frame>
    …
  </w:frameset>
```

```
</w:frameset>
```

The scrollbar element has a val attribute of auto, which specifies that the frame shall only display a scrollbar when it is needed to display all of its content. *end example*]

Parent Elements
frame (§2.15.2.16)

Attributes	Description

val (Scrollbar Display Option Value)	Specifies the criteria under which a scrollbar shall be displayed along with the contents of this frameset, as defined by the simple type referenced below.
	
	[*Example*: Consider a frameset definition within a WordprocessingML document which defines the following scrollbar visibility setting:
	
	`<w:frame>`
	`  <w:scrollbar w:val="on" />`
	`  …`
	`</w:frame>`
	
	The val attribute value of on specifies that the scrollbar shall always be displayed, even when it is not needed (i.e. when it would be displayed disabled). *end example*]
	
	The possible values for this attribute are defined by the ST_FrameScrollbar simple type (§2.18.36).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FrameScrollbar">
   <attribute name="val" type="ST_FrameScrollbar" use="required"/>
</complexType>
```

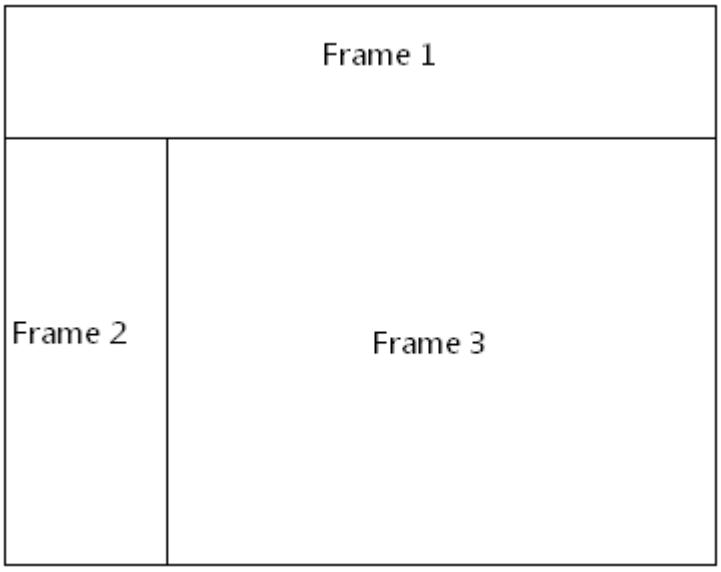
2.15.2.38 sourceFileName (Source File for Frame)

This element specifies the ID for the relationship which specifies the source file for a single frame within a frameset document.

The relationship referenced by this element's id attribute shall exist in the relationship part item for the Web Settings part,or this document shall be considered non-conformant. Also, the type of the relationship referenced by this element's id attribute shall be http://schemas.openxmlformats.org/officeDocument/2006/relationships/frame, or this document shall be considered non-conformant.

If this element is omitted, then no source file is present for the current frame, and one may be created dynamically as needed to display content within the frame.

[*Example*: Consider a WordprocessingML document which serves as the frameset container for a frameset consisting of the following three frames:



The frameset properties for this document are specified by the following WordprocessingML within the web page settings:

```
<w:frameset>
  …
  <w:frameset>
    …
    <w:frame>
      <w:name w:val="Frame 2" />
      <w:sourceFileName r:id="rId5" />
    </w:frame>
    …
  </w:frameset>
</w:frameset>
```

The sourceFileName element specifies that the contents of this frame shall be the contents of the file targeted by the relationship with ID `rId5` in the web settings part's relationship part item. *end example*]

Parent Elements
frame (§2.15.2.16)

Attributes	Description
id (Relationship to Part)	Specifies the relationship ID to a specified part.

Attributes	Description
Namespace: .../officeDocument/2006/relationships	The specified relationship shall match the type required by the parent element: • http://schemas.openxmlformats.org/officeDocument/2006/relationships/footer for the footerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/header for the headerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/font for the embedBold, embedBoldItalic, embedItalic, or embedRegular elements • http://schemas.openxmlformats.org/officeDocument/2006/relationships/printerSettings for the printerSettings element [*Example*: Consider an XML element which has the following id attribute: `<… r:id="rId10" />` The markup specifies the associated relationship part with relationship ID `rId1` contains the corresponding relationship information for the parent XML element. *end example*] The possible values for this attribute are defined by the ST_RelationshipId simple type (§7.8.2.1).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Rel">
   <attribute ref="r:id" use="required"/>
</complexType>
```

2.15.2.39 sz (Frame Size)

This element specifies the size for a single frame within a frameset.

This size shall be interpreted based on the contents of the frameLayout element (§2.15.2.17) for the parent frameset, as follows:

- If the val attribute on that element is `cols`, then this element specifies the width of the frame
- If the val attribute on that element is `rows`, then this element specifies the height of the frame

Once the axis of this measurement has been established using the criteria above, the actual value of the measurement shall be determined by the following:

- If the val attribute ends in a asterisk (*), then this measurement is a relative measurement (relative to all other frames in this frameset).
- If the val attribute ends in a percentage symbol (%), then this measurement is a percentage of the height and/or width of the parent window, respectively.
- Otherwise, the value of the val attribute specifies the size of the frame in pixels. This measurement shall be interpreted in the context of the pixelsPerInch element (§2.15.2.33) to determine the width of the resulting measurement in inches.

If this element is omitted, then no information shall be implied about the size of the current frame.

[*Example*: Consider a frameset consisting of the following three frames:

The following properties define the presentation of the top frame within this frameset:

```
<w:frameset>
  …
  <w:frame>
    <w:sz w:val="300" />
    <w:name w:val="Frame 1" />
  </w:frame>
  …
  <w:pixelsPerInch w:val="150" />
</w:frameset>
```

The sz element's val attribute specifies that the size of this frame is `300` - which translates to a height of exactly 300 pixels tall. In addition, this document specifies that the intended number of pixels per inch for this measurement is `150`, resulting in a 2" tall frame height. *end example*]

Parent Elements
frame (§2.15.2.16)

Attributes	Description
val (String Value)	Specifies that its contents will contain a string.

Attributes	Description

	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.15.2.40 sz (Nested Frameset Size)

This element specifies the size for a frameset that has been nested within another frameset. If this size appears on a root frameset, then it may be ignored and the main frameset shall encompass the entire window.

This size shall be interpreted based on the contents of the frameLayout element (§2.15.2.17) for the parent frameset (not the current nested frameset), as follows:

- If the val attribute on that element is `cols`, then this element specifies the width of the frameset
- If the val attribute on that element is `rows`, then this element specifies the height of the frameset

Once the axis of this measurement has been established using the criteria above, the actual value of the measurement shall be determined by the following:

- If the val attribute ends in a asterisk (*), then this measurement is a relative measurement (relative to all other frames in this frameset).

- If the val attribute ends in a percentage symbol (%), then this measurement is a percentage of the height and/or width of the parent frameset, respectively.
- Otherwise, the value of the val attribute specifies the size of the frameset in pixels. This measurement shall be interpreted in the context of the pixelsPerInch element (§2.15.2.33) to determine the width of the resulting measurement in inches.

If this element is omitted, then no information shall be implied about the size of the current frameset.

[*Example*: Consider a nested frameset defined as follows:

```
<w:frameset>
  …
  <w:frameset>
    <w:sz w:val="50%" />
    …
  </w:frameset>
  …
  <w:pixelsPerInch w:val="150" />
</w:frameset>
```

The sz element's val attribute specifies that the size of this nested frameset is `50%` - which translates to a width of fifty percent of the width of the parent frameset's height. *end example*]

Parent Elements
frameset (§2.15.2.18); frameset (§2.15.2.19)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`

Attributes	Description
	</w:sdtPr> In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.15.2.41 targetScreenSz (Target Screen Size for Web Page)

This element specifies the ideal minimum target screen size (width by height, specified in pixels) on which web pages generated when saving this document will be displayed. This setting may be used to optimize the output of web pages produced from this document.

If this element is omitted, then the target screen size for web pages produced from this document shall be assumed to be 800x600.

[*Example*: Consider a WordprocessingML document which contains the following content within the web settings part:

```
<w:webSettings>
  <w:targetScreenSz w:val="1600x1200" />
</w:webSettings>
```

The targetScreenSz element's val attribute has a value of 1600x1200, which specifies that a target screen size of 1600 by 1200 pixels shall be assumed when saving this document as a web page. *end example*]

Parent Elements
webSettings (§2.15.2.44)

Attributes	Description
val (Target Screen Size Value)	Specifies the target screen size for web pages produced by this document, as defined by the simple type referenced below. [*Example*: Consider a WordprocessingML document which contains the following content within the web settings part: <w:webSettings> <w:targetScreenSz w:val="1024x768" />

Attributes	Description
	</w:webSettings> The val attribute has a value of 1024x768, which specifies that a target screen size of 1024 by 768 pixels shall be assumed when saving this document as a web page. *end example*] The possible values for this attribute are defined by the ST_TargetScreenSz simple type (§2.18.93).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TargetScreenSz">
   <attribute name="val" type="ST_TargetScreenSz" use="required"/>
</complexType>
```

2.15.2.42 top (Top Border for HTML div)

This element specifies the border which shall be displayed at the top of the boundaries of the current HTML div object.

If this element is omitted, then this HTML div object shall not have a top border.

[*Example*: Consider a simple HTML document defined as follows:

```
<html>
  <body>
    <div style=" border-left-style:solid; border-right-style:groove; border-
right-width:1px; border-top-style:dashed; border-top-width:3px; border-bottom-
style:outset; border-bottom-width:3px">
      <p>paragraph of text</p>
    </div>
  </body>
</html>
```

This HTML would therefore normally appear as follows (image scaled appropriately):

Now, when this document is saved in the WordprocessingML format, the information stored on the div elements is stored in the web setting part as follows:

```
<w:divs>
  <w:div w:id="1785730240">
    <w:divBdr>
      <w:top w:val="dashed" w:sz="18" w:space="7" w:color="auto" />
      <w:left w:val="single" w:sz="24" w:space="4" w:color="auto" />
      <w:bottom w:val="outset" w:sz="18" w:color="auto" />
      <w:right w:val="threeDEngrave" w:sz="6" w:color="auto" />
    </w:divBdr>
  </w:div>
</w:divs>
```

The top element specifies border information about the top border for the single HTML `div` structure in the document; in this case, a 2.25 point bottom border of type `dashed`. The initial 3 pixel border was converted to 2.25 points using the following logic:

$$3\text{px} * \frac{1 \text{ inch}}{96 \text{ px}} * \frac{576 \text{ eighth points}}{1 \text{ inch}} = 18 \text{ eighth points } (2.25 \text{ points})$$

end example]

Parent Elements
divBdr (§2.15.2.7)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value `auto`, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create	Specifies whether the specified border should be modified to create a frame effect by

Attributes	Description
Frame Effect)	reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object. When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points. When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points. [*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:

Attributes	Description
	<w:pgBorders w:offsetFrom="page"> <w:bottom … w:space="24/> </w:pgBorders> The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*] The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).
sz (Border Width)	Specifies the width of the current border. If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value. If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value. [*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup: <w:top w:val="dashed" w:sz="24" …/> <w:left w:val="dashed" w:sz="24" …/> <w:bottom w:val="dashed" w:sz="24" …/> <w:right w:val="dashed" w:sz="24" …/> The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*] The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).
themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border. The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document. [*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup: <w:top … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />

Attributes	Description
	<w:bottom … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:left … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:right … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 = 102 = 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$.

Attributes	Description
	Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L^{'} = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255$$ $$= 153$$ $$= 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}^{'} = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color,

Attributes	Description
	whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $L' = 0.53 * 0.6 + (1 - .6)$ $= 0.71$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is single, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
    <attribute name="val" type="ST_Border" use="required"/>
    <attribute name="color" type="ST_HexColor" use="optional"/>
    <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
    <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
    <attribute name="space" type="ST_PointMeasure" use="optional"/>
    <attribute name="shadow" type="ST_OnOff" use="optional"/>
    <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.15.2.43 w (Frameset Splitter Width)

This element specifies the width of the splitters within the frameset in this WordprocessingML document. This element shall only be honored on the root frameset for this document, and may be ignored for all nested framesets in this document.

If this element is omitted, then the default width of the splitters in this document shall be 4.5 points (90 twentieths of a point) wide. If the noBorder element (§2.15.2.30) is also specified, then this element shall be ignored and no splitters shall be displayed.

[*Example*: Consider a frameset consisting of the following three frames:

The following properties define the presentation of the splitter bars within this frameset:

```
<w:frameset>
  <w:framesetSplitbar>
    <w:w w:val="200" />
    <w:color w:val="0000FF" />
  </w:framesetSplitbar>
  …
</w:frameset>
```

The w element's val attribute specifies that the splitter shall be 10 points (200 twentieths of a point) wide when the contents of this document are displayed. *end example*]

Parent Elements
framesetSplitbar (§2.15.2.20)

Attributes	Description
val (Measurement in Twentieths of a Point)	Specifies a positive measurement value, specified in twentieths of a point. This value is interpreted based on the context of the parent XML element. [*Example*: Consider the following WordprocessingML element with a val attribute containing a positive measurement in twentieths of a point: `<w:… w:val="720" />` The val attribute has a value of 720, specifying that this measurement value is 720 twentieths of a point (0.5"). This value is interpreted by the parent element as needed. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TwipsMeasure">
   <attribute name="val" type="ST_TwipsMeasure" use="required"/>
</complexType>
```

2.15.2.44 webSettings (Web Page Settings)

This element specifies the set of web page settings that have been specified for a single WordprocessingML document. This element is the root element for the Web Settings part within a WordprocessingML document.

[*Example*: Consider the following WordprocessingML fragment for the web page settings in a WordprocessingML document:

```
<w:webSettings>
  <w:frameset>
    …
  </w:frameset>
  <w:doNotUseLongFileNames w:val="true" />
</w:webSettings>
```

The webSettings element contains all of the web page settings for this document. In this case, the web page settings specified for this document are: a frameset defined using the frameset element (§2.15.2.18); and a setting specifying that when this file is saved as a web page, all resulting files shall not exceed 8.3 characters in length using the doNotUseLongFileNames element (§2.15.2.13). *end example*]

Parent Elements
Root element of WordprocessingML Web Settings part

Child Elements	Subclause
allowPNG (Allow PNG as Graphic Format)	§2.15.2.1
divs (Information about HTML div Elements)	§2.15.2.8
doNotOrganizeInFolder (Do Not Place Supporting Files in Subdirectory)	§2.15.2.10
doNotRelyOnCSS (Do Not Rely on CSS for Font Face Formatting)	§2.15.2.11
doNotSaveAsSingleFile (Recommend Web Page Format over Single File Web Page Format)	§2.15.2.12
doNotUseLongFileNames (Do Not Use File Names Longer than 8.3 Characters)	§2.15.2.13
encoding (Output Encoding When Saving as Web Page)	§2.15.2.14
frameset (Root Frameset Definition)	§2.15.2.18
optimizeForBrowser (Disable Features Not Supported by Target Web Browser)	§2.15.2.32
pixelsPerInch (Pixels per Inch for Graphics/Images)	§2.15.2.33
relyOnVML (Utilize VML When Saving as Web Page)	§2.15.2.34
saveSmartTagsAsXml (Save Smart Tag Data in XML Property Bag)	§2.15.2.36
targetScreenSz (Target Screen Size for Web Page)	§2.15.2.41

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_WebSettings">
   <sequence>
      <element name="frameset" type="CT_Frameset" minOccurs="0"/>
      <element name="divs" type="CT_Divs" minOccurs="0"/>
      <element name="encoding" type="CT_String" minOccurs="0"/>
      <element name="optimizeForBrowser" type="CT_OnOff" minOccurs="0"/>
      <element name="relyOnVML" type="CT_OnOff" minOccurs="0"/>
      <element name="allowPNG" type="CT_OnOff" minOccurs="0"/>
      <element name="doNotRelyOnCSS" type="CT_OnOff" minOccurs="0"/>
      <element name="doNotSaveAsSingleFile" type="CT_OnOff" minOccurs="0"/>
      <element name="doNotOrganizeInFolder" type="CT_OnOff" minOccurs="0"/>
      <element name="doNotUseLongFileNames" type="CT_OnOff" minOccurs="0"/>
      <element name="pixelsPerInch" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="targetScreenSz" type="CT_TargetScreenSz" minOccurs="0"/>
      <element name="saveSmartTagsAsXml" type="CT_OnOff" minOccurs="0"/>
   </sequence>
</complexType>
```

2.15.3 Compatibility Settings

The last group of settings stored in WordprocessingML is compatibility settings. *Compatibility Settings* are optional settings used to preserve visual fidelity of documents created in earlier word processing applications. Some of these settings provide affordance for specific behaviors, described in detail below; and others simply instruct applications to mimic the behavior of an existing word processing application.

If compatibility settings are needed, they are stored in the Document Settings part.

It is important to note that all compatibility settings are optional in nature - applications may freely ignore all behaviors described within this section and these settings should not be added unless compatibility is specifically needed in one or more cases. The compatibility settings are provided for backward compatibility with documents created in legacy applications. As such, a number of the settings reference specific applications and specific versions of those applications. This is solely for backward compatibility reasons, and any of those settings are ignorable.

[*Example*: Consider the following WordprocessingML fragment for the compatibility settings in a WordprocessingML document:

```
<w:settings>
  …
  <w:compat>
    <w:noTabHangInd />
  </w:compat>
</w:settings>
```

The compat element contains all of the document settings for this document. In this case, the single setting applied is the suppression of a tab stop when using a hanging indent using the noTabHangInd element (§2.15.3.37). *end example*]

2.15.3.1 adjustLineHeightInTable (Add Document Grid Line Pitch To Lines in Table Cells)

This element specifies whether a document grid defined using the docGrid element (§2.6.5) that specifies a line grid (manually adding additional pitch to each line in the section) shall also be applied to lines within table cells in this section.

Typically, when additional line pitch is added to all lines in a section via the document grid, it is not applied to text in tables. This element, when present with a val attribute value of `true` (or equivalent), specifies that additional line pitch shall be added to lines in table cells.

[*Example*: Consider a WordprocessingML document with a single section, whose document grid is defined such that 25.9 points of additional line pitch are added to each line in the section, as follows:

```
<w:docGrid w:type="lines" w:linePitch="518"/>
```

If text was entered into this section, the default behavior would have line pitch only added to lines which are not in a table cell:

This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid.

This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid.

This section has a character grid. This section has a character grid. This section has a character grid.

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:adjustLineHeightInTable />
</w:compat>
```

Then all lines in this document would have the line pitch from the document grid added to them, resulting in the following output:

This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid.

This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid. This section has a character grid.

This section has a character grid. This section has a character grid. This section has a character grid.

end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.2 alignTablesRowByRow (Align Table Rows Independently)

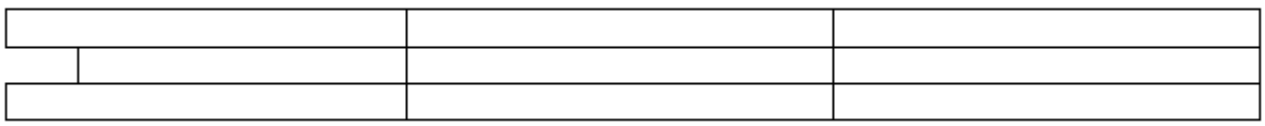
This element specifies whether applications shall align each row within a table independently based on the alignment setting of the jc element (§2.4.22) when displaying the contents of a table in a WordprocessingML document.

When the justification of a table using the jc element is typically applied, that alignment is applied to the contents of the table (the table is centered, left justified, or right-aligned), and then individual rows are laid out based on the resulting table's position. This element, when present with a val attribute value of `true` (or equivalent), specifies that each table row shall be independently aligned based on the table alignment setting, ignoring the placement of all other rows.

[*Example*: Consider a WordprocessingML document with a single centered table, whose second row is defined such that one-half of an inch is left before the row begins, as follows:

```
<w:tbl>
  <w:tblPr>
    <w:jc w:val="center" />
  </w:tblPr>
  <w:tr>
    …
  </w:tr>
  <w:tr>
    <w:trPr>
      <w:gridBefore w:val="1" />
      <w:wBefore w:w="720" w:type="dxa" />
    </w:trPr>
    …
  </w:tr>
  <w:tr>
    …
  </w:tr>
</w:tbl>
```

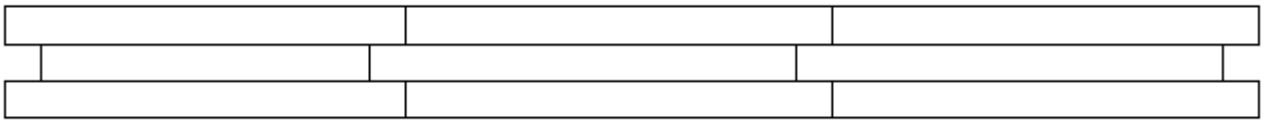
The default presentation would have the entire table centered, then the second row indented beyond that by 720 points:



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:alignTablesRowByRow />
</w:compat>
```

Then that second row would instead be centered on the page independently of the other table rows, resulting in the following output:



In this case, the wBefore element's value is ignored, since the row was centered on the line as a row, and there is no table to be indented relative to. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.3 allowSpaceOfSameStyleInTable (Allow Contextual Spacing of Paragraphs in Tables)

This element specifies whether the suppression of additional space (contextual spacing) defined using the contextualSpacing element (§2.3.1.9) shall be applied to paragraphs contained within tables.

Typically, the rules for the removal of additional paragraph spacing via the contextualSpacing element are applied to all paragraphs in a WordprocessingML document. This element, when present with a val attribute value of `true` (or equivalent), specifies that this setting shall always be ignored for paragraphs in table cells (and additional spacing shall be allowed).

[*Example*: Consider a WordprocessingML document with a default paragraph style with additional spacing after and contextual spacing set, as follows:

```
<w:style w:name="Normal" w:default="1">
  …
  <w:pPr>
    <w:spacing w:after="200" />
    <w:contextualSpacing />
  </w:pPr>
</w:style>
```

The default presentation would have the spacing suppressed between all paragraphs, since they are all of the default paragraph style defined above (contextual spacing applies):

On the Insert tab, the galleries include items that are designed to coordinate with the overall look of your document. You can use these galleries to insert tables, headers, footers, lists, cover pages, and other document building blocks. When you create pictures, charts, or diagrams, they also coordinate with your current document look.
On the Insert tab, the galleries include items that are designed to coordinate with the overall look of your document. You can use these galleries to insert tables, headers, footers, lists, cover pages, and other document building blocks. When you create pictures, charts, or diagrams, they also coordinate with your current document look.

You can easily change the formatting of selected text in the document text by choosing a look for the selected text from the Quick Styles gallery on the Home tab. You can also format text directly by using the other controls on the Home tab. Most controls offer a choice of using the look from the current theme or using a format that you specify directly. On the Insert tab, the galleries include items that are designed to coordinate with the overall look of your document. You can use these galleries to insert tables, headers, footers, lists, cover pages, and other document building blocks. When you create pictures, charts, or diagrams, they also coordinate with your current document look.

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:allowSpaceOfSameStyleInTable />
</w:compat>
```

Then the paragraphs in the table will never have their spacing suppressed, resulting in the following output:

On the Insert tab, the galleries include items that are designed to coordinate with the overall look of your document. You can use these galleries to insert tables, headers, footers, lists, cover pages, and other document building blocks. When you create pictures, charts, or diagrams, they also coordinate with your current document look.

When you create pictures, charts, or diagrams, they also coordinate with your current document look.

end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.4 applyBreakingRules (Use Legacy Ethiopic and Amharic Line Breaking Rules)

This element specifies whether applications shall use a legacy set of line breaking rules when determining line breaks for text consisting of Ethiopic and/or Amharic characters.

Typically, when line breaking this text, applications should allow line breaks to occur after a character between the UTF-16 (hexadecimal) values 0x1361 and 0x1368 when those characters appear in the document's content. This element, when present with a val attribute value of `true` (or equivalent), specifies that when a line break would occur after a character between the UTF-16 hexadecimal) values 0x1361 and 0x1368, the line break shall occur before all instances of these characters (i.e. no break opportunity shall be afforded after a character in this range).

[*Example*: Consider a WordprocessingML document with a series of Ethopic characters in this range. The default presentation would have any line breaks pushed before or after these characters, ensuring that the characters remain together on a single line.

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:applyBreakingRules />
</w:compat>
```

Then a line break opportunity shall be afforded at any point in a range of these characters, as needed. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>`

Attributes	Description
	The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.5 autofitToFirstFixedWidthCell (Allow Table Columns To Exceed Preferred Widths of Constituent Cells)

This element specifies that when performing an AutoFit on a table in a WordprocessingML document in order to display it, applications shall alter that logic slightly in order to mimic the behavior of a previous word processing application.

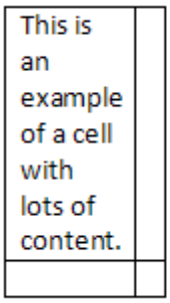
Normally, the AutoFit behavior of a table is as is described in the associated simple type. This element, when present with a val attribute value of true (or equivalent), specifies that this logic shall be changed as follows:

- If the width of a grid column in a table has been set by a preferred table cell width, then that column's width may be enlarged by the content of cells which themselves do not have a preferred width (in contrast, the normal logic never allows the content of cells to override a preferred width on a grid column).

[*Example*: Consider a WordprocessingML table with only one preferred cell width, a width of 720 points on the second cell in the first column, as follows:

```
<w:tbl>
  <w:tr>
    <w:tc>
      <w:p/>
    </w:tc>
    <w:tc>
      <w:p/>
    </w:tc>
  </w:tr>
  <w:tr>
    <w:tc>
      <w:tcPr>
        <w:tcW w:w="720" w:type="dxa" />
      </w:tcPr>
      <w:p/>
    </w:tc>
    <w:tc>
      <w:p/>
    </w:tc>
  </w:tr>
</w:tbl>
```

The default presentation would have the first column constrained to 720 points by the preferred width of the second cell in the first column:



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:autofitToFirstFixedWidthCell />
</w:compat>
```

Then the column would be resized proportionally based on the content (ignoring the preferred width in that row), resulting in the following output:

This is an example of a cell with lots of content.	

end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.6 autoSpaceLikeWord95 (Emulate Word 95 Full-Width Character Spacing)

This element specifies that applications shall emulate the behavior of a previously existing word processing application (Microsoft Word 95) when determining the spacing between full-width East Asian characters in a document's content.

[*Guidance*: To faithfully replicate this behavior, applications must imitate the behavior of that application, which involves many possible behaviors and cannot be faithfully placed into narrative for this Office Open XML Standard. If applications wish to match this behavior, they must utilize and duplicate the output of those applications. It is recommended that applications not intentionally replicate this behavior as it was deprecated due to issues with its output, and is maintained only for compatibility with existing documents from that application. *end guidance*]

Typically, applications shall not perform this compatibility. This element, when present with a val attribute value of `true` (or equivalent), specifies that applications shall attempt to mimic that existing word processing application in this regard.

[*Example*: Consider a WordprocessingML document with a series of full-width East Asian characters.

If this compatibility setting is turned on:

```
<w:compat>
  <w:autoSpaceLikeWord95 />
</w:compat>
```

Then applications should mimic the behavior of Microsoft Word 95 when determining the space between those characters, as needed. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.7 balanceSingleByteDoubleByteWidth (Balance Single Byte and Double Byte Characters)

This element specifies whether applications shall balance the width of Single Byte Character Set characters and Double Byte Character Set characters when rendering WordprocessingML documents. Specifically, this element

specifies to adjust the fixed pitch fonts' half-width space character and full-width space character to attain a 1 to 2 ratio.

[*Note*: This element is used with East Asian content. Layout and line breaking for East Asian text is dependent on the character width. Half width characters (or Hankaku characters) are one half of an em wide, and full width characters (or Zenkaku characters) are one em wide. Legacy encoding often used a single byte to encode half-width characters and two bytes to encode full width characters. *end note*]

Typically, no adjustment is done on any character when it is displayed as part of a WordprocessingML document. This element, when present with a val attribute value of `true` (or equivalent), specifies that character sizes shall be adjusted as needed to meet the 1:2 ratio described above.

[*Example*: Consider a WordprocessingML document with both SBCS and DBCS characters. The default presentation would have the text displayed as follows:

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:balanceSingleByteDoubleByteWidth />
</w:compat>
```

Then this character-level adjustment must be performed, resulting in the following output:

This adjustment is usually very minute in nature, therefore the result is better illustrated by showing how the characters after the English text were pushed out due to the width balancing of that text:

end example]

Parent Elements

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.8 cachedColBalance (Use Cached Paragraph Information for Column Balancing)

This element specifies whether applications shall incorrectly calculate the height of a paragraph for the purposes of column balancing when rendering WordprocessingML documents. Specifically, this element specifies that when a paragraph's lines have differing heights, an application shall treat this paragraph as though it had only one line equaling the full paragraph height, regardless of the actual number of lines in the paragraph.

[*Guidance*: It is recommended that applications not intentionally replicate this behavior as it was deprecated due to issues with its output, and is maintained only for compatibility with existing documents from a legacy application. *end guidance*]

Typically, lines are correctly measured for their height when balancing columns as part of a WordprocessingML document. This element, when present with a val attribute value of true (or equivalent), specifies that applications shall perform the incorrect calculation in the conditions described above.

[*Example*: Consider a WordprocessingML document with two columns of text which shall be balanced.

If this compatibility setting is turned on:

```
<w:compat>
  <w:cachedColBalance />
</w:compat>
```

Then applications should perform the calculation described above to balance the columns, as needed. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.9 compat (Compatibility Settings)

This element specifies a set of optional compatibility options for the current document.

All settings in this section are optional, but some are very commonly used by different languages, and those which are typically used are as follows:

For Thai, Lao, Khmer, Tibetan, and Armenian:

- The applyBreakingRules setting (§2.15.3.4)

For East Asian languages:

- The adjustLineHeightInTable setting (§2.15.3.1)

- The balanceSingleByteDoubleByteWidth setting (§2.15.3.7)
- The doNotExpandShiftReturn setting (§2.15.3.15)
- The doNotLeaveBackslashAlone setting (§2.15.3.16)
- The spaceForUL setting (§2.15.3.43)
- The ulTrailSpace setting (§2.15.3.55)

[*Example*: Consider a WordprocessingML document with a series of compatibility settings:

```
<w:settings>
  <w:compat>
    …
  </w:compat>
</w:settings>
```

The compat element specifies the set of compatibility settings for a document. *end example*]

```

2.15.3.10 convMailMergeEsc (Treat Backslash Quotation Delimiter as Two Quotation Marks)

This element specifies whether applications should perform a conversion of the contents of a mail merge data source when reading those contents in order to perform a mail merge operation with their contents.

Typically, the contents of a mail merge data source are read in exactly as specified when performing a mail merge with the contents of a data source. This element, when present with a val attribute value of `true` (or equivalent), specifies that applications shall interpret delimiters composed of a backslash and quotation mark (\") as two quotation marks (""), within external data sources to be connected to via a mail merge.

[*Example*: Consider a WordprocessingML document with the following content in its data source:

```
This is a \"test\".
```

The default presentation would have the resulting merged data read in just as it appears:

```
This is a \"test\".
```

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:convMailMergeEsc />
</w:compat>
```

Then instances of a backslash and quotation mark would be converted, resulting in the following output:

```
This is a ""test"".
```

end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

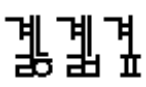
```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.11 displayHangulFixedWidth (Always Use Fixed Width for Hangul Characters)

This element specifies whether applications should assume that all characters in the Hangul Syllables Unicode sub range (character values between 0xAC00 and 0xD7FF) are of a single fixed width or shall use the characters widths defined by the font in use (typical for a proportional width font).

Typically, applications shall retrieve the character width for any character in a document from the associated font, allowing each character to be of its own width (a proportional width character). This element, when present with a val attribute value of true (or equivalent), specifies that applications shall instead assume a single fixed width for all characters in the Hangul Syllables sub range, by reading the width of Unicode character 0x4E00 from the associated font and using that width for all Hangul characters (or, if that character is not present, the next available character in the font).

[*Example*: Consider a WordprocessingML document with three Hangul characters:



The default presentation would have each of those characters using the widths defined by the font (the highlighting indicates that each character has its own width):

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:displayHangulFixedWidth />
</w:compat>
```

Then all three characters are forced to the fixed width of character 0x4E00 from the font (or, in this case, the next available character), resulting in the characters in the font being forced to that fixed width, which results in the following output:

Notice from the highlighting that the characters have been compressed to the width of the single character and displayed at that fixed width. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off.

Attributes	Description
	[*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

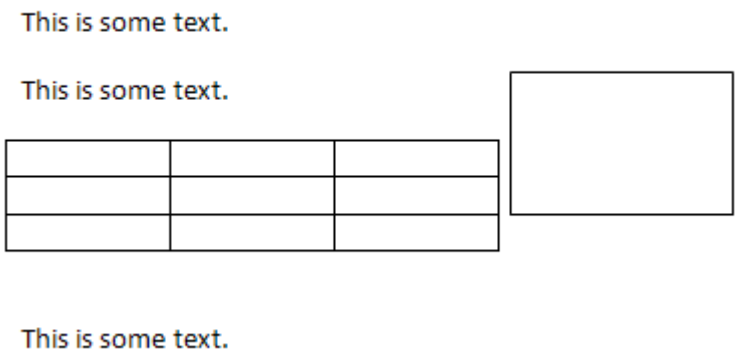
```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.12 doNotAutofitConstrainedTables (Do Not AutoFit Tables To Fit Next To Wrapped Objects)

This element specifies whether applications shall allow tables to be resized to the remaining available line width when they are using the AutoFit algorithm and part of that line is filled by a shape with a wrapping type with a value of `square` or `tight`.

Typically, a table which is AutoFit and has a preferred width shall have its width reduced in order to allow a floating shape to wrap around its contents within the document, as that shape simply reduces the width of the line and the AutoFit algorithm applies to the remaining line width. This element, when present with a val attribute value of `true` (or equivalent), specifies that tables shall never have any preferred width overridden to allow them to wrap around that floating object, and shall instead be pushed to the next full width line in the document to be displayed.

[*Example*: Consider a WordprocessingML document with a floating shape centered in the document, followed by a table with preferred cell widths of 2.22", as follows:

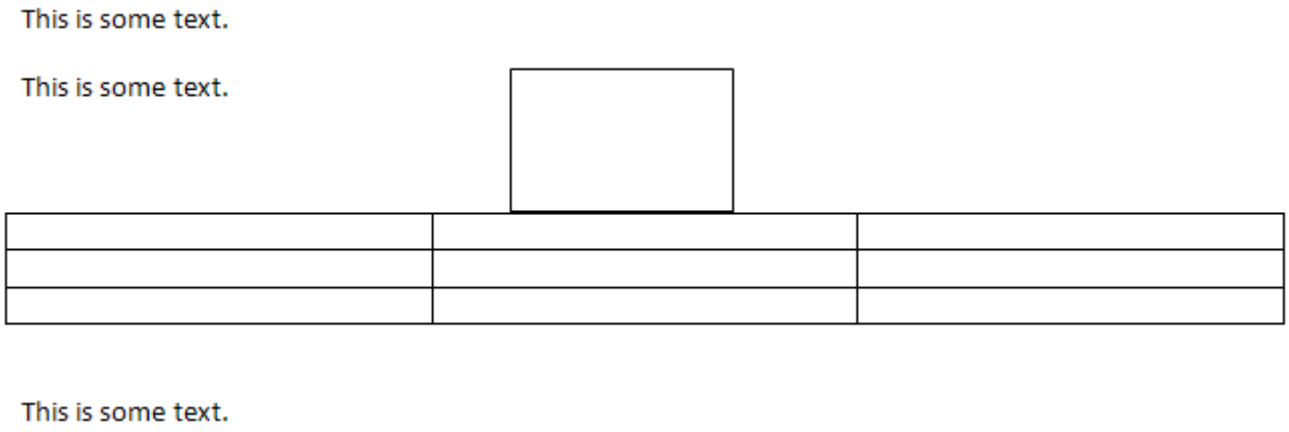


The default presentation of this document overrides the preferred cell widths to force the table to fit on the line next to the floating shape with tight wrapping.

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:dontAutofitConstrainedTables />
</w:compat>
```

Then that table is not resized, so it cannot fit and must be pushed to the next full width line, resulting in the following output:



end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

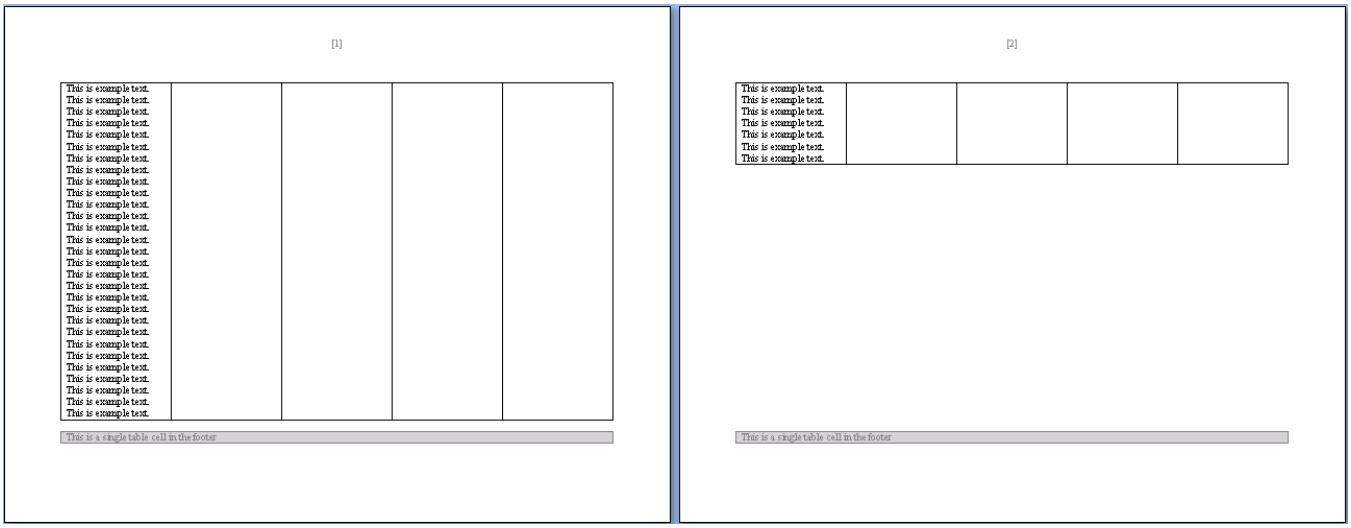
2.15.3.13 doNotBreakConstrainedForcedTable (Don't Break Table Rows Around Floating Tables)

This element specifies whether applications shall allow a table row to be split in two when its contents are displayed under the following circumstances:

- The table row exceeds one page in height (it must be split into two pages)
- The table row would need to be split in order to accommodate a floating table also on the page (tables which have been set to floating using the tblpPr element (§2.4.54))

Typically, assuming the cantSplit property (§2.4.6) is not set, a table row which cannot fit on one single page shall be split as needed around any floating table on a page, in order to allow its contents to be fully displayed across two or more pages. This element, when present with a val attribute value of `true` (or equivalent), specifies that table rows which exceed one page in height shall never be split around floating tables in the document, and shall instead be displayed on the first page below the floating table, even if that means that part of the table row is clipped by the edge of the page.

[*Example*: Consider a WordprocessingML document with a long single table row which must be split across two separate pages in the document, in order to accommodate a floating table anchored in the footer, as follows:

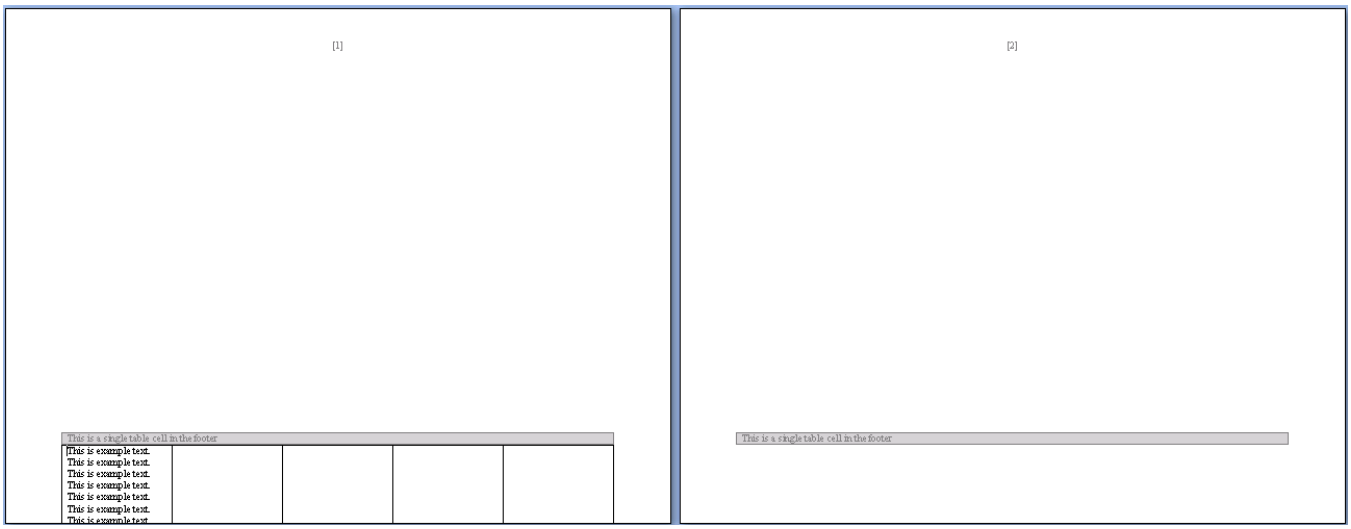


The default presentation of this document forces that row to be split as needed around that floating table.

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:dontBreakConstrainedForcedTable />
</w:compat>
```

Then that table row is never split around the floating table, so it is always placed below that floating table on the page, and allowed to flow off the page as needed, resulting in the following output:



This example, while extreme, shows how the row is placed below the floating table, rather than breaking around it. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

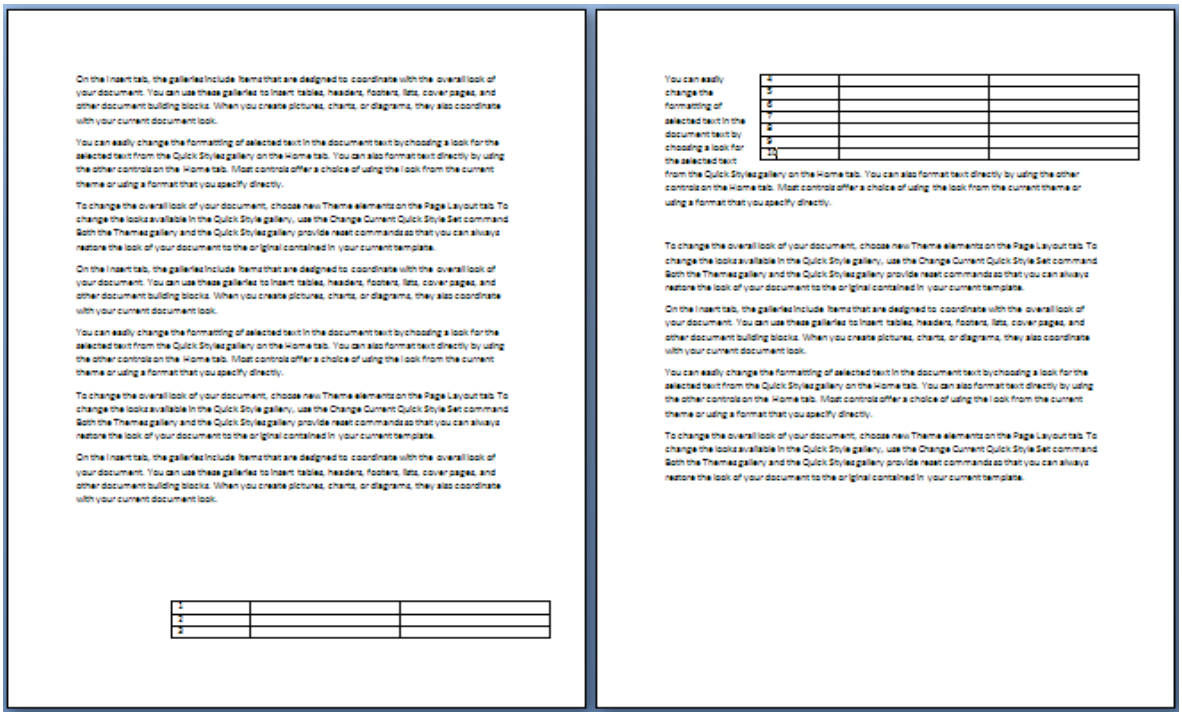
```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.14 doNotBreakWrappedTables (Do Not Allow Floating Tables To Break Across Pages)

This element specifies whether applications shall allow tables which have been set to floating using the tblpPr element (§2.4.54) shall be allowed to break across multiple pages when needed.

Typically, a table whose contents cannot all be displayed on one page is broken as needed across multiple pages in order to preserve the location of the table (just as a paragraph of multiple lines is broken across pages as needed). This element, when present with a val attribute value of `true` (or equivalent), specifies that floating tables shall never be broken across pages, and shall instead be put on the first page by adjusting the starting position of the table as needed to fit on that single page.

[*Example*: Consider a WordprocessingML document with a floating table positioned at the bottom of a page , as follows:

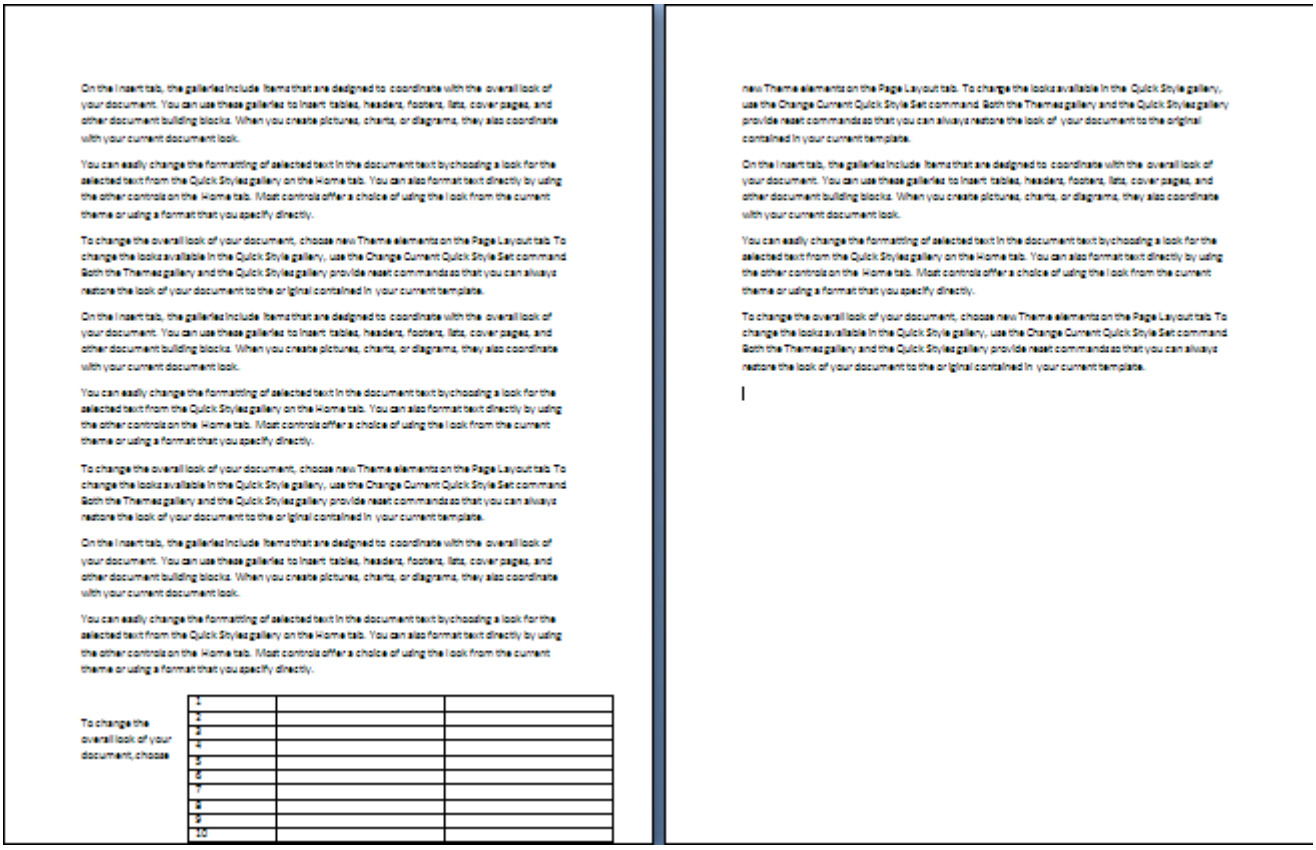


The default presentation of this document results in that table being broken across two pages of content.

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:dontBreakWrappedTables />
</w:compat>
```

Then that table is not broken across the page boundary, so it must be moved further up on the first page to accommodate its entire size, resulting in the following output:



Notice that the table now flows into the page margins in order to keep it on one page. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.15 doNotExpandShiftReturn (Don't Justify Lines Ending in Soft Line Break)

This element specifies whether applications should fully justify the contents of incomplete lines which end in a soft line break when the parent paragraph is fully justified using the jc element (§2.3.1.13).

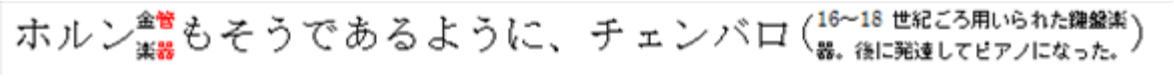
Typically, applications shall fully justify all lines in a paragraph when that setting is specified using the jc element except for the last line in the paragraph (the line ending with the paragraph mark). This element, when present with a val attribute value of `true` (or equivalent), specifies that any line which ends in a soft line break shall also not be fully justified when the paragraph specifies that setting.

[*Example*: Consider a WordprocessingML document with a paragraph whose first single line consists of East Asian characters followed by a soft paragraph mark. The default presentation would have the contents of that line fully justified:

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:doNotExpandShiftReturn />
</w:compat>
```

Then this line is not fully justified, as it ends with a soft line break, resulting in the following output:



end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off.

Attributes	Description
	[*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.16 doNotLeaveBackslashAlone (Convert Backslash To Yen Sign When Entered)

This element specifies whether applications should automatically convert the backslash character into the yen character when it is added through user keyboard input.

Typically, no automatic conversion of one character to another is done when characters are entered by the user. This element, when present with a val attribute value of true (or equivalent), specifies that all entries of the backslash (\) character shall automatically be converted to a yen symbol (¥) when the former is entered.

[*Example*: Consider a WordprocessingML document where the user types the following:

```
Hello \ world.
```

The default presentation would have exactly that:

```
Hello \ world.
```

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:doNotLeaveBackslashAlone />
</w:compat>
```

Then the backslash would be converted, resulting in the following output:

```
Hello ¥ world.
```

end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.17 doNotSnapToGridInCell (Do Not Snap to Document Grid in Table Cells with Objects)

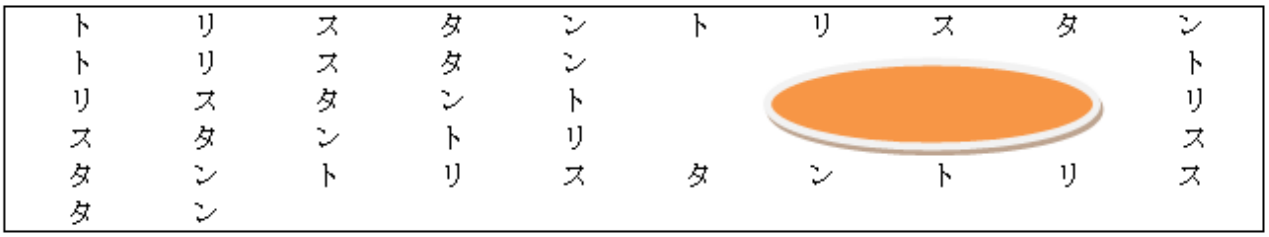
This element specifies whether a document grid defined using the docGrid element (§2.6.5) shall be applied to the contents of table cells in that section which also contain floating objects defined using the Vector Markup Language syntax. Note that the floating object must be part of the cell, and simply not displayed over the cell due to its anchoring relative to another part of the document.

Typically, if a floating object is present in a table cell, then that setting shall have no impact on whether East Asian text in that cell is snapped to the document grid (as text is always snapped to the grid). This element, when present with a val attribute value of true (or equivalent), specifies that whenever a floating object defined using VML is present in a table cell, that the cell's contents shall not be snapped to the document grid.

[*Example*: Consider a WordprocessingML document consisting of a single section, whose document grid settings specify that each page shall be exactly 10 characters wide, as follows:

```
<w:sectPr>
  <w:docGrid w:type="snapToChars" w:charSpace="146636" />
</w:sectPr>
```

If this document contains a table with a single cell, containing some text and a single shape defined using the Vector Markup Language syntax, the contents of the cell are still snapped to the 10 characters per line character grid, as follows:



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:doNotSnapToGridInCell />
</w:compat>
```

Then the presence of a floating object in each cell shall result in the document grid setting being ignored, resulting in the following output:

The additional character pitch was still added to each character on the line, but those characters are no longer snapped to the document grid. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>`

Attributes	Description
	The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.18 doNotSuppressIndentation (Do Not Ignore Floating Objects When Calculating Paragraph Indentation)

This element specifies whether applications should ignore the presence of floating objects when calculating the starting position of paragraphs which are wrapped around floating objects defined using the Vector Markup Language (VML) syntax.

Typically, the presence of a floating object on the same line or lines as a paragraph shall only affect the text when the floating object occurs where that text would normally be presented. [*Example*: Text at a 1" indentation would only be displaced by a floating object that appears at that position and not one that appears from 0" to 0.5" on the same line. *end example*].

This element, when present with a val attribute value of true (or equivalent), specifies that floating objects shall always impact paragraphs on the same line in two ways:

- If the paragraph is not numbered, then it shall tightly wrap any floating object which precedes it on the same line, ignoring its own indentation settings. [*Example*: A paragraph with a 1" left indent shall tightly wrap a floating object which appears at only 0.25" on the same line. *end example*]
- If the paragraph is numbered using the numPr element (§2.3.1.19), then it shall calculate and use its full indent relative to the edge of the floating object, not relative to the edge of the page. [*Example*: A numbered paragraph with a 1" left indent shall appear 1.5" into the page if it is preceded by a floating object which appears at 0.5" on the same line. *end example*]

[*Example*: Consider a WordprocessingML document with a narrow floating object at 0.5" on the page, surrounded by both numbered and unnumbered paragraphs.

The default presentation would have no impact on the paragraphs based on that floating object, since two two do not intersect:

One

Two

Three

Four

Five

1. One
2. Two
3. Three
4. Four
5. Five

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:doNotSuppressIndentation />
</w:compat>
```

Then the two alternate rules defined above would apply, resulting in the following output:

One

Two

Three

Four

Five

1. One
    2. Two
    3. Three
    4. Four
5. Five

end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

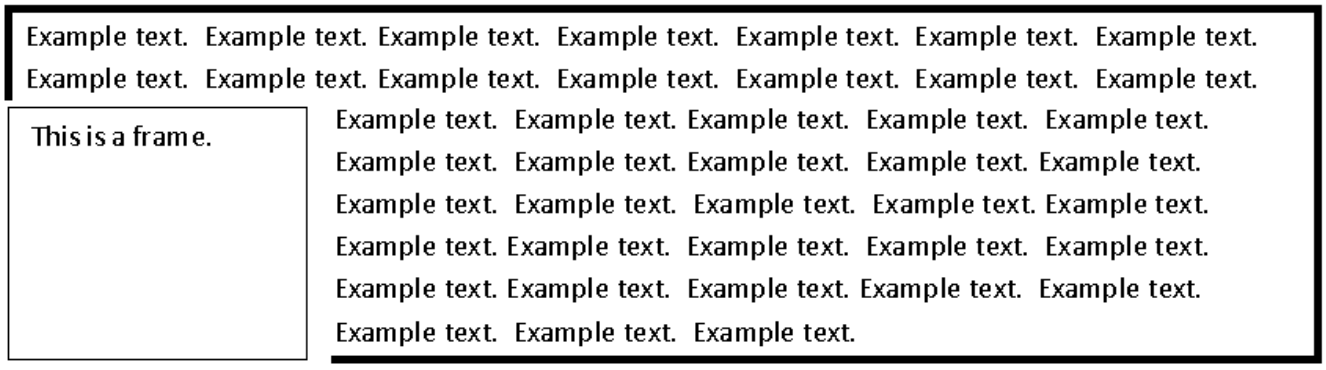
2.15.3.19 doNotSuppressParagraphBorders (Do Not Suppress Paragraph Borders Next To Frames)

This element specifies whether applications should suppress paragraph borders defined using the pBdr element (§2.3.1.24) when those borders would be displayed next to the contents of paragraphs which have been defined as frames using the framePr element (§2.3.1.11).

Typically, when a paragraph's borders appear next to a frame, those borders are suppressed to avoid having two borders in close proximity. This element, when present with a val attribute value of `true` (or equivalent), specifies that those borders shall not be suppressed.

[*Example*: Consider a WordprocessingML document with a paragraph with a paragraph border that is bounded on its bottom let side by a text frame.

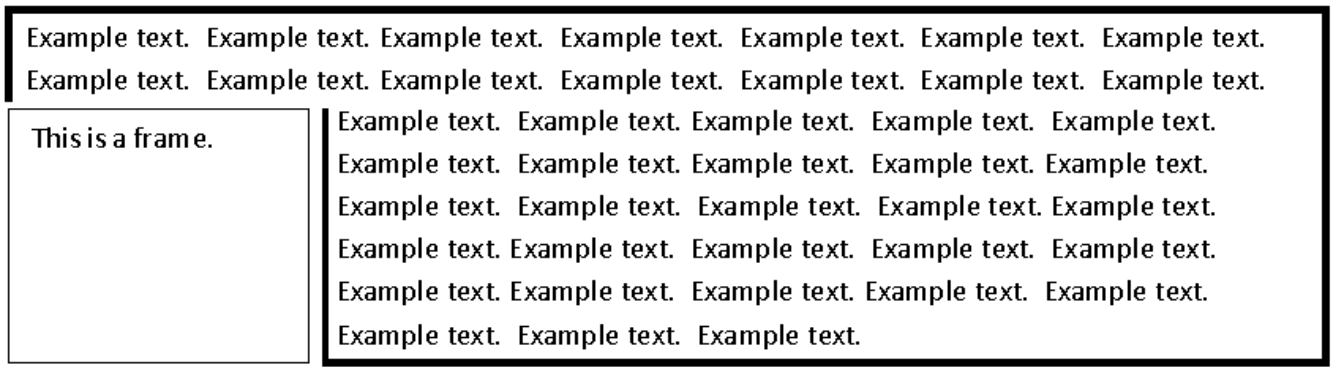
The default presentation would suppress the borders which intersect the frame (in this case, the right border of lines three through eight):



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:doNotSuppressParagraphBorders />
</w:compat>
```

Then no border suppression shall take place, resulting in the following output:



end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.20 doNotUseEastAsianBreakRules (Do Not Compress Compressible Characters When Using Document Grid)

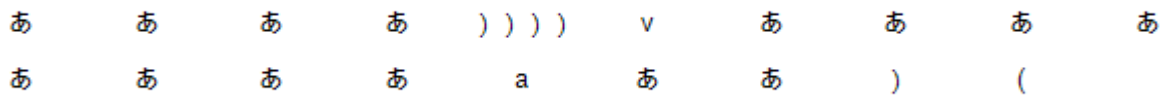
This element specifies whether applications should compress characters with identical compression rules when the document grid has been defined using the docGrid element (§2.6.5). *Compression rules* refer to the additional bearing on the left and/or right side of a typical character, which can be compressed as needed without modifying the actual width of the character (its breadth).

Typically, punctuation characters with an identical set of compression rules are compressed when the contents of a document are displayed. This element, when present with a val attribute value of true (or equivalent), specifies that if a document grid is defined for the current section, compression shall never be performed on any character - all compressible characters shall be individually snapped to the document grid.

[*Example*: Consider a WordprocessingML document with a document grid set to allow 10 characters per line:

```
<w:sectPr>
  <w:docGrid w:type="snapToChars" w:charSpace="146636" … />
</w:sectPr>
```

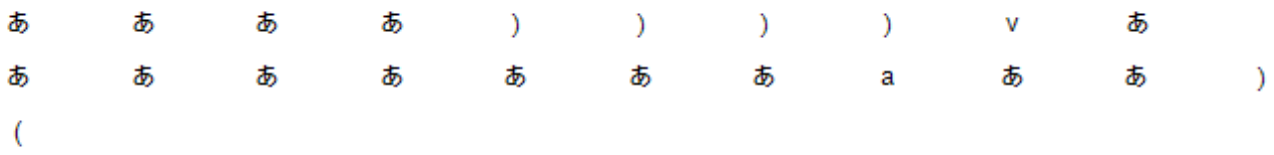
The default presentation would allow characters with identical compression rules to compress and utilize a single slot on the document grid (notice that the four parenthesis on the first line are combined since they can be compressed identically, while the two parenthesis with different compression on line two are not):



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:useEastAsianBreakRules />
</w:compat>
```

Then no character with compression is compressed and instead are snapped to the grid individually, resulting in the following output:



end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.21 doNotUseHTMLParagraphAutoSpacing (Use Fixed Paragraph Spacing for HTML Auto Setting)

This element specifies whether applications should use a fixed definition when interpreting automatic paragraph spacing defined by a value of `true` (or equivalent) on the beforeAutospacing and/or afterAutospacing attributes on the spacing element (§2.3.1.33).

Typically, applications shall interpret these settings to match the behavior of most HTML user agents, mimicking the default spacing above and below an HTML p element without additional spacing information. This element, when present with a val attribute value of `true` (or equivalent), specifies that those two attributes shall result in the following settings for each value:

- beforeAutospacing = 5 points of spacing before
- afterAutospacing = 10 points of spacing after

[*Example*: Consider a WordprocessingML document with a three paragraphs using HTML autospacing, as follows:

```
<w:p>
  <w:pPr>
    <w:spacing w:beforeAutospacing="true" w:afterAutospacing="true" />
  </w:pPr>
  <w:r>
    <w:t>Paragraph One</w:t>
  </w:r>
</w:p>
<w:p>
  <w:pPr>
    <w:spacing w:beforeAutospacing="true" w:afterAutospacing="true" />
  </w:pPr>
  <w:r>
    <w:t>Paragraph Two</w:t>
  </w:r>
</w:p>
<w:p>
  <w:pPr>
    <w:spacing w:beforeAutospacing="true" w:afterAutospacing="true" />
  </w:pPr>
  <w:r>
    <w:t>Paragraph Three</w:t>
  </w:r>
</w:p>
```

The default presentation would result in output designed to match that of all common HTML user agents:

Paragraph One.

Paragraph Two.

Paragraph Three.

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:doNotUseHTMLParagraphAutoSpacing />
</w:compat>
```

Then the paragraphs will have exact spacing of 5 points before and 10 points after, resulting in the following output:

Paragraph One.

Paragraph Two.

Paragraph Three.

Notice that the paragraphs are more condensed in the second example. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.22 doNotUseIndentAsNumberingTabStop (Ignore Hanging Indent When Creating Tab Stop After Numbering)

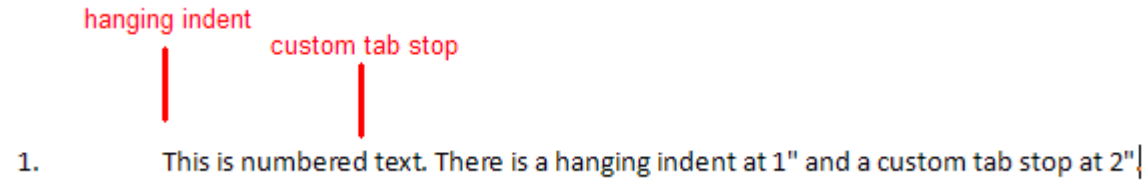
This element specifies whether applications shall use the custom tab stop generated by the hanging indent (if any) when advancing the text after the numbering for a numbered paragraph.

Typically, a hanging indent on a paragraph creates a virtual custom tab stop at that location, and therefore a tab added after the numbering on a numbered paragraph by the suff element (§2.9.30) shall advance to that tab stop, so that the text of the numbered paragraph begins at that location. This element, when present with a val attribute value of `true` (or equivalent), specifies that a tab stop added as the suffix to the numbering of a numbered paragraph shall ignore that virtual custom tab stop and shall instead advance to the next real tab stop (custom or automatic) on the current line.

[*Example*: Consider a WordprocessingML document with numbering, whose first level of numbering specifies a tab stop suffix, a hanging indent at 1", and a custom tab stop at 2":

```
<w:abstractNum w:numId="0">
  …
  <w:lvl w:ilvl="0">
    <w:suff w:val="tab" />
    <w:pPr>
      <w:ind w:left="1440" w:hanging="1440" />
      <w:tabs>
        <w:tab w:val="2880" />
      </w:tabs>
    </w:pPr>
  </w:lvl>
</w:abstractNum>
```

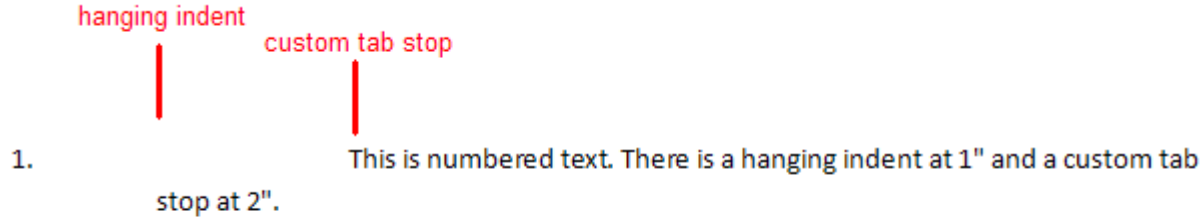
The default presentation of this document results in the tab stop generated by the numbering advancing to the virtual tab stop generated by the hanging indent at 1", as follows:



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:dontUseIndentAsNumberingTabStop />
</w:compat>
```

Then that tab suffix ignores the virtual tab stop of the hanging indent, so it must advance to the next custom tab stop on the line (at 2"), resulting in the following output:



end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

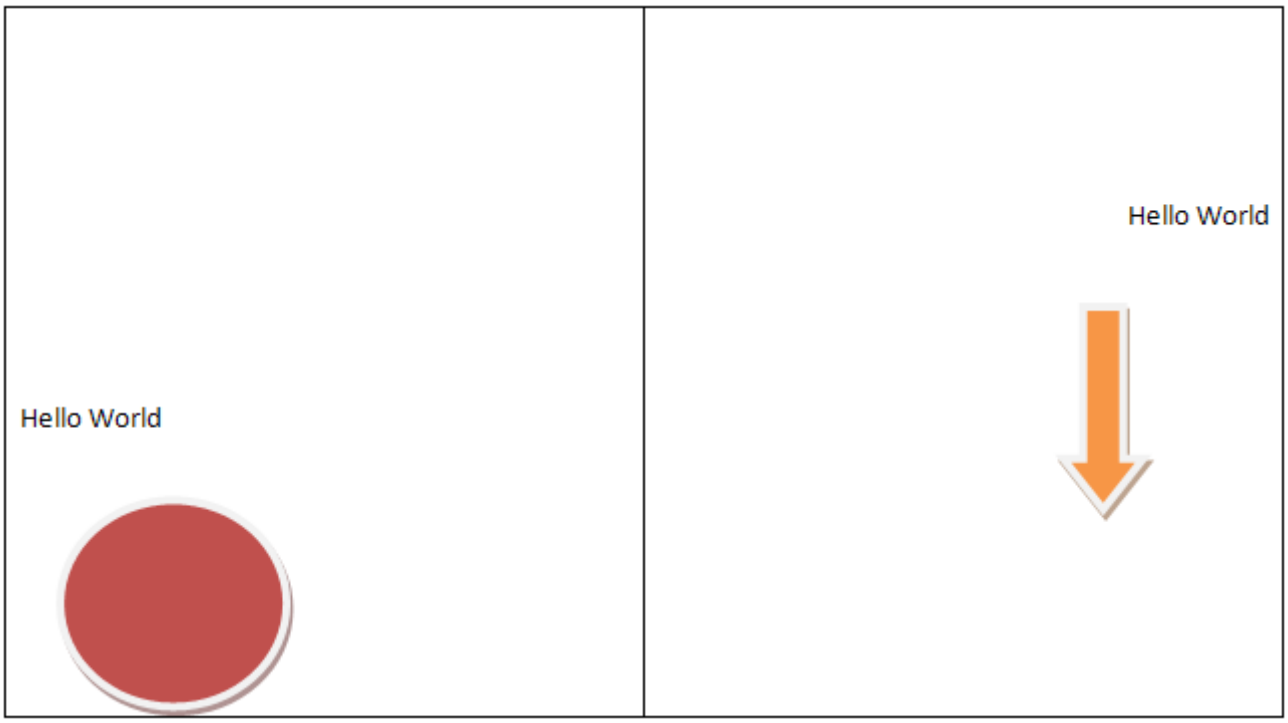
2.15.3.23 doNotVertAlignCellWithSp (Don't Vertically Align Cells Containing Floating Objects)

This element specifies whether applications shall vertically align the contents of a table cell, even when the contents of that table cell include one or more floating objects defined using the Vector Markup Language syntax. Note that the floating object must be part of the cell, and simply not displayed over the cell due to its anchoring relative to another part of the document.

Typically, if the alignment of a table cell in a WordprocessingML document is specified, then the entire contents of that cell are aligned as specified [*Example*: The entire contents of the cell are centered vertically and moved right-aligned horizontally at that point. *end example*]. This element, when present with a val attribute value of true (or equivalent), specifies that whenever a floating object defined using VML is present in a table cell, that no vertical alignment shall be applied to the contents of that cell, and the contents of the cell shall instead always be top aligned to the cell's contents.

[*Example*: Consider a WordprocessingML table with two cells, each containing some text and a single shape defined using the Vector Markup Language syntax. The first cell is vertically aligned to the bottom of the cell, and the second cell is vertically aligned to the center of the cell.

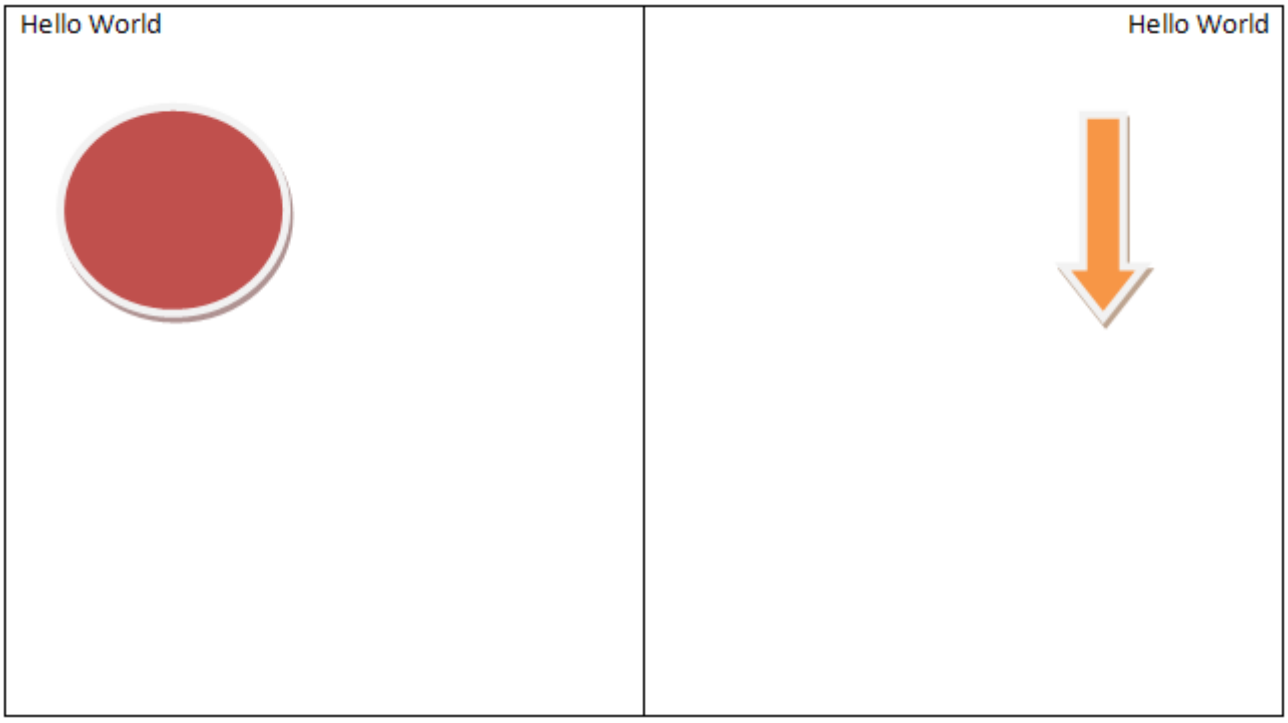
The default presentation of this document results in each cell (including the extents of the floating objects) being vertically aligned as specified, as follows:



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:dontVertAlignCellWithSp />
</w:compat>
```

Then the presence of a floating object in each cell shall result in the vertical alignment setting being ignored (each vertical alignment shall be top-aligned relative to the cell), resulting in the following output:



end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.24 doNotVertAlignInTxbx (Ignore Vertical Alignment in Textboxes)

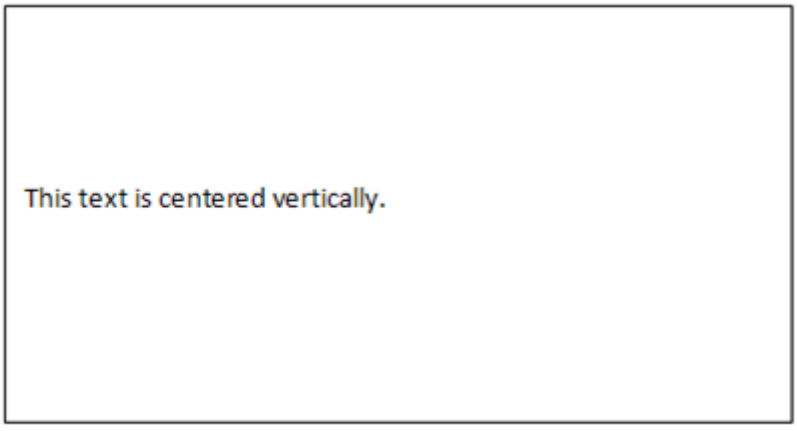
This element specifies whether applications shall allow text within text boxes to be vertically aligned when the `v-text-anchor` property is set within the parent VML shape.

Typically, if when the `v-text-anchor` property is set within the parent VML shape, then based on the value of that property, the text is top, center, or bottom aligned appropriately. This element, when present with a val attribute value of `true` (or equivalent), specifies that the property shall be ignored, and instead the contents of the table shall always be top-aligned.

[*Example*: Consider a WordprocessingML table with a single center-aligned text box:

```
<v:shape id="_x0000_s1026" type="#_x0000_t202" style="v-text-anchor:middle">
  <v:textbox>
    <w:txbxContent>
      <w:p>
        <w:r>
          <w:t>This text is centered vertically.</w:t>
        </w:r>
      </w:p>
    </w:txbxContent>
  </v:textbox>
</v:shape>
```

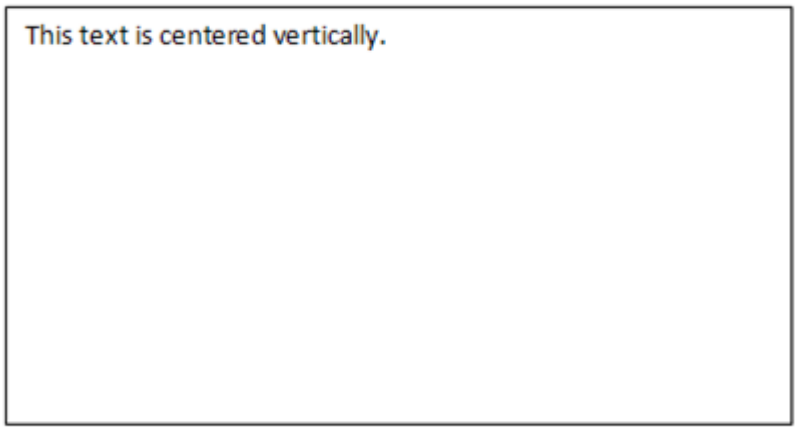
The default presentation of this document results in the contents of the text box being center aligned, as follows:



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:doNotVertAlignInTxbx />
</w:compat>
```

Then the text shall always be top aligned, regardless of the `-text-anchor` property, resulting in the following output:



end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.25 doNotWrapTextWithPunct (Do Not Allow Hanging Punctuation With Character Grid)

This element specifies whether applications shall allowing hanging punctuation when:

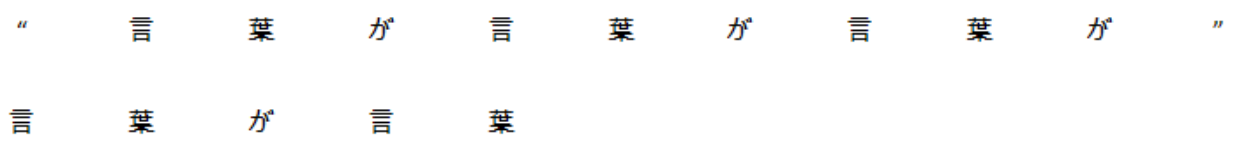
- The overflowPunct element (§2.3.1.21) is turned on for a paragraph
- A document grid is defined using the docGrid element (§2.6.5) which defines the number of characters per line

Typically, paragraphs which allow hanging punctuation shall allow the number of characters on a line as specified by the document grid to be exceeded by one in order to allow for hanging punctuation. This element, when present with a val attribute value of `true` (or equivalent), specifies that the document grid shall never be exceeded for hanging punctuation.

[*Example*: Consider a WordprocessingML document with a document grid set to allow 10 characters per line:

```
<w:sectPr>
  <w:docGrid w:type="snapToChars" w:charSpace="146636" … />
</w:sectPr>
```

If the eleventh character on the line was a punctuation characters, the default presentation would allow that character to behave as hanging punctuation on the first line:



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:wrapTextWithPunct />
</w:compat>
```

Then the character grid cannot be exceeded even for the hanging punctuation, resulting in the following output:

“ 言 葉 が 言 葉 が 言 葉

が ” 言 葉 が 言 葉

The hanging punctuation was disallowed, moving it (and the character before it, since that character cannot begin a line) to the following line. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.26 footnoteLayoutLikeWW8 (Emulate Word 6.x/95/97 Footnote Placement)

This element specifies that applications shall emulate the behavior of a previously existing word processing application (Microsoft Word 6.x/95/97) when determining the placement of the contents of footnotes relative to the page on which the footnote reference occurs. This emulation typically involves some and/or all of the footnote being inappropriately placed on the page following the footnote reference.

[*Guidance*: To faithfully replicate this behavior, applications must imitate the behavior of that application, which involves many possible behaviors and cannot be faithfully placed into narrative for this Office Open XML Standard. If applications wish to match this behavior, they must utilize and duplicate the output of those applications. It is recommended that applications not intentionally replicate this behavior as it was deprecated

due to issues with its output, and is maintained only for compatibility with existing documents from that application. *end guidance*]

Typically, applications shall not perform this compatibility. This element, when present with a val attribute value of true (or equivalent), specifies that applications shall attempt to mimic that existing word processing application in this regard.

[*Example*: Consider a WordprocessingML document with a series of footnotes.

If this compatibility setting is turned on:

```
<w:compat>
  <w:footnoteLayoutLikeWW8 />
</w:compat>
```

Then applications should mimic the behavior of Microsoft Word 6.x/95/97 when determining the placement of those footnotes on the displayed page, as needed. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.27 forgetLastTabAlignment (Ignore Width of Last Tab Stop When Aligning Paragraph If It Is Not Left Aligned)

This element specifies how applications should handle the final tab stop on a line when aligning the contents of a paragraph as specified by the jc element (§2.3.1.13) in the paragraph's properties.

Typically, aligning the contents of a paragraph involves the following:

- Determining the layout of that line before the alignment (including all tab stops)
- Aligning the resulting contents of the line

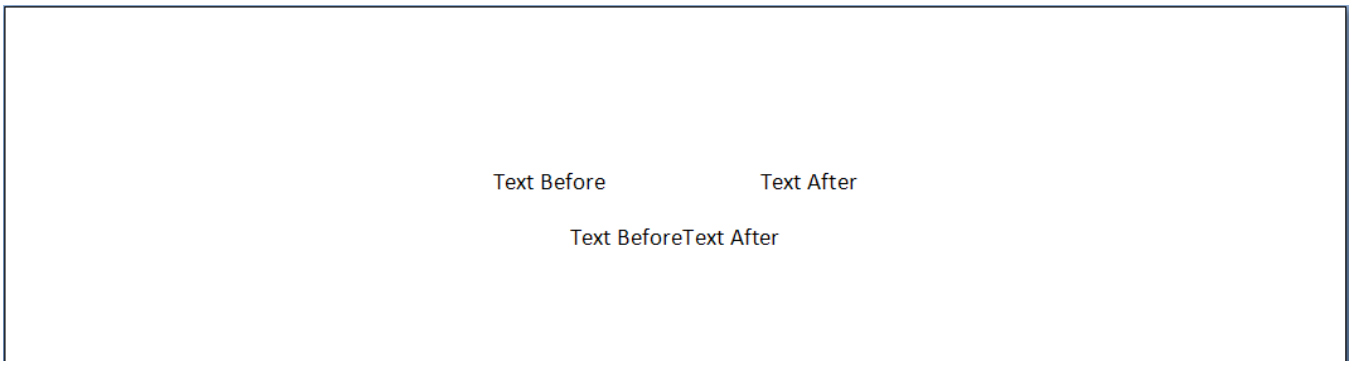
This is done to ensure that tab stops on a line do not change when the contents of the paragraph are aligned (i.e. the tab stops should not have to take into account the paragraph alignment).

This element, when present with a val attribute value of `true` (or equivalent), specifies that applications shall ignore the additional line width generated by the last tab stop (and only the last tab stop) when the alignment of the tab stop as defined by the val attribute on the tab element (§2.3.1.37) is not `left` (or `bar`, which as defined by this Office Open XML Standard, is not a tab stop per se) when determining the width of the line. The resulting full line shall then be aligned at the position where the line would have been aligned without that tab stop.

[*Example*: Consider a WordprocessingML document with two center aligned paragraphs of text - the first also containing a centered tab stop positioned at 2":

```
<w:p>
  <w:pPr>
    <w:tabs>
      <w:tab w:val="center" w:pos="2880" />
    </w:tabs>
    <w:jc w:val="center" />
  </w:pPr>
  <w:r>
    <w:t>Text Before</w:t>
    <w:tab/>
    <w:t>Text After</w:t>
  </w:r>
</w:p>
<w:p>
  <w:pPr>
    <w:jc w:val="center" />
  </w:pPr>
  <w:r>
    <w:t>Text BeforeText After</w:t>
  </w:r>
</w:p>
```

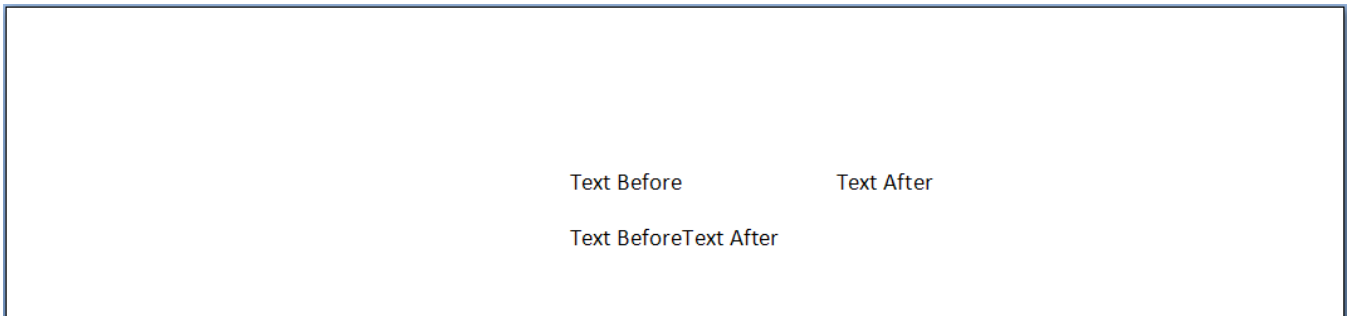
The default presentation would determine the full width of each line including the tab stops, finally aligning the resulting text to the `center` position as requested by the jc element:



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:forgetLastTabAlignment />
</w:compat>
```

Then the width added to the line by the last tab is ignored when centering the paragraph because that tab is a `center` aligned tab stop, resulting in the following output:



In the resulting output, the starting location of both lines is at the same place on the page, as the resulting width of both lines is identical when the tab stop is removed from the line width calculation. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted.

Attributes	Description
	A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

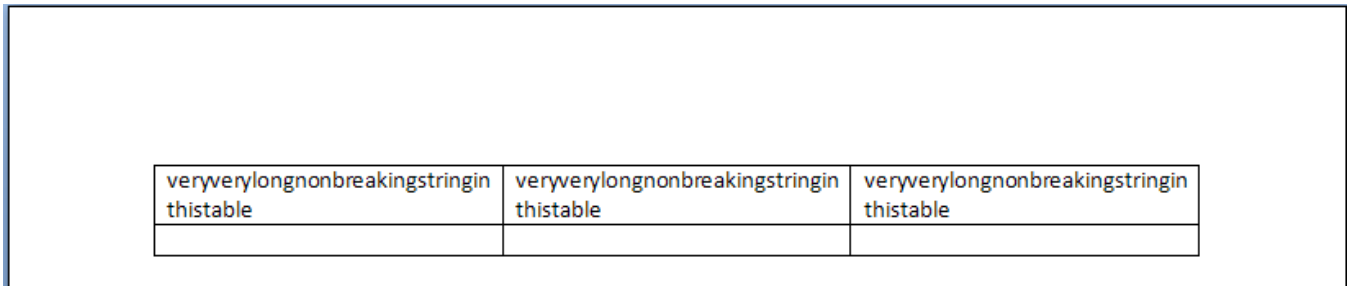
2.15.3.28 growAutofit (Allow Tables to AutoFit Into Page Margins)

This element specifies whether applications shall allow a table which is using the AutoFit table layout algorithm to extend beyond the margins of the page if the minimum width of each table cell would result in an overall table width which is wider than those page margins.

Typically, if a table is using the AutoFit layout algorithm, then based on the definition of that logic, each column in the table shall be increased to the minimum width of its contents (e.g. the longest non-breaking run of text contained within it and/or the width of an inline image contained in one of its cells) until the overall width of the table reaches that of the text extents on the page, at which point text shall be broken and images shall be clipped as needed to maintain the width of the table at the page width (i.e. the page width is an immutable maximum width for the table). This element, when present with a val attribute value of `true` (or equivalent), specifies that the minimum width of the cells shall not be constrained by the page width, and instead the table shall be allowed to extend into the page margins as needed in order to meet the minimum widths of each of its cells.

[*Example*: Consider a WordprocessingML table with three cells in each row. If the contents of each cell in that first row each contain a long non-breaking string (such that the minimum widths of each cell's contents exceed the page width), then the rules for table AutoFit specify that each cell must be broken proportionally when the overall width of the table reaches the page width.

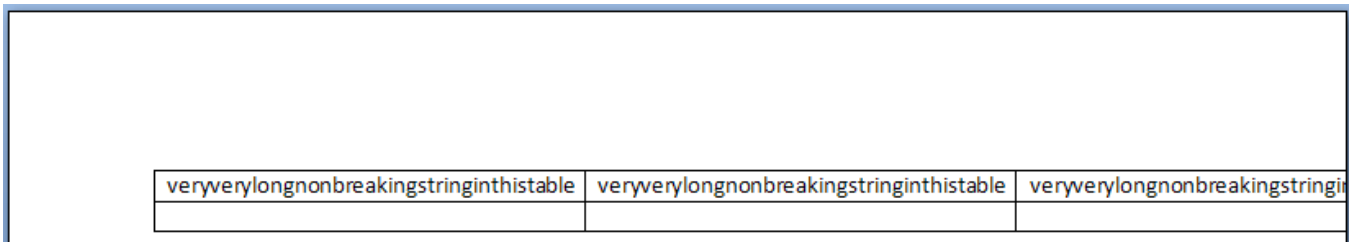
The default presentation of this document results in each cell being broken as needed to maintain the table width, as follows:



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:growAutofit />
</w:compat>
```

Then the presence of those long non-breaking strings (and the resulting large minimum widths for each table cell) shall result in a table width which is then allowed to override the page margins, resulting in the following output:



The resulting table is clipped by the edge of the page on its right side, but the minimum widths of each cell are maintained as defined by the long non-breaking string contents of each. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>`

Attributes	Description
	The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.29 layoutRawTableWidth (Ignore Space Before Table When Deciding If Table Should Wrap Floating Object)

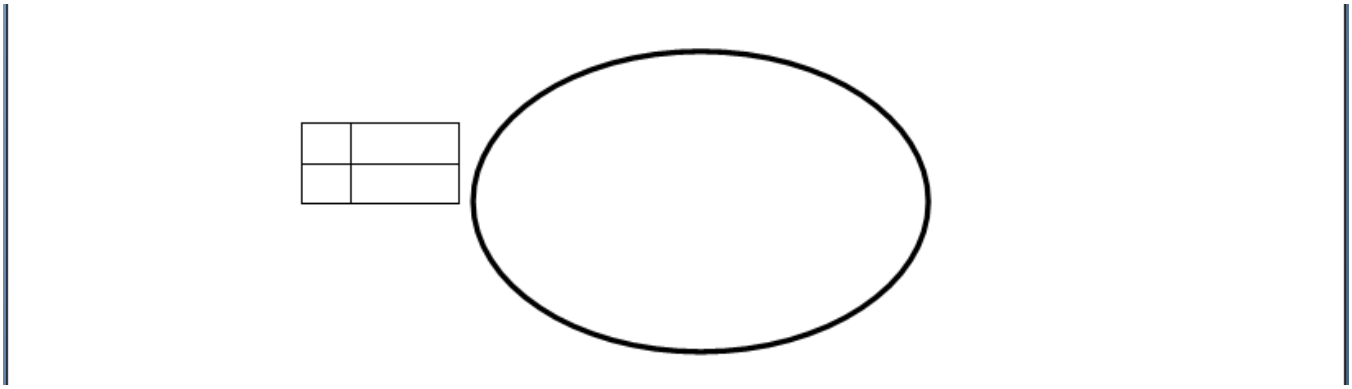
This element specifies how tables which have been indented from the margin using the tblInd element (§2.4.48) shall be wrapped around floating objects defined using the Vector Markup Language (VML) syntax.

Typically, when a table is positioned next to a floating object, the table shall only remain next to the object if it can fit in the remaining space on the line when considering the full width needed for the table: the space before the table, plus the width of the table. This element, when present with a val attribute value of true (or equivalent), specifies that the calculation determining whether the table shall fit next to the object shall not include the space before the table, even if that means that the table is actually clipped by the object.

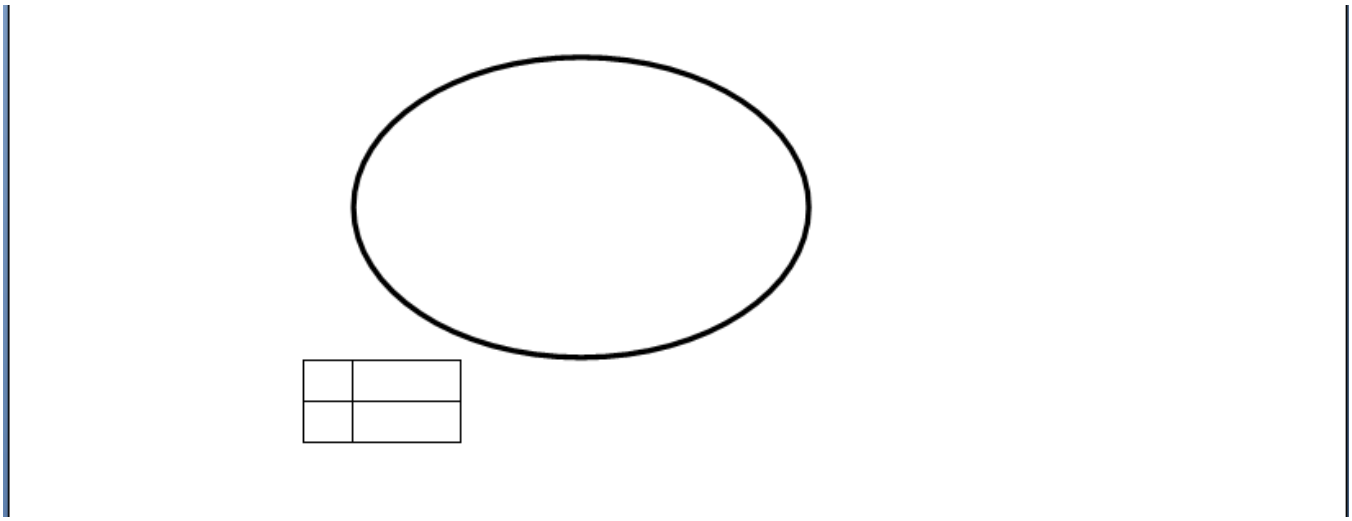
[*Example*: Consider a WordprocessingML document with a floating VML shape using square wrapping, next to a table which has been indented one inch from the left margin:

```
<w:tbl>
  <w:tblPr>
    <w:tblInd w:w="1440" w:type="dxa" />
  </w:tblPr>
  …
</w:tbl>
```

The resulting presentation would place the table next to the object:



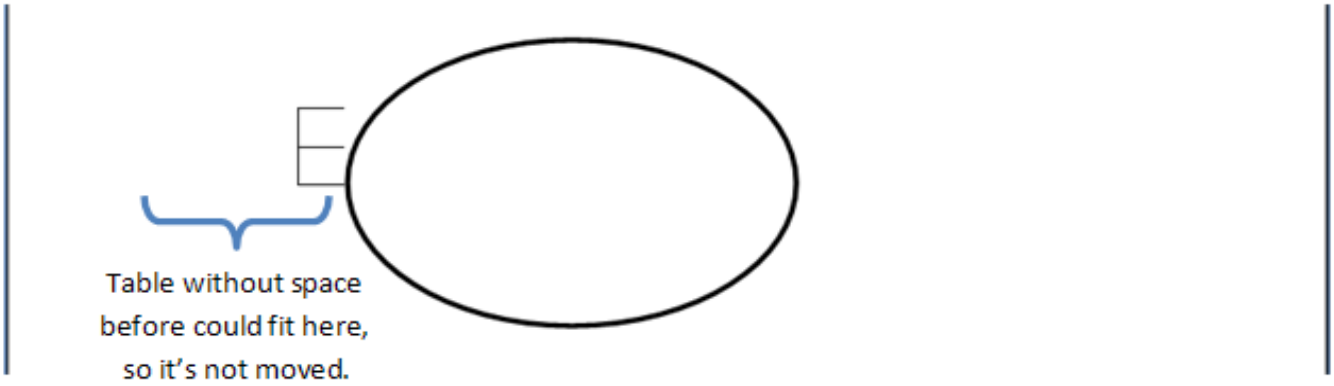
If this object is then moved to the left, such that it would clip the table, the default presentation would have the entire table moved below the shape, since it does not fit in the remaining space on the line:



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:layoutRawTableWidth />
</w:compat>
```

Then the determination to move the table is done ignoring the spaced needed before the table, resulting in the following output:



The resulting table is clipped behind the object, as the fit calculation ignores the space needed before the table. *end example*]

Attributes	Description

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

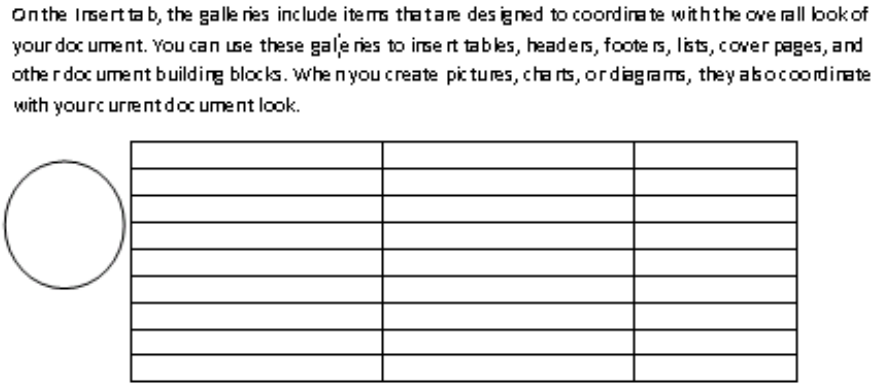
2.15.3.30 layoutTableRowsApart (Allow Table Rows to Wrap Inline Objects Independently)

This element specifies whether tables which are wrapping around floating objects defined using the Vector Markup Language (VML) syntax shall wrap around the object as a whole, or if each table row shall individually wrap the object as needed (causing a more stuttered, yet tighter, wrapping of the object).

Typically, when a table wraps around a floating object, the table must wrap the object as a unit (i.e. the whole table square wraps the object). This element, when present with a val attribute value of true (or equivalent), specifies that wrapping is applied to each row in the table one by one, even if its means that each row has a different resulting position with respect to the table.

[*Example*: Consider a WordprocessingML document with a floating VML shape using square wrapping.

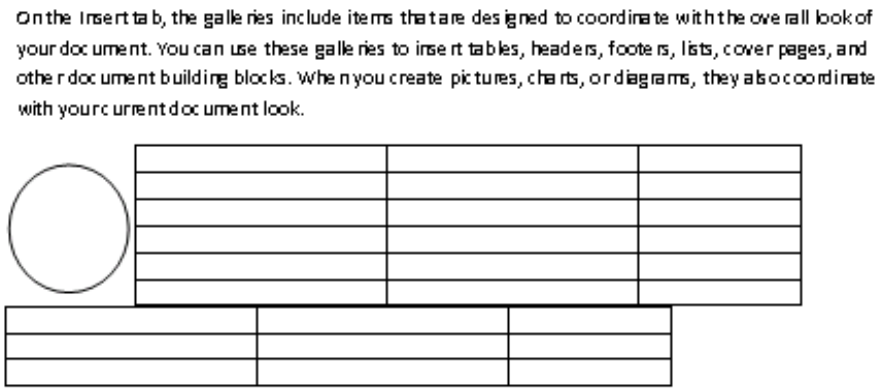
The default presentation would have the entire table wrapping around that shape:



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:layoutTableRowsApart />
</w:compat>
```

Then each row would wrap around the shape one by one, resulting in the following output:



end example]

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but

Attributes	Description
	this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.31 lineWrapLikeWord6 (Emulate Word 6.0 Line Wrapping for East Asian Text)

This element specifies that applications shall emulate the behavior of a previously existing word processing application (Microsoft Word 6.0) when determining the whitespace compression of the final character on each line in the document. This emulation typically results in characters ending a line that may be compressed on the right being compressed on the right irrespective to whether the compression will allow another character to be included on the given line or not.

[*Guidance*: To faithfully replicate this behavior, applications must imitate the behavior of that application, which involves many possible behaviors and cannot be faithfully placed into narrative for this Office Open XML Standard. If applications wish to match this behavior, they must utilize and duplicate the output of those applications. It is recommended that applications not intentionally replicate this behavior as it was deprecated due to issues with its output, and is maintained only for compatibility with existing documents from that application. *end guidance*]

Typically, applications shall not perform this compatibility. This element, when present with a val attribute value of `true` (or equivalent), specifies that applications shall attempt to mimic that existing word processing application in this regard.

[*Example*: Consider a WordprocessingML document with East Asian text.

If this compatibility setting is turned on:

```
<w:compat>
  <w:lineWrapLikeWord6 />
</w:compat>
```

Then applications should mimic the behavior of Microsoft Word 6.0 when determining the character compression of those characters at the end of each line on the displayed page, as needed. *end example*]

compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.32 mwSmallCaps (Emulate Word 5.x for the Macintosh Small Caps Formatting)

This element specifies that applications shall emulate the behavior of a previously existing word processing application (Microsoft Word 5.x for the Macintosh) when determining the resulting formatting when the smallCaps element (§2.3.2.31) is applied to runs of text within this WordprocessingML document. This emulation typically results in small caps which are smaller than typical small caps at most font sizes.

[*Guidance*: To faithfully replicate this behavior, applications must imitate the behavior of that application, which involves many possible behaviors and cannot be faithfully placed into narrative for this Office Open XML Standard. If applications wish to match this behavior, they must utilize and duplicate the output of those applications. It is recommended that applications not intentionally replicate this behavior as it was deprecated due to issues with its output, and is maintained only for compatibility with existing documents from that application. *end guidance*]

Typically, applications shall not perform this compatibility. This element, when present with a val attribute value of `true` (or equivalent), specifies that applications shall attempt to mimic that existing word processing application in this regard.

[*Example*: Consider a WordprocessingML document with small caps on its text contents.

If this compatibility setting is turned on:

```
<w:compat>
  <w:mwSmallCaps />
</w:compat>
```

Then applications should mimic the behavior of Microsoft Word 5.x for the Macintosh when determining the formatting for small caps of characters which specify this formatting, as needed.

As an example of the typical differences, the output of a normal small caps implementation (in black) and one intended to replicate Word 5.x for the Macintosh (in red) are displayed below for several font sizes:

end example]

Parent Elements

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element.

Attributes	Description
	A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.33 noColumnBalance (Do Not Balance Text Columns within a Section)

This element specifies whether the contents of sections with multiple columns defined using the cols element (§2.6.4) should automatically be balanced. In terms of column layout, *balancing* is the act of attempting to ensure that the number of lines in each column is equivalent (rather than completely filling one column before populating the next).

Typically, column balancing is automatically performed on the contents of sections with multiple columns. This element, when present with a val attribute value of true (or equivalent), specifies that column balancing shall not occur, and each column shall be filled individually until the end of the current page, until all text has been displayed, even if this means one or more columns are unused.

[*Example*: Consider a WordprocessingML document with an initial section with three columns, defined by the following section properties:

```
<w:sectPr>
  <w:cols w:num="3" w:space="720" />
</w:sectPr>
```

The default presentation would have the text in that section balanced between those three columns:

This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns.

This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns.

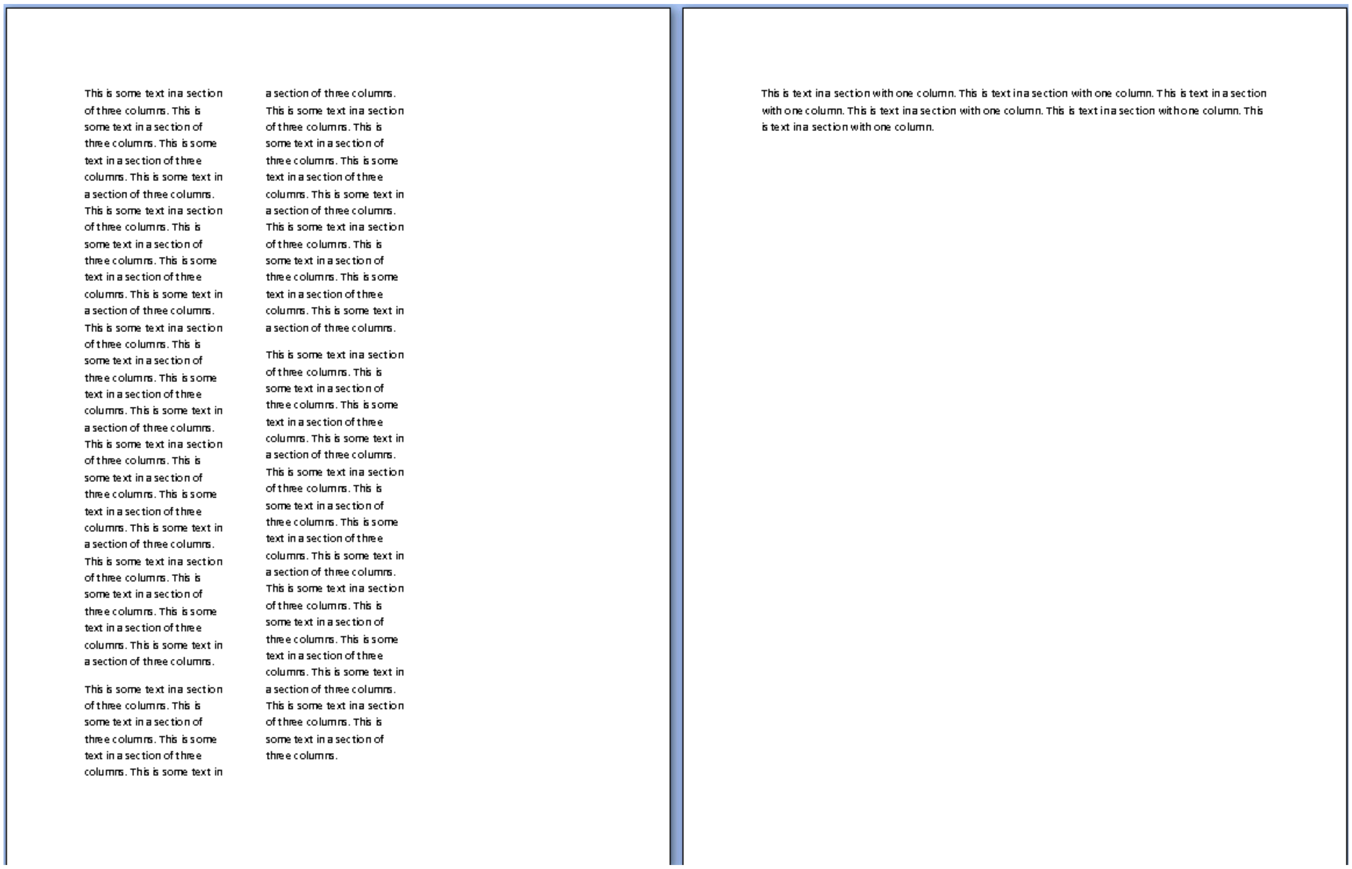
This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns. This is some text in a section of three columns.

This is text in a section with one column. This is text in a section with one column. This is text in a section with one column. This is text in a section with one column. This is text in a section with one column. This is text in a section with one column.

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:noColumnBalance />
</w:compat>
```

Then the columns are not balanced, and the contents of the section are used to fill each column to the bottom of the current page in succession, resulting in the following output:



The next section is now forced to begin on the next page, as the columns on page one extend to the bottom of that page. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.34 noExtraLineSpacing (Do Not Center Content on Lines With Exact Line Height)

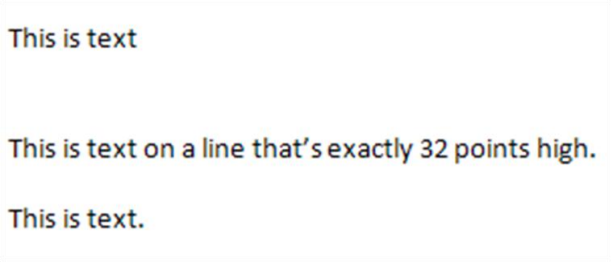
This element specifies whether an exact line height using the spacing element (§2.3.1.33) in the paragraph's properties, each line shall not be automatically centered within the given amount of line spacing.

Typically, if the exact amount of spacing allotted to a line via the paragraph properties exceeds the amount of space required by that line, then the line of text shall be automatically centered when the text of the document is displayed. This element, when present with a val attribute value of true (or equivalent), specifies thatall additional spacing shall instead be placed below the normal layout of the line of text.

[*Example*: Consider a WordprocessingML document with a line with an exact height of 32 points:

```
<w:p>
  <w:pPr>
    <w:spacing w:line="640" w:lineRule="exact" />
  </w:pPr>
  <w:r>
    <w:t>This is text on a line that's exactly 32 points high.</w:t>
  </w:r>
</w:p>
```

The default presentation would have the resulting text centered on that line:



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:noExtraLineSpacing />
</w:compat>
```

Then all line spacing is added after the text, resulting in the following output:

This is text

This is text on a line that's exactly 32 points high.

This is text.

end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.35 noLeading (Do Not Add Leading Between Lines of Text)

This element specifies whether the additional leading specified by the current font face shall be added between each line of text when that text is displayed. *Leading* refers to the additional spacing requested by a particular font in order to ensure that letters on subsequent lines do not display in a fashion where they are positioned too closely together.

Typically, leading should be added as specified by the associated font. This element, when present with a val attribute value of true (or equivalent), specifies that the additional leading specified by the font shall never be output when the text is displayed.

[*Example*: Consider a WordprocessingML document with three lines of text. The default presentation would have the text displayed as follows:

EXAMPLE TEXT

Some text.
Some text.
Some text.

However, if this compatibility setting is turned on:

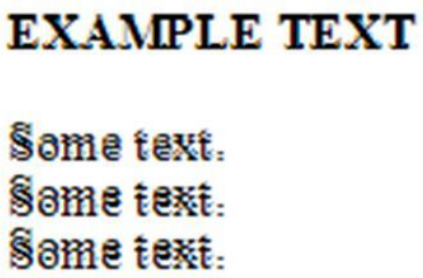
```
<w:compat>
  <w:noLeading />
</w:compat>
```

Then no leading is added between lines, resulting in the following output:

EXAMPLE TEXT

Some text.
Some text.
Some text.

This adjustment is usually very minute in nature; therefore the result is better illustrated by showing how the characters were pushed out due to the leading added to that text:



end example]

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.36 noSpaceRaiseLower (Do Not Increase Line Height for Raised/Lowered Text)

This element specifies whether the height which is allotted to any given line of text when the contents of this document are displayed shall include additional spacing in order to ensure that all raised and/or lowered text can be fully displayed.

Typically, any extra space needed is added to the line to prevent raised and lowered text from being truncated or hidden. This element, when present with a val attribute value of true (or equivalent), specifies that the height of the line shall be determined solely by the spacing settings on the parent paragraph, and any raised/lowered text shall just be clipped if it exceeds that space.

[*Example*: Consider a WordprocessingML document with both raised and lowered text. The default presentation would have that text visible:

This is text.

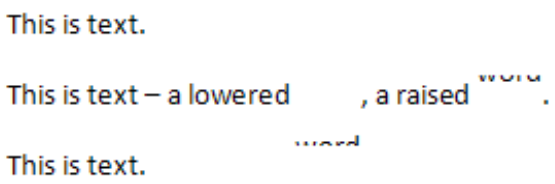
This is text – a lowered word, a raised word.

This is text.

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:noSpaceRaiseLower />
</w:compat>
```

Then no additional space should be added to the line height, resulting in the following output:



end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.37 noTabHangInd (Do Not Create Custom Tab Stop for Hanging Indent)

This element specifies whether applications should always create a hanging indent as a custom tab stop when handling tabs within the contents of a WordprocessingML paragraph. The dontUseIndentAsNumberingTabStop element (§2.15.3.22) specifies if this tab stop shall be used in the case of a tab added as the suffix to numbering in a numbered paragraph, while this element handles the same

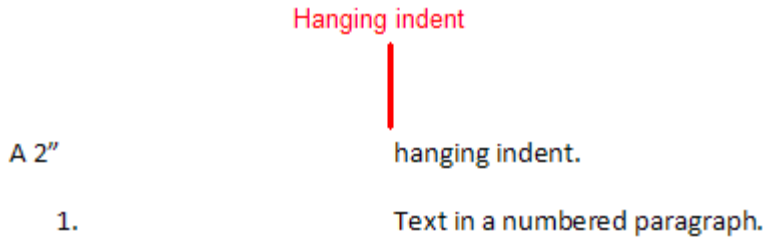
functionality in the generic case (i.e. this element, when set, renders that setting irrelevant as the tab stop is never used).

Typically, the hanging indent on a paragraph shall be treated as a custom tab stop location within that paragraph, allowing the first tab on the first line in the paragraph to advance to the location of the hanging indent. This element, when present with a val attribute value of `true` (or equivalent), specifies that no custom tab stop shall be created for a hanging indent on a line under any circumstances.

[*Example*: Consider a WordprocessingML document with two paragraphs (the second numbered, the first not), each with a 2" hanging indent defined as follows (assume the numbering suffix - not shown - is a tab character):

```
<w:p>
  <w:pPr>
    <w:ind w:left="2880" w:hanging="2880" />
  </w:pPr>
  <w:r>
    <w:t>A 2"</w:t>
    <w:tab/>
    <w:t>hanging indent</w:t>
  </w:r>
</w:p>
<w:p>
  <w:pPr>
    <w:numPr>
      <w:ilvl w:val="0" />
      <w:numId w:val="1" />
    </w:numPr>
    <w:ind w:left="2880" w:hanging="2880" />
  </w:pPr>
  <w:t>Text in a numbered paragraph.</w:t>
</w:p>
```

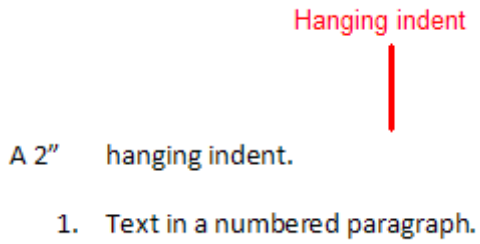
The default presentation would have both the numbering and the tab in the regular paragraph advancing to the 2" custom tab stop generated by the hanging indent:



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:noTabHangInd />
</w:compat>
```

Then no tab stop exists at 2", and therefore the tab stops must advance to the location of the next automatic tab stop for this document (which is set to occur every 0.5"), resulting in the following output:



end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.38 printBodyTextBeforeHeader (Print Body Text before Header/Footer Contents)

This element specifies the order in which the contents of the main document story and any headers and/or footers shall be sent to the printer.

Typically, the contents of a document are sent to the printer as follows:

- First, the contents of headers/footers are sent to the printer
- Finally, the contents of the main document story are sent to the printer

This element, when present with a val attribute value of `true` (or equivalent), specifies that this order shall be reversed, and that the body text shall be sent to the printer before any header/footer text. This reversal allows for the processing of PostScript codes in the text layer in the same order as afforded by some legacy word processing applications.

[*Example*: Consider a WordprocessingML document which is printed. The default resulting print order is the headers and footers for each page, followed by the page contents.

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:printBodyTextBeforeHeader />
</w:compat>
```

Then this order shall be reversed, and the page contents shall be printed before the corresponding header and/or footer for each page. *end example*]

Parent Elements

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.39 printColBlack (Print Colors as Black And White without Dithering)

This element specifies the way in which colored text and/or objects shall be handled when printed to a printer whose printer settings indicate that it can only handle black and white text.

Typically, the contents of a colored document are sent to a black and white printer using grayscale (different shades of gray) to represent each of the possible colors. This element, when present with a val attribute value of `true` (or equivalent), specifies that colors will not be printed as mapped shades of grey, but rather exclusively in solid black and white. This setting prevents the fuzzy look that may occur when gray or blue content is dithered. *Dithering* is the process by which colors are simulated using various patterns of black dots on a white background

[*Example*: Consider a WordprocessingML document which is printed to a black and white printer. The default resulting printed content is typically dithered to appear in the appropriate shade of grayscale text.

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:printColBlack />
</w:compat>
```

Then the page contents shall be printed as exclusively black or exclusively white text as needed, and no grayscale output shall occur. *end example*]

Parent Elements

val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property:

Attributes	Description
	<w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

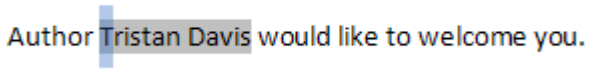
2.15.3.40 selectFldWithFirstOrLastChar (Select Field When First or Last Character Is Selected)

This element specifies whether applications should automatically select the entire contents of a field in a WordprocessingML document when the first or last character is selected.

Typically, users can select any character individually within the result of a field in the document. This element, when present with a val attribute value of true (or equivalent), specifies that selecting the first or last character of that field result shall automatically result in the selection of the entire field.

[*Example*: Consider a WordprocessingML document which contains the following (with a field marked in gray shading):

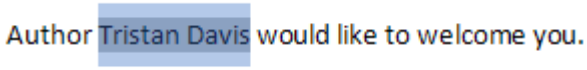
The default presentation would allow the first character of that field to be selected:



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:selectFldWithFirstOrLastChar />
</w:compat>
```

Then that selection would automatically result in the entire field being selected, resulting in the following:



end example]

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.41 shapeLayoutLikeWW8 (Emulate Word 97 Text Wrapping Around Floating Objects)

This element specifies that applications shall emulate the behavior of a previously existing word processing application (Microsoft Word 97) when determining how to wrap text around floating objects using topAndBottom wrapping defined using the Vector Markup Language (VML) syntax. This emulation typically results in the wrapping above and below the object allowing the text to wrap more tightly around the object (text wraps more tightly around the object than it normally would).

[*Guidance*: To faithfully replicate this behavior, applications must imitate the behavior of that application, which involves many possible behaviors and cannot be faithfully placed into narrative for this Office Open XML Standard. If applications wish to match this behavior, they must utilize and duplicate the output of those applications. It is recommended that applications not intentionally replicate this behavior as it was deprecated due to issues with its output, and is maintained only for compatibility with existing documents from that application. *end guidance*]

Typically, applications shall not perform this compatibility. This element, when present with a val attribute value of true (or equivalent), specifies that applications shall attempt to mimic that existing word processing application in this regard.

[*Example*: Consider a WordprocessingML document with a floating shape using top and bottom wrapping.

If this compatibility setting is turned on:

```
<w:compat>
  <w:shapeLayoutLikeWW8 />
</w:compat>
```

Then applications should mimic the behavior of Microsoft Word 97 when determining the way in which text wraps around that object, as needed. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

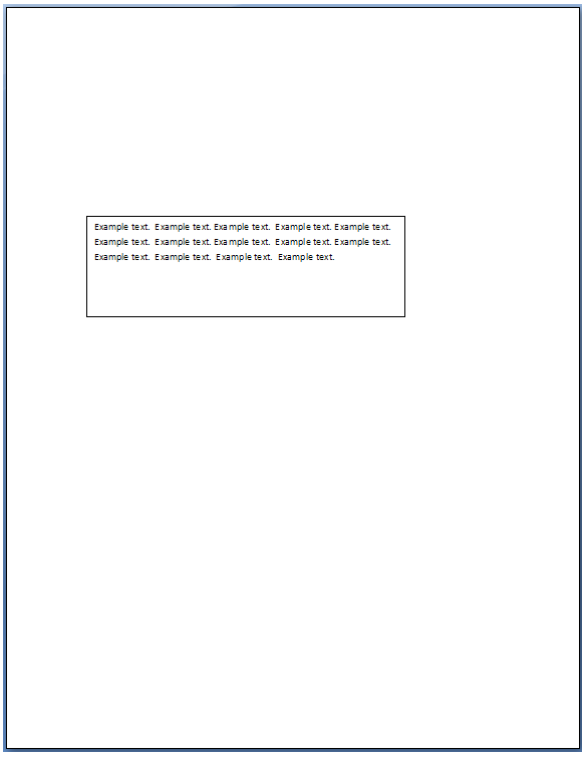
```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.42 showBreaksInFrames (Display Page/Column Breaks Present in Frames)

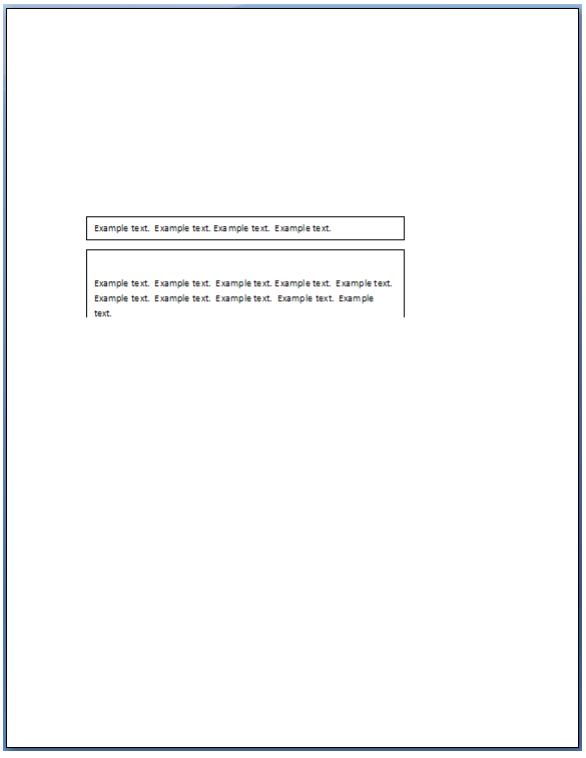
This element specifies whether applications should honor the presence of page and/or column breaks which are present within the contents of paragraphs which have been defined as frames using the framePr element (§2.3.1.11).

Typically, breaks within frames shall be ignored and shall have no effect on the display of the paragraph in which they are contained. This element, when present with a val attribute value of `true` (or equivalent), specifies that rather than completely ignoring these breaks, applications should display the break and move the remaining frame content, and all subsequent text, to the next page and/or column, as needed.

[*Example*: Consider a WordprocessingML document with a paragraph contained within a text frame:



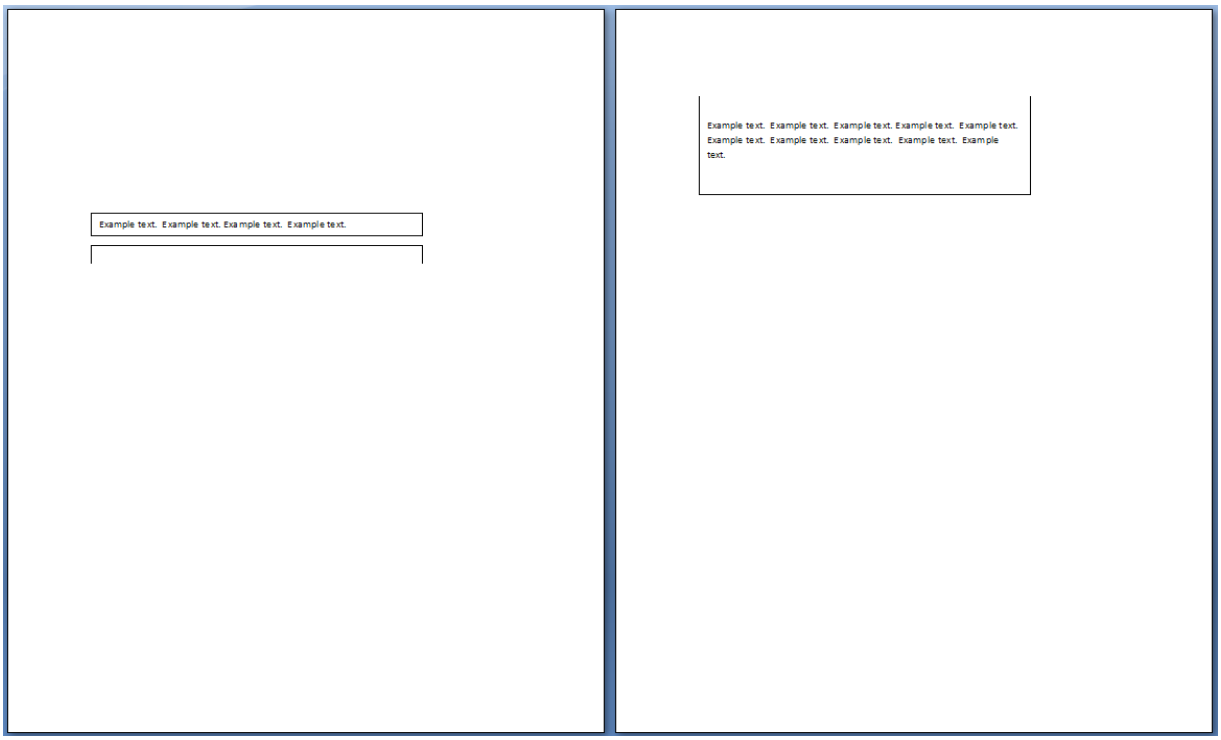
The default presentation would display the page break inline in the frame (breaking the frame into two) but would not actually break the page:



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:showBreaksInFrames />
</w:compat>
```

Then the page breaks will be used even though they are present in the frame, breaking the page and resulting in the following output:



end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property:

Attributes	Description
	<w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.43 spaceForUL (Add Additional Space Below Baseline For Underlined East Asian Text)

This element specifies whether East Asian content in a WordprocessingML document which has been underlined using the u element shall have additional descent added to the properties of the font in order to ensure that there is adequate spacing between the characters in the font and the underlining applied to the text.

Typically, no adjustments are made to the contents of text runs containing East Asian text which have been underlined. This element, when present with a val attribute value of true (or equivalent), specifies that whenever the following conditions are met:

- The text run contains East Asian characters
- The text run is not using baseline font alignment as defined by the textAlignment property

That the larger of the following two values will be added to the descent property of that font in order to provide additional padding between the text characters and the underline:

- 3 percent of the font size
- 40 twentieths of a point (31 twentieths of a point for Japanese text)

[*Example*: Consider a WordprocessingML document consisting of a single run of underlined Japanese text, as follows:

```
<w:p>
  <w:r>
    <w:rPr>
      <w:u w:type="double" />
    </w:rPr>
    <w:t>クリスタ</w:t>
  </w:r>
</w:p>
```

If this document is displayed, then the text is laid out along with the underline, as follows:

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:spaceForUL />
</w:compat>
```

Then the additional descent specified using the logic above is added to the text, resulting in the following output:

end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.44 spacingInWholePoints (Only Expand/Condense Text By Whole Points)

This element specifies how applications should apply text expansion/compression defined using the spacing element (§2.3.2.33) within a set of run properties.

Typically, as defined in the spacing element, text within runs in a WordprocessingML document may be expanded or compressed in increments of twentieths of a point. This element, when present with a val attribute value of true (or equivalent), specifies that the expansion and compression of text shall only be performed in increments of points. Any value which is not equal to an expansion or compression of a whole point shall be rounded down to the nearest whole point when the text is expanded/compressed within the WordprocessingML document.

[*Example*: Consider a WordprocessingML document with three paragraphs of text, each expanded by a varying amount, as follows:

```
<w:p>
  …
  <w:r>
    <w:t>This is text.</w:t>
  </w:r>
</w:p>
<w:p>
  …
  <w:r>
    <w:rPr>
      <w:spacing w:val="20" />
    </w:rPr>
    <w:t>This is text.</w:t>
  </w:r>
</w:p>
<w:p>
  …
  <w:r>
    <w:rPr>
      <w:spacing w:val="36" />
    </w:rPr>
    <w:t>This is text.</w:t>
  </w:r>
</w:p>
```

The default presentation would have each run of text expanded exactly as requested:

Regular Text: This is text.

Text expanded by 1 point: This is text.

Text expanded by 1.8 points: This is text.

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:spacingInWholePoints />
</w:compat>
```

Then the third line - with an expansion of 1.8 points - would instead be rounded down to the nearest whole number of points when expanded, resulting in the following output:

Regular Text: This is text.

Text expanded by 1 point: This is text.

Text expanded by 1.8 points: This is text.

In the resulting output, the second and third lines are identical, as the third line has a next expansion of exactly one point. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.45 splitPgBreakAndParaMark (Always Move Paragraph Mark to Page after a Page Break)

This element specifies whether a page break shall automatically complete the line on which it appears, moving the end of the paragraph to a new line on the next page, or if it shall behave as true run-level content within its current paragraph.

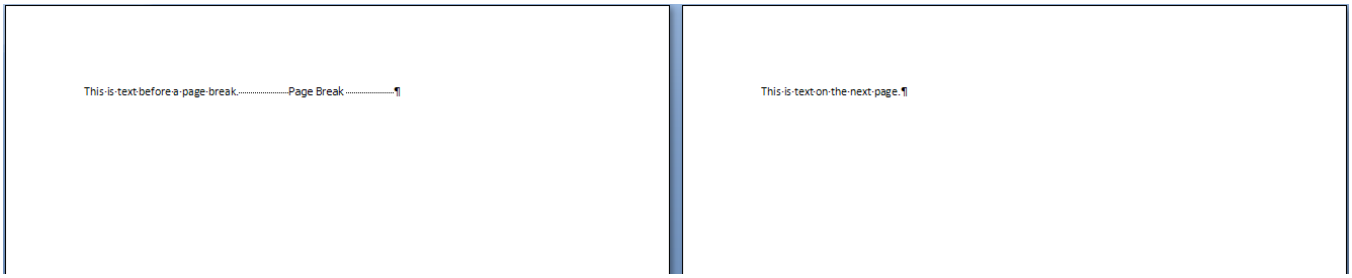
Typically, a page break defined using the br element (§2.3.3.1) is treated as run-level content, which means that although it delimits the end of the page, if there is no content after it within the current paragraph, that the paragraph shall also end on that page. This element, when present with a val attribute value of `true` (or equivalent), specifies that a page break shall always immediately end the current page, moving the paragraph mark which delimits the end of its parent paragraph to a new line on the next page.

Note that this setting only affects the case where there is no run-level content after the page break within the paragraph - if any further run content appears in the paragraph it shall appear on subsequent lines on the next page.

[*Example*: Consider a WordprocessingML document with two paragraphs of content - the first ending with a page break:

```
<w:p>
  <w:r>
    <w:t>This is text before a page break.</w:t>
    <w:br w:type="page" />
  </w:r>
</w:p>
<w:p>
  <w:r>
    <w:t>This is text on the next page.</w:t>
  </w:r>
</w:p>
```

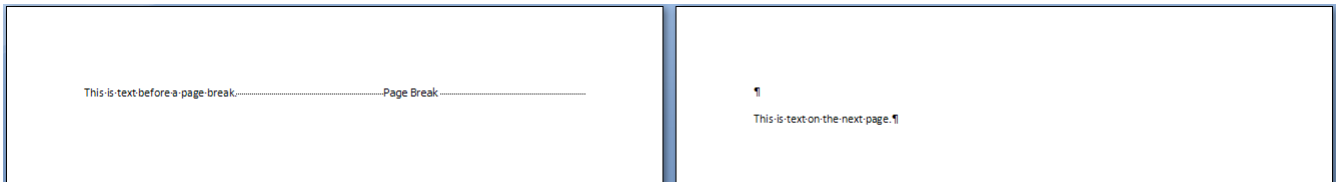
The default presentation would have the text content `This is text on the next page.` as the first line of the second page, as there is no run content after the page break in paragraph one, and therefore no need for a new line on page two (in this image, a graphical illustration of the pilcrow and the page break have been added for clarity):



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:splitPgBreakAndParaMark />
</w:compat>
```

Then even though it is followed by no additional content, the page break shall immediately end the first page, pushing the end of the first paragraph onto the first line of the second page, resulting in the following output:



end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.46 subFontBySize (Increase Priority Of Font Size During Font Substitution)

This element specifies whether applications shall increase the priority of font size when performing font substitution in a WordprocessingML document. *Font substitution* is the process by which an application determines which font to use in place of a font that is referenced by a document, but is not available to the application trying to display the document.

Typically, applications may perform font substitution using any mechanism available. This element, when present with a val attribute value of `true` (or equivalent), specifies that finding a font with a similar font size shall have increased precedence when doing font substitution for this document.

[*Example*: Consider a WordprocessingML document with a series of characters in an unavailable font. The default presentation would use any method used by the application to perform that font substitution.

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:subFontBySize />
</w:compat>
```

Then font size shall take precedence when performing font substitution for this document, as needed. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.47 suppressBottomSpacing (Ignore Exact Line Height for Last Line on Page)

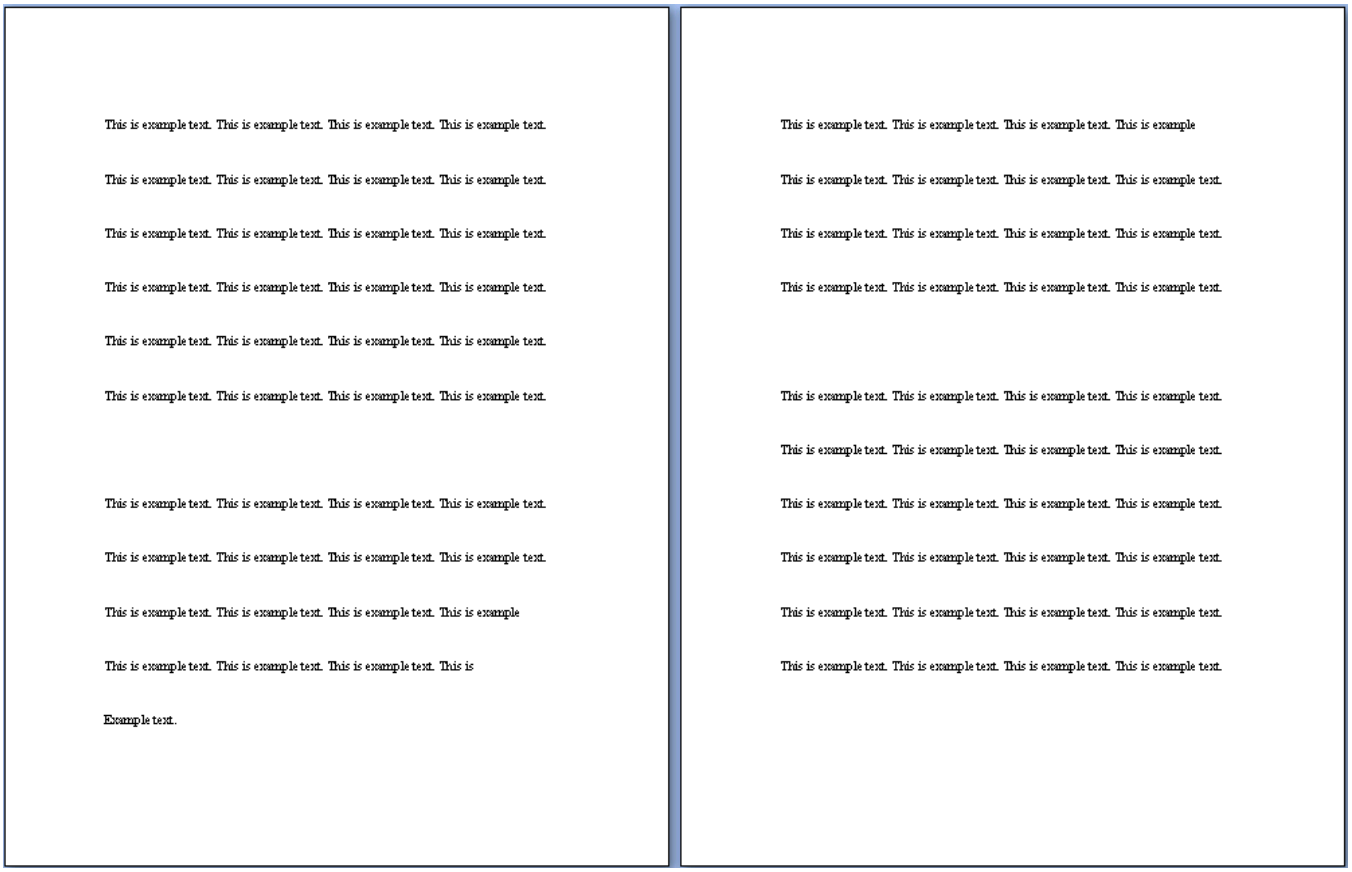
This element specifies whether an exact line height specified using the spacing element (§2.3.1.33) with a lineRule attribute value of exact shall be ignored for the last line on each page.

Typically, if an exact line height has been specified using the spacing element, then all lines within that paragraph have the necessary line spacing added to them in order to meet this constraint. This element, when present with a val attribute value of true (or equivalent), specifies that no additional spacing shall be added below the last line on each page as a result of these line spacing requirements - a line shall be placed on the bottom of the page if its characters fit on that page ignoring the necessary space after.

[*Example*: Consider a WordprocessingML document whose first paragraph has a line spacing setting requiring exactly 48 points of space per line:

```
<w:p>
  <w:pPr>
    <w:spacing w:line="960 w:lineRule="exact" />
  </w:pPr>
  …
</w:p>
```

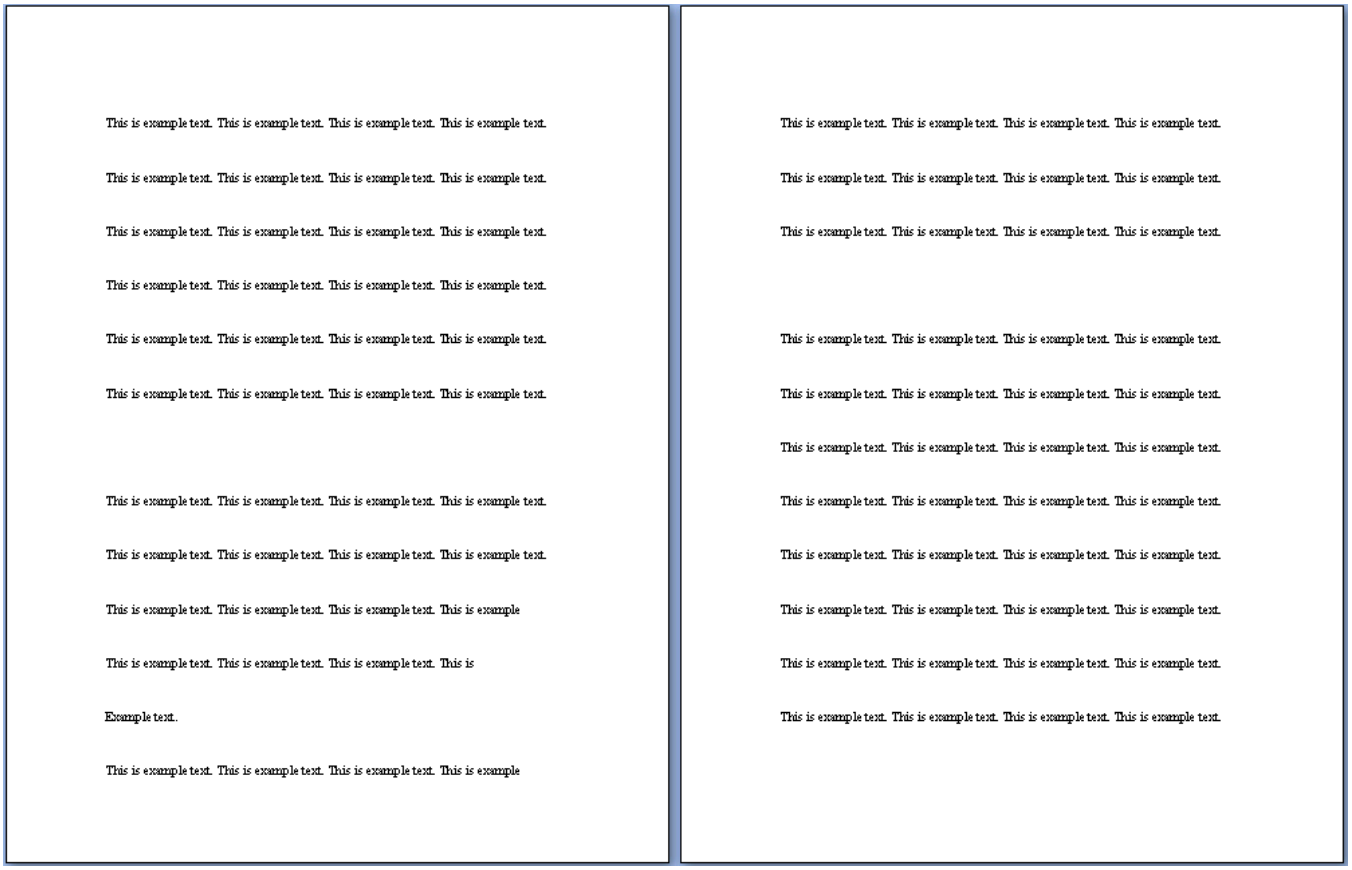
The default presentation would have the necessary amount of space added between each line such that all lines in the paragraph are centered within 48 points of spacing:



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:suppressBottomSpacing />
</w:compat>
```

Then that constraint shall be lifted for the last line on the page (although all other lines are unaffected), resulting in the following output:



The first line from the following page was moved on the first page, as without being subjected to the line height constraint, it is possible to fit it at the bottom of the first page. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.48 suppressSpacingAtTopOfPage (Ignore Minimum Line Height for First Line on Page)

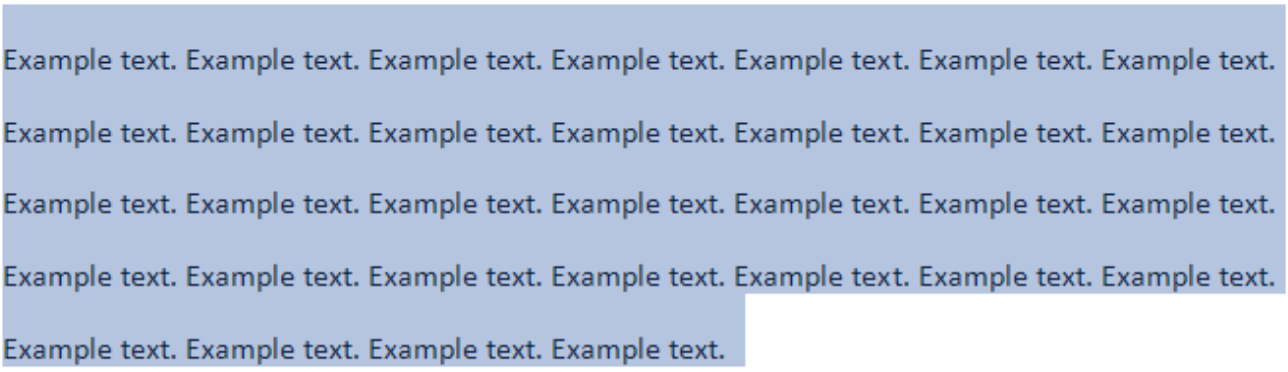
This element specifies whether the minimum line height specified using the spacing element (§2.3.1.33) with a lineRule attribute value of `atLeast` shall be ignored for the first line on each page.

Typically, if a minimum line height has been specified using the spacing element, then all lines within that paragraph have the necessary line spacing added to them in order to meet this constraint. This element, when present with a val attribute value of `true` (or equivalent), specifies that no additional spacing shall be added above the first line on each page as a result of this line spacing requirements - the top of the text characters on the first line shall be at the top edge of the page.

[*Example*: Consider a WordprocessingML document whose first paragraph has a line spacing setting requiring at least 25 points of space per line:

```
<w:p>
  <w:pPr>
    <w:spacing w:line="500" w:lineRule="atLeast" />
  </w:pPr>
  …
</w:p>
```

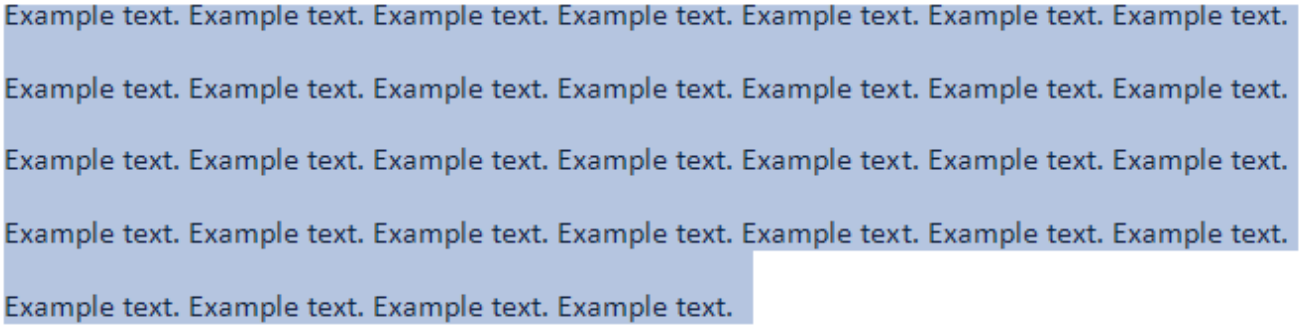
The default presentation would have the necessary amount of space added between each line such that all lines in the paragraph are centered within 25 points of spacing (highlighting has been added to the image below in order to illustrate the additional spacing above the first line):



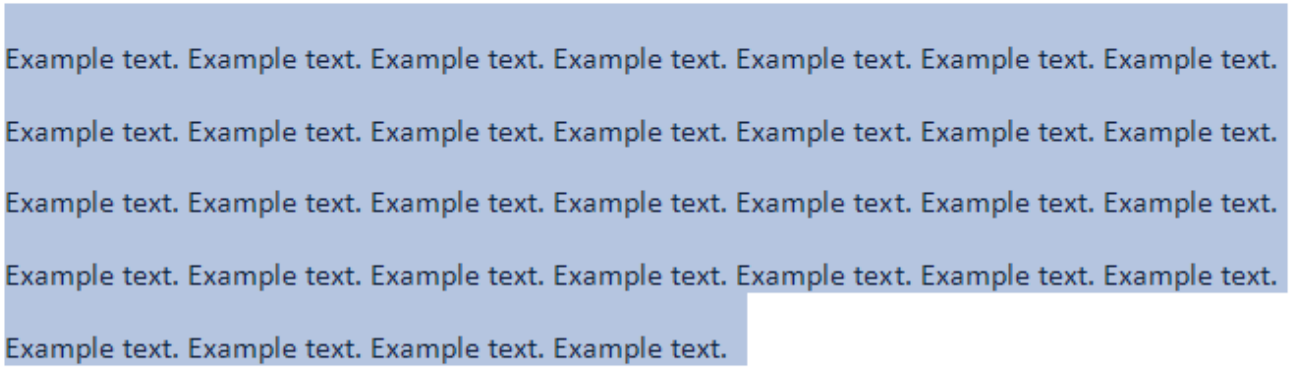
However, if this compatibility setting is turned on:

```
<w:compat>
  <w:suppressSpacingAtTopOfPage />
</w:compat>
```

Then no additional line spacing shall be added above the first line on the page (although all other lines are unaffected), resulting in the following output:



However, if this line spacing constraint was exactly 25 points, then this setting would have no effect:



end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted.

Attributes	Description
	A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.49 suppressSpBfAfterPgBrk (Do Not Use Space Before On First Line After a Page Break)

This element specifies that applications should not postpone any before paragraph spacing to the first line containing content after a page break.

Typically, a page break defined using the br element (§2.3.3.1) is treated as run-level content, which means that although it delimits the end of the page, if there is no content after it within the current paragraph, that the paragraph shall also end on that page. However, in the case where there is additional run-level content within the same paragraph, that content, although part of the same paragraph as the page break, is displayed on the following page.

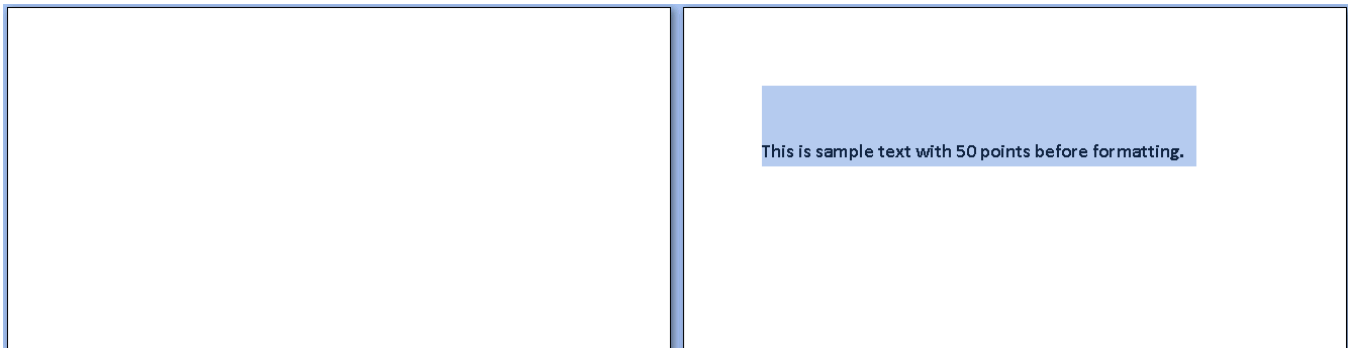
This leads to a situation where the only run content on the page with the page break is the break itself, with all subsequent content on the following page. In this case, applications shall apply the value specified by the spacing element's before attribute to the first line on the new page (since it is ostensibly the only page with content in that paragraph).

This element, when present with a val attribute value of `true` (or equivalent), specifies the paragraph before spacing shall not be 'postponed' in this way - if the line with the page break has no content, then the spacing element's before attribute is simply ignored.

[*Example*: Consider a WordprocessingML document whose first paragraph specifies that it shall be preceded by 50 points of additional spacing:

```
<w:p>
  <w:pPr>
    <w:spacing w:before="1000" />
  </w:pPr>
  <w:r>
    <w:br w:type="page" />
    <w:t>This is sample text with 50 points before formatting.</w:t>
  </w:r>
</w:p>
```

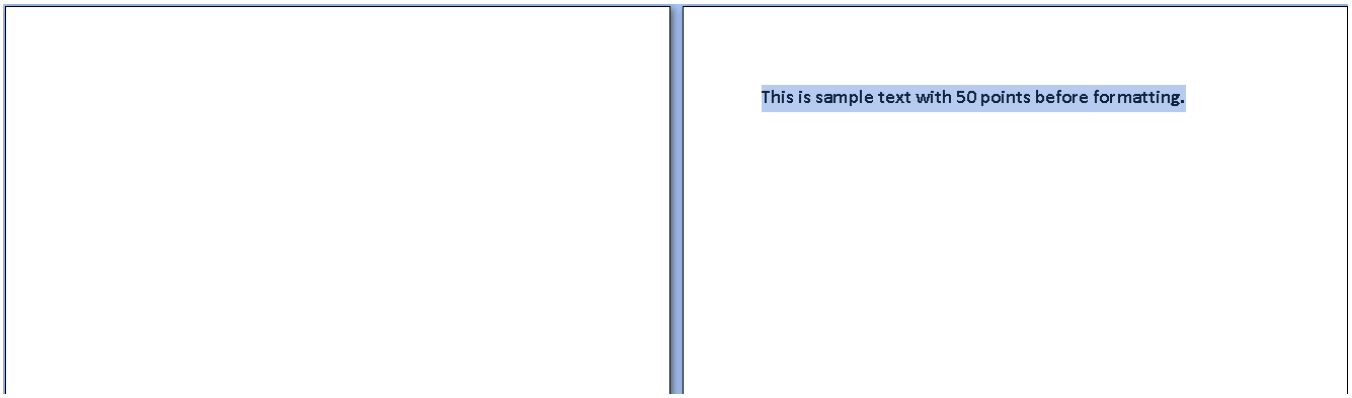
The default presentation would have the necessary amount of space added to the first line on the second page, as the page break was not preceded by any run content (highlighting has been added to the image below in order to illustrate the additional spacing above the first line):



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:suppressSpBfAfterPgBrk />
</w:compat>
```

Then the spacing shall not be added above the first line on the page (it is essentially ignored), resulting in the following output:



end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.50 suppressTopSpacing (Ignore Minimum and Exact Line Height for First Line on Page)

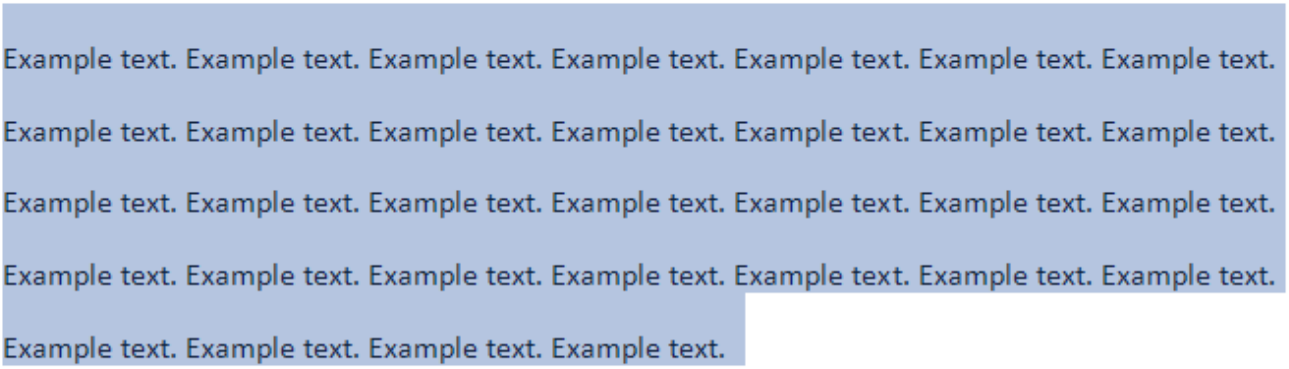
This element specifies whether the minimum line height specified using the spacing element (§2.3.1.33) with a lineRule attribute value of atLeast or exact shall be ignored for the first line on each page.

Typically, if a minimum or exact line height has been specified using the spacing element, then all lines within that paragraph have the necessary line spacing added to them in order to meet this constraint. This element, when present with a val attribute value of true (or equivalent), specifies that no additional spacing shall be added above the first line on each page as a result of these line spacing requirements - the top of the text characters on the first line shall be at the top edge of the page.

[*Example*: Consider a WordprocessingML document whose first paragraph has a line spacing setting requiring exactly 25 points of space per line:

```
<w:p>
  <w:pPr>
    <w:spacing w:line="500" w:lineRule="exact" />
  </w:pPr>
  …
</w:p>
```

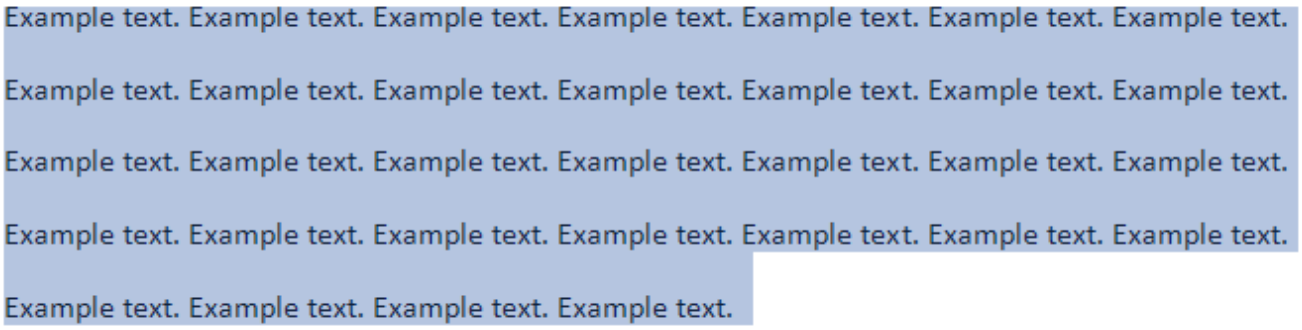
The default presentation would have the necessary amount of space added between each line such that all lines in the paragraph are centered within 25 points of spacing (highlighting has been added to the image below in order to illustrate the additional spacing above the first line):



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:suppressTopSpacing />
</w:compat>
```

Then no additional line spacing shall be added above the first line on the page (although all other lines are unaffected), resulting in the following output:



end example]

Parent Elements

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.51 suppressTopSpacingWP (Emulate WordPerfect 5.x Line Spacing)

This element specifies that applications shall emulate the behavior of a previously existing word processing application (WordPerfect 5.x) when determining the resulting spacing between lines in a paragraph using the spacing element (§2.3.1.33). This emulation typically results in line spacing which is reduced from its normal size.

[*Guidance*: To faithfully replicate this behavior, applications must imitate the behavior of that application, which involves many possible behaviors and cannot be faithfully placed into narrative for this Office Open XML Standard. If applications wish to match this behavior, they must utilize and duplicate the output of those applications. It is recommended that applications not intentionally replicate this behavior as it was deprecated due to issues with its output, and is maintained only for compatibility with existing documents from that application. *end guidance*]

Typically, applications shall not perform this compatibility. This element, when present with a val attribute value of true (or equivalent), specifies that applications shall attempt to mimic that existing word processing application in this regard.

[*Example*: Consider a WordprocessingML document with triple line spacing defined using the spacing element:

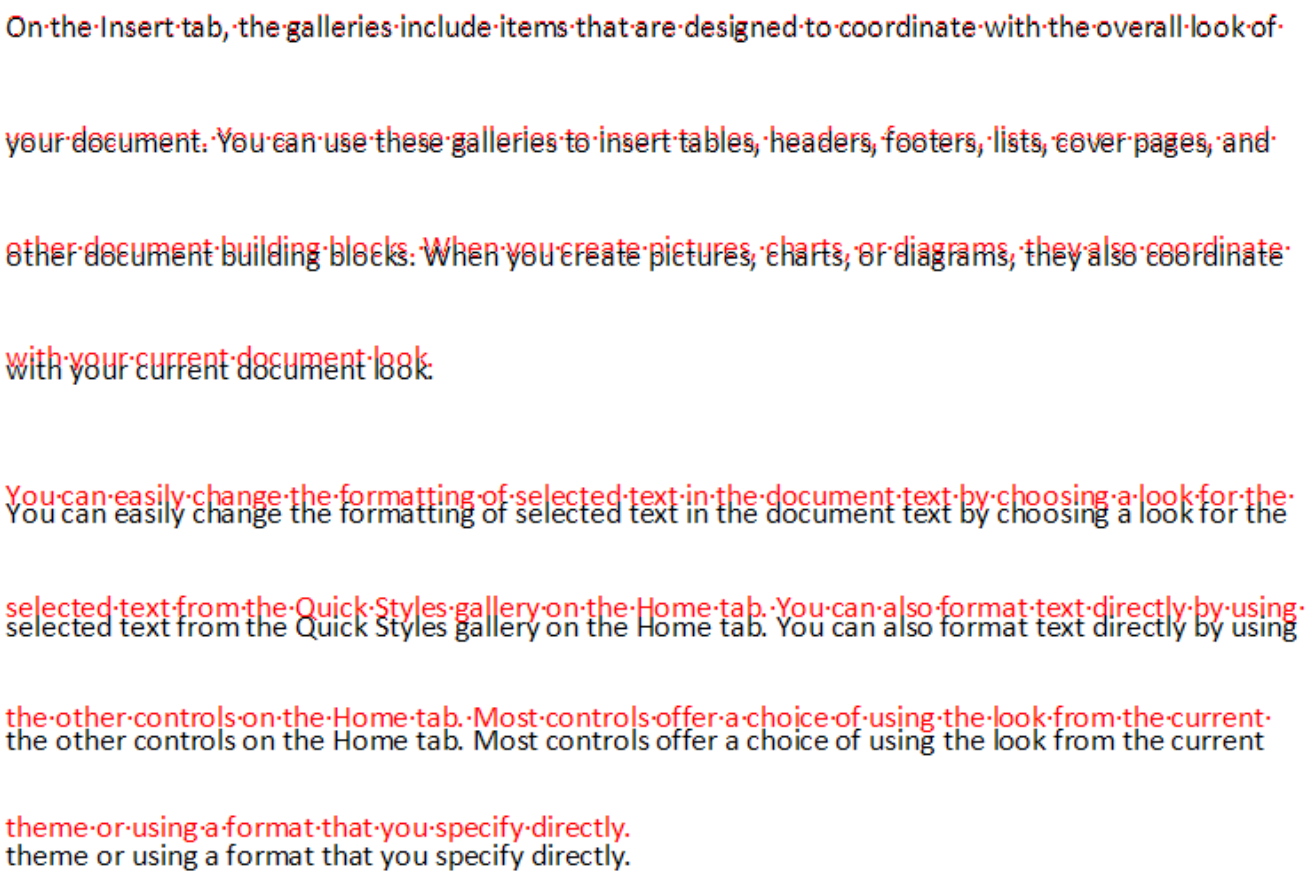
```
<w:pPr>
  <w:spacing w:line="720" w:lineRule="auto" />
</w:pPr>
```

If this compatibility setting is turned on:

```
<w:compat>
  <w:suppressTopSpacingWP />
</w:compat>
```

Then applications should mimic the behavior of WordPerfect 5.x when determining the resulting spacing between each line with additional line spacing, as needed.

As an example of the difference, the output of a normal pairing of triple spaced paragraphs (in black) and one intended to replicate WordPerfect 5.x (in red) is displayed below:



end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.52 swapBordersFacingPages (Swap Paragraph Borders on Odd Numbered Pages)

This element specifies whether left and right paragraph borders defined under the pBdr element (§2.3.1.24) shall be swapped under conditions where it is possible that the those pages are intended to be used to create a book-like publication.

Typically, no changes shall be made to the positions of paragraph borders defined under the pBdr element - a right border is always on the right, and a left border is always on the left. This element, when present with a val attribute value of true (or equivalent), specifies that under the two following conditions:

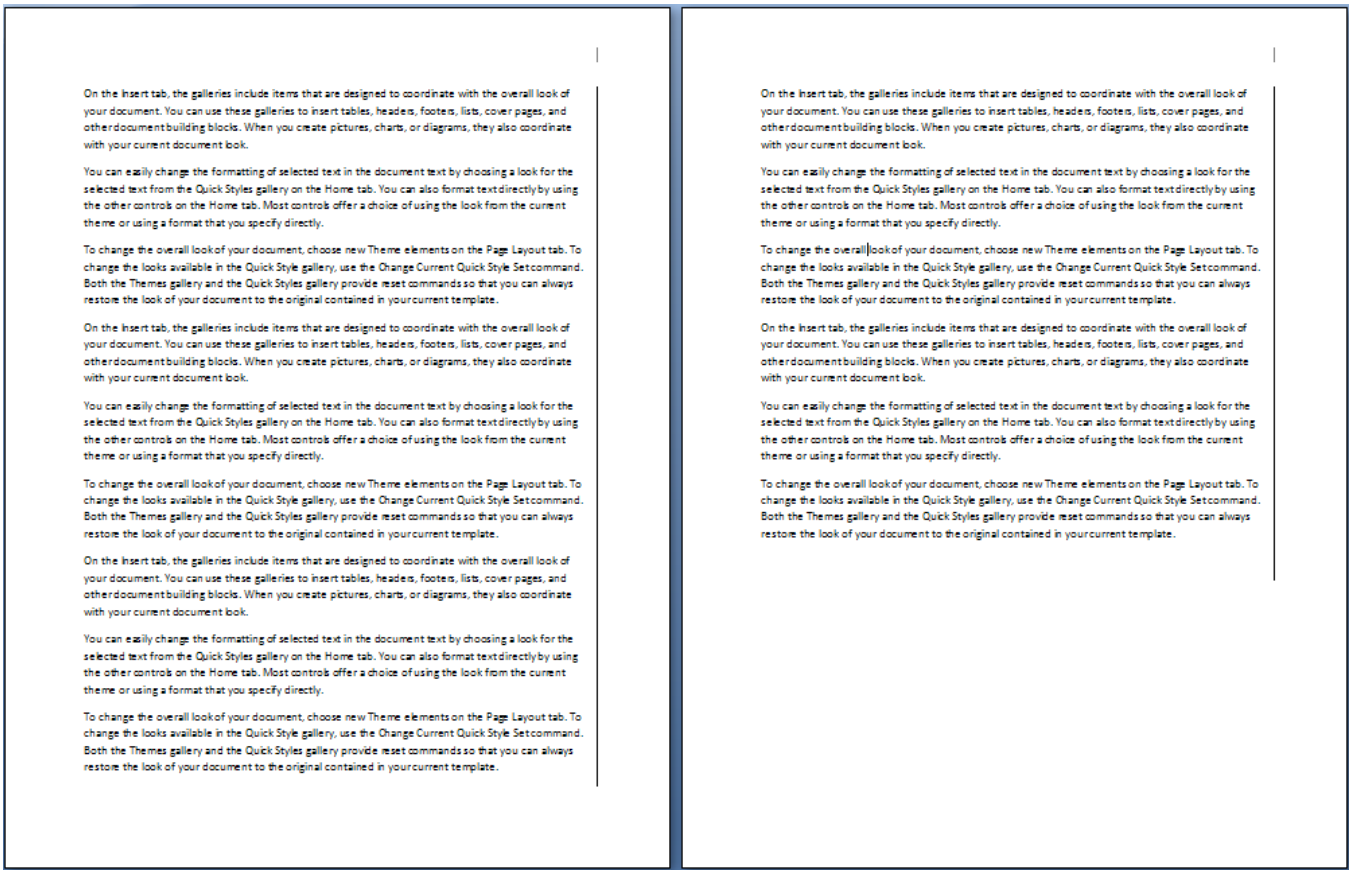
- The margins in this document are mirrored using the mirrorMargins element (§2.15.1.57)
- The header/footers in this document are different on even and odd numbered pages using the evenAndOddHeaders element (§2.10.1)

That paragraph borders on odd-numbered pages will be swapped - that is, left borders shall be displayed on the right and right borders shall be displayed on the left.

[*Example*: Consider a WordprocessingML document for which the mirrorMargins element is present, and whose default paragraph style includes a paragraph border to be displayed on the right side of each paragraph:

```
<w:style w:type="paragraph" w:default="1" w:styleId="Normal" >
  …
  <w:pPr>
    <w:pBdr>
      <w:right w:val="single" w:color="auto" />
    </w:pBdr>
    …
  </w:pPr>
</w:style>
```

If a two-page document is created using this default paragraph style, then all paragraphs will have a border on the right side, as follows:



On the Insert tab, the galleries include items that are designed to coordinate with the overall look of your document. You can use these galleries to insert tables, headers, footers, lists, cover pages, and other document building blocks. When you create pictures, charts, or diagrams, they also coordinate with your current document look.

You can easily change the formatting of selected text in the document text by choosing a look for the selected text from the Quick Styles gallery on the Home tab. You can also format text directly by using the other controls on the Home tab. Most controls offer a choice of using the look from the current theme or using a format that you specify directly.

To change the overall look of your document, choose new Theme elements on the Page Layout tab. To change the looks available in the Quick Style gallery, use the Change Current Quick Style Set command. Both the Themes gallery and the Quick Styles gallery provide reset commands so that you can always restore the look of your document to the original contained in your current template.

You can also format text directly by using the other controls on the Home tab. Most controls offer a choice of using the look from the current theme or using a format that you specify directly.

To change the overall look of your document, choose new Theme elements on the Page Layout tab. To change the looks available in the Quick Style gallery, use the Change Current Quick Style Set command. Both the Themes gallery and the Quick Styles gallery provide reset commands so that you can always restore the look of your document to the original contained in your current template.

On the Insert tab, the galleries include items that are designed to coordinate with the overall look of your document. You can use these galleries to insert tables, headers, footers, lists, cover pages, and other document building blocks. When you create pictures, charts, or diagrams, they also coordinate with your current document look.

You can easily change the formatting of selected text in the document text by choosing a look for the selected text from the Quick Styles gallery on the Home tab. You can also format text directly by using the other controls on the Home tab. Most controls offer a choice of using the look from the current theme or using a format that you specify directly.

To change the overall look of your document, choose new Theme elements on the Page Layout tab. To change the looks available in the Quick Style gallery, use the Change Current Quick Style Set command. Both the Themes gallery and the Quick Styles gallery provide reset commands so that you can always restore the look of your document to the original contained in your current template.

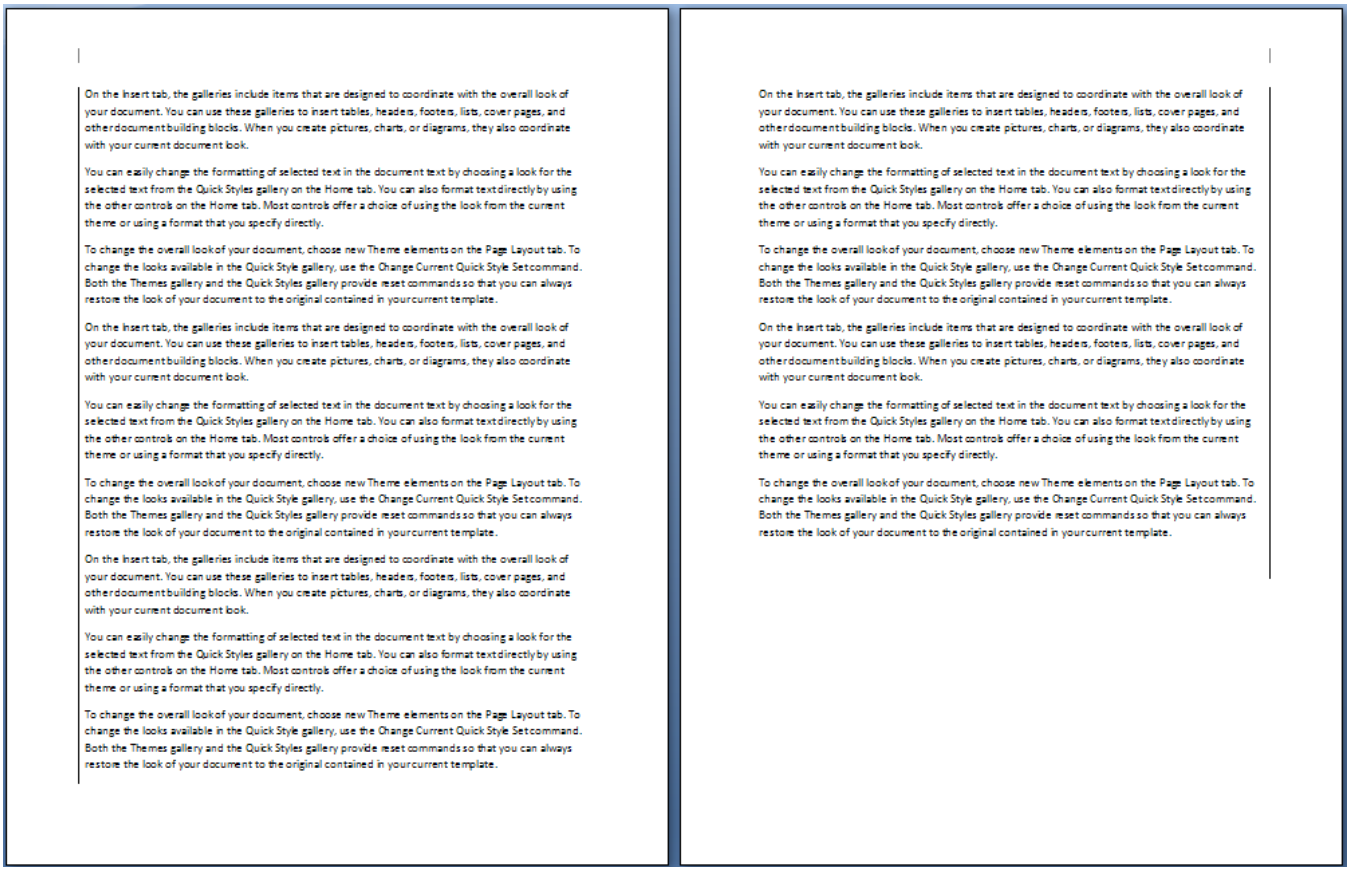
However, if this compatibility setting is turned on:

```
<w:compat>
  <w:swapBordersFacingPages />
</w:compat>
```

Then the borders on the first page (being an odd-numbered page) shall be swapped, resulting in the following output:



end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.53 truncateFontHeightsLikeWP6 (Emulate WordPerfect 6.x Font Height Calculation)

This element specifies that applications shall emulate the behavior of a previously existing word processing application (WordPerfect 6.x) when determining the character height for characters in a font. This emulation typically results slightly truncated character heights.

[*Guidance*: To faithfully replicate this behavior, applications must imitate the behavior of that application, which involves many possible behaviors and cannot be faithfully placed into narrative for this Office Open XML Standard. If applications wish to match this behavior, they must utilize and duplicate the output of those applications. It is recommended that applications not intentionally replicate this behavior as it was deprecated due to issues with its output, and is maintained only for compatibility with existing documents from that application. *end guidance*]

Typically, applications shall not perform this compatibility. This element, when present with a val attribute value of `true` (or equivalent), specifies that applications shall attempt to mimic that existing word processing application in this regard.

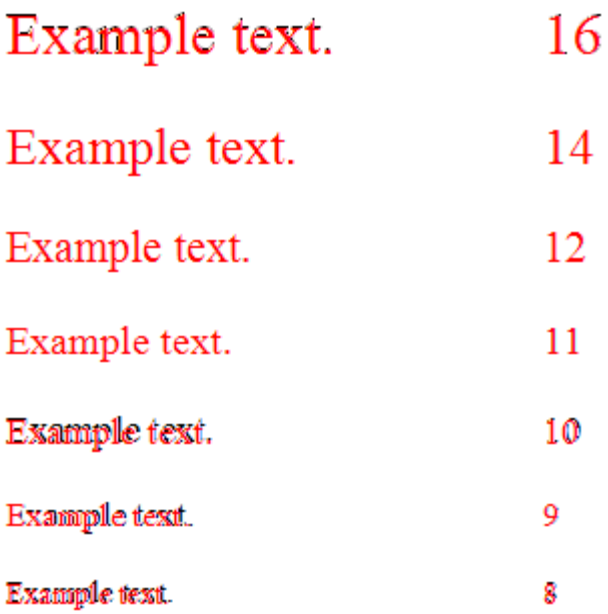
[*Example*: Consider a WordprocessingML document.

If this compatibility setting is turned on:

```
<w:compat>
  <w:truncateFontHeightsLikeWP6 />
</w:compat>
```

Then applications should mimic the behavior of WordPerfect 6.x when determining the height of characters, as needed.

As an example of the difference, the output of a normal pairing of triple spaced paragraphs (in black) and one intended to replicate WordPerfect 6.x (in red) is displayed below:



end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.54 uiCompat97To2003 (Disable Features Incompatible With Earlier Word Processing Formats)

Disable UI functionality that is not compatible with Word97-2003

Parent Elements
settings (§2.15.1.78)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.55 ulTrailSpace (Underline All Trailing Spaces)

This element specifies whether applications shall display underlining beneath all trailing spaces in the contents of a line when those contents are underlined. *Trailing spaces* are all space characters which are not followed by non-space characters on the same line.

Typically, applications do not display underlining on all trailing spaces which have the underline property applied to them. This element, when present with a val attribute value of true (or equivalent), specifies that all characters with underline applied, including trailing spaces, shall display underlining if it is applied to that content.

[*Example*: Consider a WordprocessingML document with the following line of Latin alphabetical character and punctuation, trailed by a series of spaces:

```
<w:r>
  <w:rPr>
    <w:u w:val="single"/>
  </w:rPr>
  <w:t>Example text. Example text. Example text. Example text. Example text.
</w:t>
</w:r>
```

The default presentation would have no underlining on those trailing spaces:

Example text. Example text. Example text. Example text. Example text.

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:ulTrailSpace />
</w:compat>
```

Then all trailing spaces would be underlined, resulting in the following output:

Example text. Example text. Example text. Example text. Example text.

end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.56 underlineTabInNumList (Underline Following Character Following Numbering)

This element specifies whether applications shall underline the character following the numbering defined using the suff element (§2.9.30) when both the numbering itself and the first letter of the corresponding numbered paragraph is underlined.

Typically, the tab or space character generated between numbering and the corresponding paragraph of text is never formatted, since it is automatically generated by the suff element. This element, when present with a val attribute value of `true` (or equivalent), specifies that the tab or space shall tab or space shall be underlined the same way as the numbering symbol itself in the following conditions:

- The numbering is underlined
- The first character of the paragraph is underlined

[*Example*: Consider a WordprocessingML document with two numbered paragraphs: one with underlined text and the other without. The default presentation would have the tab characters free of underlining in both cases:

1. Example Text

2. Example Text

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:underlineTabInNumList />
</w:compat>
```

Then the second paragraph meets the criteria defined above for having the suffix character underlined, resulting in the following output:

1. Example Text

2. Example Text

end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.57 useAltKinsokuLineBreakRules (Use Alternate Set of East Asian Line Breaking Rules)

This element specifies an alternate set of characters which may be used to determine which characters can begin and/or end a line when kinsoku line breaking rules are enabled using the kinsoku element (§2.3.1.16).

Typically, the characters used to determine which characters shall not end a line are those listed by the kinsoku element in the paragraph properties subclause of this document. This element, when present with a val attribute value of true (or equivalent), specifies that the following settings shall be used instead (for brevity, only those settings which are different are listed below):

Chinese (Simplified)

- Cannot start a line:
  !),.:;?]}¨·ˇ¯–‖’”…:、。〃々〉》」』】〕〗！＂＇），．：；？］｀｜｝～¢
- Cannot end a line:
  ([{·‘“〈《「『【〔〖（．［｛£¥

Chinese (Traditional)

- Cannot start a line:
  !),.:;?]}¢·——’”•…‧'-、。〉》」』】〕〞：‖｛ ‿⁀⁔▂﹀﹀﹂﹄﹏‧::?!)}}！），．：；？｜｝、

Korean

- Cannot end a line:
  ([\{£¥“ 〈 《 「 『 【 〔 $ ([{ ₩

[*Example*: Consider a line of text in a WordprocessingML document within a paragraph marked as Chinese (Simplified) which begins with a % symbol, as follows:

```
%...
```

Typically, the kinsoku settings for Chinese (Simplified) do not allow this character to begin a line, so the character before that symbol would be moved down onto this line:

```
〖%...
```

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:useAltKinsokuLineBreakRules />
</w:compat>
```

Then the alternate kinsoku rules are in place, which do not prevent the % character from beginning the new line, resulting in the following output:

```
%...
```

end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.58 useAnsiKerningPairs (Use ANSI Kerning Pairs from Fonts)

This element specifies whether applications shall use the ANSI or Unicode kerning pair information from fonts stored in the document when displaying those characters within the document's contents.

Typically, applications shall use the Unicode kerning pair information in order to determine all possible kerning pairs in the fonts in use. This element, when present with a val attribute value of `true` (or equivalent), specifies that the ANSI kerning information shall be used instead.

[*Example*: Consider a WordprocessingML document with text that contains one or more kerning pairs.

If this compatibility setting is turned on:

```
<w:compat>
  <w:useAnsiKerningPairs />
</w:compat>
```

Then the ANSI kerning pairs are used in place of the Unicode kerning pairs, potentially resulting in different line breaks.

end example]

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property:

Attributes	Description
	`<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.59 useFELayout (Do Not Bypass East Asian/Complex Script Layout Code)

This element specifies that applications shall not bypass code relating to the layout of East Asian and/or Complex Script characters when presenting this document.

[*Guidance*: Previous word processing applications relied on this flag to determine whether to perform functions which allow for the correct layout of East Asian and Complex Script text. Although current applications no longer rely on this flag (as they should correctly use the Unicode subranges and code pages of the text in use), this flag should be output in order to ensure that files with this content can be viewed correctly in previous word processors. *end guidance*]

[*Example*: Consider a WordprocessingML document with East Asian text.

If this compatibility setting is turned on:

```
<w:compat>
  <w:useFELayout />
</w:compat>
```

Then the flag is set telling previous applications that East Asian content is present, and they should display the document accordingly. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off.

Attributes	Description
	[*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.60 useNormalStyleForList (Do Not Automatically Apply List Paragraph Style To Bulleted/Numbered Text)

This element specifies whether applications shall automatically apply the paragraph style with the styleId attribute `ListParagraph` when numbering is applied to a paragraph currently formatted using the default paragraph style.

Typically, when a paragraph is formatted using the default paragraph style, and numbering is subsequently applied, the paragraph style with the styleId attribute `ListParagraph` when numbering is applied to ensure that paragraph properties are appropriate for a numbered paragraph. This element, when present with a val attribute value of `true` (or equivalent), specifies that no alternate paragraph style shall ever be applied

[*Example*: Consider a WordprocessingML document with five unnumbered paragraphs:

Example text.

Example text.

Example text.

Example text.

Example text.

If numbering is applied to the three center paragraphs, the default presentation would have the `ListParagraph` style applied as well:

Example text.

- Example text.
- Example text.
- Example text.

Example text.

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:useNormalStyleForList />
</w:compat>
```

Then the new paragraph style shall not be applied, resulting in the following output:

Example text.

- Example text.
- Example text.
- Example text.

Example text.

end example]

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/>

Attributes	Description
	The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.61 usePrinterMetrics (Use Printer Metrics To Display Documents)

This element specifies whether applications shall use the printer metrics of the currently active printer when determining how to display the contents of a WordprocessingML document. *Printer metrics* are printer-specific settings which can be queried to tell an application how and where text shall be displayed on a printed page.

Typically, applications display the content of a document in a device independent manner - the application is therefore not changing the layout of a document based on the currently attached printer, and instead shall dictate to the printer where characters shall be presented on the page when printed. This element, when present with a val attribute value of true (or equivalent), specifies that the metrics of the current printer shall be used to display the document instead.

Specifically, when this setting is enabled, the printer metrics are used to determine the number of pixels per logical inch along the screen width and height. This should then be used to compute the pixel height of the fonts requested when displaying the document, as well as to scale between any logical units within the document (e.g. drawing object sizes) to the appropriate device units. Those units would then need to be scaled back into screen units for final display to a screen, but not scaled again when displayed to a printer.

[*Note*: On the Windows platform, you can use the GetDeviceCaps function to retrieve device-specific information for the specified printer. For this specific setting, you can use GetDeviceCaps(hdc, LOGPIXELSX) and GetDeviceCaps(hdc, LOGPIXELSY) with a printer DC to retrieve the number of pixels per logical inch along the screen width and height. With this, you can then use those DPI metrics to compute a pixel value for the font request in the LOGFONT structure (the LOGFONT structure defines the attributes of a font). A common formula to do this is $S_{px} = S_{pts} * \frac{LOGPIXELSY}{72}$. *end note*]

[*Example*: Consider a WordprocessingML document. The default shall use device-independent layout to present the contents of the page.

However, if this compatibility setting is turned on:

```
<w:compat>
  <w:usePrinterMetrics />
</w:compat>
```

Then the printer metrics of the current active printer shall be used to determine the display of the contents of the document instead, as needed. *end example*]

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

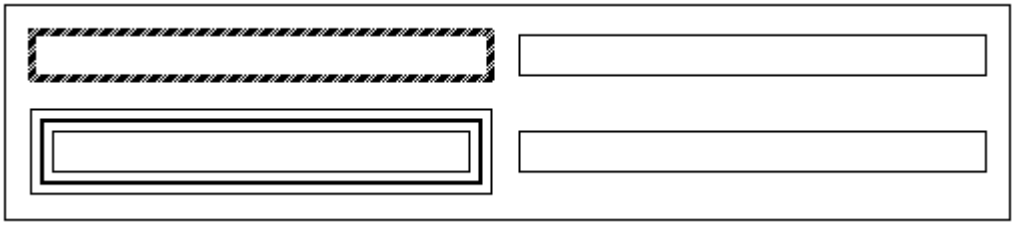
2.15.3.62 useSingleBorderforContiguousCells (Use Simplified Rules For Table Border Conflicts)

This element specifies whether applications should use an alternate simplified algorithm when handling conflicts between adjacent table borders within a table.

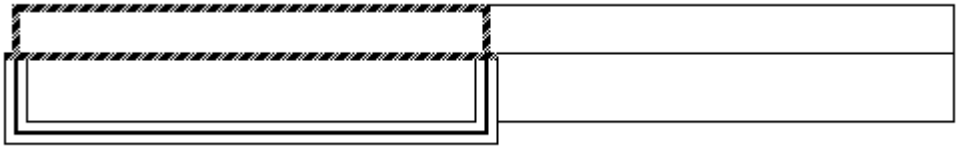
Typically, the conflicts between two adjacent table borders are handled using the conflict resolution algorithm defined in §2.4.38 of this Office Open XML Standard. This element, when present with a val attribute value of true (or equivalent), specifies that rather than using that algorithm to determine the outcome of the conflict to two adjacent borders, that the following logic shall be used instead:

- Cell borders shall supersede table borders
- Cell borders to the right shall supersede cell borders to the left (i.e. the rightmost border wins in conflicts between vertical borders)
- Cell borders below shall supersede cell borders above (i.e. the bottommost border wins in conflicts between horizontal borders)

[*Example*: Consider a WordprocessingML document with cell and table borders defined as follows. In the image below, 0.1" of padding has been added between each cell temporarily to clearly illustrate the borders on each cell and on the table:



The default presentation would have the border conflicts resolved using the algorithm defined by this Office Open XML Standard, resulting in the following table:



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:useSingleBorderForContiguousCells />
</w:compat>
```

Then the simplified table algorithm above shall be used instead (bottom and right cell borders always win), resulting in the following output:

end example]

   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.63 useWord2002TableStyleRules (Emulate Word 2002 Table Style Rules)

This element specifies that applications shall emulate the behavior of a previously existing word processing application (Microsoft Word 2002) when determining the formatting resulting from table styles applied to tables within a WordprocessingML document.

[*Guidance*: To faithfully replicate this behavior, applications must imitate the behavior of that application, which involves many possible behaviors and cannot be faithfully placed into narrative for this Office Open XML Standard. If applications wish to match this behavior, they must utilize and duplicate the output of those applications. It is recommended that applications not intentionally replicate this behavior as it was deprecated due to issues with its output, and is maintained only for compatibility with existing documents from that application. *end guidance*]

Typically, applications shall not perform this compatibility. This element, when present with a val attribute value of `true` (or equivalent), specifies that applications shall attempt to mimic that existing word processing application in this regard.

[*Example*: Consider a WordprocessingML document with a series of tables with table styles applied.

If this compatibility setting is turned on:

```
<w:compat>
  <w:useWord2002TableStyleRules />
</w:compat>
```

Then applications should mimic the behavior of Microsoft Word 2002 when determining the formatting resulting from the use of table styles. *end example*]

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.64 useWord97LineBreakRules (Emulate Word 97 East Asian Line Breaking)

This element specifies that applications shall emulate the behavior of a previously existing word processing application (Microsoft Word 97) when determining the line breaking rules for East Asian text within a WordprocessingML document.

[*Guidance*: To faithfully replicate this behavior, applications must imitate the behavior of that application, which involves many possible behaviors and cannot be faithfully placed into narrative for this Office Open XML Standard. If applications wish to match this behavior, they must utilize and duplicate the output of those applications. It is recommended that applications not intentionally replicate this behavior as it was deprecated due to issues with its output, and is maintained only for compatibility with existing documents from that application. *end guidance*]

Typically, applications shall not perform this compatibility. This element, when present with a val attribute value of true (or equivalent), specifies that applications shall attempt to mimic that existing word processing application in this regard.

[*Example*: Consider a WordprocessingML document with East Asian run content.

If this compatibility setting is turned on:

```
<w:compat>
  <w:useWord97LineBreakingRules />
</w:compat>
```

Then applications should mimic the behavior of Microsoft Word 97 when determining the line breaking from the use of the East Asian characters. *end example*]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.65 wpJustification (Emulate WordPerfect 6.x Paragraph Justification)

This element specifies that applications shall emulate the behavior of a previously existing word processing application (WordPerfect 6.x) when performing full paragraph justification using a val attribute value of both on the jc element (§2.3.1.13). This alternate justification method involves biasing towards compressing rather than expanding spaces when needed to justify a line.

[*Guidance*: To faithfully replicate this behavior, applications must imitate the behavior of that application, which involves many possible behaviors and cannot be faithfully placed into narrative for this Office Open XML Standard. If applications wish to match this behavior, they must utilize and duplicate the output of those applications. It is recommended that applications not intentionally replicate this behavior as it was deprecated due to issues with its output, and is maintained only for compatibility with existing documents from that application. *end guidance*]

Typically, applications shall not perform this compatibility. This element, when present with a val attribute value of true (or equivalent), specifies that applications shall attempt to mimic that existing word processing application in this regard.

[*Example*: Consider a WordprocessingML document with one or more paragraphs using full paragraph justification:

```
<w:p>
  <w:pPr>
    <w:jc w:val="both" />
  </w:pPr>
  …
</w:p>
```

If this compatibility setting is turned on:

```
<w:compat>
  <w:wpJustification />
</w:compat>
```

Then applications should mimic the behavior of WordPerfect 6.x when performing full justification on text in these paragraphs. *end example*]

val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.66 wpSpaceWidth (Space width)

Set the width of a space like WordPerfect 5.x.

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.15.3.67 wrapTrailSpaces (Line Wrap Trailing Spaces)

This element specifies whether applications shall perform line wrapping on trailing spaces in the contents of a line when displaying in it a paragraph. *Trailing spaces* are all space characters which are not followed by non-space characters on the same line.

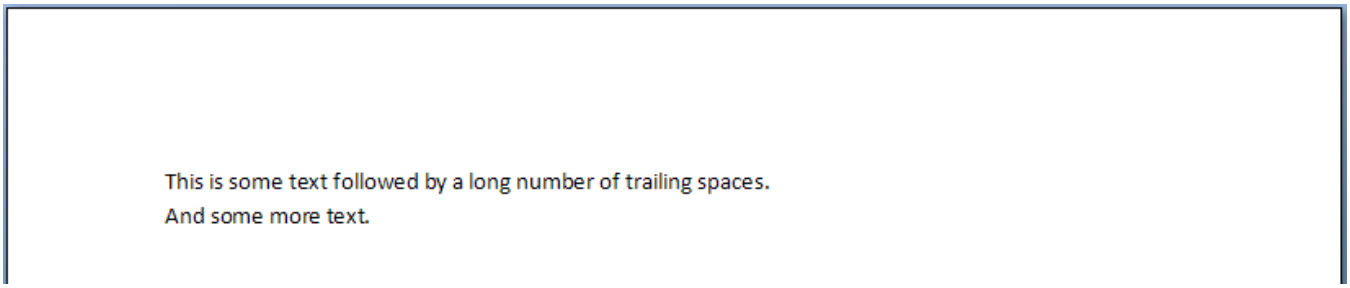
Typically, applications do not line wrap trailing spaces, instead allowing an unbounded number of trailing spaces on a line, with the next non-space character starting at the first character position on the next line. This element, when present with a val attribute value of true (or equivalent), specifies that all characters, including trailing spaces, shall be line wrapped normally.

[*Example*: Consider a WordprocessingML document with the following paragraph of text, including a long interstitial of spaces which become trailing spaces when the paragraph is displayed:

```
<w:r>
  <w:t> This is some text followed by a long number of trailing spaces.

                And some more text.</w:t>
</w:r>
```

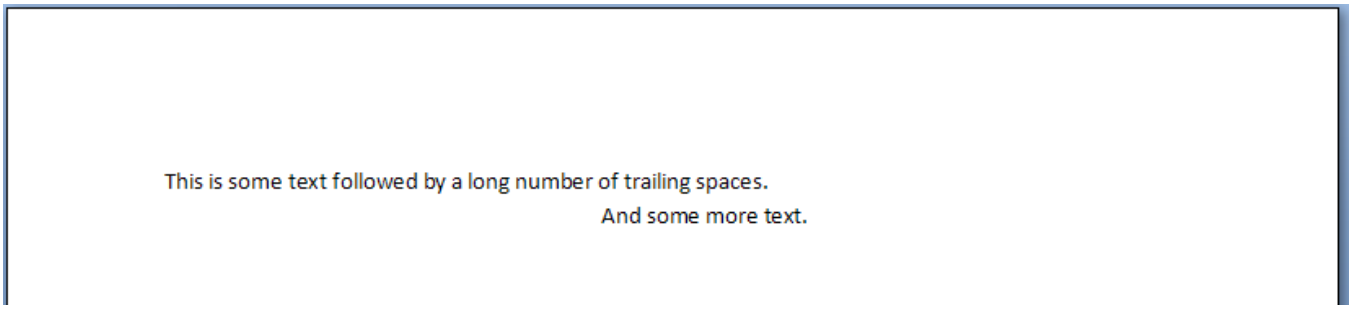
The default presentation would not wrap those trailing spaces, so the text at the end of the run would begin at the first character position on the second line:



However, if this compatibility setting is turned on:

```
<w:compat>
  <w:wrapTrailSpaces />
</w:compat>
```

Then all trailing spaces would be handled as regular characters when line wrapping, resulting in the following output:



end example]

Parent Elements
compat (§2.15.3.9)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.16 Fields & Hyperlinks

Most text in a word processing document is static; that is, unless it is directly changed as the result of editing, its contents remain the same, no matter how the rest of the document might change. However, certain useful pieces of information can change value over the life of a document. Consider the case of a reference to a page number, as in "For more information on this topic, see page 56." Clearly, hard coding the page number as 56 means that that number will need to be manually replaced as the document's size or layout is changed. Even a simple change to any margin, line spacing, or font size can invalid such references.

Fields provide a mechanism for placeholders, such as page reference numbers, that can be added to a document such that those placeholders are replaced by their corresponding values when the document is rendered for display or print. Other applications for fields include, but are not limited to, automatic numbering of tables and figures, document creation and current date and time, document author information, and the computation of totals for a table column.

A *field* is a set of codes that instructs a WordprocessingML consumer to insert text, graphics, page numbers, and other material into a document automatically. [*Example*: The DATE field causes the current date to be inserted. *end example*] The text or graphics inserted into a document when a consumer carries out a field's codes is referred to as the *field result* for that field. The act of carrying out a field's codes is referred to as a *field update*. As to how or when any field is updated is outside the scope of this Office Open XML Standard.

2.16.1 Syntax

The general syntax of a field is as follows:

field:
field-type [*instruction*]

field-type:
date-and-time
document-automation
document-information
equations-and-formulas
index-and-tables
links-and-references
mail-merge
numbering
user-information
form-field

date-and-time:
CREATEDATE | DATE | EDITTIME | PRINTDATE | SAVEDATE | TIME

document-automation:
COMPARE | DOCVARIABLE | GOTOBUTTON | IF | MACROBUTTON | PRINT

document-information:
AUTHOR | COMMENTS | DOCPROPERTY | FILENAME | FILESIZE | INFO
| KEYWORDS | LASTSAVEDBY | NUMCHARS | NUMPAGES | NUMWORDS | SUBJECT
| TEMPLATE | TITLE

equations-and-formulas:
= *formula* | ADVANCE | EQ | SYMBOL

index-and-tables:
INDEX | RD | TA | TC | TOA | TOC | XE

links-and-references:
AUTOTEXT | AUTOTEXTLIST | BIBLIOGRAPHY | CITATION | HYPERLINK |
INCLUDEPICTURE | INCLUDETEXT
| LINK | NOTEREF | PAGEREF | QUOTE | REF | STYLEREF

mail-merge:
ADDRESSBLOCK | ASK | COMPARE | DATABASE | FILLIN | GREETINGLINE | IF
| MERGEFIELD | MERGEREC | MERGESEQ | NEXT | NEXTIF | SET | SKIPIF

numbering:
AUTONUM | AUTONUMLGL | AUTONUMOUT | BARCODE | LISTNUM | PAGE | REVNUM
| SECTION | SECTIONPAGES | SEQ

user-information:
USERADDRESS | USERINITIALS | USERNAME

form-field:
FORMCHECKBOX | FORMDROPDOWN | FORMTEXT

instruction:
field
field-argument
switches
field-argument switches
switches field-argument

field-argument:
["] *text* ["]

switches:
switch
switch switches

switch:
formatting-switch
field-specific-switch

formatting-switch:
date-and-time-formatting-switch
numeric-formatting-switch
general-formatting-switch

field-specific-switch:
field-switch-character [*field-argument*]

field-switch-character:
!
one or two Latin letters

formula is discussed in §2.16.3, and *formatting-switch*es are discussed in §2.16.4.

If the *text* in a *field-argument* contains white space, the delimiting double-quote characters shall be present; otherwise, they are optional. To include a double-quote character in *text*, it shall be preceded with a backslash (\). [*Example*: The field argument `"\"name\""` results in the argument's actually being `"name"`. *end example*] To include a backslash character in *text*, it shall be preceded with another backslash (\). [*Example*: File system pathnames on some systems use a backslash as a directory separator, as in the field

```
INCLUDETEXT "E:\\ReadMe.txt"
```

in which case, each such separator needs to be preceded with a backslash, as shown above. *end example*]

Arbitrary amount of white space can occur before the first token, after the last token, and between successive tokens, including no white space at all.

[*Example*: Here are examples of some fields:

```
DATE
DATE \@ "dddd, MMMM dd, yyyy"
DATE \@ "dddd, MMMM dd, yyyy" \h
```

The field result of all three is today's date: The first field uses some implementation-defined format and the Gregorian calendar; the second field uses the specified format and the Gregorian calendar; and the third field uses the specified format and the Hijri lunar calendar. When rendered in a US-English context on December 31, 2005, the results of these fields were as follows:

```
12/31/2005
Saturday, December 31, 2005
AsSabt, Thoul Ki'dah 30, 1426
```

end example]

Except for = *formula*, the terminals of *field-type* are alphabetic tokens [*Example*: Some field-type names are ASK, COMMENTS, NEXT, and SET. *end example*]. These tokens are called *field-type names*. Field-type names are case-insensitive. [*Example*: The field-type names DATE, Date, dAtE, and date are equivalent. *end example*]

*field-switch-character*s are case-insensitive. [*Example*: \b and \B are equivalent. *end example*]

There is no ordering of *switch* entries in *switches*.

2.16.2 XML representation

Fields shall be implemented in XML using either of two approaches:

- As a *simple field implementation*, using the fldSimple element, or
- As a *complex field implementation*, using a set of runs involving the fldChar and instrText elements.

For a simple field implementation, only one element, fldSimple, shall be used, in which case, its instr attribute shall contain a *field*, and the body of the element shall contain the most recently updated field result. [*Example*: Here is the corresponding XML for a simple field implementation of DATE:

```
<w:r>
  <w:fldSimple w:instr="DATE"> 12/31/2005 </w:fldSimple>
</w:r>
```

end example]

For a complex field implementation, a set of runs shall be used with each run containing, in sequence, the following elements:

- fldChar with attribute fldCharType value begin,
- One or more instrText elements, which, collectively, contain a complete *field*,
- Optionally,
    - fldChar with attribute fldCharType value separate, which separates the field from its field result,
    - Any number of runs and paragraphs that contains the most recently updated field result, and
- fldChar with attribute fldCharType value end.

[*Note*: Fields that are for display purposes only have no need to, and do not, store a field result. *end note*][*Example*: Here is the corresponding XML for a complex field implementation of DATE:

```
<w:r>
  <w:fldChar w:fldCharType="begin"/>
</w:r>
```

```
<w:r>
  <w:instrText xml:space="preserve"> DATE </w:instrText>
</w:r>
<w:r>
  <w:fldChar w:fldCharType="separate"/>
</w:r>
<w:r>
  <w:t>12/31/2005</w:t>
</w:r>
<w:r>
  <w:fldChar w:fldCharType="end"/>
</w:r>
```

end example]

[*Note*: Every simple field implementation for a given field has a corresponding complex field implementation. However, not every complex field implementation has a corresponding simple field implementation. If some characters in a *field* have different run properties than others, that field must be implemented using multiple runs, and that requires that complex field implementation be used. For an example, see §2.16.4.3, where the first letter of a DATE field is made bold, underlined, and red, while the other letters have none of these properties. *end note*]

As shown in §2.16.1, the *instruction* of one *field* can be another *field*, allowing fields to nest. In such cases, the XML run sequence for the inner field is defined at the point of reference for that inner field, inside the outer field's XML run sequence. [*Example*: Consider the following sentence:

It's `IF DATE \@ "M-d"<>"1-1" "not "` new year's day.

The `IF` field contains the nested field `DATE \@ "M-d"`. When updated, on January 1 of any year, the result sentence is "It's new year's day." On all other days of the year, the resulting sentence is "It's not new year's day."

Here is one way of writing the corresponding XML:

```
<w:r>
  <w:t xml:space="preserve">It’s </w:t>
</w:r>
<w:r …>
  <w:fldChar w:fldCharType="begin"/>
</w:r>
<w:r>
  <w:instrText xml:space="preserve">IF </w:instrText>
</w:r>
<w:r>
  <w:fldChar w:fldCharType="begin"/>
</w:r>
```

```
<w:r>
  <w:instrText xml:space="preserve"> DATE  \@ "M-d"  </w:instrText>
</w:r>
<w:r>
  <w:fldChar w:fldCharType="separate"/>
</w:r>
<w:r …>
  <w:instrText>1-4</w:instrText>
</w:r>
<w:r>
  <w:fldChar w:fldCharType="end"/>
</w:r>
<w:r>
  <w:instrText>&lt;&gt;"1-1" "not "</w:instrText>
</w:r>
<w:r …>
  <w:fldChar w:fldCharType="separate"/>
</w:r>
<w:r …>
  <w:t xml:space="preserve">not </w:t>
</w:r>
<w:r …>
  <w:fldChar w:fldCharType="end"/>
</w:r>
<w:r>
  <w:t>new year’s day!</w:t>
</w:r>
```

end example]

2.16.3 Formulas and expressions

A field instruction can involve a calculation via a *formula*:

formula:
expression

where *expression* can be an arbitrary complex arithmetic expression involving constants (§2.16.3.1), bookmarks that refer to *expression*s (§2.16.3.2), arithmetic and logical operators (§2.16.3.3), functions (§2.16.3.4), values of cells in a table (§2.16.3.5), and *field*s that result in a single value. *expression* can contain grouping parentheses to document the default precedence or to override it.

All arithmetic terms in an *expression* are real numbers. Infinities and NaN (Not-a-Number) are not supported. [*Example*: In the expression `1/3`, although the operands appear to be integers, they are, in fact real numbers, and the result is `0.33`. *end example*]

2.16.3.1 Constants

A constant has the following form:

constant:
number

number:
whole-number-part [.]
. *fractional-part*
whole-number-part . *fractional-part*

whole-number-part:
series of one or more decimal digits

fractional-part:
series of one or more decimal digits

[*Example*: Here are some constants: `1234`, `1234.560`, `1234.`, and `.1234`. Exponents are not supported. *end example*]

2.16.3.2 Bookmarks

Any arbitrary piece of text and/or graphics in a WordprocessingML document can be assigned a name, called a *bookmark*. If a bookmark references text that represents an *expression*, that bookmark's name can be used as an operand in another *expression*. If a whole field is bookmarked, its bookmark name can also be used as an operand in an *expression*. [*Example*: Given that X is a bookmark for the text 4, Y is a bookmark for the text 2, and `Result` is a bookmark for the following field:

```
=X + Y
```

the field

```
=Result * 10
```

has the result `60`. *end example*]

2.16.3.3 Operators

The *operator*s permitted in *expression* are:

Operators		
Operator	Description	Precedence
-	Unary minus	highest
^	Powers and roots	
*	Multiplication	
/	Division	
%	Percentage	
+	Addition	

Operators		
-	Subtraction	
=	Equal to	
<>	Not equal to	
<	Less than	lowest
<=	Less than or equal to	
>	Greater than	
>=	Greater than or equal to	

Operators in *expression* having the same precedence associate left-to-right.

[*Example*: Given that X is a bookmark for the text 4, and Y is a bookmark for the text 2, the field

```
=((-1 + X^2) * 3 - Y)/2
```

produces the result `21.5`. *end example*]

The equality, inequality, and relational operators yield 1 for true and 0 for false. An expression with value 0 tests logically false while one with any non-zero value tests true.

2.16.3.4 Functions

A *function* is a predefined procedure that computes and returns a result. Functions defined below with a parameter list of *list* accept two or more arguments separated by commas (,) or semicolons (;). As to which separator is permitted, is defined by the document's listSeparator (§2.15.1.56) element. Arguments to functions can be constants, formulas, or bookmark names that refer to constants or formulas. The functions AVERAGE, COUNT, MAX, MIN, PRODUCT, and SUM can also accept references to table cells as arguments. In the context of a table cell, functions taking a *list* also accept a single argument that designates a named-list of contiguous cells (§2.16.3.5). Function names are not case-sensitive, and white space can occur between a function's name and its argument list, if any.

The functions supported are as follows:

Functions	
Function	Description
ABS(*x*)	Returns the absolute value of *x*.
AND(*x*,*y*)	Returns 1 if the logical expressions *x* and *y* are both true; otherwise, it returns 0.
AVERAGE(*list*)	Returns the average value of the items in *list*.
COUNT(*list*)	Returns the number of items in *list*.
DEFINED(*x*)	Returns 1 if the expression *x* is well formed; otherwise, it returns 0.

Functions	
FALSE	Returns 0.
INT(*x*)	Returns the value of the integer part of *x*.
MAX(*list*)	Returns the largest value in *list*.
MIN(*list*)	Returns the smallest value in *list*.
MOD(*x*,*y*)	Returns the value *x* - *ny*, for some integer *n* such that, if *y* is nonzero, the result has the same sign as *x* and magnitude less than the magnitude of *y*. If *y* is zero, a diagnostic shall be issued. (*y* need not be a whole number.) [*Example*: MOD(21,5) results in 1 MOD(21,-5) results in 1 MOD(-21,5) results in -1 MOD(-21,-5) results in -1 *end example*]
NOT(*x*)	Returns 0 if the logical expression *x* is true, or 1 if the expression is false.
OR(*x*,*y*)	Returns 1 if either or both logical expressions *x* and *y* are true; otherwise, it returns 0.
PRODUCT(*list*)	Returns the result of multiplying together all members in *list*.
ROUND(*x*,*y*)	Returns the value of *x* rounded to the specified number of decimal places indicated by floor(*y*), where floor has the mathematical meaning. If *y* is negative, any fractional part is discarded and the integer part of the value is rounded to the corresponding power of 10.
SIGN(*x*)	Returns 1 if *x* is positive; returns 0 if *x* is zero; and returns –1 if *x* is negative.
SUM(*list*)	Returns the sum of the items in *list*.
TRUE	Returns 1.

2.16.3.5 Table cell references

Items in a WordprocessingML table are organized into rows and columns with the box formed by the intersection of a row and column being called a *cell*. Cells have names such as A1, A2, B1, B2, and so on, with the letter representing a column and the number representing a row. The cell at the top-left corner of each table is named A1. Column letters are not case-sensitive.

A *cell reference* shall be one of the following:

- The name of a cell.
- A comma-separated set of cell names.
- A cell range where a colon (:) is used to separate the first and last cells in a designated range of cells that has a contiguous rectangular shape. Specifying a row or column's name only as the first and last cell in a

range, selects that whole row or column, regardless of the number of rows and columns the table has now or might have in the future.

An *expression* inside a table's cell can have operands that are references to other cells in that table.

[*Example*: Consider a table with three rows (1, 2, and 3) and two columns (A and B):

`A1 + B1`	Returns the sum of the contents of cells A1 and B1.
`SUM(A1,B2,A3)`	Returns the sum of the contents of the list of cells.
`SUM(B1:B3)`	Returns the sum of the contents of all cells between B1 and B3, inclusive.
`SUM(B:B)`	Returns the sum of the contents of all cells in column B (even if new rows are added later).
`SUM(A1:B2)`	Returns the sum of the contents of all (four) cells in the rectangular grid delimited by A1 and B2, inclusive.
`SUM(1:1,2:2)`	Returns the sum of the contents of all cells in rows 1 and 2.

end example]

When used in a table cell, the functions taking a *list* argument can have a single argument of `ABOVE`, `BELOW`, `LEFT`, or `RIGHT`, spelled in any case combination. Such lists designate, respectively, all the cells above, below, to the left of, or to the right of that cell. However, the designated range terminates if a cell with blank or non-numeric contents is reached, except that if the first cell is blank, it is treated as containing 0. [*Example*: Given the following table:

`12`	`=COUNT(BELOW)`	
	10	
2	20	`=SUM(LEFT)`
3	xxx	
`=AVERAGE(ABOVE)`	40	

`AVERAGE(ABOVE)` results in 2.5, the average of cells A4 and A3; `COUNT(BELOW)` results in 2, B2 and B3; and `SUM(LEFT)` results in 22, the sum of B3 and A3. *end example*]

An *expression* used outside a table or in a cell of one table can refer to cells in a second table by making a bookmark to that second table and qualifying cell names in that table by their table name using the form

(*tableBookmarkName cellReference*)

[*Example*: Given that `Table1` is a bookmark for a 3x2 table, `=SUM(Table1 A1:A3)` book results in the sum of column A's cells. *end example*]

2.16.4 Field formatting

The result of a field has a *format*, either by default or because that field contains a *formatting-switch*. There are three kinds of field formatting: date and time (§2.16.4.1), numeric (§2.16.4.2), and general (§2.16.4.3).

2.16.4.1 Date and time formatting

date-and-time-formatting-switch:
\@ [''] *switch-argument* ['']

A *date-and-time-formatting-switch* specifies the format of a date or time result. [*Note*: This switch is sometimes called a *picture* switch because it allows the use of symbols to represent the format of the field result. *end note*] If the result of a field is not a date or time, this switch has no effect.

Quotation marks are required around *switch-argument* if it contains white space; otherwise, they are optional.

If no *date-and-time-formatting-switch* is present, a date or time result is formatted in an implementation-defined manner.

A date and time *switch-argument* is made up of a series of *picture items*.

Date and Time Formatting Picture Items	
Picture Item	Description
d	Formats the day of(the week or day of the month as a number without a leading 0 for single-digit days.
dd	Formats the day of the week or day of the month as a number with a leading 0 for single-digit days.
ddd	Formats the day of the week or month in its abbreviated form according to the language specified by the lang element (§2.3.2.18) on the run containing the field instructions.
dddd	Formats the day of the week as its full name according to the language specified by the lang element (§2.3.2.18) on the run containing the field instructions.
M	Formats the month as a number without a leading 0 for single-digit months.
MM	Formats the month as a number with a leading 0 for single-digit months.
MMM	Formats the month in its abbreviated form according to the language specified by the lang element (§2.3.2.18) on the run containing the field instructions.
MMMM	Formats the month as its full name according to the language specified by the lang element (§2.3.2.18) on the run containing the field instructions.
yy	Formats the year as two digits with a leading 0 for years 0–9.
yyyy	Formats the year as four digits.

In the following time formats, a lowercase h indicates that time is based on a 12-hour clock, while uppercase H indicates time is based on a 24-hour clock.

Time Formatting Picture Items	
Picture Item	Description
h or H	Formats the hour without a leading 0 for single-digit hours.
hh or HH	Formats the hour with a leading 0 for single-digit hours.
m	Formats the minutes without a leading 0 for single-digit minutes.
mm	Formats the minutes with a leading 0 for single-digit minutes.
am/pm or AM/PM	Formats using an am/AM or pm/PM suffix.

Miscellaneous Formatting Picture Items	
Picture Item	Description
Other character	Includes the specified character in the result at that position. [*Note*: Commonly used characters are colon (:), hyphen (-), asterisk (*), slash (/), and space. *end note*]
'*text*'	Includes *text* in the result.
`*numbered-item*`	Includes, in Arabic numerals, the number of the preceding item numbered as a caption or resulting from a SEQ field (§2.16.5.63). *numbered-item* shall be the same name as *identifier* in that SEQ field.

[*Example*: When updated in a US-English context on the date and time shown below, the following fields produced these results:

DATE \@ "M/d/yyyy"	1/3/2006
DATE \@ "dddd, MMMM dd, yyyy"	Tuesday, January 03, 2006
DATE \@ "MMMM d, yyyy"	January 3, 2006
DATE \@ "M/d/yy"	1/3/06
DATE \@ "yyyy-MM-dd"	2006-01-03
DATE \@ "d-MMM-yy"	3-Jan-06
DATE \@ "M.d.yyyy"	1.3.2006
DATE \@ "MMM. d, yy"	Jan. 3, 06
DATE \@ "d MMMM yyyy"	3 January 2006

DATE \@ "MMMM yy"	January 06
DATE \@ "MMM-yy"	Jan-06
DATE \@ "M/d/yyyy h:mm am/pm"	1/3/2006 5:28 PM
DATE \@ "M/d/yyyy h:mm:ss am/pm"	1/3/2006 5:28:34 PM
DATE \@ "h:mm am/pm"	5:28 PM
DATE \@ "h:mm:ss am/pm"	5:28:34 PM
DATE \@ "HH:mm"	17:28
DATE \@ "'Today is 'HH:mm:ss"	Today is 17:28:34

end example]

2.16.4.2 Numeric formatting

numeric-formatting-switch:
\# ["] *switch-argument* ["]

A *numeric-formatting-switch* specifies the format of a numeric result. If the result of a field is not a number, this switch has no effect.

Quotation marks are required around *switch-argument* if it contains white space; otherwise, they are optional.

If no *numeric-formatting-switch* is present, a numeric result is formatted without leading spaces or trailing fractional zeros. If the result is negative, a leading minus sign is present. If the result is a whole number, no radix point is present.

A numeric *switch-argument* is made up of a series of *picture items*.

Numeric Formatting Picture Items	
Picture Item	Description
0	Specifies the requisite numeric positions to display in the result. If the result does not include a digit in that position, 0 is displayed. [*Example*: In a US-English context, =4+5 \# 00.00 displays "09.00". *end example*]
#	Specifies the requisite numeric positions to display in the result. If the result does not include a digit in that position, a space is displayed. Extra fractional digits are rounded off. [*Example*: =9+6 \# $### displays "$ 15". *end example*]
x	Drops digits to the left of the x placeholder. If the placeholder is to the right of the decimal point, the result is rounded to that place. [*Example*: In a US-English context, =111053+111439 \# x## displays "492", =1/8 \# 0.00x displays "0.125", and =3/4 \# .x displays ".8". *end example*]
.	Indicates the radix-point position. [*Example*: In a US-English context, =95.4 \# $###.00 displays "$ 95.40. *end example*] The radix-point

Numeric Formatting Picture Items	
	character displayed is locale-specific.
,	Separates groups of three digits. [*Example*: In a US-English context, =2456800 \# $#,###,### displays "2,456,800". *end example*] The separator character displayed is locale-specific.
-	Prepends a minus sign to a negative result, or prepends a space if the result is positive or 0. [*Example*: =80-90 \# -## displays "-10", while =90-80 \# -## displays " 80". *end example*]
+	Prepends a plus sign to a positive result, a minus sign to a negative result, or a space if the result is 0. [*Example*: =90-80 \# +## displays "+10", and =80-90 \# +## displays "-10". *end example*]
Other character	Includes the specified character in the result at that position. [*Example*: =33 \# ##% displays "33%". *end example*]
'*text*'	Includes text in the result. [*Example*: In a US-English context, if Price is a bookmark for 26.5, =Price*15% \# "##0.00 'is the sales tax'" displays "$ 3.98 is the sales tax". *end example*]
`*numbered-item*`	Includes, in Arabic numerals, the number of the preceding item numbered as a caption or resulting from a SEQ field (§2.16.5.63). *numbered-item* shall be the same name as *identifier* in that SEQ field. [*Example*: =SUM(A1:D4) \# "##0.00 'is the total of Table' `table`" displays "456.34 is the total of Table 2". *end example*]
positive-result ; *negative-result*	Specifies different sets of picture items for positive and negative results. A zero value uses the positive picture. [*Example*: =Sales95 \# $#,##0.00;-$#,##0.00 displays that bookmark's positive values using $#,##0.00, and it's negative values using -$#,##0.00. *end example*]
positive-result ; *negative-result* ; *zero-result*	Specifies different sets of picture items for positive, negative, and zero results. [*Example*: =Sales95 \# $#,##0.00;-$#,##0.00;$0 displays that bookmark's positive values using $#,##0.00, it's negative values using -$#,##0.00, and its zero values using $0. *end example*]

2.16.4.3 General formatting

general-formatting-switch:
* ["] *switch-argument* ["]

A *general-formatting-switch* specifies a variety of formats for a numeric or text result. If the result type of a field does not correspond to the format specified, this switch has no effect.

Quotation marks are required around *switch-argument* if it contains white space; otherwise, they are optional.

A *switch-argument* is made up of a series of *picture items*.

General Formatting Switch Arguments	
Switch Argument	Description
AIUEO	Formats a numeric result using hiragana characters in the traditional a-i-u-e-o

General Formatting Switch Arguments	
	order. [*Example*: `1 \* AIUEO` results in ア. *end example*] Corresponds to an ST_NumberFormat enumeration value of `aiueo`.
`ALPHABETIC`	Formats a numeric result as one or more occurrences of an uppercase alphabetic Latin character. Value 1 results in the letter A, value 2 results in the letter B, and so on up to value 26, which results in the letter Z. For values greater than 26, 26 is repeatedly subtracted from the value until the result is 26 or less. The result value determines which letter to use, and the same letter is repeated for each time 26 was subtracted from the original value. [*Example*: `=54 \* ALPHABETIC` results in "BBB" as subtracting 26 from 54 two times, results in the value 2, which is represented by the letter B. *end example*]
`alphabetic`	Formats a numeric result as one or more occurrences of an lowercase alphabetic Latin character. Value 1 results in the letter a, value 2 results in the letter b, and so on up to value 26, which results in the letter z. For values greater than 26, 26 is repeatedly subtracted from the value until the result is 26 or less. The result value determines which letter to use, and the same letter is repeated for each time 26 was subtracted from the original value. [*Example*: `=52 \* alphabetic` results in "zz" as subtracting 26 from 52 one time, results in the value 26, which is represented by the letter z.. *end example*]
`Arabic`	Formats a numeric result using Arabic cardinal numerals. [*Example*: For page 123, `PAGE \* Arabic` results in "١٢٣". *end example*] Corresponds to an ST_NumberFormat enumeration value of `decimal`.
`ARABICABJAD`	Formats a numeric result using ascending Abjad numerals. [*Example*: `12 \* ARABICABJAD` results in ك. *end example*] Corresponds to an ST_NumberFormat enumeration value of `arabicAbjad`.
`ARABICALPHA`	Formats a numeric result using characters in the Arabic alphabet. [*Example*: `12 \* ARABICABJAD` results in س. *end example*] Corresponds to an ST_NumberFormat enumeration value of `arabicAlpha`.
`ArabicDash`	Formats a numeric result using Arabic cardinal numerals, with a prefix of "- " and a suffix of " -". [*Example*: For page 123, `PAGE \* ArabicDash` results in "- ١٢٣ -". *end example*] Corresponds to an ST_NumberFormat enumeration value of `numberInDash`.
`BAHTTEXT`	Formats a numeric result using the given Thai style. [*Example*: `1 \* BAHTTEXT` results in หนึ่งบาทถ้วน. *end example*]
`Caps`	Capitalizes the first letter of each word. [*Example*: `USERNAME "mary smith" \* Caps` results in "Mary Smith", whereas `USERNAME "marysmith" \* Caps` results in "Marysmith". *end example*]
`CardText`	Formats a numeric result as lowercase cardinal text. [*Example*: For page 123, `PAGE \* CardText` results in "one hundred twenty-three". *end example*] Corresponds to an ST_NumberFormat enumeration value of `cardinalText`.
`CHARFORMAT`	See the discussion following this table.
`CHINESENUM1`	Formats a numeric result using ascending numbers from the Chinese counting system. [*Example*: `10 \* CHINESENUM1` results in 十. *end example*]

General Formatting Switch Arguments	
	Corresponds to an ST_NumberFormat enumeration value of chineseCounting.
CHINESENUM2	Formats a numeric result using sequential numbers from the Chinese simplified legal format. [*Example*: 123 * CHINESENUM2 results in 壹佰贰拾叁. *end example*] Corresponds to an ST_NumberFormat enumeration value of chineseLegalSimplified.
CHINESENUM3	Formats a numeric result using sequential numbers from the Chinese counting thousand system. [*Example*: 10 * CHINESENUM3 results in 一百二十三. *end example*] Corresponds to an ST_NumberFormat enumeration value of chineseCountingThousand.
CHOSUNG	Formats a numeric result using sequential numbers from the Korean Chosung format. [*Example*: 1 * CHOSUNG results in ㄱ. *end example*] Corresponds to an ST_NumberFormat enumeration value of chosung.
CIRCLENUM	Formats a numeric result using decimal numbering enclosed in a circle, using the enclosed alphanumeric glyph character for numbers in the range 1–20. For non-negative numbers outside this range, formats them as with ARABIC. [*Example*: 12 * CIRCLENUM results in ⑫. *end example*] Corresponds to an ST_NumberFormat enumeration value of decimalEnclosedCircle.
DBCHAR	Formats a numeric result using double-byte Arabic numbering. [*Example*: 123 * DBCHAR results in １２３. *end example*] Corresponds to an ST_NumberFormat enumeration value of decimalFullWidth.
DBNUM1	Formats a numeric result using sequential digital ideographs, using the appropriate character. [*Example*: 12 * DBNUM1 results in 一二. *end example*] Corresponds to an ST_NumberFormat enumeration value of ideographDigital.
DBNUM2	Formats a numeric result using sequential numbers from the Korean counting system. [*Example*: 12 * DBNUM2 results in 십이. *end example*] Corresponds to an ST_NumberFormat enumeration value of koreanCounting.
DBNUM3	Formats a numeric result using sequential numbers from the Japanese legal counting system. [*Example*: 12 * DBNUM3 results in 壱拾弐. *end example*] Corresponds to an ST_NumberFormat enumeration value of japaneseLegal.
DBNUM4	Formats a numeric result using sequential numbers from the Japanese digital ten thousand counting system. [*Example*: 12 * DBNUM4 results in 一二. *end example*] Corresponds to an ST_NumberFormat enumeration value of japaneseDigitalTenThousand.
DollarText	Formats a numeric result in the following form: *integer-part-as-cardinal-text* and *nn*/100 The fractional part is rounded to two decimal places, *nn*, and is formatted using

General Formatting Switch Arguments	
	Arabic cardinal numerals. [*Example*: `=1234.567 \* DollarText` results in "`one thousand two hundred thirty-four and 57/100`". *end example*]
`FirstCap`	Capitalizes the first letter of the first word. [*Example*: `USERNAME "mary smith" \* FirstCap` results in "`Mary smith`". *end example*]
`GANADA`	Formats a numeric result using sequential numbers from the Korean Ganada format. [*Example*: `12 \* GANADA` results in 타. *end example*] Corresponds to an ST_NumberFormat enumeration value of `ganada`.
`GB1`	Formats a numeric result using decimal numbering followed by a period, using the enclosed alphanumeric glyph character. [*Example*: `12 \* GB1` results in 12.. *end example*] Corresponds to an ST_NumberFormat enumeration value of `decimalEnclosedFullstop`.
`GB2`	Formats a numeric result using decimal numbering enclosed in parenthesis, using the enclosed alphanumeric glyph character. [*Example*: `12 \* GB2` results in ⑿. *end example*] Corresponds to an ST_NumberFormat enumeration value of `decimalEnclosedParen`.
`GB3`	Formats a numeric result using decimal numbering enclosed in a circle, using the enclosed alphanumeric glyph character. Once the specified sequence reaches 11, the numbers may be replaced with non-enclosed equivalents. [*Example*: `12 \* GB3` results in 12. *end example*] Corresponds to an ST_NumberFormat enumeration value of `decimalEnclosedCircleChinese`.
`GB4`	Formats a numeric result using decimal numbering enclosed in a circle, using the enclosed alphanumeric glyph character. Once the specified sequence reaches 11, the numbers may be replaced with non-enclosed equivalents. [*Example*: `12 \* GB4` results in 12. *end example*] Corresponds to an ST_NumberFormat enumeration value of `ideographEnclosedCircle`.
`HEBREW1`	Formats a numeric result using Hebrew numerals. [*Example*: `123 \* HEBREW1` results in קכג. *end example*] Corresponds to an ST_NumberFormat enumeration value of `hebrew1`.
`HEBREW2`	Formats a numeric result using the Hebrew alphabet. [*Example*: `123 \* HEBREW2` results in תתתתתמ. *end example*] Corresponds to an ST_NumberFormat enumeration value of `hebrew2`.
`Hex`	Formats the numeric result using uppercase hexadecimal digits. [*Example*: For page 355, `PAGE \* Hex` results in "`FF`". *end example*] Corresponds to an ST_NumberFormat enumeration value of `hex`.
`HINDIARABIC`	Formats a numeric result using Hindi numbers. [*Example*: `123 \* HINDIARABIC` results in ١٢٣. *end example*] Corresponds to an ST_NumberFormat enumeration value of `hindiNumbers`.
`HINDICARDTEXT`	Formats a numeric result using sequential numbers from the Hindi counting

General Formatting Switch Arguments	
	system. [*Example*: `123 \* HINDICARDTEXT` results in एक सौ तेईस. *end example*] Corresponds to an ST_NumberFormat enumeration value of `hindiCounting`.
`HINDILETTER1`	Formats a numeric result using Hindi vowels. [*Example*: `123 \* HINDILETTER1` results in ठठठठ. *end example*] Corresponds to an ST_NumberFormat enumeration value of `hindiVowels`.
`HINDILETTER2`	Formats a numeric result using Hindi consonants. [*Example*: `123 \* HINDILETTER2` results in ओओओओओओओ. *end example*] Corresponds to an ST_NumberFormat enumeration value of `hindiConsonants`.
`IROHA`	Formats a numeric result using the Japanese iroha. [*Example*: `12 \* IROHA` results in 才. *end example*] Corresponds to an ST_NumberFormat enumeration value of `iroha`.
`KANJINUM1`	Formats a numeric result using a Japanese style using sequential digital ideographs, using the appropriate character. [*Example*: `12 \* KANJINUM1` results in 一二. *end example*]
`KANJINUM2`	Formats a numeric result using the Japanese counting system. [*Example*: `12 \* KANJINUM2` results in 十二. *end example*] Corresponds to an ST_NumberFormat enumeration value of `japaneseCounting`.
`KANJINUM3`	Formats a numeric result using the Japanese legal counting system. [*Example*: `12 \* KANJINUM3` results in 壱拾弐. *end example*]
`Lower`	All letters are lowercase. [*Example*: `USERNAME "Mary Smith" \* Lower` results in "`mary smith`". *end example*]
`MERGEFORMAT`	See the discussion following this table.
`Ordinal`	Formats a numeric result using lowercase ordinal Arabic numerals. [*Example*: `=32 \* Ordinal` results in "`32nd`". *end example*] Corresponds to an ST_NumberFormat enumeration value of `ordinal`.
`OrdText`	Formats a numeric result as lowercase ordinal text. Apart from being used to round off the whole number part, the fractional part is not used. [*Example*: `=1234.567 \* OrdText` results in "`one thousand two hundred thirty-fifth`". *end example*] Corresponds to an ST_NumberFormat enumeration value of `ordinalText`.
`Roman`	Formats a numeric result using uppercase Roman numerals. [*Example*: For page 123, `PAGE \* Roman` results in "`CXXIII`". *end example*] Corresponds to an ST_NumberFormat enumeration value of `upperRoman`.
`roman`	Formats a numeric result using lowercase Roman numerals. [*Example*: For page 123, `PAGE \* roman` results in "`cxxiii`". *end example*] Corresponds to an ST_NumberFormat enumeration value of `lowerRoman`.
`SBCHAR`	Formats a numeric result using single-byte Arabic numbering. [*Example*: `123 \* SBCHAR` results in 123. *end example*]

General Formatting Switch Arguments	
	Corresponds to an ST_NumberFormat enumeration value of `decimalHalfWidth`.
THAIARABIC	Formats a numeric result using Thai numbers. [*Example*: `123 \* THAIARABIC` results in ๑๒๓. *end example*] Corresponds to an ST_NumberFormat enumeration value of `thaiNumbers`.
THAICARDTEXT	Formats a numeric result using sequential numbers from the Thai counting system. [*Example*: `123 \* THAICARDTEXT` results in หนึ่งร้อยยี่สิบสาม. *end example*] Corresponds to an ST_NumberFormat enumeration value of `thaiCounting`.
THAILETTER	Formats a numeric result using Thai letters. [*Example*: `123 \* THAILETTER` results in ฮฮฮ. *end example*] Corresponds to an ST_NumberFormat enumeration value of `thaiLetters`.
Upper	All letters are uppercase. [*Example*: `USERNAME "Mary Smith" \* Upper` results in "MARY SMITH". *end example*]
VIETCARDTEXT	Formats a numeric result using Vietnamese numerals. [*Example*: `12 \* VIETCARDTEXT` results in mười hai. *end example*] Corresponds to an ST_NumberFormat enumeration value of `vietnameseCounting`.
ZODIAC1	Formats a numeric result using sequential numerical traditional ideographs. [*Example*: `1 \* ZODIAC1` results in 甲. *end example*] Corresponds to an ST_NumberFormat enumeration value of `ideographTraditional`.
ZODIAC2	Formats a numeric result using sequential zodiac ideographs. [*Example*: `1 \* ZODIAC2` results in 子. *end example*] Corresponds to an ST_NumberFormat enumeration value of `ideographZodiac`.
ZODIAC3	Formats a numeric result using sequential traditional zodiac ideographs. [*Example*: `1 \* ZODIAC3` results in 甲子. *end example*] Corresponds to an ST_NumberFormat enumeration value of `ideographZodiacTraditional`.

The general formatting switch argument CHARFORMAT is used to set the visual appearance of a field's value by setting the first run in that field's *field-type* name to the desired state using any of the elements that can be directly nested inside the run property element, rPr. [*Example*: In a US-English context, on January 4, 2006, the field DATE * CHARFORMAT results in "1/4/2006". However, if the D in DATE is made bold, the field **D**ATE * CHARFORMAT results in "**1/4/2006**". If that D is made italic, the field *D*ATE * CHARFORMAT results in "*1/4/2006*". If that D is made bold, underlined, and red, the field **D**ATE * CHARFORMAT results in "**1/4/2006**".

The XML for the bold, underlined, red case is as follows:

```
<w:r>
  <w:fldChar w:fldCharType="begin"/>
</w:r>
<w:r>
  <w:instrText xml:space="preserve"> </w:instrText>
</w:r>
<w:r …>
  <w:rPr>
    <w:b/>
    <w:color w:val="ED1C24"/>
    <w:u w:val="single"/>
  </w:rPr>
  <w:instrText>D</w:instrText>
</w:r>
<w:r>
  <w:instrText xml:space="preserve">ATE </w:instrText>
</w:r>
<w:r>
  <w:fldChar w:fldCharType="separate"/>
</w:r>
<w:r …>
  <w:rPr>
    <w:b/>
    <w:color w:val="ED1C24"/>
    <w:u w:val="single"/>
  </w:rPr>
  <w:t>1/4/2006</w:t>
</w:r>
<w:r>
  <w:fldChar w:fldCharType="end"/>
</w:r>
```

end example]

If a format specified directly in the first run of a field's *field-type* name conflicts with a general formatting switch, the general formatting switch is ignored. [*Example*: If the first run is set in small caps and the switch `\* Lower` is also used, that switch is ignored. *end example*]

The general formatting switch argument `MERGEFORMAT` is used to apply formatting directly to part of a result such that when that result is updated, the formatting is preserved. The formatting is expressed in XML using an `rPr` element on the run that contains the most recently updated field result. [*Example*: Consider the following field:

```
TIME \@ "HH:mm:ss" \* MERGEFORMAT
```

When it is updated, the result might be 12:22:27, for example. If the seconds part of the displayed field result is underlined, as in 12:22:27, when that field is next updated, the seconds underlining is preserved. If MERGEFORMAT is omitted, the rPr element on the run that contains the most recently updated field result is ignored.

The XML generated for this is:

```
<w:r>
  <w:fldChar w:fldCharType="begin"/>
</w:r>
<w:r>
  <w:instrText xml:space="preserve"> TIME \@ "HH:mm:ss" \* MERGEFORMAT
</w:instrText>
</w:r>
<w:r>
  <w:fldChar w:fldCharType="separate"/>
</w:r>
<w:r …>
  <w:t>17:02:</w:t>
</w:r>
<w:r …>
  <w:rPr>
    <w:u w:val="single"/>
  </w:rPr>
  <w:t>32</w:t>
</w:r>
<w:r>
  <w:fldChar w:fldCharType="end"/>
</w:r>
```

end example]

2.16.5 Field definitions

The set of fields is divided into the following functional categories:

Category	Description	Fields
Date and Time	Inserts the current date and/or time, or date and/or time of some kind of event.	CREATEDATE (§2.16.5.16), DATE (§2.16.5.18), EDITTIME (§2.16.5.21), PRINTDATE (§2.16.5.54), SAVEDATE (§2.16.5.60), TIME (§2.16.5.72)
Document Automation	Compares values and takes action based on outcome, run macros, and sends a code to a printer.	COMPARE (§2.16.5.15), DOCVARIABLE (§2.16.5.20), GOTOBUTTON (§2.16.5.29), IF (§2.16.5.32), MACROBUTTON (§2.16.5.41), PRINT (§2.16.5.53)

Category	Description	Fields
Document Information	Inserts or stores information about the document.	AUTHOR (§2.16.5.4), COMMENTS (§2.16.5.14), DOCPROPERTY (§2.16.5.19), FILENAME (§2.16.5.23), FILESIZE (§2.16.5.24), INFO (§2.16.5.36), KEYWORDS (§2.16.5.37), LASTSAVEDBY (§2.16.5.38), NUMCHARS (§2.16.5.48), NUMPAGES (§2.16.5.49), NUMWORDS (§2.16.5.50), SUBJECT (§2.16.5.67), TEMPLATE (§2.16.5.71), TITLE (§2.16.5.73)
Equations and Formulas	Defines formulas and calculates results; inserts symbols.	= *formula* (§2.16.3), ADVANCE (§2.16.5.2), EQ (§2.16.5.22), SYMBOL (§2.16.5.68)
Form Fields	Allows the insertion of form fields.	FORMCHECKBOX (§2.16.5.26), FORMDROPDOWN (§2.16.5.27), FORMTEXT (§2.16.5.28)
Index and Tables	Defines entries for, and builds, a table of contents, table of figures, and table of authorities.	INDEX (§2.16.5.35), RD (§2.16.5.57), TA (§2.16.5.69), TC (§2.16.5.70), TOA (§2.16.5.74), TOC (§2.16.5.75), XE (§2.16.5.79)
Links and References	Inserts information from another place in the same document, from a different document or file, or from an AutoText entry.	AUTOTEXT (§2.16.5.8), AUTOTEXTLIST (§2.16.5.9), BIBLIOGRAPHY (§2.16.5.11), CITATION (§2.16.5.13) HYPERLINK (§2.16.5.31), INCLUDEPICTURE (§2.16.5.33), INCLUDETEXT (§2.16.5.34), LINK (§2.16.5.39), NOTEREF (§2.16.5.47), PAGEREF (§2.16.5.52), QUOTE (§2.16.5.56), REF (§2.16.5.58), STYLEREF (§2.16.5.66)
Mail Merge	Defines information that is to be used in a mail merge.	ADDRESSBLOCK (§2.16.5.1), ASK (§2.16.5.3), COMPARE (§2.16.5.15), DATABASE (§2.16.5.17), FILLIN (§2.16.5.25), GREETINGLINE (§2.16.5.30), IF (§2.16.5.32), MERGEFIELD (§2.16.5.42), MERGEREC (§2.16.5.43), MERGESEQ (§2.16.5.44), NEXT (§2.16.5.45), NEXTIF (§2.16.5.46), SET (§2.16.5.64), SKIPIF (§2.16.5.65)
Numbering	Specifies numbering for document items such as sections and pages; also bar codes.	AUTONUM (§2.16.5.5), AUTONUMLGL (§2.16.5.6), AUTONUMOUT (§2.16.5.7), BARCODE (§2.16.5.10), LISTNUM (§2.16.5.40), PAGE (§2.16.5.51), REVNUM (§2.16.5.59), SECTION (§2.16.5.61), SECTIONPAGES (§2.16.5.62), SEQ (§2.16.5.63)

Category	Description	Fields
User Information	Stores or inserts the name, initials, or address of the document user.	USERADDRESS (§2.16.5.76), USERINITIALS (§2.16.5.77), USERNAME (§2.16.5.78)

2.16.5.1 ADDRESSBLOCK

Syntax:

ADDRESSBLOCK [*switches*]

Description: Inserts a mail merge address block.

Field Value: The address block.

Switches: Zero or more of the following *field-specific-switch*es.

\c *field-argument*	*text* in this switch's *field-argument* specifies whether to include the name of the country/region: a value of 0 causes the country/region to be omitted; a value of 1 causes it to be included, and a value of 2 causes country/region to be included, but only if it is different from the value for \e.
\d	Specifies that the address is to be formatted according to the country/region of the recipient. If this switch is not used, then addresses are formatted according to some implementation-specific preference.
\e *field-argument*	*text* in this switch's *field-argument* specifies which country/region to exclude from the address block. [*Note*: This is useful when your mailing contains a mix of domestic and international recipients. *end note*] To exclude the names of more than one country or region, use a \e switch for each one.
\f *field-argument*	*text* in this switch's *field-argument* specifies the name and address format by providing a template of merge-field placeholders.
\l *field-argument*	*text* in this switch's *field-argument* specifies the language ID used to format the address. The default is to use the language ID of the first character of the document.

2.16.5.2 ADVANCE

Syntax:

ADVANCE [*switches*]

Description: Moves the starting point of text that follows the field to the right or left, up or down, or to a specific horizontal or vertical position. The switches used by this field can cause text to overlap. Text will not display if it is moved to the previous or next page, or beyond the print margins of the current page.

Field Value: None.

Switches: Zero or more of the following *field-specific-switch*es.

\d *field-argument*	Moves the text that follows the field down by the integral number of points specified by *text* in this switch's *field-argument*.
\l *field-argument*	Moves the text that follows the field left by the integral number of points specified by *text* in this switch's *field-argument*.
\r *field-argument*	Moves the text that follows the field right by the integral number of points specified by *text* in this switch's *field-argument*.
\u *field-argument*	Moves the text that follows the field up by the integral number of points specified by *text* in this switch's *field-argument*.
\x *field-argument*	Moves the text that follows the field the integral number of points specified by *text* in this switch's *field-argument* from the left edge of the column, frame, or text box.
\y *field-argument*	Moves the text that follows the field the integral number of points specified by *text* in this switch's *field-argument*. This shift is the vertical position relative to the page. The entire line of text that contains the field is moved. This switch is ignored if it specifies a location outside the page margins or if the switch is used inside any of the following: table, text box, footnote, endnote, annotation, header, or footer.

[*Example*: When the following fields are updated:

```
XX ADVANCE \u 6 XX ADVANCE \d 12 XX ADVANCE \l 20 + ADVANCE \x 150 ZZ
```

The results are:

```
XXXX
  XX+ X                ZZ
```

end example]

2.16.5.3 ASK

Syntax:

ASK *field-argument-1* *field-argument-2* [*switches*]

field-argument-1:
field-argument

field-argument-2:
field-argument

Description: Prompts the user to enter information and assigns the bookmark designated by *field-argument-1* to represent the user's response. *text* in *field-argument-2* specifies the prompt text, which is displayed in a dialog box. The prompt is displayed each time the ASK field is updated. A response remains assigned to the bookmark until a new response is entered.

Field Value: None.

Switches: Zero or more of the following *field-specific-switch*es.

`\d` *field-argument*	The *text* in this switch's *field-argument* specifies a default response if one is not entered. If no default response is specified, the most recent response is used. To specify a blank entry as the default, *field-argument* shall be `""`.
`\o`	When used in a mail merge main document, this causes the display of the prompt once instead of each time a new data record is merged. The same response is inserted in each resulting merged document.

[*Example*: When the following fields are updated and "John" is entered as the response,

```
ASK AskResponse "What is your first name?"
Hello REF AskResponse.
```

the result is

```
Hello John.
```

end example]

2.16.5.4 AUTHOR

Syntax:

AUTHOR [*field-argument*] [*switch*]

Description: Retrieves, and optionally sets, the document author's name, as recorded in the Creator element of the Core File Properties part or, if *field-argument* is present, the name specified by *text* in *field-argument*. Specifying a *field-argument* shall change Creator to *text*.

Field Value: The document author's name.

Switches: One of the following *general-formatting-switch*es: `\* Caps`, `\* FirstCap`, `\* Lower`, or `\* Upper`.

[*Example*: Consider the case in which the Creator element is as follows:

```
<Creator>William Jones</Creator>
```

and the following field is updated:

```
AUTHOR
```

The result is:

```
William Jones
```

Updating the following field:

```
AUTHOR "Tony Caruso"
```

causes the Creator element to take on the specified value. *end example*]

2.16.5.5 AUTONUM

Syntax:

AUTONUM [*switches*]

Description: In paragraphs formatted with one of the nine built-in heading styles, paragraph numbering restarts at 1 in each successive heading level. If headings that contain AUTONUM fields are followed by body text paragraphs that also contain AUTONUM fields, the paragraph numbering of the body text is restarted at 1 after each heading. If the headings don't contain AUTONUM fields, body text paragraphs that contain AUTONUM fields are numbered in a continuous, sequential series throughout the document. [*Note*: This field is supported for legacy reasons, It is recommended that LISTNUM (§2.16.5.40) be used instead. *end note*]

The XML generated for a complex field implementation shall not have the optional field value stored.

Field Value: A new paragraph number in ascending sequential order.

Switches: Zero or one of the *general-formatting-switch*es, or zero or more of the following *field-specific-switch*es.

\s *field-argument*	*text* in this switch's *field-argument* specifies the separator character to be used. If \s is omitted, a period (.) is used.

[*Example*: When the following fields are updated:

```
AUTONUM
AUTONUM \* Arabic \s :
AUTONUM \* alphabetic \s " "xxx
AUTONUM \* ROMAN
AUTONUM \* OrdText
```

The results are:

```
1.
2:
c xxx
IV.
fifth.
```

end example]

2.16.5.6 AUTONUMLGL

Syntax:

AUTONUMLGL [*switches*]

Description: For legal and technical publications, use the nine built-in heading styles to format headings in the document, and then insert an AUTONUMLGL field at the beginning of each heading paragraph. The numbers reflect the heading levels that correspond to the heading styles. If an AUTONUMLGL field is inserted in paragraphs of body text paragraphs not formatted with built-in heading styles, the number of the preceding heading is included in the paragraph number. [*Note*: This field is supported for legacy reasons, It is recommended that LISTNUM (§2.16.5.40) be used instead. *end note*]

This field only makes sense in terms of multi-level headings. Given the following headings:

Heading 1
Heading 2
Heading 2
Heading 1

this field allows

1. Heading 1
1.1. Heading 2
1.2. Heading 2
2. Heading 1

At each level, the numbering sequence does two things—it increments specific to that level, and it includes the value from the previous level.

The XML generated for a complex field implementation shall not have the optional field value stored.

Field Value: A new paragraph number in ascending sequential order.

Switches: Zero or one of the *general-formatting-switch*es, or zero or more of the following *field-specific-switch*es.

\e	Removes the trailing separator (period).
\s *field-argument*	*text* in this switch's *field-argument* specifies the separator character to be used. If \s is omitted, a period (.) is used.

[*Example*: When the following fields are updated:

```
AUTONUMLGL
AUTONUMLGL \* Arabic \s :
AUTONUMLGL \* alphabetic \s " "xxx
AUTONUMLGL \* ROMAN
AUTONUMLGL \e xxx
```

The results are:

```
1.
2:
c xxx
IV.
5xxx
```

end example]

2.16.5.7 AUTONUMOUT

Syntax:

AUTONUMOUT

Description: Use the nine built-in heading styles to format headings in the document, and then insert an AUTONUMOUT field at the beginning of each heading paragraph. The numbers reflect the heading levels that correspond to the heading styles. [*Note*: This field is supported for legacy reasons, It is recommended that LISTNUM (§2.16.5.40) be used instead. *end note*]

The XML generated for a complex field implementation shall not have the optional field value stored.

This field allows the numbering to be incremented based on the heading level. Given the following:

{AutoNumOut} Heading 1
{AutoNumOut} Heading 2
{AutoNumOut} Heading 2
{AutoNumOut} Heading 1

results in

I. Heading 1
A. Heading 2
B. Heading 2
II. Heading 1

Field Value: A paragraph number.

Switches: None.

[*Example*: When the following fields are updated:

```
AUTONUMOUT
AUTONUMOUT
```

The results are:

```
1.
2.
```

end example]

2.16.5.8 AUTOTEXT

Syntax:

AUTOTEXT *field-argument*

Description: Inserts the AutoText entry whose name is specified by *text* in *field-argument*.

Regarding XML generation, the field result is the value of the autotext. [*Note*: This can be arbitrarily complex and involve VML *end note*]

Field Value: The specified AutoText entry.

Switches: None.

[*Example*: Assuming the following entries are defined with values of current page number, salutation, and a notice:

```
AUTOTEXT "- PAGE -"
AUTOTEXT "Yours truly,"
AUTOTEXT Confidential
```

when evaluated, they might produce the following results.

```
 - 13 -
Yours truly,
CONFIDENTIAL
```

end example]

2.16.5.9 AUTOTEXTLIST

Syntax:

AUTOTEXTLIST *field-argument* [*switches*]

Description: Creates a shortcut menu based on AutoText entries in the active template. The list can vary based on the styles applied to the AutoText entries. *text* in *field-argument* is inserted into the document.

A complex field XML implementation shall be used, and the *field-argument* text shall be placed in one or more runs between the separate and end parts of the fldChar element.

Field Value: *text* in *field-argument*.

Switches: Zero or more of the following *field-specific-switch*es.

`\s` *field-argument*	Specifies that the list is to contain entries based on the style specified by *text* in this switch's *field-argument*. Without this switch, entries of the current paragraph style appear. If there are no entries for the current style, all entries appear. The style can be a paragraph style or a character style.
`\t` *field-argument*	*text* in this switch's *field-argument* specifies the text to show in the ScreenTip.

[*Example*: The field:

```
{ AUTOTEXTLIST "List of salutations" \s Salutation \t "Choose a salutation" }
```

causes the following to be displayed: In the document, the Salutation list; in the ScreenTip, `Choose a salutation`, and on the shortcut menu, the list of entries whose style is `Salutation`.

end example]

2.16.5.10 BARCODE

Syntax:

BARCODE *field-argument* [*switch*]

Description: Produces a postal bar code is a machine-readable form of address used by the U.S. Postal Service. The barcode is in the form of either a POSTNET delivery-point bar code or a Facing Identification Mark (FIM). *text* in *field-argument* can be either a postal address or a bookmark name. In the case of a postal address, all that is needed is a 5-digit or 9-digit ZIP code; the rest of the address is superfluous.

Field Value: A postal bar code.

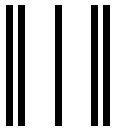
Switches: Zero or more of the following *field-specific-switch*es.

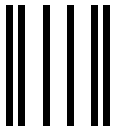
`\b`	Indicates that *text* in *field-argument* is the name of a bookmark.
`\f` *field-argument*	Inserts a Facing Identification Mark (FIM). *text* in this switch's *field-argument* shall be either "A" (courtesy reply mark) or "C" (business reply mark).
`\u`	Indicates that *text* in *field-argument* is a U.S. postal address.

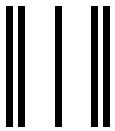
[*Example*: Consider the case in which `PostalAddress` is the name of a bookmark for the text "2051 Swans Neck Way, Reston VA 20191". When the following fields are updated:

```
BARCODE 20191
BARCODE 20191 \u
BARCODE 20191-4023 \u
BARCODE "2051 Swans Neck Way, Reston VA 20191" \u
BARCODE "2051 Swans Neck Way, Reston VA 20191" \f A
BARCODE 20191 \f C
BARCODE PostalAddress \b \f A
```

The results are:







end example]

2.16.5.11 BIBLIOGRAPHY

Syntax:

```
BIBLIOGRAPHY [ switch ]
```

Description: Retrieves and displays the contents of the document's Bibliography part in the bibliographic style specified within the SelectedStyle attribute of the Sources (§7.6.2.60) element of the Bibliography part.

Field Value: The formatted bibliographic data for all sources in the current document.

Switches: The following *field-specific-switch*.

\l *field-argument*	The *text* in this switch's *field-argument* specifies the locale that shall be used in to format the bibliographic sources in the document that do not specify a locale

	using the LCID (§7.6.2.39) element.
\f *field-argument*	The *text* in this switch's *field-argument* specifies the locale that shall be used to filter the bibliographic data to only the sources in the document that have a value matching *field-argument* in the LCID (§7.6.2.39) element.
\m *field-argument*	The *text* in this switch's *field-argument* specifies that only the source with a Tag (§7.6.2.65) element value matching *field-argument* shall be displayed in the bibliography.

[*Example:* Consider a document with bibliographic data for this Office Open XML Standard:

Author: Ecma International
Title: Office Open XML Document Interchange Specification
Year: 2006
Month: October

the following field is updated:

```
BIBLIOGRAPHY /l 1033
```

The result for MLA is:

```
Ecma International. Office Open XML Document Interchange Specification. October
2006.
```

And for APA:

```
Ecma International. (2006, October). Office Open XML Document Interchange
Specification.
```

end example]

2.16.5.12 BIDIOUTLINE

Syntax:

```
BIDIOUTLINE
```

Description: Sets the output as being right-to-left. This field is like AUTONUMOUT (§2.16.5.7), except for differences in Arabic/Hebrew numbering [*Example*: For Heading 2, BIDIOUTLINE results in א, while AUTONUMOUT results in A. *end example*]

Field Value: A paragraph number.

Switches: None.

2.16.5.13 CITATION

Syntax:

CITATION *field-argument* [*switch*]

Description: Displays the contents of the Source (§7.6.2.59) element with a Tag (§7.6.2.65) element value matching *field-argument* using the bibliographic style specified within the SelectedStyle attribute of the Sources (§7.6.2.60) element of the Bibliography part.

Field Value: The comments relating to the current document.

Switches: The following *field-specific-switch*.

\l *field-argument*	The *text* in this switch's *field-argument* specifies the locale which shall be used in conjunction with the specified bibliographic style to format the citation in the document.
\f *field-argument*	The *text* in this switch's *field-argument* specifies the prefix which shall be prepended to the citation.
\s *field-argument*	The *text* in this switch's *field-argument* specifies the suffix which shall be appended to the citation.
\p *field-argument*	The *text* in this switch's *field-argument* specifies the page number associated with the citation.
\v *field-argument*	The *text* in this switch's *field-argument* specifies the volume number associated with the citation.
\n	Specifies that the author information shall be suppressed from the citation.
\t	Specifies that the title information shall be suppressed from the citation.
\y	Specifies that the year information shall be suppressed from the citation.
\m *field-argument*	The *text* in this switch's *field-argument* specifies the Tag (§7.6.2.65) element value for another source to be included in this citation's field result.

[*Example:* Consider a case with bibliographic data for this Office Open XML Standard:

Tag: Ecma01
Author: Ecma International
Title: Office Open XML Document Interchange Specification
Year: 2006
Month: October

the following field is updated:

```
CITATION Ecma01 /l 1033
```

The result for MLA is:

```
(Ecma International)
```

And for APA:

```
(Ecma International, 2006)
```

end example]

2.16.5.14 COMMENTS

Syntax:

COMMENTS [*field-argument*] [*switch*]

Description: Retrieves, and optionally sets, the comments relating to the current document, as recorded in the Description element of the Core File Properties part or, if *field-argument* is present, the comments specified by *text* in *field-argument*. Specifying a field-argument shall change Description to *text*.

Field Value: The comments relating to the current document.

Switches: One of the following *general-formatting-switch*es: `\* Caps`, `\* FirstCap`, `\* Lower`, or `\* Upper`.

[*Example*: Consider the case in which the Description element is as follows:

```
<Description>Once upon a time, in a land far, far away ...</Description>
```

and the following field is updated:

COMMENTS

The result is:

Once upon a time, in a land far, far away ...

Updating the following field:

COMMENTS "I came, I saw, I was not impressed."

causes the Description element to take on the specified value. *end example*]

2.16.5.15 COMPARE

Syntax:

COMPARE Expression-1 Operator Expression-2

Expression-1:
expression

Expression-2:
expression

Description: Compares the values designated by *Expression-1* and *Expression-2* using the operator designated by *Operator*. [*Note*: This field can be used to create compound logical comparisons with AND and OR functions in a formula, and then by using the result of the formula in an IF field. *end note*]

Operator can be any one of the six relational and equality operators specified for *operator* (§2.16.3.3).

If *Operator* is = or <>, *Expression-2* can contain a question mark (?) to represent any single character, or an asterisk (*) to represent any string of characters. The expression shall be enclosed in quotation marks so that it is compared as a character string. If an asterisk is used in *Expression-2*, the portion of *Expression-1* that corresponds to the asterisk, plus any remaining characters in *Expression-2*, shall NOT exceed 128 characters.

Field Value: 1 if the comparison is true, or 0 if the comparison is false.

Switches: None.

[*Example*: Consider the case in which the IF field in the following example is inserted into a mail merge main document. The COMPARE fields examine the data fields CustomerNumber and CustomerRating as each data record is merged. The OR function of the formula returns the value 1 if at least one of the data fields indicates poor credit, in which case the first text in quotation marks is printed:

```
{ IF { = OR ( { COMPARE { MERGEFIELD CustomerNumber } >= 4 },
  { COMPARE { MERGEFIELD CustomerRating } <= 9 } ) } = 1
  "Credit not acceptable" "Credit acceptable"}
```

The following COMPARE field results in the value 1 if any value in the PostalCode data field is the range 98500–98599:

```
{ COMPARE "{ MERGEFIELD PostalCode }" = "985*" }
```

end example]

2.16.5.16 CREATEDATE

Syntax:

CREATEDATE [switches *]*

Description: Retrieves the date and time at which the document was created, as recorded in the DateCreated element of the Core File Properties part. By default, the Gregorian calendar is used and the *date-and-time-formatting-switch* used is implementation-defined.

Field Value: The date and time at which the document was created.

Switches: Zero or one *date-and-time-formatting-switch* and zero or one of the following *field-specific-switch*es.

\h	Use the Hijri/Lunar calendar.
\s	Use the Saka Era calendar.

[*Example*: Consider the case in which the DateCreated element is as follows:

```
<DateCreated>2006-01-05T03:31:00Z</DateCreated>
```

and the following fields are updated in a US-English context that is UTC -5:

CREATEDATE
CREATEDATE \@ "dddd, MMMM dd, yyyy HH:mm:ss"
CREATEDATE \@ "dddd, MMMM dd, yyyy HH:mm:ss" \h
CREATEDATE \@ "dddd, MMMM dd, yyyy HH:mm:ss" \s

the results are:

```
1/4/2006 10:31:00 PM
Wednesday, January 04, 2006 22:31:00
AlArbia'a, Thoul Hijjah 04, 1426 22:31:00
Budhavara, Pausa 14, 1927 22:31:00
```

end example]

2.16.5.17 DATABASE

Syntax:

DATABASE [switches *]*

Description: Inserts the results of a database query into a WordprocessingML table. If the number of columns is 62 or more, the field inserts the results of a query in columns separated by tabs. The DATABASE field contains all the information needed to connect to a database and perform an SQL query. Each time the field is updated, the database is queried again.

Field Value: The results of a database query as a WordprocessingML table.

Switches: Zero or more of the following *field-specific-switch*es.

\b *field-argument*	The *text* in this switch's *field-argument* specifies which attributes of the format set by the \l switch are to be applied to the table. If the \l switch is blank, the \b switch value shall be 16 (AutoFit). *text* can have a value that is the bitwise-or of any combination of the following: 0, None 1, Borders 2, Shading 4, Font 8, Color 16, AutoFit 32, Heading Rows 64, Last Row

	128, First Column 256, Last Column
\c *field-argument*	The *text* in this switch's *field-argument* specifies a connection to the data.
\d *field-argument*	The *text* in this switch's *field-argument* specifies the complete path and file name of the database. Used for all database queries except a query to an SQL database table using ODBC.
\f *field-argument*	The *text* in this switch's *field-argument* specifies the integral record number of the first data record to insert
\h	Inserts the field names from the database as column headings in the resulting table.
\l *field-argument*	The *text* in this switch's *field-argument* specifies the format that is to be applied to the result of the database query. If this switch is used and the \b switch doesn't specify the table attributes, an unformatted table is inserted.
\o *field-argument*	Inserts data at the beginning of a merge. By adding the \o switch to the database field, it will only get the data for the database field at the beginning of a merge instead of once for each record merged. This is a performance optimization and should only be used when the database field doesn't rely on record specific information to gather.
\s *field-argument*	The *text* in this switch's *field-argument* specifies a set of SQL instructions. Each quotation mark in the instructions shall be preceded by a backslash (\).
\t *field-argument*	The *text* in this switch's *field-argument* specifies the integral record number of the last data record to insert.

[*Example*: The following field results from a query to a database through ODBC:

```
{ DATABASE \d "C:\\Data\\Sales93.mdb" \c "DSN=MS Access Database;
  DBQ=C:\\Data\\Sales93.mdb; FIL=RedISAM"
  \s "select * from \"Customer List\"" \f "2445" \t "2486" \l "2"
```

end example]

2.16.5.18 DATE

Syntax:

DATE [switches *]*

Description: Retrieves the current date and time. By default, the Gregorian calendar is used, and the *date-and-time-formatting-switch* used is implementation-defined.

Field Value: The current date and time.

Switches: Zero or one *date-and-time-formatting-switch* and zero or one of the following *field-specific-switch*es.

\h	Use the Hijri/Lunar calendar.
\l	If no *date-and-time-formatting-switch* is used, the date shall use the date format last used by the hosting application when inserting a new DATE field.
\s	Use the Saka Era calendar.

[*Example*: Consider the case in which the following fields are updated in a US-English context on the given date and time:

DATE
DATE \@ "dddd, MMMM dd, yyyy HH:mm:ss"
DATE \@ "dddd, MMMM dd, yyyy HH:mm:ss" \h
DATE \@ "dddd, MMMM dd, yyyy HH:mm:ss" \s

the results are:

```
1/5/2006
Thursday, January 05, 2006  19:09:01
AlKhamis, Thoul Hijjah 05, 1426  19:09:01
Bruhaspathivara, Pausa 15, 1927  19:09:01
```

end example]

[*Note*: For some *date-and-time-formatting-switch*es, the DATE and TIME (§2.16.5.72) fields can produce the same result. *end note*]

2.16.5.19 DOCPROPERTY

Syntax:

DOCPROPERTY docprop-category [field-argument *] [* switches *]*

docprop-category:
AUTHOR | *BYTES* | *CATEGORY* | *CHARACTERS* | *CHARACTERSWITHSPACES*
| *COMMENTS* | *COMPANY* | *CREATETIME* | *HYPERLINKBASE* | *KEYWORDS*
| *LASTPRINTED* / *LASTSAVEDBY* | *LASTSAVEDTIME* | *LINES* | *MANAGER*
| *NAMEOFAPPLICATION* | *ODMADOCID* | *PAGES* | *PARAGRAPHS* | *REVISIONNUMBER*
| *SECURITY* | *SUBJECT* | *TEMPLATE* | *TITLE* | *TOTALEDITINGTIME* | *WORDS*

Description: Retrieves the indicated document information. For some combinations of DOCPROPERTY and *docprop-category*, there is an equivalent field, in which case, the description for the combination can be obtained from that field. For those combinations not having an equivalent field, the description is shown

directly. When used directly, some of the equivalent fields allow the value of the designated property to be changed. However, when the corresponding DOCPROPERTY field is used, such values shall not be changed. This is indicated in the following table by "Read-only operation."

docprop-category	Corresponding Field	Description
AUTHOR	AUTHOR (§2.16.5.4)	**Read-only operation.**
BYTES	FILESIZE (§2.16.5.24)	
CATEGORY	No equivalent	The contents of the Category element of the Core File Properties part.
CHARACTERS	NUMCHARS (§2.16.5.48)	
CHARACTERSWITHSPACES	No equivalent	**Like NUMCHARS, but includes all white space characters as well.**
COMMENTS	COMMENTS (§2.16.5.11)	**Read-only operation.**
COMPANY	No equivalent	The contents of the Company element of the Application-Defined File Properties part.
CREATETIME	CREATEDATE (§2.16.5.16)	
HYPERLINKBASE	No equivalent	The contents of the HyperlinkBase element of the Application-Defined File Properties part.
KEYWORDS	No equivalent	The contents of the Keywords element of the Core File Properties part.
LASTPRINTED	PRINTDATE (§2.16.5.54)	
LASTSAVEDBY	LASTSAVEDBY (§2.16.5.38)	
LASTSAVEDTIME	SAVEDATE (§2.16.5.60)	
LINES	No equivalent	The contents of the Lines element of the Application-Defined File Properties part.
MANAGER	No equivalent	The contents of the Manager element of the Application-Defined File

docprop-category	Corresponding Field	Description
		Properties part.
NAMEOFAPPLICATION	No equivalent	The contents of the Application element of the Application-Defined File Properties part.
ODMADOCID		
PAGES	NUMPAGES (§2.16.5.49)	
PARAGRAPHS	No equivalent	The contents of the Paragraphs element of the Application-Defined File Properties part.
REVISIONNUMBER	REVNUM (§2.16.5.59)	
SECURITY	No equivalent	The contents of the DocSecurity element of the Application-Defined File Properties part.
SUBJECT	SUBJECT (§2.16.5.67)	**Read-only operation.**
TEMPLATE	TEMPLATE (§2.16.5.71)	
TITLE	TITLE (§2.16.5.73)	**Read-only operation.**
TOTALEDITINGTIME	EDITTIME (§2.16.5.21)	
WORDS	No equivalent	The contents of the Words element of the Application-Defined File Properties part.

Field Value: The indicated document information.

2.16.5.20 DOCVARIABLE

Syntax:

DOCVARIABLE field-argument

Description: Inserts the string assigned to the document variable designated by *text* in *field-argument*. Each WordprocessingML document has a collection of variables. This field is used to access and display the contents of docVar (§2.15.1.30) elements in the Document Settings part.

Field Value: The value of the specified document variable.

Switches: None.

2.16.5.21 EDITTIME

Syntax:

EDITTIME [switch *]*

Description: Retrieves the total editing time, in minutes, since the document was created, as recorded in the TotalTime element of the Application-Defined File Properties part. By default, the *numeric-formatting-switch* or *general-formatting-switch* used is implementation-defined.

Field Value: The total editing time, in minutes.

Switches: Zero or one *numeric-formatting-switch* or *general-formatting-switch*.

[*Example*: Consider the case in which the TotalTime element is as follows:

```
<TotalTime>930</TotalTime>
```

and the following fields are updated in a US-English context:

```
EDITTIME
EDITTIME \* OrdText
EDITTIME \# "#,##0"
```

the results are:

```
930
nine hundred thirtieth
 930
```

end example]

2.16.5.22 EQ

Syntax:

EQ eq-primary-switch *[* switches *] ([* eq-argument-list *])*

eq-argument-list is a list of arguments separated using a separator character. For implementations using a period (.) as the radix point, the separator character is a comma (,). For implementations using a comma (,) as the radix point, the separator character is a semicolon (;).

Description: Computes the specified mathematical equation.

Field Value: The result of the specified mathematical equation. [*Note*: The result of an EQ field can be used as an argument in another EQ field's *eq-argument-list*. *end note*]

Switches: One of the following *eq-primary-switch*es: `\a`, `\b`, `\d`, `\f`, `\i`, `\l`, `\o`, `\r`, `\s`, and `\x`. Each of these switches has one or more subswitches, as shown below.

\a produces an array using the argument values in *eq-argument-list* (which are in row-major order) and the *field-specific-switch*es below:

\ac	Alignment is centered in each array column.
\al	Alignment is left in each array column.
\ar	Alignment is right in each array column.
\co *field-argument*	The number of columns in the array is specified by *text* in this switch's *field-argument*. In the absence of this switch, the number is 1.
\hs *field-argument*	Adds the integral number of points of horizontal spacing specified by *text* in this switch's *field-argument* between columns.
\vs *field-argument*	Adds the integral number of points of vertical spacing specified by *text* in this switch's *field-argument* between lines.

\b brackets the single element in *eq-argument-list* in a size appropriate for that element. The default form of brackets is parentheses. The *field-specific-switch*es below may be used:

\bc *char*	Uses the character designated by *char* as both the left and right bracket character. However, if *char* is {, [, (, or <, that character is used for the left bracket, and },],), or >, respectively, is used for right bracket.
\lc *char*	Uses the character designated by *char* as the left bracket character.
\rc *char*	Uses the character designated by *char* as the right bracket character.

\d Controls where the next character following the EQ field is drawn (that is, the displacement). *eq-argument-list* shall have no arguments. The *field-specific-switch*es below may be used:

\ba *field-argument*	Draws to the left (backward) the integral number of points specified by *text* in this switch's *field-argument*.
\fo *field-argument*	Draws to the right (forward) the integral number of points specified by *text* in this switch's *field-argument*.
\li	Underlines the space up to the next character.

\f Creates a fraction with the first argument as numerator and the second argument as denominator, centered above and below the division line, respectively. *eq-argument-list* shall have exactly two arguments. There are no *field-specific-switch*es for this switch.

\i Creates an integral using the specified or default symbol and three elements. The first argument is the lower limit, the second is the upper limit, and the third is the integrand. *eq-argument-list* shall have exactly three arguments. The *field-specific-switch*es below may be used:

\fc *char*	Uses the character designated by *char* as the fixed-height character for

	the symbol.
\in	Uses an inline format with the limits displayed to the right of the symbol instead of above and below it.
\pr	Uses the symbol Capital pi and creates a product.
\su	Uses the symbol Capital sigma and creates a summation.
\vc *char*	Uses the character designated by *char* as the variable-height character for the symbol. The symbol matches the height of the third argument.

\lf Creates a list from an arbitrary number of arguments. There are no *field-specific-switch*es for this switch.

\o Using an arbitrary number of arguments, displays each successive argument on top of the previous one. Each character is displayed within an invisible character box, with the switches being available to align the boxes on top of one another. The *field-specific-switch*es below may be used:

\ac	Alignment character box center (the default).
\al	Alignment character box left.
\ar	Alignment character box right.

\r Creates a radical. *eq-argument-list* shall have either one or two arguments. If it has one argument, the result is the square root of that argument. If it has two arguments, the result is the *n*th root of the second argument, where *n* is the first argument. There are no *field-specific-switch*es for this switch.

\s Creates a subscript or superscript. One or more arguments are permitted. If more than one element is specified, the elements are stacked and left-aligned. The *field-specific-switch*es below may be used:

\ai *field-argument*	Adds space above a line in a paragraph by the integral number of points specified by *text* in this switch's *field-argument*. The default is 2 points.
\di *field-argument*	Adds space below a line in a paragraph by the integral number of points specified by *text* in this switch's *field-argument*.
\do *field-argument*	Moves a single argument below the adjacent text by the integral number of points specified by *text* in this switch's *field-argument*. The default is 2 points.
\up *field-argument*	Moves a single argument above the adjacent text by the integral number of points specified by *text* in this switch's *field-argument*.

\x Creates one or more border segments around a single argument. By default, all four borders are added. *eq-argument-list* shall have no arguments. The *field-specific-switch*es below may be used:

\bo	Draws a horizontal border below the argument.
\le	Draws a vertical border to the left of the argument.

\ri	Draws a vertical border to the right of the argument.
\to	Draws a horizontal border above the argument.

[*Example*: When the following fields are updated:

EQ \a \co 2 \ac \hs 10 (1000, 20, A, Sunday)
EQ \b \bc \| (-100) EQ \b \bc \| (\r(3, a + b)
xx EQ \d \fo 20 () xx EQ \d \fo 30 \li ()xx
EQ \f (1, 32) EQ \f (7, 64)
EQ \i (0, ∞, x) EQ \i \su \in (0, 10, x) EQ \i \pr \in (0, 5, x)
EQ \i \fc \{ (0, 5, \f (x, 0.34)) EQ \i \vc \{ (0, 5, \f (x, 0.34))

EQ \l (0, 10)
EQ \b \lc \[\rc \) (\l (0, 10))
EQ \o (0, 0, 0) EQ \o (0, +) EQ \o \ar (0, |, _)
EQ \r (2) EQ \r (2, x)
a EQ \s \up (2) + b EQ \s \up (2)
a EQ \x (+) b a EQ \x \to \le (+) b a EQ \x \bo \ri (+) b

The results are:

1000 20

$\mathbf{0}\quad \not{0}\quad \underline{\emptyset}$

$\sqrt{2}\quad \sqrt[2]{x}$

$a^2 + b^2$

$a\boxed{+}b\quad a\sqrt{+}b\quad a\underline{+}b$

end example]

2.16.5.23 FILENAME

Syntax:

FILENAME [*switch*]

Description: Retrieves the name of the current document as stored on disk.

Field Value: The name of the current document.

Switches: One of the following *general-formatting-switch*es: * Caps, * FirstCap, * Lower, or * Upper, and zero or one of the following *field-specific-switch*es.

\p	Include the full file path name.

[*Example*: Consider the case in which the following fields are updated:

```
FILENAME \* Upper
FILENAME \p
```

the results might be:

```
FIELD DEMO SUITE.DOCX
E:\Std\OOXML\Fields\Field Demo Suite.docx
```

end example]

2.16.5.24 FILESIZE

Syntax:

FILESIZE [*switches*]

Description: Retrieves the size of the current document in bytes. [*Note*: This information is not stored inside the document's XML. It needs to be obtained from the file system. *end note*]

Field Value: The size of the current document in bytes.

Switches: Zero or one *numeric-formatting-switch* or *general-formatting-switch* and zero or one of the following *field-specific-switch*es.

\k	Round to the nearest kilobyte.
\m	Round to the nearest megabyte.

[*Example*: Consider the case in the document's size is 4,660,736 bytes and the following fields are updated:

```
FILESIZE \# #,##0
FILESIZE \k
FILESIZE \m
```

the results are:

```
4,660,736
4661
5
```

end example]

2.16.5.25 FILLIN

Syntax:

FILLIN [*field-argument*] [*switch*]

Description: Prompts the user to enter text. *text* in *field-argument* contains the prompt. The prompt is displayed each time the field is updated. When a new document is created based on a template containing FILLIN fields, those fields are updated automatically.

Field Value: The user's response.

Switches: Zero or more of the following *field-specific-switch*es.

\d *field-argument*	The *text* in this switch's *field-argument* specifies a default response if one is not entered. If no default response is specified, the most recent response is used. To specify a blank entry as the default, *field-argument* shall be "".
\o	When used in a mail merge main document, this causes the display of the prompt once instead of each time a new data record is merged. The same response is inserted in each resulting merged document.

[*Example*: The following FILLIN field helps the user fill in the correct information by displaying the patient name from the current data record:

```
FILLIN "Please enter the appointment time for MERGEFIELD PatientName :"
```

end example]

2.16.5.26 FORMCHECKBOX

Syntax:

FORMCHECKBOX

Description: Inserts a check box style form field which, when the editing of form fields is enabled using the documentProtection element (§2.15.1.28), can be checked and unchecked. An instance of this field shall be accompanied by a use of the ffData element (§2.16.17) which contains the form field's properties.

Field Value: A check box based on the properties of the ffData element (§2.16.17).

Switches: None.

[*Example*: Consider the following fields:

```
FORMCHECKBOX
```

Assuming the appropriate properties are used in the child XML elements of the field, a check box is displayed.

end example]

2.16.5.27 FORMDROPDOWN

Syntax:

FORMDROPDOWN

Description: Inserts a drop-down list style form field which, when the editing of form fields is enabled using the documentProtection element (§2.15.1.28), can be used to select an entry in the list. An instance of this field shall be accompanied by a use of the ffData element (§2.16.17) which contains the form field's properties.

Field Value: A drop-down list based on the properties of the ffData element (§2.16.17).

Switches: None.

[*Example*: Consider the following fields:

```
FORMDROPDOWN
```

Assuming the appropriate properties are used in the child XML elements of the field, a drop-down list is displayed.

end example]

2.16.5.28 FORMTEXT

Syntax:

FORMTEXT

Description: Inserts a text box style form field which, when the editing of form fields is enabled using the documentProtection element (§2.15.1.28), can be typed into. An instance of this field shall be accompanied by a use of the ffData element (§2.16.17) which contains the form field's properties.

Field Value: A text box based on the properties of the ffData element (§2.16.17).

Switches: None.

[*Example*: Consider the following fields:

```
FORMTEXT
```

Assuming the appropriate properties are used in the child XML elements of the field, a text box is displayed.

end example]

2.16.5.29 GOTOBUTTON

Syntax:

GOTOBUTTON *field-argument-1 field-argument-2*

field-argument-1:
expression

field-argument-2:
expression

Description: Inserts a jump command, such that when it is activated, the insertion point of the document is moved to the location specified by *text* in *field-argument-1*. *text* can be a bookmark, a page number, or some other item (as described below). The page number can be a reference resulting from a REF field. The other items than can be locations are:

a *n*	annotation
f *n*	footnote
l *n*	line
p *n*	page
s *n*	section

where *n* is an integer that designates the *n*th occurrence of the corresponding item (which is not necessarily the item numbered *n*).

text in *field-argument-2* is the text or graphic "button" that appears in the document, such that it can be selected to activate the jump. [*Note*: The BOOKMARK and INCLUDEPICTURE fields make for some interesting button possibilities. *end note*] The text or graphic shall appear on one line in the field result; otherwise, an error occurs.

Field Value: None.

Switches: None.

[*Example*: Consider the following fields:

```
GOTOBUTTON MyBookmark Dest
GOTOBUTTON p3 Page
GOTOBUTTON "f 2" Footnote
```

When the `Dest` "button" is activated, the insertion point becomes the location marked by `MyBookmark`. When `Page` is activated, the insertion point becomes the beginning of the third page. When Footnote is activated, the insertion point becomes the marker of the second footnote, at the place it is used in the document, not in any footnote list.

end example]

2.16.5.30 GREETINGLINE

Syntax:

GREETINGLINE [*switches*]

Description: Inserts a mail merge greeting line.

Field Value: The greeting line.

Switches: Zero or more of the following *field-specific-switch*es.

\c *field-argument*	The *text* in this switch's *field-argument* specifies the text to include in the merge field if the name field in the data source is blank.
\c *field-argument*	The *text* in this switch's *field-argument* specifies the format of the name included in the field.
\l *field-argument*	The *text* in this switch's *field-argument* specifies the language ID used to format the name. it defaults to the language ID of the first character of the document.

2.16.5.31 HYPERLINK

Syntax:

HYPERLINK *field-argument* [*switches*]

Description: When selected, causes control to jump to the location specified by *text* in *field-argument*. That location can be a bookmark or a URL.

Field Value: None.

Switches: Zero or more of the following *field-specific-switch*es.

`\l` *field-argument*	*text* in this switch's *field-argument* specifies a location in the file, such as a bookmark, where this hyperlink will jump.
`\m`	Appends coordinates to a hyperlink for a server-side image map.
`\n`	Causes the destination site to be opened in a new window.
`\o` *field-argument*	*text* in this switch's *field-argument* specifies the ScreenTip text for the hyperlink.
`\t` *field-argument*	*text* in this switch's *field-argument* specifies the target to which the link should be redirected. Use this switch to link from a frames page to a page that you want to appear outside of the frames page. The permitted values for *text* are: • `_top`, whole page (the default) • `_self`, same frame • `_blank`, new window • `_parent`, parent frame

[*Example*:

```
HYPERLINK http://www.cnu.edu/
HYPERLINK "E:\\ReadMe.txt"
```

end example]

2.16.5.32 IF

Syntax:

`IF` *Expression-1 Operator Expression-2 field-argument-1 field-argument-2*

Expression-1:
expression

Expression-2:
expression

field-argument-1:
expression

field-argument-2:
expression

Description: Compares the values designated by *Expression-1* and *Expression-2* using the operator designated by *Operator*.

Operator can be any one of the six relational and equality operators specified for *operator* (§2.16.3.3).

If *Operator* is = or <>, *Expression-2* can contain a question mark (?) to represent any single character, or an asterisk (*) to represent any string of characters. The expression shall be enclosed in quotation marks so that it is compared as a character string. If an asterisk is used in *Expression-2*, the portion of *Expression-1* that corresponds to the asterisk, plus any remaining characters in *Expression-2*, shall NOT exceed 128 characters.

Field Value: *field-argument-1* if the comparison is true; otherwise, *field-argument-2*.

Switches: None.

[*Example*: The following example specifies that if the customer order is greater than or equal to 100 units, the result is "Thanks"; but if the customer order is fewer than 100 units, the result is "The minimum order is 100 units":

```
{IF order >= 100 "Thanks" "The minimum order is 100 units" }
```

For other examples, see §2.16.2, and the COMPARE field (§2.16.5.15) and the QUOTE field (§2.16.5.55). *end example*]

2.16.5.33 INCLUDEPICTURE

Syntax:

INCLUDEPICTURE *field-argument* [*switches*]

Description: Retrieves the picture contained in the document named by *field-argument*. If *field-argument* contains white space, it shall be enclosed in double quotes. If *field-argument* contains any backslash characters, each one shall be preceded directly by another backslash character.

Field Value: The specified picture.

Switches: Zero or more of the following *field-specific-switch*es.

\c *field-argument*	If *text* in this switch's *field-argument* identifies the graphics filter to be used.
\d	Reduce the file size by not storing graphics data with the document.

[*Example*:

```
INCLUDEPICTURE "G:\\Photos\\Ellen in Oslo.jpg"
```

end example]

2.16.5.34 INCLUDETEXT

Syntax:

INCLUDETEXT *field-argument-1* [*field-argument-2*] [*switches*]

field-argument-1:
field-argument

field-argument-2:
field-argument

Description: Inserts all or part of the text and graphics contained in the document named by *field-argument-1*. If the document is a WordprocessingML document, the portion marked by the optional bookmark *field-argument-2* is inserted. If no such bookmark is specified here, the whole document is inserted. If the document is an XML file, the fragment referred to by an XPath expression in the \x switch is inserted. If no such switch is specified, the whole XML file is inserted.

If *field-argument-1* contains white space, it shall be enclosed in double quotes. If *field-argument-1* contains any backslash characters, each one shall be preceded directly by another backslash character.

Field Value: The specified text and graphics.

Switches: Zero or more of the following *field-specific-switch*es.

\!	Prevents this field from being updated unless all fields in the inserted text are first updated in their original document.
\c *field-argument*	Specifies that the file specified by *field-argument-2* shall be processed by a document filter whose name matches the corresponding *field-argument* value. Possible *field-argument* values are implementation-defined.
\n *field-argument*	The *text* in this switch's *field-argument* specifies a namespace mapping for XPath queries. This switch is required if the \x switch refers to an element by name in an XML file that declares a namespace.
\t *field-argument*	The *text* in this switch's *field-argument* specifies an XSLT for formatting XML data.
\x *field-argument*	The *text* in this switch's *field-argument* specifies the XPath for returning a fragment of data in an XML file.

[*Example*: The following field inserts the portion of the WordprocessingML document referred to by the bookmark Summary:

```
INCLUDETEXT "C:\\Winword\\Port Development RFP" Summary
```

The following field inserts the Name element of the XML document Resume.xml and applies the XSLT Display.xsl to it:

```
INCLUDETEXT "C:\\Resume.xml" \n xmlns:a=\"resume-schema\"
  \t "C:\\display.xsl" \x a:Resume/a:Name
```

end example]

2.16.5.35 INDEX

Syntax:

INDEX [*switches*]

Description: Builds an index using the index entries specified by XE fields (§2.16.5.79), and inserts that index at this place in the document. Each index entry and subentry is a separate paragraph unless the `\r` switch is used, in which case, an index entry and all its subentries together make up a paragraph.

Field Value: The index.

Switches: Zero or more of the following *field-specific-switch*es.

`\b` *field-argument*	Builds an index for the portion of the document marked by the bookmark indicated by *text* in this switch's *field-argument*.
`\c` *field-argument*	Builds an index having the number of columns per page specified by *text* in this switch's *field-argument*. That number can be 1–4. Without this switch, the number of columns is 1.
`\d` *field-argument*	The *text* in this switch's *field-argument* specifies a sequence of characters that is used to separate sequence numbers and page numbers when the `\s` switch is used. By default, a hyphen (-) is used.
`\e` *field-argument*	The *text* in this switch's *field-argument* specifies a sequence of characters that is used to separate an index entry and its first page number. By default, a comma (,) and space sequence is used. If *text* contains a horizontal tab character, the page number list is right justified in the column.
`\f` *field-argument*	Builds an index using only those entries having the entry type (§2.16.5.79) specified by *text* in this switch's *field-argument*. Without this switch, all entries included.
`\g` *field-argument*	The *text* in this switch's *field-argument* specifies a sequence of characters that is used to separate the start and end of a page range. By default, an en dash is used.
`\h` *field-argument*	Builds an index such that the *text* in this switch's *field-argument* occurs as a heading—formatted with the Index Heading style—at the start of each set of entries for any given letter. If the first letter in *text* is A or a, that letter is replaced with the corresponding letter for each letter set. To replace the default heading with a blank line, use a space as *text*. [*Example*:  *end example*]
`\k` *field-argument*	The *text* in this switch's *field-argument* specifies a sequence of characters that is used to separate an index entry and its cross reference (as produced by an XE entry (§2.16.5.79) having a `\t` switch). By default, a period (.) and space sequence is used. [*Example*:

	 *end example*]
`\l` *field-argument*	The *text* in this switch's *field-argument* specifies a sequence of characters that is used to separate two page numbers in a page number list. By default, a comma (,) and space sequence is used.
`\p` *field-argument*	Builds an index using only those entries whose first letter is in the range of letters specified by *text* in this switch's *field-argument*. The letter range has the form *startLetter*`-`*endLetter*. If *startLetter* is `!`, entries whose first character is not a letter, are also included, as are the letters starting from A. The letters in the range can be either upper- or lowercase.
`\r`	Runs subentries into the same line as the main entry. Colons (:) separate main entries from subentries; semicolons (;) separate subentries.
`\s` *field-argument*	The *text* in this switch's *field-argument* is used as a sequence name, and the sequence number is included along with the page number, these numbers being separated by a hyphen (-), by default. Use the `\d` switch to specify a separator character other than the default.
`\y`	Enables the use of yomi text for index entries.
`\z` *field-argument*	The *text* in this switch's *field-argument* is specifies the language ID used to generate the index as defined in the ST_LangCode (§2.18.52) simple type.

[*Example*: The index produced using the corresponding set of index entries and the field `INDEX \c "1" \e "`*tab*`" \g " to " \h "A" \z "1033"` is:

B

I

O

end example]

2.16.5.36 INFO

Syntax:

```
INFO info-category [ field-argument ] [ switches ]
info-category:
    AUTHOR | COMMENTS | CREATEDATE | EDITTIME | FILENAME | FILESIZE |
    | KEYWORDS | LASTSAVEDBY | NUMCHARS | NUMPAGES | NUMWORDS | PRINTDATE
    | REVNUM | SAVEDATE | SUBJECT | TEMPLATE | TITLE
```

A field of this kind is treated as if INFO was omitted and *info-category* was a *field-type name***.**

2.16.5.37 KEYWORDS

Syntax:

```
KEYWORDS [ field-argument ] [ switch ]
```

Description: Retrieves, and optionally sets, the document's keywords, as recorded in the Keywords element of the Core File Properties part or, if *field-argument* is present, the subject specified by *text* in *field-argument*. Specifying a *field-argument* shall change Keywords to *text*. The Keywords element contains a string of text whose format and semantics is unspecified by this Office Open XML Standard.

Field Value: The document's keywords

Switches: One of the following *general-formatting-switch*es: `\* Caps`, `\* FirstCap`, `\* Lower`, or `\* Upper`.

[*Example*: Consider the case in which the Keywords element is as follows:

```
<Keywords>switch, field, syntax</Keywords>
```

and the following field is updated:

KEYWORDS

The result is:

```
switch, field, syntax
```

Updating the following field:

```
KEYWORDS "field, formatting, switch, syntax"
```

causes the Subject element to take on the given value. *end example*]

2.16.5.38 LASTSAVEDBY

Syntax:

LASTSAVEDBY [*switch*]

Description: Retrieves the name of the user who last modified and saved the current document, as recorded in the LastModifiedBy element of the Core File Properties part.

Field Value: The name of the user who last modified and saved the current document.

Switches: One of the following *general-formatting-switch*es: `\* Caps`, `\* FirstCap`, `\* Lower`, or `\* Upper`.

[*Example*: Consider the case in which the LastModifiedBy element is as follows:

```
<LastModifiedBy>Elizabeth Martin</LastModifiedBy>
```

and the following field is updated:

```
LASTSAVEDBY \* Upper
```

the result might be:

```
ELIZABETH MARTIN
```

end example]

2.16.5.39 LINK

Syntax:

LINK *field-argument-1* *field-argument-2* [*field-argument-3*] [*switches*]

field-argument-1:
field-argument

field-argument-2:
field-argument

field-argument-3:
field-argument

Description: For information copied from another application, this field links that information to its original source file using OLE. The application type of the link information is specified by *field-argument-1*. The name and location of the source file is specified by *field-argument-2*. *field-argument-3* specifies the portion of the source file that's being linked. [*Example*: If the source file is a SpreadsheetML document, the reference might be to a cell reference or a named range. For a WordprocessingML document, it might be a bookmark. *end example*]

Field Value: None.

Switches: Zero or more of the following *field-specific-switch*es.

\a	Causes this field to be updated automatically.
\b	Inserts the linked object as a bitmap.
\d	Don't store the graphic data with the document, thus reducing the file size.
\f *field-argument*	Causes the linked object to update its formatting in a particular way, according to the integral value of *text* in this switch's *field-argument*. The possible values are: • 0 Maintain the formatting of the source file • 1 Not supported • 2 Match the formatting of the destination document • 3 Not supported • 4 Maintain the formatting of the source file, if the source file is a SpreadsheetML workbook • 5 Match the formatting of the destination document, if the source file is a SpreadsheetML workbook
\h	Inserts the linked object as HTML format text.
\p	Inserts the linked object as a picture.
\r	Inserts the linked object in rich-text format (RTF).
\t	Inserts the linked object in text-only format.
\u	Inserts the linked object as Unicode text.

[*Example*: The following example inserts a range of cells from a SpreadsheetML worksheet. The \a switch ensures that the information is updated in the WordprocessingML document whenever the worksheet is changed:

```
{ LINK Excel.Sheet.8 "C:\\My Documents\\Profits.xls"
   "Sheet1!R1C1:R4C4" \a \p }
```

end example]

2.16.5.40 LISTNUM

Syntax:

LISTNUM [*field-argument*] [*switches*]

Description: Computes the next integral number from the current or a specific series, or a specific number from the next or specific series. This field can be used anywhere in a paragraph, not just at its start. A LISTNUM field can be incorporated into numbering from a simple or outline-numbered list. *text* in *field-argument* is used to associates a LISTNUM field with a specific list. To emulate the behavior of the AUTONUM (§2.16.5.5), AUTONUMLGL (§2.16.5.6), and AUTONUMOUT (§2.16.5.7) fields, use the list names NumberDefault, LegalDefault, and OutlineDefault names, respectively. By default, the NumberFormat list is used.

The XML generated for a complex field implementation shall not have the optional field value stored.

There are nine levels of list, and, assuming `\s 1` for each, the result style used for each is as follows:

1	1)	4	(1)	7	1.
2	a)	5	(a)	8	a.
3	iii)	6	(iii)	9	iii.

Field Value: The next integral number from the current or a specific series, or a specific number from the next or specific series.

Switches: Zero or more of the following *field-specific-switch*es.

`\l` *field-argument*	*text* in this switch's *field-argument* is an integer that specifies the level in the list, overriding the default behavior of the field. If `\l` is omitted, for a new series, the default value is 3; otherwise, the current level is continued.
`\s` *field-argument*	*text* in this switch's *field-argument* is an integer that specifies the starting value for this field. If `\s` is omitted, for a new series, the default value is 1; otherwise, the current series numbering is continued.

[*Example*: When the following fields are updated:

```
We need to perform the following functions: LISTNUM  NumberDefault \l 3 \s 1 Get
approval for the project. LISTNUM Arrange for funding. LISTNUM Hire staff.
```

The results are:

```
We need to perform the following functions: i) Get approval for the
project. ii) Arrange for funding. iii) Hire staff.
```

When the following fields are updated:

```
LISTNUM NumberDefault \l 3 \s 1
LISTNUM
LISTNUM NumberDefault
LISTNUM NumberDefault \s 3
LISTNUM
LISTNUM NumberDefault \l 1
LISTNUM
LISTNUM NumberDefault \l 1 \s 1
```

```
LISTNUM LegalDefault \l 1 \s 1
LISTNUM LegalDefault
LISTNUM LegalDefault \l 1
LISTNUM LegalDefault \s 4
LISTNUM LegalDefault
```

The results are:

```
i)
ii)
iii)
iii)
iv)
2)
3)
1)
1.1.1.
1.1.2.
2.
2.1.4.
2.1.5.
```

end example]

2.16.5.41 MACROBUTTON

Syntax:

MACROBUTTON *field-argument-1 field-argument-2*

field-argument-1:
field-argument

field-argument-2:
field-argument

Description: Allows the macro or command designated by *text* in *field-argument-1* to be run. *text* in *field-argument-2* designates the text or graphic to appear as the "button" that is selected to run the macro or command.

Field Value: *field-argument-2*.

Switches: None.

2.16.5.42 MERGEFIELD

Syntax:

MERGEFIELD *field-argument* [*switch*]

Description: Retrieves the name of a data field designated by *text* in *field-argument* within the merge characters in a mail merge main document. When the main document is merged with the selected data source, information from the specified data field is inserted in place of the merge field.

The name designated by *text* shall match exactly the field name in the header record.

Field Value: The name of a data field designated by *text* in *field-argument*.

Switches: Zero or more of the following *field-specific-switch*es.

`\b` *field-argument*	The *text* in this switch's *field-argument* specifies the text to be inserted before the `MERGEFIELD` field if the field is not blank.
`\f` *field-argument*	The *text* in this switch's *field-argument* specifies the text to be inserted after the `MERGEFIELD` field if the field is not blank.
`\m`	Specifies that the `MERGEFIELD` field is a mapped field.
`\v`	Enables character conversion for vertical formatting.

[*Example*: Placing the following three MERGEFIELD fields together and using the `\f` switch ensures that the three fields have spaces between them, but only if the designated field information is present in the data source.

```
MERGEFIELD CoutesyTitle \f " " MERGEFIELD FirstName \f " "
  MERGEFIELD LastName
```

end example]

2.16.5.43 MERGEREC

Syntax:

MERGEREC

Description: Results in «MERGEREC». Use this in a mail merge to print the number of the corresponding merged data record in each resulting merged document. The number reflects the sequential order of the data records that were selected and possibly sorted for merging with the active main document. It does not indicate the actual order of the records as they occur in the physical data source. [*Note*: A personnel database might contain thousands of records. However, to send a form letter to employees who've reached their five-year anniversary with your company, you'd select as your data source only the records of those five-year employees, a much smaller set of records. To print a physical record number, you must include a record number field in the data source and insert the corresponding merge field in the main document. *end note*]

Field Value: «MERGEREC».

Switches: None.

[*Example*: The following example uses a MERGEREC field inside a formula to create unique invoice numbers. When the main document is merged with the data source, the number resulting from the MERGEREC field is added to the numbers representing the date and time the invoices are printed.

```
Invoice Number: = { PRINTDATE \@ "MMddyyyyHHmm" + MERGEREC }
```

The result might be:

```
Invoice Number for record 12, printed on Feb. 13, 2003 at 9:46:
  02132003094612
```

end example]

2.16.5.44 MERGESEQ

Syntax:

MERGESEQ

Description: Counts the number of data records that were successfully merged with the main document. Merged records are numbered starting from 1 each time documents are merged. [*Note*: The number might be different from the value inserted by the MERGEREC field. *end note*]

Field Value: The number of data records that were successfully merged with the main document.

Switches: None.

[*Example*: Consider the case in which only records 10–25 are merged. The MERGESEQ number corresponding to the first data record merged is 1, even though the MERGEREC number for that data record is 10. *end example*]

2.16.5.45 NEXT

Syntax:

NEXT

Description: Merges the next data record into the current resulting merged document, rather than starting a new merged document. [*Note*: This field is used when setting up a mailing label and envelope main document during a mail merge. *end note*]

Field Value: None.

Switches: None.

[*Example*: The following fields print three sets of names and phone numbers in each resulting merged document:

```
MERGEFIELD Name MERGEFIELD Phone
NEXT MERGEFIELD Name MERGEFIELD Phone
NEXT MERGEFIELD Name MERGEFIELD Phone
```

end example]

2.16.5.46 NEXTIF

Syntax:

NEXTIF *Expression-1 Operator Expression-2*

Expression-1:
expression

Expression-2:
expression

Description: Compares the values designated by *Expression-1* and *Expression-2* using the operator designated by *Operator*. If the comparison is true, the next data record is merged into the current merge document. (Merge fields that follow the NEXTIF in the main document are replaced by values from the next data record rather than the current data record.) If the comparison is false, the next data record is merged into a new merge document.

Operator can be any one of the six relational and equality operators specified for *operator* (§2.16.3.3).

A NEXTIF fields shall NOT be used in a footnote, an endnote, annotation, a header, a footer, or a data source. A NEXTIF field shall NOT be nested within any field.

Field Value: None.

Switches: None.

2.16.5.47 NOTEREF

Syntax:

NOTEREF *field-argument* [*switches*]

Description: Inserts the mark of the footnote or endnote that is marked by the bookmark specified by *text* in *field-argument*.

Field Value: The mark of the footnote or endnote.

Switches: Zero or more of the following *field-specific-switch*es.

\f	For a footnote, inserts the reference mark with the same character formatting as the Footnote Reference style. For an endnote, inserts the reference mark with the same character formatting as the Endnote Reference style.
\h	Inserts a hyperlink to the bookmarked endnote or footnote.
\p	Inserts the relative position of the footnote or endnote. If the NOTEREF field occurs before the bookmark, the result is "below". If the NOTEREF field occurs after the bookmark, the result is "above".

[*Example*: Consider the case in which a bookmark called `F10` marks the footnote of interest. When the field

```
… (see note { NOTEREF F10 }).
```

is updated, the result might be:

```
… (see note 5).
```

end example]

2.16.5.48 NUMCHARS

Syntax:

NUMCHARS [*switch*]

Description: Retrieves the number of characters in the current document, as recorded in the Characters element of the Application-Defined File Properties part.

Field Value: The number of characters in the current document.

Switches: Zero or one *numeric-formatting-switch* or *general-formatting-switch*.

[*Example*: Consider the case in the document has 6,183 words and the following fields are updated:

```
NUMCHARS
NUMCHARS \# #,##0
```

the results are:

```
6183
6,183
```

end example]

2.16.5.49 NUMPAGES

Syntax:

NUMPAGES [*switch*]

Description: Retrieves the number of pages in the current document, as recorded in the Pages element of the Application-Defined File Properties part.

Field Value: The number of pages in the current document.

Switches: Zero or one *numeric-formatting-switch* or *general-formatting-switch*.

[*Example*: Consider the case in the document has 19 pages and the following fields are updated:

```
NUMPAGES \# #,##0
NUMPAGES \* OrdText
```

the results are:

```
 19
nineteenth
```

end example]

2.16.5.50 NUMWORDS

Syntax:

NUMWORDS [*switch*]

Description: Retrieves the number of words in the current document, as recorded in the Words element of the Application-Defined File Properties part.

Field Value: The number of words in the current document.

Switches: Zero or one *numeric-formatting-switch* or *general-formatting-switch*.

[*Example*: Consider the case in the document has 1,243 words and the following fields are updated:

```
NUMWORDS
NUMWORDS \# #,##0
```

the results are:

```
1243
1,243
```

end example]

2.16.5.51 PAGE

Syntax:

PAGE [*switches*]

Description: Retrieves the number of the current page.

Field Value: The number of the current page.

Switches: Zero or more *general-formatting-switch*es.

[*Example*: When the current page number is 19 and the following fields are updated:

```
PAGE
PAGE \* ArabicDash
PAGE \* ALPHABETIC
PAGE \* roman
```

the results are:

```
19
- 19 -
S
xix
```

end example]

2.16.5.52 PAGEREF

Syntax:

PAGEREF *field-argument* [*switches*]

Description: Inserts the number of the page containing the bookmark specified by *text* in *field-argument* for a cross-reference.

Field Value: The number of the page containing the bookmark.

Switches: Zero or one of the *general-formatting-switch*es, zero or one of the *numeric-formatting-switch*es, and zero or more of the following *field-specific-switch*es.

\h	Creates a hyperlink to the bookmarked paragraph.
\p	Causes the field to display its position relative to the source bookmark. If the PAGEREF field is on the same page as the bookmark, it omits "on page #" and returns "above" or "below" only. If the PAGEREF field is not on the same page as the bookmark, the string "on page #" is used.

[*Example*: Consider the case in which a bookmark called `Worldpop1990` marks the table containing figures for 1990. When the field

```
The world population in 1991 was 5 billion; for 1990 figures,
see the table { PAGEREF Worldpop1990 \p }.
```

is updated, the position of the table is inserted in place of the field. The result is one of the following::

```
… see the table above.
… see the table below.
… see the table on page 27.
```

end example]

2.16.5.53 PRINT

Syntax:

PRINT *field-argument* [*switches*]

Description: Sends the printer-specific control code characters specified by *text* in *field-argument* to the selected printer.

Field Value: None.

Switches: Zero or more of the following *field-specific-switch*es.

\p *field-argument-1 field-argument-2*	Allows PostScript strings to be sent to the printer as native PostScript codes. PostScript commands embedded in the document are carried out in the order in which they are inserted. The y-coordinate space used for PostScript commands in as follows: The graphics origin (0,0) is in the lower-left corner of the page, and the positive directions are up and to the right. PostScript drawing instructions take place within a drawing rectangle. The graphics origin is translated to the lower-left corner of the drawing rectangle. *text* in this switch's *field-argument-1* defines the drawing rectangle on which the subsequent PostScript instructions operate. *text* in this switch's *field-argument-2* contains the PostScript instructions.

2.16.5.54 PRINTDATE

Syntax:

PRINTDATE [*switches*]

Description: Retrieves the date and time on which the document was last printed, as recorded in the LastPrinted element of the Core File Properties part. By default, the Gregorian calendar is used and the *date-and-time-formatting-switch* used is implementation-defined. For a document that has never been printed, the date and time corresponds to `0000-00-00T00:00:00` local time and each text component is XXX.

Field Value: The date and time on which the document was last printed.

Switches: Zero or one *date-and-time-formatting-switch* and zero or one of the following *field-specific-switch*es.

\h	Use the Hijri/Lunar calendar.
\s	Use the Saka Era calendar.

[*Example*: Consider the case in which the LastPrinted element is as follows:

```
<LastPrinted>2006-01-06T19:58:00Z</LastPrinted>
```

and the following fields are updated in a US-English context that is UTC -5:

```
PRINTDATE
PRINTDATE \@ "dddd, MMMM dd, yyyy  HH:mm:ss"
```

the results are:

```
1/6/2006 2:58:00 PM
Friday, January 06, 2006 14:58:00
```

For a document that has never been printed, the result is:

```
0/0/0000 0:00:00 AM
XXX, XXX 00, 0000  00:00:00
```

end example]

2.16.5.55 PRIVATE

Syntax:

PRIVATE

Description: Provides a private storage area. This field is used to store data for documents converted from other file formats. The field contains data needed for converting a document back to its original file format.

A PRIVATE field is formatted as hidden text.

Field Value: None.

Switches: None.

2.16.5.56 QUOTE

Syntax:

QUOTE *field-argument*

Description: Retrieves the text specified by *text* in *field-argument*. This text can include any other fields except AUTONUM, AUTONUMLGL, AUTONUMOUT, and SYMBOL.

Field Value: The specified text.
